Moreover, for $j\mu h \ge \epsilon_0$ all the functions are uniformly smooth.

Let us now consider the method of successive approximations applied without the reduction construction and without condition (17.3.30) and with the non-perturbed operator $\mathcal{A}_0^0 + \sigma_0 m + \bar{W}\cdot I$ where in $\bar{W}$ we set $x = y$ and skip all the terms with the factor μ^{-2}.

Let us note first of all that this construction is provided by the assumption $T\mu^{-1}h^{-1} \le \mu^{-\delta'}$ with the arbitrary small exponent $\delta' > 0$ (under conditions (17.4.1) or (17.5.1)–(17.5.2)$_{(2)}$) and therefore we need only the assumption $L \ge \mu^{\delta''-1}$ on the mollification parameter where $\delta'' > 0$ is arbitrarily small.

Furthermore, let us note that for $j > k \ge 1$ the blocks W_{jk} of the perturbed operator are

$$W_{jk} = \alpha^-_{(j-k)}(\mu^{-1}h)^{\frac{1}{2}(j-k)}\big(\frac{j!}{k!}\big)^{\frac{1}{2}}\Pi_- + \alpha^+_{(j-k)}(\mu^{-1}h)^{\frac{1}{2}(j-k)}\big(\frac{(j-1)!}{(k-1)!}\big)^{\frac{1}{2}}\Pi_+ \tag{17.6.27}$$

where $\Pi_\pm = \frac{1}{2}(I \pm \sigma_0)$ are projectors and $\alpha^\pm_{(l)} = \alpha^\pm_{(l)}(x_1, \hbar D_1, \hbar, j\hbar)$ are polynomials with respect to $z = j\hbar$; the blocks with $k > j \geq 1$ can be obtained by Hermitian conjugation.

The blocks of the perturbing operator with $j = k \geq 1$ have similar form but in them $\alpha^\pm_{(l)}(.,.,0,0) = 0$. Moreover, the blocks of the operator

$$\tilde{\psi} = \mathcal{T}^*\mathcal{F}^*\psi\mathcal{F}\mathcal{T} - \psi'(x_1, \hbar D_1)I$$

where $\psi' = \psi \circ \bar{\Psi}$ have the same form and in this case $\alpha_{\dots}$ are expressed in terms of ψ in the following way: these coefficients (and therefore the coefficients $\tilde{\psi}_{jk}$ as well) are linear combinations of $(D^\beta\psi)\circ\bar{\Psi}$ with $1 \leq |\beta| \leq K$ and in $\tilde{\psi}_{jk}$ every derivative $D^\beta\psi$ surely has a factor $j^r\hbar^{|\beta|}$ with $r \leq |\beta|$.

Finally, one can see easily that in $\tilde{\psi}_{jk}$ as well as in W_{jk} the coefficients $\alpha^\pm_{(l)}$ satisfy the equality $\alpha^+_{(l)}(.,.,0,.) = \alpha^-_{(l)}(.,.,0,.)$.

On the other hand, let us note that

$$\bigl(\tau - \sigma_0 m - \sigma_1\sqrt{2j\mu\hbar f}\bigr)^{-1} = \bigl(\tau + \sigma_0 m + \sigma_1\sqrt{2j\mu\hbar f}\bigr)\bigl(\tau^2 - m^2 - 2j\mu\hbar f^2\bigr)^{-1},$$

that $\sigma_1\Pi_\pm = \Pi_\pm\sigma_1$ and that the trace of the product of any number of matrices σ_1 and σ_0 (taken in any order) vanishes unless there is an even number of matrices each kind.

These arguments yield that modulo terms generating $O(\mu^{-s})$ after mollification with the indicated mollification scale L, the expression

$$\mp i \operatorname{tr} F_{t\to h^{-1}\tau}\Gamma\psi U^\pm \tag{17.6.28}$$

is (for $\pm \operatorname{Im}\tau < 0$) a sum of terms of the following two types:

(i) Terms of the form

$$\prod_{1\leq\iota\leq n+1} (\tau_1^2 - m^2 - 2j_\iota\mu\hbar f^2)^{-1}\times \\ (j\mu^{-1}h)^p(\mu^{-1}h)^q(j\mu h)^r(\mu h)^l\tau_1^\gamma G(j_2 - j_1, j_3 - j_1, \dots, j_n + 1 - j_1) \tag{17.6.29}$$

with $\tau_1 = \tau - \bar{W}$, $j_1 = j$, $p, q, r, l \in \frac{1}{2}\mathbb{Z}$, $\gamma, n \in \mathbb{Z}$, such that $p + r, q + l \in \mathbb{Z}$, $2(p + q) \geq \max(n, |j_1 - j_2| + \dots + |j_n - j_{n+1}|)$, $n + 1 \geq 2(r + l) + \gamma$ and with bounded coefficients $G(\dots)$.

(ii) Terms of the same form but with $j \le C$ and with G depending arbitrarily on j (in a non-polynomial way; these terms arise because in all the matrices $j, k \ge 0$ and blocks with $j = 0$ or $k = 0$ are special).

However, after we take the difference of the traces from the upper and lower complex half-planes these terms of the type (ii) will produce 0 for $|\tau| \le \epsilon$ under conditions (17.3.30) and (17.4.1). Therefore taking the difference of the traces from the upper and lower complex half-planes we again obtain formula (17.6.24) but with a more explicit formula for $f_{nr\varkappa}$.

In particular, let us calculate $f_{0r\varkappa}$; namely, $f_{0r\varkappa}$ are polynomials of $j\mu^{-1}h$, $\mu^{-1}h$, $j\mu h$ and $(m^2 + 2j\mu h f^2)^{-\frac{1}{2}}$ and all the monomials in these polynomials satisfy the following conditions:

$$1 + 2(\deg_1 + \deg_2) \ge \deg_5 \ge 2(\deg_3 + \deg_4)$$

where $\deg_k$ means the degree with respect to the k-th argument, $k = 1, \dots, 5$. Since these and the original formulae for $f_{\dots}$ should agree for $h^{\delta'} \le \mu h \le \epsilon$ we arrive to the following proposition:

Proposition 17.6.9. *In formula* (17.6.25) *the functions $f_{0r\varkappa}$ are polynomials with respect to $j\mu^{-1}h$, $\mu^{-1}h$ $j\mu h$, μh and $(m^2 + 2j\mu h f^2)^{-\frac{1}{2}}$ with the properties indicated above.*

Let us now calculate all the "other" terms in the decomposition without conditions (17.3.30) and (17.4.1). Moreover, without any loss of the generality one can assume that (17.5.1) holds. Let us temporarily assume that condition $(17.5.2)_{(2)}$ also is fulfilled.

One can see easily that these additional terms are due to the non-standard form of the blocks $\mathcal{A}^0_0$, W_{0k}, W_{k0}, ψ_{00}, ψ_{0k} and ψ_{k0}. Further, one can see easily that these terms have the same form as above but with functions $f_{n\varkappa r}$ non-regularly depending on j. Namely, these functions are now $O\big((\mu^{-1}h)^{\max(j,1)}\big)$.

However, in all cases the following remark is true:

Remark 17.6.10. All terms with $n = 0$ which are different from terms contained in $\partial_\tau h^{-2}\mathcal{N}^{\mathrm{MW}}(x, \tau, \mu h)$ have functions $f_{\dots}$ depending linearly on $D^\beta\psi \circ \bar{\Psi}$ with $1 \le |\beta| \le K$.

17.6.3 Main Theorem

Now we can obtain the main statements of this section. We need the following two definitions:

Definition 17.6.11. Let $d = 2$ and let conditions (17.1.1)–(17.1.3), (17.2.1), (17.3.1) be fulfilled. As $\tau \neq 0$ let us replace the potential V by the potential $V_\tau = V - \tau$ in the operator A. Let us introduce different *lacunary intervals*, namely

(i) $\tau \in \mathcal{Z}_{L1}$ if conditions $(17.2.28)_{1-3}$, (17.4.1), $(13.4.12)_1$, (17.3.30) and (17.6.2) are fulfilled with

$$v_\tau^{\#} = -(V-\tau)^2 + m^2 \tag{17.6.30}$$

instead of $v^{\#}$.

(ii) $\tau \in \mathcal{Z}_{L2}$ if conditions $(17.2.28)_{1-3}$, (17.4.1), $(13.4.12)_1$ and (17.6.5) are fulfilled for all $j \in \mathbb{Z}^+$.

(iii) $\tau \in \mathcal{Z}_{L3}$ if conditions $(17.2.28)_{1-3}$, (17.5.1), $(17.5.2)_{(2)}$ and (17.6.6) are fulfilled for all $j \in \mathbb{Z}^+$ and $\bar{\nu} \geq \mu^{-l}$.

(iv) $\tau \in \mathcal{Z}_{L4}$ if conditions $(17.2.28)_{1-3}$, (17.5.1), $(17.5.2)_{(2)}$ and (17.6.7) are fulfilled for all $(\varkappa, j) \in \mathfrak{Z}$.

Definition 17.6.12. Let $d = 2$ and let conditions (17.1.1)–(17.1.3), $(17.5.2)_{(2)}$, (17.3.1), (17.5.1), (17.5.41), (17.5.33), (17.6.15) and (17.6.16) be fulfilled with small enough $\delta > 0$ in (17.5.41). Then $\tau \in \tilde{\mathcal{Z}}_{L5}$.

Now repeating arguments of theorems 13.6.6, 13.6.7 we easily obtain the following:

Proposition 17.6.13. *Let $d = 2$ and let conditions* (17.1.1)–(17.1.3), (17.2.1) *and* (17.3.1) *be fulfilled. Then*

(i) If $\tau_0 \in \mathcal{Z}_L := \mathcal{Z}_{L1} \cup \dots \cup \mathcal{Z}_{L4}$ then for the L indicated above the following estimate holds:

$$\Bigl|\int \phi\bigl(\frac{\tau-\tau_0}{L}\bigr)\Bigl(\Gamma\psi e(\tau,\tau_0) - h^{-2}\int \mathcal{N}^{\mathsf{MW}}(x,\tau,\tau_0,\mu h)\psi\,dx - \sum_{\varkappa,n,r:n\leq 2r,r\leq N}\sum_j \Theta^{(n)}_{j,\varkappa nr}(\tau,\tau_0)(\mu^{-1}h)^r\Bigr)\Bigr| \leq C'\mu^{-s}h^s \tag{17.6.31}$$

where $\Theta^{(n)}_{j,\dots}(\tau,\tau_0)=\Theta^{(n)}_{j,\dots}(\tau_0)-\Theta^{(n)}_{j,\dots}(\tau)$ *and* $\Theta^{(n)}_{j,\dots}(\tau_0)=0$ *here for* $r\ge 1$.

(ii) Moreover, $\Theta_{j,\dots}$ *are defined by* (17.6.25), (17.6.26) *and the functions* $f\dots$ *are uniformly bounded and smooth with respect to all their arguments for* $\tau\in\mathcal{Z}_{L1}$.

(iii) If $\tau_0\in\tilde{\mathcal{Z}}_{L5}$ *then the left-hand expression in* (17.6.31) *does not exceed* $C'\mu\nu\zeta^{-2}h_1^s$.

Definition 17.6.14. Let $d=2$ and let us assume that there exists parameter $\eta\in(0,1)$ such that after multiplication by η^{-1} the operator A satisfies (17.1.1)–(17.1.3) with $h'=h\eta^{-1}$, $\mu'=\mu\eta^{-1}$, $m'=m\eta^{-1}$.

Further, let us assume that after this procedure $\tau'=\tau\eta^{-1}\in\mathcal{Z}_{Lk}(A')$ where A' is a new operator. Then $\tau\in\mathcal{Z}'_{Lk}:=\mathcal{Z}'_{lk}(A)$ for the original operator. Furthermore, $\tilde{\mathcal{Z}}'_{L5}$ is defined in the same way.

Proposition 17.6.13 then obviously yields

Corollary 17.6.15. *Estimate* (17.6.31) *with* $L\eta$ *instead of* L *holds for* $\tau\in\mathcal{Z}'_L$.

The same arguments yield the following

Theorem 17.6.16. *Let* $d=2$ *and let conditions* (17.1.1)–(17.1.3), (17.2.1) *and* (17.3.1) *be fulfilled. Then for* $\tau_1,\tau_2\in\mathcal{Z}'_L$ *the following estimate holds:*

$$|\Gamma\psi e(\tau_1,\tau_2)-h^{-2}\int\mathcal{N}^{\mathsf{MW}}(x,\tau_1,\tau_2,\mu h)\psi\,dx- \sum_{\varkappa,r\le N}\sum_j\Theta_{j,\varkappa 0r}(\tau_1,\tau_2)(\mu^{-1}h)^r|\le C'\mu^{-s}h^s. \tag{17.6.32}$$

In this theorem the values of the parameter η *for* τ_1 *and* τ_2 *do not necessarily coincide.*

Remark 17.6.17. $\tau\in\tilde{\mathcal{Z}}'_{L5}$ can be defined similarly. The case when $\tau_1\in\tilde{\mathcal{Z}}'_{L5}$ and $\tau\in\mathcal{Z}'_L$ or when $\tau_1,\tau_2\in\tilde{\mathcal{Z}}'_{L5}$ can be treated using by Theorem 17.6.16 and Proposition 17.6.4.

17.7 Generalizations

17.7.1 Propagation of Singularities and Improved Asymptotics

We need to revise all the results of Sections 17.2–17.5 in the manner of Section 13.7. This is very routine task and we live it to the reader just writing down dynamics:

Case $d = 3$

In this case propagation is along magnetic lines on energy level 0 and equation of the fastest movement (as rotational number is 0) is

$$\frac{dx_j}{dt} = \frac{\sqrt{V^2 - m^2}}{FV} F^j \qquad (j = 1, 2, 3) \tag{17.7.1}$$

where F^j are components of the vector intensity of the magnetic field and we assume that $V^2 - m^2 \gtrsim 1$. The natural physical system (17.7.1) should be normalized as $m \gg 1$ by adding factor $(m+1)$ to the right-hand expression:

$$\frac{dx_j}{dt} = (m+1)\frac{\sqrt{V^2 - m^2}}{FV} F^j \qquad (j = 1, 2, 3) \tag{17.7.2}$$

and as $V = m + W/m$, $m \to \infty$ it becomes

$$\frac{dx_j}{dt} = (m+1)\frac{\sqrt{2W}}{F} F^j \qquad (j = 1, 2, 3) \tag{17.7.3}$$

while for $m = 0$ it becomes

$$\frac{dx_j}{dt} = \frac{1}{F} F^j \qquad (j = 1, 2, 3). \tag{17.7.4}$$

Case $d = 2$

In this case all the results for the Schrödinger operator remain true. Now under condition (17.3.30) the drift lines are defined by the equations

$$\frac{dx}{dt} = -\frac{1}{2\mu V}\bigl(\nabla\bigl(\frac{V^2 - m^2}{F}\bigr)\bigr)^{\perp} \tag{17.7.5}$$

as we assume that $V^2 - m^2 \gtrsim 1$. The natural physical system (17.7.5) should be normalized as $m \gg 1$ by adding factor $(m+1)$ to the right-hand expression:

$$\frac{dx}{dt} = -\frac{m+1}{2\mu V}\bigl(\nabla\bigl(\frac{V^2-m^2}{F}\bigr)\bigr)^{\perp} \tag{17.7.6}$$

and as $V = m + W/m$, $m \to \infty$ it becomes

$$\frac{dx}{dt} = -\mu^{-1}\bigl(\nabla\bigl(\frac{W}{F}\bigr)\bigr)^{\perp}. \tag{17.7.7}$$

17.7.2 Getting Rid of the Condition "$v^{\#} \le -\epsilon_0$"

Let us consider the violation of the condition $v^{\#} \le -\epsilon_0$. Recall that for $d = 3$ we need this condition only for $m \le h^{-1+\delta}$ and for $d = 2$ we need it only for $\mu h \le \epsilon_0$.

Case $d = 3$

Case $m \gtrsim 1$. Let us assume first that $m \gtrsim 1$. Then one can assume that

$$V = \pm m + \frac{1}{m}W$$

with

$$|D^{\alpha}W| \le c \qquad \forall \alpha : |\alpha| \le K.$$

Let us assume for the sake of definiteness that the sign is "+" here. Then the assumption $v^{\#} \le -\epsilon_0$ means exactly that

$$W \ge \epsilon_0 \tag{17.7.8}$$

(with another constant $\epsilon_0 > 0$). Let us treat the following cases:

(a) $v^{\#} \ge \epsilon_0 \nu$ in $B(0,1)$;

(b) $v^{\#} \le -\epsilon_0 \nu$ in $B(0,1)$;

(c) $|v^{\#}| \le c\nu$ in $B(0,1)$.

In the cases (a) and (b) let us divide the operator A by $r = |v^{\#}(0)|^{\frac{1}{2}}$ and let us introduce $h' = h/r$, $\mu' = \mu/r$, $m' = m/r$ and $\nu' = \nu/r^2$. One can easily see that

$$\frac{1}{r}V = m' + \frac{1}{m'}W' \qquad \text{with} \qquad |D^{\alpha}W'| \le c \quad \forall \alpha : |\alpha| \le K.$$

Therefore we are respectively in the frameworks of the cases

(a)′ $v^{\#\prime} \ge \epsilon_0$ in $B(0,1)$;

(b)′ $v^{\#\prime} \le -\epsilon_0$ in $B(0,1)$.

Applying the arguments of Subsection 13.8.1 we obtain that in the cases (a) and (b) the condition "$v^{\#} \le -\epsilon_0$" (or "$v^{\#} \ge \epsilon_0$") in our theorems is not necessary.

Similarly, in the case (c) we take $r = \sqrt{\nu}$ and apply the same arguments. In these all cases $h' \le 1$ for $d = 3$ (because we assume that $\nu \ge h^2$); for $d = 2$ the condition ${\mu'}^{1-\delta} \ge h'$ follows from the same condition for μ, h and the restriction $\nu \ge \mu^{-l}h^l$; the same assertion is also true for condition (17.5.40).

Repeating the arguments of Subsection 13.8.1 and referring to Theorem 17.5.7 for the case $\mu' h' \ge 1$ and with a partition of unity such that $\mu' h' \le 1$ we can easily prove

Proposition 17.7.1. *Theorems 17.4.14, 17.4.15, 17.4.16, 17.4.17, 17.4.21, 17.4.22 remain true for* $m \ge 1$ *without condition* (17.3.30).

Case $m \lesssim 1$. Now let $m \lesssim 1$. Then the following cases should be considered (if necessary we apply an ϵ-admissible partition of unity):

(a) $r = |v^{\#}(0)| + \nu + \mu h \le cm^2$;

(b) $|v^{\#}(0)| \ge \epsilon_0 r \ge cm^2 + \mu h$;

(c) $\mu h \ge \epsilon_0 r \ge m^2 + |v^{\#}(0)| + \nu$.

(d) $|v^{\#}(0)| \le \epsilon_0 \nu$, $m^2 + \mu h \le \epsilon_0 \nu$.

In the case (a) division by m reduces this case to the case $h' = h/m$, $\mu' = \mu/m$, $m' = 1$, $\nu'\nu/m^2$ which has been treated already.

Similarly, in the case (b) division by $\sqrt{r}$ reduces this case to the case $h' = h/\sqrt{r}$, $\mu' = \mu/\sqrt{r}$, $\nu' = \nu/r$, $m' = m/\sqrt{r}$, $|v^{\#}(0)| \ge \epsilon_0$.

In the case (c) we get $\mu' h' = 1$ and we do not need condition (17.3.30).

In the case (d) the reduction is not complete: we can only conclude that

$$|D^\alpha V| \le c\nu' \qquad \forall \alpha : |\alpha| \le K'$$

with $\nu' = \nu^{\frac{1}{2}-\delta'}$ with any exponent $\delta' > 0$ and K' (and then $K = K(K', \delta')$ in the original conditions). Therefore one can either divide by ν' or change variables $x' = x\nu^{-\delta'}$ and divide by $\sqrt{\nu}$. In the both cases some "loss of information" happens.

Let $\mu \le h^{-1+\delta}$ as before and let us now assume $m \le 1$. Let us introduce $\rho = \gamma$ by formula (13.8.4) and let us consider the zone $\{\rho \ge \bar\rho = m^{\frac{1}{2}} + (\mu h)^{\frac{1}{4}-\delta'}\}$. Let us consider a ρ-admissible partition of unity in this zone and let us divide the operator by ρ^2 on each element of the partition.

On this element let us introduce $m' = m\rho^{-2}$, $h' = h\rho^{-3}$, $\mu' = \mu\rho^{-1}$, $\nu' = \nu\rho^{-3}$. Then for $d = 3$ the contribution of every element of the partition to the remainder estimate does not exceed $Ch^{-2}\rho^4$ and the total contribution does not exceed Ch^{-2}. So we have proven the following:

Proposition 17.7.2. *Theorem 17.4.14 remains true without conditions* (17.3.30) *and* $m \gtrsim 1$.

The same arguments give us the following

Proposition 17.7.3. *Theorem similar to 13.7.18 remains true without conditions* (17.3.30) *and* $m \ge 1$.

Case $d = 2$

Let us treat now the case $d = 2$. The same arguments as before yield the following:

Proposition 17.7.4. *(i) Theorems 17.4.15, 17.4.16, 17.4.17, 17.4.21 and 17.4.21 remain true without condition* (17.3.30) *in all the cases excluding* $m \le 1$, $1 \ge \nu \ge \epsilon_0 m^2$.

(ii) In the latter case these theorems remain true under the additional restriction

$$|D^\alpha\big(\frac{V}{\sqrt{F}}\big)| \le c\sqrt{\nu'} \qquad \forall \alpha : 1 \le |\alpha| \le K \tag{17.7.9}$$

fulfilled with $\nu' = \nu$. *This condition is fulfilled automatically with* $\nu' = \nu^{1-\delta'}$ *with arbitrary* $\delta' > 0$.

17.7.3 Getting Rid of the Condition "$F \gtrsim \epsilon_0$"

Let us now assume that condition (13.3.1) is violated.

Case $d = 3$

We know that cases $d = 3$ and $d = 2$ are vastly different; let us consider case $d = 3$ first. Let condition $(13.8.19)_n$ be fulfilled[29]. Let us apply arguments of Subsection 13.8.2. If $\mu h \le 1$ then $\mu' h' \le 1$ also and therefore we have the following

Proposition 17.7.5. *Let $d = 3$, let conditions* (17.1.1)–(17.1.3) *be fulfilled and let $\mu h \le 1$. Then under condition* $(13.8.19)_n$ *estimate* (13.8.20) *holds and in the general case estimate* (13.8.23) *holds.*

Recall that the principal part is $O(h^{-3})$ and under an obvious condition it is $\asymp h^{-3}$.

On the other hand, if $\mu h > 1$ we need to consider the zone $\{\mu' h' \ge 1, h' \le 1\}$ since all other zones have been already considered in Subsection 13.8.2. Surely, we can always include h in γ and keep $\gamma \ge h$ but then in the zone $\{\gamma \le C_0 h\}$ condition (13.3.1) is not necessarily fulfilled after rescaling. One can treat this zone by the variational method but here we simply avoid the trouble assuming that $\mu \le h^{-2}$ (and then this zone does not appear). Therefore we have the following

Proposition 17.7.6. *Let $d = 3$, let conditions* (17.1.1)–(17.1.3) *be fulfilled and let $h^{-1} \le \mu \le h^{-2}$. Then the estimate* (13.8.23) *holds with arbitrarily small $\delta > 0$. Recall that the principal part is $O(\mu h^{-2})$ and under an obvious condition it is $\asymp \mu h^{-2}$.*

Remark 13.8.8 also remains true.

Case $d = 2$

Now let $d = 2$ and let condition (17.3.30) be fulfilled. We consider the following problem to be difficult and challenging enough (but not exceedingly for PhD thesis):

---

[29] With n instead of m here and below.

Problem 17.7.7. Generalize results of Chapter 14 to magnetic Dirac operators. Here

(i) Analysis in the regular zone $X_{\mathsf{reg}} = \{|x_1| \ge C_0 \max(\mu^{-1\nu}, h)\}$ seems to be straightforward.

(ii) Analysis in the degenerate zone $X_{\mathsf{deg}} = \{|x_1| \le C_0\mu^{-1\nu}\}$ seems to be more subtle but not overly difficult as $\mu h^{\nu} \le \epsilon$.

(iii) However analysis in the degenerate zone $X_{\mathsf{deg}} = \{|x_1| \le C_1 h\}$ is definitely much more challenging as $\mu h^{\nu} \ge \epsilon$ because it requires analysis of the eigenvalues of 1-dimensional Dirac operator

$$\boldsymbol{a} = \sigma_1 D_1 + \sigma_2(\eta - x_1^{\nu}/\nu) + \sigma_0 m. \tag{17.7.10}$$

17.7.4 Other Generalizations

We consider the following problems to be difficult and challenging enough (but not exceedingly for PhD thesis):

Problem 17.7.8. Generalize results of Chapter 15 to

(i) Magnetic Schrödinger-Pauli operators. Here one needs to start from describing appropriate boundary conditions:

$$(u(x), \Lambda u(x)) \in E(x) \qquad \text{as } \ x \in \partial X, \qquad \Lambda := \sum_{j,l} \sigma_l \big(\omega^{jl} P_j + P_j \omega^{jl}\big) \tag{17.7.11}$$

where $E(x)$ is 2-dimensional space such that

$$(\sum_j \sigma_j n_j v, w) - (v, \sum_j \sigma_j n_j w) = 0 \qquad \forall v, w \in E(x), \tag{17.7.12}$$

(ii) Magnetic Dirac operators. Here one needs to start from describing appropriate boundary conditions:

$$u(x) \in E(x) \qquad \text{as } \ x \in \partial X, \tag{17.7.13}$$

where $E(x)$ is 1-dimensional space such that

$$(\sum_j \sigma_j n_j v, w) = 0 \qquad \forall v, w \in E(x), \tag{17.7.14}$$

$n(x)$ is a normal to ∂X at the point x.

Problem 17.7.9. Generalize results of Chapter 16 to

(i) Magnetic Schrödinger-Pauli operators. Again we need to assume that $V \le -\epsilon_0$.

(ii) Magnetic Dirac operators. Again we need to assume that $v^{\#} \le -\epsilon_0$.

Problem 17.7.10. Consider operator with m replaced by $J(x)$ satisfying

$$(17.7.15)_{1,2} \qquad |D^{\alpha} J(x)| \le cm \quad \forall \alpha : |\alpha| \le K, \qquad c^{-1} m \le J(x) \le cm.$$

It could be useful if we generalize the results of Chapter 23 for the global asymptotics from magnetic Schrödinger operators to the magnetic Dirac operators.

Non-Smooth Theory and Higher Dimensions

Chapter 18

2D- And 3D-Magnetic SchrÖdinger Operator with Irregular Coefficients

18.1 Introduction

18.1.1 Preliminary

This Chapter is a continuation of Chapter 13 and Sections 4.6 and 5.4. Here we deal with the Schrödinger operator with the strong magnetic field in dimensions 2 and 3 under weak smoothness assumptions.

Keeping in mind the crucial role played by the microlocal canonical form in Chapter 13, devoted to such operators in the smooth case, the lack of the ultimate smoothness here seems to be the catastrophic because complete microlocal canonical form requires such smoothness. Instead, in this Chapter we will make a *partial reduction* with a remainder which is just small enough for our needs but not excessively small, and such reduction requires much lesser smoothness.

This reduction serves two purposes.

First, if the magnetic field is not very strong $\mu \le h^{-\frac{1}{3}}$ [1)], we will use it only to prove that the singularities leave the diagonal and propagate away from it and thus the time interval for which we have the standard decomposition

[1)] We skip logarithmic factors $|\log h|^{\beta}$ in this preliminary part.

of the propagator trace could be extended from $\{|t| \le T_* = \bar{T} := \epsilon\mu^{-1}\}$ [2)] to a larger one thus improving remainder estimate $O(\mu h^{1-d})$ which is due to this rescaling as well.

Namely, for $d = 2$ we use the non-degeneracy assumption $|\nabla(V/F)| \ne 0$ and extend time to $\{|t| \le T^* = \epsilon\mu\}$ thus improving estimate to $O(\mu^{-1}h^{-1})$. We also consider a weaker non-degeneracy assumption

$$|\nabla(V/F)| + |\det \mathsf{Hess}(V/F)| \ne 0$$

but it will require at the end more smoothness.

For $d = 3$ no non-degeneracy assumption at this stage is needed: we consider zone $\{|\xi_3| \ge C\mu^{-1}\}$ where ξ_3 is a velocity along magnetic field and we use this movement to prove that the singularities leave the diagonal, increasing time interval to $\{|t| \le T^* = T^*(\xi_3) = \epsilon|\xi_3|\}$ [3)] and another zone $\{|\xi_3| \le C\mu^{-1}\}$ which is small enough to estimate it contribution to the remainder by $O(\mu^{\frac{3}{2}}h^{-\frac{3}{2}}) = O(h^{-2})$.

On the other hand, if the magnetic field is strong enough, we use this canonical form to derive spectral asymptotics as well. For $d = 3$ and $\mu h \le 1$ we do this only in the zone $\{|\xi_3| \le C_0(\mu h)^{\frac{1}{2}}\}$, treating zone $\{|\xi_3| \ge C_0(\mu h)^{\frac{1}{2}}\}$ in the same way as before. Only at this stage the qualified estimate of the remainder in canonical form is needed.

Combining the idea of this "poor man canonical form" with the ideas of Chapter 13, and Sections 4.6 and 5.4 we manage to derive sharp spectral asymptotics under very moderate smoothness conditions: namely,

(a) For $d = 2$ assuming $\mathscr{C}^{2,1}$-regularity under non-degeneracy assumption $\nabla(V/F) \ne 0$ we recover remainder estimate $O\big(\mu^{-1}h^{-1} + 1\big)$ (and the same or almost the same remainder estimate under weaker non-degeneracy assumption) – exactly as in the smooth case; under weaker smoothness assumption remainder estimate would be larger.

(b) For $d = 3$, assuming $\mathscr{C}^{1,2}$-regularity we recover remainder estimates $O\big(h^{-2} + \mu h^{-1}\big)$ (and a the same remainder estimate under weaker non-degeneracy assumption) – exactly as in the smooth case.

(c) For $d = 3$ without any non-degeneracy assumption we recover remainder estimate $O\big(h^{-2} + \mu h^{-1-2/(l+2)}\big)$ in $\mathscr{C}^{l,\sigma}$-case, with appropriate σ.

[2)] This result is just a rescaling of the standard theory (i.e. the theory with $\mu = 1$).

[3)] Actually, a bit better but we skip logarithmic factors here.

Remark 18.1.1. (i) Actually in the case of stronger magnetic field we always assume that the metrics and the magnetic field should belong to $\mathscr{C}^{2,1}$.

(ii) To recover remainder estimate $O(1)$ for $d=2$ and $\mu \gg h^{-1}$ we need to assume that the metrics and the magnetic field should belong to $\mathscr{C}^{4}$.

Recall that here and below we use

Definition 18.1.2. $\mathscr{C}^{l,\sigma}$ denotes a space of functions which $\lfloor l \rfloor$-derivatives are continuous with the continuity modulus $|x-y|^{l-\lfloor l\rfloor}\big|\log|x-y|\big|^{-\sigma}$ if $l\notin\mathbb{N}$ or $l\in\mathbb{N}$ and $\sigma\ge 0$; for $l\in\mathbb{N}$ and $\sigma<0$ one should take $l-1$ instead of $\lfloor l\rfloor$. As $l\in\mathbb{N}$ and $\sigma=0$ $\mathscr{C}^{l,0}:=\mathscr{C}^{l}$.

Also σ will be positive and large enough in the most of the statements[4)].

In this Chapter we consider $d=2$ and $d=3$ only. For $d\ge 4$ the sharp remainder estimate was not derived so far in this book even in the smooth case due to lack of the canonical form[5)]. However, in the next forthcoming Chapters 19[6)] and 20[7)] we will to cover multidimensional case as well, using the idea of the partial canonical form introduced here. However, a higher smoothness than here may be required.

So, let us consider Schrödinger operator in the strong magnetic field (13.2.1) i.e.

$$A = A_0 + V(x), \qquad A_0 = \sum_{j,k\le d} P_j g^{jk}(x) P_k, \tag{18.1.1}$$

$$P_j = hD_j - \mu V_j(x), \quad \mu \ge 1$$

with real symmetric positive metric tensor (g^{jk}), real-valued V_j, V and small parameter h and large parameter μ.

We assume that the corresponding *magnetic field intensity*

$$F^{l}(x) = \frac{1}{2}\sum_{jk} \varepsilon^{jkl}\big(\partial_{x_j} V_k - \partial_{x_k} V_j\big) \tag{18.1.2}$$

[4)] In contrast to non-magnetic case we are not obsessed here to making σ as small as possible but we are still pushing hard l down.

[5)] Because of variable multiplicities of the eigenvalues of the matrix magnetic (F_{jk}) intensity and their "high-order resonances" when one of their linear combination with integer coefficients vanishes.

[6)] Provided $\mathsf{rank}(F_{jk})(x)=d$ at each point x.

[7)] Provided $\mathsf{rank}(F_{jk})=2r<d$ at each point x.

with the standard absolutely skew-symmetric tensor ε^{jkl} [8)] does not vanish in domain in question. Note that for $d=2$ automatically $F^1=F^2=0$ and thus magnetic field is reduced to F^3.

Remark 18.1.3. For $d=3$ we can straighten vector field $\boldsymbol{F}=(F^1,F^2,F^3)$ and direct it along x_3 by an appropriate choice of variables x_1,x_2 and make $V_3=0$ by an appropriate *gauge transformation* $A\mapsto e^{-i\mu h^{-1}\Phi(x)}Ae^{i\mu h^{-1}\Phi}$.

We assume that this is has been done and impose smoothness conditions to the reduced operator.

Thus we assume that for this reduced operator

$$V_3=0,\qquad \partial_{x_3}V_k=0\quad k=1,2 \tag{18.1.3}$$

where the second condition is due to the first one and assumption $F^1=F^2=0$; then one can reduce it further to $V_2=0$ and then

$$\boldsymbol{F}=(0,0,F^3),\quad F^3=g^{-\frac{1}{2}}(\partial_{x_1}V_2-\partial_{x_2}V_1),\qquad g=\det(g^{jk})^{-1} \tag{18.1.4}$$

and the scalar intensity of magnetic field is

$$F=g_{33}^{\frac{1}{2}}|F^3|=(g^{11}g^{22}-g^{12}g^{21})^{\frac{1}{2}}|(\partial_{x_1}V_2-\partial_{x_2}V_1)|, \qquad (g_{jk})=(g^{jk})^{-1}. \tag{18.1.5}$$

In particular, for $d=2$ one can assume that $g^{33}=1$, $g^{3j}=0$ for $j=1,2$; without taking absolute value we get *pseudo-scalar intensity* then.

Further, we assume that

$$F\ge c^{-1}. \tag{18.1.6}$$

Multiplying operator by $F^{-\frac{1}{2}}$ from both sides one can further reduce to the case

$$F=1; \tag{18.1.6)*}$$

then the operator in question will be

$$\sum_{j,k} P_jF^{-1}g^{jk}P_k+F^{-1}(V-h^2V') \tag{18.1.7}$$

[8)] With non-zero components equal $\pm g^{\frac{1}{2}}$ where here and in what follows $g=\det(g^{jk})$ and $(g_{jk})=(g^{jk})^{-1}$.

with

$$V' = F^{\frac{1}{2}} \sum_{j,k} \partial_j \bigl(g^{jk} \partial_k F^{-\frac{1}{2}}\bigr) \tag{18.1.8}$$

and this perturbation will not affect our results unless $d = 2$, $\mu \ge h^{-1}$ (in which case V should be corrected).

18.1.2 Smooth Case: Survey

From Chapter 13 we know that for $d = 2$ in the smooth case one can reduce operator further to the microlocal canonical form

$$\mu^2 \sum_{m+n+p\ge 1} \omega_{m,n,p}(x_2, \mu^{-1}hD_2)\bigl(x_1^2 + \mu^{-2}h^2D_1^2\bigr)^m \mu^{-2n-p}h^p \tag{18.1.9}$$

with the principal part

$$F(x_2, \mu^{-1}hD_2)\bigl(\mu^2 x_1^2 + h^2 D_1^2\bigr) + V(x_2, \mu^{-1}hD_2) \tag{18.1.9$_0$}$$

and for $d = 3$ in the smooth case one can reduce operator to the microlocal canonical form

$$\mu^2 \sum_{m+n+p+q\ge 1} \omega_{m,q,k,p}(x_2, x_3, \mu^{-1}hD_2)\times \bigl(x_1^2 + \mu^{-2}h^2D_1^2\bigr)^m (hD_3)^q \mu^{-2m-2q-2k-p}h^p \tag{18.1.10}$$

with the principal part

$$F(x_2, \mu^{-1}hD_2)\bigl(\mu^2 x_1^2 + h^2 D_1^2\bigr) + h^2D_3^2 + V(x_2, x_3, \mu^{-1}hD_2). \tag{18.1.10$_0$}$$

Then decomposing into Hermitian functions of $\mu^{\frac{1}{2}}h^{-\frac{1}{2}}x_1$ one can replace harmonic oscillator $(h^2D_1^2 + \mu^2 x_1^2)$ by its eigenvalues $(2j+1)\mu h$ with $j \in \mathbb{Z}^+$. So, basically for $d = 2$ our operator is a kind of the mixture of the usual second order operator and a family of $\mu^{-1}h$-pseudodifferential operators while for $d = 3$ it is a kind of the mixture of the usual second order operator and a family of h-differential 1-dimensional Schrödinger operators with respect to x_3 which are also $\mu^{-1}h$-pseudodifferential operators with respect to x_2. This explains the major differences between $d = 2$ and $d = 3$:

For $d = 2$ there are sharp Landau levels $(2j+1)\mu h$ (the eigenvalues of the infinite multiplicity as g^{ik} and V are constant and domain is $\mathbb{R}^2$); without

some non-degeneracy assumption one cannot expect the remainder estimate better than $O(\mu h^{-1})$ and with an appropriate non-degeneracy assumption one can improve it up to $O(\mu^{-1}h^{-1}+1)$ because only $\asymp (\mu h)^{-1}$ of Landau levels are not classically forbidden.

Meanwhile, for $d=3$ Landau levels are rather bottoms of the branches of the continuous spectrum and the non-degeneracy assumption is not that crucial: the best possible remainder estimate is $O\big(h^{-2}+\mu h^{-1}\big)$ while the worst possible remainder estimate depends on the smoothness of the reduced operator (presuming nothing wrong happened during reduction) and is $O\big(h^{-2}+\mu h^{-1-2/(l+2)}\big)$ in the heuristic accordance with Section 5.4.

Finally, for $d\ge 4$ Landau levels are $\sum_{1\le k\le r}(2j_k+1)f_k\mu h$ where $f_k>0$, $\pm i f_k$ are non-zero eigenvalues of the matrix magnetic intensity F, $2r=\mathsf{rank}\, F$ and $j\in \mathbb{Z}^{+\,r}$, and one can think operator to be similar to 2-dimensional as $\mathsf{rank}\, F=d$ and to 3-dimensional as $\mathsf{rank}\, F<d$ but there is no complete canonical form even if $\mathsf{rank}\, F$ and multiplicities of f_k are constant because $\sum_k j_k f_k$ can vanish for some $j\in\mathbb{Z}^r$ at some points (and we call this *resonances*). This leads to the difficulties in our analysis which we tackle in Chapters 19[6] and 20[7].

18.1.3 Non-Smooth Case: Heuristics as $d=2$

In the non-smooth case we do not have the complete canonical form but actually we do not need it. Further, if magnetic field is not very strong we do not need even logarithmic uncertainty principle[9] (18.1.12) below to justify quantization of $V(x_2,\xi_2)$ because we do not quantize it in this case.

Consider ξ_2-shift for time T in the propagation. Note that it does not exceed CT and under non-degeneracy assumption $|\partial_{x_2}V|\ge\epsilon$ the shift is exactly of magnitude $\asymp T$ as $T\le \epsilon\mu$. This shift is "observable" on the "quantum level" and the propagator trace vanishes provided logarithmic uncertainty principle $T\times\varepsilon\ge Ch|\log h|$ holds; here x_2- scale is ε.

In order to be able to take T as small as $\bar{T}=\epsilon\mu^{-1}$ we need to pick up

$$\varepsilon = C\mu h|\log h| \tag{18.1.11}$$

which in addition to the semiclassical remainder estimate $O(\mu^{-1}h^{-1})$ brings an approximation error $O(h^{-2}\varepsilon^{l}|\log h|^{-\sigma})$ for coefficients belonging to $\mathscr{C}^{l,\sigma}$.

[9] Recall that in the non-smooth case we approximate operator in question by operator with ε-smooth coefficients.

This error will be small for $\mu \le h^{1-\delta}$ and $\delta = 2/(l+2)$ which would take care of $\mu \le h^{1-\delta}$ in the smooth case but we do not have such luxury now.

As μ grows larger we need to treat our operator as a family of $\mu^{-1}h$-pseudodifferential operators and then we need the logarithmic uncertainty principle $\varepsilon \times \varepsilon \ge C\mu^{-1}h|\log \mu|$

$$\varepsilon = C(\mu^{-1}h|\log \mu|)^{\frac{1}{2}} \tag{18.1.12}$$

which in addition to the semiclassical remainder estimate $O(\mu^{-1}h^{-1})$ brings an approximation error $O\big(h^{-2}\varepsilon^{l}|\log h|^{-\sigma}\big)$ as $\mu \lesssim h^{-1}$.

On the other hand, for $\mu \gtrsim h^{-1}$ and we consider the Schrödinger-Pauli operator, the semiclassical remainder estimate is $O(1)$ and an approximation error is $O\big(\mu h^{-1}\varepsilon^{l}|\log h|^{-\sigma}\big)$ from approximation of V but also $O\big(\mu^{2}\varepsilon^{\bar{l}}|\log h|^{-\bar{\sigma}}\big)$ from approximation of g^{jk}, V_j where we assume that $g^{jk}, F \in \mathscr{C}^{\bar{l},\bar{\sigma}}$.

An actual reduction and calculations are the very significant part of our analysis.

For the best results we need to pick ε to be the minimum of (18.1.11) and (18.1.12) i.e.

$$\varepsilon \coloneqq C\begin{cases} \mu h|\log h| & \text{as } \ \mu \le (h|\log h|)^{-\frac{1}{3}} \\ (\mu^{-1}h|\log \mu|)^{\frac{1}{2}} & \text{as } \ \mu \ge (h|\log h|)^{-\frac{1}{3}} \end{cases} \tag{18.1.13}$$

and the threshold is $\mu_1^* \coloneqq (h|\log h|)^{-\frac{1}{3}}$. Below it magnetic field is considered to be *weak* and above it *temperate* (and we treat these two cases differently). The second threshold is $\mu_2^* \coloneqq h^{-1}$; for μ above it we modify our conditions and only finite number of Landau levels matter; we call magnetic field *strong* then.

18.1.4 Non-Smooth Case: Heuristics as $d = 3$

In contrast to 2-dimensional case, there is a movement along x_3 with the speed $|\xi_3|$ and for time T shift with respect to x_3 is $\asymp T\cdot|\xi_3|$ (provided $|\xi_3| \ge C\mu^{-1}$ and $T \le |\xi_3|$). This shift is "observable" on the "quantum level" and the propagator trace vanishes provided the logarithmic uncertainty principle $T|\xi_3|\times|\xi_3| \ge Ch|\log h|$ holds; also we need to assume that $\varepsilon\times|\xi_3| \ge Ch|\log h|$. Here scale with respect to ξ_3 is $\epsilon|\xi_3|$.

Plugging $T = \bar{T} = \epsilon\mu^{-1}$ we arrive to the inequality

$$|\xi_3| \ge \bar{\rho} \coloneqq C\max\big(\mu^{-1}, (\mu h|\log h|)^{\frac{1}{2}}\big) \tag{18.1.14}$$

and also we need to take ε depending on ξ_3: $\varepsilon = Ch|\log h|/|\xi_3|$. Then the contribution of the *outer zone* $\{|\xi_3| \ge \bar\rho\}$ to the approximation error will be $O(h^{-2})$ under $\mathscr{C}^{1,2}$ regularity of the coefficients.

Further, in this case one can replace $T^*(\xi_3) = \epsilon|\xi_3|$ by a bit larger $T^*(\xi_3) = \epsilon|\xi_3|\big|\log|\xi_3|\big|^2$ and then the contribution of this zone to the remainder does not exceed $Ch^{-2}\int T^{*\,-1}(\xi_3)\,d\xi_3$ which does not exceed Ch^{-2} for this increased $T^*(\xi_3)$.

On the other hand, the contribution of the *inner zone* $\{|\xi_3| \le \bar\rho\}$ to the remainder does not exceed $C\mu\bar\rho h^{-2}$ which in turn does not exceed Ch^{-2} as $\mu \le \mu_1^* := (h|\log h|)^{-\frac{1}{3}}$. In this case we take $\varepsilon = Ch\log h\bar\rho^{-1}$ in the inner zone and then its contribution to the approximation error does not exceed Ch^{-2} as well. In fact we will increase this threshold to $\mu_1^* := h^{-\frac{1}{3}}$.

For $\mu \ge h^{-\frac{1}{3}}$ we will consider the outer zone in the same way as above but in the inner zone $\{|\xi_3| \le \bar\rho\}$ we will treat our operator as a family of 1-dimensional Schrödinger operators. Then one needs to take $\varepsilon = Ch|\log h|/|\xi_3|$ in this zone as well. Now theory breaks in two cases.

(a) Without the non-degeneracy assumption. Here we apply in rather straightforward manner arguments of Subsection 5.4.2.

(b) Under the non-degeneracy assumption. It is still not very useful to use shift with respect to x_3, x_2, ξ_2 because it lands us with $\varepsilon = C\mu h|\log h|$ which leads to the total approximation error $O(h^{-2})$ only under excessive smoothness assumptions. The role of this condition is more subtle: after $|\xi_3|^2$-partition with respect to x_2, x_3, ξ_2 this condition assures that the ellipticity condition fails only for elements with the total relative measure $\asymp \min\big(|\xi_3|^2/\mu h, 1\big)$ and this leads us in the end to both remainder and approximation error not exceeding Ch^{-2}.

The logarithmic uncertainty principle requires condition $|\xi_3| \ge Ch^{\frac{1}{3}}|\log h|^{\frac{1}{3}}$ which can be weaken to $|\xi_3| \ge Ch^{\frac{1}{3}}$. Zone $\{|\xi_3| \le Ch^{\frac{1}{3}}\}$ is small enough and its total contribution does not exceed Ch^{-2} as well.

Finally, for $\mu \ge h^{-1}|\log h|^{-1}$ the outer zone disappears.

18.1.5 Plan of the Chapter

Let us discuss the plan of this chapter. Sections 18.2–18.5 are devoted to 2-dimensional case and Sections 18.5–18.8 are devoted to 3-dimensional case.

In Section 18.2 we consider case $d = 2$ when magnetic field is relatively weak. Using "precanonical form" we prove our first main Theorem 18.2.9.

In Section 18.3 we consider case $d = 2$ when magnetic field is relatively strong. We derive "poor man canonical form". The true (complete) canonical form does not exist because we lack the infinite smoothness. However precanonical form exists with a rather small error but we need to plug corrected potential W instead of V and their difference is the source of correction term. This corrected potential W is an original potential V averaged along magnetrons and as $(I,\sigma) \succeq (2,1)$ their difference is sufficiently small and therefore the correction term is sufficiently small as well.

In Section 18.4 we prove major Tauberian estimates. Then in Section 18.4.5 we make calculations, prove statements our main Theorem 18.5.4 and finish 2-dimensional case.

In Section 18.6 we consider case $d = 3$ when magnetic field is relatively weak. We analyze the outer zone defined by (18.1.14) (if (x_3,ξ_3) are "free"("non-magnetic") variables) and prove that the contribution of this zone to the remainder is $O(h^{-2})$; then we prove instantly Theorem 18.6.4 and we improve it to Theorem 18.6.12 to cover the case $\mu \le h^{-\frac{1}{3}}$ rather than $\mu \le (h|\log h|)^{-\frac{1}{3}}$.

In Section 18.7 we consider case $d = 3$ when magnetic field is relatively strong. We derive "poor man canonical form".

In Section 18.8 we analyze the inner zone defined by inequality opposite to (18.1.14) as $h^{-\frac{1}{3}} \le \mu \le Ch^{-1}$ and and prove major Tauberian estimates.

Then in Section 18.4.9 we make calculations, prove statements our main Theorem 18.9.4 and 18.9.6 and finish 2-dimensional case.

In what follows we consider operator (13.2.1) assumingly that conditions (13.2.1), (13.2.4), (13.2.5) and (13.4.45).

18.1.6 Standard Results Rescaled

By the *standard results* we mean results for $\mu = 1$. While rescaling final spectral asymptotics by $x \mapsto \mu x$, $h \mapsto \mu h$ we would get the standard remainder estimate $O(h^{1-d})$ converted into $O\big((\mu h)^{1-d}\cdot \mu^d\big) = O(\mu h^{1-d})$, something which we want to improve, rescaling of the intermediate results will be much more fruitful.

Let us consider some (γ,ρ)-admissible partition in (x,ξ) and ε-mollification with respect to x with ε depending on (x,ξ) such that[10)]

$$C_s\rho^{-1}h|\log h| \le \varepsilon \le \gamma. \tag{18.1.15}$$

At first we assume that ε is a numerical small parameter.

Let $\tilde{A}$ be such approximate operator and $\tilde{e}(x,y,\tau)$ be its spectral projector. Let $U(x,y,t)$ be the Schwartz kernel of the corresponding propagator $e^{-ih^{-1}t\tilde{A}}$. We do not write $\tilde{U}$ as we will never consider propagator for the non-mollified (i.e. original) operator.

Proposition 18.1.4. *Let ε be a small numerical parameter such that*

$$\varepsilon \ge C_s h|\log h|, \tag{18.1.16}$$

and

$$\mu \le C_s^{-1}h^{-1}|\log h|^{-1}. \tag{18.1.17}$$

(i) Then

$$|\int \bar{\phi}_\zeta(\tau)\Big(d_\tau \tilde{e}(x,x,\tau) - F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t)U(x,x,t)\big)\,d\tau\Big)| \le Ch^s \tag{18.1.18}$$

provided $\bar{\phi}(\tau)=1$ for $\tau<-1$, $\bar{\phi}(\tau)=0$ for $\tau>-\frac12$, $\bar{\chi}(t)=1$ for $|t|\le\frac12$, $\bar{\chi}(t)=0$ for $|t|\ge 1$[11)]*, $T=\bar{T}:=\epsilon_0\mu^{-1}$ with small enough constant $\epsilon_0>0$, $\zeta\ge C_s\mu h|\log h|$*[12)] *and $\bar{\chi}_T(t)=\bar{\chi}(t/T)$, $\bar{\phi}_\zeta(\tau)=\bar{\phi}(\tau/\zeta)$.*

(ii) Moreover as $|\tau|\le\epsilon$

$$|F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t)-\bar{\chi}_{T_*}(t)\big)U(x,x,t)| \le Ch^s \tag{18.1.20}$$

with $T=\bar{T}$ and $T_*:=C_sh|\log h|$,

$$|F_{t\to h^{-1}\tau}\bar{\chi}_{T_*}(t)\big(U(x,x,t)-U^0(x,x,t)\big)| \le Ch^{3-d}+Ch^{1-d}\vartheta(h) \tag{18.1.21}$$

[10)] In fact both γ and especially ρ could be vectors and then assumption (18.1.15) should hold for their components.

[11)] We pick up all auxiliary functions ϕ, χ etc satisfying assumptions of Section 2.3:

$$|D^\alpha f| \le (CN)^{(|\alpha|-m)_+} \qquad \forall \alpha : |\alpha| \le N = \epsilon_s|\log h| \tag{18.1.19}$$

with large enough exponent m.

[12)] So ζ and T also satisfy logarithmic uncertainty principle $\zeta\cdot T\ge C_sh|\log h|$.

with

$$U^0(x,x,t) \coloneqq h^{-d}\int e^{ih^{-1}t\tau}\, d_\tau \tilde{\mathcal{N}}_x^{\mathsf{MW}}(\tau) \tag{18.1.22}$$

and

$$|F_{t\to h^{-1}\tau}\bar{\chi}_{T_*}(t)\big(U(x,x,t)-U^0_{\mathsf{st}}(x,x,t)\big)| \le C\mu^2 h^{3-d} + Ch^{1-d}\vartheta(h) \tag{18.1.23}$$

with

$$U^0_{\mathsf{st}}(x,x,t) \coloneqq h^{-d}\int e^{ih^{-1}t\tau}\, d_\tau \tilde{\mathcal{N}}_x^{\mathsf{W}}(\tau) \tag{18.1.24}$$

where both $\tilde{\mathcal{N}}_x^{\mathsf{W}}(\tau)$ *and* $h^{-d}\tilde{\mathcal{N}}_x^{\mathsf{MW}}(\tau)$ *are constructed for the mollified operator* $\tilde{A}$ *and* $\vartheta(t) = t^l|\log t|^{-\sigma}$ *as* $g^{jk}, F_{jk}, V \in \mathscr{C}^{l,\sigma}$.

Proof. (a) Proof of estimate (18.1.18) is standard because in the scale $x\mapsto \mu x$, $t\mapsto \mu t$, $\tau\mapsto \mu^{-1}\tau$, $\mu\mapsto 1$, $h\mapsto \mu h$ we have the standard case (with $\mu = 1$). Note that

$$\int \bar{\phi}_\zeta(\tau) F_{t\to h^{-1}\tau}\Big(\bar{\chi}_T(t)U(x,x,t)\Big)\, d\tau = \bar{\phi}_\zeta(hD_t)\Big(\bar{\chi}_T(t)U(x,x,t)\Big)\Big|_{t=0}. \tag{18.1.25}$$

Inequality (18.1.20) also follows from the same rescaling arguments applied to the standard results of Section 4.6 as we take in account the ξ-microhyperbolicity which is equivalent to (18.1.26):

$$V \le -\epsilon_0. \tag{18.1.26}$$

(b) To prove (18.1.21)–(18.1.22) and (18.1.23)–(18.1.24) we also apply rescaling arguments and recall construction of $U(x,y,t)$ by the method of successive approximations as $|t| \le C_s h|\log h|$.

However, as an unperturbed operator one can also take

$$\bar{A}(x,y,hD_x) \coloneqq \sum_{j,k} g^{jk}(y)\bar{P}_j\bar{P}_k + V(y) \tag{18.1.27}$$

with

$$\bar{P}_j = hD_j - \mu V_j(y;x), \qquad V_j(y;x) = V_j(y) + \langle \nabla V_j(y), x-y\rangle \tag{18.1.28}$$

rather than more standard $V_j(y)$ (where the former includes magnetic field and the latter does not) and here we must plug mollified $\tilde{g}^{jk}$, $\tilde{V}_j$, and $\tilde{V}$ instead of the original (non-mollified) coefficients.

One can see easily that for such operator the restriction of the spectral kernel to the diagonal $\bar{e}(y,y,\tau)$ is exactly $h^{1-d}\tilde{\mathcal{N}}_y^{\mathsf{MW}}(\tau)$ and that all other terms of the successive approximation contribute no more than $O(h^{3-d})$.

Really, the contribution of the k-th term ($k = 1,2,3,...$) does not exceed $Ch^{-d-(k-1)}T^{2k-1}$ with $T = h|\log h|$ as long as $g^{jk}, V \in \mathscr{C}^{1,1}$ and $V_j \in \mathscr{C}^{2,1}$; then each next term acquires factor T^2h^{-1}.

Thus contribution of any term with $k \ge 4$ is clearly $O(h^{3-d})$ while contribution of the third term is $O(h^{3-d}|\log h|^5)$. Further, analysis of Subsection 4.6.4 (based on the rescaling technique) shows that one can take $T = h$ in this estimate and then the contribution of the second term does not exceed Ch^{3-d} as well.

Consider the second term

$$\frac{1}{2\pi i}\Big(\bar{G}^{+}(\tilde{A}-\bar{A})\bar{G}^{+} - \bar{G}^{-}(\tilde{A}-\bar{A})\bar{G}^{-}\Big)\delta(x-y)\delta(t) \tag{18.1.29}$$

where $\bar{G}^{\pm}$ are respectively forward and backward parametrices of the evolution operator $hD_t - \bar{A}$.

Consider $\tilde{A}-\bar{A} = R_1 + R_2$ where R_1, R_2 are second order operators with the coefficients $O\big(\mu|x-y|\vartheta(|x-y|)\big)$ and $O\big(\vartheta(|x-y|)\big)$ provided $\vartheta(z) \ge Cz^2$. The same rescaling procedure implies that if we replace $\tilde{A}-\bar{A}$ in (18.1.29) by R_1, R_2, the final error will be $O\big(h^{1-d}\mu h\vartheta(h)\big)$ and $O\big(h^{1-d}\vartheta(h)\big)$ respectively. On the other hand, for $\vartheta(z) = O(z^2)$ we get $O(h^{3-d})$.

It implies estimates (18.1.21)–(18.1.22).

(c) To prove estimates (18.1.23)–(18.1.24) we need to use the same construction but with the standard unperturbed operator $\bar{A}(y, hD_x)$ instead; it is given by (18.1.27) with $\bar{P}_j = hD_j - V_j(y)$. Then one can estimate the contribution of the k-th term in the successive approximation by $Ch^{-d+k}\mu^{k-1}$ and thus all the terms but the first two contribute less than $C\mu^2h^{2-d}$. The

contribution of the first term is exactly $h^{-d}\tilde{\mathcal{N}}_y^{\mathsf{W}}(\tau)$ and the only term we need to consider is the second one.

The same argument as above work but now

$$\tilde{A}-\bar{A}=R_0+R_1+R_2,\qquad R_0=\mu\langle x-y,\nabla_y\tilde{A}(y,hD_x)\rangle.$$

Then the contributions of the term given by (18.1.29) with $\tilde{A}-\bar{A}$ replaced by R_0 will be identically 0 we get a term odd with respect to $(x-y,D_x)$ and therefore its restriction to $\{x=y\}$ vanishes.

It implies estimates (18.1.23)–(18.1.24). □

Corollary 18.1.5. *In the framework of Proposition 18.1.4(ii)*

$$h^{-1}\Big|\int^{\tau} F_{t\to h^{-1}\tau}\bar{\chi}_{T_*}(t)\big(U(x,x,t)-U^0(x,x,t)\big)\,d\tau\Big|\le Ch^{2-d}+Ch^{-d}\vartheta(h) \tag{18.1.30}$$

and

$$h^{-1}\int^{\tau} \big|F_{t\to h^{-1}\tau}\bar{\chi}_{T_*}(t)\big(U(x,x,t)-U^0_{\mathsf{st}}(x,x,t)\big)\,d\tau\big|\le C\mu^2h^{2-d}+Ch^{-d}\vartheta(h). \tag{18.1.31}$$

18.2 $d=2$: Weak Magnetic Field

We start from 2-dimensional case which is more transparent and clean.

18.2.1 Heuristics

Toy-Model

The toy-model of such operator is $h^2D_1^2(hD_2-\mu x_1)^2+V(x)$ and metaplectic map $hD_1\mapsto hD_1$, $hD_2-\mu x_1\mapsto -\mu x_1$, $x_1\mapsto x_1+\mu^{-1}hD_2$, $x_2\mapsto x_2+\mu^{-1}hD_1$ transforms this operator into

$$h^2D_1^2+\mu^2x_1^2+V(x_1+\mu^{-1}hD_2,x_2+\mu^{-1}hD_1). \tag{18.2.1}$$

In some sense this operator is modelled by

$$h^2 D_1^2 + \mu^2 x_1^2 + V(\mu^{-1} h D_2, x_2), \tag{18.2.2}$$

Then along coordinates x_2 and $\xi_2 \sim \mu^{-1} h D_2$ singularities propagate with the speed $O(\mu^{-1})$ and under assumption $|\partial_{\xi_2} V| \asymp \nu$ for time T the shift with respect to x_2 is $\asymp \mu^{-1} T \nu$. To satisfy logarithmic uncertainty principle we should assume that

$$\mu^{-1} T \nu \cdot \varepsilon \geq C \mu^{-1} h |\log(\mu^{-1} h)| \tag{18.2.3}$$

because $V(\mu^{-1} h D_2, x_2)$ is $\mu^{-1} h$-pseudodifferential operator with respect to x_2 and ε is a characteristic size in ξ_2-variable. Therefore, $\Gamma U := \int U(x, x, t) dx$ is negligible for $T_* \leq |t| \leq T^*$ with

$$T_* := C \varepsilon^{-1} \nu^{-1} h |\log(\mu^{-1} h)| \tag{18.2.4}$$

and $T^* = \epsilon \mu$ (as we will show).

On the other hand, from the standard results rescaled we know ΓU for $|t| \leq \bar{T} := \epsilon \mu^{-1}$. In order these intervals to overlap we need

$$T_* = C \varepsilon^{-1} \nu^{-1} h |\log(\mu^{-1} h)| \leq \bar{T} = \epsilon \mu^{-1}$$

i.e. $\varepsilon \geq C \mu h |\log h| \nu^{-1}$ and therefore $\mu \leq h^{-1} |\log h|^{-1}$. So, let us pick up the minimal possible value

$$\varepsilon = C \mu h \nu^{-1} |\log h| \tag{18.2.5}$$

and then the approximation error will be $C h^{-2} \vartheta(\mu h \nu^{-1} |\log h|)$.

This construction works for pretty large μ; however, these arguments are optimal only for

$$\mu \leq \bar{\mu}_1 := (h |\log h|)^{-\frac{1}{3}}. \tag{18.2.6}$$

Remark 18.2.1. In the next section we will pick up $\varepsilon = C\big(\mu^{-1} h |\log(\mu^{-1} h)|\big)^{\frac{1}{2}}$ which (for $\nu \asymp 1$) is less than $C \mu h |\log h|$ as $\mu \geq \bar{\mu}_1$.

Note that we need inequality $\varepsilon \geq C\big(\mu^{-1} h |\log(\mu^{-1} h)|\big)^{\frac{1}{2}}$ even to consider $V(\mu^{-1} h D_2, x_2)$ as a legitimate $\mu^{-1} h$-pseudodifferential operator. So, in the framework of this section $V(\mu^{-1} h D_2, x_2)$ is not even defined properly. The short answer to this obstacle is that we should work directly with operator $V(x_1 + \mu^{-1} h D_2, x_2 + \mu^{-1} h D_1)$ or just not to make any reduction but still to be able to reproduce the above arguments.

Propagation of Singularities

The goal of the this subsubsection is to prove that on the energy level 0 and below singularities propagate with respect to x_1, x_2 with the finite speed, and that with respect to "variables" $Q_j := x_j + \sum_k \beta_{jk}\mu^{-1}P_k$ (with appropriate coefficients β_{jk}) singularities propagate with the speed not exceeding $C_0\mu^{-1}$; further, the same is true for $Q'_j := Q_j + \sum_{ki} \mu^{-2}\beta'_{jki}P_kP_l$ with appropriate coefficients β'_{jki}; finally, in the latter case singularities propagate along trajectories of the "Liouvillian" field of $(V-\tau)/F$ [13].

We define β_{jk} to have Poisson brackets vanish: $\{Q_j, P_k\} \equiv 0 \mod O(\mu^{-1})$, or simply

$$Q_1 = x_1 - F_{12}^{-1}P_2, \quad Q_2 = x_2 + F_{12}^{-1}P_1, \qquad \{P_1, P_2\} = -\mu F_{12} \tag{18.2.8}$$

as we would do in the smooth case; then

$$\{A_0, Q_j\} = \mu^{-1}\sum_{ki} \alpha_{jki}P_kP_i; \tag{18.2.9}$$

where $A_0 = A - V$. In the smooth case we would be able to eliminate α_{jkl} modulo $\omega_j A_0$ and $O(\mu^{-2})$ by an appropriate choice of coefficients β'_{jki} above but now α_{jki} have smoothness $(l-1, \sigma)$ and then β'_{jki} will have the same smoothness which is not enough to plug them into Poisson brackets unless $(l, \sigma) \succeq (2, 0)$.

(18.2.10) As $(1,1) \preceq (l,\sigma) \preceq (2,0)$ let us replace coefficients β'_{jki} by their μ^{-1}-mollifications[14] which provides $\mu\vartheta(\mu^{-1})$-approximation to them.

Then for these new coefficients we have $\{A_0, Q'_j\} \equiv \mu^{-1}\omega_j A^0$ and therefore

$$\{A, Q'_j\} \equiv \mu^{-1}\big(\omega_j(\tau+V) + F_{12}^{-1}\mathcal{L}_j V - \omega_j(\tau - A)\big) \mod O\big(\vartheta(\mu^{-1}) + \mu^{-2}\big) \tag{18.2.11}$$

with $\mathcal{L}_j := (-1)^{j-1}\partial_{x_{2-j}}$ (as $g^{jk} = \delta_{jk}$ at the given point).

---

[13] Recall that

$$\frac{dx}{dt} = \mu^{-1}(\nabla(V-\tau)/F))^{\perp}. \tag{18.2.7}$$

[14] Which makes sense only as $\mu^{-1} \ge \varepsilon$ i.e. $\mu \ge (h\nu^{-1}|\log h|)^{\frac{1}{2}}$.

In the smooth case we know from Chapter 13 that $\omega_j = \mathcal{L}_j F^{-1}$ and so it should be in our case as well:

$$\{A, Q_j'\} \equiv \mu^{-1}\Big(\mathcal{L}_j\big(\frac{V-\tau}{F}\big) + \omega_j(\tau - A)\Big) \quad \mathsf{mod}\ O\big(\vartheta(\mu^{-1}) + \mu^{-2}\big) \tag{18.2.12}$$

and this equality will be sufficient to prove that singularities propagate along trajectories of (18.2.7).

Remark 18.2.2. (i) The propagation speed of (18.2.7) is $\asymp \nu\mu^{-1}$. The right-hand side of (18.2.12) is larger than the error as

$$\nu \ge C_1\mu\vartheta(\mu^{-1}) + C_1\mu^{-1}. \tag{18.2.13}$$

In particular, as $(I,\sigma) \succeq (2,0)$ we need no μ^{-1}-mollification and $\nu \ge C\mu^{-1}$.

(ii) As there is a mollification with respect to ε we also need to assume that

$$\nu \ge C_1\varepsilon^{-1}\vartheta(\varepsilon) + C_1\varepsilon \tag{18.2.14}$$

but it is more important only as $\varepsilon \ge \mu^{-1}$ i.e. when $\mu \ge (h|\log h|)^{-\frac{1}{2}}$.

(iii) In what follows we assume that <u>either</u> $(I,\sigma) \succeq (1,1)$ and non-degeneration condition

$$|\nabla V/F| \ge \epsilon_0 \tag{18.2.15}$$

is fulfilled a <u>or</u> $(I,\sigma) \succeq (2,0)$ and non-degeneracy assumption

$$|\nabla V/F| + |\det \mathsf{Hess}\, V/F| \ge \epsilon_0 \tag{18.2.16}$$

is fulfilled leaving to the reader the following problem:

Problem 18.2.3. Investigate the case when $(1,1) \prec (I,\sigma) \prec (2,0)$ and assumption (18.2.16) is replaced by the estimate to $\mathsf{mes}(\{x : |\nabla V/F| \le \nu\})$ as $\nu \to 0$; in this case $\epsilon\eta$-vicinity should be replaced by γ-vicinity with $\gamma^{-1}\vartheta(\gamma) = \epsilon\nu$. Here $\gamma \ge C_2\mu^{-1}$ due to (18.2.13).

18.2.2 Propagation of Singularities: Rigorous Results

First let us prove the finite speed of the propagation:

Proposition 18.2.4. *Let* $d \ge 2$, $\mu \le h^{-1+\delta}$ *and let*

$$M \ge \sup_{x\in\Sigma}\Big(2\sum_k g^{jk}\xi_k\Big) + \epsilon \qquad \forall j \tag{18.2.17}$$

with arbitrarily small constant $\epsilon > 0$, *where* $\Sigma := \{x\colon : \sum_{jk} g^{jk}\xi_j\xi_k + V = 0\}$.

Let ϕ_1 *be supported in* $B(0,1)$, $\phi_2 = 1$ *in* $B(0,2)$, χ *be supported in* $[-1,1]$ [15]. *Let* $\bar{T}_* = Ch|\log h| \le T \le T^{*\prime} = \epsilon_0$.

Then

$$|F_{t\to h^{-1}\tau}\chi_T(t)\big(1-\phi_{2,MT}(x-\bar{x})\big)\phi_{1,MT}(y-\bar{x})U(x,y,t)| \le Ch^s \qquad \forall \tau \le \epsilon_1 \tag{18.2.18}$$

where here and below $\epsilon_1 > 0$ *is a small enough constant.*

Remark 18.2.5. Surely results will be much more precise in the distance according to $g_{jk}V^{-1}$ metrics.

Proof. Proof follows the proof of Theorem 2.3.2. Namely, let χ be the same function as there; recall that it was supported in $(-\infty, 0]$ and satisfying certain "regularity" conditions. Then as a main auxiliary symbol we pick up

$$\chi\Big(f(x,t)-\epsilon_3\Big) \qquad \text{with} \quad f(x,t) = \frac{1}{T}\big(|x-\bar{x}|^2+\epsilon_2\big)^{\frac{1}{2}} \mp M\frac{t}{T}, \tag{18.2.19}$$

We pick signs "$\mp$" analyzing cases $\pm t > 0$. □

Now let us investigate the magnetic drift.

Proposition 18.2.6. *Let* $d = 2$ *and condition* (18.1.6) *be fulfilled. Let* $\mu_0 \le \mu \le h^{-1+\delta}$ *where here and below* $\mu_0 > 0$, C_1, *and* $1/\epsilon_1$ *are large enough constants depending on all the other constants, exponents and the choice of axillary functions below. Let* <u>*either*</u> $(I,\sigma) \succeq (1,1)$ *and* $\nu = 1$ <u>*or*</u> $(I,\sigma) \succeq (2,0)$ *and*

$$\nu \ge C_0 \max(\mu^{-1}, \varepsilon). \tag{18.2.20}$$

Consider ball $B(\bar{x}, \epsilon\nu)$.

[15] Recall that all such auxiliary functions are appropriate in the sense of Section 2.3.

(i) Assume that $|\mathcal{L}_{V/F}(\bar{y})| \le \nu$. *Let*

$$T_* := C\varepsilon^{-1}\nu^{-1}h|\log h| + C\nu^{-1}(\mu h|\log h|)^{\frac{1}{2}} \le T \le T^* = \epsilon_1\mu. \tag{18.2.21}$$

Then[16)]

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\big(1-\phi_{2,\mu^{-1}\nu T}(Q_1-\bar{x}_1, Q_2-\bar{x}_2)\big)^{\mathsf{w}}U(x,y,t)\times {}^t\big(\phi_{1,\mu^{-1}\nu T}(Q_1-\bar{x}_1, Q_2-\bar{x}_2)\big)^{\mathsf{w}}| \le Ch^s \qquad \forall \tau, |\tau| \le \epsilon_1\nu; \tag{18.2.22}$$

(ii) Assume now that $|\mathcal{L}_{V/F}(\bar{y})| \asymp \nu$. *Let* χ *be supported in* $[1-\epsilon_0, 1+\epsilon_0]$.

Further, let $\bar{x} = \bar{y} + \mu^{-1}\mathcal{L}_{V/F}(\bar{y})T$ *with* T *satisfying* (18.2.21) *and* $T \le \epsilon_1\mu$.

Then

$$|F_{t\to h^{-1}\tau}\chi_T(t)\big(1-\phi_{2,M\epsilon\mu^{-1}\nu T}(Q_1-\bar{x}_1, Q_2-\bar{x}_2)\big)^{\mathsf{w}}U(x,y,t)\times {}^t\big(\phi_{1,\epsilon\mu^{-1}T}(Q_1-\bar{y}_1, Q_2-\bar{y}_2)\big)^{\mathsf{w}}| \le Ch^s \qquad \forall \tau, |\tau| \le \epsilon_1\nu. \tag{18.2.23}$$

Proof. Proofs of both statements follow the proof of Theorem 2.3.2. Namely, let χ be the same function as there; recall that it was supported in $(-\infty, 0]$ and satisfying certain "regularity" conditions. Then as a main auxiliary symbol we pick up

$$\chi\Big(f\big(Q_1(x,\xi), Q_2(x,\xi), t\big) - \epsilon_2\Big) \qquad \text{with} \tag{18.2.24}$$

$$f(Q,t) = \frac{1}{T}\big(\mu^2\nu^{-2}|Q-\bar{Q}|^2 + \epsilon_3\big)^{\frac{1}{2}} \mp M\frac{t}{T}$$

and

$$\chi\Big(f\big(Q_1'(x,\xi), Q_2'(x,\xi), t\big) - \epsilon_2\Big) \qquad \text{with} \tag{18.2.25}$$

$$f(Q',t) = \frac{1}{T}\big(\mu^2\nu^{-2}|Q'-\bar{Q}'-\mu^{-1}\ell t|^2 + \epsilon_3\big)^{\frac{1}{2}} \pm \epsilon_4\frac{t}{T}$$

in the proofs of Statements (i) and (ii) respectively where $\epsilon_k > 0$ are small constants. We pick signs "$\mp$" analyzing cases $\pm t > 0$. Furthermore, here $\ell = \mathcal{L}_{V/F}(\bar{y})$ in the proof of Statement (ii) . □

[16)] Recall that b^{w} means Weyl quantization of symbol b and due to condition (18.2.21) logarithmic uncertainty principle holds and this quantization of the symbols involved is justified, ${}^tB$ means the dual operator.

The following corollary follows immediately from Proposition 18.2.6(ii):

Corollary 18.2.7. *(i) Statement (ii) of Proposition 18.2.6 remains true for all* T *satisfying* (18.2.21) *if we redefine* $\bar{x}$ *as* $\bar{x} = \Psi_T(\bar{y})$ *where* Ψ_t *is Liouvillian flow defined by* (18.2.7).

(ii) As $C_0\nu^{-1} \le T \le \epsilon_1\mu$

$$|F_{t\to h^{-1}\tau}\Big(\chi_T(t)\Gamma_x\big(\psi(x)U\big)\Big)| \le Ch^s \qquad \forall \tau : |\tau| \le \epsilon_1\nu. \tag{18.2.26}$$

Recall that χ *is supported in* $[-1, -\frac{1}{2}] \cup [\frac{1}{2}, 1]$.

Recall that under condition (13.4.45) i.e.

$$V \le -\epsilon_0 \tag{18.2.27}$$

estimate

$$|F_{t\to h^{-1}\tau}\Big(\chi_T(t)\Gamma\big(\psi(x)U\big)\Big)| \le Ch^s \qquad \forall \tau : |\tau| \le \epsilon_1. \tag{18.2.28}$$

holds for $Ch|\log h| \le T \le \bar{T} = \epsilon_1\mu^{-1}$. Note that $T_* \le \bar{T}$ iff

$$\nu \ge C(\mu^3 h|\log h|)^{\frac{1}{2}} \tag{18.2.29}$$

and ε is defined by (18.2.5) where we picked the smallest possible ε.

Therefore

(18.2.30) Under assumptions (18.2.27), (18.2.29) [17] and (18.2.5) estimate (18.2.28) holds for $T_* := Ch|\log h| \le T \le T^* := \epsilon_1\mu$.

Out of two conditions (18.2.29) and (18.2.5) the first is the nastiest. To weaken it we need a special analysis; however note that $\bar{T} \le \epsilon\nu^{-1}$ so we can restrict ourselves to $T \le \epsilon\nu^{-1}$ when evolution is restricted to $C_0\mu^{-1}$ vicinity of the original point.

Proposition 18.2.8. *Let assumptions of Proposition 18.2.6 be fulfilled.*

(i) Let $g^{jk} = \delta_{jk}$, $F = 1$. *Then* (18.2.28) *holds for* $T_* \le T \le T^*$ *with*

$$T_* := C\varepsilon^{-1}\nu^{-1}h|\log h|. \tag{18.2.31}$$

[17] Which we replace by (18.2.29)′.

(ii) In the general case (18.2.28) *holds for* $T_* \le T \le T^*$ *with*

$$T_* := C\varepsilon^{-1}\nu^{-1}h|\log h| + C\nu^{-1}\bigl(\bar\vartheta(\mu^{-1})h|\log h|\bigr)^{\frac12} \tag{18.2.32}$$

where $\bar\vartheta$ *is a modulus of continuity of* g^{jk} *and* F.

Proof. (i) In this case we can assume without any loss of the generality that $A_0 = h^2D_1^2 + (hD_2 - \mu x_1)^2$. Let us consider propagation with respect to ξ_2. We can use then function $f = T^{-1}\mu^{-1}\nu^{-1}\xi_2$ and as for time T shift with respect to ξ_2 is $\asymp \nu T$ and logarithmic uncertainty principle means exactly that $T \ge T_*$ with T_* defined by (18.2.31).

(ii) Consider the general case. Then without any loss of the generality we can assume that $F = 1$ (otherwise we can divide by it) and $g^{jk}(\bar x) = \delta_{jk}$, $\nabla g^{jk}(\bar x) = 0$, $V_1(\bar x) = V_2(\bar x) = 0$, $\nabla V_1(\bar x) = 0$. In this case $\mu Q_1 = \xi_2 + \mu\phi(x)$ with $\nabla\phi = O\bigl(\mu\bar\vartheta(\mu^{-1})\bigr)$ and quantization conditions is $T \ge T_*$ with T_* defined by (18.2.32). □

Now condition $T_* \le \bar T$ becomes (18.2.5) plus

$$\nu \ge C\bigl(\mu^3\bar\vartheta(\mu^{-1})h|\log h|\bigr)^{\frac12}. \tag{18.2.29}'$$

18.2.3 Main Theorem

Now we can prove main results of this section. Under assumption (18.2.15) we pick up $\varepsilon = C\mu h|\log h|$ provided $\nu = 1$ satisfies (18.2.29)′ i.e.

$$C\mu^3\bar\vartheta(\mu^{-1})h|\log h| \le 1; \tag{18.2.33}$$

as $(\bar l, \bar\sigma) = (1,1)$ it is equivalent to $\mu \le \epsilon_1 h^{-\frac12}$ and as $(\bar l, \bar\sigma) = (2,0)$ it is no restriction at all.

Under assumptions (18.2.16) (and thus $(l,\sigma) \succeq (2,0)$), (18.2.33) we introduce variable

$$\nu = \nu(x) = \epsilon|\nabla V/F| + \bar\nu, \qquad \bar\nu := C_0(\mu h|\log h|)^{\frac12} + C_0\mu^{-1} \tag{18.2.34}$$

and variable $\varepsilon = \varepsilon(x)$ by (18.2.5) where $\bar\nu$ ensures that (18.2.20) and (18.2.29)′ are fulfilled.

Let $\tilde{A}$ be ε-approximation[18)] of A.

Theorem 18.2.9. *Let $d = 2$ and A be a self-adjoint in $\mathscr{L}^2(X)$ operator defined by* (18.1.1). *Let conditions* (18.1.6) *and* (18.2.27) *be fulfilled in $B(0,1) \subset X \subset \mathbb{R}^2$.*

(i) Further, let $(l,\sigma) \succeq (1,1)$, condition (18.2.33) *be fulfilled and condition* (18.2.15) *be fulfilled in $B(0,1)$. Then estimate*

$$\mathsf{R}^{\mathsf{MW}} := \Big| \int \Big(\tilde{e}(x,x,0) - h^{-2}\mathcal{N}_2^{\mathsf{MW}}(x,0)\Big)\psi(x)dx\Big| \le C\mu^{-1}h^{-1} + Ch^{-2}\vartheta(\mu h|\log h|) \tag{18.2.35}$$

holds; this estimate also holds with the standard Weyl expression albeit with infinite[19)] *number of terms generated by the principal part:*

$$\mathsf{R}^{\mathsf{W}}_{\infty} := \Big| \int \Big(\tilde{e}(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{W}}_{2,\infty}(x,0)\Big)\psi(x)dx\Big| \le C\mu^{-1}h^{-1} + Ch^{-2}\vartheta(\mu h|\log h|). \tag{18.2.36}$$

(ii) On the other hand, let $(l,\sigma) \succeq (2,1)$, condition (18.2.33) *be fulfilled and condition* (18.2.16) *be fulfilled in $B(0,1)$. Then estimate*

$$\mathsf{R}^{\mathsf{MW}} \le C\mu^{-1}h^{-1} + C\mu^2|\log h| \tag{18.2.37}$$

holds; this estimate also holds with the standard Weyl expression R^{W}.

Proof. (i) Due to Proposition 18.2.8 estimate (18.1.20) holds with $T = T^* = \epsilon\mu$ and $T_* = Ch|\log h|$ and therefore due to theory of Section 4.6

$$|F_{t\to h^{-1}\tau}\Big(\bar{\chi}_T(t)\Gamma\big(\psi(x)U\big)\Big)| \le Ch^{-1}. \tag{18.2.38}$$

[18)] One can take two copies $\tilde{A}^{\pm}$ of approximation such that the corresponding estimate (18.2.35) or (18.2.37) holds for both and $\tilde{A}^- \le A \le \tilde{A}^+$ in the operator sense. We call them framing approximations. This remark holds for all our Theorems 18.2.9, 18.6.10, 18.9.4, 18.9.6 in full.

[19)] Actually finite, due to finite smoothness.

Therefore due to the standard Tauberian procedure

$$|\Gamma\bigl(\tilde{e}(.,.,0)\psi\bigr) - h^{-1}\int_{-\infty}^{0}\Bigl(F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_T(t)\Gamma\bigl(U\psi\bigr)\bigr)\Bigr)\,d\tau| \le \frac{C}{T^*}h^{-1} \asymp C\mu^{-1}h^{-1} \tag{18.2.39}$$

with $T = T^*$ and due to (18.1.20) with $T = Ch|\log h|$; but then

$$|\int\Bigl(\tilde{e}(x,x,0) \;-\; h^{-2}\tilde{\mathcal{N}}_2^{\mathsf{MW}}(x,0)\Bigr)\psi(x)dx| \qquad \le \qquad C\mu^{-1}h^{-1}. \tag{18.2.40}$$

Finally, one can see easily that replacing $\tilde{\mathcal{N}}_{2,\infty}^{\mathsf{W}}$ by $\mathcal{N}_2^{\mathsf{MW}}$ we make an error not exceeding $Ch^{-2}\vartheta(\varepsilon)$.

In these arguments one can replace $\mathcal{N}_2^{\mathsf{MW}}$ by $\mathcal{N}_{2,\infty}^{\mathsf{W}}$.

(ii) The same arguments work in the *exterior zone*

$$\mathcal{X}_{\mathsf{ext}} = \{x : |(\nabla V/F)(x)| \ge C\bar{\nu}\}; \tag{18.2.41}$$

therefore contribution of this zone to both the Tauberian remainder and to the left-hand expression (18.2.40) do not exceed $C\mu^{-1}h^{-1}$.

Further, contributions of the *inner zone*

$$\mathcal{X}_{\mathsf{inn}} = \{x : |(\nabla V/F)(x)| \le C\bar{\nu} \tag{18.2.42}$$

to both the Tauberian remainder and to the left-hand expression (18.2.40) do not exceed $C\mu h^{-1}\,\mathsf{mes}(\mathcal{X}') \asymp C\mu h^{-1}\bar{\nu}^2 \asymp C\mu^{-1}h^{-1} + C\mu^2|\log h|$.

Finally, one can see easily that replacing $\tilde{\mathcal{N}}_2^{\mathsf{MW}}$ by $\mathcal{N}_2^{\mathsf{MW}}$ we make an error not exceeding

$$Ch^{-2}\int_{\mathcal{X}_{\mathsf{ext}}}\vartheta\bigl(\mu h|\log h|/\nu^2\bigr)\,\nu d\nu + Ch^{-2}\vartheta(\bar{\varepsilon})\,\mathsf{mes}(\mathcal{X}')$$

with $\bar{\varepsilon} = C_0\mu h\bar{\nu}^{-1}|\log h| \asymp C_0\min\bigl((\mu h|\log h|)^{\frac{1}{2}}, \mu^2 h|\log h|\bigr)$; as $(l,\sigma) \succeq (2,1)$ we arrive to estimate (18.2.37). □

In these arguments one can replace $\mathcal{N}_2^{\mathsf{MW}}$ by $\mathcal{N}_{2,\infty}^{\mathsf{W}}$ but all extra terms do not exceed $C\mu^2$.

Corollary 18.2.10. *In the framework of Theorem 18.2.9 let* $(l,\sigma)\succeq(2,1)$ *and one of conditions* (18.2.15), (18.2.16) *be fulfilled. Then estimate*

$$\mathsf{R}^{\mathsf{MW}}=O(\mu^{-1}h^{-1}) \tag{18.2.43}$$

holds under assumption (18.2.6) *(i.e.* $\mu\le\bar\mu_1=(h|\log h|)^{\frac13}$*). The same estimate holds for* R^{W}*.*

Remark 18.2.11. Under stronger smoothness assumptions this estimate (18.2.43) holds for larger μ under assumption (18.2.15) but it does not hold for R^{W} under assumption (18.2.16).

18.3 $d=2$: Canonical Form

Now we analyze the case

$$\bar\mu_1:=(h|\log h|)^{-\frac13}\le\mu\le\bar\mu_2:=(h|\log h|)^{-1}; \tag{18.3.1}$$

the second restriction will be removed in Subsection 18.3.3.

Our arguments will not change much for larger μ as well but some of them become much simpler while other become a bit more complicated. We will take

$$\mu^{-1}\ge\varepsilon\ge C(\mu^{-1}h|\log h|)^{\frac12} \tag{18.3.2}$$

which makes it possible to use $\mu^{-1}h$-pseudodifferential operators.

18.3.1 Reduction

Main pPart of the Operator. I

Now our goal is to reduce our operator to a some kind of the canonical form. It would be easier for constant or at least smooth g^{jk} and F. However, we can overcome technical difficulties in a more general case as well. Instead of normal Fourier integral operators we will use "poor man Fourier integral operators" i.e. propagators of "rough" pseudodifferential operators.

Problem 18.3.1. In this section for a sake of simplicity of some arguments we assume that $\sigma\ge0$ but one can get rid of this assumption easily. We leave it to the reader.

In this subsection we will reduce A_0 to pre-canonical form which is really easy for constant metrics g^{jk} and F and is not needed at all for Euclidean metrics and constant F.

First of all, we can assume without any loss of the generality that

$$F^3 = F = 1. \tag{18.3.3}$$

Really, changing orientation, if necessary, we can make $F^3 > 0$. Then multiplying mollified operator by $F^{-\frac{1}{2}}$ both from the right and from the left and commuting it with P_j we will get operator of the same form with g^{jk}, V replaced by $F^{-1}g^{jk}$, $F^{-1}V$ respectively, modulo operator $h^2V'(x)$ where $V'(x)$ is a function, linear with respect to second derivatives of g^{jk} and F and thus V' does not exceed $C\bigl(1+\vartheta(\varepsilon)\varepsilon^{-2}\bigr)$; one can see easily that after multiplication by h^2 it does not exceed $C\vartheta(\varepsilon)$ which is an approximation error anyway (plus Ch^2 which is less than $C\mu^{-1}h$). Surely, such transformation would affect $e(x,x,0)$ but we will return to the original operator later.

In Chapter 13 on this step of reduction we applied $\mu^{-1}h$-Fourier integral operator and let us try the same now. Namely, let us transform our operator by operator $T(1)$, where

$$T(t) := e^{-i\mu^{-1}h^{-1}tL^{\mathsf{w}}}, \qquad L^{\mathsf{w}} = \frac{1}{2}\sum_{jk} P_j L^{jk}(x) P_k \tag{18.3.4}$$

with $L^{jk} \in \mathscr{F}^{\bar{l},\bar{\sigma}}$. Obviously L^{w} is a Weyl $\mu^{-1}h$-quantization of the symbol

$$L(x,\xi) := \mu^2 \sum_{j,k} L^{jk}(x) p_j(x,\xi) p_k(x,\xi), \qquad p_j := \xi_j - V_j(x). \tag{18.3.5}$$

Remark 18.3.2. In this subsection L, T, t do not denote the same things as everywhere else and in this and next chapters $\mathscr{F}^{l,\sigma}$ denotes space of functions functions satisfying

$$|\partial^{\nu}_{x,\xi} f| \le C_\nu \bigl(\varepsilon^{l-|\nu|}|\log\varepsilon|^{-\sigma}+1\bigr)$$

with the same constants C_ν as in Section 2.3.

Let us consider "Heisenberg evolution" $Q(t) = T(-t)\bar{Q}T(t)$ for $\mu^{-1}h$-pseudodifferential operator $\bar{Q}$; then

$$\partial_t Q(t) = i\mu^{-1}h^{-1}[L^{\mathsf{w}}, Q(t)], \qquad Q(0) = \bar{Q}. \tag{18.3.6}$$

Let us define first symbol $q(t)$ as a solution to

$$\partial_t q(t) = \{\mu^{-2} L, q\}, \qquad q(0) = \bar{q} \implies q(t) = \bar{q} \circ \Phi_t \tag{18.3.7}$$

with the standard Poison brackets where ϕ_t is a corresponding Hamiltonian flow. Let us consider differential equations defining Hamiltonian flow ϕ_t in terms of p_j and x_k:

$$\frac{d}{dt} x_j = \sum_k L^{jk} p_k, \qquad \frac{d}{dt} p_j = \sum_k \Lambda^{jk} p_k + \sum_{k,m} \beta_j^{km} p_k p_m \tag{18.3.8}$$

with $\Lambda := f(x)\ell J$, where $\Lambda = \bigl(\Lambda^{jk}\bigr)$, $\ell = \bigl(L^{jk}\bigr)$ and $J = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ are 2×2-matrices, here and below $\beta_* \in \mathscr{F}^{\bar{l}-1,\bar{\sigma}}$, $f(x) = \partial_{x_1} V_2 - \partial_{x_2} V_1$.

One can see easily that for $|t| \le c$

$$|p| \le c \implies |p \circ \phi_t| \le C|p|, \tag{18.3.9}$$

$$\phi_t \in \mathscr{F}^{\bar{l},\bar{\sigma}}, \tag{18.3.10}$$

$$p_j \circ \phi_t = e^{\Lambda(x)t} p + \sum_{j,k} \beta'_{jk} p_j p_k \qquad \text{on} \quad \{|p| \le c\mu^{-1}\}, \tag{18.3.11}$$

$$x_j \circ \phi_t - x_j = \sum_j \beta''_{jk} p_k \tag{18.3.12}$$

where $p = (p_1, p_2)$, $x = (x_1, x_2)$.

Further, one can see easily that

$$a_0 \circ \phi_t = \sum g_t^{jk} p_j p_k + M_t, \quad (g_t) = e^{t\,{}^t\Lambda(x)} (g) e^{t\Lambda(x)} \quad \text{with} \quad M_t = \sum_{i,j,k} \beta_{ijk;\,t} p_i p_j p_k \tag{18.3.13}$$

where $a_0 = \sum_{j,k} g^{jk} p_j p_k$ and (g), (g_t) denote corresponding matrices.

Now, let us consider in this region $\{|p| \le c\mu^{-1}\}$ the third and higher derivatives of the symbol $\alpha_{jk} p_j p_k$ with $\alpha_* \in \mathscr{F}^{\bar{l},\bar{\sigma}}$; then

$$|\partial^\nu_{x,\xi} (\alpha_{jk} p_j p_k)| \le C_\nu \varepsilon^{-|\nu|+l} |\log \mu|^{-\bar{\sigma}} \mu^{-2} + C \tag{18.3.14}$$

for $3 \le |\nu| \le c|\log \mu|$ where C_ν are standard constants of Section 3.2 even if $V_j \in \mathscr{F}^{\bar{l},\bar{\sigma}}$ only.

Similarly for $|\nu| \ge 3$ we have

$$|\partial^{\nu}_{x,\xi}(\beta_{ijk}p_ip_jp_k)| \le C_{\nu}\varepsilon^{-|\nu|+\bar{l}-1}|\log\mu|^{-\bar{\sigma}}\mu^{-3} + C; \tag{18.3.15}$$

and therefore $\mu^2 M_t \in \mathscr{F}^{\bar{l},\bar{\sigma}} \cap \mu^{-1}\mathscr{F}^{\bar{l}-1,\bar{\sigma}}$. Now let us pass from symbols to their quantizations. Let us recall that $(\bar{l},\bar{\sigma}) \succeq (2,0)$ and also that in the standard smooth situations and for the standard quantizations $[a^{\mathsf{w}}, b^{\mathsf{w}}] = -ih\{a,b\}^{\mathsf{w}} + O(h^3)$; then for the standard quantization of $\mu^2 a_0 \circ \phi_t$ equation (18.3.6) will be fulfilled modulo operators with A-bound[20)] not exceeding $C\mu^2(\mu^{-1}h)^2 \times \varepsilon^{-1}\mu^{-1} \times (\varepsilon^{-1}\mu^{-1} + \varepsilon^{-2}\mu^{-3})$ which in turn does not exceed $C\mu^{-1}h$.

Therefore,

(18.3.17) Transformed operator $T(-t)A_0T(t)$ differs from the quantization of the transformed symbol $\mu^2 a_0 \circ \phi_t$ by an operator with A-bound not exceeding $C\mu^{-1}h$.

Recall that A_0 is a Weyl $\mu^{-1}h$-quantization of a_0. This is as good as we need.

Now we can pick up $L^{jk} \in \mathscr{F}^{\bar{l},\bar{\sigma}}$ such that $e^{t\Lambda}(g)e^{\Lambda} = \left(\begin{smallmatrix} 1 & 0 \\ 0 & g^{-1}\end{smallmatrix}\right)$ with $g = \det(g)^{-1}$ because e^{Λ} could be any matrix with determinant equal to 1. Therefore we get that modulo operator with A-bound not exceeding $\mu^{-1}h$

$$T(-1)A_0T(1) \equiv P_1^2 + P_2(g^{-1})^{\mathsf{w}}P_2 + \mu^2 M^{\mathsf{w}}, \tag{18.3.18}$$

$$M \coloneqq a_0 \circ \phi_1 - p_1^2 - g^{-1}p_2^2, \qquad g' \coloneqq g \circ \phi_1. \tag{18.3.19}$$

Recall that according to (18.3.13) $M = \sum_{i,j,k}\beta_{ijk}p_ip_jp_k$ with $\beta_{ijk} \in \mathscr{F}^{\bar{l}-1,\bar{\sigma}}$.

Consider now how the above transformation affects V. Note that

$$|\partial^{\nu}_{x,\xi}(V \circ \phi_t)| \le C_{\nu}\varepsilon^{l-|\nu|}|\log h|^{-\sigma}$$

in the same region $\{|p| \le c\mu^{-1}\}$. Then one can see easily that

$$T(-1)VT(1) \equiv (V \circ \phi_1)^{\mathsf{w}} \tag{18.3.20}$$

[20)] Here in contrast to the standard definition we use everywhere we say that A bound of B is R if

$$\|Bu\| \le R\big(\|u\| + \|A^m u\|\big) \tag{18.3.16}$$

with some exponent m which is fixed in advance.

modulo operator with A-bound not exceeding $C(\mu^{-1}h)^2\times\varepsilon^{-1}\mu^{-1}\times\varepsilon^{l-3}|\log h|^{-\sigma}$ (which is obviously less than $C\vartheta(\varepsilon)$).

Also note that we used only that $V_1, V_2 \in \mathscr{F}^{\bar l,\bar\sigma}$. Therefore without any loss of the generality one can assume that

$$V_1 = 0, \quad P_1 = hD_1, \quad V_2, \partial_{x_1} V_2 = g^{-\frac{1}{2}} \in \mathscr{F}^{\bar l,\bar\sigma} \tag{18.3.21}$$

where the third assertion follows from the first and the second ones and

$$p_2 = \alpha(x,\xi_2)\big(x_1 - \lambda(x_2,\xi_2)\big), \qquad \alpha,\lambda \in \mathscr{F}^{\bar l,\bar\sigma}. \tag{18.3.22}$$

Main Part of the Operator. II

In this subsection we will reduce A_0 to canonical form which is really easy for constant g^{jk} and F.

Our next transformation is $T'(1)$ with

$$T'(t) = e^{-it\lambda^{\mathsf w}D_1} \qquad \text{where } \ \lambda^{\mathsf w} = \lambda^{\mathsf w}(x_2, \mu^{-1}hD_2); \tag{18.3.23}$$

then

$$T'(-t)D_1T'(t) = D_1, \quad T'(-t)\lambda^{\mathsf w}T'(t) = \lambda^{\mathsf w}, \quad T'(-t)x_1T'(t) = x_1 + t\lambda^{\mathsf w} \tag{18.3.24}$$

precisely.

To calculate transformations of other operators we need to introduce the corresponding Hamiltonian flow ϕ'_t:

$$\xi_1 = \mathsf{const},\ \lambda(x_2,\xi_2) = \mathsf{const},\ x_1 = x_1(0) + t\lambda(x_2,\xi_2), \tag{18.3.25}$$

$$\frac{d}{dt}x_2 = \xi_1\big(\partial_{\xi_2}\lambda(x_2,\xi_2)\big), \qquad \frac{d}{dt}\xi_2 = -\xi_1\big(\partial_{x_2}\lambda(x_2,\xi_2)\big). \tag{18.3.26}$$

This flow is less regular than ϕ_t:

$$|\partial^\nu_{x,\xi}\phi'_t| \le C_\nu\mu^{-1}\big(1+\varepsilon^{\bar l-1-|\nu|}|\log\mu|^{-\bar\sigma}\big). \tag{18.3.27}$$

However, using again above arguments we can estimate the difference between operators $T'(-1)\alpha^{\mathsf w}T'(1)$ and $(\alpha\circ\phi'_1)^{\mathsf w}$ with $\alpha\in\mathscr{F}^{\bar l,\bar\sigma}$: its A-bound does not exceed $(\mu^{-1}h)^2\times\varepsilon^{-1}\mu^{-1}\times\varepsilon^{-2}\mu^{-1}$ which in turn does not exceed $C\mu^{-1}h$. The same statement is true for $\mu^{-1}\beta^{\mathsf w}$ with $\beta\in\mathscr{F}^{\bar l-1,\bar\sigma}$.

Therefore, *modulo operator with* $\bar{A}_0$*-bound not exceeding* $C\mu^{-1}h$

$$T'(-1)T(-1)A_0T(1)T'(1) \equiv \bar{A}_0 + \mu^2(M')^{\mathrm{w}}, \tag{18.3.28}$$

where

$$\bar{A}_0 := \bar{P}_1^2 + \bar{P}_2^2, \quad \bar{P}_1 = hD_1, \bar{P}_2 = -\mu x_1, \tag{18.3.29}$$

$$M' = a_0 \circ \Phi - \bar{a}_0 = \sum_{i,j,k} \beta'_{ijk}\bar{p}_i\bar{p}_j\bar{p}_k \tag{18.3.30}$$

with $\bar{p}_1 := \xi_1$, $\bar{p}_2 := -x_1$, $\Phi := \phi_1 \circ \phi_1'$.

Similarly, *modulo operator with* $\bar{A}_0$*-bound not exceeding* $C\vartheta(\varepsilon)$

$$T'(-1)T(-1)VT(1)T'(1) \equiv (V \circ \Phi)^{\mathrm{w}}. \tag{18.3.31}$$

Potential

Now we have $\mu^{-1}h$-pseudodifferential operator $\bar{A}$, with the symbol $\mu^2\bar{a}_0 = \mu^2(x_1^2 + \xi_1^2)$, perturbed by $\mu^2(M')^{\mathrm{w}}$ and $(V')^{\mathrm{w}}$ with $V' = (V \circ \Phi)^{\mathrm{w}}$. The first perturbing operator would vanish for constant g^{jk} and F but the second one would still cause trouble even in this case because it's symbol depends on x_1, ξ_1 as well[21)].

Our goal is to make a perturbation a $\mu^{-1}h$-pseudodifferential operator with the symbol depending on x_2, ξ_2, and $r^2 := x_1^2 + \xi_1^2$ only.

Let us consider the smooth case first as a toy-model; then we can decompose $V \circ \Phi$ into asymptotic series with respect to x_1, ξ_1. To get rid of linear terms we need to make a shift in x_1, ξ_1 of a magnitude μ^{-2}; then the increment of $\mu^2\bar{a}_0$ will absorb these terms.

We can continue further[22)] but what we need really is an error in magnetic Weyl expression not exceeding $C\bigl(\mu^{-1}h + \vartheta(\varepsilon)\bigr)h^{-2}$. In the 3-dimensional case we will need much less than this (an error in operator $O(\mu^{-2})$ will be almost sufficiently small) but now we should request $O(\mu^{-1}h)$ error which can be as large as $O(\mu^{-4})$ now and to run things in a "smooth" manner we would need $l = 4$ while our objective is to get the best estimate as $l = 2$ [23)].

[21)] In this case Φ is a linear symplectomorphism.

[22)] We cannot eliminate terms of even degrees $2m$ completely, but we can reduce them to $\mu^2\omega_m(x_2, \xi_2)(x_1^2 + \xi_1^2)^m$; see Chapter 13.

[23)] Actually we need $l = 3$ because the "weak magnetic field" approach leads to $O\bigl(h^{-2}(\mu h|\log h|)^l\bigr)$ error and the "strong magnetic field" approach in the discussed above smooth version produces $O\bigl(h^{-2}\mu^{-l}\bigr)$ error; threshold is as $\mu = h^{-\frac{1}{2}}|\log h|^{-\frac{1}{2}}$ and to keep

Let us return to the non-smooth case and try to repeat the above arguments. To make the shift described above we need to use transformation $T''(-t) = e^{-i\mu h^{-1}tS^{\mathsf{w}}}$ with $\mu^{-1}h$-pseudodifferential operator S^{w} with the symbol belonging to $\mu^{-2}\mathscr{F}^{l,\sigma}$; on the other hand, to accommodate M' we will need to add $\mu^{-1}h$-pseudodifferential operator with the symbol satisfying improved estimate (18.3.15). Namely, one can see easily that

$$|\partial^{\nu}_{x,\xi}M'| \le C_{\nu}\varepsilon^{-|\nu|+1}|\log h|^{-1}\mu^{-3} + C\mu^{(-3+\nu_1)_-} \tag{18.3.32}$$

with ν_1 counting derivatives with respect to (x_1,ξ_1) only.

So in fact

$$S = S' + S'', \qquad S' \in \mu^{-2}\mathscr{F}^{l,\sigma}, \qquad S'' \in \mu^{-2}\mathscr{F}^{1,0} \tag{18.3.33}$$

and S'' satisfies (18.3.32); some adjustments to be done later.

Remark 18.3.3. One can check easily that such operator $T''(t)$ would be $\mu^{-1}h$-pseudodifferential operator iff

$$\mu \ge \bar{\mu}_1^* := Ch^{-\frac{1}{3}}|\log h|^{\frac{1}{3}}. \tag{18.3.34}$$

It is much simpler to analyze transformation by $\mu^{-1}h$-pseudodifferential operators than by $\mu^{-1}h$-Fourier integral operators with not very regular symbols and one can avoid some hassle if (18.3.34) holds. This restriction is not smoothness related: one just need to take away from $\mu^2 M' + V'$ a term of magnitude μ^{-1}.

One can cover case $\mu \le \bar{\mu}_1^*$ by results of the previous section; this would require $(l,\sigma) = (\bar{l},\bar{\sigma}) = (2,3)$ and assumption (18.2.15) only to achieve the best possible estimate $O(\mu^{-1}h)$. The second restriction would be the most unfortunate.

However, we will use more sophisticated arguments to cover $\mu \in [\bar{\mu}_1, \bar{\mu}_1^*]$ here and prove the best possible estimate for $\sigma = \bar{\sigma} = 1$ instead.

Let us consider corresponding Hamiltonian flow ψ_t. One can see easily that

$$|\partial^{\nu}_{x,\xi}(\psi_t - I)| \le C_{\nu}\mu^{-2}\varepsilon^{l-1-|\nu|}|\log h|^{-\sigma} + C_{\nu}\mu^{-3}\varepsilon^{-|\nu|} \tag{18.3.35}$$

error below $\mu^{-1}h$ we need $(l,\sigma) = (3,\frac{3}{2})$ and we will proceed in this assumption in our next Chapters 19 and 20 devoted to the higher dimensions.

where I is an identity map.

Using arguments of the previous subsection one can prove easily that $T''(-t)\bar{P}_j T''(t) \equiv \mu(\bar{p}_j \circ \psi_t)^{\mathsf{w}}$ modulo operator with the upper $\bar{A}_0$-bound

$$\mu(\mu^{-1}h)^2 \times \bigl(1+\mu^{-2}\varepsilon^{I-3}|\log\mu|^{-\sigma}+\mu^{-3}\varepsilon^{-2}|\log\mu|^{-1}\bigr)\times \bigl(\mu^{-2}\varepsilon^{I-4}|\log h|^{-\sigma}+\mu^{-3}\varepsilon^{-3}|\log\mu|^{-1}\bigr); \tag{18.3.36}$$

then the same is true for $T''(-t)\bar{A}_0 T''(t) \equiv \mu^2(\bar{a}_0 \circ \psi_t)^{\mathsf{w}}$.

The bad news is that this expression is not necessarily less than $C\mu^{-1}h$ even if $(I,\sigma)=(2,1)$; the trouble appears as μ is close to $h^{-\frac{1}{3}}$ in which case expression (18.3.36) is close to h. Also, expression (18.3.36) is not less than $C\vartheta(\varepsilon)$ for $I<\frac{3}{2}$ and μ close to $h^{-\frac{1}{3}}$ again.

We could avoid these problems by slightly increasing $\bar{I}$ and assuming that $I\ge\frac{3}{2}$ but there is a better way. Note that (18.3.35) with ε replaced by $\bar{\epsilon}:=\mu^{-1-\delta}$ with small enough $\delta>0$ is less than $C\bigl(\mu^{-1}h+\vartheta(\varepsilon)\bigr)$ (with the original parameter ε in the last expression). Then let us assume that

(18.3.37) $S'\in \mu^{-2}\bar{\mathscr{F}}^{I,\sigma}$ and S'' satisfies (18.3.32) with ε replaced by $\bar{\varepsilon}:=\mu^{-1-\delta}$; here and below $\bar{\mathscr{F}}^*$ means that in the definition of the class ε replaced by $\bar{\varepsilon}$ while $\mathscr{F}^*$ denotes the original class.

Then the same arguments show that

$$T''(-t)(\mu^2M'+V')^{\mathsf{w}}T''(t)\equiv\bigl((\mu^2M'+V')\circ\psi_t\bigr)^{\mathsf{w}}$$

with the same error. So, modulo operator with A-bound not exceeding $C\bigl(\mu^{-1}h+\vartheta(\varepsilon)\bigr)$ we need to consider the quantization of

$$\bigl(\mu^2\bar{a}_0+\mu^2M'+V'\bigr)\circ\psi_1. \tag{18.3.38}$$

One can see easily that $\bar{p}_j\circ\psi_t-\bar{p}_j-t\{\bar{p}_j,S'+S''\}\in\mu^{-4}\bar{\mathscr{F}}^{I-2,\sigma}$ and therefore

$$\mu^2\bigl(\bar{a}_0\circ\psi_t-t\bar{a}_0-\{\bar{a}_0,S'+S''\}\bigr)\in\mu^{-2}\bar{\mathscr{F}}^{I-1,\sigma};$$

we conclude that if $V'\in\bar{\mathscr{F}}^{I,\sigma}$ and M' satisfied (18.3.32) with ε replaced by $\bar{\varepsilon}$ then $(\mu^2M'+V')\circ\psi_t-(\mu^2M'+V')$ would belong to the same class. In this case "the main part" of (18.3.38) would be $\mu^2\bar{a}_0+\mu^2\{\bar{a}_0,S'+S''\}+\mu^2M'+V'$ and we would define S',S'' from equations

$$\{\bar{a}_0,S'\}=-\mu^{-2}(V'-W'), \tag{18.3.39}$$

$$\{\bar{a}_0,S''\}=-(M'-\mu^{-2}W''). \tag{18.3.40}$$

Since $\{\bar{a}_0, q\} = (\xi_1\partial_{x_1} - x_1\partial_{\xi_1})q$ these equations would be solvable and solutions would satisfy (18.3.37) if and only if

$$W'(x_2,\xi_2,r) = \frac{1}{2\pi}\int V'(r\cos t, r\sin t; x_2,\xi_2)\,dt, \tag{18.3.41}$$

$$W''(x_2,\xi_2,r) = \frac{1}{2\pi}\mu^2\int M'(r\cos t, r\sin t; x_2,\xi_2)\,dt, \tag{18.3.42}$$

where we recall that $r^2 = x_1^2 + \xi_1^2$.

One can calculate easily the difference between $\bigl(\mu^2\bar{a}_0 + \mu^2 M' + V'\bigr)\circ\psi_1$ and $\mu^2\bar{a}_0+\mu^2\{\bar{a}_0, S'+S''\}+\mu^2M'+V'$; it will be $O(\mu^{-2})$ which is small enough to be taken care of by $\mu^{-1}h$-pseudodifferential operator transformations in what follows. More precisely

$$N := \Bigl(\mu^2\bar{a}_0 + \mu^2 M' + V'\Bigr)\circ\psi_1 - \Bigl(\mu^2\bar{a}_0 + \mu^2\{\bar{a}_0, S'+S''\} + \mu^2 M' + V'\Bigr) \in \mu^{-2}\bar{\mathscr{F}}^{l-1,\sigma}. \tag{18.3.43}$$

Since our symbols belong to $\mathscr{F}^*$ rather than $\bar{\mathscr{F}}^*$, we just replace V', M' by their $\bar{\varepsilon}$-mollifications $\bar{V}', \bar{M}'$ and define $\bar{S}', \bar{S}'', \bar{W}', \bar{W}''$ by (18.3.39)–(18.3.42) with $\bar{V}', \bar{M}'$ instead of V', M'.

Then we have unaccounted term K^{w} in the operator *before* the last transformation with $K = (\mu^2\tilde{M}' + \tilde{V}')$, where $\tilde{M}' = M' - \bar{M}'$, $\tilde{V}' = V' - \bar{V}'$ and then $K \in \vartheta(\bar{\varepsilon})\mathscr{F}^{0,0}$ and it also belongs to the same class as $V' + \mu^2 M'$ did.

To finish this part we need to understand how operator K^{w} is transformed by $T''(1)$. One can see easily that $K = K_0 + K_1 + ... + K_m$ where K_j is the difference between ε_j and ε_{j+1}-mollifications, $\varepsilon_j = 2^j\varepsilon$ and $\varepsilon_m = \bar{\varepsilon}$. Obviously $K_j \in \vartheta(\varepsilon_j)\mathscr{F}_j^{0,0}$ where

(18.3.44) $\mathscr{F}_j^*$ denotes corresponding class with ε replaced by ε_j.

Then one can see easily that $T''(-1)K_j^{\mathrm{w}}T''(1) \equiv K_j^{\mathrm{w}}$ modulo operator with the norm not exceeding $\mu^{-2}\varepsilon_j^{l-2}|\log h|^{-\sigma}$ and then $T''(-1)K^{\mathrm{w}}T''(1) \equiv K^{\mathrm{w}}$ modulo operator with the norm not exceeding $\mu^{-2}\varepsilon^{l-2}|\log h|^{-\sigma}$ as $l<2$ or $\mu^{-2}|\log h|^{1-\sigma}$ as $l=2$ and in both cases we got $O\bigl(\vartheta(\varepsilon)\bigr)$ estimate unless $l=2, \mu \le \bar{\mu}_1^*$.

The similar calculations imply that $T''(-1)K^{\mathrm{w}}T''(1) \equiv (K')^{\mathrm{w}}$ modulo operator with the norm not exceeding $C\vartheta(\varepsilon)$ with $K' = K + \{K, \bar{S}' + \bar{S}''\}$ as $l=2$ and $\mu \in [\bar{\mu}_1, \bar{\mu}_1^*]$.

Final Reduction

Thus we arrived to operator $\bar{A}_0 + \bar{W}^{\mathsf{w}} + (L + K')^{\mathsf{w}}$ where $\bar{W} = W' + W''$, symbol L is defined by (18.3.43) and

$$K' = \sum_{0\le j\le m} K_j, \qquad K_j \in \vartheta(\varepsilon_j)\mathscr{F}_j^{0,0} \subset \mathscr{F}_j^{l,\sigma}. \tag{18.3.45}$$

Fortunately, both operators L^{w} and K'^{w} are small enough to be reduced by $\mu^{-1}h$-pseudodifferential operator.

Namely, let us consider transformation by $U = \bigl(e^{-i\mu^{-1}h^{-1}(S'''+S^{IV})}\bigr)^{\mathsf{w}}$ where S''' and S^{IV} are symbols of the same class as L and K respectively; in particular, S^{IV} admits decomposition of type (18.3.45).

One can check easily that

$$e^{-i\mu^{-1}h^{-1}(S'''+S^{IV})} \in \mathscr{F}^{0,0}$$

as long as $\mu^{-l}h^{-1}|\log h|^{-\sigma} \le C\varepsilon^{-1}$ which is always the case because $\mu \ge C(h|\log h|)^{-\frac{1}{3}}$ and we assume that

$$(l,\sigma) \succeq (1,2). \tag{18.3.46}$$

Also one can see easily that modulo operator with $\bar{A}_0$-bound not exceeding $C\bigl(\mu^{-1}h + \vartheta(\varepsilon)\bigr)$

$$U^{-1}\Bigl(\bar{A}_0 + \bigl(\bar{W} + K' + L\bigr)^{\mathsf{w}}\Bigr)U \equiv \bar{A}_0 + \bigl(\{\bar{a}_0, S''' + S^{IV}\} + \bar{W} + K + L + R\bigr)^{\mathsf{w}} \tag{18.3.47}$$

where *one needs to include* $R \in \mu^{-4}\mathscr{F}^{l-2,\sigma}$ *only for* $(l,\sigma) \succeq (2,0)$.

Now we need just to define $S''', S^{IV}, W''', W^{IV}$ from equations similar to (18.3.39)–(18.3.42):

$$\{\bar{a}_0, S'''\} = -(L - W'''), \tag{18.3.48}$$

$$\{\bar{a}_0, S^{IV}\} = -(K' - W^{IV}), \tag{18.3.49}$$

$$W'''(x_2,\xi_2,r) = \frac{1}{2\pi}\int L(r\cos t, r\sin t; x_2,\xi_2)\,dt, \tag{18.3.50}$$

$$W^{IV}(x_2,\xi_2,r) = \frac{1}{2\pi}\int K'(r\cos t, r\sin t; x_2,\xi_2)\,dt. \tag{18.3.51}$$

So, *modulo operator with* $\bar{A}_0$*-bound not exceeding* $C\bigl(\mu^{-1}h + \vartheta(\varepsilon) + \mu^{-4}\bigr)$ *we reduced* A *to* $\bar{A}_0 + W^{\mathsf{w}}$ *where* $W = \bar{W} + W'' + W'''$ *depends on* x_2, ξ_2, r *only*.

This is almost the end of the story: for $(l,\sigma) \succeq (2,0)$ and $\mu \in [\bar{\mu}_1, h^{-\frac{1}{3}}]$ one needs to make one step more: namely, there is operator R^{w} in the right-hand expression of (18.3.47) and we should make transformation $U' = \bigl(e^{-i\mu^{-1}h^{-1}S^V}\bigr)^{\mathsf{w}}$ with $S^V \in \mu^{-4}\mathscr{F}^{l-2,\sigma}$ defined by

$$\{\bar{a}_0, S'''\} = -(R - W^V) \tag{18.3.52}$$

with

$$W^V(x_2,\xi_2,r) = \frac{1}{2\pi}\int R(r\cos t, r\sin t; x_2,\xi_2)\,dt. \tag{18.3.53}$$

So, *modulo operator with* $\bar{A}_0$*-bound not exceeding* $C\bigl(\mu^{-1}h + \vartheta(\varepsilon)\bigr)$ *we reduced* A *to* $\bar{A}_0 + W^{\mathsf{w}}$ *where for* $(l,\sigma) \succeq (2,0)$ *one needs to include* W^V *into* W *as well*.

18.3.2 Calculations

Calculations. I

Now we will need to calculate W more explicitly. To do this we repeat our construction, paying attention to explicit expressions we get rather than their smoothness. Also we will consider Weyl symbols rather than operators themselves. Let us start from the beginning of Subsubsection *18.3.1.3 Potential*. There we started from symbol $\bigl(\mu^2\bar{a}_0 + b\bigr)$ with $\bigl(b = \mu^2 M' + V'\bigr)$. Then we applied ψ_1 transformation and arrived to the symbol

$$\begin{aligned}\bigl(\mu^2\bar{a}_0 + b\bigr)\circ\psi_1 = \mu^2\bar{a}_0 \,+\,& \\ \mu^2\{\bar{S},\bar{a}_0\} + \frac{1}{2}\mu^2\{\bar{S},\{\bar{S},\bar{a}_0\}\} \,+\, &\frac{1}{6}\mu^2\{\bar{S},\{\bar{S},\{\bar{S},\bar{a}_0\}\}\}+\\ b \quad + \quad \{\bar{S},b\} \quad + \quad &\frac{1}{2}\{\bar{S},\{\bar{S},b\}\} \quad + \ \ldots\end{aligned} \tag{18.3.54}$$

where $\bar{S} = \bar{S}' + \bar{S}''$ and we skipped terms not exceeding $C\bigl(\mu^{-1}h + \vartheta(\varepsilon)\bigr)$.

Plugging $\mu^2\{\bar{S},\bar{a}_0\} = -\bar{b} + \bar{W}_0$ where $\bar{b}$ is a $\bar{\varepsilon}$-mollification of b and

$$\bar{W}_0 = \mathcal{M}_r(\bar{b}) \coloneqq \frac{1}{2\pi}\int_0^{2\pi} b(r\cos t, r\sin t; x_2,\xi_2)\,dt, \tag{18.3.55}$$

we get $\mu^2\bar{a}_0 + \bar{W}_0 + b_1$ with

$$b_1 = \frac{1}{2}\{\bar{S}, -\bar{b} + \bar{W}_0\} + (b - \bar{b}) + \{\bar{S}, b\} + \frac{1}{6}\{\bar{S}, \{\bar{S}, -\bar{b} + \bar{W}_0\}\} + \frac{1}{2}\{\bar{S}, \{\bar{S}, b\}\} \tag{18.3.56}$$

as a result of Subsubsectio *18.3.1.3 Potential*.

To calculate W as a result Subsubsection *18.3.1.4 Final Reduction* (without the last step) we need to apply $\mathcal{M}_r$ to this expression:

$$W = \bar{W}_0 + (\mathcal{M}_r b_1) = \mathcal{M}_r(b) + \mathcal{M}_r\big(\{\bar{S}, -\frac{1}{2}\bar{b} + \frac{1}{2}\bar{W}_0 + b\}\big) + \frac{1}{2}\mathcal{M}_r\big(\{\bar{S}, \{\bar{S}, -\frac{1}{3}\bar{b} + \frac{1}{3}\bar{W}_0 + b\}\}\big). \tag{18.3.57}$$

Finally, if $l = 2$, $\sigma > 0$ and we want to eliminate $O(\mu^{-4})$ from an error, we need to make a last step and define S_1 from the equation

$$\mu^2\{S_1, \bar{a}_0\} = -b_1 + (W - \bar{W}_0), \tag{18.3.58}$$

calculate

$$b_2 = \frac{1}{2}\mu^2\{S_1, \{S_1, \bar{a}_0\}\} + \{S_1, \bar{W}_0\} + b_1 - (W - \bar{W}_0) = \{S_1, -\frac{1}{2}b_1 + \frac{1}{2}W + \frac{1}{2}\bar{W}_0\} + b_1 - (W - \bar{W}_0) \tag{18.3.59}$$

and add to W term $\mathcal{M}_r(b_2)$.

Let $W_0 \coloneqq \mathcal{M}_r(b)$ and $b' = \frac{1}{2}\bar{W}_0 - \frac{1}{2}\bar{b} + b$. Then

$$\partial_\phi \bar{S} = \frac{1}{2}\mu^{-2}\bar{\beta}, \qquad \text{with} \quad \beta = b - W_0, \quad \bar{\beta} = \bar{b} - \bar{W}_0. \tag{18.3.60}$$

One can see easily that $W_0 \in \mathscr{F}^{l,\sigma}$ and that $W_0 \equiv b \mod O\big(\vartheta(\bar{\varepsilon}) + \mu^{-2}\big)$.

Note that we can take $\bar{S} = 0$ as $x_1 = \xi_1 = 0$ and in this case

$$|\partial_{x_2,\xi_2}\bar{S}| \le C\mu^{-2}\big(\mu^{-1} + \bar{\varepsilon}^{l-1}|\log\mu|^{-\sigma}\big). \tag{18.3.61}$$

One can check easily that with the final error $O\big(\mu^{-1} + \vartheta(\varepsilon)\big)$ in all the above calculations one can replace the standard Poisson brackets $\{.,.\}$ by the "short" ones $\{.,.\}'$, involving only x_1, ξ_1

$$\{f, g\}' = \partial_{\xi_1} f \cdot \partial_{x_1} g - \partial_{\xi_1} g \cdot \partial_{x_1} f \tag{18.3.62}$$

which in polar coordinates (r,ϕ) at (x_1,ξ_1)-plane are

$$\{f,g\}' = r^{-1}\big((\partial_\phi f)\cdot(\partial_r g) - (\partial_\phi g)\cdot(\partial_r f)\big). \tag{18.3.63}$$

Then integrating by parts if b' is differentiated by ϕ we get easily that

$$\mathcal{M}_r\big(\{\bar S, b'\}'\big) = r^{-1}\partial_r\mathcal{M}_r(b'\partial_\phi\bar S) = \frac{1}{2}\mu^{-2}r^{-1}\partial_r\mathcal{M}_r\big(b'\bar\beta\big) \equiv W_1 \coloneqq \frac{1}{4}\mu^{-2}r^{-1}\partial_r\mathcal{M}_r\big((W_0-b)^2\big). \tag{18.3.64}$$

Further, for $(l,\sigma)\succeq(2,0)$ let us consider the last terms in (18.3.55) and $\mathcal{M}_r(b_2)$ [24]. One can see easily that only "short" Poisson brackets (18.3.62) should be considered.

Then using the same arguments as above one can prove easily that modulo $O\big(\mu^{-1}h+\vartheta(\varepsilon)\big)$ these terms are equal $\frac{1}{8}\mu^{-4}r^{-1}\partial_r\mathcal{M}_r\big(r^{-1}(b-W_0)^2W\big)$ and $\frac{1}{4}\mu^{-2}r^{-1}\partial_r\mathcal{M}_r\big((b_1-W_1)^2\big)$ respectively with b_1 *redefined as*

$$b_1 \coloneqq \frac{1}{2}\{S, b+W_0\},\quad W_1=\mathcal{M}_r(b_1). \tag{18.3.56}$$*

Calculations. II

Now we want more explicit expressions for W, W_1 via g^{jk}, V.

First of all, note that for a constant metrics g^{jk} we have $b=V'=V\circ\Phi$, where $\Phi : T^*\mathbb{R}^2\to T^*\mathbb{R}^2$ is a linear map. Then $W_0=\mathcal{M}_rV'$ and since under map Φ a circle

$$\mathcal{C}_r=\{(x_2,\xi_2)=\mathsf{const}, x_1=r\cos t, \xi_1=r\sin t\} \tag{18.3.65}$$

translates into ellipse with x-projection

$$\mathcal{E}_r(y)=\{\sum_{j,k} g_{jk}(x_j-y_j)(x_k-y_k)=r^2\} \tag{18.3.66}$$

where $y=\Phi(\bar x_2,\bar\xi_2)$ is its center and g_{jk} are elements of the inverse matrix $(g^{jk})^{-1}$, we get that

$$W_0=\mathcal{M}_{\mathcal{E}_r}(\Phi(\bar x_2,\bar\xi_2)) \tag{18.3.67}$$

[24] One can prove easily that they are not essential as $(l,\sigma)\preceq(2,0)$ and we will see that they are $\asymp\mu^{-4}$ as $(l,\sigma)\succeq(2,0)$.

which is a corresponding average of V along $\mathcal{E}_r(y)$.

Similarly, we see that

$$W_1 \equiv -\frac{1}{4}\mu^{-2}|\nabla V'|^2 \equiv -\frac{1}{4}\mu^{-2}\sum g^{jk}(\partial_{x_j}V)(\partial_{x_k}V)\circ\Phi \mod O(\mu^{-4}). \tag{18.3.68}$$

Problem 18.3.4. In the general case, the deviation of $\mathcal{C}_r\circ\Phi$ from the ellipse $\mathcal{E}_r$ (with g_{jk} calculated in the center) is $O(\mu^{-2})$ and thus

$$W \equiv \mathcal{M}_{\mathcal{E}_r}(\Phi(\bar{x}_2,\bar{\xi}_2)) \mod O(\mu^{-2}). \tag{18.3.69}$$

This does not require $l>1$. It would be nice to get more precise answer in the general case as well.

18.3.3 Strong Magnetic Field $\mu \ge \epsilon(h|\log h|)^{-1}$

In this case we cannot claim anymore that $|p_j|\le C\mu^{-1}$ in the microlocal sense even if $\mu\le ch^{-1}$ because $f\big(\mu p_1(x,\xi),\mu p_2 x,\xi),x\big)$ is no more quantizable symbol. However, now $\mu^{-1}\le\varepsilon$ and $f\big(\varepsilon^{-1}p_1(x,\xi),\varepsilon^{-1}p_2(x,\xi),x\big)$ is quantizable symbol and we can claim that $|p_j|\le C\varepsilon$ in the microlocal sense in the zone of $\tau\le C_0(1+\mu h)$ due to the standard ellipticity arguments. Basically, this makes our construction much simpler; however, we need to remember that h^2 is no more non-essential term.

Construction of Subsubsections *18.3.1.1 Main pPart of the Operator. I* and *18.3.1.2 Main Part of the Operator. II* remains the same but we need to take in account correction (18.1.8) appearing when multiplying A by $F^{-\frac12}$ from the left and right and moving both copies of $F^{-\frac12}$ inside to g^{jk}.

Further, since the principal part of operator A is of magnitude μh rather than of magnitude 1 as it was before, the error due to approximation of the main part of operator is $O\big(\mu^2\varepsilon^{\bar l}|\log\mu|^{-\bar\sigma}\big)$ and it is non-essential (i.e. $O(\mu^{-1}h+1)$) for $(\bar l,\bar\sigma)=(4,2)$ only.

In the very input of Subsubsection *18.3.1.2 Main Part of the Operator. II* we can take a Taylor decomposition with respect to (x_1,ξ_1) (as we did in the smooth case) and then modulo "non-essential symbol" (which belongs to $\big(\mu^{-1}h+\vartheta(\varepsilon)\big)\mathscr{F}^{0,0}$) we get

$$\mu^2(x_1^2+\xi_1^2)+V(x_2,\xi_2)+ \mu^2\sum_{j=0}^{3}\beta_j(x_2,\xi_2)x_1^j\xi_1^{3-j}+\sum_{j=0}^{1}\alpha_j(x_2,\xi_2)x_1^j\xi_1^{1-j}+ \mu^2\sum_{j=0}^{4}\beta'_j(x_2,\xi_2)x_1^j\xi_1^{4-j}+\sum_{j=0}^{2}\alpha'_j(x_2,\xi_2)x_1^j\xi_1^{2-j} \tag{18.3.70}$$

with $\beta_j\in \mathscr{F}^{1,1}$, $\beta_j\in \mathscr{F}^{0,1}$, $\alpha_j\in \mathscr{F}^{l-1,\sigma}$, $\beta_j\in \mathscr{F}^{l-2,\sigma}$ and we need the last term only if $l\ge 2$.

However, we need to remember the terms in decomposition of the main part; we can eliminate the third order term but we will reduce the fourth-order term. More precisely, to get rid of the third and the forth terms in (18.3.70) we use again the construction of Subsubsection *18.3.1.3 Potential* but we look explicitly for

$$S'=\sum_{j=0}^{1}\hat\alpha_j(x_2,\xi_2)x_1^j\xi_1^{1-j},\qquad S''=\mu^2\sum_{j=0}^{3}\hat\beta_j(x_2,\xi_2)x_1^j\xi_1^{3-j} \tag{18.3.71}$$

with $\hat\alpha_j,\hat\beta_j$ of the same regularity as α_j,β_j.

Now we have expression (18.3.70) without the third and the fourth terms; the fifth and the sixth terms are modified but retain $\mathscr{F}^{l-2,\sigma}$-regularity provided $(l,\sigma)\succ(2,0)$; for $(l,\sigma)\preceq(2,0)$ we get non-essential terms. For $\mu\ge c^{-1}h^{-1}$ these terms are non-essential as well. So, *in these two cases our construction is complete*.

To complete reduction for $\mu\in[(h|\log h|)^{-1},ch^{-1}]$, $(l,\sigma)\succ(2,0)$ we apply again "poor man Fourier integral operator", this time with

$$S'=\sum_{j=0}^{2}\hat\alpha'_j(x_2,\xi_2)x_1^j\xi_1^{2-j},\qquad S''=\mu^2\sum_{j=0}^{4}\hat\beta'_j(x_2,\xi_2)x_1^j\xi_1^{4-j} \tag{18.3.72}$$

with $\hat\alpha'_j,\hat\beta'_j\in\mathscr{F}^{l-2,\sigma}$. However, we cannot eliminate these terms completely, we can only to reduce them to

$$\bar\alpha(x_2,\xi_2)\big(x_1^2+\xi_1^2\big),\qquad \bar\beta(x_2,\xi_2)\big(x_1^2+\xi_1^2\big)^2 \tag{18.3.73}_{1,2}$$

respectively with $\bar\alpha,\bar\beta\in\mathscr{F}^{l-2,\sigma}$.

One can calculate easily that the final expression is resembling one from Subsubsections *18.3.2.1 Calculations. I* and *18.3.2.2 Calculations. II* because in our situation $\mathcal{M}_C f = f + \frac{1}{2}\mu^{-2}\Delta_{x_1,\xi_1} f$ modulo non-essential term and one can recalculate this way W_1 too. However, construction here reminds one of the smooth theory.

So, we have proven

Proposition 18.3.5. *Let* $d = 2$, $\mu \ge (h|\log h|)^{-\frac{1}{3}}$ *and* $(\bar{l}, \bar{\sigma}) \succeq (2, 0)$, $(l, \sigma) \succeq (1, 2)$.

Then modulo operator with $\bar{A}_0$*-bound not exceeding* $C\big(\mu^{-1}h + \vartheta(\varepsilon)\big)$ *with* $\varepsilon = C(\mu^{-1}h|\log h|)^{\frac{1}{2}}$ *one can reduce operator* A *to operator* $\bar{A}_0 + W^{\mathsf{w}}$ *where* $W = W_0 + W_1 + W_2$ *depends on* x_2, ξ_2 *and* $\mu^{-1}A_0^{\frac{1}{2}}$ *(or* $\mu^{-1}\bar{A}_0^{\frac{1}{2}}$*) only.*

18.4 $d = 2$: Tauberian Theory

18.4.1 Decomposition

We again consider more difficult case $\mu \le \epsilon(h|\log h|)^{-1}$ first; the opposite case can be considered in the same way with rather obvious modifications and simplifications.

There is not much what is left: removing non-essential operator and compensating this by adding $\mp C_0\vartheta(\varepsilon)$ to the lower/upper approximation (which in turn will not violate our estimates; see below), we get a 1-dimensional operator-valued $\mu^{-1}h$-pseudodifferential operator

$$\bar{A}_0 + W(x_2, \mu^{-1}hD_2, \mu^{-1}\bar{A}_0) \tag{18.4.1}$$

with an operator-valued symbol, acting in auxiliary space $\mathscr{L}^2(\mathbb{R})$.

Taking as in Section 13.5 decomposition into

$$\Upsilon_n(x_1) \coloneqq (\mu^{-1}h)^{-\frac{1}{4}} v_n\big((\mu^{-1}h)^{-\frac{1}{2}}x_1\big) \tag{18.4.2}$$

with Hermitian functions v_n and coefficients which are functions of x_2 we get a family of 1-dimensional $\mu^{-1}h$-pseudodifferential operators

$$\mathcal{A}_n \coloneqq r_n^2 + W(x_2, \mu^{-1}hD_2, \mu^{-1}r_n), \qquad r_n \coloneqq \big((2n+1)\mu h\big)^{\frac{1}{2}} \tag{18.4.3}$$

provided $\mu hn \le C_0$.

Even if we cannot apply directly spectral projectors associated with $\mathcal{A}_n$, we can consider propagator $e^{ih^{-1}t\tilde{A}}$ and its Schwartz kernel $u(x,y,t)$ and prove easily that for $t, |t| \le T_1 := \epsilon\mu$

$$U(x,y,t) \equiv \mathcal{T}\Big(\sum_{n\ge 0} U_n(x_2,y_2,t)\Upsilon_n(x_1)\Upsilon_n(y_1)\Big)\mathcal{T}^{-1} \tag{18.4.4}$$

modulo Schwartz kernel of an operator which becomes negligible multiplied by $\big(\psi(x)q(\mu p_1,\mu p_2)\big)^{\mathsf{w}}$ where ψ, q are smooth and supported in $B(0,\frac{1}{2})$ and $B(0,C_0)$ respectively. Recall that we call operator *negligible* if its norm does not exceed $C(\mu^{-1}h)^s$ with large enough exponent s.

Here U is the Schwartz kernel of the propagator $e^{ih^{-1}t\tilde{A}}$ of the transformed back reduced operator[25),26)]

$$\tilde{A} := \mathcal{T}\Big(\bar{A}_0 + W(x_2,\mu^{-1}hD_2,\mu^{-1}\bar{A}_0)\Big)\mathcal{T}^{-1} \tag{18.4.5}$$

which is 1-dimensional $\mu^{-1}h$-pseudodifferential operator with operator-valued symbol, $\mathcal{T}$ is a full transformation constructed in Subsection 18.3.1, and

(18.4.6) U_n are Schwartz kernels of the propagators $e^{ih^{-1}t\mathcal{A}_n}$ for $\mathcal{A}_n$.

Further, by definition $W = W_0 + W_1$ because W_2 is not essential in our sense.

18.4.2 Estimate under Assumption (18.2.15)

So, for $T = T_1$, $\tau \le c$

$$F_{t\to h^{-1}\tau}\Big(\chi_T(t)\Gamma\big(\psi(x)u(x,y,t)\big)\Big) \equiv \tag{18.4.7}$$
$$F_{t\to h^{-1}\tau}\Big(\chi_T(t)\sum_{n\ge 0}\Gamma\Big(\tilde{\psi}\big(U_n(x_2,y_2,t)\Upsilon_n(x_1)\Upsilon_n(y_1)\big)\Big)\Big)$$

modulo $O(\mu^{-s})$ where as before Γ is a trace for Schwartz kernel (restriction to the diagonal and integration) and

$$\tilde{\psi} = \mathcal{T}^{-1}\psi\mathcal{T} \tag{18.4.8}$$

[25)] Apart of just reduction we removed some "non-essential" terms.

[26)] Actually we have two of them: $\tilde{A}^{\pm}$ such that $\tilde{A}^{-} \le A \le \tilde{A}^{+}$ and A-bounds of operators $A - \tilde{A}^{\pm}$ do not exceed $C\big(\mu^{-1}h + \vartheta(\varepsilon)\big)$ (so they are operators described in footnote [18)]).

is $\mu^{-1}h$-pseudodifferential operator rather than a function; its symbol is not very regular (see below).

In this decomposition we can consider only $n \le C_1(\mu h)^{-1}$ because for any other n interval $(-\infty, C_0)$ is a classically forbidden zone for operator $\mathcal{A}_n$ and one can prove easily that their contributions do not exceed $C\mu^{-s}(\mu hn+1)^{-s}$ with the arbitrarily large s and thus their total contribution is negligible.

Note that all operators $\mathcal{A}_n$ are non-degenerate at level 0 in the sense that

$$|\mathcal{A}_n| \le \epsilon_0 \implies |\nabla_{x_2,\xi_2}\mathcal{A}_n| \asymp 1 \tag{18.4.9}$$

if and only if the original operator satisfied the non-degeneracy assumption (18.2.15) because $|\nabla(W - V/F)| \le C\mu^{-1}$.

Let us assume first that this non-degeneracy assumption holds. Then in the standard way we can prove easily that if $Q_x = q(x_2, \mu^{-1}hD_{x_2})$ and $Q'_y = q'(y_2, \mu^{-1}hD_{y_2})$ are $\mu^{-1}h$-pseudodifferential operators with symbols supported in ε-vicinity of $(\bar{x}_2, \bar{\xi}_2)$ in which condition (18.4.9) is fulfilled, then

$$F_{t\to h^{-1}\tau}\chi_T(t)\big(Q_x U_n(x_2, y_2, t)\, {}^tQ'_y\big) \tag{18.4.10}$$

is negligible provided $T \le T_1$ and $\mu^{-1}T \times \varepsilon \ge C\mu^{-1}h|\log h|$ or equivalently

$$T_* := C\varepsilon^{-1}h|\log h| \le T \le T^* := \epsilon\mu. \tag{18.4.11}$$

Recall that χ is an admissible function supported in $[-1, -\frac{1}{2}] \cup [\frac{1}{2}, 1]$. Then

$$F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(\psi(x)U(x, y, t)\big) \tag{18.4.12}$$

is negligible as well.

This statement does not look strong enough because T_* seems to be much larger than we need due to the factor ε^{-1}: the direct assault shows that $|\Gamma\psi KU|$ does not exceed Ch^{-2} (where $K = k\big(x, \mu p(x, \xi)\big)^{\mathsf{w}}$) is $\mu^{-1}h$-pseudodifferential operator cut-off; then

$$|F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t)\Gamma(\psi KU)\big)| \le Ch^{-2}T_* \tag{18.4.13}$$

for $\bar{\chi}$ supported in $[-1, 1]$ and equal 1 at $[-\frac{1}{2}, \frac{1}{2}]$ and $T \in [T_*, T^*]$; here we can take $K = I$ because $\tau \le c$ and we can apply ellipticity arguments in

zone $\{|p| \ge C'\mu^{-1}\}$; then (18.4.13) and the standard Tauberian arguments imply Tauberian spectral remainder estimate

$$\mathsf{R}^{\mathsf{T}} := |\Gamma(\psi Q_x e)(\tau) - h^{-1}\int_{-\infty}^{\tau}\Big(F_{t\to h^{-1}\tau'}\big(\bar\chi_T(t)\Gamma(\psi QU)\big)\Big)\,d\tau'| \le Ch^{-2}\frac{T_*}{T^*} \asymp Ch^{-1}\mu^{-1}\varepsilon^{-1}|\log h| \tag{18.4.14}$$

and it is close to what we are looking for (but still is not that good) only for $\varepsilon = 1$. Sure by rescaling arguments we can make $T_* = h\varepsilon^{-1}$ in the right-hand expressions of the estimates only and thus get rid of logarithmic factor (and we will do it) but it alone does not solve our problem.

The source of this trouble is that *we have ε-scale in both x_2 and ξ_2*, while in the non-magnetic case treated in Section 4.6 we had scale 1 in ξ_2.

However, there is a way to improve our analysis: what we need is an estimate

$$|F_{t\to h^{-1}\tau}\big(\bar\chi_T(t)\Gamma(\psi U)\big)| \le Ch^{-1} + C\mu h^{-2}\vartheta(\varepsilon) \tag{18.4.15}$$

which we are going to prove; then dividing the right-hand expression of (18.4.15) by T^* we get the required remainder estimate $O\big(\mu^{-1}h^{-1}+h^{-2}\vartheta(\varepsilon)\big)$.

(i) First of all, we want to deal with U_n directly. Note that

$$\tilde\psi = \psi_0(x_2,\mu^{-1}hD_2)+ \psi_1(x_2,\mu^{-1}hD_2)x_1 + \psi_2(x_2,\mu^{-1}hD_2)\mu^{-1}hD_1 + \tilde\psi'(x,\mu^{-1}hD)$$

with symbol of $\tilde\psi'$ belonging to $\mu^{-l}|\log h|^{-\sigma}\mathscr{F}^{0,0}$; for $l=2,\sigma>0$ one needs to include also the second order terms

$$\psi_{11}(x_2,\mu^{-1}hD_2)\,x_1^2 + \psi_{12}(x_2,\mu^{-1}hD_2)\,(x_1\mu^{-1}hD_1+\mu^{-1}hD_1x_1)+ \psi_{11}(x_2,\mu^{-1}hD_2)\,(\mu^{-1}hD_1)^2.$$

Let us consider $|F_{t\mapsto h^{-1}\tau}\big(\bar\chi_T(t)\tilde\psi' U\big)|$ first; due to the analysis above it does not exceed $Ch^{-2}T_*\times\mu^{-l}|\log h|^{-\sigma}$; one can see easily that it does not exceed the right-hand expression of (18.4.15).

Further, note that plugging terms linear with respect to $(x_1,\mu^{-1}hD_1)$ kills the trace while plugging quadratic terms is equivalent to plugging $(n+\frac12)\mu^{-1}h\psi'(x_2,\mu^{-1}hD_2)$ with $\psi'=\psi_{11}+\psi_{22}$.

Now we have pure $\mu^{-1}h$-pseudodifferential operators, acting on x_2 alone; we consider u_n and replace Γ by Γ' acting with respect to x_2 alone.

(ii) Second, we need to improve T_* slightly, removing $|\log h|$ factor and to get better estimates for Fourier transform. Let us consider ε-admissible partition in (x_2, ξ_2): $1 = \sum_\nu q_{(\iota)}$ and consider element $q_{(\iota)}$ of this partition.

One can easily prove by the standard rescaling technique the following estimate

$$|\Gamma'\bigl(\chi_T(t) q_{(\iota)} u_n\bigr)| \le C\varepsilon^2 \mu h^{-1} \bigl(\frac{T}{\bar{T}_*}\bigr)^s \tag{18.4.16}$$

for arbitrarily large s and $T \in [\bar{T}_*, T^*]$ where

$$\bar{T}_* := C_0 \varepsilon^{-1} h = T_*/|\log h|. \tag{18.4.17}$$

Then

$$|F_{t\to h^{-1}\tau}\bigl(\chi_T(t)\Gamma'(q_{(\iota)}U_n)\bigr)| \le C\varepsilon^2 \mu h^{-1} \bigl(\frac{T}{\bar{T}_*}\bigr)^s T \tag{18.4.18}$$

and thus

$$|F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_T(t)\Gamma'(q_{(\iota)}U_n)\bigr)| \le C\varepsilon^2 \mu h^{-1} \bar{T}_* \tag{18.4.19}$$

for any $T \in [\bar{T}_*, T^*]$.

Further, note that due to the standard ellipticity arguments

$$F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_T(t)\Gamma'(q_{(\iota)}U_n)\bigr)$$

is negligible for $|\tau| \le Ch|\log h| T^{-1}$ unless

$$|\mathcal{A}_n(x_2, \xi_2)| \le C\bigl(\varepsilon + Ch|\log h| T^{-1}\bigr) \qquad \text{on} \quad \operatorname{supp}(q_{(\iota)}), \tag{18.4.20}$$

and that

(18.4.21) Under assumption (18.2.15) the set

$$\Omega_{\tau,n} := \{(x_2, \xi_2)\colon |\mathcal{A}_n(x_2, \xi_2) - \tau| \le C\varepsilon\} \tag{18.4.22}$$

has measure $O(\varepsilon)$ for each τ, n.

Therefore as $T \ge T_*$ (and therefore $Ch|\log h|\,T^{-1} \lesssim \varepsilon$ we arrive to the estimate

$$|F_{t\to\mu^{-1}h}\bar\chi_T(t)\Gamma'(QU_n)| \le C\mu h^{-1}\,\bar T_* \times \varepsilon = C\mu \tag{18.4.23}$$

which implies (18.4.15) since we need to multiply by the number of the admissible indices (which is $\asymp (\mu h)^{-1}$) resulting in Ch^{-1} and take in account contribution of the neglected terms. Then in virtue of the standard Tauberian arguments (with $T^* \asymp \mu$) we arrive to the estimate

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{-1}h^{-1} + Ch^{-2}\vartheta(\varepsilon) \tag{18.4.24}$$

with R^{T} defined by (18.4.14) $\bar\chi = 1$ on $[-\frac12, \frac12]$, $T \in [T_*, T^*]$ which is exactly estimate we want.

18.4.3 Estimate under Assumption (18.2.16)

Now let $(I,\sigma) \succeq (2,0)$ and at some point $\bar z := (\bar x_2, \bar\xi_2)$ the following generalization of (18.4.9) holds:

$$|\nabla \mathcal{A}_n| \le \epsilon_0\nu \implies |\nabla \mathcal{A}_n(x_2,\xi_2)| \asymp \nu \tag{18.4.9}'$$

where

$$\nu \ge C_0\mu^{-1} \tag{18.4.25}$$

which in turn is larger than $C_0\varepsilon$ if $\mu \le \epsilon(h|\log h|)^{-1}$. Then (18.4.9)$'$ holds in $B(\bar z, \epsilon_0\nu)$.

Then we can take

$$T_* := C\varepsilon^{-1}\nu^{-1}h|\log h| \le T^* = \epsilon\mu \tag{18.4.17}'$$

and estimates (18.4.18) and (18.4.19) hold. On the other hand, one needs to replace (18.4.20) by

$$|\mathcal{A}_n(x_2,\xi_2)| \le C\bigl(\varepsilon\nu + Ch|\log h|\,T^{-1}\bigr) \qquad \text{on} \quad \mathsf{supp}(q_{(\iota)}), \tag{18.4.20}'$$

and instead of (18.4.21) observe that

(18.4.26) Under assumption (18.4.9)$'$

$$\Omega_{\tau,n,\nu} := \{(x_2,\xi_2) \in B(\bar z, \epsilon_0\nu)\colon |\mathcal{A}_n(x_2,\xi_2) - \tau| \le C\varepsilon\nu\} \tag{18.4.22}'$$

has measure $O(\varepsilon\nu)$ for each τ, n.

Then, as Q is supported in $B(\bar{z}, \epsilon_0\nu)$, (18.4.23) is replaced by

$$|F_{t\to\mu^{-1}h}\bar{\chi}_T(t)\Gamma'(Qu_n)| \le C\mu h^{-1}\bar{T}_* \times \nu\varepsilon = C\mu \tag{18.4.23)'}$$

and summation over n returns $C\mu(\nu^2/(\mu h)+1)$ while summation over z returns

$$C\int \mu(\nu(z)^2/(\mu h)+1)\nu^{-2}(z)\,dz \asymp Ch^{-1} + C\mu|\log\mu| \tag{18.4.27}$$

due to assumption (18.2.16). As $\mu \lesssim (h|\log h|)^{-1}$ the second term in the right-hand expression is less than the first one.

Therefore if Q is supported in the ball of radius $\asymp 1$ and is negligible on $\mathcal{X}_{\mathsf{inn}} := \{z : |\nabla W| \le C_0\mu^{-1}\}$ inequality (18.4.23) remains true and the contribution of Q to Tauberian remainder does not exceed $C\mu^{-1}h^{-1}$.

Meanwhile contribution of $\mathcal{X}_{\mathsf{inn}}$ (intersected with the ball of radius $\asymp 1$) to the Tauberian remainder does not exceed $C\mu h^{-1} \times \mathsf{mes}\,\mathcal{X}_{\mathsf{inn}} = O(\mu^{-1}h^{-1})$ in virtue of (18.2.16) again. Thus we arrive to the Tauberian estimate (18.4.24) again. Therefore we arrive to

Proposition 18.4.1. *Let $d = 2$ and $(\bar{l}, \bar{\sigma}) \succeq (2, 0)$. Further, assume that $h^{-\frac{1}{3}} \lesssim (h|\log h|)^{-\frac{1}{3}} \le \mu \le \epsilon(h|\log h|)^{-1}$ and <u>either</u>*

(i) $(l, \sigma) \succeq (1, 2)$ and assumption (18.2.15) *be fulfilled <u>or</u>*

(ii) $(l, \sigma) \succeq (2, 0)$ and assumption (18.2.16) *be fulfilled.*

Then the Tauberian estimate (18.4.24) *holds where we need to calculate the Tauberian expression*

$$h^{-2}\mathcal{N}^{\mathsf{T}} := h^{-1}\int_{-\infty}^{\tau}\Big(F_{t\to h^{-1}\tau'}\big(\bar{\chi}_T(t)\Gamma(\psi u)\big)\Big)\,d\tau' \tag{18.4.28}$$

with $T \ge T_* = C\varepsilon^{-1}h|\log h|$ in the framework of (i); in the framework of (ii) we need to take the discussed above partition and take $T \ge T_{*\iota} = C\varepsilon^{-1}\nu_\iota^{-1}h|\log h|$ on each element of this partition.

18.4.4 Case $\mu \ge \epsilon(h|\log h|)^{-1}$

As $\mu \ge \epsilon(h|\log h|)^{-1}$ we need to remember that now $\varepsilon \ge \mu^{-1}$; therefore estimates

$$|x_1| \le C_0\mu^{-1}, \qquad |\mu^{-1}hD_1| \le C_0\mu^{-1} \tag{18.4.29)$_{1,2}}$$

should be replaced by

$$|x_1| \le C_0\varepsilon, \qquad |\mu^{-1}hD_1| \le C_0\varepsilon \tag{18.4.30}_{1,2}$$

in the "domain of interest"; however, as $\mu \lesssim h^{-1}$, estimate (18.4.28) still holds in the operator sense.

Further, as $\mu \ge ch^{-1}$ we need to consider the Schrödinger-Pauli operator

$$A = \sum_{j,k} P_j g^{jk} P_k + V - \mathfrak{z}\mu hF, \qquad \text{with } P_j = hD_j - \mu V_j \tag{18.4.31}$$

with $\mathfrak{z} \in \mathbb{R}$ and to avoid hitting the spectral gap we need to consider only $\mathfrak{z} = 1, 3, 5, \dots$. Then (18.4.30) holds in microlocal sense and also in operator sense (but in the latter case one can take $\varepsilon = C(\mu^{-1}h)^{\frac{1}{2}}$).

Furthermore, one need to remember that $n \le C_0/\mu h$ should be replaced by $n \le C_0$ as $\mu \ge ch^{-1}$. This takes care of the case of assumption (18.2.15) and we arrive to the estimate (18.4.24) as $\mu \le h^{-1}$ and estimate

$$\mathsf{R}^{\mathsf{T}} \le C + C\mu h\vartheta(\varepsilon) \tag{18.4.32}$$

as $\mu \ge h^{-1}$.

Under assumption (18.2.16) the additional analysis is required since for $\{\nu \le \varepsilon\}$ the uncertainty principle breaks but the contribution of such zone to the remainder is $Ch^{-2}(\mu h + 1)\varepsilon^2$ (i.e. estimates (18.4.24) and (18.4.32) acquire additional terms $C\mu^{-1}h^{-1}|\log\mu|$ and $C|\log\mu|$ respectively.

Thus we arrive to the following:

Proposition 18.4.2. *Let* $d = 2$ *and* $(\bar{l}, \bar{\sigma}) \succeq (2, 0)$.

(i) Let $(l, \sigma) \succeq (1, 2)$ *and the non-degeneracy assumption* (18.2.15) *be fulfilled. Then for* $(h|\log h|)^{-1} \le \mu \le h^{-1}$ *the Tauberian estimate* (18.4.24) *holds for the Schrödinger operator and for* $\mu \ge h^{-1}$ *the Tauberian estimate* (18.4.32) *holds for the Schrödinger-Pauli operator* (18.4.31) *where we need to calculate the Tauberian expression* (18.4.32) *with* $T \ge T_* = C\varepsilon^{-1}h|\log h|$.

(ii) Let $(l, \sigma) \succeq (2, 0)$ *and assumption* (18.2.16) *be fulfilled. Then for* $(h|\log h|)^{-1} \le \mu \le h^{-1}$ *the Tauberian estimate*

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{-1}h^{-1} + C|\log\mu| + Ch^{-2}\vartheta(\varepsilon) \tag{18.4.33}$$

holds for the Schrödinger operator and for $\mu \ge h^{-1}$ *Tauberian estimate*

$$\mathsf{R}^{\mathsf{T}} \le C|\log \mu| + C\mu h^{-1}\vartheta(\varepsilon) \tag{18.4.34}$$

holds for the Schrödinger-Pauli operator(18.4.31) *where we need to take partition and to calculate Tauberian expression* (18.4.32) *with* $T \ge T_{*\iota} = C\varepsilon^{-1}\nu_\iota^{-1}h|\log h|$.

Repeating arguments of the smooth case (in Section 13.6) one can prove easily the following:

Remark 18.4.3. (i) For $\mu \gtrsim h^{-1}$ as usual the non-degeneracy assumptions (18.2.15) and (18.2.16) could be weaken to

$$|(2n+1-\mathfrak{z})\mu h + V| + |\nabla V/F| \ge \epsilon_0 \qquad \forall n \in \mathbb{Z}^+ \tag{18.2.15)*}$$

and

$$|(2n+1-\mathfrak{z})\mu h + V| + |\nabla V/F| + |\det \mathsf{Hess}\, V/F| \ge \epsilon_0 \qquad \forall n \in \mathbb{Z}^+ \tag{18.2.16)*}$$

respectively.

(ii) For $\mu \lesssim h^{-1}$ under condition

$$|\nabla V/F| \le \epsilon_0 \implies \det \mathsf{Hess}\, V/F \ge \epsilon_0 \tag{18.2.16)$^+$}$$

estimate (18.4.24) holds and as $\mu \gtrsim h^{-1}$ under condition

$$|(2n+1-\mathfrak{z})\mu h + V| + |\nabla V/F| \le \epsilon_0 \implies \det \mathsf{Hess}\, V/F \ge \epsilon_0 \qquad \forall n \in \mathbb{Z}^+ \tag{18.2.16)$^{*+}$}$$

estimate (18.4.32) holds.

(iii) As $\mu \gtrsim h^{-1}$ in the case of the spectral gap

$$|(2n+1-\mathfrak{z})\mu h + V| \ge \epsilon_0 \qquad \forall n \in \mathbb{Z}^+ \tag{18.4.35}$$

$\mathsf{R}^{\mathsf{T}} = O(\mu^{-s})$ as in the smooth case.

Here in Statement (i) we use the fact that under condition (18.2.16)$^+$ or (18.2.16)$^{*+}$ (in the corresponding settings) $\mathcal{A}_n$ is is either elliptic unless $\nu \asymp \bar\nu$ for some $\bar\nu \ge C_0 \max\bigl(\mu^{-1}, (\mu^{-1}h)^{\frac12}\bigr)$ or unless $\nu \le \bar\nu = C_0 \max\bigl(\mu^{-1}, (\mu^{-1}h)^{\frac12}\bigr)$.

For $\bar\nu \in [(\mu^{-1}h)^{\frac12}, (\mu^{-1}h|\log h|)^{\frac12}]$ we use the standard rescaling technique.

18.5 $d = 2$: Calculations and Main Theorems

Now our purpose is to prove main results as $\mu \ge \bar{\mu}_1$, i.e. Theorems 18.5.4 and 18.5.7 below. In the calculations we can assume that $(18.1.6)^*$ holds, i.e. $F = 1$.

18.5.1 Calculations

Step I under Assumption (18.2.15)

To calculate the Tauberian expression (18.4.28) we rewrite it modulo negligible terms as the sum with respect to n, ι of

$$\mathcal{S}_{n(\iota)} := h^{-1} \int_{-\infty}^{\tau} \Big(F_{t\to h^{-1}\tau'} \big(\bar{\chi}_T(t) \Gamma \big(\tilde{\psi}(x, \mu^{-1} hD) q^{\mathsf{w}}_{(\iota)} \big(u_n \Upsilon_n(x_1) \Upsilon_n(x_1) \big) \big) \big) \Big) \, d\tau' \tag{18.5.1}$$

with $q_{(\iota)} = q^{\mathsf{w}}_{(\iota)}(x_2, \mu^{-1} hD_2)$.

One can see easily that on the *elliptic elements* (with failed (18.4.20) or $(18.4.20)'$)

$$\mathcal{S}_{n(\iota)} \equiv \frac{1}{2\pi} \mu h^{-1} \iint \theta\big(\tau - \mathcal{A}_n(x_2, \xi_2)\big) \tilde{\psi}(x, \xi) q_{(\iota)}(x_2, \xi_2) \, dx d\xi \tag{18.5.2}$$

modulo negligible expression; here $\theta\big(\tau - \mathcal{A}_n(x_2, \xi_2)\big) = \mathsf{const}$ on $\mathsf{supp}(q_{(\iota)})$ and we need to calculate the difference between these two expressions on the *non-elliptic elements* (i.e. satisfying (18.4.20) or $(18.4.20)'$).

The total contribution of such terms is not very large: as $\mu h \lesssim 1$ and $\nu = 1$ it does not exceed $Ch^{-1} \times \mu \times \varepsilon \times 1/(\mu h)$ where the first factor is just present in (18.5.1), the second factor is the estimate (18.4.23) of the Fourier transform $(F_{t\to \mu^{-1}h} \bar{\chi}_T(t) \Gamma'(Qu_n))$, the third factor is here because this Fourier transform is negligible for $|\tau' - \tau| \ge C\varepsilon$ and the last factor is the number of n for which (18.4.20) holds on $\mathsf{supp}(q_{(\iota)})$. Still resulting expression $C\varepsilon h^{-2}$ is larger than what we need.

We apply the method of the successive approximations to calculate these terms; as unperturbed operator we take

$$\mathcal{B}_n = \mathcal{A}_n(y, \mu^{-1} hD_x). \tag{18.5.3}$$

Then

$$\mathcal{R}_n \coloneqq \mathcal{A}_n - \mathcal{B}_n = (x_2 - y_2)\mathcal{Q}_n(x, y, \mu^{-1}hD_x) \tag{18.5.4}$$

and then

$$U_n^{\pm}(x_2, y_2, t) \coloneqq \theta(\pm t)U(x_2, y_2, t) = \mp ih\mathcal{G}_n^{\pm}\delta(x_2 - y_2)\delta(t) = \mp ih\bar{\mathcal{G}}_n^{\pm}\delta(x_2 - y_2)\delta(t) \mp ih\bar{\mathcal{G}}_n^{\pm}\mathcal{R}_n\mathcal{G}_n^{\pm}\delta(x_2 - y_2)\delta(t) \tag{18.5.5}$$

where $\bar{\mathcal{G}}^{\pm}$ and $\mathcal{G}^{\pm}$ are forward/backward parametrices for the Cauchy problem for operators $hD_t - \mathcal{B}_n$ and $hD_t - \mathcal{A}_n$ respectively. Similarly,

$$U_n^{\pm}(x_2, y_2, t)\,{}^t\!Q_y = \mp ih\mathcal{G}_n^{\pm}\delta(x_2 - y_2)\,{}^t\!Q_y\delta(t) = \mp ih\bar{\mathcal{G}}_n^{\pm}\delta(x_2 - y_2)\,{}^t\!Q_y\delta(t) \mp ih\bar{\mathcal{G}}_n^{\pm}\mathcal{R}_n\mathcal{G}_n^{\pm}\delta(x_2 - y_2)Q_y^t\delta(t) \tag{18.5.6}$$

for $Q_y = Q(y_2, \mu^{-1}hD_{y_2})$ where as usual we write pseudodifferential operator acting on y on the right in accordance to matrix theory and ${}^t\!Q$ denotes the transposed operator.

So, $U_n = U_n^0 + U_n^1$ where U^0 is a Schwartz kernel of the propagator for $\mathcal{B}_n$ and

$$U_n^{1\pm} = \bar{\mathcal{G}}_n^{\pm}\mathcal{R}_n U_n^{\pm}. \tag{18.5.7}$$

As usual we take $(x_2 - y_2)$ and carry it forward to the left using commuting relation

$$[\bar{\mathcal{G}}_n^{\pm}, (x_2 - y_2)] = \bar{\mathcal{G}}_n^{\pm}[\mathcal{B}_n, x_2 - y_2]\bar{\mathcal{G}}_n^{\pm} \tag{18.5.8}$$

and in the very front this factor will be killed by Γ'. Then for our purpose we can replace $U_n^{1\pm}$ by

$$\bar{\mathcal{G}}_n^{\pm}[\mathcal{B}_n, x_2 - y_2]\bar{\mathcal{G}}_n^{\pm}\mathcal{Q}_n U_n^{0\pm}. \tag{18.5.9}$$

Let us dump it in (18.4.28). Consider first

$$F_{t\to h^{-1}\tau}\Big(\varphi_T(t)\Gamma'\Big(\big(U_n^1(\tilde{\psi}\,{}^t\!q_{(\iota)}^{\mathsf{w}})_y\big)\Big)\Big) \tag{18.5.10}$$

with <u>either</u> $\varphi_T = \bar{\chi}_T$, $T = \bar{T}_*$ <u>or</u> $\varphi_T = \chi_T$, $T \ge \bar{T}_0$; recall that $\bar{T}_* = Ch/\varepsilon$ as $\nu = 1$.

In the first case ($\varphi_T = \bar{\chi}_T$, $T = \bar{T}_*$) our estimate is rather straightforward. Note that the norm of $\bar{\mathcal{G}}_n^{\pm}$ in the strip $\{t\colon |t| \le T\}$ does not exceed $h^{-1}T$ and the norm of $[\mathcal{B}_n, x_2 - y_2]$ does not exceed $C\mu^{-1}h$. Then the factor $(x_2 - y_2)$ translates into an extra factor $C\mu^{-1}h^{-1}T^2$ in the norm estimate. For $T = \bar{T}_*$ this factor is $C\mu^{-1}h\varepsilon^{-2} = C|\log h|^{-1}$ and in the general case it will be $C|\log h|^{-1}T^2/\bar{T}_*^2$.

Further, we can assume that

(18.5.11) The operator norm of $\mathcal{R}_n$ does not exceed $C\bigl(\vartheta(\varepsilon) + \varepsilon^2\bigr)$.

Indeed, we always can make $\partial_{x_2} W$ vanish at some point of $\mathsf{supp}(q_{(\iota)})$ by an appropriate Fourier integral operator corresponding to some linear symplectomorphism at (x_2, ξ_2)-plane.

Then in this case expression (18.5.10) does not exceed $C\mu\varepsilon^{-1}\bigl(\vartheta(\varepsilon) + \varepsilon^2\bigr)$; recall that for U^0 it was just $C\mu$.

In the second case ($\varphi_T = \chi_T$, $T \ge \bar{T}_*$) we, using the standard rescaling arguments, gain an extra factor $(\bar{T}_*/T)^s$ with arbitrarily large exponent s which takes care of all $(T/\bar{T}_*)^k$ factors and summation with respect to partition of unity with respect to t. Now we can conclude that expression (18.5.10) does not exceed $C\mu\varepsilon^{-1}\bigl(\vartheta(\varepsilon) + \varepsilon^2\bigr)$ for $\varphi = \bar{\chi}$, $T = T_*$.

Then applying arguments we used to estimate the total contribution of our "special" elements $q_{(\iota)}$ to (18.4.28), we see that

(18.5.12) The total contribution of these "special" elements $q_{(\iota)}$ to (18.4.28) with U replaced by U^1 does not exceed $Ch^{-2}\vartheta(\varepsilon) + Ch^{-2}\varepsilon^2$

what is exactly what we expect mollification error would be as $(I, \sigma) \preceq (2, 0)$.

To deal with the case $(I, \sigma) \succ (2, 0)$ we note that due to the propagation speed $O(\mu^{-1})$ we can estimate $(x_2 - y_2)$ by $C\mu^{-1}T$ and as effectively T is estimated by $\bar{T}_*$ we conclude that we can assume that

(18.5.13) As $(I, \sigma) \succ (2, 0)$ the operator norm of $\mathcal{R}_n$ does not exceed $C\varepsilon'^2$ with $\varepsilon' := C\mu^{-1}h/\varepsilon$

and replace (18.5.12) by

(18.5.14) As $(I, \sigma) \succeq (2, 0)$ the total contribution of these "special" elements $q_{(\iota)}$ to (18.4.28) with U replaced by U^1 does not exceed $Ch^{-2}\varepsilon'^2 = O(\mu^{-1}h^{-1})$.

Now let us consider contribution of U^0. One can see easily that it is exactly equal to the left-hand expression of

$$\Gamma'\Big(\theta\big(\tau-\mathcal{A}_n(y_2,\mu^{-1}hD_{x_2})\big)K_{(\iota)}\Big)= (2\pi)^{-1}\mu h^{-1}\iint \theta\big(\tau-\mathcal{A}_n(x_2,\xi_2)\big)k_{(\iota)}(x_2,\xi_2)\,dx_2d\xi_2 \tag{18.5.15}$$

where $K_{(\iota)}=\tilde{\psi}_n q^{\mathsf{w}}_{(\iota)}$, $k_{(\iota)}$ is its pq-symbol[27] and

$$\tilde{\psi}_n=\langle\tilde{\psi}\Upsilon_n,\Upsilon_n\rangle \tag{18.5.16}$$

where $\Upsilon_n=\Upsilon_n(x_1)$ and $\langle .,.\rangle$ is an inner product in $\mathscr{L}^2(\mathbb{R}_{x_1})$.

The problem is that pq-symbols are not invariant with respect to Fourier integral operators and the difference between pq- and Weyl symbols is not small because of $q_{(\iota)}$. However, there is a simple walk-around. Cover our total (x_2,ξ_2)-domain by two, with $\partial_{\xi_2}W$ and $\partial_{x_2}W$ disjoint from 0 respectively. We consider the first domain; the second case will be reduced to the first one easily, by means of $\mu^{-1}h$-Fourier transform.

We can consider partition of unity (depending on n) $q'_{(\iota_1)}(x_2)q'_{(\iota_2)}(\xi_2)$ such that for each ι_1 (and each n) there is no more than one number ι_2 such that condition (18.4.20) holds on $\mathsf{supp}(q'_{(\iota_1)})\times\mathsf{supp}(q''_{(\iota_2)})$. Then all the contributions of all other elements do not depend on this Fourier integral operator and summing with respect to ι_2 we get just $q'_{(\iota_1)}(x_2)$.

But we can take the required linear symplectomorphism $(x_2,\xi_2)\mapsto(x_2,\xi_2-r_{(\iota_1)}x_2)$ and the corresponding Fourier integral operator will be just multiplication by $e^{-i\mu h^{-1}r_{(\iota)}x_2^2/2}$ which does not affect $q'_{(\iota_1)}(x_2)$. On the other hand, for $\tilde{\psi}$ the difference between different symbols does not exceed $C\mu^{-1}h$ and therefore without increasing our remainder estimate we can rewrite our final answer as

$$(2\pi)^{-1}\mu h^{-1}\sum_{n\ge 0}\iint \theta\big(\tau-\mathcal{A}_n(x_2,\xi_2)\big)\tilde{\psi}_n(x_2,\xi_2)\,dx_2d\xi_2. \tag{18.5.17}$$

Recall that so far $\mu\le(h|\log h|)^{-1}$ and assumption (18.2.15) was supposed to be fulfilled.

---

[27] Which means that $K=k(\overset{1}{x},\mu^{-1}\overset{2}{h}D_x)$.

Step I under Assumption (18.2.16)

If assumption (18.2.15) is not fulfilled we must observe that instead of claim (18.5.12) we now have that

(18.5.18) The total contribution of these "special" ν-elements $q_{(\iota)}$ to (18.4.28) with U replaced by U^1 does not exceed $Ch^{-2}\big(\vartheta(\varepsilon)+\varepsilon^2\big)\times\big(\nu^2+\mu h\big)$.

Really, in comparison with the case $\nu=1$, factor T_* (or $\bar T_*$) brings a factor ν^{-1}, and volume brings factor ν but the number of indices "n" is now $\asymp(\nu^2/(\mu h)+1)$ rather than $\asymp 1/(\mu h)$.

Further, claim (18.5.13) is preserved as factor ν in the propagation speed is compensated by factor ν^{-1} in $\bar T_*$ and therefore (18.5.14) should be replaced by

(18.5.19) As $(l,\sigma)\succeq(2,0)$ the total contribution of these "special" ν-elements $q_{(\iota)}$ to (18.4.28) with U replaced by U^1 does not exceed $Ch^{-2}\varepsilon'^2\times\big(\nu^2+\mu h\big)$.

Then we have an extra term

$$C\mu h^{-1}\big(\vartheta(\varepsilon)+\varepsilon'^2\big) \tag{18.5.20}$$

which after summation with respect to ν under assumption (18.2.16) simply acquires factor $|\log h|$; further, under assumption $(18.2.16)^+$ only ν of the same magnitude should be taken in account near each critical point and no logarithmic factor is acquired. Thus we arrive to

(18.5.21) Under assumption (18.2.16) the total contribution of these "special" elements $q_{(\iota)}$ to (18.4.28) with U replaced by U^1 does not exceed

$$C\big(h^{-2}\vartheta(\varepsilon)+\mu^{-1}h^{-1}\big)\big(1+\mu h|\log h|\big)\asymp C\big(h^{-2}\vartheta(\varepsilon)+\mu^{-1}h^{-1}\big)+C\big(\mu h^{-1}\vartheta(\varepsilon)+1\big)|\log\mu|$$

and

(18.5.22) Under assumption $(18.2.16)^+$ the total contribution of these "special" elements $q_{(\iota)}$ to (18.4.28) with U replaced by U^1 does not exceed $C\big(h^{-2}\vartheta(\varepsilon)+\mu^{-1}h^{-1}\big)$.

Sure, in our case $\mu\lesssim(h|\log h|)^{-1}$ these extra terms with logarithmic factor do not matter but they will be important otherwise.

Step II under Assumption (18.2.15)

To finish the proof of the main theorems we need to bring expression (18.5.17) with $\tau = 0$ to the more explicit form.

First of all, we need to use original (x_1, x_2)-coordinates rather than (x_2, ξ_2)-coordinates after reduction. The natural expression of the area form in (x_1, x_2)-coordinates is $\omega = \sqrt{g}\,dx_1 \wedge dx_2$ which can be considered as the area form on $\Sigma = \{p_1 = p_2 = 0\}$ such that $\omega \wedge dp_1 \wedge dp_2 = dx \wedge d\xi$.

Then after construction of Subsubsections 18.3.1.1 and 18.3.1.2 we have a symplectic map Φ which transforms Σ into $\Sigma_0 = \{x_1 = \xi_1 = 0\}$; let us denote $\Phi|_\Sigma$ by ϕ. Further, Φ transforms $g^{-\frac{1}{2}} dp_1 \wedge dp_2$ at points of Σ exactly into $-dx_1 \wedge d\xi_1$ at points of Σ_0. Therefore

$$\phi_* \omega = -dx_2 \wedge d\xi_2, \qquad \phi = \Phi|_\Sigma. \tag{18.5.23}$$

Consider next transformations of Subsection 18.3.1. If $V = 0$ then these transformations will preserve Σ_0 and be identical on it. In the general case one can check easily that these transformations transform point $(0, 0; x_2, \xi_2) \in \Sigma_0$ into

$$\begin{aligned}&\big(\zeta_1(x_2, \xi_2), \zeta_2(x_2, \xi_2); x_1 + \eta_1(x_2, \xi_2), x_2 + \eta_2(x_2, \xi_2)\big) \in \Sigma_0'\\ &\qquad \text{with } \ |\zeta_j| + |\nabla \zeta_j| \le C\mu^{-2},\ |\eta_j| + |\nabla \eta_j| \le C\mu^{-4} + C\varepsilon^l |\log \varepsilon|^{-\sigma}\end{aligned}$$

and therefore after projecting Σ_0' onto Σ_0: $(x_1, \xi_1; x_2, \xi_2) \mapsto (0, 0; x_2, \xi_2)$ we have $(1 + k) dx_2 \wedge d\xi_2$ with $k = 0$ unless $(l, \sigma) \succeq (2, 0)$ and μ is close to $h^{-\frac{1}{3}}$ and $k = \mu^{-4} k_1(x)$ in the latter case.

Therefore, instead of $-dx_2 \wedge d\xi_2$ in our formula we can use $(1+k)\sqrt{g}\,dx_1 dx_2$ and instead of $W(x_2, \xi_2, \rho_n)$ we can use $W_n := W(\phi(x_1, x_2), r_n)$.

Further, obviously one can find $w(x_1, x_2)$ of the same regularity as W such that $(2n+1)\mu h + W_n < 0$ if and only if $(2n+1)\mu h + w < 0$ and replace $W_n(x)$ by $w(x)$. One should not be very concerned with the difference between ψ and ψ_n because we are interested in the calculations when $\psi = 1$ and then $\psi_n = 1$ as well.

Anyway, one can prove easily that

$$\tilde{\psi}_n(x_2, \xi_2) = \psi \circ \phi^{-1} + \mu^{-2} \psi_n' + \mu^{-4} \psi_n''$$

where ψ_n', ψ_n'' are defined by (18.5.16) with $\tilde{\psi}$ replaced by ψ', ψ'' respectively, and with symbols ψ', ψ'' belonging to $\mathscr{F}^{l-1,\sigma}$, $\mathscr{F}^{l-2,\sigma}$ and not depending on

μ, h and one can take ψ_n'', ψ'' equal to 0 unless $(l,\sigma) \succeq (2,0)$ and μ is close to $h^{-\frac{1}{3}}$.

Then we get the final formula with the correction term

$$h^{-2}\mathcal{N}^{\mathsf{MW}}_{2,\mathsf{corr}} = \tag{18.5.24}$$
$$\frac{1}{2\pi}h^{-2}\int \sum_n \Big(\theta\big(-w-(2n+1)\mu h\big)-\theta\big(-\frac{V}{F}-(2n+1)\mu h\big)\Big)\mu h\cdot \psi(x)\,dx+$$
$$\mu^{-1}h^{-1}\int \sum_n \theta\big(-w-(2n+1)\mu h\big)(\psi_n'\circ\phi)\,dx+$$
$$\mu^{-3}h^{-1}\int \sum_n \theta\big(-w-(2n+1)\mu h\big)(\psi_n''\circ\phi + k)\,dx.$$

Consider the second term in (18.5.24). It is equal to

$$\mu^{-1}h^{-1}\int \Big(\mathsf{Tr}_1\big(\Pi_{-w}\psi'(x_1,x_2,\mu^{-1}hD_1,\xi_2)\big)\circ\phi\Big)\,dx \tag{18.5.25}$$

where Π_τ is the spectral projector in $\mathscr{L}^2(\mathbb{R})$ ($\mathbb{R}=\mathbb{R}_{x_1}$) for harmonic oscillator $\mu^2x_1^2+h^2D_1^2$ and Tr_1 is an operator trace in $\mathscr{L}^2(\mathbb{R})$, $\tau=-w$ is the spectral parameter.

One can apply Weyl formula to calculate this expression (18.5.25). The error will not exceed $C\mu^{-1}h^{-1}\times\big(1+\varepsilon^{l-2}|\log h|^{-\sigma}\big)$ where the last factor is the remainder estimate for Weyl formula for $\mathsf{Tr}_1\big(\Pi_{-w}\psi'(x_1,hD_1)\big)$ [28]. Therefore this error does not exceed desired $Ch^{-2}\big(\mu^{-1}h+\vartheta(\varepsilon)\big)=C\mu^{-1}h^{-1}+Ch^{-2}\vartheta(\varepsilon)$.

On the other hand, the Weyl answer (for the same term) is

$$\mu h^{-1}\iint \theta\big(-w-r^2\big)\psi'(x,\mu^{-1}r\cos\alpha,\mu^{-1}r\sin\alpha)\,rdrd\alpha; \tag{18.5.26}$$

plugging into (18.5.25) we get

$$h^{-2}\iiint \theta\big(-w-r^2\big)\psi'(x,\mu^{-1}r\cos\alpha,\mu^{-1}r\sin\alpha)\,rdrd\alpha dx. \tag{18.5.27}$$

Recall that

$$w-V=O\big(\vartheta(\mu^{-1})\big) \tag{18.5.28}$$

[28] Actually, C is the remainder estimate and $C\varepsilon^{l-2}|\log h|^{-\sigma}$ is an estimate for error in the calculations.

and then due to assumption (18.2.15) replacing w by V we make an error not exceeding $C\mu^{-2-l}|\log h|^{-\sigma}h^{-2}$; this expression does not exceed $Ch^{-2}\vartheta(\varepsilon)$ as $l \le 2$ and $C\mu^{-1}h^{-1}$ as $l > 2$; recall that $\mu \ge (h|\log h|)^{-\frac{1}{3}}$.

We can treat the third term in (18.5.24) in the same way. Therefore

(18.5.29) Without deterioration of the remainder estimate, the second and third terms in (18.5.24) can be rewritten as $K_1\mu^{-2}h^{-2}$ and $K_2\mu^{-4}h^{-2}$ respectively with some constants K_1, K_2.

We also claim that

(18.5.30) With an error not exceeding $C\mu^{-1}h^{-1} + Ch^{-2}\vartheta(\mu h)$ one can replace in the first term in (18.5.24) the Riemann sum by the corresponding integral.

Really, without any loss of the generality one can assume that $|\partial_{x_j}V| \ge \epsilon_0$ with either $j = 1$ or $j = 2$ and the same is true for w. Then the first part of the first term in (18.5.24) is equal to

$$h^{-2}\int \sum_n \mu h\theta\big(\tau - w - (2n+1)\mu h\big)(\partial_{x_j}w)(\partial_{x_j}w')^{-1}\psi(x)\,dx + \tag{18.5.31}$$

$$h^{-2}\mu h\int \sum_n \theta\big(\tau - w - (2n+1)\mu h\big)(\partial_{x_j}w)\big((\partial_{x_j}w)^{-1} - (\partial_{x_j}w')^{-1}\big)\psi(x)\,dx$$

where w' is μh-mollification of w. Note that $\big((\partial_{x_j}W_n)^{-1} - (\partial_{x_j}W')^{-1}\big)$ does not exceed $C(\mu h)^{l-1}|\log \mu h|^{-\sigma}$ and therefore passing in the corresponding term from the Riemann sum to the corresponding integral brings an error not exceeding $Ch^{-2}\times \mu h \times (\mu h)^{l-1}|\log \mu h|^{-\sigma}$. On the other hand, the first term in (18.5.31) is equal to

$$h^{-2}\int \sum_n \big(\tau - w - (2n+1)\mu h\big)_+\big(\partial_{x_j}(\partial_{x_j}w')^{-1}\psi(x)\big)\mu h\,dx$$

with $\big(\partial_{x_j}(\partial_{x_j}w')^{-1}\psi(x)\big)$ not exceeding $(\mu h)^{l-2}|\log \mu h|^{-\sigma}$ and passing from the Riemann sum to the corresponding integral brings an error not exceeding $Ch^{-2}\times(\mu h)^2\times(\mu h)^{l-2}|\log \mu h|^{-\sigma}$ for $(l,\sigma) \preceq (2,0)$; for $(l,\sigma) \succeq (2,0)$ we need to repeat this procedure one more time to recover the same estimate.

Thus, claim (18.5.30) has been proven and with an error not exceeding $C\bigl(\mu^{-1}h^{-1}+h^{-2}\vartheta(\mu h)\bigr)$ the first term in (18.5.24) is equal to

$$\frac{1}{4\pi}h^{-2}\int \bigl(w_- - V_-\bigr)\psi(x)\,dx = \frac{1}{4\pi}h^{-2}\int (V-w)\psi(x)\,dx$$

due to condition (18.2.27).

So we get that with the indicated error the correction term is

$$\frac{1}{4\pi}h^{-2}\int (V-w)\psi(x)\,dx + h^{-2}\bigl(K_1\mu^{-2}+K_2\mu^{-4}\bigr) \tag{18.5.32}$$

with V, K_1, K_2 not depending on μ^{-1} and w depending on it.

Comparing with the results for the weak magnetic field (see Section 18.2) when correction term is 0 [29] we see that expression (18.5.32) vanishes modulo $O\bigl(\mu^{-1}h^{-1}+\vartheta(\varepsilon)h^{-2}\bigr)$, with $\varepsilon = (\mu^{-1}h|\log h|)^{\frac12}$ and then (18.5.24) transforms into

$$h^{-2}\mathcal{N}_{2,\mathsf{corr}} \coloneqq \tag{18.5.33}$$
$$h^{-2}\int \sum_n \Bigl(\theta\bigl(\tau - W - (2n+1)\mu h\bigr) - \theta\bigl(\tau - V - (2n+1)\mu h\bigr)\Bigr)\mu h\cdot\psi(x)\,dx - \frac12 h^{-2}\int (V-W)\psi(x)\,dx$$

where we replaced notation w by W. Thus we arrive under assumption (18.2.15) to Proposition 18.5.1 below.

Step II under Assumption (18.2.16)

Note that up to (18.5.31) we have not used any non-degeneracy assumption. Next step is done on each ν-ball with $\nu \ge C_0\max\bigl((\mu h)^{\frac12}, \mu^{-1}\bigr)$ and then the factor ν^{-2} appears (in comparison with the calculations of the previous subsubsection) and it is compensated by factor ν^2 from the ball volume; summation over all balls brings either factor $\log\mu$ under assumption (18.2.16).

[29] Surely for $\mu \asymp (h|\log h|)^{-\frac13}$ we can take the same mollification but we also removed operator with A_0-bound not exceeding $\vartheta(\varepsilon)$ and one can see easily that it brings error not exceeding $Ch^{-2}\vartheta(\varepsilon)$.

However, the same factor $\log \mu$ or 1 appears under corresponding assumption in the remainder estimate as well and therefore without deterioration of the remainder we arrive to the same expression (18.5.33) for the correction term, arriving under assumption (18.2.16) to the following:

Proposition 18.5.1. *Let* $h^{-\frac{1}{3}} \lesssim \mu \lesssim (h|\log h|)^{-1}$ *and condition* (18.2.27) *be fulfilled. Then*

(i) Under non-degeneracy assumption (18.2.15) *Tauberian expression* (18.4.28) *equals*

$$h^{-2} \int \bigl(\mathcal{N}^{\mathsf{MW}}_{x}(0) + \mathcal{N}^{\mathsf{MW}}_{x,\mathsf{corr}}\bigr)\psi(x)\,dx \tag{18.5.34}$$

modulo $O\bigl(\mu^{-1}h^{-1} + h^{-2}\vartheta(\varepsilon)\bigr)$ *with* $h^{-2}\mathcal{N}^{\mathsf{MW}}_{x,\mathsf{corr}}$ *defined according to* (18.5.33).

(ii) Under non-degeneracy assumption (18.2.16) *Tauberian expression* (18.4.28) *equals* (18.2.34) *modulo* $O\bigl(\mu^{-1}h^{-1} + h^{-2}\vartheta(\varepsilon)|\log h|\bigr)$.

Calculations: $\mu \gtrsim h^{-1}|\log h|^{-1}$

In this case calculations are easy. We just should remember that as $\mu \gtrsim h^{-1}$ the correction $h^2 W'$ with W' defined by (18.5.42)–(18.5.43) below to potential.

Comparisons

We need to compare $\int \tilde{\mathcal{N}}^{\mathsf{MW}}(x,\tau)\psi(x)\,dx$ with $\int \mathcal{N}^{\mathsf{MW}}(x,\tau)\psi(x)\,dx$:

Proposition 18.5.2. *(i) Under non-degeneracy assumptions* (18.2.15) *or* $(18.2.16)^{+}$ *as* $\mu \lesssim h^{-1}$ *and* $(18.2.15)^{*}$ *or* $(18.2.16)^{*+}$ *as* $\mu \gtrsim h^{-1}$

$$h^{-2}\Bigl|\int \Bigl(\tilde{\mathcal{N}}^{\mathsf{MW}}(x,\tau) - \mathcal{N}^{\mathsf{MW}}(x,\tau)\Bigr)\psi(x)\,dx\Bigr| \le C(1+\mu h)h^{-2}\vartheta(\varepsilon) \tag{18.5.35}$$

for $|\tau| \le \epsilon$.

(ii) Under non-degeneracy assumptions (18.2.16) *as* $\mu \lesssim h^{-1}$ *and* $(18.2.16)^{*}$ *as* $\mu \gtrsim h^{-1}$

$$h^{-2}\Bigl|\int \Bigl(\tilde{\mathcal{N}}^{\mathsf{MW}}(x,\tau) - \mathcal{N}^{\mathsf{MW}}(x,\tau)\Bigr)\psi(x)\,dx\Bigr| \le C(1+\mu h)h^{-2}\vartheta(\varepsilon)|\log \varepsilon| \tag{18.5.36}$$

for $|\tau| \le \epsilon$.

Proof. Without any loss of the generality we can assume that $F = 1$.

(a) Assume first that $\vartheta(\varepsilon) \le \epsilon\mu h$ and either assumption (18.2.15) or assumption $(18.2.16)^+$ is fulfilled.

Let us introduce γ-admissible partition of unity with $\gamma = \epsilon\vartheta(\varepsilon)$. If $|V + (2j+1)\mu hF - \tau| \ge C\gamma$ for all $j \in \mathbb{Z}^+$ on some element of the partition, then on this element $\tilde{\mathcal{N}}^{\mathsf{MW}}(x,\tau)$ and $\mathcal{N}^{\mathsf{MW}}(x,\tau)$ coincide while on all other elements their difference does not exceed $C\mu h^{-1}$. However, due to (18.2.15) or $(18.2.15)^*$ the total area of the latter elements does not exceed $C\gamma(1+\mu^{-1}h^{-1})$ which yields the necessary estimate.

(b) Assume now that $\vartheta(\varepsilon) \ge \epsilon\mu h$ and assumption (18.2.15) is fulfilled. Then $\theta\big(\tau - V - (2n+1)\mu h\big)$ and $\theta\big(\tau - \tilde{V} - (2n+1)\mu h\big)$ differ for each x for no more than $C_0\vartheta(\varepsilon)/\mu h + 1$ number of indices "n" which yields the necessary estimate.

The similar analysis under one of the assumptions (18.2.16)–$(18.2.16)^{*+}$ we leave to the reader. □

We also need to compare W and V/F as $\mu \lesssim (h|\log h|)^{-1}$ (i.e. as $\mu^{-1} \gtrsim \varepsilon$). One can see easily that it is $O\big(\vartheta(\mu^{-1}) + \mu^{-2}\big)$ and we arrive to the following:

Proposition 18.5.3. *Let* $\mu \lesssim (h|\log h|)^{-1}$. *Then*

(i) Under assumption (18.2.15) *or* $(18.2.16)^+$

$$|\mathcal{N}^{\mathsf{MW}}_{2,\mathsf{corr}}| \le C \begin{cases} \vartheta(\mu h) & \text{as } \ \mu \le h^{-\frac12}, \\ \vartheta(\mu^{-1}) & \text{as } \ \mu \ge h^{-\frac12},\ (l,\sigma) \preceq (2,0), \\ \mu^{-4}h^{-2}\vartheta(\mu h) & \text{as } \ \mu \ge h^{-\frac12},\ (l,\sigma) \succ (2,0). \end{cases} \tag{18.5.37}$$

In particular, $h^{-2}\mathcal{N}^{\mathsf{MW}}_{2,\mathsf{corr}} = O(\mu^{-1}h^{-1})$ *for sure as* $(l,\sigma) \succeq (3,0)$.

(ii) Under assumption (18.2.16)

$$|\mathcal{N}^{\mathsf{MW}}_{2,\mathsf{corr}}| \le C|\log h| \begin{cases} \vartheta(\mu h) & \text{as } \ \mu \le h^{-\frac12}, \\ \vartheta(\mu^{-1}) & \text{as } \ \mu \ge h^{-\frac12},\ (l,\sigma) \preceq (2,0), \\ \mu^{-4}h^{-2}\vartheta(\mu h) & \text{as } \ \mu \ge h^{-\frac12},\ (l,\sigma) \succ (2,0). \end{cases} \tag{18.5.38}$$

In particular, $h^{-2}\mathcal{N}^{\mathsf{MW}}_{2,\mathsf{corr}} = O(\mu^{-1}h^{-1})$ *for sure as* $(I,\sigma) \succeq (3,1)$.

Proof. An easy proof is left to the reader; as $(I,\sigma) \succ (2,0)$ we need to take into account some extra correction terms of the type $K\mu^{-2}h^{-2}$ because then $W - V/F = k\mu^{-2} + O\big(\vartheta\mu^{-1})\big)$. □

18.5.2 Main Theorems

Now, assembling results of this section we arrive to our main

Theorem 18.5.4. *Let* $d = 2$ *and* A *be a self-adjoint in* $\mathscr{L}^2(X)$ *Schrödinger operator defined by* (18.1.1).

Let $g^{jk}, F, \psi \in \mathscr{C}^{\bar{I},\bar{\sigma}}$, $V \in \mathscr{C}^{I,\sigma}$ *with* $(\bar{I},\bar{\sigma}) \succeq (2,0)$, $(\bar{I},\bar{\sigma}) \succeq (I,\sigma) \succeq (1,2)$ *and let conditions* (18.1.6) *and* (18.2.27) *be fulfilled in* $B(0,1) \subset X \subset \mathbb{R}^2$.

Let $(h|\log h|)^{-\frac{1}{3}} \le \mu \le Ch^{-1}$. *Then there are two framing approximations* $\tilde{A} = \tilde{A}^{\pm}$ *as in footnote*[18)] *such that for each of them*

(i) Under assumption (18.2.15) *estimate*

$$\mathsf{R}^{\mathsf{MW}}_{*} := \Big|\int \Big(\tilde{e}(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{MW}}_{2,x}(0) - h^{-2}\mathcal{N}^{\mathsf{MW}}_{2,x\,\mathsf{corr}}(0)\Big)\psi(x)\,dx\Big| \le C\mu^{-1}h^{-1} + C\vartheta(\varepsilon)h^{-2} \tag{18.5.39}$$

holds with the standard magnetic Weyl expression $h^{-2}\mathcal{N}^{\mathsf{MW}}_{2,x}(\tau)$ *and with the correction term* $h^{-2}\mathcal{N}^{\mathsf{MW}}_{2,x\,\mathsf{corr}}(\tau)$ *defined by* (18.5.31) *with the appropriate corrected potential* $W = V/F + O\big(\vartheta(\mu^{-1}) + \mu^{-2}\big)$; *here and below* $\varepsilon = (\mu^{-1}h|\log h|)^{\frac{1}{2}}$.

(ii) Let $(I,\sigma) \succeq (2,0)$; *then under assumption* $(18.2.16)^{+}$ *the same estimate* (18.5.39) *holds.*

(iii) Let $(I,\sigma) \succeq (2,0)$; *then under assumption* (18.2.16)

$$\mathsf{R}^{\mathsf{MW}}_{*} \le C\mu^{-1}h^{-1} + C\vartheta(\varepsilon)h^{-2}|\log h| + C|\log h|. \tag{18.5.40}$$

Remark 18.5.5. Recall that the correction term has been estimated in Proposition 18.5.3. In particular, it implies estimates for R^{MW} without the correction term.

Problem 18.5.6. Either improve estimates (18.5.37), (18.5.38) of Proposition 18.5.3 or construct counter-examples showing that the improvement is impossible.

Theorem 18.5.7. *Let* $d = 2$ *and* A *be a self-adjoint in* $\mathscr{L}^2(X)$ *Schrödinger-Pauli operator defined by* (18.1.29).

Let $g^{jk}, F, \psi \in \mathscr{C}^{\bar{l},\bar{\sigma}}$, $V \in \mathscr{C}^{l,\sigma}$ *with* $(\bar{l},\bar{\sigma}) \succeq (2,0)$, $(\bar{l},\bar{\sigma}) \succeq (l,\sigma) \succeq (1,1)$ *and condition* (18.1.6) *be fulfilled in* $B(0,1) \subset X \subset \mathbb{R}^2$.

Then there are two framing approximations $\tilde{A} = \tilde{A}^{\pm}$ *as in footnote*[18] *such that for each of them*

(i) Under assumption $(18.2.15)^*$ *estimate*

$$\mathsf{R}_*^{\mathsf{MW}} \le C + C\vartheta(\varepsilon)\mu h^{-1} + C\bar{\vartheta}(\varepsilon)\mu^2 \tag{18.5.41}$$

holds with the correction term $h^{-2}\mathcal{N}^{\mathsf{MW}}_{2,x\,\mathsf{corr}}$ *defined again by* (18.5.24)[30].

(ii) Let $(l,\sigma) \succeq (2,0)$*; then under assumption* $(18.2.16)^{*+}$ *the same estimate* (18.5.40) *holds.*

(iii) Let $(l,\sigma) \succeq (2,0)$*; then under assumption* $(18.2.16)^*$

$$\mathsf{R}_*^{\mathsf{MW}} \le C\bigl(1 + \vartheta(\varepsilon)\mu h^{-1} + \bar{\vartheta}(\varepsilon)\mu^2\bigr)\,|\log \mu|. \tag{18.5.44}$$

(iv) Finally, under assumption (18.4.35) *estimate*

$$|\tilde{e}(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{MW}}_{2,x}(x,0)| \le C_s\mu^{-s} \qquad \text{for } x \in B(0,\frac{1}{2}) \tag{18.5.45}$$

holds.

---

[30] However, now $W = V + W'h^2$ with

$$W' = -\frac{1}{12}\kappa(\mathfrak{z}^2 + 2) + F^{\frac12}\sum_{j,k}\partial_j\bigl(g^{jk}\partial_k F^{-\frac12}\bigr) \tag{18.5.42}$$

and κ a curvature associated with metrics $g^{jk}F^{-1}$ (and this correction is not due to the lack of the smoothness);

$$g^{jk}F^{-1} = \alpha^2\delta_{jk} \implies \kappa = 2\Delta\log\alpha. \tag{18.5.43}$$

Further, the sum in the definition contains only a finite number of terms.

We leave to the reader an easy

Problem 18.5.8. Investigate conditions to the regularity (i.e. to (l,σ) and $(\bar{l},\bar{\sigma})$) depending on μ, h and reversely conditions to μ, h depending on the regularity required to have the same results as in the smooth case.

18.5.3 Generalizations

Vanishing V

We want to get rid of assumption (18.2.27) $V \le -\epsilon_0$. We need to deal only with the case $\mu \le \epsilon_1 h^{-1}$. We should use the same rescaling arguments as in Subsection 13.8.1 but we need to take care of ε.

Let us introduce admissible scaling functions $\gamma(x) = \epsilon|V(x)|$ and $\rho(x) = \gamma(x)^{\frac12}$. Then rescaling ball $B\big(x,\gamma(x)\big)$ to $B(0,1)$ and dividing operator by ρ^2 we find ourselves again in our settings but with h, μ replaced by $h_{\mathsf{new}} = h/\rho\gamma$, $\mu_{\mathsf{new}} = \mu\gamma/\rho$ respectively. However, we need a cut-off: in fact $\gamma(x) = \epsilon|V(x)| + \bar{\gamma}_0$ with an appropriate parameter $\bar{\gamma}_0$. Modifications in some cases are needed.

Consider first the case of Theorem 18.5.4 when $\bar{\mu}_1 = \big(h|\log h|\big)^{-\frac13} \le \mu \le h^{-1}$. Then as $\mu_{\mathsf{new}} h_{\mathsf{new}} = \mu h/\rho^2 = \mu h/\gamma$ and since we do not need assumption (18.2.27) as $\mu_{\mathsf{new}} h_{\mathsf{new}} \gtrsim 1$ we will cut of γ by picking up $\bar{\gamma}_0 = \mu h$.

Plugging μ_{new}, γ_{new} and corresponding mollification parameter

$$\varepsilon_{\mathsf{new}} = \big(\mu_{\mathsf{new}}^{-1} h_{\mathsf{new}}|\log h_{\mathsf{new}}|\big)^{\frac12} = (\mu^{-1}h)^{\frac12}\gamma^{-1}|\log(h/\gamma^{\frac32})|$$

to the remainder estimate (18.5.39) we see that the contribution of each partition element to the remainder does not exceed

$$C\mu^{-1}h^{-1}\gamma + C(\mu^{-1}h)^{\frac{l}{2}}|\log(h/\gamma^{\frac32})|^{\frac{l}{2}-\sigma}h^{-2}\gamma^{3-l}$$

and the total remainder estimate will be then due to assumption (18.2.15)

$$C\int \mu^{-1}h\gamma^{-1}\,d\gamma + C(\mu^{-1}h)^{\frac{l}{2}}\int |\log(h/\gamma^{\frac32})|^{\frac{l}{2}-\sigma}h^{-2}\gamma^{3-l}\,d\gamma.$$

The second integral is equal to the second term in the right-hand expression of (18.5.39) for $l < 2$; to handle the case $l = 2$ we need to notice that the second term in (18.5.39) is due to mollification error only but in the rescaled coordinates mollification parameter is $\varepsilon_{\mathsf{new}}$ which in the original

coordinates becomes $\varepsilon_{\mathsf{new}}\gamma = (\mu^{-1}h)^{\frac{1}{2}}|\log(h/\gamma^{\frac{3}{2}})| \le (\mu^{-1}h|\log h|)^{\frac{1}{2}}$ and thus mollification error does not exceed the second term in (18.5.39) anyway. Therefore

(18.5.46) Theorem 18.5.4(i) without condition (18.2.27) remains true with the remainder estimate $C\mu^{-1}h^{-1}|\log(\mu h)| + R_2$ where R_2 is the second term in the right-hand expression in (18.5.39).

The analysis of the case of Theorem 18.2.9 is even simpler: one need to pick $\bar{\gamma}_0 = \mu^{-2}$; then on each element after rescaling either condition (18.2.27) is fulfilled or $\gamma \asymp \bar{\gamma}_0$ and $\mu_{\mathsf{new}} \asymp 1$ and condition (18.2.27) is not needed while $h_{\mathsf{new}} \asymp \mu^3 h \le 1$.

Note that in this case $\varepsilon_{\mathsf{new}} = \mu_{\mathsf{new}}h_{\mathsf{new}}|\log h| = \mu h\gamma^{-1}|\log(h/\gamma^{\frac{3}{2}})|$ and after rescaling to original coordinates it is $\varepsilon_{\mathsf{new}}\gamma \le \mu h|\log h|$.

Then one can prove easily that

(18.5.47) Theorem 18.2.9(i) without condition (18.2.27) remains true with the remainder estimate $C\mu^{-1}h^{-1}|\log(\mu h)| + R_1$ where R_1 is the second term in the right-hand expression in (18.2.35).

Actually one can get rid of this logarithmic factor considering propagation of singularities which is going in direction orthogonal to ∇V with the speed $\asymp \mu^{-1}$. Details in the smooth case can be found in Subsection 13.8.1.

Thus we can replace $T^* = \epsilon\mu$ by $T^* = \epsilon\mu \min\bigl(|\log\gamma|, |\log(\gamma/\bar{\gamma}_0|\bigr)^{\alpha}$ in the Tauberian theorem provided $(1,\alpha) \preceq (I,\sigma)$. Also, one can calculate "the second term" and to prove that it vanishes.

After summation we get an extra term in the remainder estimate

$$C\mu^{-1}h^{-1}\int \gamma^{-1}\Bigl(|\log\gamma|^{-\sigma} + |\log(\gamma/\bar{\gamma}_0|^{-\sigma}\Bigr)\,dx \asymp C\mu^{-1}h^{-1}.$$

Therefore

(18.5.48) Theorems 18.5.4(i) and 18.2.9(i) remain true without assumption (18.2.27).

Combining with the other statements of Theorems 18.5.4 and 18.2.9 we conclude that these theorems remain true under assumption (18.2.27) replaced by

$$|V| + |\nabla V| \ge \epsilon_0. \tag{18.5.49}$$

This conclusion enables us to run rescaling again but now with the scaling function $\gamma = \epsilon\big(|V| + |\nabla V|^2\big)^{\frac{1}{2}}$ and $\rho \asymp \gamma$; then $\mu^{-1}_{\mathsf{new}} h^{-1}_{\mathsf{new}} \asymp \mu^{-1}h^{-1}\gamma^2$. Then in the framework of Theorem 18.5.4 $\varepsilon_{\mathsf{new}} = \big(\mu^{-1}h|\log(h/\gamma^2)|\big)^{\frac{1}{2}}\gamma^{-1}$, which in the original coordinates is $\varepsilon_{\mathsf{new}}\gamma \lesssim \big(\mu^{-1}h|\log h|\big)^{\frac{1}{2}}$ again.

Meanwhile in the framework of Theorem 18.2.9 $\varepsilon_{\mathsf{new}} = \mu h|\log(h/\gamma^2)|\gamma^{-2}$ and a mollification error term in the virtue of assumption (18.2.16) is

$$Ch^{-2}\int \gamma^4\big(\mu h|\log(h/\gamma^2)|\big)^l\gamma^{-2l}|\log\big(\mu h|\log(h/\gamma^2)|\big)|^{-\sigma}\,\gamma^{-1}d\gamma$$

which as one can see easily resets to the value of such term in Theorem 18.2.9. Therefore

Theorem 18.5.9. *Theorems 18.5.4 and 18.2.9 hold without assumption* (18.2.27).

Other Generalizations

We leave to the reader an easy parts (i) of the Problems 18.5.10 –18.5.12 below; on the contrary, parts (ii) look rather challenging.

Problem 18.5.10. To get rid of condition (18.1.6) (while (18.2.27) holds) under assumption

$$|\nabla(F/V)| \ge \epsilon. \tag{18.5.50}$$

(i) Use the rescaling method and recover remainder estimate $O(h^{-1})$ as $\mu \lesssim h^{-2}$.

(ii) Generalize results of *Chapter 14.* 2D-*Schrödinger Operator with the Strong Degenerating Magnetic Field* to the non-smooth case.

Problem 18.5.11. To get rid of condition $B(0,1) \subset X$.

(i) Use the rescaling method and recover remainder estimate $O(h^{-1})$ as $\mu \lesssim h^{-2}$.

(ii) Generalize results of *Chapter 15.* 2D-*Schrödinger Operator with the Strong Magnetic Field near the Boundary* to the non-smooth case.

Problem 18.5.12. (i) Generalize our results to the generalized Schrödinger-Pauli operator (17.1.6).

(ii) Generalize our results to the generalized Dirac operator (17.1.1).

Remark 18.5.13. (i) One could think about generalizing *Chapter 16. agnetic Schrödinger Operator: Short Loops, Pointwise Spectral Asymptotics and Asymptotics of Dirac Energy* to the non-smooth case but as we do not have monotonicity of $e(x,x,\tau)$ with respect to operator it does not make much sense as we need to deal with the framing approximations.

(ii) Sure, we do not have such monotonicity of $\int e(x,x,\tau)\psi(x)\,dx$ either but this kind of expressions are building blocks for $\mathsf{N}(\tau) = \int e(x,x,\tau)\,dx$.

18.6 $d = 3$: Weak Magnetic Field

In this section we consider the case

$$\mu \le \bar{\mu}_1 := C(h|\log h|)^{-\frac{1}{3}}. \tag{18.6.1}$$

In the smooth case then one needs to reduce operator to canonical form only to analyze relatively long (comparing with $\epsilon_0\mu^{-1}$) propagation of singularities but not to calculate asymptotics. The same situation preserves in non-smooth case and to recover sharp asymptotics one needs neither non-degeneracy nor extra smoothness. This is the same threshold (18.2.6) as in Section 18.2 for $d = 2$ despite completely different mechanism; in some sense this is just coincidence.

18.6.1 Preliminary Remarks

We consider the microlocally mollified Schrödinger operator in the strong magnetic field given by expression (18.1.1) with the symmetric positive matrix (g^{jk}), real-valued V_j, V and small parameters h, ε and large parameter μ. We assume that the corresponding magnetic field $\boldsymbol{F} = (F^1, F^2, F^3)$ with

$$F^l(x) := \frac{1}{2}\sum_{jk} \epsilon^{lkj} F_{kj}, \qquad F_{kj} := (\partial_{x_j} V_k - \partial_{x_k} V_j)$$

does not vanish in $B(0,1)$; then we can straighten it and direct along x_3 by an appropriate change of variables and make $V_3 = 0$ by an appropriate gauge

transformation. We assume that this has been done and impose smoothness conditions to the reduced operator.

Namely we assume that for this reduced operator conditions (18.1.3), (18.1.6) hold and

$$g^{jk}, V, F^3 \in \mathscr{F}^{1,\sigma}(B(0,1)), \qquad F^1 = F^2 = 0. \tag{18.6.2}$$

We start from the case (further restrictions to follow)

$$\varepsilon \geq Ch|\log h|, \quad \mu \leq C^{-1}h|\log h|^{-1}. \tag{18.6.3}$$

Then

$$h^{-1}[A, x_j] = \sum_k \bigl(g^{jk}P_k + P_k g^{jk}\bigr) \tag{18.6.4$_1$}$$

$$h^{-1}[A, P_3] = h^{-1}\sum_{j,k} P_j[g^{jk}, P_3]P_k + h^{-1}[V, P_3] \tag{18.6.4$_2$}$$

$$\mu^{-1}h^{-1}[A, P_j] = i(-1)^{j+1}F_{12}\sum_k (g^{53-j,k}P_k + P_k g^{3-j,k}) + \mu^{-1}h^{-1}\sum_{jk} P_j[g^{jk}, P_i]P_k + \mu^{-1}h^{-1}[V, P_i] \quad \text{for} \quad i = 1, 2 \tag{18.6.4$_3$}$$

have symbols of class $\mathscr{F}^{1,\sigma}$ in any domain $\{(x,\xi) : \ a(x,\xi) \leq c\mu^{-2}\}$ of bounded energy where

$$a(x,\xi) = a_0(x,\xi) + \mu^{-2}V, \quad a_0(x,\xi) = \sum_{j,k} g^{jk}p_j(x,\xi)p_k(x,\xi), \qquad p_j(x,\xi) \coloneqq (\xi_j - V_j). \tag{18.6.5}$$

To finish the preliminary remarks let us notice that the following statement holds

Proposition 18.6.1. *Let $f \in \mathscr{C}_0^\infty(\mathbb{R}^3)$, $f = 1$ in $B(0, C_0)$ with large enough constant C_0. Let $T \geq h^{1-\delta}$. Then under condition* (18.6.2) *with large enough constant $C = C_s$*

$$|F_{t\to h^{-1}\tau}\Bigl(1 - f\bigl(p_1(x,\xi), p_2(x,\xi), p_3(x,\xi)\bigr)\Bigr)^{\mathsf{w}}\chi_T(t)U| \leq Ch^s \qquad x, y \in B(0, \frac{1}{2}), \tau \leq c. \tag{18.6.6}$$

Proof. One can see easily that symbol $f\bigl(p_1(x,\xi), p_2(x,\xi), p_3(x,\xi)\bigr)$ is quantizable under condition (18.6.3) and the proof is rather obvious. We leave it to the reader. □

18.6.2 Heuristics

Let us consider operator (18.1.1) with the Euclidean metrics. Then for time $T(\xi_3) := \epsilon_0|\xi_3|$ the shift with respect to ξ_3 will be less than $\frac{1}{2}|\xi_3|$ and so ξ_3 will remain of the same magnitude and sign. Then the shift with respect to x_3 will be of magnitude $|\xi_3|T$ because ξ_3 is a speed of the propagation along x_3 and in order it to be observable we need logarithmic uncertainty principle

$$|\xi_3|T \cdot |\xi_3| \geq Ch|\log h| \tag{18.6.7}$$

because we need to use $|\xi_3|$-sized scale along ξ_3. This gives us the value T_* for which we can claim that $(\Gamma_x U)(t)$ is negligible for $|t| \in [T_*, T^*]$:

$$T_* = T_*(\xi_3) := Ch|\log h| \cdot |\xi_3|^{-2}. \tag{18.6.8}$$

Since we know $(\Gamma_x U)(t)$ for $|t| \leq \bar{T} := \epsilon\mu^{-1}$ due to condition (18.2.27) and rescaling, we would like to have these intervals overlap: $\bar{T} \geq T_*$ or, equivalently,

$$|\xi_3| \geq \bar{\rho}_1 := C(\mu h|\log h|)^{\frac{1}{2}} \tag{18.6.9}$$

exactly as in the smooth case in Section 13.4.

Then the contribution of the zone $\mathcal{Z}_1^c := \{(x,\xi) : \ |\xi_3| \geq \bar{\rho}_1\}$ to the remainder does not exceed

$$Ch^{-2} \int T^{*\,-1}(\xi_3)\, d\xi_3. \tag{18.6.10}$$

This integral diverges logarithmically at $\xi_3 = 0$ and is equal to $Ch^{-2}|\log \bar{\rho}_1|$; to improve remainder estimate to Ch^{-2} we will need to increase $T^*(\xi_3)$ to $T^*(\xi_3) := \epsilon|\xi_3| \cdot \big|\log|\xi_3|\big|^{\sigma'}$ with $\sigma' > 1$.

On the other hand, the contribution of the zone $\mathcal{Z}_1 := \{(x,\xi) : \ |\xi_3| \leq \bar{\rho}_1\}$ to the remainder does not exceed $Ch^{-2}\bar{T}^{-1}\bar{\rho}_1 = C\mu\bar{\rho}_1 h^{-2}$ and in order to keep it below Ch^{-2} we need to have $\mu\bar{\rho}_1 \leq C$ which is exactly condition (18.6.1).

But in this case zone $\mathcal{Z}_2 := \{(x,\xi) : \ |\xi_3| \leq \bar{\rho}_2 = C\mu^{-1}\}$ is covered by these latter arguments; therefore we can take $C\mu^{-1}$ as a critical value and replace (18.6.9) by a stronger restriction

$$|\xi_3| \geq \bar{\rho}_2 := C\mu^{-1}. \tag{18.6.11}$$

Condition (18.6.9) will be restored in Sections 18.7–18.9 where we analyze the case $\mu \geq C(h|\log h|)^{-\frac{1}{3}}$ and restriction (18.6.9) is stronger.

This analysis is basically "smoothness-independent". It allows us to apply weak magnetic field approach without any non-degeneracy assumptions.

18.6.3 Variable Parameter ε

So far we did not discuss the choice of ε; however, since the scale with respect to ξ_3 is $C|\xi_3|$ in the zone $\mathcal{Z}_2^c := \{(x,\xi) : |\xi_3| \ge \bar\rho_2\}$ the logarithmic uncertainty principle requires $\varepsilon \ge Ch|\log h| \cdot |\xi_3|^{-1}$. To reduce approximation error we pick up the smallest allowed ε there:

$$\varepsilon = Ch|\log h| \cdot |\xi_3|^{-1}. \tag{18.6.12}$$

Then

(18.6.13) The contribution of the zone $\mathcal{Z}_2^c$ to the approximation error does not exceed $Ch^{-3}\int \vartheta\big(\varepsilon(\xi_3)\big)\,d\xi_3$ which is $O(h^{-2})$ as $(l,\sigma) \succeq (1,2)$.

On the other hand, in the zone $\mathcal{Z}_2 := \{(x,\xi) : |\xi_3| \le \bar\rho_2\}$ the scale with respect to ξ_3 is $\asymp \bar\rho_2$ and the logarithmic uncertainty principle requires there $\varepsilon = \bar\varepsilon_2$ with

$$\bar\varepsilon_2 := Ch|\log h| \cdot \bar\rho_2^{-1} = C\mu h|\log h|. \tag{18.6.14}$$

Then the contribution of this zone to the approximation error will be $Ch^{-3}\bar\rho_2\vartheta(\bar\varepsilon_2)$ which is $O(h^{-2})$ as $(l,\sigma) \succeq (1,1)$.

However, if we tried to use $\varepsilon = \bar\varepsilon_2$ everywhere we would get an approximation error $Ch^{-3}\vartheta(\bar\varepsilon_2)$ which is not $O(h^{-2})$ unless stronger smoothness condition is satisfied: namely, to cover $\mu \asymp (h|\log h|)^{\frac13}$ we would need $(l,\sigma) \succeq (\frac32, 1)$.

Thus, for $d = 3$ we will need ε to be a function of ξ_3 and may be of x. We already met such situation in Section 4.6. We will pick ε to be a temperate function:

$$\rho|\nabla_\xi \varepsilon| + \gamma|\nabla_x \varepsilon| \le c\varepsilon \tag{18.6.15}$$

where (γ,ρ) is (x,ξ)-scale. In this case we introduce

$$\tilde A = \sum \psi_\alpha^* \tilde A_\alpha \psi_\alpha \tag{18.6.16}$$

where ψ_α are (γ,ρ)-admissible functions, $\psi_\alpha^*\psi_\alpha$ is a partition of unity and $\tilde A_\alpha$ are mollifications of A with $\varepsilon = \varepsilon_\alpha$ calculated at some points of the corresponding elements.

18.6.4 Rigorous Analysis

As we already mentioned we consider now the case of the weak magnetic field: $\mu \le \bar{\mu}_1 := (h|\log h|)^{-\frac{1}{3}}$ assuming that

$$l = 1, \quad \sigma > 1 \tag{18.6.17}$$

and we will not press very hard to reduce σ. Let us consider point $(\bar{x}, \bar{\xi})$ with

$$\rho := |\bar{\xi}_3| \ge \bar{\rho}_2 := C\mu^{-1}, \qquad \varepsilon = Ch\rho^{-1}|\log h|. \tag{18.6.18}$$

Recall that the second condition (to ε) means the logarithmic uncertainty principle; thus quantization is possible; we will take ε variable but depending on ξ_3 only.

Let us consider first a classical propagation starting from this point. Obviously $|d\xi_3/dt| \le C_0$ due to condition $(18.6.4)_3$ which implies that ξ_3 keeps it magnitude during time $|t| \le \epsilon_0\rho$ even in the general (not Euclidean) case but we need a bit better. Let us consider

$$\frac{d}{dt}\xi_3 = \{\mu^2 a(x,\xi), \xi_3\} = \beta(x,\xi)\xi_3 + \mu \sum_{j,k=1}^{2} \beta_{jk} p_j p_k - \partial_{x_3} V$$

with $\beta_* \in \mathscr{F}^{0,\sigma}$. In the smooth case we would be able to reduce the second term in the right-hand expression to the form $\beta'' a_0(x,\xi)$ by replacing ξ_3 by

$$\ell = \xi_3 + \sum_{j,k=1}^{2} \beta'_{jk} p_j p_k \tag{18.6.19}$$

with appropriate coefficients β'_* found from the linear algebraic system which we would get from equality

$$\{\mu^2 a(x,\xi), \ell(x,\xi)\} \equiv \beta'(x,\xi)\xi_3 + \mu\beta'' a_0(x,\xi) - \partial_{x_3} V \mod O\bigl(\mu^{-1}\bigr) \tag{18.6.20}$$

(since $|p_j| \le C\mu^{-1}$). However, in on our non-smooth case we replace β'_{jk} by their $h^{-\delta}$-mollifications with the small enough exponent $\delta > 0$; then we

would get the above equations (18.6.20) modulo $O(|\log\rho|^{-\sigma})$. Finally, one can find that $\mu^2\beta''=\partial_3 F$ and therefore

$$\{\mu^2 a(x,\xi),\ell(x,\xi)\}\equiv \beta'(x,\xi)\ell(x,\xi)+\mu^2 Fa(x,\xi)-F\partial_{x_3}(V/F) \mod O(|\log\varrho|^{-\sigma}). \tag{18.6.21}$$

Then in an appropriate time direction[31)] inequality $\pm\ell\ge\frac12\rho$ holds for $|t|\in[0,T^*]$ with

$$T^*=T^*(\rho)\coloneqq \epsilon\rho|\log\rho|^{\sigma}. \tag{18.6.22}$$

This additional logarithmic factor is a small but a crucial progress in comparison with $T^*(\rho)=\epsilon_0\varrho$ we had before.

Then using the following function with an appropriate sign ς in the standard (see Section 2.3) propagation arguments

$$\chi\Big(\pm\frac{1}{\rho}\big((\ell(x,\xi)-\ell(\bar x,\bar\xi)\big)+c\varsigma\frac{t}{T}\Big) \tag{18.6.23}$$

one can prove the similar statement on microlocal level (due to conditions (18.6.2), $(18.6.4)_{1-3}$, (18.6.17)–(18.6.18) all symbols will be quantizable):

Proposition 18.6.2. *Let conditions* (18.6.2), (18.6.3), (18.6.17)–(18.6.18) *be fulfilled.*

Let Q be h-pseudodifferential operator with the symbol supported in ρ-vicinity of $(\bar x,\bar\xi)$ with $|\bar\xi_3|=\rho\ge C\mu^{-1}$ and let Q' be h-pseudodifferential operator with the symbol equal to 1 in ρ'-vicinity of $(\bar x,\bar\xi)$ (with $\rho'=C\rho|\log\rho|^{\sigma}$), intersected with $\{|\xi_3|\ge\frac12\rho\}$.

Then $(I-Q')e^{-ih^{-1}At}Q$ is negligible for $\varsigma t\in[0,T^*]$ with $T^*=T^*(\rho)$ defined by (18.6.22) *and appropriate $\varsigma=\pm1$.*

Proof. The standard proof is left to the reader. □

This statement shows that for $\varsigma t\in[0,T^*]$ singularity of $e^{-ih^{-1}At}Q$ is confined to ρ'-vicinity of $(\bar x,\bar\xi)$ intersected with $\{|\xi_3|\ge\frac12\rho\}$.

Now let us consider classical propagation along x_3; then

$$dx_3/dt=\{\mu^2 a,x_3\}=2g^{33}\xi_3+\mu\sum_{j=1}^{2}2g^{3j}p_j.$$

[31)] That means for t of an appropriate sign; namely the sign of $-\xi_3\partial_{x_3}(V/F)$.

Replacing x_3 by

$$\phi = x_3 + \sum_{j=1}^{2} \alpha_j p_j \tag{18.6.24}$$

with appropriate coefficients α_j found from an appropriate linear algebraic system we would able in the smooth case get

$$\{\mu^2 a, \phi\} \equiv 2g^{33}\xi_3 \qquad \mathsf{mod}\ O(\mu^{-1}). \tag{18.6.25}$$

In the non-smooth case we do the same and no mollification is needed since $\alpha_j \in \mathscr{F}^{1,\sigma}$. So, the classical shift with respect to ϕ for time t with $\varsigma t \in [0, T^*]$ will be at least $\epsilon_0\rho t$ which is "observable" if $\epsilon_0\rho|t| \times \rho \geq Ch|\log h|$.

On the microlocal level using the same arguments of Section 2.3 with function

$$\chi\Big(\varsigma_1 \frac{1}{\rho T}\big(\phi(x,\xi) - \phi(y,\xi)\big) \pm c\frac{t}{T}\Big) \tag{18.6.26}$$

(which again is quantizable due to our conditions) with an appropriate sign $\varsigma_1 = \pm 1$ one can easily prove that for $\varsigma t \in [T_*, T^*]$,

$$T_* = C\rho^{-2}h|\log h| \tag{18.6.27}$$

and $\psi(x_3)$, supported in ϵ-vicinity of $\bar{x}_3$, $\psi(x_3)e^{-ih^{-1}At}Q\psi(x_3) \equiv 0$.

Then $\mathsf{Tr}\big(e^{-ih^{-1}At}Q\big) \equiv 0$. Furthermore this is true for $|t| \in [T_*, T^*]$ *with no restriction to the sign because of the trace*. Therefore we arrive

Proposition 18.6.3. *Let the above assumptions be fulfilled. Then for any* $T \in [T_*, T^*]$

$$F_{t\to h^{-1}\tau}\Big(\big(\bar{\chi}_{T^*}(t) - \bar{\chi}_T(t)\big)\Gamma(U\,{}^tQ_y)\Big) \equiv 0. \tag{18.6.28}$$

Proof. Again, the standard details are left to the reader. □

Recall that χ, $\bar{\chi}$ are admissible functions, supported in $[-1,1]$ and equal to $0,1$ respectively on $[-\frac{1}{2},\frac{1}{2}]$.

Then the same statement holds for $Q = \psi(x)\chi_\rho(hD_3)$ (we can sum with respect to the partition of unity in (x,ξ_1,ξ_2)). *From now on operator* Q *is given by this expression*.

On the other hand, from the standard theory rescaled we already know $F_{t\to h^{-1}\tau}\bigl(\bar\chi_{\bar T}(t)\Gamma(u\,{}^tQ_y)\bigr)$ with $\bar T = \epsilon_0\mu^{-1}$ and in order to combine these two results we need to have $T_* \ge \bar T$ which is equivalent to (18.6.9); this condition is wider than our current framework; right now we have $(\mu h|\log h|)^{\frac12} \lesssim \mu^{-1}$ which exactly means that $\mu \lesssim \bar\mu_1 = (h|\log h|)^{-\frac13}$.

Then from the standard theory rescaled we conclude that

$$|F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma(U\,{}^tQ_y)\bigr)| \le C\rho h^{-2} \tag{18.6.29}$$

for any $T \in [T_*, T^*]$. With this estimate the standard Tauberian arguments imply that

$$\mathsf{R}_Q^{\mathsf{T}} := |\Gamma(\tilde e\,{}^tQ_y)(\tau) - h^{-1}\int_{-\infty}^{\tau}\Bigl(F_{t\to h^{-1}\tau'}\bigl(\bar\chi_T(t)\Gamma(U\,{}^tQ_y)\bigr)\Bigr)\,d\tau'| \le C\rho h^{-2}T^{*-1} = Ch^{-2}|\log\rho|^{-\sigma}. \tag{18.6.30}$$

Let us sum with respect to partition on ξ_3 in the zone $\mathcal{Z}_2^{\mathsf{c}} = \{(x,\xi) : |\xi_3| \ge \bar\rho_2\}$. Then the right-hand expression of this estimate transforms into

$$Ch^{-2}\int_{\rho_2^*}^1 \rho^{-1}|\log\rho|^{-\sigma}\,d\rho$$

which does not exceed Ch^{-2} as long as $\sigma > 1$.

On the other hand, it follows from the standard theory rescaled that estimate (18.6.29) holds for $Q_\rho = \psi(x)\bar\chi_\rho(hD_3)$ and $T = \bar T = \epsilon\mu^{-1}$. Therefore for $\rho = \bar\rho_2$ and $\bar Q = Q_{\bar\rho_2}$ we have

$$\mathsf{R}_{\bar Q}^{\mathsf{T}} \le C\bar\rho_2 h^{-2}/\bar T = Ch^{-2}.$$

Combining this estimate with the result of the previous analysis we get the final inequality

$$\mathsf{R}_{\psi}^{\mathsf{T}} \le Ch^{-2}. \tag{18.6.31}$$

Further, from the standard theory rescaled we know $F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma(U\,{}^tQ_y)\bigr)$ for $T = \bar T$ and we get the final estimate[32)]

$$|\int\Bigl(\tilde e(x,x,\tau) - h^{-3}\tilde{\mathcal{N}}_{3,x}^{\mathsf{W}}(\tau)\Bigr)\psi(x)\,dx| \le Ch^{-2} \tag{18.6.32}$$

[32)] There should be also a term $C\mu^2h^{-1}$ in the right-hand expression but for $\mu \le h^{-\frac12}$ it is less than Ch^{-2}. We will discuss this expression with more details later.

where

$$h^{-3}\tilde{\mathcal{N}}^{\mathsf{W}}_{3,x}(\tau) = (2\pi)^{-3}\int \theta\big(\tau - \tilde{A}(x,\xi)\big)\,d\xi \tag{18.6.33}$$

and $\tilde{A}$ is a symbol of the mollified operator and this is h-pseudodifferential operator because we take ε depending on ξ_3 [33].

Now let us consider an approximation error in $h^{-3}\tilde{\mathcal{N}}^{\mathsf{W}}$. It does not exceed

$$Ch^{-3}\int \varepsilon(\rho)^{l}|\log\varepsilon(\rho)|^{-\sigma}\,d\rho \asymp Ch^{-2}|\log h|^{1-\sigma}\log\mu \tag{18.6.34}$$

which is $O(h^{-2})$ as $\sigma = 2$ [34].

This completes the proof of the following theorem:

Theorem 18.6.4. *Let $d = 3$ and A be a self-adjoint in $\mathscr{L}^2(X)$ Schrödinger operator* (18.1.1). *Let conditions* (18.1.3), (18.1.6), (18.2.27) *fulfilled in $B(0,1) \subset X \subset \mathbb{R}^3$. Let $(l,\sigma) \succeq (1,1)$.*

Let $\mu \le \bar{\mu}_1 = (h|\log h|)^{-\frac{1}{3}}$. Then for two framing approximations as in footnote [18] *estimate*

$$\mathsf{R}^{\mathsf{W}} := \Big|\int \Big(\tilde{e}(x,x,0) - h^{-3}\mathcal{N}^{\mathsf{W}}_{3,x}(0)\Big)\psi(x)\,dx\Big| \le Ch^{-2} + Ch^{-3}\vartheta(\mu h|\log h|) \tag{18.6.35}$$

holds with the standard Weyl expression

$$h^{-3}\mathcal{N}^{\mathsf{W}}_{3,x}(\tau) = \frac{1}{6\pi^2}h^{-3}\big(\tau - V(x)\big)^{\frac{3}{2}}_{+}\sqrt{g}.$$

In particular, $\mathsf{R}^{\mathsf{W}} = O(h^{-2})$ as $(l,\sigma) \succeq (1,2)$.

Recall that this theorem does not require any non-degeneracy assumption and as it is it cannot be improved significantly in the framework of the

[33] Which means that we take appropriate partition of unity, on each element take its own ε, mollify and then add. One can check easily that perturbation is small enough to preserve all our arguments.

[34] Exactly in this place we need to have variable $\varepsilon = \varepsilon(\rho)$ rather than to take its largest value $\varepsilon(\bar{\rho}_2) = C\mu h|\log h|$ which would require too restrictive smoothness conditions to get approximation error $O(h^{-2})$.

weak magnetic field approach without non-degeneracy assumptions even under improved smoothness assumptions. Later in Theorem 18.6.10 we will slightly improve this theorem with no additional assumptions (removing logarithmic factor)

In the rest of this chapter we are going to improve it under non-degeneracy assumption (18.2.15) or (18.2.16); it appears that extra smoothness will be required.

18.6.5 Outer Zone

First of all, for $\mu \le c^{-1}(h|\log h|)^{-1}$ one can apply exactly the same arguments as before[35] with

$$\rho := |\bar{\xi}_3| \ge \bar{\rho}_1 := C\big(\mu h|\log h|\big)^{\frac{1}{2}} \quad \text{and} \quad \varepsilon = Ch\rho^{-1}|\log h| \tag{18.6.36}$$

and get an estimate (18.6.30) for Q with symbol supported in $\mathcal{Z}_1^c$. Then to derive asymptotics of $\Gamma(\tilde{e}\,{}^tQ_y)$ (at this stage we include ψ in Q) we need to calculate the Tauberian expression

$$h^{-1}\int_{-\infty}^{\tau}\Big(F_{t\to h^{-1}\tau'}\big(\bar{\chi}_T(t)\Gamma(u\,{}^tQ_y)\big)\Big)\,d\tau' \tag{18.6.37}$$

with $T = \bar{T} = \epsilon_0\mu^{-1}$. Note that

(18.6.38) Under assumption (18.2.27) expression (18.6.37) with $T = \bar{T}$ equals modulo $O(h^s)$ to the same expression with $T = T_0 := Ch|\log h|$.

Really, let us break Q into few operators $Q_{(\iota)}$, with the symbols supported in ϵ-vicinity of points $(\bar{x}_{(\iota)}, \bar{\xi}_{(\iota)})$. Without any loss of the generality one can assume that $g^{jk} = \delta_{jk}$ at $\bar{x}_{(\iota)}$ [36]. Then if $|\bar{\xi}_{(\iota)j}| \ge \epsilon_0$ and $\epsilon > 0$ is small enough then both the propagation speed and scale with respect to x_j are disjoint from 0, $j = 1,2,3$ and we can apply arguments of Section 2.3.

Now, to calculate expression (18.6.37) with $T = T_0$ we can apply the method of successive approximations. However, it is not very convenient to take unperturbed operator in our standard way $\bar{A} = A(y, hD_x)$ because

[35] And we need $(\bar{l},\bar{\sigma}) \succeq (l,\sigma) \succeq (1,2)$ only.

[36] We can achieve it by a linear change of coordinates preserving direction of the magnetic field $\boldsymbol{F}$.

then one can estimate $(m+1)$-th term of (18.6.37) with the approximation plugged only by

$$h^{-3}|\log h|\big(\mu T_0^2 h^{-1}\big)^m \asymp h^{-3}|\log h|\big(\mu h|\log h|^2\big)^m$$

which is not good as μ close to $(h|\log h|)^{-1}$ even if we reduce powers of logarithms (which is not very difficult).

Instead we take unperturbed operator (18.1.27)–(18.1.28) exactly as in 2-dimensional case. Recall that without any loss of generality we assume $V_3 = 0$ and $V_j = V_j(x_1, x_2) \in \mathscr{F}^{2,2}$.

With this choice of an unperturbed operator one can estimate $(m+1)$-th term of (18.6.37) with the approximation plugged by

$$h^{-4} T_0\big(\mu T_0^3 h^{-1} + T_0^2 h^{-1}\big)^m \asymp h^{-3}|\log h| \cdot \big(h|\log h|^2\big)^m;$$

recall that $\mu \le C(h|\log h|)^{-1}$ and $T_0 \asymp Ch|\log h|$.

Using rescaling arguments one can prove rather easily that we can take effectively $T_0 \asymp h$ and thus to reduce the power of the logarithmic factors but it is not worth of our efforts now; we just notice that modulo $O(h^{-2})$ expression (18.6.37) is equal to the same expression with U replaced by $U^0 + u^1$ where U^0 and U^1 are first two terms of approximation:

$$U^0 = -ih \sum_{\varsigma=\pm} \varsigma \bar{\mathcal{G}}^{\varsigma} \delta(x-y)\delta(t), \tag{18.6.39}$$

$$U^1 = -ih \sum_{\varsigma=\pm} \varsigma \bar{\mathcal{G}}^{\varsigma} \mathcal{R} \bar{\mathcal{G}}^{\varsigma} \delta(x-y)\delta(t) \tag{18.6.40}$$

where $\bar{\mathcal{G}}^{\pm}$ are forward and backward parametrices respectively for $(hD_t - \bar{A})$ and $\mathcal{R} = A - \bar{A}$.

Now we want to get rid of the contribution of U^1 and only extra logarithmic factors in its estimate prevent us. Then we need just notice that due to the rescaling method the corresponding term in (18.6.37) with $\bar{\chi}_T$ replaced by χ_T with $T \ge T_0 := Ch^{-1}$ does not exceed $CTh^{-4} \times T^2 h^{-1} \times \big(T_0/T\big)^s$ with an arbitrarily large exponent s. Then the sum with respect to t-partition does not exceed Ch^{-2}.

On the other hand, this term calculated with $\bar{\chi}_T$ and $T = T_0$ does not exceed Ch^{-2} as well. Therefore the total contribution of U^1 to the final answer does not exceed Ch^{-2}.

Finally, let us calculate expression (18.6.37) with $U = U^0$. Without any loss of the generality one can assume that $g^{jk}(y) = \delta_{jk}$; we need later to get the answer in the invariant form. Then

$$U^0(x,y,t) = h^{-1}\iint e^{-ih^{-1}\left(-t(\xi_3^2+\tau'+V(y))+(x_3-y_3)\xi_3\right)}\, d\xi_3\, d_{\tau''}\bar{e}_y(x_1,x_2;y_1,y_2;\tau'') \tag{18.6.41}$$

where $\bar{e}_y(x_1,x_2;z_1,z_2;\tau)$ is the Schwartz kernel of the spectral projector of $\bar{P}_1^2+\bar{P}_2^2$ and "y" indicates the same point as in (18.1.27). Direct calculations of Chapter 13 show that

$$\bar{e}_y(x_1,x_2;y_1,y_2;\tau'') = \sum_{n\ge 0}\theta\big(\tau''-(2n+1)\mu hF(y)\big)F(y)\mu h^{-1} \tag{18.6.42}$$

and plugging into (18.6.41) we arrive to

$$\Gamma_y\big(U^0\,{}^tQ_y\big) = \int\sum_{n\ge 0} e^{ih^{-1}t\left(\xi_3^2+(2n+1)\mu hF(y)+V(y)\right)}\, q(\xi_3)\, d\xi_3 \times F(y)\mu h^{-2} \tag{18.6.43}$$

and consequently to

$$F_{t\to h^{-1}\tau'}\Big(\bar{\chi}_T(t)\Gamma(u\,{}^tQ_y)\Big) = \sum_{n\ge 0} T\int \widehat{\bar{\chi}}\Big(Th^{-1}\big(\tau'-(2n+1)F(y)\mu h - V(y)-\xi_3^2\big)\Big)\times q(\xi_3)\, d\xi_3 \times F(y)\mu h^{-2} \tag{18.6.44}$$

where $\widehat{\bar{\chi}}$ is a Fourier transform of $\bar{\chi}$ and modulo $O(h^{-2})$ expression (18.6.37) is finally equal to

$$h^{-3}\int \tilde{\mathcal{N}}_Q^{\mathsf{MW}}(x,\tau)\psi(x)\, dx \tag{18.6.45}$$

with

$$\tilde{\mathcal{N}}_Q^{\mathsf{MW}} := \sum_{n\ge 0}\int \theta\Big(\tau-(2n+1)F\mu h-\tilde{V}-\xi_3^2\Big)q(\xi_3)\, d\xi_3\times F\mu h. \tag{18.6.46}$$

One can check easily that $\varepsilon|\log h|^{-2}\le \rho^2$ for $\rho\ge\bar{\rho}_1$ and therefore the approximation error of $h^{-3}\tilde{\mathcal{N}}_Q^{\mathsf{MW}}$ does not exceed $C\int h^{-3}\varepsilon|\log h|^{-2}d\rho \le Ch^{-2}$ (recall that $(I,\sigma)\succeq(1,2)$). So we arrive to

Proposition 18.6.5. *Let* $(l,\sigma)\succeq(1,2)$ *and* $\bar\mu_1\le\mu\le c^{-1}(h|\log h|)^{-1}$. *Let* $Q=q(hD_3)$ *with* $q=1-\bar\chi_{\bar\rho_1}(\xi_3)$.

Then

$$|\int\Big(\Gamma_x(\tilde e\,{}^tQ_y)-h^{-3}\tilde{\mathcal N}_Q^{\mathsf{MW}}(x,\tau)\Big)\psi(x)\,dx|\le Ch^{-2} \tag{18.6.47}$$

with $\tilde{\mathcal N}_Q^{\mathsf{MW}}(x,\tau)$ *defined by* (18.6.46).

18.6.6 Analysis under Assumption (18.2.15)

Let us prove that under assumption (18.2.15) $\Gamma(U\psi\,{}^tQ_y)$ is negligible for $\bar T\le|t|\le\epsilon$ as

$$\varepsilon=C\mu h|\log h|\quad\text{in}\quad\mathcal Z_1 \tag{18.6.48}$$

and $Q=q(hD_3)$ with symbol supported in $\mathcal Z_1$. Recall that $\mathcal Z_1=\{(x,\xi):|\xi_3|\le\bar\rho_1\}$.

Proposition 18.6.6. *Let condition* (18.2.15) *be fulfilled,* $Q=q(hD_3)$ *with appropriate symbol* q *supported in* $\mathcal Z_1$. *Then*

$$|F_{t\to h^{-1}\tau}\big(\chi_T\Gamma u\psi\,{}^tQ_y\big)|\le Ch^s\qquad\forall\tau:|\tau|\le\epsilon \tag{18.6.49}$$

as $T\in[T_*,T^*]$ *where* χ *an admissible function supported in* $[-1,-\frac12]\cup[\frac12,1]$ *and here*

$$T_*=C\varepsilon^{-1}h|\log h|,\qquad T^*=\epsilon. \tag{18.6.50}$$

In particular, (18.6.49) *holds as* $T\in[\bar T,\epsilon]$ *with* $\bar T=\epsilon_0\mu^{-1}$ *for* ε *given by* (18.6.48).

We prove this proposition below, it implies

Corollary 18.6.7. *Under conditions* (18.2.15), (18.2.27) *and* (18.6.48)

$$|\int\Big(\tilde e(x,x,\tau)-\int_{-\infty}^{\tau}F_{t\to h^{-1}\tau'}\big(\bar\chi_{\bar T}u(x,x,t)\big)\Big)\psi(x)\,dx|\le Ch^{-2} \tag{18.6.51}$$

and

$$|\int\Big(\tilde e(x,x,\tau)-h^{-3}\tilde{\mathcal N}^{\mathsf{MW}}(x,\tau)\Big)\psi(x)\,dx|\le Ch^{-2}. \tag{18.6.52}$$

Remark 18.6.8. (i) Note that under assumption (18.2.15) and ε given by (18.6.48) the contribution of zone $\mathcal{Z}_1$ to the approximation error does not exceed

$$C(\mu h|\log h|)^{l+\frac12}|\log h|^{-\sigma}h^{-3} \tag{18.6.53}$$

which is in turn does not exceed Ch^{-2} as long as

$$\mu \le \mu^*_{(l,\sigma)} := Ch^{-(2l-1)/(2l+1)}|\log h|^{-1+2\sigma/(2l+1)} \tag{18.6.54}$$

while remainder estimate does not exceed Ch^{-2} anyway.

(ii) Note that $\mu^*_{(1,2)} = h^{-\frac13}|\log h|^{\frac13}$ and $\mu^*_{(l,\sigma)} \sim h^{-1+\delta}$ in the smooth case when l is large.

Proof of Proposition 18.6.6. We will use the canonical form reduction of the next Section 18.7.

Making ϵ_1-partition we can assume that on it $|\nabla V - \ell| \le \epsilon$ at each point with some fixed vector ℓ, $|\ell| \ge 4\epsilon$.

Let us consider first the case when $|\ell_\perp| \ge \frac12\epsilon$, $\ell_\perp = (\ell_1, \ell_2)$ and examine propagation of singularities with respect to (x_2, ξ_2) for the transformed operator.

To time T the shift with respect to x_2 will be $\asymp \epsilon|\ell_2|\mu^{-1}$ and the logarithmic uncertainty principle means that $\epsilon_2|\ell_2|\mu^{-1}T \times \varepsilon \ge C\mu^{-1}h|\log h|$ which for $|\ell_2| \ge \epsilon$ is equivalent to $T \ge T_*$ with T_* defined by (18.6.50).

Similarly, to time T the shift with respect to ξ_2 will be $\asymp \epsilon|\ell_1|\mu^{-1}$ and the logarithmic uncertainty principle means that $\epsilon_2|\ell_1|\mu^{-1}T \times \varepsilon \ge C\mu^{-1}h|\log h|$ which for $|\ell_1| \ge \varepsilon$ is equivalent to $T \ge T_*$ again.

We can justify this analysis by our standard propagation arguments with functions

$$\chi\bigl(\mu\frac{x_2 - y_2}{\ell_2 T} \pm \epsilon\frac{t}{T}\bigr), \qquad \chi\bigl(\mu\frac{\xi_2 - \eta_2}{\ell_1 T} \pm \epsilon\frac{t}{T}\bigr) \tag{18.6.55}$$

respectively.

On the other hand, let us consider the case $|\ell_\parallel| \ge \frac12\epsilon$ with $\ell_\parallel = \ell_3$ and examine propagation of singularities with respect to ξ_3. To time T the shift will be $\asymp \epsilon|\ell_3|$ and and the logarithmic uncertainly principle means that $\epsilon|\ell_3|\mu^{-1} \times \varepsilon \ge Ch|\log h|$ which is equivalent to $T \ge T_*$ again.

We can justify this analysis by standard means with a function

$$\chi\bigl(\frac{\xi_3-\eta_3}{\ell_3 T}\pm\epsilon\frac{t}{T}\bigr). \tag{18.6.55}_3$$

Also, in all upper bound for T is a small constant because for this time (x_2,x_3,ξ_2,ξ_3) keeps in ϵ_1-vicinity of the point of origin[37] which can be justified by standard means with functions

$$\begin{aligned}&\chi\bigl(\frac{t}{T}\pm\epsilon\mu\frac{\xi_2-\eta_2}{T}\bigr), && \chi\bigl(\frac{t}{T}\pm\epsilon\mu\frac{x_2-y_2}{T}\bigr),\\ &\chi\bigl(\frac{t}{T}\pm\epsilon\frac{\xi_3-\eta_3}{T}\bigr), && \chi\bigl(\frac{t}{T}\pm\epsilon\frac{x_3-y_3}{T}\bigr).\end{aligned} \tag{18.6.56}_{1-4}$$

Remark 18.6.9. The above proof uses canonical form (see the next Section 18.7) and therefore requires $(\bar{l},\bar{\sigma})=(2,1)$. However, one can provide an alternative proof, similar to ones in Subsection 18.2.3, which uses "precanonical" form (i.e. variables Q_1, Q_2); now it is enough $(\bar{l},\bar{\sigma})=(l,\sigma)\succeq(1,2)$. We leave easy details to the reader.

Now Statement (i) of Theorem 18.6.12 below follows from Propositions 18.6.5, 18.6.6, Corollary 18.6.7 and Remark 18.6.8.

18.6.7 Analysis under Assumption (18.2.16)

Let $(l,\sigma)\succeq(2,0)$. Then we can introduce

$$\nu=\epsilon|\nabla(V/F)|+\bar{\nu},\qquad \bar{\nu}=C_1(\mu h|\log h|)^{\frac12}\ge C_0\mu^{-1} \tag{18.6.57}$$

where the last inequality is due to $\mu\ge\epsilon(h|\log h|)^{-\frac13}$ and as $|\xi_3|\le\bar{\rho}_1$ and $\nu\ge 2\bar{\nu}$ we can apply arguments of the previous subsection with

$$\varepsilon=C_0\mu h|\nu^{-1}\log h| \tag{18.6.58}$$

and take $T_*=Ch|\log h|\nu^{-1}\varepsilon^{-1}\le\epsilon\mu^{-1}$ and $T^*\asymp 1$.

Then the contribution of the zone $\mathcal{Z}_1\cap\{|\nabla(V/F)|\ge 2\bar{\nu}\}$ to the Tauberian remainder is $O(h^{-2})$ and in virtue of assumption (18.2.16) its contribution to the approximation error does not exceed expression (18.6.53) as $l<3$.

[37] Actually it can be longer for small ℓ_3 but there is no benefit from this observation.

On the other hand, the contribution of the zone $\mathcal{Z}_1 \cap \{|\nabla(V/F)| \le 2\bar\nu\}$ to the Weyl remainder does not exceed $C\mu h^{-2}(\mu h|\log h|)^2$ where an extra factor (in comparison with the general case) $(\log \mu h|\log h)^{\frac12}$ is due to assumption (18.2.16). Finally, contribution of this zone to the approximation error also does not exceed (18.6.53).

These arguments imply Statement (ii) of Theorem 18.6.12 below.

18.6.8 Weakly-Degenerate Case

We need this subsection to improve Theorem 18.6.4 to Theorem 18.6.10 below. Let us consider point $\bar x$ in which

$$|\nabla(V/F)| \asymp \zeta \ge C'|\log h|^{-\sigma'}, \qquad (l,\sigma) \succeq (1,\sigma'). \tag{18.6.59}$$

Then the same is true in its γ-vicinity with $\gamma = h^\delta$ with some small $\delta > 0$ provided $C' = C'(\delta)$ is large enough if $(l,\sigma) = (1,\sigma')$; otherwise no restriction on C' is needed. Thus all the arguments of the previous subsection remain valid but now for time $\bar T = \epsilon\mu^{-1}$ the shift with respect to ξ_3 will be $\asymp \zeta\bar T$ provided $|\nabla_\parallel(V/F)| \asymp \zeta$ and the shift with respect to (x_2,ξ_2) will be $\asymp \mu^{-1}\zeta\bar T$ provided $|\nabla_\perp(V/F)| \asymp \zeta$ and therefore logarithmic uncertainty principle is fulfilled if

$$\varepsilon \ge C\zeta^{-1}\mu h|\log h|. \tag{18.6.60}$$

We need to assume also that $\gamma \ge C\varepsilon$ which is always the case provided $\mu \le h^{\delta_0-1}$ with $\delta_0 > \delta$.

Then we can take

$$T^* = \begin{cases} \gamma & \text{for } l = 1,\\ \epsilon\zeta & \text{for } l > 1 \end{cases} \tag{18.6.61}$$

and the contribution of this particular element $\psi_\gamma(x)q_\rho(hD_3)$ to the remainder estimate will be $O\big(\rho\gamma^3h^{-2}T^{*\,-1}\big)$ (we assume that q is compactly supported).

We can take always $\rho = C\bar\rho_1$. Recall that we estimated contribution of the partition element $\psi_\gamma(x)\big(1-q_\rho(hD_3)\big)$ to the remainder as $O\big(\gamma^3h^{-2}\big)$. Therefore the contribution of $\psi_\gamma(x)$ to the remainder is $O(\gamma^3h^{-2})$ anyway.

Now let us consider its contribution to the approximation error. In our assumptions it does not exceed

$$Ch^{-2}\gamma^3 + C\rho\gamma^3h^{-3}\vartheta(\varepsilon) \asymp Ch^{-2}\gamma^3 + C\gamma^3h^{-3}(\mu h|\log h|)^{l+\frac12}\zeta^{-l}|\log h|^{-\sigma} \tag{18.6.62}$$

and to keep it below $C\gamma^3 h^{-2}$ we need to assume that

$$\zeta \ge \mu^{(2l+1)/(2l)} h^{(2l-1)/(2l)} |\log h|^{(2l-2\sigma-1)/(2l)}; \tag{18.6.63}$$

in particular, for $(l,\sigma)=(1,2)$

$$\zeta \ge \mu^{\frac{3}{2}} h^{\frac{1}{2}} |\log h|^{-\frac{1}{2}} \tag{18.6.64}$$

which is possible only for $\mu \le h^{-\frac{1}{3}} |\log h|^{\frac{1}{3}}$.

18.6.9 Main Theorems

Now we prove

Theorem 18.6.10. *As $(\bar{l},\bar{\sigma})=(2,1)$ the conclusion of Theorem 18.6.4 remains true for $\mu \le h^{-\frac{1}{3}}$.*

Proof. To prove this theorem we need to analyze zone

$$\{\mathsf{max}\big(\mu^{-1}, (\mu h)^{\frac{1}{2}}\big) \le |\xi_3| \le (\mu h|\log h|)^{\frac{1}{2}}\}. \tag{18.6.65}$$

Let us make γ-admissible partition with $\gamma = h^{\delta}$. Then on the elements with $|\nabla(V/F)| \ge \bar{\zeta} := C_0 |\log h|^{-\sigma'}$ we can apply arguments of the previous subsection and conclude that their contribution to the Weyl remainder does not exceed $Ch^{-2}\gamma^3$.

On the other hand, consider elements with $|\nabla(V/F)| \le \bar{\zeta}$. Consider ξ_3-partition in zone (18.6.65). Using rescaling arguments one can prove easily that the contribution of such elements to the remainder does not exceed $Ch^{-2}\gamma^3\big(\rho + C\mu\rho(\mu h/\rho^2)^s\big)$; we leave the standard arguments to the reader.

Then summation with respect to ρ returns $Ch^{-2}\gamma^3\big(C\mu(\mu h)^{\frac{1}{2}}\big)$ and summation with respect to γ returns $Ch^{-2}\big(C\mu(\mu h)^{\frac{1}{2}}\big)$. □

Corollary 18.6.11. *In the framework of Theorem 18.6.4 let $(l,\sigma) \succeq (1,2)$ and $\mu \le \mu_1^* := h^{-\frac{1}{3}}$. Then $\mathsf{R}^{\mathsf{MW}} = O(h^{-2})$.*

Consider now the non-degenerate case. We have proven already

Theorem 18.6.12. *Let $d=3$ and A be a self-adjoint in $\mathscr{L}^2(X)$ Schrödinger operator* (18.1.1). *Let conditions* (18.1.3), (18.1.6), (18.2.27) *fulfilled in $B(0,1) \subset X \subset \mathbb{R}^3$. Let $(l,\sigma) \succeq (1,1)$.*

Let $h^{-\frac{1}{3}} \le \mu \le C(h|\log h|)^{-1}$, $(\bar{l},\bar{\sigma})=(2,1)$. Then for two framing approximations as in footnote[18)]

(i) Under assumption (18.2.15) *asymptotics*

$$|\int \Big(\tilde{e}(x,x,0) - h^{-2}\mathcal{N}_3^{\mathsf{MW}}(x,0)\Big)\psi(x)\,dx| \le Ch^{-2} + Ch^{-3}\vartheta(h|\log h|) + Ch^{-3}(\mu h|\log h|)^{\frac{1}{2}}\vartheta(\mu h|\log h|) \tag{18.6.66}$$

holds.

(ii) Let $(l,\sigma) \succeq (2,0)$ *and* $l < 3$. *Then under assumption* (18.2.16) *asymptotics* (18.6.66) *holds.*

We leave to the reader the following easy problem:

Problem 18.6.13. Prove that

(i) Theorems 18.6.10 and 18.6.12 remain true for $\mathsf{R}^{\mathsf{W}}_{\infty}$ and, if $\mu \le h^{-\frac{1}{2}}$, also for R^{W}.

(ii) Corollary 18.6.11 remains true for R^{W}.

18.7 $d = 3$: Canonical Form

From now on we will consider more difficult case

$$\mu \ge \bar{\mu}_1 := C^{-1}(h|\log h|)^{-\frac{1}{3}}; \tag{18.7.1}$$

further restrictions will be added later. Actually due to Theorem 18.6.10 we can consider $\mu \ge \mu_1^* := h^{-\frac{1}{3}}$.

We already know from Subsection 18.5 that the contribution of the zone $\mathcal{Z}_1^c := \{|\xi_3| \ge \bar{\rho}_1\}$ with $\bar{\rho}_1 := C(\mu h|\log h|)^{\frac{1}{2}}$ to the remainder does not exceed Ch^{-2} and therefore we can limit ourselves by zone $\mathcal{Z}_1 := \{|\xi_3| \le \bar{\rho}_1\}$.

18.7.1 Canonical Form. Preliminary Remarks

To treat this zone $\mathcal{Z}_1$ properly one needs to reduce operator to the canonical form as in Section 13.3. However, as for $d = 2$, to follow this procedure one must assume that $\varepsilon \ge C\mu^{-1}|\log h|$ at least and then the approximation error will be too large unless the regularity condition holds with $l \ge 2$.

On the other hand, these arguments still work, but for much larger μ. One of the reasons is that even if we neglect an approximation error, the remainder estimate would be at least $\mu h^{-1} \times \mathcal{R}_1$ where $\mathcal{R}_1$ is the remainder estimate for 1-dimensional Schrödinger operator.

Unless we assume that V/F is non-degenerate (i.e. either $\nabla(V/F) \neq 0$ or $\nabla^2(V/F) \neq 0$) we can derive nothing better than $\mathcal{R}_1 = O\big(h^{-2/(2+l)}\big)$ according to Section 4.6 (we neglect logarithmic factors here). Therefore we should not expect anything better than estimate $O\big(\mu h^{-1-2/(2+l)}\big)$ for our magnetic 3-dimensional Schrödinger operator anyway. For $l = 1$ this estimate coincides with $O(h^{-2})$ for $\mu \asymp h^{-\frac{1}{3}}$ exactly.

However, for μ close to $h^{-\frac{1}{3}}$ we need to modify reduction arguments properly and the rest of the section is devoted to this.

We pay mainly attention to the case

$$C_0(h|\log h|)^{-\frac{1}{3}} \le \mu \le C_0^{-1}(h|\log h|)^{-1} \tag{18.7.2}$$

and analyze zone $\mathcal{Z}_1$.

First of all we need to decide what does *non-essential* mean.

Non-Degenerate Case. Under non-degeneracy assumption (18.2.15) the contribution of zone $\mathcal{Z}_1$ to the approximation error in $h^{-3}\mathcal{N}^{\mathsf{MW}}$ does not exceed $Ch^{-3}\bar{\rho}_1 R$ where R is an upper bound for a perturbation. To prove this one needs to notice that for $\rho \le \rho_1^* := (\mu h)^{\frac{1}{2}}$ due to this assumption the measure of the zone

$$\mathcal{Y}_\rho := \big\{\rho^2 \le \min_{n\ge 0} |\tau - V - (2n+1)\mu h| \le 2\rho^2\big\} \tag{18.7.3}$$

does not exceed $C\rho^2/(\mu h)$ and its contribution to the approximation error in $h^{-3}\mathcal{N}^{\mathsf{MW}}$ does not exceed $C\big(\bar{\rho}_1 \mu h^{-2}\rho^{-1}\big)R \times \rho^2/\mu h$. Then the total contribution of $\mathcal{Z}_1$ to the approximation error does not exceed this expression integrated by $\rho^{-1}d\rho$ which gives exactly $Ch^{-3}\bar{\rho}_1 R$.

On the other hand, one can prove easily that under assumption (18.2.15) the remainder estimate is $O\big(h^{-2}\big)$ and therefore to keep approximation error below it we need to make calculations with the precision

$$R \le R^* := C\mu^{-\frac{1}{2}} h^{\frac{1}{2}} |\log h|^{-\frac{1}{2}}. \tag{18.7.4}$$

Therefore

(18.7.5) In the non-degenerate case as $(l,\sigma)=(1,2)$ in $\mathcal{Z}_1$ we can increase ε up to

$$\varepsilon^* = C\mu^{-\frac{1}{2}}h^{\frac{1}{2}}|\log h|^{\frac{3}{2}} \tag{18.7.6}$$

Case of the non-degeneracy assumption (18.2.16) does not warrant its own analysis since one expects to have the remainder estimate $O(h^{-2})$ and the approximation error as above but with an extra term $C\mu h^{-2}R^2$ which would be smaller.

General Case. In the general case (i.e. without non-degeneracy assumption) the contribution of the zone $\mathcal{Z}_1$ to the approximation error in $h^{-3}\mathcal{N}^{\mathsf{MW}}$ does not exceed $Ch^{-3}\bar{\rho}_1R+C\mu h^{-2}R^{\frac{1}{2}}$ while we expect the remainder estimate to be $O\big(h^{-2}+\mu h^{-1-2/(l+2)}|\log h|^{-\sigma/(l+2)}\big)$; then to keep approximation error below it we need to make calculations with precision

$$R_* = C\min\big(\mu^{-\frac{1}{2}}h^{\frac{1}{2}}|\log h|^{-\frac{1}{2}},\ \mu^{-2}+h^{2l/(2+l)}|\log h|^{-2\sigma/(l+2)}\big) \tag{18.7.7}$$

where $(l,\sigma)\preceq(2,1)$. Note that R given by this formula is larger than $\varepsilon^l|\log h|^{-\sigma}$ with ε defined by (18.7.1). Therefore

(18.7.8) In the general case we can increase ε up to

$$\varepsilon_* = C(R_*)^{1/l}|\log h|^{\sigma/l}. \tag{18.7.9}$$

Later further increase will be made.

18.7.2 Canonical Form. I

Let us assume that $g^{jk}\in\mathscr{F}^{2,1}$ even if one can weaken this assumption. We call term *non-essential* if its A-bound does not exceed R_* given by (18.7.7); under assumption (18.2.15) or (18.2.16) we can increase it to R^*.

Therefore, in the zone $\mathcal{Z}_1$ we have

$$\varepsilon = C(\mu^{-1}h|\log h|)^{\frac{1}{2}} \tag{18.7.10}$$

or larger. Note that for ε given by (18.7.10) the mollification error $\varepsilon^l|\log h|^{-\sigma}$ does not exceed R_*.

To transform operator A to the canonical form we would like first to transform its principal part to the "diagonal form" as it was done for $d = 2$. This can be achieved by the same transformation (18.3.4)

$$T(t) \coloneqq e^{-i\mu^{-1}h^{-1}tL^{\mathrm{w}}} \qquad \text{with} \quad L^{\mathrm{w}} = \frac{1}{2}\sum_{j,k} P_j L^{jk} P_k. \tag{18.3.4}$$

Then (18.3.5)–(18.3.8) are preserved but now we have 3×3 commutator matrix

$$J = \begin{pmatrix} J' & 0 \\ 0 & 0 \end{pmatrix} \qquad \text{with} \quad J' = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

and

$$\Lambda = f(x)\ell J = \begin{pmatrix} \Lambda' & 0 \\ \Lambda'' & 0 \end{pmatrix} \qquad \text{with} \quad \Lambda' = \begin{pmatrix} \ell^{12} & -\ell^{21} \\ \ell^{22} & -\ell^{21} \end{pmatrix}, \quad \Lambda'' = (\ell^{32} \ -\ell^{31}).$$

Then

$$e^{t\Lambda} = \begin{pmatrix} e^{t\Lambda'} & 0 \\ \Lambda'' K(t) & 1 \end{pmatrix}$$

with matrix $K(t) = (\Lambda')^{-1}(e^{t\Lambda'} - I)$ which is well defined even if Λ' is degenerate.

Therefore we can achieve $e^{t\Lambda} G e^{\Lambda}$ to be diagonal with the top-left element equal to 1. However, we cannot change g^{33} by this method unless we use "much larger" operator L (something like $\omega(x)\mu h D_3$) which is not a good idea at this moment in the non-smooth case.

The rest of the analysis of Subsubsection *18.3.1.1 Main pPart of the Operator. I* does not change and and therefore we conclude that

(18.7.11) Modulo operator with A-bound not exceeding $\mu^{-1}h$

$$T(-1)A_0 T(1) \equiv P_1^2 + P_2 (g')^{\mathrm{w}} P_2 + P_3 (g'')^{\mathrm{w}} P_3 + \mu^2 M^{\mathrm{w}}, \tag{18.7.12}$$

and

$$M \coloneqq a_0 \circ \phi_1 - p_1^2 - g'^{22} p_2^2 - g'^{33} p_2^2 \tag{18.7.13}$$

(compare with (18.3.18),(18.3.19)).

Recall that according to (18.3.13) $M = \sum_{i,j,k} \beta_{ijk}\, p_i p_j p_k$ with $\beta_{ijk} \in \mathscr{F}^{1,1}$. Finally, modulo a non-essential operator

$$T(-1)VT(1) \equiv (V \circ \phi_1)^{\mathrm{w}}. \tag{18.7.14}$$

Now, we can assume that g', g'' are functions of x only because we can achieve it modifying M but not changing its type. Further, condition $F = 1$ means that $\sqrt{g'}f = 1$ and we can apply the same construction as in Subsubsection *18.3.1.2 Main Part of the Operator. II* and therefore we can assume without any loss of the generality that

$$V_1 = V_3 = 0, \quad P_1 = hD_1 \implies V_2 = V_2(x_2, x_3), \tag{18.7.15}$$

$$V_2, \partial_{x_1} V_2 \in \mathscr{F}^{2,1} \tag{18.7.16}$$

and

$$p_2 = \alpha(x, \xi_2)\big(x_1 - \lambda(x_2, x_3, \xi_2)\big), \qquad \alpha, \lambda \in \mathscr{F}^{2,1}. \tag{18.7.17}$$

Repeating then construction of Subsubsection *18.3.1.2 Main Part of the Operator. II*, we take the next transformation $T'(t) = e^{-i\lambda^{\mathrm{w}} D_1}$. As a result we will get the operator

$$T'(-1)T(-1)A_0T(1)T'(1) \equiv \bar{A}_0 + \big(\mu^2 M'\big)^{\mathrm{w}}, \tag{18.7.18}$$

$$\bar{A}_0 \coloneqq \bar{P}_1^2 + \bar{P}_2^2 + \bar{P}_3 \alpha_0^{\mathrm{w}} \bar{P}_3, \qquad \bar{P}_1 = hD_1,\ \bar{P}_2 = -\mu x_1,\ \bar{P}_3 = hD_3, \tag{18.7.19}$$

$$M' = a_0 \circ \Phi - \bar{a}_0 = \sum_{i,j,k} \beta'_{ijk} \bar{p}_i \bar{p}_j \bar{p}_k \tag{18.7.20}$$

with $\bar{p}_1 \coloneqq \xi_1$, $\bar{p}_2 \coloneqq -x_1$, $\bar{p}_3 \coloneqq \xi_3$, $\Phi \coloneqq \phi_1 \circ \phi'_1$, where ϕ_t, ϕ'_t are corresponding Hamiltonian flows, $\alpha_0 = \alpha_0(x_2, x_3, \xi_2) \in \mathscr{F}^{2,1}$ (compare with (18.3.28)–(18.3.30)).

Further, modulo an operator with $\bar{A}_0$-bound not exceeding $C\vartheta(\varepsilon)$

$$T'(-1)T(-1)A_0T(1)T'(1) \equiv (V \circ \Phi)^{\mathrm{w}}. \tag{18.7.21}$$

So far precision was better than we actually needed: it was $\varepsilon^l |\log h|^{-\sigma}$, exactly as in Subsubsection *18.3.1.2 Main Part of the Operator. II*. We could achieve $\alpha_0 = 1$ but it would be not very useful.

18.7.3 Canonical Form. II

Now we will follow Subsubsection *18.3.1.3 Potential* but with a twist. Namely, we define S', S'', W', W'' *exactly* by (18.3.39)–(18.3.42) and apply transformation $T''(-t) = e^{-it\mu h^{-1} S^{\mathrm{w}}}$ with the phase $S = S' + S''$. Then modulo a non-essential term

$$T''(-t)\Big(\bar{A}_0 + \big(\mu^2 M' + V'\big)^{\mathrm{w}}\Big)T''(t) \equiv \Big(\big(\mu^2 \bar{a}_0 + \mu^2 M' + V'\big) \circ \psi_t\Big)^{\mathrm{w}} \tag{18.7.22}$$

where ψ_t is a corresponding Hamiltonian flow. Let us calculate symbol

$$\bigl(\mu^2\bar{a}_0 + \mu^2 M' + V'\bigr)\circ\psi_t = \mu^2\bar{a}_0 + \bigl(\mu^2 M' + V'\bigr) - t\mu^2\{\bar{a}_0, S\} \\ - t\{\mu^2 M' + V', S\} - \frac{t^2}{2}\{\{\bar{a}_0, S\}, S\} + \dots,$$

and plug $t = 1$. Then

$$\mu^2\{\bar{a}_0, S\} = 2\mu^2(\xi_1\partial_{x_1} - x_1\partial_{\xi_1})S + 2\mu^2\alpha_0^2\xi_3(\partial_{x_3}S) \ + \ \{\alpha_0^2, S\}\xi_3^2 \\ = \mu^2 M' + V' - W_0 + 2\mu^2\alpha_0^2\xi_3(\partial_{x_3}S) \ + \ \{\alpha_0^2, S\}\xi_3^2$$

where the last equality is due to (18.3.39), (18.3.40) and $W_0 = W' + W''$.

Further, let us notice that $|\xi_3| \le \mu^{-1}\bar{\rho}_1 = C(\mu^{-1}h|\log h|)^{\frac{1}{2}}$ in our zone $\mathcal{Z}_1$ where an extra factor μ^{-1} appears because in the reduction part we consider $\mu^{-1}h$-pseudodifferential operator. Then one can see easily that modulo non-essential operator (in the general sense) our transformed operator equals to the quantization of

$$\mu^2\bar{a}_0 + W_0 - 2\mu^2\alpha_0^2\xi_3(\partial_{x_3}S) - \frac{1}{2}\{\mu^2 M' + V' - W_0, S\}' \tag{18.7.23}$$

where $\{.,.\}'$ again mean "short" Poisson brackets (with respect to x_1, ξ_1 only).

Obviously the last term in (18.7.23) is $O(\mu^{-2})$ and it is essential only for $\mu \le \hat{\mu}_1 := \epsilon_0 h^{-\frac{1}{3}}|\log h|^{\frac{1}{3}}$.

Furthermore, $\partial_{x_3}S = O\bigl(\mu^{-1-l}|\log h|^{-\sigma} + \mu^{-3}\bigr)$ and therefore the second term in (18.7.23) is $O\bigl((\mu^{1-l}|\log h|^{-\sigma} + \mu^{-2})\cdot(\mu^{-1}h|\log h|)^{\frac{1}{2}}\bigr)$ which does not exceed R^* but is not necessarily smaller than R_*.

Therefore, if one of the conditions (18.2.15), (18.2.16) is fulfilled and $\mu \ge \hat{\mu}_1$ then we have finished because only the first term in (18.7.23) is essential. In this case we have arrived to the operator

$$\bar{A}_0 + W_0(x_2, x_3, \mu^{-1}hD_2, \mu^{-1}hD_3, \mu^{-1}\bar{A}_0^{\frac{1}{2}})^{\mathrm{w}} \tag{18.7.24}$$

with

$$W_0(x_2, x_3, \xi_2, \xi_3, \rho) = \mathcal{M}_\rho(\mu^2 M' + V'). \tag{18.7.25}$$

Furthermore, under one of the assumptions (18.2.15), (18.2.16) we will see later that for $\mu \le \hat{\mu}_1$ we do not need the full canonical form at all.

However, in the general case the second and the third terms in (18.7.23) are essential and we need to continue in the same way as in Subsubsection *18.3.1.4 Final Reduction*. Let us define S_1, S''', W_1, W''' in the same way as before:

$$W''' = \alpha_0^2 \partial_{x_3} \mathcal{M}_\rho S, \qquad W_1 = -\frac{1}{2}\mathcal{M}_\rho \{\mu^2 M' + V' - W_0, S\}', \tag{18.7.26}$$

$$2\mu^2(\xi_1\partial_{x_1} - x_1\partial_{\xi_1})S''' = \alpha_0^2\partial_{x_3}(S - \mathcal{M}_\rho S), \tag{18.7.27}$$

$$2\mu^2(\xi_1\partial_{x_1} - x_1\partial_{\xi_1})S_1 = -\frac{1}{2}\{\mu^2 M' + V' - W_0, S\}' + W_1; \tag{18.7.28}$$

Recall that $\alpha_0 = \alpha_0(x_2, x_3, \xi_2)$. Let us apply $\mu^{-1}h$-pseudodifferential operator transformation

$$T'''(t) = \bigl(e^{-it\mu h^{-1}(S'''\xi_3 + S_1)}\bigr)^{\mathrm{w}};$$

then

$$T'''(-1)\Bigl(\mu^2\bar{a}_0 + W_0 - 2\mu^2\alpha_0^2\xi_3(\partial_{x_3}S) - \frac{1}{2}\{\mu^2 M' + V' - W_0, S\}'\Bigr)^{\mathrm{w}} T'''(1) \equiv$$
$$\Bigl(\mu^2\bar{a}_0 + W_0 - 2\mu^2\alpha_0^2\xi_3(\partial_{x_3}S) - \frac{1}{2}\{\mu^2 M' + V' - W_0, S\}' - \mu^2\{\bar{a}_0, S'''\xi_3 + S_1\} + \dots\Bigr)^{\mathrm{w}}.$$

Plugging in (18.7.26)–(18.7.27) we see easily that

$$T'''(-1)\Bigl(\mu^2\bar{a}_0 + W_0 - 2\mu^2\alpha_0^2\xi_3(\partial_{x_3}S) - \frac{1}{2}\{\mu^2 M' + V' - W_0, S\}'\Bigr)^{\mathrm{w}} T'''(1) \equiv \bar{A}_0 + Wx_2, x_3, \mu^{-1}hD_2, \mu^{-1}hD_3, B) \tag{18.7.29}$$

where $W = W_0 + W'''\xi_3 + W_1$.

The last step is not really necessary, but we'll do it for the sake of the simple canonical form.

First of all, transformation $T^V(1)$, with $T^V(t) = e^{-it\omega^{\mathrm{w}}D_3}$ and with $\omega = \omega(x_2, x_3, \xi_2) \in \mathscr{F}^{2,1}$, transforms D_3 into $(\partial_{x_3}\omega)^{\mathrm{w}}D_3 + \beta^{\mathrm{w}}\mu^{-1}hD_3^2$ with $\beta = \beta(x_2, x_3, \xi_2, \xi_3) \in \mathscr{F}^{1,1}$ and therefore one can transform $\alpha_0^{\mathrm{w}}D_3$ into $D_3 + \beta^{\mathrm{w}}\mu^{-1}hD_3^2$. Thus, modulo a non-essential operator

$$T^V(-1)\bar{A}_0 T^V(1) \equiv h^2D_1^2 + \mu^2 x_1^2 + D_3^2. \tag{18.7.30}$$

One can also see easily that $T^V(-1)W^{\mathsf{w}}T^V(1) \equiv W^{\mathsf{w}} + K^{\mathsf{w}}\mu^{-1}hD_3$ with $K \in \mathscr{F}^{l-1,\sigma}$.

Further, modulo a non-essential term we can rewrite our reduced operator in the form $\bar{A}_0 + \bar{W}^{\mathsf{w}} + \bar{K}^{\mathsf{w}}\mu^{-1}hD_3$ with $\alpha_0 = 1$ in the expression (18.7.19) for $\bar{A}_0$ and $\bar{W} = \bar{W}(x_2, x_3, \xi_2, \mu^{-1}\bar{A}_0^{\frac{1}{2}})$ where $\bar{W} := W|_{\xi_3=0} \in \mathscr{F}^{l,\sigma}$ and $\bar{K} = \bar{K}(x_2, x_3, \xi_2, \mu^{-1}\bar{A}_0^{\frac{1}{2}})$ with $\bar{K} := (\partial_{\xi_3}W)|_{\xi_3=0} \in \mathscr{F}^{l-1,\sigma}$.

Finally, applying transformation $T^{Vl}(1)$ with $T^{Vl}(t) = e^{-it\mu^{-1}h^{-1}\omega'^{\mathsf{w}}}$ and $\omega' = \omega'(x_2, x_3, \xi_2, \mu^{-1}\bar{A}_0^{\frac{1}{2}})$, $\omega' \in \mathscr{F}^{l-1,\sigma}$ we will get (for an appropriate symbol ω') modulo negligible operator $\bar{A}_0 + \bar{W}^{\mathsf{w}}$.

18.7.4 Canonical Form. III. $\mu \ge \epsilon h^{-1}|\log h|^{-1}$

In this case again an A-bound for $\mu^{-1}P_j$ does not exceed $C\varepsilon$ and construction is absolutely straightforward as in the smooth case; we just note that $R^* = Ch$ and

$$R_* = C\min\bigl(h, h^{2l/(2+l)}|\log h|^{-2\sigma/(l+2)}\bigr) = C\begin{cases} h & \text{for } (l,\sigma) \preceq (2,0),\\ h|\log h|^{-\frac{\sigma}{2}} & \text{for } l = 2, 0 < \sigma \le 1.\end{cases} \tag{18.7.31}$$

18.8 $d = 3$: Tauberian tTheory

In this section we derive Tauberian estimates. First of all, we have decomposition similar to one we had in the 2-dimensional case.

Using this decomposition we analyze the case $\mu \ge \bar{\mu}_1$ in two different settings: under one of non-degeneracy assumptions (18.2.15), (18.2.16) we prove that the Tauberian remainder estimate does not exceed $C(1+\mu h)h^{-2}$ and that in the general case we prove that it does not exceed expression $Ch^{-2} + C\mu h^{-1}\mathcal{R}_1$ where $\mathcal{R}_1$ is the remainder estimate for 1-dimensional Schrödinger operator.

18.8.1 Decomposition

First of all, as we already mentioned, we have decomposition, similar to (18.4.3)–(18.4.4): we reduce our operator to the family of 1-dimensional

Schrödinger operators with respect to x_3 which are also $\mu^{-1}h$-pseudodifferential operators with respect to x_2

$$\mathcal{A}_n = hD_3^2 + r_n^2 + W(x_2, x_3, \mu^{-1}hD_2, \mu^{-1}r_n), \qquad r_n = \big((2n+1)\mu h\big)^{\frac{1}{2}}, \tag{18.8.1}$$

with $x' = (x_1, x_2)$ and arrive to decomposition

$$U(x, y, t) \equiv \mathcal{T}\Big(\sum_{n\ge 0} U_n(x', y', y_3, t)\Upsilon_n(x_1)\Upsilon_n(y_1)\Big)\mathcal{T}^{-1} \tag{18.8.2}$$

where $U_n(x', y', t)$ are Schwartz kernels of the propagators for $\mathcal{A}_n$.

Here we assume that $\mu \le C_0 h^{-1}$; as $\mu \ge C_0 h^{-1}$ we consider Schrödinger-Pauli operator with $\mathfrak{z} = 1$ and $r_n = 0$.

18.8.2 Reduction in the Zone $\mathcal{Z}_1$

As we mentioned, in this case we have essentially 1-dimensional Schrödinger operator (or rather a family of them). Due to Section 18.6 we need to consider zone $\mathcal{Z}_1 = \{(x, \xi) : |\xi_3| \le \bar\rho_1 = C(\mu h|\log h|)^{\frac{1}{2}}\}$ only.

Assuming first that $\vartheta(\eta) \ge \eta^2$ et us introduce admissible functions $\ell = \ell_{(n)}$ and $\varrho = \varrho_{(n)}$ of (x_2, x_3, ξ_2) similar to those introduced in Section 5.2:

$$\ell = \epsilon \min\Big\{\eta : \ |W + (2n+1)\mu h| \le \vartheta(\eta), |\nabla W| \le \eta^{-1}\vartheta(\eta)\Big\} + \bar\ell, \tag{18.8.3}$$

$$\varrho = \vartheta(\ell)^{\frac{1}{2}}$$

with $\bar\ell$ defined from equation

$$\bar\ell\vartheta(\bar\ell)^{\frac{1}{2}} = C_1 h|\log h|. \tag{18.8.4}$$

Note that as $\vartheta(\eta) \le \eta|\log\eta|^{-2}$ we conclude that

$$\bar\ell \ge (h|\log h|)^{\frac{2}{3}} \ge \bar\varepsilon = (\mu^{-1}h)^{\frac{1}{2}}|\log h| \tag{18.8.5}$$

where the last inequality is due to $\mu \ge \bar\mu_1$. Recall that $\bar\varepsilon$ was the approximation parameter in the inner zone.

We need to have approximation parameter $\varepsilon_n = \varepsilon_{(n)}$ such that $\varepsilon\varrho_n \ge Ch|\log h|$ to satisfy uncertainty principle with respect to x_3 and therefore we replace $\varepsilon_{(n)}$ by

$$\varepsilon := \varepsilon_{(n)} + \varepsilon'_{(n)}, \qquad \varepsilon'_{(n)} := Ch\varrho_{(n)}^{-1}|\log h|; \tag{18.8.6}$$

then

$$\varepsilon_{(n)} \lesssim \ell_{(n)} \quad \text{and} \quad \varepsilon_{(n)} \asymp \ell_{(n)} \iff \ell_{(n)} \asymp \bar{\ell}. \tag{18.8.7}$$

Note first that

(18.8.8) If on the given partition element

$$|W + (2n+1)\mu h| \asymp \varrho^2 = \vartheta(\ell) \geq C\mu h|\log h| \tag{18.8.9}$$

then on this element operator $\mathcal{A}_n$ is elliptic in $\mathcal{Z}_1$ and its contribution to $F_{t\to h^{-1}\tau}\bar{\chi}_T(t)U_n$ is negligible on energy levels $\tau : |\tau| \leq \epsilon_1\varrho^2$.

On the other hand,

(18.8.10) If on the given partition element

$$|\nabla W| \asymp \varrho^2\ell^{-1} = \vartheta(\ell)\ell^{-1}, \qquad \varrho^2 \geq C\mu h|\log h| \tag{18.8.11}$$

then on this element operator $\mathcal{A}_n$ is microhyperbolic with respect to (x_2, x_3, ξ_2) in $\mathcal{Z}_1$ and its contribution to Tauberian estimate with the given index n does not exceed $C\mu h^{-1}\ell^2$.

Really, microhyperbolicity with respect to (x_2, ξ_2) and propagation with respect to (ξ_2, x_2) gives us

$$T_* = Ch|\log h|/(\varrho^2\ell^{-1}\varepsilon) \tag{18.8.12}$$

and microhyperbolicity with respect to x_3 and propagation with respect to ξ_3 gives us the same answer as in these case we consider $\mu^{-1}h$-pseudodifferential and h-pseudodifferential operators respectively. One can see easily that $\varrho^2\ell^{-1} \geq C(\mu h|\log h|)^{\frac{1}{2}}$ and therefore $T_* \leq \epsilon$.

Remark 18.8.1. However, the actual estimate is based not on the propagation but on fine subpartition and ellipticity arguments exactly like in Section 18.4. We leave details to the reader.

Meanwhile one can see easily that

(18.8.13) On elements with $\varrho \geq (\mu h)^{\frac{1}{2}}$ additional approximation is not needed because $Ch\varrho^{-1}|\log h| \leq C\bar{\varepsilon}$.

Since over such element with $\varrho^2 \ge C\mu h$ ellipticity is violated only for $\asymp \varrho^2/\mu h$ indices n then due to (18.8.10) its contribution to the Tauberian remainder does not exceed $C\mu h^{-1}\ell^{-1} \times \varrho^2/\mu h \asymp Ch^{-2}\varrho^2\ell^2 \le Ch^{-2}\ell^3$. Then summation over all such elements results in $O(h^{-2})$.

Therefore we arrive to

Proposition 18.8.2. *As $(l,\sigma) \preceq (1,2)$ contribution to the Tauberian remainder with $T = \bar{T} = \epsilon$ of the complement of the zone*

$$\mathcal{Z} := \{(x,\xi) : |\xi_3| + \varrho \le C\bar{\rho}_1\} \tag{18.8.14}$$

with $\varrho := \min_n \varrho_n$, is $O(h^{-2})$.

Therefore we need to consider zone $\mathcal{Z}$ only and we divide it into an *inner zone*

$$\mathcal{Z}_{\mathsf{inn}} := \{(x,\xi) : \ |\xi_3| + \varrho \le \bar{\rho}_0 = \epsilon_0(\mu h)^{\frac{1}{2}}\} \tag{18.8.15}$$

and a *transitional zone*

$$\mathcal{Z}_{\mathsf{trans}} := \{(x,\xi) : \ \bar{\rho}_0 \le |\xi_3| + \varrho \le \bar{\rho}_1\}. \tag{18.8.16}$$

Corollary 18.8.3. *As $(l,\sigma) \preceq (2,0)$ the Tauberian remainder is $O(h^{-2})$ as $\mu \le (h|\log h|)^{-1}$.*

We leave to the reader to prove using rescaling technique (with defined above ℓ, ϱ) a bit more stronger

Proposition 18.8.4. *As $(l,\sigma) \preceq (2,0)$ contribution to the Tauberian remainder with $T = \bar{T} = \epsilon$ of the complement of the zone $\mathcal{Z}_{\mathsf{inn}}$ with $\varrho := \min_n \varrho_n$ is $O(h^{-2})$.*

Corollary 18.8.5. *As $(l,\sigma) \preceq (2,0)$ the Tauberian remainder is $O(h^{-2})$ as $\mu \lesssim h^{-1}$.*

18.8.3 Analysis in the Zone $\mathcal{Z}_{\mathsf{inn}}$

Let us consider more difficult inner zone; as $\mu \ge h^{-1}$ and we consider the Schrödinger-Pauli operator with $\mathfrak{z} = 1$. Then we can apply the same arguments as above but over one partition element ellipticity assumption

is violated for no more than 1 index n. Further, as $\ell \asymp \bar{\ell}$ (and then $\bar{\varrho}\bar{\ell} \asymp \mu h|\log h|$ contribution of the element to the asymptotics for given index n does not exceed $C\mu h^{-2}\bar{\varrho}\bar{\ell}^3 \asymp C\mu h^{-2}|\log h|\bar{\ell}^2$.

Therefore we arrive to

Proposition 18.8.6. *As $(l,\sigma) \preceq (2,0)$ contribution to the Tauberian remainder with $T = \bar{T} = \epsilon$ of the zone $\mathcal{Z}_{\mathsf{inn}}$ does not exceed*

$$C\mu h^{-1}\Big(\int_{\{\ell\ge C_0\bar{\ell}\}} \ell^{-1}\,dx'd\xi_2 + \bar{\ell}^{-1}|\log h| \int_{\{\ell\le C_0\bar{\ell}\}} dx'd\xi_2\Big) \tag{18.8.17}$$

and an extra approximation error does not exceed

$$C\mu h^{-2}\int_{\{\ell\ge C_0\bar{\ell}\}} \vartheta\big(h|\log h|/\varrho\big)\,dx'd\xi_2 + C\mu h^{-1}|\log h|\bar{\ell}^{-1}\int_{\{\ell\le C_0\bar{\ell}\}} dx'd\xi_2 \tag{18.8.18}$$

with $\ell := \min_n \ell_n$, $\varrho = \big(\vartheta(\ell)\big)^{\frac{1}{2}}$ and $\bar{\ell}$ defined by (18.8.4).

Then, under non-degeneracy assumptions (18.2.15) (as $(l,\sigma) \succeq (1,2)$) or (18.2.16) (as $(l,\sigma) = (2,0)$) both expressions (18.8.17) and (18.8.17) do not exceed $C\mu h^{-1}$ while in the general case it does not exceed $C\mu h^{-1}|\log h|\bar{\ell}^{-1}$. Combining with Proposition 18.8.4 as as $\mu h \lesssim 1$ we arrive to

Proposition 18.8.7. *(i) Let $\mu \lesssim h^{-1}$ and either $(l,\sigma) \succeq (1,2)$ and condition* (18.2.15) *be fulfilled or $(l,\sigma) \succeq (2,0)$ and condition* (18.2.16) *be fulfilled.*

Then both the Tauberian remainder and an additional approximation error do not exceed Ch^{-2}.

(ii) Let $\mu \gtrsim h^{-1}$ and either $(l,\sigma) \succeq (1,2)$ and condition (18.2.15)* *be fulfilled or $(l,\sigma) \succeq (2,0)$ and condition* (18.2.16)* *be fulfilled.*

Then both the Tauberian remainder and an additional approximation error do not exceed $C\mu h^{-1}$.

(iii) In the general case as $(\ell,\sigma) \preceq (2,0)$ both the Tauberian remainder and an additional approximation error do not exceed

$$Ch^{-2} + C\mu h^{-1}|\log h|\bar{\ell}^{-1}. \tag{18.8.19}$$

We leave to the reader the following moderately difficult problem:

Problem 18.8.8. Using rescaling arguments prove that as $(l,\sigma) \preceq (2,0)$ both contribution to the Tauberian remainder with $T = \bar{T} = \epsilon$ of the zone $\mathcal{Z}_{\mathsf{inn}}$ and extra approximation error do not exceed

$$Ch^{-2} + C\mu h^{-1}\bar{\ell}^{-1} \tag{18.8.19)*}$$

with $\bar{\ell}$ redefined by

$$\bar{\ell}\vartheta(\bar{\ell})^{\frac{1}{2}} = C_1 h. \tag{18.8.4)*}$$

where ε is also redefined as

$$\varepsilon := \varepsilon_{(n)} + \varepsilon'_{(n)}, \qquad \varepsilon'_{(n)} := Ch\varrho_{(n)}^{-1}\big(h/(\varrho_{(n)}\ell_{(n)})\big)^{-\delta'}; \tag{18.8.6)*}$$

We can generalize estimate (18.8.19)* to $(l,\sigma) \succ (2,0)$. Namely, as $(m,0) \preceq (l,\sigma) \prec (m+1,0)$ we introduce scaling functions

$$\ell = \ell_m := \epsilon \min\Big\{\eta : \ |\nabla^\alpha\big(W + (2n+1-\mathfrak{z})\mu h\big)| \le \vartheta(\eta)\eta^{-|\alpha|} \ \forall \alpha : |\alpha| \le m\Big\}, \tag{18.8.20}$$

$$\varrho = \vartheta(\ell)^{\frac{1}{2}}$$

and define $\bar{\ell}$ from (18.8.4)*.

Let us consider ℓ-admissible partition. Then we can apply the same arguments as before to cover zone $\{(x_2,x_3,\xi_2) : \varrho^2 \gtrsim \mu h\}$ and to prove that its contribution to the Tauberian remainder does not exceed Ch^{-2}.

Meanwhile contribution of zone $\{(x_2,x_3,\xi_2) : \ \ell \lesssim \bar{\ell}\}$ does not exceed $C\mu h^{-2}\bar{\varrho} \asymp C\mu h^{-1}|\log h|\bar{\ell}^{-1}$ with $\bar{\varrho} = \vartheta(\bar{\ell})^{\frac{1}{2}}$.

So, we need to cover zone $\{(x_2,x_3,\xi_2), \ell \ge C_0\bar{\ell}\}$. Consider particular element, and on this element

$$\sum_{\alpha:|\alpha|\le m} |\nabla^\alpha\big(W + (2n+1-\mathfrak{z})\mu h\big)|\ell^{|\alpha|} \asymp \varrho^2. \tag{18.8.21}$$

We will need

Proposition 18.8.9. *The contribution of each such element both to the Tauberian remainder and to an approximation error for two appropriate framing approximations do not exceed*

$$Ch^{-2}\ell^3 + C\mu h^{-1}\ell^2(h/\varrho\ell)^{-\delta} \tag{18.8.22}$$

with arbitrarily small exponent $\delta > 0$.

Proof. The proof is due to arguments of Section 5.2 based on the series of the scaling functions ℓ_k, ϱ_k with $k = m-1, \dots, 1$ defined by (18.8.20) with $\varrho(\eta) = \eta^{k+1}$ and ε_k defined by (18.8.6)* with $\delta' = \delta'_k > 0$, with the following modifications:

(a) When $\varrho_k^2 \ge \mu h$ (as $\mu h \le C_0$ only) we have an extra factor $\varrho_k^2/(\mu h)$ and therefore the first term in (18.8.21) carries no extra factor (unlike the second term).

(b) Due to factor $(h/\varrho\ell)^{-\delta}$ in the second term we do not need sophisticated arguments of Subsection 5.2.2 - the only ones where we needed a large smoothness.

Note that $\ell(h/\varrho\ell)^{\delta} \ge \bar{\ell}$. Really as δ is small enough this expression is monotone increasing function of ℓ; recall that $\ell \ge \bar{\ell}$. □

Therefore expression (18.8.22) does not exceed $C\big(h^{-2} + C\mu h^{-1}\bar{\ell}^{-1}\big)\ell^3$ and summation over partition returns $C\big(h^{-2} + C\mu h^{-1}\bar{\ell}^{-1}\big)$.

Remark 18.8.10. It follows from the analysis of the Problem 18.8.8 that under an extra non-degeneracy assumption

$$\sum_{\alpha:\ 1\le|\alpha|\le m} |\nabla^\alpha W| \ge \epsilon_0 \tag{18.8.23}_m$$

(as $\mu h \lesssim 1$) and

$$\sum_{\alpha:\ |\alpha|\le m} |\nabla^\alpha \big(W + (2n+1) - \mathfrak{z}\big)| \ge \epsilon_0 \tag{18.8.23}^*_m$$

(as $\mu h \gtrsim 1$) and with $(m,0) \prec (l,\sigma)$ both both contribution to the Tauberian remainder with $T = \bar{T} = \epsilon$ of the zone $\mathcal{Z}_{\mathsf{inn}}$ and extra approximation error do not exceed

$$Ch^{-2} + C\mu h^{-1-\delta}. \tag{18.8.24}$$

We leave to the reader the following moderately difficult problem:

Problem 18.8.11. Improve (18.8.24) to

$$Ch^{-2} + C\mu h|\log h|^{m-1}. \tag{18.8.25}_m$$

To do this one needs to improve (18.8.22) in an obvious way.

18.9 $d = 3$: Calculations and Main Theorems

18.9.1 Assembling what We Got

After corresponding estimates were derived in the previous section, following Subsection 13.5.2, we can rewrite (without increasing an error) the Tauberian expression

$$h^{-1}\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\Big(\bar{\chi}_T(t)\Gamma\big(\psi U\big)\Big)\,d\tau$$

as

$$\frac{1}{4\pi^2}\mu h^{-2}\sum_n \int \theta\big(-\xi_3^2-(2n+1)\mu h-W(x_2,x_3,\xi_2)\big)\alpha(x_2,x_3,\xi_2,\xi_3)\,dx_2dx_3d\xi_2d\xi_3$$

which in turn we can rewrite as

$$\frac{1}{2\pi^2}\mu h^{-2}\sum_n \int \big(-(2n+1)\mu h - W(x_2,x_3,\xi_2)\big)_+^{\frac12}\bar{\alpha}(x_2,x_3,\xi_2)\,dx_2dx_3d\xi_2$$

and then as

$$\frac{1}{2\pi^2}\mu h^{-2}\sum_n \int \big(-(2n+1)\mu h - W\big)_+^{\frac12}(1+\alpha')\psi F\sqrt{g}\,dx$$

where now $W = W(x,\mu^{-1})$, which in turn we rewrite as the sum of the main part $h^{-3}\mathcal{N}^{\mathsf{MW}}\psi dx$ and the correction term

$$\frac{1}{2\pi^2}\mu h^{-2}\sum_n \int \big(-(2n+1)\mu h - W\big)_+^{\frac12}(1+\alpha')\psi F\sqrt{g}\,dx- \frac{1}{2\pi^2}\mu h^{-2}\sum_n \int \big(-(2n+1)\mu h - V/F\big)_+^{\frac12}\psi F\sqrt{g}\,dx. \tag{18.9.1}$$

Note that

(18.9.2) As $\mu \gtrsim (h|\log h|)^{-1}$ the correction term does not exceed the an approximation error and thus we can skip it.

Indeed, in this case $\varepsilon \gtrsim \mu^{-1}$. Therefore in this case we are done and our main Theorems 18.9.4 and 18.9.6 below are proven.

18.9.2 Correction Term

However, in the case $h^{-\frac{1}{3}} \le \mu \lesssim C(h|\log h|)^{-1}$ we need to provide an alternative expression and the estimate for the correction term (18.9.1).

Proposition 18.9.1. *Let* $(1,2) \preceq (I,\sigma) \preceq (2,0)$. *Then modulo* $O(h^{-2})$ *one can rewrite the correction term* (18.9.1) *as*

$$h^{-3}\mathcal{N}^{\mathsf{MW}}_{\mathsf{3corr}}(x) = \frac{1}{4\pi^2}\sum_{n\ge 0}\Big(\big(\tau - W - (2n+1)\mu hF\big)_+^{\frac{1}{2}} - \big(\tau - V - (2n+1)\mu hF\big)_+^{\frac{1}{2}}\Big)\mu h^{-1}F - \frac{1}{6\pi^2}\big(W_-^{\frac{3}{2}} - V_-^{\frac{3}{2}}\big)h^{-3}. \tag{18.9.3}$$

Proof. Consider

$$\frac{1}{2\pi^2}\mu h^{-2}\sum_n \int \big(-(2n+1)\mu h - W\big)_+^{\frac{1}{2}}\alpha'\psi F\sqrt{g}\,dx$$

and replace the Riemannian sum by the corresponding integral; then with an error not exceeding

$$C\vartheta(\mu^{-1})(\mu h)^{\frac{3}{2}}h^{-3} \ll \mu^{\frac{1}{2}}h^{-\frac{3}{2}}$$

we can replace it by

$$\frac{1}{6\pi^2}\mu h^{-2}\int W_-^{\frac{3}{2}}\alpha\psi F\sqrt{g}\,dx \tag{18.9.4}$$

where with the same error we can replace W by V.

Consider (18.9.1) without α' and replace all Riemannian sums by integrals; then we get the second term in the right-hand expression of (18.9.1) with the opposite sign, making an error $O\big((\mu h)^{\frac{3}{2}}h^{-3}\big)$.

For $\mu \le h^{-\frac{1}{3}}$ the sum of this two expressions should be $O(h^{-2})$ and therefore (18.9.4) must be equal to the right-hand expression of (18.9.1). Then it is true for $\mu \ge h^{-\frac{1}{3}}$. □

Now let us estimate the correction term.

Proposition 18.9.2. *(i) Under non-degeneracy assumption* (18.2.15) *as* $(l,\sigma)\preceq(2,0)$

$$h^{-3}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}\le C(\mu h)^{\frac12}h^{-3}\begin{cases}\vartheta(\mu h) & \text{as } \mu\le h^{-\frac12},\\ \vartheta(\mu^{-1}) & \text{as } h^{-\frac12}\le\mu\le h^{-1};\end{cases}\tag{18.9.5}$$

in particular, it is $O(h^{-2})$ *provided* $(l,\sigma)\succeq(\frac32,0)$.

(ii) Under non-degeneracy assumption (18.2.16) *as* $(l,\sigma)=(2,0)$ *the correction term can be ignored.*

(iii) In the general case

$$h^{-3}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}\le C(\mu h)^{\frac12}\vartheta(\mu^{-1})h^{-3}+C\mu h^{-2}(\vartheta(\mu^{-1}))^{\frac12};\tag{18.9.6}$$

in particular, it is $O(h^{-2})$ *provided* $(l,\sigma)\succeq(2,0)$.

Proof. (a) To prove Statements (i) and (i) we first restore ξ_3 replacing $z_+^{\frac12}$ by $\frac12\int\theta(z-\xi_3^2)d\xi_3$. Then for fixed ξ_3 we apply arguments of the proof of Proposition 18.5.3, recovering estimate (18.9.5) albeit without factor $(\mu h)^{\frac12}$.

Then integration over zone $\{|\xi_3|\le(\mu h)^{\frac12}\}$ results in the right-hand expression in (18.9.5).

On the other hand, in the zone $\{|\xi_3|\ge(\mu h)^{\frac12}\}$ we can "save" one derivative by integrating by parts over ξ_3 rather x, so there will be an extra factor $(\mu h/\xi_3^2)$ which after integration over ξ_3 results in $(\mu h)^{\frac12}$ again resulting in the right-hand expression in (18.9.5).

(b) Proof of Statement (iii) is trivial. □

18.9.3 Approximation Error

Similarly to to Proposition 18.9.2 one can prove the following proposition (we leave easy details to the reader):

Proposition 18.9.3. *(i) Under non-degeneracy assumption* (18.2.15) *as* $(l,\sigma)\preceq(2,0)$ *an approximation error does not exceed*

$$C(\mu h)^{\frac12}h^{-3}\vartheta(\bar\varepsilon) \qquad \text{as } \mu\le h^{-1}\tag{18.9.7}$$

$$C\mu h^{-2}\vartheta(\bar\varepsilon) \qquad \text{as } \mu\ge h^{-1}\tag{18.9.8}$$

with

$$\bar{\varepsilon} = (\mu^{-1}h)^{\frac{1}{2}}|\log \mu|; \tag{18.9.9}$$

therefore this error is $O\big((1+\mu h)h^{-2}\big)$ *as* $(l,\sigma) \succeq (1,2)$.

(ii) As $(l,\sigma) = (2,0)$ *an approximation error is* $O\big((1+\mu h)h^{-2}\big)$.

(iii) In the general case an approximation error does not exceed (modulo remainder estimate)

$$C(\mu h)^{\frac{1}{2}}\vartheta(\bar{\varepsilon})h^{-3} + C\vartheta(\bar{\varepsilon})^{\frac{1}{2}}\mu h^{-2} \tag{18.9.10}$$

where the first term is $O\big((1+\mu h)h^{-2}\big)$ *and the second term does not exceed* $C\mu h^{-1-2/(l+2)}|\log h|^{-\sigma/(l+2)}$ *(which is the part of the remainder estimate) for sure.*

18.9.4 Main Theorems

Getting all our beans together and getting rid of assumption $F = 1$ we arrive to the following theorem:

Theorem 18.9.4. *Let* $d = 3$ *and* A *be a self-adjoint in* $\mathscr{L}^2(X)$ *operator given by* (18.1.1). *Let conditions* (18.1.3), (18.1.6) *be fulfilled in* $B(0,1) \subset X \subset \mathbb{R}^3$ *with* $(1,2) \preceq (l,\sigma) \preceq (\bar{l},\bar{\sigma}) \succeq (2,1)$. *Let* <u>*either*</u> *non-degeneracy assumption* (18.2.15) *be fulfilled* <u>*or*</u> $(l,\sigma) \succeq (2,0)$ *and non-degeneracy assumption* (18.2.16) *be fulfilled.*

(i) As $h^{-\frac{1}{3}} \le \mu \le Ch^{-1}$ *under additional condition* (18.2.27) *for two framing approximations as in footnote*[18)] *asymptotics*

$$|\int \Big(\tilde{e}(x,x,0) - h^{-3}\mathcal{N}_3^{\mathsf{MW}}(x,0) - h^{-3}\mathcal{N}_{3,\mathsf{corr}}^{\mathsf{MW}}(x,0)\Big)\psi(x)\,dx| \le Ch^{-2} \tag{18.9.11}$$

holds with magnetic Weyl expression given by $(13.2.9)_{(3)}$ *and with correction term* (18.9.3), *satisfying estimate* (18.9.5).

(ii) As $h^{-1} \le \mu$ *we consider Schrödinger-Pauli operator with* $\mathfrak{z} = 1$ *for two framing approximations as in footnote*[18)] *asymptotics*

$$\mathsf{R}^{\mathsf{MW}} := |\int \Big(\tilde{e}(x,x,0) - h^{-3}\mathcal{N}_3^{\mathsf{MW}}(x,0)\Big)\psi(x)\,dx| \le C\mu h^{-1} \tag{18.9.12}$$

holds with magnetic Weyl expression given by $(13.2.9)_{(3)}$.

Remark 18.9.5. Using rescaling technique we will be able in the next subsection to get rid of condition (18.2.27) in this and in the next theorems.

Now we are going to drop non-degeneracy assumption as $d = 3$.

Theorem 18.9.6. *Let $d = 3$ and A be a self-adjoint in $\mathscr{L}^2(X)$ operator given by* (18.1.1). *Let conditions* (18.1.3), (18.1.6) *be fulfilled in $B(0,1) \subset X \subset \mathbb{R}^3$ with $(1,2) \preceq (l,\sigma) \preceq (\bar{l},\bar{\sigma}) \succeq (2,1)$. Then*

(i) As $h^{-\frac{1}{3}} \le \mu \le Ch^{-1}$ under additional condition (18.2.27) *for two framing approximations as in footnote*[18] *asymptotics*

$$|\int \Big(\tilde{e}(x,x,0) - h^{-3}\mathcal{N}^{\mathsf{MW}}(x,0) - h^{-3}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x)\Big)\psi(x)\,dx| \le Ch^{-2} + C\mu h^{-1-2/(l+2)}|\log h|^{-\sigma/(l+2)} \tag{18.9.13}$$

holds with the magnetic Weyl expression given by $(13.2.9)_{(3)}$ *and with the correction term* (18.9.3), *satisfying estimate* (18.9.6).

(ii) As $h^{-1} \le \mu$, $F = 1$ we consider Schrödinger-Pauli operator with $\mathfrak{z} = 1$ for two framing approximations as in footnote[18] *asymptotics*

$$|\int \Big(\tilde{e}(x,x,0) - h^{-3}\mathcal{N}^{\mathsf{MW}}(x,0)\Big)\psi(x)dx| \le C\mu h^{-1-2/(l+2)}|\log h|^{-\sigma/(l+2)} \tag{18.9.14}$$

holds with magnetic Weyl expression given by $(13.2.9)_{(3)}$.

Remark 18.9.7. (i) Note that the second term in the right-hand expression (18.9.14) prevails as $\mu \ge h^{-l/(l+2)}|\log h|^{\sigma/(l+2)}$.

(ii) Using Remark 18.8.10 one can prove that under non-degeneracy assumption $(18.8.23)_m$ as $\mu h \lesssim 1$ and under non-degeneracy assumption $(18.8.23)^*_m$ as $\mu h \gtrsim 1$ with $W = V/F$, $2 \le m$, $(m,0) \prec (l,\sigma)$ remainder estimate 18.8.24 holds for R^{MW}:

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{-2} + C\mu h^{-1-\delta}. \tag{18.9.15}$$

(iii) Furthermore, using problem 18.8.11 one can prove that in the same framework remainder estimate $(18.8.25)_m$ holds for R^{MW}:

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{-2} + C\mu h|\log h|^{m-1}. \tag{18.9.16}_m$$

Problem 18.9.8. Either improve estimates (18.9.5), (18.9.6) of Proposition 18.9.2 or construct counter-examples, showing that the improvement is impossible.

18.9.5 Generalizations

Vanishing V

For $d = 3$ we need condition (18.2.27) only for $\mu h \le 1$.

(i) Consider first Theorem 18.6.10 with $\mu \le h^{-\frac{1}{3}}$. Then applying the standard scaling with $\varrho = \gamma^{\frac{1}{2}}$ and $\bar{\gamma}_0 = \mu^{-2}$ we will find ourselves either in the case of condition (18.2.27) fulfilled or in the case of $\mu_{\mathsf{new}} = 1$ when it is not needed. Then contribution of each partition element to the remainder is $O\big(h_{\mathsf{new}}^{-2}\big) = O\big(h^{-2}\gamma^3\big)$ and then the total remainder is $O(h^{-2})$. Therefore

(18.9.17) Theorem 18.6.10 holds without condition (18.2.27).

(ii) Consider now $h^{-\frac{1}{3}} \le \mu \le h^{-1}$. Then in the non-degenerate case (under assumption (18.2.15) or (18.2.16)) the remainder estimate was $O(h^{-2})$; plugging h_{new} we get the contribution of such ball to the remainder estimate does not exceed $Ch^{-2}\varrho^2\gamma^2 \asymp Ch^{-2}\gamma^3$ which results in the total contribution of all such balls $O(h^{-2})$. So,

(18.9.18) Theorem 18.9.4 holds without condition (18.2.27).

(iii) Consider the general case; recall that then estimate contains an extra term

$$R_3 := C\mu h^{-1-2/(l+2)} |\log h|^{-\sigma/(l+2)}. \tag{18.9.19}$$

However, this term does not translates well: after we plug μ_{new}, h_{new} it produces

$$C\mu h^{l/(l+2)} h^{-2} |\log(h/\varrho\gamma)|^{-\sigma/(l+2)} \times \gamma^{3-(l-1)/(2(l+2))}$$

and after multiplication by γ^{-3} we have γ in the negative degree.

On the other hand, we can introduce a different kind of scaling. Namely, introduce γ defined by

$$\gamma = \min\bigl\{\eta : \ |V| \le C\vartheta(\eta),\ |\nabla V| \le C\eta^{-1}\vartheta(\eta)\bigr\}, \tag{18.9.20}$$

$$\varrho = \gamma^{\frac{l}{2}} |\log\gamma|^{-\frac{\sigma}{2}}$$

where we assume so far that $(l,\sigma) \preceq (2,0)$.

(a) If $|V| \asymp \gamma^l |\log\gamma|^{-\sigma}$ we are in the degenerate situation with V_{new} disjoint from 0.

Plugging h_{new} into Ch^{-2} we get $Ch^{-2}\varrho^2\gamma^2$ which does not exceed $Ch^{-2}\gamma^3$. Plugging h_{new}, μ_{new} into R_3 we get

$$C\mu h^{-1-2/(l+2)} |\log(\frac{h}{\varrho\gamma})|^{-\sigma/(l+2)} \times \varrho^{2/(l+2)}\gamma^{-l/(l+2)} \times \gamma^3 \asymp \tag{18.9.21}$$

$$R_3\Bigl(|\log(\frac{h}{\rho\gamma})| \cdot |\log\gamma|/|\log h|\Bigr)^{-\sigma/(l+2)} \times \gamma^3$$

which does not exceed $R_3\gamma^3$ as $\sigma \ge 0$ and $R_3'\gamma^3$ as $\sigma < 0$ with

$$R_3' := C\mu h^{-1-2/(l+2)} |\log h|^{-\sigma/(l+2)} |\log(\mu h)|^{-\sigma/(l+2)}. \tag{18.9.22}$$

(b) If $|\nabla V| \asymp \gamma^{l-1}|\log\gamma|^{-\sigma}$ then after rescaling we find ourselves in the non-degenerate situation with V_{new} not necessarily disjoint from 0. However, we already examined this before and found that contribution of the ball to the remainder estimate would not exceed Ch_{new}^{-2} which in turn does not exceed $Ch^{-2}\gamma^3$ and then the total contribution of such balls does not exceed Ch^{-2}. So,

(18.9.23) Let $(l,\sigma) \preceq (2,0)$. Then Theorem 18.9.6 holds without condition (18.2.27) as $\sigma \ge 0$ and with the last term in the right-hand expression of (18.9.13) replace by (18.9.22) as $\sigma < 0$.

Problem 18.9.9. (i) Get rid of assumption (18.2.27) in Remark 18.9.7(ii), (iii). To do this use a scaling functions

$$\gamma = \min\bigl\{\eta : \sum_{\alpha:\,|\alpha|\le l-1} |\nabla^\alpha V/F| \le C\eta^{-|\alpha|}\vartheta(\eta)\bigr\}, \tag{18.9.24}$$

$$\varrho = \gamma^{\frac{l}{2}} |\log\gamma|^{-\frac{\sigma}{2}}.$$

(ii) Using this get rid of assumption $(I,\sigma)\preceq(2,0)$ in claim (18.9.23).

(iii) Improve our arguments and prove that one can replace R_3' by R_3 even as $\sigma<0$.

Vanishing F

We assume that g^{jk}, F^k have an extra smoothness 1 in comparison which is required in theorems we refer to. This assumption allows us to avoid problems straightening magnetic field. Let us introduce

$$\gamma=\epsilon|F|+\bar\gamma,\qquad \bar\gamma=\mu^{-\frac12}. \tag{18.9.25}$$

Then after recalling we have $\mu_{\mathsf{new}}=\mu\gamma^2$ and $h_{\mathsf{new}}=h/\gamma$.

(i) Consider first case $\mu\le h^{-\frac13}$. Then $\mu_{\mathsf{new}}\le h_{\mathsf{new}}^{-\frac13}$ as well and the contribution of $B\bigl(x,\gamma(x)\bigr)$ to the remainder is $O(h_{\mathsf{new}}^{-2})=O(h^{-2}\gamma^2)$ and the remainder does not exceed

$$Ch^{-2}\int\gamma(x)^{-1}\,dx \tag{18.9.26}$$

which does not exceed $Ch^{-2}\mu^{\frac12}$ in the general case, and $Ch^{-2}|\log\mu$, $Ch^{-2}|\log\mu$ under assumptions

$$|\nabla \boldsymbol{F}/V|\ge\epsilon_0, \tag{18.9.27}_1$$

$$\sum_{j,k}|\Delta_{jk}(\nabla\otimes\boldsymbol{F}/V)|\ge\epsilon_0 \tag{18.9.27}_2$$

respectively where $\Delta_{jk}(\nabla\otimes\boldsymbol{F})$ denote 2×2 minors of the matrix $(\nabla\otimes\boldsymbol{F})=(\partial_{x_j}F^k)$.

Note that assumption $(18.9.27)_1$ implies that after rescaling assumption (18.2.15) is fulfilled.

(ii) Consider now case $h^{-\frac13}\le\mu\le h^{-1}$. Under condition $(18.9.27)_1$ contribution of $B\bigl(x,\gamma(x)\bigr)$ to the remainder is $O(h_{\mathsf{new}}^{-2})=O(h^{-2}\gamma^2)$ and then the total remainder is $O(h^{-2}\log\mu)$ and it is $O(h^{-2})$ under assumption $(18.9.27)_2$.

We leave to the reader rather standard and tedious

Problem 18.9.10. Consider the case when assumption $(18.9.27)_1$ fails.

(iii) Finally, for $h^{-1} \lesssim \mu \lesssim h^{-2}$ magnitude of the remainder and the principal part strongly depend on the behavior of $\mathsf{mes}\{x, F(x) \le \eta\}$ as $\eta \to +0$. In particular, in the generic case

$$|\det(\nabla \otimes \boldsymbol{F})| \ge \epsilon_0 \tag{18.9.27}_3$$

the remainder is $O(\mu^{-2}h^{-4})$ while the principal part is $O(\mu^{-3}h^{-6})$ - if we consider Schrödinger operator (then for $\mu \ge C_0 h^{-2}$ principal part is 0 and remainder is $O(\mu^{-\infty})$).

(iii)* On the other hand, for Schrödinger-Pauli operator with $\mathfrak{z} = 1$ under assumption $(18.9.27)_2$ the principal part is $O(\mu h^{-2})$ and the remainder is $O(\mu h^{-1})$ as $\mu \ge h^{-1}$.

Other Generalizations

Problem 18.9.11. Get rid of condition $B(0,1) \subset X$. Use the rescaling method and recover remainder estimate $O(h^{-1})$ as $\mu \lesssim h^{-2}$.

Problem 18.9.12. (i) Generalize our results to the generalized Schrödinger-Pauli operator (17.1.6).

(ii) Generalize our results to the generalized Dirac operators (17.1.1) and (17.1.5).

Here Part (i) is easy but Part (ii) looks rather challenging.
Remark 18.5.13 stays.

Chapter 19

Multidimensional Magnetic Schrödinger Operator. Full-Rank Case

19.1 Introduction

19.1.1 Preface

In this and the next chapters we consider multidimensional Schrödinger operator

$$A = A_0 + V(x), \qquad A_0 = \sum_{j,k\le d} P_j g^{jk}(x) P_k, \tag{19.1.1}$$

$$P_j = hD_j - \mu V_j(x), \quad h \in (0,1],\ \mu \ge 1.$$

It is characterized by the *magnetic field intensity tensors* (F_{jk}) with

$$F_{jk} = \partial_k V_j - \partial_j V_k, \tag{19.1.2}$$

which is skew-symmetric $d \times d$-matrix, and $(F^j_p) = (g^{jk})(F_{kp})$ which is equivalent to the skew-symmetric matrix $(g^{jk})^{\frac12}(F_{jk})(g^{jk})^{\frac12}$.

Compare this with 2D and 3D cases when we could characterize intensity by a (pseudo)scalar F and (pseudo)vector $\boldsymbol{F}$ respectively.

Then

(19.1.3) All eigenvalues of (F^j_k) are $\pm i f_p$ ($f_l > 0$, $p = 1, \dots, r$) and 0 of multiplicity $d - 2r$ where $2r = \mathsf{rank}(F^j_k)$.

In this chapter we assume that the magnetic field intensity tensor has a full rank at each point x:

$$\mathsf{rank}(F_k^j)(x) = 2r = d \quad \text{and} \quad |(F_k^j)^{-1}(x)| \le c_0 \tag{19.1.4}$$

and (under certain conditions) we derive sharp spectral asymptotics (with the remainder estimate $O\bigl(\mu^{-1}h^{1-d}\bigr)$ as $\mu h \lesssim 1$ while the principal part has a magnitude h^{-d}. As $\mu h \gtrsim 1$ we consider the corresponding Schrödinger-Pauli operator and derive remainder estimate $O\bigl(\mu^{r-1}h^{1-r}\bigr)$ hile the principal part has a magnitude $\mu^r h^{-r}$. The typical (but different from the general case) example (already studied in Chapters 13 and 18) is 2D magnetic Schrödinger operator with $r = 1$.

As usual, we consider operator in some domain or on some manifold X with some boundary conditions, assuming that it is self-adjoint in $\mathscr{L}^2(X)$ and denote by $e(x, y, \tau)$ Schwartz' kernel of it spectral projector.

As usual we assume that conditions (13.2.4) and (13.2.5) are fulfilled i.e.

$$\epsilon_0 \le \sum_{j,k} g^{jk}\eta_j\eta_k \cdot |\eta|^{-2} \le c \quad \forall \eta \in \mathbb{R}^d \setminus 0 \quad \forall x \in B(0,1) \tag{19.1.5}$$

and

$$X \supset B(0,1). \tag{19.1.6}$$

19.1.2 Canonical Form

Recall (see e.g. Subsection 13.2.2) that if $X = \mathbb{R}^d$ and g^{jk}, F_{jk}, V are constant then operator (19.1.1) is unitary equivalent to

$$\sum_{1\le j\le r} f_j(h^2D_j^2 + \mu^2 x_j^2) + \sum_{r+1\le j\le d-2r} h^2D_j^2 + V \tag{19.1.7}$$

and $e(x, x, \tau) = h^{-d}\mathcal{N}_d^{\mathsf{MW}}(\tau)$ is defined by (13.2.9); in particular, under condition (19.1.4) decomposition (19.1.7) becomes

$$\sum_{1\le j\le r} f_j(h^2D_j^2 + \mu^2 x_j^2) + V \tag{19.1.8}$$

and

$$h^{-d}\mathcal{N}_d^{\mathsf{MW}}(\tau) := (2\pi)^{-r}\mu^r h^{-r} \sum_{\alpha\in\mathbb{Z}^{+r}} \theta\Bigl(\tau - \sum_j (2\alpha_j+1)f_j\mu h - V\Bigr) f_1\cdots f_r\sqrt{g} \tag{19.1.9}$$

with $g = \det(g_{jk})$, $(g_{jk}) = (g^{jk})^{-1}$ and Heaviside function θ.

In particular,

(19.1.10) For the toy-model operator under condition (19.1.4) (and only in this case) the spectrum is pure-point (of the infinite multiplicity) consisting of *Landau levels*

$$E_\alpha := \sum_j (2\alpha_j + 1) f_j, \qquad \alpha \in \mathbb{Z}^{+r}. \tag{19.1.11}$$

Now in the general case (i.e. for $X \neq \mathbb{R}^d$, and variable V and, may be, g^{jk}, F_{jk}) we are interested in asymptotics of the spatially mollified spectral function, i.e.

$$\mathsf{N}^{\mathsf{MW}}_\psi := \int e(x,x,0)\psi(x)\,dx \tag{19.1.12}$$

as $h \to +0, \mu \to +\infty$ where ψ is a fixed function, smooth and compactly supported in X. As $\mu h \ge C_0$ the result will be trivial and therefore instead of the original Schrödinger operator we will need to consider the generalized Schrödinger-Pauli operator

$$A - \sum_j \mathfrak{z}_j f_j \mu h \tag{19.1.13}$$

with constants $\mathfrak{z}_j \in \mathbb{R}$.

The principal part of such asymptotics under some reasonable and obvious conditions is of magnitude h^{-2r} as $\mu h \lesssim 1$ and $\mu^r h^{-r}$ as $\mu h \gtrsim 1$.

On the other hand, the remainder estimate is $O(\mu h^{1-2r} + \mu^r h^{-r})$ unless one imposes some non-degeneracy assumption while under the strongest possible assumption one can expect remainder estimate $O\big(\mu^{-1}h^{1-2r} + \mu^{r-1}h^{1-r}\big)$.

Remark 19.1.1. However, even if g^{jk}, F_{jk}, V are constant the remainder estimate is as bad as μh^{1-d} (for $\mu h \ll 1$) only if $f_1, \dots, f_r$ are commensurable. Otherwise as $\mu h \lesssim 1$ the remainder estimate is between $O\big(\mu^r h^{-r}\big)$ and $O\big(\mu h^{1-2r}\big)$ depending on the non-commensurability of $f_1, \dots, f_r$.

Probably it is the same remainder estimate as an error in the "equality"

$$h^{-d}\mathcal{N}^{\mathsf{MW}}(0) \approx h^{-d}\mathcal{N}^{\mathsf{W}}_\infty(0) \tag{19.1.14}$$

where $h^{-d}\mathcal{N}_\infty^{\mathsf{W}}$ denotes Weyl approximation with many terms. Considering the left-hand expression as an r-dimensional Riemannian sum, passing to the integral and correcting it so if instead of θ there was a smooth function we would get an error $O(h^{-d}(\mu h)^\infty)$, we get a right-hand expression.

Also obviously all Hamiltonian trajectories are periodic if and only if $f_1, \dots, f_r$ are commensurable.

Problem 19.1.2. Explore error in (19.1.14) when $f_1, \dots, f_r$ are non-commensurable. It definitely would depend on how these numbers are non-commensurable (something related to their diophantine properties - as $r = 2$ it is related to Liouville's exponent for f_1/f_2).

Recall from Section 13.3 that in the smooth case for $d = 2$ one can reduce operator in question to the canonical form

$$\sum_{m+k+j\ge 1} \mu^{2-2k-2m-j} h^j a_{m,k,j}(x_2, \mu^{-1}hD_2)\big(h^2D_1^2 + \mu^2 x_1^2\big)^m \tag{19.1.15}$$

with $a_{1,0} = F\circ\Psi_0$, $a_{0,1} = V\circ\Psi_0$ and a certain diffeomorphism $\Psi_0 : T\mathbb{R}^1 \to \mathbb{R}^2$. Then one can replace harmonic oscillator $h^2D_1^2+\mu^2x_1^2$ by one of its eigenvalues $(2\alpha+1)\mu h$ with $\alpha \in \mathbb{Z}^+$; we ignore terms with $j \ge 1$.

Thus, for $\mu h \le \epsilon_0$ our operator looked like a family (with $C_0(\mu h)^{-1}$ elements) of 1-dimensional $\mu^{-1}h$-pseudodifferential operators with the principal symbols $\big((2\alpha+1)\mu hF + V\big)\circ\Psi_0$.

Spectral asymptotics for such operators are very sensitive to the degeneracy of the symbol but under the non-degeneracy condition $|b| + |\nabla b| \ge \epsilon_1$ with $b = a_{0,1}\lambda + a_{1,0}$ with $\lambda \in \mathbb{R}^+$ this asymptotics has a principal part of the magnitude μh^{-1} and a remainder $O(1)$. This non-degeneracy condition is equivalent to $|\nabla V/F| \ge \epsilon_1$ and the final asymptotics has its principal part of magnitude h^{-2} and a remainder $O(\mu^{-1}h^{-1})$ [1)].

On the other hand, as $\mu h \ge \epsilon_0$ we had the family of no more than C_0 of $\mu^{-1}h$-pseudodifferential operators, then the non-degeneracy condition became $|(2\alpha+1)\mu h + (V/F)| + |\nabla(V/F)| \ge \epsilon_1$ and the final asymptotics has its principal part of magnitude μh^{-1} and a remainder $O(1)$ [1)].

Non-smoothness prevented us from the complete canonical form but we had a "poor man" canonical form which was sufficient; see Section 18.3.

[1)] We could also consider a weaker non-degeneracy condition invoking second derivatives.

Multidimensional case is much more tricky. Under assumption (19.1.4) one could expect a canonical form

$$\sum_{m\in\mathbb{Z}^{+r},k,j:|m|+k+j\ge 1} \mu^{2-2k-2|m|-j}h^j a_{m,k,j}(x'',\mu^{-1}hD'')H^m \tag{19.1.16}$$

with $H=(H_1,\dots,H_r)$, harmonic oscillators $H_i=h^2D_j^2+\mu^2x_i^2$ $a_{(m,0,0)}=f_j\circ\Psi_0$ as $|m|=0$ with $m_i=\delta_{ji}$ and $a_{(0,1,0)}=V\circ\Psi_0$ where now we consider diffeomorphism $\Psi_0: T\mathbb{R}^r=\mathbb{R}^{2r}\to\mathbb{R}^{2r}$ with $x''=(x_{r+1},\dots,x_{2r})$.

In this case for $\mu h\le\epsilon_0$ one would get a family (with $C_0(\mu h)^{-r}$ elements) of r-dimensional $\mu^{-1}h$-pseudodifferential operators, and *for each of them* the principal part of asymptotics would be of magnitude $\mu^r h^{-r}$, and under proper non-degeneracy assumption remainder $O(\mu^{r-1}h^{1-r})$ and the final asymptotics has its principal part of the magnitude $\mu^r h^{-r}\times(\mu h)^{-r}h^{-2r}=h^{-2r}$ and a remainder $O(\mu^{r-1}h^{1-r}\times(\mu h)^{-r}h^{-2r})=O(\mu^{-1}h^{1-2r})$.

If $\mu h\ge\epsilon_0$ and we consider operatore (19.1.13) one would have the family of no more than C_0 of $\mu^{-1}h$-pseudodifferential operators, under proper non-degeneracy condition $|b|+\nabla b|\ge\epsilon_1$, $b:=\sum_j(2\alpha_j+1)\mu h f_j+V$, the final asymptotics has its principal part of magnitude $\mu^r h^{-r}$ and a remainder $O(\mu^{-1}h^{1-r})$.

Remark 19.1.3. As $f_j=\mathsf{const}$ this non-degeneracy assumption becomes $|\nabla V|\ge\epsilon_0$ and we will be able to replace it by a weaker assumption $|\nabla V|\le\epsilon_0 \implies |\det \mathsf{Hess}\, V|\ge\epsilon_0$.

19.1.3 Resonances

However, the resonances prevent us from reducing our operator to the desired canonical form (19.1.6) even in the smooth case. In fact, *m-th order resonances*

$$\sum_j f_j\gamma_j=0 \qquad \text{as } \gamma\in\mathbb{Z}^r \text{ and } |\gamma|:=\sum_j|\gamma_j|=m\ge 2 \tag{19.1.17}$$

prevent us from reducing properly terms

$$\sum_{\alpha,\beta:|\alpha|+|\beta|=m;\ k,j} \mu^{2-2k-|\alpha|-|\beta|-j}h^j a_{\alpha,\beta;k,j}(x'',\mu^{-1}hD'')(hD')^\alpha(\mu x')^\beta. \tag{19.1.18}$$

In particular, due to the 2-*nd order resonances* $f_j \approx f_k$ ($k \neq j$) we can reduce the main part of operator only to

$$\sum_{\mathfrak{m}\in\mathfrak{M}} \sum_{j,k\in\mathfrak{m}} a_{jk}(x'', \mu^{-1}hD'')Z_j^* Z_k + a_0(x'', \mu^{-1}hD'') \tag{19.1.19}$$

with $Z_k = hD_k + i\mu x_k$ where $\mathfrak{m} \in \mathfrak{M}$ are disjoint subsets of $\{1, \dots, r\}$ and eigenvalues of each of matrices $(a_{jk})_{j,k\in\mathfrak{m}}$ are close to one another (and to f_j). This leads to the necessity of the matrix rather than the scalar non-degeneracy (microhyperbolicity) condition.

Further, the 3-*rd order resonances* $f_i \approx f_j + f_k$ (with possible $j = k$) prevent us from getting rid of the terms

$$\mu^{-1} a_{jkl}(x'', \mu^{-1}hD'')Z_j^* Z_k Z_l \tag{19.1.20}$$

and their adjoints

$$\mu^{-1} a_{jkl}^*(x'', \mu^{-1}hD'')Z_j Z_k^* Z_l^* \tag{19.1.20}^*$$

and these terms appear as the perturbations of the main part of the operator unless F_{jk} and g^{jk} are constant.

Furthermore, the fourth order resonances $f_i = f_j + f_k + f_l$ and $f_i + f_j = f_k + f_l$ where i, j, k, l may coincide but in the second case $(i, j) \neq (k, l)$ leave us with the whole bunch of terms instead of just $\mu^{-2} a_{jk} H_j H_k$ and but these terms are smaller than those produced by the third order resonances and rather harmless.

More precisely, the symbol of the reduced operator is

$$\mu^2 \sum_{\mathfrak{m}\in\mathfrak{M}} \sum_{j,k\in\mathfrak{m}} a_{jk}\zeta_j^\dagger \zeta_k + a_0 + \mu^2 \sum_{\mathfrak{n}\in\mathfrak{N}} \sum_{j,k,l\in\mathfrak{n}} \operatorname{Re} a_{jkl}\zeta_j^\dagger \zeta_k \zeta_l + \dots \tag{19.1.21}$$

where $\zeta_j = \xi_j + ix_j$ are symbols of $\mu^{-1}h$ differential operators $\mu^{-1}Z_j$ and precise definition of $\mathfrak{N}$ will appear later. Recall that † means a complex conjugation for scalars and a Hermitian conjugation for matrices.

Remark 19.1.4. (i) Resonances of m-th order become important only as smoothness is large enough (at least $(m, 0)$).

(ii) If we assume that g^{jk} and F_{jk} are constant then m-th order resonances affect only terms (19.1.18) without factor μ^2 i.e.

$$\sum_{\alpha,\beta:|\alpha|+|\beta|=m;\ k,j} \mu^{-2k-|\alpha|-|\beta|-j} h^j a_{\alpha,\beta;k,j}(x'', \mu^{-1}hD'')(hD')^\alpha (\mu x')^\beta. \tag{19.1.18}'$$

19.1.4 Dynamics and Microhyperbolicity

If operator in its canonical form is

$$\sum_{1\le j\le r} f_j(x'',\mu^{-1}hD'')(h^2D_j+\mu^2x_j^2)+V(x'',\mu^{-1}hD'') \tag{19.1.22}$$

then in the classical dynamics $(\xi_j^2+\mu^2x_j)^2=\rho_j=\mathsf{const}$ and dynamics in (x',ξ') is described by the Hamiltonian

$$b(x'',\xi'',\rho_1,\dots,\rho_r)\coloneqq \sum_{1\le j\le r} f_j(x'',\xi'')\rho_j+V(x'',\xi''); \tag{19.1.23}$$

where with respect to $x''=(x_{r+1},\dots,x_d)$ we use $\hbar$-quantization with $\hbar=\mu^{-1}h$ and therefore this dynamics is

$$\frac{dx''}{dt}=\mu^{-1}\nabla_{\xi''}b(x'',\xi''),\qquad \frac{d\xi''}{dt}=-\mu^{-1}\nabla_{x''}b(x'',\xi'') \tag{19.1.24}$$

$$b(x'',\xi'')=\tau$$

and therefore the microhyperbolicity assumption $|b-\tau|+|\nabla b|\ge\epsilon_0$ depends on $\boldsymbol{\rho}$; for each $\boldsymbol{\rho}$ with $|b(x'',\xi'',\boldsymbol{\rho})-\tau|\le\epsilon_0$ there exists direction $\ell=\ell(\boldsymbol{\rho})$ such that $\langle\ell,\nabla\rangle b(x'',\xi'',\boldsymbol{\rho})\ge\epsilon_0$ and we know that this is preserved until time $T^*=\epsilon\mu$.

However, if there are 3-rd order resonances situation becomes more complicated: ρ_j are evolving with the speed $O(1)$ and we can take only $T^*=\epsilon$ (which leads to the less sharp remainder estimate).

To remedy this situation we may assume that ℓ does not depend on $\boldsymbol{\rho}$ which is the case when $f_j=\mathsf{const}$ (then microhyperbolicity condition is $|\nabla V|\ge\epsilon_0$). More generally, we need to assume that $\{1,\dots,r\}$ is partitioned into subsets $\mathfrak{n}\in\mathfrak{N}$ such that 2-nd and 3-rd order resonances involve indices from the same subset $\mathfrak{n}$ only, and that ℓ depends on $\boldsymbol{\lambda}=(\lambda_{\mathfrak{n}})_{\mathfrak{n}\in\mathfrak{N}}$ with $\lambda_{\mathfrak{n}}=\sum_{j\in\mathfrak{n}}f_j\rho_j$ rather than on $\boldsymbol{\rho}$.

More general definitions of the microhyperbolicity and $\mathfrak{N}$-microhyperbolicity working also in the cases when even the main part is not in the form (19.1.22) will be given later (see Definitions 19.2.4 and 19.2.5).

19.1.5 Regularity Assumptions and Mollification

We assume that

$$g^{jk}\in \mathscr{C}^{\bar l,\bar\sigma},\qquad V\in\mathscr{C}^{l,\sigma}, \tag{19.1.25}$$

and

$$V_j = \partial_j \phi_j, \qquad \phi_j \in \mathscr{C}^{\bar{l}+2,\bar{\sigma}} \tag{19.1.25}_2$$

where the last assumption is a bit stronger than more natural $F_{jk} \in \mathscr{C}^{\bar{l},\bar{\sigma}}$ or $V_{\in} \mathscr{C}^{\bar{l}+1,\bar{\sigma}}$.

Also due to problems appearing when we reduce to a canonical form, mollification parameter in the intermediate magnetic field case is $\varepsilon = C\mu^{-1}$ rather than $\varepsilon = C(\mu^{-1}h|\log h|)^{\frac{1}{2}}$ as in the previous Chapter 18, therefore the threshold between weak magnetic field ($\varepsilon = C\mu h|\log h|$) and intermediate one is $\mu = (h|\log h)^{-\frac{1}{2}}$ rather than $\mu = (h|\log h)^{-\frac{1}{3}}$ and we also need to assume a larger regularity than there.

19.1.6 Plan of the Chapter

This Chapter consists of six more Sections.

As usual, we start from the Section 19.2 devoted to the weak magnetic field when asymptotics is defined by evolution to time $T = \epsilon\mu^{-1}$. We also study the classical dynamics here.

Again, following the standard scheme, Section 19.3 is devoted to the canonical form, in Section 19.4 we consider the case of the temperate magnetic field $\mu \le \epsilon(h|\log h|)^{-1}$ (overlapping with Section 19.2). Next, in Section 19.5 we consider the case of the intermediate magnetic field $\epsilon(h|\log h|)^{-1}\mu \le \epsilon h^{-1}$.

In the general case we assume some microhyperbolicity assumption (see Definition 19.2.4 but there is also stronger $\mathfrak{N}$-microhyperbolicity, see Definition 19.2.5). If there are no 2-nd order resonances, then this condition means that $\lambda_1\nabla(V/f_1) + ... + \lambda_r\nabla(V/f_r) \ne 0$ as long as $\lambda_1 \ge 0, ..., \lambda_r \ge 0$ and $\lambda_1 + ... + \lambda_r > 0$.

We also consider case of constant g^{jk}, F_{jk} and in this case instead of the microhyperbolicity assumption $\nabla V \ne 0$ we assume a weaker non-degeneracy assumption $\nabla V = 0 \implies \det \mathsf{Hess}\, V \ne 0$.

Finally, for the main course, in Section 19.6 we consider two cases of the strong magnetic field $\epsilon h^{-1} \le \mu \le Ch^{-1}$ and $\mu \ge Ch^{-1}$ respectively.

Furthermore, in Section 19.7 we consider the case when the rank of $\{\nabla(V/f_1), ..., \nabla(V/f_r)\}$ is less than r (usually $(r-1)$) at some points. There we assume that coefficients are regular.

19.2 Weak Magnetic Field

As we mentioned, in the weak magnetic field we consider original (x,ξ) coordinates. As we explained, we can take x-scale exactly as in Chapter 18

$$\varepsilon = C\mu h|\log h| \tag{19.2.1}$$

and therefore to satisfy logarithmic uncertainty principle we can take ξ-scale μ^{-1} [2)]. By no means ε is larger than $C(\mu^{-1}h|\log h|)^{\frac{1}{2}}$ needed to consider $\mu^{-1}h$-pseudodifferential operator with the symbol smooth in ε-scale in both x and ξ and therefore we cannot make a reduction here; only a some kind of the quasireduction as in Chapter 18 in the case the of the weak magnetic field is possible.

19.2.1 Heuristics. Classical dynamics

Smooth theory. Classical Dynamics

Here we are interested in the classical dynamics generated by symbol $a(x,\xi) \coloneqq \mu^2 a^0(x,\xi) + V(x)$ with

$$a^0(x,\xi) \coloneqq \sum_{j,k} g^{jk} p_j p_k, \qquad p_j = \mu^{-1}\xi_j - V_j(x) \tag{19.2.2}$$

on the energy levels close to 0 for time $t : |t| \le T^*$ with $T^* = \epsilon\mu$. On the energy levels below c_0 we have

$$|p_j| \le C\mu^{-1}. \tag{19.2.3}$$

At this heuristic stage we will not look at the smoothness (thus assuming that l is large enough).

First of all, exactly as in the previous Chapter 18, we can find $\phi_{jk} \in \mathscr{F}^{\bar{l},\bar{\sigma}}$ (see Remark 18.3.2) such that for $q_j \coloneqq x_j - \sum_k \phi_{jk}(x)p_k$

$$\{p_m, q_j\} = O(\mu^{-2}). \tag{19.2.4}$$

Really,

$$\{p_m, p_k\} = \mu^{-1}F_{km} \tag{19.2.5}$$

[2)] Recall that we consider $\mu^{-1}h$-differential operators.

and therefore $\{p_m, q_j\} = \mu^{-1}\delta_{mj} - \mu^{-1}\sum_{j,k}\phi_{jk}F_{km}$ and one needs to take

$$(\phi_{jk}) = (F_{jk})^{-1}. \tag{19.2.6}$$

Then one can see easily that

$$\{q_j, q_k\} \equiv \{x_j, q_k\} \equiv \mu^{-1}\phi_{jk} \qquad \mathsf{mod}\ O(\mu^{-2}) \tag{19.2.7}$$

and therefore

$$\mu^2\{a^0, q_j\} = O(\mu^{-1}), \qquad \{V, q_j\} = O(\mu^{-1}) \tag{19.2.8}$$

which implies that

(19.2.9) In the classical evolution at energy levels below c_0 for time $t : |t| \le \epsilon\mu$ increment of q_j does not exceed $C\mu^{-1}|t| \le \epsilon_1$;

(19.2.10) In the classical evolution at energy levels below c_0 for time $t : |t| \le \epsilon\mu$ increment of x_j does not exceed $C\mu^{-1}(|t|+1) \le \epsilon_1$.

