

Stonehenge

From Stonehenge to Drinfel'd Skipping all the Details

University of California at Berkeley Colloquium, April 20, 2000

Dror Bar-Natan, Hebrew University and MSRI

Drinfel'd

Announcement: More on the same everyday next week, 12 at Evans 939.

Creation of Adam

Michelangelo

Disclaimer

1. We'll concentrate on the beauty and ignore the cracks.
2. The speaker is an idiot.

The Gaussian linking number

Carl Friedrich Gauss

$$lk(\text{---}) = \frac{1}{2} \sum_{\text{vertical chopsticks}} (\text{signs})$$

$$\langle D, K \rangle_{\overline{\mathbb{W}}} := \left(\begin{array}{l} \text{(The signed Stonehenge)} \\ \text{(pairing of } D \text{ and } K) \end{array} \right) : \quad D = \text{---} \quad K = \text{---} \quad \Rightarrow \quad \text{---}$$

* * * count with signs

$$Z(K) := \lim_{N \rightarrow \infty} \sum_{\text{3-valent}} \frac{1}{2^c c!(N)_e} \langle D, K \rangle_{\overline{\mathbb{W}}} D \cdot \left(\begin{array}{l} \text{framing-} \\ \text{dependent} \\ \text{renormalization} \end{array} \right) \in \mathcal{A}(\mathcal{O})$$

with

$N := \# \text{ of stars}$

$c := \# \text{ of chopsticks}$

$e := \# \text{ of edges of } D$

$$\mathcal{A}(\mathcal{O}) := \text{Span} \left\langle \text{---} \right\rangle / \text{AS: } \text{---} + \text{---} = 0 \quad \text{oriented vertices} \quad \text{& more relations}$$

When deforming, catastrophes occur when:

A plane moves over an intersection point -
Solution: Impose IHX,

$$\text{---} = \text{---} - \text{---}$$

(see other side)

An intersection line cuts through the knot -
Solution: Impose STU,

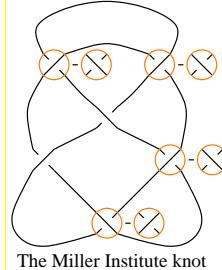

$$\text{---} = \text{---} - \text{---}$$

(similar argument)

The Gauss curve slides over a star -
Solution: Multiply by a framing-dependent counter-term.

(not shown here)

Theorem. Modulo Relations, $Z(K)$ is a knot invariant!

The Miller Institute knot

Definition. V is finite type (Vassiliev) if it vanishes on sufficiently large alternations as on the left.

Theorem. All knot polynomials (Conway, Jones, etc.) are of finite type.

Conjecture. (Taylor's theorem) Finite type invariants separate knots.

Theorem. $Z(K)$ is a universal finite type invariant!
(sketch: to dance in many parties, you need many feet).

Related to Lie algebras

$$[x,y] = xy - yx \quad [x,y,z] = [x,[y,z]] - [y,[x,z]]$$

And to Feynmann diagrams for the Chern-Simons-Witten theory:

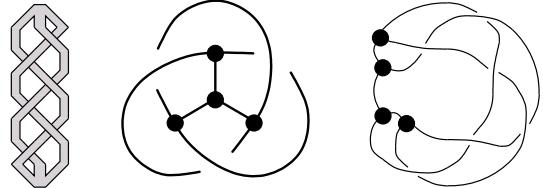

$$\int_{\text{g-connections}} \mathcal{D}A \text{hol}_K(A) \exp \left[\frac{ik}{4\pi} \int_{\mathbb{R}^3} \text{tr} \left(A \wedge dA + \frac{2}{3} A \wedge A \wedge A \right) \right]$$

Computing $Z(K)$:

:("Crossing change" is not well defined!

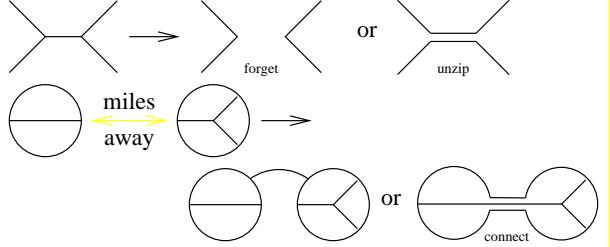

:) Switch to Embedded Trivalent (ribbon) Graphs:

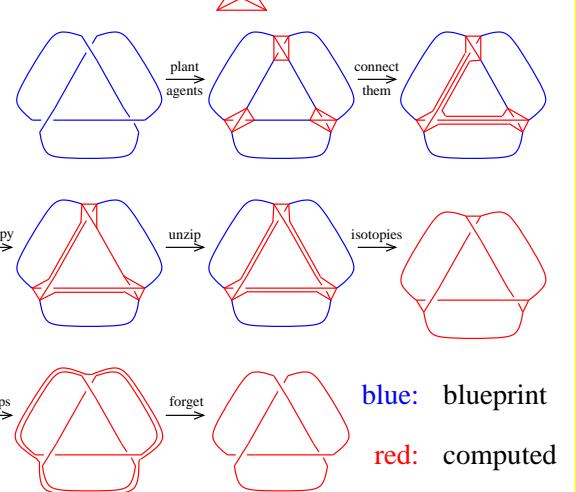

Need a new relation:

$$\text{---} + \text{---} + \text{---} = 0$$

Easy, powerful moves:

Using moves, ETG is generated by ribbon twists and the tetrahedron :

Modulo the relation(s):

$$\left(\text{---} = \text{---} \right)$$

$$\text{---} \rightarrow \text{---} \rightarrow \text{---} = \text{---} \leftarrow \text{---} \quad (+\text{more})$$

Claim. With $\Phi := Z(\Delta)$, the above relation becomes equivalent to Drinfel'd's pentagon equation of the theory of quasi-Hopf algebras:

$$(11\Delta)(\Phi) \cdot (\Delta 11)(\Phi) = (1\Phi) \cdot (1\Delta 1)(\Phi) \cdot (\Phi 1)$$

1. Is there a non-trivial embedding of 3 circles so that if any one of them is dropped the remaining two are unlinked?
 2. Is there a non-trivial embedding of a ribbon theta graph so that if any edge is dropped the remaining circle is unknotted?
 3. Is there a non-trivial embedding of the skeleton of a tetrahedron so that if any edge is dropped, the remaining theta graph is trivially embedded?
