## MAT 351: Partial Differential Equations

## Assignment 7, due November 7, 2016

## Summary

Separation of variables is a method for finding special solutions of a partial differential equation. Sometimes we can generate all solutions of the PDE from these special solutions, using the

- Superposition principle: If the PDE is linear and homogeneous, then any linear combination of solutions is again a solution.

If, moreover, its coefficients are constant, then translates and derivatives of solutions are again solutions; if the equation has additional symmetries (such as rotations and dilations), they can be used to generate yet more solutions.

To explain the method, consider the wave equation on an interval

$$
u_{t t}=c^{2} u_{x x}, \quad(0<x<\ell),
$$

with Dirichlet boundary conditions $u(0, t)=u(\ell, t)=0$. We seek solutions that can be written as a product

$$
u(x, t)=X(x) T(t)
$$

for some unknown functions $X$ and $T$. Inserting this into the PDE and collecting terms, we see that

$$
\frac{T^{\prime \prime}(t)}{c^{2} T(t)}=\frac{X^{\prime \prime}(x)}{X(x)}=:-\lambda
$$

and deduce that $\lambda$ can depend neither on $x$ nor on $t$. We obtain a system of two ODE:

$$
-X^{\prime \prime}(x)=\lambda X(x), \quad-T^{\prime \prime}(t)=c^{2} \lambda T(t) .
$$

Enforcing the Dirichlet boundary conditions $X(0)=X(\ell)=0$, we conclude that

$$
X(x)=\sin \beta x, \quad \lambda=\beta^{2}, \quad T(t)=A \cos (c \beta t)+B \sin (c \beta t),
$$

where $\beta=n \pi / \ell$ for some integer $n \geq 1$, and $A$ and $B$ are constants. We have found the special solutions

$$
u_{n}(x, t)=\cos \left(\frac{N \pi c t}{\ell}\right) \sin \left(\frac{n \pi x}{\ell}\right), \quad v_{n}(x, t)=\sin \left(\frac{N \pi c t}{\ell}\right) \sin \left(\frac{n \pi x}{\ell}\right) .
$$

Two questions remain:

- Can we construct the general solution of the wave equation from the $u_{n}$ and $v_{n}$ by superposition?
- How can we determine the coefficients in the superposition from initial values?

## Hand-in (due Monday, November 7):

Read Chapter 4.
26. A metal rod $(0<x<\ell)$ insulated along its sides but not its ends is initially at a constant temperature $u_{0}$. Suddenly both ends are plunged into a bath of temperature zero.
(a) Write the initial-value problem for the temperature.
(b) Use the formula

$$
1=\frac{4}{\pi} \sum_{k=1}^{\infty} \frac{1}{2 k+1} \sin \left(\frac{2 \pi(k+1) x}{\ell}\right), \quad(0<x<\ell)
$$

to represent the solution $u(x, t)$ as a series.
27. Apply separation of variables to the Schrödinger equation $i u_{t}=u_{x x}$ with Dirichlet boundary conditions on $0<x<1$. Here, $i$ is the imaginary unit, satisfying $i^{2}=-1$. You may find Euler's formula useful: $e^{a+i b}=e^{a}(\cos b+i \sin b)$.
28. Consider the PDE

$$
u_{r r}+\frac{1}{r} u_{r}+\frac{1}{r^{2}} u_{\theta \theta}, \quad(r>0, \theta \in \mathbb{R})
$$

with periodic boundary conditions in $\theta$, i.e., $u(r \theta+2 \pi)=u(r, \theta)$ for all $\theta$.
(a) Set $u(r, \theta)=f(r) g(\theta)$ and separate variables to obtain a pair of ODE for $f$ and $g$.
(b) Solve these ODE to obtain special solutions for the PDE. (Hint: $\operatorname{Try} f(r)=r^{\alpha}$.)

Remark: We will see later this year that this is Laplace's equation in polar coordinates.
29. Find all eigenvalues of the linear operator $A u=2 u_{x x x x}$ on the space of $2 \pi$-periodic functions.
30. Use separation of variables to find solutions of the diffusion problem $u_{t}=k u_{x x}$ with mixed boundary conditions $u(0, t)=u_{x}(\ell, t)=0$.

## Please remember:

Our first midterm test is scheduled for Wednesday November 4, in-class.