One can see easily that in the case of constant g^{jk}, F_{jk}

$$\mu^2\{a^0, q_j\} = 0, \qquad \{V, q_j\} = \mu^{-1}\sum_k \phi_{jk}\partial_k V \tag{19.2.8}'$$

and therefore

(19.2.11) In the case of constant g^{jk}, F_{jk} the classical evolution for time $t : |t| \le \epsilon\mu$ is approximately described by equation[3)]

$$\frac{d}{dt}x_j = \mu^{-1}\sum_k \phi_{jk}\partial_k V \tag{19.2.12}$$

along which V is preserved.

To describe evolution more precisely in the general case let us consider a point $\bar{x}$. Consider $\mathfrak{M}(\bar{x})$ a partition of $\{1, \dots, r\}$ such that $|(f_i - f_j)(\bar{x})| \le \epsilon$ iff i, j belong to the same element $\mathfrak{m}$ of this partition (so 2-nd order resonances involve indices from the same subset $\mathfrak{m}$ only).

[3)] This equation describes approximately coordinates x_j but *not* velocities.

Then we can introduce

$$\zeta_j(x,\xi) = \sum_{1\le k\le 2r} \alpha_{jk}(x) p_k(x,\xi), \qquad j = 1, \dots, r \tag{19.2.13}$$

with complex coefficients $\alpha_{jk} \in \mathscr{F}^{\bar{I},\bar{\sigma}}$ such that

$$\{\zeta_j, \zeta_k\} = 0, \quad \{\zeta_j^\dagger, \zeta_k\} = 2i\mu^{-1}\delta_{jk} \quad \text{at} \ \ \Sigma^0 := \big\{(x,\xi) : \ p_1 = \dots = p_{2r} = 0\big\} \tag{19.2.14}$$

where as usual † means complex conjugation, and therefore

$$\{\zeta_j, \zeta_k\} \equiv 0, \quad \{\zeta_j^\dagger, \zeta_k\} \equiv 2i\mu^{-1}\delta_{jk} \qquad \mathsf{mod}\ O(\mu^{-2}) \quad \text{as} \ \ |p| \le c\mu^{-1} \tag{19.2.15}$$

and also

$$a^0 = \frac{1}{2}\mu^2 \sum_{\mathfrak{m}} \sum_{j,k\in\mathfrak{m}} a_{jk}(x)\zeta_j^\dagger(x,\xi)\zeta_k(x,\xi) \tag{19.2.16}$$

with Hermitian matrices $\big(a_{jk}\big)_{j,k\in\mathfrak{m}}$ close to scalar matrices $f_{\mathfrak{m}} I_{\#\mathfrak{m}}$ of the same dimensions.

Note that Σ^0 is a symplectic manifold and $\mathbb{R}^d \ni x$ inherits its symplectic form, a volume form, and a Hamiltonian field (we call it "Liouvillian field") respectively:

$$\frac{1}{2}\sum_{j,k} F_{jk}\, dx_j \wedge dx_k, \tag{19.2.17}$$

$$|\det F|^{\frac{1}{2}}\, dx_1 \wedge \dots \wedge dx_d = f_1 \cdots f_r \sqrt{g}\, dx, \tag{19.2.18}$$

$$\mathcal{L}_\psi = -\sum_{j,k} \phi_{jk}(\partial_j \psi)\partial_k. \tag{19.2.19}$$

Note also that

$$a^0_{\mathfrak{m}} := \frac{1}{2}\mu^2 \sum_{j,k\in\mathfrak{m}} a_{jk}(x)\zeta_j^\dagger(x,\xi)\zeta_k(x,\xi) \tag{19.2.20}$$

satisfy

$$\{a^0, a^0_{\mathfrak{m}}\} = O(1), \qquad \{V, a^0_{\mathfrak{m}}\} = O(1). \tag{19.2.21}$$

Therefore an increment of $a^0_{\mathfrak{m}}$ for time t does not exceed $C|t|$ and thus $a^0_{\mathfrak{m}}$ are *moderate* but not necessarily *slow variables* and their increment for $t = T^* \asymp \mu$ could be rather large.

Now we can replace ζ_j by

$$\zeta_{j,\mathsf{new}} = \zeta_j - \sum_{kl} \beta_{jkm}(x)\eta_k\eta_m \tag{19.2.22}$$

with $\beta_{jkm} \in \mathscr{F}^{\bar{l}-1,\bar{\sigma}}$ to make

$$\{\zeta_j, \zeta_k\} \equiv 0, \quad \{\zeta_j^\dagger, \zeta_k\} \equiv 2i\mu^{-1}\delta_{jk} \qquad \mathsf{mod}\ O(\mu^{-3}) \tag{19.2.23}$$

where for the sake of simplicity we use notations $\eta_{2k-1} \coloneqq \mathsf{Re}\,\zeta_k$, $\eta_{2k} \coloneqq \mathsf{Im}\,\zeta_k$, $k = 1, \dots, r$.

Then

$$a^0 = \frac{1}{2}\mu^2 \sum_{\mathfrak{m}} \sum_{j,k\in\mathfrak{m}} a_{jk}(q)\zeta_j^\dagger\zeta_k + \frac{1}{3}\mu^2 \sum_{j,k,m} a_{jkl}\,\eta_j\eta_k\eta_m + \dots, \tag{19.2.24}$$

$$V = V(q) + \sum_j a_j(q)p_j + \dots \tag{19.2.25}$$

where dots denote terms with $O(\mu^{-1})$ gradients.

These cubic terms in (19.2.24) and linear terms in (19.2.25) are the only sources of the trouble because Poisson brackets $\{\tilde{a}^0_{\mathfrak{m}}, \tilde{a}^0_{\mathfrak{m}'}\} = O(\mu^{-1})$ and $\{\tilde{a}^0_{\mathfrak{m}}, V(q)\} = O(\mu^{-1})$ where $\tilde{a}^0_{\mathfrak{m}}$ are defined by (19.2.20) with $a_{jk}(x)$ replaced by $a_{jk}(q)$.

To get rid of these terms we can redefine ζ_j again replacing them by $\zeta_j + \{S, \zeta_j\}$ with

$$S = \mu \sum_{k,m,n} \gamma_{kmn}\eta_k\eta_m\eta_n + \mu^{-1} \sum_m \gamma_m\eta_m. \tag{19.2.26}$$

This replacement preserves (19.2.14), (19.2.15) and (19.2.19) and, modulo terms with $O(\mu^{-1})$ gradients, it is equivalent to the replacement of $a^0 + V$ by

$$a^0 + V + \{S, a^0 + V\}. \tag{19.2.27}$$

We can always choose γ_j killing a_j and if there is no 3-rd order resonances we can choose γ_{jkm} killing a_{jkm}; in the general case we can reduce $a^0 + V$ to

$$\sum_{\mathfrak{m}} \tilde{a}^0_{\mathfrak{m}} + \mu^2\,\mathsf{Re} \sum_{j,k,m:|f_j - f_k - f_m|\le\epsilon} a_{jkm}(q)\,\zeta_j^\dagger\zeta_k\zeta_m + V(q). \tag{19.2.28}$$

Example 19.2.1. Consider $p_j = \xi_j$ as $j = 1, \dots, r$ and $p_{j+r} = \xi_{r+j} + x_j$; then $\zeta_j = \xi_j + i(\xi_{r+j} + x_j)$. Let consider a symbol which is the real part of the quadratic form of $(\zeta_1, \zeta_1^\dagger, \dots \zeta_r, \zeta_r^\dagger)$ with a linear coefficients coinciding at $x = 0$ with $\sum_j f_j \zeta_j^\dagger \zeta_j$ with constant $f_1, \dots, f_r$.

Let the only term with non-constant coefficients be

$$2\,\mathsf{Re}\big(\alpha x_1 \zeta_2 \zeta_3\big) = \mathsf{Re}\big(\alpha i(\zeta_1^\dagger - \zeta_1 + 2i\xi_{r+1})\zeta_2\zeta_3\big) = \mathsf{Re}\big(\alpha i \zeta_1^\dagger \zeta_2 \zeta_3\big) - \mathsf{Re}\big(\alpha i \zeta_1 \zeta_2 \zeta_3\big) - 2\,\mathsf{Re}\big(\alpha \xi_{r+j} \zeta_2 \zeta_3\big)$$

with $\alpha \in \mathbb{C}$. Here ξ_{1+r} is nothing but a constant parameter in the dynamics; let pick it equal to 0.

Consider two important cases:

(i) $r = 2$, $\zeta_3 := \zeta_2$; one can see easily that we arrive exactly to the case with non-zero cubic terms (the last term in the right-hand expression could be removed but not the first one as $f_1 = 2f_2$).

(ii) $r = 3$; one can see easily that we arrive exactly to the case with non-zero cubic terms (the last term in the right-hand expression could be removed but not the first one as $f_1 = f_2 + f_3$).

Example 19.2.2. (i) Consider

$$\mu^{-2} a = f_1 \zeta_1^\dagger \zeta_1^\dagger + f_2 \zeta_2^\dagger \zeta_2^\dagger + \mathsf{Re}\big(\alpha \zeta_1^\dagger \zeta_2^2\big)$$

with $f_1 = 2f_2$; let $\varrho_j = \mu^2 \zeta_j^\dagger \zeta_j$; then

$$\frac{d\varrho_2}{dt} = \{a, \varrho_2\} = \mu^4\, \mathsf{Re}\{\alpha \zeta_1^\dagger \zeta_2^2, \zeta_2^\dagger \zeta_2\} = -4\mu^3\, \mathsf{Re}\big(\alpha i \zeta_1^\dagger \zeta_2^2\big);$$

$$\frac{d}{dt}\mu^3\, \mathsf{Re}(\alpha \zeta_1^\dagger \zeta_2^2) = \{a, \mu^3\, \mathsf{Re}(\alpha \zeta_1^\dagger \zeta_2^2)\} = 0 \implies \mu^3\, \mathsf{Re}(\alpha \zeta_1^\dagger \zeta_2^2) = |\alpha|\sigma (= \mathsf{const})$$

where σ can accept any value in the interval $[-\varrho_1^{\frac{1}{2}} \varrho_2, \varrho_1^{\frac{1}{2}} \varrho_2]$ and then

$$\frac{d^2\varrho_2}{dt^2} = \{a, \{a, \varrho_2\}\} = -4\mu^5 \{\mathsf{Re}(\alpha \zeta_1^\dagger \zeta_2^2), \mathsf{Re}(\alpha i \zeta_1^\dagger \zeta_2^2)\} = -2|\alpha|^2 \varrho_2(\varrho_2 - 4\varrho_1);$$

therefore as $2\varrho_1 + \varrho_2 = \lambda = (\mathsf{const})$ we arrive to

$$\frac{d^2\varrho_2}{dt^2} = -2|\alpha|^2(3\varrho_2^2 - 2\lambda). \tag{19.2.29}$$

Equation (19.2.29) describes a kind of oscillations in the real time in the interval

$$J_\lambda = \{\varrho_2 \ge 0,\ \ \varrho_2^3 - \lambda\varrho_2^2 + 2\sigma^2 \le 0\}.$$

Thus $a_j^0 = \varrho_j$ are really moderate but not slow variables.

(ii) Consider

$$\mu^{-2}a = f_1\zeta_1^\dagger\zeta_1^\dagger + f_2\zeta_2^\dagger\zeta_2^\dagger + f_3\zeta_3^\dagger\zeta_3^\dagger + \mathsf{Re}\big(\alpha\zeta_1^\dagger\zeta_2\zeta_3\big)$$

with $f_1 = f_2 + f_3$; let $\varrho_j = \mu^2\zeta_j^\dagger\zeta_j$; then for $j = 2, 3$

$$\frac{d\varrho_j}{dt} = \{a, \varrho_j\} = \mu^4\,\mathsf{Re}\{\alpha\zeta_1^\dagger\zeta_2\zeta_3, \zeta_j^\dagger\zeta_j\} = -2\mu^3\,\mathsf{Re}\big(\alpha i\zeta_1^\dagger\zeta_2\zeta_3\big)$$

and again $\mu^3\,\mathsf{Re}(\alpha\zeta_1^\dagger\zeta_2\zeta_3) = |\alpha|\sigma$ $(= \mathsf{const})$ where σ can accept any value in the interval $[-(\varrho_1\varrho_2\varrho_3)^{\frac12}, (\varrho_1\varrho_2\varrho_3)^{\frac12}]$

$$\frac{d^2\varrho_2}{dt^2} = \{a, \{a, \varrho_j\}\} = -2\mu^5\{\mathsf{Re}(\alpha\zeta_1^\dagger\zeta_2\zeta_3), \mathsf{Re}(\alpha i\zeta_1^\dagger\zeta_2\zeta_3)\} = \\ - |\alpha|^2(\varrho_2\varrho_3 - \varrho_1\varrho_2 - \varrho_1\varrho_3).$$

Due to the first equation with $j = 2, 3$ $\varrho_2 - \varrho_3 = \mathsf{const}$ and $\varrho_{2,3} = \varrho \pm \eta$ with constant η and $\varrho = \frac12(\varrho_2 + \varrho_3)$; therefore as $f_1\varrho_1 + f_2\varrho_2 + f_3\varrho_3 = \mathsf{const}$ we conclude that $\varrho_1 = -\varrho + \lambda$ and arrive to equation

$$\frac{d^2\varrho}{dt^2} = -|\alpha|^2(3\varrho^2 - 2\lambda\varrho + \eta^2). \tag{19.2.30}$$

Again, equation (19.2.30) describes a kind of oscillations in the real time in the interval

$$J_{\lambda,\eta} = \{\varrho \ge 0,\ \ \varrho^3 - \lambda\varrho^2 + \eta^2\varrho - \lambda\eta^2 + \sigma^2 \le 0\}.$$

Thus $a_j^0 = \varrho_j$ again are really moderate but not slow variables.

To have a_j^0 as slow variables we need either to assume that there are no cubic terms (i.e. either F_{jk}, g^{jk} are constant or there are no third order resonances) or to group them together.

The important role will be played by partition $\mathfrak{N} = \mathfrak{N}_\epsilon(\bar{x})$ of $\{1, \dots, r\}$ such that

(19.2.31) $j \neq k$ belong to the same element $\mathfrak{n} \in \mathfrak{N}$ if there exists l such that either $|f_j - f_k - f_l| \le \epsilon$ or $|f_k - f_j - f_l| \le \epsilon$ or $|f_l - f_j - f_k| \le \epsilon$.

Remark 19.2.3. (i) Then, according to this definition l also belongs to the same element $\mathfrak{n}$. We do not exclude $l = j$ or $l = k$.

(ii) Obviously $\mathfrak{M}$ is a subpartition of $\mathfrak{N}$; recall that $\mathfrak{M}$ groups together only indices j, k such that $f_j \approx f_k$.

(iii) It may happen that indices j, k must belong to the same element $\mathfrak{n} \in \mathfrak{N}$ even if they are not part of the same resonance equation (f.e. $1, 2$ are swapped together by $f_1 \approx 2f_2$ and $2, 3$ are swapped together by $f_2 \approx f_3$). This was not the case with $\mathfrak{M}$.

(iv) We do not assume that $\mathfrak{N}$ is the finest partition satisfying (19.2.31) as we do not want to exclude possibility to take $\#\mathfrak{N} = 1$ (i.e. no partition at all).

Then, after we got rid of all non-resonant cubic term let us define

$$\tilde{a}^0_{\mathfrak{n}} := \sum_{\mathfrak{m}\subset\mathfrak{n}} \tilde{a}_{\mathfrak{m}} + \mu^2 \operatorname{Re} \sum_{j,k,m\in\mathfrak{n}} a_{jkm}(q)\zeta_j^\dagger \zeta_k \zeta_m. \tag{19.2.32}$$

Then

$$\{\tilde{a}^0_{\mathfrak{n}}, \tilde{a}^0_{\mathfrak{n}'}\} = O(\mu^{-1}), \qquad \{\tilde{a}^0_{\mathfrak{n}}, V(q)\} = O(\mu^{-1}) \tag{19.2.33}$$

and therefore

(19.2.34) In the classical evolution at energy levels below c_0 for time $t : |t| \le \epsilon\mu$ increment of $\tilde{a}^0_{\mathfrak{n}}$ does not exceed $C\mu^{-1}|t| \le \epsilon_1$ (so $\tilde{a}^0_{\mathfrak{n}}$ are slow variables);

and

(19.2.35) In the classical evolution at energy levels below c_0 for time $t : |t| \le \epsilon\mu$ increment of $a^0_{\mathfrak{n}} := \sum_{\mathfrak{m}\subset\mathfrak{n}} a^0_{\mathfrak{m}}$ does not exceed $C\mu^{-1}(|t| + 1) \le \epsilon_1$.

It follows from (19.2.7) that

$$\{q_j, q_k\} \equiv \mu^{-1} f_{jk}(q) + O(\mu^{-2}) \tag{19.2.7}'$$

and then one can reintroduce $q_j := x_j - \sum_k f_{jk}(x)\eta_k - \sum_{k,m} \rho_{jkm}(x)\eta_k\eta_m$ to make

$$\{\eta_k, q_j\} = O(\mu^{-3}). \tag{19.2.36}$$

Then

$$\{a^0 + V, q_j\} \equiv \mu^2 \sum_{k,m} \{a_{km}, q_j\}\zeta_k\zeta_m^\dagger + \{V(q), q_j\} \quad \mathsf{mod}\ O(\mu^{-3}). \tag{19.2.37}$$

Microhyperbolicity

Let us introduce microhyperbolicity condition provided a_0 does not vanish i.e.

$$V \le -\epsilon_0; \tag{19.2.38}$$

we are not interested in the classically forbidden case of $V \ge \epsilon_0$.

Definition 19.2.4. We call the magnetic Schrödinger operator *microhyperbolic* at point $\bar{x}$ if for each $\boldsymbol{\tau} = (\tau_{\mathfrak{m}})_{\mathfrak{m}\in\mathfrak{M}}$, such that $|\sum_{\mathfrak{m}\in\mathfrak{M}} \tau_{\mathfrak{m}} + V| \le \epsilon$, there exists vector $\ell = \ell(\bar{z}, \boldsymbol{\tau}) \in \mathbb{R}^{2r}$, such that

$$-\mu^2 \sum_{j,k} \bigl(\ell(a_{jk}a_0^{-1})\bigr)\zeta_j^\dagger\zeta_k \ge \epsilon_0 \tag{19.2.39}$$

as long as

$$\mu^2 \sum_{j,k\in\mathfrak{m}} a_{jk}\zeta_j^\dagger\zeta_k = \tau_{\mathfrak{m}} \qquad \forall \zeta \in \mathbb{C}^r \quad \forall \mathfrak{m} \in \mathfrak{M}. \tag{19.2.40}$$

Definition 19.2.5. Let $\mathfrak{N} = \mathfrak{N}(\bar{x})$ satisfy (19.2.31). We call the magnetic Schrödinger operator $\mathfrak{N}$-*microhyperbolic* at point $\bar{x}$ if for each $\boldsymbol{\tau} = (\tau_{\mathfrak{n}})_{\mathfrak{n}\in\mathfrak{N}}$, such that $|\sum_{\mathfrak{n}\in\mathfrak{N}} \tau_{\mathfrak{n}} + V| \le \epsilon$, there exists vector $\ell = \ell(\bar{z}, \boldsymbol{\tau}) \in \mathbb{R}^{2r}$ such that (19.2.39) holds as long as

$$\mu^2 \sum_{j,k\in\mathfrak{n}} a_{jk}\zeta_j^\dagger\zeta_k = \tau_{\mathfrak{n}} \qquad \forall \zeta \in \mathbb{C}^r \quad \forall \mathfrak{n} \in \mathfrak{N}. \tag{19.2.41}$$

Then we conclude that

(19.2.42) If magnetic Schrödinger operator is microhyperbolic at point $\bar{x}$ then $\sum_j \ell_j q_j$ will increase with the exact rate $\asymp \mu^{-1}$ for time $|t| \le T^* = \epsilon$

and

(19.2.43) If magnetic Schrödinger operator is either $\mathfrak{N}$-microhyperbolic at point $\bar{x}$ or contains no cubic terms[4] then in the frames of the smooth theory one can take $T^* = \epsilon\mu$.

Here both microhyperbolicity and $\mathfrak{N}$-microhyperbolicity obviously mean "on the energy level 0".

Example 19.2.6. (i) If F_{jk}, g^{jk} are constant, then the microhyperbolicity condition means exactly that $|\nabla V| \ge \epsilon$. In this case also $\mathfrak{N}$-microhyperbolicity condition is fulfilled with $\#\mathfrak{N} = 1$.

(ii) If there are no 2-nd order resonances[5] then the microhyperbolicity condition means exactly that

$$|\sum_k \lambda_k \nabla \log(-V/f_k)| \ge \epsilon_0 \qquad \forall \lambda_1 \ge 0, \dots, \lambda_r \ge 0 : \ \lambda_1 + \dots + \lambda_r = 1. \tag{19.2.44}$$

Then there exists vector ℓ such that

$$\sum_k \lambda_k \langle \ell, \nabla \rangle \log(-V/f_k) \ge \epsilon_0 \qquad \forall \lambda_1 \ge 0, \dots, \lambda_r \ge 0 : \ \lambda_1 + \dots + \lambda_r = 1$$

and then we have $\mathfrak{N}$-microhyperbolicity with $\#\mathfrak{N} = 1$. So in this case the notions of microhyperbolicity and $\mathfrak{N}$-microhyperbolicity also coincide.

This assumption (19.2.44) is fulfilled provided $\nabla(V/f_1), \dots, \nabla(V/f_r)$ are linearly independent.

Problem 19.2.7. Either prove that the the notions of microhyperbolicity and $\mathfrak{N}$-microhyperbolicity coincide in the general case or construct a counter-example.

---

[4] Which happens for example if either there are no 3-rd order resonances or if F_{jk}, g^{jk} are constant.

[5] Or, more generally, if eigenvalues f_j of (F_k^j) have constant multiplicities.

Non-Smooth Theory

Consider what happens for not very large smoothness. First of all, all our analysis above obviously holds as $(l,\sigma)\succeq(2,0)$.

Furthermore, as long as we do not need to analyze $a_{\mathfrak{n}}^0$ (i.e. if we have $\#\mathfrak{N}=1$ in the $\mathfrak{N}$-microhyperbolicity condition) $\mathscr{C}^1$-smoothness is sufficient: to estimate by $O(\mu^{-1})$ the rate of change of q we need to have only $\{\zeta_j, q_k\}=O(\mu^{-2})$ and $\{x_j, q_k\}=O(\mu^{-1})$.

Microhyperbolicity arguments require $\{\zeta_j, q_k\}=o(\mu^{-2})$ and calculation of $\{x_j, q_k\}$ modulo $o(\mu^{-1})$. To do it we just need to mollify $\mathscr{C}$-coefficients ρ_{jkm} with the mollification parameter $o(1)$.

If $(l,\sigma)\prec(2,0)$ and $\#\mathfrak{N}>1$ in the $\mathfrak{N}$-microhyperbolicity condition, we need to analyze evolution of $a_{\mathfrak{n}}^0$ more carefully. One can see easily that in this case

$$\{a_{\mathfrak{n}}^0, a\}=O\big(\mu^{-l+1}|\log\mu|^{-\sigma}\big) \tag{19.2.45}$$

because one can consider 3-rd order and linear terms and replace them by their μ^{-1}-mollifications with respect to η and Q; then for mollified terms this estimate would hold and for mollification error it would hold as well since the gradient of the error would be $O(\mu^{1-l}|\log\mu|^{-\sigma})$.

Therefore under $\mathfrak{N}$-microhyperbolicity assumption with $\#\mathfrak{N}>1$ one can take

$$T^*=\epsilon\begin{cases}\mu & (l,\sigma)\succeq(2,0),\\ \mu^{l-1}|\log\mu|^{\sigma} & (l,\sigma)\prec(2,0)\end{cases} \tag{19.2.46}$$

and in the end of the day semiclassical error will be $O\big(h^{1-d}T^{*-1}\big)$ which is exactly the first term in estimate (19.2.87) below.

19.2.2 Semiclassical Propagation

Now moving from the classical dynamics to the rigorous analysis we prove few statements, assuming that

$$\mu_0\le\mu\le\mu_2^*=\epsilon_1(h|\log h|)^{-1} \tag{19.2.47}$$

and

$$\varepsilon\ge Ch|\log h| \tag{19.2.48}$$

where here and below μ_0, C are large enough constants.

(19.2.49) In the statements of this subsubsection ϕ_1 is supported in $B(0,1)$, $\phi_2 = 1$ in $B(0,2)$ and χ is supported in $[-1,1]$ [6].

General Theory

Proposition 19.2.8 [7]**.** *Let* $\mu \le \epsilon h^{-1}|\log h|^{-1}$ [8] *and let*

$$M \ge \sup_{\{\sum_{j,k} g^{jk}\xi_j\xi_k + V = 0\}} 2\sum_k g^{jk}\xi_k + \epsilon \tag{19.2.50}$$

with arbitrarily small constant $\epsilon > 0$.

Let

$$Ch|\log h| \le T \le T^{*\prime} := \epsilon_0. \tag{19.2.51}$$

Then

$$|F_{t\to h^{-1}\tau}\chi_T(t)\big(1-\phi_{2,MT}(x-\bar{x})\big)\phi_{1,MT}(y-\bar{x})U(x,y,t)| \le Ch^s \quad \forall \tau \le \epsilon_1 \tag{19.2.52}$$

where here and below $\epsilon_1 > 0$ *is a small enough constant.*

Proposition 19.2.9 [9]**.** *Let condition* (19.1.4) *be fulfilled and let*

$$T_* := C\varepsilon^{-1}h|\log h| + C(\mu h|\log h|)^{\frac{1}{2}} \le T \le T^* = \epsilon_0\mu. \tag{19.2.53}$$

(i) Then

$$|F_{t\to h^{-1}\tau}\chi_T(t)\big(1-\phi_{2,\mu^{-1}MT}(q_1-\bar{x}_1,\dots,q_d-\bar{x}_d)\big)^{\mathsf{w}}_x \times U(x,y,t)\,{}^t\big(\phi_{1,\mu^{-1}MT}(q_1-\bar{x}_1,\dots,q_d-\bar{x}_d)\big)^{\mathsf{w}}_y| \le Ch^s \qquad \forall \tau : |\tau| \le \epsilon_1 \tag{19.2.54}$$

where here and below $\mu_0 > 0$, C_1, M *are large enough constants. Here and below* b^{w} *means Weyl* $\mu^{-1}h$*-quantization of symbol* b *and due to condition* (19.2.53) *logarithmic uncertainty principle holds and this quantization of the symbols involved is justified.*

---

[6] Recall that all such auxiliary functions are appropriate in the sense of Section 2.3.

[7] Finite speed of propagation with respect to x; cf. Proposition 18.2.4.

[8] Lower bound condition is not needed in this statement.

[9] Magnetic propagation; cf. Proposition 18.2.6.

(ii) In particular, for $T \ge C_1$ this inequality holds for $q_1, \dots, q_d$ replaced by $x_1, \dots, x_d$.

Proposition 19.2.10. *Let $\nu = C\mu h\varepsilon^{-1}|\log h| + C(\mu h|\log h|)^{\frac12}$.*

(i) Let $\#\mathfrak{M} \ge 2$. Then

$$|F_{t\to h^{-1}\tau}\chi_T(t)\bigl(1-\phi_{2,MT+\nu}(a_{\mathfrak m}-\tau_{\mathfrak m})\bigr)^{\mathsf w}_x\times U(x,y,t)\,{}^t\bigl(\phi_{1,MT+\nu}(a_{\mathfrak m}-\tau_{\mathfrak m})\bigr)^{\mathsf w}_y| \le Ch^s \qquad \forall \tau : |\tau|\le \epsilon_1. \tag{19.2.55}$$

(ii) Let $\#\mathfrak{N} \ge 2$ and $\nu = T^{*\,-1}$ with T^* defined by (19.2.46)*. Then*

$$|F_{t\to h^{-1}\tau}\chi_T(t)\bigl(1-\phi_{2,\nu T+\nu}(a_{\mathfrak n}-\tau_{\mathfrak n})\bigr)^{\mathsf w}_x\times U(x,y,t)\,{}^t\bigl(\phi_{1,\nu T+\nu}(a_{\mathfrak n}-\tau_{\mathfrak m})\bigr)^{\mathsf w}_y| \le Ch^s \qquad \forall \tau : |\tau|\le \epsilon_1. \tag{19.2.56}$$

Proofs of Propositions 19.2.8–19.2.10. All Propositions 19.2.8–19.2.10 are proven by the same scheme as in Section 2.3:

(a) To prove that the speed with respect to x does not exceed M one can use function

$$\chi\Bigl(\bigl(\frac{|x-\bar x|^2}{T^2}+\epsilon^2\bigr)^{\frac12} - C\varsigma\frac{t}{T}\Bigr) \tag{19.2.57}$$

with χ function of the same type as used in the proof of Theorem 2.3.1, $\varsigma = \pm 1$ depending on the time direction and arbitrarily small constant $\epsilon > 0$.

(b) To prove that the speed with respect to Q does not exceed $C\mu^{-1}$ one can use function

$$\chi\Bigl(\bigl(\frac{\mu^2|q-\bar q|^2}{T^2}+\epsilon^2\bigr)^{\frac12} - C\varsigma\frac{t}{T}\Bigr). \tag{19.2.58}$$

(c) To prove that the speed with respect to $a_{\mathfrak n}$ does not exceed $v = T^{*\,-1}$ with T^* defined by (19.2.46) one can use function

$$\chi\Bigl(\bigl(\frac{|a_{\mathfrak n}-\tau_{\mathfrak n}|^2}{v^2T^2}+\epsilon^2\bigr)^{\frac12} - C\varsigma\frac{t}{T}\Bigr) \tag{19.2.59}$$

and to prove that the speed with respect to $a_{\mathfrak m}$ does not exceed $v = C$ one can use the same function (19.2.59) with $\mathfrak n$ replaced by $\mathfrak m$. □

Corollary 19.2.11. *(i) Let* $\#\mathfrak{M} \ge 2$. *Then (in the microlocal sense)* $\{\mathsf{a}_{\mathfrak{m}}\}$ *stays in the* ϵ*-vicinity of value* $\boldsymbol{\tau}$ *for time* $T^* = \epsilon$.

(ii) Let $\#\mathfrak{N} \ge 2$. *Then (in the microlocal sense)* $\{\mathsf{a}_{\mathfrak{n}}\}$ *stays in the* ϵ*-vicinity of value* $\boldsymbol{\tau}$ *for time* T^* *defined by* (19.2.46).

Microhyperbolic Theory

In this subsubsection function χ is supported in $[-1,-\frac{1}{2}]\cup[\frac{1}{2},1]$ and $\bar\chi$ is supported in $[-1,1]$ and $\bar\chi = 1$ on $[-\frac{1}{2},\frac{1}{2}]$ [6)].

Proposition 19.2.12. [10)] *Let* $(I,\sigma) \succeq (1,2)$ *and*

$$\mu_0 \le \mu \le \mu_1^* := \epsilon_1(h|\log h|)^{-\frac{1}{2}}, \tag{19.2.60}$$

$$\varepsilon = C'\mu h|\log h|, \tag{19.2.61}$$

$$\bar T = \epsilon\mu^{-1} \tag{19.2.62}$$

where large enough constant C' *is chosen in the very last moment. Then*

(i) Under microhyperbolicity condition (see Definition 19.2.4) let us pick up $T^* = \epsilon$.

(ii) Under $\mathfrak{N}$*-microhyperbolicity condition (see Definition 19.2.5) let us define* T^* *by* (19.2.46) *as* $\#\mathfrak{N} \ge 2$ *and* $T^* = \epsilon\mu$ *as* $\#\mathfrak{N} = 1$ [11)].

Then for $T \in [\bar T, T^*]$, $\tau \in [-\epsilon_1,\epsilon_1]$

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\psi U| \le Ch^s. \tag{19.2.63}$$

Proof. (a) Let us first try function

$$\chi\Big(\frac{\mu}{T}\langle \ell, q-\bar q\rangle + \epsilon\varsigma\frac{t}{T}\Big) \tag{19.2.64}$$

with $\ell = \ell(y;\tau_1,\dots,\tau_{\#\mathfrak{N}})$.

One can check easily that it is an admissible symbol as long in scale $\rho = \gamma = \mu T$ with respect to x and ξ and the logarithmic uncertainty

[10)] Weak magnetic field case.

[11)] So under $\mathfrak{N}$-microhyperbolicity condition $T^* = \epsilon\mu$ unless $\#\mathfrak{N} \ge 2$ and $(I,\sigma) \prec (2,0)$.

principle $\rho\gamma \ge C\mu^{-1}h|\log h|$ is fulfilled[12)] as

$$T \ge T_* := C(\mu h|\log h|)^{\frac12}; \tag{19.2.65}$$

then $T_* \le \bar{T} = \epsilon_1\mu^{-1}$ as

$$\mu \le \epsilon_3(h|\log h|)^{-\frac13}. \tag{19.2.66}$$

Then our standard analysis like in Theorem 2.3.1, together with Propositions 19.2.8–19.2.9 and Corollary 19.2.11[13)] imply estimate (19.2.63).

(b) Now let us consider the case when

$$\epsilon_3(h|\log h|)^{-\frac13} \le \mu \le \epsilon_1(h|\log h|)^{-\frac12}, \tag{19.2.67}$$

$$\epsilon\mu^{-1} \le T \le C(\mu h|\log h|)^{\frac12}; \tag{19.2.68}$$

then

$$\varepsilon \ge C(\mu^{-1}h|\log h|)^{\frac12} \ge \mu^{-1}T, \tag{19.2.69}$$

function (19.2.64) is not necessarily admissible symbol and one needs a bit more subtle arguments.

Let us consider a small vicinity of y. Without any loss of the generality one can assume that $\phi_{jk}(y) = 0$ as $|j-k| \ne r$ (otherwise one can achieve it by a rotation). After this, without any loss of the generality one can assume that $\ell = (\ell', 0)$ where $x' = (x_1, \dots, x_r)$, $x'' = (x_{r+1}, \dots, x_{2r})$ etc. as we can achieve it by rotations in the planes (x_j, x_{j+r}), $j = 1, \dots, r$.

Recall that by definition

$$q_j = x_j - \sum_k \phi_{jk}p_k + \frac12\sum_{i,k}\beta_{jik}p_ip_k,$$

where β_{jik} are (mollified) coefficients chosen to eliminate linear with respect to $(p_1, \dots, p_d)$ terms in $\{p_k, q_j\}$. Consider function

$$\chi\Big(\frac{\mu}{T}\langle\ell, q-\bar{q}\rangle + \epsilon\varsigma\frac{t}{T}\Big) = \chi\Big(\frac{\mu}{T}\big(\langle\ell', x-\bar{x}'\rangle - \sum_{j,k}\ell_j\phi_{jk}p_k + \frac12\sum_{i,j,k}\ell_j\beta_{jik}p_ip_k\big)\Big) \tag{19.2.70}$$

[12)] To fulfill logarithmic uncertainty principle we also need $\rho\varepsilon \ge C\mu^{-1}h|\log h|$, but it will be fulfilled automatically as $T \ge \bar{T}$ and $\varepsilon \ge C'\mu h|\log h|$.

[13)] If we are in framework of Statement (ii) with $\#\mathfrak{N} \ge 2$.

and use a vector scale $(\boldsymbol{\gamma}, \boldsymbol{\rho})$ with respect to (x, ξ) with

$$\rho_j \gamma_j \ge C\mu^{-1}h|\log h|. \tag{19.2.71}$$

Consider the first derivatives of the argument of χ; we want them to be bounded *after rescaling*.

Let us take $\gamma_j = \gamma$, $\rho_j = \rho$ as $j = 1, \dots, r$ and $\gamma_j = \rho$, $\rho_j = \gamma$ as $j = r+1, \dots, 2r$ with $\rho \ge \gamma$; then $|\phi_{jk} - \phi_{jk}(y)| \le c\rho$.

Note that to have the first derivatives with respect to x' bounded by $C_0\gamma^{-1}$ one needs to take $\gamma = \mu^{-1}T$ [14] as $j = 1, \dots, r$.

Further, to have the first derivatives with respect to ξ' bounded by $C_0\rho^{-1}$ one needs to take $\rho = (\mu^{-1}T)^{\frac{1}{2}}$ as $j = 1, \dots, r$. Then the first derivatives with respect to ξ'' are also bounded by $C_0\gamma^{-1}$ and to have the first derivatives with respect to x'' bounded by $C_0\rho^{-1}$ one needs to have $|\partial_j p_k| \le c\rho$ as $j = 1, \dots, r$, $k = j + r$ or, equivalently, $\partial_j V_k(y) = 0$ for indicated j, k; this could be achieved by a gauge transformation.

To satisfy (19.2.71) one needs then

$$T \ge C\mu(\mu^{-1}h|\log h|)^{\frac{2}{3}}; \tag{19.2.72}$$

one can see easily that $T = \bar{T} = \epsilon\mu^{-1}$ fits if and only if μ satisfies (19.2.60). Then picking up $\gamma = C\min\bigl(\mu h|\log h|, \mu^{-1}T\bigr)$ and $\rho = \gamma^{\frac{1}{2}}$ we see that (19.2.71) holds and (19.2.70) is an admissible symbol.

Then our standard analysis like in Theorem 2.3.1, together with Propositions 19.2.8–19.2.9 and Corollary 19.2.11[13] imply estimate (19.2.63). □

Applying the same arguments as in Parts (a) and (b) of the proof, in the cases $T \ge C(\mu h|\log h|)^{\frac{1}{2}}$ and $T \le C(\mu h|\log h|)^{\frac{1}{2}}$ respectively one can prove easily

Proposition 19.2.13. [15] *Let $(l, \sigma) \succeq (1, 2)$, microhyperbolicity condition be fulfilled and*

$$\epsilon_1(h|\log h|)^{-\frac{1}{2}} \le \mu \le \epsilon(h|\log h|)^{-1}, \tag{19.2.73}$$

$$C'(\mu^{-1}h|\log h|)^{\frac{1}{2}} \le \varepsilon \le C'\mu h|\log h|, \tag{19.2.74}$$

$$T_* = C\max\Bigl(\varepsilon^{-1}h|\log h|,\ \mu(\mu^{-1}h|\log h|)^{\frac{2}{3}}\Bigr) \tag{19.2.75}$$

[14] Or less; we always take the maximal value.

[15] Weak magnetic field approach.

where large enough constant C' is chosen in the very last moment. Then

(i) For $T \in [T_*, T^*]$, $\tau \in [-\epsilon_1, \epsilon_1]$ estimate (19.2.63) *holds where $T^* = \epsilon$.*

(ii) Furthermore, under $\mathfrak{N}$-microhyperbolicity this estimate holds with T^* defined as in Proposition 19.2.12(ii).

Then we arrive immediately to

Corollary 19.2.14. *In the framework of Propositions 19.2.12, 19.2.13*

$$|F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t) - \bar\chi_{T'}(t)\bigr)\Gamma\psi U| \le Ch^s \tag{19.2.76}$$

with $T_* \le T' \le T \le T^*$ with T_* defined by (19.2.75) *and T^* defined in Proposition 19.2.12(i), (ii).*

Recall that $\bar\chi$ is an admissible function supported in $[-1,1]$ and equal 1 at $[-\frac{1}{2}, \frac{1}{2}]$.

19.2.3 Tauberian Theory

Corollary 19.2.15. *In the framework of Proposition 19.2.12*

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma(\psi U)| \le Ch^{1-d} \qquad \forall \tau : |\tau| \le \epsilon \tag{19.2.77}$$

and

$$\mathsf{R}^{\mathsf{T}} := |\Gamma(\psi\tilde e)(\tau) - h^{-1}\int_{-\infty}^{\tau}\Bigl(F_{t\to h^{-1}\tau'}\bar\chi_T(t)\Gamma(\psi U)\Bigr)\,d\tau'| \le CT^{*\,-1}h^{1-d} \qquad \forall \tau : |\tau| \le \epsilon \tag{19.2.78}$$

for any $T \in [\bar T, T^*]$.

Proof. Rescaling $x \mapsto \mu x$, $\varepsilon \mapsto \mu\varepsilon$, $t \mapsto \mu t$, $h \mapsto \mu h$, $T_0 \mapsto \epsilon$ we arrive to the standard Schrödinger operator (i.e. with $\mu = 1$), we can apply our standard methods. Then estimate (19.2.77) holds for $T = \bar T$. Combining with (19.2.76) we arrive to (19.2.77) with arbitrary $T \in [\bar T, T^*]$.

Applying Tauberian arguments we arrive then to the Tauberian estimate (19.2.78). □

19.2.4 Main Theorem

Now under assumption (19.2.60) we need to calculate the Tauberian expression

$$h^{-1}\int_{-\infty}^{\tau}\Big(F_{t\to h^{-1}\tau'}\bar{\chi}_T(t)\Gamma(\psi U)\Big)\,d\tau'. \tag{19.2.79}$$

with $T = Ch|\log h|$.

Using rescaling to the standard Schrödinger operator we get that it is equal to

$$\sum_{m,n\ge 0}\kappa_{nm}h^{-d+2m+2n}\mu^{2n} \tag{19.2.80}$$

as all other coefficients vanish under assumption (19.2.38).

Taking only term $\kappa_{00}h^{-d}$ we get the standard Weyl expression

$$h^{-d}\int \mathcal{N}^{\mathsf{W}}(\tau,x)\psi(x)\,dx \tag{19.2.81}$$

with an error $O(\mu^2h^{2-d})$ which is $O(\mu^{-1}h^{1-d})$ as $\mu\le h^{-\frac{1}{3}}$.

Further, taking only terms $\kappa_{00}h^{-d}+\kappa_{10}h^{2-d}\mu^2$ we commit an error $O(h^{2-d}+\mu^4h^{4-d})$ which is $O(\mu^{-1}h^{1-d})$ as $\mu\le h^{-\frac{3}{5}}$. One can calculate this correction term $\kappa_{10}h^{2-d}\mu^2$ easily. More generally, taking n-terms we make an error $O(\mu^{2n}h^{2n-d})$ arriving to

$$|\Gamma(\psi\tilde{e})\tau) - h^{-d}\int \tilde{\mathcal{N}}^{\mathsf{W}}_{(n)}(x,\tau)\psi(x)\,dx| \le CT^{*-1}h^{1-d}+C\mu^{2n}h^{2n-d} \qquad \forall \tau : |\tau|\le \epsilon \tag{19.2.82}$$

where $h^{-d}\mathcal{N}^{\mathsf{W}}_{(n)}$ denotes n-term Weyl expression i.e. cut the asymptotic sum

$$h^{-d}\mathcal{N}^{\mathsf{W}}_{(\infty)} := \sum_{n\ge 0}\varkappa_{n0}(x)h^{-d}(\mu h)^{2n}. \tag{19.2.83}$$

Instead let us notice that $\kappa_{n0}=\int \varkappa_{n0}(x,\tau)\psi(x)\,dx$ where $\varkappa_{n0}(x,\tau)$ depends only on g^{jk}, V and $\partial_k V_j$ calculated at point x, and thus with the indicated error to calculate (19.2.79) with Γ_y instead of Γ and with $\psi = 1$

and one can consider Schrödinger operator

$$\bar{A} = \sum_{j,k} \bar{g}^{jk} \bar{P}_j \bar{P}_k + \bar{V}, \qquad \bar{g}^{jk} = g^{jk}(y),\ \bar{V} = V(y), \tag{19.2.84}$$

$$\bar{P}_j = hD_j - V_j(y) - \sum_k (\partial_k V_j)(y)(x_k - y_k)$$

and for this operator expression in question is exactly $h^{-d}\tilde{\mathcal{N}}^{\mathsf{MW}}(y,\tau)$.

So, under assumption (19.2.60) we have proven

$$|\Gamma(\psi\tilde{e})\tau) - h^{-d}\int \tilde{\mathcal{N}}^{\mathsf{MW}}(x,\tau)\psi(x)\,dx| \le CT^{*-1}h^{1-d} \tag{19.2.85}$$

$$\forall \tau : |\tau| \le \epsilon$$

where for $\mu \le Ch^{-\frac{1}{3}}$ one can replace $\tilde{\mathcal{N}}^{\mathsf{MW}}$ by $\tilde{\mathcal{N}}^{\mathsf{W}}$.

Thus taking into account that the difference between either Weyl or magnetic Weyl expressions for the original and mollified operator does not exceed $C\varepsilon^{l}|\log\varepsilon|^{-\sigma}h^{-d}$ we arrive to the main theorem of this section:

Theorem 19.2.16. *Let assumptions* (19.1.4)–(19.1.6), $(19.1.25)_{1-3}$ *with* $(\bar{l},\bar{\sigma}) \succeq (l,\sigma) \succeq (1,2)$ *and* (19.2.38) *be fulfilled. Let* $\mu \le \mu_2^* = C(h|\log h|)^{-\frac{1}{2}}$. *Then there are two framing approximations*[18)] *(see f.e. Theorem 18.2.9) such that the following statements are true:*

(i) Let $\mathfrak{N}$*-microhyperbolicity condition (see Definition 19.2.5) be fulfilled. Then if* <u>*either*</u> $(l,\sigma) \succeq (2,0)$ <u>*or*</u> $\#\mathfrak{N} = 1$, *then*

$$\mathsf{R}^{\mathsf{MW}} := |\int \Big(\tilde{e}(x,x,0) - h^{-d}\mathcal{N}^{\mathsf{MW}}(x,0)\Big)\psi(x)\,dx| \le \tag{19.2.86}$$

$$C\mu^{-1}h^{1-d} + C(\mu h)^{l}|\log h|^{l-\sigma}h^{-d}$$

and if $(l,\sigma) \prec (2,0)$ <u>*and*</u> $\#\mathfrak{N} \ge 2$ *then*

$$\mathsf{R}^{\mathsf{MW}} \le C\mu^{l-l}h^{1-d}|\log\mu|^{-\sigma} + C(\mu h)^{l}|\log h|^{l-\sigma}h^{-d}. \tag{19.2.87}$$

(ii) Let microhyperbolicity condition (see Definition 19.2.4) be fulfilled. Then

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C(\mu h)^{l}|\log h|^{l-\sigma}h^{-d}. \tag{19.2.88}$$

Corollary 19.2.17. *If* $(l,\sigma) \succeq (3,1)$ *then in the framework of Syatement (i) asymptotics*

$$\mathsf{R}^{\mathsf{MW}} \le C\mu^{-1}h^{1-d} \tag{19.2.89}$$

holds as $\mu \le C(h|\log h|)^{-\frac{1}{2}}$.

Remark 19.2.18. (i) The above estimates hold for $\mathsf{R}^{\mathsf{W}}_{(2)}$ as well.

(ii) Theorem 19.2.16 can be extended to the case $C(h|\log h|)^{-\frac{1}{2}} \le \mu \le h^{\delta-1}$ but it will be our theorem of choice only as $\mu \le h^{-\frac{1}{2}}$.

(iii) In the case $C(h|\log h|)^{-\frac{1}{2}} \le \mu \le h^{\delta-1}$ we need to take n such that $(2n,0) \succeq (l,\sigma)$.

(iv) This remark also applies to Theorem 19.2.19 below.

The general case of weak magnetic field is completed.

19.2.5 Special Case of Constant g^{jk}, F_{jk}

Assume now that g^{jk} and F_{jk} are constant. Then without any loss of the generality one can assume that

$$g^{jk} = \delta_{jk}, \qquad F_{jk} = f_j\delta_{k,j+r} - f_k\delta_{j,k-r} \tag{19.2.90}$$

and

$$V_j = 0 \quad \text{as} \quad j = 1,\dots,r \qquad V_j = f_{j-r}x_{j-r} \quad \text{as} \quad j = r+1,\dots,2r. \tag{19.2.91}$$

Then all the arguments of the previous Subsections could be easily simplified as we can assume without any loss of the generality that $\ell = (0,\ell'')$ and consider the shift with respect to ξ''. Then the logarithmic uncertainty principle would mean $T\varepsilon \ge Ch|\log h|$ and thus we can take $\varepsilon = C\mu h|\log h|$ to accommodate $T = \bar{T} \asymp \mu^{-1}$.

However, we can make better than this and allow critical points. Let us first consider a point $\bar{x}$ such that at this point

$$|\nabla V| \asymp \nu \ge \bar{\nu} := C_0 \max\bigl(\mu^{-1}, \mu h|\log h|\bigr) \tag{19.2.92}$$

where we pick $\bar{\nu}$ exactly as in the 2D-case.

Then $|\nabla V| \asymp \nu$ in $B(\bar{x}, 2\epsilon_1\nu)$ and it follows from our analysis that the evolution (including microlocal one) which starts at $B(\bar{x}, \epsilon_1\nu)$ does not leave $B(\bar{x}, 2\epsilon_1\nu)$ for time $T^* = \epsilon\mu$.

On the other hand, the shift in ξ'' is $\asymp T\nu$ and the logarithmic uncertainty principle requires $T\nu \cdot \varepsilon \ge Ch|\log h|$ and we can take

$$\varepsilon = C\begin{cases} \mu h\nu^{-1}|\log h| & \nu \ge \bar{\nu},\\ \mu h\bar{\nu}^{-1} & \nu \le \bar{\nu}\end{cases} \tag{19.2.93}$$

where $\nu \le \bar{\nu}$ means that $|\nabla V| \le C\bar{\nu}$ in $\bar{x}$ and its $2\bar{\nu}$-vicinity.

Then contribution of $B(x, \nu)$ to the Tauberian remainder does not exceed $C\mu^{-1}h^{1-d}\nu^d$ as $\nu \ge \bar{\nu}$ and $C\mu h^{1-d}\bar{\nu}^d$ as $\nu \le \bar{\nu}$ and in the latter case we take $T^* = \epsilon\mu^{-1}$. Summation over partition returns

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{-1}h^{1-d} + C\mu h^{1-d}\,\mathsf{mes}\big(\{x:\ |\nabla V(x)| \le \bar{\nu}\}\big) \tag{19.2.94}$$

which in turn implies the same estimate for $\mathsf{R}^{\mathsf{W}}_{(\infty)}$ calculated for mollified operator and under assumption (19.2.38) an error when we pass from mollified to the original operator error becomes

$$Ch^{-d}\int \varepsilon^l|\log\varepsilon|^{-\sigma}\,dx \asymp Ch^{-d}\int (\mu h)^l|\log(\mu h/\nu)|^{-\sigma}\nu^{-l}\,dx. \tag{19.2.95}$$

Assuming that $(l, \sigma) \succeq (2, 0)$ and imposing generic non-degeneracy condition

$$|\nabla V| \le \epsilon \implies |\det \mathsf{Hess}\, V| \ge \epsilon \tag{19.2.96}$$

we conclude that expression (19.2.94) does not exceed

$$C\mu^{-1}h^{1-d} + C\mu(\mu h|\log h|)^{d/2}h^{1-d} \tag{19.2.97}$$

which even in the worst case $d = 4$ does not exceed $C\mu^{-1}h^{1-d}$ as $\mu \le (h|\log h|)^{-\frac{1}{2}}$.

Meanwhile as $l < d$ expression (19.2.95) does not exceed $C(\mu h)^l|\log h|^{-\sigma}h^{-d}$ and as $l \ge d$ this expression does not exceed (19.2.97) and therefore both expressions (19.2.94) and (19.2.95) do not exceed

$$C\mu^{-1}h^{1-d} + C\mu(\mu h|\log h|)^{d/2}h^{1-d} + C(\mu h)^l|\log h|^{-\sigma}h^{-d}. \tag{19.2.98}$$

Then we arrive to

Theorem 19.2.19. *Let assumptions* (19.1.4)–(19.1.6), $(19.1.6)_3$ *with* $(I,\sigma)\succeq(1,2)$ *and* (19.2.38) *be fulfilled. Let* g^{jk}, F_{jk} *be constant.*

Then there are two framing approximations[18] *(see Chapter 18) such that the following statements are true:*

(i) Under microhyperbolicity assumption $|\nabla V|\ge\epsilon$ *estimate* (19.2.86) *holds.*

(ii) Under assumptions $(I,\sigma)\succeq(2,0)$ *and* (19.2.96) R^{MW} *does not exceed* (19.2.98).

19.3 Canonical Form

19.3.1 Toy-Model

Assume now that g^{jk} and F_{jk} are constant. Then without any loss of the generality we can assume that $V_j(x)$ are linear functions.

Then A^0 is transformed into exactly

$$\sum_{1\le j\le r} f_j\Big(h^2D_j^2+\mu^2x_j^2\Big) \tag{19.3.1}$$

by $\mu^{-1}h$-metaplectic transformation which consists of the following steps:

(i) Change of variables $(x,\mu^{-1}hD)\mapsto(Qx,\ {}^tQ^{-1}\mu^{-1}hD)$ transforming g^{jk} into δ_{jk} and F into matrix with $F_{j,j+r}=f_j$, $F_{j+r,j}=-f_j$ and other elements 0. It transforms $V(x)$ into $V(Qx)$.

(ii) Gauge transformation (multiplication by $e^{i\mu h^{-1}S(x)}$ with quadratic form $S(x)$, transforming $V_j(x)$ into 0 and $V_{j+r}(x)$ into f_jx_j for $j=1,\dots,r$ [16]. Then A^0 is transformed into

$$h^2\sum_{1\le j\le r}\Big(D_j^2+\big(D_{j+r}-f_j\mu h^{-1}x_j\big)^2\Big) \tag{19.3.2}$$

and $V(x)$ is preserved.

(iii) Partial $\mu^{-1}h$-Fourier transform:

$$(x',x'';\mu^{-1}hD',\mu^{-1}hD')\mapsto(x',-\mu^{-1}hD'';\mu^{-1}hD',x'')$$

[16] Thus we achieve (19.2.90)–(19.2.91).

transforming A^0 into

$$h^2 \sum_{1\le j\le r} \Big(D_j^2 + \mu^2 h^{-2} \big(x_{j+r} - f_j x_j\big)^2 \Big) \tag{19.3.3}$$

and $V(x)$ into $V(x', -\mu^{-1}hD'')$.

(iv) Change of variables

$$(x', x''; \mu^{-1}hD', \mu^{-1}hD') \mapsto (x' - Kx'', x''; \mu^{-1}hD', \mu^{-1}hD'' + {}^tK\mu^{-1}hD')$$

with $K_{j,j+r} = f_j\delta_{j,k-r}$, transforming A^0 into

$$\sum_{1\le j\le r} \Big(h^2 D_j^2 + f_j^2\mu^2 x_j^2 \Big)$$

and V into $\tilde{V} \coloneqq V(x' - Kx'', \mu^{-1}hD'' - {}^tK\mu^{-1}hD')$ with Weyl quantization. Finally, $x_j \mapsto f_j^{\frac{1}{2}} x_j$, $D_j \mapsto f_j^{-\frac{1}{2}} D_j$ reduces operator A^0 into (19.3.1) and transforms $\tilde{V}$ accordingly.

This example already demonstrates why we need $\varepsilon \gtrsim \mu^{-1}$: we need to fulfill equation similar to one considered in Section 18.3

$$\sum_j f_j \partial_{\phi_j} L \approx \tilde{V} - W \tag{19.3.4}$$

where L is a symbol of the operator generating transformation, $\tilde{V}$ is defined above, W is its replacement in the canonical form and (ρ_j, ϕ_j) are polar coordinates in (x_j, ξ_j)-plane.

But then if $f_1, \dots, f_r$ are commensurable, for generic $\tilde{V}$ one cannot satisfy this equation with an error better than $O(\mu^{-l}|\log\mu|^{-\sigma})$ and with L which is 2π-periodic with respect to all arguments ϕ_j and $W = W(\rho_1, \dots, \rho_r)$ as W would need to depend on some linear combinations of ϕ_j.

Problem 19.3.1. Explore what is possible when $f_1, \dots, f_r$ are non-commensurable, and we try to satisfy (19.3.4) with a better error. It definitely would depend on how these numbers are non-commensurable (something related to their diophantine properties - as $r = 2$ it is related to the Liouville's exponent for f_1/f_2).

19.3.2 General Case: Framework

Now we need to reduce our operator to a canonical form assuming that $(\bar{l},\bar{\sigma}) \succeq (2,1)$ and

$$\mu_1^* := \epsilon_1(h|\log h|)^{-\frac{1}{2}} \le \mu \le \mu_2^* := \epsilon(h|\log h|)^{-1} \tag{19.3.5}$$

(case $\mu \ge \mu_2^*$ and especially case $\mu \ge \mu_3^* := \epsilon h^{-1}$ we consider later). As we mentioned we will need to assume that

$$\varepsilon \ge C_0\mu^{-1} \tag{19.3.6}$$

rather than

$$\varepsilon \ge C(\mu^{-1}h|\log h|)^{\frac{1}{2}} \tag{19.3.7}$$

as in Chapter 18. This larger ε makes certain parts of our construction much simpler but leads to a larger error. In this and following Sections we consider $\mu^{-1}h$-quantization.

19.3.3 Reducing the Main Part

First we need to reduce the main part. Consider point x in the vicinity of $\bar{x}$ and consider Hamiltonian fields H_{η_j} of η_j reduced to Σ_x^0 where we recall that η_j are linear combinations of $p_j = \xi_j - V_j$: $\eta_{2k-1} := \operatorname{Re}\zeta_k$, $\eta_{2k} := \operatorname{Im}\zeta_k$, $k = 1,\dots,r$ and ζ_k are defined by (19.2.13)–(19.2.14) (rather than redefined by (19.2.22)–(19.2.23)). Also recall that $\Sigma^0 = \{\eta_1 = \dots = \eta_{2r} = 0\}$.

Consider symplectic map e^{tH_q} where $q = q(x;\eta_1,\dots,\eta_d)$ is a quadratic form

$$q(x;\eta_1,\dots,\eta_d) = \frac{1}{2}\sum_{i,j} q_{ij}(x)\eta_i\eta_j \tag{19.3.8}$$

with $q_{ij} \in \mathscr{F}^{\bar{l},\bar{\sigma}}$ where $\mathscr{F}^{l,\sigma}$ are defined in Remark 18.3.2. Note that

$$\frac{d}{dt}(\eta_k \circ e^{tH_q}) = \{q,\eta_k\}\circ e^{tH_q} \equiv \sum_{i,j} q_{ij}\{\eta_i,\eta_k\}\eta_i \circ e^{tH_q} \tag{19.3.9}$$

modulo quadratic form. Then using arguments of Subsection 18.3.1 one can prove easily that

$$\eta_k \circ e^{H_q} = \sum_j \beta_{kj}(x)\eta_j + \sum_{i,j}\beta'_{kij}(x,\xi)\eta_i\eta_j \tag{19.3.10}$$

with $\beta_{jk} \in \mathscr{F}^{\bar{l},\bar{\sigma}}$, $\beta'_{kij} \in \mathscr{F}^{\bar{l}-1,\bar{\sigma}}$. Here $\mathcal{B} := (\beta_{jk}) = e^{\mathcal{Q}\Lambda}$ with $\mathcal{Q} = (q_{kj})$ and $\Lambda = (\Lambda_{jm})$ where $\Lambda_{jm} = 1$ as $j = 2i-1$, $m = 2i$, $\Lambda_{jm} = -1$ as $j = 2i$, $m = 2i-1$ and $\Lambda_{jm} = 0$ in all other cases. Recall that $\{\eta_j, \eta_m\}\big|_{\Sigma^0} = \Lambda_{jm}$.

Obviously,

(19.3.11) For a given matrix $\mathcal{B} \in \mathscr{F}^{\bar{l},\bar{\sigma}}$ one can find a symmetric matrix $\mathcal{Q} = (q_{ij})$ of the same regularity such that $\mathcal{B} = e^{\mathcal{Q}\Lambda}$ if and only if $\mathcal{B}$ is a *symplectic matrix* i.e.

$$\mathcal{B}^{\dagger}\Lambda\mathcal{B} = \Lambda. \tag{19.3.12}$$

In particular, one can transform (modulo quadratic forms): η_1 into p_1, η_2 into $\beta_{22}p_2$ with β_2 disjoint from 0 [17], and η_3 into $p_{33} + \beta_{31}p_1 + \beta_{32}p_2$, and η_4 into $\beta_{44}p_3 + \beta_{41}p_1 + \beta_{42}p_2$ etc:

$$\mathcal{B}\eta_m = \eta'_m := \qquad p_m + \sum_{j\le 2k-2} \beta_{mj}p_j \qquad \text{as} \quad m = 2k-1, \tag{19.3.13}$$

$$\mathcal{B}\eta_m = \eta'_m := \beta_{mm}p_m + \sum_{j\le 2k-2} \beta_{mj}p_j \qquad \text{as} \quad m = 2k \tag{19.3.14}$$

where coefficients $\beta_{jk} \in \mathscr{F}^{\bar{l},\bar{\sigma}}$ are chosen to satisfy

$$\{\eta'_j, \eta'_m\} = \Lambda_{jm}. \tag{19.3.15}$$

Now let us consider $\mu^{-1}h$-differential operator $Q = q^{\mathrm{w}}$ and transformation $T(t) = e^{it\mu h^{-1}Q}$ ("poor man's Fourier integral operator").

Using arguments of Subsection 18.3.1 one can prove easily that

$$T(1)\eta_k^{\mathrm{w}}T(-1) \equiv (\eta'_k)^{\mathrm{w}} + \Big(\sum_{i,j} \beta'_{kij}\eta'_i\eta'_j\Big)^{\mathrm{w}} \tag{19.3.16}$$

modulo operator with the norm not exceeding $C\mu^{-2}h$. Then for

$$A^0 = \mu^2\Big(\sum_{jk} a_{jk}(x)\,\eta_j\eta_k\Big)^{\mathrm{w}} \tag{19.3.17}$$

[17] Since $\{p_1, p_k\}$ is disjoint from 0 for some k and we just rename x_k into x_2 and v.v.

we have

$$T(1)A^0T(-1)\equiv \mu^2\Big(\sum_{j,k} a_{jk}(x)\,\eta'_j\eta'_k\Big)^{\mathsf{w}}+\mu^2\Big(\sum_{i,j,k} b'_{ijk}\,\eta'_i\eta'_j\eta'_k\Big)^{\mathsf{w}} \tag{19.3.18}$$

modulo operator with the norm not exceeding $C\mu^{-1}h$ where $b'_{ijk}\in \mathscr{F}^{\bar{l}-1,\bar{\sigma}}$; for simplicity of notations we skip $'$ in what follows.

Also, the same arguments show that

$$T(-1)V(x)T(1)\equiv V(x)+\sum_j (b''_j\,\eta_j)^{\mathsf{w}} \tag{19.3.19}$$

modulo operator with the norm not exceeding $C\mu^{-2}+C\mu^{-l}|\log h|^{-\sigma}$ where $b''_j\in \mathscr{F}^{l-1,\sigma}$.

Recall that while a_{jk}, V are functions depending on x only, b'_{ijk}, b''_j are complete symbols. In the end of the day we decompose them in the powers of $\eta_1,\dots,\eta_{2r}$ as far as their smoothness allows.

Due to construction $\eta_1=p_1=\xi_1-V_1(x)$ [18]. Note that we can get rid of V_1 using gauge transform, after which condition $(19.1.25)_2$ still holds.

Remark 19.3.2. Exactly here we need this condition $(19.1.25)_2$ rather than more natural condition $V_j\in \mathscr{C}^{\bar{l}+1,\bar{\sigma}}$. Otherwise we would be forced to confine ourselves to $C\varepsilon$-vicinity of $\bar{x}$ which would cause problems in Section 19.4.

Then according to commutation property $\partial_{x_1}\eta_2=1$ on Σ^0. Further, by its construction η_2 does not depend on $\xi_1,\xi_3,\dots,\xi_d$ and therefore

$$\eta_2=\alpha(x,\xi_2)\big(x_1-\lambda(x',\xi_2)\big),\qquad \alpha\big|_{\Sigma^0}=1 \tag{19.3.20}$$

with $\alpha\in \mathscr{F}^{\bar{l},\bar{\sigma}}$, $\lambda\in \mathscr{F}^{\bar{l}+1,\bar{\sigma}}$ and $x'=(x_2,\dots,x_d)$.

Let us redefine

$$\eta_2\coloneqq \big(x_1-\lambda(x',\xi_2)\big). \tag{19.3.21}$$

(19.3.22) Without any loss of the generality we assume that $\bar{x}=0$; otherwise in what follows one should replace x by $x-\bar{x}$.

---

[18] Recall that η_k means η'_k defined by (19.3.13).

Now we want to transform η_2 into x_1. To achieve this goal let us consider $T'(t) = e^{i\mu h^{-1}(\xi_1\lambda)^w}$. Then we have the series of exact equalities

$$T'(-t)D_1T(t) = D_1, \quad T'(-t)\lambda^{\mathsf{w}}T'(t) = \lambda^{\mathsf{w}}, \quad T'(-t)x_1T'(t) = x_1 + t\lambda^{\mathsf{w}}. \tag{19.3.23}$$

Therefore $T'(1)$ will transform "new" η_2^{w} into x_1. Now we need to check how this transformation will affect η_j^{w} with $j \ge 3$ and also α^{w}, b_{jk}^{w}, b_{ijk}^{w}, and finally V and $(b_j''\eta_j)^{\mathsf{w}}$.

Note that Hamiltonian function $p_1\lambda$ belongs to $\mathscr{F}^{\bar l+2,\bar\sigma}$ [19]. Therefore Hamiltonian map $\Phi_t = e^{tH_{p_1\lambda}}$ belongs to $\mathscr{F}^{\bar l+1,\bar\sigma}$ as $t \in [0,1]$ and then

$$\|T'(-t)\eta_j^{\mathsf{w}}T(t) - (\eta_j\circ\Phi_t)^{\mathsf{w}}\| \le C(\mu^{-1}h)^2\Big(1+\varepsilon^{\bar l+2-3}|\log\varepsilon|^{-\bar\sigma}\Big)\times\Big(1+\varepsilon^{\bar l+1-3}|\log\varepsilon|^{-\bar\sigma}\Big) \le C\mu^{-2}h, \tag{19.3.24}$$

$$\|T'(-t)b_{jk}^{\mathsf{w}}T(t) - (b_{jk}\circ\Phi_t)^{\mathsf{w}}\| \le C(\mu^{-1}h)^2\Big(1+\varepsilon^{\bar l-3}|\log\varepsilon|^{-\bar\sigma}\Big)\times\Big(1+\varepsilon^{\bar l+1-3}|\log\varepsilon|^{-\bar\sigma}\Big) \le C\mu^{-1}h, \tag{19.3.25}$$

$$\|T'(-t)b_{ijk}^{\mathsf{w}}T(t) - (b_{ijk}\circ\Phi_t)^{\mathsf{w}}\| \le C(\mu^{-1}h)^2\Big(1+\varepsilon^{\bar l-4}|\log\varepsilon|^{-\bar\sigma}\Big)\times\Big(1+\varepsilon^{\bar l+1-3}|\log\varepsilon|^{-\bar\sigma}\Big) \le Ch, \tag{19.3.26}$$

Furthermore, (19.3.25) also holds for α (coefficient in (19.3.20)) instead of b_{jk}.

Therefore

(19.3.27) Transformation of A^0 given by (19.3.17) by $T'(1)$ leads to the same expression (19.3.17) but all the symbols η_j', b_{jk}' and b_{ijk}' are replaced by $\eta_j'\circ\Phi_1$, $b_{jk}'\circ\Phi_1$ and $b_{ijk}'\circ\Phi_1$ respectively and the total error does not exceed $C\mu^{-1}h$.

Remark 19.3.3. Now η_1, η_2 are redefined as $p_1\circ\Phi_1 = \xi_1$, $p_2\circ\Phi_1 = x_1$ respectively.

---

[19] Really, $\lambda \in \mathscr{F}^{\bar l+1,\sigma}$ and multiplication by p_1 increases regularity by 1 due to inequalities $|p_j| \le c\mu^{-1} \le \varepsilon$ due to (19.2.2).

Let us consider η_j with $j \ge 3$. Note that $\{p_1, \eta_j\} = 0$ on Σ^0 and therefore

$$\eta_j \circ \Phi_t = \eta_j + k_j \eta_1 + \sum_{k,i} \gamma_{jik} p_i p_k. \tag{19.3.28}$$

The same arguments hold for x_j with $j \ge 2$. Therefore, moving errors arising in the quadratic part of A^0 into its cubic part, we can replace $\eta_j \circ \Phi_t$ by $\eta_j + k_j p_1$ for $j \ge 3$, and $x_j \circ \Phi_t$ by x_j for $j \ge 2$; moreover, in b_{jk} we can replace $x_1 \circ \Phi_1 = x_1 - \lambda(x', \xi_2)$ just by $-\lambda(x', \xi_2)$.

Further, from the beginning η_j with $j \ge 3$ could depend on ξ_1 (see (19.3.13), (19.3.14)). After above transformation $\eta_j \circ \Phi_1$ could acquire "more" ξ_1. Note however that originally $\{\eta_j, \eta_2\} = 0$ on Σ^0 and $\eta_2 \circ \Phi_1 = x_1$; therefore $\{\eta_j \circ \Phi_1, x_1\} = 0$ on Σ^0 and therefore in $\eta_j \circ \Phi_1$, which are linear combination of $p_k \circ \Phi_1$, we can replace $p_k \circ \Phi_1$ by $\xi_k - V_k(0, x'')$ as $k \ge 3$ (modifying again cubic terms) where temporarily $x'' = (x_2, \dots, x_d)$.

Thus we arrive to the same quadratic expression but with $p_1 = \xi_1$, $p_2 = x_1$, $p_k = \xi_k - V_k(x_2, \dots, x_d; \xi_2)$, $b_{jk} = b_{jk}(x_2, x_3, \dots, x_d; \xi_2)$.

Repeating this process, in the end of the day we arrive to the same quadratic expression with $\eta_{2k-1} = \xi_k$, $\eta_{2k} = x_k$ $(k = 1, \dots, r)$, $b_{jk} = b_{jk}(x'', \xi'')$ where now $x'' := (x_{r+1}, \dots, x_{2r})$, $\xi'' := (\xi_{r+1}, \dots, \xi_{2r})$:

$$\mu^2 \sum_{j,k} b_{jk}(x'', \mu^{-1} h D'')\, \eta_j^{\mathrm{w}} \eta_k^{\mathrm{w}} + \mu^2 \Big(\sum_{j,k,m} b_{jkm}\, \eta_j \eta_k \eta_m \Big)^{\mathrm{w}} \tag{19.3.29}$$

with $b_{jkm} = b_{jkm}(x, \xi) \in \mathscr{F}^{\bar{l}-1, \bar{\sigma}}$.

Also, considering transformation of $V(x)$ we see that at each step the semiclassical error does not exceed $C(\mu^{-1}h)^2 \varepsilon^{l-3} |\log h|^{-\sigma} \le C\mu^{-1}h$ and in the end of the day we arrive to

$$W(x'', \mu^{-1} h D'') + \Big(\sum_j b_j\, \eta_j \Big)^{\mathrm{w}} \tag{19.3.30}$$

with $W \in \mathscr{F}^{l,\sigma}$ and $b_j = b_j(x, \xi) \in \mathscr{F}^{l-1,\sigma}$.

Therefore we have proven

Proposition 19.3.4. *Let conditions* (19.1.4), (19.3.5) *and* (19.3.6) *be fulfilled,* $\bar{x}$ *be a fixed point and* $\varepsilon \le R \le \epsilon_2$ *with a small enough constant* ϵ_2. *Then there exists a bounded operator* $\mathcal{T}$ *such that*

(i) For operators $Q = q^{\mathrm{w}}$ *with symbol* q *supported in* $B(0,R) \subset \mathbb{R}^{2d}$ *and* $Q' = q_1'^{\mathrm{w}}$ *with* q_1' *supported in* $B((\bar{x},0), 2C_1R) \subset \mathbb{R}^{2d}$ *and equal* 1 *in* $B((\bar{x},0), C_1R) \subset \mathbb{R}^{2d}$ *the following equalities hold modulo negligible operators*

$$(I - Q_1')\mathcal{T}Q \equiv 0, \tag{19.3.31}$$

$$\mathcal{T}^*\mathcal{T}Q \equiv Q \tag{19.3.32}$$

and modulo operators with norm not exceeding $C\mu^{-1}h$

$$\mathcal{T}^*\psi\mathcal{T} \equiv \bar{\psi}^{\mathrm{w}}, \tag{19.3.33}$$

$$\mathcal{T}^*A\mathcal{T}Q \equiv \mathcal{A}Q \tag{19.3.34}$$

with

$$\mathcal{A} = \sum_{i,j} b_{ij}(x'', \mu^{-1}hD'')\bar{P}_i\bar{P}_j + \mu^2\Big(\sum_{i,j,k} b_{ijk}\bar{p}_i\bar{p}_j\bar{p}_k\Big)^{\mathrm{w}} + b_0(x'', \mu^{-1}hD'') + \Big(\sum_j b_i\bar{p}_i\Big)^{\mathrm{w}} \tag{19.3.35}$$

where $b_{ij} \in \mathscr{F}^{\bar{l},\bar{\sigma}}$, $b_{ijk} = b_{ijk}(x,\xi) \in \mathscr{F}^{\bar{l}-1,\bar{\sigma}}$, $b_0 \in \mathscr{F}^{l,\sigma}$, $b_i = b_i(x,\xi) \in \mathscr{F}^{l-1,\sigma}$ *are real-valued,*

$$\bar{p}_{2k-1} = \xi_k, \quad \bar{p}_{2k} = x_k, \qquad k = 1, \dots, r, \tag{19.3.36}$$

$\bar{P}_i = \mu\bar{p}_i^{\mathrm{w}}$, $x' = (x_1, \dots, x_r)$, $x'' = (x_{r+1}, \dots, x_{2r})$ *etc; recall that* $\psi = \psi(x)$ *is a smooth function.*

(ii) For operators $Q' = q'^{\mathrm{w}}$ *with symbol* q' *supported in* $B((\bar{x},0), R) \subset \mathbb{R}^{2d}$ *and* $Q_1 = q_1^{\mathrm{w}}$ *with symbol* q_1 *supported in* $B(0, 2C_1R) \subset \mathbb{R}^{2d}$ *and equal* 1 *in* $B(0, C_1R) \subset \mathbb{R}^{2d}$

$$\|Q'\mathcal{T}(1 - Q_1)\| \le Ch^s. \tag{19.3.37}$$

Remark 19.3.5. (i) Calculations show that

$$b_{ij} = b_{ij}' \circ \Psi_0, \qquad b_0 = V \circ \Psi_0, \quad \bar{\psi} = \psi \circ \Psi \tag{19.3.38}$$

where Ψ is a symplectic map $\mathbb{R}^{2d} \supset B(0,R) \to B((\bar{x},0), 2C_1R)$ and $\Psi_0 = \Pi_x\Psi\big|_{\bar{\Sigma}^0}$ with $\bar{\Sigma}^0 := \{x' = \xi' = 0\}$ and

$$|\det D\Psi_0| = f_1 \cdots f_r. \tag{19.3.39}$$

(ii) Recall that one can rewrite quadratic part as

$$\mu^2 \sum_{\mathfrak{m}\in\mathfrak{M}} \sum_{j,k\in\mathfrak{m}} a_{jk}(x'', \mu^{-1}hD'')\, Z_j^* Z_k - \mu h \sum_k a_{kk}(x'', \mu^{-1}hD'') \tag{19.3.40}$$

with $Z_k = \mu^{-1}hD_k - ix_k$, $Z_k^* = \mu^{-1}hD_k + ix_k$.

(iii) In particular, if $\#\mathfrak{m} = 1$ for all $\mathfrak{m} \in \mathfrak{M}$ (no 2-nd order resonances) one can rewrite quadratic form as

$$\sum_{1\le k\le r} f_j(x'', \mu^{-1}hD'') \left(h^2 D_k^2 + \mu^2 x_k^2\right). \tag{19.3.41}$$

19.3.4 Reducing Next Terms

There is very little what we can do else because of all the resonances. We already finished the transformation of the "main part"

$$\mathcal{A}_0 := \sum_{i,j} b_{ij}(x'', \mu^{-1}hD'')\bar{P}_i\bar{P}_j + b_0(x'', \mu^{-1}hD'') \tag{19.3.42}$$

where one can rewrite quadratic part as (19.3.40); in what follows the quadratic part and the potential of operator generate corrections which could be written in the form

$$\mu^2 \sum_{\alpha:\ 3\le|\alpha|\le\lceil(\bar{l},\bar{\sigma})\rceil+1} b''_\alpha(x'', \mu^{-1}hD'')\,(\bar{p}^\alpha)^{\mathsf{w}} \tag{19.3.43}$$

and

$$\sum_{\alpha:1\le|\alpha|\le\lceil(l,\sigma)\rceil-1} b'''_\alpha(x'', \mu^{-1}hD'')\,(\bar{p}^\alpha)^{\mathsf{w}} \tag{19.3.44}$$

modulo terms with norms not exceeding $C\mu^{-\bar{l}}|\log\mu|^{-\bar{\sigma}}$ and $C\mu^{-l}|\log\mu|^{-\sigma}$ respectively with $b''_\alpha \in \mathscr{F}^{\bar{l}+2-|\alpha|,\bar{\sigma}}$ and $b'''_\alpha \in \mathscr{F}^{l-|\alpha|,\sigma}$.

Here and below $\lceil(l,\sigma)\rceil = \lceil l\rceil$ unless $l \in \mathbb{Z}, \sigma > 0$ in which case $\lceil(l,\sigma)\rceil = l+1$ etc.

The major problem are resonances. The 2-nd order resonances ($f_i = f_j$ as $i \ne j$) prevent us from the diagonalization of the quadratic form as in (19.3.41). We can only rewrite quadratic form as (19.3.40).

Now it is easy to get rid of non-resonant terms of the 3-rd order in the main part and of 1-st order terms in V. Let us consider transformation

$$U = \Big(e^{i\mu^{-1}h^{-1}\left(\mu^2 S_3(x'',\xi'';x',\xi')+S_1(x'',\xi'';x',\xi')\right)}\Big)^{\mathsf{w}} \tag{19.3.45}$$

which is a pseudodifferential operator as $\mu \ge Ch^{-\frac{1}{3}}|\log h|^{\frac{1}{3}}$. As a result the principal part $\mathcal{A}_0$ does not change, and the next terms

$$\mathcal{A}_1 \coloneqq \mu^2 a_1^{\mathsf{w}} \qquad a_1 \coloneqq \sum_{\alpha:|\alpha|=3} b''_\alpha(x'',\xi'')\,\bar p^\alpha + \sum_{\alpha:|\alpha|=1} b'''_\alpha(x'',\xi'')\,\bar p^\alpha \tag{19.3.46}$$

(which have norms $O(\mu^{-1})$) are replaced by

$$\mathcal{A}_1 + \big\{\tilde a^0, \mu^2 S_3 + S_1\big\}'^{\mathsf{w}} + \dots \tag{19.3.47}$$

with $\tilde a^0 = \sum_{i,j} b_{ij}(x'',\xi'')\,p_i p_j$ and the "short" Poisson brackets $\{.,.\}'$ (i. e. with respect to (x',ξ') only).

Here dots denote terms of the same type (19.3.43) with $|\alpha| \ge 4$ (modulo $O(\mu^{-\bar l}|\log\mu|^{-\bar\sigma})$) and of the type (19.3.44) with $|\alpha| \ge 2$ (modulo $O(\mu^{-l}|\log\mu|^{-\sigma})$).

One can see easily that by an appropriate choice of S_3 and S_1 we can eliminate all terms in the "main part" $\mu^2 a_1 + \big\{\tilde a^0, \mu^2 S_3 + S_1\big\}'$ save corresponding to the 3-rd order resonances, namely

$$\mathsf{Re}\Big(\mu^2 \sum_{m,j,k} b''_{mjk}(x'',\xi'')\,\zeta_m^\dagger \zeta_j \zeta_k\Big) \tag{19.3.48}$$

where $\zeta_m = \xi_m + ix_m$, $m = 1,\dots,r$ as we can assume without any loss of the generality that

$$\{\tilde a^0, \zeta_m\}' = \sum_n i f_{mn}\zeta_n \tag{19.3.49}$$

where matrix (f_{mn}) has only positive eigenvalues f_k.

Note that sum (19.3.48) is restricted to indices m, j, k such that f_m is not disjoint from $f_j + f_k$; in particular $b''_{mjk} = 0$ unless $m, j, k \in \mathfrak{n}$ with $\mathfrak{n} \in \mathfrak{N}$.

Further, one can get rid of the non-resonant 4-th order terms in (19.3.43) and 2-nd order terms in (19.3.44) in the same way. However, while the 2-nd order resonant terms are only

(19.3.50) $\zeta_j^\dagger \zeta_k$ with j, k belonging to the same $\mathfrak{m}$-group,

the 4-th order resonant terms include

(19.3.51) $\zeta_j^\dagger \zeta_k \zeta_m \zeta_n$ and $\zeta_j \zeta_k^\dagger \zeta_m^\dagger \zeta_n^\dagger$ with f_j not disjoint from $f_k + f_m + f_n$

and also

(19.3.52) $\zeta_j^\dagger \zeta_k^\dagger \zeta_m \zeta_n$ with $f_j + f + k$ not disjoint from $f_m + f_n$

which we never intended to cover. The same is true for 5-th order resonant terms as well etc.

Still we need to have some concern about only the 3-rd, the 4-th and the 5-th order terms in (19.3.43) and the 2-nd and the 3-rd order terms in (19.3.44) because for $\mu \ge \epsilon(h|\log h|)^{-\frac{1}{2}}$ only these terms could be larger than $C\mu^{-1}h$.

Thus we arrive to

Proposition 19.3.6. *Let conditions* (19.1.4), (19.3.5) *and* (19.3.6) *be fulfilled, $\bar{x}$ be a fixed point. Then there exists a bounded operator $\mathcal{T}$ such that*

(i) For operators $Q = q^{\mathsf{w}}$ with the symbol q supported in $B(0,R) \subset \mathbb{R}^{2d}$ and $Q' = {q_1'}^{\mathsf{w}}$ with the symbol q_1' supported in $B((\bar{x},0),1) \subset \mathbb{R}^{2d}$ and equal 1 in $B((\bar{x},0),1) \subset \mathbb{R}^{2d}$ equalities (19.3.31) *and* (19.3.32) *hold modulo negligible operators and equalities* (19.3.33) *and* (19.3.34) *hold modulo operators with the norms not exceeding $C\bigl(\mu^{-1}h + \mu^{-l}|\log h|^{-\sigma}\bigr)$ with*

$$\mathcal{A} = \mathcal{A}_0 + \mu^2 \operatorname{Re} \sum_{\alpha,\beta:\ 3\le|\alpha|+|\beta|\le\lceil(l,\sigma)\rceil+1} b''_{\alpha\beta}(x'', \mu^{-1}hD'')\left(\zeta^\alpha \zeta^{\dagger\,\beta}\right)^{\mathsf{w}} + \operatorname{Re} \sum_{\alpha,\beta:\ 1\le|\alpha|+|\beta|\le\lceil(l,\sigma)\rceil-1} b'''_{\alpha\beta}(x'', \mu^{-1}hD'')\left(\zeta^\alpha \zeta^{\dagger\,\beta}\right)^{\mathsf{w}} \tag{19.3.53}$$

with $\mathcal{A}_0$ defined by (19.3.42) *(and equal to* (19.3.40)*) and with the symbols $b''_{\alpha\beta}, b'''_{\alpha\beta} \in \mathscr{F}^{l-|\alpha|-|\beta|,\sigma}$ and $b''_{\alpha\beta} = b'''_{\alpha\beta} = 0$ unless*

$$|\sum_j (\alpha_j - \beta_j) f_j| \le \epsilon \tag{19.3.54}$$

with arbitrarily small constant $\epsilon > 0$.

(ii) Further,

$$\bar{\psi} = \sum_{\alpha,\beta\colon 1\le|\alpha|+|\beta|\le\lceil(l,\sigma)\rceil-1} \bar{\psi}_{\alpha\beta}(x'',\xi'')\,\zeta^{\alpha}\zeta^{\dagger\beta}, \tag{19.3.55}$$

where $\bar{\psi}_{\alpha\beta}\in \mathscr{F}^{l-|\alpha|-|\beta|,\sigma}$ *and*

$$\bar{\psi}_{00} = \psi\circ \Psi_0, \tag{19.3.56}$$

$$\bar{\psi}_{\alpha\beta} = \sum_{\gamma\colon 1\le|\gamma|\le|\alpha|+|\beta|} c_{\alpha\beta\gamma}(\partial_x^{\gamma}\psi)\circ\Psi_0 \quad \textit{as}\ \ |\alpha|+|\beta|\ge 1; \tag{19.3.57}$$

(iii) Statement (ii) of Proposition 19.3.4 remains true.

Recall that only cubic terms are obstacles in the proof that $\tilde{a}^0_{\mathsf{m}}$ evolve slowly i.e. with the speed $O(\mu^{-1})$; we prove this statement only for $\tilde{a}^0_{\mathsf{n}}$.

19.3.5 Intermediate and Strong Magnetic Field Cases

Intermediate Magnetic Field Case

The same construction works in the intermediate magnetic field case

$$\mu_2^* := \epsilon(|\log h|)^{-1} \le \mu \le \mu_3^* := \epsilon h^{-1} \tag{19.3.58}$$

but in this case one needs to take parameter ε according to (19.3.7), i.e. $\varepsilon = C(\mu^{-1}h|\log h|)^{\frac12}$ or larger since it is larger now than $C\mu^{-1}$. Then restriction to p_j is now

$$|p_j|\le C\varepsilon. \tag{19.3.59}$$

However, in the operator rather than microlocal sense we have still

$$\|p_j^{\mathsf{w}}\|\le C\mu^{-1} \tag{19.3.60}$$

on the energy levels below c_0 and we should estimate perturbations based on this estimate rather than (19.3.59).

Note, that now we need to take in account only the 3-rd and the 4-th order terms in the first sum in the right-hand expression of (19.3.53) and only the 1-st and the 2-nd order terms in the second sum in the right-hand expression of (19.3.53). Similarly, in (19.3.55) we need to sum as $|\alpha|+|\beta|\le 2$.

Strong Magnetic Field Case

The same construction also works in the strong magnetic field case

$$\mu \ge \mu_3^* := \epsilon h^{-1} \tag{19.3.61}$$

we should take again ε by (19.3.7) and inequality (19.3.59) again holds in the microlocal sense but (19.3.60) is replaced by

$$\|p_j^{\mathsf{w}}\| \le \varsigma := C(\mu^{-1}h)^{\frac{1}{2}} \tag{19.3.62}$$

Really, then

$$\mathcal{A} \equiv \mu^2 \sum_{\mathfrak{m}\in\mathfrak{M}} \sum_{j,k\in\mathfrak{m}} a_{jk}(x', \mu^{-1}hD')\, Z_j^* Z_k + b_0'(x', \mu^{-1}hD') \tag{19.3.63}$$

with symbol $b_0' \in \mathscr{F}^{l,\sigma}$.

Then the principal part of operator $\bar{A}_0$ is of magnitude $C\mu h$ while norms of perturbations $\bar{A}_1$, $\bar{A}_2$, $\bar{A}_3$, $\bar{A}_4$ do not exceed $C\mu h\varsigma$, $C\mu h\varsigma^2 = Ch^2$, $C\mu h\varsigma^3$, $C\mu h\varsigma^4 = C\mu^{-1}h^3$ respectively and only the last one could be ignored for really large μ. This is the reason beyond correction $h^{-d}\mathcal{N}^{\mathsf{MW}}_{\mathsf{2corr}}$ in Theorem 19.6.26 below. It is an also one of the reasons beyond the last term in the right-hand expression of estimate (19.6.65) and the corresponding extra-smoothness requirement there to get the best possible estimate; another reason is the mollification error.

Anyway, in both intermediate and strong magnetic field cases we arrive to

Proposition 19.3.7. *All statements of Proposition 19.3.6 remains true in both intermediate and strong magnetic field cases with* (19.3.34) *fulfilled modulo operator $\mathcal{R}$ such that*

$$\|\mathcal{R}v\| \le C\Big(\varepsilon^{l}|\log\mu|^{-\sigma} + \mu h\varepsilon^{\bar{l}}|\log\mu|^{-\bar{\sigma}}\Big)\|v\| + \varepsilon^{-\bar{l}}|\log\mu|^{-\bar{\sigma}}\|\mathcal{A}v\| \qquad \forall v \tag{19.3.64}$$

with ε given by (19.3.7).

19.4 Temperate Magnetic Field

Let us consider temperate magnetic field case (19.3.5). While generally we assume that microhyperbolicity condition is fulfilled, in Subsection 19.4.7 we consider the case of constant g^{jk}, F_{jk} when V has critical points.

19.4.1 Mid-Range Propagation

By mid-range propagation we assume propagation for operator $\mathcal{A}$ and thus for operator $\mathcal{T}^*\mathcal{A}\mathcal{T}$ as $T \in [T'_*, T^{*\prime}]$ with

$$T^{*\prime} = C(\mu h|\log h|)^{\frac{1}{2}}, \tag{19.4.1}$$

$$T'_* = C\varepsilon^{-1}h|\log h| \le C\mu h|\log h|; \tag{19.4.2}$$

we are interested almost exclusively in the extending Proposition 19.2.12. Here $T^{*\prime}$ is what used to be T_* [20] and T'_* is the same as T_* as if $\mathcal{A}$ was $\mu^{-1}h$-pseudodifferential operator $\mathcal{A}(x'', \mu^{-1}hD'')$ satisfying microhyperbolicity condition.

Remark 19.4.1. Recall that then $\varepsilon \gtrsim \mu^{-1}$ but we also assume that $\varepsilon \le h^{\delta}$ to avoid some complications as otherwise logarithmic uncertainty principle should be replaced by a microlocal uncertainty principle and below $T'_* = Ch^{1-\delta}$.

However, T'_* is still pretty large unless we increase ε and thus smoothness assumptions. Instead, in the next Section we consider (smoothness-dependent) rate of decay of the left-hand expression of (19.2.63) on interval $[T''_*, T^{*\prime\prime}]$ with $T^{*\prime\prime} = T'_*$ and $T''_* = Ch$.

Consider some point $(\bar{x}, \bar{\xi})$. During time $T^{*\prime}$ (as now we assume that $(\bar{\ell}, \bar{\sigma}) \succeq (2, 0)$) (x'', ξ'') will stay in $C(\mu^{-1}h|\log h|)^{\frac{1}{2}}$-vicinity of $(\bar{x}'', \bar{\xi}'')$ in both classical and microlocal senses (we can follow Proposition 19.2.9 for the proof in the microlocal sense).

According to Subsection 19.3.4

$$A_{\mathcal{T}} := \mathcal{T}^* A \mathcal{T} = \mathcal{A} + \mathcal{R}, \tag{19.4.3}$$

with

$$\mathcal{A} = \sum_{0\le m\le \lceil (l,\sigma)\rceil -1} \mathcal{A}_m, \tag{19.4.4}$$

$$\mathcal{R} = \rho(x, \mu^{-1}hD), \qquad \rho \in \mu^{-l}|\log \mu|^{-\sigma}\mathscr{F}^{0,0}, \tag{19.4.5}$$

[20] See (19.2.53) and (19.2.65) as, for a intermediate magnetic field we have already proven that trace is negligible as $T'_* \le T \le T^*$.

$\mathcal{A}_0$ given by (19.3.42) (where one can rewrite quadratic part as (19.3.40) in the general case and as (19.3.41) as $\#\mathfrak{m}=1$ for all $\mathfrak{m}$) and

$$\mathcal{A}_m = \mu^2 \operatorname{Re} \sum_{\alpha,\beta:\ 3\le|\alpha|+|\beta|=m+2} b''_{\alpha\beta}(x'', \mu^{-1}hD'')\left(\zeta^{\alpha}\zeta^{\dagger\,\beta}\right)^{\mathsf{w}} + \operatorname{Re} \sum_{\alpha,\beta:1\le|\alpha|+|\beta|=m} b'''_{\alpha\beta}(x'', \mu^{-1}hD'')\left(\zeta^{\alpha}\zeta^{\dagger\,\beta}\right)^{\mathsf{w}} \tag{19.4.6}$$

(see (19.3.53)) and $\zeta_j = \xi_j + ix_j$, $\zeta_j^{\dagger} = \xi_j - ix_j$, $j=1,\dots,r$.

Remark 19.4.2. Surely we need to remember that $\mathcal{A}$ and $A_{\mathcal{T}} \coloneqq \mathcal{T}^*A\mathcal{T}$ are close but not equal. In Chapter 18 we considered $\mathcal{A}$ and took $\mathcal{T}\mathcal{A}\mathcal{T}^*$ as an approximation[21)] but now we have the global reduction only in the special case of condition (19.1.25) while until the next Section we need only a weaker assumption $V_j \in \mathscr{C}^{\bar{l}+1,\bar{\sigma}}$.

The following statements hold both for propagators $\boldsymbol{U}' = \boldsymbol{U}_{\mathcal{T}} \coloneqq \mathcal{T}^* e^{-h^{-1}\boldsymbol{A}t}\mathcal{T}$ and its Schwartz kernel $U' \coloneqq U_{\mathcal{T}}$ and for $\boldsymbol{U}' = e^{ih^{-1}\mathcal{A}t}$ and its Schwartz kernel U'.

Proposition 19.4.3. *Let U' be defined in Remark 19.4.2. Let ϕ_1 be supported in $B(0,1)$, $\phi_2=1$ in $B(0,2)$, χ be supported in $[-1,1]$. Let $Q_k = \phi_{k,M\mu^{-1}\mathcal{T}}(x''-\bar{x}'',\xi''-\bar{\xi}'')^{\mathsf{w}}$.*

(i) Then for $T^{*\prime} \le T \le C$ and large enough constant M

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\bigl(1-Q_{2x}\bigr)U_{\alpha\beta}(x,y,t)\,{}^tQ_{1,y}| \le C\mu^{-s} \qquad \forall \tau \le c. \tag{19.4.7}$$

(ii) Further, the same estimate holds for $T'_* \le T \le C$ if we replace $\phi_*(x'',\xi'')$ by $\phi_*(x''_I, \mu^{-1}hD''_{II})$ with an arbitrary partition $x''=(x''_I;x''_{II})$.

Proposition 19.4.4. *Let U' be defined in Remark 19.4.2. Assume that $m \coloneqq \#\mathfrak{M} \ge 2$ and let ϕ_j be functions as before.*

Then for $C(\mu h|\log h|)^{\frac12} \le T \le c_0$

$$|F_{t\to h^{-1}\tau}\chi_T(t)\bigl(1-\phi_{2,T}(\mu^2 a^0_{\mathfrak{m}_1}-\tau_1,\dots,\mu^2 a^0_{\mathfrak{m}_m}-\tau_m)\bigr)^{\mathsf{w}}\times \times U'(x,y,t)\,{}^t\bigl(\phi_{1,T}(\mu^2 a^0_{\mathfrak{m}_1}-\tau_1,\dots,\mu^2 a^0_{\mathfrak{m}_m}-\tau_m)\bigr)^{\mathsf{w}}_y| \le C\mu^{-s} \quad \forall \tau:\ |\tau|\le\epsilon_1. \tag{19.4.8}$$

[21)] Recall that actually we consider A_ε instead of A, so we already have an approximation.

Proof of Propositions 19.4.3–19.4.4. Both Propositions 19.4.3–19.4.4 are proven by the same scheme as in Chapter 18:

To prove Proposition 19.4.3(i), (ii) one can use functions

$$\chi\Big(\big(\frac{\mu^2(|x''-\bar{x}''|^2+|\xi''-\bar{\xi}''|^2)}{T^2}+\epsilon^2\big)^{\frac{1}{2}}-C\varsigma\frac{t}{T}\Big) \tag{19.4.9}$$

and

$$\chi\Big(\big(\frac{\mu^2(|x_I''-\bar{x}_I''|^2+|\xi_{II}''-\bar{\xi}_{II}''|^2)}{T^2}+\epsilon^2\big)^{\frac{1}{2}}-C\varsigma\frac{t}{T}\Big) \tag{19.4.10}$$

respectively with χ function of the same type as used in Theorem 2.3.1 and $\varsigma=\pm 1$ depending on time direction and arbitrarily small constant $\epsilon>0$.

To prove Proposition 19.4.4 one can use function

$$\chi\Big(\big(\frac{\mu^4\sum_j|a_{\mathfrak{m}_j}-\tau_{\mathfrak{m}_j}|^2}{T^2}+\epsilon^2\big)^{\frac{1}{2}}-C\varsigma\frac{t}{T}\Big). \tag{19.4.11}$$

Because $T\le\epsilon_0$ and we picked up velocity with respect to $a_{\mathfrak{m}_j}$, the 3-rd order resonances do not pose any problem here. □

Even if at this stage the decomposition into Hermitian functions is not very useful, we can study propagation using only functions of (x'',ξ'',t).

Proposition 19.4.5. *Let U' be defined in Remark 19.4.2. Let microhyperbolicity condition (see Definition 19.2.4) be fulfilled. Then for $T\in[T'_*,c_0]$, $\tau\in[-\epsilon',\epsilon']$*

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma QU|\le C\mu^{-s} \tag{19.4.12}$$

where $Q=Q(x,\mu^{-1}hD)$.

Proof. Observe that without any loss of the generality one can assume that $\ell(\bar{x}'',\bar{\xi}'';\bar{\tau}_1,\dots,\bar{\tau}_m)$ is equal to $(\ell',0)$. Otherwise one can achieve it by a linear symplectic transformation in (x'',ξ'') and corresponding FIO (which will be a metaplectic operator in this case). Then using

$$\chi\Big(\mu T^{-1}\langle\ell',x''-y''\rangle\pm\epsilon tT^{-1}\Big) \tag{19.4.13}$$

which is an admissible pseudodifferential symbol one can prove in the standard way that

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma''Qu|\le C\mu^{-s} \tag{19.4.14}$$

where here and below Γ'' is a partial trace (with respect to x'' only). □

Propositions 19.2.13 and 19.4.5 imply immediately

Corollary 19.4.6. *(i) Under microhyperbolicity condition estimate* (19.2.63) *holds for* $T \in [T'_*, T^*]$ *with* $T^* = \epsilon$.

(ii) Under $\mathfrak{N}$*-microhyperbolicity condition one can take* T^* *defined by* (19.2.46).

(iii) Also estimate (19.2.76) *holds with* T_* *replaced by the lesser value* T'_*.

Corollary 19.4.7. *Estimates* (19.2.86)–(19.2.88) *hold under corresponding assumptions of Theorem 19.2.16 in the case of* $\mu \le h^{\delta-1}$ *(albeit they are not optimal).*

Proof. Picking $\varepsilon = C\mu h|\log h|$ we get approximation error $Ch^{-d}(\mu h)^l|\log h|^{l-\sigma}$ and $T'_* = \epsilon\mu^{-1}$. Then we again have estimates (19.2.77), (19.2.78) and need just calculate expression (19.2.79) which is equivalent (modulo negligible) to (19.2.80) where without spoiling remainder estimate we can take only terms with $m = 0$ and $n \le n(\delta)$ as $\mu \le h^{-1+\delta}$ with arbitrarily small exponent $\delta > 0$. The rest repeats arguments of Subsection 19.2.4. □

19.4.2 Short-Range Theory: Framework

Still, $T_* = C\varepsilon^{-1}h|\log h|$ is too large. Really, the Tauberian method implies that the remainder does not exceed

$$\frac{1}{T}\sup_{|\tau|\le\epsilon}|F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma U\psi\bigr)| \tag{19.4.15}$$

while the principal part is

$$\frac{1}{h}\int_{-\infty}^{0}\Bigl(F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma U\psi\bigr)\Bigr)\,d\tau. \tag{19.4.16}$$

We will reduce (19.4.16) to a more explicit form in Subsection 19.4.5 (where this Subsection approach will be crucial as well) but now let us consider expression (19.4.15). To decrease it one should increase T but generally supremum also grows proportionally T and there is no improvement; the following estimate

$$|F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma U\psi\bigr)| \le CT\Bigl(h^{-2r}+\mu^r h^{-r}\Bigr) \qquad \forall \tau \le c \tag{19.4.17}$$

rather easily follows from

$$|\phi(hD_t)(\bar{\chi}_T(t)\Gamma U\psi)| \le C\Big(h^{-2r}+\mu^r h^{-r}\Big). \tag{19.4.18}$$

However, results of the previous Subsection shows that while taking $T=T^*$ one can take $\bar{\chi}_{T_*}(t)$ and then (19.4.15) becomes $CT_*T^{*-1}\big(h^{-2r}+\mu^r h^{-r}\big)$. It equals to our dream remainder estimate as $T_* := C_0 h$. Recall that $T_* := C\varepsilon^{-1}h|\log h|$.

Note that even in the smooth case T_* is larger[22)].

We cannot just take $T_* = C_0 h$ because $F_{t\to h^{-1}\tau}\big(\chi_T(t)\Gamma U\psi\big)$ is not negligible for $T\in [C_0h,\, T_*]$; instead our goal is to prove under microhyperbolicity condition that for $T\in (C_0h,\, T_*)$

$$|F_{t\to h^{-1}\tau}\big(\chi_T(t)\Gamma U\psi\big)| \le CT\Big(h^{-2r}+\mu^r h^{-r}\Big)\times \big(\frac{h}{T}\big)^l |\log(\frac{h}{T})|^{-\sigma} \qquad \forall \tau : |\tau|\le \epsilon'. \tag{19.4.19}$$

As $(l,\sigma)\succ(1,1)$ it would imply that left-hand expression of (19.4.17) with $T=T_*$ does not exceeds its right-hand expression with $T=C_0h$ i.e. that in the estimates effectively $T_*=C_0h$.

To achieve this goal we apply η-mollification to $A_{\mathcal{T}}$; this will lead to approximation error in $F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t)\Gamma U\psi\big)$ which we are going to estimate and to (kind of) negligibility estimate of it after mollification. Minimizing the sum by η (which will depend on T) we will arrive to (19.4.19) for non-mollified operator (surely, the original mollification will be still here).

Alternatively we can try the partition approach like in the previous Chapter 18.

19.4.3 Toy-Model: Some Classes of Pseudodifferential Operators

We start from related simple results (we will need them anyway):

Proposition 19.4.8. *Let $A=A(x,hD)$ be a (matrix) self-adjoint h-pseudodifferential operator in $\mathbb{R}^r$ with symbol $a\in \mathscr{F}^{l,\sigma}$ and satisfying microhyperbolicity condition on level $\tau=0$:*

$$\langle(\ell a)v, v\rangle \ge \epsilon\|v\|^2 - C\|(a-\tau)v\|^2 \qquad \forall v \quad \forall (x,\xi). \tag{19.4.20}$$

[22)] Since "no mollifications needed" has its own pitfalls, we would need actually request $T_*=h^{1-\delta}$ with arbitrarily small exponent $\delta>0$ rather than $T_*=Ch|\log h|$.

Let U be a Schwartz kernel of $e^{-ih^{-1}A}$. Finally, let $\psi \in \mathscr{C}_0^\infty$ be supported in the small vicinity of 0.

(i) Let $I > 1$. Then for $T \in [Ch^{1-\delta}, T^*]$ with arbitrarily small exponent $\delta > 0$ and small enough constant T^*

$$|\phi(hD_t)\chi_T(t)(\Gamma U\psi_y)| \le Ch^{-r}\bigl(\frac{h}{T}\bigr)^{I-1}\bigl(1+\frac{T\varepsilon}{h}\bigr)^{-s}|\log\frac{h}{T}|^{-\sigma}, \tag{19.4.21}$$

$$|F_{t\to h^{-1}\tau}\chi_T(t)(\Gamma U\psi_y)| \le Ch^{1-r}\bigl(\frac{h}{T}\bigr)^{I-1}\bigl(1+\frac{T\varepsilon}{h}\bigr)^{-s}|\log\frac{h}{T}|^{-\sigma} \tag{19.4.22}$$

as $\tau : |\tau| \le \epsilon$ with arbitrarily large exponent s.

(ii) Let $I = 1, \sigma \ge 2$. Then for $T \in [Ch^{1-\delta}, T^*]$ with arbitrarily small exponent $\delta > 0$ and small enough constant T^*

$$|\phi(hD_t)\chi_T(t)(\Gamma U\psi_y)| \le Ch^{-r}|\log\frac{h}{T}|^{-\sigma}\bigl(1+\frac{T\varepsilon}{h}\bigr)^{-s} + Ch^{-r}|\log\frac{h}{T}|^{-s}, \tag{19.4.23}$$

$$|F_{t\to h^{-1}\tau}\chi_T(t)(\Gamma U\psi_y)| \le Ch^{1-r}|\log\frac{h}{T}|^{-\sigma}\bigl(1+\frac{T\varepsilon}{h}\bigr)^{-s} + Ch^{1-r}|\log\frac{h}{T}|^{-s} \tag{19.4.24}$$

as $\tau : |\tau| \le \epsilon$ with arbitrarily large exponent s.

Toy-model. Before an actual proof, let us start with a simple example (actually arising as $d = 2$[23]):

In the case of scalar operator $\Gamma(U\psi)$ is something like $h^{-d}I_1$ with

$$I_1 = \int e^{ih^{-1}\lambda(z)t}q(z)\,dz \tag{19.4.25}$$

and $F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(U\psi)$ is $h^{1-d}I_2$ with

$$I_2 = h^{-1}\iint \chi(t/T)e^{ih^{-1}\lambda(z)t}q(z)\,dz\,dt. \tag{19.4.26}$$

[23] In this case one can apply successive approximations on this stage and to arrive to oscillatory integral expression.

Let us consider the case $T \le \varepsilon^{-1}h$, $l > 1$.

Replacing λ by its η-mollification we make an error $O\big(\vartheta(\eta)\big)$ in λ which leads to error $O\big(Th^{-1}\vartheta(\eta)\big)$ in I_1. In the same time a (multiple) integration by parts with respect to t shows that the error in I_2 is does not exceed

$$Ch^{-2}T^2 \int (Th^{-1}|\lambda - \tau| + 1)^{-2}\, dz \times \vartheta(\eta) \le Ch^{-1}T\vartheta(\eta). \tag{19.4.27}$$

Consider now I_1 and I_2 with mollified λ assuming that $|\partial_{z_1}\lambda| \ge \epsilon$. A multiple integration by parts with respect to z_1 will transform modified I_1 into $(h/T)^k \int e^{ih^{-1}\lambda(z)t} q_k(z)\, dz$ where $q_k = O\big(\eta^{-k-1}\vartheta(\eta)\big)$ as k is large enough and therefore modified expression I_1 is $O\big((h/T)^k\eta^{-k-1}\vartheta(\eta)\big)$.

We can treat expression I_2 in the similar way, but we add an integration by parts with respect to t as well and use of nondegeneracy condition as above. Then modified expression I_2 has the same upper estimate.

Therefore both original expressions I_1 and I_2 do not not exceed

$$CTh^{-1}\vartheta(\eta) + \big(\frac{h}{T}\big)^k \eta^{-k-1}\vartheta(\eta).$$

Picking (near) optimal $\eta = h/T$ we get estimates

$$|I_k| \le C\big(\frac{h}{T}\big)^{-1}\vartheta\big(\frac{h}{T}\big).$$

It proves (19.4.21), (19.4.22) in this special case. □

Proof of Proposition 19.4.8. (a) Note first that due to the standard propagation results for $T \ge Ch\varepsilon^{-1}|\log h|$ left-hand expressions in (19.4.21), (19.4.22) are negligible. Thus we need to consider only $T \le T'_* := Ch\varepsilon^{-1}|\log h|$. We can consider χ supported in $[\frac12, 1]$ and until the end of the proof t, T_k are positive.

Consider η-mollification A_η of operator A with respect to (x,ξ) [24]:

$$1 \gg \eta \ge \varepsilon. \tag{19.4.28}$$

Then the error in the operator (the difference between A_η and A) will not exceed $C\vartheta(\eta)$ in the sense that

$$\|(A_\eta - A)\| \le C\vartheta(\eta) \tag{19.4.29}$$

[24] It means that we mollify its Weyl symbol; recall that original symbol is regular in ε-scale.

and identity

$$e^{ih^{-1}tA} = e^{ih^{-1}tA_\eta} + ih^{-1}\int_0^t e^{ih^{-1}(t-t')A}(A-A_\eta)e^{ih^{-1}t'A_\eta}\,dt' \tag{19.4.30}$$

implies that

$$\|\big(e^{ih^{-1}tA} - e^{ih^{-1}tA_\eta}\big)\| \le CTh^{-1}\vartheta(\eta) \qquad \text{as } |t|\le T, \tag{19.4.31}$$

$$|\chi_T(t)\Gamma\big((U_\eta - U)\psi_y\big)| \le Ch^{-d-1}T\vartheta(\eta) \tag{19.4.32}$$

for the standard cut-off ψ in $B\big((\bar{x},\bar{\xi}),1\big)\subset\mathbb{R}^{2r}_{(x,\xi)}$; this is exactly what we got in the toy-model.

On the other hand, microhyperbolicity condition (19.4.20) and Theorem 2.3.1 imply that $\phi(hD_t)\big(\chi_T(t)\Gamma U_\eta\psi_y\big)$ is negligible provided

$$h^\delta \ge \eta \ge ChT^{-1}|\log h| \tag{19.4.33}$$

(and $\mathsf{supp}(\phi)\subset[-\epsilon,\epsilon]$) and picking minimal $\eta = ChT^{-1}|\log h|$ we arrive to inequality

$$|\phi(hD_t)\Gamma\chi_T(t)U\psi| \le Ch^{-d}\big(\frac{h}{T}\big)^{l-1}\cdot|\log h|^{l-\sigma} \tag{19.4.34}$$

due to $T\ge h^{1-\delta}$. This inequality is almost as good as (19.4.21): we have an extra factor $|\log h|^l$ in the right-hand expression.

(b) To get gid of this $|\log h|^l$ factor we need a more delicate analysis. First, let us iterate (19.4.30):

$$\begin{aligned} e^{ih^{-1}tA} = \sum_{0\le p\le m-1}\frac{1}{p!}i^p h^{-p}\int_{\Delta_p} e^{ih^{-1}(t-t_1-\dots-t_p)A_\eta}(A-A_\eta)\times \\ e^{ih^{-1}t_1A_\eta}(A-A_\eta)e^{ih^{-1}t_2A_\eta}\cdots e^{ih^{-1}t_{p-1}A_\eta}(A-A_\eta)e^{ih^{-1}t_pA_\eta}\,dt_1\cdots dt_p + R_m \end{aligned} \tag{19.4.35}$$

with the remainder

$$\begin{aligned} R_m = \frac{1}{m!}i^m h^{-m}\int_{\Delta_m} e^{ih^{-1}(t-t_1-\dots-t_m)A_\eta}(A-A_\eta)\times \\ e^{ih^{-1}t_1A_\eta}(A-A_\eta)e^{ih^{-1}t_2A_\eta}\cdots e^{ih^{-1}t_{m-1}A_\eta}(A-A_\eta)e^{ih^{-1}t_mA}\,dt_1\cdots dt_m. \end{aligned} \tag{19.4.36}$$

Then the trace norm of the remainder does not exceed $C\big(Th^{-1}\vartheta(\eta)\big)^m h^{-d}$ and it is less than the right-hand expression of (19.4.21) for large enough m (because we gain factor $(h/T)^{l-1}|\log(h/T)|^{l-\sigma}$ on each step).

Now as we take $p=1$ we need to consider

$$e^{ith^{-1}A_\eta}\big(ih^{-1}t(A-A_\eta)\big)\psi. \tag{19.4.37}$$

Without any loss of the generality one can assume that the direction of microhyperbolicity is $\ell=\partial_{\xi_1}$. Let us apply ϵT-admissible partition with respect to x_1: $\psi'=\psi'\sum_\nu \varphi_k(x_1)$. Here and below φ (with different indices) are ϵT-admissible functions.

Due to (19.4.33) the logarithmic uncertainty principle $T\times\eta\ge C'h|\log h|$ holds and therefore due to the microhyperbolicity $\varphi_\nu e^{ith^{-1}A}\equiv \varphi_\nu e^{ith^{-1}A}\tilde\varphi_\nu$ (modulo operator, negligible after cut-off $\phi(hD_t)$) as $\frac12 T\le t\le T$ where the distance between $\operatorname{supp}(\tilde\varphi_\nu)$ and $\operatorname{supp}(\varphi_\nu)$ is exactly of magnitude $\mu^{-1}T$. Then to prove (19.4.21) it is sufficient to estimate properly a trace norm of $\sum_\nu \tilde\varphi_\nu B\psi\varphi'_\nu\times(h/T)^{-1}$. To do this it is sufficient to prove that

(19.4.38) The operator norm of each "sandwich" $\tilde\varphi_\nu B\psi'\varphi_\nu$ does not exceed

$$M:=\big(\frac{h}{T}\big)^l\big(1+\frac{h}{T\varepsilon}\big)^{-s}|\log\big(\frac{h}{T}\big)|^{-\sigma}.$$

Really, then the trace norm of each "sandwich" will be $CTh^{-r}\times M_k$ where T is x_1-size of $\operatorname{supp}(\varphi_\nu)$. Then after summation with respect to ν factor T disappears and we estimate the trace norm of (19.4.37) (after $\phi(hD_t)$ cut-off) by $h^{-r}M\big(h/T\big)^{-1}$, which implies (19.4.21) and (19.4.23).

For $p\ge 2$ we replace the integral over Δ_p by the sum of the integrals over $\Delta_p\cap\{|t_j-\bar t_j|\le\epsilon' T,\ j=1,\dots,p\}$ with very small constants ϵ'.

We also place partitions elements around each copy of the operator exponent, so $e^{ih^{-1}t_jA_\eta}$ is now replaced by $\varphi_{\nu_{2j}}e^{ih^{-1}t_jA_\eta}\varphi_{\nu_{2j+1}}$, $t_0=t-t_1-\dots-t_p$.

Then <u>either</u> supports of $\varphi_{\nu_{2j+1}}$ and $\phi_{\nu_{2j+2}}$ are disjoint by a distance at least $\epsilon\mu^{-1}T$ for some j and we have a sandwich $\varphi_{\nu_{2j+1}}B\varphi_{\nu_{2j+2}}$ of the type described in (19.4.38), <u>or</u> supports of φ_{ν_0} and $\varphi_{\nu_{2p+1}}$ are disjoint by a distance at least $\epsilon\mu^{-1}T$ (and then after taking trace we get negligible term) <u>or</u> $\varphi_{\nu_{2j}}e^{ih^{-1}t_jA_\eta}\varphi_{\nu_{2j+1}}$ is a negligible operator.

Since any sandwich has a norm not exceeding $C\eta^l|\log\eta|^{-\sigma}$ and is accompanied by a factor T/h, it brings as a result a factor $(T/h)^{l-1}|\log(T/h)|^{l-\sigma}$.

To estimate the norm of a sandwich coming from (19.4.36)-term let us consider the sequence of mollifications A_ρ with $\rho = \rho_n = 2^n\rho_0$, $\rho_0 = \max\bigl(h/T, \varepsilon\bigr)$ and $n = 1, 2, \dots, \bar n$ such that $\rho_{\bar n+1} = \eta$.

Then operator $B = \sum_{0\le n\le \bar n} B_n$ with $B_n = A_{\rho_n} - A_{\rho_{n+1}}$ has a $\vartheta(\rho)\mathscr{F}^{0,0}_\rho$ symbol with $\rho := \rho_n$. Then the norm of the sandwich $\tilde\varphi_\nu B_n\varphi_\nu$ does not exceed $C\vartheta(\rho)\times(h/T\rho)^s$ with arbitrarily large s and summation with respect to n does not exceed the same expression with $\rho = \rho_0 = hT^{-1}$; so we get $\vartheta(h/T)\bigl(1 + T\varepsilon/h\bigr)^{-s}$ which is exactly M as defined in (19.4.38).

Thus (19.4.21) and (19.4.23) are proven.

(c) To prove (19.4.22) consider first the case $l > 1$. Then plugging (19.4.35)–(19.4.36) we see that for large enough m we can skip R_m. Also we can skip term with $p = 0$ because it involves only η-admissible operators. Applying the above arguments we need to estimate

$$|F_{t\to h^{-1}\tau}\chi_T(t)(\Gamma v_p\psi_y)| \tag{19.4.39}$$

with v_p a Schwartz kernel of the term in (19.4.35) with the same notations as above. Let us consider $p = 1$ first. One can see easily that

$$\begin{aligned}
&F_{t\to h^{-1}\tau}\Bigl(\chi_T(t)e^{ith^{-1}A_\eta}\Bigr) = \\
&(2\pi)^{-1}\int \chi_T(t)e^{ith^{-1}(A_\eta-\tau)}\,dt = \\
&(2\pi)^{-1}\int \chi_T(t)\bigl(-h^2\partial_t^2+\gamma^2\bigr)^q e^{ith^{-1}(A_\eta-\tau)}\bigl((A_\eta-\tau)^2+\gamma^2\bigr)^{-q}\,dt = \\
&(2\pi)^{-1}\bigl(\frac{h}{T}\bigr)^q\int \chi_{(q),T}(t)e^{ith^{-1}(A_\eta-\tau)}\bigl((A_\eta-\tau)^2+\gamma^2\bigr)^{-q}\,dt
\end{aligned} \tag{19.4.40}$$

with $\chi_{(q)}(t) = (-\partial_t + \gamma^2T^2h^{-2})^q\chi(t)$. Let us pick up $\gamma = \rho_0$.

Let us multiply (19.4.40) from the left by φ'_ν which is equal to 1 in ϵT-vicinity of $\operatorname{supp}(\varphi_\nu)$. Then modulo negligible we can multiply it from the right by $\tilde\varphi_\nu$ which is equal to 0 in ϵT-vicinity of $\operatorname{supp}(\varphi_\nu)$:

$$\begin{aligned}
&F_{t\to h^{-1}\tau}\bigl(\chi_T(t)\varphi'_\nu\, e^{ith^{-1}A_\eta}\bigr) \equiv \\
&\qquad (2\pi)^{-1}\bigl(\frac{h}{T}\bigr)^q\int \chi_{(q),T}(t)\varphi'_\nu\, e^{ith^{-1}(A_\eta-\tau)}\bigl((A_\eta-\tau)^2+\gamma^2\bigr)^{-q}\tilde\varphi_\nu\,dt
\end{aligned} \tag{19.4.41}$$

and therefore

$$(19.4.42)\quad F_{t\to h^{-1}\tau}\bigl(\chi_T(t)\varphi'_\nu\, e^{ith^{-1}A_\eta}\bigr)B\varphi_\nu \equiv$$
$$(2\pi)^{-1}\bigl(\frac{h}{T}\bigr)^q \int \chi_{(q),T}(t)\varphi'_\nu\, e^{ith^{-1}(A_\eta-\tau)}\tilde\varphi_\nu\bigl((A_\eta-\tau)^2+\gamma^2\bigr)^{-q}\tilde\varphi'_\nu\cdot \underbrace{\tilde\varphi_\nu B\varphi_\nu}_{\text{sandwich}}\,dt$$

where the origin of both factors $\tilde\varphi'_\nu$ is clear: the first one is again due to the propagation and the second one is just taken of $\tilde\varphi_\nu$.

Let us note that $\chi_{(q)}$ is a function bounded by $C\bigl(1+\varepsilon T/h\bigr)^{2q}$. Further, note that we already proved that the operator norm of the "sandwich" does not exceed $C\gamma^{lp}|\log h|^{-p\sigma}\bigl(1+\varepsilon T/h\bigr)^{-s}$ and therefore (19.4.22) for term with $p=1$ follows from estimate

$$(19.4.43)\qquad \sum_\nu \|\tilde\varphi'_\nu\bigl((A_\eta-\tau)^2+\gamma^2\bigr)^{-q}\tilde\varphi'_\nu\|_1 \le Ch^{-r}\gamma^{1-2q}$$

where $\|.\|_1$ means the trace norm.

(d) Let us prove (19.4.43). Because operator is positive, its left-hand expression does not exceed

$$(19.4.44)\qquad \mathsf{Tr}\bigl(\bigl((A_\eta-\tau)^2+\gamma^2\bigr)^{-q}\psi\bigr).$$

Let us consider γ-admissible partition; recall that $\gamma\ge\varepsilon$. Because in $B(z,\gamma)$ with $z=(x,\xi)$ variation of symbol of A_η does not exceed $C\gamma$, we conclude that (19.4.44) does not exceed

$$Ch^{-r}\int_{\mathcal{D}} \mathsf{Tr}'\bigl((a(z)-\tau)^2+\gamma^2\bigr)^{-s}\,dz = C\mu^{-r}h^r\int_{\mathcal{D}}\sum_J\bigl((\omega_J-\tau)^2+\gamma^2\bigr)^{-s}\,dz$$

where $a(z)$ is a (matrix) symbol of A_η and Tr' means a (matrix) trace, ω_J are eigenvalues of a (in order) and integrals are taken over bounded domain in $\mathcal{D}\subset\mathbb{R}^{2r}_{x'',\xi''}$.

Then (19.4.43) follows from

$$(19.4.45)\qquad \int\bigl(|\omega_j(z)-\tau|+\gamma\bigr)^{-q}\,dz \le C\gamma^{1-2q}$$

as $q>\frac12$ which, in turn, follows from the microhyperbolicity. Really, without any loss of the generality one can assume that $\ell=\partial_{z_1}$. Then uniformly with

respect to $z' = (z_2, \dots, z_d)$ $\epsilon \le \partial_{z_1}\omega_j \le C$ which instantly yields that even if we restrict ourselves by integral over z_1, (19.4.45) still holds.

Therefore *for a term with* $p = 1$ *estimate* (19.4.22) *is proven*. For $p \ge 2$ we need to modify our trace trick. Consider $(p+1)$-dimensional integrals representing corresponding terms

$$(19.4.46)\quad (2\pi)^{-1}h^{-p}\int_{\{t\ge t_1+\dots+t_p\}} \chi_T(t) e^{ih^{-1}\left((t-t_1-\dots-t_p)A_\eta - t\tau\right)} B\times e^{it_1h^{-1}A_\eta} B\cdots B e^{it_kh^{-1}A_\eta}\, dt_1\cdots dt_p\, dt.$$

Substituting

$$e^{ih^{-1}\left((t-t_1-\dots-t_p)A_\eta - t\tau\right)} = (-h^2\partial_t^2+\gamma^2)(A_\eta^2+\gamma^2)^{-1} e^{ih^{-1}\left((t-t_1-\dots-t_p)A_\eta - t\tau\right)}$$

and integrating one time by parts with respect to t we gain factor $(h/T)^2\big((A_\eta-\eta)^2+\gamma^2\big)^{-1}$ with χ, replaced by $\chi_{(1)} = (-\partial_t^2 + h^{-2}T^2\gamma^2)\chi$, but we also get new terms

$$(19.4.47)\quad ch^{1-p}\int \chi_T(t_1+\dots+t_p)\big((A_\eta-\eta)^2+\gamma^2\big)^{-1}\times e^{-ih^{-1}t\tau} B e^{it_1h^{-1}A_\eta} B\cdots B e^{it_ph^{-1}A_\eta}\, dt_1\cdots dt_p$$

and may be

$$(19.4.48)\quad ch^{2-p}\int \chi_T(t_1+\dots+t_{p-1})\big((A_\eta-\eta)^2+\gamma^2\big)^{-1}\times e^{-ih^{-1}t\tau} B e^{it_1h^{-1}A_\eta} B\cdots B e^{it_{p-1}h^{-1}A_\eta}\, dt_1\cdots dt_{p-1}$$

with some other functions χ. These new terms are just lesser-dimensional integrals of the same type. As before we frame operator exponents by φ_* functions before applying this trick.

(e) Now let $l = 1$, $\sigma > 1$. We need to consider R_m and generated by its expression which is $(m+1)$-dimensional integral

$$(19.4.49)\quad (2\pi)^{-1}h^{-m}\int_{\{t\ge t_1+\dots+t_m\}} \chi_T(t) e^{ih^{-1}\left((t-t_1-\dots-t_m)A_\eta - t\tau\right)} B\times e^{it_1h^{-1}A_\eta} B\cdots B e^{it_mh^{-1}A}\, dt_1\cdots dt_m\, dt.$$

We treat it in the same way as before, but in the end we apply estimate

$$\|(A_\eta + i\gamma)^{-1}\psi\|_1 \le Ch^{-r}\begin{cases} \gamma^{1-q} & \text{as } q>1,\\ |\log\gamma| & \text{as } q=1,\end{cases} \tag{19.4.50}$$

which is proven the same way (but simpler) as (19.4.43); we see that (19.4.49) does not exceed $Ch^{1-r}\bigl(\eta|\log h|^{-\sigma}Th^{-1}\bigr)^m|\log h| = Ch^{1-r}|\log h|^{m(1-\sigma)+1}$ as $T\ge h^{1-\delta}$; for large m it is less than the right-hand expression in (19.4.24).

Further, one can treat m-dimensional integral (19.4.48) in the same way. So, *estimates* (19.4.22) *and* (19.4.24) *are proven completely*. □

19.4.4 Short-Term Estimates

So, let us consider dynamics generated by our reduced operator as

$$T : h^{1-\delta}\le T\le T_* := C\mu h|\log h| \tag{19.4.51}$$

with arbitrarily small exponent $\delta>0$. Note that we need to consider only $T\ge \bar T := \epsilon_0\mu^{-1}$ because for $|t|\le \bar T$ standard theory takes place. Another restriction from below will appear later.

Recall that as $T\ll 1$ we do not need to distinguish microhyperbolicity and $\mathfrak{N}$-microhyperbolicity.

Proposition 19.4.9. *Let microhyperbolicity condition be fulfilled. Let ϕ be supported in the small vicinity of 0.*

(i) Let $l>1$. Then for $T\in[Ch^{1-\delta}, T_*]$ with arbitrarily small exponent $\delta>0$

$$|\phi(hD_t)\chi_T(t)(\Gamma U\psi)| \le Ch^{-d}\bigl(\frac{h}{T}\bigr)^{l-1}|\log\frac{h}{T}|^{-\sigma}\bigl(1+\frac{T\varepsilon}{h}\bigr)^{-s}, \tag{19.4.52}$$

$$|F_{t\to h^{-1}\tau}\chi_T(t)(\Gamma U\psi)| \le Ch^{1-d}\bigl(\frac{h}{T}\bigr)^{l-1}|\log\frac{h}{T}|^{-\sigma}\bigl(1+\frac{T\varepsilon}{h}\bigr)^{-s} \tag{19.4.53}$$

as $|\tau|\le\epsilon$ with arbitrarily large exponent s.

(ii) Let $l=1, \sigma\ge 2$. Then for $T\in[Ch^{1-\delta}, T_*]$ with arbitrarily small exponent $\delta>0$ estimates

$$|\phi(hD_t)\chi_T(t)(\Gamma U\psi)| \le Ch^{-d}\big(\frac{h}{T}\big)^{l-1}|\log\frac{h}{T}|^{-\sigma}\big(1+\frac{T\varepsilon}{h}\big)^{-s} + Ch^{-d}|\log\frac{h}{T}|^{-s}, \tag{19.4.54}$$

$$|F_{t\to h^{-1}\tau}\chi_T(t)(\Gamma U\psi)| \le Ch^{1-d}\big(\frac{h}{T}\big)^{l-1}|\log\frac{h}{T}|^{-\sigma}\big(1+\frac{T\varepsilon}{h}\big)^{-s} + Ch^{1-d}|\log\frac{h}{T}|^{-s} \tag{19.4.55}$$

as $|\tau|\le\epsilon$ *with arbitrarily large exponent* s.

Proof. As in the previous Subsection 19.4.3, we can consider χ supported in $[\frac12,1]$ and in what follows t, T_k are positive.

Consider η-mollification $\mathcal{A}_\eta$ of operator $A_\mathcal{T}$ with respect to x'',ξ'' with η satisfying (19.4.28). Then the error in the operator (i.e. the difference between A_η and A) will not exceed $C\eta^l|\log\eta|^{-s}$ in the sense that

$$\|(A_\eta - A)v\| \le C\eta^l|\log\eta|^{-s}\Big(\|Av\|+\|v\|\Big), \tag{19.4.56}$$

and then we just follow the proof of Proposition 19.4.8 with the following modifications:

(a) we consider $\mu^{-1}h$-pseudodifferential operators with respect to x'' with "matrix" symbols a; furthermore, factor $(\mu h)^{-r}$ comes from the "matrix" trace.

(b) Between different copies of $\mathcal{B}$ we place not only $\varphi_{(\lambda)\nu j}$ but also Q'_j where Q'_j are cut-offs with respect to (x',ξ') keeping all in zone $\{|x'|+|\xi'|\le C\mu^{-1}\}$ (and also $a_\mathfrak{m}$ in vicinity of $\tau_\mathfrak{m}$ for all $\mathfrak{m}\in\mathfrak{M}$).

(c) We remember that $\psi_\mathcal{T} = \psi(x',\mu^{-1}D';x'',\mu^{-1}hD'')$ with $\mathscr{F}^{l,\sigma}$-symbol and we need to mollify ψ as well. Then there will be either $\psi_{\mathcal{T}\eta}$ or $(\psi_{\mathcal{T}\eta}-\psi_\mathcal{T})$ factor; in the latter case it is possible that it is the only factor containing difference. In the former case we follow Subsection 19.4.2, in the latter case we just note that the norm of $(\psi_{\mathcal{T}\eta}-\psi_\mathcal{T})$ is $O(\eta^l|\log\eta|^{-\sigma})$ exactly as in $(A_{\mathcal{T}\eta}-A_\mathcal{T})$ but this time it is not accompanied by a rather large factor T/h and this makes things much more comfortable. □

Then summing over partition of $[-T_*,T_*]\setminus[-T'_*,T'_*]$ with $T'_* = Ch^{1-\delta}$ we get immediately inequality

$$|F_{t\to h^{-1}\tau}\big(\bar\chi_{T_*}(t)-\bar\chi_{T'_*}(t)\big)\Gamma(U\psi)| \le Ch^{1-d}. \tag{19.4.57}$$

Really, the left-hand expression here does not exceed the right-hand expression of (19.4.52) integrated over $\frac{dT}{T}$ from T'_* to T_* which, in turn, does not exceed Ch^{1-d}; contribution of extra term (19.4.54) as $l = 1$ does not exceed Ch^{1-d} as well. On the other hand, we know from rescaling of the standard results that (for $\mu \le \mu_2^*$)

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(U\psi)| \le Ch^{1-d} \tag{19.4.58}$$

as $T = T'_*$ and therefore it holds for $T = T_*$ and it follows from Section 19.2, that (19.4.58) holds for $T = T^*$. Recall that under microhyperbolicity assumption $T^* = \epsilon$ and under $\mathfrak{N}$-microhyperbolicity assumption $T^* = \epsilon\mu$ as either $\#\mathfrak{N} = 1$ or $(l,\sigma) \succeq (2,0)$ and $T^* = \epsilon\mu^{l-1}|\log\mu|^\sigma$ otherwise.

Then standard the Tauberian arguments imply immediately

Corollary 19.4.10. *Under microhyperbolicity condition as $\mu \le h^{\delta-1}$ estimate* (19.2.78) *holds.*

In the case $h^{\delta-1} \le \mu \le \mu_2^*$ we will need analysis of the next Subsection 19.4.5 to prove this statement. Anyway, we need it to get more explicit formula than (19.2.78) provides.

19.4.5 Calculations

In this subsection we still under assumption (19.3.5) will replace rather implicit Tauberian expression formula by a more explicit one and we finish the proof of the crucial inequality

$$|F_{t\to h^{-1}\tau}\Gamma\bar{\chi}_{T_*}(t)U\psi| \le Ch^{1-2r} + C\mu^r h^{1-r}. \tag{19.4.59}$$

Our tool will be method of successive approximations on a rather short interval $[-T_*, T_*]$.

Preliminary Remarks

Now we have a remainder estimate proven in some cases (see Corollary 19.4.10). However, its principal part is given by rather implicit Tauberian expression

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\,\mathsf{Tr}\big(e^{ih^{-1}tA_T}\psi_T\big)\Big)\,d\tau \tag{19.4.60}$$

with arbitrary $T \ge T_* = C\varepsilon^{-1}h|\log h|$ and $\psi_{\mathcal{T}} = \mathcal{T}^*\psi\mathcal{T}$.

Surely, microhyperbolicity condition is fulfilled only at levels close to 0 but as usual we do not need it otherwise. Really, let us decompose expression (19.4.60) into sum of

$$\int_{-\infty}^{0} \bar{\phi}_L(\tau)\Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\,\mathsf{Tr}\big(e^{ih^{-1}t\mathcal{A}}\psi_{\mathcal{T}}\big)\Big)\,d\tau \tag{19.4.61}$$

and

$$\int_{-\infty}^{\infty} \phi_L(\tau)\Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\,\mathsf{Tr}\big(e^{ih^{-1}t\mathcal{A}}\psi_{\mathcal{T}}\big)\Big)\,d\tau \tag{19.4.62}$$

where $\bar{\phi}$, ϕ are admissible functions, $\bar{\phi}$ is supported in $[-1,1]$ and equal 1 in $[-\frac{1}{2},\frac{1}{2}]$, $\phi = \theta(-\tau)\big(1-\bar{\phi}(\tau)\big)$, L is a small constant. Now we can use microhyperbolicity in the first term and replace $T = T^*$ by any $T \in [T_*, T^*]$. On the other hand, one can rewrite the second expression as

$$\Big(\phi_L(hD_t)\big(\bar{\chi}_T(t)\,\mathsf{Tr}\big(e^{ih^{-1}t\mathcal{A}}\psi_{\mathcal{T}}\big)\big)\Big)\Big|_{t=0} \tag{19.4.63}$$

and then one can replace here $T = T^*$ by any $T \in [T', T^*]$ where $T' = CL^{-1}h|\log\mu| \ll T_*$. One can see easily that expression (19.4.63) is of magnitude $h^{-d} + \mu^r h^{-r}$ and therefore we expect the principal part of asymptotics of the same magnitude. We assume that microhyperbolicity is in the direction ∂_{ξ_1}.

Recall that

$$\int_{-\infty}^{0} h^{-1}\Big(F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(U\psi\big)\Big)\,d\tau = T^{-1}\Big(F_{t\to h^{-1}\tau}\check{\chi}_T(t)\Gamma\big(U\psi\big)\Big)\Big|_{\tau=0} \tag{19.4.64}$$

with $\check{\chi}(t) = it^{-1}\chi(t)$; this formula as usual plays very important role below.

Remark 19.4.11. It follows from Propositions 19.4.9, 19.5.10–19.6.20 that in their framework expression (19.4.64) does not exceed $Ch^{-d}\big(h/T\big)^{l}|\log\big(h/T\big)|^{-\sigma}$ and thus

$$\int_{-\infty}^{0} h^{-1}\Big|\Big(F_{t\to h^{-1}\tau}(\bar{\chi}_{T_*}(t)-\bar{\chi}_T(t))\Gamma\big(U\psi\big)\Big)\,d\tau\Big| \le C\big(h^{-d}+\mu^r h^{-r}\big)\big(\frac{h}{T}\big)^{l}|\log\big(\frac{h}{T}\big)|^{-\sigma}. \tag{19.4.65}$$

In particular for $T = \bar{T}_* := \varepsilon^{-1}h$ the right-hand expression does not exceed the remainder estimates we want to prove (in any of our cases). We can even reduce T if the smoothness allows.

In particular, as $T = \epsilon\mu^{-1}$ (and therefore $\varepsilon = \mu h$) we get a remainder estimate $Ch^{-d}(\mu h)^l|\log\mu|^{-\sigma}$ which is a bit better than in Theorem 19.2.16.

Successive Approximation Method

We apply method of successive approximations to calculate both terms (19.4.61) and (19.4.62). We consider our operator $A_{\mathcal{T}}(x', hD'; x'', hD_{x''})$ as a matrix operator and then we take $A_{\mathcal{T}}(x', hD', y'', hD_{x''})$ for unperturbed operator $\bar{A}_{\mathcal{T}}$ (simplifying it later).

Then one can see easily that each next term of successive approximations gets an extra factor $\bar{\mathcal{G}}^{\pm}R$ or $\mathcal{G}^{\pm}R$ where $\bar{\mathcal{G}}^{\pm}$ and $\mathcal{G}^{\pm}$ are forward and backward parametrices of $hD_t - \bar{A}_{\mathcal{T}}$ and $hD_t - A_{\mathcal{T}}$ respectively and by Duhamel principle their operator norms on interval $[-T, T]$ do not exceed Th^{-1}.

Mollified by τ Asymptotics

Each next term of successive approximations when plugged there adds a factor $\|R\|$ to its estimate from above.

Really, it follows from the fact that $t^{-1}\bar{\mathcal{G}}^{\pm}$ and $t^{-1}\mathcal{G}^{\pm}$ are operators with norms h^{-1} and factor t either annuls the corresponding term, or is replaced by its commutator with $\phi_L(hD_t)$ thus releasing factor h. So, with expression (19.4.63) any perturbation with norm $O(h^{\delta})$ would be good enough to have only a bounded number of successive approximations to be considered, but $(x_j - y_j)$ is even better: as usual

$$\bar{\mathcal{G}}^{\pm}(x_j - y_j) = (x_j - y_j)\bar{\mathcal{G}}^{\pm} - \bar{\mathcal{G}}^{\pm}[\bar{A}, x_j]\bar{\mathcal{G}}^{\pm} \tag{19.4.66}$$

and similarly for $\mathcal{G}^{\pm}$, and as explained, these parametrices plugged into expression (19.4.63) do not increase an upper estimate, while the norm of $[\bar{A}, x_j]$ is $O(\mu^{-1}h)$.

Further, each perturbation of the form $(A_{\mathcal{T}} - \mathcal{A})$ adds a factor $\mu^{-l}|\log h|^{-\sigma}$ to the corresponding term in (19.4.63); we take $\bar{\mathcal{A}}$ as unperturbed operator in this Subsubsection.

So any term of the successive approximation but the first one, leads to term in (19.4.63) not exceeding $\bigl(\mu^{-1}h + \mu^{-l}|\log h|^{-\sigma}\bigr) \times h^{-d}$ which, in turn, does not exceed the remainder estimate. Therefore

(19.4.67) Modulo remainder estimate one can replace in (19.4.63) operator $A_{\mathcal{T}}$ by $\bar{\mathcal{A}}$ leading to expression

$$(19.4.68)\quad (2\pi)^{-r}\mu^r h^{-r}\times \int\int \bar{\phi}_L(\tau)\, d_\tau\Big(\mathsf{Tr}'\Big(\theta\big(\tau-\mathcal{A}(x'',\xi'')\big)\psi_{\mathcal{T}}(x'',\xi'')\Big)\Big)\, dx''d\xi''$$

where both $\mathcal{A}(x'',\xi'')$ and $\psi_{\mathcal{T}}(x'',\xi'')$ are considered as "matrices" i.e. as operators in auxiliary space $\mathbb{H}=\mathscr{L}^2(\mathbb{R}^r)$, $\theta\big(\tau-\mathcal{A}(x'',\xi'')\big)$ is its spectral projector and $\mathsf{Tr}'=\mathsf{Tr}_{\mathbb{H}}$ is a "matrix" trace.

Unmollified Asymptotics. I

Unfortunately things are not that good for expression (19.4.61) because parametrices are "worth" of T/h and therefore in view of (19.4.66) factor (x_j-y_j) is "worth" of $T^2h^{-2}\times\mu^{-1}h \asymp \varepsilon^{-2}\mu^{-1}h|\log h|^2 \asymp \mu h|\log h|^2$ (as $T=T_*$) which is not that small, especially for large μ.

In 2D-case considered in the previous Chapter 18 we could always arrange (after an appropriate symplectic map[25)]) to have (x_j-y_j) accomplished by an extra factor $\big(\varepsilon+\varepsilon^{l-1}|\log\varepsilon|^{-\sigma}\big)+\varepsilon^2$ because we considered a scalar symbol.

Here we have essentially a matrix symbol and this trick does not work (however it will work for a strong magnetic field). A bit larger ε does not help much as μ is close to h^{-1}. Further, perturbation $(A_{\mathcal{T}}-\mathcal{A})$ is "worth" of $Th^{-1}\times\mu^{-l}|\log\mu|^{-\sigma}\asymp\varepsilon^{-1}\mu^{-l}|\log h|^{1-\sigma}$ (again as $T=T_*$). In 2D-case we just removed such term at the very beginning.

However, using methods of Subsection 19.4.4 we will be able to insert a factor $\big(h/T\big)^{l}|\log(h/T)|^{-\sigma}$ into estimates of successive the approximation terms which will take care of few copies of factor Th^{-1}.

So, our goal now is to evaluate properly

$$(19.4.69)\qquad F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(U\psi\big)=F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(U_{\mathcal{T}}\psi_{\mathcal{T}}\big)$$

as $|\tau|\le\epsilon$.

Recall the successive approximation method is the following procedure: rewriting down

$$(19.4.70)\qquad (hD_t-A_{\mathcal{T}})U_{\mathcal{T}}^{\pm}=\mp ih\delta(t)\delta(x-y)$$

[25)] Which after quantization gives us a metaplectic transformation.

with $U^{\pm} = U\theta(\pm t)$ and thus

$$U^{\pm}_{T} = \mp ih\mathcal{G}^{\pm}\delta(t)\delta(x-y) \tag{19.4.71}$$

as

$$(hD_t - \bar{A}_{T})U^{\pm}_{T} = \mp ih\delta(t)\delta(x-y) + (A_{T} - \bar{A}_{T})U^{\pm} \tag{19.4.72}$$

with $U^{\pm} = U\theta(\pm t)$ and thus

$$U^{\pm}_{T} = \mp ih\bar{\mathcal{G}}^{\pm}\delta(t)\delta(x-y) + \bar{\mathcal{G}}^{\pm}(A_{T} - \bar{A}_{T})U^{\pm} \tag{19.4.73}$$

we can iterate the last equation few times:

$$\begin{aligned} U^{\pm}_{T} = \mp ih \sum_{0\le k\le m-1} \Big(\bar{\mathcal{G}}^{\pm}(A_{T} - \bar{A}_{T})\Big)^{k} \bar{\mathcal{G}}^{\pm}\delta(t)\delta(x-y) \\ \mp ih\Big(\bar{\mathcal{G}}^{\pm}(A_{T} - \bar{A}_{T})\Big)^{m} \mathcal{G}^{\pm}\delta(t)\delta(x-y); \end{aligned} \tag{19.4.74}$$

however, our latest technique allows usually to take $m = 1$. Applying ψ_{T} from the right we get that

$$\begin{aligned} U^{\pm}_{T} = \mp ih \sum_{0\le k\le m-1} \Big(\bar{\mathcal{G}}^{\pm}(A_{T} - \bar{A}_{T})\Big)^{k} \bar{\mathcal{G}}^{\pm}\delta(t)\mathcal{K}_{\psi}(x,y) \\ \mp ih\Big(\bar{\mathcal{G}}^{\pm}(A_{T} - \bar{A}_{T})\Big)^{m} \mathcal{G}^{\pm}\delta(t)\mathcal{K}_{\psi}(x,y) \end{aligned} \tag{19.4.75}$$

where $\mathcal{K}_{\psi}(x,y)$ is the Schwartz kernel of ψ_{T}.

(19.4.76) From now on Γ means that we set both Schwartz kernel arguments equal to y' (the same we used in the successive approximations) and then integrate.

Proposition 19.4.12. *In the framework of Proposition 19.4.9 for* $T \in [T', T^{*}]$, $T' := h^{1-\delta}$,

$$\begin{aligned} T^{-1}|F_{t\to h^{-1}\tau}\chi_{T}(t)\Gamma\Big(\bar{\mathcal{G}}^{\pm}(A_{T} - \bar{A}_{T})\mathcal{G}^{\pm}\delta(t)\mathcal{K}_{\psi}\Big)| \le \\ C\mu^{-1}h^{1-d}\big(\frac{h}{T}\big)^{l-2}|\log h|^{-\sigma}. \end{aligned} \tag{19.4.77}$$

Therefore

$$|\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_{T^*}(t)-\bar{\chi}_{T'}(t)\bigr)\Gamma\Bigl(\bar{\mathcal{G}}^{\pm}(A_{\mathcal{T}}-\bar{A}_{\mathcal{T}})\mathcal{G}^{\pm}\delta(t)\mathcal{K}_{\psi}\Bigr)\,d\tau| \le C\begin{cases}\mu^{-1}h^{1-d} & \text{as } (l,\sigma)\succeq(2,1),\\ \mu^{1-l}h^{1-d}|\log h|^{-\sigma} & \text{as } (l,\sigma)\prec(2,1)\end{cases} \tag{19.4.78}$$

and thus does not exceed remainder estimate of Theorem 19.4.17 below.

Proof. Rewriting

$$A_{\mathcal{T}}-\bar{A}_{\mathcal{T}}=\sum_j (x_j-y_j)R_j,\qquad R_j=R_j(x',\mu^{-1}hD';x'',y'',\mu^{-1}hD'') \tag{19.4.79}$$

we see that

$$\Bigl(\bar{\mathcal{G}}^{\pm}(A_{\mathcal{T}}-\bar{A}_{\mathcal{T}})\mathcal{G}^{\pm}\delta(t)\mathcal{K}_{\psi}\Bigr)= \sum_j\Bigl(\bar{\mathcal{G}}^{\pm}R_j\mathcal{G}^{\pm}\delta(t)\mathcal{K}_{\psi,j}\Bigr)-i\mu^{-1}h\sum_j\Bigl(\bar{\mathcal{G}}^{\pm}R_j\mathcal{G}^{\pm}A_{\mathcal{T}}^{(j)}\mathcal{G}^{\pm}\delta(t)\mathcal{K}_{\psi}\Bigr) \tag{19.4.80}$$

where we used the standard commutation relation (19.4.66) and $\mathcal{K}_{\psi j}=(x_j-y_j)\mathcal{K}_{\psi}$ is the Schwartz kernel of $[x_j,\psi]$. Note that symbols of $\bar{A}_{\mathcal{T}}^{(j)}$, R_j belong to $\mathscr{F}^{l-1,\sigma}$ while symbol of $[x_j,\psi]$ belongs to $\mu^{-1}h\mathscr{F}^{l-1,\sigma}$.

Therefore due to the Duhamel formula the left-hand expression of (19.4.77) is an absolute value of the sum of

$$\begin{aligned}&-i\mu^{-1}hT^{-1}F_{t\to h^{-1}\tau}\chi_{\mathcal{T}}(t)\,\mathsf{Tr}\sum_j\Bigl(\bar{\mathcal{G}}^{\pm}R_j\mathcal{G}^{\pm}A_{\mathcal{T}}^{(j)}\mathcal{G}^{\pm}\psi_{\mathcal{T}}\Bigr)=\\ &-i\mu^{-1}h^{-1}\,T^{-1}F_{t\to h^{-1}\tau}\chi_{\mathcal{T}}(t)\times\\ &\sum_j\mathsf{Tr}\Bigl(\int_{\{t_1+t_2\le t\}}e^{ih^{-1}(t-t_1-t_2)\bar{A}_{\mathcal{T}}}R_j e^{ih^{-1}t_1A_{\mathcal{T}}}A_{\mathcal{T}}^{(j)}e^{ih^{-1}t_2A_{\mathcal{T}}}\psi_{\mathcal{T}}\,dt_1\,dt_2\Bigr)\end{aligned} \tag{19.4.81}$$

and

$$\begin{aligned}&T^{-1}F_{t\to h^{-1}\tau}\chi_{\mathcal{T}}(t)\,\mathsf{Tr}\sum_j\Bigl(\bar{\mathcal{G}}^{\pm}R_j\mathcal{G}^{\pm}[x_j,\psi_{\mathcal{T}}]\Bigr)=\\ &T^{-1}F_{t\to h^{-1}\tau}\chi_{\mathcal{T}}(t)\sum_j\mathsf{Tr}\Bigl(\int_{\{t_1\le t\}}e^{ih^{-1}(t-t_1)\bar{A}_{\mathcal{T}}}R_j e^{ih^{-1}t_1A_{\mathcal{T}}}[x_j,\psi_{\mathcal{T}}]\,dt_1\Bigr).\end{aligned} \tag{19.4.82}$$

For $\eta = Ch T^{-1}|\log h|$ let us make η-mollification $A_{\mathcal{T}\eta}$ of (symbol) of $A_{\mathcal{T}}$ and also of ψ; thus we will get also $\bar{A}_{\mathcal{T}\eta}$. Note that the left-hand expression of (19.4.77) with $A_{\mathcal{T}}$, $\bar{A}_{\mathcal{T}}$ replaced by $A_{\mathcal{T}\eta}$, $\bar{A}_{\mathcal{T}\eta}$ is negligible again due to Proposition 19.4.3. Really, both operators $A_{\mathcal{T}\eta}$, $\bar{A}_{\mathcal{T}\eta}$ are microhyperbolic in the same direction.

Consider the difference between expressions (19.4.80) for η-mollified and original operators.

To do this we apply formula (19.4.35)–(19.4.36) assuming first that $l > 1$ and skipping the negligible remainder. Then the difference in (19.4.81) will be operator

$$-i\mu^{-1}h^{-1-k}F_{t\to h^{-1}\tau}\chi_T(t)\sum_j \mathsf{Tr}$$

applied to the sum of the following terms (with the constant coefficients)

$$\mu^{-1}h^{-1-k-k_1-k_2}\int_{\Delta_k} e^{ih^{-1}(t-t_1-t_2-\ldots-t_k)\bar{A}_{\mathcal{T}\eta}}\mathcal{C}_1 e^{ih^{-1}t_1\bar{A}_{\mathcal{T}\eta}}\mathcal{C}_2\cdots\mathcal{C}_k e^{ih^{-1}t_k\bar{A}_{\mathcal{T}\eta}}\psi'$$

where operators $\mathcal{C}_k$ are in a some order:

(a) one copy of $\bar{A}^{(j)}_{\mathcal{T}\eta}$ or $(\bar{A}^{(j)}_{\mathcal{T}\eta} - A^{(j)}_{\mathcal{T}\eta})$,

(b) one copy of $R_{j\eta}$ or $(R_{j\eta} - R_j)$ and

(c) $(\bar{A}_{\mathcal{T}} - \bar{A}_{\mathcal{T}\eta})$ constitute the rest;

also $\psi' = \psi_{\mathcal{T}\eta}$ or $\psi' = (\psi_{\mathcal{T}} - \psi_{\mathcal{T}\eta})$ and among all the factors there must be at least one factor which is the difference between mollified and non-mollified operators.

Acting as in the proof of Proposition 19.4.8 we can also gain the factor $h^{2q}T^{-2q}\big((\bar{A}_{\mathcal{T}\eta}-\tau)^2+\gamma^2\big)^{-q}$ replacing χ by $(-\partial_t^2+\gamma^2T^2h^{-2})^q\chi$. Further, 2D-integral can also appear instead of 3D one (one extra integral comes from the Fourier transform).

Note that

(a) each factor $(\bar{A}_{\mathcal{T}} - \bar{A}_{\mathcal{T}\eta})$ or $(A_{\mathcal{T}} - A_{\mathcal{T}\eta})$ is worth of $\eta'|\log h|^{-\sigma}$ and is accompanied by a factor not exceeding Th^{-1} while

(b) each factor $(\bar{A}^{(j)}_{\mathcal{T}} - \bar{A}^{(j)}_{\mathcal{T}\rho})$ or $(R_{j\eta} - R_j)$ is worth of $\eta'^{-1}|\log h|^{-\sigma}$ and $(\psi_{\mathcal{T}} - \psi_{\mathcal{T}\eta})$ is worth of $\eta'|\log h|^{-\sigma}$.

Then using estimate (19.4.50) with $\gamma = h/T$ one can derive easily that the difference does not exceed $C\mu^{-1}h^{1-d}\big(h/T\big)^{l-2}|\log h|^{l-\sigma}$ and we arrive to the estimate different from the desired one by an extra factor $|\log h|^{l}$.

There are many methods to get rid of this factor; let us apply the cheapest one. First, let we apply m iterations in successive approximations and note that each extra iteration brings the factor $\mu^{-1}h \times T^2h^{-2} \le \mu h \le |\log h|^{-1}$ and use the same arguments as above; we conclude that instead of $\mathcal{G}^{\pm}$ we need to consider $\big(\bar{\mathcal{G}}^{\pm}(A_{\mathcal{T}} - \bar{A}_{\mathcal{T}})\big)^k\bar{\mathcal{G}}^{\pm}$; so we got rid of $\mathcal{G}^{\pm}$ but paid for this by a bit more complicated expression. This expression includes also $[x_j - x_k, R_j]$, $[x_j - x_k, A^{(j)}]$ etc but one can see easily that the corresponding terms would satisfy the desired estimate.

Also, because $l > 1$ we see from the above mollification arguments that all the terms with more than one factor of $(\bar{A}_{\mathcal{T}} - \bar{A}_{\mathcal{T}\eta})$, $(\bar{A}^{(j)}_{\mathcal{T}} - \bar{A}^{(j)}_{\mathcal{T}\eta})$ and $(R_j - R_{j\eta})$ satisfy the desired estimate and thus we need to consider only terms with exactly one such factor. Further, terms containing factor $(\psi_{\mathcal{T}} - \psi_{\mathcal{T}\eta})$ satisfy this estimate for sure.

Furthermore, if we replace in such factor η by $\rho_0 = h/T$ we will get terms which can be properly estimated and thus in the terms under consideration we can replace $(\bar{A}_{\mathcal{T}} - \bar{A}_{\mathcal{T}\eta})$ by $(\bar{A}_{\mathcal{T}\rho_0} - \bar{A}_{\mathcal{T}\eta}) = \sum_n \mathcal{B}_n$, also replace $(\bar{A}^{(j)}_{\mathcal{T}} - \bar{A}^{(j)}_{\mathcal{T}\eta})$ by $(\bar{A}^{(j)}_{\mathcal{T}\rho_0} - \bar{A}^{(j)}_{\mathcal{T}\eta}) = \sum_n \mathcal{B}'_n$, and replace $(R_j - R_{j\eta})$ by $(R_{j\rho_0} - R_{j\eta}) = \sum_n \mathcal{B}''_n$ where $\mathcal{B}_n := (\bar{A}_{\mathcal{T}\rho_n} - \bar{A}_{\mathcal{T}\rho_{n+1}})$ etc where again $\rho_n = 2^n\rho_0$.

Now we can just repeat arguments of the proof of Proposition 19.4.8, related to $\mu^{-1}T$-partition with respect to x_1 assuming that microhyperbolicity direction is ∂_{ξ_1}.

On the other hand, if $l = 1$, using (19.4.49) and related integration by part trick (but without $\mu^{-1}T$-partition), one can see easily that the far terms in the successive approximation satisfy estimate in question and thus we got rid of $\mathcal{G}^{\pm}$ leaving only $\bar{\mathcal{G}}^{\pm}$.

We can apply the mollification and formulae (19.4.35)–(19.4.36) skipping terms generated by (19.4.36); then we arrive to an estimate which contains in comparison with the desired one an extra factor $|\log h|$ and all the terms save the same as above surely satisfy the desired estimate. Now we just apply the same $\mu^{-1}T$-partition with respect to x_1 etc as above.

Analysis of the expression (19.4.82) uses the same technique but is simpler. □

Unmollified Asymptotics. II

Now we are in the shortest-range zone $|t| \le \bar{T} := h^{1-\delta}$. Then as $\mu \le \epsilon h^{\delta-1}$ we can apply rescaling arguments and arrive to estimate (19.4.59) which implies the corresponding Tauberian estimate.

However, as $\epsilon h^{\delta-1} \le \mu \le \epsilon(h|\log h|)^{-1}$ we still need to estimate $F_{t\to h^{-1}\tau}\bar{\chi}_T\Gamma(U_T\psi_T)$. Using a successive approximation method in its rough form we conclude that modulo term not exceeding $CTh^{-d}\times \mu^{-1}h(T/h)^2 \asymp \mu^{-1}h^{1-d-3\delta}$ we can replace here U by U^0_T which is a Schwartz kernel of $e^{ih^{-1}t\bar{A}}$. Then calculations show that for $T=\bar{T}$ and $\bar{\chi}=1$ on $[-\frac12,\frac12]$

$$F_{t\to h^{-1}\tau}\bar{\chi}_T\Gamma(u^0_T\psi_T) \equiv (2\pi)^{-r}\mu^r h^{1-r}\partial_\tau \int \mathsf{Tr}'\Big(\theta\big(\tau-\mathcal{A}(x'',\xi'')\big)\psi_T(x'',\xi'')\Big)\,dx''d\xi'' \tag{19.4.83}$$

modulo negligible term where $\theta\big(\tau-\mathcal{A}(x'',\xi'')\big)$ is the spectral projector of $\mathcal{A}$ considered as operator in $\mathbb{H}$, $\psi(x'',\xi'')$ is also operator in $\mathbb{H}$ and Tr' is a trace in $\mathbb{H}$.

One can see easily that due to the microhyperbolicity condition for small increment $d\tau$ eigenvalue $\omega_\jmath(x'',\xi'')$ of matrix $\mathcal{A}(x'',\xi'')$ belongs to $[\tau,\tau+d\tau]$ only for (x'',ξ'') belonging to the set of measure not exceeding $Cd\tau$. Since there are $\asymp(\mu h)^{-r}$ of such eigenvalues we conclude that expression (19.4.83) does not exceed Ch^{1-d}.

This and the previous arguments imply immediately estimate (19.4.57) with $T=\bar{T}$ and thus the same estimate (19.4.57) with $T=T_*$ and thus (19.4.57) with $T=T^*$. Then the standard Tauberian arguments imply estimate (19.2.78). So we have proven

Proposition 19.4.13. *Under either microhyperbolicity or $\mathfrak{N}$-microhyperbolicity condition for $\mu\le\epsilon(h|\log h|)^{-1}$ estimates* (19.4.57) *and* (19.2.78) *hold.*

Still we need to get more a explicit formula:

Proposition 19.4.14. *Under either microhyperbolicity or $\mathfrak{N}$-microhyperbolicity condition for $\mu\le\epsilon(h|\log h|)^{-1}$*

$$|\Gamma(\psi\tilde{e})(\tau) - (2\pi)^{-r}\mu^r h^{-r}\int \mathsf{Tr}'\Big(\theta\big(\tau-A_T(x'',\xi'')\big)\psi_T(x'',\xi'')\Big)\,dx''d\xi''| \le C\mu^{-1}h^{1-d}\Big(1+\varepsilon'^{-2}|\log h|^{-\sigma}\Big). \tag{19.4.84}$$

Proof. In view of what we have proven already we need to prove that

$$|h^{-1}\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\Big(\bar{\mathcal{G}}^{\pm}(A_{\mathcal{T}}-\bar{A}_{\mathcal{T}})\mathcal{G}^{\pm}\delta(t)\mathcal{K}_{\psi}\Big)\,d\tau| \tag{19.4.85}$$

with $T=\bar{T}$ does not exceed right-hand expression of (19.4.84).

Consider expression (19.4.85) first. Clearly it does not exceed $C\mu^{-1}h^{-d-2}T^3$ and for $T=\bar{T}$ it is just $C\mu^{-1}h^{1-d-3\delta}$ and therefore the required estimate holds as $l<2$; so we need to consider case $l\ge 2$ only.

Applying then the brute-force successive approximations we conclude that replacing in (19.4.85) $\mathcal{G}^{\pm}$ by $\bar{\mathcal{G}}^{\pm}$ leads to a much smaller error. Also, note that

$$A_{\mathcal{T}}-\bar{A}_{\mathcal{T}}=\sum_j (x_j-y_j)\bar{A}_{\mathcal{T}(j)}+\sum_{j,k}(x_j-y_j)(x_k-y_k)R'_{jk}$$

with $R'_{jk}\in \mathscr{F}^{l-2,\sigma}$. Then using the commutator equality for all (x_j-y_j) factors, we conclude that the contribution of these terms will be also much smaller. In the end we are left with the term

$$-i\mu^{-1}\sum_j F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\,\mathsf{Tr}\Big(\bar{\mathcal{G}}^{\pm}\bar{A}_{\mathcal{T}(j)}\bar{\mathcal{G}}^{\pm}\bar{A}^{(j)}_{\mathcal{T}}\bar{\mathcal{G}}^{\pm}\psi_{\mathcal{T}}\Big) \tag{19.4.86}$$

which is reduced to

$$\begin{aligned} i(2\pi)^{-r}\mu^{r-1}h^{-r}\sum_j F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\,\mathsf{Tr}'\int\Big(&\mathcal{G}^{\pm}(x'',\xi'')A_{\mathcal{T}(j)}\\ &(x'',\xi'')\mathcal{G}^{\pm}(x'',\xi'')A^{(j)}_{\mathcal{T}}(x'',\xi'')\mathcal{G}^{\pm}(x'',\xi'')\psi^0(x'',\xi'')\Big)\,dx''d\xi'' \end{aligned} \tag{19.4.87}$$

where we have just matrix-valued symbols $a(x'',\xi'')=A_{\mathcal{T}}(x'',\xi'')$ and $\mathcal{G}^{\pm}(x'',\xi'')$ and we replaced matrix-valued function $\psi_{\mathcal{T}}(x'',\xi'')$ by the scalar-valued one $\psi^0(x'',\xi'')$; this is legitimate since $\psi_{\mathcal{T}}(x'',\xi'')\equiv\psi^0(x'',\xi'')$ modulo $O(\mu^{-1})$.

Using that $\partial_{x_j}\mathcal{G}^{\pm}(x'',\xi'')=\mathcal{G}^{\pm}(x'',\xi'')A_{\mathcal{T}(j)}(x'',\xi'')\partial_{x_j}\mathcal{G}^{\pm}(x'',\xi'')$ and similar identity for ∂_{ξ_j} one can rewrite (19.4.87) due to the trace property and scalar nature of ψ^0 as

$$\begin{aligned} &(2\pi)^{-r}\mu^{r-1}h^{-r}F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\times\\ &\mathsf{Tr}'\int\Big(\mathcal{G}^{\pm}(x'',\xi'')B(x'',\xi'')\mathcal{G}^{\pm}(x'',\xi'')\Big)\psi^0(x'',\xi'')\,dx''d\xi''+\\ &\frac{i}{2}(2\pi)^{-r}\mu^{r-1}h^{-r}F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\,\mathsf{Tr}'\int\mathcal{G}^{\pm}(x'',\xi'')\psi'(x'',\xi'')\,dx''d\xi'' \end{aligned} \tag{19.4.88}$$

with $B = -\frac{i}{2}\sum_j A^{(j)}_{\mathcal{T}(j)}$ and $\psi' = \sum_j \psi^{0(j)}_{(j)}$.We can rewrite the first term here as the convolution with respect to τ of $L\cdot \widehat{\bar{\chi}}(L\tau)$ (with $L = Th^{-1}$) with

$$(19.4.89)\quad (2\pi)^{-r}\mu^{r-1}h^{-r}\,\mathsf{Tr}'\,\partial_\tau\times \int \theta\big(\tau - A_{\mathcal{T}}(x'',\xi'')\big)B(x'',\xi'')\psi^0(x''\xi'')\,dx''d\xi''.$$

Due to the microhyperbolicity and monotonicity of θ with respect to τ this convolution does not exceed $C\mu^{r-1}h^{1-r}\times(\mu h)^{-r}\times(1+\mu^{2-l}|\log\mu|^{-\sigma})$ where the last factor is just upper bound of $B(x'',\xi'')$ and $(\mu h)^{-r}$ comes from the trace Tr' and what we got does not exceed the right-hand expression of (19.4.84).

We can rewrite the second term in (19.4.89) as the convolution with respect to τ of $L\widehat{\bar{\chi}}(L\tau)$ (with $L = Th^{-1}$) with

$$(19.4.90)\qquad (2\pi)^{-r}\mu^{r-1}h^{-r}\,\mathsf{Tr}'\int \theta\big(\tau - A_{\mathcal{T}}(x'',\xi'')\big)\psi'(x''\xi'')\,dx''d\xi''$$

and this convolution does not exceed the same expression where factor $(1+\mu^{2-l}|\log\mu|^{-\sigma})$ this time is an upper bound for ψ'. □

Unmollified Asymptotics. III

Now we can decompose expression

$$(19.4.91)\qquad (2\pi)^{-r}\mu^{r}h^{-r}\int \mathsf{Tr}'\,\theta\big(\tau - A_{\mathcal{T}}(x'',\xi'')\big)\psi_{\mathcal{T}}(x'',\xi'')\,dx''d\xi''$$

as

$$(19.4.92)\quad (2\pi)^{-r}\mu^{r}h^{-r}\int \mathsf{Tr}'\,\theta\big(\tau - \mathcal{A}_0(x'',\xi'')\big)\psi^0(x'',\xi'')\,dx''d\xi'' + h^{-d}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$$

with

$$(19.4.93)\quad \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} := (2\pi)^{-r}(\mu h)^r\int \mathsf{Tr}'\Big(\theta\big(\tau - A_{\mathcal{T}}(x'',\xi'')\big) - \theta\big(\tau - \mathcal{A}_0(x'',\xi'')\big)\Big)\times \psi^0(x'',\xi'')\,dx''d\xi''+$$
$$(2\pi)^{-r}(\mu h)^r\int \mathsf{Tr}'\,\theta\big(\tau - A_{\mathcal{T}}(x'',\xi'')\big)\times \big(\psi_{\mathcal{T}}(x'',\xi'') - \psi^0(x'',\xi'')\big)\,dx''d\xi''$$

Then making change of variables Ψ_0 in the integration and using (19.2.18) and (19.3.39) for the Jacobian we conclude that

(19.4.94) The first term in (19.4.92) equals to

$$h^{-d}\int \mathcal{N}^{\mathsf{MW}}(x,\tau)\psi(x)\,dx.$$

Let us represent expression (19.4.93) as

$$\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} = \int \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr},x}(\tau)\psi(x)\,dx. \tag{19.4.95}$$

While it is clearly the case with the first term in (19.4.93), in the second term we can rewrite

$$\psi_{\mathcal{T}}(x'',\xi'') - \psi^0(x'',\xi'') = \sum_{1\le|\alpha|+|\beta|\le m} \psi_{\alpha\beta}(x'',\xi'')(x')^{\alpha}(\mu^{-1}hD')^{\beta} + O(\mu^{-l}|\log\mu|^{-\sigma}) \tag{19.4.96}$$

with $m = \lfloor (l,\sigma)\rfloor$; then we can just skip the last term (because the output of it will be $O(\mu^{-l}|\log\mu|^{-\sigma}h^{-d})$). Since

$$\psi_{\alpha\beta}\circ\Psi_0 = \sum_{\gamma:1\le\gamma\le|\alpha|+\beta|} \rho_{\alpha\beta\gamma}\partial^{\gamma}\psi(x)$$

we can always rewrite the second term in the required form as well. What we are lacking is the estimate for these two terms.

Proposition 19.4.15. *(i) In the case of the intermediate magnetic field under the microhyperbolicity condition*

$$\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} \le C\begin{cases} \mu^{-l}|\log\mu|^{-\sigma} & \text{as } l<2;\\ \mu^{-2}(\mu h)^{l-2}|\log(\mu h)|^{-\sigma} + \mu^{-1}h & \text{as } l>2.\end{cases} \tag{19.4.97}$$

(ii) In particular, $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} \le C\mu^{-1}h$ *for* $(l,\sigma)\succeq(3,0)$.

Therefore $(2,0)\prec(l,\sigma)\prec(3,0)$ is the only case when we cannot skip $h^{-d}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ in the final answer.

Proof. (i) Assume first that $(l,\sigma)\preceq(2,0)$.

First of all, let us replace $A_{\mathcal{T}}$ by $\mathcal{A}$. Due to the microhyperbolicity and the fact that $(A_{\mathcal{T}}-\mathcal{A})$ is bounded by $C\mu^{-l}|\log\mu|^{-\sigma}$, such operation causes an admissible error $O(\mu^{-l}|\log\mu|^{-\sigma}h^{-d})$.

Replacing in the second term in (19.4.93) $\mathcal{A}$ by $\mathcal{A}_0$ we get an error $O(\mu^{-2})$. Really, each factor $\bigl(\theta(\tau-\mathcal{A})-\theta(\tau-\mathcal{A}_0)\bigr)$ and $(\psi_{\mathcal{T}}-\psi^0)$ contributes the factor μ^{-1} into the remainder estimate. So we need to consider the second term in (19.4.93) with $A_{\mathcal{T}}$ replaced by $\mathcal{A}_0$ and with $(\psi_{\mathcal{T}}-\psi^0)$ replaced by ψ^1,

$$\psi^m=\sum_{|\alpha|+|\beta|=m}\psi_{\alpha\beta}(x'',\xi'')(x')^{\alpha}(\mu^{-1}hD')^{\beta} \tag{19.4.98}$$

but then after taking trace Tr' we get 0.

In the first term in (19.4.93) $\mathcal{A}=\mathcal{A}_0+\mathcal{A}_1$. Consider $\mathcal{A}_0$ as an unperturbed operator and $\mathcal{A}_0+\mathcal{A}_1$ as a perturbed one. Let us return back to representation (19.2.78).

We claim that

(19.4.99) As $m>l+1$, the contribution of m-th term of successive approximations does not exceed $Ch^{-d}\vartheta(\mu^{-1})$.

Really, replace $\mathcal{A}_0$ and $\mathcal{A}_1$ by their η-mollifications. Then, in virtue of our previous arguments, replacing η-mollification of $\mathcal{A}_0$ by its 2η-mollification we get an error not exceeding

$$Ch^{-d}\vartheta(\eta)\times\Bigl(\frac{\mu^{-1}T}{h}\Bigr)^{m-1}\times\Bigl(1+\frac{\eta T}{h}\Bigr)^{-s} \tag{19.4.100}$$

and similarly replacing η-mollification of $\mathcal{A}_1$ by its 2η-mollification we get an error not exceeding the same expression with an factor $\vartheta(\eta)$ replaced by $hT^{-1}\vartheta(\eta)\eta^{-1}$; thus we get the same expression (19.4.100).

Summation with respect to η returns $Ch^{-d}\vartheta\bigl(h/T\bigr)\times\bigl(T/\mu h\bigr)^{m-1}$ and then summation with respect to $T\le C\mu h$ returns this expression as $T=\mu h$ i.e. $Ch^{-d}\vartheta(\mu^{-1})$. On the other hand, as $T\ge C\mu h$ we just do not need to consider successive approximations but the whole difference.

Further, as we have η-mollified $\mathcal{A}_0$ and $\mathcal{A}_1$, the contribution of this term does not exceed

$$Ch^{1-d}T^{-1}\times \big(\frac{\mu^{-1}T}{h}\big)^{m-1}\times \big(1+\frac{\eta T}{h}\big)^{-s}$$

and taking $\eta=\epsilon$ we get $Ch^{-d}\mu^{1-m}$ after summation with respect to T. So (19.4.99) is proven.

Therefore for $l<2$ we can take $m=3$ i.e. take only two terms of the successive approximations.

Note that the first term of the successive approximations annihilates with the corresponding expression for an unperturbed operator.

Recall that

$$\mathcal{A}_0=\Big(\mu^2\sum_{j,k} a_{jk}\zeta_j^\dagger\zeta_k+V\Big)^{\mathsf{w}}$$

preserves spaces $\mathscr{H}_n$ and

$$\mathcal{A}_1=\Big(2\operatorname{Re}\mu^2\sum_{j,k,p} b_{jkp}\zeta_j^\dagger\zeta_k\zeta^p+\sum_k b_k\zeta_k\Big)^{\mathsf{w}}$$

maps $\mathscr{H}_n$ into $\mathscr{H}_{n+1}\oplus\mathscr{H}_{n-1}$ and therefore after taking trace the second term of successive approximations results in 0 for ψ_T replaced by ψ^0.

We need also to consider the similar expressions for ψ_T replaced by ψ^1 but in this case the first term of successive approximations vanishes and the second term has a desired estimate.

(ii) On the other hand, for $l>2$, $(l,\sigma)\preceq(3,0)$ we need to remember that $\mathcal{A}=\mathcal{A}_0+\mathcal{A}_1+\mathcal{A}_2$, $\psi_T=\psi^0+\psi^1+\psi^2$ and also we need to consider four extra terms (the rest definitely is estimated in a desired way) which are[26)]

$$ih^{-1}\int_{-\infty}^0 F_{t\to h^{-1}\tau}\bar\chi_T(t)\operatorname{Tr}\Big(\sum_{\pm}\mp\mathcal{G}_0^{\pm}\mathcal{A}_1\mathcal{G}_0^{\pm}\mathcal{A}_1\mathcal{G}_0^{\pm}\psi^0\Big)\,d\tau, \tag{19.4.101}$$

$$ih^{-1}\int_{-\infty}^0 F_{t\to h^{-1}\tau}\bar\chi_T(t)\operatorname{Tr}\Big(\sum_{\pm}\mp\mathcal{G}_0^{\pm}\mathcal{A}_2\mathcal{G}_0^{\pm}\psi^0\Big)\,d\tau, \tag{19.4.102}$$

$$ih^{-1}\int_{-\infty}^0 F_{t\to h^{-1}\tau}\bar\chi_T(t)\operatorname{Tr}\Big(\sum_{\pm}\mp\mathcal{G}_0^{\pm}\mathcal{A}_1\psi^1\Big)\,d\tau, \tag{19.4.103}$$

$$ih^{-1}\int_{-\infty}^0 F_{t\to h^{-1}\tau}\bar\chi_T(t)\operatorname{Tr}\Big(\sum_{\pm}\mp\mathcal{G}_0^{\pm}\psi_2\Big)\,d\tau \tag{19.4.104}$$

[26)] As we return back to parametrices, cut-off on interval $[-\hat T,\hat T]$ etc.

with $T = \hat{T} = \mu h$ and $\mathcal{G}_0^{\pm}$ parametrices of $hD_t - \mathcal{A}_0$. Here Tr means that we take $x = y$ and then integrate; recall that all operators here depend on y.

Really, even as $l = 3$ we need to consider to $m = 4$ but this term vanishes in virtue the above arguments related to $\mathscr{H}_n$-scale.

Replacing $\bar{\chi}_T(t)$ by $\chi_T(t)$ and applying the same technique as before we find that such modified expressions (19.4.101)–(19.4.104) do not exceed $C\mu^{-2}h^{-d}(h/T)^{l-2}|\log(h/T)|^{-\sigma}$.

Then after summation over t-partition we find that the contribution of segment $[\bar{T}, \hat{T}]$ is estimated now by $C\mu^{-2}h^{-d}(h/\bar{T})^{l-2}|\log(h/\bar{T})|^{-\sigma}$. We take $\bar{T} = \epsilon\mu^{-1}$. This is clearly possible provided

$$\mu \le h^{\delta-1}. \tag{19.4.105}$$

Assuming this, let us consider contribution of $[-\bar{T}, \bar{T}]$. Returning from $\mathcal{T}$ reduction to the initial settings we can rewrite (19.4.101)–(19.4.104) (modulo terms, estimated properly) as the similar expressions but with $\mathcal{G}_0^{\pm}$ replaced by parametrices $\bar{G}^{\pm}$ of operator $\bar{A}$, given by (19.2.84):

$$\bar{A} = \sum_{j,k} \bar{g}^{jk}\bar{P}_j\bar{P}_k + \bar{V}, \qquad \bar{g}^{jk} = g^{jk}(y), \bar{V} = V(y), \tag{19.4.106}$$

$$\bar{P}_j = hD_j - V_j(y) - \sum_k (\partial_k V_j)(y)(x_k - y_k),$$

and $\mathcal{A}_j$ and ψ^j are replaced by

$$\bar{A}_j = \sum_{\alpha:|\alpha|\ge 2+j} \mu^{2-|\alpha|} b_\alpha(y)\bar{P}^\alpha + \sum_{\alpha:|\alpha|\ge j} \mu^{-|\alpha|} b_\alpha(y)\bar{P}^\alpha, \tag{19.4.107}$$

and

$$\bar{\psi}^j = \sum_{\alpha:|\alpha|\ge j} \mu^{-|\alpha|}\psi_\alpha(y)\bar{P}^\alpha \tag{19.4.108}$$

respectively.

Note that the coefficients of all operators are smooth in ε-scale with $\varepsilon = \mu^{-1}$ which is larger than $Ch|\log h|$ required by the standard theory which is applicable then (after we scale $x \mapsto \mu x$, $h \mapsto \mu h$, $t \mapsto \mu t$ producing that

(a) before rescaling the contributions of intervals $[-\epsilon\mu^{-1}, -Ch|\log h|]$ and $[Ch|\log h|, \epsilon\mu^{-1}]$ are negligible and

(b) the contribution of interval $[-Ch|\log h|, Ch|\log h|]$ is equal to $\mu^{-2}\sum_{j\ge 0}\kappa_j(\mu h)^j$ with the coefficients κ_j which do not depend on μ, h.

We should not care about terms with $j \ge 1$ here because these terms do not exceed $C\mu^{-1}h^{1-d}$. Therefore,

$$h^{-d}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} = \kappa_0\mu^{-2}h^{-d} + O\big(\mu^{-2}(\mu h)^{l-2}|\log(\mu h)|^{-\sigma} + \mu^{-1}h\big)$$

(we can alway replace it modulo properly estimated).

Now notice that the "main part" of asymptotics is $h^{-d}\int \mathcal{N}^{\mathsf{MW}}(x)\psi(x)\,dx$ which in comparison with Theorem 19.2.16 for $\mu \asymp (h|\log h|)^{-\frac{1}{2}}$ implies that $\kappa_0 = 0$.

Therefore, under assumption (19.4.105) statement (ii) of proposition is proven.

(iii) To get rid of assumption (19.4.105) let us return to terms (19.4.101)–(19.4.104) with $\bar{\chi}$ replaced by χ and with $T \ge \epsilon\mu^{-1}$.

Each of these expressions is equal to $\mu^{-2}h^{-d}f(T/h, \mu h)$ and therefore the above arguments imply estimate

$$\mu h|\log h| \le \epsilon, \quad T \ge h^{1-\delta}, \quad 1 \ge \varepsilon \ge C_0\mu^{-1} \implies |f(\frac{T}{h}, \mu h)| \le C(\frac{h}{T})^{l-2}|\log(\frac{h}{T})|^{-\sigma}. \tag{19.4.109}$$

This is a really strange inequality because its assumptions involve T and h separately but its conclusion contains them only as T/h. This gives us a certain flexibility. Namely, let us assume that

$$h \le T \le h^{1-\delta} \tag{19.4.110}$$

(otherwise everything is fine) and replace $h \mapsto h\lambda$, $T \mapsto T\lambda$, $\mu \mapsto \mu\lambda^{-1}$ which affects neither μh nor (h/T). Assumptions of (19.4.109) should be fulfilled now with these modified h, T, μ. To fulfil the second one we take $\lambda = h^{-1}(hT^{-1})^{1/\delta}$ and this is greater than 1 due to (19.4.110).

The first of the assumptions of (19.4.109) will survive[27] but the third one is now replaced by a more restrictive condition $\varepsilon \ge C_0\mu^{-1}\lambda$. To get rid

[27] In fact, it will be fulfilled as long as $\mu h|\log(h/T)| \le \epsilon'$.

of it let us apply $C\mu^{-1}\lambda$-mollification which leads to the error in $f(T/h, \mu h)$, not exceeding

$$C(\mu^{-1}\lambda)^{l-1}|\log \mu^{-1}\lambda|^{-\sigma}\bigl(\frac{T}{h}\bigr)^2 + C(\mu^{-1}\lambda)^{l}|\log \mu^{-1}\lambda|^{-\sigma}\bigl(\frac{T}{h}\bigr)^3.$$

This is clearly less than the right-hand expression in (19.4.109) provided $T \ge h(\mu h)^{-\delta'}$ with arbitrarily small exponent $\delta' > 0$ (δ depends on it). It also implies $1 \ge \varepsilon$.

Now inequality (19.4.109) is proven under this humble assumption. Then one can take $\bar{T} = \epsilon\mu^{-1}$ which clearly satisfies it.

The rest of arguments of Part (ii) hold without any modifications. □

Remark 19.4.16. Case $l = 2$ is obviously missing in the statement of Proposition 19.4.15.

(i) Using the same arguments as above we find that contribution of zone $\{\bar{T} \le |t| \le \hat{T}\}$ does not exceed $C\mu^{-2}h^{-d}|\log(\mu h)|^{1-\sigma}$ as $\sigma > 1$ and $C\mu^{-2}h^{-d}|\log h|^{1-\sigma}$ as $\sigma < 1$ and $C\mu^{-2}h^{-d}|\log\bigl(|\log(\mu h)|/|\log h|\bigr)|$ as $\sigma = 1$.

On the other hand, contribution of zone $\{|t| \le \bar{T}\}$ will be smaller as $\sigma \le 1$ and $\kappa_0\mu^{-2}h^{-d} + O\bigl(\mu^{-2}h^{-d}|\log(\mu h)|^{1-\sigma}\bigr)$ as $\sigma > 1$ and the same arguments as above show that $\kappa_0 = 0$.

Therefore in comparison with the case $l \ne 2$ an extra factor $|\log \mu h|$ appears as $\sigma \ne 1$; as $\sigma = 1$ it is $|\log \mu h| \cdot |\log\bigl(|\log(\mu h)|/|\log h|\bigr)|$.

(ii) Further, if <u>either</u> there are no third-order resonances <u>or</u> g^{jk} and F_{jk} are constant, then $\mathcal{A}_1 = 0$ after proper reduction. We can exploit it properly only for $\sigma \le 0$: one can see easily that then $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} \le C\mu^{-2}|\log h|^{-\sigma}$.

This concludes the proof of Theorem 19.4.17 below.

19.4.6 Main Theorem

Now combining all the results of this Section we arrive to

Theorem 19.4.17. *Let assumptions* (19.1.4)–(19.1.6), $(19.1.25)_{1-3}$ *with* $(\bar{l}, \bar{\sigma}) \succeq (l, \sigma) \succeq (1, 2)$, $(\bar{l}, \bar{\sigma}) \succeq (2, 1)$ *and* (19.2.38) *be fulfilled. Let*

$$\mu_1^* := C(h|\log h|)^{-\frac{1}{2}} \le \mu \le \mu_2^* := \epsilon'(h|\log h|)^{-1} \tag{19.4.111}$$

with sufficiently small constant $\epsilon' > 0$.

Then there are two framing approximations[18] *(see Chapter 18) such that*

(i) Let $\mathfrak{N}$*-microhyperbolicity condition (see Definition 19.2.5) be fulfilled. Then if* <u>*either*</u> $(l,\sigma) \succeq (2,0)$ <u>*or*</u> $\#\mathfrak{N} = 1$*, then*

$$\mathsf{R}_1^{\mathsf{MW}} := \Bigl| \int \Bigl(\tilde{e}(x,x,0) - h^{-d}\mathcal{N}^{\mathsf{MW}}(x,0) - h^{-d}\mathcal{N}^{\mathsf{MW}}_{1\mathsf{corr}}(x,0)\Bigr)\psi(x)\,dx\Bigr| \le C\mu^{-1}h^{1-d} + C\mu^{-l}|\log h|^{-\sigma}h^{-d} \tag{19.4.112}$$

and if $(l,\sigma) \prec (2,0)$ <u>*and*</u> $\#\mathfrak{N} \ge 2$ *then*

$$\mathsf{R}_1^{\mathsf{MW}} \le C\mu^{l-l}h^{1-d}|\log\mu|^{-\sigma} + C\mu^{-l}|\log h|^{-\sigma}h^{-d}. \tag{19.4.113}$$

(ii) Let microhyperbolicity condition (see Definition 19.2.4) be fulfilled. Then

$$\mathsf{R}_1^{\mathsf{MW}} \le Ch^{1-d}| + C\mu^{-l}|\log h|^{-\sigma}h^{-d}. \tag{19.4.114}$$

Remark 19.4.18. (i) Condition (19.4.111) means exactly that estimate (19.4.112) is stronger than (19.2.86), (19.2.87).

(ii) If $(l,\sigma) \succeq (3,1)$ then the best remainder estimate (19.2.89) holds as $\mu \le \mu_2^*$.

19.4.7 Special Case of Constant g^{jk}, F_{jk}

Framework; Mid- and Long-Range Propagation

Consider now the case of constant g^{jk} and F_{jk}, $(l,\sigma) \succeq (2,0)$ and V having only non-degenerate critical points. Our goal is to extend results obtained for V which does not have any critical points.

We assume that $l < 4$ as $l > 3$ will be sufficient for the remainder estimate $O(\mu^{-1}h)$. Note that the contribution of $\{x:\ |\nabla V| \le \bar{\nu} := C_1\mu^{-\frac{1}{2}}\}$ to the remainder does not exceed $C\bar{\nu}^d\mu h^{1-d} = O(\mu^{-1}h^{-1})$ and therefore we need to consider domain $\{x:\ |\nabla V| \ge \bar{\nu}\}$ only.

Let us introduce in this domain

$$\varepsilon = C_0\mu^{-1}\nu^{-1} \le \nu, \qquad \nu := |\nabla V|. \tag{19.4.115}$$

One can see easily that

(19.4.116) Mollification error does not exceed $C\mu^{-l}|\log h|^{-\sigma}h^{-d}$

exactly as in the case when V does not have critical points.

Exactly as in Subsection 19.4.1 one can prove easily that

(19.4.117) At $B(y,\nu(y))$ with $\nu(y)\ge\bar\nu$ estimates (19.4.7) and (19.4.8) hold for $T\in[T_*,T^*]$ with $T^*=\epsilon\mu$ and

$$T_*=C\varepsilon^{-1}\nu^{-1}h|\log h|\asymp C\mu h|\log h|. \tag{19.4.118}$$

Short-Range Theory

Short-range theory as in Subsections 19.4.2–19.4.4 is more complicated:

Proposition 19.4.19. *Let $\psi\in\mathscr{C}_0^\infty(B(y,\nu(y))$ with $\nu(y)\ge\bar\nu$ and let ϕ be supported in L-vicinity of 0, $L\ge\nu^2+\mu h+h/T$.*

Then for $T\in[Ch^{1-\delta},T^*]$ with arbitrarily small exponent $\delta>0$ such that $T\ge\nu^{-2}h$

$$|\phi(hD_t)\chi_T(t)(\Gamma U\psi)|\le CL\nu^{d+1}h^{-d}\Big(\frac{h}{\nu T}\Big)^{l-1}|\log\frac{h}{\nu T}|^{-\sigma}\Big(1+\frac{h}{\nu T\varepsilon}\Big)^{-s}, \tag{19.4.119}$$

$$|F_{t\to h^{-1}\tau}\chi_T(t)(\Gamma U\psi)|\le CL\nu^{d-1}h^{1-d}\Big(\frac{h}{\nu T}\Big)^{l-1}|\log\frac{h}{\nu T}|^{-\sigma}\Big(1+\frac{h}{\nu T\varepsilon}\Big)^{-s} \tag{19.4.120}$$

as $\tau\le c$ with arbitrarily large exponent s.

Idea of the proof. The proof follows the same scheme as Proposition 19.4.9. Instead of giving the full proof, which we leave to the reader, let us consider the toy-model for the proof of Proposition 19.4.8.

Consider again I_1,I_2 defined by (19.4.25) and (19.4.26) respectively. Replace λ by its η-mollification with $\eta\le\epsilon\nu h^\delta$. Then an error in I_1 is $O\big(h^{-1}T\vartheta(\eta)\nu^d\big)$ (just acquires factor ν^d as a volume of $B(y,\nu(y))$ in comparison with the original toy-model) while an error in I_2 is given by the left-hand expression of (19.4.27) which does not exceed $Ch^{-1}T\vartheta(\eta)\nu^{d-2}$ now.

Obviously I_1 with mollified λ does not exceed $C(h/\nu T)^k\eta^{-k-1}\vartheta(\eta)\nu^d$ and I_2 with mollified λ does not exceed $C\nu^{-1}(h/\nu T)^k\eta^{-k-1}\vartheta(\eta)\nu^d$ and therefore

$$I_1+\nu^2I_2\le Ch^{-1}T\Big(1+\nu(h/\nu T)^{k+1}\eta^{-k-1}\Big)\vartheta(\eta)\nu^d.$$

Taking near optimal $\eta = h/T\nu^{1-\delta'}$ we conclude that

$$I_1 + \nu^2 I_2 \le Ch^{-1}T\vartheta(h/\nu T)\nu^d.$$

Note that $\eta \le h^\delta \nu$ as $T \ge \max(h^{1-\delta}, h/\nu^2)$.

This would imply for a single $\mu^{-1}h$-operator estimates as in the proof of Proposition 19.4.9 but with T replaced by $T\nu$ and with extra factors ν^{d+1} and ν^{d-1}. However, we also need to take into account that the ellipticity is broken for no more than $CL(\mu h)^{-r}$ multiindices $\alpha \in \mathbb{Z}^{+r}$ rather than $(\mu h)^{-r}$ as it was for $\nu \asymp 1$ and this leads to an extra factor CL.

Easy details are left to the reader. □

Then summation of the right-hand expression of (19.4.120) for $T \ge h/\nu^2$ returns $O(\nu^d h^{1-d})$.

On the other hand note that

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)(\Gamma U\psi)| \le CT\nu^d h^{-d}$$

and plugging $T = h/\nu^2$ into the right-hand expression we get $C\nu^{d-2}h^{1-d}$.

Corollary 19.4.20. *In the framework of Proposition 19.4.19 as either $\mu \le h^{\delta-1}$ or $\nu \le h^\delta$*

(i) Estimate holds

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)(\Gamma U\psi)| \le C\nu^{d-2}h^{1-d} \tag{19.4.121}$$

for $T \le T^* = \epsilon\mu$.

(ii) Therefore contribution of $B(y,\nu(y))$ to the Tauberian remainder estimate does not exceed $C\mu^{-1}\nu^{d-2}h^{1-d}$.

Calculations

Following Subsection 19.4.5 we arrive to expression (19.4.83) where now $\mathcal{A} = \mathcal{A}_0 + \mu^{-2}\mathcal{A}_2 + \mathcal{A}'$ with $\mathcal{A}' = O(\varepsilon^l|\log\varepsilon|^{-\sigma})$ and applying the method of the successive approximations we conclude first that modulo $o(h^{1-d})$ we can replace here $\mathcal{A}$ by $\mathcal{A}_0$ and then (19.4.121) holds without restriction "either $\mu \le h^{\delta-1}$ or $\nu \le h^\delta$".

Summation with respect to a partition of unity results in the remainder estimate $O(\mu^{-1}h^{1-d})$ under assumption (19.2.26). Therefore

(19.4.122) Under assumption (19.2.96) Tauberian remainder is $O(\mu^{-1}h^{1-d})$.

Further, let us consider expression (19.4.83) integrated with respect to τ. Let us skip $\mathcal{A}'$; one can see easily that the contribution of $B(y,\nu(y))$ to the error does not exceed $C\big(h^{-d}+\mu h^{1-d}\nu^{-2}\big)\nu^d\varepsilon^l|\log\varepsilon|^{-\sigma}$ and summation with respect to partition of unity results in $O(h^{-d}\varepsilon^l|\log\varepsilon|^{-\sigma})$.

Furthermore, skipping term $\mu^{-2}\mathcal{A}_2$ results in the correction term which after replacing a Riemann sum by an integral as $\nu^2\ge\mu h$ results in the expression $\mu^{-2}h^{-d}\int\kappa_0(y)\,dy$; contribution of $B(y,\nu(y))$ into an error does not exceed

$$C\mu^{-2}h^{-d}(\mu h/\nu^2)^{l-2}|\log(\mu h/\nu^2)|^{-\sigma}\nu^d$$

and summation with respect to partition of unity results in

$$C\mu^{-2}h^{-d}(\mu h)^{l-2}|\log(\mu h)|^{-\sigma}. \tag{19.4.123}$$

Meanwhile, skipping term $\mu^{-2}\mathcal{A}_2$ as $\nu^2\le\mu h$ results in an error; one can prove easily that the contribution of $B(y,\nu(y))$ into this error does not exceed $C\mu^{-1}h^{1-d}\nu^{d-2}$. Treating all other terms (arising when we replace ψ by ψ^0) in the similar way we arrive to a correction term not exceeding (19.4.123) as "final" κ_0 must be 0.

Main Theorem

Then we arrive to

Theorem 19.4.21. *Let assumptions* (19.1.4)–(19.1.6), $(19.1.25)_3$ *with* $(l,\sigma)\succeq(1,2)$ *and* (19.2.38) *be fulfilled. Let* g^{jk}, F_{jk} *be constant.*

Then there are two framing approximations[18)] *(see Chapter 18) such that the following statements are true:*

(i) Under microhyperbolicity assumption $|\nabla V|\ge\epsilon$ *estimate* (19.4.112) *holds.*

(ii) Under assumptions $(l,\sigma)\succeq(2,0)$ *and* (19.2.96) *estimate* (19.4.112) *holds.*

(iii) We can skip the correction term unless $(2,0)\prec(l,\sigma)\prec(3,0)$ *in which case it does not exceed* (19.4.123).

(iv) We have remainder estimate $O(\mu^{-1}h^{1-d})$ *as* $\mu\ge(h|\log h|)^{-\frac12}$ *provided* $(l,\sigma)\succeq(3,1)$.

19.5 Intermediate Magnetic Field

19.5.1 Framework and Special Cases

Let now

$$\mu_2^* := \epsilon(h|\log h|)^{-1} \le \mu \le \mu_3^* := \epsilon h^{-1}. \tag{19.5.1}$$

Then we need to modify our arguments in several ways. First of all now, as $(\mu^{-1}h|\log h|)^{\frac{1}{2}} \ge \mu^{-1}$ we must assume that

$$\varepsilon \ge C(\mu^{-1}h|\log h|)^{\frac{1}{2}}. \tag{19.5.2}$$

Then under $\mathfrak{N}$-microhyperbolicity condition with $\#\mathfrak{N} = 1$ we are done and we have immediately the first clause (either) of our final Theorem 19.5.2 below which differs from Theorem 19.4.17(i) only by a choice of ε and thus by a mollification error.

Furthermore, in the case of the constant g^{jk}, F_{jk} we are done as well and we have immediately our final Theorem 19.5.3 which differs from Theorem 19.4.21 in the same way.

However, under either microhyperbolicity condition with $\#\mathfrak{M} \ge 2$ or $\mathfrak{N}$-microhyperbolicity condition with $\#\mathfrak{N} \ge 2$ we were dealing with the partition of energies and then variables (x', ξ') are no more microlocal as logarithmic uncertainty principle for them fails and our approach here needs to be modified.

Still, we are also done if we either use microhyperbolicity assumption and there are no 2-nd order resonances or we use $\mathfrak{N}$-microhyperbolicity assumption and there are no 2-nd and 3-rd order resonances.

Really, in these cases we need to consider operators

$$a_j = f_j(x'', \mu^{-1}hD'')(h^2D_j^2 + \mu^2 x_j^2) \tag{19.5.3}$$

with $\mathfrak{m} = \{j\}$ and $\mathfrak{n} = \{j\}$ respectively and instead we can consider commuting operators $(h^2D_j^2 + \mu^2 x_j^2)$ and we do not need to have logarithmic uncertainty principle for these variables to establish the following proposition similar to Proposition 19.2.10(i),(ii) with small constant νT:

Proposition 19.5.1. *Let either there are no 2-nd order resonances and $T^* = \epsilon$ or there are no 2-nd and 3-rd order resonances and $T^* = \epsilon\mu$. Let $\mu \le \epsilon_0 h^{-1}$.*

Let $B_j = (h^2 D_j^2 + \mu^2 x_j^2)$ *and* $\boldsymbol{B} = (B_1, \dots, B_d)$. *Let* ϕ_1, ϕ_2 *be two functions with*

$$\operatorname{dist}(\operatorname{supp}(\phi_1), \operatorname{supp}(\phi_2)) \ge (T/T^* + \epsilon_1) \tag{19.5.4}$$

the following estimate holds:

$$\|\big(\phi_2(\boldsymbol{B})\big)_x U\, {}^t\big(\phi_1(\boldsymbol{B})\big)_y\| \le Ch^s. \tag{19.5.5}$$

Then we have immediately clause or of our final Theorem 19.5.2.

Thus we arrive to our first main theorem in the case of a strong magnetic field:

Theorem 19.5.2. *Let assumptions* (19.1.4)–(19.1.6), $(19.1.25)_{1-3}$ *with* $(\bar l, \bar\sigma) \succeq (l, \sigma) \succeq (1, 2)$, $(\bar l, \bar\sigma) \succeq (2, 1)$ *and* (19.2.38) *be fulfilled. Let* μ *satisfy* (19.5.1).

Then there are two framing approximations[18] *(see Chapter 18) such that*

(i) Let $\mathfrak{N}$*-microhyperbolicity condition (see Definition 19.2.5) be fulfilled and either* $\#\mathfrak{N} = 1$ *or there be no* 2*-nd and* 3*-rd order resonances. Then*

$$\mathsf{R}_1^{\mathsf{MW}} := \Big| \int \Big(\tilde e(x, x, 0) - h^{-d} \mathcal{N}^{\mathsf{MW}}(x, 0) - h^{-d} \mathcal{N}^{\mathsf{MW}}_{1\mathsf{corr}}(x, 0) \Big) \psi(x)\, dx \Big| \le C\mu^{-1} h^{1-d} + C\mu^{-\frac{l}{2}} |\log h|^{\frac{l}{2}-\sigma} h^{-d+\frac{l}{2}} \tag{19.5.6}$$

(ii) Let microhyperbolicity condition (see Definition 19.2.4) be fulfilled and there are be no 2*-nd order resonances. Then*

$$\mathsf{R}_1^{\mathsf{MW}} \le Ch^{1-d} + C\mu^{-\frac{l}{2}} |\log h|^{\frac{l}{2}-\sigma} h^{-d+\frac{l}{2}}. \tag{19.5.7}$$

Theorem 19.5.3. *Let assumptions* (19.1.4)–(19.1.6), $(19.1.25)_3$ *with* $(l, \sigma) \succeq (1, 2)$ *and* (19.2.38) *be fulfilled. Let* g^{jk}, F_{jk} *be constant.*

Then there are two framing approximations[18] *(see Chapter 18) such that the following statements are true:*

(i) Under microhyperbolicity assumption $|\nabla V| \ge \epsilon$ *estimate* (19.5.6) *holds.*

(ii) Under assumptions $(l, \sigma) \succeq (2, 0)$ *and* (19.2.96) *estimate* (19.5.6) *holds.*

19.5.2 Partition of the Energy Space

Consider the general case now. To prove a statement similar to Proposition 19.4.5 under either microhyperbolicity condition with $\#\mathfrak{M} \ge 2$ or $\#\mathfrak{N}$-microhyperbolicity condition with $\#\mathfrak{N} \ge 2$ one needs to consider evolution of $a_{\mathfrak{m}}$ or $a_{\mathfrak{n}}$ and the main trouble is that we can microlocalize them only in the box of size $\mu^2\varepsilon^2 \asymp \mu h|\log h|$ which is by no means smaller than ϵ. We need instead *operator localization*: something like Proposition 19.5.1 but with $\boldsymbol{B} = (B_1, \dots, B_m)$ with $B_{\mathfrak{m}}$ operators "close" to $a^0_{\mathfrak{m}} - \tau_{\mathfrak{m}}$, $m = \#\mathfrak{M}$ [28)].

Therefore we need to define function of operators and thus operators need to be self-adjoint and "almost commute".

Let B be an operator of the form

$$B = \sum_{i,k\in\mathfrak{m}} \bigl(\beta^{\mathrm{w}}_{j,k}(x'', \mu^{-1}hD'')\, Z_j Z_k^*, \qquad Z_j = hD_j + i\mu x_j \tag{19.5.8}$$

where $\beta_{jk} \in \mathscr{F}^{2,0}$, $\beta_{jk} = \beta^{\dagger}_{kj}$ and the complex sesquilinear form $\sum_{j,k} \beta_{jk}\zeta_j\zeta_k^{\dagger}$ is positive definite; here $\mathfrak{m}$ is just a subset in $\{1, \dots, d\}$.

This will be sufficient to study propagation if either $T^* = \epsilon$ or $T^* = \epsilon\mu$ and there are no 3-rd order resonances; however if $T^* = \epsilon\mu$ and there are 3-rd order resonances we consider

$$\begin{aligned} B = \sum_{j,k\in\mathfrak{n}} \bigl(\beta^{\mathrm{w}}_{jk}(x'', \mu^{-1}hD'')\, Z_j Z_k + \\ \mu^{-1} \sum_{j,k,m\in\mathfrak{n}} \Bigl(\beta^{\mathrm{w}}_{jkm}(x'', \mu^{-1}hD'')\, Z_j Z_k Z_m^* + \beta^{\dagger\,\mathrm{w}}_{jkm}(x'', \mu^{-1}hD'')\, Z_m Z_k^* Z_j^*\Bigr) + \\ C_0\mu^{-2}\Bigl(\sum_{j\in\mathfrak{n}} Z_j^* Z_j\Bigr)^2 \end{aligned} \tag{19.5.8$'$}$$

where $\beta_{jkm} \in \mathscr{F}^{1,0}$ and the last term is added to make the symbol positive.

Then this operator is self-adjoint and

$$\phi(B) = \int e^{itB}\hat{\phi}(t)\, dt \tag{19.5.9}$$

where $\hat{\phi}$ is a Fourier transform.

[28)] Or similar estimate with $\mathfrak{m}$ and $\mathfrak{M}$ replaced by $\mathfrak{n}$ and $\mathfrak{N}$.

Let temporarily $A = \alpha^{\mathrm{w}}(x'', \mu^{-1}hD'')$ or

$$A = \sum_j \Big(\alpha^{\mathrm{w}}(x'', \mu^{-1}hD'')Z_j + \alpha^{\dagger\mathrm{w}}(x'', \mu^{-1}hD'')Z_j^*\Big) \tag{19.5.10}$$

with $\alpha \in \mathscr{F}^{1,0}$. Let us consider $[\phi(B), A]$. Note first that

$$e^{itB}Ae^{-itB} = \sum_{0\le k\le m-1} \frac{1}{k!}(it)^k \operatorname{Ad}_B^k(A) + \frac{1}{(m-1)!}(it)^m \int_0^1 (1-z)^{m-1} e^{itzB} \operatorname{Ad}_B^m(A) e^{-itzB}\, dz$$

where

$$\operatorname{Ad}_B^0 A \coloneqq A, \quad \operatorname{Ad}_B^m A \coloneqq \big[B, \operatorname{Ad}_B^{m-1} A\big]. \tag{19.5.11}$$

and therefore

$$[e^{i\tau B}, A] = \sum_{1\le k\le m-1} \frac{1}{k!}(it)^k \operatorname{Ad}_B^k(A) e^{itB} + \frac{1}{(m-1)!}(it)^m \int_0^1 (1-z)^{m-1} e^{itzB} \operatorname{Ad}_B^m(A) e^{it(1-z)B}\, dz$$

and

$$[\phi(B), A] = \sum_{1\le k\le m-1} \frac{1}{k!} \operatorname{Ad}_B^k(A)\phi^{(k)}(B) + \frac{1}{m!}\int_{-\infty}^{\infty}\int_0^1 e^{itzB} \operatorname{Ad}_B^m(A) e^{it(1-z)B} \widehat{\phi^{(m)}}(t)\, dzdt. \tag{19.5.12}$$

Consider repeated commutators $\operatorname{Ad}_B^k(A)$. Note first that if B is of the form (19.5.8), A is defined by (19.5.10) and if in the commutators we consider only derivatives with respect to (x', ξ') then obviously these shortened commutators would be also of the form (19.5.10) but with norms $C_1(C_0\mu h)^k$.

On the other hand, in virtue of Proposition 1.A.1 we can find uniformly smooth function $\phi = \phi_n$, $\phi_n \ge \frac{1}{2}$ on the given interval and such that $|\phi^{(k)}| \le C_0^{k+1} n^k$ as $k \le m+2 \le n$. Then terms in the sum in the right-hand

expression in (19.5.12) would not exceed $C_1(C_0\mu h)^k n^k k^{-k}$ which is $O(h^s)$ as $\mu h \le \epsilon$ and

$$k \ge C_s|\log h|/|\log \mu h|, \qquad n \le \epsilon_0 k/(\mu h). \tag{19.5.13}$$

Let us now consider complete commutators. Then as $\beta_{jk} \in \mathscr{F}^{2,0}$, $\alpha_j \in \mathscr{F}^{1,0}$ we conclude that in comparison with $\mathsf{Ad}_B^{m-1}(A)$ each term in $\mathsf{Ad}_B^m(A)$ acquires either factor $C_0\mu h$ (if there are only differentiations with respect to (x',ξ') or $C_1\mu^{-1}h\varepsilon^{-1}N$ where $N = \mu h^{-1}\varepsilon^2$; it happens as long as $k \le N$, which is obviously the case; recall that $\varepsilon \ge C(\mu^{-1}h|\log h|)^{\frac12}$.

Further, similarly one can estimate an integral term in (19.5.12). Furthermore, similar arguments work for operator B defined by (19.5.8)$'$.

Therefore we arrive to

Proposition 19.5.4. *As ε is defined by* (19.5.2) *(or larger)*

$$[\phi(B), A] \equiv \sum_{1\le k\le M-1} \frac{1}{k!}\,\mathsf{Ad}_B^k(A)\phi^{(k)}(B), \tag{19.5.14}$$

$$\text{with} \quad M = C_1|\log h|/|\log(\mu h)|.$$

Similarly one can see easily that

$$e^{itB_1}e^{it'B_2}e^{-itB_1}e^{-it'B_2} \sim I + \sum_{p,q} \frac{1}{p!q!}(it)^p(it')^q L_{pq}$$

with

$$L_{pq} = \sum_{1\le j\le p}\sum_{1\le k\le q} \frac{p!q!}{j!k!(p-j)!(q-k)!} B_1^j B_2^k (-B_1)^{p-j}(-B_2)^{q-k} = \tag{19.5.15}$$

$$\begin{cases} \displaystyle\sum_{1\le k\le q} \frac{q!}{k!(q-k)!}\,\mathsf{Ad}_{B_1}^p(B_2^k)(-B_2)^{q-k} = \\ \displaystyle\sum_{1\le j\le p} \frac{p!}{j!(p-j)!} B_1^{p-j}\,\mathsf{Ad}_{B_2}^q((-B_1)^j); \end{cases}$$

we will use the first (the second) expression as $q \le p$ ($p \le q$) respectively.

Then one can prove easily

Proposition 19.5.5. *As ε is defined by* (19.5.2) *(or larger)*

$$[\phi_1(B_1),\phi_2(B_2)] \equiv \sum_{1\le q,p\le M-1} \frac{1}{p!q!} L_{pq}\phi_2^{(q)}(B_2)\phi_1^{(p)}(B_1), \tag{19.5.16}$$

$$\text{with}\quad M = C_1|\log h|/|\log(\mu h)|.$$

Proof. We leave an easy proof using the same arguments as the proof of Proposition 19.5.4 to the reader. □

Corollary 19.5.6. *If* $\mathsf{dist}(\mathsf{supp}(\phi_1),\mathsf{supp}(\phi_k)) \ge \epsilon_0$, $i_1 = i_k$ *and* $\mu h \le \epsilon$ *then*

$$\phi_1(B_{i_1})\phi_2(B_{i_2})\cdots\phi_k(B_{i_k}) \equiv 0. \tag{19.5.17}$$

Proof. If $k = 3$ multiplying (19.5.16) with B_1, B_2 replaced by B_{i_1}, B_{i_2} respectively by $\phi_k(B_{i_1})$ on its right and using $\phi_1^{(p)}(B_{i_1})\phi_{i_3}(B_{i_3}) = 0$ we arrive to the required equality.

In the general case let φ be functions such that $\varphi = 1$ in vicinity of $\mathsf{supp}(\phi_k)$ and $\varphi = 0$ in vicinity of $\mathsf{supp}(\phi_1)$. Then in virtue of (19.5.17) with $k = 3$ we can insert $\varphi(B_{i_1})$ between $\phi_{k-2}(B_{i_{k-2}})$ and $\phi_{k-1}(B_{i_{k-1}})$ and apply induction with respect to k. □

This is very important: we can localize with respect to $B_1,\dots,B_k$ *simultaneously* by $\phi_1(B_1)\phi_2(B_2)\cdots\phi_k(B_k)$.

19.5.3 Propagation

Now we can apply the same arguments as in Theorem 2.3.1. Consider operator

$$\chi\bigl(\epsilon^{-1}(B-s)+\frac{t}{T}\bigr) \tag{19.5.18}$$

and apply it to $U^{\pm} = \theta(t)U$. Then

$$(hD_t - A)U^{\pm} = \mp ih\delta(t)\delta(x-y) \tag{19.5.19}$$

and applying $\mu^{-1}h$-pseudodifferential operator cutoff we get

$$(hD_t - A)W^{\pm} = \mp ihf(x,y) \qquad \text{with} \tag{19.5.20}$$

$$W = U\,{}^t\bar{\varphi}_y(B)\,{}^tQ_y,\quad f = \delta(t)\delta(x-y)\,{}^t\bar{\varphi}_y(B)\,{}^tQ_y,$$

where $\bar{\varphi}$ is supported in vicinity of $\tau \in \mathbb{R}$ while χ is our standard function and then

$$|T\,\mathsf{Re}\, ih^{-1}\Big(\Big[(hD_t - A), \chi\big(\epsilon^{-1}(B-\tau)+\frac{t}{T}\big)\Big]W^{\pm}, W^{\pm}\Big)| \le Ch^{2s}. \tag{19.5.21}$$

Transforming this inequality we get

$$|\Big(\chi'\big(\epsilon^{-1}(B-\tau)+\frac{t}{T}\big)W^{\pm}, W^{\pm}\Big)| \le T\epsilon^{-1}|\Big(\Big[A, \chi\big(\epsilon^{-1}(B-\tau)+C_0\frac{t}{T}\big)\Big]W^{\pm}, W^{\pm}\Big)| + Ch^{2s} \tag{19.5.22}$$

where χ' is derivative of χ.

Approximating commutator by Poisson brackets (multiplied by $(-ih)$) we get

$$\epsilon^{-1}T\{a,b\}\chi'\big(\epsilon^{-1}(B-\tau)+\frac{t}{T}\big)$$

with the first factor being an operator with a norm not exceeding $\frac{1}{2}$ provided

$$T \le T^* := \begin{cases} \epsilon_1 & \text{as } b = a_{\mathfrak{m}}, \\ \epsilon_1\mu & \text{as } b = a_{\mathfrak{n}} + O(\mu^{-2}), \quad (l,\sigma) \succeq (2,0), \\ \epsilon_1\mu^{l-1}|\log\mu|^{-\sigma} & \text{as } b = a_{\mathfrak{n}} + O(\mu^{-2}), \quad (l,\sigma) \prec (2,0) \end{cases} \tag{19.5.23}$$

where ϵ_1 is small enough constant.

Therefore, taking χ to be a primitive of function φ^2, considering next terms of the commutator and assuming that

$$\|\varphi\big(\epsilon^{-1}(B-\tau)+\frac{t}{T}-\epsilon_2\big)W^{\pm}\| \le Ch^{s-\delta} \tag{19.5.24}$$

with a small exponent $\delta > 0$, we get

$$\|\varphi\big(\epsilon^{-1}(B-\tau)+\frac{t}{T}\big)W^{\pm}\|^2 \le C_1\Big(\sum_{1\le m\le M}\frac{1}{m!}\eta^m\|\varphi^{(m)}\big(\epsilon^{-1}(B-\tau)+\frac{t}{T}\big)W^{\pm}\|\Big)^2 + Ch^{2s} \tag{19.5.25}$$

with $\eta = C_0\mu h$.

Plugging $\frac{1}{m!}\eta^m\varphi^{(m)}$ instead of φ and $(M-m)$ instead of M into inequality (19.5.25) we conclude that

$$\Big(\frac{1}{m!}\eta^m\|\varphi^{(m)}\big(\epsilon^{-1}(B-\tau)+\frac{t}{T}\big)W^{\pm}\|\Big)^2 \tag{19.5.26}$$

also does not exceed the right-hand expression of (19.5.25).

Taking a sum with respect to m, $0\le m\le M$, and again increasing C_0, C_1 we get that expression

$$\sum_{0\le m\le M}\Big(\frac{1}{m!}\eta^m\|\varphi^{(m)}\big(\epsilon^{-1}(B-\tau)+\frac{t}{T}\big)W^{\pm}\|\Big)^2 \tag{19.5.27}$$

does not exceed itself multiplied by $C_1\eta$ plus Ch^{2s}. Taking η small enough we conclude that (19.5.24) holds with $\epsilon_2=0$ and $\delta=0$. Consequently increasing s by δ and doubling ϵ_2 we get rid of assumption (19.5.24). Thus

$$\|\varphi\big(\epsilon^{-1}(B-\tau)+C_0\mu^{-1}t\big)U\,{}^t\bar\varphi_y(B)\,{}^tQ_yg\|\le Ch^s. \tag{19.5.28}$$

Further, we can plug $-(B-\tau)$ instead of $(B-\tau)$ into (19.5.28). Therefore we have proven

Proposition 19.5.7. *Let $\bar\varphi$ be supported in ϵ-vicinity of τ and $\varphi=1$ in 2ϵ-vicinity of τ. Then for $T\le T^*$ defined by* (19.5.23)

$$\|\big(I-\varphi(B)\big)U\,{}^t\bar\varphi_y(B)\,{}^tQ_y\|\le Ch^s. \tag{19.5.29}$$

Using Corollary 19.5.6 which allows us to apply simultaneous cut-off by

$$\Phi(B_1,\dots,B_\nu):=\varphi_1(B_1)\cdot\varphi_2(B_2)\cdots\varphi_\nu(B_\nu) \tag{19.5.30}$$

we arrive to

Corollary 19.5.8. *Let functions $\bar\varphi_j$ be supported in ϵ-vicinities of τ_j and let $\varphi_j=1$ in 2ϵ-vicinities of τ_j. Then for $T\le T^*$ defined by* (19.5.23)

$$\|\big(1-\Phi(B_1,\dots,B_\nu)\big)U\,{}^t\bar\Phi_y(B_1,\dots,B_\nu)\,{}^tQ_y\|\le Ch^s. \tag{19.5.31}$$

Recall that we consider set of B_j coinciding either with $\{a_{\mathfrak m}\}_{\mathfrak m\in\mathfrak M}$ or with $\{a_{\mathfrak n}+O(\mu^{-2})\}_{\mathfrak n\in\mathfrak N}$.

19.5.4 Propagation and Microhyperbolicity

Consider now the proof that singularities leave diagonal – again as Theorem 2.3.1 with

$$\phi = \langle \ell, x-y\rangle \mp \epsilon t T^{-1}. \tag{19.5.32}$$

We plug-in

$$W = U\,{}^t\big(\Phi(B_1,\dots,B_\nu)\big)_y\,{}^tQ_y \tag{19.5.33}$$

localizing x near y and B_j near τ_j for all j, and take $\ell = \ell(y,\boldsymbol{\tau})$.

To recover the proof we need to estimate from below quadratic form

$$(\mu^2 \sum_{j,k} p_j^{\mathrm{w}} K_{jk} p_k^{\mathrm{w}} w, w)$$

with $w = \chi(\phi)^{\mathrm{w}} W$, $W = \bar{\Phi}(B_1,\dots,B_\nu)U$ and $K_{jk} = \ell(g^{jk})$; one can assume that $V = -1$.

Due to Proposition 19.5.8 one can replace W by $\Phi(B_1,\dots,B_\nu)W$ with a bit more wide supports of φ_j than those of $\bar{\varphi}_j$.

Let us introduce μ^{-1}-admissible partition $\psi_\nu(x)$ and on each element of it apply gauge transformation making $|V_j| \le C\mu^{-1}$. Rescaling $x \mapsto \mu(x-\bar{x}_\nu)$ we get (μh)-pseudodifferential operators μp_j^{w} and $\mu^2 \sum_{j,k} p_j^{\mathrm{w}} K_{jk} p_k^{\mathrm{w}}$ while $\Phi(B)$ is a legitimate (μh)-pseudodifferential operator as well.

Then for $\mu h \le \epsilon_1$

$$\Phi(B_1,\dots,B_\nu)^*\Big(\mu^2 \sum_{j,k} p_j^{\mathrm{w}} K_{jk} p_k^{\mathrm{w}} - \epsilon_0 + C\mu h\Big)\Phi(B_1,\dots,B_\nu)$$

is non-negative operator and

$$\Phi(B_1,\dots,B_\nu)^*\mu^2 \sum_{j,k} p_j^{\mathrm{w}} K_{jk} p_k^{\mathrm{w}} \Phi(B_1,\dots,B_\nu) \ge \frac{1}{2}\epsilon_0 \Phi(B_1,\dots,B_\nu)^*\Phi(B_1,\dots,B_\nu)$$

in the operator sense and therefore

$$\Big(\mu^2 \sum_{j,k} p_j^{\mathrm{w}} K_{jk} p_k^{\mathrm{w}} w, w\Big) \ge \frac{1}{2}\epsilon_0 \|w\|^2 - Ch^s; \tag{19.5.34}$$

the rest of the proof needs no modifications.

Now applying the same approach as in the proof of Proposition 19.2.13 we arrive to

Proposition 19.5.9. *Let* either $\mathfrak{M}$*-microhyperbolicity assumption* or $\mathfrak{N}$*-microhyperbolicity assumption be fulfilled.*

Then estimate (19.2.63) *holds for* $T \in [T_*, T^*]$ *with* T^* *defined by* (19.5.23) *and* $T_* = C\varepsilon^{-1}h|\log h| \le \epsilon_1(\mu h|\log h|)^{\frac12}$.

Proof. An easy proof we leave to the reader. □

19.5.5 Short-Range Estimates

In this strong magnetic field case we can apply the same arguments as in Subsection 19.4.4 combined with Corollary 19.5.8 and extend Proposition 19.4.9:

Proposition 19.5.10. *Both statements (i), (ii) of Proposition 19.4.9 remain true in the case of the strong magnetic field as well.*

Proof. Just repeating proof of Proposition 19.4.9 without any significant difference. We use that in the operator sense $|x'| + |\xi'| \le C\mu^{-1}$ still even if in the microlocal sense one should put $C(\mu^{-1}h|\log h|)^{\frac12}$ instead.

Easy details are left to the reader. □

19.5.6 Calculations

In the strong magnetic field case one can apply the same arguments in the successive approximation method remembering that now $\varepsilon \ge C(\mu^{-1}h|\log h|)^{\frac12}$ and $\bar{T}_0 \le h\varepsilon^{-1} \le (\mu h|\log h|^{-1})^{\frac12}$.

Then Propositions 19.4.12–19.4.14 and their proofs remain true with this minor modification:

Proposition 19.5.11. *Under microhyperbolicity condition for* $\mu \le \epsilon h^{-1}$

(i) Estimates (19.4.77) *and* (19.4.78) *hold.*

(ii) Estimates (19.4.57), (19.2.78) *and* (19.4.84) *hold.*

Furthermore, arguments of Proposition 19.4.15 related to $T \ge \bar{T} = \epsilon\mu^{-1}$ do not change either. However, we need to reconsider contribution of the segment $[-\bar{T}, \bar{T}]$ as $l > 2$. Again, we need to consider only the sum of terms (19.4.101)–(19.4.104).

We already know from the proof of Proposition 19.4.15(ii) that under assumptions $\mu h|\log h \le \epsilon$ and $\varepsilon \ge C\mu^{-1}$ this sum does not exceed $C\mu^{-2}h^{-d}(\mu h)^{l-2}|\log(\mu h|)^{-\sigma}$.

On the other hand, all terms (19.4.101)–(19.4.104) with $T = \bar{T}$ and their sum have the form $\mu^{-2}h^{-d}f(\mu h)$ and then repeating arguments of Part (iii) of the proof of Proposition 19.4.15 with $\lambda = \mu^K h^{K-1}$ we arrive to the same estimate $C\mu^{-2}h^{-d}(\mu h)^{l-2}|\log(\mu h|)^{-\sigma}$ for the sum as $\mu h \le \epsilon'$. Furthermore, Remark 19.4.16 remains true as well:

Proposition 19.5.12. *Statements of Proposition 19.4.15 and Remark 19.4.16 remain true as well.*

19.5.7 Main Theorems

Thus we arrive to the following

Theorem 19.5.13. *Let assumptions* (19.1.4)–(19.1.6), $(19.1.25)_{1-3}$ *with* $(\bar{l}, \bar{\sigma}) \succeq (l, \sigma) \succeq (1, 2)$, $(\bar{l}, \bar{\sigma}) \succeq (2, 1)$ *and* (19.2.38) *be fulfilled.*

Let

$$\mu_2^* := \epsilon(h|\log h|)^{-1} \le \mu \le \mu_3^* := \epsilon' h^{-1} \tag{19.5.35}$$

with sufficiently small constant $\epsilon' > 0$. *Then for two framing approximations*

(i) Under $\mathfrak{N}$*-microhyperbolicity condition (see Definition 19.2.5) estimate* (19.5.6) *holds.*

(ii) Under microhyperbolicity condition (see Definition 19.2.4) estimate (19.5.7) *holds.*

Remark 19.5.14. (i) Obviously Theorem 19.5.13 generalizes Theorem 19.5.2; recall that our second main theorem is Theorem 19.5.3.

(ii) Theorems 19.5.2 and 19.5.3 hold for very strong magnetic field (19.6.1) as well but then we can still relax definition of $\mathfrak{N}$-hyperbolicity (see condition (19.6.13) below).

19.6 Intermediate and Strong Magnetic Field

19.6.1 Framework

The remaining case $\mu \ge \mu_3^* = \epsilon_1 h^{-1}$ is split into two subcases:

$$\mu_3^* = \epsilon_1 h^{-1} \le \mu \le \mu_4^* = C_0 h^{-1}, \tag{19.6.1}$$

$$\mu \ge \mu_4^* = C_0 h^{-1} \tag{19.6.2}$$

which we refer as *very strong* and *superstrong* magnetic field cases respectively.

In the former subcase we know that the spatial speed of the propagation is $O(\mu^{-1})$ but we have not estimated the propagation speed with respect to the energy partition and thus we cannot use microhyperbolicity condition except $\mathfrak{N}$-microhyperbolicity condition with $\#\mathfrak{N} = 1$. Further, this condition should be modified to accommodate spectral gaps.

In the latter subcase (19.6.2) we have nothing about propagation at all. Recall that in this case we need to consider the generalized Schrödinger-Pauli operator (19.1.13).

19.6.2 Hermitian Decomposition

In both cases, however, we can apply a very usefully decomposition

$$U_{\mathcal{T}}(x,y,t) = \sum_{\alpha\in\mathbb{Z}^{+r}} U_{\alpha\beta}(x'',y'',t)\Upsilon_\alpha(x')\Upsilon_\beta(y') \tag{19.6.3}$$

with

$$\Upsilon_\alpha(x') \coloneqq \mu^{\frac12 r} h^{-\frac12 r} \upsilon_\alpha\big(\mu^{\frac12} h^{-\frac12} x'\big), \qquad \upsilon_\alpha(x) = \prod_{1\le j\le r} \upsilon_{\alpha_j}(x_j). \tag{19.6.4}$$

Recall that υ_{α_j} are 1-dimensional Hermite functions.

Note that

$$\mathcal{A}_0\Big(u_\alpha(x'')\Upsilon_\alpha(x')\Big) = \sum_{\beta:|\beta|=|\alpha|,\,|\beta-\alpha|=0,2} \Big(\mu h \mathcal{A}^0_{\beta\alpha}(x'',\mu^{-1}hD'') + \delta_{\alpha\beta}\, q_0(x'',\mu^{-1}hD'')\Big) u_\alpha\cdot \Upsilon_\beta(x') \tag{19.6.5}$$

where

$$\mathcal{A}^0_{\beta\alpha} = \begin{cases} \sum_j (2\alpha_j + 1) b_{jj} & \text{as } \beta = \alpha, \\ 2\sqrt{\alpha_j \beta_k}\, b_{jk} & \text{as } \beta_i - \alpha_i = \delta_{ik} - \delta_{ij}. \end{cases} \tag{19.6.6}$$

Further,

(19.6.7) $\mathbb{H}_n \coloneqq \{\sum_{\alpha:|\alpha|=n} v_\alpha(x'')\Upsilon_\alpha(x')\}$ are invariant subspaces of both $\mathcal{A}_0$ and $\mathcal{A}^0$

and

$$\mathsf{Spec}\big(\mathcal{A}^0_{\alpha\beta}(x'',\xi'')\big)_{\alpha,\beta}\Big|_{\mathbb{H}_n} = \Big\{\sum_j (2\alpha_j+1) f_j,\ |\alpha| = n\Big\}. \tag{19.6.8}$$

19.6.3 Propagation

Special Case of Constant g^{jk}, F_{jk}

This is far the easiest case. First, we can assume without any loss of the generality that

$$\mathcal{A} = \mathcal{A}_0. \tag{19.6.9}$$

Really, no cubic terms appear from the "kinetic" part of Hamiltonian $\sum_j g^{jk} P_j P_k$ and the first-order terms appearing from the potential are eliminated in the process of reduction.

Further, we can skip an error $O(\varepsilon^l |\log \varepsilon|^{-\sigma})$ and for $(l,\sigma) \succeq (2,0)$ we can skip quadratic terms appearing from the potential because in the operator sense they are less than $\mu^{-2}(\mathcal{A}^0 + 1)$ and since our reduction in this case is global, we can just take approximate operator as $\mathcal{T}\mathcal{A}_0\mathcal{T}^*$.

Furthermore, we can assume without any loss of the generality that $b_{jk} = f_j \delta_{jk}$ and then

$$\mathcal{A}\Big(u_\alpha(x'')\Upsilon_\alpha(x')\Big) = \Big(\sum_j (2\alpha_j+1) f_j \mu h + q_0\Big) u_\alpha(x'') \cdot \Upsilon_\alpha(x'). \tag{19.6.10}$$

Now we are dealing with r-dimensional scalar $\mu^{-1}h$-pseudodifferential operators and the proofs of the following two statements are obvious:

Proposition 19.6.1. *Let g^{jk}, F_{jk} be constant and one of conditions* (19.6.1), (19.6.2) *be fulfilled. Let $Q = q(x', \mu^{-1}hD')$. Assume that on the support of q an ellipticity condition*

$$|\sum_i (2\alpha_i + 1) f_i \mu h + V - \tau| \ge \epsilon_1 \qquad \forall \alpha \in \mathbb{Z}^{+r}. \tag{19.6.11}$$

is fulfilled.

Then for $T \ge T_* := Ch|\log \mu|$

$$|F_{t\to h^{-1}\tau}\Big(\bar{\chi}_T(t) U_T\, {}^tQ_y\Big)| \le CT\mu^{-s}. \tag{19.6.12}$$

Proof. An easy proof based on our standard elliptic arguments is left to the reader. □

Proposition 19.6.2. *Let g^{jk}, F_{jk} be constant and one of conditions* (19.6.1), (19.6.2) *be fulfilled. Let $Q = q(x', \mu^{-1}hD')$.*

(i) Assume that on the support of q a microhyperbolicity condition

$$|\sum_i (2\alpha_i + 1) f_i \mu h + V - \tau| + |\nabla V| \ge \epsilon_1 \qquad \forall \alpha \in \mathbb{Z}^{+r}. \tag{19.6.13}$$

is fulfilled. Then for $T \in [T_*, T^*]$

$$|F_{t\to h^{-1}\tau}\Big(\chi_T(t) \Gamma' U_T\, {}^tQ_y\Big)| \le C\mu^{-s}. \tag{19.6.14}$$

(ii) Assume that on the support of q condition

$$|\sum_i (2\alpha_i + 1) f_i \mu h + V - \tau| \le \epsilon \implies |\nabla V| \asymp \epsilon_1 \nu \qquad \forall \alpha \in \mathbb{Z}^{+r} \tag{19.6.15}$$

with $C_0(\mu^{-1}h|\log h|)^{\frac{1}{2}} \le \nu \le \epsilon$. Then for $T \in [T_*, T^*]$ (19.6.14) *holds where now $T_* = C_0\nu^{-1}\mu h|\log \mu|$.*

Proof. An easy proof based on our standard microhyperbolicity arguments is left to the reader. □

Intermediate Magnetic Field: General Operators

Assume that condition (19.6.1) holds.

Consider operator $A_{\mathcal{T}}$ as a $\mu^{-1}h$-pseudodifferential operator with respect to x' with a "matrix" symbol with values in $\mathcal{L}(\mathbb{H},\mathbb{H})$ where $\mathbb{H}=\mathscr{L}^2(\mathbb{R}^r_{x'})$ and $\mathcal{L}(\mathbb{H}_1,\mathbb{H}_2)$ is the space of linear operators from $\mathbb{H}_2$ to $\mathbb{H}_1$.

Obviously, operator $\mathcal{A}$ does not belong to this class, but we can also replace $A_{\mathcal{T}}$ by $\mathcal{A}_0+Q_1^*(A_{\mathcal{T}}-\mathcal{A}_0)Q_1$ where $Q_1=I-\phi(\varepsilon^{-1}x',\varepsilon^{-1}\mu^{-1}hD')$ and ϕ is supported in $2C_1$-vicinity and equal 1 in C_1-vicinity of $0\in\mathbb{R}^d_{x'',\xi''}$. Applied to U, Q_1 produces negligible output[29]. Therefore:

Proposition 19.6.3. *Let condition* (19.6.1) *be fulfilled. Assume that on the support of* q *the ellipticity condition* (19.6.11) *is fulfilled and let* $Q=q(x'',\mu^{-1}hD'')$. *Then for* $T\ge Ch|\log h|$, $\tau\in[-\epsilon',\epsilon']$ *(with small enough constant* $\varepsilon'>0$*) estimate* (19.6.12) *holds.*

Furthermore,

Proposition 19.6.4. *Let condition* (19.6.1) *be fulfilled. Assume that on the support of* q *for a symbol* $\mathcal{A}_0$ *the standard microhyperbolicity assumption*

$$\big\langle\big(\ell\mathcal{A}_0(x'',\xi'')\big)v,v\big\rangle\ge\epsilon_0\|v\|^2-C\|\mathcal{A}_0v\|^2\qquad\forall v\in\mathbb{H} \tag{19.6.16}$$

is fulfilled and let $Q=q(x'',\mu^{-1}hD'')$. *Then for* $T\in[T'_*,T^*]$ *estimate* (19.6.14) *holds.*

Proof. An easy proof based on the standard arguments of the proof of Theorem 2.3.1 is left to the reader. □

Remark 19.6.5. Note that we need the single direction ℓ. We just cannot localize in $(\mu^2\mathsf{a}^0_{\mathsf{n}_1},\dots,\mu^2\mathsf{a}^0_{\mathsf{n}_\nu})$ even after our reduction. This is really frustrating because Poisson brackets $\big\{\mu^2\mathsf{a}^0_{\mathsf{n}_j},\mu^2\mathsf{a}^0_{\mathsf{n}_k}\big\}$ are $O(\mu^3h|p|^4)$ which is $O(\mu h^3|\log h|^2)$ even in the microlocal sense.

Strong Magnetic Field Case. Reduction

Assume that condition (19.6.2) holds. Then we should take into account that unless F_{jk},g^{jk} are constant (the case we already considered), generally

[29] After applying $F_{t\to h^{-1}\tau}\bar{\chi}_T(t)$ with $\tau\le c$ and $Ch|\log h|\le T\le ch^{-s}$.

variations of $\mu h f_j$ are of magnitude $\mu h \gg 1$. To overcome this difficulty we need to modify our assumptions.

First, we need to replace the Schrödinger operator by the generalized Schrödinger-Pauli operator (19.1.13).

Ellipticity condition would mean that

$$|\sum_j \big(\mathfrak{z}_j - (2\alpha_j+1)\big) f_j| \ge \epsilon \qquad \forall \alpha \in \mathbb{Z}^{+r} \tag{19.6.17}$$

but we concentrate mainly on the opposite case

$$\mathfrak{z}_j = 2\alpha_j + 1 \qquad \text{as} \quad \alpha \in \mathfrak{A} \subset \mathbb{Z}^{+r}, \tag{19.6.18}$$

$$|\sum_j (\mathfrak{z}_j - 2\alpha_j - 1) f_j| \ge \epsilon \qquad \forall \alpha \in \mathbb{Z}^{+r} \setminus \mathfrak{A} \tag{19.6.19}$$

and $C_0 = C_0(\epsilon)$ in condition (19.6.2). Then obviously $\mathfrak{A}$ is a finite subset.

We still need to deal with the fact that we have only local reduction and thus $A_{\mathcal{T}}$ differs from $\mathcal{A}$ by operator $\mathcal{A}'$ with symbol belonging to $\omega \mathscr{F}^{0,0}$ with

$$\omega = \varepsilon^l |\log \mu|^{-\sigma} + \mu h \varepsilon^{\bar l} |\log \mu|^{-\bar\sigma}. \tag{19.6.20}$$

Proposition 19.6.6. *Let $b \in \mathscr{F}^{0,0}$ be supported in $\{|x'| + |\xi'| \le c\varepsilon\}$. Then operator*

$$b^{\mathsf{w}}_{\alpha\beta} : \mathbb{K} \ni v \to \langle b^{\mathsf{w}}(v \otimes \Upsilon_\beta), \Upsilon_\alpha\rangle \in \mathbb{K}, \qquad \mathbb{K} := \mathscr{L}^2(\mathbb{R}^r_{x''}) \tag{19.6.21}$$

has norm

$$\|b^{\mathsf{w}}_{\alpha\beta}\| \le C e^{-\epsilon|\alpha-\beta|}. \tag{19.6.22}$$

Proof. Obviously, it is sufficient to prove this proposition as $x' \in \mathbb{R}^1$ (with $x'' \in \mathbb{R}^r$). Then since

$$H_j \Upsilon_\beta = (2\beta_j + 1)\mu h \Upsilon_\beta, \qquad H_j := \mu h (|\zeta_j|^2)^{\mathsf{w}} = \mu^2 x_j^2 + h^2 D_j^2 \tag{19.6.23}$$

we conclude that

$$b^{\mathsf{w}}_{\alpha\beta} = (\alpha_j - \beta_j)^{-1} \big\{|\zeta_j|^2, b\big\}^{\mathsf{w}}_{\alpha\beta} \tag{19.6.24}$$

and continuing this process we conclude that $b^{\mathsf{w}}_{\alpha\beta} = (\alpha_j - \beta_j)^{-n} (b_{(n)})^{\mathsf{w}}_{\alpha\beta}$ with $b_{(0)} = b$ and $b_{(n)} = \big\{|\zeta_j|^2, b_{(n-1)}\big\}$.

One can see easily $b_{(n)} \in C^n n! \mathscr{F}^{0,0}$ uniformly with respect to n [30] operator norm of $b^{\mathsf{w}}_{(n)}$ in $\mathcal{L}(\mathbb{H}\otimes\mathbb{K}, \mathbb{H}\otimes\mathbb{K})$ does not exceed $C^n n!$ and then operator norm of $b^{\mathsf{w}}_{\alpha\beta}$ in $\mathcal{L}(\mathbb{K},\mathbb{K})$ does not exceed $|\alpha_j-\beta_j|^{-n} C^n n!$. It reaches minimum $e^{-\epsilon|\alpha_j-\beta_j|}$ as $n = C^{-1}|\alpha_j-\beta_j|$. □

No 2-nd Order Resonances Case. Assume first that all f_j are disjoint. Then

$$\mathcal{A}_0 = \sum_{1\le j\le r} b_j(x'', \mu^{-1}hD'')\big(\mu^2 x_j^2 + h^2 D_j^2\big) + b_0(x'', \mu^{-1}hD'') \tag{19.6.25}$$

and

$$\mathcal{A}_0\big(v(x'')\Upsilon_\alpha(x')\big) = (W_\alpha v)\Upsilon_\alpha(x') \tag{19.6.26}$$

where W_α is $(\mu^{-1}h)$-pseudodifferential operator with the principal symbol

$$W_\alpha = \big(V + \sum_j (2\alpha_j + 1 - \mathfrak{z}_j) f_j \mu h\big) \circ \Psi_0. \tag{19.6.27}$$

Proposition 19.6.7. *Let ellipticity condition* (19.6.17) *be fulfilled and let condition* (19.6.2) *be fulfilled at $\bar{x}$ with $C_0 = C_0(\epsilon)$. Then modulo $O(\mu^{-s})$*

$$F_{t\to h^{-1}\tau}\bar{\chi}_T(t)U_{\alpha\beta} \equiv 0 \qquad \forall \tau : |\tau| \le \epsilon'\mu h \qquad \text{in } \ \Omega\times\Omega \tag{19.6.28}$$

where $\Omega = B(\bar{z}'', C_0\varepsilon) \subset \mathbb{R}^{2r}_{x'',\xi''}$ is a domain in which reduction is done, $\bar{z}'' = (\bar{x}'', \bar{x}'') = \Psi_0^{-1}(\bar{x})$.

Proof. Proof due to the standard elliptic arguments is left to the reader. □

Proposition 19.6.8. *Let conditions* (19.6.18)–(19.6.19) *be fulfilled and let condition* (19.6.2) *be fulfilled at $\bar{x}$ with $C_0 = C_0(\epsilon)$. Assume that all f_j are disjoint. Let $T = \mu^m$ with large enough m. Then*

(i) As $\alpha \notin \mathfrak{A}$

$$F_{t\to h^{-1}\tau}\bar{\chi}_T(t)U_{\alpha\beta} \equiv \sum_{\alpha'\in\mathfrak{A}} E_{\alpha\alpha',x} F_{t\to h^{-1}\tau}\bar{\chi}_T(t)U_{\alpha'\beta} \tag{19.6.29}$$
$$\forall \tau : |\tau| \le \epsilon'\mu h \qquad \text{in } \ \Omega\times\Omega$$

[30] With simultaneous decay of the number of derivatives checked, but everything works as long as $n \le \epsilon|\log\varepsilon|$.

where $E_{\alpha\alpha'} = E_{\alpha\alpha'}(\tau, x'', \mu^{-1}hD'')$ *are pseudodifferential operators with the norms*

$$\|E_\alpha\| \le C(\mu h)^{-1}\Big((\mu^{-1}h)^{\frac{1}{2}\delta(\alpha)} + e^{-|\alpha-\bar\alpha|}\omega\Big) \tag{19.6.30}$$

and a similar dual equation holds; here

$$\delta(\alpha) := \min_{\alpha'\in\mathfrak{A}} |\alpha - \alpha'|. \tag{19.6.31}$$

(ii) As $\alpha \notin \mathfrak{A}$ *and* $\beta \neq\notin \mathfrak{A}$

$$F_{t\to h^{-1}\tau}\bar\chi_T(t)U_{\alpha\beta} \equiv \sum_{\alpha',\beta'\in\mathfrak{A}} E_{\alpha\alpha',x}F_{t\to h^{-1}\tau}\bar\chi_T(t)U_{\alpha'\beta'}\,{}^tE_{\beta\beta',y} \qquad \forall \tau : |\tau| \le \epsilon'\mu h \quad \text{in } \Omega\times\Omega. \tag{19.6.32}$$

(iii) Further, $\boldsymbol{U} := \{U_{\alpha\beta}\}_{\alpha,\beta\in\mathfrak{A}}$ *satisfies*

$$F_{t\to h^{-1}\tau}\bar\chi_T(t)\Big(\big(hD_t - W_\alpha(x'', \mu^{-1}hD'')\big)U_{\alpha\beta} - \sum_{\alpha'\in\mathfrak{A}} W'_{\alpha\alpha'}(x'', \mu^{-1}hD'')U_{\alpha'\beta}\Big) \equiv 0 \qquad \forall \tau : |\tau| \le \epsilon'\mu h \quad \text{in } \Omega\times\Omega \tag{19.6.33}$$

and adjoint equation with respect to y'' *where* W_α *is defined by* (19.6.27) *and* $W'_{\alpha\alpha'}$ *are* $\mu^{-1}h$*-pseudodifferential operator with symbol belonging to* $(\omega + h^2)\mathscr{F}^{0,0}$.

Proof. (a) Plugging representation (19.6.3) into equation $\big(hD_t - A_{\mathcal{T},x}\big) = 0$ and using (19.6.26)–(19.6.27), form of $\mathcal{A}$ and applying Proposition 19.6.6 to $A_{\mathcal{T}} - \mathcal{A}$ we arrive to the system

$$\big(hD_t - W_\alpha - W'_\alpha\big)U_{\alpha\beta} \equiv \sum_{\gamma\neq\alpha} B_{\alpha\gamma}\,U_{\gamma\beta} \qquad \text{in } \Omega\times\mathbb{R}^{2r} \tag{19.6.34}$$

with W'_α not including hD_t. Here and below all operators are acting with respect to x''. We also get an adjoint system

$$U_{\alpha\beta}\,{}^t\big(hD_t - W_\beta - W'_\beta\big) \equiv \sum_{\gamma\neq beta} U_{\alpha\gamma}\,{}^tB_{\gamma\beta} \qquad \text{in } \mathbb{R}^{2r}\times\Omega \tag{19.6.34}'$$

with operators acting with respect to y''.

Applying $F_{t\to h^{-1}\tau}\bar\chi_T(t)$ with T described above, we arrive to the system

$$\big(\tau - W_\alpha - W'_\alpha\big)v_{\alpha\beta} - \equiv \sum_{\gamma\neq\alpha} B_{\alpha\gamma}\, v_{\gamma\beta} \qquad \text{in } \ \Omega\times\mathbb{R}^{2r}, \tag{19.6.35}$$

with $v_{\alpha\beta} = F_{t\to h^{-1}\tau}\bar\chi_T(t)U_{\alpha\beta}$ and a similar dual system.

Due to assumptions (19.6.18)–(19.6.19) all operators $\big(\tau - W_\alpha - W'_\alpha\big)$ with $\alpha\notin\mathfrak{A}$ are elliptic with inverse operators norms of magnitude $\big(\mu h\delta(\alpha)\big)^{-1}$ as $|\tau|\le \epsilon\mu h$.

Note that even in the worst case $B_{\alpha\beta}$ are operators with the symbols belonging to $\mu h(\mu^{-1}h|\alpha|)^{\frac12}\mathscr{F}^{0,1}$. Then by the successive approximations

$$v_{\alpha\beta} = \sum_{\alpha'\in\mathfrak{A}} E_{\alpha\alpha'}v_{\alpha'\beta} \qquad \text{as } \ \alpha\notin\mathfrak{A} \tag{19.6.36}$$

where each $E_{\alpha\alpha'}$ is the sum of terms of the following type:

$$(\tau - W_\alpha)^{-1}B'_{\alpha\alpha_1}(\tau - W_{\alpha_1})^{-1}B'_{\alpha_1\alpha_2}\cdots(\tau - W_{\alpha_k})^{-1}B'_{\alpha_k\alpha'} \tag{19.6.37}$$

with $k\ge 0$ where $B'_{\gamma\gamma'}$ are operators with symbols belonging to $\mu h(\mu^{-1}h|\alpha|)^{\frac12}\mathscr{F}^{0,1}$. For the sake of simplicity we included W'_α into W_α.

Similarly,

$$v_{\alpha\beta} = \sum_{\beta'\in\mathfrak{A}} v_{\alpha\beta'}\,{}^tE_{\beta\beta'} \qquad \text{as } \ \alpha\notin\mathfrak{A} \tag{19.6.36}'$$

Then both Statements (i) and (ii) follow then from formulae (19.6.36), (19.6.36)′ and (19.6.37).

(b) Plugging (19.6.27), (19.6.3) into equation $(hD_t - A_{\mathcal{T}x})u = 0$ and a dual equation with respect to y, we arrive to an equation similar to (19.6.33) (as well as an adjoint equation with respect to y):

$$\big(\tau - W_\alpha\big)v_{\alpha\beta} \equiv \sum \mathcal{W}_{\alpha\alpha'}v_{\alpha'\beta} \qquad \text{in } \ \Omega\times\mathbb{R}^{2r} \tag{19.6.38}$$

where $\mathcal{W}_{\alpha\alpha'}$ is a sum of terms of of (19.6.37) type with an extra factor on their left:

$$(\mu^{-1}h)^{\frac p2}B'_{\alpha\alpha_1}(\tau - W_{\alpha_1})^{-1}B'_{\alpha_1\alpha_2}\cdots(\tau - W_{\alpha_k})^{-1}B'_{\alpha_k\alpha'} \tag{19.6.39}$$

with $B'_{\bar\alpha\alpha}$ of the same type as above; $p=0$ here. Note that

$$(\tau - W_\gamma)^{-1} = (W_{\alpha'} - W_\gamma)^{-1} - (\tau - W_\gamma)^{-1}(\tau - W_{\alpha'})(W_{\alpha'} - W_\gamma)^{-1} \tag{19.6.40}$$

in $\Omega \times \mathbb{R}^{2r}$.

We apply this formula to $(\tau - W_{\alpha_k})^{-1}$. Then we drag $(\tau - W_{\alpha'})$ to the right. If it perishes at commuting, we get the same expression with the same k but with p replaced by $p+1$ because in the commuting we gain $\varepsilon^{-1}\mu^{-1}h$ factor. Continuing this process with $(\tau - W_{\alpha_{k-1}})$ etc we arrive to

$$\bigl(\tau - W_\alpha\bigr)v_{\alpha\beta} \equiv \sum_{\alpha'\in\mathfrak{A}} \Bigl(W''_{\alpha\alpha'} + \mathcal{W}''_{\alpha\alpha'}\,(\tau - W_{\alpha'}) + \mathcal{W}'''_{\alpha\alpha'}\Bigr)v_{\alpha'\beta} \qquad \text{in } \ \Omega\times\mathbb{R}^{2r} \tag{19.6.41}$$

where $W''_{\alpha\alpha'}$ does not depend on τ, $\mathcal{W}'''_{\alpha\alpha'}$ is the sum of products of (19.6.39) type with p replaced by $p+1$, $\mathcal{W}''_{\alpha\alpha'}$ is the sum of products of (19.6.39) type with p replaced by $p+2$ and k replaced by $k-1$. Considering system (19.6.41) as a $(\#\mathfrak{A})\times(\#\mathfrak{A})$-matrix equation and multiplying by $(I+\mathcal{W}'')$ one can rewrite this system as (19.6.38) with W_α replaced by $W_\alpha + W''_{\alpha\alpha}$ and $\mathcal{W}'''_{\alpha\alpha'}$ of the same type with p replaced by $p+1$.

Continuing this process we arrive to negligible $\mathcal{W}'''_{\alpha\alpha'}$. Statement (iii) is proven. □

Remark 19.6.9. (i) It follows from our construction that an added correction modulo $(\omega+\mu^{-1}h)\mathscr{F}^{0,0}$ is equal to

$$W'_{\alpha\alpha'} = \sum_{\beta:|\alpha-\beta|=|\alpha-\beta|=1} B_{\alpha\beta}(W_\beta)^{-1}B_{\beta\alpha'} \tag{19.6.42}$$

with $B_{\alpha\beta}$ appearing exclusively from cubic terms in $\mathcal{A}$.

(ii) Further, note that these terms are $b_{m;jk}Z_m^*Z_jZ_k$ and $b^*_{m;jk}Z_mZ_j^*Z_k^*$ with f_m not disjoint from f_j+f_k. Conditions (19.6.18)–(19.6.19) and $\#\mathfrak{A}=1$, $\alpha\in\mathfrak{A}$ imply that $\alpha_m=0$ <u>and</u> either $\bar\alpha_j=0$ or $\bar\alpha_k=0$ if $j\ne k$ and $\alpha_j=0,1$ as $j=k$. Therefore cubic terms, applied to $v(x'')\Upsilon_{\bar\alpha}(x')$, produce 0, and therefore $W'_{\alpha\alpha'}\in(\omega+\mu^{-1}h)\mathscr{F}^{0,0}$.

However, correction $W'_{\alpha\alpha'}\equiv h^2\sum_j \kappa_j Z_j^*Z_j \mod O(\omega+\mu^{-1}h)$ has been already generated in the process of reduction in Section 19.3. Still we see that it 0 in the case of constant g^{jk}, F_{jk}.

2-nd Order Resonances Case. Consider now a more general case when some of f_j are not disjoint; assume that f_j is disjoint from the rest of eigenvalues as $j = 1, \dots, p$ and is not as $j = p+1, \dots, r$. Then

$$\mathcal{A}_0 = \sum_{1\le j\le p} f_j(x'', \mu^{-1}hD'')\big(\mu^2 x_j^2 + h^2 D_j^2\big) + \sum_{p+1\le j,k\le r} b_{jk}(x'', \mu^{-1}hD'')\big(Z_j^* Z_k + \mu h\delta_{jk}\big) + b_0(x'', \mu^{-1}hD''). \tag{19.6.43}$$

Assume that

$$\alpha_j = 0 \quad \text{as} \quad j = p+1, \dots, r \qquad \forall \alpha \in \mathfrak{A}. \tag{19.6.44}$$

Note that conditions (19.6.18)–(19.6.19) and $\#\mathfrak{A} = 1$ yield (19.6.44).

Due to (19.6.18)–(19.6.19) and (19.6.44) $\mathcal{A}_0$ restricted to $v(x'')\Upsilon_{\bar\alpha}(x')$ equals

$$\mathcal{A}_0 = \sum_{1\le j\le p} f_j(x'', \mu^{-1}hD'')\big(2\bar\alpha_j + 1\big)\mu h + b_0(x'', \mu^{-1}hD''); \tag{19.6.45}$$

then arguments of the proof of Proposition 19.6.7 still work but instead of the individual subspaces $\mathscr{H}_\alpha := \big\{v(x'')\Upsilon_\alpha(x')\big\}$ for $\alpha = (\alpha'; \alpha'') = (\alpha_1, \dots, \alpha_p; \alpha_{p+1}, \dots, \alpha_r)$ one should consider subspaces

$$\mathscr{H}_{\alpha', n} := \Big\{ \sum_{|\alpha''|=n} v_{(\alpha';\alpha'')}(x'')\, \Upsilon_{(\alpha';\alpha'')}(x') \Big\}.$$

Therefore we have

Proposition 19.6.10. *Propositions 19.6.7 and 19.6.8 holds even if f_i are not necessary disjoint but* (19.6.44) *is fulfilled.*

Strong Magnetic Field Case. Propagation

So under assumption $\#\mathfrak{A} = 1$ basically we reduced our operator to a single r-dimensional $\mu^{-1}h$-pseudodifferential operator $W_{\bar\alpha}$ with a principal symbol $V \circ \Psi_0$ while under assumption (19.6.44) we have a matrix-operator with the diagonal principal part instead. Then in the framework of (19.6.18)–(19.6.19) we can impose an ellipticity

$$|V| \ge \epsilon_0 \tag{19.6.46}$$

or a microhyperbolicity

$$|V| + |\nabla V| \ge \epsilon_0 \tag{19.6.47}$$

or as $(l,\sigma) \succeq (2,0)$ a non-degeneracy assumption

$$|V| + |\nabla V| + |\det \mathsf{Hess}\, V| \ge \epsilon_0. \tag{19.6.48}$$

Proposition 19.6.11. *Let conditions* (19.6.2), (19.6.18)–(19.6.19), *and* (19.6.44) *be fulfilled. Then under assumption* (19.6.46) *estimate* (19.6.28) *holds.*

Proof. The standard elliptic arguments applied to equation (19.6.33) yield that under condition (19.6.46) estimate (19.6.28) holds as $\tau \le \epsilon'$, $\alpha, \beta \in \mathfrak{A}$. Then in virtue of Propositions 19.6.8 and 19.6.10 this is true for all α, β. Easy details we leave to the reader. □

Proposition 19.6.12. *Let conditions* (19.6.2), (19.6.18)–(19.6.19), *and* (19.6.44) *be fulfilled.*

Then for $T_* \le T \le T^* = \epsilon_0 T$, $T \ge C\varepsilon^{-1}h|\log \mu|$ *and large enough constant* M

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t) Q'_x U_{\alpha\beta}(x,y,t)\, {}^tQ''_y| \le C\mu^{-s} \qquad \forall \tau \le c. \tag{19.6.49}$$

as $\tau \le \epsilon'$ *and distance between supports of (symbols of)* Q' *and* Q'' *is at least* $C\mu^{-1}T$.

Proof. The standard propagation arguments applied to equation (19.6.33) yield that (19.6.49) holds as $\alpha, \beta \in \mathfrak{A}$. Then in virtue of Propositions 19.6.8 and 19.6.10 this is true for all α, β. Easy details we leave to the reader. □

Proposition 19.6.13. *Let conditions* (19.6.2) *and* (19.6.18)–(19.6.19), (19.6.44) *be fulfilled. Further, let microhyperbolicity condition* (19.6.47) *be fulfilled.*

Then for $T_* \le T \le T^* = \epsilon_0 T$, $T \ge C\varepsilon^{-1}h|\log \mu|$ *and large enough constant* M

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t) Q'_x U_{\alpha\beta}(x,y,t)\, {}^tQ''_y| \le C\mu^{-s} \qquad \forall \tau \le c. \tag{19.6.50}$$

as $\tau \le \epsilon'$ *and distance between the most distant points of supports of (symbols of)* Q' *and* Q'' *is at most* $C\epsilon\mu^{-1}T$.

Proof. The standard propagation arguments applied to equation (19.6.33) yield that (19.6.50) holds as $\alpha, \beta \in \mathfrak{A}$. Then in virtue of Propositions 19.6.8 and 19.6.10 this is true for all α, β. Easy details we leave to the reader. □

Corollary 19.6.14. *(i) In the framework of Proposition 19.6.12*

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\psi'(x)U(x,y,t)\psi''(y)| \le C\mu^{-s} \qquad \forall \tau \le c \tag{19.6.51}$$

as $\tau \le \epsilon'$ and distance between supports of (symbols of) ψ' and ψ'' is at least $C\mu^{-1}T$ under additional assumption

$$T \ge C_0(\mu h|\log h|)^{\frac{1}{2}}. \tag{19.6.52}$$

(ii) In the framework of Proposition 19.6.13

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\psi'(x)U(x,y,t)\psi''(y)| \le C\mu^{-s} \qquad \forall \tau \le c \tag{19.6.53}$$

as $\tau \le \epsilon'$ and distance between the most distant points of supports of (symbols of) Q' and Q'' is at most $C\epsilon\mu^{-1}T$ under additional assumption (19.6.52).

Corollary 19.6.15. *In the framework of Proposition 19.6.13*

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\psi'(x)U(x,y,t)\psi''(y)| \le C\mu^{-s} \qquad \forall \tau \le c. \tag{19.6.54}$$

Remark 19.6.16. (i) One can prove easily that under assumptions (19.6.2), (19.6.18)–(19.6.19) and (19.6.44) as $(I,\sigma) \succeq (2,0)$ singularities propagate along trajectories

$$\frac{dx_j}{dt} = \mu^{-1}\sum_k \Phi^{jk}\partial_{x_k}V \tag{19.6.55}$$

($\tau : |\tau| \le \epsilon'$) where $(\Phi^{jk}) = (F_{jk})^{-1}$. In particular, $V_{\bar{\alpha}}$ is an integral.

(ii) For $d = 2$ even condition $(I,\sigma) \succeq (2,0)$ is not necessary.

Remark 19.6.17. As $g^{jk} = \mathsf{const}$, $F_{jk} = \mathsf{const}$ all our results remain true even if there are 2-nd order resonances and (19.6.44) fails.

We leave to the reader the following

Problem 19.6.18. Formulate and prove similar results as $|\nabla V| \asymp \nu \ge C\varepsilon$ (instead of $|\nabla V| \asymp 1$).

19.6.4 Short-Range Estimates

Intermediate Magnetic Field

As before the case $\epsilon_1 h^{-1} \le \mu \le C_0 h^{-1}$ is just a variation of the strong magnetic field case but with the mandatory assumption $\#\mathfrak{N} = 1$ and the microhyperbolicity condition required only for $\tau = \sum_j (2\alpha_j + 1)\mu h f_j$ with $\alpha \in \mathbb{Z}^{+r}$. Using the same arguments as in the proof of Proposition 19.4.9 we arrive to

Proposition 19.6.19. *Let $\epsilon h^{-1} \le \mu \le C_0 h^{-1}$, $\varepsilon \ge (\mu^{-1} h |\log h|)^{\frac{1}{2}}$, and $T_* = C\varepsilon^{-1} h |\log h|$.*

Let microhyperbolicity condition (19.6.13) *be fulfilled and let $T \in [h^{1-\delta}, T_*]$ with an arbitrarily small exponent $\delta > 0$. Then both Statements (i) and (ii) of Proposition 19.4.9 remain true.*

Proof. Easy details are left to the reader. □

Strong Magnetic Field

Let us assume now that $\mu \ge \mu_4^* = C_0 h^{-1}$ and we consider generalized Schrödinger-Pauli operator (19.1.13).

We need to assume now that either g^{jk}, F_{jk} are constant or conditions (19.6.18)–(19.6.19), (19.6.44) are fulfilled. Exactly the same method as before leads us to similar results:

Proposition 19.6.20. *Let $\mu \ge C_0 h^{-1}$, $\varepsilon \ge (\mu^{-1} h |\log h|)^{\frac{1}{2}}$, and $T_* = C\varepsilon^{-1} h |\log h|$. Let conditions* (19.6.18)–(19.6.19), (19.6.44), *and microhyperbolicity condition* (19.6.47) *be fulfilled.*

(i) Let $l > 1$. Then for $T \in [C\mu^{\delta} h, T_*]$ with an arbitrarily small exponent $\delta > 0$

$$|\phi(hD_t)\chi_T(t)(\Gamma U \psi_y)| \le C\mu^r h^{-r} \Big(\frac{h}{T}\Big)^{l-1} \Big(1 + \frac{h}{T\varepsilon}\Big)^{-s} |\log \frac{h}{T}|^{-\sigma} \tag{19.6.56}$$

and

$$|F_{t\to h^{-1}\tau}\chi_T(t)(\Gamma U \psi_y)| \le C\mu^r h^{1-r} \Big(\frac{h}{T}\Big)^{l-1} \Big(1 + \frac{h}{T\varepsilon}\Big)^{-s} |\log \frac{h}{T}|^{-\sigma} \tag{19.6.57}$$

as $|\tau| \le \epsilon$ with arbitrarily large exponent s.

(ii) Let $l = 1, \sigma \ge 2$. *Then for* $T \in [Ch^{1-\delta}, T_*]$ *with an arbitrarily small exponent* $\delta > 0$ *and small enough constant* T_*

$$|\phi(hD_t)\chi_T(t)(\Gamma U\psi_y)| \le C\mu^r h^{-r}|\log\frac{h}{T}|^{-\sigma}\big(1+\frac{T\varepsilon}{h}\big)^{-s} + C\mu^r h^{-r}|\log\frac{h}{T}|^{-s}, \tag{19.6.58}$$

and

$$|F_{t\to h^{-1}\tau}\chi_T(t)(\Gamma U\psi_y)| \le C\mu^r h^{1-r}|\log\frac{h}{T}|^{-\sigma}\big(1+\frac{T\varepsilon}{h}\big)^{-s} + C\mu^r h^{1-r}|\log\frac{h}{T}|^{-s} \tag{19.6.59}$$

as $|\tau| \le \epsilon$ *with arbitrarily large exponent* s.

Remark 19.6.21. As $g^{jk} = \mathsf{const}, F_{jk} = \mathsf{const}$ all our results remain true even if there are 2-nd order resonances and (19.6.44) fails.

Problem 19.6.22. Formulate and prove similar results as $|\nabla V| \asymp \nu \ge C\varepsilon$ (instead of $|\nabla V| \asymp 1$).

19.6.5 Calculations

Now Propositions 19.6.19 and 19.6.20 imply immediately

Proposition 19.6.23. *In the frameworks of Propositions 19.6.19 and 19.6.20 the following estimates hold:*

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma(U\psi)| \le C\mu^r h^{1-r}, \tag{19.6.60}$$

$$T^{-1}|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(\bar{\mathcal{G}}^{\pm}(A_T-\bar A_T)\mathcal{G}^{\pm}\delta(t)\mathcal{K}_\psi\big)| \le C\mu^{r-1}h^{1-r}\big(\frac{h}{T}\big)^{l-2}|\log\mu|^{-\sigma} \tag{19.6.61}$$

and

$$|\Gamma(\psi\tilde e)(\tau) - h^{-1}\int_{-\infty}^{\tau}\big(F_{t\to h^{-1}\tau'}\bar\chi_T(t)\Gamma(\psi u)\big)\,d\tau'| \le C\mu^{r-1}h^{1-r} \quad \forall \tau : |\tau| \le \epsilon \tag{19.6.62}$$

with $T \in [T_*, T^*]$, $T_* = Ch\mu^\delta$, $T^* := \epsilon\mu$, $|\tau| \le \epsilon$.

In turn, Proposition 19.6.23 immediately implies

Proposition 19.6.24. *In the frameworks of Propositions 19.6.19 and 19.6.20*

$$|h^{-1}\int_{-\infty}^{\tau}\bigl(F_{t\to h^{-1}\tau'}\bar{\chi}_T(t)\Gamma(\psi u)\bigr)\,d\tau'- (2\pi)^{-r}\mu^{r-1}h^{-r}\,\mathsf{Tr}'\,\theta\bigl(\tau-\mathcal{A}(x'',\xi'')\bigr)\psi^0(x'',\xi'')\,dx''d\xi''| \le C\mu^{r-1}h^{1-r}+C\mu^r h^{-r}\varepsilon'|\log\mu|^{-\sigma} \qquad \forall \tau : |\tau|\le\epsilon. \tag{19.6.63}$$

19.6.6 Main Theorems

Finally we immediately arrive to two Theorems 19.6.25 and 19.6.26 below:

Theorem 19.6.25. *Let assumptions* (19.1.4)–(19.1.6), $(19.1.25)_{1-3}$ *with* $(\bar{l},\bar{\sigma})\succeq(l,\sigma)\succeq(1,2)$, $(\bar{l},\bar{\sigma})\succeq(2,1)$ *be fulfilled. Let*

$$\mu_3^*:=\epsilon h^{-1}\le\mu\le\mu_4^*:=C_0h^{-1} \tag{19.6.64}$$

with sufficiently small constant $\epsilon'>0$. *Assume that the microhyperbolicity condition* (19.6.16) *is fulfilled.*

Then there are two framing approximations[18] *(see Chapter 18) such that:*

$$\mathsf{R}^{\mathsf{MW}}:=|\int\Bigl(\tilde{e}(x,x,0)-h^{-d}\mathcal{N}^{\mathsf{MW}}(x,0)\Bigr)\psi(x)\,dx|\le C\mu^{r-1}h^{1-r}+C\mu^r h^{-r}(\mu^{-1}h)^{\frac{l}{2}}|\log\mu|^{\frac{l}{2}-\sigma}+C\mu^{r+1}h^{1-r}(\mu^{-1}h)^{\frac{\bar{l}}{2}}|\log\mu|^{\frac{\bar{l}}{2}-\bar{\sigma}}. \tag{19.6.65}$$

Theorem 19.6.26. *Let assumptions* (19.1.4)–(19.1.6), $(19.1.25)_{1-3}$ *with* $(\bar{l},\bar{\sigma})\succeq(l,\sigma)\succeq(1,2)$, $(\bar{l},\bar{\sigma})\succeq(2,1)$ *be fulfilled. Let*

$$\mu_4^*:=C_0h^{-1}\le\mu \tag{19.6.66}$$

with sufficiently small constant $\epsilon'>0$. *Consider generalized Schrödinger-Pauli operator. Assume that* (19.6.18)–(19.6.19) *and* <u>*either*</u> *microhyperbolicity condition* (19.6.47) <u>*or*</u> *nondegeneracy condition* (19.6.48) *are fulfilled.*

Then there are two framing approximations[18] *(see Chapter 18) such that:*

$$\mathsf{R}_2^{\mathsf{MW}}:=|\int\Bigl(\tilde{e}(x,x,0)- h^{-d}\mathcal{N}^{\mathsf{MW}}(x,0)-h^{-d}\mathcal{N}_{2\mathsf{corr}}^{\mathsf{MW}}(x,0)\Bigr)\psi(x)\,dx|\le C\mu^{r-1}h^{1-r}+C\mu^r h^{-r}(\mu^{-1}h)^{\frac{l}{2}}|\log\mu|^{\frac{l}{2}-\sigma}+C\mu^{r+1}h^{1-r}(\mu^{-1}h)^{\frac{\bar{l}}{2}}|\log\mu|^{\frac{\bar{l}}{2}-\bar{\sigma}} \tag{19.6.67}$$

with

$$h^{-d}\mathcal{N}^{\mathsf{MW}}_{2\mathsf{corr}}(x,\tau) := (2\pi)^{-r}\mu^r h^{2-r}\sum_{\alpha\in\mathfrak{A}\subset\mathbb{Z}^{+r}}\delta\Big(\tau-\sum_j(2\alpha_j+1)f_j\mu h - V\Big)W'_\alpha \tag{19.6.68}$$

with $W'_\alpha = O(1)$.

Remark 19.6.27. The exact formula for W'_α is rather complicated; however $W'_\alpha = 0$ provided g^{jk}, F_{jk} are constant.

Problem 19.6.28. Derive explicit formula for W'_α.

Finally, consider spectral gaps:

Theorem 19.6.29. *Let assumptions* (19.1.4)–(19.1.6), $(19.1.25)_{1-3}$ *with* $(\bar I,\bar\sigma)\succeq(I,\sigma)\succeq(1,2)$, $(\bar I,\bar\sigma)\succeq(2,1)$ *be fulfilled. Consider two cases:*

(i) Let assumptions (19.6.64) *and* (19.6.11) *be fulfilled.*

(ii) Let assumptions (19.6.66), (19.6.18)–(19.6.19) *and either* $\#\mathfrak{A}=0$ *or* (19.6.46) *be fulfilled.*

Then in both cases (i) and (ii) there are two framing approximations[18)] *(see Chapter 18) such that*

$$\mathsf{R}^{\mathsf{MW}}\le C\mu^{-s} \tag{19.6.69}$$

with arbitrarily large s.

19.7 Simple Degeneration

Now we want to consider the case of the degeneration but completely different from one when g^{jk}, F_{jk} constant and V having non-degenerate critical points.

19.7.1 Framework

Assume now that

(19.7.1) There are no 2-nd order resonances i.e. eigenvalues f_j of (F_k^j) are simple

albeit the microhyperbolicity condition (see Definition 19.2.4) is violated i.e. there exists $\boldsymbol{\lambda} = (\lambda_1, \dots, \lambda_r)$ with

$$\lambda_1 \ge 0, \dots, \lambda_r \ge 0, \quad \lambda_1 + \dots + \lambda_r = 1 \tag{19.7.2}$$

such that

$$\sum_k \lambda_k \nabla \log(-V/f_k)(\bar{x}) = 0; \tag{19.7.3}$$

let $\mathbb{K}$ be the set of $\boldsymbol{\lambda}$, satisfying (19.7.2).

Further, let us assume that

$$\operatorname{rank}\bigl\{\nabla \log(-V/f_1)(\bar{x}), \dots, \nabla \log(-V/f_r)(\bar{x})\bigr\} \ge m \tag{19.7.4}$$

with $1 \le m \le r-1$.

Note that if $m = r-1$ (case of the *simple degeneration* then $\boldsymbol{\lambda} = (\lambda_1, \dots, \lambda_r) \in \mathbb{K}$ in (19.7.3) is defined uniquely; more generally, $\boldsymbol{\lambda} \in \mathbb{K}$ is defined uniquely modulo elements of $(r-m-1)$-dimensional subspace $\mathbb{L}$ and

$$|\sum_k \lambda_k \nabla \log(-V/f_k)(\bar{x})| \asymp \nu := \operatorname{dist}(\boldsymbol{\lambda}, \mathbb{L}') \qquad \forall \boldsymbol{\lambda} \in \mathbb{K} \tag{19.7.5}$$

where affine subspace $\mathbb{L}'$ is defined by (19.7.3) and $\lambda_1 + \dots + \lambda_r = 1$.

We consider only the smooth case i.e. assume that

$$g^{jk}, V_j, V \in \mathscr{C}^K \tag{19.7.6}$$

with sufficiently large $K = K(d)$. Then (19.7.5) remains true in $\epsilon\nu$-vicinity of x.

19.7.2 Weak Magnetic Case

Using standard reduction we reach

$$\mathcal{A} = \mu h \sum_j f_j(x'', \mu^{-1}hD'')\big(x_j^2 + D_j^2\big) + O(\mu^{-l}) \tag{19.7.7}$$

with $l = 2, 1$ if there are no 3-rd order resonances and in the general case respectively.

We leave to the reader the following

Problem 19.7.1. (i) Prove by our standard method that one can localize with respect to $\mu h\big(x_j^2 + D_j^2\big)$ modulo $O(\mu^{1-l}T + C\mu h|\log h|)$.

(ii) Prove by the method of Section 19.5 that one can localize with respect to $\mu h\big(x_j^2 + D_j^2\big)$ modulo $O(\mu^{1-l}T + C\mu h)$.

Assume that the localization is done in vicinity of $\boldsymbol{\tau}$. Consider symbol

$$b(x'', \xi''; \boldsymbol{\tau}) = \sum_j f_j(x'', \xi'')\tau_j. \tag{19.7.8}$$

Consider point $(\bar{x''}, \bar{\xi''})$. Then if in its γ-vicinity

$$|\nabla b| \asymp \nu\gamma^{-1}, \quad |b| \lesssim \nu, \qquad \nu = \gamma^2, \tag{19.7.9}$$

$$\gamma \ge C_0 \max(\mu^{-1}, (\mu^{-1}h|\log h|)^{\frac{1}{2}}); \tag{19.7.10}$$

then the shift for time T is $\asymp \mu^{-1}\nu T$ and it is observable if $\mu^{-1}\nu T \times \gamma \ge C\mu^{-1}h|\log h|$ and one can take $T = \epsilon_0\mu^{-1}$ as long as

$$\gamma \ge \bar{\gamma} := C_0 \max\big((\mu h|\log h|)^{\frac{1}{2}}, \mu^{-l}\big); \tag{19.7.11}$$

here the last requirement ($\gamma \ge C_0\mu^{-l}$) is needed to counter the irreducible terms of order $l+2$ but it contributes only $C\mu h^{1-d} \times \mu^{-l} = C\mu^{1-l}h^{1-d}$ into the final remainder estimate. Then one can take

$$T^* \asymp \mu^{l-1}\gamma \tag{19.7.12}$$

and $T_* = \epsilon_0\mu^{-1}$ and then contribution of γ-vicinity to Tauberian remainder does not exceed $C\gamma^{2d}h^{1-d}T^{*-1} \asymp C\gamma^{2d-1}\mu^{1-l}h^{1-d}$ and then contribution of zone $\{\gamma \ge \bar{\gamma}\}$ to such remainder does not exceed

$$C\mu^{1-l}h^{1-d} \int_{\{\gamma \ge \bar{\gamma}\}} \gamma^{-1}\, dx''d\xi''d\boldsymbol{\tau}, \tag{19.7.13}$$

while contribution of zone $\{\gamma \le \bar{\gamma}\}$ does not exceed

$$C\mu h^{1-d}\,\mathsf{mes}\big(\{\gamma \le \bar{\gamma}\}\big) \tag{19.7.14}$$

and the total remainder does not exceed (19.7.13)+(19.7.14):

$$C\mu^{1-l}h^{1-d}\int_{\gamma\ge\bar{\gamma}} \gamma^{-1}\,dM(\gamma) + C\mu h^{1-d}M(\bar{\gamma}) \tag{19.7.15}$$

with

$$M(\gamma) \coloneqq \mathsf{mes}_{3r}\big(\{(x'',\xi'',\boldsymbol{\tau}) : |\nabla_{x'',\xi''}b(x'',\xi'',\boldsymbol{\tau})| \asymp \gamma\}\big) = \int M(x'',\xi'';\gamma)\,dx''d\xi'', \tag{19.7.16}$$

$$M(x'',\xi'';\gamma) = \mathsf{mes}_{r}\big(\{(\boldsymbol{\tau}) : |\nabla_{x'',\xi''}b(x'',\xi'',\boldsymbol{\tau})| \asymp \gamma\}\big). \tag{19.7.17}$$

Note that

(19.7.18) Under assumption $(19.7.4)_m$ $M(x'',\xi'';\gamma) = O(\gamma^m)$.

Problem 19.7.2. Justify the following statement: we have $(3r-1)$-dimensional variable $(x,\boldsymbol{\lambda})$ (due to restriction $\lambda_1+...+\lambda_r=1$) and (19.7.3) imposes $2r$ restrictions; thus it happens generically on a variety of dimension $(r-1)$. However, $(19.7.4)_m$ with $m=(r-2)$ imposes $(2r-1)$ further restrictions more and thus never happens generically.

So let us assume that assumption $(19.7.4)_{r-1}$ is fulfilled. Then there exists a single $\boldsymbol{\lambda}=\boldsymbol{\lambda}(x)$ minimizing

$$|\sum_k \lambda_k \nabla \log(-V/f_k)|^2. \tag{19.7.19}$$

Let us assume that

$$\nabla(\sum \lambda_i \log(-V/f_i)) = 0 \implies \mathsf{rank}\big\{\sum_i \partial_j(\lambda_i\partial_k \log(-V/f_i))\big\}_{j,k=1,\dots,2r} = n. \tag{19.7.20}_n$$

Note that

(19.7.21) Under assumptions $(19.7.4)_{r-1}$ and $(19.7.20)_n$ $M(\gamma) = O(\gamma^{m+n})$.

Problem 19.7.3. Prove that generically (19.7.9) is fulfilled with $n = r+1$ and therefore $M(\gamma) = \gamma^{2r}$.

Therefore under assumption $(19.7.4)_{r-1}$ we conclude that

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{-1}h^{1-d} + C\mu(\mu h|\log h|)^{\frac{1}{2}(r-1)}h^{1-d} \tag{19.7.22}$$

and under assumptions $(19.7.4)_{r-1}$ and $(19.7.20)_{r+1}$

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{1-l}h^{1-d} + C\mu(\mu h|\log h|)^{r}h^{1-d}. \tag{19.7.23}$$

Further, the same estimates hold for $\mathsf{R}^{\mathsf{W}}_{(\infty)}$.

Remark 19.7.4. Actually summation with respect to the partition as $r = 2$ and only the first assumption is fulfilled returns $\mu^{1-l}h^{1-d}\log\mu$ instead of the first term.

However, as $m = 1$ we can consider propagation in the direction of ν increasing and we would be able to take $T^* \asymp \mu\nu^{1-\delta}$ if there are no 3-rd order resonances and $T^* \asymp \nu^{1-\delta}$ otherwise (we used similar arguments multiple times, for example in the analysis of the exterior zone for 3D magnetic Schrödinger) and then we would arrive to (19.7.22) again.

Remark 19.7.5. Using rescaling technique one can get rid of logarithmic factors arriving to

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{-1}h^{1-d} + C(\mu h)^{\frac{1}{2}(r+1)}h^{-d} \tag{19.7.22}^*$$

and

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{1-l}h^{1-d} + C(\mu h)^{r+1}h^{-d}. \tag{19.7.23}^*$$

respectively.

Therefore we arrive to the same estimates for $\mathsf{R}^{\mathsf{W}}_{(\infty)}$.

Theorem 19.7.6. *Let assumptions* (19.1.4)–(19.1.6), (19.7.6) *and* (19.2.38) *be fulfilled.*

Then under assumption $(19.7.4)_{r-1}$

$$\mathsf{R}^{\mathsf{MW}} \le C\mu^{-1}h^{1-d} + C(\mu h)^{\frac{1}{2}(r+1)}h^{-d} \tag{19.7.24}$$

and under assumptions $(19.7.4)_{r-1}$ *and* $(19.7.20)_{r+1}$

$$\mathsf{R}^{\mathsf{MW}} \le C\mu^{1-l}h^{1-d} + C(\mu h)^{r+1}h^{-d}. \tag{19.7.25}$$

respectively.

Proof. We leave to the reader the transition from $\mathsf{R}^{\mathsf{W}}_{(\infty)}$ to R^{MW}. □

19.7.3 Temperate Magnetic Field

Let us assume now that either $(19.7.4)_{r-1}$ is fulfilled and $(\mu h)^{(r+1)/2} \ge C\mu^{-1}h$ which is equivalent to

$$C_0 h^{-(r-1)/(r+3)} \le \mu \le \epsilon h^{-1} \tag{19.7.26}$$

or both $(19.7.4)_{r-1}$ and $(19.7.20)_{r+1}$ are fulfilled and $(\mu h)^{(r+1)} \ge C\mu^{-1}h$ which is equivalent to

$$C_0 h^{-r/(r+2)} \le \mu \le \epsilon h^{-1}. \tag{19.7.27}$$

Tauberian Remainder: the Toy-Model

Assume temporarily that there are no resonances of order less than L with large enough L except the trivial ones i.e. with the irreducible terms

$$\mu^{2-L} b_\beta(x'', \mu^{-1}hD'')(h^2D_1^2 + \mu^2 x_1^2)^{\beta_1} \cdots (h^2D_r^2 + \mu^2 x_r^2)^{\beta_r}; \tag{19.7.28}$$

then in view of (19.7.26) or (19.7.27) we can skip all the terms corresponding to resonances of order $\ge L$ (with a very small error) and we get a family of r-dimensional $\mu^{-1}h$-pseudodifferential operators and we can apply our standard theory to them.

Under the non-degeneracy assumption $(19.7.20)_{r+1}$ all of these operators satisfy non-degeneracy assumption "no degenerate critical points" and therefore the individual remainder estimate would be $O\big((\mu^{-1}h)^{1-r}\big)$; then multiplying by the number of operators $\asymp (\mu h)^{-r}$ we get $O(\mu^{-1}h^{1-d})$.

Meanwhile without assumption $(19.7.20)_{r+1}$ these operators could be highly degenerate and the individual remainder estimate would be $O\big((\mu^{-1}h)^{-r}\big)$ and thus we do not expect a total remainder estimate better than this one.

Let us prove that this is also a total remainder estimate. According to Subsection 5.2.4 we can introduce an admissible function $\ell = \ell(z, \boldsymbol{\lambda})$ with $z = (x'', \xi'')$ such that in $B(z, \ell(z))$

$$\ell(z, \boldsymbol{\lambda}) \asymp \sum_{\alpha:|\alpha|\le m} |\nabla^\alpha b(z, \boldsymbol{\lambda})|^{\frac{1}{m+1-|\alpha|}} \tag{19.7.29}$$

and then we redefine

$$\ell(z, \boldsymbol{\lambda}) \coloneqq \max\bigl(\ell(z, \boldsymbol{\lambda}), \bar{\ell}\bigr), \qquad \bar{\ell} = C_0(\mu^{-1}h)^{\frac{1}{2}(1-\delta)} \tag{19.7.30}$$

with arbitrarily large m and arbitrarily small $\delta > 0$.

Then again according to the same Subsection 5.2.4 the Tauberian remainder for individual $\boldsymbol{\lambda}$ does not exceed

$$C\mu^{r-1}h^{1-r-\delta'} \int \ell(z, \boldsymbol{\lambda})^{-2}\, dz + C\mu^r h^{-r} \int_{\ell(z,\boldsymbol{\lambda})\le\bar{\ell}} dz \tag{19.7.31}$$

and therefore the total Tauberian remainder does not exceed

$$C\mu^{r-1}h^{1-r-\delta'} \sum_{\boldsymbol{\lambda}} \int \ell(z, \boldsymbol{\lambda})^{-2}\, dz + C\mu^r h^{-r} \sum_{\boldsymbol{\lambda}} \int_{\ell(z,\boldsymbol{\lambda})\le\bar{\ell}} dz \tag{19.7.32}$$

where $\boldsymbol{\lambda}$ runs through the lattice.

Note that $\gamma \coloneqq \ell_1 \le C\ell^m$ (where $\ell = \ell_m$). Therefore $\ell \asymp \bar{\ell}$ implies that $\gamma \lesssim \mu h$ provided

$$m(r+1) > 6. \tag{19.7.33}$$

But then for each z there exist no more than C_0 values of $\boldsymbol{\lambda}$ such that $\ell(z, \boldsymbol{\lambda}) \le \bar{\ell}$ and therefore the second term in (19.7.32) is $O(\mu^r h^{-r})$. This statement remains valid as we redefine $\bar{\ell} = (\mu h)^{1/(m-1)}$.

Meanwhile for any given z the number of $\boldsymbol{\lambda}$ such that $\ell(z, \boldsymbol{\lambda}) \le \ell$ does not exceed $C_0(\mu h)^{-r}\gamma^r + C_0 \lesssim C_0(\mu h)^{-r}\ell^{(m-1)r} + C_0$ and therefore the first term in (19.7.32) does not exceed

$$C\mu^{-1}h^{1-d-\delta'} \int \ell^{mr-2}\, dz + C\mu^r h^{-r}. \tag{19.7.34}$$

Since $mr > 2$ this term is $O(\mu^{-1}h^{1-d-\delta'})$ which is almost exactly what we need. And it is less than $C\mu^r h^{-r}$ unless $\mu \le Ch^{-(r-1)/(r+1)-\delta''}$ so we need to consider only this case.

To cover this case we need to make $\delta' = 0$. Then we need to consider only elements of ℓ_m-partition with $\ell = \ell_m \ge h^{\delta}$. However, if we consider elements of ℓ_{m-1}-partition with $\ell_{m-1} \le h^{\delta_1}$ (but $\ell_m \ge h^{\delta}$), their contribution to the remainder will be properly estimated as well, so we need to consider only elements of ℓ_{m-1}-partition with $\ell_{m-1} \ge h^{\delta_1}$; continuing this process we conclude that we need to consider only balls with $\ell_1 \ge h^{\delta_{m-1}}$. But this is exactly γ and we can apply weak magnetic field approach.

Tauberian Estimates: the General Case

As far as Tauberian estimate is concerned everything remains the same as long as $\ell^{m+1} \ge \mu^{-L}$ where μ^{-L} is the magnitude of the highest irreducible "extra" terms. Further, let

$$(19.7.29)' \quad \ell(z,\boldsymbol{\lambda}) \asymp \sum_{\alpha:1\le|\alpha|\le m} |\nabla^{\alpha} b(z,\boldsymbol{\lambda})|^{\frac{1}{m+1-|\alpha|}} + \min_{s:|s|\le C_0\mu^{-L}} |b(z,\boldsymbol{\lambda})+s|^{\frac{1}{m+1}}$$

(in contrast to (19.7.29) term with $\alpha = 0$ is modified).

However, this would be absorbed by the case $\ell^m \le \mu h$ provided $\mu^{-L} \le \mu h$.

(a) If $L = 1$ we are are looking at the remainder estimate $O(h^{1-d})$ i.e. we need to consider the case $\mu \ge h^{-(r-1)/(r+1)}$ and therefore $\mu \ge h^{-\frac12}$ as $r \ge 3$ and $\mu \ge h^{-\frac13}$ as $r = 2$. However, condition of absorption is $\mu^{-1} \le \mu h$; so as $r \ge 3$ everything is fine: we arrive to the remainder estimate $O\big(h^{1-2r} + \mu^r h^{-r}\big)$.

If $r = 2$ we also arrive to this remainder estimate unless $h^{-\frac13} \le \mu \le h^{-\frac12}$ in which case the remainder estimate is

$$(19.7.35) \quad Ch^{-3} + C\min\big((\mu h)^{\frac32}, \mu^{-2}\big)h^{-4} = Ch^{-3} + Ch^{-4}\begin{cases} (\mu h)^{\frac32} & \text{as } \mu \le h^{-\frac37},\\ \mu^{-2} & \text{as } \mu \ge h^{-\frac37}.\end{cases}$$

(b) If $L = 2$ we are are looking at remainder estimate $O(\mu^{-1}h^{1-d})$ and therefore we need to consider case of (19.7.26) i.e. $\mu \ge h^{-\frac13}$ as $r \ge 3$ and $\mu \ge h^{-\frac15}$ as $r = 2$. However, condition of absorption is $\mu^{-2} \le \mu h$; so as $r \ge 3$ everything is fine: we arrive to the remainder estimate $O\big(\mu^{-1}h^{1-2r} + \mu^r h^{-r}\big)$.

If $r=2$ the same arguments work for $L=4$. As $L=2$ we also get this remainder estimate unless $h^{-\frac{1}{5}} \le \mu \le h^{-\frac{1}{3}}$ when we get

$$C\mu^{-1}h^{-3} + C\min\big((\mu h)^{\frac{3}{2}}, \mu^{-4}\big)h^{-4} = C\mu^{-1}h^{-3} + Ch^{-4}\begin{cases}(\mu h)^{\frac{3}{2}} & \text{as } \mu \le h^{-\frac{3}{11}},\\ \mu^{-2} & \text{as } \mu \ge h^{-\frac{3}{11}}.\end{cases} \tag{19.7.36}$$

(c) If $r=2$, $L=3$ contribution of perturbation is $O(\mu^{-6}h^{-3}) = O(\mu^{-1}h^{-1})$ as $\mu \ge h^{-\frac{1}{5}}$ and therefore we get a proper remainder estimate.

Therefore we arrive to

Proposition 19.7.7. *Let $\mu \le \epsilon h^{-1}$ and assumption $(19.7.4)_{r-1}$ be fulfilled. Then*

(i) If $L=1$

$$\mathsf{R}^{\mathsf{T}} \le Ch^{1-2r} + C\mu^r h^{-r} \tag{19.7.37}$$

unless $r=2$, $h^{-\frac{1}{3}} \le \mu \le h^{-\frac{1}{2}}$ when R^{T} does not exceed expression (19.7.35).

(ii) If $L=2$

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{-1}h^{1-2r} + C\mu^r h^{-r} \tag{19.7.38}$$

unless $r=2$, $h^{-\frac{1}{5}} \le \mu \le h^{-\frac{1}{3}}$ when R^{T} does not exceed expression (19.7.36); furthermore, as $r=2$, $L=3$ estimate (19.7.38) holds.

Assume now that extra assumption $(19.7.20)_{r+1}$ is fulfilled. Then

(d) If $L=1$ we are looking for the remainder $O(h^{1-d})$ i.e. we need to consider a case $(\mu h)^{r+1} \ge h$ i.e. $\mu \ge h^{-\frac{2}{3}}$ and then the contribution to the remainder of the degeneration will be $O\big(((\mu^{-1/2})^{2r}h^{-2r}\big) = O(h^{1-2r})$.

(e) If $L=2$ we are looking for the remainder $O(\mu^{-1}h^{1-d})$ i.e. we need to consider a case of (19.7.27) i.e. $\mu \ge h^{-\frac{1}{2}}$ and then contribution to the remainder of the degeneration will be $O\big(((\mu^{-2/2})^{2r}h^{-2r}\big) = O(\mu^{-1}h^{1-2r})$.

Proposition 19.7.8. *Let $\mu \le \epsilon h^{-1}$ and assumptions $(19.7.4)_{r-1}$ and $(19.7.20)_{r+1}$ be fulfilled. Then*

(i) If $L = 1$

$$\mathsf{R}^{\mathsf{T}} \le Ch^{1-d}. \tag{19.7.39}$$

(ii) If $L = 2$

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{-1}h^{1-d}. \tag{19.7.40}$$

Calculations: the Toy-Model

In the toy-model case we get the Tauberian expression $h^{-d}\mathcal{N}^{\mathsf{T}}$ with

$$\mathcal{N}^{\mathsf{T}} := \sum_{\alpha} \mu^r h^r \theta\big(1 - b_0(x,\alpha) - \mu^{-2}b_1(x,\alpha) - ...\big)\times \big(\psi_0(x) + \mu^{-2}\psi_1(x,\alpha) + ...\big) f_1 \cdots f_r \sqrt{g}\, dx \tag{19.7.41}$$

and if we remove all powers of μ^{-2} then we get the final answer.

If $\mu \ge h^{-\frac{1}{3}}$ we can following our approach skip instantly $O(\mu^{-4})$; we can also remove $O(\mu^{-2})$ but add a correction term instead which can be written as $\kappa\mu^{-2}$ and prove that an error does not exceed $C\mu^{-1}h$ provided $r \ge 3$; then we conclude that $\kappa = 0$ and therefore as $r \ge 3$ we arrive modulo $O(\mu^{-1}h)$ to $\mathcal{N}^{\mathsf{MW}}$. Therefore for the toy-model operator with $r \ge 3$ we arrive to the desired formula.

For $r = 2$ situation is more complicated: we can assume only that $\mu \ge h^{-\frac{1}{5}}$ and then we can skip instantly only $O(\mu^{-6})$ (rather than $O(\mu^{-4})$); we can also remove $O(\mu^{-4})$ but add a correction term instead which will be given by (19.4.93).

For $r = 2$ and $\mu \ge h^{-\frac{1}{3}}$ we can remove $O(\mu^{-2})$ and add a correction term instead which will be 0 but only modulo $O(\mu^{-2}(\mu h)^{\frac{1}{2}}h^{-4}) = O(\mu^{-\frac{3}{2}}h^{-\frac{7}{2}})$.

On the other hand, under assumption $(19.7.20)_{r+1}$ we can deal with $O(\mu^{-2})$ terms with an error $O(\mu^{-2}(\mu h)^r h^{-2d})$ which is $O(\mu^{-1}h^{1-2d})$ even as $r = 2$. We leave all details to the reader.

Thus we arrive to the following theorem:

Theorem 19.7.9. *Let assumptions* (19.1.4)–(19.1.6), (19.7.6) *and* (19.2.38) *be fulfilled. Let there be no resonances of the* 2*-nd and* 3*-rd order, and no non-trivial resonances of order less than* L *(with large enough* L*) and let assumption* $(19.7.4)_{r-1}$ *be fulfilled. Then*

(i) As $r \ge 3$, $\mu \le \epsilon(h|\log h|)^{-1}$

$$\mathsf{R}^{\mathsf{MW}} \le C\mu^{-1}h^{1-2r} + C\mu^{r}h^{-r}. \tag{19.7.42}$$

(ii) If $r = 2$, $h^{-\frac{1}{5}} \le \mu \le \epsilon(h|\log h|)^{-1}$

$$\mathsf{R}^{\mathsf{MW}}_1 := \Big| \int \Big(\tilde{e}(x,x,0) - h^{-d}\mathcal{N}^{\mathsf{MW}}(x,0) - h^{-d}\mathcal{N}^{\mathsf{MW}}_{1\mathsf{corr}}(x,0)\Big)\psi(x)\,dx\Big| \le C\mu^{-1}h^{1-d} + C\mu^{2}h^{-2} \tag{19.7.43}$$

where $\mathcal{N}^{\mathsf{MW}}_{1\mathsf{corr}}(x,0)\Big)$ *is defined by* (19.4.93) *and* $\mathcal{A}_{\mathcal{T}} = \mathcal{A}_0 + \mu^{-2}\mathcal{A}_2$*; in particular, as* $r = 2$, $h^{-\frac{1}{3}} \le \mu \le \epsilon(h|\log h|)^{-1}$ *this correction term does not exceed* $C\mu^{-\frac{3}{2}}h^{-\frac{7}{2}}$ *and therefore one can skip it as* $\mu \ge h^{-\frac{3}{7}}$.

(iii) On the other hand, under assumption $(19.7.20)_{r+1}$

$$\mathsf{R}^{\mathsf{MW}} \le C\mu^{-1}h^{1-2r}. \tag{19.7.44}$$

Calculations: the General Case

Consider now the general case. Assume first that there are no 3-rd order resonances. Then both arguments of the proof and statements of Theorem 19.7.9 obviously remain true with the singular exception of Statement (ii) where now we need to take

$$\mathcal{A}_{\mathcal{T}} = \mathcal{A}_0 + \mu^{-2}\mathcal{A}_2 + \mu^{-3}\mathcal{A}_3 \tag{19.7.45}$$

and $\mathcal{A}_2$ may contain also a non-diagonal part (if there are non-trivial 4-th order resonances) and $\mathcal{A}_3$ is purely a non-diagonal term (if there are 5-th order resonances).

Now we would like to get rid of all non-diagonal terms in $\mu^{-2}\mathcal{A}_2$ and $\mu^{-3}\mathcal{A}_3$. It works as long as $\mu \ge h^{-\frac{1}{3}}$ and $\mu \ge h^{-\frac{1}{4}}$ respectively. Then we will have another correction term. However, it will be a bit smaller than $\mu^{-L}(\mu h)^{\frac{1}{2}}h^{-4}$. Namely if we take in account only the leading term in ψ, i.e. ψ_0, we get a non-diagonal term with the trace 0 in the second approximation term and the error will be $O(\mu^{-\frac{3}{2}L}h^{-4})$ which is a bit better than $O(\mu^{-L}(\mu h)^{\frac{1}{2}}h^{-4})$ if $\mu^{L+1}h \ge 1$.

Modulo this term there will be term coming from $\psi_1\mu^{-1}$ and our standard arguments yield that it will not exceed $O(\mu^{-L-1}h^{-4})$ which is exactly what we got before if $L=2$. However, if $L=3$ one can see easily that the first perturbation term would be out-of-diagonal by more than 1 and we need "interact" it with $\psi_2\mu^{-2}$ to get non-0 trace and this term will be $O(\mu^{-L-2}h^{-4})$.

Therefore we arrive to

Theorem 19.7.10. *Let assumptions* (19.1.4)–(19.1.6), (19.7.6) *and* (19.2.38) *be fulfilled. Let there be no resonances of the* 2*-nd and* 3*-rd order and let assumption* $(19.7.4)_{r-1}$ *be fulfilled. Then*

(i) Statements (i) and (iii) of Theorem 19.7.9 hold; Statement (ii) remains true without any modifications if there are no non-trivial 4*-th and no* 5*-th order resonances.*

(ii) In Statement (ii) of Theorem 19.7.9 one should take $\mathcal{A}_{\mathcal{T}}$ *in the form* (19.7.45) *but the conclusion about magnitude of the correction term remains true.*

(iii) If $r=2$ *and there are non-trivial* 4*-th order resonances and we take* $\mathcal{A}_{\mathcal{T}}=\mathcal{A}_0+\mu^{-2}\mathcal{A}_2$ *and remove from* $\mathcal{A}_2$ *non-diagonal terms, estimate*

$$\mathsf{R}_1^{\mathsf{MW}}\le C\mu^{-1}h^{-3}+C\mu^{2}h^{-2}+C\mu^{-3}h^{-4} \tag{19.7.46}$$

holds as $\mu\ge h^{-\frac{1}{3}}$*; in particular* (19.7.43) *holds as* $\mu\ge h^{-\frac{2}{5}}$.

(iv) If $r=2$ *and there are no non-trivial* 4*-th order resonances but there are* 5*-th order resonances and we take* $\mathcal{A}_{\mathcal{T}}=\mathcal{A}_0+\mu^{-2}\mathcal{A}_2$*, estimate*

$$\mathsf{R}_1^{\mathsf{MW}}\le C\mu^{-1}h^{-3}+C\mu^{2}h^{-2}+C\mu^{-\frac{9}{2}}h^{-4} \tag{19.7.47}$$

holds as $\mu\ge h^{-\frac{1}{4}}$*; in particular* (19.7.43) *holds as* $\mu\ge h^{-\frac{2}{7}}$.

Assume now that there are 3-rd order resonances. Then for $r\ge 3$ the weak magnetic field approach gives remainder estimate $O(h^{1-d})$ as $\mu\le h^{-\frac{1}{2}}$ and an error when we remove $O(\mu^{-1})$ non-diagonal term is $O(\mu^{-2}h^{-d})=O(h^{1-d})$ as $\mu\ge h^{-\frac{1}{2}}$. Therefore we are done.

If $r=2$ and both assumptions $(19.7.4)_1$ and $(19.7.20)_3$ are fulfilled, the weak magnetic field approach gives remainder estimate $O(h^{-3})$ as $(\mu h)^3\le h$

i.e. as $\mu \le h^{-\frac{2}{3}}$ and an error when we remove $O(\mu^{-1})$ non-diagonal term is $O(\mu^{-2}h^{-4}) = O(h^{-3})$ as $\mu \ge h^{-\frac{2}{3}}$. Therefore we are done as well.

Consider case $r = 2$ and only assumption $(19.7.4)_1$ is fulfilled. Then the weak magnetic field approach gives remainder estimate $O(h^{-3})$ as $\mu \le h^{-\frac{1}{4}}$. Then we have a proper remainder estimate with the correction term defined by

$$\mathcal{A}_{\mathcal{T}} = \mathcal{A}_0 + \mu^{-1}\mathcal{A}_1 + \mu^{-2}\mathcal{A}_2 + \mu^{-3}\mathcal{A}_3; \tag{19.7.48}$$

however in virtue of our previous arguments skipping $O(\mu^{-3})$ term would lead to an error $O(\mu^{-4}(\mu h)^{\frac{1}{2}}h^{-4}) = O(h^{-3})$ then. Therefore we arrive to

Theorem 19.7.11. *Let assumptions* (19.1.4)–(19.1.6), (19.7.6) *and* (19.2.38) *be fulfilled. Let there be no resonances of the* 2*-nd order and let assumption* $(19.7.4)_{r-1}$ *be fulfilled. Then*

(i) If $r \ge 3$, $\mu \le \epsilon(h|\log h|)^{-1}$

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-2r} + C\mu^r h^{-r}. \tag{19.7.49}$$

(ii) If $r = 2$, $h^{-\frac{1}{5}} \le \mu \le \epsilon(h|\log h|)^{-1}$

$$\mathsf{R}_1^{\mathsf{MW}} := \Big| \int \Big(\tilde{e}(x,x,0) - h^{-d}\mathcal{N}^{\mathsf{MW}}(x,0) - h^{-d}\mathcal{N}^{\mathsf{MW}}_{1\mathsf{corr}}(x,0)\Big)\psi(x)\,dx\Big| \le Ch^{-3} + C\mu^2 h^{-2} \tag{19.7.50}$$

where $\mathcal{N}^{\mathsf{MW}}_{1\mathsf{corr}}(x,0)$ *is defined by* (19.4.93) *and* $\mathcal{A}_{\mathcal{T}}$ *is defined by* (19.7.48) *without the last term; in particular, as* $r = 2$, $h^{-\frac{1}{2}} \le \mu \le \epsilon(h|\log h|)^{-1}$ *this correction term does not exceed* $C\mu^{-\frac{3}{2}}h^{-4}$ *and therefore one can skip it as* $\mu \ge h^{-\frac{4}{7}}$.

(iii) On the other hand, under assumption $(19.7.20)_{r+1}$

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-2r}. \tag{19.7.51}$$

Remark 19.7.12. Further, skipping $O(\mu^{-2})$ term in $\mathcal{A}_{\mathcal{T}}$ leads to an error $O(\mu^{-2}(\mu h)^{\frac{1}{2}}h^{-4})$ which is $O(h^{-3})$ as $\mu \ge h^{-\frac{1}{3}}$.

Furthermore, skipping $O(\mu^{-1})$ non-diagonal term leads to an error $O(\mu^{-\frac{3}{2}}h^{-4}) = O(h^{-3})$ as $\mu \ge h^{-\frac{2}{3}}$.

19.7.4 Intermediate Magnetic Field

The case of the intermediate magnetic field is easy:

Theorem 19.7.13. *Let assumptions* (19.1.4)–(19.1.6), (19.7.6) *and* (19.2.38) *be fulfilled. Let there be no resonances of the* 2*-nd order, and let assumption* $(19.7.4)_{r-1}$ *be fulfilled. Let* $\epsilon(h|\log h|)^{-1} \le \mu \le \epsilon h^{-1}$.

(i) Assume that there no resonances of the 3*-rd order as well. Then estimate* (19.7.42) *holds and under assumption* $(19.7.20)_{r+1}$ *estimate* (19.7.44) *holds.*

(ii) In the general case estimate (19.7.49) *holds and under assumption* $(19.7.20)_{r+1}$ *estimate* (19.7.50) *holds.*

Proof. An easy proof using arguments of Section 19.5 is left to the reader. □

19.7.5 Conclusion to Section

There is no theory of intermediate and strong magnetic field separate from theory of Section 19.6

Problem 19.7.14. Prove similar results under assumptions $(19.7.4)_m$ and $(19.7.20)_n$ with $0 \le m < r-1$ and $1 \le m+n \le 2r$.

19.7.6 Final Remarks

Vanishing V

Remark 19.7.15. (i) In Sections 19.2–19.5 we divided by V in the microhyperbolicity or $\mathfrak{N}$-microhyperbolicity assumptions. However, it is not a problem: we could assume in advance that

$$|V| + |\nabla V| \ge \epsilon_0 \tag{19.7.52}$$

and then the microhyperbolicity or $\mathfrak{N}$-microhyperbolicity conditions will be needed in zone $\{x : |V(x)| \ge \epsilon'\}$ only.

(ii) We can assume instead that

$$|V| + |\nabla V| \le \epsilon_0 \implies |\det \mathsf{Hess}\, V| \ge \epsilon_0. \tag{19.7.53}$$

Really then due to a rescaling technique we can ensure microhyperbolicity condition (except a small zone) after rescaling as $|V| \le \epsilon'$ and then the microhyperbolicity or $\mathfrak{N}$-microhyperbolicity conditions will be needed in zone $\{x : |V(x)| \ge \epsilon'\}$ only.

We leave to the reader the following problem:

Problem 19.7.16. (i) Using rescaling technique like in Subsection 18.9.5 get rid of assumption $|V| \ge \epsilon_0$ in the framework of Sections 19.2, 19.4, and 19.5.

(ii) Using rescaling technique get rid of assumption $|V| \ge \epsilon_0$ in the framework of Sections 19.2, 19.4, and 19.5.

Pointwise Asymptotics

We strongly believe that the following problem is both extremely challenging and interesting:

Problem 19.7.17. For operators of the type considered in this Chapter (namely, Sections 19.2–19.6) construct theory similar to theory of Chapter 16.

(i) Let us discuss the toy-model with constant g^{jk}, F_{jk}, and linear V. Then A is a sum of 2D-operators and the $U(x,y,t)$ is a product of 2D-propagators which after rescaling $x \mapsto \mu x$, $t \mapsto \mu t$ are given by (16.2.9)–(16.2.10) with t replaced by $f_j t$ and α_j replaced by $f_j^{-1}\alpha_j$. Then we come to the oscillatory integral with respect to t of (16.2.22) type (and we will need to multiply it later by $\mu^{-r}h^{-r}$) but with a phase function which is the sum of (16.2.23)-type expressions

$$\phi(t) = -t^2 \sum_j \alpha_j^2 \cot(f_j t) - t(\tau - \beta), \qquad \beta = -\mu^{-2} \sum_j \alpha_j^2 f_j^{-1} \tag{19.7.54}$$

and with factor $\mu^2 \csc(t)$ replaced by $\mu^{2r} \csc(f_1 t)\cdots\csc(f_r t)$. Now analysis of the stationary points becomes really difficult. The stationary phase equation

$$-2t \sum_j \alpha_j^2 \cot(f_j t) + t^2 \sum_j \alpha_j^2 f_j \csc^2(f_j t) - (\tau - \beta) = 0 \tag{19.7.55}$$

is equivalent to

$$-2t\cot(f_j t) + t^2\alpha_j^2 f_j \csc^2(f_j t) - \tau_j = 0, \tag{19.7.56}$$

$$\sum \tau_j = \tau - \beta. \tag{19.7.57}$$

This system is not easy to handle for large t if f_j are not commensurable.

(ii) However, in the case when $f_1 = ... = f_r = 1$ which is supposedly the worst case scenario we get almost (16.2.23) exactly

$$\phi(t) = -t^2\cot(t) + t\mu^{-2}\alpha^2 - t\tau \tag{19.7.58}$$

but factor $\mu^{2r}(\csc(t))^r$ with $r \geq 2$ rather than $r = 1$ will be a game-changer in all Tauberian estimates as $\mu \leq h^{-1}$.

Problem 19.7.18. (i) Prove that for the toy-model with $f_1 = ... = f_r$

$$\mathsf{R}^{\mathsf{T}} \leq C \begin{cases} \mu^{-1}h^{1-d} & \text{as } \mu_0 \leq \mu \leq h^{-\frac{1}{2}}, \\ \mu h^{2-d} & \text{as } h^{-\frac{1}{2}} \leq \mu \leq h^{-1}, \\ \mu^{r-\frac{1}{2}}h^{-r+\frac{1}{2}} & \text{as } \mu \geq h^{-1}; \end{cases} \tag{19.7.59}$$

(ii) Prove the same in the case of commensurable $f_1, ..., f_r$.

(iii) Investigate the case of non-commensurable $f_1, ..., f_r$.

Problem 19.7.19. (i) Calculate Tauberian expressions using stationary phase methods as $\mu \leq h^{\delta-\frac{1}{2}}$.

(ii) Investigate the matching cases when V is non-linear.

Chapter 20

Multidimensional Magnetic Schrödinger Operator. Non-Full-Rank Case

20.1 Introduction

20.1.1 Preface

In this chapter we consider multidimensional Schrödinger operator (19.1.1)

$$A = A_0 + V(x), \qquad A_0 = \sum_{j,k\le d} P_j g^{jk}(x) P_k, \tag{20.1.1}$$

$$P_j = hD_j - \mu V_j(x), \quad h \in (0,1],\ \mu \ge 1.$$

Recall that it is characterized by *magnetic field intensity tensors* (F_{jk}) with

$$F_{jk} = \partial_k V_j - \partial_j V_k, \tag{20.1.2}$$

which is skew-symmetric $d \times d$-matrix, and $(F^j_p) = (g^{jk})(F_{kp})$, which is unitarily equivalent to the skew-symmetric matrix $(g^{jk})^{\frac12}(F_{jk})(g^{jk})^{\frac12}$. Then all the eigenvalues of (F^j_k) (with multiplicities) are $\pm i f_p$ ($f_p > 0$, $p = 1, \dots, r$) and 0 of multiplicity $q = d - 2r$ where $2r = \mathsf{rank}(F^j_k)$.

In this chapter we assume first that the magnetic field intensity matrix has a constant but not full rank:

$$\mathsf{rank}(F_{jk}) = 2r = d - q, \quad q \ge 1, \tag{20.1.3}$$

and

$$|\big((F_{jk})\big|_{\mathcal{K}^\perp}\big)^{-1}| \le c_0 \tag{20.1.4}$$

where $\mathcal{K} = \mathsf{Ker}(F_{jk})$ and $\mathcal{K}^\perp = \mathsf{Ran}(F_{jk})$ and (under certain conditions) we derive sharp spectral asymptotics (in this case with the remainder estimate $O(h^{1-d} + \mu^r h^{1-r-q})$. The typical example (already studied in Chapters 13 and 18) is 3D magnetic Schrödinger operator.

Remark 20.1.1. Obviously, the most interesting case is $q = 1$ which is the generic case for skew-symmetric real $d \times d$-matrices. However it does not exclude thi type generic matrix-valued functions with extra degenerations at some points.

Condition (20.1.3)–(20.1.4) is equivalent to (20.1.3) and

$$|f_p| \ge \epsilon_0 \qquad p = 1, \dots, r; \tag{20.1.5}$$

however, later we replace it with a *multiscale assumption* according to which $f_1, \dots, f_r$ are broken into groups of different magnitudes which will allow us to analyze generalizations.

Recall that we consider operator in some domain or on some manifold X with some boundary conditions, assuming that it is self-adjoint in $\mathscr{L}^2$ and denote by $e(x, y, \tau)$ Schwartz' kernel of it's spectral projector.

There is a profound difference between the full-rank case considered in Chapter 19 and non-full-rank case considered here: in the full-rank case in its canonical form the magnetic Schrödinger operator is reduced to the family of r-dimensional $\mu^{-1}h$-pseudodifferential operators and therefore we can expect asymptotics with the remainder estimate (in the smooth case) as good as

$$C(\mu h^{-1})^{r-1} \times \big(1 + (\mu h)^{-r}\big) = C\big(\mu^{-1}h^{1-d} + \mu^{r-1}h^{1-r}\big),$$

where the first factor is the remainder estimate for a single scalar $\mu^{-1}h$-pseudodifferential operator and the second factor is the number of these operators to be taken into account; however, one needs some non-degeneracy (microhyperbolicity) assumption; otherwise the remainder estimate could be as bad as $C\big(\mu h^{1-d} + \mu^r h^{-r}\big)$ which is the magnitude of the principal part as $\mu \ge h^{-1}$.

On the other hand, in the non-full-rank case in its canonical form the magnetic Schrödinger operator is reduced to the family of q-dimensional

Schrödinger operators which are also r-dimensional $\mu^{-1}h$-pseudodifferential operators and in the best case we can expect asymptotics with the remainder estimate

$$Ch^{1-q}\times(\mu h^{-1})^r\times\bigl(1+(\mu h)^{-r}\bigr)\asymp C\bigl(h^{1-d}+\mu^r h^{1-r}\bigr),$$

with the principal part of magnitude

$$h^{-q}\times(\mu h^{-1})^r\times\bigl(1+(\mu h)^{-r}\bigr)\asymp h^{-d}+\mu^r h^{r-d}$$

however, the non-degeneracy condition is not needed at all (if smoothness allows) as $q\ge 2$; case $q=1$ is slightly more complicated.

We see that there is a more subtle distinction between $q=1$ and $q\ge 2$; actually $q=2$ might stay apart from $q\ge 3$ due to the lack of the smoothness. There is even more subtle distinction between $r=1$ and $r\ge 2$ but it makes the difference only as $q=0,1$ setting $d=2,3$ a bit apart (and in fact it plays role mainly in the non-smooth case).

20.1.2 Assumptions

Note first that $\mathcal{K}=\mathsf{Ker}\,F=\mathsf{Ker}\,\omega_F$ with $\omega_F=\sum_{j,k}F_{jk}dx_j\wedge dx_k=\frac{1}{2}d\sum_j V_j dx_j$ and therefore $d\omega_F=0$ and in virtue of Frobenius theorem

(20.1.6) If $\mathsf{rank}\,F=d-q$ at each point x, then $\mathcal{K}(x)=\mathsf{Ker}\,F(x)$ is an integrable foliation of q-dimensional spaces, which means that for any y there exists a q-dimensional manifold $K=K_y\ni y$ such that $T_xK=\mathcal{K}(x)$ at any point $x\in K$.

Then there exists a coordinate system $x=(x''';x^\perp)=(x_1,\dots,x_q;x_{q+1},\dots,x_d)$ with $x^\perp=\mathsf{const}$ along leafs K_y of the above foliation. This (almost) fixes $x^\perp$ and also implies that in this coordinate system

$$F_{jk}=0\qquad\text{if } j=1,\dots,q \text{ or } k=1,\dots,q. \tag{20.1.7}$$

Then there exists function ϕ, such that $V_j=\partial_j\phi$ for $j=1,\dots,q$ and one can eliminate V_j for all $j=1,\dots,q$ by a gauge transformation[1)]. So, we can assume that

$$V_j=0 \text{ if } j=1,\dots,q \quad(\implies V_j=V_j(x^\perp) \text{ if } j=q+1,\dots,d. \tag{20.1.8}$$

[1)] Really, we always can eliminate V_1; but then $V_{j,1}=V_{1,j}=0$ and $V_j=V_j(x_2,\dots,x_d)$. Then we can eliminate V_2 etc repeating previous arguments for $V_1,\dots,V_q$. Actually we can eliminate also V_{q+1}.

Now we assume that these reductions are already made and after these reductions

$$g^{jk} \in \mathscr{C}^{\bar{l},\bar{\sigma}}, \qquad V \in \mathscr{C}^{l,\sigma}, \tag{20.1.9}_{1,3}$$

and

$$V_j = \partial_j \phi_j, \qquad \phi_j \in \mathscr{C}^{\bar{l}+2,\bar{\sigma}} \tag{20.1.9}_{2}$$

where the last assumption is a bit stronger than a more natural assumption $F_{jk} \in \mathscr{C}^{\bar{l},\bar{\sigma}}$ or $V_{\in}\mathscr{C}^{\bar{l}+1,\bar{\sigma}}$; cf. $(19.1.25)_{1-3}$. Again, $(\bar{l},\bar{\sigma}) \succeq (l,\sigma) \succeq (1,1)$. Assume also that

$$q = 1 \implies g^{jd} = \delta_{jd}, . \tag{20.1.10}$$

We also assume that

$$|V| \geq \epsilon. \tag{20.1.11}$$

20.1.3 Canonical Form

Recall (see Section 13.2.2) that if $X = \mathbb{R}^d$ and g^{jk}, F_{jk}, V are constant then the magnetic Schrödinger operator is unitarily equivalent to operator

$$\sum_{1\leq j\leq r} f_j(h^2D_j^2 + \mu^2 x_j^2) + \sum_{r+1\leq j\leq d-2r} h^2D_j^2 + V \tag{20.1.12}$$

and that $e(x,x,\tau) = h^{-d}\mathcal{N}_d^{\mathsf{MW}}(\tau)$ where

$$\mathcal{N}_d^{\mathsf{MW}}(\tau) := \varpi_{d-2r}(2\pi)^{-d+r}\mu^r h^r \sum_{\alpha\in\mathbb{Z}^{+r}} \Big(\tau - \sum_j (2\alpha_j+1) f_j \mu h - V\Big)_+^{\frac{q}{2}} f_1\cdots f_r\sqrt{g} \tag{20.1.13}$$

and ϖ_k is a volume of unit ball, $g = \det(g^{jk})^{-1}$.

Now in the general case (for variable V and, may be, g^{jk}, F_{jk}) we are interested in the asymptotics of $\int e(x,x,0)\psi(x)\,dx$ as $h\to+0, \mu\to+\infty$ where ψ is a fixed function, smooth and compactly supported in X.

It is known from Section 13.3 that in the smooth case for $d=3$ one can reduce magnetic Schrödinger operator to its canonical form

$$\mu^2 \sum_{m+p+j+k\geq 1} a_{m,p,j,k}(x_2,x_3,\mu^{-1}hD_2)\times \\ \times \big(x_1^2 + \mu^{-2}h^2D_1^2\big)^m (hD_3)^{2p}\mu^{-2m-2j-2p-k}h^k \tag{20.1.14}$$

with the "main part"

$$(20.1.14)_0 \quad a_{1,0,0}(x_2,x_3,\mu^{-1}hD_2)\big(\mu^2x_1^2+h^2D_1^2\big)+ h^2D_3^2+a_{0,1,0}(x_2,x_3,\mu^{-1}hD_2).$$

with $a_{1,0,0}=F\circ\Psi_0$, $a_{0,1,0}=V\circ\Psi_0$ and certain diffeomorphism $\Psi_0: T\mathbb{R}^1\times\mathbb{R}\to\mathbb{R}^3$; we ignore terms with $k\ge 1$ or $m+p+j\ge 2$. Then one can replace harmonic oscillator $\big(h^2D_1^2+\mu^2x_1^2\big)$ by one of its eigenvalues $(2\alpha+1)\mu h$.

Multidimensional case is much more tricky. The main part of the canonical form will be

$$(20.1.15) \quad \sum_{j,k\le r} Z_k^*\,a_{jk}^{\mathrm{w}}(x'',x''',\mu^{-1}hD'')Z_j+ \sum_{2r+1\le j,k\le d} h^2D_j\,b_{jk}^{\mathrm{w}}(x'',x''',\mu^{-1}hD'')D_k+a_0^{\mathrm{w}}(x'',x''',\mu^{-1}hD'')$$

with $Z_j=(hD_j-i\mu x_j)$, $Z_j^*=(hD_j+i\mu x_j)$ $j=1,\dots,r$, $x''=(x_{r+1},\dots,x_{2r})$, $x'''=(2r+1,\dots,d)$. Here $(a_{jk})_{j,k=1,\dots,r}$ is a Hermitian positive definite matrix with eigenvalues $f_1,\dots,f_r$ and $(b_{jk})_{j,k=2r+1,\dots,d}$ is a real symmetric positive definite matrix. We would like to have (a_{jk}) in the diagonal form; then instead of (20.1.15) we would have

$$(20.1.16) \quad \sum_{j} f_j^{\mathrm{w}}(x'',x''',\mu^{-1}hD'')\big(H_j-\mu h\big)+ \sum_{2r+1\le j,k\le d} h^2D_j\,b_{jk}^{\mathrm{w}}(x'',x''',\mu^{-1}hD'')D_k+a_0(x'',x''',\mu^{-1}hD'')^{\mathrm{w}}$$

with 1D-harmonic oscillators $H_j=(h^2D_j^2+\mu^2x_j^2)$. However, second-order resonances $f_j=f_k$ with $j\ne k$ prevent us; in the general case we can assume only that locally

$$(20.1.17) \quad \sum_{\mathfrak{m}\in\mathfrak{M}}\sum_{j,k\in\mathfrak{m}} a_{jk}(x'',x''',\mu^{-1}hD'')Z_j^*Z_k+ \sum_{2r+1\le j,k\le d} h^2D_j\,b_{jk}^{\mathrm{w}}(x'',x''',\mu^{-1}hD'')D_k+a_0(x'',\mu^{-1}hD'',x'')$$

where $\mathfrak{m}\in\mathfrak{M}$ are disjoint subsets of $\{1,\dots,r\}$ and eigenvalues of each of matrices $(a_{jk})_{j,k\in\mathfrak{m}}$ are close to one another. This leads to the necessity

of the matrix rather than the scalar non-degeneracy (microhyperbolicity) condition.

The reduction of non-principal terms of operator are prevented by higher-order resonances (see Chapter 19); we discuss it later.

20.1.4 Microhyperbolicity

Thus we arrive to the final the *microhyperbolicity assumption* at point $\bar{z} = (\bar{x}'', \bar{x}''', \bar{\xi}'')$ and thus at point $\bar{x} = \Psi_0^{-1}(z)$:

Definition 20.1.2. Assume that

(20.1.18) Set $\{1, \dots, r\}$ is split into disjoint groups $\mathfrak{m} \in \mathfrak{M}(\bar{z})$ and matrix (a_{ij}) is block-diagonal and in a small vicinity of $\bar{z}$ its blocks are close to scalar matrices $f_{\mathfrak{m}} I_{\#\mathfrak{m}}$ where $f_{\mathfrak{m}}$ are disjoint.

Then we call operator *microhyperbolic* if for each real vector $\boldsymbol{\tau} = (\tau_{\mathfrak{m}})_{\mathfrak{m}\in\mathfrak{M}}$ such that $|\sum_{\mathfrak{m}\in\mathfrak{M}} \tau_{\mathfrak{m}} + V| \le \epsilon$ there exists vector $\ell = \ell(\bar{z}, \boldsymbol{\tau}) \in \mathbb{R}^{2r+q}$ such that

$$\mu^2 \sum_{j,k} \bigl(\ell\bigl(a_{jk} a_0^{-1}\bigr)\bigr)\zeta_j^\dagger \zeta_k \ge \epsilon_1 \qquad \forall \zeta \in \mathbb{C}^r \tag{20.1.19}$$

as long as

$$a_{\mathfrak{m}} = \sum_{j,k\in\mathfrak{m}} a_{jk}\zeta_j^\dagger \zeta_k = \mu^2 \tau_{\mathfrak{m}} \qquad \forall \mathfrak{m} \in \mathfrak{M}. \tag{20.1.20}$$

Remark 20.1.3. (i) To impose this condition we need to assume first that symbol a_0 does not vanish; thus we need assumption (20.1.11).

(ii) Exactly as in Chapters 13 and 18 we do not need microhyperbolicity assumption if magnetic field is weak enough.

(iii) In contrast to Chapters 13 and 18 we do not need the microhyperbolicity assumption if $q \ge 3$, and also in $q = 2$ if there are no 3-rd order resonances.

(iv) In contrast to Chapter 19 we no longer consider $\mathfrak{N}$ partition of $\{1, \dots, r\}$ joining in one group all possible 3-rd order resonances as well; the reason is that now we need to consider evolution with $|t| \le \epsilon_0$ instead of $|t| \le \epsilon_0 \mu$ as it was in Chapter 19 and therefore 3-rd order resonances are not a problem anymore here.

In the case of $\mu h \ge \epsilon$ we will need to reformulate microhyperbolicity assumption.

20.1.5 Plan of the Chapter

In Section 20.2 we develop weak magnetic field approach to cover both weak magnetic field case and the outer zone in the temperate magnetic field case. Definition of the "weak" magnetic field depends on q.

In Section 20.3 we reduce operator to its canonical form which basically is what we got in previous Chapter 19 albeit with the coefficient depending on all variable x plus a "free" Hamiltonian (i.e. without magnetic field) in q-dimensional space.

Sections 20.4 and 20.5 are devoted to the remainder estimate with the Tauberian main part of asymptotics in the cases of the temperate and a stronger[2)] magnetic field respectively. In all these two and the next two sections the presence of 3-rd order resonances and corresponding non-removable terms poses one of the main obstacles. As $q \ge 3$ ($q \ge 2$ provided there are no such terms) we recover the remainder estimate $O\bigl(h^{1-d}(1+\mu h)\bigr)$ but in the remaining cases the remainder estimate is not as good unless we impose microhyperbolicity or non-degenerateness condition.

Calculations and simplifications of the Tauberian main part are done in Sections 20.6 and 20.7 in the cases of the intermediate and a stronger[2)] magnetic field respectively.

Finally, in Section 20.8 we consider the case when one pair of the non-zero eigenvalues of F_K^j vanishes on the manifold of codimension 3. It is more complicated than in 3D-case because different eigenvalues have different magnitudes and a simple rescaling does not work.

20.2 Weak Magnetic Field Case

Analysis in this case follows one of Section 18.6 without serious modifications. We assume that $\mu \le h^{\delta-1}$. Let us assume that f operator conditions (20.1.3)–(20.1.4), (20.1.9) are fulfilled.

[2)] I.e. either intermediate, or strong magnetic field.

20.2.1 Preliminary Remarks

Let us start from the case (further restrictions to follow)

$$\varepsilon \ge Ch|\log h|, \quad \mu \le \epsilon(h|\log h|)^{-1}. \tag{20.2.1}$$

Obviously

$$[P_j, P_k] = i\mu h F_{jk}. \tag{20.2.2}$$

Recall that ε is a mollification parameter. Consider in the framework of (20.1.7) commutators

$$h^{-1}[A, x_m] = \sum_k \bigl(g^{mk}P_k + P_k g^{mk}\bigr), \qquad m = 1, \dots, d, \tag{20.2.3}$$

$$h^{-1}[A, P_m] = h^{-1}\sum_{j,k} P_j[g^{jk}, P_m]P_k + h^{-1}[V, P_m] \quad m = 1, \dots, q, \tag{20.2.4}$$

and

$$\mu^{-1}h^{-1}[A, P_m] = \sum_{j,k}\bigl(g^{jk}F_{jm}P_k + P_j g^{jk}F_{km}\bigr) + \mu^{-1}h^{-1}\sum_{jk} P_j[g^{jk}, P_m]P_k + \mu^{-1}h^{-1}[V, P_m] \qquad m = q+1, \dots, d. \tag{20.2.5}$$

These commutators have symbols of the class $\mathscr{F}^{l,\sigma}$ in any domain $\{(x,\xi) : a(x,\xi) \le c\}$ of the bounded energy where

$$a(x,\xi) = a_0(x,\xi) + V, \qquad a_0(x,\xi) = \mu^2 \sum_{j,k} g^{jk} p_j(x,\xi)p_k(x,\xi), \tag{20.2.6}$$

$$p_j(x,\xi) \coloneqq (\xi_j - V_j);$$

recall that classes $\mathscr{F}^{l,\sigma}$ are introduced in Chapter 18. To finish the preliminary remarks let us notice that the following statement holds

Proposition 20.2.1. [3] *Let $f \in \mathscr{C}_0^\infty(\mathbb{R}^d)$, $f = 1$ in $B(0, C_0)$ with large enough constant C_0. Let $T \ge h^{1-\delta}$. Then under condition* (20.2.1) *with large enough constant $C = C_s$*

$$|F_{t\to h^{-1}\tau}\Bigl(1 - f\bigl(p_1(x,\xi), p_2(x,\xi), \dots, p_d(x,\xi)\bigr)\Bigr)^{\mathrm{w}}\chi_T(t)u| \le Ch^s \tag{20.2.7}$$

$$\forall x, y \in B(0, \frac{1}{2}) \qquad \forall \tau \le c.$$

[3] Microlocal boundaries for P_j. Compare with Proposition 18.6.1.

Proof. One can see easily that symbol $f\big(p_1(x,\xi), p_2(x,\xi), \dots, p_d(x,\xi)\big)$ is quantizable under condition (20.2.1) and the proof of Proposition 20.2.1 is rather obvious. Further standard details we leave to the reader. □

20.2.2 Tauberian Estimate

Outer Zone: General Case

Let us prove several results about propagation:

Proposition 20.2.2 [4]**.** *Let* $\mu \le \epsilon(h|\log h|)^{-1}$ *and let*

$$M \ge \sup_{\sum_{jk} g^{jk}\xi_j\xi_k + V = 0} 2\sum_k g^{jk}\xi_k + \epsilon \tag{20.2.8}$$

with arbitrarily small constant $\epsilon > 0$.

Let ϕ_1 *be supported in* $B(0,1)$, $\phi_2 = 1$ *in* $B(0,2)$, χ *be supported in* $[-1,1]$ [5]. *Finally, let* $T_* = Ch|\log h| \le T \le T^* = \epsilon_0$.

Then

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\psi_{2x}U(x,y,t)\,\psi_{1y}| \le Ch^s \qquad \forall x,y\ \forall \tau \le \epsilon_1 \tag{20.2.9}$$

for

$$\psi_{2x} = \big(1 - \phi_{2,MT}(x-\bar{x})\big), \quad \psi_{1y} = \phi_{1,MT}(y-\bar{x})$$

where here and below $\epsilon_1 > 0$ *is a small enough constant.*

Proposition 20.2.3 [6]**.** *Let* $\mu \le \epsilon h^{\delta-1}$ *and let*

$$T_* = C\varepsilon^{-1}h|\log h| \le T \le T^* = \epsilon_0. \tag{20.2.10}$$

Then

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)Q_{2x}\psi_{2x}U(x,y,t)\psi_{1y}\,{}^tQ_{1y}| \le Ch^s \qquad \forall x,y\ \forall \tau \le \epsilon_1 \tag{20.2.11}$$

for $Q_{2x} = \big(1 - \phi_{2,MT}(hD_x''' - \bar{\xi}''')\big)$ *and* $Q_{1y} = \phi_{1,MT}(hD_y''' - \bar{\xi}''')$, *where here and below* $\psi_{1,2}$ *are admissible functions supported in* $B(0,\frac{1}{2})$ *and* $\psi_{1x} = \psi_1(x)$, $\psi_{2y} = \psi_2(y)$.

---

[4] Finite speed of propagation with respect to x; cf. Propositions 18.2.4 and 19.2.8.

[5] Recall that we pick up all such auxiliary functions to be admissible in the sense of Section 2.3.

[6] Finite speed of propagation with respect to P'''; cf. Proposition 18.6.2.

Proposition 20.2.4 [7]**.** *Let* $\mu \le \epsilon h^{\delta-1}$ *and condition* (20.2.10) *be fulfilled, and let*

$$|\bar{\xi}'''| := \rho \ge C\varepsilon^{-1}h|\log h| + C\mu^{-1}. \tag{20.2.12}$$

Then for

$$T_* := C(\mu^{-1}h|\log h|)^{\frac12} + C\rho^{-2}h|\log h| \le T \le T^* := \epsilon\rho \tag{20.2.13}$$

estimate

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma U(x,y,t)\psi_y\, {}^tQ_y| \le Ch^s \qquad \forall \tau \le \epsilon_1 \tag{20.2.14}$$

holds for $Q_y = \phi_{1,\frac12\rho}(hD_y''' - \bar{\xi}''')$.

Proofs of Propositions 20.2.2–20.2.4. Proofs of these propositions repeat proofs of the corresponding propositions of Chapters 18 and 19 and are left to the reader. □

Now let us pick up

$$\varepsilon = C\rho^{-1}h|\log h|. \tag{20.2.15}$$

Then any $T \in [\epsilon_0\mu^{-1}, \epsilon\rho]$ satisfies condition (20.2.13) as long as

$$\rho \ge \bar{\rho}_1 := C\max\bigl(\mu^{-1}, (\mu h|\log h|)^{\frac12}\bigr). \tag{20.2.16}$$

This is a definition of the *outer zone* and ε is defined by (20.2.15) there.

Therefore the contribution of the zone $\{|\xi''| \asymp \rho\}$ with given $\rho \ge \bar{\rho}_1$ to the Tauberian remainder does not exceed $Ch^{1-d}T^{*\,-1}\rho^{q-1}$, where ρ^{q-1} is the measure of $\{\xi''' :\ a(x,\xi) = 0,\ |\xi'''| \asymp \rho\}$; then the total contribution of the outer zone to the Tauberian remainder does not exceed

$$Ch^{1-d}\int \frac{1}{T^*(\rho)}\rho^{q-1}\,d\rho \tag{20.2.17}$$

with all integrals here and until the end of the section taken from $\bar{\rho}_1$ to 1, and plugging $T^*(\rho) \asymp \rho$ we get $Ch^{1-d}\int \rho^{q-2}\,d\rho \asymp h^{1-d}$ provided $q \ge 2$.

So, we have proven

Proposition 20.2.5. *Let* $q \ge 2$, ε *and* $\bar{\rho}_1$ *be defined by* (20.2.15) *and* (20.2.16)*, and* $(l,\sigma) = (1,1)$*. Then the contribution of the outer zone* $\{|\xi'''| \ge \bar{\rho}_1\}$ *to the Tauberian remainder with* $T = \epsilon\mu^{-1}$ *is* $O(h^{1-d})$.

[7] Singularities leave diagonal; cf. Proposition 18.6.3.

Outer Zone: Special Case $q = 1$

As $q = 1$ expression (20.2.17) with $T^*(\rho) = \epsilon\rho$ results in $Ch^{1-d}|\log\mu|$ and to get rid of this factor $|\log\mu|$ we need to increase $T^*(\rho)$. We consider few cases in the increased generality and complexity.

(i) If g^{jk} and F_{jk} are constant it is easy: we can take

$$T^*(\rho) = C\rho|\log\rho|^2 \tag{20.2.18}$$

as in section Section 18.6 provided $(l,\sigma) \succeq (1,2)$ and we can consider propagation in an appropriate time direction (in which ξ_1 increases); see Section 18.6 for details. Namely, let us cover $B(0,1)$ by balls of radii $\gamma = \rho^{\delta_1}$ (with a small exponent $\delta_1 > 0$). In each element one of the following cases holds:

$$|\partial_{x_1} V(x,\xi)| \asymp \varrho \ge \bar{\varrho} := C_0|\log\rho|^{-2}, \tag{20.2.19}$$

$$|\partial_{x_1} V(x,\xi)| \le \bar{\varrho}. \tag{20.2.20}$$

During propagation the classical trajectory does not leave the initial ball. Furthermore, in the case (20.2.20) $|d\xi_1/dt| = |\partial_{x_1} V|$ does not exceed $\bar{\varrho}$ and $|\xi_1| \ge \frac{1}{2}\rho - \bar{\varrho}|t| \ge \frac{1}{3}\rho$ as $|t| \le T^*(\rho)$ defined by (20.2.18).

On the other hand, in the case (20.2.19) $|d\xi_1/dt|$ is larger than ϱ and does not change sign for $|t| \le T^*(\rho)$. Then $|\xi_1| \ge \frac{1}{2}\rho + \varrho|t|$ for $0 \le \pm t \le T(\rho)$ with an appropriate sign.

In both cases x_1 shifts away from its initial position and for time t (of the appropriate sign in the case (20.2.19)) this shift is of magnitude $\rho|t| + \varrho|t|^2$ as $\epsilon\mu^{-1} = T_* \le \pm t \le T^*(\rho)$ (with an appropriate sign) and we can take a prescribed $T^*(\rho) = \epsilon\rho|\log\rho|^2$ and recover $O(h^{1-d})$ in (20.2.17).

(ii) Similar arguments work if f_j have constant multiplicities. Really, we can rewrite then the symbol as

$$a(x,\xi) = \xi_1^2 + \mu^2 \sum_{1\le j\le r} f_j(\eta_{2j-1}^2 + \eta_{2j}^2) + V \tag{20.2.21}$$

with η_k being linear combinations of $p_1, \dots, p_{2r}$ (with $\mathscr{F}^{1,2}$ coefficients) such that

$$\mu\{\eta_k, \eta_m\} \equiv \Lambda_{km} \tag{20.2.22}$$

modulo linear combinations of $\eta_1, \dots, \eta_{2r}$ with $\mathscr{F}^{0,2}$ coefficients where $\Lambda_{km} = 1$ if $k = 2j-1, m = 2j$ for some j, $\Lambda_{km} = -1$ if $k = 2j, m = 2j-1$ for some j, $\Lambda_{km} = 0$ otherwise.

