

## The Pure Virtual Braid Group is Quadratic, II

Examples and Interpretations

Example.

$$K = \left\langle \begin{array}{c} \text{braids} \\ \text{with one crossing} \end{array} \right\rangle \quad I = \left\langle \begin{array}{c} \text{braids} \\ \text{with two crossings} \end{array} \right\rangle$$

(goes back to [Koh])

$(K/I^{p+1})^* = (\text{invariants of type } p) =: \mathcal{V}_p$

$$(I^p/I^{p+1})^* = \mathcal{V}_p/\mathcal{V}_{p-1} \quad V = \langle t^{ij} | t^{ij} = t^{ji} \rangle = \langle \mid \boxed{\text{H}} \rangle$$

$$\ker \bar{\mu}_2 = \langle [t^{ij}, t^{kl}] = 0 = [t^{ij}, t^{ik} + t^{jk}] \rangle = \langle 4T \text{ relations} \rangle$$

$$A = q(K) = \left( \begin{array}{l} \text{horizontal chord diagrams} \\ \text{mod 4T} \end{array} \right) = \left\langle \begin{array}{c} \text{horizontal chord diagrams} \\ \text{mod 4T} \end{array} \right\rangle / 4T$$

Z: universal finite type invariant, the Kontsevich integral.

$PvB_n$  is the group

$$\langle \sigma_{ij} : 1 \leq i \neq j \leq n \rangle / \begin{array}{l} \sigma_{ij}\sigma_{ik}\sigma_{jk} = \sigma_{jk}\sigma_{ik}\sigma_{ij} \\ \sigma_{ij}\sigma_{kl} = \sigma_{kl}\sigma_{ij} \end{array}$$

[Kau, KL]

of "pure virtual braids" ("braids when you look", "blunder braids"):

$$\sigma_{24} = \text{braids with one crossing} \quad R3: \quad \text{braids with two crossings} = \text{braids with three crossings}$$

The Main Theorem [Lee].  $PvB_n$  is quadratic.

$$A_n = q(PvB_n).$$

$$I = \left\langle \begin{array}{c} \text{braids} \\ \text{with two crossings} \end{array} \right\rangle$$

with  $\mathbb{X} = \tilde{\sigma}_{ij} = \sigma_{ij} - 1 = \mathbb{X} - \mathbb{X}$ ,  
the "semi-virtual crossing".

$$V = I/I^2 = \left\langle \begin{array}{c} \text{v-braids} \\ \text{with one crossing} \end{array} \right\rangle / (\mathbb{X} = \mathbb{X})$$

Goussarov-Polyak-Viro

$$a_{24} = \left\langle \begin{array}{c} \text{braids} \\ \text{with three crossings} \end{array} \right\rangle$$

$$A_n = TV / \langle [a_{ij}, a_{ik}] + [a_{ij}, a_{jk}] + [a_{ik}, a_{jk}], c_{kl}^{ij} = [a_{ij}, a_{kl}] \rangle,$$

$$y_{ijk} = \boxed{\text{H}} + \boxed{\text{H}} + \boxed{\text{H}} - \boxed{\text{H}} - \boxed{\text{H}} - \boxed{\text{H}}$$

$I^p$ .

$$\left\langle \begin{array}{c} \text{braids} \\ \text{with } p \text{ crossings} \end{array} \right\rangle = \left\langle \begin{array}{c} \text{braids} \\ \text{with } p-1 \text{ crossings} \end{array} \right\rangle + \left\langle \begin{array}{c} \text{braids} \\ \text{with } p-1 \text{ crossings} \end{array} \right\rangle$$

James Gillespie's Sightline #2 (1984) is a syzygy, and (arguably) Toronto's largest sculpture. Find it next to University of Toronto's Hart House.

Dror Bar-Natan and Peter Lee in Oregon, August 2011

<http://www.math.toronto.edu/~drorbn/Talks/Oregon-1108/>

$\mathfrak{R}_2(PvB_n)$  is generated as a vector space by  $C_{kl}^{ij}$  and

$$Y_{ijk} := \begin{array}{c} \text{braids with } i,j,k \text{ crossings} \\ \text{with one crossing} \end{array} = \begin{array}{c} \text{braids with } i,j,k \text{ crossings} \\ \text{with two crossings} \end{array}$$

Syzygy Completeness, for  $PvB_n$ , means:

$$\mathfrak{R}_p = \bigoplus_{j=1}^{p-1} \mathfrak{R}_{p,j} \xrightarrow{\partial} I^p \xrightarrow{\pi} V^{\otimes p}$$

$$\{\tilde{\sigma}_{12} : Y_{345} : \tilde{\sigma}_{67} : \dots\} \longrightarrow$$

$$\{\tilde{\sigma}_{12} : Y_{345} : \tilde{\sigma}_{67} : \dots\} \longrightarrow \{a_{12}y_{345}a_{67} \dots\}$$

Is every relation between the  $y_{ijk}$ 's and the  $c_{kl}^{ij}$ 's also a relation between the  $Y_{ijk}$ 's and the  $C_{kl}^{ij}$ 's?

$$\begin{array}{c} \text{The Group } PvB_n \\ \text{Generators: } \sigma_{ij} \xrightarrow{i \quad j} \\ \text{Relations:} \\ C_{kl}^{ij}: \quad \text{braids with } i,j,k,l \text{ crossings} = \text{braids with } i,j,k,l \text{ crossings} \\ Y_{ijk}: \quad \text{braids with } i,j,k \text{ crossings} = \text{braids with } i,j,k \text{ crossings} \\ \text{A Syzygy:} \end{array}$$

Theorem S. Let  $D$  be the free associative algebra generated by symbols  $a_{ij}$ ,  $y_{ijk}$  and  $c_{kl}^{ij}$ , where  $1 \leq i, j, k, l \leq n$  are distinct integers. Let  $D_0$  be the part of  $D$  with only  $a_{ij}$  symbols and let  $D_1$  be the span of the monomials in  $D$  having only  $a_{ij}$  symbols, with exactly one exception that may be either a  $y_{ijk}$  or a  $c_{kl}^{ij}$ . Let  $\partial : D_1 \rightarrow D_0$  be the map defined by

$$\begin{aligned} y_{ijk} &\mapsto [a_{ij}, a_{ik}] + [a_{ij}, a_{jk}] + [a_{ik}, a_{jk}] \\ c_{kl}^{ij} &\mapsto [a_{ij}, a_{kl}] \end{aligned}$$

Then  $\ker \partial$  is generated by a family of elements readable from the picture above and by a few similar but lesser families.