Then the derivative of $\mu^2(\eta_{2j-1} + i\eta_{2j})(\eta_{2k-1} - i\eta_{2k})$ along classical trajectories

$$|\mu^2\{a, (\eta_{2j-1} + i\eta_{2j})(\eta_{2k-1} - i\eta_{2k})\}| \le M(1 + \mu|f_j - f_k|) \qquad \forall j, k \tag{20.2.23}$$

is bounded as $f_j = f_k$ and during time T its variation does not exceed CT which is way less than $\epsilon\bar{\varrho}$. This could be justified on the quantum level as well because one can quantize symbol

$$f\big(\bar{\varrho}^{-1}\big((\eta_{2j-1} + i\eta_{2j})(\eta_{2k-1} - i\eta_{2k}) - \lambda\big)\big)$$

with function f supported in $[-c, c]$ and $|\lambda| \le c$.

Consider now $\{a, \xi_1\}$; modulo $O(\rho)$ it is equal to $-\partial_{x_1} V + \mu^2 \sum_{j,k} \alpha_{jk}\eta_j\eta_k$ with $\mathscr{F}^{0,2}$ coefficients. Then we can find α'_{jk} such that

$$\begin{aligned}\big\{a, \xi_1 - \mu \sum_{j,k} \alpha_{jk}\eta_j\eta_k\big\} \equiv \\ - \partial_{x_d} V + \mu^2 \sum_{j,k:f_j=f_k} \alpha''_{jk}(\eta_{2j-1} + i\eta_{2j})(\eta_{2k-1} - i\eta_{2k})\end{aligned} \tag{20.2.24}$$

modulo $O(\bar{\varrho})$: we remove all non-resonance terms but previously we make ρ^δ-mollification of α_{jk} thus making $O(\bar{\varrho})$ error. But then all the above arguments work since correction $\mu \sum_{j,k} \alpha_{jk}\eta_j\eta_k$ does not exceed $C\mu^{-1} \le \epsilon\rho$. The role of $-\partial_{x_1} V$ is played now by the right-hand expression of (20.2.24).

(iii) Consider now the general case. First of all let us make again $\gamma = \rho^{\delta_1}$-covering and consider one element. Then the symbol could be rewritten in the form

$$a(x, \xi) = \xi_1^2 + \sum_{\mathfrak{m}} a_{\mathfrak{m}} + V, \tag{20.2.25}$$

where

$$a_{\mathfrak{m}} = \mu^2 \sum_{j,k\in\mathfrak{m}} a_{jk}(\eta_{2j-1} - i\eta_{2j})(\eta_{2k-1} + i\eta_{2k}) \tag{20.2.26}$$

with Hermitian matrices $a_{\mathfrak{m}} = (a_{jk})_{j,k\in\mathfrak{m}}$ whose eigenvalues are $f_j(x)$, f_j and f_k differ by less than ϵ (more than 2ϵ) as j, k belong to the same group $\mathfrak{m}$ (different groups, respectively).

Consider traceless matrices $b_{\mathfrak{m}} = a_{\mathfrak{m}} - \frac{1}{(\#\mathfrak{m})}\operatorname{tr} a_{\mathfrak{m}}\cdot I_{\mathfrak{m}}$ with the corresponding unit matrices $I_{\mathfrak{m}}$ and matrices $c_{\mathfrak{m}} = \partial_{x_1} b_{\mathfrak{m}}$ calculated at some fixed point of this partition element. Without any loss of the generality one can assume that each $c_{\mathfrak{m}}$ is a diagonal matrix; let classify its eigenvalues into groups: λ_j and λ_k differ less than $\epsilon\bar{\varrho}$ (more than $2\epsilon\bar{\varrho}$) as j, k belong to the same subgroup $\mathfrak{n} \subset \mathfrak{m}$ (different subgroups, respectively).

Then one can cover each element of partition by $\gamma_1 = \rho^{\delta_1+\delta_2}$ subelements of two kinds:

(a) With f_j, f_k different by less than γ_1 for some j, k belonging to the different subgroups. One can prove easily that the total measure of this type elements (i.e. of all elements together) does not exceed $C\bar{\varrho}$ and thus their total contribution to the Tauberian remainder does not exceed $Ch^{1-d}|\log\rho|^{-2}$ which after integration over $d\rho/\rho$ results in $O(h^{1-d})$.

(b) With f_j, f_k different by more than γ_1 for all j, k belonging to the different subgroups. Then we can rewrite (20.2.25) with $\mathfrak{n}$ (which indicates the finer partition) instead of $\mathfrak{m}$ and to prove that $|\{a, a_{\mathfrak{n}}\}| \le C\gamma^{-\delta_3}$ where exponent δ_3 could be made arbitrarily small (by taking all the previous exponents small). Then $a_{\mathfrak{n}}$ are conserved modulo $O(\bar{\varrho})$ in the classical evolution.

Moreover, we can make even finer subpartition depending on subelement such that $|f_j - f_k| \le C\bar{\varrho}$ if j, k belong to the same element of it.

But then $f_{\mathfrak{n}}\mu^2\sum_{j\in\mathfrak{n}}(\eta_{2j-1}^2 + \eta_{2j}^2)$ are conserved modulo $O(\bar{\varrho})$ and then it is also true for $a_{\mathfrak{n}}$ and $a_{\mathfrak{m}}$ as well and also

$$\{a, \xi_1 - \mu\sum_{j,k}\alpha_{jk}\eta_j\eta_k\} \equiv \sum_j \lambda_j(\eta_{2j-1}^2 + \eta_{2j}^2) \mod O(\bar{\varrho})$$

for appropriate α_{jk}.

But then arguments of Parts (i) and (ii) work and the total contribution of elements of type (b) does not exceed $Ch^{1-d}|\log\rho|^{-2}$ as well and after integration over $d\rho/\rho$ we get $O(h^{1-d})$ again. So we have proven

Proposition 20.2.6. *Let $q = 1$, ε and $\bar{\rho}_1$ be defined by* (20.2.15) *and* (20.2.16)*, and $(I, \sigma) = (1, 2)$. Then the contribution of the outer zone $\{|\xi'''| \ge \bar{\rho}_1\}$ to the Tauberian remainder with $T = \epsilon\mu^{-1}$ is $O(h^{1-d})$.*

Remark 20.2.7. Similar arguments were applied in Section 7.5 to study propagation near the boundary.

Conclusion

We have not specified ε for $\rho = |\xi'''| \le \bar{\rho}_1$ but it is reasonable to take there $\varepsilon = C\bar{\rho}_1^{-1}h|\log h|$ and therefore

$$\varepsilon = C\begin{cases} \rho^{-1}h|\log h| & \rho \gtrsim \bar{\rho}_1, \\ \bar{\rho}_1^{-1}h|\log h| & \rho \lesssim \bar{\rho}_1. \end{cases} \tag{20.2.27}$$

Remark 20.2.8. Note that the threshold for $\bar{\rho}_1$ is $\mu = \bar{\mu} = C(h|\log h|)^{-\frac{1}{3}}$: $\bar{\rho}_1 = C\mu^{-1}$ as $\mu \le \bar{\mu}$, and $\bar{\rho}_1 = C(\mu h|\log h|)^{\frac{1}{2}}$ as $\mu \ge \bar{\mu}$.

On the other hand, the standard estimate in the complementary *inner zone* $\{|\xi'''| \le \bar{\rho}_1\}$ brings the Tauberian remainder estimate

$$Ch^{1-d} \times \mu\bar{\rho}_1^q \asymp Ch^{1-d} \times \mu(\mu h|\log h|)^{\frac{q}{2}} + Ch^{1-d}\mu^{1-q}. \tag{20.2.28}$$

Combining with Propositions 20.2.5 and 20.2.6 we arrive to

Proposition 20.2.9. *(i) In the framework of either Proposition 20.2.5 or 20.2.6*

$$\mathsf{R}^{\mathsf{T}} := |\Gamma(\tilde{e}\psi)(\tau) - h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau'}\bar{\chi}_T(t)\Gamma(U\psi)| \le Ch^{1-d} + C\mu(\mu h|\log h|)^{\frac{q}{2}}h^{1-d} \qquad \forall \tau : |\tau| \le \epsilon_1 \tag{20.2.29}$$

where the left-hand expression is the total Tauberian remainder with $T = \epsilon\mu^{-1}$.

(ii) Furthermore, this estimate holds with any $T \ge \bar{T}$ *with* $\bar{T} = Ch|\log h|$.

20.2.3 Main Theorems

General Case

Now in virtue of the standard results rescaled we can replace the Tauberian expression by the multiterm Weyl expression $h^{-d}\tilde{\mathcal{N}}^{\mathsf{W}}_{(\infty)}$ defined by (19.2.83) for

approximate operators. Then we can replace R^{T} by $\tilde{\mathsf{R}}^{\mathsf{W}}_{(\infty)}$ also for approximate operators (where tilde means that we consider approximate operators).

Note that the contribution of the outer zone to the approximation error does not exceed

$$C\int \Big(\frac{h|\log h|}{\rho}\Big)^{l}\Big(1+\frac{\mu h|\log h|}{\rho}\Big)\,|\log(\rho^{-1}h|\log h|)|^{-\sigma}\rho^{q-1}\,d\rho\times h^{-d} \tag{20.2.30}$$

and this expression is $O(h^{1-d})$ provided

$$\text{Either}\quad q\ge 2,\ (l,\sigma)\succeq(1,1)\quad \underline{\text{or}}\quad q=1,\ (l,\sigma)\succeq(1,2). \tag{20.2.31}$$

Also one can prove easily that replacing $h^{-d}\mathcal{N}^{\mathsf{W}}_{(\infty)}$ by the magnetic Weyl expression $h^{-d}\mathcal{N}^{\mathsf{MW}}$ does not increase an error and therefore we arrive to the following

Theorem 20.2.10. *Let conditions* (20.1.1), (20.1.5), (20.1.7), (20.1.8)–(20.1.11), *and* (20.2.31) *be fulfilled, and* $\mu\le h^{\delta-1}$.

Then there exist two framing approximations (see footnote [18)] *of Chapter 18) such that for both of them*

$$\mathsf{R}^{\mathsf{MW}}=\Big|\int \Big(\tilde{e}(x,x,\tau)-h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau)\Big)\psi(x)\,dx\Big|\le Ch^{1-d}+C\mu h^{1-d}(\mu h|\log h|)^{\frac{q}{2}}; \tag{20.2.32}$$

the same estimate holds for $\mathsf{R}^{\mathsf{W}}_{(\infty)}$.

Remark 20.2.11. (i) Theorem 20.2.10 uses no non-degeneracy condition and it does not benefit from the stronger smoothness assumptions.

(ii) For $\mu\le\bar{\mu}_q$,

$$\bar{\mu}_{(q)}\coloneqq (h|\log h|)^{-q/(q+2)} \tag{20.2.33}$$

estimate

$$\mathsf{R}^{\mathsf{MW}}\le Ch^{1-d} \tag{20.2.34}$$

holds. In particular, $\bar{\mu}_{(1)}=C(h|\log h|)^{-\frac{1}{3}}=\bar{\mu}_1$, $\bar{\mu}_{(2)}=C(h|\log h|)^{-\frac{1}{2}}$ and $\bar{\mu}_{(q)}\ge C(h|\log h|)^{-\frac{3}{5}}$ as $q\ge 3$.

Problem 20.2.12. Using rescaling technique get rid of logarithms in the definitions of $\bar{\rho}_1$ and thus in estimates (20.2.29), (20.2.32) and in (20.2.33):

$$\mathsf{R}^{\mathsf{T}} \le Ch^{1-d} + C(\mu h)^{1+\frac{q}{2}} h^{-d} \tag{20.2.29}^*$$

and

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C(\mu h)^{1+\frac{q}{2}} h^{-d}. \tag{20.2.32}^*$$

Microhyperbolic Case

To push μ in Theorem 20.2.10 up[8)] we need the microhyperbolicity assumption and some extra smoothness.

First of all, let us improve our results about propagation of singularities:

Proposition 20.2.13. *Let $\bar{\mu}_{(q)} \le \mu \le \epsilon h^{-1}|\log h|^{-1}$ and the microhyperbolicity assumption (see Definition 20.1.2) be fulfilled. Then for $C\varepsilon^{-1}h|\log h| \le T \le T^* = \epsilon_1$ estimate* (20.2.14) *holds.*

Proof. An easy proof based on technique of subsections 18.6.6 and 19.2.2 we leave to the reader. □

In the inner zone $\{\rho \le \bar{\rho}_1\}$ we can select $\varepsilon = C\mu h|\log h|$ (if $\mu \ge (h|\log h|)^{-\frac{1}{3}}$) and then for Q with the symbol supported there estimate (20.2.14) holds for $T_* = \epsilon\mu^{-1} \le T \le T^* = \epsilon_1$.

Redefining in the outer zone ε, so finally

$$\varepsilon = C \begin{cases} \max\bigl(\mu h|\log h|\bigl(\frac{\bar{\rho}_1}{\rho}\bigr)^s, \rho^{-1}h|\log h|\bigr) & \rho \ge \bar{\rho}_1, \\ \bar{\varepsilon} := \mu h|\log h| & \rho \le \bar{\rho}_1 \end{cases} \tag{20.2.35}$$

and combining with Proposition 20.2.4 we get then that for Q with the symbol supported in the outer zone estimate also (20.2.14) holds for $T_* \le T \le T^*$.

Thus we arrive to

Proposition 20.2.14. *Let $(h|\log h|)^{-\frac{1}{3}} \lesssim \mu \le \epsilon(h|\log h|)^{-1}$ and the microhyperbolicity assumption (see Definition 20.1.2) be fulfilled. Let ε be defined by* (20.2.35).

Then estimate (20.2.14) *holds with $Q = I$ and any $T \in [T_*, T^*]$, $T_* = \epsilon\mu^{-1}$, $T^* = \epsilon_1$.*

[8)] Actually we need to do this for $q = 1$ only.

Combining with the standard results rescaled and applying the standard Tauberian technique we arrive to estimate (20.2.29) again.

Note that an approximation error in the operator does not exceed

$$C\varepsilon^{q}|\log\varepsilon|^{-\sigma}| + C\mu\varepsilon^{\bar{l}+1}|\log\varepsilon|^{-\bar{\sigma}} \tag{20.2.36}$$

where one can skip the second term as $\varepsilon \lesssim \mu^{-1}$ which is the case in the inner zone iff $\mu \lesssim (h|\log h|)^{-\frac{1}{3}}$; then it is true in the outer zone as well.

Then one can prove easily that an approximation error in both R^{MW} and $\mathsf{R}^{\mathsf{W}}_{(\infty)}$ does not exceed (20.2.35) calculated as $\varepsilon = \bar{\varepsilon}$, multiplied by $\bar{\rho}_1^{\frac{q}{2}} h^{-d}$ i.e.

$$C(\mu h|\log h|)^{l+\frac{q}{2}}|\log h|^{-\sigma}h^{-d} + C(\mu h|\log h|)^{2+\bar{l}+\frac{q}{2}}|\log h|^{-1-\bar{\sigma}}h^{-1-d} \tag{20.2.37}$$

where one can skip the second term if $\mu \lesssim (h|\log h|)^{-\frac{1}{2}}$. This proof uses the microhyperbolicity assumption for $q = 1$ and we consider R^{MW}.

However if $\ell_\perp = 0$ we can take mollification with $\varepsilon = Ch\rho^{-1}|\log h|$ with respect to all variables x and also an extra mollification with ε defined by (20.2.35) with respect to x'''; then an approximation error will be given by (20.2.37) but without the second term.

One can prove easily that the difference between $h^{-d}\mathcal{N}^{\mathsf{MW}}$ and $h^{-d}\mathcal{N}^{\mathsf{W}}_{(\infty)}$ does not exceed (20.2.37) without second term.

This implies

Theorem 20.2.15. *Let conditions* (20.1.1), (20.1.5), (20.1.7), (20.1.8)–(20.1.11), *and* (20.2.31) *be fulfilled, and* $\mu \le h^{\delta-1}$.

Let the microhyperbolicity assumption (see Definition 20.1.2) be fulfilled. Then there exist two framing approximations (see footnote [18)] *of Chapter 18) such that for both of them*

(i) The following estimate holds

$$\begin{aligned}\mathsf{R}^{\mathsf{MW}} \le{}& Ch^{1-d}+\\ & C(\mu h|\log h|)^{l+\frac{q}{2}}|\log h|^{-\sigma}h^{-d} + C(\mu h|\log h|)^{2+\bar{l}+\frac{q}{2}}|\log h|^{-1-\bar{\sigma}}h^{-1-d}.\end{aligned} \tag{20.2.38}$$

(ii) Furthermore, if <u>*either*</u> $\mu \le \bar{\mu}_2 = C(h|\log h|)^{-\frac{1}{2}}$ <u>*or*</u> $\ell_\perp = 0$ *in the microhyperbolicity assumption, then one can skip the last term in the right-hand expression of* (20.2.38)*:*

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C(\mu h|\log h|)^{l+\frac{q}{2}}h^{-d}|\log h|^{-\sigma}. \tag{20.2.39}$$

(iii) In particular, $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d}$ *as* $q=1$, $(l,\sigma)=(\frac{3}{2},1)$ *and* $\mu \le \bar{\mu}_2$.

Recall that all these estimates hold for $\mathsf{R}^{\mathsf{W}}_{(\infty)}$ as well.

Problem 20.2.16. Using rescaling technique replace $\mu h|\log h|$ by μh in the definitions of $\bar{\rho}_1$ and ε and thus in estimates (20.2.38) and (20.2.39):

$$(20.2.38)^* \quad \mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C(\mu h)^{l+\frac{q}{2}}|\log h|^{-\sigma}h^{-d} + C(\mu h)^{2+\bar{l}+\frac{q}{2}}|\log h|^{-\bar{\sigma}}h^{-1-d}$$

and

$$(20.2.39)^* \qquad \mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C(\mu h)^{l+\frac{q}{2}}h^{-d}|\log h|^{-\sigma}.$$

Special Case of Constant g^{jk}, F_{jk}

Consider now the case of constant g^{jk} and F_{jk}; then without any loss of the generality one can assume that

(20.2.40) $g^{jk}=\delta_{jk}$ and $F_{jk}=\pm f_i$ for $j=q+i, k=q+i+r$ and $j=q+i+r, k=q+i$ with $i=1,\dots,r$ and $F_{jk}=0$ otherwise.

Then the microhyperbolicity assumption is equivalent to

$$(20.2.41) \qquad |\nabla V| \ge \epsilon_0.$$

We replace it by the non-degeneracy condition

$$(20.2.42) \qquad |\nabla V| \le \epsilon_0 \implies |\det \mathsf{Hess}\, V| \ge \epsilon_0.$$

We leave to the reader the following

Problem 20.2.17. Let conditions (20.1.1), (20.1.5), (20.1.7), (20.1.8), $(20.1.9)_3$, (20.1.11), and (20.2.31) be fulfilled, and $\mu \le h^{\delta-1}$.

Assume that g^{jk}, F_{jk} are constant and (20.2.42) is fulfilled.

(i) Using arguments similar to those of Subsection 19.2.5 prove that for appropriate framing approximations

$$(20.2.43) \qquad \mathsf{R}^{\mathsf{T}} \le Ch^{1-d} + C\mu(\mu h|\log h|)^{q+r}h^{1-d}$$

where $q+r=\frac{1}{2}q+\frac{1}{2}d$ and

$$(20.2.44) \quad \mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C\mu(\mu h|\log h|)^{q+r}h^{1-d} + C(\mu h|\log h|)^{l+\frac{q}{2}}|\log h|^{-\sigma}h^{-d}.$$

(ii) Adding rescaling arguments prove that for appropriate framing approximations

$$\mathsf{R}^{\mathsf{T}} \le Ch^{1-d} + C(\mu h)^{q+r+1}h^{-d} \tag{20.2.43}^*$$

and

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C(\mu h)^{q+r+1}h^{-d} + C(\mu h)^{l+\frac{q}{2}}|\log h|^{-\sigma}h^{-d}. \tag{20.2.44}^*$$

20.3 Canonical Form

20.3.1 Pilot-Model

Assume temporarily that g^{jk} and F_{jk} are constant. Then without any loss of the generality we can assume $V_j(x)$ are linear functions.

Then A^0 is transformed into exactly

$$\sum_{1\le k\le q} h^2D_k^2 + \sum_{1\le j\le r} f_j\Big(h^2D_{r+j}^2 + \mu^2 x_{r+j}^2\Big) \tag{20.3.1}$$

by $\mu^{-1}h$-metaplectic transformation which consists of the following steps:

(i) Change of variables $(x, \mu^{-1}hD) \mapsto (Qx, {}^tQ^{-1}\mu^{-1}hD)$ transforming g^{jk} into δ_{jk} and F into matrix satisfying (20.2.40). It transforms $V(x)$ into $V(Qx)$.

(ii) Gauge transformation (multiplication by $e^{i\mu h^{-1}S(x)}$ with quadratic form $S(x)$), transforming $V_j(x)$ into 0 for $j = 1, \dots, q+r$ and $V_{j+r+q}(x)$ into $f_j x_{j+q}$ for $j = 1, \dots, r$. Then A^0 is transformed into

$$\sum_{1\le k\le q} h^2D_k^2 + h^2\sum_{1\le j\le r}\Big(D_{q+j}^2 + \big(D_{q+j+r} - f_j\mu h^{-1}x_{q+j}\big)^2\Big) \tag{20.3.2}$$

and $V(x)$ is preserved.

(iii) [(iii)–(iv)] Partial $\mu^{-1}h$-Fourier transform, change of variables like in Subsection 19.3.1 A^0 into

$$\sum_{1\le k\le q} h^2D_k^2 + \sum_{1\le j\le r}\Big(h^2D_j^2 + f_j^2\mu^2x_j^2\Big)$$

and V into $\tilde{V} := V(x''', x' - Kx'', \mu^{-1}hD'' - {}^tK\mu^{-1}hD')$ with Weyl quantization. Finally, $x_j \mapsto f_j^{\frac{1}{2}}x_j$, $D_j \mapsto f_j^{-\frac{1}{2}}D_j$ reduces operator A^0 into (20.3.1) and transforms $\tilde{V}$ accordingly.

20.3.2 General Case: Framework

We can assume now that

$$\bar{\mu}_{(q)} = C(h|\log h|)^{-\frac{q}{q+2}} \le \mu \le \epsilon(h|\log h|)^{-1} \tag{20.3.3}$$

(a case of larger μ we'll consider later; we also can redefine $\bar{\mu}_{(q)} = Ch^{-\frac{q}{q+2}}$).

Anyway we need to consider an inner zone

$$\mathcal{Z}_{\mathsf{inn}} := \{|\xi'''| \le \bar{\rho}_1 = C(\mu h|\log h|)^{\frac{1}{2}}\} \tag{20.3.4}$$

and in this zone in the general case we already set $\varepsilon = C(\mu^{-1}h|\log h|)^{\frac{1}{2}}$. However we reset it to a far larger value $\varepsilon = C\mu^{-1}$ thus defining

$$\varepsilon = \begin{cases} C\mu^{-1}\bigl(\dfrac{\bar{\rho}_1}{\rho}\bigr)^s + C\rho^{-1}h|\log h| & \text{as } \rho \ge \bar{\rho}_1, \\ C\mu^{-1} & \text{as } \rho \le \bar{\rho}_1 \end{cases} \tag{20.3.5}$$

with a possible increase later.

From this section point of view there are two different cases $q = 1$ and $q \ge 2$; if either the microhyperbolicity assumption is fulfilled or g^{jk}, F_{jk} are constant and the non-degeneracy condition (20.2.42) is fulfilled, then $\bar{\mu}_{(1)}$ is pushed up and $q = 1$ falls in the latter case as well.

Really, for $q \ge 2$, $\mu \ge \bar{\mu}_{(2)} = (h|\log h|)^{-\frac{1}{2}}$ (and thus $\mu^{-l}|\log h|^{-\sigma} \le \mu h$ even as $(l,\sigma) = (1,1)$) this will bring an approximation error not exceeding

$$C\mu^r h^{-r}(\mu h|\log h|)^{\frac{q}{2}-1}\mu^{-l}|\log h|^{-\sigma} \times (\mu h)^{1-r}|\log h|$$

where the first factor estimates an error in each term in the sum defining $h^{-d}\mathcal{N}^{\mathsf{MW}}$ and the second factor estimates the number of the terms effected; the result is $O\bigl(h^{1-d}\bigr)$ for sure.

As $q = 1$ we need to assume that[9)]

$$\bar{\rho}_2 := \bigl(\mu^{-l}|\log h|^{-\sigma}\bigr)^{\frac{1}{2}} \le \rho_1^* := (\mu h)^{\frac{1}{2}} \iff \mu \ge (h|\log h|^{\sigma})^{1/(l+1)}). \tag{20.3.6}$$

[9)] This is not necessarily true as $q = 1$; however without this assumption no improvement of the previous section results is possible.

Consider strip $\{\rho \le |\xi'''| \le 2\rho\}$ with $\bar\rho_2 \le \rho \le \bar\rho_1$ where an approximation error can be estimated similarly by

$$Ch^{-d}\rho\bar\rho_2^2 + C\mu h^{1-d}\rho^{-1}\bar\rho_2^2$$

and after summation over ρ we conclude that the contribution of the zone $\{\bar\rho_2 \le |\xi'''| \le \bar\rho_1\}$ to an approximation error does not exceed

$$Ch^{-d}(\mu h|\log h|)^{\frac12}\mu^{-l}|\log h|^{-\sigma} + Ch^{1-d}\mu^{1-\frac{l}{2}}|\log h|^{-\frac{\sigma}{2}}. \tag{20.3.7}$$

Meanwhile, in the zone $\{|\xi'''| \le C\bar\rho_2\}$ no more than $C(\mu h)^{1-r}$ terms in the sum defining $h^{-d}\mathcal{N}^{\mathsf{MW}}$ are affected and an error in each does not exceed $C\mu^r h^{-r}\bar\rho_2$; this brings an approximation error estimate $C\mu h^{1-d}\bar\rho_2$ which is the exactly the second term in (20.3.7).

Remark 20.3.1. Expression (20.3.7) is $O\big(h^{1-d}\big)$ for all $\mu \ge C(h|\log h|)^{-\frac13}$ iff $(l,\sigma) \succeq (2,1)$.

On the other hand, if $q = 1$ and the microhyperbolicity assumption (see Definition 20.1.2) is fulfilled, then an the approximation error does not exceed

$$Ch^{-d}(\mu h|\log h|)^{\frac12}\mu^{-l}|\log h|^{-\sigma} \tag{20.3.8}$$

and it should be weighted against Theorem 20.2.15; so in this case for $\mu \le \bar\mu_{(2)} = C(h|\log h|)^{-\frac12}$ we use Theorem 20.2.15 and for $\mu \ge \bar\mu_{(2)}$ we will use the intermediate magnetic field construction; an approximation error estimate in both cases is $O\big(h^{1-d}\big)$ for all corresponding μ iff $(l,\sigma) \succeq (\frac32, 1)$.

Similar arguments work if $q = 1$, g^{jk}, F_{jk} are constant and non-degeneracy condition (20.2.42) is fulfilled; we refer in this case to Problem 20.2.17 as $\mu \le \bar\mu_{(2)}$.

Thus we have proven

Proposition 20.3.2. *Let ε be defined by* (20.3.5). *Then*

(i) If $q \ge 2$, $(l,\sigma) \succeq (1,1)$ and $\mu \ge (h|\log h|)^{-\frac12}$, then a mollification error is $O(h^{1-d})$.

(ii) If $q = 1$, $(l,\sigma) \succeq (1,2)$, $\mu \ge (h|\log h|)^{-\frac13}$ and condition (20.3.6) *is fulfilled, then a mollification error does not exceed* (20.3.7).

(iii) If $q = 1$, $(l,\sigma) \succeq (1,2)$, $\mu \ge (h|\log h|)^{-\frac12}$ and <u>either</u> the microhyperbolicity assumption is fulfilled <u>or</u> g^{jk}, F_{jk} are constant and non-degeneracy condition (20.2.42) *is fulfilled, then a mollification error does not exceed* (20.3.8).

20.3.3 Reduction. Main Part

So we can start from the operator

$$A=\sum_{1\le j,k\le d} P_j^* g^{jk} P_k + V, \qquad P_j = hD_j - \mu V_j \tag{20.3.9}$$

with

$$[P_j, P_k] = i\mu h F_{jk} \tag{20.3.10}$$

where

$$F_{jk}=0 \quad \text{as} \quad j\le q \text{ or } \quad k\le q;\ \operatorname{rank}(F_{jk})_{j,k=1,\dots,2r}=2r, \tag{20.3.11}$$

and we can assume without any loss of the generality at some point $\bar{x}$ matrix (F_{jk}) is in the canonical form; namely

$$F_{jk}(\bar{x})=\begin{cases} f_i & \text{as } \ j=q+i, k=q+r+i,\ i=1,\dots,r,\\ -f_i & \text{as } \ k=q+i, j=q+r+i,\ i=1,\dots,r,\\ 0 & \text{otherwise.}\end{cases}$$

Then without any loss of the generality we can assume that in its vicinity

$$F_{jk}=0\neq 0 \implies j\ge q+1,\ k\ge q+1 \quad \text{and} \quad \exists \mathfrak{m}\in\mathfrak{M}: j,k\in\mathfrak{m}. \tag{20.3.12}$$

Proposition 20.3.3. *Let*

$$\mathcal{L}=\mu^2\Big(\sum_{j,k\le d}\beta^{jk}p_jp_k\Big)^{\mathsf{w}} \tag{20.3.13}$$

with $\beta^{jk}=\beta^{kj}\in \mathscr{F}^{\bar{l},\bar{\sigma}}$. *Then modulo operators with symbols belonging to* $\mu^{-2}\mathscr{F}^{\bar{l}-1,\bar{\sigma}}$

$$e^{\frac{i}{2}\mu^{-1}h^{-1}t\mathcal{L}}(p_j)^{\mathsf{w}}e^{-\frac{i}{2}\mu^{-1}h^{-1}t\mathcal{L}}\equiv\Big(\sum_k \big(e^{\Lambda t}\big)_j^k p_k\Big)^{\mathsf{w}} \tag{20.3.14}$$

with matrix $\Lambda=(\Lambda_{jk})_{j,k}=(F_{jp})(\beta^{pk})$.

Proof. An easy proof following arguments of Sections 18.7 and 19.3 is left to the reader. □

One can see easily that due to (20.1.7)–(20.1.8)

$$e^{\Lambda t} = \begin{pmatrix} I & 0 \\ \int_0^t e^{\Lambda' t'} \Lambda''\, dt' & e^{\Lambda' t} \end{pmatrix}$$

with $\Lambda' = (\Lambda_{jk})_{j,k\ge q+1}$, $\Lambda'' = (\Lambda_{jk})_{j\le q+1, k\le q}$. It provides us with the first step of the reduction:

Step 1 Applying transformation $\exp(\frac{i}{2}\mu^{-1}h^{-1}\mathcal{L})$ with operator $\mathcal{L}$ defined by (20.3.13) with appropriate coefficients β^{jk} one can transform operator A to the block form

$$\mu^2 \sum_{q+1\le j,k\le q+r} \zeta_j^{\dagger\,\mathrm{w}} a^{jk\,\mathrm{w}} \zeta_k^{\mathrm{w}} + \mu^2 \sum_{j,k\le q} p_j^{\mathrm{w}} a^{jk\,\mathrm{w}} p_k^{\mathrm{w}} + a_0^{\mathrm{w}} + \frac{1}{2}\big(B + B^*\big), \tag{20.3.15}$$

$$B = \Big(\mu^2 \sum_{j,k,m} b^{jkm} p_j p_k p_m + \sum_j b^j p_j\Big)^{\mathrm{w}} \tag{20.3.16}$$

$$\zeta_j = p_j + i p_{j+r} \text{ with } j = q+1, \dots, q+r, \tag{20.3.17}$$

$$a^{jk} \ne 0 \implies \exists \mathfrak{m} : j, k \in \mathfrak{m}; \tag{20.3.18}$$

let us recall that $\mathfrak{M}$ is the resonance partition at point $\bar{x}$.

(20.3.19) Here and below $a^{jk} \in \mathscr{F}^{\bar{l},\bar{\sigma}}$, $a_0 \in \mathscr{F}^{l,\sigma}$, $b^{jkl} \in \mathscr{F}^{\bar{l}-1,\bar{\sigma}}$, $b^j \in \mathscr{F}^{l-1,\sigma}$ and while $a^{jk} = a^{jk}(x)$ we have $b^{jkl} = b^{jkl}(x, \mu^{-1}\xi)$, $b^j = b^j(x,\mu^{-1}\xi)$ and c^{w} means h- rather than $\mu^{-1}h$-quantization of symbol c.

Step 2 Applying an appropriate gauge transformation we can achieve

$$V_k = 0 \text{ as } k \le q+r \text{ and } V_k = V_k(x_{q+1}, \dots, x_d) \text{ for } k = q+r+1, \dots, d \tag{20.3.20}$$

where condition $(20.1.9)_2$ provides $\mathscr{F}^{\bar{l}+1,\bar{\sigma}}$-regularity of new V_k. This is the only reason for this condition. Then

$$p_j = 0 \ \ \forall j = q+r+1, \dots, d \iff x_j = \lambda_j(x'', \xi') \ \ \forall j = q+1, \dots, q+r \tag{20.3.21}$$

with $x' = (x_{q+1}, \dots, x_{q+r})$, $\xi' = (\xi_{q+1}, \dots, \xi_{q+r})$, $x'' = (x_{q+r+1}, \dots, x_{q+2r})$, $\xi'' = (\xi_{q+r+1}, \dots, \xi_{q+2r})$, and $\lambda_j \in \mathscr{F}^{\bar{l}+1,\bar{\sigma}}$.

After this, following arguments of Sections 18.3, 18.7, and 19.3 and applying transformation $e^{i\mu^{-1}\mathcal{L}'}$ with $\mathcal{L}' = \sum_{q+1\le j\le q+r} \lambda_j^{\mathrm{w}} D_{j+r}$ we can transform operator (20.3.15) to the form (20.3.15)–(20.3.16) but now with

$$\zeta_j = \eta_j + i\eta_{j+r},\ \eta_j = \mu^{-1}\xi_j,\ \eta_{j+r} = x_j \qquad j = q+1, \dots, q+r, \tag{20.3.22}$$

$$\eta_j = \mu^{-1}\xi_j \qquad j = 1, \dots, q. \tag{20.3.23}$$

However in contrast to the previous step of the reduction now

$$a^{jk} = a^{jk}(x', \mu^{-1}\xi''; x'''), \quad a_0 = a_0(x', \mu^{-1}\xi''; x''')$$

rather than $a^{jk} = a^{jk}(x)$, $a_0 = a_0(x)$.

Remark 20.3.4. (i) One can see easily that if f_j have constant multiplicities, then the operator can be reduced on *Step 1* to the form

$$\mu^2 \sum_{q+1\le j\le q+r} \zeta_j^{\dagger\,\mathrm{w}} f_j^{\mathrm{w}} \zeta_j^{\mathrm{w}} + \mu^2 \sum_{j,k\le q} p_j^{\mathrm{w}} a^{jk\,\mathrm{w}} p_k^{\mathrm{w}} + a_0^{\mathrm{w}} + \frac{1}{2}\bigl(B + B^*\bigr) \tag{20.3.24}$$

and this form will be preserved after *Step 2*.

(ii) One can see easily that if $q = 1$, then after *Step 2* by means of transformation $e^{ih^{-1}\mathcal{L}''}$ with $\mathcal{L}'' = \frac{1}{2}(hD_1 k^{\mathrm{w}} + k^{\mathrm{w}} hD_1)$, $k = k(x', x_d, \mu^{-1}\xi'')$ one can reduce operator to the same form (20.3.15) but with $a^{11} = 1$.

(iii) In the general case we can achieve $a^{jk} = \delta_{jk}$ for $j, k = 1, \dots, q$ only assuming that g^{jk}, F_{jk} are constant.

20.3.4 Reduction. Junior Terms

Recall that junior terms are of the form $\frac{1}{2}(B+B^*)$ with B defined by (20.3.16) with $b^{jkm} = b^{jkm}(x, \mu^{-1}\xi)$ and $b^j = b^j(x, \mu^{-1}\xi)$.

Remark 20.3.5. As $(1,1) \preceq (l,\sigma) \preceq (2,0)$ one can rewrite B in the same form but with

$$b^{jkm} = b^{jkm}(x', \mu^{-1}\xi''; x'''), \qquad b^j = b^j(x', \mu^{-1}\xi''; x''') \tag{20.3.25}$$

modulo operator B' with the symbol belonging to $\mu^{-l}|\log\mu|^{-\sigma}\mathscr{F}^{0,0}$. Our reduction is done modulo operators of this type.

Then applying operator $e^{i\mu^{-2}h^{-1}\mathcal{L}_1}$ with

$$\mathcal{L}_1 = \Big(\sum_{\alpha:1\le|\alpha|\le 3} \beta^{(\alpha)}\mu^{|\alpha|}\eta^{\alpha}\Big)^{\mathsf{w}}, \tag{20.3.26}$$

where $\eta^{\alpha} = \eta_1^{\alpha_1}\cdots\eta_d^{\alpha_d}$, one can reduce operator to the same form (20.3.15) with

$$\begin{aligned} B \equiv \mu^2\Big(&\sum_{q+1\le j,k,m\le q+r} b^{jkm}\zeta_j^{\dagger}\zeta_k\zeta_m + \\ &\sum_{q+1\le j,k\le q+r,\ 1\le m\le q} b^{jkm}\eta_m\zeta_j^{\dagger}\zeta_k + \sum_{1\le j,k,m\le q} b^{jkm}\eta_m\eta_j\eta_k + \sum_{1\le j\le q} b^{j}\eta_j\Big)^{\mathsf{w}}. \end{aligned} \tag{20.3.27}$$

Here in the first term $b^{jkm} = 0$ unless $|f_j - f_k - f_m| \le \epsilon$ and in the second term $b^{jkm} = 0$ unless $|f_j - f_k| \le \epsilon$ (so there are the 3-rd and 2-nd order resonances respectively). Further, $b^{jkm} = 0$ always for constant g^{jk}, F_{jk}.

Also, in (20.3.26) $\beta^{(\alpha)}$ belongs to $\mathscr{F}^{\bar{l}-1,\bar{\sigma}}_{x'}$, $\mathscr{F}^{l-1,\sigma}_{x'}$ as $|\alpha|\ge 2$, $|\alpha| = 1$ respectively; also $b^{jkm} \in \mathscr{F}^{\bar{l}-1,\bar{\sigma}}_{x'}$, $b^{j} \in \mathscr{F}^{l-1,\sigma}_{x'}$.

Remark 20.3.6. (i) In the intermediate magnetic field case $|\eta_j| \le C\mu^{-1}$ in the microlocal sense (on the energy levels below c) and therefore junior terms are of magnitude μ^{-1} and skipping them we would arrive to an approximation error $Ch^{-d}(\mu h|\log h|)^{\frac{q}{2}}\mu^{-1}$ (as either $q\ge 2$, or $q = 1$ and the microhyperbolicity assumption is fulfilled, or $(l,\sigma)\succeq(2,0)$, and non-degeneracy assumption is fulfilled) which is $O(h^{1-d})$ as $q\ge 3$ and $O(h^{1-d}|\log h|)$ as $q = 2$.

Thus, in the case of an intermediate magnetic field only for $q = 1, 2$ we will need to take junior terms into account at all. This will be a minor annoyance for $q = 2$ but a major obstacle for $q = 1$, when without either microhyperbolicity or non-degeneracy assumptions this error would be $O\big(h^{-d}(\mu h|\log h|)^{\frac{1}{2}}\mu^{-1} + \mu^{\frac{1}{2}}h^{1-d}\big)$ but even under the microhyperbolicity or non-degeneracy assumptions these terms cannot be simply ignored.

(ii) Actually, not all of these terms are equally bad: terms containing factor(s) η_m with $1\le m\le q$ are of magnitude $O(\mu^{-1}|\xi'''|)$ and can be simply ignored if $q = 2$ but even if $q = 1$ they are minor annoyances. Only the first term in (20.3.27) are really important.

(iii) One can see easily that if $q = 1$ and f_j have constant multiplicities, then by means of transformation $e^{i\mu^{-1}h^{-1}\mathcal{L}'_1}$ with

$$\mathcal{L}'_1 = \mu^2\Big(\sum_{\mathfrak{m}}\sum_{j,k\in\mathfrak{m}} c^{jk}\zeta_j^\dagger\zeta_k + c_0\eta_1^2 + c_1\Big)^{\mathsf{w}}$$

with $c^{jk} = c^{jk}(x'', x_d, \mu^{-1}\xi'')$, $c_j = c_j(x'', x_d, \mu^{-1}\xi'')$ one can remove from B all terms containing factor η_1 thus arriving to

$$B \equiv \mu^2\Big(\sum_{q+1\le j,k,m\le q+r} b^{jkm}\zeta_j^\dagger\zeta_k\zeta_m\Big)^{\mathsf{w}}. \tag{20.3.28}$$

Therefore, we constructed operator $\mathcal{T}$ with the properties described below:

Proposition 20.3.7. *Let $(\bar{l},\bar{\sigma}) = (2,1)$, $(1,1) \preceq (l,\sigma) \preceq (2,0)$. Then there exists an operator $\mathcal{T}$ such that*

$$\mathcal{T}^*\mathcal{T}\bar{Q}\bar{\psi} \equiv \bar{Q}\bar{\psi}, \tag{20.3.29}$$

$$\mathcal{T}^*Q_1\mathcal{T}(I-\bar{Q})\bar{\psi} \equiv 0, \tag{20.3.30}$$

$$\mathcal{T}^*(I-Q_2)\mathcal{T}\bar{Q}\bar{\psi} \equiv 0 \qquad \mathsf{mod}\ \mu^{-\infty}(\mathscr{F}^{0,0})^{\mathsf{w}}, \tag{20.3.31}$$

$$\mathcal{T}^*\mathcal{A}\mathcal{T}\bar{Q}\bar{\psi} \simeq A\bar{Q}\bar{\psi}, \qquad \mathsf{mod}\ \mu^{-l}|\log h|^{-\sigma}(\mathscr{F}^{0,0})^{\mathsf{w}} \tag{20.3.32}$$

as $\bar{\psi} \in \mathscr{C}_0^\infty(B(0,1))$, $\bar{Q} = \bar{Q}(hD''')$ has a symbol which is supported in $\{|\xi'''| \le 2C\bar{\rho}_1\}$ and equal to 1 in $\{|\xi'''| \le 2C\bar{\rho}_1\}$, Q_1 and Q_2 are the same type operators but with symbols which are supported in $\{|\xi'''| \le 2\bar{\rho}_1\}$ and $\{|\xi'''| \le 2C^2\bar{\rho}_1\}$ and equal to 1 in $\{|\xi'''| \le \bar{\rho}_1\}$ and $\{|\xi'''| \le C^2\bar{\rho}_1\}$ respectively with large enough constant C, $\mathcal{A}$ is the reduced operator in the form (20.3.15) *with junior terms defined by* (20.3.27).

Further, if $q = 1$ and f_j have constant multiplicities, junior are terms defined by (20.3.28).

Remark 20.3.8. (i) Note that while (20.3.29)–(20.3.31) hold modulo negligible operator, (20.3.32) is satisfied modulo $\mu^{-1}h$-pseudodifferential operators with symbols of $\mu^{-l}|\log h|^{-\sigma}\mathscr{F}^{0,0}$, and to emphasize the difference we use "$\simeq$" instead of "$\equiv$".

(ii) In contrast to almost all this Chapter in Propositions 20.3.7, 20.3.9 b^{w} means $\mu^{-1}h$-quantization of symbol b.

We also need the following properties of operator constructed above:

Proposition 20.3.9. *Furthermore the constructed operator has the following properties:*

(i) For functions $\bar{\psi}=1$ *in* $B(0,\frac{3}{4})$ *and* $\psi\in \mathscr{C}_0^\infty(B(0,\frac{1}{2}))$

$$\psi\bar{Q}\bar{\psi}\equiv \mathcal{T}^*\tilde{\psi}^{\mathsf{w}}\mathcal{T}\bar{Q}\bar{\psi}, \tag{20.3.33}$$

$$\tilde{\psi}\simeq \psi_0(x'',x''',\xi'')+\sum_{1\le j\le d}\psi_j(x'',x''',\xi'')\eta_j \qquad \mathsf{mod}\ \mu^{-l}|\log h|^{-\sigma}\mathscr{F}^{0,0}. \tag{20.3.34}$$

(ii) For operator $Q=Q^{\mathsf{w}}(hD''')$ *as above*

$$\mathcal{T}^*Q\mathcal{T}\bar{\psi}\simeq \big(Q(f(x,\xi))\big)^{\mathsf{w}}\bar{\psi} \qquad \mathsf{mod}\ \mu^{-l}|\log h|^{-\sigma}(\mathscr{F}^{0,0})^{\mathsf{w}}, \tag{20.3.35}$$

$$f(x,\xi)\simeq \xi'''-\sum_{1\le j\le 2r}\kappa_j\eta_j-\mu^{-1}\kappa_0 \qquad \mathsf{mod}\ \mu^{-l}|\log h|^{-\sigma}\mathscr{F}^{0,0} \tag{20.3.36}$$

with coefficients $\kappa_j=\kappa_j(x'',x''',\mu^{-1}\xi'')$ *and all estimates holding for* $|\eta_j|\le C\mu^{-1}$, $\psi_j,\alpha_j\in \mathscr{F}^{l-1,\sigma}$.

Proof. We prove more difficult Statement (ii) leaving easier Statement (i) to the reader.

(i) On *Step 1* of the main part reduction we considered operator $e^{\frac{i}{2}\mu^{-1}h^{-1}t\mathcal{L}}$ with the corresponding symplectomorphism which is equivalent to the map $f_t:(x,\eta_1,\dots,\eta_d)\to(x,\eta_1,\dots,\eta_d)$ which is of $\mathscr{F}^{\bar{l},\bar{\sigma}}$ class. Let $Q_t=\big(Q(f_t)\big)^{\mathsf{w}}$; then the principal symbol of operator

$$\frac{\partial}{\partial t}Q_t+\frac{i}{2}\mu^{-1}h^{-1}\big[\mathcal{L},Q_t\big] \tag{20.3.37}$$

vanishes and then as long as $(\bar{l},\bar{\sigma})\succeq(2,1)$ and $\varepsilon\ge C(\mu^{-1}h|\log h|)^{\frac{1}{2}}$ the norm of this operator does not exceed

$$C\mu^{-1}h^{-1}\times\big(\frac{h}{\rho}\big)^2\le C\mu^{-1}h(\mu h|\log h)^{-1}=C\mu^{-2}|\log h|^{-1}$$

for $\rho\ge C(\mu h|\log h|)^{\frac{1}{2}}$. Then the norm of the operator

$$\frac{d}{dt}\Big(e^{-\frac{i}{2}\mu^{-1}h^{-1}t\mathcal{L}}Q_te^{\frac{i}{2}\mu^{-1}h^{-1}t\mathcal{L}}\Big) \tag{20.3.38}$$

does not exceed $C\mu^{-2}|\log h|^{-1}$ and then the same is true for operators

$$e^{-\frac{i}{2}\mu^{-1}h^{-1}t\mathcal{L}}Q_te^{\frac{i}{2}\mu^{-1}h^{-1}t\mathcal{L}}-Q \quad\text{and}\quad e^{\frac{i}{2}\mu^{-1}h^{-1}t\mathcal{L}}Qe^{-\frac{i}{2}\mu^{-1}h^{-1}t\mathcal{L}}-Q_t. \tag{20.3.39}$$

(ii) The same arguments work perfectly on *Step 2* of the main part reduction.

(iii) Now consider the junior terms reduction. First of all, there are removable terms $\sum_{q+1\le j\le q+2r}\beta_j\eta_j$ with $\beta_j=\beta_j(x'',\mu^{-1}\xi'')$, $\beta_j\in\mathscr{F}^{l-1,\sigma}$ which are removed by a transformation of the same type as above with $\mathcal{L}=\mu^{-1}\sum_{1\le j\le 2r}\beta'_j\eta_j$ and $\beta'_j=\beta'_j(x'',\mu^{1}\xi'')$, $\beta'_j\in\mathscr{F}^{l-1,\sigma}$ as well.

Then the corresponding Hamiltonian map is of class $\mathscr{F}^{l,\sigma}$ and then the principal symbol of operator (20.3.34) vanishes and the norm of this operator does not exceed

$$C\mu^{2-l}|\log h|^{-\sigma}\times\mu^{-1}h^{-1}\times\Big(\big(\frac{h}{\rho}\big)^2+\mu^{-1}h\big(\frac{h}{\rho}\big)\times\mu^{2-l}|\log h|^{-\sigma}\Big)\le C\mu^{-l}|\log h|^{-\sigma}\times\frac{\mu h}{\rho^2}$$

which is less than $C\mu^{-l}|\log h|^{-\sigma}$ and then the same estimate holds for operators (20.3.38)–(20.3.39).

With the removable third and second order terms the construction is the same but simpler since these terms are coming from the principal part which belongs to $\mathscr{F}^{2,1}$ for sure. □

Remark 20.3.10. In Chapter 18 in the case $d=3$ we took $\varepsilon=C(\mu^{-1}h|\log h|)^{\frac12}$ instead of $C\mu^{-1}$. The above construction would not work. In this case note first that the rescaling $x\mapsto\varepsilon^{-1}(x-\bar x)$ and taking $\hbar=\mu^{-1}h\varepsilon^{-2}=C^{-1}|\log h|^{-1}$ we will see that the original operator $\bar\chi(hD_1/\rho)$ becomes $\bar\chi(\hbar D_1)$ and $\mu^{-1}h^{-1}\mathcal{L}$ becomes $\nu\ell(x,\hbar D)$ with $\nu=\mu^{-2}\varepsilon^{-1}=C^{-1}(\mu^3h|\log h|)^{-\frac12}\le\epsilon_1$ and therefore $e^{i\mu^{-1}h^{-1}\mathcal{L}}$ becomes $\hbar$-pseudodifferential operator with "analytic" symbol (more precisely its symbol and those of Q satisfy assumptions of Subsection 1.1.3).

Then $e^{-i\mu^{-1}h^{-1}\mathcal{L}}Qe^{i\mu^{-1}h^{-1}\mathcal{L}}$ becomes $\hbar$-pseudodifferential operator which means that in the original scale it is $\mu^{-1}h$-pseudodifferential operator with $\mathscr{F}^{0,0}$ symbol supported in $\{|\xi_3|\le 2C\rho\}$ and equal 1 in $\{|\xi_3|\le C\rho\}$ with $\rho=\bar\rho_1=C(\mu h|\log h|)^{\frac12}$.

20.3.5 Temperateg and Stronger Magnetic Field

In this case we have

$$\mu\ge\epsilon(h|\log h|)^{-1}\tag{20.3.40}$$

and

$$\varepsilon = C(\mu^{-1}h|\log\mu|)^{\frac{1}{2}}. \tag{20.3.41}$$

Then construction of Subsections 3.3–3.4 works on every its step. Now in a microlocal sense $|\eta_j| \le C(\mu^{-1}h|\log h|)^{\frac{1}{2}}$ (on the energy levels below c), and therefore junior terms seem to be of magnitude $C\mu^2(\mu^{-1}h|\log\mu|)^{\frac{3}{2}}$ and cannot be skipped; even next junior terms are of magnitude $C\mu^2(\mu^{-1}h|\log\mu|)^2$ which is $O(h)$ as $h|\log\mu|^2 \le C$ only.

In fact, however, as we will see, junior terms will have no impact because the microlocal estimate will be replaced by an operator one $|\eta_j^{\mathsf{w}}| \le C(\mu^{-1}h)^{\frac{1}{2}}$ which is sufficient to estimate junior terms by Ch as long as $\mu \le C_0h^{-1}$ (strong and very strong magnetic field).

Further, for $\mu h \ge C_0h^{-1}$ (*strong* magnetic field, we consider Schrödinger-Pauli operator then) only the lowest Landau level is important where irreducible terms due to the 3-rd order resonances vanish and irreducible terms due to the 4-th order resonances are of magnitude $C\mu^2(\mu^{-1}h)^2 = O(h^2)$ in the operator sense.

20.4 Temperate Magnetic Field: Estimates

In this section we assume that the magnetic field is intermediate i.e. condition (20.3.3) is fulfilled. In this case we know that the contribution of the outer zone $\Omega_{\mathsf{out}} := \{|\xi'''| \ge \bar\rho_1 := C(\mu h|\log h|)^{\frac{1}{2}}\}$ to the Tauberian estimate with $T = \epsilon\mu^{-1}$ is $O(h^{-2})$ and therefore we need to consider a complementary zone $\Omega^{\mathsf{c}}_{\mathsf{out}} = \{|\xi'''| \le \bar\rho_1 := C(\mu h|\log h|)^{\frac{1}{2}}\} = \Omega_{\mathsf{intm}} \cup \Omega_{\mathsf{inn}}$ with an *intermediate zone*

$$\Omega_{\mathsf{intm}} := \bigl\{\bar\rho_1^* := C\max\bigl(\mu^{-1}, (\mu h)^{\frac{1}{2}}\bigr) \le |\xi'''| \le \bar\rho_1 = (\mu h|\log h|)^{\frac{1}{2}}\bigr\} \tag{20.4.1}$$

and an inner zone $\Omega_{\mathsf{inn}} = \{|\xi'''| \le \bar\rho_1^*\}$.

20.4.1 Intermediate Zone

General Arguments

Let us consider an intermediate zone (20.4.1). We split it into strips $\mathcal{Z}_\rho$ with ρ in the indicated framework:

$$\mathcal{Z}_\rho := \{(x,\xi) :\ \rho \le |\xi'''| \le 2\rho\}, \qquad \bar\rho_1^* \le \rho \le \bar\rho_1. \tag{20.4.2}$$

Proposition 20.4.1. *Let condition* (20.3.3) *be fulfilled and let* $Q = Q^{\mathrm{w}}$ *be an operator with the symbol supported in the strip* $\mathcal{Z}_\rho$*, and such that*

$$|\partial^\alpha_{x,\xi} Q| \le C_\alpha \rho^{-|\alpha|} \qquad \forall \alpha, \tag{20.4.3}$$

and let $\psi \in \mathscr{C}_0^\infty(B(0,1))$.

Let $\chi \in \mathscr{C}_0^\infty([-1,-\frac12] \cup [\frac12, 1])$. *Then estimate*

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma Q\psi U| \le Ch^{-d}T\rho^q\bigl(\rho^2 + \rho T + \mu^{-1}\bigr)\bigl(\frac{h}{\rho^2 T}\bigr)^s \tag{20.4.4}$$

holds as

$$T_* = \frac{h}{\rho^2} \le T \le T^* = \epsilon\rho \tag{20.4.5}$$

with an arbitrarily large exponent s.

Proof. Proof repeats those of analysis in Section 18.8. First of all, let us make γ-partition with respect to (x'', ξ'', x''') with

$$\gamma \ge C\mu^{-1} + C(\mu^{-1}h|\log h|)^{\frac12} \tag{20.4.6}$$

and consider some element $\psi'(x)$ of this partition supported in $B(\bar x, \gamma)$. Let us reduce operator to its canonical form in $B(\bar x, 2\gamma)$; without any loss of the generality one can assume that this canonical form is

$$\sum_{1\le j\le r} \bar f_j(h^2 D^2_{q+j} + \mu^2 x^2_{q+j}) + \sum_{1\le j\le q} h^2 \bar g^{jk} D_j D_k + \bar V + O(\gamma) \tag{20.4.7}$$

there where $\bar f_j$, $\bar g^{jk}$ and $\bar V$ are constant (and we can assume that $\bar g^{jk} = \delta_{jk}$, $O(\gamma)$ covers variations of f_j, V as well as unremovable terms and we are discussing only $B(\bar x, 2\gamma)$.

Let us decompose $\mathsf{U} := \mathcal{T}U$ into the sum

$$(\mathcal{T}U)(x,y,t) = \sum_{\alpha,\beta\in\mathbb{Z}^{+\,r}} \mathsf{U}_{\alpha,\beta}(x'', x''', y'', y''', t)\Upsilon_\alpha(x')\Upsilon_\beta(y') \tag{20.4.8}$$

with $\Upsilon_\alpha(x') = \hbar^{-\frac{r}{2}}\prod_j \upsilon_{\alpha_j}(x_{q+j}/\hbar)$, $\hbar = (\mu^{-1}h)^{\frac12}$ and Hermite functions υ_*.

Then modulo $O(\gamma)$ in $\mathscr{L}^2$-norm operator $\mathcal{A}$ applied to the terms containing $\Upsilon_\alpha(x')$ in this sum becomes

$$\bar{\mathcal{A}}_\alpha = \sum_{1\le j\le r} \bar f_j(2\alpha_j + 1)\mu h + \sum_{1\le j\le q} h^2 D_j^2 + \bar V \tag{20.4.9}$$

which is a temporary notation.

Let us strengthen condition (20.4.6) assuming that

$$\gamma \ge \rho^2 + \mu h + \mu^{-1}. \tag{20.4.10}$$

Then using our standard methods one can prove easily that for $Q' = Q\mathcal{T}\psi'\mathcal{T}^*$ the following inequality holds

$$\begin{aligned} |F_{t\to h^{-1}\tau}\chi_T(t)\Gamma' Q'\psi \mathsf{U}_{\alpha,\beta}| \le \\ C\mu^r h^{-r-q}\rho^q\gamma^d T \times \Big(\big(\frac{h}{\rho^2 T}\big)^s + \big(\frac{h}{\rho\gamma}\big)^s + \big(\frac{\mu^{-1}h}{\gamma^2}\big)^s\Big)\times \\ \Big(\frac{\gamma}{\gamma + |\mu h \sum_j \bar{f}_j(\alpha_j - \bar{\alpha}_j)|}\Big)^s \times \Big(\frac{\gamma}{\gamma + |\mu h \sum_j \bar{f}_j(\beta_j - \bar{\alpha}_j)|}\Big)^s \end{aligned} \tag{20.4.11}$$

with some $\bar{\alpha} = \bar{\alpha}(\tau) \in \mathbb{Z}^{+r}$ where

$$\Gamma' v := \int v|_{x''=y'',x'''=y'''}\, dy''\, dy'''. \tag{20.4.12}$$

Here factor $\mu h^{1-d}\rho^q\gamma^d$ in the right-hand expression comes as a trace norm of $Q'\mathsf{U}_{\alpha,\beta}$; factor T is a result of integration with respect to t in the Fourier transform, the second factor is the sum of three terms: the first one $\big(h/(\rho^2 T)\big)^s$ is due to the microhyperbolicity with respect to ξ''' and rescaling while terms $\big(h/(\rho\gamma)\big)^s$ and $\big(\mu^{-1}h/(\gamma^2)\big)^s$ are operator calculus errors.

Finally, two last factors in the right-hand expression of (20.4.11) are due to the ellipticity of operators $\big(hD_t - \bar{\mathcal{A}}_\alpha\big)$ and $\big(hD_t - \bar{\mathcal{A}}_\beta\big)$ respectively.

More precisely, let us note that operator $\big(\bar{\mathcal{A}}_\alpha + O(\gamma) - \tau\big)$ is elliptic in this vicinity as long as $\alpha \notin \mathfrak{A}$ where

$$\mathfrak{A} := \{\alpha \in \mathbb{Z}^{+r} : |\sum_j (2\alpha_j + 1)\bar{f}_j\mu h + \bar{V} - \tau| \le \gamma\}. \tag{20.4.13}$$

Really, we can express there $\mathsf{U}_{\alpha,*}$ with $\alpha \notin \mathfrak{A}$ via $\mathsf{U}_{\alpha',*}$ with $\alpha' \in \mathfrak{A}$. Namely, for $\alpha \notin \mathfrak{A}$ we have

$$\begin{aligned} |F_{t\mapsto h^{-1}\tau}\chi_T(t)Q'\mathsf{U}_{\alpha,\beta}| \le \\ \max_{\alpha'\in\mathfrak{A}} |F_{t\mapsto h^{-1}\tau}\chi_T(t)Q'\mathsf{U}_{\alpha',\beta}| \times \Big(\gamma\big(|\sum_j (2\alpha_j+1)\bar{f}_j\mu h + \bar{V}| + \gamma\big)^{-1}\Big)^s \end{aligned} \tag{20.4.14}$$

The similar inequality holds for $\mathsf{U}_{*,\beta}$ with $\beta \notin \mathfrak{A}$. Finally, for $\mathsf{U}_{\alpha,\beta}$ with arbitrary $\alpha, \beta \notin \mathfrak{A}$

$$|F_{t\mapsto h^{-1}\tau}\chi_T(t)Q'U\alpha,\beta| \le \max_{\alpha',\beta'\in\mathfrak{A}} |F_{t\mapsto h^{-1}\tau}\chi_T(t)Q'\mathsf{U}_{\alpha',\beta'}|\times \tag{20.4.15}$$
$$\Big(\gamma\big(|\sum_j (2\alpha_j+1)\bar{f}_j\mu h+\bar{V}|+\gamma\big)^{-1}\Big)^s \times \Big(\gamma\big(|\sum_j (2\beta_j+1)\bar{f}_j\mu h+\bar{V}|+\gamma\big)^{-1}\Big)^s$$

which in combination with the microhyperbolicity arguments justifies (20.4.11).

Note also that $\#\mathfrak{A} \le C\gamma(\mu h)^{-r}$. Then (20.4.11) implies

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma Q'\psi U| \le \tag{20.4.16}$$
$$C\mu^r h^{-r-q}\rho^q\gamma^d T \times \Big(\big(\frac{h}{\rho^2 T}\big)^s + \big(\frac{h}{\rho\gamma}\big)^s + \big(\frac{\mu^{-1}h}{\gamma^2}\big)^s\Big) \times \gamma(\mu h)^{-r} =$$
$$Ch^{-d}T\rho^q\gamma^{d+1}\Big(\big(\frac{h}{\rho^2 T}\big)^s + \big(\frac{h}{\rho\gamma}\big)^s + \big(\frac{\mu^{-1}h}{\gamma^2}\big)^s\Big).$$

Restoring to original Q, ψ (by summation over x-partition) we lose factor γ^d. As exponent s is large enough, the optimal value of γ honoring (20.4.10) is $\gamma = \rho T + \rho^2 + \mu^{-1}$ because for $\rho \ge \mu^{-1}$ (which we assume) $\gamma^2 \ge \mu^{-1}\rho^2 T$.

Then we arrive to estimate (20.4.4). □

Proposition 20.4.1 implies immediately estimate

$$|F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t) - \bar{\chi}_{\bar{T}}(t)\big)\Gamma Q\psi U| \le Ch^{-d}\mu^{-1}\rho^q(\rho^2+\mu^{-1}) \times \big(\frac{\mu h}{\rho^2}\big)^s \tag{20.4.17}$$

with $\bar{\chi} \in \mathscr{C}_0^\infty([-1,1])$ equal 1 on $[-\frac{1}{2},\frac{1}{2}]$, $T_* = \epsilon\mu^{-1}$ as T satisfies

$$\bar{T} = \epsilon\mu^{-1} \le T \le T^* = \epsilon\rho. \tag{20.4.18}$$

In turn (20.4.17) implies

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma Q\psi U| \le Ch^{-d}\mu^{-1}\rho^q(\rho^2+\mu^{-1}) \times \big(\frac{\mu h}{\rho^2}\big)^s + Ch^{1-d}\rho^q \tag{20.4.19}$$

where $C\rho^q h^{1-d}$ estimates $|F_{t\to h^{-1}\tau}\bar{\chi}_{T_*}(t)\Gamma Q\psi U|$ due to the standard results rescaled.

Therefore the standard Tauberian arguments immediately imply estimate

$$\mathsf{R}^{\mathsf{T}}_{Q} \coloneqq |\Gamma(Q\psi\tilde{e}) - h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar{\chi}_{T}(t)\Gamma Q\psi u\Big)\,d\tau| \le \tag{20.4.20}$$
$$CT^{-1}\Big(Ch^{-d}\mu^{-1}\rho^{q}(\rho^{2}+\mu^{-1})\times\big(\frac{\mu h}{\rho^{2}}\big)^{s} + Ch^{1-d}\rho^{q}\Big) =$$
$$Ch^{-d}\mu^{-1}\rho^{q-1}(\rho^{2}+\mu^{-1})\times\big(\frac{\mu h}{\rho^{2}}\big)^{s} + Ch^{1-d}\rho^{q-1}$$

with any

$$T_{*} \coloneqq Ch|\log h|/\rho^{2} \le T \le \epsilon\rho. \tag{20.4.21}$$

Case $q \ge 2$

Consider $q \ge 2$ (we analyze the case of $q = 1$ later). Integrating the first term in the right-hand expression of (20.4.20) by $d\rho/\rho$ from $\bar{\rho}_{1}^{*} = C(\mu h)^{\frac{1}{2}}$ to $\bar{\rho}_{1}$ we get its value as $\rho = \bar{\rho}_{1}^{*}$; one can see easily that the result will be then less than Ch^{1-d}. The same integration by $d\rho/\rho$ applied to the second term in the right-hand expression of (20.4.20) results in $O(h^{1-d})$ for sure.

Thus for $q \ge 2$ in the whole intermediate zone $\{\bar{\rho}_{1}^{*} \le |\xi'''| \le \bar{\rho}_{1}\}$ we get a proper remainder estimate

$$\mathsf{R}^{\mathsf{T}}_{1\,Q} \coloneqq |\Gamma(Q\psi\tilde{e}) - h^{-1}\int_{-\infty}^{0}\sum_{0\le n\le \bar{n}}\Big(F_{t\to h^{-1}\tau}\bar{\chi}_{T_{n}}(t)\Gamma Q_{n}\psi U\Big)\,d\tau| \le \tag{20.4.22}$$
$$Ch^{1-d}$$

as $Q = \sum_{0\le n\le \bar{n}} Q_{n}$, where Q_{n} are operators with the symbols supported in $\{\rho_{n} \le |\xi'''| \le \rho_{n+1}\}$, $\rho_{n} = 2^{n}\bar{\rho}_{1}^{*}$, $\rho_{\bar{n}} \asymp \bar{\rho}_{1}$, and satisfying (20.4.3), $Ch|\log h|/\rho_{n}^{2} \le T_{n} \le \epsilon\rho_{n}$. Therefore we arrive to

Proposition 20.4.2. *For $q \ge 2$ in the framework of Proposition 20.4.1 estimate* (20.4.22) *holds for operator $Q = Q^{\mathsf{w}}$ with the symbol supported in $\Omega_{\mathsf{intm}} = \{\bar{\rho}_{1}^{*} \le |\xi'''| \le \bar{\rho}_{1}\}$ and satisfying* (20.4.3).

Now let us consider the expression

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\chi_{T}(t)\Gamma Q\psi U\Big)\,d\tau \tag{20.4.23}$$

where again Q is an operator with the symbol supported in $\mathcal{Z}_\rho$, $T \in [T_*, T^*]$, $T^* = \epsilon\rho$, $\rho \in [\bar\rho_1^*, \bar\rho_1]$. Recall that $\chi \in \mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1])$. Also recall that one can rewrite (20.4.23) as

$$T^{-1}\Bigl(F_{t\to h^{-1}\tau}\check\chi_T(t)\Gamma Q\psi U\Bigr)\Big|_{\tau=0} \tag{20.4.24}$$

with $\check\chi(t) = it^{-1}\chi(t)$ and due to Proposition 20.4.1 expression (20.4.24) does not exceed

$$Ch^{-d}\rho^{q+2}\times \bigl(\frac{h}{T\rho^2}\bigr)^s. \tag{20.4.25}$$

Making a summation with respect to $T \in [T_*, T^*]$ we get its value at $T = \bar T = \epsilon\mu^{-1}$ i.e. $Ch^{-d}\rho^{q+2}(\mu h/\rho^2)^s$. Then after summation with respect to $\rho \in [\bar\rho_1^*, \bar\rho_1]$ we get its value at $\rho = \bar\rho_1^*$ i.e. $Ch^{-d}(\mu h)^{\frac{q}{2}+1}$. Estimating roughly contribution of the inner zone $\Omega_{\mathsf{inn}} = \{|\xi'''| \le C\bar\rho_1^*\}$ by $C\mu h^{1-d}(\bar\rho_1^*)^q$ and estimating contribution of the outer zone by Ch^{1-d} due to the results of Section 20.2 we arrive to the estimate

$$\mathsf{R}^{\mathsf{T}} = |\Gamma(\psi\tilde e) - h^{-1}\int_{-\infty}^0 \Bigl(F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma\psi U\Bigr)\,d\tau| \le Ch^{1-d} + C(\mu h)^{\frac{q}{2}+1}h^{-d} \tag{20.4.26}$$

with $T = \bar T = \epsilon\mu^{-1}$.

On the other hand, due to the standard results rescaled for $q \ge 2$

$$|h^{-1}\int_{-\infty}^0 \Bigl(F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma\psi U\Bigr)\,d\tau - h^{-d}\int \mathcal{N}^{\mathsf{MW}}(x,\tau)\psi(x)\,dx| \le Ch^{1-d} + C(\mu h)^{\frac{q}{2}+1}h^{-d} \tag{20.4.27}$$

as $T = \bar T$ because with our choice (20.3.5) for ε, a mollification error does not exceed Ch^{1-d} as well.

Thus we arrive to

Theorem 20.4.3. *Let conditions* (20.1.1), (20.1.5), (20.1.7), (20.1.8)–(20.1.11), *and* (20.2.31) *be fulfilled,* $(\bar l, \bar\sigma) = (2,1)$, $(l,\sigma) = (1,1)$.

Let $q \ge 2$ *and condition* (20.3.3) *be fulfilled.*

(i) Then there exist two framing approximations (see footnote [18)] of Chapter 18) such that for both of them

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + Ch^{-d}(\mu h)^{\frac{q}{2}+1}; \tag{20.4.28}$$

in particular $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d}$ *as*

$$\mu \le \bar{\mu}^*_{(q)} := Ch^{-\frac{q}{q+2}}. \tag{20.4.29}$$

(ii) Furthermore, the same estimates hold for $\mathsf{R}^{\mathsf{W}}_{(\infty)}$.

Now we can assume instead of (20.3.3) that

$$\bar{\mu}^*_{(q)} \le \mu \le \epsilon(h|\log h|)^{-1}. \tag{20.4.30}$$

In this case we will use the following corollary of (20.4.20):

Proposition 20.4.4. *Let* $q \ge 2$ *and* (20.4.30) *hold and* $Q = Q(hD''')$, $Q = Q(\xi''')$ *be operator with symbol supported in* $\mathcal{Z}_\rho$, $\bar{\rho}^*_1 \le \rho \le \bar{\rho}_1$, $\psi \in \mathscr{C}^\infty_0(B(0,1))$. *Then*

$$\mathsf{R}^{\mathsf{T}}_Q = |\Gamma(Q\tilde{e}) - h^{-1}\int_{-\infty}^0 \Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma Q\psi U\Big)\,d\tau| \le Ch^{1-d}\rho^{q-1} \tag{20.4.31}$$

as $Ch|\log h|/\rho^2 \le T \le T^* = \epsilon\rho$ *and*

$$\mathsf{R}^{\mathsf{T}}_{\bar{T},Q} = |\Gamma(Q\tilde{e}) - h^{-1}\int_{-\infty}^0 \Big(F_{t\to h^{-1}\tau}\bar{\chi}_{\bar{T}}(t)\Gamma Q\psi U\Big)\,d\tau| \le Ch^{1-d}\rho^{q-1} + Ch^{-d}\big(\frac{\mu h}{\rho^2}\big)^s\rho^q. \tag{20.4.32}$$

with $\bar{T} = \epsilon\mu^{-1}$.

Note that the right-hand expression of (20.4.31) integrated by $d\rho/\rho$ does not exceed Ch^{1-d}.

Case $q \ge 2$ (Some Calculations)

Now we can apply the technique of the previous subsubsection to calculate the Tauberian expression

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\phi_T(t)\Gamma Q\psi U\Big)\,d\tau \tag{20.4.33}$$

with $\phi=\bar\chi$. Let us consider the difference

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\phi_T(t)\Gamma Q\psi (U-U')\Big)\,d\tau \tag{20.4.34}$$

between (20.4.33) and the same expression for the perturbed operator $A'=A+O(\mu^{-1})$. Then expression (20.4.34) is equal to $I_0+I_1+...+I_{\bar n}$ where I_0 is defined by (20.4.34) with $\phi=\bar\chi$ and T replaced by $T_*=\epsilon\mu^{-1}$ and I_n are defined by (20.4.34) with $\phi=\chi$ and $T=2^n\bar T$, $n=1,...,\bar n$, $\bar n=\lceil T/\bar T\rceil$.

Applying arguments of the previous subsubsection and observing that

(20.4.35) An operator norm of $\Big(e^{ih^{-1}tA}-e^{ih^{-1}tA'}\Big)$ does not exceed $C\mu^{-1}h^{-1}T$ as $|t|\asymp T$,

we conclude that I_n does not exceed expression (20.4.25) multiplied by $C\mu^{-1}h^{-1}T$ as $n\ge 1$, i.e.

$$|h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\chi_T(t)\Gamma Q\psi (U-U')\Big)\,d\tau|\le Ch^{-d}\rho^{q+2}\times\big(\frac{h}{\rho^2T}\big)^s\times\mu^{-1}h^{-1}T. \tag{20.4.36}$$

Recall that with cut-off χ_T we can replace h^{-1} by T^{-1} and χ by $\check\chi$ like in (20.4.24), also $\rho^2\ge\mu h\ge\mu^{-1}$ due to $\mu\ge h^{-\frac12}$ as $q\ge 2$.

After summation with respect to n (i.e. T) we get the same expression I_0 with $T=\bar T$:

$$|h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\big(\bar\chi_T(t)-\bar\chi_{\bar T}(t)\big)\Gamma Q\psi (U-U')\Big)\,d\tau|\le C\mu^{-2}h^{-d-1}\rho^{q+2}\big(\frac{\mu h}{\rho^2}\big)^s. \tag{20.4.37}$$

Note that the right-hand expression in (20.4.37), integrated by $d\rho/\rho$ from $\bar{\rho}_1^*$ to 1, does not exceed its value as $\rho = \bar{\rho}_1^*$ i.e. $C\mu^{-2}h^{-d-1}(\mu h)^{\frac{1}{2}(q+2)} = Ch^{1-d}(\mu h)^{\frac{1}{2}(q-2)}$.

Therefore for $q \ge 2$ and Q supported in the intermediate zone expression (20.4.34) is equal to I_0 modulo $O(h^{1-d})$. However, for I_0 we can apply the standard theory rescaled and replace it by the difference of the Weyl expressions for A and A' (we will do it in Section 20.6). So far we proved

Proposition 20.4.5. *In the framework of Proposition 20.4.4*

$$|\Gamma(Q\psi\tilde{e}) - h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma Q\psi U^0 - F_{t\to h^{-1}\tau}\bar{\chi}_{\bar{T}}(t)\Gamma Q\psi(U-U^0)\Big)\,d\tau| \le Ch^{1-d} \tag{20.4.38}$$

where U^0 is a Schwartz kernel of $e^{ih^{-1}tA^0}$, $A^0 = \mathcal{T}^*\mathcal{A}^0\mathcal{T}$,

$$\mathcal{A}^0 := \mu^2 \sum_{q+1\le j,k\le q+r} \zeta_j^{\dagger\mathsf{w}} a^{jk\mathsf{w}}\zeta_k^{\mathsf{w}} + h^2\sum_{j,k\le q} D_j g^{jk\mathsf{w}} D_k + a_0^{\mathsf{w}} \tag{20.4.39}$$

is the main part of $\mathcal{A}$.

Case $q = 1$

Let us repeat arguments of Subsubsection 20.4.1.1 first as $q = 1$,

$$(h|\log h|)^{-\frac{1}{3}} \le \mu \le \epsilon(h|\log h|)^{-1}, \tag{20.4.40}$$

$$|\xi_1| \asymp \rho \ge \bar{\rho}_1^* = C(\mu h)^{\frac{1}{2}} + C\mu^{-1}. \tag{20.4.41}$$

The first problem is that the factor $(\rho^2 + \mu^{-1})$ in the right-hand expression of (20.4.17) is too large as $\mu \le Ch^{-\frac{1}{2}}$; further, even if there are no unremovable cubic terms, one should take factor $(\rho^2 + \rho^{-1}h|\log h|)$ instead because we need to take $C\rho^{-1}h|\log h|$ scale with respect to x_1. We handled this problem in Chapter 18 as $d = 3$ and the idea from there (may be combined with the idea used in Subsection 20.2.3) is applicable now.

(i) The factor problem is rather simple. Let us assume first that g^{jk}, F_{jk} are constant (and in particular there no unremovable cubic terms).

Then this problem arrises only as $\rho^3 \le h|\log h|$ which implies $\mu \le h^{-\frac{1}{3}}|\log h|^{\frac{2}{3}}$.

Let us consider a γ-covering with $\gamma = \rho^\delta$ and consider separately two types of elements:

(a) Elements with $|\nabla V| \ge \zeta = |\log h|^{-2}$. If $|\partial_{x_1} V| \ge \zeta$ we have that ξ_1-shift for time $T \in [T_*, \rho^{\delta_1}]$, $T_* = \epsilon\mu^{-1}$ is of magnitude no less than ζT and then since logarithmic uncertainty principle is fulfilled

$$\mu^{-1}\zeta \times \varepsilon \asymp \mu^{-2}\zeta \ge Ch|\log h|$$

we conclude that $\chi_T \Gamma Q\psi u$ is negligible; otherwise $|\nabla_\perp V| \ge \zeta$ and similar arguments work for (x'', ξ'')-shifts.

(b) Elements with $|\nabla V| \le \zeta$. We can take on them $\gamma = C(\mu^{-1}h)^{\frac{1}{2}}|\log h|$ which is larger than $C\rho^{-1}h|\log h|$ and replace the term γ by $C(\zeta\gamma + \gamma'|\log h|^{-\sigma})$ which does not exceed $C\mu h$. In this case one can take $T_1 = \epsilon\rho\zeta^{-1}$.

(ii) Similar analysis combined with ideas of Subsection 20.2.3 works in the general case as long as there are no unremovable cubic terms. We leave all the details to the reader.

(iii) If there are unremovable terms of this type one can replace decomposition (20.4.8) by a similar decomposition with Υ_α orthonormal eigenfunctions of an auxiliary operator

$$\boldsymbol{a} = \mathcal{A}_0 + \mu^{-1} \sum_{j,k,m \le 2r} \beta_{jkm} L_j L_k L_m + C_0 \mu^{-2} \mathcal{A}_0^2 \tag{20.4.42}$$

with

$$\mathcal{A}_0 = \sum_{1 \le j \le r} \bar{f}_j \bigl(\mu^2 h^2 D_{q+j}^2 + x_{q+j}^2\bigr), \tag{20.4.43}$$

where $L_{2j-1} = \mu h D_{q+j}$, $L_{2j} = x_{q+j}$ and Υ_β are replaced by their complex conjugates). We added the last term in (20.4.42) to make operator non-negative and self-adjoint; this term is $O(\mu^{-2})$ on U and thus it is included in the approximation error estimate $O(\mu^{-l}|\log\mu|^{-\sigma})$ anyway. We got operator (20.4.43) by rescaling $x' \mapsto \mu^{-1}x'$, $D_j \mapsto \mu D_j$.

For an eigenvalue counting function $\boldsymbol{n}(\tau, \hbar)$ of this operator $\boldsymbol{a}$ in $\mathscr{L}^2(\mathbb{R}^r)$ the standard semiclassical eigenvalue asymptotics holds

$$\boldsymbol{n}(\tau, \hbar) = \boldsymbol{n}^{\mathsf{W}}(\tau, \hbar) + O(\hbar^{1-r}), \qquad \boldsymbol{n}^{\mathsf{W}} \asymp \hbar^{-r} \qquad \text{as } \hbar \to +0 \tag{20.4.44}$$

and in particular

$$\boldsymbol{n}(\tau + \hbar, \hbar) - \boldsymbol{n}(\tau, \hbar) = O(\hbar^{1-r}) \tag{20.4.45}$$

where $\boldsymbol{n}^{\mathsf{W}}$ means Weyl expression for $\boldsymbol{a}$ and we plug $\hbar = \mu h$.

Then the same modifications hold for estimates (20.4.17) and (20.4.19) as well and then the standard Tauberian arguments improve estimate (20.4.20) to

$$\mathsf{R}^{\mathsf{T}}_{Q} \le C\Big(h^{-d}\mu^{-1}\rho^2 \times \big(\frac{\mu h}{\rho^2}\big)^{s} + Ch^{1-d}\Big)\,|\log \rho|^{-2} \tag{20.4.46}$$

as $\mu \le h^{\delta-1}$ because $T^* \ge \epsilon_1\rho|\log\rho|^2$ now.

Integrating the right-hand expression over $d\rho/\rho$ from $\bar{\rho}_1^*$ to $\bar{\rho}_1$ we get $O(h^{1-d})$ then as long as $\mu \le h^{\delta-1}$. However for $h^{\delta-1} \le \mu \le \epsilon(h\log h|)^{-1}$ we can take only $T^* = \epsilon_1\rho$ and recover estimate $O(h^{1-d}|\log h|)$.

On the other hand, under the microhyperbolicity assumption for $\mu \le \epsilon(h|\log h|)^{-1}$ we can take $T^* = \epsilon_1$ and recover estimate $O(h^{1-d})$ again.

Thus we have proven

Proposition 20.4.6. *Let $q = 1$, $(l,\sigma) = (1,2)$. Then*

(i) Estimate (20.4.28) *holds. In particular for $\mu \le Ch^{-\frac{1}{3}}$ sharp remainder estimate $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d}$ holds.*

(ii) In the framework of Proposition 20.4.2 $\mathsf{R}^{\mathsf{T}}_{1\,Q}$ defined by (20.4.22) *does not exceed $Ch^{1-d}|\log h|$ where again $T_n = \epsilon\rho_n$.*

(iii) If <u>either</u> $\mu \le h^{\delta-1}$ <u>or</u> f_j have constant multiplicities <u>or</u> the microhyperbolicity condition is fulfilled at level 0, then $\mathsf{R}^{\mathsf{T}}_{1\,Q}$ defined by (20.4.22) *does not exceed Ch^{1-d} where $T_n = \rho_n|\log\rho_n|^2$.*

(iv) Furthermore, if Q is supported in $\{|\xi'''| \ge \rho\}$ and equal 1 in $\{2|\xi'''| \ge \rho\}$ then $\mathsf{R}^{\mathsf{T}}_{\bar{T}\,Q}$ defined by (20.4.32) *does not exceed $Ch^{1-d} + Ch^{-d}\rho\big(\mu h/\rho^2\big)^{s}$.*

Case $q = 1$ (Calculations)

Let us apply for $q = 1$ the same arguments as we did for $q \ge 2$ in Subsubsection 20.4.1.3. However as perturbation is $O(\mu^{-1})$ it makes sense only for $\mu \ge h^{-\frac{1}{2}}$ resulting in $Ch^{1-d}(\mu h)^{-\frac{1}{2}} = C\mu^{-\frac{1}{2}}h^{\frac{1}{2}-d}$ which is less than the weak magnetic field estimate only in this case.

On the other hand, as perturbation is $O(\mu^{-1})$ these arguments make sense as $\mu \ge h^{-\frac{1}{3}}$ resulting in $C\mu^{-\frac{3}{2}}h^{\frac{1}{2}-d} = O(h^{1-d}$.

Leaving easy details to the reader we arrive to the following

Proposition 20.4.7. [10] *In the framework of Proposition 20.4.6*

(i) Estimate (20.4.38) *holds as either there are no* 3*-rd order resonances or we include in unperturbed operator* $\mathcal{A}^0$ *non-removable* $O(\mu^{-1})$ *terms like in* (20.4.42)*.*

(ii) If there are non-removable $O(\mu^{-1})$ *terms and we do not include them into* $\mathcal{A}^0$ *then as* $\mu \ge h^{-\frac{1}{2}}$ *the left-hand expression of* (20.4.38) *does not exceed* $C\mu^{-\frac{1}{2}}h^{\frac{1}{2}-d}$*.*

We will return to the intermediate zone (for $q = 1$) later under microhyperbolicity or non-degeneracy assumptions.

20.4.2 Inner Zone

Now let us consider an *inner zone*

$$\Omega_{\mathsf{inn}} = \{|\xi'''| \le \bar{\rho}_1^* = (\mu h)^{\frac{1}{2}}\}. \tag{20.4.47}$$

Case $q \ge 2$

Assume that $q \ge 2$ and (20.4.30) holds. Then one can see easily that

(20.4.48) The perturbation of the magnitude $O(\mu^{-1})$ in $\Omega_{\mathsf{inn}} \cup \Omega_{\mathsf{intm}}$ leads to an error $O(\mu^{-1}\bar{\rho}_1^{*q}h^{-d}) = O(h^{1-d})$ in $h^{-d}\mathcal{N}_Q^{\mathsf{MW}}$.

Therefore for $q \ge 2$ instead of $\mathcal{A}$ one can consider in $\Omega_{\mathsf{inn}} \cup \Omega_{\mathsf{intm}}$ a reduced operator $\mathcal{A}^0$ with the coefficients

$$a^{jk\,\mathsf{w}} = a^{jk}(x'', x''', \mu^{-1}hD''), \qquad g^{jk\,\mathsf{w}} = g^{jk}(x'', x''', \mu^{-1}hD''),$$
$$a_0^{\mathsf{w}} = a_0(x'', x''', \mu^{-1}hD''), \qquad \zeta_j^{\mathsf{w}} = \mu^{-1}hD_j + ix_j$$

where $a^{jk} = 0$ unless $\exists \mathfrak{m} : j, k \in \mathfrak{m}$; this substitution leads to an error $O(h^{1-d})$ in $\mathsf{R}_Q^{\mathsf{T}}$. However we provided different arguments for inner zone Ω_{inn} and intermediate zone Ω_{intm} to justify this replacement.

Moreover, if f_j had constant multiplicities we would have even

$$\mathcal{A}^0 = \mu^2 \sum_{j\le r} f_j\big(h^2D_j^2 + \mu^2x_j^2 - \mu h\big) + h^2 \sum_{j,k\ge 2r+1} D_j^{\mathsf{w}} g^{jk\,\mathsf{w}} D_k^{\mathsf{w}} + a_0^{\mathsf{w}} \tag{20.4.49}$$

[10] Cf. Proposition 20.4.5

and decomposing $\mathcal{T}U$ into (20.4.8) series we would arrive to the family of operators

$$\mathcal{A}_\alpha := h^2 \sum_{j,k\ge 2r+1} D_j g^{jk\,\mathsf{w}} D_k + W_\alpha^{\mathsf{w}}, \qquad W_\alpha = a_0 + \sum_{j\le r} (2\alpha_j+1)\mu h f_j \tag{20.4.50}$$

with $\alpha \in \mathbb{Z}^{+r}$ and we would be able to apply without any significant modifications analysis of Sections 4.6 and 5.4.

However, we need to consider more general operator (20.4.39). Consider operator $Q = Q^{\mathsf{w}}$ with symbol supported in $\mathcal{Z}_\rho$ with $\rho \le \bar\rho_1^*$.

Repeating arguments of the proof of Proposition 20.4.1 we arrive to estimate (20.4.16) where $Q' = \mathcal{T} Q \psi' \mathcal{T}^*$, ψ' is an element of γ-admissible partition in (x'', x''', ξ''), $\gamma \ge \mu h$.

Restoring to Q we arrive to the estimate

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma Q\psi U| \le Ch^{-d} T\rho^q\gamma\Big(\big(\frac{h}{\rho^2 T}\big)^s + \big(\frac{h}{\rho\gamma}\big)^s + \big(\frac{\mu^{-1}h}{\gamma^2}\big)^s\Big). \tag{20.4.51}$$

As $q \ge 2$ and $\mu \ge \bar\mu^*_{(q)}$ we can take $\gamma \ge \mu h$ and $\rho \ge \bar\rho_0 \ge \mu^{-\frac12}$; remaining *inner core*

$$\Omega^0_{\mathsf{inn}} = \{|\xi'''| \le \bar\rho_0\} \tag{20.4.52}$$

will be considered separately. Then both $h/(\rho\gamma) = 1/(\mu\rho)$ and $\mu^{-1}h/\gamma^2 = 1/(\mu^3 h)$ do not exceed h^δ and we arrive to the estimate

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma Q\psi U| \le C\mu h^{1-d} T\rho^q\big(\frac{h}{\rho^2 T}\big)^s \tag{20.4.53}$$

which in turn implies

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma Q\psi U| \le C\mu h^{1-d}\rho^q \times \frac{h}{\rho^2} = C\mu h^{2-d}\rho^{q-2}, \tag{20.4.54}$$

$$\text{as} \quad T_* := \epsilon\frac{h}{\rho^2} \le T \le T^* = \epsilon\rho.$$

Therefore, the contribution of zone $\mathcal{Z}_\rho$ to the remainder is $O(\mu h^{2-d}\rho^{q-3})$; integrated over $d\rho/\rho$ it results in $O(\mu h^{2-d}) = O(h^{1-d})$ for $q \ge 4$, $O(\mu h^{2-d}|\log h|) = O(h^{1-d})$ for $q = 3$ and $O(\mu h^{2-d}\bar\rho_0^{-1})$ for $q = 2$.

On the other hand, contribution of the inner core Ω^0_{inn} to the remainder is $O(\mu h^{1-d}\bar\rho_0^q)$.

Therefore we arrive to the remainder estimate $O\big(h^{1-d}+\mu h^{1-d}\bar\rho_0^q\big)$ as $q\ge 3$ and $O\big(\mu h^{1-d}(\bar\rho_0^2+h\bar\rho_0^{-1})\big)$ as $q=2$ and we need to pick-up

$$\bar\rho_0=\max\big(h^{\frac13},\mu^{-\frac12}\big), \tag{20.4.55}$$

then finally arriving to the remainder estimate $O(h^{1-d})$ as $q\ge 3$ and $O\big(h^{1-d}+\mu h^{\frac53-d}\big)$ as $q=2$ [11].

Thus we have proven

Proposition 20.4.8. *Let $q\ge 2$, condition* (20.4.30) *be fulfilled and $Q=Q(hD''')$ be operator with the symbol $Q(\xi''')$ supported in $\{|\xi'''|\le C\bar\rho_1\}$, $\psi\in\mathscr{C}_0^\infty(B(0,1))$. Then*

(i) Estimate

$$\mathsf{R}_Q^{\mathsf{T}}\le Ch^{1-d} \tag{20.4.56}$$

holds provided <u>either</u> $q\ge 3$ <u>or</u> $q=2$ and $\mu\le h^{-\frac23}$.

(ii) Estimate

$$\mathsf{R}_Q^{\mathsf{T}}\le C\mu h^{\frac23-d} \tag{20.4.57}$$

holds as $q=2$ and $\mu\ge h^{-\frac23}$

where in both cases $\bar\chi\in\mathscr{C}_0^\infty([-1,1])$, $\bar\chi=1$ on $[-\frac12,\frac12]$, $Q=\sum_{0\le n\le\bar n}Q_n$, Q_n are operators with symbols supported in $\{\frac12\rho_n\le|\xi'''|\le 2\rho_n\}$ as $n=1,\dots,\bar n$, and in $\{|\xi'''|\le 2\rho_0\}$ as $j=0$, $\rho_n=2^n\rho_0^*$, $\bar n=\lfloor\log\bar\rho_1/\rho_0^*\rfloor+1$, $T_n=\epsilon\rho_n$ ($n\ge 1$), $T_0=\epsilon\mu^{-1}$.

Further, both statements remain true with U replaced by U^0 which is the Schwartz kernel of $e^{ih^{-1}tA_0}$.

Case $q=1$

In contrast to the previous case $q\ge 2$ skipping $O(\mu^{-1})$ terms is not now generally justified. Because of this we need to modify now arguments of Subsubsection 20.4.2.1, in the same manner as we modified arguments of Subsubsections 20.4.1.2–20.4.1.3 in Subsubsections 20.4.1.4–20.4.1.4.

[11] Similarly we would get $O\big(h^{1-d}+\mu h^{\frac43-d}\big)$ as $q=1$ but there is a lot of other things to consider.

So let us proceed without skipping such terms first, assuming that

$$Ch^{-\frac{1}{3}} \le \mu \le \epsilon(h|\log h|)^{-1}, \tag{20.4.58}$$

$$C\mu^{-1} \le |\xi_1| \asymp \rho \le \bar{\rho}_1^* = (\mu h)^{\frac{1}{2}}. \tag{20.4.59}$$

Starting from (20.4.51) with $\gamma = \mu h$ due to the above arguments we arrive to

$$|F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_T(t) - \bar{\chi}_{T_*}(t)\bigr)\Gamma Q\psi U| \le C\mu h^{1-d}\rho\Bigl(T_*\bigl(\frac{h}{\rho^2 T_*}\bigr)^s + T\bigl(\frac{h}{\rho\gamma}\bigr)^s + T\bigl(\frac{\mu^{-1}h}{\gamma^2}\bigr)^s\Bigr) \tag{20.4.60}$$

if $T_* = h/\rho^2 \le T \le T^* = \epsilon\rho$ and thus

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma Q\psi U| \le C\mu h^{1-d}\rho\Bigl(\frac{h}{\rho^2} + T\bigl(\frac{h}{\rho\gamma}\bigr)^s + T\bigl(\frac{\mu^{-1}h}{\gamma^2}\bigr)^s\Bigr). \tag{20.4.61}$$

Therefore due to the standard Tauberian arguments

$$|\Gamma(Q\psi\tilde{e}) - h^{-1}\int_{-\infty}^{0}\Bigl(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma Q\psi U\Bigr)\,d\tau| \le C\mu T^{-1}h^{1-d}\rho\Bigl(\frac{h}{\rho^2} + T\bigl(\frac{h}{\rho\gamma}\bigr)^s + T\bigl(\frac{\mu^{-1}h}{\gamma^2}\bigr)^s\Bigr) \asymp C\mu h^{1-d}\rho\Bigl(h\rho^{-3} + \bigl(\frac{h}{\rho\gamma}\bigr)^s + \bigl(\frac{\mu^{-1}h}{\gamma^2}\bigr)^s\Bigr). \tag{20.4.62}$$

After integration the right-hand expression over $d\rho/\rho$ with ρ ranging from $\bar{\rho}_0$ to $\bar{\rho}_1^*$,

$$\bar{\rho}_0 = Ch^{\frac{1}{3}} \ge C\mu^{-1} \qquad \text{as} \quad \mu \ge h^{-\frac{1}{3}}, \tag{20.4.63}$$

we get

$$C\mu h^{1-d}\rho\Bigl(h\rho^{-3} + \bigl(\frac{h}{\rho\gamma}\bigr)^s\Bigr)\Big|_{\rho=\bar{\rho}_0} + C\mu h^{1-d}\rho\bigl(\frac{\mu^{-1}h}{\gamma^2}\bigr)^s\Big|_{\rho=\bar{\rho}_1^*} \tag{20.4.64}$$

where all terms except $C\mu h^{2-d}\bar{\rho}_0^{-2} = C\mu h^{\frac{4}{3}-d}$ do not exceed Ch^{1-d}.

Also, contribution of the inner core $\Omega^0_{\mathsf{inn}} = \{|\xi_1| \le \bar{\rho}_0\}$ does not exceed $C\mu h^{1-d}\bar{\rho}_0 = C\mu h^{\frac{4}{3}-d}$ as well.

Therefore, the final estimate is $Ch^{1-d} + C\mu h^{\frac{4}{3}-d}$. Thus we arrive to

Proposition 20.4.9. *Let $q = 1$, condition* (20.4.30) *be fulfilled and $Q = Q(hD''')$ be operator with the symbol $Q(\xi''')$ supported in $\{|\xi'''| \le C\bar\rho_1\}$, $\psi \in \mathscr{C}_0^\infty(B(0,1))$. Then*

$$\mathsf{R}^{\mathsf{T}}_{1\,Q} \le Ch^{1-d} + C\mu h^{\frac{4}{3}-d} \tag{20.4.65}$$

where $\mathsf{R}^{\mathsf{T}}_{1\,Q}$ is defined by (20.4.22) *with $Q = \sum_{0\le n\le \bar n} Q_n(hD''')$, Q_n are operators with symbols supported in $\{\frac12\rho_n \le |\xi'''| \le 2\rho_n\}$ as $n = 1, \dots, \bar n$, and in $\{|\xi'''| \le 2\rho_0\}$ as $n = 0$, $\rho_n = 2^n\bar\rho_0$, $\bar n = \lfloor \log \bar\rho_1/\bar\rho_0\rfloor + 1$, $T_n = \epsilon\rho_n$ ($n \ge 1$), $T_0 = \epsilon\mu^{-1}$.*

20.4.3 Cases $q = 1, 2$ Revised

We repeat arguments of Subsection 20.4.2 as $q = 1, 2$, but we will use certain additional assumptions to improve remainder estimates.

Microhyperbolicity Assumption

Let us assume first that the microhyperbolicity assumption (see Definition 20.1.2) is fulfilled. Note that (20.4.11) implies that

$$\begin{aligned}|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma Q'\psi U| \le C\mu^r h^{r-d} T\rho^q \times \\ \Big(\big(\frac{h}{\rho^2 T}\big)^s + \big(\frac{h}{\rho\gamma}\big)^s + \big(\frac{\mu^{-1}h}{\gamma^2}\big)^s\Big)\times \\ \gamma^s \int_{B(z,2\gamma)} \|\operatorname{tr}\big(\mathcal{A}(x', x''', \xi'') + i\gamma\big)^{-s}\|\, dx''\, dx'''\, d\xi''\end{aligned} \tag{20.4.66}$$

where $B(z,\gamma) \supset \operatorname{supp}(Q')$, $\mathcal{A}$ is an operator reduced and considered as an operator in $\mathscr{L}^2(\mathbb{R}^r, \mathbb{C})$ and $\|.\|$ is an operator norm there. Then the same estimate (with an integral over $B(0,1)$) holds as Q' is replaced by Q.

Further, one can prove easily that

(20.4.67) Due to the microhyperbolicity assumption the last integral in (20.4.66) is of magnitude $\gamma(\mu h)^{-r}$ as $\gamma \ge \rho^2$; even condition $\gamma \ge \mu^{-1}$ is not needed anymore if we consider operator (20.4.41) from the very beginning[12)].

[12)] If $q \ge 2$ we can skip all $O(\mu^{-1})$ terms. If $q = 1$ we preserve all the terms which do not contain factor hD_1, we skip all such terms containing $(hD_1)^2$ because this leads to the approximation error $\rho^2\mu^{-1}$ and then we remove as in Chapter 18 all such terms containing hD_1 exactly in power 1.

Then (20.4.66) becomes

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma Q\psi U| \le Ch^{-d}\gamma T\rho^q \times \Big(\big(\frac{h}{\rho^2 T}\big)^s + \big(\frac{h}{\rho\gamma}\big)^s + \big(\frac{\mu^{-1}h}{\gamma^2}\big)^s\Big) \tag{20.4.68}$$

as $T_* = h/\rho^2 \le T \le T^* = \epsilon\rho$ and picking up $\gamma = \rho^2$, $\rho \ge \bar\rho_0 = h^{\frac{1}{3}-\delta} \ge \mu^{-1}$ we rewrite the right-hand expression here as $Ch^{-d}T\rho^{q+2}\big(\frac{h}{\rho^2 T}\big)^s$.

Remark 20.4.10. Note that we changed here (under the microhyperbolicity assumption) definition of $\bar\rho_0$ and the corresponding notion of the inner core Ω^0_{inn}.

Then (20.4.68) implies that

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma Q\psi U| \le Ch^{1-d}\rho^q \tag{20.4.69}$$

as long as $T \le \epsilon\rho$, $\rho \ge \bar\rho_0$.

However, due to the microhyperbolicity assumption $F_{t\to h^{-1}\tau}\chi_T(t)\Gamma Q\psi U$ is negligible as long $Ch|\log h|\varepsilon^{-1} \le T \le \epsilon$ and $T = \epsilon\rho$ satisfies this inequality as long as

$$\rho \ge C\bar\rho_0, \quad \varepsilon \ge Ch\rho^{-1}|\log h|. \tag{20.4.70}$$

Therefore, (20.4.70) yields that (20.4.69) holds for $T \le \epsilon$.

Then we can apply the standard Tauberian arguments resulting in the estimate with the right-hand expression $Ch^{1-d}\rho^q$. This last estimate holds for $\rho \le \bar\rho_1$ as well. Integration of this expression over $d\rho/\rho$ implies the remainder estimate $O(h^{1-d})$.

Consider now the contribution of the inner core $\Omega^0_{\mathsf{inn}} = \{|\xi'''| \le \bar\rho_0\}$. In this zone we get estimate

$$|F_{t\to h^{-d}\tau}\bar\chi_T(t)\Gamma Q\psi U| \le Ch^{-d}\bar\rho_0^{q+3}, \tag{20.4.71}$$

as $T = \rho$ and $\rho := \bar\rho_0$ there; then the standard microhyperbolicity arguments push it to $T = \epsilon$ under condition (20.4.70) and then the standard Tauberian arguments imply that the contribution of this zone to the remainder does not exceed $Ch^{-d}\bar\rho_0^{q+3}$ which is $O(h^{1-d})$ as $q \ge 1$ and δ small enough.

Thus under microhyperbolicity assumption the Tauberian remainder estimate is $O(h^{1-d})$ even as $q = 1, 2$ but we need to look at an approximation error; one can prove easily that for smallest $\varepsilon := C\rho^{-1}h|\log h|$ satisfying (20.4.70) it is also $O(h^{1-d})$.

Thus we arrive to

Proposition 20.4.11. *Under the microhyperbolicity assumption* $\mathsf{R}^{\mathsf{T}}_Q$ *does not exceed* Ch^{1-d} *where* $\mathsf{R}^{\mathsf{T}}_Q$ *is given by* (20.4.20) *with* $T = \epsilon$.

Special Case of Constant g^{jk}, F_{jk}

Recall that if F_{jk}, g^{jk} are constant then there are no non-removable $O(\mu^{-1})$ terms and the microhyperbolicity assumption is (20.2.41).

Using arguments similar to those used in Subsection 19.4.7 one can prove easily that one can replace it by non-degeneracy condition (20.2.42):

Problem 20.4.12. Let conditions (20.1.1), (20.1.5), (20.1.7), (20.1.8), $(20.1.9)_3$, (20.1.11), and (20.2.31) be fulfilled, and $\mu \le \epsilon(h|\log h|)^{-1}$.

Further, let g^{jk}, F_{jk} be constant, $(I, \sigma) = (2, 0)$ and assumption (20.2.42) be fulfilled.

Prove that $\mathsf{R}^{\mathsf{T}} = O(h^{1-d})$.

Case of f_j Having Constant Multiplicities

Assume that f_j have constant multiplicities. Then in both inner and intermediate zones after reduction and skipping $O(\mu^{-1})$ terms which are due to the 3-rd order resonances and all smaller terms[13)] instead of "matrix" operator we get a family of "scalar" operators

$$A_\alpha(x'', x''', \mu^{-1}hD'', hD''') = \sum_{q+1\le j,k\le q+r} (hD_j)g^{jk}(x'', x''', \mu^{-1}hD''')(hD_k) + V_\alpha(x'', x''', \mu^{-1}hD''') \tag{20.4.72}$$

and we can study them separately. Let us apply the standard rescaling procedure: for each index α we introduce functions $\gamma = \gamma_\alpha$ and $\varrho = \varrho_\alpha$ by

$$\gamma = \inf\bigl\{t : \vartheta(t) \ge \rho^2 + |V_\alpha(x'', x''', \xi'')|, \vartheta(t)t^{-1} \ge |\nabla V_\alpha(x'', x''', \xi'')|\bigr\} + \bar\gamma, \tag{20.4.73}$$

[13)] The case of $q = 1$ where there are such terms will be considered in details in the next Subsection 20.4.3.4

$$\varrho = \vartheta(\gamma)^{\frac{1}{2}}, \tag{20.4.74}$$

with

$$\bar{\varrho} = \vartheta(\bar{\gamma})^{\frac{1}{2}}, \qquad \bar{\varrho}\bar{\gamma} = Ch \implies \bar{\varrho} = h^{\frac{l}{l+2}} |\log \mu|^{-\frac{l\sigma}{2(l+2)}}, \quad \bar{\gamma} = h^{\frac{2}{l+2}} |\log h|^{\frac{\sigma}{l+2}} \tag{20.4.75}$$

where we assume that

$$(1,1) \preceq (l,\sigma) \preceq (2,0). \tag{20.4.76}$$

Note that $\gamma^2 \ge C\mu^{-1}h|\log h|$.

(i) Consider first elements with $\gamma \ge C\bar{\gamma}$. Calculating contribution of each element of $(\gamma;\rho)$-partition with respect to $(x'',x''',\xi'';\xi''')$ we can apply elliptic arguments unless $\epsilon\varrho \le \rho \le C\varrho$; in the latter case we can apply microhyperbolic arguments; then the contribution of each element to the remainder estimate does not exceed $C\mu^r h^{r-d+1}\varrho^{q-1}\gamma^{d-1}$ in the latter case and

$$C\mu^r h^{r-d+1}\rho^{q-1}\gamma^{d-1} \times \Big(\frac{h}{(\rho+\varrho)\gamma}\Big)^s$$

in the former one.

Then the contribution of each such element $\mathcal{W}$ of γ-partition with respect to (x'',x''',ξ') [14] to the remainder also does not exceed $C\mu^r h^{r-d+1}\varrho^{q-1}\gamma^{d-1}$.

Then the total contribution of such elements to the Tauberian remainder for given α does not exceed

$$C\int \mu^r h^{r-d+1}\varrho_\alpha^{q-1}\gamma_\alpha^{-1}\,dz$$

with $z=(x'',x''',\xi'')$ and after summation over all indices we get

$$C\sum_{\alpha\in\mathbb{Z}^{+r}} \mu^r h^{r-d+1}\int \varrho_\alpha^{q-1}\gamma_\alpha^{-1}\,dz. \tag{20.4.77}$$

[14] More precisely, of $\mathcal{W}\times\{|\xi'''|\le C\rho_1^*\}$.

(ii) On the other hand, contribution of each element of γ-partition with $\gamma \le C\bar\gamma$ does not exceed $C\mu^r h^{r-d}\gamma^d \bar\varrho^q$ and their total contribution does not exceed (20.4.77) as well.

Since for given (z,ρ)

$$\#\{\alpha \in \mathbb{Z}^{+r} : \epsilon\rho^2 \le \varrho_\alpha^2 \le c\rho^2\} \le C(\mu h)^{-r}(\rho^2+\mu h), \tag{20.4.78}$$

expression (20.4.77) does not exceed

$$C\mu h^{2-d}\int \varrho_1^{q-1}\gamma_1^{-1}\,dz + Ch^{1-d}\int \rho^q \gamma(\rho)^{-1}\,d\rho \tag{20.4.79}$$

where $\gamma_1 = \min_\alpha \gamma_\alpha$ and ϱ_1 corresponds to it, $\gamma(\rho)$ is defined from equation $\vartheta(\gamma)=\rho$.

One can see easily that the second term in (20.4.79) does not exceed Ch^{1-d}, while the first term does not exceed

$$C\mu h^{2-d}\int \gamma^{\frac12(q-1)l-2}|\log\gamma|^{-\frac12(q-1)\sigma}\,d\gamma$$

which in turn does not exceed $C\mu h^{1-d}\bar\varrho^q$ unless $q=2$, $l=2$. In the latter case $\sigma\le 0$ and the first term does not exceed $C\mu h^{2-d}|\log h|^{-\sigma}$. In both cases we arrive to the remainder estimate

$$\mathsf{R}^{\mathsf{T}}_{1\,Q} \le Ch^{1-d} + C\mu h^{1-d+\frac{ql}{l+2}}|\log\mu|^{-\frac{q\sigma}{(l+2)}} \tag{20.4.80}$$

which is exactly remainder estimate (20.6.89) below. Recall that it is $C\mu h^{2-d}$ as $(l,\sigma)=(2,0)$. Here $T=\gamma/\varrho$.

Thus we have proven

Proposition 20.4.13. *Let $q=1,2$, $\mu \ge \bar\mu^*_{(q)}$, f_j have constant multiplicities and $\mathcal{A}$ contain no unremovable cubic terms*[15]*. Let $Q=Q(hD''')$, $Q=Q(\xi''')$ be operator with the symbol supported in $\{|\xi'''|\le C\bar\rho_1\}$, $\psi\in \mathscr{C}_0^\infty(B(0,1))$.*

Then estimate (20.4.80) *holds with $\mathsf{R}^{\mathsf{T}}_{1\,Q}$ defined by* (20.4.22) *with $Q=\sum_{0\le n\le \bar n} Q_n(hD''')$, where Q_n are operators with symbols supported in $\{\frac12\gamma_n\le\gamma\le 2\gamma_n\}$ as $n=1,\dots,\bar n$, and in $\{\gamma\le 2\bar\gamma\}$ as $n=0$, $\bar n = \lfloor \log\bar\gamma\rfloor+1$, $\gamma_n = 2^{-n}$, $T_n = C\gamma_n^{1-\frac{l}{2}}|\log\gamma_n|^{-\frac{\sigma}{2}}$ $(n\ge 1)$, $T_0=\epsilon\mu^{-1}$.*

[15] May be we just dropped them in the interior zone causing an error $O(h^{1-d})$ if either $q=2$ or $q=1$ and each of these terms contained factor $\mu^{-1}hD_1$ and an error $O(\mu^{\frac12}h^{1-d})$ in the general case as $q=1$.

On the other hand, if $q = 1$ skipping unremovable cubic terms in $\mathcal{A}$ comes with a price of $O(\mu^{\frac12} h^{1-d} + \mu^{-\frac12} h^{\frac12-d})$ error. If we would prefer not to remove them, we cannot treat separate equations.

Case of Constant f_j

However we can do as well as before assuming that

$$f_j = \mathsf{const}, \quad j = 1, \dots, r \tag{20.4.81}$$

which by no means excludes variable g^{jk}, F_{jk} or unremovable cubic terms.

Really, under assumption (20.4.81) we can introduce

$$\gamma = \mathsf{inf}\big\{ t : \vartheta(t) \ge \rho^2, \vartheta(t) t^{-1} \ge |\nabla V(x'', x''', \xi'')| \big\} + \bar{\gamma}, \tag{20.4.82}$$

and ϱ by (20.4.74) and $\bar{\varrho}$, $\bar{\gamma}$ by (20.4.75). Then we can apply our standard arguments as long as

$$\rho^2 + |\nabla V| \ge C\mu^{-1} \tag{20.4.83}$$

which will be fulfilled automatically for $\gamma \ge C\bar{\gamma}$ as long as

$$\bar{\rho} \ge C\mu^{-\frac12} \iff \mu \ge Ch^{-\frac{2l}{l+2}} |\log h|^{\frac{2\sigma}{l+2}} \tag{20.4.84}$$

with the right-hand expression exceeding $h^{-\frac12}$ for sure.

Therefore, under condition (20.4.84) estimate (20.4.80) holds. On the other hand, if condition (20.4.84) is violated, we need also consider elements with violated condition (20.4.83), in particular, with $|\nabla V| \le C\mu^{-1}$ and

$$\gamma \le \hat{\gamma} = C\mu^{-\frac1l} |\log h|^{\frac{\sigma}{l}}, \tag{20.4.85}$$

Instead of γ partition we consider $\mathsf{max}(\gamma, \hat{\gamma})$-partition and on elements with $\gamma = \hat{\gamma}$ let us introduce

$$\gamma' = \hat{\gamma}\mu\rho^2 + \bar{\gamma}', \qquad \varrho' = \rho + \bar{\rho}', \tag{20.4.86}$$

$$\bar{\gamma}' = \mu^{\frac13} \hat{\gamma}^{\frac13} h^{\frac23} = h^{\frac23} \mu^{\frac{l-1}{3l}} |\log h|^{\frac{\sigma}{3l}}, \qquad \bar{\rho}' = \mu^{-\frac13} \hat{\gamma}^{-\frac13} h^{\frac13} \tag{20.4.87}$$

Then we arrive to the remainder estimate $Ch^{1-d} + C\mu h^{2-d} \bar{\gamma}'^{-1}$:

Proposition 20.4.14. *Let $q = 1$, $\mu \ge \bar{\mu}^*_{(1)}$ and condition* (20.4.81) *be fulfilled. Then*

(i) Under condition (20.4.84) *estimate* (20.4.80) *holds.*

(ii) If condition (20.4.84) *is violated then estimate*

$$\mathsf{R}^{\mathsf{T}}_{1\,Q} \le Ch^{1-d} + C\mu h^{1-d+\frac{l}{l+2}}|\log\mu|^{-\frac{\sigma}{(l+2)}} + C\mu^{\frac{2l+1}{3l}}h^{\frac{4}{3}-d}|\log\mu|^{-\frac{\sigma}{3l}} \tag{20.4.88}$$

holds.

Remark 20.4.15. (i) Condition (20.4.84) means exactly that the third term in the right-hand expression of (20.4.88) does not exceed the second one.

(ii) If condition (20.4.81) is violated one needs to take in account that as the main part is of the form $\xi_1^2 + \sum_{1\le j\le r} f_j^{\mathsf{w}}(\mu^2 x_{1+j}^2 + h^2 D_{1+j}^2) + V^{\mathsf{w}}$ with $f_j = f_j(x'', x_1, \xi'')$, $V = V(x'', x_1, \xi'')$, its gradient with respect to x'', x_d, ξ'' depends on the localization with respect to $\bigl\{(\mu^2 x_{1+j}^2 + h^2\xi_{1+j}^2), j = 1, \dots, r\bigr\}$ and there is at least one obstacle to it: due to the logarithmic uncertainty principle these quantities are defined with $C\mu h|\log h|$ precision.

Therefore one must take $\hat\gamma^{l-1}|\log\hat\gamma|^{-\sigma}| \ge C\mu h|\log h|$ in the arguments leading to Proposition 20.4.14 which deteriorates estimate (20.4.80). It does not look worth needed efforts.

(iii) Another approach would be to drop unremovable cubic terms as $\rho \ge \hat\varrho$ paying the price of $O(h^{2-d}\hat\varrho^{-1})$ for this and apply the same arguments as above. Then the remainder estimate is $C\mu h^{\frac{4}{3}-d}\hat\varrho^{\frac{2}{3}}\hat\gamma^{\frac{1}{3}}$ where $\hat\gamma = \hat\varrho^{\frac{2}{l}}|\log h|^{\frac{\sigma}{l}}$ and one should optimize the answer with respect to $\hat\varrho$ which is not $\mu^{-\frac{1}{2}}$ anymore.

We leave to the reader the following generalization of Problem 20.4.12:

Problem 20.4.16. Under assumption (20.4.81) (and, in particular, in the case of constant g^{jk}, F_{jk}) prove remainder estimate $\mathsf{R}^{\mathsf{T}} = O(h^{1-d})$ under non-degeneracy assumption (20.2.42).

20.4.4 Improved Remainder Estimates

There are peculiar cases when without microhyperbolicity or non-degeneracy assumptions one can improve general remainder estimate $\mathsf{R}^{\mathsf{T}}_{1\,Q} \le Ch^{1-d} + C\mu h^{1+\frac{q}{3}-d}$ or estimates (20.4.80), (20.4.88). It happens only for $r \ge 2$.

Note that the factor estimating the number of indices one needs to take in account is actually $\bigl(\boldsymbol{n}(\tau,\mu h) - \boldsymbol{n}(\tau - C\rho^2, \mu h)\bigr)$ where $\boldsymbol{n}(\tau,\mu h)$ is an eigenvalue counting function for operator $\boldsymbol{a}$ in $\mathscr{L}^2(\mathbb{R}^r,\mathbb{C})$ calculated at any point (x'', x''', ξ'') at $\mathsf{supp}(Q)$ while so far we used estimate $C\bigl(\rho^2 + \mu h\bigr)(\mu h)^{-r}$ for this difference.

Therefore as $(l,\sigma) \preceq (2,0)$ one can replace term $C\mu h^{1-d}\bar\varrho^q$ which we have in the framework of Proposition 20.4.13 by

$$
\begin{aligned}
(20.4.89)\quad & C\mu^r h^{r-d+1}\times \\
& \int\int_{\bar\varrho}^{\rho_1^*} \bigl(\boldsymbol{n}(x,\tau,\mu h) - \boldsymbol{n}(x,\tau - C\rho^2,\mu h)\bigr)\rho^{q-1}\gamma^{-1}\,d\rho\,dx + \\
& C\mu^{r+1}h^{r-d}\int \bigl(\boldsymbol{n}(x,\tau,\mu h) - \boldsymbol{n}(x,\tau - C\bar\varrho^2,\mu h)\bigr)\bar\varrho^q\,dx
\end{aligned}
$$

with $\gamma = \varrho^{2/l}|\log\rho|^{\sigma/l}$, $\bar\varrho = h^{l/(l+2)}|\log h|^{-\sigma/(l+2)}$ where we already returned to coordinates x.

Also, in the general settings one can replace term $C\mu h^{1+\frac{q}{3}-d}$ by expression (20.4.89) with $\gamma = \rho^2$ and $\bar\varrho = h^{\frac13}$.

Consider two examples

Example 20.4.17. Consider eigenvalue counting function $\boldsymbol{n}_0 = \boldsymbol{n}_0(\tau,\hbar)$ of operator $\boldsymbol{a}_0 = \mathcal{A}_0$ in $\mathscr{L}^2(\mathbb{R}^r,\mathbb{C})$; since $\mathcal{A}_0$ depends on (x'',x'',ξ''), so does $\boldsymbol{n}_0$ and we can always return to variable x by map Ψ_0. Since $\mathcal{A}_0$ contains only quadratic terms one can calculate $\boldsymbol{n}_0$ explicitly

$$
(20.4.90)\qquad \boldsymbol{n}_0(\tau,\hbar) = \#\bigl\{\alpha\in\mathbb{Z}^{+\,r} : \sum_j (2\alpha_j+1)f_j\hbar + V < \tau\bigr\}.
$$

If all $f_1,\dots,f_r$ are commensurable then

$$
\boldsymbol{n}_0(\tau,\hbar) - \boldsymbol{n}_0(\tau-\lambda,\hbar) \le C\hbar^{1-r}(\lambda+\hbar)
$$

is the best possible estimate ($\lambda\ge 0$); otherwise from

$$
\begin{aligned}
(20.4.91)\quad \boldsymbol{n}_0(\tau,\hbar) - \boldsymbol{n}_0(\tau-\lambda,\hbar) = \sum_{n\ge 0} \#\bigl\{\alpha'\in\mathbb{Z}^{+\,r-1} : \sum_{j\ge 2}\frac{f_j}{f_1}(2\alpha_j+1)\hbar \in \\
[f_1^{-1}(\tau-V) - 2(n+1) - f_1^{-1}\lambda,\, f_1^{-1}(\tau-V) - 2(n+1))\bigr\}
\end{aligned}
$$

one can derive a better estimate $C\hbar^{-r}(\lambda+\nu(\hbar))$ with $\nu(\hbar) = C\hbar^{\kappa}$, $\kappa>1$ depending on Diophantine properties of $\{f_2/f_1,\dots,f_r/f_1\}$ (see G. Harman [1]).

Example 20.4.18. Let us assume that[16)]

$$
(20.4.92)\qquad \operatorname{rank}\{\nabla\frac{f_2}{f_1},\dots,\nabla\frac{f_r}{f_1}\} \ge \kappa - 1 \qquad \forall x.
$$

[16)] Actually we need a quantitative version of this condition and only at points where ∇V is a linear combination of $\nabla f_1,\dots,\nabla f_r$.

One can easily recover an integrated version of (20.4.91), namely

$$|\int_{B(0,1)} \big(\boldsymbol{n}_0(x,\hbar,\tau') - \boldsymbol{n}_0(x,\hbar,\tau')\big)\,dx| \le C\hbar^{-r}\big(|\tau-\tau'| + \nu(\hbar)\big) \tag{20.4.93}$$
$$\forall \hbar \in (0,1)\ \forall \tau,\tau' : |\tau| \le \epsilon, |\tau'| \le \epsilon$$

with $\nu(\hbar) = C\hbar^{\kappa}$. Really, one needs just to consider ζ-admissible partition in $(\alpha\hbar, x)$-space with the scaling function $\zeta = \epsilon|\nabla(\tau - V - \sum_j (2\alpha_j+1)f_j\hbar)|$.

Furthermore, these arguments show that for $\boldsymbol{n}$ the left-hand expression of (20.4.93) does not exceed $C\hbar^{1-r}\big(\lambda + \hbar^{\kappa} + \mu^{-\kappa}\big)$.

Then we arrive to

Proposition 20.4.19. *Let condition* (20.4.93) *hold for* $\boldsymbol{n}_0$ *which is an eigenvalue counting function for* $\mathcal{A}_0$. *Let* $\bar{\mu}^*_{(q)} \le \mu \le \epsilon(h\log h|)^{-1}$.

(i) Let <u>*either*</u> $q=2$ <u>*or*</u> $q=1$ *and* $\mathcal{A}$ *contain no unremovable cubic terms*[17]. *Then*

$$\mathsf{R}^{\mathsf{T}}_{1\,Q} \le Ch^{1-d} + C\nu(\mu h)h^{\frac{q}{3}-d}. \tag{20.4.94}$$

(ii) Assuming instead that $\boldsymbol{n}$ *which is an eigenvalue counting function for* $\boldsymbol{a}$, *satisfies* (20.4.93), *we need in Statement (i) neither assumption "*$\mathcal{A}$ *contains no unremovable cubic terms" nor* (20.4.93) *for* $\boldsymbol{n}_0$.

(iii) Let $q=1$ *and* $\mathcal{A}$ *contain unremovable cubic terms and* $\mu \ge (h|\log h|)^{-\frac{1}{2}}$. *Then*

$$\mathsf{R}^{\mathsf{T}}_{1\,Q} \le Ch^{1-d} + C\nu(\mu h)h^{\frac{1}{3}-d} + C\mu^{-1}h^{\frac{1}{3}-d}. \tag{20.4.95}$$

Proof. Statements (i) and (ii) follow directly from the above arguments. In Statement (iii) one needs to notice that (20.4.93) for $\boldsymbol{n}_0$ implies

$$\int \big(\boldsymbol{n}(x,\tau,\hbar) - \boldsymbol{n}(x,\tau-\lambda,\hbar)\big)\,dx \le C\big(\lambda + \mu^{-1} + \nu(\hbar)\big)\hbar^{-r}. \tag{20.4.96}$$

Easy details we leave to the reader. □

[17] Unremovable cubic terms containing hD_1 are allowed.

Remark 20.4.20. (i) If $q = 1$ and (20.4.93) holds then skipping unremovable cubic terms leads to an error not exceeding

$$C\nu(\mu h)\mu^{-\frac{1}{2}}h^{-d} + C\mu^{-\frac{3}{2}}h^{-d}. \tag{20.4.97}$$

(ii) If $\mu \ge h^{-\frac{2}{3}}$ last terms in the right-hand expression of (20.4.95) and in (20.4.97) do not exceed Ch^{1-d}.

Similarly one can prove

Proposition 20.4.21. *Let $q = 1, 2$ and f_j have constant multiplicities. Let condition* (20.4.93) *hold for $\boldsymbol{n}_0$. Let $\bar{\mu}^*_{(q)} \le \mu \le \epsilon(h|\log h|)^{-1}$.*

(i) Let <u>either</u> $q = 2$ <u>or</u> $q = 1$ and $\mathcal{A}$ contain no unremovable cubic terms. Then

holds if (20.4.84) *fails.*

20.5 Stronger Magnetic Field: Estimates

In this section we derive Tauberian remainder estimates the remaining cases: the *intermediate magnetic field* $\epsilon(h|\log h|)^{-1} \le \mu \le \epsilon h^{-1}$, *intermediate-strong magnetic field* $\epsilon h^{-1} \le \mu \le C_0 h^{-1}$ and *strong magnetic field* $\mu \ge C_0 h^{-1}$.

20.5.1 Intermediate Magnetic Field

General Settings

Consider now the intermediate magnetic field case

$$\epsilon(h|\log h|^{-1}) \le \mu \le \epsilon h^{-1}. \tag{20.5.1}$$

Recall that the reduction to the canonical form was done with a greater

$$\varepsilon = C\bigl(\mu^{-1}h|\log h|\bigr)^{\frac{1}{2}} \tag{20.5.2}$$

rather than $C\mu^{-1}$; furthermore, an outer zone is empty now (but intermediate zone still present) and $\bar\rho_1 = C$ rather than $\bar\rho_1 = C\bigl(\mu h|\log h|\bigr)^{\frac{1}{2}}$.

As $q \ge 2$ throwing away $O(\mu^{-1})$ terms brings an $O(h^{1-d})$ error of $h^{-d}\mathcal{N}^{\mathsf{MW}}$. Then all the arguments of Subsections 20.4.1 and 20.4.2 remain true and the Tauberian remainder estimate will be $O(h^{1-d})$ if $q \ge 3$, $O(\mu h^{\frac{5}{3}-d})$ if $q = 2$ and $O(\mu h^{\frac{4}{3}-d})$ if $q = 1$; in the latter case contribution of the intermediate zone is estimated by $Ch^{1-d}|\log h|$ rather than by Ch^{1-d}. Therefore in the general settings previous results hold without any modifications:

Proposition 20.5.1. *Propositions 20.4.1, 20.4.2, 20.4.4–20.4.9 and theorem 20.4.3 remain valid for the strong magnetic field case* (20.5.1) *as well.*

Therefore in what follows we need to consider cases $q = 1, 2$ only.

Microhyperbolic Case

We must distinguish two cases:

(i) The microhyperbolicity direction ℓ does not depend on $\boldsymbol{\tau}$. In this case all the arguments of Subsubsection 20.4.3.1 remain true and the remainder estimate is $O(h^{1-d})$.

In particular, the case of f_j having constant multiplicities is covered. Really, in this case the microhyperbolicity condition means exactly that at each point x

$$\sum_{1\le j\le r_1} \tau_j \nabla\big(\frac{f_j}{V}\big) = 0, \quad \forall_j\ \tau_j \ge 0 \implies \forall_j\ \tau_j = 0; \tag{20.5.3}$$

then there exists a vector $\ell = \ell(x)$ such that

$$\langle \ell, \nabla\big(\frac{f_j}{V}\big)\rangle > 0 \qquad \forall j \tag{20.5.4}$$

which exactly means microhyperbolicity in direction ℓ.

(ii) Microhyperbolicity condition is fulfilled with ℓ depending on $\boldsymbol{\tau}$. Then as in Subsection 19.5.2 one needs to study partition of the phase space and select ϵ small enough in the upper bound for μ in (20.5.1); then all the previous results will still hold.

So, we have proven

Proposition 20.5.2. *In the intermediate magnetic field case Proposition 20.4.11 holds provided either microhyperbolicity direction does not depend on $\boldsymbol{\tau}$ or ϵ small enough in the upper bound for μ in* (20.5.1).

Special Case of Constant g^{jk}, F_{jk}

We leave to the reader the following

Problem 20.5.3. [18)] Prove that in the intermediate magnetic field case (20.5.1) $\mathsf{R}^{\mathsf{T}} = O(h^{-1})$ provided g^{jk} and F_{jk} are constant and non-degeneracy assumption (20.2.42) is fulfilled.

Case of f_j Having Constant Multiplicities

Assuming that there are no cubic terms we get a family of separate operators $\mathcal{A}_\alpha$ and all the previous arguments hold bringing us remainder estimate (20.4.80). On the other hand, as $q = 1$ dropping unremovable cubic terms produces an error $C\mu^{\frac12}h^{1-d}$ which is less than the right-hand expression of (20.4.80) unless $l = 2$, $\sigma \in (-4, 0]$. In this case assuming (20.4.81) one can prove easily (20.4.80) as well. So we arrive to

[18)] Cf. Problem 20.4.12.

Proposition 20.5.4. *(i) In the intermediate magnetic field case as f_j have constant multiplicities estimate* (20.4.80) *holds unless $q = 1$, $(I, \sigma) \succeq (2, -4)$ and there are unremovable cubic terms.*

(ii) In this exceptional case should include an extra term $C\mu^{\frac{1}{2}}h^{1-d}$ in the right-hand expression.

Case of Constant f_j

We leave to the reader the following

Proposition 20.5.5. *In the intermediate magnetic field case Proposition 20.4.14 holds.*

and

Problem 20.5.6. [19] Prove that in the intermediate magnetic field case (20.5.1) $\mathsf{R}^{\mathsf{T}} = O(h^{-1})$ provided f_j are constant and the non-degeneracy assumption (20.2.42) is fulfilled.

Improvement without Microhyperbolicity

Furthermore, under condition (20.4.93) for $\boldsymbol{n}_0$ we get remainder estimate (20.4.94) in the framework of Proposition 20.4.19(i) which is an extremely small improvement now.

Moreover, if f_j have constant multiplicities we can recover (20.4.98) in the framework of Proposition 20.4.21(i).

Proposition 20.5.7. *In the intermediate magnetic field Propositions 20.4.19 and 20.4.21 hold.*

20.5.2 Intermediate-Strong Magnetic Field

Consider now the intermediate-strong magnetic field case

$$\epsilon h^{-1} \le \mu \le C_0 h^{-1}. \tag{20.5.5}$$

Then the same arguments as before but in simplified form hold and one can prove easily

[19] Cf. Problem 20.4.16.

Proposition 20.5.8. *In the intermediate-strong magnetic field case*

(i) In the general settings remainder estimate

$$\mathsf{R}^{\mathsf{T}} \le Ch^{1-d}\begin{cases} 1 & \text{for } q \ge 3,\\ h^{-\frac{1}{3}} & \text{for } q = 2,\\ h^{-\frac{2}{3}} & \text{for } q = 1 \end{cases} \tag{20.5.6}$$

(ii) If $q = 1, 2$ and f_j have constant multiplicities then the remainder estimate

$$\mathsf{R}_1^{\mathsf{T}} \le Ch^{1-d} + Ch^{-d+\frac{lq}{l+2}}|\log h|^{-\frac{lq\sigma}{2(l+2)}} \tag{20.5.7}$$

holds.

Note that we can ignore cubic terms (which are $O(h)$ now). In the strong magnetic field case we need to modify the microhyperbolicity assumption:

Definition 20.5.9. In the case of the intermediate-strong magnetic field we call operator *microhyperbolic* (on energy level τ) if there exists vector $\ell = \ell(\bar{z}) \in \mathbb{R}^{2r+q}$ such that

$$\mu^2 \sum_{j,k\ge q+1} \bigl(\ell(a_{jk}a_0^{-1})\bigr)\zeta_j^{\dagger}\zeta_k \ge \epsilon_1 \qquad \forall \zeta \in \mathbb{C}^r \tag{20.1.19}$$

as long as

$$a = \mu^2\tau; \tag{20.5.8}$$

we also need to modify non-degeneracy assumption (20.2.42) (see (20.5.10) below).

Proposition 20.5.10. *In the case intermediate-strong magnetic field*

(i) If $q = 1, 2$ and the microhyperbolicity condition (see Definition 20.5.9) is fulfilled then the remainder estimate $\mathsf{R}^{\mathsf{T}} \le C\mu h^{2-d}$ holds.

(ii) If f_j are constant and either the microhyperbolicity condition

$$|V - \tau - \sum_j (2\alpha_j + 1)\mu h \mathsf{f}_j| + |\nabla V| \ge \epsilon_0 \tag{20.5.9}$$

or the non-degeneracy condition

$$|V - \tau - \sum_j (2\alpha_j + 1)\mu h \mathsf{f}_j| + |\nabla V| \le \epsilon_0 \implies |\det \mathsf{Hess}\, V| \ge \epsilon_0 \tag{20.5.10}$$

is fulfilled then the remainder estimate $\mathsf{R}^{\mathsf{T}} \le C\mu h^{2-d}$ holds (in the latter case we assume that $(l, \sigma) \succeq (2, 0)$).

20.5.3 Strong Magnetic Field

The last and the easiest case to consider is the strong magnetic field case $\mu \ge C_0 h^{-1}$. In this case we need to consider Schrödinger-Pauli operator. Then we arrive to a single operator

$$\mathcal{A}_0 = h^2 \sum_{2r+1\le j,k\le d} D_j g^{jk}(x'', x''', \mu^{-1}hD'')D_k + a_0(x'', x''', \mu^{-1}hD'') \tag{20.5.11}$$

where we recall that

$$a_0 = W \circ \Psi_0, \qquad W = V - \sum_j f_j \mu h \tag{20.5.12}$$

belongs to $\mathscr{F}^{l,\sigma}$ uniformly.

Surely we get a system, but all other components $\mathsf{U}_{\alpha,\beta}$ (with $(\alpha,\beta)\ne 0$) could be expressed via $\mathsf{U}_{0,0}$. Then the principal part of asymptotics (as $|W|\le c$) is of magnitude $\mu^r h^{r-d}$. For the remainder estimate we have

Proposition 20.5.11. *In the case of the strong magnetic field*

(i) For $q\ge 3$ remainder estimate $\mathsf{R}^{\mathsf{T}} \le C\mu^r h^{r+1-d}$ holds.

(ii) For $q=1,2$ and the microhyperbolicity condition (20.5.9) *fulfilled, the remainder estimate $\mathsf{R}^{\mathsf{T}} \le C\mu^r h^{r+1-d}$ holds.*

(iii) For $q=2$ and $(l,\sigma)\succeq(2,1)$ the remainder estimate $\mathsf{R}^{\mathsf{T}} \le C\mu^r h^{r+1-d}$ holds.

(iv) For $q=1$, $(l,\sigma)\succeq(2,1)$, and non-degeneracy condition (20.5.10) *fulfilled the remainder estimate $\mathsf{R}^{\mathsf{T}} \le C\mu^r h^{r+1-d}$ holds.*

(v) For $q=2$, $(l,\sigma)\prec(2,0)$ and for $q=1$ the remainder estimate

$$\mathsf{R}^{\mathsf{T}} \le C\mu^r h^{r-d} \begin{cases} h^{\frac{2l}{l+2}} |\log h|^{-\frac{2\sigma}{l+2}} & \text{for } q=2,\\ h^{\frac{l}{l+2}} |\log h|^{-\frac{\sigma}{l+2}} & \text{for } q=1 \end{cases} \tag{20.5.13}$$

holds.

On the other hand, both mollification and approximation errors in the operator are $O(h)$; then if either $q\ge 2$ or microhyperbolicity or non-degeneracy

assumptions are fulfilled then both mollification and approximation errors in the magnetic Weyl expression are $O(h)$ multiplied by $\mu^r h^{r-d}$ i.e. $\mu^r h^{r+1-d}$.

Furthermore, if $q = 1$ and we consider the general case, then both mollification and approximation errors are $O(h^{\frac{1}{2}})$ multiplied by $\mu^r h^{r-d}$ i.e. $\mu^r h^{r+\frac{1}{2}-d}$.

In all these cases both mollification and approximation errors do not exceed the remainder estimate.

20.6 Intermediate Magnetic Field: Calculations

Now we need to derive more explicit expressions rather than the Tauberian expression

$$h^{-1}\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(U\psi_y\, {}^tQ_y)\,d\tau \tag{20.6.1}$$

or the sum of those with different T where $\psi_y = \psi(y)$, $Q_y = Q(y, hD_y)$.

20.6.1 Weak Magnetic Field Redone

Recall that the weak magnetic field case is when $\mu \le h^{\delta-1}$ and we derived asymptotics with the principal part given by (20.6.1) with $Q = I$, $T = \epsilon\mu^{-1}$ and with some remainder estimate derived without reduction to the canonical form.

Note that the mollified operator $\tilde{A}$ is microhyperbolic in the direction $\langle \xi, \partial_\xi\rangle$ due to condition (20.1.11). Further, in the zone $\{|\xi'''| \ge \epsilon'\}$ this operator is a differential operator since we take there $\varepsilon = Ch|\log h|$ which does not depend on $|\xi'''|$.

On the other hand, in the zone $\{|\xi'''| \le \frac{1}{2}\epsilon\}$ operator $\tilde{A}$ is microhyperbolic in direction $\langle \xi', \partial_{\xi'}\rangle + \langle \xi'', \partial_{\xi''}\rangle$ and it is a differential operator with respect to x', x'' since mollification parameter $\varepsilon = C\rho^{-1}h|\log h|$ does not depend on ξ', ξ''.

Therefore due to the standard results rescaled $F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(U\psi_y)$ is negligible as $|\tau| \le \epsilon'$ and $T \in [T_*, \bar{T}]$, $T_* = Ch|\log h|$, $\bar{T}_0 = \epsilon\mu^{-1}$. Therefore, due to (20.2.29) we can take $T = T_*$ in (20.6.1) with only $O(h^s)$ difference. It happens in the proof of Theorems 20.2.10, 20.2.15, and 20.4.3.

Then we can launch the successive approximation method with the unperturbed operator

$$\bar{A} = \sum_{j,k} \bar{P}_j \bar{g}^{jk} \bar{P}_k + \bar{V}, \tag{20.6.2}$$

$$\bar{g}^{jk} = g^{jk}(y),\ \bar{V} = V(y),\ \bar{P}_k = hD_k - \mu V_k(y) - \mu \sum_j (\partial_k V)(y)(x_k - y_k)$$

and plug it into (20.6.1). In what we get then the first term does not exceed $CTh^{-1-d} = Ch^{-d}|\log h|$. Perturbation can be written as

$$\sum B_j(x_j - y_j) + \mu \sum_{j,k} B_{jk}(x_j - y_j)(x_k - y_k) + ...$$

with h-differential operators $B_{...}$ and since each factor $(x_j - y_j)$ according to our standard approach leads to an extra factor T in the estimate, one can see easily that each next term in the successive approximations gains factor $Ch^{-1}T\big(T^2 + \mu T^3\big) \le Ch|\log h|$ [20].

Therefore as we are looking for $O(h^{1-d})$ error, only first two terms should be considered. The first term results exactly (20.6.1) in with $U(x,y,t)$ replaced by $\bar{U}(x,y,t)$ and it is exactly

$$h^{-d} \int \tilde{\mathcal{N}}^{\mathsf{MW}}(y,\tau)\psi(y)\,dy \tag{20.6.3}$$

with $O(h^s)$ error[21].

The second term consists of two parts; one of them is generated by the perturbation

$$R_1 = \sum_{j,k,m} \bar{P}_j(\partial_m g^{jk})(y)(x_m - y_m)\bar{P}_k + \sum_m (\partial_m V)(y)(x_m - y_m) \tag{20.6.4}$$

and it is obviously 0, while the second part is generated by

$$R_2 = \sum_{j,k} \Big((P_j - \bar{P}_j)\bar{g}^{jk}\bar{P}_k + \bar{P}_j \bar{g}^{jk}(P_k - \bar{P}_k) + (P_j - \bar{P}_j)\bar{g}^{jk}(P_k - \bar{P}_k) \Big) \tag{20.6.5}$$

and is obviously $O(h^{-d-2}\mu T^3) = O(h^{1-d})$.

Therefore

---

[20] Recall that factor Th^{-1} comes from Duhamel principle.

[21] After we replaced U by $\bar{U}$ we can replace T by ∞ with $O(h^s)$ error since then (20.2.29) holds for any $T \ge \epsilon\rho$ with $O(h^s T^{-s})$ error and it will be exactly (20.6.3).

(20.6.6) In the case of the weak magnetic field approach we can replace the Tauberian expression (20.6.1) by (20.6.3) without deterioration of the remainder estimate[22)].

Remark 20.6.1. This takes care of Theorems 20.2.10 and 20.4.3–with R^{MW} rather than $R^{\mathsf{W}}_{(\infty)}$ remainder. Also under microhyperbolicity or non-degeneracy conditions it takes care of Theorem 20.2.15 and Problem 20.2.17 respectively.

20.6.2 Decomposition

Decomposition. Part I

Now let us consider temperate magnetic field $\bar{\mu}^*_{(q)} \le \mu \le \epsilon(h|\log h|)^{-1}$.

Then there is a *standard zone* where we use the already derived estimate for $\mathsf{R}^{\mathsf{T}}_{Q}$ with $T = \bar{T}$; this standard zone contains an outer zone $\Omega_{\mathsf{out}} = \{|\xi'''| \ge \bar{\rho}_1\}$ but could be wider due to the microhyperbolicity or non-degeneracy assumptions. Recall that due to assumption (20.1.11) in this standard zone we can replace $\bar{T}$ by $T_* = Ch|\log h|$.

The unexpectedly difficult (as $q = 1$) problem is to join asymptotics derived in the standard zone with a cut-off operator $I - \mathcal{T}\mathcal{Q}\mathcal{T}^*$ and in the remaining non-standard zone where we employ cut-off operator $\mathcal{T}\mathcal{Q}\mathcal{T}^*$. To tackle it better let us rewrite the formula we derived for the answer:

$$h^{-1}\sum_n \int_{-\infty}^{0} F_{t\to h^{-1}\tau}\bar{\chi}_{T_n}(t)\Gamma(U\psi_y\, {}^tQ_n y)\, d\tau \tag{20.6.7}$$

where Q_n are appropriate elements of the partition of I and T_n are already chosen. The asymptotics with this principal part and different remainder estimates were derived in Section 20.4. Actually one can replace here T_n by larger values without the affecting remainder estimate, but let us do a bit differently. Considering some term here with $Q = Q_n$ and $T = T_n$ one can rewrite it as

$$h^{-1}\int_{-\infty}^{0} \sum_{0\le m<\infty} \phi_{m,L_m}(\tau)\Big(F_{t\to h^{-1}\tau}\bar{\chi}_{T_n}(t)\Gamma\big(U\psi_y\, {}^tQ_y\big)\Big)\, d\tau \tag{20.6.8}$$

where $\mathsf{supp}(\phi_0) \subset [-2,2]$, $L_0 = C\bar{\rho}_1$, $\mathsf{supp}(\phi_m) \subset [-2,-1]$, $L_m = 2^m L_0$ as $m \ge 1$ and ϕ_{m,L_m} form partition of 1: $\sum_{0\le m<\infty}\phi_{m,L_m}(\tau) = 1$ as $\tau \le 0$.

[22)] We need also to replace $\tilde{\mathcal{N}}^{\mathsf{MW}}$ by $\mathcal{N}^{\mathsf{MW}}$ but estimate of the approximation error is already done; in what follows we will not distinguish between $\mathcal{N}^{\mathsf{MW}}$ and $\tilde{\mathcal{N}}^{\mathsf{MW}}$ keeping in mind that we always must include an approximation error estimate in our final statement.

Note that one can rewrite each term with $m>0$ in (20.6.8) as

$$\phi_{m,L_m}(hD_t)\Big(\varphi_T(t)\Gamma\big(U\psi_y\,{}^tQ_y\big)\Big)\Big|_{t=0}, \quad \text{with } \varphi=\bar{\chi},\ T=T_n. \tag{20.6.9}$$

Let us consider (20.6.9) with $\varphi=\chi$ and $T\ge hL_m^{-1}$. Using arguments of Subsection 20.4.1 one can estimate such term by

$$Ch^{-d-1}\rho^q L_m^2 T\times \big(\frac{h}{TL_m}\big)^s \tag{20.6.10}$$

where factors L_m, T are due to the integrations with respect to τ, t respectively and another factor L_m is due to the calculation of the number of contributing indices α; we assume that

$$L_m\ge C(\mu^{-1}+\rho^2). \tag{20.6.11}$$

Further, the same $Ch^{-d}\rho^q L_m$ estimate holds for (20.6.9) terms with $\varphi=\bar{\chi}$ and $TL_m=1$ as well. Then the sum with respect to t-partition results in $Ch^{-d}\rho^q L_m$, and then the sum with respect to τ partition results in $C\rho^q h^{-d}$ because $\max L_m\asymp 1$ here; terms with $L_m\ge C$ are less than $Ch^s L_m^{-s}$ due to the standard ellipticity arguments.

Let us employ a method of the successive approximations described in Subsection 20.6.1 and plug it into (20.6.9). Obviously, estimate $C\rho^q h^{-d}$ for the first term is fulfilled.

A perturbation with factor (x_j-y_j) will result either in the factor CT^2h^{-1} if commuting with A or $\bar{A}$, or in the factor $CT\rho^{-1}$ if commuting with Q, or, what is equivalent, in factors hL_m^{-2} and $hL_m^{-1}\rho^{-1}$ respectively thus resulting in the estimates

$$Ch^{1-d}\rho^q L_m^{-1}\times\big(\frac{h}{TL_m}\big)^s \quad\text{and}\quad Ch^{1-d}\rho^{q-1}\times\big(\frac{h}{TL_m}\big)^s \tag{20.6.12}$$

respectively.

Note that the commutator with Q_n (and thus the second of these expressions) appears in the sum only as $T\ge \epsilon T_n$; as for $T\le \epsilon T_n$ commutators from adjacent elements compensate one another.

Therefore taking the sum with respect to t-partition and then with respect to m we get

$$Ch^{1-d}\rho^q L_0^{-1}, \qquad Ch^{1-d}\rho^{q-1}\times\big(\frac{h}{T_nL_0}\big)^s \tag{20.6.13}$$

respectively. We can always take $L_0 = \bar{\rho}_1$ since $T_n \ge \mu^{-1}$ for sure and get $O(h^{1-d})$. As $q \ge 2$ we can do even better but it does not matter. Then both terms in (20.6.13) do not exceed Ch^{1-d} and remain this way after we sum over partition in zone $\{|\xi'''| \le \bar{\rho}_1\}$.

Therefore, in the terms with $m > 0$ we can completely ignore partition and consider only the first term of the successive approximations, Further, after this we can take T_n arbitrarily large (thus we can take $T_n = +\infty$); then after easy calculations we get

$$h^{-d} \int_{-\infty}^{0} \int \bigl(1 - \phi_{0,L_0}(\tau)\bigr)\, d_\tau \mathcal{N}^{\mathsf{MW}}(x,\tau)\, \psi(x)\, dx. \tag{20.6.14}$$

So we proved estimate

$$\begin{aligned} |h^{-1} \int_{-\infty}^{0} \bigl(1 - \phi_{0,L_0}(\tau)\bigr) \sum_n \Bigl(F_{t\to h^{-1}\tau}\bar{\chi}_{T_n}(t)(\Gamma U \psi_y\, {}^t Q_{ny})\Bigr)\, d\tau - \\ h^{-d} \int_{-\infty}^{0} \int \bigl(1 - \phi_{0,L_0}(\tau)\bigr)\, d_\tau \mathcal{N}^{\mathsf{MW}}(x,\tau)\, \psi(x)\, dx| \le Ch^{1-d}. \end{aligned} \tag{20.6.15}$$

Now we need to consider terms with $m = 0$ i.e.

$$h^{-1} \int_{-\infty}^{0} \phi_{0,L_0}(\tau) \Bigl(F_{t\to h^{-1}\tau}\bar{\chi}_{T}(t)\Gamma(U\psi_y\, {}^t Q_{ny})\Bigr)\, d\tau, \qquad T = T_n. \tag{20.6.16}$$

Instead we consider the same expression (20.6.16) but with $T = \bar{T} = \epsilon\mu^{-1}$ and consider a correction later. We remember that $T_n \ge \bar{T}$ in the intermediate and interior zones. Thus, let us consider expression (20.6.16) with $T = \bar{T}$.

Now we want to replace $\bar{T}$ by a lesser value. We could replace it by $T_* = Ch|\log h|$ with a negligible error before but it is not the case anymore since as a result of mollification and transformation the symbol of operator satisfies only an estimate

$$|\partial_\xi^\alpha a| \le C\bar{\rho}_1^{l-|\alpha|} |\log \bar{\rho}_1|^{-\sigma} + C \tag{20.6.17}$$

in the intermediate and interior zones. However then we can take there

$$T_* = C\bar{\rho}_1^{-1} h|\log h| \le \bar{T} \tag{20.6.18}$$

Now let us apply the same successive approximations to calculate expression (20.6.16) with $T = T_*$.

Then the perturbation with the factor $(x_j - y_j)$ results in the factor $T^2h^{-1} = \bar{\rho}_1^{-2}h|\log h|^2$ and extra factor $\bar{\rho}_1^{-2}|\log h|^2$ (in comparison with h) is well absorbed by ρ^{q+1} at least as $q \ge 2$, $\mu \le h^{-1}|\log h|^{-2}$.

One can consider both cases $q = 1$ and the exceptional case $\mu \ge h^{-1}|\log h|^{-2}$ either using rescaling arguments thus punishing $T \ge h/\bar{\rho}_1$ by the factor $\big(h/(\bar{\rho}_1 T)\big)^s$ or just by taking the two-terms approximation instead of the one-term and proving that the second term is identically 0.

Furthermore, a perturbation containing factor $\mu(x_j - y_j)(x_k - y_k)$ will get an extra factor $\mu T^3 h^{-1} = \mu h^2|\log h|^3\bar{\rho}_1^{-3}$ which should be treated in the same way. We leave the easy standard details to the reader.

Therefore we can again consider only the first term of the successive approximations but in contrast to the previous part we cannot tend $T = T_n$ to infinity in this approximation term unless in the outer zone. Then the answer will be similar to one given in (20.6.14), namely

$$h^{-1}\int_{-\infty}^{0} \phi_{0,L_0}(\tau)\Big(F_{t\to h^{-1}\tau}\bar{\chi}_{T_*}(t)\Gamma\big(\bar{U}\psi_y\big)\Big)\,d\tau = h^{-d}\int_{-\infty}^{0}\int \big(\phi(\tau)+\omega(\tau)\big)\,d_\tau \mathcal{N}^{\mathsf{MW}}(x,\tau)\,\psi(x)\,dx \tag{20.6.19}$$

with

$$\omega(\tau) = T_* h^{-1}\int_{-\infty}^{0} \phi(\tau')(\tau')\hat{\bar{\chi}}\big(\frac{(\tau'-\tau)T_*}{h}\big)\,d\tau' - \phi(\tau), \tag{20.6.20}$$

where $\phi = \phi_{0,L_0}$.

Here $\omega(\tau) \ne 0$ because we cannot replace T_* by $+\infty$. Instead we replaced back T_* by $\bar{T}$ since operator $\bar{A}$ has the same propagation with respect to x properties as A and therefore even with Γ_y instead of Γ the difference is negligible.

Let us define

$$\mathcal{N}_{\mathcal{Q}}^{\mathsf{MW}}(x,0) := (2\pi)^{-d+2r}h^r\mu^r \sum_{\alpha\in\mathbb{Z}^{+\,r}}\int_{\Omega_\alpha(x,\tau)} f_1\cdots f_r\,\frac{\sqrt{g}}{\sqrt{g}'''}\,\mathcal{Q}(\xi''')\,d\xi''', \tag{20.6.21}$$

with

$$\Omega_\alpha(x,\tau) = \big\{\xi : V + \sum_j (2\alpha_j+1)\mu h + \sum_{1\le j,k\le q} g^{jk}\xi_j\xi_k + V \le \tau\big\}, \tag{20.6.22}$$

where g^{jk} with $j,k=1,\dots,q$ denote coefficients after we reduce operator $\bar{A}$ to its canonical form

$$\sum_{1\le j\le r} f_j(h^2D_{q+j}^2+\mu^2x_{q+j}^2)+\sum_{1\le j,k\le q} g^{jk}h^2D_jD_k+V, \tag{20.6.23}$$

and $g'''=\det(g^{jk})^{-1}_{j,k=1,\dots,q}$.

Then $\mathcal{N}^{\mathsf{MW}}=\mathcal{N}^{\mathsf{MW}}_{\mathcal{Q}}+\mathcal{N}^{\mathsf{MW}}_{1-\mathcal{Q}}$. Plugging this into (20.6.14), (20.6.19) and adding we get in our calculation a candidate to the final answer

$$\begin{aligned} &h^{-d}\int \mathcal{N}^{\mathsf{MW}}(x,0)\psi(x)\,dx+\\ &\qquad h^{-d}\int_{-\infty}^{0}\int \omega(\tau)d_\tau\mathcal{N}^{\mathsf{MW}}(x,\tau)\,\psi(x)\,dx\equiv\\ &h^{-d}\int \mathcal{N}^{\mathsf{MW}}(x,0)\psi(x)\,dx+h^{-d}\int_{-\infty}^{0}\int \omega(\tau)d_\tau\mathcal{N}^{\mathsf{MW}}_{\mathcal{Q}}(x,\tau)\,\psi(x)\,dx \end{aligned} \tag{20.6.24}$$

modulo negligible error where $\mathcal{Q}$ is supported in $\{|\xi'''|\le 2\bar{\rho}_1\}$ and equal 1 in $\{|\xi'''|\le 2\bar{\rho}_1\}$.

Now it is a time to recall a correction

$$h^{-1}\sum_n\int_{-\infty}^{0}\phi_{0,L_0}(\tau)\Big(F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T_n}(t)-\bar{\chi}_{\bar{T}}(t)\big)\Gamma\big(U\psi_y\,{}^t\mathcal{Q}_{ny}\big)\Big)\,d\tau \tag{20.6.25}$$

because we replaced T_n by $\bar{T}$ in the intermediate and inner zones. Thus the following statement is proven:

Proposition 20.6.2. *In the framework of Proposition 20.4.4 expression* (20.6.7) *with summation over all zones modulo* $O(h^{1-d})$ *is equal to*

$$\begin{aligned} &h^{-d}\int \mathcal{N}^{\mathsf{MW}}(x,0)\psi(x)\,dx+\\ &\qquad h^{-d}\int_{-\infty}^{0}\int \omega(\tau)d_\tau\mathcal{N}^{\mathsf{MW}}_{\mathcal{Q}}(x,\tau)\,\psi(x)\,dx+\\ &h^{-1}\sum_n\int_{-\infty}^{0}\phi_{0,L_0}(\tau)\Big(F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T_n}(t)-\bar{\chi}_{\bar{T}}(t)\big)\Gamma\big(U\tilde{\psi}_y\,{}^t\mathcal{Q}_{ny}t\big)\Big)\,d\tau \end{aligned} \tag{20.6.26}$$

where $U=\mathcal{T}^*U\,{}^t\mathcal{T}_y^*$, $\tilde{\psi}=\mathcal{T}^*\psi\mathcal{T}$, $\mathcal{Q}_n=\mathcal{T}^*Q_n\mathcal{T}$ *and here we can take* $\mathcal{Q}_n=\mathcal{Q}_n(hD''')$ *elements of partition in zone* $\{|\xi'''|\le 2\bar{\rho}_1\}$, $\mathcal{Q}=\sum_n\mathcal{Q}_n$.

Now what we need is to estimate the sum of the second and the third terms in the right-hand expression of (20.6.26) (but not separately).

Decomposition. Part II

Let us consider the remaining inexplicit terms in the the the sum in expression (20.6.26)

$$h^{-1}\int_{-\infty}^{0}\phi(\tau)\Big(F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T_n}(t)-\bar{\chi}_{\bar{T}}(t)\big)\Gamma\big(U\tilde{\psi}_y\,{}^t\mathcal{Q}_y\big)\Big)\,d\tau \tag{20.6.27}$$

where we renamed ϕ_{0,L_0} into $\phi(\tau)$ (so, in (20.6.20) ϕ is no more ϕ_{0,L_0}) and for the sake of simplicity we skip index n.

Let us apply the same decomposition technique to $\phi(\tau)$ as we did to 1: $\phi(\tau)=\sum_{m\ge 0}\phi_{m,L_m}(\tau)$ with lesser L_m than before and rewrite (20.6.27) as the sum of (20.6.9)-type terms

$$h^{-1}\int_{-\infty}^{0}\phi_{m,L_m}(\tau)\Big(F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T_n}(t)-\bar{\chi}_{\bar{T}}(t)\big)\Gamma\big(U\tilde{\psi}_y\,{}^t\mathcal{Q}_y\big)\Big)\,d\tau. \tag{20.6.28}$$

Replacing $\big(\bar{\chi}_{T_n}(t)-\bar{\chi}_{\bar{T}}(t)\big)$ by $\chi_T(t)$ we find that each obtained term with $m>0$ does not exceed (20.6.10) again; however, there is a difference: after summation with respect to T ranging from $\bar{T}$ now to T_n we get that expression (20.6.28) does not exceed

$$C\rho^q h^{-d}L_m\times\big(\frac{\mu h}{L_m}\big)^s \tag{20.6.29}$$

as long $L_0\ge\mu h$ and $m>0$. After summation with respect to L_m it gives us $C\mu\rho^q h^{1-d}$.

These arguments would enable us to set $L_0=\mu h$ albeit condition $L\ge\rho^2+\mu^{-1}+\mu h$ prevents us.

Let us assume now that $\mu\ge h^{-\frac12}$; then we can take

$$L_0=C\rho^2+C\mu h; \tag{20.6.30}$$

analysis in the case $q=1$, $h^{-\frac13}\le\mu\le h^{-\frac12}$ will be done later with or without microhyperbolicity or non-degeneracy assumptions.

Let us employ the same method of the successive approximations with an unperturbed operator $\bar{\mathcal{A}}=\mathcal{A}_0(y'',y''',\mu^{-1}hD'',hD''')$ considered as an operator with operator valued symbol in $\mathscr{L}^2(\mathbb{R}^d)$. Then the perturbation is

$$\sum_{1\le j\le q+r}(x_j-y_j)a_j(x'',y'',x''',y''',\mu^{-1}hD'',hD''')+ \\ b(x'',y'',x''',y''',\mu^{-1}hD'',hD''') \tag{20.6.31}$$

with $b = O(\mu^{-1})$.

Consider the second term of the successive approximations plugged into (20.6.28) with $m > 0$ and transform it in our usual way. Then the factor $(x_j - y_j)$ in the first part of perturbation (20.6.28) should commute with either $\mathcal{G}^{\pm}$ bringing thus factor $\rho T^2 h^{-1}$ as $1 \le j \le q$ or the smaller factor $\mu^{-1} T^2 h^{-1}$ as $q+1 \le j \le q+r$ or with $\mathcal{Q}$ bringing factor $\rho^{-1} T$.

However again commuting with $\mathcal{Q}$ in the final run (after summation with respect to n) should be considered only as $T \ge T_n$ and since $T_n \ge \epsilon h \rho^{-2}$ due to the analysis of Section 20.4 the first factor is larger anyway.

Thus from the first part of perturbation we get terms estimated by (20.6.10) multiplied by one these factors: so we get

$$
\begin{aligned}
&(20.6.32)_1 \qquad && Ch^{-d}\rho^q L \times \bigl(\frac{h}{TL}\bigr)^s \times \rho T^2 h^{-1},\\
&(20.6.32)_2 \qquad && Ch^{-d}\rho^q L \times \bigl(\frac{h}{TL}\bigr)^s \times \mu^{-1} T^2 h^{-1},\\
&(20.6.32)_3 \qquad && Ch^{-d}\rho^q L \times \bigl(\frac{h}{TL}\bigr)^s \times T\rho^{-1}
\end{aligned}
$$

respectively because in our analysis $T \ge \epsilon\mu^{-1}$, $L \ge \mu h$.

On the other hand, the second part of the perturbation (20.6.31) brings factor $C\mu^{-1}Th^{-1}$ or equivalently $C\mu^{-1}L^{-1}$ thus giving us

$$
C\mu^{-1}\rho^q h^{-d} \times \bigl(\frac{h}{TL}\bigr)^s. \tag{20.6.33}
$$

Summation of $(20.6.32)_1$–$(20.6.32)_3$, (20.6.33) with respect to L, T results in the same expressions but with the minimal possible values, i.e. $T = \mu^{-1}$ and $L = \rho^2 + \mu h$; so the result of the summation for each of the expressions $(20.6.32)_{1-3}$ does not exceed

$$
C\mu^{-1}\rho^{q+1} h^{-d} \times \bigl(\frac{\mu h}{\rho^2 + \mu h}\bigr)^s, \tag{20.6.34}
$$

while the result for (20.6.33) does not exceed

$$
C\mu^{-1}\rho^{q} h^{-d} \times \bigl(\frac{\mu h}{\rho^2 + \mu h}\bigr)^s. \tag{20.6.35}
$$

Integration over $d\rho/\rho$ brings instead of (20.6.34), (20.6.35) their values as $\rho = \bar{\rho}_1^*$; the first one is always $O(h^{1-d})$ while the second one is $O(h^{1-d})$ as

$q \ge 2$ only and is $O(\mu^{-\frac12} h^{\frac12-d})$ as $q = 1$. We can do better than this but marginally. We will do it later.

Therefore, replacing U by its one-term approximation

$$\bar{\mathsf{U}} = -ih^{-1}\bar{\mathcal{G}}^{+}\delta(x-y)\delta(t) + ih^{-1}\bar{\mathcal{G}}^{-}\delta(x-y)\delta(t) \tag{20.6.36}$$

in each term of (20.6.28) with $m > 0$ brings the total error $O(h^{1-d})$ unless $q = 1$ and $\mathcal{A}$ contains (unremovable) cubic terms; in the latter case the total error is $O(\mu^{-\frac12} h^{\frac12-d})$.

Thus, let us plug $\bar{\mathsf{U}}$ into expression (20.6.28). Recall that the symbol of $\tilde{\psi}$ is given by (20.3.34). But then the remainder estimate $O(\mu^{-1}|\log h|^{-1})$ in this expression should be multiplied by $C\bar{\rho}_1\rho^q h^{-d}$ (recall that an extra factor $\bar{\rho}_1$ comes from the support of ϕ) and it results in $O(h^{1-d})$.

Furthermore, terms containing factors η_j^{w} with $j = q+1, \dots, d$ result in 0 because these terms applied to $v(x'', x''')\Upsilon_\alpha(x')$ result in

$$\sum_{\beta:|\alpha-\beta|=1} v_\beta(x'', x''')\Upsilon_\alpha(x')$$

while $\mathcal{A}_0$ "honors" $|\alpha|$.

Finally, terms containing η_j^{w} with $j = 1, \dots, q$ also result in 0 since we can take $\mathcal{Q}_n$ even with respect to ξ''' and $\mathcal{A}_0$ is even as well.

Therefore it suffices to plug only ψ_0 instead of $\tilde{\psi}$. We can also replace T_n by any larger value, say infinity. But then using the change of the coordinates Ψ_0 we get exactly the second term of (20.6.26) with the opposite sign and with ω defined by (20.6.20) for $\phi = \phi_{m,L_m}$. Then we arrive to (20.6.26) with $L_0 = \mu h + \rho^2$ (which now depends on n).

We also need to look at the case $m = 0$. So far we considered both intermediate and inner zones. Consider now intermediate zone only. Then all the above arguments remain true with the only difference that factor $\big(h/(\rho^2 T)\big)^s$ is now due to estimate (20.4.4) rather than τ-mollification.

Therefore we conclude that

(i) If <u>either</u> $q \ge 2$ <u>or</u> $q = 1$ and $\mathcal{A}$ contains no (unremovable) cubic terms then the expression

$$\begin{aligned} |\sum_n h^{-d} \int_{-\infty}^{0} \int \omega(\tau) d_\tau \mathcal{N}^{\mathsf{MW}}_{\mathcal{Q}_n}(x,\tau)\, \psi(x)\, dx + \\ h^{-1} \sum_n \int_{-\infty}^{0} \phi_{0,L_0}(\tau) \Big(F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T_n}(t) - \bar{\chi}_{\bar{T}}(t)\big) \Gamma \mathsf{U} \tilde{\psi}_y\, {}^t\mathcal{Q}_{ny} \Big)\, d\tau| \end{aligned} \tag{20.6.37}$$

with summation over n such that $\mathcal{Q}_n$ belongs to the intermediate zone does not exceed Ch^{1-d}.

(ii) If $q=1$ and $\mathcal{A}$ contains (unremovable) cubic terms then this expression (20.6.37) does not exceed $C\mu^{-\frac{1}{2}}h^{\frac{1}{2}-d}$.

Combining Proposition 20.6.2 we arrive to

Proposition 20.6.3. *In the framework of Proposition 20.4.4 let us assume that* $h^{-\frac{1}{2}}\le \mu\le \epsilon(h|\log h|)^{-1}$.

Then one can rewrite expression (20.6.7) *as* (20.6.26) *with* $L_0=C\mu h$ *and* ϕ, ω *defined accordingly and one should take* $\mathcal{Q}_n=\mathcal{Q}_n(hD''')$ *elements of partition in the inner zone* $\{|\xi'''|\le \rho_1^*\}$, $\mathcal{Q}=\sum_n \mathcal{Q}_n$ *and the error is*

(i) $O(h^{1-d})$ *if* <u>*either*</u> $q\ge 2$ <u>*or*</u> $q=1$ *and* $\mathcal{A}$ *contains no (unremovable) cubic terms.*

(ii) $O(\mu^{-\frac{1}{2}}h^{\frac{1}{2}-d})$ *if* $q=1$ *and* $\mathcal{A}$ *contains (unremovable) cubic terms.*

Recall that the only cubic terms which matter are those which do not contain hD_j with $1\le j\le q$.

20.6.3 Inner Zone: General Settings

Now in virtue of Proposition 20.6.3 we need to consider only an inner zone $\Omega_{\mathsf{inn}}=\{|\xi'''|\le \bar{\rho}_1^*\}$. In the general setting there is no point to take $L_0\le \mu h$ because we cannot improve estimate $O\big((\mu h)^{-r}\big)$ for the number of indices making contributions as τ runs an interval of length L_0. Because of this (as $m=0$) one should replace $(20.6.32)_{1-3}$ by

$$(20.6.38)_1 \qquad C\mu\rho^q h^{1-d}\times \min\Big(\big(\frac{h}{T\rho^2}\big)^s,1\Big)\times \rho T^2h^{-1},$$

$$(20.6.38)_2 \qquad C\mu\rho^q h^{1-d}\times \min\Big(\big(\frac{h}{T\rho^2}\big)^s,1\Big)\times \mu^{-1} T^2h^{-1},$$

$$(20.6.38)_3 \qquad C\mu\rho^q h^{1-d}\times \min\Big(\big(\frac{h}{T\rho^2}\big)^s,1\Big)\times T\rho^{-1}$$

respectively where factor $(h/T\rho^2)^s$ as $T\ge h/\rho^2$ is due to the estimate (20.4.4). Furthermore, $(20.6.38)_3$ one should count with $T\ge \epsilon T_n\asymp \rho$ only.

After summation with respect to T we get instead of expressions $(20.6.38)_{1-2}$ their values as $T = h/\rho^2$ and instead of expression $(20.6.38)_3$ its value as $T = \rho$ i.e.

$$(20.6.39)_{1-3} \qquad C\mu\rho^{q-3}h^{2-d}, \quad C\rho^{q-4}h^{2-d}, \quad C\mu\rho^{q}h^{1-d}\bigl(\frac{h}{\rho^3}\bigr)^s$$

respectively.

Finally, after summation with respect to $\rho \ge h^{\frac{1}{3}}$ we get $O(h^{1-d})$ as $q \ge 3$, $O(\mu h^{\frac{5}{3}-d})$ as $q = 2$, and $O(\mu h^{\frac{4}{3}-d})$ as $q = 1$.

On the other hand, instead of (20.6.33) we get

$$(20.6.40) \qquad C\mu\rho^{q}h^{1-d} \times \min\Bigl(\bigl(\frac{h}{T\rho^2}\bigr)^s, 1\Bigr) \times \mu^{-1}Th^{-1}$$

and summation with respect to T results in $C\rho^{q-2}h^{1-d}$.

Summation of this expression with respect to ρ should be taken over $\rho \ge \max\bigl(\mu^{-\frac{1}{2}}, h^{\frac{1}{3}}\bigr)$ only; it results in $O(h^{1-d})$ as $q \ge 3$, $O(h^{1-d}|\log \mu^2 h|)$ as $q = 2$, and $O(\mu^{\frac{1}{2}}h^{1-d})$ as $q = 1$.

To get rid of the factor $|\log \mu^2 h|$ as $q = 2$ one should consider two-term approximation; then (20.6.40) will be replaced by

$$(20.6.40)^* \qquad C\mu\rho^{q}h^{1-d} \times \min\Bigl(\bigl(\frac{h}{T\rho^2}\bigr)^s, 1\Bigr) \times \mu^{-2}T^2h^{-2}$$

which results in $C\mu^{-1}\rho^{-2}h^{1-d}$ after summation with respect to T and in $O(h^{1-d})$ after summation with respect to ρ.

On the other hand, consider the second part of perturbation (20.6.31); one can rewrite it as $b(y'', y''', \mu^{-1}hD'', hD''')$. Really, since this part contains unremovable cubic terms, symbol b belongs to $\mathscr{F}^{1,1}$ and thus freezing $x'' = y''$, $x''' = y'''$ one makes an error which could be accommodated in the first part of (20.6.31) and treated correspondingly.

However, the second term in the approximation of U is

$$(20.6.41) \qquad \bar{\mathsf{U}}' = -ih\bar{\mathcal{G}}^{+}\bar{B}\bar{\mathcal{G}}^{+}\delta(x-y)\delta(t) + ih\bar{\mathcal{G}}^{-}\bar{B}\bar{\mathcal{G}}^{-}\delta(x-y)\delta(t).$$

and plugging ψ_0 instead of $\tilde{\psi}$ results in the trace equal to 0.

Really, operators $\mathcal{A}_0$ and thus $\bar{\mathcal{G}}^{\pm}$ transform $v(x'', x''')\Upsilon_\alpha(x')$ into the sum of terms $v_\beta(x'', x''')\Upsilon_\beta(x')$ with $|\beta - \alpha| = 0, 2$ while operator $\bar{B}'$ transforms

$v(x'',x''')\Upsilon_\alpha(x')$ into the sum of terms $v_\beta(x'',x''')\Upsilon_\beta(x')$ with $|\beta-\alpha|=1,3$ where

$$\bar{b}'=\sum_{(j,k,m)\in\mathfrak{J}_3\cup\mathfrak{J}_1} b_{jkm}\eta_j\eta_k\eta_m, \qquad \bar{b}''=\sum_{(j,k,m)\in\mathfrak{J}_2\cup\mathfrak{J}_0} b_{jkm}\eta_j\eta_k\eta_m$$

and $\mathfrak{J}_s=(j,k,m)$ with exactly s of j,k,m in $\{q+1,\dots,d\}$.

Meanwhile symbol $\bar{b}''$ is odd with respect to ξ''' while everything else is even and thus the corresponding part of the second term vanishes after integration with respect to ξ'''.

Furthermore, plugging $(\tilde{\psi}-\psi_0)$ instead of $\tilde{\psi}$ produces an extra factor μ^{-1} in the estimate which is more than enough to compensate the logarithmic factor.

Now we need to estimate the contribution of the inner core $\Omega^0_{\mathsf{inn}}=\{|\xi'''|\le\bar{\rho}_0\}$ with

(a) $\bar{\rho}_0=h^{\frac{1}{3}}$ if <u>either</u> there are no unremovable cubic terms <u>or</u> $\mu\ge h^{-\frac{2}{3}}$,

(b) $\bar{\rho}_0=\mu^{-\frac{1}{2}}$ if there are unremovable cubic terms <u>and</u> $\mu\le h^{-\frac{2}{3}}$.

However, it follows from Section 20.4 that we can consider this zone as a single partition element and set $T_n=\bar{T}=\epsilon\mu^{-1}$ here thus bringing an extra term $C\bar{\rho}_0^q\bar{T}^{-1}h^{1-d}=C\bar{\rho}_0^q\mu h^{1-d}$ into the remainder estimate; the latter expression is $O(h^{1-d})$ as $q\ge 3$, and $C\mu h^{\frac{5}{3}-d}$ as $q=2$.

As $q=1$ this expression is equal to $C\mu h^{\frac{4}{3}-d}$ if either $\mu\ge h^{-\frac{2}{3}}$ or there are no unremovable cubic terms in $\mathcal{A}$; otherwise (if $\mu\le h^{-\frac{2}{3}}$ and there are unremovable cubic terms in $\mathcal{A}$) this expression is equal to $C\mu^{\frac{1}{2}}h^{1-d}$.

Therefore with the error described one can replace U by $\bar{\mathsf{U}}$ in (20.6.27). Furthermore, we can replace $\tilde{\psi}$ by ψ_0 there with $O(h^{1-d})$ error.

Now we can preserve the remainder while increasing T_n to ∞. Really, consider

$$h^{-1}\int_{-\infty}^{0}\phi_{0,L_0}(\tau)\Big(F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\bar{\mathsf{U}}\psi_{0\,y}\,{}^t\mathcal{Q}_y\Big)\,d\tau \tag{20.6.42}$$

with $T\ge Ch\rho^{-2}$; it does not exceed

$$Ch^{-d}\times\mu h\times\rho^q\times\Big(\frac{h}{\rho^2 T}\Big)^s \tag{20.6.43}$$

exactly as would be for U but now we can take any $T \ge Ch\rho^{-2}$ because $\bar{\mathcal{A}}$ is a constant coefficient operator-valued operator. Summation with respect to $T \ge T_n$ results in the value of (20.6.43) with $T = T_n$ which is ρ in these settings i.e. we get

$$Ch^{1-d}\bigl(\rho^2+\mu h\bigr)\rho^q \times \Bigl(\frac{h}{\rho^3}\Bigr)^s \tag{20.6.44}$$

and after summation with respect to ρ we get its value as $\rho = h^{\frac{1}{3}}$ which is $C\mu h^{\frac{q}{3}+1-d}$.

But then after obvious calculations the second and the new third term in formula (20.6.26) just cancel one another and we are left with just the first term.

So we had proven

Proposition 20.6.4. *In the framework of Proposition 20.4.4 let us consider* $h^{-\frac{1}{2}} \le \mu \le \epsilon(h|\log h|)^{-1}$.

Then one can rewrite expression (20.6.7) *as* $h^{-d}\int \mathcal{N}^{\mathsf{MW}}(x,0)\,\psi(x)\,dx$ *with an error*

(i) $O(h^{1-d})$ *if* $q \ge 3$.

(ii) $O(h^{1-d}+\mu h^{\frac{5}{3}-d})$ *if* $q = 2$.

(iii) $O(\mu h^{\frac{4}{3}-d})$ *if* $q = 1$ *and either* $\mu \ge h^{-\frac{2}{3}}$ *or* $\mathcal{A}$ *contains no (unremovable) cubic terms.*

(iv) $O(\mu^{\frac{1}{2}}h^{1-d})$ *if* $q = 1$, $\mu \ge h^{-\frac{2}{3}}$ $q = 1$ *and* $\mathcal{A}$ *contains (unremovable) cubic terms.*

Remark 20.6.5. (i) When we say "unremovable cubic terms" we mean *only* terms $b_{jkm}\eta_j\eta_k\eta_m$ with $j \ge q+1$, $k \ge q+1$, $m \ge q+1$. Really, any other term bears an extra factor ρ and if $\mathcal{A}$ contains only these terms one can take $\bar{\rho}_0 = Ch^{\frac{1}{3}}$ and the above analysis of Subsection 20.6.2 and this Subsection produces an error $O(h^{1-d})$ (we get rid of factor $|\log \mu^2 h|$ in the same way as we did it for $q = 2$ in the proof of Proposition 20.6.4).

(ii) In the next Subsection 20.6.4 we show that under either microhyperbolicity or non-degeneracy assumptions these unremovable cubic terms do not cause any corrections even as $q = 1$. Further, in Subsection 20.6.4 we also derive asymptotics with a better remainder estimate.

(iii) In Subsection 20.6.5 we derive asymptotics with a correction term due to the unremovable cubic terms and with a better remainder estimate.

Proposition 20.6.4 together with the remainder estimate of Proposition 20.4.4 and with a mollification error estimate imply Theorem 20.6.17 below.

20.6.4 Improved Error Estimates

Microhyperbolicity Assumption

If either $q=2$ or $q=1$ and there are no unremovable cubic terms, everything is easy: under the microhyperbolicity condition one can replace in the estimates $(20.6.38)_{1-3}$ factor μh by factor ρ^2 as $\rho \ge \bar{\rho}_0 = Ch^{\frac{1}{3}}$; then instead of expressions $(20.6.39)_{1-3}$ we will get expressions

$$(20.6.45)_{1-3} \qquad C\rho^{q-1}h^{1-d}, \qquad C\mu^{-1}\rho^{q-2}h^{1-d}, \qquad C\rho^{q+2}h^{-d}\bigl(\frac{h}{\rho^3}\bigr)^s$$

respectively which will result after integration over $d\rho/\rho$ in $O(h^{1-d})$ in each of them[23].

Further, contribution of the inner core is estimated in Section 20.4 by $C\bar{T}^{-1}\bar{\rho}_0^{q+2}h^{1-d} = O(\mu h^{2-d})$ as we take $T_n = \bar{T}$ there. So we can again replace U by $\bar{\mathsf{U}}$ and then $\tilde{\psi}$ by ψ_0 and after this we replace T_n by ∞. Then after obvious calculations we estimate expression (20.6.28) by Ch^{1-d} and thus expression (20.6.26) will be reduced modulo $O(h^{1-d})$ to its first term.

On the other hand, factor μh is replaced by ρ^2 in the expression(20.6.40) as well thus resulting after summation with respect to T in $C\mu^{-1}\rho^q h^{-d}$; after summation with respect to ρ we get $C\mu^{-\frac{1}{2}}h^{\frac{1}{2}-d}$ as $q=1$. Even use of two-term approximation gives us $(20.6.40)^*$ multiplied by $\rho^2/(\mu h)$ and after summation with respect to T and then by ρ we get $C\mu^{-2}h^{-\frac{1}{3}-d}$ which is $O(h^{1-d})$ only for $\mu \ge h^{-\frac{2}{3}}$.

However, if $\mathcal{A}$ contains no unremovable cubic terms in the sense of Remark 20.6.5(i), one should replace there factor $\mu^{-1}T$ by $\mu^{-1}\rho T$; thus we get

$$C\mu^{-1}T\rho^4 h^{-d}\min\Bigl(\bigl(\frac{h}{T\rho^2}\bigr)^s, 1\Bigr)$$

[23] Sure in the first expression as $q=1$ we get $Ch^{1-d}|\log h|$ but we consider two-term approximation as above and also we replace $\tilde{\psi}$ by ψ_0; then the error term results in $O(h^{1-d})$ while the second term (20.6.41) resulting in 0.

in both cases instead of (20.6.40). Then after summation with respect to T we get $C\mu^{-1}\rho^2 h^{-d}$ and after integration over $d\rho/\rho$ we get $C\mu^{-1}\bar{\rho}_1^{*2}h^{-d} = Ch^{1-d}$.

Also, we need to cover also the case $(h|\log h|)^{-\frac{1}{2}} \le \mu \le h^{-\frac{1}{2}}$ (lesser μ are covered by the weak magnetic field case due to the microhyperbolicity) but one can easily weaken an assumption $\mu \ge h^{-\frac{1}{2}}$ if $\mathcal{A}$ contains no unremovable cubic terms.

So, we can plug $\bar{\mathsf{U}}$ instead of U (and ψ_0 instead of $\tilde{\psi}$) and thus we have proven

Proposition 20.6.6. *Let $(h|\log h|)^{-\frac{1}{2}} \le \mu \le \epsilon(h|\log h|)^{-1}$. Then in the framework of Proposition 20.4.4 under the microhyperbolicity assumption (see Definition 20.1.2) one can rewrite expression* (20.6.7) *as*

$$h^{-d}\int \mathcal{N}^{\mathsf{MW}}(x,0)\psi(x)\,dx \tag{20.6.46}$$

with $O(h^{1-d})$ error provided <u>either</u> $q = 2$ <u>or</u> $q = 1$ and $\mathcal{A}$ contains no unremovable cubic terms (in the sense of Remark 20.6.5(i)).

However, we want to get rid of this extra assumption and thus we want to consider case "$q = 1$, $\mathcal{A}$ contains unremovable cubic terms". To do this we must reexamine an intermediate zone as well.

Our main idea is to estimate decay of $F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\psi_0\mathcal{Q}U$ more accurately, using the microhyperbolicity conditions it was done in Subsections 19.4.1–19.4.4.

Proposition 20.6.7. *Let $(h|\log h|)^{-\frac{1}{2}} \le \mu \le \epsilon(h|\log h|)^{-1}$. Then in the framework of Proposition 20.4.4 under the microhyperbolicity assumption (see Definition 20.1.2)*

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\tilde{\psi}\mathcal{Q}U| \le CT\rho^{q+2}h^{-d}\bigl(\frac{h}{T}\bigr)^{l-1}|\log\bigl(\frac{h}{T}\bigr)|^{-\sigma}\times \min\Bigl(\bigl(\frac{h}{\rho^2 T}\bigr)^{s},1\Bigr) \tag{20.6.47}$$

as $\bar{\rho}_0 = h^{-\frac{1}{3}} \le \rho \le \bar{\rho}_1$, $|\tau| \le \epsilon$.

Proof. The proof repeats those of Propositions 19.4.3 and 19.4.4 and is based on η-approximation of $\mathcal{A}$ with $hT^{-1} \le \eta \le ChT^{-1}|\log h|$. Easy details are left to the reader. □

After we improved our estimate by an extra factor $(h/T)^{l-1}|\log(h/T)|^{-\sigma}$ we can do more precise estimates.

Recall that

$$h^{-1}\int_{-\infty}^{0}\phi_{0,L_0}(\tau)\Big(F_{t\to h^{-1}\tau}\chi_T(t)\tilde{\psi}\mathcal{Q}_n\mathsf{U}\Big)\,d\tau = iT^{-1}\Big(F_{t\to h^{-1}\tau}\check{\chi}_T(t)\tilde{\psi}\mathcal{Q}_n\mathsf{U}\Big)\Big|_{\tau=0} - iT^{-1}L_0^{-1}\int_{-\infty}^{0}\phi'_{0,L_0}(\tau)\Big(F_{t\to h^{-1}\tau}\check{\chi}_T(t)\tilde{\psi}\mathcal{Q}_n U\Big)\,d\tau \tag{20.6.48}$$

with $\check{\chi}(t)=t^{-1}\chi(t)$ and ϕ'_0 derivative of ϕ_0; recall that $\phi_0(0)=1$. Here L_0 could be larger than ρ^2 to accommodate a weaker assumption $\rho\le\mu^{-\frac12}$. Then Proposition 20.6.7 implies that for $q=1$ the right-hand expression of (20.6.48) does not exceed

$$C\rho^3h^{-d}\big(\frac{h}{T}\big)^{l-1}|\log\big(\frac{h}{T}\big)|^{-\sigma}\times\min\Big(\big(\frac{h}{\rho^2T}\big)^{s},1\Big). \tag{20.6.49}$$

Integrating this expression (20.6.49) over dT/T from $T=\bar{T}$ to $T=\infty$ we get this expression as $T=\bar{T}$ and then integrating over $d\rho/\rho$ from $\bar{\rho}_)=h^{\frac13}$ to $\rho=\bar{\rho}_1$ as $(h|\log h|)^{-\frac12}\le\mu\le h^{-\frac23}$ we get this expression as $\rho=\bar{\rho}_0$ i.e.

$$C(\mu h)^{l+\frac12}|\log h|^{-\sigma}h^{-d} \tag{20.6.50}$$

which does not exceed an approximation error

$$C\mu^{-l}\bar{\rho}_1|\log h|^{-\sigma}h^{-d}=C\mu^{\frac12-l}h^{\frac12-d}|\log h|^{\frac12-\sigma} \tag{20.6.51}$$

as $\mu\le h^{-\frac12}$. Therefore, in this case we can plug $\bar{\mathsf{U}}$ instead of U (and ψ_0 instead of $\tilde{\psi}$).

Thus it remains to consider the case $h^{-\frac12}\le\mu\le h^{-\frac23}$. Consider expression (20.6.49) with $T=\mu^{-1}$ and the last factor equal to 1. Integrating it with respect to $d\rho/\rho$ from $\bar{\rho}_0=h^{-\frac13}$ to $\rho=\mu^{-\frac12}$, we get its value as $\rho=\mu^{-\frac12}$ which is

$$C\mu^{-\frac32}(\mu h)^{l-1}|\log h|^{-\sigma}h^{-d} \tag{20.6.52}$$

and which does not exceed approximation error as $l\le\frac32$ and Ch^{1-d}) as $l>\frac32$. These arguments estimate contribution of the inner core as well. Therefore we estimated properly contribution of the inner zone $\{|\xi'''|\le C\mu^{-\frac12}\}$.

Consider now ρ ranging from $\mu^{-\frac{1}{2}}$ to $\bar{\rho}_1$. We also apply the above arguments as $T \ge \mu h \ge h/\rho^2$, resulting after integration over dT/T in

$$C\rho^3\mu^{1-l}|\log h|^{-\sigma}\bigl(\frac{1}{\mu\rho^2}\bigr)^s h^{-d}. \tag{20.6.53}$$

As $\bar{T} \le T \le \mu h$ we apply the two-term approximation method with the second term resulting in 0 in the final answer and with an error estimate

$$C\rho^3 h^{-d}\bigl(\frac{h}{T}\bigr)^{l-1}|\log\bigl(\frac{h}{T}\bigr)|^{-\sigma} \times \bigl(\frac{T}{\mu h}\bigr)^2 \times \min\Bigl(\bigl(\frac{h}{\rho^2 T}\bigr)^s, 1\Bigr) \tag{20.6.54}$$

which can be easily proven by arguments of Propositions 19.4.3, 19.4.4 and 19.4.15. After integration over dT/T we get

$$C\rho^{2l-3}\mu^{-2}|\log\rho|^{-\sigma}h^{-d} \times \min\Bigl(\bigl(\frac{\mu h}{\rho^2}\bigr)^s, 1\Bigr). \tag{20.6.55}$$

Finally, integration of (20.6.53) over $d\rho/\rho$ in the indicated limits results in its value at the lower limit $\rho = \mu^{-\frac{1}{2}}$; this result does not exceed $\mu^{-\frac{1}{2}-l}|\log h|^{-\sigma}h^{-d}$ which again does not exceed an approximation error (20.6.51). This is also true for expression (20.6.55) as $l < \frac{3}{2}$; as $l = \frac{3}{2}$ we get $C\mu^{-2}|\log h|^{-\sigma}h^{-d} \times |\log \mu^2 h|$ which also does not exceed approximation error.

So again we can replace U by $\bar{\mathsf{U}}$ and $\tilde{\psi}$ by ψ_0. Moreover, after this replacement we can replace $T_n = \epsilon$ by $T_n = \infty$ with a negligible error. Thus we have proven

Proposition 20.6.8. *Let $q = 1$ and $(h|\log h|)^{-\frac{1}{2}} \le \mu \le \epsilon(h|\log h|)^{-1}$. Then in the framework of Proposition 20.4.4 under microhyperbolicity assumption (see Definition 20.1.2) one can rewrite expression* (20.6.7) *as* (20.6.46) *with $O\bigl(h^{1-d} + \mu^{\frac{1}{2}-l}h^{\frac{1}{2}-d}|\log h|^{\frac{1}{2}-\sigma}\bigr)$ error.*

Proposition 20.6.8 together with remainder estimate of Proposition 20.4.11 and with mollification error estimate imply Theorem 20.6.15 below.

Case of f_j Having Constant Multiplicities

If we drop all junior terms we get a family of scalar operators and everything is easy. However while covering case $q = 2$ this would not cover case $q = 1$

even if the unremovable cubic terms contain hD_1. So we need more delicate arguments.

Note that instead of $\mathcal{Q}_n(hD''')$ we have now $\mathcal{Q}_n(x'', x''', \mu^{-1}hD'')\mathcal{Q}'_m(hD''')$ where $\mathcal{Q}'_m$ are elements of ρ-partition, $\mathcal{Q}_n$ are elements of γ-partition with γ, ϱ introduced by (20.4.73)–(20.4.74).

(i) Consider first elements with $\varrho \ge C\bar{\varrho}$ and $\rho \ge \epsilon\varrho$.

Then one should multiply (20.4.49) by $\gamma^d \times \varrho^2/\gamma$ where factor γ^d comes from $\mathcal{Q}_n$ and factor ϱ^2/γ (which is greater than μ^{-1}) comes from the estimate of $|\nabla_{x'',x''',\xi'''}A|$.

Then expressions $(20.6.39)_{1-3}$ become

$$(20.6.56)_{1-3} \quad C\mu\varrho^{q-1}h^{2-d}\gamma^{d-1}, \qquad C\varrho^{q-2}h^{2-d}\gamma^{d-1}, \qquad C\mu\varrho^{q+2}h^{1-d}\min\Big(\big(\frac{h}{\varrho^3}\big)^s, 1\Big)\gamma^{d-1}$$

respectively and the second and the third expressions do not exceed the first one.

(ii) On the other hand, as $\rho \le \epsilon\varrho$, $\varrho \ge C\bar{\varrho}$ we can rescale problem to the microhyperbolic one with $x \mapsto x\gamma$, $h \mapsto h/(\varrho\gamma)$, $\mu^{-1}h \mapsto \mu^{-1}h\gamma^{-2}$. Then the total contribution of elements with fixed n and different m does not exceed $(20.6.56)_1$ again. therefore, $(20.6.56)_1$ estimates the contribution of element $\mathcal{Q}_n$.

After summation over partition $(20.6.56)_1$ results in

$$\mu h^{2-d}\int \varrho^{q-1}\gamma^{-1}\,dx''dx'''d\xi'' \tag{20.6.57}$$

which does not exceed the right hand expression in (20.6.90) (or (20.4.80)).

(iii) Finally, the same estimate remains true as $\varrho \asymp \bar{\varrho}$ because now we estimate the contribution to each of the second and the third term of (20.6.7) rather than to their sum.

(iv) Similarly, if unremovable cubic terms contain factor hD_1 then we get that the contribution of $\mathcal{Q}_n$ instead of (20.6.51) is estimated by

$$C\mu h^{1-d}\varrho^q\gamma^d\min\big(\mu^{-1}\varrho^{-1}, 1\big) \le Ch^{1-d}\varrho^{q-1}\gamma^d \tag{20.6.58}$$

and the total contribution of all elements does not exceed Ch^{1-d} because then μ scales as $\mu\varrho$ [24)].

(v) On the other hand, if there are unremovable cubic terms without factor hD_1 then (20.6.58) is replaced by

$$C\mu h^{1-d}\varrho^q\gamma^d \min\bigl(\mu^{-1}\varrho^{-2},1\bigr) \le Ch^{1-d}\varrho^{q-1}\gamma^d \tag{20.6.59}$$

and summation results in $C\mu^{\frac12}h^{1-d}$ and Ch^{1-d} as $q=1,2$ respectively.

Thus we arrive to

Proposition 20.6.9. *Let $q=1,2$ and f_j have constant multiplicities.*

(i) Let <u>either</u> $q=2$ <u>or</u> $q=1$ and there are no unremovable cubic terms. Then with an error not exceeding the right-hand expression of (20.4.79) *one can rewrite* (20.6.7) *as* (20.6.46).

(ii) Let $q=1$ and there are unremovable cubic terms. Then with an error not exceeding the right-hand expression of (20.4.80) *plus $C\mu^{\frac12}h^{1-d}$ one can rewrite* (20.6.7) *as* (20.6.46).

Proposition 20.6.9 together with remainder estimate of Proposition 20.4.13 and with mollification error estimate imply Theorem 20.6.23 below.

We leave to the reader the following easy:

Problem 20.6.10. Let f_j be constant and non-degeneracy condition (20.2.42) be fulfilled. Prove that with $O(h^{1-d})$ error one can rewrite (20.6.7) as (20.6.46).

Number-Theoretical Arguments

Now it is easy to prove

Proposition 20.6.11. *In the framework of Proposition 20.4.19(i) one can rewrite expression* (20.6.7) *as* (20.6.46) *with an error not exceeding the right-hand expressions of* (20.6.82), (20.6.84) *below for $q=2,1$ respectively.*

[24)] Parameter $\mu^{-1}h$ scales independently from μ and h because we deal with the reduced form of operator.

Proposition 20.6.11 together with remainder estimate of Proposition 20.4.19 and with mollification error estimate imply Statements (i) and (ii) ofTheorem 20.6.21 below.

A bit more sophistication requires

Proposition 20.6.12. *In the framework of Proposition 20.4.21(i) one can rewrite expression* (20.6.7) *as* (20.6.46) *with an error not exceeding the right-hand expressions of* (20.6.90), (20.6.91) *below as* $q = 2, 1$ *respectively.*

Proof. One needs just to replace $\tilde{\psi}$ by ψ_0, then consider two term approximations (the second term will result in 0 in the end), and then replace T_n by ∞. In the intermediate zone estimates repeat those of the generic case.

In the inner zone we need to consider integral (20.6.57) and notice that contribution in it of all elements with $c^{-1}t \le \varrho \le ct$, $t \le (\mu h)^{\frac{1}{2}}$ does not exceed

$$Ch^{1-d}\varrho^{q-1}\gamma^{-1}\big(\varrho^2 + \nu(\mu h)\big)$$

with ϱ defined by given γ and thus this integral does not exceed

$$Ch^{1-d}\int \varrho^{q+1}\gamma^{-1}\,dx + C\nu(\mu h)h^{1-d}\int \varrho^{q-1}\gamma^{-1}\,dx$$

and plugging $\varrho = \gamma^{\frac{l}{2}}|\log\gamma|^{-\frac{\sigma}{2}}$ and replacing dx by $\gamma^{-1}d\gamma$ we find that the first term does not exceed Ch^{1-d} provided <u>either</u> $q = 2$ <u>or</u> $q = 1$, $(l,\sigma) \succ (1,1)$ while the second integral does not exceed

$$C\nu(\mu h)h^{1-d}\bar{\varrho}^{q-1}\bar{\gamma}^{-1} \asymp C\nu(\mu h)\bar{\varrho}^{q}h^{-d}$$

unless $q = 2$, $l = 2$ in which case the second term does not exceed $C\nu(\mu h)h^{1-d}|\log h|^{-\sigma}$. □

Proposition 20.6.12 together with remainder estimate of Proposition 20.4.21 and with mollification error estimate imply Theorem 20.6.25 below.

20.6.5 $q = 1$: Asymptotics with Correction

We want to improve remainder estimates in asymptotics as $q = 1$ and $\mathcal{A}$ has non-removable cubic terms. To do this we need to add some correction to $h^{-d}\mathcal{N}^{\mathsf{MW}}$.

First of all, note that if both $\bar{\chi}$ and ϕ are proper functions[25)] and $L_0 \ge C\mu h|\log h|$, we can rewrite Tauberian expression (20.6.7) in (20.6.26) form with $O(h^s)$ error because (20.6.9) with $\varphi_T = \chi_T$ and with $m > 0$ is negligible as $TL_m \ge Ch|\log h|$.

To calculate the last term in (20.6.26) we apply the same successive approximation method as before but with an unperturbed operator $\bar{\mathcal{A}} = \mathcal{A}_1(y'', y''', \mu^{-1}hD'', hD''')$ where in $\mathcal{A}_1$ we include unremovable cubic terms

$$\mathcal{B} = \mu^2 \sum_{j,k,m,\ge 2} \bigl(b_{jkm}\eta_j\eta_k\eta_m\bigr)^{\mathsf{w}} \tag{20.6.60}$$

but do not include the similar terms with at least one of the indices j, k, m equal 1[26)]; obviously such unremovable terms contain either one or three such indices.

Then the last term in the perturbation (20.6.31) will contain at least one factor η_1 and thus we get an extra factor ρ in the corresponding estimates. Then instead of an unwanted term $C\rho\mu h^{1-d} \times (\mu\rho^2)^{-2}$ calculated as $\rho = \max\bigl(\mu^{-\frac{1}{2}}, \bar{\rho}_0\bigr)$ in an estimate, we get $C\rho\mu h^{1-d} \times (\mu\rho)^{-2}$, also calculated as $\rho = \max\bigl(\mu^{-\frac{1}{2}}, \bar{\rho}_0\bigr)$, which results in the error estimate $O(h^{1-d})$; here we take the same two-term approximation because we still need to consider the second term to avoid extra $|\log h|$ factor.

However, we need to consider it only as b contains exactly one factor hD_1 because otherwise we gain one more extra factor ρ. We also can replace $\tilde{\psi}$ by ψ_0 with impunity because the we get an error not exceeding $CL_0\rho\mu^{-1}h^{-d} = C\rho|\log h|h^{1-d}$ which does not exceed Ch^{1-d} as $\mu \le h^{-1}|\log h|^{-3}$ and is much less than the remainder estimate otherwise (actually we can replace in the above estimate L_0 by μh but we do not need it). But then the second term in this approximation will be odd with respect to ξ_1 and result in 0 in the final answer.

So, all estimates of Propositions 20.6.4 , 20.6.9, and 20.6.11 related to the case "$q = 1$ and $\mathcal{A}$ contains no unremovable cubic terms" hold for an error term arising if we replace in the last term of (20.6.26) U by $\hat{\mathsf{U}}$ and also replace $\tilde{\psi}$ by ψ_0. Here and below $\hat{\mathsf{U}}$ is our "new" first term, i.e. the first term in our new approximations.

Therefore in comparison with our previous calculations we get an extra

---

[25)] In Section 2.3 sense.

[26)] We also include $C\mu^{-2}\mathcal{A}_0^2$ to have operator semibounded from below

term

$$h^{-1}\sum_n \int_{-\infty}^{0} \phi_{0,L_0}(\tau)\times \Big(F_{t\to h^{-1}\tau}\big(\bar\chi_{T_n}(t)-\bar\chi_{\bar T}(t)\big)\Gamma\big((\hat{\mathsf{U}}-\bar{\mathsf{U}})\psi_{0y}\,{}^t\mathcal{Q}_{ny}\big)\Big)\,d\tau \tag{20.6.61}$$

where $\bar{\mathsf{U}}$ is the "old" first term in the successive approximations.

This is a correction term in question but we want to rewrite it in a more explicit form. First of all, we can replace here T_n by $+\infty$ (using the same arguments as before) and also replace $\bar T$ by $\bar T' = Ch|\log h|$ because $\big(F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(\mathsf{U}'\psi_{0y}\,{}^t\mathcal{Q}_{ny})\big)$ is negligible as $T\in[\bar T', \bar T]$, $|\tau|\le CL_0$ for both $\mathsf{U}'=\bar{\mathsf{U}}$ and $\mathsf{U}'=\hat{\mathsf{U}}$.

However if we consider expression

$$h^{-1}\sum_n \int_{-\infty}^{0} \phi_{0,L_0}(\tau)\Big(F_{t\to h^{-1}\tau}\bar\chi_{\bar T'}(t)\Gamma\big((\hat{\mathsf{U}}-\bar{\mathsf{U}})\psi_{0y}\,{}^t\mathcal{Q}_{ny}\big)\Big)\,d\tau \tag{20.6.62}$$

and apply the method of successive approximation to calculate it (considering $\bar{\mathcal{A}}_0$ as an unperturbed operator and $\bar{\mathcal{A}}_1$ as a perturbed one, we can get easily an error estimate $C\rho|\log h|^2h^{1-d}$ for it which is again less than the remainder estimate we are looking for.

Thus modulo term not exceeding the remainder estimate we can rewrite expression (20.6.61) as the same expression but with $\bar\chi_T$ replaced by 1 and with $\bar\chi_{\bar T}$ replaced by 0 i.e. as

$$h^{-1}\sum_n \int_{-\infty}^{0} \phi_{0,L_0}(\tau)\Big(F_{t\to h^{-1}\tau}\Gamma(\hat{\mathsf{U}}-\bar{\mathsf{U}})\psi_{0y}\,{}^t\mathcal{Q}_{ny}\Big)\,d\tau \tag{20.6.63}$$

which in turn is exactly equal to $h^{-d}\int \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,0)\psi(x)\,dx$ with

$$\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} := (2\pi)^{-d+r}(\mu h)^r \int \big(1-\phi_{0,L_0}(\tau)\big)\times d_\tau\Big(\int \big(\boldsymbol{n}(x,\tau-z^2)-\boldsymbol{n}_0(x,\tau-z^2)\big)\mathcal{Q}(z)\,dz\times f_1\cdots f_r\sqrt{g}\Big). \tag{20.6.64}$$

Thus we arrive to

Proposition 20.6.13. *Let* $q = 1$, $(h|\log h|)^{-\frac{1}{3}} \le \mu \le (h|\log h|)^{-1}$ *and* $\mathcal{A}$ *contain unremovable cubic terms. Let* $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ *be the difference between expression* (20.6.7) *and*

$$h^{-d}\int \bigl(\mathcal{N}^{\mathsf{MW}}(x,0)+\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,0)\bigr)\,\psi(x)dx \tag{20.6.65}$$

where $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *is defined by* (20.6.64) *with* $L_0 = C_0\mu h|\log h|$ *with large enough constant* C_0 *and a proper symbol* $\mathcal{Q}$ *equal* 1 *in* $\{|z| \le C\bar{\rho}_1\}$ *and* $\boldsymbol{n}_0$ *and* $\boldsymbol{n}$ *are eigenvalue counting functions for* $1\mathsf{D}$*-operators* $\boldsymbol{a}_0$ *and* $\boldsymbol{a}$ *respectively. Then*

(i) In the general settings $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ *does not exceed* $C\mu h^{\frac{4}{3}-d}$.

(ii) In the framework of Proposition 20.4.14 $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ *does not exceed the right-hand expression of* (20.4.88).

(iii) In the framework of Proposition 20.4.19(iii) $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ *does not exceed the right-hand expression of* (20.4.95).

(iv) In the framework of Proposition 20.4.21(ii) $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ *does not exceed the right-hand expression of* (20.4.99) *as condition* (20.4.85) *is violated.*

(v) In the framework of Proposition 20.4.21(iii) $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ *does not exceed the right-hand expression of* (20.4.101) *as condition* (20.4.85) *is violated.*

This proposition together with corresponding results of Section 20.4 implies all statement of theorems dealing with $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ rather than R^{MW} of Theorems 20.6.19(i) and 20.6.23(ii) below.

It follows from Proposition 20.6.13(iii) that in the framework of (20.4.93) with $\nu(\hbar) = \hbar^2$ we do not need any correction. On the other hand, the following example shows the need in the correction term.

Example 20.6.14. Consider the case $q = 1$, $r = 2, 3$ and $f_j = \mathsf{const}$ and commensurable and there are unremovable cubic terms in $\mathcal{A}$ so that the $\mathcal{A}_1 = \mathcal{A}_0 + \mu^{-1}\mathcal{E}$ with $\mathcal{E}$ commuting with $\mathcal{A}$ (at each point x). Furthermore, let us assume that one of the following conditions is fulfilled:

$$r = 2, \quad f_1 = 2f_2, \tag{20.6.66)$_2$}$$

$$r = 3, \quad f_1 = f_2 + f_3, \quad f_2 \ne f_3. \tag{20.6.66)$_3$}$$

Then

$$\mathcal{A}_0 = 2Z_1^*Z_1 + Z_2^*Z_2 + D_1^2, \qquad \mathcal{E} = (\omega Z_1^*Z_2^2) + (\omega Z_1^*Z_2^2)^*,$$
$$\mathcal{A}_0 = f_1Z_1^*Z_1 + f_2Z_2^*Z_2 + f_3Z_3^*Z_3 + D_1^2, \quad \mathcal{E} = (\omega Z_1^*Z_2Z_3) + (\omega Z_1^*Z_2Z_3)^*$$

respectively with $\omega = \omega(x'', x''', \mu^{-1}hD'')$ [27].

We can already apply Proposition 20.6.13, getting for $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ better estimate than estimate $C\mu^{\frac12}h^{1-d}$ for R^{MW}, but we can improve further the former one.

Let us assume that $|\omega| \ge \epsilon$. Then (assuming large enough smoothness of symbols) one can apply a transformation by operator $e^{i\hbar^{-1}\mathcal{L}}$ with $\mathcal{L} = \sum_j \beta_j Z_j^*Z_j$ with Hermitian $\beta_j = \beta_j(x'', x''', \mu^{-1}hD'')$ and transform operator (modulo terms containing factors $\mu^{-1}hD_1$ or μ^{-2}) to the same form but with Hermitian operator ω. So, $\mathcal{E} = \omega\mathcal{E}_0$ with

$$\mathcal{E}_0 = \begin{cases} Z_1^*Z_2^2 + Z_1Z_2^{*\,2} & r = 2 \\ Z_1^*Z_2Z_3 + Z_1Z_2^*Z_3^* & r = 3 \end{cases} \tag{20.6.67}$$

commuting with $\mathcal{E}_0$. Then one can decompose with respect to common eigenfunctions of $\mathcal{A}_0$ and $\mathcal{E}_0$ and to break the systems into separate equations and one can easily prove that

$$\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}} \le C\mu h^{\frac32-d} \tag{20.6.68}$$

without any microhyperbolicity or non-degeneracy condition; note that the right-hand expression is much less than $C\mu^{\frac12}h^{1-d}$ as $\mu h \ll 1$).

Let us select $V = -\sum_j (2\bar\alpha_j + 1)f_j\mu h$ and $\mu \ge h^{-\frac12}$.

Further, let us replace $\boldsymbol{n}(x, -z^2, \hbar)$ by

$$\#\bigl\{\alpha : \sum_j (2\alpha_j + 1)f_j\mu h + V < 0\bigr\} + \boldsymbol{m}(x, -\xi_d^2, \hbar)\theta(\rho^2 - z^2) \tag{20.6.69}$$

where $\boldsymbol{m}(x, \lambda, \hbar)$ is an eigenvalue counting function for operator $\mathcal{E}$ restricted to the linear span of Υ_α such that $\sum_j (2\alpha_j + 1)f_j\mu h + V = 0$. Then the error in $h^{-d}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ will not exceed $C\mu\rho h^{1-d} \times (\mu\rho^2)^{-2}$. Taking $\rho = \bar\rho_1^*$ we get this error not exceeding $C\mu^{-\frac52}h^{-\frac12-d} \ll \mu^{\frac12}h^{1-d}$ as long as $\mu \gg h^{-\frac12}$.

[27] One should not forget to add $C\mu^{-2}\mathcal{A}_0^2$ to avoid some non-semi-boundedness related problems.

But then

$$\int \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,0)\psi(x)\,dx = (\mu h)^r \iint \boldsymbol{m}(x,-\xi_d^2,\hbar)\theta(\rho^2-\xi_d^2)\psi(x)\,dx\,d\xi_1 + O(C\mu^{-\frac{5}{2}}h^{-\frac{1}{2}}) \tag{20.6.70}$$

which is exactly of magnitude $\mu^{-\frac{1}{2}}\times \mu h = \mu^{\frac{1}{2}}h^{1-d}$ and one cannot skip it without increasing the remainder estimate.

20.6.6 Main tTheorems

Microhyperbolicity Assumption

We assume first that the microhyperbolicity condition (see Definition 20.1.2) is fulfilled. Assume that

$$\bar{\mu}_{(2)} = C(h|\log h|)^{-\frac{1}{2}} \le \mu \le \epsilon(h|\log h|)^{-1}. \tag{20.6.71}$$

The low bound is justified as $q\ge 2$ since otherwise Theorem 20.2.10 provides $O(h^{1-d})$ remainder estimate. For $q=1$ justification is that we will need to take $\varepsilon = C\mu^{-1}$ and it is smaller than $\varepsilon = C\mu h|\log h|$ used in the previous results if and only if $\mu \ge \bar{\mu}_{(2)}$. The only exception (when we can take $\varepsilon = C(\mu^{-1}h|\log h|)^{\frac{1}{2}}$) is the case $r=1$ but then $q\ge 2$ since we assume that $d\ge 4$.

We also assume that

(20.6.72) Either $q\ge 2$ and $(l,\sigma)\succeq(1,1)$ or $q=1$ and $(l,\sigma)\succeq(1,2)$.

Theorem 20.6.15. *Let conditions* (20.1.1)–(20.1.11), (20.6.62) *and* (20.6.71) *be fulfilled. Further, let the microhyperbolicity condition (see Definition 20.1.2) be fulfilled. Then there exist two framing approximations (see footnote* [18)] *of Chapter 18) such that*

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + Ch^{-d}(\mu h|\log h|)^{\frac{q}{2}}\mu^{-l}|\log h|^{-\sigma}. \tag{20.6.73}$$

Corollary 20.6.16. *Under the microhyperbolicity condition for* $\mu \le \epsilon(h|\log h|)^{-1}$ *the sharp remainder estimate* $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d}$ *holds as either* $q\ge 2$ *and* $(l,\sigma)\succeq(1,1)$ *or* $q=1$ *and* $(l,\sigma)\succeq(\frac{3}{2},1)$.

General Case

Now let us consider the temperate magnetic field without microhyperbolicity assumption.

Theorem 20.6.17. *Let conditions* (20.1.1)–(20.1.11), (20.6.72) *and* (20.6.71) *be fulfilled. Then there exist two framing approximations such that*

(i) For $q \ge 3$, $(l,\sigma) = (1,1)$, $(\bar{l},\bar{\sigma}) = (2,1)$ *estimate* $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d}$ *holds.*

(ii) For $q = 2$, $(l,\sigma) = (1,1)$, $(\bar{l},\bar{\sigma}) = (2,1)$ *estimate*

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C\mu h^{\frac{5}{3}-d} \tag{20.6.74}$$

holds; in particular, $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d}$ *as* $\mu \le h^{-\frac{2}{3}}$.

(iii) For $q = 1$, $(l,\sigma) = (1,2)$ *estimate*

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C\mu h^{\frac{4}{3}-d} + C\mu^{\frac{1}{2}}h^{1-d} \tag{20.6.75}$$

holds.

Remark 20.6.18. (i) Note that estimates (20.6.74), (20.6.75) are better than (20.2.32) with $q = 2, 1$ respectively iff $\mu \ge (h|\log h|)^{-\frac{1}{2}}$.

(ii) The second terms in (20.6.74), (20.6.75) are due to the remainder estimates for q-dimensional Schrödinger operator (it is not important that operator in question is also r-dimensional $\mu^{-1}h$-pseudodifferential operator). These estimates correspond to the $\mathscr{C}^{1,1}$-smoothness and cannot be improved in the general case even if we assume much the larger smoothness because we have a matrix, not a scalar h-pseudodifferential operator as for $d = 3$. However, in certain cases we can do better than this; we need to consider $q = 1, 2$ only.

(iii) In (20.6.75) the third term estimates an approximation error arising when we skip irreducible $O(\mu^{-1})$ terms due; we can prevent these terms under certain conditions.

Theorem 20.6.19. *Let* $q = 1$, $(1,2) \preceq (l,\sigma) \preceq (2,0)$ *and conditions* (20.1.1)–(20.1.11), *and* (20.6.71) *be fulfilled. Then there exist two framing approximations such that*

(i) Estimate

$$\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}} := \Bigl|\int \Bigl(e(x,x,\tau) - h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau) - h^{-d}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,\tau)\Bigr)\psi(x)\,dx\Bigr| \le Ch^{1-d} + C\mu h^{\frac{4}{3}-d} + C\mu^{1-\frac{l}{2}}h^{1-d}|\log h|^{-\frac{\sigma}{2}} \tag{20.6.76}$$

holds where

$$|\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,\tau)| \le C\mu^{\frac{1}{2}}h \tag{20.6.77}$$

is defined by formula (20.6.70) *and in the general case one cannot improve estimates* (20.6.75), (20.6.77).

(ii) If one of the following conditions

(20.6.78) *There are no third-order resonances;*

$$g^{jk} = \mathsf{const},\ F_{jk} = \mathsf{const} \tag{20.6.79}$$

is fulfilled then estimate (20.6.76) *holds for* R^{MW}.

As $r \ge 2$ and condition (20.6.71) is fulfilled let us consider

$$\boldsymbol{n}_0(x,\hbar,\tau) := \#\bigl\{\alpha \in \mathbb{Z}^{+r}, \sum_j (2\alpha_j+1)f_j(x)\hbar + V(x) < \tau\bigr\}. \tag{20.6.80}$$

Let us assume that estimate (20.4.93) holds with $\nu(\hbar) = o(\hbar)$.

Remark 20.6.20. Estimate (20.4.93) holds with $\nu(\hbar) = \hbar$ for sure and it holds with $\nu(\hbar) = \hbar^{\kappa}$, $\kappa > 1$ if <u>either</u> f_j have constant multiplicities and

$$\mathsf{rank}\{\nabla\frac{f_2}{f_1}, \dots, \nabla\frac{f_r}{f_1}\} \ge \kappa - 1 \qquad \forall x \tag{20.6.81}$$

<u>or</u> $\frac{f_j}{f_1} = \mathsf{const}$ and the system $\bigl\{\frac{f_2}{f_1}, \dots, \frac{f_r}{f_1}\bigr\}$ has some Diophantine properties[28)].

Under condition (20.4.93) we can improve Theorems 20.6.17 and 20.6.19 as $q = 1, 2$:

[28)] See Examples 20.4.17 and 20.4.18 for details.

Theorem 20.6.21. *Let* $q = 1, 2$ *and conditions* (20.1.1)–(20.1.11), (20.6.71), (20.4.93) *be fulfilled. Then there exist two framing approximations such that*

(i) For $q = 2$, $(l, \sigma) = (1, 1)$, $(\bar{l}, \bar{\sigma}) = (2, 1)$ *estimate*

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C\nu(\mu h)h^{\frac{2}{3}-d} \tag{20.6.82}$$

holds.

(ii) For $q = 1$, $(1, 2) \preceq (l, \sigma) \preceq (2, 0)$ *estimates*

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C\mu^{-\frac{1}{2}}h^{\frac{1}{2}-d}|\log h|^{\frac{1}{2}} + C\nu(\mu h)\bigl(h^{\frac{1}{3}-d} + \mu^{-\frac{1}{2}}h^{-d}\bigr), \tag{20.6.83}$$

$$\begin{aligned}\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}} \le{}& Ch^{1-d} + C\mu^{\frac{1}{2}-l}h^{\frac{1}{2}-d}|\log h|^{\frac{1}{2}-\sigma}+\\ & C\bigl(\nu(\mu h) + \mu^{-1}\bigr) \times \bigl(h^{\frac{1}{3}-d} + \mu^{-\frac{l}{2}}h^{-d}|\log h|^{-\frac{\sigma}{2}}\bigr)h^{-d}\end{aligned} \tag{20.6.84}$$

hold.

(iii) For $q = 1$, $(1, 2) \preceq (l, \sigma) \preceq (2, 0)$ *as one of conditions* (20.6.78), (20.6.79) *is fulfilled the following estimate holds:*

$$\begin{aligned}\mathsf{R}^{\mathsf{MW}} \le{}& Ch^{1-d} + C\mu^{\frac{3}{2}-l}h^{\frac{3}{2}-d}|\log h|^{\frac{1}{2}-\sigma}+\\ & C\nu(\mu h)\bigl(h^{\frac{1}{3}-d} + \mu^{-\frac{l}{2}}h^{-d}|\log h|^{-\frac{\sigma}{2}}\bigr).\end{aligned} \tag{20.6.85}$$

Recall that Proposition 20.6.13 estimates $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ defined as a difference between expressions (20.6.7) and (20.6.65). One can prove easily that

Theorem 20.6.22. *In the framework of Statements (i)–(v) of Proposition 20.6.13 the corresponding estimates hold also for* $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ *defined by* (20.6.76) *and* (20.6.64).

Case of f_j Having Constant Multiplicities

Assume now that

(20.6.86) Matrix (F^j_k) has eigenvalues $\pm i f_m$ of constant multiplicities.

Then the microhyperbolicity assumption is equivalent to

$$|V + \sum_{1\le j\le r} f_j\tau_j| + |\nabla(V + \sum_{1\le j\le r} f_j\tau_j)| \ge \epsilon \qquad \forall \tau_1, \dots, \tau_r \in \mathbb{R}^+. \tag{20.6.87}$$

Further, if

$$f_2/f_1 = \mathsf{const}, \dots, f_r/f_1 = \mathsf{const} \tag{20.6.88}$$

then (20.6.87) is equivalent to

$$|\nabla \frac{V}{f_1}| \ge \epsilon. \tag{20.6.89}$$

Theorem 20.6.23. *Let conditions* (20.1.1)–(20.1.11), (20.6.72), *and* (20.6.86) *be fulfilled. Then there exist two framing approximations such that*

(i) For $q = 2$, $(1,1) \preceq (l,\sigma) \preceq (2,0)$, $(\bar{l},\bar{\sigma}) = (2,1)$ *estimate*

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C\mu h^{1-d+\frac{ql}{l+2}} |\log \mu|^{-\frac{q\sigma}{(l+2)}} \tag{20.6.90}$$

holds.

In particular, $R^{\mathsf{MW}} \le Ch^{1-d}$ *as* $(l,\sigma) = (2,0)$.

(ii) As $q = 1$, $(1,2) \preceq (l,\sigma) \preceq (2,0)$, $(\bar{l},\bar{\sigma}) = (2,1)$ *estimate*

$$\begin{aligned} \mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}} \le{}& Ch^{1-d} + C\mu h^{2-d-\frac{2}{l+2}} |\log h|^{-\frac{\sigma}{(l+2)}} + \\ & Ch^{1-d}(\mu h|\log h|)^{\frac{1}{2}} \mu^{1-l} |\log h|^{-\sigma} + C\mu^{1-\frac{l}{2}} h^{1-d} |\log h|^{-\frac{\sigma}{2}} + \\ & C\mu^{\frac{2l+1}{3l}} h^{\frac{4}{3}-d} |\log h|^{-\frac{\sigma}{3l}} \end{aligned} \tag{20.6.91}$$

holds.

(iii) As $q = 1$, $(1,2) \preceq (l,\sigma) \preceq (2,0)$, $(\bar{l},\bar{\sigma}) = (2,1)$ *and one of conditions* (20.6.78), (20.6.79) *is fulfilled estimate*

$$\begin{aligned} \mathsf{R}^{\mathsf{MW}} \le{}& Ch^{1-d} + C\mu h^{2-d-\frac{2}{l+2}} |\log h|^{-\frac{\sigma}{(l+2)}} + \\ & Ch^{1-d}(\mu h|\log h|)^{\frac{1}{2}} \mu^{1-l} |\log h|^{-\sigma} + C\mu^{1-\frac{l}{2}} h^{1-d} |\log h|^{-\frac{\sigma}{2}} \end{aligned} \tag{20.6.92}$$

holds.

Remark 20.6.24. (i) Note that the right-hand expression of (20.6.91) contains an extra term (in comparison with (20.6.92).

(ii) Also note that for $q = 1$ estimate (20.6.90) is better than (20.2.32) as

$$\mu^{l+1} h |\log h|^{\sigma+1} \ge 1; \tag{20.6.93}$$

in particular, as $(l, \sigma) = (2, 0)$ we get estimate $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C\mu h^{\frac{3}{2}-d}$ which always is better than (20.2.32) as $\mu \ge \bar{\mu}_{1(1)}$.

Under condition (20.4.93) one can improve Theorem 20.6.23:

Theorem 20.6.25. *Let conditions* (20.1.1)–(20.1.11), (20.6.72) *and* (20.6.86), *and* (20.4.93) *be fulfilled. Then there exist two framing approximations such that*

(i) As $q = 2$, $(1, 1) \preceq (l, \sigma) \preceq (2, 0)$, $(\bar{l}, \bar{\sigma}) = (2, 1)$ *estimate*

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C\nu(\mu h) h^{1-d+\frac{l-2}{l+2}} |\log h|^{-\frac{2\sigma}{l+2}} \tag{20.6.94}$$

holds.

(ii) As $q = 1$, $(1, 2) \preceq (l, \sigma) \preceq (2, 0)$, $(\bar{l}, \bar{\sigma}) = (2, 1)$ *and one of conditions* (20.6.78), (20.6.79) *is fulfilled estimate*

$$\begin{aligned} \mathsf{R}^{\mathsf{MW}} \le {} & Ch^{1-d} + Ch^{-d}(\mu h |\log h|)^{\frac{1}{2}} \mu^{-l} |\log h|^{-\sigma} \\ & C\nu(\mu h)\Big(h^{1-d-\frac{2}{l+2}} |\log h|^{-\frac{\sigma}{(l+2)}} + C\mu^{-\frac{l}{2}} h^{-d} |\log h|^{-\frac{\sigma}{2}}\Big) \end{aligned} \tag{20.6.95}$$

holds.

(iii) If $f_1 = \mathsf{const}$, *...*, $f_r = \mathsf{const}$, $(l, \sigma) \succeq (2, 0)$ *and nondegeneracy assumption* (20.2.42) *is fulfilled then* $\mathsf{R}^{\mathsf{MW}} = O(h^{1-d})$.

20.7 Stronger Magnetic Field: Calculations and Main Results

In this section we consider the cases of the intermediate magnetic field as $\epsilon(h|\log h|)^{-1} \le \mu \le \epsilon h^{-1}$, or as the intermediate-strong magnetic field $\epsilon h^{-1} \le \mu \le C_0 h^{-1}$ and of strong magnetic field as $\mu \ge C_0 h^{-1}$.

20.7.1 Intermediate Magnetic Field

Calculations

Consider now case of the intermediate magnetic field $\epsilon(h|\log h|)^{-1} \le \mu \le \epsilon h^{-1}$. The same arguments work again, with no outer zone and necessity to join outer and intermediate zones. Because of this one should deal directly with (20.6.7) rather than (20.6.26).

Therefore (20.6.7) is preserved modulo $O(h^s)$ as T_n are replaced by some lesser values which depend on the assumptions described in the previous subsections; then we apply the method of the successive approximations in the same way as above replacing U by $\bar{\mathsf{U}}$ and $\tilde{\psi}$ by ψ_0 and estimating an error in (20.6.7) cause by this; finally we replace T'_n by T_n again with $O(h^s)$ error and then T_n by $+\infty$. We leave easy details to the reader.

Then one can easily prove several propositions below; we leave easy and standard details to the reader. The first proposition holds for both intermediate and intermediate-strong magnetic field:

Proposition 20.7.1. *Let* $\epsilon(h|\log h|)^{-1} \le \mu \le C_0 h^{-1}$, $(l,\sigma) = (1,1)$ *as* $q \ge 2$, $(l,\sigma) = (1,2)$ *as* $q = 1$. *Then one can rewrite* (20.6.7) *as* (20.6.46) *with an error not exceeding* Ch^{1-d} *as* $q \ge 2$, $C\mu^{\frac{1}{2}}h^{1-d}$ *as* $q = 1$ [29].

Proposition 20.7.2. *Let* $\epsilon h^{-1}|\log h|^{-1} \le \mu \le \epsilon h^{-1}$, $(l,\sigma) \succeq (1,1)$ *as* $q \ge 2$, $(l,\sigma) \succeq (1,2)$ *as* $q = 1$. *Then under the microhyperbolicity condition (see Definition 20.1.2) one can rewrite* (20.6.7) *as* (20.6.46) *with an error not exceeding* Ch^{1-d}.

Proposition 20.7.3. *Statements of Propositions 20.6.9–20.6.13, Theorem 20.6.22, Problem 20.6.10 and Example 20.6.14 remain true for* $\epsilon(h|\log h|)^{-1} \le \mu \le \epsilon h^{-1}$.

Proofs of Propositions 20.7.1–20.7.3. We leave all easy details to the reader.□

Main Results

Recall that in the case of the intermediate magnetic field we pick up

$$\varepsilon \asymp C(\mu^{-1}h|\log h|)^{\frac{1}{2}} + Ch|\log h| \asymp h|\log h| \tag{20.7.1}$$

[29] One can improve it as there are no unremovable cubic terms but there is no point as the general remainder estimate $O(\mu h^{\frac{4}{3}-d})$ is larger.

The first of our theorems hold for both intermediate and intermediate-strong magnetic field:

Theorem 20.7.4. *Let* $\epsilon(h|\log h|)^{-1} \le \mu \le C_0 h^{-1}$. *Let conditions* (20.1.1)–(20.1.11) *and* (20.6.72) *be fulfilled. Then there exist two framing approximations (see footnote* [18)] *of Chapter 18) such that*

(i) For $q \ge 3$, $(l,\sigma) = (1,1)$, $(\bar{l},\bar{\sigma}) = (2,1)$ *sharp remainder estimate* $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d}$ *holds.*

(ii) For $q = 2$, $(l,\sigma) = (1,1)$, $(\bar{l},\bar{\sigma}) = (2,1)$ *estimate* (20.6.74) *holds:* $\mathsf{R}^{\mathsf{MW}} \le C\mu h^{\frac{5}{3}-d}$.

(iii) For $q = 1$, $(1,2) \preceq (l,\sigma) \preceq (\bar{l},\bar{\sigma}) = (2,1)$ *estimate* (20.6.75) *holds:* $\mathsf{R}^{\mathsf{MW}} \le C\mu h^{\frac{4}{3}-d}$.

In all other cases we need to restrict ourselves here to the intermediate magnetic field case. Here conclusion is very simple: all results of Subsection 20.6.6 remain valid:

Theorem 20.7.5. *Let* $\epsilon(h|\log h|)^{-1} \le \mu \le \epsilon h^{-1}$. *Let conditions* (20.1.1)–(20.1.11), *and* (20.6.72) *be fulfilled.*

Further, let <u>*either*</u> *the microhyperbolicity assumption (see Definition 20.1.2)* <u>*or*</u> $(l,\sigma) = (2,0)$, $f_1 = \mathsf{const}, \dots, f_r = \mathsf{const}$ *and the nondegeneracy assumption* (20.2.42) *be fulfilled.*

Then there exist two framing approximations such that $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d}$.

Theorem 20.7.6. *In the case of the intermediate magnetic field* $\epsilon(h|\log h|)^{-1} \le \mu \le \epsilon h^{-1}$ *all statements of Theorems 20.6.23 and 20.6.25 remain true.*

Proofs of Theorems 20.7.4–20.7.6. We leave all easy details to the reader.□

20.7.2 Intermediate-Strong Magnetic Field

Calculations

Consider now case of the intermediate-strong magnetic field $\epsilon h^{-1} \le \mu \le C_0 h^{-1}$. The same arguments work again, with no intermediate zone anymore. We do not need consider the general case as it is covered by Theorem 20.7.4. Thus we should consider only $q = 1, 2$.

On the other hand, the microhyperbolicity and non-degeneracy assumptions should be modified to Definition 20.5.9 and (20.5.10) (again the non-degeneracy assumption is considered as $f_1, \dots, f_r/f_1$ are constant).

Finally, number theoretical arguments are no more applicable at all.

Again one can prove easily propositions below; we leave all easy details to the reader:

Proposition 20.7.7. *Let* $\epsilon h^{-1} \le \mu \le C_0 h^{-1}$, *and* $(l,\sigma) = (1,1)$ *as* $q \ge 2$, $(l,\sigma) = (1,2)$ *as* $q = 1$. *Then one can rewrite expression* (20.6.7) *as* (20.6.46) *with an error not exceeding* Ch^{1-d} *as* $q \ge 2$, $Ch^{\frac{1}{2}-d}$ *as* $q = 1$.

Proposition 20.7.8. *Let* $\epsilon h^{-1} \le \mu \le C_0 h^{-1}$, $(l,\sigma) = (1,1)$ *as* $q \ge 2$, $(l,\sigma) = (1,2)$ *as* $q = 1$. *Then under the microhyperbolicity condition (see Definition 20.5.9) with* ℓ *independent on* $\boldsymbol{\tau}$ *one can rewrite* (20.6.7) *as* (20.6.46) *with an error not exceeding* Ch^{1-d}.

Proposition 20.7.9. *Statements of Propositions 20.6.9 and Problem 20.6.10 remain true as* $\epsilon h^{-1} \le \mu \le C_0 h^{-1}$.

Main Theorems

We arrive then to the following theorems:

Theorem 20.7.10. *Let* $\epsilon h^{-1} \le \mu \le C_0 h^{-1}$. *Let conditions* (20.1.1)–(20.1.11), *and* (20.6.72) *be fulfilled.*

Further, let <u>*either*</u> *the microhyperbolicity assumption (see Definition 20.5.9)* <u>*or*</u> $(l,\sigma) = (2,0)$, $f_1 = \mathsf{const}, \dots, f_r = \mathsf{const}$ *and the nondegeneracy assumption* (20.5.10) *be fulfilled.*

Then there exist two framing approximations such that $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d}$.

Theorem 20.7.11. *In the case of the intermediate-strong magnetic field* $\epsilon h^{-1} \le \mu \le C_) h^{-1}$ *all statements of Theorem 20.6.23 remain true.*

Proofs of Theorems 20.7.10–20.7.11. We leave all easy details to the reader.□

20.7.3 Strong Magnetic Field

Consider now case of strong magnetic field $\mu \ge C_0 h^{-1}$ and a magnetic Schrödinger-Pauli operator.

Then we need to modify condition $(20.1.9)_3$, replacing $(20.1.9)_{1,3}$ by

$$g^{jk}, F_{jk} \in \mathscr{C}^{\bar{l},\bar{\sigma}}, \qquad W = V + \mu h \sum_j f_j \in \mathscr{C}^{l,\sigma} \tag{20.7.2}$$

and assuming that

$$W + 2f_j \mu h \geq \epsilon \qquad \forall j. \tag{20.7.3}$$

Under these assumptions we have really a scalar operator, and should take

$$\varepsilon = Ch|\log h| \tag{20.7.4}$$

and the microhyperbolicity condition (see Definition 20.5.9) transforms into

$$|W| + |\nabla W| \geq \epsilon \tag{20.7.5}$$

while non-degeneracy assumption (20.5.10) transforms into

$$|W| + |\nabla W| \leq \epsilon \implies |\det \mathsf{Hess}\, W| \geq \epsilon. \tag{20.7.6}$$

Skipping calculations (which are not much different from what we did before, so we leave the easy details to the reader) we arrive immediately to

Theorem 20.7.12. *Let $\mu \geq C_0 h^{-1}$ and let conditions* (20.1.1)–(20.1.8), $(20.1.9)_2$, (20.6.72), (20.7.2), *and* (20.7.3) *be fulfilled. Then*

(i) For $q \geq 3$ remainder estimate $\mathsf{R}^{\mathsf{MW}} \leq C\mu^r h^{r+1-d}$ holds.

(ii) For $q = 1, 2$ and the microhyperbolicity condition (20.5.9) *fulfilled, the remainder estimate $\mathsf{R}^{\mathsf{MW}} \leq C\mu^r h^{r+1-d}$ holds.*

(iii) For $q = 2$ and $(l, \sigma) \succeq (2, 1)$ the remainder estimate $\mathsf{R}^{\mathsf{MW}} \leq C\mu^r h^{r+1-d}$ holds.

(iv) For $q = 1$, $(l, \sigma) \succeq (2, 1)$, and non-degeneracy condition (20.5.10) *fulfilled the remainder estimate $\mathsf{R}^{\mathsf{MW}} \leq C\mu^r h^{r+1-d}$ holds.*

(v) As <u>either</u> $q = 2$, $(l, \sigma) \prec (2, 0)$ <u>or</u> $q = 1$ then the remainder estimate

$$\mathsf{R}^{\mathsf{MW}} \leq C\mu^r h^{r-d} \begin{cases} h^{\frac{2l}{l+2}} |\log h|^{-\frac{2\sigma}{l+2}} & \text{as} \quad q = 2, \\ h^{\frac{l}{l+2}} |\log h|^{-\frac{\sigma}{l+2}} & \text{as} \quad q = 1 \end{cases} \tag{20.7.7}$$

holds.

Remark 20.7.13. Under assumption (20.7.3) the main part of asymptotics is

$$h^{-d}\int \mathcal{N}_d^{\mathsf{MW}}(x,\tau)\psi(x)\,dx = \omega_{d-2r}(2\pi)^{-d+r}\mu^r h^{-d+r}\int \Bigl(\tau - \sum_j f_j\mu h - V\Bigr)_+^{\frac{q}{2}} f_1\cdots f_r\sqrt{g}\psi(x)\,dx. \tag{20.7.8}$$

20.8 Degenerating Magnetic Field

Remark 20.8.1. One can get rid of assumption $|V|\ge\epsilon$ as $\mu\le\epsilon h^{-1}$ easily (see Subsubsection 18.9.5.1).

Condition that non-zero eigenvalues of F_k^j are uniformly disjoint from 0 is more subtle. Basically we want to apply arguments of Subsubsection 18.9.5.2 but we should take into account that different eigenvalues have different magnitudes.

Usually we assume that $q=1$ (so at generic point only 1 eigenvalue is 0), but at this moment we just assume

(20.8.1) At each point matrix $F_k^j(x)$ has at least q eigenvalues equal to 0 and let $\pm if_j(x)$ denote other eigenvalues (which may be also vanish at some points[30)]

Let us introduce

$$\gamma(x) = \epsilon_0 \min_j f_j(s) \tag{20.8.2}$$

where in partitions but not in statements we replace γ by $\mathsf{max}(\gamma,\bar\gamma)$ and $\bar\gamma$ will be chosen later.

20.8.1 Weak Magnetic Field

Consider some point y, its $\gamma(y)$ vicinity and classify $f_1,\dots,f_r$ into two groups: those which are greater than $4\nu\gamma$ (we denote them by $f_{r'+1},\dots,f_r$) and those which are less than $\nu\gamma$ (we denote them by $f_1,\dots,f_{r'}$); an appropriate constant

[30)] We will need to assume that these eigenvalues do not vanish in the generic points.

$\nu = \nu(y) \in [c_0, c_1]$ exists with arbitrarily large $c_0 \ge 1$ and $c_1 = c_1(c_0)$. Then the similar inequalities

$$f_j(x) \le 2\nu\gamma(y) \quad \forall j = 1, \dots, r', \qquad f_j \ge 3\nu\gamma(y) \quad \forall j = r'+1, \dots, r \tag{20.8.3}$$

hold in γ-vicinity of y; here $r' = r'(y)$.

We claim that

(20.8.4) As $\gamma(y) \ge C_0\mu^{-1}$ the contribution of $B(y, \gamma(y))$ to the remainder does not exceed

$$C\big(\gamma^{-1} + \mu(\mu h|\log h|)^{\frac{q}{2}}\big)h^{1-d}\gamma^d. \tag{20.8.5}$$

Really, one can use the weak magnetic field approach and take $T_* = \epsilon\mu^{-1}$. Further, one can take $T^* = T^*(y, |\xi'''|) = \epsilon\gamma(y)|\xi'''|$ and after summation with respect to ξ''' we get (20.8.5) as $q \ge 2$; as $q = 1$ we get the same expression albeit with an extra logarithmic factor in the first term and we get rid of it exactly in the same manner as in Subsubsection 20.2.2.2.

Here $C\mu(\mu h|\log h|)^{\frac{q}{2}}h^{1-d}\gamma^d$ estimates a contribution of the complementary zone $\Omega^{\mathsf{c}}_{\mathsf{out}} = \{|\xi'''| \le \bar\rho_1\}$ with $\bar\rho_1 = C\max\big((\mu h|\log h|)^{\frac12}, \mu^{-1}\gamma^{-1}\big)$ as $\bar\rho_1 = C(\mu h|\log h|)^{\frac12} \ge C\mu^{-1}\gamma^{-1}$; otherwise contribution of the complementary zone does not exceed $C\bar\rho_1\mu h^{1-d}\gamma^d \asymp C\gamma^{-1}h^{1-d}$ which is the first term in (20.8.5).

This estimate (20.8.5) could be improved but it does not make any difference. Summation with respect to all balls with $\gamma \gtrsim \bar\gamma$ results in

$$Ch^{1-d}\int_{\{\gamma(x)\ge\bar\gamma\}} \gamma^{-1}\,dx + C\mu(\mu h|\log h|)^{\frac{q}{2}}h^{1-d}; \tag{20.8.6}$$

while contribution of all balls with $\gamma \lesssim \bar\gamma$ does not exceed

$$C\mu h^{1-d}\int_{\{\gamma(x)\le C_0\bar\gamma\}} dx; \tag{20.8.7}$$

Thus the total remainder R^{T} does not exceed

$$Ch^{1-d} + C\mu(\mu h|\log h|)^{\frac{q}{2}}h^{-d}h^{1-d} + Ch^{1-d}\Big(\int_{\{\gamma(x)\ge\bar\gamma\}} \gamma^{-1}\,dx + C\mu\int_{\{\gamma(x)\le C_0\bar\gamma\}} dx\Big) \tag{20.8.8}$$

where we included the first term for "compatibility" only (it does not exceed the second line anyway) and the optimal results are achieved as $\bar{\gamma} \asymp \mu^{-1}$.

We leave to the reader to prove by our standard arguments that the same estimate holds for R^{MW} and $\mathsf{R}^{\mathsf{W}}_{(\infty)}$. Then we arrive to the following

Theorem 20.8.2. *(i) Theorem 20.2.10 remains true without assumption* (20.1.4)*, replaced by* (20.8.1)*, but with the right-hand expression* (20.8.8)*.*

(ii) Under assumption

$$\int_{\mu^{-1}}^{1} \gamma^{-1} d\mu(\gamma) < \infty \tag{20.8.9}$$

with

$$\mu(\gamma) \coloneqq \mathsf{mes}\big(\{x\colon \gamma(x) < \gamma\}\big) \tag{20.8.10}$$

an extra term (the second line in (20.8.8)*) is* $O(h^{1-d})$ *and one can skip it.*

Problem 20.8.3. In our usual manner get rid of logarithmic factor in the second term of (20.8.8).

Problem 20.8.4. Prove that in the generic setting $\mu(\gamma) = O(\gamma^3)$.

20.8.2 Temperate Magnetic Field

General Case

Situation is rather simple if $r = 1$ (or all eigenvalues f_j have the same magnitude $\asymp \gamma$): then we can use the same simple rescaling technique as in Subsubsection 18.9.5.2. However in the general case there are some eigenvalues $\asymp \gamma$ and there are some much larger eigenvalues, may be of magnitude 1.

Notice that after rescaling the eigenvalue of magnitude γ would have magnitude $\mu\gamma^2$ and to deal with this properly we need $\mu\gamma^2 \gg 1$ (or at least $\mu\gamma^2 \ge C_0$) i.e. $\gamma \gg \mu^{-\frac{1}{2}}$ (or at least $\gamma \ge C_0\mu^{-\frac{1}{2}}$).

One possible approach is to apply in the *singular zone* $\{x:\ \gamma(x) \le \bar{\gamma}\}$ the rough estimate $C\mu h^{1-d}\mu(\bar{\gamma})$ which works rather well as

$$\mu(\gamma) = O(\gamma^{\kappa}) \qquad \text{with } \ \kappa > 2; \tag{20.8.11}$$

then we can take $\bar{\gamma} = \mu^{-1/\kappa}$.

In the *regular zone* $\{x\colon \gamma(x)\ge \bar\gamma\}$ one can go to the same canonical form as without degeneration but instead of error $O(\mu^{-m})$ error would become $O(\mu^{-m}\gamma^{-2m})$ in the principal part, and instead of $O(\mu^{-m}h^n)$ error would become $O(\mu^{-m}h^n\gamma^{-2m-n})$ in the lower terms.

Then we conclude that

(20.8.12) As $\gamma(y)\ge C_0\mu^{-\frac12}$ the contribution of $B(y,\gamma(y))$ to the Tauberian remainder does not exceed $O\bigl(h^{1-d}\gamma^{d-1}\bigr)$ as $q\ge 3$, $O\bigl(h^{1-d}\gamma^{d-1}+\mu h^{\frac53-d}\gamma^{d-\frac23}\bigr)$ as $q=2$, and $O\bigl(h^{1-d}\gamma^{d-1}+\mu h^{\frac43-d}\gamma^{d-\frac13}\bigr)$ as $q=1$.

Then summation with respect to partition results in

(20.8.13) Under assumption (20.8.11) Tauberian remainder estimate is $O\bigl(h^{1-d}\bigr)$ as $q\ge 3$, $O\bigl(h^{1-d}+\mu h^{\frac53-d}\bigr)$ as $q=2$, and $O\bigl(h^{1-d}+\mu h^{\frac43-d}\bigr)$ as $q=1$.

Here we took into account that the contribution of the *singular zone* $\{x\colon \gamma(x)\ge \bar\gamma\}$ is $O(\bar\gamma^{\kappa}\mu h^{1-d})=O(h^{1-d})$.

Let us calculate errors. First of all, in the regular zone removal of $O(\mu^{-1}\gamma^{-2})$ terms brings an error $O((\mu^{-1}\gamma^{-2})^{q/2}h^{-d}\gamma^d)$ as $q\ge 2$ (we apply all the arguments used to and then summation with respect to partition results in $O(h^{1-d})$ under assumption (20.8.11). The same is true if we remove $O(\mu^{-2}\gamma^{-4})$ terms as $q=1$.

As $q=1$ and there are unremovable $O(\mu^{-1}\gamma^{-2})$ terms we just go after $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$; as our goal is to estimate a correction we use the weak magnetic field estimate as $\mu\le h^{-\frac12}$ and also as $\mu\ge h^{-\frac12}$ but $\gamma\le(\mu^2h)^{-\frac12}$; in the latter case summation over such partition elements results in $O(\mu^{\frac12}h^{1-d})$.

Further, as $\gamma\ge(\mu^2h)^{-\frac12}$ and we estimate a correction we follow the arguments of Section 20.6. Finally we use a mollification parameter $\varepsilon=(\mu\gamma^2)^{-1}$ after rescaling or $\varepsilon=(\mu\gamma)^{-1}$ before. Leaving many rather not-very difficult but still delicate details to the reader we formulate the following

Problem 20.8.5. Prove that under assumption (20.8.11) Theorems 20.6.17 and 20.6.19(i),(ii) remain true[31)].

Results under Microhyperbolicity or Non-Degeneracy Assumptions

It becomes a bit difficult to formulate the microhyperbolicity or non-degeneracy assumptions. First we assume that

[31)] Obviously, condition (20.6.79) in Theorem 20.6.19(ii) fails.

(20.8.14) f_j ($j = 2, \dots, r$) are disjoint from 0, $f_1 \asymp \gamma(x) = \mathsf{dist}(x, Y)$ where Y is $\mathscr{C}^{2,1}$-manifold of codimension 3 and $|\nabla f_1| \asymp 1$.

Then without any loss of the generality one can assume that

(20.8.15) At points of Y matrices (g^{jk}) and (F_{jk}) satisfy $g^{jk} = 0$ as $j = 1, 2, 3$, $k = 4, \dots, d$ (and symmetrically) and $F_{jk} = 0$ as $j = 1, 2, 3$, $k = 1, \dots, d$ (and symmetrically).

Let us consider submatrices g'', F'' of these matrices, consisting of elements g^{jk}, F_{jk} with $j, k = 4, \dots, d$. Then canonical form is

$$\mathsf{a}(y, z; \xi'; \zeta_1, \dots, \zeta_r) = \mathsf{g}(y, z; \xi') + f_1(y, z)|\zeta_1|^2 + \mathsf{a}''(y, z; z_2, \dots, \zeta_r) + V(y, z) + \dots \tag{20.8.16}$$

where y are coordinates along Y and $z = (z_1, z_2, z_3)$ are additional coordinates (so $Y = \{z = 0\}$) and

$$|\nabla_z f_1| \asymp 1, \qquad |\nabla_y f_1| = O(|z|), \tag{20.8.17}$$

$\mathsf{g}(y, z; \eta)$ is a non-degenerate quadratic form with respect to η, $\mathsf{a}'(y, z; z_2, \dots, \zeta_r)$ is a Hermitian form with respect to $\zeta_2, \dots, \zeta_r$, .

Further, $f_1^2 = b(y; z) + O(|z|^3)$ where $b(y; z)$ is a non-degenerate quadratic form with respect to z and without any loss of the generality one can assume that $b(y; z) = |z|^2$. Then in the ball $B((y, z), \epsilon_0|z|)$ we can use microhyperbolicity arguments as long as either $|\xi'| \ge \epsilon_0$ or $|\zeta_1| \ge C_0$.

Therefore if we are close to the energy level 0, we need to consider only $|\xi'| \le \epsilon_0$ and $|\zeta_1| \le C_0$ but then the derivatives with respect to z of the first two terms in the right-hand expression of (20.8.16) are $O(|z|)$ and we need to consider only derivatives of

$$\mathsf{a}''(y, z; \zeta_2, \dots, \zeta_r) + V(y, z) \tag{20.8.18}$$

as long as it close to our energy level 0.

Therefore we can apply microhyperbolicity arguments there as well provided ψ is supported in the small tubular vicinity of Y and (20.8.18) satisfies microhyperbolicity assumption with respect to y (as $z = 0$). Leaving many rather not-very difficult but still delicate details to the reader we formulate Problem 20.8.6(i) below.

On the other hand, assume that (20.8.18) is not microhyperbolic. Assume that

(20.8.19) Either $r = 2$ or $f_2|_Y, \dots, f_r|_Y$ are constant.

Further, assume that $V/f_2|_Y$ has only non-degenerate critical points. Without any loss of the generality one can assume that $f_2 = \mathsf{const}$ and there is just one critical point 0. One can see easily that if $\mathsf{g}(y, z; \xi') = \bar{\mathsf{g}}(z; \xi') + O(|y|^2)$ and $b(y; z) = \bar{b}(z) + O(|y|^2)$ then $|\nabla_y \mathsf{a}(y, z; \xi'; \zeta_1, \dots, \zeta_r)| \asymp |y|$ at energy level 0 and we can apply non-degeneracy arguments easily. In the general case however one can see easily that on the energy level 0

$$|\nabla_y \mathsf{a}(y, z; \xi'; \zeta_1, \dots, \zeta_r)| \ge \epsilon |y - \bar{y}(z, \xi', |\zeta_1|)|$$

and again we can apply non-degeneracy arguments. Leaving many rather not-very difficult but still delicate details to the reader we formulate Problem 20.8.6(ii) below.

Problem 20.8.6. Let assumptions (20.8.14)–(20.8.15) be fulfilled and let a cut-off function ψ be supported in the sufficiently small vicinity of Y.

(i) Introduce a microhyperbolicity assumption as a microhyperbolicity assumption for these matrices g'', F'' and V along Y and prove under this assumption the remainder estimate $O(h^{1-d})$.

(ii) Also, as (20.8.19) is fulfilled, formulate a non-degeneracy assumption as non-degeneracy of critical points of $V/f_2|_Y$ and prove under this assumption the remainder estimate $O(h^{1-d})$.

Other Improved Results

Situation becomes even more delicate as only assumptions (20.8.14)–(20.8.15) are fulfilled. Let us assume that either $r = 2$ or $f_2|_Y, \dots, f_r|_Y$ are constant. Then we can use "microhyperbolicity" arguments and take $T_* = \epsilon\mu^{-1}$ unless gradient with respect to z is small enough which is the case as in the decomposition $|\alpha_1 - \bar{\alpha}_1| \ge C|\log h|$ which boils down to an extra factor $C\mu h|\log h|$ in the remainder estimate.

Using rescaling technique we can get of the logarithm improving this factor to $C\mu h$.

Problem 20.8.7. Let assumptions (20.8.14)–(20.8.15), and (20.8.19) be fulfilled and let a cut-off function ψ be supported in the sufficiently small vicinity of Y.

(i) Prove remainder estimates

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C\mu^2 \begin{cases} h^{\frac{8}{3}-d} & \text{as } \ q=2, \\ h^{\frac{7}{3}-d} & \text{as } \ q=1; \end{cases} \tag{20.8.20}$$

(ii) Provided there are no 3-rd- order resonances prove remainder estimates $\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d}$ as $q=2$ and

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{1-d} + C\mu^2 h^{\frac{5}{2}-d} \qquad \text{as } \ q=1. \tag{20.8.21}$$

(iii) Improve estimate (20.8.21) depending on (I,σ).

(iv) Derive estimates for $\mathsf{R}^{\mathsf{W}}_{(\infty)}$ improving those of Subsection 20.8.1; here and in (v) one should consider also $q \ge 3$.

(v) Under microhyperbolicity or non-degeneracy assumptions of Subsubsection 20.8.2.1 further improve these estimates.

20.8.3 Intermediate and Intermediate-Strong Magnetic Field

Intermediate magnetic field basically repeats the intermediate magnetic field case leading us to Part (i) of 20.8.7 below; in the case of the intermediate-strong magnetic field the microhyperbolicity or non-degeneracy conditions should be modified and Problem 20.8.7 should be skipped, leading us to Part (ii) below:

Problem 20.8.8. (i) Solve Problems 20.8.5, 20.8.6, and 20.8.7 in the case of the intermediate magnetic field.

(ii) Solve Problems 20.8.5 and 20.8.6 in the case of the intermediate-strong magnetic field; in this case the microhyperbolicity and non-degeneracy conditions are restricted to $\alpha' = (\alpha_2, \dots, \alpha_r)$ such that

$$|V + \sum_j (2\alpha_j + 1) f_j \mu h| \le \epsilon.$$

20.8.4 Strong Magnetic Field

Theory of the strong magnetic field comes in two flavors: for the Schrödinger operator and for the Schrödinger-Pauli operator.

Schrödinger Operator

In the case of the Schrödinger operator the classically allowed zone is empty unless all f_j vanish at Y; we assume for simplicity hat

$$f_j(x) \asymp \gamma(x) = \mathsf{dist}(x, Y) \qquad \forall j = 1, \dots, r \tag{20.8.22}$$

where Y is $\mathscr{C}^{2,1}$ manifold of codimension 3. Then the classically allowed zone is where after rescaling $\mu \mapsto \mu_{\mathsf{new}} = \mu\gamma^2$ and $h \mapsto h_{\mathsf{new}} = h/\gamma$ we have $\mu_{\mathsf{new}} h_{\mathsf{new}} \lesssim 1$ i.e. $\gamma \le \bar{\gamma} := 1/(\mu h)$. In the border we have $h_{\mathsf{new}} \asymp \mu h^2$, $\mu_{\mathsf{new}} \asymp h_{\mathsf{new}}^{-1}$. To be in the framework of the semiclassical theory we need to assume that $h_{\mathsf{new}} \ll 1$ i.e. $\mu \ll h^{-2}$.

Problem 20.8.9. Under assumption (20.8.22) consider the Schrödinger operator:

(i) Let $\mu \ge C_0 h^{-2}$; then $e(x, y, 0) = O(\mu^{-\infty})$.

(ii) Let $C_0 h^{-1} \le \mu \le C_0 h^{-2}$; then the principal part of the asymptotics is given by a magnetic Weyl expression and has a magnitude of the intermediate-strong magnetic field rescaled case multiplied by $\bar{\gamma}^{3-d}$, namely

$$h_{\mathsf{new}}^{-d} \bar{\gamma}^{3-d} \asymp h^{-d} \bar{\gamma}^3 \asymp \mu^{-3} h^{-3-d} \tag{20.8.23}$$

while the error coincides with one of the intermediate-strong magnetic field case rescaled, multiplied by $\bar{\gamma}^2$:

$$\mathsf{R}^{\mathsf{MW}} \le C h_{\mathsf{new}}^{1-d} \bar{\gamma}^{3-d} \asymp C \mu^{-2} h^{-1-d} \qquad \text{as} \quad q \ge 3, \tag{20.8.24}$$

$$\mathsf{R}^{\mathsf{MW}} \le C h_{\mathsf{new}}^{\frac{q}{3}-d} \bar{\gamma}^{3-d} \asymp C \mu^{-3+\frac{q}{3}} h^{-3+\frac{2q}{3}-d} \qquad \text{as} \quad q \le 3; \tag{20.8.25}$$

in the general case.

(iii) Further, assuming that

$$|f_j - f_k| \asymp \gamma \qquad \forall j \ne k \tag{20.8.26}$$

prove for $(I, \sigma) = (2, 0)$ estimate (20.8.24) as $q = 2$ and

$$\mathsf{R}^{\mathsf{MW}} \le h_{\mathsf{new}}^{\frac{1}{2}-d} \bar{\gamma}^{3-d} \asymp \mu^{-\frac{5}{2}} h^{-2-d} \qquad q = 1; \tag{20.8.27}$$

Also consider $(I, \sigma) \prec (2, 0)$ for $q = 1, 2$ and $(I, \sigma) \succ (2, 0)$ for $q = 1$.

(iv) Furthermore, introduce a notions of microhyperbolicity and non-degeneracy and under these assumptions prove estimate (20.8.24) as $q = 1, 2$.

Schrödinger-Pauli Operator

In the of the Schrödinger-Pauli operator the classically allowed zone does not shrink and we need neither assumption that $\mu \le C_0 h^{-2}$ nor that all f_j vanish on Y; so we return to our previous assumption that only f_1 vanishes on Y.

However in the inner zone $\{x\colon \gamma(x) \le C_0/(\mu h)\}$ we do not have a "scalar operator case" anymore and it can spoil the remainder estimate as $q = 1, 2$. It does not happen, however, it does not happen as $\mu \ge C_0 h^{-2}$ as well. Thus we arrive to Parts (i) and (ii) of Problem 20.8.10 below.

However we are essentially in the "constant multiplicities of f_j" case as f_1 is disjoint from all others and with $f_2, \dots, f_r$ we are restricted to the lowest Landau level. Further, microhyperbolicity with respect to z arguments work unless $\alpha_1 \le C_1$ and therefore we can formulate notions of the microhyperbolicity and non-degeneracy in the terms of $W|_Y$.

Problem 20.8.10. Under assumptions (20.8.14)–(20.8.15) for the Schrödinger-Pauli operator

(i) Prove that the principal part of the asymptotics is as if there was no degeneration at all (i.e. of magnitude $\mu^r h^{r-d}$)).

(ii) Prove that as $q \ge 3$ the remainder estimate is as if there was no degeneration at all (i.e. $O\big(\mu^r h^{1+r-d}\big)$).

(iii) Formulate notions of the microhyperbolicity and non-degeneracy in the terms of $W|Y$ and prove that under either of these assumptions the remainder estimate is also $O\big(\mu^r h^{1+r-d}\big)$.

(iv) In the general case of $q = 1, 2$ as $(I, \sigma) = (2, 0)$ prove that the remainder estimate is as if there was no degeneration at all (i.e. $O\big(\mu^r h^{1+r-d}\big)$ for $q = 2$ and $O\big(\mu^r h^{\frac{1}{2}+r-d}\big)$ for $q = 1$); also consider $(I, \sigma) \prec (2, 0)$ for $q = 1, 2$ and $(I, \sigma) \succ (2, 0)$ for $q = 1$.

Part IX

Magnetic Schrödinger Operator in Dimension 4

Chapter 21

4D-Schrödinger Operator with the Strong Degenerating Magnetic Field

21.1 Introduction

We continue analysis of the Schrödinger operator with the strong degenerating magnetic field, started in Chapter 14. Now we consider 4-dimensional case, assuming that magnetic field is generic degenerated and under certain conditions we derive spectral asymptotics with the principal part $\asymp h^{-4}$ and the remainder estimate $O(\mu^{-1/2}h^{-3})$ where $\mu \gg 1$ is the intensity of the field and $h \ll 1$ is the Plank constant; $\mu h \le 1$.

These asymptotics can contain correction terms of magnitude $\mu^{5/4}h^{-3/2}$ corresponding to the short periodic trajectories.

21.1.1 Framework

We continue analysis of he Schrödinger operator with the strong degenerating magnetic field, started in Chapter 14

$$A = \frac{1}{2}\Big(\sum_{j,k} P_j g^{jk}(x) P_k - V\Big), \qquad P_j = D_j - \mu V_j \tag{21.1.1}$$

where g^{jk}, V_j, V are smooth real-valued functions of $x \in \mathbb{R}^2$ and (g^{jk}) is positive-definite matrix, $0 < h \ll 1$ is a Planck parameter and $\mu \gg 1$ is a

coupling parameter. We assume that A is a self-adjoint operator.

Now let us consider 4-dimensional case, assuming that magnetic field is generic degenerated, i.e. of Martinet-Roussarie type (see J. Martinet [1] and R. Roussarie [1]) which will be described in details in Subsection 21.2.1. Here we just mention that in this case magnetic field F (which currently is considered as a closed 2-form) degenerates on the manifold Σ of dimension 3 and $\dim \operatorname{Ker} F = 2$ at Σ.

Further, $\dim(\operatorname{Ker} F \cap T\Sigma) = 1$ at $\Sigma \setminus \Lambda$ and $\operatorname{Ker} F \subset T\Sigma$ at Λ where $\Lambda \subset \Sigma$ is 1-dimensional manifold; furthermore, an angle between $\operatorname{Ker} F$ and $T\Sigma$ is exactly of magnitude $\operatorname{dist}(x, \Lambda)$. Finally, in an appropriate coordinates $\Sigma = \{x_1 = 0\}$, $\Lambda = \{x_1 = x_3 = x_4 = 0\}$ and *magnetic lines* $\frac{dx}{dt} \in \operatorname{Ker} F \cap T\Sigma$ are circles $\{x_1 = 0, x_2 = \operatorname{const}, x_3^2 + x_4^2 = \operatorname{const}\}$.

Our goal is to find asymptotics of $\int e(x, x, 0)\psi(x)\, dx$ with respect to h, μ, where $e(x, y, \tau)$ is the Schwartz kernel of the spectral projector of A and ψ is a smooth function supported in the vicinity of Σ. I assume that $\mu h \le \operatorname{const}$ (otherwise $e(x, y, 0) = O(\mu^{-\infty})$).

In the next Chapter 22 we are gong to analyze the case of the generic non-degenerating field.

Recall that magnetic field is characterized by $F_{jk} = \partial_j V_k - \partial_k V_j$. However, from the point of view of the classical and quantum dynamics and spectral asymptotics properties of $(F_k^j) = (g^{jl})(F_{lk})$ are more important than those of (F_{jk}). Let $\pm if_1, \pm if_2$ be eigenvalues of (F_k^j), $f_j \ge 0$. Then with the correct choice of notations $f_1 \asymp \operatorname{dist}(x, \Sigma)$ and $f_2 \asymp 1$.

21.1.2 Plan of the Chapter

First of all, in Section 21.2 we study the *weak magnetic case* $\mu \le h^{-\delta}$ with sufficiently small exponent $\delta > 0$ and derive remainder estimate $O(\mu^{-1/2}h^{-3})$ as the main part is given by the standard Weyl formula. We also analyze there the geometry of the degenerate magnetic field and the corresponding classical and quantum dynamics.

Then, assuming that magnetic field is not weak but *moderate* $h^{-\delta} \le \mu \le ch^{-1}$ in the next Section 21.3 we consider the different canonical forms of the operator in question; this canonical forms contain powers of μ^{-1}. There are universal canonical forms and also specific canonical forms as $\operatorname{dist}(x, \Sigma) \gg \mu^{-1/2}$ or as $\operatorname{dist}(x, \Lambda) \gg \mu^{-1/2}$.

Next, in Section 21.4 we derive remainder estimates $O(\mu^{-1/2}h^{-3} + \mu^2 h^{-2})$ in the general case and $O(\mu^{-1/2}h^{-3})$ as $\mu \ge h^{-2/5}$ and some non-degeneracy

condition (depending on the magnitude of μ) is fulfilled. The main part of this estimate is given by the *standard Tauberian formula*

$$h^{-1}\int_{-\infty}^{0}\Bigl(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma u Q_y^t\Bigr)\,d\tau \tag{21.1.2}$$

where u is the Schwartz kernel of $e^{ih^{-1}tA}$, $Q=I$ and as usual $\bar{\chi}_T(t)$ equals 1 as $|t|\le \frac{1}{2}T$ and vanishes as $|t|\ge T$, T is rather arbitrary from interval $[T_0, T_1]$ and the main fight is to make T_0 as small and T_1 as large as possible. More precisely, the main part of asymptotics is given by the sum of expressions (21.1.2) with $Q=Q_{(\iota)}$ making partition of unity and $T=T_\iota\in [T_{(\iota)0}, T_{(\iota)1}]$.

After this in Section 21.5 we calculate expression (21.1.2) in more explicit way and prove main theorems.

Finally, Subsection 21.5.4 is devoted to the analysis of some special cases.

21.2 Weak Magnetic Field

21.2.1 Geometry of Degenerating Magnetic Field

So let $F_{jk}(x)=\partial_j V_k-\partial_k V_j$ be components of the matrix intensity of magnetic field; then $\omega=\sum_{j,k}F_{jk}dx_j\wedge dx_k = d\bigl(\sum_k V_k dx_k\bigr)$ is the corresponding magnetic 2-form. According to J. Martinet [1], the generic form in dimension 4 never degenerates completely and has rank 2 on the submanifold Σ of codimension 1; more precisely, let

$$\Sigma := \bigl\{x : \operatorname{rank}\omega(x)=2\bigr\}; \tag{21.2.1}$$

then

(21.2.2) For a generic 2-form ω, Σ is the smooth manifold of codimension 1 and if $\pm if_1$, $\pm if_2$ are eigenvalues of the corresponding matrix (F_{jk}), $f_2\ge f_1\ge 0$ [1)] then $f_2(x)\ge\epsilon$ and $f_1(x)\asymp \operatorname{dist}(x,\Sigma)$.

Let us consider $\operatorname{Ker}F(x)\cap T_x\Sigma$ in points of Σ. At each point it can be of dimension either 1 or 2; let

$$\Lambda := \bigl\{x\in\Sigma : \dim\bigl(\operatorname{Ker}F(x)\cap T_x\Sigma\bigr)=2\bigr\}; \tag{21.2.3}$$

according to R. Roussarie [1]

[1)] This is a temporary notation, corresponding to Euclidean metrics $g^{jk}=\delta_{jk}$.

(21.2.4) For a generic 2-form ω Λ is the smooth manifold of dimension 1; moreover, in the appropriate coordinates

$$\omega = dx_1 \wedge dx_2 + x_3 dx_2 \wedge dx_3 + d\big(x_1x_3 + x_2x_4 - \frac{1}{3}x_3^3\big) \wedge dx_4. \tag{21.2.5}$$

One can rewrite (21.2.5) as

$$d\Big(\big(x_1 - \frac{1}{2}(x_3^2 + x_4^2)\big)d(x_2 + \frac{1}{2}x_3x_4) + (x_3^2 + x_4^2)x_1 - \frac{1}{4}(x_3^2 + x_4^2)^2\Big);$$

after transformation $x_2 \mapsto x_2 - \frac{1}{2}x_3x_4$ we get instead

$$\begin{aligned}\omega &= dx_1 \wedge dx_2 - x_4 dx_1 \wedge dx_3 + x_3 dx_1 \wedge dx_4 \\ &\quad + x_3 dx_2 \wedge dx_3 + x_4 dx_2 \wedge dx_4 + 2\big(x_1 - \frac{1}{2}(x_3^2 + x_4^2)\big)dx_3 \wedge dx_4 \\ &= d\big(x_1 - \frac{1}{2}r^2\big) \wedge dx_2 + r^2 dx_1 \wedge d\theta + 2\big(x_1 - \frac{1}{2}r^2\big)rdr \wedge d\theta \\ &= d\Big((x_1 - \frac{1}{2}r^2)dx_2 + (x_1 - \frac{1}{4}r^2)r^2 d\theta\Big)\end{aligned} \tag{21.2.6}$$

where $x_3 = r\cos\theta$, $x_4 = r\sin\theta$. In contrast to the original Roussarie's 2-form (21.2.5) this latter form is obviously (x_3, x_4)-circular symmetric. Then

$$\Sigma = \{x_1 = 0\}, \quad \Lambda = \{x_1 = x_3 = x_4 = 0\} \tag{21.2.7}$$

and *magnetic lines* defined by

$$\frac{dx}{dt} \in \operatorname{Ker} F(x) \cap T_x\Sigma, \quad x \in \Sigma \tag{21.2.8}$$

are helices $\{x_1 = 0, x_3 = r\cos\theta, x_4 = r\sin\theta, x_2 = \mathsf{const} - r^2\theta/2\}$ (with $r = \mathsf{const}$) winding around Λ.

Further, away from Λ one can rewrite

$$\omega = 2x_1 dx_1 \wedge d\theta + dy \wedge dz, \qquad y = x_1 - \frac{1}{2}r^2, \quad z = x_2 - 2y\theta \tag{21.2.9}$$

and therefore there I have just a direct sum of two 2-dimensional magnetic fields; the first one is a generic degenerating field and second one is nondegenerate.

21.2.2 Classical dDynamics

Classical dynamics described by the classical Hamiltonian

$$a(x,\xi) = \frac{1}{2}\Big(\sum_{j,k} g^{jk}(x)p_j p_k - V\Big), \qquad p_j = \xi_j - \mu V_j \tag{21.2.10}$$

corresponding to operator (21.1.1), is much more complicated than the geometry because it also depends on the metrics (g^{jk}) and the scalar potential V; however, it appears that it depends mainly on f_1, f_2 which are eigenvalues of $-i(F_k^j)$ [2)] (where $(F_k^j) = (g^{jl})(F_{lk})$) and V and even on their ratios f_1/V and f_2/V rather than these functions themselves. It also depends on the partition of energy (see below).

Examples

Let us start from considering few examples.

Example 21.2.1. Let F_{jk}, g^{jk} and V are constant (which is not the case in this Chapter). Then $\mathbb{R}^4 = \mathbb{K}_1 \oplus \mathbb{K}_2$ where $\mathbb{K}_j$ here and below are eigenspaces of $-(F_k^j)^2$ corresponding to eigenvalues f_j^2, $\dim \mathbb{K}_j = 2$. Then the kinetic part of the Hamiltonian splits into $a^0 = a_1^0 + a_2^0$ where a_j^0 are Hamiltonians on $\mathbb{K}_j$ and a_j^0 are movement integrals and the classical dynamics splits into two *cyclotron* movements along elliptical orbits in $\mathbb{K}_j$ with the angular velocities μf_j; the sizes of these ellipses are $\asymp (\mu f_j)^{-1}(a_j^0)^{1/2}$.

Example 21.2.2. (i) Let in the framework of the previous example V be variable. Then a_j are no more movement integrals but they evolve with the average speeds[3)] $O(\mu^{-1})$ and in addition to the fast cyclotron movements there appear also slow *drift* movements along $\mathbb{K}_j$ with the speeds of $\asymp \mu^{-1}a_j^0|\nabla_{\mathbb{K}_j}(V/f_j)|$; these drifts are orthogonal to $\nabla_{\mathbb{K}_j}(V/f_j)$. So these drifts depend on the instant energy partition.

(ii) As (g^{jk}) and (F_{jk}) and thus f_j become variable, the spaces $\mathbb{K}_j$ rotate with the average speeds $O(\mu^{-1})$ but the previous statements remain true.

[2)] In contrast to footnote [1)] this is the final definition.

[3)] While the speed of spatial movement is $\asymp 1$ the drift is much slower and one can calculate all functions of x in the instant cyclotron centers.

Example 21.2.3. At points disjoint from Λ one can assume that magnetic field corresponds to $\omega = x_1 dx_1 \wedge dx_2 + dx_3 \wedge dx_4$; we used 2-form (21.2.9) and redefined coordinates $x' = (x_2, x_3, x_4)$ in the obvious way.

Assume that the metrics in these coordinates is Euclidean $g^{jk} = \delta_{jk}$ and that $V = V(x_1, x_2)$. Then $a_1 = a_1^0 - \frac{1}{2}V$ and $a_2 = a_2^0$ are movement integrals as in Example 21.2.1 and the movement splits into two movements again: one of them is the cyclotron movement in (x_3, x_4) and another one is described by Hamiltonian a_1 in coordinates (x_1, x_2). It was studied in details in Chapter 14.

Then there are *outer* and *inner* zones $\mathcal{Z}_{\mathsf{out}}$ and $\mathcal{Z}_{\mathsf{inn}}$ respectively; in the outer zone x_1 should be much larger than the cyclotron radius (associated with a_1) which is $O(\mu^{-1}|x_1|^{-1})$ and this is the case as $\mathcal{Z}_{\mathsf{out}} = \{|x_1| \ge C\mu^{-1/2}\}$. However, now a_1^0 is not necessarily disjoint from 0 (which was an assumption in Chapter 14) and we will need to take it into account and redefine zones.

Still we can conclude from Chapter 14 that if a trajectory $(x(t), \xi(t))$ on the energy level $\le c$ starts from the point $(x(0), \xi(0))$ with $x(0) \in B(0, \frac{1}{2}) \cap \{x : |x_1| = \gamma \ge C^2\mu^{-1/2}\}$, then $x(t) \in B(0, \frac{1}{2}) \cap \{x : C^{-1}\gamma \le |x_1| \le C\gamma\}$ as $|t| \le \epsilon\mu\gamma^2$. Further, the drift speed is $O(\mu^{-1}\gamma^{-2})$; this estimate is sharp as long as a_1^0 is disjoint from 0. So again we have the cyclotron movement with angular velocities $\asymp \mu|x_1|$ and μ and the drift movement mainly along x_2.

On the other hand, if a trajectory $(x(t), \xi(t))$ on the energy level $\le c$ starts from the point $(x(0), \xi(0))$ with $x(0) \in B(0, \frac{1}{2}) \cap \{x : |x_1| \le C\mu^{-1/2}\}$ then $x(t) \in B(0, \frac{1}{2}) \cap \{x : |x_1| \le C^2\mu^{-1/2}\}$ as $|t| \le \epsilon$ and the averaged propagation speed is $O(1)$; this estimate is sharp for the "typical" (in the heuristic sense) trajectory. In this case there are no separate cyclotron and drift movements along $\mathbb{K}_1$ but the cyclotron movement along $\mathbb{K}_2$ remains.

Example 21.2.4. Assume that in some coordinates $(x_1, \dots, x_4)$ 2-form ω is defined by (21.2.6) and also $g^{jk} = \delta_{jk}$. Let $V = \mathsf{const}$. Let us show that the conclusion of the previous example remains true (with the drift directed mainly along magnetic lines).

However, now the angle between $\mathbb{K}_1(x)$ and $T_x\sigma$ is of magnitude r and therefore to prevent cyclotron movements from hitting Σ it is sufficient to assume that $C\mu^{-1}\gamma^{-1}r \le \gamma$ and to keep r of the same magnitude along trajectory it is sufficient to assume that $r \ge C\mu^{-1}\gamma^{-1}$.

Alternatively we can assume that $r \le C\mu^{-1}\gamma^{-1}$ and then it will remain this way and the first inequality should be fulfilled with $r = C\mu^{-1}\gamma^{-1}$. So

we get zone

$$\mathscr{Z}_{\mathsf{out}} = \big\{C\mu^{-1}\gamma^{-1} \le r \le \epsilon\mu\gamma^2\big\}\cup \big\{r \le C\mu^{-1}\gamma^{-1}, C\mu^{-1}\gamma^{-1} \le \epsilon\mu\gamma^2\big\} = \big\{\gamma \ge C\max(\mu^{-2/3}, \mu^{-1/2}r^{1/2})\big\}. \tag{21.2.11}$$

Precise Calculations

Example 21.2.5 (Example 21.2.4 reloaded). Let us instead of rather heuristic arguments of Example 21.2.4 apply precise calculations. With ω defined by (21.2.6) and $g^{jk} = \delta_{jk}$

$$a = \frac{1}{2}\Big(\xi_1^2 + \xi_r^2 + W(x_1, r)\Big) \tag{21.2.12}$$

with

$$W(x_1, r) = \Big(\xi_2 - \mu(x_1 - \frac{1}{2}r^2)\Big)^2 + r^{-2}\Big(\xi_\theta - \mu(x_1 - \frac{1}{2}r^2)r^2\Big)^2 = (r^2+1)\Big(\mu\big(x_1 - \frac{1}{2}r^2\big) - \frac{\xi_\theta - \xi_2 r^2}{r^2+1}\Big)^2 + \frac{1}{r^2(r^2+1)}\big(\xi_\theta - \xi_2 r^2\big)^2. \tag{21.2.13}$$

Then ξ_θ and ξ_2 are movement integrals and the dynamics is restricted to the zone $\mathscr{Y}_{\xi_2,\xi_\theta} = \big\{(x_1, r) : W(x_1, r) \le c\big\}$. While W is nonnegative and convex in the vicinity of $(0,0)$ it is a degenerate as $\xi_2 = \xi_\theta = 0$: $W = \mu^2(1+r^2)\big(x_1 - \frac{1}{2}r^2\big)^2$ and so particle seems to move far away if time is unbounded.

Therefore we will need to bound time (but this bound will be large enough to sustain a nice remainder estimate).

General Case. I

Now we can consider rigorously the general case. Let $\Bbbk_\alpha = (\Bbbk_\alpha^m)$ be eigenvectors of $(F^j_{,k}) = (g^{jl})(F_{lk})$ corresponding to eigenvalues if_α ($\alpha = 1, 2$); then $\Bbbk_\alpha^\dagger$ are eigenvectors corresponding to eigenvalues $-\mathit{if}_\alpha$:

$$\sum_k F^j_{,k}\Bbbk^k_\alpha = \mathit{if}_\alpha \Bbbk^j_\alpha, \qquad \sum_k F^j_{,k}\Bbbk^{\dagger k}_\alpha = -\mathit{if}_\alpha \Bbbk^{\dagger j}_\alpha. \tag{21.2.14}$$

Let us normalize them so that

$$\sum_{j,k} g_{jk}\Bbbk^j_\alpha \Bbbk^k_\beta = 0, \qquad \sum_{j,k} g_{jk}\Bbbk^{\dagger j}_\alpha \Bbbk^{\dagger k}_\beta = 0, \qquad \sum_{j,k} g_{jk}\Bbbk^j_\alpha \Bbbk^{\dagger k}_\beta = 2\delta_{\alpha\beta}. \tag{21.2.15}$$

where the second equations in (21.2.14), (21.2.15) follow from the first ones.

(21.2.16) One can select $\Bbbk_j \in \mathscr{C}^\infty$ satisfying (21.2.14) and (21.2.15) in domain $\Omega = B(0,1) \cap \{|x_1 \le \epsilon\}$ [4)].

Indeed, this statement is true for $\Bbbk_2$; therefore $\mathbb{K}_1 \in \mathscr{C}^\infty$ and (F^j_k) transforms $\mathbb{K}_1 \in \mathscr{C}^\infty$ into itself and is skew-symmetric with respect to (g^{jk}). Then in the orthonormal real base on $\mathbb{K}_1$ $F = \begin{pmatrix} 0 & f_1 \\ -f_1 & 0 \end{pmatrix}$ with $f_1 \in \mathscr{C}^\infty$ and one can select $\Bbbk_1 \in \mathscr{C}^\infty$.

Let

$$(21.2.17)\quad Z_\alpha(x,\xi) = \sum_m \Bbbk^m_\alpha(x) p_m(x,\xi), \quad Z^\dagger_\alpha(x,\xi) = \sum_m \Bbbk^{\dagger m}_\alpha(x) p_m(x,\xi),$$
$$p_m = \xi_m - \mu V_m(x), \qquad \{p_j, p_k\} = -\mu F_{jk}$$

where the second equation follows from the first one. Then since

$$(21.2.18)\quad |p_j(x,\xi)| \le c_1 \text{ on the energy levels } \{(x,\xi) : a(x,\xi) \le c_0\}$$

we arrive to

$$(21.2.19)\quad \{Z_\alpha, Z_\beta\} \equiv \{Z^\dagger_\alpha, Z^\dagger_\beta\} \equiv 0, \quad \{Z_\alpha, Z^\dagger_\beta\} \equiv 2i\mu f_\alpha \delta_{\alpha\beta} \quad \mathsf{mod}\ O(1).$$

Further, note that corrected x_j:

$$(21.2.20)\qquad x'_j = x_j - \mu^{-1} \sum_k \check{F}^{jk} p_k, \quad \text{where} \quad \sum_k \check{F}^{jk} F_{kl} = \delta_{jl}$$

satisfy

$$(21.2.21)\qquad \{x'_j, p_k\} = O(\mu^{-1}\gamma^{-2}),$$
$$(21.2.22)\qquad \{x'_j, x'_k\} = \mu^{-1}\check{F}^{jk} + O(\mu^{-2}\gamma^{-3}).$$

Also note that

$$(21.2.23)\qquad a^0(x,\xi) := \frac{1}{2}\sum_{k,l} g^{kl} p_k p_l = \frac{1}{2}\Bigl(|Z_1|^2 + |Z_2|^2\Bigr)$$

and therefore

$$(21.2.24)\quad \{a^0, Z_\alpha\} \equiv \{a, Z_\alpha\} \equiv -i\mu f_\alpha Z_\alpha, \quad \{a^0, Z^\dagger_\alpha\} \equiv \{a, Z^\dagger_\alpha\} \equiv i\mu f_\alpha Z^\dagger_\alpha$$

[4)] Provided we redefine temporarily f_1 so that $f_1/x_1 > 0$.

and

$$\{a^0, b_\alpha\} \equiv \{a, b_\alpha\} \equiv 0 \quad \mathsf{mod}\ O(1) \tag{21.2.25}$$

where $b_\alpha := |Z_\alpha|^2$.

More precisely, equalities (21.2.19) are fulfilled modulo linear forms[5)] and therefore $\{a^0, b_\alpha\}$ is a cubic form[5)] and $\{a, b_\alpha\}$ is a cubic form[5)] plus a linear form[5)] . Moreover, these cubic terms should contain at least one factor Z_1 or $Z_1^\dagger$ and also at least one factor Z_2 or $Z_2^\dagger$.

(21.2.26) Then correcting b_α ($\alpha = 1, 2$) by cubic terms[5)] plus linear terms[5)], both multiplied by μ^{-1}, one can eliminate from $\{a, b_\alpha\}$ all cubic terms except those with $Z_1 Z_2 Z_2^\dagger$ and $Z_1^\dagger Z_2 Z_2^\dagger$ and all linear terms except those with Z_1 and $Z_1^\dagger$. Then these remaining terms produce $O(\mu^{-1})$ error.

Further, correcting in the zone $\mathcal{Z}_{\mathsf{out}} = \{C\mu^{-1/2} \le |x_1| \le \epsilon\}$ by cubic and linear terms of the above type but with coefficients of the type "$x_1^{-1} \times$ smooth function" one can eliminate the rest of the terms but now instead of $O(\mu^{-1})$ error we get $O(\mu^{-1} x_1^{-2})$ error:

(21.2.27) In the classical dynamics one can correct $b_\alpha = |Z_\alpha|^2$ by $O(\mu^{-1} x_1^{-1})$ so that their propagation speeds would be $O(\mu^{-1} x_1^{-2})$. Therefore as long as $x(t) \in \Omega$ and $|x_1(t)| \asymp \gamma$, $|t| \le T$ the following holds:

$$|Z_\alpha(t)|^2 = |Z_\alpha(0)|^2 + O\big(\mu^{-1}\gamma^{-1} + \mu^{-1}\gamma^{-2}T\big).$$

Similarly, consider $\{a, x_j\}$ which is a linear form[5)]. One can correct x_j in the same way arriving to

(21.2.28) In the classical dynamics one can correct x_j by $O(\mu^{-1} x_1^{-1})$ so that their propagation speeds would be $O(\mu^{-1} x_1^{-2})$. Therefore as long as $x(t) \in \Omega$ and $|x_1(t)| \asymp \gamma$, $|t| \le T$

$$x_j(t) = x_j(0) + O\big(\mu^{-1}\gamma^{-1} + \mu^{-1}\gamma^{-2}T\big).$$

[5)] With respect to $(Z_1, Z_1^\dagger, Z_2, Z_2^\dagger)$ with smooth complex coefficients depending on x.

Moreover, equalities (21.2.25) and (21.2.26) with b_α replaced by x_j corrected yield that

$$\frac{dx}{dt} \in \mathbb{K}_1(x) + O(\mu^{-1}x_1^{-1}) \qquad \text{for } x, \text{ corrected modulo } O(\mu^{-1}x_1^{-1}). \tag{21.2.29}$$

Still it is not yet what we want which is to calculate $\{a, x_j\}$ modulo $O(\mu^{-1}x_1^{-1})$. However, let us consider first

$$b_3' := -\operatorname{Re}\Big(i\mu^{-1}\{Z_1^\dagger, x_1\}\phi(x)^{-1}Z_1\Big) + x_1^2, \qquad \phi = f_1/x_1 \tag{21.2.30}$$

and note that $\{Z_1Z_1^\dagger, b_3'\} = O(\mu^{-1})$. Also note that $\{a, b_3'\}$ is a linear form of $Z_2, Z_2^\dagger$ modulo $O(\mu^{-1})$ and therefore it could be corrected by a linear form of $Z_2, Z_2^\dagger$ multiplied by μ^{-1} so that after correction $\{a, b_3'\} = O(1)$. Therefore we arrive to two following statements:

(21.2.31) In the classical dynamics one can correct $b_3 = x_1^2$ by $O(\mu^{-1})$ so that its propagation speed would be $O(\mu^{-1})$. Therefore

$$x_1^2(t) = x_1^2(0) + O\big(\mu^{-1} + \mu^{-1}T\big)$$

and statements (21.2.27) and (21.2.28) hold without precondition "as long as $x(t) \in \Omega$ and $|x_1(t)| \asymp \gamma$", because it is fulfilled automatically for $x(0) \in B(0, \frac{1}{2}) \cap \{\frac{1}{2}\gamma \le |x_1(0)| \le 2\gamma\}$, $T = \epsilon\mu\gamma^2$, $\gamma \ge \bar\gamma_1 = C\mu^{-1/2}$.

(21.2.32) Also, trajectory originated in $B(0, \frac{1}{2}) \cap \{|x_1| \le \gamma\}$ remains in $B(0,1) \cap \{|x_1| \le C\gamma\}$ as $\gamma = \bar\gamma_1$, $T = \epsilon$.

Furthermore, as long as $|x_1| \le c\gamma$ and $|\{Z_1, x_1\}| \le cr$, correction is $O\big(\mu^{-1}(r+\gamma)\big)$ and therefore $x_1^2(t) = x_1^2(0) + O\big(\mu^{-1}(r+\gamma) + \mu^{-1}T\big)$. Then we arrive to

(21.2.33) As long as $|\{Z_1, x_1\}| \le cr$ along trajectory, statements (21.2.31) and (21.2.32) hold with $\bar\gamma_1 = C\mu^{-1} + C\mu^{-1/2}r^{1/2}$. Moreover, $|\{Z_1, x_1\}(t)| \le cr$ provided it was fulfilled (with constant $c/2$) at $t = 0$ and $T = \epsilon\mu\gamma^2 r$, $r \ge \mu^{-1/2} + \gamma$.

General Case. II

Now let us return to calculation of $\{a, x_j\}$ modulo $O(\mu^{-1})$ where we will correct x_j. Any error, larger than this, comes from eliminating linear terms containing Z_1 or $Z_1^\dagger$, namely $\mathsf{Re}\big(\{Z_1^\dagger, x_j\}Z_1\big)$. This expression was eliminated by adding $\mu^{-1}f_1^{-1}\,\mathsf{Re}(i\{Z_1, x_j\}Z_1^\dagger)$ to x_j which in turn generates an error

$$\mu^{-1}\,\mathsf{Re}\, i\Big(\big\{a, f_1^{-1}\{Z_1, x_j\}\big\}Z_1^\dagger + f_1^{-1}\{Z_1^\dagger, x_j\}\big(i\{a, Z_1^\dagger\} - \mu f_1 Z_1\big)\Big). \tag{21.2.34}$$

In this expression (21.2.34) the part containing factors Z_2 and $Z_2^\dagger$ in the combinations Z_2, Z_2^2, $Z_2^\dagger$, $Z_2^{\dagger\,2}$ can be eliminated by the same way as above; the corresponding correction has an extra factor $O(\mu^{-1})$ and the corresponding error just acquires factor $O(\mu^{-1}x_1^{-1})$; therefore resulting error will be $O\big(\mu^{-2}x_1^{-3}|Z_1| + \mu^{-2}x_1^{-2}\big) = O\big(\mu^{-1} + \mu^{-1}\gamma^{-1}\rho\big)$ provided

$$|Z_1| \le c\rho, \qquad \gamma \ge c\mu^{-1/2}. \tag{21.2.35}$$

This leaves us with expression (which we do not call an error anymore)

$$\frac{1}{2}\Big(-\mu^{-1}x_1^{-2}\phi^{-1}\{Z_1Z_1^\dagger, x_1\}\,\mathsf{Re}(i\{Z_1, x_j\}Z_1^\dagger) + \mu^{-1}x_1^{-1}\,\mathsf{Re}\big(\alpha\{Z_1, x_j\}\big)|Z_2|^2\Big) \tag{21.2.36}$$

with the complex-valued coefficient $\alpha = \alpha(x')$ provided

$$f_1 = \phi(x')x_1 + O(x_1^2), \qquad x' := (x_2, x_3, x_4). \tag{21.2.37}$$

Note that the first term in (21.2.36) is equal to

$$\begin{aligned} &-\mu^{-1}x_1^{-2}\phi^{-1}\cdot\mathsf{Re}(\{Z_1, x_1\}Z_1^\dagger)\cdot\mathsf{Re}(i\{Z_1, x_j\}Z_1^\dagger) \\ &= \frac{1}{4}\mu^{-1}x_1^{-2}\phi^{-1} \\ &\times \mathsf{Re}\, i\Big(2\{Z_1^\dagger, x_1\}\{Z_1^\dagger, x_j\}Z_1^2 + \big(-\{Z_1^\dagger, x_1\}\{Z_1, x_j\} + \{Z_1^\dagger, x_j\}\{Z_1, x_1\}\big)|Z_1|^2\Big) \end{aligned} \tag{21.2.38}$$

and one needs to calculate coefficients at Z_1^2, $|Z_1|^2$ as $x_1 = 0$ only.

Therefore we need to calculate $\Bbbk_1$ as $x_1 = 0$. Let us decompose F_{jk}, g_{jk} and $\Bbbk_1$ into powers of x_1; then $F_{jk}\Bbbk_1 = if_1\Bbbk_1$ implies that

$$F_{jk}^0\Bbbk_1^0 = 0, \qquad (F_{jk}^1 - i\phi g_{jk}^0)\Bbbk_1^0 + F_{jk}^0\Bbbk_1^1 = 0, \tag{21.2.39}$$

where F_{jk} corresponds to symplectic form (21.2.6) and therefore

$$F = \begin{pmatrix} 0 & 1 & -x_4 & x_3 \\ -1 & 0 & x_3 & x_4 \\ x_4 & -x_3 & 0 & 2\bigl(x_1 - \frac{1}{2}(x_3^2 + x_4^2)\bigr) \\ -x_3 & -x_4 & -2\bigl(x_1 - \frac{1}{2}(x_3^2 + x_4^2)\bigr) & 0 \end{pmatrix}. \tag{21.2.40}$$

Then (21.2.39) and (21.2.40) imply for the "differentiation" part of Z_1

$$Z_{1,\ \mathrm{diff}}|_{x_1=0} = \alpha\Bigl(\bigl(r^{-1}\partial_\theta - r\partial_2\bigr) + \beta\bigl(r\partial_1 + \partial_r\bigr)\Bigr) \qquad \text{with} \quad c^{-1} \le |\alpha| \le c,\ c^{-1} \le \operatorname{Re} i\beta \le |\beta| \le c. \tag{21.2.41}$$

Then

$$\operatorname{Re} i\bigl(\{Z_1^\dagger, x_1\}Z_1\bigr)\big|_{x_1=0} = 2|\alpha|^2 \operatorname{Re}(i\beta)\bigl(\partial_\theta - r^2\partial_2\bigr) \tag{21.2.42}$$

is the differentiation along magnetic lines. Further, without any loss of the generality one can assume that $\alpha = 1$.

General Case. III

Consider first $\psi = x_1 - r^2/2$ which is a regular function of x; note that $Z_1\psi = O(x_1)$; therefore ψ can be corrected by $O(\mu^{-1})$ so that $\frac{d}{dt}\psi = O(\mu^{-1})$ and therefore original ψ is preserved modulo $O\bigl(\mu^{-1}(T+1)\bigr)$. Since we already know that x_1 is preserved modulo $O\bigl(\mu^{-1}\gamma^{-1}r(T+1)\bigr)$ we conclude that

Proposition 21.2.6. *Let us consider classical dynamics in* $\Omega = B(0,1) \cap \{|x_1| \le C\epsilon\}$, *originated in* $\Omega' = B(0,\frac{1}{2}) \cap \{|x_1| \le \epsilon\}$.

(i) If in the original point $|x_1| = \gamma$ *with* $\gamma \ge C\max(\mu^{-1}r^{-1}, r^2)$ *then both* $|x_1(t)|$ *and* $r(t)$ *remain of the same magnitudes as* $T = \epsilon\mu\gamma r$.

(ii) If in the original point $r^2 \ge \gamma \ge C\mu^{-1/2}r^{1/2}$ *then both* $|x_1(t)|$ *and* $r(t)$ *remain of the same magnitudes as* $T = \epsilon\mu\gamma^2 r^{-1}$.

(iii) If in the original point $\gamma \ge C\mu^{-2/3}$ *and* $r \le c\mu^{-1}\gamma^{-1}$ *then* $|x_1(t)|$ *remains of the same magnitude while* $r(t) \le 2c\mu^{-1}\gamma^{-1}$ *as* $T = \epsilon$.

(iv) If in the original point $|x_1| \le \gamma = c\mu^{-1/2}r^{1/2}$ *and* $r \ge C\mu^{-1/3}$ *then* $r(t)$ *remains of the same magnitude while* $|x_1(t)| \le C\gamma$ *as* $T = \epsilon$.

(v) If in the original point $|x_1| \le \gamma = c\mu^{-2/3}$ *and* $r \le c\mu^{-1/3}$ *then* $r(t) \le C\mu^{-1/3}$ *and* $|x_1(t)| \le C\gamma$ *as* $T = \epsilon$.

On the other hand, on the energy level τ one can rewrite the last term in (21.2.36) as $\mu^{-1}x_1^{-1}\,\mathsf{Re}(\sigma\{Z_1, x_j\})(\tau + V)$ modulo $O(\mu^{-1} + \mu^{-1}\gamma^{-1}\rho^2)$. Consider (21.2.38). Using the same technique as before one can eliminate

$$\mu^{-1}x_1^{-2}\phi^{-1} \cdot \mathsf{Re}\, i\Big(2\{Z_1^\dagger, x_1\}\{Z_1^\dagger, x_j\}Z_1^2\Big)$$

by $\mu^{-2}x_1^{-3}\phi^{-2}\cdot\mathsf{Re}\Big(\{Z_1^\dagger, x_1\}\{Z_1^\dagger, x_j\}Z_1^2\Big)$ correction (which is $O(\mu^{-2}\gamma^{-3}r\rho^2) = O(\mu^{-1}\gamma^{-1}\rho^2)$) as $\gamma \ge \mu^{-1/2}r^{1/2}$ adding $O(\mu^{-2}\gamma^{-4}r^2\rho^2 + \mu^{-2}\gamma^{-3}\rho^2)$ error; this error is less than $\epsilon\mu^{-1}\gamma^{-2}r\rho^2$ as $\gamma \ge C\mu^{-1/2}r^{1/2}$.

Also, any Z_1 or $Z_1^\dagger$ unbalanced in the product could be treated in the same way as before. Then we arrive to

Proposition 21.2.7. *As* $\gamma \ge C\mu^{-1/2}r^{1/2}$ *the propagation speed with respect to* θ *is*

$$\begin{aligned} (21.2.43)\quad & v(\rho; x, \mu^{-1}) \\ & = \mu^{-1}\gamma^{-2}\kappa(x, \rho^2, \mu)\Big(\rho^2 + r^{-1}\kappa_2(x, \rho^2, \mu)\gamma\Big) + O\Big(\mu^{-2}\gamma^{-3}\rho r^{-1}\Big) \end{aligned}$$

with κ, κ_2 *bounded and* κ *disjoint from* 0.

We also need to consider dynamics of $b_2 = |Z_2|^2$ more precisely. Note that

$$\big\{|Z_2|^2, a\big\} = \frac{1}{2}\,\mathsf{Re}\Big(\Big(\{Z_2, Z_1\}Z_1^\dagger + \{Z_2, Z_1^\dagger\}Z_1 - \{Z_2, V\}\Big)Z_2^\dagger\Big)$$

is a combination of cubic and linear terms (see footnote[5)]) and the only terms where factor Z_1 is not compensated by $Z_1^\dagger$ and v.v. come from

$$(21.2.44)\qquad \{Z_2, Z_1\} = \alpha_{11}Z_2 + \alpha_{12}Z_2^\dagger + \beta_{11}Z_1 + \beta_{12}Z_1^\dagger,$$

$$(21.2.45)\qquad \{Z_2, Z_1^\dagger\} = \alpha_{21}Z_2 + \alpha_{22}Z_2^\dagger + \beta_{21}Z_1 + \beta_{22}Z_1^\dagger;$$

these terms are equal to $\mathsf{Re}(\sigma Z_1)|Z_2|^2$ with $\sigma := \alpha_{11}^{\dagger} + \alpha_{21}$. We need to calculate β as $x_1 = 0$. All other terms could be corrected by $O(\mu^{-1})$ leading to $O(\mu^{-1})$ error while this one is corrected by $\mu^{-1}x_1^{-1}\phi\,\mathsf{Re}(i\beta Z_1)|Z_2|^2$ leading to $O(\mu^{-1}x_1^{-2})$ error; we will calculate this latter error more precisely below. Since

$$\alpha_{11} = (2i\mu f_2)^{-1}\bigl\{\{Z_2, Z_1\}, Z_2^{\dagger}\bigr\},$$
$$\alpha_{21} = (2i\mu f_2)^{-1}\bigl\{\{Z_2, Z_1^{\dagger}\}, Z_2^{\dagger}\bigr\}$$

calculated as $Z_1 = Z_2 = 0$, we conclude that

$$\sigma = (2i\mu f_2)^{-1}\bigl(-\bigl\{\{Z_2, Z_1\}, Z_2^{\dagger}\bigr\} + \bigl\{\{Z_2^{\dagger}, Z_1\}, Z_2\bigr\} = \\ -(i\mu f_2)^{-1}\bigl\{\{Z_2, Z_2^{\dagger}\}, Z_1\bigr\}.$$

Therefore correction is $O(\mu^{-1}\gamma^{-1}\rho)$ and then the part of an error, with factors Z_2 and $Z_2^{\dagger}$ balanced is $O(\mu^{-1}\gamma^{-1} + \mu^{-1}\gamma^{-2}\rho r)$.

Moreover, the part of $\{|Z_2|^2, a\}$ where Z_2 and $Z_2^{\dagger}$ are balanced is $\kappa|Z_2|^2$ with

$$\kappa = (2\mu f_2)^{-1}\,\mathsf{Re}\Bigl(\bigl\{i\{Z_2, Z_2^{\dagger}\}, Z_1\bigr\}\big|_{Z_1=Z_2=0} Z_1^{\dagger}\Bigr)$$

since $i\{Z_2, Z_2^{\dagger}\}$ is real; further, this expression is equal to

$$(2f_2)^{-1}\{f_2, |Z_1|^2\} + O(\rho\gamma) + O(\mu^{-1}\gamma^{-1}) = \\ (2f_2)^{-1}\{f_2, a\} - (2f_2)^{-1}\{f_2, |Z_2|^2\} + O(\rho\gamma) + O(\mu^{-1}\gamma^{-1}).$$

Note that $f_2^{-1}\{f_2, |Z_2|^2\}$ has unbalanced Z_2 or $Z_2^{\dagger}$ and thus is eliminated by $O(\mu^{-1})$ correction. Therefore we arrive to an error $-(2f_2)^{-1}\{f_2, a\}|Z_2|^2$.

Thus

(21.2.46) One can correct $|Z_2|^2$ by $O(\mu^{-1} + \mu^{-1}\gamma^{-1}\rho)$ term so that the propagation speed after correction would be $O(\mu^{-1}\gamma^{-1} + \mu^{-1}\gamma^{-2}\rho r)$.

(21.2.47) Moreover, one can correct $f_2^{-1}|Z_2|^2$ by $(\mu^{-1} + \mu^{-1}\gamma^{-1}\rho^2)$ term so that the propagation speed after correction would be $O(\mu^{-1} + \mu^{-1}\gamma^{-2}\rho^2)$.

We will also need the shorter term classical dynamics result:

Proposition 21.2.8. *Let us consider dynamics described in Proposition 21.2.6(i)–(v). Then* $\mathsf{dist}(x(t),(x(0)) \ge \epsilon\rho t$ *as* $|t| \le T_1 = \epsilon\,\mathsf{min}(\mu^{-1}\gamma^{-1},\rho)$.

Remark 21.2.9. It effectively makes $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ because contribution to the remainder of the subzone $\{|x_1| \asymp \gamma, |Z_1| \le \rho, \rho \le \mu^{-1}\gamma^{-1}\}$ is $O(\mu h^{-3} \times \mu^{-2}\gamma^{-2} \times \gamma) = O(\mu^{-1}h^{-3}\gamma^{-1})$ which after summation over zone $\{\gamma \ge \mu^{-1/2}\}$ results in $O(\mu^{-1/2}h^{-3})$.

21.2.3 Quantum Dynamics. I. Outer Zone

In this subsection we begin to deal with the quantum dynamics and the new parameter h appears; so one can now compare μ and h. Here we assume that the magnetic field is rather weak; more precise requirements should vary from statement to statement but actually we do not care very much now and will just assume as needed that

$$C \le \mu \le h^{-\delta} \tag{21.2.48}$$

with small enough exponent $\delta > 0$; we do not want to push it up so far.

Short sScale Dynamics

As we have mentioned there are few time scales and the shortest one is $\asymp \mu^{-1}$. Let us deal with it first. Scaling $x \mapsto \mu x$, $t \mapsto \mu t$, $h \mapsto \mu h$, $\mu \mapsto 1$ we find ourselves with the standard Schrödinger operator with the propagator which is a standard Fourier integral operator. Returning to the original scale we arrive to

Proposition 21.2.10. *(i) As* $|t| \le T_0 = C\mu^{-1}$ *propagator* $e^{ih^{-1}At}$ *is* h*-FIO corresponding to the classical dynamics* $\Phi_t = e^{tH_a}$ *with Hamiltonian* $a(x,\xi)$.

(ii) In particular, if $\psi \in \mathscr{C}_0^\infty(B(\bar{x},\epsilon\gamma))$

$$e^{2\pi i\mu^{-1}h^{-1}\bar{f}_2^{-1}A}\psi \equiv e^{2\pi i\mu^{-1}h^{-1}\bar{f}_2^{-1}B}\psi \tag{21.2.49}$$

with $\bar{f}_2 = f_2(\bar{x})$ *and the standard* h*-pseudodifferential operator* $\gamma^{-1}B$.

Proof. Let us consider classical dynamics Φ_t first; in (x,p) variables it is described by

$$\frac{dx_j}{dt} = \mu^{-1}\sum_k K_{jk}(x)p_k, \tag{21.2.50}$$

$$\frac{dp_j}{dt} = \sum_k L_{jk}(x)p_k + \mu^{-1}\sum_{kl} L_{jkl}(x)p_k p_l + \mu^{-1}L_j(x) \tag{21.2.51}$$

(after rescaling $t \mapsto \mu^{-1}t$) with uniformly smooth coefficients K_*, L_*. Therefore in these coordinates $\Phi_t : (x,p) \mapsto \big(x+\mu^{-1}X(x,p,t), Y(x,p,t)\big)$. Thus $e^{ih^{-1}At}$ is a product of FIO corresponding to the symplectomorphism Φ_t (a standard quantization, phase function is defined in the standard way and the symbol is just 1) and some PDO.

In particular, one can see easily that $\Phi_t - I = O(\gamma)$ as $t = 2\pi\bar{f}_2^{-1}$; therefore we conclude that $\Phi_t = e^{\gamma H_b}$ with some symbol $b = b(\mu^{-1}x, Z)$. Quantizing it we get that (21.2.49) holds but with an extra PDO factor $\mathcal{Q}$ between FIO and ψ. However, then one can perturb B by operator $\gamma^{-1}hB_1$ so that

$$e^{2\pi i\mu^{-1}h^{-1}\bar{f}_2^{-1}B}\mathcal{Q} \equiv e^{2\pi i\mu^{-1}h^{-1}\bar{f}_2^{-1}(B+\gamma^{-1}hB)};$$

we leave this easy exercise to the reader. □

Proposition 21.2.11. *Let condition*

$$V \ge \epsilon_0 \tag{21.2.52}$$

be fulfilled. Then

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(u\psi Q\big)| \le C'h^s \qquad \forall \tau : |\tau| \le \epsilon \tag{21.2.53}$$

as $\mu \ge K$, $\bar{T} := Ch|\log h| \le T \le 2\pi(1-\epsilon_0)\mu^{-1}\bar{f}_2^{-1}$, $\gamma \le \epsilon$ *where* ψ *is supported in* $B(\bar{x},\gamma)$, γ *is calculated in* $\bar{x}$, Q *is an arbitrary* h*-PDO* [6].

Now let us consider in the outer zone the intermediate scale dynamics:

[6] Recall that $\chi \in \mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1])$, $\bar\chi \in \mathscr{C}_0^\infty([-1,1])$ are our usual cut-off functions, $\chi_T(t) = \chi(t/T)$ etc. and $\Gamma_x(u) = u(x,x)$, $\Gamma u = \int u(x,x)\,dx$.

Proposition 21.2.12. *Consider* $\bar{x} \in \mathcal{Z}_{\mathsf{out}} \coloneqq \{\gamma \ge C\mu^{-1/2}\}$. *Then as* $|t| \le C\mu^{-1}\gamma^{-1}$ $e^{ih^{-1}At}$ *is* h*-FIO corresponding to the classical dynamics* $\Phi_t = e^{tH_a}$ *with Hamiltonian* a *and*

$$e^{ih^{-1}tA}\psi \equiv e^{ih^{-1}t''A}e^{ih^{-1}t'B}\psi \tag{21.2.54}$$

where $t' = 2\pi\mu^{-1}\bar{f}_2^{-1}n$, $n = \bigl\lfloor (2\pi)^{-1}\bar{f}\mu t\bigr\rfloor$, $t'' = t - t'$.

Proof. Formula (21.2.54) follows from (21.2.49) and the fact that $|x_1|$ retains its magnitude in the classical dynamics in the zone $\mathcal{Z}_{\mathsf{out}}$. □

Proposition 21.2.13. *(i) Let* $\mu \le \epsilon h^{-1}|\log h|^{-1}$, $\bar{x} \in \mathcal{Z}_{\mathsf{out}}$ *and* Q *be* h*-PDO with the symbol supported in* $\{|Z_1| \ge \rho\}$ *with*

$$\rho \ge C\mu^{-1}\gamma^{-1} + C(\mu h\gamma|\log h|)^{1/2}. \tag{21.2.55}$$

Then (21.2.53) *holds as* $C\rho^{-2}h|\log h| \le T \le T_1 \coloneqq \epsilon_1\mu^{-1}\gamma^{-1}$.

(ii) In particular, let

$$\rho \ge C\mu^{-1}\gamma^{-1} + C(\mu h|\log h|)^{1/2}. \tag{21.2.56}$$

Then estimate (21.2.53) *holds as* $\bar{T} = Ch|\log h| \le T \le \epsilon_1\mu^{-1}\gamma^{-1}$.

Proof. Let us temporarily direct $\mathbb{K}_1$ as a coordinate plane[7] $\{x_1, x_2\}$ and consider ρ-admissible partition in (ξ_1, ξ_2). Then one can see easily that the propagation along $\mathbb{K}_1$ has the speed $\asymp \rho$. Further, condition (21.2.55) ensures that ρ retains its magnitude since the propagation speed of $|Z_1|^2$ does not exceed $C_0\mu^{-1}\rho^2\gamma^{-2} + C_0\mu^{-1}$ and $|Z_1|^2$ is corrected by $O(\rho\mu^{-1})$. Furthermore, the last term in (21.2.55) ensures the logarithmic uncertainty principle.

Then for time T the shift along $\mathbb{K}_1$ is exactly of magnitude ρT and the logarithmic uncertainty principle $\rho T \times \rho \ge Ch|\log h|$ is fulfilled as long as $T \ge T' = C\rho^{-2}h|\log h|$. This implies Statement (i).

Now it follows from Statement (i) and Proposition 21.2.11 that estimate (21.2.53) holds as $\bar{T} = Ch|\log h| \le T \le T_1 = \epsilon\mu^{-1}\gamma^{-1}$ provided $T' \le \epsilon\mu^{-1}$ which means upgrade of condition (21.2.55) to (21.2.56). □

[7] For $T \le c\mu^{-1}\gamma^{-1}$ and $\gamma \ge C\mu^{-1/2}$ with $C = C(\epsilon, c)$ our propagation is confined to $B(\bar{x}, \epsilon\gamma)$.

Dynamics and Remainder Estimate. I

On the other hand one can see easily that the contribution to the remainder of the rather thin subzone where $|x_1| \asymp \gamma$ and condition (21.2.56) is violated does not exceed $C\mu h^{-3}\big(\mu^{-2}\gamma^{-2} + \mu h|\log h|\big)\gamma$; further, summation of this expression over $\mathcal{Z}_{\mathsf{out}}$ results in $C\mu^{-1/2}h^{-3} + C\mu^2 h^{-2}|\log h|$. Therefore we have proven

Proposition 21.2.14. *Contribution to the remainder of the subzone of* $\mathcal{Z}_{\mathsf{out}}$ *where condition* (21.2.55) *is violated is* $O\Big(\mu^{-1/2}h^{-3} + \mu^2 h^{-2}|\log h|\Big)$. *In particular, this contribution is* $O(\mu^{-1/2}h^{-3})$ *as* $\mu \le C(h|\log h|)^{-2/5}$.

Remark 21.2.15. Actually, one can get rid of logarithmic factors here but under assumption (21.2.48) it is not needed; this estimate (without logarithmic factor) is the best possible if no non-degeneracy condition is assumed.

From now on we will consider only the *main subzone* of $\mathcal{Z}_{\mathsf{out}}$ where condition (21.2.56) is fulfilled and thus estimate (21.2.53) holds with $\bar{T} \le T \le T_1$. We need to estimate its contribution to the remainder estimate.

First of all one needs the quantum version of the results of the previous subsection.

Proposition 21.2.16. *Let condition* (21.2.48) *be fulfilled. Let function* ψ *be properly supported in* $B(\bar{x}, \gamma')$, *and* Q *be properly supported in* $\{|Z_1| \le \rho\}$ *with* $\rho \ge C_0\mu^{-1/2}$ *and*

$$\gamma' \ge C\rho^{-1}h|\log h|. \tag{21.2.57}$$

Further, let $\gamma \ge C_0\mu^{-1/2}$ *and* $T \le T_2 := \epsilon\mu\gamma^2$ *and let* $x'' = (x_3, x_4)$. *Then*

(i) If

$$r = |\bar{x}''| \ge r' := C_0\mu^{-1}\gamma^{-1} + C_0\gamma' \tag{21.2.58}$$

then estimate

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)(1-\psi_1)(u\psi_y Q_y^t)| \le Ch^s \tag{21.2.59}$$

holds provided $\psi_1 = 1$ *in the domain*

$$\Big\{x : C_0^{-1}\gamma \le |x_1| \le C_0\gamma,\ C_0^{-1}r \le |x''| \le C_0 r, \\ \mathsf{dist}(x, \bar{x}) \ge C_0\gamma' + C_0\mu^{-1}\gamma^{-1} + C_0\mu^{-1}(r+\gamma)\gamma^{-2}T\Big\}. \tag{21.2.60}$$

(ii) On the other hand, if condition (21.2.58) *is violated then estimate* (21.2.59) *holds provided* $\psi_1 = 1$ *in the domain*

$$\Big\{x : C_0^{-1}\gamma \le |x_1| \le C_0\gamma,\ |x''| \le C_0 r', \quad \operatorname{dist}(x, \bar{x}) \ge C_0\gamma' + C_0\mu^{-1}\gamma^{-1} + C_0\mu^{-1}(r'+\gamma)\gamma^{-2}T\Big\}. \tag{21.2.61}$$

Proof. Proof is the standard one (see e.g. Chapter 2) based on the analysis of the symbol

$$\varpi\Big(\frac{1}{T}\Big(t \pm \epsilon v^{-1}\big(X(x,\xi) - X(y,\xi)\big)\Big)\Big) \tag{21.2.62}$$

where ϖ is the same function as in Chapter 2, $X(x,\xi)$ is one of the corrected symbols x_1^2, $x_1 - \frac{1}{2}|x''|^2$ and x_j with $j = 1, \dots, 4$ and v is the corresponding speed, namely μ^{-1}, μ^{-1} and $\mu^{-1}x_1^{-2}r$ respectively.

Obviously, it is sufficient to consider T such that the last term in definitions of (21.2.60), (21.2.61) is dominant: $\mu^{-1}(r+\gamma)\gamma^{-2}T \ge \gamma' + \mu^{-1}\gamma^{-1}$. One can see easily that under this condition and (21.2.48) symbol (21.2.62) is quantizable; here also one can be more specific about exponent $\delta > 0$ in condition (21.2.48). □

Now we want to be more precise for smaller r, ρ:

Proposition 21.2.17. *In the framework of Proposition 21.2.16 as* $T \le \epsilon\mu\gamma^2\rho$ *estimate*

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)(1-Q_1)\psi_1(u\psi_y Q_y^t)| \le Ch^s \tag{21.2.63}$$

holds provided $Q_1 = I$ *in the domain* $\{c^{-1}\rho \le |Z_1| \le c\rho\}$ *and estimate* (21.2.59) *holds provided* $\psi_1 = 1$ *in the domain*

$$\Big\{x : C_0^{-1}\gamma \le |x_1| \le C_0\gamma,\ C_0^{-1}r \le |x''| \le C_0 r, \quad \operatorname{dist}(x, \bar{x}) \ge C_0\gamma' + C_0\mu^{-1}\gamma^{-1} + C_0\mu^{-1}\gamma^{-2}(r\rho^2+\gamma)T\Big\} \tag{21.2.64}$$

as $r \ge r'$*, and in the domain*

$$\Big\{x : C_0^{-1}\gamma \le |x_1| \le C_0\gamma,\ |x''| \le C_0 r', \quad \operatorname{dist}(x, \bar{x}) \ge C_0\gamma' + C_0\mu^{-1}\gamma^{-1} + C_0\mu^{-1}\gamma^{-2}(r'\rho^2+\gamma)T\Big\}. \tag{21.2.65}$$

as $r \le r'$.

Proof. Proof is standard, based on the symbol (21.2.62) which is quantizable due to assumption (21.2.48); here again X is one of the corrected symbols $|Z_1|^2$, x' and v is the corresponding upper bound for a speed, namely $\mu^{-1}\gamma^{-2}\rho$, $\mu^{-1}\gamma^{-2}(\rho^2+\gamma)$ respectively. □

Note that under assumption (21.2.48) $r' \asymp \mu^{-1}\gamma^{-1}$ and we want to eliminate the corresponding subzone from the future analysis. Really, let us note that the contribution of the subzone $\{\gamma \le |x_1| \le 2\gamma, |x''| \le r, |Z_1| \le \rho\}$ to the remainder is $O(T_1^{-1}h^{-3}r^2\rho^2\gamma) = O(\mu h^{-3}r^2\rho^2\gamma^2)$ (since we already eliminated subzone where condition (21.2.56) is violated) and plugging $r\rho = \mu^{-1}\gamma^{-1}$ results in $O(\mu^{-1}h^{-3})$. Then summation with respect to γ results in $O(\mu^{-1}h^{-3}|\log\mu|)$. So, we conclude that

(21.2.66) Contribution to the remainder of subzone $\mathcal{Z}_{\mathsf{out}} \cap \{r\rho \le C\mu^{-1}\gamma^{-1}\}$ is $o(\mu^{-1/2}h^{-3})$.

Dynamics and Remainder Estimate. II

From now on we restrict ourselves to the analysis of the subzone $\mathcal{Z}_{\mathsf{out}} \cap \{r\rho \ge C\mu^{-1}\gamma^{-1}\}$.

Now one can see that in $\mathcal{Z}_{\mathsf{out}}$ function $v(\rho; x, \mu^{-1})$ defined by (21.2.43) has no more than one root $\rho \ge C\mu^{-1}r^{-1}\gamma^{-1}$; let us denote it by $w = w(x, \mu^{-1})$. Otherwise (if such root does not exist) we set $w = 0$. One can see easily that

$$v(\rho; x, \mu^{-1}) \asymp \mu^{-1}\gamma^{-2}(\rho^2 - w^2). \tag{21.2.67}$$

If $\rho - w \asymp \Delta$ then the propagation speed for corrected symbol θ is $v(\rho, .)$; then the linear shift for time $\epsilon\mu^{-1}\gamma^{-1}$ is $\asymp r\mu^{-2}\gamma^{-3}\rho\Delta$ (where r appears because θ is an angle). This shift is observable as long as the logarithmic uncertainty principle $r\mu^{-2}\gamma^{-3}\rho\Delta \times \Delta \ge Ch|\log h|$ holds[8] i.e.

$$\Delta \ge C\mu\big(h|\log h|\big)^{1/2}\rho^{-1/2}\gamma^{3/2}r^{-1}. \tag{21.2.68}$$

Since the propagation speed for symbol corrected $|Z_1|^2$ is $O(\mu^{-1}\gamma^{-2}\rho^2)$, the magnitude of Δ is preserved during the time interval $T'' = \epsilon\mu\gamma^2\rho^{-1}\Delta$ which is larger than $C\mu^{-1}\gamma^{-1}$ as

$$\Delta \ge C\mu^{-2}\rho^{-1}\gamma^{-3}. \tag{21.2.69}$$

[8] Now Δ is the scale in ρ.

This condition is stronger than (21.2.68) as $r \ge \mu^{-1}$ and (21.2.48) is fulfilled with small enough $\delta > 0$.

To justify this assertion properly one needs to operate with the quantizable symbols and one can see easily that this is the case under assumptions (21.2.48) with small enough $\delta > 0$ and (21.2.68). Then the contribution to the remainder of the corresponding subzone (where magnitudes of γ, ρ, r and Δ are fixed) does not exceed $Cr^2h^{-3}\rho\gamma\Delta/T'' = C\mu^{-1}h^{-3}r^2\rho^2\gamma^{-1}$.

Let us note that as magnitudes of γ, r, ρ are fixed and Δ ranges from $C\mu^{-2}\rho^{-1}\gamma^{-3}$ dictated by (21.2.69) to $\epsilon\rho$, the number of such elements does not exceed $C\log\mu$. So the summation with respect to this zone results in $C\mu^{-1}h^{-3}r^2\rho^2\gamma^{-1}\log\mu$. Further, as $\Delta \ge \epsilon\rho$, there are no more than C such elements and therefore the contribution to the remainder of the part of the zone

$$\mathcal{Y}_{\gamma,\rho,r} := \Big\{\frac{1}{2}\gamma \le |x_1| \le 2\gamma,\ \frac{1}{2}\rho \le |Z_1| \le 2\rho,\ \frac{1}{2}r \le |x''| \le 2r\Big\} \tag{21.2.70}$$

where condition (21.2.69) is fulfilled does not exceed $C\mu^{-1}h^{-3}r^2\rho^2\gamma^{-1}\log\mu$ as well. Summation with respect to ρ with $\rho \le C(\gamma/r)^{1/2}$ results in $C\mu^{-1}h^{-3}r\log\mu$ and then the summation with respect to all r, γ results in $\mu^{-1}h^{-3}|\log\mu|^2 = o(\mu^{-1/2}h^{-3})$. Therefore contribution to the remainder of the part of the zone $\mathcal{Z}_{\mathsf{out}}$ where $r \ge \mu^{-1}\gamma^{-1}$, $\rho^2 \le C\gamma$ and condition (21.2.69) is fulfilled is $O(\mu^{-1/2}h^{-3})$.

The same arguments one can apply as $\rho^2 \ge C\gamma/r$ but in this case $\Delta = \epsilon\rho$ and condition (21.2.67) is fulfilled automatically, there will be no factor $\log\mu$ and the summation of $C\mu^{-1}h^{-3}r^2\rho^2\gamma^{-1}$ with respect to ρ, r, γ results in $C\mu^{-1/2}h^{-3}$.

Therefore we arrive to

(21.2.71) Contribution to the remainder e of the subzone of $\mathcal{Z}_{\mathsf{out}}$ where condition (21.2.69) is fulfilled is $O(\mu^{-1/2}h^{-3})$.

Finally, contribution to the remainder of the subzone $\mathcal{Y}_{\gamma,\rho}$ with $\gamma \ge C\mu^{-1/2}$ where condition (21.2.69) is violated does not exceed

$$C\big(h^{-3}\rho\gamma \times \mu^{-2}\rho^{-1}\gamma^{-3} \times T_1^{-1}\big) = C\mu^{-1}\gamma^{-1}h^{-3}$$

since $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ and summation with respect to γ results again in $O(\mu^{-1/2}h^{-3})$.

Combining with (21.2.71) we obtain immediately

Proposition 21.2.18. *Under assumption* (21.2.48) *the contribution to the remainder of the zone* $\mathcal{Z}_{\mathsf{out}}$ *is* $O\big(\mu^{-1/2}h^{-3}\big)$.

21.2.4 Quantum Dynamics. II. Inner Zone

Now we need to analyze the contribution to the remainder estimate of the *inner zone* $\mathcal{Z}_{\mathsf{inn}} = \{|x_1| \le \bar{\gamma}_0 = C\mu^{-1/2}\}$ under assumption (21.2.48). Both classical and quantum dynamics are confined to this zone as $T \le \epsilon$ and it starts in $B(0, \frac{1}{2})$; propagation speed with respect to x does not exceed C_0. Note that the correction procedure still works as long as one eliminates only unbalanced factors Z_2, $Z_2^\dagger$.

Dynamics and Remainder Estimate. III

Contribution to the remainder estimate of the subzone $\{|Z_1| \le \rho, |x_1| \le \gamma\}$ does not exceed $CT^{-1}h^{-3}\rho^2 r^2\gamma = C\mu h^{-3}\gamma\rho^2$ with $T = T_0 = \epsilon\mu^{-1}$; plugging $\gamma = c\mu^{-1/2}$ and $\rho = c\mu^{-1/2}$ we get $O(\mu^{-1/2}h^{-3})$ and therefore one needs to consider only the contribution to the remainder estimate of the subzone $\mathcal{Z}_{\mathsf{inn}} \cap \{|Z_1| \ge C\mu^{-1/2}\}$; but then Proposition 21.2.12 remains true here and one can increase $T = T_0$ to $T = T_1 = \epsilon\mu^{-1/2}$ [9)].

Then the contribution to the remainder estimate of the zone $\{|Z_1| \le \rho, |x_1| \le \gamma, |x''| \le r\}$ does not exceed $CT^{-1}h^{-3}\rho^2 r^2\gamma = C\mu^{1/2}h^{-3}\gamma r^2\rho^2$ with $T = \epsilon\mu^{-1/2}$; in particular, the total contribution of the inner zone $\mathcal{Z}_{\mathsf{inn}}$ is $O(h^{-3})$ and one needs to recover factor $\mu^{-1/2}$.

To recover this factor one needs just to increase $T = T_1 = \epsilon\mu^{-1/2}$ to $T = T_2 = \epsilon$. Before doing this just note that the contributions to the remainder estimates of subzones $\mathcal{Z}_{\mathsf{inn}} \cap \{|Z_1| \le c\mu^{-1/4}\}$, $\mathcal{Z}_{\mathsf{inn}} \cap \{|x''| \le c\mu^{-1/4}\}$ and $\mathcal{Z}_{\mathsf{inn}} \cap \{|Z_1| \cdot |x''| \le c\mu^{-1/4}|\log\mu|^{-1}\}$ are $O(\mu^{-1/2}h^{-3})$ and therefore

(21.2.72) One needs to consider only the contribution to the remainder of the subzone $\mathcal{Z}_{\mathsf{inn}} \cap \{|x''| \ge c_1\mu^{-1/4},\ |Z_1| \ge c_1\mu^{-1/4},\ |Z_1|\cdot|x''| \ge c_1\mu^{-1/4}|\log\mu|^{-1}\}$.

Let us recall that the classical dynamics which starts in the subzone $\{|x_1| \le \gamma, |x''| = r \ge C_1\mu^{-1/4}\}$ remains in $\{|x_1| \le C\gamma, \big||x''| - r\big| \le C_1\mu^{-1/2}r^{-1}\}$ as $T = \epsilon$; actually it could be larger as $\rho r \ll 1$.

[9)] As in footnote [6)] one must take $T_1 = \epsilon\min(\mu^{-1/2}, \rho)$ but contribution to the remainder estimate of subzone $\mathcal{Z}_{\mathsf{inn}} \cap \{|Z_1| \le \mu^{-1/2}\}$ is $O(\mu h^{-3}\rho^2\gamma) = O(\mu^{-1/2}h^{-3})$.

Repeating arguments of the proof of Proposition 21.2.16 one can justify it easily for quantum propagation as well:

Proposition 21.2.19. *Under assumption* (21.2.48) *with small enough* $\delta > 0$ *the quantum dynamics which starts in the subzone* $\{|x_1| \le \gamma, |x''| = r \ge C_1\mu^{-1/4}\}$ *remains in* $\{|x_1| \le C\gamma, \big||x''| - r\big| \le C_1\mu^{-1/2}r^{-1}\}$ *as* $T = \epsilon$.

Now let us consider again function $\frac{1}{2}x_1^2$; then

$$\frac{1}{2}\{a, x_1^2\} = \mathsf{Re}\Big(\{Z_1^\dagger, x_1\}x_1Z_1 + \{Z_2^\dagger, x_1\}x_1Z_2\Big) \tag{21.2.73}$$

and thus should be corrected by

$$\mu^{-1}\,\mathsf{Re}\, i\Big(\{Z_1^\dagger, x_1\}f_1^{-1}x_1Z_1 + \{Z_2^\dagger, x_1\}f_2^{-1}x_1Z_2\Big) \tag{21.2.74}$$

which is $O(\mu^{-1}r)$ as $r \ge \mu^{-1/2}$ and leads to the new error

$$\begin{aligned}\mu^{-1}\,\mathsf{Re}\, i\Big(&\big\{a, \{Z_1^\dagger, x_1\}f_1^{-1}x_1\big\}Z_1 + \{Z_1^\dagger, x_1\}f_1^{-1}x_1\big(\{a, Z_1\} + i\mu Z_1\big) + \\ &\big\{a, \{Z_2^\dagger, x_1\}f_2^{-1}x_1\big\}Z_2 + \{Z_2^\dagger, x_1\}f_2^{-1}x_1\big(\{a, Z_2\} + i\mu Z_2\big)\Big).\end{aligned} \tag{21.2.75}$$

This new error is $O(\mu^{-1})$ and thus taking $T = \epsilon r$ one can see that the oscillation of x_1^2 would be $O(\mu^{-1}r)$ which leads to

Proposition 21.2.20. *(i) The classical dynamics which starts in the subzone* $\{|x_1| = \gamma, |x''| = r \ge C_1\mu^{-1/4}\}$ *with* $C_0\mu^{-1/2}r^{1/2} \le \gamma \le C_0\mu^{-1/2}$ *remains in* $\{C^{-1}\gamma \le |x_1| \le C\gamma\}$ *as* $T = \epsilon r$.

(ii) The classical dynamics which starts in the subzone $\{|x_1| \le \gamma, |x''| = r \ge C_1\mu^{-1/4}\}$ *with* $\gamma = C_0\mu^{-1/2}r^{1/2}$ *remains in* $\{|x_1| \le C\gamma\}$ *as* $T = \epsilon r$.

(iii) Under assumption (21.2.48) *with small enough* $\delta > 0$ *statements (i),(ii) remain true for a quantum dynamics as well.*

Therefore one can see that the dynamics in the zones described in Proposition 21.2.20(i),(ii) are different with the dynamics in the former resembling the dynamics in $\mathcal{Z}_{\mathsf{out}}$. Then the arguments of the previous Subsection 21.2.3

work perfectly in the zone described in Proposition 21.2.20(i) tedious but easy[10)] details we leave to the reader:

Proposition 21.2.21. *Under assumption* (21.2.48) *with sufficiently small* $\delta > 0$ *the contribution to the remainder estimate of the zone* $\{C_0\mu^{-1/2}|x''|^{1/2} \le |x_1| \le C_0\mu^{-1/2}\}$ *does not exceed* $C\mu^{-1/2}h^{-3}$.

Thus we are left with the zone

$$\{C_1\mu^{-1/6} \le |x''| \le c, \quad |x_1| \le C_1\mu^{-1/2}|x''|^{1/2}\}. \tag{21.2.76}$$

Again the dynamics in the zones $\mathcal{Y}_{\gamma,\rho,r}$ with $\rho r \le \epsilon\mu\gamma^2$ and $\rho r \ge \epsilon\mu\gamma^2$ are very different with the former one more similar to the dynamics in the outer zone (as long as it remains there).

Furthermore, similarly the propagation speed of the symbol $|Z_1|^2$, corrected by $O(\mu^{-1}\gamma^{-1}r|Z_1| + \mu^{-1})$ does not exceed $C\bigl(\mu^{-1}\gamma^{-2}r|Z_1| + \mu^{-1}\bigr)$ and therefore the propagation speed of $|Z_1|$ does not exceed $C\bigl(\mu^{-1}\gamma^{-2}r + \mu^{-1/2}\bigr)$ and thus magnitude of $|Z_1| \asymp \rho$ is preserved on the time interval $T = \epsilon\bigl(\mu^{-1}\gamma^{-2}r + \mu^{-1/2}\bigr)^{-1}\rho$ as long as $\gamma \ge C(\mu r\rho)^{1/2}$. As a result we arrive to

Proposition 21.2.22. *(i) The classical dynamics which starts in the subzone* $\{|x_1| = \gamma, |x''| = r \ge C_1\mu^{-1/4}, |Z_1| = \rho\}$ *with* $C_0\mu^{-1/2}r^{1/2}\rho^{1/2} \le \gamma \le C_0\mu^{-1/2}$ *remains in* $\{C^{-1}\rho \le |Z_1| \le C\rho\}$ *as* $T = \epsilon\min\Bigl(r, \mu\gamma r\rho^{-1}, \mu^{-1}\rho^{-1}\Bigr)$.

(ii) The classical dynamics which starts in the subzone $\{|x_1| \le \gamma, |x''| = r \ge C_1\mu^{-1/4}, |Z_1| = \rho\}$, *with* $\gamma = C_0\mu^{-1/2}r^{1/2}\rho^{1/2}$ *remains in* $\{C^{-1}\rho \le |Z_1| \le C\rho\}$ *as* $T = \epsilon\min\Bigl(r, \mu\gamma r\rho^{-1}, \mu^{-1}\rho^{-1}\Bigr)$.

(iii) Under assumption (21.2.48) *with small enough* $\delta > 0$ *Statements (i) and (ii) remain true for a quantum dynamics as well.*

Dynamics and Remainder Estimate. IV

Then again arguments of the previous subsection work perfectly in the zone described in Proposition 21.2.22(i); tedious but easy details (see footnote [9)] with the obvious modifications.) I leave to the reader:

[10)] Because one needs to worry only about eliminating factor $\mu^{1/2}$ while in the previous subsection the ofending factor was $\mu^{3/2}$. One can just take $\Delta = C\mu^{-1/2}$. Also one can assume that $|x_1| \ge \hat{\gamma} = c_1\mu^{-3/5}$; otherwise $|x''| \le r = c_2\mu^{-1/5}$ and the contribution to the remainder estimate of this zone would be $O(\mu h^{-3}\gamma^2 r^2) = O(\mu^{-1/2}h^{-3})$.

But then $\rho \ge \mu^{-1}\gamma^{-1}$ in the zone of interest and one can finally upgrade $T_1 = \epsilon\mu^{-1/2}$ to $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ and the crude estimate to $O(\mu h^{-3}\rho^2\gamma^2 r^2)$.

Proposition 21.2.23. *Under assumption* (21.2.48) *with sufficiently small* $\delta > 0$ *the contribution to the remainder of the zone* $\{C_0\mu^{-1/2}|x''|^{1/2}|Z_1|^{1/2} \le |x_1| \le C_0\mu^{-1/2}\}$ *does not exceed* $C\mu^{-1/2}h^{-3}$.

Therefore we are left with the *true inner zone*

$$\mathcal{Z}^0_{\mathsf{inn}} := \{|x_1| \le C_1\mu^{-1/2}|x''|^{1/2}|Z_1|^{1/2}\}. \tag{21.2.77}$$

Similarly to claim (21.2.72)

(21.2.78) One needs to consider only the contribution to the remainder of the subzone $\mathcal{Z}^0_{\mathsf{inn}} \cap \{|x''| \ge c_1\mu^{-1/6},\ |Z_1| \ge c_1\mu^{-1/6},\ |Z_1|\cdot|x''| \ge c_1\mu^{-1/6}|\log\mu|^{-1}\}$.

Let us consider classical dynamics in this zone first; we are interested in the time interval $T \le \epsilon r$. There

$$\{a, Z_1\} = \{Z_1^\dagger, Z_1\}Z_1 + \{Z_2^\dagger, Z_1\}Z_2 + \{Z_2, Z_1\}Z_2^\dagger - \{V, Z_1\}$$

and then we correct Z_1 to

$$\zeta_1 = Z_1 + i\mu^{-1}f_2^{-1}\{Z_2^\dagger, Z_1\}Z_2 - i\mu^{-1}f_2^{-1}\{Z_2, Z_1\}Z_2^\dagger \tag{21.2.79}$$

satisfying

$$\begin{aligned}\{a, \zeta_1\} \equiv\ & \{Z_1^\dagger, Z_1\}Z_1 - \\ & if_2^{-1}\mu^{-1}\Big(\big\{Z_2, \{Z_2^\dagger, Z_1\}\big\} - \big\{Z_2^\dagger, \{Z_2, Z_1\}\big\}\Big)|Z_2|^2 - \{V, Z_1\} = \\ & \{Z_1^\dagger, Z_1\}Z_1 + if_2^{-1}\mu^{-1}\big\{Z_1, \{Z_2, Z_2^\dagger\}\big\}|Z_2|^2 - \{V, Z_1\} \equiv \\ & \{Z_1^\dagger, Z_1\}Z_1 - f_2^{-1}\{Z_1, f_2\}|Z_2|^2 - \{V, Z_1\} \qquad \mathsf{mod}\ O(\mu^{-1/2}).\end{aligned}$$

Since we do not mind to change the speed to one of the same magnitude and we consider only level 0, we can assume without any loss of the generality that

$$f_2 = 1; \tag{21.2.80}$$

then finally $\{a, \zeta_1\} \equiv \{\zeta_1^\dagger\zeta_1 - V, \zeta_1\} \mod O(\mu^{-1/2})$.

Also corrected functions x_j satisfy $\{a, x_j'\} \equiv \{\zeta_1^\dagger\zeta_1 - V, x_j'\} \mod O(\mu^{-1/2})$ and we arrive to the following conclusion:

(21.2.81) Under assumption (21.2.80) the classical dynamics in the zone $\{|x_1| \le C\mu^{-1/2}\}$ in variables x_j, Z_1, Z_2 is described modulo $O(\mu^{-1} + \mu^{-1/2}T)$ by the solution to the short system

$$\frac{dZ_1}{dt} = \frac{1}{2}\{Z_1^\dagger Z_1 - V, Z_1\}, \tag{21.2.82}$$

$$\frac{dx_j}{dt} = \frac{1}{2}\{Z_1^\dagger Z_1 - V, x_j\}, \tag{21.2.83}$$

$$\{Z_1, Z_2\} = O(\mu^{-1}), \quad \{Z_1, Z_2^\dagger\} = O(\mu^{-1}). \tag{21.2.84}$$

Further, for each given initial point one can replace all functions modulo $(x_1 - \frac{1}{2}r^2)$, $(x_2 - \theta r^2)$ so that we get two-dimensional system in variables (r, θ) described by the Hamiltonian $\frac{1}{2}(Z_1^\dagger Z_1 - V)$ with $Z_1, Z_1^\dagger$ satisfying commutator relation

$$\{Z_1, Z_1^\dagger\} = \mu\phi\bar{r}(r - \bar{r}) + O(\mu^{-1})) \tag{21.2.85}$$

which is exactly system studied extensively in Chapter 14 with magnetic field $\phi(r - \bar{r})$ and coupling constant $\bar{\mu} = \mu\bar{r}$. Condition (21.2.77) means exactly that we are in the inner zone $\{|r - \bar{r}| \le C\bar{\mu}^{-1/2}|Z_1|^{1/2}\}$ for this system; since (in contrast to Chapter 14) $|Z_1|$ is not disjoint from 0 anymore one needs to define inner zone in this way.

Then the drift speed with respect to θr is

$$\asymp \Big(\eta - k^*\phi^{-1/2}\rho\Big)\rho r \tag{21.2.86}$$

where constant $k^* \approx 0.66$ is defined in Chapter 14 and η is the corrected symbol $\mu x_1^2/2$ which leads to its propagation speed given by (21.2.75) multiplied by μ.

One can see easily that the fourth term there

$$\{Z_2^\dagger, x_1\}f_2^{-1}x_1\big(\{a, Z_2\} + i\mu Z_2\big)$$

is $O(\mu^{-1/2})$. Further, the third term $\big\{a, \{Z_2^\dagger, x_1\}f_2^{-1}x_1\big\}Z_2$ could be rewritten modulo $O(\mu^{-1/2})$ and terms with unbalanced $Z_2, Z_2^\dagger$ as $|\{Z_2, x_1\}|^2 f_2^{-1}|Z_2|^2$ and disappears after applying $\operatorname{Re} i$.

So we are left with just two terms

$$\operatorname{Re} i\Big(\big\{a, \{Z_1^\dagger, x_1\}\phi^{-1}\big\}Z_1 + \{Z_1^\dagger, x_1\}\phi^{-1}\big(\{a, Z_1\} + i\mu Z_1\big)\Big) \tag{21.2.87}$$

where $\phi = f_1/x_1$ and one can replace a by $Z_1^\dagger Z_1 - V$ (other terms have unbalanced $Z_2, Z_2^\dagger$).

Dynamics and Remainder Estimate. V

So we are *exactly* in the situation described in Chapter 14. Recall that that in Chapter 14 symbol Z_1 could be reduced to

$$Z_1 = e^{i\beta(x)}\Big(\xi_1 + i\alpha(x)\big(\xi_2 - V_2(x)\big)\Big) \tag{21.2.88}$$

with real-valued α, β, V_2 such that $\alpha = 1 + O(x_1)$, $V_2 = x_1^2/2 + O(x_1^3)$.

One can see easily that in this case that corrected μx_1^2 would be $\xi_2 + O(\mu^{-1/2})$; recall that in Chapter 14 exactly deviation of ξ_2 from $k^*\phi^{-1/2}\rho$ was used as the measure of the drift with $\rho = V^{1/2}$. Note that the potential V now should be replaced by $(V - E_2)$ with $E_2 = |Z_2^2|$.

Therefore due to the logarithmic uncertainty principle the violation of periodicity is observable after the first turn as

$$\Big(\eta - k^*\phi^{-1/2}\rho\Big)\rho r\mu^{-1/2} \times \Big(\eta - k^*\phi^{-1/2}\rho\Big) \ge Ch|\log h|; \tag{21.2.89}$$

under assumption (21.2.48) the latter condition is the automatic corollary of

$$\Delta = |\eta - k^*\phi^{-1/2}\rho| \ge C\mu^{-1/2}r^{-1/2}\rho^{-1/2}. \tag{21.2.90}$$

Under this condition the drift speed for the "short" system is greater than $C\epsilon_1\mu^{-1/2}$ which is the larger than the error in the drift speed $c\mu^{-1/2}$ (see (21.2.81).

In this case $T_1 = \epsilon r\Delta$ and the rest is easy but extra logarithmic factor would appear; however, considering the right direction one can take $T_1 = \epsilon r\rho^{1/2}\Delta^{1/2}$ and following Chapter 14 with the standard justification on the quantum level one can prove easily that

(21.2.91) The contribution of the zone where condition (21.2.90) is fulfilled to the remainder is $O(\mu^{-1/2}h^{-3})$.

On the other hand, contribution to the remainder of the zone where this condition is violated would not exceed

$$C\Big(\int \mu^{-1/2}h^{-3}r^{-1/2}\rho^{-1/2}rdrd\rho\Big) = O(\mu^{-1/2}h^{-3})$$

as well.

So, the main result of this section is proven:

Proposition 21.2.24. *Under assumption* (21.2.48) *with small enough* $\delta > 0$ *the remainder estimate is* $O(\mu^{-1/2}h^{-3})$ *while the principal part is given by the standard Weyl formula (which is equal modulo the remainder estimate to magnetic Weyl formula).*

This statement implies trivially

Corollary 21.2.25. *Under assumptions* (21.2.48) *and*

$$V \geq \epsilon_0 > 0. \tag{21.2.92}$$

the following estimate holds:

$$|\int \big(e(x,x,0) - \mathcal{N}^{\mathsf{MW}}(x,0)\big)\psi(x)\,dx| \leq C\mu^{-1/2}h^{-3} + C\mu^2h^{-2} \tag{21.2.93}$$

where

$$\mathcal{N}^{\mathsf{MW}}(x,\tau) = (2\pi)^{-2}\mu^2h^{-2} \sum_{(m,n)\in\mathbb{Z}^{+\,2}} \theta\big(2\tau + V - (2m+1)\mu h f_1 - (2n+1)\mu h f_2\big) f_1 f_2 \sqrt{g}. \tag{21.2.94}$$

21.3 Temperate and Intermediate Magnetic Field. Canonical Forms

Now let us consider the main case

$$h^{-\delta} \leq \mu \leq Ch^{-1} \tag{21.3.1}$$

with an arbitrarily small exponent $\delta > 0$. In this section we consider different canonical forms of the magnetic Schrödinger operator in question (depending on the zone).

21.3.1 Precanonical Form

Precanonical Form. I

Let

$$U_2(x,\xi) = f_2(x)^{-1/2} Z_2(x,\xi) \tag{21.3.2}$$

Then

$$-i\mu^{-1}\{U_2, U_2^\dagger\} \equiv 2 \qquad \mathsf{mod}\ \mathcal{O}_k \tag{21.3.2}_k$$

with $k = 1$ where $\mathcal{O}_k := \mathcal{O}_k(\mu^{-1}Z_1, \mu^{-1}Z_1^\dagger, \mu^{-1}Z_2, \mu^{-1}Z_2^\dagger)$ is the space of the sums of polynomials containing monoms of order k or higher with respect to $(\mu^{-1}Z_1, \mu^{-1}Z_1^\dagger, \mu^{-1}Z_2, \mu^{-1}Z_2^\dagger)$ with the coefficients, smoothly depending on x.

Note that correcting U_2 by $U_2\mathcal{O}_k$ one trades $(21.3.2)_k$ by $(21.3.3)_{k+1}$ and therefore after an appropriate correction $(21.3.2)_k$ holds with arbitrarily large $k = M$.

Thus, correcting U_2:

$$U_2 \mapsto U_2 + \sum_{\substack{k+l+p+q\ge 2\\ k\ge 1}} \alpha_{klpq}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{1-k-l-p-q} \tag{21.3.4}$$

one one can achieve

$$-i\mu^{-1}\{U_2, U_2^\dagger\} \equiv 2 \qquad \mathsf{mod}\ O(\mu^{-M}) \tag{21.3.5}$$

with arbitrarily large M. Note that $\{U_2, Z_1\} \equiv \{U_2^\dagger, Z_1\} \equiv 0$ modulo $\mathcal{O}_1$ both originally and after correction (21.3.4). We claim that

Proposition 21.3.1. *Correcting*

$$Z_1 \mapsto Z_1 + \sum_{\substack{k+l+p+q\ge 2\\ k+l\ge 1}} \alpha'_{klpq}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{1-k-l-p-q}, \tag{21.3.6}$$

$$x_j \mapsto x_j + \sum_{k+l\ge 1} \alpha''_{jklpq}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{-k-l-p-q}, \tag{21.3.7}$$

one can arrange

$$\{U_2, x_j\} \equiv \{U_2, Z_1\} \equiv \{U_2, Z_1^\dagger\} \equiv 0, \tag{21.3.8}$$

$$\{U_2^\dagger, x_j\} \equiv \{U_2^\dagger, Z_1\} \equiv \{U_2^\dagger, Z_1^\dagger\} \equiv 0 \qquad \mathsf{mod}\ O(\mu^{-M}). \tag{21.3.9}$$

Proof. Indeed, correcting in the way described (but with the sum over $k \ge 1$ rather than $k + l \ge 1$) we can achieve (21.3.9). However, *so far corrected symbol x_j is not necessarily real-valued and corrected symbols Z_1 and $Z_1^\dagger$ are not necessarily complex conjugate*.

Then due to (21.3.9), (21.3.5) and Poisson identity $\{U_2^\dagger, \{U_2, y\}\} \equiv 0$ with $y = x_j, Z_1, Z_1^\dagger$. Therefore

$$\{U_2, Z_1\} \equiv \sum_{l+p+q\ge 1} \beta_{lpq}(x) U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{1-l-p-q},$$
$$\{U_2, Z_1^\dagger\} \equiv \sum_{l+p+q\ge 1} \beta'_{lpq}(x) U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{1-l-p-q},$$
$$\{U_2, x_j\} \equiv \sum_{l+p+q\ge 1} \beta''_{jlpq}(x) U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{-l-p-q}$$

where x, Z_1 and $Z_1^\dagger$ are already corrected symbols. Since at this moment x_j are not necessarily real-valued one needs to plug them formally into functions and use a Taylor decomposition with respect to $\mu^{-1}Z_1, \mu^{-1}Z_2, \mu^{-1}U_1, \mu^{-1}U_2$.

Then one can correct x_j, Z_1 and $Z_1^\dagger$ according to formulae (21.3.7), (21.3.8) with summation over $k = 0$ so that (21.3.8) holds.

Note that instead of Z_1 and $Z_1^\dagger$ one could consider $\mathsf{Re}\, Z_1$ and $\mathsf{Im}\, Z_1$ and correct them deriving (21.3.8)–(21.3.9). At this moment corrected symbols x_j, $\mathsf{Re}\, Z_1$ and $\mathsf{Im}\, Z_1$ are not necessarily real-valued. However, U_2 and $U_2^\dagger$ are truly complex conjugate and then (21.3.8)–(21.3.9) for corrected symbols x_j, $\mathsf{Re}\, Z_1$, $\mathsf{Im}\, Z_1$ imply the same equalities for the real parts of them. Let us replace then (corrected) symbols x_j, $\mathsf{Re}\, Z_1$ and $\mathsf{Im}\, Z_1$ by their real parts. After this (corrected) symbols x_j become real-valued and (corrected) symbols $Z_1 = \mathsf{Re}\, Z_1 + i\, \mathsf{Im}\, Z_1$ and $Z_1^\dagger = \mathsf{Re}\, Z_1 - i\, \mathsf{Im}\, Z_1$ become complex conjugate.□

Precanonical Form. II

One can rewrite operator in question in these new variables as

$$\begin{aligned}(21.3.10)\quad 2A \equiv f_2(x) U_2^\dagger U_2 + Z_1^\dagger Z_1 - V(x)& \\ + \sum_{k+l+p+q\ge 3} b_{klpq}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{2-k-l-p-q}& \\ + \sum_{k+l+p+q\ge 3} b'_{klpq}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{-k-l-p-q}&\end{aligned}$$

modulo lower order terms where the first line is the "main part" and the second and third lines are the "perturbation"; here the first part of the "perturbation" comes from $f_2 U_2^\dagger U_2 + Z_1^\dagger Z_1$ and the second part comes from $-V$.

Proposition 21.3.2. *For arbitrarily large M there exist $\epsilon = \epsilon(M) > 0$ and a real valued symbol*

$$\mathcal{L} = \sum_{k+l\ge 1} \ell_{kpqm}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{-1-k-l-p-q-m} \tag{21.3.11}$$

such that in the strip $\{|x_1| < \epsilon\}$ the following equality holds (so far only for the principal symbols of operators in question):

(21.3.12)
$$A^{\#} := e^{-i\mu^{-1}h^{-1}\mathcal{L}} A e^{i\mu^{-1}h^{-1}\mathcal{L}} \equiv \frac{1}{2}\Big(f_2(x^{\#}) U_2^{\#} U_2^{\#\dagger} + Z_1^{\#} Z_1^{\#\dagger} - V(x^{\#})\Big) + \sum_{2k+p+q+2m\ge 3} B_{kpqm}(x^{\#}) \big(U_2^{\#} U_2^{\#\dagger}\big)^k Z_1^{\#\, p} Z_1^{\#\dagger\, q} \mu^{2-2k-p-q-2m}$$

where $e^{-i\mu^{-1}h^{-1}\mathcal{L}}$, $e^{i\mu^{-1}h^{-1}\mathcal{L}}$ are (formal) $\mu^{-1}h$-FIOs and

$$x_j^{\#} = e^{-i\mu^{-1}h^{-1}\mathcal{L}} x_j e^{i\mu^{-1}h^{-1}\mathcal{L}}, \quad U_2^{\#} = e^{-i\mu^{-1}h^{-1}\mathcal{L}} U_2 e^{i\mu^{-1}h^{-1}\mathcal{L}}, \quad Z_1^{\#} = e^{-i\mu^{-1}h^{-1}\mathcal{L}} Z_1 e^{i\mu^{-1}h^{-1}\mathcal{L}} \tag{21.3.13}$$

are linked to the original symbols x_j, U_2, Z_1 by formulae similar to (21.3.4), (21.3.6) *and* (21.3.7) *but containing also factors μ^{-1} exactly on the same role as U_2 or $U_2^{\dagger}$ so that $k+l$ in the condition of summation is replaced by $k+l+m$* [11].

All equalities here hold modulo $O(\mu^{-M})$.

Proof. Proof is standard (see Chapter 19). The problem of the resonances is avoided because we remove only terms $b_*(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q}$ with $k \ne l$ which leads to the denominator $\mu\big((k-l)f_2 + (p-q)f_1\big)$ in the correction term; this denominator is of magnitude $\mu(k-l)$ since $k \ne l$, $f_2 \asymp 1$ and $f_1 \asymp |x_1| \le \epsilon(M)$. □

[11] More precisely,

$$U_2 \mapsto U_2^{\#} = U_2 + \sum_{k+l+p+q+m\ge 2} \alpha_{klpqm}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{1-k-l-p-q-m}, \tag{21.3.4}$$

$$Z_1 \mapsto Z_1^{\#} = Z_1 + \sum_{k+l+p+q+m\ge 2} \alpha'_{klpqm}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{1-k-l-p-q-m}, \tag{21.3.6}$$

$$x_j \mapsto x_j^{\#} = x_j + \sum_{k+l+p+q+m\ge 1} \alpha''_{jklpqm}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{-k-l-p-q-m}. \tag{21.3.7}$$

Now one can upgrade all the above arguments to operators so that equalities (21.3.5), (21.3.8) and (21.3.9) hold for commutators rather than for Poisson brackets and (21.3.12) is replaced by

$$(21.3.12)^* \quad A^{\#} := e^{-i\mu^{-1}h^{-1}\mathcal{L}} A e^{i\mu^{-1}h^{-1}\mathcal{L}} \equiv \frac{1}{2}\Big(f_2^{\mathsf{w}} U_2^* \bullet U_2 + Z_1^* \bullet Z_1 - V^{\mathsf{w}}\Big) + \sum_{2k+p+q+2m+2s\ge 3} B^{\mathsf{w}}_{kpqms} (U_2 \bullet U_2^*)^l Z_1^p Z_1^{*\,q} \mu^{2-2k-2m-p-q-s} h^s$$

where a^{w} is the Weyl quantization of symbol a and one should remember that the corrected symbol x is not just a function of coordinates but of the symbols and therefore the functions of x are replaced by the symbols of $\mu^{-1}h$-PDOs. Here and below $\bullet$ means the symmetrized product: $K \bullet L = \frac{1}{2}(KL + LK)$. Therefore, we arrive to

Proposition 21.3.3. *For arbitrarily large M and arbitrarily small $\delta > 0$ there exist $\epsilon = \epsilon(M, \delta) > 0$ and a real valued symbol*

$$(21.3.11)^* \quad \mathcal{L} = \sum_{k+l+p+q+m+2s\ge 1} \ell_{kpqms}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{-1-k-l-p-q-m-s} h^s$$

such that under assumption (21.3.1) *in the strip $\{|x_1| < \epsilon\}$ formula* $(21.3.12)^*$ *holds where $e^{-i\mu^{-1}h^{-1}\mathcal{L}}$, $e^{i\mu^{-1}h^{-1}\mathcal{L}}$ are $\mu^{-1}h$-FIOs and $x_j^{\#}, U_2^{\#}, Z_1^{\#}$ are full symbols still defined by* (21.3.13) *and they are linked to the original symbols x_j, Z_1, U_2 by formulae similar to* $(21.3.4)^*$,$(21.3.6)^*$,$(21.3.7)^*$ *but containing also factors $(\mu^{-1}h)$ of the "double value" of U_2 or $U_2^\dagger$ or μ^{-1} so that $k+l+m$ in the condition of summation is replaced by $k+l+m+2s$* [12)].

All equalities here and below hold modulo $O(h^M)$.

Precanonical Form. III

Note that due to (21.3.5) for $U_2^{\#}$ there exists $\mu^{-1}h$-FIO $\mathcal{F}$ such that

$$(21.3.14) \qquad \mathcal{F}^*\mathcal{F} \equiv \mathcal{F}\mathcal{F}^* \equiv I \qquad \text{and} \qquad \mathcal{F}^* U_2^{\#} \mathcal{F} \equiv (hD_2 - i\mu x_2).$$

[12)] More precisely

$$(21.3.4)^{**} \quad U_2 \mapsto U_2^{\#} = U_2 + \sum_{k+l+p+q+m+2s\ge 2} \alpha_{klpqms}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{1-k-l-p-q-m-s} h^s,$$

$$(21.3.6)^{**} \quad Z_1 \mapsto Z_1^{\#} = Z_1 + \sum_{k+l+p+q+m+2s\ge 2} \alpha'_{klpqmm}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{1-k-l-p-q-m-s} h^s,$$

$$(21.3.7)^{**} \quad x_j \mapsto x_j^{\#} = x_j + \sum_{k+l+m+2s\ge 1} \alpha''_{jklpqms}(x) U_2^k U_2^{\dagger\, l} Z_1^p Z_1^{\dagger\, q} \mu^{-k-l-p-q-m-s} h^s,$$

Then

$$\mathcal{F}^*(U_2^{\#} \bullet U_2^{\#\dagger})\mathcal{F} \equiv \bigl(h^2D_2^2 + \mu^2 x_2^2\bigr) \tag{21.3.15}$$

and also due to (21.3.8) and (21.3.9) $\mu^{-1}\mathcal{F}^* Z_1^{\#}\mathcal{F}$, $\mathcal{F}^* x_j^{\#}\mathcal{F}$ and $\mathcal{F}^* B_{kpqms}\mathcal{F}$ are $\mu^{-1}h$-PDOs with symbols depending only on x', ξ' ($x' = (x_1, x_3, x_4)$).

Let us redefine $Z_1^{\#} := \mu^{-1}\mathcal{F}^* Z_1^{\#}\mathcal{F}$, $B^{\mathsf{w}}_{kpqms} := \mathcal{F}^* B^{\mathsf{w}}_{kpqms}\mathcal{F}$ and $A^{\#} := \mathcal{F}^* A^{\#}\mathcal{F}$; then also automatically $Z_1^{\#\dagger} := \mu^{-1}\mathcal{F}^* Z_1^{\#\dagger}\mathcal{F}$ is an adjoint operator. Recall that f_2^{w} and B^{w}_{kpqms} are operators with the real-valued symbols and $A^{\#}$ is again defined by (21.3.12)*.

Now one can decompose u into series

$$u(x,y,t) = \sum_{n,n'\in\mathbb{Z}^+} \mu h^{-1} u_{nn'}(x',y',t)\,\Upsilon_n(x_2)\Upsilon_{n'}(y_2), \tag{21.3.16}$$

$$\Upsilon_n(x_2) := \upsilon_n\bigl(\mu^{1/2}h^{-1/2}x_2\bigr)$$

where υ_n are (real-valued and orthonormal) Hermite functions and then replace operator $\bigl(h^2D_2^2 + \mu^2 x_2^2\bigr)$ by $(2n+1)\mu h$, thus reducing operator $A^{\#}$ to the family of 3-dimensional $\mu^{-1}h$-PDOs

$$\mathcal{A}_n := \frac{1}{2}\Bigl(f_2^{\#}(2n+1)\mu h + (Z_1^{\#} \bullet Z_1^{\#\dagger}) - V^{\#}\Bigr) + \tag{21.3.17}$$

$$\sum_{2k+p+q+2m+2s\ge 1} B^{w}_{kpqms} \times \bigl((2n+1)\mu h\bigr)^k Z_1^{\# p} Z_1^{\#\dagger q} \mu^{2-2k-2m-p-q-s} h^s;$$

again the first line is the *main part* of operator and $f^{\#}$, $V^{\#}$ are transformed f_2 and V.

Remark 21.3.4. (i) In this and below formulae one actually needs to consider

$$n \le C_0/(\mu h) + C|\log h|. \tag{21.3.18}$$

Really, we are interested in the domain in the phase space where $\{a \le c\}$ or, equivalently, $\{|U_2| \le c, |Z_1| \le c\}$. Note that condition $\{|U_2| \le \varrho\}$ does not contradict to the logarithmic uncertainty principle as long as $\varrho^2 \ge C\mu h|\log h|$ and thus one can take an upper bound for a as $\varrho^2 = c + C\mu h|\log h|$ which implies (21.3.18). This estimate perfectly suits our purposes as long as

$$h^{-\delta} \le \mu \le \epsilon h^{-1}|\log h|^{-1}. \tag{21.3.19}$$

(ii) From the operator point of view which one needs to apply only as

$$\epsilon h^{-1}|\log h|^{-1} \le \mu \le \epsilon h^{-1} \tag{21.3.20}$$

in the final analysis we need to consider only $n \le C_0/(\mu h)$.

Remark 21.3.5. (i) Obviously $f_j^{\#}$, $V^{\#}$ and $\mu^{-1}Z_1^{\#}$ are $\mu^{-1}h$-PDOs with symbols $f_j \circ \Psi_2$, $V \circ \Psi_2$ and $\mu^{-1}Z_1 \circ \Psi_2$ respectively where $\Psi_2 : \mathbb{R}^6 \ni (x', \xi') \to x \in \mathbb{R}^4$ is some smooth map. Actually we are interested in the symbols of $f_2^{\#}$ and $V^{\#}$ only modulo symbols of $\mu^{-1}Z_1^{\#}$, $\mu^{-1}Z_1^{\#\dagger}$ and therefore actually we are interested only in the map $\Sigma \to \mathbb{R}^4$. However, at this moment we do not have a natural parametrization of Σ.

(ii) Note that $f_1^{\#}$ is not necessarily x_1 anymore. Still since $\nabla \operatorname{Re} Z_1$, $\nabla \operatorname{Im} Z_1$, $\nabla \operatorname{Re} Z_2$, $\nabla \operatorname{Im} Z_2$ and ∇f_1 were linearly independent[13] this linear independence statement is true for $\nabla \operatorname{Re} Z_1^{\#}$, $\nabla \operatorname{Im} Z_1^{\#}$ and $\nabla f_1^{\#}$ [14] as well. Therefore after $\mu^{-1}h$-FIO transformation (in $(x', \mu^{-1}hD')$) one can achieve $f_1^{\#} = x_1$.

So, we arrive to

Proposition 21.3.6. *Let condition* (21.3.1) *be fulfilled. Then by means of* $\mu^{-1}h$*-transform, decomposition* (21.3.16) *and one more* $\mu^{-1}h$*-transform one can reduce operator to the family of* 3*-dimensional operators* (21.3.17) *with* n *satisfying* (21.3.18) *and with*

$$i\mu^{-1}\{Z_1^{\#}, Z_1^{\#\dagger}\} = f_1^{\#} = x_1 \qquad \operatorname{mod}(Z_1, Z_1^{\dagger}). \tag{21.3.21}$$

21.3.2 Canonical Form away from Λ

Canonical Form away from Λ. I

Let us consider first the canonical form in the subdomain, disjoint from Λ which means that

$$|\{Z_1, f_1\}| \ge \epsilon_0. \tag{21.3.22}$$

Let us reduce (21.3.17) to a canonical form (multiplied by an elliptic operator). Note that the multiplication of $Z_1^{\#}$ by symbol β implies the multiplication of $Z_1^{\#\dagger}$ by $\beta^{\dagger}$ and therefore the multiplication of $f_1^{\#}$ by $|\beta|^2$

[13] All the linear independence statements are uniform.

[14] Where in the former case it was $\nabla_{x,\xi}$ and in the latter one $\nabla_{x',\xi'}$; recall that $x' = (x_1, x_3, x_4)$.

modulo $\mathcal{O}_1$ and finally the multiplication of $\{Z_1^\#, f_1^\#\}$ by $|\beta|^2\beta$ modulo $\tilde{\mathcal{O}}_1$ as well where here and below $\tilde{\mathcal{O}}_m$ means the sum of monoms of the type $\alpha_{ljk}\mu^{l-m}x_1^l Z_1^{\#\,j} Z_1^{\#\dagger\,k}$ with $m \ge j+k+l$ and smooth coefficients α_{ljk}. Also to maintain (21.3.12) and (21.3.17) one needs to multiply operators A and $\mathcal{A}_n$ (and thus $f_2^\#$, $V^\#$ and all the perturbation terms) by $|\beta|^2$.

Then picking up

$$\beta = \{Z_1^\#, f_1^\#\}^\dagger \cdot |\{Z_1^\#, f_1^\#\}|^{-4/3}$$

one can achieve

$$\{Z_1^\#, f_1^\#\} = 1 + \alpha \tag{21.3.23}$$

with $\alpha \in \tilde{\mathcal{O}}_m$ and $m = 1$. Consequently, multiplying $Z_1^\#$ by $(1+\beta)$ with $\alpha \in \tilde{\mathcal{O}}_m$ one changes $\{Z_1^\#, f_1^\#\}$ by $(2\beta+\beta^\dagger)\{Z_1^\#, f_1\}$ modulo $\tilde{\mathcal{O}}_{m+1}$ and picking $\beta = \frac{1}{3}\alpha^\dagger - \frac{2}{3}\alpha$ one can achieve (21.3.23) with $\alpha \in \tilde{\mathcal{O}}_M$ with arbitrarily large M (and after asymptotic summation with $M = \infty$). Unfortunately elements of $\tilde{\mathcal{O}}_M$ (in contrast to elements of $\mathcal{O}_M$) are not necessarily negligible unless $|x_1| \le h^\delta$.

However, one can observe easily that multiplying $Z_1^\#$ by $(1+\beta)$ with $\beta \in \mathcal{O}_m \cap \tilde{\mathcal{O}}_\infty$ we change $\{Z_1^\#, f_1^\#\}$ by $\{Z_1^\#, \phi\}$ with

$$\phi = f_1(\beta + \beta^\dagger) + i\mu^{-1}\{Z_1^\#, \beta^\dagger\} - i\mu^{-1}\{Z_1^{\#\dagger}, \beta\}$$

modulo $\mathcal{O}_m \cap \tilde{\mathcal{O}}_\infty$. Obviously there exists $\beta \in \mathcal{O}_1 \cap \tilde{\mathcal{O}}_\infty$ eliminating error α in (21.3.23) modulo $\mathcal{O}_1 \cap \tilde{\mathcal{O}}_\infty$. One can see easily that the only restriction to $\phi \in \mathcal{O}_{m-1} \cap \tilde{\mathcal{O}}_\infty$ is that it must be real valued.

Therefore step by step one can make $\mathsf{Re}\,\alpha \in \mathcal{O}_M \cap \tilde{\mathcal{O}}_\infty$: $\{\mathsf{Re}\, Z_1, f_1\} \equiv 1 \mod \mathcal{O}_M \cap \tilde{\mathcal{O}}_\infty$ with arbitrarily large M. But then picking up

$$f_1^\# = i\mu^{-1}\{Z_1^\#, Z_1^{\#\dagger}\} = 2\mu^{-1}\{\mathsf{Re}\, Z_1^\#, \mathsf{Im}\, Z_1^\#\}$$

we get

$$\big\{\mathsf{Re}\, Z_1^\#, \{\mathsf{Im}\, Z_1^\#, f_1\}\big\} = \big\{\mathsf{Im}\, Z_1^\#, \{\mathsf{Re}\, Z_1^\#, f_1\}\big\} \in \mathcal{O}_{M-1} \cap \tilde{\mathcal{O}}_\infty$$

and since $\{\mathsf{Im}\, Z_1^\#, f_1\} \in \mathcal{O}_{M-1}$ as $f_1 = 0$ and $\{\mathsf{Re}\, Z_1^\#, f_1^\#\} \sim 1$ we derive that $\{\mathsf{Im}\, Z_1^\#, f_1\} \in \mathcal{O}_{M-1} \cap \tilde{\mathcal{O}}_\infty$. Then

$$-i\mu^{-1}\{Z_1^\#, Z_1^{\#\dagger}\} = 2f_1^\#, \qquad \{Z_1^\#, f_1^\#\} \equiv 1 \mod O(\mu^{-M}) \tag{21.3.24}$$

and then after an appropriate $\mu^{-1}h$-FIO transformation

$$Z_1^{\#} \equiv hD_1 + i\bigl(hD_3 - \frac{1}{2}\mu x_1^2\bigr) \tag{21.3.25}$$

(again we are using a linear independence of $\nabla \operatorname{Re} Z_1^{\#}$, $\nabla \operatorname{Im} Z_1^{\#}$ and ∇f_1). However, one can replace operators $\beta(x', \mu^{-1}hD')$ by their decompositions into powers of $\mu^{-1}hD_1 = \frac{1}{2}(Z_1^{\#} + Z_1^{\#\dagger})$ and $\mu^{-1}hD_3 - \frac{1}{2}x_1^2 = \frac{1}{2i}\mu^{-1}(Z_1^{\#} - Z_1^{\#\dagger})$ thus arriving to decomposition (21.3.26) below with all the operators of the $\beta(x_1, x'', \mu^{-1}hD_4; \mu^{-1}h)$ and the following statement has been proven:

Proposition 21.3.7. *Let conditions* (21.3.1) *and* (21.3.22) *be fulfilled. Then by means of $\mu^{-1}h$-transform, decomposition* (21.3.16) *and one more $\mu^{-1}h$-transform one can reduce original operator A to the family of 3-dimensional operators*

$$\mathcal{A}_n = \frac{1}{2}\sigma\Bigl((Z_1^{\#} \bullet Z_1^{\#\dagger}) - W_n^{\#} + \sum_{2k+p+q+2m+2s\ge 3} B^{\mathsf{w}}_{kpqms} \times \bigl((2n+1)\mu h\bigr)^k Z_1^{\#\,p} Z_1^{\#\dagger\,q} \mu^{2-2k-2m-p-q-s} h^s\Bigr) \tag{21.3.26}$$

where symbol $\sigma = |\{Z_1, f_1\}|^{2/3}$ is bounded and disjoint from 0, $Z_1^{\#}$ given by (21.3.25) *and*

(21.3.27) $W_n^{\#}$ *is an operator with the symbol $\sigma^{-1}\bigl(V - f_2(2n+1)\mu h\bigr) \circ \Psi$ where Ψ is the smooth diffeomorphism $\mathbb{R}^4 \to \mathbb{R}^4$, with $D\Psi$ transforming $\operatorname{Span}\bigl((0,1,0;0),(0,0,0;1)\bigr)$ into $\mathbb{K}_2$ and $\operatorname{Span}\bigl((1,0,0,0),(0,0,1,0)\bigr)$ into $\mathbb{K}_1$, and, in particular, $(0,0,1;0)$ into some element of $\mathbb{K}_1$ of $(0,*,*,*)$ form. Further, $|\det D\Psi^{-1}| = f_2$.*

Again the first line in (21.3.26) *is the main part.*

Canonical Form away from Λ. II

Now let us consider domain where condition (21.3.22) is violated. Note first that $\bigl\{(x,\xi) : f_1 = Z_1 = \{Z_1, f_1\} = 0\bigr\}$ was an involutive manifold of codimension 5 in $\mathbb{R}^4 \times \mathbb{R}^4$ with

(21.3.28) ∇f_1, $\nabla \operatorname{Re} Z_1$, $\nabla \operatorname{Im} Z_1$, $\nabla\{\operatorname{Re} Z_1, f_1\}$ and $\nabla\{\operatorname{Im} Z_1, f_1\}$ linearly independent on Λ' [13)].

Also note that

$$\{Z_1, x_1\} = x_3 + ix_4, \quad \{Z_1, x_3\} = x_3 + ix_4, \quad \{Z_1, x_4\} = x_4 - ix_3 \qquad \text{as} \ \ x_1 = 0$$

and

$$\{\alpha^{\#}, \beta^{\#}\} = \{\alpha, \beta\} + i\mu^{-1} f_2^{-1}\Big(\{Z_2^{\dagger}, \alpha\}\{Z_2, \beta\} - \{Z_2, \alpha\}\{Z_2^{\dagger}, \beta\}\Big) + O(\mu^{-2}). \tag{21.3.29}$$

However, $\{Z_2, x_j\}$ are actually arbitrary and therefore while we know that

$$\Lambda^{\#} = \big\{f_1^{\#} = Z_1^{\#} = \{Z_1^{\#}, f_1^{\#}\} = 0\big\} \tag{21.3.30}$$

is a manifold of codimension 5 with

(21.3.31) $\nabla f_1^{\#}$, $\nabla \operatorname{Re} Z_1^{\#}$, $\nabla \operatorname{Im} Z_1^{\#}$, $\nabla\{\operatorname{Re} Z_1^{\#}, f_1\}$ and $\nabla\{\operatorname{Im} Z_1^{\#}, f_1^{\#}\}$ linearly independent on $\Lambda^{\#}$ [13),14)]

but its symplectic structure is not fixed and there is no canonical form uniformly near $\Lambda^{\#}$.

Instead let us consider point $\bar{z}$ ($= (0,0) \in \mathbb{R}^6$ for simplicity of notations) with

$$|f_1| \le \gamma = \epsilon r^2, \quad |\{Z_1, f_1\}| = r \qquad \text{with} \ \ r \ge \mu^{\delta - 1/3}, \tag{21.3.32}$$

and reduce an operator to a canonical form in its $\epsilon(\gamma, r)$-vicinity with respect to $(x_1; x_2, x_3, x_4)$, leaving domain $\{|f_1| \ge \epsilon |\{Z_1, f_1\}|^2\}$ for a later analysis.

Then after reduction of the previous subsection condition (21.3.32) remains valid for $Z_1^{\#}$ and $f_1^{\#}$; therefore now multiplication by a symbol $\beta = \{Z_1^{\#}, f_1^{\#}\}^{\dagger} \cdot |\{Z_1^{\#}, f_1^{\#}\}|^{-4/3} r^{1/3}$ provides a modified equality (21.3.23), namely,

$$\{Z_1^{\#}, f_1^{\#}\} = r + \alpha. \tag{21.3.33}$$

However, β is an uniformly smooth symbol; more precisely $\beta = \hat{\beta}(r^{-1}x', r^{-1}\xi')$ with uniformly smooth symbol $\hat{\beta}$, which means that after original rescaling $x' \mapsto rx'$ [15)] $\beta = \hat{\beta}(x, \mu^{-1} h r^{-2} D')$ and $x_1^{-1}\alpha$ is of the same type.

[15)] Since symplectic structure of $\Lambda^{\#}$ is not defined one cannot confine this non-smoothness to a couple of coordinates.

Continuing as before[16] one can achieve a modified equality (21.3.24), namely,

$$-i\mu^{-1}r^{-1}\{Z_1^{\#}, Z_1^{\#\dagger}\} = 2f_1^{\#}, \qquad \{Z_1^{\#}, f_1^{\#}\} \equiv r \mod O(\mu^{-s}) \tag{21.3.34}$$

where now $\mu^{-1}r^{-1}Z_1$ is $\mu^{-1}hr^{-2}$-PDO and then modified equality (21.3.25)

$$Z_1^{\#} \equiv \bigl(rh_*D_1 + h_*D_4\bigr) + i\bigl(h_*D_3 - \frac{1}{2}\mu r x_1^2\bigr) \tag{21.3.35}$$

where extra terms h_*D_4 and h_*D_3 appear because (original) $\nabla \operatorname{Re} Z_1$ and $\nabla \operatorname{Im} Z_1$ are linearly independent, $h_* = hr^{-1}$.

Then after another rescaling $x_1 \mapsto rx_1$, $D_1 \mapsto r^{-1}D_1$ (21.3.35) becomes

$$Z_1^{\#} \equiv \bigl(h_*D_1 + h_*D_4\bigr) + i\bigl(h_*D_3 - \frac{1}{2}\mu r^3 x_1^2\bigr)$$

and after transformation $(x_1, x_3, x_4; D_1, D_3, D_4) \mapsto (x_1, x_3, x_4{+}x_1; D_1{-}D_4, D_3, D_4)$ becomes

$$Z_1^{\#} = h_*D_1 + i\bigl(h_*D_3 - \frac{1}{2}\mu_* x_1^2\bigr), \qquad h_* = hr^{-1}, \quad \mu_* = \mu r^3 \tag{21.3.36}$$

which is exactly equality (21.3.25) with h and μ replaced by h_* and μ_* respectively.

Observe that operators $\beta(r^{-1}x', \mu^{-1}hr^{-1}D'; \mu^{-1}hr^{-2})$ (with the smooth symbol β) were transformed subsequently into $\beta(x', \mu^{-1}hr^{-1}D'; \mu^{-1}hr^{-2})$, then into $\beta(rx_1, x'', \mu^{-1}hr^{-3}D_1, \mu^{-1}hr^{-2}D''; \mu^{-1}hr^{-2})$ and finally into

$$\beta(rx_1, x'', \mu^{-1}hr^{-3}D_1, \mu^{-1}hr^{-2}D_3, \mu^{-1}hr^{-2}D_4; \mu^{-1}hr^{-3}).$$

Therefore we arrive to (21.3.17)-like decomposition with $Z_1^{\dagger}$ given by (21.3.36) and σ, W_n and B^{w}_{kpqms} of the above type. However, one can replace such operators by their decompositions into powers of $\mu^{-1}hr^{-3}D_1 = \frac{1}{2}\mu^{-1}r^{-2}(Z_1^{\#} + Z_1^{\#\dagger})$ and $\mu^{-1}hr^{-2}D_3 - \frac{1}{2}r^2x_1^2 = \frac{1}{2i}\mu^{-1}r^{-1}(Z_1^{\#} - Z_1^{\#\dagger})$ thus arriving to decomposition (21.3.38) below with all the operators of the simplified type

$$\beta(rx_1, x'', \mu^{-1}hr^{-2}D_4; \mu^{-1}hr^{-3}); \tag{21.3.37}$$

factors $\mu^{-1}hr^{-4}$ appear because one needs to commute $Z_1^{\#}, Z_1^{\#}$ between themselves and with operators of (21.3.37)-type.

So, we finally arrive to

[16] With effective semiclassical parameter $\mu^{-1}hr^{-2}$ rather than $\mu^{-1}h$.

Proposition 21.3.8. *Let conditions* (21.3.1) *and* (21.3.32) *be fulfilled. Then by means of* $\mu^{-1}h$*-FIO transform, decomposition* (21.3.14) *and the series of rescalings and* $\mu^{-1}hr^{-2}$*-FIO transform one can reduce described above original operator* A *to the family of* 3*-dimensional operators*

$$\mathcal{A}_n := \frac{1}{2}\sigma^{\#}\Big((Z_1^{\#}\bullet Z_1^{\#\dagger}) - W_n^{\#} + \sum_{2k+p+q+2m+2s\geq 3} B^{\mathrm{w}}_{kpqms}\times \big((2n+1)\mu h\big)^k Z_1^{\#\,p} Z_1^{\#\dagger\,q}\,\mu^{2-2k-2m-p-q-s}h^s r^{-2p-2q-4m-4s}\Big) \tag{21.3.38}$$

where $\sigma^{\#}$ *is transformed operator with symbol* $\sigma = |\{Z_1, f_1\}|^{2/3}r^{-2/3}$ *which is bounded and disjoint from* 0 *and* $Z_1^{\#}$ *given by* (21.3.35).

Again the first line in (21.3.38) *is the main part.*

Remark 21.3.9. (i) Here operators $\sigma^{\#}$, $W_n^{\#}$ and B^{w}_{kpqms} are of the (21.3.37)-type with uniformly smooth symbol β. Therefore these symbols are quantizable provided under assumption (21.3.32) for sure;

(ii) We leave for a Section 21.4 the the calculation of the symbol of W and the discussion of the corresponding diffeomorphism.

(iii) Reduction has been done in the colored zone on Figure 21.1.

Canonical Form away from Λ. III

Let us look what happens with the cut-off symbol ψ as a result of these transformations. After transformations of Subsubsections 21.3.1.1 and 21.3.1.2 after decomposition (21.3.16) it becomes a matrix operator

$$\sum_{k,l}\phi_{kl}(x', \mu^{-1}hD')\mu^{-k-l}U_2^k U_2^{\dagger l}$$

with basis-shifting (in $\mathscr{L}^2(\mathbb{R})$) operators $\big(2(n+1)\mu h\big)^{-1/2}U_2^{\dagger}$ and $\big(2n\mu h\big)^{-1/2}U_2$.

Then after transformations of Subsubsection 21.3.2.2 this matrix operator becomes

$$\sum_{k,l,p,q,m,s} \phi^{\mathrm{w}}_{klpqms} U_2^k U_2^{\dagger l} Z_1^{\#\,p} Z_1^{\#\dagger\,q}\,\mu^{-k-l-m-p-q-s}h^s r^{-2p-2q-2m-4s} \tag{21.3.39}$$

with the scalar main part of the form (21.3.37).

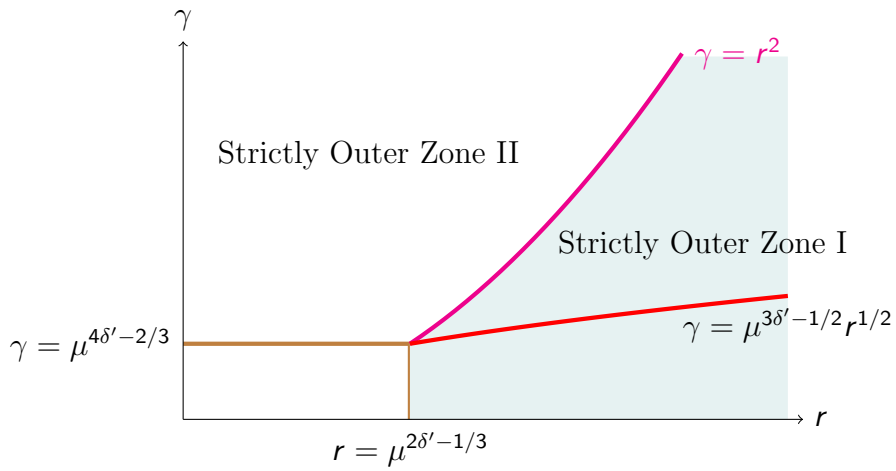

Figure 21.1: Reduction was done in the colored zone.

21.3.3 Canonical Form in the Strictly Outer Zone

Canonical Form in the Strictly Outer Zone. I

Now one can properly redefine the first part of the *outer zone*

$$\mathcal{Z}_{\mathsf{out},I} := \Big\{ C\mu^{-1/2}\mathsf{dist}(x,\Lambda)^{1/2} \le \mathsf{dist}(x,\Sigma) \le \epsilon\, \mathsf{dist}(x,\Lambda)^2 \Big\} \tag{21.3.40}$$

which in the notations $\mathsf{dist}(x,\Sigma) = |x_1|$ and $\mathsf{dist}(x,\Lambda) \asymp r$ is described as $\{\mu^{-1/2} r^{1/2} \le |x_1| \le \epsilon r^2\}$. Note that after rescaling of the previous section $x_1 \mapsto x_1 r^{-2}$, $\mu \mapsto \mu_* = \mu r^3$ it becomes $\{|x_1| \ge C\mu_*^{-1/2}\}$.

In this subsubsection we restrict ourselves to the part of *strictly outer zone*

$$\mathcal{Z}^*_{\mathsf{out},I} := \Big\{ C\mu^{3\delta-1/2}\mathsf{dist}(x,\Lambda)^{1/2} \le \mathsf{dist}(x,\Sigma) \le \epsilon\, \mathsf{dist}(x,\Lambda)^2 \Big\} \tag{21.3.41}$$

which in the same notations is $\{\mu^{-1/2} r^{1/2} \le |x_1| \le \epsilon r^2\}$ and after rescaling becomes $\{|x_1| \ge C\mu_*^{3\delta-1/2}\}$ (may be with a different $\delta > 0$) and provides a nice quantization of all symbols below.

Then since $\mu_* \ge h^{-\delta}$ one can apply the canonical form of the Schrödinger operator with the strong magnetic field. Let us consider an operator obtained after reduction of the previous subsection; there $|x_1| \asymp \gamma_* = \gamma r^{-2}$ if originally $|x_1| \asymp \gamma$. Notation $\gamma = r^2$ was temporary.

Applying rescaling $(x_1, x_3) \mapsto (x_1\gamma_*, x_3\gamma_*)$ one arrives to transformed (21.3.36) of the same type but with h_* and μ_* replaced by $h_*\gamma_*^{-1} = hr\gamma^{-1}$ and $\mu_*\gamma_*^2 = \mu\gamma^2 r^{-1}$ respectively:

$$Z_1^{\#} = \mu\gamma^2 r^{-1}\Big(\hbar D_1 + i\big(\hbar D_3 + \frac{1}{4}x_1^2\big)\Big) \tag{21.3.42}$$

with $|x_1| \asymp 1$ and

$$\hbar = \mu^{-1}hr^2\gamma^{-3} \le c\mu^{1/2}h^{1+3\delta}r^{1/2} \ll ch^{1/2}. \tag{21.3.43}$$

Also $\mu^{-1}hr^{-2}D_3 \mapsto \mu^{-1}h\gamma^{-1}D_3$.

Let us consider the part where $x_1 > 0$; another part is separated and treated exactly in the same manner. Introducing

$$U_1 = x_1^{-1/2}\Big(\hbar D_1 + i\big(\hbar D_3 + \frac{1}{4}x_1^2\big)\Big) \tag{21.3.44}$$

one can see easily that

$$|U_1| \le c\nu^{-1}, \qquad \nu := \mu\gamma^2 r^{-1} \ge h^{-\delta}, \tag{21.3.45}$$

$$\{U_1, U_1^\dagger\} \equiv 1 \qquad \mathsf{mod}\ U_1, U_1^\dagger \tag{21.3.46}$$

where (21.3.45) follows from $|Z_1^{\#}| \le c$ and (21.3.46) is understood in the sense of $\hbar$-symbols.

Therefore there exists $\hbar$-FIO transformation $\mathcal{F}'$ of $(x_1, x_3; \hbar D_1, \hbar D_3)$ thus not affecting $(x_4, \mu^{-1}hr^{-2}D_4)$ such that

$$U_1 \mapsto U_1^{\#} \equiv \hbar D_1 + ix_1 \qquad \mathsf{mod}\ \mathcal{O}_2(U_1, U_1^\dagger); \tag{21.3.47}$$

then operator (21.3.38) is transformed into

$$\begin{aligned}\frac{1}{2}\sigma\sigma_1\Big(&\nu^2 U_1^{\#} \bullet U_1^{\#\dagger} - W_n^{\#\#} + \\ &\sum_{2k+p+q+2m+2s+2l\ge 3} B^{\mathsf{w}}_{kpqmsl}\times \\ &\big((2n+1)\mu h\big)^k\big(\nu U_1^{\#}\big)^p\big(\nu U_1^{\#\dagger}\big)^q\mu^{2-2k-2m-p-q-s}h^s r^{-2p-2q-4m-4s}\hbar^l\Big)\end{aligned} \tag{21.3.48}$$

with $W_n^{\#\#}$ which is the transformation of $x_1^{-1}W_n^{\#}$.

Here all the operators σ, σ_1, $W_n^{\#\#}$ and B^{w}_{kpqmsl} are of the type

$$\beta(x_1, x_3, x_4; \hbar D_1, \hbar D_3, \mu^{-1}hr^{-2}D_4).$$

Note that $\hbar\nu = hr\gamma^{-1} \ll \mu^{1/2}hr^{1/2} \le h^{1/2}$ in the zone in question. One can decompose all such operators into power series with respect to x_1, $\hbar D_1$ and rewrite (21.3.48) with all operators of the type

$$\beta(x_3, x_4; \hbar D_3, \mu^{-1}hr^{-2}D_4), \qquad \hbar = \mu^{-1}hr^2\gamma^{-3} \tag{21.3.49}$$

and with $\bigl(\nu U_1^{\#}\bigr)^p$, $\bigl(\nu U_1^{\#\dagger}\bigr)^q$ replaced by $\bigl(\nu U_1^{\#}\bigr)^{p+p'}\nu^{-p'}$, $\bigl(\nu U_1^{\#\dagger}\bigr)^{q+q'}\nu^{-q'}$ respectively since $\nu \ge h^{-\delta}$.

Repeating arguments of the previous subsections one can transform this operator into

$$\begin{aligned}\frac{1}{2}\sigma\sigma_1\Bigl(&\nu^2 U_1^{\#}\bullet U_1^{\#\dagger} - W_n^{\#\#}+\\ &\sum_{2q+2l+2j\ge 3} B^{\mathrm{w}}_{qjl}\times \bigl(\nu^2 U_1^{\#}\bullet U_1^{\#\dagger}\bigr)^q \nu^{2-2q-2j}\hbar^l+\\ &\sum_{2k+2q+2m+2s+2l\ge 3} B^{\mathrm{w}}_{kqjmsl}\times\\ &\bigl((2n+1)\mu h\bigr)^k\bigl(\nu^2 U_1^{\#}\bullet U_1^{\#\dagger}\bigr)^q \mu^{2-2k-2m-2q-s}h^s r^{-4q-4m-4s}\nu^{-2j}\hbar^l\Bigr)\end{aligned} \tag{21.3.50}$$

where the second line comes from decomposing of $W_n^{\#\#}$ and because it is rescaled before

$$|B_{qjl}| \le C\gamma r^{-1}, \tag{21.3.51}$$

Now one can apply decomposition with respect to $\hbar^{-1/4}v_p(\hbar^{-1/2}x_1)$:

$$u_{nn'}(x', y', t) = \sum_{p,p'\in\mathbb{Z}^+} \hbar^{-1}u_{npn'p'}(x'', y'', t)\, v_p\bigl(\hbar^{-1/2}x_1\bigr)v_{p'}\bigl(\hbar^{-1/2}y_1\bigr) \tag{21.3.52}$$

with $x'' = (x_3, x_4)$. Then the operator (21.3.50) becomes

$$\begin{aligned}\frac{1}{2}\sigma\sigma_1\Bigl(&(2p+1)\mu h\gamma - W_n^{\#\#}+\\ &\sum_{2q+2l+2j\ge 3} B^{\mathrm{w}}_{qjl}\times \bigl((2p+1)\mu h\gamma\bigr)^q \nu^{2-2q-2j}\hbar^l+\\ &\sum_{2k+2q+2m+2s+2l\ge 3} B^{\mathrm{w}}_{kqjmsl}\times\\ &\bigl((2n+1)\mu h\bigr)^k\bigl((2p+1)\mu h\gamma\bigr)^q \mu^{2-2k-2m-2q-s}h^s r^{-4q-4m-4s}\nu^{-2j}\hbar^l\Bigr).\end{aligned} \tag{21.3.53}$$

since $\nu^2\hbar = \mu h\gamma$ and $2k+2q+2m+2s+2j+2l \ge 3$ is equivalent to $k+q+m+s+j+l \ge 2$.

In the decomposition (21.3.53) the role of m, s, j and l is just to bound a magnitude and indicate dependence on μ and h since dependence on r, γ (but not magnitude) is not important. However, $\nu = \mu\cdot\gamma^2 r^{-1} \le \mu r^2$, $\hbar = \mu^{-1}h\cdot r^2\gamma^{-3} \ge \mu^{-1}hr^{-4}$; therefore one can join terms with $s>0$ or $m>0$ to the terms with $s=0$ and $m=0$ without changing $s+l$, $m+j$ thus getting the simplified correction term

$$\sum_{k+q+j+l\ge 2} B^{\mathsf{w}}_{kqjmsl} \times \bigl((2n+1)\mu h\bigr)^k \bigl((2p+1)\mu h\gamma\bigr)^q \mu^{2-2k-2q} h^s r^{-4q}\nu^{-2j}\hbar^l.$$

Therefore we arrive to the following

Proposition 21.3.10. *Let condition* (21.3.1) *be fulfilled. Let us consider zone* $\mathcal{Z}^*_{\mathsf{out},l}$, *described by* (21.3.40).

Then by means of $\mu^{-1}hr^{-2}$*-FIO transforms, decomposition* (21.3.16), *the "special"* $\hbar$*-FIO transform and decomposition* (21.3.52) *one can reduce the original operator* A *to the family of* 2*-dimensional operators*

$$\mathcal{A}_{np} \coloneqq \frac{1}{2}\sigma\sigma_1\Bigl(H_{pn} + \sum_{k+q+j+l\ge 2} B^{\mathsf{w}}_{kqjmsl} \times \bigl((2n+1)\mu h\bigr)^k \bigl((2p+1)\mu h\gamma\bigr)^q \mu^{2-2k-2q} h^s r^{-4q}\nu^{-2j}\hbar^l\Bigr) \tag{21.3.54}$$

with $n \le C_0/(\mu h)$, $p \le C_0/(\mu h\gamma)$ *where all operators are of* (21.3.49)*-type and* σ, σ_1 *are bounded and disjoint from* 0.

Remark 21.3.11. (i) While in the canonical form (21.3.38) only one cyclotron movement was separated, in the canonical form (21.3.54) both of them are separated leaving only pure drift movement which will be studied in the next section.

(ii) We leave for the next Section 21.4 the discussion of the actual elements where reduction was done, corresponding diffeomorphism and the calculation of the symbol of W.

(iii) Cut-off symbol ψ which after previous transformations became (21.3.39) now becomes

$$\sum_{k,i,p,q,s,l} \phi_{kipqsl}\times U_2^{i}U_2^{\dagger\,k}U_1^{\#\,p}U_1^{\#\dagger\,q}\mu^{-i-k-2m-p-q-s}h^{s}r^{-2p-2q-4m-4s}\nu^{-2j-i-k}\hbar^{l} \tag{21.3.55}$$

with (21.3.49)-type operators ϕ_{kipqsl}.

Canonical Form in the Strictly Outer Zone. II

Now our goal is to achieve a similar reduction in the second part of the *outer zone*

$$\mathcal{Z}^{*}_{\mathsf{out},II} = \Big\{ C\,\mathsf{max}\big(\mathsf{dist}(x,\Lambda)^2, \mu^{4\delta-2/3}\big) \le \mathsf{dist}(x,\Sigma) \le \epsilon\Big\}. \tag{21.3.56}$$

Then the previous subsection 21.3.2 becomes irrelevant; however, we can start from (21.3.17). Again without any loss of the generality one can assume that $f_1^{\#} = x_1$. Let us consider a point $\bar{z} = (\bar{x}', \bar{\xi}') \in \mathbb{R}^6$ and an element (21.3.55) with $\gamma = |\bar{x}_1'|$ and $r = \gamma^{1/2}$ (exactly as in the previous subsection it was defined the other way. Without any loss of the generality one can assume that $\bar{z} = (\gamma, 0, \dots, 0)$.

Consider Taylor decomposition (with a remainder) of $\mu^{-1}Z_1^{\#}$ with respect to x', $\mu^{-1}hD'$ and r (in r-vicinity of 0 all of them are $O(r)$); then due to $\{Z_1^{\#}, Z_1^{\#\dagger}\} = O(r)$, $\{Z_1, x_1\} = O(r)$ and without any loss of the generality one can assume that $\mu^{-1}Z_1^{\#} = \mu^{-1}hD_3 + i\mu^{-1}hD_4 + O(r^2)$. Note that $\mu^{-1}hD_1$ could be either with a square (or some higher degree), or with a linear, or with a quadratic factor with respect to other variables.

Also note that the quadratic terms in $O(r^2)$ containing exclusively x_3, x_4 must commute with $D_3 + iD_4$ (otherwise $\{Z_1^{\#}, Z_1^{\#\dagger}\} \sim 2x_1$ would not be possible) and therefore must be of the form $c(x_3 + ix_4)^2$. However, one could remove such terms by $\mu^{-1}h$-PDO affecting only $x'', \mu^{-1}hD''$ and leaving x_1, $\mu^{-1}hD_1$ intact. So, terms in the decomposition must contain either one of the factors x_1, $\mu^{-1}hD_3$, $\mu^{-1}hD_4$, or two factors $\mu^{-1}hD_1$, or three factors x_3, x_4; also x_1 must be accompanied by $O(r)$-type factor.

Then scaling $x'' \mapsto rx'$, $x_1 \mapsto r^2x_1$, $D'' \mapsto r^{-1}D''$, $D_1 \mapsto r^{-2}D_1$ and dividing by r^3 one gets completely legitimate $\mu^{-1}hr^{-4}$-PDO where each factor $\mu^{-1}hD''$ can accommodate division by r^3 and $\mu^{-1}hD_1$ can accommodate division by r^2 but there either at least two such factors, or there is an extra $O(r)$ type factor. This operator, with the semiclassical parameter $\hbar = \mu^{-1}h\gamma^{-2}$ satisfies again $\{Z_1^{\#}, Z_1^{\#\dagger}\} \sim 2x_1$ but must be considered

near point $(1,0,\dots,0)$ and then by the standard arguments one can reduce operator to the canonical form (21.3.54) with all the operators of the type

$$\beta(x_3,x_4;\hbar D_3,\hbar D_4),\qquad \hbar=\mu^{-1}h\gamma^{-2}. \tag{21.3.57}$$

Note that as $r=\gamma^{1/2}$ this is consistent with the definition of $\hbar$ in the zone $\mathcal{Z}_{\mathsf{out},I}$ but form (21.3.57) is more general then (21.3.49).

So, we arrive to

Proposition 21.3.12. *Let condition* (21.3.1) *be fulfilled. Then one can reduce the original operator* A *to the family* (21.3.54) *of* 2*-dimensional operators with* $n\le C_0/(\mu h)$, $p\le C_0/(\mu h\gamma)$ *where all operators are of* (21.3.49)*-type and* σ, σ_1 *are bounded and disjoint from* 0.

Remark 21.3.13. All Statements (i)–(iii) of Remark 21.3.11 remain valid.

Canonical Form in the Strictly Outer Zone. III

We would like to finish this section by the following

Remark 21.3.14. In 2D-case canonical form was derived in Chapter 14

$$\mathcal{A}_p=\sigma\sigma_1\Bigl((2p+1)\mu h\gamma-W^{\#\#}+\sum_{2l+2j+2t\ge 3} B^{\mathsf{w}}_{ljt}\times\bigl((2p+1)\mu h\gamma\bigr)^l\times\mu^{2-2l-2j-t}h^t\gamma^{-4j-3t}\Bigr) \tag{21.3.58}$$

with

$$W^{\#\#}_n=\beta(\gamma^{-1}x_3,\mu^{-1}h\gamma^{-2}D_3). \tag{21.3.59}$$

There instead of 2-parameter family of 2-dimensional PDOs we had only 1-parametric family of 1-dimensional PDOs.

21.4 Remainder Estimates

In this section we derive remainder estimates with the main part in the standard but rather implicit form which is the sum of the Tauberian expressions (21.1.2)

$$h^{-1}\sum_{\iota}\int_{-\infty}^{0}\Bigl(F_{t\to h^{-1}\tau}\bar{\chi}_{T_\iota}(t)\Gamma u Q^t_{\iota y}\Bigr)\,d\tau \tag{21.4.1}$$

with Q_ι partition of unity and an appropriate T_ι where as in previous Chapters $\bar{\chi}_T(t) = \bar{\chi}(t/T)$ and $\bar{\chi}$ is supported in $[-1,1]$ and equal 1 at $[-\frac{1}{2},\frac{1}{2}]$, while the remainder estimate could depend on non-degeneracy condition.

We are going to consider different zones and apply different approaches and use different canonical forms in each of them; let us start from the strictly outer zone.

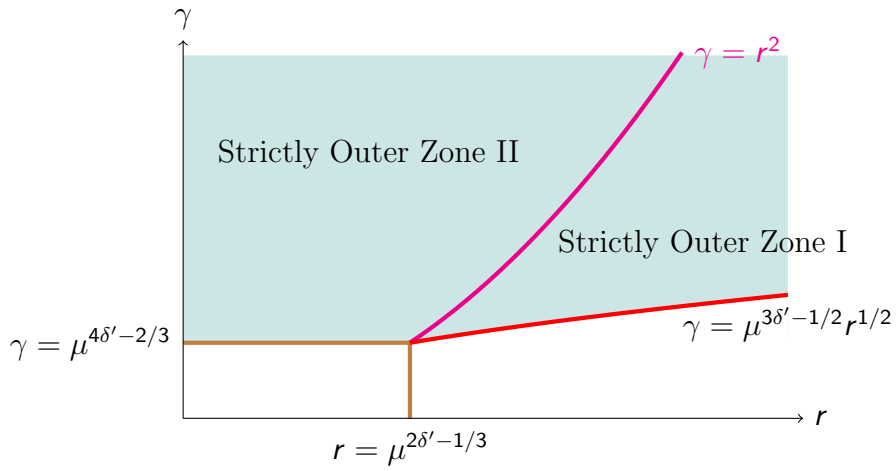

Figure 21.2: Our first target is strictly outer zone.

21.4.1 Estimates in the Strictly Outer Zone

Let us start from the most massive *Strictly Outer Zone I* $\mathcal{Z}^*_{\mathsf{out},I}$ described in (21.3.40) with an arbitrarily small exponent $\delta_0 > 0$ and sufficiently small constant $\epsilon > 0$.

Estimates in the Strictly Outer Zone. I

After rescalings and transformations described in the previous section the original operator *somewhere* there was reduced to the family of two-dimensional $(\hbar_3,\hbar_4)$-PDOs $\mathcal{A}_{pn}(x'',\hbar_3 D_3,\hbar_4 D_4)$ defined by (21.3.54) with

$$\hbar_3 = \mu^{-1} h r^2 \gamma^{-3} \ll \mu^{1/2} h, \qquad \hbar_4 = \mu^{-1} h r^{-2} \ll \mu^{-1/3} h; \tag{21.4.2}$$

one needs to consider only magnetic numbers

$$n \le C_0 (\mu h)^{-1}, \qquad p \le C_0 (\mu h \gamma)^{-1} \qquad \text{as } \mathsf{dist}(x,\Sigma) \asymp \gamma; \tag{21.4.3}$$

these two restrictions mean that energy levels do not exceed ϵ.

These final operators are defined in $B(0,1)$. Therefore

(21.4.4) A contribution of each (pair,element)[17] to to the asymptotics is $O\big(\hbar_3^{-1}\hbar_4^{-1}\big) = O\big(\mu^2 h^{-2}\gamma^3\big)$ [18].

However, one can see easily that this element before the final reduction was the "slab" $B(0,1)\cap\{|x_1-\bar{x}_1|+|x_3-\bar{x}_3|\le \epsilon\gamma_*\}$ with $\gamma_* = \gamma r^{-2}$, $|\bar{x}_1|\asymp \gamma_*$ where here $B(0,1)$ is an image of the original element $B(y',r)\cap \mathcal{Z}_{\mathsf{out},I}$. Therefore the total contribution of the given pair (p,n) over subzone

$$\mathcal{Z}_{(r,\gamma)} = \big\{\gamma \le \mathsf{dist}(x,\Sigma)\le 2\gamma,\ r\le \mathsf{dist}(x,\Lambda)\le 2r\big\}$$

with $r\ge \epsilon\gamma^{1/2}$ to the asymptotics is $O\big(\mu^2h^{-2}\gamma^3\times r^2\gamma^{-1}\big) = O\big(\mu^2h^{-2}\gamma^2r^2\big)$ and the total contribution of this subzone $\mathcal{Z}_{(r,\gamma)}$ to the asymptotics is $O\big(\mu^2h^{-2}\gamma^2r^2\times(\mu h\gamma)^{-1}\times(\mu h)^{-1}\big) = O\big(h^{-4}\gamma r^2\big)$ where the second and the third factors are numbers of permitted indices p and n respectively.

Then

(21.4.5) the total contribution of zone $\mathcal{Z}^*_{\mathsf{out},I}$ to asymptotics is $O(h^{-4})$ [19].

The same approach works in $\mathcal{Z}^*_{\mathsf{out},II}$: here one has the family of two-dimensional $\hbar_3$-PDO $\mathcal{A}_{pn}(x'',\hbar_3D_3,\hbar_3D_4)$ with $\hbar_3 = \mu^{-1}h\gamma^{-2}$. Therefore a contribution of each (pair,element) to to the asymptotics is $O(\hbar_3^{-2}) = O(\mu^2h^{-2}\gamma^4)$. However, there was nondiscriminatory rescaling $(x_3,x_4,\xi_3,\xi_4)\mapsto (r^{-1}x_3,r^{-1}x_4,r^{-1}\xi_3,r^{-1}\xi_4)$ while the number of such balls should be $O(r^{-2})$ since $\mathsf{codim}_\Sigma\Lambda = 2$.

Therefore the total contribution of the given pair (p,n) over subzone

$$\bar{\mathcal{Z}}_{(r,\gamma)} = \big\{\gamma \le \mathsf{dist}(x,\Sigma)\le 2\gamma,\ \mathsf{dist}(x,\Lambda)\le 2r\big\}$$

with $r=\gamma^{1/2}$ to the asymptotics is $O(\mu^2h^{-2}\gamma^3)$, the total contribution of subzone $\bar{\mathcal{Z}}_{(r,\gamma)}$ to the asymptotics is $O(h^{-4}\gamma^2)$ and

(21.4.6) The total contribution of zone $\mathcal{Z}^*_{\mathsf{out},II}$ to asymptotics is $O(h^{-4})$.

Now we need to analyze the contribution of such elements to the remainder estimate.

---

[17] Where here and below a pair is (p,n) and an element means the final element $B(0,1)$.

[18] And for many pairs it is actually of this magnitude.

[19] And is actually of this magnitude under assumption (21.2.92) as $\mu\le\epsilon h^{-1}$. These results are consistent with what one can get without reduction.

Estimates in the Strictly Outer Zone. II

Let us consider some index pair (p,n) and some final $B(0,1)$ element. Assume first that after all these transformations operator $\mathcal{A}_{pn}$ is *regular* on this (pair,element) in the sense of (21.4.7), (21.4.8) and (21.4.10) below

$$\eta_\alpha |\nabla^\alpha_{x'',\xi''} \mathcal{A}_{pn}| \le c_\alpha \ell \qquad \forall \alpha : 0 < |\alpha| \le K, \tag{21.4.7}$$

with $\eta_\alpha = 1$ as $\alpha = (*,0,*,0)$ and $\eta_\alpha = \gamma r^{-2}$ otherwise and ℓ satisfying

$$\ell \ge h^{-K_0}. \tag{21.4.8}$$

Then the propagation speed with respect to $(x_3, \hbar_3 D_3)$ is $O(\ell\hbar_3/h) = O(\ell\mu^{-1}r^2\gamma^{-3})$ and the propagation speed with respect to $(x_4, \hbar_4 D_4)$ is $O(\ell\hbar_4/h \times r^2/\gamma) = O(\ell\hbar_3/h)$ as well. Therefore the dynamics starting in $B(0,\frac12)$ is retained in $B(0,1)$ as $|t| \le T_1$ with

$$T_1 = \epsilon h \ell^{-1}\hbar_3^{-1} \asymp \mu\gamma^3 r^{-2}\ell^{-1}. \tag{21.4.9}$$

Recall that $\hbar_3 \gg \hbar_4$. In the same time under respective assumptions

$$|\nabla_{x_3,\xi_3}\mathcal{A}_{pn}| + \zeta |\nabla_{x_4,\xi_4}\mathcal{A}_{pn}| \asymp \ell, \quad \zeta = \gamma r^{-2} \tag{21.4.10}$$

one can pick up T_0 from the uncertainty principle[20] $\ell\hbar_j h^{-1} T_0 \ge \hbar_j h^{-\delta'}$ [21] or equivalently

$$T_0 = C h^{1-\delta'}\ell^{-1}. \tag{21.4.11}$$

with an arbitrarily small exponent $\delta' > 0$.

Then the contribution of this (pair,element) to the remainder does not exceed

$$C\hbar_3^{-1}\hbar_4^{-1} \times T_0 T_1^{-1} \asymp \hbar_4^{-1} h^{-\delta'} = \mu h^{-1-\delta'} r^2 \tag{21.4.12}$$

where $C\hbar_3^{-1}\hbar_4^{-1} \times T_0$ estimates $\sup_{|\tau|\le\epsilon} |F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma\big(u\psi\big)|$ and factor T_1^{-1} is due to the standard Tauberian approach.

Therefore in comparison with the estimate of the contribution to the asymptotics (21.4.4) the estimate of the contribution to the remainder picked

[20] We do not need the logarithmic uncertainty principle in this place and use the simpler version of the microlocal uncertainty principle.

[21] Alternatively one could scale $x_4 \mapsto (\hbar_4/\hbar_3)^{1/2}x_4$, $\xi_4 \mapsto (\hbar_4/\hbar_3)^{1/2}\xi_1$, $\hbar_4 \mapsto \hbar_3$.

an extra factor $\hbar_3 h^{-\delta'}$ with an arbitrarily small exponent $\delta' > 0$; actually one can reduce δ' to 0 but it is not needed here.

Let us pick up $(p,\mathsf{element})$, then break this element into ζ-subelements with respect to (x_4, ξ_4); then on each such subelement operator $\mathcal{A}_{pn}$ is elliptic[22] $|\mathcal{A}_{pn}| \ge \epsilon\ell$ for all indices n but $C\big(\ell/(\mu h)+1\big)$ of them. Therefore the total contribution to the remainder the pair $(p,\mathsf{element})$ combination such that conditions (21.4.7), (21.4.8) and (21.4.10) are fulfilled with $\ell \le \bar\ell$ does not exceed

$$C\mu h^{-1-\delta'} r^2 \times \big(\bar\ell(\mu h)^{-1}+1\big) = C\big(\bar\ell + \mu h\big) h^{-2-\delta'} r^2. \tag{21.4.13}$$

Then summation over $\mathcal{Z}_{(r,\gamma)}$ results in

$$Ch^{-4}\gamma r^2 \times \mu^{-1} h r^2 \gamma^{-3} \times h^{-\delta'}(\bar\ell + \mu h) = C\big(\bar\ell + \mu h\big)\mu^{-1} h^{-3-\delta'} r^4 \gamma^{-2} \tag{21.4.14}$$

and therefore

(21.4.15) The total contribution to the remainder of all $(\mathsf{pair},\mathsf{element})$ combinations residing in $\mathcal{Z}_{(r,\gamma)} \subset \mathcal{Z}^*_{\mathsf{out},I}$ and satisfying conditions (21.4.7), (21.4.8) and (21.4.10) with $\ell \le \bar\ell$ does not exceed (21.4.14).

It implies

(21.4.16) The total contribution to the remainder of all $(\mathsf{pair},\mathsf{element})$ combinations residing in the *far outer zone*

$$\mathcal{Z}^*_{\mathsf{out},I} \cap \big\{\mathsf{dist}(x,\Sigma) \ge \mu^{-1/4} h^{-\delta'} \mathsf{dist}(x,\Lambda)^2\big\}$$

and satisfying conditions (21.4.7), (21.4.8) and (21.4.10) does not exceed $C\mu^{-1/2}h^{-3}$.

The same arguments work for $\bar{\mathcal{Z}}_{(r,\gamma)}$ with $r = \gamma^{1/2}$ resulting in the estimate $C\mu^{-1}h^{-3-\delta'}$ of its contribution to the remainder; summation over $\mathcal{Z}^*_{\mathsf{out},II}$ results in expression $o(\mu^{-1/2}h^{-3})$. Therefore

[22] See next Subsubsection 21.4.1.3 for justification; to prove (21.4.16) and (21.4.17) which are main results of this subsubsection one does not need these arguments.

(21.4.17) The total contribution to the remainder of all (pair,element) combinations residing in $\mathcal{Z}^*_{\mathsf{out},II}$ and satisfying conditions (21.4.7), (21.4.8) and (21.4.10) with $\zeta = 1$ [23)] does not exceed $C\mu^{-1/2}h^{-3}$.

We consider the exceptional regular elements (i.e. not covered by (21.4.16)) in the next subsubsection. The rest of the analysis of this subsection is devoted to detecting and analysis of the irregular elements.

Estimates in the Strictly Outer Zone. III

Note that

$$H_{pn} = \Big(\phi_1^{-1}\big(V - (2n+1)\mu h f_2 - (2p+1)\mu h f_1\big)\Big) \circ \Psi \tag{21.4.18}$$

with uniformly smooth map Ψ which does not depend on V; this exonerates elliptic arguments of the previous Subsubsection and in particular (21.4.15) since perturbation part satisfies $|\partial_n \mathcal{B}_{pn}| \ll \mu h$; one can consider n and p as continuous parameters.

Proposition 21.4.1. *(i) After reduction in $\mathcal{Z}^*_{\mathsf{out},I}$ symbols $W \circ \Psi$, $f_1 \circ \Psi$, $f_2 \circ \Psi$ satisfy conditions* (21.4.7) *and* (21.4.8) *with $\ell = \gamma r^{-1}$ and indicated above η_α and ζ. Furthermore,*

$$|\nabla_{x_3,\xi_3} f_1 \circ \Psi| \asymp \gamma. \tag{21.4.19}$$

(ii) After reduction in $\mathcal{Z}^*_{\mathsf{out},II}$ symbols $W \circ \Psi$, $f_1 \circ \Psi$, $f_2 \circ \Psi$ satisfy conditions (21.4.7) *and* (21.4.8) *with $\ell = \gamma r^{-1}$; furthermore*

$$|\nabla_{x'',\xi''} f_1 \circ \Psi| \asymp \gamma. \tag{21.4.20}$$

Proof. Proof follows easily from the reductions and is left to the reader. More precise results will be needed and proven later. □

Therefore

(21.4.21) As $p \ge C_0/(\mu h r)$ symbols H_{pq} satisfy conditions (21.4.7), (21.4.8) and (21.4.10 with $\ell = \mu h \gamma p \ge C_0 \gamma / r$.

[23)] One should pick up here $\zeta_1 = 1$ because $\hbar_3 = \hbar_4$.

On the other hand, one can prove easily from the reduction that

(21.4.22) Perturbation symbols $\mathcal{B}_{pn}$ satisfy conditions (21.4.7) and (21.4.8) with ℓ replaced by $\ell' = h^2\gamma^{-2}r^2(p+1)^2 + \mu^{-1}h\gamma^{-3}r^2 \ll \mu h\gamma(p+1)$.

Note that if we restrict ourselves only by $p \le C_0/(\mu hr)$ (condition to be explained later) instead of $p \le C_0/(\mu h\gamma)$, transition from (21.4.13) to (21.4.14) picks up an extra factor γ/r and therefore

(21.4.23) The total contribution to the remainder of all (pair,element) combinations with $p \le C_0/(\mu hr)$, residing in $\mathcal{Z}^*_{\mathsf{out},I}$ and satisfying conditions (21.4.7), (21.4.8) and (21.4.10) does not exceed $C\mu^{-1/2}h^{-3}$.

Now we want to cover indices $p \ge C_0/(\mu hr)$ and elements in $\mathcal{Z}^*_{\mathsf{out},I}$ which are not in the far outer zone and prove that their total contribution to the remainder also does not exceed $C\mu^{-1/2}h^{-3}$. To achieve this we plan to gain a factor γr^{-2} in the estimates of the previous Subsubsection 21.4.1.2, starting from (21.4.12), by increasing T_1 given by (21.4.9) to

$$T_2 = \epsilon r\mu_*\gamma_*^2 = \epsilon\mu\gamma^2. \tag{21.4.24}$$

Note that (21.4.9) appeared because it is a time for which propagation is confined to $B(0,1)$ in the final reduction, for larger t shift with respect to (x_3,ξ_3) would be too large while shift with respect to (x_4,ξ_4) would be still less than ϵ as $|t| \le T_2$.

However, considering propagation after intermediate reduction (i.e. reduction of Subsection 21.3.2) the shift with respect to x_3 would be of magnitude $\mu_*^{-1}\gamma_*^{-2}(\mu h\gamma p)|t|$ which would be observable but less than 1 as $T_1 \le |t| \le T_2$; this propagation just moves to the adjacent "slabs" in the intermediate element $B(0,1)$ corresponding to the different final elements.

Then the contribution of such (pair,element) to the remainder is estimated by a modified expression (21.4.12)

$$C\hbar_3^{-1}\hbar_4^{-1} \times T_0\,T_2^{-1} \asymp \mu h^{-1-\delta'}\gamma\ell^{-1} \asymp \mu h^{-1-\delta'}\gamma, (\mu h\gamma p)^{-1} \tag{21.4.25}$$

which leads to the modified expression (21.4.14)

$$\mu h^{-1-\delta'}\gamma r^{-2} \times (\mu h)^{-1} \times (\mu h\gamma)^{-1}|\log h| \times r^2\gamma^{-1} \tag{21.4.26}$$

where the second, the third and the fourth factors estimate respectively the number of indices n, the sum of $(\mu h\gamma p)^{-1}$ with respect to p and the number of the final elements with given (r,γ).

Then the sum with respect to γ could be estimated by by the same expression with $\gamma = \mu^{-1/2-\delta} r^{1/2}$, which is $C\mu^{-1/2-\delta} h^{-3-\delta'} r^{3/2} |\log h|$; finally summation with respect to r results in $O(\mu^{-1/2} h^{-3})$ as $\delta' > 0$ is small enough.

Therefore we arrive to

(21.4.27) The total contribution to the remainder of all (pair,element) combinations with $p \ge C_0/(\mu hr)$, residing in $\mathcal{Z}^*_{\mathsf{out},I}$ does not exceed $C\mu^{-1/2} h^{-3}$

which together with (21.4.23 concludes the analysis of regular elements; their total contribution to the remainder is $O(\mu^{-1/2} h^{-3})$.

Estimates in the Strictly Outer Zone. IV

Therefore in what follows we are interested only in non-regular elements, with $p \le C_0/(\mu hr)$; then H_{pn} with n violating ellipticity condition satisfies (21.4.7) and (21.4.8) with $\ell = \gamma r^{-1}$ in $\mathcal{Z}^*_{\mathsf{out},I}$ and with $\ell = \gamma r^{-1}$, $\eta_\alpha = (1,1,1,1)$ in $\mathcal{Z}^*_{\mathsf{out},II}$.

First, consider elements in $\mathcal{Z}^*_{\mathsf{out},I}$ with fixed $p \le C_0/(\mu hr)$ and n. After rescaling

$$x_4 \mapsto \gamma r^{-2} x_4, \quad \xi_4 \mapsto \gamma r^{-2} \xi_4 \quad \hbar_4 \mapsto \hbar'_4 := \mu^{-1} h \gamma^{-2} r^2 \tag{21.4.28}$$

symbol $\gamma^{-1} r H_{pn}$ becomes uniformly smooth and therefore one can introduce a scaling function

$$\ell = \ell_{pn}(x'', \xi'') = \epsilon r \gamma^{-1} |\nabla_{x'',\xi''} \mathcal{A}_{pn}| + \bar{\ell}_0, \qquad \bar{\ell}_0 = C\hbar_3^{1/2} h^{-\delta''}; \tag{21.4.29}$$

obviously, $|\nabla \ell| \le \frac{1}{2}$. Let us introduce ℓ-admissible partition of $B(0,1)$. Then the symbols are still quantizable after rescaling $(x'', \xi'') \mapsto \ell^{-1}(x'', \xi'')$, $\hbar_3 \mapsto \ell^{-2}\hbar_3$, $\hbar'_4 \mapsto \ell^{-2}\hbar'_4$.

Further, as $\ell \ge 2\bar{\ell}_0$, the propagation speed does not exceed

$$v \asymp \mu^{-1}\gamma^{-3} r^2 |\nabla \mathcal{A}_{pn}| \asymp \mu^{-1} r \gamma^{-2} \ell \tag{21.4.30}$$

in the corresponding partition subelement[24)] (in the coordinates before rescaling of the subelements) and therefore the dynamics started in $B(z, \ell(z))$ remains in $B(z, 2\ell(z))$ as $|t| \le T_1$ with

$$T_1 = \epsilon \ell v^{-1} = \epsilon \mu r^{-1} \gamma^2. \tag{21.4.31}$$

[24)] We call this partition elements "subelements" because actually $B(0,1)$ itself is a rescaled partition element by itself.

On the other hand, the shift $v|t|$ is observable as $|t| \ge T_0$ with T_0 defined from the uncertainty principle

$$vT_0 \times \ell \ge \hbar_3 h^{-\delta'}. \tag{21.4.32}$$

Indeed, if $|\nabla_{x_3,\xi_3}\mathcal{A}_{pn}| \asymp \ell\gamma$ then the propagation speed with respect to (x_3,ξ_3) is exactly of magnitude v and the uncertainty principle is due to (21.4.32). Otherwise $|\nabla_{x_4,\xi_4}\mathcal{A}_{pn}| \asymp \ell\gamma$ and the propagation speed with respect to (x_4,ξ_4) is exactly of magnitude $v\gamma$ and the uncertainty principle is $\gamma vT_0 \times \ell \ge \hbar_2 h^{-\delta'} r^{-1}$ which is due to (21.4.32) as well.

Thus one can pick up

$$T_0 = \hbar_3 h^{-\delta'} v^{-1}\ell^{-1} \asymp h^{1-\delta'}\gamma^{-1} r\ell^{-2}. \tag{21.4.33}$$

Therefore the contribution of this partition subelement to the remainder does not exceed

$$C\hbar_3^{-1}\hbar_4'^{-1}\ell^4 \times T_0\, T_1^{-1} = C\mu h^{-1-\delta'}\gamma^2 r^{-2}\ell^2 \tag{21.4.34}$$

while in comparison its contribution to the main part of asymptotics does not exceed $C\hbar_3^{-1}\hbar_4'^{-1}\ell^4 = C\mu^2 h^{-2}\gamma^5\ell^4$.

On the other hand, the contributions of the subelement with $\ell \le \bar\ell_0$ to both the main part and the remainder do not exceed

$$C\hbar_3^{-1}\hbar_4'^{-1}\ell^4 = C\mu^2 h^{-2} r^{-4}\gamma^5 \bar\ell_0^4, \tag{21.4.35}$$

which is less than (21.4.34) (with a larger but still arbitrarily small exponent δ').

Let us notice that for given index p and ℓ-element operator $\mathcal{A}_{pn}$ is elliptic as $|n-\bar n|\mu h \ge C_0\ell^2\gamma r^{-1}$ for some $\bar n$; therefore ellipticity fails for no more than $\bigl(C_0\ell^2\gamma r^{-1}(\mu h)^{-1}+1\bigr)$ indices n.

Then the contribution to the remainder of all the indices n (while index p and ℓ-subelement remain fixed) does not exceed

$$C\mu h^{-1-\delta'}\gamma^2\ell^2 \times \bigl(C_0\ell^2\gamma(\mu h r)^{-1}+1\bigr). \tag{21.4.36}$$

For

$$\ell \ge \bar\ell_1 := \epsilon_1 \mu^{1/2} h^{1/2} r^{1/2}\gamma^{-1/2} \tag{21.4.37}$$

this expression is $\asymp Ch^{-2-\delta'}\gamma^3 r^{-1}\ell^4$ and the sum over ℓ-subelements in $B(0,1)$ with ℓ satisfying (21.4.37) results in $Ch^{-2-\delta'}\gamma^3 r^{-1}$.

Then the sum over all such subelements residing in $\mathcal{Z}_{(r,\gamma)}$ does not exceed

$$Ch^{-2-\delta'}\gamma^3 r^{-1}\times r^2\gamma^{-2}\times r^2\gamma^{-1} = Ch^{-2-\delta'}r^3 \tag{21.4.38}$$

where the second factor in the left-hand expression is the number of elements which appeared after rescaling (21.4.28) and the corresponding partition we made in the beginning of Subsubsection and the third factor is the number of the "slabs" corresponding to the final elements after the second transformation in the "intermediate" ball $B(0,1)$ obtained after the first transformation.

Then the sum over the whole $\mathcal{Z}^*_{\mathsf{out},I}$ does not exceed $Ch^{-2-\delta'}|\log h|$. So far index p remains fixed; the sum over $p\le C_0/(\mu h)$ does not exceed $C\mu^{-1}h^{-3-\delta'}|\log h| = O(\mu^{-1/2}h^{-3}$. Thus we arrive to

(21.4.39) The total contribution to the remainder of all (pair, subelement) combinations in zone $\mathcal{Z}^*_{\mathsf{out},I}$ with $\ell\ge \bar\ell_1$ does not exceed $C\mu^{-1/2}h^{-3}$.

Therefore only subelements with $\ell\le \bar\ell_1$ remain to be considered.

For such subelements expression (21.4.36) becomes $C\mu h^{-1-\delta'}\gamma^2\ell^2$; however, since without non-degeneracy condition the number of such subelements in $B(0,1)$ could be $\asymp \ell^{-4}$, the sum would become singular. To overcome this obstacle let us redefine the scaling function (21.4.29) in the manner more suitable for the analysis of elements with $\ell\le\bar\ell_1$:

$$\ell^* = \ell(x'',\xi'') = \epsilon\min_{p,n}\Big(\gamma^{-2}r^2|\nabla_{x'',\xi''}\mathcal{A}_{pn}|^2 + r\gamma^{-1}|\mathcal{A}_{pn}|\Big)^{1/2} + \bar\ell_0, \tag{21.4.40}$$
$$\text{with}\quad \bar\ell_0 = \hbar_3^{1/2}h^{-\delta'} = \mu^{-1/2}h^{1/2-\delta''}\gamma^{-3/2}r.$$

Note that as the minimum in the right-hand expression is achieved for $(p,n)=(\bar p,\bar n)(x'',\xi'')$, for every index p inequality $\ell\ge \ell_p = \ell^*+\epsilon|p-\bar p|\mu hr$ holds as the $n=n(p,(x'',\xi''))$ is selected to break ellipticity condition; this index $\bar n$ is unique.

Then the contribution of all subelements with $\ell^*\asymp\lambda$ in $B(0,1)$ (obtained after rescaling (21.4.28)) to the remainder (after summation with respect to n and $p=\bar p$) does not exceed the sum with respect to p of expressions (21.4.36):

$$C\mu h^{-1-\delta'}\gamma^2\sum_{p\ne\bar p}\big(\lambda+\epsilon|p-\bar p|\mu hr\big)^{-2}; \tag{21.4.41}$$

we included in this sum only p with $|p-\bar{p}| \ge 1$ leaving *special* $((\bar{n},\bar{p})$, subelement) combinations for a special consideration. Expression (21.4.41) obviously does not exceed $C\mu^{-1}h^{-3-\delta'}\gamma^2 r^{-2}$ and therefore the contribution of all such (pair, subelement) combinations residing in $\mathcal{Z}_{(r,\gamma)}$ does not exceed

$$C\mu^{-1}h^{-3-\delta'}r^{-2}\times r^2\gamma^{-2}\times r^2\gamma^{-1} = C\mu^{-1}h^{-3-\delta'}r^2\gamma^{-1}$$

with the same origin of the second and the third factors in the left-hand expression as in (21.4.38).

Finally, after summation over $\mathcal{Z}^*_{\mathsf{out},I}$ one gets $O(\mu^{-1/2}h^{-3})$. Therefore we arrive to

(21.4.42) The total contribution to the remainder of all $((p,n)$, subelement) combinations in zone $\mathcal{Z}^*_{\mathsf{out},I}$ with $\ell \le \bar{\ell}_1$ and $(p,n)\ne(\bar{p},\bar{n})$ does not exceed $C\mu^{-1/2}h^{-3}$.

Estimates in the Strictly Outer Zone. V

So, in what follows we need to consider only *special* $((\bar{n},\bar{p})$, subelement) combinations with $\ell^* \le \bar{\ell}_1$. Exactly for these combinations non-degeneracy condition becomes crucial. In the general case however, $\mathcal{A}_{pn}$ with $(p,n) = (\bar{p},\bar{n})$ could be "flat" and then there would be no difference between estimates of the contribution of such subelement to the remainder and to the main part of the asymptotics which would be $C\hbar_3^{-1}\hbar_4'^{-1} \asymp \mu^2h^{-2}\gamma^5r^{-2}$. Then the contribution of all such (pair, subelement) combinations residing in $\mathcal{Z}_{(r,\gamma)}$ does not exceed

$$C\mu^2h^{-2}\gamma^5r^{-2}\times r^2\gamma^{-2}\times r^2\gamma^{-1} = C\mu^2h^{-2}\gamma^2r^2 \tag{21.4.43}$$

with the same origin of the second and the third factors in the left-hand expression as in (21.4.38).

Finally, after summation over $\mathcal{Z}^*_{\mathsf{out},I}$ one gets $O(\mu^{-1/2}h^{-3})$. Therefore we arrive to

(21.4.44) The total contribution to the remainder of all $((p,n)$, subelement) combinations in zone $\mathcal{Z}^*_{\mathsf{out},I}$ with $\ell \le \bar{\ell}_1$ and $(p,n) = (\bar{p},\bar{n})$ does not exceed $C\mu^2h^{-2}$.

Combining with (21.4.39), (21.4.42) we arrive to

Proposition 21.4.2. *Under assumption* (21.3.1) *the total contribution to the remainder of the zone* $\mathcal{Z}^*_{\mathsf{out},I}$ *does not exceed* $C\mu^2h^{-2} + C\mu^{-1/2}h^{-3}$.

Remark 21.4.3. All the arguments leading to Proposition 21.4.2 are applicable in $\mathcal{Z}^*_{\mathsf{out},II}$ with the following minor modifications and simplifications:

(i) Operators $\mathcal{A}_{pn}$ are $\hbar_3$-PDOs from the very beginning (so there is no need in (21.4.28) rescaling; there are no "slabs" etc, everything is homogeneous.

(ii) A factor r^2 in estimates translates into γ which makes life easier; in particular there is no need in the special propagation analysis leading to (21.4.27).

Therefore

(iii) $O(\mu^{-1/2}h^{-3})$ estimate for the contribution into the remainder of all $((p,n),\mathsf{subelement})$ combinations in zone $\mathcal{Z}^*_{\mathsf{out},II}$ with either $\ell \ge \bar{\ell}_1$ or $\ell \le \bar{\ell}_1$ and $(p,n) \ne (\bar{p},\bar{n})$ and

(iv) $O(\mu^2h^{-2}\gamma^3)$ estimate for the contribution into the remainder of all $((p,n),\ \mathsf{subelement})$ combinations in zone $\mathcal{Z}^*_{\mathsf{out},II} \cap \{\mathsf{dist}(x,\Sigma) \le \gamma\}$ with $\ell \le \bar{\ell}_1$ and $(p,n) = (\bar{p},\bar{n})$.

In particular, we arrive to

Proposition 21.4.4. *Under assumption* (21.3.1) *the total contribution to the remainder of the zone* $\mathcal{Z}^*_{\mathsf{out},II}$ *does not exceed* $C\mu^2h^{-2} + C\mu^{-1/2}h^{-3}$.

Estimates in the Strictly Outer Zone. VI

Estimate (21.2.93) $O\big(\mu^2h^{-2} + \mu^{-1/2}h^{-3}\big)$ is the best possible in the general case (see Subsection 21.5.4) and it coincides with the best possible $O(\mu^{-1/2}h^{-3})$ as $\mu \le h^{-2/5}$; so $\mu \ge h^{-2/5}$ until the end of this subsection.

However, one can do better under some non-degeneracy conditions. Namely, as before one can estimate the contribution of the special pair $((\bar{p},\bar{n}),$ $\mathsf{subelement})$ to the remainder by $C\mu h^{-1-\delta'}\gamma^2\ell^2$ as $\ell \ge \bar{\ell}_0$ (see (21.4.34)) and by $C\mu^2r^{-2}\gamma^5$ (see (21.4.35)) where now ℓ^* defined by (21.4.40) and ℓ as the paragraph below that. Therefore the contribution to the remainder of all the special subelements residing in the final element $B(0,1)$ (obtained after

rescaling and partition (21.4.28)) does not exceed

$$C\mu h^{-1-\delta'}\gamma^2 r^{-2}\int_{\{\bar\ell_0\le \ell^*\le \bar\ell_1\}} \ell^{*\,-2}\,dx''d\xi'' + C\mu^2 h^{-2} r^{-4}\gamma^5 \int_{\{\ell^*\le \bar\ell_0\}} dx''d\xi'', \tag{21.4.45}$$

where we recall that $\bar\ell_0 = \mu^{-1/2}h^{1/2-\delta''}\gamma^{-3/2}r$ and $\bar\ell_1 = \mu^{1/2}h^{1/2}r^{1/2}\gamma^{-1/2}$.

Then the total contribution to the remainder of all the special subelements with Ψ-image residing in $\mathcal{Z}_{(r,\gamma)}\subset \mathcal{Z}^*_{\mathsf{out},I}$ to the remainder does not exceed

$$C\mu h^{-1-\delta'}\gamma^2 r^{-2}\int_{\{\bar\ell_0\le \ell^*\circ\Psi^{-1}\le \bar\ell_1\}\cap \mathcal{Z}_{(r,\gamma)}} \ell^{*\,-2}\,|\det D\Psi|^{-1}\,dx + C\mu^2 h^{-2} r^{-4}\gamma^5 \int_{\{\ell^*\circ\Psi^{-1}\le \bar\ell_0\}\cap \mathcal{Z}_{(r,\gamma)}} |\det D\Psi|^{-1}\,dx.$$

Since

$$|\det D\Psi| \asymp \gamma^4 r^{-4} \tag{21.4.46}$$

one can rewrite this expression as

$$C\mu h^{-1-\delta'}\int_{\{\bar\ell_0\le \ell^*\circ\Psi^{-1}\le \bar\ell_1\}\cap \mathcal{Z}} \gamma^{-2}r^2\ell^{*\,-2}\,dx + C\mu^2 h^{-2}\int_{\{\ell^*\circ\Psi^{-1}\le \bar\ell_0\}\cap \mathcal{Z}} \gamma\,dx \tag{21.4.47}$$

with $\mathcal{Z} = \mathcal{Z}_{(r,\gamma)}$.

We leave to the reader the similar analysis in $\mathcal{Z}^*_{\mathsf{out},II}$ leading to the same estimate for the contribution of $\bar{\mathcal{Z}}_{(r,\gamma)}\subset \mathcal{Z}^*_{\mathsf{out},II}$ with $r=\gamma^{1/2}$:

Proposition 21.4.5. *Under assumption* (21.3.1)

(i) The total contribution of the special subelements with Ψ-image residing in $\mathcal{Z}_{(r,\gamma)}\subset \mathcal{Z}^*_{\mathsf{out},I}$ does not exceed (21.4.47) *with $\mathcal{Z} = \mathcal{Z}_{(r,\gamma)}$.*

(ii) The total contribution of the special subelements with Ψ-image residing in $\bar{\mathcal{Z}}_{(r,\gamma)}\subset \mathcal{Z}^*_{\mathsf{out},II}$ does not exceed (21.4.47) *with $\mathcal{Z} = \bar{\mathcal{Z}}_{(r,\gamma)}$. where $r=\gamma^{1/2}$.*

(iii) The total contribution of all the special subelements (with Ψ*-image residing in* $\mathcal{Z}^*_{\mathsf{out}}$ *does not exceed* (21.4.47) *with* $\mathcal{Z} = \mathcal{Z}^*_{\mathsf{out}}$.

Note that all elements of the matrix $D\Psi$ do not exceed $C\gamma r^{-1}$. Combining with (21.4.47) and (21.4.18) one can conclude that all elements of $D\Psi^{-1}$ do not exceed $C\gamma^{-1}r$. Therefore if ℓ^* was defined by (21.4.40) with H_{pn} instead of $\mathcal{A}_{pn}$ then the following inequality would hold

$$\ell^* \circ \Psi^{-1} \ge L \coloneqq \epsilon|\nabla_{\Sigma}(V/f_2)| + \min_n |\nabla_{\Sigma}(V/f_2) - (2n+1)\mu h|. \tag{21.4.48}$$

Then under assumption

$$|\big(\frac{V}{f_2}\big) - (2n+1)\mu h| + |\nabla_{\Sigma}\big(\frac{V}{f_2}\big)| \ge \epsilon_0 \qquad \forall n \in \mathbb{Z}^+ \tag{21.4.49}$$

$\ell^* \asymp 1$ even if ℓ^* are defined by $\mathcal{A}_{pn}$ and the first term in (21.4.46) does not exceed $C\mu h^{-1-\delta'}\gamma^{-1}r^4$ while the second term vanishes and the total contribution of $\mathcal{Z}^*_{\mathsf{out},I}$ to the remainder does not exceed $C\mu^{3/2}h^{-1}$.

Therefore we arrive to

Proposition 21.4.6. *Under assumptions* (21.3.1) *and* (21.4.49) *the total contribution of* $\mathcal{Z}^*_{\mathsf{out}}$ *to the remainder does not exceed* $C\mu^{-1/2}h^{-3}$.

Furthermore, under assumption (21.4.48) and condition

$$\exists n \in \mathbb{Z}^+ : \ |\frac{V}{f_2} - (2n+1)f_2\mu h| + |\nabla_{\Sigma}\big(\frac{V}{f_2}\big)| \le \epsilon_0 \implies \tag{21.4.50}_q$$

$\mathsf{Hess}_{\Sigma}\big(\frac{V}{f_2}\big)$ has at least q eigenvalues with absolute values greater than ϵ_0,

one can see easily that expression (21.4.47) with $\mathcal{Z} = \mathcal{Z}^*_{\mathsf{out}}$ does not exceed $C\mu^{3/2}h^{-1}$ plus expression

$$C\mu^2h^{-2}\int \gamma \bar{\ell}_0^q \, dx \tag{21.4.51}_q$$

which is

$$\asymp \iint_{\Omega} J_q \, \gamma^{-1} d\gamma \cdot r^{-1} dr, \qquad J_q = h^{-2\delta''}\mu^2h^{-2}(\mu^{-1}hr^2\gamma^{-3})^{q/2}r^2\gamma^2$$

with integral taken over $\Omega = \{\mu^{\delta'-1/2}r^{1/2} \le \gamma \le r^2 \le 1\}$.

Obviously, expression $(21.4.51)_2$ does not exceed J_2 calculated as $\gamma = \mu^{\delta'-1/2}$, $r = 1$ which is $O(\mu^{-1/2}h^{-3})$. Further, expression $(21.4.51)_1$ does not exceed J_1 calculated as $\gamma = r = 1$ which is $C\mu^{3/2}h^{-3/2-\delta''}$ with arbitrarily small $\delta'' > 0$.

Then in the framework of

$$(21.4.52)_q \quad |\nabla_\Sigma(\frac{V}{f_2})| \le \epsilon_0 \implies$$

$\mathsf{Hess}_\Sigma(\frac{V}{f_2})$ has at least q eigenvalues with absolute values greater than ϵ_0 ,

one arrives to the following statement[25]:

Proposition 21.4.7. *Let condition* (21.3.1) *be fulfilled. Then*

(i) Under assumption $(21.4.52)_2$ *the total contribution to the remainder of the zone* $\mathcal{Z}^*_{\mathsf{out}}$ *with does not exceed* $C\mu^{-1/2}h^{-3}$.

(ii) Under assumption $(21.4.52)_1$ *the total contribution to the remainder estimate the zone* $\mathcal{Z}^*_{\mathsf{out}}$ *does not exceed* $C\mu^{3/2}h^{-3/2-\delta} + C\mu^{-1/2}h^{-3}$ *with arbitrarily small* $\delta'' > 0$.

Proof. To get rid of assumption (21.4.28) one needs to take in account perturbation term $\mathcal{B}$ in $\mathcal{A}_{pn}$; then $\ell^* \circ \Psi^{-1} \ge L - |\nabla_\Sigma \mathcal{B}_{pn} \circ \Psi^{-1}|$. Thus it would be enough to replace $\bar\ell_0$ by $\bar\ell_0 + |\nabla_\Sigma \mathcal{B}_{pn} \circ \Psi^{-1}|$ in $(21.4.51)_q$.

There are two leading terms in $\mathcal{B}_{pn}$; the first one is $\mu^{-2}r^2\gamma^{-4}((2p+1)\mu h\gamma)^2$; since $p \le C_0/(\mu hr)$ this term does not exceed $C\mu^{-2}\gamma^{-2}$. The second term is $O(\mu^{-1}hr^2\gamma^{-3})$ but looking its origin one can notice that it must contain $|\nabla_\Sigma(V/f_2)|^2$; then

$$|\nabla_\Sigma \mathcal{B}_{pn} \circ \Psi^{-1}| \le L_1 \coloneqq C\mu^{-2}\gamma^{-3}r.$$

Plugging $\bar\ell_0 = \mu^{-2}\gamma^{-3}r$ into $(21.4.51)_1$ results in $O(\mu^{1/2}h^{-2})$. □

Remark 21.4.8. (i) Note that in the extra terms $O(\mu^2h^{-2})$ and $O(\mu^{3/2}h^{-3/2-\delta''})$ appearing in the general case and under assumption $(21.4.50)_q$ the main contributor is far outer zone where $\gamma \approx 1$ and $r \approx 1$ while in the sharp estimate $O(\mu^{-1/2}h^{-3})$ the main contributor is zone where $\gamma \approx \mu^{-1/2}$ and $r \approx 1$.

[25] Still under assumption (21.4.48).

(ii) Actually one can greatly improve remainder estimate in $(21.4.50)_1$ case using more refined partition-rescaling technique like in the proof of Proposition 21.5.3. We believe that it can be even brought to $O(\mu^{-1/2}h^{-3})$. However, we think that really interesting are only general ($q = 0$) and generic ($q = 3$) cases.

21.4.2 Estimates in the Near Outer Zone

After deriving remainder estimates in $\mathcal{Z}^*_{\mathsf{out}}$ we need to consider the remaining part of $\mathcal{Z}_{\mathsf{out}}$ (which will be the *near outer zone*

$$\mathcal{Z}'_{\mathsf{out}} = \mathcal{Z}_{\mathsf{out}} \cap \{\mathsf{dist}(x, \Sigma) \le \mu^{-1/2}h^{-\delta}\} \tag{21.4.53}$$

and the *inner zone*. However, we also introduce and start from the *inner core* where we are able to apply pretty non-sophisticated approach and still derive proper estimates, just to keep r more disjoint from 0 to be able to use canonical form (21.3.38).

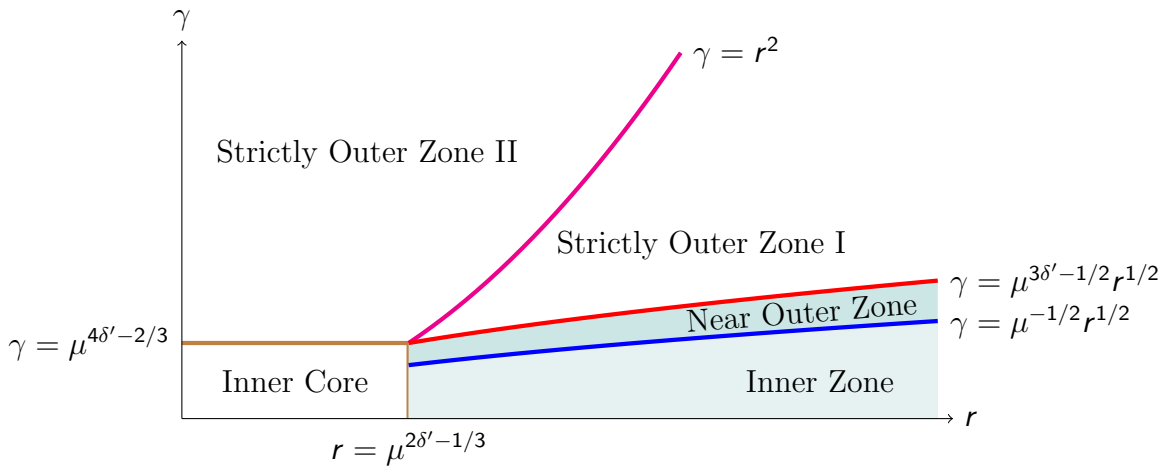

Figure 21.3: Zones.

Estimates in the Near Outer Zone. I

In this subsection our goal is to derive remainder estimate $O(\mu^{-1/2}h^{-3} + \mu^2h^{-2})$. Therefore our approach here would be pretty unsophisticated. Note first that

(21.4.54) The contribution of the domain

$$\bigl\{\mathsf{dist}(x,\Lambda)\le r,\ \mathsf{dist}(x,\Sigma)\le\gamma,\ |Z_1|\le\rho\bigr\} \tag{21.4.55}$$

to the remainder does not exceed $C\mu h^{-3}\gamma r^2\rho^2$ (while the main part of asymptotics is given by (21.4.1) with $T_0\ge Ch|\log h|$);

therefore considering *inner core* defined by (21.4.55) with $r=\mu^{-1/3+2\delta'}$, $\gamma=\mu^{-2/3+4\delta'}$ one gets $O(\mu^{-1/3+6\delta'}h^{-3})$.

This remainder estimate is very rough and should be improved despite rather unambitious goal of this Subsubsection. However, let us observe first that considering the strip $\{|x_1|\le\mu^{-1/2+3\delta'}\}$ and thus taking $r=1$, $\rho=1$ and $\gamma=\mu^{-1/2+3\delta'}$ one would get the remainder estimate $O(\mu^{1/2+3\delta'}h^{-3})$ which is $O(\mu^2h^{-3})$ as long as $\mu\ge h^{-2/3-\delta}$. Further, the contribution of this zone to the asymptotics is $O(h^{-4}\gamma r^2)$ and thus taking $r=1$, $\rho=1$ and $\gamma=\mu^{3\delta'-1/2}$ one would get $O(\mu^{-1/2+3\delta'}h^{-4})$ which is $O(\mu^2h^{-2})$ as $\mu\ge h^{\delta-4/5}$. Therefore in what follows until the end of Subsubsection one can assume that

$$h^{-\delta}\le\mu\le h^{\delta-1}. \tag{21.4.56}$$

Note first that

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(uQ_y^\dagger)|\le Ch^s \tag{21.4.57}$$

as Q is supported in $\bar{Z}_{(\gamma)}:=\{|x_1|\le\gamma\}$ and $T_0\le T\le T_1$ with $T_0=Ch|\log h|$ and $T_1=\epsilon\mu^{-1}$; this statement is empty in the case of the *very strong magnetic field*

$$\epsilon(h|\log h|)^{-1}\le\mu\le Ch^{-1} \tag{21.4.58}$$

which is not the case now.

However, looking at the propagation in direction $\mathbb{K}_1$ as $|Z_1|\asymp\rho$ one can easily notice that the propagation speed is $\asymp\rho$ and the shift for time T is $\asymp\rho T$; this shift is observable as $\rho^2T\ge Ch|\log h|$. Therefore (21.4.56) holds as $T_0\le T\le T_1$ with $T_0=C\rho^{-2}h|\log h|$ and $T_1=\epsilon\mu^{-1}\gamma^{-1}$. Under assumption $\gamma\ge C_0\mu^{-1/2}$ this short evolution is contained in $\epsilon_1\gamma$-vicinity of the original point[26)].

[26)] One can improve this statement and the estimate following from it.

These two intervals $[Ch|\log h, \epsilon\mu^{-1}]$ and $[C\rho^{-2}h|\log h|, \epsilon\mu^{-1}\gamma^{-1}]$ overlap as

$$\rho \ge (C\mu h|\log h|)^{1/2} \tag{21.4.59}$$

and therefore we arrive to

(21.4.60) Under assumptions (21.4.56) and (21.4.59) estimate (21.4.57) holds as $T \in [T_0, T_1]$ with $T_0 = Ch|\log h|$, $T_1 = \epsilon \min\big(\mu^{-1}\gamma^{-1}, \mu^{-1/2}\big)$.

Therefore the contribution of the domain

$$\big\{\mathsf{dist}(x, \Lambda) \le r,\ \mathsf{dist}(x, \Sigma) \le \gamma,\ |Z_1| \ge C(\mu h|\log h|)^{1/2}\big\} \tag{21.4.61}$$

to the remainder does not exceed $C\mu h^{-3}r^2\gamma(\gamma + \mu^{-1/2})$.

Combining with (21.4.54) we arrive to

Proposition 21.4.9. *Contribution of domain* (21.4.55) *with* $\rho \asymp 1$ *to the remainder does not exceed*

$$C\mu h^{-3}r^2\gamma(\gamma + \mu^{-1/2}) + C\mu^2 h^{-2}\gamma r^2|\log h| \tag{21.4.62}$$

while the main part of asymptotics is given by (21.1.2) *with (any)* $T_0 \ge C\mu h|\log h|$.

Remark 21.4.10. Estimate (21.4.62) is sufficient for our limited goal here. In particular, it covers the inner core giving remainder estimate $O(\mu^{-1/2}h^{-3} + \mu^{2/3+\delta}h^{-2})$ which is not only better than $O(\mu^{-1/2}h^{-3} + \mu^2 h^{-2})$ but than $O(\mu^{-1/2}h^{-3} + \mu^{3/2}h^{-3/2})$.

So, we need to cover the *near outer* and *inner* zones; in both $\gamma \le r^2$ and therefore we can use canonical form (21.3.38). Even without it, according to Section 21.2 the drift speed is $\asymp \mu^{-1}\rho^2 r\gamma^{-2}$ as $\rho^2 r \ge C_0\gamma$.

Then the shift for time T is observable as $\mu^{-1}\rho^2 r\gamma^{-2}T \times \rho \ge Ch|\log h|$; plugging $T = \mu^{-1}\gamma^{-1}$ one gets $(21.4.63)_2$ below and therefore *in the zone* (21.4.57) *one can upgrade* $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ *to* $T_1 = \epsilon\mu\gamma^2$ *provided*

$$\rho^2 r \ge c\gamma, \qquad \rho^3 r \ge C\mu^2\gamma^3 h|\log h|. \tag{21.4.63}$$

However, the contribution to the remainder of the part of $\mathcal{Z}'_{\mathsf{out}}$ where $T_1 = \epsilon\mu\gamma^2$ is $O(\mu^{-1/2}h^{-3})$. Therefore *one needs to consider only part of* $\mathcal{Z}'_{\mathsf{out}}$

where at least one of conditions $(21.4.63)_{1,2}$ *is violated*. At this moment one can ignore subzone $\{\rho \le C(\mu h|\log h|)^{1/2}\}$ and therefore one can upgrade $T_1 = \epsilon\mu^{-1}$ to $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ with no penalty.

Moreover, using $O(\mu h^{-3} r^2\gamma^2\rho^2)$ estimate (with $r = 1, \gamma = h^{-1/2+3\delta'}$) one can see easily that the contribution to the remainder of the zone where condition $(21.4.63)_2$ is violated does not exceed $C\mu^{1/3}h^{-7/3-\delta}$ which is $o(\mu^{-1/2}h^{-3} + \mu^2 h^{-2})$.

Therefore one needs to consider only zone where condition $(21.4.63)_1$ is violated; again due to $O(\mu h^{-3}\gamma^2\rho^2 r^2)$ estimate its contribution to the remainder does not exceed $C\mu^{-1/2}h^{-3-\delta}$ which is only marginally short of what we want (and only the case $\mu \le h^{-2/5-\delta}$ needs to be considered).

The proper estimate of the zone where condition $(21.4.63)_1$ is violated can be done easily on the base of Proposition 21.2.7. Indeed, the drift speed is $\asymp \mu^{-1}(\rho+\rho')\Delta r\gamma^{-2}$ with $\rho' = O(\gamma r^{-1})$, $\Delta = |\rho - \rho'|$ and therefore one can upgrade $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ to $T_1 = \epsilon\mu\gamma^2$ as

$$\mu^{-1}(\rho+\rho')\Delta r\gamma^{-2} \times \mu^{-1}\gamma^{-1} \times \Delta \ge Ch|\log h|$$

with $\rho' = O(\gamma^{1/2}r^{-1/2})$. Therefore one can take

$$\bar{\Delta} = C\mu\gamma^{3/2}r^{-1/2}(h|\log h|)^{1/2}(\rho+\rho')^{-1/2};$$

then as $|\rho - \rho'| \ge \bar{\Delta}$ one can take $T_1 = \epsilon\mu\gamma^2$.

On the other hand, the contribution of the zone $\{(x,\xi) : |\rho-\rho'| \le \bar{\Delta}\} \cap \mathcal{Z}_{(r,\gamma)}$ to the remainder does not exceed

$$C\mu h^{-3} r^2 \rho' \gamma r^2 \bar{\Delta} = C\mu^2 h^{-3} r^2 \gamma^{5/2} r^{3/2} (h|\log h|)^{1/2} \rho'^{1/2}.$$

Since $\rho' \le c(\gamma/r)^{1/2}$ the latter expression does not exceed $C\mu^2 h^{-3}\gamma^{11/4} r^{5/4}(h|\log h|)^{1/2}$. In particular, the contribution to the remainder of the part of $\mathcal{Z}_{(\gamma)}$ where condition $(21.4.63)_1$ is violated does not exceed $C\mu^2 h^{-5/2}\gamma^{11/4}|\log h|^{1/2}$ and therefore the contribution of the corresponding part of $\mathcal{Z}'_{\mathsf{out}}$ does not exceed $C\mu^{5/8}h^{-5/2-\delta}$.

Therefore we arrive to

Proposition 21.4.11. *Under assumption* (21.3.1) *the total contribution to the remainder of zone* $\mathcal{Z}'_{\mathsf{out}}$ *does not exceed* $C(\mu^{-1/2}h^{-3} + \mu^2 h^{-2})$.

Estimates in the Near Outer Zone. II

Now we need to improve the previous estimate under non-degeneracy condition. However, let us summarize the remainder estimate we actually derived:

(i) The inner core intersected with $\{\rho \ge C(\mu h|\log h|)^{1/2}\}$ contributed $O(\mu h^{-3}\bar\gamma_0^2\bar r_0^2) = o(\mu^{-1/2}h^{-3})$ where $\bar\gamma_0 = \mu^{-2/3+4\delta'}$, $\bar r_0 = \mu^{-1/3+2\delta'}$.

(ii) $\mathcal{Z}'_{\mathsf{out}} \cap \{\rho \ge C(\mu h|\log h|)^{1/2}\}$ contributed $O(\mu h^{-3}\bar\gamma_1^2(\mu h\bar\gamma_1)^{2/3}) = O(\mu^{1/3}h^{-7/3-\delta''})$ where $\bar\gamma_1 = \mu^{-1/2+4\delta'}$.

(iii) Zone $\{|x_1| \le \bar\gamma_1\}\cap\{\rho \le C(\mu h|\log h|)^{1/2}\}$ contributed $O(\mu^2h^{-2}\bar\gamma_1|\log h|) = O(\mu^{1/2+\delta''}h^{-2})$.

Each of estimates in (ii), (iii) is less than $O(\mu^{-1/2}h^{-3})$ as $\mu \le h^{-1/2+\delta}$. Therefore in what follows one can assume that

$$h^{-1/2+\delta} \le \mu \le Ch^{-1}. \tag{21.4.64}$$

The better analysis is based on the canonical form (21.3.38). However, this requires the inner core to be treated separately:

Proposition 21.4.12. *Under assumption* (21.4.64) *the contribution of the zone*

$$\mathcal{Z}^0_{(r)} := \{\mathsf{dist}(x,\Sigma) \le r^2,\ \mathsf{dist}(x,\Lambda) \le r\}$$

with $r \ge \mu^{-1/3+2\delta'}$ *does not exceed* $C\mu h^{-3}r^6$ *while the principal part of asymptotics is given by* (21.1.2) *with* $T = \bar T := Ch|\log h|$.

Proof. Looking at the canonical form (21.3.17) and scaling $x'' \mapsto x''r^{-1}$, $x_1 \mapsto x_1r^{-1}$, $\mu \mapsto \mu_* = \mu r^3$, $h \mapsto h_* = hr^{-1}$ one gets 2-dimensional magnetic Schrödinger operator with parameters μ_*, h_*, which also is 1-dimensional $\hbar_4$-PDO with respect to x_4 with $\hbar_4 = \mu^{-1}hr^{-2}$; for such Schrödinger operators one can prove easily that the main part of asymptotics is given by Weyl formula and is of magnitude $\hbar_4^{-1}h_*^{-2} = \mu h^{-3}r^4$ while the remainder estimate gains the factor $\mu_*h_* = \mu hr^2$ and thus is of magnitude $\mu^2h^{-2}r^6$.

Indeed, if $\mu_* = 1$ it would follow from the standard results (and no non-degeneracy condition is needed); as $\mu_* \ge 1$ one needs just apply extra rescaling $x' \mapsto x'\mu_*$ which is also rather standard. □

Corollary 21.4.13. *Therefore even without nondegeneracy conditions contribution of the (extended) inner core $\mathcal{Z}^0_{(r)}$ with $r = \mu^{-1/4}$ to the remainder does not exceed $C\mu^{-1/2}h^{-3}$.*

Thus in what follows we can apply canonical form (21.3.38). Let us fix some index n and some final $B(0,1)$ element where in contrary to Subsection 21.4.1 final means "only after reduction to (21.3.38)". This element is either *regular*, when on the original $B(\bar{x}', \epsilon r)$ element

$$|Vf_2^{-1} - (2n+1)\mu h| + |\nabla_{x'}\big(Vf_2^{-1} - (2n+1)\mu h\big)|^2 \asymp L^2 \ge r^2 \tag{21.4.65}$$

or *singular* when on the original $B(\bar{x}', \epsilon r)$ element

$$|Vf_2^{-1} - (2n+1)\mu h| + |\nabla_{x'}\big(Vf_2^{-1} - (2n+1)\mu h\big)|^2 \le r^2. \tag{21.4.66}$$

Since analysis of the regular elements is similar to the analysis of the singular elements but simpler, we consider only singular elements, leaving regular elements to the reader.

Let us introduce the scaling function with respect to (x_3, x_4, ξ_4)

$$\ell = \ell_n = \epsilon r^{-1}|\nabla_{x_3,x_4,\xi_4} Vf_2^{-1}| + \bar{\ell} \tag{21.4.67}$$

where $\bar{\ell} \ge C\gamma r^{-1}|\log h|$ will be chosen later. With respect to $|Z_1^{\#}|$ we use scaling function $\rho = \epsilon\big(|Z_1| + r^{1/2}\ell\big)$. Then ellipticity of $\mathcal{A}_n$ is not broken unless $\big(Vf_2^{-1} - (2n+1)\mu h\big) \asymp \rho^2$ or $\rho \le cr^{1/2}\ell$.

Then it follows from the standard theory that for u_n holds as Q is supported in the corresponding ℓ-partition element, $T \in [T_0, T_1]$, $\tau \le Cr\ell^2$ with

$$T_0 = Ch\big(\rho^2 + r\ell^2\big)^{-1}|\log h|, \tag{21.4.68}$$

$$T_1 = \epsilon\mu^{-1}\gamma^{-1}, \tag{21.4.69}$$

$$\rho + r^{1/2}\ell \ge C\bar{\rho}_0 := C(\mu h\gamma|\log h|)^{1/2} \tag{21.4.70}$$

and moreover, under these conditions

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(u_n Q y^{\dagger})| \le C\mu h^{-2} r^3 \ell^3 \gamma. \tag{21.4.71}$$

Therefore we arrive to

(21.4.72) While the contribution of this $(\ell;\rho)$-subelement into asymptotics does not exceed $C\mu h^{-3}r^3\big(\rho^2+r\ell^2\big)\ell^3\gamma$, its contribution to the remainder so far does not exceed

$$C\mu h^{-3}r^3\big(\rho^2+r\ell^2\big)\ell^3\gamma\times T_0T_1^{-1}=C\mu^2h^{-2}r^3\ell^3\gamma^2.$$

Note that for each $(\ell;\rho)$-partition subelement in $(x_3,x_4,\xi_4;\xi_1,\xi_3)$ the number of indices n satisfying (21.4.67) and also violating ellipticity does not exceed

$$M:=C_0(\mu h)^{-1}(\rho^2+r\ell^2)+1. \tag{21.4.73}$$

Also note that under assumption $(21.4.50)_q$ the total number of ℓ-subelements is $O(\ell^{q-3})$. Then the total contribution of all ℓ-elements to the asymptotics (as magnitudes of r,γ are given) does not exceed

$$C\mu h^{-3}\gamma r^{(2-q)_+}(\rho^2+r\ell^2)\times\Big(C_0(\mu h)^{-1}(\rho^2+r\ell^2)+1\Big)\times\ell^q \tag{21.4.74}$$

which one can sum nicely to its value at maximal $\ell=1$, $\rho=1$ and then to maximal $r=1$, $\gamma=\mu^{\delta-1/2}$ resulting $Ch^{-4}\mu^{\delta-1/2}$.

On the other hand, the total contribution of ℓ-subelements to the remainder so far does not exceed

$$C\mu^2h^{-2}\gamma^2r^{(2-q)_+}\times\Big(C_0(\mu h)^{-1}(\rho+r\ell)^2+1\Big)\times\ell^q \tag{21.4.75}$$

which one can also sum nicely according to the same principles but the sum is $C\mu h^{-3}\gamma^2$ not estimated that well and ℓ,r close to 1 are problematic. Therefore we want to increase T_1.

Recall that $W_n=\omega\big(Vf_2^{-1}-(2n+1)\mu h\big)$ with $\omega=(\sigma\sigma_1)^{-1}f_2$ and here (see Proposition 21.3.8) $\omega\sim|\{Z_1,f_1\}|^{-2/3}$ rescaled; therefore for "small" ρ calculation of ∇W_n and $\omega\nabla\big(Vf_2^{-1}-(2n+1)\mu h\big)$ are equivalent modulo $\omega\rho^2r^{-1}$. Note that

(21.4.76) As $\big(Vf_2^{-1}-(2n+1)\mu h\big)\asymp\rho^2$ and $\ell\ge C\rho^2r^{-1}$ the propagation speed with respect to x_4 does not exceed $C\mu^{-1}r^{-1}\ell$ and is of this magnitude as $|\partial_{\xi_4}W_n|\asymp\ell$; then the shift with respect to x_4 is observable as

$$\mu^{-1}r^{-1}\ell T\times\ell\ge C\mu^{-1}r^{-2}h|\log h|; \tag{21.4.77}$$

(21.4.78) As $\big(Vf_2^{-1}-(2n+1)\mu h\big)\asymp\rho^2$ and $\ell\ge C\rho^2r^{-1}$ the propagation speed with respect to $\mu^{-1}hD''$ does not exceed $C\mu^{-1}r^{-1}\ell$ and is of this magnitude as $|\partial_{x''}W_n|\asymp\ell$; then the shift with respect to $\mu^{-1}hD''$ is observable under the same condition;

(21.4.79) Finally, in the short-term propagation (as $T \le \epsilon\mu^{-1}\gamma^{-1}$) the propagation speed with respect to (x_1, x_3) is of magnitude $|Z_1| \asymp \rho$ and the shift is observable as $\rho T \times \rho \ge Ch|\log h|$.

On the other hand,

(21.4.80) Let $\rho^2 \ge C\gamma$; then the drift speed (in the rescaled coordinates) with respect to x'' is of magnitude $C\mu^{-1}\gamma^{-2}\rho^2$ and the shift for time T is observable as

$$\mu^{-1}\gamma^{-2}\rho^2 T \times \rho \ge Chr^{-1}|\log h|. \tag{21.4.81}$$

Therefore one can increase $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ provided one of the conditions (21.4.77), (21.4.81) holds with $T = T_1$. Plugging $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ into (21.4.77), (21.4.81) we get

$$\rho \ge \bar{\rho} \coloneqq C\bigl(\mu^2 h\gamma^3 r^{-1}|\log h|\bigr)^{1/3} + C\gamma^{1/2}, \tag{21.4.82}$$

$$\ell \ge \bar{\ell} \coloneqq C\bigl(\mu h\gamma r^{-1}|\log h|\bigr)^{1/2} + C\rho^2 r^{-1} \tag{21.4.83}$$

respectively.

Now consider increased T_1. We claim that

(21.4.84) Under assumption (21.4.83) one can take $T = \epsilon\mu\gamma^2\ell$.

Indeed, then magnitude of $|\nabla_{x_1,x_4,\xi_4} W_n|$ changes by no more than $\epsilon\ell$ as long as $\rho \le \epsilon_1$; however, as $\rho \ge \epsilon$ condition (21.4.82) is fulfilled and one can take $T_2 = \epsilon\mu\gamma^2$.

Therefore the contribution to the remainder of the zone with the given magnitudes of ρ, ℓ, γ, r satisfying (21.4.83) does not exceed expression (21.4.74) multiplied by $T_0 T_2^{-1}$; the resulting expression does not exceed

$$\begin{aligned} C\mu h^{-3}\gamma r^{(2-q)_+}(\rho^2 + r\ell^2) \times \Bigl(C_0(\mu h)^{-1}(\rho + r\ell)^2 + 1\Bigr) \times \ell^q \\ \times h(\rho^2 + r\ell^2)^{-1} \times \mu^{-1}\gamma^{-2}\ell^{-1} \\ = C\mu^{-1}h^{-3}\gamma^{-1}r^{(2-q)_+}\Bigl((\rho + r\ell)^2 + \mu h\Bigr)\ell^{q-1}. \end{aligned} \tag{21.4.85}$$

Then summation with respect ℓ, ρ results in $C\mu^{-1}h^{-3}\gamma^{-1}r$ as $q > 1$ (then one should take q slightly larger than 1). As $q = 1$ one gets $C\mu^{-1/2}h^{-3}(1 + \mu h|\log h|)$ as provided summation is taken over $\rho \le c(\ell + |\log h|^{-1})$; but the latter case is covered by arguments below.

(21.4.86) Under assumptions (21.4.82) and $\rho \ge r^{1/2}\ell$ one can take $T_2 = \epsilon\mu\gamma^2\rho r^{-1/2}$.

Indeed, in this case due to bounds for propagation and drift speeds this guarantees that both $|\nabla_{x_1,x_4,\xi_4} W_n|$ and $W_n \asymp |Z_1|^2$ change by no more than $r^{-1/2}\rho$, $\epsilon_1\rho^2$ respectively during the evolution.

Now instead of (21.4.85) we get

$$\begin{aligned}(21.4.87)\quad C\mu h^{-3}\gamma r^{(2-q)_+}(\rho^2 + r\ell^2) \times \Big(C_0(\mu h)^{-1}(\rho + r\ell)^2 + 1\Big) \times \ell^q \\ \times h(\rho^2 + r\ell^2)^{-1} \times \mu^{-1}\gamma^{-2}\rho^{-1} \\ \le C\mu^{-1}h^{-3}\gamma^{-1}r^{(2-q)_+}\Big((\rho + r\ell)^2 + \mu h\Big)\ell^q\rho^{-1}\end{aligned}$$

and summation with respect to ρ, ℓ, γ, r results in $C\mu^{-1/2}h^{-3}$. Therefore

(21.4.88) The total contribution to the remainder of elements in $\mathcal{Z}''_{\mathsf{out}}$ satisfying (21.4.70) and one of conditions (21.4.82), (21.4.83) does not exceed $C\mu^{-1/2}h^{-3}$.

Estimates in the Near Outer Zone. III

Thus we are left with two types of elements, which are not covered by the above arguments:

(21.4.89) With $\bar\rho_0 \le \rho \le \bar\rho = C(\mu^2 h\gamma^3 r^{-1}|\log h|)^{1/3} + C\gamma^{1/2}$ and $\ell \le \bar\ell \asymp r^{-1}\bar\rho_0 + \rho^2 r^{-1}$;

(21.4.90) With $\rho \le \bar\rho_0 = C(\mu h\gamma)^{1/2}$ and $\ell \le \bar\ell \asymp r^{-1/2}\bar\rho_0$.

For (21.4.89)-type elements $r\ell^2 \le \rho^2$ and expression (21.4.74) becomes

$$C\mu h^{-3}\gamma r^{(2-q)_+}\rho^2 \times \Big((\mu h)^{-1}\rho^2 + 1\Big) \times \bar\ell^q;$$

multiplying it by $T_0 T_1^{-1} = Ch\rho^{-2}|\log h| \cdot \mu\gamma$ one gets

$$C\mu^2 h^{-2}\gamma^2 r^{(2-q)_+} \times \Big((\mu h)^{-1}\rho^2 + 1\Big) \times \bar\ell^q|\log h|,$$

which after summation over ρ becomes

$$(21.4.91)\qquad C\mu^2 h^{-2}\gamma^2 r^{(2-q)_+} \times \Big((\mu h)^{-1}\bar\rho^2 + 1\Big) \times \bar\ell^q|\log h|.$$

Meanwhile for (21.4.90)-type elements expression (21.4.74) becomes

$$C\mu h^{-3}\gamma r^{(2-q)_+}\bar{\rho}_0^2\bar{\ell}^q. \tag{21.4.92}$$

Let us plug $\bar{\rho}$, $\bar{\rho}_0$, $\bar{\ell}$ and γ; one can take

$$\gamma = \mu^{-1/2}r^{1/2},\ \bar{\rho}_0 = (\mu h r^{1/2})^{1/2}, \bar{\rho} = (\mu^{1/2}hr^{1/2})^{1/3} + \mu^{-1/4}r^{1/4} \text{ and}$$
$$\bar{\ell} = (\mu^{1/2}hr^{-1/2})^{1/2} + (\mu^{1/2}h)^{2/3}r^{-2/3} + \mu^{-1/2}r^{-1/2}$$

and compensate this by multiplication the result by $h^{-\delta''}$ with an arbitrarily small exponent $\delta'' > 0$.

Take first $\bar{\ell} = \bar{\ell}_1 := (\mu^{1/2}hr^{-1/2})^{1/2}$; note that then in (21.4.91), (21.4.92) factor $r^{-q/4}$ coming from $\bar{\ell}^q$ is more than compensated by the factor r coming from γ^2 or $\gamma\bar{\rho}_0^2$ respectively. Therefore summation with respect to γ, r results in the same expressions calculated as $r = 1$, $\gamma = \mu^{-1/2}$, $\bar{\ell} = \bar{\rho}_0 = (\mu^{1/2}h)^{1/2}$ and $\bar{\rho} = (\mu^{1/2}h)^{1/3} + \mu^{-1/4}$:

$$Ch^{-3}\Big((\mu^{1/2}h)^{2/3} + \mu^{-1} + \mu h\Big)(\mu^{1/2}h)^{q/2} \times h^{-\delta''}, \tag{21.4.93}$$

$$C\mu^{1/2}h^{-3}(\mu^{1/2}h)^{(2+q)/2} \times h^{-\delta''}. \tag{21.4.94}$$

One can see easily that both these expressions do not exceed

(a) $C\big(\mu^{-1/2}h^{-3} + \mu^{3/2}h^{-3/2}\big)$ as $q = 1$;

(b) $C\big(\mu^{-1/2}h^{-3} + \mu^{1/2+\delta''}h^{-2}\big)$ as $q = 2$;

(c) $C\mu^{-1/2}h^{-3}$ as $q = 3$.

However, one should consider (21.4.91) with $\bar{\ell} = \bar{\ell}_2 := (\mu^{1/2}h)^{2/3}r^{-2/3}$ and $\bar{\ell} = \bar{\ell}_3 := \mu^{-1/2}r^{-1/2}$; as $q = 1$ one can take again $r = 1$ obviously; as $q = 2$ it is not so but one can take then by $q = 9/5$ arriving to $O(\mu^{-1/2}h^{-3})$.

Then combining with (21.4.88) we arrive to

Proposition 21.4.14. *The total contribution to the remainder of the zone* $\mathcal{Z}'_{\mathsf{out}}$ *does not exceed* $C\mu^{-1/2}h^{-3} + C\mu^{3/2}h^{-3/2}$ *under assumption* $(21.4.50)_1$, $C\mu^{-1/2}h^{-3} + C\mu^{3/2}h^{-1-\delta}$ *under assumption* $(21.4.50)_2$ *and* $C\mu^{-1/2}h^{-3}$ *under assumption* $(21.4.50)_3$.

Remark 21.4.15. The main part of this asymptotics is given by expression (21.1.2) with $T = \bar{T}_0$.

21.4.3 Estimates in the Inner Zone

Now we want to consider the *inner zone*

$$\mathcal{Z}_{\mathsf{inn}} := \bigl\{\mathsf{dist}(x,\Sigma) \le \bar{\gamma}_0 = c\mu^{-1/2}\cdot \mathsf{dist}(x,\Lambda)^{1/2}\bigr\}, \tag{21.4.95}$$

in turn consisting of the *inner bulk zone*

$$\mathcal{Z}_{\mathsf{inn},II} := \mathcal{Z}_{\mathsf{inn}} \cap \bigl\{|Z_1|\cdot \mathsf{dist}(x,\Lambda) \le \epsilon\mu\cdot \mathsf{dist}(x,\Sigma)^2\bigr\}, \tag{21.4.96}$$

which mimics the outer (bulk) zone $\mathcal{Z}_{\mathsf{out}}$ and the *true inner zone*

$$\mathcal{Z}_{\mathsf{inn},I} := \mathcal{Z}_{\mathsf{inn}} \cap \bigl\{|Z_1|\cdot \mathsf{dist}(x,\Lambda) \ge \epsilon\mu\cdot \mathsf{dist}(x,\Sigma)^2\bigr\}, \tag{21.4.97}$$

which mimics the inner zone for 2-dimensional Schrödinger operator. One needs to remember that trajectories can leave one of them and enter another one after a while.

Note first that the inner core is already covered by Proposition 21.4.12, so in the definition of the inner zone we can include condition $\mathsf{dist}(x,\Lambda)\ge \mu^{-1/4}$ and therefore use canonical form (21.4.30) there. Actually using the same method as in the proof of Proposition 21.4.12, one can provide estimate $O(\mu h^{-3}r^2\gamma^2) = O(h^{-3}r^3)$ thus covering even $\mathcal{Z}_{\mathsf{inn}}\cap\{\mathsf{dist}(x,\Lambda)\le \mu^{-1/6}\}$ but we do not need this.

Estimates in the Inner Zone. I

We start from the inner bulk zone $\mathcal{Z}_{\mathsf{inn},II}$. Let $|Z_1|\asymp \rho$, $\rho r\le \epsilon\mu\gamma^2$ and condition (21.4.82) be fulfilled. Then exactly as in the outer zone the drift speed is $\asymp \mu^{-1}\rho^2 r\gamma^{-2}\le c\rho$ and evolution speed with respect to hD_4 does not exceed c; then for time $T_1 = \epsilon\rho r$ dynamics remains in $\mathcal{Z}_{\mathsf{inn},II}$. Therefore in the domain where condition (21.4.82) is fulfilled and $\rho\ge C(\mu h|\log h|)^{1/2}$ one can take $T_1=\epsilon\rho r$ and $T_0 = Ch|\log h|$; however, in the estimates this logarithmic factor is not needed.

Therefore the contribution to the remainder of this domain intersected with $\mathcal{Z}_{(r,\gamma,\rho)}$ does not exceed $Ch^{-3}\gamma T_1^{-1}r^2\rho^2 = C\mu^{-1/2}h^{-3}r^2\rho$ and the summation with respect to (r,γ,ρ) results in $O(\mu^{-1/2}h^{-3})$.

On the other hand, consider the domain where condition (21.4.82) is violated, but still $\rho\ge\bar{\rho}_1$. The contribution to the remainder of this domain intersected with $\mathcal{Z}_{(r,\gamma,\rho)}$ does not exceed $C\mu h^{-3}\gamma^2 r^2\rho^2$ where two factors γ come as the width of the strip and the part of $T_1^{-1}\asymp\mu\gamma$. The summation with respect to (r,γ,ρ): $r\rho^2\le c\gamma$ results in $C\mu^{-1/2}h^{-3}$.

Further, consider domain where condition (21.4.83) is violated but still $\rho \ge \bar\rho_1$. In the similar manner one can estimate its contribution to the remainder by $C\mu h^{-3}\gamma_0^2(\mu^{1/2}h|\log h|)^{2/3}$ which is $o(\mu^2h^{-2}+\mu^{-1/2}h^{-3})$ for sure and is $O(\mu^{-1/2}h^{-3})$ as $\mu \le C(h|\log h|)^{-4/5}$.

Finally, contribution to the remainder of the domain where $\rho \le \bar\rho_1$ does not exceed $C\mu\gamma\bar\rho_1^2 = C\mu^{3/2}h^{-2}|\log h|$.

Thus we arrive to

Proposition 21.4.16. *(i) Contribution of $\mathcal{Z}_{\mathsf{inn},II}$ to the remainder is $O(\mu^2h^{-2}+\mu^{-1/2}h^{-3})$ for sure.*

(ii) Furthermore, this contribution is is $O(\mu^{-1/2}h^{-3})$ as $\mu \le C(h|\log h|)^{-1/2}$.

(iii) Again the main part of this asymptotics is given by expression (21.1.2).

Estimates in the Inner Zone. II

Again, the estimate achieved in Proposition 21.4.16 is good in the general case but should be improved under non-degeneracy condition as

$$c(h|\log h|)^{-1/2} \le \mu \le Ch^{-1}. \tag{21.4.98}$$

Again one should consider regular final elements and singular ones and we consider only latter. Further, introducing the scaling function ℓ_n by (21.4.67) we can define T_0 and T_1 by (21.4.68), (21.4.69) as (21.4.70) holds; furthermore, estimate (21.4.71) holds.

Further, if condition (21.4.83) is fulfilled, we can increase T_1 to $T_2 = \epsilon\ell$ since on this time interval both $|\nabla_{x_1,x_4,\xi_4}W_n|$ and $|W_n|$ change by no more than $\epsilon_1 \min(\ell, r)$.

Then repeating the arguments of Subsubsection 21.4.2.2 we find that the contribution of this part of $\mathcal{Z}'_{\mathsf{inn},II}$ to the remainder does not exceed expression similar to (21.4.85) but with $\mu^{-1}\gamma^{-2}$ replaced by 1:

$$\begin{aligned} C\mu h^{-3}\gamma r^{(2-q)_+}(\rho^2+r\ell^2) \times \Big(C_0(\mu h)^{-1}(\rho+r\ell)^2+1\Big) \\ \times \ell^q \times h(\rho^2+r\ell^2)^{-1}\times \ell^{-1} \\ = Ch^{-3}\gamma r^{(2-q)_+}\Big((\rho+r\ell)^2+\mu h\Big)\ell^{q-1}. \end{aligned} \tag{21.4.99}$$

Then the sum with respect to (ℓ,ρ,r)-partition with $\rho \ge \ell$ does not exceed $Ch^{-3}\gamma$ as $q \ge 2$ and $Ch^{-3}\gamma|\log h|$ as $q = 1$ and one can get rid of logarithmic factor exactly as in the analysis in $\mathcal{Z}'_{\mathsf{out},II}$.

Furthermore, if condition (21.4.82) is fulfilled instead of (21.4.83) and $\rho \ge R^{1/2}\ell$, we can increase T_1 to $T_2 = \epsilon\rho$ and the contribution of this part of $\mathcal{Z}'_{\mathsf{inn},II}$ to the remainder does not exceed expression similar to (21.4.87) but with $\mu^{-1}\gamma^{-2}$ replaced by 1:

$$\begin{aligned}(21.4.100)\quad C\mu h^{-3}\gamma r^{(2-q)_+}(\rho^2+r\ell^2)\times \Big(C_0(\mu h)^{-1}(\rho+r\ell)^2+1\Big)\\ \times \ell^q \times h(\rho^2+r\ell^2)^{-1}\times \rho^{-1}\\ = Ch^{-3}\gamma r^{(2-q)_+}\Big(\rho^2+\mu h\Big)\ell^q\rho^{-1}.\end{aligned}$$

Summation with respect to (ℓ,ρ,r)-partition results in $Ch^{-3}\gamma + C\mu h^{-2}\gamma|\log h|$. Therefore the sum with respect to γ-partition with $\rho \ge \ell$ does not exceed $C\mu^{-1/2}h^{-3}$ as $q \ge 2$ and $\mu^{-1/2}h^{-3} + C\mu^{1/2}h^{-2}|\log h|$ as $q = 1$.

On the other hand, due to the same arguments as in Subsubsection 21.4.2.3 the contribution to the remainder of the domain where both conditions (21.4.82) and (21.4.83) are violated but (21.4.70) still holds does not exceed (21.4.91). Then the summation with respect to (ℓ,ρ,r,γ) partition results again in $C\mu h^{-2}(\mu^{1/2}h|\log h|)^{q/2} + O(\mu^{-1/2}h^{-3})$.

Finally, contribution of the domain where (21.4.70) fails is tackled in the same way as in Subsubsection 21.4.2.3 and estimated by (21.4.92).

So, we arrive to the following copy-cat of Proposition 21.4.14 and Remark 21.4.15:

Proposition 21.4.17. *The total contribution to the remainder of the zone* $\mathcal{Z}_{\mathsf{inn},II}$ *does not exceed* $C\mu^{-1/2}h^{-3} + C\mu^{3/2}h^{-3/2}$ *under assumption* $(21.4.50)_1$, $C\mu^{-1/2}h^{-3} + C\mu^{3/2}h^{-1}|\log h|$ *under assumption* $(21.4.50)_2$ *and* $C\mu^{-1/2}h^{-3}$ *under assumption* $(21.4.50)_3$.

Again the main part of this asymptotics is given by expression (21.1.2).

Estimates in the Inner Zone. III

Now let us consider the *true inner zone* $\mathcal{Z}_{\mathsf{inn},I}$ defined by (21.4.99). The crucial difference between this zone and $\mathcal{Z}_{\mathsf{out}} \cap \mathcal{Z}_{\mathsf{inn},II}$ is that in the classical evolution magnitude of $\mathsf{dist}(x,\Sigma)$ is not necessarily preserved[27)].

Recall that this subzone (as the whole inner zone) should be studied as $r = \mathsf{dist}(x,\Lambda) \ge c\mu^{-1/4}$. Also recall that the contribution of

[27)] As $|Z_1|\cdot \mathsf{dist}(x,\Lambda) \ge C\mu\cdot \mathsf{dist}(x,\Sigma)^2$ it is not preserved for sure; in the rest of this zone variation of $\mathsf{dist}(x,\Sigma)$ is of the magnitude of $\mathsf{dist}(x,\Sigma)$.

the subzone $\{|Z_1| \le C(\mu h \log h)^{1/2}\}$ to the remainder does not exceed $C\mu h^{-3}\gamma \times \mu h|\log h| = C\mu^{3/2}h^{-2}|\log h|)$ which is $O(\mu^2 h^{-2})$ for sure and $O(\mu^{-1/2}h^{-3})$ as $\mu \le c(h|\log h|)^{-1/2}$.

Let us introduce $\gamma = \mu^{-1/2}(r\rho)^{1/2}$; then in the classical evolution γ is the magnitude of $\max \operatorname{dist}(x, \Sigma)$ along the cyclotron movement. Note that the contribution of subzone $\{(\mu h|\log h|)^{1/2} \le |Z_1| \le \rho\}$ to the remainder does not exceed $C\mu h^{-3}\gamma^2\rho^2 = Ch^{-3}\rho^3$ which sums to $O(\mu^{-1/2}h^{-3})$ in subzone $\{\rho \le c\mu^{-1/6}|\log h|^{-1/3}\}$.

Let us consider first the general case of $q = 0$ when our goal is remainder estimate $O(\mu^{-1/2}h^{-3}+\mu^2 h^{-2})$. Since in this case the total contribution of the zone $\mathcal{Z}_{\mathsf{inn},I} \cap \{|Z_1| \ge C(\mu h|\log h|)^{1/2}\}$ to the remainder is $O(h^{-3})$, one needs to analyze only case $\mu \le h^{-1/2}$ and only subzone $\{\rho \ge c(\mu^{-1/6} + \mu^{2/3}h^{1/3})\}$.

We are going to prove that the contribution of $\mathcal{Z}_{\mathsf{inn},I}\cap\{\rho \ge C(\mu h|\log h|)^{1/2}\}$ to the remainder does not exceed $C\mu^{-1/2}h^{-3} + C(\mu^{1/2}h|\log h|)^{1/2}h^{-3}$ (see Proposition 21.4.19) but we prefer a bit less direct way to do this; we are concentrating on this zone due to the previous remarks and because we do not have non-degeneracy condition at the moment. Thus one can take $T_0 = Ch|\log h|$ and $T_1 = \epsilon\mu^{-1/2}\gamma^{-1} = \epsilon\mu^{-1}(\rho r)^{-1}$. Let us try to increase it.

According to the series of propositions of Subsubsection 21.2.4 the drift speed in the inner zone is $\kappa r\rho(\xi_3 - k^*\rho) + O(\mu^{-1/2})$. Then the shift during one cyclotron movement is $\asymp r\rho(\xi_3 - k^*\rho)T_1$ provided

$$r\rho|\xi_3 - k^*\rho| \ge C\mu^{-1/2} \tag{21.4.101}$$

and it is observable as long as

$$r\rho|\xi_3 - k^*\rho| \times \mu^{-1/2} \times |\xi_3 - k^*\rho| \ge Ch|\log h|$$

or equivalently

$$\begin{aligned} |\xi_3 - k^*\rho| &\ge C(r\rho)^{-1/2}(\mu h\gamma|\log h|)^{1/2} \\ &= C(r\rho)^{-1/4}(\mu^{1/2}h|\log h|)^{1/2}. \end{aligned} \tag{21.4.102}$$

Both conditions (21.4.101), (21.4.102) are fulfilled as

$$|\xi_3 - k^*\rho| \ge \Delta := c(r\rho)^{-1/4}(\mu^{1/2}h|\log h|)^{1/2} + c\mu^{-1/2}(r\rho)^{-1/2}. \tag{21.4.103}$$

Then as (21.4.103) is fulfilled[28)] one can upgrade T_1 to $T_2 = \epsilon r|\xi_3 - k^*\rho|$ because then not only magnitude of ρ but also of $|\xi_3 - k^*\rho|$ will be pre-

[28)] This makes sense as $\Delta \le \rho$: i.e.

$$\rho \ge \bar\rho_2 := r^{-1/5}(\mu^{1/2}h|\log h|)^{2/5} + \mu^{-1/3}r^{-1/3}; \tag{21.4.104}$$

otherwise one needs to take $\Delta = c\rho$, thus redefining $\Delta := \min(\Delta, \bar\rho_2)$.

served during the evolution. Furthermore, taking the evolution in the right time direction it could be increased to $T_2^* = \epsilon r|\xi_3 - k^*\rho|^{1-\delta'}$ exactly as in Chapter 14. Then the standard arguments imply

(21.4.105) The contribution of the subzone of $\mathcal{Z}_{\mathsf{inn},I}$, where condition (21.4.103) is fulfilled, intersected with $\{\rho \ge C(\mu h|\log h|)^{1/2}\}$, to the remainder does not exceed $C\mu^{1/2}h^{-3}$.

So, one needs to study *near periodic zone*

$$\mathcal{Z}_{\mathsf{per}} = \big\{|\xi_3 - k^*\rho| \le \Delta\big\}, \tag{21.4.106}$$

intersected with $\{|Z_1| \asymp \rho\} \cap \{\mathsf{dist}(x,\Lambda) \asymp r\}$ as long as

$$\rho \ge C(\mu h|\log h|)^{1/2} + \bar\rho_2.$$

Note however, that if $r \le \epsilon$ then $|\nabla\omega| \asymp r^{-1}\omega$ and $|\mathsf{Hess}\,\omega| \asymp r^{-2}\omega$ and therefore in the rescaled coordinates $|\nabla_{x_3,x_4,\xi_4} W_n| \asymp \rho^2$ as $r \le \epsilon$ and $\rho^2 \ge Cr$ and $|\mathsf{Hess}_{x_3,x_4,\xi_4}\, W_n| \asymp \rho^2$ as $r \le \epsilon$ and $\rho \ge Cr$. In the first case periodicity is broken for sure and in the second case periodicity is not broken only as $|\nabla W_n| \le C(\mu\gamma h)^{1/2}$ which in intersection with $\mathcal{Z}_{\mathsf{per}}$ has measure not exceeding $C\mu^{1/2}h\gamma$ instead of $C(\mu^{1/2}h)^{1/2}\gamma$ and since one can take $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ here for sure the contribution of the reduced periodic zone to the remainder does not exceed $Ch^{-4} \times (\mu^{1/2}h|\log h|)\gamma \times \mu h\gamma \le C\mu^{1/2}h^{-2}|\log h|$ thus implying

Proposition 21.4.18. *The contribution of*

$$\mathcal{Z}_{\mathsf{inn},I} \cap \{|Z_1| \ge C(\mu h|\log h|)^{1/2} + Cr\}$$

to the remainder does not exceed $C\mu^{-1/2}h^{-3}$.

Again the main part of this asymptotics is given by expression (21.1.2).

Therefore, only case $\rho \le Cr$ and thus $\gamma \le C\mu^{-1/2}r$ remains to be analyzed.

Proposition 21.4.19. *The contribution of* $\mathcal{Z}_{\mathsf{inn},I} \cap \{|Z_1| \ge C(\mu h|\log h|)^{1/2}\}$ *to the remainder does not exceed* $C\mu^{-1/2}h^{-3} + C(\mu^{1/2}h|\log h|)^{1/2}h^{-3}$.

Again the main part of this asymptotics is given by expression (21.1.2).

Proof. Now we are concentrating only on even more reduced zone. In particular, (21.4.104) implies $r \ge (\mu^{1/2}h|\log h|)^{1/3} + \mu^{-1/4}$.

One can take $T_1 = \epsilon\mu^{-1/2}(r\rho)^{-1/2}$ as condition (21.4.103) fails. Then the contribution of $\mathcal{Z}_{\mathsf{per}}$ to the remainder does not exceed

$$C\mu h^{-3}\gamma^2 r^2\rho\Delta = Ch^{-3}r^3\rho^2\Delta = Ch^{-3}r^3\rho^2\Big(c(r\rho)^{-1/4}(\mu^{1/2}h|\log h|)^{1/2} + c\mu^{-1/2}(r\rho)^{-1/2}\Big). \tag{21.4.107}$$

Obviously when taking sum with respect to (r,ρ) partition the latter expression sums to itself with $\bar{\Delta} = \Delta|_{r=1,\rho=1,\gamma=\mu^{-1/2}}$:

$$\bar{\Delta} = C(\mu^{1/2}h|\log h|)^{1/2} + C\mu^{-1/2}. \tag{21.4.108}$$

Then expression (21.4.107) becomes $O\big(\mu^{-1/2}h^{-3} + h^{-3}(\mu^{1/2}h|\log h|)^{1/2}\big)$.

Finally, one can check easily that the contribution of subzone $\big\{\bar{\rho}_2 \ge \rho \ge C(\mu h|\log h|)^{1/2}\big\}$ is just $O(\mu h^{-3}\gamma^2\bar{\rho}_2^2)$ which is less than this. □

Estimates in the Inner Zone. IV

Again we would like to improve the remainder estimate achieved in Proposition 21.4.19 under non-degeneracy condition $(21.4.50)_q$ with $q \ge 1$ also getting rid of assumption $|Z_1| \ge C(\mu h|\log h|)^{1/2}$. In the analysis below instead of W_n we consider its pullback $\omega(V - (2n+1)f_2\mu h)$ in the rescaled coordinates x' on Σ; it is useful for Hessians but it transforms into properties of W_n since we are interested only in the measures of sets $|\nabla W_n| \asymp \lambda$.

Proposition 21.4.20. *As $\mu \le ch^{-1}|\log h|^{-K}$ the contribution of $\mathcal{Z}_{\mathsf{inn},I} \cap \{|Z_1| \ge Cr\}$ to the remainder does not exceed $C\mu^{-1/2}h^{-3}$.*

Proof. Let us introduce

$$\ell = \ell_n = \epsilon r^{-1}|\nabla_{x_3,x_4,\xi_4} W_n| + \bar{\ell}, \tag{21.4.109}$$

and

$$\varrho = \varrho_n = \epsilon|\xi_3 - k^* W_n^{1/2}| + \Delta. \tag{21.4.110}$$

Then the contribution of (r,ρ,ℓ)-elements to the asymptotics does not exceed (21.4.74)-like expression

$$C\mu h^{-3}\gamma r^2(\rho^2 + r\ell^2) \times \Big(C_0(\mu h)^{-1}(\rho + r\ell^2) + 1\Big); \tag{21.4.111}$$

if $\rho^2 + r\ell^2 \le C\mu h\gamma|\log h|$ then also $r^2 \le C\mu h\gamma|\log h|$ and (21.4.111 does not exceed $C\mu^3 h^{-1}\gamma^3|\log h|^2 \le C\mu^{3/2}h^{-1}|\log h|^2$. So let us consider $\rho^2 + r\ell^2 \ge C\mu h\gamma|\log h|$.

If $\rho^2 \ge Cr$ then periodicity is broken for sure (since $\nabla W_n| \ge \epsilon\rho^2 - Cr$ and one can instantly upgrade $T_0 = Ch|\log h|(\rho^2 + r\ell^2)^{-1}$ to $T_2 = \epsilon$. Otherwise it could be done as $\ell \ge C(\mu h|\log h|)^{1/2}$. Then contribution of such elements to the remainder does not exceed

$$\begin{aligned}(21.4.112)\quad C\mu h^{-3}\gamma r^2(\rho^2 + r\ell^2) \times \Big(C_0(\mu h)^{-1}(\rho + r\ell^2) + 1\Big) \\ \times h|\log h|(\rho^2 + r\ell^2)^{-1} \\ = C\mu h^{-2}\gamma r^2 \times \Big(C_0(\mu h)^{-1}(\rho + r\ell^2) + 1\Big)|\log h|\end{aligned}$$

because $|\operatorname{Hess} W_n| \ge \epsilon\rho^2 - Cr^2$ and one can delete safely logarithmic factor because it is not in the estimate of the Fourier transform.

Otherwise one can take $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ and then one gets

$$\begin{aligned}(21.4.113)\quad C\mu h^{-3}\gamma r^2(\rho^2 + r\ell^2) \times \Big(C_0(\mu h)^{-1}(\rho + r\ell^2) + 1\Big) \\ \times h|\log h|(\rho^2 + r\ell^2)^{-1}\mu\gamma \times \ell\Delta \\ = C\mu^2 h^{-2}\gamma^2 r^2 \times \Big(C_0(\mu h)^{-1}(\rho + r\ell^2) + 1\Big)\bar{\ell}\Delta|\log h| \le Ch^{-3} \times (\mu^{1/2}h) \\ = C\mu^{1/2}h^{-2}|\log h|^2\end{aligned}$$

where one copy of $(\mu^{1/2}h|\log h|)^{1/2}$ comes as the width of zone with respect to ξ_3 and another as the width with respect to $|\nabla W_n|$. □

Proposition 21.4.21. *Let condition* $(21.4.50)_1$ *be fulfilled. Then*

(i) The total contribution of $\mathcal{Z}_{\mathsf{inn},I} \cap \{|Z_1| \le \epsilon r\}$ *to the remainder does not exceed* $C\mu^{-1/2}h^{-3}$ *as* $\mu \le h^{-1}|\log h|^{-K}$.

(ii) The total contribution of $\mathcal{Z}_{\mathsf{inn},I} \cap \{|Z_1| \ge \epsilon r\}$ *to the remainder does not exceed*

$$(21.4.114)\qquad C\mu^{-1/2}h^{-3} + C\mu^{5/4}h^{-3/2}|\log h|^{1/2};$$

in particular it is $O(\mu^{-1/2}h^{-3})$ *as* $\mu \le h^{-6/7}|\log h|^{-2/7}$ [29].

[29] Actually We are going to prove later that one can drop logarithmic factors. In this case estimate cannot be improved without either additional assumptions or correction terms.

Again the main part of this asymptotics is given by expression (21.1.2).

Proof. Note that the most delicate is the case $\epsilon r \le \rho \le cr$ when even condition $(21.4.50)_2$ does not yield $(21.4.50)_1$ for W_n [30)]

(a) Consider first $r \le \epsilon_1$, $\rho \asymp r$, $\gamma \asymp \mu^{-1/2} r^{1/2} \rho^{1/2} \asymp \mu^{-1/2} r$.

Let us introduce a scaling function

$$\ell_n = \epsilon r^{-1} |\nabla W_n| + \frac{1}{2}\bar{\ell}, \qquad \bar{\ell} = C(\mu^{1/2} h |\log h|)^{1/2} \tag{21.4.115}$$

and the corresponding subpartition as $\rho \le cr$. Note that actually $\ell \ge \bar{\ell} = C(\mu\gamma r^{-1} h |\log h|)^{1/2}$ is the condition that for time $T_1 = \epsilon\mu^{-1}\gamma^{-1}$ the shift is observable. Then exactly as before

(21.4.116) The total contribution to the remainder of all ℓ-elements with $\ell \ge \bar{\ell}$, $\rho \asymp r$ does not exceed $C\mu^{-1/2} h^{-3}$.

So only $\ell \le \bar{\ell}$ subelements remain to be considered. Note that after rescaling $|\nabla\omega f_2| \asymp 1$ and therefore

(21.4.117) For each $\bar{\ell}$-subelement there exists number $\bar{n}$ such that $|\nabla\omega(V - (2n+1) f_2 \mu h| \ge \bar{\ell}$ as $|n - \bar{n}| \ge C\bar{\ell}(\mu h)^{-1}$ and therefore over each $\bar{\ell}$-element there are no more than $M = C\bar{\ell}(\mu h)^{-1}$ other appropriate indices.

Therefore the total contribution of them to the remainder does not exceed

$$\begin{aligned} &C\mu h^{-3}\gamma r^2(\rho^2 + r\ell^2) \times \Big(C_0(\mu h)^{-1}\bar{\ell} + 1\Big) \\ &\qquad \times h(\rho^2 + r\ell^2)^{-1} \times \mu\gamma\Delta \asymp C\mu h^{-2} r^3 \times \Big(\bar{\ell}^2(\mu h)^{-1} + \bar{\ell}\Big) \end{aligned} \tag{21.4.118}$$

since $\Delta \asymp \bar{\ell}$.

After summation over r-partition one gets $C\mu^{1/2} h^{-3} |\log h| + C\mu h^{-2}\bar{\ell}$ which is exactly (21.4.114).

[30)] However, $(21.4.50)_1$ with the first and the second order derivatives taken only with respect to Λ implies such condition for W_n thus eliminating vicinity of Λ from the contributing more than $C\mu^{-/2} h^{-3}$ to the remainder.

(b) Consider now $r \asymp 1$, $\rho \asymp 1$, $\gamma \asymp \mu^{-1/2}$. One needs to recover an extra factor μh in comparison with estimate of Proposition 21.4.19 and only case $\mu \ge h^{\delta-2/3}$ needs to be considered.

Let us assume first that

$$|\operatorname{Hess}\Big(\frac{V}{f_2}\Big)| \ge \epsilon_0 \tag{21.4.119}$$

and let us fix

$$\zeta \ge \bar{\zeta} = C\big(\mu^{1/2}h|\log h|\big)^{\frac{1}{3}} + \epsilon\mu h \tag{21.4.120}$$

and examine subzone

$$\Omega_\zeta := \big\{\exists n \in \mathbb{Z}^+ : \ |\operatorname{Hess} W_n| \asymp \zeta\big\}. \tag{21.4.121}$$

Let us introduce ζ-admissible partition in this zone; as $r \le \zeta$ one should replace it by r-admissible partition. Note that one can assume that

(21.4.122) For each element of such partition no more than $M := C_0\zeta(\mu h)^{-1}$ magnetic numbers n satisfy condition $|\operatorname{Hess} W_n| \asymp \zeta$.

Indeed, if $|\nabla\omega f_2| \asymp 1$ then arguments of (a) work. Further, if $|\nabla\omega f_2| \le \epsilon_1$ but $|\nabla f_2^{-1}V| \asymp 1$ then $|\nabla\omega V| \asymp 1$ and then $|\nabla W_n| \asymp 1$ for all $n \le C(\mu h)^{-1}$ and everything is easy. So, let both $|\nabla\omega f_2| \le \epsilon_1$ and $|\nabla f_2^{-1}V| \le \epsilon_1$. Then as $|\operatorname{Hess}(\omega f_2)| \asymp 1$ then (21.4.122) is obviously true.

Finally, if $|\operatorname{Hess}(\omega f_2)| \le \epsilon_1$ then (21.4.119) implies that $|\operatorname{Hess}(\omega V)| \asymp 1$ and then $|\operatorname{Hess} W_n| \asymp 1$ for all $n \le C(\mu h)^{-1}$.

Then for each index n described (21.4.122) all the above arguments could be repeated but with

$$\ell = \zeta^{-1}|\nabla W_n| + \frac{1}{2}\bar{\ell}, \qquad \bar{\ell} := C(\zeta^{-1}\mu h|\log h|)^{1/2} \tag{21.4.123}$$

leading to the contribution to the remainder

$$C\mu^2h^{-3}\gamma^2 \times \zeta(\mu h)^{-1} \times h|\log h| \times \bar{\ell}\Delta \asymp C\mu^{1/2}h^{-2}|\log h|^2 \tag{21.4.124}$$

since $\zeta\bar{\ell} = \Delta$.

Therefore we are left with $\zeta = \bar{\zeta}$ and only with indices n satisfying $|\operatorname{Hess} W_n| \le \bar{\zeta}$. Here one needs to consider only subelements with $\ell \le \bar{\ell}$ i.e. with

$$|\nabla W_n \le C\bar{\zeta}^2. \tag{21.4.125}$$

Thus we are looking on $\bar{\zeta}$ partition elements satisfying this condition.

Assume first that $|\operatorname{Hess}(\omega f_2)| \asymp 1$. Let us introduce scaling function

$$\ell = |\nabla \omega f_2| + \frac{1}{2}\bar{\ell}; \tag{21.4.126}$$

then as $\ell \ge \bar{\ell}$ over each such subelement leave no more than $C\bar{\zeta}^2/(\mu h\ell)$ indices n satisfying (21.4.126) and then (21.4.124) is replaced by

$$C\mu^2 h^{-3}\gamma^2 \times \bar{\zeta}^2\ell^{-1}(\mu h)^{-1} \times h|\log h| \times \Delta \asymp Ch^{-3}\Delta\bar{\zeta}^2\ell^{-1}|\log h|; \tag{21.4.127}$$

alternatively one can replace (21.4.124) by

$$C\mu^2 h^{-3}\gamma^2 \times \bar{\zeta}(\mu h)^{-1} \times h|\log h| \times \ell\Delta \asymp Ch^{-3}\Delta\bar{\zeta}\ell|\log h| \tag{21.4.128}$$

where ℓ is a width of of the strip where $|\nabla\omega f_2| \le \ell$.

Comparing (21.4.127) and (21.4.128) one can see that the best choice of $\bar{\ell}$ is $\bar{\ell} = \bar{\zeta}^{1/2}$; then both of them become $Ch^{-3}\Delta\bar{\zeta}^{3/2}|\log h| \asymp C\mu^{1/2}h^{-3}|\log h|^2$.

On the other hand, if $|\operatorname{Hess}(\omega f_2)| \le \epsilon_1$ then due to the arguments proving (21.4.122) this analysis is not needed.

Furthermore, if (21.4.119) is replaced by condition

$$|\nabla\Big(\frac{V}{f_2}\Big)| \ge \epsilon_0 \tag{21.4.129}$$

the analysis is essentially the same, but simpler, with (21.4.121)–(21.4.122) replaced by

$$\zeta \ge \bar{\zeta} = c(\mu^{1/2}h|\log h|)^{\frac{1}{2}} + \mu h, \tag{21.4.130}$$

$$\Omega_\zeta := \big\{\exists n \in \mathbb{Z}^+ : \ |\nabla W_n| \asymp \zeta\big\}, \tag{21.4.131}$$

respectively and in (21.4.123) $\operatorname{Hess} W_n| \asymp \zeta$ is replaced by $|\nabla W_n| \asymp \zeta$.

(c) Finally as $\rho \le \epsilon r$ condition $(21.4.50)_1$ translates for a similar condition to W_n and then one can apply the arguments similar to those of Proposition 21.4.20 which imply (i). We leave easy details to the reader.

(d) Analysis of $\rho^2 \le c(\mu h|\log h|)^{1/2}$ is also easy. Let us introduce ℓ by (21.4.115). Then as $\rho^2 + r\ell^2 \le C\mu^{1/2}h|\log h|$ factor $(\rho^2 + r\ell^2)$ takes care of everything; otherwise factor Δ is retained but factor $(\rho^2 + r\ell^2)$ translates in the end into extra factor $\mu h|\log h$. We leave easy details to the reader. □

Estimates in the Inner Zone. V

Now, the better remainder estimate should be pursued only as

$$\mu \ge h^{-6/7}|\log h|^{-2/7}. \tag{21.4.132}$$

Further, as $q = 0, 1$ the contribution of $\mathcal{Z}_{\mathsf{per}}$ to the remainder is better than the remainder estimates $O(\mu^{-1/2}h^{-3} + \mu^2 h^{-2})$, $O(\mu^{-1/2}h^{-3} + \mu^{3/2}h^{-2-\delta})$ and therefore only $q = 2, 3$ should be considered.

Moreover, it follows from the proof of Proposition 21.4.21 that if summation is taken over $\mathcal{Z}_{\mathsf{per}} \cap \{\mathsf{dist}(x, \Lambda) \le r\}$ then the second term in (21.4.114) would get an extra factor r^4 (from $r^2\gamma^2$) and therefore only zone $\mathcal{Z}_{\mathsf{per}} \cap \{\mathsf{dist}(x, \Lambda) \ge \bar{r} = \mu^{-1/16}|\log h|^{-1/8}\}$ should be considered.

Moreover, then $\bar{\zeta} \asymp \mu h$ (which is much larger than the first term in (21.4.119) and therefore for each $\bar{\zeta}$-partition subelement only one magnetic number n should be considered.

There is a minor problem as $\mu \ge h^{-1}|\log h|^{-K}$ because then contributions of $\{\rho \le \epsilon r\}$ and $\{\rho \ge Cr\}$ were estimated by $\mu^{1/2}h^{-2}|\log h|^K$; however, in this case there also factor r^2 at least coming if looking at $\mathcal{Z}_{\mathsf{per}} \cap \{\mathsf{dist}(x, \Lambda) \le r\}$ and therefore one needs to consider only $\mathcal{Z}_{\mathsf{per}} \cap \{\mathsf{dist}(x, \Lambda) \ge |\log h|^{-K}\}$. Then in the first case condition $(21.4.50)_2$ supplies factor $(\mu^{1/2}h|\log h)^{1/2}|\log h|^K$ which is more than enough to take care of $|\log h|^K$; however, we will just include both cases in the final analysis.

Then repeating all arguments of Subsubsections 14.3.4.3 and 14.3.4.4 with the obvious modifications, due to the presence of r (which is greater than $\bar{r} \ge \bar{r}$) and of $(x_2, \mu^{-1}hD_2)$ in all the operators, one can prove easily the following

Proposition 21.4.22. *Under assumption* $(21.4.50)_2$ *the total contribution of* $\mathcal{Z}_{\mathsf{inn},I} \cap \{|Z_1| \ge \epsilon\}$ *to the remainder does not exceed* $C\mu^{-1/2}h^{-3}$ *while the*

main part of the asymptotics is given by (21.1.2) *plus a correction term*

$$\int \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x',\tau)\psi(x')\,dx', \tag{21.4.133}$$

where temporarily

$$\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} := h^{-1}\int\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T}(t)-\bar{\chi}_{T_0}(t)\big)\big(\Gamma_x(uQ^t_y)\big)\Big)\,d\tau dx_1 \tag{21.4.134}$$

and in this formula one can choose arbitrarily

$$T_0 \in [Ch|\log h|, \epsilon' \mu^{-1/2}\gamma^{-1}], \tag{21.4.135}$$

$$T \ge Cr^{-1/2}(h|\log h|)^{1/2}\big(\max(\big|\xi_3 - k^*|Z_1|\big|, h^{1/2})\big)^{-1} \tag{21.4.136}$$

and pseudodifferential $Q \equiv I$ *in* $\mathcal{Z}_{\mathsf{per}} \cap \{\mathsf{dist}(x,\Lambda) \ge \bar{r}\}$ *and supported in the same zone, slightly inflated.*

In the next section this correction term will be rewritten in a more explicit form.

Conclusion

So, with the remainder estimates described in Theorems 21.5.23, 21.5.28 below asymptotics are derived where the main parts are given by rather implicit formula (21.5.1) below.

The analysis in framework of Theorem 21.5.30 is similar but much simpler. We leave it to the reader.

21.5 Calculations and Main Results

So, according to the previous Section 21.5, with the remainder estimates described there the main part of the asymptotics of $\int e(x,x,0)\psi(x)\,dx$ is given by

$$\sum_{\iota} h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar{\chi}_{T_\iota}(t)\Gamma\big(u\psi Q^t_{\iota y}\big)\Big)\,d\tau \tag{21.5.1}$$

where Q_ι form an appropriate partition of unity and $T_\iota \ge T_{(\iota)0}$ also described there.

In this section we will make all the calculations transforming implicit expression (21.5.1) to a more explicit form, namely to

$$\int \mathcal{N}^{\mathsf{MW}}(x,0)\psi(x)\,dx. \tag{21.5.2}$$

There are many methods to make a reduction and we will employ them depending on the power of the magnetic field and non-degeneracy condition.

Also we will calculate expression(21.4.127) in a more explicit form.

21.5.1 Temperate Magnetic Field

Temperate Magnetic Field. I

Recall that we proved that for $\mu \le h^{-\delta}$ the remainder estimate $O(\mu^{-1/2}h^{-3})$ holds while the main part is given by (21.1.2) with $T = \bar{T} := Ch|\log h|$. Now we want to prove the same under a larger upper bound for μ; further, increasing μ we want to recover a remainder estimate consistent with those in Theorems 21.5.23, 21.5.28, 21.5.30 while keeping the main part given by (21.1.2) with $T = \bar{T}$. To do this we need to estimate properly (21.2.23)-like correction term

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T'}(t)-\bar{\chi}_{T''}(t)\big)\big(\Gamma u Q_y^t\big)\Big)\,d\tau \tag{21.5.3}$$

with $T' = T_0$ derived in Section 21.4 and $T'' = \bar{T}$ [31]. This will let us to rewrite (21.1.2) as a Weyl expression, may be with $O(\mu^2h^{-2})$ correction. Here $Q = \psi$ but in the analysis below we will need more general PDOs.

This expression (21.5.3) is the sum of expressions of the type

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\big(\bar{\chi}_{2T}(t)-\bar{\chi}_{T}(t)\big)\Gamma u Q_y^t\Big)\,d\tau = iT^{-1}\Big(F_{t\to h^{-1}\tau}\chi_T(t)\Gamma u Q_y^t\Big)\Big|_{\tau=0} \tag{21.5.4}$$

with $\chi(t) = t^{-1}\big(\bar{\chi}(\frac{1}{2}t)-\bar{\chi}(t)\big)$ and $T = 2^k T''$, k running from 2 to $\lceil \log_2(T'/T'')\rceil$.

Proposition 21.5.1. *Let assumptions of Theorem 21.5.23 below with*

$$h^{-\delta} \le \mu \le \epsilon(h|\log h|)^{-1} \tag{21.5.5}$$

[31] However, in what follows we will consider some other parameters $T' > T''$.

be fulfilled and let Q *be supported in* $\{\mathsf{dist}(x,\Sigma)\le\gamma\}$ *with* $\gamma\ge\mu^{-1/2}$.

Then expression (21.5.3) *with* $T'=\epsilon\mu^{-1}\gamma^{-1}$ *and* $T''=\bar{T}$ *does not exceed* $C\mu^{-1/2}h^{-3}+C\mu^2h^{-2}$ [32].

Proof. Note first that expression (21.5.4) with $T\in[\bar{T},\epsilon\mu^{-1}]$ is negligible due to condition (21.2.92). So, until the end of the proof we can consider $T''=\epsilon\mu^{-1}$.

Further, note that, as Q is supported in $\{|Z_1|^2\ge C\mu h|\log h|\}$ expression (21.5.4) with $T\in[T'',T']$ is negligible as well. Then for a general PDO Q expression (21.5.4) does not exceed $C\mu^2h^{-2}|\log h|$.

Then proposition is proven as $\mu\le c(h|\log h|)^{-2/5}$ and until the end of the proof we can assume that

$$(h|\log h|)^{2/5}\le\mu\le\epsilon(h|\log h|)^{-1}. \tag{21.5.6}$$

Further, as Q is supported in $\{\mathsf{dist}(x,\Sigma)\le\bar{\gamma}_3=c|\log h|^{-1}\}$, expression (21.5.3) would not exceed $C\mu^2h^{-2}\bar{\gamma}_3|\log h|\asymp\mu^2h^{-2}$ and as Q is supported in $\{|Z_1|^2\le c\mu h\}$ expression (21.5.3) would not exceed $C\mu^2h^{-2}$ as well.

So, the only zone in question is

$$\big\{C_0\mu h\le\rho^2\le C\mu h|\log h|\big\}\cap\big\{\mathsf{dist}(x,\Sigma)\asymp\gamma,|Z_1|\asymp\rho\big\} \tag{21.5.7}$$

with $|\log h|^{-1}\le\gamma\le\epsilon$. In this zone one needs to consider expression (21.5.4).

Using precanonical form and decomposition (21.3.16) one can rewrite (21.5.4) as the sum of the similar expressions but with u,Q,Γ replaced by u_n, Q_n and Γ' respectively:

$$iT^{-1}\Big(F_{t\to h^{-1}\tau}\chi_T(t)\Gamma' u_nQ_{ny}^t\Big)\Big|_{\tau=0}. \tag{21.5.8}$$

From the decomposed problem

$$(hD_t-\mathcal{A}_n)u_{nn'}\equiv 0, \tag{21.5.9}$$

$$u_{nn'}|_{t=0}\equiv\delta_{nn'}\delta(x'-y') \tag{21.5.10}$$

one can prove not only that expression (21.5.8) is negligible as $T\ge T_\rho:=Ch\rho^{-2}|\log h|$ but also that its absolute value does not exceed $C\mu h^{-2}\gamma\rho^2\big(h\rho^{-2}T\big)^{-s}$

[32] Term $C\mu^{-1/2}h^{-3}$ is probably of no need in some estimates here and below but it is in the remainder estimate anyway.

as $t \le T_\rho$. The summation of this expression with respect to T from $\epsilon\mu^{-1}$ to ∞ results in $C\mu h^{-2}\gamma\rho^2\bigl(\mu h\rho^{-2}\bigr)^{-s}$.

Further, summation of the latter expression with respect to n results in

$$C\mu h^{-2}\gamma\rho^2\bigl(\mu h\rho^{-2}\bigr)^{-s} \times \rho^2(\mu h)^{-1} = Ch^{-3}\rho^4\bigl(\mu h\rho^{-2}\bigr)^{-s}$$

since no more than $\rho^2(\mu h)^{-1}$ numbers n violate the ellipticity of $\mathcal{A}_n$.

Finally, the summation with respect to $\rho \ge c(\mu h)^{1/2}$ results in $C\mu^2h^{-2}\gamma$. So, one can conclude that expression (21.5.3) with indicated T' and T'' by absolute value does not exceed $C\mu^2h^{-2}$. □

One can improve the above error estimate under nondegeneracy condition.

Proposition 21.5.2. *Let assumptions of Theorem 21.5.23 below and condition* (21.5.6) *be fulfilled. Further, let Q be supported in $\{\mathsf{dist}(x,\Sigma) \le \gamma\}$ with $\gamma \ge \mu^{\delta-1/2}$. Finally, let condition* $(21.4.52)_q$ *with $q = 1, 2$ be fulfilled.*

Then expression (21.5.3) *with $T' = \epsilon\mu^{-1}\gamma^{-1}$, $T'' = \bar{T}$ and Q supported in $\{\mathsf{dist}(x,\Sigma) \le \gamma\}$ does not exceed*

$$C\mu^{-1/2}h^{-3} + C(\mu h)^{2+q/2}|\log h|^K h^{-4}\gamma. \tag{21.5.11}_q$$

Proof. There is no need to consider the inner core. Further, due to Proposition 21.5.1 the case $\mu \le Ch^{-2/5}$ is already covered. So, let us assume that $\mu \ge h^{-2/5}$.

Consider precanonical form (21.3.17) and define $\ell = |\nabla_v^\#$, $\rho = |Z_1^\#|$. Then even as $\rho \le \bar{\rho} := C(\mu h|\log h|)^{1/2}$ but $\ell \ge \bar{\ell} := \bar{\rho}$ one can still trade $T' = \epsilon\mu^{-1}\gamma^{-1}$ to $T'' = \epsilon\mu^{-1}$ because then the shift for time $T \in [\epsilon\mu^{-1}, T'']$ is still observable. Here perturbation terms and their derivatives are at most $C\mu^{-2} \ll \bar{\ell}$.

On the other hand, the total contribution to the remainder of all partition elements with $\rho \le \bar{\rho}$, $\ell \le \bar{\ell}$, $\mathsf{dist}(x,\Sigma) \le \gamma$ does not exceed $C\bar{\rho}^2\bar{\ell}^{2+q}\gamma h^{-4}$ which is exactly expression $(21.5.11)_q$. □

Remark 21.5.3. While the error estimate of Proposition 21.5.1 is as good as we need in the general case, the error estimate of Proposition 21.5.2 is as good as we need under assumption $(21.4.52)_q$ only under some restrictions to μ and/or γ.

Temperate Magnetic Field. II

Now we want to trade $T'' = \epsilon\mu^{-1}\gamma^{-1}$ to a larger value T_0 which provides the remainder estimate derived in Section 21.4. For this we will need to use some canonical forms and thus different zones will be treated separately.

Let us start from the strictly outer zone.

Proposition 21.5.4. *Let assumptions of Theorem 21.5.23 below and condition* (21.5.5) *be fulfilled and let* Q *be supported in* $\mathcal{Z}^*_{\mathsf{out}} \cap \{\mathsf{dist}(x,\Sigma) \le \gamma\}$ *with* $\gamma \ge C_0\mu^{\delta-1/2}$. *Then*

(i) In the general case expression (21.5.3) *with* $T' = T_0$ *and* $T'' = \bar{T}$ *does not exceed*

$$(21.5.12)_q \quad C\mu^{-1/2}h^{-3} + C(\mu h)^{(4+q)/2}h^{-4}\gamma|\log h|^K + C(\mu h)^{(3+q)/2}h^{-4}\gamma^2|\log h|^K$$

with $q = 0$.

(ii) Under assumption $(21.4.52)_q$ *this expression does not exceed* $(21.5.12)_q$.

Proof. One needs to consider only Q supported in a zone in which in the proofs of Propositions 21.5.1 and 21.5.2 term (21.5.3) with $T' = \epsilon\mu^{-1}$ and $T'' = \bar{T}$ is negligible. Then we are going to prove remainder estimate$(21.5.12)_q$ without the second term.

(a) Assume first that Q is supported in $\mathcal{Z}_{(r,\gamma)} \subset \mathcal{Z}^*_{\mathsf{out},I}$.

Let us consider canonical form (21.3.54) and introduce scaling function $\ell = \ell^*$ by (21.4.40) and ℓ as the paragraph below that that. If $\ell \ge 1$ (i.e. $p \ge Cr^{-1}(\mu h)^{-1}$) we do not partition the "final" ball $B(0,1)$ corresponding to the original $(\gamma;\gamma r^{-1})$ element; otherwise we make ℓ-subpartition.

Then on any given ℓ subpartition element the propagation speed with respect to x_3 does not exceed $\mu^{-1}\gamma^{-2}r\ell_p$; further, the propagation speed is of this magnitude as $|\partial_{\xi_3}H_{pn}| \asymp \ell$; in this case the shift for time T is observable as it satisfies the logarithmic uncertainty principle

$$\mu^{-1}\gamma^{-2}\ell \times T \times \ell \ge Cr^2\mu^{-1}h\gamma^{-3}|\log h|.$$

Plugging $T \asymp \mu^{-1}\gamma^{-1}$ we arrive to

$$\ell \ge \bar{\ell}_1 := C\big(\mu h|\log h|\big)^{1/2}. \tag{21.5.13}$$

Similarly, considering propagations with respect to other variables one arrives to the same conclusion as $|\nabla W_{np}| \asymp \ell$.

Note that for given index p and for index n violating ellipticity $\ell \asymp \ell_p = \bigl(\ell^* + r|p-\bar{p}|\mu h\bigr)$ with some $\bar{p} \le C_0(\mu h)^{-1}$.

Further, on each ℓ^* subpartition element condition (21.5.13) is fulfilled for all indices p as $\ell^* \ge \bar{\ell}_1$ and condition (21.5.13) is violated for no more than $C_0\bar{\ell}_1(r\mu h)^{-1}$ ($\gg 1$) indices p as $\ell^* \le \bar{\ell}_1$. Furthermore, for each such index p ellipticity is violated by no more than $C_0\bigl(\bar{\ell}_1^2\gamma(r\mu h)^{-1}+1\bigr)$ indices n.

Therefore the total contribution to (21.5.3) of all singular subelements (i.e. subelements with $\ell^* \le C_0\bar{\ell}_1$) belonging to $\mathcal{Z}_{(r,\gamma)}$ does not exceed

$$C\mu^2h^{-2}\gamma^2r^2 \times \Bigl(\bar{\ell}_1(r\mu h)^{-1}+1\Bigr) \times \Bigl(\bar{\ell}_1^2\gamma(r\mu h)^{-1}+1\Bigr) \times \ell_1^q; \tag{21.5.14}$$

since the second and the third factors do not exceed $C\bar{\ell}_1(r\mu h)^{-1}$ and $C|\log h|^K$ respectively, we get $Ch^{-4}\bigl(\mu h\bigr)^{(3+q)/2}\gamma^2|\log h|^K$. This expression sums with respect to r,γ to the same expression calculated at the maximal values of γ and $r=1$, and multiplied by $|\log h|$, which is exactly expression $(21.5.12)_q$. We increase K as needed.

(b) Zone $\mathcal{Z}^*_{\mathsf{out},II}$ is treated in the same way. □

While estimates $(21.5.11)_q$ with $q \ge 0$ and even $(21.5.12)_q$ with $q \ge 1$ are sufficient for our needs, $(21.5.12)_0$ is not and needs to be improved to $(21.5.12)_q$ with q arbitrarily close to 1:

Proposition 21.5.5. *Let assumptions of Theorem 21.5.23 below and condition* (21.5.5) *be fulfilled and let Q be supported in $\mathcal{Z}^*_{\mathsf{out}} \cap \{\mathsf{dist}(x,\Sigma) \le \gamma\}$ with $\gamma \ge C_0\mu^{\delta-1/2}$. Then expression* (21.5.3) *with $T' = T_0$ and $T'' = \bar{T}$ does not exceed*

$$C\mu^{-1/2}h^{-3} + C\mu^2h^{-2}\gamma|\log h| + C(\mu h)^{(3+q)/2}h^{-4}\gamma^2|\log h|^K \tag{21.5.15}$$

with $q<1$ arbitrarily close to 1.

Proof. Again, one needs to consider only Q supported in a zone $\{|Z_1| \ge C(\mu h|\log h|)^{1/2}\}$ in which in the proof of Proposition 21.5.1 term (21.5.3) with $T' = \epsilon\mu^{-1}$ and $T'' = \bar{T}$ is negligible. Then we are going to prove (21.5.15) without the second term.

(a) Assume first that Q is supported in $\mathcal{Z}_{(r,\gamma)} \subset \mathcal{Z}^*_{\mathsf{out},I}$. One needs to consider only $p \le C_0(r\mu h)^{-1}$.

Let us introduce the scaling function and ℓ-admissible partition the in the "final" ball $B(0,1)$ corresponding to the original $(\gamma;\gamma r^{-1})$ element:

$$\ell^*_k = \ell_k := \min_{n,p} \epsilon \Big(\zeta^{-1} \sum_{j\le k} |\nabla^j \mathcal{A}_{np}|^{(m+1)/(k+1-j)}\Big)^{1/(m+1)} + \bar\ell_k \tag{21.5.16}$$

with $k = m$, $\zeta = \gamma r^{-1}$ and

$$\bar\ell_k = \big(\mu h |\log h|^K\big)^{1/(k+1)}. \tag{21.5.17}$$

As $m = 1$ this function coincides with ℓ^* given by (21.4.40).

Consider first partition m-*singular* groups $((p,n),\mathsf{element})$ i.e. groups such that

$$|\partial^\alpha \mathcal{A}_{np}| \le c\zeta \ell^{k-|\alpha|} \qquad \forall \alpha : |\alpha| \le k \tag{21.5.18}$$

with $k = m$, $\ell = \bar\ell_m$ and $\zeta = \zeta_m$.

Then contribution of all m-singular groups in $\mathcal{Z}_{(r,\gamma)}$ could be estimated in the same manner as before (see (21.5.14)):

$$C\mu^2 h^{-2} r^2 \gamma^2 \times \Big(\zeta \ell^k (\gamma\mu h)^{-1} + 1\Big) \times \Big(\zeta \ell^{k+1} (\mu h)^{-1} + 1\Big) \tag{21.5.19}$$

with the same k, ℓ and ζ as in (21.5.18). Here the second factor estimate the number of indices p involved and the third factor indicates the number of indices n violating ellipticity of $\mathcal{A}_{pn}$ for given p.

The groups which are not k-singular are k-*regular*, i.e. they satisfy (21.5.18) with some $\ell \ge 2\bar\ell_k$ and also

$$|\partial^\alpha \mathcal{A}_{np}| \asymp \zeta_k \ell^{k-|\alpha|} \qquad \text{for some } \alpha : |\alpha| \le k. \tag{21.5.20}$$

Then one can rescale such element to $B(0,1)$. After this rescaling conditions (21.5.18) and (21.5.20) are fulfilled with $\ell := 1$ and $\zeta := \zeta\ell^k$. So, one can apply the same rescaling and partition to it with $(k-1)$ instead of k and with crucial ℓ (separating $(k-1)$-singular from $(k-1)$-regular) equal to $\bar\ell_{k-1}/\ell_k$. This means that if one returns to the original element, the radius of the k-singular element would be $\bar\ell_k$ every time.

This continuation however, has a new property: every time when regular or singular ℓ'-subelements appear inside some regular elements, their relative densities do not exceed ℓ'/ℓ (all the time we refer to the same scale) and therefore the absolute density of all ℓ'-subelements does not exceed $C\ell'\bar{\ell}_m^{-1}$. Therefore the total contribution of all k-singular elements does not exceed (21.5.19) multiplied by $\bar{\ell}_k\bar{\ell}_m^{-1}$

$$C\bar{\ell}_m^{-1}\mu^2h^{-2}r^2\gamma^2 \times \Big(\zeta\ell^{k+1}(\gamma\mu h)^{-1}+\ell\Big)\times\Big(\zeta\ell^{k+1}(\mu h)^{-1}+1\Big) \tag{21.5.21}$$

with $\ell=\bar{\ell}_k$ and $\zeta=\gamma r^{-1}$ since we know that ζ does not increase (even if it is different in the different elements). Then two last factors do not exceed $|\log h|^K$ for sure and the total contribution of all singular $((p,n),\mathsf{subelement})$ groups does not exceed $\bar{\ell}_m^{-1}\mu^2h^{-2}\gamma^2r^2|\log h|^K$ and summation with respect to (r,γ) results in the same expression with the maximal values of γ and $r=1$.

Microlocally this is sound as logarithmic uncertainty principle

$$\bar{\ell}_k^2 \ge \mu^{-1}hr^2\gamma^{-3}|\log h|^K \tag{21.5.22}$$

and to satisfy it for any $\gamma \gg \mu^{-1/2}r^{1/2}$ one needs to take $k=1$.

This leaves us with 1-regular groups and there are three types of them:

(A) With $\zeta\ell^2 \le \gamma r^{-1}\mu h|\log h|^K$, which are covered by the same estimate (21.5.21).

(B) With $\zeta\ell^2 \ge \gamma r^{-1}\mu h|\log h|^K$; for them the shift $\mu^{-1}\gamma^{-2}r\zeta\ell T$ with $T=\mu^{-1}\gamma^{-1}$ is observable since $\mu^{-1}r^2\gamma^{-3}\zeta\ell\times\mu^{-1}\gamma^{-1}\times\ell \ge Cr^2\mu^{-1}h\gamma^{-3}$.

(C) 0-regular groups but then $\mathcal{A}_{pn}$ is just elliptic on the corresponding elements.

(b) Zone $\mathcal{Z}^*_{\mathsf{out},II}$ is treated in the same way. □

Temperate Magnetic Field. III

Recall that in the general case our purpose is the remainder estimate $O(\mu^{-1/2}h^{-3}+\mu^2h^{-2})$.

Proposition 21.5.6. *Let assumptions of Theorem 21.5.23 below be fulfilled. Then*

(i) As

$$h^{-\delta} \le \mu \le \bar{\mu}_0 := h^{\delta-2/5} \tag{21.5.23}$$

$\int e(x,x,\tau)\psi(x)\,dx$ *is given modulo* $O(\mu^{-1/2}h^{-3})$ *by expression* (21.1.2) *with* $T = \bar{T}$.

(ii) Moreover, as

$$h^{\delta-2/5} \le \mu \le h^{\delta-1} \tag{21.5.24}$$

and $\psi(x)$ *is a nice*[33] *function supported in* $\{|x_1| \le \bar{\gamma}_2 = \mu^{-\delta'}\}$ $\int e(x,x,\tau)\psi(x)\,dx$ *is given modulo* $O(\mu^{-1/2}h^{-3} + \mu^2 h^{-3})$ *by expression* (21.1.2) *with* $T = \bar{T}$.

Proof. Combining Propositions 21.4.2, 21.4.4 and 21.5.5 we conclude that this estimate holds in the framework of Statement (i) for ψ supported in $\mathcal{Z}^*_{\mathsf{out}}$ and in the framework of Statement (ii) for ψ supported in $\mathcal{Z}^*_{\mathsf{out}} \cap \{|x_1| \le \mu^{-\delta}\}$.

In Propositions 21.4.11, 21.4.14, 21.4.16 and 21.4.19 it was essentially proven that this estimate holds for ψ supported in the near outer zone $\mathcal{Z}'_{\mathsf{out}}$, inner core, inner bulk zone $\mathcal{Z}_{\mathsf{inn},II}$ and true inner zone $\mathcal{Z}_{\mathsf{inn},I}$ respectively. □

21.5.2 Final Calculations

Final cCalculations. I

Now we want just to calculate (21.1.2) with $T = Ch|\log h|$. It is well-known (see for example Proposition 13.4.20) that

Proposition 21.5.7. *Let* $\mu \le h^{-1+\delta}$ *with arbitrarily small* $\delta > 0$. *Then under assumption* (21.2.92)

(i) Asymptotics holds

$$h^{-1}\int_{-\infty}^{\lambda} \Bigl(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma_x u Q_y^t\Bigr)\,d\tau \sim \sum_{(n,m)\in\mathbb{Z}^{+2}} \kappa_{n,m,Q}(x,\lambda)h^{-4+2m+2n}\mu^{2n} \tag{21.5.25}$$

as $|\lambda| \le \epsilon$, $\bar{T} \le T \le \epsilon\mu^{-1}$.

[33] F.e. $\psi(x) = \psi_1(x_1/\bar{\gamma}_2)\psi_2(x_2,x_3,x_4)$.

(ii) Moreover, as $Q = Q(x)$ $\kappa_{n,0,Q}(x,.) = \kappa_{n,0,I}(x,.)Q(x)$ *and*

$$Th^{-1}\int_{-\infty}^{\infty} \widehat{\bar{\chi}}\big((\lambda-\tau)Th^{-1}\big)\mathcal{N}^{\mathsf{MW}}(x,\tau)\,d\tau \sim \sum_{n\in\mathbb{Z}^+} \kappa_{n,0,I}(x,\lambda)h^{-4+2m+2n}\mu^{2n} \tag{21.5.26}$$

with the Standard Weyl Expression

$$\kappa_{0,0,I}(x,\lambda)h^{-4} = \mathcal{N}^{\mathsf{W}}(x,\tau) \coloneqq \frac{1}{32\pi^2}(2\tau+V)^2\sqrt{g}. \tag{21.5.27}$$

Combining Propositions 21.5.6(i) and 21.5.7(i) we arrive to

Corollary 21.5.8. *Under assumptions* (21.2.92) *and* (21.5.23) *modified asymptotics* (21.2.93) *(with* $\mathcal{N}^{\mathsf{MW}}$ *replaced by* $\mathcal{N}^{\mathsf{W}}$*) holds.*

To prove Theorem 21.5.23 under assumption (21.5.23) it is sufficient to estimate properly

$$\Big|\int \Big(\mathcal{N}^{\mathsf{MW}}(x,\lambda) - \mathcal{N}^{\mathsf{W}}(x,\lambda)\Big)\psi(x)\,d\tau\Big| \tag{21.5.28}$$

which due to Proposition 21.5.7(ii) is equivalent to

$$\Big|\int \Big(\mathcal{N}^{\mathsf{MW}}(x,\lambda) - Th^{-1}\int_{-\infty}^{\infty} \widehat{\bar{\chi}}\big((\lambda-\tau)Th^{-1}\big)\mathcal{N}^{\mathsf{MW}}(x,\tau)\,d\tau\Big)\psi(x)\,d\tau\Big|. \tag{21.5.29}$$

Proposition 21.5.9. *(i) Under assumptions* (21.2.92) *and* (21.5.23) *both expressions* (21.5.28) *and* (21.5.29) *with* $\lambda = 0$ *do not exceed* $C\mu^{-1/2}h^{-3}$*.*

(ii) Under assumptions (21.2.92) *and* (21.5.24) *both expressions* (21.5.28) *and* (21.5.29) *with* $\lambda = 0$ *and a nice*[33)] *function* ψ *supported in* $\{|x_1| \le \bar{\gamma}_2 = \mu^{-\delta'}\}$ *do not exceed* $C\mu^{-1/2}h^{-3} + C\mu^2h^{-2}$*.*

Proof. Proof is standard, based on the same scaling functions and partition as in the proof of Proposition 21.5.5 as ψ is supported in $\mathcal{Z}^*_{\mathsf{out}}$. These arguments work in the other zones as well since we do not need uncertainty principle anymore. We leave the easy details to the reader. □

Now Propositions 21.5.6(i), 21.5.7 and 21.5.9(i) imply

Corollary 21.5.10. *Under assumptions* (21.2.92) *and* (21.5.23) *asymptotics* (21.2.93) *holds.*

Final Calculations. II

In view of Theorem 21.5.23 below nondegeneracy condition should be used only as

$$ch^{\delta-2/5} \le \mu \le Ch^{-1} \tag{21.5.30}$$

with $\delta = 0$. Then, under assumption $(21.4.52)_1$ the remainder estimate derived in section 21.4 is $O(\mu^{-1/2}h^{-3} + \mu^{3/2}h^{-3/2-\delta})$ i.e. it is $O(\mu^{-1/2}h^{-3})$ as $\mu \le h^{\delta-3/4}$ and then there is no need to invoke $(21.4.52)_q$ with $q \ge 2$. However, it makes life much easier and we will do it right now leaving more difficult analysis for the later; so $\delta > 0$ is arbitrarily small in this Subsubsection.

First of all one needs to prove

Proposition 21.5.11. *Let conditions* (21.2.92) *and* $(21.4.52)_q$ *be fulfilled and* $\mu \le h^{\delta-1}$. *Let* ψ *be a nice function supported in* $\{|x_1| \le \gamma\}$ *with* $\mu^{1/2-\delta} \le \gamma \le \epsilon$. *Then* $\int e(x,x,\tau)\psi(x)\,dx$ *is given by expression* (21.1.2) *with* $T = \bar{T}$ *with an error not exceeding* $(21.5.12)_q$.

Proof. Combining Propositions 21.4.7 and 21.5.4 we conclude that the statement holds for ψ supported in $\mathcal{Z}^*_{\mathsf{out}} \cap \{|x_1| \le \gamma\}$.

In Propositions 21.4.14, 21.4.12, 21.4.17 and 21.4.22 it was essentially proven that this estimate holds for ψ supported in the near outer zone $\mathcal{Z}'_{\mathsf{out}}$, inner core, inner bulk zone $\mathcal{Z}_{\mathsf{inn},II}$ and true inner zone $\mathcal{Z}_{\mathsf{inn},I}$ respectively. □

Propositions 21.5.9 and 21.5.7 imply

Corollary 21.5.12. *Let conditions* (21.2.92) *and* $(21.4.52)_q$ *be fulfilled and* $\mu \le h^{\delta-1}$. *Then*

(i) One can define the main part of asymptotics by (21.1.2) *with* $T = Ch|\log h|$ *(or equivalently by* (21.5.26)*) while the the remainder does not exceed* $(21.5.12)_q$ *with* $\gamma = 1$.

(ii) In particular, the remainder is $O(\mu^{-1/2}h^{-3})$ *as*

$$\mu \le \bar{\mu}_q := h^{-\frac{q+1}{q+4}} |\log h|^{-K} \tag{21.5.31}_q$$

under assumption $(21.4.52)_q$ *with* $q \ge 1$*; in particular* $\bar{\mu}_2 = \mu^{-1/2}|\log h|^{-K}$ *and* $\bar{\mu}_3 = \mu^{-4/7}|\log h|^{-K}$.

In what follows we refer to the case of $(21.5.31)_q$ as a *moderate magnetic field*. While we can get rid of logarithmic factors, there is no point to do it right now.

To prove Theorem 21.5.28 one needs to estimate properly expressions (21.5.28) and (21.5.29).

Proposition 21.5.13. *Let conditions* (21.2.92) *and* $(21.4.52)_q$ *be fulfilled and* $\mu \le h^{\delta-1}$. *Let* ψ *be a nice function supported in* $\{|x_1| \le \gamma\}$ *with* $\mu^{\delta-1/2} \le \gamma \le \epsilon$. *Then*

(i) Both expressions (21.5.28) *and* (21.5.29) *do not exceed* $(21.5.12)_q$.

(ii) In particular, as $\gamma = 1$ *both expressions* (21.5.28) *and* (21.5.29) *do not exceed* $C\mu^{-1/2}h^{-3}$ *as* $\mu \le \mu_q$.

Proof. Proof is standard, based on the same scaling functions and partition as in the proof of Proposition 21.5.4 as ψ is supported in $\mathcal{Z}^*_{\mathsf{out}}$. These arguments work in the other zones as well since we do not need uncertainty principle anymore. We leave the easy details to the reader. □

Corollary 21.5.14. *Theorem 21.5.28 below is proven as* $\mu \le \mu_q$.

Final Calculations. III

Now we want to prove Theorems 21.5.23, 21.5.28 below as $\mu \ge \bar{\mu}_q$ defined by (21.5.23), $(21.5.31)_q$ for $q = 0$ and $q \ge 1$ respectively. To do this we need to consider expression (21.1.2) localized in this singular zone because in the regular zone one can always apply (21.1.2) with $Q = I$ even if the expression is not as explicit as in the case $Q = I$.

Proposition 21.5.15. *One can rewrite with the same error as a remainder estimate derived in Section 21.4 expression* (21.1.2) *as*

$$\int \widehat{\mathcal{N}}^{\mathsf{MW}}_{\bar{Q}}(x,0)\psi(x)\,dx \tag{21.5.32}$$

with

$$\widehat{\mathcal{N}}^{\mathsf{MW}}_{\bar{Q}}(x,0) \coloneqq \mathsf{const}\sum_{n,p}\Big(\theta(\mathcal{A}_{pn})\bar{Q}_{pn}\Big)\Big|_{(x'',\xi'')=\Psi^{-1}(x)} \times f_1(x)f_2(x)\mu^2h^{-2} \tag{21.5.33}$$

with exactly the same constant as in $\mathcal{N}^{\mathsf{MW}}$.

Proof. Proof is rather standard: we consider canonical form of the operator and in this form I apply the method of successive approximations with operator in question $\mathcal{A}_{p,n}(x,\mu^{-1}hD_x)$ and unperturbed operator $\mathcal{A}_{p,n}(y,\mu^{-1}hD_x)$. We leave details repeating those in my multiple papers to the reader. □

Remark 21.5.16. Obviously, defining $\widehat{\mathcal{N}}^{\mathsf{MW}}_{\bar{Q}}$ by (21.5.33) but with $\mathcal{A}_{pn}$ replaced by $\mathcal{A}^0_{pn}$ one would get exactly

$$\mathcal{N}^{\mathsf{MW}}_{\bar{Q}}(x,0) \coloneqq \mathsf{const}\sum_{n,p}\theta\Big(V(x)-(2n+1)\mu hf_2(x)-(2p+1)\mu hf_1(x)\Big)f_1(x)f_2(x)\bar{Q}_{pn}\mu^2h^{-2} \tag{21.5.34}$$

where $\mathcal{A}^0_{pn}$ is obtained from $\mathcal{A}_{pn}$ by replacing perturbation terms $\mathcal{B}_{pn}$ by 0.

While one can take $Q=I$ and then $\bar{Q}_{np}$ will be the diagonal elements of ψ transformed according to (21.3.55) expression (21.5.33) is not very explicit either because of presence of $\mathcal{B}_{pn}$ and the similar terms in (21.3.55). Because of this we want to take Q supported in as small zone as possible; the only restriction so far is that $Q\equiv I$ in the singular zone

$$\Omega_{\mathsf{sing}} \coloneqq \big\{\ell^*\le \bar{\ell}_1 = C(r\mu h|\log h|)^{1/2},\quad |p-\bar{p}|\le r^{-1}\bar{\ell}_1(\mu h)^{-1}, \quad |n-\bar{n}|\le C\gamma r^{-1}\bar{\ell}_1^2(\mu h)^{-1}+1\big\}. \tag{21.5.35}$$

Therefore we will take Q supported in this zone (with increased C).

Furthermore, we actually need to consider not expression (21.5.32) but only its correction with respect to what is given by magnetic Weyl formula; namely

$$\int \Big(\widehat{\mathcal{N}}^{\mathsf{MW}}_{\bar{Q}}(x,0)-\mathcal{N}^{\mathsf{MW}}_{\bar{Q}}(x,0)\Big)\psi(x)\,dx. \tag{21.5.36}$$

Final Calculations. IV

Now our goal is to estimate expression (21.5.36). We do it first under assumption $(21.4.50)_q$ (including formally $q=0$) and in the next Subsubsection 21.5.2.5 we improve case $q=0$ in the same manner as Proposition 21.5.5 improves Proposition 21.5.4.

Proposition 21.5.17. *Let norms of perturbation operators do not exceed* $c\varepsilon$*,*

$$\varepsilon \le \mu h \tag{21.5.37}$$

and Q *be supported in* $\mathcal{Z}^*_{\mathsf{out}}$*. Then expression* (21.5.36) *does not exceed*

$$(21.5.38)_q \qquad \begin{cases} C\varepsilon\gamma^2(\mu h)^{(1+q)/2}h^{-4}|\log h|^K & q\ge 2,\\ C\gamma^2\Big(\varepsilon(\mu h)h^{-4}+C\varepsilon^{1/2}(\mu h)^2h^{-4}\Big)|\log h|^K & q=1,\\ C\varepsilon^{1/2}(\mu h)h^{-4}\gamma^2|\log h|^K + C\gamma^2(\mu h)^2h^{-4} & q=0. \end{cases}$$

Proof. Let us introduce a scaling function by (21.4.40). Further, we replace ℓ by $\mathsf{min}(\ell, r)+\varepsilon^{1/2}$. Then in as $\ell=\ell_{pn}\ge C\bar{\ell}_1$, the contribution of all ℓ_{pn} groups to (21.5.36) does not exceed the left-hand expression of (21.5.14) with (ℓ instead of $\bar{\ell}_1 = C(r\mu h|\log h|)^{1/2}$), multiplied by $C\varepsilon\ell^{-2}$:

$$C\mu^2h^{-2}\gamma^2r^{(2-q)_+}\times\Big(\ell(r\mu h)^{-1}+1\Big)\times\Big(\ell^2\gamma(r\mu h)^{-1}+1\Big)\times\ell^{q-2}\varepsilon; \tag{21.5.39}$$

one can prove it easily by considering such elements and integrating by parts if $\ell\ge c\varepsilon^{1/2}$. Here the third factor does not exceed $|\log h|^K$ for sure as $\ell^2\le \mu h|\log h|^K$ and $\gamma\le r^2$.

Then as $q\ge 2$ (21.5.39) sums with respect to ℓ to its value as ℓ reaches its maximum $\mathsf{min}(\bar{\ell}_1, r)$; then it sums with respect to r to the the first line in $(21.5.38)_q$.

As $q=1$ one gets

$$C(\mu h)h^{-4}r\gamma^2\Big(\varepsilon+(\mu h)\varepsilon\ell^{-1}\Big)|\log h|^K;$$

one can estimate $\ell^{-1}\varepsilon$ by $\varepsilon^{1/2}$ as $\ell\ge\epsilon^{1/2}$ and the summation results in the second line in $(21.5.38)_q$.

The same approach works as $q=0$ as well but results in an unwanted now factor $|\log h|^K$ at $C(\mu h)^2h^{-4}\gamma^2$. However, as $\ell\ge\varepsilon^{1/2}|\log h|^{K_1}$ with the

large enough exponent K_1 one can estimate the fourth factor in (21.5.39) by $|\log h|^{-K_1}$ and all summations will result in $C(\mu h)^2 h^{-4}\gamma^2 |\log h|^{K_0-K_1}$ with K_0 independent on K_1; choosing K_1 large enough one gets $C\mu^2 h^{-2}\gamma^2$.

On the other hand, one can estimate contribution of all groups with $\ell \le \varepsilon^{1/2}|\log h|^{K_1}$ does not exceed the product of the first three factors in (21.5.39) with $\ell = \varepsilon^{1/2}|\log h|_1^K$ (since one does not need to use an integration by parts then) which does not exceed after summation with respect to r, γ the third line in $(21.5.38)_q$. □

Recall that the "perturbation" terms in (21.3.50) are

$$\sum_{2q+2l+2j\ge 3} B^{\mathsf{w}}_{qjl} \times \bigl((2p+1)\mu h\gamma\bigr)^q \nu^{2-2q-2j}\hbar^l + \sum_{2k+2q+2m+2s+2l\ge 3} B^{\mathsf{w}}_{kqjmsl} \times \bigl((2n+1)\mu h\bigr)^k \bigl((2p+1)\mu h\gamma\bigr)^q \times \mu^{2-2k-2m-2q-s} h^s r^{-4q-4m-4s}\nu^{-2j}\hbar^l\Bigr).$$

and due to (21.3.51) their norms do not exceed $C\mu^{-2}r\gamma^{-3}$ and thus one can take

$$\varepsilon = C\min(\mu^{-2}\gamma^{-3}, \mu^{-1-\delta}\gamma^{-1}) \tag{21.5.40}$$

as $|x_1| \asymp \gamma$ since $r \le \min(1, \mu^{1-\delta}\gamma^2)$ in $\mathcal{Z}^*_{\mathsf{out}}$. Then condition (21.5.37) translates into

$$\gamma \ge \bar\gamma_2 := C\min\bigl(\mu^{-1}h^{-1/3}, \mu^{\delta-2}h^{-1}\bigr) = \begin{cases} \mu^{-1}h^{-1/3} & \text{as } \mu \le h^{\delta'-2/3},\\ \mu^{\delta-2}h^{-1} & \text{as } \mu \le h^{\delta'-2/3}. \end{cases} \tag{21.5.41}$$

Final Calculations. V

Consider $q = 0$ first. Then plugging (21.5.40) into $(21.5.38)_0$ and taking the sum with respect to γ one gets the same expression calculated as $\gamma = 1$ i.e. $Ch^{-3}|\log h|^K + C\mu^2 h^{-2}$ which is $O(\mu^2 h^{-2})$ as $\mu \ge h^{-1/2}|\log h|^K$. Therefore due to due to Propositions 21.5.6, 21.5.11, 21.5.15 and 21.5.17 we arrive to

Corollary 21.5.18. *Estimate* (21.2.93) *holds as* $\mu \ge h^{-1/2}|\log h|^K$.

Remark 21.5.19. As $h^{\delta-1} \le \mu \le ch^{-1}$ the contribution of zone $\{|x_1| \le h^{\delta'}\}$ to the asymptotics is $O(h^{-4+\delta'}) = O(\mu^2 h^{-2})$ and one does not need to use Propositions 21.5.6 and 21.5.11.

So estimate (21.2.93) remains to be proven as $h^{\delta-2/5} \le \mu \le h^{-1/2}|\log h|^K$; we will do it in the next Subsubsection.

Consider case $q \ge 1$ now. Plugging (21.5.41) into (the first term of) $(21.5.38)_q$ one gets $C(\mu h)^{(1+q)/2} h^{-4} \min(\mu^{-2}\gamma^{-1}, \mu^{2-\delta}\gamma)$; after summation with respect to $\gamma \ge \bar{\gamma}_2$ one the same expression $(21.5.38)_q$ calculated at

$$\gamma = \bar{\gamma}_3 := \max(\bar{\gamma}_2, \mu^{\delta-1/2}) = \begin{cases} \mu^{-1}h^{-1/3} & \text{as } \mu \le h^{\delta'-2/3}, \\ \mu^{\delta-1/2} & \text{as } \mu \le h^{\delta'-2/3}. \end{cases} \tag{21.5.42}$$

Thus we get remainder estimate $C(\mu h)^{(q-1)/2} h^{-8/3}|\log h|^K = O(\mu^{-1/2})$ as $\mu \le h^{\delta'-2/3}$ and $C(\mu h)^{(q-2/2} h^{-5/2}\mu^{-\delta}$ as $\mu \ge h^{\delta'-2/3}$; the latter expression is $O(\mu^{-1/2}h^{-3})$ for $q \ge 2$.

So, as $q = 2$ one gets $O(\mu^{-1/2}h^{-3})$ as an estimate of the contribution $\mathcal{Z}^*_{\mathsf{out}} \cap \{|x_1| \ge \bar{\gamma}_2\}$ into

$$|\int \bigl(e(x,x,0) - \mathcal{N}^{\mathsf{MW}}(x,0)\bigr)\psi(x)\,dx| \tag{21.5.43}$$

On the other hand, due to Propositions 21.5.9, 21.5.11 and 21.5.13 and their corollaries and also Propositions 21.4.20, 21.4.21, 21.4.22 contribution of zone $\mathcal{Z}^*_{\mathsf{out}} \cap \{|x_1| \le \bar{\gamma}_2\} \cup \mathcal{Z}'_{\mathsf{out}} \cup \mathcal{Z}_{\mathsf{inn}}$ to (21.5.42) is estimated by $(21.5.12)_q$ calculated at $\gamma = \bar{\gamma}_3$. One can see easily that the result is $O(\mu^{-1/2}h^{-3})$ as $\mu \le h^{\delta-2/3}$, $q \ge 2$; as $\mu \ge h^{\delta-2/3}$ one gets

$$C\mu^{-1/2}h^{-3} + C(\mu h)^{(2+q)/2}h^{-3}\mu^{\delta+1/2} + C(\mu h)^{(1+q)/2}h^{-3}\mu^{\delta}$$

where the third term is far less than the second one.

Then for $q = 2$ this result does not exceed $C\mu^{-1/2}h^{-3}$ as $\mu \le h^{\delta'-2/3}$ and Proposition 21.5.20(i) below is proven. On the other hand, as $\mu \ge h^{\delta'-4/5}$ $\bar{\gamma}_2$ is below of the bottom of $\mathcal{Z}^*_{\mathsf{out}}$ (see Figure 21.2) and therefore Proposition 21.5.20(ii) is proven:

Proposition 21.5.20. *Let conditions* (21.2.92) *and* $(21.4.50)_2$ *be fulfilled. Then*

(i) As $\mu \le h^{\delta'-2/3}$ *expression* (21.5.42) *does not exceed* $C\mu^{-1/2}h^{-3}$ *and therefore estimate* (21.5.47) *below holds with* $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} = 0$.

(ii) As $h^{\delta'-2/3} \le \mu \le ch^{-1}$ *contribution of* $\mathcal{Z}^*_{\mathsf{out}}$ *into the* (21.5.43) *does not exceed* $C\mu^{-1/2}h^{-3}$ *while contribution of* $\mathcal{Z}'_{\mathsf{out}} \cup \mathcal{Z}_{\mathsf{inn}}$ *(including the inner core) does not exceed*

$$C\mu^{-1/2}h^{-3} + C\mu^{5/2+\delta}h^{-1}. \tag{21.5.44}$$

Remark 21.5.21. Plugging (21.5.40) into the second term of $(21.5.38)_1$ one gets after summation its value as $\gamma = 1$ i.e. $C\mu h^{-2}|\log h|^K$. Because this and other ugly terms and because estimate under assumption $(21.4.50)_1$ is not a part of my core theorems, We are no more considering $q = 1$, leaving to the reader either to derive some estimate of (21.5.43) or to derive $O(\mu^{-1/2}h^{-3} + \mu^{3/2}h^{-\delta-3/2})$ estimate of some more complicated expression.

Final Calculations. VI

To finish the proof of Theorem 21.5.23 below we need to prove

Proposition 21.5.22. *Let condition* (21.2.92) *be fulfilled,* $h^{\delta-2/5} \le \mu \le Ch^{-1}$ *and* ψ *be a nice function supported in* $\{\bar\gamma_2 = \mu^{-\delta'} \le |x_1| \le \epsilon\}$ *with small enough exponents* $\delta > 0$, $\delta' > 0$. *Then*

$$|\int \Bigl(\widehat{\mathcal{N}}(x,0) - \mathcal{N}^{\mathsf{MW}}(x,0)\Bigr)\psi(x)\,dx| \le C\mu^2h^{-2}. \tag{21.5.45}$$

Proof. One needs to consider only zone $r \ge \mu^{-\delta'}$. Here and in the assumption $\delta' > 0$ could be taken arbitrarily small.

Let me introduce scaling function ℓ_m as in the proof of Proposition 21.5.5 and the corresponding partition. Then due to the same analysis as in Proposition 21.5.5 the contribution of all the m-regular groups with to the remainder is less than $C\mu^{-1/2}h^{-3} + C\mu^{-2-\delta''}h^{-2}$.

So one needs to consider only m-singular $((p,n),\mathsf{subelement})$ groups. Corresponding subelements are of the size $\bar\ell = (\mu h|\log h|^K)^{1/(m+1)}$ and on each such group $|\partial^2\mathcal{A}_{pn}| \le C(\mu h|\log h|)^{(m-1)/(m+1)}$. Consider $\epsilon\mu h$-subpartition. Then for each element of it and for each index p

$$|V(x) - f_1(x)(2p+1)\mu h - f_2(x)(2n+1)\mu h| \ge \epsilon_0\mu h|n - n(p)|$$

and the same is true for this expression perturbed by $\mathcal{B}_{pn} = O(\varepsilon)$, $\varepsilon = \mu^{-2+4\delta'}$, and also for each element there exists index $\bar{p}$ such that

$$|\nabla\big(V(x) - f_1(x)(2p+1)\mu h - f_2(x)(2n+1)\mu h\big)| \ge \epsilon_0 \mu h |p - \bar{p}|$$

as $n = n(p)$.

Then repeating arguments of the proof of Proposition 21.5.20 one can see easily that the left hand expression of (21.5.45) does not exceed

$$C\mu^{-2}h^{-2}\big(1 + \varepsilon \sum_{k\ge 1} (\mu h k)^{-1}\big) \le C\mu^{-2}h^{-2}$$

since $\varepsilon \ll \mu h$ so perturbation does not violate ellipticity of elliptic $\mathcal{A}_{pn}$. □

Thus we arrive to the first of the main results of this chapter

Theorem 21.5.23. *Let F be of Martinet-Roussarie type and condition* (21.2.92) *$V \ge \epsilon_0 > 0$ be fulfilled. Let ψ be supported in the small vicinity of Σ. Then estimate* (21.2.93)

$$|\int \big(e(x,x,0) - \mathcal{N}^{\mathsf{MW}}(x,0)\big)\psi(x)\,dx| \le C\mu^{-1/2}h^{-3} + C\mu^2 h^{-2} \tag{21.2.93}$$

holds where $\mathcal{N}^{\mathsf{MW}}(x,\tau)$ defined by (21.2.94)

$$\mathcal{N}^{\mathsf{MW}}(x,\tau) = (2\pi)^{-2}\mu^2 h^{-2} \sum_{(m,n)\in\mathbb{Z}^{+\,2}} \theta\Big(2\tau + V - (2m+1)\mu h f_1 - (2n+1)\mu h f_2\Big) f_1 f_2 \sqrt{g} \tag{21.2.94}$$

is Magnetic Weyl Expression.

Remark 21.5.24. Without any additional conditions remainder estimate (21.2.93) is sharp. An extra term $O(\mu^2 h^{-2})$ in its right-hand expression is due to the possibility that for some pair $(m,n) \in \mathbb{Z}^{+\,2}$ function $V - (2m+1)\mu h f_1 - (2n+1)\mu h f_2$ identically vanishes in the vicinity of some point of Σ. However, it is not as bad as it could be in the case of constant commensurable f_1, f_2 in which case $V - (2m+1)\mu h f_1 - (2n+1)\mu h f_2$ could vanish up to $\asymp (\mu h)^{-1}$ pairs $(m,n) \in \mathbb{Z}^{+\,2}$ and the remainder estimate would be the worst possible $O(\mu h^{-3})$.

21.5.3 Stronger Magnetic Field

To prove Theorem 21.5.28 below or slightly worse estimate under assumption $(21.4.50)_2$ one needs to improve estimate (21.5.44) of the contribution of $\mathcal{Z}'_{\mathsf{out}} \cup \mathcal{Z}_{\mathsf{inn}}$ (including the inner core) into remainder as $\mu \ge h^{\delta-2/3}$ and to calculate correction term (21.4.133)–(21.4.134) as $\mu \ge h^{-6/7}|\log h|^{-2/7}$.

Stronger Magnetic Field. I

To improve estimate (21.5.44) of the contribution of $\mathcal{Z}'_{\mathsf{out}} \cup \mathcal{Z}_{\mathsf{inn}}$ (including the inner core) into remainder without calculating the correction term one can notice that this expression is given by (21.1.2) with $T = T_0 = Ch|\log h|(\rho^2+\ell^2)^{-1}$ matching one for 2-dimensional magnetic Schrödinger operator (21.3.26) and therefore the asymptotics with the Weyl expression for (21.3.26) which one can rewrite easily as

$$(21.5.46) \qquad (2\pi)^{-2}\mu h^{-3}\theta\Big(2\tau + V - (2n+1)\mu h f_2 - (2p+1)\mu h f_1\Big) f_1 f_2 \sqrt{g}$$

where we skipped perturbation $\mathcal{B}'_n = O(\mu^{-2})$ which under assumption $(21.4.50)_2$ leads to the relative error $O(\mu^{-2})$.

Observe that each expression (21.5.46) is of magnitude μh^{-3} and after integration over $\big(\mathcal{Z}'_{\mathsf{out}} \cup \mathcal{Z}_{\mathsf{inn}}\big)$ it acquires factor $\gamma = \mu^{-1/2} r^{1/2}$ and after summation over n it acquires factor $(\mu h)^{-1}$; so we get a required expression

$$\int \mathcal{N}^{\mathsf{MW}}(x,\tau)\psi(x)\,dx$$

of magnitude $\mu^{\delta-1/2}h^{-4}$ as ψ is supported in $\big(\mathcal{Z}'_{\mathsf{out}} \cup \mathcal{Z}_{\mathsf{inn}}\big)$, an error has magnitude

$$\mu^{\delta-1/2}h^{-4}r^{5/2} \times \mu^{-2} = \mu^{\delta-5/2}h^{-4} = O(\mu^{-1/2}h^{-3}).$$

Therefore we arrive to our final result:

Theorem 21.5.25. *Let F be of Martinet-Roussarie type and condition* (21.2.92) *be fulfilled. Let ψ be supported in the small vicinity of Σ. Then*

(i) Under assumption $(21.4.50)_3$ *estimate*

$$(21.5.47) \quad \Big|\int \big(e(x,x,0) - \mathcal{N}^{\mathsf{MW}}(x,0)\big)\psi(x)\,dx - \int_\Sigma \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x',\tau)\psi(x')\,dx'\Big| \le C\mu^{-\frac{1}{2}}h^{-3}$$

holds where dx' *is the standard density on* Σ *and* $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x',\tau)$ *is a correction term (which is* $O(\mu^{5/4}h^{-3/2})$*)*

$$\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x') = (2\pi)^{-\frac{3}{2}}\mu h^{-2}\hbar^{\frac{1}{2}}\kappa^{-\frac{1}{2}}\sum_{n\in\mathbb{Z}^+}\big(V-(2n+1)f_2\mu h\big)^{1/8}\phi^{1/4} \times G\Big(\frac{S_0\big(V-(2n+1)f_2\mu h\big)^{3/4}\phi^{-1/2}}{2\pi\hbar}\Big) f_2\sqrt{g'}\Big|_{\Sigma} \tag{21.5.48}$$

where $g' = g^{11}g$ *and* $\sqrt{g'}\,dx'$ *is a Riemannian density on* Σ*,*

$$\phi = \|\nabla_{\mathbb{K}_1} f_1|_{\mathbb{K}_1}\| \tag{21.5.49}$$

where $\|.\|$ *corresponds to the Riemannian metrics* (g_{jk}) *restricted to* $\mathbb{K}_1$*.*

(ii) Under assumption $(21.4.50)_2$ *the left hand expression of estimate* (21.5.47) *does not exceed* $C\mu^{-1/2}h^{-3}+Ch^{\delta-5/2}$ *with an arbitrarily small exponent* $\delta>0$*.*

Remark 21.5.26. One can see easily that only zone $\{\mathsf{dist}(x,\Lambda)\asymp 1\}$ contributes after integration since otherwise $|\nabla_\Sigma\big(\big(V-(2n+1)f_2\mu h\big)\phi^{-2/3}\big)|$ is disjoint from 0.

Proof of Theorem 21.5.25. So far $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ is defined by (21.4.133)–(21.4.134) and is $O(\mu^{5/4}h^{-3/2}|\log h|^{1/2})$; we want to derive a more explicit representation given by (21.5.48).

First of all note that one can rewrite formula (14.4.63)in the form which does not require $g^{jk}|_\Sigma = \delta_{jk}$:

Lemma 21.5.27. *One can rewrite formula* (14.4.63) *as*

$$\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr},d=2} := (2\pi)^{-3/2}h^{-1}\hbar^{1/2}\kappa^{-1/2}V^{(\nu-1)/4\nu}\phi^{1/2\nu}G\Big(\frac{S_0V^{(\nu+1)/(2\nu)}\phi^{-1/\nu}}{2\pi\hbar}\Big)\sqrt{g'}\Big|_{\Sigma} \tag{21.5.50}$$

where $\hbar=\mu^{1/\nu}h$*,* $g'=g_{22}=g^{11}g$ *so* $\sqrt{g'}\,dx_2$ *is a Riemannian density on* Σ*,*

$$\phi = \big(f\cdot\mathsf{dist}(x,\Sigma)^{1-\nu}\big)\big|_{\Sigma}, \tag{21.5.51}$$

$\mathsf{dist}(.,.)$ *is calculated according to the Riemannian metrics* (g_{jk}) *and function* G *is given by* (14.4.64)*.*

Indeed, in this formula V, ϕ and $\sqrt{g'}\,dx_2$ are invariant with respect to change of the coordinates while multiplication of operator by ω^2 is equivalent to substitution $g^{jk} \mapsto \omega^2 g^k$ and $V \mapsto \omega^2 V$ which leads to $f \mapsto \omega^2 f$, $g' \mapsto \omega^{-2} g'$, $\mathsf{dist}(x,\Sigma) \mapsto \omega^{-2}\mathsf{dist}(x,\Sigma)$ (up to a factor equal 1 at Σ) and $\phi \mapsto \omega^{\nu+1}\phi$; so $V^{(\nu+1)/(2\nu)}\phi^{-1/\nu}$ and $V^{(\nu-1)/4\nu}\phi^{1/2\nu}\sqrt{g'}$ are invariants.

As $\nu = 2$ and $\mu \le Ch^{-1}$ (21.4.51)–(21.4.53) become

$$\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr},d=2} \equiv (2\pi)^{-3/2} h^{-1}\hbar^{1/2}\kappa^{-1/2} V^{1/8}\phi^{1/4} G\Big(\frac{S_0 V^{3/4}\phi^{-1/2}}{2\pi\hbar}\Big)\sqrt{g'}\Big|_{\Sigma} \tag{21.5.52}$$

with an error $O(h^{-1}\hbar) = O(\mu^{-1/2}h^{-1})$ and

$$\phi = \|\nabla f\| = \big(\sum_{j,k} g^{jk}\partial_j f \partial_k f\big)^{1/2}\big|_{\Sigma}, \tag{21.5.53}$$

where norm $\|.\|$ corresponds to the Riemannian metrics (g_{jk}). □

Stronger Magnetic Field. II

In the next few statements we are improving remainder estimate of Theorem 21.5.25.

Theorem 21.5.28. *Let F be of Martinet-Roussarie type, conditions* (21.2.92) *and*

$$|\big(\frac{V}{f_2}\big) - (2n+1)\mu h| + |\nabla_{\Sigma}\big(\frac{V}{f_2}\big)| \le \epsilon_0 \implies |\det \mathsf{Hess}_{\Sigma}\big(\frac{V}{f_2}\big)| \ge \epsilon_0 \quad \forall n \in \mathbb{Z}^+ \tag{21.5.54}$$

be fulfilled. Let ψ be supported in the small vicinity of Σ. Then estimate (21.5.47) *holds*

$$|\int \big(e(x,x,0) - \mathcal{N}^{\mathsf{MW}}(x,0)\big)\psi(x)\,dx - \int_{\Sigma} \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x',\tau)\psi(x')\,dx'| \le C\mu^{-\frac{1}{2}}h^{-3}. \tag{21.5.47}$$

Remark 21.5.29. (i) The first term in the left-hand expression of (21.5.54) is meaningful only in the case of the *intermediate-strong magnetic field* $\mu h \ge \epsilon$; so as $\mu h \le \epsilon$ condition (21.5.54) is equivalent to

$$|\nabla_{\Sigma}\big(\frac{V}{f_2}\big)| \le \epsilon_0 \implies |\det \mathsf{Hess}_{\Sigma}\big(\frac{V}{f_2}\big)| \ge \epsilon_0. \tag{21.5.55}$$

(ii) One can weaken condition (21.5.54) to $(21.4.50)_q$ with $q = 1, 2, 3$ depending on the magnitude of μ; as $\mu h \le \epsilon$ it is equivalent to $(21.4.52)_q$; obviously (21.5.54), (21.5.55) are equivalent to $(21.4.50)_3$, $(21.4.52)_3$ respectively.

(iii) Under stronger condition (21.4.49) the proof of Theorem 21.5.28 is much easier; as $\mu h \ll 1$ this condition is equivalent to

$$|\nabla_{\Sigma}\Big(\frac{V}{f_2}\Big)| \ge \epsilon_0. \tag{21.5.56}$$

(iv) In the very special cases (see Subsection 21.5.4) one can derive remainder estimate (21.5.47) without condition (21.5.54) or even $(21.4.50)_1$. Then the correction term could be larger, up to $O(\mu^{1/4}h^{-5/2})$.

Stronger Magnetic Field. III

Theorem 21.5.30. *Let F is of Martinet-Roussarie type and condition* (21.4.49) *be fulfilled. Then as ψ is supported in the small vicinity of $\Sigma \cap \{V = 0\}$ asymptotics* (21.5.47) *holds with $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x', \tau) = 0$.*

Proof. This proof cannot be obtained by the simple rescaling since $f_2\mu$ and $f_1\mu/|x_1|$ scale differently. However, arguments of Sections 21.2, 21.4 and 21.5 work with little or no modifications:

(i) *Modifications in Section 21.2*

(a) Propositions 21.2.6–21.2.10 do not require condition (21.2.92) while Proposition 21.2.11 holds under assumption (21.4.49) instead of (21.2.92) where $\bar{T} = Ch|\log h|/\ell$ with

$$\ell = \epsilon \max\big(|x_1|, |V|\big) + \hat{\ell}, \qquad \hat{\ell} = C\mu h|\log h|, \tag{21.5.57}$$

instead of $\bar{T} = Ch|\log h|$.

(b) Further, Propositions 21.2.12 and 21.2.13(i) do not require assumption (21.2.92), and Proposition 21.2.13(ii) holds with modified $\bar{T}$ under assumption (21.4.49). Therefore Proposition 21.2.14 also remains true: one needs to estimate $|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(u\psi_y Q_y^t)|$ as $T = \bar{T}$ and this is done easily as $\ell \ge 3\hat{\ell}$ by rescaling and standard Schrödinger operator analysis; as $\ell \ge 3\hat{\ell}$ it can be done easily by more crude approach as well.

(c) Furthermore, Propositions 21.2.16 and 21.2.17 do not require assumption (21.2.92) and due to the previous modifications arguments of Proposition 21.2.18 lead to the same estimate $O(\mu^{-1/2}h^{-3})$ for the contribution of $\mathcal{Z}_{\mathsf{out}}$ to the remainder estimate under assumption (21.4.49).

(d) Finally, Propositions 21.2.19–21.2.20 also do not require assumption (21.2.92) and Proposition 21.2.21 holds under assumption (21.4.49) instead of (21.2.92); Proposition 21.2.22 also does not require (21.2.92) and Propositions 21.2.23 and 21.2.24 hold under assumption (21.4.49).

(ii) *Modifications in Section 21.3.* Section 21.3 does not require condition (21.2.92) at all.

(iii) *Modifications in Section 21.4*

(a) In Section 21.4 analysis in the strictly outer zone $\mathcal{Z}^*_{\mathsf{out}}$ (Subsection 21.4.1) leading to Propositions 21.4.2 and 21.4.4 does not require condition (21.2.92); the analysis and condition (21.4.49) leads to Proposition 21.4.6 which is the worthy substitution for Proposition 21.4.7.

(b) In the arguments of Subsections 21.4.2 and 21.4.3 in the absence of condition (21.2.92) one again should pick up $\bar{T} = Ch|\log h|/\ell$ with ℓ defined by (21.5.57); in comparison with the arguments of these Subsections the factor ℓ^{-1} appears but it is compensated by a factor $(|W|+\mu h)$ which appears due the change of range of factors ρ^2 or $(2n+1)\mu h$. This would add an extra term $C\mu^{1/2}h^{-2}|\log h|$ to the remainder estimate which is subordinate as $\mu \le C(h|\log h|)^{-1}$.

(c) On the other hand, as $\mu \ge (h|\log h|)^{-1}$ we can take $\epsilon\ell$-admissible partition with respect to x' and note that as $W \le \epsilon_1\mu h$ at some partition element, it will be classically forbidden and therefore its contribution to the asymptotics would be 0; moreover, with the rescaling method I can in the right-hand expression of estimates and using condition (21.4.49) we can take $\bar{T} = Ch$ there thus getting rid of the logarithmic factor:

Proposition 21.5.31. *The total contribution of zones $\mathcal{Z}'_{\mathsf{out}}$ and $\mathcal{Z}_{\mathsf{inn}} \setminus \mathcal{Z}_{\mathsf{per}}$ to the remainder does not exceed $C\mu^{-1/2}h^{-3}$ under assumption* (21.4.49) *while the main part of asymptotics is given by* (21.1.2) *with $T = Ch|\log h|$.*

Moreover, in the vicinity of $\{W = 0\}$ condition (21.4.49) also reads as

$$|\nabla_{\Sigma}\big(V\phi^{-3/2}\big)| \ge \epsilon_0 \tag{21.5.58}$$

which kills periodicity for all n not just for all n but one as it would be the case far from $\{W = 0\}$ thus leading to

Proposition 21.5.32. *The total contribution of zone $\mathcal{Z}_{\mathsf{per}}$ to the remainder does not exceed $C\mu^{-1/2}h^{-3}$ under assumption* (21.4.49) *while the main part of asymptotics is given by* (21.1.2) *with $T = \bar{T}$ modified as above and no correction term is needed.*

(iv) *Modifications in Section 21.5.*

(a) In Section 21.5 condition (21.4.49) allows me to trade easily $T = Ch|\log h|$ to $T = \epsilon\mu^{-1}$ to $T = \epsilon\mu^{-1}\gamma^{-1}$ to $T = \epsilon\mu\gamma^2$ as each next expression is larger than the previous one thus leading to Theorem 21.5.30 as $\mu \le h^{\delta-1}$ covering everything by a moderate magnetic field approach.

(b) Alternatively as $\mu \ge h^{\delta-1}$ the strong magnetic field approach works well: in $\mathcal{Z}^*_{\mathsf{out}}$ one can just skip $O(\mu^{-2}\gamma^{-3})$ perturbation thus replacing $\widehat{\mathcal{N}}^{\mathsf{MW}}$ by $\mathcal{N}^{\mathsf{MW}}$ as in Proposition 21.5.17 with an error well below $\mu^{-1/2}h^{-3}$; similarly in $\mathcal{Z}'_{\mathsf{out}} \cup \mathcal{Z}_{\mathsf{inn}}$ one can just skip $O(\mu^{-2})$ perturbation thus getting magnetic Weyl expression again.

We leave easy details to the reader. □

21.5.4 Remarks

Special Case

Consider the special case of operator A defined as $A_I + A_{II}$ where A_I, A_{II} are operators of type (21.1.1) in variables $x_I = (x_1, x_2)$ and $x_{II} = (x_3, x_4)$ respectively with magnetic intensities $f_1(x_I) = |x_1|$ and $f_2(x_{II}) = 1$:

$$A_I = h^2D_1^2 + \big(hD_2 - \mu x_1^2/2\big)^2 - 1, \tag{21.5.59}$$

and

$$A_{II} = h^2D_3^2 + \big(hD_4A - \mu x_3\big)^2. \tag{21.5.60}$$

One can separate variables and prove spectral asymptotics with the remainder estimate $h^{-2}R_1$ where R_1 is the remainder estimate for operator $A_I + \tau$ for the worst possible $\tau > 0$. According to Chapter 14 $R_1 = O(\mu^{-1/2}h^{-1})$.

Then the main part of asymptotics is exactly as in estimate (21.5.47) with the correction term is given by (21.5.48) and this term is $O(h^{-3}\hbar^{1/2})$ [34].

The leading part of the correction term is rather irregular: it is equal to $(2\pi)^{-3/2}h^{-3}\hbar^{1/2}\kappa^{-1/2}I_n$ with

$$I(\varepsilon,\hbar) := \tag{21.5.61}$$

$$\sum_{n\in\mathbb{Z}^+}\big(V-(2n+1)f_2\varepsilon\big)^{1/8}\phi^{1/4}G\Big(\frac{S_0\big(V-(2n+1)f_2\varepsilon\big)^{3/4}\phi^{-1/2}}{2\pi\hbar}\Big)f_2\sqrt{g'}\Big|_{\Sigma}\varepsilon$$

with $\hbar=\mu^{1/2}h\ll\varepsilon=\mu h\ll 1$.

Obviously that $I_n=O(1)$ and but it is not clear that no better estimate like $I_n=O(\varepsilon^\sigma)$ is possible; one can see easily that $\sup_{\varepsilon'\asymp\varepsilon,\hbar'\asymp\hbar}|I(\varepsilon',\hbar')|\ge c^{-1}\varepsilon$.

We hope that some readers will be able make a numerical experiments.

About Term $C\mu^2h^{-2}$ in the remainder estimate

Is term $O(\mu^{-2}h^{-2})$ really needed in the general case? The answer most likely is positive. Consider operator A defined as A_I+A_{II} where

$$A_I=h^2D_1^2+\big(hD_2-\mu x_1^2/2\big)^2-1-kx_1 \tag{21.5.62}$$

and A_{II} is given by (21.5.60). Then

$$W_{pn} := \tag{21.5.63}$$

$$V-(2n+1)f_2\mu h-(2p+1)f_1\mu h=1+kx_1-(2n+1)\mu h-(2p+1)|x_1|\mu h$$

and as $k=(2p+1)\mu h$, $1=(2n+1)\mu h$ then $\{W_{pn}=0\}=\{x_1>0\}$.

While it does not mean that $\{\mathcal{A}_{pn}=0\}=\{x_1>0\}$ because of perturbation, we believe that perturbing slightly A_I one get achieve the latter result. We leave it to the reader.

21.5.5 Strong and Superstrong Magnetic Field Cases

Consider now the case $\mu h\ge C_0$ with sufficiently large C and operator (21.1.1) with V replaced by $V+\mu h\mathfrak{z}_2f_2+\mu h\mathfrak{z}_1$ [35]:

$$A=\frac{1}{2}\Big(\sum_{j,k}P_jg^{jk}(x)P_k-V-\mu h\mathfrak{z}_2f_2-\mu h\mathfrak{z}_1\Big). \tag{21.5.64}$$

[34] So one loses factor μh in comparison with Theorem 21.5.28 in the estimate of the correction term.

[35] Otherwise we would not get non-trivial results, see Problem 21.5.33(i).

Easy Analysis

We believe that the following problems are not very challenging:

Problem 21.5.33. Prove that

(i) If $\mathfrak{z}_2 < 1$ and $\mu h \ge C_0 = C_0(\mathfrak{z}_2)$, then $e(x,y,0) = O(\mu^{-s})$ for $x, y \in \mathcal{U}$, where $\mathcal{U} = \mathcal{U}(\mathfrak{z}_1, \mathfrak{z}_2)$ is the small vicinity of Σ.

(ii) If $\mathfrak{z}_2 = 1$, $\mathfrak{z}_1 < 1$ and $C_0 h^{-1} \le \mu \le ch^{-2}$, where $C_0 = C_0(\mathfrak{z}_1)$ then $e(x,y,0) = O(\mu^{-s})$ for $x, y : \mathsf{dist}(x,\Sigma) + \mathsf{dist}(y,\Sigma) \ge C(\mu h)^{-1}$.

(iii) If $1 < \mathfrak{z}_2 \notin 2\mathbb{Z}^+ + 1$ and $\mu h \ge C_0 = C_0(\mathfrak{z}_2)$, then in the vicinity of Σ, dividing operator by μh we reduce problem to one with $\mu_{\mathsf{new}} = \mu^{\frac12} h^{-\frac12}$ and $h_{\mathsf{new}} = \mu^{-\frac12} h^{\frac12}$ satisfying conditions of Theorem 21.5.28.

The analysis in the case $\Lambda = \emptyset$ seems to be reasonably challenging:

Problem 21.5.34. Let $\Lambda = \emptyset$.

(i) Investigate the case of $\mu h \ge C_0$, $\mathfrak{z}_2 = 1$, $\mathfrak{z}_1 < 1$. Prove that the the remainder estimates of Chapter 14, multiplied by μh^{-1} also hold: namely,

(ia) Let $C_0 h^{-1} \le \mu \le C_1 h^{-2}$. Then the main part has a magnitude of $\mu^{-1} h^{-3} \times \mu h^{-1} = h^{-4}$, and under appropriate assumptions the remainder is $O(\mu^{-\frac12} h^{-1} \times \mu h^{-1}) = O(\mu^{\frac12} h^{-2})$.

(ib) Let $\mu \ge C_1 h^{-2}$. Then the main part is 0 and the remainder is $O(\mu^{-s})$.

(ii) Investigate the case of $\mu h \ge C_0$, $\mathfrak{z}_2 = 1$, $\mathfrak{z}_1 \ge 1$. Prove that the the remainder estimates of Chapter 14, multiplied by μh^{-1} also hold: namely,

(iia) Let $C_0 h^{-1} \le \mu \le C_1 h^{-2}$. Then the main part has a magnitude of $\mu h^{-1} \times \mu h^{-1} = \mu^2 h^{-2}$, and under appropriate assumptions the remainder is $O(\mu^{-\frac12} h^{-1} \times \mu h^{-1}) = O(\mu^{\frac12} h^{-2})$.

(iib) Let $\mu \ge C_1 h^{-2}$. Then the main part has a magnitude of $\mu^2 h^{-2}$, and under appropriate assumptions the remainder is $O(1 \times \mu h^{-1}) = O(\mu h^{-1})$.

(iii) In the framework of (i) and (ii) write down main term of the asymptotics in the terms of the eigenvalue counting function of operator (14.8.9):

$$L(\eta;\mathfrak{z}) = D_1^2 + \bigl(\eta - x_1^2/2\bigr)^2 - \mu h x_1 \mathfrak{z}. \tag{21.5.65}$$

(iv) Investigate the case of $\mu h \ge C_0$, $\mathfrak{z}_2 = 2\bar{n}+1$, $1 \ge \bar{n} \in \mathbb{Z}^+$. Then we have a mixture of operators from (i) or (ii) (with $n = \bar{n}$) and Problem 21.5.33(iii) (with $n < \bar{n}$).

Difficult Analysis

Assume now that $\Lambda \ne \emptyset$.

The following problems seem to be extremely challenging:

Problem 21.5.35. Let $\Lambda \ne \emptyset$, $\mathfrak{z}_2 = 1$. Prove Statements (ia) and (iia) of Problem 21.5.34.

In particular, use reduction as in Section 21.3 albeit with Figure 21.1 modified by $\mu^{-1} \mapsto \mu^{-\frac{1}{2}} h^{\frac{1}{2}}$.

Problem 21.5.36. Let $\Lambda \ne \emptyset$, $\mathfrak{z}_2 = 1$, $\mathfrak{z}_1 < 1$ and $\mu \ge C_1 h^{-2}$.

(i) Recall that in Chapter 14 important role was played by $W = V/\phi_1$ restricted to Σ, with $\phi_1 = |\{Z_1, f_1\}| \asymp r$ near Λ where $r(x) = \mathsf{dist}(x, \Lambda)$ [36]. Namely, the spectral parameter in the spectral projector of $L(\eta; \mathfrak{z})$ is $V/(\phi_1 \mu h^2)$.

Then $e(x, y, 0) = O(\mu^{-s})$ for all x, y with $r(x) + r(y) \ge C_1/(\mu h^2)$. Therefore domain where $e(x, y, 0)$ is not negligible shrinks not only towards Σ, but also towards Λ. Then the contribution of $\{x\colon r(x) \asymp r\}$ to the main term is $\asymp \mu h^{-3} r^2$ and the magnitude of main term is its value as $r = (\mu h^2)^{-1}$, i.e. $\asymp \mu^{-1} h^{-7}$.

(ii) Prove that the contribution of $\{x\colon r(x) \asymp r\}$ to the remainder is $O(\mu^{\frac{1}{2}} h^{-2} r^{\frac{1}{2}})$ [37] and the remainder is is its value as $r = (\mu h^2)^{-1}$, i.e. $O(h^{-3})$.

(iii) Then the main term is larger than the remainder estimate if and only if $\mu \lesssim h^{-4}$.

(iv) Prove that $e(x, y, 0) = O(\mu^{-s})$ for $\mu \ge C_2 h^{-4}$.

(v) As $\mu \le C_2 h^{-4}$ derive asymptotics with the better remainder esrimate than in Statement (iii) with the main part referring to the toy-model (21.2.41). Do we need another microhyperbolicity type assumption?

Problem 21.5.37. Derive spectral asymptotic if either $\mathfrak{z}_2 > 1$ or $\mathfrak{z}_2 = 1$, $\mathfrak{z}_1 \ge 1$. Prove Statement (iib) of 21.5.34.

[36] Indeed, see (21.2.41) for the toy-model.

[37] Cf. Problem 21.5.34(ia).

Etc

The following problem seems to be interesting as well:

Problem 21.5.38. Consider genuine Schrödinger-Pauli and Dirac operators

(i) In the framework of Chapter 14.

(ii) In the framework of this chapter.

Chapter 22

Generic 4D-Schrödinger Operator with the Strong Magnetic Field

22.1 Introduction

Sharp spectral asymptotics for multidimensional Magnetic Schrödinger were obtained in Chapters 19 and 20 in full- and non-full-rank cases respectively[1)]. The results, as one could expect from the analysis of 2- and 3-dimensional cases, were rather different.

However, there are two problems with these results: first, the rank of the magnetic intensity matrix there was supposed to be constant which is not necessarily the case even if only generic magnetic fields are considered; second, while both the maximal rank[2)] and microhyperbolicity[3)] conditions are stable with respect to the small perturbations, they both are not generic in the sense that even in a small but fixed domain a general Magnetic Schrödinger operator is not necessarily approximated by operators satisfying any of these conditions: exactly in the same way as stationary points are not necessarily removable.

However, the analysis of Chapters 19 and 20 leads us to the following conjecture for even-dimensional Magnetic Schrödinger operators:

[1)] We mean the rank of magnetic intensity matrix (F_{jk}).

[2)] We mean that the rank of (F_{jk}) is $2\lfloor d/2 \rfloor$ at each point.

[3)] Which was assumed in Chapter 19.

Conjecture 22.1.1. *As $\mu \le ch^{-1}$ the main part of asymptotics is given by $\mathcal{N}^{\mathsf{MW}}$ while*

(i) For fixed (g^{jk}) and general $(V_j), V$ the remainder estimate is $O(\mu h^{1-d})$.

(ii) For fixed (g^{jk}) and generic (V_j) (i.e. $(V_1, \dots, V_d) \notin \mathfrak{A}_g$ where $\mathfrak{A}_g$ is nowhere dense closed set) and general V the remainder estimate is $O(\mu^{-1}h^{1-d} + \mu^{d/2}h^{-d/2})$ provided (F_{jk}) has the full rank everywhere and $O(\mu^{-1/2}h^{1-d} + \mu^{d/2}h^{-d/2})$ otherwise.

(iii) For fixed (g^{jk}) and generic (V_j, V) (i.e. $(V_1, \dots, V_d; V) \notin \mathfrak{B}_g$ where $\mathfrak{B}_g$ is nowhere dense closed set) the remainder estimate is $O(\mu^{-1}h^{1-d})$ provided (F_{jk}) has the full rank everywhere and $O(\mu^{-1/2}h^{1-d})$ otherwise.

While Statement (i) is trivial, (ii) and (iii) are rather difficult and our goal is rather limited: to prove them as $d = 4$. For $d = 2$ it was done in Chapter 14. Further, in the small vicinity of the set $\{x : \mathsf{rank}(F_{jk})(x) \le 2\}$ it was done in Chapter 21 Thus, we will need to investigate the case of $\mathsf{rank}(F_{jk}) = 4$ at every point.

So, operator in question is

$$A = \frac{1}{2}\Big(\sum_{j,k} P_j g^{jk}(x) P_k - V\Big), \qquad P_j = D_j - \mu V_j \tag{22.1.1}$$

with smooth[4)] symmetric positive definite matrix (g^{jk}) and smooth real-valued potentials $(V_1, \dots, V_d; V)$ and $\mu \gg 1$, $h \ll 1$. Assuming that A is self-adjoint, let $E(\tau)$ be the spectral projector of A and $e(x, y, \tau)$ be its Schwartz' kernel. These assumptions are fulfilled during the whole Chapter.

Magnetic field is characterized by a skew-symmetric matrix (F_{jk}), $F_{jk} = \partial_j V_k - \partial_k V_j$ and more precisely by $(F^j_k) = (g^{j*})(F_{*k})$ and its eigenvalues $\pm i f_j$, $f_j \ge 0$. As $d = 4$ these are f_1 and f_2.

It is proven in Martinet [1] that

(22.1.2) For generic $(V_1, \dots, V_4)$ f_1 and f_2 do not vanish simultaneously.

Remark 22.1.2. (i) If one of f_1, f_2 vanishes then (for generic $(V_1, \dots, V_4)$ locally situation of Chapter 21 occurs and the remainder estimate is $O(\mu^{-1/2}h^{-3})$ for generic V and $O(\mu^{-1/2}h^{-3} + \mu^2 h^{-2})$ for general V (detailed assumptions

[4)] Smooth means either infinitely smooth or belonging to $\mathscr{C}^K$ with large enough K.

see in Chapter 21) and we exclude this case from the analysis, assuming that

$$f_1 \ge \epsilon_0,\ f_2 \ge \epsilon_0. \tag{22.1.3}$$

(ii) As condition (22.1.4) below is fulfilled and $\mu h \ge c$ then the main part of asymptotics is 0 and the remainder estimate is $O(\mu^{-s})$ with an arbitrarily large exponent s (see f.e. Chapter 13) and therefore in what follows we assume that

$$1 \le \mu \le ch^{-1}. \tag{22.1.4}$$

Our goal is to consider 4-dimensional Schrödinger operator with the generic non-degenerating magnetic field and for a generic potential derive spectral asymptotics with the remainder estimate $O(\mu^{-1}h^{-3})$ and the principal part $\asymp h^{-4}$ where $h \ll 1$ is Planck constant and $\mu \gg 1$ is the intensity of the magnetic field. For general potentials remainder estimate $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$ will be achieved.

Plan of the Chapter

Section 22.2 is devoted to the geometry (discussion of what is the generic case) and the preliminary analysis in the cases when results of Chapter 19 imply Theorem 22.6.4 immediately.

In Section 22.3 we tackle the weak magnetic field case ($\mu \le h^{-\delta_0}$ with sufficiently small exponent $\delta_0 > 0$) proving the standard Weyl formula with the remainder $O(\mu^{-1}h^{-3})$.

Sections 22.4 and 22.5 are devoted to the case when $h^{-\delta_0} \le \mu \le ch^{-1}$ with arbitrarily small exponent $\bar{\delta} > 0$ and one can reduce operator to the microlocal canonical form. More precisely, in Section 22.4 we prove asymptotics with the announced remainder estimates but with the implicitly given main part

$$h^{-1}\sum_{\iota}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar{\chi}_{T_\iota}(t)\Gamma u Q_{\iota y}^{t}\Big)\,d\tau \tag{22.1.5}$$

where u is the Schwartz' kernel of the propagator $e^{ih^{-1}tA}$ and Q_ι are pseudodifferential partition elements (see details in my previous papers); in this proof estimate of

$$|\Big(F_{t\to h^{-1}\tau}\bar{\chi}_{T_\iota}(t)\Gamma u Q_{\iota y}^{t}\Big)| \tag{22.1.6}$$

plays the crucial role.

In Section 22.5 we replace (22.1.6) by the standard Magnetic Weyl formula and estimate an error arising from this.

Finally, in Section 22.6 we consider the case when condition

$$V \ge \epsilon_0 > 0 \tag{22.1.7}$$

is violated.

22.2 Geometry and Preliminary Analysis

22.2.1 Geometry

Proposition 22.2.1. *Let either g^{jk} be fixed and then V_j be generic, or, alternatively, V_j be fixed and then g^{jk} be generic. Further, let condition* (22.1.3) *be fulfilled. Then*

(22.2.1) $\Sigma := \{x\colon f_1(x) = f_2(x)\}$ *is a smooth 2-dimensional manifold:* $\Sigma = \{x\colon v_1(x) = v_2(x) = 0\}$ *with appropriate smooth functions v_1 and v_2 such that ∇v_1 and ∇v_2 linearly independent at any point of Σ and*

$$\operatorname{dist}(x,\Sigma) \asymp |f_1 - f_2| = 2(v_1^2 + v_2^2)^{1/2}. \tag{22.2.2}$$

Furthermore, $f_1 + f_2$ and $(f_2 - f_1)^2$ are smooth functions.

(22.2.3) *Consider symplectic form corresponding to F_{jk}*

$$\omega = \frac{1}{2}\sum_{jk} F_{jk}\,dx_j \wedge dx_k; \tag{22.2.4}$$

then $\omega|_\Sigma$ is either non-degenerate or it is generic degenerate[5] *i.e. $\Theta_1 := \{x \in \Sigma,\ \{v_1, v_2\} = 0\}$ is a submanifold of dimension 1 and $\nabla_\Sigma\{v_1, v_2\}$ is disjoint from 0 at Θ_1.*

(22.2.5) *Function $f_1 f_2^{-1}$ has only non-degenerate critical points outside of Σ and near Σ $|\nabla(f_1 f_2^{-1})|$ is disjoint from 0.*

Proof. We leave an easy proof to the reader. □

[5] Exactly as Σ was in Chapter 14.

22.2.2 Microhyperbolicity Condition

Preliminary Analysis

First, let me discuss the case when magnetic intensities f_1 and f_2 are disjoint. Then they are smooth. It still does not exclude third-order resonances $f_1 = 2f_2$ and $f_2 = 2f_1$ [6].

Then there are two cyclotron movements and the drift with the velocity $O(\mu^{-1})$ which we want to calculate. Let

$$p_j = \xi_j - \mu V_j. \tag{22.2.6}$$

Note that

$$x'_j := x_j - \mu^{-1} \sum_l \phi^{jl} p_l, \tag{22.2.7}$$

$$(\phi^{**}) := (F_{**})^{-1} \tag{22.2.8}$$

satisfy

$$\{p_k, x'_j\} = -\mu^{-1} \sum_l \{p_k, \phi^{jl}\} p_l \tag{22.2.9}$$

and therefore

$$\begin{aligned} &\Big\{\frac{1}{2}\sum_{k,m} g^{km} p_k p_m, x'_j\Big\} \\ &\qquad = \frac{1}{2}\sum_{k,m} \{g^{km}, x'_j\} p_k p_m - \mu^{-1} \sum_{k,m,l} g^{km} \{p_k, \phi^{jl}\} p_m p_l \\ &\qquad = \mu^{-1} \sum_{k,m,l} \Big(\frac{1}{2}\phi^{jl}\{p_l, g^{km}\} - \{p_l, \phi^{jk}\} g^{ml}\Big) p_k p_m. \end{aligned} \tag{22.2.10}$$

Proposition 22.2.2. *Let $f_1 \neq f_2$ in Ω; then one can correct*

$$x'_j \mapsto x''_j := x'_j - \frac{1}{2}\mu^{-1} \sum_{k,m} \beta^{jkm} p_k p_m \tag{22.2.11}$$

[6] Higher-order resonances are not a problem according to Chapter 19, at least under microhyperbolicity condition.

so that

$$\Big\{\frac{1}{2}\sum_{k,m} g^{km}p_k p_m, x_j''\Big\} = \mu^{-1}\Big(\{f_1, x_j\}_F b_1 + \{f_2, x_j\}_F b_2\Big) + O(\mu^{-2}) \tag{22.2.12}$$

where in the Birkhoff normal form $a = f_1 b_1 + f_2 b_2 + \dots$ *and*

$$\{w_1, w_2\}_F := \sum_{k,l} \phi^{kl}\partial_k w_1 \cdot \partial_l w_2 \tag{22.2.13}$$

are Poisson brackets associated with symplectic form $\omega = \omega_F$.

Microhyperbolicity Condition. I

Microhyperbolicity condition of Chapter 19 then means for $d = 4$ and $f_1 \neq f_2$ that

$$\begin{aligned}|V - (2p+1)f_1\mu h - (2n+1)f_2\mu h| \le \epsilon \implies \\ |\langle \ell, \nabla\big(V - (2p+1)f_1\mu h - (2n+1)f_2\mu h\big)\rangle| \ge \epsilon\end{aligned} \tag{22.2.14}$$

where ℓ ($|\ell| \asymp 1$) is the *microhyperbolicity direction* (at the given point x) and (n,p) are *magnetic indices*. However, there actually were two microhyperbolicity conditions in Chapter 19: in the weaker condition ℓ could depend not only on x but also on magnetic indices while in the stronger one it was assumed that ℓ is the same for all pairs (n,p) connected by the third order resonance. Respectively, the remainder estimates derived in Chapter 19 were $O(h^{1-d})$ under weaker condition and $O(\mu^{-1}h^{1-d})$ under stronger one.

In the relatively simple case of $d = 4$ the resonance means $kf_1 = lf_2$ where $k, l \in \mathbb{Z}^+$ are coprimes, $(k+l)$ is the *order of the resonance*. So under the stronger microhyperbolicity condition if either $2f_1 - f_2 = 0$ or $f_1 - 2f_2 = 0$ at x then ℓ should not depend on (n,p) satisfying the the left-hand inequality in (22.2.14).

Remark 22.2.3. Case $d = 4$ is relatively simple because there are only two magnetic intensities f_1 and f_2 and thus it is impossible to have collisions between two second-order resonances (of the type $f_j = f_k$), two third order resonances (of the types $f_j = 2f_k$ or $f_j = f_k + f_l$) or the second and the third order resonances.

Further, as $|kf_1 - lf_2| \le \epsilon$ there could be other resonances only of order $m(\epsilon)$ or higher; $m(\epsilon) \to +\infty$ as $\epsilon \to +0$.

So, as $d = 4$ and f_1 is disjoint from f_2 and $\mu h \le \epsilon_1$ (where $\epsilon_1 > 0$ depends on ϵ in the microhyperbolicity condition) both microhyperbolicity conditions are equivalent to

$$|\nabla\big(\alpha \log f_1 + (1-\alpha)\log f_2 - \log V\big)| \ge \epsilon \qquad \forall \alpha : 0 \le \alpha \le 1. \tag{22.2.15}$$

On the other hand, as $\mu h \ge \epsilon_1$ condition (22.2.15) should be checked only at points where *ellipticity condition*

$$|V - (2p+1)f_1\mu h - (2n+1)f_2\mu h| \ge \epsilon \qquad \forall (p,n) \in \mathbb{Z}^{+\,2} \tag{22.2.16}$$

is violated.

Remark 22.2.4. Recall that under condition (22.2.16) on $\mathsf{supp}(\psi)$ the remainder estimate is $O(\mu^{-s}h^s)$ with an arbitrarily large exponent s and the similar result would hold in any dimension provided $\mathsf{rank}(F_{jk}) = d$ at each point.

So, Theorems 19.2.16, 19.2.19, 19.4.17, 19.4.21, 19.5.2, 19.5.3, and 19.5.13 imply

Corollary 22.2.5. *Let $d = 4$ and conditions* (22.1.7), $f_1 \ne f_2$ *and* (22.2.15) *be fulfilled at* $\mathsf{supp}(\psi)$. *Then the remainder is $O(\mu^{-1}h^{-3})$ while the main part of asymptotics is given by the Magnetic Weyl formula.*

Microhyperbolicity Condition. II

This leaves us with bad points where condition (22.2.15) is violated. So let us consider set Λ_α of critical points of

$$\phi_\alpha := \alpha \log f_1 + (1-\alpha)\log f_2 - \log V. \tag{22.2.17}$$

Proposition 22.2.6. *Let g^{jk}, V_j be fixed and let V be generic. Then*

(i) Λ_α is a finite set, continuously depending on $\alpha \in [0,1]$.

(ii) There exist $0 < \alpha_1 < \alpha_2 < \dots < \alpha_J < 1$ such that for $\alpha \notin \{\alpha_1, \dots, \alpha_J\}$ function ϕ_α has non-degenerate critical points, while for $\alpha = \alpha_j$ function ϕ_α has also isolated critical points but in one of them $\mathsf{rank}\,\mathsf{Hess}\,\phi_\alpha = 3$.

(iii) As $\bar{\alpha} \in \{\alpha_1, \dots, \alpha_J\}$ *and* $\bar{x}$ *is a critical point of* $\phi_{\bar{\alpha}}$ *with* $\operatorname{rank} \operatorname{Hess} \phi_{\bar{\alpha}}(\bar{x}) = 3$*, in an appropriate (smooth) coordinate system in vicinity of* $\bar{x} = 0$

$$\phi_\alpha = \frac{1}{3}x_1^3 - (\alpha - \bar{\alpha})x_1 \pm_2 \frac{1}{2}x_2^2 \pm_3 \frac{1}{2}x_3^2 \pm_4 \frac{1}{2}x_4^2 \tag{22.2.18}$$

with independent signs $\pm_k$*.*

Proof. An easy proof is left to the reader. □

Remark 22.2.7. (i) Assume that at some point $\bar{x}$

$$|\nabla(f_1 f_2^{-1})| \ge \epsilon_0. \tag{22.2.19}$$

Then in the vicinity of $\bar{x}$

$$|\nabla\phi_\alpha| \ge \epsilon|\alpha - \bar{\alpha}(x)| \qquad \forall \alpha : 0 \le \alpha \le 1 \tag{22.2.20}$$

with smooth function $\bar{\alpha}(x)$.

(ii) On the other hand, if $\bar{x}$ is an isolated critical point of $f_1 f_2^{-1}$ then as V is generic $|\nabla\phi_\alpha| \ge \epsilon$ for all $\alpha \in [0,1]$ in the vicinity of $\bar{x}$.

22.2.3 Analysis near Σ: Geometry

Preliminary Remarks

Consider now $\Sigma = \{x : f_1 = f_2\}$ assuming that (22.2.1) holds; then the microhyperbolicity condition at point $x \in \Sigma$ means exactly that

$$\frac{1}{2}\ell\big((f_1 + f_2)V^{-1}\big) \ge \big((\ell v_1)^2 + (\ell v_2)^2\big)^{1/2} V^{-1} + \epsilon \tag{22.2.21}$$

where ℓ again is the microhyperbolicity direction, or, equivalently,

$$\Big|\frac{1}{2}\nabla\big((f_1 + f_2)V^{-1}\big) - (\beta_1\nabla v_1 + \beta_2\nabla v_2)V^{-1}\Big| \ge \epsilon \qquad \forall \beta = (\beta_1, \beta_2) \in \mathbb{R}^2 : |\beta| \le 1. \tag{22.2.22}$$

Remark 22.2.8. Note that the microhyperbolicity condition could be violated only at stationary points of $f_1 V^{-1}|_\Sigma$ and only at those of them where

$$\frac{1}{2}\nabla\big((f_1 + f_2)V^{-1}\big) = (\beta_1\nabla v_1 + \beta_2\nabla v_2)V^{-1} \tag{22.2.23}$$

with $\beta_1^2 + \beta_2^2 \le 1$.

Let Σ_0 be the set of stationary points of $f_1 V^{-1}|_\Sigma$; at each point of Σ_0 decomposition (22.2.23) holds; let us denote by Σ_0^+, Σ_0^-, Σ_0^0 the subsets of Σ_0 where $\beta_1^2+\beta_2^2>1$, $\beta_1^2+\beta_2^2<1$ and $\beta_1^2+\beta_2^2=1$ respectively. Then the microhyperbolicity condition holds at Σ_0^+.

So, main theorems of Chapter 19 imply

Corollary 22.2.9. *Let $d=4$ and conditions* (22.2.1) *and* (22.1.7) *be fulfilled. Let ψ be supported in the small vicinity of $\bar{x}\in\Sigma_0^+$. Then the remainder is $O(\mu^{-1}h^{-3})$ while the main part of asymptotics is given by magnetic Weyl formula.*

Geometry. I

One can prove easily two following propositions:

Proposition 22.2.10. *Let $d=4$ and condition* (22.2.1) *be fulfilled. Let V be generic satisfying* (22.1.7)*. Then*

(22.2.24) *Σ_0 consists of the finite number of non-degenerate stationary points of $f_1 V^{-1}|_\Sigma$; these points are generic;*

(22.2.25) *$0<\beta_1^2+\beta_2^2<1$ at each point of $\Sigma_0\setminus\Sigma_0^+$.*

Proposition 22.2.11. *Let $d=4$ and condition* (22.2.1) *be fulfilled. Let $\bar{x}\in\Sigma_0^-$ with $0<\beta_1^2+\beta_2^2<1$ in decomposition* (22.2.23)*. Then in the vicinity of $\bar{x}$*

$$\Lambda:=\bigl\{x: f_1\neq f_2 \text{ and } \exists\alpha\in[0,1]:\quad \nabla\phi_\alpha=0\bigr\}\cup\{\bar{x}\} \tag{22.2.26}$$

is a smooth curve passing through $\bar{x}$ and transversal to Σ; moreover

$$\bar{\alpha}(\bar{x})=\frac{1}{2}\bigl(1\pm(\beta_1^2+\beta_2^2)^{1/2}\bigr). \tag{22.2.27}$$

22.3 Weak Magnetic Field Case

In this section we are going to prove the remainder estimate $O(\mu^{-1}h^{-3})$ for general V as

$$c\le\mu\le h^{-\delta_0} \tag{22.3.1}$$

with small exponent $\delta_0>0$.

22.3.1 Weak Magnetic Field Case. I

Assume first that condition (22.2.19) is fulfilled.

Proposition 22.3.1. *Let conditions* $f_1 \neq f_2$ *and* (22.2.19) *be fulfilled at* $\mathsf{supp}(\psi)$. *Then under condition* (22.3.1) *the remainder is* $O(\mu^{-1}h^{-3})$ *while the main part of asymptotics is given by Weyl formula.*

Proof, Part I. Assume first that there are no resonances of order lesser than M on $\mathsf{supp}(\psi)$:

$$|kf_1 - lf_2| \geq \epsilon, \qquad \forall k, l \in \mathbb{Z}^+ : k + l \leq M. \tag{22.3.2}$$

Then one can reduce operator to the normal form without cubic and "unbalanced" fourth order terms and then along Hamiltonian trajectories

$$\frac{d}{dt}x_j = \frac{\partial}{\partial \xi_j}a, \qquad \frac{d}{dt}\xi_j = -\frac{\partial}{\partial x_j}a \tag{22.3.3}$$

of

$$a(x,\xi) \coloneqq \frac{1}{2}\Big(\sum_{j,k} p_j g^{jk}(x) p_k - V\Big), \qquad p_j = \xi_j - \mu V_j \tag{22.3.4}$$

the following relations hold:

$$\frac{d}{dt}b_j = \{a, b_j\} = O(\mu^{-2}) \tag{22.3.5}$$

where $b_j = \frac{1}{2}(f_j \circ \Psi)(x_j^2 + \xi_j^2) + O(\mu^{-2})$ are quadratic terms in the Birkhoff normal form; see details in Chapter 19 or below.

Therefore in the "corrected" coordinates x'' defined by (22.2.11) along Hamiltonian trajectories

$$\frac{d}{dt}x''_j = \mu^{-1}\big(\beta_{j1}(x'')b_1(x,\xi) + \beta_{j2}(x'')b_2(x,\xi)\big) + O(\mu^{-3}) \tag{22.3.6}$$

and

$$|\frac{d^2}{dt^2}x''| \leq C\mu^{-1}|\frac{d}{dt}x''| + C(\mu^{-4}). \tag{22.3.7}$$

Thus if

$$\mu|\frac{d}{dt}x''| \asymp \rho \geq C\mu^{-2} \tag{22.3.8}$$

then for time $T_1 = \epsilon\mu$ this relation (22.3.8) is retained and also variation of dx''/dt would be less than $C\epsilon\rho\mu^{-1}$. Then there is a fixed direction ℓ, $|\ell| \asymp 1$ such that for $|t| \le T_1$

$$\langle \ell, \frac{d}{dt} x'' \rangle \ge \epsilon_0 \mu^{-1} \rho; \tag{22.3.9}$$

ℓ is a sort of the microhyperbolicity direction. Without any loss of the generality one can assume that $\ell = (1,0,0,0)$ and therefore the shift of x_1'' for time T is exactly of magnitude $\rho\mu^{-1}T$.

According to the logarithmic uncertainty principle this shift is microlocally observable as

$$\rho\mu^{-1}T \times \rho \ge Ch|\log h| \tag{22.3.10}$$

Plugging $T = T_0 = \epsilon\mu^{-1}$ one gets $\rho^2 \ge C\mu^2 h|\log h|$ which would hold for $\rho \ge C\mu^{-2}$ as $\mu \le h^{-\delta}$.

Therefore in this case the contribution of zone (22.3.6) to the remainder does not exceed

$$Ch^{-3}\rho \times T_1^{-1} \asymp C\mu^{-1}h^{-3}\rho$$

where factor ρh^{-3} is due to the estimate of

$$|F_{t\to h^{-1}\tau}\bigl(\bar\chi_{T_0}(t)\Gamma Qu\bigr)| \le C\rho h^{-3}, \tag{22.3.11}$$

Q is the cut-off operator in zone (22.3.8), u is the Schwartz kernel of $e^{-ih^{-1}tA}$ and other standard notations are used.

To prove estimate (22.3.11) let us make ρ-admissible partition in ξ; then one can prove easily that the contribution of each such element to the left hand expression does not exceed $C\rho^3h^{-3}$ because the propagation speed with respect to x is $\asymp 1$ as $|t| \le T_0$ and therefore one can trade T_0 to $\bar T = Ch\rho^{-1}|\log h|$ in the left hand expression of (22.3.11) with a negligible error and in the estimate even to $\bar T = C\rho^{-1}h$ (one can prove easily by the rescaling).

On the other hand, the number of the partition elements for each x (and therefore in its vicinity) so that $hD_t - A$ is not elliptic and (22.3.8) holds is obviously $O(\rho^{-2})$; so the left-hand expression of (22.3.11) does not exceed $C\rho^3h^{-3} \times \rho^{-2}$.

Summation of $O(\mu^{-1}h^{-3})$ with respect to ρ results in $C\mu^{-1}h^{-3}$ and therefore we have proven that

(22.3.12) In the framework of Proposition and (22.3.2) the total contribution of zone

$$\{\mu|\frac{d}{dt}x''| \ge \bar\rho \coloneqq C\mu^{-2}\} \tag{22.3.13}$$

to the remainder is $O(\mu^{-1}h^{-3})$.

On the other hand, contribution of zone

$$\{\mu|\frac{d}{dt}x''| \le \bar\rho = C\mu^{-2}\} \tag{22.3.14}$$

to the remainder does not exceed $C\bar\rho h^{-3}\times T_0^{-1} = C\mu^{-1}h^{-3}$ where for cut-off operator in this zone estimate (22.3.11) holds with $\rho=\bar\rho$.

So, the remainder does not exceed $C\mu^{-1}h^{-3}$ while the main part of the asymptotics is given by the standard Tauberian formula (22.1.5) with $T = Ch|\log h|$. One can easily rewrite (22.1.5) with $T = Ch|\log h|$ as

$$\int \mathcal{N}^{\mathsf{W}}(x,0)\psi(x)\,dx + O(\mu^2h^{-2}).$$

Furthermore, one can replace here $\mathcal{N}^{\mathsf{W}}(x,0)$ by $\mathcal{N}^{\mathsf{MW}}(x,0)$ with the same error. The proof is standard, easy and left to the reader. □

Let us allow resonances.

Proof, Part II. (i) Let us consider now the case when $(kf_1 - lf_2)$ is not disjoint from 0. We will analyze the third order resonance which is worst case scenario leaving the easier case of higher order resonances to the reader.

So, now $(f_1 - 2f_2)$ is not disjoint from 0 (but then one can assume that $(kf_1 - lf_2)$ is as $l \ne 2k$, $k \le M$). Then one can reduce a operator to a (pre)canonical form

$$\frac{1}{2}\Big(f_1(x')Z_1^*Z_1 + f_2(x')Z_2^*Z_2 + \mu^{-1}\operatorname{Re}\beta(x')Z_1^*Z_2^2\Big) + O(\mu^{-2}) \tag{22.3.15}$$

with

$$\{Z_j, Z_k\} \equiv 0, \qquad \{Z_j^*, Z_k\} \equiv 2\mu\delta_{jk} \qquad \mathsf{mod}\ O(\mu^{-s}). \tag{22.3.16}$$

$$\{Z_j, x_k'\} \equiv \{Z_j,^* x_k'\} \equiv 0 \qquad \mathsf{mod}\ O(\mu^{-s}), \tag{22.3.17}$$

$$\{x_j', x_k'\} \equiv \mu^{-1}\phi^{jk}(x') \qquad \mathsf{mod}\ O(\mu^{-2}) \tag{22.3.18}$$

where

$$x' \equiv x \qquad \mathsf{mod}\ O(\mu^{-1}). \tag{22.3.19}$$

Due to (22.2.19) one can assume without any loss of the generality that

$$f_1 - 2f_2 = x_1. \tag{22.3.20}$$

(ii) Now let us consider elements of the partition with

$$|x_1| \asymp \gamma, \qquad \gamma \ge C\mu^{-1}. \tag{22.3.21}$$

Then one can get rid of the cubic term in (22.3.15) by means of the transformation with the generating function $\gamma^{-1}\mu^{-2}\,\mathsf{Re}\,\beta Z_1^* Z_2^2$ with γ-admissible function β (all other cubic terms are "regular" and one can get rid of them in the regular way), leading to the error which, as one can easily check, is the sum of terms of the types $\gamma^{-1}\mu^{-2}\,\mathsf{Re}\,\beta Z_j^* Z_j Z_2^* Z_2$ and also some smaller terms; one can continue this process getting rid of all "unbalanced" terms up to order M. Also one can introduce corrected x'' so that

$$\frac{d}{dt}x_j'' = \mu^{-1}\bigl(\beta_{j1}(x'')b_1 + \beta_{j2}(x'')b_2\bigr) + O(\mu^{-3}\gamma^{-1}) \tag{22.3.22}$$

(compare with (22.3.6). However, this would be slightly short of what is needed and one can improve a term $O(\mu^{-3}\gamma^{-1})$ in (22.3.22) to

$$\sum_{k+l=2} \beta_{kl}(x'')b_1^k b_2^l + O(\mu^{-3-\kappa}\gamma^{-1-\kappa})$$

with $\kappa > 0$. Then the contribution of the zone

$$\bigl\{|x_1| \asymp \gamma,\ \mu|\frac{d}{dt}x''| \le C\mu^{-2-\kappa}\gamma^{-1-\kappa}\bigr\}$$

to the remainder does not exceed $C\mu h^{-3}\gamma \times \mu^{-2-\kappa}\gamma^{-1-\kappa} \asymp C\mu^{-1-\kappa}h^{-3}\gamma^{-\kappa}$ where the first factor γ is the measure. Proof is similar to one in Part I, with estimate (22.3.11) replaced by

$$|F_{t\to h^{-1}\tau}\bigl(\bar\chi_{T_0}(t)\Gamma Qu\bigr)| \le C\rho\gamma h^{-3}, \tag{22.3.23}$$

now Q is the cut-off operator in zone (22.3.8) intersected with $\{|x_1| \asymp \gamma\}$. Obviously summation with respect to $\gamma \ge C\mu^{-1}$ results in $O(\mu^{-1}h^{-3})$.

So one needs to consider the zone where

$$\mu|\frac{d}{dt}x''| \asymp \rho \ge C\mu^{-2-\kappa}\gamma^{-\kappa}, \tag{22.3.24}$$

which implies that

$$|\mu\frac{d}{dt}\big(\beta_{j1}(x'')b_1 + \beta_{j2}(x'')b_2\big)| \le C\rho + C\mu^{-K}\gamma^{-K} \tag{22.3.25}$$

and therefore one can take

$$T_1 = \epsilon\,\mathsf{min}\big(\mu\gamma\rho^{-1},\ \mu,\ \rho\mu^{K}\gamma^{K}\big) \tag{22.3.26}$$

where the restriction $T \le \epsilon\gamma\rho^{-1}$ preserves the magnitude of $|x_1|$.

Therefore the contribution of the zone

$$\big\{|x_1| \asymp \gamma,\ \mu|\frac{d}{dt}x''| \asymp \rho\big\}$$

with $\gamma \ge C\mu^{-1}$, $\rho \ge C\mu^{-2-\kappa}\gamma^{-\kappa}$ to the remainder does not exceed

$$Ch^{-3}\rho\gamma\Big(\mu^{-1}\gamma^{-1}\rho + 1 + \mu^{-K}\gamma^{-K}\Big) \asymp C\mu^{-1}h^{-3}\Big(\rho^2 + \rho\gamma + \mu^{1-K}\gamma^{1-K}\Big). \tag{22.3.27}$$

Obviously, summation with respect to ρ, γ results in $C\mu^{-1}h^{-3}|\log\mu|$.

(iii) Now we want to improve this estimate getting rid of $\log\mu$ factor. Note first that the second term in (22.3.25) sums to $O(\mu^{-1}h^{-3})$, while the first and third terms sum to $O(\mu^{-1}h^{-3})$ over zones complemental to $\{\rho \ge \mathsf{max}(\gamma, |\log\mu|^{-1/2})\}$ and $\{\gamma \le \mathsf{min}(\rho,\ \mu^{-1+\kappa})\}$ respectively.

However, in the first zone one can take $T_1 = \epsilon\mu\gamma^{1-\kappa}$ (rather than $T_1 = \epsilon\mu\gamma$) since in an appropriate time direction $|x_1| \gtrsim \gamma$ for this time. Then an extra factor γ^{κ} in the remainder estimate prevents appearance of the logarithmic factor.

Let us introduce $W(x') = Vf_1^{-1}|_{x_1=0}$ and a scaling function $\zeta = \epsilon|\nabla' W| + \gamma$. Then one can upgrade T_1 to

$$T_1 = \epsilon\,\mathsf{min}\big(\mu\gamma\zeta^{-1},\ \mu,\ \rho^{1-\kappa}\mu^{K}\gamma^{K}\big) \tag{22.3.28}$$

Really, $\mu|\frac{d}{dt}x_1| \le C\zeta$ and one can select direction of time to replace ρ by $\rho^{1-\kappa}$. Then the total contribution to the remainder of all partition elements with $\zeta \le \gamma^\kappa$ is $O(\mu^{-1}h^{-3})$.

On the other hand, as $\zeta \ge \gamma^\kappa$ and $\gamma \le \mu^{-1+\kappa}$ one can obviously take $T_1 = \epsilon\mu\zeta$ and then the total contribution of such partition elements to the remainder does not exceed $C\mu^{-1}\zeta^{-1}h^{-3}\gamma \ll \mu^{-1}h^{-3}$.

(iv) Finally, let us consider now zone where

$$|x_1| \le \gamma = C\mu^{-1}. \tag{22.3.29}$$

Then we are not getting rid of the cubic terms and should take $T_1 = \epsilon\rho$ which one can easily upgrade to $T_1 = \epsilon\rho^{1-\kappa}$ [7] leading to the contribution of this zone to the remainder not exceeding $C\mu^{-1}h^{-3}$ where factor μ^{-1} is the measure of zone defined by (22.3.29). □

22.3.2 Weak Magnetic Field Case. II

Now let us allow $f_1 f_2^{-1}$ to have critical points. However, for the generic magnetic field these critical points are not resonances.

Proposition 22.3.2. *Let conditions* $f_1 \ne f_2$, (22.3.2) *and*

$(22.3.30)_q$ $|\nabla(f_1 f_2^{-1})| \le \epsilon_0 \implies$
$\mathsf{Hess}(f_1 f_2^{-1})$ *has at least* q *eigenvalues with absolute values greater than* ϵ_0

be fulfilled at $\mathsf{supp}(\psi)$ *with* $q \ge 3$. *Then under condition* (22.3.1) *the remainder is* $O(\mu^{-1}h^{-3})$ *while the main part of asymptotics is given by Weyl formula.*

Proof. Let $\gamma = \epsilon|\nabla(f_1 f_2^{-1})| + \bar\gamma$, $\bar\gamma = C\mu^{-1}$. Let us consider γ-admissible partition with respect to x.

[7] One can see easily that in this zone $\frac{d}{dt}b_j = \{a, b_j\} = O(1)$ and $(\frac{d}{dt})^2 b_j = \{a, \{a, b_j\}\} = O(1)$; one can prove that the microhyperbolicity is preserved with respect to the same vector $\ell\rho^{-1}$.

Then similarly to part (i) of the proof of Proposition 22.3.1 one can take $T_1 = \epsilon\mu\rho^{2-\delta'}\gamma$ with ρ defined by (22.3.8). Note that

$$|\alpha\nabla(f_1V^{-1}) + (1-\alpha)\nabla(f_2V^{-1})| \ge \epsilon\gamma|\alpha - \bar{\alpha}(x)| \qquad \forall \alpha : 0 \le \alpha \le 1 \tag{22.3.31}$$

and therefore the measure in ξ-space gets a factor γ^{-1} but the measure in x-space gets a factor γ^q due to condition condition $(22.3.30)_q$.

Then (22.3.11) and (22.3.23) are replaced by the similar estimate with the right hand expression $C\rho\gamma^{q-1}h^{-3}$.

So, the total contribution (ρ,γ)-elements to the remainder does not exceed

$$C\mu^{-1}h^{-3}\rho\gamma^{q-1} \times \rho^{\kappa-1}\gamma^{-1} \asymp C\mu^{-1}h^{-3}\gamma^{q-2}\rho^{\kappa}. \tag{22.3.32}$$

Summation with respect to (ρ,γ) results in $C\mu^{-1}h^{-3}$ as $q \ge 3$ and in $C\mu^{-1}h^{-3}|\log\mu|$ as $q = 2$ and this is the total contribution of the zone $\{\rho\gamma \ge C\mu^{-2}\}$.

On the other hand, contribution of the zone $\{\rho\gamma \le C\mu^{-2}\}$ to the remainder is $O(\mu h^{-3} \times \mu^{-2})$ since its measure is $O(\mu^{-2})$ under condition $(22.3.30)_3$; under condition $(22.3.30)_2$ an extra logarithmic factor appears as well. □

Remark 22.3.3. Probably one can get rid of logarithmic factors as $q = 2$ and derive some estimate as $q = 1$. We leave it to the curious reader.

22.3.3 Weak Magnetic Field Case. III

Now let us consider the vicinity of $\Sigma = \{x\colon f_1(x) = f_2(x)\}$.

Proposition 22.3.4. *Assume that* $|f_1 - f_2| \asymp \operatorname{dist}(x,\Sigma)$ *where* Σ *is a* 2*-dimensional manifold. Let* ψ *be supported in the small vicinity of* Σ*. Then under condition* (22.3.1) *the remainder is* $O(\mu^{-1}h^{-3})$ *while the main part of asymptotics is given by Weyl formula.*

Proof. Let us introduce a scaling function

$$\gamma = \epsilon\operatorname{dist}(x,\Sigma) + \frac{1}{2}\bar{\gamma}, \qquad \bar{\gamma} = C\mu^{-1}. \tag{22.3.33}$$

Then

$$|\alpha\nabla(f_1V^{-1}) + (1-\alpha)\nabla(f_2V^{-1})| \ge \epsilon|\alpha - \bar\alpha(x)| \qquad \forall\alpha : 0\le\alpha\le 1 \tag{22.3.34}$$

holds with γ-admissible $\bar\alpha$ and also (22.3.8) and (22.3.9) hold. Therefore one can take $T_1 = \epsilon\rho^{1-\kappa}\gamma\mu$. Then the contribution of all (γ,ρ) elements to the remainder does not exceed (22.3.32) with $q = 3$ [8] and summation over $\{\gamma \ge C\mu^{-1}, \rho\gamma \ge C\mu^{-2}\}$ results in $O(\mu^{-1}h^{-3})$.

Meanwhile, the contributions of zones $\{x : \gamma \ge C\mu^{-1}, \rho\gamma \le C\mu^{-2}\}$ and $\{x : \gamma \le C\mu^{-1}\}$ to the remainder are $O(\mu h^{-3}\times\mu^{-2}) = O(\mu^{-1}h^{-3})$ since the measures of these zones are $O(\mu^{-2})$. □

Summarizing what is proven one gets

Proposition 22.3.5. *Let (g^{jk}) be fixed and then (V_j) be generic, more precisely:*

(i) Outside of $\Sigma = \{x : f_1 = f_2\}$ critical points of $f_1f_2^{-1}$ satisfy $(22.3.30)_3$ *and* (22.3.2)*.*

(ii) Σ be smooth 2-dimensional manifold and $|f_1 - f_2| \asymp \mathsf{dist}(x,\Sigma)$.

Finally, let V be general but satisfying (22.1.7) *at $\mathsf{supp}(\psi)$. Then under condition* (22.3.1) *the remainder is $O(\mu^{-1}h^{-3})$ while the main part of asymptotics is given by Weyl formula.*

Proposition 22.3.6. *In the framework of Proposition 22.3.5 Weyl and Magnetic Weyl expressions differ by (far less than) $O(\mu^{-1}h^{-3})$.*

Proof. An easy proof is left to the reader. □

Remark 22.3.7. Definitely M in condition (22.3.2) "critical points of $f_1f_2^{-1}$ are not resonances of order not exceeding M" should not be too large and we leave to the curious reader to investigate it.

[8] In comparison with Proposition 22.3.2 there is no factor γ in the right hand expression of (22.3.34) and therefore no factor γ^{-1} in the estimate of the measure in ξ space.

22.4 Temperate Magnetic Field Case: Estimates

22.4.1 Canonical Form

From now one can assume that

$$h^{-\delta_0} \le \mu \le ch^{-1} \tag{22.4.1}$$

with some small fixed exponent $\delta_0 > 0$. Then we can reduce operator to a canonical form (depending on additional assumptions) and also make decomposition with respect to Hermite functions, thus arriving to 2-parametric matrices of 2D $\mu^{-1}h$-PDOs $\mathcal{A}_{pn}(x', \mu^{-1}hD')$ where ere and below $x' = (x_1, x_2)$.

More precisely, assuming that there are no resonances of order not exceeding M:

$$|kf_2 - lf_1| \ge \epsilon \qquad \forall (k,l) \in \mathbb{Z}^{+\,2} : k + l \le M, \tag{22.4.2}$$

a canonical form contains diagonal elements

$$\mathcal{A}_{pn} = \frac{1}{2}\Big(f_1^{\#}(2p+1)\mu h + f_2^{\#}(2n+1)\mu h - V^{\#} + \sum_{l+m+k+j\ge 2} b_{lmkj}\big((2p+1)\mu h\big)^l \big((2n+1)\mu h\big)^m \mu^{3-2l-2m-2k-j} h^j \Big) \tag{22.4.3}$$

with $f_j^{\#} = f_j^{\#}(x', \mu^{-1}hD')$, $V^{\#} = V^{\#}(x', \mu^{-1}hD')$, $b_{lmkj} = b_{lmkj}(x', \mu^{-1}hD')$ while all non-diagonal elements are $O(\mu^{2-M})$.

We will discuss later an alternative form for $M = 2$.

22.4.2 General Estimates at Regular Points

Assume first that there are no resonances of order not exceeding large $M = M(\delta_0)$. Then under condition (22.4.1) perturbation $O(\mu^{2-M})$ is negligible and (22.4.3) is a true diagonal canonical form (with a negligible perturbation).

General Estimates at Regular Points. I

In this case an analysis is easy:

Proposition 22.4.1. *Let there be no resonances of order not exceeding (large enough)* M *and condition* (22.2.19) *be fulfilled at* $\mathsf{supp}(\psi)$. *Then under condition* (22.4.1)

(i) The standard implicit asymptotic formula (22.1.5) *holds with the remainder estimate* $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$.

(ii) In particular, remainder estimate is $O(\mu^{-1}h^{-3})$ *as* $\mu \le h^{-1/3}$.

Proof. (a) Let us for each *pair* (p,n) introduce scaling function

$$\rho_{pn}=\epsilon\big(|\mathcal{A}_{pn}|+|\nabla\mathcal{A}_{pn}|^2\big)^{1/2}+\bar\rho, \qquad \bar\rho = C(\mu^{-1}h|\log h|)^{1/2}+C\mu^{-2} \tag{22.4.4}$$

and a corresponding partition. Then

(22.4.5) The contribution of each *group* $(p,n,\mathsf{element})$ to the main part of asymptotics is $\lesssim \mu^2h^{-2}\rho^4$ [9)].

On the other hand, one can take

$$T_1=\epsilon\mu \tag{22.4.6}$$

since the propagation speed is of magnitude μ^{-1} and also

$$T_0=Ch\rho^{-2}|\log h|. \tag{22.4.7}$$

Note that $T_0\le \epsilon_0\mu^{-1}$ provided

$$\rho\ge\bar\rho_1=C(\mu h|\log h|)^{1/2} \tag{22.4.8}$$

and in this case one can trade T_0 to $\bar T=Ch|\log h|$ in (22.1.5) as $\sum Q_\iota=I$; there will be also the correction term arising from elements failing condition (22.4.8); see Section 22.5. Moreover,

(22.4.9) In the estimate of expression (22.1.6) one can replace T_0 by $T_0^*=Ch\rho^{-2}$.

[9)] And often enough is is of this amplitude, so summation results in the correct magnitude of the main part.

Therefore, the contribution of an element to the remainder does not exceed

$$C\mu^2h^{-2}\rho^4 \times h\rho^{-2} \times \mu^{-1} \times \bigl(\rho^2(\mu h)^{-1}+1\bigr) \times \bigl(\rho(\mu h)^{-1}+1\bigr) \times \rho^{-4} \tag{22.4.10}$$

where $Ch\rho^{-2}|\log h|$ and $Ch\rho^{-2}$ play the roles of T_0 and T_0^* in formulae (22.1.5) and (22.1.6) respectively. Also the numbers of indices n [10)] and p [11)] are estimated by $C\bigl(\rho^2(\mu h)^{-1}+1\bigr)$ and $C\bigl(\rho(\mu h)^{-1}+1\bigr)$ respectively.

One can rewrite expression (22.4.9) as

$$C\mu^{-1}h^{-3}\rho + Ch^{-2}\rho^{-1} + C\mu h^{-1}\rho^{-2}; \tag{22.4.11}$$

then in the zone

$$\bigl\{\rho \ge \bar\rho := C(\mu^{-1}h|\log h|)^{1/2}\bigr\} \tag{22.4.12}$$

the first term sums to $C\mu^{-1}h^{-3}$ while the last two terms sum to their values as $\rho=\bar\rho$, which are $O(h^{-5/2}\mu^{1/2}) = O(\mu^{-1}h^{-3}+\mu^2h^{-2})$ for sure and $O(\mu^2h^{-2})$ respectively.

(b) Meanwhile, with the same main part the total contribution to the remainder of all groups with $\{\rho\le\bar\rho\}$ trivially does not exceed

$$C\mu^2h^{-2}\bigl(\bar\rho^2(\mu h)^{-1}+1\bigr) \times \bigl(\bar\rho(\mu h)^{-1}+1\bigr) \le C\mu h^{-3}\bar\rho + C\mu^2h^{-2}. \tag{22.4.13}$$

Obviously, this expression is $O(\mu^{-1}h^{-3})$ as $\mu \le C(h|\log h|)^{-1/3}$ and $O(\mu^2h^{-2})$ as $\mu \ge Ch^{-1/3}|\log h|^{1/3}$.

(c) To finish the proof we need to reconsider contribution to the remainder of the elements with $\{\rho_{pn}\le\bar\rho\}$ in the border case

$$h^{-1/3}|\log h|^{-1/3} \le \mu \le h^{-1/3}|\log h|^{1/3}. \tag{22.4.14}$$

Let us introduce another scaling function

$$\varrho = \epsilon|\nabla^2\mathcal{A}_{pn}| + \frac{1}{2}\bar\varrho, \qquad \bar\varrho = |\log h|^{-K}, \tag{22.4.15}$$

calculated with (p,n) delivering minimum to ρ_{pn} and let us introduce the corresponding partition.

[10)] For which ellipticity is violated for a given p.

[11)] Such that $\rho_{pn}\asymp\rho$ as n violates ellipticity.

Then for any element with $\varrho \ge \bar{\varrho}$ one can calculate easily that the relative measure of the zone $\{(x', \xi') : \ \min_{p,n} \rho_{pn} \le C\bar{\rho}\}$ is $O(\bar{\rho}|\log h|^K)$ and then the total contribution of zone $\{(x', \xi') : \ \rho \le \bar{\rho},\ \varrho \ge C\bar{\varrho}\}$ to the remainder is much less than $O(\mu^{-1}h^{-3})$.

On the other hand, let us consider elements with $\varrho \le C\bar{\varrho}$. Since the total contribution of subelements with $\rho \le \rho_1^* := C(\mu h)^{1/2}$ to the remainder is estimated properly, one needs to consider only subelements with $\rho_1^* \le \rho \le \bar{\rho}_1$.

But on such subelements $\rho\varrho^{-1}$ is a scaling function as well and using it one can easily decrease T_0 to $Ch|\log h|\bar{\varrho}\rho^{-2}$ leaving $T_1 = \epsilon\mu$; this will add an extra factor $|\log h|^{2-K}$ to the estimate of the contribution of this zone to the remainder and this factor leads to the needed estimate $O(\mu^{-1}h^{-3})$. □

General Estimates at Regular Points. II

Assume now that the is a critical point of $f_1 f_2^{-1}$:

Proposition 22.4.2. *Let there be no resonances of order not exceeding (large enough) M and condition* $(22.3.30)_3$ *be fulfilled at* $\operatorname{supp}(\psi)$. *Then under condition* (22.4.1)

(i) The standard implicit asymptotic formula holds with the remainder estimate $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$.

(ii) In particular, the remainder estimate is $O(\mu^{-1}h^{-3})$ as $\mu \le Ch^{-1/3}$.

Proof. (a) The arguments of the proof of Proposition 22.4.1 still work without condition (22.2.19) with the exception of the estimate $C\big(\rho(\mu h)^{-1}+1\big)$ of the number of the indices "p".

However, let us introduce another scaling function

$$\gamma := \epsilon_1 |\nabla(f_1 f_2^{-1})| \tag{22.4.16}$$

and if on some group $\rho_{pn} \le \gamma$, then the number of indices "p" should be estimated by $C\big(\rho(\gamma\mu h)^{-1} + 1\big)$; otherwise this number should be estimated by $C\big((\mu h)^{-1} + 1\big)$.

Note that if condition $\rho_{pn} \lesssim \gamma$ (or $\rho_{pn} \gtrsim \gamma$) is fulfilled at some point of ρ-element, then the same condition (with another implicit constant) is fulfilled at any other point of this element.

Anyway, this modification adds no more than one factor γ^{-1} to the estimate, but the factor γ^q comes from condition $(22.3.30)_q$; then summation over γ-partition results in the same estimate $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$ as $q\ge 2$ and in the same estimate but with an extra logarithmic factor as $q=1$. Since we do not use microlocal γ-partition, no estimate of γ from below is needed.

Therefore

(22.4.17) The total contribution of elements with $\rho_{pn}\ge \bar\rho$ to the remainder is $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$.

(b) Meanwhile, the contribution of zone $\{x:\ \rho\le\bar\rho,\ |\nabla(f_1f_2^{-1})|\le\gamma\}$ to the remainder does not exceed $C\mu h^{-3}\bar\rho\gamma^{q-1}+C\mu^2h^{-2}\gamma^q$ which sums to $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$ except in the border case (22.4.14). However, even in this case $q=2$ only a contribution of zone $\{x:|\nabla(f_1f_2^{-1})|\ge|\log h|^{-1}\}$ is not properly estimated. However, one can tackle it by the same arguments as in the part (c) of the proof of Proposition 22.4.1. □

Remark 22.4.3. Probably one can get rid of logarithmic factors as $q=1$.

22.4.3 Sharp Asymptotics at Regular Points

The purpose of this and the next odd-numbered subsections is to consider the case

$$ch^{-1/3}\le\mu\le ch^{-1} \tag{22.4.18}$$

and derive some under non-degeneracy condition remainder estimate $O(\mu^{-1}h^{-3})$.

Sharp Asymptotics at Regular Points. I

Note first that

(22.4.19) In the generic case $\nabla(f_1f_2^{-1})(\bar x)=0$ implies $\nabla(Vf_1^{-1})(\bar x)\ne 0$ and the then microhyperbolicity condition holds with any ℓ such that $\langle\ell,\nabla(Vf_1^{-1})\rangle>0$

and therefore the following statement is generic:

(22.4.20) Let $\nabla(f_1f_2^{-1})(\bar x)=0$ and $\nabla(Vf_1^{-1})(\bar x)\ne 0$. Then for any ψ supported in the small vicinity of $\bar x$ asymptotics with the magnetic Weyl main part and remainder estimate $O(\mu^{-1}h^{-3})$ holds.

Sharp Asymptotics at Regular Points. II

Therefore in what follows one can assume that $\nabla(f_1 f_2^{-1})$ is disjoint from 0. Further, one should consider only vicinities of points where microhyperbolicity condition (22.2.15) is violated.

Proposition 22.4.4. *Let conditions* (22.1.7) *and* (22.4.18) *be fulfilled. Moreover, let us assume that on* $\mathsf{supp}(\psi)$ *there are no resonances of order not exceeding* M *and also* $|\nabla(f_1 f_2^{-1})| \ge \epsilon_0$. *Furthermore, let condition*

$$(22.4.21)_q \quad \nu(\rho) := \mathsf{mes}\big\{(x,\alpha):\ 0\le\alpha\le 1,\ |\nabla\big(\alpha\log f_1 + (1-\alpha)\log f_2 - \log V\big)|\le\rho\big\} = O(\rho^q) \qquad \text{as}\ \ \rho\to+0$$

be fulfilled with $q>1$. *Then asymptotics with the standard implicit main part* (22.1.5) *and the remainder estimate*

$$(22.4.22)_q \qquad O\big(\mu^{-1}h^{-3} + \mu^2 h^{-2}(\mu^{-1}h)^{(q-1)/2}|\log h|^{(q+1)/2}\big)$$

holds.

Proof. As $T = Ch\rho^{-2}|\log h|$ the contribution to the remainder of ρ-elements does not exceed (22.4.10) multiplied by $\nu(\rho)\rho^{-1}$

$$\begin{aligned} C\mu h^{-1}\rho^{-2}\big(\rho^2(\mu h)^{-1}+1\big)\times\big(\rho(\mu h)^{-1}+1\big)\times\nu(\rho)\rho^{-1} &\\ \asymp C\mu h^{-1}\big(\rho^3(\mu h)^{-2}+\rho(\mu h)^{-1}+1\big)\nu(\rho)\rho^{-3} &\\ \le C\mu^{-1}h^{-3}\rho^q + Ch^{-2}\rho^{q-2} + C\mu h^{-1}\rho^{q-3} & \end{aligned}$$

where the last factor in the left-hand expression is the total measure of ρ-elements.

Here the first term in the right-hand expression always sums to $O(\mu^{-1}h^{-3})$ while the second and the third factor sum to their values as $\rho=1$ (i.e. $O(\mu^{-1}h^{-3})$ for sure) plus their values as $\rho=\bar\rho = C(\mu^{-1}h|\log h|)^{1/2}$ which do not exceed the second term in $(22.4.22)_q$. As $q=2,3$ the second or the third term respectively acquires an extra logarithmic factor but it does not change the estimate.

Furthermore, contribution of the zone $\{\rho\le\bar\rho\}$ to the remainder does not exceed $C\mu h^{-3}\nu(\bar\rho)+C\mu^2h^{-2}\nu(\bar\rho)\bar\rho^{-1}$ which is the second term in $(22.4.22)_q$.□

Corollary 22.4.5. *In the framework of Proposition 22.4.4 the remainder estimate* $O(\mu^{-1}h^{-3})$ *holds as* $q>3$.

Remark 22.4.6. In the generic case condition $(22.4.21)_4$ is fulfilled.

Sharp Asymptotics at Regular Points. III

Let us consider a special case

$$\epsilon h^{-1} \le \mu \le c h^{-1}. \tag{22.4.23}$$

Proposition 22.4.7. *Let conditions* (22.1.7) *and* (22.4.23) *be fulfilled. Moreover, let us assume that on* $\mathsf{supp}(\psi)$ *there are no resonances of order not exceeding* M *and also* $|\nabla(f_1 f_2^{-1})| \ge \epsilon_0$. *Furthermore, let condition*

$$\begin{aligned}(22.4.24)_r \quad & |(2p+1)\mu h f_1 V^{-1} + (2n+1)\mu h f_2 V^{-1} - 1| + \\ & |\nabla\big((2p+1)\mu h f_1 V^{-1} + (2n+1)\mu h f_2 V^{-1} - 1\big)| \le \epsilon_0 \implies \\ & \mathsf{Hess}\big((2p+1)\mu h f_1 V^{-1} + (2n+1)\mu h f_2 V^{-1} - 1\big) \ \textit{has at least } r \textit{ eigenvalues} \\ & \textit{with absolute values greater than } \epsilon_0\end{aligned}$$

be fulfilled with $r \ge 1$. *Then asymptotics with the standard implicit main part* (22.1.5) *and the remainder estimate* $(22.4.22)_{r+1}$ *i.e.* $O(h^{-2}+h^{r-4}|\log h|^{(r+2)/2})$ *holds.*

Proof. Follows easily the proof of Proposition 22.4.4. □

Remark 22.4.8. One can get rid of the logarithmic factors in estimate $(22.4.22)_q$ but we do not care since we are interested only in the generic cases $q = 4$, $r = 4$.

22.4.4 General Asymptotics at Resonances

Now assume that there are (k, l) resonances of order $m = k + l \ge 3$. However, considering ϵ_1-vicinity of any point one can assume that

(22.4.25) There are no (k', l')-resonances with $k' + l' \le M$ unless $k'/k = l'/l \in \mathbb{Z}$.

General Asymptotics at Resonances. I

So, let us consider

$$\Xi_{kl} = \{x : \ f_1 k = f_2 l\} \tag{22.4.26}$$

which under condition (22.4.4) is a smooth surface. One can assume without any loss of the generality that the analogue of (22.3.20) holds: $kf_1 - lf_2 = x_1$ while (x_2, ξ_1, ξ_2) are coordinates on Ξ_{kl}. Let us introduce a scaling function

$$\gamma = \epsilon|x_1| + \frac{1}{2}\bar{\gamma}, \qquad \bar{\gamma} = \mu^{-1+\delta} \tag{22.4.27}$$

with arbitrarily small exponent $\delta > 0$.

Proposition 22.4.9. *Let conditions* (22.4.25) *with* $k + l = m \geq 3$ *and* (22.2.19) *be fulfilled at* $\mathsf{supp}(\psi)$. *Then under condition* (22.4.1) *asymptotics with the standard implicit main part* (22.1.5) *and the remainder estimate* $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$ *holds.*

Proof, Part I. We will give the proof working the worst-case scenario $m = 3$; as $m \geq 4$ one can simplify the proof. In this part we are going to prove that

(22.4.28) The contribution of the zone $\{|x_1| \geq \bar{\gamma}\}$ to the remainder is $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$.

After reduction to precanonical form with non-diagonal terms corresponding to resonances, in this zone one can get rid of non-diagonal terms (modulo $O(\mu^{-M})$). Let us consider scaling function ρ_{pn} introduced by (22.4.4) for a full symbol of $\mathcal{A}_{pn}$.

(a) Consider first subzone

$$\bigl\{x : \ |x_1| \geq \mathsf{max}(\rho, \bar{\gamma})\bigr\}. \tag{22.4.29}$$

Then one can apply the same arguments as in the proof of Proposition 22.4.1; however, there is a problem[12]: as function of x_1 ρ_{pn} remains γ-admissible only as

$$\gamma \geq \bar{\gamma}_1 := \mu^{(4-2m)/3}. \tag{22.4.30}$$

So far the arguments as in the proof of Proposition 22.4.1 result in[13]

[12] It is not a problem at all as $m = 5$ and rather a marginal problem as $m = 4$ but for $d = 3$ this requires a certain attention.

[13] The border case (22.4.14) (may be with the different powers of logarithm) should be covered only in zone $\{|\log h|^{-K_1} \leq |x_1| \leq \epsilon\}$.

(22.4.31) The contribution of the zone $\{x:\ |x_1|\ge \mathsf{max}(\rho,\bar\gamma_1)\}$ with $\bar\gamma_1 = \mu^{-2/3}$ to the remainder is $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$.

(b) Consider now subzone

$$\{\gamma\ge\bar\gamma,\ \rho\ge\gamma,\}. \tag{22.4.32}$$

Note that here the derivatives of $\mathcal{A}_{pn}$ with respect to x_1 and to (x_2,ξ_1,ξ_2) have different values: while the derivative with respect to x_1 measures speed with respect to ξ_1 and the shift with respect to ξ_1 is quantum observable as $|\nabla_{x_1}\mathcal{A}_{pn}|\times\gamma\ge C\mu^{-1}h|\log h|$ provided γ is the scale with respect to x_1, other derivatives measure speed with respect to (ξ_2,x_1,x_2) and the shift is quantum observable as $|\nabla'\mathcal{A}_{pn}|\times\zeta\ge C\mu^{-1}h|\log h|$, provided ζ is the scale with respect to these variable where here and below $\nabla' := \nabla_{x_2,\xi_1,\xi_2}$.

So, let us introduce the third scaling function

$$\zeta_{pn} = \epsilon\big(|\mathcal{A}_{pn}|+|\nabla'\mathcal{A}_{pn}|^2\big)^{1/2}+(\rho\gamma)^{1/2} \tag{22.4.33}$$

where the last term will be actually included later.

Then one can make a ζ-admissible partition. So we have now (γ,ρ,ζ) elements with $\gamma\le\zeta\le\rho$ where ζ is the scale with respect to (x_2,ξ_1,ξ_2) and γ is the scale with respect to x_1 while ρ at this moment lost its scaling role. However, while ζ is γ-admissible function with respect to x_1, ρ preserves its magnitude in as x_1 varies by $O(\gamma)$ only under condition

$$\rho\ge\mu^{-2}\gamma^{-2}. \tag{22.4.34}$$

We claim that that then

$$T_0 = Ch|\log h|\big(\rho\gamma+\zeta^2\big)^{-1},\qquad T_0^* = Ch\big(\rho\gamma+\zeta^2\big)^{-1} \tag{22.4.35}$$

while

$$T_1 = \epsilon\mu\,\mathsf{min}\big(\zeta\rho^{-1},\gamma\zeta^{-1}\big)\asymp\epsilon\mu\zeta\gamma\big(\rho\gamma+\zeta^2\big)^{-1}. \tag{22.4.36}$$

Really, as $\rho\gamma\asymp\zeta^2$ a propagation speed with respect to ξ_1 is $\asymp\rho$ it is dual to x_1 of the scale γ. Meanwhile, speeds with respect to all other variables are bounded by $C\zeta$ and for given T_1 magnitudes of ζ,γ,ρ are preserved.

On the other hand, as $\rho\gamma\le\epsilon_1\zeta^2$ propagation speed with respect to (x_1,x_2,ξ_2) is $\asymp\zeta$ and they are dual to (ξ_1,ξ_2,x_2) of the scale ζ while propagation speed with respect to ξ_1 is bounded by $C\rho$ and for given T_1 magnitudes of ζ,γ,ρ are preserved.

We leave to the reader the standard justification on the quantum level (based on the energy estimates approach).

Thus $T_0^* T_1^{-1} \asymp \mu^{-1} h \gamma^{-1} \zeta^{-1}$; in virtue of the last term in the definition of ζ one can skip $\rho\gamma$ in $(\zeta^2 + \rho\gamma)$ here and below.

Then the total contribution of all (ρ, ζ, γ) elements to the remainder does not exceed

$$C\mu^2 h^{-2} \times \gamma \times T_0^* T_1^{-1} \times \bigl((\rho\gamma + \zeta^2)(\mu h)^{-1} + 1\bigr) \times \bigl(\rho(\mu h)^{-1} + 1\bigr) \tag{22.4.37}$$

where $C\bigl((\rho\gamma + \zeta^2)(\mu h)^{-1} + 1\bigr) \asymp C\bigl((\zeta^2(\mu h)^{-1} + 1\bigr)$ is an upper bound for a number of indices n violating ellipticity for a given index p.

If one picks up only "1" from both factors with the parentheses in (22.4.37) and replaces $T_0 T_1^{-1}$ by 1, then summation with respect to partitions results in $C\mu^2 h^{-2}$; on the other hand, since $\zeta^2 \le \rho$, one can rewrite the above expression (22.4.37) as

$$C\mu h^{-1} \times \zeta^{-1}\bigl(\zeta^2(\mu h)^{-1} + 1\bigr) \times \rho(\mu h)^{-1} \asymp Ch^{-2}\bigl(\zeta(\mu h)^{-1} + \zeta^{-1}\bigr)\rho. \tag{22.4.38}$$

Then summation with respect to ζ from $(\rho\gamma)^{1/2}$ to ρ results in

$$Ch^{-2}\rho\bigl(\rho(\mu h)^{-1} + \rho^{-1/2}\gamma^{-1/2}\bigr) \asymp C\mu^{-1}h^{-3}\rho^2 + Ch^{-2}\rho^{1/2}\gamma^{-1/2}. \tag{22.4.39}$$

The second term in the right hand expression sums with respect to (ρ, γ) to $Ch^{-2}\bar{\gamma}^{-1/2} \ll C\mu^2 h^{-2}$. However, the first term sums to $C\mu^{-1}h^{-3}|\log h|$ and this logarithmic factor appears due to summation with respect to γ.

To get rid of this factor let us notice that only case $\mu \le h^{-1/3}|\log h|^{1/3}$ needs to be addressed and only zone $\{\zeta \ge \gamma^{\kappa}\}$ should be reconsidered (with an arbitrarily small exponent $\kappa > 0$); in this case $\zeta \gg (\rho\gamma)^{1/2}$. Moreover, only term $Ch^{-4}\rho\zeta^2\gamma \times T_0^* T_1^{-1}$ in (22.4.37) should be reexamined.

However, then one does not need to use the canonical form but rather a weak magnetic field approach and take $T_0^* = h\zeta^{-2}$ and $T_1 = \mu\zeta$ and the contribution of this zone to the term in question does not exceed $C\mu^{-1}h^{-3}\int \zeta^{-1}\,d\gamma \le C\mu^{-1}h^{-3}$. Therefore

(22.4.40) The contribution of the zone $\bigl\{\rho \ge \max(\gamma, \mu^{-2}\gamma^{-2}),\ \gamma \ge \bar{\gamma}\bigr\}$ to the remainder is $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$.

(c) Now let us consider the remaining part of the zone $\{\epsilon \ge \gamma \ge \bar{\gamma}\}$. In this zone let us introduce the scaling function

$$\eta = \mu^2\gamma^3\rho. \tag{22.4.41}$$

Then ρ as a function of x_1 is η-admissible. Let us modify definition (22.4.33) etc replacing γ by η:

$$\zeta_{pn} = \epsilon\bigl(|\mathcal{A}_{pn}| + |\nabla'\mathcal{A}_{pn}|^2\bigr)^{1/2} + (\rho\gamma)^{1/2} \tag{22.4.33}$$

and then (22.4.35), (22.4.36) are also modified in the same way (anyway, terms $\rho\gamma$ originally and $\rho\eta$ now are not important):

$$T_1 = \epsilon\mu\,\min\bigl(\zeta\rho^{-1}, \eta\zeta^{-1}\bigr) \asymp \epsilon\mu\eta\zeta^{-1} \tag{22.4.35}$$

and $T_0^* T_1^{-1} \asymp \mu^{-1}h\eta^{-1}\zeta^{-1}$.

Then modified (22.4.37) and (22.4.38) expressions

$$\begin{aligned} C\mu h^{-1} \times \zeta^{-1}\bigl(\zeta^2(\mu h)^{-1} + 1\bigr) \times \rho(\mu h)^{-1}\gamma\eta^{-1} \\ \asymp Ch^{-2} \times \bigl(\zeta(\mu h)^{-1} + \zeta^{-1}\bigr)\rho\gamma\eta^{-1} \end{aligned} \tag{22.4.37}$$

estimate contribution of all $(\rho, \gamma, \eta, \zeta)$ elements. Here an (unpleasant) factor $\gamma\eta^{-1}$ appears since the measure of the strip remains γ and γ^{-1} is replaced by η^{-1} in $T_0^* T_1^{-1}$.

Plugging η into (22.4.37)* one gets

$$C\mu^{-3}h^{-3}\gamma^{-2}\zeta + C\mu^{-2}h^{-2}\gamma^{-2}\zeta^{-1} \tag{22.4.42}$$

and the first term sums to $o(\mu^{-1}h^{-3})$.

The second term sums with respect to ζ to its value at the smallest ζ satisfying conditions $T_1 = \mu\eta\zeta^{-1} \ge T_0 = h\zeta^{-2}$ and $\zeta \ge (\rho\eta)^{1/2}$:

$$\zeta = \max\bigl(\mu^{-1}h\eta^{-1}, (\rho\eta)^{1/2}\bigr) = \max\bigl(\mu^{-3}h\rho^{-1}\gamma^{-3}, \rho\mu\gamma^{3/2}\bigr); \tag{22.4.43}$$

so one gets

$$C\mu^{-2}h^{-2}\gamma^{-2}\,\min\bigl(h^{-1}\rho\mu^3\gamma^3, \rho^{-1}\mu^{-1}\gamma^{-3/2}\bigr)$$

which sums with respect to ρ to $C\mu^{-1}h^{-5/2}\gamma^{-5/4}$ and then with respect to γ to $O(\mu^{1/4}h^{-5/2}) \ll \bigl(\mu^{-1}h^{-3} + \mu^2h^{-2}\bigr)$.

On the other hand, if $T_1 \le T_0$ then one just replaces T_1 by T_0 and gets $Ch^{-4}\zeta^2\rho\gamma + C\mu h^{-3}\rho\gamma$ with $\zeta = (\rho\eta)^{1/2}$ i.e.

$$Ch^{-4}(\rho\eta)^{1/2}\rho\gamma + C\mu h^{-3}\rho\gamma \asymp Ch^{-4}\mu\rho^2\gamma^{5/2} + C\mu h^{-3}\rho\gamma \tag{22.4.44}$$

and it happens only if $(\rho\eta)^{1/2} \le \mu^{-1}h\eta^{-1}$ or equivalently $\rho \le \bar{\rho} := \mu^{-2}h^{1/2}\gamma^{-9/4}$. Plugging $\bar{\rho}$ in (22.4.44) we get $C\big(h^{-3}\mu^{-3}\gamma^{-2} + \mu^{-1}h^{-5/2}\gamma^{-5/4}\big)$; summation with respect to γ results in $o(\mu^{-1}h^{-3} + \mu^{1/4}h^{-5/2})$. Therefore

Statement (22.4.28) *is proven.* □

Proof of Proposition 22.4.9, Part II. We are left with the zone $\{|x_1| \le \bar{\gamma}\}$; its contribution to the remainder does not exceed $C\mu h^{-3}\bar{\gamma} = C\mu^{\delta}h^{-3}$ which is $O(\mu^2h^{-2})$ as $\mu \ge h^{-1/2-\delta'}$ and therefore only case $\mu \le h^{-1/2-\delta'}$ needs to be addressed. In this zone we use precanonical form with non-diagonal matrix elements but without singular terms.

Let $\mathcal{A}^0_{pn}$ denote diagonal matrix elements. One can see easily that

$$|\nabla'\mathcal{A}^0_{pn}| \equiv |\nabla'\log(f_jV^{-1})| \qquad \mathsf{mod}\ O(\gamma) \qquad \text{as}\ \ |x_1| \le \gamma \tag{22.4.45}$$

(as $\mathcal{A}_{pn}$ is non-elliptic) does not actually depend on p; let us define

$$\zeta := |\nabla'\log(f_jV^{-1}|\big|_{x_1=0} + (\rho\gamma)^{1/2}. \tag{22.4.46}$$

Let us define ρ_{pn} as before but with $\mathcal{A}^0_{pn}$ instead of $\mathcal{A}_{pn}$.

Note that in contrast to ζ ρ_{pn} strongly depends on p.

Then, as before $\mu^{-1}\rho$ controls the propagation speed with respect to x_1 and thus bounds the propagation speed with respect to ζ while $\mu^{-1}\zeta$ controls the propagation speed with respect to (x_1, x_2, ξ_2) as long as $\zeta \ge C\gamma$, $\rho \ge C\gamma$. Recall that $\gamma \ge C\mu^{-1}$.

However, the propagation speed with respect to ρ is a different matter. Considering commutator of

$$\mathcal{A} = f_1V^{-1}Z_1^*Z_1 + f_2Z_2^*Z_2 + 2\mu^{-1}\,\mathsf{Re}\big(\beta Z_1^*Z_2^2\big) + ...$$

(assuming that resonance is $2f_2 = f_1$) with

$$\partial_{x_1}\mathcal{A}^0 = \varkappa Z_1^*Z_1 + \omega\mathcal{A}^0 + ...\,, \qquad \varkappa = f_1\big(\partial_{x_1}(\log(f_1f_2^{-1})\big) \tag{22.4.47}$$

(with $\dots = O(\gamma)$) one can see easily that

$$\varkappa\mu^{-1}\bigl[\mathcal{A}, \partial_{x_1}\mathcal{A}^0\bigr] \equiv \bigl[\mathsf{Re}\,\beta Z_1^* Z_2^2, Z_1^* Z_1\bigr] = 2\varkappa\,\mathsf{Re}\,\beta Z_1^* Z_2^2 \mod O(\gamma) \tag{22.4.48}$$

which is bounded by 1. Therefore

(22.4.49) The propagation speed with respect to ρ does not exceed 1. Furthermore, ρ is properly defined as $\rho \ge C\mu h|\log h|$ (the logarithmic uncertainty principle).

Without nondegeneracy condition there is not much use of ζ; let us consider elements with $\rho \ge C\gamma$. Due to (22.4.49) we can pick up $T_1 = \epsilon\rho$. Then the contribution to the remainder of all such elements does not exceed

$$C\mu^2 h^{-2}\gamma \times h\zeta^{-2}\rho^{-1}\bigl(\zeta^2(\mu h)^{-1}+1\bigr)\times\bigl(\rho(\mu h)^{-1}+1\bigr) \tag{22.4.50}$$

and as long we include $O(\mu^2 h^{-2})$ into final remainder estimate we can skip "+1" in the last factor (due to the same arguments as before) resulting in

$$C\mu h^{-2}\gamma\zeta^{-2}\bigl(\zeta^2(\mu h)^{-1}+1\bigr) \asymp Ch^{-3}\gamma + C\mu h^{-2}\zeta^{-2}\gamma \le Ch^{-3}\gamma + C\mu h^{-2}\rho^{-1}; \tag{22.4.51}$$

as $\gamma = \bar\gamma$ this expression does not exceed $Ch^{-3}\bar\gamma + C\mu h^{-2}\rho^{-1}$ which sums with respect to ρ to $Ch^{-3}\bar\gamma|\log h| + C\mu h^{-2}\bar\rho^{-1}$ and the last term is $O(\mu^2 h^{-2})$.

On the other hand, in the zone $\{\rho \le \bar\rho\}$ we pick up $T_0^* T_1^{-1} = 1$ and its contribution to the remainder does not exceed $C\bar\rho^2\bar\gamma^2 h^{-4} + C\mu h^{-3}\bar\rho\bar\gamma + C\mu^2 h^{-2}$.

Therefore, as $h^{-1/3-\delta'} \le \mu \le h^{-1/2-\delta'}$, the contribution to the remainder of the zone $\{|x_1| \le \bar\gamma = \mu^{-1+\delta}\}$ with sufficiently small $\delta = \delta(\delta') > 0$ does not exceed $C\mu^2 h^{-2}$. In this case Proposition 22.4.9 is also proven. □

We will need the following

Proposition 22.4.10. *Let conditions* (22.1.7), (22.4.1) *and* $|f_1 - f_2| \ge \epsilon$ *be fulfilled. Let us consider the precanonical form.*

Finally, let $\mathcal{Q}$ *be a* ρ*-admissible partition element element in* (q_1, q_2)*, then quantized as* $\mathcal{Q}\bigl((h^2D_3^2 + \mu^2 x_3^2), (h^2 D_4^2 + \mu^2 x_4^2)\bigr)$ *with*

$$\rho \ge C\mu h|\log h| + C\bar\gamma_0^k \gamma^{1-k} \tag{22.4.52}$$

and ψ be γ-admissible with respect to x_1, either supported in $\{|x_1| \asymp \gamma\}$ as $\gamma > \bar{\gamma}_0 := C\mu^{-1}$ or supported in $\{|x_1| \lesssim \gamma\}$ as $\gamma = \bar{\gamma}_0$. Then

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(\psi \mathcal{Q} u Q_y^t)| \le Ch^s, \tag{22.4.53}$$

and

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(\psi \mathcal{Q} u Q_y^t)| \le C\rho\gamma h^{-3} \tag{22.4.54}$$

as $|\tau| \le \epsilon$ and

$$Ch|\log h|\rho^{-1} \le T \le \epsilon\mu^{-1}. \tag{22.4.55}$$

Proof. Consider the propagation with respect to either $(x_3, \mu^{-1}hD_3)$ or $(x_4, \mu^{-1}hD_4)$. Due to (22.1.7) on the energy levels close to 0 at least one of the symbols of $\mu^2 x_j^2 + h^2 D_3^j$ is of magnitude 1 ($j = 3, 4$). The propagation speed with respect to $(x_3, x_4, \mu^{-1}hD_3, \mu^{-1}hD_4)$ is $\asymp 1$. Therefore one can trade $T \le \epsilon\mu^{-1}$ to $\bar{T} = Ch|\log h|$ and in the estimate of Fourier transform to $\bar{T}^* = Ch$. The remaining part of the proof is easy and left to the reader.□

Proof of Proposition 22.4.9, Part III. Therefore only case $h^{-\delta_0} \le \mu \le h^{-1/3-\delta'}$ remains to be addressed where $\delta_0 > 0$ is small and fixed and $\delta' > 0$ is arbitrarily small. It follows from Parts I, II that exponents $\delta > 0$ in the definition of $\bar{\gamma}$ and $\delta' > 0$ are *independently* small.

(a) Let us consider elements with $|\nabla'(V^{-1}f_j)| \asymp \varsigma \ge C\gamma$. Then as $T_0 = Ch|\log h|(\varsigma^2 + \rho\gamma)^{-1} \le \epsilon\rho$, i.e. as

$$\rho \ge \varrho := C\min\bigl(h|\log h|\varsigma^{-2}, (\gamma^{-1}h|\log h|)^{1/2}\bigr) + C\gamma, \tag{22.4.56}$$

ρ is preserved on the time interval T_0 which can be traded to $T_1 = \epsilon\mu\varsigma$. Therefore the contribution to the remainder of all such elements does not exceed

$$C\rho\gamma(\varsigma^2 + \mu h)h^{-4}T_0^* T_1^{-1} \asymp C\mu^{-1}h^{-3}\rho\gamma\varsigma^{-1} + Ch^{-2}\rho\gamma\varsigma^{-3}; \tag{22.4.57}$$

summation with respect to ς, ρ, γ trivially results in $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$.

On the other hand, one can see easily that if (22.4.56) is violated, then $C\varrho$ remains an upper bound for ρ at time $|t| \le T_0 = Ch|\log h|\varsigma^{-1}$; therefore contribution of such elements to the remainder does not exceed

$$\begin{aligned} &C\rho\gamma(\varsigma^2 + \varrho\gamma + \mu h)h^{-4}T_0^* T_1^{-1} \\ &\qquad \asymp C\mu^{-1}h^{-3}\varrho\gamma\varsigma^{-1} + C\mu^{-1}h^{-3}\varrho^2\gamma^2\varsigma^{-3} + Ch^{-2}\rho\gamma\varsigma^{-3} \end{aligned} \tag{22.4.58}$$

which does not exceed the same expression with $\varsigma = \gamma$ and corresponding ϱ; one can see easily that $\varrho \le \gamma h^{-5\delta'}$ and (22.4.58) is $o(\mu^{-1}h^{-3})$.

Therefore only elements with $|\nabla' V^{-1} f_j| \le C\gamma$ remain to be treated, where either $|x_1| \le \gamma = C\mu^{-1}$ or $C\mu^{-1} \le |x_1| \asymp \gamma \le \mu^{-1+\delta}$.

(b) Let us consider the propagation speed with respect to ρ more precisely. Note that as $|x_1| \asymp \gamma \ge C\mu^{-1}$ one can translate non-diagonal term $\mu^{-1}\operatorname{Re}(\omega Z_1^* Z_2^2)$ into

$$\mu^{-2}x_1^{-1}|\omega|^2(Z_1^* Z_1 - 4z_2^* Z_2)Z_2^* Z_2 + ...$$

with

$$\rho = -\mu^{-2}x_2^{-1}|\omega|^2(Z_1^* Z_1 - 4z_2^* Z_2)Z_2^* Z_2 + ...$$

Then $[a,\rho] = O(\mu^{-s}\gamma^{-s} + \mu^{-1})$ and furthermore along trajectories $[a,\rho](t) = [a,\rho](0) + O((\mu^{-s}\gamma^{-s}|t|)$ (where s is an arbitrarily large exponent and $\delta = \delta(s) > 0$ is small enough) and therefore

(22.4.59) ρ preserves both its sign and the bound from below as $\rho(0) \ge C\mu^{-s}\gamma^{1-s}$ and $|t| \le T_1$ with

$$(22.4.60)\quad T_1 \coloneqq \epsilon\rho^{1/2}\mu^{s/2}\gamma^{s/2} \quad \text{as} \quad \bar\gamma_0 = C\mu^{-1} \le \gamma \le \bar\gamma,\ \rho \ge C\mu^{-s/2}\gamma^{1-s/2}$$

(where $\rho = \rho(0)$). Therefore the contribution of the corresponding strip to the remainder does not exceed

$$G(\rho,\gamma) \coloneqq C\mu^2 h^{-2}\gamma \times h\rho^{-2} \times \bigl((\rho^2+\gamma^2)(\mu h)^{-1}+1\bigr) \times \rho(\mu h)^{-1} \times \rho^{-1/2}\mu^{-s/2}\gamma^{-s/2}.$$

Therefore after summation over $\rho \ge C\mu^{-s/6}\gamma^{1-s/6}$ we arrive to the expression $G(1,\gamma) + G(\mu^{-s/6}\gamma^{1-s/2})$ and for large enough s summation with respect to γ results in $G(1,\mu^{-1}) + G(\mu^{-1}\mu^{-1})$ which is $O(\mu^{-1}h^{-3})$.

Meanwhile, the contribution of the zone $\{|x_1| \asymp \gamma, \rho \le \varrho \coloneqq C\mu^{-s/6}\gamma^{1-s/6}\}$ to the remainder due to Proposition 22.4.10 does not exceed $C\varrho\gamma\mu h^{-3} \asymp C\mu^{-s/6}\gamma^{1-s/6}h^{-3}$ and summation with respect to γ results in $C\mu^{-1}h^{-3}$. Therefore

(22.4.61) Contribution of zone $\{\bar\gamma_0 \le |x_1| \le \bar\gamma\}$ to the remainder is $O(\mu^{-1}h^{-3})$.

(c) Similar arguments work for zones $\{|x_1| \le \bar\gamma_0,\ \rho \ge \varrho := C\mu^{-1}\}$ with $T_1 = C\rho^{1/2}$ and for $\{|x_1| \le \bar\gamma_0,\ \rho \le \varrho\}$ and therefore

(22.4.62) Contribution of the zone $\{|x_1| \le \bar\gamma_0\}$ to the remainder is $O(\mu^{-1}h^{-3})$.

This concludes Part III and the whole proof. □

22.4.5 Sharp Asymptotics at Resonances

In this subsection we are going to prove sharp remainder estimate under generic assumptions to V. We know from Proposition 22.2.6 that in the generic situation critical points of $\phi_\alpha = \alpha \log f_1 + (1-\alpha)\log f_2 - \log V$ are non-degenerate except of discrete values of $\alpha = \alpha_j$. One can prove easily that

(22.4.63) In the generic case degenerate critical points α_j of ϕ_α are not resonances. Then as $\alpha \ne \alpha_j$ the set of critical points is a smooth 1-dimensional curve parametrized by α and resonance surface is 3D surface.

(22.4.64) In the generic case these curve and resonance surface Ξ_{kl} meet at isolated points and are transversal in them.

Then

$$(22.4.65)_{q,r}\quad \tilde\nu(\rho,\zeta,\gamma) := \mathsf{mes}\Big\{(x,\alpha):\ |kf_1 - lf_2| < \gamma,\ |\nabla'\big(\alpha\log f_1 + (1-\alpha)\log f_2 - \log V\big)| \le \zeta,\ |\nabla\big(\alpha\log f_1 + (1-\alpha)\log f_2 - \log V\big)| \le \rho\Big\} \le C\rho^{q-r}\zeta^r\gamma \quad \text{as}\ \ \rho\ge\gamma,\ \rho\ge\zeta\ge(\rho\gamma)^{1/2}$$

with $r = 3$, $q = 4$.

Proposition 22.4.11. *Let us assume that* $|f_1 - f_2| \ge \epsilon_0$ *and* $|\nabla(f_1 f_2^{-1})| \ge \epsilon_0$ *on* $\mathsf{supp}(\psi)$. *Furthermore, let conditions* (22.1.7), $(22.4.21)_q$ *with* $q > 3$ *and* $(22.4.65)_{q,r}$ *be fulfilled with* $r > 2$, $q > 3$. *Then under condition* (22.4.18) *asymptotics with the standard implicit main part* (22.1.5) *and the remainder estimate* $O(\mu^{-1}h^{-3})$ *holds.*

Proof, Part I. We will follow the proof of Proposition 22.4.7 and use the same numbering of its parts.

(a) Repeating arguments leading to the proof of statements of Proposition 22.4.4 one can prove easily the following analogue of (22.4.40):

(22.4.66) Under condition $(22.4.21)_q$ the contribution of the zone $\{x: |x_1| \ge \mathsf{max}(\rho, \mu^{-2/3})\}$ to the remainder does not exceed $(22.4.22)_q$.

(b) Consider zone: $\{\rho \ge \mathsf{max}(\gamma, \mu^{-2}\gamma^{-2},\ \gamma \ge \bar{\gamma}\}$. Then the total contribution of all (ρ,ζ,γ) elements does not exceed expression (22.4.38) multiplied by $\tilde{\nu}(\rho,\zeta,\gamma)\rho^{-1}$:

$$C\mu h^{-1}\big(\zeta(\mu h)^{-1}+\zeta^{-1}\big)\times\big(\rho(\mu h)^{-1}+1\big)\times\rho^{q-r-1}\zeta^{r} \tag{22.4.67}$$

where we used $(22.4.65)_{q,r}$ to estimate $\tilde{\nu}$. Then as $r>1$ summation with respect to ζ results in the same expression as $\zeta=\rho$; further as $q>3$ summation with respect to ρ results in the same expression as $\rho=1$ which is $C\mu^{-1}h^{-3}$ and summation with respect to γ results in $C\mu^{-1}h^{-3}|\log h|$. One can get rid of the logarithmic factor using the same arguments as in the f proof of Proposition 22.4.4.

(c) Consider the remaining part of zone $\{\epsilon \ge \gamma \ge \bar{\gamma}\}$ and introduce scaling function η by (22.4.41). Then one gets $(22.4.37)^*$ modified in the same way as in the f proof of Proposition 22.4.4 and multiplied by $\eta\gamma^{-1}\tilde{\nu}(\rho\gamma)^{-1}$:

$$C\mu h^{-1}\big(\zeta(\mu h)^{-1}+\zeta^{-1}\big)\times\big(\rho(\mu h)^{-1}+1\big)\times\eta\gamma^{-1}\times\rho^{q-r-s-1}\zeta^{r}. \tag{22.4.67}^*$$

Then as in (b) summation with respect to ζ results in its value as $\zeta=\rho$:

$$C\mu h^{-1}\big(\rho(\mu h)^{-1}+\rho^{-1}\big)\times\big(\rho(\mu h)^{-1}+1\big)\times\mu^{2}\varrho^{-2}\gamma^{3}\rho\gamma^{-1}\times\rho^{q-s-1}\gamma^{s-1}$$

and summation with respect to ρ returns the above expression at its largest value which is $\mu^{-2}\gamma^{-2}\varrho^{2}$; the result does not exceed $C\mu^{-1-\delta'}h^{-3}$ and summation with respect to γ returns $o(\mu^{-1}h^{-3})$. □

Remark 22.4.12. (i) Again as the order of resonance $m\ge 4$, analysis of (c) is not needed;

(ii) Furthermore, the rough remainder estimate of zone $\{|x_1| \le \bar\gamma\}$ returns $O(\mu^{-1}h^{-3})$ as $m \ge 5$ and $\mu \le h^{\delta'-1}$ and $O(\mu^{-1+\delta}h^{-3})$ as either $m = 4$ or $m = 5$, $h^{\delta'-1} \le \mu \le ch^{-1}$.

Proof, Part II. (a) Analysis in the zone $\{|x_1| \le \bar\gamma\}$ is now simpler. Note first that the contribution of the zone $\{\zeta \le \bar\gamma\}$ to the remainder does not exceed $C\mu h^{-3}\bar\gamma^{r+1} = O(\mu^{-1}h^{-3})$ as $r > 1$ and $\delta < \delta(r)$.

(b) Consider zone $\{\zeta \ge C\bar\gamma\}$. Then defining T_0, T_0^* by (22.4.35) and T_1 by (22.4.36) one estimates contribution of $(\rho, \bar\gamma, \zeta)$ elements by (22.4.50) multiplied by $\tilde\nu(\rho\bar\gamma)^{-1}$:

$$C\mu^2h^{-2}\bar\gamma \times h\zeta^{-2} \times \bigl(\zeta^2(\mu h)^{-1} + 1\bigr) \times \rho(\mu h)^{-1} \times \bigl(\mu^{-1}\bar\gamma^{-1/2} + \rho^{-1}\bigr) \times \rho^{q-r-2}\zeta^r \tag{22.4.68}$$

and summation with respect to ζ results in its value as $\zeta = \rho$ (now we need $r > 2$)

$$C\mu h^{-2}\bar\gamma \times \bigl(\rho^2(\mu h)^{-1} + 1\bigr) \times \bigl(\mu^{-1}\bar\gamma^{-1/2} + \rho^{-1}\bigr) \times \rho^{q-3}$$

and summation with respect to ρ results in $Ch^{-3}\bar\gamma$ which is marginally worse than $O(\mu^{-1}h^{-3})$. To improve it one can sum to $\zeta \le \mu^{-\kappa}$ and in zone $\{\zeta \ge \mu^{-\kappa}\}$ one can take $T_1 = \epsilon\mu\zeta$. □

22.4.6 General Estimates near Σ

Now let us consider the vicinity of $\Sigma = \{f_1 = f_2\} = \{v_1 = v_2 = 0\}$ where

$$v_1|_\Sigma = v_2|_\Sigma = 0,\ (\nabla v_1)|_\Sigma \text{ and } (\nabla v_2)|_\Sigma \text{ are linearly independent} \tag{22.4.69}$$

and near Σ

$$f_{1,2} = f \pm (v_1^2 + v_2^2)^{1/2}, \qquad f > 0. \tag{22.4.70}$$

This analysis is simpler than near third order resonances because codimension of Σ is now 2 and everywhere factor γ^1 reflecting measure should be replaced by γ^2.

Proposition 22.4.13. *Let condition* (22.2.1)–(22.2.2) *be fulfilled and let* ψ *be supported in the small vicinity of* Σ.

The standard implicit asymptotic formula (22.1.5) *holds with the remainder estimate* $O(\mu^{-1}h^{-3} + \mu^2h^{-2})$.

Proof. (a) Note first that

(22.4.71) The contribution of the zone $\{\mathsf{dist}(x,\Sigma)\le\gamma\}$ to the remainder does not exceed $C\mu h^{-3}\gamma^2$ and as

$$\gamma := \mathsf{dist}(x,\Sigma) \asymp |f_1-f_2| \le \bar\gamma_1 := c\mu^{-1}+c(\mu h)^{1/2} \tag{22.4.72}$$

this contribution is $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$.

On the other hand,

(22.4.73) One can reduce operator to the canonical form without non-diagonal terms as long as

$$\gamma \ge \bar\gamma := \mu^{-1/2}h^{1/2-\delta'}+\mu^{-2}h^{-\delta'}. \tag{22.4.74}$$

The second term in (22.4.74) appears because one needs to get rid of terms $Z_1^iZ_1^{*j}Z_2^kZ_2^{*l}$ with $i+k=j+l$ but $(i,j)\ne(k,l)$ and these terms are of magnitude $O(\mu^{-2})$ unless $i+j+k+l=2$ in which case one just diagonalizes the quadratic form and it is where the first term in in (22.4.74) comes from.

It is important that $\bar\gamma\le\bar\gamma_1$. In the quest for remainder estimate $O(\mu^{-1}h^{-3})$ one would need to take $\bar\gamma=c\mu^{-1}$ and $\bar\gamma\le\bar\gamma_1$ would hold as $\mu\le h^{\delta'-1}$.

(b) Making $\epsilon\gamma$-admissible partition and ρ-admissible subpartition with

$$\rho=\epsilon|\nabla\phi_\alpha|\gamma+\frac{1}{2}\bar\rho,\qquad \bar\rho=\bigl(C\mu^{-1}h|\log h|\bigr)^{1/2} \tag{22.4.75}$$

one can take

$$T_0^*=Ch\rho^{-2}\gamma,\qquad T_1=\epsilon\mu\gamma \tag{22.4.76}$$

and the total contribution to the remainder of (γ,ρ) subelements with $\rho\ge\varrho$ to the remainder does not exceed

$$\begin{aligned} C\mu^2h^{-2}\times\mu^{-1}h\rho^{-2}\times\bigl(\rho^2(\mu h\gamma)^{-1}+1\bigr)\times\bigl(\rho(\mu h\gamma)^{-1}+1\bigr)\times\gamma^2 \\ \asymp C\mu^{-1}h^{-3}\rho+C\rho^{-1}h^{-2}\gamma+C\mu h^{-1}\rho^{-2}\gamma^2 \end{aligned} \tag{22.4.77}$$

where γ^2 is their total measure. The right-hand expression sums with respect to $\rho\in(\bar\rho,\gamma)$ to $G(\gamma):=C\mu^{-1}h^{-3}\gamma+Ch^{-2}\bar\rho^{-1}\gamma+C\mu h^{-1}\bar\rho^{-2}\gamma^2$. Then with respect to γ it sums to $G(1)=O\bigl(\mu^{-1}h^{-3}+\mu^{1/2}h^{-5/2}+\mu^2h^{-2}\bigr)$ where the middle term is less than the sum of two others.

(c) Meanwhile, the total contribution to the remainder of $(\bar\rho,\gamma)$ subelements does not exceed

$$C\mu^2h^{-2}\times\bigl(\bar\rho^2(\mu h\gamma)^{-1}+1\bigr)\times\bigl(\bar\rho(\mu h\gamma)^{-1}+1\bigr)\times\gamma^2\asymp Ch^{-4}\bar\rho^3+C\mu h^{-3}\gamma\bar\rho+C\mu^2h^{-2}\gamma^2. \tag{22.4.78}$$

This expression sums with respect to γ to its value as $\gamma=1$ resulting in

$$C\mu^{-3/2}h^{-5/2}|\log h|^{3/2}+C\mu^{1/2}h^{-5/2}|\log h|^{1/2}+C\mu^2h^{-2}.$$

Note that the first and the third term are properly estimated and the second terms is properly estimated save border case $h^{-1/3}|\log h|^{-K}\le\mu\le h^{-1/3}|\log h|^{K}$ which is treated as in the part (c) of the Proof of Proposition 22.4.1.

(d) Finally, as $\gamma\le\bar\gamma$ one does not need a subpartition; the contribution to the remainder does not exceed $C\mu h^{-3}\bar\gamma^2$ due to an analogue of Proposition 22.4.10 below. □

Proposition 22.4.14. *Proposition 22.4.10 remains true near* Σ *(i.e. without condition* $|f_1-f_2|\ge\epsilon$ *provided at point* $\bar x$ *main part of precanonical form is* $f_1(\mu^2x_3^2+h^2D_3^2)+f_2(\mu^2x_4^2+h^2D_4^2)$.

Proof. Proof basically repeats the one of Proposition 22.4.10. □

22.4.7 Sharp Asymptotics near Σ

Sharp Asymptotics near Σ. I

Now let us improve the results of the previous subsection. Let us observe that

(22.4.79) Microhyperbolicity condition holds at $\bar x\in\Sigma$ iff $\nabla(fV^{-1})$ is not a linear combination of $\nabla(v_1V^{-1})$, $\nabla(v_2V^{-1})$ with coefficients $(\beta_1,\beta_2)\in\mathbb{R}^2\cap B(0,1)$ [14].

In virtue of Chapter 19 we have already

[14] In the uniform sense, i.e. (22.2.22)

Proposition 22.4.15. *If* (22.2.22) *is fulfilled on* $\mathsf{supp}(\psi)$ *then the standard formula holds with* $\bar{T} = Ch|\log h|$.

Now let us analyze the meaning of condition (22.2.22). First of all, it is fulfilled as $\nabla_\Sigma(fV^{-1}) \neq 0$. So one needs to consider only set Σ_0 of the critical points of $fV^{-1}\big|_\Sigma$:

$$\Sigma_0 = \big\{x \in \Sigma,\ \nabla_\Sigma(fV^{-1}) = 0\big\}. \tag{22.4.80}$$

Then

Proposition 22.4.16. *For generic* V

(22.4.81) Σ_0 *consists of separate non-degenerate points.*

(22.4.82) *Magnetic form* ω_f *restricted to* Σ *is the generic closed form on* Σ *and thus degenerates on the smooth curve* $\{\{v_1, v_2\} = 0\}$.

(22.4.83) ω_M *does not degenerate on* Σ_0 *(which is equivalent to* $\{v_1, v_2\} \neq 0$ *on* Σ_0*).*

One can write down many generic properties, but they are overkill.

Sharp Asymptotics near Σ. II

First let us improve the remainder under condition (22.4.84) below (recall that $f = \frac{1}{2}(f_1 + f_2)$):

Proposition 22.4.17. *Let at some point* $\bar{x} \in \Sigma$

$$|\nabla(fV^{-1})| \geq \epsilon_0. \tag{22.4.84}$$

Then as ψ *is supported in the small enough vicinity of* $\bar{x}$ *the standard implicit formula holds with the remainder* $O\big(\mu^{-1}h^{-3} + \mu^{3/2}h^{-3/2}|\log h|\big)$.

Proof. (a) Note that here in contrast to (22.2.22) the complete gradient is considered. One needs to consider the case when microhyperbolicity condition is not fulfilled in $\bar{x} = 0$; then

$$\nabla(fV^{-1}) = \beta_1\nabla(v_1V^{-1}) + \beta_2\nabla(v_2V^{-1}) \qquad \text{at } \bar{x}, \tag{22.4.85}$$
$$\beta = (\beta_1, \beta_2) \in \mathbb{R}^2 : 1 \geq |\beta| \geq \epsilon_0$$

where $|\beta| \ge \epsilon_0$ due to (22.4.84).

Let us consider $\phi_\alpha = \alpha(f_1 V^{-1}) + (1-\alpha)(f_2 V^{-1})$; note that one can extend β_j to the vicinity of $\bar{x}$ so that

$$fV^{-1} = \tilde{f}(w) + \beta_1(w) v_1 V^{-1} + \beta_2(w) v_2 V^{-1} + O(|v|^2)$$

where $w = (w_1, w_2)$ are coordinates on Σ.

Without any loss of the generality one can assume that $\beta_2(w) = 0$; then under conditions (22.4.84), (22.4.85)

$$|\nabla \phi_\alpha| \ge \epsilon_1 \big(|(v_2 - \omega v_1^2)(v_1^2 + v_2^2)^{-1/2}| + |\alpha - \bar{\alpha}| \big) \tag{22.4.86}$$

where $\omega = \omega(w, v_1)$ is a smooth function.

(b) Let us follow the proof of Proposition 22.4.13. In part (b) estimate (22.4.77) (for contribution of all elements with $\rho \ge \varrho$) gains a factor $\rho\gamma^{-1}$ and becomes

$$C\mu^{-1}h^{-3}\rho^2\gamma^{-1} + Ch^{-2} + C\mu h^{-1}\rho^{-1}\gamma. \tag{22.4.77)*}$$

This expression sums with respect to ρ ranging from $\bar{\rho}$ to γ to

$$C\mu^{-1}h^{-3}\gamma + Ch^{-2}|\log h| + C\mu h^{-1}\bar{\rho}^{-1}\gamma.$$

Then summation with respect to γ results in

$$C\mu^{-1}h^{-3} + Ch^{-2}|\log h|^2 + C\mu^{3/2}h^{-3/2}$$

which is less than the announced estimate.

(c) In part (b) estimate (22.4.78) (for the contribution of all elements with $\rho \le \bar{\rho}$) gains a factor $\bar{\rho}\gamma^{-1}$ and becomes

$$Ch^{-4}\bar{\rho}^4\gamma^{-1} + C\mu h^{-3}\bar{\rho}^2 + C\mu^2 h^{-2}\bar{\rho}\gamma. \tag{22.4.78)*}$$

This expression sums with respect to γ to

$$C\mu^{-2}h^{-2}|\log h|^2\bar{\gamma}^{-1} + Ch^{-2}|\log h|^2 + C\mu^{3/2}h^{-3/2}|\log h|^{1/2}$$

which is also less than the announced remainder estimate.

(d) Finally, as $\gamma \le \bar{\gamma}$ one does not need a subpartition; the contribution to the remainder does not exceed $C\mu h^{-3}\bar{\gamma}^2 = C\mu^{-1}h^{-3} + C\mu^{-1/2}h^{\delta-5/2}$ and the second term here is obviously much less than the announced estimate. □

So, condition (22.4.84) is a kind of non-degeneracy condition, improving the remainder estimate.

Sharp Asymptotics near Σ. III

Let us now use the remaining non-degeneracy conditions.

Proposition 22.4.18. *Let conditions* (22.4.18) *and*

$$(22.4.87)_r \quad |(2p+2)\mu hfV^{-1}-1| + |\nabla_\Sigma\big((2p+2)\mu hfV^{-1}-1\big)| \le \epsilon_0 \implies \mathsf{Hess}_\Sigma\big((2p+2)\mu hfV^{-1}-1\big) \text{ has at least } r \text{ eigenvalues with absolute values greater than } \epsilon_0$$

be fulfilled. Then

(i) The total remainder is given by $(22.4.21)_{r+1}$ *while the main part is given by the standard implicit formula* (22.1.5).

(ii) Under condition (22.4.84) *the total remainder is given by* $(22.4.21)_{r+2}$ *as* $r=1$ *while the main part is given by the standard implicit formula* (22.1.5).

(iii) Under conditions (22.4.84) *and* (22.4.83) *the total remainder is* $O(\mu^{-1}h^{-3})$ *as* $r=2$ *while the main part is given by the standard implicit formula* (22.1.5).

Proof. (a) Under condition (22.4.84) the total contribution to the remainder of all (γ,ρ)-elements does not exceed $(22.4.77)^*$ i.e.

$$(22.4.88)_k \qquad C\mu^{-1}h^{-3}\rho^{k+1}\gamma^{-k} + C\rho^{k-1}\gamma^{1-k}h^{-2} + C\mu h^{-1}\gamma^{2-k}\rho^{k-2}$$

with $k=1$ while without it it does not exceed the same expression with $k=0$.

Further, under extra condition $(22.4.87)_r$ this expression acquires factor $C\rho^r\gamma^{-r}$. Therefore again $(22.4.88)_q$ with $q=k+r$ gives a proper estimate for the total contribution of all (γ,ρ)-elements to the remainder.

Consider summation with respect to $\bar\rho \le \rho \le \gamma \le 1$. The first term sums to $C\mu^{-1}h^{-3}$ independently on q; the second term sums to $Ch^{-2}|\log h|^2$ as $q=1$ and to $Ch^{-2}|\log h|$ as $q\ge 2$; the third term sums to $C\mu h^{-1}\bar\rho^{-1}$ as $q=1$, to $C\mu h^{-1}|\log h|^2$ as $q=2$ and to $C\mu h^{-1}|\log h|$ as $q=3$.

Therefore in all cases but one the remainder estimate $(22.4.21)_q$ with $q=k+r$ is proven; this exceptional case is $q=3$, $\mu \ge h^{-1}|\log h|^{-1}$ when the estimate $O(h^{-2}|\log h|)$ is recovered; recall that only zone $\{\rho\ge\bar\rho,\ \gamma\ge\bar\gamma\}$ is covered so far.

(b) To cover the remaining case let us introduce a scaling function $\zeta = \epsilon|\nabla_{\Sigma} f V^{-1}| + \bar{\rho}$ on Σ; one can extend this function to

$$\zeta = \epsilon|\nabla_{\Sigma} f V^{-1}| + \gamma. \tag{22.4.89}$$

Then in arguments above one can replace factor $\rho^2\gamma^{-2}$ by ζ^2 and then contribution of zone $\{\zeta \le \gamma^{\delta'}\}$ would be $O(\mu^{-1}h^{-3})$ as $q = 3$; so only subzone $\{\zeta \ge \gamma^{\delta'}\}$ remains to be treated. In this subzone one can take

$$T_0^* = Ch\zeta^{-2}, \qquad T_1 = \epsilon\mu\gamma \tag{22.4.90}$$

where one can take $T_0^* = Ch\zeta^{-2}$ rather than $T_0^* = Ch\zeta^{-1}\gamma^{-1}$ due to (22.4.83). Then the total contribution of such (γ, ζ) elements to the remainder does not exceed

$$C\mu^2h^{-2}\zeta^2\gamma^2 \times h\zeta^{-2} \times \mu^{-1}\zeta^{-1} \times \big((\zeta^2+\gamma)(\mu h)^{-1}+1\big) \times (\mu h)^{-1}$$

where $\zeta^2\gamma^2$ is the measure and $(\mu h)^{-1}$ and $\big((\zeta^2+\gamma)(\mu h)^{-1}+1\big)$ are estimates of the numbers of indices "p" and corresponding indices "n"; noting that $\zeta^2 \ge \gamma$ one can rewrite this expression as

$$C\mu^{-1}h^{-3}\gamma^2\zeta + Ch^{-2}\gamma^2\zeta^{-1}$$

and the summation with respect to $\zeta \ge \gamma^{\delta'}$ and γ results in $O(\mu^{-1}h^{-3})$.

Thus estimate $(22.4.21)_q$ for contribution of zone $\{\rho \ge \bar{\rho},\ \gamma \ge \bar{\gamma}\}$ is established.

(c) Further, contribution of (γ, ρ) elements with $\rho \le \bar{\rho}$, $\gamma \ge \bar{\gamma}$ to the remainder does not exceed (22.4.77) as $k = 0$ or $(22.4.77)^*$ as $k = 1$ multiplied by $\bar{\rho}^r\gamma^{1-r}$ i.e.

$$Ch^{-4}\bar{\rho}^{q+3}\gamma^{-q} + C\mu h^{-3}\bar{\rho}^{q+1}\gamma^{1-q} + C\mu^2h^{-2}\bar{\rho}^q\gamma^{3-q} \tag{22.4.91}_q$$

and one can check easily that summation with respect to $\gamma \ge \bar{\gamma}$ results in expression not exceeding $(22.4.21)_q$.

(d) Finally, contribution of zone $\{\gamma \le \bar{\gamma}\}$ to the remainder does not exceed $C\mu h^{-3}\bar{\gamma}^2$ which is $O(\mu^{-1}h^{-3})$ unless $\mu \ge h^{2\delta-1}$ and even in this case it is less than $(22.4.21)_1$.

Therefore as $q \geq 2$ we need some better arguments in this zone. Again, one needs to consider only part of it with $\{\zeta \geq \mu^{-\delta'}\}$ as contribution of the zone $\{\zeta \leq \bar{\zeta}\}$ does not exceed $C\mu h^{-3}\bar{\gamma}^2\bar{\zeta}^2$.

As using precanonical form the speed would be $O(\mu^{-1})$ and since only a magnitude of ζ is important for us and also inequality $\zeta \geq \gamma^{\delta'}$, one can take

$$T_0^* = Ch\zeta^{-1}\bar{\gamma}^{-1}, \qquad T_1 = \epsilon\mu\bar{\gamma}^{1-\delta''} \tag{22.4.92}$$

where an appropriate time direction for this T_1 is taken. In these arguments we do not assume (22.4.83) and and thus T_0 is not as it was in (b) (surely, some improvements are possible but not needed).

Then the total contribution to the remainder of ζ-elements does not exceed

$$Ch^{-4}\zeta^r\bar{\gamma}^2 \times h\zeta^{-1}\bar{\gamma}^{-1} \times \mu^{-1}\bar{\gamma}^{\delta''-1} \asymp C\mu^{-1}h^{-3}\zeta^{r-1}\bar{\gamma}^{\delta''}$$

which sums with respect to ζ to $C\mu^{-1}h^{-3}|\log h|\bar{\gamma}^{\delta''} = o(\mu^{-1}h^{-3})$ even as $r = 1$. □

Remark 22.4.19. (i) Since in the generic case in the critical points of $fV^{-1}|_\Sigma$ are non-degenerate (i.e. (22.4.81) is fulfilled) and also (22.4.82), (22.4.83) hold, the remainder estimate is $O(\mu^{-1}h^{-3})$.

(ii) Probably one can get rid of logarithmic factors in the above estimates but we do not care.

22.4.8 Summary

Proposition 22.4.20. *Let (g^{jk}) be fixed and then (V_j) be be generic, more precisely:*

(i) Outside of $\Sigma = \{x : \ f_1 = f_2\}$ critical points of $f_1 f_2^{-1}$ satisfy (22.3.30)$_3$ *and* (22.3.2)*.*

(ii) Σ be smooth 2-dimensional manifold and $|f_1 - f_2| \asymp \mathsf{dist}(x, \Sigma)$.

Further, let V be general but satisfying (22.1.7) *at $\mathsf{supp}(\psi)$.*

Then under condition (22.4.1) *the remainder is $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$ while the main part of asymptotics is given by implicit formula* (22.1.5)*.*

Proposition 22.4.21. *Let in the framework of Proposition 22.4.20* V *be generic i.e.*

(i) Outside of Σ *and resonances condition* $(22.4.21)_4$ *be fulfilled.*

(ii) Near resonances condition $(22.4.65)_{4,3}$ *be fulfilled.*

(iii) At Σ *conditions* (22.4.81)–(22.4.84) *be fulfilled*[15)]*.*

Let V *satisfy* (22.1.7) *at* $\mathsf{supp}(\psi)$*. Then under condition* (22.4.18) *the remainder is* $O(\mu^{-1}h^{-3})$ *while the main part of asymptotics is given by implicit formula* (22.1.5)*.*

22.5 Calculations

The purpose of this section is to pass from the implicit formula (22.1.5) to more explicit one, namely either (22.6.6) or (22.6.4) below with more or less explicit expression for $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$. It will be done by different methods depending on the magnitude of μ and also non-degeneracy conditions and the methods applied will be used in the classification. Our main concern will be to prove such formula under either no non-degeneracy condition at all or under the generic non-degeneracy condition.

22.5.1 Temperate Magnetic Field

In this subsection we will use formula (22.1.5) with $T_0 \le \epsilon\mu^{-1}$ and derive a remainder estimate. More precisely, if in Section 22.4 T was given by (22.1.5) with $T_0 \ge \epsilon\mu^{-1}$ and we replace it by $T_0 = \epsilon\mu^{-1}$ and estimate an error.

This error actually is the contribution of the affected domain to the remainder with some $T_0 \ll \mu^{-1}$ (usually $T_0 = Ch|\log h|$ under condition (22.1.7)) and $T_1 = \epsilon\mu^{-1}$.

Further, under condition (22.1.7) we can trade $T \le \epsilon\mu^{-1}$ to $T = Ch|\log h|$ and then we can apply the standard approach; we will assume here by default that

$$h^{-\delta_0} \le \mu \le h^{-1+\delta_0} \tag{22.5.1}$$

leaving case $\le h^{-1+\delta_0} \le \mu \le ch^{-1}$ for a separate consideration.

[15)] Actually these conditions should be fulfilled at $\Sigma_0^+ \cup \Sigma_0^0$ only.

Temperate Magnetic Field. I

Let us consider regular points first.

Proposition 22.5.1. *Assume that there are no resonances of order not exceeding* M *and also* $|\nabla(f_1 f_2^{-1})| \ge \epsilon_0$ *on* $\mathsf{supp}(\psi)$. *Further, assume that condition* (22.4.21)$_q$ *with* $q \ge 1$ *is fulfilled. Then under condition* (22.5.1) *the remainder estimate is given by*

$$O\Big(\mu^{-1}h^{-3} + (\mu h)^{(q+2)/2}h^{-4}|\log h|^{q/2}\Big) \tag{22.5.2}_q$$

while the main term of asymptotics given by (22.1.5) *with any* $T \ge \epsilon\mu^{-1}$.

Proof. First of all, observe that as $q = 1$ this remainder estimate is $O\big(\mu^{-1}h^{-3}+(\mu h)^{3/2}h^{-4}|\log h|^{1/2}\big)$ which is no smaller than $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$ given by Proposition 22.4.1 and as $q > 1$ remainder estimate (22.5.2)$_q$ is no smaller than (22.4.22)$_q$ given by Proposition 22.4.4; so both of these propositions could be applied and one needs to estimate a substitution $T_0 \mapsto \epsilon\mu^{-1}$ error.

According to the proofs of these propositions $T_0 = Ch\rho^{-2}|\log h|$ which is less than $\epsilon\mu^{-1}$ as

$$\rho \ge \bar\rho_1 := (C\mu h|\log h|)^{1/2}. \tag{22.5.3}$$

Thus one can take there $T_0 = \epsilon\mu^{-1}$.

On the other hand, contribution of zone $\{\rho \le \bar\rho_1\}$ to the remainder with $T = \epsilon\mu^{-1}$ does no exceed $C\mu h^{-3}\nu(\bar\rho_1) \le C\mu h^{-3}\bar\rho_1^q$ which is exactly the second term in (22.5.2)$_q$. □

Corollary 22.5.2. *Let conditions of Proposition 22.5.1 be fulfilled. Then under assumption* (22.1.7)

(i) The remainder estimate is given by (22.5.2)$_q$ *while the main term of asymptotics given by*

$$\int \mathcal{N}^{\mathsf{MW}}(x,0)\psi(x)\,dx. \tag{22.5.4}$$

(ii) In particular, the remainder estimate is $O(\mu^{-1}h^{-3})$ *as* $\mu \le \bar\mu_q := C(h|\log h|)^{-q/(q+4)}$ *where in the general case* $\bar\mu_1 = C(h|\log h|)^{-1/5}$ *and in the generic case* $\bar\mu_4 = C(h|\log h|)^{-1/2}$.

Proof. According to Proposition 22.5.1 with the remainder estimate $(22.5.2)_q$ the main part of asymptotics is given by (22.1.5) with $T = \epsilon\mu^{-1}$. However, then under condition (22.1.7) one can trade $T = \epsilon\mu^{-1}$ to any $T \ge \bar{T} := Ch|\log h|$. The rest is proven by the standard successive approximation method, applied to the original operator (rather than to the canonical form); one can take as an unperturbed operator the same operator with the coefficients frozen at y which leads to the Weyl expression perturbed by

$$\sum_{m\ge 0, n\ge 1} \kappa_{mn} h^{-4+2m+2n}\mu^{2n}$$

where terms with $n \ge 2$ or $m \ge 1$ do not exceed the announced remainder estimate. Alternatively one can take as an unperturbed operator the same operator with g^{jk}, V frozen at y and with V_j replaced by $V_j(y) + \sum_k (\partial_k V_j)(y)(x_k - y_k)$ which leads directly to Magnetic Weyl expression. Details see in (18.1.28). □

Temperate Magnetic Field. II

Now we want to improve the result in the general case and allow non-degenerate critical points of $f_1 f_2^{-1}$.

Proposition 22.5.3. *Assume that $f_1 \ne f_2$ and there are no resonances of order not exceeding M and also critical points of $f_1 f_2^{-1}$ are non-degenerate on $\mathsf{supp}(\psi)$. Then under condition* (22.5.1) *the remainder estimate is given by* $(22.5.2)_q$ *with any $q < 2$ arbitrarily close to 2 while the main term of asymptotics given by the standard implicit formula with any $T \ge \epsilon\mu^{-1}$.*

Proof. Again, this remainder estimate is no smaller than $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$ given by Proposition 22.4.2, so again one needs to estimate an error arising from the substitution $T_0 \mapsto \epsilon\mu^{-1}$.

Proof follows ideas of the proof of Proposition 21.5.5. Let us introduce functions ℓ_k, $k = 1, \dots, K$ in the same proof but with $\gamma = 1$ and again let $\bar{\ell}_k = (\mu h|\log h|^J)^{1/(k+1)}$.

(a) Assume first that $|\nabla(f_1 f_2^{-1})| \ge \epsilon_0$. Then the arguments of the mentioned proof survive with this simplification.

(b) Assume now that $f_1 f_2^{-1}$ has one non-degenerate critical point $\bar{x}$. Consider first zone where $\ell_K(x) \le \gamma(x) := \frac{1}{2}|x - \bar{x}|$.

Then the number of indices "p" does not exceed $C\big(\ell_k^K(\mu h\gamma)^{-1}+1\big)$ (where the second term is the smallest one) while the number of indices "n" for each p does not exceed $C\big(\ell_K^{K+1}(\mu h)^{-1}+1\big)$ and the total contribution to the asymptotics of all such elements with $\ell_K \asymp \bar\ell_K$ and fixed magnitude of $\gamma(x)\asymp\gamma$ for some k does not exceed

$$C\mu^2h^{-2}h^{-2}\times\big(\ell_K^{K+1}(\mu h)^{-1}+1\big)\times\ell_k^K(\mu h\gamma)^{-1}\times\gamma^4$$

where γ^4 is the total measure of zone $\{\gamma(x)\asymp\gamma\}$. This expression does not exceed $C\mu^2h^{-2}\bar\ell_K^{-1}\gamma^3|\log h|^J$ and summation with respect to γ results in $C\mu^2h^{-2}\bar\ell_K^{-1}|\log h|^J\lesssim C(\mu h)^{2-\delta}h^{-4}$ as $\delta>1/K$.

On the other hand, repeating arguments of the proof of Proposition 21.5.5 one can see easily that the total contribution to the substitution error (when one replaces $T_0\ge\epsilon\mu^{-1}$ by $T_0=\epsilon\mu^{-1}$) of all elements with $\ell_K\ge C_0\bar\ell_K$ does not exceed $C\mu^{-1}h^{-3}+C\mu^2h^{-2}\bar\ell_K^{-1}$ which results in the same estimate.

(c) Alternatively, assume that $\ell_j\le\gamma\le\ell_{j+1}$ for some $j\le K-1$. Again one needs to consider elements with $\ell_k\asymp\bar\ell_k\le\gamma$ for some $k\le j$. Then in virtue of the same arguments of the proof of Proposition 21.5.5 the contribution to the asymptotics does not exceed

$$C\mu^2h^{-2}\ell_k^{-1}\gamma^{-1}|\log h|^J\times\gamma^4\times\ell_k\gamma^{-1}\asymp C\mu^2h^{-2}|\log h|^J\gamma^2$$

where the last factor $\ell_k\gamma^{-1}$ is the upper bound of the relative measure of ℓ_k elements to γ.

Again summation with respect to γ results in $C\mu^2h^{-2}|\log h|^J$.

(d) Finally, consider elements with $\ell_1\ge\gamma$. Then we redefine $\gamma=\ell_1$ and only $\ell\asymp\bar\ell_1$ should be considered since otherwise $T_0\le\epsilon\mu^{-1}$.

Contribution of such elements to the remainder with $T_0=\epsilon\mu^{-1}$ does not exceed $C\mu h^{-3}\bar\ell_1^4=O(\mu^3h^{-1}|\log h|^J)$. □

Temperate Magnetic Field. III

Now we want to attack resonances.

Proposition 22.5.4. *Assume that that* $|f_1-f_2|\ge\epsilon_0$ *and* $|\nabla(f_1f_2^{-1})|\ge\epsilon_0$ *on* $\mathsf{supp}(\psi)$. *Let consider asymptotics with the main part given by the standard*

implicit formula with any $T \ge \epsilon\mu^{-1}$. *Then under condition* (22.5.1) *the remainder does not exceed* $(22.5.2)'_q$ [16] *with* $q < 2$ *arbitrarily close to* 2.

Proof, Part I. Let us consider first zone $\{|x_1| \ge \bar\gamma\}$ and apply to the canonical form the same method as in the proof of Proposition 22.5.3. Again we assume that there is just one resonance surface $\Xi = \{x_1 = 0\}$.

However, definition of ℓ_k involves derivatives of order k and they are unbounded (with respect to x_1) as $\gamma^{k+1} \le \mu^{4-2m}$. To avoid this problem we rescale first $B(y, \gamma(y))$ into $B(0,1)$ and then apply this method. However, such rescaling would replace ρ by $\rho\gamma$ and ℓ by $\ell\gamma$ and leave $\rho\ell \ge C\mu h|\log h|$ intact. Then the main part of the remainder estimate gets factor γ^{-1} since the number of indices "p" will be $\rho(\mu h\gamma)^{-1}$ because the derivative with respect to x_1 for "p" and "$(p+1)$" would differ by $\mu h\gamma$.

So, the contribution of zone $\{x : \gamma(x) \asymp \gamma\}$ to the error estimate in question does not exceed $C(\mu h)^q h^{-4}$ with $q < 2$ arbitrarily close to 2; factor γ^{-1} discussed above is compensated by the same factor coming from the measure. Summation with respect to γ results in the similar answer (extra factor $|\log h|$ is covered by miniscule decrease of q).

This works as long as $|x_1| \ge \bar\gamma$ with

$$\bar\gamma = \mu^{2-m+\delta'} + \mu^{-2} \tag{22.5.5}$$

where the last term dominates as $m \ge 5$ only and guarantees that $\gamma \ge C\mu^{-1}h^{1-\delta}$.

Therefore,

(22.5.6) Contribution of zone $\{\bar\gamma \le |x_1| \le \epsilon\}$ to the remainder does not exceed $C\mu^{-1}h^{-3} + C(\mu h)^q h^{-4}$.

In particular, as $m = 5$ proposition is proven since the contribution of zone $\{|x_1| \le \bar\gamma$ to the remainder does not exceed $C\mu h^{-3}\bar\gamma$. □

Proof of Proposition 22.5.4, Part II. On the other hand, in zone $\{|x_1| \le \bar\gamma\}$ one can use precanonical form and contribution of the subzone $\{\rho \ge \bar\rho := C\max(\bar\gamma, \mu h|\log h|\bar\gamma^{-1})\}$ to the error is negligible while contribution of the subzone $\{\rho \le \bar\rho\}$ to the remainder does not exceed $C\mu h^{-3}\bar\gamma\bar\rho = C\mu h^{-3}\bar\gamma^2 + C\mu^2 h^{-2}|\log h|$; picking $\bar\gamma$ as $m = 4$ results in the proper estimate then.

[16] Where $'$ denotes that the power of $|\log h|$ could be larger.

However, as $m = 3$ one recovers only remainder estimate $C\mu^{-1+2\delta'}h^{-3} + C(\mu h)^q h^{-4}$ which is the required estimate as $\mu \ge h^{-1/3+\delta'}$ and only marginally worse otherwise. To recover the proper estimate one needs to reexamine the zone $\{|x_1| \le \bar\gamma, \rho \le \bar\gamma\} \setminus \{|x_1| \le \bar\gamma_0, \rho \le \bar\gamma_0\}$ since the contribution to the remainder of the latter does not exceed $C\mu^{-1}h^{-3}$. Without any loss of the generality one can assume that the non-diagonal term does not depend on x_1 since one can remove a term divisible by x_1 by the same method as for $|x_1| \ge \bar\gamma$ was removed the whole term.

In the subzone $\{\max(\rho, \bar\gamma_0) \le |x_1| \le \bar\gamma\}$ one can pick up $T_0 = Ch|\log h|\rho^{-2}$ which is less than $\epsilon\mu^{-1}$ unless $\rho \le \bar\rho := C(\mu h|\log h|)^{1/2}$ (which is less than μ^{-1} and the contribution to the remainder of the subzone $\{|x_1| \le \bar\gamma,\ \rho \le \bar\rho\}$ does not exceed

$$C\mu h^{-4}\bar\rho\bar\gamma = C\mu^{-1}h^{-3} \times \mu^{\delta}(\mu^3 h|\log h|)^{1/2} \le C\mu^{-1}h^{-3}$$

as $\mu \le h^{-1/3+\delta'}$ and $\delta = \delta'$.

In the subzones $\{|x_1| \asymp \gamma \le \rho\}$ with $\bar\gamma_0 \le \gamma \le \bar\gamma_1$ and $\{|x_1| \le \gamma = \bar\gamma_0 \le \rho\}$ one can take $T_0 = Ch|\log h|(\rho\gamma)^{-1}$ which is less than $\epsilon\mu^{-1}$ here for sure. □

Remark 22.5.5. It can happen that T_1 described in Section 22.4 is less than $\epsilon\mu^{-1}$. Then one can take $T_0 \le \epsilon\mu^{-1}$ anyway.

Temperate Magnetic Field. IV

Let us derive sharp remainder estimates in the resonance case:

Proposition 22.5.6. *Assume that that* $|f_1 - f_2| \ge \epsilon_0$ *and also* $|\nabla(f_1 f_2^{-1})| \ge \epsilon_0$ *on* $\mathsf{supp}(\psi)$. *Further, assume that conditions* (22.5.1) *and* $(22.4.21)_q$ *are fulfilled with* $q > 2$ *and that on (any) resonance surface* Ξ

$(22.5.7)_r$ $\mathsf{Hess}_\Xi\big(\mu h f V^{-1} - 1\big)$ *has at least* r *eigenvalues with absolute values greater than* ϵ_0

with $r = q - 1$.

Then the remainder estimate is given by $(22.5.2)'_q$ *while the main term of asymptotics given by the standard implicit formula with any* $T \ge \epsilon\mu^{-1}$.

Proof. Due to Proposition 22.5.3 one should cover only case $\mu \ge h^{-1/3+\delta'}$. Assumptions of proposition imply that condition $(22.4.65)_{r+1,r}$ holds. While

one can apply Proposition 22.4.10 directly only as $r > 2$, the proof of it yields that under condition (22.5.7) with $r = 1, 2$ the remainder estimate $O\big(\mu^{-1}h^{-3} + \mu^{2-r/2}h^{2+r/2}|\log h|^J\big)$ holds, which is not worse than $(22.5.2)_{r+1}$. Let us apply the same partition to zones as in Propositions 22.4.9, 22.4.10.

Then zone

$$\{\gamma \ge \mathsf{max}(\rho, \bar\gamma_2 := C\,\mathsf{max}(\mu^{-2/3}, (\mu h|\log h|)^{1/2}))\}$$

is covered by the arguments used in the proof of Proposition 22.5.1; its contribution to the error does not exceed $(22.5.2)_q$. Meanwhile, in the subzone $\{\rho \ge \gamma \ge \bar\gamma_2)\}$ one can take $T_0 = Ch|\log h|\bar\gamma_2^{-2}$ which is less than $\epsilon\mu^{-1}$.

Further, in the subzone $\{\bar\gamma \le |x_1| \asymp \gamma \le \bar\gamma_2\}$ one can take $T_0 = Ch|\log h|\zeta^{-2}$ which is less than $\epsilon\mu^{-1}$ unless $\zeta \le C(\mu h|\log h|)^{1/2}$. Similarly, in the subzone $\{|x_1| \le \bar\gamma\}$ one can take $T_0 = Ch|\log h|\zeta^{-2}$ as well. Note that the contribution of the zone

$$\{|x_1| \le \bar\gamma_2, \zeta \le \bar\zeta := C(\mu h|\log h|)^{1/2}\}$$

to the remainder does not exceed $C\mu h^{-3}\bar\gamma_2\bar\zeta^r$ which does not exceed the second term in $(22.5.2)_{r+1}$ as $\bar\zeta \asymp \bar\gamma_2$ i.e. $\mu^{-2/3} \le C(\mu h|\log h|)^{1/2}$ i.e. as $\mu \ge C(h|\log h|)^{-3/7}$.

Further, as $\mu \le C(h|\log h|)^{-3/7}$ let us consider zone $\{|x_1| \le \bar\gamma_2\}$ and use the precanonical form here. Then the contribution of the subzone $\{|x_1| \le \bar\gamma_2,\ \rho \le \bar\rho_2,\ \zeta \le \bar\zeta\}$ to the remainder does not exceed $C\mu h^{-3}\bar\gamma_2\bar\rho_2\bar\zeta^r$ which does not exceed the second term in $(22.5.2)_{r+1}$ as $\bar\zeta \ge \bar\gamma_2\bar\rho_2$.

Therefore one can pick up $\bar\rho_2 = \bar\zeta\bar\gamma_2^{-1}$; one can see easily that $\bar\rho_2 \gg \mu^{-2/3}$ and $\bar\rho_2\bar\gamma_2 \gg C\mu h|\log h|$ and then $T_0 \le Ch|\log h|\bar\rho_2^{-1}\bar\gamma_2^{-1} \ll \epsilon\mu^{-1}$ and the contribution of the zones $\{|x_1| \le \bar\gamma_2,\ \rho \ge \bar\rho_2\}$ and $\{|x_1| \le \bar\gamma_2,\ \zeta \ge \bar\zeta\}$ to the error is negligible. □

Temperate Magnetic Field. V

Finally, let us consider the vicinity of Σ.

Proposition 22.5.7. *Let conditions* (22.2.1)–(22.2.2), (22.5.1) *be fulfilled and let* ψ *be supported in the small vicinity of* Σ.

Then the remainder estimate is given by $(22.5.2)'_q$ *with any* $q < 2$ *arbitrarily close to* 2 *while the main term of asymptotics given by the standard implicit formula with any* $T \ge \epsilon\mu^{-1}$.

Proof. Again this remainder estimate is no smaller than $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$ delivered by Proposition 22.4.13.

Applying the same approach as in the Part I of the proof of Proposition 22.5.4 (which is applicable as $\gamma \ge \bar{\gamma}_2 := \mathsf{max}\big((\mu h|\log h|)^{1/2}, \mu^{-1}\big)$ now) we conclude after summation with respect to γ that the contribution of the zone $\{x : \gamma(x) \asymp \gamma\}$ (where $\gamma(x) = \mathsf{dist}(x, \Sigma)\}$) to the error does not exceed $C(\mu h)^q h^{-4}\gamma$ with $q < 2$ arbitrarily close to 1. Here an extra factor γ appears because the measure of $\{x : \gamma(x) \asymp \gamma\}$ is $\asymp \gamma^2$ rather than $\asymp \gamma$ as it was before. Then after summation we conclude that

(22.5.8) The contribution of the zone $\{x : \mathsf{max}((\mu h, \mu^{-1}) \le \gamma(x) \le \gamma\}$ to the error is $O\big((\mu h)^q h^{-4}\gamma\big)$. In particular, it is $O\big((\mu h)^q h^{-4}\big)$ as $\gamma = \epsilon$.

Meanwhile, the contribution of the zone $\{x : \gamma(x) \le \bar{\gamma}_2\}$ to the error does not exceed $C\mu h^{-3}\bar{\gamma}_2^2 \asymp (\mu^{-1}h^{-3}+\mu^2h^{-2})$. □

Temperate Magnetic Field. VI

Let us improve the above estimate under generic conditions.

Proposition 22.5.8. *Let conditions* (22.2.1)–(22.2.2), (22.5.1) *and* $(22.4.87)_r$ *with* $r = 1, 2$ *be fulfilled. Let* ψ *be supported in the small enough vicinity of* Σ. *Then*

(i) The total remainder is given by $(22.5.2)'_{r+1}$ *while the main part is given by the standard implicit formula with any* $T \ge \epsilon\mu^{-1}$.

(ii) Under condition (22.4.84) *the total remainder is given by* $(22.5.2)'_{r+2}$ *as* $r = 0, 1$ *while the main part is given by the standard implicit formula with any* $T \ge \epsilon\mu^{-1}$.

(iii) Under conditions (22.4.84) *and* (22.4.83) *the total remainder is given by* $(22.5.2)'_{r+2}$ *as* $r = 2$ *while the main part is given by the standard implicit formula with any* $T \ge \epsilon\mu^{-1}$.

Proof. Again let us note that the remainder estimate given by Proposition 22.4.17 as $r = 0$ and Proposition 22.4.18 as $r = 1, 2$ is no worse than one announced here.

In the zone $\{\gamma \ge \mathsf{max}(\rho, (\mu h|\log h)^{1/2}, \mu^{-1})\}$ the same arguments as in the proof of Proposition 22.5.3 are applied, and conditions $(22.4.87)_r$ and

(22.4.84) add factors $(\mu h|\log h|)^{r/2}$ and $(\mu h|\log h|)^{1/2}\gamma^{-1}$ respectively to the measure of the zone $\{\rho \le (\mu h|\log h|)^{1/2}$.

Then after summation with respect to γ one arrives to the estimate $(22.5.2)'_{r+k+1}$ of the contribution of this zone to the error estimate and $k=1$ under condition (22.4.84) and $k=0$ otherwise.

Meanwhile, $T_0 \le \epsilon\mu^{-1}$ in the zone $\{\rho \ge \gamma \ge C\max((\mu h|\log h|)^{1/2}, \mu^{-1})\}$.

So, one needs to consider zone $\{\gamma \le C\bar\gamma_2\}$. In this zone condition (22.4.74) has no value. Contribution of this zone to the remainder obviously does not exceed $(22.5.2)'_2$. Therefore case $r+k\le 1$ is covered.

Let us introduce ζ as before. As *either* $\zeta\le\gamma$ *or* condition (22.4.83) is fulfilled, one can take $T_0 = Ch\zeta^{-2}$ and then only the subzone $\{\zeta \le C(\mu h|\log h|)^{1/2}\}$ should be considered; then condition $(22.4.87)_r$ adds an extra factor $(\mu h|\log h|)^{r/2}$ to the measure and to the estimate which becomes $(22.5.2)'_{r+2}$.

That leaves us with the analysis of the zone $\{\zeta\ge\gamma\}\cap\{\gamma\le\bar\gamma_2\}$ and only without condition (22.4.83), in which case only estimate $(22.5.2)'_4$ should be proven under condition $(22.4.87)_1$. However, then one can take $T_0 = C\mu h|\log h|\gamma^{-1}\zeta^{-1}$ and then only the subzone $\zeta \le C\mu h|\log h|\gamma^{-1}$ remains to be considered. Its contribution to the remainder does not exceed $C\mu h^{-3}\times\mu h|\log h|\gamma^{-1}\times\gamma^2$ which sums with respect to γ ranging from $\bar\gamma_1 := \max(C\mu h|\log h|, \mu^{-1})$ to $\bar\gamma_2$ to $C\mu^2h^{-2}|\log h|\bar\gamma_2$ which is properly estimated. Meanwhile, contribution of the zone $\{x : \gamma(x)\le\bar\gamma_1\}$ to the remainder does not exceed $C\mu h^{-3}\bar\gamma_1^2$ and is properly estimated as well. □

Conclusion

Corollary 22.5.9. *Let conditions of one of Propositions 22.5.3–22.5.8 be fulfilled. Further, let condition* (22.1.7) *be fulfilled. Then*

(i) The remainder estimate is $(22.5.2)'_q$ *where*

(a) $q<2$ *is arbitrarily close to* 2 *in the general case (Propositions 22.5.3, 22.5.4, 22.5.7) and*

(b) q *is described in the corresponding case (Propositions 22.5.1, 22.5.6, 22.5.8),*

while the main part of asymptotics is given by (22.5.4).

(ii) In particular, the remainder estimate is $O(\mu^{-1}h^{-3})$ *as* $\mu\le\bar\mu_q := Ch^{-q/(q+4)}|\log h|^{-K}$. *In particular*

(a) in the general case $\bar{\mu}_1 = Ch^{\delta-1/3}$

(b) in the generic case $\bar{\mu}_4 = h^{-1/2}|\log h|^{-K}$.

Proof. Proof coincides with the proof of Corollary 22.5.2. □

Then we get immediately

Corollary 22.5.10. *(i) Theorem 22.6.3 below is proven with* $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} = 0$ *as* $\mu \le h^{\delta-1/3}$.

(ii) Theorem 22.6.4 below is proven as $\mu \le Ch^{-1/2}|\log h|^{-K}$.

22.5.2 Intermediate Magnetic Field

In this Subsection we assume that

$$h^{-1/3} \le \mu \le ch^{-1} \tag{22.5.9}$$

sometimes making separate considerations for the case of the *intermediate strong* magnetic field

$$h^{-1}|\log h|^{-K} \le \mu \le ch^{-1} \tag{22.5.10}$$

as needed. Also in the general case we consider a special range $h^{-1/3+\delta} \le \mu \le h^{-1/3-\delta}$.

Strong Magnetic Field. I

We start from the regular points.

Proposition 22.5.11. *Assume that there are no resonances of order not exceeding* M *and also* $|\nabla(f_1 f_2^{-1})| \ge \epsilon_0$ *on* $\mathsf{supp}(\psi)$. *Further, assume that condition* $(22.4.21)_q$ *with* $q \ge 1$ *is fulfilled and*

$$\mu^{-1}h|\log h| \le \varepsilon \le \mu h \tag{22.5.11}$$

where $\varepsilon := \mu^{-2}$ *here.*

Then the remainder does not exceed

$$(22.5.12)_q \quad C\mu^{-1}h^{-3} + Ch^{-4}(\mu h|\log h|)^{q/2}\varepsilon + \begin{cases} 0 & q \ge 3, \\ \mu^2 h^{-2}\varepsilon^{(q-1)/2} & 2 \le q < 3, \\ \bigl(\mu^2 h^{-2}\varepsilon^{(q-1)/2} + \mu h^{-3}\varepsilon^{q/2}\bigr) & 1 \le q < 2 \end{cases}$$

while the main term of asymptotics given by (22.5.4).

Proof. The proof follows the sequence of the proofs of Propositions 21.5.15, 21.5.17 with $\varepsilon = \mu^{-2}$ and 21.5.20(i):

(a) First, using the method of successive approximations, we rewrite the implicit formula as expression (22.5.4) plus a (temporary) *correction term*

$$\sum_{\iota} \int \Big(\widehat{\mathcal{N}}^{\mathsf{MW}}_{\bar{Q}_\iota}(x,0) - \mathcal{N}^{\mathsf{MW}}_{\bar{Q}_\iota}(x,0) \Big)\, dx \tag{22.5.13}$$

with an integrand defined by (21.5.32):

$$\widehat{\mathcal{N}}^{\mathsf{MW}}_{\bar{Q}}(x,0) \coloneqq \mathsf{const} \sum_{n,p} \Big(\theta(\mathcal{A}_{pn})\bar{Q} \Big)\Big|_{(x'',\xi'')=\Psi^{-1}(x)} \times f_1(x) f_2(x) \mu^2 h^{-2} \tag{22.5.14}$$

while

$$\mathcal{N}^{\mathsf{MW}}_{\bar{Q}}(x,0) \coloneqq \mathsf{const} \sum_{n,p} \theta\Big(V(x) - (2n+1)\mu h f_2(x) - (2p+1)\mu h f_1(x) \Big) f_1(x) f_2(x) \bar{Q} \mu^2 h^{-2} \tag{22.5.15}$$

where Q_ι cover zone with $T_0 \ge \epsilon\mu^{-1}$ (i.e. $\rho \le C(\mu h|\log h|)^{1/2}$); here const meant the same constant as in the definition of $\mathcal{N}^{\mathsf{MW}}$.

(b) Then we need to estimate expression (22.5.13). Now, however, one needs only analysis which was used in Chapter 21 in the strictly outer zone. The crucial moment is the estimate of the correction term as in Proposition 21.5.17 which was

$$C\mu^2 h^{-2} \times h\rho^{-2} \times \varepsilon h^{-1} \times \big(\rho^2(\mu h)^{-1} + 1\big) \times \big(\rho(\mu h)^{-1} + 1\big)\rho^{q-1} \asymp C\mu^2 h^{-2} \varepsilon \big(\rho^2(\mu h)^{-1} + 1\big) \times \big(\rho(\mu h)^{-1} + 1\big)\rho^{q-3} \tag{22.5.16}$$

and one needs to sum this expression with respect to ρ ranging from $\varepsilon^{1/2}$ ($= \mu^{-1/2}$ as $\varepsilon = \mu^{-2}$) to $\bar{\rho} \coloneqq C(\mu h|\log h|)^{1/2}$. Then

(A) As $q > 3$ expression (22.5.16) sums to its value as $\rho = \bar{\rho}$, which is exactly $C\varepsilon(\mu h|\log h|)^{q/2} h^{-4}$.

(B) As $1 < q \le 3$ an extra term due to summation of $C\mu^2h^{-2}\varepsilon\rho^{q-3}$ appears in the estimate. As $q < 3$ this results in the value of this term as $\rho = \varepsilon^{1/2}$ which is $C\mu^2h^{-2}\varepsilon^{(q-1)/2}$ while as $q = 3$ it results in $C\mu^2h^{-2}\varepsilon \log(\mu h|\log h|\varepsilon^{-1})$.

(C) Further, as $1 \le q \le 2$ one should take in account also $C\mu h^{-3}\varepsilon\rho^{q-2}$ which sums to $C\mu h^{-3}\varepsilon^{q/2}$ as $1 < q < 2$ and $C\mu h^{-3}\varepsilon|\log h|$ as $q = 2$.

(c) Finally, in the zone $\{\rho \le \varepsilon^{1/2}\}$ one simply considers its contribution to the remainder with $T = \epsilon\mu^{-1}$ rather than to the correction:

$$C\mu^2h^{-2} \times \bigl(\rho^2(\mu h)^{-1} + 1\bigr) \times \bigl(\rho(\mu h)^{-1} + 1\bigr)\rho^{q-1}\big|_{\rho=\varepsilon^{1/2}} \asymp C\mu h^{-3}\varepsilon^{q/2} + C\mu^2h^{-2}\varepsilon^{(q-1)/2}. \tag{22.5.17}$$

This concludes the proof. □

To cover properly the case of the *intermediate strong* magnetic field (22.5.10) let us rewrite the implicit formula as

$$\int \widehat{\mathcal{N}}_l^{\mathsf{MW}}(x,0)\,dx \tag{22.5.18}$$

and then as $q > 3$ rewrite it as the three term decomposition with respect to ε; then the third (remainder) term is $o(\mu^{-1}h^{-3})$ while the second term is given by a two-dimensional Riemannian sum proportional μ^{-2} with the steps $2f_1\mu h$ and $2f_2\mu h$.

Replacing this Riemannian sum by an integral one can see easily that again with an error $o(\mu^{-1}h^{-3})$ the second term is $\varkappa\mu^{-2}h^{-4}$ which disagrees with expression as $\mu \le h^{-1}|\log h|^{-K}$ unless $\varkappa = 0$. Combining with the previous proposition we arrive to

Proposition 22.5.12. *In the framework of Proposition 22.5.11 with* $q > 3$ *asymptotics with the main part* (22.5.4) *and* $O(\mu^{-1}h^{-3})$ *remainder holds.*

Combining Propositions 22.5.11 and 22.5.12, Corollary 22.5.2 and results of Section 22.3 we conclude that

(22.5.19) In the framework of Proposition 22.5.11 in the generic case $q > 3$ estimate $O(\mu^{-1}h^{-3})$ is proven for the complete range of μ ($1 \le \mu \le ch^{-1}$). Meanwhile, in the general case $q = 1$ estimate $O(\mu^2h^{-2})$ is proven as $h^{-1/2}|\log h|^K \le \mu \le ch^{-1}$.

Intermediate Magnetic Field. II

Now we want to improve result in the general case.

Proposition 22.5.13. *Assume that $f_1 \neq f_2$ and there are no resonances of order not exceeding M and also critical points of $f_1 f_2^{-1}$ are non-degenerate on $\mathsf{supp}(\psi)$. Then as $\mu \geq h^{-1/3}$ the remainder estimate is given by* $(22.5.12)_q$ *with any $q < 2$ arbitrarily close to 2 while the main term of asymptotics given by* (22.5.4).

Proof. Proof follows ideas of the proof of Proposition 21.5.22. Let us introduce functions ℓ_k, $k = 1, \dots, K$ in the same proof but with $\gamma = 1$ and again let $\bar{\ell}_k = (\mu h |\log h|^J)^{1/(k+1)}$.

(a) Assume first that $|\nabla(f_1 f_2^{-1})| \geq \epsilon_0$. Then the arguments of the mentioned proof survive with this simplification.

(b) Assume now that $f_1 f_2^{-1}$ has one non-degenerate stationary point $\bar{x}$. Assume first that $\ell_K \leq \gamma$ where $\gamma = \frac{1}{2}|x - \bar{x}|$. Then the number of indices "p" does not exceed $C\ell_k^k/(\mu h \gamma)$ and the contribution of all such elements with $\ell_k \asymp \bar{\ell}_k$ for some $k = 1, \dots, (K-1)$ to the correction term does not exceed $C(\mu h)^{1-\delta} \cdot \mu^{-2} h^{-4} \gamma^{-1} \times \gamma^4 |\log h|^J$ where γ^4 is the total measure of such elements, $\delta = 1/K$ and J is large enough. Summation with respect to γ results in the announced estimate.

On the other hand, the total contribution to the correction of all elements with $\ell_k \geq C_0 \bar{\ell}_k$ does not exceed $C\mu^{-1}h^{-3} + C\mu h^{-3} \cdot \mu^{-2} \bar{\ell}_K^{-1}$.

(c) Alternatively, assume that $\ell_j \leq \gamma \leq \ell_{j+1}$. Again one needs to consider elements with $\ell_k \asymp \bar{\ell}_k \leq \gamma$ for some $k \leq j$. Then the contribution to the correction term does not exceed $C\mu h^{-3} \times \mu^{-2}\gamma^{-1} \times \gamma^4 \times \gamma^{-1} |\log h|$ where the second factor γ^{-1} appears since the relative measure of ℓ_k elements to γ elements does not exceed $\ell_k \gamma^{-1}$. Again summation with respect to γ results in $C\mu^{-1}h^{-3}|\log h|^J$.

(d) Finally, consider elements with $\ell_1 \geq \gamma$. Then we redefine $\gamma = \ell_1$ and only $\ell_1 \asymp \bar{\ell}_1$ should be considered. Contribution of such elements to the correction does not exceed $Ch^{-4} \times \mu^{-2} \bar{\ell}_1^4 = O(\mu^{-1}h^{-3})$. □

Therefore we arrive to

(22.5.20) In the general case asymptotics with the main part (22.5.4) and the remainder estimate $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$ holds unless

$$h^{-1/3+\delta}\le \mu \le h^{-1/3-\delta} \tag{22.5.21}$$

in which case the remainder estimate is $O(\mu^{-1}h^{-3-\delta})$ containing an extra factor $h^{-\delta}$; $\delta>0$ is an arbitrarily small exponent.

Intermediate Magnetic Field. III

Let us recover remainder estimate $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$ in the latter case (22.5.21) (introducing some correction term). Using the same arguments as above we can purge from $\mathcal{A}_{pn}$ in (22.5.14) all terms which are even marginally less than μ^{-2}; it includes all higher order terms and also the difference between $\mu^{-2}\mathcal{B}_{pn}$ and $\mu^{-2}\mathcal{B}_{\bar p,\bar n}$ where $\bar p=\alpha/(2f_1\mu h)$ and $\bar n=(1-\alpha)/(2f_2\mu h)$, $\alpha=\alpha(x)$ is the minimizer of $|\nabla\phi_\alpha|^2$.

Then $\mathcal{B}_{pn}$ becomes $\mathcal{B}_{\bar p,\bar n}=\omega(x)$ [17]. However, let us include this modified term $\mu^{-2}\mathcal{B}_{pn}$ for all p, n and not only for those for which $T_0\ge\epsilon\mu^{-1}$. Then one needs to correct this alternation by the term $\varkappa\mu^{-2}h^{-4}$ with $\varkappa$ selected so it would result in the correction term 0, if one replaces the Riemann sum by the corresponding integral because it would provide the result for $\mu\ge h^{-1/3-\delta}$ and it should agree with the results of the previous subsubsection. We leave the easy but tedious details to the reader. Then we arrive to

Proposition 22.5.14. *Assume that $f_1\ne f_2$ and there are no resonances of order not exceeding M and also the critical points of $f_1f_2^{-1}$ are non-degenerate on $\mathsf{supp}(\psi)$. Then for μ satisfying* (22.5.21) *the remainder estimate is $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$ while the main part of the asymptotics is given by*

$$\int \Bigl(\mathcal{N}^{\mathsf{MW}}(x,0)+\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,0)\Bigr)\psi(x)\,dx \tag{22.5.22}$$

with

$$\begin{aligned}&\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,\tau)= \\ &(2\pi)^{-2}\mu^2h^{-2}\sum_{(p,n)\in\mathbb{Z}^{+2}}\Bigl(\theta\bigl(2\tau+V-(2p+1)\mu hf_1-(2n+1)\mu hf_2-\omega(x)\mu^{-2}\bigr)- \\ &\qquad\theta\bigl(2\tau+V-(2p+1)\mu hf_1-(2n+1)\mu hf_2\bigr)\Bigr)f_1f_2\sqrt{g} \\ &\qquad+(4\pi)^{-2}\mu^{-2}h^{-4}(2\tau+V)\omega\sqrt{g}.\end{aligned} \tag{22.5.23}$$

[17] Which is the smooth function outside of the critical points of $f_1f_2^{-1}$.

Remark 22.5.15. (i) Here

$$\int \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,\tau)\psi(x)\,dx = O(\mu^{-1}h^{-3-\kappa})$$

with an arbitrarily small exponent $\kappa > 0$ [18].

(ii) Furthermore, under nondegeneracy condition

$$\sum_{|\beta|\le K} |\nabla^\beta \phi_\alpha| \ge \epsilon_0 \qquad \forall x\ \forall \alpha \in [0,1] \tag{22.5.24}$$

with arbitrarily large K one can skip a correction term without deteriorating remainder estimate unless $h^{-1/3}|\log h|^{-J} \le \mu \le h^{-1/3}|\log h|^{J}$ and with the remainder estimate $O(h^{-8/3}|\log h|^{J})$ in this border case [19]. We suspect that one can get rid of logarithmic factors and to prove an estimate $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$ even in the border case.

(iii) However, we could not find any example demonstrating that this correction term is not superficial and without (22.5.24) one cannot skip it without penalty. Clarification of this would be interesting.

On the other hand, correction term in Chapter 21 was not superficial for sure.

Intermediate Magnetic Field. IV

Now we want to attack resonances. Let us start from the generic case. First, after rescaling again in the same manner as before one can see easily that the contribution of zone $\{|x_1 \asymp \gamma\}$ to an error does not exceed $C\mu h^{1-d}\varepsilon^{1-\kappa}$ where factor γ^{-1} appearing from the calculation of the number of indices "p" is compensated by factor γ appearing from the measure. Then this contribution does not exceed $C\mu h^{-3}(\mu^{4-2m}\gamma^{-1})^{(1-\kappa)}$ if only terms originated from non-diagonal terms are removed and summation with respect to $\gamma \ge \bar\gamma$ results in the value of this expression as $\gamma = \bar\gamma$ and as $m \ge 4$ it is $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$. Recall that $\bar\gamma = \mu^{\delta-2}$ as $m = 4$ and $\bar\gamma = C\mu^{-2}$ as $m \ge 5$.

---

[18] It follows from Proposition 22.5.3.

[19] Notice that under condition (22.5.24) $\bar\ell_K \asymp 1$ in the proof of Propositions 22.5.3, 22.5.13.

On the other hand, in the zone $\{|x_1| \le \bar\gamma\}$ one can apply Proposition 22.4.10 and get $C(\mu h)^{3/2}h^{-4}\bar\gamma|\log h|^J$ which is $o(\mu^{-1}h^{-3}+\mu^2h^{-2})$ as well (as $m\ge 4$).

Now after singular terms from operator are removed it can be treated as if there was no resonance resulting in two following statements:

Proposition 22.5.16. *Assume that $f_1\ne f_2$ and $|\nabla(f_1f_2^{-1})|\ge\epsilon_0$ on $\operatorname{supp}(\psi)$. Furthermore, assume that there are no third-order resonances on $\operatorname{supp}(\psi)$.*

Then

(i) As $\mu\ge h^{-1/3-\delta}$ the remainder estimate is $O(\mu^2h^{-2})$ while the main term of asymptotics given by (22.5.4)*.*

(ii) As $h^{-1/3+\delta}\le\mu\le h^{-1/3-\delta}$ statement of Remark 22.5.15(i) holds; furthermore, under condition (22.5.24) *one can skip correction term with $O(\mu^2h^{-2}|\log h|^J)$ penalty*[20)]*.*

Intermediate Magnetic Field. V

Consider resonances of order 3 now. As $\mu\ge h^{-1/3-\delta}$ in the virtue of the above arguments, the contribution of the zone

$$\bigl\{|x_1|\ge\bar\gamma_3\coloneqq\mu^{-3}h^{-1-\delta}\bigr\} \tag{22.5.25}$$

to the correction does not exceed $C\mu^2h^{-2}$.

Moreover, the contribution of the zone

$$\bigl\{|x_1|\le\bar\gamma_2\coloneqq(\mu h)^{1/2}|\log h|^{-1/2}\bigr\} \tag{22.5.26}$$

to the correction also does not exceed $C\mu^2h^{-2}$. However, zone

$$\bigl\{\bar\gamma_2\le|x_1|\le\bar\gamma_3\bigr\} \tag{22.5.27}$$

needs to be reexamined; here $\bar\gamma_2\ge\bar\gamma$ as $\mu\ge h^{-1/3-\delta}$ and as $\mu\ge h^{-3/7-\delta'}$ zone (22.5.27) disappears. In virtue of arguments of Subsection 22.5.2 the contribution of this zone does not exceed $C\mu^2h^{-2-\kappa}$ with arbitrarily small $\kappa>0$ and now we want to improve it marginally.

We claim that

[20)] Which is probably superficial.

Proposition 22.5.17. *For any $\delta > 0$ there exists $K = K(\delta)$ such that if $\mu^{-1+\delta} \le \gamma \le \mu^{-\delta}$ and $B(y, \gamma(y))$ with $\gamma(y) \asymp \gamma$ is rescaled to $B(0,1)$ then either*

$$\sum_{|\alpha|\le K} |\partial_z^\alpha \mathcal{A}_{pn}| \asymp \varsigma \qquad \forall z \in B(0,1) \tag{22.5.28}$$

with some ς or

$$\sum_{|\alpha|\le K} |\partial_z^\alpha \mathcal{A}_{pn}| \le \varsigma \qquad \forall z \in B(0,1) \tag{22.5.29}$$

with $\varsigma = \mu h^{1-\kappa}\gamma$ where (continuous) parameters p and n are selected so

$$\mathcal{A}_{pn}(y) = \partial_{x_1}\mathcal{A}_{pn}(y) = 0. \tag{22.5.30}$$

Proof. Note that before rescaling $\mathcal{A}_{pn} = \mathcal{A}^0_{pn} + x_1^{-1}\mu^{-2}\mathcal{B}_{pn} + ...$ with smooth symbols. Then decomposing all smooth symbols into Taylor series at y one can prove proposition easily since high powers of there contain high powers of γ and thus are small. □

Proposition 22.5.18. *In the framework of Proposition 22.5.17 the contribution of the zone $\{\mu^{-1+\delta} \le |x_1| \le \mu^{-\delta}\}$ to the error is $O(\mu^{-1}h^{-3} + \mu^2 h^{-2}|\log h|^J)$.*

Proof. Proof repeats those which we had before. One needs to construct ℓ_k corresponding to $\varsigma\mathcal{A}_{pn}$ and then $(\mu h|\log h|)$ as minimal value for ℓ_k^{k+1} should be replaced by $\varsigma^{-1}(\mu h|\log h|)$ and there will be no final division by $\bar\ell_K$ which would be $\asymp 1$. That will give $C\mu^2h^{-2} \times |\log h| \times |\log h|\gamma^{-1} \times \gamma$ where the factors γ^{-1} and γ appear from division by $(\mu h\gamma)$ and the measure.

Then summation with respect to γ results in an extra $|\log h|$ factor. □

Remark 22.5.19. (i) Under condition

$$\sum_{|\beta|\le K} |\nabla_\Xi^\beta V f_1^{-1}| \ge \epsilon_0 \qquad \forall x \tag{22.5.31}$$

with arbitrarily large K one can skip a correction term without deteriorating remainder estimate unless $h^{-1/3}|\log h|^{-J} \le \mu \le h^{-1/3}|\log h|^J$ and with the remainder estimate $O(h^{-8/3}|\log h|^J)$ in this border case. We suspect that one can get rid of logarithmic factors and to prove an estimate $O(\mu^{-1}h^{-3}+\mu^2h^{-2})$ even in the border case.

(ii) One can easily construct a correction term in the case of third-order resonances but an expression seems rather too complicated. So we leave it to the curious reader.

Intermediate Magnetic Field. VI

Let us consider the generic case now:

Proposition 22.5.20. *Assume that that* $|f_1-f_2|\ge \epsilon_0$ *and also* $|\nabla(f_1f_2^{-1})|\ge \epsilon_0$ *on* $\mathsf{supp}(\psi)$. *Further let us assume that conditions* $(22.4.21)_4$ *and* $(22.5.7)_3$ *are fulfilled.*

Then the remainder is $O(\mu^{-1}h^{-3})$ *while the main term of asymptotics given by* (22.5.4).

Proof. Again it is sufficient to consider the case of the single resonance surface $\Xi=\{x_1=0\}$.

(a) Combining in the zone $\{|x_1|\asymp \gamma\ge \bar\gamma:=\mu^{\delta-1}\}$ arguments of the proofs of Proposition 22.5.6 and 22.5.11 one can estimate contribution of it to the correction terms by $C(\mu h|\log h|)^{q/2}h^{-4}\gamma\times \mu^{-2}\gamma^{-1}$ which after summation with respect to γ results in $C(\mu h|\log h|)^{q/2}\mu^{-2}h^{-4}|\log h|$, which in turn is $O(\mu^{-1}h^{-3})$ as long as $\mu\le h^{-1}|\log h|^{-J}$.

(b) In the zone $\{|x_1|\le \bar\gamma\}$ one can use arguments of the proofs of Proposition 22.5.7 and estimate the contribution of this zone to the correction term arising as $T\ge T_0$ is replaced by $T=\epsilon\mu^{-1}$ by $C(\mu h|\log h|)^{5/2}h^{-4}\bar\gamma$ which is $O(\mu^{-1}h^{-3})$ as $\mu\le h^{-3/5+\delta'}$.

(c) Let $\mu\ge h^{-5/3+\delta'}$. In the zone $\{|x_1|\le \bar\gamma\}$ one can consider the precanonical form and then the contribution of this zone to the correction term does not exceed $C(\mu h|\log h|)^{3/2}\mu^{-1}h^{-4}\bar\gamma$ which is $O(\mu^{-1}h^{-3})$ as $\mu\le h^{-1+\delta'}$.

The direct calculation shows that the first approximation term actually vanishes as it comes from the "main perturbation term" and is odd with respect to x_1, and its estimate contains an extra factor $\bar\gamma$ otherwise.

So the correction terms, associated with zone $\{|x_1|\le \bar\gamma\}$, do not exceed

$$C(\mu h)^{3/2}\mu^{-1}h^{-4}\bar\gamma^2+C(\mu h)^{1/2}\mu^{-2}h^{-4}\bar\gamma=o(\mu^{-1}h^{-3})$$

(d) Finally, arguments of (a) should be slightly improved as $\mu\ge h^{-1}|\log h|^{-J}$. Namely the source of term containing logarithmic factor is the only perturbation of the type $C\mu^{-2}x_1^{-1}B(x',\mu^{-1}hD)$ but then if ψ is even with respect

to x_1 the results of calculation will be 0 and if ψ contains factor x_1 it would compensate x_1^{-1} and no logarithm would appear. □

Intermediate Magnetic Field. VII

Now we need to consider the vicinity of Σ. Let us start from the general case first.

Then scaling $x \to x/\gamma$, $h \to h/\gamma$, $\mu \to \mu\gamma$ and applying the same arguments as in the resonance case we estimate the contribution of the zone $\{\gamma(x) \asymp \gamma\}$ to the correction term by

$$C\mu h^{-3}\gamma^{-1} \times (\mu^{-2}\gamma^{-1})^{1-\kappa} \times \gamma^2$$

which in comparison to resonance case gains an extra factor γ and thus sums to its values as $\gamma = 1$, which is $C\mu^{-1+\kappa}h^{-3}$ which in turn is $O(\mu^2 h^{-2})$ as $\mu \ge h^{-1/3-\delta'}$. We ignore again term which sums to $C\mu^2 h^{-2}$ in the end of the day.

Meanwhile, contribution of the zone $\{\gamma(x) \le \bar\gamma\}$ does not exceed $C\mu h^{-3}\bar\gamma^2 = O(\mu^2 h^{-2})$.

Thus we arrive to the following statement:

Proposition 22.5.21. *Statement of Proposition 22.5.3 remains true in the vicinity of* Σ.

Remark 22.5.22. (i) Under condition

$$\sum_{|\beta|\le K} |\nabla_\Sigma^\beta V f_1^{-1}| \ge \epsilon_0 \qquad \forall x \tag{22.5.32}$$

with arbitrarily large K one can skip a correction term without deteriorating remainder estimate unless $h^{-1/3}|\log h|^{-J} \le \mu \le h^{-1/3}|\log h|^J$ and with the remainder estimate $O(h^{-8/3}|\log h|^J)$ in this border case. We suspect that one can get rid of logarithmic factors and to prove an estimate $O(\mu^{-1}h^{-3}+\mu^2 h^{-2})$ even in the border case.

(ii) One can easily construct a correction term in the case $\Sigma \ne \emptyset$ resonances but an expression seems rather too complicated. So we leave it to the curious reader.

Intermediate Magnetic Field. VIII

Finally let us consider the generic case near Σ. Using the same arguments as before we arrive to

Proposition 22.5.23. *Under non-degeneracy conditions* (22.4.83) *and* (22.4.84) *for ψ supported in the vicinity of Σ, the remainder estimate is $O(\mu^{-1}h^{-3})$ while the main part is given by the magnetic Weyl formula.*

22.6 Vanishing V Case

22.6.1 Generic Case

In the generic case, as $V = 0$, $|\nabla V| \ge \epsilon$ and then the microhyperbolicity condition of Chapter 13 holds and then

Proposition 22.6.1. *Assume that*

$$|V| + |\nabla V| \ge \epsilon. \tag{22.6.1}$$

Then in any dimension without no condition to F_{jk} other than $|\det(F_{jk})| \ge \epsilon$ for ψ supported in the small vicinity of the surface

$$\Delta := \{x : \ V(x) = 0\} \tag{22.6.2}$$

the asymptotics with the main part given by Magnetic Weyl expression and the remainder estimate $O(\mu^{-1}h^{1-d})$ holds.

This covers the generic case completely.

22.6.2 General Case

However, the general case is more complicated. Let us introduce a scaling function

$$\ell = \epsilon\big(|V| + |\nabla V|^2\big)^{1/2} + \frac{1}{2}\bar{\ell}, \qquad \bar{\ell} = \epsilon_0 \max\big((\mu h)^{1/2}, \mu^{-1}\big) \tag{22.6.3}$$

with dominating the second and the first terms in $\bar{\ell}$ as $\mu \le h^{-1/3}$ and $\mu \ge h^{-1/3}$ respectively.

Let us apply scaling $x \mapsto x\ell$, $h \mapsto h\ell^{-2}$, $\mu \mapsto \mu$, $V \mapsto V\ell^{-2}$: and consider the following cases:

(a) Let $\ell \le \epsilon_0(\mu h)^{1/2}$. Then we are in the classically forbidden zone and the contributions of ℓ-element to the principal part and the remainder estimate are 0 and negligible respectively.

(b) Let $\ell \ge \bar{\ell}$ and $|\nabla V| \asymp \ell$. Then after rescaling we are in the framework of Subsection 22.6.1 and the contribution of ℓ-element to the remainder is $O(\mu^{-1}h^{-3}\ell^6)$ and the total contribution of all ℓ-elements to the remainder is $O(\mu^{-1}h^{-3}\ell^2)$ and we are done here.

(c) Also, the contribution of all elements with $\ell \asymp \mu^{-1}$ to the remainder is $O(\mu h^{-3}\bar{\ell}^2)$ which is $O(\mu^{-1}h^{-3})$. So case $\ell \asymp \bar{\ell}$ is completely covered.

(d) Let us consider $V \asymp \ell^2$, $\ell \ge \bar{\ell}$; then condition $V \asymp 1$ is recovered after rescaling but now conditions to F_{jk} could fail; actually these condition do not fail completely, but are replaced by somewhat weaker condition with extra factors ℓ or ℓ^2 in the estimates from below. However, in the weak magnetic field case this weakened condition is enough; we leave the easy and tedious details to the reader:

Proposition 22.6.2. *As F_{jk} is generic and $\mu \le h^{-\delta}$ the remainder estimate $O(\mu^{-1}h^{-3})$ holds.*

Now one can assume that $h^{-\delta} \le \mu \le ch^{-1}$. Then since in Section 22.4 no condition "$|V| \ge \epsilon$" was required, the remainder estimate is $O(\mu^{-1}h^{-3} + \mu^2 h^{-2})$ but the principal part is given by the implicit formula (22.1.5) rather than by the magnetic Weyl expression (22.5.4) and now we need to modify arguments of Section 22.5 to pass from (22.1.5) to (22.5.4).

Note that in this implicit formula one always can take $T_0 = \epsilon\mu^{-1}$ with an arbitrarily small constant $\epsilon > 0$. Then in the virtue of arguments of the proof of Propositions 22.5.3 , 22.5.4 and 22.5.8 we get the remainder estimate $O(\mu^{-1}h^{-3} + \mu^2 h^{-2-\delta})$ with an arbitrarily small exponent $\delta > 0$.

However, in the contrast to the analysis in Subsection 22.5.1, without condition "$|V| \ge \epsilon$" it does not translates into $T_0 = Ch|\log h|$ but rather into $T_0 = Ch\ell^{-2}|\log h|$ after the above partition is applied. Nevertheless this last implicit formula (22.1.5) translates (with the same error) into Weyl or Magnetic Weyl formula. Therefore Theorem 22.6.3 below with the correction term 0 is proven for $\mu \le h^{-1/3-\delta}$ with an arbitrarily small exponent $\delta > 0$.

The similar arguments work as $\mu \ge h^{-1/3-\delta'}$ since one again refers to any $T_0 \le \epsilon\mu^{-1}$. So, Both Theorem 22.6.3 and Theorem 22.6.4 below hold without condition $|V| \ge \epsilon$.

Theorem 22.6.3. *Let* (g^{jk}) *be fixed and* $(V_1, \dots, V_4)$ *be generic. Further, let conditions* (22.1.3) *and* (22.1.4) *be fulfilled and* ψ *be a smooth function. Then*

$$|\int \big(e(x,x,0) - \mathcal{N}^{\mathsf{MW}}(x,0)\big) - \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,0)\big)\psi(x)\,dx| \le C\mu^{-1}h^{-3} + C\mu^2 h^{-2} \tag{22.6.4}$$

where

$$\mathcal{N}^{\mathsf{MW}}(x,\tau) = (2\pi)^{-2}\mu^2 h^{-2} \sum_{(m,n)\in\mathbb{Z}^{+\,2}} \theta\big(2\tau + V - (2m+1)\mu h f_1 - (2n+1)\mu h f_2\big) f_1 f_2 \sqrt{g} \tag{22.6.5}$$

is Magnetic Weyl Expression, $g = \mathsf{det}(g^{jk})^{-1}$, $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *is a correction term, defined by* (22.5.23).

Theorem 22.6.4. *Let* (g^{jk}) *be fixed and* $(V_1, \dots, V_4; V)$ *be generic. Further, let conditions* (22.1.3) *and* (22.1.4) *be fulfilled and* ψ *be a smooth function. Then*

$$|\int \big(e(x,x,0) - \mathcal{N}^{\mathsf{MW}}(x,0)\big)\psi(x)\,dx| \le C\mu^{-1}h^{-3}. \tag{22.6.6}$$

Remark 22.6.5. (i) More precise conditions describing conditions for $(V_1, \dots, V_d)$ in Theorem 22.6.3 and for $(V_1, \dots, V_d; V)$ in Theorem 22.6.4 were formulated in Section 22.5.

(ii) We were able to prove that one can skip $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,0)$ and preserve remainder estimate (22.6.4) unless $h^{-1/3+\delta} \le \mu \le h^{-1/3-\delta}$; in the latter case the remainder estimate (22.6.5) should be replaced by $h^{-8/3-\delta}$; however, we suspect that one can always skip $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,0)$ and preserve remainder estimate (22.6.4).

Part X

Eigenvalue Asymptotics for Schrödinger and Dirac Operators with the Strong Magnetic Field

Chapter 23

Eigenvalue asymptotics. 2D Case

23.1 Introduction

In this chapter we obtain eigenvalue asymptotics for 2D-Schrödinger, Schrödinger-Pauli and Dirac operators in the situations in which the role of the magnetic field is important. We have seen in Chapters 13 and 17 that these operators are essentially different and they also differ significantly from the corresponding 3D-operators.

While we are trying to emulate results of Chapter 11, we find ourselves now in the very different situation. Indeed, for operators we study the remainder estimates in the local spectral asymptotics under non-degeneracy assumptions are better than for similar operators with the magnetic field. However, as we seen in Chapters 14 and 15 these remainder estimates deteriorate if the magnetic field degenerates or there is a boundary. This significantly limits our ability to consider the cases when magnetic field asymptotically degenerates at the point of singularity (finite or infinite) along some directions, or domains with the boundary.

We start from Section 23.2 in which we consider the case when the spectral parameter is fixed ($\tau = \mathsf{const}$) and study asymptotics with respect to μ, h exactly like in Section 11.1 we considered asymptotics with respect to h. However, since now we have two parameters, we need to consider an interplay between them: while always $h \to +0$, we cover $\mu \to +0$, μ remains disjoint from 0 and ∞ and $\mu \to \infty$, which in turn splits into subcases

$\mu h \to 0$, μh remains disjoint from 0 and ∞ and $\mu h \to \infty$.

In Section 23.3 we consider asymptotics with $\mu = h = 1$ and with the spectral parameter τ tending to $+\infty$ for the Schrödinger and Schrödinger-Pauli operators and to $\pm\infty$ for the Dirac operator. We consider bounded domains with the singularity at some point and external domains with the singularity at infinity. In the latter case the specifics of the 2D magnetic Schrödinger and Schrödinger-Pauli operators manifest itself in the better remainder estimate (and in the larger principal part for the Schrödinger-Pauli operator) than in the non-magnetic case. Furthermore, in contrast to the non-magnetic case there are non-trivial results for the Dirac operator. This happens only in even dimensions.

In Section 23.4 we consider asymptotics with the singularity at infinity and $\mu = h = 1$ and with τ tending to $+0$ for the Schrödinger and Schrödinger-Pauli operators and to $\pm(M - 0)$ for the Dirac operator. Again the specifics of the 2D magnetic Schrödinger and Schrödinger-Pauli operators manifest itself in the better remainder estimate (and in the larger principal part for the Schrödinger-Pauli operator) than in non-magnetic case.

It includes the most interesting case (see Subsection 23.4.1) when magnetic field is either constant or stabilizes fast at infinity and potential decays at infinity. As we know if magnetic field and potential were constant then the operator would have purely point spectrum of infinite multiplicity and each eigenvalue (Landau level) would be disjoint from the rest. Now we have a sequences of eigenvalues tending to the Landau level either from below, or from above, or from both sides and we are interested in their asymptotics. In contrast to the rest of the section we consider multidimensional case as well. In contrast to Section 11.6 there are non-trivial results for fast decaying potentials as well.

In Section 23.5 we consider asymptotics with respect to μ, h, τ, like in Section 11.7 again with significant differences mentioned above.

Finally, in Appendix 23.A.1 the self-adjointness of the 2D-Dirac operator with a very singular magnetic field is proven.

The Schrödinger operator theory is more extensive than the Dirac operator theory: there are many more meaningful problems and questions for the Schrödinger operator than for the Dirac operator. Also, the 2D-theory is more extensive and provides more accurate remainder estimates than the 3D-theory considered in the next Chapter 24. These circumstances are not due to the technical difficulties but are instead due to the fact that the spectrum of the Schrödinger operator is discrete more often than the

spectrum of the Dirac operator in dimension $d = 2$ the spectrum is discrete more often than in dimension $d = 3$.

23.2 Asymptotics with Fixed Spectral Parameter

In this section we consider asymptotics with a fixed spectral parameter for 2-dimensional magnetic Schrödinger, Schrödinger-Pauli and Dirac operators and discuss some of the generalizations[1)].

As in Chapters 9–12 we will introduce a semiclassical zone and a singular zone, where $\rho\gamma \ge h$ and $\rho\gamma \le h$ respectively. In the semiclassical zone we apply asymptotics of Chapters 13–22 (but mainly of 13 and 19–in the multidimensional case). In the singular zone we need to apply estimates for a number of eigenvalues; usually it would be sufficient to use non-magnetic estimate[2)] for number of eigenvalues which trivially follows from standard one but if needed one can use more delicate estimates.

23.2.1 Schrödinger Operator

Estimates of the Spectrum

Consider first the Schrödinger operator (13.2.1)

$$A = \sum_{j,k} P_j g^{jk} P_k + V, \qquad \text{with} \quad P_j = hD_j - \mu V_j \tag{23.2.1}$$

where g^{jk}, V_j, V satisfy (13.2.2) and (13.2.4) i.e.

$$\epsilon|\xi|^2 \le \sum_{j,k} g^{jk}\xi_j\xi_k \le c|\xi|^2 \qquad \forall \xi \in \mathbb{R}^d. \tag{23.2.2}$$

Without any loss of the generality we can fix $\tau = 0$ and then in the important function $V_{\mathsf{eff}} F_{\mathsf{eff}}^{-1}$ the parameters μ and h enter as factors. Thus, we treat the operator (13.2.1) assuming that it is self-adjoint.

[1)] Mainly to higher dimensions with full-rank magnetic field.

[2)] With V modified accordingly; for example, for the Schrödinger and Schrödinger-Pauli operators V_- is replaced by $C\big((1-\epsilon)V - C_\epsilon \mu^2 |\vec{V}|^2\big)_-$.

We make assumptions similar to those of Chapter 9

$$(23.2.3)_{1-3} \quad |D^\alpha g^{jk}| \le c\gamma^{-|\alpha|}, \quad |D^\alpha F_{jk}| \le c\rho_1\gamma^{-|\alpha|}, \quad |D^\alpha V| \le c\rho^2\gamma^{-|\alpha|}$$

where scaling function $\gamma(x)$ and weight functions $\rho(x), \rho_1(x)$ satisfy the standard assumptions $(9.1.6)_1$ and $(9.1.6)_2$. Then

$$(23.2.4)_{1,2} \qquad \mu_{\text{eff}} = \mu\rho_1\gamma\rho^{-1}, \qquad h_{\text{eff}} = h\rho^{-1}\gamma^{-1}.$$

Let us introduce a *semiclassical zone*

$$(23.2.5) \qquad X' = \{x\colon \rho\gamma \ge h\}$$

and a *singular zone*

$$(23.2.6) \qquad X'' = \{x\colon \rho\gamma \le 2h\}.$$

Further, let us introduce two other overlapping zones

$$(23.2.7) \qquad X'_1 = \{x \in X_{\text{scl}}\colon \mu\rho_1 \le 2c\rho\gamma^{-1}\}$$

and

$$(23.2.8) \qquad X'_2 = \{x \in X'\colon \mu\rho_1 \ge c\rho\gamma^{-1}\}$$

where the magnetic field $\mu_{\text{eff}} = \mu\rho_1\rho^{-1}\gamma$ is *normal* ($\mu_{\text{eff}} \le 2c$) and where it is *strong* ($\mu_{\text{eff}} \ge c$) respectively. We assume that

$$(23.2.9) \qquad |F| \ge \epsilon\rho_1 \qquad \text{in} \quad X'_2$$

where F_{jk} and F are the tensor and scalar intensities of the magnetic field.

Moreover, let us assume that

$$(23.2.10)_1 \qquad B\big(x, \gamma(x)\big) \subset X \qquad \forall x \in X'_{2-},$$

and

$$(23.2.10)_2 \qquad u\big|_{\partial X \cap B\left(x,\gamma(x)\right)} = 0 \qquad \forall x \in X' \quad \forall u \in \mathfrak{D}(A)$$

where

$$(23.2.11) \qquad X'_{2-} = \{x \in X'_2\colon V + \mu hF \ge \epsilon\rho^2\}$$

and

$$(23.2.12) \qquad X'_{2+} = \{x \in X'\colon V + \mu hF \le 2\epsilon\rho^2\}.$$

Finally, let the standard boundary regularity condition be fulfilled:

(23.2.13) For every $y \in X$, $\partial X \cap B(y, \gamma(y)) = \{x_k = \phi_k(x_{\hat{k}})\}$ with

$$|D^\alpha \phi_k| \le c\gamma^{-|\alpha|}$$

and $k = k(y)$.

Due to $(23.2.10)_1$ we need this condition only as $y \in X'_1 \cup X'_{2-}$. Finally, in X'_{2-} let one of the following non-degeneracy conditions

$$|V + (2n+1)\mu hF| + |\nabla VF^{-1}|\gamma \ge \epsilon\rho^2 \qquad \forall n \in \mathbb{Z}^+, \tag{23.2.14}$$

$$|V + (2n+1)\mu hF| + |\nabla VF^{-1}|\gamma \le \epsilon\rho^2\epsilon \implies \det \mathsf{Hess}(VF^{-1}) \ge \epsilon\rho^4\rho_1^{-2}\gamma^{-4} \qquad \forall n \in \mathbb{Z}^+, \tag{23.2.15}$$

$$|V + (2n+1)\mu hF| + |\nabla VF^{-1}|\gamma \le \epsilon\rho^2\epsilon \implies |\det \mathsf{Hess}(VF^{-1})| \ge \epsilon\rho^4\rho_1^{-2}\gamma^{-4} \qquad \forall n \in \mathbb{Z}^+, \tag{23.2.16}$$

be fulfilled.

Recall that according to Chapter 13 the contribution of the partition element $\psi \in \mathscr{C}_0^K(B(y, \frac{1}{2}\gamma(y))$ to the principal part of asymptotics is

$$\mathcal{N}^-(\mu, h) = \mathcal{N}^{\mathsf{MW}-}(\mu, h) := h^{-2} \int \mathcal{N}^{\mathsf{MW}}(x, \mu h)\psi(x)\, dx \tag{23.2.17}$$

with $\mathcal{N}^{\mathsf{MW}}(x, \mu h)$ given by (13.2.9) with $d = 2$.

On the other hand, its contribution to the remainder does not exceed $Ch^{-1}\rho\gamma$ if $\mu\rho_1\gamma \le c\rho$ and it does not exceed $C\mu^{-1}h^{-1}\rho^2\rho_1^{-1}$ if $\mu\rho_1\gamma \ge c\rho$ but $\mu h\rho_1 \le \rho^2$, $y \in X'_+$ and assumption (23.2.15) is fulfilled[3)], and it does not exceed $C(\mu^{-s}\rho_1^{-s}\gamma^{-2s})$ if $C\mu\rho_1\gamma \ge \rho$, $\mu h\rho_1 \le \rho^2$, $y \in X'_{2-}$.

Then we get estimate of N^- from below by the magnetic Weyl approximation $\mathcal{N}^-(\mu, h)$ minus corresponding remainder, and also from above

[3)] It does not exceed the same expression with an extra logarithmic factor under assumption (23.2.16) but logarithmic factor could be skipped if we add corrections at the points with negative $\det \mathsf{Hess}(VF^{-1})$.

by magnetic Weyl approximation plus corresponding remainder, provided $X = X'$ (so, there is no singular zone $X'' = \emptyset$):

$$h^{-d}\int_{X'} \mathcal{N}^{\mathsf{MW}}(x,\mu h)\,dx - CR_1 \le \mathsf{N}^-(0) \le h^{-d}\int_{X'} \mathcal{N}^{\mathsf{MW}}(x,\mu h)\,dx + CR_1 + C'R_2 \tag{23.2.18}$$

with

$$R_1 = \mu^{-1}h^{1-d}\int_{X'_+} \rho^d \rho_1^{-1}\gamma^{-2}\,dx, \tag{23.2.19}$$

$$R_2 = \mu h^{s-d}\int_{X'_-} \rho_1 \rho^{d-s-1}\gamma^{1-s}\,dx \tag{23.2.20}$$

provided

$$\mu\rho_1\gamma \ge \rho \tag{23.2.21}$$

where the latter condition could be assumed without any loss of the generality, C' depens also on s and ϵ.

We leave to the reader the following not very challenging set of problems:

Problem 23.2.1. (i) Consider the case $X'' \neq \emptyset$ and prove the estimate from above with an extra term C_1R_0 like in estimate (9.1.29) (Theorem 9.1.7) with R_0 defined in the same way as in Section 9.1.

(ii) Consider multidimensional case; then we need to impose more sophisticated non-degeneracy assumptions (see Chapter 19).

(iii) Incorporate results of Chapters 14, 15, 18, 19 (in non-smooth settings), 21 and 22.

(iv) Using arguments and methods of Chapter 10 and results of Chapter 17 consider Dirac operator (in the full-rank case).

Basic Results

In what follows $h \to +0$ and the semiclassical zone X' expands to X while μ is either bounded (then we can assume that the zone of the strong magnetic field X'_2 is fixed) or tends to ∞ (then X'_2 expands to X). We assume that all

conditions of the previous subsection are fulfilled with $\mu = h = 1$ but we will assume them fulfilled in the corresponding zones.

The other important question is whether $\mu h \to 0$, remains bounded and disjoint from 0 or tends to ∞.

Finally, we should consider the singular zone X''. In order to avoid this task we assume initially that

$$\rho_1\gamma^2 + \rho\gamma \ge \epsilon. \tag{23.2.22}$$

Then we obtain the following assertion from the arguments of the previous Subsection 23.2.1.1:

Theorem 23.2.2. *Let $d = 2$ and let the Schrödinger operator A satisfy conditions* (23.2.15), (23.2.2), $(23.2.3)_{1-3}$, (23.2.9) *in the corresponding regions where ρ, ρ_1, γ satisfy* $(9.1.6)_1$–$(9.1.6)_4$, $(23.2.10)_{1,2}$, (23.2.22).

Let $\rho_1 \ge \epsilon\rho\gamma^{-1}$ and

$$\rho^2\rho_1^{-1}\gamma^{-2} \in \mathscr{L}^1\bigl(X \cap \{V + tF \le \epsilon\rho^2\}\bigr), \tag{23.2.23}$$

$$\rho_1^{-s}\gamma^{-2s-d} \in \mathscr{L}^1(X) \tag{23.2.24}$$

with some $s \ge 0$ and $t \ge 0$. Then for $h \to +0$, $1 \le \mu$ such that $\mu h \le t$ the "standard" asymptotics

$$\mathsf{N}^-(\mu, h) = \mathcal{N}^-(\mu, h) + O(\mu^{-1}h^{-1}) \tag{23.2.25}$$

holds with

$$\mathcal{N}^-(\mu, h) := h^{-d}\int \mathcal{N}^{\mathsf{MW}}(x, \mu h)\, dx. \tag{23.2.26}$$

Power Singularities

Example 23.2.3. (i) Let 0 be an *inner singular point*[4] and let conditions of Theorem 23.2.2 be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$ and let $m_1 < \min(m-1, 2m)$ [5),6)].

[4] I.e. $0 \in \bar{X}$ is an isolated point of $\mathbb{R}^2 \setminus X$.

[5] One can construct such potential (V_1, V_2) easily; f.e. $V_1 = -x_2|x|^{m_1}$, $V_2 = x_1|x|^{m_1}$ for $m_1 \ne 2$; for $m_1 = -2$ one needs to multiply V_1, V_2 by $\log|x|$.

[6] To have the non-degeneracy condition (23.2.15) fulfilled in the vicinity of 0 we assume that

$$|\nabla VF^{-1}| \ge C\rho^2\rho_1^{-1}\gamma^{-1} \qquad \text{as } |x| \le \epsilon; \tag{23.2.27}$$

in Statement (ii) one should replace $|x| \le \epsilon$ by $|x| \ge c$.

Let $V + \mu hF \ge \epsilon\rho^2$ on $(\partial X \setminus 0) \cup \{x\colon |x| \ge c\}$.

Then conditions (23.2.23), (23.2.24) are fulfilled automatically and asymptotics (23.2.25)–(23.2.26) holds for μ disjoint from 0 and $h \to +0$.

Further,

$$\mathcal{N}^-(\mu, h) = \begin{cases} O(h^{-2}) & m > -1, \\ O\big(h^{-2}(|\log(\mu h)| + 1)\big) & m = -1, \\ O\big(h^{-2}(\mu h)^{2(m+1)/(2m-m_1)}\big) & m < -1. \end{cases} \tag{23.2.28}$$

Furthermore, one can replace "$= O$"with "$\asymp$" if <u>either</u> $m > -1$, $\mu h \le t$ and

$$\{X \setminus 0, V \le -tF - \epsilon\} \ne \emptyset \tag{23.2.29}$$

<u>or</u> $m \le -1$ and

$$V \le -\epsilon\rho^2 \qquad \text{in} \quad \Gamma \cap \{|x| \le \epsilon\} \subset X \tag{23.2.30}$$

where Γ is an open non-empty sector (cone) with vertex at 0, and $\mu h \le t$ with a small enough constant $t > 0$.

(ii) Let infinity be an *inner singular point*[7)] and let conditions of Theorem 23.2.2 be fulfilled with $\gamma = \epsilon\langle x\rangle$, $\rho\langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$ and let $m_1 > \max(m-1, 2m)$[5),6)]. Let $V + \mu hF \ge \epsilon\rho^2$ on ∂X.

Then conditions (23.2.23) and (23.2.24) are fulfilled automatically and asymptotics (23.2.25)–(23.2.26) holds for μ disjoint from 0 and $h \to +0$.

Further,

$$\mathcal{N}^-(\mu, h) = \begin{cases} O(h^{-2}) & m < -1, \\ O\big(h^{-2}(|\log(\mu h)| + 1)\big) & m = -1, \\ O\big(h^{-2}(\mu h)^{2(m+1)/(2m-m_1)}\big) & m > -1. \end{cases} \tag{23.2.28$'$}$$

Furthermore, one can replace "$= O$" by "$\asymp$" if <u>either</u> $m < -1$, $\mu h \le t$ and (23.2.29) is fulfilled <u>or</u> $m \le -1$,

$$V \le -\epsilon\rho^2 \qquad \text{in} \quad \Gamma \cap \{|x| \ge c\} \subset X \tag{23.2.30$'$}$$

where Γ is an open non-empty sector (cone) with vertex at 0, and $\mu h \le t$ with a small enough constant $t > 0$.

[7)] I.e. $\mathbb{R}^2 \setminus X$ is compact.

(iii) One can easily see that for $m > -1$ in (i), $m < -1$ in (ii)

$$\mathcal{N}^{-}(\mu, h) = \mathcal{N}^{\mathsf{W}-}(\mu, h) + O\big(h^{-2}(\mu h)^{(2m+2)/(2m-m_1)}\big) \tag{23.2.31}$$

under condition (23.2.15) where $\mathcal{N}^{\mathsf{W}-}$ is the standard Weyl expression[8]. Therefore for $\mu \le h^p$ with $p = (2-m_1)/(4m-m_1+2)$ the asymptotics remain true with $\mathcal{N}^{-}$ replaced by $\mathcal{N}^{\mathsf{W}-}$.

On the other hand, under condition (23.2.30) or (23.2.30)$^{\#}$ (respectively) $\mathcal{N}^{\mathsf{W}-} - \mathcal{N}^{\mathsf{MW}-} \ge \epsilon h^{-2}(\mu h)^{(2m+2)/(2m-m_1)}$. Thus, for $\mu > h^p$ one cannot replace $\mathcal{N}^{-}$ by $\mathcal{N}^{\mathsf{W}-}$ and preserve the remainder estimates. Note that p is not necessarily negative in our conditions! Therefore, due to the singularity, the magnetic field can be essential even for a fixed μ. In what follows we leave this type of analysis to the reader.

Example 23.2.4. (i) Assume now that $m_1 \ge \min(m-1, 2m)$, $m_1 \ne 2m$[9], while all other assumptions of Example 23.2.3(i) are fulfilled. Since we want to have a finite $\mathcal{N}^{-}$ and (23.2.30) to be fulfilled we need to assume that $m > -1$. Then $\mathcal{N} \asymp h^{-2}$. Let us calculate the remainder estimate.

(a) Assume first that $m-1 \le m_1 < 2m$; then $\int \rho_1^{-1}\rho^2\,dx < \infty$ and then contribution of the semiclassical zone $X' = \{x\colon |x| \ge r_0 = h^{1/(m+1)}\}$ to the remainder is $O(\mu^{-1}h^{-1})$ and we need to estimate the contribution of the singular zone $X'' = \{x\colon |x| \le r_0\}$. Without any loss of the generality we can assume that $|\vec{V}| \le C\rho_1\gamma$[10]. Then CLR[11] implies that the contribution of X'' to the asymptotics does not exceed $Ch^{-2}\int_{X''}(\rho^2 + \mu^2\rho_1^2\gamma^2)\,dx \asymp C$.

(b) Let now $m_1 > 2m$; then we need to consider zones

$$X_2' = \{x\colon |x| \ge r_1 = \mu^{-1/(m_1+1-m)}\}$$

where $\mu_{\mathsf{eff}} \ge 1$,

$$X_1' = \{x\colon r_0 \le |x| \le r_1\}$$

where $\mu_{\mathsf{eff}} \le 1$ and $h_{\mathsf{eff}} \le 1$ and X''. Contributions of X_2', X_1' to the remainder do not exceed $K_1 := C\mu^{-1}h^{-1}\int_{X_2'}\rho_1^{-1}\rho^2\,dx$ and $K_1 := Ch^{-1}\int_{X_1'}\rho\gamma^{-1}\,dx$ respectively.

---

[8] Rather than the magnetic Weyl expression $\mathcal{N}^{\mathsf{MW}-}$.

[9] Otherwise we could not satisfy(23.2.27).

[10] One can prove it easily taking $V_1 = -\partial_2\phi$, $V_2 = \partial_1\phi$ with ϕ solving $\Delta\phi = F$.

[11] Sure, CLR does not hold for $d = 2$ but we can use more complicated Rozenblioum's estimate exactly like in Section 11.1.

Obviously, $K_1 \asymp K_2 \asymp Ch^{-1}r_1^{m+1} \asymp Ch^{-1}\mu^{-(m+1)/(m_1+m-1)}$ for $m_1 > 2m$.

Finally, contribution of X'' to the asymptotics is $O(1)$.

Thus as $h \to +0$, μ is disjoint from 0 and μh is disjoint from infinity, we have asymptotics

$$\mathsf{N}^-(\mu, h) = \mathcal{N}^-(\mu, h) + \begin{cases} O(h^{-1}\mu^{-1}) & m_1 < 2m, \\ O(h^{-1}\mu^{-(m+1)/(m_1+1-m)}) & m_1 > 2m. \end{cases} \tag{23.2.32}$$

(ii) Assume now that $m_1 \le \max(m-1, 2m)$ while all other assumptions of Example 23.2.3(ii) are fulfilled and $m < -1$. Again, considering cases

(a) $2m < m_1 < m-1$ and

(b) $m_1 < 2m$

we arrive to the asymptotics

$$\mathsf{N}^-(\mu, h) = \mathcal{N}^-(\mu, h) + \begin{cases} O(h^{-1}\mu^{-1}) & m_1 > 2m, \\ O(h^{-1}\mu^{-(m+1)/(m_1+1-m)}) & m_1 < 2m. \end{cases} \tag{23.2.32}^{\#}$$

Consider now fast increasing μ so that $\mu h \to \infty$. We will get non-trivial results only when domain defined by $\mu_{\mathsf{eff}} h_{\mathsf{eff}} \le C_0$ shrinks but remains non-empty which happens only in the frameworks of subcases (b) of Example 23.2.4.

Example 23.2.5. (i) In the framework of Example 23.2.4(i) with $m_1 > 2m$ consider $\mu h \to \infty$. Then the allowed domain is

$$\{x\colon |x| \lesssim r_2 = (\mu h)^{-1/(m_1-2m)}\} \tag{23.2.33}$$

and we have $r_0 \le r_1 \le r_2$ if $\mu \lesssim h^{-(m_1+1-m)/(m+1)}$ while for $\mu \gtrsim h^{-(m_1+1-m)/(m+1)}$ inequalities go in the opposite direction.

Therefore as $h \to +0$, $ch^{-1} \le \mu \le h^{-(m_1+1-m)/(m+1)}$ asymptotics (23.2.32) holds and one can see easily that $\mathcal{N}^-(\mu, h) \asymp h^{-2}r_2^{2m+2}$:

$$\mathcal{N}^-(\mu, h) \asymp \mu^{-2(m+1)/(m_1-2m)} h^{-2(m_1+1-m)/(m_1-2m)}. \tag{23.2.34}$$

(ii) Similarly, in the framework of Example 23.2.4(ii) with $m_1 < 2m$ asymptotics (23.2.32)$^{\#}$ and (23.2.34) hold as $h \to +0$, $ch^{-1} \le \mu \le h^{-(m_1+1-m)/(m+1)}$.

Let us consider $\mu \to \mu_0$ where $\mu_0 \ge 0$ is fixed.

Example 23.2.6. (i) Let us consider singularity at 0. In this case we are in the framework of Section 11.1 provided $m > -1$, $m_1 > -2$. So we need to consider the case when either $m \le -1$ or $m_1 \le -2$ and $m_1 \ne 2m$.

(a) The contribution of the semiclassical zone to the remainder is $O(h^{-1})$ only if $m > -1$.

(b) Assume now that $m \le -1$; then we need to assume that $m_1 < 2m$ and we have a normal magnetic field zone $X_1' = \{x\colon |x| \ge r_1 = \mu^{-1/(m_1-m+1)}\}$, strong magnetic field zone $X_2' = \{x\colon r_0 = (\mu h)^{-1/(m_1-2m)} \le |x| \le r_1\}$, and forbidden zone $X_3' = \{x\colon |x| \le r_1\}$. One can check that $r_0 < r_1$. Then the contribution to the remainder of X_1' and X_2' are both $O(h^{-1}r_1^{m+1}) = O(h^{-1}\mu^{-(m+1)/(m_1-m+1)})$ as $m < -1$ while for $m = -1$ contribution of X_1' is $O(h^{-1}(|\log\mu| + 1))$ and of X_2' is $O(h^{-1})$. Contribution of X_3' is smaller. So we get a remainder estimate

$$\mathsf{N}^-(\mu,h) = \mathcal{N}^-(\mu,h) + \begin{cases} O(h^{-1}), & m > -1,\\ O(h^{-1}(|\log\mu| + 1)) & m = -1,\\ O(h^{-1}\mu^{-(m+1)/(m_1-m+1)}) & m < -1. \end{cases} \tag{23.2.35}$$

Meanwhile, one can prove easily that

$$\mathcal{N}^-(\mu,h) \asymp \begin{cases} h^{-2} & m > -1,\\ h^{-2}(|\log\mu h| + 1) & m = -1,\\ h^{-2(m_1-m+1)/(m_1-2m)}\mu^{-2(m+1)/(m_1-2m)} & m < -1. \end{cases} \tag{23.2.36}$$

under assumption (23.2.30).

(ii) Similarly, consider the singularity at infinity. Then

(a) Let $m < -1$; then the remainder estimate is $O(h^{-1})$.

(b) Let $m \ge -1$, $m_1 > 2m$. Then

$$\mathsf{N}^-(\mu,h) = \mathcal{N}^-(\mu,h) + \begin{cases} O(h^{-1}) & m < -1,\\ O(h^{-1}(|\log\mu| + 1)) & m = -1,\\ O(h^{-1}\mu^{-(m+1)/(m_1-m+1)}) & m > -1. \end{cases} \tag{23.2.35}^{\#}$$

and

$$(23.2.36)^{\#}\quad \mathcal{N}^{-}(\mu,h)\asymp \begin{cases} h^{-2} & M<-1,\\ h^{-2}(|\log \mu h|+1) & m=-1,\\ h^{-2(m_1-m+1)/(m_1-2m)}\mu^{-2(m+1)/(m_1-2m)} & m>-1. \end{cases}$$

under assumption $(23.2.30)^{\#}$.

Improved Remainder Estimates

Let us improve remainder estimates (23.2.32), $(23.2.32)^{\#}$, (23.2.35), $(23.2.35)^{\#}$ under certain non-periodicity-type assumptions.

Example 23.2.7. (i) In the framework of Example 23.2.6(i) with $m>-1$ the contribution to the remainder of the zone $\{x\colon |x|\le \varepsilon\}$ does not exceed σh^{-1} with $\sigma=\sigma(\varepsilon)\to 0$ as $\varepsilon\to +0$. Then the standard arguments imply that under the standard non-periodicity assumption for Hamiltonian billiards[12)] with the Hamiltonian

$$(23.2.37)\qquad a(x,\xi,\mu_0)=\sum_{j,k} g^{jk}(\xi_j-\mu_0 V_j)(\xi_k-\mu_0 V_k)+V(x)$$

the improved asymptotics

$$(23.2.38)\qquad \mathsf{N}^{-}(\mu,h)=\mathcal{N}^{-}(\mu,h)+\kappa_1 h^{-1}+o(h^{-1})$$

holds as $h\to +0$, $\mu\to\mu_0$ where $\kappa_1 h^{-1}$ is the contribution of ∂X calculated as $\mu=\mu_0$. However, in the general case we cannot replace $\mathcal{N}^{\mathsf{MW}-}$ by $\mathcal{N}^{\mathsf{W}-}$ even if $\mu_0=0$.

(ii) Similarly in the framework of Example 23.2.6(ii) with $m<-1$ under the standard non-periodicity assumption for Hamiltonian billiards[12)] with the Hamiltonian (23.2.37) asymptotics (23.2.38) holds as $h\to +0$, $\mu\to\mu_0$.

(iii) In the framework of Example 23.2.6(i) with $m<-1$ the contributions to the remainder of the zones $\{x\colon |x|\le \varepsilon r_1\}$ and $\{x\colon |x|\ge \varepsilon^{-1} r_1\}$ do not exceed $\sigma h^{-1} r_1^{m+1}$ with $\sigma=\sigma(\varepsilon)\to 0$ as $\varepsilon\to +0$. After scaling $x\mapsto x r_1^{-1}$ etc

[12)] On the energy level 0.

the magnetic field in the zone $\{x\colon \varepsilon r_1 \le |x| \le \varepsilon^{-1} r_1\}$ becomes disjoint from 0 and ∞.

Assume that g^{jk}, V_j, V stabilize to positively homogeneous of degrees $0, m_1+1, 2m$ functions g^{jk0}, V_j^0, V^0 as $x \to 0$:

$$D^\alpha\bigl(g^{jk} - g^{jk0}\bigr) = o\bigl(|x|^{-|\alpha|}\bigr), \tag{23.2.39}$$

$$D^\alpha\bigl(V_j - V_j^0\bigr) = o\bigl(|x|^{m_1+1-|\alpha|}\bigr), \tag{23.2.39}$$

$$D^\alpha\bigl(V - V^0\bigr) = o\bigl(|x|^{2m-|\sigma|}\bigr) \qquad \forall \alpha : |\alpha| \le 1. \tag{23.2.39}$$

Then the standard arguments imply that under the standard non-periodicity assumption for Hamiltonian trajectories[12),13)] with the Hamiltonian

$$a^0(x,\eta) = \sum_{j,k} g^{jk0}(\eta_j - V_j^0)(\eta_k - V_k^0) + V_0 \tag{23.2.40}$$

the improved asymptotics

$$\mathsf{N}^-(\mu, h) = \mathcal{N}(\mu, h) + o\bigl(h^{-1}\mu^{-(m+1)/(m_1+1-m)}\bigr) \tag{23.2.41}$$

holds as $h \to +0$, $\mu \to 0$.

(iv) Similarly in the framework of Example 23.2.6(ii) with $m > -1$ let stabilization conditions $(23.2.39)^{\#}_{1-3}$ be fulfilled. Then under the standard non-periodicity assumption for Hamiltonian trajectories[12),13)] with the Hamiltonian (23.2.40) asymptotics (23.2.41) holds as $h \to +0$, $\mu \to 0$.

(v) In the framework of Example 23.2.6(i) with $m = -1$ the contributions to the remainder of the zone $\{x : |x| \le r_1\}$ does not exceed Ch^{-1}, while the contributions to the remainder of the zones $\{x : r_1 \le |x| \le r_1\mu^{-\delta}\}$ and $\{x : |x| \ge \mu^\delta\}$ do not exceed $C\delta h^{-1}|\log\mu|$ respectively. So, only zone $\{x : r_1\mu^{-\delta} \le |x| \le \mu^\delta\}$ should be treated. After rescaling magnetic field in this zone is small.

Let stabilization conditions $(23.2.39)_{1,3}$ be fulfilled. Then the standard arguments imply that under the standard non-periodicity assumption for Hamiltonian trajectories[12),13)] with the Hamiltonian

$$a^0(x,\eta) = \sum_{j,k} g^{jk0}\eta_j\eta_k + V_0 \tag{23.2.42}$$

[13)] In $T^*(\mathbb{R}^2 \setminus 0)$.

the improved asymptotics

$$\mathsf{N}^-(\mu,h) = \mathcal{N}(\mu,h) + o(h^{-1}|\log\mu|) \tag{23.2.43}$$

holds as $h\to+0$, $\mu\to 0$.

(vi) Similarly in the framework of Example 23.2.6(ii) with $m=-1$ let stabilization conditions $(23.2.39)^{\#}_{1,3}$ be fulfilled. Then under the standard non-periodicity assumption for Hamiltonian trajectories[12),13)] with the Hamiltonian (23.2.42) asymptotics (23.2.43) holds as $h\to+0$, $\mu\to 0$.

Consider now case of $\mu\to\infty$; we would like to improve estimates (23.2.32) for $m_1\ge 2m$ and $(23.2.32)^{\#}$ for $m_1\le 2m$. Recall that these estimates hold provided $\mu\lesssim h^{-(m_1+1-m)/(m+1)}$.

Example 23.2.8. (i) In the framework of Example 23.2.4(i) with $m_1>2m$ let stabilization conditions $(23.2.39)_{1-3}$ be fulfilled. Then using arguments of Example 23.2.7(iii) one can prove easily that under the the standard non-periodicity assumption for Hamiltonian trajectories[12),13)] with the Hamiltonian (23.2.40) asymptotics (23.2.41) holds as $h\to+0$, $\mu\to\infty$ provided $\mu = o\bigl(h^{-(m_1+1-m)/(m+1)}\bigr)$.

(ii) Similarly in the framework of Example 23.2.4(ii) with $m_1<2m$ let stabilization conditions $(23.2.39)^{\#}_{1-3}$ be fulfilled. Then under the the standard non-periodicity assumption for Hamiltonian trajectories[12),13)] with the Hamiltonian (23.2.40) asymptotics (23.2.41) holds as $h\to+0$, $\mu\to\infty$ provided $\mu = o\bigl(h^{-(m_1+1-m)/(m+1)}\bigr)$.

Degenerations

Consider magnetic field with degeneration.

Example 23.2.9. (i) Let 0 be an inner singular point of X and all assumptions of Example 23.2.3 (i) be fulfilled, except (23.2.9) $F\asymp\rho_1$ which is replaced now by

$$|F| + |\nabla F|\gamma \asymp \rho_1. \tag{23.2.44}$$

let $\Sigma=\{x\colon F_{12}=0\}$ be the manifold of degeneration, $\mathcal{Z}=\{x\colon |F|\le\epsilon\rho_1\}$ be the vicinity of the degeneration. Then we need to refer to Chapter 14.

To have $\mu_{\text{eff}} \gg 1$, and also $\mu_{\text{eff}} \ge Ch_{\text{eff}}^{-2}$ near singularity with as before $\mu_{\text{eff}} = \mu|x|^{m_1+1-m}$, $h_{\text{eff}} = h|x|^{-m-1}$ we assume that $m_1 < 3m+1$ if $m \le -1$. Assume that $m_1 < \min(m-1, 3m+1)$.

We preserve the non-degeneracy assumption (23.2.27) in $X \setminus \mathcal{Z}$ and replace it by[14)]

$$|\nabla_\Sigma W| \asymp \rho^2 \rho_1^{-\frac{2}{3}} \gamma^{-\frac{1}{3}} \tag{23.2.45}$$

where $W : |W| \lesssim \rho^2 \rho_1^{-\frac{2}{3}} \gamma^{\frac{2}{3}}$ is introduced according to Chapter 14. Then in addition to $m_1 \ne 2m$ we assume also that $m_1 \ne 3m+1$.

Recall that for the Schrödinger operator instead of $C\mu_{\text{eff}}^{-1} h_{\text{eff}}^{-1}$ the local remainder estimate now is $C\mu_{\text{eff}}^{-\frac{1}{2}} h_{\text{eff}}^{-1} \asymp C\mu^{-\frac{1}{2}} h^{-1} \gamma^{\frac{1}{2}(-m_1+3m+1)}$ and summation with respect to partition of unity returns $O(\mu^{-\frac{1}{2}} h^{-1})$ as $h \to +0$, μ is disjoint from 0 and $\mu^2 h$ is disjoint from infinity.

One can prove easily that $\mathcal{N}^-(\mu, h) \asymp h^{-2}$ as $\mu \lesssim h^{-1}$ and $\mathcal{N}^-(\mu, h) \asymp \mu^{-1} h^{-3}$ as $h^{-1} \lesssim \mu \lesssim h^{-2}$ exactly like in the regular case.

(ii) Similar results hold in the case when infinity is an inner singular point, $m_1 > \max(m-1,\, 3m+1)$.

The following problems are not very challenging but interesting:

Problem 23.2.10. (i) Consider the case of 0 being an inner singular point, $m > -1$, $m_1 \ge m-1$. The threshold value is $m_1 = 3m+1$. Assume that $h \to +0$.

(a) Consider cases $1 \lesssim \mu \lesssim h^{-1}$ and $h^{-1} \lesssim \mu \lesssim h^{-2}$ (cf. Example 23.2.4). Prove that in the case $m-1 \le m_1 < 3m+1$ the remainder estimate is $O(-\mu^{\frac{1}{2}} h^{-1})$. Derive the remainder estimate in the case $m_1 > 3m+1$. Calculate the magnitude of $\mathcal{N}^-$.

(b) Consider case $m_1 > 3m+1$ and $\mu \gtrsim h^{-2}$ (cf. Example 23.2.5). Derive the remainder estimate. Calculate the magnitude of $\mathcal{N}^-$.

(c) Consider $\mu \to 0$ (cf. Example 23.2.6 and possibly Example 23.2.7). Derive the remainder estimate. Calculate the magnitude of $\mathcal{N}^-$.

[14)] We need it mainly to avoid correction terms.

(ii) Similarly consider the case of 0 being an inner singular point, $m > -1$, $m_1 \le m-1$.

Example 23.2.11. Stronger asymptotic degenerations are not easily accessible. F.e. even if Chapter 14 provides us with tools to consider $F_{12} = x_1^n |x|^{m_1-n}$ with $n = 2 \ge$, it does not provide us with a tool to deal with the "small perturbations" like $F_{12} = x_1^n |x|^{m_1-n} + b x_1^{n-2} |x|^{m_2-n+2}$ with $m_2 > m_1$ ($m_2 < m_1$), if we consider vicinity of 0 (infinity respectively).

We want to recover whatever remainder estimates are possible.

(i) Case $n = 2$ and $b > 0$ should be the easiest as then the perturbation helps: the first rescaling is the standard $x \mapsto 2(x-y)r^{-1}$, $r = |y|$ in $B(y, \frac{1}{2}r)$, transforming it to $B(0,1)$, and as before $h \mapsto h_{\text{eff}} = hr^{-m-1}$, $\mu \mapsto \mu_{\text{eff}} = \mu r^{m_1+1}$ and perturbing field has the strength $\varepsilon\mu$ with $\varepsilon = r^{m_2-m_1}$.

Then the second rescaling $x \to (x-y)\gamma^{-1}$ with $\gamma = |F|^{1/2}$ as long as $|F| \ge \bar\gamma = C_0 \max(\mu^{-1/3}, \varepsilon^{\frac{1}{2}})$ and $\bar\gamma$ otherwise. Therefore the contribution of $B(y, \gamma(y))$ to the remainder does not exceed $C\mu^{-1}h^{-1}\gamma^{-2}$ and the summation over partition results in $C\mu^{-1}h^{-1}\bar\gamma^{-3}$, i.e. $Ch^{-1}\min(1, \mu^{-1}\varepsilon^{-\frac{3}{2}})$.

We leave to the reader to plug $h_{\text{eff}}, \mu_{\text{eff}}$ instead of μ, h and take a summation over the primary partition.

(ii) Cases $n = 3$ and $b > 0$ and $n = 2, 3$ and $b < 0$ are harder but for m_2 close enough to m_1 we refer to Chapter 14 after the second rescaling.

Then the second rescaling is the same $x \to (x-y)\gamma^{-1}$ with $\gamma = |F|^{1/n}$ as long as $|F| \ge \bar\gamma = C_0 \max(\mu^{-1/(n+1)}, \varepsilon^{\frac{1}{2}})$ and $\bar\gamma$ otherwise. Repeating the above arguments we conclude that the contribution of this zone is Ch^{-1} for $\varepsilon \le \mu^{-2/(n+1)}$ and $Ch^{-1}\mu^{-1}\varepsilon^{-(n+1)/2}$ for $\varepsilon \le \mu^{-2/(n+1)}$.

In the former case we are done, in the latter we need to explore zone $|F| \le \varepsilon^{n/2}$. Rescaling we get $\mu' = \mu\varepsilon^{(n+1)/2}$ and $h' = h\varepsilon^{-1/2}$. Then we can refer to Chapter 14 rather than Chapter 13 and the contribution of $B(y, \varepsilon^{1/2})$ to the remainder does not exceed $C\mu^{-1/2}h^{-1}\varepsilon^{-(n-1)/4}$ and summation over this zone results in $C\mu^{-1/2}h^{-1}\varepsilon^{-(n+1)/4}$, which is greater than the contribution of the previous zone.

Again, we leave to the reader to plug $h_{\text{eff}}, \mu_{\text{eff}}$ instead of μ, h and take a summation over the primary partition.

Power sSingularities. II

Let us modify our arguments for the case $\rho_3 < 1$. Namely, in addition to $(23.2.3)_{1-3}$ we assume that

$$(23.2.46)_{1,2} \qquad |D^\alpha g^{jk}| \le c\rho_2\gamma^{-|\alpha|}, \qquad |D^\alpha F_{jk}| \le c\rho_2\rho_1\gamma^{-|\alpha|},$$

$$(23.2.46)_3 \qquad |D^\alpha \frac{V}{F}| \le c\rho_3\rho^2\rho_1^{-1}\gamma^{-|\alpha|} \qquad \forall \alpha : 1 \le |\alpha| \le K$$

with $\rho_3 \le \rho_2 \le 1$ in the corresponding regions where $\rho, \rho_1, \gamma, \rho_3$ are scaling functions.

Recall that in Chapter 13 operator was reduced to the canonical form with the term, considered to be negligible, of magnitude $\rho_2\mu_{\text{eff}}^{-2N}$. In this case impose non-degeneracy assumptions

$$(23.2.47)^* \quad \bigl|V + (2n+1)\mu hF\bigr| \le \epsilon_0\rho_3\rho^2, \quad n \in \mathbb{Z}^+ \implies |\nabla v^*| \ge \epsilon_0\rho_3\rho^2\rho_1^{-1}\gamma^{-1}$$

and

$$(23.2.48) \qquad \rho_3 \ge C_0\rho_2(\mu\rho_1\gamma\rho^{-1})^{-N}$$

where v^* is what this reduction transforms VF^{-1} to and (23.2.48) means that "negligible" terms do not spoil $(23.2.47)^*$.

Then according to Chapter 13 the contribution of $B(x,\gamma)$ to the Tauberian remainder does not exceed

$$(23.2.49) \qquad C\bigl(\rho_3\mu_{\text{eff}}^{-1}h_{\text{eff}}^{-1} + 1\bigr)$$

while the approximation error does not exceed

$$(23.2.50) \qquad C\rho_2\rho_3^{-1}\mu_{\text{eff}}^{1-2N}h_{\text{eff}}^{-1}\underbrace{\bigl(\rho_3\mu_{\text{eff}}^{-1}h_{\text{eff}}^{-1} + 1\bigr)}\min\bigl((\mu_{\text{eff}}h_{\text{eff}}\rho_3^{-1})^s, 1\bigr)$$

with arbitrarily large s and therefore selected factor could be skipped.

Example 23.2.12. (i) Let 0 be an inner singular point[4)] and let assumptions $(23.2.46)_{1-3}$ be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^m\bigl(\bigl|\ln|x|\bigr| + 1\bigr)^\alpha$, $\rho_1 = |x|^{2m}\bigl(\bigl|\ln|x|\bigr| + 1\bigr)^\beta$, $\rho_2 = 1$ and $\rho_3 = \bigl(\bigl|\ln|x|\bigr| + 1\bigr)^{-1}$.

Assume that

(23.2.51) Either $m < -1$ and $\beta > 2\alpha$ or $m = -1$ and $\beta > \max(\alpha, 2\alpha)$.

Then (23.2.48) is fulfilled with $N = 1$ and we can replace (23.2.47)* by

$$\text{(23.2.47)} \quad \bigl|V + (2n+1)\mu h F\bigr| \le \epsilon_0\rho_3\rho^2, \quad n \in \mathbb{Z}^+ \implies |\nabla V F^{-1}| \ge \epsilon_0\rho_3\rho^2\rho_1^{-1}\gamma^{-1}$$

Then (23.2.49) becomes $C\bigl(\mu^{-1}h^{-1}|\log r|^{2\alpha-\beta-1} + 1\bigr)$ and for $s = 2$ the summation over zone $\{\mu_{\text{eff}} h_{\text{eff}} \lesssim 1\} = \{\mu h|\log r|^{\beta-2\alpha} \lesssim 1\}$ results in $C\bigl((\mu h)^{-1} + (\mu h)^{-1/(\beta-2\alpha)}\bigr)$.

Meanwhile, (23.2.50) with $N = 1$ becomes $C(\mu h)^s|\log r|^{s(\beta-2\alpha+1)+2}$ in the zone $\{\mu h|\log r|^{\beta-2\alpha+1} \le 1\}$ and the summation over this zone results in $C(\mu h)^{-3/(\beta-2\alpha+1)}$.

On the other hand, (23.2.50) with $N = 1$ becomes $C\mu^{-1}h^{-1}|\log r|^{1-\beta+2\alpha}$ in the zone $\{\mu h|\log r|^{\beta-2\alpha+1} \ge 1,\ \mu h|\log r|^{\beta-2\alpha} \le 1\}$ and the summation over this zone results in $O(\mu^{-1}h^{-1})$ as $\beta > 2\alpha+2$, $C(\mu h)^{-2/(\beta-2\alpha)}$ as $\beta < 2\alpha+2$ and $C\mu^{-1}h^{-1}|\log(\mu h)|$ as $\beta = 2\alpha+2$. Therefore, we conclude that the remainder is $O(R)$ with

$$\text{(23.2.52)} \qquad R := \begin{cases} (\mu h)^{-1} & \beta > 2\alpha+2, \\ (\mu h)^{-1}|\log(\mu h)| & \beta = 2\alpha+2, \\ (\mu h)^{-2/(\beta-2\alpha)} & 2\alpha < \beta < 2\alpha+2. \end{cases}$$

In particular, for $\beta \ge 2\alpha+2$ asymptotics (23.2.25)–(23.2.26) hold for $h \to +0$, μ disjoint from 0 and μh disjoint from infinity[15)].

One can see easily that under condition (23.2.30) for $\mu h \le t$ with small enough $t > 0$

$$\text{(23.2.53)}_1 \qquad \mathcal{N}^-(\mu, h) \asymp h^{-2}\bigl|\log(\mu h)\bigr| \qquad \text{for } \ m = -1, \alpha = -\frac{1}{2},$$

$$\text{(23.2.53)}_2 \qquad \mathcal{N}^-(\mu, h) \asymp h^{-2}(\mu h)^{(2\alpha+1)/(\beta-2\alpha)} \qquad \text{for } \ m = -1, \alpha > -\frac{1}{2}$$

and

$$\text{(23.2.53)}_3 \quad \epsilon h^{-2}\exp\bigl(\epsilon(\mu h)^{1/(2\alpha-\beta)}\bigr) \le \mathcal{N}^-(\mu, h) \le C_1 h^{-2}\exp\bigl(C_1(\mu h)^{1/(2\alpha-\beta)}\bigr)$$

[15)] Provided $V + \mu h F \ge \epsilon\rho^2$ on ∂X.

for $m<-1$ where $C_1>\epsilon>0$ are constants.

On the other hand, for $m=-1$, $\alpha<-\frac12$ the equivalence $\mathcal{N}^-(\mu,h)\asymp h^{-2}$ holds.

(ii) Let infinity be an inner singular point[7)] and let $(23.2.46)_{1-3}$ be fulfilled with $\gamma=\epsilon\langle x\rangle$, $\rho=\langle x\rangle^m\bigl(\log\langle x\rangle+1\bigr)^{\alpha}$, $\rho_1=\langle x\rangle^{2m}\bigl(\log\langle x\rangle+1\bigr)^{\beta}$, $\rho_2=1$, $\rho_3=\bigl(\log\langle x\rangle+1\bigr)^{-1}$. Assume that

$(23.2.51)^{\#}$ Either $m>-1$ and $\beta>2\alpha$ or $m=-1$ and $\beta>\max(\alpha,2\alpha)$.

Then all the statements of (i) remain true with the obvious modification: condition (23.2.30) should be replaced by $(23.2.30)^{\#}$ and estimates $(23.2.53)_3$ hold for $m>-1$.

Let us investigate further the case of $\beta\le 2\alpha+2$. Assume the following non-degeneracy assumption

$$-\langle x,\nabla\rangle VF^{-1}\ge\epsilon|\log|x||^{2\alpha-\beta-1}\qquad\text{for }\ |x|\le\epsilon. \tag{23.2.54}$$

In fact, we need to check it for $V^*=V+\mu^{-2}\omega_1$, but this condition for V and V^* are equivalent as long as $\mu_{\mathsf{eff}}^{-2}\ge C_0\rho_3$. This condition is fulfilled automatically for all r provided either $m<-1$ or $\beta>\alpha+\frac12$.

Consider first the semiclassical error. Recall that the contribution of the partition element does not exceed (23.2.49) and only summation over zone where $\rho_3\lesssim\mu_{\mathsf{eff}}h_{\mathsf{eff}}\lesssim 1$ could bring an error, exceeding $C\mu^{-1}h^{-1}$.

Assume first that $m<-1$. Then in this zone $(\mu h)^{-1/(2m+2)}|\log\mu h|^a\lesssim r\lesssim(\mu h)^{-1/(2m+2)}|\log\mu h|^b$ and then its contribution is $C|\log(\mu h)|=O(\mu^{-1}h^{-1})$.

Consider the case $m=-1$. In this case the problematic zone is $\mathcal{Z}:=\{(\mu h)^{-1/(\beta-2\alpha+1)}\lesssim|\log r|\lesssim(\mu h)^{-1/(\beta-2\alpha)}\}$. Observe that $\int_{\mathcal{Z}}\gamma^{-2}\,dx\asymp(\mu h)^{-1/(\beta-2\alpha)}$ which is $O(\mu^{-1}h^{-1})$ provided $\beta\ge 2\alpha+1$.

We can improve these arguments in the following way. Let us observe that the zone $\{|\log r|\le C_0(\mu h)^{-1/(\beta-2\alpha)}\}$ consists of the *spectral strips*

$$\Pi_n=\{x\colon \bigl|v^*+(2n+1)\mu h\bigr|\le C_1|\log r|^{-1}\} \tag{23.2.55}$$

with $v^*:=(V+\omega_1\mu^{-2})F^{-1}$ with $n=0,\dots,n_0=C_1(\mu h)^{-1/(\beta-2\alpha+1)}$, separated by the *lacunary strips*.

Condition (23.2.54) provides that for fixed n and $x|x|^{-1}$ (thus, only $|x|$ varies) on Π_n the inequality $\bigl|\mathfrak{d}\log|x|\bigr| \le C_1$ holds where $\mathfrak{d}f$ means the oscillation of f (on Π_n) and the constant C_1 does not depend on $n, x|x|^{-1}, \mu, h$.

Therefore one can easily see that the contribution of each strip Π_n to the semiclassical remainder does not exceed C and their total contribution does not exceed $Cn_0 = O(\mu^{-1}h^{-1})$.

Meanwhile, contribution of each lacunary strip does not exceed the contribution of the adjacent spectral strip, multiplied by $C\rho_3^{-1} \times (\mu_{\text{eff}}^{-1}h_{\text{eff}})^s$ and one can see easily that their total contribution is $O(\mu^{-1}h^{-1})$. Therefore

(23.2.56) If in the framework of Example 23.2.12(i) either $m < -1$ or $m = -1, \beta > \alpha + \frac{1}{2}$ then the semiclassical error is $O(\mu^{-1}h^{-1})$.

The same arguments work for the approximation error (23.2.50) with $N = 1$: the contribution of the spectral strip gains factor ρ_3 and the contribution of the lacunary strip is 0. Then the total approximation error does not exceed "improved" (23.2.52):

$$R := \begin{cases} (\mu h)^{-1} & \beta > 2\alpha + 1, \\ (\mu h)^{-1}|\log(\mu h)| & \beta = 2\alpha + 1, \\ (\mu h)^{-1/(\beta - 2\alpha)} & 2\alpha < \beta < 2\alpha + 1. \end{cases} \tag{23.2.57}$$

Then we arrive to

Example 23.2.13. (i) Let all the assumptions of Example 23.2.12(i) be fulfilled, in particular (23.2.51). Moreover, let us assume that (23.2.54) is fulfilled and either $m < -1$ or $\beta > \alpha + \frac{1}{2}$. Then for $h \to +0$, μ disjoint from 0 and μh disjoint from infinity the asymptotics

$$\mathsf{N}^-(\mu, h) = \mathcal{N}^-(\mu, h) + O(R) \tag{23.2.58}$$

holds with R defined by (23.2.57).

(ii) Let all the assumptions of Example 23.2.12(ii) be fulfilled. Moreover, let us assume that condition

$$\langle x, \nabla\rangle VF^{-1} \ge \epsilon|\log x|^{2\alpha-\beta-1} \qquad \text{for } |x| \ge c. \tag{23.2.54}^{\#}$$

is fulfilled and either $m > -1$ or $\beta \ge \alpha + \frac{1}{2}$. Then for $h \to +0$, μ disjoint from 0 and μh disjoint from infinity the asymptotics (23.2.58) holds. with R defined by (23.2.57).

If we want to improve the remainder estimate in the case $\beta \le 2\alpha+1$ we should take $N=2$, which would make our formulae more complicated but still "computable". Then expression (23.2.50) with $N=2$ acquires (in comparison with the same expression with $N=1$) the factor $\mu^{-2}r^{-2(m+1)}|\log r|^{-2(\beta-\alpha)}$ and becomes

$$\mu^{-3}r^{-2(m+1)}|\log r|^{-3\beta+4\alpha+1}. \tag{23.2.59}$$

Further, we can get gain a factor $|\log r|^{-1}$ dues to above arguments concerning spectral and lacunary zones. Then after the summation we get $O(\mu^{-3}h^{-1})$ if either $m<-1$ or $m=-1$, $3\beta>4\alpha+1$. However if $m=-1$ this is the case due to $\beta>2\alpha$ and $\beta\ge\alpha+\frac12$. Then we arrive to

Example 23.2.14. (i) Let all the assumptions of Example 23.2.12(i) be fulfilled, in particular (23.2.51). Moreover, let us assume that (23.2.54) is fulfilled and either $m<-1$ or $\beta>\alpha+\frac12$.

Then for $h\to+0$, μ disjoint from 0 and μh disjoint from infinity the asymptotics

$$\mathsf{N}^-(\mu,h)=\mathcal{N}^{-\prime}(\mu,h)+O(\mu^{-1}h^{-1}) \tag{23.2.60}$$

holds where

$$\mathcal{N}^{-\prime}(\mu,h)=\int h^{-2}\mathcal{N}^{\mathsf{MW}\prime}(x,\mu h)\,dx \tag{23.2.61}$$

and $\mathcal{N}^{\mathsf{MW}\prime}$ is defined by (13.5.133) with $\psi=1$.

(ii) Let all the assumptions of Example 23.2.12(ii) be fulfilled. Moreover, let us assume that condition $(23.2.54)^{\#}$ is fulfilled and either $m>-1$ or $\beta>\alpha+\frac12$. Then for $h\to+0$, μ disjoint from 0 and μh disjoint from infinity the asymptotics 23.2.60–23.2.61 holds.

Remark 23.2.15. Asymptotics (23.2.60)–(23.2.61) still holds if $m=-1$ and $2\alpha<\beta\le\alpha+\frac12$ (and therefore $\alpha<\frac12$) under assumption (23.2.62) below.

Indeed, recall that we need $\beta>\alpha+\frac12$ only to ensure that inequality (23.2.54) for V implies the same inequality for V^*. This conclusion should be checked as $|\log r|\le C_0(\mu h)^{-1/(\beta-2\alpha)}$ only. Observe that this conclusion still holds in the case under consideration if $\mu^{-2}(\mu h)^{(2\beta-2\alpha-1)/(\beta-2\alpha)}\le\epsilon$, i.e.

$$\mu\ge Ch^{(2\beta-2\alpha-1)/(1-2\alpha)}. \tag{23.2.62}$$

Then the semiclassical error does not exceed $C\mu^{-1}h^{-1}$ and an approximation error does not exceed $C\mu^{-3}h^{-1}(\mu h)^{-(4\alpha-3\beta+1)/(\beta-2\alpha)}$ (multiplied by $|\log(\mu h)|$ if $4\alpha-3\beta+1=0$). One can prove easily that it is less than $C\mu^{-1}h^{-1}$ under assumption (23.2.62).

We leave to the reader

Problem 23.2.16. (i) Consider cases of $\mu\to\mu_0>0$ and $\mu\to\mu_0=0$ like in Example 23.2.6.

(ii) Consider cases of $m>-1$ and singularity at 0, $m<-1$ and singularity at infinity, and $m=-1$, $\alpha<0$ and singularity either at 0 or at infinity. In these three cases assumption $\beta>2\alpha$ is not necessary; therefore, one needs to consider also the case $\beta<2\alpha$.

(iii) Furthermore, in the framework of (ii) and $\beta<2\alpha$ consider the case of $\mu h\to\infty$ like in Example 23.2.5.

Exponential Singularities

Consider now singularities of the exponential type. The following example follows immediately from Theorem 23.2.2:

Example 23.2.17. (i) Let 0 be an inner singular point[4)] and let conditions of Theorem 23.2.2 be fulfilled with $\gamma=\epsilon|x|^{1-\beta}$, $\rho=\exp(a|x|^{\alpha})$, $\rho_1=\exp(b|x|^{\beta})$ with either $0>\alpha>\beta$, $a>0$, $b>0$ or $0>\alpha=\beta$, $b>2a>0$.

Let $V+\mu hF\ge\epsilon\rho^2$ on $(\partial X\setminus 0)\cup\{x\colon |x|\ge c\}$. Then conditions (23.2.23) and (23.2.24) are fulfilled automatically and for $\mu\ge 1$, $h\to+0$ asymptotics (23.2.25)–(23.2.26) hold.

Moreover, under condition (23.2.30) for $\alpha=\beta$, $\mu h<t$ with a small enough constant $t>0$

$$\mathcal{N}^-(\mu,h)\asymp h^{-2}(\mu h)^{-2a/(b-2a)}|\log\mu h|^{\frac{2}{\alpha}-1}; \tag{23.2.63}$$

otherwise the left-hand expression is "O" only.

(ii) Let infinity be an inner singular point[7)] and let conditions of Theorem 23.2.2 be fulfilled with $\gamma=\epsilon\langle x\rangle^{1-\beta}$, $\rho=\exp(a\langle x\rangle^{\alpha})$, $\rho_1=\exp(b\langle x\rangle^{\beta})$ where either $0<\alpha<\beta$, $a>0$, $b>0$ or $0<\alpha=\beta$, $b>2a>0$.

Let $V + \mu hF \ge \epsilon\rho^2$ on ∂X. Then conditions (23.2.23)–(23.2.24) are fulfilled automatically and asymptotics (23.2.25)–(23.2.26) hold.

Moreover, under condition (23.2.30)$^{\#}$ for $\alpha = \beta$, $\mu h < t$ with a small enough constant $t > 0$ (23.2.45) holds; otherwise the left-hand expression is "O" only.

We leave to the reader the following

Problem 23.2.18. Calculate magnitude of $\mathcal{N}^-(\mu, h)$ as $\alpha < \beta$ in Example 23.2.17.

Example 23.2.19. (i) Let 0 be an inner singular point[4]. Assume that conditions of Theorem 23.2.2 are fulfilled with $\gamma = \epsilon|x|^{1-\beta}$, $\rho = |x|^m \exp(|x|^\beta)$, $\rho_1 = |x|^{m_1} \exp(2|x|^\beta)$, $\rho_2 = 1$, $\rho_3 = |x|^{-\beta}$ and let $\beta < 0$, $m_1 < 2m$.

Let $V + \mu hF \ge \epsilon\rho^2$ on $(\partial X \setminus 0) \cup \{x\colon |x| \ge c\}$. Then conditions (23.2.24), (23.2.48) are fulfilled automatically.

Moreover, condition

$$\int \rho_3^{-1}\rho_1^{-1}\rho^2 \, dx < \infty \tag{23.2.64}$$

is fulfilled provided $2m+3\beta > m_1$; then asymptotics (23.2.25)–(23.2.26) holds. Moreover, under condition (23.2.30) while we cannot calculate magnitude of $\mathcal{N}^-(\mu, h)$ itself, we conclude that

$$\log(\mathcal{N}^-(\mu, h)) \asymp (\mu h)^{\beta/(2m-m_1)}). \tag{23.2.65}$$

(ii) Let infinity be an inner singular point[7]. Assume that conditions of Theorem 23.2.2 are fulfilled with $\gamma = \epsilon_0\langle x\rangle^{1-\beta}$, $\rho = \langle x\rangle^m \exp(\langle x\rangle^\beta)$, $\rho_1 = \langle x\rangle^{m_1} \exp(2\langle x\rangle^\beta)$, $\rho_2 = 1$, $\rho_3 = \langle x\rangle^{-\beta}$ where $\beta > 0$, $m_1 > 2m$.

Let $V + \mu hF \ge \epsilon\rho^2$ on ∂X. Then condition (23.2.64) is fulfilled provided $2m+3\beta < m_1$; then asymptotics (23.2.25)–(23.2.26) holds. Moreover, under condition (23.2.30)$^{\#}$ estimates (23.2.65) hold.

Consider case of $2m + 3\beta \le m_1$, $2m + 3\beta \ge m_1$ in the frameworks of Statements (i) and (ii) respectively. One can get some remainder estimates albeit less precise. We want to improve them using the same technique as in Subsubsection *23.2.1.6. Power sSingularities. II.* However now things are a bit simpler. First of all, condition $\mu_{\text{eff}}^{-2} \le \rho_3$ is fulfilled automatically.

Contribution of the zone $\mathcal{Z}_1 = \{r \ge (\mu h)^{1/(-\beta-m_1+2m)}\}$ where $\rho_3 \ge \mu_{\text{eff}} h_{\text{eff}}$ to the semiclassical error does not exceed $(\mu h)^{-1} \int_{\mathcal{Z}_1} \rho_3 \rho_1^{-1} \rho^2 \gamma^{-2}\, dx$. Contribution of the zone $\mathcal{Z}_2 = \{(\mu h)^{1/(-m_1+2m)} \le r \le (\mu h)^{1/(-\beta-m_1+2m)}\}$ where $\rho_3 \le \mu_{\text{eff}} h_{\text{eff}} \lesssim 1$ to the semiclassical error does not exceed $\int_{\mathcal{Z}_2} \rho_3 \gamma^{-2}\, dx$ due to the same "spectal and lacunary strips" arguments. Then the semiclassical error is does not exceed $C(\mu h)^{-1}$ provided $m_1 < 2m + \beta$.

Further, contributions of these zones $\mathcal{Z}_j$ to the approximation error with $N = 1$ do not exceed $C\mu^{-1}h^{-1} \int_{\mathcal{Z}_j} \rho_1^{-1} \rho^2 \gamma^{-2}\, dx$ and the approximation error is $O(\mu^{-1}h^{-1})$ provided $m_1 < 2m + 2\beta$.

On the other hand, one can see easily that the approximation error with $N = 2$ is $O(\mu^{-1}h^{-1})$ for sure. We arrive to the following

Example 23.2.20. (i) Let all the assumptions of Example 23.2.19(i) be fulfilled. Moreover, let us assume that condition

$$-\langle x, \nabla\rangle VF^{-1} \ge \epsilon |x|^{2m-m_1} \qquad \text{for } |x| \le \epsilon. \tag{23.2.66}$$

is fulfilled.

Then for $h \to +0$, μ disjoint from 0 and μh disjoint from infinity the asymptotics (23.2.25)–(23.2.26) holds provided $m_1 < 2m + 2\beta$ and asymptotics (23.2.60)–(23.2.61) holds with $\mathcal{N}^{\mathsf{MW}\prime}$ defined by (13.5.133) with $\psi = 1$ provided $m_1 < 2m + \beta$.

(ii) Let all the assumptions of Example 23.2.12(ii) be fulfilled. Moreover, . Moreover, let us assume that condition

$$\langle x, \nabla\rangle VF^{-1} \ge \epsilon |x|^{2m-m_1} \qquad \text{for } |x| \ge \epsilon. \tag{23.2.66}^{\#}$$

is fulfilled.

Then for $h \to +0$, μ disjoint from 0 and μh disjoint from infinity the asymptotics (23.2.25)–(23.2.26) holds provided $m_1 > 2m + 2\beta$ and asymptotics (23.2.60)–(23.2.61) holds with $\mathcal{N}^{\mathsf{MW}\prime}$ defined by (13.5.133) with $\psi = 1$ provided $m_1 > 2m + \beta$.

Example 23.2.21. (i) In the framework of Example 23.2.17(i) assume that (23.2.66) is fulfilled. Moreover, let

$$|D^\sigma g^{jk}| \le c|x|^{-|\sigma|}, \qquad |D^\sigma \log F| \le c|x|^{\beta-|\sigma|}, \qquad |D^\sigma V/F| \le c|x|^{2m-m_1-|\sigma|} \qquad \forall \sigma : 1 \le |\sigma| \le 2. \tag{23.2.67}$$

Then for $h \to +0$, $1 \le \mu = O(h^{-1})$ asymptotics (23.2.25)–(23.2.26) holds provided $m_1 < 2m + \beta$.

Indeed, one can easily see that under condition (23.2.67)

$$|\omega_1| \le C_1 F^{-1} |x|^{\beta+4m-2m_1-2} = \omega_1^* \tag{23.2.68}$$

while the general theory yields only that

$$|\omega_1| \le C_1 F^{-1} |x|^{2\beta+4m-2m_1-2}.$$

Then the error $|\mathcal{N}^-(\mu, h) - \mathcal{N}^{-\prime}(\mu, h)|$ does not exceed

$$C\mu^{-1}h^{-1} \int_{\{\rho_1\mu h \le \rho_3\rho^2\}} \rho_1^2 \rho^{-2} \rho_3^{-1} \omega_1^* \, dx + Ch^{-2} \int_{\{\rho_3\rho^2 \le \rho_1\mu h \le C_0\rho^2\}} \rho_1 (\omega_1^* \mu^{-2} + \chi_\Pi) \, dx$$

where χ_Π is the characteristic function of the set

$$\Pi = \bigcup_{n\in\mathbb{Z}^+} \{x\colon \big|v + (2n+1)\mu h\big| \le C_1 \mu^{-2} \omega_1^*\}.$$

Applying estimate (23.2.68) and condition (23.2.66) one can prove that this error is $O(\mu^{-1}h^{-1})$.

(ii) Similarly, in the framework of Example 23.2.17(ii) assume that $(23.2.66)^\#$ is fulfilled. Moreover, let

$$|D^\sigma g^{jk}| \le c\langle x\rangle^{-|\sigma|}, \qquad |D^\sigma \log F| \le c\langle x\rangle^{\beta-|\sigma|} \qquad |D^\sigma V/F| \le c\langle x\rangle^{2m-m_1-|\sigma|} \qquad \forall \sigma : 1 \le |\sigma| \le 2. \tag{23.2.67}^\#$$

Then for $h \to +0$, $1 \le \mu = O(h^{-1})$ asymptotics (23.2.25)–(23.2.26) holds provided $m_1 > 2m + \beta$.

We leave to the reader:

Problem 23.2.22. Consider cases of $\mu \to \mu_0 > 0$ and $\mu \to \mu_0 = 0$ like in Example 23.2.6.

23.2.2 Schrödinger-Pauli Operators

Consider now Schrödinger-Pauli operators, either genuine (0.34) or generalized (13.6.3). The principal difference is that now F does not "tame" singularities of V, on the contrary, it needs to be "tamed" by itself. As a result there are fewer examples than for the Schrödinger. Also we do not have a restriction $\mu_{\text{eff}} h_{\text{eff}} = O(1)$ which we had in the most of the previous Subsection 23.2.1. Then we need to add 1 and $\mu_{\text{eff}} h_{\text{eff}}^{-1} = \mu h^{-1} \rho_1 \gamma^2$ to the contributions of this element to the remainder estimate and $\mathcal{N}^-(\mu, h)$ respectively.

Because of this, here we do not consider an abstract theorem like Theorem 23.2.2, but go directly to the examples.

Example 23.2.23[16]. (i) Let 0 be an inner singular point[4] and $\gamma = \epsilon|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$ and let $m > -1$, $2m \ne m_1 > -2$. Let our usual non-degeneracy assumptions be fulfilled. Then, in comparison with the theory of the previous Subsection 23.2.1, we need to consider also the the zone $\mu_{\text{eff}} h_{\text{eff}} \gtrsim 1$.

Its contribution to the remainder does not exceed $C \int \gamma^{-2}\, dx$ while its contribution to $\mathcal{N}^-(\mu, h)$ does not exceed $C\mu h^{-1} \int \rho_1\, dx$. Indeed, contributions of each γ-element do not exceed C and $C\mu_{\text{eff}} h_{\text{eff}}^{-1} \asymp C\mu h^{-1} \rho_1 \gamma^2$.

(a) Let $m_1 > 2m$; then this zone is disjoint from 0 and this expression is $O(1)$. Furthermore, contribution of the zone $\{r \le \mu^{-1/(m_1+1-m)}\}$ where $\mu_{\text{eff}} \lesssim 1$ to the remainder does not exceed $Ch^{-1} \int \rho\gamma^{-1}\, dx$, taken over this zone, and it is $\asymp h^{-1}\mu^{-(m+1)/(m_1+1-m)}$ and we arrive to (23.2.70)–(23.2.71) below; cf. (23.2.32).

(b) Consider now the case $m_1 < 2m$. In this case zone where $\mu_{\text{eff}} h_{\text{eff}} \gtrsim 1$ is not disjoint from 0 and we need to consider also a singular zone $\{r \le \bar{r} := (\mu^{-1}h)^{-1/(m_1-2m)}\}$ where $\mu_{\text{eff}}^{-1} h_{\text{eff}} \gtrsim 1$.

However due to the variational estimates as before

(23.2.69) For the disk $\{x\colon |x| \le 2\bar{r}\}$ with the Dirichlet boundary conditions

$$\mathsf{N}^-(\mu, h) \le Ch^{-2}\bar{r}^{2m+2} + C(\mu h^{-1})^2 \bar{r}^{2(m_1+2)}$$

which is $O(1)$ due to the choice of $\bar{r}$.

[16] Cf. Example 23.2.3.

We leave to the reader to prove (23.2.69) and (23.2.69)$^{\#}$ below and to justify the final result using methods of Section 10.1:

$$\mathsf{N}^-(\mu,h) = \mathcal{N}^-(\mu,h) + \begin{cases} O(h^{-1}\mu^{-1}+1) & m_1 < 2m, \\ O(h^{-1}\mu^{-(m+1)/(m_1+1-m)})+1 & m_1 > 2m. \end{cases} \tag{23.2.70}$$

with

$$\mathcal{N}^-(\mu,h) \asymp h^{-2} + \mu h^{-1}. \tag{23.2.71}$$

(ii) Let infinity be an inner singular point[7)] and $\gamma = \epsilon\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$ and let $m < -1$, $2m \ne m_1 < -2$. Let Let our usual non-degeneracy assumptions be fulfilled. Then again we need to consider cases (a) $m_1 < 2m$ and (b) $m_1 > 2m$ and in the latter case we need to consider contribution of zone $\{r \le \bar{r} := (\mu^{-1}h)^{-1/(m_1-2m)}\}$.

However due to variational estimates

(23.2.69)$^{\#}$ For the zone $\{x\colon |x| \ge \frac{1}{2}\bar{r}\}$ with the Dirichlet boundary conditions

$$\mathsf{N}^-(\mu,h) \le Ch^{-2}\bar{r}^{2m+2} + C(\mu h^{-1})^2\bar{r}^{2(m_1+2)}$$

which is again $O(1)$ due to the choice of $\bar{r}$. Then

$$\mathsf{N}^-(\mu,h) = \mathcal{N}^-(\mu,h) + \begin{cases} O(h^{-1}\mu^{-1}+1) & m_1 > 2m, \\ O(h^{-1}\mu^{-(m+1)/(m_1+1-m)})+1 & m_1 < 2m. \end{cases} \tag{23.2.70}$$

and (23.2.71) hold.

We leave to the reader the following problems:

Problem 23.2.24. (i) As 0 is an inner point consider both Schrödinger and Schrödinger-Pauli operators as

(a) $\gamma = |x|$, $\rho = |x|^m$, $m > -1$ and $\rho_1 = |x|^{-2}|\log|x||^{\beta}$ [17)].

[17)] One should take $\beta < -1$ for the Schrödinger-Pauli operator.

(b) $\gamma = |x|$, $\rho = |x|^{-1}|\log|x||^{\alpha}$, $\alpha < -\frac{1}{2}$ [18] and $\rho_1 = |x|^{m_1}|$, $m_1 > -2$.

(ii) As infinity is an inner point consider both Schrödinger and Schrödinger Pauli operators as

(a) $\gamma = |x|$, $\rho = |x|^{m}$, $m < -1$ and $\rho_1 = |x|^{-2}|\log|x||^{\beta}$ [17].

(b) $\gamma = |x|$, $\rho = |x|^{-1}|\log|x||^{\alpha}$, $\alpha < -\frac{1}{2}$ [18] and $\rho_1 = |x|^{m_1}$, $m_1 > -2$.

For the Schrödinger operator in cases (a) non-trivial results could be also obtained even as $\mu h \to +\infty$.

Problem 23.2.25. Let either 0 or infinity be an inner singular point.

Using the same arguments and combining them with the arguments of Subsubsection *23.2.1.6. Power sSingularities. II* consider both Schrödinger-Pauli and Schrödinger operators with $\gamma = |x|$, $\rho = |x|^{-1}|\log|x||^{\alpha}$, $\rho_1 = |x|^{-2}|\log|x||^{\beta}$ [17].

Take into account whether $\beta > 2\alpha$ or $\beta < 2\alpha$. For the Schrödinger operator in case $\beta < 2\alpha$ non-trivial results could be obtained even as $\mu h \to +\infty$.

23.2.3 Dirac Operator

Preliminaries

Let us now consider the generalized magnetic Dirac operator (17.1.1)

$$A = \frac{1}{2}\sum_{l,j} \sigma_l\big(\omega^{jl}P_j + P_j\omega^{jl}\big) + \sigma_0 M + I\cdot V, \qquad P_j = hD_j - \mu V_j \tag{23.2.72}$$

where $\sigma_0, \sigma_1, \sigma_2$ are 2×2-matrices.

We are interested in $\mathsf{N}(\tau_1,\tau_2)$, the number of eigenvalues in (τ_1,τ_2) [19] with $\tau_1 < \tau_2$, fixed in this subsection.

The theory of the Dirac operator is more complicated than the theory of the Schrödinger operator because it is different in the cases when $V \pm M$ [20] and F tend to 0 and (or) ∞ and thus singularities at 0 and at infinity should be treated differently.

---

[18] One needs to consider cases $\alpha < -1$, $\alpha = -1$, $-1 < \alpha < -\frac{1}{2}$ separately.

[19] Assuming that this interval does not contain essential spectrum; otherwise $\mathsf{N}(\tau_1,\tau_2) := \infty$. It is more convenient for us to exclude both ends of the segment.

[20] If $V \pm M \in [\tau_1+\epsilon, \tau_2-\epsilon]$ for both signs $\pm$, then infinity is not a singular point.

Furthermore, the theory of the magnetic Dirac operator is even more complicated. Indeed, the "pointwise Landau levels" are $V \pm \bigl(M^2 + 2j\mu hF\bigr)^{\frac{1}{2}}$ with $j = 0, 1, 2, ...$ but one of those is, in fact, excepted: with the same sign as ςF_{12} and $j = 0$. Recall that $\varsigma = \pm 1$ is defined by (17.1.14)

$$\sigma_0\sigma_1\sigma_2 = \varsigma i. \tag{23.2.73}$$

Without any loss of generality one can assume that

$$\varsigma = 1, \qquad F_{12} > 0. \tag{23.2.74}$$

Then the Landau levels (at the point x) are $V + \bigl(M^2 + 2j\mu hF\bigr)^{\frac{1}{2}}$ with $j = 1, 2, 3, ...$ and $V - \bigl(M^2 + 2j\mu hF\bigr)^{\frac{1}{2}}$ with $j = 0, 1, 2, ...$ But then the negative V could be "tamed" by a larger F. This allows us to get meaningful results in the situations impossible for non-magnetic Dirac operator: V as singular at 0 as $|x|^m$ with $m \le -1$ or $V + M$ as singular at infinity as $|x|^{2m}$ with $m \ge -1$ (as $M > 0$) provided it is negative there. Furthermore, if $F \to \infty$ as $|x| \to \infty$, we can get meaningful results even if $M = 0$.

On the other hand, we often *should prove* that the Dirac operator is essentially self-adjoint while the Schrödinger operator is *obviously* semibounded and therefore essentially self-adjoint. We do this in Appendix 23.A.1.

Therefore, we treat the operator given by (23.2.72) under the following assumptions

$$|D^\alpha \omega^{jk}| \le c\gamma^{-|\alpha|}, \qquad |D^\alpha F| \le c\rho_1\gamma^{-|\alpha|}, \tag{23.2.75}_{1-2}$$

$$|D^\alpha V| \le c\min\bigl(\rho, \frac{1}{M}\rho^2\bigr)\gamma^{-|\alpha|} \qquad (\alpha \ne 0) \quad \forall \alpha : |\alpha| \le K, \tag{23.2.75}_3$$

$$(V - \tau_2 - M)_+ \le c\min\bigl(\rho, \frac{1}{M}\rho^2\bigr), \tag{23.2.75}_{4+}$$

$$(V - \tau_1 + M)_- \le c\min\bigl(\rho, \frac{1}{M}\rho^2\bigr) \tag{23.2.75}_{4-}$$

and also $(23.2.3)_{1-3}$, (23.2.2) for $g^{jk} = \sum_{l,r} \omega^{jl}\omega^{kr}\delta_{lr}$ and (23.2.9) (with $F > 0$). In what follows $(23.2.75)_4$ means the pair of conditions $(23.2.75)_{4\pm}$.

Moreover, let condition (23.2.13) be fulfilled and

$$\bar{X}'' \cap \partial X = \emptyset, \tag{23.2.76}$$

$$|V_j| \le c\rho, \quad |D_j\omega^{kl}| \le c\rho \qquad \text{in} \quad X''. \tag{23.2.77}$$

Finally, we assume that

(23.2.78) Either $\partial X = \emptyset$ or $\mu = O(1)$ and $\partial X \cap X_2' = \emptyset$ (in what follows).

Asymptotics. I

Example 23.2.26[21]. Let condition (23.2.74) be fulfilled.

(i) Let 0 be an inner singular point and let all the above conditions, be fulfilled with $\gamma = \epsilon_0|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$, $m_1 < \min(m-1,\, 2m)$.

Further, let

$$-V \ge \epsilon \min(\rho,\, \frac{\rho^2}{M}) \qquad \forall x : |x| \le \epsilon \tag{23.2.79}$$

and let non-degeneracy condition

$$\begin{aligned} &\bigl|V + \varsigma\bigl(M^2 + 2j\mu hF\bigr)^{\frac12} - \tau_\iota\bigr| \le \epsilon\rho \implies \\ &\qquad |\nabla v_\iota| \ge \epsilon\rho_1\rho^2\gamma^{-1} \qquad \text{or} \qquad \det \operatorname{Hess} v_\iota \ge \epsilon\rho_1^{-2}\rho^4\gamma^{-4} \qquad \text{or} \\ &\qquad |\nabla V| \ge \epsilon\rho\gamma^{-1} \qquad \text{and} \quad M \le \epsilon'\rho \quad \forall (j,\varsigma) \ne (0,1) \end{aligned} \tag{23.2.80}$$

be fulfilled with a small enough constant $\epsilon' = \varepsilon(c, \epsilon, \epsilon_0) > 0$; this assumption is a part of condition (23.2.80))[22].

(a) Let $m < 0$, $\tau_1 < \tau_2$. Then for $h \to +0$, $1 \le \mu = O(h^{-1})$ asymptotics (23.2.25)–(23.2.26) holds with $\mathcal{N}$ defined by $(17.1.12)_2$ with $d = 2$. Moreover,

$$\mathcal{N}(\tau_1, \tau_2, \mu, h) \asymp \begin{cases} h^{-2} & m \ge -1, \\ h^{-2}(\mu h)^{2(m+1)/(2m-m_1)} & m < -1. \end{cases} \tag{23.2.81}$$

(b) Let $m > 0$, $M > 0$, $\tau_1 \in (-M, M)$, $\tau_2 = M$. Then for $h \to +0$, $1 \le \mu = O(h^{-1})$ asymptotics (23.2.25)–(23.2.26) holds with $\mathcal{N}$ defined by $(17.1.12)_2$ with $d = 2$. Moreover, equivalence (23.2.28) holds.

(ii) Let infinity be an inner singular point and let all the above conditions be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m_1 > \max(m-1,\, 2m)$.

Further, let

$$-V \ge \epsilon \min(\rho,\, \frac{\rho^2}{M}) \qquad \forall x : |x| \ge c \tag{23.2.79}^{\#}$$

and let non-degeneracy condition (23.2.80) be fulfilled.

---

[21] Cf. Example 23.2.3.

[22] Recall that $v_\iota = F^{-1}\bigl((V-\tau_\iota)^2 - M^2\bigr)$ and the conditions should be fulfilled for both $\iota = 1, 2$.

(a) Let $m > 0$, $\tau_1 < \tau_2$. Then for $h \to +0$, $1 \le \mu = O(h^{-1})$ asymptotics (23.2.25)–(23.2.26) holds with $\mathcal{N}$ defined by $(17.1.12)_2$ with $d = 2$. Moreover,

$$\mathcal{N}^-(\tau_1, \tau_2, \mu, h) \asymp h^{-2}(\mu h)^{2(m+1)/(2m-m_1)}. \tag{23.2.81}^{\#}$$

(b) Let $m < 0$, $M > 0$, $\tau_1 \in (-M, M)$, $\tau_2 = M$. Then for $h \to +0$, $1 \le \mu = O(h^{-1})$ asymptotics (23.2.25)–(23.2.26) holds with $\mathcal{N}$ defined by $(17.1.12)_2$ with $d = 2$. Moreover, equivalence $(23.2.28)^{\#}$ holds.

Example 23.2.27[23)]. Let condition (23.2.74) be fulfilled.

(i) Let 0 be an inner singular point and let all the above conditions, be fulfilled with $\gamma = \epsilon_0|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$, $m_1 > 2m$, $m > -1$.

Further, let assumption (23.2.79) and non-degeneracy condition (23.2.80) be fulfilled. Let either

(a) $m < 0$, $\tau_1 < \tau_2$ or

(b) $m > 0$, $M > 0$, $\tau_1 \in (-M, M)$, $\tau_2 = M$.

Then for $h \to +0$, $1 \le \mu$ asymptotics (23.2.32), (23.2.26) holds with $\mathcal{N}$ defined by $(17.1.12)_2$ with $d = 2$.

Moreover, $\mathcal{N}(\tau_1, \tau_2, \mu, h) \asymp h^{-2}$ as $\mu h \lesssim 1$ and (23.2.34) holds as $\mu h \gtrsim 1$.

(ii) Let infinity be an inner singular point and let all the above conditions be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m_1 < 2m$, $m < -1$.

Further, let assumption $(23.2.79)^{\#}$ and non-degeneracy condition (23.2.80) be fulfilled. Let $M > 0$, $\tau_1 \in (-M, M)$, $\tau_2 = M$. Then for $h \to +0$, $1 \le \mu$ asymptotics $(23.2.32)^{\#}$, (23.2.26) holds with $\mathcal{N}$ defined by $(17.1.12)_2$ with $d = 2$.

Moreover, $\mathcal{N}(\tau_1, \tau_2, \mu, h) \asymp h^{-2}$ as $\mu h \lesssim 1$ and (23.2.34) holds as $\mu h \gtrsim 1$.

We leave to the reader the following problems:

Problem 23.2.28. Modify for the Dirac operator under assumption (23.2.79) or $(23.2.79)^{\#}$ (as 0 or infinity is an inner singular point, respectively) in the frameworks of

[23)] Cf. Examples 23.2.4 and 23.2.5.

(a) Examples 23.2.6, 23.2.7, 23.2.8 , 23.2.9, 23.2.11 (power singularities) and Problem 23.2.10,

(b) Examples 23.2.12, 23.2.13, 23.2.14 and Problem 23.2.16 (power-logarithmic singularities),

(c) Examples 23.2.17, 23.2.19, 23.2.20, 23.2.21 and Problems 23.2.18, 23.2.22 (exponential singularities).

Asymptotics. II

While under assumptions (23.2.79), (23.2.79)$^{\#}$ the Dirac operator behaves as the Schrödinger operator, under the same assumptions albeit with an opposite sign the the Dirac operator behaves as the Schrödinger-Pauli operator.

Example 23.2.29[24]. Let condition (23.2.74) be fulfilled.

(i) Let 0 be an inner singular point and let all the above conditions, be fulfilled with $\gamma = \epsilon_0|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$, $m_1 > 2m$, $m > -1$.

Further, let assumption

$$V \geq \epsilon \min(\rho, \frac{\rho^2}{M}) \qquad \forall x : |x| \leq \epsilon \tag{23.2.82}$$

and non-degeneracy condition (23.2.80) be fulfilled.

(a) $m < 0$, $\tau_1 < \tau_2$ or

(b) $m > 0$, $M > 0$, $\tau_1 = -M$, $\tau_2 \in (-M, M)$.

Then for $h \to +0$, $1 \leq \mu$ asymptotics (23.2.32), (23.2.26) holds with $\mathcal{N}$ defined by $(17.1.12)_2$ with $d = 2$.

Moreover, $\mathcal{N}(\tau_1, \tau_2, \mu, h) \asymp \mu h^{-1} + h^{-2}$.

(ii) Let infinity be an inner singular point and let all the above conditions be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m_1 < 2m$, $m < -1$.

Further, let assumption

$$V \geq \epsilon \min(\rho, \frac{\rho^2}{M}) \qquad \forall x : |x| \geq c \tag{23.2.82}$$

[24] Cf. Example 23.2.23.

and non-degeneracy condition (23.2.80) be fulfilled. Let $M > 0$, $\tau_1 = -M$, $\tau_2 \in (-M, M)$. Then for $h \to +0$, $1 \le \mu$ asymptotics $(23.2.32)^{\#}$, (23.2.26) holds with $\mathcal{N}$ defined by $(17.1.12)_2$ with $d = 2$.

Moreover, $\mathcal{N}(\tau_1, \tau_2, \mu, h) \asymp \mu h^{-1} + h^{-2}$.

Problem 23.2.30. (a) Modify Problem 23.2.27 under assumptions (23.2.82) or $(23.2.82)^{\#}$ (if 0 or infinity is an inner singular point, respectively).

(b) Consider degenerations like in Subsubsection *23.2.1.5. Degenerations*.

Finally, we leave to the reader

Problem 23.2.31. Generalize results of this section to the even-dimensional full-rank case. In particular, consider power singularities[25)].

23.3 Asymptotics of Large Eigenvalues

In this section we consider the case when $\mu = h = 1$ are fixed and we consider the asymptotics of the eigenvalues, tending to $+\infty$ and for Dirac operator also to $-\infty$.

Here we consider the case of the spectral parameter tending to $+\infty$ (and for the Dirac operator we consider $\tau \to -\infty$ as well).

23.3.1 Singularities at the Point

We consider series of example with singularities at the point.

Schrödinger Operator

Example 23.3.1. (i) Let X be a compact domain and conditions $(23.2.3)_{1-3}$ be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$ with $m_1 < 2m$. Let

$$(23.3.1)_{1,2} \qquad |F| \ge \epsilon_0 \rho_1, \qquad |\nabla F| \ge \epsilon_0 \rho_1 \gamma^{-1} \qquad \text{for } |x| \le \epsilon.$$

[25)] Note that for $m_1 \ne -2$ one can construct V_j positively homogeneous of degrees m_1+1 such that F_{jk} is non-degenerate. F.e. one can take $V_{2j-1} = \frac{1}{2} x_{2j} |x|^{m_1}$, $V_{2j} = -\frac{1}{2} x_{2j-1} |x|^{m_1}$, $j = 1, 2, \dots, d/2$, in which case $f_1 = |(m_1+2)/2| \cdot |x|^{m_1}$, $f_2 = \dots = f_{d/2} = |x|^{m_1}$. See for details Appendix 24.A.3.

Then for the Schrödinger operator as $\tau \to +\infty$

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(d-1)/2}) \tag{23.3.2}$$

while $\mathcal{N}^-(\tau) \asymp \tau^{d/2}$.

Indeed, we need to consider only case $m_1 \le -2$ (otherwise it is covered by Section 11.2). Assume for simplicity, that $V = 0$ (modification in the general case is trivial). Then we need to consider zones $\mathcal{X}_1 = \{x\colon |x| \ge \tau^{1/2(m_1+1)}\}$ where $\mu_{\mathsf{eff}} = |x|^{m_1+1}\tau^{-1/2} \le 1$ and $\mathcal{X}_2 = \{x\colon |x| \le \tau^{1/2(m_1+1)}\}$ where $\mu_{\mathsf{eff}} \ge 1$. Meanwhile $h_{\mathsf{eff}} = \tau^{-1/2}|x|^{-1}$.

Contribution to the remainder of the γ-element from $\mathcal{X}_1$ does not exceed $Ch_{\mathsf{eff}}^{1-d} = C\tau^{(d-1)/2}\gamma^{d-1}$ while contribution to the remainder of the γ-element from $\mathcal{X}_2$ does not exceed $C\mu_{\mathsf{eff}}^{-1}h_{\mathsf{eff}}^{1-d} = C\tau^{d/2}\gamma^{d-2-m_1} \le C\tau^{(d-1)/2}\gamma^{d-1}$ and the rest is easy.

(ii) Under proper assumptions the same proof is valid in the full-rank even-dimensional case.

(iii) The similar proof is valid for $d = 3$ and under proper assumptions it is valid in the maximal-rank odd-dimensional case (while contribution to the remainder of γ-element from $\mathcal{X}_2$ is $O(\tau^{(d-1)/2}\gamma^{d-1})$).

(iv) On the other hand, without assumption $(23.3.1)_2$ contribution to the remainder γ-element from $\mathcal{X}_2$ is $O(\tau^{(d-2)/2}\gamma^{d+m_1})$ but we need to consider only $\gamma \gtrsim \tau^{1/m_1}$ (otherwise $\mu_{\mathsf{eff}}h_{\mathsf{eff}} \ge C_0$) and we arrive to the remainder estimates $O(\tau^{(d-1)/2})$ as $m_1 \ge -2d$ and $O(\tau^{d/2+d/m_1})$ as $m_1 \le -2d$.

Definitely these arguments are far from optimal for $d = 3$ or in the maximal-rank odd-dimensional case; we leave this case to the next Chapter 24.

Let us note that the case $m < -1$, $m_1 \ge m-1$ is covered by Chapter 11; we need to assume that

$$V \ge \epsilon_0\rho^2 \qquad \text{as } |x| \le \epsilon. \tag{23.3.3}$$

Example 23.3.2. (i) Let X be a compact domain and conditions $(23.2.3)_{1-3}$, $(23.3.1)_1$ be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$ and with $m < -1$, $2m \le m_1 < m-1$. Then we need to assume that

$$V + F \ge \epsilon_0\rho^2 \qquad \text{as } |x| \le \epsilon \tag{23.3.3}'$$

which for $m_1 > 2m$ is equivalent to (23.3.3).

We need also to have some non-degeneracy assumption. Assume that[26)]

$$\tau \ge V + F, \qquad |\nabla(\tau - V)F^{-1}|\gamma \le \epsilon_0 \tau F^{-1} \implies |\nabla^2(\tau - V)F^{-1}|\gamma^2 \ge \epsilon_0 \tau F^{-1} \qquad \text{as } |x| \le \epsilon. \tag{23.3.4}$$

Then asymptotics (23.3.2) holds while $\mathcal{N}^-(\tau) \asymp \tau^{d/2}$.

Indeed, it follows from Chapter 13 (see condition (13.4.54)) that in this case the contribution to the remainder of the γ-element from $\mathcal{X}_2$ is also $O(h_{\mathsf{eff}}^{-d+1})$.

(ii) Under proper assumptions the same proof is valid in the maximal-rank multidimensional case.

(iii) Without assumption (23.3.4) we can apply arguments of Example 23.3.1(iv), however cutting of as $|x| \le \tau^{1/(2m)}$ and we arrive to the remainder estimate $O(\tau^{(d-1)/2})$ as $d + m_1 \ge m$ and $O(\tau^{d(1/2+1/(2m))+(m_1-2m)/(2m)})$ as $d + m_1 \le m$.

Again, these arguments are far from optimal for $d = 3$ or in the maximal-rank odd-dimensional case.; we leave this case to the next Chapter 24.

Schrödinger-Pauli Operator

Next, consider Schrödinger-Pauli operators. We will need to impose (23.3.3) and the related non-degeneracy assumption

$$|\nabla V| \ge \epsilon_0 \rho^2 \gamma^{-1} \qquad \text{for } |x| \le \epsilon. \tag{23.3.5}$$

Example 23.3.3. (i) Let X be a compact domain, $d = 2$. Let conditions $(23.2.3)_{1-3}$, $(23.3.1)_{1,2}$, (23.3.3) and (23.3.5) be fulfilled with $\gamma = \epsilon$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$.

Let <u>either</u> $m_1 < \min(2m, -2)$ <u>or</u> $2m \le m_1 < m-1$ and condition (23.3.4) be fulfilled.

Then for the Schrödinger-Pauli operator as $\tau \to +\infty$ asymptotics (23.3.2) holds while

$$\mathcal{N}^-(\tau) \asymp \tau^{(m_1+2)/(2m)} + \tau. \tag{23.3.6}$$

[26)] One can check easily that this condition or a similar condition in the multidimensional case is fulfilled provided F and V stabilize as $|x| \to 0$ to V^0 and F^0, positively homogeneous of degrees $2m$ and m_1 respectively.

Indeed, if $m_1 \ge 2m$ then no modification to the arguments of Examples 23.3.1 and 23.3.2 is needed; if $m_1 < 2m$ we also need to consider the zone $\{\tau^{1/(2m)} \lesssim |x| \lesssim \tau^{1/m_1}\}$. The contribution of the corresponding partition element to the principal part of the asymptotics is $O(r^{m_1}\gamma^2)$ ($r = |x| \asymp \gamma$) while its contribution to the remainder is $O(\tau^{1/2}\gamma + 1)$.

(ii) One can generalize this example to the even-dimensional full-rank case; then

$$\mathcal{N}^-(\tau) \asymp \tau^{(m_1+2)d/(4m)} + \tau^{d/2} \tag{23.3.7}$$

and the remainder is $O(R)$ with

$$R = \tau^{(m_1+2)(d-2)/(4m)} + \tau^{(d-1)/2}. \tag{23.3.8}$$

Dirac Operator

Finally, consider Dirac operator. We want to consider either $\mathsf{N}(0,\tau)$ with $\tau \to +\infty$ and $\mathsf{N}(\tau,0)$ as $\tau \to -\infty$.

Example 23.3.4. Let X be a compact domain, $d = 2$ and conditions $(23.2.75)_{1-2}$, $(23.3.1)_{1,2}$ and

$$|D^\alpha V| \le c\rho\gamma^{-|\alpha|} \tag{23.3.9}$$

be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$ and $m_1 < \min(2m, -2)$. Let assumption (23.2.74) be fulfilled as $|x| \le \epsilon$.

(i) Let $V < M$ in the vicinity of 0. Then for the Dirac operator asymptotics

$$\mathsf{N}(0,\tau) = \mathcal{N}(0,\tau) + O(\tau) \tag{23.3.10}$$

holds as $\tau \to +\infty$ and $\mathcal{N}(0,\tau) \asymp \tau^2$.

Indeed, assumption $V < M$ guarantees that $V - (M^2 + 2jF)^{\frac12}$ with $j = 0, 1, ...$ do not contribute.

(ii) Let $V^2 < M^2 + F$ in the vicinity of 0 and

$$V \le -\epsilon_0\rho, \qquad |\nabla V| \ge \epsilon_0\rho\gamma^{-1} \qquad \text{as } |x| \le \epsilon. \tag{23.3.11}_2$$

Then for the Dirac operator asymptotics

$$\mathsf{N}(\tau,0) = \mathcal{N}(\tau,0) + O(|\tau|^{\frac12}) \tag{23.3.12}$$

and

$$\mathcal{N}(\tau,0) \asymp \tau^2 + |\tau|^{(m_1+2)/m} \tag{23.3.13}$$

holds as $\tau \to -\infty$.

Indeed, assumption $V^2 < M^2 + F$ guarantees that $V + (M^2 + 2jF)^{\frac12}$ with $j = 1, \dots$ do not contribute.

We leave to the reader

Problem 23.3.5. (i) Extend results of Example 23.3.4(i) to the case $2m \le m_1 < m-1$.

(ii) Expand results of Example 23.3.4(ii) to the case $m_1 = 2m < -2$.

In both Statements (i) and (ii) one needs to formulate the analogue of the non-degeneracy assumption (23.3.4).

(iii) Consider the full-rank even-dimensional case.

Miscellaneous Singularities

Consider now miscellaneous singularities in the point, restricting ourselves to $d = 2$:

Example 23.3.6. Let X be a compact domain, $d = 2$ and conditions $(23.2.3)_{1-3}$, $(23.3.1)_{1,2}$ and (23.3.3) be fulfilled with $\gamma = \epsilon|x|$, $\rho = |\log|x||^{\sigma}$, $\rho_1 = |x|^{m_1}$, $\sigma > 0$, $m_1 < -2$.

Then for the Schrödinger-Pauli operator asymptotics (23.3.2) holds and

$$\log(\mathcal{N}^-(\tau)) \asymp \tau^{-(m_1+2)/2\sigma}. \tag{23.3.14}$$

Example 23.3.7. Let X be a compact domain, $d = 2$ and conditions $(23.2.3)_{1-3}$, $(23.3.1)_{1,2}$ be fulfilled with $\gamma = \epsilon|x|^{1-\beta}$, $\rho_1 = \exp(b|x|^{\beta})$, $\beta < 0$, $b > 0$ and with $\rho = \exp(a|x|^{\alpha})$ where <u>either</u> $\beta < \alpha < 0$ <u>or</u> $\beta = \alpha$ and $b > 2a$.

(i) Then for Schrödinger operator asymptotics (23.3.2) holds and $\mathcal{N}^-(\tau) \asymp \tau$ as $\tau \to +\infty$.

Indeed, as $\beta > -1$ it is easy, and as $\beta \le -1$ one can apply the same arguments as in Example 23.3.23 below (in which case Remark 23.3.11(iii) does not apply.

(ii) Let also conditions $(23.2.3)_{1,3}$, (23.3.3) and (23.3.5) be fulfilled with $\gamma = \epsilon|x|^{1-\alpha}$. Then for the Schrödinger-Pauli operator asymptotics (23.3.2) holds with

$$\mathcal{N}^-(\tau) \asymp \tau^{b/2a} |\log \tau|^{(2-\beta)/\beta} \qquad \text{as } \alpha = \beta, \tag{23.3.15}$$

$$\log(\mathcal{N}^-(\tau)) \asymp |\log \tau|^{\beta/\alpha} \qquad \text{as } \beta < \alpha < 0. \tag{23.3.16}$$

Indeed, in this case the forbidden zone is $\{x\colon |x| \le r^*\}$ with $r_* = \epsilon|\log\tau|^{1/\alpha}$ and contribution of the zone $\{x\colon |x| \ge r_*\}$ to the "extra" remainder does not exceed $\int r^{-1-2\beta} r\,dr$, taken over this zone, which is $r_*^{-2\beta} \asymp |\log\tau|^{2\beta/\alpha}$.

Example 23.3.8. and conditions $(23.2.3)_{1-3}$, $(23.3.1)_{1,2}$ be fulfilled with $\gamma = \epsilon|x|^{1-\beta}$, $\rho_1 = \exp(b|x|^\beta)$, $\beta < 0$, $b > 0$ and with $\rho = |x|^{2m}$.

(i) Then Schrödinger operator is covered by the previous Example 23.3.7..

(ii) Let conditions $(23.2.3)_{1,3}$, (23.3.3), (23.2.23) be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^m$, $m < 0$.

Then for the Schrödinger-Pauli operator the following asymptotics holds:

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{1/2} + \tau^{\beta/(2m)}) \tag{23.3.17}$$

holds with

$$\log(\mathcal{N}^-(\tau)) \asymp \tau^{\beta/(2m)}. \tag{23.3.18}$$

Indeed, in this case $r_* = \tau^{1/(2m)}$ (cf. Example 23.3.7(i)).

Indeed, the contributions of the zone where $\mu_{\mathsf{eff}} h_{\mathsf{eff}} \le C$ to the main term of the asymptotics and to the remainder estimates are $\int_{\mathcal{X}} \rho_1 r\,dr$ and $\int_{\mathcal{Z}} \gamma^{-2} r\,dr$ where $\mathcal{X} = \{x\colon : V(x) \le \tau\}$ and $\mathcal{Z}$ is a γ-vicinity of ∂X; so we get (23.3.18) (we cannot get magnitude of $\mathcal{N}^-(\tau)$ itself precisely) and $\bar r$ with $\bar r = \tau^{1/(2m)}$.

The following problem seems to be very challenging:

Problem 23.3.9. Using the fact that singularities propagate along the drift lines, and the length of the drift line is $\asymp \bar r$ rather than $\asymp \bar\gamma = \bar r^{1-\beta}$ prove that the contribution of $\mathcal{Z}$ to the remainder is in fact $O(1)$ and thus improve the remainder estimate (23.3.17) to $O(\tau^{1/2})$.

Problem 23.3.10. Extend results of Examples 23.3.6, 23.3.7 and 23.3.8 to the Dirac operator.

Remark 23.3.11. (i) Observe that the contribution to the remainder of the zone $\{x\colon |x|\le \varepsilon\}$ does not exceed $\varepsilon^{\sigma}\tau^{(d-1)/2}$ with $\sigma>0$ in the frameworks of Example 23.3.1(i), Example 23.3.1(iv) with $m_1>-2d$, Example 23.3.2(i), Example 23.3.2(iii) with $d+m_1>m$ and Example 23.3.3.

The same is correct in Example 23.3.6 and Examples 23.3.7 and 23.3.8 with $0>\beta>-1$.

Therefore, in these cases under the standard non-periodicity condition to the geodesic flow with reflections from ∂X the asymptotics

$$\mathsf{N}(\tau)=\mathcal{N}(\tau)+\varkappa_1\tau^{\frac12}+o\bigl(\tau^{\frac12}\bigr) \tag{23.3.19}$$

holds with the standard coefficient $\varkappa_1$.

(ii) The similar statement (with τ replaced by τ^2) is true in the framework of Example 23.3.4.

(iii) Since we used local estimates $O(h_{\mathsf{eff}}^{-1})$ rather than $O(\mu_{\mathsf{eff}}^{-1}h_{\mathsf{eff}}^{-1})$ as $\mu_{\mathsf{eff}}\ge 1$ (the latter gave us no advantage) we do not need 0 to be an inner singular point; the same results hold for $0\in\partial X$ under Dirichlet or Neumann boundary condition.

Problem 23.3.12. In the frameworks of Examples 23.3.1(i), 23.3.1(iv), 23.3.2(i), 23.3.2(iii) and 23.3.3 estimate $|\mathcal{N}^-(\tau)-\kappa_0\tau^{d/2}|$.

Furthermore, in the frameworks of Examples 23.3.4 (i), (ii) estimate $|\mathcal{N}(0,\tau)-\kappa_0\tau^2|$ and $|\mathcal{N}(\tau,0)-\kappa_0\tau^2|$ respectively.

Finally, consider the case when the singularity is located on the curve.

Example 23.3.13. Let X be a compact domain, $d=2$ and conditions $(23.2.3)_{1-3}$, $(23.3.1)_{1,2}$ be fulfilled with $\gamma=\epsilon\delta(x)$, $\rho_1=\delta(x)^m$, $\rho_1=\delta(x)^{m_1}$ with $m_1<\min(2m,-2)$ where $\delta(x)=\mathsf{dist}(x,L)$, $m<0$, L is <u>either</u> a closed curve ($q=1$) <u>or</u> a closed set of Minkowski dimension $q<1$.

(i) Then for the Schrödinger operator asymptotics (23.3.2) holds for $\tau\to+\infty$ and $\mathcal{N}^-(\tau)\asymp\tau$.

Indeed, using the same arguments as before we can get a remainder estimate $O(\tau^{1/2})$ if $q<1$ and $O(\tau^{\frac12}|\log\tau|)$ if $q=1$ but in the latter case we can get rid of logarithm using standard propagation arguments.

(ii) Let also conditions (23.3.3) and (23.3.5) be fulfilled with $m > -1$. Then for the Schrödinger-Pauli operator asymptotics holds

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{1/2} + \tau^{(q-2)/(2m)}) \tag{23.3.20}$$

holds while

$$\mathcal{N}^-(\tau) \asymp \tau + \tau^{(m_1+q)/(2m)}. \tag{23.3.21}$$

Indeed, in this case a forbidden zone is $\{x\colon \delta(x) \le \delta_* = \epsilon\tau^{1/(2m)}\}$ and contributions of the zone $\{x\colon \delta(x) \ge \delta_*\}$ to the main term of the asymptotics and the remainder are $\asymp \delta_*^{m_1+q}$ and δ_*^{q-2} respectively.

Problem 23.3.14. (i) Explore, if we can using propagation arguments improve remainder estimate (23.3.20).

(ii) Extend results of Example 23.3.13 to different types of the singularities along L and/or Dirac operator.

23.3.2 Singularities at Infinity

Let us consider *unbounded domains:*

Power Singularities: Schrödinger Operator

Let us start from the power singularities.

Example 23.3.15[27]. (i) Let X be a connected exterior domain[28] with $\mathscr{C}^K$ boundary, $d = 2$. Let conditions (23.2.2) and $(23.2.3)_{1-3}$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m_1 > 2m$. Further, let

$$|F| \ge \epsilon_0\rho_1, \qquad |\nabla F| \ge \epsilon_0\rho_1\gamma^{-1} \qquad \text{for } |x| \ge c. \tag{23.3.1}$$

Then for the Schrödinger operator the following asymptotics holds:

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(m_1+2)/2(m_1+1)}) \tag{23.3.22}$$

with

$$\mathcal{N}^-(\tau) \asymp \tau^{(m_1+2)/m_1}. \tag{23.3.23}$$

---

[27] Cf. Example 23.3.1.

[28] I.e. a domain with compact complement $\complement X$ in $\mathbb{R}^d$.

Indeed, there will be zone $X_1' = \{|x| \le \tau^{1/2(m_1+1)}\}$ with $\mu_{\text{eff}} = |x|^{m_1+1}\tau^{-1/2} \lesssim 1$ and a zone $X_2' = \{|x| \ge \tau^{1/2(m_1+1)}\}$ with $\mu_{\text{eff}} \ge 1$. Contribution of the partition element in X_1' to the remainder is $O(h_{\text{eff}}^{-1}) = O(\tau^{1/2}\gamma)$ and the total contribution of X_1' is $O(\tau^{(m_1+2)/2(m_1+1)})$. On the other hand, contribution of the partition element in X_2' to the remainder is $O(\mu_{\text{eff}}^{-1}h_{\text{eff}}^{-1}) = O(\tau\gamma^{-m_1})$ and the total contribution of this zone is $O(\tau^{(m_1+2)/2(m_1+1)})$ again.

(ii) Under proper assumptions the similar asymptotics holds in the full-rank even-dimensional case:

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(d-1)(m_1+2)/2(m_1+1)}) \tag{23.3.24}$$

with

$$\mathcal{N}^-(\tau) \asymp \tau^{d(m_1+2)/(2m_1)}. \tag{23.3.25}$$

Example 23.3.16[29]. (i) Let X be a connected exterior domain[28] with $\mathscr{C}^K$ boundary. Let conditions (23.2.2), $(23.2.3)_{1-3}$ and $(23.3.1)_1^{\#}$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m > 0$, $m - 1 < m_1 \le 2m$.

Then we need to assume that

$$V + F \ge \epsilon_0\rho^2 \qquad \text{as} \quad |x| \ge c \tag{23.3.3}^{\#\prime}$$

which for $m_1 < 2m$ is equivalent to

$$V \ge \epsilon_0\rho^2 \qquad \text{as} \quad |x| \ge c \tag{23.3.3}^{\#}$$

We need also to have some non-degeneracy assumption. Assume that (cf. (23.2.16))[30]

$$\begin{aligned} &\tau \ge V + F, \qquad |\nabla(\tau - V)F^{-1}|\gamma \le \epsilon_0\tau F^{-1} \\ &\qquad \implies |\det \mathsf{Hess}(\tau - V)F^{-1}|\gamma^2 \ge \epsilon_0\tau F^{-1} \qquad \text{as} \quad |x| \ge c. \end{aligned} \tag{23.3.27}$$

---

[29] Cf. Example 23.3.2.

[30] One can see easily, that if F, V stabilize at infinity to functions F^0, V^0, positively homogeneous of degrees $m_1 \ge 0$, $2m$ respectively, then even stronger non-degeneracy assumption (cf. (23.2.14)) holds:

$$\tau \ge V + F \implies |\nabla(\tau - V)F^{-1}|\gamma \ge \epsilon_0\tau \qquad \text{as} \quad |x| \ge c. \tag{23.3.26}$$

On the other hand, for $m_1 < 0$ condition (23.3.26) is fulfilled if $w(\theta) = F^{0\,-2m}V^{0\,m_1}$ has only nodegenerate critical points on $\mathbb{S}^1$.

Then for the Schrödinger operator asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(R), \tag{23.3.28}$$

holds with

$$R = \begin{cases} \tau^{(m_1+2)/2(m_1+1)} & m_1 > 0, \\ \tau |\log \tau|^2 & m_1 = 0, \\ \tau^{1-m_1/(2m)} |\log \tau| & m-1 < m_1 < 0, \end{cases} \tag{23.3.29}$$

and

$$\mathcal{N}^-(\tau) \asymp \tau^{(m+1)/m}. \tag{23.3.30}$$

Indeed, the contribution of γ-element in X_2' (see Example 23.3.15) to the remainder does not exceed $C\mu_{\mathsf{eff}}^{-1} h_{\mathsf{eff}}^{-1} |\log \mu_{\mathsf{eff}}| = C\tau r^{-m_1} |\log r r_*^{-1}|$, $r_* = \tau^{1/(2(m_1+1)}$. Then summation with respect to partition returns R; we need to take into account that $\{|x| \ge C\tau^{1/(2m)}\}$ is a forbidden zone. Meanwhile, contribution of X_1' does not exceed $C\tau^{(d-1)/2} r_*^{d-1}$.

(ii) As $m_1 < 0$ we can get rid of the logarithmic factor in the remainder estimate, if we define $\mathcal{N}^-(\tau)$ by the corrected magnetic Weyl formula; similarly, for $m_1 = 0$ we can then replace $|\log \tau|^2$ by $|\log \tau|$.

Also for $m_1 = 0$ we can $|\log \tau|^2$ by $|\log \tau|$ under assumption

$$\begin{aligned} &\tau \ge V + F, \qquad |\nabla(\tau - V)F^{-1}|\gamma \le \epsilon_0 \tau F^{-1} \\ &\qquad \implies \det \mathsf{Hess}(\tau - V)F^{-1}\gamma^2 \ge \epsilon_0 \tau F^{-1} \qquad \text{as } |x| \ge c. \end{aligned} \tag{23.3.31}$$

(iii) Under proper assumptions the similar asymptotics holds in the full-rank even-dimensional case:

$$R = \begin{cases} \tau^{(d-1)(m_1+2)/2(m_1+1)} & m_1 > d-2, \\ \tau^{d/2} |\log \tau|^2 & m_1 = d-2, \\ \tau^{d/2+(d-2-m_1)/(2m)} |\log \tau| & m-1 < m_1 < d-2, \end{cases} \tag{23.3.32}$$

with

$$\mathcal{N}^-(\tau) \asymp \tau^{d(m_1+2)/(2m_1)}. \tag{23.3.33}$$

Moreover, we can get rid of one logarithmic factor under assumption similar to (23.3.31).

Let is improve (23.3.29) using arguments associated with long-range dynamics:

Example 23.3.17. Let $m_1 > 0$ in the framework of Examples 23.3.15(i) or 23.3.16(i). Moreover, let the stabilization conditions

$$(23.3.34)_1 \qquad D^\sigma(g^{jk} - g^{jk0}) = o(|x|^{-|\sigma|}),$$

$$(23.3.34)_2 \qquad D^\sigma(V_j - V_j^0) = o(|x|^{m_1+1-|\sigma|}) \qquad \forall \sigma : |\sigma| \le 1$$

be fulfilled for $|x| \to \infty$ with the positively homogeneous functions $g^{jk0}, V_j^0 \in \mathscr{C}^K(\mathbb{R}^2 \setminus 0)$ of degrees 0 and $m_1 + 1$ respectively. Let the standard non-periodicity condition be fulfilled for the Hamiltonian

$$(23.3.35) \qquad H^0 = |x|\Big(\sum_{j,k} g^{jk0}(\xi_j - V_j^0)(\xi_k - V_k^0) - 1\Big)$$

on the energy level 0. Then for the Schrödinger operator as $\tau \to +\infty$ the following asymptotics holds:

$$(23.3.36) \qquad \mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + o\big(\tau^{\frac{1}{2}(m_1+2)/(m_1+1)}\big).$$

Indeed, let us observe that for $m_1 > 0$ the main contribution to the remainder estimate (23.3.29) is given by the zone $\{\varepsilon \le |x|\tau^{-1/2(m_1+1)} \le \varepsilon^{-1}\}$ with an arbitrarily small constant $\varepsilon > 0$. In this zone the magnetic field is normal, $\mu_{\mathsf{eff}} \lesssim 1$ (for every fixed $\varepsilon > 0$) and $V \ll \tau$, $|\nabla V| \ll \tau|x|^{-1}$ Applying the improved Weyl asymptotics here we obtain (23.3.36).

Remark 23.3.18. Similar improvements are possible in the full-rank even-dimensional case.

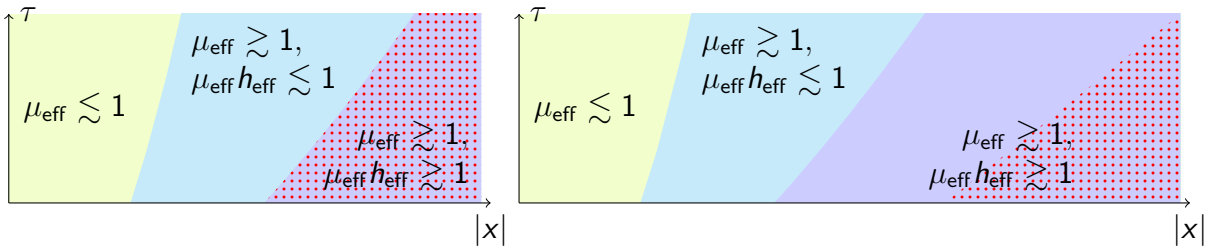
Power Singularities: Schrödinger-Pauli Operator

Next, consider Schrödinger-Pauli operators. We will need to impose $(23.3.3)^\#$ and the related non-degeneracy assumption

$$(23.3.5)^\# \qquad |\nabla V| \ge \epsilon_0 \rho^2 \gamma^{-1} \qquad \text{for } |x| \ge c.$$

Example 23.3.19[31]. Let $(23.3.3)^\#$ and $(23.3.5)^\#$ be fulfilled. Then for the Schrödinger-Pauli operator

[31] Cf. Example 23.3.3.



(a) Schrödinger operator (b) Schrödinger-Pauli operator

Figure 23.1: $m_1 > 2m$; dots show the forbidden zone

(i) In the framework of Examples 23.3.15 and 23.3.16 asymptotics (23.3.22) and (23.3.29)–(23.3.29) hold, respectively.

(ii) In the framework of Example 23.3.19(i), asymptotics (23.3.36) holds.

(iii) Further,

$$\mathcal{N}^-(\tau) \asymp \tau^{(m+1)/m} + \tau^{(m_1+2)/(2m)}. \tag{23.3.37}$$

(iv) Finally, under proper assumptions one can consider the full-rank even-dimensional case and prove asymptotics with the remainder estimate $O(R)$, with $R := R_1 + R_2$ where R_1 is the remainder estimate for the Schrödinger operator,

$$R_2 = \tau^{(m_1+2)(d-2)/(4m)} \tag{23.3.38}$$

and

$$\mathcal{N}^-(\tau) \asymp \tau^{d(m+1)/(2m_1)} + \tau^{d(m_1+2)/(4m)}. \tag{23.3.39}$$

Power Singularities: Dirac Operator

Finally, consider the Dirac operators. We want to explore either $\mathsf{N}(0,\tau)$ with $\tau \to +\infty$ and $\mathsf{N}(\tau,0)$ as $\tau \to -\infty$.

Example 23.3.20. Let X be a connected exterior domain with $\mathscr{C}^K$ boundary, $d = 2$. Let conditions (23.2.2), $(23.2.75)_{1-2}$, $(23.3.1)^{\#}_{1,2}$ and (23.3.9) be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m_1 > \max(2m,-2)$. Further, let assumption (23.2.74) be fulfilled as $|x| \le \epsilon$.

(i) Let $V < M$ in the vicinity of infinity. Then as $\tau \to +\infty$ for the Dirac operator asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(m_1+2)/(m_1+1)}) \tag{23.3.40}$$

holds with

$$\mathcal{N}^-(\tau) \asymp \tau^{2(m_1+2)/m_1}. \tag{23.3.41}$$

(ii) Let $V^2 < M^2 + F$ in the vicinity of infinity and

$$V \le -\epsilon_0\rho, \qquad |\nabla V| \ge \epsilon_0\rho\gamma^{-1} \qquad \text{as } |x| \ge c. \tag{23.3.11}$$$^{\#}_{2}$

Then as $\tau \to -\infty$ for the Dirac operator asymptotics (23.3.40) holds with

$$\mathcal{N}^-(\tau) \asymp \tau^{2(m+1)/m} + \tau^{2(m_1+2)/(2m)}. \tag{23.3.42}$$

We leave to the reader

Problem 23.3.21. (i) Using arguments of Example 23.3.16 extend results of Example 23.3.20(i) to the case $2m \ge m_1 > m-1$.

(ii) Using arguments of Examples 23.3.16 and 23.3.19 expand results of Example 23.3.20(ii) to the case $m_1 = 2m < -2$.

In both Statements formulate the analogue of the non-degeneracy assumption (23.3.4)$^{\#}$.

(iii) Consider the full-rank even-dimensional case.

Problem 23.3.22. Extend to the Dirac operator results of Example 23.3.17; one still defines Hamiltonian H^0 by (23.3.35).

Exponential Singularities

Consider now an exponential growth at infinity.

Example 23.3.23. Let X be a connected exterior domain with $\mathscr{C}^K$ boundary. Let conditions (23.2.2), (23.2.3)$_{1-3}$, (23.3.1)$^{\#}_{1,2}$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle^{1-\beta}$, $\rho = \exp(a\langle x\rangle^{\alpha})$, $\rho_1 = \exp(b\langle x\rangle^{\beta})$, $\beta > 0$ and either $\beta > \alpha$ or $\beta = \alpha$ and $b > 2a > 0$.

(i) Then for the Schrödinger operator the following asymptotics holds:

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O\bigl(\tau^{\frac{1}{2}}|\log\tau|^{1/\beta}\bigr) \tag{23.3.43}$$

with

$$\mathcal{N}^-(\tau) \asymp \tau|\log\tau|^{2/\beta}. \tag{23.3.44}$$

Indeed, using described γ, consider zone $\{\bar{r} \le |x| \le C|\log\tau|^{1/\beta}\}$, where $\mu_{\mathsf{eff}} = F\gamma\tau^{-1/2} \gtrsim 1$ and $F \le c\tau$; here $\bar{r}$ is defined by $\bar{r}^{1-\beta}\exp(b\bar{r}^{\beta}) = \tau^{1/2}$. Then contribution of γ-element to the remainder does not exceed $C\mu_{\mathsf{eff}}^{-1}h_{\mathsf{eff}}^{-1} = \tau\exp(-br^{\beta})$ with $r = |x|$ and the total contribution of this zone does not exceed CR with

$$R = \int_{\bar{r}} \tau\exp(-br^{\beta})r^{-2+2\beta}r\,dr,$$

which is equal to the integrand, multiplied by $r^{1-\beta}$ and calculated as $r = \bar{r}$: $R \asymp \tau\exp(-b\bar{r}^{\beta})\bar{r}^{\beta} = \tau^{1/2}\bar{r}$ with $\bar{r} \asymp |\tau|^{1/\beta}$.

On the other hand, consider zone $\{|x| \le \bar{r}\}$, where we can redefine $\gamma = \bigl(\tau^{1/2}r^{(1-\beta)\delta}\exp(-br^{\beta})\bigr)^{1/(1+\delta)}$ with $\delta > 0$; then its contribution to the remainder does not exceed CR with

$$R = \int^{\bar{r}} \tau^{1/2}\bigl(\tau^{1/2}r^{(1-\beta)\delta}\exp(-br^{\beta})\bigr)^{-1/(1+\delta)}r\,dr,$$

which is also equal to the integrand, multiplied by $r^{1-\beta}$ and calculated as $r = \bar{r}$: $R \asymp \tau^{1/2}\bigl(\tau^{1/2}\bar{r}^{(1-\beta)\delta}\exp(-b\bar{r}^{\beta})\bigr)^{-1/(1+\delta)}\bar{r}^{2-\beta} = \tau^{1/2}\bar{r}$ again.

(ii) Let also conditions $(23.2.3)_{1,3}$, $(23.3.3)^{\#}$ and $(23.3.5)^{\#}$ be fulfilled with $\gamma = \epsilon|x|^{1-\alpha}$. Then for the Schrödinger-Pauli operator asymptotics (23.3.43) holds with

$$\mathcal{N}^-(\tau) \asymp \tau^{b/(2a)}|\log\tau|^{(2-\beta)/\beta} \qquad \beta = \alpha, \tag{23.3.45}$$

$$\log(\mathcal{N}^-(\tau)) \asymp |\log\tau|^{\beta/\alpha} \qquad \beta > \alpha. \tag{23.3.46}$$

Indeed, in this case the forbidden zone is $\{x\colon |x| \ge r_* = c|\log\tau|^{1/\alpha}$ (cf. Example 23.3.7 (ii)).

Example 23.3.24. Let X be a connected exterior domain with $\mathscr{C}^K$ boundary. Let conditions (23.2.2), $(23.2.3)_{1-3}$, $(23.3.1)^{\#}_{1,2}$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle^{1-\beta}$,

$\rho = \exp(a\langle x\rangle^{\alpha})$, $\rho_1 = \exp(b\langle x\rangle^{\beta})$, $\beta > 0$ and $\beta = \alpha$ and $2a > b > a > 0$. Let conditions $(23.3.3)^{\#}$ and $(23.3.5)^{\#}$ be also fulfilled.

Then for both Schrödinger and Schrödinger-Pauli operators (23.3.43) and (23.3.44) hold. Indeed, the forbidden zone is the same as in the previous example.

Example 23.3.25. Let X be a connected exterior domain with $\mathscr{C}^K$ boundary. Let conditions (23.2.2), $(23.2.3)_{1-3}$, $(23.3.1)^{\#}_{1,2}$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle^{1-\beta}$, $\rho_1 = \exp(b\langle x\rangle^{\beta})$, $\beta > 0$ and $\rho = \langle x\rangle^{m}$, $m > 0$.

(i) Then the Schrödinger operator is covered by Example (i).

(ii) Let also conditions $(23.2.3)_{1,3}$, $(23.3.3)^{\#}$ and $(23.3.5)^{\#}$ be fulfilled with $\gamma = \epsilon|x|$. Then for the Schrödinger-Pauli operator the following asymptotics holds holds:

$$\mathsf{N}^{-}(\tau) = \mathcal{N}^{-}(\tau) + O(\tau^{1/2}|\log\tau|^{1/\beta} + \tau^{\beta/(2m)}) \tag{23.3.47}$$

and

$$\log(\mathcal{N}^{-}(\tau)) \asymp |\tau|^{\beta/(2m)}. \tag{23.3.48}$$

Indeed, in this case the forbidden zone is $\{x\colon |x| \ge r_* = c|\tau|^{1/(2m)}$ (cf. Example 23.3.8 (ii)).

The following problem seems to be very challenging:

Problem 23.3.26 [32]**.** Using the fact that singularities propagate along the drift lines, and the length of the drift line is $\asymp \bar{r}$ rather than $\asymp \bar{\gamma} = \bar{r}^{1-\beta}$ prove that the contribution of $\mathcal{Z}$ to the remainder is in fact $O(1)$ and thus improve the remainder estimate (23.3.17) to $O(\tau^{1/2})$.

Problem 23.3.27. (i) Consider Dirac operator in the same settings as in Example 23.3.23.

(ii) Since for Schrödinger, Schrödinger-Pauli and Dirac operators the main contribution to the remainder is delivered by the zone where $\varepsilon \le \mu_{\mathsf{eff}} \le \varepsilon^{-1}$ (and $V \ll \tau$), while the contribution of the zones of the zones where $\mu_{\mathsf{eff}} \le \varepsilon$ and $\mu_{\mathsf{eff}} \ge \varepsilon^{-1}$ do not exceed $\sigma(\varepsilon)\tau|\log\tau|^{1/\beta}$ with $\sigma = o(1)$ as $\varepsilon \to 0$, derive remainder estimate $o(\tau|\log\tau|^{1/\beta})$ under non-periodicity condition for the Hamiltonian similar to (23.3.35).

[32] Cf. Problem 23.3.9

(iii) Consider Schrödinger-Pauli and Dirac operators in the same settings as in Example 23.3.11 albeit with V of the logarithmic growth at infinity (i.e. with $\rho = |\log|x||^{\alpha}$, $\gamma = \epsilon|x|$).

More challenging is the following

Problem 23.3.28. (i) In the frameworks of Examples 23.3.1, 23.3.2, 23.3.3 and 23.3.4 allow degenerations of F.

(ii) In the frameworks of Examples 23.3.2, 23.3.3 and 23.3.4 allow degenerations of V.

23.4 Asymptotics of Small Eigenvalues

Now we consider external domains and asymptotics of eigenvalues tending to some finite limit.

23.4.1 Operators Stabilizing at Infinity

We begin with the analysis of the Schrödinger operator A defined by (23.2.1) under assumption (23.2.2) assuming that

$$(23.4.1)_{1-3} \qquad \mathsf{g} \to \mathsf{g}_{\infty}, \quad \mathsf{F} \to \mathsf{F}_{\infty}, \quad V \to 0 \qquad \text{as } |x| \to \infty.$$

Recall that $\mathsf{F} \coloneqq (F_{jk})$ with $F_{jk} = \partial_k V_j - \partial_j V_k$, $\mathsf{g} \coloneqq (g^{jk})$.

We start from the theorem, describing the essential spectrum of A:

Theorem 23.4.1. *Let X be an exterior domain*[33)]*. with $\mathscr{C}^K$ boundary. Let the Schrödinger operator A satisfy conditions* (23.2.1)*,* (23.2.2)*, and* $(23.4.1)_{1-3}$*. Then*

(i) If $\operatorname{rank} \mathsf{F}_{\infty} = 2r = d$ *then*

$$(23.4.2) \qquad \operatorname{Spec}_{\mathsf{ess}}(A) = \{\sum_j \mathfrak{z}_j f_{\infty,j} : \mathfrak{z} = (\mathfrak{z}_1, \dots, \mathfrak{z}_r) \in (2\mathbb{Z}^+ + 1)^r\}$$

where $\pm i f_{\infty,j}$ are eigenvalues of $g_{\infty}\mathsf{F}_{\infty}$, $f_{\infty,j} > 0$, $j = 1, \dots, r$.

[33)] I.e. with a compact complement. If $X \neq \mathbb{R}^d$, then the appropriate boundary condition are given on ∂X such that operator is self-adjoint. In other words, infinity is an isolated singular point; see [7)].

(ii) If $\mathsf{rank}\,\mathsf{F}_\infty = 2r < d$ *then* $\mathsf{Spec}_{\mathsf{ess}}(A) = [f^*, \infty)$ *with* $f_* = f_{\infty,1} + ... + f_{\infty,r}$.

Proof. Indeed, one can see easily that $\mathsf{Spec}_{\mathsf{ess}}(A)$ coincides with $\mathsf{Spec}(A_\infty)$ where A_∞ is a toy-model operator in $\mathbb{R}^d$ with $\mathsf{g} = \mathsf{g}_\infty$, $\mathsf{F} = \mathsf{F}_\infty$ and $V = 0$. For such operator we calculated spectrum in Theorem 13.2.1. □

Remark 23.4.2. (i) Similarly, for Schrödinger-Pauli operator $\mathsf{Spec}_{\mathsf{ess}}(A)$ is defined by (23.4.2) albeit with $\mathfrak{z}$ running $(2\mathbb{Z}^+)^r$ if $\mathsf{rank}\,\mathsf{F}_\infty = 2r = d$ and $\mathsf{Spec}_{\mathsf{ess}}(A) = [0, \infty)$ if $\mathsf{rank}\,\mathsf{F}_\infty = 2r < d$.

(ii) Further, for the Dirac operator $\mathsf{Spec}_{\mathsf{ess}}(A)$ also coincides with $\mathsf{Spec}(A_\infty)$, calculated in Theorem 17.1.2.

In this section we assume that

$$\mathsf{rank}\,F_\infty = d; \tag{23.4.3}$$

very different and a more complicated case of $\mathsf{rank}\,F_\infty < d$ is left for the next Chapter 24.

According to Theorem 23.4.1(i) under assumption (23.4.3) the essential spectrum consists of separate points, which are points of the pure point spectrum (of infinite multiplicity) of the limiting operator A_∞. We are interested in the asymptotics of eigenvalues of A tending to some fixed $\tau^* \in \mathsf{Spec}_{\mathsf{ess}}(A)$. Namely, let us introduce

$$\mathsf{N}^-(\eta) = \mathsf{N}(\tau^* - \epsilon, \tau^* - \eta) \tag{23.4.4}_-$$

and

$$\mathsf{N}^+(\eta) = \mathsf{N}(\tau^* + \eta, \tau^* + \epsilon) \tag{23.4.4}_+$$

with a small constant $\epsilon > 0$ and a small parameter $\eta \to +0$. We also introduce

$$\mathfrak{W} := \{\mathfrak{z} \in (2\mathbb{Z}^+ + 1)^r : \sum_j \mathfrak{z}_j f_{\infty,j} = \tau^*\}. \tag{23.4.5}$$

To characterize the rate of the decay at infinity we assume that

$$|\nabla^\alpha(\mathsf{g} - \mathsf{g}_\infty)| = o(\rho^2\gamma^{-|\alpha|}), \qquad |\nabla^\alpha(\mathsf{F} - \mathsf{F}_\infty)| = o(\rho^2\gamma^{-|\alpha|}),$$
$$|\nabla^\alpha V| = O(\rho^2\gamma^{-|\alpha|}) \qquad \text{as } |x| \to \infty \quad \forall \alpha. \tag{23.4.6}_{1-3}$$

Theorem 23.4.3. *Let X be a connected exterior domain with $\mathscr{C}^K$ boundary. Let the Schrödinger operator A satisfy conditions* (23.2.1), (23.2.2) *and* $(23.4.6)_{1-3}$ *with scaling functions*[34] *such that $\gamma \to \infty$ and $\rho \to 0$ as $|x| \to \infty$.*

Let $\operatorname{rank} \mathsf{F}_\infty = 2r = d$. Moreover let

$$(23.4.7)_\mp \qquad \mp V \ge -\epsilon\rho^2 \implies |\nabla V| \ge \epsilon_0 \rho^2 \gamma^{-1} \qquad \text{as} \quad |x| \ge c.$$

(i) Then

$$(23.4.8) \qquad |\mathsf{N}^\mp(\eta) - \mathcal{N}^\mp(\eta)| \le C \int_{\mathcal{Z}(\eta)} \gamma^{-2}\, dx + C \int \gamma^{-s}\, dx$$

where

$$(23.4.9) \qquad \mathcal{N}^\mp(\eta) \coloneqq (2\pi)^{-r} \sum_{\mathfrak{z}\in\mathfrak{Z}} \int_{\{x:\, \mp V_\mathfrak{z}(x) \ge \eta\}} f_1 f_2 \cdots f_r \sqrt{g}\, dx$$

$g = \det \mathsf{g}^{-1}$, $\pm i f_j$ *are eigenvalues of* gF, $f_j > 0$, $j = 1, \dots, r$, *and*

$$(23.4.10) \qquad V_\mathfrak{z}(x) \coloneqq V(x) + \sum_j \mathfrak{z}_j (f_j(x) - f_{\infty,j}),$$

$\mathcal{Z}(\eta)$ *is $\epsilon\gamma$-vicinity*[35] *of* $\Sigma(\eta) = \{x:\ \mp V_\mathfrak{z}(x) = \eta\}$.

(ii) Further, under assumption

$$(23.4.11)_\mp \qquad \mp V \ge \epsilon_0 \rho^2$$

$\tau^* \pm 0$ *is not a limit point of the discrete spectrum.*

Proof. Indeed, in the zones $\mathcal{Z}(\eta)$ and

$$(23.4.12) \qquad \Omega(\eta) \coloneqq \{x:\, |\mp V(x) - \eta| \ge \epsilon(\rho^2 + \eta)\},$$

it suffices to make γ-admissible partition of unity and observe that after rescaling $B(x, \gamma(x)) \mapsto B(0,1)$ we have $\mu \mapsto \mu_{\mathsf{new}} = \mu\gamma\rho^{-1}$, $h \mapsto h_{\mathsf{new}} = h\gamma^{-1}\rho^{-1}$ and therefore $\mu h \mapsto \mu h/\rho^2$, $\mu^{-1}h \mapsto \mu^{-1}h\gamma^{-2}$ and before rescaling $\mu = h = 1$.

---

[34] Recall that this means that $|\nabla\gamma| \le c$ and $|\nabla\rho \le c\rho\gamma^{-1}$.

[35] I.e. $\mathcal{Z}(\eta) = \bigcup_{x\in\Sigma(\eta)} B(x, \epsilon\gamma(x)))$.

Applying Theorem 13.5.32 for $d = 2$ and Theorem 19.6.25 for $d \ge 4$ we estimate contribution of $\mathcal{Z}(\eta)$ to the remainder by the first term in the right-hand expression of (23.4.8).

Further, applying Theorem 13.6.6 for $d = 2$ and similar results of Section 19.6 for $d \ge 4$ case we estimate contribution of $\Omega(\eta) \cap \{\rho^2 \ge \eta\}$ to the remainder by the second term in the right-hand expression of (23.4.8).

In the same way we estimate contribution of $\Omega(\eta) \cap \{\rho^2 \le \eta\}$ to the remainder by the second term in the right-hand expression of (23.4.8) albeit now we use scale $\mu \mapsto \mu_{\mathsf{new}} = \mu\gamma_\eta\eta^{-\frac12}$, $h \mapsto h_{\mathsf{new}} = h\gamma^{-1}\eta^{-\frac12}$. □

We discuss possible generalizations later; right now we want just get two simple corollaries which follow immediately from Theorem 23.4.3:

Example 23.4.4. (i) In the framework of Theorem 23.4.3 with $\gamma = \langle x\rangle$, $\rho = \langle x\rangle^m$, $m < 0$

$$|\mathsf{N}^{\mp}(\eta) - \mathcal{N}^{\mp}(\eta)| \le C \begin{cases} |\log\eta| & \text{for } d = 2,\\ \eta^{(d-2)/(2m)} & \text{for } d \ge 4 \end{cases} \tag{23.4.13}$$

with $\mathcal{N}^{\mp}(\eta) = O(\eta^{d/(2m)})$. Further, $\mathcal{N}^{\mp}(\eta) \asymp \eta^{d/(2m)}$ if condition $(23.4.11)_{\mp}$ is fulfilled in some non-empty cone.

(ii) Furthermore, if condition $(23.4.11)_{\mp}$ is fulfilled, then for $d = 2$

$$\mathsf{N}^{\mp}(\eta) = \mathcal{N}^{\mp}(\eta) + O(1). \tag{23.4.14}$$

Example 23.4.5. (i) In the framework of Theorem 23.4.3 with $\gamma = \langle x\rangle^{1-\sigma}$, $\rho \le \exp(-\epsilon\langle x\rangle^{\sigma})$, $0 < \sigma < 1$

$$\mathsf{N}^{\mp}(\eta) = \mathcal{N}^{\mp}(\eta) + O(|\log\eta|^{2+(d-2)/\sigma}) \tag{23.4.15}$$

with $\mathcal{N}^{\mp}(\eta) = O(|\log\eta|^{d/\sigma})$. Further, $\mathcal{N}^{\mp}(\eta) \asymp |\log\eta|^{d/\sigma}$ if condition $(23.4.11)_{\mp}$ is fulfilled in some non-empty cone and $\rho \ge \exp(-c\langle x\rangle^{\sigma})$.

(ii) Furthermore, if condition $(23.4.11)_{\mp}$ is fulfilled then the remainder estimate (23.4.15) could be improved to

$$\mathsf{N}^{\mp}(\eta) = \mathcal{N}^{\mp}(\eta) + O(|\log\eta|^{2+(d-2)/\sigma}). \tag{23.4.16}$$

The following problem seems to be very challenging:

Problem 23.4.6 [36]**.** Let $d = 2$, $\mathsf{log}(\pm V(x)) = |x|^{\beta}\phi(x)$ where $|\nabla\phi| \le C$. Then the drift line is of the length asymp r. Improve the remainder estimate (23.4.15) to $O(1)$.

Remark 23.4.7. (i) We need conditions $(23.4.6)_{1-3}$ only for $|\alpha| \le 3$ due to Section 19.6 and we need "o" in this condition only for $|\alpha| \le 1$. Further, if ϵ_0 in conditions $(23.4.7)_{\mp}$ and $(23.4.11)_{\mp}$ is fixed we can replace "$= o(\rho^2\gamma^{-|\alpha|})$" by "$\le \epsilon_1\rho^2\gamma^{-|\alpha|}$" with $\epsilon_1 = \epsilon_1(\epsilon_0)$.

(ii) If $\#\mathfrak{W} = 1$ we can have "O" but replace V in $(23.4.7)_{\mp}$ and $(23.4.11)_{\mp}$ by $V_{\mathfrak{z}}$.

We leave to the reader the series of the following not challenging but interesting problems:

Problem 23.4.8. (i) Consider even faster decaying $\rho \le \mathsf{exp}(-|x|\gamma^{-1}(|x|))$ with monotone increasing $\gamma(t)$ such that $\gamma'(t) = o(\gamma(t)t^{-1})$ and $\gamma(t) \to \infty$ as $t \to \infty$ and prove the remainder estimate

(a) $O(t^d\gamma(t)^{-2})$ in the general case and

(b) $O(t^{d-1}\gamma(t)^{-1})$ under assumption $(23.4.11)_{\mp}$

while $\mathcal{N}^{\mp}(\eta) = O(t^d)$ in the general case and $\mathcal{N}^{\mp}(\eta) \asymp t^d$ under assumption $(23.4.11)_{\mp}$ fulfilled some non-empty cone Γ as $|x| \ge c$. Here $t = t(\eta)$ recovered from $t\gamma(t)^{-1} \asymp |\log\eta|$.

While proof of Theorem 23.4.3 provides proper estimates of the contributions to the remainder of the zones $\mathcal{Z}(\eta)$ and $\Omega^{+}(\eta) \setminus \mathcal{Z}(\eta)$ it fails in the zone $\Omega^{-}(\eta) \setminus \mathcal{Z}(\eta)$ where $\Omega^{\pm}(\eta) := \{x\colon |V_{\mathfrak{z}}(x)| \gtrless \eta\}$. However one can use here $\gamma_\eta = \frac{1}{2}(r - r(\eta))$ instead of γ.

(ii) For example, consider $\gamma(t) = (\mathsf{log}_{(n)}\, t)^{\sigma}$, where $\mathsf{log}_{(n)}\, t$ is n-tuple logarithm[37] with $\sigma > 0$. Then $t(\eta) = |\log\eta||\mathsf{log}_{(n+1)}\,\eta|^{\sigma}$.

(iii) Consider even $\mathsf{exp}(-c\varepsilon|x|) \le \rho \le \mathsf{exp}(-\varepsilon|x|)$, $\gamma = \varepsilon^{-1}$ with sufficiently small $\varepsilon \le \varepsilon(c, \epsilon_0, \Gamma)$ and condition $(23.4.11)_{\mp}$ fulfilled in some non-empty cone Γ. Then

$$\mathsf{N}^{\mp}(\eta) \asymp \varepsilon^{-d}|\log\eta|^{d}. \tag{23.4.17}$$

[36] Cf. Problem 23.3.9.

[37] I.e. $\mathsf{log}_{(1)}\, t = \log t$ and $\mathsf{log}_{(n)}\, t = \mathsf{log}(\mathsf{log}_{(n-1)}\, t)$.

Remark 23.4.9. Asymptotics in the case of $\rho \le \exp(-\epsilon_0|x|)$ or even compactly supported V is out of reach of our methods.

Amazingly such asymptotics (without remainder estimate) were obtained in papers M. Melgaard and G. Rozenblum [1], G. Rozenblum and G. Tashchiyan [1, 2] G. Raikov and S. Warzel [1] by completely different methods.

Problem 23.4.10. Consider slowly decreasing potentials with $\gamma \asymp |x|$ and $\rho = |\log_{(n)} |x||^{-\sigma}$ with $\sigma > 0$.

In this case we need to replace assumptions $(23.4.6)_{1-3}$ with $|\alpha| \ge 1$ and $(23.4.7)_{\mp}$ by

$$(23.4.6)'_{1-3} \quad |\nabla^\alpha (g - g_\infty)| = o(\varrho\rho^2\gamma^{-|\alpha|}), \qquad |\nabla^\alpha (F - F_\infty)| = o(\varrho\rho^2\gamma^{-|\alpha|}),$$
$$|\nabla^\alpha V| = O(\varrho\rho^2\gamma^{-|\alpha|}) \qquad \text{as } |x| \to \infty \quad \forall \alpha : |\alpha| \ge 1.$$

and

$$(23.4.7)'_{\mp} \qquad \mp V \ge -\epsilon\rho^2 \implies |\nabla V| \ge \epsilon_0 \varrho\rho^2\gamma^{-1} \qquad \text{as } |x| \ge c.$$

respectively where ϱ is another γ-admissible scaling function; $\varrho \le 1$.

Here again we apply Theorems 13.5.32 and 13.7.6 for $d = 2$ and results of Section 19.6 for $d \ge 4$.

The first of the following problems seems to be challenging enough while the second one is rather easy:

Problem 23.4.11. Using results of Chapter 15 consider 2-dimensional domains X with are γ-admissible boundaries, f.e. domains which are conical outside of the ball $B(0, c)$. Neumann boundary conditions would be especially interesting and challenging.

Problem 23.4.12. Generalize results of this subsection to genuine Schrödinger-Pauli and Dirac operators. While in the former case no modifications is needed (except the Landau levels), in the latter case we need to consider two cases

(a) $M^2 + 2jF_\infty > 0$ and potential $V \sim \rho^2$ at infinity.

(b) $M^2 + 2jF_\infty = 0$ and potential $V \sim \rho$ at infinity.

It is so because $M^2 + 2jF_\infty$ plays a role of the mass.

23.4.2 Operators Stabilizing at Infinity. II

Assume now that g and F stabilize at infinity to $\mathsf{g}_\infty = \mathsf{g}_\infty(\theta)$, $\mathsf{F}_\infty = \mathsf{F}_\infty(\theta)$, positively homogeneous of degree 0, and $V \to 0$. Then one can see easily that the for the Schrödinger and Schrödinger-Pauli operators essential spectrum of A consists of (possibly overlapping) *spectral bands* $\Pi_{\mathfrak{z}}$

$$\mathsf{Spec}_{\mathsf{ess}}(A) = \bigcup_{\mathfrak{z}\in\mathfrak{Z}} \Pi_{\mathfrak{z}}, \qquad \Pi_{\mathfrak{z}} := \bigl\{\sum_j \mathfrak{z}_j f_{\infty,j}(\theta), : \theta \in [0, 2\pi]\bigr\}. \tag{23.4.18}$$

with the *spectral gaps* between them.

In particular, for the Schrödinger operator all spectral bands in the generic case have non-zero width while for the Schrödinger-Pauli operator $\Pi_0 = \{0\}$. Then under proper assumptions for the eigenvalues tending to $+0$ or -0 the results of the previous Subsection 23.4.1 hold. In this subsection we are interested in the asymptotics of the eigenvalues tending to the border between a spectral gap and a spectral bund of non-zero width.

Further, for $d = 2$ in the generic case there could be an infinite number of spectral gaps, but for $d \ge 4$ there is only finite number of them.

Similarly, for the Dirac operator essential spectrum consists of the spectral bunds, one of them consisting of a single point M or $-M$.

Theorem 23.4.13. *Let S be a Schrödinger or Schrödinger-Pauli operator. Let conditions* $(23.4.6)_{1-3}$ *are fulfilled with g_∞, F_∞ positively homogeneous of degree 0, $\gamma = \epsilon|x|$, $\rho = |x|^m$, $m < 0$. Let $x = r\theta$ with $r = |x|$, and $\theta \in \mathbb{S}^{d-1}$.*

Assume for simplicity[38] *that*

$$\tau^* = \textstyle\sum_j \mathfrak{z}_j f_{\infty,j}(\theta) \text{ if and only if } \mathfrak{z} = \bar{\mathfrak{z}} \text{ and } \theta = \bar{\theta}, \tag{23.4.19}$$

$$f_{\infty,1}(\theta), \dots, f_{\infty,r}(\theta) \text{ are disjoint,} \tag{23.4.20}$$

$$\pm \sum_j \bar{\mathfrak{z}}_j f_{\infty,j}(\theta) \ge \epsilon|\theta - \bar{\theta}|^{2n} \tag{23.4.21}_{\pm}$$

and

$$|\partial^\alpha \sum_j \bar{\mathfrak{z}}_j f_{\infty,j}(\theta)| \le c_\alpha |\theta - \bar{\theta}|^{2n-|\alpha|} \qquad \forall \alpha : |\alpha| \le 2n. \tag{23.4.22}$$

[38] Otherwise we will get the sums of asymptotics.

Under assumption $(23.4.21)_+$ *let* $\mathsf{N}^-(\eta) \coloneqq \mathsf{N}(\tau^* - \epsilon, \tau^* - \eta)$ *and under assumption* $(23.4.21)_-$ *let* $\mathsf{N}^+(\eta) \coloneqq \mathsf{N}(\tau^* + \eta, \tau^* + \epsilon)$.

(i) Let

$$(23.4.23)_{\mp,1,2} \qquad \mp V(r\bar{\theta}) \ge \epsilon r^{2m}, \quad \mp \partial_r V(r\bar{\theta}) \ge \epsilon r^{2m-1} \qquad \text{as} \quad r \ge c$$

and $m + n > 0$. *Then as* $\eta \to +0$

$$\mathsf{N}^{\mp}(\eta) = \mathcal{N}^{\mp}(\eta) + O(\eta^{((m+n)(d-3)+n)/(2mn)} \tag{23.4.24}$$

with

$$\mathcal{N}^{\mp}(\eta) = (2\pi)^{-r} \int_{\{x:\, \mp V_\mathfrak{z} \ge \eta\}} f_1 \cdots f_r \, dx \asymp \eta^{((m+n)(d-1)+n)/(2mn)}, \tag{23.4.25}$$

$$V_\mathfrak{z}(x) \coloneqq V(x) + \sum_j \bar{\mathfrak{z}}_j (f_j(x) - f_{\infty,j}(\bar{\theta})). \tag{23.4.26}$$

(ii) On the other hand, under assumption $(23.4.23)_\pm$ $\mathsf{N}^{\mp}(\eta) = O(1)$.

Proof. Assume that $\bar{\theta} = (1, 0, \dots, 0)$, $x = \{x_1; x'\} = (x_1; x_2, \dots, x_d)$. Observe that outside of $\mathcal{X}(\eta) = \{x\colon |x'| \le c r^{1+m/n},\ 0 < x_1 = r \le c\eta^{1/(2m)}\}$ is a forbidden zone and one can prove easily that its contribution to the remainder is $O(1)$. On the other hand, contribution to the remainder of $\gamma'(r)$-partition element in $\mathcal{X}'(\tau)$ is $O(\gamma^{d-2})$ and the total remainder does not exceed $\int_{\{r \le c\eta^{1/(2m)}\}} {\gamma'}^{d-3}(r)\, dr$ which results in (23.4.24). □

The following problem is rather easy:

Problem 23.4.14. Derive similar results for the Dirac operator.

The following problem looks challenging:

Problem 23.4.15. Investigate what happens if $m + n \le 0$. Our methods provide only $\mathsf{N}^{\mp}(\eta) = O(\eta^{-1/(2n)})$. Probably methods of Section 12.3 could provide an answer.

23.4.3 Case $F \to \infty$ as $|x| \to \infty$

In this subsection we consider cases of $F \to \infty$ and $V \to 0$ as $|x| \to \infty$. In this case the Schrödinger operator does not have any essential spectrum at all and thus is not the subject of our analysis, while for the Schrödinger-Pauli and Dirac operators essential spectrum consists of just one point: 0 and $\pm M$

respectively (see Theorem 17.1.2 to find out which; if $d = 2$ it is determined by signs of F_{12} and ς). Again due to the specifics of the problem we can consider the multidimensional case without any modifications.

It turns out that for $d = 2$ the remainder estimate is as in the previous Subsection 23.4.1, while the magnitude of the principal part is larger but it is still given by the same formula).

Let for the Schrödinger-Pauli operator $\mathsf{N}^-(\eta)$ be a number of eigenvalues in $(-\epsilon, -\eta)$ and $\mathsf{N}^+(\eta)$ be a number of eigenvalues in (η, ϵ).

Theorem 23.4.16 [39]**.** *(i) Let X be a connected exterior domain with $\mathscr{C}^K$ boundary. Let conditions* (23.2.2), $(23.2.3)_{1-3}$ *and* $(23.4.7)_{\mp}$ *be fulfilled with scaling functions γ, ρ and ρ_1, $\rho \to 0$, $\rho_1 \to \infty$ and $\rho_1\gamma^2 \to \infty$ as $|x| \to \infty$. Assume that*

$$|\mathsf{F}^{-1}| \le c\rho_1^{-1} \qquad \text{for } |x| \ge c \tag{23.4.27}$$

and

(23.4.28) *For each $j \ne k$ <u>either</u> $f_j = f_k$ <u>or</u> $|f_j - f_k| \ge \epsilon\rho_1$ for all $|x| \ge c$.*

Then for the Schrödinger-Pauli operator

$$\mathsf{N}^{\mp}(\eta) = \mathcal{N}^{\mp}(\eta) + O(R) \tag{23.4.29}$$

where

$$\mathcal{N}^{\mp}(\eta) := (2\pi)^{-r} \int_{\{x:\, \mp V(x) \ge \eta\}} f_1 f_2 \cdots f_r \sqrt{g}\, dx \tag{23.4.30}$$

$$R = C \int_{\mathcal{Z}(\eta)} \rho_1^{r-1}\gamma^{-2}\, dx + C \int \rho_1^{r-s}\gamma^{-2s}\, dx \tag{23.4.31}$$

holds, $r = d/2$, $\mathcal{Z}(\eta)$ is $\epsilon\gamma$-vicinity[35] *of $\Sigma(\eta) = \{x:\, \mp V(x) = \eta\}$.*

(ii) Further, under assumption $(23.4.11)_{\mp}$ *0 ± 0 is not a limit point of the discrete spectrum.*

---

[39] Cf. Theorem 23.4.3.

[40] Cf. Example 23.4.4.

Example 23.4.17[40]. (i) In the framework of Theorem 23.4.16 with $\gamma = \langle x\rangle$, $\rho = \langle x\rangle^{m}$, $\rho_1 = \langle x\rangle^{m_1}$, $m < 0 < m_1$ estimate (23.4.29) holds with

$$R = \begin{cases} |\log \eta| & \text{for } d = 2, \\ \eta^{(d-2)k/(2m)} \qquad k = (m_1+2)/2 & \text{for } d \ge 4 \end{cases} \tag{23.4.32}$$

and with $\mathcal{N}^{\mp}(\eta) = O(\eta^{(dk/(2m)})$. Further, $\mathcal{N}^{\mp}(\eta) \asymp \eta^{dk/(2m)}$ if condition $(23.4.11)_{\mp}$ is fulfilled in some non-empty cone.

(ii) Furthermore, if condition $(23.4.11)_{\mp}$ is fulfilled, then even for $d = 2$ $R = 1$.

Example 23.4.18. (i) Let conditions (23.2.2), $(23.2.3)_2$, (23.4.24), (23.4.28) be fulfilled with $\gamma = \langle x\rangle^{1-\beta}$, $\rho = \langle x\rangle^{m}$, $\rho_1 = \exp(b\langle x\rangle^{\beta})$, $m < 0$, $\beta > 0$.

Further, let conditions $(23.2.3)_{1,3}$ and $(23.4.7)_{\mp}$ be fulfilled with $\rho = \langle x\rangle^{m}$, $\gamma = \epsilon\langle x\rangle$. Then the following asymptotics holds:

$$\mathsf{N}^{\mp}(\eta) = \mathcal{N}^{\mp}(\eta) + O(\eta^{(d-2+2\beta)/(2m)}) \tag{23.4.33}$$

and

$$\log(\mathcal{N}^{\pm}(\eta)) = O(\eta^{\beta/(2m)}). \tag{23.4.34}$$

(ii) Let conditions (23.2.2), $(23.2.3)_{1-3}$ and $(23.4.7)_{\mp}$ be fulfilled with $\gamma = \langle x\rangle^{1-\alpha}$, $\rho = \exp(a\langle x\rangle^{\alpha})$, $\rho_1 = \langle x\rangle^{m_1}$, $a < 0$, $\alpha > 0$, $m_1 > 0$, $m_1 + 2(1-\alpha) > 0$. Then following asymptotics holds:

$$\mathsf{N}^{\mp}(\eta) = \mathcal{N}^{\mp}(\eta) + O(|\log \eta|^{(d-2+2\alpha)/\alpha}) \tag{23.4.35}$$

and

$$\mathcal{N}^{\pm}(\eta) = O(|\log \eta|^{(d+m_1)/\alpha}). \tag{23.4.36}$$

(iii) Moreover, if condition $(23.4.11)_{\mp}$ is fulfilled, then the remainder estimate (23.4.35) could be improved to

$$\mathsf{N}^{\mp}(\eta) = \mathcal{N}^{\mp}(\eta) + O(|\log \eta|^{(d-2+\alpha)/\alpha}) \tag{23.4.37}$$

(iv) Let conditions (23.2.2) and $(23.2.3)_{1-3}$ be fulfilled with $\gamma = \langle x\rangle^{1-\sigma}$, $\rho = \exp(a\langle x\rangle^{\alpha})$, $\rho_1 = \exp(b\langle x\rangle^{\beta})$, $a < 0 < b$, $\alpha > 0$, $\beta > 0$, $\sigma = \max(\alpha, \beta)$.

Further, let conditions $(23.2.3)_{1,3}$ and $(23.4.7)_{\mp}$ be fulfilled with $\gamma = \langle x\rangle^{1-\alpha}$, $\rho = \exp(a\langle x\rangle^{\alpha})$. Then the following asymptotics holds:

$$\mathsf{N}^{\pm}(\eta) = \mathcal{N}^{\mp}(\eta) + O(|\log\eta|^{(d-2+2\sigma)/\alpha}) \tag{23.4.38}$$

and

$$\log(\mathcal{N}^{\pm}(\eta)) = O(|\log\eta|^{\beta/\alpha}). \tag{23.4.39}$$

(v) Moreover, if condition $(23.4.11)_{\mp}$ is fulfilled, then the remainder estimate (23.4.38) could be improved to

$$\mathsf{N}^{\mp}(\eta) = \mathcal{N}^{\mp}(\eta) + O(|\log\eta|^{(d-2+2\sigma-\alpha)/\alpha}) \tag{23.4.40}$$

(vi) Furthermore, if condition $(23.4.11)_{\mp}$ is fulfilled in some non-empty cone then there is "$\asymp \cdot$" rather than "$= O(.)$" in (23.4.34), (23.4.36) and (23.4.39).

Problem 23.4.19. Again, one can hope to improve estimates (23.4.37) and (23.4.40) in the same way as specified in Problem 23.4.6.

We leave to the reader

Problem 23.4.20[41]. Consider the Dirac operator. In this case $\mathsf{N}^{-}(\eta)$ is a number of eigenvalues in $(\pm M - \epsilon, \pm M - \eta)$ and $\mathsf{N}^{+}(\eta)$ is a number of eigenvalues in $(\pm M + \eta, \pm M + \epsilon)$, $0 < \eta < \epsilon$ and $\pm M$ is a point of the essential spectrum.

We need to distinguish two cases

(a) $M > 0$ and potential $V \sim \rho^2$ at infinity.

(b) $M = 0$ and potential $V \sim \rho$ at infinity.

23.4.4 Case $F \to 0$ as $|x| \to \infty$

In this subsection we consider cases of $F \to 0$ and $V \to 0$ as $|x| \to \infty$. In this case the essential spectra of the Schrödinger and Schrödinger-Pauli operators are $[0, \infty)$; however, as $V = o(F)$ as $|x| \to \infty$ the Schrödinger operator has only a finite number of the negative eigenvalues and thus is not a subject of our analysis while the Schrödinger-Pauli operator is.

Further, the Dirac operator has its essential spectrum $(-\infty, -M]\cup[M, \infty)$ and we need to assume that $M > 0$.

[41] Cf. Problem 23.4.12.

It turns out that the remainder estimate is as in Subsection 23.4.1, while the magnitude of the principal part is smaller but it is still given by the same formula).

Theorem 23.4.21 [42]**.** *(i) Let X be a connected exterior domain with $\mathscr{C}^K$ boundary. Let conditions* (23.2.2)*,* $(23.2.3)_{1-3}$*,* (23.2.19)*,* (23.4.24) *and* (23.4.28) *and* $(23.4.7)_{\mp}$ *(with sign "$-$") be fulfilled with scaling functions γ, ρ and ρ_1, $\rho \to 0$, $\rho_1 \to 0$ and $\rho_1\gamma^2 \to \infty$, $\rho_1\rho^{-2} \to \infty$ as $|x| \to \infty$. Then for the Schrödinger-Pauli operator* (23.4.29)–(23.4.32) *holds*[43]*.*

(ii) Further, under assumption $(23.4.11)_{\mp}$ *(with sign "$-$") $0-0$ is not a limit point of the discrete spectrum.*

Example 23.4.22 [44]. (i) Let conditions of Theorem 23.4.21 be fulfilled with $\gamma = \langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m < 0$, $\max(2m, -2) < m_1 < 0$.

Then estimate (23.4.29) [43] holds with R defined by (23.4.32) and with $\mathcal{N}^-(\eta) = O(\eta^{dk/(2m)})$. Further, $\mathcal{N}^-(\eta) \asymp \eta^{dk/(2m)}$ if condition $(23.4.11)_-$ is fulfilled in some non-empty cone.

(ii) Furthermore, if condition $(23.4.11)_-$ is fulfilled, then even for $d = 2$ $R = 1$.

Example 23.4.23. (i) Let conditions of Theorem 23.4.21 be fulfilled with $\gamma = \epsilon\langle x\rangle$, $\rho_1 = \langle x\rangle^{-2}|\log\langle x\rangle|^{\beta}$, $\beta > 0$. Let either $\rho = \langle x\rangle^m$ with $m < -1$ or $\rho = \langle x\rangle^{-1}|\log\langle x\rangle|^{\alpha}$ with $2\alpha < \beta$. Then the remainder estimate is $O(R)$ with R defined by (23.4.32) and $\mathcal{N}^-(\eta) = O(S)$ with

$$S = \begin{cases} |\log\eta|^{\beta+1} & d = 2, \\ |\eta^{(d-2)/(2m)}|\log\eta|^{\beta} & d \ge 4. \end{cases} \tag{23.4.41}$$

Further, $\mathcal{N}^-(\eta) \asymp S$ if condition $(23.4.11)_-$ is fulfilled in some non-empty cone.

(ii) Furthermore, if condition $(23.4.11)_-$ is fulfilled, then even for $d = 2$ $R = 1$.

---

[42] Cf. Theorems 23.4.3 and 23.4.16.

[43] With the sign "$-$".

[44] Cf. Examples 23.4.4 and 23.4.17.

Example 23.4.24[45]. (i) Let conditions of Theorem 23.4.21 be fulfilled with $\gamma = \langle x\rangle^{1-\alpha}$, $\rho = \exp(a\langle x\rangle^{\alpha})$, $\rho_1 = \langle x\rangle^{m_1}$, $a < 0$, $\alpha > 0$, $m_1 < 0$, $m_1 + 2 - 2\alpha > 0$. Then the remainder estimate is $O(R)$ with R defined by (23.4.35) and (23.4.36) holds.

(ii) Further, if condition $(23.4.11)_{\mp}$ is fulfilled, then the remainder estimate (23.4.35) could be improved to (23.4.37).

(iii) Furthermore, if condition $(23.4.11)_{-}$ is fulfilled in some non-empty cone then there is $\asymp$ in (23.4.36).

Problem 23.4.25. Again, one can hope to improve estimates (23.4.37) and (23.4.40) in the same way as specified in Problem 23.4.6.

We also leave to the reader

Problem 23.4.26[46]. Consider in this framework the Dirac operator. In this case $\mathsf{N}^{-}(\eta)$ is a number of eigenvalues in $(\pm M - \epsilon, \pm M - \eta)$ and $\mathsf{N}^{+}(\eta)$ is a number of eigenvalues in $(\pm M + \eta, \pm M + \epsilon)$, $0 < \eta < \epsilon$ and $\pm M$ is a point of the accumulation of the discrete spectrum.

We need to assume that $M > 0$ and potential $V \sim \rho^2$ at infinity.

Consider now the case when condition $\rho^2 = o(\rho_1)$ as $|x| \to \infty$ is not fulfilled. Then the results will be similar to those of Section 23.3.

Example 23.4.27[47]. (i) Let X be a connected exterior domain[28] with $\mathscr{C}^K$ boundary and $d = 2$. Let conditions (23.2.2), $(23.2.3)_{1-3}$ and $(23.3.1)_1^{\#}$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^{m}$, $\rho_1 = \langle x\rangle^{m_1}$, $-1 < m < 0$, $m - 1 < m_1 \le 2m$.

Assume that conditions (23.3.27) and (23.3.28) are fulfilled. Then for the Schrödinger operator asymptotics

$$\mathsf{N}^{-}(\eta) = \mathcal{N}^{-}(\eta) + O(\eta^{1-m_1/(2m)}) \tag{23.4.42}$$

holds as $\eta \to +0$ with

$$\mathcal{N}^{-}(\eta) = O(\eta^{(m+1)/m}). \tag{23.4.43}$$

Indeed, it follows from the arguments of Example 23.3.15; we need to take into account that $\{|x| \ge C\tau^{1/(2m)}\}$ is a forbidden zone.

[45] Cf. Example 23.4.18.

[46] Cf. Problem 23.4.12 and 23.4.20.

[47] Cf. Example 23.3.16.

(ii) Similar results hold in the full-rank even-dimensional case:

$$\mathsf{N}^-(\eta) = \mathcal{N}^-(\eta) + O(\eta^{1-m_1/(2m)+(d-2)(m+1)/(2m)}) \tag{23.4.44}$$

holds as $\eta \to +0$ with

$$\mathcal{N}^-(\eta) = O(\eta^{d(m+1)/(2m)}). \tag{23.4.45}$$

We leave to the reader:

Problem 23.4.28. Consider the case of $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^{-2}|\log x|^{\alpha}$, $\rho_1 = \langle x\rangle^{-2}|\log x|^{\beta}$, $2\alpha \ge \beta > \alpha$.

We also leave to the reader

Problem 23.4.29[48]. Consider in this framework the Dirac operator with $M > 0$. In this case both points $M - 0$ and $-M + 0$ could be limits of the discrete spectrum simultaneously.

23.5 Multiparameter Asymptotics

In this section we consider asymptotics with respect to three parameters μ, h and τ; here spectral parameter τ tends either to $\pm\infty$ or to the border of the essential spectrum or to $-\infty$ (for Schrödinger and Schrödinger-Pauli operators) or to the border of the spectrum. In two last cases presence of $h \to +0$ is crucial. We consider here only $d = 2$ and $h \ll 1$.

23.5.1 Asymptotics of Large Eigenvalues

In this subsection $\tau \to +\infty$ for the Schrödinger and Schrödinger-Pauli operators and $\tau \to \pm\infty$ for the Dirac operator. We consider the Schrödinger and Schrödinger-Pauli operators, leaving the Dirac operator to the reader.

Example 23.5.1. Assume first that $\psi \in \mathscr{C}_0^\infty$ and there are no singularities on $\mathsf{supp}(\psi)$. We consider

$$\mathsf{N}^-_\psi(\tau) = \int e(x,x,\tau)\psi(x)\,dx. \tag{23.5.1}$$

Then for scaling $A \mapsto \tau^{-1}A$ leads to $h \mapsto h\tau^{-1/2}$ and $\mu \to \mu\tau^{-1/2}$.

[48] Cf. Problems 23.4.12, 23.4.20 and 23.4.26.

(i) If $\mu \lesssim \tau^{1/2}$ then we can apply the standard theory with the "normal" magnetic field; we need to assume that $h \ll \tau^{1/2}$ and we need neither condition $d = 2$, nor $F \geq \epsilon_0$, nor $\partial X = \emptyset$; the principal part of the asymptotics has magnitude $h^{-d}\tau^{d/2}$ and the remainder estimate is $O\big(h^{1-d}\tau^{(d-1)/2}\big)$ which one can even improve to $o\big(h^{1-d}\tau^{(d-1)/2}\big)$ under proper non-periodicity assumption.

(ii) Let $\mu \gtrsim \tau^{1/2}$, $\mu h \lesssim \tau$. Then we can apply the standard theory with the "strong" magnetic field; we assume that $d = 2$, $\partial X = \emptyset$ and $F \geq \epsilon_0$. Then the principal part of the asymptotics has magnitude $h^{-2}\tau$ and under non-degeneracy assumptions

$$\nabla F = 0 \implies \det \mathsf{Hess}\, F \geq \epsilon \tag{23.5.2}$$

and

$$\nabla F = 0 \implies |\det \mathsf{Hess}\, F| \geq \epsilon \tag{23.5.3}$$

fulfilled on $\mathsf{supp}(\psi)$ the remainder estimate is $O(\mu^{-1}h^{-1}\tau)$ and $O(\mu^{-1}h^{-1}\tau(|\log(\mu\tau^{-1/2})| + 1)$ respectively[49]. Without non-degeneracy assumption the remainder estimate is $O(\mu h^{-1})$.

(iii) If $\mu \gtrsim \tau^{1/2}$, $\mu h \geq c\tau$ than $\mathsf{N}^-(\tau) = 0$ for the Schrödinger operator; for the Schrödinger-Pauli operator the principal part of the asymptotics has magnitude μh^{-1} and under non-degeneracy assumptions (23.5.2) and (23.5.3) the remainder estimate is $O(1)$ and $O(\log \mu)$ respectively (or better for τ belonging to the spectral gap).

Example 23.5.2[50]. Let X be a connected exterior domain with $\mathscr{C}^K$ boundary. Let conditions (23.2.2), $(23.2.3)_{1-3}$, $(23.3.1)^{\#}_{1,2}$, be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m_1 > 2m \geq 0$. Consider the Schrödinger operator and assume that

$$\tau \geq \mu h, \qquad \tau^{2m-m_1} \leq \epsilon(\mu h)^{2m}. \tag{23.5.4}_{1,2}$$

Then

$$\mathcal{N}^-(\tau, \mu, h) \asymp \tau^{(2+m_1)/m_1} h^{-2(1+m_1)/m_1} \mu^{-2/m_1}. \tag{23.5.5}$$

[49] In the letter case logarithmic factor could be removed by adding a correction term.
[50] Cf. Example 23.3.15.

(i) Further, if $\tau \gtrsim \mu^2$, then the zone of the strong magnetic field $\mu_{\mathsf{eff}} = \mu\langle x\rangle^{m_1+1}\tau^{-1/2} \geq C$ is contained in $\{x\colon |x| \geq c\}$ and here we have non-degeneracy condition fulfilled. Then the remainder estimate is $O(R)$ with

$$R = \tau^{(m_1+2)/2(m_1+1)}\mu^{-1/(m_1+1)}h^{-1}, \tag{23.5.6}$$

which could be improved under non-periodicity assumption; see Example 23.3.18.

(ii) On the other hand, if $\mu^2 \gg \tau$, then the contribution of the zone $\{x\colon |x| \geq c\}$ to the remainder is $O(\mu^{-1}h^{-1}\tau)$. The contribution of the zone $\{x\colon |x| \leq c\}$ to the remainder is $O(\mu^{-1}h^{-1}\tau)$ provided $X = \mathbb{R}^2$ and non-degeneracy assumption (23.5.2) is fulfilled (etc) and $O(\mu h^{-1})$ in the general case.

(iii) Let us replace $(23.5.4)_2$ by the opposite inequality, and assume $(23.3.3)^{\#}$. Then (23.5.5) is replaced by $\mathcal{N}^-(\tau,\mu,h) \asymp h^{-2}\tau^{(m+1)/m}$. Let us discuss R.

(a) If $\mu\tau^{(m_1+1-m)/(2m)} \lesssim 1$, then $\mu_{\mathsf{eff}} \lesssim 1$ as $|x| \lesssim \tau^{1/(2m)}$ and $R = h^{-1}\tau^{(m+1)/(2m)}$.

(b) If $\mu\tau^{(m_1+1-m)/(2m)} \gtrsim 1$, but $\mu^2\tau \lesssim 1$, then R is given by (23.5.6).

(c) If $\mu^2 \gg \tau$, then we are in the framework of (ii).

Example 23.5.3[51]. In the framework of Example 23.5.2 for the Schrödinger-Pauli operator under assumption $(23.3.3)^{\#}$ the remainder estimate is the same as in Statement (iii) while

$$\mathcal{N}^-(\tau,\mu,h) \asymp h^{-2}\tau^{(m+1)/m} + \mu h^{-1}\tau^{(m_1+2)/(2m)}. \tag{23.5.7}$$

We leave to the reader

Problem 23.5.4. Consider the Schrödinger and Schrödinger-Pauli operators

(i) In the same framework albeit with condition $m_1 > 2m$ replaced by $2m \geq m_1 \geq 0$. Assume that $(23.3.3)^{\#}$ is fulfilled.

Then magnitude of $\mathcal{N}^-(\tau,\mu,h)$ is described in Examples 23.5.2 and 23.5.3. Under proper non-degeneracy assumption (which we leave to the reader to formulate) derive the remainder estimate.

[51] Cf. Example 23.3.19.

(ii) In the same framework as in (i) albeit in with $m_1 < 0$ (magnetic field is stronger in the center but there is no singularity), in which case the center can become a classically forbidden zone.

(iii) With other types of the behaviour at infinity.

Problem 23.5.5. For the Dirac operators derive similar results as $\tau \to \pm\infty$.

23.5.2 Asymptotics of the Small Eigenvalues

In this subsection for the Schrödinger and Schrödinger-Pauli operators we consider asymptotics of eigenvalues tending to -0.

Example 23.5.6[52]. Let X be a connected exterior domain with $\mathscr{C}^K$ boundary. Let conditions (23.2.2), $(23.2.3)_{1-3}$, $(23.3.1)_1^{\#}$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $-1 < m < 0$, $m_1 > m-1$.

Consider the Schrödinger operator and assume that

$$(23.5.8)_{1,2} \qquad 1 \ge \mu h, \qquad |\tau|^{2m-m_1} \le \epsilon(\mu h)^{2m}.$$

Then $\mathcal{N}^-(\tau,\mu,h) = O(h^{-2}|\tau|^{(m+1)/m})$ as $\tau \to -0$ with "$\asymp$" instead of "$= O$" if condition $(23.4.11)_{\mp}$ (with the sign "$-$") fulfilled in some non-empty cone.

Further, under non-degeneracy assumption (23.3.27) the contribution to the remainder of zone $\{x\colon |x| \ge c\}$ is $O(R)$ with

(i) If $\mu|\tau|^{(m_1+1-m)/(2m)} \lesssim 1$ then $R = h^{-1}|\tau|^{(m+1)/(2m)}$.

(ii) Let $\mu|\tau|^{(m_1+1-m)/(2m)} \gtrsim 1$. Then

(a) If $m_1 < 2m$ then $R = \mu^{-1}h^{-1}|\tau|^{(2m-m_1)/(2m)}$.

(b) If $m_1 = 2m$ then $R = \mu^{-1}h^{-1}|\log\mu|$.

(c) If $m_1 > 2m$ then $R = h^{-1}\mu^{(m+1)/(m_1+1-m)}$ for $\mu \lesssim 1$ and $R = \mu^{-1}h^{-1}$ for $\mu \gtrsim 1$.

Example 23.5.7[53]. In the framework of Example 23.5.6 for the Schrödinger-Pauli operator under assumption $(23.3.3)^{\#}$ the contribution to the remainder of the zone $\{x\colon |x| \ge c\}$ the same as in Example 23.5.6(ii) while

$$(23.5.9) \qquad \mathcal{N}^-(\tau,\mu,h) = O(h^{-2}|\tau|^{(m+1)/m} + \mu h^{-1}|\tau|^{(m_1+2)/(2m)})$$

[52] Cf. Example 23.4.22.

[53] Cf. Example 23.4.22.

$\asymp$ if condition $(23.4.11)_{\mp}$ (with the sign "$-$") fulfilled in some non-empty cone.

Problem 23.5.8. Consider the Schrödinger and Schrödinger-Pauli operators if

(i) If condition $(23.5.8)_1$ is violated (then there could be a forbidden zone in the center).

(ii) $m_1 \le m-1$.

(iii) With other types of the behaviour at infinity.

Problem 23.5.9. Consider the Schrödinger and Schrödinger-Pauli operators in the framework of Subsections 23.4.1 and 23.4.2 if

(i) $\mu h = 1$; then the essential spectrum does not change.

(ii) $\mu h \to \infty$; then only point 0 of the essential spectrum is preserved for the Schrödinger-Pauli operators, while others go to $+\infty$. Consider $\mathsf{N}^{\pm}(\eta)$ with $\eta \to 0$.

(iii) $\mu h \to 0$; then only point 0 of the essential spectrum is preserved for the Schrödinger-Pauli operators, while others move towards it. Consider $\mathsf{N}^{-}(\eta)$ with $\eta \to 0$ for both Schrödinger and Schrödinger-Pauli operators.

Problem 23.5.10. (i) Consider the Schrödinger-Pauli operators in the framework of Subsection 23.4.3.

(ii) Consider the Schrödinger and Schrödinger-Pauli operators in the framework of Subsection 23.4.4.

Problem 23.5.11. For the Dirac operators derive similar results as $M \ne 0$ and $\tau \to M-0$ and $-M+0$; or as $M=0$ albeit $m_1 \ge 0$.

23.5.3 Case of $\tau \to +0$

In this subsection $\tau \to +0$ for the Schrödinger and Schrödinger-Pauli operators and $\tau \to \pm M \pm 0$ for the Dirac operator. Consider the Schrödinger and Schrödinger-Pauli operators first.

Example 23.5.12[54]. Let $V > 0$ everywhere except $V(0) = 0$. Let conditions (23.2.2), $(23.2.3)_{1-3}$, $(23.3.1)^{\#}_{1,2}$, be fulfilled with $\gamma = \epsilon_0|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$, $m_1 > 2m \ge 0$. Consider the Schrödinger operator and assume that $\tau \to +0$.

(i) Let

$$(23.5.10)_{1,2} \qquad \mu \ll \tau^{(m_1+2)/2} h^{-(m_1+1)}, \qquad \tau^{2m-m_1} \le \epsilon(\mu h)^{2m}.$$

Then (23.5.5) holds.

Then the remainder estimate is $O(R)$ with defined by (23.5.6) which could be improved under non-periodicity assumption; see Example 23.3.18.

(ii) Let us replace $(23.5.10)_2$ by the opposite inequality, and assume $(23.3.3)^{\#}$. Then (23.5.5) is replaced by $\mathcal{N}^-(\tau, \mu, h) \asymp h^{-2}\tau^{(m+1)/m}$. Let us discuss R.

(a) If $\mu\tau^{(m_1+1-m)/(2m)} \lesssim 1$, then $\mu_{\text{eff}} \lesssim 1$ as $|x| \lesssim \tau^{1/(2m)}$ and $R = h^{-1}\tau^{(m+1)/(2m)}$.

(b) If $\mu\tau^{(m_1+1-m)/(2m)} \gtrsim 1$, but $\mu^2\tau \lesssim 1$, then R is given by (23.5.6).

Example 23.5.13[55]. In the framework of Example 23.5.12 for the Schrödinger-Pauli operator under assumption $(23.3.3)^{\#}$ the remainder estimate is the same as in Statement (ii) while (23.5.7) holds.

We leave to the reader

Problem 23.5.14[56]. Consider the Schrödinger and Schrödinger-Pauli operators

(i) In the same framework albeit with condition $m_1 > 2m$ replaced by $2m \ge m_1 \ge 0$. Assume that $(23.3.3)^{\#}$ is fulfilled.

Then magnitude of $\mathcal{N}^-(\tau, \mu, h)$ is described in Examples 23.5.12 and 23.5.13. Under proper non-degeneracy assumption (which we leave to the reader to formulate) derive the remainder estimate.

(ii) In the same framework as in (i) albeit in with $m_1 < 0$ (magnetic field is stronger in the center but there is no singularity), in which case the center can become a classically forbidden zone.

---

[54] Cf. Example 23.5.2.
[55] Cf. Example 23.5.3.
[56] Cf. Problem 23.5.4.

(iii) With other types of the behaviour at infinity.

Problem 23.5.15. For the Dirac operators derive similar results as $\tau \to \pm(M+0)$.

23.5.4 Case of $\tau \to -\infty$

In this subsection for the Schrödinger and Schrödinger-Pauli operators we consider asymptotics with $\tau \to -\infty$.

In this subsection for the Schrödinger and Schrödinger-Pauli operators we consider asymptotics of eigenvalues tending to -0.

Example 23.5.16[57]. Let $X \ni 0$ and let conditions (23.2.2), $(23.2.3)_{1-3}$, $(23.3.1)_1^{\#}$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $-1 < m < 0$, $m_1 > m-1$.

Consider the Schrödinger operator and assume that

$$(23.5.11)_{1,2} \qquad h \ll |\tau|^{(m+1)/(2m)}, \qquad |\tau|^{m_1-2m} \le \epsilon(\mu h)^{2m}.$$

Then $\mathcal{N}^-(\tau,\mu,h) = O(h^{-2}|\tau|^{(m+1)/m})$ as $\tau \to -0$ with $\asymp$ if condition $(23.4.11)_{\mp}$ (with the sign "$-$") fulfilled in some non-empty cone.

(i) If $\mu|\tau|^{(m_1+1-m)/(2m)} \lesssim 1$ then $R = h^{-1}|\tau|^{(m+1)/(2m)}$.

(ii) Let $\mu|\tau|^{(m_1+1-m)/(2m)} \gtrsim 1$. Then

(a) If $m_1 < 2m$ then $R = \mu^{-1}h^{-1}|\tau|^{(2m-m_1)/(2m)}$.

(b) If $m_1 = 2m$ then $R = \mu^{-1}h^{-1}|\log\mu|$.

(c) If $m_1 > 2m$ then $R = h^{-1}\mu^{(m+1)/(m_1+1-m)}$ for $\mu \lesssim 1$ and $R = \mu^{-1}h^{-1}$ for $\mu \gtrsim 1$.

Example 23.5.17[58]. In the framework of Example 23.5.16 for the Schrödinger-Pauli operator under assumption $(23.3.3)^{\#}$ the contribution to the remainder of the zone $\{x\colon |x| \ge c\}$ the same as in Example 23.5.16(ii) while

$$(23.5.12) \qquad \mathcal{N}^-(\tau,\mu,h) = O\bigl(h^{-2}|\tau|^{(m+1)/m} + \mu h^{-1}|\tau|^{(m_1+2)/(2m)}\bigr)$$

$\asymp$ if condition $(23.4.11)_{\mp}$ (with the sign "$-$") fulfilled in some non-empty cone.

---

[57] Cf. Example 23.4.22.

[58] Cf. Example 23.4.22.

Problem 23.5.18. Consider the Schrödinger and Schrödinger-Pauli operators if

(i) $m_1 \le m-1$.

(ii) With other types of the behaviour at 0.

23.A Appendices

23.A.1 Self-Adjointness of the Dirac Operator

The Dirac operators treated in this Chapter are surely self-adjoint in the case of an exterior domain with the singularity at infinity. However, the same fact should be proven for an interior domain with singular points. We consider a single singular point at 0.

Theorem 23.A.1. *Let $X \subset \mathbb{R}^2/(\bar\gamma_1\mathbb{Z}\times\bar\gamma_2\mathbb{Z})$ $(0<\bar\gamma_j\le\infty)$ be an open domain. Let conditions* (23.2.2), $(23.2.3)_{1-3}$, (23.2.13) *be fulfilled. Further, let*

$$(23.A.1)_{1,2} \qquad F\ge\epsilon\rho_1 \qquad |V|\ge\epsilon\rho as\ \ |x|\le\epsilon.$$

Let us assume that there exists a neighborhood of ∂X, denoted by Y, such that for every $r>0$ the inequalities

$$(23.A.2)_{1-3} \qquad \rho_1\ge\varepsilon\rho^2,\quad (\rho\gamma)^s\ge\varepsilon\rho_1,\quad \rho\ge 1,$$

$$(23.A.3) \qquad \bigl|V+\sqrt{2j\mu hF}\bigr|\ge\varepsilon\sqrt{\rho}_1-\varepsilon^{-1} \qquad \forall j\in\mathbb{Z}^+\setminus 0,$$

$$(23.A.4) \qquad |V|\ge\varepsilon\rho-\varepsilon^{-1}$$

are fulfilled on $Y\cap X\cap\{|x|\le r\}$ with appropriate $\varepsilon=\varepsilon(r)>0$.

Then for $\mu>0$, $h>0$ the operator A with domain $\mathfrak{D}(A)=\mathscr{C}_0^1(X,\mathbb{H})$ is essentially self-adjoint in $\mathscr{L}^2(X,\mathbb{H})$.

Proof. Let us consider the adjoint operator A^*. This operator is defined by the same formula with $\mathfrak{D}(A^*)=\{u\in\mathscr{L}^2, Au\in\mathscr{L}^2\}$ with Au calculated as a distribution. We should prove that $\mathsf{Ker}(A^*\pm iI)=0$ for both signs. So, here and below let $u\in\mathscr{L}^2$ and $(A^*\pm iI)u=0$ for some sign.

The microlocal canonical form of Section 17.2 yields the inequality

$$\|\rho v\| \le M\bigl(\|Av\| + \|v\| + \|\gamma^{-1}v\|\bigr) \qquad \forall v \in \mathscr{C}_0^1\bigl(B(y, \frac{1}{2}\gamma(y))\bigr) \qquad \forall y \in X_r = X \cap \{|x| \le r\} \tag{23.A.5}$$

with a constant $M = M(r)$; all the constants now depend on μ and h.

Let us prove that $(\rho\gamma)^n u \in \mathscr{L}^2(X_r)$ for every $r > 0$ by induction on n. This is true for $n = 0$ by the assumption $u \in \mathscr{L}^2$.

Let $(\rho\gamma)^n u \in \mathscr{L}^2(X_r)$ for some n; then $v = \gamma(\rho\gamma)^n u$ also belongs to $\mathscr{L}^2(X_r)$ and

$$Av = [A, \gamma(\rho\gamma)^n]u \mp iv.$$

One can easily see that $[A, \gamma(\rho\gamma)^n]$ is a matrix-valued function the matrix norm of which does not exceed $M(\rho\gamma)^n$. Therefore, taking a γ-admissible partition of unity in a neighborhood of X_r we see that $\sum_\nu \|A\psi_\nu v\|^2 < \infty$ and therefore (23.A.5) yields that $\sum_\nu \|\rho\psi_\nu v\|^2 < \infty$. Therefore $\rho v = (\rho\gamma)^{n+1}u \in \mathscr{L}^2(X_r)$ and the induction step is complete.

Thus we have proven that $(\rho\gamma)^n u \in \mathscr{L}^2(X_r)$ for every $r > 0$. Then $\rho_1 u \in \mathscr{L}^2(X_r)$ by $(23.A.2)_2$. The ellipticity of A yields that $D_j u \in \mathscr{L}^2(X_r)$. Therefore, if $\psi \in \mathscr{C}_0^1\bigl(\mathbb{R}^2/(\bar\gamma_1\mathbb{Z} \times \bar\gamma_2\mathbb{Z})\bigr)$ then $\psi u \in \mathfrak{D}(\bar A)$ where $\bar A$ is the closure of A. Moreover,

$$(\bar A \pm iI)\psi u = [\bar A, \psi]u.$$

Calculating the real part of the inner product with $i\psi u$ we obtain the inequality

$$\|\psi u\| \le \max|\nabla\psi^2| \cdot \|u\|^2.$$

Let us take $\psi = \psi^0(x/r)$ where $\psi^0 \in \mathscr{C}_0^1$ is a fixed function equal to 1 in a neighborhood of 0. Then for $r \to +\infty$ we see that the left-hand expression of this inequality tends to $\|u\|^2$ and the right-hand expression tends to 0. Therefore $u = 0$. □

Theorem 23.A.2. *Let all of the conditions of Theorem 23.A.1 excluding condition* $(23.A.2)_{1-3}$ *be fulfilled with* $\gamma = \epsilon_0|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$, $m_1 \le 2m$, $m_1 < -2$. *Then the Dirac operator has a self-adjoint extension for* $\mu > 0$, $h > 0$.

Proof. For $m < -1$ condition $(23.A.2)_{1-3}$ is also fulfilled and therefore the operator A is essentially self-adjoint. So, let us treat the case $m \ge -1$. Let us consider the Dirac operator A_D with the potential $V_t = V + tW$ where $t > 0$, W is a potential which is regular away from $\{x = 0\}$, and $W = \pm|x|^{m'}$ in a neighborhood of $x = 0$ with $-1 > m' > \frac{1}{2}m_1$. This operator is essentially self-adjoint by Theorem 23.A.1. For $m < 0$ let us choose the sign of W coinciding with the sign of V on a neighborhood of 0 (condition $(23.A.1)_2$ yields that this is possible).

For $m \ge 0$ let us choose an appropriate interval $[\tau_1, \tau_2]$ with $\tau_1 < \tau_2$. Then applying the results of Section 23.3 we see that the number of eigenvalues of the operator $\bar{A}_t$ lying in the interval $[\tau_1, \tau_2]$ is bounded uniformly with respect to $t > 0$. Then there exists a sequence $t_k \to +0$ such that there exist $\tau_1' < \tau_2'$ which do not depend on k and such that $[\tau_1', \tau_2'] \cap \mathsf{Spec}(\bar{A}_t) = \emptyset$ for $t = t_k$.

Let $\tau = \frac{1}{2}(\tau' + \tau_2')$; then all the operators $(\bar{A}_t - \tau)^{-1}$ are uniformly bounded and $\|A_t u\| \ge \epsilon\|u\|$ $\forall u \in \mathfrak{D}(A_t)$ for $t = t_k$. Then the same is true for A. Therefore A has a self-adjoint extension $\tilde{A}$ satisfying the same estimate.

Comments

In addition to papers, mentioned in Remark 23.4.9 I would like also mention S. Solnyshkin [1], A. Sobolev [1–4], Y. Colin de Verdiere [8, 9], A. Morame [3, 4], A. Morame &J. Nourrigat [1] and H. Tamura [6–9], M. Birman & G. Raikov [1], G. Raikov [2–9].

Chapter 24

Eigenvalue asymptotics. 3D Case

24.1 Introduction

In this chapter we obtain eigenvalue asymptotics for 3D-Schrödinger, Schrödinger-Pauli and Dirac operators in the situations in which the role of the magnetic field is important. We have seen in Chapters 13 and 17 that these operators are essentially different and they also differ significantly from the corresponding 2D-operators which we considered in the previous Chapter 23.

Now we *usually* find ourselves in the situation much closer to Chapter 11 than Chapter 23 was. Indeed, our local asymptotics now are the same as without magnetic field, under very week non-degeneracy assumptions. We also allow boundaries and a singular points, finite or infinite, belonging to the boundary.

We start from Section 24.2 in which we consider the case when the spectral parameter is fixed ($\tau = \mathsf{const}$) and study asymptotics with respect to μ, h exactly like in Section 11.1 we considered asymptotics with respect to h. However, since now we have two parameters, we need to consider an interplay between them: while always $h \to +0$, we cover $\mu \to +0$, μ remains disjoint from 0 and ∞ and $\mu \to \infty$, which in turn splits into subcases $\mu h \to 0$, μh remains disjoint from 0 and ∞ and $\mu h \to \infty$.

In Section 24.3 we consider asymptotics with $\mu = h = 1$ and with τ tending to $+\infty$ for the Schrödinger and Schrödinger-Pauli operators and to $\pm\infty$ for the Dirac operator. We consider bounded domains with the

singularity at some point and unbounded domains with the singularity at infinity.

In Section 24.4 we consider asymptotics with the singularity at infinity and $\mu = h = 1$ and with τ tending to $+0$ for the Schrödinger and Schrödinger-Pauli operators and to $\pm(M - 0)$ for the Dirac operator.

It includes the most interesting case (see Subsection 23.4.2) when magnetic field is either constant or stabilizes fast at infinity and potential fast decays at infinity in the direction of magnetic field. In this case we consider a reduced one-dimensional operator which has just one negative eigenvalue $\Lambda(x')$ and it turns out that the asymptotics of the eigenvalues tending to the bottom of the continuous spectrum for 3D-operator coinsides with the asymptotics obtained in Subsection 23.4.1 for 2D-operator with the potential $\Lambda(x')$. In contrast to the rest of the section we consider multidimensional case as well.

In Section 24.5 we consider asymptotics with respect to μ, h, τ, like in Sections 11.7 and 23.5 again with significant differences mentioned above.

Finally, in Appendices 24.A.1 and 24.A.2 we investigate 1D-Schrödinger operators and in Appendix 24.A.3 we construct examples of vector potentials with different rates of growth of the magnetic field at infinity.

24.2 Asymptotics with Fixed Spectral Parameter

In this section we consider asymptotics with a fixed spectral parameter for 3-dimensional magnetic Schrödinger, Schrödinger-Pauli and Dirac operators and discuss some of the generalizations[1)].

As in Chapters 9–12 and 23 we will introduce a semiclassical zone and a singular zone, where $\rho\gamma \ge h$ and $\rho\gamma \le h$ respectively. In the semiclassical zone we apply asymptotics of Chapters 13, 18 and 20–in the multidimensional case. In the singular zone we need to apply estimates for a number of eigenvalues; usually it would be sufficient to use non-magnetic estimate[2)] for number of eigenvalues which trivially follows from standard one but if needed one can use more delicate estimates.

[1)] Mainly to higher dimensions with maximal-rank magnetic field.

[2)] With V modified accordingly; for example, for the Schrödinger and Schrödinger-Pauli operators V_- is replaced by $C\big((1-\epsilon)V - C_\epsilon \mu^2 |\vec{V}|^2\big)_-$.

24.2.1 Schrödinger Operator

Estimates of the Spectrum

Consider first the Schrödinger operator (13.2.1) where g^{jk}, V_j, V satisfy (13.2.2) and (13.2.4) i.e.

$$\epsilon|\xi|^2 \le \sum_{j,k} g^{jk}\xi_j\xi_k \le c|\xi|^2 \qquad \forall \xi \in \mathbb{R}^d. \tag{24.2.1}$$

Without any loss of the generality we can fix $\tau = 0$ and then in the important function $V_{\mathsf{eff}}F_{\mathsf{eff}}^{-1}$ the parameters μ and h enter as factors. Thus, we treat the operator (13.2.1) assuming that it is self-adjoint.

We make assumptions the same assumptions 23.2.3 i.e.

$$|D^\alpha g^{jk}| \le c\gamma^{-|\alpha|}, \quad |D^\alpha F_{jk}| \le c\rho_1\gamma^{-|\alpha|}, \quad |D^\alpha V| \le c\rho^2\gamma^{-|\alpha|} \tag{24.2.2}$$

where scaling function $\gamma(x)$ and weight functions $\rho(x), \rho_1(x)$ satisfy the standard assumptions $(9.1.6)_1$ and $(9.1.6)_2$. Then

$$\mu_{\mathsf{eff}} = \mu\rho_1\gamma\rho^{-1}, \qquad h_{\mathsf{eff}} = h\rho^{-1}\gamma^{-1}. \tag{24.2.3}$$

Let us introduce a *semiclassical zone* $X' = \{x\colon \rho\gamma \ge h\}$ and a *singular zone* $X'' = \{x\colon \rho\gamma \le 2h\}$ by (23.2.5) and (23.2.6) respectively.

Further, let us introduce two other overlapping zones $X_1' = \{x \in X_{\mathsf{scl}}\colon \mu\rho_1 \le 2c\rho\gamma^{-1}\}$ and $X_2' = \{x \in X'\colon \mu\rho_1 \ge c\rho\gamma^{-1}\}$ where the magnetic field $\mu_{\mathsf{eff}} = \mu\rho_1\rho^{-1}\gamma$ is *normal* ($\mu_{\mathsf{eff}} \le 2c$) and where it is *strong* ($\mu_{\mathsf{eff}} \ge c$) respectively (see (23.2.7) and (23.2.8). We also assume that

$$|F| \ge \epsilon\rho_1 \qquad \text{in} \quad X_2' \tag{24.2.4}$$

where F_{jk}, F^j and F are the tensor, vector (as $d = 3$) and scalar intensities of the magnetic field respectively. Moreover, let us assume that

$$u\big|_{\partial X \cap B\left(x,\gamma(x)\right)} = 0 \qquad \forall x \in X_2' \quad \forall u \in \mathfrak{D}(A); \tag{24.2.5}$$

we do not need $(23.2.10)_1$ since in 3D the boundary does not lead to the deterioration of the remainder estimate. We define $X_-' = \{x \in X_2'\colon V + \mu hF \ge \epsilon\rho^2\}$ and $X_{2+}' = \{x \in X'\colon V + \mu hF \le 2\epsilon\rho^2\}$ by (23.2.10) and (23.2.11) respectively.

Finally, let the standard boundary regularity condition be fulfilled:

(24.2.6) For every $y \in X$, $\partial X \cap B(y, \gamma(y)) = \{x_k = \phi_k(x_{\hat{k}})\}$ with

$$|D^\alpha \phi_k| \le c\gamma^{-|\alpha|}$$

and $k = k(y)$.

Recall that according to Chapter 13 the contribution of the partition element $\psi \in \mathscr{C}_0^K(B(y, \frac{1}{2}\gamma(y))$ to the principal part of asymptotics is

$$\mathcal{N}^-(\mu, h) = \mathcal{N}^{\mathsf{MW}-}(\mu, h) \coloneqq h^{-3} \int \mathcal{N}^{\mathsf{MW}}(x, \mu h)\psi(x)\, dx \tag{24.2.7}$$

with $\mathcal{N}^{\mathsf{MW}}(x, \mu h)$ given by (13.2.9) with $d = 3$.

On the other hand, its contribution to the remainder does not exceed $Ch^{-2}\rho^2\gamma^2$ if $\mu\rho_1\gamma \le c\rho$ or $\mu\rho_1\gamma \ge c\rho$ but $\mu h\rho_1 \le \rho^2$, $y \in X'_+$ and non-degeneracy assumption

$$\sum_{\alpha:|\alpha|\le k} |\nabla^\alpha (VF^{-1} + (2n+1)\mu h)|\gamma^{|\alpha|} \ge \epsilon\rho^2\rho_1^{-1} \qquad \forall n \in \mathbb{Z}^+ \tag{24.2.8}$$

is fulfilled[3], and it does not exceed $C(\mu^{-s}\rho_1^{-s}\gamma^{-2s})$ if $C\mu\rho_1\gamma \ge \rho$, $\mu h\rho_1 \le \rho^2$, $y \in X'_{2-}$.

Then we get estimate of N^- from below by the magnetic Weyl approximation $\mathcal{N}^-(\mu, h)$ minus corresponding remainder, and also from above by magnetic Weyl approximation plus corresponding remainder, provided $X = X'$ (so, there is no singular zone $X'' = \emptyset$):

$$h^{-d} \int_{X'} \mathcal{N}^{\mathsf{MW}}(x, \mu h)\, dx - CR_1 \le \mathsf{N}^-(0) \le h^{-d} \int_{X'} \mathcal{N}^{\mathsf{MW}}(x, \mu h)\, dx + CR_1 + C'R_2 \tag{24.2.9}$$

with

$$R_1 = \mu^{-1}h^{1-d} \int_{X'_+} \rho^{d-1}\gamma^{-1}\, dx, \tag{24.2.10}$$

$$R_2 = \mu h^{s-d} \int_{X'_-} \rho_1\rho^{d-s-1}\gamma^{1-s}\, dx \tag{24.2.11}$$

[3] It does not exceed the same expression plus $\mu h^{-1-\delta}\rho_1\rho^\delta\gamma^{2+\delta}$ in the general case; here $\delta > 0$ is arbitrarily small but K in $(24.2.2)_{1-3}$ depends on it.

provided

$$\mu\rho_1\gamma \ge \rho \tag{24.2.12}$$

where the latter condition could be assumed without any loss of the generality, C' depens also on s and ϵ [4].

We leave to the reader the following not very challenging set of problems:

Problem 24.2.1. (i) Consider in the current framework Problems 23.2.1(i), (ii), (iv).

(ii) Using results of Subsubsection *13.8.2.1 Case* $d = 3$ replace condition $(24.2.8)_k$ by $(13.8.19)_m$.

In what follows $h \to +0$ and the semiclassical zone X' expands to X while μ is either bounded (then we can assume that the zone of the strong magnetic field X_2' is fixed) or tends to ∞ (then X_2' expands to X). We assume that all conditions of the previous subsection are fulfilled with $\mu = h = 1$ but we will assume them fulfilled in the corresponding zones.

The other important question is whether $\mu h \to 0$, remains bounded and disjoint from 0 or tends to ∞.

Finally, we should consider the singular zone X''. In order to avoid this task we assume initially that

$$\rho_1\gamma^2 + \rho\gamma \ge \epsilon. \tag{24.2.13}$$

Power Singularities

Example 24.2.2 [5]. (i) Let X be a compact domain, $0 \in \bar{X}$ and let conditions $(24.2.8)_k$, (24.2.1), $(24.2.2)_{1-3}$, (24.2.4) and (24.2.6) be fulfilled with $\gamma = \epsilon_0|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$, $m_1 < 2m \le -2$ [6),7)].

Then, for the Schrödinger operator the following asymptotic holds as $h \to +0$, μh bounded:

$$\mathsf{N}^-(\mu, h) = \mathcal{N}^-(\mu, h) + \begin{cases} O(h^{-2}(\mu h)^{2(m+1)/(2m-m_1)}) & m < -1, \\ O(h^{-2}(|\log \mu h| + 1)) & m = -1 \end{cases} \tag{24.2.14}$$

---

[4] Cf. (23.2.18)–(23.2.21).

[5] Cf. Example 23.2.3.

[6] Such potential (V_1, V_2, V_3) exists, see Appendix 24.A.3.

[7] The non-degeneracy condition $(24.2.8)_2$ is fulfilled in the vicinity of 0 if V, F stabilize as $x \to 0$ to V^0, F^0 positively homogeneous of degrees $2m, m_1$ respectively.

with

$$\mathcal{N}^-(\mu,h)=\begin{cases} O(h^{-3}(\mu h)^{2(m+1)/(2m-m_1)}) & m<-1,\\ O(h^{-3}(|\log \mu h|+1)) & m=-1.\end{cases} \tag{24.2.15}$$

Furthermore, one can replace in (24.2.15) "$=O$" with "$\asymp$" if

$$V\le -\epsilon\rho^2 \qquad \text{in} \quad \Gamma\cap\{|x|\le\epsilon\}\subset X \tag{24.2.16}$$

where Γ is an open non-empty sector (cone) with vertex at 0, and $\mu h\le t$ with small enough $t>0$.

(ii) Let X be unbounded domain and let conditions $(24.2.8)_k$, (24.2.1), $(24.2.2)_{1-3}$, (24.2.4) and (24.2.6) be fulfilled with $\gamma=\epsilon_0\langle x\rangle$, $\rho\langle x\rangle^m$, $\rho_1=\langle x\rangle^{m_1}$, $m_1>2m\ge -2$ [6),6)].

Then for the Schrödinger operator asymptotics (24.2.14) holds as $h\to+0$, μh bounded.

Further, (24.2.15) holds and one can replace "$=O$" by "$\asymp$" if

$$V\le -\epsilon\rho^2 \qquad \text{in} \quad \Gamma\cap\{|x|\ge c\}\subset X \tag{24.2.16)$^\#$}$$

where Γ is an open non-empty sector (cone) with vertex at 0, and $\mu h\le t$ with small enough $t>0$.

Example 24.2.3[8)]. (i) Assume now that $m>-1$ while all other assumptions of Example 24.2.2(i) are fulfilled. Then $\mathcal{N}^-(\mu,h)=O(h^{-3})$. Let us calculate the remainder estimate and prove that

$$\mathsf{N}^-(\mu,h)=\mathcal{N}^-(\mu,h)+O(h^{-2}). \tag{24.2.17}$$

Obviously, the contribution of the regular zone $X'=\{x\colon |x|\ge r^*=h^{1/(m+1)}\}$ is $O(h^{-2})$ and we need to consider the contribution of the singular zone $X''=\{x\colon |x|\le r_2\}$.

(a) Assume first that $m_1\ge m-1$. If $\mu r_1^{m_1+1-m}\le c$, then by virtue of CLR we estimate contribution of X''

$$Ch^{-3}\int_{X''}\bigl(r^{3m}+\mu^3 r^{3(m_1+1)}\bigr)\,dx\asymp h^{-3}\bigl(r_1^{3m+3}+\mu^3 r_1^{3m_1+6}\bigr)=O(1). \tag{24.2.18}$$

[8)] Cf. Example 23.2.4.

Indeed, we can take $\vec{V} = O(r^{m_1+1})$.

On the other hand, if $\mu r_1^{m_1+1-m} \ge c$, the same estimate would work for $X''' = \{x\colon |x| \le r_{**} = \mu^{-1/(m_1+1-m)}\}$ while contribution of $X'' \setminus X'''$ does not exceed due to Chapter 13

$$C \int_{X''\setminus X'''} (\mu r^{m_1+1-m})^{-s} r^{-3}\, dx = O(|\log h|) \tag{24.2.19}$$

(actually it is $O(1)$ if $m_1 > m-1$).

(b) Let now $m_1 < m-1$. If $\mu r_1^{m_1+1-m} \ge c$, then we can apply estimate (24.2.19) in the whole zone X''.

On the other hand, if $\mu r_1^{m_1+1-m} \le c$, then we can apply estimate (24.2.19) in the zone X''' and estimate (24.2.18) in $X'' \setminus X''$.

(ii) Assume now that $m < -1$ while all other assumptions of Example 24.2.2(ii) are fulfilled. Again, considering cases

(a) $m_1 \le m-1$ and

(b) $m_1 > m-1$

we arrive to the asymptotics (24.2.17) and $\mathcal{N}^-(\mu, h) = O(h^{-3})$.

Consider now fast increasing μ so that $\mu h \to \infty$. We will get non-trivial results only when domain defined by $\mu_{\text{eff}} h_{\text{eff}} \le C_0$ shrinks but remains non-empty which happens only if $m_1 > 2m$, $m_1 < 2m$ in the frameworks of Example 24.2.3(i) and (ii) respectively.

Example 24.2.4[9]. (i) In the framework of Example 24.2.3(i) with $m_1 > 2m$ consider $\mu h \to \infty$. Then the allowed domain is

$$\{x\colon |x| \lesssim r_2 = (\mu h)^{-1/(m_1-2m)}\} \tag{24.2.20}$$

and we have $r_1 \le r_2$ if $\mu \lesssim h^{-(m_1+1-m)/(m+1)}$ while for $\mu \gtrsim h^{-(m_1+1-m)/(m+1)}$ inequalities go in the opposite direction.

Therefore as $h \to +0$, $ch^{-1} \le \mu \le h^{-(m_1+1-m)/(m+1)}$ asymptotics

$$\mathsf{N}^-(\mu, h) = \mathcal{N}^-(\mu, h) + O(\mu^{-2(m+1)/(m_1-2m)} h^{-2(m_1+1-m)/(m_1-2m)}) \tag{24.2.21}$$

holds and one can see easily that $\mathcal{N}^-(\mu, h) \asymp h^{-2} r_2^{2m+2}$:

$$\mathcal{N}^-(\mu, h) \asymp \mu^{-3(m+1)/(m_1-2m)} h^{-3(m_1+1-m)/(m_1-2m)}. \tag{24.2.22}$$

[9] Cf. Example 23.2.5.

(ii) Similarly, in the framework of Example 24.2.3(ii) with $m_1 < 2m$ asymptotics (24.2.21) and (24.2.22) hold as $h \to +0$, $ch^{-1} \le \mu \le h^{-(m_1+1-m)/(m+1)}$.

Improved Remainder Estimates

Let us improve remainder estimates under certain non-periodicity-type assumptions.

Example 24.2.5[10]. (i) In the case of the singularity at 0 with $m > -1$ the contribution to the remainder of the zone $\{x\colon |x| \le \varepsilon\}$ does not exceed σh^{-1} with $\sigma = \sigma(\varepsilon) \to 0$ as $\varepsilon \to +0$. Then the standard arguments imply that under the standard non-periodicity assumption for Hamiltonian billiards[11] with the Hamiltonian

$$a(x,\xi,\mu_0) = \sum_{j,k} g^{jk}(\xi_j - \mu_0 V_j)(\xi_k - \mu_0 V_k) + V(x) \tag{24.2.23}$$

the improved asymptotics

$$\mathsf{N}^-(\mu,h) = \mathcal{N}^-(\mu,h) + \kappa_1 h^{-2} + o(h^{-2}) \tag{24.2.24}$$

holds as $h \to +0$, $\mu \to \mu_0$ where $\kappa_1 h^{-2}$ is the contribution of ∂X calculated as $\mu = \mu_0$.

(ii) Similarly in the case of the singularity at infinity with $m < -1$ under the standard non-periodicity assumption for Hamiltonian billiards[11] with the Hamiltonian (24.2.23) asymptotics (24.2.24) holds as $h \to +0$, $\mu \to \mu_0$.

(iii) In the case of the singularity at 0 with $m < -1$ (and thus $m_1 < 2m$) and $h \to 0$, $\mu h \to 0$ the contributions to the remainder of the zone $\{x\colon |x| \ge \varepsilon^{-1} r_2\}$ with $r_2 = (\mu h)^{-1/(2m-m_1)}$ do not exceed $\sigma h^{-2} r_2^{m+1}$ with $\sigma = \sigma(\varepsilon) \to 0$ as $\varepsilon \to +0$. After scaling $x \mapsto x r_2^{-1}$ etc the magnetic field in the zone $\{x\colon |x| \le \varepsilon^{-1} r_2\}$ becomes strong.

Assume that g^{jk}, V_j, V stabilize to positively homogeneous of degrees $0, m_1+1, 2m$ functions g^{jk0}, V_j^0, V^0 as $x \to 0$: namely, assume that $(23.2.39)_{1-3}$ are fulfilled. Then the standard arguments imply that under the standard non-periodicity assumption for 1-dimensional Hamiltonian

[10] Cf. Example 23.2.7.

[11] On the energy level 0.

movement along magnetic lines (see Subsection 13.7.2) the improved asymptotics

$$\mathsf{N}^-(\mu,h)=\mathcal{N}(\mu,h)+o\bigl(h^{-2}(\mu h)^{-2(m+1)/(m_1-2m)}\bigr) \tag{24.2.25}$$

holds as $h\to+0$, $\mu h\to 0$. Furthermore, if 0 is not an inner point and domain stabilizes to the conical X^0 near it, we need to consider movement along magnetic lines with reflection at ∂X^0 and include into asymptotics the term $\kappa_1 h^{-2}(\mu h)^{-2(m+1)/(m_1-2m)}$ which comes out from the contribution of ∂X^0:

$$\mathsf{N}^-(\mu,h)=\mathcal{N}(\mu,h)+\kappa_1 h^{-2}(\mu h)^{-2(m+1)/(m_1-2m)}+ o\bigl(h^{-2}(\mu h)^{-2(m+1)/(m_1-2m)}\bigr) \tag{24.2.26}$$

(iv) In the case of the singularity at $0\in X$ with $m_1<2m=-2$ the main contribution to the remainder comes from the zone $\{x\colon \varepsilon^{-1}r_2\le |x|\le \varepsilon\}$. After rescaling magnetic field in this zone is strong.

Let stabilization conditions $(23.2.39)_{1,3}$ be fulfilled. Then the standard arguments imply that under the same non-periodicity assumption as in (iii) the improved asymptotics

$$\mathsf{N}^-(\mu,h)=\mathcal{N}(\mu,h)+o(h^{-2}|\log(\mu h)|) \tag{24.2.27}$$

holds as $h\to+0$, $\mu h\to 0$. Furthermore, if 0 is not an inner point and domain near it stabilizes to the conical X^0 near it,

$$\mathsf{N}^-(\mu,h)=\mathcal{N}(\mu,h)+\kappa_1 h^{-2}\log(\mu h)+o(h^{-2}|\log(\mu h)|); \tag{24.2.28}$$

again, an extra term comes out from the contribution of ∂X^0.

Remark 24.2.6. Statements, similar to (iii), (iv) but with the singularity at infinity seem to have impossible conditions.

Power Singularities. II

Let us modify our arguments for the case $\rho_3<1$. Namely, in addition to $(24.2.2)_{1-3}$ we assume that

$$|D^\alpha g^{jk}|\le c\rho_2\gamma^{-|\alpha|},\qquad |D^\alpha F_{jk}|\le c\rho_2\rho_1\gamma^{-|\alpha|}, \tag{24.2.29}_{1,2}$$

$$|D^\alpha \frac{V}{F}|\le c\rho_3\rho^2\rho_1^{-1}\gamma^{-|\alpha|}\qquad \forall \alpha\colon 1\le|\alpha|\le K \tag{24.2.29}_{3}$$

with $\rho_3 \le \rho_2 \le 1$ in the corresponding regions where $\rho, \rho_1, \gamma, \rho_3$ are scaling functions.

Recall that in Chapter 13 operator was reduced to the canonical form with the term, considered to be negligible, of magnitude $\rho_2\mu_{\mathsf{eff}}^{-2N}$. In this case impose non-degeneracy assumptions

$$(24.2.30)^*_k \qquad \sum_{\alpha:|\alpha|\le k} |\nabla^\alpha (v^* + (2n+1)\mu h)|\gamma^{|\alpha|} \ge \epsilon\rho_3\rho^2 \qquad \forall n \in \mathbb{Z}^+$$

and

$$\rho_3 \ge C_0\rho_2(\mu\rho_1\gamma\rho^{-1})^{-N} \tag{24.2.31}$$

where v^* is what this reduction transforms VF^{-1} to and (24.2.31) means that "negligible" terms do not spoil $(24.2.30)^*_k$.

Then according to Chapter 13 the contributions of $B(x,\gamma)$ to the both to the Tauberian remainder and an approximation error do not exceed $C\rho^2\gamma^{-1}h^{-2}$.

Example 24.2.7[12]. (i) Let $0 \in \bar{X}$ be a singular point and let assumptions $(24.2.29)_{1-3}$ be fulfilled with $\gamma = \epsilon_0|x|$, $\rho = |x|^{-m}\bigl(\bigl|\ln|x|\bigr| + 1\bigr)^{\alpha}$, $\rho_1 = |x|^{-2m}\bigl(\bigl|\ln|x|\bigr| + 1\bigr)^{\beta}$, $\rho_2 = 1$ and $\rho_3 = \bigl(\bigl|\ln|x|\bigr| + 1\bigr)^{-1}$.

Assume that

$$m = -1, \beta > \max(\alpha, 2\alpha). \tag{24.2.32}$$

Then (24.2.31) is fulfilled with $N = 1$ and we can replace $(24.2.30)^*_k$ by

$$(24.2.30)_m \qquad \sum_{\alpha:|\alpha|\le k} |\nabla^\alpha (VF^{-1} + (2n+1)\mu h)|\gamma^{|\alpha|} \ge \epsilon\rho_3\rho^2 \qquad \forall n \in \mathbb{Z}^+.$$

Therefore, we conclude that the remainder is $O(R)$ with

$$R := \begin{cases} h^{-2} & \alpha < -\dfrac{1}{2}, \\ h^{-2}|\log(\mu h)| & \alpha = -\dfrac{1}{2}, \\ h^{-2}(\mu h)^{-(2\alpha+1)/(\beta-2\alpha)} & 2\alpha < \beta < 2\alpha + 2. \end{cases} \tag{24.2.33}$$

[12] Cf. Example 23.2.12.

One can see easily that under condition (24.2.16) for $\mu h \le t$ with small enough $t > 0$

$$\mathcal{N}^-(\mu, h) \asymp \begin{cases} h^{-3} & \alpha < -\frac{1}{3}, \\ h^{-3}(|\log(\mu h)| + 1) & \alpha = -\frac{1}{3}, \\ h^{-3}(\mu h)^{-(3\alpha+1)/(\beta-2\alpha)} & \alpha > -\frac{1}{3}. \end{cases} \tag{24.2.34}$$

(ii) Let infinity be a singular point and let conditions $(24.2.29)_{1-3}$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m\big(\log\langle x\rangle + 1\big)^\alpha$, $\rho_1 = \langle x\rangle^{2m}\big(\log\langle x\rangle + 1\big)^\beta$, $\rho_2 = 1$, $\rho_3 = \big(\log\langle x\rangle + 1\big)^{-1}$. Assume that (24.2.32) is fulfilled.

Then all the statements of (i) remain true with the obvious modification: condition (24.2.16) should be replaced by $(24.2.16)^\#$.

Problem 24.2.8. [12] Consider

(i) Case of a singular point at 0, $m < -1$, $\beta > 2\alpha$.

(ii) Case of a singular point at infinity, $m < -1$, $\beta > 2\alpha$.

In both cases $\log(\mathcal{N}^-(\mu, h)h^3) \asymp (\mu h)^{-1/(\beta-2\alpha)}$ and $\log(\mathcal{N}^-(\mu, h)/R^{3/2}) \sim 1$.

Exponential Singularities

Consider now singularities of the exponential type.

Since we assume only that either $0 \in \bar{X}$ or X is a unbounded domain and $\gamma(x) \ll |x|$, it can happen that

$$\operatorname{mes}(\{x \in X\colon |x| \le r\}) \asymp r^n \tag{24.2.35}$$

with $n \ne d$ (more precisely, $n \ge d$ if 0 is a singular point and $n \le d$ is infinity is a singular point). See Figure 11.10 for unbounded domains; for singularity at 0 it is a spike:

Example 24.2.9 [13]. (i) Let $0 \in \bar{X}$ be a singular point and let our standard assumptions be fulfilled with $\gamma = \epsilon_0|x|^{1-\beta}$, $\rho = \exp(a|x|^\beta)$, $\rho_1 = \exp(b|x|^\beta)$ with $\beta < 0$, $b > 2a > 0$.

[13] Cf. Example 23.2.17.

Figure 24.1: Domains of the type (24.2.35)

Then for $\mu h < t$ with a small enough constant $t > 0$

$$\mathsf{N}^-(\mu, h) = \mathcal{N}^-(\mu, h) + O(h^{-2}(\mu h)^{-2a/(b-2a)} |\log(\mu h)|^{(n-1)/\beta}), \tag{24.2.36}$$

$$\mathcal{N}^-(\mu, h) = O(h^{-3}(\mu h)^{-3a/(b-2a)} |\log(\mu h)|^{n/\beta-1}). \tag{24.2.37}$$

(ii) Let infinity be a singular point and let our standard assumptions be fulfilled with $\gamma = \epsilon_0\langle x\rangle^{1-\beta}$, $\rho = \exp(a\langle x\rangle^{\beta})$, $\rho_1 = \exp(b\langle x\rangle^{\beta})$ where $\beta > 0$, $b > 2a > 0$.

Then asymptotics (24.2.36)–(24.2.37) holds.

We leave to the reader the following

Problem 24.2.10. (i) Consider the case of a singular point at 0 and $\gamma = \epsilon_0|x|^{1-\beta}$, $\rho = |x|^m \exp(|x|^{\beta})$, $\rho_1 = |x|^{m_1}\exp(2|x|^{\beta})$, $\rho_2 = 1$, $\rho_3 = |x|^{-\beta}$, $\beta < 0$, $m_1 < 2m$.

(ii) Consider the case of a singular point at infinity and $\gamma = \epsilon_0\langle x\rangle^{1-\beta}$, $\rho = \langle x\rangle^m \exp(\langle x\rangle^{\beta})$, $\rho_1 = \langle x\rangle^{m_1}\exp(2\langle x\rangle^{\beta})$, $\rho_2 = 1$, $\rho_3 = \langle x\rangle^{-\beta}$, $\beta > 0$, $m_1 > 2m$.

We leave to the reader:

Problem 24.2.11. Consider cases of $\mu \to \mu_0 > 0$ and $\mu \to \mu_0 = 0$.

24.2.2 Schrödinger-Pauli Operators

Consider now Schrödinger-Pauli operators, either genuine (0.34) or generalized (13.6.3). The principal difference is that now F does not "tame" singularities of V, on the contrary, it needs to be "tamed" by itself. As a

result there are fewer examples than for the Schrödinger. Also we do not have a restriction $\mu_{\text{eff}} h_{\text{eff}} = O(1)$ which we had in the most of the previous Subsection 24.2.1.

Example 24.2.12[14]. (i) Let 0 be a singular point and let our standard assumptions be fulfilled with $\gamma = \epsilon_0|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$ and let $m > -1$, $2m \ne m_1 > -2$. Then, in comparison with the theory of the previous Subsection 24.2.1, we need to consider also the the zone $\mu_{\text{eff}} h_{\text{eff}} \gtrsim 1$, and also a singular zone where $h_{\text{eff}} \gtrsim 1$.

The contribution to the remainder of the regular part (defined by $\mu_{\text{eff}} h_{\text{eff}} \gtrsim 1$, $h_{\text{eff}} \lesssim 1$) does not exceed $C\mu h^{-1} \int \rho_1 \gamma^{-1}\, dx$ while its contribution to $\mathcal{N}^-(\mu, h)$ does not exceed $C\mu h^{-2} \int \rho_1 \rho\, dx$. Indeed, contributions of each γ-element do not exceed $C\mu_{\text{eff}} h_{\text{eff}}^{-1} \asymp C\mu h^{-1}\rho_1\gamma^2$ and $C\mu_{\text{eff}} h_{\text{eff}}^{-2} \asymp C\mu h^{-2}\rho_1\rho\gamma^3$.

Consider now the singular zone $\{x\colon |x| \le h^{1/(m+1)}\}$. We claim that

(24.2.38) Contribution of the singular zone to the asymptotics does not exceed $C(\mu h + 1)$.

Indeed, if $\mu h \le 1$ it suffices to apply CLR as in 2D-case. If $\mu h \ge 1$, then CLR returns $\mu^{3/2} h^{1/2}$ and we need to be more tricky. Without any loss of the generality we can assume that $V_1 = 0$ and then apply (variant of) CLR for 1D-operator $h^2 D_1^2 - |x|^{2m}$ and for 2D-operator $h^2|D|^2 - \mu^2|x|^{m_1} - |x|^{2m}$. We leave details to the reader.

$$N^-(\mu, h) = \mathcal{N}^-(\mu, h) + O(\mu h^{-1} + h^{-2}) \tag{24.2.39}$$

with

$$\mathcal{N}^-(\mu, h) = O(\mu h^{-2} + h^{-3}) \tag{24.2.40}$$

where under condition (24.2.16) fulfilled in non-empty cone "$= O(\cdot)$"could be replaced by "$\asymp \cdot$".

(ii) Let infinity be a singular point and let our standard assumptions be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$ and let $m < -1$, $2m \ne m_1 < -2$. Then the same arguments yield (24.2.39)–(24.2.40) again.

We leave to the reader the following problems:

[14] Cf. Example 24.2.2.

Problem 24.2.13. (i) As 0 is a singular point consider both Schrödinger and Schrödinger-Pauli operators as

(a) $\gamma = |x|$, $\rho = |x|^m$, $m > -1$ and $\rho_1 = |x|^{-2}|\log|x||^{\beta}$ [15].

(b) $\gamma = |x|$, $\rho = |x|^{-1}|\log|x||^{\alpha}$, $\alpha < -\frac{1}{2}$ and $\rho_1 = |x|^{m_1}|$, $m_1 > -2$.

(ii) As infinity is a point consider both Schrödinger and Schrödinger Pauli operators as

(a) $\gamma = |x|$, $\rho = |x|^m$, $m < -1$ and $\rho_1 = |x|^{-2}|\log|x||^{\beta}$ [15].

(b) $\gamma = |x|$, $\rho = |x|^{-1}|\log|x||^{\alpha}$, $\alpha < -\frac{1}{2}$ [15] and $\rho_1 = |x|^{m_1}$, $m_1 > -2$.

For the Schrödinger operator in cases (a) non-trivial results could be obtained even as $\mu h \to +\infty$.

Problem 24.2.14. Let either 0 or infinity be a singular point.

Using the same arguments and combining them with the arguments of Subsubsection *24.2.1.6. Power Singularities. II* consider both Schrödinger-Pauli and Schrödinger operators with $\gamma = |x|$, $\rho = |x|^{-1}|\log|x||^{\alpha}$, $\rho_1 = |x|^{-2}|\log|x||^{\beta}$, $\alpha < -\frac{1}{2}$, $\beta < -1$.

For the Schrödinger operator in case $\beta < 2\alpha$ non-trivial results could be obtained even as $\mu h \to +\infty$.

The following problem seems to be rather challenging:

Problem 24.2.15. Investigate $\rho_1 = |x|^{-2}$.

24.2.3 Dirac Operator

Preliminaries

Let us now consider the generalized magnetic Dirac operator (17.1.1) either

$$A = \frac{1}{2}\sum_{l,j} \sigma_l\big(\omega^{jl}P_j + P_j\omega^{jl}\big) + \sigma_0 M + I\cdot V, \qquad P_j = hD_j - \mu V_j \tag{24.2.41}$$

where $\sigma_0, \sigma_1, \sigma_2, \sigma_3$ are 4×4-matrices and $M > 0$ or

$$A = \frac{1}{2}\sum_{l,j} \sigma_l\big(\omega^{jl}P_j + P_j\omega^{jl}\big) + I\cdot V, \qquad P_j = hD_j - \mu V_j \tag{24.2.42}$$

[15] One should take $\beta < -1$ for the Schrödinger-Pauli operator.

where $\sigma_1, \sigma_2, \sigma_3$ are 2×2-matrices and $M = 0$.

We are interested in $\mathsf{N}(\tau_1, \tau_2)$, the number of eigenvalues in (τ_1, τ_2) [16] with $\tau_1 < \tau_2$, fixed in this subsection.

In contrast to 2D-case relations similar to (23.2.73)–(23.2.74) do not matter. Tthe Landau levels (at the point x) are $V \pm \bigl(M^2 + 2j\mu hF\bigr)^{\frac{1}{2}}$ with $j = 0, 1, 2, 3, ...$ and magnetic Dirac operator *always* behaves like Schrödinger-Pauli operator.

Therefore, we treat the operator given by (24.2.41) under the following assumptions

$$(24.2.43)_{1-2} \qquad |D^\alpha \omega^{jk}| \le c\gamma^{-|\alpha|}, \qquad |D^\alpha F| \le c\rho_1\gamma^{-|\alpha|},$$

$$(24.2.43)_{3} \qquad |D^\alpha V| \le c\min\bigl(\rho, \frac{1}{M}\rho^2\bigr)\gamma^{-|\alpha|} \qquad (\alpha \ne 0) \quad \forall \alpha\colon |\alpha| \le K,$$

$$(24.2.43)_{4+} \qquad (V - \tau_2 - M)_+ \le c\min\bigl(\rho, \frac{1}{M}\rho^2\bigr),$$

$$(24.2.43)_{4-} \qquad (V - \tau_1 + M)_- \le c\min\bigl(\rho, \frac{1}{M}\rho^2\bigr)$$

and also $(24.2.2)_{1-3}$, (24.2.1) for $g^{jk} = \sum_{l,r} \omega^{jl}\omega^{kr}\delta_{lr}$ and (24.2.4) (with $F > 0$). In what follows $(24.2.43)_4$ means the pair of conditions $(24.2.43)_{4\pm}$.

Moreover, let condition (24.2.6) be fulfilled and

$$(24.2.44) \qquad \bar{X}'' \cap \partial X = \emptyset,$$

$$(24.2.45) \qquad |V_j| \le c\rho, \quad |D_j\omega^{kl}| \le c\rho \qquad \text{in} \quad X''.$$

Finally, we assume that

(24.2.46) Either $\partial X = \emptyset$ or $\mu = O(1)$ and $\partial X \cap X_2' = \emptyset$ (in what follows).

Asymptotics

Example 24.2.16 [17]. (i) Let 0 be an inner singular point and let all the above conditions, be fulfilled with $\gamma = \epsilon_0|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$, $m_1 > 2m$, $m > -1$.

[16] Assuming that this interval does not contain essential spectrum; otherwise $\mathsf{N}(\tau_1, \tau_2) := \infty$. It is more convenient for us to exclude both ends of the segment.

[17] Cf. Example 24.2.12.

Further, let assumption

$$|V| \ge \epsilon \min(\rho, \frac{\rho^2}{M}) \qquad \forall x\colon |x| \le \epsilon \tag{24.2.47}$$

and non-degeneracy condition $(24.2.8)_k$ be fulfilled.

(a) $m < 0$, $\tau_1 < \tau_2$ or

(b) $m > 0$, $M > 0$, $\tau_1 = -M$, $\tau_2 \in (-M, M)$.

Then for $h \to +0$, $1 \le \mu$ asymptotics

$$\mathsf{N}(\tau_1, \tau_2; \mu, h) = \mathcal{N}(\tau_1, \tau_2; \mu, h) + O(\mu h^{-1} + h^{-2}) \tag{24.2.48}$$

holds with $\mathcal{N}$ defined by $(17.1.12)_1$ with $d = 3$, $r = 1$. Moreover, $\mathcal{N}(\tau_1, \tau_2, \mu, h) \asymp \mu h^{-2} + h^{-3}$.

(ii) Let infinity be an inner singular point and let all the above conditions be fulfilled with $\gamma = \epsilon_0 \langle x \rangle$, $\rho = \langle x \rangle^m$, $\rho_1 = \langle x \rangle^{m_1}$, $m_1 < 2m$, $m < -1$.

Further, let assumption

$$|V| \ge \epsilon \min(\rho, \frac{\rho^2}{M}) \qquad \forall x\colon |x| \ge c \tag{24.2.47}^{\#}$$

and non-degeneracy condition $(24.2.8)_k$ be fulfilled. Let $M > 0$, $\tau_1 = -M$, $\tau_2 \in (-M, M)$. Then for $h \to +0$, $1 \le \mu$ asymptotics (24.2.48) holds with $\mathcal{N}$ defined by $(17.1.12)_1$ with $d = 3$, $r = 1$. Moreover, $\mathcal{N}(\tau_1, \tau_2, \mu, h) \asymp \mu h^{-2} + h^{-3}$.

Problem 24.2.17. Generalize results of this section to the odd-dimensional maximal-rank case. In particular, consider power singularities.

24.3 Asymptotics of Large Eigenvalues

In this section we consider the case when μ and h are fixed and we consider the asymptotics of the eigenvalues, tending to $+\infty$ and for Dirac operator also to $-\infty$.

Here we consider the case of the spectral parameter tending to $+\infty$ (and for the Dirac operator we consider $\tau \to -\infty$ as well).

24.3.1 Singularities at the Point

We consider series of example with singularities at the point.

Schrödinger Operator

Example 24.3.1. (i) Let X be a compact domain, $0 \in \bar{X}$ and let conditions $(24.2.2)_{1-3}$ and (24.2.6) be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$, $m_1 < 2m$. Let

$$|F| \ge \epsilon_0 \rho_1 \qquad \text{for } |x| \le \epsilon. \tag{24.3.1}$$

Then for the Schrödinger operator as $\tau \to +\infty$

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(d-1)/2}) \tag{24.3.2}$$

while $\mathcal{N}^-(\tau) \asymp \tau^{d/2}$.

Indeed, we need to consider only case $m_1 \le -2$ (otherwise it is covered by Section 11.2). Assume for simplicity, that $V = 0$ (modification in the general case is trivial). Recall that $\mu_{\mathsf{eff}} = |x|^{m_1+1}\tau^{-1/2}$ and $h_{\mathsf{eff}} = \tau^{-1/2}|x|^{-1}$. Then under week non-degeneracy assumption[18)] contribution to the remainder of any element with $\mu_{\mathsf{eff}} h_{\mathsf{eff}} \le c$ does not exceed $C h_{\mathsf{eff}}^{1-d} = C\tau^{(d-1)/2}\gamma^{d-1}$ while contribution to the remainder of the γ-element $\mu_{\mathsf{eff}} h_{\mathsf{eff}} \ge c$ does not exceed $C\mu_{\mathsf{eff}}^{-s} h_{\mathsf{eff}}^{-d-s}$ and the rest is easy. Without non-degeneracy assumption we need to add to the contribution of the γ-element $C\mu_{\mathsf{eff}} h_{\mathsf{eff}}^{1-d-\delta}$, which after summation results in $O(\tau^{(d-1-\delta')/2})$.

(ii) Under proper assumptions the same proof is valid in the odd-dimensional maximal-rank case.

Let us note that the case $m < -1$, $m_1 \ge m-1$ is covered by Chapter 11; we need to assume that

$$V \ge \epsilon_0 \rho^2 \qquad \text{as } |x| \le \epsilon. \tag{24.3.3}$$

Example 24.3.2. (i) Let X be a compact domain, $0 \in \bar{X}$ and let conditions $(24.2.2)_{1-3}$, (24.2.6) and $(24.3.1)_1$ be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^m$,

[18)] Which we do not, however, assume fulfilled at this example.

$\rho_1 = |x|^{m_1}$ and with $m < -1$, $2m \le m_1 < m-1$. Then we need to assume that

$$V + F \ge \epsilon_0 \rho^2 \qquad \text{as } |x| \le \epsilon \tag{24.3.3}'$$

which for $m_1 > 2m$ is equivalent to (24.3.3).

By the same reason as in the previous Example 24.3.1 we do not need any non-degeneracy assumption. Then asymptotics (24.3.2) holds while $\mathcal{N}^-(\tau) \asymp \tau^{d/2}$.

(ii) Under proper assumptions the same proof is valid in the odd-dimensional maximal-rank case.

Schrödinger-Pauli Operator

Next, consider Schrödinger-Pauli operators. We will need to impose (24.3.3) and the related non-degeneracy assumption

$$\sum_{\alpha: 1 \le |\alpha| \le k} |\nabla^\alpha V| \gamma^{|\alpha|} \ge \epsilon \rho^2 \qquad \text{as } |x| \le \epsilon \tag{24.3.4}_k$$

Example 24.3.3. (i) Let X be a compact domain, $0 \in \bar{X}$ and let conditions $(24.2.2)_{1-3}$, (24.2.6), (24.3.1), (24.3.3) and $(24.3.4)_k$ be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$, $m < -1$.

Then for the Schrödinger-Pauli operator as $\tau \to +\infty$ asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(m_1+2)/(2m)} + \tau) \tag{24.3.5}$$

holds while

$$\mathcal{N}^-(\tau) \asymp \tau^{(m_1+m+3)/(2m)} + \tau^{3/2}. \tag{24.3.6}$$

Indeed, if $m_1 \ge 2m$ then no modification to the arguments of Examples 24.3.1 and 24.3.2 is needed; if $m_1 < 2m$ we also need to consider the zone where $\mu_{\mathsf{eff}} h_{\mathsf{eff}} \gtrsim 1$.

The contribution of the corresponding partition element to the principal part of the asymptotics is $\mu_{\mathsf{eff}} h_{\mathsf{eff}}^{-2}$ while its contribution to the remainder is $O(\mu_{\mathsf{eff}} h_{\mathsf{eff}}^{-1})$; also, zone $\{x\colon |x| \le \epsilon \tau^{1/(2m)}\}$ is forbidden.

(ii) Without condition $(24.3.4)_k$ one needs to add $\mu_{\mathsf{eff}} h_{\mathsf{eff}}^{-1-\delta}$ to the contribution of the partition element to the remainder; it does not affect the remainder estimate $O(\tau)$ if $m_1 > 2m+2$; if $m_1 \le 2m+2$ we arrive to the remainder estimate $O(\tau^{(m_1+2)/(2m)+\delta})$.

(iii) One can generalize this example to the odd-dimensional maximal-rank case; then

$$\mathcal{N}^-(\tau) \asymp \tau^{(m_1+m+3)(d-1)/(4m)} + \tau^{d/2} \tag{24.3.7}$$

and the remainder is $O(R)$ with

$$R = \tau^{(m_1+2)(d-1)/(4m)} + \tau^{(d-1)/2}. \tag{24.3.8}$$

Problem 24.3.4. (i) Investigate the case of $\gamma = \epsilon|x|$, $\rho = |x|^{-1}|\log|x||^{\alpha}$, $\alpha > 0$, $\rho_1 = |x|^{m_1}$, $m_1 < -2$.

(ii) Investigate the case of $\gamma = \epsilon|x|$, $\rho = |x|^{-1}|\log|x||^{\alpha}$, $\rho_1 = |x|^{-2}|\log|x||^{\beta}$, $\beta > \alpha > 0$.

The following problem seems to be challenging; we don't know even if $\mathsf{N}^-(\tau) < \infty$ for $\tau > 0$.

Problem 24.3.5. (i) Investigate the case of $\gamma = \epsilon|x|$, $\rho = |x|^{-1}|\log|x||^{\alpha}$, $\alpha \le 0$, $\rho_1 = |x|^{m_1}$, $m_1 < -2$.

(ii) Investigate the case of $\gamma = \epsilon|x|$, $\rho = |x|^{m}$, $\rho_1 = |x|^{m_1}|$, $m_1 < -2$, $-1 < m < 0$.

Miscellaneous Singularities

Consider now miscellaneous singularities in the point.

Example 24.3.6. Let $0 \in \bar{X}$ be a compact domain, and let conditions $(24.2.2)_{1-3}$, (24.2.6) and (24.3.1) be fulfilled with $\gamma = \epsilon|x|^{1-\beta}$, $\rho_1 = \exp(b|x|^{\beta})$, $\beta < 0$, $b > 0$ and with $\rho = \exp(a|x|^{\beta})$ where $b > 2a$. Assume also that

$$\sum_{\alpha:1\le|\alpha|\le k} |\nabla^{\alpha} F|\gamma^{|\alpha|} \ge \epsilon\rho_1 \qquad \text{as } |x| \le \epsilon. \tag{24.3.9}_k$$

(i) Then for the Schrödinger operator $\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau)+O(R)$ with $\mathcal{N}^-(\tau) \asymp \tau^{3/2}$ and

$$R = \begin{cases} \tau & \beta \ge -2, \\ \tau|\log\tau|^{(2+\beta)/\beta} & \beta < -2. \end{cases} \tag{24.3.10}$$

Indeed, this is trivial unless $\beta > -2$. If $\beta \le -2$ we need to take into account that the forbidden zone where $\mu_{\mathsf{eff}} h_{\mathsf{eff}} \ge C_0$ is $\{z\colon |x| \le \epsilon_0 |\log\tau|^{1/\beta}\}$. Then we get the remainder $O(\tau r_*^{2+\beta})$ for $\beta < -2$ and $O(\tau|\log r_*|)$ for $\beta = -2$.

Consider $\beta = -2$. Since $\mu_{\mathsf{eff}} \lesssim 1$ in the zone $\{x\colon |x| \ge r^* := C|\log\tau|^{1/\beta}\}$, we can take $\gamma \asymp |x|^{1-\beta'}$ with $\beta' > -2$ there and the contribution of this zone to the remainder is $O(\tau)$. Meanwhile, the contribution of the zone $\{x\colon r_* \le |x| \le r^*\}$ to the remainder is $O(\tau|\log(r_*/r^*)|) = O(\tau)$.

(ii) Let conditions (24.3.3) and $(24.3.4)_k$ be fulfilled. Then for the Schrödinger-Pauli operator asymptotics $\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(R)$ holds with

$$R = \tau^{b/2a}|\log\tau|^{2/\beta} \tag{24.3.11}$$

and

$$\mathcal{N}^-(\tau) \asymp \tau^{b/2a+1/2}|\log\tau|^{(3-\beta)/\beta}. \tag{24.3.12}$$

(iii) On the other hand, let $a < b \le 2a$ and conditions (24.3.3) and $(24.3.4)_k$ Be fulfilled. Then for both Schrödinger and Schrödinger-Pauli operators $\mathcal{N}^-(\tau) \asymp \tau^{3/2}$ and R is defined by (24.3.10).

Moreover, for $b < 2a$ we do not need the non-degeneracy assumption $(24.3.9)_k$ because in the allowed zone $\{x\colon V(x) \le C\tau\}$ we have $\mu_{\mathsf{eff}} \le h_{\mathsf{eff}}^{\delta-1}$.

Problem 24.3.7. Extend results of Example 24.3.6 to the Dirac operator.

Remark 24.3.8. (i) Observe that the contribution to the remainder of the zone $\{x\colon |x| \le \varepsilon\}$ does not exceed $\varepsilon^\sigma \tau^{(d-1)/2}$ with $\sigma > 0$ in the frameworks of some above examples (sometimes under certain additional assumptions).

Therefore, in these cases under the standard non-periodicity condition to the geodesic flow with reflections from ∂X the asymptotics

$$\mathsf{N}(\tau) = \mathcal{N}(\tau) + \varkappa_1 \tau + o(\tau) \tag{24.3.13}$$

holds with the standard coefficient $\varkappa_1$.

(ii) The similar statement (with τ replaced by τ^2) is true for the Dirac operator.

Problem 24.3.9. In the frameworks of the examples above estimate $|\mathcal{N}^-(\tau) - \kappa_0\tau^{d/2}|$.

Finally, consider the case when the singularity is located on the curve or a surface (or a more general set).

Example 24.3.10. Let $0 \in \bar{X}$ be a compact domain, and let conditions $(24.2.2)_{1-3}$, (24.2.6) and (24.3.1) be fulfilled with $\gamma = \epsilon_0\delta(x)$, $\rho_1 = \delta(x)^m$, $\rho_1 = \delta(x)^{m_1}$ with $m_1 < \min(2m, -2)$ where $\delta(x) = \operatorname{dist}(x, L)$, $m < 0$, L is a set of Minkowski codimension $p > 1$ or a smooth surface; in the latter case we assume also that $(24.3.9)_k$ is fulfilled.

(i) Then for the Schrödinger operator asymptotics (24.3.2) holds for $\tau \to +\infty$ and $\mathcal{N}^-(\tau) \asymp \tau^{3/2}$.

Indeed, using the same arguments as before we can get a remainder estimate $O(\tau)$ if $p > 1$ or $O(\tau|\log\tau|)$ if $p = 1$ but in the latter case we can get rid of logarithm using standard propagation arguments.

(ii) Let also conditions (24.3.3) and $(24.3.4)_k$ be fulfilled. Then for the Schrödinger-Pauli operator asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau + \tau^{(m_1+2-p)/(2m)}) \tag{24.3.14}$$

holds while

$$\mathcal{N}^-(\tau) \asymp \tau + \tau^{(m_1+m+3-p)/(2m)}. \tag{24.3.15}$$

Problem 24.3.11. Extend results of Example 24.3.10 to different types of the singularities along L.

24.3.2 Singularities at iInfinity

Let us consider *unbounded domains:*

Power sSingularities: Schrödinger Operator

Let us start from the power singularities.

Example 24.3.12[19]. (i) Let X be an unbounded domain. Let conditions (24.2.1), (24.2.6), $(24.2.2)_{1-3}$, (24.3.1) and $(24.3.9)_k$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m_1 > 2m$.

Then for the Schrödinger operator the following asymptotics holds:

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(m_1+2)/m_1}) \tag{24.3.16}$$

with

$$\mathcal{N}^-(\tau) \asymp \tau^{3(m_1+2)/(2m_1)}. \tag{24.3.17}$$

The proof is standard.

(ii) Under proper assumptions the similar asymptotics holds in the odd-dimensional maximal-rank case:

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(d-1)(m_1+2)/(2m_1)}) \tag{24.3.18}$$

with

$$\mathcal{N}^-(\tau) \asymp \tau^{d(m_1+2)/(2m_1)}. \tag{24.3.19}$$

Example 24.3.13[20]. (i) Let X be an unbounded domain. Let conditions (24.2.1), (24.2.6), $(24.2.2)_{1-3}$ and $(24.3.1)^\#$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m > 0$, $m - 1 < m_1 \le 2m$.

Let us assume that <u>either</u> $m_1 = 2m$ and

$$V + F \ge \epsilon_0\rho^2 \qquad \text{as} \quad |x| \ge c \tag{24.3.3}^{\#\prime}$$

<u>or</u> $m_1 < 2m$ and

$$V \ge \epsilon_0\rho^2 \qquad \text{as} \quad |x| \ge c \tag{24.3.3}^{\#}$$

Assume that if $m_1 = 2m$ then

$$\tau \ge V + F \implies \sum_{\alpha:1\le|\alpha|\le k} |\nabla(\tau - V)F^{-1}|\gamma^{|\alpha|} \ge \epsilon_0\tau\rho_1^{-1} \qquad \text{as} \quad |x| \ge c. \tag{24.3.20}_k$$

---

[19] Cf. Example 24.3.1.

[20] Cf. Example 24.3.2.

Then for the Schrödinger operator asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(d-1)(m+1)/(2m)}), \tag{24.3.21}$$

holds with

$$\mathcal{N}^-(\tau) \asymp \tau^{d(m+1)/(2m)}. \tag{24.3.22}$$

(ii) Under proper assumptions the similar asymptotics holds in the odd-dimensional maximal-rank case.

Power Singularities: Schrödinger-Pauli Operator

Next, consider Schrödinger-Pauli operators. We will need to impose $(24.3.3)^{\#}$ and the related non-degeneracy assumption

$$\sum_{\alpha:1\le|\alpha|\le k} |\nabla^\alpha V|\gamma^{|\alpha|} \ge \epsilon\rho_1 \qquad \text{as } |x| \ge \epsilon. \tag{24.3.4}$$

Example 24.3.14[21]. Let $(24.3.3)^{\#}$ and $(24.3.4)^{\#}_k$ be fulfilled. Then for the Schrödinger-Pauli operator

(i) In the framework of Example 24.3.12

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(m_1+2)/(2m)}) \tag{24.3.23}$$

with

$$\mathcal{N}^-(\tau) \asymp \tau^{(m_1+m+3)/(2m)}. \tag{24.3.24}$$

(ii) In the framework of Example 24.3.13

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O(\tau^{(m+1)/m}) \tag{24.3.25}$$

with

$$\mathcal{N}^-(\tau) \asymp \tau^{3(m+1)/(2m)}). \tag{24.3.26}$$

(iii) Finally, under proper assumptions one can consider the odd-dimensional maximal-rank case and prove asymptotics with the remainder estimate $O(R)$, with

$$R(\tau) = \begin{cases} \tau^{(d-1)(m_1+2)/(4m)} & m_1 > 2m, \\ \tau^{(d-1)(m+1)/(2m)} & m_1 \le 2m, \end{cases} \tag{24.3.27}$$

[21] Cf. Example 24.3.3.

and

$$\mathcal{N}^-(\tau) \asymp \begin{cases} \tau^{(d-1)(m_1+2)/(4m)+(m+1)/(2m)} & m_1 > 2m, \\ \tau^{d(m+1)/(2m)} & m_1 \le 2m, \end{cases} \tag{24.3.28}$$

Exponential Singularities

Consider now an exponential growth at infinity.

Example 24.3.15. Let X be an unbopunded domain. Let conditions (24.2.1), $(24.2.2)_{1-3}$, (24.2.4), (24.2.6) and $(24.3.9)_k$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle^{1-\beta}$, $\rho = \exp(a\langle x\rangle^{\alpha})$, $\rho_1 = \exp(b\langle x\rangle^{\beta})$, $\beta > 0$ and either $\beta > \alpha$ or $\beta = \alpha$ and $b > 2a > 0$.

(i) Then for the Schrödinger operator the following asymptotics holds:

$$\mathsf{N}^-(\tau) = \mathcal{N}^-(\tau) + O\bigl(\tau|\log\tau|^{(2+\beta)/\beta}\bigr) \tag{24.3.29}$$

with

$$\mathcal{N}^-(\tau) \asymp \tau^{3/2}|\log\tau|^{3/\beta}. \tag{24.3.30}$$

(ii) Let $\alpha = \beta$ and conditions $(24.3.3)^{\#}$ and $(24.3.4)^{\#}_k$ be fulfilled. Then for the Schrödinger-Pauli operator asymptotics holds

$$R(\tau) = \tau^{b/2a}|\log\tau|^{2/\beta} \tag{24.3.31}$$

and

$$\mathcal{N}^-(\tau) \asymp \tau^{(b+a)/2a}|\log\tau|^{3/\beta}. \tag{24.3.32}$$

(iii) On the other hand, let $\beta = \alpha$, $a < b \le 2a$ and conditions $(24.3.3)^{\#}$ and $(24.3.4)^{\#}_k$ Be fulfilled. Then for both Schrödinger and Schrödinger-Pauli operators $\mathcal{N}^-(\tau) \asymp \tau^{3/2}$ and R is defined by (24.3.10).

Moreover, for $b < 2a$ we do not need the non-degeneracy assumption $(24.3.9)_k$ because in the allowed zone $\{x\colon V(x) \le C\tau\}$ we have $\mu_{\mathsf{eff}} \le h_{\mathsf{eff}}^{\delta-1}$.

We leave to the reader

Problem 24.3.16. (i) Consider the Schrödinger-Pauli operators in the same settings as in Example 24.3.15, albeit with ρ of the power growth at infinity.

(ii) Consider the Schrödinger-Pauli operators in the same settings as in Example 24.3.14 albeith with V of the logarithmic growth at infinity (i.e. with $\rho = |\log|x||^{\alpha}$, $\gamma = \epsilon|x|$).

24.4 Asymptotics of Small Eigenvalues

In this section we need to consider first miscellaneous asymptotics (cf. Subsections 23.4.3 and 23.4.4) and only after case of F stabilizing at infinity (cf. Subsections 23.4.1 and 23.4.2).

24.4.1 Miscellaneous Asymptotics

Case $F \gtrsim 1$ as $|x| \to \infty$

In this subsection we consider cases of either $F \to \infty$ or $F \asymp 1$ and $V \to 0$ as $|x| \to \infty$. If $F \to \infty$ the Schrödinger operator either does not have any essential spectrum "at infinity"[22]; if $F \asymp 1$ we do not assume any stabilization conditions so far. Anyway, the Schrödinger operator is not the subject of our analysis, while for the Schrödinger-Pauli and Dirac operators essential spectrum "at infinity" equals $[0,\infty)$ and $(-\infty, M] \cup [M,\infty)$ respectively[23].

Again due to the specifics of the problem we can consider the multidimensional case with minimal modifications. In this case we assume that

(24.4.1) $\mathsf{rank}\, F = 2p$ as $|x| \ge c$ and $f_1 \asymp f_2 \asymp ... \asymp f_p \asymp \rho_1$ as $|x| \ge c$

and

(24.4.2) For each $j \ne k$ either $f_j = f_k$ or $|f_j - f_k| \ge \epsilon\rho_1$ for all $|x| \ge c$.

Let for the Schrödinger-Pauli operator $\mathsf{N}^-(\eta)$ be a number of eigenvalues in $(-\epsilon, -\eta)$ and $\mathsf{N}^+(\eta)$ be a number of eigenvalues in (η, ϵ).

Theorem 24.4.1[24]**.** *Let X be an unbounded domain. Let conditions* (24.2.1), $(24.2.2)_{1-3}$, (24.4.1), (24.4.2) *and* $(24.3.4)_k^{\#}$ *be fulfilled with scaling functions γ, ρ and ρ_1, $\rho \to 0$, $\rho_1 \gtrsim 1$, $\rho_1\gamma/\rho \to \infty$ and $\rho\gamma \to \infty$ as $|x| \to \infty$. Then for the Schrödinger-Pauli operator the following asymptotics holds*

[22] More precisely, the lowest Landau level tends to $+\infty$ as $|x| \to \infty$.

[23] Again, understood in the sense of the Lanfdau levels.

[24] Cf. Theorem 23.4.16.

$\mathsf{N}^-(\eta) = \mathcal{N}^-(\eta) + O(R)$ *where*

$$\mathcal{N}^-(\eta) := (2\pi)^{-d+p}\varpi_{d-2p}\int_{\{x:\,-V(x)\ge\eta\}} f_1 f_2\cdots f_p(-V-\eta)_+^{(d-2p)/2}\sqrt{g}\,dx \tag{24.4.3}$$

and

$$R = C\int_{\{x:\,-V(x)\ge\eta\}} \rho_1^p \rho^{d-2p-1}\gamma^{-1}\,dx + C\int \rho_1^{p-s}\gamma^{-2s}\,dx. \tag{24.4.4}$$

Example 24.4.2. Let X be an unbounded domain. Let conditions (24.2.1), $(24.2.2)_{1-3}$, (24.2.6), (24.4.1), (24.4.2) and $(24.3.4)_k^{\#}$ be fulfilled with scaling functions $\gamma = \epsilon\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $-1 < m < 0 \le m_1$.

Then for the Schrödinger-Pauli operator

$$R = \eta^{(m_1+2)(d-1)/(4m)} \tag{24.4.5}$$

and

$$\mathcal{N}^-(\eta) = O(\eta^{(m_1+2)(d-1)/(4m)+(m+1)/(2m)}). \tag{24.4.6}$$

Further, we can replace "$= O(\cdot)$" by "$\asymp \cdot$ if condition $V \le -\epsilon\rho^2$ is fulfilled in some non-empty cone.

We leave to the reader

Problem 24.4.3. (i) Consider the case of $\gamma = \epsilon\langle x\rangle$, $\rho = \langle x\rangle^{-1}|\log\langle x\rangle|^\alpha$, $\rho_1 = \langle x\rangle^{m_1}$, $m_1 \ge 0$, $\alpha > 0$.

(ii) Consider the case of $\gamma = \epsilon\langle x\rangle$, $\rho = |\log\langle x\rangle|^\alpha$, $\rho_1 = \langle x\rangle^{m_1}$, $m_1 \ge 0$, $\alpha < 0$.

(iii) Consider the case of $\gamma = \langle x\rangle^{1-\beta}$, $\rho_1 = \exp(b\langle x\rangle^\beta)$, $\beta > 0$ while conditions to V, g^{jk} are fulfilled with $\gamma = \epsilon\langle x\rangle$, and either $\rho = \langle x\rangle^{-1}|\log\langle x\rangle|^\alpha$, $\alpha > 0$ or $\rho = |\log\langle x\rangle|^\alpha$, $\alpha < 0$.

Problem 24.4.4. Consider the Dirac operator. In this case $\mathsf{N}^-(\eta)$ is a number of eigenvalues in $(M-\epsilon, M-\eta)$ and $\mathsf{N}^+(\eta)$ is a number of eigenvalues in $(-M+\eta, -M+\epsilon)$, $0 < \eta < \epsilon$, $M > 0$.

Case $F \to 0$ as $|x| \to \infty$

In this subsection we consider cases of $F \to 0$ and $V \to 0$ as $|x| \to \infty$. In this case the essential spectra of the Schrödinger and Schrödinger-Pauli operators are $[0, \infty)$; however, as $V = o(F)$ as $|x| \to \infty$ the Schrödinger operator has only a finite number of the negative eigenvalues and thus is not a subject of our analysis while the Schrödinger-Pauli operator is.

Further, the Dirac operator has its essential spectrum $(-\infty, -M] \cup [M, \infty)$ and we need to assume that $M > 0$.

Theorem 24.4.5 [25]**.** *Let X be an unbounded domain. Let conditions* (24.2.1), $(24.2.2)_{1-3}$, (24.2.6), (24.4.1), (24.4.2) *and* $(24.3.4)_k^{\#}$ *be fulfilled with scaling functions γ, ρ and ρ_1, $\rho \to 0$, $\rho_1 \to 0$, $\rho_1 \rho/\rho^2 \ge C_0$ and $\rho\gamma \to \infty$ as $|x| \to \infty$.*

Then for the Schrödinger-Pauli operator $\mathsf{N}^-(\eta) = \mathcal{N}^-(\eta) + O(R)$ with $\mathcal{N}^-(\eta)$ and R defined by (24.4.3)– (24.4.4).

Example 24.4.6. Let conditions of Theorem 24.4.5 be fulfilled with $\gamma = \langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m < 0$, $\max(2m, -2) < m_1 < 0$.

Then all statements of the Example 24.4.2 remain true.

Example 24.4.7. Let conditions of Theorem 24.4.5 be fulfilled with $\gamma = \epsilon\langle x\rangle$, $\rho_1 = \langle x\rangle^{-2} |\log\langle x\rangle|^{\beta}$, $\rho = \langle x\rangle^{-1} |\log\langle x\rangle|^{\alpha}$ with $0 < 2\alpha < \beta$. Then

$$R = |\log \eta|^{(\beta p + \alpha(d-2p-1)+1)/2} \tag{24.4.7}$$

and $\mathcal{N}^-(\eta) = O(S)$ with

$$S = |\log \eta|^{(\beta p + \alpha(d-2p)+1)/2} \tag{24.4.8}$$

Further, $\mathcal{N}^-(\eta) \asymp S$ if condition $V \le -\epsilon\rho^2$ is fulfilled in some non-empty cone.

We also leave to the reader

Problem 24.4.8. Consider in this framework the Dirac operator. In this case $\mathsf{N}^-(\eta)$ is a number of eigenvalues in $(M - \epsilon, M - \eta)$ and $\mathsf{N}^+(\eta)$ is a number of eigenvalues in $(-M + \eta, -M + \epsilon)$, $0 < \eta < \epsilon$. We need to assume that $M > 0$ and potential $V \sim \rho^2$ at infinity.

[25] Cf. Theorem 24.4.1.

Consider now the case when condition $\rho^2 = o(\rho_1)$ as $|x| \to \infty$ is not fulfilled. Then the results will be similar to those of Section 24.3.

Example 24.4.9. (i) Let X be an unbounded domain with $\mathscr{C}^K$ boundary. Let conditions (24.2.1), $(24.2.2)_{1-3}$, (24.2.6), (24.4.1), (224.4.2) and $(24.3.4)_k^{\#}$ be fulfilled with scaling functions $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $-1 < m < 0$, $m - 1 < m_1 < 2m$.

Then for the Schrödinger and Schrödinger-Pauli operators asymptotics

$$R = \eta^{(m+1)(d-1)/2m} \tag{24.4.9}$$

and

$$S = \eta^{(m+1)(d-1)/2m} \tag{24.4.10}$$

(ii) Similar results hold if $m_1 = 2m$ but as $p = 1$ one needs to assume a non-degeneracy assumption (we leave it to the reader) and for the Schrödinger operator $\mathcal{N}^-(\eta) \asymp S$ provided $V + F \le -\epsilon\rho^2$ in some non-empty cone.

We leave to the reader:

Problem 24.4.10. Consider the case of $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^{-2}|\log x|^{\alpha}$, $\rho_1 = \langle x\rangle^{-2}|\log x|^{\beta}$, $2\alpha \ge \beta > \alpha$.

Problem 24.4.11. Consider in this framework the Dirac operator with $M > 0$.

24.4.2 Case $\operatorname{rank} F_\infty = d - 1$. Fast Decaying Potential

Consider case of stabilization at infinity (cf. Subsection 23.4.1)

$$\mathsf{g} \to \mathsf{g}_\infty, \quad \mathsf{F} \to \mathsf{F}_\infty, \quad V \to 0 \qquad \text{as} \quad |x| \to \infty. \tag{24.4.11}_{1-3}$$

Recall that $\mathsf{F} := (F_{jk})$ with $F_{jk} = \partial_k V_j - \partial_j V_k$, $\mathsf{g} := (g^{jk})$.

Assume now that

$$\operatorname{rank} \mathsf{F}_\infty = 2p \text{ while } d = 2p + 1 \tag{24.4.12}$$

and potential V decays faster than in the previous subsection–at least in the direction of the magnetic field.

Preliminary aAnalysis

Observe first that

(24.4.13) If F and g are constant than without any loss of the generality we can assume that $g^{jk} = \delta_{jk}$ and $\mathsf{Ker}\,\mathsf{F} = \mathbb{R}^{d-2p} \times \{0\}$.

Indeed we can achieve it by a linear change of the coordinates. In the general case under assumption (24.4.12) we can assume that

$$\mathsf{Ker}\,\mathsf{F} = \mathbb{R} \times \{0\} \qquad \text{as} \quad |x| \ge c \tag{24.4.14}$$

and

$$V_1 = 0 \qquad \text{as} \quad |x'| \ge c \tag{24.4.15}$$

where $x = (x_1; x')$. Indeed, we can achieve (24.4.14) by the change of the coordinate system which straightens magnetic lines[26)] and we can achieve 24.4.15) by the gauge transformation.

These two assumptions imply $V_j = v_j(x')$ for $j = 2, \dots, d$ and together with stabilization as $x_1 \to \infty$ we conclude that F is constant. Without any loss of the generality we can assume that

(24.4.16) $\mathsf{g}_\infty = \delta_{jk}$, $F_{jk} = 0$ unless either $j = 2l$, $k = 2l+1$ when $F_{jk} = f_{\infty,l}$, or $j = 2l+1$, $k = 2l$ when $F_{jk} = -f_{\infty,l}$.

(24.4.17) By means of the allowed change of the coordinates[26)] on each magnetic line[27)] $\{x\colon x' = y'\}$ with $|y'| \ge c$ we can achieve

$$g^{jd} = 0 \qquad j = 0, \dots, d. \tag{24.4.18}$$

Remark 24.4.12. One can prove easily that in this reduction V is perturbed by $O(\rho^4\gamma^{-2})$ which would not affect the principal part and an error estimate.

[26)] After this we are allowed only changes $x \mapsto y$ with $y' = y'(x')$ and $y_d = y_d(x)$.

[27)] But not necessarily on all of them in simultaneously.

As (24.4.14), (24.4.15) and (24.4.18) [28] are fulfilled consider 1D-operator on $\mathbb{R} \ni z$

$$\mathcal{L}(y') \coloneqq D_z g^{11}(z;y') D_z + V^*(z;y'), \tag{24.4.19}$$

$$V^*(x) \coloneqq V(x) + \sum_j (f_j(x) - f_\infty). \tag{24.4.20}$$

Let us consider operator for which (24.4.14) and (24.4.15) are fulfilled allowing instead some anisotropy:

$$|\nabla^\alpha (\mathsf{g} - \mathsf{g}_\infty)| = o(\rho^2 \gamma^{-|\alpha'|} \gamma_1^{-\alpha_1}), \tag{24.4.21}_1$$

$$|\nabla^\alpha V| = O(\rho^2 \gamma^{-|\alpha'|} \gamma_1^{-\alpha_1}), \tag{24.4.21}_2$$

$$|\nabla^\alpha F_{jk}| = O(\rho^2 \gamma^{-|\alpha'|} \gamma_1^{-\alpha_1}) \qquad \text{as } |x| \to \infty \quad \forall \alpha \tag{24.4.21}_3$$

with scaling functions

$$\gamma_1(x') \ge 1, \qquad \gamma = \gamma(x') \to \infty \quad \text{as } |x'| \to \infty \tag{24.4.22}_{1-2}$$

$$\rho(x) = \varrho(x') \varrho_1(x_1/\gamma_1) \tag{24.4.23}$$

such that

$$|\nabla \gamma| \le \frac{1}{2}, \qquad |\nabla \gamma_1| \le \frac{1}{2} \gamma_1 \gamma^{-1}, \tag{24.4.24}$$

$$|\varrho_1| \le 1, \qquad \int_{\mathbb{R}} |t| \varrho_1^2(t)\, dt < \infty, \tag{24.4.25}$$

$$|\nabla \varrho| \le \varrho \gamma^{-1}, \qquad |\nabla \varrho_1| \le \varrho_1 \gamma^{-1} \tag{24.4.26}$$

$$\zeta \coloneqq \varrho^2 \gamma_1 \to 0 \qquad \text{as } |x'| \to \infty. \tag{24.4.27}$$

In virtue of Proposition 24.A.1 operator $\mathcal{L}(x')$ has a finite number of negative eigenvalues for all x' and no more than one negative eigenvalue as $|x'| \ge c$; further, under assumption

$$W(x') \coloneqq -\frac{1}{2} \int_{\mathbb{R}} V^*(x_1;x')\, dx_1 > 0 \quad \text{and} \quad W(x') \asymp \zeta \quad \text{as } |x'| \ge c, \tag{24.4.28}$$

[28] Only as $x' = y'$.

there is exactly one negative eigenvalue $\lambda(x')$ and

$$\nabla^{\alpha'}\bigl(\lambda(x')+W(x')^2\bigr)=o(\zeta^2\gamma^{-|\alpha'|}) \tag{24.4.29}$$

while

$$\nabla^{\alpha'}W=O(\zeta\gamma^{-|\alpha'|}) \tag{24.4.30}$$

and

$$\|\nabla^{\alpha}v\|=O(\gamma^{-|\alpha'}\gamma_1^{-\alpha_1}). \tag{24.4.31}$$

Here $v=v(x_1;x')$ is a corresponding eigenfunction.

Main Theorem

The principal result of this subsection is the following theorem:

Theorem 24.4.13. *Let conditions* $(24.4.11)_{1-3}$, (24.4.14), (24.4.15), $(24.4.21)_{1-3}$, $(24.4.22)_{1-2}$, (24.4.24)–(24.4.28) *be fulfilled. Moreover, let*

$$|\nabla W|\ge \epsilon_0\zeta^2\gamma^{-1} \qquad \textit{as}\quad |x|\ge c. \tag{24.4.32}$$

Then

$$|\mathsf{N}^-(\eta)-\mathcal{N}^-(\eta)|\le C\int_{\mathcal{Z}(\eta)}\gamma^{-2}\,dx',+C\int\gamma^{-s}\,dx' \tag{24.4.33}$$

where

$$\mathcal{N}^-(\eta)\coloneqq(2\pi)^{-r}\int_{\{x:\,-\lambda\ge\eta\}} f_{\infty,1}f_{\infty,2}\cdots f_{\infty,r}\,dx' \tag{24.4.34}$$

$\mathcal{Z}(\eta)$ *is* $\epsilon\gamma$*-vicinity of* $\Sigma(\eta)=\{x':\,-\lambda(x')=\eta\}$*; cf.* [34] *of Chapter 23.*

Proof. (a) We know that

$$\mathsf{N}^-(\eta)=\mathsf{N}^-(A-f^*_\infty+\eta)=\mathsf{N}^-(\mathsf{A}_\eta)=\mathsf{Tr}(E_\eta(0)), \tag{24.4.35}$$

where

$$\mathsf{A}_\eta\coloneqq J^{-\frac12}(A-f^*_\infty+\eta)J^{-\frac12} \tag{24.4.36}$$

is a self-adjoint operator in $\mathscr{L}^2(\mathbb{R}^d)$ and $E_\eta(\tau)$ is the spectral projector of this operator and $J\asymp\rho^2$ is such that

$$|\nabla^{\alpha}J|=O(J\gamma^{-|\alpha'|}\gamma_1^{-|\alpha_1|}) \qquad \forall\alpha. \tag{24.4.37}$$

We consider only $\eta > 0$ and for any fixed $\eta > 0$ and τ this projector is finite-dimensional and its Schwartz kernel belongs to $\mathscr{S}(\mathbb{R}^{2d})$ uniformly on $\tau \le \tau_0$. Let us note that

$$((A-f_\infty^*)v, v) \ge (1-\epsilon)((A_\infty - f_\infty^*)v, v) - C\|\rho v\|^2 \qquad \forall v \in \mathscr{C}_0^2(\mathbb{R}^d) \tag{24.4.38}$$

where $(A_\infty - f_\infty^*)$ is non-negative.

Indeed, without any loss of the generality one can assume that

$$A_\infty = D_1^2 + \sum_{1\le j\le p} \big(D_{2j}^2 + (D_{2j+1} + f_j x_{2j})^2\big). \tag{24.4.39}$$

Then

$$A_\infty - f_\infty = D_1^2 + \sum_{1\le j\le p} Z_j^* Z_j \tag{24.4.40}$$

with

$$Z_j = iD_{2j} + (D_{2j+1} + f_j x_{2j}). \tag{24.4.41}$$

On the other hand, $A - A_\infty$ is a linear combination of D_1^2, $D_1 Z_j$, $D_1 Z_j^*$, $Z_j^* Z_k$, $Z_j Z_k^*$, $Z_j Z_k$, $Z_j^* Z_k^*$, Z_j, Z_j^* and 1 with the coefficients β_* satisfying

$$|\nabla^\alpha \beta_*| = O(\rho^2 \gamma^{-|\alpha'|}\gamma_1^{-\alpha_1}) \qquad \forall \alpha. \tag{24.4.42}$$

Then extra terms in (Av, v) do not exceed

$$C\Big(\|\rho D_1 v\|^2 + \sum_j \|\rho Z_j v\|^2 + \sum_j \|\rho Z_j^* v\|^2 + \|\rho v\|^2\Big),$$

where obviously

$$\|\rho Z_j^* v\|^2 \le C\Big(\|\rho Z_j v\|^2 + \|\rho v\|^2\Big).$$

This inequality (24.4.38) immediately yields estimates

$$\|D_1 J^{-\frac12} E_\eta(\tau)\| \le C, \qquad \|Z_j J^{-\frac12} E_\eta(\tau)\| \le C \quad j = 1, \dots, p, \tag{24.4.43}_{1,2}$$

$$\|J^{-\frac12} E_\eta(\tau)\| \le C\eta^{-\frac12}, \qquad \|E_\eta(\tau)\| \le 1 \tag{24.4.43}_{3,4}$$

and therefore

$$\|Z_j^* J^{-\frac12} E_\eta(\tau)\| \le C\eta^{-\frac12}, \quad \|Z_j^* E_\eta(\tau)\| \le C \tag{24.4.43}_{5,6}$$

for operator norms where here and below $\tau \le \tau_0$.

Then one can prove easily that

(24.4.44) Let Q be a product of several factors D_1, $Z_\bullet$ and $Z_\bullet^*$. Then $\|QJ^{-\frac12}E_\eta(\tau)\| \le C$ provided there more of factors D_1, $Z_\bullet$ than of $Z_\bullet^*$, and $\|QJ^{-\frac12}E_\eta(\tau)\| \le C\eta^{-\frac12}$, $\|QE_\eta(\tau)\| \le C$ provided there as many of factors D_1, $Z_\bullet$ as of $Z_\bullet^*$.

Then this claim remains true for Q replaced by $Q' := D_{x'}^\alpha Q$ for any α and then in virtue of the embedding theorem this is also true for the operator norm from $\mathscr{L}^2(\mathbb{R}^d) \mapsto \mathscr{L}^2(\mathbb{R}^d)$ replaced by the operator norm from $\mathscr{L}^2(\mathbb{R}^d) \mapsto \mathscr{L}^2(\mathbb{R})$ taken over any magnetic line $\{x\colon x' = y'\}$ uniformly with respect to y'. In particular,

$$\|D_1 J^{-\frac12}E_\eta(\tau)v\|_{\mathscr{L}^2(\mathbb{R})} \le C\|v\| \qquad \text{and} \qquad \|E_\eta(\tau)v\|_{\mathscr{L}^2(\mathbb{R})} \le C\|v\|$$

and therefore

$$|\bigl(E_\eta(\tau)v\bigr)(x)| \le \underbrace{CJ^{\frac12}(x)\Bigl(J_0^{-\frac12}(x')\gamma_1^{-1} + \langle x_1\rangle^{\frac12}\Bigr)}\,\|v\|$$

with $J_0(x') = \max_{x_1} J(x_1, x')$. So, we estimated the operator norm of $w \to (E_\eta(\tau)w)(x)$ from $\mathscr{L}^2(\mathbb{R}^d)$ to $\mathbb{C}$; therefore

$$|e_\eta(x,x,\tau)| \le CJ(x)\Bigl(J_0^{-1}(x')\gamma_1^{-1} + \langle x_1\rangle\gamma_1^2\Bigr)$$

and therefore $|\int e_\eta(x,x,\tau)\,dx_1| \le C(1+\varrho^2(x')\gamma_1^2) \le C$ due to properties of J, ϱ and ϱ_1. Therefore we have proven:

Proposition 24.4.14. *In the framework of Theorem 24.4.13 and the definitions of J and $e_\eta(x,y,\tau)$,*

$$\int_{|x'|\le r} e_\eta(x,x,\tau)\,dx = O(1)$$

for all $\eta > 0$, $\tau \le \tau_0$ and for any fixed r and τ_0.

Recall that $e_\eta(x,y,\tau)$ is the Schwartz kernel of $E_\eta(\tau)$. So, we only need to treat the contribution of the zone $\{x\colon |x'| \ge r\}$.

(b) Let us fix $y' \in \mathbb{R}^d$ and consider $\psi(x')$, $\psi \in \mathscr{C}_0^K\bigl(B(y', \frac12\gamma)\bigr)$ with $\gamma = \gamma(y')$ such that $|D^\alpha\psi| \le c\gamma^{-|\alpha'|}$ $\forall \alpha' : |\alpha'| \le K$. We want to derive asymptotics of

$$\int \psi(x')e_\eta(x,x,0)\,dx = \int \psi\,\mathsf{Tr}_{\mathbb{H}}\bigl(e_\eta(x',x',0)\bigr)\,dx' = \mathsf{Tr}(\psi E_\eta(0)), \tag{24.4.45}$$

where $\mathsf{e}_\eta(x',y',\tau)$ is the family of operators in $\mathbb{H}$ with Schwartz kernel $e_\eta(x,y,\tau)$. Let us rescale $x'_{\mathsf{new}} = (x'-y')\gamma^{-1}$, $x_{1\mathsf{new}} = x_1\gamma_1^{-1}$. Then we obtain the standard LSSA problem for an operator with an operator-valued symbol, with the semiclassical parameters $h=\gamma^{-1}$ and $h_1=\gamma_1^{-1}$ and with magnetic field intensity parameter $\mu=\gamma$. Recall that the rescaled operator is

$$h_1^2D_1^2 + \sum_{1\le j\le p}\Bigl(h^2D_{2j}^2 + \bigl(hD_{2j+1} - h^{-1}f_jx_{2j}\bigr)^2\Bigr) + \rho^2A', \tag{24.4.46}$$

where $A'=a'(x,h_1D_1,hD',h)$ is an operators with uniformly smooth symbol a' (we consider it more carefully later). Let $U(x,y,t)$ be the Schwartz kernel of the operator $\exp(ih^{-2}t\mathsf{A}_\eta)$. Later we rescale t. Then

$$(h^2D_t - \mathsf{A}_\eta)U=0, \qquad U|_{t=0} = \gamma^{2p}\delta(x-y)I \tag{24.4.47}$$

So let ψ be a γ-admissible partition element. It follows from (24.4.44) that the operator norm (from $\mathscr{L}^2(\mathbb{R}^d)$ to $\mathscr{L}^2(\mathbb{R}^d)$) of $Q\psi E_\eta(\tau)Q^*$ does not exceed C for the operators Q which are products of several factors h_1D_1, $Z_\bullet$ and $Z_\bullet^*$ [29] and there are more factors of h_1D_1, $Z_\bullet$ and than of $Z_\bullet^*$. Then the operator norm of $F_{t\to h^{-2}\tau}\chi_T(t)Q\psi UQ^*$ does not exceed CT for the operators Z listed above where $\chi\in \mathscr{C}_0^K(\mathbb{R})$ is fixed and $T\ge T_0$ with constant $T_0>0$.

Let us apply the transformation $\mathcal{T}=\mathcal{T}_0^{-1}\mathcal{T}_1\mathcal{T}_0$ where $\mathcal{T}_0 = F_{x'''\to h^{-2}\xi'''}$, $x'=(x'',x''')$, $x''=(x_2,x_4,\dots,x_{d-1})$, $x'''=(x_3,x_5,\dots,x_d)$ and the same partition for $\xi'=(\xi'',\xi''')$, and

$$\mathcal{T}_1v(x_2,\xi_3,x_4,\dots,\xi_d) = v(x_2-f_1^{-1}\xi_3,\xi_3,\dots,x_{d-1}-f_p^{-1}\xi_d,\xi_d). \tag{24.4.48}$$

Then instead of hD_{2j} and $(hD_{2j+1}-h^{-1}f_jx_{2j})$ we obtain hD_{2j} and $-h^{-1}x_{2j+1}$ respectively. Let Ψ be the corresponding linear symplectic transformation. Let $\bar U = \mathcal{T}_x\psi' U^t\mathcal{T}_y$ where ψ' is supported in $B(0,1-\epsilon)$ [30] and equals 1 in $B(0,1-2\epsilon)$.

Let us decompose $U(x,y,t)$ in terms of the functions

$$\Upsilon_\varsigma(x'') = h^{-\frac12}v_{\varsigma_1}(x_2h^{-1})h^{-\frac12}v_{\varsigma_2}(x_4h^{-1})\cdots h^{-\frac12}v_{\varsigma_p}(x_{2p}h^{-1}) \tag{24.4.49}$$

and $\Upsilon_\nu(y'')$:

$$\bar U(x,y,t) = \sum_{\varsigma,\nu\in\mathbb{Z}^+}\Upsilon_\varsigma(x'')\Upsilon_\nu(y'')U_{\varsigma\nu}(x_1,x''';y_1,y''';t). \tag{24.4.50}$$

---

[29] Due to (24.4.41) now $Z_j = ihD_{2j} + (hD_{2j+1}+h^{-1}f_jx_{2j})$.

[30] We shifted the coordinate system so that our partition element is supported there.

We make the same decomposition for $E(x,y,\tau)$. Then the above estimates yield that

(24.4.51) The operator norm of $F_{t\to h^{-2}\tau}\chi_T(t)U_{\varsigma\nu}$ does not exceed CT.

Next, the standard ellipticity arguments show that

(24.4.52) The operator norm of[31)] $F_{t\to h^{-2}\tau}\chi_T(t)J^{-\frac12}(x_1)U_{\varsigma\nu}$ does not exceed $C\varrho^{|\varsigma|-1}T$ for $\varsigma\neq 0$, and also the operator norm of $F_{t\to h^{-2}\tau}\chi_T(t)J^{-\frac12}(y_1)U_{\varsigma\nu}$ does not exceed $C\varrho^{|\nu|-1}T$ for $\nu\neq 0$, and, finally, the operator norm of $F_{t\to h^{-2}\tau}\chi_T(t)J^{-\frac12}(x_1)J^{-\frac12}(y_1)U_{\varsigma\nu}$ does not exceed $C\varrho^{|\nu|+|\varsigma|-2}T$ for $\nu\neq 0$ and $\varsigma\neq 0$ and the same is true if we apply $D^k_{x_1}$ and $D^l_{y_1}$.

Moreover, for $\varsigma=\nu=0$ we have

(24.4.53) The operator norm of $F_{t\to h^{-2}\tau}\chi_T(t)D^k_{x_1}J^{-\frac12}(x_1)U_{00}$ does not exceed CT for $k\geq 1$, and also the operator norm of $F_{t\to h^{-2}\tau}\chi_T(t)D^l_{y_1}J^{-\frac12}(y_1)U_{00}$ does not exceed CT for $l\geq 1$, and, finally, the operator norm of

$$F_{t\to h^{-2}\tau}\chi_T(t)D^k_{x_1}D^l_{y_1}J^{-\frac12}(x_1)J^{-\frac12}(y_1)U_{00}$$

does not exceed CT for $k\geq 1$ and $l\geq 1$.

Then

$$\mathsf{Tr}(\psi E)=\sum_{\varsigma,\nu} h^{|\varsigma-\nu|}\,\mathsf{Tr}(\psi_{\varsigma\nu}E_{\varsigma,\nu})+O(h^s) \tag{24.4.54}$$

where we have the original expression on the left-hand side, $\psi_{\varsigma\nu}=\psi_{\varsigma\nu}(x''',h^2D''',h^2)$, $\psi_{\varsigma\varsigma}(x''',\xi''',0)=\psi(x''',\xi''')$. Moreover, $\mathsf{supp}(\psi_{\varsigma\nu})\subset\mathsf{supp}(\psi)$ and one can replace $\psi_{\varsigma\nu}-\delta_{\varsigma\nu}\psi$ by a linear combination of the derivatives of ψ of non-zero order.

[31)] In the obvious situations we do not distinguish operators and their Schwartz kernels.

(c) It follows from Proposition 24.A.1 that operator $(A - f^*_\infty)J^{-1}$ is elliptic outside of $\mathcal{Z}(\eta)$ and then one can prove easily that the total contribution of $\mathbb{R}^d \setminus \mathcal{Z}(\eta)$ to the remainder does not exceed

$$C \int \gamma^{-s}\, dx', \tag{24.4.55}$$

while its contribution to the principal part of asymptotics is given by the Tauberian expression.

(d) From now on ψ' is a partition element in $\mathcal{Z}(\eta)$. Recall that

$$(h^2 D_t - J^{-\frac{1}{2}} A J^{-\frac{1}{2}}) = 0, \qquad U|_{t=0} = \delta(x-y). \tag{24.4.56}$$

and the dual equation with respect to y. Then using ellipticity arguments we can express $U_{\varsigma\nu}$ with $|\varsigma| + |\nu| \ge 1$ via U_{00} via some (h_1, h^2)-pseudodifferential operators (with respect to (x_1, x''')) and h_1^2 and then plugging back into equation we get

$$(h^2 D_t - J_0^{-\frac{1}{2}} A_0 J_0^{-\frac{1}{2}}) = 0, \qquad U_{00}|_{t=0} = M\delta(x-y). \tag{24.4.57}$$

where A_0 differs from $h_1^2 D_1 + V^* + \eta$, with $V^* = V + f^* - f^*_\infty$ by $o(\rho^2)$; from the beginning we could assume that $g^{11} = 1$. Here J_0 and A_0 are (h_1, h^2)-pseudodifferential operators (with respect to (x_1, x'''))-pseudodifferential operators. Let $\hbar := h^2$. Let us observe that in virtue of Proposition 24.A.1 the operator $J_0^{-\frac{1}{2}} A_0 J_0^{-\frac{1}{2}}$ has discrete spectrum in $\mathbb{H}$ and all the eigenvalues of this operator excluding at most one are positive and uniformly disjoint from 0 and there is one (the lowest) eigenvalue $\Lambda = \Lambda(x''', \xi''', \eta)$ which is $O(1)$; moreover, due to (24.4.32) it satisfies the microhyperbolicity condition

$$|\Lambda| + |\nabla \Lambda| \asymp 1. \tag{24.4.58}$$

Then there exists a symbol $q(x''', \xi''', \hbar) : \mathbb{H} \to \mathbb{C} \oplus \mathbb{H}$ such that for the operator $Q = q(x''', \hbar D''', \hbar)$ and for $U' = QU_{00}Q^*$ we obtain separate equations for all four blocks of $U' = \begin{pmatrix} U'_{00} & U'_{01} \\ U'_{10} & U'_{11} \end{pmatrix}$. Moreover, for the blocks U'_{10} and U'_{11} the equations are elliptic for $\tau \le \epsilon_1 \hbar$ and for U'_{10} and U'_{11} this is true for the dual equations. Therefore $U' \equiv \begin{pmatrix} u & 0 \\ 0 & 0 \end{pmatrix}$ with $u = U'_{00}$ and

$$F_{t\to\hbar^{-1}\tau}\chi_T(t)\,\mathsf{Tr}(\psi U) \equiv F_{t\to\hbar^{-1}\tau}\chi_T(t)\,\mathsf{Tr}(\psi'' u) \tag{24.4.59}$$

for $\tau \le \epsilon_0 h^2$, $T \in (h^{-\delta}, \epsilon_0)$ where $\psi'' = \psi''(x''', h'''D''', \hbar)$. We have an equation for u:

$$(\hbar D_t - \Lambda)u = 0 \tag{24.4.60}$$

where Λ is an $\hbar$-pseudodifferential operator. More precisely: due to the microhyperbolicity we conclude that

(24.4.61) The contribution of the partition element to the final answer is given by Tauberian expression with $T = \hbar^{1-\delta}$ with an error $O(1)$.

Therefore, the total contribution of $\mathcal{Z}(\eta)$ to the remainder does not exceed $C \int_{\mathcal{Z}(\eta)} \gamma^{-2}\, dx$ (in the original coordinates).

(e) Employing the method of the successful approximations and picking $\psi = 1$, and we conclude that the final answer is given by (24.4.34) since since $\Lambda < 0 \iff \lambda < -\eta$. We leave easy details to the reader. □

Remark 24.4.15. If $V^*(x) \asymp |x|^{-2}$ then (formally) $W(x') \asymp |x'|^{-1}$ and $\lambda(x') \asymp |x'|^{-2}$ and $\mathcal{N}(\eta) \asymp \eta^{-r}$ as follows from the results of Subsection 24.4.1.

Generalizations

Remark 24.4.16. (i) For the Schrödinger-Pauli operator Theorem 24.4.13 obviously holds albeit with $f^* = f^*_\infty = 0$.

(ii) The same is true for the Dirac operator. The proof is essentially the same. We need to assume that the mass $M \neq 0$, otherwise the spectral gap $(-M, M)$ is empty. Then we consider $\mathsf{N}^-(\eta) = \mathsf{N}(0, M-\eta)$ and $\mathsf{N}^+(\eta) = \mathsf{N}(-M+\eta, 0)$. Instead of 0 we can take any $\bar\tau \in (-M, M)$ which preserves the result modulo $O(1)$.

Let us consider $\mathsf{N}^-(\eta)$. Modulo $O(1)$ it equals to $\tilde{\mathsf{N}}(\eta; -\epsilon_2, 0)$, where $\tilde{\mathsf{N}}(\eta; \tau_1, \tau_2)$ is the number of eigenvalues of the problem

$$(A - M + \eta)v + \tau \mathsf{J} v = 0 \tag{24.4.62}$$

belonging to the interval (τ_1, τ_2) and $\mathsf{J} = \frac{1}{2}(I + \sigma_0)J$ where J was introduced in the proof of Theorem 24.4.13. This problem is equivalent to the problem

$$(\mathcal{A}_\eta - \tau J)w = 0, \qquad \mathcal{A}_\eta = \mathcal{L}^*(2M - \eta - V)^{-1}\mathcal{L} + V + \eta, \tag{24.4.63}$$

where we assume that

$$\sigma_0 = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}, \quad \sigma_j = \begin{pmatrix} 0 & \sigma_j' \\ \sigma_j' & 0 \end{pmatrix}, \quad \sigma_j'^* = \sigma_j' \ (j = 1, \dots, d) \tag{24.4.64}$$

and

$$\mathcal{L} = \sum_{1\le j\le d} \frac{1}{2}(P_k\omega^{jk} + \omega^{jk}P_k)\sigma_j'. \tag{24.4.65}$$

One can easily transform $\mathcal{A}_\eta$ to the form of the Schrödinger-Pauli operator with the metric $\tilde{g}^{jk} = (2M - \eta - V)^{-1}g^{jk}$.

Example 24.4.17. (i) In the standard isotropic case $\gamma_1 = \gamma = \langle x' \rangle$ and as $\rho(x) = \langle x \rangle^l$ with $l < -2$; then for W defined by (24.4.28) satisfies similar conditions with $m = 2l + 1$ and thus we are in the framework of Example 23.4.4.

(ii) However, we can also consider $\rho(x) = \langle x \rangle^l \langle x' \rangle^p$ with $l < -2$; then $m = 2l + 2p + 1$.

(iii) We can also consider faster and slower decaying potentials, as soon as W^2 satisfies conditions imposed on V in Subsection 24.4.1. See Example 23.4.5, Problems 23.4.8 and 23.4.10.

Example 24.4.18. Let us consider the case when at infinity f_j stabilize not to $f_\infty = \mathsf{const}$ but to $f_\infty(\theta)$, $\theta = x'/|x'| \in \mathbb{S}^{d-2}$.

Then as long as other assumptions are fulfilled, we arrive to asymptotics described in Theorem 23.4.13; again, instead of $V(x')$ we have $\Lambda(x')$ in the conditions and in the expression for $\mathcal{N}^-(\eta)$.

Remark 24.4.19. Let us consider an auxiliary operator with potential V which is $\asymp |x_1|^{-2}$ as $x_1 \to \infty$. One can easily prove (see Proposition 24.A.3 below) that if

$$V^* \ge -\frac{1}{4}|x|^{-2} \qquad \forall x\colon |x| \ge C, \tag{24.4.66}$$

then the number of negative eigenvalues is finite and there is no more than one negative eigenvalue if this inequality holds for all x. Moreover, under the conditions

$$V^* \ge (\epsilon - \frac{1}{4})|x|^{-2} \qquad \forall x\colon |x| \ge C \tag{24.4.66}^*$$

and (24.A.12) with arbitrarily small $\epsilon > 0$ all the statements of Proposition 24.A.1 remain true. Furthermore, under condition (24.4.66)*

$$\langle \mathsf{a}v, v\rangle \ge \frac{\epsilon}{2}\|\langle x\rangle^{-1}v\|^2 - C\|\langle x\rangle^{-s}v\|^2 \qquad \forall v \tag{24.4.67}$$

with arbitrarily large s. Therefore we can cover the case

$$\rho(x) = \langle x\rangle^{-2}\langle x'\rangle^{p+2}, \qquad p < -1 \tag{24.4.68}$$

provided

$$V^* \ge (\epsilon - \frac{1}{4})|x|^{-2} \qquad \forall x\colon |x_1| \ge c|x'| \tag{24.4.69}$$

with arbitrarily small $\epsilon > 0$. The remainder estimate is the same $O(1)$ as above. The details are left to the reader.

Remark 24.4.20. Let $\mathsf{rank}\,\mathsf{F}(x) = 2r \le d-2$ (as $|x| \ge c$). Then the auxiliary operator is $(d-2r)$-dimensional and does not have negative eigenvalues at all in the assumptions of this subsection.

Then one can prove easily that $\mathsf{N}^-(\eta) = O(1)$. In particular, if $\gamma_1 = \gamma = \langle x'\rangle$ and $\rho = \langle x'\rangle^m$, $\mathsf{N}^-(\eta) = O(1)$ for $m < -1$ (and even for $m = -1$ under assumption (24.4.69) but there is a non-trivial asymptotics for $m > -1$; see Subsection 24.4.3 below.

Possible Generalizations

Consider the case when condition (24.4.28) is not fulfilled. We believe that while the Part (i) is not extremely challenging, the Part (ii) is:

Problem 24.4.21. (i) Prove that the main part of the asymptotics is still given by (24.4.34).

(ii) Prove that (24.4.33) still holds.

24.4.3 Case $\mathsf{rank}\, F_\infty = d-1$. Slow Decaying Potential

Now we consider the case as in the previous Subsection 24.4.2 but we assume that the potential V which either decays slower than x_1^{-2} or as x_1^{-2} but fails condition (24.4.66)*. We only sketch the main arguments.

Main Theorem (Statement)

We assume that

$$(24.4.70)_1 \quad |\nabla^\alpha (\mathsf{g} - \mathsf{g}_\infty)| = o(\rho^2 \langle x'\rangle^{-|\alpha'|} \langle x\rangle^{-\alpha_1}),$$

$$(24.4.70)_2 \quad |\nabla^\alpha V| = O(\rho^2 \langle x'\rangle^{-|\alpha'|} \langle x\rangle^{-\alpha_1}),$$

$$(24.4.70)_3 \quad |\nabla^\alpha (F_{jk} - F_{\infty,jk})| = O(\rho^2 \langle x'\rangle^{-|\alpha'|} \langle x\rangle^{-\alpha_1}) \qquad \text{as } |x| \to \infty \quad \forall \alpha$$

where

$$\rho = \langle x\rangle^{-q} \langle x'\rangle^{m+q} \tag{24.4.71}$$

$q > 0$, $m < 0$. Further, as $m + q = 0$ we assume in addition that

$$(24.4.72)_1 \quad |\nabla^\alpha (\mathsf{g} - \mathsf{g}_\infty)| = O(\rho^2 \langle x'\rangle^{2-|\alpha'|} \langle x\rangle^{-2-\alpha_1}),$$

$$(24.4.72)_2 \quad |\nabla^\alpha V| = O(\rho^2 \langle x'\rangle^{2-|\alpha'|} \langle x\rangle^{-2-\alpha_1}),$$

$$(24.4.72)_3 \quad |\nabla^\alpha (F_{jk} - F_{\infty,jk})| = O(\rho^2 \langle x'\rangle^{2-|\alpha'|} \langle x\rangle^{-2-\alpha_1}) \quad \text{as } |x| \to \infty \quad \forall \alpha' : |\alpha'| \ge 1.$$

Theorem 24.4.22. *Let conditions* $(24.4.70)_{1-3}$ *be fulfilled. Let one of two assumptions be fulfilled:*

(i) $m + q < 0$ *and*

$$-\langle x', \nabla' V^*\rangle \ge \epsilon \rho^2 \qquad \forall x\colon |x'| \ge C_0. \tag{24.4.73}$$

(ii) $m + q = 0$, *conditions* $(24.4.72)_{1-3}$ *be also fulfilled*

$$-\langle x', \nabla' V^*\rangle \ge \epsilon \rho^2 \langle x'\rangle^2 \langle x\rangle^{-2} \qquad \forall x\colon |x'| \ge C_0. \tag{24.4.74}$$

Then

$$\mathsf{N}^-(\eta) = \mathcal{N}^-(\eta) + O(R(\eta)) \tag{24.4.75}$$

with

$$\mathcal{N}^-(\eta) = (2\pi)^{-r} \int \boldsymbol{n}(x',\eta) f_{\infty,1} f_{\infty,2} \cdots f_{\infty,r}\, dx' \tag{24.4.76}$$

and

$$R(\eta) = \int_{\Lambda(\eta)} \bigl(\boldsymbol{n}(x',\eta)+1\bigr)\langle x'\rangle^{-2}\, dx' + \int \gamma^{-s}\, dx' \tag{24.4.77}$$

where $\boldsymbol{n}(x',\eta)$ *is the number of eigenvalues of the operator* $\mathcal{L}(x')$ *which are less than* $-\eta$ *and* $\Lambda(\eta)$ *is* $\epsilon\gamma$*-vicinity of* $\Sigma(\eta) = \{x' \colon \boldsymbol{n}(x',\eta) > 0\}$, $\gamma = \langle x'\rangle$ *and* $\mathcal{L}(x')$ *is defined by* (24.4.19)–(24.4.20).

Proof of Theorem 24.4.22: Propagation of Singularities

Again let us consider the number of negative eigenvalues of operator A_η, defined by (24.4.36) with

$$J(x) = j(x')\langle x\rangle^{-2p}\langle x'\rangle^{2p} \qquad p = \begin{cases} q & \text{if } \ m+q<0,\\ q+1 & \text{if } \ m+q=0 \end{cases} \tag{24.4.78}$$

and γ-admissible function $j(x')$. Let $\rho = \langle x'\rangle^{2m}$. As in the previous Subsection 24.4.2 we consider A_η as operator in $\mathscr{L}^2(\mathbb{R}^{2r},\mathbb{H})$ with $\mathbb{H} = \mathscr{L}^2(\mathbb{R},\mathbb{C})$. As usual after proper scaling $h = \rho^{-1}\gamma^{-1}$ and $\mu = \rho^{-1}\gamma$.

Again let consider the corresponding propagator. Our first goal is to estimate the propagation speed with respect to x' from above and then to estimate it under the microhyperbolicity condition also from below.

Proposition 24.4.23. *Let assumptions* $(24.4.70)_{1-3}$ *be fulfilled with* $m<0$ *and* $0<q\le 1$. *Further, let for* $m+q=0$ *assumptions* $(24.4.72)_{1-3}$ *be fulfilled as well.*

Then the propagation speed with respect to x' *does not exceed* $C_0 j^{-1}\rho^2\gamma^{-1}$ *(before scaling) and therefore singularity initially supported in* $B(y',\frac{1}{2}\bar\gamma)$ *is confined to* $B(y',\gamma)$ *for* $T \le T^* = \epsilon j \rho^{-2}\gamma^2$ *calculated at* y'*:*

$$\bigl\|\!\bigl| F_{t\to h^{-1}\tau}\bar\chi_T(t)\psi(x')(1-\psi_0(y'))u(x,y,t)\bigr|\!\bigr\| \le CT\gamma^{-s} \tag{24.4.79}$$

provided $\psi \in \mathscr{C}_0^\infty B(y',\frac{1}{2}\gamma)$, $\psi_0 \in \mathscr{C}_0^\infty B(y',\gamma)$, $\psi_0 = 1$ *in* $B(y',\gamma)$, $\gamma = \gamma(y')$, $|\tau|\le\epsilon$, $\|\!|\cdot|\!\|$ *is a standard operator norm from* $\mathscr{L}^2(\mathbb{R}^d)$ *to* $\mathscr{L}^2(\mathbb{R}^d)$.

Proposition 24.4.24. *In the framework of Proposition 24.4.23 assume that the microhyperbolicity assumption* (24.4.73) *is fulfilled for* $m+q<0$ *and the microhyperbolicity assumption* (24.4.74) *is fulfilled for* $m+q=0$. *Then the propagation speed with respect to* x' *in an appropriate direction is greater than* $\epsilon_1 j^{-1}\rho^2\gamma^{-1}$ *(before scaling) and therefore*

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma'(u\psi)|\le C\gamma^{d-1}(T/T_*)^{-s}\qquad \text{for } |\tau|\le\epsilon \tag{24.4.80}$$

where, as usual, $\chi\in \mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1])$, $\psi\in \mathscr{C}_0^\infty(B(x',\frac12\gamma(x'))$ *and* $T\in[T_*,T^*]$, $T_*=cj^{-1}\rho^{-2}$ *and* $\gamma=\gamma(y')$.

Proofs of Propositions 24.4.23 and 24.4.24. Standard proofs are left to the reader. We just observe the following:

If $m+q<0$ then due to $(24.4.70)_{1-3}$ and (24.4.78) the drift speed with respect to x' does not exceed $cj^{-1}\rho^2\gamma^{-1}$ (Proposition 24.4.23) and is exactly of this magnitude due to (24.4.73) (Proposition 24.4.23). This is also true for $m+q=0$ due to $(24.4.72)_{1-3}$ and (24.4.78), and (24.4.74). □

Proof of Theorem 24.4.22: Estimates

Now we can use the standard successive approximations method leading us to the estimate

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma'(u\psi)|\le C\gamma^{d-1} \tag{24.4.81}$$

and then to estimate

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma(u\psi)|\le C\gamma^{d-1}N \tag{24.4.82}$$

as $T_*\le T\le T^*$ and $|\tau|\le\epsilon$, where $N=\sup_{B(y',(1+\epsilon)\gamma)}\boldsymbol{n}(x',\eta)$. The latter estimate leads us to the estimate (24.4.77) to the Tauberian error and in the conjugation with successive approximation method to the estimate (24.4.77) itself.

Discussion

Remark 24.4.25. If we replace $\boldsymbol{n}(x',\eta)$ by the corresponding 1D-Weyl expression, we will get

$$\mathsf{N}^-(\eta)=\mathcal{N}^{\mathsf{MW}\,-}(\eta)+O(R(\eta)+R_1(\eta)) \tag{24.4.83}$$

with

$$\mathcal{N}^{\mathsf{MW}-}(\eta) = (2\pi)^{-r} \int (-V^* - \eta)_+^{\frac{1}{2}} / \sqrt{g^{11}} f_{\infty,1} f_{\infty,2} \cdots f_{\infty,r}\, dx \tag{24.4.84}$$

and

$$R_1(\eta) = \int_{\Lambda(\eta)} dx'. \tag{24.4.85}$$

Remark 24.4.26. (i) Obviously $V(x) = -\langle x\rangle^{-2q} U(x')$ with U positively homogeneous of degree $2(m+q)$ satisfies $(24.4.70)_{1-3}$, and for $q+m=0$ it also satisfies $(24.4.72)_{1-3}$.

(ii) Furthermore, if $U \asymp \langle x'\rangle^{2(m+q)}$ this V satisfies (24.4.73) if $q+m<0$ and (24.4.74) if $q+m=0$.

(iii) On the other hand, it does not satisfy (24.4.73) if $q+m>0$.

Example 24.4.27. Let us evaluate magnitudes of $\mathcal{N}^-(\eta)$, $R(\eta)$ and $R_1(\eta)$, defined by (24.4.76), (24.4.77) and (24.4.85). To do this consider $\boldsymbol{n}(x',\eta)$. We are interested only in the case of $0 < q \le 1$ since $q>1$ combined with $m+q \le 0$ would imply $m<-1$ and this is covered by previous Subsection 24.4.2. One can see easily that in this case Theorem 24.4.22 is a special case of Theorem 24.4.13 as $\boldsymbol{n}(x',\eta) \le 1$ for $|x'| \ge c$ and $\boldsymbol{n}(x',\eta) \le C$ as $|x'| \le c$.

Assume that $0<q<1$. Then $\boldsymbol{n}(x',\eta) \asymp \eta^{(q-1)/(2q)} \gamma^{(m+q)/q}$ with $\gamma = \langle x'\rangle$ as $\gamma \le \epsilon \min(\bar\gamma_1, \bar\gamma_2)$ with

$$\bar\gamma_1 = \eta^{(1-q)/(2(m+q))}, \qquad \bar\gamma_2 = \eta^{1/(2m)} \tag{24.4.86}$$

and relying upon Proposition 24.A.4 we conclude that

$$\boldsymbol{n}(x',\eta) \asymp \eta^{(q-1)/(2q)} \gamma^{(m+q)/q} \qquad \text{as } \ \gamma \le \epsilon \min(\bar\gamma_1, \bar\gamma_2) \tag{24.4.87}$$

provided $m+q<0$. On the other hand, obviously $\boldsymbol{n}(x',\eta)=0$ as $\gamma \ge C\bar\gamma_2$. Recall that $m<0$. Observe that $\bar\gamma_1 \ge \bar\gamma_2$ for $\eta \le 1$ if and only if $m \in [-1,0)$.

(a) Let $m \in [-1,0)$. Then (24.4.87) holds as $\gamma \le \epsilon\bar\gamma_2$ and we conclude that

$$\mathcal{N}^-(\eta) \asymp \eta^{(d+m)/(2m)}, \quad R(\eta) \asymp \eta^{(d+m-2)/(2m)}, \quad R_1(\eta) = \eta^{(d-1)/(2m)}. \tag{24.4.88}_{1-3}$$

(b) Let $m < -1$. Then (24.4.87) holds as $\gamma \le \epsilon\bar{\gamma}_1$ and contributions of the zone $\mathcal{X}_0 = \{x\colon |x'| \lesssim \bar{\gamma}_1\}$ to $\mathcal{N}^-(\eta)$ and $R(\eta)$ are respectively of the magnitudes $\eta^{(1-q)(d-1)/2(m+q)}$ and $\eta^{(1-q)(d-3)/2(m+q)}$.

We need to consider the zone $\mathcal{X}_1 := \{x\colon \bar{\gamma}_1 \lesssim |x'| \lesssim \bar{\gamma}_2\}$ separately.

(c) If $1 > q > \frac{1}{2}$ we in virtue of Proposition 24.A.6 $\boldsymbol{n}(x',\eta) \asymp 1$ if $\gamma \le \epsilon\bar{\gamma}_3$ and $\boldsymbol{n}(x',\eta) = 0$ if $\gamma \ge C\bar{\gamma}_3$ with $\bar{\gamma}_3 = \eta^{1/2(2m+1)}$; one can see easily that $\bar{\gamma}_1 \le \bar{\gamma}_3 \le \bar{\gamma}_2$. Then contribution of $\mathcal{X}_1$ to $\mathcal{N}^-(\eta)$ and $R(\eta)$ are of magnitudes $\bar{\gamma}_3^{d-1}$ and $\bar{\gamma}_3^{d-3}$ respectively except the case $d = 3$ when the contribution to $R(\eta)$ is of magnitude $|\log(\eta)|$.

Combining with Statement (b) we conclude that $\mathcal{X}_1$ contributes more to $\mathcal{N}^-(\eta)$ and $R(\eta)$ than $\mathcal{X}_0$ and therefore

$$\mathcal{N}^-(\eta) \asymp \eta^{(d-1)/2(2m+1)}, \quad R(\eta) \asymp \eta^{(d-3)/2(2m+1)} \tag{24.4.89}_{1,2}$$

except the case $d = 3$ when $R(\eta)$ is of magnitude $|\log(\eta)|$. Meanwhile, $R_1(\eta)$ is of the same magnitude as $\mathcal{N}^-(\eta)$.

(d) If $0 < q \le \frac{1}{2}$ then in virtue of Proposition 24.A.8 with $\varepsilon = \gamma^{2(m+q)}$ we conclude that $\boldsymbol{n}(x',\eta) \asymp 1$ if $\gamma \le \epsilon\bar{\gamma}_1$ and $\boldsymbol{n}(x',\eta) = 0$ if $\gamma \ge C\bar{\gamma}_1$. Combining with Statement (b) we conclude that in this case

$$\mathcal{N}^-(\eta) \asymp \eta^{(1-q)(d-1)/2(m+q)}, \quad R(\eta) \asymp \eta^{-(q-1)(d-3)/2(m+q)}. \tag{24.4.90}_{1,2}$$

Meanwhile, $R_1(\eta)$ is of the same magnitude as $\mathcal{N}^-(\eta)$.

Problem 24.4.28. As $d = 3$ derive remainder estimate $O(1)$ in the framework of Example 24.4.27(c). This analysis should be done in the zone $\mathcal{X}_1$ and we need to consider the spectral stripes $\Lambda_k := \{x'\colon \lambda_k(x') \asymp \eta\}$ and zone $\mathcal{X}_1 \setminus (\Lambda_1 \cup \Lambda_2 \cup ... \cup \Lambda_K)$ separately.

Example 24.4.29. (a) If $q > 1$ then $\boldsymbol{n}(x',\eta) \le C\gamma^{m+1}$ with $m + 1 < 0$ since we need to assume that $m + q \le 0$ in virtue Remark 24.4.26(iii) which puts us in the framework of Subsection 24.4.2.

(b) If $q = 1$, $m < -1$ then $\boldsymbol{n}(x',\eta) = 0$ for $|x'| \ge c$ which leads only to the estimate $\mathsf{N}^-(\eta) \le C|\log\eta|$ rather than asymptotics.

(c) Thus, consider $q = 1$, $m = -1$. Then $\boldsymbol{n}(x', \eta) \lesssim \gamma^{m+1} |\log(\gamma/\bar{\gamma})|$ and $\boldsymbol{n}(x', \eta) = 0$ if $\gamma \ge C\bar{\gamma}$, $\bar{\gamma} = \eta^{-1/2}$.

This leads to

$$\mathcal{N}^-(\eta) \lesssim \eta^{-(d-1)/2}, \qquad R(\eta) \asymp \eta^{-(d-3)/2} \tag{24.4.91}_{1,2}$$

again except $d = 3$, in which case $R(\eta) \asymp |\log \eta|^2$. However, under assumption $V \le -C_0 \langle x \rangle^{-2}$ with sufficiently large C_0, we conclude that $\boldsymbol{n}(x', \eta) \asymp \gamma^{m+1} |\log(\gamma/\bar{\gamma})|$ if $\gamma \le \epsilon\bar{\gamma}$ and then $\mathcal{N}^-(\eta) \asymp \eta^{-(d-1)/2}$.

Problem 24.4.30. Let us consider the case $m + q > 0$. In this case we do not have a microhyperbolicity condition and we can apply only more simple and less precise approach of Subsection 24.4.1. So, we leave to the reader to derive the remainder estimate in the following cases:

(a) Let $0 < q < 1$ [32]. Then, exactly as in Example 24.4.27(a) (24.4.87) holds if $\gamma \le \epsilon\bar{\gamma}_2 = \eta^{1/(2m)}$ and $\boldsymbol{n}(x', \eta) = 0$ if $\gamma \ge \bar{\gamma}_2$ and therefore $(24.4.88)_1$ holds.

(b) Let $q = 1$ [32]. Then we have the same magnitude of $\boldsymbol{n}(x', \eta)$ as in Example 24.4.29(c) and $\mathcal{N}^-(\eta) \asymp \eta^{(d+m)/(2m)}$.

(c) Let $q > 1$. Then for $m < -1$ we are in the framework of Subsection 24.4.2, and for $m = -1$ we are either in the framework of that Subsection or close to it.

So, let us assume that $m \in (-1, 0)$. In this case $\boldsymbol{n}(x', \eta) \lesssim \gamma^{m+1}$, $\boldsymbol{n}(x', \eta) \asymp \gamma^{m+1}$ for $\gamma \le \epsilon\bar{\gamma}_2$ and $\boldsymbol{n}(x', \eta) = 0$ for $\gamma \ge C\bar{\gamma}_2$. Then $(24.4.88)_1$ holds.

Finally, we leave to the reader

Problem 24.4.31. Consider the case of $\operatorname{rank} \mathsf{F} = d - 2r \le d - 2$. To do so we need to modify Theorem 24.4.22 in rather obvious way, in this case $x' = (x''; x') = (x_1, \dots, x_n; x_{n+1}, \dots, x_d)$ with $n = d - 2r$ and $\mathcal{L}(x')$ is n-dimensional Schrödinger operator.

[32] And then $m \in (-1, 0)$.

24.5 Multiparameter Asymptotics

In this section we consider asymptotics with respect to three parameters μ, h and τ; here spectral parameter τ tends either to $\pm\infty$ or to the border of the essential spectrum or to $-\infty$ (for Schrödinger and Schrödinger-Pauli operators) or to the border of the spectrum. In two last cases presence of $h \to +0$ is crucial. We consider here only $d = 2$ and $h \ll 1$.

24.5.1 Asymptotics of Large Eigenvalues

In this subsection $\tau \to +\infty$ for the Schrödinger and Schrödinger-Pauli operators and $\tau \to \pm\infty$ for the Dirac operator. We consider the Schrödinger and Schrödinger-Pauli operators, leaving the Dirac operator to the reader.

Example 24.5.1. Assume first that $\psi \in \mathscr{C}_0^\infty$ and there are no singularities on $\mathsf{supp}(\psi)$. We consider

$$\mathsf{N}_\psi^-(\tau) = \int e(x,x,\tau)\psi(x)\,dx. \tag{24.5.1}$$

Then for scaling $A \mapsto \tau^{-1}A$ leads to $h \mapsto h_{\mathsf{eff}} = h\tau^{-1/2}$ and $\mu \to \mu_{\mathsf{eff}} = \mu\tau^{-1/2}$.

(i) If $\mu \lesssim \tau^{1/2}$ then we can apply the standard theory with the "normal" magnetic field; we need to assume that $h \ll \tau^{1/2}$ and we need neither condition $d = 3$, nor $F \ge \epsilon_0$, nor $\partial X = \emptyset$; the principal part of the asymptotics has magnitude $h^{-d}\tau^{d/2}$ and the remainder estimate is $O\big(h^{1-d}\tau^{(d-1)/2}\big)$ which one can even improve to $o\big(h^{1-d}\tau^{(d-1)/2}\big)$ under proper non-periodicity assumption.

(ii) Let $\mu \gtrsim \tau^{1/2}$, $\mu h \lesssim \tau$. Then we can apply the standard theory with the "strong" magnetic field; we assume that $d = 3$ and $F \ge \epsilon_0$. Then the principal part of the asymptotics has magnitude $h^{-3}\tau^{3/2}$ and under weak non-degeneracy assumption (which is needed, only in the case $\mu_{\mathsf{eff}} \le h_{\mathsf{eff}}^{\delta-1}$) fulfilled on $\mathsf{supp}(\psi)$ the remainder estimate is $O(h^{-2}\tau)$ and marginally worse without non-degeneracy assumption

(iii) If $\mu \gtrsim \tau^{1/2}$, $\mu h \ge c\tau$ than $\mathsf{N}^-(\tau) = 0$ for the Schrödinger operator; for the Schrödinger-Pauli operator the principal part of the asymptotics has magnitude μh^{-1} and under weak non-degeneracy assumptions the remainder estimate is $O(\mu h^{-1})$.

Example 24.5.2[33]. Let X be an unbounded domain. Let conditions (24.2.1), (24.2.6), $(24.2.2)_{1-3}$, (24.3.1) and $(24.3.9)_k$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $m_1 > 2m$. Consider the Schrödinger operator and assume that

$$(24.5.2)_{1,2} \qquad \tau \ge \mu h, \qquad \tau^{2m-m_1} \le \epsilon(\mu h)^{2m}.$$

Then

$$\mathcal{N}^-(\tau,\mu,h) \asymp \tau^{3(2+m_1)/(2m_1)} h^{-3(1+m_1)/m_1}\mu^{-3/m_1}. \tag{24.5.3}$$

(i) Further, if $\tau \gtrsim \mu^2$, then the zone of the strong magnetic field $\mu_{\mathsf{eff}} = \mu\langle x\rangle^{m_1+1}\tau^{-1/2} \ge C$ is contained in $\{x\colon |x| \ge c\}$ and here we have non-degeneracy condition fulfilled. Then the remainder estimate is $O(R)$ with

$$R = \tau^{(2+m_1)/m_1} h^{-2(1+m_1)/m_1}\mu^{2/m_1}. \tag{24.5.4}$$

(ii) On the other hand, if $\mu^2 \gg \tau$, then the contribution of the zone $\{x\colon |x| \ge c\}$ to the remainder is $O(R)$ with R defined by (24.5.4). The contribution of the zone $\{x\colon |x| \le c\}$ to the remainder is $O(h^{-2}\tau)$ under weak non-degeneracy assumption fulfilled there.

(iii) Let us replace $(24.5.2)_2$ by the opposite inequality, and assume $(24.3.3)^\#$. Then (24.5.3) is replaced by $\mathcal{N}^-(\tau,\mu,h) \asymp h^{-3}\tau^{3(m+1)/(2m)}$ while under non-degeneracy assumption

$$R = h^{-2}\tau^{(m+1)/m}. \tag{24.5.5}$$

Example 24.5.3[34]. In the framework of Example 24.5.2 for the Schrödinger-Pauli operator under assumption $(23.3.3)^\#$

$$\mathcal{N}^-(\tau,\mu,h) \asymp h^{-3}\tau^{3(m+1)/(2m)} + \mu h^{-2}\tau^{(m_1+m+3)/(2m)}. \tag{24.5.6}$$

$$R = h^{-2}\tau^{(m+1)/m} + \mu h^{-1}\tau^{(m_1+2)/(2m)} \tag{24.5.7}$$

We leave to the reader

Problem 24.5.4. Consider the Schrödinger and Schrödinger-Pauli operators with other types of the behaviour at infinity.

Problem 24.5.5. For the Dirac operators derive similar results as $\tau \to \pm\infty$.

[33] Cf. Example 24.3.12.

[34] Cf. Example 24.3.14.

24.5.2 Asymptotics of the Small Eigenvalues

In this subsection for the Schrödinger and Schrödinger-Pauli operators we consider asymptotics of eigenvalues tending to -0.

Example 24.5.6[35]. Let X be an unbounded domain. Let conditions (24.2.1), $(24.2.3)_{1,2}$, $(24.3.1)_1^{\#}$ be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $-1 < m < 0$, $m_1 > m-1$.

Consider the Schrödinger operator and assume that

$$(24.5.8)_{1,2} \qquad 1 \ge \mu h, \qquad |\tau|^{2m-m_1} \le \epsilon(\mu h)^{2m}.$$

Then $\mathcal{N}^-(\tau) = O(h^{-3}|\tau|^{3(m+1)/(2m)})$ as $\tau \to -0$ with "$\asymp$" instead of "$= O$" if condition $V \le -\epsilon\rho^2$ fulfilled in some non-empty cone.

Further, under the non-degeneracy assumption $(24.3.4)_k^{\#}$ the contribution to the remainder of the zone $\{x\colon |x| \ge c\}$ is $O(h^{-2}|\tau|^{(m+1)/m})$.

Example 24.5.7[36]. In the framework of Example 24.5.6 for the Schrödinger-Pauli operator under assumption $(24.3.3)^{\#}$ the contribution to the remainder of the zone $\{x\colon |x| \ge c\}$ is $O(R)$ with

$$R = h^{-2}|\tau|^{(m+1)/m} + \mu h^{-1}|\tau|^{(m_1+2)/(2m)}, \tag{24.5.9}$$

while

$$\mathcal{N}^-(\tau) = O\bigl(h^{-3}|\tau|^{3(m+1)/(2m)} + \mu h^{-2}|\tau|^{(m_1+m+3)/(2m)}\bigr) \tag{24.5.10}$$

with "$\asymp$" instead of "$= O$" if condition $V \le -\epsilon\rho^2$ fulfilled in some non-empty cone.

Problem 24.5.8. Consider the Schrödinger and Schrödinger-Pauli operators if

(i) If condition $(24.5.8)_1$ is violated (then there could be a forbidden zone in the center).

(ii) With other types of the behaviour at infinity.

Problem 24.5.9. Consider the Schrödinger and Schrödinger-Pauli operators in the framework of Subsections 24.4.2 and 24.4.3 if

---

[35] Cf. Example 24.4.2.

[36] Cf. Example 24.4.2.

(i) $\mu h = 1$; then the essential spectrum does not change.

(ii) $\mu h \to \infty$; then the limit of the essential spectrum is $\emptyset$ (for the Schr]"odinger operator) and $[0,\infty)$ (for the Schrödinger-Pauli operator). Consider $\mathsf{N}^-(\eta)$ with $\eta \to 0$.

(iii) $\mu h \to 0$; then the limit of the essential spectrum is $[0,\infty)$ (for both the Schrödinger and Schrödinger-Pauli operators). Consider $\mathsf{N}^-(\eta)$ with $\eta \to 0$.

Problem 24.5.10. For the Dirac operators derive similar results as $M \neq 0$ and $\tau \to M - 0$ and $-M + 0$.

24.5.3 Case of $\tau \to +0$

In this subsection $\tau \to +0$ for the Schrödinger and Schrödinger-Pauli operators and $\tau \to \pm M \pm 0$ for the Dirac operator. Consider the Schrödinger and Schrödinger-Pauli operators first.

Example 24.5.11[37]. Let $V > 0$ everywhere except $V(0) = 0$. Let conditions (24.2.1), $(24.2.2)_{1-3}$ and (24.3.1) be fulfilled with $\gamma = \epsilon_0|x|$, $\rho = |x|^m$, $\rho_1 = |x|^{m_1}$, $m_1 > 2m \geq 0$. Consider the Schrödinger operator and assume that $\tau \to +0$.

(i) Let

$$(24.5.11)_{1,2} \qquad \mu \ll \tau^{(m_1+2)/2} h^{-(m_1+1)}, \qquad \tau^{2m-m_1} \leq \epsilon(\mu h)^{2m}.$$

Then (24.5.3) holds while the remainder estimate is $O(R)$ with defined by (24.5.4).

(ii) Let us replace $(24.5.11)_2$ by the opposite inequality, and assume $(24.3.3)^{\#}$. Then (24.5.3) is replaced by $\mathcal{N}^-(\tau) \asymp h^{-3}\tau^{3(m+1)/(2m)}$ while $R = h^{-2}\tau^{(m+1)/2m}$.

Example 24.5.12[38]. In the framework of Example 24.5.11 for the Schrödinger-Pauli operator under assumption $(24.3.3)^{\#}$ both (24.5.6) and (24.5.7) hold.

We leave to the reader

[37] Cf. Example 24.5.2.
[38] Cf. Example 24.5.3.

Problem 24.5.13[39]. Consider the Schrödinger and Schrödinger-Pauli operators

(i) In the same framework albeit with condition $m_1 > 2m$ replaced by $2m \ge m_1 \ge 0$. Assume that $(24.3.3)^{\#}$ is fulfilled.

Then magnitude of $\mathcal{N}^-(\tau)$ is described in Examples 24.5.11 and 24.5.12. Under proper non-degeneracy assumption (which we leave to the reader to formulate) derive the remainder estimate.

(ii) In the same framework as in (i) albeit in with $m_1 < 0$ (magnetic field is stronger in the center but there is no singularity), in which case the center can become a classically forbidden zone.

(iii) With other types of the behaviour at infinity.

Problem 24.5.14. For the Dirac operators derive similar results as $\tau \to \pm(M+0)$.

24.5.4 Case of $\tau \to -\infty$

In this subsection for the Schrödinger and Schrödinger-Pauli operators we consider asymptotics with $\tau \to -\infty$.

In this subsection for the Schrödinger and Schrödinger-Pauli operators we consider asymptotics of eigenvalues tending to -0.

Example 24.5.15[40]. Let $X \ni 0$ and let conditions (24.2.1), $(24.2.2)_{1-3}$, (24.3.1) and a week non-degeneracy assumption be fulfilled with $\gamma = \epsilon_0\langle x\rangle$, $\rho = \langle x\rangle^m$, $\rho_1 = \langle x\rangle^{m_1}$, $-1 < m < 0$, $m_1 > m-1$.

Consider the Schrödinger operator and assume that

$$(24.5.12)_{1,2} \qquad h \ll |\tau|^{(m+1)/(2m)}, \qquad |\tau|^{m_1-2m} \le \epsilon(\mu h)^{2m}.$$

Then $\mathcal{N}^-(\tau) = O(h^{-3}|\tau|^{3(m+1)/(2m)})$ as $\tau \to -0$ with "$\asymp$" instead of "$= O$" if condition $V \le -\epsilon\rho^2$ as $|x| \le \epsilon$ fulfilled in some non-empty cone and $R = h^{-2}|\tau|^{(m+1)/m}$.

---

[39] Cf. Problem 24.5.4.

[40] Cf. Example 24.4.2.

Example 24.5.16[41]. In the framework of Example 24.5.15 for the Schrödinger-Pauli operator under assumption (24.3.3)$^{\#}$

$$\mathcal{N}^-(\tau) = O\big(h^{-3}|\tau|^{3(m+1)/(2m)} + \mu h^{-2}|\tau|^{(m_1+m+3)/(2m)}\big) \tag{24.5.13}$$

and

$$R = h^{-2}|\tau|^{(m+1)/m} + \mu h^{-1}|\tau|^{(m_1+2)/(2m)}\big) \tag{24.5.14}$$

with "$\asymp$" instead of "$= O$" if condition $V \le -\epsilon\rho^2$ as $|x| \le \epsilon$ fulfilled in some non-empty cone.

Problem 24.5.17. Consider the Schrödinger and Schrödinger-Pauli operators if with other types of the behaviour at 0.

24.A Appendices

24.A.1 1D Schrödinger Operator

Operators of the type we consider here studied by many authors. Related statements could be found in many books, including Chapter XIII, Part 2 of N. Danford and J. T. Schwarz [1], M. S. Birman and M. Z. Solomyak [23] and V. Maz'ya and I. Verbitsky [1].

Proposition 24.A.1. *Let us consider the operator*

$$\boldsymbol{a}_\varepsilon = D_t g_\varepsilon(t) D_t + \varepsilon^{-1} V_\varepsilon(t) \tag{24.A.1}$$

in $\mathbb{H} = \mathscr{L}^2(\mathbb{R})$ *with* $D = D_t$, $V_\varepsilon(x) = V(\frac{x}{\varepsilon})$, *etc.*, $t \in \mathbb{R}$,

$$\epsilon_0 \le g \le c, \quad |V| \le \rho^2, \quad 0 \le \rho \le c, \quad \|\rho\|_{\mathscr{L}^1} + \|\rho^2 t\|_{\mathscr{L}^1} \le c. \tag{24.A.2}$$

Then

(i) The number of negative eigenvalues of the operator $\boldsymbol{a}$ *does not exceed* C_0 *for* $|\varepsilon| \le 1$.

(ii) The number of negative eigenvalues of the operator $\boldsymbol{a}$ *does not exceed* 1 *for* $|\varepsilon| \le \epsilon$ *with a small enough constant* $\epsilon > 0$.

[41] Cf. Example 24.4.2.

(iii) Further, let us assume that

$$W = -\frac{1}{2}\int_{-\infty}^{+\infty} V(t)\,dt \geq \epsilon_0. \tag{24.A.3}$$

Then for $\varepsilon \in (0, \epsilon]$ *there is exactly one negative eigenvalue* $\lambda(\varepsilon)$ *and*

$$-\epsilon_2 \geq \lambda \geq -c_1. \tag{24.A.4}$$

(iv) Furthermore, let us assume that (24.A.3) *holds and*

$$|g - 1| \leq c\rho. \tag{24.A.5}$$

Then

$$|\lambda + W^2| \leq C_0\varepsilon. \tag{24.A.6}$$

(v) Moreover, let us assume that (24.A.3) *holds and that* g *and* V *depend on the parameter* $z \in \Omega$ *and*

$$|D_z^\alpha g| \leq c, \quad |D_z^\alpha V| \leq c\rho^2 \qquad \forall \alpha : |\alpha| \leq K. \tag{24.A.7}$$

Then

$$|D_z^\alpha \lambda| \leq C_0; \tag{24.A.8}$$

moreover, under the condition

$$|D_z^\alpha g| \leq c\rho \qquad \forall \alpha : |\alpha| \leq K \tag{24.A.9}$$

we obtain that

$$|D_z^\alpha(\lambda + W^2)| \leq C_0\varepsilon. \tag{24.A.10}$$

(vi) Finally, let $v \in \mathbb{H}$, $\|v\| = 1$ *be an appropriate eigenfunction of* $\boldsymbol{a}$ *with eigenvalue* λ*. Then*

$$\|D_z^\alpha v\| \leq C_0, \qquad \|D_z^\alpha D_t v\| \leq C_0, \qquad \|D_z^\alpha v\|_\infty \leq C_0, \tag{24.A.11}_{1-3}$$

where $\|.\|_p$ *means the* $\mathscr{L}^p$*-norm and we skip* $p = 2$ *in this notation.*

Proof. Statement (i) follows from the fact that the operator $\rho^s(D_3^2 + 1)^{-s}$ is compact in $\mathbb{H}$ for any $s > 0$.

In order to prove Statement (ii) let us consider the quadratic form $Q(u) = \langle \boldsymbol{a}u, u\rangle$ on the subspace $\mathbb{H}_1 = \{u \in \mathbb{H}, \int_{-\varepsilon}^{\varepsilon} u\,dt = 0\}$ of codimension 1 [42] Obviously $|u(t)| \le 3(|t|+\varepsilon)^{\frac12}\|D_t u\|$ for $u \in \mathbb{H}_1$ and therefore

$$|\langle V_\varepsilon u, u\rangle| \le C_0\varepsilon^2\|D_t^2 u\|^2$$

in virtue of (24.A.2). Then (24.A.2) yields that the quadratic form $Q(u)$ is positive definite on $\mathbb{H}_1$ for $|\varepsilon| \le \sigma_2$ and therefore $\boldsymbol{a}$ has no more than one negative eigenvalue λ. Moreover, for arbitrary $u \in \mathbb{H}$ the inequality $|u(t)| \le \sigma\|D_t u\| + C_\sigma\|u\|$ with arbitrarily small $\epsilon > 0$ yields that

$$|\langle V_\varepsilon u, u\rangle| \le c_0\sigma\varepsilon\|D_t u\|^2 + C_\sigma\varepsilon\|u\|^2$$

and hence $Q(u)$ is uniformly semibounded from below and therefore

$$\lambda \ge -C_0. \tag{24.A.12}$$

Let v be the corresponding eigenfunction with $\|v\| = 1$ (if there exists a negative eigenvalue). Then obviously $|v(t)| \le C_0$ and then $|D_t v(t)| \le C_0$ and hence $|v(t) - v(0)| \le C_0|t|$. Then (24.A.2), (24.A.5) yield that

$$|Q(v) - \bar{Q}(v)| \le C_1\varepsilon$$

for the quadratic form $\bar{Q}(u) = \|D_t u\|^2 - W|u(0)|^2$. Therefore $\lambda \ge \bar{\lambda} - C_1\varepsilon$ where $\bar{\lambda}$ is the lower bound of $\bar{Q}(u)\|u\|^{-2}$ at $\mathbb{H}$.

One can apply the same arguments to the eigenvalues and eigenfunctions of $\bar{Q}$; as a result we obtain that $\bar{\lambda} \ge \lambda - C_1\varepsilon$. On the other hand, one can see easily that $\bar{\lambda} = -\frac14 W^2$ if $W > 0$ (otherwise $\bar{Q}$ is non-negative definite) and $\bar{v}(t) = \frac{W}{2}\exp(-\frac12 W|x|)$ and hence we obtain that for $W > 0$ there is a negative eigenvalue and (24.A.6) holds.

Moreover, if (24.A.5) is violated then one can treat the quadratic form $C_0\|D_t^2\| + \varepsilon^{-1}(V_\varepsilon u, u)$ instead of the original one and since (24.A.4) holds for this form it remains true for the original one.

So all the statements excluding those associated with derivatives on z are proven[43].

[42] One can consider the subspace $\{u \in \mathfrak{D}(\boldsymbol{a}), u(0) = 0\}$ as well.

[43] One can easily prove that for $W < 0$ and small enough ε the operator $\boldsymbol{a}$ is non-negative definite. We think that it would be nice to treat the case $W = 0$. However we are not an expert here.

The proof of (24.A.8), (24.A.11) is standard, due to K. O. Friedrichs [1]. Let these estimates be proven for $|\alpha| \le n$; then applying the operator ∂_z^α with $|\alpha| = n$ to the equation

$$(a - \lambda)v = 0 \tag{24.A.13}$$

we obtain

$$\sum_{\beta \le \alpha} \frac{\alpha!}{\beta!(\alpha-\beta)!}(a-\lambda)^{(\alpha-\beta)}v^{(\beta)} = 0 \tag{24.A.14}$$

with $u^{(\alpha)} = \partial_z^\alpha u$.

Let us multiply this equation by v. Then terms with $v^{(\alpha)}$ disappear and we obtain terms with $|\beta| < n$

$$\langle g_\varepsilon^{(\alpha-\beta)} D_t v^{(\beta)}, D_t v\rangle, \quad \varepsilon^{-1}\langle V_\varepsilon^{(\alpha-\beta} v^{(\beta)}, v\rangle, \quad \lambda^{(\alpha-\beta)}\langle v^{(\beta)}, v\rangle. \tag{24.A.15}$$

Terms of the first and second types are bounded in virtue of $(24.A.11)_2$, $(24.A.11)_3$ respectively for $|\beta| < n$. Terms of the third type are bounded for $\beta \ne 0$ by (24.A.8), $(24.A.11)_1$. Therefore the remaining term

$$-\lambda^{(\alpha)}\|v\|^2$$

should also be bounded and (24.A.8) holds for $|\alpha| = n$. Let us consider equation (24.A.14); we now multiply it by $w = v^{(\alpha)}$. We obtain terms with $|\beta| \le n$

$$\langle g_\varepsilon^{(\alpha-\beta)} v^{(\beta)}, w\rangle, \quad \varepsilon^{-1}\langle V_\varepsilon^{(\alpha-\beta} v^{(\beta)}, w\rangle, \quad \lambda^{(\alpha-\beta)}\langle v^{(\beta)}, w\rangle.$$

For $|\beta| < n$ terms of the first and second type do not exceed $C\|D_t w\|$ and $C\|w\|_\infty$ due to $(24.A.11)_2$, $(24.A.11)_3$. Finally, terms of the third type for $|\beta| < n$ do not exceed $C\|w\|$ due to (24.A.8) and $(24.A.11)_1$. Thus

$$|\langle (a-\lambda)w, w\rangle| \le C\|D_t w\| + C\|w\|$$

because $\|w\|_\infty \le C\|D_t w\| + C\|w\|$. Taking into account that $\lambda \le -\epsilon_0$ we obtain from this inequality that

$$\|D_t w\|^2 + \|w\|^2 \le C\varepsilon^{-1}|\langle V_\varepsilon w, w\rangle| + C. \tag{24.A.16}$$

Let us assume that $v(0) = 1$. Surely, we should reject the condition $\|v\| = 1$ but our above arguments yield that $\|v\| \asymp |v(0)|$. Then $w(0) = 0$ and

$|w(t)| \le |t|^{\frac12}\|D_t w\|$ and therefore $|\langle V_\varepsilon w, w\rangle| \le C\varepsilon^2\|D_t w\|$ and therefore (24.A.16) yields $(24.A.11)_{1,2}$ for $|\alpha| = n$; $(24.A.11)_3$ follows from these estimates.

In order to prove (24.A.10) let us note that equation (24.A.14) and $(24.A.11)_{1-3}$ yield that

$$\|D_z^\alpha D_t v\|_\infty \le C_0 \tag{24.A.11}_4$$

and therefore under condition (24.A.9) terms of the first type in (24.A.15) do not exceed $C\varepsilon$. Moreover,$(24.A.11)_4$ yields that

$$|v(t) - v(0)| \le C_0|t|, \qquad |D_z^\alpha v| \le C_0|t| \quad \forall \alpha \ne 0$$

(because of condition $v(0) = 1$) and therefore terms of the second type in (24.A.15) do not exceed $C\varepsilon$ for $\beta \ne 0$. Moreover, the error does not exceed $C\varepsilon$ if we replace $v(t)$ by $v(0)$ in this term with $\beta = 0$; we then obtain $W^{(\alpha)}|v(0)|^2$ and under additional the restriction $W = \mathsf{const}$ this term vanishes. Then induction on n yields that $|\lambda^{(\alpha)}| \le C_0\varepsilon$ under this restriction. So under this restriction (24.A.10) holds. However one can reduce the general case to the case $W = 1$ by introducing $t' = tW^{-1}$ and multiplying a by W^2. □

Remark 24.A.2. Applying the above results one can find v in the form

$$v = \exp\Big(\int_0^t \phi_\varepsilon(t')dt'\Big)\cdot\big(1 + \varepsilon^2\psi_\varepsilon + ...\big) \tag{24.A.17}$$

where the number of terms depends on m and $\lambda = -W^2 + \mu\varepsilon + \cdots$ with $\partial_t\phi = V$ and one can obtain $\mu \ne 0$ in the generic case; so estimate (24.A.6) is the best possible estimates without this correction term. Therefore (24.4.33) remains true with $\lambda(x')$ replaced by $-W(x')^2$ provided $m \le -2$ and $\rho(x) = \langle x\rangle^m$, $\gamma(x) = \gamma_1(x) = \langle x\rangle$.

For $m > -2$ this is correct with the remainder estimate $O\big(\eta^{(m+2)(2m+1)^{-1}}\big)$ coinciding with the principal part for $m = -1$ (in the framework of Remark 24.4.19).

Proposition 24.A.3. *(i) Under condition* (24.4.66) *the operator $\mathcal{L}$ has a finite number of negative eigenvalues.*

(ii) Moreover, if this condition is fulfilled for all x then there is at most one negative eigenvalue.

(iii) On the other hand, if

$$W \le -(\frac{1}{4}+\epsilon)|x|^{-2} \qquad \forall x\colon x \ge C \tag{24.A.18}$$

then there is an infinite number of negative eigenvalues.

Proof. To prove Statements (i) and (ii) one needs to prove the estimate

$$\|u'\|^2 \ge \frac{1}{4}\||x|^{-1}u\|^2 \qquad \forall u : u(0)=0 \tag{24.A.19}$$

where $\|u\|$ is the $L^2(\mathbb{R}^+)$-norm. However, the left side is equal to

$$\|x^{\frac{1}{2}}\bigl(ux^{-\frac{1}{2}}\bigr)' + \frac{1}{2}x^{-1}u\|^2 = \|x^{\frac{1}{2}}\bigl(ux^{-\frac{1}{2}}\bigr)'\|^2 + \frac{1}{4}\||x|^{-1}u\|^2$$

provided $u = o(x^{\frac{1}{2}})$ as $x \to 0$.

To prove Statement (iii) it is sufficient to prove that the inequality $\|u'\|^2 \le (\frac{1}{4}+\epsilon)\||x|^{-1}u\|^2$ is fulfilled on some subspace of $\mathscr{L}^2([1,\infty))$ of infinite dimension. It is sufficient to prove that for any n this inequality is fulfilled on some function supported in $[L^n, L^{n+1}]$ with sufficiently large L.

Further, due to homogeneity it is sufficient to consider only $n=0$. Substituting $u = x^{\frac{1}{2}}v$, $x = e^t$ we obtain that it is sufficient to fulfill the inequality $\|v'\|^2 \le \epsilon\|v\|^2$ with some v such that $v(0) = v(\log L) = 0$. But this is obvious provided L is large enough. □

24.A.2 1D Schrödinger Operator. II

We consider operator

$$\boldsymbol{b}_\varepsilon = D^2 + \varepsilon V(x) \tag{24.A.20}$$

with

$$|V| \le \rho^2 = \langle x\rangle^{-2q}, \qquad V \le -\epsilon_0\rho^2 \qquad \text{for } |x| \ge c, \tag{24.A.21}$$

$0 < q \le 1$, and $\varepsilon > 0$.

We are interested in $\boldsymbol{n}_\varepsilon(\eta)$, the number of eigenvalues of $\boldsymbol{b}_\varepsilon$ which are less than $-\eta$. Consider first the corresponding Weyl's expression

$$\mathsf{n}^{\mathsf{W}}_\varepsilon(\eta) := (2\pi)^{-1}\int (\varepsilon V(x)-\eta)_+^{\frac{1}{2}}\,dx. \tag{24.A.22}$$

Proposition 24.A.4. *(i) If* $\mathsf{n}_\varepsilon^W(\eta) \ge C_0$ *then* $\boldsymbol{n}_\varepsilon(\eta) \asymp \mathsf{n}^{\mathsf{W}}(\varepsilon,\eta)$.

(ii) If $\mathsf{n}^W(\varepsilon,\eta) \le C_0$ *then* $\boldsymbol{n}\varepsilon(\eta) \le C_1$.

Remark 24.A.5. Obviously $\mathsf{n}_\varepsilon^W(\eta) \asymp \varepsilon^{(2q-1)/2q}\eta^{-(1-q)/2q}$ and $\mathsf{n}_\varepsilon^W(\eta) \le C_0$ if and only if $\eta \ge c_0\varepsilon^{(2q-1)/(1-q)}$.

Proof of Proposition 24.A.3. One can easily prove Statement (i) using our semiclassical theory.

On the other hand, one can easily prove Statement (ii) using variational methods, and covering $\mathbb{R}$ by a finite number of intervals $[L_k, L_{k+1}]$ and $[-L_{k+1}, -L_k,]$ with $k = 1, \dots, n-1$, $[L_n, \infty]$ and $[-\infty, -L_n]$ and $[-L_0, L_0]$ such that $L_{k+1} = \epsilon_0 L_k^q \varepsilon^{-1/2}$, $L_0 = 1$, $L_n \ge c_0\eta^{-1/2q}\varepsilon^{1/2q}$.

We leave the easy details to the reader. □

Now we need to figure out when $\boldsymbol{n}_\varepsilon(\eta) \ge 1$. To do so we need to evaluate the lowest eigenvalue $\lambda(\varepsilon) < 0$ of operator (24.A.20).

Proposition 24.A.6. *Let* $V \in \mathscr{L}^1(\mathbb{R})$ *and* $W > 0$. *Then*

$$\lambda(\varepsilon) = -\varepsilon^2(W^2 + o(1)) \qquad \textit{textas} \quad \varepsilon \to 0 \tag{24.A.23}$$

with W *defined by* (24.A.3).

Remark 24.A.7. (i) Since after scaling $x \mapsto x/\varepsilon$ and multiplication by ε^{-1} with ε operator (24.A.20) becomes (24.A.1), this is consistent with (24.A.6).

(ii) For $V = -\langle x\rangle^{-2q}$ we have $W < \infty$ if and only if $q > \frac{1}{2}$.

Proof of Proposition 24.A.6. (a) We can apply Proposition 24.A.1 for $V \ge 0$, $V = 0$ as $|t| \ge \varepsilon^{-1}$. Therefore $\boldsymbol{b}'_\varepsilon = D^2 + V'(x) \ge -C\varepsilon^2$ where $V' = V(x)$ as $|x| \le t$, $V(x) = 0$ as $|x| \ge t$. Indeed it is true for V replaced by $-C\rho(x)^2$.

Consider $t_n = 2^n$ and consider $V_0(x) = V(x)$ as $|x| \le t_0$, $V_n(x) = V(x)$ as $t_{n-1} \le |x| \le t_n$ and vanishing on all other segments. Consider

$$\sigma_n > 0, \qquad \sum_n \sigma_n \le 1 \tag{24.A.24}$$

Then

$$\boldsymbol{b}_\varepsilon \ge \sum_n \boldsymbol{b}_{n,\varepsilon}, \qquad \boldsymbol{b}_{n,\varepsilon} = \sigma_n D^2 + \varepsilon V_n(x).$$

Scaling $x \mapsto x/t_n$ we have $\boldsymbol{b}_{n,\varepsilon} \mapsto \sigma_n t_n^{-2}\big[D^2 + \sigma_n^{-1}\varepsilon t_n^2 \rho(t_n)^2 U_n(x)\big]$, with $U_n(x) = \rho(t_n)^{-2} V_n(x/t_n)$ and if $\sigma_n^{-1}\varepsilon t_n^2\rho(t_n)^2 \le 1$ we can apply the above estimate to the operator in the brackets. On the other hand, it is greater than $-C\varepsilon\sigma_n^{-1}\rho(t_n)^2$ and we can apply this estimate even without this condition; so we arrive to $\boldsymbol{b}_{n,\varepsilon} \ge \sigma_n^{-1}\varepsilon^2 t_n^2 \rho(t_n)^4$ and therefore $]\boldsymbol{b}_\varepsilon \ge -C\varepsilon^2$ provided

$$\sum_n \sigma_n^{-1}\varepsilon^2 t_n^2 \rho(t_n)^4 \le C_0. \tag{24.A.25}$$

Picking up $\sigma_n = \epsilon_0 t_n \rho(t_n)^2$ we satisfy both (24.A.24) and (24.A.25).

(b) Consider now t such that $t\rho(t)^2 \le \delta^2$. Then $|W_1 - W| \le C\delta^2$ with $W_1 = -\frac{1}{2}\int_{-t}^{t} V(x)\,dx$. Therefore $\boldsymbol{b}_\varepsilon = \boldsymbol{b}_{1,\varepsilon} + \boldsymbol{b}_{2,\varepsilon}$ with $\boldsymbol{b}_{1,\varepsilon} = (1-\delta)D^2 + \varepsilon V_1(x)$, $\boldsymbol{b}_{2,\varepsilon} = \delta D^2 + \varepsilon V_2(x)$. Applying Proposition 24.A.1 to $\boldsymbol{b}_{1,\varepsilon}$ and the results of Part (a) to $\boldsymbol{b}_{2,\varepsilon}$ we conclude that $\boldsymbol{b}_\varepsilon \ge -\varepsilon^2(W^2 + C\delta) \implies \lambda(\varepsilon) \ge -\varepsilon^2(W^2 + C\delta)$.

Similarly, $\boldsymbol{b}_{3,\varepsilon} = (1+\delta)D^2 - V_1(x) \ge \boldsymbol{b}_\varepsilon + \boldsymbol{b}_{4,\varepsilon}$ and applying Proposition 24.A.1 to $\boldsymbol{b}_{3,\varepsilon}$ and the results of Part (a) to $\boldsymbol{b}_{4,\varepsilon}$ we conclude that $\lambda(\varepsilon) \le -\varepsilon^2(W^2 - C\delta)$.

Since we can take $\delta > 0$ arbitrarily small we arrive to (24.A.23). □

Let $0 < q \le \frac{1}{2}$. Then the integral defining W in (24.A.23), diverges (logarithmically, as $q = \frac{1}{2}$).

Proposition 24.A.8. *Let* $0 < q < \frac{1}{2}$. *Then*

(i) $\lambda \ge -\varepsilon^{1/(1-q)}$.

(ii) Assume that $V(x) \sim V^0(x)$ *as* $|x| \to \infty$ *where* $V^0(x) = V_\pm |x|^{-2q}$ *as* $\pm x > 0$. *Let either* $V_+ < 0$ *or* $V_- < 0$ *and let* $\mu < 0$ *be the lowest eigenvalue of the operator* $\boldsymbol{a}^0 = D^2 + V^0(x)$. *Then*

$$\lambda = \varepsilon^{1/(1-q)}(\mu + o(1)) \qquad \text{as} \quad \varepsilon \to 0. \tag{24.A.26}$$

Proof. Observe first that for $0 < q < \frac{1}{2}$ operator $\boldsymbol{a}^0$ is properly defined and semibounded from below and in the framework of Statement (ii) it has an infinite number of negative eigenvalues.

(i) Replacing V by $-C|x|^{-2q}$ and using scaling $x \mapsto c\varepsilon^{-1/2(1-q)}x$ we arrive to operator $\varepsilon^{1/(1-q)}\boldsymbol{a}^0 \ge -C\varepsilon^{1/(1-q)}$. Thus we arrive to Statement (i).

(ii) Observe that in the framework of Statement (ii)

$$b_\varepsilon \ge b_{1,\varepsilon} + b_{2,\varepsilon}$$

with

$$b_{1,\varepsilon} = (1-\delta)D^2 - \varepsilon(V^0(x) + \delta|x|^{-2q}), \qquad b_{1,\varepsilon} = \sigma D^2 - \varepsilon U(x)$$

with arbitrarily small $\sigma > 0$ and U supported in $[-t, t]$ with $t = t(\delta)$. Then $b_{1,\varepsilon} \ge (\mu_1 - C\delta)\varepsilon^{1/(1-q)}$, $b_{2,\varepsilon} \ge C(t,\delta)\varepsilon^2$ and therefore $\lambda(\varepsilon) \ge (\mu_1 - 2C\delta)\varepsilon^2$.

Similarly, one can prove that $\lambda(\varepsilon) \le (\mu_1 + 2C\delta)\varepsilon^2$. Since we can take $\delta > 0$ arbitrarily small we arrive to (24.A.26). □

Problem 24.A.9. (i) Using arguments of the proof of Part (a) of Proposition 24.A.6 prove that if $\int_{\mathbb{R}} \rho^2(x)\,dx = \infty$ then $\lambda(\varepsilon) \ge -C\eta$ where $\eta = \eta(\varepsilon)$ is defined from

$$\eta^{\frac12} = \varepsilon \int_{x:\ \varepsilon\rho(x)^2 \ge \eta} \rho^2(x)\,dx \tag{24.A.27}$$

which is consistent with $\varepsilon^{1/(1-q)}$ in the framework of Proposition 24.A.8 but also works for $\rho(x) = |x|^{-q}|\log|x||^p$ with <u>either</u> $0 < q < \frac12$ <u>or</u> $q = \frac12$, $p \ge -\frac12$.

(ii) Derive asymptotics of $\lambda(\varepsilon)$ in the framework of Statement (i); the most interesting and difficult case seems to be $q = \frac12$.

(iii) Provide a better error estimate in (24.A.23) and (24.A.26).

24.A.3 Examples of Vector Potential

In this Appendix we prove that the results of this Chapter are meaningful. The only questionable part of their conditions is the existence of vector potentials with the given properties of the scalar intensities F and the doubts are only in the three-dimensional case. The construction of a conformal asymptotic Euclidean metric tensor[44] g^{jk} and the construction of a scalar potential V are obvious in all cases and are left to the reader. Analysis of the two-dimensional case is also obvious. In what follows $g^{jk} = \delta^{jk}$.

[44] I.e., a tensor $g^{jk} = \delta^{jk}(1+\varphi)$ with $|1+\varphi| \ge \epsilon > 0$ such that $D^\alpha\varphi = o(\gamma^{-|\alpha|})$ as $|x| \to \infty$ or $|x| \to 0$ for all α.

In what follows $\Lambda_{(2n)}$ be a block-diagonal $2n\times 2n$-matrix with n diagonal 2×2-blocks $\lambda = \left(\begin{smallmatrix} 0 & 1\\ -1 & 0\end{smallmatrix}\right)$ (and non-diagonal blocks 0). Further, let $\Lambda_{(2n+1)}$ be a block-diagonal $(2n+1)\times(2n+1)$-matrix with n diagonal 2×2-blocks λ and 1×1-block and all non-diagonal blocks equal 0.

Lemma 24.A.10. *(i) Let $d = 2n$ and $V_j = (\Lambda x)_j\sigma(|x|)$. Then eigenvalues of (F_{jk}) are $\pm i f_1(x), \dots, \pm i f_n(x)$ with*

$$(24.A.28)_{1,2}\quad f_1(x) = 2\sigma(|x|) + |x|\sigma'(|x|), \qquad f_2(x) = \dots = f_n(x) = 2\sigma(|x|).$$

(ii) Let $d = 2n+1$ and $V_j = (\Lambda x)_j\sigma(|x|)$. Then eigenvalues of (F_{jk}) are $\pm i f_1(x), \dots, \pm i f_n(x), 0$ with $f_2, \dots, f_n$ defined by $(24.A.28)_{1,2}$ and

$$(24.A.29)\qquad f_1(x)^2 = (2\sigma(|x|) + |x'|^2|x|^{-1}\sigma'(|x|))^2 + x_d^2|x'|^2|x|^{-4}\sigma(|x|)'^2,$$

$x' = (x_1, \dots, x_{d-1})$.

Proof. (i) Without any loss of the generality one can assume that $x_j = 0$ for $j = 3, \dots, d$ since we can always reach it by a rotation, commuting with Λ. Then $F_{jk} = 2\sigma\Lambda_{jk}$ if either $j \ge 3$ or $k \ge 3$ and $F_{jk} = (2\sigma + |x|\sigma')\Lambda_{jk}m$ for $j, k \le 2$ which implies Statement (i).

(ii) Without any loss of the generality one can assume that $x_j = 0$ for $j = 3, \dots, d-1$. Then again $F_{jk}(x) = 2\sigma\Lambda_{jk}$ if either $j = 3, \dots, d-1$ or $k = 3, \dots, d-1$ and therefore again $f_2 = \dots = f_n$ are defined by $(24.A.28)_2$.

Meanwhile $F_{12} = (2\sigma + |x'|^2|x|^{-1}\sigma')$, $F_{13} = x_2x_d|x|^{-1}\sigma'$, $F_{12} = -x_1x_d|x|^{-1}\sigma'$, and $f_1^2 = F_{12}^2 + F_{13}^2 + F_{23}^2$ which implies (24.A.29). □

We start from power singularities:

Example 24.A.11. (i) In the framework of Lemma 24.A.10(i) with $\sigma = |x|^m$ $f_1 = (2+m)|x|^m$. In particular, $|f_1| \asymp |x|^m$ if $m \ne -2$.

(ii) In the framework of Lemma 24.A.10(ii) with $\sigma = |x|^m$

$$(24.A.30)\qquad f_1^2 = \big((2 + m|x'|^2|x|^{-2})^2 + m^2|x'|^2x_d^2|x|^{-4}\big)|x|^{2m}.$$

In particular, $|f_1| \asymp |x|^m$ if $m \ne -2$.

Example 24.A.12. In the framework of Lemma 24.A.10(ii) with $\sigma = |x|^m$ let us define $V_d = a|x|^{m+1}$. Again, without any loss of the generality we can assume that $x_j = 0$, $j = 3, \dots, d-1$. In this case the only F_{jk} to change are F_{1d}, F_{2d} (and F_{d1}, F_{d2}) and therefore $f_2, \dots, f_n$ are still defined by $(24.A.28)_2$. One can prove easily that

$$f_1^2 = \bigl((2+m|x'|^2|x|^{-2})^2 + m^2x_d^2|x'|^2|x|^{-4} + (m+1)^2a^2|x'|^2|x|^{-2}\bigr)|x|^{2m}. \tag{24.A.31}$$

In particular, $f_1 \asymp |x|^m$ if $a \neq 0$.

Example 24.A.13. (i) In the framework of Lemma 24.A.10(i) with $\sigma = \langle x\rangle^m$ $f_1 = (2+m|x|\langle x\rangle^{-2})\langle x\rangle^m$. In particular, $|f_1| \asymp |x|^m$ if $m > -2$.

(ii) In the framework of Lemma 24.A.10(ii) with $\sigma = \langle x\rangle^m$

$$f_1^2 = \bigl((2+m|x'|^2\langle x\rangle^{-2})^2 + m^2|x'|^2x_d^2\langle x\rangle^{-4}\bigr)\langle x\rangle^{2m}. \tag{24.A.32}$$

In particular, $f_1 \asymp \langle x\rangle^m$ if $m > -2$.

(iii) In the framework of Lemma 24.A.10(ii) with $\sigma = \langle x\rangle^m$ and $V_d = a\langle x\rangle^{m+1}$

$$f_1^2 = \bigl((2+m|x'|^2\langle x\rangle^{-2})^2 + m^2x_d^2|x'|^2\langle x\rangle^{-4} + (m+1)^2a^2|x'|^2\langle x\rangle^{-2}\bigr)|x|^{2m}. \tag{24.A.33}$$

In particular, $f_1 \asymp \langle x\rangle^m$ if $a \neq 0$.

Consider now power-log singularities.

Example 24.A.14. (i) In the framework of Lemma 24.A.10(i) with $\sigma = |x|^m\ell(x)^\beta$, $\ell(x) = |\log|x|| + C_0$ (with sufficiently large C_0) $f_1 \asymp \sigma$ if $m \neq -2$ and $f_1 = \beta|x|^{-2}\ell^{\beta-1}$ if $m = -2$.

(ii) In the framework of Lemma 24.A.10(ii) with $\sigma = |x|^m\ell(x)^\beta$, $\ell(x) = |\log|x|| + C_0$ (with sufficiently large C_0) $f_1 \asymp \sigma$ if $m \neq -2$.

(iii) In the framework of Lemma 24.A.10(ii) with $\sigma = \langle x\rangle^m$ and $V_d = a|x|^{m+1}\ell(x)^\beta$ $f_1 \asymp \sigma$ if $a \neq 0$.

Example 24.A.15. (i) In the framework of Lemma 24.A.10(i) with $\sigma = \langle x\rangle^m \ell(x)^\beta$, $\ell(x) = \log\langle x\rangle + C_0$ (with sufficiently large C_0) $f_1 \asymp \sigma$ if $m > -2$.

(ii) In the framework of Lemma 24.A.10(ii) with $\sigma = \langle x\rangle^m \ell(x)^\beta$, $\ell(x) = \log\langle x\rangle + C_0$ (with sufficiently large C_0) $f_1 \asymp \sigma$ if $m > -2$.

(iii) In the framework of Lemma 24.A.10(ii) with $\sigma = \langle x\rangle^m \ell(x)^\beta$ and $V_d = a\langle x\rangle^{m+1}\ell(x)^\beta$ $f_1 \asymp \sigma$ if $a \neq 0$.

Consider now exponential potentials.

Example 24.A.16. Let $d = 2$. Then

(i) $V_1 = -x_2|x|^m \exp(|x|^\beta)$, $V_2 = x_1|x|^m \exp(|x|^\beta)$ with $\beta > 0$ provide $f \asymp |x|^{m+\beta-1}\exp(|x|^\beta)$ as $|x| \geq c$.

(ii) The same example with $\beta < 0$ provide $f \asymp |x|^{m+\beta-1}\exp(|x|^\beta)$ as $|x| \leq \epsilon$.

For $d = 3$ we need to be more crafty.

Example 24.A.17. Let $d = 3$.

(i) Consider

$$V_1 = \exp(\nu(x))\cos\big(\psi(x)\big)|x|^m, \tag{24.A.34}_1$$

$$V_2 = \exp(\nu(x))\sin\big(\psi(x)\big)|x|^m, \qquad V_3 = 0 \tag{24.A.34}_{2,3}$$

with $\nu(x) = |x|^\beta$, $\beta > 0$. Then

$$|\nabla^\alpha V_j| \leq c_\alpha \exp(a|x|^\beta)|x|^{(\beta-1)|\alpha|+m} \qquad \forall \alpha \tag{24.A.35}$$

as $|x| \gtrsim 1$ provided $|\nabla\psi| \lesssim |x|^{\beta-1}$. Moreover, one can see easily that

$$F \geq (\epsilon_0 b - C)|x|^{\beta-1+m}\exp(|x|^\beta) \tag{24.A.36}$$

provided $|\partial\psi| \geq b|x|^{\beta-1}$ as $|x| \geq c$. One can take

$$\psi(x', x_3) = \int_0^{x_3} (|x'|^2 + y^2)^{(\beta-1)/2}\, dy, \qquad x' = (x_1, x_2)$$

satisfying these restrictions.

(ii) Similarly, for $\beta < 0$ this constructions work for $|x| \leq \epsilon$.

Consider now quasihomogeneous case. In what follows $L = (l_1, l_2)$ for $d = 2$, $L = (l_1, l_2, l_3)$ for $d = 3$

$$[x]_L = \Big(\sum_j x_j^{2n/l_j}\Big)^{1/2n} \tag{24.A.37}$$

is L-quasihomogeneous length, and n is large so functions are smmoth in $\mathbb{R}^d \setminus 0$.

Example 24.A.18. (i) Let $d = 2$ and $L = (l_1, l_2)$ with $1 = l_1 < l_2$. Let

$$V_1 = -ax_2[x]_L^m, \qquad V_2 = x_1[x]_L^m. \tag{24.A.38}$$

Then $F \asymp [x]_L^m$ for $[x]_L \ge c$ provided $m \ne -(1 + l_2)$ and a is properly chosen.

(ii) Let $d = 2$ and $L = (l_1, l_2)$ with $1 = l_1 > l_2 > 0$. Let V_1, V_2 are defined by (24.A.38). Then $F \asymp [x]_L^m$ for $[x]_L \le \epsilon$ provided $m \ne -(1 + l_2)$ and a is properly chosen.

Example 24.A.19. (i) Let $d = 3$ and $L = (l_1, l_2, l_3)$ with $1 = l_1 \le l_2 \le l_3$. Let

$$V_1 = 0, \qquad V_2 = x_1[x]_L^m, \qquad V_3 = x_1[x]_L^{m+1}, \tag{24.A.39}$$

$$V_1 = -x_2[x]_L^m, \qquad V_2 = x_1[x]_L^m, \qquad V_3 = 0 \tag{24.A.40}$$

if $m \ne -1$, $m = -1$ respectively. Then $F \asymp [x]_L^m$ for $[x]_L \ge c$.

(ii) Let $d = 2$ and $L = (l_1, l_2)$ with $1 = l_1 \ge l_2 \ge l_3 > 0$. Let V_1, V_2, V_3 are defined by (24.A.39) or (24.A.39) if $m \ne -1$, $m = -1$ respectively. Then $F \asymp [x]_L^m$ for $[x]_L \le \epsilon$.

Example 24.A.20. Let $d = 3$, $X = (\mathbb{R}^2 \setminus 0) \times \mathbb{R}/\mathbb{Z} \ni (x', x_3) = (x_1, x_2, x_3)$, $m \ne -2$ and

$$V_1 = x_2|x'|^m, \quad V_2 = -x_1|x'|^m, \quad V_3 = a|x'|^{m+2} \tag{24.A.41}$$

positively homogeneous on x' of degrees $m + 1$, $m + 1$, $m + 2$ respectively[45]. Then $F^3 \ne 0$, $|x'| = \mathsf{const}$ along integral curves of the vector field $\frac{1}{F^3}(F^1, F^2, F^3)$ and for irrational a/π these curves are not closed.

[45] Then F^1, F^2, F^3 are positively homogeneous of degrees $m+1$, $m+1$, m respectively.

Part XI

Application to Multiparticle Quantum Theory

Chapter 25

No Magnetic Field Case

25.1 Introduction

The purpose of this Part is to apply semiclassical methods developed in the previous parts to the theory of heavy atoms and molecules. Because of this we combine our semiclassical methods with the traditional methods of that theory, mainly function-analytic.

In this Chapter we consider the case without magnetic field. Next chapters will be devoted to the cases of the self-generated magnetic field, strong external magnetic field and the combined external and self-generated fields. Basically this Chapter should be considered as an introduction.

We explore the ground state energy, an excessive negative charge, ionization energy and excessive negative charge when atoms can still bind into molecules.

25.1.1 Framework

Let us consider the following operator (quantum Hamiltonian)

$$\mathsf{H} = \mathsf{H}_N := \sum_{1\le j\le N} H_{V,x_j} + \sum_{1\le j<k\le N} |x_j - x_k|^{-1} \tag{25.1.1}$$

on

$$\mathfrak{H} = \bigwedge_{1\le n\le N} \mathsf{H}, \qquad \mathsf{H} = \mathscr{L}^2(\mathbb{R}^d, \mathbb{C}^q) \tag{25.1.2}$$

with

$$H_V = D^2 - V(x) \tag{25.1.3}$$

describing N same type particles in the external field with the scalar potential $-V$ (it is more convenient but contradicts notations of the previous chapters), and repulsing one another according to the Coulomb law.

Here $x_j \in \mathbb{R}^d$ and $(x_1, \dots, x_N) \in \mathbb{R}^{Nd}$, potential $V(x)$ is assumed to be real-valued. Except when specifically mentioned we assume that

$$V(x) = \sum_{1\le m\le M} \frac{Z_m}{|x - \mathsf{y}_m|} \tag{25.1.4}$$

where $Z_m > 0$ and y_m are charges and locations of nuclei.

Mass is equal to $\frac{1}{2}$ and the Plank constant and a charge are equal to 1 here. The crucial question is the quantum statistics.

(25.1.5) We assume that the particles (electrons) are *fermions*. This means that the Hamiltonian should be considered on the *Fock space* $\mathfrak{H}$ defined by (25.1.2) of the functions antisymmetric with respect to all variables $(x_1, \varsigma_1), \dots, (x_N, \varsigma_N)$.

Here $\varsigma \in \{1, \dots, q\}$ is a *spin variable*.

Remark 25.1.1. (i) Meanwhile for *bosons* one should consider this operator on the space of symmetric functions. The results would be very different from what we will get here. Since our methods fail in that framework, we consider only fermions here.

(ii) In this Chapter we do not have magnetic field and we can assume that $q = 1$; for $q \ge 1$ no modifications of our arguments is required and results are the same albeit with different numerical coefficients. In the next chapters we introduce magnetic field (external or self-generated) we will be interested in $d = 3$, $q = 2$ and

$$H_{V,A} = \big((i\nabla - A)\cdot \boldsymbol{\sigma}\big)^2 - V(x) \tag{25.1.6}$$

where $\boldsymbol{\sigma} = (\sigma_1, \sigma_2, \sigma_3)$, σ_k are Pauli matrices.

Let us assume that

(25.1.7) Operator H is self-adjoint on $\mathfrak{H}$.

As usual we will never discuss this assumption.

25.1.2 Problems to Consider

We are interested in the *ground state energy* $\mathsf{E} = \mathsf{E}_N$ of our system i.e. in the lowest eigenvalue of the operator $\mathsf{H} = \mathsf{H}_N$ on $\mathfrak{H}$:

$$\mathsf{E} := \inf \operatorname{Spec} \mathsf{H} \qquad \text{on } \mathfrak{H}; \tag{25.1.8}$$

more precisely we are interested in the asymptotics of $\mathsf{E}_N = \mathsf{E}(\underline{\mathsf{y}}; \underline{Z}; N)$ as V is defined by (25.1.4) and $N \asymp Z := Z_1 + Z_2 + ... + Z_M \to \infty$ and we are going to prove that[1)] E is equal to *Thomas-Fermi energy* $\mathcal{E}^{\mathsf{TF}}$ with Scott and Dirac-Schwinger corrections and with $o(Z^{\frac{5}{3}})$ error.

Here we use notations $\underline{\mathsf{y}} = (\mathsf{y}_1, \dots, \mathsf{y}_M)$, $\underline{Z} = (Z_1, \dots, Z_M)$.

We are also interested in the asymptotics for the *ionization energy*

$$\mathsf{I}_N := \mathsf{E}_{N-1} - \mathsf{E}_N. \tag{25.1.9}$$

It is well-known (see G. Zhislin [1]) that $\mathsf{I}_N > 0$ as $N \le Z$ (i.e. molecule can bind at least Z electrons) and we are interested in the following question: estimate *maximal excessive negative charge*

$$\max_{N:\ \mathsf{I}_N > 0} (N - Z) \tag{25.1.10}$$

i.e. *how many extra electrons can bind a molecule?*.

All these questions so far were considered in the framework of the fixed positions $\mathsf{y}_1, \dots, \mathsf{y}_M$ but we can also consider

$$\widehat{\mathsf{E}} = \widehat{\mathsf{E}}_N = \widehat{\mathsf{E}}(\underline{\mathsf{y}}; \underline{Z}; N) = \mathsf{E} + U(\underline{\mathsf{y}}; \underline{Z}) \tag{25.1.11}$$

with

$$U(\underline{\mathsf{y}}; \underline{Z}) := \sum_{1 \le m < m' \le M} \frac{Z_m Z_{m'}}{|\mathsf{y}_m - \mathsf{y}_{m'}|} \tag{25.1.12}$$

and

$$\widehat{\mathsf{E}}(\underline{Z}; N) = \inf_{\mathsf{y}_1, \dots, \mathsf{y}_M} \widehat{\mathsf{E}}(\underline{\mathsf{y}}; \underline{Z}; N) \tag{25.1.13}$$

and replace I_N by $\widehat{\mathsf{I}}_N = -\widehat{\mathsf{E}}_N + \widehat{\mathsf{E}}_{N-1}$ and modify all our questions accordingly. We call these frameworks *fixed nuclei model* and *free nuclei model* respectively.

In the free nuclei model we can consider two other problems:

[1)] Under reasonable assumption $|\mathsf{y}_m - \mathsf{y}_{m'}| \gg Z^{-\frac{1}{3}}$ for all $m \ne m'$.

(a) Estimate from below *minimal distance between nuclei* i.e.

$$a := \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}|$$

for which such minimum is achieved;

(b) Estimate *maximal excessive positive charge*

$$\max_N \bigl\{ Z - N \colon \widehat{\mathsf{E}} < \min_{\substack{N_1,\dots,N_M:\\ N_1+\dots N_M=N}} \sum_{1\le m\le M} \mathsf{E}(Z_m; N_m)\bigr\} \tag{25.1.14}$$

for which molecule does not disintegrates into atoms[2)].

25.1.3 Thomas-Fermi Theory

The first approximation is the Thomas-Fermi theory. Let us introduce the *spacial density* of the particle with the state $\Psi \in \mathfrak{H}$:

$$\rho(x) = \rho_\Psi(x) = N \int |\Psi(x, x_2, \dots, x_N)|^2 \, dx_2 \cdots dx_N \tag{25.1.15}$$

where $|\cdot|$ means a norm in $\mathbb{C}^{Nq}$ and antisymmetricity of Ψ implies that it does not matter what variable x_j is replaced by x while in the general case one should sum on $j = 1, \dots, N$. Let us write the Hamiltonian, describing the corresponding "quantum liquid":

$$\mathcal{E}(\rho) = \int \tau(\rho(x))\, dx - \int V(x)\rho(x)\, dx + \frac{1}{2}\mathsf{D}(\rho,\rho), \tag{25.1.16}$$

with

$$\mathsf{D}(\rho,\rho) = \iint |x-y|^{-1}\rho(x)\rho(y)\, dxdy \tag{25.1.17}$$

where τ is the energy density of a gas of noninteracting electrons. Namely,

$$\tau(\rho) = \sup_{w\ge 0}\bigl(\rho w - P(w)\bigr) \tag{25.1.18}$$

[2)] One can ask the same question about disintegration into smaller molecules but our methods are too crude to distinguish between such questions.

is the Legendre transform of the *pressure* $P(w)$ given by the formula

$$P(w) = \varkappa_1 w_+^{\frac{d}{2}+1}, \qquad \varkappa_1 = 2(2\pi)^{-d}(d+2)^{-1}\varpi_d q. \tag{25.1.19}$$

The classical sense of the second and the third terms in the right-hand expression of (25.1.16) is clear and the density of the kinetic energy is given by $\tau(\rho)$ in the semiclassical approximation (see Remark 25.1.2). So, the problem is

(25.1.20) Minimize functional $\mathcal{E}(\rho)$ defined by (25.1.16) under restrictions:

$$\rho \ge 0, \qquad \int \rho\, dx \le N. \tag{25.1.21}_{1,2}$$

The solution if exists is unique because functional $\mathcal{E}(\rho)$ is strictly convex (see below). The existence and the property of this solution denoted further by ρ^{TF} is known in the series of physically important cases.

Remark 25.1.2. If w is the negative potential then

$$\operatorname{tr} e(x,x,0) \approx P'(w) \tag{25.1.22}$$

defines the density of all non-interacting particles with negative energies at point x and

$$\int_{-\infty}^{0} \tau\, d_\tau \operatorname{tr} e(x,x,\tau) dx \approx -\int P(w)\, dx \tag{25.1.23}$$

is the total energy of these particles; here $\approx$ means "in the semiclassical approximation".

We consider in the case of $d = 3$ a large (heavy) molecule with potential (25.1.4). It is well-known[3] that

Proposition 25.1.3. *(i) For $V(x)$ given by* (25.1.4) *minimization problem* (25.1.20) *has a unique solution $\rho = \rho^{\mathsf{TF}}$; then denote $\mathcal{E}^{\mathsf{TF}} := \mathcal{E}(\rho^{\mathsf{TF}})$;*

(ii) Equality in $(25.1.21)_2$ *holds if and only if $N \le Z := \sum_m Z_m$.*

[3] E. Lieb, "Thomas-Fermi and related theories of atoms and molecules", [4], pp. 263–301.

(iii) Further, ρ^{TF} does not depend on N as $N \ge Z$.

(iv) Thus

$$\int \rho^{\mathsf{TF}}\,dx = \min(N, Z), \qquad Z := \sum_{1\le m\le M} Z_m. \tag{25.1.24}$$

25.1.4 Main Results Sketched and Plan of the Chapter

In the first half of the Chapter we derive asymptotics for ground state energy and justify Thomas-Fermi theory.

First of all, in Section 25.2 we reduce the calculation of E to calculation of $\mathsf{N}_1(H_W - \nu)$ and to estimate for $\mathsf{D}\big(e(x,x,\nu) - \rho, e(x,x,\nu) - \rho\big)$ where $\mathsf{N}_1(H_W - \nu) = \mathsf{Tr}((H_W - \nu)^-)$ is the sum of the negative eigenvalues of operator $H_W - \nu$ $H_W = D^2 - W$, $W = W^{\mathsf{TF}}$, $\rho = \rho^{\mathsf{TF}}$ are Thomas-Fermi potential and Thomas-Fermi density respectively (or their appropriate approximations), ν is either λ_N (N-th eigenvalue of H_W) or its appropriate approximation and $e(x,y,\nu)$ is the Schwartz kernel of $E(\nu)$ which is the spectral projector of H_W.

Section 25.3 is devoted to the systematic presentation of the Thomas-Fermi theory.

Further, in Section 25.4 we apply our standard semiclassical arguments and calculate $\mathsf{N}_1(H_W - \nu)$ and estimate $\mathsf{D}\big(e(x,x,\nu) - \rho, e(x,x,\nu) - \rho\big)$ and also $|\lambda_N - \nu|$ where now ν is the chemical potential (which is the Thomas-Fermi approximation to λ_N). As a result under appropriate restrictions to N, Z and

$$a := \min_{1\le m<m'\le M} |\mathsf{y}_j - \mathsf{y}_k| \gg Z^{-\frac{1}{3}} \tag{25.1.25}$$

we prove that

$$\mathsf{E} = \mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} + \mathsf{Dirac} + \mathsf{Schwinger} + o(Z^{\frac{5}{3}}) \tag{25.1.26}$$

and

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}}) = o(Z^{\frac{5}{3}}) \tag{25.1.27}$$

where

$$\mathsf{Scott} = \frac{q}{2} \sum_{1\le m\le M} Z_m^2 \tag{25.1.28}$$

$$\mathsf{Dirac} = -\bigl(\frac{6}{\pi q}\bigr)^{\frac{1}{3}} \int \rho^{\mathsf{TF}\,\frac{4}{3}}\, dx, \tag{25.1.29}$$

$$\mathsf{Schwinger} = \bigl(\frac{q}{6\pi^2}\bigr)^{\frac{2}{3}} \int^{\mathsf{TF}\,\frac{4}{3}}\, dx \tag{25.1.30}$$

and Ψ is the ground state.

Remark 25.1.4. (i) Actually we will recover even slightly better remainder estimate $O(Z^{\frac{5}{3}-\delta})$ in (25.1.26) and (25.1.27) as $a \ge Z^{-\frac{1}{3}+\delta_1}$.

(ii) Condition $a \gtrsim Z^{-\frac{1}{3}}$ bans nuclei to be so close that the repulsion energy between them be much larger than the total energy of all the electrons. Estimates in case when this condition is violated will be also proven;

(iii) Keeping in mind that there is no binding in Thomas-Fermi theory (and this statement could be quantified) one gets immediately that in the free nuclei model $a \ge Z^{-\frac{5}{21}}$ and therefore remainder estimate $O(Z^{\frac{5}{3}-\delta})$ holds.

(iv) Due to scaling in the Thomas-Fermi theory (see Proposition 25.3.3 and Appendix 25.A.4) $\mathcal{E}^{\mathsf{TF}} \sim q^{\frac{2}{3}} Z^{\frac{7}{3}} = q^3 (q^{-1}Z)^{\frac{3}{7}}$, $\mathsf{Scott} \sim qZ^2 = q^3(q^{-1}Z)^2$, Dirac is $\sim q^{\frac{1}{3}} Z^{\frac{5}{3}} = q^2 (q^{-1}Z)^{\frac{5}{3}}$ and $\mathsf{Schwinger}$ is $\sim q^{\frac{4}{3}} Z^{\frac{5}{3}} = q^3 (q^{-1}Z)^{\frac{5}{3}}$.

In the second half of the Chapter we apply estimate (25.1.27) to investigate negatively and positively charged systems. In Section 25.5 we consider negatively charged systems and derive an upper estimate for the excessive negative charge $(N - Z)$ such that $\mathsf{I}_N > 0$ and ionization energy I_N itself.

In Section 25.6 we derive upper and lower estimates for $\mathsf{I}_N + \nu$ and an upper estimate for the excessive positive charge for which in the framework of the free nuclei model $a < \infty$.

25.2 Reduction to Semiclassical Theory

To justify the heuristic formula $\mathsf{E} \sim \mathcal{E}^{\mathsf{TF}} = \mathcal{E}(\rho^{\mathsf{TF}})$ and to find an error estimate let us deduce the lower and upper estimates for E.

25.2.1 Lower Estimate

For the lower estimate we apply the *electrostatic inequality* due to E. H. Lieb:

$$\sum_{1\le j<k\le N}\int |x_j-x_k|^{-1}|\Psi(x_1,\dots,x_N)|^2\,dx_1\cdots dx_N \ge \frac{1}{2}\mathsf{D}(\rho_\Psi,\rho_\Psi)-C\int \rho_\Psi^{\frac{4}{3}}(x)\,dx \tag{25.2.1}$$

with ρ_Ψ defined by (25.1.15).

Remark 25.2.1. Inequality (25.2.1 holds for all (not necessarily antisymmetric) functions Ψ with $\|\Psi\|_{L^2(\mathbb{R}^{3N})}=1$.

Therefore

$$\langle \mathsf{H}_N\Psi,\Psi\rangle \ge \sum_{1\le j\le N}\langle H_{V,x_j}\Psi,\Psi\rangle+\frac{1}{2}\mathsf{D}\big(\rho_\Psi,\rho_\Psi\big)-C\int\rho_\Psi^{\frac{4}{3}}(x)\,dx = \sum_{1\le j\le N}\langle H_{W,x_j}\Psi,\Psi\rangle+\frac{1}{2}\mathsf{D}\big(\rho_\Psi-\rho,\rho_\Psi-\rho\big)-\frac{1}{2}\mathsf{D}\big(\rho,\rho\big)-C\int\rho_\Psi^{\frac{4}{3}}(x)\,dx \tag{25.2.2}$$

where $\langle\cdot,\cdot\rangle$ means the inner product in $\mathfrak{H}$ and H_W is one-particle Schrödinger operator with the potential

$$W=V-|x|^{-1}*\rho, \tag{25.2.3}$$

where ρ is an arbitrary chosen real-valued non-negative function.

The physical sense of the second term in W is transparent: it is a potential created by a charge $-\rho$. Skipping the positive second term in the right-hand expression of (25.2.2) and believing that the last term is not very important for the ground state function Ψ [4)] we see that we need to estimate from below the first term.

Here assumption that Ψ is antisymmetric is crucial. Namely, for general (or symmetric–does not matter) Ψ the best possible estimate is $N\lambda_1$ where λ_1 is the lowest eigenvalue of H_W (we always assume that there is sufficiently many eigenvalues under the bottom of the essential spectrum of H_W) and we

[4)] When we derive also an upper estimate for E we will get an upper estimate for this term as a bonus.

cannot apply semiclassical theory. However, for antisymmetric Ψ situation is rather different.

Namely, let $\lambda_1 \le \lambda_2 \le \lambda_3 \le \dots$ be negative eigenvalues of H_W (on $\mathsf{H} = \mathscr{L}^3(\mathbb{R}^3, \mathbb{C}^q)$. Then the first term in the right-hand expression of (25.2.2) is bounded from below by

$$\sum_{1\le j\le N} \lambda_j = \mathsf{N}_1(H_W - \bar\lambda) + \bar\lambda N \tag{25.2.4}$$

where $\mathsf{N}(B)$, $\mathsf{N}_1(B) = \mathsf{Tr}(B^-)$ are the number and the sum of all the negative eigenvalues of operator B respectively such that $\mathsf{Spec}_{\mathsf{ess}}(B) \subset \mathbb{R}^+$ provided $\bar\lambda = \lambda_N < 0$; the latter assumption is equivalent to

$$\mathsf{N}(H_W) \ge N. \tag{25.2.5}$$

Applying the semiclassical approximation (which needs to be justified!) one gets

$$\mathsf{N}_1(H_W - \bar\lambda) = \mathcal{N}_1(H_W - \bar\lambda) + \mathsf{error}_1 \tag{25.2.6}$$

with

$$\mathcal{N}_1(H_W - \bar\lambda) := -\int P\big(W(x) + \bar\lambda\big)\, dx \tag{25.2.7}$$

and error_0 *an error in the semiclassical approximation* for $\mathsf{N}_1(H_W - \bar\lambda)$. Therefore the lower estimate for the ground state energy is

$$\mathsf{E} \ge -\int P(W + \bar\lambda)\, dx + \bar\lambda N - \frac{1}{2}\mathsf{D}(\rho,\rho) - \mathsf{error} \tag{25.2.8}$$

where error now includes both an estimate for $\int \rho_\Psi^{\frac{4}{3}}\, dx$ and the semiclassical remainder estimate.

Furthermore, applying a semiclassical approximation for the number $\mathsf{N}(H_W - \bar\lambda)$ of eigenvalues below $\bar\lambda$ (and this number should be approximately N) one gets an equality

$$N = \mathcal{N}(H_W - \bar\lambda) + \mathsf{error}_0 \tag{25.2.9}$$

with

$$\mathcal{N}(H_W - \bar\lambda) := \int P'\big(W(x) + \bar\lambda\big)\, dx \tag{25.2.10}$$

and error_0 *an error in the semiclassical approximation* for $\mathsf{N}(H_W - \bar\lambda)$.

To get the best possible lower estimate one should pick up ρ delivering maximum to the functional

$$-\int P\big(W(x)+\nu\big)\,dx + \nu N - \frac{1}{2}\mathsf{D}(\rho,\rho) \tag{25.2.11}$$

($\nu = \bar\lambda$ here) under assumptions $(25.1.21)_{1,2}$ and (25.2.3) as we skip all the errors.

One can see that the optimal choice is the *Thomas-Fermi potential* W^{TF} *and density* ρ^{TF}. The above arguments are very standard in MQT with $\rho = \rho^{\mathsf{TF}}$, $W = W^{\mathsf{TF}}$ [5)] from the very beginning.

On the other hand, let us consider the Euler-Lagrange equation for $\rho = \rho^{\mathsf{TF}}$ under condition $\int \rho\,dx = N$:

$$\tau'(\rho) - W = \nu \quad (\rho > 0), \qquad W = V - |x|^{-1} * \rho \tag{25.2.12}$$

with the Lagrange factor ν [6)]. Expressing ρ and integrating we get

$$N = \mathcal{N}(H_W - \nu) = \int P'\big(W(x)+\nu\big)\,dx. \tag{25.2.13}$$

Comparing (25.2.12) and (25.2.13) we get that with some error $\bar\lambda \sim \nu$. Substituting to the first term in (25.2.6) $\bar\lambda = \nu$ and $\nu - W = -\tau'_B(\rho)$ we get the lower estimate $\mathsf{E} \ge \mathcal{E}^{\mathsf{TF}} - \mathsf{error}$.

Remark 25.2.2. (i) Instead of (25.2.6) we will use a better estimate[7)];

(ii) To minimize errors we will also recalculate (25.2.4) effectively replacing $\bar\lambda$ by ν:

$$\sum_{1\le j\le N} \lambda_j = \sum_{1\le j\le N} (\lambda_j - \nu) + \nu N \ge \mathsf{N}_1(H_W - \nu) + \nu N. \tag{25.2.14}$$

The advantage is that we even do not mess up with the semiclassical asymptotics for $\mathsf{N}(H_W - \nu)$. Further, one can replace here N by $\int \rho^{\mathsf{TF}}\,dx$: (these quantities fail to be equal only for $N > Z$ i.e. for $\nu = 0$).

[5)] Or some their close approximations.

[6)] Called *chemical potential* and in contrast to $\bar\lambda$ belonging to Thomas-Fermi theory.

[7)] With $\mathcal{E}^{\mathsf{TF}}$ replaced by $\mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} + \mathsf{Schwinger}$ and with much smaller error_1 than for a simple semiclassical approximation.

(iii) Recall that we assumed that $\lambda_N < 0$ i.e. (25.2.5) holds. In the opposite case

$$\mathsf{N}(H_W) < N. \tag{25.2.15}$$

we estimate the first term in the right-hand expression of (25.2.2) from below by $\mathsf{N}_1(H_W)$ i.e. we will get the same formula but with $\nu = 0$.

25.2.2 Upper Estimate

To get the upper estimate one takes a test function $\Psi(x_1, \dots, x_N)$ which is not a ground state here but an antisymmetrization with respect to $(x_1, \dots, x_N)$ of the product $\phi_1(x_1) \cdots \phi_N(x_N)$ where $\phi_1, \dots, \phi_N$ are orthonormal eigenfunctions of H_W corresponding to eigenvalues $\lambda_1, \dots, \lambda_N$, provided $\lambda_N < 0$. Namely this function minimizes the first term in the right-hand expression of (25.2.2).

One can write

$$\Psi = \frac{1}{N!} \det\bigl(\phi_i(x_j)\bigr)_{i,j=1,\dots,N} \tag{25.2.16}$$

and it is called the *Slater determinant*. Obviously, $\|\Psi\| = 1$ and

$$\rho_\Psi(x) = \operatorname{tr} e_N(x,x) \tag{25.2.17}$$

where

$$e_N(x,y) = \sum_{1\le j\le N} \phi_j(x)\phi_j^\dagger(y) \tag{25.2.18}$$

is the Schwartz kernel of the projector to the subspace spanned on $\{\phi_j\}_{1\le j\le N}$.

Remark 25.2.3. If $q \ge 2$ then $\phi_j = \phi_j(x,\varsigma)$ and $\Psi(x_1,\varsigma_1;\dots;x_N,\varsigma_N)$ is an antisymmetrization with respect to $(x_1,\varsigma_1;\dots;x_N,\varsigma_N)$ of the product $\phi_1(x_1,\varsigma_1)\cdots\phi_N(x_N,\varsigma_N)$.

Easy calculations show that

$$\begin{aligned}\langle \mathsf{H}\Psi, \Psi\rangle = &\sum_{1\le j\le N} \lambda_j + \frac{1}{2}\mathsf{D}(\rho_\Psi - \rho, \rho_\Psi - \rho)\\ &- \frac{1}{2}\mathsf{D}(\rho,\rho) - \frac{1}{2}\iint |x-y|^{-1} \operatorname{tr} e_N^\dagger(x,y) e_N(x,y)\, dxdy.\end{aligned} \tag{25.2.19}$$

The first term in the right-hand expression again is equal to the middle expression in (25.2.4) which does not exceed

$$\mathsf{N}_1(H_W-\nu)+\nu N+|\lambda_N-\nu|\cdot|\mathsf{N}(H_W-\nu)-N|. \tag{25.2.20}$$

Really, we need to consider (non-zero) terms which do not cancel in

$$\sum_{j\le N}(\lambda_j-\nu)-\sum_{\lambda_j<\nu}(\lambda_j-\nu) \tag{25.2.21}$$

and their absolute value does not exceed $|\lambda_N-\nu|$ while their number does not exceed $|\mathsf{N}(H_W-\nu)-N|$.

Again, discounting all the errors and considering semiclassical approximation (including $\rho_\Psi(x)\sim P'\big(W(x)+\nu\big)\big)$ we arrive to a functional

$$-\int P\big(W(x)+\nu\big)\,dx+\nu N-\frac{1}{2}\mathsf{D}(\rho,\rho)+ \frac{1}{2}\mathsf{D}(P'(W+\nu)-\rho,P'(W+\nu)-\rho) \tag{25.2.22}$$

which needs to be minimized under assumptions $(25.1.21)_{1,2}$ and (25.2.3). This functional differs from (25.2.11) which was minimized by the last term. One can prove that (25.2.22) minimizes as $\rho=\rho^{\mathsf{TF}}$, $W=W^{\mathsf{TF}}$ and ν is a chemical potential. So again we may pick them (or their appropriate approximations) up from the very beginning.

Therefore in addition to a semiclassical error_1 [7] of the previous subsection we need to consider also semiclassical errors

$$\mathsf{D}\big(\mathsf{tr}\,e(x,x,\nu)-P'(W+\nu),\mathsf{tr}\,e(x,x,\nu)-P'(W+\nu)\big), \tag{25.2.23}$$

$$\mathsf{D}\big(e(x,x,\nu)-e_N(x,x),e(x,x,\nu)-e_N(x,x)\big) \tag{25.2.24}$$

where $e(x,y,\nu)$ is the Schwartz kernel of the spectral projector $\theta(\tau-H_W)$ of H_W,

$$N(H_W-\nu)-\int P'(W+\nu)\,dx \tag{25.2.25}$$

and

$$\lambda_N-\nu. \tag{25.2.26}$$

Remark 25.2.4. (i) Recall that we assumed that $\lambda_N < 0$ i.e. (25.2.5) holds. In the opposite case (25.2.15) selecting appropriate $\phi_j(x)$ with $j = \mathsf{N}(H_W) + 1, \dots, N$ we with arbitrarily small error estimate the first term in the right-hand expression of (25.2.2) from above by $\mathsf{N}_1(H_W)$ as i.e. we will get the same formula but with $\nu = 0$ and we also will need to estimate (25.2.23) with $\nu = 0$.

(ii) To make this case compatible with the case (25.2.5) we will need to estimate $|\nu|$ (and $|N - Z|$) under assumption (25.2.15); we will also compare $\mathcal{E}^{\mathsf{TF}}$ calculated for such ν (or, equivalently, N as they are connected) and $\nu = 0$ (and $N = Z$).

(iii) Sure ρ^{TF} and W^{TF} depend on ν (or N) but we will prove that for $N - Z$ relatively small we can do all calculations as $\nu = 0$ (and $N = Z$).

(iv) If we are interested in the estimate for $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}})$ where Ψ is the ground state, we do not need to calculate a semiclassical error in $\mathsf{N}_1(H_W - \nu)$. In fact, we can simply stick with $\mathsf{N}_1(H_W - \bar{\lambda})$ with $\bar{\lambda} = \lambda_N$ under assumption (25.2.5) and $\bar{\lambda} = 0$ otherwise. As a result in certain cases our estimate for $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}})$ will be better than the error in an approximation for E and we need the former rather than the latter for the results of the second half of this Chapter. Especially significant the difference will be when we introduce magnetic field.

25.2.3 Remarks and Dirac Correction

Now almost everything is in framework of the theory we developed; the only missing is an estimate

$$\int \rho_\Psi^{\frac{4}{3}} dx \le CZ^{\frac{5}{3}} \tag{25.2.27}$$

for a reasonable candidate Ψ to the ground state; one can find it in E. Lieb's *Selecta*[3)].

However if we want a more sharp asymptotics with Dirac–Schwinger terms, we need a remainder estimate $o(Z^{\frac{5}{3}})$ or better; luckily there is improved electrostatic inequality due to Theorem 1, G. Graf and J. P. Solovej [1] (see also V. Bach [1]).

Theorem 25.2.5. *Let $N \ge \epsilon Z$. Then for the ground state Ψ*

$$\mathsf{E}_{\mathsf{HF}} \ge \mathsf{E} \ge \mathsf{E}_{\mathsf{HF}} - CZ^{\frac{5}{3}-\delta} \tag{25.2.28}$$

and

$$\mathsf{E} \ge \mathsf{E}_{\mathsf{DS}} - CZ^{\frac{5}{3}-\delta} \tag{25.2.29}$$

with some exponent $\delta > 0$ where

$$\mathsf{E}_{\mathsf{HF}} \coloneqq \inf_{\Psi} E_{\mathsf{HF}}(\Psi), \tag{25.2.30}$$

where in (25.2.30) Ψ *runs through Slater determinants*[8] *and*

$$E_{\mathsf{HF}}(\Psi) \coloneqq \sum_{1\le j\le N} \langle H_{V,x_j}\Psi, \Psi\rangle + \frac{1}{2}\mathsf{D}\big(\rho_\Psi, \rho_\Psi\big) - \frac{1}{2}\iint |x-y|^{-1}\,\mathsf{tr}\, e_N^\dagger(x,y)e_N(x,y)\,dxdy, \tag{25.2.31}$$

$$E_{\mathsf{DS}} \coloneqq \sum_{j:1\le j\le N;\lambda_j<0} \lambda_j - \frac{1}{2}\mathsf{D}(\rho^{\mathsf{TF}},\, \rho^{\mathsf{TF}}) - \kappa_{\mathsf{Dirac}} \int {\rho^{\mathsf{TF}}}^{\frac{4}{3}}\,dx, \tag{25.2.32}$$

$\kappa_{\mathsf{Dirac}} = (6/\pi q)^{\frac{1}{3}}$ *is a Dirac constant.*

Here (25.2.28)–(25.2.31) are (1.15), (1.16), (1.8), (1.6) respectively and (25.2.32) is a combination of (1.12) and (25.3.30) of this paper[9]. Actually we need only (25.2.29) and (25.2.32).

As we are going to prove that the last terms in (25.2.31) and (25.2.19) coincide modulo $O(Z^{\frac{5}{3}-\delta})$ we made a necessary step completely.

25.3 Thomas-Fermi Theory

Thomas-Fermi theory is well-developed in the no-magnetic-field case. We cannot suggest any better reading than E. Lieb's *Selecta*[3].

In the Thomas-Fermi theory N is a real nonnegative number (not necessarily an integer).

---

[8] Albeit not necessarily of eigenfunctions of H_W. See Appendix 25.A.4.

[9] We do not have a coefficient $\frac{1}{2}$ in the definition of $\mathsf{D}(.,.)$ but G. Graf and J. P. Solovej [1] have.

25.3.1 Existence

Let us recall that in order to get the best lower estimate (neglecting semiclassical errors) one needs to maximize

$$\Phi_*(W+\nu) \coloneqq -\int P(W+\nu)\,dx - \frac{1}{8\pi}\|\nabla(W-V)\|^2 \tag{25.3.1}$$

given by (25.2.11) where we used equalities

$$\mathsf{D}(\rho,\rho) = -(\rho, W-V) = \frac{1}{4\pi}\|\nabla(W-V)\|^2, \tag{25.3.2}$$

$$\rho \coloneqq \frac{1}{4\pi}\Delta(W-V), \tag{25.3.3}$$

$\|.\|$ means $\mathscr{L}^2$-norm and $W \to 0$ as $|x| \to \infty$.

On the other hand, to get the best possible upper estimate (neglecting semiclassical errors) one needs to minimize

$$\Phi^*(\rho',\nu) \coloneqq \int \bigl(\tau(\rho') - V\rho'\bigr)\,dx + \frac{1}{2}\mathsf{D}(\rho',\rho') - \nu\int \rho'\,dx \tag{25.3.4}$$

where

$$\rho' \coloneqq P'(W+\nu) \tag{25.3.5}$$

and $\tau(\rho)$ the Legendre transformation (25.1.18) of P. Recall that according to (25.1.19)

$$P(w) = \frac{q}{15\pi^2}w_+^{\frac{5}{2}}, \qquad P'(w) = \frac{q}{6\pi^2}w_+^{\frac{3}{2}} \tag{25.3.6}_{1,2}$$

and therefore

$$\tau(\rho) = \frac{3}{5}\bigl(6\pi^2 q^{-1}\bigr)^{\frac{2}{3}}\rho^{\frac{5}{3}}. \tag{25.3.7}$$

Proposition 25.3.1. *In our assumptions for any fixed $\nu \le 0$*

(i) $\Phi_*(W+\nu)$ is a strictly concave functional.

(ii) $\Phi^*(\rho)$ is a strictly convex functional.

(iii) $\Phi_*(W+\nu) \le \Phi^*(\rho,\nu)$ for any $\rho \ge 0$ and W.

(iv) These extremal problems have a common solution W and ρ and

$$\rho = \frac{1}{4\pi}\Delta(W-V) = P'(W+\nu), \tag{25.3.8}$$

$$W = o(1) \qquad \text{as } |x| \to \infty. \tag{25.3.9}$$

(v) On the other hand, solution of (25.3.8)–(25.3.9) *is the solution of the both extremal problems.*

(vi) Neither of these problem has a solution for $\nu > 0$.

(vii) Function

$$\mathcal{N}(\nu) = \int P'(W+\nu)\,dx \tag{25.3.10}$$

is continuous and monotone increasing at $(-\infty, 0]$ *with* $\mathcal{N}(\nu) \to 0$ *as* $\nu \to -\infty$ *and* $\mathcal{N}(0) = Z$.

(viii) For ν *and* N *linked by* $N = \mathcal{N}(\nu)$ *solutions of the problem above coincide with* ρ^{TF}, W^{TF} *of the problem* (25.1.20) *and one can skip condition* $(25.1.20)_2$ *for* $N \ge Z$ *and*

$$\mathcal{E}^{\mathsf{TF}} = \Phi(W^{\mathsf{TF}}+\nu) + \nu N = \Phi^*(\rho^{\mathsf{TF}}, \nu) + \nu N. \tag{25.3.11}$$

Proof. The proof of Statements (i) and (ii) is obvious; therefore both problems have unique solutions. Comparing Euler-Lagrange equations we get that these solutions coincide which yields Statements (iv) and (iii).

Proof of Statements (v)–(viii) is also rather obvious. □

Proposition 25.3.2. *For arbitrary* W *the following estimates hold with absolute constants* $\epsilon_0 > 0$ *and* C_0*:*

$$\epsilon_0 \mathsf{D}(\rho-\rho^{\mathsf{TF}}, \rho-\rho^{\mathsf{TF}}) \le \Phi_*(W^{\mathsf{TF}}+\nu) - \Phi_*(W+\nu) \le C_0 \mathsf{D}(\rho-\rho', \rho-\rho') \tag{25.3.12}$$

and

$$\epsilon_0 \mathsf{D}(\rho'-\rho^{\mathsf{TF}}, \rho'-\rho^{\mathsf{TF}}) \le \Phi^*(\rho,\nu) - \Phi^*(\rho^{\mathsf{TF}}, \nu) \le C_0 \mathsf{D}(\rho-\rho', \rho-\rho') \tag{25.3.13}$$

with $\rho = \frac{1}{4\pi}\Delta(W-V)$, $\rho' = P'(W+\nu)$.

Proof. This proof is rather obvious as well. □

25.3.2 Properties

Proposition 25.3.3. *The solution of the Thomas-Fermi problem has following scaling properties*

$$W^{\mathsf{TF}}(x;\, \underline{Z};\, \underline{y};\, N;\, q) = q^{\frac{2}{3}} N^{\frac{4}{3}} W^{\mathsf{TF}}(q^{\frac{2}{3}} Z^{\frac{1}{3}} x;\, N^{-1}\underline{Z};\, q^{\frac{2}{3}} N^{\frac{1}{3}}\underline{y};\, 1;\, 1), \tag{25.3.14}$$

$$\rho^{\mathsf{TF}}(x;\, \underline{Z};\, \underline{y};\, N;\, q) = N^2 q^2 \rho^{\mathsf{TF}}(q^{\frac{2}{3}} Z^{\frac{1}{3}} x;\, N^{-1}\underline{Z};\, q^{\frac{2}{3}} N^{\frac{1}{3}}\underline{y};\, 1;\, 1), \tag{25.3.15}$$

$$\mathcal{E}^{\mathsf{TF}}(\underline{Z};\, \underline{y};\, N;\, q) = q^{\frac{2}{3}} N^{\frac{7}{3}} \mathcal{E}^{\mathsf{TF}}(N^{-1}\underline{Z};\, q^{\frac{2}{3}} N^{\frac{1}{3}}\underline{y};\, 1;\, 1), \tag{25.3.16}$$

$$\nu^{\mathsf{TF}}(\underline{Z};\, \underline{y};\, N;\, q) = q^{\frac{2}{3}} N^{\frac{4}{3}} \nu^{\mathsf{TF}}(N^{-1}\underline{Z};\, q^{\frac{2}{3}} N^{\frac{1}{3}}\underline{y};\, 1;\, 1) \tag{25.3.17}$$

where $\nu^{\mathsf{TF}} = \nu$ is the chemical potential; recall that $\underline{Z} = (Z_1, \dots, Z_M)$ and $\underline{y} = (y_1, \dots, y_M)$ are arrays and parameter q also enters into Thomas-Fermi theory.

Proof. Proof is trivial by scaling. □

Since we can exclude q by scaling, we do not indicate dependence on it anymore. The following properties of Thomas-Fermi potential and density in the case of the single atom ($M = 1$) are well-known:

Proposition 25.3.4. *Let $M = 1$. Then the solution of the Thomas-Fermi problem has the following properties:*

(i) $W^{\mathsf{TF}}(x; Z_m, y_m; N)$ and $\rho^{\mathsf{TF}}(x; Z_m, y_m; N)$ are spherically symmetric (with respect to y_m) and are non-increasing convex functions of $|x - y_m|$.

(ii) If $N = Z_m$, then

$$W^{\mathsf{TF}} \asymp \min\bigl(Z_m|x - y_m|^{-1}, |x - y_m|^{-4}\bigr), \tag{25.3.18}$$

$$\rho^{\mathsf{TF}} \asymp \min\bigl(Z_m^{\frac{3}{2}}|x - y_m|^{-\frac{3}{2}}, |x - y_m|^{-6}\bigr) \tag{25.3.19}$$

with the threshold at $|x - y_m| \asymp r_m^* = Z_m^{-\frac{1}{3}}$ when $W^{\mathsf{TF}} \asymp Z_m^{\frac{4}{3}}$ and $\rho^{\mathsf{TF}} \asymp Z_m^2$.

(iii) If $\epsilon Z_m \le N < Z_m$, then

$$-\nu \asymp |Z_m - N|^{\frac{4}{3}} \tag{25.3.20}$$

and (25.3.18) *holds as $|x - y_m| \le \bar{r}_m$ where*

$$\bar{r}_m = -\nu^{-1}|Z_m - N|^{-1} \asymp |Z_m - N|^{-\frac{1}{3}} \tag{25.3.21}$$

for atoms denotes the exact radius of the support of ρ^{TF} (see Statement (iv).

(iv) On the other hand,

$$W^{\mathsf{TF}} = (Z_m - N)|x - \mathsf{y}_m|^{-1} \qquad \text{as} \quad |x - \mathsf{y}_m| \ge \bar{r}_m \tag{25.3.22}$$

and $\rho^{\mathsf{TF}} = 0$ *as* $|x - \mathsf{y}_m| \ge \bar{r}_m$*;*

(v) Meanwhile, $W^{\mathsf{TF}} \asymp -\nu$ *and* $\rho^{\mathsf{TF}} = O\big(|Z_m - N|^2\big)$ *as* $|x - \mathsf{y}_m| \asymp \bar{r}_m$*.*

(vi) Finally,

$$-\langle x - \mathsf{y}_m, \nabla W\rangle \asymp W. \tag{25.3.23}$$

Consider now the molecular case ($M \ge 2$):

Proposition 25.3.5. *(i) Let* $M \ge 2$*. Then*

$$\nu \asymp |Z - N|^{\frac{4}{3}} \tag{25.3.24}$$

and

$$\sum_m \epsilon W_m^{\mathsf{TF}}(c(x - \mathsf{y}_m)) \le W^{\mathsf{TF}} \le c \sum_m W_m^{\mathsf{TF}}(\epsilon(x - \mathsf{y}_m)) \tag{25.3.25}$$

where $Z = Z_1 + \ldots + Z_M$ *and* W_m^{TF} *denotes an atomic Thomas-Fermi potential with the charge* Z_m *located at* 0 *and the same chemical potential* ν*. Here* ϵ *and* c *depend only on* M*.*

(ii) In particular, if $N < Z$ *and* $|x - \mathsf{y}_m| \ge c\bar{r}_m$ *for all* $m = 1, \ldots, M$*, then*

$$W^{\mathsf{TF}}(x) \asymp \sum_m |Z - N||x - \mathsf{y}_m|^{-1} \tag{25.3.26}$$

and

$$\rho^{\mathsf{TF}}(x) = 0. \tag{25.3.27}$$

Proof. Proof is due to the comparison arguments of E. Lieb, J. P. Solovej and J. Yngvason [1,3]. □

Proposition 25.3.6. *(i) Let* $N \le Z$ *and*

$$\ell(x) = \frac{1}{2} \min_m |x - \mathsf{y}_m|, \tag{25.3.28}$$

$$\zeta(x) = \big(W^{\mathsf{TF}}(x)\big)^{\frac{1}{2}}. \tag{25.3.29}$$

Then

$$\zeta(x) \le \bar{\zeta}(x) = C \begin{cases} Z^{\frac12}\ell(x)^{-\frac12} & \text{as } \ell(x) \le Z^{-\frac13}, \\ \ell(x)^{-2} & \text{as } Z^{-\frac13} \le \ell(x) \le |Z-N|^{-\frac13}, \\ |Z-N|^{\frac12}\ell(x)^{-\frac12} & \text{as } \ell(x) \ge |Z-N|^{-\frac13}; \end{cases} \tag{25.3.30}$$

$\zeta(x)$ and $\bar{\zeta}(x)$ are both ℓ-admissible and

$$\bigl|D^\alpha W^{\mathsf{TF}}(x)\bigr| \le C_\alpha \zeta(x)^2\, \ell(x)^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le 3, \tag{25.3.31}$$

and

$$|D^\alpha W^{\mathsf{TF}}(x) - D^\alpha W^{\mathsf{TF}}(y)| \le C_3 \zeta(x)^2 \ell(x)^{-\frac72} |x-y|^{\frac12} \qquad \forall x, y : |x-y| \le \epsilon \ell(x) \tag{25.3.32}$$

(ii) Unless $\zeta(x) \asymp (-\nu)^{\frac12}$ estimates (25.3.32) *hold for all α.*

Proof. This proof is rather obvious corollary of the Euler-Lagrange equation. □

Remark 25.3.7. Let

$$Z_m \asymp N \qquad \forall m. \tag{25.3.33}$$

Then $\zeta(x) \asymp \bar{\zeta}(x)$.

Theorem 25.3.8 [10]**.** *Consider $\mathcal{E}^{\mathsf{TF}}$ and*

$$\widehat{\mathcal{E}}^{\mathsf{TF}} := \mathcal{E}^{\mathsf{TF}} + U, \tag{25.3.34}$$

$$U = U(Z_1, \dots, Z_M; \mathsf{y}_1, \dots, \mathsf{y}_M) = \sum_{1 \le m < m' \le M} \frac{Z_m Z_{m'}}{|\mathsf{y}_m - \mathsf{y}_{m'}|}. \tag{25.3.35}$$

Select a nucleus y_m and a unit vector n such that

$$\langle \mathsf{y}_k - \mathsf{y}_m, \mathsf{n}\rangle \le 0 \qquad \forall k \tag{25.3.36}$$

and plug $\mathsf{y}_m + \alpha\mathsf{n}$ instead of y_m into $\mathcal{E}^{\mathsf{TF}}$ and into $\widehat{\mathcal{E}}^{\mathsf{TF}}$ [11]*. Then*

[10] Theorem 1 of R. Benguria [1]; see proof in Appendix 25.A.6.

[11] So all other nuclei are confined in half-space and y_m moves away outside.

(i) $\widehat{\mathcal{E}}^{\mathsf{TF}}_{\alpha}$ *is a non-increasing function of* $\alpha \ge 0$*;*

(ii) $\mathcal{E}^{\mathsf{TF}}_{\alpha}$ *is a non-decreasing function of* $\alpha \ge 0$*;*

(iii) For fixed $\alpha > 0$ $\widehat{\mathcal{E}}^{\mathsf{TF}}_{\alpha} - \widehat{\mathcal{E}}^{\mathsf{TF}}_{0}$ *is non-decreasing function of* N*;*

(iv) For fixed $\alpha > 0$ $\mathcal{E}^{\mathsf{TF}}_{\alpha} - \mathcal{E}^{\mathsf{TF}}_{0}$ *is non-decreasing function of* N*.*

Equality

$$\nu = \frac{\partial \mathcal{E}^{\mathsf{TF}}}{\partial N} \tag{25.3.37}$$

implies that (iii) is equivalent to

$$\nu_{\alpha} \ge \nu_0. \tag{25.3.38}$$

Theorem 25.3.9 [12]**.** *(i) For fixed* $Z_1, \dots, Z_M; \mathsf{y}_1, \dots, \mathsf{y}_M$ *and* $N = Z$

$$\lambda^7 \widehat{\mathcal{E}}^{\mathsf{TF}}(\underline{Z}; \lambda \underline{y}; N) = \widehat{\mathcal{E}}^{\mathsf{TF}}(\lambda^3 \underline{Z}; \underline{\mathsf{y}}; \lambda^3 N) \tag{25.3.39}$$

is positive non-decreasing function of $\lambda > 0$ *and has a finite limit as* $\lambda \to +\infty$*.*

(ii) This limit does not depend on $Z_1, \dots, Z_M$*.*

Remark 25.3.10. One can observe easily that the same scaling property without assumption $N = Z$ holds for $\mathcal{E}^{\mathsf{TF}}$ and U as well.

These two theorems and remark imply immediately

Proposition 25.3.11. *Let assumption* (25.3.33) *be fulfilled. Then*

$$\widehat{\mathcal{E}}^{\mathsf{TF}}(\underline{Z}; \underline{\mathsf{y}}; N) - \min_{\substack{N_1,\dots,N_M: \\ N_1+\dots N_M = N}} \sum_{1 \le m \le M} \mathcal{E}^{\mathsf{TF}}(Z_m; N_m) \ge \epsilon \min(a^{-7}, Z^{\frac{7}{3}}) \tag{25.3.40}$$

where

$$a = \frac{1}{2} \min_{m<m'} |\mathsf{y}_m - \mathsf{y}_{m'}|. \tag{25.3.41}$$

[12] (1.8)–(1.9) of H. Brezis and E. Lieb [1].

Proof. In virtue of theorem 25.3.8(i) it suffices to prove proposition for $M = 2$ (all other nuclei could be pulled to infinity), and in virtue of theorem 25.3.8(iii) it suffices to prove proposition for $Z = N$.

Then the proof is due to theorem 25.3.9(i) and (25.3.33), which provides uniformity. □

Remark 25.3.12. In virtue of (25.3.37) the minimum (with respect to $N_1, \dots, N_M$) in the sum in the right hand expression is reached when $\nu_j = \nu_k$ for all j, k. The same is true for a system of isolated molecules.

Proposition 25.3.13 (Non-Binding Theorem). *Let $\mathcal{Q}$ denote Thomas-Fermi excess energy which is the left-hand expression of* (25.3.40)*. Then*

$$\mathsf{D}(\rho^{\mathsf{TF}} - \bar{\rho}^{\mathsf{TF}},\, \rho^{\mathsf{TF}} - \bar{\rho}^{\mathsf{TF}}) \le C\mathcal{Q}, \qquad \bar{\rho}^{\mathsf{TF}} := \sum_{1\le m\le M} \rho_m^{\mathsf{TF}}. \tag{25.3.42}$$

Proof. We follow "non-binding" proof due to Baxter with small modification.

According to Baxter's Lemma (see Proposition 25.A.5) there exist g, $0 \le g \le \rho^{\mathsf{TF}}$ and $h = \rho^{\mathsf{TF}} - g$ such that $g * |x|^{-1} = V_1$ a.e. when $h > 0$ and $g * |x|^{-1} \le V_1$ a.e. when $h = 0$. Here $V_m = Z_m|x - \mathsf{y}_m|^{-1}$.

Let $\alpha = \int g\,dx$, $\beta = \int h\,dx$ and let $\mathcal{E}_1^{\mathsf{TF}}$, $\mathcal{E}_{(1)}^{\mathsf{TF}}$ be Thomas-Fermi energies for the first atom and for the rest of molecule respectively and ρ_1^{TF}, $\rho_{(1)}^{\mathsf{TF}}$ be corresponding Thomas-Fermi densities. Then

$$\min_{N_1+N'\le N}\Bigl(\mathcal{E}_1^{\mathsf{TF}}(N_1) + \mathcal{E}_{(1)}^{\mathsf{TF}}(N')\Bigr) \le \mathcal{E}_1(\alpha) + \mathcal{E}_{(1)}(\beta)$$

with

$$\begin{aligned}\mathcal{E}_1(\alpha) &\le \mathcal{E}_1(g) - \epsilon\mathsf{D}(\rho_1^{\mathsf{TF}} - g,\, \rho_1^{\mathsf{TF}} - g)\\ &= \int \tau(g)\,dx - \int V_1 g\,dx + \frac{1}{2}\mathsf{D}(g,g) - \epsilon\mathsf{D}(\rho_1^{\mathsf{TF}} - g,\, \rho_1^{\mathsf{TF}} - g)\end{aligned}$$

and

$$\begin{aligned}\mathcal{E}_{(1)}(\beta) &\le \mathcal{E}_{(1)}(h) - \epsilon\mathsf{D}(\rho_{(1)}^{\mathsf{TF}} - h,\, \rho_{(1)}^{\mathsf{TF}} - h)\\ &= \int \tau(h)\,dx - \int (V - V_1)h\,dx + \frac{1}{2}\mathsf{D}(h,h) - \epsilon\mathsf{D}(\rho_{(1)}^{\mathsf{TF}} - h,\, \rho_{(1)}^{\mathsf{TF}} - h)\end{aligned}$$

and therefore

$$\mathcal{E}_1(g)+\mathcal{E}_{(1)}(h)=\int \bigl(\tau(g)+\tau(h)-V(g+h)\bigr)\,dx + \frac{1}{2}\mathsf{D}(g+h,g+h)+\int (V-V_1)g\,dx+\int V_1 h\,dx-\mathsf{D}(g,h)$$

with

$$\int \bigl(\tau(g)+\tau(h)-V(g+h)\bigr)\,dx+\frac{1}{2}\mathsf{D}(g+h,g+h) \le \int \bigl(\tau(g+h)-V(g+h)\bigr)\,dx+\frac{1}{2}\mathsf{D}(g+h,g+h)=:\mathcal{E}(g+h)=\mathcal{E}(\rho) \tag{25.3.43}$$

due to superadditivity of $\tau(\cdot)$ (that is $\tau(g+h)\ge\tau(g)+\tau(h)$ as $h\ge 0, h\ge 0$). Further,

$$\int (V-V_1)g\,dx=\int \sum_{2\le m\le M}\frac{Z_m}{|x-y_m|}g(x)\,dx = \int \sum_{2\le m\le M} Z_m\delta(x-y_m)(|x|^{-1}*g)\,dx \le \int \sum_{2\le m\le M}\delta(x-y_m)V_1(x)\,dx = \sum_{2\le m\le M}\frac{Z_1Z_m}{|\mathsf{y}_1-\mathsf{y}_m|}$$

due to properties g and

$$\int V_1 h\,dx-\mathsf{D}(g,h)=\int (V_1-|x|^{-1}*g)h\,dx=0$$

due to properties g, h.

Therefore

$$\min_{N_1+N'\le N}\Bigl(\mathcal{E}_1^{\mathsf{TF}}(N_1)+\mathcal{E}_{(1)}^{\mathsf{TF}}(N')\Bigr)\le \mathcal{E}(g+h)+\sum_{2\le m\le M}\frac{Z_1Z_m}{|\mathsf{y}_1-\mathsf{y}_m|} - \epsilon\mathsf{D}(\rho_1^{\mathsf{TF}}-g,\,\rho_1^{\mathsf{TF}}-g)-\epsilon\mathsf{D}(\rho_{(1)}^{\mathsf{TF}}-h,\,\rho_{(1)}^{\mathsf{TF}}-h). \tag{25.3.44}$$

Then

$$\mathsf{D}(\rho^{\mathsf{TF}}-\rho_1^{\mathsf{TF}}-\rho_{(1)}^{\mathsf{TF}},\rho^{\mathsf{TF}}-\rho_1^{\mathsf{TF}}-\rho_{(1)}^{\mathsf{TF}})\le 2\mathsf{D}(g-\rho_1^{\mathsf{TF}},g-\rho_1^{\mathsf{TF}})+2\mathsf{D}(h-\rho_{(1)}^{\mathsf{TF}},h-\rho_{(1)}^{\mathsf{TF}})\le C\mathcal{Q}. \tag{25.3.45}$$

Using induction with respect to M we arrive to (25.3.42). □

Problem 25.3.14. Find the stronger lower bound in (25.3.40) as $N < Z$. Would be the left-hand expression $\asymp \min(a^{-7} + |Z-N|^2 a^{-1}, Z^{\frac{7}{3}})$?

25.4 Application of Semiclassical Methods

25.4.1 Asymptotics of the Trace

In this subsection we calculate asymptotics of $\mathsf{Tr}((H_W - \nu)^-)$. Here we need to consider both inner and outer zones.

An *inner zone* (near nucleus y_m) is a ball where $V_j = Z_m|x-\mathsf{y}_m|^{-1}$ dominates $W - V_m$. For a single nucleus ($M = 1$) it is defined by

$$|x-\mathsf{y}_m| \le \epsilon Z_m^{-\frac{1}{3}} \tag{25.4.1}$$

but in the case $M \ge 2$ there are another restrictions

$$|x-\mathsf{y}_m| \le \epsilon \min_{m'\neq m}\Big(Z_m(Z_m+Z_{m'})^{-1}|\mathsf{y}_m-\mathsf{y}_{m'}|\Big) \tag{25.4.2}$$

and

$$|x-\mathsf{y}_m| \le Z_m\nu^{-1} \tag{25.4.3}$$

but we shrink this zone to

$$|x-\mathsf{y}_m| \le r_m \coloneqq \epsilon \min\big(Z_m Z^{-1}a, Z_m^{-\frac{1}{3}}\big). \tag{25.4.4}$$

Let us consider contribution of the zone $\mathcal{X}_m$ described by (25.4.4) to $\mathsf{N}_1(H_W-\nu) = \mathsf{Tr}((H_W-\nu)^-)$, both into the principal part of asymptotics and the remainder. Let ψ_m be a partition element concentrated in $\mathcal{X}_m$ and equal to 1 in $\{x\colon |x-\mathsf{y}_m| \le \frac{1}{2}r_m\}$. Then, according to Theorem 12.6.8,

$$\mathsf{Tr}\big((H_W-\nu)^-\psi_m\big) = \int \mathsf{Weyl}_1(x)\psi_m(x)\,dx + \mathsf{Scott}_m + O(R_m) \tag{25.4.5}$$

where $\mathsf{Weyl}_1(x)$ and Scott_m are calculated for the case $q = 1$ and then multiplied by q [13]:

$$\mathsf{Weyl}_1(x) \coloneqq -\frac{q}{15\pi^2}\big(W(x)+\nu\big)_+^{\frac{5}{2}} \tag{25.4.6}$$

[13] As operator $H_w - \nu$ is nothing but q copies of $\Delta - (W+\nu)$.

while R_m is $C\zeta^2(\zeta\ell) = C\zeta^3\ell$ calculated on its border i.e.

$$R_m = CZ_m^{\frac{5}{3}} + CZ_m^{\frac{3}{2}} r_m^{-\frac{1}{2}} \le CZ^{\frac{5}{3}} + CZ^{\frac{3}{2}} a^{-\frac{1}{2}}. \tag{25.4.7}$$

Really, one needs just to rescale $x \mapsto (x - \mathsf{y}_m) r_m^{-1}$ and $\tau \mapsto \tau Z_m^{-1} r_m$ and introduce a semiclassical parameter $\hbar = Z_m^{\frac{1}{2}} r_m^{\frac{1}{2}}$.

Remark 25.4.1. (i) Clearly, these arguments work only if $r_m \ge Z_m^{-1}$ (i.e. $Z_m^2 \ge a^{-1}Z$).

(ii) On the other hand, if $Z_m^2 \ge a^{-1}Z$ but $a \ge Z^{-1}$ we define $r_m = a^{\frac{1}{2}} Z^{-\frac{1}{2}}$ and we do not include Scott_m [14] into the principal expression; moreover, in this case we include $\mathcal{X}_m$ into a singular zone and use variational methods to estimate its contribution into the principal part of asymptotics; it will not exceed $CZa^{-1} \le CZ^{\frac{3}{2}} a^{-\frac{1}{2}}$.

(iii) Furthermore, if $a \le Z^{-1}$, we set $r_m = Z^{-1}$ and we do not include any Scott_m [14] into the principal part of asymptotics and include all $\mathcal{X}_m$ into singular zones; using variational methods we estimate their contributions into the principal part of asymptotics by CZ^2.

Therefore we conclude that

(25.4.8) The total contribution of all inner zones into remainder does not exceed the right-hand expression of (25.4.7) as $a \ge Z^{-1}$ and CZ^2 as $a \le Z^{-1}$.

Let us consider contributions of the *outer zone* $\mathcal{X}_0$ which is complimentary to the union of all inner zones. Then

$$\mathsf{Tr}\big((H_W - \nu)^- \psi_0\big) = \int \mathsf{Weyl}_1(x)\psi_0(x)\,dx + O(R_0) \tag{25.4.9}$$

with $\mathsf{Weyl}_1(x)$ defined by (25.4.6) where

$$R_0 = \int_{\mathcal{X}_0} C\bar{\zeta}(x)^3 \ell^{-2}\,dx \tag{25.4.10}$$

[14] However it will be less than the remainder estimate, so we can include it into the principal part of asymptotics anyway.

and

$$\bar{\zeta} = \begin{cases} Z^{\frac{1}{2}}\ell^{-\frac{1}{2}} & \text{as } \ell \le Z^{-\frac{1}{3}}, \\ \ell^{-2} & \text{as } \ell \ge Z^{-\frac{1}{3}}. \end{cases} \tag{25.4.11}$$

We justify (25.4.9)–(25.4.11) a bit later by an appropriate partition of unity. One can see easily that the contribution of the zone $\{x\colon \ell(x) \le Z^{-\frac{1}{3}}\}$ into expression (25.4.10) does not exceed the same expression as in (25.4.8) and that the contribution of the zone $\{x\colon \ell(x) \ge Z^{-\frac{1}{3}}\}$ into (25.4.10) does not exceed $CZ^{\frac{5}{3}}$. Then we arrive to

Theorem 25.4.2. *Let $W = W^{\mathsf{TF}}$, $N \asymp Z$, $W = W^{\mathsf{TF}}$. Then*

$$\mathsf{Tr}\big((H_W - \nu)^-\big) = \int \mathsf{Weyl}_1(x)\,dx + \sum_{1\le m\le M} \mathsf{Scott}_m + O(R), \tag{25.4.12}$$

with

$$R := \begin{cases} CZ^{\frac{5}{3}} + CZ^{\frac{3}{2}}a^{-\frac{1}{2}} & \text{as} \quad a \ge Z^{-1}, \\ CZ^2 & \text{as} \quad a \le Z^{-1}. \end{cases} \tag{25.4.13}$$

Proof. (i) Consider $\nu = 0$ first. Then we just apply ℓ-admissible partition of unity. Sure, $\zeta\ell \le 1$ as $\ell \ge 1$ but we can deal with it either by taking $\zeta = \ell^{-1}$ here or considering it as a singular zone and applying here variational estimate as well.

(ii) Variational estimate works for $\nu < 0$ as well; furthermore, zone $\{x\colon W(x) \le (1-\epsilon)\nu, \ell \ge |\nu|^{-\frac{1}{2}}\}$ is classically forbidden.

(iii) However as $\nu \le -c$ we have a little problem as W^{TF} is not very smooth, it is only $\mathscr{C}^{\frac{7}{2}}$ as $W \asymp -\nu$. The best[15)] way to deal with it is to take $\varepsilon\ell$-mollification with $\varepsilon = \hbar^{1-\delta}$, $\hbar = (\zeta\ell)^{-1}$, use rough microlocal analysis of Section 4.6 and the bracketing; it will bring an approximation error not exceeding $C\varepsilon^{\frac{7}{2}}\hbar^{-3}|\nu|$ which does not exceed $|\nu| = O(|Z-N|^{\frac{4}{3}})$. We leave easy details to the reader. □

Now we arrive to the lower estimate for E:

[15)] From the point of view of generalization to the case when magnetic field is present and it is not too weak, so magnetic version of W^{TF} has multiple singularities.

Corollary 25.4.3. *Let $N \asymp Z$. Then*

$$\mathsf{E} \geq \mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} - CR \tag{25.4.14}$$

with R defined by (25.4.13).

Proof. We know from Subsection 25.2.1 that

$$\mathsf{E} \geq \mathsf{N}_1(H_W - \nu) + \nu N - \frac{1}{2}\mathsf{D}(\rho,\rho) - CZ^{\frac{5}{3}} \tag{25.4.15}$$

as W is given by (25.2.3). In virtue of Theorem 25.4.2

$$\mathsf{E} \geq \int \mathsf{Weyl}_1(x)\,dx + \nu \int \mathsf{Weyl}(x)\,dx - \frac{1}{2}\mathsf{D}(\rho,\rho) + \mathsf{Scott} - CR \tag{25.4.16}$$

where we also plugged instead of N as $N < Z$ (and $\nu < 0$)

$$N = \int \mathsf{Weyl}(x)\,dx \tag{25.4.17}$$

with

$$\mathsf{Weyl}(x) = \frac{q}{6\pi^2}\big(W(x) + \nu\big)_+^{\frac{3}{2}}. \tag{25.4.18}$$

One can check easily that three first terms in the right-hand expression of (25.4.18) constitute exactly $\Phi_*(W+\nu)$ coinciding with $\mathcal{E}^{\mathsf{TF}}$ as $W = W^{\mathsf{TF}}$.□

Remark 25.4.4. (i) As $a \leq Z^{-\frac{1}{3}}$ using the same method one can prove a slightly better remainder estimate–with $Z^{\frac{3}{2}}a^{-\frac{1}{2}}$ replaced by

$$\sum_{1\leq m<m'\leq M} \min\Big((Z_m + Z_{m'})^{\frac{3}{2}}|x_m - \mathsf{y}_{m'}|^{-\frac{1}{2}}, (Z_m + Z_{m'})^2\Big) \tag{25.4.19}$$

allowing to lighter nuclei to be closer one to another.

(ii) To improve this estimate further, allowing lighter nuclei to be closer to heavier, ones one needs to improve Theorem 12.6.8 which seems to be too difficult task for a such little gain.

25.4.2 Upper Estimate for E

Recall that in virtue of Subsection 25.2.2

$$\mathsf{E} \le \mathsf{N}_1(H_W-\nu)+\nu N - \frac{1}{2}\mathsf{D}(\rho,\rho)+ |\lambda_N-\nu|\cdot|\mathsf{N}(H_W-\nu)-N| + \frac{1}{2}\mathsf{D}(\operatorname{tr} e_N(x,x)-\rho, \operatorname{tr} e_N(x,x)-\rho\big) \tag{25.4.20}$$

and thus we need to estimate two last terms in the right-hand expression.

Estimating $|\lambda_N-\nu|$

First, we need to estimate $|\lambda_N-\nu|$. We will use the heuristic equality $\mathsf{N}(H_W-\lambda_N)\approx N$ or more precisely two inequalities

$$\mathsf{N}(H_W-\lambda_N-0)\le N\le \mathsf{N}(H_W-\lambda_N+0) \tag{25.4.21}$$$_{1,2}$

and equality

$$\int \mathsf{Weyl}(x)\,dx = \min(N,Z) \tag{25.4.22}$$

where the right inequality (25.4.21)$_2$ is valid only if $\lambda_N<0$ i.e. $\mathsf{N}(H_W)\ge N$.

Case $\lambda_N<\nu$. Then we will use (25.4.21)$_2$ and to calculate $\mathsf{N}(H_W-\lambda_N+0)$ we will use semiclassical approximation:

$$\mathsf{N}(H_W-\lambda_N+0)=\int \mathsf{Weyl}(x,\lambda_N)\,dx + O(R_0) \tag{25.4.23}$$

with the semiclassical error

$$R_0=\int \zeta^2\ell^{-1}\,dx \tag{25.4.24}$$

with the integral not exceeding

$$CZ\int_{\{|x|\le Z^{-\frac{1}{3}}\}} |x|^{-2}\,dx + C\int_{\{|x|\ge Z^{-\frac{1}{3}}\}} |x|^{-5}\,dx \asymp CZ^{\frac{2}{3}};$$

again we need to consider separately the case of $N\ge Z$ and $\nu=0$, when integral (25.4.24) is taken over $\mathbb{R}^3$, and the case of $N<Z$ and $\nu<0$, when this integral should be taken over $\{x\colon \ell(x)\le C(Z-N)^{-\frac{1}{3}}\}$; in the latter

case to cover non-smoothness we consider an approximation (mollification) of W and an approximation error $\varepsilon^{\frac{7}{2}}\hbar^{-3} \ll 1$. Therefore

$$\int \mathsf{Weyl}(x,\lambda_N)\,dx \ge N - CZ^{\frac{2}{3}}. \tag{25.4.25}$$

Comparing with (25.4.22) we conclude that

$$\int \Big(\big(W(x)+\nu\big)_+^{\frac{3}{2}} - \big(W(x)+\lambda_N\big)_+^{\frac{3}{2}}\Big)\,dx \le CZ^{\frac{2}{3}}. \tag{25.4.26}$$

Here an integrand is non-negative (since $\lambda_N < \nu$). Further, one can see easily that the main contribution to this integral is delivered by the zone $\{x\colon \ell(x) \asymp |\lambda_N|^{-\frac{1}{4}}\}$ [16] and the whole integral is $\asymp |\lambda_N|^{-\frac{1}{4}}|\nu-\lambda_N|$. Therefore (25.4.26) yields that

$$|\lambda_N-\nu| \le C\big(|\nu|+|\lambda_N-\nu|\big)^{\frac{1}{4}}Z^{\frac{2}{3}},$$

which is equivalent to

$$|\lambda_N-\nu| \le CZ^{\frac{8}{9}} + C|\nu|^{\frac{1}{4}}Z^{\frac{2}{3}} \asymp CZ^{\frac{8}{9}} + C(Z-N)_+^{\frac{1}{3}}Z^{\frac{2}{3}} \le CZ. \tag{25.4.27}$$

In particular,

(25.4.28) If $|\nu| \le c_0 Z^{\frac{8}{9}}$ (i.e. $(Z-N)_+ \le c_1 Z^{\frac{2}{3}}$), then $|\lambda_N| \le C_0 Z^{\frac{8}{9}}$

and also

$$|\lambda_N-\nu|\cdot|\mathsf{N}(H_W-\nu)-N| \le CZ\cdot Z^{\frac{2}{3}} = CZ^{\frac{5}{3}}. \tag{25.4.29}$$

Case $\lambda_N \ge \nu$. Then we will use the left inequality $(25.4.21)_1$, but if $\mathsf{N}(H_W) < N$ then integral (25.4.24) is diverging.

To avoid all related difficulties we will consider first the case when we necessarily conclude that $|\lambda_N| \ge (1-\epsilon)|\nu|$. To do so observe that even if the main contribution to the integral (25.4.26) [17] is delivered by the zone $\{x\colon \ell(x) \asymp (Z-N)|\lambda_N|^{-1} \asymp |\nu|^{\frac{3}{4}}|\lambda_N|^{-1}\}$, we will ignore this observation and consider a larger zone $\{x\colon \ell(x) \le C_0|\nu|^{-\frac{1}{4}}\}$ instead of $\{x\colon \ell(x) \le C_0|\nu|^{\frac{3}{4}}|\lambda_N|^{-1}\}$ [18].

One can prove easily that

---

[16] Provided $|\lambda_N| \le C_0 Z^{\frac{4}{3}}$. On the other hand, if $|\lambda_N| \ge C_0 Z^{\frac{4}{3}}$ one can see easily that (25.4.26) is $\asymp Z$ because $|\nu| \le c_0 Z^{\frac{4}{3}}$ due to $N \asymp Z$.

[17] Now an integrand is non-positive.

[18] Obviously these zones coincides as $|\nu| \asymp |\lambda_N|$.

(25.4.30) The contribution of the zone $\{x\colon \ell(x) \le C_0|\nu|^{-\frac14}\}$ to the semiclassical remainder, when calculating $\mathsf{N}(H_W - \lambda_N)$, does not exceed $CZ^{\frac23}$.

Therefore we arrive to the estimate

$$|\lambda_N - \nu| \le C|\nu|^{\frac14} Z^{\frac23} \asymp C(Z-N)_+^{\frac13} Z^{\frac23} \le CZ \tag{25.4.31}$$

(cf. (25.4.27)). In particular, we conclude that

(25.4.32) If $|\nu| \ge CZ^{\frac89}$ (i.e. $(Z-N) \ge CZ^{\frac23}$), then $|\lambda_N| \asymp |\nu|$

(cf. (25.4.28)). Then one can easily recover (25.4.27) completely. Since $|\mathsf{N}(H_W - \nu) - N| \le CZ^{\frac23}$ we arrive to (25.4.29).

Case $|\nu| \le \eta = CZ^{\frac89}$. This case (i.e. $(Z-N) \le \eta^{\frac34} = CZ^{\frac23}$) is the most important one. The easiest way to tackle it is to pick up ρ^{TF} and W^{TF} calculated as if $\nu = 0$ i.e. $Z = N$; that means the change of the test function Ψ in the upper estimate.

We need to modify an upper estimate of $\sum_{1\le j\le N} \lambda_j$. To do this we note that

$$\lambda_N \ge -\eta \tag{25.4.33}$$

and

(25.4.34) A number of eigenvalues between λ_N (if $\lambda_N < 0$) and 0 does not exceed $CZ^{\frac23} + C\eta^{\frac34}$,

which can be proven easily by our standard methods. Therefore

$$\sum_{1\le j\le N} \lambda_j \le \mathsf{Tr}(H_W^-) + C\eta\big(Z^{\frac23} + \eta^{\frac34}\big) \tag{25.4.35}$$

and the last term is less than $CZ^{\frac53}$ as long as $\eta \le CZ^{\frac{20}{21}}$ which is fulfilled.

In this last case[19)] we arrive to an upper estimate with $\mathcal{E}^{\mathsf{TF}}$ calculated as if $\nu = 0$ i.e. $\mathcal{E}^{\mathsf{TF}}(\underline{Z}; \underline{y}; Z)$ which is less than $\mathcal{E}^{\mathsf{TF}}(\underline{Z}; \underline{y}; N)$. Actually the difference between these two is $\asymp |\nu|^{\frac74} \le |\eta|^{\frac74}$.

[19)] Pending an analysis of the next subsubsection.

Estimating D-Term

We need to estimate the last term in the right-hand expression of (25.4.20); we estimate it by

$$\begin{aligned}(25.4.36)\quad & C_0\mathsf{D}\big(\operatorname{tr} e(x,x,\nu)-P'(W+\nu),\operatorname{tr} e(x,x,\nu)-P'(W+\nu)\big)\\ &+C_0\mathsf{D}\big(\operatorname{tr} e(x,x,\nu)-\operatorname{tr} e_N(x,x),\operatorname{tr} e(x,x,\nu)-\operatorname{tr} e_N(x,x)\big)\\ &+C_0\mathsf{D}\big(\rho-P'(W+\nu),\rho-P'(W+\nu)\big),\end{aligned}$$

where the last term vanishes as $\rho=\rho^{\mathsf{TF}}$, $W=W^{\mathsf{TF}}$; however, for some technical reasons we want to avoid this assumption.

Estimating the First Term. To estimate the first term in (25.4.36) we apply the semiclassical asymptotics

$$\operatorname{tr} e(x,x,\nu)=\mathsf{Weyl}(x)+O(\zeta^2\ell^{-1}), \tag{25.4.37}$$

where $\mathsf{Weyl}(x)=P'(W(x)+\nu)$ and therefore this term does not exceed

$$\iint \zeta(x)^2\zeta(y)^2\ell(x)^{-1}\ell(y)^{-1}|x-y|^{-1}\,dxdy. \tag{25.4.38}$$

Estimating this integral by the double sum of the integrals over domains $\{(x,y)\colon \ell(x)\le Z^{-\frac{1}{3}},\ell(y)\le Z^{-\frac{1}{3}}\}$ and $\{(x,y)\colon \ell(x)\ge Z^{-\frac{1}{3}},\ell(y)\ge Z^{-\frac{1}{3}}\}$ we get

$$CZ^2\iint_{\{|x|\le Z^{-\frac{1}{3}},|y|\le Z^{-\frac{1}{3}}\}} |x|^{-2}|y|^{-2}|x-y|^{-1}\,dxdy \tag{25.4.39}$$

and

$$C\iint_{\{|x|\ge Z^{-\frac{1}{3}},|y|\ge Z^{-\frac{1}{3}}\}} |x|^{-3}|y|^{-3}|x-y|^{-1}\,dxdy \tag{25.4.40}$$

respectively, and rescaling we get the same integrals but both with the "threshold" 1 rather than $Z^{-\frac{1}{3}}$ and both with factor $Z^{\frac{5}{3}}$ rather than Z^2 or 1 respectively; one can see easily that both obtained integrals (without factor $Z^{\frac{5}{3}}$) are $\asymp 1$. Therefore, expression (25.4.38) is $O(Z^{\frac{5}{3}})$.

Therefore we proved

Proposition 25.4.5. *As $W=W^{\mathsf{TF}}$ the first term in* (25.4.36) *does not exceed $CZ^{\frac{5}{3}}$.*

Remark 25.4.6. (i) For $N \ge Z$ and $\nu = 0$ we used that $\zeta \le C_1\ell^{-2}$ for $\ell \ge Z^{-\frac{1}{3}}$.

(ii) For $N < Z$ and $\nu < 0$ we used that zone $\{x\colon \ell \ge C(Z-N)^{-\frac{1}{3}}\}$ is classically forbidden ($W+\nu<0$ there) and therefore integral is taken over zone $\{x\colon \ell \le C(Z-N)^{-\frac{1}{3}}\}$ where $\zeta \le C_1\ell^{-2}$.

(iii) As $N<Z$ W^{TF} is not very smooth near $W+\nu=0$ but one can handle it by rescaling arguments.

(iv) Alternatively (preferably[15)]) one can replace W^{TF} by its mollification $W^{\mathsf{TF}}_\varepsilon$.

Remark 25.4.7. Estimating this term, and also the second D-term (in the next paragraph) we need to estimate the contribution of the singular zone $\{x\colon \ell(x) \le \bar{r} = Z^{-1}\}$ where effective semiclassical parameter is less than 1. We claim that there

$$e(x,x,\lambda) \le CZ^3 \qquad \text{for } \lambda \le cZ^2. \tag{25.4.41}$$

Indeed, it is true if $\ell(x)\ge 1$. Also operator H is bounded from below by $-CZ^2$. And finally, in the ball of $B(\mathsf{y}_m, \epsilon Z^{-1})$ operator Δ is larger than $Z|x-\mathsf{y}_m|^{-1}$. We leave the easy details to the reader.

Therefore the contribution of this zone into N-term is $O(CZ^3\bar{r}^3) = O(1)$, into both D-terms is $O(Z^6\bar{r}^5) = O(Z)$, and into T-term is $O(Z^5\bar{r}^3) = O(Z^2)$.

Estimating the Second Term. Consider now the second term in (25.4.36). Due to the arguments of the previous paragraph modulo $O(Z^{\frac{5}{3}})$ one can rewrite it as

$$C_1\mathsf{D}\big(P'(W+\lambda_N)-P'(W+\nu), P'(W+\lambda_N)-P'(W+\nu)\big). \tag{25.4.42}$$

Really, if we replace $\mathsf{tr}\, e(x,x,\nu)$ and $\mathsf{tr}\, e_N(x,x)$ by $\mathsf{Weyl}(x,\nu)$ and $\mathsf{Weyl}(x,\lambda_N)$ respectively we make a semiclassical errors estimated by $Z^{\frac{5}{3}}$ provided either $\lambda_N < \nu$ or $\lambda_N \asymp \nu$ which is always the case unless $|\nu| \le CZ^{\frac{8}{9}}$ but in this case we just "cheat" resetting everything to the case $\nu = 0$.

Let us estimate (25.4.42). According to the previous Subsubsection 25.4.2.1 there are two cases:

(i) $N \ge Z - CZ^{\frac{2}{3}}$, in which case $|\nu| \le CZ^{\frac{8}{9}}$ and $|\lambda_N| \le CZ^{\frac{8}{9}}$, and (25.4.42) does not exceed

$$C|\nu-\lambda_N|^2 \iint_{\{\ell(x)\le L,\ell(y)\le L\}} |x-y|^{-1}\zeta(x)\zeta(y)\,dxdy + C\iint_{\{\ell(x)\ge L,\ell(y)\ge L\}} |x-y|^{-1}\zeta(x)^3\zeta(y)^3\,dxdy$$

with $L = |\lambda_N - \nu|^{-\frac{1}{4}}$; one can calculate easily that both terms are of the magnitude $C|\lambda_N-\nu|^{\frac{7}{4}} \le CZ^{\frac{14}{9}} \ll Z^{\frac{5}{3}}$.

(ii) $N \le Z - CZ^{\frac{2}{3}}$, in which case (25.4.42) does not exceed

$$C|\nu-\lambda_N|^2 \iint_{\{\ell(x)\le L,\ell(y)\le L\}} |x-y|^{-1}\zeta(x)\zeta(y)\,dxdy$$

with $L = |\nu|^{-\frac{1}{4}}$ and this integral does not exceed $|\lambda_N-\nu|^2|\nu|^{-\frac{1}{4}}$ which due to (25.4.27) does not exceed $C(Z-N)^{\frac{1}{3}}Z^{\frac{4}{3}} \le CZ^{\frac{5}{3}}$.

Estimating the Third Term. The third term in (25.4.36) does not exceed

$$C_1\mathsf{D}\big(\rho-\rho^{\mathsf{TF}},\,\rho-\rho^{\mathsf{TF}}\big)+ C_1\mathsf{D}\big(P'(W+\nu)-P'(W^{\mathsf{TF}}+\nu),\,P'(W+\nu)-P'(W^{\mathsf{TF}}+\nu)\big)$$

and we leave to the reader an easy proof that both terms here are $O(Z^{\frac{5}{3}-\delta})$ as W is a described mollification of W^{TF}.

Finally, a Theorem

As we finished an upper estimate for E we arrive to the following main result:

Theorem 25.4.8. *Let $N \asymp Z$ and let Ψ be a ground state. Then*

$$|\mathsf{E}-\mathcal{E}^{\mathsf{TF}}-\mathsf{Scott}| \le C\begin{cases} Z^{\frac{5}{3}}+a^{-\frac{1}{2}}Z^{\frac{3}{2}} & \text{as}\quad a\ge Z^{-1},\\ Z^2 & \text{as}\quad a\le Z^{-1},\end{cases} \tag{25.4.43}$$

where a is the minimal distance between nuclei.

25.4.3 Improved Asymptotics

So far as $a \ge Z^{-\frac{1}{3}}$ we recovered only $O(Z^{\frac{5}{3}})$ for both error estimate in E and (as a coproduct, see Subsection 25.4.4) for $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}})$.

Our purpose is to improve them to $o(Z^{\frac{5}{3}})$ (or slightly better) as $a \gg Z^{-\frac{1}{3}}$ and recover the Schwinger and Dirac terms. To do so in the lower estimate for E one just need an improved electrostatic inequality (see Theorem 25.2.5) and also improved semiclassical estimates in $\mathsf{Tr}((H_W - \nu)^-)$ and $\mathsf{N}(H_W - \nu)$.

For the improved upper estimate we will need also to improve estimate $\frac{1}{2}\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}})$ for the test function Ψ and apply an estimate

$$|\frac{1}{2}\iint |x-y|^{-1} \operatorname{tr} e_N(x,y)e_N^\dagger(x,y)\,dxdy + \kappa_{\mathsf{Dirac}} \int \rho^{\mathsf{TF}\,\frac{4}{3}}(x)\,dx| \le Z^{\frac{5}{3}-\delta} \tag{25.4.44}$$

which is due to Theorem 6.4.17[20].

Remark 25.4.9. (i) Only contributions to the remainder of zones

$$\{x\colon Z^{-\frac{1}{3}-\delta_1} \le |x - \mathsf{y}_m| \le Z^{-\frac{1}{3}} b^{\delta_1}\} \tag{25.4.45}$$

with $b := \min(aZ^{\frac{1}{3}}, 1)$ (where now we assume that $b \ge 1$) should be considered because the contributions of both zones $\{x\colon \ell(x) \le Z^{-\frac{1}{3}} b^{-\delta_1}\}$ and $\{x\colon \ell(x) \le Z^{-\frac{1}{3}} b^{\delta_1}\}$ are $O(Z^{\frac{5}{3}} b^{-\delta})$.

(ii) Only m with $Z_m \ge Z b^{-\delta_2}$ should be considered because contributions of other m are are $O(Z^{\frac{5}{3}} b^{-\delta})$ as well.

Proposition 25.4.10. *Let ϑ be a (small) parameter such that $b^{-\delta_2} \le \vartheta \le 1$; consider m with $Z_m \ge Z\vartheta^{\delta_1}$. Let $\phi(x) = \psi(r^{-1}(x - \mathsf{y}_m))$ with $\psi \in \mathscr{C}_0^\infty(B(0,1))$ and r defined below.*

(i) Further, let $(Z-N)^{-\frac{1}{3}} \ge r = Z^{-\frac{1}{3}}\vartheta^{-1}$. Then inequalities

$$\Big|\int \phi(x) \int_{-\infty}^{\lambda} \big(e(x,x,\lambda') - \mathsf{Weyl}(x,\lambda')\big)\,dxd\lambda' - \mathsf{Scott} - \mathsf{Schwinger}\Big| \le CZ^{\frac{5}{3}}\vartheta^{\delta}, \tag{25.4.46}$$

[20] This theorem implies the above estimate with $\delta = 1$ which is definitely overkill for our purposes.

$$\Big|\int \phi(x)\big(e(x,x,\lambda)-\mathsf{Weyl}(x,\lambda)\big)\,dx\Big| \le CZ^{\frac{2}{3}}\vartheta^{\delta} \tag{25.4.47}$$

and

$$\mathsf{D}\Big(\phi\big(e(x,x,\lambda)-\mathsf{Weyl}(x,\lambda)\big),\phi\big(e(x,x,\lambda)-\mathsf{Weyl}(x,\lambda)\big)\Big)\le CZ^{\frac{5}{3}}\vartheta^{\delta} \tag{25.4.48}$$

hold with some exponent $\delta>0$ for all $\lambda\le 0$ and for ϕ which is r-admissible.

(ii) On the other hand, let $(Z-N)^{-\frac{1}{3}}\le r$. Let W be a constructed above mollification of W^{TF}. Then

(a) Estimates (25.4.46)–(25.4.48) *hold for all $\lambda\le\nu$.*

(b) Further, estimates (25.4.47), (25.4.48) *hold for $\lambda\in[\nu,0]$ such that $\mathsf{N}(H-\lambda)\le N$.*

(c) Furthermore, in this last case

$$|\lambda-\nu|\le CZ^{\frac{2}{3}}(Z-N)^{\frac{1}{3}}\vartheta^{\delta}. \tag{25.4.49}$$

To prove these statements we need to study behavior of the Hamiltonian trajectories. First we want to prove that in the indicated zone W^{TF} is a weak perturbation of W_m^{TF} which is a single atom Thomas-Fermi potential with Z_m and with $\nu_m=\nu$.

Proposition 25.4.11. *In the framework of Proposition 25.4.10 in $B(\mathsf{y}_m,r)$*

$$|D^{\alpha}(W^{\mathsf{TF}}-W_m^{\mathsf{TF}})|\le c_{\alpha}W_m^{\mathsf{TF}}|x-\mathsf{y}_m|^{-|\alpha|}\vartheta^{\delta}. \tag{25.4.50}$$

This estimate holds for all α as $W^{\mathsf{TF}}/(-\nu)$ is disjoint from 1; otherwise it holds for $|\alpha|\le 3$ and

$$|D^{\alpha}(W^{\mathsf{TF}}-W_m^{\mathsf{TF}})(x)-D^{\alpha}(W^{\mathsf{TF}}-W_m^{\mathsf{TF}})(y)|\le cW_m^{\mathsf{TF}}|x-\mathsf{y}_m|^{-\frac{7}{2}}|x-y|^{\frac{1}{2}}\vartheta^{\delta} \tag{25.4.51}$$

for $|\alpha|=3$ and $|x-\mathsf{y}_m|\asymp|y-y_m|\asymp(Z-N)^{-\frac{1}{3}}$.

Proof. An easy proof based on the variational approach is left to the reader.□

Next, let us consider a manifold $\Sigma_\lambda = \{(x,\xi)\colon H(x,\xi) = \lambda\}$ with the classical Hamiltonian $H(x,\xi) = |\xi|^2 - W(x)$, and let us introduce a measure μ_λ with the density $dxd\xi : dH$ on Σ_λ; this measure is invariant with respect to the Hamiltonian flow with the Hamiltonian $H(x,\xi)$. Note that $\mu_\lambda(\Sigma_\lambda) \asymp Z$.

Proposition 25.4.12. *In the framework of Proposition 25.4.10 there exists a set $\Sigma'_{\lambda,\vartheta} \subset \Sigma_\lambda$ such that*

$$\mu_\lambda(\Sigma'_{\lambda,\vartheta}) \le C\vartheta^\delta Z \tag{25.4.52}$$

and through each point (x,ξ) belonging to $\vartheta(Z^{-\frac{1}{3}}, Z^{\frac{2}{3}})$-vicinity of $\Sigma_\lambda \setminus \Sigma'_{\lambda,\vartheta}$ in $T^*\mathbb{R}^3$ there passes a Hamiltonian trajectory $(x(t),\xi(t))$ of H of the length $T = Z^{-1}\vartheta^{-\delta}$ along which

$$\bigl|D^\alpha_{(xZ^{\frac{1}{3}},\xi Z^{-\frac{2}{3}})}\bigl(x(t)Z^{\frac{1}{3}}, \xi(t)Z^{-\frac{2}{3}}\bigr)\bigr| \le C\vartheta^{-K} \qquad \forall \alpha : |\alpha| \le k \tag{25.4.53}$$

and

$$|x(t) - x(0)|Z^{\frac{1}{3}} + |\xi(t) - \xi(0)|Z^{-\frac{2}{3}} \ge \vartheta^K |t| Z, \tag{25.4.54}$$

where m is arbitrary and K, δ depend on k.

Proof. We will just sketch the proof.

(i) Consider first the case $M = 1$. Then the the classical dynamical system is completely integrable since both the angular momentum and the energy are preserved.

First, let us include into $\Sigma'_{\lambda,\vartheta}$ all the points (x,ξ) with trajectories not residing over $\{\vartheta^{\delta'} Z^{-\frac{1}{3}} \le \ell(x) \le Z^{-\frac{1}{3}}\vartheta^{-\delta'}\}$ for all $t : |t| \le T$ [21].

Further, if $(Z - N)_+ \ge Z\vartheta^{\delta''}$ we also include into $\Sigma'_{\lambda,\vartheta}$ all the points (x,ξ) with the trajectories not residing over $B\bigl(\mathsf{y}_1, (1-\vartheta^{\delta'})\bar r\bigr)$; recall that for atoms $\bar r$ is an *exact* radius of $\mathsf{supp}(\rho^{\mathsf{TF}})$. Then (25.4.52)–(25.4.53) hold and we reduce δ, δ' if necessary.

It is known that not all the Hamiltonian trajectories are closed (see Appendix 25.A.2). Then one can prove easily that adding to $\Sigma'_{\lambda,\vartheta}$ the set satisfying (25.4.52) we can fulfill (25.4.52) and (25.4.54) as well[22]. One can find the similar arguments in the proof of Theorem 7.4.12.

---

[21] I.e. trajectories, leaving this "comfort zone" for some $t : |t| \le T$.

[22] It is important that in the classical dynamics is completely integrable.

(ii) The general case $M \ge 2$ is due of this particular one, Proposition 25.4.11 and trivial perturbation arguments. □

Proof of Proposition 25.4.10. Now estimates (25.4.46) and (25.4.47) follow from Propositions 25.4.11 and 25.4.12 and the standard arguments. Note that if $(Z-N)_+ \ge Z\vartheta^{\delta''}$ we need to mollify W^{TF} in the standard way.

To prove estimate (25.4.48) we can use decomposition (16.4.1) and apply to the contribution of zone $\{(x,y)\colon |x-y| \ge Z^{-\frac{1}{2}}\vartheta^{\delta'}\}$ the same standard arguments. Meanwhile one can notice that the contribution of the zone $\{(x,y)\colon |x-y| \ge Z^{-\frac{1}{2}}\vartheta^{\delta'}\}$ is $O(Z^{\frac{5}{3}-\delta})$. □

Combining all these improvements we arrive to

Theorem 25.4.13. *Let $N \asymp Z$. Let $a \ge Z^{-\frac{1}{3}}$ and let Ψ be a ground state. Then*

$$|\mathsf{E} - \mathcal{E}^{\mathsf{TF}} - \mathsf{Scott} - \mathsf{Dirac} - \mathsf{Schwinger}| \le CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + (aZ^{\frac{1}{3}})^{-\delta}\bigr). \tag{25.4.55}$$

25.4.4 Corollaries and Discussion

Estimates for $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}})$

Recall that in the lower estimate there was in the left-hand expression a non-negative term $\frac{1}{2}\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}})$ which we so far just dropped. Then in the frameworks of Theorems 25.4.8 and 25.4.13 we conclude that this term does not exceed the right-hand expressions of (25.4.43) and (25.4.55) respectively.

However, we can do better in the case $a \le Z^{-\frac{1}{3}}$. Indeed, recall that the term $a^{-\frac{1}{2}}Z^{\frac{3}{2}}$ in the remainder estimate (25.4.43) appeared *only* because we replaced $\mathsf{Tr}((H_W-\nu)^-)$ by its Weyl approximation (with correction terms) which we by no means need for estimating this term since $\mathsf{Tr}((H_W-\nu)^-)$ was present in both lower and upper estimates. Then we arrive to the following

Theorem 25.4.14. *Let $N \asymp Z$ and let Ψ be a ground state. Then*

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) \le CQ := C\begin{cases} Z^{\frac{5}{3}} & \text{if} \quad a \le Z^{-\frac{1}{3}},\\ Z^{\frac{5}{3}}\bigl(Z^{-\delta} + (aZ^{\frac{1}{3}})^{-\delta}\bigr) & \text{if} \quad a \ge Z^{-\frac{1}{3}}. \end{cases} \tag{25.4.56}$$

Estimates for Distance between Nuclei in the Free Nuclei Model

Let us estimate from below the distance between nuclei in the stable molecule in the free nuclei model (with the full energy optimized with respect to the position of the nuclei).

Theorem 25.4.15. *Let $M \ge 2$ and let condition* (25.3.33) *be fulfilled. Assume that*

$$\mathsf{E}(\underline{Z};\underline{\mathsf{y}};N) + \sum_{1\le m<m'\le M} Z_jZ_k|\mathsf{y}_m-\mathsf{y}_{m'}|^{-1} \le \min_{\substack{N_1,\dots,N_M:\\ N_1+\dots+N_M=N}} \sum_{1\le m\le M} \mathsf{E}(Z_m;N_m) \tag{25.4.57}$$

Then

$$|\mathsf{y}_m-\mathsf{y}_{m'}| \ge \epsilon Z^{-\frac{5}{21}+\delta_1} \qquad \forall m\ne m' \tag{25.4.58}$$

and

$$|\widehat{\mathsf{E}}^{\mathsf{TF}}(\underline{Z};N) - \widehat{\mathcal{E}}^{\mathsf{TF}}(\underline{Z};N) - \mathsf{Scott} - \mathsf{Dirac} - \mathsf{Schwinger}| \le CZ^{\frac{5}{3}-\delta}. \tag{25.4.59}$$

Proof. Note first that $|\mathsf{E}| \le CZ^{\frac{7}{3}}$ and in virtue of Theorem 25.4.8 we can replace E by $\mathcal{E}^{\mathsf{TF}}$ with $O(Z^2)$ error:

$$\mathcal{E}^{\mathsf{TF}}(\underline{Z};\underline{\mathsf{y}};N) + \sum_{1\le m<m'\le M} Z_jZ_k|\mathsf{y}_m-\mathsf{y}_{m'}|^{-1} \le \min_{\substack{N_1,\dots,N_M:\\ N_1+\dots+N_M=N}} \sum_{1\le m\le M} \mathcal{E}^{\mathsf{TF}}(Z_m;N_m) - CZ^2; \tag{25.4.60}$$

which in virtue of Proposition 25.3.11 is impossible unless $a^{-7} \le CZ^2$ i.e. $a \ge \epsilon Z^{-\frac{2}{7}} \gg Z^{-\frac{1}{3}}$.

Then, again in virtue of Theorem 25.4.8 we can replace E by $\mathcal{E}^{\mathsf{TF}} + \mathsf{Scott}$ with $O(Z^{\frac{5}{3}})$ error. Let us take into account that for molecule Scott equals the sum of Scott_m. Therefore in (25.4.60) we can replace CZ^2 by $CZ^{\frac{5}{3}}$. Applying again Proposition 25.3.11 we conclude that $a \ge \epsilon Z^{-\frac{5}{21}}$.

Let us improve this estimate further. In virtue of Theorem 25.4.13 we can replace E by $\mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} + \mathsf{Dirac} + \mathsf{Schwinger}$ with $O(Z^{\frac{5}{3}-\delta_2})$ error. However one needs to compare Dirac–Schwinger correction for the molecule with the sums of such corrections for separate atoms:

Proposition 25.4.16. *If* $a \ge Z^{-\frac{1}{3}+\delta_1}$ *and*

$$\mathcal{E}^{\mathsf{TF}}(\underline{Z};\underline{\mathsf{y}};N) = \sum_{1\le m\le M} \mathcal{E}^{\mathsf{TF}}(Z_m;N_m) + O(Z^{\frac{7}{3}-\delta_1}) \tag{25.4.61}$$

where $N = N_1 + ... + N_M$, *then*

$$\int \rho^{\mathsf{TF}\,\frac{4}{3}}\,dx = \sum_{1\le m\le M} \int (\rho_m^{\mathsf{TF}})^{\frac{4}{3}}\,dx + O(Z^{\frac{5}{3}-\delta_2}), \tag{25.4.62}$$

where $\rho_m^{\mathsf{TF}} = \rho^{\mathsf{TF}}(x-\mathsf{y}_m;Z_m;N_m)$ *are atomic Thomas-Fermi densities.*

Proof of this Proposition 25.4.16 will be provided immediately. Therefore Dirac and Schwinger correction terms for a molecule are equal to the sums of Dirac_m and $\mathsf{Schwinger}_m$ correction terms respectively with $O(Z^{\frac{5}{3}-\delta_2})$ error and in (25.4.60) we can replace CZ^2 by $CZ^{\frac{5}{3}-\delta_2}$.

Applying Proposition 25.3.11 again we conclude that $a \ge Z^{\frac{5}{21}+\delta}$. □

Proof of Proposition 25.4.16. Note that the left-hand expression of (25.3.42) is equal to

$$\|\nabla\big(W^{\mathsf{TF}} - \bar{W}^{\mathsf{TF}}\big)\|^2 \qquad \text{with} \quad \bar{W}^{\mathsf{TF}} \coloneqq \sum_{1\le m\le M} W_m^{\mathsf{TF}} \tag{25.4.63}$$

and therefore this expression is less than $CQ \le CZ^{\frac{7}{3}-\delta_1}$ as well. Then since $a \ge Z^{-\frac{1}{3}+\delta_1}$ we conclude that if we restrict the norm to the zone $\{x : |x-\mathsf{y}_m| \le Z^{-\frac{1}{3}+\delta}\}$, we can replace $\bar{\rho}^{\mathsf{TF}}$ and $\bar{W}^{\mathsf{TF}}$ by ρ_m^{TF} and W_m^{TF} respectively in (25.3.42), (25.4.63).

Using Thomas-Fermi equations we conclude that in this zone

$$|D^\alpha(W^{\mathsf{TF}} - W_m^{\mathsf{TF}})| \le C_\alpha W_m^{\mathsf{TF}} \ell^{-|\alpha|} Z^{-\delta_2} \qquad \forall \alpha : |\alpha| \le 2 \tag{25.4.64}$$

and then $|(\rho^{\mathsf{TF}\,\frac{4}{3}} - (\rho_m^{\mathsf{TF}})^{\frac{4}{3}}| \le C(\rho_m^{\mathsf{TF}})^{\frac{4}{3}} Z^{-\delta_2}$ which implies (25.4.62) because $\int (\rho_m^{\mathsf{TF}})^{\frac{4}{3}}\,dx \asymp Z^{\frac{5}{3}}$ and contributions of zone $\{x : \ell(x) \ge Z^{-\frac{1}{3}+\delta}\}$ to each integral is $O(Z^{\frac{5}{3}-\delta})$. □

The following problem seems to be very challenging:

Problem 25.4.17. In the framework of the free nuclei model consider the case when assumption (25.3.33) is violated, i.e. when some nuclei are much lighter than the others. We do not need this assumption for

Theorems 25.4.8, 25.4.13 or 25.4.14 but we need to estimate from below the minimal distance between nuclei a.

We cannot do this without some generalization of Proposition 25.3.11, which we definitely do not expect to survive in its current form without assumption (25.3.33). It would be unrealistic to expect any estimate from below for $a_m := \min_{m' \neq m} |y_m - y_{m'}|$ without some estimate from below for Z_m.

The following problem seems to be reasonably challenging:

Problem 25.4.18. (i) Let us discuss the case $M = 2$ and $Z_2 \ll Z_1$, $a \le Z^{-\frac{1}{3}}$. Then there is an unpleasant remainder $O(a^{-\frac{1}{2}} Z^{\frac{3}{2}})$ in the trace asymptotics. Let us discuss how one can improve it.

Let us observe that in $\mathbb{R}^3 \setminus B(y_1, Cb)$ we have $W_1^{\mathsf{TF}} \gg W_2^{\mathsf{TF}}$, where $b = \min(Z_2^{-\frac{1}{3}+\delta}, aZ_2Z^{-1})$. One can expect that we can modify W^{TF} in $B(y_1, Cr_2)$ to W so that the dynamical systems corresponding to Hamiltonians H_W and H_{W_1} would be close; then for H_W we would be able to recover trace asymptotics with the remainder estimate $O(Z^{\frac{5}{3}-\delta})$.

Meanwhile, if $b \ge Z_2^{-1}$, i.e. $a \ge Z_2^{-2}Z$, the contribution of $B(y_1, Cr_2)$ to the trace remainder would be $O(b^{-\frac{1}{2}} Z_2^{\frac{3}{2}}) = O(Z_2^{\frac{5}{3}-\delta}) + O(a^{-1/2} Z_2 Z^{1/2})$ and we would improve $O(a^{-\frac{1}{2}} Z^{\frac{3}{2}})$ to $O(Z^{\frac{5}{3}-\delta} + a^{-\frac{1}{2}} Z_2 Z^{\frac{1}{2}})$.

On the other hand, if $b \le Z_2^{-1}$, i.e. $a \le Z_2^{-2}Z$, the contribution of $B(y_1, Cr_2)$ to the trace remainder would be $O(Z_2^2)$, so we would get the remainder $O(Z^{\frac{5}{3}-\delta} + Z_2^2)$.

In particular, we get $O(Z^{\frac{5}{3}-\delta})$ provided $Z_2 \le Z^{\frac{5}{6}-\delta}$.

(ii) Generalize for $M \ge 2$.

25.5 Negatively Charged Systems

In this section we consider the case $N \ge Z$ and provide upper estimates for excessive negative charge $(N - Z)$ if $I_N > 0$ and for ionization energy $I_N := E_{N-1} - I_N$.

25.5.1 Estimates of the Correlation Function

First of all, we provide some estimates which will be used for both negatively and positively charged systems. Let us consider the ground-state function $\Psi(x_1, \varsigma_1; \dots; x_N, \varsigma_N)$ and the corresponding density $\rho_\Psi(x)$.

The crucial role plays estimate (25.4.56) $\mathsf{D}\bigl(\rho_\psi - \rho^{\mathsf{TF}},\, \rho_\psi - \rho^{\mathsf{TF}}\bigr) \le CQ$ of Theorem 25.4.14 and the difference between upper and lower bounds for E_N (with $\mathsf{N}_1(H_W - \nu) + \nu N$ not replaced by its semiclassical approximation).

Let us consider the *classical density* of the electron system

$$\varrho_{\underline{x}}(x) = \sum_{1\le j\le N} \delta(x - x_j) \tag{25.5.1}$$

and the *smeared classical density*

$$\varrho_{\underline{x},\varepsilon}(x) = \varrho_{\underline{x}} * \phi_\varepsilon = \sum_{1\le j\le N} \phi_\varepsilon(x - x_j), \tag{25.5.2}$$

where ε will be chosen later; here $(\underline{x}, \underline{\varsigma}) = (x_1, \varsigma_1; \dots, x_N, \varsigma_N) \in (\mathbb{R}^3 \times \mathbb{C}^q)^N$,

(25.5.3) $\phi_\varepsilon(z) = \varepsilon^{-3}\phi(z\varepsilon^{-1})$, $\phi \in \mathscr{C}_0^\infty\bigl(B(0, \frac12)\bigr)$ is a spherically symmetric, non-negative function such that $\int \phi(x)\,dx = 1$.

Then $\int \phi_\varepsilon(x) f(x)\,dx = f(0) + O(\varepsilon^2)$ for any $f \in \mathscr{C}^2$. Let us consider

$$K_{N,\varepsilon}(\underline{x}) := \frac12 \mathsf{D}\bigl(\varrho_{\underline{x},\varepsilon}(\cdot) - \rho_\varepsilon(\cdot),\, \varrho_{\underline{x},\varepsilon}(\cdot) - \rho_\varepsilon(\cdot)\bigr), \tag{25.5.4}$$

where $\rho := \rho^{\mathsf{TF}}$ and $\rho_\varepsilon = \phi_\varepsilon * \rho$.

Using Newton's screening theorem[23)] we conclude that

$$\sum_{1\le j<k\le N} |x_j - x_k|^{-1} \ge \frac12 \mathsf{D}\bigl(\varrho_{\underline{x},\varepsilon}(\cdot),\, \varrho_{\underline{x},\varepsilon}(\cdot)\bigr) - C\varepsilon^{-1}N \tag{25.5.5}$$

where the last term estimates

$$\sum_{1\le j\le N} \mathsf{D}\bigl(\phi_\varepsilon(x - x_j), \phi_\varepsilon(x - x_j)\bigr).$$

On the other hand,

$$\frac12 \mathsf{D}\bigl(\varrho_{\underline{x},\varepsilon}(\cdot),\, \varrho_{\underline{x},\varepsilon}(\cdot)\bigr) = \int \varrho_{\underline{x},\varepsilon}(|x|^{-1} * \rho_\varepsilon)\,dx + K_{N,\varepsilon}(\underline{x}) - \frac12 \mathsf{D}(\rho_\varepsilon, \rho_\varepsilon) \tag{25.5.6}$$

[23)] That uniformly charged sphere $S(0, r)$ creates potential $v(x) = -q\min(|x|^{-1}, r^{-1})$ where q is the total charge of the sphere.

and therefore

$$\mathsf{H}_N \geq \sum_{1\leq j\leq N} H_{W_\varepsilon}(x_j) + K_{N,\varepsilon}(\underline{x}) - \frac{1}{2}\mathsf{D}(\rho_\varepsilon,\rho_\varepsilon) - C\varepsilon^{-1}N \tag{25.5.7}$$

on $(\mathscr{L}^2(\mathbb{R}^3,\mathbb{C}^q))^N$ where W_ε is the *smeared potential*:

$$W_\varepsilon(x) = V(x) - |x|^{-1} * \rho_\varepsilon. \tag{25.5.8}$$

Observe that the smeared potential does not depend on $\underline{x}$ and is defined via ρ rather than ρ_Ψ.

Also let us define

$$N_{x,\varepsilon}(x_2,\dots,x_N) \coloneqq \sum_{2\leq j\leq N} (\chi_x * \phi_\varepsilon)(x_j) \tag{25.5.9}$$

and

$$\bar{N}_{x,\varepsilon} \coloneqq \int \rho_\varepsilon(y)\chi_x(y)dy \tag{25.5.10}$$

with $\chi_x(y) \coloneqq \chi(x,y)$, $\chi \in \mathscr{C}^\infty(\mathbb{R}^6)$.

Furthermore, let us consider function $\theta \in \mathscr{C}^\infty(\mathbb{R}^3)$ such that

$$0 \leq \theta \leq 1. \tag{25.5.11}$$

Finally, consider

$$\mathscr{J}_\varepsilon \coloneqq \Big|\int \Big(\rho^{(2)}_\Psi(x,y) - \rho_\varepsilon(y)\rho_\Psi(x)\Big)\theta(x)\chi(x,y)\,dxdy\Big| \tag{25.5.12}$$

where $\rho^{(2)}_\Psi(\cdot,\cdot)$ is the *quantum correlation function,*

$$\rho^{(2)}_\Psi(x,y) \coloneqq N(N-1)\int |\Psi(x,y,x_3,\dots,x_N)|^2\, dx_3\cdots dx_N, \tag{25.5.13}$$

$$\int \rho^{(2)}_\Psi(x,y)dy = (N-1)\rho_\Psi(x), \tag{25.5.14}$$

$$\Theta = \Theta_\Psi \coloneqq \int \theta(x)\rho_\Psi(x)dx. \tag{25.5.15}$$

Obviously

$$\begin{aligned}\mathcal{J}_\varepsilon &\le \int \rho^{(2)}_\Psi(x,y)\big|(\chi_x * \phi_\varepsilon)(y) - \chi_x(y)\big|\theta(x)\,dxdy \\ &\quad + N\int |\Psi(x,x_2,\dots,x_N)|^2\big|N_{x,\varepsilon}(x_2,\dots,x_N) - \bar N_{x,\varepsilon}\big|\theta(x)\,dxdx_2\cdots dx_N \\ &\le CN\varepsilon\|\nabla_y\chi\|_{\mathscr{L}^\infty}\Theta \\ &\qquad + \Big(N\int |\Psi(x,x_2,\dots,x_N)|^2|N_{x,\varepsilon} - \bar N_{x,\varepsilon}|^2\theta(x)\,dxdx_2\cdots dx_N\Big)^{\frac12}\Theta^{\frac12}\end{aligned}$$

where we used Cauchy-Schwartz inequality.

Since

$$\begin{aligned}(25.5.16)\quad &N_{x,\varepsilon}(x_2,\dots,x_N) - \bar N_{x,\varepsilon} \\ &\qquad = \int \Big(\sum_{2\le j\le N}\phi_\varepsilon(y-x_j) - \rho_\varepsilon(y)\Big)\chi(x,y)\,dxdy,\end{aligned}$$

we again from Cauchy-Schwartz inequality conclude that

$$(25.5.17)\qquad \big|N_{x,\varepsilon} - \bar N_{x,\varepsilon}|^2 \le C\|\nabla_y\chi\|^2_{\mathscr{L}^2}\cdot K_{N-1,\varepsilon}(x_2,\dots,x_N).$$

Note that

$$\begin{aligned}(25.5.18)\quad &\sum_{1\le j\le N}\langle \mathsf{H}_N\theta^{\frac12}(x_j)\Psi, \theta^{\frac12}(x_j)\Psi\rangle = \\ &\qquad \mathsf{E}_N\int\int \theta(x)\rho_\Psi(x)\,dx + \int |\nabla\theta^{\frac12}|^2(x)\rho_\Psi(x)\,dx\end{aligned}$$

and then (25.5.7) yields that

$$\begin{aligned}(25.5.19)\quad &\mathsf{E}_N\int\theta(x)\rho_\Psi(x)\,dx \ge -\int |\nabla\theta^{\frac12}(x)|^2\rho_\Psi(x)\,dx \\ &\qquad + \sum_{1\le j,k\le N}\langle H_{W_{\varepsilon,x_k}}\theta^{\frac12}(x_j)\Psi,\theta^{\frac12}(x_j)\Psi\rangle \\ &+ N\int K_{N,\varepsilon}(\underline{x})\theta(x_1)|\Psi(x_1,\dots,x_N)|^2\,dx_1\dots dx_N - \frac12\mathsf{D}(\rho_\varepsilon,\rho_\varepsilon)\Theta - C\varepsilon^{-1}N\Theta.\end{aligned}$$

Also note that

(25.5.20) The sum of $(N-1)$ lowest eigenvalues of H_{W_ε} on $\mathcal{H}$ is greater than $\big(\nu N + \mathsf{N}_1(H_{W_\varepsilon} - \nu)\big)$.

Then the second term in the right-hand expression of (25.5.19) is bounded from below by $\big(\nu N + \mathsf{N}_1(H_{W_\varepsilon} - \nu)\big)\Theta$, while the left-hand expression is $\mathsf{E}_N\Theta$. Therefore assembling terms proportional to Θ we conclude that

$$
\begin{aligned}
(25.5.21)\quad (1 + C\varepsilon^{-1}N)S_\varepsilon\Theta + \int |\nabla\theta^{\frac12}(x)|^2\rho_\Psi(x)\,dx& \\
\geq \sum_j \langle H_{W_\varepsilon,x_j}\theta^{\frac12}(x_j)\Psi, \theta^{\frac12}(x_j)\Psi\rangle& \\
+ N\int K_{N,\varepsilon}(x_1,\dots,x_N)\theta(x_1)|\Psi(x_1,\dots,x_N)|^2\,dx_1\cdots dx_N&
\end{aligned}
$$

with

$$
S_\varepsilon = \mathsf{E}_N - \nu N - \mathsf{N}_1(H_{W_\varepsilon} - \nu) + \frac{1}{2}\mathsf{D}(\rho_\varepsilon, \rho_\varepsilon). \tag{25.5.22}
$$

Due to the non-negativity of operator D_x^2, the second term in the right-hand expression of (25.5.21) is greater than $-CT_\varepsilon\Theta$ with

$$
T_\varepsilon = \sup_{\mathsf{supp}(\theta)} W_\varepsilon; \tag{25.5.23}
$$

so we arrive to

$$
\begin{aligned}
(25.5.24)\quad N\int K_{N,\varepsilon}(x_1,\dots,x_N)\theta(x_1)|\Psi(x_1,\dots,x_N)|^2\,dx_1\cdots dx_N \leq& \\
C\big(S_\varepsilon + T_\varepsilon + \varepsilon^{-1}N\big)\Theta + R&
\end{aligned}
$$

with

$$
R = \int |\nabla\theta^{\frac12}|^2\rho_\Psi\,dx. \tag{25.5.25}
$$

Combining this inequality with (25.5.13), (25.5.17) we conclude that

$$
\begin{aligned}
(25.5.26)\quad \mathcal{J}_\varepsilon \leq C\sup_x \|\nabla_y\chi_x\|_{\mathscr{L}^2(\mathbb{R}^3)}\Big(\big(S_\varepsilon + T_\varepsilon + \varepsilon^{-1}N\big)\Theta + R\Big)^{\frac12}\Theta^{\frac12}& \\
+ C\varepsilon N\|\nabla_y\chi\|_{\mathscr{L}^\infty}\Theta&
\end{aligned}
$$

due to obvious estimate

$$K_{N-1,\varepsilon}(x_2,\dots,x_N) \le 2K_{N,\varepsilon}(x_1,\dots,x_N) + \varepsilon^{-1}N. \tag{25.5.27}$$

Now we want to estimate S_ε from above and for this we need an upper estimate for E_N. Recall that due to the arguments of Subsection 25.2.2

$$\mathsf{E}_N \le \mathsf{N}_1(H_{W_\varepsilon}-\nu)+\nu N \\ + \frac{1}{2}\mathsf{D}(\mathsf{tr}(e_\varepsilon(x,x,\nu))-\rho_\varepsilon,\ \mathsf{tr}(e_\varepsilon(x,x,\nu))-\rho_\varepsilon) - \frac{1}{2}\mathsf{D}(\rho_\varepsilon,\rho_\varepsilon)$$

where $e_\varepsilon(x,y,\tau)$ is the Schwartz kernel of the spectral projector of H_{W_ε}. Therefore $S_\varepsilon \le CQ$ provided we manage to prove that

(25.5.28) Right-hand expressions in (25.2.23)–(25.2.26) satisfy the same estimates as before if we plug W_ε instead of W.

So, we need to calculate both semiclassical errors (which are calculated for $W_\varepsilon = V - |x|^{-1} * \rho_\varepsilon$ with $\rho_\varepsilon = \rho^{\mathsf{TF}} * \phi_\varepsilon$)exactly in the same way as for $W = W^{\mathsf{TF}}$) and the principal parts, and in calculations of

$$\mathsf{D}\big(P'(W_\varepsilon+\nu)-\rho,\ P'(W_\varepsilon+\nu)-\rho\big) \tag{25.5.29}$$

and

$$\mathsf{D}(\rho_\varepsilon-\rho,\ \rho_\varepsilon-\rho) \tag{25.5.30}$$

Observe that

$$|\rho_\varepsilon-\rho| \le C\begin{cases} Z^{\frac{3}{2}}\ell^{-\frac{3}{2}} & \text{for } \ell \le 2\varepsilon, \\ \varepsilon^2 Z^{\frac{3}{2}}\ell^{-\frac{7}{2}} & \text{for } 2\varepsilon \le \ell \le Z^{-\frac{1}{3}}, \quad \ell \not\asymp \bar r, \\ \varepsilon^2\ell^{-8} & \text{for } \ell \ge Z^{-\frac{1}{3}}, \qquad \ell \not\asymp \bar r, \\ \varepsilon^{\frac{3}{2}}\ell^{-\frac{15}{2}} & \text{for } \ell \asymp \bar r \end{cases} \tag{25.5.31}$$

which implies that expression (25.5.30) does not exceed $\varepsilon^2 Z^3$. Recall that $\bar r = (Z-N)_+^{-\frac{1}{3}}$ if $N \asymp Z$.

On the other hand, $W_\varepsilon - W = -|x|^{-1} * (\rho_\varepsilon - \rho) = (|x|^{-1} - |x|^{-1} * \phi_\varepsilon) * \rho$ where $\rho = \rho^{\mathsf{TF}}$, which implies

$$|W_\varepsilon - W| \le C\begin{cases} \varepsilon^{\frac{1}{2}} Z^{\frac{3}{2}} & \text{for } \ell \le 2\varepsilon, \\ \varepsilon^2 Z^{\frac{3}{2}}\ell^{-\frac{3}{2}} & \text{for } 2\varepsilon \le \ell \le Z^{-\frac{1}{3}}, \\ \varepsilon^2\ell^{-6} & \text{for } \ell \ge Z^{-\frac{1}{3}} \end{cases} \tag{25.5.32}$$

and then expression (25.5.29) does not exceed $\varepsilon^2 Z^3$.

Furthermore, the smearing error in the principal part of the asymptotics of $\int e(x,x,\tau)\,dx$, namely

$$|\int \big(P'(W_\varepsilon+\nu)-P'(W+\nu)\big)\,dx|, \tag{25.5.33}$$

does not exceed $C\varepsilon^2 Z^{\frac{5}{3}}$.

Choosing $\varepsilon = Z^{-\frac{2}{3}}$ we estimate these two terms by $CZ^{\frac{5}{3}}$, and simultaneously $\varepsilon^{-1}N \asymp Z^{\frac{5}{3}}$.

With this choice a smearing error does not exceed $CZ^{\frac{3}{2}}\varepsilon^{\frac{3}{2}} = O(Z^{\frac{1}{2}})$ which is less than the semiclassical error. Then $S \le CQ$. So, we derived estimate (25.5.34) below for $\mathcal{J}_\varepsilon$. Since

$$|\mathcal{J}_\varepsilon - \mathcal{J}| \le C\varepsilon Z \|\nabla_y \chi_x\|_{\mathscr{L}^\infty}\Theta$$

we arrive to the following

Proposition 25.5.1. *If θ, χ are as above, $\varepsilon \le Z^{-\frac{2}{3}}$ then*

$$\mathcal{J} = |\int \Big(\rho^{(2)}_\Psi(x,y)-\rho(y)\rho_\Psi(x)\Big)\theta(x)\chi(x,y)\,dxdy| \le \tag{25.5.34}$$

$$C\sup_x \|\nabla_y\chi_x\|_{\mathscr{L}^2(\mathbb{R}^3)}\Big((\bar{Q}+\varepsilon^{-1}N+T)^{\frac{1}{2}}\Theta + R^{\frac{1}{2}}\Theta^{\frac{1}{2}}\Big) + C\varepsilon N\|\nabla_y\chi\|_{\mathscr{L}^\infty}\Theta$$

with $\Theta = \Theta_\Psi$ defined by (25.5.15) *and T, R defined by* (25.5.23), (25.5.25) *respectively, and*

$$\bar{Q} = \max(Q,\, Z^{\frac{5}{3}}). \tag{25.5.35}$$

Remark 25.5.2. (i) The estimates for expression (25.5.29), (25.5.30) and (25.5.33) imply also that the smearing error in the principal part of asymptotics of the energy, namely

$$|\int \big(P(W_\varepsilon+\nu)-P(W+\nu)\big)\,dx| \tag{25.5.36}$$

does not exceed $C\varepsilon^2 Z^2$; to prove this directly is also possible simce $|x|^{-1}$ is harmonic function as $x \ne 0$.

(ii) Estmate of (25.5.30) by $C\varepsilon^2 Z^3$ cannot be improved.

(iii) In what follows $N \asymp Z$ and $\varepsilon = Z^{-\frac{2}{3}}$.

25.5.2 Excessive Negative Charge

We will prove the following

Theorem 25.5.3. *Let condition* (25.3.33) *be fulfilled. Then*

(i) Let $\mathsf{I}_N > 0$. *For a single atom and for molecule the fixed nuclei model the following estimate holds*

$$(N-Z)_+ \le CZ^{\frac{5}{7}}. \tag{25.5.37}$$

(ii) In particular, for molecule in the free nuclei model let $\widehat{\mathsf{I}}_N > 0$. *Then estimate* (25.5.37) *holds.*

Proof. We will follow C. L. Fefferman and L. A. Seco [1], L. A. Seco, I. M. Sigal and J. P. Solovej [1] and, in the case of several nuklei, J. P. Solovej [1].

(a) Let us select $\theta = \theta_{(b)}(x)$

$$\begin{aligned} &\mathsf{supp}(\theta) \subset \{x:\ \ell(x) \ge b\}, \qquad \mathsf{supp}(1-\theta) \subset \{x:\ \ell(x) \le 2b\}, \\ &0 \le \theta \le 1, \qquad |\nabla\theta^{\frac12}| + |\nabla(1-\theta)^{\frac12}| \le Cb^{-1}. \end{aligned} \tag{25.5.38}$$

Observe that $\mathsf{H}_N\Psi = \mathsf{E}_N\Psi$ yields

$$\begin{aligned} &\mathsf{E}_N \int \rho_\Psi(x)\varphi(x)\theta(x)\,dx = \sum_j \langle \Psi, \varphi(x_j)\theta(x_j)\mathsf{H}_N\Psi\rangle = \\ &\sum_j \langle \varphi(x_j)^{\frac12}\theta^{\frac12}(x_j)\Psi, \varphi(x_j)^{\frac12}\theta^{\frac12}(x_j)\mathsf{H}_N\Psi\rangle - \sum_j \|\nabla\big(\theta^{\frac12}(x_j)\varphi(x_j)^{\frac12}\big)\Psi\|^2 \end{aligned} \tag{25.5.39}$$

where we pick up

$$\varphi(x) = ZV(x)^{-1} \asymp \ell(x). \tag{25.5.40}$$

Isolating the contribution of j-th electron in j-th term we get

$$\begin{aligned} &\mathsf{E}_N \int \rho_\Psi(x)\varphi(x)\theta\,dx \ge \mathsf{E}_{N-1} \int \rho_\Psi(x)\varphi(x)\theta(x)\,dx + \\ &\sum_j \langle \Psi, \varphi(x_j)\theta(x_j)\Big(-V(x_j) + \sum_{k:k\ne j} |x_j - x_k|^{-1}\Big)\Psi\rangle - \sum_j \|\nabla\big(\theta^{\frac12}(x_j)\varphi(x_j)^{\frac12}\big)\Psi\|^2 \end{aligned} \tag{25.5.41}$$

due to non-negativity of operator D_x^2.

Now let us select b to be able to calculate the magnitude of $\Theta = \Theta_\Psi$ defined by (25.5.1). Observe that

$$|\int (1-\theta(x))\big(\rho_\Psi(x)-\rho(x)\big)\,dx| \tag{25.5.42}$$

$$\le C\mathsf{D}(\rho_\Psi-\rho,\rho_\Psi-\rho)^{\frac12}\|\nabla(1-\theta)^{\frac12}\| \asymp C\mathsf{D}(\rho_\Psi-\rho,\rho_\Psi-\rho)^{\frac12} b^{\frac12} \le CQ^{\frac12}b^{\frac12},$$

$$\int \big(\rho_\Psi(x)-\rho(x)\big)\,dx = N-Z \tag{25.5.43}$$

and

$$\int \theta(x)\rho(x)\,dx \asymp b^{-3} \tag{25.5.44}$$

as long as

$$\epsilon_1 Z^{-\frac13} \le b \le \epsilon (Z-N)_+^{-\frac13} \tag{25.5.45}$$

because $\rho(x) \asymp |x|^{-6}$ as long as $\epsilon_1 Z^{-\frac13} \le |x| \le c_0(Z-N)_+^{-\frac13}$.

Therefore

$$\int \theta(x)\rho_\Psi(x)\,dx \asymp b^{-3} + (N-Z)_+ \tag{25.5.46}$$

provided

$$b \le \epsilon_1 \min\big((Q^{-\frac17}+Q^{-1}(N-Z)_+^2),\,(Z-N)_+^{-\frac13}\big). \tag{25.5.47}$$

Therefore let us pick up $b = \epsilon_1 Q^{-\frac17}$; it does not conflict with (25.5.45) provided

$$N \ge Z - C_0 Q^{\frac37} \tag{25.5.48}$$

and then

$$\Theta \asymp Q^{\frac37} + Q^{-3}(N-Z)_+^6. \tag{25.5.49}$$

Then the same arguments imply that the last term in the right-hand expression of (25.5.41) does not exceed $Cb^{-1}\Theta$; therefore we arrive to inequality

$$\begin{aligned} \mathsf{I}_N \int \rho_\Psi(x)\varphi(x)\theta(x)\,dx \le Z\int \theta(x)\rho_\Psi(x)\,dx \\ - \iint \rho_\Psi^{(2)}(x,y)\varphi(x)|x-y|^{-1}\theta(x)\,dxdy + Cb^{-1}\Theta = \\ = Z\Theta_\Psi - \iint \rho_\Psi^{(2)}(x,y)\varphi(x)|x-y|^{-1}\big(1-\theta(y)\big)\theta(x)\,dxdy \\ -\frac12\iint \rho_\Psi^{(2)}(x,y)\big(\varphi(x)+\varphi(y)\big)|x-y|^{-1}\theta(y)\theta(x)\,dxdy + Cb^{-1}\Theta. \end{aligned} \tag{25.5.50}$$

(b) Let

$$\theta_0+\theta_1=1,\qquad 0\le\theta_0\le 1,\qquad |\nabla\theta_m^{\frac12}|\le C\beta^{-1}, \tag{25.5.51}$$

$$\mathsf{supp}(\theta_1)\subset\{x\colon \ell(x)\le 2\beta\},\ \mathsf{supp}(\theta_0)\subset\{x\colon \ell(x)\ge\beta\},\ \text{and}\ \beta=\tfrac14 b. \tag{25.5.52}$$

Then

$$\begin{aligned}\iint \rho^{(2)}_\Psi(x,y)\varphi(x)|x-y|^{-1}\theta(x)(1-\theta(y))\,dxdy&\\ \ge \iint \rho^{(2)}_\Psi(x,y)\varphi(x)|x-y|^{-1}\theta(x)\theta_1(y)\,dxdy&\\ \ge \iint \rho_\Psi(x)\rho(y)\varphi(x)|x-y|^{-1}\theta(x)\theta_1(y)\,dxdy&\\ - C\bigl(\beta^{\frac12}\bar{Q}^{\frac12}+\beta^{-1}Z^{\frac13}\bigr)\Theta_\Psi&\end{aligned} \tag{25.5.53}$$

where we applied Proposition 25.5.1 with

$$\chi(x,y)=\theta_1(y)\varphi(x)|x-y|^{-1}$$
$$\implies \|\nabla_y\chi\|_{\mathscr{L}^\infty(\mathbb{R}^3_y)}\le C\beta^{-1},\quad \|\nabla_y\chi\|_{\mathscr{L}^2(\mathbb{R}^3_y)}\le C\beta^{\frac12}.$$

Further, for $\ell(x)\ge b$

$$\begin{aligned}\int \rho(y)|x-y|^{-1}\theta_1(y)\,dy&\\ = \int \rho(y)|x-y|^{-1}\,dy - \int \rho(y)|x-y|^{-1}\theta(x)\theta_0(y)\,dy&\\ = V(x)-W(x)+O(\ell(x)^{-1}b^{-3}) = V(x)+O(\ell(x)^{-1}b^{-3})&\end{aligned} \tag{25.5.54}$$

because $W(x)=O(\ell(x)^{-4})$ and $\rho(y)=O(\ell(y)^{-6})$ as $\nu=0$ and $\ell(x)\gtrsim b$, $\ell(y)\gtrsim Z^{-\frac13}$.

Since $\varphi(x)=ZV(x)^{-1}\asymp\ell(x)$ we conclude that

(25.5.55) The first line in the right-hand expression of (25.5.50) does not exceed $\bigl(Z-N+Cb^{-3}+Cb^{\frac12}\bar{Q}^{\frac12}\bigr)\Theta_\Psi$.

(c) Consider the second line. Observe that

$$\varphi(x)+\varphi(y)=\varphi(x)\varphi(y)\sum_{1\le m\le M} z_m|x-\mathsf{y}_m|^{-1}|y-\mathsf{y}_m|^{-1}\big(|x-\mathsf{y}_m|+|y-\mathsf{y}_m|\big) \\ \ge \sum_{1\le m\le M}\varphi(x)\varphi(y)z_m|x-y|$$

with $z_m = Z_m Z^{-1}$ and therefore this term does not exceed

(25.5.56)
$$-\frac{1}{2}\sum_{1\le m\le M} z_m\iint \rho^{(2)}_{\Psi}(x,y)|x-\mathsf{y}_m|^{-1}|y-\mathsf{y}_m|^{-1}\varphi(x)\varphi(y)\theta(x)\theta(y)\,dxdy \\ \le -\frac{1}{2}\sum_{1\le m\le M} z_m\Big\{\Big(\int \rho_{\Psi}(x)\varphi(x)\theta(x)|x-\mathsf{y}_m|^{-1}\,dx\Big)^2 \\ -\int \rho_{\Psi}(x)\varphi^2(x)\theta(x)^2|x-\mathsf{y}_m|^{-2}\,dx\Big\} \\ \le -\epsilon_1\Big(\int \rho_{\Psi}(x)\theta(x)\,dx\Big)^2 + C_1\int \rho_{\Psi}(x)\theta(x)^2\,dx$$

where the first inequality is due to inequality $\langle F^2\rangle \ge \langle F\rangle^2$ where $\langle .\rangle$ is an average with respect to density $\rho^{(2)}_{\Psi}(x,y)$ and equality $\int \rho^{(2)}_{\Psi}(x,y)\,dy = (N-1)\rho_{\Psi}(x)$.

Therefore

(25.5.57) The second line in the right-hand expression of (25.5.50) does not exceed $\big(-\epsilon_2\Theta_{\Psi} + Cb^{-1}\big)\Theta_{\Psi}$.

Since the left-hand expression of (25.5.50) is greater than $\epsilon b\mathsf{I}_N\Theta_{\Psi}$ and since Θ_{Ψ} is disjoint from 0 we conclude that

$$b\mathsf{I}_N \le C(Z-N) - \epsilon_2\Theta_{\Psi} + Cb^{\frac{1}{2}}\bar{Q}^{\frac{1}{2}} + Cb^{-3} \tag{25.5.58}$$

and therefore due to assumption $\mathsf{I}_N > 0$ and (25.5.46)

$$N - Z \le C(b\bar{Q})^{\frac{1}{2}} + Cb^{-3} \tag{25.5.59}$$

which implies (25.5.37) under optimal choice $b = \epsilon\bar{Q}^{\frac{1}{7}} = \epsilon Z^{-\frac{5}{21}}$, satisfying (25.5.47) unless (25.5.37) is fulfilled. □

25.5.3 Estimate for Ionization Energy

Continuing arguments of the proof of Theorem 25.5.3, we see that estimate (25.5.58) implies that under conditions (25.5.47) and (25.5.48) with $Q = Z^{\frac{5}{3}}$

$$\mathsf{I}_N \le Cb^{-1}(Z-N)_+ + Cb^{-\frac{1}{2}}\bar{Q}^{\frac{1}{2}} \le C_1(Z-N)_+^{\frac{4}{3}} + C_1 Q^{\frac{1}{14}}\bar{Q}^{\frac{1}{2}} \tag{25.5.60}$$

where we took the largest $b = \epsilon_1 \min\bigl(Q^{-\frac{1}{7}}, (Z-N)_+^{-\frac{1}{3}}\bigr)$ such that $\Theta_\Psi > 0$.

Then we arrive to the following

Theorem 25.5.4. *Let condition* (25.3.33) *be fulfilled.*

(i) Then the following estimate holds:

$$\mathsf{I}_N \le C(Z-N)_+^{\frac{4}{3}} + CZ^{\frac{20}{21}}. \tag{25.5.61}$$

(ii) Further, under assumption

$$a := \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge Z^{-\frac{1}{3}} \tag{25.5.62}$$

the following estimate holds

$$\mathsf{I}_N \le C(Z-N)_+^{\frac{4}{3}} + CZ^{\frac{20}{21}}\bigl(Z^{-\delta} + (aZ^{\frac{1}{3}})^{-\delta}\bigr). \tag{25.5.63}$$

(iii) Furthermore, for $M \ge 2$ in the framework of free nuclei model (assuming that the molecule exists; see Theorem 25.6.3)

$$\widehat{\mathsf{I}}_N \le CZ^{\frac{20}{21}-\delta'}. \tag{25.5.64}$$

Remark 25.5.5. (i) Classical theorem of G. Zhislin [1] implies that the system can bind at least Z electrons; the proof is based on the demonstration that the energy of the system with $N < Z$ electrons plus one electron on the distance r is increasing as $r \to +\infty$ because potential created by the system with $N < Z$ electrons behaves as $(Z-N)|x|^{-1}$ as $|x| \to \infty$.

(ii) If we assume that $N \ge 2Z$ then the proof of Theorem 25.5.3 implies that $I_N = 0$; so we actually do not need assumption (25.3.33) in Theorems 25.5.3 and 25.5.4.

(iii) In the proof of Theorem 25.5.4(ii) we use that under assumption (25.5.62) $Q = Z^{\frac{5}{3}}\bigl(Z^{-\delta} + (aZ^{\frac{1}{3}})^{-\delta}\bigr)$.

(iv) In the proof of Theorems 25.5.3(ii) and 25.5.4(iii) we note that tearing of one electron in free nuclei model is easier than in the fixed nuclei model.

(v) We are interested in the cases when the first term in the right-hand expressions (25.5.61) and (25.5.63) does not exceed the second ones.

It would be interesting to make the following improvements:

Problem 25.5.6. Improve Proposition 25.5.1 so that we could have $\bar{Q} := \mathsf{max}(Q, Z^{\frac{5}{3}-\delta})$ rather than $\bar{Q} := \mathsf{max}(Q, Z^{\frac{5}{3}})$. This would lead to the improvement of Theorem 25.5.3 and similar theorems in the forthcoming chapters.

25.6 Positively Charged Systems

In this section we consider the case of positively charged system with violated assumption (25.5.61) i.e. with

$$Z - N \ge C_0 Q^{\frac{3}{7}} \tag{25.6.1}$$

with sufficiently large constant C_0 and the same Q as before.

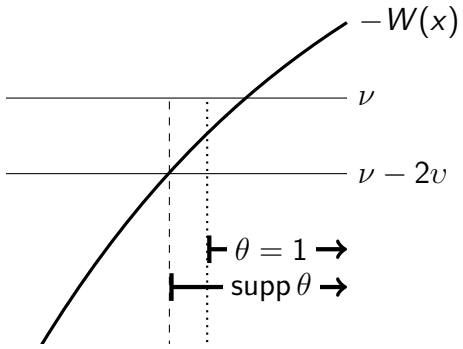
First let us find asymptotics of the ionization energy; the principal term will be $-\nu$ but we need to estimate a remainder.

25.6.1 Estimate from above for Ionization Energy

In this subsection we will prove that under assumption (25.6.1)

$$\mathsf{I}_N \le -\nu + C\upsilon \tag{25.6.2}$$

with $\upsilon \ll |\nu|$ to be defined below. Similar estimates from below will be proven in the next Subsection 25.6.2.



As $M = 1$ construction is well-known: let us pick up function θ such that $\theta = 1$ as $|x-\mathsf{y}_m| \ge \bar{r}-\beta$ and $\theta = 0$ as $|x-\mathsf{y}_m| \le \bar{r}-2\beta$ where $\bar{r}$ is an exact radius of support ρ^{TF}. Here $\beta \ll \bar{r}$. As $M \ge 1$ let us pick instead

$$\theta(x) = f^2\big(\upsilon^{-1}[W(x)+\nu]\big) \tag{25.6.3}$$

where $f \in \mathscr{C}^\infty(\mathbb{R})$, supported in $(-\infty, 2)$ and equal 1 in $(-\infty, 1)$, $\upsilon \le \nu$.

(a) We will assume first that

$$a \ge \bar{r} = C_1(Z-N)^{-\frac{1}{3}} \tag{25.6.4}$$

with sufficiently large C_1; we will discuss droppin g this assumption later. Then as we know that ρ^{TF} is supported in $c\bar{r}$-vicinity of nuclei, we conclude that "atoms" are rather disjoint.

One can see easily that then as long as $W+\nu \approx 0$

$$|\nabla W| \asymp \bar{r}^{-5}; \tag{25.6.5}$$

then the width of the zone $\{x\colon 0 \le W(x)+\nu \le 2\upsilon\}$ is $\asymp \upsilon|\nabla W|^{-1} \asymp \beta = \upsilon\bar{r}^5$ and

$$\Theta^{\mathsf{TF}} := \int \rho^{\mathsf{TF}}\theta(x)\,dx \asymp \upsilon^{\frac{3}{2}} \times \beta\bar{r}^2 = \upsilon^{\frac{5}{2}}\bar{r}^7 \tag{25.6.6}$$

while $\|\nabla\theta\| \asymp \beta^{-\frac{1}{2}}\bar{r} = \upsilon^{-\frac{1}{2}}\bar{r}^{-\frac{3}{2}}$ for θ supported in $\{x\colon 0 \le W(x)+\nu \le 3\upsilon\}$ and equal 1 in $\{x\colon \upsilon \le W(x)+\nu \le 2\upsilon\}$. On the other hand

$$\begin{aligned} &|\int (\rho_\Psi - \rho^{\mathsf{TF}})\theta\,dx| = \frac{1}{4\pi}|\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \Delta\theta)| \\ &\qquad \le \mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}})^{\frac{1}{2}}\mathsf{D}(\Delta\theta,\, \Delta\theta)^{\frac{1}{2}} \le CQ^{\frac{1}{2}}\|\nabla\theta\|_{\mathscr{L}^2} \le C\beta^{-\frac{1}{2}}\bar{r}Q^{\frac{1}{2}}. \end{aligned} \tag{25.6.7}$$

Therefore to ensure that $\Theta = \Theta_\Psi$ has the same magnitude (25.6.6) we pick up the smallest υ such that $\upsilon^{\frac{5}{2}}\bar{r}^7 \ge C\upsilon^{-\frac{1}{2}}\bar{r}^{-\frac{3}{2}}Q^{\frac{1}{2}}$ i.e.

$$\upsilon := C_2\bar{r}^{-\frac{17}{6}}Q^{\frac{1}{6}} \qquad (\iff \beta = C_2\bar{r}^{\frac{13}{6}}Q^{\frac{1}{6}}); \tag{25.6.8}$$

then

$$\Theta \asymp \bar{r}^{-\frac{1}{12}} Q^{\frac{5}{12}} \tag{25.6.9}$$

Then (25.5.15) is fulfilled. Note that $\upsilon \lesssim \nu = \bar{r}^{-4}$ iff $(Z-N) \gtrsim Q^{\frac{3}{7}}$ exactly as we assumed. Then inequality (25.5.50) is replaced by

$$\begin{aligned} \mathsf{I}_N \int \ell(x)\rho_\Psi(x)\theta(x)\,dx \le \int \theta(x)V(x)\ell(x)\rho_\Psi(x)\,dx \\ - \int \rho^{(2)}_\Psi(x,y)\ell(x)|x-y|^{-1}\theta(x)\,dxdy + C\beta^{-2}\bar{r}\Theta \end{aligned} \tag{25.6.10}$$

where $C\beta^{-2}\bar{r}\Theta$ estimates the last term in the right-hand expression of (25.5.41). Then

$$\begin{aligned} \mathsf{I}_N \int \ell(x)\rho_\Psi(x)\theta(x)\,dx \le \int \theta(x)V(x)\ell(x)\rho_\Psi(x)\,dx \\ - \int \Big(\rho^{(2)}_\Psi(x,y) - \rho_\Psi(x)\rho(y)\Big)\ell(x)|x-y|^{-1}\theta(x)\,dxdy \\ - \int \rho_\Psi(x)\rho(y)\ell(x)|x-y|^{-1}\theta(x)\,dxdy + C\beta^{-2}\bar{r}\Theta. \end{aligned} \tag{25.6.11}$$

Let us estimate from above

$$\begin{aligned} - \int \Big(\rho^{(2)}_\Psi(x,y) - \rho_\Psi(x)\rho(y)\Big)\ell(x)|x-y|^{-1}\theta(x)\,dxdy \le \\ - \int \Big(\rho^{(2)}_\Psi(x,y) - \rho_\Psi(x)\rho(y)\Big)\big(1-\omega(x,y)\big)\ell(x)|x-y|^{-1}\theta(x)\,dxdy \\ + \int \rho_\Psi(x)\rho(y)\omega(x,y)\ell(x)|x-y|^{-1}\theta(x)\,dxdy \end{aligned} \tag{25.6.12}$$

with $\omega = \omega_\gamma$: $\omega = 0$ for $|x-y| \ge 2\gamma$ and $\omega = 1$ for $|x-y| \le \gamma$, $\gamma \ge \beta$.

To estimate the first term in the right-hand expression one can apply Proposition 25.5.1 with

$$\chi(x,y) = \big(1-\omega(x,y)\big)\ell(x)|x-y|^{-1}.$$

In this case $\|\nabla_y \chi\|_{\mathscr{L}^2} \asymp C\bar{r}\gamma^{-\frac{1}{2}}$, $\|\nabla_y \chi\|_{\mathscr{L}^\infty} \asymp \bar{r}\gamma^{-2}$ and plugging $P = \beta^{-2}\Theta$ and $T = |\nu|$, $\varepsilon = Z^{-\frac{2}{3}}$ we conclude that this term does not exceed

$$C\bar{r}\big(\gamma^{-\frac{1}{2}}\bar{Q}^{\frac{1}{2}} + CZ^{\frac{2}{3}}\gamma^{-2}\big)\Theta, \qquad \bar{Q} = \max(Q, Z^{\frac{5}{3}}). \tag{25.6.13}$$

Consider the second term in the right-hand expression of (25.6.12). Note that

$$\int \rho(y)\omega(x,y)|x-y|^{-1}\,dy \le C(\bar r^{-\frac{15}{2}}\gamma^{\frac72}+\upsilon^{\frac32}\gamma^2)$$

since $\rho(y)\asymp \big(W(y)+\nu\big)^{\frac32}$ and $|\nabla W|\asymp \bar r^{-5}$; then this term does not exceed $C(\bar r^{-\frac{15}{2}}\gamma^{\frac72}+\upsilon^{\frac32}\gamma^2)\bar r\Theta$.

Adding to (25.6.13) we get

$$C\Big(\gamma^{-\frac12}\bar Q^{\frac12}+CZ^{\frac23}\gamma^{-2}+\bar r^{-\frac{15}{2}}\gamma^{\frac72}+\upsilon^{\frac32}\gamma^2\Big)\bar r\Theta.$$

Optimizing with respect to $\gamma=\bar Q^{\frac15}\upsilon^{-\frac35}$ we get $C\upsilon^{\frac{3}{10}}\bar Q^{\frac25}\bar r\Theta$ and (25.6.11) becomes

$$\begin{aligned}(25.6.14)\quad (\mathsf{I}_N+\nu)\int \ell(x)\rho_\psi(x)\theta(x)\,dx \le\\ \int \theta(x)\big(W(x)+\nu\big)\ell(x)\rho_\psi(x)\,dx + C\upsilon^{\frac{3}{10}}\bar Q^{\frac25}\bar r\Theta \le\\ C\big(\upsilon+\upsilon^{\frac{3}{10}}\bar Q^{\frac25}\big)\bar r\Theta\,,\end{aligned}$$

where we took into account that $V-|x|^{-1}*\rho=W$, and that $W+\nu\le 3\upsilon$ on $\mathsf{supp}(\theta)$.

Since a factor at $(\mathsf{I}_N+\nu)$ in the left-hand expression of (25.6.14) is obviously $\asymp \bar r\Theta$ we arrive to $(\mathsf{I}_N+\nu)\le C\upsilon+\upsilon^{\frac{3}{10}}\bar Q^{\frac25}$.

Recalling definition (25.6.8) of υ we arrive to an upper estimate in Theorem 25.6.1 below:

$$(25.6.15)\qquad \mathsf{I}_N+\nu\le C\upsilon = C(Z-N)^{\frac{17}{18}}Q^{\frac16}.$$

Indeed, it is true if $Q\ge Z^{\frac53}$ (we are interested in the general approach) and because then $\upsilon\ge \upsilon^{\frac{3}{10}}Q^{\frac25}$ due to assumption (25.6.1).

On the other hand, if $Q=Z^{\frac53}(aZ^{\frac13})^{-\delta}$, $aZ^{\frac13}\ge 1$, then we get an extra term $CQ^{\frac{1}{20}}(Z-N)^{\frac15}Z^{\frac23}$ but we can skip it decreasing unspecified exponent $\delta>0$ in the definition of Q.

(b) To get rid of assumption (25.6.4) we observe that we used only its corollary (25.6.5). If we do not have such assumption instead of equality

(25.6.6) we have inequality $\Theta^{\mathsf{TF}} \gtrsim \upsilon^{\frac{5}{2}}\bar{r}^7$ (but probably equality still holds). However we have a problem to estimate $|\Theta - \Theta^{\mathsf{TF}}|$: namely, we need to estimate the second factor in the product $\mathsf{D}(\rho - \rho^{\mathsf{TF}}, \rho - \rho^{\mathsf{TF}})^{\frac{1}{2}}\|\nabla\theta^{\frac{1}{2}}\|$ in (25.6.7).

Observe that we select f in (25.6.3) such that $|f'| \le c\delta^{-1}f^{1-\sigma/2}$ with arbitrarily small $\delta > 0$ and constant c which does not depend on δ.

$$b^2\|\nabla\theta^{\frac{1}{2}}\|^2 \le C\delta^{-2}\iint_{\mathcal{Z}} \theta^{1-\delta}\,dx \le C\delta^{-2}\Big(\int_{\mathcal{Z}} \theta\,dx\Big)^{1-\delta}\Big(\int_{\mathcal{Z}} 1\,dx\Big)^{\delta} \le C\delta^{-2}\upsilon^{-\frac{3}{2}(1-\delta)}\big(\Theta^{\mathsf{TF}}\big)^{1-\delta}\bar{r}^{3\delta}$$

with $\mathcal{Z} = \mathsf{supp}(\nabla\theta)$ and $b = \upsilon\bar{r}^5$ and an error is less than $\epsilon\Theta^{\mathsf{TF}}$ with $\Theta^{\mathsf{TF}} \ge \epsilon\upsilon^{\frac{5}{2}}\bar{r}^7$ as long as

$$\upsilon = CQ^{\frac{1}{6}}\bar{r}^{-\frac{17}{6}} \times \sigma^{-\frac{1}{3}}\bar{r}^{-7\sigma}Q^{-\sigma}$$

with $\sigma = \delta/(36 + 6\delta)$ and C which does not depend on σ. Optimizing the right-hand expression by $\sigma > 0$ we arrive to estimate (25.6.15) with marginally larger error:

$$\mathsf{I}_N + \nu \le C(Z - N)^{\frac{17}{18}}Q^{\frac{1}{6}} \times \log^{\frac{1}{3}}\big((Z - N)Q^{-\frac{3}{7}}\big). \tag{25.6.16}$$

Estimate T could be done in the same manner but here slight increase of it does not matter.

25.6.2 Estimate from below for Ionization Energy

In this subsection we will prove that under assumption (25.6.1)

$$\mathsf{I}_N \ge -\nu - C\upsilon \tag{25.6.17}$$

with $\upsilon \ll |\nu|$ to be defined below.

Let $\Psi = \Psi_N(x_1, \dots, x_N)$ be the ground state for N electrons, $\|\Psi\| = 1$; consider an antisymmetric test function

$$\tilde{\Psi} = \tilde{\Psi}(x_1, \dots, x_{N+1}) = \Psi(x_1, \dots, x_N)u(x_{N+1}) - \sum_{1\le j\le N} \Psi(x_1, \dots, x_{j-1}, x_{N+1}, x_{j+1}, \dots, x_N)u(x_j). \tag{25.6.18}$$

Then

$$\mathsf{E}_{N+1}\|\tilde\Psi\|^2 \le \langle \mathsf{H}_{N+1}\tilde\Psi,\tilde\Psi\rangle = N\langle \mathsf{H}_{N+1}\Psi u,\tilde\Psi\rangle = N\langle \mathsf{H}_N\Psi u,\tilde\Psi\rangle + N\langle H_{V,x_{N+1}}\Psi u,\tilde\Psi\rangle + N\langle \sum_{1\le i\le N}|x_i-x_{N+1}|^{-1}\Psi u,\tilde\Psi\rangle = (\mathsf{E}_N-\nu')\|\tilde\Psi\|^2 + N\langle H_{W+\nu',x_{N+1}}\Psi u,\tilde\Psi\rangle + N\langle\big(\sum_{1\le i\le N}|x_i-x_{N+1}|^{-1}-(V-W)(x_{N+1})\big)\Psi u,\tilde\Psi\rangle$$

and therefore

$$N^{-1}(\mathsf{I}_{N+1}+\nu')\|\tilde\Psi\|^2 \ge -\langle H_{W+\nu',x_{N+1}}\Psi u,\tilde\Psi\rangle - \langle\big(\sum_{1\le i\le N}|x_i-x_{N+1}|^{-1}-(V-W)(x_{N+1})\big)\Psi u,\tilde\Psi\rangle \tag{25.6.19}$$

with $\nu'\ge\nu$ to be chosen later. One can see easily that

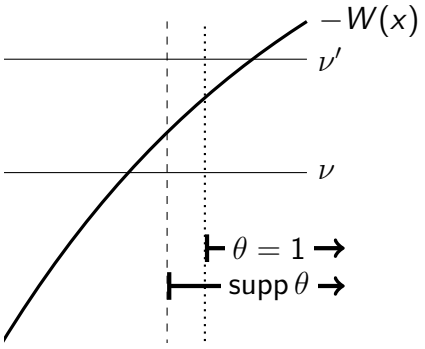
$$N^{-1}\|\tilde\Psi\|^2 = \|\Psi\|^2\cdot\|u\|^2 - N\int \Psi(x_1,\dots,x_{N-1},x)\Psi^\dagger(x_1,\dots,x_{N-1},y)u(y)u^\dagger(x)\,dx_1\cdots dx_{N-1}\,dxdy \tag{25.6.20}$$

where † means a complex or Hermitian conjugation.

Note that every term in the right-hand expression in (25.6.19) is the sum of two terms: one with $\tilde\Psi$ replaced by $\Psi(x_1,\dots,x_N)u(x_{N+1})$ and another with $\tilde\Psi$ replaced by $-N\Psi(x_1,\dots,x_{N-1},x_{N+1})u(x_N)$. We call these terms *direct* and *indirect* respectively.

Obviously, in the direct and indirect terms u appears as $|u(x)|^2\,dx$ and as $u(x)u^\dagger(y)\,dxdy$ respectively, multiplied by some kernels.

Recall that u is an arbitrary function. Let us take $u(x)=\theta^{\frac12}(x)\phi_j(x)$ where ϕ_j are orthonormal eigenfunctions of $H_{W+\nu}$ and $\theta(x)$ is β-admissible function supported in $\{x:\ -\upsilon\ge W(x)+\nu\ge\frac23\nu\}$ and equal 1 in $\{x:\ -2\upsilon\ge W(x)+\nu\ge\frac12\nu\}$, satisfying (25.5.11), and $\beta=\upsilon\bar r^5$.



Let us substitute it into (25.6.19), multiply by $\varphi(\lambda_j L^{-1})$ and take sum with respect to j.

We get the same expressions with $|u(x)|^2\,dx$ and $u(x)u^\dagger(y)\,dxdy$ replaced by $F(x,x)\,dx$ and $F(x,y)\,dxdy$ respectively with

$$F(x,y)=\int \varphi(\lambda L^{-1})\,d_\lambda e(x,y,\lambda). \tag{25.6.21}$$

Here $\varphi(\tau)$ is a fixed $\mathscr{C}^\infty$ non-negative function equal to 1 as $\tau\le \frac{1}{2}$ and equal to 0 as $\tau\ge 1$ and $L=\nu'-\nu=6\upsilon$.

Under described construction and procedures the direct term generated by $N^{-1}\|\tilde{\Psi}\|^2$ is

$$\int \theta(x)\varphi(\lambda L^{-1})\,d_\lambda e(x,x,\lambda)\,dx \tag{25.6.22}$$

and applying the semiclassical approximation we get

$$\Theta \coloneqq \int \varphi(\lambda L^{-1})\,d_\lambda P'(W+\nu-\lambda)\,dx. \tag{25.6.23}$$

(a) Observe that under assumptions (25.3.33) and (25.6.4) [24] the remainder estimate is $C\hbar^{-1}\bar{r}^2b^{-2}=C\upsilon^{\frac{1}{2}}\bar{r}^2b^{-1}=C\upsilon^{-\frac{1}{2}}\bar{r}^{-3}$; one can prove it easily by partition of unity on $\mathsf{supp}(\theta)$ and applying the semiclassical asymptotics with effective semiclassical parameter $\hbar=1/(\upsilon^{\frac{1}{2}}b)=\upsilon^{-\frac{3}{2}}\bar{r}^{-5}$.

On the other hand, indirect term generated by $N^{-1}\|\tilde{\Psi}\|^2$ is

$$-N\int \theta^{\frac{1}{2}}(x)\theta^{\frac{1}{2}}(y)\Psi(x_1,\dots,x_{N-1},x)\Psi^\dagger(x_1,\dots,x_{N-1},y)\times F(x,y)\,dxdydx_1\cdots dx_{N-1} \tag{25.6.24}$$

and since the operator norm of $F(.,.,.)$ is 1 the absolute value of this term does not exceed

$$N\int \theta(x)|\Psi(x_1,\dots,x_{N-1},x)|^2\,dx=\int \theta(x)\rho_\Psi(x)\,dx\le \int \theta(x)\rho^{\mathsf{TF}}(x)\,dx+CQ^{\frac{1}{2}}\|\nabla\theta^{\frac{1}{2}}\| \tag{25.6.25}$$

where we applied (25.5.6). Observe that $\rho^{\mathsf{TF}}=0$ on $\mathsf{supp}(\theta)$ and under assumption (25.6.4) [24] $\|\nabla\theta^{\frac{1}{2}}\|\asymp b^{-\frac{1}{2}}\bar{r}\asymp\zeta^{-\frac{1}{2}}\bar{r}^{-\frac{3}{2}}$.

[24] Or rather its corollary (25.6.5).

Recall that $P'(W^{\mathsf{TF}}+\nu)=\rho^{\mathsf{TF}}$. We will take $\nu'=\nu+L$ large enough to keep Θ larger than all the remainders including those due to replacement W by W^{TF} and ρ_Ψ by ρ^{TF} in the expression above. One can see easily that

$$\Theta \asymp \hbar^{-3}\times b^{-2}\bar r^2 \asymp \upsilon^{\frac{3}{2}} b\bar r^2 \asymp \upsilon^{\frac{5}{2}}\bar r^7. \tag{25.6.26}$$

Therefore

(25.6.27) If $\upsilon = C_0\bar r^{-\frac{17}{6}}Q^{\frac{1}{6}}$ and $Z-N\ge C_0 Z^{\frac{5}{7}}$ the total expression generated by $N^{-1}\|\tilde\Psi\|^2$ is greater than $\epsilon\Theta$ with $\Theta=\upsilon^{\frac{5}{2}}\bar r^7$.

Now let us consider direct terms in the right-hand expression of (25.6.19). The first of them is

$$\begin{aligned}
&-\int \theta^{\frac{1}{2}}(x)\varphi(\lambda L^{-1})\,d_\lambda\big(H_{W+\nu',x}\theta^{\frac{1}{2}}(x)e(x,y,\lambda)\big)_{y=x}\,dx = \\
&\qquad -\int \theta(x)\varphi(\lambda L^{-1})\,d_\lambda\big(H_{W+\nu',x}e(x,y,\lambda)\big)_{y=x}\,dx \\
&\qquad\qquad -\frac{1}{2}\int \varphi(\lambda L^{-1})[[H_W,\theta^{\frac{1}{2}}],\theta^{\frac{1}{2}}]\,d_\lambda e(x,x,\lambda)\ge \\
&\int \theta(x)(\nu'-\nu-\lambda)\varphi(\lambda L^{-1})\,d_\lambda e(x,x,\lambda)\,dx - C\int |\nabla\theta^{\frac{1}{2}}|^2 e(x,x,\nu')dx.
\end{aligned} \tag{25.6.28}$$

Note that the absolute value of last term in the right-hand expression of (25.6.28) does not exceed $Cb^{-1}\bar r^2 L^{\frac{3}{2}}\asymp C\upsilon^{\frac{1}{2}}\bar r^{-3}\ll C\upsilon\Theta$.

The second direct term in the right-hand expression is

$$\begin{aligned}
&-\int \theta(x)\Big(\rho_\Psi * |x|^{-1} - (V-W)(x)\Big)F(x,x)\,dx = \\
&\qquad -\mathsf{D}\big(\rho_\Psi-\bar\rho,\theta(x)F(x,x)\big)\ge \\
&-C\mathsf{D}\big(\rho_\Psi-\rho,\rho_\Psi-\rho\big)^{\frac{1}{2}}\cdot \mathsf{D}\Big(\theta^{\frac{1}{2}}F(x,x),\theta^{\frac{1}{2}}F(x,x)\big)\Big)^{\frac{1}{2}} \ge -CQ^{\frac{1}{2}}\bar r^{\frac{15}{2}}\upsilon^{\frac{5}{2}}
\end{aligned} \tag{25.6.29}$$

provided $V-W=|x|^{-1}*\rho$ with $\mathsf{D}(\rho-\rho^{\mathsf{TF}},\,\rho-\rho^{\mathsf{TF}})\le CQ$; the absolute value of this term is $\ll\upsilon\Theta$.

Further, the first indirect term in the right-hand expression of (25.6.19) is

$$
\begin{aligned}
(25.6.30)\quad & -N\int \theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},x)\Psi^{\dagger}(x_1,\dots,x_{N-1},y)\times \\
&\qquad \varphi(\lambda L^{-1})\,d_\lambda\big(H_{W+\nu',x}\theta^{\frac12}(x)e(x,y,\lambda)\big)\,dxdydx_1\cdots dx_{N-1} = \\
& -N\int \theta^{\frac12}(y)\theta^{\frac12}(x)\Psi(x_1,\dots,x_{N-1},x)\Psi^{\dagger}(x_1,\dots,x_{N-1},y)\times \\
&\qquad \varphi(\lambda L^{-1})(\nu'-\nu-\lambda)\,d_\lambda e(x,y,\lambda)\,dxdydx_1\cdots dx_{N-1} \\
& -N\int \theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},x)\Psi^{\dagger}(x_1,\dots,x_{N-1},y)\times \\
&\qquad \varphi(\lambda L^{-1})[H_{W,x},\theta^{\frac12}(x)]\,d_\lambda e(x,y,\lambda)\,dxdydx_1\cdots dx_{N-1}.
\end{aligned}
$$

Note that one can rewrite the sum of the first terms in the right-hand expressions in (25.6.28) and (25.6.30) as $\sum_j \varphi(\lambda_j L^{-1})(\nu'-\nu-\lambda_j)\|\widehat{\Psi}_j\|^2$ with

$$
\widehat{\Psi}_j(x_1,\dots,x_{N-1}) \coloneqq \int \Psi(x_1,\dots,x_{N-1},x)\theta^{\frac12}(x)\phi_j(x)\,dx
$$

and therefore this sum is non-negative.

One can prove easily that the absolute value of the second term in (25.6.30) is less than

$$
C\upsilon^{\frac12}b^{-1}\int \rho_\Psi(y)\theta^{\frac12}(y)\,dy \le C\upsilon^{-\frac12}\bar{r}^{-5}\Theta \ll \upsilon\Theta.
$$

Therefore

(25.6.31) The sum of the first direct and indirect terms in the right-hand expression of (25.6.19) is greater than $-C\upsilon\Theta$.

Finally, we need to consider the second indirect term generated by the right-hand expression of (25.6.19)

$$
\begin{aligned}
(25.6.32)\quad & -\int\Big(\sum_{1\le i\le N}|y-x_i|^{-1}-(V-W)(y)\Big)\times \\
&\qquad \Psi(x_1,\dots,x_N)\Psi^{\dagger}(x_1,\dots,x_{N-1},y)\theta^{\frac12}(x_N)\theta^{\frac12}(y)F(x_N,y)\,dx_1\cdots dx_N dy =
\end{aligned}
$$

$$= -\int \Big(|y|^{-1} * \rho_{\underline{x}}(y) - (V-W)(y)\Big)\Psi(x_1,\dots,x_N)\Psi^\dagger(x_1,\dots,x_{N-1},y)\times \theta^{\frac12}(x_N)\theta^{\frac12}(y)F(x_N,y)\,dx_1\cdots dx_N dy$$

$$-\int \Big(\sum_{1\le i\le N}|y-x_i|^{-1} - |y|^{-1} * \rho_{\underline{x}}(y)\Big)\Psi(x_1,\dots,x_N)\Psi^\dagger(x_1,\dots,x_{N-1},y)\times \theta^{\frac12}(x_N)\theta^{\frac12}(y)F(x_N,y)\,dx_1\cdots\, dx_N dy;$$

recall that $\rho_{\underline{x}}$ is a smeared density, $\underline{x}=(x_1,\dots,x_N)$.

Since $|y|^{-1} * \rho_{\underline{x}}(y) - (V-W)(y) = |y|^{-1} * (\rho_{\underline{x}} - \rho)$, the first term in the right-hand expression is equal to

$$\int \theta^{\frac12}(x_N)\Psi(x_1,\dots,x_N)\times \mathsf{D}_y\Big(\rho_{\underline{x}}(y)-\rho(y), F(x_N,y,\lambda)\theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},y)\Big)\,dx_1\cdots dx_N \tag{25.6.33}$$

and its absolute value does not exceed

$$\Big(N\int \mathsf{D}\big(\rho_{\underline{x}}(\cdot)-\rho(\cdot),\rho_{\underline{x}}(\cdot)-\rho(\cdot)\big)|\Psi(x_1,\dots,x_N)|^2\theta(x_N)\,dx_1\cdots dx_N\Big)^{\frac12} \times N^{-\frac12}\Big(\int \mathsf{D}_y\Big(F(x_N,y)\theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},y), F(x_N,y)\theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},y)\Big)\,dx_1\cdots dx_N\Big)^{\frac12}. \tag{25.6.34}$$

Due to estimate (25.5.24) and definition (25.5.4) as the first factor in (25.6.34) does not exceed $\big((Q+T+\varepsilon^{-1}N)\Theta+R\big)^{\frac12}$, where we assume that $\varepsilon \le Z^{-\frac23}$ and $\Theta \asymp b^{-\frac12}Q^{\frac12}\bar r$ is now an upper estimate for $\int \theta(y)\rho_\Psi(y)\,dy$-like expressions; due to our choice of υ it coincides with $\Theta = \upsilon^{\frac52}\bar r^7$.

Then according to (25.5.25) $R \asymp Cb^{-2}\Theta \ll Q\Theta$ and according to (25.5.23) $T \ll Q$ and therefore in all such inequalities we may skip R and T terms; so we get $C(Q+\varepsilon^{-1}N)^{\frac12}\Theta^{\frac12}$.

Meanwhile, the second factor in (25.6.34) (without square root) is equal to

$$N^{-1}\int L^{-2}\varphi'(\lambda L^{-1})\varphi'(\lambda' L^{-1})|y-z|^{-1}\underbrace{e(x_N,y,\lambda)}\,\theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},y)\times \underbrace{e(x_N,z,\lambda')}\,\theta^{\frac12}(z)\Psi^\dagger(x_1,\dots,x_{N-1},z)\,dydz\,dx_1\cdots dx_{N-1}\underbrace{dx_N}\,d\lambda d\lambda';$$

after integration by x_N we get instead of marked terms $e(y,z,\lambda)$ (recall that $e(.,.,.)$ is the Schwartz kernel of projector and we keep $\lambda<\lambda'$) and then integrating with respect to λ' we arrive to

$$N^{-1}\int |y-z|^{-1}F(y,z)\theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},y)\times \theta^{\frac12}(z)\Psi^\dagger(x_1,\dots,x_{N-1},z)\,dydz\,dx_1\cdots dx_{N-1}\,,$$

where now F is defined by (25.6.21) albeit with φ^2 instead of φ. This latter expression does not exceed

$$N^{-1}\iint |y-z|^{-1}|F(y,z)|\theta^{\frac12}(y)|\Psi(x_1,\dots,x_{N-1},y)|^2\times dydz\,dx_1\cdots dx_{N-1}. \tag{25.6.35}$$

Then due to Proposition 25.A.3 expression $\int |y-z|^{-1}|F(y,z)|\,dz$ does not exceed $Cb^{-1}\hbar^{-1}\asymp \upsilon^{\frac12}$, and thus expression (25.6.35) does not exceed $CZ^{-2}\upsilon^{\frac12}\Theta$ and therefore the second factor in (25.6.34) does not exceed $CN^{-1}\upsilon^{\frac14}\Theta^{\frac12}$ and the whole expression (25.6.34) does not exceed

$$C(Q+\varepsilon^{-1}N)^{\frac12}\Theta^{\frac12}\times N^{-1}\upsilon^{\frac14}\Theta^{\frac12}= CN^{-1}(Q+\varepsilon^{-1}N)^{\frac12}\upsilon^{\frac14}\Theta\,.$$

Therefore we conclude that

(25.6.36) As $\varepsilon\ge Z^{-1}\upsilon^{-\frac32}$ the first term in the right-hand expression of (25.6.32) does not exceed $C\upsilon\Theta$.

Further, we need to estimate the second term in the right-hand expression of (25.6.32). It can be rewritten in the form

$$\sum_{1\le i\le N}\int U(x_i,y)\Psi(x_1,\dots,x_N)\Psi^\dagger(x_1,\dots,x_{N-1},y)\theta^{\frac12}(x_N)\theta^{\frac12}(y)\times F(x_N,y)\,dx_1\cdots dx_N dy\,, \tag{25.6.37}$$

where $U(x_i,y)$ is the difference between potential generated by the charge $\delta(x-x_i)$ and the same charge smeared; note that $U(x_i,y)$ is supported in $\{(x_i,y)\colon |x_i-y|\le\varepsilon\}$. Let us estimate the i-th term in this sum with $i<N$ first; multiplied by $N(N-1)$, it does not exceed

(25.6.38)
$$N\biggl(\int |U(x_i,y)|^2|\Psi(x_1,\dots,x_N)|^2\theta^{\frac12}(x_N)\theta^{\frac12}(y)|F(x_N,y)|\,dx_1\cdots dx_N dy\biggr)^{\frac12}\times$$
$$N\biggl(\int \omega(x_i,y)|\Psi(x_1,\dots,x_{N-1},y)|^2\theta^{\frac12}(x_N)\theta^{\frac12}(y)|F(x_N,y)|\,dx_1\cdots dx_N dy\biggr)^{\frac12};$$

here ω is ε-admissible and supported in $\{(x_i,y)\colon |x_i-y|\le 2\varepsilon\}$ function. Due to Proposition 25.A.3 in the second factor $\int \theta^{\frac12}(x_N)|F(x_N,y)|\,dx_N\le C$ and therefore the whole second factor does not exceed

$$C\underbrace{\biggl(\int \theta^{\frac12}(x)\omega(x,y)\rho^{(2)}_\Psi(x,y)\,dxdy\biggr)}^{\frac12} \tag{25.6.39}$$

where we replaced x_i by x. According to Proposition 25.5.1 in the selected expression one can replace $\varrho^{(2)}_\Psi(x,y)$ by $\rho_\Psi(x)\rho(y)$ with an error which does not exceed

$$C\Bigl(\sup_x \|\nabla_y\chi_x\|_{\mathscr{L}^2(\mathbb{R}^3)}\bigl(Q+\varepsilon^{-1}N\bigr)^{\frac12}+C\varepsilon N\|\nabla_y\chi\|_{\mathscr{L}^\infty}\Bigr)\Theta,$$

which, as we plug $\sup_x \|\nabla_y\chi_x\|_{\mathscr{L}^2(\mathbb{R}^3)}\asymp\varepsilon^{\frac12}$, $\|\nabla_y\chi\|_{\mathscr{L}^\infty}\asymp\varepsilon^{-1}$ becomes $CN\Theta$.

Meanwhile, let us consider

$$\int |U(x_i,y)|^2\theta^{\frac12}(y)|F(x_N,y)|\,dy. \tag{25.6.40}$$

Again due to Proposition 25.A.3 it does not exceed

$$C\upsilon^{\frac32}\int |U(x_i,y)|^2\theta^{\frac12}(y)\bigl(|x_N-y|\upsilon^{\frac12}+1\bigr)^{-s}\,dy$$

and this integral should be taken over $B(x_i,\varepsilon)$, with $|U(x_i,y)|\le|x_i-y|^{-1}$, so (25.6.40) does not exceed $C\varepsilon\upsilon^{\frac32}\omega'(x_i,x_N)$ with $\omega'(x,y)=\bigl(1+\upsilon^{\frac12}|x-y|\bigr)^{-s}$

(provided $\varepsilon \le \upsilon^{-\frac12}$ which will be the case). Therefore the first factor in (25.6.38) does not exceed

$$C\varepsilon^{\frac12}\upsilon^{\frac34}\Bigl(\underbrace{\int \theta^{\frac12}(x)\omega'(x,y)\rho^{(2)}_\Psi(x,y)\,dxdy}\Bigr)^{\frac12}. \tag{25.6.41}$$

Therefore in selected expression one can replace $\rho^{(2)}_\Psi(x,y)$ by $\rho_\Psi(x)\rho(y)$ with an error which does not exceed what we got before but with ε replaced by $\upsilon^{-\frac12}$, i.e. also $CN\Theta$.

However in both selected expressions replacing $\rho^{(2)}_\Psi(x,y)$ by $\rho_\Psi(x)\rho(y)$ we get just 0. Therefore expression (25.6.38) does not exceed $C\varepsilon^{\frac12}\upsilon^{\frac34}Z\Theta$ which does not exceed $C\upsilon\Theta$ provided $\varepsilon \le C\upsilon^{\frac12}Z^{-2}$.

So, we have two restrictions to ε from above: the last one and $\varepsilon \le Z^{-\frac23}$ and one can see easily that both of them are compatible with restriction to ε in (25.6.36) provided $\upsilon \ge C_0Q^{\frac37}$, $Q \ge Z^{\frac53-\delta}$.

Finally, consider term in (25.6.37) with $i = N$ (multiplied by N):

$$N\int U(x_N,y)|\Psi(x_1,\dots,x_N)|^2\theta^{\frac12}(x_N)\theta^{\frac12}(y)F(x_N,y)\,dx_1\cdots dx_N dy; \tag{25.6.42}$$

due to Cauchy inequality it does not exceed

$$\begin{aligned} &N\Bigl(\int |x_N-y|^{-2}|\Psi(x_1,\dots,x_N)|^2\theta^{\frac12}(x_N)\theta^{\frac12}(y)\,dx_1\cdots dx_N dy\Bigr)^{\frac12}\times\\ &\qquad N\Bigl(\int |F(x_N,y)|^2|\Psi(x_1,\dots,x_N)|^2\theta^{\frac12}(x_N)\theta^{\frac12}(y)\,dx_1\cdots dx_N dy\Bigr)^{\frac12}, \end{aligned} \tag{25.6.43}$$

where both integrals are taken over $\{|x_N-y|\le\varepsilon\}$ and integrating with respect to y there we get that it does not exceed

$$C\varepsilon^{\frac12}\Theta^{\frac12}\times \upsilon^{\frac34}\varepsilon^{\frac32}\Theta^{\frac12} = C\upsilon^{\frac34}\varepsilon^2\Theta \ll \upsilon\Theta.$$

Therefore the right-hand expression in (25.6.19) is $\ge -C\upsilon\Theta$ and recalling that $\nu'-\nu = O(\upsilon)$ we recover an lower estimate in Theorem 25.6.1 below under assumption (25.6.4):

$$\mathsf{I}_N + \nu \ge -C\upsilon = -C(Z-N)^{\frac{17}{18}}Q^{\frac16}. \tag{25.6.44}$$

(b) In the general case, following arguments of the part (a) of Theorem 25.6.1 we recover estimate

$$\mathsf{I}_N + \nu \ge C\upsilon \ge -C(Z-N)^{\frac{17}{18}} Q^{\frac{1}{6}} \times \log^{\frac{1}{3}}\bigl((Z-N)Q^{-\frac{3}{7}}\bigr). \tag{25.6.45}$$

Combining with a lower estimate (25.6.15) or (25.6.16) and recalling estimate (25.4.5) for Q we arrive to

Theorem 25.6.1. *Let condition* (25.3.33) *be fulfilled and let* $N \le Z - C_0 Q^{\frac{3}{7}}$ *with* $Q \le C_1 Z^{\frac{5}{3}}$. *Then in the framework of fixed nuclei model*

(i) In the general case $Q = Z^{\frac{5}{3}}$

$$|\mathsf{I}_N + \nu| \le C(Z-N)^{\frac{17}{18}} Z^{\frac{5}{18}} \times \log^{\frac{1}{3}}\bigl((Z-N)Q^{-\frac{3}{7}}\bigr). \tag{25.6.46}$$

(ii) Under assumption (25.6.4) *as* $Q = Z^{\frac{5}{3}}$

$$|\mathsf{I}_N + \nu| \le C(Z-N)^{\frac{17}{18}} Z^{\frac{5}{18}}. \tag{25.6.47}$$

(iii) Further, as

$$a := \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge Z^{-\frac{1}{3}}$$

we can take $Q = Z^{\frac{5}{3}}\bigl(Z^{-\delta} + (aZ^{\frac{1}{3}})^{-\delta}\bigr)$ *and then both estimates* (25.6.46) *and* (25.6.47) *hold with an extra factor* $\bigl(Z^{-\delta'} + (aZ^{\frac{1}{3}})^{-\delta'}\bigr)$ *in the right-hand expressions.*

Remark 25.6.2. (i) In virtue of Theorem 25.6.3 stable molecules do not exist in the free nuclei model as $Z - N \ge CQ^{\frac{3}{7}}$ and in the atomic case $\widehat{\mathsf{I}}_N = \mathsf{I}_N$.

(ii) Observe that the relative error in the estimates (25.6.46) and (25.6.47) is $\asymp \upsilon/\nu$; in particular, in (25.6.47) it is $\asymp (Z-N)^{-\frac{7}{18}} Q^{\frac{1}{6}}$ and in (25.6.46) it acquires factor $\log^{\frac{1}{3}}\bigl((Z-N)Q^{-\frac{3}{7}}\bigr)$. Both of these expressions are $\lesssim 1$ due to assumption (25.6.1) and they are $\asymp 1$ as $Z - N \asymp Q^{\frac{3}{7}}$.

25.6.3 Estimate for Excessive Positive Charge

To estimate excessive positive charge when molecules can still exist in free nuclei model we apply arguments of section 5 of B. Ruskai and J. P. Solovej [1]. In view of Theorem 25.4.15 it is sufficient to consider the case

$$a := \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge C_0\bar{r}. \tag{25.6.48}$$

Therefore in Thomas-Fermi theory ρ^{TF} is supported in separate "atoms".

Let us consider a-admissible functions $\theta_m(x)$, supported in $B(\mathsf{y}_m, \frac{1}{3}a)$ for $m = 1, \dots, M$ and in $\{|x - \mathsf{y}_m| \ge \frac{1}{4}a \ \ \forall m = 1, \dots, M\}$ for $m = 0$, such that

$$\theta_0^2 + \dots + \theta_M^2 = 1. \tag{25.6.49}$$

Then for the ground state Ψ

$$\mathsf{E}_N = \langle \mathsf{H}\Psi, \Psi\rangle = \sum_{\alpha} \langle \theta_\alpha \mathsf{H} \theta_\alpha \Psi, \Psi\rangle - \sum_{\alpha, j} \|(\nabla_j \theta_\alpha)\Psi\|^2 \tag{25.6.50}$$

with the sum over of $(M+1)$-cluster decompositions $\alpha = (\alpha_0, \dots, \alpha_M)$ of $\{1, \dots, N\}$ and $\theta_\alpha(\underline{x}) = \prod_{0\le m\le M}\prod_{i\in\alpha_m}\theta_m(x_i)$; $j = 1, \dots, N$. Then for any given α

$$\mathsf{H} = \sum_{0\le m\le M} \mathsf{H}_{\alpha_m} + J_\alpha \tag{25.6.51}$$

with the *cluster Hamiltonians* H_{α_m}, involving only potential of m-th nucleus (no nucleus potential as $m = 0$) and only electrons belonging to α_m and therefore satisfying

$$\mathsf{H}_{\alpha_m} \ge \mathsf{E}_{\mathsf{atom}}(N_m(\alpha), Z_m), \qquad \mathsf{H}_{\alpha_0} \ge 0, \tag{25.6.52}$$

and with the *intercluster Hamiltonian* (actually, just potentials)

$$\begin{aligned} J_\alpha = \sum_{1\le m\le M}\sum_{i\notin\alpha_m} -Z_m|x_i - \mathsf{y}_m|^{-1} \\ + \sum_{m<l}\sum_{i\in\alpha_m, j\in\alpha_l} |x_i - x_j|^{-1} + \sum_{m<l} Z_m Z_l |\mathsf{y}_l - \mathsf{y}_m|^{-1}. \end{aligned} \tag{25.6.53}$$

Let us note that

$$\sum_{\alpha} \theta_\alpha^2 J_\alpha = \sum_{0\le m<l\le M} J_{ml} \tag{25.6.54}$$

with J_{ml} given by (32)–(33) of B. Ruskai–J. P. Solovej [1] if $m, l > 0$ and $m = 0$ respectively:

$$J_{ml} = Z_m Z_l |\mathsf{y}_m - \mathsf{y}_l|^{-1} - Z_m \sum_i \theta_l^2(x_i)|x_i - \mathsf{y}_m|^{-1} - Z_l \sum_i \theta_m^2(x_i)|x_i - \mathsf{y}_l|^{-1} + \sum_{i \neq j} \theta_m^2(x_i)\theta_l^2(x_j)|x_i - x_j|^{-1}, \tag{25.6.55}$$

and

$$J_{0l} = \sum_i \theta_0^2(x_i)\Big(-Z_l|x_i - \mathsf{y}_l|^{-1} + \sum_j \theta_l^2(x_j)|x_i - x_j|^{-1}\Big). \tag{25.6.56}$$

Then we recover (35) of B. Ruskai–J. P. Solovej [1]

$$\langle J_{ml}\Psi, \Psi\rangle = Z_m Z_l |\mathsf{y}_m - \mathsf{y}_l|^{-1} - Z_l \int \rho_\Psi(x)\theta_m^2(x)|x - \mathsf{y}_l|^{-1}\,dx - Z_m \int \rho_\Psi(x)\theta_l^2(x)|x - \mathsf{y}_m|^{-1}\,dx + \int \rho_\Psi^{(2)}(x,y)\theta_m^2(x)\theta_l^2(y)\,dxdy. \tag{25.6.57}$$

Applying estimate (25.4.56) (replacing first θ_m with $m = l, \dots, M$ by $\tilde\theta_m$ supported in $B(\mathsf{y}_l, c\bar r)$ and estimating an error), we conclude that

$$\int \rho_\Psi(x)\theta_m^2(x)|x - \mathsf{y}_l|^{-1} = \int \rho^{\mathsf{TF}}(x)\theta_m^2(x)|y - \mathsf{y}_l|^{-1}\,dx + O(Y)|\mathsf{y}_m - \mathsf{y}_l|^{-1} \tag{25.6.58}$$

and

$$\int \rho_\Psi(x)\theta_m^2(x)dyx = \mathsf{N}_m^{\mathsf{TF}} + O(Y) \tag{25.6.59}$$

with

$$N_m^{\mathsf{TF}} = \int \rho^{\mathsf{TF}}(x)\theta_m^2(x)\,dx, \tag{25.6.60}$$

where here and below $Y = (Q\bar r)^{\frac12}$, $\bar Y = (\bar Q \bar r)^{\frac12}$ (compare with (36)–(37) of B. Ruskai–J. P. Solovej [1]) which yields

$$\int \rho_\Psi(x)\big(1 - \sum_{1\le m\le M} \tilde\theta_m(x)\big)\,dx \le CY \tag{25.6.61}$$

and we prove that (25.6.59) holds for θ_m as well (compare with (38) of B. Ruskai–J. P. Solovej [1]).

Let us estimate the last term in (25.6.57) by Proposition 25.5.1 with $\theta(x) = \tilde{\theta}_m^2(x)$ and $\chi(x,y) = \tilde{\theta}_l^2(y)|x-y|^{-1}$,

$$\begin{aligned}(25.6.62)\quad \int \rho_\Psi^{(2)}(x,y)\theta_m^2(x)\theta_l^2(y)|x-y|^{-1}\,dxdy \geq \\ \int \rho_\Psi^{(2)}(x,y)\theta_m^2(x)\tilde{\theta}_l^2(y)|x-y|^{-1}\,dxdy \geq \\ \int \rho_\Psi(x)\rho^{\mathsf{TF}}(y)\theta_m^2(x)\tilde{\theta}_l^2(y)|x-y|^{-1}\,dxdy - \\ C\bar{Y}\int \rho_\Psi(x)\theta_m^2(x)|\mathsf{y}_m-\mathsf{y}_l|^{-1}\end{aligned}$$

because $\|\nabla_y \chi_x\|_{\mathscr{L}^2} \leq C\bar{r}^{\frac{1}{2}}|\mathsf{y}_m-\mathsf{y}_l|^{-1}$ and

$$R = \int |\nabla\theta_m|^2\rho_\Psi(x)\,dx \leq Ca^{-2}Y.$$

Repeating the same trick with replacing $\rho_\Psi(x)$ by $\rho^{\mathsf{TF}}(x)$ we get that it is larger than

$$(25.6.63)\quad \int \rho^{\mathsf{TF}}(x)\rho^{\mathsf{TF}}(y)\theta_m^2(x)\theta_l^2(y)\ |x-y|^{-1}\,dxdy - CN\bar{Y}|\mathsf{y}_m-\mathsf{y}_l|^{-1}.$$

Then we conclude that

$$\begin{aligned}(25.6.64)\quad \langle J_{ml}\Psi,\Psi\rangle \geq \int \big(Z_m\delta(x-\mathsf{y}_m)-\rho^{\mathsf{TF}}(x)-CY\big) \\ \times\big(Z_l\delta(y-\mathsf{y}_l)-\rho^{\mathsf{TF}}(x)-CY\big)\theta_m^2(x)\theta_l^2(y)|x-y|^{-1}\,dxdy \\ - CN\bar{Y}|\mathsf{y}_m-\mathsf{y}_l|^{-1}\end{aligned}$$

and finally

$$\begin{aligned}(25.6.65)\quad &\langle J_{ml}\Psi,\Psi\rangle \\ &\geq (Z_m-N_m^{\mathsf{TF}}-CY)\cdot(Z_l-N_l^{\mathsf{TF}}-Y)|\mathsf{y}_l-\mathsf{y}_m|^{-1} - C_1N\bar{Y}|\mathsf{y}_m-\mathsf{y}_l|^{-1}\end{aligned}$$

(compare with (39) of B. Ruskai–J. P. Solovej [1]) provided

$$\begin{aligned}(25.6.66)\quad \Big|\int \rho^{\mathsf{TF}}(y)|x-y|^{-1}\tilde{\theta}_m(x)\,dy - N_m^{\mathsf{TF}}|x-\mathsf{y}_m|^{-1}\Big| \leq \\ C(Z-N)|x-\mathsf{y}_m|^{-1}\end{aligned}$$

for $|x - y_m| \ge C\bar{r}$. Similarly, under the same condition (25.6.66)

$$\langle J_{0l}\Psi, \Psi\rangle \ge -CY(Z-N) - C_1 N\bar{Y}a^{-1} \tag{25.6.67}$$

(compare with (40) of B. Ruskai–J. P. Solovej [1]).

Let us note that the absolute value of the last term in the right-hand expression of (25.6.50) does not exceed $Ca^{-2}Y$ due to (25.6.59). Now stability condition yields

$$J = \sum_{0\le m<l\le M} J_{ml} \le CYa^{-2} + C(Z-N)Ya^{-1} + C_1 N\bar{Y}a^{-1}. \tag{25.6.68}$$

This inequality, (25.6.48) and Proposition 25.6.5 below yield that

$$Z - N \le CY + CN^{\frac12}\bar{Y}^{\frac12} \le C_1 N^{\frac12}\bar{Y}^{\frac12} \le C_2 N^{\frac{11}{6}}(Z-N)^{\frac16} \tag{25.6.69}$$

because $\bar{r} \asymp (Z-N)^{-\frac13}$ and $\bar{Q} \asymp Z^{\frac53}$ thus proving the following theorem:

Theorem 25.6.3. *Let condition* (25.3.33) *be fulfilled. Then in the framework of free nuclei model with $M \ge 2$ the stable molecule does not exist unless*

$$Z - N \le Z^{\frac{11}{13}}. \tag{25.6.70}$$

Remark 25.6.4. Unfortunately, we do not prove that molecules exist for any values of $Z_1, \dots, Z_m$ and N. We are not aware of any rigorous result of this type in the frameworks of our models.

Proposition 25.6.5. *Let* (25.6.48) *be fulfilled. Then inequality* (25.6.66) *holds and*

$$J \ge \epsilon(Z-N)^2 a^{-1}. \tag{25.6.71}$$

Proof. Note first that

$$\mathcal{E}^{\mathsf{TF}} \le \mathcal{E}(\bar{\rho}) = \sum_j \mathcal{E}(\rho_j^{\mathsf{TF}}) + J^{\mathsf{TF}}(\bar{\rho}) \le \sum_j \mathcal{E}^{\mathsf{TF}}(\rho_j^{\mathsf{TF}}) + C(Z-N)^2 a^{-1} \tag{25.6.72}$$

with $\bar{\rho} = \sum_j \rho_j^{\mathsf{TF}}$ while

$$\sum_j \mathcal{E}(\rho_j^{\mathsf{TF}}) \le \sum_j \mathcal{E}(\theta_j \rho^{\mathsf{TF}}); \tag{25.6.73}$$

then

$$J^{\mathsf{TF}}(\rho^{\mathsf{TF}}) \le C(Z-N)^2 a^{-1} \tag{25.6.74}$$

and using (25.6.70) we conclude that

$$\mathsf{D}(\rho^{\mathsf{TF}} - \bar{\rho}, \rho^{\mathsf{TF}} - \bar{\rho}) \le C(Z-N)^2 a^{-1}. \tag{25.6.75}$$

Further,

$$\Lambda := \sum_j \mathsf{D}(\rho^{\mathsf{TF}}\theta_j - \rho_j^{\mathsf{TF}}, \rho^{\mathsf{TF}}\theta_j - \rho_j^{\mathsf{TF}}) \le \mathsf{D}(\rho^{\mathsf{TF}} - \bar{\rho}, \rho^{\mathsf{TF}} - \bar{\rho}) + C\bar{r}a^{-1}\Lambda \tag{25.6.76}$$

and combining with (25.6.74) we conclude that

$$\Lambda \le C(Z-N)^2 a^{-1} \tag{25.6.77}$$

due to (25.6.48). Combining with $\rho_j^{\mathsf{TF}} * |x|^{-1} = N_j^{\mathsf{TF}} |x - \mathsf{y}_j|^{-1}$ for $|x - \mathsf{y}_j| \ge r_j$ we arrive to (25.6.66). Further,

$$J^{\mathsf{TF}}(\rho^{\mathsf{TF}}) \ge J^{\mathsf{TF}}(\bar{\rho}) - C\Lambda^{\frac{1}{2}}\bar{r}\,\frac{1}{2}(Z-N)a^{-\frac{3}{2}} - C\Lambda\bar{r}^{-1} \tag{25.6.78}$$

which together with (25.6.76) and (25.6.77) yields (25.6.71). □

25.A Appendices

25.A.1 Electrostatic Inequalities

We know already that there are two sources of errors in the lower estimate: due to electrostatic inequality (25.2.1) and semiclassical errors. For the first error in the case $\vec{B} = \mathsf{const}$ E. Lieb, J. P. Solovej and J. Yngvason [3] provide the (almost) perfect estimate; the reader can find the proof based on the magnetic Lieb–Thirring inequality (and this inequality as well) in that paper (p. 122) which in the case of $\vec{B} = 0$ becomes

Theorem 25.A.1. *For the ground state* Ψ *of* (25.1.1) *with potential* (25.1.4)

$$\int \rho_\Psi^{\frac{4}{3}}\,dx \le CZ^{\frac{5}{6}}N^{\frac{1}{2}}\big(Z+N\big)^{\frac{1}{3}} \tag{25.A.1}$$

otherwise.

In particular for $c^{-1}N \le Z \le cN$ *the right-hand expression does not exceed* $CZ^{\frac{5}{3}}$.

On the other hand, for $B = 0$ there is a more precise inequality due to V. Bach [1] and G. Graf and J. P. Solovej [1]:

Theorem 25.A.2. *For the ground state* Ψ *of* (25.1.1) *with potential* (25.1.4)

$$\langle H\Psi,\Psi\rangle \ge \mathsf{N}_1(A-\nu)+\nu N-\frac{1}{2}\iint |x-y|^{-1}|e(x,y,\nu)|^2\,dxdy - CN^{\frac{5}{3}-\delta} \tag{25.A.2}$$

with some exponent $\delta > 0$.

We will discuss magnetic field case in more details in the Appendix to the next Chapter 26.

25.A.2 Hamiltonian Trajectories

We are going to prove that for $W = W^{\mathsf{TF}}$ in $M = 1$ case the generic trajectory on the energy level ν is not periodic. We use some ideas from V. Arnold [2], pages 37–38. Recall that in this case $W = W(r)$ ($r = |x-\mathsf{y}_1|$) and angular momentum $\vec{M}$ is a motion integral. Then any trajectory lies on some plane and if $M = |\vec{M}| > 0$ it lies in $\{0 < r < \bar{r}\}$ where W is analytic and $W(\bar{r}) = -\nu$.

(25.A.3) Let us assume that all the trajectories on the energy level ν are periodic.

Then the rotation number

$$\Phi = \int_{r_1}^{r_2} \frac{M\,dr}{r^2\sqrt{2\big(W(r)+\nu\big)-M^2r^{-2}}} \tag{25.A.4}$$

showing the increment of the polar angle over a half-trajectory should be πk^{-1} with $k \in \mathbb{N}$ and should not depend on M where $r_1 \le r_2$ are roots of $\big(W(r)+\nu\big) - M^2 r^{-2} = \nu$. So, Φ should be the same for all trajectories on the energy level ν. One can see easily that for $M \to 0$ Φ tends to those of the Coulomb potential. So, $\Phi = 2\pi$ for all trajectories on the energy level ν.

Let r_0 be a root of $F(r) = 2\big(W(r)+\nu\big) + r^4\big(W'(r)\big)^2 = 0$. One can see easily that $F(\bar r) > 0$, $F(r) \to \infty$ as $r \to 0$ and $F'(r) < 0$ because

$$W' < 0, \qquad W'' + 2rW' = r^{-1}(r^2 W')' = r\Delta W > 0. \tag{25.A.5}$$

So, the unique root exists. Then $r = r_0$ is a circular motion with $M = -r_0^3 W'(r_0)$.

Then (V. Arnold [2], problem 2 at page 37)

$$\Phi \to \pi \sqrt{W'/(3W' + rW'')^{-1}}\big|_{r=r_0} = \Phi_0$$

for trajectories tending to circular. However, $3W' + rW'' > W'$ due to (25.A.5) and then $\Phi_0 > \pi$. Contradiction to assumption (25.A.3).

25.A.3 Some Spectral Function Estimates

Proposition 25.A.3. *For Schrödinger operator with $W \in \mathscr{C}^\infty$ and for $\phi \in \mathscr{C}_0^\infty([-1,1])$ the following estimate holds for any s:*

$$|F(x,y)| \le Ch^{-3}\big(1 + h^{-1}|x-y|\big)^{-s}, \tag{25.A.6}$$

$$F(x,y) := \int \phi(\lambda)\, d_\lambda e(x,y,\lambda). \tag{25.A.7}$$

Proof. Let $u(x,y,t) = \int e^{-ih^{-1}t\lambda}\, d_\lambda e(x,y,\lambda)$ be the Schwartz's kernel of $e^{-ih^{-1}Ht}$.

Fix y. Note first that $\mathscr{L}^2$-norm[25)] of $\phi(hD_t)\chi(t)\omega(x)u(x,y,t)$ is less than Ch^s as $\chi \in \mathscr{C}_0^\infty([-\epsilon,\epsilon])$ and $\omega \in \mathscr{C}^\infty$ supported in $\{|x-y| \ge \epsilon_1\}$ ($\epsilon_1 = C\epsilon$) due to the finite speed of propagation of singularities.

We conclude then that $\mathscr{L}^2$-norm of $\phi(hD_t)\chi(t)\omega(x)u(x,y,t)$ is less than Ch^s for $\omega \in \mathscr{C}^\infty$ supported in $\{x\colon |x-y| \ge C\}$.

Then $\mathscr{L}^2$-norm of $\partial_t^l \nabla^\alpha \phi(hD_t)\chi(t)\omega(x)u$ does not exceed Ch^s. Then due to imbedding inequality $\mathscr{L}^\infty$-norm of $\phi(hD_t)\chi(t)\omega(x)u$ does not exceed

[25)] With respect to x, t here and below.

Ch^s. Setting $t = 0$ and using this inequality and $|F(x,y)| \le Ch^{-3}$ (due to Chapter 4) we get that $|F(x,y)| \le Ch^s$ for $|x-y| \ge \epsilon_0$;

Now let us consider general $|x-y| = r \ge Ch$. Rescaling $x-y \mapsto (x-y)r^{-1}$ we need to rescale $h \mapsto hr^{-1}$ and rescaling above inequality and keeping in mind that $F(x,y)$ is a density with respect to x we get $|F(x,y)| \le Ch^s r^{-3-s}$ which is equivalent to (25.A.6)–(25.A.7). □

25.A.4 Calculation of Scott, Dirac and Schwinger correction terms

Consider multiparticle Schrödinger operator (with a single nucleus, but for multiple nuclei our result will be the same) in $\bigwedge_{1\le n\le N} \mathscr{L}^2(\mathbb{R}^3, \mathbb{C}^q)$:

$$\mathsf{H} := \sum_{1\le n\le N} \Big[-\frac{\hbar^2}{2\mathsf{m}}\Delta_{x_n} - \frac{Z\mathsf{e}^2}{|x_n|}\Big] + \sum_{1\le n<n'\le N} \frac{\mathsf{e}^2}{|\mathsf{x}_n - \mathsf{x}_{n'}|}; \tag{25.A.8}$$

dividing by e^2 we get

$$\mathsf{G} := \sum_{1\le n\le N} \Big[-\gamma\Delta_{x_n} - \frac{Z}{|x_n|}\Big] + \sum_{1\le n<n'\le N} \frac{1}{|\mathsf{x}_n - \mathsf{x}_{n'}|}; \tag{25.A.9}$$

with

$$\gamma = \frac{\hbar^2}{2\mathsf{m}\mathsf{e}^2}. \tag{25.A.10}$$

First we consider case $Z = \gamma = q = 1$.

Scott correction term

To calculate Scott correction term we need to calculate the limit as $\eta \to +0$ of

$$\mathsf{Tr}[(H+\eta)^-] + \frac{1}{15\pi^2}\int (V-\eta)_+^{5/2}\,dx \tag{25.A.11}$$

with

$$H = -\Delta - V(x), \qquad V(x) = |x|^{-1} \tag{25.A.12}$$

where the second term in (25.A.10) is the Weyl expression for the first one. Since eigenvalues of H are $-\frac{1}{4n^2}$ of multiplicity n^2, the first term in (25.A.11) is equal to

$$\sum_{n:\ 4n^2\eta<1} \Big(-\frac{1}{4n^2}+\eta\Big)n^2 = -\frac{1}{4}n+\frac{1}{6}n(n+1)(2n+1)\eta \tag{25.A.13}$$

as

$$\eta = \frac{1}{4(n+\alpha)^2}, \qquad 0\le \alpha \le 1 \tag{25.A.14}$$

while the second term in (25.A.10) is equal to

$$\frac{4}{15\pi}\int_0^{\eta^{-1}} (\eta^{-1}-r)^{5/2} r^{-1/2}\,dr = \frac{4}{15\pi}\eta^{-1/2}B(7/2,1/2) = \frac{1}{12}\eta^{-1/2}. \tag{25.A.15}$$

Plugging (25.A.14) into (25.A.13) and (25.A.15) and calculating the limit of (25.A.11) we conclude thar $\kappa_{\mathsf{Scott}} = \frac{1}{2}$.

Dirac correction term

To calculate Dirac correction term we need to calculate a constant, as $d=1$ and $q=1$. To do this it is sufficient to calculate expression (25.A.18) below where $e(x,y,\tau)$ is a Schwartz kernel of the projector for $-\Delta-1$, i.e.

$$e(x,y,0) = \frac{1}{8\pi^3}\int_{|\xi|\le 1} e^{i\langle x-y,\xi\rangle}\,d\xi \tag{25.A.16}$$

and we can assume that $x-y=(r,0,0)$; then

$$e(x,y,0) = \frac{1}{8\pi^3}\int_{|\xi|\le 1} e^{ir\xi_1}d\xi_1 d\xi' = \frac{1}{8\pi^2}\int_{-1}^{1}\cos(r\xi_1)(1-\xi_1^2)\,d\xi_1 = \frac{1}{2\pi^2 r^3}\big(\sin(r)-r\cos(r)\big). \tag{25.A.17}$$

Then

$$\int |x-y|^{-1}|e(x,y,0)|^2\,dy = \frac{1}{\pi^3}\int_0^\infty r^{-5}\big(\sin(r)-r\cos(r)\big)^2\,dr\,.$$

Integrating by parts we get

$$\begin{aligned}&\frac{1}{8\pi^3 r^4}\Big(-2r^2+2r\sin(2r)+\cos(2r)-1\Big)\Big|_{r=0}^{r=\infty}\\ &\qquad=-\frac{1}{2r^4}\Big(-2r^2+2r\big(2r-\frac{1}{6}(2r)^3\big)-\frac{1}{2}(2r)^2+\frac{1}{24}(2r)^4\Big)\Big|_{r=0}\\ &\qquad\qquad=-\frac{1}{8\pi^3 r^4}\Big(-\frac{1}{6}(2r)^4+\frac{1}{24}(2r)^4\Big)=\frac{1}{6\pi^3}.\end{aligned}$$

Therefore,

$$\mathsf{Dirac}=\frac{1}{6\pi^3}(W^{\mathsf{TF}}-\nu)_+^2\,dx=\big(\frac{6}{\pi}\big)^{\frac{1}{3}}\int \rho^{\mathsf{TF}}\,dx \tag{25.A.18}$$

because for $q=\gamma=1$

$$\rho^{\mathsf{TF}}=\frac{q}{6\pi^2}(W^{\mathsf{TF}}-\nu)_+^{3/2} \tag{25.A.19}$$

where ν is a chemical potential.

Schwinger correction term

Let $H=-h^2\Delta+V$ and $a=|\xi|^2-V(x)$ its Weyl symbol. Consider modulo $O(h^4)$ symmetric product

$$\frac{1}{2}\Big(((\tau-a)^{-1})^{\mathsf{w}}(\tau-a)^{\mathsf{w}}+(\tau-a)^{\mathsf{w}}((\tau-a)^{-1})^{\mathsf{w}}\Big)=I-\frac{h^2}{4}B^{\mathsf{w}}$$

with

$$B=\sum_{\alpha\colon|\alpha|=2}\frac{1}{\alpha!}\Big((\tau-a)^{(\alpha)}((\tau-a)^{-1})_{(\alpha)}+(\tau-a)_{(\alpha)}((\tau-a)^{-1})^{(\alpha)}\Big),$$

where b^{w} means Weyl quantization of b, and we used the simple observation that $(\tau-a)^{(\alpha)}_{(\beta)}=0$ as $\alpha\neq 0,\beta\neq 0$

$$\begin{aligned}&=\frac{1}{2}\sum_{j,k}\Big((\tau-a)^{(jk)}((\tau-a)^{-1})_{(jk)}+(\tau-a)_{(jk)}((\tau-a)^{-1})^{(jk)}\Big)\\ &=2\sum_j\Big((\tau-a)^{-2}V_{(jj)}-(\tau-a)^{-3}V_{(j)}^2\Big)+4\sum_{j,k}(\tau-a)^{-3}V_{(jk)}\xi_j\xi_k.\end{aligned}$$

Therefore Weyl symbol of $(\tau-H)^{-1}$ is equal to

$$(\tau-a)^{-1}+\frac{h^2}{4}(\tau-a)^{-1}B$$

and Weyl symbol of the symmetric product $\frac{1}{2}\bigl(\psi(x)(\tau-H)^{-1}+\tau-H)^{-1}\psi(x)\bigr)$ is calculated in the same way

$$(\tau-a)^{-1}\psi+\frac{h^2}{4}(\tau-a)^{-1}\psi B-\frac{h^2}{4}\sum_{\alpha\colon|\alpha|=2}\bigl((\tau-a)^{-1}\bigr)^{(\alpha)}\psi_{(\alpha)}\,,$$

but integration with respect to ξ (since we integrate by parts) kills the last term and we get that the coefficient at $h^2\psi$ is

$$\begin{aligned}&\frac{1}{2}\sum_j\int\Bigl((\tau-a)^{-3}V_{(jj)}-(\tau-a)^{-4}V_{(j)}^2\Bigr)\,d\xi+i\sum_{j,k}\int(\tau-a)^{-4}V_{(jk)}\xi_j\xi_k\,d\xi\\&=\int\Bigl(\frac{1}{2}(\tau-a)^{-3}\Delta V-\frac{1}{2}(\tau-a)^{-4}|\nabla V|^2+\frac{1}{3}(\tau-a)^{-4}|\xi|^2\Delta V\Bigr)\,d\xi\\&=i\partial_\tau^2\int\frac{1}{4}(\tau-a)^{-1}\Delta V\,d\xi+\partial_\tau^3\int(\tau-a)^{-1}\Bigl(\frac{1}{12}|\nabla V|^2-\frac{1}{18}|\xi|^2\Delta V\Bigr)\,d\xi.\end{aligned}$$

Taking real residue we get

$$\begin{aligned}&\partial_\tau^3\int\frac{1}{4}\theta(\tau-a)\Delta V\,d\xi+\partial_\tau^4\int\theta(\tau-a)\Bigl(\frac{1}{12}|\nabla V|^2-\frac{1}{18}|\xi|^2\Delta V\Bigr)\,d\xi\\&=4\pi\partial_\tau^3\Bigl[\frac{1}{6}(\tau+V)_+^{3/2}\Delta V+\frac{1}{18}\partial_\tau(\tau+V)_+^{3/2}|\nabla V|^2-\frac{1}{45}\partial_\tau(\tau+V)_+^{5/2}\Delta V\Bigr]\\&=\frac{\pi}{3}\partial_\tau^2\Bigl[(\tau+V)_+^{1/2}\Delta V+\frac{1}{2}(\tau+V)_+^{-1/2}|\nabla V|^2\Bigr]=\frac{2\pi}{9}\partial_\tau^2\Delta\Bigl[(\tau+V)_+^{3/2}\Bigr]\\&\qquad\qquad=\frac{\pi}{3}\partial_\tau\Delta\Bigl[(\tau+V)_+^{1/2}\Bigr].\end{aligned}$$

Multiplying by $\frac{1}{8\pi^3}\psi$ and integrating with respect to x and τ, plugging $V=W^{\mathsf{TF}}$, $\tau=\nu$ and $\psi=(W^{\mathsf{TF}}-V)$, we get

$$\begin{aligned}\mathsf{Schwinger}&=\frac{\pi}{24\pi^3}\int\Delta(W^{\mathsf{TF}}-V)\cdot W^{\mathsf{TF}\,1/2}\,dx\\&=\frac{1}{24\pi^2}\int 4\pi\rho^{\mathsf{TF}}(6\pi^2\rho^{\mathsf{TF}})^{\frac{1}{3}}\,dx=(6\pi^2)^{-\frac{2}{3}}\int\rho^{\mathsf{TF}\,\frac{4}{3}}\,dx.\end{aligned}\tag{25.A.20}$$

General case

Scaling $x\mapsto\gamma x$ and multiplying by γ we get from operator (25.A.10) the same operator with $\gamma=1$. This preserves Z and we have a scaling $\mathsf{E}\mapsto\gamma^{-1}\mathsf{E}$.

Meanwhile

$$\rho^{\mathsf{TF}}(x) \mapsto \gamma^3 \rho^{\mathsf{TF}}(\gamma x)$$

preserves $N = \int \rho^{\mathsf{TF}}(x)\,dx$) and

$$\int \rho^{\mathsf{TF}\,\frac{4}{3}}\,dx \mapsto \gamma \int \rho^{\mathsf{TF}\,\frac{4}{3}}\,dx, \qquad \int \rho^{\mathsf{TF}\,\frac{5}{3}}\,dx \mapsto \gamma^2 \int \rho^{\mathsf{TF}\,\frac{5}{3}}\,dx,$$
$$\int V\rho^{\mathsf{TF}}\,dx \mapsto \gamma^{-1} \int V\rho^{\mathsf{TF}}\,dx, \qquad \mathsf{D}(\rho^{\mathsf{TF}}, \rho^{\mathsf{TF}}) \mapsto \gamma^{-1}\mathsf{D}(\rho^{\mathsf{TF}}, \rho^{\mathsf{TF}})$$

Therefore

(25.A.21) $\mathcal{E}^{\mathsf{TF}}_{q,Z}$, $\mathsf{Scott}_{q,Z}$, $\mathsf{Dirac}_{q,Z}$ and $\mathsf{Schwinger}_{q,Z}$ could be obtained from the corresponding expressions for $\gamma = 1$ by multiplication by γ^{-1}, while $\int \rho^{\mathsf{TF},\,\frac{4}{3}}\,dx$ and $\int \rho^{\mathsf{TF},\,\frac{5}{3}}\,dx$ are obtained from the corresponding expression by multiplication by γ and γ^2 respectively.

Next we want to look on dependence on q. In Thomas-Fermi theory we have

$$\Delta(W^{\mathsf{TF}} - V) = 4\pi\rho^{\mathsf{TF}} = \frac{2q}{3\pi} W^{\mathsf{TF}\,3/2}, \qquad \int \rho^{\mathsf{TF}} = N/Z. \tag{25.A.22}$$

Therefore

(25.A.23) $\mathcal{E}^{\mathsf{TF}}_{q,Z}$ could be obtained from the corresponding expression for $q = 1$ by scaling with $\gamma = q^{\frac{2}{3}}$ and multiplication by $q^{\frac{1}{3}}$, while $\int \rho^{\mathsf{TF},\,\frac{4}{3}}\,dx$ and $\int \rho^{\mathsf{TF},\,\frac{5}{3}}\,dx$ is obtained from the corresponding expression by multiplication by $q^{\frac{2}{3}}$ and $q^{\frac{4}{3}}$.

Since Scott, Dirac and $\mathsf{Schwinger}$ also are given by Weyl expressions through W^{TF} with factor q we arrive to

Theorem 25.A.4. *As* $\mathsf{e} = 1$

$$\mathcal{E}^{\mathsf{TF}} = \int \left(\kappa\rho^{\mathsf{TF}\,\frac{5}{3}} - V\rho^{\mathsf{TF}}\right) dx + \frac{1}{2}\mathsf{D}(\rho^{\mathsf{TF}}, \rho^{\mathsf{TF}}) \tag{25.A.24}$$

$$\kappa = \frac{6^{\frac{4}{3}}}{15}\pi^{\frac{2}{3}} q^{-\frac{1}{3}}\gamma^{-3},$$

$$\text{Scott} = \frac{1}{2}\gamma^{-1}q \sum_{1\le m\le M} Z_m^2\,, \tag{25.A.25}$$

$$\text{Dirac} = -\big(\frac{6}{\pi q}\big)^{\frac{1}{3}}\gamma^{-2}\int \rho^{\mathsf{TF}\frac{4}{3}}\,dx, \tag{25.A.26}$$

$$\text{Schwinger} = \big(\frac{q}{6\pi^2}\big)^{\frac{2}{3}}\gamma^{-2}\int \rho^{\mathsf{TF}\frac{4}{3}}\,dx. \tag{25.A.27}$$

25.A.5 Baxter's Lemma

Proposition 25.A.5 (Baxter's Lemma) [26]**.** *Let $V \in \mathscr{D}$ and let $\rho(x) \ge 0$ be a given function with $\psi_\rho := |x|^{-1} * \rho \in \mathscr{D}$. Assume $\rho \in \mathscr{L}^p$ for some $p > \frac{3}{2}$ and $\mathsf{D}(\rho,\,\rho) < \infty$. Then there exists g with $0 \le g(x) \le \rho(x)$ such that $\psi_g := |x|^{-1} * g$ satisfies $\psi_g = V(x)$ a.e. when $g(x) < \rho(x)$ and $\psi_g(x) \le V(x)$ a.e.*

Proof. Baxter proves this when p and g are measures. We following E. H. Lieb give a simpler proof for functions. Consider

$$\mathcal{E}(g) := \frac{1}{2}\mathsf{D}(g,g) - \int Vg\,dx \qquad \text{and} \qquad E = \inf_{0\le g\le\rho} \mathcal{E}(g).$$

Let g^n be a minimizing sequence. There exists a subsequence that converges weakly in $\mathscr{L}^p$ to some g and, by Mazur's theorem (1933), there exists a sequence h^n of convex combinations of the g^n that converges strongly to g in $\mathscr{L}^p$. Then a subsequence of the h^n converges a.e. to g.

Clearly, $0 \le h^n(x) \le \rho(x)$. Since $\mathcal{E}(g)$ is convex (this is crucial) $\mathcal{E}(h^n) \to E$ but, by dominated convergence, $\mathcal{E}(h^n) \to \mathcal{E}(g)$. So g minimizes $\mathcal{E}$ and satisfies (a.e.): $V(x) = \psi_g(x)$ when $0 < g(x) < \rho(x)$ and $\psi_g(x) \ge V(x)$ when $g(x) = 0$ and $\rho(x) > 0$.

We have to eliminate the possibility $f(x) = \psi_g(x) - V(x) > 0$ when $g(x) = 0$. We claim $\psi_g \in \mathscr{D}$ and hence $f(x)$ is continuous and goes to zero at infinity. Since $g \le \rho$ we have $\psi_g \le \psi_\rho$ and therefore $\psi_g \to 0$ at infinity.

To examine the continuity at $x = 0$, write $\psi_g = h + (\psi_g - h)$ where $h = |x|^{-1} * (\chi g)$ where χ is the characteristic function of the ball $B(0,1)$. Clearly $\psi_g - h$ is continuous at $x = 0$. Moreover, $\chi g \in \mathscr{L}^p \cap \mathscr{L}^1$ so $h \in \mathscr{D}$ by Lemma 3.1 of *Selecta*. It is here that $p > \frac{3}{2}$ is used.

[26] See J. R. Baxter [1] and E. H. Lieb *Selecta* "Thomas-Fermi and related theories of atoms and molecules", [4], pp. 263–301.

Now, since $f \in \mathscr{D}$, $\Omega = \{\{x\colon f(x) > 0\}$ is open and, since $x \in \Omega \implies g(x) = 0$, f is is subharmonic on Ω. But $f(x)$ vanishes on the boundary of Ω and also at infinity, so Ω is empty. □

25.A.6 Dependence of Thomas-Fermi energy of the nuclear coordinates

Our main goal is to prove Theorem 25.3.8. We follow R. Benguria [1].

Regularized Thomas-Fermi theory

Let ϕ be a non-negative real-valued spherically symmetric function belonging to $\mathscr{C}_0^\infty(\mathbb{R}^+)$, monotone non-increasing function of $|x|$, supported in $B(0,1)$ and $\int \phi(x)\,dx = 1$ and let $\phi_\varepsilon = \varepsilon^{-3}\phi(\varepsilon^{-1}x)$.

For $0 < \varepsilon < a$ (recall that a is the minimal distance between nuclei), define

$$V_\varepsilon(x) = (\phi_\varepsilon * V)(x) \tag{25.A.28}$$

(i.e., V_ε is the Coulomb potential corresponding to smeared nuclei; we have imposed an upper bound on a so that the smeared nuclei do not overlap). Since $V \in \mathscr{L}^1_{\mathsf{loc}}$ $V_\varepsilon \in \mathscr{C}_0^\infty(\mathbb{R}^3)$.

Let us define a regularized Thomas-Fermi theory by the functional

$$\Phi^*_\varepsilon(\rho, \mathsf{y}_1, \dots, \mathsf{y}_M) = \int \tau(\rho)\,dx - \int V_\varepsilon(x)\rho\,dx + \frac{1}{2}\mathsf{D}(\rho,\,\rho) + U_\varepsilon, \tag{25.A.29}$$

$$U_\varepsilon = \sum_{1\le m<m'\le M} Z_m Z_{m'} \int |x - y - \mathsf{y}_m + \mathsf{y}_{m'}|^{-1}\phi_\varepsilon(x)\phi_\varepsilon(y)\,dxdy. \tag{25.A.30}$$

That is, the functional is of exactly the same form as the TF functional, the only change being in that we have smeared the singularities of V(x). We have also changed the constant term U by U_ε which represents the interaction between the smeared nuclei.

The minimization problem associated with Φ^*_s is contained in the family of variational principles studied in E. H. Lieb and B. Simon [1] and H. Brezis and E. H. Lieb [1]. We summarize below those properties of this regularized Thomas-Fermi theorem:

(i) This problem, has a unique solution for $0 < N \le Z$. For $N > Z$ there is no solution. That Z is the largest N for which there is a solution follows from H. Brezis and E. H. Lieb [1], Theorem 3(c), since

$$\int -\Delta V_\varepsilon \, dx = \int (-\Delta V_\varepsilon)_+ \, dx = \sum_{1 \le m \le M} Z_m = Z.$$

(ii) The unique minimizing ρ_ε satisfies the Euler equation

$$\tau'(\rho_\varepsilon) = (W_\varepsilon + \nu)_+ \tag{25.A.31}$$

for some $\nu \le 0$, where

$$W_\varepsilon = V_\varepsilon - |x|^{-1} * \rho_\varepsilon \tag{25.A.32}$$

(iii) $W_\varepsilon(x)$ and thus $\rho_\varepsilon(x)$ are continuous everywhere and they go to zero at infinity. This follows from (25.A.32), since $V_\varepsilon(x)$ is continuous everywhere and goes to zero at infinity and so does $|x|^{-1} * \rho_\varepsilon$ (see E. H. Lieb and B. Simon [1], Theorem II.25) because $\rho_\varepsilon \in \mathscr{L}^{\frac{5}{3}} \cap \mathscr{L}^1$ and $|x|^{-1} \in \mathscr{L}^{\frac{5}{2}} + \mathscr{L}^4$.

Let us define the total energy of the regularized Thomas-Fermi theory by

$$\widehat{\mathcal{E}}_\varepsilon(N, \mathsf{y}_1, \dots, \mathsf{y}_M) = \min\Big(\Phi_\varepsilon(\rho, \mathsf{y}_1, \dots, \mathsf{y}_M) \colon \int \rho_\varepsilon \, dx = N\Big)$$

and the corresponding electronic contribution by

$$\mathcal{E}_\varepsilon(N, \mathsf{y}_1, \dots, \mathsf{y}_M) = \widehat{\mathcal{E}}_\varepsilon(N, \mathsf{y}_1, \dots, \mathsf{y}_M) - U_\varepsilon(\mathsf{y}_1, \dots, \mathsf{y}_M).$$

We are interested in the dependence of $\widehat{\mathcal{E}}_\varepsilon$ and $\mathcal{E}_\varepsilon$ on the nuclear coordinates; in particular let us keep $\mathsf{y}_2, \dots, \mathsf{y}_M$ fixed and study the change on $\widehat{\mathcal{E}}_\varepsilon$ and $\mathcal{E}_\varepsilon$ under the shift $\mathsf{y}_1 \mapsto \mathsf{y}_1 + \alpha \mathsf{n}$ with $\alpha \ge 0$ and $\mathsf{n} \in \mathbb{R}^3$. Denote by

$$\widehat{\mathcal{E}}_\varepsilon(N, \alpha) = \widehat{\mathcal{E}}_\varepsilon(N, \mathsf{y}_1 + \alpha \mathsf{n}, \mathsf{y}_2, \dots, \mathsf{y}_M)$$

and

$$\mathcal{E}_\varepsilon(N, \alpha) = \mathcal{E}_\varepsilon(N, \mathsf{y}_1 + \alpha \mathsf{n}, \mathsf{y}_2, \dots, \mathsf{y}_M).$$

In the same way let us introduce V^α and $V^\alpha_\varepsilon = \phi_\varepsilon * V^\alpha$. We have the following

Theorem 25.A.6 [27]**.** *Let ρ_ε^α be the unique minimizing ρ for $\Phi_\varepsilon^*(\rho)$ with y_1 replaced by $\mathsf{y}_1 + \alpha\mathsf{n}$ and $\int \rho_\varepsilon^\alpha \, dx = N$. Then, the functions $\alpha \to \widehat{\mathcal{E}}_\varepsilon(N, \alpha)$ and $\alpha \to \mathcal{E}_\varepsilon(N, \alpha)$ are continuously differentiable and*

$$\frac{\partial \mathcal{E}_\varepsilon(N,\alpha)}{\partial \alpha} = -\int \frac{\partial V_\varepsilon^\alpha(x)}{\partial \alpha} \rho_\varepsilon^\alpha(x)\, dx \tag{25.A.33}$$

$$= Z_1 \int (\mathsf{n} \cdot \nabla \phi_\varepsilon(y)) \psi^\alpha(y + \mathsf{y}_1 + \alpha\mathsf{n})\, dy \tag{25.A.34}$$

and

$$\frac{\partial \widehat{\mathcal{E}}_\varepsilon(N,\alpha)}{\partial \alpha} = -\, Z_1 \int (\mathsf{n} \cdot \nabla \phi_\varepsilon(y)) \varphi^\alpha(y + \mathsf{y}_1 + \alpha\mathsf{n})\, dy \tag{25.A.35}$$

where $\psi^\alpha := |x|^{-1} * \rho^\alpha$ and $\varphi^\alpha = V_\varepsilon^\alpha - \psi^\alpha$.

Proof. Let us first prove that the mapping α to the right-hand expression of (25.A.33) is continuous. We need only prove continuity at $\varepsilon = 0$. Note that $V_\varepsilon^\alpha \to V_\varepsilon$ in $\mathscr{L}^{\frac{5}{2}} + \mathscr{L}^4$ (Lemma 25.A.12(i)), and therefore $\rho^\alpha \to \rho^0$ in $\mathscr{L}^{\frac{5}{3}}$ because of Theorem II.15 in [1]. Since $\|\rho^\alpha\|_{\mathscr{L}^1} \le N$ we also have $\rho^\alpha \to \rho^0$ in weak $\mathscr{L}^p$ for any p: $1 < p < \frac{5}{3}$. Let $Y^\alpha := \dfrac{\partial V_\varepsilon^\alpha(x)}{\partial \alpha}$, we have

$$\int Y^\alpha \rho^\alpha \, dx - \int Y^0 \rho^0 \, dx = \int (Y^\alpha - Y^0)\rho^\alpha \, dx + \int Y^0(\rho^\alpha - \rho^0)\, dx. \tag{25.A.36}$$

The first term in the right side of (25.A.36) goes to 0 as $\alpha \to 0^+$ because $Y^\alpha \to Y^0$ in $\mathscr{L}^{\frac{5}{2}} + \mathscr{L}^4$ and ρ^α is bounded in $\mathscr{L}^{\frac{5}{3}} \cap \mathscr{L}^{\frac{4}{3}}$. Also the second term in in the right side of (25.A.36) goes to 0 as $\alpha \to 0^+$ because $Y^0 \in \mathscr{L}^{\frac{5}{2}} + \mathscr{L}^4$ and $\rho^\alpha \to \rho^0$ in weak $\mathscr{L}^{\frac{4}{3}}$. Hence continuity of the right-hand expression has been established.

Now, we prove differentiability of $\widehat{\mathcal{E}}_\varepsilon(N, \alpha)$. Again we need only prove it at $\alpha > 0$. For $\alpha > 0$, $\widehat{\mathcal{E}}_\varepsilon(N, \alpha) - \widehat{\mathcal{E}}_\varepsilon(N, 0)$ does not exceed

$$\Big(\Phi_\varepsilon^*(\rho^0, \mathsf{y}_1 + \alpha\mathsf{n}, \mathsf{y}_2, \dots, \mathsf{y}_M) - U_\varepsilon(y_1 + \alpha\mathsf{n}, \mathsf{y}_2, \dots, \mathsf{y}_M\Big) - \Big(\Phi_\varepsilon^*(\rho^0, \mathsf{y}_1, \mathsf{y}_2, \dots, \mathsf{y}_M) - U_\varepsilon(y_1 \mathsf{y}_2, \dots, \mathsf{y}_M\Big)$$

[27] A Feynman-Heltman theorem for regularized Thomas-Fermi.

by the minimization property of ρ^α, and it is equal to

$$-\int \Big(V_\varepsilon^\alpha - V_\varepsilon\Big)\rho^\alpha \, dx. \tag{25.A.37}$$

Also, by the minimization property of ρ^0, $\widehat{\mathcal{E}}_\varepsilon(N,\alpha) - \widehat{\mathcal{E}}_\varepsilon(N,0)$ is larger than or equal to

$$-\int \Big(V_\varepsilon^\alpha - V_\varepsilon\Big)\rho^0 \, dx. \tag{25.A.38}$$

Now, $\alpha^{-1}\big(V_\varepsilon^\alpha - V_\varepsilon\big) \to \frac{V_\varepsilon^\alpha}{\partial\alpha}\big|_{\alpha=0}$ in $\mathscr{L}^{\frac{5}{2}} + \mathscr{L}^4$ (see Lemma 25.A.12(ii)) and $\rho^0 \in \mathscr{L}^{\frac{5}{3}} \cap \mathscr{L}^1$. Hence by Hölder inequality, expression (25.A.37) divided by α converges to $-\int \frac{V_\varepsilon^\alpha}{\partial\alpha}\big|_{\alpha=0}\rho^0 \, dx$. Similarly, one can prove that expression (25.A.38) divided by α converges to the same limit as $\alpha \to 0^+$ and, therefore,

$$\lim_{\alpha\to 0^+}\Big(\widehat{\mathcal{E}}_\varepsilon(N,\alpha) - \widehat{\mathcal{E}}_\varepsilon(N,0)\Big) = -\int \frac{V_\varepsilon^\alpha}{\partial\alpha}\big|_{\alpha=0}\rho^0 \, dx. \tag{25.A.39}$$

A similar argument controls the same limit as $\alpha \to 0^-$. Thus $\widehat{\mathcal{E}}_\varepsilon(N,\alpha)$ is continuously differentiable in α and its derivative is given by (25.A.33).

In order to prove (25.A.34), we just compute

$$\frac{\partial V_\varepsilon^\alpha}{\partial\alpha}(x) = Z_1 \int \phi_\varepsilon(y)\mathsf{n}\cdot\nabla_y|x-y-\mathsf{y}_1-\alpha\mathsf{n}|^{-1}\, dy$$

and after introducing this expression in (25.A.33), we integrate by parts.

Finally, since $U_\varepsilon(\mathsf{y}_1+\alpha\mathsf{n},\mathsf{y}_2,\dots,\mathsf{y}_M)$ is continuously differentiable with respect to α (see Lemma 25.A.12(iii)), $\alpha \to \mathcal{E}_\varepsilon(N,\alpha)$ is continuously differentiable.

Moreover,

$$\begin{aligned}\frac{\partial U_\varepsilon(\mathsf{y}_1+\alpha\mathsf{n},\mathsf{y}_2,\dots\mathsf{y}_M)}{\partial\alpha} \\ = -Z_1\int (\mathsf{n}\cdot\nabla\phi_\varepsilon(y))\, V_\varepsilon^\alpha(y+\mathsf{y}_1+\alpha\mathsf{n})\, dy\end{aligned} \tag{25.A.40}$$

and adding the right sides of (25.A.34) and (25.A.40) we get the right side of (25.A.35). □

Proof of Theorem 25.3.8

We will need some geometric preliminaries. For n, a unit vector in $\mathbb{R}^3$ and $d \geq 0$, let

$$L(\mathsf{n}, d) = \{x \in \mathbb{R}^3 \colon x \cdot \mathsf{n} = d\} \quad \text{and} \quad L^{\pm}(\mathsf{n}, d) = \{x \in \mathbb{R}^3 \colon x \cdot \mathsf{n} \lessgtr d\}.$$

For any function $f \colon \mathbb{R}^3 \to \mathbb{R}$ we define

$$f^+(x) = f(x), \quad \text{and} \quad f^-(x) = f(x + 2(d - x \cdot \mathsf{n})\mathsf{n}),$$

for every $x \in L^+(\mathsf{n}, d) \cup L(\mathsf{n}, d)$, i.e., $f^-(x)$ is just the reflection of f through the plane $L(\mathsf{n}, d)$.

In order to prove Theorem 25.3.8 we will need the following:

Lemma 25.A.7 [28]**.** *Let* n *and* d *be such that* $\mathsf{y}_m \in L^+(\mathsf{n}, d) \cup L(\mathsf{n}, d)$ *for all* $1 \leq m \leq M$ *and choose*

$$\varepsilon < \min_{1 \leq m \leq M} \big(\mathsf{dist}(\mathsf{y}_m,\, L(\mathsf{n}, d)) \colon \mathsf{y}_m \notin L(\mathsf{n}, d)\big)$$

this condition on a *insures that the smeared nuclei with* $\mathsf{y}_m \notin L(\mathsf{n}, d)$ *are supported on* $L^+(\mathsf{n}, d)$*).*

Let $\rho_\varepsilon(x)$ *be the unique solution to the regularized TF equation* (25.A.31) *and* W_ε *the corresponding potential* (25.A.32)*. Then*

(i) $h_\varepsilon(x) \coloneqq W_\varepsilon^+(x) - W_\varepsilon^-(x) > 0$ *for all* $x \in L^+(\mathsf{n}, d)$*.*

(ii) For each $x \in L^+(\mathsf{n}, d)$*,* $h_\varepsilon(x)$ *strictly decreases when* N *increases, and*

(iii) $\rho_\varepsilon^+(x) - \rho_\varepsilon^-(x) \geq 0$ *for all* $x \in L^+(\mathsf{n}, d)$*.*

Proof. (i) Certainly $h_\varepsilon(x) = 0$ for $x \in \partial L^+(\mathsf{n}, d) = L(\mathsf{n}, d)$ and at infinity. Let $D = \{x \in L^+(\mathsf{n}, d) \colon h_\varepsilon(x) < 0\}$. Since $W_\varepsilon(x)$ is continuous everywhere, D is open. On D, $-(4\pi)^{-1}\Delta h_\varepsilon \geq \rho_\varepsilon^-(x) - \rho_\varepsilon^+(x) > 0$ since, through (25.A.31), $\varphi_\varepsilon^-(x) > \varphi_\varepsilon^+(x)$ implies $\rho_\varepsilon^-(x) - \rho_\varepsilon^+(x) > 0$. Thus, $h_\varepsilon(x)$ is superharmonic on D, so D is empty.

By the strong maximum principle, $h_\varepsilon(x) > 0$, in fact, for $x \in L^+(\mathsf{n}, d)$.

[28] Lemma 3 of R. Benguria [1].

(ii) Let $N' < N$ with corresponding $h'_\varepsilon(x)$ and $h_\varepsilon(x)$. We want to prove that $B := \{x \in L^+(\mathsf{n}, d)\colon h_\varepsilon(x) - h'_\varepsilon(x) > 0\}$ is empty. Since the h_ε and h'_ε are continuous, B is open and $h_\varepsilon - h'_\varepsilon = 0$ on $L(\mathsf{n}, d)$ and at infinity. We have

$$-(4\pi)^{-1}\Delta(h_\varepsilon - h'_\varepsilon) = -b_+^{\frac{3}{2}} + c_+^{\frac{3}{2}} + p_+^{\frac{3}{2}} - q_+^{\frac{3}{2}} =: r$$

with

$$b = W_\varepsilon^+ - \mu, \quad b = W_\varepsilon^- - \nu, \quad p = W'^{+_\varepsilon} - \nu', \quad q = W_\varepsilon'^{-s} - \nu'.$$

By (i) (E. H. Lieb and B. Simon [1], Theorem V.9), $b > c \geq q$ and $b \geq p > q$, for all $x \in L^+(\mathsf{n}, d)$. On B, $b + q > c + p$. Thus $r < 0$ on B, whence $h_\varepsilon(x) - h'_\varepsilon(x)$ is subharmonic on B and therefore B is empty. Again, once can prove the stronger result that $h_\varepsilon(x) - h'_\varepsilon(x) < 0$ for $x \in L^+(\mathsf{n}, d)$. T

(iii) Trivially, (i) implies (iii) through the Tomas-Fermi equation (25.A.31). □

Remark 25.A.8. The proof of Lemma 25.A.7(i) is analogous to the proof of Teller's lemma (E. H. Lieb and B. Simon [1], Theorem V.8).

By the same argument one can prove the following lemma:

Lemma 25.A.9 [29]**.** *Let* n *and* d *be such that* $\mathsf{y}_m \in L^+(\mathsf{n}, d)$ *for all* $m = 1, \dots, M$*, let* $\rho(x)$ *be Thomas-Fermi density and* V *be the Coulomb potential. Then*

$$\rho^+(x) > \rho^-(x) \qquad \forall x \in L^+(\mathsf{n}, d)$$

and

$$V^+(x) > V^-(x) \qquad \forall x \in L^+(\mathsf{n}, d).$$

We will now prove the analog of Theorem 25.3.8 for the regularized Thomas-Fermi model:

Theorem 25.A.10 [30]**.** *Fix* Z_m*,* $m = 1, \dots, M$ *and* $N \leq Z$*. Fix*m *and assume that* y_m *is such that*

$$\mathsf{y}_{m'} \in L^+(\mathsf{n}, \mathsf{n} \cdot \mathsf{y}_m) \cup L(\mathsf{n}, \mathsf{n} \cdot \mathsf{y}_m) \qquad \forall m' \neq m \tag{25.A.41}$$

[29] Lemmas 4, 5 of R. Benguria [1].
[30] Theorem 6 of R. Benguria [1].

for some fixed unit vector $\mathsf{n} \in \mathbb{R}^3$. *Let*

$$\mathcal{E}_\varepsilon(N, \alpha) \coloneqq \mathcal{E}_\varepsilon(N, \mathsf{y}_1, \dots, \mathsf{y}_{m-1}\mathsf{y}_m + \alpha\mathsf{n}, \mathsf{y}_{m+1}, \dots, \mathsf{y}_M)$$

and

$$\widehat{\mathcal{E}}_\varepsilon(N, \alpha) \coloneqq \widehat{\mathcal{E}}_\varepsilon(N, \mathsf{y}_1, \dots, \mathsf{y}_{m-1}\mathsf{y}_m + \alpha\mathsf{n}, \mathsf{y}_{m+1}, \dots, \mathsf{y}_M).$$

Then

(i) $\widehat{\mathcal{E}}_\varepsilon(N, \alpha)$, *is a monotonic non-increasing function of* $\alpha \geq 0$;

(ii) $\mathcal{E}_\varepsilon(N, \alpha)$ *is a monotonic non-decreasing function of* $\alpha \geq 0$;

(iii) For fixed $\alpha > 0$, $\widehat{\mathcal{E}}_\varepsilon(N, \alpha) - \widehat{\mathcal{E}}_\varepsilon(N, 0)$ *is non-decreasing in* N,

(iv) For fixed $\alpha > 0$ $\mathcal{E}_\varepsilon(N, \alpha) - \mathcal{E}_\varepsilon(N, 0)$ *is non-decreasing in* N.

Proof. (i) By the Feynman-Hellman Theorem 25.A.6 [see (25.A.35)],

$$\frac{\partial \widehat{\mathcal{E}}_\varepsilon(N, \alpha)}{\partial \alpha} = -Z_1 \int (\mathsf{n} \cdot \nabla \phi_\varepsilon(y)) \varphi^\alpha(y + \mathsf{y}_1 + \alpha\mathsf{n})\, dy. \tag{25.A.42}$$

We can write the right side of (25.A.42) with $\alpha = 0$ as

$$-Z_m \int_{y \in L^+(\mathsf{n}, \mathsf{n}\cdot\mathsf{y}_m)} \big(\mathsf{n} \cdot \nabla \phi_\varepsilon(y - \mathsf{y}_m)\big) \varphi_\varepsilon(y)\, dy \tag{25.A.43}$$

because $\mathsf{n} \cdot \nabla \phi_\varepsilon(y - \mathsf{y}_m)$ only changes sign under a reflection (of y) through $L(\mathsf{n}, \mathsf{n} \cdot \mathsf{y}_m)$. Here $\varphi_\varepsilon^\pm$ are defined as in (25.A.41) with respect to the plane $L(\mathsf{n}, \mathsf{n} \cdot \mathsf{y}_m)$.

Note that $\mathsf{n} \cdot \nabla \phi_\varepsilon(y - \mathsf{y}_m) \geq 0$ for all $y \in L^+(\mathsf{n}, \mathsf{n} \cdot \mathsf{y}_m) \cup L(\mathsf{n}, \mathsf{n} \cdot \mathsf{y}_m)$ because $\phi(y)$ is spherically symmetric and decreasing by $|y|$ and $\varphi_\varepsilon^+(y) \geq \varphi_\varepsilon^-(y)$ for all $y \in L^+(\mathsf{n}, \mathsf{n} \cdot \mathsf{y}_m) \cup L(\mathsf{n}, \mathsf{n} \cdot \mathsf{y}_m)$ (Lemma 25.A.7(i)), expression (25.A.43) is non-positive and Statement (i) follows.

(ii) By integration by parts one can write (25.A.33) as

$$\frac{\partial \mathcal{E}_\varepsilon(N, \alpha)}{\partial \alpha} = Z_j \int p_j(x) \rho_\varepsilon(x)\, dx$$

with

$$p_m(x) = \mathsf{n} \cdot \nabla_v x \int \phi_\varepsilon(x - y) |y - \mathsf{y}_m|^{-1}\, dy.$$

As before, we have as $\alpha = 0$

$$\frac{\partial \mathcal{E}_\varepsilon(N,\alpha)}{\partial \alpha} = Z_m \int_{x \in L^+(\mathsf{n},\mathsf{n}\cdot \mathsf{y}_m)} p_j(x)\big(\rho_\varepsilon^+(x) - \rho_\varepsilon^-(y)\big)\, dx \tag{25.A.44}$$

because $p_m(x)$ only changes sign under a reflection (of x) through $L(\mathsf{n}, \mathsf{n}\cdot \mathsf{y}_m)$. Moreover, $p_m(x) \geq 0$ for all $x \in L^+(\mathsf{n}, \mathsf{n}\cdot \mathsf{y}_m) \cup L(\mathsf{n}, \mathsf{n}\cdot \mathsf{y}_m)$ again because $\phi_\varepsilon * |x - \mathsf{y}_m|^{-1}$ is spherically symmetric and decreasing by $|x|$). Hence, Statement (ii) follows from (25.A.44) and Lemma 25.A.7(iii).

(iii) Write $\widehat{\mathcal{E}}_\varepsilon(N,\alpha) - \widehat{\mathcal{E}}_\varepsilon(N,0) = \int_0^\alpha \frac{\partial \widehat{\mathcal{E}}_\varepsilon(N,\alpha)}{\partial \alpha}\, d\alpha$. Now, for every fixed α integrand is an increasing function of N because of (25.A.43) and Lemma 25.A.7(ii). This proves Statement (iii). Obviously Statements (iii) and (iv) are equivalent. □

After all these preliminaries we can go to the

Proof of Theorem 25.3.8. Due to Lemma 25.A.12(iv), $V_\varepsilon \to V$ as $s \to 0^+$ in $\mathscr{L}^{\frac{5}{2}} + \mathscr{L}^4$.

Therefore, Theorem II.15 in E. H. Lieb and B. Simon [1] implies that, for fixed N, $\mathcal{E}_\varepsilon(N, \mathsf{y}_1, \dots, \mathsf{y}_M) \to \mathcal{E}_\varepsilon(N, \mathsf{y}_1, \dots, \mathsf{y}_M)$ as $\varepsilon \to 0^+$. Hence Statements (ii) and (iv) of Theorem 25.3.8 follow from Statements (ii) and (iv) of Theorem 25.A.10.

Now, by Lemma 25.A.12(v) $U_\varepsilon \to U$ as $\varepsilon \to 0^+$, hence for fixed N, $\widehat{\mathcal{E}}_\varepsilon(N, \mathsf{y}_1, \dots, \mathsf{y}_M) \to \widehat{\mathcal{E}}_\varepsilon(N, \mathsf{y}_1, \dots, \mathsf{y}_M)$ as $\varepsilon \to 0^+$. Hence Statements (i) and (iii) of Theorem 25.3.8 follow from Statements (i) and (iii) of Theorem 25.A.10. □

Electronic contribution to the Born-Oppenheimer energy

The electronic contribution to the Born-Oppenheimer energy for a system of $N = 1$ electron and M (fixed) nuclei located at $\mathsf{y}_m \in \mathbb{R}^3$, with positive charge Z_m is defined by E. H. Lieb and B. Simon [2]

$$\mathsf{E}(\mathsf{y}_1, \dots, \mathsf{y}_M) \coloneqq \inf \mathsf{Spec}(H) \tag{25.A.45}$$

with

$$H = -\Delta - V(x), \tag{25.A.46}$$

The behavior of $\mathsf{E}(\mathsf{y}_1, \dots, \mathsf{y}_M)$ as a function of the nuclear coordinates has been studied in E. H. Lieb and B. Simon [2] and T. Hoffman-Ostenhof [1]. In

particular, it has been shown that $\mathsf{E}(\mathsf{y}_1, \dots, \mathsf{y}_M)$ is monotonic non-decreasing under the dilation $\mathsf{y}_m \mapsto t\mathsf{y}_m$ $(t > 1)$, for all m. Here we add the following result

Theorem 25.A.11 [31]**.** *Fix Z_m, $m = 1, \dots, M$. Fix m and assume that y_m is such that*

$$(\mathsf{y}_m - \mathsf{y}_{m'}) \cdot \mathsf{n} \geq 0 \qquad \forall m' \neq m \tag{25.A.47}$$

for some fixed unit vector $\mathsf{n} \in \mathbb{R}^3$. Then $\mathsf{E}(\mathsf{y}_1, \dots, \mathsf{y}_{m-1}, \mathsf{y}_m + \alpha\mathsf{n}, \mathsf{y}_{m+1}, \dots \mathsf{y}_M)$ is a monotonic non-decreasing function of $\alpha \geq 0$.

Auxiliary statements

Let $f \in \mathscr{L}^{\frac{5}{2}} + \mathscr{L}^4)$ and define $f_\varepsilon = \phi_\varepsilon * f$, with ϕ_ε defined above.

Lemma 25.A.12 [32]**.** *(i) Let $f_\varepsilon^\alpha := f_\varepsilon(x - \alpha\mathsf{y})$, $\alpha > 0$, $\mathsf{y} \in \mathbb{R}^3$. Then $f_\varepsilon^\alpha \to f_\varepsilon$ in $(\mathscr{L}^{\frac{5}{2}} + \mathscr{L}^4)$ as $\alpha \to 0^+$.*

(ii) $\alpha^{-1}(f_\varepsilon^\alpha - f_\varepsilon) \to \frac{\partial f_\varepsilon^\alpha}{\partial \alpha}\big|_{\alpha=0}$.

(iii) $U_\varepsilon^\alpha := U_\varepsilon(\mathsf{y}_1, \dots, \mathsf{y}_{m-1}, \mathsf{y}_m + \alpha\mathsf{n}, \mathsf{y}_{m+1}, \dots \mathsf{y}_M)$ is continuousy differentiable by α and

$$\frac{\partial U_\varepsilon^\alpha}{\partial \alpha} = -Z_m \int (\mathsf{n} \cdot \phi_\varepsilon(y)) V_\varepsilon^\alpha(y + \mathsf{y}_m + \alpha\mathsf{n})\, dy. \tag{25.A.48}$$

(iv) $f_\varepsilon \to f$ in $(\mathscr{L}^{\frac{5}{2}} + \mathscr{L}^4)$ as $\varepsilon \to 0^+$.

(v) $U_\varepsilon \to U$ as $\varepsilon \to 0^+$.

Comments

There are papers of physicists. L.H. Thomas and E. Fermi have suggested in 1927 that a large Coulomb system (atom or molecule) in the ground state looks like a classical gas but with the Pauli principle, so, leading to the first term $\mathcal{E}^{\mathsf{TF}}$ in the asymptotics. The second term of asymptotics was conjectured by J. M.C. Scott in 1952 as a contribution of those electrons which move very close to the nuclei. Next terms, Dirac and Schwinger corrections were conjectured in 1930 and 1980, respectively.

[31] Theorem 7 of R. Benguria [1].

[32] Lemmas A.1–A.5 of R. Benguria [1].

The mathematical rigorous papers one can separated into several groups:

First, there are papers concerning only the Thomas–Fermi model (so, studying the Thomas-Fermi equation, may be, with some modifications, without any consideration of the quantum mechanical model, even if the latter was a source for the former). Most notably H. Brezis, H. and E. Lieb E. [1], R. Benguria [1], R. Benguria, R. and Lieb E. H. [1].

The second group consists of the papers, justifying Thomas–Fermi model as an approximation to the quantum mechanical model: E. H. Lieb and B. Simon, [1], where the leading term was derived; also certain properties of the the Thomas–Fermi model were established.

Next, W. Hughes [1] and H. Siedentop and R. Weikart [1–3] justified the Scott correction term in the atomic case, while V. Ivrii and M. Sigal [1] justified it in the molecular case.

Then, C. Fefferman and L. Seco [2] justified Dirac and Schwinger correction terms in the atomic case, while V. Ivrii justified them in [21] (even in the case of the relatively weak magnetic field). J. P. Solovej, J. P., T. Ø. Sørensen and W. L. Spitzer [1] recovered Scott correction term in the relativistic case (under assumption preventing relativistic instability).

The third group consists of the papers, related to the ground state energy problem: B. Ruskai and J. P. Solovej [1], J. P. Solovej [1] and L. A. Seco, I. M. Sigal, and J. P. Solovej [1].

Finally, we already mentioned papers which provided the solid functional-analytical base for all this construction. Pretty complete survey could be found in C. L. Fefferman, V. Ivrii, L. A. Seco, and I. M. Sigal [1].

Addendum

Further development (with references) could be found in several articles (in the same volume of our online monograph)

1. *Upper estimates for the electronic density in heavy atoms and molecules*,
2. *Scott and Thomas-Fermi approximations to electronic density* (survey),
3. *Asymptotics of the ground state energy in the relativistic settings*,
4. *Asymptotics of the ground state energy in the relativistic settings and with self-generated magnetic field*

and references there.

Important Remarks

Sections 25.5 and 25.6 were rewritten. The reason is that the printed version of this monograph contains crucial errors in the proofs of Theorem 25.5.2 (see Theorem 25.5.3 here) and Theorem 25.6.3.

1. The first error in the proof of Theorem 25.5.2 occurred only in the case $M \geq 2$. It has been corrected.

2. The second one has not been corrected and we cannot prove the estimate of the excessive negative charge better than $O(Z^{\frac{5}{7}})$ even for the case $M = 1$. The reason is that we need to use $Q \geq Z^{\frac{5}{3}}$ in Proposition 25.5.1.

3. The error in the proof of Theorem 25.6.3 has been fixed but this Theorem became much weaker, with the estimate $O(Z^{\frac{11}{13}})$ instead of $O(Z^{\frac{5}{7}-\delta})$.

All these errors propagated to Sections 26.7 and 26.8 will be corrected as well. Some other improvement were done: added proof of Theorem 25.3.8 in Appendix 25.A.6.

Chapter 26

The Case of External Magnetic Field

26.1 Introduction

In this Chapter we repeat analysis of the previous Chapter 25 but in the case of the constant external magnetic field[1)].

26.1.1 Framework

Let us consider the following operator (quantum Hamiltonian)

$$\mathsf{H} = \mathsf{H}_N \coloneqq \sum_{1\le j\le N} H_{A,V,x_j} + \sum_{1\le j<k\le N} |x_j - x_k|^{-1} \tag{26.1.1}$$

on

$$\mathfrak{H} = \bigwedge_{1\le n\le N} \mathsf{H}, \qquad \mathsf{H} = \mathscr{L}^2(\mathbb{R}^d, \mathbb{C}^q) \tag{26.1.2}$$

with

$$H_{V,A} = \big((i\nabla - A)\cdot\boldsymbol{\sigma}\big)^2 - V(x) \tag{26.1.3}$$

describing N same type particles in the external field with the scalar potential $-V$ and vector potential $A(x)$, and repulsing one another according to the Coulomb law.

[1)] Actually we need a magnetic field either sufficiently weak or close to a constant on the very small scale.

Here $x_j \in \mathbb{R}^d$ and $(x_1, \dots, x_N) \in \mathbb{R}^{dN}$, potentials $V(x)$ and $A(x)$ are assumed to be real-valued. Except when specifically mentioned we assume that

$$V(x) = \sum_{1\le k\le M} \frac{Z_m}{|x - \mathsf{y}_m|} \tag{26.1.4}$$

where $Z_m > 0$ and y_m are charges and locations of nuclei. Here $\boldsymbol{\sigma} = (\sigma_1, \sigma_2, \dots, \sigma_d)$, σ_k are $q \times q$-Pauli matrices.

So far in comparison with the previous Chapter 25 we only changed (25.1.3) to (26.1.3) introducing magnetic field. Now spin enters not only in the definition of the space but also into operator through matrices σ_k. Since we need $d = 3$ Pauli matrices it is sufficient to consider $q = 2$ but we will consider more general case as well (but q should be even).

Remark 26.1.1. In the case of the the constant magnetic field $\nabla \times A$

$$H_{A,V} = \bigl(-i\nabla - A(x)\bigr)^2 + \boldsymbol{\sigma}\cdot(\nabla \times A) - V(x) \tag{26.1.5}$$

In the case $d = 2$ this operator downgrades to

$$H_{A,V} = \bigl(-i\nabla - A(x)\bigr)^2 + \sigma_3(\nabla \times A) - V(x) \tag{26.1.6}$$

Again, let us assume that

(26.1.7) Operator H is self-adjoint on $\mathfrak{H}$.

As usual we will never discuss this assumption.

26.1.2 Problems to Consider

As in the previous Chapter we are interested in the *ground state energy* $\mathsf{E} = \mathsf{E}_N$ of our system i.e. in the lowest eigenvalue of the operator $\mathsf{H} = \mathsf{H}_N$ on $\mathfrak{H}$:

$$\mathsf{E} := \inf \operatorname{Spec} \mathsf{H} \qquad \text{on } \mathfrak{H}; \tag{26.1.8}$$

more precisely, we are interested in the asymptotics of $\mathsf{E}_N = \mathsf{E}(\underline{\mathsf{y}}; \underline{Z}; N)$ as V is defined by (26.1.4) and $N \asymp Z := Z_1 + Z_2 + \dots + Z_M \to \infty$ and we are going

to prove that[2] E is equal to *Magnetic Thomas-Fermi energy* $\mathcal{E}_B^{\mathsf{TF}}$, possibly with the Scott , Dirac and Schwinger correction terms given by (25.1.28), (25.1.29) and (25.1.30) with $q = 2$ respectively and with an appropriate error.

We are also interested in the asymptotics for the *ionization energy*

$$\mathsf{I}_N := \mathsf{E}_{N-1} - \mathsf{E}_N \tag{26.1.9}$$

and we also would like to estimate *maximal excessive negative charge*

$$\max_{N:\, \mathsf{I}_N>0} (N - Z). \tag{26.1.10}$$

All these questions so far were considered in the framework of the fixed positions $\mathsf{y}_1, \dots, \mathsf{y}_M$ but we can also consider

$$\widehat{\mathsf{E}} := \widehat{\mathsf{E}}_N = \widehat{\mathsf{E}}(\underline{\mathsf{y}}; \underline{Z}; N) = \mathsf{E} + U(\underline{\mathsf{y}}; \underline{Z}) \tag{26.1.11}$$

with

$$U(\underline{\mathsf{y}}; \underline{Z}) := \sum_{1\le m<m'\le M} \frac{Z_m Z_{m'}}{|\mathsf{y}_m - \mathsf{y}_{m'}|} \tag{26.1.12}$$

and

$$\widehat{\mathsf{E}}(\underline{Z}; N) = \inf_{\mathsf{y}_1,\dots,\mathsf{y}_M} \widehat{\mathsf{E}}(\underline{\mathsf{y}}; \underline{Z}; N) \tag{26.1.13}$$

and replace I_N by $\widehat{I}_N = \widehat{\mathsf{E}}_{N-1} - \widehat{\mathsf{E}}_N$ and modify all our questions accordingly. We call these frameworks *fixed nuclei model* and *free nuclei model* respectively.

In the free nuclei model we can consider two other problems:

(a) Estimate from below *minimal distance between nuclei* i.e.

$$\min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}|$$

for which such minimum is achieved.

(b) Estimate *maximal excessive positive charge*

$$\max_N \bigl\{(Z - N)\colon \widehat{\mathsf{E}} < \min_{\substack{N_1,\dots,N_M:\\ N_1+\dots N_M=N}} \sum_{1\le m\le M} \mathsf{E}(Z_m; N_m)\bigr\} \tag{26.1.14}$$

for which molecule does not disintegrates into atoms.

[2] Under reasonable assumption to the minimal distance between nuclei.

26.1.3 Magnetic Thomas-Fermi Theory

As in the previous Chapter 25 the first approximation is the Hartree-Fock (or Thomas-Fermi) theory. Let us introduce the *spacial density* of the particle with the state $\Psi \in \mathfrak{H}$:

$$\rho(x) = \rho_\Psi(x) = N \int |\Psi(x, x_2, \dots, x_N)|^2 \, dx_2 \cdots dx_N. \tag{26.1.15}$$

Let us write the Hamiltonian, describing the corresponding "quantum liquid":

$$\mathcal{E}_B(\rho) = \int \tau_B(\rho(x)) \, dx - \int V(x)\rho(x) \, dx + \frac{1}{2}\mathsf{D}(\rho, \rho), \tag{26.1.16}$$

with

$$\mathsf{D}(\rho, \rho) = \iint |x - y|^{-1} \rho(x)\rho(y) \, dxdy \tag{26.1.17}$$

where τ_B is the energy density of a gas of noninteracting electrons:

$$\tau_B(\rho) = \sup_{w \geq 0} \bigl(\rho w - P_B(w)\bigr) \tag{26.1.18}$$

is the Legendre transform of the *pressure* $P_B(w)$ given by the formula

$$P_B(w) = \varkappa_1 B \Bigl(\frac{1}{2} w_+^{\frac{d}{2}} + \sum_{j \geq 1} (w - 2jB)_+^{\frac{d}{2}}\Bigr) \tag{26.1.19}$$

with $\varkappa_1 = (2\pi)^{-1} q, (3\pi^2)^{-1} q$ for $d = 2, 3$ respectively.

The classical sense of the second and the third terms in the right-hand expression of (26.1.16) is clear and the density of the kinetic energy is given by $\tau_B(\rho)$ in the semiclassical approximation (see remark 26.1.2). So, the problem is

(26.1.20) Minimize functional $\mathcal{E}_B(\rho)$ defined by (26.1.16) under restrictions:

$$\rho \geq 0, \qquad \int \rho \, dx \leq N. \tag{26.1.21}_{1,2}$$

The solution if exists is unique because functional $\mathcal{E}_B(\rho)$ is strictly convex (see below). The existence and the property of this solution denoted further by ρ_B^{TF} is known in the series of physically important cases.

Remark 26.1.2. If w is the negative potential then

$$\operatorname{tr} e(x,x,0) \approx P'_B(w) \tag{26.1.22}$$

defines the density of all non-interacting particles with negative energies at point x and

$$\int_{-\infty}^{0} \tau\, d_\tau \operatorname{tr} e(x,x,\tau) dx \approx -\int P_B(w)\, dx \tag{26.1.23}$$

is the total energy of these particles; here $\approx$ means "in the semiclassical approximation".

We consider in the case of $d = 3$ a large (heavy) molecule with potential (25.1.4). It is well-known[3] that

Proposition 26.1.3. *(i) For $V(x)$ given by* (26.1.4) *minimization problem* (26.1.20) *has a unique solution $\rho = \rho_B^{\mathsf{TF}}$; then denote $\mathcal{E}_B^{\mathsf{TF}} := \mathcal{E}_B(\rho_B^{\mathsf{TF}})$.*

(ii) Equality in $(26.1.21)_2$ *holds if and only if $N \le Z := \sum_m Z_m$.*

(iii) Further, ρ^{TF} does not depend on N as $N \ge Z$.

(iv) Thus

$$\int \rho_B^{\mathsf{TF}}\, dx = \min(N,Z), \qquad Z := \sum_{1\le m\le M} Z_m. \tag{26.1.24}$$

26.1.4 Main Results Sketched and Plan of the Chapter

In the first half of this Chapter we derive asymptotics for ground state energy and justify Thomas-Fermi theory. As construction of Section 25.2 works with minimal modifications (see Section 26.6) in the magnetic case as well we start immediately from magnetic Thomas-Fermi theory in Section 26.2.

We discover that there are three different cases: *a moderate magnetic field case* $B \ll Z^{\frac{4}{3}}$ when $\mathcal{E}_B^{\mathsf{TF}} \asymp Z^{\frac{5}{3}}$ and $\mathcal{E}_B^{\mathsf{TF}} = \mathcal{E}_0^{\mathsf{TF}}(1+o(1))$, *a strong magnetic field case* $B \gg Z^{\frac{4}{3}}$ when $\mathcal{E}_B^{\mathsf{TF}} \asymp B^{\frac{2}{5}} Z^{\frac{9}{5}}$ and $\mathcal{E}_B^{\mathsf{TF}} = \bar{\mathcal{E}}_B^{\mathsf{TF}}(1+o(1))$ where $\bar{\mathcal{E}}_B^{\mathsf{TF}}$

[3] Section IV of E. H. Lieb, J. P. Solovej and J. Yngvason [3].

is Thomas-Fermi potential derived as $P_B(w) = \frac{1}{2}\varkappa_1 w^{\frac{d}{2}}$ (cf. (26.1.19)), and *an intermediate case* $B \sim Z^{\frac{4}{3}}$.

Then we apply semiclassical methods (like in Section 25.4) albeit now our analysis is way more complicated due to two factors: the semiclassical theory of the magnetic Schrödinger operator is more difficult than the corresponding theory for the non-magnetic Schrödinger operator and also Thomas-Fermi potential W^{TF} is not very smooth in the magnetic case, so we need to approximate it by a smooth one (on a microscale).

We discover that both semiclassical methods and Thomas-fermi theory are relevant only if $B \ll Z^3$. The case of the superstrong magnetic field $B \gg Z^3$ was considered in E. H. Lieb, J. P. Solovej and J. Yngvason [1].

First of all, in Section 26.3 we consider the case $M = 1$; then the Thomas-Fermi potential W_B^{TF} is non-degenerate and in this case we derive sharp spectral asymptotics.

Next, in Section 26.4 we consider the case $M \geq 2$ but we analyze only zone $\{W_B^{\mathsf{TF}} + \nu \gtrsim B\}$ where ν is a chemical potential and B is an intensity of the magnetic field. A certain weaker non-degeneracy condition is satisfied due to the Thomas-Fermi equation and we derive almost sharp spectral asymptotics.

Furthermore, in Section 26.5 we analyze in the case $M \geq 2$ the *boundary strip* $\{W^{\mathsf{TF}} + \nu \lesssim B\}$ containing the boundary of $\mathsf{supp}(\rho_B^{\mathsf{TF}})$; this is the most difficult case to analyze and our remainder estimates are not sharp unless $N \geq Z - CZ^{\frac{2}{3}}$.

Finally, in Section 26.6 we derive asymptotics of the ground state energy. Their precision (or lack of it) follows from the precision of the corresponding semiclassical results; so our results in the case $M = 1$ are sharp, but our results in the case $M \geq 2$ (especially if $N \leq Z - CZ^{\frac{2}{3}}$) are not.

In the second half of this Chapter we consider related problems. In Section 26.7 (cf. Section 25.5) we consider negatively charged systems ($N \geq Z$) and estimate both ionization energy I_N and excessive negative charge $(N - Z)_+$ [4)].

In Section 26.8 (cf. Section 25.6) we consider positively charged systems ($N \leq Z$) and estimate the remainder $|\mathsf{I}_N + \nu|$ in the formula $\mathsf{I}_N \approx -\nu$; for $M \geq 2$ we also consider a free nuclei model and estimate from below the distance between nuclei and an excessive positive charge $(Z - N)_+$ when atoms can be bound into molecule[4)].

[4)] In the (magnetic) Thomas-Fermi theory both answers are 0.

Appendices contain some auxiliary material, most notably, electrostatic inequalities in Appendix 26.A.1 and also Zhislin's theorem (that system can bind at least Z electrons) in Appendix 26.A.4–all in the case of magnetic field.

26.2 Magnetic Thomas-Fermi Theory

26.2.1 Framework and Existence

The Thomas-Fermi theory is well developed in the magnetic case as well albeit in the lesser degree than in the non-magnetic one. The most important source now is Section IV of E. H. Lieb, J. P. Solovej and J. Yngvason [3].

Again as in the previous Chapter 25 to get the best lower estimate for the ground state energy (neglecting semiclassical errors) one needs to maximize functional $\Phi_{B,*}(W+\nu)$ defined by (25.3.1) albeit with the pressure $P_B(w)$ given for $d=2,3$ by (26.1.19). Formulae (25.3.2) and (25.3.3) also remain valid.

Further, to get the best upper estimate (neglecting semiclassical errors) one needs to minimize functional $\Phi^*_B(\rho',\nu)$ defined by (25.3.4) where (25.3.4) remains valid with P replaced by P_B and respectively $\tau(\rho')$ replaced by $\tau_B(\rho')$ which is Legendre transformation of P_B (see (26.1.18)).

Since P_B is given by much more complicated expression (26.1.19) rather than $(25.3.6)_1$, and respectively

$$P'_B(w) = \frac{d}{2}\varkappa_1 B\Big(\frac{1}{2}w_+^{\frac{d}{2}-1} + \sum_{j\ge 1}(w-2jB)_+^{\frac{d}{2}-1}\Big) \tag{26.2.1}$$

(cf. $(25.3.6)_2$), there is no explicit expression for τ_B similar to (25.3.7).

Remark 26.2.1. (i) $B(x) = |\nabla \times A(x)|$.

(ii) From now on we will assume that $d=3$.

(iii) P_B is a strictly convex function and therefore τ_B is also a strictly convex function[5)].

[5)] As $d=2$, P_B is a convex and piecewise linear function and therefore τ_B is also a convex function.

(iv) $P_B(w) \to P_0(w)$, $P'_B(w) \to P'_0(w)$ and $\tau_B(\rho) \to \tau_0(\rho)$ as $B \to 0$ where (without subscript "0") the limit functions have been defined by $(25.3.6)_{1,2}$ and (25.3.7) respectively.

Remark 26.2.2. (i) Alternatively we minimize $\mathcal{E}_B(\rho) = \Phi^*_B(\rho, 0)$ under assumptions

$$(26.2.2)_{1,2} \qquad \rho \ge 0, \qquad \int \rho \, dx \le N.$$

(ii) So far in comparison with the previous Chapter 25 we changed only definition of $P_B(w)$ and $\tau_B(\rho)$ respectively. Note that $P_B(w)$ belongs to $\mathscr{C}^{\frac{d}{2}+1}$ (as $d = 2, 3$) as function of w; this statement will be quantified later.

(iii) While not affecting existence (with equality in $(26.2.2)_1$ iff $N \le Z$) and uniqueness of solution, it affects other properties, especially as $B \ge Z^{\frac{4}{3}}$.

Proposition 26.2.3. *In our assumptions for any fixed $\nu \le 0$ Statements (i)–(viii) of Proposition 25.3.1 hold.*

Proof. The proof is the same as of Proposition 25.3.1. The proof that threshold $\nu = 0$ matches to $N = Z$ are theorems 4.9 and 4.10 of Section IV of E. H. Lieb, J. P. Solovej and J. Yngvason [3]. □

Note that (25.3.8)–(25.3.9) and (25.3.10) become

$$\rho = \frac{1}{4\pi}\Delta(W - V) = P'_B(W + \nu), \tag{26.2.3}$$

$$W = o(1) \qquad \text{as} \quad |x| \to \infty \tag{26.2.4}$$

and

$$\mathcal{N}(\nu) = \int P'_B(W + \nu) \, dx \tag{26.2.5}$$

respectively.

Similarly, Proposition 25.3.2 remains true:

Proposition 26.2.4. *For arbitrary W the following estimates hold with absolute constants $\epsilon_0 > 0$ and C_0:*

$$\epsilon_0 \mathsf{D}(\rho - \rho^{\mathsf{TF}}, \rho - \rho^{\mathsf{TF}}) \le \Phi_{B,*}(W^{\mathsf{TF}} + \nu) - \Phi_{B,*}(W + \nu) \le C_0 \mathsf{D}(\rho - \rho', \rho - \rho') \tag{26.2.6}$$

and

$$\epsilon_0 \mathsf{D}(\rho' - \rho^{\mathsf{TF}}, \rho' - \rho^{\mathsf{TF}}) \le \Phi^*_B(\rho, \nu) - \Phi^*_B(\rho^{\mathsf{TF}}, \nu) \le C_0 \mathsf{D}(\rho - \rho', \rho - \rho') \tag{26.2.7}$$

with $\rho = \frac{1}{4\pi}\Delta(W - V)$, $\rho' = P'_B(W + \nu)$.

Proof. This proof is rather obvious as well. □

26.2.2 Properties

Proposition 26.2.5. *The solution of the magnetic Thomas-Fermi problem has the following scaling properties*

$$W^{\mathsf{TF}}(x;\, \underline{z};\, \underline{y};\, B;\, N;\, q) = q^{\frac{2}{3}} N^{\frac{4}{3}} W^{\mathsf{TF}}(q^{\frac{2}{3}} N^{\frac{1}{3}} x;\, N^{-1}\underline{z};\, q^{\frac{2}{3}} N^{\frac{1}{3}} \underline{y};\, q^{-\frac{2}{3}} N^{-\frac{4}{3}} B;\, 1; 1), \tag{26.2.8}$$

$$\rho^{\mathsf{TF}}(x;\, \underline{z};\, \underline{y};\, B;\, N;\, q) = q^2 N^2 \rho^{\mathsf{TF}}(q^{\frac{2}{3}} N^{\frac{1}{3}} x;\, N^{-1}\underline{z};\, q^{\frac{2}{3}} N^{\frac{1}{3}} \underline{y};\, q^{-\frac{2}{3}} N^{-\frac{4}{3}} B;\, 1; 1), \tag{26.2.9}$$

$$\mathcal{E}^{\mathsf{TF}}(\underline{z};\, \underline{y};\, B;\, N;\, q) = q^{\frac{2}{3}} N^{\frac{7}{3}} \mathcal{E}^{\mathsf{TF}}(N^{-1}\underline{z};\, q^{\frac{2}{3}} N^{\frac{1}{3}} \underline{y};\, q^{-\frac{2}{3}} N^{-\frac{4}{3}} B;\, 1;\, 1), \tag{26.2.10}$$

$$\nu^{\mathsf{TF}}(\underline{z};\, \underline{y};\, B;\, N;\, q) = q^{\frac{2}{3}} N^{\frac{4}{3}} \nu^{\mathsf{TF}}(N^{-1}\underline{z};\, q^{\frac{2}{3}} N^{\frac{1}{3}} \underline{y};\, q^{-\frac{2}{3}} N^{-\frac{4}{3}} B;\, 1;\, 1) \tag{26.2.11}$$

where $\nu^{\mathsf{TF}} = \nu$ *is the chemical potential; recall that* $\underline{z} = (z_1, \dots, z_M)$ *and* $\underline{y} = (y_1, \dots, y_M)$ *are arrays and parameter* q *also enters into Thomas-Fermi theory.*

In particular, ν^{TF} *and* B *scale the same way.*

Proof. Proof is trivial by scaling. □

Now one can guess that there are two cases $B \ll Z^{\frac{4}{3}}$ and $B \gg Z^{\frac{4}{3}}$ (recall that $N \asymp Z$) in which magnetic Thomas-Fermi theory looks very different (and also an intermediate case $B \sim Z^{\frac{4}{3}}$). To explain this difference let us consider one atom case:

First of all recall that if $B = 0$ and $N = Z$ theory (as $M = 1$) has just one parameter and we can get rid of it by rescaling; $W^{\mathsf{TF}} \asymp Z\ell^{-1}$ as $\ell \lesssim Z^{-\frac{1}{3}}$ and $W^{\mathsf{TF}} \asymp \ell^{-4}$ as $\ell \gtrsim Z^{-\frac{1}{3}}$. Then

$$\mathsf{W}^{\mathsf{TF}\,\frac{3}{2}} \ell^3 \asymp Z^{\frac{3}{2}} \ell^{\frac{3}{2}}, \quad \mathsf{W}^{\mathsf{TF}\,\frac{5}{2}} \ell^3 \asymp Z^{\frac{5}{2}} \ell^{\frac{1}{2}}$$

and

$$\mathsf{W}^{\mathsf{TF}}\tfrac{3}{2}\ell^3 \asymp \ell^{-3}, \quad \mathsf{W}^{\mathsf{TF}}\tfrac{5}{2}\ell^3 \asymp \ell^{-7}$$

respectively where the first factors are spacial densities of the charge and (negative) Thomas-Fermi energy respectively and therefore zone $\ell \asymp Z^{-\frac{1}{3}}$ provides the main contributions into both.

Therefore, if in this *main zone* $B \ll W^{\mathsf{TF}} \asymp Z^{\frac{4}{3}}$ we guess that the magnetic theory is similar to non-magnetic one, and actually it is true.

However, let us study an atomic case rigorously. Let $M = 1$, $\mathsf{y}_m = 0$ and $N \le Z$. Then

(26.2.12) W_B^{TF} is a spherically symmetric, and it is monotone non-increasing function of $|x|$; $W_B^{\mathsf{TF}} \to +0$ as $|x| \to \infty$;

$$W_B^{\mathsf{TF}}(x) \le -\nu \implies W_B^{\mathsf{TF}} = |x|^{-1}(Z - N). \tag{26.2.13}$$

Indeed, (26.2.12) is obvious and (26.2.13) follows from it and Newton screening theorem.

Two propositions below treat cases $B \lesssim Z^{\frac{4}{3}}$ and $B \gtrsim Z^{\frac{4}{3}}$ respectively; in the former case there is another fork: $B \lesssim (Z - N)_+^{\frac{4}{3}}$ and $B \gtrsim (Z - N)_+^{\frac{4}{3}}$.

Proposition 26.2.6. *Let $M = 1$, $\mathsf{y}_m = 0$, $N \asymp Z_m$ and $B \le Z^{\frac{4}{3}}$.*

(i) Then

$$W_B^{\mathsf{TF}} \le \min(Z|x|^{-1}, C|x|^{-4}) \tag{26.2.14}$$

and

$$\rho_B^{\mathsf{TF}} \le C\min(Z^{\frac{3}{2}}|x|^{-\frac{3}{2}} + BZ^{\frac{1}{2}}|x|^{-\frac{1}{2}}, |x|^{-6} + B|x|^{-2}). \tag{26.2.15}$$

(ii) There exists

$$\bar{r}_m \asymp \min\bigl(B^{-\frac{1}{4}}, (Z - N)_+^{-\frac{1}{3}}\bigr) \tag{26.2.16}$$

such that $W_B^{\mathsf{TF}} \gtrless -\nu$ as $|x| \lesseqgtr \bar{r}_m$ and then $\rho_B^{\mathsf{TF}} = 0$ iff $x \ge \bar{r}_m$.

(iii) (26.2.14) *and* (26.2.15) *become equivalencies ($\asymp$) as $|x| \le (1 - \epsilon)\bar{r}_m$.*

(iv) $B \le (Z-N)_+^{\frac{4}{3}}$ *implies* $\bar{r}_m \asymp (Z-N)_+^{-\frac{1}{3}}$, $\nu \asymp (Z-N)_+^{\frac{4}{3}}$ *and*

$$W^{\mathsf{TF}} + \nu \asymp (Z-N)_+^{\frac{5}{3}}(\bar{r}_m - |x|), \qquad -\partial_{|x|} W^{\mathsf{TF}} \asymp (Z-N)_+^{\frac{5}{3}} \quad \text{if } (1-\epsilon)\bar{r}_m \le |x| \le \bar{r}_m. \tag{26.2.17}$$

(v) $B \ge (Z-N)_+^{\frac{4}{3}}$ *implies* $\bar{r}_m \asymp B^{-\frac{1}{4}}$, $\nu \asymp (Z-N)_+ B^{\frac{1}{4}} \lesssim B$ *and*

$$W^{\mathsf{TF}} + \nu \asymp B^2(\bar{r}_m - |x|)^4 + B^{\frac{1}{2}}(Z-N)_+(\bar{r}_m - |x|) \qquad -\partial_{|x|} W^{\mathsf{TF}} \asymp B^2(\bar{r}_m - |x|)^3 + B^{\frac{1}{2}}(Z-N)_+ \quad \text{as } (1-\epsilon)\bar{r}_m \le |x| \le \bar{r}_m. \tag{26.2.18}$$

Proposition 26.2.7. *Let* $M = 1$, $\mathsf{y}_m = 0$, $N \asymp Z_m$ *and* $B \ge Z^{\frac{4}{3}}$.

(i) Then

$$W_B^{\mathsf{TF}} \le Z|x|^{-1} \tag{26.2.19}$$

and

$$\rho_B^{\mathsf{TF}} \le CZ^{\frac{3}{2}}|x|^{-\frac{3}{2}} + CBZ^{\frac{1}{2}}|x|^{-\frac{1}{2}}. \tag{26.2.20}$$

(ii) There exist $\bar{r}_m$ *and* $\bar{r}'_m$,

$$\bar{r}_m \asymp B^{-\frac{2}{5}}Z^{\frac{1}{5}}, \qquad \bar{r}'_m \asymp B^{-1}Z_m, \tag{26.2.21}$$

such that $W_B^{\mathsf{TF}} \gtrless B$ *as* $|x| \lessgtr \bar{r}_m$, $W_B^{\mathsf{TF}} \gtrless -\nu$ *as* $|x| \lessgtr \bar{r}'_m$ *and then* $\rho_B^{\mathsf{TF}} = 0$ *iff* $x \ge \bar{r}_m$.

(iii) (26.2.19)–(26.2.20) *become equivalencies* ($\asymp$) *as* $|x| \le (1-\epsilon)\bar{r}_m$.

(iv) $\nu \asymp (Z-N)_+ B^{\frac{2}{5}} Z^{-\frac{1}{5}} \lesssim B$ *and*

$$W^{\mathsf{TF}} + \nu \asymp B^2(\bar{r}_m - |x|)^4 + \bar{r}_m^{-2}(Z-N)_+(\bar{r}_m - |x|) \tag{26.2.22}$$

and

$$-\partial_{|x|} W^{\mathsf{TF}} \asymp B^2(\bar{r}_m - |x|)^3 + \bar{r}_m^{-2}(Z-N)_+ \tag{26.2.23}$$

as $(1-\epsilon)\bar{r}_m \le |x| \le \bar{r}_m$.

Proofs of Propositions 26.2.6 and 26.2.7. Proofs easily follow from equation and "boundary conditions" satisfied by $w(r)$ where $r = |x|$:

$$w'' + 2r^{-1}w = P'_B(w+\nu), \tag{26.2.24}$$

$$w = r^{-1}Z_m + O(1) \qquad \text{as} \quad r \to 0, \tag{26.2.25}$$

$$w(\bar{r}_m) = -\nu, \qquad w'(\bar{r}_m) = \nu\bar{r}_m^{-1} \tag{26.2.26}$$

where $\nu = -(Z_m - N)_+\bar{r}_m^{-1}$. □

Corollary 26.2.8. *Let $M = 1$, $\mathsf{y}_m = 0$ and $N \asymp Z_m$. Then*

(i) $W_B^{\mathsf{TF}} \lesssim B$ if $|x| \ge \bar{r}'_m$ where $\bar{r}'_m \asymp B^{-1}Z_m$ as $B \ge Z_m^{\frac{4}{3}}$ and $\bar{r}'_m \asymp B^{-\frac{1}{4}}$ as $B \le cZ_m^{\frac{4}{3}}$.

(ii) As $B \lesssim Z_m^{\frac{4}{3}}$ the main contribution to both the charge and the Thomas-Fermi energy is delivered by zone $\{x\colon |x| \asymp r_m^*\}$ with $r_m^* = Z_m^{-\frac{1}{3}}$; in particular, then $\mathcal{E}_B^{\mathsf{TF}} \asymp \mathcal{E}^{\mathsf{TF}} \asymp Z_m^{\frac{7}{3}}$; further, in this case $W_B^{\mathsf{TF}} \asymp W^{\mathsf{TF}}$ in the zone $\{x\colon |x| \lesssim \epsilon\bar{r}_m\}$.

(iii) Further, $\mathcal{E}_B^{\mathsf{TF}} \sim \mathcal{E}^{\mathsf{TF}}$ as $B \ll Z_m^{\frac{4}{3}}$; furthermore, in this case $W_B^{\mathsf{TF}} \sim W^{\mathsf{TF}}$ in the zone $\{x\colon |x| \ll \bar{r}_m\}$.

(iv) On the other hand, as $B \ge Z^{\frac{4}{3}}$, the main contributions to the total charge and energy are delivered by $\{x\colon |x| \asymp \bar{r}_m\}$ and in particular $\rho_m \asymp BZ_m^{\frac{1}{2}}\bar{r}_m^{\frac{5}{2}}$ and

$$\mathcal{E}_B^{\mathsf{TF}} \asymp BZ_m^{\frac{3}{2}}\bar{r}_m^{\frac{3}{2}} \asymp B^{\frac{2}{5}}Z_m^{\frac{9}{5}}. \tag{26.2.27}$$

Recall that $\bar{r}_m \asymp B^{-\frac{1}{4}}$ as $B \le Z_m^{\frac{4}{3}}$ and $\bar{r}_m \asymp B^{-\frac{2}{5}}Z_M^{\frac{1}{5}}$ as $B \ge Z_M^{\frac{4}{3}}$. Note that Proposition 25.3.5 (comparing W^{TF} for molecule with the sum of those for single atoms) still holds. Therefore we conclude that

Corollary 26.2.9. *(i) Assume that*

$$Z_1 \asymp Z_2 \asymp \ldots \asymp Z_M. \tag{26.2.28}$$

Then all statements of corollary 26.2.8 remain true for $M \ge 2$ with $|x|$ and Z_m replaced by $\ell(x)$ and Z and $\bar{r}_m$, $\bar{r}'_m$, r_m^* by $\bar{r}$, $\bar{r}'$, r^* respectively.

(ii) In the general case global statements remain true, pointwise statements remain true without modification only as $\ell(x) = \ell_m(x) := |x - \mathsf{y}_m|$ *with* $Z_m \asymp Z$.

Remark 26.2.10. (i) Also holds Proposition 25.3.13 as it uses only super-additivity of $\tau(\rho)$ and $\tau_B(\rho)$ is also super-additive (this follows from convexity of $\tau_B(\rho)$ and equality $\tau_B(0) = 0$).

(ii) However there is a significant difference: if there is no magnetic field atoms really repulse one another on any distances and we can attribute it to either excessive positive charge as $N < Z$ or their infinite spatial size as $N = Z$. However with magnetic field atoms have a finite size even as $N = Z$ and they do not repulse one another on the large distances. In particular, Proposition 26.2.11 below holds.

Proposition 26.2.11. *Let* $N = Z$ *and*

$$|\mathsf{y}_m - \mathsf{y}_{m'}| \ge \bar{r}_m + \bar{r}_{m'} \qquad \forall m:\ 1 \le m < m' \le M. \tag{26.2.29}$$

Then

$$\mathcal{E}_B^{\mathsf{TF}}(\underline{Z}, \underline{\mathsf{y}}, B, Z) = \sum_{1\le m\le M} \mathcal{E}_B^{\mathsf{TF}}(Z_m, \mathsf{y}_m, B, Z_m) \tag{26.2.30}$$

and

$$\rho_B^{\mathsf{TF}}(x, \underline{Z}, \underline{\mathsf{y}}, B, Z) = \sum_{1\le m\le M} \rho_B^{\mathsf{TF}}(x, Z_m, \mathsf{y}_m, B, Z_m). \tag{26.2.31}$$

Proposition 26.2.12. *(i)* ν *is monotone increasing function of* N.

(ii) $W_B(x)$ *is monotone non-increasing function of* N.

(iii) $W_B(x) + \nu$ *is monotone non-decreasing function of* N *; in particular* ρ_B *can only increase as* N *increases.*

(iv) ν *is monotone non-increasing function of* Z_m.

(v) $W_B(x)$ *is monotone non-decreasing function of* Z_m.

Proof. (i) Statement (i) follows from the strict convexity of $\mathcal{E}(\rho)$: consider two solutions with corresponding subscripts. Then $\mathcal{E}(\rho) - \mathcal{E}(\rho_j) > \nu_j(N - N_j)$ for any non-negative $\rho \ne \rho_j$ and $N = \int \rho\, dx$.

In particular, $\mathcal{E}(\rho_1) - \mathcal{E}(\rho_2) > \nu_2(N_1 - N_2)$ and $\mathcal{E}(\rho_2) - \mathcal{E}(\rho_1) > \nu_1(N_2 - N_1)$ and then $(\nu_1 - \nu_2)(N_1 - N_2) > 0$.

(ii) Indeed, consider $N_1 < N_2$ and in the definition of W_2 slightly decrease $Z_1, \dots, Z_M$ thus replacing them by $Z'_1, \dots, Z'_M$. Then $W_1 > W_2$ for large $|x|$, $W_1 - W_2 \to +\infty$ as $x \to \mathsf{y}_m$ and therefore if Statement (ii) fails, then $W_1 - W_2$ reaches non-positive minimum at some regular point $\bar{x}$; at this point $W_1 \le W_2$ and

$$0 \le \frac{1}{4\pi}\Delta(W_1 - W_2) = P'(W_1 + \nu_1) - P'(W_2 + \nu_2).$$

This is possible only if at this point $W_2 + \nu_2 \le 0$ and $W_1 + \nu_1 < 0$. Then in the small vicinity $\Delta(W_1 - W_2) \le 0$ and $\bar{x}$ cannot be a point of minimum unless $W_1 - W_2 = \mathsf{const}$ there. Then any point of this vicinity is also a point of minimum and then due to standard analytic arguments $W_1 - W_2 = \mathsf{const}$ everywhere which is impossible.

So, $W_1(x; Z_1, \dots, Z_M) > W_2(x; Z'_1, \dots, Z'_M)$. Taking limit as $Z'_m \to Z_m$ we arrive to $W_1(x; Z_1, \dots, Z_M) \ge W_2(x; Z_1, \dots, Z_M)$.

(iii) Proof of Statement (iii) is similar but roles of W_1 and W_2 are played by $W_2 + \nu_2$ and $W_1 + \nu_1$ respectively.

(iv) Let $Z_{m,2} > Z_{m,1}$ for all m. Assume that $\nu_2 > \nu_1$. Then similar arguments prove that $W_2 + \nu_2 \ge W_1 + \nu_1$ and thus $\rho_2 \ge \rho_1$ everywhere which is impossible unless there are just identical equalities as $W_2 + \nu_2 > 0$, which is impossible.

(v) Finally, after Statement (iv) was established, the same arguments prove Statement (v). □

As far as we know Theorem 1 of R. Benguria [1] (see Theorem 25.3.8) has not been proven in the case of magnetic field; however one can see easily that arguments of of R. Benguria's proof (see Appendix 25.A.6) remain partially valid and we arrive to

Theorem 26.2.13. *Statements (i) and (ii) of Theorem 25.3.8*[6] *hold in the case of the constant external magnetic field.*

Remark 26.2.14. On the other hand, proofs of Statements (iii) and (iv) of Theorem 25.3.8 (that for fixed $\alpha > 0$ $\widehat{\mathcal{E}}^{\mathsf{TF}}_\alpha - \widehat{\mathcal{E}}^{\mathsf{TF}}_0$ and $\mathcal{E}^{\mathsf{TF}}_\alpha - \mathcal{E}^{\mathsf{TF}}_0$ are non-decreasing function of N) fail; more precisely, the proof of Lemma 25.A.7(ii) fails.

[6] That $\widehat{\mathcal{E}}^{\mathsf{TF}}_\alpha$ is a non-increasing function of $\alpha \ge 0$ and $\mathcal{E}^{\mathsf{TF}}_\alpha$ is a non-decreasing function of $\alpha \ge 0$.

Problem 26.2.15. (i) Investigate how $\mathsf{supp}(\rho_B^{\mathsf{TF}})$ depends on B and on Z in the atomic case $M = 1$.

(ii) More generally, investigate how $\mathsf{supp}(\rho_B^{\mathsf{TF}})$ depends on B and on Z in the case $M \ge 2$.

26.2.3 Positive Ions

In view of Remark 26.2.10 we need to consider repulsion of positive ions in more details. Our purpose is to prove

Theorem 26.2.16. *Let condition* (26.2.28) *be fulfilled. Then the energy excess is estimated from below*

$$\mathcal{Q} := \widehat{\mathcal{E}}_B^{\mathsf{TF}} - \sum_{1\le m\le M} \mathcal{E}_{B,m}^{\mathsf{TF}} \ge \epsilon (Z-N)_+^2 a^{-1}. \tag{26.2.32}$$

Note first that

$$\begin{aligned}\mathsf{D}\bigl(\rho_{B(\nu)}^{\mathsf{TF}} - \rho_{B,0}^{\mathsf{TF}},\, \rho_{B(\nu)}^{\mathsf{TF}} - \rho_{B(0)}^{\mathsf{TF}}\bigr) + {}& \\ \int \bigl(P'_B(W_{B(\nu)}^{\mathsf{TF}} + \nu) - P'_B(W_{B(0)}^{\mathsf{TF}})\bigr)\bigl(W_{B(\nu)}^{\mathsf{TF}} + \nu - W_{B(0)}^{\mathsf{TF}})\bigr)\,dx = {}& \\ \nu \int \bigl(P'_B(W_{B(\nu)}^{\mathsf{TF}} + \nu) - P'_B(W_{B(0)}^{\mathsf{TF}} + 0)\bigr)\,dx & \end{aligned} \tag{26.2.33}$$

with the right-hand expression equal $\nu(N-Z) \asymp (Z-N)^2 \bar{r}^{-1}$ and due to monotonicity $P'_B(w)$ we conclude that

Proposition 26.2.17. *Let condition* (26.2.28) *be fulfilled. Then*

$$\mathsf{D}\bigl(\rho_{B(\nu)}^{\mathsf{TF}} - \rho_{B(0)}^{\mathsf{TF}},\, \rho_{B,\nu}^{\mathsf{TF}} - \rho_{B(0)}^{\mathsf{TF}}\bigr) \le C(Z-N)^2 \bar{r}^{-1}. \tag{26.2.34}$$

Proof of Theorem 26.2.16. Step 1. Note first that due to non-negativity of the expression

$$\widehat{\mathcal{E}}_B^{\mathsf{TF}}(\underline{Z}, \underline{y}, N) - \min_{N_1+N'=N} \bigl(\mathcal{E}_B^{\mathsf{TF}}(Z_1, N_1) - \widehat{\mathcal{E}}_B^{\mathsf{TF}}(\underline{Z}', \underline{y}', N')\bigr) \tag{26.2.35}$$

(see proof of Proposition 25.3.13 which persists even if there is constant magnetic field, see Remark 26.2.10) it is sufficient to prove theorem only for $M = 2$. From now on we assume that $M = 2$.

Step 2. According to Proposition 25.3.13

$$\mathsf{D}(\rho_B^{\mathsf{TF}} - \rho_{B,1}^{\mathsf{TF}} - \rho_{B,2}^{\mathsf{TF}}) \le C\mathcal{Q}. \tag{26.2.36}$$

Therefore due to superadditivity τ_B

$$\mathcal{Q} \ge -\int V_1\rho_{B,2}^{\mathsf{TF}}\,dx - \int V_2\rho_{B,1}^{\mathsf{TF}}\,dx + \mathsf{D}(\rho_{B,2}^{\mathsf{TF}}, \rho_{B,1}^{\mathsf{TF}}) + Z_1Z_2a^{-1} - C\mathcal{Q} \tag{26.2.37}$$

and it is sufficient to prove the same estimate from below for the right-hand expression without the last term. However this is easy if $a \ge \bar{r}_1 + \bar{r}_2$ since $V_m = |x - \mathsf{y}_m|^{-1}Z_m$ and $\rho_{B,m}^{\mathsf{TF}} = \rho_{B,m}^{\mathsf{TF}}(|x - \mathsf{y}_m|)$ are spherically symmetric functions[7)].

Therefore for $a \ge \bar{r}_1 + \bar{r}_2$ inequality (26.2.32) has been proven and in what follows we can assume that $a \le \bar{r}_1 + \bar{r}_2$. Further, applying Theorem 26.2.13 we conclude then that

(26.2.38) Inequality (26.2.32) holds for $a \ge \epsilon\bar{r}$.

Step 3. Recall that the bulk of electrons are in the zone $\{\ell(x) \asymp r^*\}$ [8)]. Based on this one can prove easily that as $a \le \epsilon\bar{r}$ the right-hand hand expression of (26.2.37) is greater than $(1-\epsilon_1)a^{-1}Z_1Z_2$ and therefore

(26.2.39) As $B \ge Z^{\frac{4}{3}}$ and $a \le \epsilon r^*$ we have $\mathcal{Q} \ge (1-\epsilon_1)a^{-1}Z_1Z_2$

and combining with (26.2.38) we conclude that (26.2.32) holds for $B \gtrsim Z^{\frac{4}{3}}$ and for $B \lesssim Z^{\frac{4}{3}}$ we need to consider the case $\epsilon_0 r^* \le a \le \epsilon\bar{r}$ with arbitrarily small constant ϵ.

Replacing then P_B by P_0 and noting that an error will not exceed $C_0\bar{r}B^2 \le C_1\epsilon a^{-7}$ while $\mathcal{Q} \ge \epsilon_0 a^{-7}$ for $B = 0$ we conclude that (26.2.32) holds as $\epsilon_0 r^* \le a \le c\bar{r}$ and $(Z - N) \le C_2 a^{-3}$.

Finally, as $(Z - N) \ge C_2 a^{-3}$ we see that $\bar{r} \le C_0(Z-N)^{-\frac{1}{3}} \le \epsilon a$ and (26.2.32) holds again. □

[7)] However this is not true in general as $a < \bar{r}_1 + \bar{r}_2$. Really, consider $N_m = Z_m$ and uniformly charged spheres. Then the right-hand expression of (26.2.37) is 0 as $a \ge \bar{r}_1 + \bar{r}_2$ and is negative and decays as a decays from $\bar{r}_1 + \bar{r}_2$ to $\max(\bar{r}_1, \bar{r}_2)$ and it increases again as a decays from $\max(\bar{r}_1, \bar{r}_2)$ to 0.

[8)] I.e. zone $\{c(\epsilon)^{-1}r^* \le \ell(x) \le c(\epsilon)r^*\}$ contains at least $(1-\epsilon)N$ electrons.

Even if we do not need it for our purposes we want to consider the repulsion of too close neutral atoms:

Theorem 26.2.18. *Let condition* (26.2.28) *be fulfilled and* $N = Z$.

(i) If $B \le Z^{\frac{4}{3}}$ *and* $a \le \epsilon \bar{r}$ *then*

$$\mathcal{Q} \asymeq \begin{cases} a^{-1}Z^2 & a \le Z^{-\frac{1}{3}} \\ a^{-7} & a \ge Z^{-\frac{1}{3}}. \end{cases} \tag{26.2.40}$$

(ii) If $B \le Z^{\frac{4}{3}}$, $a \ge \epsilon \bar{r}$ *and*

$$0 < \max_{1 \le m < m' \le M} \bigl(\bar{r}_m + \bar{r}_{m'} - |\mathsf{y}_m - \mathsf{y}_{m'}|\bigr) = \varepsilon \bar{r} \tag{26.2.41}$$

with exact radius $\bar{r}_m$ *of* m*-th atom (that is,* $\mathsf{supp}(\rho^{\mathsf{TF}}_{B,m} = B((\mathsf{y}_m, \bar{r}_m))$ *and* $\varepsilon \in (0, c)$ *then*

$$\mathcal{Q} \asymeq B^{\frac{7}{4}} \varepsilon^7. \tag{26.2.42}$$

(iii) If $B \ge Z^{\frac{4}{3}}$, $a \le \epsilon \bar{r}$ *then*

$$\mathcal{Q} \asymeq a^{-1} Z^2. \tag{26.2.43}$$

(iv) If $B \ge Z^{\frac{4}{3}}$, $a \ge \epsilon \bar{r}$ *and* (26.2.41) *holds with* $\varepsilon \in (0, c)$ *then*

$$\mathcal{Q} \asymeq B^{\frac{2}{5}} Z^{\frac{9}{5}} \varepsilon^7. \tag{26.2.44}$$

Proof. (a) Since $\mathcal{E}^{\mathsf{TF}}_B \asymeq \mathcal{E}^{\mathsf{TF}}_{B,m} \asymeq \mathsf{max}(Z^{\frac{7}{3}}; B^{\frac{2}{5}} Z^{\frac{9}{5}})$ even without assumption $N = Z$ we conclude that $\mathcal{Q} \asymeq a^{-1}Z^2$ as long as $a \le \epsilon_0 r^* = \epsilon_0 \,\mathsf{min}(Z^{-\frac{1}{3}}; B^{-\frac{2}{5}} Z^{\frac{1}{5}})$ which proves Statement (i) as $a \le \epsilon_0 Z^{-\frac{1}{3}}$ and also Statement (iii).

(b) Observe that $\mathcal{E}^{\mathsf{TF}}_B = \mathcal{E}^{\mathsf{TF}}_0 + O(B^{\frac{7}{4}})$ and $\mathcal{E}^{\mathsf{TF}}_{B,m} = \mathcal{E}^{\mathsf{TF}}_{0,m} + O(B^{\frac{7}{4}})$ as $a \ge \epsilon_0 Z^{-\frac{1}{3}}$ where $\mathcal{E}^{\mathsf{TF}}_0$ and $\mathcal{E}^{\mathsf{TF}}_{0,m}$ are non-magnetic Thomas-Fermi energies and therefore $\mathcal{Q} \coloneqq \mathcal{Q}_B = \mathcal{Q}_0 + O(B^{\frac{7}{4}})$ and since $\mathcal{Q}_0 \asymeq a^{-7}$, we arrive to $\mathcal{Q}_B \asymeq a^{-7}$ as $\epsilon_0 Z^{-\frac{1}{3}} \le a \le \epsilon B^{-\frac{1}{4}}$.

(c) Thus we need to prove Statements (ii) and (iv). Assume first that $\varepsilon \in (0, \epsilon]$ with sufficiently small constant $\epsilon > 0$.

$$
\begin{aligned}
(26.2.45)\quad & -\int P_B(W)\,dx - \frac{1}{2}\mathsf{D}(\rho,\,\rho) \le \mathcal{E}_B^{\mathsf{TF}} \\
& \le -\int P_B(W)\,dx - \frac{1}{2}\mathsf{D}(\rho,\,\rho) + \frac{1}{2}\mathsf{D}(P_B'(W)-\rho,\,P_B'(W)+\rho)
\end{aligned}
$$

with arbitrary ρ and $W = V - |x|^{-1} * \rho$. Let us plug $\rho = \sum_{1\le m\le M}\rho_m$ with $\rho_M \coloneqq \rho_{B,m}^{\mathsf{TF}}$; then $W = \sum_{1\le m\le M} W_m$, $W_m = W_{B,m}^{\mathsf{TF}}$. Let us compare different terms in the left and right side expressions of (26.2.45) and the corresponding sums of these terms for separate atoms.

First, consider

$$
\frac{1}{2}\mathsf{D}(\rho_1+\dots+\rho_m,\,\rho_1+\dots+\rho_m) - \sum_{1\le m\le M}\frac{1}{2}\mathsf{D}(\rho_m,\,\rho_m) = \sum_{1\le m<m'\le M}\mathsf{D}(\rho_m,\,\rho_{m'})
$$

and as $m \ne m'$

$$
\begin{aligned}
(26.2.46)\quad & \mathsf{D}(\rho_m,\,\rho_{m'}) \\
& = \frac{Z_m Z_{m'}}{|\mathsf{y}_m - \mathsf{y}_{m'}|} - \int_{\mathcal{Z}_{mm'}}\Big(\int_{\mathcal{Y}_{m'}\setminus B(\mathsf{y}_{m'},|x-\mathsf{y}_{m'}|)}\rho_{m'}(y)\,dy\Big)\frac{\rho_m(x)}{|x-\mathsf{y}_{m'}|}\,dx
\end{aligned}
$$

with $\mathcal{Z}_{mm'} = \mathcal{Y}_m \cap \mathcal{Y}_{m'}$, $\mathcal{Y}_m = B(\mathsf{y}_m, \bar{r}_m)$. Indeed, using Newton's screening theorem and that ρ_m and $\rho_{m'}$ are spherically symmetric about y_m and $\mathsf{y}_{m'}$ correspondingly, and $\mathsf{y}_m \notin B(\mathsf{y}_{m'}, \bar{r}_{m'})$ and $\mathsf{y}_{m'} \notin B(\mathsf{y}_m, \bar{r}_m)$ as $\varepsilon \le \epsilon$ we have

$$
\begin{aligned}
&\iint_{(\mathcal{Y}_m\setminus\mathcal{Z}_{mm'})\times\mathcal{Y}_{m'}}\frac{\rho_m(x)\rho_{m'}(y)}{|x-y|}\,dxdy + \iint_{\mathcal{Z}_{mm'}\times\mathcal{Y}_{m'}}\frac{\rho_m(x)\rho_{m'}(y)}{|x-y|}\,dxdy \\
&\qquad = \int_{\mathcal{Y}_m\setminus\mathcal{Z}_{mm'}}\frac{\rho_m(x)Z_{m'}}{|x-\mathsf{y}_{m'}|}\,dx + \iint_{\mathcal{Z}_{mm'}\times\mathcal{Y}_{m'}}\frac{\rho_m(x)\rho_{m'}(y)}{|x-y|}\,dxdy \\
&= \int_{\mathcal{Y}_m}\frac{\rho_m(x)Z_{m'}}{|x-\mathsf{y}_{m'}|}\,dx - \int_{\mathcal{Z}_{mm'}}\frac{\rho_m(x)Z_{m'}}{|x-\mathsf{y}_{m'}|}\,dx + \iint_{\mathcal{Z}_{mm'}\times\mathcal{Y}_{m'}}\frac{\rho_m(x)\rho_{m'}(y)}{|x-y|}\,dxdy \\
&\qquad = \frac{Z_m Z_{m'}}{|\mathsf{y}_m-\mathsf{y}_{m'}|} - \int_{\mathcal{Z}_{mm'}}\Big(\frac{Z_{m'}}{|x-\mathsf{y}_{m'}|} - \int_{\mathcal{Y}_{m'}}\frac{\rho_{m'}(y)}{|x-y|}\,dy\Big)\rho_m(x)\,dx
\end{aligned}
$$

and the last expression is equal to the right-hand expression of (26.2.46).

Next, consider

$$\int \Big(P_B(W_1 + ... + W_m) - \sum_{1\le m\le M} P_B(W_m)\Big)\, dx \tag{26.2.47}$$

and the last term in the right-hand expression of (26.2.45); one can see easily that they are given by integrals over $\mathcal{Z} = \bigcup_{1\le m<m'\le M} \mathcal{Z}_{mm'}$ and $\mathcal{Z}\times\mathcal{Z}$ respectively.

Remark 26.2.19. (A) The last term in the right-hand expression of (26.2.46) is $O(S\varepsilon^7)$ with S defined by

$$G \coloneqq \begin{cases} B & \text{if } B \le Z^{\frac{4}{3}}, \\ B^{\frac{2}{5}} Z^{\frac{4}{5}} & \text{if } B \ge Z^{\frac{4}{3}} \end{cases}, \qquad S \coloneqq \begin{cases} B^{\frac{7}{4}} & \text{if } B \le Z^{\frac{4}{3}}, \\ B^{\frac{2}{5}} Z^{\frac{9}{5}} & \text{if } B \ge Z^{\frac{4}{3}}. \end{cases} \tag{26.2.48}$$

The last term in the right-hand expression of (26.2.46) is $\asymp S\varepsilon^7$ provided

$$0 < \bar{r}_m + \bar{r}_{m'} - |\mathsf{y}_m - \mathsf{y}_{m'}| \asymp \varepsilon \bar{r}. \tag{26.2.49}$$

(B) Expression (26.2.47) is $O(S\varepsilon^8)$.

(C) The last term in the right-hand expression of (26.2.45) is $O(S\varepsilon^{\frac{15}{2}})$.

Indeed, in all integrands in (A)–(C) $W_m = O(G\varepsilon^4)$, $\rho_m = P'_B(W_m) = O(BG^{\frac{1}{2}}\varepsilon^2)$, and the same is true for $W_{m'}$ and $\rho_{m'}$. Further, the volume of $\mathcal{Z}_{mm'}$ is $\asymp \bar{r}^3\varepsilon^2$ and the volume of $\mathcal{Y}_{m'} \setminus B(\mathsf{y}_{m'}, |x-\mathsf{y}_{m'}|)$ is $O(\bar{r}^3\varepsilon)$ and $\int_{\mathcal{Z}_{mm'}} |x-y|^{-1}\, dxdy = O(\bar{r}^5\varepsilon^{\frac{15}{2}})$.

Furthermore, under assumption (26.2.49) there are $\mathcal{W}_{mm'} \subset \mathcal{Z}_{mm'}$ and $\mathcal{W}_{m'} \subset \mathcal{Y}_{m'} \setminus B(\mathsf{y}_{m'}, |x-\mathsf{y}_{m'}|)$ of the volumes $\asymp \bar{r}^3\varepsilon^2$ and $\asymp \bar{r}^3\varepsilon$ correspondingly such that there $\rho_m \asymp \rho_{m'} \asymp G\varepsilon^2$.

Finally, in the integrand in (B) $P_B(W_m) = O(BG^{\frac{3}{2}}\varepsilon^6)$.

Since

$$\widehat{\mathcal{E}}^{\mathsf{TF}}_B = \mathcal{E}^{\mathsf{TF}}_B + \sum_{1\le m<m'\le M} \frac{Z_m Z_{mm'}}{|\mathsf{y}_m - \mathsf{y}_{m'}|} \tag{26.2.50}$$

and

$$\mathcal{Q} = \widehat{\mathcal{E}}^{\mathsf{TF}}_B - \sum_{1\le m\le M} \mathcal{E}^{\mathsf{TF}}_{B,m} \tag{26.2.51}$$

we conclude that $\mathcal{Q} \asymp S\varepsilon^7$ as $\varepsilon \in (0, \epsilon]$ with sufficiently small constant $\epsilon > 0$, and in this case Statements (ii) and (iv) of the theorem are proven.

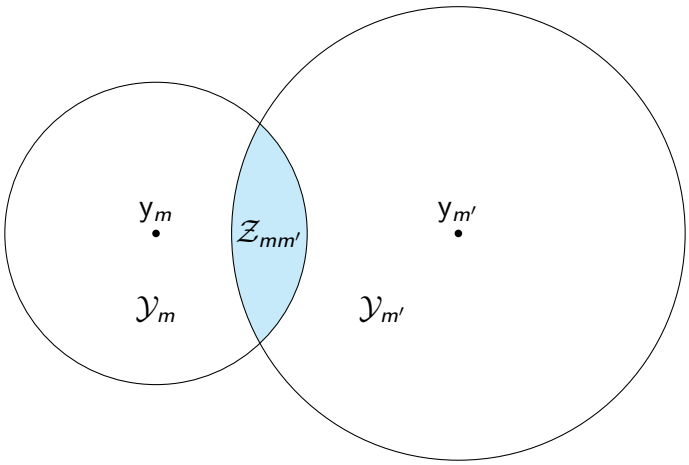


Figure 26.1: The thickness of the "lens" $\mathcal{Z}_{mm'}$ is $\asymp \varepsilon\bar{r}$ and its width is $\asymp \varepsilon^{\frac{1}{2}}\bar{r}$

(d) The above arguments simplified imply that $\mathcal{Q} \lesssim S$ as $\varepsilon \in (0, c]$ with arbitrarily large constant $c > 0$.

Let us estimate $\mathcal{Q}$ from below, assuming that $\varepsilon \in [\epsilon, c)$ with small constant $\epsilon > 0$ from Part (c). Due to Theorem 26.2.13 (Benguria's theorem in the case of magnetic field, Statement refthm-25.3.8-i) one can move y_m to y'_m, $m = 1, \dots, M$ so that $\widehat{\mathcal{E}}^{\mathsf{TF}}_B(\mathsf{y}_1, \dots, \mathsf{y}_M) \geq \widehat{\mathcal{E}}^{\mathsf{TF}}_B(\mathsf{y}'_1, \dots, \mathsf{y}'_M)$ and for $\mathsf{y}'_1, \dots, \mathsf{y}'_M$ assumption (26.2.41) holds with $\varepsilon = \epsilon$.

Then it follows from Part (c) that (26.2.42) and (26.2.44) hold for the new arrangement as $B \leq Z^{\frac{4}{3}}$ and $B \geq Z^{\frac{4}{3}}$ respectively, which mean exactly that $\mathcal{Q} \gtrsim S$.

Remark 26.2.20. These two figures show thresholds for $B \leq Z^{\frac{4}{3}}$ and $B \geq Z^{\frac{4}{3}}$ respectively:

26.3 Applying Semiclassical Methods: $M = 1$

26.3.1 Heuristics

Let us consider first a mock proof of our main results; we deal here *as if* W^{TF}_B *was very smooth* which it is not the case; however later we will show that its smoothness is sufficient to employ arguments of Chapter 18 rather

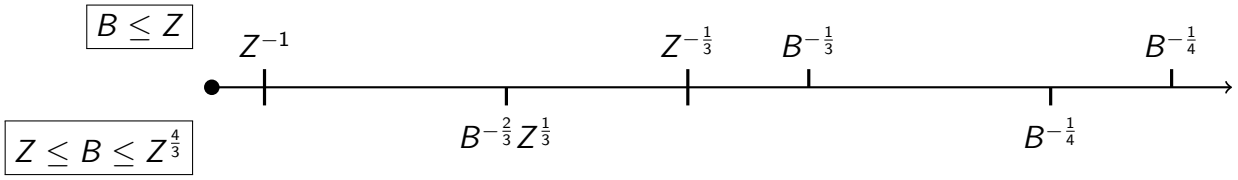

Figure 26.2: Let $B \le Z^{\frac{4}{3}}$. Then at $\{\ell \asymp Z^{-\frac{1}{3}}\}$ are contained both the bulk of charge and the bulk of energy, $\ell \asymp \mathsf{min}((Z-N)_+^{-\frac{1}{3}}, B^{-\frac{1}{4}}\}$ is the border of $\mathsf{supp}(\rho_B^{\mathsf{TF}})$; $\ell \asymp Z^{-1}$ is the Scott distance; here $h \asymp 1$. Further, $\ell \asymp B^{-\frac{1}{3}}$ if $B \le Z$ and $\ell \asymp B^{-\frac{2}{3}}Z^{\frac{1}{3}}$ if $Z \le B \le Z^{\frac{4}{3}}$ separates $\{\mu \lesssim 1\}$ (on the left) and $\{\mu \gtrsim 1\}$ (on the right).

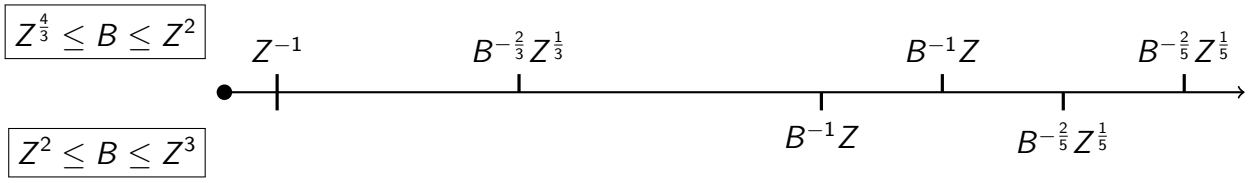

Figure 26.3: Let $Z^{\frac{4}{3}} \le B \le Z^3$. Then at $\{\ell \asymp Z^{-\frac{2}{5}}B^{\frac{1}{5}}\}$ are contained both the bulk of charge and the bulk of energy and it is also the border of $\mathsf{supp}(\rho_B^{\mathsf{TF}})$; $\ell \asymp Z^{-1}$ is the Scott distance; here $h \asymp 1$. Further, if $Z^{\frac{4}{3}} \le B \le Z^2$ $\ell \asymp B^{-\frac{2}{3}}Z^{\frac{1}{3}}$ separates $\{\mu \lesssim 1\}$ (on the left) and $\{\mu \gtrsim 1\}$ (on the right) and $\ell \asymp B^{-1}Z$ separates $\{\mu h \lesssim 1\}$ (on the left) and $\{\mu h \gtrsim 1\}$ (on the right).

than those of Chapter 13. We also will deal as if non-degeneracy conditions were satisfied leaving them also to more rigorous arguments below.

It will allow us to establish our target remainder estimates which we will be able to prove rigorously for $M = 1$ (in this section) while for $M \ge 2$ (in the next two sections) our results will be not that good.

Total Charge

Consider

$$\int e(x,x,\nu)\psi(x)\,dx, \tag{26.3.1}$$

first with γ-admissible $\psi(x)$, where $\gamma \le \epsilon\ell$. Recall that $\ell(x) = \mathsf{min}_m |x - y_m|$ is the distance to the nearest nucleus.

General Arguments. The main part of the semiclassical expression for (26.3.1) is of magnitude $h'^{-3}+\mu' h'^{-2} \asymp \zeta^3\gamma^3 + B\zeta\gamma^3$ with $h'=1/(\zeta\gamma)$ and $\mu'=B\gamma/\zeta$.

Indeed, let us rescale $x\mapsto x/\gamma$ and $\tau\mapsto \tau/\zeta^2$ which leads to $h=1\mapsto h'$ and $B\mapsto \mu'$. In particular, for $\gamma\asymp \ell$ we get

$$\zeta^3\ell^3 + B\zeta\ell^3. \tag{26.3.2}$$

Meanwhile, the remainder in the semiclassical expression for (26.3.1) does not exceed $Ch'^{-2}+C\mu' h'^{-1}\asymp \zeta^2\gamma^2+B\gamma^2$ (gaining factor h' in comparison to the main part; here we need the smoothness and if $\mu'\ge h'^{\delta-1}$ we also need the non-degeneracy); for $\gamma\asymp\ell$ we get

$$\zeta^2\ell^2 + B\ell^2. \tag{26.3.3}$$

Sure, we ignored the fact that $h'\le 1$ does not necessarily hold even if $\gamma\asymp\ell$ but we believe that the contributions to the main part and the remainder of these zones will be less than of zone where this inequality holds, provided $B\ll Z^3$.

Finally, let us sum expressions (26.3.2) and (26.3.3) with respect to ℓ-partition.

Moderate Magnetic Field. Consider the case $B\le Z^{\frac43}$ first. Then for $\ell\le Z^{-\frac13}$ we plug $\zeta = Z^{\frac12}\ell^{-\frac12}$ into (26.3.2) and (26.3.3) resulting in

$$Z^{\frac32}\ell^{\frac32} + BZ^{\frac12}\ell^{\frac52} \qquad \text{and} \qquad Z\ell + B\ell^2 \tag{26.3.4}_{0,1}$$

in the main part and in the remainder respectively and the summation over zone $\{x\colon \ell(x)\le Z^{-\frac43}\}$ results in the same expressions with $\ell = Z^{-\frac13}$, i. e. in $Z+BZ^{-\frac13}\asymp Z$ and $Z^{\frac23}+BZ^{-\frac23}\asymp Z^{\frac23}$ respectively.

On the other hand, for $\ell\ge Z^{-\frac13}$ we plug $\zeta=\ell^{-2}$ into (26.3.2) and (26.3.3) resulting in

$$\ell^{-3}+B\ell \qquad \text{and} \qquad \ell^{-2}+B\ell^2; \tag{26.3.5}_{0,1}$$

then summation over zone $\{x\colon Z^{-\frac13}\le \ell(x)\le \bar r = B^{-\frac14}\}$ results in $Z+B^{\frac34}\asymp Z$ and $Z^{\frac23}+B^{\frac12}\asymp Z^{\frac23}$ respectively.

Strong Magnetic Field. Consider the case $B \ge Z^{\frac{4}{3}}$ now. Then the threshold $Z^{-\frac{1}{3}}$ disappears and we sum expressions $(26.3.4)_{0,1}$ over zone $\{x\colon \ell(x) \le \bar{r} \coloneqq Z^{\frac{1}{5}}B^{-\frac{2}{5}}\}$, resulting in $Z^{\frac{9}{5}}B^{-\frac{3}{5}}+Z \asymp Z$ and $Z^{\frac{6}{5}}B^{-\frac{2}{5}}+Z^{\frac{2}{5}}B^{\frac{1}{5}} \asymp Z^{\frac{2}{5}}B^{\frac{1}{5}}$ respectively.

Therefore, for both cases $B \lessgtr Z^{\frac{4}{3}}$ we arrive to

(26.3.6) The total charge is $\mathsf{min}(N, Z)$ (due to the choice of ν) with the remainder estimate $O\big(\mathsf{max}(Z^{\frac{2}{3}}, Z^{\frac{2}{5}}B^{\frac{1}{5}})\big)$ which is $O(Z^{\frac{2}{3}})$ if $B \le Z^{\frac{4}{3}}$ and $O(Z^{\frac{2}{5}}B^{\frac{1}{5}})$ if $Z^{\frac{4}{3}} \le B \le Z^3$.

Remark 26.3.1. Remainder is less than the main part if $Z^{\frac{2}{5}}B^{\frac{1}{5}} \lesssim Z$ i.e. $B \le Z^3$. It means exactly that $\zeta\ell \ge 1$ if $\ell = \bar{r}$ (in the case $B \ge Z^{\frac{4}{3}}$), or, in other words that $h \lesssim 1$. The same is true for all other semiclassical asymptotics below.

If $B \ll Z^3$ we arrive to asymptotics, ig $B \lesssim Z^3$ we have estimates and in the case of superstrong magnetic field $B \gg Z^3$ Thomas-Fermi theory is not valid for our main model.

Semiclassical D-Term

Consider now the semiclassical D-term

$$\mathsf{D}\big(e(x,x,\nu) - \rho_B^{\mathsf{TF}}(x),\ e(x,x,\nu) - \rho_B^{\mathsf{TF}}(x)\big). \tag{26.3.7}$$

General Arguments. We do not have appropriate asymptotics for $e(x,x,\nu)$ in the case of the magnetic field[9)] but we apply Fefferman–de Llave decomposition (16.4.1):

$$|x-y|_\gamma^{-1}(x,y) \coloneqq |x-y|\varphi(\gamma^{-1}|x-y|) = \gamma^{-4}\int \psi_{1,\gamma}(x,z)\psi_{2,\gamma}(y,z)\,dz \tag{26.3.8}$$

where $\varphi \in \mathscr{C}^\infty([1,2])$.

Therefore contribution of $B(z,\gamma) \times B(z',\gamma)$ with $3\gamma \le |z-z'| \le 4\gamma$, $\gamma \le \epsilon\ell(z)$ to such term does not exceed $C\big(\zeta^2\gamma^2 + B\gamma^2\big)^2\gamma^{-1}$. There are $\asymp \ell^3\gamma^{-3}$ of such pairs with $\ell(x) \asymp \ell$ and their total contribution does not exceed $C\big(\zeta^2 + B\big)^2\ell^3$.

[9)] Unless we really assume that W is smooth and apply results sections 16.6–16.9.

Now we need to sum over $\gamma^{-1}\,d\gamma$ which does not look good because it leads to the logarithmic divergency but there is a simple remedy: we treat this way only pairs $t\ell \le |z-z'| \le \ell$ and apply for pairs with $|z-z'| \le t\ell$ pointwise asymptotics; then we get

$$C(\zeta^2+B)^2\ell^3\big(1+(\log B\ell/\zeta)_+\big); \tag{26.3.9}$$

to get rid of this logarithmic factor we apply more delicate arguments similar to those of Subsection 16.10.3.

Thus, ignoring this logarithmic factor we conclude that the contribution of all pairs (z,z') with $\ell(z)\asymp\ell(z')\asymp\ell$ does not exceed $C(\zeta^2+B)^2\ell^3$ while contribution of all pairs (z,z') with $\ell(z)\asymp\ell_1\not\asymp\ell(z')\asymp\ell_2$ does not exceed $C(\zeta_1^2+B)(\zeta_2^2+B)\ell_1^2\ell_2^2(\ell_1+\ell_2)^{-1}$.

Finally let us sum these expressions over partitions of unity.

Moderate Magnetic Field. Consider the case $B\le Z^{\frac{4}{3}}$. Then summation over zone $\{\ell_1\le Z^{-\frac{1}{3}},\ \ell_2\le Z^{-\frac{1}{3}}\}$ results in $CZ^{\frac{5}{3}}$ and the same is also true for summation over zone $\{Z^{-\frac{1}{3}}\le\ell_1\le B^{-\frac{1}{4}},\ Z^{-\frac{1}{3}}\le\ell_2\le B^{-\frac{1}{4}}\}$.

Obviously, in such estimates, if there is a fixed number of zones, we do not need to sum over "mixed" pairs when z and z' belong to different zones.

Strong Magnetic Field. Consider the case $B\ge Z^{\frac{4}{3}}$. Then summation over zone $\{\ell_1\le Z^{\frac{1}{5}}B^{-\frac{2}{5}},\ \ell_2\le Z^{\frac{1}{5}}B^{-\frac{2}{5}}\}$ results in $CZ^{\frac{3}{5}}B^{\frac{4}{5}}$.

Therefore, for both cases $B\lessgtr Z^{\frac{4}{3}}$ we arrive to

(26.3.10) Term (26.3.7) does not exceed $C\max(Z^{\frac{5}{3}}, Z^{\frac{3}{5}}B^{\frac{4}{5}})$ which is $CZ^{\frac{5}{3}}$ if $B\le Z^{\frac{4}{3}}$ and $CZ^{\frac{3}{5}}B^{\frac{4}{5}}$ if $Z^{\frac{4}{3}}\le B\le Z^3$.

Remark 26.3.2[10]. Estimating this term, and also the second D-term (in the next paragraph) we need to estimate the contribution of the singular zone $\{x\colon \ell(x)\le \bar r = Z^{-1}\}$ where effective semiclassical parameter is less than 1. We claim that there

$$e(x,x,0)\le C(BZ+Z^3)\qquad \text{for}\quad \lambda\le cZ^2. \tag{26.3.11}$$

Indeed, it is true if $\ell(x)\ge 1$. Also operator H is bounded from below by $-CZ^2$. And finally, in the ball of $B(\mathsf{y}_m,\epsilon Z^{-1})$ operator Δ is larger than $Z|x-\mathsf{y}_m|^{-1}$. We leave the easy details to the reader.

[10] Cf. Remark 25.4.7.

Therefore for $B \le Z^2$ the contribution of this zone into N-term is $O(CZ^3\bar{r}^3) = O(1)$, into both D-terms is $O(Z^6\bar{r}^5) = O(Z)$, and into T-term is $O(Z^5\bar{r}^3) = O(Z^2)$ exactly as in Chapter 25. On the other hand, for $Z^2 \le B \le Z^3$ the contribution of this zone into N-term is $O(CBZ\bar{r}^3) = O(BZ^{-2})$, into both D-terms is $O(B^2Z^2\bar{r}^5) = O(B^2Z^{-3})$, and into T-term is $O(BZ^3\bar{r}^3) = O(B)$.

$|\lambda_N - \nu|$ and another D-Term

Consider two other non-trace terms in the upper estimate.

Moderate Magnetic Field. In the case $B \le Z^{\frac{4}{3}}$ we established the remainder in the total charge $O(Z^{\frac{2}{3}})$. Then using our standard arguments we conclude easily that $|\lambda_N - \nu| = O(Z)$ and then

$$|\lambda_N - \nu| \cdot |\mathsf{N}(\nu) - N| \le CZ^{\frac{5}{3}} \tag{26.3.12}$$

and

$$\begin{aligned}\mathsf{D}\big(&P'_B(W_B^{\mathsf{TF}}(x) + \lambda_N) - P'_B(W_B^{\mathsf{TF}}(x) + \nu),\\ &P'_B(W_B^{\mathsf{TF}}(x) + \lambda_N) - P'_B(W_B^{\mathsf{TF}}(x) + \nu)\big) \le CZ^{\frac{5}{3}};\end{aligned} \tag{26.3.13}$$

combining with the estimate of the previous subsubsection we conclude that

$$\mathsf{D}(\rho_\Psi - \rho_B^{\mathsf{TF}}, \rho_\Psi - \rho_B^{\mathsf{TF}}) \le CQ = O(Z^{\frac{5}{3}}), \tag{26.3.14}$$

exactly as in (25.4.56).

Strong Magnetic Field. Let now $Z^{\frac{4}{3}} \le B \le Z^3$. Then we established the remainder in the total charge $O(Z^{\frac{2}{5}}B^{\frac{1}{5}})$ and for the semiclassical D-term we established estimate $O(Z^{\frac{3}{5}}B^{\frac{4}{5}})$. Therefore to estimate

$$|\lambda_N - \nu| \cdot |\mathsf{N}(\nu) - N| \le CZ^{\frac{3}{5}}B^{\frac{4}{5}} \tag{26.3.15}$$

as well we want to prove that

$$|\lambda_N - \nu| = O(Z^{\frac{1}{5}}B^{\frac{3}{5}}). \tag{26.3.16}$$

Observe that $|\nu| \lesssim Z\bar{r}^{-1} \asymp Z^{\frac{4}{5}}B^{\frac{2}{5}} \le CB$. Therefore if $|\lambda_N - \nu| \le \frac{1}{2}|\nu|$ we conclude that

$$|\int \bigl(P'_B(W^{\mathsf{TF}}_B(x)+\lambda_N) - P'_B(W^{\mathsf{TF}}_B(x)+\nu)\bigr)\,dx| \ge \epsilon|\lambda_N-\nu|B\int (W+\nu)^{-\frac{1}{2}}_+\,dx \tag{26.3.17}$$

with the integral taken over zone $\{x\colon W(x)+\nu \ge |\lambda_N-\nu|\}$.

One can see easily that as $|\lambda_N-\nu| \le \epsilon|\nu|$ the right-hand expression of (26.3.17) is larger than $\epsilon|\lambda_N-\nu|\cdot Z^{\frac{1}{5}}B^{-\frac{2}{5}}$ and it must be less than $CZ^{\frac{2}{5}}B^{\frac{1}{5}}$: $|\lambda_N-\nu|Z^{\frac{1}{5}}B^{-\frac{2}{5}} \le CZ^{\frac{2}{5}}B^{\frac{1}{5}}$ which implies (26.3.16).

Let us estimate the left-hand expression of (26.3.13). For this, however, estimate (26.3.16) is insufficient. We consider here only the atomic case. Then using (26.2.22)–(26.2.23) one can prove easily that the right-hand expression of (26.3.17) is of magnitude

$$|\lambda_N-\nu|\cdot B\bar{r}^2 \times \underbrace{(|\nu|\bar{r}^{-1})^{-\frac{1}{3}}B^{-\frac{1}{3}}} \asymp |\lambda_N-\nu|\cdot|\nu|^{-\frac{1}{3}}Z^{\frac{7}{15}}B^{-\frac{4}{15}}$$

provided $|\lambda-N| \le \epsilon\nu$, where the selected factor is just $\int (B^2z^4+|\nu|\bar{r}^{-1})^{-\frac{1}{2}}_+\,dz$ (appearing due to (26.2.22)–(26.2.23)). Comparing with $Z^{\frac{2}{5}}B^{\frac{1}{5}}$ we conclude that

(a) If $|\nu| \ge C_1Z^{-\frac{1}{10}}B^{\frac{7}{10}}$ $(= C_1Z^{\frac{2}{5}}B^{\frac{3}{5}} \times Z^{-\frac{3}{10}}B^{\frac{1}{10}})$ then

$$|\lambda_N-\nu| \le C|\nu|^{\frac{1}{3}}Z^{-\frac{1}{15}}B^{\frac{7}{15}} \tag{26.3.18}$$

which is less than $\epsilon|\nu|$ and coincides with (26.3.16) as $(Z-N)_+ \asymp Z$.

(b) If $|\nu| \ge C_1Z^{-\frac{1}{10}}B^{\frac{7}{10}}$ then $|\lambda_N-\nu| \le C_2Z^{-\frac{1}{10}}B^{\frac{7}{10}}$.

In the former case one can prove easily that the left-hand expression of (26.3.13) does not exceed $CZ^{\frac{3}{5}}B^{\frac{4}{5}}$.

In the latter case (exactly as in Subsection 25.4.2) we consider Thomas-Fermi theory with $\nu = 0$ i.e. $N = Z$ and also prove that that

(26.3.19) The left-hand expression of (26.3.16) does not exceed $Q = CZ^{\frac{3}{5}}B^{\frac{4}{5}}$.

In particular, we slightly improve estimate (26.3.15) to $|\nu|^{\frac{1}{3}}Z^{\frac{3}{5}}B^{\frac{2}{3}}$ as well (if $(Z-N) \ll Z$).

Therefore in our framework we estimated all non-trace terms in the upper estimate by $CZ^{\frac{3}{5}}B^{\frac{4}{5}}$ and therefore "proved" estimate

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}_B, \rho_\Psi - \rho^{\mathsf{TF}}_B) \le CQ = O(Z^{\frac{3}{5}}B^{\frac{4}{5}}). \tag{26.3.20}$$

Trace

Consider now $\mathsf{Tr}((H_{A,W}-\nu)^-)$. This term is of magnitude $\int(\zeta^5+B\zeta^3)\,dx$ and one can see easily that it is $\asymp Z^{\frac{7}{3}}$ for $B\le Z^{\frac{4}{3}}$ and $\asymp B^{\frac{2}{5}}Z^{\frac{9}{5}}$ for $Z^{\frac{4}{3}}\le B\le Z^3$.

Meanwhile, consider the remainder. Again for simplicity consider only the atomic case. If $B\le Z$ the contribution of the zone $\{x\colon \ell(x)\le Z^{-\frac{1}{3}}\}$ is $O(Z^{\frac{5}{3}})$ (we need to include Scott correction term in the main part) while the contribution of the zone $\{x\colon \ell(x)\ge Z^{-\frac{1}{3}}\}$ does not exceed

$$C\int(\zeta^3+B\zeta)\ell^{-2}\,dx \tag{26.3.21}$$

taken over this zone and it is $\asymp Z^{\frac{5}{3}}$ as well.

If $Z\le B\le B^2$ the contribution of the zone $\{x\colon \ell(x)\le b\coloneqq B^{-\frac{2}{3}}Z^{\frac{1}{3}}\}$ is $O(b^{-\frac{1}{2}}Z^{\frac{3}{2}})=O(Z^{\frac{4}{3}}B^{\frac{1}{3}})$ and we need to include Scott correction term. Meanwhile, the contribution of the zone $\{x\colon \ell(x)\ge b\}$ does not exceed integral (26.3.21) taken over this zone which is $\asymp Z^{\frac{4}{3}}B^{\frac{1}{3}}+Z^{\frac{3}{5}}B^{\frac{4}{5}}$ where the last term coincides with estimate for (26.3.7) if $B\ge Z^{\frac{4}{3}}$ and does not exceed $CZ^{\frac{5}{3}}$ if $B\le Z^{\frac{4}{3}}$.

Finally, if $Z^2\le B\le B^3$ we need to reset $b=Z^{-1}$ because $h=1/(\zeta\ell)$ becomes $\gtrsim 1$ inside. Then we do not need Scott correction term and the contributions of the zone $\{x\colon \ell(x)\le b\}$ to both the main part and the remainder do not exceed $C\int(\zeta^5+B\zeta^3)\,dx\asymp Z^2+B\asymp B$.

Further, the contribution of the zone $\{x\colon \ell(x)\ge b\}$ to the remainder does not exceed integral (26.3.21) taken over this zone which results in $CB+CZ^{\frac{3}{5}}B^{\frac{4}{5}}$ and the second term dominates due to assumption $B\ll Z^3$. Thus we arrive to

(26.3.22) The main therm in $\mathsf{Tr}((H_{A,W}-\nu)^-)$ is of magnitude $Z^{\frac{7}{3}}$ for $B\le Z^{\frac{4}{3}}$ and $B^{\frac{2}{5}}Z^{\frac{9}{5}}$ for $Z^{\frac{4}{3}}\le B\le Z^3$, while the remainder estimate is $O(Z^{\frac{5}{3}})$ for $B\le Z$, $O(Z^{\frac{4}{3}}B^{\frac{1}{3}})$ for $Z\le B\le Z^{\frac{4}{3}}$, and $O(Z^{\frac{4}{3}}B^{\frac{1}{3}}+Z^{\frac{3}{5}}B^{\frac{4}{5}})$ for $Z^{\frac{4}{3}}\le B\le Z^3$.

If $B\le Z^{\frac{7}{4}}$ we need to include into main part Scott correction term.

Discussion

Now let us formulate our expectations:

Remark 26.3.3. We expect

(i) Estimate (26.3.14) for $B \le Z^{\frac{4}{3}}$ and estimate (26.3.20) for $Z^{\frac{4}{3}} \le B \le Z^3$.

(ii) Furthermore, since for $B \le Z^{\frac{4}{3}}$ the main contribution to all terms needed to derive this estimate is delivered by the zone $\{x\colon \ell(x) \approx Z^{-\frac{1}{3}}\}$ and the effective magnetic field is $\mu = B\ell/\zeta \approx BZ^{-1}$ we expect improved to "o" (or better) estimate (26.3.14) if $B \ll Z$ and $a \gg Z^{-\frac{1}{3}}$ [11)].

(iii) Statement, similar to (ii) should be also true for the trace term; however then we need to include the Schwinger term.

(iv) The remainder estimate for the ground state energy is maximum of the remainder estimate for the non-trace and trace terms; therefore we expect the same remainder estimate as in (26.3.22); Statement, similar to (ii) should be also correct for the ground state energy. However then we need to include both Schwinger and Dirac terms.

(v) We expect the described remainder estimate of the trace term and the ground state energy if a is large enough; otherwise it should contain term $O(a^{-\frac{1}{2}}Z^{\frac{3}{2}})$ ifs $B \le Z^{\frac{7}{4}}$ and $a \ge Z^{-1}$ (and in this case we include Scott correction term).

Remark 26.3.4. The other difference between cases $B \le Z^{\frac{4}{3}}$ and $B \ge Z^{\frac{4}{3}}$ is that $\mu h = B\zeta^{-2} \lesssim 1$ in the former case if $\ell(x) \le \bar{r}$; however in the latter case it happens only if $\ell(x) \le B^{-1}Z$ but in the zone $\{x\colon B^{-1}Z \le \ell(x) \le B^{-\frac{2}{5}}Z^{\frac{1}{5}}\}$ an opposite inequality holds.

26.3.2 Smooth Approximation

An approach described in Subsection 26.3.1 hits two obstacles: the non-smoothness of W_B^{TF} and its possible degeneration i.e. ∇W_B^{TF} is not disjoint from 0. However non-smoothness of W_B^{TF} is due to the non-smoothness of P_B. So we want to consider first the zone where we can just replace $P_B(W+\nu)$ by $P(W+\nu)$ and therefore W_B^{TF} by some smooth function W which does not necessary coincides with W^{TF}.

Trivial Arguments

Obviously we can do this as an effective magnetic field $\mu = B\ell/\zeta \lesssim 1$. In this case we do not need assumption $W + \nu \asymp \zeta^2$ and therefore we can

[11)] Recall that $a = \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}|$ is the minimal distance between nuclei.

take $\zeta = \ell^{-4}$ as $B \lesssim Z^{\frac{4}{3}}$ and $\ell \gtrsim Z^{-\frac{1}{3}}$ and $\zeta = Z^{\frac{1}{2}}\ell^{-\frac{1}{2}}$ in all other cases. Therefore zone in question is

$$\mathcal{X}_1 \coloneqq \{x\colon \ell(x) \le r_1\} \tag{26.3.23}$$

$$\text{with}\quad r_1 = \begin{cases} B^{-\frac{1}{3}} & \text{if}\ \ 1 \le B \lesssim Z, \\ B^{-\frac{2}{3}} Z^{\frac{1}{3}} & \text{if}\ \ Z \lesssim B \lesssim Z^2. \end{cases}$$

In this zone $\mathcal{X}_1$ for such modified W we can unleash the full power of the same smooth theory as in Section 25.4 and prove easily the following

Proposition 26.3.5. *Let $1 \le B \le Z^2$. Then*

(i) A contribution of zone $\mathcal{X}_1$ defined by (26.3.23) *to*

$$\int \Big(e(x,x,\nu) - P'(W(x)+\nu)\Big)\,dx \tag{26.3.24}$$

does not exceed $CZ^{\frac{2}{3}}$ while its contribution to

$$\mathsf{D}\Big(e(x,x,\nu) - P'(W(x)+\nu), e(x,x,\nu) - P'(W(x)+\nu)\Big) \tag{26.3.25}$$

does not exceed $CZ^{\frac{5}{3}}$, and its contribution to

$$\int \Big(e_1(x,x,\nu) + P(W(x)+\nu)\Big)\,dx - \mathsf{Scott} \tag{26.3.26}$$

does not exceed $CZ^{\frac{5}{3}} + Ca^{-\frac{1}{2}} Z^{\frac{3}{2}} + CZ^{\frac{4}{3}} B^{\frac{1}{3}}$ [11], [12].

(ii) Further, if $B \ll Z$ and $a \gg Z^{-\frac{1}{3}}$ we can recover for these contributions estimates $CZ^{\frac{2}{3}}\upsilon$, $CZ^{\frac{5}{3}}\upsilon$ and $CZ^{\frac{5}{3}}\upsilon$ respectively with

$$\upsilon \coloneqq Z^{-\delta} + (aZ^{\frac{1}{3}})^{-\delta} + (BZ^{-1})^{\delta} \tag{26.3.27}$$

where expression (26.3.26) *should be modified to*

$$\int \big(e_1(x,x,\nu) - P(W(x)+\nu)\big)\,dx - \mathsf{Scott} - \mathsf{Schwinger}. \tag{26.3.28}$$

Furthermore in this case contribution of $\mathcal{X}_1$ to

$$\frac{1}{2}\int \mathsf{tr}\big(e^{\dagger}(x,y,\nu)e(x,y,\nu)\big)\,dxdy - \mathsf{Dirac} \tag{26.3.29}$$

does not exceed $CZ^{\frac{5}{3}-\delta}$.

[11] If $a \lesssim Z^{-1}$ we skip Scott and reset $a = Z^{-1}$ in the remainder estimate which become CZ^2.

Remark 26.3.6. (i) So far we should use $P(.)$ instead of $P_B(.)$ but we will prove that the same results would hold for P_B as well.

(ii) In the next subsubsections we expand this zone to one defined by $\mu \le h^{-\frac{1}{3}}$ [13)] but for trace term we still need a separate analysis as $\mu \lesssim 1$.

(iii) The same estimates hold if we replace in all expressions (26.3.24)–(26.3.28) P by P_B.

(iv) We assumed that $B \le Z^2$ since otherwise $h \gtrsim 1$ not only in $\mathcal{X}_1$ but even in $\{x\colon W^{\mathsf{TF}}(x) \ge B\}$.

(v) Note that if $r_1 \gtrsim (Z-N)_+^{-\frac{1}{3}}$ this zone (and the whole analysis) could be cut short since outside zone in question $W+\nu \ge 0$. From Chapter 25 we already know how to deal with such irregularities.

(vi) We need to assume that $a \ge Z^{-\frac{1}{3}}$ and to include the second term $(aZ^{\frac{1}{3}})^{-\delta}$ in the definition of υ only as we estimate the trace term (26.3.26).

Remark 26.3.7. (i) If either $a \ll Z^{-\frac{1}{3}}$ or $B \gg Z$ we estimated (26.3.5) by $Ca^{-\frac{1}{2}}Z^{\frac{3}{2}} + CZ^{\frac{4}{3}}B^{\frac{1}{3}}$. While the first term does not bother us since assumption $a \ll \min(Z^{-\frac{1}{3}}, B^{-\frac{1}{4}})$ is unrealistic, the second term is troublesome. Let us assume that $a \ge Z^{-\frac{1}{3}}$.

We can marginally improve this estimate of expression (26.3.26) to $CZ^{\frac{5}{3}} + o\bigl(Z^{\frac{4}{3}}B^{\frac{1}{3}}\bigr)$.

First, observe, that this term $CZ^{\frac{3}{2}}B^{\frac{1}{3}}$ appears as $b^{-\frac{1}{2}}Z^{\frac{3}{2}}$ with $b = B^{-\frac{2}{3}}Z^{\frac{2}{3}} \ll 1$. Therefore we need to estimate this way only contribution of the zone $\mathcal{Y} := \{x\colon b^{\delta} \le \ell(x)Z^{\frac{1}{3}} \le b^{-\delta}\}$ and it is sufficient to investigate the corresponding classical dynamics in the zone $\mathcal{Y}_1 := \{x\colon b^{2\delta} \le \ell(x)Z^{\frac{1}{3}} \le b^{-2\delta}\}$.

Indeed, to recover estimate we have now, we used a classical dynamics on $\Sigma := \{(x,\xi)\colon H(x,\xi)=0\}$ for time $T(x) = Z^{-1}\ell(x)^{\frac{3}{2}}$.

Further, one can see easily that along classical trajectories, starting in $\Sigma|_{\mathcal{Y}}$, $\ell(x) \le b^{-2\delta}$ for time $T = b^{-\sigma}T_0$ with $\sigma = \sigma(\delta) > 0$.

On the other hand, the invariant measure of $\Sigma_r = \{(x,\xi) \in \Sigma, \ell(x) \asymp r\}$ is $\asymp r^2 Z$ and since the spatial speed there is $O(Z^{\frac{1}{2}}r^{-\frac{1}{2}})$ we conclude that

[13)] Or even to $\mu \le h^{-\frac{3}{5}}$ under non-degeneracy assumption (26.3.35) with $\gamma = \ell$, in particular, in the atomic case.

(26.3.30) The invariant measure of the points in $\Sigma|_{\mathcal{Y}}$, such that the classical trajectories starting from them do not remain in $\mathcal{Y}_1$ for time $T = b^{-\sigma}T_0$, does not exceed $b^{2+\sigma}Z^{\frac{1}{3}}$.

(ii) Now it is sufficient to explore the classical dynamics with the Hamiltonian, corresponding to the Coulomb potential and constant magnetic field, and to prove that

(26.3.31) The invariant measure of the periodic points Σ is 0.

To do so, we need to prove that there are non-periodic trajectories, which do not hit an origin. It is sufficient to consider trajectories belonging to the plane $\{z = 0\}$; we assume that magnetic intensity is $(0, 0, B)$. See Part (iii).

(iii) To improve this estimate further we need to investigate the classical dynamics in more details, and it seems to be a daunting, if not impossible task. Indeed, while in 2D the system is completely integrable[14)], it does not seem so in 3D as we know only two first integrals, energy E and $M_z = (x\dot{y} - y\dot{x}) + \frac{1}{2}B(x^2 + y^2)$.

Formal Expansion

Now we want to expand zone $\mathcal{X}_1$. Note first that

$$P'_B(W + \nu) - P'(W + \nu) = O(B^{\frac{3}{2}}) \tag{26.3.32}$$

and

$$P_B(W + \nu) - P(W + \nu) - \kappa_1 B^2(W + \nu)^{\frac{1}{2}} = O(B^{\frac{5}{2}}). \tag{26.3.33}$$

Really, one can consider $P'_B(w)$ and $P_B(w)$ as Riemann sums for integrals $P'(w)$ and $P(w)$ respectively; see Appendix 26.A.3 for details.

However under non-degeneracy assumption $|\nabla W| \asymp \zeta^2\ell^{-1}$ we can do better with the integrated expressions.

[14)] And easily solvable in the polar coordinates since $E = \frac{1}{2}\dot{r}^2 + V^*(r)$ with effective potential $V^*(r) = \frac{1}{2}r^2(M_z r^{-2} - B/2)^2 - r^{-1}$, and the corrected angular momentum $M_z = r^2\dot{\theta} + \frac{1}{2}Br^2$. One can see easily that $V^*(r) \to +\infty$ as $r \to +0$ or $r \to +\infty$ and has a single nondegenerate minimum. Therefore along each trajectory r oscillates between $r_{\min}$ and $r_{\max}$. If all trajectories on the energy level E were periodic, then the number of oscillations was constant for increment θ equal to $2\pi n$ with some $n \in \mathbb{Z}^+$. But this is definitely not the case since the number of oscillations tends to ∞ as $M_z/B \to +\infty$.

Proposition 26.3.8. *Assume that in* $B(z,\gamma)$

$$|\nabla^\alpha W| \le C_\alpha \zeta^2 \gamma^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le n, \tag{26.3.34}$$

$$|\nabla W| \ge \epsilon \zeta^2 \gamma^{-1}, \tag{26.3.35}$$

and

$$B \le \zeta^2. \tag{26.3.36}$$

Then

$$\int \phi(x)\Big(P'_B(W(x)+\nu) - \tilde{P}'_B(W(x)+\nu)\Big)\,dx = O(B^2\zeta^{-1}\gamma^3), \tag{26.3.37}$$

$$\int \phi(x)\Big(P_B(W(x)+\nu) - \tilde{P}'_B(W(x)+\nu)\Big)\,dx = O(B^5\zeta^{-5}\gamma^3) \tag{26.3.38}$$

and

$$\mathsf{D}\Big(\phi(x)\big(P'_B(W(x)+\nu) - \tilde{P}'_B(W(x)+\nu)\big), \phi(x)\big(P'_B(W(x)+\nu) - \tilde{P}'_B(W(x)+\nu)\big)\Big) = O(B^5\zeta^{-4}\gamma^5) \tag{26.3.39}$$

with

$$\tilde{P}_B(w) \coloneqq P(w) + \big(\kappa_1 P''(w)B^2 + \kappa_2 P^{IV} B^4\big)\cdot\big(1-\varphi(w/B)\big) \tag{26.3.40}$$

where $\varphi \in \mathscr{C}^\infty([-2,2])$, $\varphi = 1$ *on* $[-1,1]$.

Proof. Rescaling $x \mapsto x\gamma^{-1}$, $w \mapsto w\zeta^{-2}$ and therefore $B \mapsto \beta = B\zeta^{-2}$ one can reduce the case to $\gamma = \zeta = 1$, $\beta \le 1$ [15]. Then estimates (26.3.37) and (26.3.38) are trivially proven by (multiple) integration by parts which integrates P_β on each step increasing its smoothness[16].

To prove estimate (26.3.39) we apply decomposition (26.3.8). Integration by parts shows that (26.3.37) with t-admissible function ϕ is $O(\beta^3 t^{\frac{3}{2}})$ if $t \ge \beta$ and therefore the contribution of the zone $\{(x,y)\colon |x-y| \asymp t\}$ is $O(\beta^6 t^3 \times t^{-4})$. Then the total contribution of the zone $\{(x,y)\colon |x-y| \ge \beta\}$ is $O(\beta^5)$. Meanwhile a total contribution of the zone $\{(x,y)\colon |x-y| \le \beta\}$ is $O(\beta^3 \times \beta^2)$.

[15] Recall that $\beta = \mu h$ with $\mu = B\gamma/\zeta$ and $h = 1/\zeta\gamma$.

[16] In fact one can prove then estimates $O(\beta^s)$ but adding correction terms $\sum \kappa_k \beta^{2k}$. However this improvement is not carried on to (26.3.39) in full.

Therefore we expect that the zone $\mathcal{X}_1$ defined by $\mu \lesssim 1$ could be expanded to the zone $\mathcal{X}_1'$ defined by $\mu \lesssim h^{-\frac{1}{3}}$ [13] or even larger[17]; furthermore, under assumption $|\nabla W| \asymp \zeta^2\ell^{-1}$ we can define $\mathcal{X}_1'$ by $\mu \lesssim h^{-\frac{3}{5}}$ or even larger[17].

Expansion: Justification

Now however we need to deal with $e(x,x,\nu)$ rather than $P_B'(W(x)+\nu)$ (etc).

Proposition 26.3.9. *Assume that in $B(z,\gamma)$ conditions* (26.3.34), $\zeta\gamma \ge 1$ *and*

$$B \le c\zeta^2(\zeta\gamma)^{-\delta} \tag{26.3.41}$$

are fulfilled. Then for γ-admissible ϕ

$$\int \phi(x)\Big(e(x,x,\nu) - \tilde{P}_B'(W(x)+\nu)\Big)\,dx = O(\zeta^2\gamma^2), \tag{26.3.42}$$

$$\int \phi(x)\Big(e_1(x,x,\tau) - \tilde{P}_B(W(x)+\nu)\Big)\,dx = O(\zeta^3\gamma) \tag{26.3.43}$$

and

$$\mathsf{D}\Big(\phi(x)\big(e(x,x,\nu) - \tilde{P}_B'(W(x)+\nu)\big), \phi(x)\big(e(x,x,\nu) - \tilde{P}_B'(W(x)+\nu)\big)\Big) = O(\zeta^4\gamma^3). \tag{26.3.44}$$

Proof. Estimates (26.3.42) and (26.3.43) are due to Chapter 13. Really, rescale $x \mapsto x\gamma^{-1}$, $\tau \mapsto \tau\zeta^{-2}$ and $h = 1 \mapsto h = \gamma^{-1}\zeta^{-1}$, $B \mapsto \mu = B\gamma\zeta^{-1}$.

To prove (26.3.44) let us apply decomposition (26.3.8); then according to (26.3.42) $J(t)$ (defined as expression (26.3.42) with $t\gamma$-admissible ϕ_t) does not exceed $C\zeta^2\gamma^2t^2$ as long as $t\zeta\gamma \ge 1$; therefore contribution of zone $\{(x,y)\colon |x-y| \asymp t\}$ into the left-hand expression of (26.3.44) does not exceed $C(\zeta^2\gamma^2t^2)^2 \times t^{-4}\gamma^{-1} \asymp C\zeta^4\gamma^3$.

Then summation over $t \ge \mu^{-1} = B^{-1}\gamma^{-1}\zeta$ returns $C\zeta^4\gamma^3\int t^{-1}\,dt \asymp C\zeta^4\gamma^3\log\mu$ (we assume that $\mu \ge 2$; case $\mu \lesssim 2$ has been covered already). So, the total contribution of zone $\{(x,y)\colon |x-y| \ge \mu^{-1}\}$ does not exceed $C\zeta^4\gamma^3\log\mu$.

---

[17] We do not need for each ℓ have a sharp remainder estimates but need only them to sum to a sharp estimate.

Let us get rid of the logarithmic factor. Returning back to $B(z,t)$ stretched to $B(0,1)$ one can see easily that conditions of Proposition 13.7.25 are fulfilled as well with $T = \min\bigl(t^{-\delta}, h^{-\delta}t^{\delta}\bigr)$ and thus $|J(t)| \le C(ht^{-1})^{-2}T^{-1} \le Ch^{-2}t^2\bigl(t^{\delta} + h^{\delta}t^{-\delta}\bigr)$. Plugging into (26.3.8) we get

$$Ch^{-4}\gamma^{-1}\int_{\mu^{-1}}^{1} t^{-1}\bigl(t^{\delta} + h^{\delta}t^{-\delta}\bigr)\,dt \asymp Ch^{-4}\gamma^{-1} = C\zeta^4\gamma^3.$$

On the other hand, in zone $t \le \mu^{-1}$ we use the trivial estimate

$$e(x,x,\nu) - P'(W(x)+\nu) = O(\mu\zeta^2\gamma^2)$$

(due to simple rescaling $x \mapsto \mu x$) and its contribution to the left-hand expression of (26.3.44) does not exceed $C(\mu\zeta^2\gamma^2)^2 \times \mu^{-2}\gamma^{-1} \asymp C\zeta^4\gamma^3$. □

Combining with estimates (26.3.32) and (26.3.33) we arrive to Statement (i) below; combining with Proposition 26.3.7 to Statement (ii):

Corollary 26.3.10. *Assume that in $B(z,\gamma)$ conditions* (26.3.34) *and $\zeta\gamma \ge 1$ are fulfilled. Let ϕ be γ-admissible function.*

(i) Let

$$B \le c\zeta^{\frac{4}{3}}\gamma^{-\frac{2}{3}}; \tag{26.3.45}$$

then

$$\int \phi(x)\Bigl(e(x,x,\nu) - \tilde{P}'_B(W(x)+\nu)\Bigr)\,dx = O(\zeta^2\gamma^2), \tag{26.3.46}$$

$$\int \phi(x)\Bigl(e_1(x,x,\tau) - \tilde{P}_B(W(x)+\nu)\Bigr)\,dx = O(\zeta^3\gamma) \tag{26.3.47}$$

and

$$\mathsf{D}\Bigl(\phi(x)\bigl(e(x,x,\nu) - \tilde{P}'_B(W(x)+\nu)\bigr), \phi(x)\bigl(e(x,x,\nu) - \tilde{P}'_B(W(x)+\nu)\bigr)\Bigr) = O(\zeta^4\gamma^3). \tag{26.3.48}$$

(ii) Let assumption (26.3.35) *be fulfilled and*

$$B \le c\zeta^{\frac{8}{5}}\gamma^{-\frac{2}{5}}. \tag{26.3.49}$$

Then (26.3.46)–(26.3.48) *hold.*

26.3.3 Rough Approximation

Unless our analysis has been cut short with $r_1 \gtrsim (Z-N)_+^{-\frac{1}{3}}$, we need to consider the zone $\{x\colon \ell(x) \ge r_1\}$ with redefined r_1, so that this zone is described by $\mu \gtrsim h^{-\frac{1}{3}}$ or $\mu \gtrsim h^{-\frac{3}{5}}$ in the general or non-degenerate (i.e. satisfying assumption (26.3.35)) cases respectively.

In this zone the replacement of P_B by P and thus W_B^{TF} by some smooth function leads to the error which is too large. Therefore instead in this zone we consider $\varepsilon\ell$-mollification of W_B^{TF} with $\varepsilon \ll 1$ (after rescaling $x \mapsto x/\ell$). In contrast to potentials considered in Chapter 18 function W_B^{TF} is more regular.

Properties of Mollification

First, recall regularity properties of W_B^{TF}:

Proposition 26.3.11. *W_B^{TF} have the following properties:*

$$|\nabla^\alpha W_B^{\mathsf{TF}}(x)| \le c_\alpha \zeta(x)^2 \ell(x)^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le 2, \tag{26.3.50}$$

$$\begin{aligned} |\nabla^\alpha \bigl(W_B^{\mathsf{TF}}(x) - W_B^{\mathsf{TF}}(y)\bigr)| \le {}& \\ & c_0 B\ell(x)^{-\frac{5}{2}}|x-y|^{\frac{1}{2}} + c_0\zeta(x)^2\ell(x)^{-3}|x-y| \\ & \forall |\alpha| = 2 \quad \forall x,y\colon |x-y| \le \epsilon\ell(x) \end{aligned} \tag{26.3.51}$$

where we recall

$$\zeta(x) = \min\bigl(Z^{\frac{1}{2}}\ell(x)^{-\frac{1}{2}}, \ell(x)^{-2}\bigr) \qquad \text{if } \ B \le Z^{\frac{4}{3}}, \tag{26.3.52}$$

$$\zeta(x) = Z^{\frac{1}{2}}\ell(x)^{-\frac{1}{2}} \qquad \text{if } \ B \ge Z^{\frac{4}{3}}; \tag{26.3.53}$$

Proof. This proof is rather obvious corollary of the Thomas-Fermi equation (26.2.3). See also arguments below. □

Let us consider $B(z,\ell(z))$ with $\zeta^2 \gtrsim B$ and rescale $x \mapsto x\ell^{-1}$, $W \mapsto w = \zeta^{-2}(W+\nu)$ (where we included ν for a convenience). After such rescaling $w \in \mathscr{C}^{\frac{5}{2}}$ uniformly, but there is more: Thomas-Fermi equation (26.2.3) translates into

$$\frac{1}{4\pi}\Delta w = \ell^2 P'_\beta(w) = \ell^2\zeta P'(w) + \ell^2\zeta\bigl(P'_\beta(w) - P'(w)\bigr) \tag{26.3.54}$$

with $\beta = B\zeta^{-2}$; observe that $P'_B(W)$ is positively homogeneous of degree 3 with respect to (W, B).

Note that parameter $\eta := \zeta\ell^2 \lesssim 1$ and $\eta \asymp 1$ if and only if $B \lesssim Z^{\frac{4}{3}}$ and $\ell \gtrsim Z^{-\frac{4}{3}}$ (in which case $\zeta \asymp \ell^{-2}$).

Also note that the first term and the second terms in the right-hand expression of (26.3.54) belong to $\mathscr{C}^{\frac{5}{2}}$ and $\beta\eta\mathscr{C}^{\frac{1}{2}}$ respectively uniformly[18] and

$$\beta\eta = \beta\zeta\ell^2 = B\zeta^{-1}\ell^2, \qquad \eta := \zeta\ell^2 \qquad \text{if } \beta \lesssim 1. \tag{26.3.55}$$

Because of this $w \in \mathscr{C}^{\frac{9}{2}} \oplus \beta\eta\mathscr{C}^{\frac{5}{2}}$ again uniformly. Iterating, we conclude that $w \in \mathscr{C}^n \oplus \beta\eta\mathscr{C}^{\frac{5}{2}}$ with arbitrarily large exponent n.

On the other hand, if $B \gtrsim \zeta^2$ (i.e. $\beta \gtrsim 1$) without invoking P'_B one can prove easily that $w \in \eta\mathscr{C}^{\frac{5}{2}}$ with

$$\eta := \beta\zeta\ell^2 = B\zeta^{-1}\ell^2 \qquad \text{if } \beta \gtrsim 1. \tag{26.3.55}'$$

Therefore we have proven

(26.3.56) $w \in \mathscr{C}^n \oplus \beta\eta\mathscr{C}^{\frac{5}{2}}$ with arbitrarily large exponent n as $\beta \lesssim 1$ and $w \in \eta\mathscr{C}^{\frac{5}{2}}$ as $\beta \gtrsim 1$

and one can see easily that

(26.3.57) Parameter $\eta = B\zeta^{-1}\ell^2$ is $O(1)$ and $\eta \asymp 1$ iff <u>either</u> $B \le Z^{\frac{4}{3}}$ and $\ell \asymp B^{-\frac{1}{4}}$ <u>or</u> $B \ge Z^{\frac{4}{3}}$ and $\ell \asymp B^{-\frac{2}{5}}Z^{\frac{1}{5}}$ (i.e. near border of $\mathsf{supp}(\rho_B^{\mathsf{TF}})$, uncut by ν).

Remark 26.3.12. It may seem strange to define η differently as $\beta \lesssim 1$ and $\beta \gtrsim 1$ but there is a good reason for this when we consider the case of $M \ge 2$. Anyway, η is the magnitude of the right-hand expression of (26.3.54).

Proposition 26.3.13. *(i) Let w_ε be a ε-mollification of w with $\varepsilon \lesssim \min(\beta, h^\delta)$ (recall that $h = 1/(\zeta\ell)$). Then if $\beta \lesssim 1$ the following estimates hold:*

$$|\nabla^\alpha(w - w_\varepsilon)| \le c_\alpha\beta\eta\varepsilon^{\frac{5}{2}-|\alpha|} \qquad \forall \alpha : |\alpha| \le 2, \tag{26.3.58}$$

$$|P_\beta(w) - P_\beta(w_\varepsilon)| \le c\beta\eta\varepsilon^{\frac{5}{2}} \tag{26.3.59}$$

and

$$|P'_\beta(w) - P'_\beta(w_\varepsilon)| \le c\beta^{\frac{3}{2}}\eta^{\frac{1}{2}}\varepsilon^{\frac{5}{4}} + c\beta\eta\varepsilon^{\frac{5}{2}}; \tag{26.3.60}$$

[18] I.e. norms do not depend on any parameters.

(ii) On the other hand, if $\beta \gtrsim 1$ *the right-hand expressions of* (26.3.58)–(26.3.60) *should be replaced by the similar expressions albeit without* β*:*

$$|\nabla^{\alpha}(w - w_{\varepsilon})| \le c_{\alpha}\eta\varepsilon^{\frac{5}{2}-|\alpha|} \qquad \forall \alpha : |\alpha| \le 2, \tag{26.3.58}'$$

$$|P_{\beta}(w) - P_{\beta}(w_{\varepsilon})| \le c\eta\varepsilon^{\frac{5}{2}} \tag{26.3.59}'$$

and

$$|P'_{\beta}(w) - P'_{\beta}(w_{\varepsilon})| \le c\eta^{\frac{1}{2}}\varepsilon^{\frac{5}{4}}. \tag{26.3.60}'$$

(iii) Further, under assumption $|\nabla w| \asymp 1$ *in both cases*

$$|\int \phi(x)\big(P_{\beta}(w) - P_{\beta}(w_{\varepsilon})\big)\,dx| \le c\eta\varepsilon^{\frac{7}{2}}, \tag{26.3.61}$$

$$|\int \phi(x)\big(P'_{\beta}(w) - P'_{\beta}(w_{\varepsilon})\big)\,dx| \le c\eta\varepsilon^{\frac{9}{4}} \tag{26.3.62}$$

and

$$\mathsf{D}\big(\phi(P'_{\beta}(w) - P'_{\beta}(w_{\varepsilon})),\, \phi(P'_{\beta}(w) - P'_{\beta}(w_{\varepsilon}))\big) \le c\eta^{2}\varepsilon^{\frac{9}{2}}. \tag{26.3.63}$$

Proof. Proof of Statement (i) is trivial; in particular, we observe that $\eta\varepsilon^{\frac{5}{2}} \lesssim \beta$.

Proof of Statement (iii) is also easy since then w_{ε} is different from w on the set of measure $\asymp \beta^{-1}\varepsilon$ if $\beta \le C_0$ and on the set of measure $\asymp \varepsilon$ if $\beta \ge C_0$. Actually w is uniformly smooth if $\beta \gtrsim 1$ and $\ell(x) \le \epsilon\bar{r}$ and we do not need any mollification here.

One definitely can improve estimates (26.3.61)–(26.3.63) but we do not need it. □

Consider now the analytical expressions and estimate the semiclassical errors.

Remark 26.3.14. (i) From now on until the end of this Section we assume that $M = 1$ to avoid possible degenerations.

(ii) Recall that we can reduce operator with mollified potential to a canonical form provided $\varepsilon \ge C(\mu^{-1}h)^{\frac{1}{2}}|\log\mu|$ (see Section 18.7). However here we will have a much better estimate since we will take $\varepsilon \ge h^{\frac{2}{3}-\delta}$.

Charge Term

Let us consider the *charge term* i.e. expression $\int e(x,x,\nu)\,dx = (\mathsf{Tr}\,\theta(\nu - H))$.

Regular Zone. Then the results of Section 18.9 implies that as

$$W+\nu \asymp \zeta^2 \tag{26.3.64}$$

and

$$|\nabla W| \asymp \zeta^2\ell^{-1} \tag{26.3.65}$$

contribution of the ball $B(x,\ell(x))$ to expression (26.3.24) does not exceed $C(1+\mu h)h^{-2} \asymp C\zeta^2\ell^2 + CB\ell^2$ exactly as in the mock proof.

Then summation with respect to ℓ-partition in this zone results in $CB^{\frac{2}{3}}$ as $B\le Z$, $CZ^{\frac{2}{3}}$ as $Z\le B\le Z^{\frac{4}{3}}$ and $CB^{\frac{1}{5}}Z^{\frac{2}{5}}$ as $Z^{\frac{4}{3}}\le B\le Z^3$.

Remark 26.3.15. (i) Condition (26.3.64) is fulfilled as $\ell(x)\le \epsilon\bar{r}$.

(ii) Further, since $M=1$ both conditions (26.3.64) and (26.3.65) are fulfilled if $|x|\le (1-\epsilon)\bar{r}_m$ (we pick up $\mathsf{y}_m=0$ and $\bar{r}_m$ exact radius of $\mathsf{supp}(\rho_B^{\mathsf{TF}})$).

Border Strip. Now we need to consider the contribution of the border strip $\mathcal{Y}:=\{x\colon \gamma(x)\le\epsilon\}$ with $\gamma(x)=\epsilon(\bar{r}-|x|)\bar{r}^{-1}$ and $\bar{r}:=\bar{r}_m$. Here $\ell\asymp\bar{r}$, $\zeta\asymp\bar{\zeta}$ with

$$\bar{r}\asymp \begin{cases} (Z-N)_+^{-\frac{1}{3}} & \text{if } B\le (Z-N)_+^{\frac{4}{3}},\\ B^{-\frac{1}{4}} & \text{if } (Z-N)_+^{\frac{4}{3}}\le B\le Z^{\frac{4}{3}},\\ Z^{\frac{1}{5}}B^{-\frac{2}{5}} & \text{if } Z^{\frac{4}{3}}\le B\le CZ^3 \end{cases} \tag{26.3.66}$$

and

$$\bar{\zeta}\asymp \begin{cases} (Z-N)_+^{\frac{2}{3}} & \text{if } B\le (Z-N)_+^{\frac{4}{3}},\\ B^{\frac{1}{2}} & \text{if } (Z-N)_+^{\frac{4}{3}}\le B\le Z^{\frac{4}{3}},\\ Z^{\frac{2}{5}}B^{\frac{1}{5}} & \text{if } Z^{\frac{4}{3}}\le B\le CZ^3 \end{cases} \tag{26.3.67}$$

and scaling we get $\mu=B\bar{r}\bar{\zeta}^{-1}$ and $h=\bar{\zeta}^{-1}\bar{r}^{-1}$ here.

Let us consider first the case $\nu=0$. Then both conditions (26.3.64) and (26.3.65) are fulfilled albeit with $\ell_1=\gamma(x)\bar{r}$ and $\varsigma(x)=\bar{\zeta}\gamma(x)^2$ instead of ℓ and ζ.

Thus if $\varsigma\ell_1\ge 1$ (i.e. $\gamma\ge\bar{\gamma}:=h^{\frac{1}{3}}$), the contribution of the ball $B(x,\gamma(x)\bar{r})$ to the remainder does not exceed $C\mu h^{-1}\gamma^2$ [19] and therefore the total contribution of zone $\mathcal{Y}_1:=\{x\colon \bar{\gamma}\le\gamma(x)\le\epsilon\bar{r}\}$ to the remainder does not

[19] Really, after additional rescaling $x\mapsto x\gamma^{-1}$, $w\mapsto w\gamma^{-2}$ we have $\mu_1=\mu\gamma^{-1}$, $h_1=h\gamma^{-3}$ and $\mu_1h_1^{-1}=\mu h^{-1}\gamma^2$.

exceed

$$C\mu h^{-1}\int \gamma(x)^{-1}\,dx \asymp C\mu h^{-1}|\log h| = CB\bar{r}^2|\log h| \tag{26.3.68}$$

which is $O(Z^{\frac{2}{3}})$ as long as $B \le Z^{\frac{4}{3}}(\log Z)^{-2}$.

Further, the same approach works if $|\nu| \lesssim \bar{\zeta}^2\bar{\gamma}^3 \asymp \bar{\zeta}^2 h \asymp \bar{\zeta}\bar{r}^{-1}$ which is equivalent to $(Z-N)_+ \le \bar{\zeta}$ (then $|\nabla W| \asymp \varsigma^2\ell_1^{-1}$ if $\gamma(x) \ge \bar{\gamma}$) and also if this condition is violated but $|\nu| \le \bar{\zeta}^2$; in the latter case we need to pick up $\bar{\gamma} = \bar{\gamma}_1 := |\nu|^{\frac{1}{3}}\bar{\zeta}^{-\frac{2}{3}}$.

To get rid of the logarithmic factor let us consider propagation. Recall that it goes along magnetic lines i.e. that (x_1, x_2) remains constant. Let us consider propagation in the direction in which $|x_3|$ increases (i.e. $\gamma(x)$ decays); we do not need to consider zone $\mathcal{Y}_1 \cap \{|x_3| \le Z^{-\delta}\bar{r}\}$ since contribution of this zone (26.3.68) is $o(B\bar{r}^2)$.

One can see easily that we can follow dynamics which does not return for a time $T_1^*(x) := T_1(x)(\gamma(x)/\bar{\gamma})^{\delta}$ where $T(x) \asymp \ell_1^{-1}\varsigma^{-1} \asymp \bar{r}\bar{\zeta}^{-1}\gamma^{-1}$ is a time required for this dynamics to pass though $B(x, \ell_1(x))$. Therefore one can replace (26.3.68) by

$$C\mu h^{-1}\int_{\{x:\,\gamma(x)\ge\bar{\gamma}\}} \bar{\gamma}^{\delta}\gamma(x)^{-1-\delta}\,dx \asymp C\mu h^{-1} = CB\bar{r}^2. \tag{26.3.69}$$

Further, as $|\nu| \ge B\bar{r}$ we need also to consider zone $\mathcal{Y}_0 := \{x:\,\gamma(x) \le \bar{\gamma}\}$. In this zone we take $\ell_1 = \bar{\ell}_1 = \bar{\gamma}\bar{r}$ and $\varsigma = \bar{\varsigma} = (|\nu|\bar{\gamma})^{\frac{1}{2}}$ with $\ell_1\varsigma \ge 1$ and since $|\nabla W| \asymp \varsigma^2\ell_1^{-1}$, contribution of $B(x, \ell_1(x))$ to the remainder does not exceed $CB\bar{\ell}_1^2$ and the total contribution of $\mathcal{Y}_2$ does not exceed $CB\bar{r}^2$ which what exactly we achieved for zone $\mathcal{Y}_1$ after we got rid of logarithm. We take mollification parameter $\varepsilon = \bar{\varsigma}^{-1}Z^{\delta}$ [20].

Furthermore, zone $\mathcal{Y}_3 = \{x:\,|x| \ge \bar{r} + \bar{\ell}_1\}$ is classically forbidden. So we can take here

$$\ell_1(x) = \epsilon(|x| - \bar{r}), \qquad \varsigma(x) = \min\bigl(\bar{\varsigma}\bar{\ell}_1^{-\frac{1}{2}}\ell_1(x)^{\frac{1}{2}}, |\nu|^{\frac{1}{2}}\bigr) \tag{26.3.70}$$

and prove easily that its contribution also does not exceed $CB\bar{r}^2$.

Returning to the case $|\nu| \lesssim \bar{\zeta}$ we see that the contribution of zone $\mathcal{Y}_2$ to the remainder does not exceed $CB\bar{r}^2$ because effective semiclassical

[20] One can see easily that the resulting errors in the expressions(26.3.24) and (26.3.25)–(26.3.26) will not violate our claims.

parameter here is $h_1 = 1$ and non-degeneracy condition is of no concern for us. We take mollification parameter $\varepsilon = \bar{\varsigma}^{-1} Z^{\delta}$ [20].

Moreover, we can modify W in $\mathcal{Y}_2$ (make it negative there) so that this zone would be classically forbidden with ℓ_1, ς defined by (26.3.70) with $|\nu|$ replaced by $\bar{\zeta}$.

Finally in the case $B \le |\nu|$ (i. e. $B \le C(Z-N)_+^{\frac{4}{3}}$ we can apply the above arguments with $\bar{\gamma} = 1$ and arrive to the same result. Therefore we proved in all cases

(26.3.71) If $M = 1$ the total contribution of the border strip $\mathcal{Y}$ to the remainder in the charge term is $O(B\bar{r}^2)$ which does not exceed $CB^{\frac{1}{2}}$ as $B \le Z^{\frac{4}{3}}$ and $CB^{\frac{1}{5}} Z^{\frac{2}{5}}$ if $Z^{\frac{4}{3}} \le B \le Z^3$.

Conclusion. If $Z^2 \le B \le Z^3$ we need to estimate also contribution of the *inner core* $\mathcal{X}_0 := \{x\colon \ell(x) \le CZ^{-1}\}$. By means of variational methods we will prove (see Corollary 26.A.5)

(26.3.72) If $Z^2 \le B \le Z^3$ the contributions of $\mathcal{X}_0$ to both $\int e(x,x,\nu)\,dx$ and $\int P'_B(W(x)+\nu)\,dx$ do not exceed CBZ^{-2}.

Then we arrive to the following

Proposition 26.3.16. *Let $M = 1$. Then*

(i) For constructed above potential W expression (26.3.24) *does not exceed $CZ^{\frac{2}{3}} + CB^{\frac{1}{5}} Z^{\frac{2}{5}}$.*

(ii) If $B \le Z$ expression (26.3.24) *does not exceed $C(B+1)^{\delta} Z^{\frac{2}{3}-\delta}$.*

Trace Term

Let us consider the *trace term* i.e. expression $\int e_1(x,x,\nu)\,dx = \mathsf{Tr}((H-\nu)^-)$.

Regular Zone. Here again let us consider first zone where $|x| \le (1-\epsilon)\bar{r}$. Then the contribution of $B(x, \ell(x))$ to the Tauberian remainder[21] does not exceed $C\zeta^2(h^{-1}+\mu) \asymp C\zeta^3\ell + CB\zeta\ell$ as in the mock proof and the summation over zone results in $CZ^{\frac{5}{3}} + CZ^{\frac{4}{3}} B^{\frac{1}{3}} + CZ^{\frac{3}{5}} B^{\frac{4}{5}}$.

[21] We will consider a bit later transition from the Tauberian expression to the magnetic Weyl expression.

Border Strip. Again in zone $\mathcal{Y}_1$ contribution of $B(x,\gamma(x))$ does not exceed $CB\varsigma\ell_1$ and the summation over this zone returns

$$CB\int \varsigma\ell_1^{-2}\,dx \tag{26.3.73}$$

and plugging $\ell_1 = \bar{r}\gamma$ and $\varsigma = \bar{\zeta}\gamma^2$ results in $CB^{\frac{5}{4}}$ as $B \lesssim Z^{\frac{4}{3}}$ and $CB^{\frac{4}{5}}Z^{\frac{3}{5}}$ otherwise. The analysis of zone $\mathcal{Y}_0$ if there $\mathcal{Y}_2 = \emptyset$ is also easy.

Consider zones $\mathcal{Y}_2$ and $\mathcal{Y}_0$. The same arguments as before imply that their contributions to the remainder do not exceed $CB\bar{r}^2\bar{\varsigma}\bar{\ell}_1^{-1}$ which is what we got before.

Justification: from Tauberian to Magnetic Weyl Expression.

Case $\mu h \le C_0$. We need to prove that with the announced error we can replace the Tauberian expression by magnetic Weyl one. Note that the canonical form of $\zeta^{-2}H_{A,W}$ as described in Sections 13.3 and 18.7 is

$$\begin{aligned}\mathcal{H} = \mathcal{H}_0 + {}& \\ & \mu^{-2}\omega_1(x_1,\mu^{-1}hD_1,x_3) + \mu^{-2}\omega_2(x_1,\mu^{-1}hD_1,x_3)(x_2^2+\mu^2h^2D_2^2) \\ & + \mu^{-1}h\omega_3(x_1,\mu^{-1}hD_1,x_3) + O\big(\mu^{-3}h(\gamma+\mu^{-1})^{-\frac{3}{2}} + \mu^{-4}\big)\end{aligned} \tag{26.3.74}$$

with

$$\mathcal{H}_0 = h^2D_3^2 - (x_2^2+\mu^2h^2D_2^2 \pm \mu h) + w(x_1,\mu^{-1}hD_1,x_3) \tag{26.3.75}$$

and

$$\gamma = \epsilon \min_j |w - 2j\mu h| \tag{26.3.76}$$

where we used the fact that $w \in \mu h\mathscr{C}^{\frac{5}{2}} + \mathscr{C}^n$, $\mu^{-3}h = \mu^{-4}\cdot\mu h$. Here we have signs "+" and "−" on $q/2$ of the diagonal elements equally.

Then the Tauberian expression is

$$\begin{aligned}\mathsf{const}\cdot\mu h^{-2}\int \sum_{j\ge 0}\big(w - 2j\mu h - \mu^{-2}\omega_1 - 2j\mu^{-1}h\omega_2\big)_+^{\frac{3}{2}}\times & \\ \big(\psi + \mu^{-2}\psi_1 + 2j\mu^{-1}h\psi_2\big)\,dx & \end{aligned} \tag{26.3.77}$$

where term with $j=0$ enters with the weight $\frac{1}{2}$ and an error does not exceed

$$Ch^{-3}\Big(\mu^{-4}+\mu^{-3}h\int(\gamma+\mu^{-1})^{-\frac{3}{2}}\,dx\Big)\asymp C\mu^{-\frac{7}{2}}h^{-3}$$

because an integral does not exceed $C\mu^{\frac{1}{2}}(\mu h)^{-1}$; since $\mu\ge h^{-\frac{3}{5}}$ this error does not exceed $Ch^{-\frac{9}{10}}$ which is better than $O(h^{-1})$.

On the other hand, if we consider the difference between (26.3.77) and the same expression with $\omega_1=\omega_2=\psi_1=\psi_2=0$ and consider it as a Riemannian sum and replace it by an integral we get $G\mu^{-2}h^{-3}$ with an error not exceeding $C\mu^{-4}(\mu h)^{\frac{1}{2}}h^{-3}$ which is even less. Therefore (26.3.77) becomes

$$\int P_{\mu h}(w)\psi\,dx+G\mu^{-2}h^{-3}$$

and comparing with the result if $\mu\asymp h^{-\frac{3}{5}}$ when we get the same answer albeit with $G=0$ we conclude that G *must* be 0. This concludes the justification in $\mathcal{X}_2$.

Case $\mu h\ge C_0$. In this case we need a simplified version of (26.3.74) $\mathcal{H}=\mathcal{H}_0+O(\mu^{-1}h)$ and we need to consider only $j=0$ and replacing $\mathcal{H}$ by $\mathcal{H}_0$ brings and error $C\mu h^{-2}\times\mu^{-1}h=O(h^{-1})$. This takes care of $\mathcal{X}_2$ and after scaling of $\mathcal{Y}$.

Conclusion. As $Z^2\le B\le Z^3$ we need to estimate also contribution of $\mathcal{X}_0=\{x\colon \ell(x)\le CZ^{-1}\}$. By means of variational methods we will prove (see Corollary 26.A.5)

(26.3.78) For $Z^2\le B\le Z^3$ the contributions of $\mathcal{X}_0$ to both $\int e_1(x,x,\nu)\,dx$ and $\int P'_B(W(x)+\nu)\,dx$ do not exceed CB.

Then we arrive to the following

Proposition 26.3.17. *Let $M=1$. Then*

(i) For constructed above potential W expression (26.3.26) *does not exceed $CZ^{\frac{5}{3}}+CZ^{\frac{4}{3}}B^{\frac{1}{3}}+CZ^{\frac{3}{5}}B^{\frac{4}{5}}$.*

(ii) If $B\le Z$ expression (26.3.26) *does not exceed $C(B+1)^{\delta}Z^{\frac{5}{3}-\delta}$ (but one should subtract a Schwinger term from the trace).*

Semiclassical D-Term: Local Theory

Unfortunately, we do not have any non-smooth theory (cf. Section 16.8) here so far but actually we almost do not need it since singularities are rather rare. Let us introduce a scaling function (26.3.76) and consider

$$J_\lambda(z) = \int \phi_{z,\lambda}(x)\big(e(x,x,\tau) - P_\beta(w(x)+\tau)\big)\,dx \tag{26.3.79}$$

with $\phi_{z,\lambda}(x) = \phi(\lambda^{-1}(x-z))$ and $\lambda \le \gamma(z)$. Scaling $x \mapsto \lambda^{-1}(x-z)$ we have $\mu \mapsto \mu' = \lambda\mu$ and $h \mapsto h' = \lambda^{-1}h$.

Then, according to Section 13.5

$$|J_\lambda(z)| \le Ch'^{-2}(1+\mu'h') \asymp C\lambda^2 h^{-2}(1+\mu h) \tag{26.3.80}$$

as long as $\lambda \ge h$.

Really, a transition from the Tauberian decomposition to magnetic Weyl one in this case is easy: skipping all perturbation terms $O(\mu^{-2}+\mu^{-1}h)$ in (26.3.74) and also setting $\psi_1 = \psi_2 = 0$ results in an error $O\big(\mu^{-2}h^{-3}+h^{-1}\big)$ in (26.3.77)-like expression albeit with the power $\frac12$ rather than $\frac32$ and without integration:

$$\mathsf{const}\cdot \mu h^{-2}\sum_{j\ge 0}\big(w - 2j\mu h - \mu^{-2}\omega_1 - 2j\mu^{-1}h\omega_2\big)_+^{\frac12}\times \big(\psi + \mu^{-2}\psi_1 + 2j\mu^{-1}h\psi_2\big); \tag{26.3.81}$$

scaling produces expression smaller than (26.3.80).

Let us apply this estimate (26.3.80) to the Fefferman–de Llave decomposition (26.3.8).

Case $\mu \le C_0 h^{-1}$.

(i) Consider first a pair (z,z') such that $|z'-z''| \le \epsilon_0\gamma(z')$; then also $|z'-z''| \le \epsilon_0\gamma(z'')$ and we take $\lambda = \epsilon|z'-z''|$.

Then in the virtue of (26.3.80) the total contribution to D-term of all such pairs belonging to $B(z,\gamma(z))$, and with $|z'-z''| \asymp \lambda$ does not exceed

$$C\gamma^3\lambda^{-3}\times\lambda^{-1}\times\lambda^2h^{-4}(1+\mu h)^2 \asymp C\gamma^3h^{-4}(1+\mu h)^2 \tag{26.3.82}$$

where $C\gamma^3\lambda^{-3}$ estimate the number of such pairs, λ^{-1} the inverse distance between them, and $C\lambda^2h^{-2}(1+\mu h)$ is the right-hand expression of (26.3.80).

Then summation over $\lambda \in (\mu^{-1}, \gamma)$ results in $C\gamma^3(1+\mu h)^2 h^{-4}|\log(\mu\gamma)|$.

Further, summation over all balls $B(z,\gamma) \subset B(0,1)$ with $\gamma(z) \asymp \gamma$ results in $C(\mu h)^{-1}\gamma h^{-4}|\log(\mu\gamma)|$ since there are $\asymp (\mu h)^{-1}\gamma^{-2}$ such balls due to non-degeneracy assumption $|\nabla w| \asymp 1$. Summation over $\gamma \in (\mu^{-1}, \mu h)$ results in $Ch^{-4}|\log(\mu^2 h)|$.

As $\lambda \le \mu^{-1}$ we can apply standard non-magnetic methods without Fefferman–de Llave decomposition (26.3.8). Coefficients are smooth after scaling as long as $\varepsilon \ge \mu^{-1}$.

(ii) Consider *disjoint* pairs (z', z'') with $|z'-z''| \ge \max\bigl(\gamma(z'), \gamma(z'')\bigr)$. Here estimate (26.3.80) is not sufficient and it should be replaced by

$$|J_\gamma(z)| \le C\lambda^3 h^{-2}(1+\mu h) \tag{26.3.83}$$

as long as

$$\gamma \ge h^{\frac{2}{3}-\delta}. \tag{26.3.84}$$

Really, the shift for time T with respect to ξ_3 is $\asymp T$ provided $|\nabla_{x_3} w| \asymp 1$ and this shift is observable if $T \times \gamma \gtrsim h^{1-\delta}$. Similarly, in the canonical form the shift for time T with respect to $\mu^{-1}\xi_i$ is $\asymp \mu^{-1}T$ provided $|\nabla_{x_i} w| \asymp 1$ and this shift is observable if $\mu^{-1}T \times \gamma \gtrsim \mu^{-1}h^{1-\delta}$. In both cases shift with $T \in (\gamma^{\frac12}, \epsilon_0)$ is observable under assumption (26.3.84) and therefore we can extend $T \asymp \gamma^{\frac12}$ to $T \asymp 1$.

Note that for $\varepsilon \ge h^{\frac{2}{3}-\delta}$ assumption (26.3.84) is fulfilled automatically. Then contribution of each disjoint pair to D-term does not exceed

$$Ch^{-4}(1+\mu h)^2\gamma(z')^3\gamma(z'')^3|z'-z''|^{-1}$$

and the total contribution does not exceed

$$Ch^{-4}(1+\mu h)^2 \iint |z'-z''|^{-1}\,dz'dz'' \asymp Ch^{-4}(1+\mu h)^2.$$

(iii) To shed of logarithm in (i) we need a slightly better estimate than (26.3.80). The same arguments as in Part (ii) result in

$$|J_\lambda(z)| \le C\lambda^2 h^{-2}(1+\mu h)\cdot(1+\lambda\gamma/h)^{-\delta}. \tag{26.3.85}$$

Really, we just advance from time $T \asymp \lambda$ to $T \asymp \lambda(1+\lambda\gamma/h)^{\delta}$.

Then the same factor is acquired by the right-hand expression of (26.3.82) and the summation with respect to $\lambda \in (h\gamma^{-1}, \gamma)$ results in $C\gamma^3(1+\mu h)^2h^{-4}$ but summation with respect to $\lambda \in (\mu^{-1}, h\gamma^{-1})$ results

$$C\gamma^3(1+\mu h)^2h^{-4}\bigl(1+|\log(\mu h\gamma^{-1})|\bigr).$$

Further, summation over all balls $B(z,\gamma) \subset B(0,1)$ with $\gamma(z) \asymp \gamma$ results in $C(\mu h)^{-1}\gamma(1+\mu h)^2h^{-4}\bigl(1+|\log(\mu h\gamma^{-1})|\bigr)$ and, finally, summation over $\gamma \lesssim \mu h$ results in $Ch^{-4}(1+\mu h)^2$.

Note that in all cases perturbation terms in (26.3.74) and (26.3.81) result in the error not exceeding the announced one.

Case $\mu \ge C_0h^{-1}$. So far factor $(1+\mu h)$ was for a compatibility only. Now it is important.

Exactly the same arguments work as $\mu \ge C_0h^{-1}$ with a minor modifications:

(a) $\gamma(x)$ now is defined by (26.3.76) with $j=0$ and its upper bound is 1 rather than μh.

(b) Also the number of γ-balls is $\asymp \gamma^{-2}$ rather than $\asymp (\mu h)^{-1}\gamma^{-2}$;

(c) λ now runs from h to γ in (i) and (iii).

(d) We need to estimate contribution of pairs (z',z'') with $|z'-z''| \le h$. One can see easily that $e(x,x,\tau) \le \mu h^{-2}$ and therefore the total contribution of these pairs does not exceed $C\mu^2h^{-4}\iint |z'-z''|^{-1}\,dz'dz'' \asymp C\mu^2h^{-4}\times h^2 \asymp C\mu^2h^{-2}$.

Therefore we have the following

Proposition 26.3.18. *As $|\nabla w| \asymp 1$ and $\varepsilon \ge h^{\frac{2}{3}-\delta}$ in $B(0,1)$ and $\phi \in \mathscr{C}^\infty(B(0,\frac{1}{2}))$*

$$\mathsf{D}\Bigl(\phi\bigl(e(x,x,\tau)-P'_\beta(w(x)+\tau)\bigr),\phi\bigl(e(x,x,\nu)-P'_\beta(w(x)+\tau)\bigr)\Bigr) \le C(1+\mu h)^2h^{-4}. \tag{26.3.86}$$

Remark 26.3.19. One can see easily that one can select $\varepsilon \ge h^{\frac{2}{3}-\delta}$ such that expressions (26.3.61), (26.3.62) and (26.3.62) will be respectively $O(h^{2+\delta})$, $O(h^{1+\delta})$ and $O(h^{2+\delta})$.

Semiclassical D-Term: Global Theory

Regular Zone. The above results allow us to consider a total contribution of zone $\mathcal{X}_2$ into semiclassical D-term. As before let us consider ℓ-admissible partition of unity there and apply it to Fefferman–de Llave decomposition (26.3.8). Then the total contribution of the elements which are not disjoint does not exceed

$$\sum_n \ell_n^{-1}\bigl(1+B\zeta_n^{-2}\bigr)^2\ell_n^4\zeta_n^4 \asymp \int \underbrace{\bigl(\zeta^4+B^2\bigr)\ell^3}\ \ell^{-1}d\ell \tag{26.3.87}$$

where $\bigl(1+B\zeta_n^{-2}\bigr)^2$ and $\ell_n^4\zeta_n^4$ are $(1+\mu h)$ and h^{-4} respectively and ℓ_n^{-1} is a scaling factor.

Then if $\zeta^2 = Z\ell^{-1}$, an integral equals to the value of the selected expression as ℓ reaches its maximum, i.e. for $\ell = Z^{-\frac{1}{3}}$ for $B \le Z^{\frac{4}{3}}$ and $\ell = Z^{\frac{1}{5}}B^{-\frac{2}{5}}$ for $Z^{\frac{4}{3}} \le B \le Z^3$ and we arrive to $CZ^{\frac{5}{3}}$ and $CZ^{\frac{3}{5}}B^{\frac{4}{5}}$ respectively.

On the other hand, if $\zeta^2 = \ell^{-4}$ an integral equals to the value of the selected expression as ℓ reaches its minimum, i.e. for $\ell = Z^{-\frac{1}{3}}$ and only in the case $B \le Z^{\frac{4}{3}}$ and we arrive to $CZ^{\frac{5}{3}}$ again.

Furthermore, the total contribution of the disjoint elements does not exceed

$$\sum_{n,p} |z_n-z_p|^{-1}\bigl(1+B\zeta_n^{-2}\bigr)\bigl(1+B\zeta_p^{-2}\bigr)\ell_n^2\zeta_n^2\ell_p^2\zeta_p^2 \asymp \iint \underbrace{(\ell+\ell')^{-1}\bigl(\zeta^2+B\bigr)\ell^2\bigl(\zeta'^2+B\bigr)\ell'^2}\ \ell^{-1}d\ell\,\ell'^{-1}d\ell'. \tag{26.3.88}$$

Then if $\zeta^2 = Z\ell^{-1}$ and $\zeta'^2 = Z\ell'^{-1}$ an integral equals to the value of the selected expression as both ℓ and ℓ' reach their maxima, and we arrive to $CZ^{\frac{5}{3}}$ and $CZ^{\frac{3}{5}}B^{\frac{4}{5}}$ respectively.

On the other hand, if $\zeta^2 = \ell^{-4}$ and $\zeta'^2 = \ell'^{-4}$ (we do not need to consider mixed pair) an integral equals to the value of the selected expression as both ℓ and ℓ' reach their minima, and we arrive to $CZ^{\frac{5}{3}}$.

Therefore (combining with Proposition 26.A.5 as $Z^2 \le B \le Z^3$) we arrive to

Proposition 26.3.20. *Let $M = 1$. Then*

(i) The total contribution of the zone $\{x\colon \ell(x) \le (1-\epsilon)\bar{r}\}$ *to the semiclassical* D*-term does not exceed* $CZ^{\frac{5}{3}}$ *and* $CZ^{\frac{3}{5}}B^{\frac{4}{5}}$ *for* $B \le Z^{\frac{4}{3}}$ *and for* $Z^{\frac{4}{3}} \le B \le Z^3$ *respectively.*

(ii) If $B \le Z$ *this contribution does not exceed* $C(B+1)^{\delta}Z^{\frac{5}{3}-\delta}$.

Border Strip. Border strip $\mathcal{Y} = \{x\colon (1-\epsilon)\bar{r} \le \ell(x) \le (1+\epsilon)\bar{r}\}$ is more subtle. Here we need to use the same $\ell_1(x) = \epsilon_0(\bar{r} - |x|)$ partition as before.

Remark 26.3.21. $\mathcal{Y}$ is already covered by our arguments if $\bar{r} \asymp (Z-N)_+^{-\frac{1}{3}}$.

Close Elements. Consider first contribution of elements which are not disjoint. It is given by the left-hand expression of (26.3.87) with ℓ, ζ replaced by $\ell_1(x) = \bar{r}\gamma(x)$ and $\varsigma(x) = \bar{\zeta}\gamma(x)^2$ respectively. However since the layer $\{x\colon \gamma(x) \asymp \gamma\}$ contains $\asymp \gamma^{-2}$ elements the right-hand expression should be replaced by

$$\int \underbrace{B^2\bar{r}^3\gamma}\, \gamma^{-1}d\gamma \asymp B^2\bar{r}^3$$

since $\varsigma^2 \le B$; so we arrive to $O\bigl(\max(B^{\frac{5}{4}}, Z^{\frac{3}{5}}B^{\frac{4}{5}})\bigr)$.

Meanwhile for $\mathcal{Y}_2$ we have $\gamma(x) = \bar{\gamma} \le 1$ and $\varsigma(x) = \bar{\varsigma} = \bar{\zeta}\bar{\gamma}^2$ and its contribution does not exceed what we got for $\mathcal{Y}_1$.

Disjoint Elements. Consider contribution of the disjoint elements. It is given by the left-hand expression of (26.3.88) with ℓ, ζ replaced by γ and ς respectively. Note that $\sum_{n,p} |z_n - z_p|^{-1} \asymp \bar{r}^{-1}\gamma^{-2}\gamma'^{-2}$ where we sum with respect to all pairs with $\gamma_n \asymp \gamma$ and $\gamma_p \asymp \gamma'$. Therefore the right-hand expression should be replaced by

$$\int \underbrace{\bar{r}^3B^2}\, \gamma^{-1}d\gamma\, \gamma'^{-1}d\gamma' \tag{26.3.89}$$

which leads to $C\bar{r}^3B^2|\log(\bar{r}^{-1}\bar{\gamma})|^2$ which differs from what we got before by a logarithmic factor. To get rid of it we will use exactly the same trick as in Paragraph *26.3.3.2.2. Border Strip.* proving Proposition 26.3.16 because considering disjoint pairs we consider the same objects as there. Then instead of (26.3.89) we arrive to

$$\int \underbrace{\bar{r}^3B^2\gamma^{-\delta}\gamma'^{-\delta}\bar{\gamma}^{2\delta}}\, \gamma^{-1}d\gamma\, \gamma'^{-1}d\gamma'$$

which results in $C\bar{r}^3B^2$.

Meanwhile for $\mathcal{Y}_2$ we have $\gamma(x) = \bar{\gamma} \le \bar{r}$ and $\varsigma(x) = \bar{\varsigma} = \bar{\zeta}\bar{\gamma}^2$ and its contribution does not exceed what we got for $\mathcal{Y}_1$.

Conclusion. Finally, analysis in the outer zone is trivial. Therefore we arrive

Proposition 26.3.22. *Let $M = 1$. Then for constructed above potential W*

(i) Expression (26.3.25) *does not exceed $CZ^{\frac{5}{3}} + CZ^{\frac{3}{5}}B^{\frac{4}{5}}$.*

(ii) If $B \le Z$ expression (26.3.25) *does not exceed $C(B+1)^{\delta}Z^{\frac{5}{3}-\delta}$.*

26.4 Applying Semiclassical Mmethods: $M \ge 2$

Let us consider now the molecular case ($M \ge 2$). The major problem is that the non-degeneracy condition $|\nabla w| \asymp 1$ is not necessarily fulfilled. Therefore we need to find an alternative approach to the zone where $\mu \ge h^{-\frac{1}{3}}$) (with $\mu = B\ell\zeta^{-1}$ and $h = 1/\ell\zeta$). Recall that it consists of three smaller zones: zone $\mathcal{X}_2 := \{\mu h \le C_0,\ W_B^{\mathsf{TF}} \ge \epsilon_0\zeta^2\}$ [22], zone $\mathcal{X}_3 := \{\mu h \ge C_0,\ W_B^{\mathsf{TF}} \ge \epsilon_0\zeta^2\}$ [23], and the (most difficult) *boundary strip* $\mathcal{Y} = \{W_B^{\mathsf{TF}} \le \epsilon_0\zeta^2\}$, which we leave for the next Section 26.5.

26.4.1 Scaling Functions in Zone $\mathcal{X}_2$

Step 1. We will use the scaling method in this zone; the good news is that W_B^{TF} is sufficiently regular after a proper rescaling and also sufficiently non-degenerate. Recall that after we rescale $x \mapsto \bar{\ell}^{-1}(x-\bar{x})$, $\tau \mapsto \bar{\zeta}^{-2}\tau$ in the ball $B(\bar{x}, \frac{1}{2}\bar{\ell})$ with $\bar{\ell} = \ell(\bar{x})$, $\bar{\zeta} = Z^{\frac{1}{2}}\bar{\ell}^{-1}$, the rescaled potential $w = \bar{\zeta}^{-2}W_B^{\mathsf{TF}}$ satisfies in $B(0,2)$ equation

$$\frac{1}{4\pi}\Delta w = \eta P'_\beta(w) \qquad \text{with } \eta = \bar{\zeta}\bar{\ell}^2 \lesssim 1, \quad \beta = \mu h = B\bar{\zeta}^{-2} \le 1 \tag{26.4.1}$$

and therefore in $B(0,1)$

$$w = -\frac{1}{4\pi}\int |x-z|^{-1}\eta P'_\beta(w(z))\phi(z)\,dz + w' \tag{26.4.2}$$

with $\phi \in \mathscr{C}_0^\infty(B(0,\frac{5}{6}))$ and $w' \in \mathscr{C}_0^\infty(B(0,\frac{3}{4}))$.

[22] Only if $B \le C_1Z^2$; this zone disappears for $C_1Z^2 \le B \lesssim Z^3$.

[23] Only if $Z^{\frac{4}{3}} \lesssim B \lesssim Z^3$; this zone disappears for $B \lesssim Z^{\frac{4}{3}}$.

Remark 26.4.1. (i) If $\zeta^2 \asymp Z\ell^{-1}$ then $\eta = Z^{\frac12}\ell^{\frac32} \le 1$; this happens for $B \le Z^{\frac43}$, $\ell \lesssim Z^{-\frac13}$ and for $B \ge Z^{\frac43}$, $\ell \lesssim B^{-\frac13}$.

(ii) If $\zeta^2 \asymp \ell^{-2}$ then $\eta \asymp 1$; this happens only for $B \le Z^{\frac43}$, $\ell \gtrsim Z^{-\frac13}$.

Let us introduce a function

$$\gamma_0(x) = \Big(\min_j |w - 2j\beta|^3 + |\nabla w|^4 + |\nabla^2 w|^6 + |\nabla^3 w'|^{12}\Big)^{\frac{1}{12}}. \tag{26.4.3}$$

Remark 26.4.2. We cannot replace w' by w in the last term because $w \in \mathscr{C}^{\frac52}$ only rather than $\mathscr{C}^3$.

Proposition 26.4.3. *$\gamma_0(x)$ is a scaling function i.e. $|x-y| \le \epsilon\gamma_0(x) \implies \gamma_0(y) \asymp \gamma_0(x)$.*

Proof. (a) If w belonged to $\mathscr{C}^4$ (and we would put w instead of w' in the last term of (26.4.3)) then we would just prove that $|\nabla\gamma_0| \le c$. Here we should be more subtle. We need to prove that if

$$\min_j |w - 2j\beta| \le \gamma_0^4, \qquad |\nabla w| \le \gamma_0^3, \tag{26.4.4}_{1,2}$$

$$|\nabla^2 w| \le \gamma_0^2, \qquad |\nabla^3 w'| \le \gamma_0 \tag{26.4.4}_{3,4}$$

at point x, then at point y the same inequalities hold with γ_0 replaced by $c\gamma_0$ [24]. Definitely this is true for $(26.4.4)_4$ since w' is smooth.

(b) Consider $|\nabla^2 w|$. Consider $|\Lambda_\alpha w(y) - \Lambda_\alpha w(x)|$ with $\Lambda_\alpha = \nabla^\alpha - \frac13\delta_{ij}\Delta$, $\alpha = (i,j)$. Then due to (26.4.2)

$$|\Lambda_{\alpha,y} w(y) - \Lambda_{\alpha,x} w(x)| \le \\ |\eta \int \big(\Lambda_{\alpha,x}|x-z|^{-1} - \Lambda_{\alpha,y}|y-z|^{-1}\big) P'_\beta(w(z))\phi(z)\,dz| + \epsilon_1\gamma_0^2 \tag{26.4.5}$$

where the last term estimates $|\Lambda_{\alpha,y} w'(y) - \Lambda_{\alpha,x} w'(x)|$ and we used $(26.4.4)_4$. Integrals here are understood in the sense of the principal value (vrai) and $\epsilon_1 = \epsilon_1(\epsilon) \to +0$ as $\epsilon \to +0$.

Note that the integral in expression (26.4.5) does not change if we add to $P'_\beta(w)$ any constant with respect to z.

[24] We need to prove a bit of converse as well; see Part (c).

Let us consider first this integral over $\{z\colon |x-z|\ge 2\gamma_0\}$, provided $\gamma_0\ge |x-y|$, and note that this integral does not exceed

$$\eta\Big|\int |x-z|^{-4}|x-y|\times \\ \big(|\nabla w(x)|\cdot|x-z|+|\nabla^2 w(x)|\cdot|x-z|^2+|x-z|^{\frac{5}{2}}\big)^{\frac12}\,dz\Big|\le C\epsilon_1\eta.$$

Consider now integral over zone $\{z\colon |x-z|\le 2\gamma_0\}$:

$$|\eta\int \Lambda_{\alpha,x}|x-z|^{-1}\cdot\big(P'_\beta(w(z))-P'_\beta(w(x))\big)\,dz|$$

and note that it also does not exceed $\epsilon_1\eta$. Further, t same arguments work for this integral with x replaced by y but still integrated over zone $\{z\colon |x-z|\le 2\gamma_0\}$ (one needs to remember that $|\nabla w(x)-\nabla w(y)|=O(\gamma_0)$ and $|\nabla^2 w(x)-\nabla^2 w(y)|=O(\gamma_0^{\frac12})$).

Furthermore, the same arguments work also for these expressions integrated over $\{z\colon |y-z|\le 2\gamma_0\}$ and we are left with

$$|\eta\int \omega(x,y,z)\big(P'_\beta(w(x))-P'_\beta(w(y))\big)\,dz|$$

integrated over zone $\{z\colon |x-z|\asymp\gamma_0\}$ and $\omega\asymp\gamma_0^{-3}$ and one can estimate it by $\epsilon_1\eta$ easily in the same way. Therefore since $|\Delta w(x)-\Delta w(y)|$ does not exceed $\epsilon_1\eta$ we conclude that $|\nabla^2 w(x)-\nabla^2 w(y)|$ does not exceed $\epsilon_1(\eta+\gamma_0^2)$.

However (26.4.2) implies that $\eta\le c\gamma_0^2$ since $P'_\beta(w)\asymp 1$ in $\mathcal{X}_2$ and therefore $|\nabla^2 w(x)-\nabla^2 w(y)|\le\epsilon_1\gamma_0^2$ in $B(x,\gamma_0)$.

Finally, combining this inequality with $(26.4.4)_2$ we conclude that $|\nabla w(x)-\nabla w(y)|\le\epsilon_1\gamma_0^3$ in $B(x,\gamma_0)$; finally, combining with $(26.4.4)_1$ we conclude that $|w(x)-w(y)|\le\epsilon_1\gamma_0^4$ in $B(x,\gamma_0)$.

(c) Therefore $(26.4.4)_{1-4}$ are fulfilled in $y\in B(x,\epsilon\gamma_0)$ with γ_0 replaced by $\gamma_0(1+C\epsilon_1)$. Further, if we redefine γ_0 as the minimal scale such that inequalities $(26.4.4)_{1-4}$ are fulfilled in x, then $(26.4.4)_{1-4}$ fail in $y\in B(x,\epsilon\gamma_0)$ with γ_0 replaced by $\gamma_0(1-C\epsilon_1)$. Therefore with appropriate $\epsilon>0$ we conclude that $\frac12\le\gamma_0(x)/\gamma_0(y)\le 2$.

Obviously, $\gamma_0\asymp\gamma_{0\mathsf{old}}$ where $\gamma_{0\mathsf{old}}$ was defined by (26.4.3) and therefore the same conclusion also holds for $\gamma_{0\mathsf{old}}$. □

Now let us reintroduce the scaling function

$$(26.4.3)^* \quad \gamma_0(x) = \epsilon\Big(\min_j |w - 2j\beta|^3 + |\nabla w|^4 + |\nabla^2 w|^6 + |\nabla^3 w'|^{12}\Big)^{\frac{1}{12}} + C_0 h^{\frac{1}{3}} + C_0 \eta^{\frac{1}{2}}.$$

Then

(26.4.6) $|x-y| \le 2\gamma_0(x) \implies \gamma_0(y) \asymp \gamma_0(x)$ and $(26.4.4)_{1-4}$ hold (with some constant factor in the right-hand expression).

Consider $B(\bar{x}, \bar{\gamma}_0)$, $\bar{\gamma}_0 = \gamma_0(\bar{x})$, and scale again $x \mapsto \bar{\gamma}_0^{-1}(x - \bar{x})$, $\tau \mapsto \bar{\gamma}_0^{-4}\tau$ and respectively $w \mapsto w_1 = \bar{\gamma}_0^{-4}(w - 2\bar{\jmath}\beta))$, $h \mapsto h_1 = h\bar{\gamma}_0^{-3}$. Further, since after rescaling $|\Delta w_1| = O(\eta\bar{\gamma}_0^{-2})$ we set $\eta \mapsto \eta_1 = \eta\bar{\gamma}_0^{-2}$.

Due to cut-off in the end of $(26.4.3)^*$ $h_1 \lesssim 1$ and $\eta_1 \lesssim 1$. If $\bar{\gamma}_0 \asymp h^{\frac{1}{3}}$ then $h_1 \asymp 1$ and we are done. If $\bar{\gamma}_0 \asymp \eta^{\frac{1}{2}}$ then $\eta_1 \asymp 1$ and we proceed to *Step 3.*.

Step 2. So, let $\eta_1 \ll 1$. Let us introduce a scaling function in $B(0,1)$ obtained after the previous rescaling:

$$(26.4.7) \qquad \gamma_1(x) = \epsilon\Big(\min_j |w_1 + 2(\bar{\jmath} - j)\beta\bar{\gamma}_0^{-4}|^2 + |\nabla w_1|^3 + |\nabla^2 w_1|^6\Big)^{\frac{1}{6}}.$$

Then

$$(26.4.8)_{1-2} \qquad \min_j |w_1 + 2(\bar{\jmath} - j)\beta\bar{\gamma}_0^{-4}| \le C_0\gamma_1^3, \qquad |\nabla w_1| \le C_0\gamma_1^2,$$

$$(26.4.8)_3 \qquad |\nabla^2 w_1| \le C_0\gamma_1.$$

Remark 26.4.4[25]. Since now we do not have the third derivative in (26.4.7), we do not need in w_1' in the definition of γ_1, only in the proof of Proposition 26.4.5 below.

Proposition 26.4.5. *(i) $\gamma_1(x)$ is a scaling function:* $|x-y| \le 2\gamma_1(x) \implies \gamma_1(y) \asymp \gamma_1(x)$.

(ii) If $\eta_1 \le \epsilon_0$ then

$$(26.4.9) \qquad |\nabla^2 w_1(x) - \nabla^2 w_1'(x)| \le \epsilon_2\gamma_1, \qquad w_1' = (w' - \bar{\jmath}\beta)\gamma_0^{-4}.$$

[25] Cf. Remark 26.4.2.

Proof. Proof is similar but simpler than one of Proposition 26.4.3; it is based on the rescaled version of (26.4.1)–(26.4.2):

$$\frac{1}{4\pi}\Delta w_1 = \eta_1 P_\beta(w_1\bar\gamma_0^4 + 2\bar\jmath\beta), \qquad \eta_1 = \eta\bar\gamma_0^{-2} \le 1 \tag{26.4.10}$$

and therefore in $B(0,1)$

$$w_1 = -\frac{1}{4\pi}\int |x-z|^{-1}\eta_1 P'_\beta(w_1(z)\bar\gamma_0^4 + 2\bar\jmath\beta)\phi(z)\,dz + w'_1. \tag{26.4.11}$$

□

Now let us reintroduce the scaling function

$$\gamma_1(x) = \epsilon\Big(\min_j |w_1 + 2(\bar\jmath - j)\beta\bar\gamma_0^{-4}|^2 + |\nabla w_1|^3 + |\nabla^2 w_1|^6\Big)^{\frac16} + C_0 h_1^{\frac25}. \tag{26.4.7)*}$$

Then

(26.4.12) $|x-y| \le 2\gamma_0(x) \implies \gamma_0(y) \asymp \gamma_0(x)$ and $(26.4.8)_{1-3}$ hold (with some constant factor in the right-hand expression).

Let us consider $\bar x \in B(0,1)$ (it is a new point), $B(\bar x, \bar\gamma_1)$, $\bar\gamma_1 = \gamma_1(\bar x)$, and scale again $x \mapsto \bar\gamma_1^{-1}(x-\bar x)$, $\tau \mapsto \bar\gamma_1^{-3}\tau$ and respectively $w_1 \mapsto w_2 = \bar\gamma_1^{-3} w_1$, $h_1 \mapsto h_2 = h_1\bar\gamma_1^{-\frac52}$.

If $\bar\gamma_1 \asymp h_1^{\frac25}$ then $h_2 \asymp 1$ and we are done. If $|\nabla w_2| \asymp 1$ we are done as well.

Step 3. So, consider the remaining case $|\nabla^2 w_2| \asymp 1$. Then we introduce the scaling function (now, we have no doubt that this is a scaling function):

$$\gamma_2(x) = \epsilon\Big(\min_j |w_2 + 2(\bar\jmath - j)\beta\bar\gamma_0^{-4}\bar\gamma_1^{-3}| + |\nabla w_2|^2\Big)^{\frac12} + C_0 h_2^{\frac12}. \tag{26.4.13}$$

Let us consider $\bar x \in B(0,1)$ (it is a new point), $B(\bar x, \bar\gamma_2)$, $\bar\gamma_2 = \gamma_2(\bar x)$, and scale again $x \mapsto \bar\gamma_2^{-1}(x-\bar x)$, $\tau \mapsto \bar\gamma_2^{-2}\tau$ and respectively $w_2 \mapsto w_3 = \bar\gamma_2^{-2} w_2$, $h_2 \mapsto h_3 = h_2\bar\gamma_2^{-2}$.

If $\bar\gamma_2 \asymp h_1^{\frac12}$ then $h_3 \asymp 1$ and we are done. If $|\nabla w_3| \asymp 1$ we are done as well.

Step 4. Finally, introduce

$$\gamma_3(x) = \epsilon \min_j |w_3 + 2(\bar{j} - j)\beta\bar{\gamma}_0^{-4}\bar{\gamma}_1^{-3}\bar{\gamma}_2^{-2}| + Ch_3^{\frac{2}{3}}. \tag{26.4.14}$$

26.4.2 Zone $\mathcal{X}_2$: Semiclassical N-Term

Now we apply scaling the arguments using scaling functions γ_{1-3} constructed above.

We revert our steps. While we call γ_{1-3} *relative scaling functions* let us introduce *absolute scaling functions* $\alpha_0(x) = \gamma_0(x)$, $\alpha_1(x) = \gamma_0(x)\gamma_1(x)$, $\alpha_2(x) = \gamma_0(x)\gamma_1(x)\gamma_2(x)$, and $\alpha_3(x) = \gamma_0(x)\gamma_1(x)\gamma_2(x)\gamma_3(x)$ [26].

We need first

Proposition 26.4.6. *Consider $B(0,1)$ and assume that in it*

$$|\nabla w| \asymp \theta, \tag{26.4.15}$$

and

$$|\nabla^2 w| \le c\theta. \tag{26.4.16}$$

Let

$$\gamma(x) := \epsilon \min_j |w - 2\mu hj|\theta^{-1} + \hbar^{\frac{2}{3}} \tag{26.4.17}$$

and

$$\varepsilon \ge \hbar^{\frac{2}{3}-\delta}, \qquad \hbar := h\theta^{-\frac{1}{2}}. \tag{26.4.18}$$

Let $\varphi \in \mathscr{C}_0^\infty([-\epsilon_0, \epsilon_0])$. Then for $\alpha \le \bar{\gamma} := \gamma(\bar{x})$,

$$\Big| \int \phi_\alpha(x)\Big(e_\varphi(x,x,\tau) - P'_{\mu h,\varphi}\big(w(x)+\tau\big)\Big)\,dx\Big| \le C\mu h^{-1}\alpha^3 + C\mu h^{-1}\alpha^3\bar{\gamma}^{-1}(\hbar\bar{\gamma}^{-\frac{1}{2}}\alpha^{-1})^s \tag{26.4.19}$$

with

$$e_\varphi(x,y,\tau) := \varphi\big(h^2 D_{x_3}^2(\mu h)^{-1}\big)e(x,y,\tau) \tag{26.4.20}$$

and Weyl expression

$$P'_{\beta,\varphi}(w+\tau) = \mathsf{const}\sum_j \beta(w+\tau-2j\mu h)^{\frac{1}{2}}\varphi(w+\tau-2j\mu h) \tag{26.4.21}$$

[26] So far we ignore the very first scaling $x \mapsto (x-\bar{x})\ell^{-1}$. Therefore really absolute scaling functions would be $\alpha_j\ell$.

with the standard constant where for each x only one term is present in this sum. Here we take large $s > 0$ as $\hbar \le \bar\gamma\alpha$ and $s = 0$ otherwise.

Proof. The proof is standard and based on the standard reduction to the canonical form, standard estimates for $U(x,y,t)$ a Schwartz kernel of propagator $e^{i\hbar^{-1}\theta^{-1}tH}$:

$$|F_{t\to\hbar^{-1}\tau}\int \bar\chi_T(t)\phi_\alpha(x)U_\varphi(x,x,t)\,dx| \le C\mu h^{-1}\alpha^3 \tag{26.4.22}$$

for $T \asymp 1$ and

$$|F_{t\to\hbar^{-1}\tau}\int \phi_\alpha(x)\big(\bar\chi_T(t)-\bar\chi_{\bar T}(t)\big)U_\varphi(x,x,t)\,dx| \le C\mu h^{-1}\alpha^3(\hbar\bar\gamma^{-\frac12}\alpha^{-1})^s \tag{26.4.23}$$

with $\bar T = \epsilon\gamma^{\frac12}$ where U_φ is defined similarly to (26.4.20).

Here obviously we can skip in (26.4.19) all perturbation terms in the argument and in ϕ_α transformed. □

Then plugging into (26.4.19) $\alpha = \gamma$ $(= \bar\gamma)$, we have factor $(h\gamma^{-\frac32})^s$ in the second term.

There are two cases: $\theta \le \mu h$ and $\theta \ge \mu h$.

In the former case $\theta \le \mu h$, taking the sum over γ-partition of 1-element we estimate the same expressions with ϕ_1 instead of ϕ_γ by their right-hand expressions integrated over $\gamma^{-3}\,d\gamma$ which returns $C\mu h^{-1}$.

On the other hand, in the latter case $\theta \ge \mu h$, let $\lambda = \mu h\theta^{-1}$. Taking the sum over γ_3-partition of λ-element ϕ_λ by the right-hand expressions which returns $C\mu h_2^{-1}\lambda^2$. In this case summation over λ-partition return $C\theta h^{-2}$.

In both cases we arrive to the following estimate:

$$|\int \phi(x)\Big(e_\varphi(x,x,\tau) - P'_{\mu h,\varphi}\big(w(x)+\tau\big)\Big)\,dx| \le C\theta h^{-2} + C\mu h^{-1}. \tag{26.4.24}$$

Applying this estimate after α_2-scaling we conclude that the left-hand expression with $\phi = \phi_{\alpha_2}$ (in the non-scaled settings) does not exceed $C\theta h^{-2}\alpha_2^2 + C\mu h^{-1}\alpha_2^2$. Here the first term is $O(h^{-2}\alpha_2^3)$ and the summation over 1-element returns $O(h^{-2})$.

Consider the second term $C\mu h^{-1}\alpha_2^2 = C\mu h^{-1}\gamma_0^2\gamma_1^2\gamma_2^2$. Then summation over α_2-partition of α_1-element returns

$$C\mu h^{-1}\gamma_0^2\gamma_1^2 \int \gamma_2^2 \times \gamma_2^{-3}\, dx \asymp C\mu h^{-1}\gamma_0^2\gamma_1^2(1+|\log \hat{\gamma}_2|)$$

where $\hat{\gamma}_k$ is a minimal value of γ_k over γ_{k-1}-element. However in fact there will be no logarithmic factor because in virtue of equation (26.4.1) there is a positive eigenvalue of $\mathsf{Hess}\, w_2$ of the maximal size (cf. Section 5.2.1). Therefore, in fact, we have $C\mu h^{-1}\gamma_0^2\gamma_1^2$.

Now summation over α_1-partition of α_0-element returns

$$C\mu h^{-1}\gamma_0^2 \int \gamma_1^2 \times \gamma_1^{-3}\, dx \asymp C\mu h^{-1}\gamma_0^2(1+|\log \hat{\gamma}_1|).$$

Finally, summation over α_0-partition of 1-element returns

$$C\mu h^{-1} \int \gamma_0^2(1+|\log \hat{\gamma}_1|) \times \gamma_0^{-3}\, dx \asymp C\mu h^{-1}\hat{\gamma}_0^{-1}(1+|\log \check{\gamma}_1|),$$

where $\check{\gamma}_k$ is an absolute minimum of γ_k. However $\gamma_0^2 \ge \eta$ and $\gamma_1 \ge \eta$ and therefore expression above does not exceed $C\mu h^{-1}\eta^{-\frac{1}{2}}(1+|\log \eta|)$.

Remark 26.4.7. Recall that we estimated only the cut-off expression. To calculate the full expression we need to calculate also the contribution of the zone $\{\xi_3^3 \ge \mu h\}$. However this is easy.

Really, instead of $\varphi(h^2D_3^2/(\mu h))$ consider $\varphi'(h^2D_3^2/\theta)$ with $\varphi' \in \mathscr{C}^\infty([1,4])$ and $\epsilon\mu h \le \theta \le 1$. Without any scaling one can prove easily that such modified expression (26.4.24) does not exceed $C\theta h^{-2}$. We leave easy details to the reader.

Therefore plugging $\theta = 2^n\mu h$ and taking a sum over $n = 0, \dots, \lfloor |\log_2 \mu h| \rfloor$ we get the required expressions. Also note that in such expressions we need to consider perturbed argument $w + \mu^{-2}\omega_1 + j\mu^{-1}h\omega_2$ (all other terms which are $O(\mu^{-4} + \mu^{-\frac{3}{2}}h)$ could be skipped and also a perturbed function transformed).

Remark 26.4.8. (i) However we need to get rid of these perturbations for $\theta \le \mu h^{1-\delta}$ only. Indeed, for $\theta \ge \mu h^{1-\delta}$ we need canonical form *only* to study propagation and calculations could be performed without it. But then

getting rid of the perturbation is trivial provided this perturbation does not exceed $C\mu h^{1+\delta}$ which is the case if

$$\mu \ge h^{-\frac{1}{3}-\delta}. \tag{26.4.25}$$

(ii) Note that in the smooth approximation contributions of $\mathcal{X}_1$ is always less than $CZ^{\frac{2}{3}-\delta_1}$, $C\max(Z^{\frac{5}{3}}, Z^{\frac{3}{5}}B^{\frac{4}{5}})Z^{-\delta_1}$ or $C\max(Z^{\frac{5}{3}}, Z^{\frac{3}{5}}B^{\frac{4}{5}})Z^{-\delta_1} + CB^{\frac{1}{2}}Z^{\frac{7}{6}-\delta_1}$ respectively with an exception of the first two and only in the case of the threshold value $\ge Z^{-\frac{1}{3}-\delta_2}$. However in this case $\eta \ge Z^{-\delta_3}$ and the errors of the smooth approximation approach in fact are less than $CZ^{\frac{2}{3}-\delta_4}$, $CZ^{\frac{5}{3}-\delta_4}$ as well. Therefore there are in fact no exception.

(iii) It is important to have $\varepsilon \le \mu h$ and with $\varepsilon = \hbar^{\frac{2}{3}-\delta}$, $\hbar = h\theta^{-\frac{1}{2}}$ it means $\mu \ge h^{-\frac{1}{3}-\delta}\theta^{\frac{1}{3}-\frac{1}{2}\delta}$ which is due to (26.4.25).

Therefore we conclude that in the completely non-scaled settings with $\phi = \phi_\ell(x)$

$$|\int \phi(x)\Big(e(x,x,\tau) - P'_B\big(W(x)+\tau\big)\Big)| \le C\zeta^2\ell^2 + CB\ell\zeta^{-\frac{1}{2}}(1+|\log \ell^2\zeta|) \tag{26.4.26}$$

where the first term is Ch^{-2} and the second term is $C\mu h^{-1}\eta^{-\frac{1}{2}}(1+|\log\eta|)$; recall that $h^{-1} \asymp \ell\zeta$, $\mu \asymp B\ell\zeta^{-1}$ and $\eta \asymp \ell^2\zeta$. In comparison with the non-degenerate case $|\nabla W_B^{\mathsf{TF}}| \asymp \zeta^2\ell^{-1}$ we acquired the last term.

Assume first that condition (26.2.28) is fulfilled. Then

(i) If $B \le Z^{\frac{4}{3}}$, $\ell \le Z^{-\frac{1}{3}}$ we have $\zeta = Z^{\frac{1}{2}}\ell^{-\frac{1}{2}}$ and the right-hand expression of (26.4.26) returns $CZ\ell + CB\ell^{\frac{5}{4}}Z^{-\frac{1}{4}}$ and the summation with respect to ℓ results in its value as $\ell = Z^{-\frac{1}{3}}$ i.e. $CZ^{\frac{2}{3}} + CBZ^{-\frac{2}{3}}$ with the dominating first term.

(ii) If $B \le Z^{\frac{4}{3}}$, $\ell \ge Z^{-\frac{1}{3}}$ we have $\zeta = \ell^{-2}$ and the right-hand expression of (26.4.26) returns $C\ell^{-2} + CB\ell^2$. We need to sum as long as $\mu h \le 1$ i.e. $Z^{-\frac{1}{3}} \le \ell \le B^{-\frac{1}{4}}$ and the summation returns $CZ^{\frac{2}{3}} + CB^{\frac{1}{2}}$ with the dominating first term.

(iii) If $Z^{\frac{4}{3}} \le B \le Z^2$, $\ell \le B^{-1}Z$ we have $\zeta = Z^{\frac{1}{2}}\ell^{-\frac{1}{2}}$ and the right-hand expression of (26.4.26) returns $CZ\ell + CBZ^{-\frac{1}{4}}\ell^{\frac{5}{4}}$. Then summation results in $CZ^2B^{-1} + CZ^2B^{-\frac{1}{4}}Z \lesssim Z^{\frac{2}{3}}$.

If assumption (26.2.28) is not fulfilled we can estimate in the first term of the right-hand expression of (26.4.26) parameter ζ from above by $\min(Z^{\frac12}\ell^{-\frac12}, \ell^{-2})$ and in the second term from below by $\zeta_m = \min(Z_m^{\frac12}\ell_m^{-\frac12}, \ell_m^{-2})$ if $\ell = \ell_m := |x - y_m|$ and repeat all above arguments.

Therefore we arrive to the Statement (i) of Proposition 26.4.9 below. Furthermore, note that for $B \le Z$ the zone $\mathcal{X}_2$ is contained in the zone $\{x\colon \ell(x) \ge B^{-\frac{3}{10}} \ge Z^{-\frac{3}{10}}\}$ (really, $\mu \ge h^{-\frac13}$ in $\mathcal{X}_2$) and we arrive to the Statement (ii) below.

Proposition 26.4.9. *(i) For $B \le Z^2$ the contribution of zone $\mathcal{X}_2$ to the expression*

$$\int \bigl(e(x,x,\nu) - P'_B(W(x)+\nu)\bigr)\,dx \tag{26.4.27}$$

does not exceed $CZ^{\frac23}$.

(ii) For $B \le Z$ the contribution of zone $\mathcal{X}_2$ to the expression (26.4.27) *does not exceed $CZ^{\frac23-\delta}$.*

26.4.3 Zone $\mathcal{X}_2$: Semiclassical D-Term

Further, we need to estimate the *semiclassical* D*-term*

$$\mathsf{D}\Bigl(\phi_\alpha[e(x,x,\nu) - P'_B(W(x)+\nu)], \phi_\alpha[e(x,x,0) - P'_B(W(x)]\Bigr) \tag{26.4.28}$$

where $\phi_\alpha(x)$ is an α-admissible function. Again we revert our steps.

Consider $B(x,\bar\alpha_3)$ and apply Fefferman–de Llave decomposition (26.3.8). Then in the framework of Proposition 26.4.6 contribution of pairs $B(x,\alpha)$ and $B(y,\alpha)$ with $3\alpha \le |x-y| \le 4\alpha$ does not exceed the right-hand expression of (26.4.19) squared and multiplied by α^{-4}, where $C\alpha^{-3}$ estimates the number of the pairs and α^{-1} is the inverse distance. At this moment we discuss a cut-off version of (26.4.28) i.e. with $e_\varphi(.,.,.)$ and $P'_{\mu h,\varphi}(.)$. So, we have

$$C\mu^2 h^{-2}\bigl(1+\gamma_3^{-1}(h_2\gamma_3^{-\frac12}\alpha^{-1})^s\bigr)^2\alpha^4.$$

Then integrating this expression with respect to $\alpha^{-1}\,d\alpha$ with $\alpha \le \gamma_3$ we arrive to $C\mu^2h^{-2}\bigl(\gamma_3^4 + h_2^2\gamma_3\bigr)$.

Therefore we conclude that

(26.4.29) A cut-off version of expression (26.4.28) with $\alpha = \alpha_3$ does not exceed $C\mu^2 h^{-2}\bigl(\gamma_3^4 + h_2^2\gamma_3\bigr)\alpha_2^3$

The first term here $C\mu^2 h^{-2}\gamma_3^4\alpha_2^3$ does not exceed $C\mu^2 h^{-2}\alpha_3^3$ (recall that $\alpha_j = \alpha_{j-1}\gamma_j$) and the summation over α_3-partition of 1-element returns $C\mu^2 h^{-2}$.

Consider the second term $C\mu^2 h^{-2}h_2^2\gamma_3\alpha_2^3$; its summation with respect to α_3-partition of α_2-element returns $C\mu^2 h^{-2}\alpha_2^3 h_2^2 \int \gamma_3^{-2}\,d\gamma_3 \lesssim C\mu^2 h^{-2}\alpha_2^3$ (really, recall that according to (26.4.14) $\gamma_3 \ge h_3^{\frac{2}{3}}$) and then the summation over α_2-partition of 1-element returns $C\mu^2 h^{-2}$.

Consider $B(x,\bar\alpha_2)$ and apply Fefferman–de Llave decomposition (26.3.8). There are two kinds of pairs:

(a) those with $|x-y| \ge \epsilon(\alpha_3(x)+\alpha_3(y))$ for all (x,y) and

(b) those with $|x-y| \le \min(\alpha_3(x),\alpha_3(y))$ for all (x,y).

The total contribution of the pairs of the second type (i.e. summation is taken over *all* pairs of α_3-elements in $B(0,1)$) as we already know is $O(\mu^2 h^{-2})$. Meanwhile according to the analysis in the previous Subsection 26.4.2 a contribution of one pair of kind (a) does not exceed

$$C\underbrace{\bigl(h^{-2}+\mu h^{-1}\gamma_0^{-1}\gamma_1^{-1}\gamma_2^{-1}\gamma_3^{-1-\delta}\bar\gamma_3^{\delta}\bigr)\alpha_3^3}_{\text{at } x}\times \underbrace{\bigl(h^{-2}+\mu h^{-1}\gamma_0^{-1}\gamma_1^{-1}\gamma_2^{-1}\gamma_3^{-1-\delta}\bar\gamma_3^{\delta}\bigr)\alpha_3^3}_{\text{at } y}\times|x-y|^{-1}$$

where each of two first factors is just an estimate of the integral (26.4.24) calculated over corresponding domain. If we take the first term in the first factor and sum over α_3-partition of 1-element we get only the second factor multiplied by μh^{-1} and then summation was done in the previous subsection. Similarly we can deal with the first term in the second factor. On the other hand, if we take only second factors and sum over pairs of α_3-subelements of the same α_2-element we get

$$C\mu^2 h^{-2}\gamma_0^{-2}\gamma_1^{-2}\gamma_2^{-2}\alpha_2^5 \asymp C\mu^2 h^{-2}\alpha_2^3.$$

Then summation with respect to α_2-partition of 1-element returns $C\mu^2 h^{-2}$.

Consider now $B(\bar x,\bar\alpha_1)$ and apply here Fefferman-de Llave decomposition (26.3.8). There are two kinds of pairs:

(a) those with $|x-y| \ge \epsilon(\alpha_2(x)+\alpha_2(y))$ for all (x,y) and

(b) those with $|x-y| \le \mathsf{min}(\alpha_2(x),\alpha_2(y))$ for all (x,y).

According to the above analysis the total contribution of the pairs of the second type (i.e. the summation is taken over *all* pairs of α_2-elements in $B(0,1)$) as we already know is $O(\mu^2 h^{-2})$. Meanwhile according to the analysis in the previous Subsection 26.4.2 a contribution of one pair of kind (a) does not exceed

$$C\underbrace{\bigl(h^{-2}+\mu h^{-1}\gamma_0^{-1}\gamma_1^{-1}\gamma_2^{-1}\bigr)\alpha_3^3}_{\text{at } x}\times\underbrace{\bigl(h^{-2}+\mu h^{-1}\gamma_0^{-1}\gamma_1^{-1}\gamma_2^{-1}\bigr)\alpha_3^3}_{\text{at } y}\times|x-y|^{-1}$$

and here again we can "forget" about the first terms in each factor. Then the summation with respect to pairs of α_2-subelements of the same α_1-element results in $C\mu^2h^{-2}\gamma_0^{-2}\gamma_1^{-2}\alpha_1^5 \asymp C\mu^2h^{-2}\alpha_1^3$ where we avoid logarithmic factor in virtue of the same positive eigenvalue of $\mathsf{Hess}\, w$. Summation with respect to α_1-admissible partition of 1-element returns $C\mu^2h^{-2}$.

Consider now $B(\bar{x},\bar{\alpha}_0)$ and apply here Fefferman–de Llave decomposition. Again there are two kinds of pairs and the total contributions of the pairs of the second kind we already calculated and contribution of the pairs of α_1-subelements of the same 1-element does not exceed

$$C\mu^2h^{-2}\gamma_0^{-2}(1+|\log\hat{\gamma}_1|)^2\alpha_0^5 \lesssim C\mu^2h^{-2}(1+|\log\eta|)^2\alpha_0^3$$

and the summation with respect to α_0-partition of 1-element returns $C\mu^2h^{-2}(1+|\log\eta|)^2$.

Finally, consider $B(\bar{x},1)$ and apply here Fefferman-de Llave decomposition. Again there are two kinds of pairs and the total contributions of the pairs of kind (b) we already estimated while the total contribution of the pairs of kind (a) does not exceed $Ch^{-4}+C\mu^2h^{-2}\eta^{-1}(1+|\log\eta|)^2$ where we recalled the forgotten terms.

Again, this is estimate for cut-off expression. Going to uncut expression we repeat the same trick as before but as we deal with D-term we need to consider "mixed" pairs when one "factor" comes with θ and another with θ' but then contribution of such pair does not exceed $C(\nu h^{-4})^{\frac12}(\nu' h^{-4})^{\frac12}$. Easy details are left to the reader.

Therefore returning to the original scale we conclude that the contribution of ℓ-layer to (26.4.28) does not exceed

$$C\zeta^4\ell^3 + CB^2\ell\zeta^{-1}(1+|\log\ell^2\zeta|)^2 \tag{26.4.30}$$

which is exactly the right-hand expression of (26.4.26) squared and multiplied by ℓ^{-1} due to scaling.

Remark 26.4.10. In comparison with the non-degenerate case $|\nabla W_B^{\mathsf{TF}}| \asymp \zeta^2\ell^{-1}$ we acquired the last term.

Assume first that condition (26.2.28) is fulfilled. Then

(i) For $B \le Z^{\frac{4}{3}}$, $\ell \le Z^{-\frac{1}{3}}$ we have $\zeta = Z^{\frac{1}{2}}\ell^{-\frac{1}{2}}$ and expression (26.3.42) returns $CZ^2\ell + CB^2\ell^{\frac{3}{2}}Z^{-\frac{1}{2}}$ and the summation with respect to ℓ results in its value as $\ell = Z^{-\frac{1}{3}}$ i.e. $CZ^{\frac{5}{3}} + CB^2Z^{-1}$ with the dominating first term.

(ii) For $B \le Z^{\frac{4}{3}}$, $\ell \ge Z^{-\frac{1}{3}}$ we have $\zeta = \ell^{-2}$ and expression (26.3.42) returns $C\ell^{-5} + CB^2\ell^3$. We need to sum as long as $\mu h \le 1$ i.e. $Z^{-\frac{1}{3}} \le \ell \le B^{-\frac{1}{4}}$ and the summation returns $CZ^{\frac{5}{3}} + CB^{\frac{5}{4}}$ with the dominating first term.

(iii) For $Z^{\frac{4}{3}} \le B \le Z^2$, $\ell \le B^{-1}Z$ we have $\zeta = Z^{\frac{1}{2}}\ell^{-\frac{1}{2}}$ and expression (26.3.42) returns $CZ^2\ell + CB^2Z^{-\frac{1}{2}}\ell^{\frac{3}{2}}$. Then the summation results in $CZ^3B^{-1} + CB^{\frac{1}{2}}Z \lesssim Z^{\frac{3}{5}}B^{\frac{4}{5}}$.

Sure, we need to consider also mixed pairs of the layers and their contributions are

$$C\bigl(\zeta^2\ell^2 + CB\ell\zeta^{-\frac{1}{2}}(1+|\log \ell^2\zeta|)\bigr)\times\bigl(\zeta'^2\ell'^2 + CB\ell'\zeta'^{-\frac{1}{2}}(1+|\log \ell'^2\zeta'|)\bigr)\times(\ell+\ell')^{-1}$$

and the summation with respect to ℓ and ℓ' returns the same expression as above.

If assumption (26.2.28) is not fulfilled we use the same trick as in the previous Subsection 26.4.2. Therefore we arrive to the Statement (i) of Proposition 26.4.11 below. Applying the same arguments as in the proof of Proposition 26.4.9 we arrive to the Statement (ii):

Proposition 26.4.11. *(i) For $B \le Z^2$ the contribution of the zone $\mathcal{X}_2\times\mathcal{X}_2$ to expression* (26.4.28) *does not exceed $C\max(Z^{\frac{5}{3}}, Z^{\frac{3}{5}}B^{\frac{4}{5}})$.*

(ii) For $B \le Z$ contribution of the zone $\mathcal{X}_2 \times \mathcal{X}_2$ to expression (26.4.28) *does not exceed $CZ^{\frac{5}{3}-\delta}$.*

26.4.4 Semiclassical T-Term

Semiclassical T-Term: Zone $\mathcal{X}_1$ Extended

First let us cover zone $\mathcal{X}_1$ extended.

What is $\mathcal{X}_1$ Extended? To define this zone $\mathcal{X}_1' := \{x\colon \ell(x) \le r\}$, where we define W using P rather than P_B let first us analyze the precise extension in the framework of N- and D-terms. For N-term we have approximation error and corresponding D-term not exceeding respectively $C(\mu h)^2\eta^{-\frac12}h^{-3} = CB^2\zeta^{-\frac32}\ell^2$ and this expression squared and multiplied by ℓ^{-1} i.e. $CB^4\zeta^{-3}\ell^3$. Finally, both expressions are summed to their values as $\ell = r$. Recall that either $\zeta = Z^{\frac12}\ell^{-\frac12}$ or $\zeta = \ell^{-2}$.

(i) Consider first $B \le Z^{\frac43}$. Then we want these errors not to exceed respectively $CZ^{\frac23}$ and $CZ^{\frac53}$. Obviously, if $r \ge Z^{-\frac13}$ the first condition is more restrictive. In this case plugging $\zeta = r^{-2}$ and we set $CB^2r^5 = Z^{\frac23}$ i.e. $r = B^{-\frac25}Z^{\frac{2}{15}}$. Then $r \ge Z^{-\frac13}$ as long as $B \le Z^{\frac76}$.

Then $\mu = Br^3 = B^{-\frac15}Z^{\frac{6}{15}} \ge Z^{\frac16}$ and $h = B^{-\frac25}Z^{\frac{2}{15}} \ge Z^{-\frac13}$; and one can see easily that $\mu \gtrsim h^{-\frac12}$ provided $\ell(x) \ge r$.

(ii) Consider next $Z^{\frac76} \le B \le Z^{\frac43}$. Then for $r \le Z^{-\frac13}$ we have $\zeta = Z^{\frac12}r^{-\frac12}$. In this case the second requirement is more restrictive and we set $B^4Z^{-\frac32}r^{\frac92} = Z^{\frac53}$, i.e. $r = B^{-\frac89}Z^{\frac{19}{27}}$. Then $\mu = B^{-\frac13}Z^{\frac59}$ and $h = Z^{-\frac12}r^{-\frac12} = B^{\frac49}Z^{-\frac{23}{27}}$ and $\mu \ge h^{-\frac37}$; this is better than $h^{-\frac13}$.

However, we can do better than this: observe that $\mu h \le \eta$ if and only if $r \ge B^2Z^{-3}$ i.e. $B \le Z^{\frac{50}{39}}$, which is greater than $Z^{\frac76}$ but less than $Z^{\frac43}$, so we test μ and h in this case: $\mu = Z^{\frac{5}{39}}$ and $h = Z^{\frac{11}{39}}$ and $\mu \ge h^{-\frac{5}{11}}$ provided $\ell(x) \ge r$.

If $B \ge Z^{\frac{5}{11}}$ we will use another estimate for D-term: namely it does not exceed $(\mu h)^3h^{-6}r^{-1} = B^3r^5$ and we want it not to exceed $Z^{\frac53}$, so $r = Z^{\frac13}B^{-\frac35}$ (which is still less than $Z^{-\frac13}$) and $\mu = B^{\frac{1}{10}}$ and $h = B^{\frac{3}{10}}Z^{-\frac23}$ and we test it as $B = Z^{\frac43}$ when $\mu = B^{\frac{1}{10}}$ and $h = B^{-\frac15}$, so exponent $-\frac{5}{11}$ fits again.

(iii) Finally, if $Z^{\frac43} \le B \le Z^3$ then the error D-term does not exceed B^3r^5 and we want it not to exceed $B^{\frac45}Z^{\frac35}$. So, we pick up $r = B^{-\frac{11}{25}}Z^{\frac{3}{25}}$, $\mu = B^{\frac{17}{50}}Z^{-\frac{8}{25}}$, $h = B^{\frac{11}{50}}Z^{-\frac{14}{25}}$ and exponent $-\frac{5}{11}$ fits again.

When we can Use the same Method for T-Term? As far as semi-classical T-expression is concerned an approximation error of such approach in the localized and scaled settings is $C(\mu h)^{\frac52}h^{-3}$ [27] which is $O(h^{-1})$ only

[27] If instead of $P_B(W)$ we use $P(W)+\frac12 P''(W)B^2$ rather than $P(W)$. This modification does not affect our previous arguments.

if $\mu \ge h^{-\frac{1}{5}}$. One can extend it to $\mu \ge h^{-\frac{1}{5}-\delta}$ using the same trick as in Remark 26.4.8 but we need to do better than this.

On the other hand, observe that in fact an approximation error does not exceed[27] $C(\mu h)^3\eta^{-\frac{1}{2}}h^{-3} \asymp CB^3\ell^2\zeta^{-\frac{7}{2}}$ in the localized scaled settings. The simple proof is left to the reader. This is translated into $CB^3\ell^2\zeta^{-\frac{3}{2}}$ into unscaled settings. Summation with respect to $\ell \le r$ returns its value as $\ell = r$.

So we get CB^3r^5 as $B \le Z^{\frac{4}{3}}$ and $r \ge Z^{-\frac{1}{3}}$. Consider first $B \le Z$. In this case we want $CB^3r^5 \le CZ^{\frac{5}{3}}$ and we pick up $r = B^{-\frac{3}{5}}Z^{\frac{1}{3}}$ which is greater than $Z^{-\frac{1}{3}}$ provided $B \le Z^{\frac{10}{9}}$. Then $\mu = Br^3 = B^{-\frac{4}{5}}Z \ge Z^{\frac{1}{5}}$ and $h = r = B^{-\frac{3}{5}}Z^{\frac{1}{3}} \ge Z^{-\frac{4}{15}}$ and $\mu \ge h^{-\frac{3}{4}}$.

If $Z \le B \le Z^{\frac{4}{3}}$ but still $r \ge Z^{-\frac{1}{3}}$ we want $CB^3r^5 \le CZ^{\frac{4}{3}}B^{\frac{1}{3}}$[28] and we pick up $r = B^{-\frac{8}{15}}Z^{\frac{4}{15}}$ and we want it to be greater than $Z^{-\frac{1}{3}}$ i.e. $B \le Z^{\frac{9}{8}}$. Then $\mu = Br^3 = B^{-\frac{3}{5}}Z^{\frac{4}{5}} \ge Z^{\frac{1}{8}}$ and $h = B^{-\frac{8}{15}}Z^{\frac{4}{15}} \ge B^{-\frac{1}{3}}$ and $\mu \ge h^{-\frac{3}{8}}$. It is not as good as $\mu \ge h^{-\frac{3}{7}}$.

Then we use the smooth canonical form. In the operator perturbation terms have factors μ^{-2}, μ^{-4} etc and we can use the standard approach to get rid of $\mu^{-4} \le \mu h$, so we need to consider only μ^{-2}.

However let before scaling the second derivative of W be of magnitude θ; then after scaling it becomes of magnitude $\theta' = \gamma_0^2\gamma_1^2\theta$ and then the perturbation is of magnitude $\theta\mu^{-2}$ but contribution of the error will be (after we compare the true Riemann sum and the corresponding integral and their difference $Ch^{-3}\nu\mu^{-2}(\mu h)^2(\theta')^{-\frac{1}{2}}\times\alpha_1^3 \le C\theta^{\frac{1}{2}}h^{-1}\gamma_0^{-1}\gamma_1^{-1}\alpha_1^3 \le Ch^{-1}\gamma_1^{-\frac{1}{2}}\alpha_1^3$ where we used that $\theta \le C\gamma_0^2\gamma_1$. Then summation over α_1-partition of α_0 element returns $Ch^{-1}\alpha_0^3$ and the summation over γ_0-partition returns Ch^{-1} as desired. Therefore we covered zone $\mathcal{X}_1$ for T-term.

Semiclassical T-Term: Zone $\mathcal{X}_2$

Tauberian Estimate. Tauberian estimate for cut-off expression is rather simple:

$$C\mu h^{-1}\gamma_0^{-1}\gamma_1^{-1}\gamma_2^{-1}\times h\gamma_0^{-3}\gamma_1^{-\frac{5}{2}}\gamma_1^{-2}\times\gamma_0^4\gamma_1^3\gamma_2^2\alpha_2^3 \asymp C\mu\gamma_1^{-\frac{1}{2}}\gamma_2^{-1}\alpha_2^3$$

which nicely sums to $C\mu$ without logarithm due to the same positive eigenvalue arguments as before; for θ-cut-off with $\theta \ge \mu h$ we get the same albeit

[28] Because the semiclassical remainder estimate is not better than this. Actually, due to Remark 26.3.7 we can do marginally better than this, but we leave this analysis to the reader.

with γ_j defined by the same formula albeit with $(w_j - 2j\mu h s_j^{-1})$ replaced by θs_j^{-1} where s_j^{-1} means the scale; and this should be multiplied by $\theta/(\mu h)$. The result nicely sums to Ch^{-1}. This is what was required.

Magnetic Weyl Expression. Now we will get the same answer albeit $C\mu^{-4}$ term will be supplemented by $C\mu^{-\frac{3}{2}}h$ which in cut-off sum adds $C\mu^{-\frac{3}{2}}h \times \mu h^{-2} \le Ch^{-1}$.

We can use the standard approach, with an error $C\mu^{-\frac{3}{2}}h \times \theta/(\mu h) \times \mu h^{-2} \asymp C\theta\mu^{-\frac{3}{2}}h^{-2}$ which means that we can take $\theta = \mu^{\frac{3}{2}}h$ which is sufficient to deal with $\theta \ge C\mu^{\frac{3}{2}}h$; in particular, for $\mu \ge h^{\frac{2}{3}}$ we are done. But for $\theta \ge \mu h^{1-\delta}$ we can apply the weak magnetic field approach, which is sufficient. So we arrive to inequality

$$|\int_{-\infty}^{\tau}\int \phi(x)\Big(e_\varphi(x,x,\tau) - P'_{\beta,\varphi}\big(w(x)+\tau\big)\Big)\,dx\,d\tau| \le Ch^{-1} \tag{26.4.31}$$

and therefore we arrive to

Proposition 26.4.12. *(i) If $B \le Z^2$ the contribution of zone $\mathcal{X}_2$ to the expression*

$$\int_{-\infty}^{\tau}\int \phi(x)\Big(e_\varphi(x,x,\tau) - P'_{B,\varphi}\big(W(x)+\tau\big)\Big)\,dx\,d\tau \tag{26.4.32}$$

does not exceed $C\max\big((Z+B)^{\frac{1}{3}}Z^{\frac{4}{3}}, Z^{\frac{3}{5}}B^{\frac{4}{5}}\big)$.

(ii) If $B \le Z$ the contribution of zone $\mathcal{X}_2$ to expression (26.4.32) *does not exceed $CZ^{\frac{5}{3}-\delta}$.*

Mollification Errors. Further, we need to estimate

$$\int \phi(x)\Big(P'_B(W(x)+\tau)) - P'_B(W_B^{\mathsf{TF}}(x)+\tau))\Big)\,dx, \tag{26.4.33}$$

$$\int \phi(x)\Big(P_B(W(x)+\tau)) - P_B(W_B^{\mathsf{TF}}(x)+\tau))\Big)\,dx, \tag{26.4.34}$$

$$\mathsf{D}\Big(\phi(x)\big(P'_B(W(x)+\tau)) - P'_B(W_B^{\mathsf{TF}}(x)+\tau)\big),\ \phi(x)\big(P'_B(W(x)+\tau)) - P'_B(W_B^{\mathsf{TF}}(x)+\tau)\big)\Big) \tag{26.4.35}$$

and

$$\|\phi(x)\nabla\big(W(x)-W_B^{\mathsf{TF}}(x)\big)\|^2. \tag{26.4.36}$$

We start from local versions (so in fact we dealing with w and w_β^{TF}).

Obviously after all rescalings $\hbar = h\gamma_0^{-3}\gamma_1^{-\frac{5}{2}}\gamma_2^{-2}$ and therefore $\varepsilon = \hbar^{\frac{3}{2}} = h^{\frac{3}{2}}(\gamma_0^{-3}\gamma_1^{-\frac{5}{2}}\gamma_2^{-2})^{-\frac{3}{2}}$ where we set $\delta = 0$ but we will show that we have a reserve to set it as $\delta > 0$ if we want to estimate (26.4.33) by h and (26.4.34)–(26.4.36) by h^2.

We claim that

$$|w - w_\beta^{\mathsf{TF}}| \le C\varsigma := C\beta\eta\big(\gamma_0^4\gamma_1^3\gamma_2^2\varepsilon\big)^{\frac{5}{2}}. \tag{26.4.37}$$

and

$$|\nabla(w - w_\beta^{\mathsf{TF}})| \le C\varsigma_1 := C\beta\eta\big(\gamma_0^4\gamma_1^3\gamma_2^2\varepsilon\big)^{\frac{3}{2}}. \tag{26.4.38}$$

Indeed, it follows from equation (26.4.2).

Then the contribution of α_2-element to (26.4.34) does not exceed $C\varsigma\varepsilon\alpha_2^3$ as measure of zone of α_2-element where $w \ne w_\beta^{\mathsf{TF}}$ is $O(\varepsilon\alpha_2^3)$. One can see easily that $\varsigma\varepsilon = O(h^{\frac{7}{3}})$ and therefore $C\varsigma\varepsilon\alpha_2^3 = O(h^{\frac{7}{3}}\alpha_2^3)$ and the summation over α_2-partition of 1-element returns $O(h^{\frac{7}{3}})$.

Modulo above calculations the contribution of α_2-element to (26.4.33) does not exceed $C\beta\varsigma^{\frac{1}{2}}\varepsilon\alpha_3^2$. One can check easily that $\varsigma\varepsilon = O(h^{\frac{3}{2}}\gamma_2^{-\frac{1}{2}})$ and therefore $C\varsigma^{\frac{1}{2}}\varepsilon\alpha_2^3 = O(h^{\frac{7}{3}}\alpha_1^3\gamma_2^{\frac{5}{2}})$ and the summation over α_2-partition of α_1-element returns $O(h^{\frac{3}{2}}\alpha_1^3)$ and then the summation over α_1-partition of 1-element returns $O(h^{\frac{3}{2}})$.

Similarly, expression (26.4.35) with $\phi = \phi_{\alpha_2}$ does not exceed $C\varsigma\varepsilon_2\alpha_2^5 \le Ch^3\alpha_2^4$ and the summation over α_2-partition of 1-element returns $O(h^3)$. However we need to consider disjoint pairs of α_2-elements belonging to given α_1-element and their contribution does not exceed

$$Ch^3\int \gamma_{2x}^{-\frac{1}{2}}\gamma_{2y}^{-\frac{1}{2}}|x-y|^{-1}\,dxdy \le Ch^2\alpha_1^5$$

and then summation over α_1-partition of 1-element returns $O(h^{\frac{3}{2}})$. We need also to consider disjoint pairs of α_1-elements belonging to given 1-element and their contribution does not exceed $Ch^3\int |x-y|^{-1}\,dxdy = O(h^3)$.

Finally, contribution of α_2-element to (26.4.36) does not exceed $C\varsigma_1^2\varepsilon\alpha_2^3$ and one can check easily that this does not exceed $C\alpha_1^3\gamma_2^{\frac{8}{3}}h^{\frac{8}{3}}$ and the summation over α_2-partition of α_1-element returns $C\alpha_1^3h^{\frac{8}{3}}$; then summation over 1-partition of 1-element returns $O(h^{\frac{8}{3}})$.

So, the scaled versions of (26.4.33) and (26.4.34)–(26.4.36) do not exceed Ch and Ch^2 respectively. Then the original versions of (26.4.33), (26.4.34), (26.4.34), and (26.4.36) do not exceed respectively $C\zeta^3\ell^3\times(\zeta\ell)^{-1}=C\zeta^2\ell^2$, $C\zeta^5\ell^3\times(\zeta\ell)^{-2}=C\zeta^3\ell$, $C\zeta^6\ell^5\times(\zeta\ell)^{-2}=C\zeta^4\ell^3$, and $C\zeta^4\ell\times(\zeta\ell)^{-2}=C\zeta^2\ell^{-1}\le C\zeta^4\ell^3$.

Leaving the easy details to the reader we arrive to

Proposition 26.4.13. *(i) Contribution of zone $\mathcal{X}_2$ to the mollification error* (26.4.33) *does not exceed $CZ^{\frac{2}{3}}$.*

(ii) Contribution of zone $\mathcal{X}_2$ to the mollification error (26.4.34) *does not exceed $CZ^{\frac{5}{3}}+o(Z^{\frac{4}{3}}B^{\frac{1}{3}})$.*

(iii) Contributions of zone $\mathcal{X}_2$ to the mollification errors (26.4.35) *and* (26.4.36) *do not exceed $CZ^{\frac{5}{3}}$.*

and

Proposition 26.4.14. *Let $B\le Z$. Then*

(i) Contribution of zone $\mathcal{X}_2$ to the mollification error (26.4.33) *does not exceed $CB^{\delta}Z^{\frac{2}{3}-\delta}$.*

(ii) Contributions of zone $\mathcal{X}_2$ to the mollification errors (26.4.35)–(26.4.35) *do not exceed $CB^{\delta}Z^{\frac{5}{3}-\delta}$.*

Remark 26.4.15. Consider the mollification parameter in "absolute" scale (i.e. ℓ-scale): $\varepsilon=\gamma_0\gamma_1\gamma_2\gamma(h/\gamma_0^3\gamma_1^{\frac{5}{2}}\gamma_2^2)^{\frac{2}{3}-\delta}$. One can see easily that $\varepsilon\ge h^{\frac{2}{3}-\delta}\ge(\mu^{-1}h)^{\frac{1}{2}-\delta_1}$ which makes reduction possible.

Remark 26.4.16. All statements of Propositions 26.4.13 and 26.4.14 are valid for semiclassical errors as well except statements, concerning T-term; tose should include also terms $Ca^{-\frac{1}{2}}Z^{\frac{3}{2}}$ for $a\le Z^{-\frac{1}{3}}$ and $Ca^{-\delta}Z^{\frac{5}{3}+\frac{1}{3}\delta}$ for $a\ge Z^{-\frac{1}{3}}$.

26.4.5 Zone $\mathcal{X}_3$

Zone $\mathcal{X}_3$ defined by $\mu h \ge C_0$, $h \le 1$, $\{x\colon \ell(x) \le \epsilon_0 \bar{r}\}$ appears only as $Z^{\frac{4}{3}} \le B \le Z^3$. In this zone W_B^{TF} is smooth and no mollification is necessary. Further, in this zone the canonical form contains only one number $j = 0$ and $|D^\alpha W| \le C_\alpha \zeta^2 \ell^{-|\alpha|}$ and $W \asymp \zeta^2$.

Therefore we have non-degeneracy condition fulfilled and applying the standard theory we conclude that in the scaled version contribution of $B(0,1)$ to the semiclassical errors in N- and T-terms and into D-term are $C\mu h^{-1}$, $C\mu$ and $C\mu^2 h^{-2}$ respectively.

In the unscaled version they become $CB\ell^2$, $CB\ell\zeta \le CBZ^{\frac{1}{2}}\ell^{\frac{1}{2}}$ and $CB^2\ell^3$ and after summation (where for D-term we need to consider mixed contribution of different layers) we arrive to the same expressions calculated as $\ell = \bar{r} = B^{-\frac{2}{5}} Z^{\frac{1}{5}}$ i.e. $CB^{\frac{1}{5}} Z^{\frac{2}{5}}$, $CB^{\frac{4}{5}} Z^{\frac{3}{5}}$ and $CB^{\frac{4}{5}} Z^{\frac{3}{5}}$ respectively. Thus we have proven

Proposition 26.4.17. *Let $Z^{\frac{4}{3}} \le B \le Z^3$. Then*

(i) Contribution of zone $\mathcal{X}_3$ to the N*-error does not exceed $CZ^{\frac{2}{5}} B^{\frac{1}{5}}$.*

(ii) Contributions of zone $\mathcal{X}_3$ to the T*-error and* D*-term do not exceed $CZ^{\frac{3}{5}} B^{\frac{4}{5}}$.*

26.5 Semiclassical Analysis in the Boundary Strip for $M \ge 2$

To finish our analysis we need to get the same estimates as before in the *boundary strip*

$$\mathcal{Y} := \{x\colon W(x) + \nu \le \epsilon G,\ \epsilon \bar{r} \le \ell(x) \le c\bar{r}\} \tag{26.5.1}$$

with

$$G := \begin{cases} (Z-N)_+^{\frac{4}{3}} & \text{for } B \le (Z-N)_+^{\frac{4}{3}}, \\ B & \text{for } (Z-N)_+^{\frac{4}{3}} \le B \le Z^{\frac{4}{3}}, \\ Z^{\frac{4}{5}} B^{\frac{2}{5}} & \text{for } B \ge Z^{\frac{4}{3}}. \end{cases} \tag{26.5.2}$$

which coincides with (26.2.48) as $B \ge (Z-N)^{\frac{4}{3}}$. Recall that $\bar{r} = (Z-N)_+^{-\frac{1}{3}}$, $\bar{r} = B^{-\frac{1}{4}}$ and $\bar{r} = B^{-\frac{2}{5}} Z^{\frac{1}{5}}$ in these three cases respectively. Analysis of

the *external zone* $\mathcal{X}_4 := \{x\colon \ell(x) \ge C_1\bar{r}\}$ will be trivial and *inner zone* $\{x\colon W(x)+\nu \ge \epsilon G\}$ has been covered already.

26.5.1 Properties of W_B^{TF} if $N = Z$

Let us explore properties of W_B^{TF} in $\mathcal{Y}$ if $N = Z$ [29] Let us rescale $x \mapsto x' = x\bar{r}^{-1}$, $W \mapsto w = G^{-1}W$ and define $h = G^{-\frac12}\bar{r}^{-1}$, $\mu = G^{-\frac12}B\bar{r}$. Then

(a) In the case $B \le Z^{\frac43}$ we need to rescale $w(x') = B^{-1}W_B^{\mathsf{TF}}(x'\bar{r})$ and take $h = B^{-\frac14} \le 1$, $\mu = B^{\frac14} \ge 1$, $\mu h = 1$.

(b) On the other hand, for $B \ge Z^{\frac43}$ one should set $w(x') = \bar{r}Z^{-1}W_B^{\mathsf{TF}}(x'\bar{r})$ and $h = (Z\bar{r})^{-\frac12} = (BZ^{-3})^{\frac15} \le 1$, $\mu = BZ^{-\frac12}\bar{r}^{\frac32} = B^{\frac25}Z^{-\frac15} \ge 1$, $\mu h = B^{\frac35}Z^{-\frac45} \ge 1$ ($\mu h \asymp 1$ iff $B \lesssim Z^{\frac43}$, $h \asymp 1$ iff $B \asymp Z^3$).

We will use now only rescaled coordinates unless the opposite is specified. Then in $\mathcal{Y}$ rescaled

$$\Delta w = \kappa w_+^{\frac12}, \qquad \kappa = 12, \qquad w \to \theta = \nu\bar{\zeta}^{-2} \quad \text{as} \quad |x| \to \infty, \tag{26.5.3}$$

with $\bar{\zeta} := G^{\frac12}$ where one can always get $\kappa = 12$ after rescaling $w \mapsto 144\kappa^{-2}w$.

Proposition 26.5.1. *Let $Z = N$. Then in $\mathcal{Y}$ after rescaling*

$$|D^\alpha w| \le C_\alpha w\gamma^{-|\alpha|} \qquad \forall \alpha \tag{26.5.4}$$

with the scaling function $\gamma = w^{\frac14}$ and

$$|\nabla w^{\frac14}| \le 1 + Cw^t \tag{26.5.5}$$

with some constant C and exponent $t > 0$.

Proof. (a) Rescaling $x \mapsto x\bar{r}^{-1}$ we get an equations $(26.5.3)_0 = (26.5.3)$ with $\theta = 0$. We know that $W = 0$ for $\ell(x) \ge c\bar{r}$; so after rescaling $w = 0$ for $\ell(x) \ge c$. On the other hand, $w \asymp 1$ as $\ell(x) \le \epsilon$ (uniformly with respect to all the parameters).

Let us consider solution of the equation

$$\Delta w_s = 12 w_+^s \tag{26.5.6}$$

[29] I.e. $\nu = 0$ and $G = B\bar{r}^{-4}$.

in $\Omega = \{w \le \epsilon, \ell \le c\}$ with the boundary condition $w_s = w$ at $\partial\Omega$; $s > \frac{1}{2}$.

Note first that $w_s \ge 0$. Really, w_s is the solution of the variational problem to minimize

$$\|\nabla w\|^2 + 24(s+1)^{-1} \int w_+^{s+1}\, dx \tag{26.5.7}$$

and one makes this functional only less replacing w by w_+.

Further, the standard maximum principle arguments show that $w_s \searrow$ as $s \searrow$ [30]. Obviously $w_s \searrow w$ and $w_s \to w$ in $\mathscr{C}^\infty$ in $\{x\colon w(x) > 0\}$ as $s \searrow \frac{1}{2}$.

We claim that

$$w_s \in \mathscr{C}^{4s+2}. \tag{26.5.8}$$

To prove (26.5.8) note first that $w \in \mathscr{C}^{2-\delta'}$ uniformly with respect to all the parameters for any $\delta' > 0$. Then $w_s^s \in \mathscr{C}^{s-\delta}$ and then (26.5.6) yields that $w_s \in \mathscr{C}^{2+s-\delta}$ as soon as $s - \delta \notin \mathbb{Z}$. Then since $w_s \ge 0$ we get $|\nabla w_s| \le c w_s^{\frac{1}{2}}$ and so $w_s^s \in \mathscr{C}^{s-\frac{1}{2}}$. Then equation (26.5.6) again yields that $w_s \in \mathscr{C}^{s+\frac{3}{2}}$.

Now we need more subtle arguments. First, for $|y| = 1$

$$w_s(x+ty) = w_s(x) + t(\nabla w_s)_x \cdot y + \frac{1}{2}(\nabla^2 w_s)_x(y)t^2 + O\big(t^3\big). \tag{26.5.9}$$

Then the lowest eigenvalue ς of $\nabla^2 w_s$ at x should be greater than $-C w_s^{\frac{1}{3}}$. Indeed, otherwise we can take y as the corresponding eigenvector and t with $|t| = \epsilon\varsigma$ and with a sign making second term non-positive and get $w_s(x+ty) < 0$.

This lower estimate for eigenvalues of $\nabla^2 w_s$ and equation (26.5.6) yield that $|\nabla^2 w_s| \le C w_s^{\frac{1}{3}}$. But then $|\nabla w_s| \le C w_s^{\frac{2}{3}}$. Really, otherwise picking $y = |\nabla w_s|^{-1}\nabla w_s$ with $|t| = \epsilon |\nabla w_s|^{\frac{1}{2}}$ and an appropriate sign we would get $w_s(x+ty) < 0$.

These estimates yield that $w_s(x') \asymp w_s(x)$ in $B\big(x, \gamma(x)\big)$ with $\gamma(x) = \epsilon w_s^{\frac{1}{3}}$. Then $w_s^s \in \mathscr{C}^{\frac{3}{2}}$. In fact, let us consider $f = w_s^{s-1}\nabla w$ and $|f(x) - f(x')|$. Let

[30] If $\Delta w_i = f_i(w_i)$ in Ω, $f_i(w) \nearrow$ as $w \nearrow$ and $f_1(w) \ge f_2(w)$ then $\Delta(w_1 - w_2) > 0$ as $w_1 > w_2$ and then $w_1 - w_2$ does not reach maximum inside Ω.

us consider first $|x-x'| \ge \frac{1}{3}\bigl(\gamma(x)+\gamma(x')\bigr)$; since $|f(x)| \le \gamma(x)^{\frac{1}{2}}$ at each point we get that $|f(x)-f(x') \le |x-x'|^{\frac{1}{2}}$.

On the other hand, for $|x-x'| \le \frac{1}{3}\bigl(\gamma(x)+\gamma(x')\bigr)$ we conclude that $\gamma(x) \asymp \gamma(x')$ and $|f(x)-f(x')| \le |\nabla f|\cdot|x-x'| \le |x-x'|^s$ due to inequality $|\nabla f| \le |\nabla^2 w_s| w_s^{s-1} + |\nabla w_s|^2 w_s^{s-2} \le C\gamma^{s-1}$.

Therefore $w_s^s \in \mathscr{C}^{s+1}$ and equation (26.5.6) yields that $w_s \in \mathscr{C}^{3+s}$.

(b) In the next round we assume that $w_s \in \mathscr{C}^{4+s-\delta}$ with *some* $\delta \in (0,1)$. Then

$$
\begin{aligned}
(26.5.10)\quad & w_s(x+ty) \le \\
& w_s(x) + t(\nabla w_s)_x \cdot y + \frac{1}{2}(\nabla^2 w_s)_x(y)t^2 + \frac{1}{6}(\nabla^3 w_s)_x(y)t^3 + C|t|^p
\end{aligned}
$$

with $p = \min(4, 4+s-\delta)$.

We claim now that the lowest possible eigenvalue ς of $\bigl(\nabla^2 w_s\bigr)_x$ is greater than $-Cw_s^{(p-2)/p}$. Really, otherwise let us pick up y as the corresponding eigenvector, t with $|t| = \epsilon|\varsigma|^{1/(p-2)}$ and with a sign making expression

$$
t(\nabla w_s)_x \cdot y + \frac{1}{6}t^3(\nabla^3 w_s)_x(y)
$$

non-positive and get $w_s(x+ty) < 0$ again. Now equation (26.5.6) yields that inequality

$$
(26.5.11)_k \qquad |\nabla^k w_s| \le C w_s^{(p-k)/p}
$$

holds with $k=2$.

Further, we claim that this inequality holds with $k=1,3$. Indeed, if one or both of these inequalities are violated then let us take corresponding y and t with

$$
|t| = \epsilon\Bigl(|\nabla w_s|^{1/(p-1)} + |\nabla^3 w_s(y)|^{1/(p-3)}\Bigr)
$$

(calculated on y); replacing ϵ by 2ϵ if necessary we get

$$
|t(\nabla w_s)_x \cdot y + \frac{1}{6}t^3(\nabla^3 w_s)_x(y)\bigr| \ge \epsilon_0 |t(\nabla w_s)_x \cdot y| + |\frac{1}{6}t^3(\nabla^3 w_s)_x(y)|
$$

and choosing an appropriate sign of t we get $w(x+ty) < 0$.

Therefore inequalities $(26.5.11)_{1-3}$ *hold*. The same arguments as above with $\gamma = w_s^{1/p}$ lead us to $w^s \in \mathscr{C}^{ps}$ and then equation (26.5.6) yields that $w_s \in \mathscr{C}^{ps+2}$. So, now we came back with δ replaced by $\delta' = 2 + s - ps$ and one can see easily that if $\delta > s$ then $\delta' = s + (2 - 4s) + (\delta - s)s$ and after few repeats $\delta < s$. Then we get (26.5.8). Unfortunately, constants depend on s due to the fact that $\Delta w \in \mathscr{C}^2$ fails to yield $w \in \mathscr{C}^4$.

(c) Now we are going to finish the proof of (26.5.4). Let us consider w_s again and let $\gamma = \gamma_{s,\delta} = w_s^{1/(4-\delta)}$. Due to the previous inequalities $\gamma \in \mathscr{C}^1$. We claim that $|\nabla\gamma|$ is bounded uniformly with respect to s, δ. Note first that $\Delta\gamma^{4-\delta} = \gamma^{(4-\delta)s}$ implies that

$$a|\nabla\gamma|^2 + b\gamma\Delta\gamma = \gamma^\sigma \tag{26.5.12}$$

with $a = \frac{1}{12}(4-\delta)(3-\delta)$, $b = \frac{1}{12}(4-\delta)$, and $\sigma = 4s - 2 + (1-s)\delta$. Let $\psi = |\nabla\gamma|^2$; obviously ψ is uniformly bounded at $\partial\Omega$. Let us consider maximum of ψ reached inside Ω. At the point of maximum

$$\sum_i \gamma_{x_i x_j}\gamma_{x_i} = 0 \tag{26.5.13}$$

and

$$\frac{1}{2}\Delta\psi = \sum_{i,j}\gamma^2_{x_i x_j} + \sum_i \gamma_{x_i}\big(\Delta\gamma\big)_{x_i} = \sum_{i,j}\gamma^2_{x_i x_j} + b^{-1}\sum_i \gamma_{x_i}\Big(\gamma^{-1}\big(\gamma^\sigma - a|\nabla\gamma|^2\big)\Big)_{x_i}.$$

Due to (26.5.12) and due to (26.5.13) this expression is equal to

$$\sum_{i,j}\gamma^2_{x_i x_j} - b^{-1}\gamma^{-2}|\nabla\gamma|^2\big(\gamma^\sigma - a|\nabla\gamma|^2\big) + b^{-1}\sigma\gamma^{\sigma-2}|\nabla\gamma|^2$$

and therefore at an inner point of minimum $a|\nabla\gamma|^2 \le \gamma^\sigma$. So, $|\nabla\gamma| \le C$ is proven and for $s \searrow \frac{1}{2}$, $\delta \searrow 0$ we get that $|\nabla w^{\frac{1}{4}}| \le C$.

Let us pick $\gamma(x) = \epsilon' w^{\frac{1}{4}}(x)$; then $|\nabla w| \le \frac{1}{2}$ and $w(x) \asymp w(\mathsf{x})$ in $B\big(x, \gamma(\mathsf{x})\big)$. This and equation (26.5.6) easily yield (26.5.4).

To prove inequality (26.5.5) let us consider w_s again and let us take now $\psi = |\nabla\gamma|^2 - F\gamma^{2t}$ with $t > 0$; obviously ψ is non-positive at $\partial\Omega$ for

sufficiently large F. Let us consider maximum of ψ reached inside Ω. At the point of maximum

$$\sum_i \gamma_{x_i x_j}\gamma_{x_i} - Ft\gamma^{2t-2}\gamma_{x_j} = 0 \tag{26.5.13$'$}$$

and the same arguments as before (plus inequality $|\nabla\gamma| \le C_0$) show that at an inner point of maximum $a|\nabla\gamma|^2 \le \gamma^\sigma + CtF\gamma^{2t}$ where C does not depend on F and small $t > 0$. Then at this point $\psi \le 1$ for small enough $t > 0$ and as $s \to \frac{1}{2}$ and $\delta \to 0$ we get (26.5.5). □

The following statement heavily uses estimate (26.5.5):

Proposition 26.5.2. *The following estimate holds*

$$\mathsf{D}(\gamma^{-1+s}, \gamma^{-1+s}) \le Cs^{-2} \tag{26.5.14}$$

with some constant C which does not depend on $s \in (0,1)$ where we set $\gamma^{-1+s} := w_+^{\frac{1}{4}(-1+s)}$ (i.e. it is 0 as $w \le 0$).

Proof. As in the notations of the proof of Proposition 26.5.1 $\delta = 0$ and $s = \frac{1}{2}$ we have (26.5.12) with $a = 1$, $b = 3$ and $\sigma = 0$:

$$\frac{1}{3}\gamma\Delta\gamma + |\nabla\gamma|^2 = 1. \tag{26.5.15}$$

Then

$$\gamma^{-1+s} = \gamma^{-1+s}|\nabla\gamma|^2 + \frac{1}{3}\gamma^s\Delta\gamma = (1 - \frac{s}{3})\gamma^{-1+s}|\nabla\gamma|^2 + \frac{1}{3(1+s)}\Delta\gamma^{1+s}$$

and

$$\begin{aligned}\mathsf{D}(\gamma^{-1+s}, \gamma^{-1+s}) \le (1 - \frac{s}{3})\mathsf{D}(\gamma^{-1+s}|\nabla\gamma|^2, \gamma^{-1+s}) + C \le \\ (1 - \frac{s}{3})\mathsf{D}(\gamma^{-1+s}, \gamma^{-1+s}) + C\mathsf{D}(\gamma^{-1+t+s}, \gamma^{-1+s}) + C\end{aligned}$$

due to (26.5.5) and this yields

$$\mathsf{D}(\gamma^{-1+s}, \gamma^{-1+s}) \le Cs^{-2}\mathsf{D}(\gamma^{-1+t+s}, \gamma^{-1+t+s}) + Cs^{-1}.$$

Substituting $s + mt$ instead of s, $0 \le m \le Ct^{-1}$ we recover (26.5.14). □

26.5.2 Analysis in the Boundary Strip $\mathcal{Y}$ for $N \ge Z$

We consider now the case of if $N \ge Z$ (i.e. $\nu = 0$ and $G = B\bar{r}^{-4}$).

It is really easy to construct the proper potential in this case: we just take

$$w_\varepsilon = w\phi_\varepsilon, \qquad \phi_\varepsilon = f\bigl(w\varepsilon^{-4}\bigr) \tag{26.5.16}$$

with $f \in \mathscr{C}^\infty((\frac12,\infty))$, $\mathsf{supp}(f) \subset (\frac12,\infty)$, $0 \le f \le 1$, $f(t) = 1$ for $t > 1$. Note that due to (26.5.3)

$$\begin{aligned}&\mathsf{D}(\gamma^{-1}\phi_\varepsilon, \gamma^{-1}\varphi_\varepsilon) \le C\varepsilon^{-2s}\mathsf{D}(\gamma^{s-1},\gamma^{s-1}) \le Cs^{-2}\varepsilon^{-2s},\\ &\mathsf{D}(1-\phi_\varepsilon, 1-\phi_\varepsilon) \le C\varepsilon^{2-2s}\mathsf{D}(\gamma^{s-1},\gamma^{s-1}) \le Cs^{-2}\varepsilon^{2-2s};\end{aligned}$$

then minimizing with respect to s $(= |\log\varepsilon|^{-1})$ the right-hand expression we conclude that

$$\mathsf{D}\bigl(\gamma^{-1}\phi_\varepsilon, \gamma^{-1}\varphi_\varepsilon\bigr) + \varepsilon^{-2}\mathsf{D}\bigl(1-\phi_\varepsilon, 1-\phi_\varepsilon\bigr) \le C\bigl(1+|\log\varepsilon|\bigr)^2 \tag{26.5.17}$$

and therefore

$$\int \gamma^{-1}\phi_\varepsilon\,dx + \varepsilon^{-1}\int (1-\phi_\varepsilon)\,dx \le C\bigl(1+|\log\varepsilon|\bigr). \tag{26.5.18}$$

Remark 26.5.3. (i) Recall that all these integrals are taken over domain $\{x\colon w(x) > 0\}$. To avoid possible troubles we pick $\varepsilon = h^{\frac13}$ and set in the zone $\{x\colon w(x) \le C_0 h^{\frac43}\}$

$$\gamma(x) = \mathsf{dist}(x, \{w \ge 2C_0h^{\frac43}\}),$$

$$w_\varepsilon = \begin{cases} -\gamma^4\phi'_\varepsilon & \text{for } \gamma \le \varepsilon,\\ -\varepsilon^4 & \text{for } \gamma \ge \varepsilon\end{cases} \tag{26.5.16}'$$

with $\phi'_\varepsilon = f(\gamma\varepsilon^{-1})$ and then in the complemental domain $\{x\colon w(x) \le -\varsigma^2\}$ our assumptions are fulfilled with $\varsigma = \varepsilon^2$ and $\varsigma\gamma = \gamma^3 \ge h$.

(ii) Further, for $\varepsilon = h^{\frac13-\delta}$ with sufficiently small exponent $\delta > 0$ it does not break estimate for mollification error in T-term.

(iii) Furthermore, for $t > \varepsilon$

$$\mathsf{mes}(\{x\colon \gamma(x) \le t\}) \le Ct^3\varepsilon^{-3}\,\mathsf{mes}(\{x\colon \gamma(x) \le \epsilon\varepsilon\})$$

and therefore

$$h^s \int \gamma^{-1-s}\varsigma^{-s}\,dx \le C\varepsilon^{-1}\,\mathsf{mes}(\{x\colon \gamma(x)\le \epsilon\varepsilon\}) \le CL \coloneqq C(1+|\log h|)$$

for sufficiently large s.

Using these estimates and the last remark we can prove easily

Proposition 26.5.4. *Let $N \ge Z$. Then*

(i) Contribution of $\mathcal{Y}\cup\mathcal{X}_4$ with external zone $\mathcal{X}_4 \coloneqq \{x\colon w(x)=0\}$ *to mollification and semiclassical errors in* N*-term do not exceed $CT_0\varepsilon^3(1+|\log\varepsilon|)$ and $R_0(1+|\log\varepsilon|)$ respectively with*

$$(26.5.19)_1 \quad T_0 = B^{\frac34},\qquad R_0 = B^{\frac12},\qquad T = B^{\frac74},\qquad R = B^{\frac54} \qquad \text{for } B \le Z^{\frac43}$$

and

$$(26.5.19)_2 \quad T_0 = Z,\qquad R_0 = B^{\frac15}Z^{\frac25},\qquad T = Z^{\frac95}B^{\frac25},\qquad R = Z^{\frac35}B^{\frac45} \qquad \text{for } Z^{\frac43} \le B \le Z^3.$$

(ii) Contribution of $\mathcal{Y}\cup\mathcal{X}_4$ to mollification and semiclassical D*-terms do not exceed $CT\varepsilon^6(1+|\log\varepsilon|)^2$ and $R(1+|\log\varepsilon|)^2$ respectively.*

(iii) Contribution of $\mathcal{Y}\cup\mathcal{X}_4$ to both mollification and semiclassical errors in T*-term do not exceed $CT\varepsilon^7(1+|\log\varepsilon|)$ and CR respectively.*

Proof. Really, estimates for mollification errors and terms immediately follow from the inequality

$$\mathsf{mes}(\{x\colon w(x)\le \varepsilon^4\}) \le C\varepsilon(1+|\log\varepsilon|) \tag{26.5.20}$$

which is due to (26.5.18).

Let us consider semiclassical errors and terms.

(i) Let us consider N-term first. Let us consider all possible balls and their contributions: the contribution of each ball $B\big(x,\gamma(x)\big)$ to the semiclassical error does not exceed $C\mu h^{-1}\gamma^2 \asymp CB\bar{r}^2\gamma^2$ and the total contribution does not exceed

$$CR_0 \int \gamma(x)^{-1}\,dx \le CR_0\big(1+|\log\varepsilon|\big) \tag{26.5.21}$$

where $R_0 = B\bar{r}^2$; recall that $\gamma(x)\ge\varepsilon$.

(ii) Consider semiclassical D-term. Let us consider all possible balls and their contributions: the similar arguments with the analysis of disjoint balls of different types and with analysis of the intersecting balls (of the same type) lead us to the proper estimate of the contribution of $\mathcal{Y}_4 \cup \mathcal{X}_4$ to semiclassical D-term: namely, it does not exceed $CR_0^2\bar{r}^{-1}\bigl(1+|\log\varepsilon|\bigr)^2$ (i.e. expression (26.5.21) squared and multipled by $C\bar{r}^{-1}$) where $R_0^2\bar{r}^{-1} \asymp R$.

(iii) Consider T-term. Let us consider all possible balls and their contributions. Contribution of each ball $B\bigl(x,\gamma(x)\bigr)$ to the semiclassical error does not exceed $C\bar{\zeta}^2\mu\varsigma^2\gamma \asymp CB\bar{\zeta}^2\bar{r}\varsigma\gamma^2$ and the total contribution does not exceed

$$CR\int \varsigma(x)\gamma(x)^{-2}\,dx \asymp CR \tag{26.5.22}$$

where $R = B\bar{\zeta}^2\bar{r}$ and $\varsigma(x) \asymp \gamma(x)^2$. □

Then picking appropriate $\varepsilon = h^{\frac{1}{3}}$ we arrive to

Corollary 26.5.5. *Let $N \ge Z$. Then*

(i) Contributions of $\mathcal{Y}\cup\mathcal{X}_4$ to all errors in N-terms do not exceed CR_0L with $L = (1+|\log BZ^{-3}|)$.

(ii) Contribution of $\mathcal{Y}\cup\mathcal{X}_4$ to all D-terms do not exceed CRL^2.

(iii) Contribution of $\mathcal{Y}\cup\mathcal{X}_4$ to all errors in T-terms do not exceed CR.

We will sum contributions of all zones to errors in Propositions 26.5.14 and 26.5.17 below.

Remark 26.5.6. Could we get rid of the logarithmic factors i.e. make $L = 1$ as it was in the case $M = 1$?

(i) With the mollification errors we need to replace (26.5.20) by

$$\mathsf{mes}\bigl(\{x\colon w(x) \le \varepsilon^4\}\bigr) \le C\varepsilon; \tag{26.5.23}$$

(ii) With the semiclassical terms our arguments here are insufficient even if we established (26.5.23); we need extra propagation arguments in the direction of decaying w along magnetic lines–exactly as in the case $M = 1$. Surely there could be points where such arguments do not work; f.e. consider

$M = 2$ and nuclei so that $|\mathsf{y}_1 - \mathsf{y}_2|$ is slightly less than $\bar{r}_1 + \bar{r}_2$ where $\bar{r}_{1,2}$ are precise radii of support. Then w reaches its minimum at $\mathcal{Y}$.

So, we need to prove that the measure of such points is sufficiently small (f.e. less than $C|\log BZ^{-3}|^{-1}$).

Unfortunately, we do not know how to make the above remark work and we suggest

Problem 26.5.7. Follow through the discussed plan. For $M = 2$ it could be easier due to the rotational symmetry of the potential W_B^{TF}.

26.5.3 Analysis in the Boundary Strip $\mathcal{Y}$ for $N < Z$

Now let us consider the case of $N < Z$ (i.e. $\nu < 0$).

Case $B \ge (Z-N)_+^{\frac{4}{3}}$

We start from the case $B \ge (Z-N)_+^{\frac{4}{3}}$ when $\bar{r} = \min(B^{-\frac{1}{4}}, Z^{\frac{1}{5}}B^{-\frac{2}{5}})$ matching cases $B \lesssim Z^{\frac{4}{3}}$ and $Z^{\frac{4}{3}} \lesssim B \lesssim Z^3$.

Remark 26.5.8. (i) The results of the previous Subsection 26.4.2 remain true as long as $|\nu|G^{-1} \le C_0 h^{\frac{4}{3}}$; in other words, as $(Z-N)_+ \le C_0 G\bar{r}h^{\frac{4}{3}}$. Plugging $\bar{r}$, G and h, we rewrite it as

$$(Z-N)_+ \le C_0 \min\bigl(B^{\frac{5}{12}},\, Z^{\frac{1}{5}}B^{\frac{4}{15}}\bigr) \tag{26.5.24}$$

matching cases $B \lesssim Z^{\frac{4}{3}}$ and $Z^{\frac{4}{3}} \lesssim B \lesssim Z^3$.

(ii) Therefore in this Subsection we assume that condition (26.5.24) fails. Let $\theta = |\nu|G^{-1} \asymp (Z-N)_+ \cdot \max\bigl(B^{-\frac{3}{4}},\, Z^{-1}\bigr)$, also matching cases $B \lesssim Z^{\frac{4}{3}}$ and $Z^{\frac{4}{3}} \lesssim B \lesssim Z^3$.

Proposition 26.5.9. *Consider dependence of $W_B^{\mathsf{TF}} = W_{B(\nu)}^{\mathsf{TF}}(x)$ on ν. Then*

(i) $W_{B(\nu)}^{\mathsf{TF}}(x) + \nu$ is non-decreasing with respect to ν at each point x.

(ii) $W_{B(\nu)}^{\mathsf{TF}}(x)$ is non-increasing with respect to ν at each point x.

(iii) In particular, $W_{B(\nu)}^{\mathsf{TF}}(x) + \nu \nearrow W_{B(0)}^{\mathsf{TF}}(x)$ and $W_{B(\nu)}^{\mathsf{TF}}(x) \searrow W_{B(0)}^{\mathsf{TF}}(x)$ at each point x as $\nu \nearrow 0$.

Proof. (i) Consider $W_j := W^{\mathsf{TF}}_{B(\nu_j)} + \nu_j$ with $0 > \nu_1 > \nu_2$. One can prove easily that $W^{\mathsf{TF}}_B - V$ is a continuous function and since

$$W_1 - W_2 \to \nu_1 - \nu_2 \qquad \text{as } \ell(x) \to \infty \tag{26.5.25}$$

with $\nu_1 - \nu_2 > 0$ we conclude that $W_1 \ge W_2$ at each point x (which is exactly our Statement (i)) unless $W_1 - W_2$ achieves a negative minimum at some point x^*:

(a) Let $x^* \ne \mathsf{y}_m$; then $\Delta(W_1 - W_2)(x^*) = P'_B(W_1) - P'_B(W_2) \le 0$ because $W_1 < W_2$ at x^* and therefore x^* cannot be such point.

(b) Let $x^* = \mathsf{y}_m$. From Thomas-Fermi equations for $W_{1,2}$ one can prove easily that

$$(W_1 - W_2)(x) = (W_1 - W_2)(\mathsf{y}_m) + L_m(x - \mathsf{y}_m) + \kappa_m |x - y_m|^{\frac{3}{2}} (W_1 - W_2)(\mathsf{y}_m) + O(|x - \mathsf{y}_m|^2)$$

near y_m where $L_m(x)$ is a linear function and $\kappa_m > 0$ and therefore if $(W_1 - W_2)(\mathsf{y}_m) < 0$, y_m cannot be a minimum point either.

(ii) So, $W_1 \ge W_2$ and therefore $\Delta(W_1 - W_2)(x^*) = P'_B(W_1) - P'_B(W_2) \ge 0$ and $W_1 - W_2$ is a subharmonic function. Then due to (26.5.25) we conclude that $W_1 - W_2 \le \nu_1 - \nu_2$ i.e. $W^{\mathsf{TF}}_{B,(\nu_1)} \le W^{\mathsf{TF}}_{B,(\nu_2)}$ at each point.

(iii) Statement (iii) follows from Statements (i) and (ii). □

From Statements (i) and (iii) we conclude immediately that

Corollary 26.5.10. *(i)* $\rho^{\mathsf{TF}}_{B(\nu)}(x)$ *is non-decreasing with respect to* ν *at each point* x.

(ii) $\rho^{\mathsf{TF}}_{B(\nu)}(x) \nearrow \rho^{\mathsf{TF}}_{B(0)}(x)$ *at each point* x *as* $\nu \nearrow 0$.

Therefore in the zone $\{x \in \mathcal{Y}\colon W^{\mathsf{TF}}_{B(\nu)} \ge (1+\epsilon)|\nu|\}$ we can apply the same (γ, ς) scaling with $\varsigma = \gamma^2$ defined for $\nu = 0$. Indeed, we know that there $W^{\mathsf{TF}}_{B(\nu)} + \nu \asymp W^{\mathsf{TF}}_{B(0)} \asymp \varsigma^2$ and $\varsigma = \gamma^2$.

Then Thomas-Fermi equation (26.2.3) implies that

$$|\nabla^\alpha W^{\mathsf{TF}}_{B(\nu)}| \le C_\alpha \varsigma^2 \gamma^{-|\alpha|} \qquad \forall \alpha \tag{26.5.26}$$

and then we arrive to the Statement (i) in Proposition 26.5.11 below. On the other hand, in the zone $\{x\colon W^{\mathsf{TF}}_{B(\nu)} \le (1-\epsilon)|\nu|\}$ we can apply the

same arguments but this zone is classically forbidden and we arrive to Statement (ii) below. In both cases $\varsigma\gamma \ge h$ (where in the latter case γ is the distance from x to $W^{\mathsf{TF}}_{B(\nu)}$ (scaled) and $\varsigma = |\theta|^{\frac12}$ in virtue of Remark 26.5.8.

Proposition 26.5.11. *Let* <u>*either*</u> $B \le Z^{\frac43}$ *and* $|\nu|^{\frac34} \ge Z^{\frac23}$ <u>*or*</u> $Z^{\frac43} \le B \le Z^3$ *and* $|\nu|^{\frac34} \ge B^{\frac12}$. *Then*

(i) Contributions of zone $\{x\colon W^{\mathsf{TF}}_B(x) \ge (1+\epsilon_0)|\nu|\}$ *to the semiclassical errors in* N- *and* T*-terms and into semiclassical* D*-term do not exceed* CR_0L, CR *and* CRL^2 *respectively.*

(ii) Contributions of zone $\{x\colon W^{\mathsf{TF}}_B(x) \le (1-\epsilon_0)|\nu|\}$ *to the semiclassical errors in* N- *and* T*-terms and into semiclassical* D*-term do not exceed* CR_0L, CR *and* CRL^2 *respectively.*

Remark 26.5.12. Here actually we can replace L by $L_* = 1 + |\log\theta|$ with

$$\theta = |\nu| G^{-1} \asymp \begin{cases} (Z-N)_+ B^{-\frac34} & \text{if } (Z-N)_+^{\frac43} \le B \le Z^{\frac43}, \\ (Z-N)_+ Z^{-1} & \text{if } Z^{\frac43} \le B \le Z^3; \end{cases} \tag{26.5.27}$$

Therefore we need to explore the following zone

$$\mathcal{Y}^* := \{x\colon (1-\epsilon_0)|\nu| \le W^{\mathsf{TF}}_B(x) \le (1+\epsilon_0)|\nu|\}$$

in the framework of Proposition 26.5.11. In virtue of Remark 26.5.8 $\hbar \lesssim 1$ where

$$\hbar = h\theta^{-\frac34} \asymp \begin{cases} (Z-N)_+^{-\frac34} B^{\frac{5}{16}} & \text{if } B \le Z^{\frac43}, \\ (Z-N)_+^{-\frac34} Z^{\frac{3}{20}} B^{\frac15} & \text{if } Z^{\frac43} \le B \le Z^3. \end{cases} \tag{26.5.28}$$

Let us rescale the ball $B(.,\alpha)$ to $B(.,1)$ by $x \mapsto x\alpha^{-1}$ with $\alpha = \theta^{\frac14}$ (after we already rescaled $x \mapsto x\bar r^{-1}$). After this let us introduce scaling function γ_0 by (26.4.3). Then let us introduce consequently scaling functions γ_1 by (26.4.7), γ_2 by (26.4.13) and γ_3 by (26.4.14) [31].

Consider contributions of different balls in this hierarchy into semiclassical and approximation errors in N- and T-terms and into D semiclassical and approximation D-terms.

[31] With $j = \bar\jmath = 0$ and corrected as in $(26.4.3)^*$ and $(26.4.7)^*$.

(i) Consider first semiclassical error in N-term. Due to Chapter 18 the contribution of α_j element does not exceed $C B\ell_j^2 = C B\bar{r}^2\alpha_j^2$ for $j = 3, 2$, where recall that $\alpha_j = \gamma_0 \cdots \gamma_j$.

Then for $j = 2$ we have $C B\bar{r}^2\alpha_2^2 = C B\bar{r}^2\alpha_1^2\gamma_1^2$ and therefore we estimate the contribution of α_1 element by $C B\bar{r}^2\alpha_1^2 \int \gamma_2^{-1}\, dx$ [32], which also results in $C B\bar{r}^2\alpha_1^2$ but with the logarithmic factor. However we can get rid of this factor due to a simple observation:

(26.5.29) If $\gamma_2 \le \epsilon$ then $\mathsf{Hess}(w_1)$ has at least two eigenvalues of magnitude 1 due to $|\Delta w_1| \le \epsilon_1$.

Then the contribution of α_0 element does not exceed $C B\bar{r}^2\alpha_0^2 \int \gamma_1^{-1}\, dx$ [32]; we claim that it is $C B\bar{r}^2\alpha_0^2$. Indeed, we need to consider only points with $\gamma_1 \le \epsilon$ and there we use a similar observation:

(26.5.30) If $\gamma_1 \le \epsilon$ then $|\nabla^3 w'| \asymp 1$ and also $|\nabla^3 w' - e\otimes e\otimes e| \ge c^{-1}$ for any $e \in \mathbb{R}^3$ due to $|\partial_j \Delta w_1| \le \epsilon_1$; here $\nabla^3 w'$ is a 3-tensor of the third derivatives of w'.

Further, the contribution of α element does not exceed $C B\bar{r}^2\alpha^2 \int \gamma_0^{-1}\, dx$ [32]; since $\gamma \ge \bar{\gamma}_0 = \hbar^{\frac{1}{3}}$, we estimate it by $C B\bar{r}^2\alpha^2\hbar^{-\frac{1}{3}}$.

Finally, since $\bar{r}^{-1}\mathcal{Y}^*$ is covered by no more than $C L_*\alpha^{-2}$ such elements[33], we conclude that

(26.5.31) The total contribution of $\mathcal{Y}^*$ into the semiclassical (and also approximation) errors in N-term does not exceed $C B\bar{r}^2\hbar^{-\frac{1}{3}}L_*$, where $L_* := (1 + |\log\theta|)$.

Plugging values of $\hbar$ and θ, we arrive to expression (26.5.33) in Proposition 26.5.13(i) below.

(ii) Similarly, in virtue of Subsubsection *26.3.1.2. Semiclassical* D*-Term* we know the that the contribution of the non-disjoint pair of α_j-elements to the semiclassical D-term does not exceed $C B^2\ell^3 = C B^2\bar{r}^3\alpha_j^3$ for $j = 3, 2$.

---

[32] With the integral calculated in the scaled coordinates.

[33] Indeed, due to Subsection 26.5.1 $\mathsf{mes}(\bar{r}^{-1}\mathcal{Y}^*) \le C\alpha L_*$.

Therefore the contribution of all non-disjoint pairs of α_2 subelements to the same expression for α_1 element does not exceed $CB^2\bar{r}^3\alpha_1^3$. Adding all disjoint pairs, we get[32)]

$$CB^2\bar{r}^3\alpha_1^3 \iint |x-y|^{-1}\gamma_2(x)^{-1}\gamma_2(y)^{-1}\,dxdy. \tag{26.5.32}$$

Then using the results of Part (i) together with observation (26.5.29) we arrive to $CB^2\bar{r}^3\alpha_1^3$. So, contribution of the non-disjoint pair of α_1-elements to the semiclassical D-term does not exceed $CB^2\ell^3 = CB^2\bar{r}^3\alpha_1^3$.

Further, continuing in the same manner, we estimate the contribution of the non-disjoint pair of α_0-elements by $CB^2\bar{r}^3\alpha_0^3$.

Furthermore, in the same manner we estimate the contribution of the non-disjoint pair of α-elements by expression (26.5.32) with γ_2 replaced by γ_0, which does not exceed $CB^2\bar{r}^3\alpha^3\hbar^{-\frac{2}{3}}$.

Finally, adding contribution of all non disjoint pairs and using results of Part (i), we conclude that the total contribution of $\mathcal{Y}^*\times\mathcal{Y}^*$ into the semiclassical (and also approximation) D-terms does not exceed the final expression we recovered there, squared and multiplied by $\bar{r}^{-1}$, i.e. $CB^2\bar{r}^3\hbar^{-\frac{2}{3}}L_*^2$.

Plugging values of $\hbar$ and θ we arrive to expression (26.5.34) in Proposition 26.5.13(ii) below.

(iii) Due to Chapter 18 the contribution of α_j element to the semiclassical error in T-term does not exceed $CB\ell_*\zeta_*$ as $j=3,2$. Note that $\zeta = G^{\frac12}\gamma_0^2\gamma_1^{\frac32}\gamma_2\gamma_3^{\frac12}$ and $\zeta = G^{\frac12}\gamma_0^2\gamma_1^{\frac32}\gamma_1$ for $j=3,2$. Here we took $\theta=\alpha=1$ thus covering the whole zone $\mathcal{Y}$.

Then the contribution of α_2-element does not exceed $CBG^{\frac12}\bar{r}\gamma_0^3\gamma_1^{\frac52}\gamma_2^2$. Further, the contribution of α_1-element does not exceed $CBG^{\frac12}\bar{r}\gamma_0^3\gamma_1^{\frac52}\int\gamma_2^{-1}\,dx$ [32)], resulting in $CBG^{\frac12}\bar{r}\gamma_0^3\gamma_1^{\frac52}$ in virtue of the same observation (26.5.29).

Further, the contribution of α_0-element does not exceed $CBG^{\frac12}\bar{r}\gamma_0^3\int\gamma_1^{-\frac12}$ resulting in $CBG^{\frac12}\bar{r}\gamma_0^3$ in virtue of the same observation (26.5.30).

Finally, the total contribution of $\mathcal{Y}$ does not exceed $CBG^{\frac12}\bar{r} = CB^2\bar{r}^3 = \max(B^{\frac54}, Z^{\frac35}B^{\frac45})$.

Therefore we arrive to

Proposition 26.5.13. *In the framework of Proposition 26.5.13 there exists potential W_ε such that*

(i) Contributions of $\mathcal{Y}^*$ to both semiclassical and approximation errors for N*-term do not exceed*

$$(Z-N)_+^{\frac14} L \times (B^{\frac{19}{48}};\ Z^{\frac{7}{20}} B^{\frac{2}{15}}), \tag{26.5.33}$$

where here and below we list different values for $(Z-N)_+^{\frac43} \le B \le Z^{\frac43}$ and for $Z^{\frac43} \le B \le Z^3$.

(ii) Contributions of $\mathcal{Y}^* \times \mathcal{Y}^*$ to both semiclassical and approximation D*-terms do not exceed*

$$(B^{\frac{25}{24}};\ Z^{\frac12} B^{\frac23}). \tag{26.5.34}$$

(iii) Contributions of $\mathcal{Y}^*$ to both semiclassical and approximation errors for T*-term do not exceed*

$$(B^{\frac54};\ Z^{\frac35} B^{\frac45}). \tag{26.5.35}$$

Case $B \le (Z-N)_+^{\frac43}$

Now let us consider the case $B \le (Z-N)_+^{\frac43}$. In this case the *boundary strip*

$$\mathcal{Y} := \{x\colon |W(x)+\nu| \le \epsilon|\nu|\} \tag{26.5.36}$$

consists of two subzones

$$\mathcal{Y}_1 := \{x\colon \epsilon B \le |W(x)+\nu| \le \epsilon|\nu|\} \tag{26.5.37}$$

and

$$\mathcal{Y}^* := \{x\colon |W(x)+\nu| \le \epsilon B\}. \tag{26.5.38}$$

Applying arguments of Section 26.4 (more precisely, analysis in zones $\mathcal{X}_1$, $\mathcal{X}_1$ extended and $\mathcal{X}_2$) one can prove easily that

Proposition 26.5.14. *Let $B \le (Z-N)_+^{\frac43}$. Then*

(i) Contributions of $\mathcal{Y}_1$ into semiclassical and approximation errors in N*-term do not exceed $C|\nu|\bar{r}^2 \asymp C(Z-N)_+^{\frac23}$.*

(ii) Contributions of $\mathcal{Y}_1 \times \mathcal{Y}_1$ *into semiclassical and approximation* D*-terms do not exceed* $C|\nu|^2\bar{r}^3 \asymp C(Z-N)_+^{\frac{5}{3}}$.

(iii) Contribution of $\mathcal{Y}_1$ *into semiclassical and approximation errors in* T*-term do not exceed* $C|\nu|^{\frac{3}{2}}\bar{r} \asymp C(Z-N)_+^{\frac{5}{3}}$.

Proof. We leave easy details to the reader. □

On the other hand, applying arguments of the previous Subsubsection *26.5.3.1. Case* $B \ge (Z-N)_+^{\frac{4}{3}}$ with $\theta = 1$, $\hbar = |\nu|^{-\frac{1}{2}}\bar{r}^{-1} \asymp (Z-N)_+^{-\frac{1}{3}}$ one can prove easily the following

Proposition 26.5.15. *Let* $B \le (Z-N)_+^{\frac{4}{3}}$. *Then*

(i) Contributions of $\mathcal{Y}_2$ *into semiclassical and approximation errors in* N*-term do not exceed* $C(Z-N)_+^{-\frac{5}{9}}B$.

(ii) Contributions of $\mathcal{Y}_2 \times \mathcal{Y}_2$ *into semiclassical and approximation* D*-terms do not exceed* $C(Z-N)_+^{-\frac{7}{9}}B^2$.

(iii) Contribution of $\mathcal{Y}_2$ *into semiclassical and approximation errors in* T*-term do not exceed* $C(Z-N)_+^{\frac{5}{3}}$.

Proof. We leave easy details to the reader.

26.5.4 Summary

Adding contributions of all other zones we arrive to

Proposition 26.5.16. *Let* $M \ge 2$. *Then for the constructed potential* W

(i) Total semiclassical and approximation errors in N*-term do not exceed*

$$C\begin{cases} CZ^{\frac{2}{3}} + (Z-N)_+^{-\frac{5}{9}}B & \text{if } B \le (Z-N)_+^{\frac{4}{3}},\\ Z^{\frac{2}{3}} + B^{\frac{1}{2}}L + (Z-N)_+^{\frac{1}{4}}B^{\frac{19}{48}}L_* & \text{if } (Z-N)_+^{\frac{4}{3}} \le B \le Z^{\frac{4}{3}},\\ Z^{\frac{2}{5}}B^{\frac{1}{5}}L + (Z-N)_+^{\frac{1}{4}}Z^{\frac{7}{20}}B^{\frac{2}{15}}L_* & \text{if } Z^{\frac{4}{3}} \le B \le Z^3 \end{cases} \tag{26.5.39}$$

where $L_* = (1 + |\log\theta|)$ *with* $\theta = |\nu|G^{-1} = (Z-N)_+ \cdot \max(B^{-\frac{3}{4}}, Z^{-1})$ *and* $L = (1 + |\log BZ^3|)$.

(ii) Both semiclassical and approximation D*-terms do not exceed*

$$C\begin{cases} Z^{\frac{5}{3}} + (Z-N)_+^{-\frac{7}{9}} B^2 & \text{if } B \le (Z-N)_+^{\frac{4}{3}}, \\ Z^{\frac{5}{3}} + B^{\frac{5}{4}} L^2 + (Z-N)_+^{\frac{1}{2}} B^{\frac{25}{24}} L_*^2 & \text{if } (Z-N)_+^{\frac{4}{3}} \le B \le Z^{\frac{4}{3}}, \\ Z^{\frac{3}{5}} B^{\frac{4}{5}} L^2 + (Z-N)_+^{\frac{1}{2}} Z^{\frac{1}{2}} B^{\frac{2}{3}} L_*^2 & \text{if } Z^{\frac{4}{3}} \le B \le Z^3. \end{cases} \tag{26.5.40}$$

(iii) Total approximation error in T*-term does not exceed*

$$CQ \coloneqq C \max\bigl(Z^{\frac{5}{3}},\, Z^{\frac{3}{5}} B^{\frac{4}{5}}\bigr) = C \begin{cases} Z^{\frac{5}{3}} & \text{if } B \le Z^{\frac{4}{3}}, \\ Z^{\frac{3}{5}} B^{\frac{4}{5}} & \text{if } Z^{\frac{4}{3}} \le B \le Z^3. \end{cases} \tag{26.5.41}$$

(iv) Total semiclassical error in T*-term does not exceed*

$$CQ + CZ^{\frac{4}{3}} B^{\frac{1}{3}} + CZ^{\frac{3}{2}} a^{-\frac{1}{2}} \tag{26.5.42}$$

provided $a \ge Z^{-1}$*; for* $a \le Z^{-1}$ *the last term should be replaced by* CZ^2*.*

Also we arrive to

Proposition 26.5.17. *Let* $M \ge 2$*,* $B \le Z$ *and* $a \ge Z^{-\frac{1}{3}}$*. Then for the constructed potential* W

(i) Total semiclassical and approximation errors in N*-term do not exceed* $CZ^{\frac{2}{3}}\bigl((BZ^{-1})^{\delta} + (aZ^{\frac{1}{3}})^{-\delta} + Z^{-\delta}\bigr)$*.*

(ii) Both semiclassical and approximation D*-terms and semiclassical and approximation errors in* T*-term do not exceed* $CZ^{\frac{5}{3}}\bigl((BZ^{-1})^{\delta} + (aZ^{\frac{1}{3}})^{-\delta} + Z^{-\delta}\bigr)$*.*

26.6 Ground State Energy

26.6.1 Lower Estimates

Now the lower estimates for the ground state energy E_N are already proven: in virtue of the analysis given in Subsection 25.2.1 we know that

$$\mathsf{E}_N \ge \Phi_*(W) + \Bigl(\mathsf{Tr}(H_{A,W} - \nu)^- + \int P_B(W+\nu)\, dx\Bigr) - \nu N \tag{26.6.1}$$

for *arbitrary* potential W and $\nu \le 0$; picking Thomas-Fermi potential $W = W_B^{\mathsf{TF}}$ and chemical potential ν, we arrive to estimate (26.6.2) below with $W = W_B^{\mathsf{TF}}$ and $Q = 0$.

However we use slightly different potential W and arrive to estimate (26.6.2) below where CQ, defined by (26.5.42), estimates an approximation error; replacing T-term by its semiclassical approximation and applying Proposition 26.5.16(iii) and 26.5.17(ii), we arrive to estimates (26.6.3)–(26.6.6) below:

Proposition 26.6.1. *Let $B \le Z^3$. Then*

(i) The following estimate holds with an approximate potential W we constructed:

$$E^{\mathsf{TF}} \ge \mathcal{E}^{\mathsf{TF}} + \Bigl(\mathsf{Tr}((H_{A,W}-\nu)^-) + \int P_B(W+\nu)\,dx\Bigr) - CQ \tag{26.6.2}$$

with Q defined by (26.5.41)*; further, for $W = W_B^{\mathsf{TF}}$ this estimate holds with $Q = 0$.*

(ii) The following estimates hold for $M = 1$ and $M \ge 2$ respectively

$$E^{\mathsf{TF}} \ge \mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} - CQ - CZ^{\frac{4}{3}}B^{\frac{1}{3}} \tag{26.6.3}$$

and

$$E^{\mathsf{TF}} \ge \mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} - CQ - CZ^{\frac{4}{3}}B^{\frac{1}{3}} - CZ^{\frac{3}{2}}a^{-\frac{1}{2}} \tag{26.6.4}$$

provided $a \ge Z^{-1}$ [34] *and $B \le Z^2$; on the other hand, if $a \le Z^{-1}$, we can skip* Scott *and replace the last term in (26.4.2) by CZ^2.*

(iii) As $B \le Z$ the following estimates hold for $M = 1$ and $M \ge 2$, $a \ge Z^{-\frac{1}{3}}$ respectively

$$E^{\mathsf{TF}} \ge \mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} + \mathsf{Dirac} + \mathsf{Schwinger} - CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + (BZ^{-1})^{\delta}\bigr) \tag{26.6.5}$$

and

$$E^{\mathsf{TF}} \ge \mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} + \mathsf{Dirac} + \mathsf{Schwinger} - CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + (BZ^{-1})^{\delta} + (aZ^{\frac{1}{3}})^{-\delta}\bigr). \tag{26.6.6}$$

[34] Recall that a is the minimal distance between nuclei.

26.6.2 Upper Estimate: General Scheme

On the other hand, the upper estimate is more demanding. Recall that, according to Subsection 25.2.2, for the upper estimate in addition to the trace we need to estimate also $|\lambda_N - \nu|$ where $\lambda_N < 0$ is N-th eigenvalue of $H_{A,W}$ and $\lambda_N = 0$ if $H_{A,W}$ has less than N negative eigenvalues, and the product

$$|\lambda_N - \nu| \cdot |\mathsf{N}(H_{A,W}) - N| \tag{26.6.7}$$

and also three D-terms: two of them are semiclassical:

$$\mathsf{D}\Big(e(x,x,\lambda) - P'_B(W(x)+\lambda),\, e(x,x,\lambda) - P'_B(W(x)+\lambda)\Big) \tag{26.6.8}_{1,2}$$

with $\lambda = \nu$ and $\lambda = \lambda_N$ and also

$$\mathsf{D}\Big(P'_B(W(x)+\lambda_N) - P'_B(W(x)+\nu),\, P'_B(W(x)+\lambda_N) - P'_B(W(x)+\nu)\Big). \tag{26.6.9}$$

For this purpose our tool will be semiclassical estimates for two semiclassical N-terms

$$\int \Big(e(x,x,\lambda) - P'_B(W(x)+\lambda)\Big)\,dx \tag{26.6.10}_{1,2}$$

also with $\lambda = \nu$ and $\lambda = \lambda_N$ and also estimate from below for the third N-term

$$\Big|\int \Big(P'_B(W(x)+\lambda_N) - P'_B(W(x)+\nu)\Big)\,dx\Big|. \tag{26.6.11}$$

26.6.3 Upper Estimate as $M = 1$

Estimate for $|\lambda_N - \nu|$

We start from the easier case $M = 1$. Exactly as in Subsection 25.2.2 we have two cases: in the first case $|\nu|$ is small enough so we construct W^{TF} with $\nu = 0$ and estimate $|\lambda_N|$, and in the second case we prove that $\lambda_N \asymp \nu$ and estimate $|\lambda_N - \nu| \le \epsilon|\nu|$.

Proposition 26.6.2. *Let $M = 1$, $B \le Z^3$.*

(i) Assume first that

$$(Z-N)_+ \le K \coloneqq C_0 \max\bigl(Z^{\frac{2}{3}},\, Z^{\frac{2}{5}} B^{\frac{1}{5}}\bigr) \tag{26.6.12}$$

and let us construct W *as if* $\nu = 0$ *i.e.* $N = Z$. *Then*

$$|\lambda_N| \le C_1 \max\bigl(Z^{\frac{8}{9}},\, B^{\frac{2}{3}}\bigr). \tag{26.6.13}$$

(ii) Assume now that

$$(Z-N)_+ \ge K = C_0 \max\bigl(Z^{\frac{2}{3}},\, Z^{\frac{2}{5}} B^{\frac{1}{5}}\bigr) \tag{26.6.14}$$

with sufficiently large C_0. *Then* $\lambda_N \asymp \nu$ *and*

$$|\lambda_N - \nu| \le C_1 \max\bigl(Z^{\frac{2}{3}},\, B^{\frac{1}{2}}\bigr) |\nu|^{\frac{1}{4}}. \tag{26.6.15}$$

Proof. (i) In the framework of Statement (i) assume first that $B \ge (Z-N)_+^{\frac{4}{3}}$. One can see easily that then

(26.6.16) Expression (26.6.11) is

$$\asymp B|\lambda_N|^{\frac{1}{2}} \times \underbrace{\Bigl(\frac{|\lambda_N|}{G}\Bigr)^{\frac{1}{4}} \bar{r}^3}_{} \asymp |\lambda_N|^{\frac{3}{4}} \min\bigl(1,\, B^{-\frac{3}{10}} Z^{\frac{2}{5}}\bigr)$$

where $(|\lambda_N|/G)^{\frac{1}{4}}\bar{r}$ is a width of the zone where $0 < W \le -\lambda_N$ and the selected factor is the volume of this zone. Indeed, $W \asymp (\bar{r} - |x|)_+^4 \bar{r}^{-4} G$ for $|x| \asymp \bar{r}$.

However this expression (26.6.11) should be less than $C \max\bigl(Z^{\frac{2}{3}},\, Z^{\frac{2}{5}} B^{\frac{1}{5}}\bigr)$ which is exactly an error estimate in the semiclassical expression for N. Thus

$$|\lambda_N|^{\frac{3}{4}} \min\bigl(1,\, Z^{\frac{2}{5}} B^{-\frac{3}{10}}\bigr) \le C \max\bigl(Z^{\frac{2}{3}},\, Z^{\frac{2}{5}} B^{\frac{1}{5}}\bigr) \tag{26.6.17}$$

where everywhere the first and the second cases are as $B \le Z^{\frac{4}{3}}$ and $Z^{\frac{4}{3}} \le B \le Z^3$ respectively. The last inequality is equivalent to (26.6.13).

On the other hand, if $B \le (Z-N)_+^{\frac{4}{3}}$, inequality (26.6.17) is replaced by $|\lambda_N|^{\frac{3}{4}} \le C Z^{\frac{2}{3}}$ which coincides with (26.6.17) with B reset to $(Z-N)_+^{\frac{4}{3}}$ and also with the same inequality derived for $B = 0$ in Subsection 25.4.2; therefore (26.6.13) holds in this case as well.

(ii) One can prove easily that

(26.6.18) If condition (26.6.14) is fulfilled, and expression (26.6.11) does not exceed the semiclassical error estimate $C_0 \mathsf{max}(Z^{\frac{2}{3}}, Z^{\frac{2}{5}}B^{\frac{1}{5}})$, then $\lambda_N \asymp \nu$ and, furthermore, expression (26.6.11) is

$$\asymp B|\lambda_N - \nu| \int P''_B(W+\nu)\,dx \asymp B|\lambda_N - \nu| \int (W+\nu)_+^{-\frac{1}{2}}\,dx, \tag{26.6.19}$$

which for $B \ge (Z-N)_+^{\frac{4}{3}}$ is

$$\asymp B\bar{r}^3|\lambda_N - \nu| \cdot |\nu|^{-\frac{1}{2}}\Big(\frac{|\nu|}{G}\Big)^{\frac{1}{4}} \asymp |\lambda_N - \nu| \cdot |\nu|^{-\frac{1}{4}}\,\mathsf{min}\big(1,\, B^{-\frac{3}{10}}Z^{\frac{2}{5}}\big) \tag{26.6.20}$$

and this should be less than $C\,\mathsf{max}\big(Z^{\frac{2}{3}},\, Z^{\frac{2}{5}}B^{\frac{1}{5}}\big)$, and this implies (26.6.15).

On the other hand, if $B \le (Z-N)_+^{\frac{4}{3}}$, then the right-hand expression of (26.6.19) is $\asymp |\lambda_N - \nu|\bar{r} \asymp |\lambda_N - \nu|(Z-N)_+^{-\frac{1}{3}}$ and this should be less than $CZ^{\frac{2}{3}}$, and this implies (26.6.15) in this case as well. □

Proposition 26.6.2 immediately implies

Corollary 26.6.3. *In the frameworks of Proposition 26.6.2(i), (ii),*

$$|\lambda_N - \nu| \cdot \mathsf{N}([\lambda_N, \nu]) \le CQ, \tag{26.6.21}$$

where $\mathsf{N}(\lambda_N, \nu)$ *is the number of (non-zero) eigenvalues on interval* $[\lambda_N, \nu]$ *or* $[\nu, \lambda_N]$ [35].

Estimate for D-Terms

Proposition 26.6.4. *In the frameworks of Proposition 26.6.2(i),(ii) expressions*

$$\mathsf{D}\big(e(x,x,\lambda) - P'_B(W+\lambda),\, e(x,x,\lambda) - P'_B(W+\lambda)\big) \tag{26.6.22}$$

with $\lambda = \nu$ [35] *and with* $\lambda = \lambda_N$ *and*

$$\mathsf{D}\big(P'_B(W+\nu) - P'_B(W+\lambda),\, P'_B(W+\nu) - P'_B(W+\lambda_N)\big) \tag{26.6.23}$$

with $\lambda = \lambda_N$ *do not exceed* $C\,\mathsf{max}(Z^{\frac{5}{3}}, Z^{\frac{3}{5}}B^{\frac{4}{5}})$.

[35] Recall, that the frameworks of Proposition 26.6.2(i) we pick up $\nu = 0$.

Proof. Recall that we already derived in Section 26.3 this estimate for D-term (26.6.22) with $\lambda = \nu$. Further, the same estimate for this term with $\lambda = \lambda_N$ can be proven exactly in the same way; we leave easy details to the reader.

Furthermore, one can derive the same estimate for D-term (26.6.23) using Proposition 26.6.2; again we leave easy details to the reader. □

Remark 26.6.5. Let $B \le Z$. Then in (26.6.12)–(26.6.15) and therefore also in (26.6.19) and in Proposition 26.6.4 one can replace C_0 and C by $C_0\varepsilon$ and $C\varepsilon$ respectively with the small parameter ε: $\max\bigl(Z^{-\delta}, (BZ^{-1})^{\delta}\bigr) \le \varepsilon \le 1$.

Summary

Then following the scheme of Subsection 25.4.4 we arrive to upper estimates in Theorem 26.6.6 below (lower estimates have been proven in Proposition 26.6.1). Furthermore, based on estimates (26.6.2) and (26.6.24) and the fact, that the left-hand term in (26.6.28) should fit into the "gap" between them (see Section 25.2), we also arrive to Theorem 26.6.7 below:

Theorem 26.6.6. *Let $M = 1$, $B \le Z^3$. Then*

(i) The following estimate holds:

$$E^{\mathsf{TF}} \le \mathcal{E}^{\mathsf{TF}} + \Bigl(\mathsf{Tr}\bigl((H_{A,W} - \nu)^-\bigr) + \int P_B\bigl(W^{\mathsf{TF}}(x) + \nu\bigr)\,dx\Bigr) + CQ \tag{26.6.24}$$

with $Q = \max\bigl(Z^{\frac{5}{3}}, Z^{\frac{3}{5}}B^{\frac{4}{5}}\bigr)$.

(ii) The following estimate holds:

$$E^{\mathsf{TF}} \le \mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} + CQ + CZ^{\frac{4}{3}}B^{\frac{1}{3}}. \tag{26.6.25}$$

Here for $Z^2 \le B \le Z^3$ one can skip Scott.

(iii) If $B \le Z$, then

$$E^{\mathsf{TF}} \ge \mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} + \mathsf{Dirac} + \mathsf{Schwinger} + CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + (BZ^{-1})^{\delta}\bigr). \tag{26.6.26}$$

Theorem 26.6.7. *Let $M = 1$, $B \le Z^3$. Then*

(i) The following estimate holds:

$$\mathsf{D}(\rho_\Psi - \rho_B^{\mathsf{TF}}, \rho_\Psi - \rho_B^{\mathsf{TF}}) \le CQ. \tag{26.6.27}$$

(ii) If $B \le Z$, then

$$\mathsf{D}(\rho_\Psi - \rho_B^{\mathsf{TF}}, \rho_\Psi - \rho_B^{\mathsf{TF}}) \le CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + (BZ^{-1})^{\delta}\bigr). \tag{26.6.28}$$

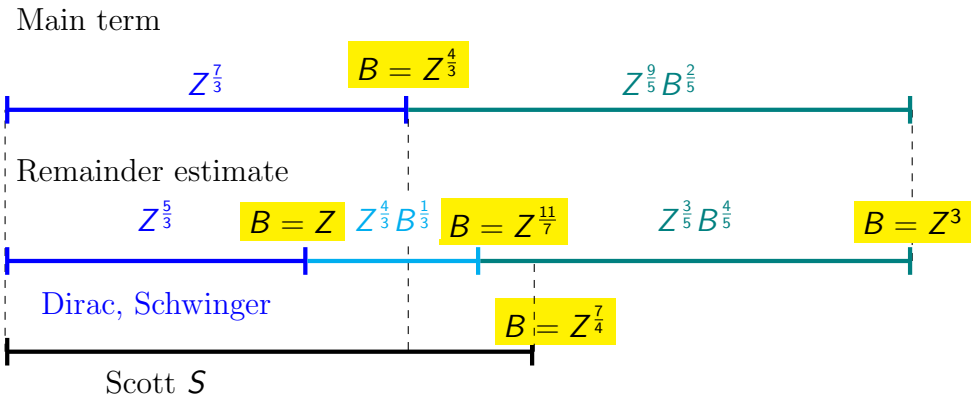

Figure 26.4: This figure illustrates the remainder estimate for E_N. Thresholds $B = Z^\star$ are shown in the yellow boxes.

26.6.4 Upper Estimate as $M \ge 2$

Estimate for $|\lambda_N - \nu|$

Again we need to consider two cases: *almost neutral molecules* (systems) when $(Z-N)_+ \le C_0K$ with K slightly redefined below and we can set $\nu = 0$ in the definition of Thomas-Fermi potential and establish estimate for $|\lambda_N|$ (and for optimal ν we have the same estimate for both $|\nu|$ and λ_N) and *not almost neutral molecules* (systems) when $(Z-N)_+ \ge C_0K$ and we can prove that $|\lambda_N| \asymp |\nu|$ and estimate $|\lambda_N - \nu|$.

Proposition 26.6.8 [36]**.** *Let $M \ge 1$, $B \le Z^3$ and condition* (26.2.28) *be fulfilled.*

(i) Assume first that

$$(Z-N)_+ \le K := C_0 \begin{cases} Z^{\frac{2}{3}} + B^{\frac{1}{2}}L & \text{if } B \le Z^{\frac{4}{3}}, \\ Z^{\frac{1}{5}}B^{\frac{4}{15}}L & \text{if } Z^{\frac{4}{3}} \le B \le Z^3 \end{cases} \tag{26.6.29}$$

[36] Cf. Proposition 26.6.2.

and let us construct W *as if* $\nu = 0$ *i.e.* $N = Z$. *Then*

$$|\lambda_N| \le C_1 \begin{cases} Z^{\frac{8}{9}} + B^{\frac{2}{3}} L^{\frac{4}{3}} & \text{if } B \le Z^{\frac{4}{3}}, \\ Z^{\frac{1}{5}} B^{\frac{4}{15}} L^{\frac{4}{3}} & \text{if } Z^{\frac{4}{3}} \le B \le Z^3; \end{cases} \tag{26.6.30}$$

recall that $L = |\log BZ^{-3}|$.

(ii) Assume now that

$$(Z - N)_+ \ge K \tag{26.6.31}$$

with sufficiently large C_0 *in the definition of* K. *Then* $\lambda_N \asymp \nu$ *and moreover*

$$|\lambda_N - \nu| \le C \max\bigl(Z^{\frac{2}{3}}, B^{\frac{1}{2}} L_1\bigr) |\nu|^{\frac{1}{4}}, \tag{26.6.32}$$

where

$$L_1 = \begin{cases} 1 & \text{if } B \le (Z - N)_+^{\frac{4}{3}}, \\ |\log((Z - N)_+ / B^{\frac{3}{4}}| & \text{if } (Z - N)_+^{\frac{4}{3}} \le B \le Z^{\frac{4}{3}}, \\ |\log(Z - N)_+ / B^{\frac{4}{5}} Z^{\frac{3}{5}}|) & \text{if } Z^{\frac{4}{3}} \le B \le Z^3. \end{cases} \tag{26.6.33}$$

(iii) For $M = 1$ *one can take* $L = L_1 = 1$.

Proof. We will apply arguments slightly more sophisticated than the obvious ones, used in the proof of Proposition 26.6.2. These better arguments will allow us to derive slightly better estimates for $|\lambda_N - \nu|$ as $(Z - N)_+ \ge CK$, and for threshold K itself.

Recall that estimates for $|\lambda_N - \nu|$ are derived by comparison of expression (26.6.11) and the semiclassical errors for the number of eigenvalues below $\lambda = \nu$ and $\lambda = \lambda_N$: expression (26.6.11) should be less than the sum of these semiclassical errors.

Consider contribution of each ball

$$B(x, \ell(x)) \subset \mathcal{Y} = \{x \colon \min_m |x - \mathsf{y}_m| \ge \epsilon \bar{r}\} \tag{26.6.34}$$

to semiclassical errors as $\lambda = \nu$ and $\lambda = \lambda_N$ and compare it with its contribution to (26.6.11):

(a) Each ball contributes no more than $CB\ell^2$ to the first error (with $\lambda = \nu$) where due to our choice $\zeta\ell \ge 1$.

(b) Further, each ball with $\zeta \ge C_1|\lambda_N - \nu|^{\frac12}$ contributes no more than $CB\ell^2$. On the other hand, each ball with $\zeta \le C_1|\lambda_N - \nu|^{\frac12}$ contributes no more than $CB\ell^{3-\sigma}|\lambda_N - \nu|^{\sigma/2}$ to the second error (with $\lambda = \lambda_N$); here $\sigma = \frac13$ is due to rescaling.

(c) Meanwhile, each ball with $\zeta \ge C_1|\lambda_N - \nu|^{\frac12}$ contributes no less than $\epsilon_0 B|\lambda_N - \nu|\zeta^{-1}\ell^3$, and each ball with $\zeta \ge C_1|\lambda_N - \nu|^{\frac12}$ contributes no less than $\epsilon_0|\lambda_N - \nu|^{\frac12}\ell^3$ to expression (26.6.11) and it is larger than the contributions of this ball to each of semiclassical errors (multiplied by C) as long as

$$(26.6.35)_{1,2} \qquad \zeta^2 \ge |\lambda_N - \nu| \ge C_2\zeta\ell^{-1}, \qquad |\lambda_N - \nu| \ge C_2\ell^{-2}.$$

Obviously in Statements (i), (ii) we can assume that

(26.6.36) Inequalities (26.6.30) and (26.6.32) respectively (with C replaced by arbitrarily large C_3) are violated.

(i)(a) Assume first that $(Z-N)_+^{\frac43} \le B \le Z^3$. Then in the framework of assumption $\zeta = B^2\ell^4$ with minimal $\ell = B^{-\frac13}$ and therefore $(26.6.35)_{1,2}$ are fulfilled for $\ell \le C_2B^{-1}|\lambda_N|$. Therefore we need to account for the semiclassical errors contributed by an inner shell (not exceeding $C\max(Z^{\frac23}, B^{\frac12})$) and by zone $\mathcal{Y} \cap \{\ell \ge C_2B^{-1}|\lambda_N|\}$; there $\zeta \ge C_1|\lambda_N|^{\frac12}$ and therefore its contribution does not exceed $CB\int \ell(x)^{-1}\,dx$ with integral over this zone and it does not exceed $CB\bar{r}^2L$.

So, these truncated semiclassical errors do not exceed $C\max(Z^{\frac23}, B\bar{r}^2L)$. Meanwhile, expression (26.6.11) is no less than $CB^{\frac12}\bar{r}^2|\lambda_N|^{\frac34}$. Therefore comparing these two expressions as $B \le Z^{\frac43}$ and as $Z^{\frac43} \le B \le Z^3$ we arrive to (26.6.30).

(b) Consider the remaining case $B \le (Z-N)_+^{\frac43}$. Semiclassical arguments remain valid while estimate of (26.6.11) from below by $\epsilon_0|\lambda_N|^{\frac34}$ also could be proven easily.

(ii)(a) Again, assume first that $(Z-N)_+^{\frac43} \le B \le Z^3$. Again, in the calculation of the truncated semiclassical errors we integrate over zone $\{\ell \ge C_2B^{-1}|\lambda_N - \nu|\}$ where $\zeta \ge C_1|\lambda_N|^{\frac12}$ and therefore its contribution does not exceed $CB\int \ell(x)^{-1}\,dx$ with integral over this zone and it does not exceed $CB\bar{r}^2L_1$ [37].

[37] In Statement (i) this leads only to insignificant improvement.

Again, expression (26.6.21) is larger than the expressions afterwards and comparing with the semiclassical error estimate we arrive to (26.6.32).

(b) Consider the remaining case $B \le (Z-N)_+^{\frac{4}{3}}$. Semiclassical arguments remain valid while estimate of (26.6.11) from below by $\epsilon_0|\lambda_N - \nu|\cdot|\lambda_N|^{-\frac{1}{4}}$ also could be proven easily.

(iii) Recall that for $M = 1$ the semiclassical error estimate hold with $L = L_1 = 1$. □

Then we arrive immediately to

Corollary 26.6.9. *In the framework of Proposition 26.6.8* $|\lambda_N-\nu|\cdot \mathsf{N}([\lambda_N,\nu])$ *does not exceed expression* (26.5.40).

Estimate for D-Terms for Almost Neutral sSystems

We need to estimate the semiclassical error D-term (26.6.22) with $\lambda = \lambda_N$ because for $\lambda = \nu$ we already estimated it, and also we need to estimate another D-term (26.6.23). We start from the latter one. Recall that under assumption (26.6.29) we take $\nu = 0$. The trivial estimate is based on

$$|P'_B(W) - P'_B(W+\lambda)| \le CW^{\frac{1}{2}}|\lambda| + CBW^{-\frac{1}{4}}|\lambda|^{\frac{3}{4}}, \tag{26.6.37}$$

leading to

$$J \le C\mathsf{D}(W^{\frac{1}{2}},\, W^{\frac{1}{2}})|\lambda|^2 + CB^2|\lambda|^{\frac{3}{2}}\mathsf{D}(W^{-\frac{1}{4}}\theta,\, W^{-\frac{1}{4}}\theta) \tag{26.6.38}$$

where here and below J is expression (26.6.23), θ is a characteristic function of the domain $\{x\colon \gamma(x) \ge h^{\frac{1}{3}}\}$ and we can ignore the contribution of the zone $\{x\colon \gamma(x) \le h^{\frac{1}{3}}\}$. Really, the contribution of this zone does not exceed a semiclassical error estimate $R \coloneqq C\max(Z^{\frac{5}{3}},\, Z^{\frac{3}{5}}B^{\frac{4}{5}}L^2)$.

Note that even without assumption (26.6.29)

$$\mathsf{D}(W^{\frac{1}{2}},\, W^{\frac{1}{2}}) \asymp (B^{-\frac{1}{4}};\, B^{-\frac{8}{5}}Z^{\frac{9}{5}}) \qquad \text{for } \ B \le Z^{\frac{4}{3}},\, Z^{\frac{4}{3}} \le B \le Z^3 \tag{26.6.39}$$

respectively and (26.6.30) implies that the first term in the right-hand expression of (26.6.38) is much less than R.

Meanwhile, under assumption (26.6.29)

$$\mathsf{D}(W^{-\frac{1}{4}}\theta, W^{-\frac{1}{4}}\theta) \asymp B^{-1}\mathsf{D}(\ell^{-1}\theta, \ell^{-1}\theta) \asymp B^{-1}\bar{r}^3\mathsf{D}(\gamma^{-1}\theta, \gamma^{-1}\theta) \tag{26.6.40}$$

where in the right-hand expression D and γ, θ are in the scale $x \mapsto x\bar{r}^{-1}$ and then $\mathsf{D}(\gamma^{-1}\theta, \gamma^{-1}\theta) \asymp L^2$ so the second term in (26.6.38) does not exceed $CB\bar{r}^3|\lambda_N|^{\frac{3}{2}}L^2$ which due to (26.6.30) does not exceed

$$R := C\max\bigl(Z^{\frac{5}{3}},\, Z^{\frac{3}{5}}B^{\frac{4}{5}}L^4\bigr). \tag{26.6.41}$$

Consider now term (26.6.22) with $\lambda = \lambda_N$. Let us consider zones $\Omega_1 := \{x\colon |\lambda - \nu| \lesssim \zeta\ell^{-1}\}$ and $\Omega_2 := \{x\colon |\lambda - \nu| \gtrsim \zeta\ell^{-1}\}$.

Note that the contribution to the term in question of each pair of balls contained in $\Omega_1 \times \Omega_1$ does not exceed estimate for the same term with $\lambda = \nu$; really, after rescaling $x \mapsto x/\ell$ and $\tau \mapsto \tau/\zeta^2$ we conclude that the difference between energy levels does not exceed local semiclassical parameter $C/(\zeta\ell)$.

Therefore the total contribution of $\Omega_1 \times \Omega_1$ to this term does not exceed $C\max\bigl(Z^{\frac{5}{3}},\, Z^{\frac{3}{5}}B^{\frac{4}{5}}L^2\bigr)$.

On the other hand, the contribution to the term in question of each pair of balls contained in $\Omega_2 \times \Omega_2$ does not exceed its contribution to (26.6.25) and therefore the total contribution of $\Omega_2 \times \Omega_2$ to this term does not exceed expression (26.6.41). Thus, term (26.6.22) with $\lambda = \lambda_N$ does not exceed (26.6.41).

Therefore we arrive immediately to

Theorem 26.6.10. *Let $M \ge 2$, $B \le Z^3$ and condition* (26.2.28) *be fulfilled. Then under assumption* (26.6.29)

(i) The following estimate holds:

$$E^{\mathsf{TF}} \le \mathcal{E}^{\mathsf{TF}} + \Bigl(\mathsf{Tr}\bigl((H_{A,W} - \nu)^-\bigr) + \int P_B(W^{\mathsf{TF}} + \nu)\,dx\Bigr)+ C\max\bigl(Z^{\frac{5}{3}},\, Z^{\frac{3}{5}}B^{\frac{4}{5}}L^4\bigr). \tag{26.6.42}$$

(ii) If $a \ge Z^{-1}$ then the following estimate holds:

$$E^{\mathsf{TF}} \le \mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} + C\max\bigl(Z^{\frac{5}{3}},\, Z^{\frac{3}{5}}B^{\frac{4}{5}}L^4\bigr) + CZ^{\frac{4}{3}}B^{\frac{1}{3}} + Ca^{-\frac{1}{2}}Z^{\frac{3}{2}}; \tag{26.6.43}$$

if $a \le Z^{-1}$ one should replace the last term in the right-hand expression by CZ^2 and skip Scott.

(iii) If $B \le Z$ and $a \ge Z^{-\frac{1}{3}}$

$$E^{\mathsf{TF}} \le \mathcal{E}^{\mathsf{TF}} + \mathsf{Scott} + \mathsf{Dirac} + \mathsf{Schwinger}+ CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + (BZ^{-1})^{\delta} + (aZ^{\frac{1}{3}})^{-\delta}\bigr). \tag{26.6.44}$$

Here proof of Statement (iii) is due to the same arguments as in the case $B = 0$. Combining with the estimate from below we also conclude that

Theorem 26.6.11. *(i) In the framework of Theorem 26.6.10 the following estimate holds:*

$$\mathsf{D}\big(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}}\big) \le Q := C\max\big(Z^{\frac{5}{3}};\, Z^{\frac{3}{5}}B^{\frac{4}{5}}L^4\big). \tag{26.6.45}$$

(ii) In the framework of Theorem 26.6.10(iii) the following estimate holds:

$$\mathsf{D}\big(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}}\big) \le CZ^{\frac{5}{3}}\big(Z^{-\delta} + (BZ^{-1})^{\delta} + (aZ^{\frac{1}{3}})^{-\delta}\big). \tag{26.6.46}$$

Estimate for D-Terms for Positively Charged sSystems

Let assumption (26.6.31) be fulfilled. Let $W = W_\nu$ and $\ell = \ell_\nu$ be a potential and a scaling function (used to derive semiclassical remainder estimates) for this $\nu < 0$ (and $N < Z$) while W_0 and ℓ_0 be a potential and a scaling function for $\nu = 0$ (and $N = Z$).

Let us start from rather trivial arguments. Note that

$$|P'_B(W+\lambda) - P'_B(W+\nu)| \le CW^{\frac{1}{2}}|\lambda-\nu|\theta_1 + CB|\lambda-\nu|^{\frac{1}{2}}\theta_2, \tag{26.6.47}$$

where θ_1 and θ_2 are characteristic functions of $\mathcal{Y}_1 = \{x\colon W(x) + \nu \ge C_0|\nu|\}$ and $\mathcal{Y}_2 = \{x\colon 0 < W(x) + \nu \le C_0|\nu|\}$ respectively. Let

$$J_k := \mathsf{D}\big([P'_B(W+\lambda_N) - P'_B(W+\nu)]\theta_k,\, [P'_B(W+\lambda_N) - P'_B(W+\nu)]\theta_k\big).$$

Then in virtue of (26.6.47)

$$J_1 \le C\mathsf{D}(W^{\frac{1}{2}}\theta_1, W^{\frac{1}{2}}\theta_1)|\lambda_N - \nu|^2.$$

Note that[38)]

$$\mathsf{D}(W^{\frac{1}{2}}\theta_1,\, W^{\frac{1}{2}}\theta_1) \asymp \big((Z-N)_+^{-\frac{1}{3}};\, B^{-\frac{1}{4}};\, Z^{\frac{9}{5}}B^{-\frac{8}{5}}\big).$$

Then, using inequality (26.6.32) one can prove easily that $J_1 \le CZ^{\frac{5}{3}}$.

However estimate for a contribution of zone $\mathcal{Y}_2$ is much worse:

$$J_2 \le CB^2\mathsf{D}(\theta_2,\theta_2)|\lambda_N - \nu| \le CB^2\bar{r}^3(|\nu|/B^2)^{\frac{1}{2}}L_1^2|\lambda_N - \nu|, \tag{26.6.48}$$

[38)] In our three cases $B \le (Z-N)_+^{\frac{4}{3}}$, $(Z-N)_+^{\frac{4}{3}} \le B \le Z^{\frac{4}{3}}$, and $Z^{\frac{4}{3}} \le B \le Z^3$ respectively.

where for $B \le (Z-N)_+^{\frac{1}{3}}$ we should replace $(|\nu|/B^2)^{\frac{1}{2}}L_1^2$ by $\bar{r}^2$. Then, using (26.6.32), we conclude that for $(Z-N)_+^{\frac{4}{3}} \lesssim B \lesssim Z^3$

$$J_2 \le CB\bar{r}^3|\nu|^{\frac{3}{4}}L_1^2 \max(Z^{\frac{2}{3}}, B^{\frac{1}{2}}) \asymp CB(Z-N)_+^{\frac{3}{4}}\bar{r}^{\frac{9}{4}} \max(Z^{\frac{2}{3}}, B^{\frac{1}{2}}L_1)L_1^2,$$

and therefore we arrive to the last two cases below; the first case is proven similarly:

$$J_2 \le C \begin{cases} (Z-N)_+^{-\frac{4}{3}} Z^{\frac{2}{3}} B^2, \\ (Z-N)_+^{\frac{3}{4}} B^{\frac{7}{16}} \max(Z^{\frac{2}{3}}, B^{\frac{1}{2}}L_1)L_1^2, \\ (Z-N)_+^{\frac{3}{4}} Z^{\frac{9}{20}} B^{\frac{3}{5}} L_1^3 \end{cases} \tag{26.6.49}$$

in our three cases.

This is really shabby estimate. To improve it let us observe that

(26.6.50) If estimate $|\lambda_N - \nu| \le C \max(B^{\frac{2}{3}}, (Z-N)_+^{\frac{8}{9}})$ holds, then J_2 does not exceed (26.5.40)

and therefore we can assume that

$$|\lambda_N - \nu| \ge C \max((Z-N)_+^{\frac{8}{9}};\, B^{\frac{2}{3}}). \tag{26.6.51}$$

Let us estimate the truncated semiclassical error[39)].

Proposition 26.6.12. *(i) Let* $(Z-N)_+^{\frac{4}{3}} \le B \le Z^3$ *and*

$$C_0 B^{\frac{2}{3}} \le |\lambda_N - \nu| \le C_1 B^{\frac{1}{2}}|\nu|^{\frac{1}{4}}. \tag{26.6.52}$$

Then the truncated semiclassical error in N*-term does not exceed*

$$F := CZ^{\frac{2}{3}} + CB\bar{r}^2(|\nu|/B^2)^{\frac{1}{4}}L \times (B^{-1}|\lambda_N - \nu|)^{-1}. \tag{26.6.53}$$

(ii) Let $(Z-N)_+^{\frac{4}{3}} \le B \le Z^3$ *and*

$$C_1 B^{\frac{1}{2}}|\nu|^{\frac{1}{4}} \le |\lambda_N - \nu| \le C_1 B^{\frac{1}{2}}|\nu|^{\frac{1}{4}}L. \tag{26.6.54}$$

Then the truncated semiclassical error does not exceed

$$F := CZ^{\frac{2}{3}} + CB\bar{r}^2 L. \tag{26.6.55}$$

[39)] I.e. contribution to such error of the zone, where it exceeds the contribution to the principal part.

(iii) Let $B \le (Z-N)_+^{\frac{4}{3}}$ *and*

$$(Z-N)_+^{\frac{8}{9}} \le |\lambda_N - \nu| \le C_1(Z-N)_+. \tag{26.6.56}$$

Then the truncated semiclassical error does not exceed

$$F := CZ^{\frac{2}{3}} + C(Z-N)_+^{\frac{5}{3}}|\lambda_N - \nu|^{-1}. \tag{26.6.57}$$

(iv) Let $B \le (Z-N)_+^{\frac{4}{3}}$ *and*

$$C_0(Z-N)_+ \le |\lambda_N - \nu| \le C_1 Z^{\frac{2}{3}}(Z-N)_+^{\frac{1}{3}}. \tag{26.6.58}$$

Then the truncated semiclassical error does not exceed $F := CZ^{\frac{2}{3}}$.

Proof. The easy proof, which uses arguments of the proof of Proposition 26.6.8, is left to the reader. □

Proposition 26.6.13. *In the framework of Proposition 26.6.12(i)–(iv) term* (26.6.25) *does not exceed*

$$CF^{\frac{5}{3}}(B|\lambda_N - \nu|^{\frac{1}{2}})^{\frac{1}{3}} + (26.5.40)$$

with F *defined in the corresponding cases in Proposition 26.6.12.*

Proof. Using Proposition 26.6.8 one can prove easily that

(26.6.59) Contribution of $\{x\colon \ell(x) := \min_m |x - y_m| \le \epsilon\bar{r}\}$ to (26.6.25) does not exceed $CZ^{\frac{5}{3}}$.

Now we need to estimate the excess of expression (26.6.25) over semiclassical D-term (with $\lambda = \nu$), which has been estimated by (26.5.40). To do so we need to estimate

$$\mathsf{D}\big([P_B(W+\nu) - P_B(W+\lambda)]\theta,\, [P_B(W+\nu) - P_B(W+\lambda)]\theta\big) \tag{26.6.60}$$

which is the contribution of the domain $\Omega' := \{x\colon \ell(x) \le CB^{-1}|\lambda - \nu|\}$ where θ is the characteristic function of Ω'. Recall that in the complimentary domain $|P_B(W+\nu) - P_B(W+\lambda)| \le C\ell^{-1}$. Let us consider

$$\mathsf{D}\big([P_B(W+\nu) - P_B(W+\lambda)]\theta_0,\, [P_B(W+\nu) - P_B(W+\lambda)]\theta_0\big) \tag{26.6.61}$$

and

$$\mathsf{D}\bigl([P_B(W+\nu)-P_B(W+\lambda)]\theta_t,\,[P_B(W+\nu)-P_B(W+\lambda)]\theta_{t'}\bigr), \tag{26.6.62}$$

where θ_0 is a characteristic function of

$$\Omega'_0 \coloneqq \{x\colon \ell(x) \le t_0 \coloneqq (|\lambda_N-\nu|B^{-2})^{\frac14}\}$$

and θ_t is a characteristic function of $\Omega'_t \coloneqq \{x\colon t \le \ell(x) \le 2t\}$ with $t \ge t' \ge t_0$.

Observe that, when calculating expression (26.6.11), the contribution of Ω'_0 is $\asymp B|\lambda_N-\nu|^{\frac12}\,\mathsf{mes}(\Omega'_0)$, and therefore due to Proposition 26.6.12

$$\mathsf{mes}(\Omega'_0) \le CF\bigl(B|\lambda_N-\nu|^{\frac12}\bigr)^{-1}, \tag{26.6.63}$$

while term (26.6.61) is

$$\asymp B^2|\lambda_N-\nu|\mathsf{D}(\theta_0,\theta_0) \le CB^2|\lambda_N-\nu|\bigl(\mathsf{mes}(\Omega_0)\bigr)^{\frac53} \le CF^{\frac53}\bigl(B|\lambda_N-\nu|^{\frac12}\bigr)^{\frac13},$$

where the middle inequality

$$\mathsf{D}(\chi_G,\chi_G) \le C\bigl(\mathsf{mes}(G)\bigr)^{\frac53} \tag{26.6.64}$$

is well known[40)] and the last one is due to (26.6.63); χ_G denotes characteristic function of G.

Similarly, when calculating expression (26.6.11), one can see easily that the contribution of Ω'_t is $\asymp B|\lambda_N-\nu|(B^2t^4)^{-1}\,\mathsf{mes}(\Omega'_t)$ and therefore

$$\mathsf{mes}(\Omega'_t) \le CF|\lambda_N-\nu|^{-1}t^2, \tag{26.6.65}$$

while term (26.6.62) is $\asymp |\lambda_N-\nu|^2t^{-2}t'^{-2}\mathsf{D}(\theta_t,\theta_{t'})$, which does not exceed

$$C|\lambda_N-\nu|^2t^{-2}t'^{-2}\,\mathsf{mes}(\Omega_t)\,\mathsf{mes}(\Omega_{t'})\bigl[\max\bigl(\mathsf{mes}(\Omega_t),\,\mathsf{mes}(\Omega_{t'})\bigr)\bigr]^{-\frac13} \tag{26.6.66}$$

due to inequality

$$\mathsf{D}(\chi_G,\chi_{G'}) \le C\,\mathsf{mes}(G)\,\mathsf{mes}(G')\bigl[\max\bigl(\mathsf{mes}(G),\,\mathsf{mes}(G')\bigr)\bigr]^{-\frac13}, \tag{26.6.67}$$

which trivially follows from the obvious inequality $\mathsf{D}(\chi_G,\delta_z) \le C(\mathsf{mes}(G))^{\frac23}$, where $\delta_z(x)=\delta(x-z)$.

[40)] Really, among uniform solids of equal mass and density the ball has the least potential energy; then $C=\frac15(12\pi)^{\frac13}$.

Due to (26.6.65) expression (26.6.66) does not exceed $CF^{\frac{5}{3}}t^{-\frac{2}{3}}$; recall that $t \ge t'$. Since summation with respect to $t \ge t'$ and then with respect to $t' \ge t_0$ returns $CF^{\frac{5}{3}}t_0^{-\frac{2}{3}}$, we conclude that term (26.6.61) with θ_0 replaced by θ'' (the characteristic function of $\{x\colon \ell(x) \ge t_0\}$) also does not exceed $CF^{\frac{5}{3}}(B|\lambda_N - \nu|^{\frac{1}{2}})^{\frac{1}{3}}$. □

So, we have now two estimates for an excess of expression (26.6.25) over (26.5.40): one estimate is

$$CF^{\frac{5}{3}}(B|\lambda_N - \nu|^{\frac{1}{2}})^{\frac{1}{3}} \tag{26.6.68}$$

with $F = F(|\lambda_N - \nu|)$ derived in Proposition 26.6.12 and another one is due to (26.6.48). Let us consider the best of them. Note that estimate (26.6.68) consists of two terms each due to the corresponding term in the definition of F. The second term in the framework of Proposition 26.6.12(i) is

$$C\bigl(B^{\frac{3}{2}}\bar{r}^2|\nu|^{\frac{1}{4}}L|\lambda_N - \nu|^{-1}\bigr)^{\frac{5}{3}}\bigl(B|\lambda_N - \nu|^{\frac{1}{2}}\bigr)^{\frac{1}{3}} \asymp B^{\frac{17}{6}}\bar{r}^{\frac{10}{3}}|\nu|^{\frac{5}{12}}L^{\frac{5}{3}}|\lambda_N - \nu|^{-\frac{3}{2}}.$$

Then, taking minimum of this expression and $CB\bar{r}^3|\nu|^{\frac{1}{2}}L^2|\lambda_N - \nu|$, we see that this minimum does not exceed

$$C\bigl(B^{\frac{17}{6}}\bar{r}^{\frac{10}{3}}|\nu|^{\frac{5}{12}}L^{\frac{5}{3}}\bigr)^{\frac{2}{5}}\bigl(B\bar{r}^3|\nu|^{\frac{1}{2}}L^2\bigr)^{\frac{3}{5}} \asymp CB^{\frac{5}{3}}\bar{r}^{\frac{8}{3}}(Z-N)_+^{\frac{7}{15}}L^{\frac{28}{15}} \asymp$$
$$C\begin{cases}(Z-N)_+^{\frac{7}{15}}BL^{\frac{28}{15}} & \text{if } (Z-N)_+^{\frac{4}{3}} \le B \le Z^{\frac{4}{3}},\\ (Z-N)_+^{\frac{7}{15}}Z^{\frac{8}{15}}B^{\frac{3}{5}}L^{\frac{28}{15}} & \text{if } Z^{\frac{4}{3}} \le B \le Z^3,\end{cases}$$

which is achieved for $|\lambda_N - \nu| \asymp B^{\frac{11}{15}}\bar{r}^{\frac{2}{15}}|\nu|^{-\frac{1}{30}}L^{-\frac{2}{15}}$. One can see easily that this expression does not exceed (26.5.40).

Therefore in the framework of Proposition 26.6.12(i)(ii) we can select $F = (Z^{\frac{2}{3}} + B\bar{r}^2L)$ according to (26.6.55), arriving to

$$C(Z^{\frac{2}{3}} + B\bar{r}^2L)^{\frac{5}{3}}B^{\frac{1}{3}}|\lambda_N - \nu|^{\frac{1}{6}} \le C(Z^{\frac{2}{3}} + B\bar{r}^2L)^{\frac{5}{3}}B^{\frac{1}{3}}(Z^{\frac{2}{3}} + B^{\frac{1}{2}}L_1)^{\frac{1}{6}}|\nu|^{\frac{1}{24}},$$

which we can rewrite (slightly increasing powers of logarithms) as two last cases in expression

$$C\begin{cases}(Z-N)_+^{\frac{1}{18}}Z^{\frac{11}{9}}B^{\frac{1}{3}} & \text{if } B \le (Z-N)_+^{\frac{4}{3}},\\ (Z-N)_+^{\frac{1}{24}}(Z^{\frac{11}{9}} + B^{\frac{11}{12}}L^4)B^{\frac{11}{32}} & \text{if } (Z-N)_+^{\frac{4}{3}} \le B \le Z^{\frac{4}{3}},\\ (Z-N)_+^{\frac{1}{24}}Z^{\frac{79}{120}}B^{\frac{23}{30}} & \text{if } Z^{\frac{4}{3}} \le B \le Z^3.\end{cases} \tag{26.6.69}$$

In the framework of Proposition 26.6.12(iii) one should replace $(\nu/B^2)^{\frac{1}{4}}$ by $\bar{r}$ and L by 1, so $B^{\frac{3}{2}}\bar{r}^2|\nu|^{\frac{1}{4}}L|\lambda_N-\nu|^{-1}\mapsto B^2\bar{r}^3|\lambda_N-\nu|^{-1}$; further, one should preserve $B|\lambda_N-\nu|^{\frac{1}{2}}$ and therefore the second term becomes

$$\bigl(B^2\bar{r}^3|\lambda_N-\nu|^{-1}\bigr)^{\frac{5}{3}}\bigl(B|\lambda_N-\nu|^{\frac{1}{2}}\bigr)^{\frac{1}{3}}\asymp B^{\frac{11}{3}}\bar{r}^5|\lambda_N-\nu|^{-\frac{3}{2}}$$

and taking minimum of it and (26.6.48) we again get a term lesser than (26.5.40).

Meanwhile, the first term becomes $Z^{\frac{10}{9}}B^{\frac{1}{3}}|\lambda_N-\nu|^{\frac{1}{6}}\le (Z-N)_+^{\frac{1}{18}}Z^{\frac{11}{9}}B^{\frac{1}{3}}$ occupying the first line in (26.6.69).

Therefore we have proven

Proposition 26.6.14. *If $M\ge 2$, $B\le Z^3$ all three* D*-terms do not exceed* (26.5.40) + (26.6.69).

Summary

Therefore all error terms in the upper estimate do not exceed (26.5.40) and we arrive to

Theorem 26.6.15. *Let $M\ge 2$, $B\le Z^3$. Then*

(i) The following estimate holds:

$$E^{\mathsf{TF}}\le \mathcal{E}^{\mathsf{TF}}+\Bigl(\mathsf{Tr}\bigl((H_{A,W}-\nu)^-\bigr)+\int P_B(W^{\mathsf{TF}}+\nu)\,dx\Bigr)+ (26.5.40)+(26.6.69). \tag{26.6.70}$$

(ii) The following estimate holds for $a\ge Z^{-1}$:

$$E^{\mathsf{TF}}\le \mathcal{E}^{\mathsf{TF}}+\underbrace{\mathsf{Scott}+CZ^{\frac{4}{3}}B^{\frac{1}{3}}+a^{-\frac{1}{2}}Z^{\frac{3}{2}}}+(26.5.40)+(26.6.69); \tag{26.6.71}$$

for $a\le Z^{-1}$ one should replace selected terms by CZ^2.

(iii) If $B\le Z$ and $a\ge Z^{-\frac{1}{3}}$

$$E^{\mathsf{TF}}\ge \mathcal{E}^{\mathsf{TF}}+\mathsf{Scott}+\mathsf{Dirac}+\mathsf{Schwinger}+ CZ^{\frac{5}{3}}\bigl(Z^{-\delta}+(BZ^{-1})^{\delta}+(aZ^{\frac{1}{3}})^{-\delta}\bigr). \tag{26.6.72}$$

We also arrtive to

Theorem 26.6.16. *(i) In the framework of Theorem 26.6.15(i) the following estimate holds:*

$$\mathsf{D}\bigl(\rho_\psi - \rho^{\mathsf{TF}}, \rho_\psi - \rho^{\mathsf{TF}}\bigr) \le (26.5.40) + (26.6.69). \tag{26.6.73}$$

(ii) In the framework of Theorem 26.6.15(iii) (albeit without assumption $a \ge Z^{-\frac{1}{3}}$) the following estimate holds:

$$\mathsf{D}\bigl(\rho_\psi - \rho^{\mathsf{TF}}, \rho_\psi - \rho^{\mathsf{TF}}\bigr) \le CQ \coloneqq CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + (BZ^{-1})^{\delta}\bigr). \tag{26.6.74}$$

Remark 26.6.17. In virtue of Remark 26.3.7 we can replace term $CZ^{\frac{4}{3}}B^{\frac{1}{3}}$ to $o(Z^{\frac{4}{3}}B^{\frac{1}{3}})$. This is also true in the case of the better estimates $M = 1$.

We leave to the reader the following easy problem:

Problem 26.6.18. Investigate conditions to $(Z-N)_+$ so that terms (26.5.40) and (26.6.69) do not spoil the upper estimate for E_N or $\mathsf{D}(\rho_\Psi - \rho_B^{\mathsf{TF}},\ \rho_\Psi - \rho_B^{\mathsf{TF}})$.

26.7 Negatively Charged Systems

In this section we following Section 25.5 consider the case $N \ge Z$ and provide upper estimates for the excessive negative charge $(N-Z)$ if $\mathsf{I}_N > 0$ and for the ionization energy I_N.

26.7.1 Estimates of the Correlation Function

First of all we provide some estimates which will be used for both negatively and positively charged systems. Let us consider the ground-state function $\Psi(x_1, \varsigma_1; \dots; x_N, \varsigma_N)$ and the corresponding density $\rho_\Psi(x)$. Again the crucial role play estimates[41)]

$$\mathsf{D}\bigl(\rho_\Psi - \rho_B^{\mathsf{TF}},\ \rho_\Psi - \rho_B^{\mathsf{TF}}\bigr) \le Q \tag{26.7.1}$$

[41)] Namely, estimate (26.6.27) of Theorem 26.6.7 for $M = 1$, and similar estimates (26.6.45) of Theorem 26.6.11 and (26.6.73) of Theorem 26.6.16 for $M \ge 2$.

For $B \le Z$ and $a \ge Z^{-\frac{1}{3}}$, we use estimate (26.6.74) in all cases.

where Q is just the right-hand expression of the corresponding estimate. Recall that the same estimate holds also for difference between upper and lower bounds for E_N (with $\mathsf{Tr}((H_W-\nu)^-)+\nu N$ not replaced by its semiclassical approximation).

Remark 26.7.1. (i) Similarly to Subsection 25.5.1 $\rho := \rho_B^{\mathsf{TF}}$, $W = W_B^{\mathsf{TF}}$, $\rho_\varepsilon := \phi_\varepsilon * \rho$, $W_\varepsilon = |x|^{-1} * \rho_\varepsilon$ with ϕ_ε defined in Proposition 25.5.1.

(ii) All arguments and conclusions of Subsection 25.5.1 up to but excluding estimates (25.5.31)–(25.5.32) are not related to the Schrödinger operator and remain true.

So we need to calculate both the semiclassical errors and the principal parts. Note that *all semiclassical errors for W_ε do not exceed those obtained for W we selected*. Consider approximations errors in the principal part, namely

$$\mathsf{D}\bigl(P'(W_\varepsilon+\nu)-P'(W+\nu),\, P'(W_\varepsilon+\nu)-P'(W+\nu)\bigr) \tag{26.7.2}$$

and

$$\mathsf{D}(\rho_\varepsilon-\rho,\,\rho_\varepsilon-\rho) \tag{26.7.3}$$

since we already estimated terms $\mathsf{D}\bigl(P'(W+\nu)-\rho,\, P'(W+\nu)-\rho\bigr)$ and $\mathsf{D}(\rho_\Psi-\rho,\,\rho_\Psi-\rho)$ by Q.

Note that while since now $\rho=\rho_B^{\mathsf{TF}}$ is only $\mathscr{C}^{\frac12}$ function (in the corresponding scale) and estimate (25.5.31) fails, estimate (25.5.32) survives after minor modification:

$$|W-W_\varepsilon| \le C(1+\ell\varepsilon^{-1})^{-2}\zeta^2 \tag{26.7.4}$$

with the corresponding scaling function ζ and then

$$\begin{aligned}|P'(W_\varepsilon+\nu)-P'(W+\nu)|&\\ \le C(1+\ell\varepsilon^{-1})^{-2}\zeta^3 + C(1+\ell\varepsilon^{-1})^{-1}\zeta B&\end{aligned} \tag{26.7.5}$$

and therefore expression (26.7.2) does not exceed $C\bigl(Z^3\varepsilon^2+ZB^2\varepsilon^2\bar r^2\bigr)$ and it does not exceed $C\max(Z^{\frac53}, B^{\frac45}Z^{\frac35})$ for

$$\varepsilon = \min(Z^{-\frac23},\, Z^{\frac25}B^{-\frac45}) \tag{26.7.6}$$

and this does not exceed $C\bar{Q}$, where as before $\bar{Q} = \mathsf{max}(Q,\, Z^{\frac{5}{3}})$.

Further, consider expression (26.7.3); it is equal to $|(W_\varepsilon - W, \rho_\varepsilon - \rho)|$ and one can prove easily the same estimate for it:

$$\mathsf{D}(\rho_\varepsilon - \rho,\, \rho_\varepsilon - \rho) \le C\bar{Q}. \tag{26.7.7}$$

Furthermore, under this restriction we estimate an error in the principal part of asymptotics of $\int e(x,x,\lambda)\,dx$

$$|\int \big(P'(W_\varepsilon + \nu) - P'(W+\nu)\big)\,dx| \le C\big(Z^{\frac{3}{2}}\varepsilon^{\frac{3}{2}} + Z^{\frac{1}{2}}B\varepsilon\bar{r}^{\frac{3}{2}}\big), \tag{26.7.8}$$

which is less than the semiclassical error.

Then $S \coloneqq S_\varepsilon \le C\bar{Q}$ with S_ε defined by (25.5.22). So, the following proposition is proven:

Proposition 26.7.2 [42]**.** *If θ, χ are as in Subsection 25.5.1, then estimate* (25.5.34) *holds, namely,*

$$\mathcal{J} = |\int \Big(\rho^{(2)}_\Psi(x,y) - \rho(y)\rho_\Psi(x)\Big)\theta(x)\chi(x,y)\,dxdy| \le \tag{26.7.9}$$

$$C\sup_x \|\nabla_y \chi_x\|_{\mathscr{L}^2(\mathbb{R}^3)}\Big((\bar{Q} + \varepsilon^{-1}N + T)^{\frac{1}{2}}\Theta + R^{\frac{1}{2}}\Theta^{\frac{1}{2}}\Big) + C\varepsilon N\|\nabla_y\chi\|_{\mathscr{L}^\infty}\Theta$$

with $\Theta = \Theta_\Psi$ defined by (25.5.15) *and T and R defined by* (25.5.23) *and* (25.5.25) *respectively with ε, defined by* (26.7.7)*.*

Recall that $\rho^{(2)}_\Psi(x,y)$ defined by (25.5.13) is the *quantum correlation function*. Observe that the threshold value again is $B \asymp Z^{\frac{4}{3}}$.

26.7.2 Excessive Negative Charge

We are going to prove the following theorem, similar to Theorem 25.5.3:

Theorem 26.7.3. *Assume that $\mathsf{I}_N > 0$. Then in the fixed nuclei model*

(i) For $B \le Z^{\frac{20}{21}}$ the following estimate holds:

$$N - Z \le CZ^{\frac{5}{7}}. \tag{25.5.37}$$

[42] Cf. Proposition 25.5.1.

(ii) If $Z^{\frac{20}{21}} \le B \le Z^3$ *then*

$$N - Z \le C(\bar{r}Q)^{\frac{1}{2}}. \tag{26.7.10}$$

In particular for $M = 1$

$$N - Z \le C \begin{cases} B^{-\frac{1}{8}} Z^{\frac{5}{6}} & as \quad Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}}, \\ B^{\frac{1}{5}} Z^{\frac{2}{5}} & as \quad Z^{\frac{4}{3}} \le B \le Z^3 \end{cases} \tag{26.7.11}$$

and for $M \ge 2$

$$N - Z \le C \begin{cases} B^{-\frac{1}{8}} Z^{\frac{5}{6}} + B^{\frac{1}{2}} L & as \quad Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}}, \\ B^{\frac{1}{5}} Z^{\frac{2}{5}} L & as \quad Z^{\frac{4}{23}} \le B \le Z^3 \end{cases} \tag{26.7.12}$$

with $L = |\log(BZ^{-3})|$.

Proof. Let us follow the proof of Theorem 25.5.3 with the necessary modifications:

(a) Let us select $\theta = \theta_{(b)}$ according to (25.5.38):

$$\begin{aligned} &\operatorname{supp}(\theta) \subset \{x : \ \ell(x) \ge b\}, \qquad \operatorname{supp}(1-\theta) \subset \{x : \ \ell(x) \le 2b\}, \\ &0 \le \theta \le 1, \qquad |\nabla \theta^{\frac{1}{2}}| + |\nabla (1-\theta)^{\frac{1}{2}}| \le Cb^{-1}. \end{aligned} \tag{25.5.38}$$

Note that again equation $\mathsf{H}_N \Psi = \mathsf{E}_N \Psi$ yields identity (25.5.39), where we pick up again according to (25.5.40) $\varphi = ZV(x)^{-1} \asymp \ell(x)$ and isolating the contribution of j-th electron in j-th term we get inequality (25.5.41):

$$-\mathsf{I}_N \int \rho_\Psi(x) \ell(x) \theta \, dx \ge \tag{25.5.41}$$

$$\sum_j \langle \Psi, \ell(x_j)\theta(x_j) \Big(-V(x_j) + \sum_{k:k\ne j} |x_j - x_k|^{-1} \Big) \Psi \rangle - \sum_j \|\nabla \big(\theta^{\frac{1}{2}}(x_j) \ell(x_j)^{\frac{1}{2}} \big) \Psi\|^2$$

now due to the non-negativity of operator $\big((D_x - A(x)) \cdot \boldsymbol{\sigma}\big)^2$.

Now let us again select b to be able to calculate the magnitude of Θ_Ψ. Note that inequality (25.5.42) holds. Then repeating our arguments, leading to (25.5.46) we see that there are two cases:

(i) $B \lesssim Z^{\frac{20}{21}}$ which is equivalent to $\bar{Q}^{\frac{1}{7}} \lesssim \bar{r}$ in which case we take $b = \epsilon \bar{Q}^{\frac{1}{7}} = \epsilon Z^{\frac{5}{21}}$ and then (25.5.46) holds. Then we can apply all arguments of the proof of Theorem 25.5.3 and arrive to the same estimate; thus we arrive to Statement (i).

(ii) $Z^{\frac{20}{21}} \lesssim B \le Z^3$ which is equivalent to $\bar{Q}^{\frac{1}{7}} \lesssim \bar{r}$ in which case we take $b = C_0 \bar{r}$ and then $\Theta_\Psi \asymp (N - Z)_+$ provided (26.7.10) with large enough constant C is violated. We need to prove that it is incompatible with $\mathsf{I}_N > 0$. We will do it below.

(b) So we take $b = C_0 \bar{r}$ and then, assuming that (26.7.10) with large enough constant C fails, we have $\Theta_\Psi \asymp (N - Z)_+ > 0$ and

$$\rho_B^{\mathsf{TF}}(x) = W_B^{\mathsf{TF}}(x) = 0 \qquad \text{on} \quad \mathsf{supp}(\theta_0) \tag{26.7.13}$$

where θ_0 and θ_1 satisfy (25.5.51) and $\varphi(x) = ZV(x)^{-1}$ again.

Then the proof goes even simpler: while arriving to (25.5.53)

$$\begin{aligned} \iint \rho_\Psi^{(2)}(x,y)\varphi(x)|x-y|^{-1}\theta(x)(1-\theta(y))\,dxdy & \\ \ge \iint \rho_\Psi^{(2)}(x,y)\varphi(x)|x-y|^{-1}\theta(x)\theta_1(y)\,dxdy & \\ \ge \iint \rho_\Psi(x)\rho(y)\varphi(x)|x-y|^{-1}\theta(x)\theta_1(y)\,dxdy & \\ - C\bigl(\beta^{\frac12}\bar{Q}^{\frac12} + \beta^{-1}Z^{\frac13}\bigr)\Theta_\Psi & \end{aligned} \tag{25.5.53}$$

due to (26.7.13) we can simply skip $\theta_1(y)$ in the right-hand expression and observe that $\int \rho(y)\varphi(x)|x-y|^{-1} = V(x)$.

Thus we arrive to the following statement, similar to (25.5.55):

(26.7.14) The first line in the right-hand expression of (25.5.50) does not exceed $\bigl(Z - N + Cb^{\frac12}\bar{Q}^{\frac12} Cb^{-1}Z^{\frac13}\bigr)\Theta_\Psi$.

(c) Then continuing arguments of Part (c) of the proof of Theorem 25.5.3 we arrive to estimate

$$N - Z \le C(b\bar{Q})^{\frac12} + Cb^{-1}Z^{\frac13} \tag{26.7.15}$$

which differs from (25.5.59) by the last term $Cb^{-1}Z^{\frac13}$ instead of Cb^{-3}. With $b = C_0\bar{r}$ the second term is smaller and we arrive to (26.7.11).

(d) Recalling that $\bar{Q} = \max(Z^{\frac{5}{3}}, B^{\frac{4}{5}}Z^{\frac{3}{5}})$ for $M = 1$ and $\bar{Q} = \max(Z^{\frac{5}{3}} + B, B^{\frac{4}{5}}Z^{\frac{3}{5}})$ for $M = 1$ we arrive to (26.7.11); on the other hand, $\bar{Q} = \max(Z^{\frac{5}{3}} + B^{\frac{5}{4}}L^2, B^{\frac{4}{5}}Z^{\frac{3}{5}}L^2)$. for $M \ge 2$ and we arrive to (26.7.12). □

26.7.3 Estimate for Ionization Energy

Let us estimate the ionization energy, assuming that

(26.7.16) $(Z - N)_+$ does not exceed $C(b\bar{Q})^{\frac{1}{2}}$ with b defined in the proof of Theorem 26.7.3 [43].

Assume, however, first that $\nu = 0$ (in particular it happens as $N \ge Z$). Few cases are possible:

(i) $B \le Z^{\frac{20}{21}}$ and $(Z - N)_+ \le C_0 Z^{\frac{5}{7}}$. In this case we act exactly as in Subsection 25.5.2: we pick up $b = \epsilon Z^{-\frac{5}{21}}$ with a small enough constant $\epsilon' > 0$; then

$$|\int \theta_b(x)\big(\rho_\Psi - \rho\big)\,dx| \le Cb^{\frac{1}{2}}Q^{\frac{1}{2}}, \tag{26.7.17}$$

while

$$\int \theta_b(x)\rho\,dx \asymp b^{-3} \tag{26.7.18}$$

and therefore

$$\Theta := \int \theta_b(x)\rho_\Psi\,dx \asymp b^{-3} \tag{26.7.19}$$

and

$$|\int \theta(x)\big(\rho_\Psi - \rho\big)\,dx| \le \epsilon''\Theta. \tag{26.7.20}$$

Then all corresponding estimates of Subsection 25.5.3 yield that $\mathsf{I}_N \le CZ^{\frac{20}{21}}$.

In all other cases one needs to replace θ_b by a function which is not b-admissible, exactly like we did in Section 25.6.

(ii) Let $Z^{\frac{20}{21}} \le B \le Z^3$ and $M = 1$. Let here $\bar{r}$ be the exact radius of $\mathsf{supp}(\rho)$, $\rho = \rho_B^{\mathsf{TF}}$ and $W = W_B^{\mathsf{TF}}$, which were obtained in the Thomas-Fermi theory with $\nu = 0$. Recall that $\bar{r} \asymp \max(B^{-\frac{1}{4}}; B^{-\frac{2}{5}}Z^{\frac{1}{5}})$ and $\bar{Q} \asymp \max(Z^{\frac{5}{3}}; B^{\frac{4}{5}}Z^{\frac{3}{5}})$.

[43] That is (25.5.37), or (26.7.20) in the framework of the corresponding Statement.

Also recall that $W \asymp Gt^4$ and $\rho \asymp BG^{\frac12}$ for $r = (1-t)\bar r$ with $1-\epsilon \le t \le 1$, where here and below

$$G \coloneqq \min(B;\, B^{\frac25} Z^{\frac45}). \tag{26.7.21}$$

We take in this case $\bar r t$-admissible function θ, equal 0 for $|x-y| \le \bar r(1-t)$ and equal 1 for $|x-y| \ge \bar r(1-\frac12 t)$. Then

(26.7.22) In all the above estimates one needs to replace $Cb^{-1}\Theta_{b(1-\epsilon)}$ by $C\bar r^{-1}t^{-1}\Theta'$ with Θ' defined by θ' which is also $\bar r t$-admissible and equal 1 in $\epsilon \bar r t$-vicinity of $\operatorname{supp}(\theta)$.

Then estimates (26.7.17)–(26.7.20) are replaced by

$$|\int \theta(x)\big(\rho_\Psi - \rho\big)\,dx| \le CQ^{\frac12} \times \|\nabla\theta\| \asymp Ct^{-\frac12}\bar r^{\frac12} Q^{\frac12} \tag{26.7.23}$$

while

$$\int \theta(x)\rho\,dx \asymp BG^{\frac12}\bar r^3 t^3 \tag{26.7.24}$$

and therefore

$$\Theta \coloneqq \int \theta(x)\rho_\Psi\,dx \asymp BG^{\frac12}\bar r^3 t^3. \tag{26.7.25}$$

Therefore (26.7.20) holds provided the right-hand expression of (26.7.23) does not exceed the right-hand expression of (26.7.25), multiplied by ϵ:

$$t = t_* \coloneqq C_0 B^{-\frac27} G^{-\frac17} \bar r^{-\frac57} Q^{\frac17} = C_1 \max(B^{-\frac14} Z^{\frac{5}{21}};\, B^{\frac{2}{35}} Z^{-\frac{6}{35}}) \tag{26.7.26}$$

where we picked up the smallest possible value of t. Note that

(26.7.27) $t \asymp 1$ as either $B \asymp Z^{\frac{20}{21}}$ or $B \asymp Z^3$.

Further, let us estimate from above

$$\begin{aligned} \mathcal{I}' = -\int \Big(\rho_\Psi^{(2)}(x,y) - \rho_\Psi(x)\rho(y)\Big)\ell(x)|x-y|^{-1}\theta(x)\,dxdy \le \\ -\int \Big(\rho_\Psi^{(2)}(x,y) - \rho_\Psi(x)\rho(y)\Big)\big(1-\omega_\tau(x,y)\big)\ell(x)|x-y|^{-1}\theta(x)\,dxdy + \\ \int \rho_\Psi(x)\rho(y)\omega_\tau(x,y)\ell(x)|x-y|^{-1}\theta(x)\,dxdy \end{aligned} \tag{26.7.28}$$

with $\omega_\tau(x,y)=0$ as $|x-y|\ge 2\tau\bar r$ and $\omega_\tau(x,y)=1$ as $|x-y|\le \tau\bar r$, with $\tau\in(t,1)$.

Then due to Proposition 26.7.2 with

$$\chi(x,y)=\bigl(1-\omega_\tau(x,y)\bigr)|x-y|^{-1}$$

the first term in the right-hand expression does not exceed $C\bar r^{\frac12}\tau^{-\frac12}\bar Q^{\frac12}\Theta$ since $\|\nabla_y\chi_x\|_{\mathscr{L}^2(\mathbb{R}^3)}\asymp(\bar r\tau)^{-\frac12}$ and also one can prove easily that all other terms in $\Bigl(\bigl(Q+\varepsilon^{-1}N+T\bigr)^{\frac12}\Theta+R^{\frac12}\Theta^{\frac12}\Bigr)$ do not exceed $CQ^{\frac12}\Theta$.

Meanwhile, the second term in in the right-hand expression of (26.7.28) does not exceed $CBG^{\frac12}\tau^2\times\bar r^3\tau^2\times\Theta$ because $\rho(y)\le CBG^{\frac12}\tau^2$ if $|x-y|\le 2\tau\bar r$, $x\in\mathsf{supp}(\theta)$, and therefore $\int\rho(y)\omega_\tau(x,y)\,dy\le CBG^{\frac12}\tau^4$.

Minimizing their sum

$$C\Bigl(\bar r^{\frac12}\tau^{-\frac12}Q^{\frac12}+BG^{\frac12}\bar r^3\tau^4\Bigr)\Theta$$

with respect to $\tau\ge t$ [44)], we arrive to estimate

$$\mathscr{I}'\le C\bar r^{\frac79}Q^{\frac49}B^{\frac19}G^{\frac{1}{18}}\Theta.$$

Then exactly as in the proof of Theorem 25.5.4 we have estimate

$$\bar r\,\mathsf{I}_N\le C(Z-N)_+ + C\bar r^{\frac79}Q^{\frac49}B^{\frac19}G^{\frac{1}{18}}, \tag{26.7.29}$$

and therefore we arrive to the estimate

$$\mathsf{I}_N\le C\bar r^{-1}(Z-N)_+ + C\bar r^{-\frac29}Q^{\frac49}B^{\frac19}G^{\frac{1}{18}}, \tag{26.7.30}$$

which implies (26.7.32) under assumptions (26.7.31) and $N\ge Z$.

Furthermore, estimate (26.7.34) under assumptions (26.7.33) and $N\ge Z$ is due to the fact that for $B\le Z$ one can upgrade $Q=Z^{\frac53}$ to $Q=Z^{\frac53}\bigl(B^\delta Z^{-\delta}+Z^{-\delta}\bigr)$.

Theorem 26.7.4. *Let* $M=1$ *and assumption* (25.3.33) *be fulfilled.*

[44)] One can see easily that minimum is achieved as $\tau\asymp t^{\frac79}$.

(i) Then for $B \le Z^3$ and

$$(Z-N)_+ \le C_0 \begin{cases} Z^{\frac{5}{7}} & \text{if } B \le Z^{\frac{20}{21}}, \\ B^{-\frac{1}{8}} Z^{\frac{5}{6}} & \text{if } Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}}, \\ B^{\frac{1}{5}} Z^{\frac{2}{5}} & \text{if } Z^{\frac{4}{3}} \le B \le Z^3 \end{cases} \tag{26.7.31}$$

the following estimate holds

$$\mathsf{I}_N \le C \begin{cases} Z^{\frac{20}{21}}, & \\ B^{\frac{2}{9}} Z^{\frac{20}{27}} & \text{if } Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}}, \\ B^{\frac{26}{45}} Z^{\frac{4}{15}} & \text{if } Z^{\frac{4}{3}} \le B \le Z^3. \end{cases} \tag{26.7.32}$$

(ii) Furthermore for $B \le Z$ under assumption (26.7.31)

$$(Z-N)_+ \le C_0 \begin{cases} Z^{\frac{5}{7}-\delta} & \text{if } B \le Z^{\frac{20}{21}}, \\ B^{-\frac{1}{8}+\delta} Z^{\frac{5}{6}-\delta} & \text{if } Z^{\frac{20}{21}} \le B \le Z \end{cases} \tag{26.7.33}$$

the following estimate holds

$$\mathsf{I}_N \le C \begin{cases} Z^{\frac{20}{21}-\delta'} & \text{if } B \le Z^{\frac{20}{21}}, \\ B^{\frac{2}{9}+\delta'} Z^{\frac{20}{27}-\delta'} & \text{if } Z^{\frac{20}{21}} \le B \le Z. \end{cases} \tag{26.7.34}$$

Proof in the general settings. To prove estimates (26.7.32) and (26.7.34) in the general settings (i.e. without assumption $N \ge Z$) observe that for $N < Z$

$$\begin{aligned} \mathsf{D}(\rho_N^{\mathsf{TF}} - \rho_Z^{\mathsf{TF}},\, \rho_N^{\mathsf{TF}} - \rho_Z^{\mathsf{TF}}) &\le C(Z-N)^2 \bar{r}^{-1} \asymp \\ & C \max\bigl((Z-N)^{\frac{7}{3}};\, C(Z-N)^2 B^{\frac{1}{4}};\, C(Z-N)^2 B^{\frac{2}{5}} Z^{-\frac{1}{5}}\bigr) \end{aligned} \tag{26.7.35}$$

(where subscript here denotes the number of electrons rather than the intensity of the magnetic field) because the same estimate holds for $\mathcal{E}_N^{\mathsf{TF}} - \mathcal{E}_Z^{\mathsf{TF}}$:

$$0 \le \mathcal{E}_N^{\mathsf{TF}} - \mathcal{E}_Z^{\mathsf{TF}} \le C(Z-N)^2 \bar{r}^{-1}, \tag{26.7.36}$$

which itself follows from

$$\frac{\partial \mathcal{E}^{\mathsf{TF}}}{\partial N} = \nu \asymp (Z-N)\bar{r}^{-1}. \tag{26.7.37}$$

Therefore to preserve our estimates we need to assume that the right-hand expression of (26.7.35) does not exceed Q; this assumption is equivalent to $(Z-N)_+ \le \min(Z^{\frac{5}{7}}; Z^{\frac{5}{6}}B^{-\frac{1}{8}})$ for $B \le Z^{\frac{4}{3}}$ which is exactly the first and the second cases in (26.7.31) (and these cases in (26.7.33) appear in the same way), and to $(Z-N)_+ \le CB^{\frac{1}{5}}Z^{\frac{2}{5}}$ for $Z^{\frac{4}{3}} \le B \le Z^3$, which is exactly the third case in (26.7.35).

Also there is a term $C(Z-N)_+\bar{r}^{-1}$ in the estimate of I_N. However, under assumption (26.7.35) this term does not exceed the right hand expression of (26.7.35) or (26.7.37), in fact coincides with it only in the first case. □

Consider now $M \ge 2$. Assume that $B \ge Z^{\frac{20}{21}}$ since the opposite case has been analyzed already.

Let us pick up $\bar{r}t$-admissible function θ such that $\theta = 1$ if $W \le C_0Gt^4$ and $\theta = 0$ if $W \ge 2C_0Gt^4$. In this case ($M \ge 2$) we can claim only that $\|\nabla\theta\| \le Ct^{-\frac{1}{2}}\bar{r}^{\frac{1}{2}}|\log t|^{\frac{1}{2}}$ and therefore we arrive to the following modifications of (26.7.23)–(26.7.26):

$$|\int \theta(x)\big(\rho_\Psi - \rho\big)\,dx| \le Ct^{-\frac{1}{2}}|\log t|^{\frac{1}{2}}\bar{r}^{\frac{1}{2}}\bar{Q}^{\frac{1}{2}}, \tag{26.7.23)'}$$

while

$$BG^{\frac{1}{2}}\bar{r}^3t^3 \lesssim \int \theta(x)\rho\,dx \lesssim BG^{\frac{1}{2}}|\log t|\bar{r}^3t^3 \tag{26.7.24)'}$$

and therefore

$$\Theta := \int \theta(x)\rho_\Psi\,dx \gtrsim BG^{\frac{1}{2}}\bar{r}^3t^3 \tag{26.7.25)'}$$

for

$$t \ge t_* := C_0B^{-\frac{2}{7}}G^{-\frac{1}{7}}\bar{r}^{-\frac{5}{7}}\bar{Q}^{\frac{1}{7}}|\log t|^{\frac{2}{7}}. \tag{26.7.26)'}$$

Now we need to look more carefully at $\bar{Q}$, especially because while it may contain "rogue" factor L or L^2, it can also be large as $(Z-N)_+$ is large. Fortunately, this is not the case in the current framework:

Proposition 26.7.5. *(i) Under condition* (26.7.41) *below* $\bar{Q}$ *is as in the case* $N = Z$ *i.e.*

$$\bar{Q} = \begin{cases} Z^{\frac{5}{3}} + B^{\frac{5}{4}}L^2 & \text{if } B \le Z^{\frac{4}{3}}, \\ B^{\frac{4}{5}}Z^{\frac{3}{5}}L^2 & \text{if } Z^{\frac{4}{3}} \le B \le Z^3. \end{cases} \tag{26.7.38}$$

(ii) Furthermore, if $B \le Z$ *and* $a \ge Z^{-\frac{1}{3}}$ *under condition* (26.7.43) *below* $\bar{Q}$ *is exactly as in the case* $N = Z$*, i.e.*

$$\bar{Q} = Z^{\frac{5}{3}}\bigl(Z^{-\delta} + (aZ^{\frac{1}{3}})^{-\delta} + (BZ^{-1})^{\delta}\bigr). \tag{26.7.39}$$

Proof. One can either derive it from the existing estimates or just repeat estimates with $\nu = 0$ adding $(Z-N)_+^2 \bar{r}^{-1}$ to $\bar{Q}$. We leave easy details to the reader.

Therefore all the above arguments could be repeated with this new expression $\bar{Q}$ which also acquires factor $|\log t|$ (due to this factor in the estimate of $\|\nabla\theta\|$ and this factor boils to $L_1^{\frac{1}{2}}$ with

$$L_1 = \begin{cases} |\log BZ^{-\frac{20}{21}}| + 1 & Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}}, \\ |\log BZ^{-3}| + 1 & Z^{\frac{4}{3}} \le B \le Z^3. \end{cases} \tag{26.7.40}$$

Therefore we arrive to

Theorem 26.7.6. *Let* $M \ge 2$*. Then*

(i) For

$$(Z-N)_+ \le C_0 \begin{cases} Z^{\frac{5}{7}} & \text{if } B \le Z^{\frac{20}{21}}, \\ Z^{\frac{5}{6}} B^{-\frac{1}{8}} + B^{\frac{1}{2}} L & \text{if } Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}}, \\ B^{\frac{1}{5}} Z^{\frac{2}{5}} L & \text{if } Z^{\frac{4}{3}} \le B \le Z^3 \end{cases} \tag{26.7.41}$$

the following estimate holds

$$\mathsf{I}_N \le C L_1^{\frac{2}{9}} \begin{cases} Z^{\frac{20}{21}} & \text{if } B \le Z^{\frac{20}{21}}, \\ Z^{\frac{20}{27}} B^{\frac{2}{9}} + B^{\frac{7}{9}} L^{\frac{8}{9}} & \text{if } Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}} \\ Z^{\frac{4}{15}} B^{\frac{26}{45}} L^{\frac{8}{9}} & \text{if } Z^{\frac{4}{3}} \le B \le Z^3. \end{cases} \tag{26.7.42}$$

(ii) Furthermore, for $B \le Z$*,* $a \ge Z^{-\frac{1}{3}}$ *and*

$$(Z-N)_+ \le C_0 \varsigma^{\delta} \begin{cases} Z^{\frac{5}{7}} & \text{if } B \le Z^{\frac{20}{21}}, \\ Z^{\frac{5}{6}} B^{-\frac{1}{8}} & \text{if } Z^{\frac{20}{21}} \le B \le Z, \end{cases} \tag{26.7.43}$$

with

$$\varsigma = Z^{-1} + BZ^{-1} + a^{-1}Z^{\frac{1}{3}} \tag{26.7.44}$$

the following estimate holds

$$\mathsf{I}_N \le CL_1^{\frac{2}{9}}\varsigma^{\delta'} \begin{cases} Z^{\frac{20}{21}} & \text{if } B \le Z^{\frac{20}{21}}, \\ Z^{\frac{20}{27}}B^{\frac{2}{9}} & \text{if } Z^{\frac{20}{21}} \le B \le Z. \end{cases} \tag{26.7.45}$$

26.8 Positively Charged Systems

Now let us estimate from above and below the ionization energy in the case when $N < Z$ and condition (26.7.31) (if $M = 1$) or (26.7.41) (if $M \ge 2$) fails. We also estimate excessive the positive charge in the case of $M \ge 2$ and free nuclei model. We will follow arguments of the corresponding three subsections of Section 25.6.

26.8.1 Upper Estimate for Ionization Energy: $M = 1$

Consider first the case of $M = 1$. Then for $B = 0$ arguments are well-known (see Section 25.6) but we repeat them for $B > 0$: we pick up β-admissible function θ such that $\theta = 1$ if $|x - \mathsf{y}_1| \ge \bar{r} - \beta$ and $\theta = 0$ if $|x - \mathsf{y}_1| \le \bar{r} - 2\beta$ where $\bar{r}$ is an exact radius of support of ρ^{TF} (see the very beginning of Subsection 25.6.1) and $\beta \ll \bar{r}$. Recall that

$$\bar{r} \asymp \begin{cases} (Z-N)^{-\frac{1}{3}} & \text{if } B \le Z^{\frac{20}{21}}, \\ \min\bigl((Z-N)^{-\frac{1}{3}}, B^{-\frac{1}{4}}\bigr) & \text{if } Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}}, \\ B^{-\frac{2}{5}}Z^{\frac{1}{5}} & \text{if } Z^{\frac{4}{3}} \le B \le Z^{3}, \end{cases} \tag{26.8.1}$$

where in the first case we used that $Z - N \ge Z^{\frac{5}{7}}$ while in the second case both subcases $(Z-N)^{-\frac{1}{3}} \gtrless B^{-\frac{1}{4}}$ are possible.

We can assume without any loss of the generality that $\mathsf{y}_1 = 0$. Now in the spirit of Subsection 25.6.1 we need to select as we did in Subsection 26.7.3 the smallest β such that

$$\Theta^{\mathsf{TF}} := \int \theta(x)\rho^{\mathsf{TF}}(x)\,dx \ge C\beta^{-\frac{1}{2}}\bar{r}\bar{Q}^{\frac{1}{2}} \tag{26.8.2}$$

implying that

$$\Theta_\Psi \coloneqq \int \theta(x)\rho_\Psi(x)\,dx \asymp \Theta^{\mathsf{TF}}, \tag{26.8.3}$$

where the right-hand expression of (26.8.2) estimates $|\int \theta(x)(\rho^{\mathsf{TF}}-\rho_\Psi)\,dx|$ (recall that it does not exceed $\|\nabla\theta\|\cdot \mathsf{D}(\rho^{\mathsf{TF}}-\rho_\Psi, \rho^{\mathsf{TF}}-\rho_\Psi)^{\frac12}$). Again as in Subsection 25.6.1 $\rho^{\mathsf{TF}}=\rho^{\mathsf{TF}}_N$ is calculated for the actual value of $N<Z$.

Then, following Subsubsection 25.6.1, eventually we arrive to estimate (25.6.10), namely:

$$\begin{aligned}\mathsf{I}_N \int \ell(x)\rho_\Psi(x)\theta(x)\,dx \le{}& \int \theta(x)V(x)\ell(x)\rho_\Psi(x)\,dx\\ &- \int \Big(\rho^{(2)}_\Psi(x,y)-\rho_\Psi(x)\rho(y)\Big)\ell(x)|x-y|^{-1}\theta(x)\,dxdy\\ &- \int \rho_\Psi(x)\rho(y)\ell(x)|x-y|^{-1}\theta(x)\,dxdy + C\beta^{-2}\bar r\Theta,\end{aligned} \tag{26.8.4}$$

and then estimate from above the second term in the right-hand expression

$$\begin{aligned}&- \int \Big(\rho^{(2)}_\Psi(x,y)-\rho_\Psi(x)\rho(y)\Big)\ell(x)|x-y|^{-1}\theta(x)\,dxdy \le\\ &\quad - \int \Big(\rho^{(2)}_\Psi(x,y)-\rho_\Psi(x)\rho(y)\Big)\big(1-\omega(x,y)\big)\ell(x)|x-y|^{-1}\theta(x)\,dxdy\\ &\qquad + \int \rho_\Psi(x)\rho(y)\omega(x,y)\ell(x)|x-y|^{-1}\theta(x)\,dxdy\end{aligned} \tag{26.8.5}$$

with $\omega=\omega_\gamma$: $\omega=0$ if $|x-y|\ge 2\gamma$ and $\omega=1$ if $|x-y|\le\gamma$, $\gamma\ge\beta$ (see (25.6.12)). To estimate the first term in the right-hand expression of (26.8.5) one can apply Proposition 25.5.1. In this case $\|\nabla_y\chi\|_{\mathscr{L}^2}\asymp C\bar r\gamma^{-\frac12}$, $\|\nabla_y\chi\|_{\mathscr{L}^\infty}\asymp \bar r\gamma^{-2}$ and plugging $R=\beta^{-2}\Theta$ and $T=|\nu|$, $\varepsilon=Z^{-\frac23}$ we conclude that this term does not exceed (25.6.13)

$$C\bar r\big(\gamma^{-\frac12}Q^{\frac12}+Z^{\frac13}\gamma^{-2}\big)\Theta \tag{26.8.6}$$

(if $Q\ge Z^{\frac53}$; otherwise here we should reset here $Q\coloneqq Z^{\frac53}$).

Note that if $0\le \bar r-|x|\asymp\beta$ then

$$W+\nu\asymp \upsilon \coloneqq \max\Big\{\big(\frac{|\nu|\beta}{\bar r}\big);\ G\big(\frac{\beta}{\bar r}\big)^4\Big\}, \tag{26.8.7}$$

with G defined by (26.2.48) and therefore

$$\rho \asymp \max\Big\{\big(\frac{|\nu|\beta}{\bar r}\big)^{\frac32};\ B\big(\frac{|\nu|\beta}{\bar r}\big)^{\frac12};\ BG^{\frac12}\big(\frac{\beta}{\bar r}\big)^2\Big\} \tag{26.8.8}$$

where the first and the second clauses are forks of the first clause in (26.8.7) since in the second clause automatically $W+\nu \le B$ for $0 \le \bar r - |x| \lesssim \beta$; therefore

$$\int \rho(x)\theta(x)\,dx \asymp \max\Big\{\big(\frac{|\nu|\beta}{\bar r}\big)^{\frac32};\ \ B\big(\frac{|\nu|\beta}{\bar r}\big)^{\frac12};\ BG^{\frac12}\big(\frac{\beta}{\bar r}\big)^2\Big\}\beta\bar r^2, \tag{26.8.9}$$

and therefore (26.8.2) holds if and only if

$$\max\Big\{\big(\frac{|\nu|}{\bar r}\big)^{\frac32}\beta^3;\ \ B\big(\frac{|\nu|}{\bar r}\big)^{\frac12}\beta^2;\ BG^{\frac12}\big(\frac{1}{\bar r}\big)^2\beta^{\frac72}\Big\}\bar r \ge CQ^{\frac12}; \tag{26.8.10}$$

then

$$\beta = \min\Big\{Q^{\frac16}|\nu|^{-\frac12}\bar r^{\frac16};\ B^{-\frac12}Q^{\frac14}|\nu|^{-\frac14}\bar r^{-\frac14};\ B^{-\frac27}G^{-\frac17}Q^{\frac17}\bar r^{\frac27}\Big\} \tag{26.8.11}$$

and in the corresponding cases

$$\upsilon = \Big\{Q^{\frac16}|\nu|^{\frac12}\bar r^{-\frac56};\ B^{-\frac12}Q^{\frac14}|\nu|^{\frac34}\bar r^{-\frac54};\ B^{-\frac87}G^{\frac37}Q^{\frac47}\bar r^{-\frac{20}{7}}\Big\}. \tag{26.8.12}$$

Observe, however, that for $B \lesssim Q^{\frac47}$ and $|\nu| \lesssim Q^{\frac47}$ we do not need these arguments; simpler arguments of Subsection 25.5.3 show that in this case $|\mathsf{I}_N| \le CQ^{\frac47}$.

On the other hand, for $B \lesssim Q^{\frac47}$ but $|\nu| \gtrsim Q^{\frac47}$, we pick $\gamma = Q^{\frac18}|\nu|^{-\frac{15}{32}}$, like in Subsection 25.6.1, and observe that $|\nu|\bar r^{-1}\gamma \gtrsim B$ and therefore we conclude that $\mathsf{I}_N + \nu \le CQ^{\frac16}|\nu|^{\frac{17}{24}}$, exactly like in that subsection. Therefore we arrive to

Proposition 26.8.1. *Let $B \le C_0 Z^{\frac{20}{21}}$. Then*

(i) If $|\nu| \le C_0 Z^{\frac{20}{21}}$, then estimate $\mathsf{I}_N \le CZ^{\frac{20}{21}}$ holds like in the case $B=0$.

(ii) If $|\nu| \ge C_0 Z^{\frac{20}{21}}$, then estimate $\mathsf{I}_N + \nu \le CZ^{\frac{5}{18}}|\nu|^{\frac{17}{24}}$ holds like in the case $B=0$.

Therefore in what follows we assume that $B \ge Q^{\frac47}$. One can see easily that then $\beta \le \bar r$.

Meanwhile, the same arguments imply that the second term in the right-hand expression of (26.8.5) is of magnitude

$$\mathsf{max}\Big\{\big(\frac{|\nu|\gamma}{\bar{r}}\big)^{\frac{3}{2}};\ \ B\big(\frac{|\nu|\gamma}{\bar{r}}\big)^{\frac{1}{2}};\ BG^{\frac{1}{2}}\big(\frac{\gamma}{\bar{r}}\big)^{2}\Big\}\gamma^{2}$$

and we need to minimize

$$\gamma^{-\frac{1}{2}}Q^{\frac{1}{2}}+\mathsf{max}\Big\{\big(\frac{|\nu|\gamma}{\bar{r}}\big)^{\frac{3}{2}},\ \ B\big(\frac{|\nu|\gamma}{\bar{r}}\big)^{\frac{1}{2}};\ BG^{\frac{1}{2}}\big(\frac{\gamma}{\bar{r}}\big)^{2}\Big\}\gamma^{2},$$

which is achieved when

$$\gamma^{-\frac{1}{2}}Q^{\frac{1}{2}}\asymp \mathsf{max}\Big\{\big(\frac{|\nu|\gamma}{\bar{r}}\big)^{\frac{3}{2}};\ \ B\big(\frac{|\nu|\gamma}{\bar{r}}\big)^{\frac{1}{2}};\ BG^{\frac{1}{2}}\big(\frac{\gamma}{\bar{r}}\big)^{2}\Big\}\gamma^{2}.$$

Let us compare this equation with equation to β. It is the same albeit with factor $\bar{r}^2$ rather than γ^2. Therefore if $\gamma \ge \bar{r}$ then $\gamma \le \beta \le \bar{r}$ which is a contradiction. Thus $\gamma \le \bar{r}$ but then $\gamma \ge \beta$.

Therefore we conclude that this term does not exceed

$$\varsigma := \mathsf{max}\Big\{Q^{\frac{7}{16}}\big(\frac{|\nu|}{\bar{r}}\big)^{\frac{3}{16}};\ Q^{\frac{5}{12}}B^{\frac{1}{6}}\big(\frac{|\nu|}{\bar{r}}\big)^{\frac{1}{12}};\ Q^{\frac{4}{9}}B^{\frac{1}{9}}G^{\frac{1}{18}}\bar{r}^{-\frac{2}{9}}\Big\}, \tag{26.8.13}$$

and to estimate $\mathsf{I}_N+\nu$ we need just to compute its sum with υ defined by (26.8.12).

Therefore we conclude that

$$\mathsf{I}_N+\nu \le C(\upsilon+\varsigma). \tag{26.8.14}$$

Remark 26.8.2. Observe that

$$\upsilon(Z,B,|\nu|)=Z^{\frac{20}{21}}\upsilon(1,Z^{-\frac{20}{21}}B,|\nu|Z^{-\frac{20}{21}}|\nu|) \qquad \text{if } \ Z^{\frac{20}{21}}\le B\le Z^{\frac{4}{3}} \tag{26.8.15}$$

and

$$\upsilon(Z,BZ^{-3},|\nu|)=Z^{2}\upsilon(1,Z^{-3}B,|\nu|Z^{-2}|\nu|) \quad \text{if } \ Z^{\frac{4}{3}}\le B\le Z^{3}, \tag{26.8.16}$$

and ς has the same scaling properties.

Therefore we can make all calculations with $Z=1$ and then scale. Leaving easy calculations to the reader, we arrive to

Proposition 26.8.3. *(i) For* $Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}}$

$$I_N + \nu \le C \begin{cases} Z^{\frac{5}{18}}|\nu|^{\frac{17}{24}} & \text{if } |\nu| \ge Z^{-\frac{20}{51}} B^{\frac{24}{17}}, \\ Z^{\frac{5}{12}} B^{-\frac{1}{2}} |\nu|^{\frac{17}{16}} & \text{if } B \le |\nu| \le Z^{-\frac{20}{51}} B^{\frac{24}{17}}, \\ Z^{\frac{5}{48}} B^{-\frac{3}{16}} |\nu|^{\frac{3}{4}} & \text{if } Z^{\frac{5}{12}} B^{\frac{9}{16}} \le |\nu| \le B, \\ Z^{\frac{25}{36}} B^{\frac{3}{16}} |\nu|^{\frac{1}{12}} & \text{if } Z^{\frac{5}{9}} B^{\frac{5}{12}} \le |\nu| \le Z^{\frac{5}{9}} B^{\frac{9}{16}}, \\ Z^{\frac{20}{27}} B^{\frac{2}{9}} & \text{if } |\nu| \le Z^{\frac{5}{9}} B^{\frac{5}{12}}. \end{cases} \tag{26.8.17}$$

(ii) In particular,

$$I_N \le C Z^{\frac{20}{27}} B^{\frac{2}{9}} \qquad \text{if } |\nu| \le Z^{\frac{20}{27}} B^{\frac{2}{9}}. \tag{26.8.18}$$

(iii) For $Z^{\frac{4}{3}} \le B \le Z^3$

$$I_N + \nu \le C \begin{cases} Z^{\frac{7}{30}} B^{\frac{8}{15}} |\nu|^{\frac{1}{12}} & \text{if } |\nu| \ge Z^{\frac{2}{5}} B^{\frac{8}{15}}, \\ Z^{\frac{4}{15}} B^{\frac{26}{45}} & \text{if } |\nu| \le Z^{\frac{2}{5}} B^{\frac{8}{15}}. \end{cases} \tag{26.8.19}$$

(iv) In particular,

$$I_N \le C Z^{\frac{4}{15}} B^{\frac{26}{45}} \qquad \text{if } |\nu| \le Z^{\frac{4}{15}} B^{\frac{26}{45}}. \tag{26.8.20}$$

Remark 26.8.4. Recall that $Q = Z^{\frac{5}{3}}\bigl(B^{\delta}+1\bigr)Z^{-\delta}$ if $B \le Z$; therefore we can add factor $\bigl(B^{\delta'}+1\bigr)Z^{-\delta'}$ in all estimates of Propositions 26.8.1 and 26.8.3.

26.8.2 Lower Estimate for Ionization Energy: $M = 1$

Now let us derive an estimate $I_N + \nu$ from below. Let $\Psi = \Psi_N(x_1, \dots, x_N)$ be the ground state for N electrons, $\|\Psi\| = 1$; consider an antisymmetric *test function*

$$\tilde{\Psi} = \tilde{\Psi}(x_1, \dots, x_{N+1}) = \Psi(x_1, \dots, x_N)u(x_{n+1}) - \sum_{1 \le j \le N} \Psi(x_1, \dots, x_{j-1}, x_{N+1}, x_{j+1}, \dots, x_N)u(x_j) \tag{26.8.21}$$

Then exactly as in Subsection 25.6.2

$$\mathsf{E}_{N+1}\|\tilde\Psi\|^2 \le \langle \mathsf{H}_{N+1}\tilde\Psi,\tilde\Psi\rangle = N\langle \mathsf{H}_{N+1}\Psi u,\tilde\Psi\rangle = N\langle \mathsf{H}_N\Psi u,\tilde\Psi\rangle + N\langle H_{V,x_{N+1}}\Psi u,\tilde\Psi\rangle + N\langle \sum_{1\le i\le N}|x_i-x_{N+1}|^{-1}\Psi u,\tilde\Psi\rangle = (\mathsf{E}_N-\nu')\|\tilde\Psi\|^2 + N\langle H_{W+\nu',x_{N+1}}\Psi u,\tilde\Psi\rangle + N\langle\big(\sum_{1\le i\le N}|x_i-x_{N+1}|^{-1}-(V-W)(x_{N+1})\big)\Psi u,\tilde\Psi\rangle$$

and therefore

$$N^{-1}(\mathsf{I}_{N+1}+\nu')\|\tilde\Psi\|^2 \ge -\langle H_{W+\nu',x_{N+1}}\Psi u,\tilde\Psi\rangle - \langle\big(\sum_{1\le i\le N}|x_i-x_{N+1}|^{-1}-(V-W)(x_{N+1})\big)\Psi u,\tilde\Psi\rangle \tag{26.8.22}$$

and

$$N^{-1}\|\tilde\Psi\|^2 = \|\Psi\|^2\cdot\|u\|^2 - N\int \Psi(x_1,\dots,x_{N-1},x)\Psi^\dagger(x_1,\dots,x_{N-1},y)u(y)u^\dagger(x)\,dx_1\cdots dx_{N-1}\,dxdy \tag{26.8.23}$$

as in (25.6.19) and (25.6.20) respectively where † means a complex or Hermitian conjugation and $\nu'\ge\nu$ to be chosen later.

Note that every term in the right-hand expression in (26.8.22) is the sum of two terms: one with $\tilde\Psi$ replaced by $\Psi(x_1,\dots,x_N)u(x_{N+1})$ and another with $\tilde\Psi$ replaced by $-N\Psi(x_1,\dots,x_{N-1},x_{N+1})u(x_N)$. We call these terms, as in Subsection 25.6.2, *direct* and *indirect* respectively.

Obviously, in the direct and indirect terms u appears as $|u(x)|^2\,dx$ and as $u(x)u^\dagger(y)\,dxdy$ respectively multiplied by some kernels.

Recall that u is an arbitrary function. Let us take $u(x)=\theta^{\frac12}(x)\phi_j(x)$ where ϕ_j are orthonormal eigenfunctions of $H_{W+\nu}$ and $\theta(x)$ is β-admissible function which is supported in $\{x:\ -\upsilon\ge W(x)+\nu\ge\frac23\nu\}$ and equal 1 in $\{x:\ -2\upsilon\ge W(x)+\nu\ge\frac12\nu\}$, satisfying (25.5.11), and υ is related to β as in the previous Section 26.7:

$$\upsilon = C\max(\nu\bar r^{-1}\beta;\ G\bar r^{-4}\beta^4). \tag{26.8.24}$$

Let us substitute it into (26.8.22), multiply by $\varphi(\lambda_j L^{-1})$ and take the sum with respect to j; then we get the same expressions with $|u(x)|^2\,dx$ and $u(x)u^\dagger(y)\,dxdy$ replaced by $F(x,x)\,dx$ and $F(x,y)\,dxdy$ respectively with

$$F(x,y)=\int \varphi(\lambda L^{-1})\,d_\lambda e(x,y,\lambda). \tag{26.8.25}$$

Here $\varphi(\tau)$ is a fixed $\mathscr{C}^\infty$ non-negative function equal to 1 for $\tau\le \frac{1}{2}$ and equal to 0 for $\tau\ge 1$ and $L=\nu'-\nu=6\upsilon$.

Under described construction and procedures the direct term generated by $N^{-1}\|\tilde\Psi\|^2$ is

$$\int \theta(x)\varphi(\lambda L^{-1})\,d_\lambda e(x,x,\lambda)\,dx. \tag{26.8.26}$$

Then, applying semiclassical approximation, we get

$$\Theta_\Psi := \int \varphi(\lambda L^{-1})\,d_\lambda P'_B(W+\nu-\lambda)\,dx. \tag{26.8.27}$$

Consider the remainder estimate. Assume that $M=1$ (case $M\ge 2$ will be considered later). Then since $L=C_1\upsilon$ the remainder does not exceed

$$Ch^s(\mu h+1)\beta^{-2}\bar r^2, \tag{26.8.28}$$

where

$$h=1/(\upsilon^{\frac{1}{2}}\beta) \tag{26.8.29}$$

and

$$\mu=B\beta\upsilon^{-\frac{1}{2}}; \tag{26.8.30}$$

one can prove it easily by partition of unity on $\mathsf{supp}(\theta)$ and applying semiclassical asymptotics with effective semiclassical parameter h and magnetic parameter μ.

On the other hand, the indirect term generated by $N^{-1}\|\tilde\Psi\|^2$ is

$$-N\int \theta^{\frac{1}{2}}(x)\theta^{\frac{1}{2}}(y)\Psi(x_1,\dots,x_{N-1},x)\Psi^\dagger(x_1,\dots,x_{N-1},y)\times F(x,y)\,dxdydx_1\cdots dx_{N-1}, \tag{26.8.31}$$

and since the operator norm of $F(.,.,.)$ is 1, the absolute value of this term does not exceed

$$N\int \theta(x)|\Psi(x_1,\dots,x_{N-1},x)|^2\,dx = \int \theta(x)\rho_\Psi(x)\,dx \le \int \theta(x)\rho^{\mathsf{TF}}(x)\,dx + CQ^{\frac12}\|\nabla\theta^{\frac12}\| \tag{26.8.32}$$

where $\rho^{\mathsf{TF}}=0$ on $\mathsf{supp}(\theta)$ and $\|\nabla\theta^{\frac12}\| \asymp \beta^{-\frac12}\bar r$.

Recall that $P'(W^{\mathsf{TF}}+\nu)=\rho^{\mathsf{TF}}$. We will take $\nu'=\nu+L$ to keep Θ_Ψ larger than all the remainders including those due to replacement W by W^{TF} and ρ by ρ^{TF} in the expression above. One can observe easily that then β should satisfy (26.8.10); let us define β and then υ by (26.8.11) and (26.8.12) respectively. Then

$$\Theta_\Psi \asymp \bigl(\upsilon^{\frac32}+B\upsilon^{\frac12}\bigr)\beta\bar r^2. \tag{26.8.33}$$

Therefore

(26.8.34) Let $h\le\epsilon_0$ (i.e. $\upsilon^{\frac12}\beta\ge C_0$), and β,υ be defined by (26.8.11) and (26.8.12) respectively. Then expression (26.8.33) is larger than $C_0\beta^{-\frac12}Q^{\frac12}$ and the total expression generated by $N^{-1}\|\tilde\Psi\|^2$ is greater than $\epsilon\Theta$ with $\Theta=\Theta_\Psi$ defined by (26.8.33).

Now let us consider the direct terms in the right-hand expression of (26.8.22). The first of them is like in (25.6.28)

$$\begin{aligned} &-\int \theta^{\frac12}(x)\varphi(\lambda L^{-1})\,d_\lambda\bigl(H_{W+\nu',x}\theta^{\frac12}(x)e(x,y,\lambda)\bigr)_{y=x}\,dx = \\ &\qquad -\int \theta(x)\varphi(\lambda L^{-1})\,d_\lambda\bigl(H_{W+\nu',x}e(x,y,\lambda)\bigr)_{y=x}\,dx \\ &\qquad\qquad -\frac12\int \varphi(\lambda L^{-1})[[H_W,\theta^{\frac12}],\theta^{\frac12}]\,d_\lambda e(x,x,\lambda) \ge \\ &\int \theta(x)(\nu'-\nu-\lambda)\varphi(\lambda L^{-1})\,d_\lambda e(x,x,\lambda)\,dx - C\int |\nabla\theta^{\frac12}|^2 e(x,x,\nu')dx. \end{aligned} \tag{26.8.35}$$

Observe that the absolute value of last term in the right-hand expression of (26.8.35) does not exceed $C\beta^{-1}\bar r^2\bigl(\upsilon^{\frac32}+B\upsilon^{\frac12}\bigr)\asymp\beta^{-2}\Theta$.

The second direct term in the right-hand expression of (26.8.22) is like in (25.6.29)

$$\begin{aligned}(26.8.36)\quad &-\int \theta(x)\Big(\rho_\Psi * |x|^{-1} - (V-W)(x)\Big)F(x,x)\,dx = \\ &\qquad -\mathsf{D}\big(\rho_\Psi - \bar\rho, \theta(x)F(x,x)\big) \ge \\ &-C\mathsf{D}\big(\rho_\Psi-\rho,\rho_\Psi-\rho\big)^{\frac12}\cdot \mathsf{D}\Big(\theta^{\frac12}F(x,x),\theta^{\frac12}F(x,x)\big)\Big)^{\frac12} \ge -CQ^{\frac12}\bar r^{-\frac12}\Theta,\end{aligned}$$

provided $V-W = |x|^{-1}*\rho$ with $\mathsf{D}(\rho-\rho^{\mathsf{TF}},\rho-\rho^{\mathsf{TF}})\le CQ$.

Further, the first indirect term in the right-hand expression of (26.8.22) is like in (25.6.30)

$$\begin{aligned}(26.8.37)\quad &-N\int \theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},x)\Psi^\dagger(x_1,\dots,x_{N-1},y)\times \\ &\qquad \varphi(\lambda L^{-1})\,d_\lambda\big(H_{W+\nu',x}\theta^{\frac12}(x)e(x,y,\lambda)\big)\,dxdydx_1\cdots dx_{N-1} = \\ &-N\int \theta^{\frac12}(y)\theta^{\frac12}(x)\Psi(x_1,\dots,x_{N-1},x)\Psi^\dagger(x_1,\dots,x_{N-1},y)\times \\ &\qquad \varphi(\lambda L^{-1})(\nu'-\nu-\lambda)\,d_\lambda e(x,y,\lambda)\,dxdydx_1\cdots dx_{N-1} \\ &-N\int \theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},x)\Psi^\dagger(x_1,\dots,x_{N-1},y)\times \\ &\qquad \varphi(\lambda L^{-1})[H_{W,x},\theta^{\frac12}(x)]\,d_\lambda e(x,y,\lambda)\,dxdydx_1\cdots dx_{N-1}.\end{aligned}$$

Observe that one can rewrite the sum of the first terms in the right-hand expressions in (26.8.35) and (26.8.37) as $\sum_j \varphi(\lambda_j L^{-1})(\nu'-\nu-\lambda_j)\|\widehat\Psi_j\|^2$ with

$$\widehat\Psi_j(x_1,\dots,x_{N-1}) \coloneqq \int \Psi(x_1,\dots,x_{N-1},x)\theta^{\frac12}(x)\phi_j(x)\,dx$$

and therefore this sum is non-negative.

One can see easily that the absolute value of the second term in the right-hand expression of (26.8.37) does not exceed

$$\int \rho_\Psi(y)\theta^{\frac12}(y)\,dy \times \beta^{-1}\int \theta_1(x)e(x,x,\nu')\,dx \asymp C\Theta\times C\big(\upsilon^{\frac32}+B\upsilon\big)\bar r^2 \asymp C\beta^{-\frac32}\bar r Q^{\frac12}\Theta$$

due the choice of β. This is larger than the absolute value of the right-hand expression in (26.8.36). Therefore (cf. 25.6.31) we conclude that

(26.8.38) The sum of the first direct and indirect terms in the right-hand expression of (26.8.22) is greater than $-C\beta^{-\frac{3}{2}}\bar{r}Q^{\frac{1}{2}}\Theta$.

Finally, we need to consider the second indirect term generated by the right-hand expression of (26.8.22):

$$
\begin{aligned}
(26.8.39)\quad & -\int \Big(\sum_{1\le i\le N} |y-x_i|^{-1} - (V-W)(y)\Big)\times \\
& \Psi(x_1,\dots,x_N)\Psi^{\dagger}(x_1,\dots,x_{N-1},y)\theta^{\frac{1}{2}}(x_N)\theta^{\frac{1}{2}}(y)F(x_N,y)\,dx_1\cdots dx_N dy = \\
& -\int \Big(|y|^{-1} * \varrho_{\underline{x}}(y) - (V-W)(y)\Big)\Psi(x_1,\dots,x_N)\Psi^{\dagger}(x_1,\dots,x_{N-1},y)\times \\
& \qquad \theta^{\frac{1}{2}}(x_N)\theta^{\frac{1}{2}}(y)F(x_N,y)\,dx_1\cdots dx_N dy \\
& -\int \Big(\sum_{1\le i\le N} |y-x_i|^{-1} - |y|^{-1} * \varrho_{\underline{x}}(y)\Big)\Psi(x_1,\dots,x_N)\Psi^{\dagger}(x_1,\dots,x_{N-1},y)\times \\
& \qquad \theta^{\frac{1}{2}}(x_N)\theta^{\frac{1}{2}}(y)F(x_N,y)\,dx_1\cdots\, dx_N dy;
\end{aligned}
$$

recall that $\varrho_{\underline{x}}$ is a smeared density, $\underline{x} = (x_1,\dots,x_N)$.

Since $|y|^{-1} * \varrho_{\underline{x}}(y) - (V-W)(y) = |y|^{-1} * (\varrho_{\underline{x}} - \rho)$, the first term in the right-hand expression is equal to

$$
\begin{aligned}
(26.8.40)\quad & \int \theta^{\frac{1}{2}}(x_N)\Psi(x_1,\dots,x_N)\times \\
& \mathsf{D}_y\Big(\varrho_{\underline{x}}(y)-\rho(y), F(x_N,y,\lambda)\theta^{\frac{1}{2}}(y)\Psi(x_1,\dots,x_{N-1},y)\Big)\,dx_1\cdots dx_N
\end{aligned}
$$

and its absolute value does not exceed

$$
\begin{aligned}
(26.8.41)\quad & \Big(N\int \mathsf{D}\big(\varrho_{\underline{x}}(\cdot)-\rho(\cdot), \varrho_{\underline{x}}(\cdot)-\rho(\cdot)\big)|\Psi(x_1,\dots,x_N)|^2\theta(x_N)\,dx_1\cdots dx_N\Big)^{\frac{1}{2}}\times \\
& N^{-\frac{1}{2}}\Big(\mathsf{D}_y\Big(F(x_N,y,\lambda)\theta^{\frac{1}{2}}(y)\Psi(x_1,\dots,x_{N-1},y), \\
& \qquad F(x_N,y,\lambda)\theta^{\frac{1}{2}}(y)\Psi(x_1,\dots,x_{N-1},y)\Big)\,dx_1\cdots dx_N\Big)^{\frac{1}{2}}.
\end{aligned}
$$

Recall that the first factor is equivalently defined by (25.5.4) and therefore due to estimate (25.5.24) it does not exceed $\bigl((Q+T+\varepsilon^{-1}N)\Theta+R\bigr)^{\frac12}$, where we assume that $\varepsilon\le Z^{-\frac23}$ and $\Theta\asymp \beta\bigl(\upsilon^{\frac32}+B\upsilon^{\frac12}\bigr)\bar r^2\beta \asymp \beta^{-\frac12}\bar r Q^{\frac12}$ is now an upper estimate for $\int \theta(y)\rho_\Psi(y)\,dy$-like expressions.

Then, according to (25.5.25), $R\asymp C\beta^{-2}\Theta \ll Q\Theta$ and, according to (25.5.23), $T\ll Q$ and therefore in all such inequalities we may skip R and T terms; so we get $C(Q+\varepsilon^{-1}N)^{\frac12}\Theta^{\frac12}$.

Meanwhile, the second factor in (26.8.41) (without square root) is equal to

$$N^{-1}\int L^{-2}\varphi'(\lambda L^{-1})\varphi'(\lambda' L^{-1})|y-z|^{-1}\underbrace{e(x_N,y,\lambda)}\,\theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},y)\times \underbrace{e(x_N,z,\lambda')}\,\theta^{\frac12}(z)\Psi^\dagger(x_1,\dots,x_{N-1},z)\,dydz\,dx_1\cdots dx_{N-1}\underbrace{dx_N}\,d\lambda d\lambda';$$

after integration with respect to x_N we get instead of the marked terms $e(y,z,\lambda)$ (recall that $e(.,.,.)$ is the Schwartz kernel of the projector and we keep $\lambda<\lambda'$) and then, integrating with respect to λ' we arrive to

$$N^{-1}\int |y-z|^{-1}F(y,z)\theta^{\frac12}(y)\Psi(x_1,\dots,x_{N-1},y)\times \theta^{\frac12}(z)\Psi^\dagger(x_1,\dots,x_{N-1},z)\,dydz\,dx_1\cdots dx_{N-1},$$

where now F is defined by (26.8.25) albeit with φ^2 instead of φ. This latter expression does not exceed

$$N^{-1}\iint |y-z|^{-1}|F(y,z)|\theta^{\frac12}(y)|\Psi(x_1,\dots,x_{N-1},y)|^2\times dydz\,dx_1\cdots dx_{N-1}. \tag{26.8.42}$$

Then due to Proposition 26.A.6 expression $\int |y-z|^{-1}|F(y,z)|\,dz$ does not exceed $C\beta^{-1}(h^{-1}+\mu)\asymp \upsilon^{\frac12}+B\upsilon^{-\frac12}$, and thus expression (26.8.42) does not exceed $CZ^{-2}\bigl(\upsilon^{\frac12}+B\upsilon^{-\frac12}\bigr)\Theta$. Therefore the second factor in (26.8.41) does not exceed $CN^{-1}\bigl(\upsilon^{\frac14}+B^{\frac12}\upsilon^{-\frac14}\bigr)\Theta^{\frac12}$ and the whole expression (26.8.41) does not exceed

$$C(Q+\varepsilon^{-1}N)^{\frac12}\Theta^{\frac12}\times N^{-1}\bigl(\upsilon^{\frac14}+B^{\frac12}\upsilon^{-\frac14}\bigr)\Theta^{\frac12}= CN^{-1}(Q+\varepsilon^{-1}N)^{\frac12}\bigl(\upsilon^{\frac14}+B^{\frac12}\upsilon^{-\frac14}\bigr)\Theta.$$

Finally we arrive to

Proposition 26.8.5 [45]**.** *Let*

$$\upsilon \ge \max\bigl(Z^{-\frac{4}{3}}Q^{\frac{2}{3}};\, Z^{-\frac{4}{5}}Q^{\frac{2}{5}}B^{\frac{2}{5}}\bigr) \tag{26.8.43}$$

and

$$\varepsilon \ge Z^{-1}\max(\upsilon^{-\frac{3}{2}}, B\upsilon^{-\frac{5}{2}}). \tag{26.8.44}$$

Then the first term in the right-hand expression of (26.8.39) *does not exceed* $C\upsilon\Theta$.

Further, we need to estimate the second term in the right-hand expression of (26.8.39). It can be rewritten in the form

$$\sum_{1\le i\le N}\int U(x_i,y)\Psi(x_1,\dots,x_N)\Psi^\dagger(x_1,\dots,x_{N-1},y)\theta^{\frac{1}{2}}(x_N)\theta^{\frac{1}{2}}(y)\times F(x_N,y)\,dx_1\cdots dx_N dy, \tag{26.8.45}$$

where $U(x_i,y)$ is the difference between two potentials, one generated by the charge $\delta(x-x_i)$ and another by the same charge smeared; note that $U(x_i,y)$ is supported in $\{(x_i,y)\colon |x_i-y|\le\varepsilon\}$. Let us estimate the i-th term in this sum with $i<N$ first. Multiplied by $N(N-1)$, it does not exceed

$$N\biggl(\int |U(x_i,y)|^2|\Psi(x_1,\dots,x_N)|^2\theta^{\frac{1}{2}}(x_N)\theta^{\frac{1}{2}}(y)|F(x_N,y)|\,dx_1\cdots dx_N dy\biggr)^{\frac{1}{2}}\times N\biggl(\int \omega(x_i,y)|\Psi(x_1,\dots,x_{N-1},y)|^2\theta^{\frac{1}{2}}(x_N)\theta^{\frac{1}{2}}(y)|F(x_N,y)|\,dx_1\cdots dx_N dy\biggr)^{\frac{1}{2}} \tag{26.8.46}$$

here ω is ε-admissible and supported in $\{(x_i,y)\colon |x_i-y|\le 2\varepsilon\}$ function.

Due to Proposition 26.A.6 in the second factor

$$\int \theta^{\frac{1}{2}}(x_N)|F(x_N,y)|\,dx_N \le C(1+\mu h) \asymp C(1+B\upsilon^{-1})$$

and therefore the whole second factor does not exceed

$$C\Bigl(\int \theta^{\frac{1}{2}}(x)\omega(x,y)\varrho^{(2)}_\Psi(x,y)\,dxdy\Bigr)^{\frac{1}{2}}(1+B\upsilon^{-1})^{\frac{1}{2}}, \tag{26.8.47}$$

[45] Cf. claim (25.6.36).

where we replaced x_i by x. According to Proposition 25.5.1 in the selected expression one can replace $\rho^{(2)}_\Psi(x,y)$ by $\rho_\Psi(x)\rho(y)$, with an error which does not exceed

$$C\Big(\sup_x \|\nabla_y \chi_x\|_{\mathscr{L}^2(\mathbb{R}^3)}\big(Q+\varepsilon^{-1}N\big)^{\frac12} + C\varepsilon N\|\nabla_y\chi\|_{\mathscr{L}^\infty}\Big)\Theta.$$

When we plug $\sup_x \|\nabla_y\chi_x\|_{\mathscr{L}^2(\mathbb{R}^3)} \asymp \varepsilon^{\frac12}$, $\|\nabla_y\chi\|_{\mathscr{L}^\infty}\asymp \varepsilon^{-1}$ this expression becomes $CN\Theta$.

Meanwhile, consider

$$\int |U(x_i,y)|^2\theta^{\frac12}(y)|F(x_N,y)|\,dy. \tag{26.8.48}$$

Again, due to Proposition 26.A.6, it does not exceed

$$C\big(\upsilon^{\frac32}+B\upsilon^{\frac12}\big)\int |U(x_i,y)|^2\theta^{\frac12}(y)\big(|x_N-y|\upsilon^{\frac12}+1\big)^{-s}\,dy$$

and this integral should be taken over $B(x_i,\varepsilon)$, with $|U(x_i,y)|\le |x_i-y|^{-1}$, so (26.8.48) does not exceed

$$C\varepsilon\big(\upsilon^{\frac32}+B\upsilon^{\frac12}\big)\omega'(x_i,x_N)$$

with $\omega'(x,y)=\big(1+\upsilon^{\frac12}|x-y|\big)^{-s}$ (provided $\varepsilon\le \upsilon^{-\frac12}$ which will be the case). Therefore the first factor in (26.8.46) does not exceed

$$C\varepsilon^{\frac12}\big(\upsilon^{\frac34}+B^{\frac12}\upsilon^{\frac14}\big)\Big(\underbrace{\int \theta^{\frac12}(x)\omega'(x,y)\rho^{(2)}_\Psi(x,y)\,dxdy}\Big)^{\frac12}. \tag{26.8.49}$$

Therefore in the selected expression one can replace $\rho^{(2)}_\Psi(x,y)$ by $\rho_\Psi(x)\rho(y)$ with an error which does not exceed what we got before but with ε replaced by $\upsilon^{-\frac12}$, i.e. also $CN\Theta$.

However, in both selected expressions, (26.8.47) and (26.8.49), replacing $\rho^{(2)}_\Psi(x,y)$ by $\rho_\Psi(x)\rho(y)$ we get just 0. Therefore expression (26.8.46) does not exceed $C\varepsilon^{\frac12}\big(\upsilon^{\frac34}+B^{\frac12}\upsilon^{\frac14}\big)Z\Theta$, which, in turn, does not exceed $C\upsilon\Theta$ provided $\varepsilon\le C\upsilon^{\frac12}\big(1+B\upsilon^{-1}\big)^{-1}Z^{-2}$.

So, we have two restriction to ε from above: the last one and $\varepsilon\le Z^{-\frac23}$ and one can see easily that both of them are compatible with restriction to ε in (26.8.43); also we can see easily that condition (26.8.43) is weaker than

$\upsilon \ge \{Z^{\frac{20}{21}} : Z^{\frac{20}{27}}B^{\frac{2}{9}} : Z^{\frac{4}{15}}B^{\frac{26}{45}}\}$ if $\{B \le Z^{\frac{20}{21}};\ Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}};\ Z^{\frac{4}{3}} \le B \le Z^{3}\}$ respectively.

Finally, consider term in (26.8.45) with $i = N$ (multiplied by N):

$$N \int U(x_N, y)|\Psi(x_1, \dots, x_N)|^2 \theta^{\frac{1}{2}}(x_N)\theta^{\frac{1}{2}}(y)F(x_N, y)\, dx_1 \cdots dx_N dy \tag{26.8.50}$$

due to Cauchy inequality it does not exceed

$$N\Big(\int |x_N - y|^{-2}|\Psi(x_1, \dots, x_N)|^2 \theta^{\frac{1}{2}}(x_N)\theta^{\frac{1}{2}}(y)\ dx_1 \cdots dx_N dy\Big)^{\frac{1}{2}} \times N\Big(\int |F(x_N, y)|^2|\Psi(x_1, \dots, x_N)|^2 \theta^{\frac{1}{2}}(x_N)\theta^{\frac{1}{2}}(y)\ dx_1 \cdots dx_N dy\Big)^{\frac{1}{2}} \tag{26.8.51}$$

where both integrals are taken over $\{|x_N - y| \le \varepsilon\}$. Integrating with respect to y there we get that it that it does not exceed

$$C\varepsilon^{\frac{1}{2}}\Theta^{\frac{1}{2}} \times \big(\upsilon^{\frac{3}{4}} + B\upsilon^{\frac{1}{4}}\big)\varepsilon^{\frac{3}{2}}\Theta^{\frac{1}{2}} = C\big(\upsilon^{\frac{3}{4}} + B\upsilon^{\frac{1}{4}}\big)\varepsilon^{2}\Theta \ll \upsilon\Theta.$$

Therefore the right-hand expression in (26.8.22) is $\ge -C\upsilon\Theta$ and recalling that $\nu' - \nu = O(\upsilon)$ we recover a lower estimate $\mathsf{I}_N + \nu \ge -C\upsilon$ in Theorem 26.8.6 below. Here υ must be found from (26.8.11)–(26.8.12) and must satisfy $\upsilon \le |\nu|$.

Combining this estimate with the estimate from the above, derived in Proposition 26.8.3 we arrive to

Theorem 26.8.6. *Let $M = 1$. Let condition* (26.2.28) *be fulfilled. Then*

(i) For $B \le Z^{\frac{20}{21}}$ and $|\nu| \ge Z^{\frac{20}{21}}$

$$|\mathsf{I}_N + \nu| \le CZ^{\frac{5}{18}}|\nu|^{\frac{17}{24}}. \tag{26.8.52}$$

(ii) For $Z^{\frac{20}{21}} \le B \le Z^{\frac{4}{3}}$ and $|\nu| \ge Z^{\frac{20}{27}}B^{\frac{2}{9}}$ estimate (26.8.17) *from above and a similar estimate rom below hold:*

$$\mathsf{I}_N + \nu \ge -C \begin{cases} Z^{\frac{5}{18}}|\nu|^{\frac{17}{24}} & \text{if } \ B \le Z^{\frac{5}{18}}|\nu|^{\frac{17}{24}}, \\ Z^{\frac{5}{12}}B^{-\frac{1}{2}}|\nu|^{\frac{17}{16}} & \text{if } \ Z^{\frac{5}{18}}|\nu|^{\frac{17}{24}} \le B \le |\nu|, \\ Z^{\frac{5}{12}}B^{-\frac{3}{16}}|\nu|^{\frac{3}{4}} & \text{if } \ |\nu| \le B \le Z^{-\frac{20}{7}}|\nu|^{4}, \\ Z^{\frac{20}{21}} & \text{if } \ Z^{-\frac{20}{7}}|\nu|^{4} \le B. \end{cases} \tag{26.8.53}$$

(iii) For $Z^{\frac{20}{21}} \le B \le Z^3$ *and* $|\nu| \ge Z^{\frac{4}{15}} B^{\frac{26}{45}}$ *estimate* (26.8.19) *from above and a similar estimate from below hold:*

$$I_N + \nu \ge -C \begin{cases} Z^{\frac{7}{30}} B^{\frac{8}{15}} |\nu|^{\frac{1}{12}} & \text{if } |\nu| \ge Z^{\frac{2}{5}} B^{\frac{8}{15}}, \\ Z^{\frac{4}{15}} B^{\frac{26}{45}} & \text{if } |\nu| \le Z^{\frac{2}{5}} B^{\frac{8}{15}}. \end{cases} \tag{26.8.54}$$

Remark 26.8.7. Recall that $Q = Z^{\frac{5}{3}}\bigl(B^{\delta}+1\bigr)Z^{-\delta}$ as $B \le Z$; therefore we can add factor $\bigl(B^{\delta'}+1\bigr)Z^{-\delta'}$ in all estimates of Theorem 26.8.6.

26.8.3 Estimates for Ionization Energy: $M \ge 2$

Recall that for $M \ge 2$ we have only estimate (26.6.73):

$$\mathsf{D}(\rho_\Psi - \rho,\, \rho_\Psi - \rho) \le \bar{Q}) := (26.5.40) + (26.6.69).$$

Then exactly the same arguments lead us to the following theorem (we leave all details to the reader):

Theorem 26.8.8. *Let* $M \ge 2$. *Then*

(i) Estimate $\mathsf{I}_N + \nu \le C(\upsilon + \varsigma)$ *holds with* υ *and* ς *defined by* (26.8.11)–(26.8.12) *and* (26.8.13) *albeit with* Q *replaced by* $\bar{Q}$.

(ii) Estimate $\mathsf{I}_N + \nu \ge -C\upsilon$ *holds with* υ *defined by* (26.8.11)–(26.8.12) *albeit with* Q *replaced by* $\bar{Q}$.

Therefore the case when $\bar{Q} \le Q$ is not affected. One can see easily that it happens for sure as $B \le Z^{\frac{20}{17}} L^{-\kappa}$ where $\kappa > 0$ is some exponent.

We leave to the reader

Problem 26.8.9. (i) Find explicit formula for $\upsilon + \varsigma$ and υ.

(ii) Find $\nu^* = \nu^*(Z, B)$ and $\nu_* = \nu_*(Z, B)$ such that $|\nu| \lesssim \upsilon + \varsigma$ iff and only if $\nu \lesssim \nu^*$ and $|\nu| \lesssim \upsilon$ iff and only if $\nu \lesssim \nu_*$.

26.8.4 Free Nuclei Model

In this subsection we consider two extra problems appearing in the free nuclei model–estimate the minimal distance between nuclei and the maximal excessive positive charge when system does not break apart. We also slightly improve estimates for the maximal negative charge and for the ionization energy.

Preliminary Arguments

Recall that we assume that

$$\mathsf{Q} := \widehat{\mathsf{E}} - \sum_{1\le m\le M} \mathsf{E}_m < 0 \tag{26.8.55}$$

where

$$\widehat{\mathsf{E}} = \mathsf{E} + \sum_{1\le m<m'\le M} \frac{Z_m Z_{m'}}{|\mathsf{y}_m - \mathsf{y}_{m'}|}. \tag{26.8.56}$$

We apply estimate from below for $\widehat{\mathsf{E}}$ delivered by Proposition 26.6.1(ii), and estimates from above for E_m, delivered by Theorem 26.6.6(ii); then

$$\widehat{\mathcal{E}}^{\mathsf{TF}} + \mathsf{Scott} - \sum_{1\le m\le M} \Bigl(\mathcal{E}_m^{\mathsf{TF}} - \mathsf{Scott}_m\Bigr) \le CQ + CZ^{\frac{4}{3}}B^{\frac{1}{3}} + Ca^{-\frac{1}{2}}Z^{\frac{3}{2}}$$

or, equivalently, due to equality $\mathsf{Scott} = \sum_{1\le m\le M} \mathsf{Scott}_m$ and non-binding theorem

$$0 \le \mathcal{Q} := \widehat{\mathcal{E}}^{\mathsf{TF}} - \sum_{1\le m\le M} \mathcal{E}_m^{\mathsf{TF}} \le CQ + CZ^{\frac{4}{3}}B^{\frac{1}{3}} + Ca^{-\frac{1}{2}}Z^{\frac{3}{2}}. \tag{26.8.57}$$

Assume that assumption (26.2.28) is fulfilled. Then $\mathcal{Q} \asymp \mathcal{E}^{\mathsf{TF}}$ for $a \le \epsilon r^*$ with $r^* = \min(Z^{-\frac{1}{3}}; B^{-\frac{2}{5}}Z^{\frac{1}{5}})$ and therefore

(26.8.58) In the free nuclei model $a \ge \epsilon r^*$.

Then the last term in (26.8.57) is not needed.

Remark 26.8.10. (i) Obviously, the second term $CZ^{\frac{4}{3}}B^{\frac{1}{3}}$ in the right-hand expression of (26.8.57) matters only if $Z \le B \le Z^{\frac{11}{7}}$; however we will show that it could be skipped even in this case.

(ii) All these estimates hold also for $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}})$ because this term is present in the estimate from below.

Minimal Distance

We are going to improve (26.8.58). Consider the case $B \le Z^{\frac{4}{3}}$ first. Then since $\mathcal{Q} \ge \epsilon_0 a^{-7}$ for $\epsilon r^* \le a \le \epsilon \bar{r}$ (where in this case $r^* = Z^{-\frac{1}{3}} \le \bar{r} = B^{-\frac{1}{4}}$), we conclude that $a \gtrsim Z^{-\frac{5}{21}}$ provided $B \le Z^{\frac{20}{21}}$. Then we conclude that $a \ge Z^{-\frac{5}{21}}$ as long as it is less than $\epsilon\bar{r}$ and we arrive to Statement (i) of Theorem 26.8.11 below:

Theorem 26.8.11. *Let condition* (26.2.28) *be fulfilled. Then in the free nuclei model*

(i) For $B \le Z^{\frac{20}{21}}$ *the minimal distance satisfies*

$$a \ge \epsilon Z^{-\frac{5}{21}} \tag{26.8.59}$$

(ii) For $Z^{\frac{20}{21}} \le B \le Z^3$ *the distances satisfy*

$$|\mathsf{y}_m - \mathsf{y}_{m'}| \ge \bar{r}_m + \bar{r}_{m'} - C\varepsilon\bar{r} \qquad \forall m \ne m' \tag{26.8.60}$$

with

$$\varepsilon = C(S^{-1}Q)^{\frac{1}{7}} \tag{26.8.61}$$

with S *defined by* (26.2.48) *and* Q *defined by* (26.6.45)*, where* $\bar{r}_m$ *denote the exact radii of* $\mathsf{supp}(\rho_m^{\mathsf{TF}})$*. In particular up to a logarithmic factor*

$$\varepsilon = C \begin{cases} B^{-\frac{1}{4}+\delta} Z^{\frac{5}{21}} & Z^{\frac{5}{21}} \le B \le Z^{\frac{4}{3}}, \\ B^{\frac{2}{35}} Z^{-\frac{6}{35}} & Z^{\frac{4}{3}} \le B \le Z^3. \end{cases} \tag{26.8.62}$$

(iii) In both cases

$$\mathsf{D}(\rho_B^{\mathsf{TF}} - \rho_{B,1}^{\mathsf{TF}} - \dots - \rho_{B,M}^{\mathsf{TF}};\ \rho_B^{\mathsf{TF}} - \rho_{B,1}^{\mathsf{TF}} - \dots - \rho_{B,M}^{\mathsf{TF}}) \le CQ. \tag{26.8.63}$$

Proof. To prove Statement (ii) we will apply Theorem 26.2.18 and to prove Statement (iii) we will apply Theorem 26.2.13 and to do this we need to prove that

$$\mathcal{Q} \coloneqq \widehat{\mathcal{E}}_B^{\mathsf{TF}} - \sum_{1 \le m \le M} \mathcal{E}_{B,m}^{\mathsf{TF}} \le CQ \tag{26.8.64}$$

assuming that

$$\widehat{\mathsf{E}} - \sum_{1 \le m \le M} \mathsf{E}_m \le 0. \tag{26.8.65}$$

(i) We claim first that

$$a \ge \epsilon r^* = \epsilon \min(Z^{-\frac{1}{3}};\ B^{-\frac{1}{4}};\ B^{-\frac{2}{5}} Z^{\frac{1}{5}}). \tag{26.8.66}$$

Indeed, it follows from the fact that $\mathsf{E} \asymp \mathsf{E}_m \asymp \max(Z^{\frac{7}{3}}; B^{\frac{2}{5}} Z^{\frac{9}{5}})$ and if (26.8.65) is violated then $\widehat{\mathsf{E}} \ge \epsilon_1 a^{-1} Z^2$ which would imply $\widehat{E} \ge \epsilon_2 a^{-1} Z^2$ which contradicts (26.8.65).

Then $\mathsf{E} \ge \mathcal{E}^{\mathsf{TF}}_B - CQ - CB^{\frac{1}{3}}Z^{\frac{4}{3}}$ and $\mathsf{E}_m \le \mathcal{E}^{\mathsf{TF}}_{B,m} + CQ + CB^{\frac{1}{3}}Z^{\frac{4}{3}}$ and then (26.8.65) implies that

$$\mathcal{Q} \le CQ + CB^{\frac{1}{3}}Z^{\frac{4}{3}} \tag{26.8.67}$$

which together with (26.8.65) implies

$$a \ge \epsilon \bar{r} = \epsilon \min(Z^{-\frac{5}{21}};\, B^{-\frac{1}{4}};\, B^{-\frac{2}{5}}Z^{\frac{1}{5}}). \tag{26.8.68}$$

(ii) In order to get rid of the last term in the right-hand expression of (26.8.67) (which is less than the first term unless $Z \le B \le Z^{\frac{11}{7}}$) we apply now estimate from below for $\widehat{\mathsf{E}}$ delivered by Proposition 26.6.1(i), and estimates from above for E_m, delivered by Theorem 26.6.6(i); then instead of this term and the difference between Scott correction terms for E and for $\sum_{1\le m\le M} \mathsf{E}_m$ (which is equal to 0 under assumption (26.8.66)) we have

$$\Bigl(\mathsf{Tr}((H_{A,W}-\nu)^-) + \int P_B(W^{\mathsf{TF}}+\nu)\,dx\Bigr) - \sum_{1\le m\le M}\Bigl(\mathsf{Tr}((H_{A,W_m}-\nu')^-) + \int P_B(W^{\mathsf{TF}}+\nu')\,dx\Bigr), \tag{26.8.69}$$

where W and W_m are approximations of W^{TF}_B and $W_{B,m}$ respectively and we know that $\nu' = \nu_1 = ... = \nu_M$.

Let us apply partition of unity $\phi_0 + \phi_1 + ... + \phi_M = 1$ with ϕ_m supported $B(\mathsf{y}_m, \epsilon 2\bar{r})$ in equal 1 in $B(\mathsf{y}_m, \epsilon\bar{r})$ as $m = 1, ..., M$ where we decrease constant $\epsilon > 0$ as needed.

Then our standard methods imply that the absolute values of

$$\mathsf{Tr}\bigl((H_{A,W}-\nu)^-\phi_0\bigr) + \int P_B(W^{\mathsf{TF}}+\nu)\phi_0(x)\,dx, \tag{26.8.70}$$

and

$$\mathsf{Tr}\bigl((H_{A,W_m}-\nu')^-\phi_{m'}\bigr) + \int P_B(W^{\mathsf{TF}}_m+\nu')\phi_{m'}\,dx \tag{26.8.71}$$

with $m = 1, ..., M$, $m' = 0, 1, ..., M$, $m' \ne m$ do not exceed CQ [46]. Therefore we need to estimate an absolute value of

$$\mathsf{Tr}\bigl(\bigl[(H_{A,W}-\nu)^- - (H_{A,W_m}-\nu')^-\bigr]\phi_m\bigr) + \int \bigl(P_B(W^{\mathsf{TF}}+\nu) - P_B(W^{\mathsf{TF}}_m+\nu')\bigr)\phi_m\,dx. \tag{26.8.72}$$

[46] Recall that W and W_m are approximations to W^{TF} and W^{TF}_m.

To do this recall that due to Theorem 26.2.13

$$\mathsf{D}(\rho-\rho_1-...-\rho_M,\, \rho-\rho_1-...-\rho_M)\le C\mathcal{Q}; \tag{26.8.73}$$

one can prove easily that there also

$$|W-W_m|\le CT := C\mathcal{Q}^{\frac12}\bar r^{-\frac12}+C(Z-N)\bar r^{-1} \tag{26.8.74}$$

and, moreover,

$$|\nabla(W-W_m)|\le CT\bar r^{-1}= C\mathcal{Q}^{\frac12}\bar r^{-\frac32}+C(Z-N)\bar r^{-2}, \tag{26.8.75}$$

$$|\nabla^2(W-W_m)|\le CT\bar r^{-2}= C\mathcal{Q}^{\frac12}\bar r^{-\frac52}+C(Z-N)\bar r^{-3}. \tag{26.8.76}$$

Then using our standard methods one can prove easily that an absolute value of expression (26.8.72) with ϕ_m replaced by ℓ-admissible function ψ_m does not exceed

$$CTh^{-2}(1+\mu h) \tag{26.8.77}$$

with our standard

$$h=Z^{-\frac12}r^{-\frac12},\qquad \mu = BZ^{-\frac12}r^{\frac32} \tag{26.8.78}$$

if <u>either</u> $B\le Z^{\frac43}$, $\ell\asymp r\le r^*=Z^{-\frac13}$ <u>or</u> $Z^{\frac43}\le B\le Z^3$, $\ell\asymp r\le \bar r$ and with

$$h=r,\qquad \mu = Br^3 \tag{26.8.79}$$

if $B\le Z^{\frac43}$ and $r^*\lesssim \ell\asymp \bar r$.

Plugging (26.8.78) and (26.8.79) and summing over partition we arrive to $CTZ^{\frac23}$ as $Z^{\frac{20}{21}}\le B\le Z^{\frac43}$ and $CTZ^{\frac25}B^{\frac15}$ as $Z^{\frac43}\le B\le Z^3$.

Plugging $T=(Z-N)\bar r^{-1}$ we get expressions which are much smaller than $\epsilon(Z-N)^2\bar r^{-1}$ due to (26.8.68); plugging $T=\mathcal{Q}^{\frac12}\bar r^{-\frac12}$ we get terms smaller than $\epsilon'\mathcal{Q}+C(\epsilon')B^{\frac14}Z^{\frac43}$ if $B\le Z^{\frac43}$ and $\epsilon'\mathcal{Q}+C(\epsilon')Z^{\frac35}B^{\frac45}$ if $Z^{\frac43}\le B\le Z^3$; here $\epsilon'>0$ is arbitrarily small and thus term (26.8.72) does not make any difference.

Then we arrive to $\mathcal{Q}\le C\mathcal{Q}$ which is Statement (iii). Finally, using Theorem 26.2.18(i) we arrive to Statement (ii). □

Let $B \le Z$ and $a \ge \epsilon \bar{r}$. Then in the proof of Theorem 26.8.11 we can apply improved remainder estimates, namely $Q = (rZ^{\frac{1}{3}})^{-\delta'} = Z^{\frac{5}{3}-\delta}(1+B^{\delta})$ with r defined from $\mu = O(h^{\delta'})$ with $\mu = Br/r^{-2}$, $h = r$, and we conclude that

$$\mathcal{Q} \le CQ = CZ^{\frac{5}{3}-\delta}(1+B^{\delta}) \tag{26.8.80}$$

and we arrive to

Theorem 26.8.12. *Let condition* (26.2.28) *be fulfilled. Then in the free nuclei model*

(i) For $B \le Z^{\frac{20}{21}(1-\delta)}$ *the minimal distance satisfies*

$$a \ge \epsilon Z^{-\frac{5}{21}(1-\delta)} \tag{26.8.81}$$

and

$$\mathsf{D}(\rho_B^{\mathsf{TF}} - \rho_{B,1}^{\mathsf{TF}} - ... - \rho_{B,M}^{\mathsf{TF}};\, \rho_B^{\mathsf{TF}} - \rho_{B,1}^{\mathsf{TF}} - ... - \rho_{B,M}^{\mathsf{TF}}) \le CZ^{\frac{5}{3}(1-\delta)}. \tag{26.8.82}$$

(ii) For $Z^{\frac{20}{21}(1-\delta)} \le B \le Z$ *the distances satisfy* (26.8.60) *with*

$$\varepsilon = B^{-\frac{1}{4}+\frac{1}{7}\delta_1} Z^{\frac{5}{21}-\frac{1}{7}\delta_1} \tag{26.8.83}$$

and

$$\mathsf{D}(\rho_B^{\mathsf{TF}} - \rho_{B,1}^{\mathsf{TF}} - ... - \rho_{B,M}^{\mathsf{TF}};\, \rho_B^{\mathsf{TF}} - \rho_{B,1}^{\mathsf{TF}} - ... - \rho_{B,M}^{\mathsf{TF}}) \le CB^{\delta_1} Z^{\frac{5}{3}-\delta_1}. \tag{26.8.84}$$

Since $\mathcal{Q} \ge \epsilon a^{-1}(Z-N)^2$ we arrive to

Proposition 26.8.13. *Let condition* (26.2.28) *be fulfilled. Then*

(i) If $(Z-N) \ge C(Qa)^{\frac{1}{2}}$ *where* Q *is our remainder estimate in the ground state energy, then in free nuclei model minimal distance between nuclei must be at least* a*.*

(ii) In particular, if $(Z-N) \ge C_1(Q\bar{r})^{\frac{1}{2}}$ *then in free nuclei model minimal distance between nuclei must be at least* $C_0\bar{r}$ *and molecule consists of separate atoms.*

Problem 26.8.14. Can we using the fact that as $B \ge Z$ overlapping of $B(\mathsf{y}_m, \bar{r}_m)$ and $B(\mathsf{y}_{m'}, \bar{r}_{m'})$ is relatively small, improve Q to $\max(Z^{\frac{5}{3}};\, B^{\frac{4}{5}}Z^{\frac{3}{5}})$ that is without factor L^4?

Estimate of Excessive Positive Charge

To estimate excessive positive charge when molecules can still exist in free nuclei model we apply arguments of section 5 of B. Ruskai and J. P. Solovej [1]. In view of Proposition 26.8.13 for $(Z-N)$ violating (26.8.88) below it is sufficient to assume that (25.6.48) is satisfied:

$$a := \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge C_0\bar{r}. \tag{26.8.85}$$

i.e. in Thomas-Fermi theory ρ^{TF} is supported in the separate "atoms". Indeed, it is the case if $C_0Z^{\frac{20}{21}} \le B \le Z^3$ but also it is so if $B \le C_0Z^{\frac{20}{21}}$ and $(Z-N)_+ \ge C_1Z^{\frac{5}{7}}$ since then $\bar{r} \asymp (Z-N)_+^{-\frac{1}{3}}$.

Like in Subsection 25.6.3 consider a-admissible functions $\theta_m(x)$, supported in $B(\mathsf{y}_m, \frac{1}{3}a)$ as $m = 1, \dots, M$ and in $\{|x-\mathsf{y}_{m'}| \ge \frac{1}{4}a \ \ \forall m' = 1, \dots, M\}$ as $m = 0$, and satisfying (25.6.49):

$$\theta_0^2 + \dots + \theta_M^2 = 1. \tag{26.8.86}$$

Then for the ground state Ψ equalities (25.6.50)–(25.6.51) hold with *cluster Hamiltonians* H_{α_m} with the *cluster Hamiltonians* H_{α_m}, involving only potential of m-th nucleus (no nucleus potential as $m = 0$) and only electrons belonging to α_m and with the *intercluster Hamiltonian* J_α defined by (25.6.53) and satisfying (25.6.54) with J_{ml} defined by (25.6.55)–(25.6.56). Furthermore, equality (25.6.57) holds.

Applying Proposition 25.5.1 and estimate (25.4.56) (replacing first θ_k with $k = 1, \dots, M$ by $\tilde{\theta}_k$, supported in $B(\mathsf{y}_k, c\bar{r})$, and estimating the resulting error), we conclude that equalities (25.6.58)–(25.6.59) hold with $Y = Q^{\frac{1}{2}}\bar{r}^{\frac{1}{2}}$ since $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) \le CQ$.

The last term in (25.6.57) is estimated by Proposition 25.5.1 and estimate (26.8.73) instead of (25.4.56) and the same replacement trick; so we arrive to (25.6.62) and repeating the same trick we get that it is larger than (25.6.63).

Again let us note that the absolute value of the last term in the right-hand expression of (25.6.57) does not exceed $Ca^{-2}Y$ due to (25.6.59). Now stability condition yields that (26.6.61) must be fulfilled.

Then we conclude that (25.6.65) and (25.6.67) and then (25.6.68) hold with J_{ml} defined by (25.6.55) and (25.6.55) provided (25.6.66) is fulfilled as $|x-\mathsf{y}_m| \ge C\bar{r}$.

This inequality, (26.8.85) and Proposition 25.6.5 (which is the special case of Theorem 26.2.13) yield that

$$Z - N \le C\bar{Y} + C(Z\bar{Y})^{\frac{1}{2}}, \qquad \bar{Y} = (\bar{r}\bar{Q})^{\frac{1}{2}}. \tag{26.8.87}$$

Now we need to consider twocases:

(a) $B \le Z^{\frac{4}{3}}$; then $\bar{r} = \min\big((Z-N)^{-\frac{1}{3}};\, B^{-\frac{1}{4}}\big)$ and we conclude that

$$(Z-N) \le C \min\big(Z^{\frac{11}{13}};\, B^{-\frac{1}{16}} Z^{\frac{11}{12}}\big)$$

with a threshold at $B = Z^{\frac{44}{39}}$.

(b) $Z^{\frac{4}{3}} \le B \le Z^3$; then plugging $\bar{r} = B^{-\frac{2}{5}} Z^{\frac{1}{5}}$ and $\bar{Q} = B^{\frac{4}{5}} Z^{\frac{3}{5}}$ we arrive to $Z - N \le C B^{\frac{1}{10}} Z^{\frac{7}{10}}$.

Then we arrive to the following

Theorem 26.8.15 [47]**.** *Let condition* (26.2.28) *be fulfilled.*

Then in the framework of the free nuclei model with $M \ge 2$ the stable molecule does not exist unless

$$(Z-N) \le C_1 \begin{cases} Z^{\frac{11}{13}} & \text{if } B \le Z^{\frac{44}{39}}, \\ B^{-\frac{1}{16}} Z^{\frac{11}{12}} & \text{if } Z^{\frac{44}{39}} \le B \le Z^{\frac{4}{3}}, \\ B^{\frac{1}{10}} Z^{\frac{7}{10}} & \text{if } Z^{\frac{4}{3}} \le B \le Z^3. \end{cases} \tag{26.8.88}$$

26.A Appendices

26.A.1 Electrostatic Inequalities

There are two kinds of electrostatic inequalities: those which hold for any fermionic state Ψ and those which hold only for the ground-state (or near ground state) Ψ. Inequalities of the first kind do not depend on the quantum Hamiltonian and they are (25.2.1) repeated here:

$$\sum_{1\le j<k\le N} \int |x_j - x_k|^{-1} |\Psi(x_1, \dots, x_N)|^2 \, dx_1 \cdots dx_N \ge \frac{1}{2}\mathsf{D}(\rho_\Psi, \rho_\Psi) - C \int \rho_\Psi^{\frac{4}{3}}(x)\, dx \tag{26.A.1}$$

[47] Cf. Theorem 25.6.3.

and (26.A.5) below.

Inequalities of the second kind are for $B = 0$:

$$\sum_{1\le j<k\le N}\int |x_j - x_k|^{-1}|\Psi(x_1,\dots,x_N)|^2\,dx_1\cdots dx_N \ge \frac{1}{2}\mathsf{D}(\rho_\Psi,\rho_\Psi) - CZ^{\frac{5}{3}}, \tag{26.A.2}$$

and more precise one (26.A.26) below.

For $\vec{B} = \mathsf{const}$ there is an inequality established in E. Lieb, J. P. Solovej and J. Yngvason [3] (p. 122):

Theorem 26.A.1. *Let $\vec{B} = \mathsf{const}$. Then for the ground state Ψ*

$$\int \rho_\Psi^{\frac{4}{3}}\,dx \le CZ^{\frac{5}{6}}N^{\frac{1}{2}}(Z+N)^{\frac{1}{3}}\bigl(1+BZ^{-\frac{4}{3}}\bigr)^{\frac{2}{5}}; \tag{26.A.3}$$

In particular, for $c^{-1}N \le Z \le cN$ the right-hand expression does not exceed

$$CZ^{\frac{5}{3}}\bigl(1+BZ^{-\frac{4}{3}}\bigr)^{\frac{2}{5}} \asymp C\begin{cases} Z^{\frac{5}{3}} & \text{if } B \le Z^{\frac{4}{3}},\\ Z^{\frac{17}{15}}B^{\frac{2}{5}} & \text{if } B \ge Z^{\frac{4}{3}}.\end{cases} \tag{26.A.4}$$

We want to establish inequality, similar to (25.A.2), but in the magnetic case. We will use for this the following

Theorem 26.A.2 [48]**.** *Fix $0 < \delta \le 1/6$. Then for any density matrix F and any density $\rho_0(x) \ge 0$ the following inequality holds*

$$\sum_{1\le j<k\le N}\int |x_j - x_k|^{-1}|\Psi(x_1,\dots,x_N)|^2\,dx_1\cdots dx_N \ge \mathsf{D}(\rho_0,\rho_\gamma) - \frac{1}{2}\mathsf{D}(\rho_0,\rho_0) - \frac{1}{2}\sum_{\varsigma,\varsigma'}\iint |F(x,\varsigma;y,\varsigma')|^2|x-y|^{-1}\,dxdy - C\|\rho\|_{5/3}^{5/6}\cdot\|\rho\|_1^{1/6+\delta}\cdot\upsilon(\gamma,F)^{1/3-\delta}, \tag{26.A.5}$$

where $\rho = \rho_0 + \rho_F + \rho_\Psi$, $\upsilon(\gamma,F) \coloneqq \mathsf{Tr}(\gamma(I-F))$ and

$$\gamma = \gamma_\Psi(x,y) = N\int \Psi(x,x_2,\dots,x_N)\Psi^\dagger(y,x_2,\dots,x_N)\,dx_2\cdots x_N \tag{26.A.6}$$

is two-point one particle density.

[48] Lemma 6 of G. Graf and J. P. Solovej [1].

Recall that $\|.\|_p$ denotes $\mathscr{L}^p$-norm.

There is a connection between (26.A.1) and (26.A.5): if we set $F = 0$, we get $\varsigma = \|\rho\|_1$ and the last term in (26.A.5) becomes $\|\rho\|_{5/3}^{5/6} \cdot \|\rho\|_1^{1/2}$. On the other hand, $\|\rho\|_{4/3}^{4/3} \le \|\rho\|_{5/3}^{5/6} \cdot \|\rho\|_1^{1/2}$, so (26.A.5) is slightly deteriorated (26.A.1) with $F = 0$ but with "free" ρ_0.

Let us follow G. Graf and J. P. Solovej [1] further albeit in the case of magnetic field. Let us estimate first $\|\rho\|_{5/3}$.

If $\rho = \rho^{\mathsf{TF}}$ direct calculations show that for $N \asymp Z$

$$\int \rho^{\mathsf{TF}}\,dx = \min(Z, N), \tag{26.A.7}$$

$$\int {\rho^{\mathsf{TF}}}^{\frac{4}{3}}\,dx \asymp C{\rho^*}^{\frac{4}{3}} {r^*}^3 = CZ^{\frac{5}{3}}\bigl(1 + BZ^{-\frac{4}{3}}\bigr)^{\frac{2}{5}}, \tag{26.A.8}$$

$$\int {\rho^{\mathsf{TF}}}^{\frac{5}{3}}\,dx \asymp C{\rho^*}^{\frac{5}{3}} {r^*}^3 = CZ^{\frac{7}{3}}\bigl(1 + BZ^{-\frac{4}{3}}\bigr)^{\frac{4}{5}} \tag{26.A.9}$$

with

$$r^* = \min(Z^{-\frac{1}{3}}, B^{-\frac{2}{5}}Z^{\frac{1}{5}}) \asymp Z^{-\frac{1}{3}}\bigl(1 + BZ^{-\frac{4}{3}}\bigr)^{-\frac{2}{5}}, \tag{26.A.10}$$

$$\rho^* = \min(N, Z){r^*}^{-3} \tag{26.A.11}$$

and we use $\|\rho\|_{5/3}^{5/6} \cdot \|\rho\|_1^{1/2} \asymp \|\rho\|_{4/3}^{4/3}$ for $\rho = \rho^{\mathsf{TF}}$.

If $\rho = \rho_\Psi$ we use magnetic Lieb–Thirring inequality (see f.e. Theorem 2.2 in L. Erdös [1])

$$\mathsf{Tr}(H_{A,W}^-) \ge -C\int P_B(W)\,dx \tag{26.A.12}$$

and therefore

$$\begin{aligned}\langle \mathsf{H}\Psi, \Psi\rangle \ge \mathsf{Tr}((H_{A,W})^-) + \int W\rho_\Psi\,dx \\ - \int V\rho_\Psi\,dx + \frac{1}{2}\mathsf{D}(\rho_\Psi, \rho_\Psi) - C\|\rho_\Psi\|_{4/3}^{4/3},\end{aligned} \tag{26.A.13}$$

which due to (26.A.12) is greater than

$$\begin{aligned}\int \bigl(-CP_B(W) + W\rho_\Psi\bigr)\,dx - \\ \int V\rho_\Psi\,dx + \frac{1}{2}\mathsf{D}(\rho_\Psi, \rho_\Psi) - C\|\rho_\Psi\|_{4/3}^{4/3} \ge \\ 3\epsilon_0\int \tau_B(\rho_\Psi)\,dx - \int V\rho_\Psi\,dx + \frac{1}{2}\mathsf{D}(\rho_\Psi, \rho_\Psi) - C\|\rho_\Psi\|_{4/3}^{4/3}\end{aligned} \tag{26.A.14}$$

where we picked up $W : CP'_B(W) = \rho_\Psi$.

The first two terms in the right-hand expression are estimated from below by

$$2\epsilon_0 \int \tau_B(\rho_\Psi)\,dx - C\int P_B(V)\phi\,dx - C\int V\rho_\Psi(1-\phi)\,dx,$$

where $\mathsf{supp}(\phi) \subset \{x\colon \ell(x) \le 2r^*\}$ and $\mathsf{supp}(1-\phi) \subset \{x\colon \ell(x) \ge r^*\}$.

One can see easily that the absolute value of the second term is $\asymp Z^{\frac{7}{3}}\bigl(1+BZ^{-\frac{4}{3}}\bigr)^{\frac{2}{5}}$, while the absolute value of the third term does not exceed $CZ\int V(1-\phi)\,dx \asymp CZ^2 r^{*\,-1}$ which does not exceed the same expression $Z^{\frac{7}{3}}\bigl(1+BZ^{-\frac{4}{3}}\bigr)^{\frac{2}{5}}$. Therefore

$$\langle \mathsf{H}\Psi,\Psi\rangle + C_1 Z^{\frac{7}{3}}\bigl(1+BZ^{-\frac{4}{3}}\bigr)^{\frac{2}{5}} \ge 2\epsilon_0\int \tau_B(\rho_\Psi)\,dx + \frac{1}{2}\mathsf{D}(\rho_\Psi,\rho_\Psi) - C\|\rho_\Psi\|_{4/3}^{4/3}. \tag{26.A.15}$$

Note that $\|\rho_\Psi\|_{4/3}^{4/3}$, calculated over domain $\{x\colon \rho_\Psi(x) \ge B^{\frac{4}{3}}\}$, does not exceed $C\|\rho_\Psi\|_{5/3}^{5/6}\cdot\|\rho\|_1^{\frac{1}{2}}$ with norms, calculated over the same domain, which does not exceed $CT^{\frac{1}{2}}Z^{\frac{1}{2}}$ with $T = \int \tau_B(\rho_\Psi)\,dx$.

Meanwhile, $\|\rho_\Psi\|_{4/3}^{4/3}$, calculated over domain $\{x\colon \rho_\Psi(x) \le B^{\frac{4}{3}}\}$, does not exceed $C\|\rho\|_3^{\frac{1}{2}}\cdot\|\rho\|_1^{\frac{5}{6}}$ with norms, calculated over the same domain, which does not exceed $CZ^{\frac{1}{2}}B^{\frac{1}{3}}T^{\frac{1}{6}}$.

Therefore

$$\|\rho_\Psi\|_{4/3}^{4/3} \le CT^{\frac{1}{2}}Z^{\frac{1}{2}} + CZ^{\frac{5}{6}}B^{\frac{1}{3}}T^{\frac{1}{6}} \tag{26.A.16}$$

and therefore (26.A.15) implies that if

$$\langle \mathsf{H}\Psi,\Psi\rangle \le C_1 Z^{\frac{7}{3}}\bigl(1+BZ^{-\frac{4}{3}}\bigr)^{\frac{2}{5}}, \tag{26.A.17}$$

then

$$T = \int \tau_B(\rho_\Psi)\,dx \le C_2 Z^{\frac{7}{3}}\bigl(1+BZ^{-\frac{4}{3}}\bigr)^{\frac{2}{5}} \tag{26.A.18}$$

and

$$\|\rho_\Psi\|_{4/3}^{4/3} \le CZ^{5/3}\bigl(1+BZ^{-\frac{4}{3}}\bigr)^{\frac{2}{5}}; \tag{26.A.19}$$

taking $F = 0$ we arrive to (26.A.3) if $N \asymp Z$.

However, on our preparatory step we need to estimate also $\|\rho_\Psi\|_{5/3}^{5/3}$ and due to (26.A.18) we need to consider only norms over $\{x\colon \rho_\Psi(x) \ge B^{\frac{4}{3}}\}$. Then $\|\rho_\Psi\|_{5/3}^{5/3} \le C\|\rho_\Psi\|_{4/3}^{16/15} \cdot \|\rho_\Psi\|_3^{3/5}$ and plugging the same estimates (26.A.19), (26.A.19) we conclude that

$$\|\rho_\Psi\|_{5/3}^{5/3} \le CZ^{7/3}\bigl(1 + BZ^{-\frac{4}{3}}\bigr)^{\frac{4}{5}}. \tag{26.A.20}$$

Now we assume that $B \le Z^3$, take $F = e(x,y,\nu)$, where $e(x,y,\nu)$ is the Schwartz kernel of spectral projector for potential W, approximating W^{TF} and $\nu \le 0$ is a chemical potential. One can prove easily that $\|\rho_F\|_{5/3}^{5/3}$ satisfies the same estimate and we need to estimate $\mathsf{Tr}\bigl(\gamma_\Psi(I - E(\mu))\bigr)$.

Consider

$$\begin{aligned} N\langle H_{A,W(x_1)}\Psi,\Psi\rangle - \mathsf{Tr}(HE(\nu)) - \alpha\,\mathsf{Tr}\bigl(\gamma_\Psi(I-E(\nu))\bigr) &\\ \ge \int_{\beta<0} \beta\, d_\beta\, \mathsf{Tr}\, E(\beta) - \int_{\beta\le\nu} (\beta - \nu + \alpha)\, d_\beta\, \mathsf{Tr}\, E(\beta) &\\ = -\int_{\nu-\alpha<\beta<\nu} (\beta-\nu+\alpha) d_\beta E(\beta) &\\ = -\alpha E(\nu) + \int_{\nu-\alpha<\beta<\nu} E(\beta)\, d\beta. & \end{aligned} \tag{26.A.21}$$

We can replace $E(\beta)$ by $\int P'(W+\beta)\,dx$ with a resulting error $O(Z\alpha\hbar^\delta)$, $\hbar \coloneqq BZ^{-3}$. Then the right-hand expression becomes

$$\begin{aligned} -L(\alpha) \coloneqq \int \Bigl(-\alpha P_B'(W+\nu) + \int_0^\alpha P_B'(W+\nu-\beta)\,d\beta\Bigr)\,dx = &\\ -\int_0^\alpha (\alpha-\beta)\Bigl(\int P_B''(W+\nu-\beta)\,dx\Bigr)\,d\beta. & \end{aligned} \tag{26.A.22}$$

Therefore

$$\begin{aligned} \alpha\Bigl(\mathsf{Tr}\bigl(\gamma_\Psi(I-E(\mu))\bigr) - CZ\hbar^\delta\Bigr) \le &\\ \underbrace{N\langle H_{A,W(x_1)}\Psi,\Psi\rangle - \mathsf{Tr}(HE(\nu))}\, + L(\alpha). & \end{aligned} \tag{26.A.23}$$

Note that adding to the selected terms $-\frac{1}{2}\mathsf{D}(\rho^{\mathsf{TF}},\rho^{\mathsf{TF}})$ we obtain exactly the snippet, occurring in the lower estimate of E_N, but in virtue of the upper

estimate it should not exceed $Q = CZ^{\frac{5}{3}}\big(1 + BZ^{-\frac{4}{3}}\big)^{\frac{2}{5}} \le CZ^{\frac{5}{3}} + Ch^2Z^{\frac{7}{3}}$, and therefore, plugging $\alpha = Z^{\frac{4}{3}}\hbar^{\delta}$, we conclude that

$$\mathsf{Tr}\big(\gamma_\Psi(I - E(\mu)\big) \le Z\hbar^{\delta} \tag{26.A.24}$$

provided we prove that

$$L(\alpha) \le Q \qquad \text{for } \ \alpha = Z^{\frac{4}{3}}\hbar^{\delta}. \tag{26.A.25}$$

Therefore modulo proof of (26.A.25) we arrive to the estimate (26.A.26) below:

Theorem 26.A.3. *Let $N \asymp Z$ and $B \le Z$. Then for the ground state energy*

$$\sum_{1\le j<k\le N} \int |x_j - x_k|^{-1} |\Psi(x_1, \dots, x_N)|^2 \, dx_1 \cdots dx_N \ge \tag{26.A.26}$$
$$\frac{1}{2}\mathsf{D}(\rho^{\mathsf{TF}}, \rho^{\mathsf{TF}}) + \mathsf{Dirac} - CZ^{\frac{5}{3}-\delta}(1 + B^{\delta})$$

To prove (26.A.25) we note that $0 \le P''_B(w) \asymp w^{\frac{1}{2}} + Bw^{-\frac{1}{2}}$. One can prove easily then that $L(\alpha) \le C\alpha^{\frac{7}{4}} + CB^{\frac{1}{4}}\alpha^{\frac{3}{2}}$, which obviously implies (26.A.25).

26.A.2 Very Strong Magnetic Field Case

Let us consider now case $Z^2 \le B \le Z^3$.

Proposition 26.A.4. *Consider the Schrödinger operator $H_{A,W}$ with a constant magnetic field of intensity B and potential W: $W \le Z|x|^{-1}$. Let $\phi(x) \coloneqq \phi_r(x)$ be r-admissible function. Then if $Z^2 \lesssim B \lesssim Z^3$ and $r \asymp Z^{-1}$*

$$|e(x, y, 0)| \le CZB \qquad \textit{in } \ B(0, r) \tag{26.A.27}$$

and

(26.A.28) *All eigenvalues are $\ge -CZ^2$.*

Proof. Without any loss of the generality one can assume that

$$H_{A,W} = D_3^2 + D_2^2 + (D_1 - Bx_2)^2 - W. \tag{26.A.29}$$

Consider $f \in \mathscr{L}^2$; then $\|E(\lambda)f\| \le \|f\|$ and then one can prove easily (26.A.28) and inequality

$$\|H_{A,0}E(\lambda)f\| \le (CZ^2 + \lambda_+)\|f\|. \tag{26.A.30}$$

Indeed, $\frac{1}{2}D_3^2 + CZ^2 \ge W$ in the operator sense.

Then (26.A.30) implies that in $B(0,r)\times B(y',r')$ with $r' = B^{-\frac{1}{2}}$

$$|P^\alpha E(\lambda)f| \le CZ^{\alpha_3}B^{\frac{1}{2}|\alpha'|} \qquad \forall \alpha : |\alpha| \le 2\ \forall \lambda \le Z^2$$

with $P = (D_1 - Bx_2, D_2, D_3)$ and therefore $\|E(\lambda)f\|_{\mathscr{C}} \le CZ^{\frac{1}{2}}B^{\frac{1}{2}}\|f\|$. Then $\|E(x,.,\lambda)\|_{\mathscr{L}^2_y}\| \le CZ^{\frac{1}{2}}B^{\frac{1}{2}}$.

Repeating the same arguments with respect to y we arrive to estimate (26.A.27). □

The following corollary follows immediately:

Corollary 26.A.5. *In the framework of Proposition 26.A.4 with $\phi \in \mathscr{L}^\infty(B(0,r))$, $\|\phi\|_{\mathscr{L}^\infty} \le 1$*

$$|\int \phi(x)e(x,x,0)\,dx| \le CZ^{-2}B, \tag{26.A.31}$$

$$\mathsf{D}\big(\phi(x)e(x,x,0), \phi(x)e(x,x,0)\big) \le CZ^{-3}B^2 \tag{26.A.32}$$

and

$$|\int_{-\infty}^0 \int \phi(x)e(x,x,\tau)\,d\tau dx| \le CB. \tag{26.A.33}$$

26.A.3 Riemann Sums and Integrals

If $f \in \mathscr{C}^\infty(\mathbb{R}^+)$ and fast decays at $+\infty$, then

$$f(0)h + \sum_{n\ge 1} 2f(2nh)h \sim \int_0^\infty f(t)\,dt + \sum_{m\ge 1}\kappa_m f^{(2m-1)}(0)h^{2m}, \tag{26.A.34}$$

$$\sum_{n\ge 0} 2f((2n+1)h)h \sim \int_0^\infty f(t)\,dt + \sum_{m\ge 1}\kappa'_m f^{(2m-1)}(0)h^{2m} \tag{26.A.35}$$

as $h \to +0$. The proofs of both formulae follow from the Taylor's decomposition and observation that the odd powers of h should disappear. Taking

$f(t) = e^{-tz/h}$ with $\operatorname{Re} z > 0$ we arrive to

$$1 - \frac{\cosh(z)}{\sinh(z)} z \sim \sum_{m\ge 1} \kappa_m z^{2m}, \tag{26.A.36}$$

$$1 - \frac{1}{\sinh(z)} z \sim \sum_{m\ge 1} \kappa'_m z^{2m} \tag{26.A.37}$$

for $|z| \ll 1$. In particular, $\kappa_1 = \frac{1}{3}$ and $\kappa'_1 = -\frac{1}{6}$.

26.A.4 Some Spectral Ffunction Estimates

Proposition 26.A.6. *For the Schrödinger operator with $A, W \in \mathscr{C}^\infty$ and for $\phi \in \mathscr{C}_0^\infty([-1,1])$ the following estimate holds for any s:*

$$|F(x,y)| \le C(\mu h + 1) h^{-3} \big(1 + h^{-1}|x-y|\big)^{-s} \tag{26.A.38}$$

where

$$F(x,y) := \int \phi(\lambda)\, d_\lambda e(x,y,\lambda). \tag{26.A.39}$$

Proof. Let $u(x,y,t) = \int e^{-ih^{-1}t\lambda}\, d_\lambda e(x,y,\lambda)$ be the Schwartz's kernel of $e^{-ih^{-1}Ht}$.

Let us fix y. Note first that $\mathscr{L}^2$-norm[49)] of $\phi(hD_t)\chi(t)\omega(x)u(x,y,t)$ is less than Ch^s for $\chi \in \mathscr{C}_0^\infty([-\epsilon,\epsilon])$ and $\omega \in \mathscr{C}^\infty$ supported in $\{x\colon |x-y| \ge \epsilon_1\}$ (with $\epsilon_1 = C\epsilon$) due to the finite speed of propagation of singularities.

We conclude then that $\mathscr{L}^2$-norm of $\phi(hD_t)\chi(t)\omega(x)u(x,y,t)$ does not exceed $C(\mu h+1)h^s$ for $\omega \in \mathscr{C}^\infty$ supported in $\{x\colon |x-y| \ge C\}$.

Then $\mathscr{L}^2$-norm of $\partial_t^l \nabla^\alpha \phi(hD_t)\chi(t)\omega(x)u$ does not exceed $C(\mu h+1)h^s$. Therefore due to imbedding inequality $\mathscr{L}^\infty$-norm of $\phi(hD_t)\chi(t)\omega(x)u$ also does not exceed $C(\mu h+1)h^s$. Setting $t=0$ and using this inequality and estimate $|F(x,y)| \le C(\mu h+1)h^{-3}$ (due to Chapter 7), we conclude that $|F(x,y)| \le C(\mu h+1)h^s$ for $|x-y| \ge \epsilon_0$.

Now let us consider general x with $|x-y| = r \ge Ch$. Then rescaling $(x-y) \mapsto (x-y)r^{-1}$ we need also to rescale $h \mapsto hr^{-1}$, $\mu \mapsto \mu r$ and rescaling the above inequality and keeping in mind that $F(x,y)$ is a density with respect to x, we conclude that $|F(x,y)| \le Ch^s r^{-3-s}$ which is equivalent to (26.A.38)–(26.A.39). □

[49)] With respect to x, t here and below.

26.A.5 Zhislin's Theorem for Constant Magnetic Field

We provide just a scheme to prove Zhislin's theorem in the case of the constant magnetic field. In this analysis $\underline{Z}$, $\underline{y}$, N and B are constant.

Proposition 26.A.7. *Let $\Psi = \Psi_N$ be the ground state with the energy $\mathsf{E}_N < \mathsf{E}_{N-1}$. Then*

(i) $\Psi \in \mathscr{C}^1$ and $\Psi = O(e^{-\epsilon|\underline{x}|})$ as $|\underline{x}| \to \infty$.

(ii) Let $N < Z$. Then $V_\Psi - V \in \mathscr{C}^2$ and $V_\Psi = (Z-N)|x|^{-1} + O(|x|^{-2})$, $\nabla V_\Psi = (Z-N)|x|^{-2} + O(|x|^{-3})$ as $|x| \to \infty$.

Proof. Obvious proof is left to the reader. □

Theorem 26.A.8 (Zhislin's theorem). $\mathsf{E}_{N+1} < \mathsf{E}_N$ *for $N < Z$.*

Proof. We can assume that $\mathsf{E}_N < 0$ and the ground state energy exists. Really, it is true for some $N < Z$ and if we prove that then automatically $\mathsf{E}_{N+1} < \mathsf{E}_N$, then it would be true for $(N+1)$ as well, so we may go by induction.

Consider $\Psi = \Psi_N(x_1, \dots, x_N)$ and also $\tilde{\Psi}_{N+1}$, which is an antisymmetrized $\Psi_N(x_1, \dots, x_N)u(x_{N+1})$ (cf. (26.8.21)):

$$\tilde{\Psi} = \tilde{\Psi}(x_1, \dots, x_{N+1}) = \Psi(x_1, \dots, x_N)u(x_{n+1}) - \sum_{1 \le j \le N} \Psi(x_1, \dots, x_{j-1}, x_{N+1}, x_{j+1}, \dots, x_N)u(x_j). \tag{26.A.40}$$

Then like in the estimate of the ionization energy (cf. (26.8.22)–(26.8.23)):

$$N^{-1}\mathsf{I}_{N+1}\|\tilde{\Psi}\|^2 \ge -\langle H_{V,x_{N+1}}\Psi u, \tilde{\Psi}\rangle - \langle \sum_{1 \le i \le N} |x_i - x_{N+1}|^{-1}\Psi u, \tilde{\Psi}\rangle \tag{26.A.41}$$

and

$$N^{-1}\|\tilde{\Psi}\|^2 = \|\Psi\|^2 \cdot \|u\|^2 - N\int \Psi(x_1, \dots, x_{N-1}, x)\Psi^\dagger(x_1, \dots, x_{N-1}, y)u(y)u^\dagger(x)\, dx_1 \cdots dx_{N-1}\, dxdy. \tag{26.A.42}$$

Now let us consider u supported in $\{x\colon \frac{1}{2}a \le |x| \le 3a\}$ with a to be chosen later. Then in virtue of Proposition 26.A.7(i) modulo $O(e^{-\epsilon_1 a})$ we can replace in the right-hand expressions $\tilde{\Psi}$ by $\Psi_N(x_1,\dots,x_N)u(x_{N+1})$ resulting in $-\langle H_W u, u\rangle$ and $\|u\|^2$ respectively with $W = V_\Psi$ defined in Proposition 26.A.7(ii).

Therefore all we need to prove this theorem is to be able to select u with $\|u\| \asymp 1$, supported in $\{x\colon a \le |x| \le 3a\}$ and with $\langle H_W u, u\rangle \le -\epsilon_0 a^{-1}$.

In virtue of Proposition 26.A.7(ii) $V_\Psi \ge \epsilon_0 a^{-1}$ in $\{x\colon a \le |x| \le 3a\}$ and therefore we can replace W by $\epsilon_0 a^{-1}$. Without any loss of the generality one can assume that $A = (Bx_2, 0, 0)$. Recall that for the linear vector-potential $\vec{A}$ operator $H_0 = ((i\nabla - A)\cdot\boldsymbol{\sigma})^2$ is a direct sum of $H_0^+ = (i\nabla - A)^2 + B$ and $H_0^- = (i\nabla - A)^2 - B$; so we can consider only the latter. Note that $H_0^- = (i\partial_1 - Bx_2)^2 - \partial_2^2 - \partial_3^2$ and $H_0^- v = 0$ with $v = \exp(-\frac{1}{2}B(x_2-a)^2 + iBax_1)$.

Then $u = v(x)\chi(r^{-1}(x-\bar{x}))$ with $\chi \in \mathscr{C}^\infty(B(0,1))$, $\chi = 1$ in $B(0,\frac{1}{2})$, $\bar{x} = (0, 2a, 0)$, $r = \frac{1}{3}a$ is a required function. □

Comments

We already mentioned papers E. H. Lieb, J. P. Solovej and J. Yngvason [1,3] where asymptotics of the ground state energy were derived in the cases $B \ll Z^3$ and $B \gg Z^3$ respectively. Intermediate case $B \sim Z^3$ was covered also in E. H. Lieb, J. P. Solovej and J. Yngvason [1]. Even without remainder estimates certain results concerning ionization energy and maximal possible positive and negative charges were also derived.

Remainder estimates in the case $B \ll Z^3$ were derived by V. Ivrii in [20,21]. Unfortunately there are gaps in the proofs of the second paper in the case of $M \ge 2$ and large $Z - N > 0$ which I was unable to fill.; so our results in this case are not as sharp as they supposed to be.

Important Remarks

Sections 26.7 and 26.8 were rewritten. The reason is that the printed version of this monograph contains crucial errors in the proof of Theorem 26.7.4 (see Theorem 26.7.3 here); errors 1 and 2 from the list below propagated from Section 25.6.

1. The first one occurred only in the case $M \ge 2$. It has been corrected.

2. The second one has not been corrected and we cannot prove the estimate of the excessive negative charge better than $O(Z^{\frac{5}{7}})$ even for the case $M = 1$.

3. The error in the proof of Theorem 26.8.15 has been fixed but this Theorem became much weaker.

4. The proof of Proposition 26.8.11 (Theorem 26.8.11 here) there was incomplete; it has been completed and now we have a way better estimate than proposed in Problem 26.8.14 there.

Chapter 27

The Case of Self-Generated Magnetic Field

27.1 Introduction

We are going to replace Schrödinger operator without magnetic field as in Chapter 25 or with a constant magnetic field as in Chapter 26 by Schrödinger operator

$$H = H_{A,V} = \big((D - A)\cdot\boldsymbol{\sigma}\big)^2 - V(x) \tag{27.1.1}$$

with unknown magnetic field A but then to add to the ground state energy of the atom (or molecule) the energy of magnetic field (see selected term in (27.1.2) thus arriving to

$$\mathsf{E}(A) = \inf \mathsf{Spec}(\mathsf{H}_{A,V}) + \underbrace{\alpha^{-1}\int |\nabla\times A|^2\,dx} \tag{27.1.2}$$

with N-particle quantum Hamiltonian $\mathsf{H}_{A,V}$ defined by (26.1.1) and a parameter $\alpha \in (0, \kappa^* Z^{-1}]$ with small constant $\kappa^* > 0$.

Then finally

$$\mathsf{E}^* = \inf_{A\in\mathscr{H}^1_0} \mathsf{E}(A) \tag{27.1.3}$$

defines a ground state energy with a *self-generated magnetic field*[1)].

[1)] This notion was introduced in series of papers L. Erdös, S. Fournais and J. P. Solovej [1,3,4]; see also L. Erdös and J. P. Solovej [1].

First of all we are lacking so far a semiclassical local theory and we are developing it in Section 27.2 where we consider one-particle quantum Hamiltonian

$$H = H_{A,V} = \big((hD - A)\cdot\boldsymbol{\sigma}\big)^2 - V(x) \tag{27.1.4}$$

but instead of $\inf \mathsf{Spec}(\mathsf{H}_{A,V})$ we consider $\mathsf{Tr}^-(H_{A,V})$ which as we already know is what replaces $\inf \mathsf{Spec}(\mathsf{H}_{A,V})$ if electrons do not interact (then if electrons interact we will need to replace V by W which includes a potential generated by the electron cloud and justify this by estimating an error).

We define the energy of the magnetic field as in (27.1.2) but with κ replaced by κh^{d-1} (here $d \ge 2$ is arbitrary) and we prove that for $d = 2, 3$ in this framework a self-generated magnetic field is weak and the asymptotics with the remainder $O(h^{2-d})$ (or even $o(h^{2-d})$ under standard assumption of the global nature) is exactly as for $\kappa = 0$ (i.e. with $A = 0$). In the latter case asymptotics includes the Schwinger correction term $\varkappa_2 h^{-1}$.

Then in Section 27.3 we consider operator with potential having Coulomb-type singularities and combining results and arguments of Sections 27.2 and 12.6 prove for $d = 3$ that

$$\mathsf{Tr}^-(H_{A,V}) = \mathsf{Weyl}_1 + 2S(\kappa)h^{-2} + O\big(\kappa|\log\kappa|^{\frac{1}{3}}h^{-\frac{4}{3}} + h^{-1}\big) \tag{27.1.5}$$

provided $\kappa < \kappa^*$ (which is a small constant) and there is just one singularity; when there are several singularities with a minimal distance $a \gg 1$ between them we prove that

$$\mathsf{Tr}^-(H_{A,V}) = \mathsf{Weyl}_1 + 2S(\kappa)h^{-2} + O\big(\kappa|\log\kappa|^{\frac{1}{3}}h^{-\frac{4}{3}} + h^{-1} + \kappa a^{-3}h^{-2}\big). \tag{27.1.6}$$

If $\kappa \ll h^{\frac{1}{3}}|\log h|^{-\frac{1}{3}}$ then under standard assumption about trajectories we can upgrade this asymptotics to even sharper with the remainder estimate $o(h^{-1})$ and with the Schwinger correction term.

Further, in Section 27.4 we apply these results to provide estimates from above and below for the total energy (27.1.3). As a byproduct we also estimate $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\ \rho_\Psi - \rho^{\mathsf{TF}})$ where Ψ is a ground state for a near-minimizer A.

This estimate enables us in Section 27.5 to derive upper estimates for the excessive negative charge, estimates or asymptotics for the ionization energy, and in the free nuclei model also for the minimal distance between nuclei and (in the case of molecule) for the excessive positive charge.

27.2 Local Semiclassical Trace Asymptotics

27.2.1 Toy-Model

Statement of the Pproblem

Let us consider operator (27.1.1) in $\mathbb{R}^d$ with $d = 3$ where A, V are real-valued functions and $V \in \mathscr{L}^{\frac{5}{2}} \cap \mathscr{L}^4$, $A \in \mathscr{H}^1_0$. Then this operator is self-adjoint. We are interested in $\mathsf{Tr}^-(H_{A,V})$ (the sum of all negative eigenvalues of this operator). Let

$$\mathsf{E}^* := \inf_{A\in\mathscr{H}^1_0(B(0,r))} \mathsf{E}(A), \tag{27.2.1}$$

$$\mathsf{E}(A) := \Bigl(\mathsf{Tr}^-\, H_{A,V} + \kappa^{-1}h^{-2}\int |\partial A|^2\, dx\Bigr) \tag{27.2.2}$$

with $\partial A = (\partial_i A_j)$ a matrix; here and below r is a parameter and constants do not depend on it.

The estimate from above is delivered by $A = 0$ and Weyl formula with an error $O(h^{-1})$ as $V \in \mathscr{C}^{2,1}$ [2)]

$$\mathsf{E}^* \le \mathsf{Weyl}_1 + O(h^{-1}); \tag{27.2.3}$$

where

$$\mathsf{Weyl}(\tau) = \frac{1}{3\pi^2}h^{-3}\int (V+\tau)_+^{\frac{3}{2}}\, dx, \tag{27.2.4}$$

and

$$\mathsf{Weyl}_1 = \int_{-\infty}^{0} \tau \mathsf{d}_\tau \mathsf{Weyl}(\tau) = -\frac{2}{15\pi^2}\int V_+^{\frac{5}{2}}\, dx. \tag{27.2.5}$$

Also for estimates $o(h^{-2})$ we need to include into Weyl_1 the corresponding boundary term. Now our goal is to provide an estimate from below

$$\mathsf{E}^* \ge \mathsf{Weyl}_1 - O(h^{-1}); \tag{27.2.6}$$

We will use also $\mathsf{Weyl}(x,\tau)$ and $\mathsf{Weyl}_1(x)$ defined the same way albeit without integration with respect to x.

[2)] Recall that this means that the second derivatives of V are continuous with the continuity modulus $O(|\log|x-y||^{-1})$, see Section 4.6. If there is a boundary it does not pose any problem provided it is in the classically forbidden region.

Preliminary Analysis

So, let us estimate $\mathsf{E}(A)$ from below. First we need the following really simple

Proposition 27.2.1. *Let $V \in \mathscr{L}^{\frac{5}{2}} \cap \mathscr{L}^4$. Then*

$$\mathsf{E}^* \geq -Ch^{-3} \tag{27.2.7}$$

and either

$$\frac{1}{\kappa h^2} \int |\partial A|^2 \, dx \leq Ch^{-3} \tag{27.2.8}$$

or $\mathsf{E}(A) \geq ch^{-3}$.

Proof. Using the Magnetic Lieb–Thirring inequality (5) of E. H. Lieb, M. Loss, M. and J. P. Solovej [1])

$$\int \operatorname{tr} e_1(x,x,\tau)\, dx \geq - Ch^{-3} \int V_+^{\frac{5}{2}}\, dx - Ch^2 \Big(h^{-2} \int |\partial A|^2\, dx\Big)^{\frac{3}{4}} \Big(h^{-8} \int V_+^4\, dx\Big)^{\frac{1}{4}}, \tag{27.2.9}$$

we conclude that for any $\delta > 0$

$$\mathsf{E}(A) \geq -Ch^{-3} - C\delta^3 h^{-3} + \big(\kappa^{-1}h^{-2} - \delta^{-1}h^{-1}\big) \int |\partial A|^2\, dx \tag{27.2.10}$$

which implies both assertions of this proposition. □

Proposition 27.2.2. *Let $V_+ \in \mathscr{L}^{\frac{5}{2}} \cap \mathscr{L}^4$, $\kappa \leq ch^{-1}$ and*

$$V \leq -C^{-1}(1+|x|)^{\delta} + C. \tag{27.2.11}$$

Then there exists a minimizer A.

Proof. Consider a minimizing sequence A_j. Without any loss of the generality one can assume that $A_j \to A_\infty$ weakly in $\mathscr{H}^1$ and in $\mathscr{L}^6$ and strongly in $\mathscr{L}^p_{\mathsf{loc}}$ with any $p < 6$ [3]. Then A_∞ is a minimizer.

Really, due to (27.2.8) and (7.2.11) negative spectra of $H_{A_j,V}$ are discrete and the number of negative eigenvalues is bounded by $N = N(h)$. Consider

[3] Otherwise we select a converging subsequence.

ordered eigenvalues $\lambda_{j,k}$ of $H_{A_j,V}$. Without any loss of the generality one can assume that $\lambda_{j,k}$ have limits $\lambda_{\infty,k} \le 0$ (we go to the subsequence if needed).

We claim that $\lambda_{\infty,k}$ are also eigenvalues and if $\lambda_{\infty,k} = ... = \lambda_{\infty,k+r-1}$ then it is eigenvalue of at least multiplicity r. Indeed, let $u_{j,k}$ be corresponding eigenfunctions, orthonormal in $\mathscr{L}^2$. Then in virtue of A_j being bounded in $\mathscr{L}^6$ and $V \in \mathscr{L}^4$ we can estimate

$$\|Du_{j,k}\| \le K\|u_{j,k}\|_6^{1-\sigma} \cdot \|u_{j,k}\|^{\sigma} \le K\|Du_{j,k}\|^{1-\sigma} \cdot \|u_{j,k}\|^{\sigma}$$

with $\sigma > 0$ which implies $\|Du_{j,k}\| \le K$. Also assumption (27.2.11) implies that $\|(1+|x|)^{\delta/2}u_{j,k}\|$ are bounded and therefore without any loss of the generality one can assume that $u_{j,k}$ converge strongly.

Then

$$\lim_{j\to\infty} \mathsf{Tr}^-(H_{A_j,V}) \ge \mathsf{Tr}^-(H_{A_\infty,V}), \tag{27.2.12}$$

$$\liminf_{j\to\infty} \int |\partial A_j|^2 \,dx \ge \int |\partial A_\infty|^2 \,dx \tag{27.2.13}$$

and therefore $\mathsf{E}(A_\infty) \le \mathsf{E}^*$. Then A_∞ is a minimizer and there are equalities in (27.2.12)–(27.2.13) and, in particular, there no negative eigenvalues of $H_{A_\infty,V}$ other than $\lambda_{\infty,k}$. □

Remark 27.2.3. We do not know if a minimizer is unique. Also we do not impose here any restrictions on r, K (which may depend on h) in (27.2.11) or $\kappa > 0$. From now on until the further notice let $A = A_h$ be a minimizer.

Proposition 27.2.4. *In the framework of Proposition 27.2.2 let A be a minimizer. Then*

$$\frac{2}{\kappa h^2}\Delta A_j(x) = \Phi_j := \tag{27.2.14}$$
$$-\mathsf{Re}\,\mathsf{tr}\Big[\sigma_j\Big((hD-A)_x \cdot \boldsymbol{\sigma} e(x,y,\tau) + e(x,y,\tau)\,{}^t(hD-A)_y \cdot \boldsymbol{\sigma}\Big)\Big]\Big|_{y=x}$$

where $A = (A_1, A_2, A_3)$, $\boldsymbol{\sigma} = (\sigma_1, \sigma_2, \sigma_3)$ and $e(x,y,\tau)$ is the Schwartz kernel of the spectral projector $\theta(-H)$ of $H = H_{A,V}$ and tr is a matrix trace.

Proof. Consider variation δA of A and variation of $\mathsf{Tr}^-(H) = \mathsf{Tr}(H^-)$ where $H^- = H\theta(-H)$ is a negative part of H. Note that the spectral projector of H is

$$\theta(\tau - H) = \frac{1}{2\pi i}\int_{-\infty}^{\tau} \mathsf{Res}_{\mathbb{R}}(\tau - H)^{-1} \tag{27.2.15}$$

and therefore

$$\delta \operatorname{Tr}\big(\theta(\tau - H)\big) = \frac{1}{2\pi i}\int_{-\infty}^{\tau} \operatorname{Res}_{\mathbb{R}} \operatorname{Tr}\big((\tau - H)^{-1}(\delta H)(\tau - H)^{-1}\big) =$$
$$\frac{1}{2\pi i}\int_{-\infty}^{\tau} \operatorname{Res}_{\mathbb{R}} \operatorname{Tr}\big((\delta H)(\tau - H)^{-2}\big) = -\partial_\tau \frac{1}{2\pi i}\int_{-\infty}^{\tau} \operatorname{Res}_{\mathbb{R}} \operatorname{Tr}\big((\delta H)(\tau - H)^{-1}\big) =$$
$$-\partial_\tau \operatorname{Tr}\big((\delta H)\theta(\tau - H)\big).$$

Plugging it into

$$\operatorname{Tr}^-(H) = \int_{-\infty}^{0} \tau d_\tau \operatorname{Tr}\big(\theta(\tau - H)\big) = -\int_{-\infty}^{0} \operatorname{Tr}\big(\theta(\tau - H)\, d\tau\big) \tag{27.2.16}$$

and integrating with respect to τ we arrive after simple calculations to

$$\delta \operatorname{Tr}^-(H - \tau) = \operatorname{Tr}\big((\delta H)\theta(\tau - H)\big) = \sum_j \int \Phi_j(x)\delta A_j(x)\, dx \tag{27.2.17}$$

where $\Phi(x)$ is the right-hand expression of (27.2.14). Therefore

$$\delta \mathsf{E}(A) = \sum_j \int \big(\Phi_j(x) - \frac{2}{\kappa h^2}\Delta A_j(x)\big)\delta A_j(x)\, dx \tag{27.2.18}$$

which implies (27.2.14). □

Proposition 27.2.5. *If for* $\kappa = \kappa^*$

$$\mathsf{E}^* \geq \mathsf{Weyl}_1 - CM \tag{27.2.19}$$

with $M \geq Ch^{-1}$ *then for* $\kappa \leq \kappa^*(1 - \epsilon_0)$

$$\frac{1}{\kappa h^2}\int |\partial A|^2\, dx \leq C_1 M. \tag{27.2.20}$$

Proof. Proof is obvious based also on the upper estimate $\mathsf{E}^* \leq \mathsf{Weyl}_1 + Ch^{-1}$. □

Estimates

Proposition 27.2.6. *Let estimate* (27.2.20) *be fulfilled and let*

$$\varsigma = \kappa M h \le c. \tag{27.2.21}$$

Then for $\tau \le c$

(i) Operator norm in $\mathscr{L}^2$ *of* $(hD)^k \theta(\tau - H)$ *does not exceed* C *for* $k = 0, 1, 2$.

(ii) Operator norm in $\mathscr{L}^2$ *of* $(hD)^k \big((hD - A)\cdot \sigma\big)\theta(\tau - H)$ *does not exceed* C *for* $k = 0, 1$.

Proof. (i) Let $u = \theta(\tau - H)f$. Then $\|u\| \le \|f\|$ and since

$$\|A\|_{\mathscr{L}^6} \le C\|\partial A\| \le C(\kappa M)^{\frac12} h \tag{27.2.22}$$

we conclude that

$$\begin{aligned}\|hDu\| \le \|(hD - A)u\| + \|Au\| \le \|(hD - A)u\| + C\|A\|_{\mathscr{L}^6}\cdot \|u\|_{\mathscr{L}^3} \le \\ \|(hD - A)u\| + C(\kappa M)^{\frac12} h \|u\|^{1/2}\cdot \|u\|^{1/2}_{\mathscr{L}^6} \le \\ \|(hD - A)u\| + C(\kappa M h)^{\frac12} \|u\|^{1/2}\cdot \|hDu\|^{1/2} \le \\ \|(hD - A)u\| + \frac{1}{2}\|hDu\| + C\kappa M h\|u\|;\end{aligned}$$

therefore due to (27.2.21)

$$\|hDu\| \le 2\|(hD - A)u\| + C\kappa M h\|u\|. \tag{27.2.23}$$

On the other hand, for $B = \nabla \times A$ and $\tau \le c$

$$\begin{aligned}\|(hD - A)u\|^2 \le C\|u\|^2 + (h|B|u, u) \le C\|u\|^2 + h\|B\|\cdot \|u\|^2_{\mathscr{L}^4} \le \\ C\|u\|^2 + C(\kappa M)^{\frac12} h^2 \|u\|\cdot \|u\|_{\mathscr{L}^6} \le C\|u\|^2 + C(\kappa M)^{\frac12} h\|u\|\cdot \|hDu\| \le \\ C(1 + \kappa M h^2 + \kappa^{\frac32} M^{\frac32} h^2)\|u\|^2 + \frac{1}{2}\|(hD - A)u\|^2\end{aligned}$$

and due to (27.2.23) we conclude that

$$\|(hD - A)u\| \le C\|u\| \quad \text{and} \quad \|hDu\| \le C(1 + \kappa M h)\|u\| \tag{27.2.24}$$

provided $\kappa M h^{1+\delta} \le c$ for sufficiently small $\delta > 0$. Therefore under assumption (27.2.21) for $k = 0, 1$ statement (i) is proven.

Further, since $(hD)^2 = (hD - A)^2 + A(hD - A) + AhD - h[D, A]$ we in the same way as before (and using (27.2.24)) conclude that

$$\|(hD)^2 u\| \le C\|u\|^2 + \frac{1}{4}\|hD(hD - A)u\| + \frac{1}{4}\|h^2 D^2 u\|$$

and therefore

$$\|h^2 D^2 u\| \le C\|u\|^2 + C\|AhDu\|$$

and repeating the same arguments we get $\|h^2 D^2 u\| \le C\|u\|$; so for $k = 2$ Statement (i) is also proven.

(ii) Statement (ii) is proven in the same way. □

Corollary 27.2.7. *Let* (27.2.20) *and* (27.2.21) *be fulfilled. Then for* $\tau \le c$

$$e(x, x, \tau) \le C h^{-3} \tag{27.2.25}$$

and

$$|((hD - A) \cdot \boldsymbol{\sigma}) e(x, y, \tau)|_{x=y}| \le C h^{-3}. \tag{27.2.26}$$

Proof. Let us prove that

(27.2.27) Operator norms from $\mathscr{L}^2$ to $\mathscr{C}$ of both operators $\theta(\tau - H)$ and $((hD - A) \cdot \boldsymbol{\sigma})\theta(\tau - H)$ do not exceed $Ch^{-\frac{3}{2}}$.

Indeed, Proposition 27.2.6 and embedding theorem imply that the operator norm of $\theta(\tau - H)$ from $\mathscr{L}^2$ to C does not exceed $Ch^{-\frac{3}{2}}$. Then due to interpolation operator norms of $\theta(\tau - H)$ from $\mathscr{L}^2$ to $\mathscr{L}^3$ and $\mathscr{L}^6$ do not exceed $Ch^{-\frac{1}{2}}$ and Ch^{-1} respectively.

Let $v = ((hD - A) \cdot \boldsymbol{\sigma})u$, $u = \theta(\tau - H)f$, $\|f\| = 1$. We know that $\mathscr{L}^6$-norms of Hu and u do not exceed Ch^{-1}, and then it is true for $((hD - A) \cdot \boldsymbol{\sigma})u\|$ as well.

Then $\|Au\|_{\mathscr{L}^3} \le C\|A\|_{\mathscr{L}^6}\|f\|_{\mathscr{L}^6} \le Ch^{-\frac{1}{2}}$ and $\|Du\|_{\mathscr{L}^3} \le Ch^{-\frac{3}{2}}$ which together with $\|u\|_{\mathscr{L}^2} \le C$ implies that $\|u\|_{\mathscr{L}^p} \le Ch^{-3/2+3/p}$ for $2 \le p < \infty$. Then $\|Au\|_{\mathscr{L}^4} \le C\|A\|_{\mathscr{L}^6}\|u\|_{\mathscr{L}^{12}} \le Ch^{-\frac{1}{4}}$ and $\|Du\|_{\mathscr{L}^4} \le Ch^{-\frac{5}{4}}$. Together with $\|u\| \le C$ it implies $\|u\| \le Ch^{-\frac{3}{2}}$. So, (27.2.27) has been proven.

Then the same estimate for holds adjoint operators which imply both statements of the corollary. □

Corollary 27.2.8. *Let* (27.2.20) *and* (27.2.21) *be fulfilled and* A *be a minimizer. Then*

$$\|\partial A\|_{\mathscr{C}^{1-\delta}} \le C\kappa h^{-1} \tag{27.2.28}$$

and

$$\|\partial A\|_{\mathscr{L}^\infty} \le C'_\delta h^{-\frac{4}{5}-\delta} \tag{27.2.29}$$

where $\mathscr{C}^\theta$ *is the scale of Hölder spaces and* $\delta > 0$ *is arbitrarily small.*

Proof. Really, due to (27.2.14) minimizer A satisfies $\|\Delta A\|_{\mathscr{L}^\infty} \le C\kappa h^{-1}$. Also we know that $\|\partial A\| \le C(\kappa M h^2)^{\frac12} \le Ch^{\frac12}$ due to (27.2.21). Then (27.2.28) holds due to the standard properties of the elliptic equations[4)].

Therefore if at some point y we have $|\partial A(y)| \gtrsim \mu$, it is true in its $\epsilon(\mu h\kappa^{-1})^{1-\delta}$-vicinity (provided $\mu \le \kappa h^{-1}$) and then

$$\|\partial A\|^2 \gtrsim \mu^2(\mu h\kappa^{-1})^{3(1-\delta)}$$

and we conclude that

$$\mu^2(\mu h\kappa^{-1})^{3(1-\delta)} \le C\kappa h^2 M \iff \mu^{5-3\delta} \le C\kappa^{4-3\delta}h^{-1+3\delta}M$$

and one can see easily that (27.2.29) holds due to (27.2.21) and assumption $h^{-1} \le M \lesssim h^{-3}$.

On the other hand, if $\mu \ge \kappa h^{-1}$ then we need to take ϵ-vicinity and then $\mu^2 \le C\kappa M h^2 \le Ch^{\frac12}$ where we used (27.2.21) again. Therefore (27.2.29) has been proven. □

Remark 27.2.9. (i) It is not clear if it is possible to generalize this theory to arbitrary $d \ge 2$ with the magnetic field energy given by

$$\frac{1}{\kappa h^{d-1}} \int \left(|\partial A|^2 - |\nabla \cdot A|^2\right) dx. \tag{27.2.30}$$

Surely one should use generalized Pauli matrices σ_j in the definition of the operator: for $d = 2$ one can prove that $\mathsf{E}(A)$ is bounded from below and a minimizer exists; for $d = 4$ one can prove that $\mathsf{E}(A)$ is bounded from below if $\kappa \le \epsilon_0 h$; especially problematic is the case $d \ge 5$ since then $A \in \mathscr{H}^1$ does not guarantee enough regularity.

(ii) Therefore while arguments of Subsection 27.2.2 below remain valid for $d \ge 4$, so far they remain conditional (if a minimizer exists and satisfies some crude estimates).

[4)] Actually we can slightly improve this statement.

27.2.2 Microlocal Analysis Unleashed

Sharp Estimates

Now we can unleash the full power of microlocal analysis but we need to extend it to our framework. It follows by induction from (27.2.28)–(27.2.29) and the arguments we used to derive these estimates that

$$\|\partial A\|_{\mathscr{C}^{n-\delta}} \le C_n \kappa h^{-1-n} \qquad \forall n \in \mathbb{Z}^+, \tag{27.2.31}$$

so A is "smooth" in $\varepsilon = h$ scale while for rough microlocal analysis as in Section 2.3 one needs at least $\varepsilon = Ch|\log h|$. We consider in this section arbitrary $d \ge 2$; see however Remark 27.2.9.

Proposition 27.2.10. *For a commutator of a pseudodifferential operator with a smooth symbol and $\mathscr{C}^{\theta+1}$-function $A(x)$ a usual commutator formula holds modulo $O(h^{\theta+1}\|\partial A\|_\theta)$ for any non-integer $\theta > 0$ where*

$$\|f\|_\theta := \begin{cases} \displaystyle\sum_{\alpha:|\alpha|=\theta} \sup_x |\partial^\alpha f(x)| & \theta \in \mathbb{Z}^+, \\ \displaystyle\sum_{\alpha:|\alpha|=\lfloor\theta\rfloor} \sup_{x\neq y} |x-y|^{\lfloor\theta\rfloor-\theta}\cdot|\partial^\alpha f(x)-\partial^\alpha f(y)| & \theta \notin \mathbb{Z}^+. \end{cases} \tag{27.2.32}$$

Proof. Easy proof is left to the reader. □

Proposition 27.2.11. *Assume that*

$$\|\partial V\|_{\mathscr{C}(B(0,2))} \le C_0 \tag{27.2.33}$$

and

$$\mu := \|\partial A\|_{\mathscr{C}(B(0,2))} \le C_0. \tag{27.2.34}$$

Let $U(x,y,t)$ be the Schwartz kernel of $e^{ih^{-1}tH_{A,V}}$. Then for $T \asymp 1$

(i) Estimate

$$\|F_{t\to h^{-1}\tau}\chi_T(t)(hD_x)^\alpha(hD_y)^\beta\psi_1(x)\psi_2(y)U\| \le Ch^s \tag{27.2.35}$$

holds for all $\alpha : |\alpha| \le 2$, $\beta : |\beta| \le 2$, s and all $\psi_1, \psi_2 \in \mathscr{C}_0^\infty(B(0,1))$, such that $\operatorname{dist}(\operatorname{supp}(\psi_1), \operatorname{supp}(\psi_2)) \ge C_0 T$ and $\tau \le c_0$; here $\|.\|$ means an operator norm from $\mathscr{L}^2$ to $\mathscr{L}^2$.

(ii) Estimate

$$\|F_{t\to h^{-1}\tau}\chi_T(t)(hD_x)^\alpha(hD_y)^\beta\varphi_1(hD_x)\varphi_2(hD_y)U\| \le Ch^s + Ch^\theta\big(\|\!|A|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big) \tag{27.2.36}$$

holds for all $\alpha : |\alpha| \le 2$, $\beta : |\beta| \le 2$, s *and all* $\varphi_1, \varphi_2 \in \mathscr{C}_0^\infty$, *such that* $\mathsf{dist}(\mathsf{supp}(\varphi_1), \mathsf{supp}(\varphi_2)) \ge C_0T$, *and* $\tau \le c_0$.

(iii) If also in $B(0,2)$

$$\epsilon_0 \le |V| \le c \tag{27.2.37}$$

then for a small constant $T = \epsilon$ *estimate*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)(hD_x)^\alpha(hD_y)^\beta U\| \le Ch^s + Ch^\theta\big(\|\!|A|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big) \tag{27.2.38}$$

holds for all $\alpha : |\alpha| \le 2$, $\beta : |\beta| \le 2$, s *and all* $\psi_1, \psi_2 \in \mathscr{C}_0^\infty(B(0,1))$, *such that* $\mathsf{diam}(\mathsf{supp}(\psi_1) \cup \mathsf{supp}(\psi_2)) \le \epsilon_0 T$ *and* $|\tau| \le \epsilon$.

Proof. Let $u = e^{ith^{-1}H}f$ with arbitrary $f \in \mathscr{L}^2$.

(i) Statement (i) is easily proven by the same arguments as in the proof of Theorem 2.1.2: we consider just usual function $\phi(x)$ and operators of multiplication like $\chi(\phi(x))$ so there are no "bad" commutators due to non-smoothness of A or V.

(ii) Statement (ii) is also proven by the same arguments; however in this case $\phi = \phi(x,\xi)$ so we need to involve "bad" commutators but their contributions are bounded by

$$C\|Q_1u\| \cdot \Big(h^{1+\theta}\big(\|\!|A|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big)\|u\| + h^{1+\delta}\|Q'u\|\Big)$$

in the right-hand expression while the left-hand expression is $\epsilon h\|Q_1u\|^2$ where Q, Q_1, and Q' are operators with symbols $\chi(\phi(x,\xi))$, $\chi_1(\phi(x,\xi))$, and $\chi_1(\phi(x,\xi)-\eta)$ respectively, $\eta > 0$ is an arbitrarily small constant (so the latter symbol has a bit larger support than the former one), $\delta > 0$ is a small exponent, $\chi_1(t) = (-\chi'(t))^{\frac12}$, and f.e. $\chi(t) = e^{-|t|^{-1}}$ for $t < 0$, $\chi(t) = 0$ for $t \ge 0$.

Therefore we conclude that

$$\|Qu\| \le Ch^{\theta}\big(\|\!|A|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big)\|u\| + Ch^{\delta}\|Q'u\|$$

and similarly we can estimate $\|Q'u\|$ with $\|Q''u\|$ in the right-hand expression etc and thus we conclude that

$$\|Qu\| \le Ch^{\theta}\big(\|\!|A|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big)\|u\| + Ch^{s}\|u\|$$

which is what we need.

(iii) Statement (iii) is easily proven by the same arguments as in the proof of Theorem 2.1.2: we consider just usual function $\phi(x)$ and operators of multiplication like $\chi(\phi(x))$ so there are no "bad" commutators due to non-smoothness of A or V. However we need to consider a contribution of u which is not confined to the small vicinity of (y,η) and we need Statement (ii) for this so the last term in the right-hand expression of (27.2.38) is inherited.

We leave easy details to the reader. □

Remark 27.2.12. In Proposition 27.2.11

(i) Statement (i) means the finite propagation speed with respect to x.

(ii) Statement (ii) means the finite propagation speed with respect to ξ and the last term in the right-hand expression of (27.2.36) is due to the non-smoothness of A and V.

(iii) Statement (iii) means that under assumption (27.2.37) there actually is a propagation with respect to x.

(iv) So far we have not assumed that V is very smooth function; we actually do not need it at all: it is sufficient to assume that ∂V is very smooth in the microscale $\varepsilon = h^{1-\delta}$; one can actually invoke more delicate arguments of the proof of Theorem 2.3.1 and deal with microscale $\varepsilon = Ch|\log h|$.

Therefore in the framework of Proposition 27.2.11(iii) estimate

$$|F_{t\to h^{-1}\tau}\chi_T(t)\big((hD_x)^{\alpha}(hD_y)^{\beta}U(x,y,t)\big)\big|_{x=y}| \le Ch^{1-d+s}T^{-s} + CT^2h^{-d+\theta}\big(\|\!|A|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big) \tag{27.2.39}$$

holds for all $\alpha : |\alpha| \le 2$, $\beta : |\beta| \le 2$, s for $T = \epsilon$ and $|\tau| \le \epsilon$ where as usual $\chi \in \mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1])$, $\chi_T(t) = \chi(t/T)$.

Let us consider $T \in (Ch, \epsilon)$; then we apply the standard rescaling $t \mapsto tT^{-1}$, $x \mapsto xT^{-1}$, $h \mapsto hT^{-1}$ and assumptions (27.2.33), (27.2.34) are replaced by weaker assumptions

$$T\|\partial V\|_{\mathscr{C}(B(x,1))} \le C_0 \tag{27.2.33}'$$

and

$$T\|\partial A\|_{\mathscr{C}(B(x,1))} \le C_0. \tag{27.2.34}'$$

Further, $\|\!|A|\!\|_{\theta+1}$ and $\|\!|V|\!\|_{\theta+1}$ acquire factor $T^{\theta+1}$.

Furthermore, since $U(x,y,t)$ is a density with respect to y we need to add factor T^{-d} to the right-hand expression and due to $F_{t\to h^{-1}\tau}$ we need to add another factor T and after these substitution and multiplications we arrive to

Proposition 27.2.13. *Let $h \le T \le \epsilon$ and assumptions* (27.2.33)′, (27.2.34)′ *and* (27.2.37) *be fulfilled. Then estimate* (27.2.39) *holds.*

Next we apply our standard arguments:

Proposition 27.2.14. *In the framework of Proposition 27.2.13 let $\bar\chi \in \mathscr{C}_0^\infty([-1,1])$. Then the following estimates hold:*

$$|F_{t\to h^{-1}\tau}\bigl[\bar\chi_T(t)\bigl((hD_x)^\alpha (hD_y)^\beta U(x,y,t)\bigr)\bigr]\big|_{x=y}| \le Ch^{1-d} + CT^2h^{-d+\theta}\bigl(\|\!|A|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\bigr) \tag{27.2.40}$$

and

$$|\bigl[\bigl((hD_x - A(x))\cdot\boldsymbol{\sigma}\bigr)^\alpha \bigl((hD_y - A(y))\cdot\boldsymbol{\sigma}\bigr)^\beta e(x,y,t)\bigr]\big|_{x=y} - \mathsf{Weyl}_{\alpha,\beta}(x)| \le Ch^{1-d}\bigl(1+\|\partial A\|_{\mathscr{C}(B(x,1))}+\|\partial V\|_{\mathscr{C}(B(x,1))}\bigr) + Ch^{-d+\frac12(\theta+1)}\bigl(\|\!|A|\!\|_{\theta+1}+\|\!|V|\!\|_{\theta+1}\bigr)^{\frac12} \tag{27.2.41}$$

where

$$\mathsf{Weyl}_{\alpha,\beta}(x) := \mathsf{const}\, h^{-d}\int_{\{H(x,\xi)\le\tau\}} \bigl((\xi - A(x))\cdot\boldsymbol{\sigma}\bigr)^{\alpha+\beta}\, d\xi \tag{27.2.42}$$

is the corresponding Weyl expression and

$$H(x,\xi) = \big((\xi - A(x))\cdot\sigma\big)^2 - V(x); \tag{27.2.43}$$

in particular $\mathsf{Weyl}_{\alpha,\beta}(x) = 0$ *for* $|\alpha| + |\beta| = 1$.

Proof. Obviously, the summation of (27.2.39) over $Ch \le |t| \le T$ and a trivial estimate by Ch^{1-d} of the contribution of the interval $|t| \le Ch$ implies (27.2.40).

Then the standard Tauberian arguments imply that the left-hand expression of (27.2.41) does not exceed the right-hand expression of (27.2.40), divided by T, i.e.

$$CT^{-1}h^{1-d} + CTh^{-d+\theta}\big(\|\!|A|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big).$$

Optimizing with respect to $T \le \epsilon$, such that $(27.2.33)'$, $(27.2.34)'$ hold, we pick up $T = T^*$ with

$$T^* = \epsilon \min\Big(1,\ \big(\|\partial A\|_{\mathscr{C}(B(x,1))} + \|\partial V\|_{\mathscr{C}(B(x,1))}\big)^{-1},\ h^{-\frac{1}{2}(\theta-1)}\big(\|\!|A|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big)^{-\frac{1}{2}}\Big). \tag{27.2.44}$$

Meanwhile the Tauberian formula and (27.2.39) imply that the contribution of the interval $\{t : |t| \asymp T\}$ with $h \le T \le T^*$ to the Tauberian expression does not exceed the right-hand expression of (27.2.39) divided by T, i.e.

$$Ch^{1-d+s}T^{-s-1} + CTh^{-d+\theta}\|\partial A\|_{\mathscr{C}^\theta};$$

summation over $T_* := h^{1-\delta} \le T \le T^*$ results in the right-hand expression of (27.2.41).

So, we need to calculate only the contribution of $\{t : |t| \le T_*\}$ but one can see easily that modulo indicated error it coincides with $\mathsf{Weyl}_{\alpha,\beta}$. □

Remark 27.2.15. For $d \ge 3$ one can skip assumption (27.2.37).

Indeed, we can apply the standard rescaling technique: $x \mapsto x\ell^{-1}$, $h \mapsto \hbar = h\ell^{-\frac{3}{2}}$, $A \mapsto A\ell^{-\frac{1}{2}}$, $V \mapsto V\ell^{-1}$ with $\ell = \max(\epsilon|V|\nu^{-1},\ h^{\frac{2}{3}}\nu^{-\frac{1}{3}})$, $\nu = (1 + |\partial V|_{\mathscr{C}})$; see Section 5.2.

Application

Let us apply developed technique to estimate a minimizer.

Proposition 27.2.16. *Let $\kappa \le c$ and let A be a minimizer. Let*

$$\mu := \|\partial A\|_{\mathscr{C}} \le Ch^{-1+\delta}. \tag{27.2.45}$$

For $d = 2$ let assumption (27.2.37) *be also fulfilled. Then for $\theta \in (1,2)$ estimate*

$$\|\partial A\|_{\mathscr{C}^{\theta-1}} + h^{\theta-1}\|\partial A\|_{\mathscr{C}^{\theta}} \le C\kappa\big(1 + \|V\|_{\mathscr{C}^1} + h^{\frac{1}{2}(\theta-1)}\|V\|^{\frac{1}{2}}_{\mathscr{C}^{\theta+1}}\big) + C\|\partial A\|' \tag{27.2.46}$$

holds with

$$\|\partial A\|' := \sup_y \|\partial A\|_{\mathscr{L}^2(B(y,1))}. \tag{27.2.47}$$

Proof. Consider expression for ΔA. According to equation (27.2.14) and Proposition 27.2.14 $(|\Delta A| + |h\partial\Delta A|)$ does not exceed the right-hand expression of (27.2.41) multiplied by $C\kappa h^{d-1}$ i.e.

$$\|\Delta A\|_{\mathscr{C}} + \|h\partial\Delta A\|_{\mathscr{C}} \le C\kappa\Big(1 + |\partial A|_{\mathscr{C}} + |\partial V|_{\mathscr{C}} + h^{\frac{1}{2}(\theta-1)}\|\partial A\|^{\frac{1}{2}}_{\mathscr{C}^{\theta}} + h^{\frac{1}{2}(\theta-1)}\|\partial V\|^{\frac{1}{2}}_{\mathscr{C}^{\theta}}\Big), \tag{27.2.48}$$

where we replaced $\|\!|A|\!\|_{\theta+1}$ and $\|\!|V|\!\|_{\theta+1}$ by larger $\|\partial A\|_{\mathscr{C}^{\theta}}$ and $\|\partial V\|_{\mathscr{C}^{\theta}}$ respectively.

Then the regularity theory for elliptic equations implies that

(27.2.49) For any $\theta' \in (1,2)$ $h^{\theta'-1}\|\partial A\|_{\mathscr{C}^{\theta'}}$ does not exceed this expression (27.2.48) plus $C\|\partial A\|'$.

Observe that that $\|\partial A\|_{\mathscr{C}}$ does not exceed $(\epsilon\|\partial A\|_{\mathscr{C}^{\theta}} + C'_{\epsilon}\|\partial A\|')$ with arbitrarily small constant $\epsilon > 0$ and therefore

$$h^{\theta-1}\|\partial A\|_{\mathscr{C}^{\theta}} + \epsilon^{-1}\|\partial A\|_{\mathscr{C}} \tag{27.2.50}$$

does not exceed expression (27.2.48) plus $C'_{\epsilon}\|\partial A\|'$ where we used (27.2.49) for $\theta' = \theta$.

Comparing (27.2.50) and (27.2.48) we conclude that for $\kappa \le c$ and sufficiently small constant $\epsilon > 0$ we can eliminate in the derived inequality both contributions of ∂A to (27.2.48) thus we arrive to (27.2.46). □

Having this strong estimate to A allows us to prove

Theorem 27.2.17. *Let $\kappa \le c$, (27.2.45) be fulfilled, and let $d \ge 3$. Assume that*

$$\|V\|_{\mathscr{C}^{\theta+1}} \le c \tag{27.2.51}$$

with $\theta \in (1,2)$. Then

$$\mathsf{E}^* = \mathsf{Weyl}_1 + O(h^{2-d}) \tag{27.2.52}$$

and a minimizer A satisfies

$$\|\partial A\| \le C\kappa^{\frac12} h^{\frac12} \tag{27.2.53}$$

and

$$\|\partial A\|_{\mathscr{C}^{\theta-1}} + h^{\theta-1}\|\partial A\|_{\mathscr{C}^{\theta}} \le C\kappa^{\frac12} h^{\frac12} + C\kappa. \tag{27.2.54}$$

Proof. (a) In virtue of (27.2.40) the Tauberian error when calculating $\mathsf{Tr}(H^-_{A,V})$ does not exceed the right-hand expression of (27.2.40) multiplied by CT^{-2} i.e.

$$Ch^{1-d}T^{-2} + Ch^{-d+\theta}\bigl(\|\!|A|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\bigr). \tag{27.2.55}$$

Assumption (27.2.51) allows us to simplify this expression and take $T \asymp (1+\mu)^{-1}$; applying estimate (27.2.46) we conclude that the Tauberian error does not exceed

$$C(1+\mu)^2 h^{2-d} + C(\kappa + \|\partial A\|')h^{2-d}. \tag{27.2.56}$$

We claim that

(27.2.57) Weyl error[5)] when calculating $\mathsf{Tr}(H^-_{A,V})$ also does not exceed (27.2.56).

Then

$$\begin{aligned}(27.2.58)\quad \mathsf{E}(A) \ge{}& \\ &\mathsf{Weyl}_1 - C(1+\mu)^2h^{2-d} - C(\kappa + \|\partial A\|')h^{2-d} + \kappa^{-1}h^{1-d}\|\partial A\|^2 \ge \\ &\mathsf{Weyl}_1 - Ch^{2-d} + \frac{1}{2\kappa}h^{1-d}\|\partial A\|^2\end{aligned}$$

[5)] I.e. error when we replace Tauberian expression by Weyl expression.

because $\mu \le C\|\partial A\|' + 1$ due to (27.2.46) and assumption (27.2.51). This implies an estimate of E^* from below and combining with the estimate $\mathsf{E}^* \le \mathsf{E}^*(0) = \mathsf{Weyl}_1 + Ch^{2-d}$ from above we arrive to (27.2.52) and (27.2.53) and then to (27.2.54) due to (27.2.46) and assumption (27.2.51).

(b) To prove (27.2.57) let us plug A_ε instead of A into $e_1(x,x,0)$. Then in virtue of the rough microlocal analysis the contribution to Weyl error of the interval $\{t : T_* \le |t| \le \epsilon\}$ with $T_* = h^{1-\delta}$ would be negligible and the contribution of the interval $\{t : |t| \le T_*\}$ would be $\mathsf{Weyl}_1 + O(h^{2-d})$.

(c) Now let us calculate an error which we made plugging A_ε instead of A into $e_1(x,x,0)$. Obviously it does not exceed $Ch^{-d}\|A - A_\varepsilon\|_{\mathscr{C}}$ and since $\|A - A_\varepsilon\|_{\mathscr{C}} \le C\varepsilon^{\theta+1}\|\partial A\|_{\mathscr{C}^\theta}$ this error does not exceed $Ch^{\theta+1-d-4\delta}\|\partial A\|_{\mathscr{C}^\theta}$, which is marginally worse than what we are looking for.

However it is good enough to recover a weaker version of (27.2.52) and (27.2.53) with an extra factor $h^{-\delta_1}$ in their right-hand expressions. Then (27.2.46) implies a bit weaker version of (27.2.54) and in particular that its left-hand expression does not exceed C.

Knowing this, let us consider the two term approximation. With the above knowledge one can prove easily that the error in two term approximation does not exceed $Ch^{3-d-\delta'}$ with $\delta' = 100\delta$.

Then the second term in the Tauberian expression is

$$\int \big((H_{A,V} - H_{A_\varepsilon,V})e^{\mathsf{T}}_{(\varepsilon)}(x,y,0)\big)\big|_{y=x}\,dx, \tag{27.2.59}$$

where subscript $_{(\varepsilon)}$ means that we plugged A_ε instead of A and superscript $^{\mathsf{T}}$ means that we consider Tauberian expression with $T = T^* = \epsilon$. But then the contribution of the interval $\{t : T_* \le |t| \le T^*\}$ is also negligible and modulo $Ch^{\theta+2-d-4\delta}\|\partial A\|_{\mathscr{C}^\theta}$ we get a Weyl expression. However

$$(H_{A,V} - H_{A_\varepsilon,V}) = -2(\xi - A_\varepsilon)\cdot(A - A_\varepsilon) + |A - A_\varepsilon|^2. \tag{27.2.60}$$

Observe that the first term in the right-hand expression kills the Weyl expression since an integrand is odd with respect to $(\xi - A_\varepsilon)$ while the second term as one can see easily makes it smaller than $Ch^{3-d-\delta'}$. Therefore (27.2.57) has been proven. □

Remark 27.2.18. (i) For $d = 2$ we cannot drop assumption (27.2.37) at this stage we did it for $d \ge 3$. However results of the next section allow us to cure this problem using the partition-and-rescaling technique.

(ii) Actually for $V \in \mathscr{C}^{2,1}$ we have an estimate

$$|\partial A(x) - \partial A(y)| \le C\kappa|x-y|(|\log|x-y|| + 1) + C\mu. \tag{27.2.61}$$

Combining with (27.2.53) we conclude that

$$\|\partial A\|_{\mathscr{C}} \le C\kappa^{(d+1)/(d+2)}|\log h|^{d/(d+2)}h^{1/(d+2)}. \tag{27.2.62}$$

(iii) If (27.2.51) holds for $(h\partial)^m V$ with $m \in \mathbb{Z}^+$ then (27.2.53) and (27.2.53) also hold for $(h\partial)^m A$ instead of A; further, if $(h\partial)^m V \in \mathscr{C}^{2,1}$ then (27.2.61) and (27.2.62) also hold for $(h\partial)^m A$ instead of A.

Classical Dynamics and Sharper Estimates

Now we want to improve the remainder estimate $O(h^{2-d})$ to $o(h^{2-d})$. Sure, we need to impose condition to the classical dynamical system and since $|\partial A| = O(h^\delta)$ with $\delta > 0$ due to (27.2.62), it should be dynamical system associated with the Hamiltonian flow generated by $H_{0,V}$:

(27.2.63) The set of periodic points of the dynamical system associated with Hamiltonian flow generated by $H_{0,V}$ has measure 0 on the energy level 0.

Recall that on the energy level $\{(x,\xi) : H_{0,V}(x,\xi) = \tau\}$ a natural density $d\mu_\tau = dxd\xi : dH|_{H=\tau}$ is defined.

The problem is we do not have a quantum propagation theory for $H_{A,V}$ as A is not a "rough" function (i.e. smooth in microscale ε). However it is a rather regular function, almost $\mathscr{C}^2$, and $(A - A_\varepsilon)$ is rather small: $|A - A_\varepsilon| \le \eta := Ch^{2-3\delta}$ and $|\partial(A - A_\varepsilon)| \le Ch^{1-3\delta}$ and therefore we can apply a method of successive approximations with the unperturbed operator $H_{A_\varepsilon,V}$ as long as $\eta T/h \le h^\sigma$ i.e. as $T \le h^{1-4\delta}$. Here we, however, have no use for such large T and consider $T = O(h^{-\delta})$.

Consider

$$F_{t\to h^{-1}\tau}\chi_T(t)U(x,y,t), \tag{27.2.64}$$

and consider terms of successive approximations. Then if we forget about microhyperbolicity arguments the first term will be $O(h^{-d}T)$, the second term $O(h^{-1-d}\eta T^2) = O(h^{1-d-\delta'})$ and the error term $O(h^{-2-d}\eta^2 T^3) = O(h^{2-d-\delta''})$.

Therefore since our goal is $O(h^{1-d})$ we need to consider the first two terms only. The first term is the same expression (27.2.64) with U replaced by $U_{(\varepsilon)}$.

Consider the second term, it corresponds to $U'_{(\varepsilon)}(x,y,t)$ which is the Schwartz kernel of operator

$$\mathsf{U}'_{(\varepsilon)} := ih^{-1}\int_0^t e^{i(t-t')h^{-1}H_{A_\varepsilon,V}}\big(H_{A,V}-H_{A_\varepsilon,V}\big)e^{it'h^{-1}H_{A_\varepsilon,V}}\,dt' \tag{27.2.65}$$

and then

$$\mathsf{Tr}\big(\mathsf{U}'_{(\varepsilon)}\psi\big) = ih^{-1}\,\mathsf{Tr}\Big(\big(H_{A,V}-H_{A_\varepsilon,V}\big)e^{ih^{-1}tH_{A_\varepsilon,V}}\psi^1(t)\Big) \tag{27.2.66}$$

where

$$\psi^1(t) := \int_0^t e^{ih^{-1}t'H_{A_\varepsilon,V}}\psi e^{-ih^{-1}t'H_{A_\varepsilon,V}}\,dt'$$

is h-pseudodifferential operator with a rough symbol and $\psi^1(t)\sim t$.

Really, one can prove easily studying first the Hamiltonian flow equation and then the transport equations that $\psi_t := e^{ih^{-1}tH_{A_\varepsilon,V}}\psi e^{-ih^{-1}tH_{A_\varepsilon,V}}$ is a h-pseudodifferential operator with a rough symbol and its corresponding norm is bounded.

Note that

$$ih^{-1}F_{t\to h^{-1}\tau}e^{ih^{-1}tH_{A_\varepsilon,V}}\psi^1(t) = (2\pi)\int\big(F_{t\to h^{-1}\tau'}e^{ih^{-1}tH_{A_\varepsilon,V}}\big)\hat f(h^{-1}(\tau-\tau'))\,d\tau'$$

with $\hat f = F_{t\to\tau}f_t$, $f_t = \chi_T(t)\psi^1(t)$ and therefore (27.2.65)–(27.2.66) imply that

$$|F_{t\to h^{-1}\tau}\chi_T(t)\,\mathsf{Tr}\,\mathsf{U}'_{(\varepsilon)}\psi| \le C\eta T^2h^{-d} \tag{27.2.67}$$

where in comparison with the trivial estimate we gained the factor h.

We can plug here $T'\in(T_*,T)$ instead of T and, taking summation by T' from $T_*=\epsilon$ to T, we conclude that estimate (27.2.67) also holds for $\chi_T(t)$ replaced by $\big(\bar\chi_T(t)-\bar\chi_{T_*}(t)\big)$ (provided $\bar\chi=1$ on $(-\frac12,\frac12)$) and since $\eta T^2\le h^{1+\delta}$ for $T\le h^{-\delta}$ we see that the right-hand expression (27.2.67) does not exceed $Ch^{1-d+\delta}$.

On the other hand, our traditional methods imply that

$$|F_{t\to h^{-1}\tau}\chi_T(t)\,\mathsf{Tr}\big(e^{ith^{-1}H_{A_\varepsilon,V}}\psi\big)| \le Ch^{1-d}T\mu(\Pi_{T,\zeta})+C_{T,\zeta}h^{1-d+\delta} \tag{27.2.68}$$

where Π_T is the set of points on energy level 0, periodic with periods not exceeding T, $\Pi_{T,\zeta}$ is its ζ-vicinity, $\zeta>0$ is arbitrarily small; recall that for $d=2$ we assume that condition (27.2.37) is fulfilled.

Here again we can plug any $T' \in (T_*, T)$ instead of T and after summation with respect to T' we conclude that (27.2.68) also holds with $\chi_T(t)$ replaced by $\big(\bar\chi_T(t) - \bar\chi_{T_*}(t)\big)$.

Combining with estimate for $\big(e^{ith^{-1}H_{A_\varepsilon,V}} - e^{ith^{-1}H_{A_\varepsilon,V}}\big)$ we conclude that

$$|F_{t\to h^{-1}\tau}\big(\bar\chi_T(t) - \bar\chi_{T_*}(t)\big)\,\mathsf{Tr}\big(e^{it'h^{-1}H_{A,V}}\psi\big)| \le Ch^{1-d}\,T\mu(\Pi_{T,\zeta}) + C_{T,\zeta}h^{1-d+\delta}$$

and since

$$|F_{t\to h^{-1}\tau}\bar\chi_{T_*}(t)\,\mathsf{Tr}\big(e^{it'h^{-1}H_{A,V}}\psi\big)| \le Ch^{1-d}$$

we conclude that

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\,\mathsf{Tr}\big(e^{it'h^{-1}H_{A,V}}\psi\big)| \le Ch^{1-d} + Ch^{1-d}\,T\mu(\Pi_{T,\zeta}) + C_{T,\zeta}h^{1-d+\delta}. \tag{27.2.69}$$

Then the Tauberian error does not exceed the right-hand expression of (27.2.69) multiplied by ChT^{-2} and it is less than $CT^{-1}h^{2-d}$.

Consider now the Tauberian expression and again apply the two-term approximation for $e^{ih^{-1}tH_{A,V}}$ considering $e^{ih^{-1}tH_{A_\varepsilon,V}}$ as an unperturbed operator; then the error will be less than $Ch^{2-d+\delta}$.

Consider the second term after taking trace; it is $O(h^{2-d-4\delta})$, so it is just slightly too large. Further, if $\psi = I$ one can calculate it easily and observe that it is $O(h^{2-d+\delta})$ provided $V \in \mathscr{C}^{2,1}$.

Finally, the first term is what we get for $e^{ih^{-1}tH_{A_\varepsilon,V}}$ and in virtue of rough microlocal analysis the contribution of the interval $\{t\colon T_* \le |t| \le T\}$ does not exceed $Ch^{2-d}\mu(\Pi_{T,\zeta}) + C_{T,\zeta}h^{2-d+\delta}$ and the contribution of the interval $\{t\colon |t| \le T_*\}$ is $\mathsf{Weyl}_1 + O(h^{2-d+\delta})$.

Then we arrive to

Theorem 27.2.19. *Let $\kappa \le c$, (27.2.45) and (27.2.51) be fulfilled. Furthermore, let condition (27.2.63) be fulfilled*[6]*. Then*

$$\mathsf{E}^* = \mathsf{Weyl}_1^* + o(h^{2-d}) \tag{27.2.70}$$

where

$$\mathsf{Weyl}_1^* = \mathsf{Weyl}_1 + \varkappa h^{2-d}\int V_+^{\frac{d}{2}}\Delta V\,dx \tag{27.2.71}$$

calculated in the standard way for $H_{0,V}$ and a minimizer A satisfies similarly improved versions of (27.2.53) and (27.2.54).

[6] I.e. $\mu_0(\Pi_\infty) = 0$.

Remark 27.2.20. (i) Recall that for $d = 2$ so far we assume (27.2.37). However we need it only to estimate ∂A. Indeed, even in the case of very degenerate potential V the "magnetic" correction will be small since $|\partial A|$ is small.

(ii) Under stronger assumptions to the Hamiltonian flow one can recover better estimates like $O(h^{2-d}|\log h|^{-2})$ or even $O(h^{2+\delta-d})$ (like in Subsubsection 4.5.4.3 *Sharper Remainder Estimates*).

(iii) We leave to the reader to calculate the numerical constants $\varkappa_*$ here and in (27.2.76) below, $\varkappa = \varkappa_1 - \frac{2}{d}\varkappa_2$.

(iv) However, even if $\psi \neq I$ we can observe that it is sufficient to consider only principal terms and then the second term in approximations is also $O(h^{2-d+\delta})$ provided $V \in \mathscr{C}^{2,1}$ as long as principal symbol of $\psi(x)$ is even with respect to ξ, in particular, if $\psi = \psi(x)$.

27.2.3 Local Theory

Localization and Estimate from above

The results of the previous Subsection 27.2.2 have two critical shortcomings: first, they impose the excessive initial requirement (27.2.21) to κ as we need to start from $M \le ch^{-3}$; second, they are not local. However, curing the second shortcoming, we make the way to addressing the first one as well, using the partition and rescaling technique.

We can localize $\mathsf{Tr}^-(H) = \mathsf{Tr}(H^-)$, which is the first term in $\mathsf{E}(A)$, either in our traditional way as $\mathsf{Tr}(H^-\psi^2)$ or in the way favored by some mathematical physicists[7]: namely, we take $\mathsf{Tr}^-(\psi H\psi)$ where in both cases $\psi \in \mathscr{C}_0^\infty(B(0,\frac{1}{2}))$, $0 \le \psi \le 1$ and some other conditions will be imposed to it later. Observe that

$$\mathsf{Tr}^-(\psi H\psi) \ge \mathsf{Tr}(\psi H^-\psi) = \int e_1(x,x,0)\psi^2(x)\,dx. \tag{27.2.72}$$

Really, let us decompose operator $H = H\theta(-H) + H(1-\theta(-H))$, where $\theta(\tau - H)$ is a spectral projector of H, and therefore in the operator sense $H \ge H^- := H\theta(-H)$ and $\psi H\psi \ge \psi H^-\psi$, and therefore all negative eigenvalues

[7] See f. e. L. Erdös, S. Fournais. and J. P. Solovej [4].

of $\psi H\psi$ are greater than or equal to eigenvalues of the negative operator $\psi H^{-}\psi$, and then

$$\mathsf{Tr}^{-}(\psi H\psi) \ge \mathsf{Tr}(\psi H^{-}\psi) = \mathsf{Tr}\Big(\int_{-\infty}^{0} \tau\, d_{\tau}\theta(\tau - H)\psi^2\Big), \tag{27.2.73}$$

which is exactly the right-hand expression of (27.2.72).

Remark 27.2.21. Each approach has its own advantages.

(i) In particular, no need to localize A (see (ii)) and the fact that Proposition 27.2.5 obviously remains true are advantages of $\mathsf{Tr}^{-}(\psi H\psi)$-localization.

(ii) Further, sinces $\mathsf{Tr}^{-}(\psi H\psi)$ does not depend on A outside of $B(0, \frac{3}{4})$ we may assume that $A = 0$ outside of $B(0,1)$. Really, we can always subtract a constant from A without affecting traces and also cut-off A outside of $B(0,1)$ in a way such that $A' = A$ in $B(0, \frac{3}{4})$ and $\|\partial A'\| \le c\|\partial A\|_{B(0,1)}$; the price is to multiply κ by c^{-1}–as long as principal parts of asymptotics coincide.

(iii) On the other hand, additivity rather than sub-additivity of (27.2.88) and the trivial estimate from the above are advantages of $\mathsf{Tr}(\psi H^{-}\psi)$-localization; therefore it is more advantageous.

(iv) In the next Chapter 28 (in Section 28.2) we will use more $\mathsf{Tr}^{-}(\psi H\psi)$-localization for preliminary estimates from below and simplify many arguments of this Section. We apply these modifications and simplifications to this Section in the final version of the Book.

We will use both methods and here we provide an upper estimate for the larger expression $\mathsf{Tr}^{-}(\psi H\psi)$ and a lower estimate for the lesser expression $\mathsf{Tr}(\psi H^{-}\psi)$. Let us estimate from the above:

Proposition 27.2.22. *Assume that $V \in \mathscr{C}^{2,1}$, $d \ge 2$. Let $\ell(x)$ be a scaling function*[8] *and ψ be a function such that $|\partial^{\alpha}\psi| \le c\psi\ell^{-\sigma|\alpha|}$ for all $\alpha : |\alpha| \le 2$ and $|\psi| \le c\ell^{\sigma(1+\delta)}$ with $\sigma > 1$ and $\delta > 0$*[9].

Then, if $A = 0$,

$$\mathsf{Tr}^{-}(\psi H\psi) = \int \mathsf{Weyl}_1(x)\psi^2(x)\, dx + O(h^{2-d}) \tag{27.2.74}$$

[8] I.e. $\ell \ge 0$ and $|\partial\ell| \le \frac{1}{2}$.

[9] Such compactly supported functions obviously exist.

and under assumption (27.2.63)

$$\mathsf{Tr}^-(\psi H\psi) = \int \mathsf{Weyl}_1^*(x)\psi^2(x)\,dx + o(h^{2-d}) \tag{27.2.75}$$

with

$$\mathsf{Weyl}_1^*(x) = \mathsf{Weyl}_1(x) + \varkappa_1 h^{-1} V_+^{\frac{d}{2}}\Delta V + \varkappa_2 h^{-1} V_+^{\frac{d}{2}-1}|\nabla V|^2 \tag{27.2.76}$$

calculated in the standard way for $H_{0,V}$.

Proof. Let us consider $\tilde{H} = \psi H\psi$ as a Hamiltonian and let $\tilde{e}(x,y,\tau)$ be the Schwartz kernel of its spectral projector. Then

$$\mathsf{Tr}^-(\psi H\psi) = \int \tilde{e}_1(x,x,0)\,dx = \sum_j \int \tilde{e}_1(x,x,0)\psi_j^2\,dx, \tag{27.2.77}$$

where ψ_j^2 form a partition of unity in $\mathbb{R}^d$ and we need to calculate the right hand expression. The problem is that $\tilde{H}$ is not a usual Schrödinger operator because of the degenerating factor ψ on each side.

Consider first an $\epsilon\ell$-admissible partition of unity in $B(0,1)$. Let us consider γ-scale in such element where $\gamma = \epsilon\ell^\sigma$ and we will use 1-scale in ξ. Then after rescaling $x \mapsto x\gamma^{-1}$ the semiclassical parameter rescales $h \mapsto h_{\mathsf{new}} = h\gamma^{-1}$ and the contribution of each γ-subelement to a semiclassical remainder does not exceed $C\psi^2(h/\gamma)^{2-d}$ with $\psi \le \gamma^{1+\delta}$, having the same magnitude over element as long as $\gamma \ge 2h$. Then the contribution of ℓ-element to a semiclassical error does not exceed $C\psi^2(h/\gamma)^{2-d}\times \ell^d\gamma^{2-d} \asymp Ch^{2-d}\psi^2\gamma^{-2}\ell^d \le Ch^{2-d}\ell^{d+2\delta}$.

Note that expression (27.2.77) only increases if we sum only with respect to elements where $\ell^\sigma \ge h$. Therefore we arrive to estimate

$$\mathsf{Tr}^-(\psi H\psi) \le \int \mathsf{Weyl}_1(x)\psi^2(x)\,dx + Ch^{2-d},$$

where integration is taken over a domain $\{x\colon \ell(x) \ge h^{1/\sigma}\}$. Note that we can extend this integral to $\mathbb{R}^d$: indeed, it will add negative term with absolute value not exceeding $Ch^{-d}\times h^{2+\delta}$ as $\psi \le h^{1+\delta}$ there and it is absorbed by the remainder estimate. □

Corollary 27.2.23. *In the framework of Proposition 27.2.22*

$$\mathsf{E}_\psi^* \coloneqq \inf_A \mathsf{E}_\psi(A) \le \int \mathsf{Weyl}_1(x)\psi^2(x)\,dx + Ch^{2-d} \tag{27.2.78}$$

and under assumption (27.2.63)

$$\mathsf{E}^*_\psi \le \int \mathsf{Weyl}_1(x)\psi^2(x)\,dx + Ch^{2-d} \tag{27.2.79}$$

with

$$\mathsf{E}_\psi(A) \coloneqq \mathsf{Tr}^-(\psi H\psi) + \frac{1}{\kappa h^2}\int |\partial A|^2\,dx. \tag{27.2.80}$$

Proof. Indeed, we just pick $A = 0$. □

Estimate from below

Now let us estimate *redefined* $\mathsf{E}_\psi(A)$,

$$\mathsf{E}_\psi(A) \coloneqq \int e_1(x,x,0)\psi^2(x)\,dx + \frac{1}{\kappa h^{d-1}}\int |\partial A|^2\,dx, \tag{27.2.81}$$

from below. However we need an equation for an optimizer and it would be easier for us to deal with even lesser expression involving τ-regularization. Let us rewrite the first term in the right-hand expression in the form

$$\int_{-\infty}^0 \bar\varphi(\tau/L)\tau\, d_\tau e(x,x,\tau) + \int_{-\infty}^0 (1-\bar\varphi(\tau/L))\tau\, d_\tau e(x,x,\tau) \ge \int_{-\infty}^L \Big(\bar\varphi(\tau/L)(\tau-L)\, d_\tau e(x,x,\tau) + (1-\bar\varphi(\tau/L))\tau\, d_\tau e(x,x,\tau)\Big),$$

where $\bar\varphi \in \mathscr{C}_0^\infty([-1,1])$ equals 1 in $[-\frac12,\frac12]$ and let us estimate from below

$$\mathsf{E}'_\psi(A) \coloneqq \int \Big(\int_{-\infty}^L \bar\varphi(\tau/L)(\tau-L) d_\tau e(x,x,\tau)(x) + (1-\bar\varphi(\tau/L))(\tau-L)\, d_\tau e(x,x,\tau)\Big)\psi^2(x)\,dx + \frac{1}{kh^{1-d}}\int |\partial A|^2\,dx. \tag{27.2.82}$$

Let us generalize Proposition 27.2.4:

Proposition 27.2.24. *Let A be a minimizer of $\mathsf{E}'_\psi(A)$. Then*

$$\frac{2}{\kappa h^{1-d}}\Delta A_j(x) = \Phi_j \coloneqq \mathsf{Re}\,\mathsf{tr}\Big[\sigma_j\Big((hD-A)_x\cdot\boldsymbol{\sigma}\mathcal{K}(x,y,\tau) + \mathcal{K}(x,y,\tau)\,{}^t(hD-A)_y\cdot\boldsymbol{\sigma}\Big)\Big]\Big|_{y=x} \tag{27.2.83}$$

with

$$\mathcal{K} = \int_{-\infty}^{L} \mathsf{SK}\Big[\bar{\varphi}(\tau/L)(\tau-L)\,\mathsf{Res}_{\mathbb{R}}(\tau-H)^{-1}\psi^2(\tau-H)^{-1}+ \\ (1-\bar{\varphi}(\tau/L))\tau(\tau-L)\,\mathsf{Res}_{\mathbb{R}}(\tau-H)^{-1}\psi^2(\tau-H)^{-1}\Big](x,y)\,d\tau,$$

where we use a temporary notation $\mathsf{SK}[B](x,y)$ *for the Schwartz kernel of operator* B*.*

Proof. Follows immediately from the proof of Proposition 27.2.4. □

Proposition 27.2.25. *Let* $d=3$ *and assumptions* (27.2.20) *and* (27.2.21) *be fulfilled. Then for* $\tau \le c$

(i) Operator norm in $\mathscr{L}^2$ *of* $(hD)^k(\tau-H)^{-1}$ *does not exceed* $C|\operatorname{Im}\tau|^{-1}$ *for* $k=0,1,2$*;.*

(ii) Operator norm in $\mathscr{L}^2$ *of* $(hD)^2\big((hD-A)\cdot\boldsymbol{\sigma}\big)(\tau-H)^{-1}$ *does not exceed* $C|\operatorname{Im}\tau|^{-1}$ *for* $k=0,1,2$*.*

Proof. Proof follows the same scheme as the proof of Proposition 27.2.6. □

Proposition 27.2.26. *Let* $d=3$ *and assumptions* (27.2.20) *and* (27.2.21) *be fulfilled. Then* $|\Phi(x)| \le Ch^{-3}$*.*

Proof. Let us estimate

$$|\int \tau\varphi(\tau/L)\,\mathsf{Res}_{\mathbb{R}}\,\mathsf{SK}\Big[Q(\tau-H)^{-1}\psi^2(\tau-H)^{-1}\Big](x,y)\,d\tau|, \tag{27.2.84}$$

where $L \le c$ and $\varphi \in \mathscr{C}_0^\infty([-1,1])$ and also a similar expression with a factor $(\tau-L)$ instead of τ; here either $Q=I$, or $Q=(hD_k-A_k)_x$ or $Q=(hD_k-A_k)_y$.

Proposition 27.2.25 implies that the Schwartz kernel of the integrand does not exceed $Ch^{-3}|\operatorname{Im}\tau|^{-2}$ and therefore expression (27.2.84) does not exceed $CL^2\times h^{-3}L^{-2}=Ch^{-3}$.

Then what comes out in Φ from the term with the factor $\bar{\phi}(\tau/h)$ does not exceed Ch^{-3}.

Then, representing $\big(1-\bar{\phi}(\tau/h)\big)$ as a sum of $\varphi(\tau/L)$ with $L=2^nh$ with $n=0,\dots,\lfloor|\log h|\rfloor+c$, we estimate the output of each term by Ch^{-3} and thus the whole sum by $Ch^{-3}|\log h|$.

To get rid of the logarithmic factor we use equality

$$(\tau - H)^{-1}\psi(\tau - H)^{-1} = - \partial(\tau - H)^{-1}\psi + (\tau - H)^{-2}[h, \psi](\tau - H)^{-1}; \tag{27.2.85}$$

if we plug only the second part, we recover a factor h/L, where h comes from the commutator and $1/L$ from the increased singularity; an extra operator factor in the commutator is not essential. Then summation over partition results in Ch^{-3}.

Plugging only the first part we do not use the above decomposition but the equality $\mathsf{Res}_{\mathbb{R}}(\tau - H)^{-1}\, d\tau = d_\tau \theta(\tau - H)$. □

Corollary 27.2.27. *Let $d = 3$, assumptions* (27.2.20) *and* (27.2.21) *be fulfilled and A be a minimizer. Then* (27.2.28) *and* (27.2.29) *hold.*

Proof. Proof follows the proof of Corollary 27.2.8. □

Now we can recover both Proposition 27.2.16 and our both main Theorems 27.2.17 and 27.2.19:

Theorem 27.2.28. *Let $d = 3$ and assumptions* (27.2.20) *and $\kappa \le c$ be fulfilled. Then*

(i) The following estimate holds:

$$\mathsf{E}^*_\psi - \int \mathsf{Weyl}_1(x)\psi^2(x)\, dx = O(h^{2-d}) \tag{27.2.86}$$

and and a minimizer A satisfies (27.2.53) *and* (27.2.54)*.*

(ii) Furthermore, let assumption (27.2.63) *be fulfilled (i.e. $\mu_0(\Pi_\infty) = 0$). Then*

$$\mathsf{E}^*_\psi - \int \mathsf{Weyl}^*_1(x)\psi^2(x)\, dx = o(h^{2-d}) \tag{27.2.87}$$

and a minimizer A satisfies similarly improved versions of (27.2.53) *and* (27.2.54)*.*

27.2.4 Rescaling

Now we apply the rescaling. We consider only $d = 3$ here.

Case $\kappa \le 1$

We already have an upper estimate: see Corollary 27.2.23. Let us prove a lower estimate[10]. Consider an error

$$\Big(\int \mathsf{Weyl}_1(x)\psi^2\,dx - \mathsf{E}_\psi(A)\Big)_+. \tag{27.2.88}$$

Obviously, Tr^- is sub-additive

$$\mathsf{Tr}^-(\sum_j \psi_j H \psi_j) \ge \sum_j \mathsf{Tr}^-(\psi_j H \psi_j), \tag{27.2.89}$$

and therefore so is $\mathsf{E}_\psi(A)$ under assumption that $\psi_j \in \mathscr{C}_0^2(B(x_j, \frac{1}{2}\ell_j))$, where multiplicity of covering by $B(x_j,\ell_j))$ does not exceed C_0 and we are allowed to replace κ by $C_1\kappa$ in the right-hand expression[11].

Then we need to consider each partition element and use a lower estimate for it. While considering partition we use so called *ISM identity*: if

$$\sum_j \psi_j^2 = 1, \tag{27.2.90}$$

we have

$$H = \sum_j \big(\psi_j H \psi_j + \frac{1}{2}[[H,\psi_j],\psi_j]\big) = \sum_j \psi_j \big(H + \frac{1}{2}\sum_k [[H,\psi_k],\psi_k]\big)\psi_j, \tag{27.2.91}$$

where the second equality is due to the fact that $[[H,\psi_j],\psi_j]$ is an ordinary function.

In virtue of Proposition 27.2.5, from the very beginning we need to consider

$$M = \kappa^\beta h^{-1-\alpha} \tag{27.2.92}$$

[10] But only for $\mathsf{E}_\psi(A)$ defined by (27.2.80).

[11] Really, $\|\partial A\|^2 \ge c\sum_j \|\partial A_j\|^2$ with $A_j(x) = (A(x)-A_j(x_j))\psi_j'$ with $\psi_j' \in \mathscr{C}_0^2(B(x_j, \frac{7}{8}\ell_j))$ equal 1 in $B(x_j, \frac{3}{4}\ell_j)$).

with $\alpha = 2$, $\beta = 0$ and $\kappa \le c$. But we need to satisfy precondition (27.2.21) which is then

$$\kappa^{\beta+1} h^{-\alpha} \le c. \tag{27.2.93}$$

Therefore, if condition (27.2.93) is fulfilled with $\alpha = 0$, we conclude that the final error is indeed $O(h^{-1})$ or even $o(h^{-1})$ (under assumption (27.2.63)) without any precondition.

Let precondition (27.2.93) fail. Let us use γ-admissible partition of unity ψ_j^2 with ψ_j satisfying after rescaling assumptions of Proposition 27.2.22.

Note that rescaling $x \mapsto x\gamma^{-1}$ results in $h \mapsto h_{\text{new}} = h\gamma^{-1}$ and after rescaling in the new coordinates $\|\partial A\|^2$ acquires factor γ^{d-2} and thus factor $\kappa^{-1}h^{-2}$ becomes $\kappa^{-1}h^{-2}\gamma^{d-2} = \kappa_{\text{new}}^{-1}h_{\text{new}}^{-2}$ with $\kappa \mapsto \kappa_{\text{new}} = \kappa\gamma$.

Then *after rescaling* precondition (27.2.93) is satisfied provided *before rescaling* $\kappa^{\beta+1}h^{-\alpha}\gamma^{\alpha+\beta+1} \le c$. Thus, let us pick up the largest γ satisfying this: $\gamma = \kappa^{-(\beta+1)/(\alpha+\beta+1)}h^{\alpha/(\alpha+\beta+1)}$. Obviously, if before rescaling condition (27.2.93) fails, then $h \ll \gamma \le 1$.

But then expression (27.2.88) with ψ replaced by ψ_j does not exceed $Ch_{\text{new}}^{-1} = C(h\gamma^{-1})^{-1}$ and the total expression (27.2.88) does not exceed $C(h\gamma^{-1})^{-1}\gamma^{-3} = Ch^{-1}\gamma^{-2} = C\kappa^{\beta'}h^{-1-\alpha'}$ with

$$\beta' = 2(\beta+1)/(\alpha+\beta+1), \qquad \alpha' = 2\alpha/(\alpha+\beta+1).$$

Therefore, actually we can pick up M with α, β replaced by α', β' and we have a precondition (27.2.93) with these new α', β' and we do not need an old precondition. Repeating the rescaling procedure again, we derive a proper estimate with again weaker precondition etc.

One can see easily that $\alpha' + \beta' + 1 = 3$ and therefore on each step $\alpha + \beta + 1 = 3$ and we have a recurrent relation for α': $\alpha' = \frac{2}{3}\alpha$; and therefore we have sequence for α which decays and becomes arbitrarily small. Therefore precondition (27.2.93) has been reduced to a much weaker assumption $\kappa \le h^{\delta}$ and under it estimate $M = O(h^{-1})$ has been established. Furthermore, after this under assumption (27.2.63) we can prove even sharper asymptotics.

To weaken assumption $\kappa \le h^{\delta}$ to $\kappa \le c$ we can use rescaling $x \mapsto x\gamma^{-1}$ with $\gamma = h^{\delta}$. We arrive to the error estimate $O(h^{-1-\delta})$ and therefore optimizer satisfies $\|\nabla \times A\| \le h^{\frac{1}{2}-\delta}$ (where δ is increased if necessary but remains arbitrarily small). Repeating the arguments of the proof of Proposition 27.2.6, instead of $\|\Delta A\|_{\mathscr{L}^\infty} = O(1)$ we arrive to $\|\Delta A\|_{\mathscr{L}^\infty} = O(h^{-\delta})$

and to $\|\partial^2 A\|_{\mathscr{L}^\infty} = O(h^{-\delta})$; then $\|\partial A\|_{\mathscr{L}^\infty} = O(h^{\frac{1}{2}-\delta})$; it is more than sufficient to unleash the microlocal analysis technique without any need to appeal to Proposition 27.2.6 which is the only place where we needed assumption (27.2.21).

Thus we arrive to

Theorem 27.2.29. *Let $d = 3$, $V \in \mathscr{C}^{2,1}$, $\kappa \le c$ and let ψ satisfy assumption of Proposition 27.2.22. Then*

(i) Asymptotics (27.2.86) *holds.*

(ii) Further, if assumption (27.2.63) *is fulfilled then asymptotics* (27.2.86) *holds.*

(iii) If (27.2.86) *or* (27.2.87) *holds for $E_\psi(A)$ (we need only an estimate from below) then $\|\partial A\| = O((\kappa h)^{\frac{1}{2}})$ or $\|\partial A\| = o((\kappa h)^{\frac{1}{2}})$ respectively.*

Case $1 \le \kappa \le h^{-1}$

In this framework we can consider even the case $1 \le \kappa \le h^{-1}$. The simple rescaling-and-partition arguments with $\gamma = \kappa^{-1}$ lead to the following

(27.2.94) If $1 \le \kappa \le h^{-1}$, then the remainder estimate $O(\kappa^2 h^{-1})$ holds and for a minimizer A satisfies $\|\partial A\|^2 \le C\kappa^3 h$.

However we would like to improve it and, in particular, to prove that if κ is moderately large then the remainder estimate is still $O(h^{-1})$ and even $o(h^{-1})$ under non-periodicity assumption.

Theorem 27.2.30. *Let $d = 3$, $V \in \mathscr{C}^{2,1}$, and let ψ satisfy assumptions of Proposition 27.2.22. Then*

(i) For

$$\kappa \le \kappa_h^* := \epsilon h^{-\frac{1}{4}} |\log h|^{-\frac{3}{4}} \tag{27.2.95}$$

asymptotics (27.2.86) *holds.*

(ii) Furthermore, for $\kappa = o(\kappa_h^*)$ and assumption (27.2.63) *is fulfilled then asymptotics* (27.2.87) *holds.*

(iii) If $\kappa_h^* \le \kappa \le ch^{-1}$ the following estimate holds:

$$|\mathsf{E}_\psi^* - \int \mathsf{Weyl}_1(x)\psi^2(x)\,dx| \le Ch^{-3}(\kappa h)^{\frac{8}{3}}|\log \kappa h|^2. \tag{27.2.96}$$

Proof. (i) From (27.2.46) we conclude for $\kappa \ge c$ that

$$h^{1-\theta}|\partial A|_{\mathscr{C}^\theta} \le C\kappa(\kappa + \bar\mu).$$

Then, using arguments of Subsection 27.2.2, one can prove easily that for $\kappa \le h^{\sigma-\frac12}$

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)(hD_x)^\alpha(hD_x)^\beta\big(U(x,y,t) - U_{(\varepsilon)}(x,y,t) - U'_{(\varepsilon)}(x,y,t)\big)| \le Ch^{1-d},$$

where we use the same 2-term approximation, $T = \epsilon\bar\mu^{-1}$. Let us take then $x = y$, multiply by $\varepsilon^{-d}\psi(\varepsilon^{-1}(y-z))$ and integrate over y. Using the rough microlocal analysis technique, one can prove easily that from both $U_{(\varepsilon)}(x,y,t)$ and $U'_{(\varepsilon)}(x,y,t)$ we get $O(h^{-2})$ and in the end of the day we arrive to the estimate $|\Delta A_\varepsilon| \le C\kappa\bar\mu$, which implies

$$|\partial^2 A_\varepsilon| \le C\kappa\bar\mu|\log h| + C\mu, \tag{27.2.97}$$

where obviously one can skip the last term. Here we used the regularity property of the Laplace equation. For our purpose it is much better than the estimate $|\partial^2 A_\varepsilon| \le C\kappa^2|\log h| + C\mu$, which one could derive easily.

Again, using arguments of Subsection 27.2.2, one can prove easily that

$$|\operatorname{Tr}(\psi H^-_{A,V}\psi) - \operatorname{Tr}(\psi H^-_{A_\varepsilon,V}\psi)| \le C\bar\mu^2 h^{2-d} \tag{27.2.98}$$

and therefore

$$|\operatorname{Tr}(\psi H^-_{A,V}\psi) - \int \mathsf{Weyl}_1(x)\psi^2(x)\,dx| \le C\bar\mu^2 h^{2-d} \tag{27.2.99}$$

and finally for an optimizer

$$\|\partial A\|^2 \le C\kappa\bar\mu^2 h. \tag{27.2.100}$$

Here μ and $\bar\mu$ were calculated for A, but it does not really matter since due to the estimate $|\partial^2 A| \le C\kappa^2 h^{-\delta}$ we conclude that $|\partial A - \partial A_\varepsilon| \le C\kappa^2 h^{-\delta}\varepsilon \le C$ due to restriction to κ.

Then, for $d = 3$

$$\mu^2\big(\mu/(\kappa\bar{\mu}|\log h|)\big)^3 \le \kappa\bar{\mu}^2 h \tag{27.2.101}$$

and if $\mu \ge 1$ we have $\bar{\mu} = \mu$ and (27.2.101) becomes $\kappa^{-3}|\log h|^{-3} \le C\kappa h$ which is impossible under (27.2.95).

So, $\mu \le 1$ and (27.2.101) implies (27.2.86) and (27.2.100), (27.2.101) imply that for an optimizer $\|\partial A\| \le C(\kappa h)^{\frac{1}{2}}$ and $\mu \le C\kappa^4 h|\log h|^d$. So Statement (i) is proven.

(ii) Proof of Statement (ii) follows then in virtue of arguments of Subsection 27.2.2.

(iii) If $\kappa_h^* \le \kappa \le h^{-1}$ we apply the partition-and-rescaling technique. Then $h \mapsto h' = h\gamma^{-1}$ and $\kappa \mapsto \kappa' = \kappa\gamma$ and to get into the framework of (27.2.95) we need $\gamma = \epsilon\kappa^{-\frac{4}{3}}h^{-\frac{1}{3}}|\log(\kappa h)|^{-1}$, leading to the remainder estimate $Ch^{-1}\gamma^{-2}$, which proves Statement (iii). □

Problem 27.2.31. Repeat arguments of Subsubsections *27.2.1.2. Preliminary Analysis* and *27.2.1.3. Estimates* and of this Subsection for $d \ne 3$. When they hold?

27.3 Global Trace Asymptotics in the Case of Coulomb-Like Singularities

27.3.1 Problem

We consider the same operator (27.1.4) as before in $\mathbb{R}^3$ but now we assume that V has Coulomb-like singularities. Namely let $\mathsf{y}_m \in \mathbb{R}^3$ ($m = 1, \dots, M$, where M is fixed) be singularities ("nuclei"). We assume that

$$V = \sum_{1\le m\le M} \frac{z_m}{|x - \mathsf{y}_m|} + W(x) \tag{27.3.1}$$

where

$$z_m \ge 0,\ z_1 + \dots + z_M \asymp 1, \tag{27.3.2}$$

and

$$|D^{\alpha}W| \le C_{\alpha} \sum_{1\le m\le M} z_m\big(|x-y_m|+1\big)^{-1}|x-y_m|^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le 2, \tag{27.3.3}$$

but at the first stages we will use some weaker assumptions. Later we assume that $V(x)$ decays at infinity sufficiently fast. Let us define $\mathsf{E}^*)$ and $\mathsf{E}(A)$ by (27.2.2)–(27.2.1). Finally, let $\ell(x)\min_{1\le m\le M}\ell_m(x)$ with $\ell_m(x) := \frac{1}{2}|x-y_m|$.

In this and next Sections we assume that

$$\kappa \in (0,\kappa^*] \text{ where } 0<\kappa^* \text{ is a small constant.} \tag{27.3.4}$$

For $\kappa = 0$ we set $A = 0$ and consider $\mathsf{E} := \mathsf{Tr}^-(H_{A,V})$; then our results are covered by Chapter 25.

27.3.2 Estimates of a Minimizer

Let us consider a Hamiltonian with potential V and let A be a magnetic potential, minimizing expression (27.2.2). We say that A is a *minimizer* and in the framework of our problems we will prove it existence.

Preliminary Analysis

First, we start from the roughest possible estimate:

Proposition 27.3.1. *Let V satisfy* (27.3.1)–(27.3.3) *and let $\kappa \le \kappa^*$. Then the near-minimizer A satisfies*

$$\Big|\int \big(\mathsf{tr}\, e_{A,1}(x,x,0) - \mathsf{Weyl}_1(x)\big)\,dx\Big| \le Ch^{-2} \tag{27.3.5}$$

and

$$\|\partial A\| \le C\kappa^{\frac{1}{2}}. \tag{27.3.6}$$

Proof. Definitely (27.3.5)–(27.3.6) follow from the results of L. Erdös, S. Fournais, and J. P. Solovej [3] but we give an independent easier proof, based on our Subsection 27.2.1.

(a) First, let us pick up $A = 0$ and consider $\mathsf{Tr}\big(\psi_\ell \theta(-H)\psi_\ell\big)$ with cut-offs $\psi_\ell(x) = \psi((x-y_m)/\ell)$ where $\psi \in \mathscr{C}_0^\infty(B(0,1))$ and equals 1 in $B(0,\frac{1}{2})$. Here and below $\theta(\tau - H_{A,V})$ is a spectral projector of H.

Then

$$|\mathsf{Tr}\big(\psi_\ell H_{A,V}^-(0)\psi_\ell\big)| \le Ch^{-2} \qquad \text{for } \ell = \ell_* := h^2. \tag{27.3.7}$$

On the other hand, contribution of $B(x,\ell)$ with $\ell(x) \ge \ell_*$ to the Weyl error does not exceed $C\zeta^2\hbar^{-1} = C\zeta^3\ell h^{-1}$ where $\hbar = h/(\zeta\ell)$ in the rescaling; so after summation over $\ell \ge \ell_*$ we also get $O(h^{-2})$ provided $\zeta^2 \le C\ell^{-1}$. Therefore we arrive to the following rather easy inequality:

$$|\int \big(\mathsf{tr}\, e_{0,1}(x,x,0) - \mathsf{Weyl}_1(x)\big)\,dx| \le Ch^{-2}. \tag{27.3.8}$$

This is what the rescaling method gives us without careful the study of the singularity.

(b) On the other hand, consider $A \ne 0$. Let us prove first that

$$\mathsf{Tr}^-(\psi_\ell H \psi_\ell) \ge -Ch^{-2} - Ch^{-2}\int |\partial A|^2\,dx \qquad \text{for } \ell = \ell_*. \tag{27.3.9}$$

Rescaling $x \mapsto (x-y_m)/\ell$ and $\tau \mapsto \tau/\ell$ and therefore $h \mapsto h\ell^{-\frac{1}{2}} \asymp 1$ and $A \mapsto A\ell^{\frac{1}{2}}$ (because the singularity is Coulomb-like), we arrive to the same problem with the same κ (in contrast to Subsection 27.2.4 where $\kappa \mapsto \kappa\ell$ because of the different scale in τ and h) and with $\ell = h = 1$.

In this case the required estimate follows from L. Erdös, J. P. Solovej [1] (we reproduce Lemma 2.1 of this paper in Appendix 27.A.1.

(c) Consider now function ψ_ℓ as in (c) with $\ell \ge \ell_*$. Then according to Theorem 27.2.29 rescaled

$$\mathsf{Tr}^-\big(\psi_\ell H_{A,V}\psi_\ell\big) - \int \mathsf{Weyl}_1(x)\psi_\ell^2(x)\,dx \ge -C\zeta^3\ell h^{-1} - Ch^{-2}\int_{B(x,2\ell/3)} |\partial A|^2\,dx. \tag{27.3.10}$$

Really, rescaling of the first part is a standard one and in the second part we should have in the front of the integral a coefficient $\kappa^{-1}h^{-2}\zeta^2 \times \zeta^{-2}\ell(h/\zeta\ell)^{-2}$

where factor ζ^2 comes from the scaling of the spectral parameter, factor ζ^{-2} comes from the scaling of the magnitude of A, factor $\ell = \ell^3 \times \ell^{-2}$ comes from the scaling of dx and ∂ respectively, and $\hbar := h/(\zeta\ell)$ is a semiclassical parameter after rescaling. Therefore this expression acquires a factor $\zeta^2\ell \le C$.

Then we conclude that

$$\int \bigl(\operatorname{tr} e_{A,1}(x,x,0) - \mathsf{Weyl}_1(x)\bigr)\,dx \ge -Ch^{-2} - Ch^{-2}\int |\partial A|^2\,dx \tag{27.3.11}$$

and adding the magnetic field energy $\kappa^{-1}h^{-2}\|\partial A\|^2$ we find out that

$$\mathsf{E}(A) - \int \mathsf{Weyl}_1(x)\,dx \ge \mathsf{E}(0) - \int \mathsf{Weyl}_1(x)\,dx + (\kappa^{-1}-C)h^{-2}\|\partial A\|^2 - Ch^{-2} \tag{27.3.12}$$

since $\mathsf{Weyl}_1(x)$ does not depend on A. However due to (a) the right-hand expression is greater than $(\kappa^{-1}-C)h^{-2}\|\partial A\|^2 - Ch^{-2}$.

On the other hand, since A is supposed to be a near-minimizer, the left-hand expression of (27.3.12) should not exceed the same expression for $A=0$ plus Ch^2, i.e. Ch^2 due to (a) again. Then due to)(27.3.4) we arrive to (27.3.5) and (27.3.6). □

Proposition 27.3.2. *Let V satisfy* (27.3.1)–(27.3.3)*. Then there exists a minimizer A.*

Proof. After Proposition 27.3.1 has been proven we just repeat arguments of the proof of Proposition 27.2.2. If $V \in \mathscr{L}^{\frac{5}{2}}$ no change would be required but for $V \notin \mathscr{L}^{\frac{5}{2}}$ one needs to consider modifications as in Remark 27.3.3 below. □

Remark 27.3.3. We are a bit ambivalent about a convergence of $\int \mathsf{Weyl}_1(x)\,dx$ at infinity, since for the Coulomb potential it diverges. To avoid this issue, however, we can either assume in addition that $V \in \mathscr{L}^{\frac{5}{2}}$, or tackle it as in Proposition 27.3.16 below.

Estimates to a Minimizer. I

Let us repeat arguments of Subsubsection *27.2.1.3. Estimates.* However our task now is much more complicated: while we know a priory that $\|\partial A\|^2 \le C\kappa$ we will not be able to improve it significantly (or at all for $\kappa \asymp 1$).

Recall equation (27.2.14) for a minimizer A. After rescaling $x \mapsto x/\ell$, $\tau \mapsto \tau/\zeta^2$, $h \mapsto \hbar = h/(\zeta\ell)$, $A \mapsto A\zeta^{-1}\ell$ this equation becomes

$$\Delta A_j = -2\kappa\zeta^2\ell\hbar^2 \operatorname{Re}\operatorname{tr}\Big[\sigma_j\Big(\big(\hbar Dk - \zeta^{-1}A\big)_x\cdot\boldsymbol{\sigma} e(x,y,\tau) + e(x,y,\tau)\,{}^t\big(\hbar D - \zeta^{-1}A\big)_y\cdot\boldsymbol{\sigma}\Big)\Big]\Big|_{y=x} \tag{27.3.13}$$

and since so far $\zeta^2\ell = 1$ we arrive to

$$\Delta A_j = -2\kappa\hbar^2 \operatorname{Re}\operatorname{tr}\Big[\sigma_j\Big(\big(\hbar D - \zeta^{-1}A\big)_x\cdot\boldsymbol{\sigma} e(x,y,\tau) + e(x,y,\tau)\,{}^t\big(\hbar D - \zeta^{-1}A\big)_y\cdot\boldsymbol{\sigma}\Big)\Big]\Big|_{y=x}. \tag{27.3.14}$$

(a) Plugging $u = \psi\theta(-H)f$ with cut-off function ψ and repeating arguments of Subsubsection *27.2.1.3. Estimates*, we conclude that in the rescaled coordinates

$$\begin{aligned}\|(\hbar D_x\cdot\boldsymbol{\sigma})u\| &\le \|((\hbar D_x - A)\cdot\boldsymbol{\sigma})u\| + C\|A\|_{\mathscr{L}^6}\cdot\|u\|_{\mathscr{L}^3}\\ &\le \|((\hbar D_x - A)\cdot\boldsymbol{\sigma})u\| + C\hbar^{-\frac12}\|A\|_{\mathscr{L}^6}\cdot\|u\|^{\frac12}\cdot\|\hbar D_x u\|^{\frac12}\\ &\le \|((\hbar D_x - A)\cdot\boldsymbol{\sigma})u\| + \frac12\|\hbar D_x u\| + C(\hbar^{-\frac12}\|A\|_{\mathscr{L}^6})^2\|u\|,\end{aligned} \tag{27.3.15}$$

where $\|A\|_{\mathscr{L}^6}$ calculated in the rescaled coordinates is equal to $\|A_{\mathsf{orig}}\|_{\mathscr{L}^6,\mathsf{orig}}$ (where subscripts "orig"means that the norm is calculated in the original coordinates and A) which does not exceed $C\kappa^{\frac12}$ due to (27.3.6)[12] and therefore (since $\|(\hbar D_x\cdot\boldsymbol{\sigma})u\| = \|\hbar D_x u\|$)

$$\|\hbar D_x u\| \le C\big(1+\kappa\hbar^{-1}\big)\|f\|. \tag{27.3.16}$$

Continuing arguments of Subsubsection *27.2.1.3. Estimates*, we conclude that in the rescaled coordinates

$$\|(\hbar D_x)^k u\| \le C\big(1+\kappa\hbar^{-1}\big)^k\|f\|, \tag{27.3.17}$$

$$\|(\hbar D_x)^k((\hbar D_x - A)\cdot\boldsymbol{\sigma})u\| \le C(1+\kappa\hbar^{-1})^k\|f\|, \tag{27.3.18}$$

[12] As usual we assume that the average of A over $B(x,1)$ is 0.

for $k = 0, 1, 2$ and therefore

$$\|\Delta A\|_{\mathscr{L}^\infty(B(x,1))} \le C\kappa\hbar^{-1}(1+\kappa\hbar^{-1})^3. \tag{27.3.19}$$

Here we estimate different norms of A locally. Then either

$$\|\partial A\|_{\mathscr{L}^\infty(B(x,\frac{3}{4}))} + \hbar^\delta \|\partial^2 A\|_{\mathscr{L}^\infty(B(x,\frac{3}{4}))} \le C\kappa\hbar^{-1}(1+\kappa\hbar^{-1})^3 \tag{27.3.20}$$

or

$$\|\partial A\|_{\mathscr{L}^\infty(B(x,1-\epsilon))} + \hbar^\delta \|\partial^2 A\|_{\mathscr{L}^\infty(B(x,1-\epsilon))} \le C\|\partial A\| = C\|\partial A_{\mathsf{orig}}\|_{\mathsf{orig}} \le C\kappa^{\frac{1}{2}} \tag{27.3.21}$$

In the latter case (27.3.21) we have in the original coordinates

$$\|\partial A\|_{\mathscr{L}^\infty(B(x,\ell))} \le C\kappa^{\frac{1}{2}}\ell^{-\frac{3}{2}} \tag{27.3.22}$$

and we are rather happy because then the effective intensity of the magnetic field in $B(x,\ell)$ is $\zeta^{-1}\ell\|\partial A\|_{\mathscr{L}^\infty(B(x,1-\epsilon))} \le C\kappa^{\frac{1}{2}}$.

(b) The former case (27.3.20) is much more complicated because our estimate is really poor for $\kappa \asymp 1$ and we are going to act only in the assumption (27.3.4). Assume that

$$\|\partial A\|_{\mathscr{L}^\infty(B(x,1-\epsilon))} \le \mu \tag{27.3.23}$$

with $\mu \ge \hbar^{-\sigma}$. Selecting $u = \psi\theta(-H)f$ with γ-admissible ψ we conclude that $\|(A\cdot\boldsymbol{\sigma})u\| \le \|A\|_{\mathscr{L}^\infty}\|u\| \le C\mu\gamma\|u\|$ (assuming without any loss of the generality that $A = 0$ at some point of $\mathsf{supp}(\psi)$) and that

$$\|(\hbar D)^k u\| \le C(1+\hbar\gamma^{-1}+\mu\gamma)^k,$$
$$\|(\hbar D)^k((\hbar D - A)\cdot\boldsymbol{\sigma})u\| \le C(1+\hbar\gamma^{-1}+\mu\gamma)^{k+1},$$

and therefore

$$|\Gamma_x(\hbar D_x - A)\cdot\boldsymbol{\sigma})e(.,.,0)| \le C\hbar^{-3}(1+\hbar\gamma^{-1}+\mu\gamma)^{\frac{7}{2}},$$

and then

$$\|\Delta A\|_{\mathscr{L}^\infty(B(x,1-\epsilon))} \le C\hbar^{-1}(1+\hbar\gamma^{-1}+\mu\gamma)^{\frac{7}{2}}.$$

Optimizing with respect to $\gamma = \mu^{-\frac{1}{2}}h^{\frac{1}{2}}$ we conclude that either

$$\|\partial^2 A\|_{\mathscr{L}^\infty(B(x,1-\epsilon))} \le C\hbar^{-1-\delta}(1+\hbar\mu)^{\frac{7}{4}} \tag{27.3.24}$$

or (27.2.21) holds. In the former case of (27.3.24), using the second of estimates

$$\|A\|_{\mathscr{L}^\infty(B(x,1-\epsilon))} \le C\|\partial^2 A\|^{\frac{1}{5}}_{\mathscr{L}^\infty(B(x,1-\epsilon))}\|\partial A\|^{\frac{4}{5}}, \tag{27.3.25}$$

$$\|\partial A\|_{\mathscr{L}^\infty(B(x,1-\epsilon))} \le C\|\partial^2 A\|^{\frac{3}{5}}_{\mathscr{L}^\infty(B(x,1-\epsilon))}\|\partial A\|^{\frac{2}{5}} \tag{27.3.26}$$

we conclude that (27.3.23) holds with $\mu = \mu'$,

$$\mu' := \hbar^{-\frac{3}{5}-\delta}(1+\hbar\mu)^{\frac{21}{20}}$$

and one can see easily that starting from $\mu = \hbar^{-4}$ as given by (27.3.20), we can arrive after number of iterations to $\mu = \hbar^{-\frac{3}{5}-\delta}$ and therefore

$$\|\partial^k A\|_{\mathscr{L}^\infty(B(x,1-\epsilon))} \le C\hbar^{-\frac{1}{5}(1+2k)-\delta} \qquad k = 0,1,2. \tag{27.3.27}$$

(c) This estimate (27.3.27) is good enough to launch our microlocal arguments. Assuming (27.3.23) with $\mu \le h^{\sigma-1}$ we estimate as in Section 27.2

$$|\Gamma_x((\hbar D_x - A)\cdot\boldsymbol{\sigma})e(.,.,0)| \le C\mu\hbar^{-\delta},$$

and then

$$\|\partial^2 A\|_{B(x,1-\epsilon)} \le C\mu h^{-\delta},$$

and therefore

$$\|\partial A\|_{B(x,1-\epsilon)} \le C\mu^{\frac{3}{5}} h^{-\delta},$$

resulting in $\mu := \mu^{\frac{3}{5}} h^{-\delta}$ and after a number of iterations we get $\mu = h^{-\delta}$, and therefore iterating this procedure one more time and taking into account factor κ we arrive to

(27.3.28) Either (27.3.21) holds or

$$\|\partial^2 A\|_{\mathscr{L}^\infty(B(x,1-\epsilon))} \le C\kappa h^{-\delta}. \tag{27.3.29}$$

However to prove that the effective magnetic field is $O(1)$ we need to modify these arguments, and we do it in the next subsubsection.

Estimates to a Minimizer. II

In this step we repeat arguments of Subsubsection *27.2.2.1. Sharp Estimates*, but now we have a problem: we cannot use $\mu = \|\partial A\|_\infty$ since we have domains $\mathcal{X}_r = \{x : \ell(x) \ge r\}$ rather than the whole space. So we get the following analogue of (27.2.48) where A is still rescaled and the norms are calculated in the rescaled coordinates:

$$\|\Delta A\|_{\mathscr{C}(B(x,\frac34))} + \hbar\|\Delta\partial A\|_{\mathscr{C}(B(x,\frac34))} \le C\kappa\Big(1 + |\partial A|_{\mathscr{C}(B(x,1)} + h^{\frac12(\theta-1)}\|\partial A\|_{\mathscr{C}^{\theta}\frac12(B(x,1))}\Big), \tag{27.3.30}$$

which implies

$$\|\partial A\|_{\mathscr{C}(B(x,\frac12))} + \hbar^{\theta-1}\|\partial A\|_{\mathscr{C}^\theta(B,(x,\frac12))} \le \epsilon\hbar^{(\theta-1)}\zeta^{-1}\|\partial A\|_{\mathscr{C}^\theta(B(x,1))} + C\kappa\|\partial A\|_{\mathscr{C}(B(x,1))} + C\|\partial A\|_{\mathscr{L}^2(B(x,1))} \tag{27.3.31}$$

and the last term in the right-hand expression does not exceed $C\kappa^{\frac12}$.

Let $\nu(r) = \sup_{x:\,\ell(x)\ge r} f(x)$, where $f(x)$ is the left-hand expression of (27.3.16), calculated for given x in the rescaled coordinates. Then (27.3.31) implies that for $\kappa \in (0,\kappa^*)$ (where $\kappa^* > 0$ is a small constant)

$$\nu(r) \le \frac12\nu(\frac12 r) + C\kappa^{\frac12},$$

which in turn implies that

$$\nu(r) \le \frac12\nu(2^{-n}r) + 2C\kappa^{\frac12}, \qquad n \ge 1,$$

and therefore

$$\nu(r) \le 4C\kappa^{\frac12} + 4\sup_{C_0h^2\le\ell(x)\le 2C_0h^2} f(x) \le C_1\kappa^{\frac12}$$

due to the rough estimate (because $\hbar \asymp 1$ for $\ell(x) \asymp h^2$). Then returning to the original (not rescaled) coordinates and to the original (not rescaled) potential A we arrive to estimates (27.3.32) and (27.3.33) below:

Proposition 27.3.4. *Let $\kappa \le \kappa^*$, $\zeta = c\ell^{-\frac12}$. Let A be a minimizer. Then for $\ell(x) \ge \ell_* = h^2$ estimate* (27.3.22) *holds and also*

$$|\partial^2 A(x) - \partial^2 A(y)| \le C\kappa^{\frac12}\ell^{-\frac52}|x-y|^\theta \ell^{\theta/2}\ell_*^{-\theta/2} \qquad 0<\theta<1, \tag{27.3.32}$$

and

$$|\partial A(x) - \partial A(y)| \le C\kappa^{\frac12}\ell^{-\frac52}|x-y|(1+|\log|x-y||). \tag{27.3.33}$$

Remark 27.3.5. (i) So far we used only assumption that

$$|\partial^\alpha V| \le C\zeta^2\ell^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le 2 \tag{27.3.34}$$

with $\zeta = \ell^{-\frac12}$ but even this was excessive.

(ii) In this framework however we cannot prove better estimates because (27.3.22) always remains a valid alternative even if $\zeta \ll \ell^{-\frac12}$.

(iii) Originally we need an assumption (27.2.37) $|V| \ge \epsilon_0$, but for $d = 3$ one can easily get rid of it by the standard rescaling technique.

Consider now zone $\{x :\ \ell(x) \le \ell_*\}$:

Proposition 27.3.6. *Let $\kappa \le \kappa^*$, $\zeta \le c\ell^{-\frac12}$. Let A be a minimizer. Then $|\partial A| \le C\kappa^{\frac12}h^{-3}$ for $\ell(x) \le \ell_* = h^2$.*

Proof. Proof is standard, based on the rescaling (then $\hbar = 1$) and equation (27.2.14) for a minimizer A. We leave easy details to the reader. □

Let us slightly improve estimate to a minimizer A. We already know that $|\partial A(x)| \le C_0\beta$ with $\beta = \ell^{-\frac32}$ and using the standard rescaling technique we conclude that

$$|\Delta A| \le C\kappa\zeta^2\beta + C\kappa\zeta^3\ell^{-1}, \tag{27.3.35}$$

which does not exceed $C\kappa\ell^{-\frac52}$ which implies

Proposition 27.3.7. *In our framework*

(i) If $\ell(x) \ge \ell_* \coloneqq h^2$, then

$$|A| \le C\kappa\ell^{-\frac12}, \qquad |\partial A| \le C\kappa\ell^{-\frac32} \tag{27.3.36}$$

and

$$|\partial A(x) - \partial A(y)| \le C_\theta\kappa\ell^{-\frac32-\theta}|x-y|^\theta \qquad \text{as } |x-y| \le \frac12\ell(x) \tag{27.3.37}$$

for any $\theta \in (0,1)$.

(ii) If $\ell(x) \le \ell_*$, then these estimates hold with $\ell(x)$ replaced by ℓ_*.

Remark 27.3.8. (i) Here in comparison with old estimates we replaced factor $\kappa^{\frac12}$ by κ which is an advantage.

(ii) These estimates imply that $\int_{\{x:\,\ell(x)\le 1\}} |\partial A|^2\,dx \le C\kappa^2|\log h|$ while in fact it must not exceed $C\kappa$.

Estimates to a Minimizer. III

Consider now external zone $\mathcal{Y} := \{x\colon \ell(x) \ge 1\}$ and assume that

$$\zeta(x) \le C\ell(x)^{-\nu} \qquad \text{for } \ell(x) \ge 1 \tag{27.3.38}$$

with $\nu > 1$.

Then if also $|\partial A(x)| = O(\ell(x)^{-\nu_1})$ for $\ell(x) \ge 1$ then the right hand expression of (27.3.35) does not exceed $C\kappa(\ell^{-3\nu-1} + \ell^{-\nu_1-2\nu})$ and therefore we *almost* upgrade estimate for $|\partial A(x)|$ to $O(\ell^{-3\nu} + \ell^{-\nu_1-2\nu+1})$ and repeating these arguments sufficiently many times to $O(\ell^{-3\nu})$.

However, there are several obstacles to this conclusion: first, if $\nu > 1$ we conclude that

$$A_j = \sum_m \alpha_{j,m}|x - \mathsf{y}_m|^{-1} + O(\ell^{-1-\delta})$$

with constant $\alpha_{j,m}$; however assumption $\nabla \cdot A = 0$ implies $\alpha_{j,m} = 0$ and we pass this obstacle.

Indeed, let our equation be $\Delta A_j = \Phi_j$ and therefore

$$A_j(x) = -\frac{1}{4\pi}\int |x-y|^{-1}\Phi_j(y)\,dy.$$

Let a be the minimal distance between nuclei, $1 = \sum_{0\le m\le M}\phi_m$ where ϕ_m is supported in $\frac{1}{3}a$-vicinity of y_m and equals 1 in $\frac{1}{4}a$-vicinity of y_m, $m = 1, \dots, 1$. Let

$$I_{j,m} = \int \Phi_j(y)\phi_m(y)\,dy, \qquad \eta = \max_{1\le m\le M}|I_{j,m}|.$$

Then if x belongs to b-vicinity of y_m with $b \le \epsilon a$ one can prove easily that

$$|\partial_{x_k}\int |x-y|^{-1}\Phi_j(y)\phi_{m'}(y)\,dy| \le C\eta a^{-2} + Ca^{-3}$$

for $m' = 0, 1, \dots, M$, $m' \ne m$.

Also one can prove easily that

$$|\partial_{x_j}\Big(\int |x-y|^{-1}\Phi_j(y)\phi_{m'}(y)\,dy - |x-\mathsf{y}_m|^{-1}I_{j,m}\Big)| \le C|x-\mathsf{y}_m|^{-3},$$

and combining with the previous inequality and with equation $\nabla \cdot A = 0$ we conclude that $|I_{m,j}| \le C\eta a^{-2}b^2 + Ca^{-3}b^2 + Cb^{-1}$ for $b \le \epsilon a$. Then selecting

$b = \epsilon_1 a$ with sufficiently small constant ϵ_1, we conclude that $\eta \le Ca^{-1}$ which in turn implies that $|\partial_k A_j(x)| \le C\ell^{-3}$.

The second obstacle

$$A_j = \sum_{k,m} \alpha_{jk,m}(x_k - y_{k,m})|x - y_m|^{-3} + O(\ell^{-2})$$

with constant $\alpha_{jk,m}$ we cannot pass since assumption $\nabla \cdot A = 0$ implies only that modulo gradient $A = \sum_m \beta_m \times \nabla \ell_m^{-1}$ with constant vectors β_m and one cannot do anything about this.

Therefore we upgrade (27.3.36)–(27.3.37) there:

Proposition 27.3.9. *In our framework assume additionally that* (27.3.38) *holds. Then for* $\nu > \frac{4}{3}$

$$|A| \le C\kappa\ell^{-2}, \qquad |\partial A| \le C\kappa\ell^{-3} \tag{27.3.39}$$

and

$$|\partial A(x) - \partial A(y)| \le C_\theta \kappa \ell^{-3-\theta}|x-y|^\theta \qquad \text{as } |x-y| \le \frac{1}{2}\ell(x) \tag{27.3.40}$$

if $\ell(x) \ge 1$ *(for all* $\theta \in (0,1)$*).*

Remark 27.3.10. (i) In application to the ground state energy we are interested in $\nu = 2$.

(ii) Observe that for $a \ge 1$

$$\int_{\{\ell(x) \asymp a\}} |\partial A|^2 \, dx = O(\kappa^2 a^{-3}). \tag{27.3.41}$$

(iii) We were not able to improve (27.3.39)–(27.3.41) no matter how fast ζ decays.

27.3.3 Basic Trace Estimates

Recall that the standard Tauberian theory results in the remainder estimate $O(h^{-2})$. Indeed, since the effective magnetic field intensity is no more than $C\kappa$, the contribution of $B(x, \ell(x))$ to the Tauberian error[13)] does not exceed

[13)] And then to the Weyl error because we will explain transition from the Tauberian to Weyl estimates below.

$C\zeta^2 \times \hbar^{-1} = C\zeta^3\ell h^{-1}$, which for $\zeta \asymp \ell^{-\frac{1}{2}}$ translates into $C\ell^{-\frac{1}{2}}h^{-1}$ and summation over domain $\{x : \ell(x) \ge \ell_* = h^2\}$ results in Ch^{-2}. On the other hand, contribution of the domain $\{x : \ell(x) \le \ell_* = h^2\}$ into asymptotics does not exceed $C\hbar^{-3}\ell_*^{-1} = Ch^{-2}$ for $\hbar = 1$.

However, now we can unleash arguments of V. Ivrii and I. M. Sigal [1]. Recall that we are looking at

$$\mathsf{Tr}(\psi H^-_{A,V}\psi) = \mathsf{Tr}(\phi_1 H^-_{A,V}\phi_1) + \mathsf{Tr}(\phi_2 H^-_{A,V}\phi_2) \tag{27.3.42}$$

where $\psi^2 = \phi_1^2 + \phi_2^2$, $\mathsf{supp}(\phi_1) \subset \{x, |x| \le 2r\}$, $\mathsf{supp}(\phi_2) \subset \{x, r \le |x| \le b\}$ and we compare it with the same expression calculated for H_{A,V^0} with $V^0 = Z_m|x|^{-1}$. Here we assume that

$$a \le 1, \qquad z \asymp 1 \tag{27.3.43}$$

and

$$|D^\alpha(V - V^0)| \le c_0 a^{-1}\ell^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le 3. \tag{27.3.44}$$

The latter assumption is too restrictive and could be weaken. Then if $\phi(x)$ is an ℓ-admissible partition element

$$\mathsf{Tr}\big(\theta(-H^-_{A,V})\phi^2\big) = \int \mathsf{Weyl}(x)\phi^2(x)\,dx + O(rh^{-2}) \tag{27.3.45}$$

and

$$\mathsf{Tr}\big(H^-_{A,V}\phi^2\big) = \int \mathsf{Weyl}_1(x)\phi^2(x)\,dx + O(r^{-\frac{1}{2}}h^{-1}), \tag{27.3.46}$$

where the error estimates are $O(\hbar^{-2})$ and $O(\zeta^2\hbar^{-1})$ respectively. One can justify transition from the Tauberian to Weyl errors by considering Tauberian expressions and considering $H_{A_\varepsilon,V}$ and $H_{A,V}$ as unperturbed and perturbed operators respectively; their difference is $O(\zeta^3\varepsilon^2)$ with $\varepsilon = \hbar^{1-\delta}$.

Then the contribution[14)] of the time interval $\{t\colon t \asymp T\}$ to the Tauberian expression for (27.3.45) of the first term in the approximation does not exceed $C\hbar^{-4}T \times (\hbar T^{-1})^s$, of the second term $C\hbar^{-4}T \times (\hbar T^{-1})^s T\hbar^{-1}\varepsilon^2$, and of the third term $C\hbar^{-4}T \times (\hbar T^{-1})T^2\hbar^{-2}\varepsilon^4$. One can see easily that the end of the day the first term gives us the Weyl expression, the second term turns out to be 0, and the third term is less than the announced error.

Similarly, the contribution[14)] of the time interval $\{t\colon t \asymp T\}$ to the Tauberian expression for (27.3.46) of the first term in the approximation does not

[14)] After standard rescaling $x \mapsto x\ell^{-1}$, $\xi \mapsto \xi\zeta^{-1}$, $h \mapsto \hbar$, $\tau \mapsto \tau\zeta^{-2}$, and $t \mapsto t\zeta\ell^{-1}$.

exceed $C\zeta^2\hbar^{-4}T\times(\hbar T^{-1})^s$, of the second term $C\zeta^2\hbar^{-4}T\times(\hbar T^{-1})^s T\hbar^{-1}\varepsilon^2$ and of the third term $C\hbar^{-4}T\times(\hbar T^{-1})^2T^2\hbar^{-2}\varepsilon^4$. Again, in the end of the day the first tem gives us the Weyl expression, the second term turns out to be 0, and the third term is less than the announced error.

The same estimates also hold for operator H_{A,V^0} and then using ℓ-admissible partition of unity we conclude that

$$\mathsf{Tr}\big(\phi_2(H^-_{A,V}-H^-_{A,V^0})\phi_2\big)= \int \big(\mathsf{Weyl}_1(x)-\mathsf{Weyl}^0_1(x)\big)\,\phi_2^2(x)\,dx + O(r^{-\frac12}h^{-1}), \tag{27.3.47}$$

where Weyl^0_1 and Weyl^0 are calculated for operator with potential V^0. Indeed, we just proved this for each operator $H_{A,V}$ and H_{A,V^0} separately.

On the other hand, considering $V^\eta = V^0(1-\eta)+V\eta = V^0+W\eta$ and following V. Ivrii and I. M. Sigal [1], we can rewrite the similar expression albeit for $\phi_2=1$ as

$$\mathsf{Tr}\Big(\int_0^1 W\theta(-H_{A,V^\eta})\,d\eta\Big) \tag{27.3.48}$$

and applying the semiclassical approximation (under the temporary assumption that W is supported in the domain $\{x:\ |x|\le 4r\}$) one can prove that for $\phi_1=1$

$$\mathsf{Tr}\big(\phi_1(H^-_{A,V}-H^-_{A,V^0})\phi_1\big)= \int \big(\mathsf{Weyl}_1(x)-\mathsf{Weyl}^0_1(x)\big)\,\phi_1^2(x)\,dx + O(a^{-1}rh^{-2}). \tag{27.3.49}$$

Really, due to (27.3.45) and (27.3.44) the contribution of the ball $B(x,\ell(x))$ does not exceed $Ca^{-1}\hbar^{-2}=Ca^{-1}\ell(x)h^{-2}$ and summation with respect to partition with $\ell(x)\le 4r$ returns $Ca^{-1}rh^{-2}$); meanwhile, the contribution of $\{x:\ell(x)\le\ell_*\}$ does not exceed $Ca^{-1}\hbar^{-2}=Ca^{-1}$ since there $\hbar=1$.

One can get easily rid of the temporary assumption and take ϕ_1 supported in $\{x:\ell(x)\le 2r\}$ instead.

Therefore we arrive to

Proposition 27.3.11. *Under assumption* (27.3.44)

$$\mathsf{Tr}\big(\psi(H^-_{A,V}-H^-_{A,V^0})\psi\big)= \int \big(\mathsf{Weyl}_1(x)-\mathsf{Weyl}^0_1(x)\big)\,\psi^2(x)\,dx + O\big(a^{-\frac13}h^{-\frac43}\big). \tag{27.3.50}$$

Really, $a^{-\frac{1}{3}}h^{-\frac{4}{3}}$ is $r^{-\frac{1}{2}}h^{-1}+a^{-1}rh^{-2}$ optimized by $r\asymp r_*:=(ah)^{\frac{2}{3}}$; since $h^2\le a$ we note that $h^2\le r_*\le a$.

Corollary 27.3.12. *(i) For $M=1$ equality* (27.3.50) *remains valid with $\psi=1$ and $a=1$.*

(ii) For $M\ge 2$ and $a\ge h^2$ equality (27.3.50) *becomes*

$$\mathsf{Tr}\big(\psi(H^-_{A,V}-H^-_{A,V^0})\psi\big)= \int \big(\mathsf{Weyl}_1(x)-\mathsf{Weyl}^0_1(x)\big)\,\psi^2(x)\,dx + O\big((a^{-\frac{1}{3}}+1)h^{-\frac{4}{3}}\big), \tag{27.3.51}$$

where we reset case $a\ge 1$ to $a=1$.

27.3.4 Improved Trace Estimates

Improved Tauberian Estimates

Let us apply much more advanced arguments of Section 12.6; recall that these arguments are using the long term propagation of singularities. Unfortunately, using these arguments, we are not able to improve the above results unless $\kappa\ll 1$.

First, let us consider ψ, which is r-admissible partition element located in $\{x:\ell(x)\asymp r\}$, and we need to estimate an absolute value of

$$F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\,\mathsf{Tr}\big(e^{ih^{-1}tH}\psi\big), \tag{27.3.52}$$

and to do it we need to estimate the same expression with $\bar{\chi}_T(t)$ replaced by $\chi_{T'}(t)$ with $t_0\le T'\le T$ where $t_0=\epsilon\ell\zeta^{-1}=\epsilon r^{\frac{3}{2}}$. We can break $\psi=\psi^+ +\psi^-$ with $\psi^\pm=\psi^\pm(x,hD)$ such that the trajectories in the positive (negative) time direction from support of its symbol $\psi^+(x,\xi)$ are going after time Ct_0 in the direction of increased $\ell(x)$, and since we consider the trace we need to consider only ψ^+ and only $\chi\in\mathscr{C}^\infty([\frac{1}{2},1])$.

The trouble is that we have not rough but non-smooth magnetic field[15]; so let us consider $t_0+t_1+\dots+t_n\asymp T'$ where $t_j=\epsilon r_j^{\frac{3}{2}}$, $r_j=c^j r$, $j=0,1,\dots,n$,

[15] More precisely, A is rough but with the roughness parameter $\hbar$ which is a bit too small.

and let us estimate an error appearing when we replace in (modified) (27.3.52) $e^{ih^{-1}tH}\psi^+$ by

$$e^{ih^{-1}(t-t_n)H}\psi^+_{n+1}e^{ih^{-1}t_nH}\psi^+_n\cdots e^{ih^{-1}t_1H}\psi^+_1e^{ih^{-1}t_0H}\psi^+ \tag{27.3.53}$$

with ψ^+_j defined similarly and Hamiltonian flow from $\mathsf{supp}(\psi^+_j)$ for $t=t_j$ is inside $\{(x,\xi)\colon \psi^+_{j+1}(x,\xi)=1\}$. Therefore we need to estimate an error when we insert ψ^+_j.

According to our propagation results (namely, Proposition 27.2.11) after $\psi^+_1,\dots,\psi^+_{j-1}$ were inserted, insertion of ψ^+_j brings a relative error not exceeding $C\big(\hbar_j^\theta \|\partial A\|_{\theta,Y_j}+\hbar_j^{s+1}\big)$, where $\hbar_j=hr_j^{-\frac12}$ and Y_j is an ϵr_j-vicinity of the x-projection of $\mathsf{supp}(\psi_j)$; s is an arbitrarily large exponent.

Recall that $\|\partial A\|_{\theta,Y_j}\le C\kappa\hbar_j^{1-\theta}$ for $\theta\in(1,2)$; therefore this relative error does not exceed $C\hbar_j(\kappa+\hbar_j^s)$. Therefore inserting all ψ^+_j brings a relative error $C\sum_{j\ge0}\hbar_j(\kappa+\hbar_j^s)\asymp C\hbar(\kappa+\hbar^s)$ and since a priory expression (27.3.52) is bounded by $C\hbar^{-3}T$ we conclude that

(27.3.54) The absolute value of expression (27.3.52) with $\bar\chi_T(t)$ replaced by $\chi_{T'}(t)$ with $T_*\asymp r^{\frac32}\le T'\le T^*$ [16] does not exceed $C\hbar^{-2}(\kappa+\hbar^s)T'$.

Then an absolute value of expression (27.3.52) with $\bar\chi_T(t)$ replaced by $(\bar\chi_T(t)-\bar\chi_{T_*})$ does not exceed $C\hbar^{-2}(\kappa+\hbar^s)$ and since expression (27.3.52) with $T=T_*$ does not exceed $C\hbar^{-2}t_0$ we conclude that

(27.3.55) The absolute value of expression (27.3.52) with $T_*\le T\le T^*$ does not exceed $C\hbar^{-2}T_*+C\hbar^{-2}(\kappa+\hbar^s)T$.

Then we conclude that

(27.3.56) An error when we replace $\mathsf{Tr}\big(\theta(-H_{A,V})\psi\big)$ by its Tauberian expression with "time" T does not exceed $C\hbar^{-2}\big(T_*T^{-1}+\kappa+\hbar^s\big)$

and

(27.3.57) An error when we replace $\mathsf{Tr}\big(H^-_{A,V}\psi\big)$ by its Tauberian expression with "time" T does not exceed $C\hbar^{-1}\big(T_*T^{-1}+\kappa+\hbar^s\big)T_*T^{-1}\zeta^2$.

---

[16] We discuss the choice of T^* later.

In the latter statement we need to remember how everything scales.

Observe that presence of the magnetic field due to its estimates relatively perturbs dynamics by $O(\kappa)$ and therefore if κ is sufficiently small (i.e. $\kappa \le \kappa^*$) it does not affect T^*. Then assuming that

$$|\nabla^\alpha (V - V^0)| \le \epsilon a^{-1} r^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le 1, \qquad V^0 = Z r^{-1} \text{ with } \quad Z \asymp 1, \quad a \ge h^{2-\delta} \tag{27.3.58}$$

we can take $T^* \asymp a^{\frac{3}{2}}$ and therefore we conclude that the Tauberian error in (27.3.57) does not exceed

$$Ch^{-1} a^{-\frac{3}{2}} r \bigl(r^{\frac{3}{2}} a^{-\frac{3}{2}} + \kappa + h^s r^{-\frac{1}{2}s}\bigr) \tag{27.3.59}$$

and we arrive to Statement (i) in Proposition 27.3.13 below.

Meanwhile, the Tauberian error in $\mathsf{Tr}\bigl((H^-_{A,V} - H^-_{A,V^0})\psi\bigr)$ does not exceed

$$Ca^{-1} h^{-2} r \bigl(r^{\frac{3}{2}} a^{-\frac{3}{2}} + \kappa + h^s r^{-\frac{1}{2}s}\bigr) \tag{27.3.60}$$

and we arrive to Statement (ii) below:

Proposition 27.3.13. *Assume that* (27.3.58) *is fulfilled and let ψ be ℓ-admissible function supported in $\{x\colon \ell(x) \asymp r\}$ with $h^2 \le r \le a$. Let A satisfy minimizer estimate. Then*

(i) The Tauberian error with $T = T^* \asymp a^{\frac{3}{2}}$ in $\mathsf{Tr}\bigl(H^-_{A,V}\psi\bigr)$ does not exceed (27.3.59)*.*

(ii) The Tauberian error with $T = T^* \asymp a^{\frac{3}{2}}$ in $\mathsf{Tr}\bigl((H^-_{A,V} - H^-_{A,V^0})\psi\bigr)$ does not exceed (27.3.60)*.*

Proof. An easy proof following arguments of Section 12.6 is left to the reader. □

Observe that in the deduction of Statement (i) summation with respect to $r : b \le r \le a$ returns $Ch^{-1}a^{-\frac{1}{2}}$ and in the deduction of (ii) summation with respect to $r : h^2 \le r \le b$ returns $Ch^{-2}\bigl(a^{-\frac{5}{2}} b^{\frac{5}{2}} + \kappa a^{-1} b\bigr) + Ca^{-1}$. Note also that Statement (ii) remains true for r-admissible function supported in $\{x\colon \ell(x) \le r\}$ with $r \asymp h^2$. Then we arrive to

Corollary 27.3.14. *Assume that* (27.3.58) *is fulfilled. Then*

(i) Let ϕ_2 be ℓ-admissible function supported in $\{x\colon b \le \ell(x) \le a\}$. Then the Tauberian error with $T = T^* \asymp a^{\frac{3}{2}}$ in $\mathsf{Tr}\big(H^-_{A,V}\phi_2\big)$ does not exceed $Ch^{-1}a^{-\frac{1}{2}}$.

(ii) Let ϕ_1 be ℓ-admissible function supported in $\{x\colon \ell(x) \le b\}$. Then the Tauberian error with $T = T^* \asymp a^{\frac{3}{2}}$ in $\mathsf{Tr}\big((H^-_{A,V} - H^-_{A,V^0})\phi_1\big)$ does not exceed $Ch^{-2}\big(a^{-\frac{5}{2}}b^{\frac{5}{2}} + \kappa a^{-1}b\big) + Ca^{-1}$.

Remark 27.3.15. Obviously we do not need any new assumptions on κ to estimate the sum of expressions obtained in Statements (i) and (ii) of Corollary 27.3.14 by $Ch^{-1}a^{-\frac{1}{2}}$ (as $b \le a^{\frac{1}{2}}h$) here but we need to move from Tauberian expression to Weyl expression.

Improved Weyl Estimates

Note that in virtue of (27.3.54) for element ψ the contribution of the time interval $\{t\colon |t| \asymp T'\}$ to the Tauberian expression for $\mathsf{Tr}\big(H^-_{A,V}\psi\big)$ does not exceed $C\hbar^{-1}\big(\kappa + \hbar^s\big)T_*T'^{-1}\zeta^2$, and therefore, replacing $\bar\chi_T(t)$ by $\bar\chi_{T_*}(t)$ we introduce an error not exceeding

$$C\hbar^{-1}\big(\kappa + \hbar^s\big)\zeta^2 \asymp Ch^{-1}r^{-\frac{1}{2}}\big(\kappa + h^s r^{-\frac{1}{2}s}\big) \tag{27.3.61}$$

and summation with respect to $r : b \le r \le a$ returns

$$Ch^{-1}b^{-\frac{1}{2}}\big(\kappa + h^s b^{-\frac{1}{2}s}\big). \tag{27.3.62}$$

On the other hand, also in virtue of (27.3.54) for element ψ the contribution of the time interval $\{t\colon |t| \asymp T'\}$ to the Tauberian expression for $\mathsf{Tr}\big((H^-_{A,V} - H^-_{A,V^0})\psi\big)$ does not exceed $C\hbar^{-2}a^{-1}\big(\kappa + \hbar^s\big)$, and therefore replacing $\bar\chi_T(t)$ by $\bar\chi_{T_*}(t)$ we introduce an error not exceeding

$$Ch^{-2}a^{-1}r\big(\kappa + h^s r^{-\frac{1}{2}s}\big)|\log T/T_*|.$$

Further, in virtue of (27.3.55) the Tauberian error does not exceed $Ch^{-2}a^{-1}r\big(r^{\frac{3}{2}}T^{-1} + \kappa + h^s r^{-\frac{1}{2}s}\big)$, and adding these two errors together and optimizing their sum by $T \le a^{\frac{3}{2}}$ we get $T \asymp r^{\frac{5}{2}}(\kappa + h^s r^{-\frac{1}{2}s})^{-1}$ and the sum

$$Ch^{-2}a^{-1}r\big(\kappa + h^s r^{-\frac{1}{2}s}\big)\big(|\log(\kappa + h^s r^{-\frac{1}{2}s})| + 1\big) + Ch^{-2}a^{-\frac{5}{2}}r^{\frac{5}{2}}. \tag{27.3.63}$$

Meanwhile repeating arguments of Subsection 27.3.3 one can see easily that

(27.3.64) The difference between the Tauberian expression with $T = T_*$ and the Weyl expression for $\mathsf{Tr}\big(H^-_{A,V}\psi\big)$ does not exceed (27.3.61) with any $s < 2$

and

(27.3.65) The difference between the Tauberian expression with $T = T_*$ and the Weyl expression for $\mathsf{Tr}\big((H^-_{A,V} - H^-_{A,V^0})\psi\big)$ does not exceed

$$Ch^{-2}a^{-1}r\big(\kappa + h^s r^{-\frac{1}{2}s}\big) \tag{27.3.66}$$

with any $s < 2$ and thus does not exceed (27.3.63).

Summation with respect to $r : h^2 \le r \le b$ of (27.3.63) returns

$$Ch^{-2}a^{-1}b\kappa|\log\kappa| + Ch^{-2}b^{\frac{5}{2}}a^{-\frac{5}{2}} + Ca^{-1}; \tag{27.3.67}$$

adding expression (27.3.62) and optimizing the sum by b: $h^2 \le b \le a$ we get $b \asymp (ah|\log\kappa|)^{\frac{2}{3}}$ and expression

$$Ch^{-\frac{4}{3}}a^{-\frac{1}{3}}\kappa|\log\kappa|^{\frac{1}{3}} + Ch^{-1}a^{-\frac{1}{2}}. \tag{27.3.68}$$

Thus we have proven

Proposition 27.3.16. *(i) In the framework of Proposition 27.3.11*

$$\mathsf{Tr}\big(\psi(H^-_{A,V} - H^-_{A,V^0})\psi\big) = \tag{27.3.69}$$
$$\int \big(\mathsf{Weyl}_1(x) - \mathsf{Weyl}^0_1(x)\big)\,\psi^2(x)\,dx + O\big(h^{-\frac{4}{3}}a^{-\frac{1}{3}}\kappa|\log\kappa|^{\frac{1}{3}} + h^{-1}a^{-\frac{1}{2}}\big).$$

(ii) In particular, if

$$\kappa \le ca^{-\frac{1}{6}}h^{\frac{1}{3}}|\log ah^{-2}|^{-\frac{1}{3}} \tag{27.3.70}$$

the error in (27.3.69) *does not exceed* $Ch^{-1}a^{-\frac{1}{2}}$ *exactly as in the case without magnetic field.*

Remark 27.3.17. (i) Obviously we could consider $a = 1$ and then just rescale $x \mapsto xa^{-1}$, $\tau \mapsto \tau a$, $h \mapsto ha^{-\frac{1}{2}}$.

(ii) One may wonder if the same approach works for estimate of A. First of all, there is no improvement for estimate for $|\partial^2 A|$ because it follows from the estimate for $|\Delta A|$ which is a pointwise estimate.

(iii) Still, since ∂A and A are mollifications of ΔA one can improve estimates for them if $\kappa \ll 1$ and $\ell \ll a$; however, there are no improvements if either $\kappa \asymp 1$ or $\ell \ge a$. Since these improvements do not lead to the improvements of our final results we do not pursue them.

27.3.5 Single Singularity

Coulomb Potential

Consider now exactly Coulomb potential: $V = Z|x|^{-1}$. Let us establish the existence of the Scott correction:

Proposition 27.3.18. *Let $V = Z|x|^{-1}$, $h > 0$, $Z > 0$ and $0 < \kappa \le \kappa^*$. Then*

(i) The following limit exists

$$\lim_{r\to\infty}\Biggl(\inf_{A}\Bigl(\mathsf{Tr}\bigl((\phi_r H_{A,V}\phi_r)^-\bigr)+\frac{1}{\kappa h^2}\int |\partial A|^2\,dx\Bigr) - \int \mathsf{Weyl}_1(x)\phi_r^2(x)\,dx\Biggr) =: 2Z^2h^{-2}S(Z\kappa). \tag{27.3.71}$$

(ii) And it coincides with

$$\lim_{\eta\to 0^+}\Biggl(\inf_{A,V}\Bigl(\mathsf{Tr}\bigl((H_{A,V}+\eta)^-\bigr)\Bigr)+\frac{1}{\kappa h^2}\int |\partial A|^2\,dx - \int \mathsf{Weyl}_1(H_{A,V}+\eta,x)\,dx\Biggr), \tag{27.3.72}$$

(iii) And also with

$$\inf_{A}\Biggl(\int \Bigl(e_1(H_{A,V};x,x,0)-\mathsf{Weyl}_1(H_{A,V},x)\Bigr)\,dx+ \frac{1}{\kappa h^2}\int |\partial A|^2\,dx\Biggr). \tag{27.3.73}$$

(iv) We also can replace in Statement (i) $\mathsf{Tr}\big((\phi_r H_{A,V}\phi_r)^-\big)$ *by* $\mathsf{Tr}\big(\phi_r H^-_{A,V}\phi_r\big)$.

Here $\phi \in \mathscr{C}_0^\infty(B(0,1))$, $\phi = 1$ *in* $B(0,\frac12)$, $\phi_r = \phi(x/r)$.

Proof. Observe first that due to scaling $x \mapsto Zh^{-2}x$, $A \mapsto Z^{-1}hA$ and $\partial A \mapsto z^{-2}h^3\partial A$ one needs to consider only $Z = h = 1$; all expressions on the left scale exactly as $Z^2h^{-2}S(Z\kappa)$.

(i) Let us compare

$$Q(r,\kappa,A) \coloneqq \mathsf{Tr}\big((\phi_r H_{A,V}\phi_r)^-\big) - \int \mathsf{Weyl}_1(H_{A,V},x)\phi_r^2(x)\,dx + \frac{1}{\kappa}\int |\partial A|^2\,dx$$

and $Q(r',\kappa,A)$ with $r \ge 1$ and $r' \ge 2r$. Note that

$$\begin{aligned} Q(r',\kappa,A) \ge\ & Q(r,(1+\epsilon)\kappa,A) + \\ & \sum_{1\le j\le J}\Big(\mathsf{Tr}\big((\psi_{2^jr}H_{A,V}\psi_{2^jr})^-\big) - \int \mathsf{Weyl}_1(H_{A,V},x)\psi_{2^jr}^2(x)\,dx + \\ & \qquad \frac{\epsilon}{2\kappa}\int |\partial A|^2\bar\psi_{2^jr}^2(x)\,dx\Big), \end{aligned}$$

where ψ and $\bar\psi$ are smooth compactly supported functions, equal 0 in $B(0,\frac12)$ and $\bar\psi = 1$ in the vicinity of $\mathsf{supp}(\psi)$, $J = \lfloor \log_2 r'/r\rfloor$, $\epsilon > 0$ is arbitrarily small.

Therefore we can replace in the sum A by A_j and $\bar\psi_{2^jr}$ by 1 in $\int |\partial A|^2\bar\psi_{2^jr}^2(x)\,dx$; but then in the virtue of Section 27.2 each term in the sum is bounded from below by $-C'(\epsilon)\int \rho^3\ell^{-1}\bar\psi_t\,dx = -C'(\epsilon)t^{-\frac12}$ with $t = 2^jr$. Then

$$Q(r',\kappa,A) \ge Q(r,(1+\epsilon)\kappa,A) - C'(\epsilon)r^{-\frac12}. \tag{27.3.74}$$

We know that $Q(r,(1+\epsilon)\kappa,A)$ is bounded from below by $-C(r)$ but now we conclude that this bound is uniform with respect to r, which implies that $2S(\kappa) \coloneqq \liminf_{r\to+\infty}\inf_A Q(r,\kappa,A) > -\infty$. Further, (27.3.74) implies that

$$2S(\kappa) + C'(\epsilon)r^{-\frac12} \ge \inf_A Q(r,(1+\epsilon)\kappa,A)$$

and therefore

$$\limsup_{r\to+\infty}\inf_A Q(r,\kappa,A) \le 2S((1+\epsilon)^{-1}\kappa). \tag{27.3.75}$$

Furthermore, plugging $A=0$ we can see easily that $Q(r,\kappa,A)$ is uniformly bounded from above and therefore $2S(\kappa)<+\infty$; also our arguments imply that $\int |\partial A|^2\,dx$ is uniformly bounded for near optimizers and therefore $S(\kappa)$ is continuous with respect to $\kappa<\kappa^*$; combining with (27.3.75) we arrive to Statement (i).

(ii) Similarly, (27.3.74) holds with $H_{A,V}$ replaced by $H_{A,V}+\eta$ and then we can take $r'=\infty$ and apply $\inf_A$ to both sides arriving to

$$\inf_A\Biggl(\mathsf{Tr}\bigl((H_{A,V}+\eta)^-\bigr)-\int \mathsf{Weyl}_1(H_{A,V+\eta},x)\,dx+\frac{1}{\kappa}\int|\partial A|^2\,dx\Biggr)\geq \inf_A\Biggl(\mathsf{Tr}\bigl((\phi_r(H_{A,V}+\eta)\phi_r)^-\bigr)-\int \mathsf{Weyl}_1(H_{A,V+\eta},x)\phi_r^2(x)\,dx+ \frac{1}{(1+\epsilon)\kappa}\int|\partial A|^2\Biggr)\,dx-C'(\epsilon)r^{-\frac12}.$$

After this as $\eta\to+0$ the right-hand expression tends to itself with $\eta=0$; tending $r\to+\infty$ we get there $2S((1+\epsilon)\kappa)$ in virtue of Statement (i) and tending $\epsilon\to+0$ we arrive to

$$\liminf_{\eta\to+0}\inf_A\Biggl(\mathsf{Tr}\bigl((H_{A,V}+\eta)^-V-\int \mathsf{Weyl}_1(H_{A,V+\eta},x)\,dx+ \frac{1}{\kappa}\int|\partial A|^2\,dx\Biggr)\geq 2S(\kappa). \tag{27.3.76}$$

On the other hand, consider

$$\mathsf{Tr}\bigl((H_{A,V}+\eta)^-\bigr)-\int \mathsf{Weyl}_1(H_{A,V+\eta},x)\,dx+\frac{1}{\kappa}\int|\partial A|^2\,dx$$

and replace $\mathsf{Tr}\bigl((H_{A,V}+\eta)^-\bigr)$ by

$$\underbrace{\mathsf{Tr}\bigl((H_{A,V}+\eta)^-\phi_r^2\bigr)+\frac{1}{\kappa}\int|\partial A|^2\,dx}+\mathsf{Tr}\bigl((H_{A,V}+\eta)^-(1-\phi_r^2)\bigr). \tag{27.3.77}$$

Let A be a minimizer of the first expression; then in virtue of Propositions 27.2.24–27.2.26 this minimizer is sufficiently "good" on ϵr-vicinity of $\mathsf{supp}(1-\phi_r^2)$ and also the the difference between the second term and its Weyl expression does not exceed $Cr^{-\frac12}$; one can prove it easily by $\ell(x)$-admissible

partition of unity as in Part (i) of the proof and we leave details to the reader.

Observe that the first term in (27.3.77) is $\inf_A \mathsf{Tr}\big(\phi_r \big(H_{A,V}+\eta\big)^{-}\phi_r\big)$. In this expression we can take limit as $\eta \to +0$ just setting $\eta = 0$ and therefore the left-hand expression in (27.3.76) with $\liminf$ replaced by $\limsup$ does not exceed

$$\inf_A \Big(\mathsf{Tr}\big(\phi_r H^{-}_{A,V}\phi_r\big) - \int \mathsf{Weyl}_1(H_{A,V},x)\phi_r^2(x)\,dx + \frac{1}{\kappa}\int |\partial A|^2\,dx\Big) + Cr^{-\frac{1}{2}};$$

taking limit as $r \to +\infty$ we conclude that the left-hand expression in (27.3.76) with $\liminf$ replaced by $\limsup$ does not exceed

$$\liminf_{r\to+\infty}\inf_A \Big(\mathsf{Tr}\big(\phi_r H^{-}_{A,V}\phi_r\big) - \int \mathsf{Weyl}_1(H_{A,V},x)\phi_r^2(x)\,dx + \frac{1}{\kappa}\int |\partial A|^2\,dx\Big).$$

This expression does not exceed (27.3.71) and therefore combining with (27.3.76) we prove Statements (ii) and (iv).

(iii) Similarly,

$$\int \Big(e_1(H_{A,V};x,x,0) - \mathsf{Weyl}_1(H_{A,V},x)\Big)\phi_r^2(x)\,dx + \frac{1}{\kappa}\int |\partial A|^2\,dx \ge$$
$$\inf_A \Big(\mathsf{Tr}\big((\phi_r H_{A,V}\phi_r)^{-}\big) - \int \mathsf{Weyl}_1(x)\phi_r^2(x)\,dx + \frac{1}{\kappa}\int |\partial A|^2\Big) - Cr^{-\frac{1}{2}}$$

and therefore

$$\inf_A \liminf_{r\to\infty} \int \Big(e_1(H_{A,V};x,x,0) - \mathsf{Weyl}_1(H_{A,V},x)\Big)\phi_r^2(x)\,dx+$$
$$\frac{1}{\kappa}\int |\partial A|^2\,dx \ge 2S(\kappa).$$

On the other hand, as in Part (ii) of the proof, taking A to be a minimizer of the first expression in (27.3.77), we see that

$$\inf_A \limsup_{r\to\infty} \int \Big(e_1(H_{A,V};x,x,0) - \mathsf{Weyl}_1(H_{A,V},x)\Big)\phi_r^2(x)\,dx+$$
$$\frac{1}{\kappa}\int |\partial A|^2\,dx \le 2S(\kappa)$$

and Statement (iii) has been proven. □

Remark 27.3.19. (i) Statements similar to (i), (ii) were proven in L. Erdös, S. Fournais, and J. P. Solovej [3] (see Theorem 2.4 and Lemma 2.5 respectively).

(ii) Again as observed in in L. Erdös, S. Fournais, and J. P. Solovej [3] we do not know if

(a) $S(\kappa) < S(0) = \frac{1}{2}$ for $\kappa > 0$ or just

(b) $S(\kappa) = S(0)$ for $\kappa < \kappa^*$ and $S(\kappa) = -\infty$ for $\kappa > \kappa^*$.

If we knew that the optimizer is unique, then obviously $A = 0$ and it would be relatively easy but rather unexciting the latter case.

(iii) While we assumed that $\kappa < \kappa^*$ with $\kappa^* > 0$ and it is possible that $S(\kappa) = -\infty$ as $\kappa > \kappa^*$ with some $\kappa^* < \infty$ we are not aware about any proof of this, so in fact it could happen that $\kappa^* = +\infty$ and then condition $\kappa < \kappa^*$ is superficial and one needs to study asymptotics of $S(\kappa)$ as $\kappa \to +\infty$.

Proposition 27.3.20. *For* $0 < \kappa < \kappa'$

$$S(\kappa') \le S(\kappa) \le S(\kappa') + C\kappa'(\kappa^{-1} - \kappa'^{-1}). \tag{27.3.78}$$

Proof. Monotonicity of $S(\kappa)$ is obvious.

Let $0 < \kappa < \kappa' < \kappa'' \le \kappa^*$. Then for any $\varepsilon > 0$ if $r = r_\varepsilon$ is large enough then the left-hand expression in (27.3.71) for κ' (without $\inf$ and $\lim$) is greater than $S(\kappa'') - \varepsilon + (\kappa'^{-1} - \kappa''^{-1})\|\partial A\|^2$; also, if A is an almost minimizer there, it is less than $S(\kappa') + \varepsilon$.

Therefore $(\kappa'^{-1} - \kappa''^{-1})\|\partial A\|^2 \le |S(\kappa'') - S(\kappa')| + 2\varepsilon$. But then

$$\begin{aligned} S(\kappa) - \varepsilon \le S(\kappa') + \varepsilon + (\kappa^{-1} - \kappa'^{-1})\|\partial A\|^2 \le \\ S(\kappa') + \varepsilon + C(\kappa^{-1} - \kappa'^{-1})(\kappa'^{-1} - \kappa''^{-1})^{-1}\big(|S(\kappa'') - S(\kappa')| + 2\varepsilon\big) \end{aligned}$$

and therefore

$$(\kappa^{-1} - \kappa'^{-1})^{-1}|S(\kappa) - S(\kappa')| \le (\kappa'^{-1} - \kappa''^{-1})^{-1}|S(\kappa') - S(\kappa'')| \tag{27.3.79}$$

which for $\kappa'' = \kappa^*$ implies (27.3.78). □

Remark 27.3.21. Using global equation (27.2.14) we conclude that for $Z = h = 1$

$$|\partial^\alpha A| \le C\kappa \ell^{-1-|\alpha|} \qquad \text{if } \ell \ge 1,\ |\alpha| \le 1, \tag{27.3.80}$$

$$|\partial^\alpha A| \le C\kappa \qquad \text{if } \ell \le 1,\ |\alpha| \le 1, \tag{27.3.81}$$

$$\|\partial A\|^2 \le C\kappa^2. \tag{27.3.82}$$

Then

$$S'(\kappa) \le C, \qquad |S(\kappa(1+\eta)) - S(\eta)| \le C\kappa\eta. \tag{27.3.83}$$

Main Theorem

In the "atomic" case $M = 1$ we arrive instantly to the following theorem:

Theorem 27.3.22. *Let $M = 1$ and $\kappa \le \kappa^*$. Then*

(i) Asymptotics holds

$$\mathsf{E}^* = \int \mathsf{Weyl}_1(x)\,dx + 2z^2 S(z\kappa)h^{-2} + O(h^{-\frac{4}{3}}\kappa|\log\kappa|^{\frac{1}{3}} + h^{-1}). \tag{27.3.84}$$

(ii) If $\kappa = o(h^{\frac{1}{3}}|\log h|^{-\frac{1}{3}})$, then

$$\mathsf{E}^* = \int \mathsf{Weyl}_1^*(x)\,dx + 2z^2 S(z\kappa)h^{-2} + o(h^{-1}). \tag{27.3.85}$$

Proof. If A satisfies the minimizer properties, then in virtue of Proposition 27.3.16

$$\mathsf{Tr}^-(H_{A,V}) - \int \mathsf{Weyl}_1(x)\,dx \equiv \mathsf{Tr}^-(H_{A,V^0}) - \int \mathsf{Weyl}_1^0(x)\,dx + O(h^{-\frac{4}{3}}\kappa|\log\kappa|^{\frac{1}{3}} + h^{-1}) \tag{27.3.86}$$

and adding magnetic energy and plugging either minimizer for V or for V^0 we get

$$\begin{aligned}\inf_A \Big(\mathsf{Tr}^-(H_{A,V}) - \int \mathsf{Weyl}_1(x)\,dx + \frac{1}{\kappa h^2}\int |\partial A|^2\,dx\Big) \lessgtr \\ \inf_A \Big(\mathsf{Tr}^-(H_{A,V^0}) - \int \mathsf{Weyl}_1^0(x)\,dx + \frac{1}{\kappa h^2}\int |\partial A|^2\,dx\Big) \\ \pm C(h^{-\frac{4}{3}}\kappa|\log\kappa|^{\frac{1}{3}} + h^{-1}).\end{aligned} \tag{27.3.87}$$

Obviously if V (and surely V^0) are not sufficiently fast decaying at the infinity, the left (and for sure the right hand) expression in (27.3.86) should be regularized as in Subsubsection *27.3.5.1. Coulomb Potential*. However for potential decaying fast enough (faster than $|x|^{-2-\delta}$) the regularization is not needed.

For V^0 we have an exact expression which concludes the proof of Statement (i).

The proof of Statement (ii) is similar albeit with the small improvement, based on the behavior of the classical dynamics (without magnetic field) exactly as in Chapter 25. □

27.3.6 Several Singularities

Consider now the "molecular" case $M \ge 2$. Then we need more delicate arguments.

Decoupling of Singularities

Consider partition of unity $1 = \sum_{0\le m\le M} \psi_m^2$ where ψ_m is supported in $\frac{1}{3}a$-vicinity of y_m for $m = 1, \dots, M$ and $\psi_0 = 0$ in $\frac{1}{4}a$-vicinities of y_m ("near-nuclei" and "between-nuclei"partition elements).

Estimate from above. Then

$$\mathsf{Tr}(H^-_{A,V}) = \sum_{0\le m\le M} \mathsf{Tr}(\psi_m H^-_{A,V}\psi_m), \tag{27.3.88}$$

and to estimate E^* from the above we impose an extra condition to A:

$$A = 0 \qquad \text{for } \ \ell(x) \ge \frac{1}{5}a. \tag{27.3.89}$$

Then in this framework we estimate

$$\mathsf{Tr}^-(\psi_0 H^-_{A,V}\psi_0) - \int \mathsf{Weyl}_1(x)\psi_0^2(x)\,dx \le Ch^{-1}a^{-\frac{1}{2}}. \tag{27.3.90}$$

Proof of this inequality is trivial by using ℓ-admissible partition and applying results of the theory without any magnetic field.

Thus, to estimate E^* from above[17] we just need to estimate from above the minimum with respect to A satisfying (27.3.89) of the expression

$$\mathsf{Tr}(\psi_m H^-_{A,V}\psi_m) - \int \mathsf{Weyl}_1(x)\psi_m^2(x)\,dx + \frac{1}{\kappa h^2}\int_{\{\ell_m(x)\le \frac{1}{5}a\}} |\partial A|^2\,dx. \tag{27.3.91}$$

Estimate from below. In this case we use the same partition of unity $\{\psi_m^2\}_{j=0,1,\dots,M}$ and estimate

$$\mathsf{Tr}(H^-_{A,V}) \ge \sum_{0\le m\le M} \mathsf{Tr}^-(\psi_m H_{A,V'}\psi_m) \tag{27.3.92}$$

with

$$V' = V + 2h^2 \sum_{0\le m\le M} (\partial\psi)^2, \tag{27.3.93}$$

and we also use decomposition

$$\int |\partial A|^2\,dx = \sum_{0\le m\le M}\int \omega_m^2 |\partial A|^2\,dx \tag{27.3.94}$$

with

$$\omega_m(x) = 1 \ \text{ if } \ \ell_m(x) \le \frac{1}{10}a, \quad \omega_m(x) \ge 1 - C\varsigma \ \text{ if } \ \ell_m(x) \le \frac{1}{2}a \quad \text{for } \ m = 1, \dots, M, \tag{27.3.95}$$

$$\omega_0 \ge \epsilon_0\varsigma \quad \text{if } \ \ell(x) \ge \frac{1}{5}a. \tag{27.3.96}$$

So far $\varsigma > 0$ is a constant but later it will become a small parameter. Then since

$$\mathsf{Tr}^-(\psi_0 H_{A,V'}\psi_0) - \int \mathsf{Weyl}_1(x)\psi_0^2(x)\,dx + \frac{1}{\kappa h^2}\int \omega_0^2|\partial A|^2\,dx \ge Ch^{-1}a^{-\frac{1}{2}} \tag{27.3.97}$$

(again proven by partition) in virtue of the previous Section 27.2 we are left with the estimates from below for

$$\mathsf{Tr}^-(\psi_m H_{A,V'}\psi_m) - \int \mathsf{Weyl}_1(x)\psi_m^2(x)\,dx + \frac{1}{\kappa h^2}\int \omega_m^2|\partial A|^2\,dx. \tag{27.3.98}$$

[17] Modulo error in (27.3.51).

Remark 27.3.23. (i) Note that the error in Weyl_1 when we replace V' there by V does not exceed $Ch^{-1}(1+a^{-\frac12})$ which is less than the error in (27.3.51). Here we can also assume that A satisfies (27.3.89); we need just to replace ς by $\epsilon_0\varsigma$ in (27.3.95)–(27.3.96).

(ii) We can further go down by replacing $\mathsf{Tr}^-(\psi_m H_{A,V'}\psi_m)$ by $\mathsf{Tr}(\psi_m H^-_{A,V'}\psi_m)$.

(iii) Therefore we basically have the same object for both estimates albeit with marginally different potentials (V in the estimate from above and V' in the estimate from below) and with a weight ω_m^2 satisfying (27.3.95)–(27.3.96); in both cases $\omega=1$ if $\ell(x)\le \frac{1}{10}a$ but in the estimate from above $\omega(x)$ grows to C_0 and in the estimate from below $\omega(x)$ decays to ς if $\ell(x)\ge \frac13 a$ and in both cases condition (27.3.89) could be either imposed or skipped.

(iv) From now on we consider a single singularity at 0 and we skip subscript m. However if there was a single singularity from the beginning, all arguments of this and forthcoming paragraphs would be unnecessary.

Scaling. Now we apply scaling arguments:

(i) We are done as $Z\asymp 1$ but as $Z\ll 1$ [18] we need a bit more fixing. The problem is that $V\asymp Z\ell^{-1}$ only for $|x|\le aZ$; otherwise $V\lesssim a^{-1}$ (where we still assume that $a\le 1$). To deal with this we apply in the zone $\{x\colon aZ\le |x|\le a\}$ the same procedure as before and its contribution to the error will be $Ch^{-1}a^{-\frac12}$ as $\rho=a^{-\frac12}$ here. Actually we also need to keep $|x|\ge Z^{-1}h^2$; so we assume that $Z^{-1}h^2\le Za$, i.e. $Z\ge a^{-\frac12}h$.

Now let us scale $x\mapsto x'=x(aZ)^{-1}$, and multiply $H_{a,V}$ by a and therefore also multiply A by $a^{\frac12}$, so $A\mapsto A'=a^{\frac12}A$, $h\mapsto h'=ha^{-\frac12}Z^{-1}$; then the magnetic energy becomes

$$\kappa^{-1}h^{-2}Z\int \omega^2(x)|\partial' A'|^2\,dx',$$

where factors a^{-1} and aZ come from substitution $A=a^{-\frac12}A'$ and scaling respectively. We need to multiply it by a (since we multiplied an operator); then plugging $h^{-2}=h'^{-2}a^{-1}Z^{-2}$ we get the same expression as before but with $Z'=1$, $a'=1$ and $h'=ha^{-\frac12}Z^{-1}\le 1$ and $\kappa'=\kappa Z$ instead of h and κ.

[18] Since Z denotes Z_m now we assume only that $Z_1+\ldots+Z_M\asymp 1$.

If we prove here an error $O\big(h'^{-1}+\kappa'|\log\kappa'|^{\frac{1}{3}}h'^{-\frac{4}{3}}\big)$, then the final error will be this expression multiplied by a^{-1}, i.e. $O\big(a^{-\frac{1}{2}}Zh^{-1}+\kappa a^{-\frac{1}{2}}Z^{\frac{7}{3}}|\log\kappa Z|^{\frac{1}{3}}h^{-\frac{4}{3}}\big)$, which is less than the same expression with $Z=1$.

(ii) On the other hand, let $Z\le a^{-\frac{1}{2}}h$. Recall, we assume that $a\ge C_0h^2$. Then we can apply the same arguments as before but with $\bar{Z}=a^{-\frac{1}{2}}h$ and we arrive to the same situation as before albeit with $h'=1$, $a'=1$, $\kappa'=\kappa a^{-\frac{1}{2}}h$ and with $Z'=Z\bar{Z}^{-1}$. Then we have the trivial error estimate $O(a^{-1})$ which is less than $O(a^{-\frac{1}{2}}h^{-1})$.

Main Results

Combining results of the previous subsubsections and paragraphs with Proposition 27.3.9 we arrive to

Theorem 27.3.24. *Let $M\ge 2$, $\kappa\le\kappa^*$ and (27.3.38) hold with $\nu>\frac{4}{3}$. Then*

(i) The following asymptotics holds

$$\mathsf{E}^*=\int \mathsf{Weyl}_1(x)\,dx+2\sum_{1\le m\le M} z_m^2 S(z_m\kappa)h^{-2}+O(R_1+R_2) \tag{27.3.99}$$

with

$$R_1=\begin{cases} h^{-1}+\kappa|\log\kappa|^{\frac{1}{3}}h^{-\frac{4}{3}} & \text{if } a\ge 1,\\ a^{-\frac{1}{2}}h^{-1}+\kappa|\log\kappa|^{\frac{1}{3}}a^{-\frac{1}{3}}h^{-\frac{4}{3}} & \text{if } h^2\le a\le 1\end{cases} \tag{27.3.100}$$

and

$$R_2=\kappa h^{-2}\begin{cases} a^{-3} & \text{if } a\ge |\log h|^{\frac{1}{3}},\\ |\log h^2a^{-1}|^{-1} & \text{if } h^2\le a\le |\log h|^{\frac{1}{3}}.\end{cases} \tag{27.3.101}$$

(ii) If $\kappa=o(h^{\frac{1}{3}}|\log h|^{-\frac{1}{3}})$, $\kappa a^{-3}=o(h)$ and $a^{-1}=o(1)$, then

$$\mathsf{E}^*=\int \mathsf{Weyl}_1^*(x)\,dx+2\sum_{1\le m\le M} z_m^2 S(z_m\kappa)h^{-2}+o(h^{-1}). \tag{27.3.102}$$

Proof. To prove theorem we need to prove the following estimate

$$\frac{1}{\kappa}\|\partial A\|^2_{\{b\le\ell(x)\le 2b\}},\le Cb^{-3} \tag{27.3.103}$$

where $r_* \le b \le a$ is a "cut-off". On the other hand, we know that

$$\frac{1}{\kappa}\|\partial A\|^2 = -\frac{\partial S}{\partial \kappa} = O(1) \tag{27.3.104}$$

and we need to recover the last factor in the definition of R_2.

For $a \ge 1$ we can have κa^{-3} because in virtue of (27.3.41) the square of the partial norm in (27.3.104) does not exceed $Ca^{-3}\kappa^2$.

On the other hand, for $h^2 \le r_* \le a$ we can select $b : r_* \le b \le a$ such that the partial norm in (27.3.104) does not exceed $C|\log(a/h^2)|^{-1} \cdot \|\partial A\|^2$. □

Remark 27.3.25. (i) For $a \le |\log h|$ we do not need assumption (27.3.38).

(ii) Following arguments of Section 12.6 estimates (27.3.85) and (27.3.104) could be improved to $O(h^{-1+\delta})$ provided $a \ge h^{-\delta_1}$, $\kappa \le h^{\frac{1}{3}+\delta_1}|\log h|^{-\frac{1}{3}}$ and $\kappa \le a^3 h^{1+\delta_1}$.

Problems and rRemarks

The following problem seems to be really challenging and we have no idea how to approach it:

Problem 27.3.26. (i) For $\kappa \in [0, \kappa^*]$ with small enough $\kappa^* > 0$ does $S(\kappa)$ really depend on κ or $S(\kappa) = S(0)$ (see Remark 27.3.19)?

(ii) If $S(\kappa)$ really depends on κ, what is asymptotic behavior of $S(\kappa) - S(0)$ as $\kappa \to +0$: can one improve $S(\kappa) - S(0) = O(\kappa)$?

(iii) Do we really need an assumption $\kappa \in [0, \kappa^*]$ (again see Remark 27.3.19)?

(iv) Can one improve estimates to minimizer?

27.4 Asymptotics of the Ground State Energy

27.4.1 Problem

Now we are ready to tackle our original object (27.1.2)–(27.1.3). So, let us consider our usual quantum Hamiltonian

$$\mathsf{H} = \sum_{1\le j\le N} H^0_{x_j} + \sum_{1\le j<k\le N} |x_j - x_k|^{-1} \tag{27.4.1}$$

in

$$\mathfrak{H} = \bigwedge_{1\le n\le N} \mathsf{H}, \qquad \mathsf{H} = \mathscr{L}^2(\mathbb{R}^3, \mathbb{C}^2) \tag{27.4.2}$$

with

$$H^0 = \big((i\nabla - A)\cdot \boldsymbol{\sigma}\big)^2 - V(x). \tag{27.4.3}$$

We are interested in the *ground state energy* $\mathsf{E}^*_N(A)$ of our system i.e. in the lowest eigenvalue of the operator H on $\mathfrak{H}$:

$$\mathsf{E}^*_N(0) = \inf \mathsf{Spec}(\mathsf{H}) \qquad \text{on} \quad \mathfrak{H} \tag{27.4.4}$$

if $A = 0$ and more generally in

$$\mathsf{E}^*_N = \inf_A \Big(\inf \mathsf{Spec}_{\mathfrak{H}}(\mathsf{H}) + \frac{1}{\alpha}\int |\nabla \times A|^2\, dx\Big), \tag{27.4.5}$$

where

$$V(x) = \sum_{1\le m\le M} \frac{Z_m}{|x - \mathsf{y}_m|} \tag{27.4.6}$$

$$N \asymp Z \gg 1, \qquad Z := Z_1 + \dots + Z_M, \qquad Z_1 > 0, \dots, Z_M > 0, \tag{27.4.7}$$

M is fixed, under assumption

$$0 < \alpha \le \kappa^* Z^{-1} \tag{27.4.8}$$

with sufficiently small constant $\kappa^* > 0$.

Our purpose is to derive an asymptotics

$$\mathsf{E}^*_N \approx \mathcal{E}^{\mathsf{TF}}_N + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m) \tag{27.4.9}$$

and estimate an error (usually) provided

$$b := \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge Z^{-\frac{1}{3}}. \tag{27.4.10}$$

Recall that the Thomas-Fermi potential W^{TF} and the Thomas-Fermi density ρ^{TF} satisfy equations

$$\rho^{\mathsf{TF}} = \frac{1}{3\pi^2}(W^{\mathsf{TF}} + \nu)^{\frac{3}{2}}_+ \tag{27.4.11}$$

and

$$W^{\mathsf{TF}} = V^0 + |x|^{-1} * \rho^{\mathsf{TF}}, \tag{27.4.12}$$

where ν is a chemical potential.

27.4.2 Lower Estimate

Consider corresponding to H quadratic form exactly as in Sections 25.2 and 26.6

$$\begin{aligned}(27.4.13)\quad \langle \mathsf{H}\Psi,\Psi\rangle &= \sum_j (H^0_{x_j}\Psi,\Psi) + (\sum_{1\le j<k\le N} |x_j-x_k|^{-1}\Psi,\Psi) = \\ &\sum_j (H_{x_j}\Psi,\Psi) + ((V-W)\Psi,\Psi) + (\sum_{1\le j<k\le N} |x_j-x_k|^{-1}\Psi,\Psi)\end{aligned}$$

with

$$(27.4.14)\qquad H = \big((i\nabla - A)\cdot\boldsymbol{\sigma}\big)^2 - W(x)$$

where we select W later. By Lieb-Oxford inequality the last term is estimated from below:

$$(27.4.15)\qquad \langle \sum_{1\le j<k\le N} |x_j-x_k|^{-1}\Psi,\Psi\rangle \ge \frac{1}{2}\mathsf{D}(\rho_\Psi,\rho_\Psi) - C\int \rho_\Psi^{\frac{4}{3}}\,dx,$$

where

$$(27.4.16)\qquad \rho_\Psi(x) = N\int |\Psi(x,x_2,\dots,x_N)|^2\,dx_2\cdots dx_N$$

is a spatial density associated with Ψ and

$$(27.4.17)\qquad \mathsf{D}(\rho,\rho') := \iint |x-y|^{-1}\rho(x)\rho'(y)\,dxdy.$$

Therefore again repeating arguments of Section 25.2 we estimate H from below:

$$\begin{aligned}(27.4.18)\quad &\langle \mathsf{H}\Psi,\Psi\rangle \ge \\ &\sum_j (H_{x_j}\Psi,\Psi) - 2((V-W)\Psi,\Psi) + \frac{1}{2}\mathsf{D}(\rho_\Psi,\rho_\Psi) - C\int \rho_\Psi^{\frac{4}{3}}\,dx = \\ &\sum_j (H_{x_j}\Psi,\Psi) - \mathsf{D}(\rho,\rho_\Psi) + \frac{1}{2}\mathsf{D}(\rho_\Psi,\rho_\Psi) - C\int \rho_\Psi^{\frac{4}{3}}\,dx = \\ &\sum_j (H_{x_j}\Psi,\Psi) - \frac{1}{2}\mathsf{D}(\rho,\rho) + \frac{1}{2}\mathsf{D}(\rho-\rho_\Psi,\rho-\rho_\Psi) - C\int \rho_\Psi^{\frac{4}{3}}\,dx\end{aligned}$$

swhere

$$W - V = |x|^{-1} * \rho. \tag{27.4.19}$$

Note that due to antisymmetricity of Ψ

$$\sum_j (H_{x_j}\Psi, \Psi) \geq \sum_{1\leq j\leq N:\ \lambda_j<0} \lambda_j \geq \mathsf{Tr}^-(H), \tag{27.4.20}$$

where λ_j are eigenvalues of H.

To estimate the last term in (27.4.18) we reproduce the proof of Lemma 4.3 from L. Erdös, S. Fournais and J. P. Solovej [3]:

According to magnetic Lieb–Thirring inequality for $U \geq 0$:

$$\sum_{j\leq N} \langle (H^0_{x_j} - U)\Psi, \Psi\rangle \geq -C\int U^{5/2}\,dx - C\gamma^{-3}U^4\,dx - \gamma\int B^2\,dx \tag{27.4.21}$$

where $B = \nabla \times A$, $\gamma > 0$ is arbitrary. Then, selecting $U = \beta\,\mathsf{min}(\rho_\Psi^{5/3}, \gamma\rho_\Psi^{4/3})$ with $\beta > 0$ sufficiently small but independent from γ, we ensure that $\frac{1}{2}U\rho_\Psi \geq CU^{5/2} + C\gamma^{-3}U^4$ and then

$$\sum_{j\leq N} \langle (H^0_{x_j})\Psi, \Psi\rangle \geq \epsilon\int \mathsf{min}(\rho_\Psi^{5/3}, \gamma\rho^{4/3})\,dx, -\gamma\int B^2\,dx, \tag{27.4.22}$$

which implies

$$\int \rho_\Psi^{4/3}dx \leq \gamma^{-1}\int \mathsf{min}(\rho_\Psi^{5/3}, \gamma\rho^{4/3})\,dx + \gamma\int \rho_\Psi\,dx \leq c\gamma^{-1}\sum_{j:\lambda_j<0} \langle (H^0_{x_j})\Psi, \Psi\rangle + c\int B^2\,dx + c\gamma N \tag{27.4.23}$$

where we use $\int \rho_\Psi\,dx = N$.

Remark 27.4.1. As one can prove easily (see also L. Erdös, S. Fournais and J. P. Solovej [3]) that

$$\sum_{j\leq N} \langle (H^0_{x_j})\Psi, \Psi\rangle \leq CZ^{\frac{4}{3}}N \tag{27.4.24}$$

even if $N \not\asymp Z$; then we conclude that

$$\int \rho_\Psi^{4/3} dx \le CZ^{\frac{2}{3}} N + C_1 \int B^2 \, dx. \tag{27.4.25}$$

It is sufficient unless we want to recover Dirac and Schwinger correction terms (given by (25.1.29) and (25.1.30) with $q = 2$) which unfortunately is possible only if $\alpha \ll Z^{-\frac{10}{9}} |\log Z|^{-\frac{1}{3}}$. To recover remainder estimate $o(Z^{\frac{5}{3}})$ (or marginally better) we just apply Theorem 26.A.2. We will do it later (see Theorem 27.4.5).

Therefore skipping the non-negative third term in the right-hand expression of (27.4.18) we conclude that

$$\begin{aligned} \langle \mathsf{H}\Psi, \Psi\rangle + \frac{1}{\alpha}\int |\nabla \times A|^2 \, dx \ge \\ \mathsf{Tr}^-(H) + (\frac{1}{\alpha} - C_1)\int |\nabla \times A|^2 \, dx - \frac{1}{2}\mathsf{D}(\rho,\rho) - CZ^{\frac{5}{3}}. \end{aligned} \tag{27.4.26}$$

Applying Theorem 27.3.24 we conclude that

(27.4.27) The sum of the first and the second terms in the right-hand expression of (27.4.26) is greater than

$$\mathcal{E}^{\mathsf{TF}} + \sum_m 2Z_m^2 S(\alpha Z_m) - CZ^{\frac{4}{3}}(R_1 + R_2)$$

with R_1 and R_2 defined by (27.3.100) and (27.3.101) respectively with $\kappa = \alpha Z$, $h = Z^{-\frac{1}{3}}$ and

$$a \coloneqq Z^{\frac{1}{3}} \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}|. \tag{27.4.28}$$

To prove this claim one needs just to rescale

$$\begin{aligned} x \mapsto xZ^{\frac{1}{3}}, \quad a \mapsto aZ^{\frac{1}{3}}, \quad W \mapsto Z^{-\frac{4}{3}} W, \\ A \mapsto A, \quad \nabla \times A \mapsto Z^{\frac{1}{3}} \nabla \times A \end{aligned} \tag{27.4.29}_{1-5}$$

and introduce

$$h = Z^{-\frac{1}{3}}, \quad \kappa = \alpha Z. \tag{27.4.30}$$

Observe that due to $(27.4.29)_3$ we need to multiply our estimate by $Z^{\frac{4}{3}}$.

Here one definitely needs the regularity properties like in Section 27.3 but we have them since $\rho = \rho^{\mathsf{TF}}$, $W = W^{\mathsf{TF}}$. Also one can see easily that "$-C_1$" brings correction not exceeding $C_2\alpha Z^2$ as $\alpha Z \le 1$.

Meanwhile for $\rho = \rho^{\mathsf{TF}}$, $W = W^{\mathsf{TF}}$

$$\frac{2}{15\pi^2}\int W^{\frac{5}{2}}\,dx - \frac{1}{2}\mathsf{D}(\rho,\rho) = \mathcal{E}^{\mathsf{TF}}. \tag{27.4.31}$$

Lower estimate of Theorem 27.4.3 below has been proven.

Remark 27.4.2. $\rho = \rho^{\mathsf{TF}}$, $W = W^{\mathsf{TF}}$ delivers the maximum of the right-hand expression of (27.4.31) among ρ, W satisfying (27.4.19).

27.4.3 Upper Estimate

Upper estimate is easy. Plugging as in Section 25.2 Ψ, the *Slater determinant* (25.2.16) of $\psi_1,\dots,\psi_N$, where $\psi_1,\dots,\psi_N$ are eigenfunctions of $H_{A,W}$ we get

$$\begin{aligned}\langle \mathsf{H}\Psi,\Psi\rangle = {}& \mathsf{Tr}^-(H_{A,W}-\lambda_N) + \lambda_N N + \\ & \int (W-V)(x)\rho_\Psi(x)\,dx + \frac{1}{2}\mathsf{D}(\rho_\Psi,\rho_\Psi) - \\ & \frac{1}{2}N(N-1)\iint |x_1-x_2|^{-1}|\Psi(x_1,x_2,x_3,\dots,x_N)|^2\,dx_1\cdots dx_N,\end{aligned} \tag{27.4.32}$$

where we do not care about the last term since we drop it (again as long as we cannot get sharp enough estimate) and the first term in the second line is in fact $-\mathsf{D}(\rho,\rho_\Psi)$, provided (27.4.19) holds. Thus we get

$$\begin{aligned}\mathsf{Tr}^-(H_{A,W}-\lambda_N) + \lambda_N N - \frac{1}{2}\mathsf{D}(\rho,\rho) + \frac{1}{2}\mathsf{D}(\rho_\Psi-\rho,\rho_\Psi-\rho) + \\ \frac{1}{\alpha}\int |\partial A|^2\,dx,\end{aligned} \tag{27.4.33}$$

where we added the magnetic energy. Definitely we have several problems here: λ_N depends on A and there may be less than N negative eigenvalues.

However in the latter case we can obviously replace N by the lesser number $N' := \max(n \le N, \lambda_n \le 0)$ since E^*_N is decreasing function of N. In this case the first term in (27.4.33) would be just $\mathsf{Tr}^-(H_{A,W})$ and the second

would be 0. Then we apply theory of the previous Section 27.3 immediately without extra complications.

Consider A a minimizer (or its mollification) for operator $H_{A,W} - \mu$ with potential $W = W^{\mathsf{TF}}$ and $\mu \le 0$. Then

$$\mathsf{N}(\mu) := \#\{\lambda_k < \mu\} = \int (W+\mu)_+^{\frac{3}{2}}\, dx + O(Z^{\frac{2}{3}}). \tag{27.4.34}$$

One can prove (27.4.34) easily using the regularity properties of A established in the previous Section 27.3 and the same rescaling (27.4.29)–(27.4.30) as before. We leave this easy proof to the reader.

Therefore, repeating arguments of Subsubsection *25.4.2.1. Estimating* $|\lambda_N - \nu|$, we conclude that either $N \ge Z - C_0 Z^{\frac{2}{3}}$ and then $|\nu| \le C_1 Z^{\frac{8}{9}}$ and we can take $\mu = 0$ and $|\lambda_{N'}| \le C_1 Z^{\frac{8}{9}}$ or $N \le Z - C_0 Z^{\frac{2}{3}}$ and then we take $\mu = \nu$, $|\lambda_N| \asymp |\nu| \asymp (Z-N)_+^{\frac{4}{3}}$ and $|\lambda_N - \nu| \le C_1 |\nu|^{\frac{1}{4}} Z^{\frac{2}{3}}$.

After this, following again to arguments of Subsection 25.4.2, we conclude that

(27.4.35) Expression (27.4.33) without term $\frac{1}{2}\mathsf{D}(\rho_\Psi - \rho, \rho_\Psi - \rho)$ does not exceed

$$\mathcal{E}^{\mathsf{TF}} + \sum_m 2Z_m^2 S(\alpha Z_m) + CZ^{\frac{4}{3}}(R_1 + R_2)$$

with R_1 and R_2 defined by (27.3.100) and (27.3.101) respectively with $\kappa = \alpha Z$, $h = Z^{-\frac{1}{3}}$ and a defined by (27.4.28).

Now we need to estimate properly $\mathsf{D}(\rho_\Psi - \rho, \rho_\Psi - \rho)$ which as in i.e. Subsubsection *25.4.2.2. Estimating* D*-Term* does not exceed the sum of

$$\mathsf{D}(e(x,x,\mu) - \mathsf{Weyl}(x,\mu),\ e(x,x,\mu) - \mathsf{Weyl}(x,\mu)), \tag{27.4.36}$$

$$\mathsf{D}(e(x,x,\lambda_N) - \mathsf{Weyl}(x,\lambda_N),\ e(x,x,\lambda_N) - \mathsf{Weyl}(x,\lambda_N)) \tag{27.4.37}$$

and

$$\mathsf{D}(\mathsf{Weyl}(x,\mu) - \mathsf{Weyl}(x,\lambda_N),\ \mathsf{Weyl}(x,\mu) - \mathsf{Weyl}(x,\lambda_N)). \tag{27.4.38}$$

Next, following arguments of Subsubsection *25.4.2.2. Estimating* D*-Term*, one can prove easily that due to regularity properties of A both semiclassical (27.4.36) and (27.4.37) terms do not exceed $CZ^{\frac{5}{3}}$ and due to estimates for $|\lambda_N - \mu|$ the last term does (27.4.38) not exceed $CZ^{\frac{5}{3}}$ as well.

This concludes the proof of the upper estimate in Theorem 27.4.3 below.

27.4.4 Main Theorems

Theorem 27.4.3. *(i) Under assumptions* (27.4.7) *and* (27.4.8) *the following asymptotics holds*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m) + O\big(Z^{\frac{4}{3}}(R_1+R_2)\big) \tag{27.4.39}$$

with R_1 and R_2 defined by (27.3.100) *and* (27.3.101) *respectively with $\kappa = \alpha Z$, $h = Z^{-\frac{1}{3}}$ and a defined by* (27.4.28), *$a = \infty$ for $M = 1$.*

(ii) In particular, under assumption (27.4.10) *the following asymptotics holds*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m) + O\big(\alpha|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^{\frac{5}{3}} + \alpha b^{-3} Z^2\big). \tag{27.4.40}$$

Recall that $\mathcal{E}^{\mathsf{TF}}_N$ is a *Thomas-Fermi energy* and $S(\alpha Z_m)Z_m^2$ are magnetic *Scott correction terms*.

Theorem 27.4.4. *(i) Let assumptions* (27.4.7) *and* (27.4.8) *be fulfilled and let $\Psi = \Psi_{\boldsymbol{A}}$ be a ground state for a near optimizer $\boldsymbol{A}$ of the original multiparticle problem. Then*

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}}) \le CZ^{\frac{5}{3}}. \tag{27.4.41}$$

(ii) Furthermore, as $b \ge Z^{-\frac{1}{3}}$

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}}) \le CZ^{\frac{5}{3}}\big(Z^{-\delta} + (bZ^{\frac{1}{3}})^{-\delta} + (\alpha Z)^{\delta}\big). \tag{27.4.42}$$

Proof. (i) Note that all the terms in estimates from below and from above are $O(Z^{\frac{5}{3}})$ except the common term

$$\mathsf{Tr}^-(H_{A,W} + \mu) + \frac{1}{\alpha}\int |\nabla \times A|^2\, dx, \tag{27.4.43}$$

where A is a minimizer for this term and therefore estimate (27.4.41) has been proven because estimate from below also contains $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}})$.

(ii) To prove Statement (ii) one needs

(a) To improve estimate (27.4.34) to

$$\mathsf{N}(\mu) = \int (W+\mu)_+^{\frac{3}{2}}\,dx + O\bigl(Z^{\frac{2}{3}}\bigl[Z^{-\delta} + (bZ^{\frac{1}{3}})^{-\delta} + (\alpha Z)^{\delta}\bigr]\bigr); \tag{27.4.44}$$

(b) To estimate terms (27.4.36)–(27.4.38) by the right-hand expression of (25.4.45); and

(c) To accommodate Dirac term in both upper and lower estimates.

Tasks (a), (b) are easy and we leave it to the reader (cf. arguments of Subsection 25.4.3); we use that after rescaling effective magnetic field intensity becomes $O(\alpha Z)$ in the zone $\{x : \ell(x) \asymp Z^{-\frac{1}{3}}\}$ due to already established estimates to A.

To fulfill task (c) observe that in the upper estimate we already have term

$$-\frac{1}{2}\,\mathsf{tr}\iint |x-y|^{-1} e_N(x,y) e_N^{\dagger}(x,y)\,dxdy. \tag{27.4.45}$$

On the other hand, in virtue of Theorem 26.A.2 we replace in the lower estimate term $-C\int \rho_\Psi^{\frac{4}{3}}(x)\,dx$ by (27.4.6) with $O(Z^{\frac{5}{3}-\delta})$ error (again we leave easy details to the reader).

One can prove by the same arguments as as in the non-magnetic case that for $\alpha Z \le \kappa^*$ it is $\mathsf{Dirac} + O(Z^{\frac{5}{3}-\delta})$. □

Finally, combining arguments sketched in the proof of Theorem 27.4.4 with the improved estimate of (27.4.43) (see Theorem 27.3.24(ii)) we arrive to

Theorem 27.4.5. *Let assumptions* (27.4.8) *and* (27.4.10) *be fulfilled, and let* $\alpha \le Z^{-\frac{10}{9}}|\log Z|^{-\frac{1}{3}}$. *Then*

$$\mathsf{E}_N^* = \mathcal{E}_N^{\mathsf{TF}} + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m) + \mathsf{Dirac} + \mathsf{Schwinger} + O\bigl(\alpha|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^{\frac{5}{3}-\delta} + \alpha b^{-3} Z^2\bigr) \tag{27.4.46}$$

where Dirac *and* $\mathsf{Schwinger}$ *are* Dirac *and* Schwinger correction terms *defined exactly as in non-magnetic case by* (25.1.29) *and* (25.1.30) *respectively.*

27.4.5 Free Nuclei Model

Consider now free nuclei model (see Subsubsection *25.4.4.2). Estimates for Distance between Nuclei in the Free Nuclei Model*).

Theorem 27.4.6. *Let us consider* $\mathsf{y}_m = \mathsf{y}_m^*$ *minimizing the full energy*

$$\widehat{\mathsf{E}}_N^* := \mathsf{E}_N^* + \sum_{1\le m<m'\le M} Z_m Z_{m'} |\mathsf{y}_m - \mathsf{y}_{m'}|^{-1}. \tag{27.4.47}$$

Assume that

$$Z_m \asymp N \qquad \forall m = 1, \dots, M. \tag{27.4.48}$$

Then

$$b \ge \min\bigl(Z^{-\frac{5}{21}+\delta},\, Z^{-\frac{5}{21}}(\alpha Z)^{-\delta},\, \alpha^{-\frac{1}{4}} Z^{-\frac{1}{2}}\bigr) \tag{27.4.49}$$

and in the remainder estimates in (27.4.40) *and* (27.4.46) *one can skip* b*-connected terms; so we arrive to*

$$\mathsf{E}_N^* = \mathcal{E}_N^{\mathsf{TF}} + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m) + O\bigl(\alpha |\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^{\frac{5}{3}}\bigr) \tag{27.4.50}$$

and

$$\mathsf{E}_N^* = \mathcal{E}_N^{\mathsf{TF}} + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m) + \mathsf{Dirac} + \mathsf{Schwinger} + O\bigl(\alpha |\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^{\frac{5}{3}-\delta}\bigr) \tag{27.4.51}$$

respectively and also the same asymptotics with $\widehat{\mathsf{E}}_N^*$ *and* $\widehat{\mathcal{E}}_N^{\mathsf{TF}}$ *instead of* E_N^* *and* $\mathcal{E}_N^{\mathsf{TF}}$.

Proof. Optimization with respect to $\mathsf{y}_1, \dots, \mathsf{y}_M$ implies

$$\mathsf{E}^* + \sum_{1\le m<m'\le M} \frac{Z_m Z_{m'}}{|\mathsf{y}_m - \mathsf{y}_{m'}|} < \sum_{1\le m\le M} \mathsf{E}_m^* \tag{27.4.52}$$

where $\mathsf{E}^* = \mathsf{E}^*(\mathsf{y}_1, \dots, \mathsf{y}_M; Z_1, \dots, Z_m, N)$ and $\mathsf{E}_m^* = \mathsf{E}^*(\mathsf{y}_m, Z_m)$ are calculated for separate atoms. In virtue of Theorem 27.4.3

$$\mathcal{E}^{\mathsf{TF}} + \sum_{1\le m<m'\le M} \frac{Z_m Z_{m'}}{|\mathsf{x}_m - \mathsf{x}_{m'}|} - \sum_{1\le m\le M} \mathcal{E}_m^{\mathsf{TF}} \le C\alpha |\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^{\frac{5}{3}} + C\alpha b^{-3} Z^2. \tag{27.4.53}$$

However due to the strong non-binding theorem in Thomas-Fermi theory the left-hand expression is $\gtrsim b^{-7}$ for $b \ge Z^{-\frac{1}{3}}$ and therefore (27.4.53) implies

$$b \gtrsim \min\bigl(Z^{-\frac{5}{21}},\, \alpha^{-\frac{1}{7}}|\log(\alpha Z)|^{-\frac{1}{21}} Z^{-\frac{25}{63}},\, \alpha^{-\frac{1}{4}} Z^{-\frac{1}{2}}\bigr)$$

where the third expression is larger than the second one for sure. Unfortunately, for $\alpha \ge Z^{-\frac{10}{9}-\delta'}$ it is not as good as we claimed in (27.4.49). Still this estimate implies both (27.4.50) and (27.4.51).

To prove estimate (27.4.49) we observe that $b \gg Z^{-\frac{2}{7}}$ [19)] and then we employ arguments used in the proof of Theorem 26.8.11 and prove that

$$|\mathsf{Tr}^-(H_{A,W}+\mu) - \sum_{1\le m\le M} \mathsf{Tr}^-(H_{A,W_m}+\mu) - \int \Bigl(\mathsf{Weyl}(H_{A,W}+\mu;\, x) - \sum_{1\le m\le M} \mathsf{Weyl}(H_{A,W_m}+\mu;\, x)\Bigr)\, dx| \le CZ^{\frac{5}{3}}\bigl(Z^{-\delta}+(\alpha Z)^{\delta}\bigr),$$

where A be a minimizer for "molecular" expression (27.4.45) and W_m are atomic potentials. The same estimate holds if we replace $\mathsf{Tr}^-(H_{A,W_m}+\mu)$ by $\mathsf{Tr}^-(H_{A_m,W_m}+\mu)$ with $A_m = A\phi(b^{-1}|x-\mathsf{y}_m|)$ with $\phi \in \mathscr{C}_0^\infty(B(0,\frac{1}{3})$, equal 1 in $B(0,\frac{1}{4})$. We leave an easy proof to the reader.

Then using the lower estimate for $\inf \mathsf{Spec}_{\mathfrak{H}}(\mathsf{H})$ and upper estimates for both $\inf \mathsf{Spec}_{\mathfrak{H}_m}(\mathsf{H}_m)$ through $\mathsf{Tr}^-(H_{A,W}+\mu)$ and $\mathsf{Tr}^-(H_{A_m,W_m}+\mu')$ respectively (where H_m are associated with H_{A_m,W_m}) we arrive to

$$\inf \mathsf{Spec}_{\mathfrak{H}}(\mathsf{H}) \ge \sum_{1\le m\le M} \inf \mathsf{Spec}_{\mathfrak{H}_m}(\mathsf{H}_m) + \mathcal{E}^{\mathsf{TF}} - \sum_{1\le m\le M} \mathcal{E}_m^{\mathsf{TF}} - CZ^{\frac{5}{3}}\bigl(Z^{-\delta}+(\alpha Z)^{\delta}\bigr)$$

and therefore

$$\mathsf{E}_A \ge \sum_{1\le m\le M} \mathsf{E}_{m,A_m} + \mathcal{E}^{\mathsf{TF}} - \sum_{1\le m\le M} \mathcal{E}_m^{\mathsf{TF}} - CZ^{\frac{5}{3}}\bigl(Z^{-\delta}+(\alpha Z)^{\delta}\bigr) - C\alpha b^{-3}Z^2, \tag{27.4.54}$$

where the last term is due to replacement of $\frac{1}{\alpha}\int |\nabla\times A|^2\, dx$ by "atomized" expressions $\sum_{1\le m\le M} \frac{1}{\alpha}\int |\nabla\times A_m|^2\, dx$.

[19)] There is no binding with $b \le Z^{-\frac{1}{3}}$ because remainder estimate is (better than) CZ^2 and binding energy excess is $\asymp Z^{\frac{7}{3}}$.

The last inequality (27.4.54) then obviously holds with A_m replaced by optimizers for "atomic" expressions (27.4.45) and *now* strong non-binding theorem implies that

$$b^{-7} \le CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + (\alpha Z)^{\delta}\bigr) + C\alpha b^{-3}Z^2$$

which implies (27.4.49) where we change $\delta > 0$ as needed. □

27.5 Miscellaneous Problems

Recall that in our analysis in Sections 25.5 and 25.6 the crucial role was played by an estimate of $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}})$ and since what we have now (see Theorem 27.4.4) is (almost) as good as we had then, all arguments of these Sections still work with the minimal modifications. We leave most of the easy details to the reader but we need to deal with different magnetic fields for different N.

27.5.1 Excessive Negative Charge

Theorem 27.5.1 [20]**.** *Let condition* (27.4.48) *be fulfilled.*

(i) In the framework of the fixed nuclei model let us assume that $\mathsf{I}^*_N := \mathsf{E}^*_{N-1} - \mathsf{E}^*_N > 0$. *Then*

$$(N-Z)_+ \le CZ^{\frac{5}{7}}. \tag{27.5.1}$$

(ii) In the framework of the free nuclei model let us assume that $\widehat{\mathsf{I}}^*_N := \widehat{\mathsf{E}}^*_{N-1} - \widehat{\mathsf{E}}^*_N > 0$. *Then estimate* (27.5.1) *holds.*

Proof. The proof follows the proof of Theorem 25.5.3; since it is not specific to the case where there is no magnetic field, we find that $(N-Z)_+ \le Q^{\frac{3}{7}}$, where Q is an estimate for $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}})$, which we established already; recall that the equivalence $\rho^{\mathsf{TF}} \asymp \ell^{-6}$ for $\ell \gtrsim Z^{-\frac{1}{3}}$ also plays an important role.

Here we pick up $A = A_N$ [21] and conclude that

$$\mathsf{I}_N(A) := \mathsf{E}_{N-1}(A) - \mathsf{E}_N(A) \ge \mathsf{E}^*_{N-1} - \mathsf{E}^*_N > 0,$$

and then repeat arguments of the proof of Theorem 25.5.3.

We leave the remaining easy details to the reader. □

[20] Cf. Theorem 25.5.3.

[21] Exactly as in the analysis of free nuclei model we pick up $\underline{y}$ for N-electrons we pick now A for N electrons.

27.5.2 Estimates for Ionization Energy

Theorem 27.5.2 [22]**.** *Let condition* (27.4.48) *be fulfilled.*

(i) Then the following estimate holds:

$$\mathsf{I}^*_N \le C(Z-N)^{\frac{4}{3}}_+ + CZ^{\frac{20}{21}}. \tag{27.5.2}$$

(ii) Further, under assumption

$$a := \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge Z^{-\frac{1}{3}} \tag{27.5.3}$$

the following estimate holds

$$\mathsf{I}^*_N \le C(Z-N)^{\frac{4}{3}}_+ + CZ^{\frac{20}{21}}\bigl(Z^{-\delta} + (aZ^{\frac{1}{3}})^{-\delta}\bigr). \tag{27.5.4}$$

(iii) Furthermore, for $M \ge 2$ in the framework of free nuclei model (assuming that the molecule exists; see Theorem 27.5.6)

$$\widehat{\mathsf{I}}^*_N \le CZ^{\frac{20}{21}-\delta'}. \tag{27.5.5}$$

Proof. Recall that Theorem 25.5.4 was proven simultaneously with Theorem 25.5.3; we follow the same scheme here picking up $A = A_N$ [21]. Thus here and in the first part of the proof of Theorem 27.5.3 we estimate from above $\mathsf{I}^*_N(A)$.

Again the remaining easy details a left to the reader. □

Theorem 27.5.3 [23]**.** *Let condition* (25.3.33) *be fulfilled and let $N \le Z - C_0Q^{\frac{3}{7}}$ with $Q \le C_1Z^{\frac{5}{3}}$. Then in the framework of fixed nuclei model*

(i) In the general case $Q = Z^{\frac{5}{3}}$

$$|\mathsf{I}^*_N + \nu| \le C(Z-N)^{\frac{17}{18}}Z^{\frac{5}{18}} \times \log^{\frac{1}{3}}\bigl((Z-N)Q^{-\frac{3}{7}}\bigr). \tag{27.5.6}$$

(ii) Under assumption (27.5.3) *as $Q = Z^{\frac{5}{3}}$*

$$(\mathsf{I}^*_N + \nu)_-| \le C(Z-N)^{\frac{17}{18}}Z^{\frac{5}{18}}. \tag{27.5.7}$$

[22] Cf. Theorem 25.5.4.

[23] Cf. Theorem 25.6.1.

(iii) Further, under assumption (27.5.3) *we can take* $Q = Z^{\frac{5}{3}}\big(Z^{-\delta}+(aZ^{\frac{1}{3}})^{-\delta}\big)$ *and then both estimates* (27.5.6) *and* (27.5.7) *hold with an extra factor* $\big(Z^{-\delta'} + (aZ^{\frac{1}{3}})^{-\delta'}\big)$ *in the right-hand expressions.*

Proof. To estimate $\mathsf{I}^*_N + \nu$ from above we follow exactly the arguments of Subsection 25.6.1 to estimate $\mathsf{I}_N(A_N) \ge \mathsf{I}^*_N$. □

Problem 27.5.4. To prove the same estimate for $(\mathsf{I}^*_N + \nu)_-$.

Remark 27.5.5. To estimate $\mathsf{I}^*_N + \nu$ from below we need to pick up $A = A_{N-1}$ rather than $A = A_N$; then

$$\mathsf{I}_N(A) = \mathsf{E}_{N-1}(A) - \mathsf{E}_N(A) \le \mathsf{E}^*_{N-1} - \mathsf{E}^*_N = \mathsf{I}^*_N$$

and we should follow the arguments of Subsection 25.6.2. However, in contrast to all other proofs of this Section, here we should use the spectral properties of $H_{A,W}$ (or at least an estimate from above for its lowest eigenvalue after localization to $\mathsf{supp}(\theta)$, while in all other results we need an estimate from below for the same lowest eigenvalue after localization to $\mathsf{supp}(\theta)$).

To estimate from above the lowest eigenvalue of $H_{A,W}$ we need some uniform (i.e. with constants which do not depend on N) smoothness estimates for A_{N-1} where A_{N-1} is the minimizer for $\mathsf{E}_{N-1}(A)$ as defined in Sections 27.4 and here (rather than as defined in Sections 27.2–27.3).

While (27.A.1) is an analogue of (27.2.14), it is still not the same, and while it implies some estimate, it is not even remotely as good as we achieved in Sections 27.2 and 27.3.

Sure ρ_Ψ is not very smooth either but it close to rather smooth ρ^{TF}; on the other hand, the minimizer A_N is an almost-minimizer for the one-particle trace problem studied Sections 27.2–27.3 but we don't know how close it to the minimizer (or one of the minimizers) of the latter problem.

27.5.3 Free Nuclei Model: Excessive Positive Charge

Theorem 27.5.6 [24]**.** *Let condition* (25.3.33) *be fulfilled. Then in the framework of free nuclei model with* $M \ge 2$ *the stable molecule does not exist unless*

$$Z - N \le Z^{\frac{11}{13}}. \tag{27.5.8}$$

[24] Cf. Theorem 25.6.3.

Proof. Again we just repeat the proof of Theorem 25.6.3; we leave all easy details to the reader. □

27.A Appendices

27.A.1 Minimizers and Ground States

First, establish a conditional existence of the minimizer[25)] and the corresponding ground state of the original problem:

Theorem 27.A.1. *Let $\alpha Z < \kappa^*$ and let $\mathsf{E}_N^* < \mathsf{E}_{N-1}^*$. Then there exist a minimizer $A = A_N$ for the original multiparticle problem and the corresponding ground state Ψ_N.*

Proof. We know that for $\alpha Z < \kappa^*$ (with $\kappa^* > 0$ which does not depend on Z or positions of the nuclei) $\mathsf{E}^*(A)$ is bounded from below; then $\|\nabla \times A'\|^2$ is bounded from above for a near-minimizer A' (but constants do depend on Z and $(\kappa^* - \alpha Z)$ here). On the other hand, for $A' \in \mathscr{C}_0^\infty$ and $\mathsf{E}_N(A') < \mathsf{E}_{N-1}(A')$ there exists a ground state $\Psi_N(A')$.

Therefore if $A_{(k)} \in \mathscr{C}_0^\infty$ is a minimizing sequence for $\mathsf{E}_N(A)$ we have also a sequence $\Psi_N(A_{(k)})$ with $\|\Psi_N(A_{(k)})\| = 1$. Going if necessary to the subsequence, we can assume that $A_{(k)}$ converges weakly in $\mathscr{H}^1$ and strongly in $\mathscr{L}^p_{\mathsf{loc}}$ for any $p < 6$; let A be its limit.

One can prove easily that $\Psi_N(A_{(k)})$ converge weakly in $\mathscr{H}^1$ and strongly in $\mathscr{L}^2$ to Ψ and

$$(\mathsf{H}_{A,V}\Psi, \Psi) = \lim_{k\to\infty} (\mathsf{H}_{A_{(k)},V}\Psi_N(A_{(k)}), \Psi_N(A_{(k)})),$$

and then

$$(\mathsf{H}_{A,V}\Psi, \Psi) + \frac{1}{\alpha} = \lim_{k\to\infty} \mathsf{E}_N(A_{(k)}),$$

which is E_N^* since $A_{(k)}$ is a minimizing sequence and then Ψ must be a ground state. □

Now in this framework we establish properties of the minimizer and the ground state:

[25)] We do not know if it is unique.

Proposition 27.A.2 [26]**.** *Let $\Psi = \Psi_N$ and $A = A_N$ be a ground state and minimizer with energy $\mathsf{E}^*_N < \mathsf{E}^*_{N-1}$.*

(i) $\Psi \in \mathscr{C}^1$ and $\Psi = O(e^{-\epsilon|\underline{x}|})$ as $|\underline{x}| \to \infty$.

(ii) $A \in \mathscr{C}^1$ and $A = O(|x|^{-2})$, $\nabla \times A = O(|x|^{-3})$ as $|x| \to \infty$.

(iii) Let $N < Z$. Then $V_\Psi - V \in \mathscr{C}^1$ and $V_\Psi = (Z-N)|x|^{-1} + O(|x|^{-2})$, $\nabla V_\Psi = -(Z-N)x|x|^{-3} + O(|x|^{-3})$ as $|x| \to \infty$.

Proof. An obvious proof, using also an equation

$$\frac{2}{\alpha}\Delta A_j = \\ -2N\,\mathsf{Re}\,\mathsf{tr}\int \Psi^\dagger(x,x_2,\dots,x_N)\sigma_j(D-A)_x\cdot\boldsymbol{\sigma}\Psi(x,x_2,\dots,x_N)\,dx_2\cdots dx_N, \tag{27.A.1}$$

is left to the reader. This equation is similar to (27.2.14) and is also derived from variational principles, its right-hand expression is $\frac{\delta\Lambda}{\delta A}$ where Λ is the lowest eigenvalue of $\mathsf{H}_{A,V}$ on Fock' space.

27.A.2 Zhislin's Theorem

Theorem 27.A.3 (Zhislin's theorem) [27]**.** *$\mathsf{E}^*_{N+1} < \mathsf{E}^*_N$ if $N < Z$.*

Proof. An easy proof repeating with obvious modifications proof of Theorem 26.A.8 is left to the reader. □

27.A.3 L. Erdös–J. P. Solovej's Lemma

We reproduce here Lemma 2.1 from L. Erdös, J. P. Solovej [1].

Lemma 27.A.4. *There is a positive universal constant κ^* such that for any Z, α with $Z\alpha \le \kappa^*$ we have*

$$\inf_N \inf_A H_{A,V} \ge -CZ^{\frac{7}{3}}\delta^{1/2} - Z^{\frac{2}{3}}\delta^{-2}$$

if $CZ^{-\frac{2}{3}} \le \delta \le C_1$ with a sufficiently large constant C.

[26] Cf. Proposition 26.A.7.

[27] Cf. Theorem 26.A.8.

Proof. Consider a pair of smooth functions θ_0 and θ_1, such that $\theta_0^2+\theta_1^2=1$, $\mathsf{supp}(\theta_1)\subset B(0,2r)$, $\theta_1=1$ on $B(0,r)$, and $|\nabla\theta_0|$, $|\nabla\theta_1|\le Cr^{-1}$ with $r=\delta Z^{-\frac{1}{3}}$.

Let $\tilde\chi_0$ be a smooth cutoff function, supported on $B(0,3r)$ such that $|\nabla\tilde\chi_0|\le Cr^{-1}$ and $\tilde\chi_0=1$ on $B(0,2r)$. Let $\bar A$ be an average of A over $B(0,3r)$. Let $A_0\coloneqq(A-\bar A)\tilde\chi_0$, $B_0\coloneqq\nabla\times A_0$; then

$$\nabla\otimes A_0=\tilde\chi_0\nabla\otimes A+(A-\bar A)\otimes\nabla\tilde\chi_0.$$

Clearly

$$\int_{\mathbb{R}^3}B_0^2\,dx\le\int_{\mathbb{R}^3}|\nabla\otimes A_0|^2\,dx\le 2\int_{\mathbb{R}^3}\tilde\chi_0^2|\nabla\otimes A|^2\,dx+Cr^{-2}\int_{B(0,3r)}(A-\bar A)^2\,dx$$
$$\le C_1\int_{B(0,3r)}|\nabla\otimes A|^2\,dx$$

for some universal constant C_1, where in the last step we used the Poincaré inequality. Let φ be a real phase such that $\nabla\varphi=\bar A$. Since $\tilde\chi_0\equiv 1$ on the support of θ_1, we have

$$\theta_1 H_{A,0}\theta_1=\theta_1 e^{-i\varphi}H_{A-\bar A,0}e^{i\varphi}\theta_1=\theta_1 e^{-i\varphi}H_{A_0,V}e^{i\varphi}\theta_1.$$

After these localizations, we have

(27.A.2) $H^1_{N,Z;A}\coloneqq$

$$\sum_{j=1}^N\Big[\theta_1\Big(H_{A,0}-\frac{Z}{|x|}-\big(|\nabla\theta_0|^2+|\nabla\theta_1|^2\big)\theta_1\Big]_j+\frac{1}{\alpha}\int_{B(0,3r)}|\nabla\otimes A|^2\,dx$$
$$\ge\sum_{j=1}^N\Big[\theta_1 e^{-i\varphi}\big(H_{A_0,0}-W(x)\big)e^{i\varphi}\theta_1\Big]_j+\frac{1}{2C_1\alpha}\int B_0^2\,dx$$

with

$$W(x)=\Big[\frac{Z}{|x|}+Cr^{-2}\Big]\,\mathbf{1}(|x|\le 2r),$$

where $\mathbf{1}(X)$ is a characteristic function of X.

Now we use the "running energy scale" argument in E. Lieb, M. Loss, M. and J. Solovej [1].

$$\begin{aligned}(27.A.3)\quad \sum_{j=1}^{N}\Big[\theta_1 e^{-i\varphi}\big[H_{A',0}-W\big]e^{i\varphi}\theta_1\Big]_j &\ge -\int_0^\infty \mathsf{N}_{-e}(H_{A',0}-W)\,de\\ &\ge -\int_0^\mu \mathsf{N}_{-e}(H_{A',0}-W)\,de-\int_\mu^\infty \mathsf{N}_0\big(\frac{\mu}{e}H_{A',0}-W+e\big)\,de\\ &\ge -\int_0^\mu \mathsf{N}_{-e}(H_{A',0}-W)\,de-\int_\mu^\infty \mathsf{N}_0\big(H_{A',0}-\frac{e}{\mu}W+\frac{e^2}{\mu}\big)\,de,\end{aligned}$$

where $\mathsf{N}_{-e}(H)$ denotes the number of eigenvalues of a self-adjoint operator H below $-e$.

In the first term we use the bound $H_{A_0,0}\ge (D-A_0)^2-|B_0|$ and the CLR (i.e. Cwikel-Lieb-Rozenblum) bound:

$$\begin{aligned}(27.A.4)\quad \int_0^\mu \mathsf{N}_{-e}(H_{A_0,0}-W)\,de &\le C\int_0^\mu de\int_{\mathbb{R}^3}(W+|B_0|-e)_+^{\frac{3}{2}}\,dx\\ &\le C\int_0^\mu de\int_{\mathbb{R}^3}(W-e/2)_+^{\frac{3}{2}}\,dx+C\int_0^\mu de\int_{\mathbb{R}^3}(|B_0|-e^2/2\mu)_+^{\frac{3}{2}}\,dx\\ &\le C\int_{\mathbb{R}^3}W^{\frac{5}{2}}\,dx+C\mu^{\frac{1}{2}}\int_{\mathbb{R}^3}B_0^2\,dx=CZ^{\frac{5}{2}}r^{\frac{1}{2}}+Cr^{-2}+C\mu^{\frac{1}{2}}\int_{\mathbb{R}^3}B_0^2\,dx.\end{aligned}$$

In the second term of (27.A.3) we use

$$\begin{aligned}H_{A_0,0}-\frac{e}{\mu}W\ge \frac{1}{2}\big[(D-A_0)^2-\frac{2eZ}{\mu|x|}\,\mathbf{1}(|x|\le 2r)\big]\\ +\frac{1}{2}(D-A_0)^2-|B_0|-\frac{Ce}{\mu r^2}\,\mathbf{1}(|x|\le 2r),\end{aligned}$$

and that

$$(D-A_0)^2-\frac{2eZ}{\mu|x|}\,\mathbf{1}(|x|\le 2r)\ge (D-A_0)^2-\frac{4eZ}{\mu|x|}\ge -\big(\frac{2eZ}{\mu}\big)^2$$

i.e.

$$H_{A_0,0}-\frac{e}{\mu}W\ge \frac{1}{2}(D-A_0)^2-2\big(\frac{eZ}{\mu}\big)^2-|B_0|-\frac{Ce}{\mu r^2}\,\mathbf{1}(|x|\le 2r).$$

Let $\mu = 4Z^2$, then using $Ce/\mu r^2 \le e^2/4\mu$ for $\mu \le e$ (i.e. $C \le (\delta Z^{2/3})^2$), we get

$$\begin{aligned}(27.A.5)\quad &\int_\mu^\infty \mathsf{N}_0\bigl(H_{A_0,0} - \frac{e}{\mu}W + \frac{e^2}{\mu}\bigr)\,de \\ &\le \int_\mu^\infty \mathsf{N}_0\bigl(\frac{1}{2}(D-A_0)^2 - |B_0| + \frac{e^2}{4\mu}\bigr)\,de \le C\int_0^\mu de \int_{\mathbb{R}^3} (|B_0| - e^2/4\mu)_+^{3/2}\,dx \\ &\le C\mu^{\frac{1}{2}}\int_{\mathbb{R}^3} B_0^2\,dx.\end{aligned}$$

Note that if $Z\alpha \le \kappa^*$ with some sufficiently small universal constant κ^*, then (27.A.5) can be controlled by the corresponding term in (27.A.2). Combining the estimates (27.A.2), (27.A.3), (27.A.4) and (27.A.5), we obtain

$$H_{A,V} \ge -CZ^{\frac{5}{2}}r^{\frac{1}{2}} - Cr^{-2}$$

and lemma follows. □

Comments

The problem was considered first in several papers of L. Erdös, J. P. Solovej [1] and L. Erdös, S. Fournais, J. P. Solovej [1, 3, 4].

The same problem in the relativistic case was considered in L. Erdös, S. Fournais, J. P. Solovej [2] (under assumption preventing relativistic instability).

Important Remarks

Section 27.5 was rewritten. See Important Remarks to Chapter 25.

Chapter 28

The Case of Combined Magnetic Field

28.1 Introduction

In this Chapter instead of the Schrödinger operator without magnetic field as in Chapter 25, or with a constant magnetic field as in Chapter 26, or with a self-generated magnetic field as in Chapter 27 we consider the Schrödinger operator (27.1.1) with unknown magnetic field A, but then we add to the ground state energy of the atom (or molecule) the energy of the self-generated magnetic field (see selected term in (28.1.1) thus arriving to

$$\mathsf{E}(A) = \inf \mathsf{Spec}(\mathsf{H}_{A,V}) + \underbrace{\alpha^{-1} \int |\nabla \times (A - A^0)|^2 \, dx} \tag{28.1.1}$$

where $A^0 = \frac{1}{2} B(-x_2, x_1, 0)$ is a constant *external magnetic field*.

Then finally

$$\mathsf{E}^* = \inf_{A - A^0 \in \mathscr{H}^1_0} \mathsf{E}(A), \tag{28.1.2}$$

defines a ground state energy with a *combined magnetic field* A while $A' := A - A^0$ is a *self-generated magnetic field*.

Note that

$$\int |\nabla \times (A - A^0)|^2 \, dx = \int \bigl(|\nabla \times A|^2 - |\nabla \times A^0|^2\bigr) \, dx \tag{28.1.3}$$

which seems to be a more "physical" definition.

28.1.1 Plan of the Chapter

First of all, we are lacking so far a *semiclassical local theory* and we are developing it in Sections 28.2–28.4, where we consider a one-particle quantum Hamiltonian (28.2.1) with the external constant magnetic field A^0 of intensity β, $h \ll 1$ and a self-generated magnetic field $(A - A^0)$. Here theory significantly depends if $\beta h \lesssim 1$ or $\beta h \gtrsim 1$ as it was in the case without a self-generated magnetic field.

While Section 28.2 is preparatory and rather functional-analytical, Sections 28.3 and 28.4 are microlocal; they cover cases $\beta h \lesssim 1$ and $\beta h \gtrsim 1$ respectively. These three sections are similar to a single Section 27.2. However in Sections 28.3 and 28.4 various non-degeneracy assumptions play a very significant role, especially for large β.

Then in Section 28.5 we consider a global theory if a potential has Coulomb singularities and (in some statements) behaves like (magnetic) Thomas-Fermi potential both near singularities and far from them.

Finally, in Section 28.6 we apply these results to our original problem of the ground state energy so far assuming that the number of nuclei is 1. One can recover the same results if $M \ge 2$ but the external magnetic field B is weak enough. No surprise that the theory is different in the cases $B \le Z^{\frac{4}{3}}$ and $Z^{\frac{4}{3}} \le B \ll Z^3$ (see Chapter 25 where this difference appears). Since as $M = 1$ the strongest non-degeneracy assumption is surely achieved and as $M \ge 2$ much weaker non-degeneracy assumption is achieved in the border zone (see Chapter 25) our remainder estimates for large B significantly differ in the atomic and molecular cases.

In Appendix 28.A we first generalize Lieb-Loss-Solovej estimate to the case of the combined magnetic field (which is necessary if $\beta h \gtrsim 1$), then establish electrostatic inequality in the current settings and finally study very special pointwise spectral expressions for a Schrödinger operator in $\mathbb{R}^3$ with linear magnetic and scalar potentials (we considered such operators already in Section 16.6)

28.1.2 Unfinished Business

One can apply these results to estimates of the excessive positive and negative charges (the estimates for excessive positive charges, if $M \ge 2$ in the free nuclei framework) and estimates or asymptotics of the ionization energy in the same manner as we did it in Chapters 25–27; however there are no new

ideas but rather tedious calculations and we leave it to those readers who decide to explore these topics, which is clearly serious task.

28.2 Local Semiclassical Trace Asymptotics: Preparation

28.2.1 Toy-Model

Let us consider operator (27.1.4)

$$H = H_{A,V} = \big((hD - A)\cdot \boldsymbol{\sigma}\big)^2 - V(x) \tag{28.2.1}$$

in $\mathbb{R}^3$ where A, V are real-valued functions and $V \in \mathscr{C}^{\frac{5}{2}}$, $A - A^0 \in \mathscr{H}^1_0$. Then operator $H_{A,V}$ is self-adjoint. We are interested in $\mathsf{Tr}^-(H_{A,V}) = \mathsf{Tr}^-(H^-_{A,V})$ (the sum of all negative eigenvalues of this operator). Let

$$\mathsf{E}^* = \mathsf{E}^*_\kappa := \inf_{A-A^0\in\mathscr{H}^1_0} \mathsf{E}(A), \tag{28.2.2}$$

where

$$\mathsf{E}(A) = \mathsf{E}_\kappa(A) := \Big(\mathsf{Tr}^-(H_{A,V}) + \kappa^{-1}h^{-2}\int |\partial(A-A^0)|^2\,dx\Big) \tag{28.2.3}$$

with a matrix $\partial A = (\partial_i A_j)_{i,j=1,2,3}$. Recall that A^0 is a linear potential, $A^0(x) = \frac{1}{2}\beta(-x_2, x_1, 0)$. We consider rather separately cases

$$\beta h \lesssim 1 \qquad \text{and} \qquad \beta h \gtrsim 1 \tag{28.2.4}_{1,2}$$

of the *moderate* and *strong* external magnetic field.

To deal with the described problem we need to consider first a formal semiclassical approximation.

28.2.2 Formal Semiclassical Theory

Semiclassical Theory: $\beta h \lesssim 1$

Let us replace the trace expression $\mathsf{Tr}(H^-_{A,V}\psi)$ by its magnetic semiclassical approximation $-h^{-3}\int P_{Bh}(V)\psi\,dx$ where $B = |\nabla\times A|$ is a scalar intensity of the magnetic field and $P_*(.)$ is a pressure. Then $\mathsf{E}(A) \approx \mathcal{E}(A)$ with

$$\mathcal{E}(A) = \mathcal{E}_\kappa(A) := -h^{-3}\int P_{Bh}(V)\psi\,dx + \frac{1}{\kappa h^2}\int |\partial A'|^2\,dx. \tag{28.2.5}$$

Assuming that $|\partial A'| \ll \beta$, $A' = (A - A^0)$ we find out that

$$
\begin{aligned}
(28.2.6)\quad & -h^{-3}\int P_{Bh}(V)\psi\,dx \\
&\approx -h^{-3}\int \Big(P_{\beta h}(V) - \partial_\beta P_{\beta h}(V)(B-\beta)\psi\Big)\,dx \\
&\approx -h^{-3}\int P_{\beta h}(V)\psi\,dx \\
&\quad - h^{-3}\int \Big[\partial_{x_2}\big(\partial_\beta P_{\beta h}(V)\psi\big)\cdot A'_1 - \partial_{x_1}\big(\partial_\beta P_{\beta h}(V)\psi\big)\cdot A'_2\Big]\,dx,
\end{aligned}
$$

where we used that

$$
B \approx \beta - \partial_{x_2}A'_1 + \partial_{x_1}A'_2 \tag{28.2.7}
$$

and integrated by parts. Then $\mathcal{E}(A) \approx \bar{\mathcal{E}}(A)$ with

$$
\begin{aligned}
&(28.2.8)\quad \bar{\mathcal{E}}(A) = \bar{\mathcal{E}}_\kappa(A) \coloneqq -h^{-3}\int P_{\beta h}(V)\psi\,dx \\
&-h^{-3}\int \Big[\partial_{x_2}\big(\partial_\beta P_{\beta h}(V)\psi\big)\cdot A'_1 - \partial_{x_1}\big(\partial_\beta P_{\beta h}(V)\psi\big)\cdot A'_2\Big]\,dx + \frac{1}{\kappa h^2}\int |\partial A'|^2\,dx
\end{aligned}
$$

and replacing approximate equalities by exact ones and optimizing with respect to A' we arrive to

$$
\begin{aligned}
&(28.2.9)\quad \Delta A'_1 = -\frac{1}{2}\kappa h^{-1}\partial_{x_2}\big(\partial_\beta P_{\beta h}(V)\psi\big), \quad \Delta A'_2 = \frac{1}{2}\kappa h^{-1}\partial_{x_1}\big(\partial_\beta P_\beta(V)\psi\big), \\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \Delta A'_3 = 0
\end{aligned}
$$

and

$$
\mathcal{E}^*_\kappa \coloneqq \inf_{A:\ A-A^0\in \mathscr{H}^1_0} \mathcal{E}_\kappa(A) \approx \bar{\mathcal{E}}^*_\kappa \coloneqq \inf_{A:\ A-A^0\in \mathscr{H}^1_0} \bar{\mathcal{E}}_\kappa(A). \tag{28.2.10}
$$

To justify our analysis we need to justify approximate equality

$$
\begin{aligned}
&(28.2.11)\quad -h^{-3}\int P_{Bh}(V)\,dx + \frac{1}{\kappa h^2}\int |\partial A'|^2\,dx \\
&\qquad \approx -h^{-3}\int P_{\beta h}(V)\psi dx - h^{-3}\int \Big[\partial_\beta P_{\beta h}(V)\psi(-\partial_{x_2}A'_1 + \partial_{x_1}A'_2)\Big]\,dx + \\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \frac{1}{\kappa h^2}\int |\partial A'|^2\,dx
\end{aligned}
$$

and estimate an error when we minimize the right-hand expression instead of the left-hand one. To do this observe that (even without assumptions $Bh \lesssim 1$, $\beta h \lesssim 1$)

$$|P_{Bh}(V) - P_{\beta h}(V) - \partial_{\beta h} P_{\beta h}(V)\cdot(B-\beta)h| \le C(B-\beta)^2h^2 + C|B-\beta|^{\frac{3}{2}}\beta h^{\frac{5}{2}}. \tag{28.2.12}$$

Indeed, one can prove it easily recalling that

$$P_{\beta h}(V) = \varkappa_0 \sum_{j\ge 0}(1-\frac{1}{2}\delta_{j0})(V-2j\beta h)_+^{\frac{3}{2}}\beta h \tag{28.2.13}$$

and considering cases $\beta h \gtrsim 1$, $Bh \gtrsim 1$, $|B-\beta| \gtrsim \beta h$, analyzing different terms in (28.2.13) and observing that the last term in (28.2.12) appears only in the case $\beta h \lesssim 1$, $|B-\beta| \lesssim \beta$.

Then since $|B-\beta| \le |B'|$ (where $B' = |\partial(A-A^0)|$) we conclude that the left-hand expression of (28.2.11) is greater than

$$-h^{-3}\int P_{\beta h}(V)\psi\,dx - C\|B'\|\beta h^{-1} - C\|B'\|^{\frac{3}{2}}\beta h^{-\frac{1}{2}} + \kappa^{-1}h^{-2}\|B'\|^2,$$

where we used that

$$|\partial_{\beta h} P_{\beta h}(V)| \le C\beta h \qquad \text{if } V \le c; \tag{28.2.14}$$

then a minimizer for the left-hand expression of (28.2.11) must satisfy

$$\|B'\| \le C\kappa\beta h \tag{28.2.15}$$

and one can observe easily that the same is true and for the minimizer for the right-hand expression as well.

Also observe that

$$B = \beta + \partial_{x_1}A'_2 - \partial_{x_2}A'_1 + O(\beta^{-1}|B'|^2). \tag{28.2.16}$$

Then for both minimizers the differences between the left-hand and right-hand expressions of (28.2.11) do not exceed $C\kappa^{\frac{5}{2}}\beta^{\frac{5}{2}}$ and therefore

$$|\mathcal{E}^* - \bar{\mathcal{E}}^*| \le C\kappa^{\frac{5}{2}}\beta^{\frac{5}{2}}. \tag{28.2.17}$$

One can calculate easily the minimizer for

$$-h^{-3}\int \Big[\partial_\beta P_{\beta h}(V)\psi(-\partial_{x_2}A'_1+\partial_{x_1}A'_2)\Big]\,dx+\frac{1}{\kappa h^2}\int |\partial A'|^2\,dx \tag{28.2.18}$$

and conclude that $A'_j=\kappa\beta h a_j$ with $a_3=0$ and

$$\Delta a_1=-(\beta h)^{-1}\partial x_2\partial_{\beta h}P_{\beta h}(V),\quad \Delta a_2=(\beta h)^{-1}\partial x_1\partial_{\beta h}P_{\beta h}(V) \tag{28.2.19}$$

and the minimum is negative and $O(\kappa\beta^2)$; we call it *correction term*; in fact, $\|\partial A'\|\asymp \kappa\beta h$ and the minimum is $\asymp -\kappa\beta^2$ in the generic case.

Then a minimum of the left-hand expression of (28.2.11) is equal to the minimum of the right-hand expression modulo $O(\kappa^{\frac{3}{2}}\beta^{\frac{5}{2}}h)$.

Remark 28.2.1. (i) One can improve this estimate under non-degeneracy assumptions (28.3.60) or (28.3.65). However even in the general case observe that

$$\begin{aligned}&\mathcal{E}(A'')-\mathcal{E}(A')\\ &\geq -C\beta h^{-\frac{1}{2}}\|B'-B''\|^{\frac{3}{2}}-C\beta h^{-\frac{1}{2}}\|B'\|^{\frac{1}{2}}\cdot\|B'-B''\|+2\epsilon_0\kappa^{-1}h^{-2}\|\partial(A'-A'')\|^2\\ &\geq -C\kappa^2\beta^2h+\epsilon_0\kappa^{-1}h^{-2}\|\partial(A'-A'')\|^2\end{aligned}$$

if A' is the minimizer for $\bar{\mathcal{E}}$ and therefore since $\|B'\|\leq C\kappa\beta h$ we conclude that

$$\mathcal{E}^*\geq \mathcal{E}(A')-C\kappa^2\beta^2h \tag{28.2.20}$$

and

$$\|\partial(A'-A'')\|\leq C\kappa^{\frac{3}{2}}\beta h^{\frac{1}{2}} \tag{28.2.21}$$

if A'' is an almost-minimizer for $\mathcal{E}(A'')$.

(ii) Observe, that picking up $A'=0$ and applying arguments of Chapter 18 we can derive an upper estimate

$$\mathsf{E}^*\leq -\int P_{\beta h}(V)\psi\,dx+O(h^{-1}); \tag{28.2.22}$$

however this estimate is not sharp for $\kappa\beta^2\gg h^{-1}$ because $\mathcal{E}^*$ is less than the main term here with a gap $\asymp\kappa\beta^2$. For $\kappa\asymp 1$ it gives us a proper upper estimate only if $\beta\leq h^{-\frac{1}{2}}$.

Therefore for $\kappa\beta^2\gg h^{-1}$ an upper estimate is not as trivial as in Chapter 26; in the future we pick up as A' a minimizer for $\bar{\mathcal{E}}(A)$ (mollified by x as this minimizer is not smooth enough).

Semiclassical Theory: $\beta h \gtrsim 1$

Consider $\beta h \ge 1$. Without any loss of the generality one can assume that $\|V\|_{\mathscr{L}^\infty} \le \beta h$ and $\|\partial A'\|_{\mathscr{L}^\infty} \le \frac{1}{2}\beta$. Then in the definition (28.2.13) of $P_{\beta h}(V)$ (etc) remains only term with $j = 0$:

$$P_{\beta h}(V) = \frac{1}{2}\varkappa_0 V_+^{\frac{3}{2}} \beta h, \tag{28.2.13)'}$$

which leads to simplifications of $\mathcal{E}(A')$ and $\bar{\mathcal{E}}(A')$; both of them become

$$\frac{1}{2}\varkappa_0 \beta h^{-2} \int V_+^{\frac{3}{2}} \psi \, dx + \frac{1}{2}\varkappa_0 h^{-2} \int V_+^{\frac{3}{2}} \big(\partial_{x_1} A'_2 - \partial_{x_2} A'_1\big)\psi \, dx + \kappa^{-1} h^{-2} \|\partial A'\|^2 \tag{28.2.8)'}$$

modulo $O(\beta^{-1} h^{-2} \|B'\|^2)$ and equations to the minimizer become

$$\Delta A'_1 = -\frac{1}{2}\varkappa_0 \kappa \partial_{x_2}\big(V_+^{\frac{3}{2}}\psi\big), \quad \Delta A'_2 = \frac{1}{2}\varkappa_0 \kappa \partial_{x_1}\big(V_+^{\frac{3}{2}}\psi\big), \quad \Delta A'_3 = 0. \tag{28.2.9)'}$$

Then $\|B'\| \asymp \kappa$ and a correction term is negative and $\asymp -\kappa h^{-2}$ in the generic case. An error $O(\beta^{-1} h^{-2} \|B'\|^2)$ becomes $O(\kappa \beta^{-1} h^{-2})$ (and thus not exceeding microlocal error $O(\beta)$).

28.2.3 Estimate from below

Basic Estimates

Let us estimate $\mathsf{E}(A)$ from below. First we need the following really simple

Proposition 28.2.2 [1]**.** *Consider operator $H_{A,V}$, defined on $\mathscr{H}^2(B(0,1)) \cap \mathscr{H}^1_0(B(0,1))$* [2]*. Let $V \in \mathscr{L}^4$.*

(i) Let $\beta h \le 1$. Then

$$\mathsf{E}^* \ge -Ch^{-3} \tag{28.2.23}$$

and either

$$\frac{1}{\kappa h^2} \int |\partial(A - A^0)|^2 \, dx \le Ch^{-3} \tag{28.2.24}$$

or $\mathsf{E}(A) \ge ch^{-3}$.

---

[1] Cf. Proposition 27.2.1.

[2] I.e. on $\mathscr{H}^2(B(0,1))$ with the Dirichlet boundary conditions.

(ii) Let $\beta h \ge 1$. Then

$$\mathsf{E}^* \ge -C\beta h^{-2} - C\kappa^{\frac{1}{3}}\beta^{\frac{4}{3}}h^{-\frac{4}{3}} \tag{28.2.25}$$

and either

$$\frac{1}{\kappa h^2}\int |\partial(A-A^0)|^2\,dx \le C\beta h^{-2} + C\kappa^{\frac{1}{3}}\beta^{\frac{4}{3}}h^{-\frac{4}{3}} \tag{28.2.26}$$

or $\mathsf{E}(A) \ge C\beta h^{-2} + C\kappa^{\frac{1}{3}}\beta^{\frac{4}{3}}h^{-\frac{4}{3}}$.

(iii) Furthermore, let $\beta h \ge 1$ and

$$\kappa\beta h^2 \le c. \tag{28.2.27}$$

Then

$$\mathsf{E}^* \ge -C\beta h^{-2} \tag{28.2.28}$$

and either

$$\frac{1}{\kappa h^2}\int |\partial(A-A^0)|^2\,dx \le C\beta h^{-2} \tag{28.2.29}$$

or $\mathsf{E}(A) \ge C\beta h^{-2}$.

Proof. Using estimate (28.A.2) [3] we have

$$\begin{aligned}\mathsf{E}(A) \ge{}& -C(1+\beta h)h^{-3}\\ &- C\beta h^{-\frac{3}{2}}\Big(\int |\partial A'|^2\,dx\Big)^{\frac{1}{4}} - Ch^{-\frac{3}{2}}\Big(\int |\partial A'|^2\,dx\Big)^{\frac{3}{4}} + \frac{1}{\kappa h^2}\Big(\int |\partial A'|^2\,dx\Big),\end{aligned} \tag{28.2.30}$$

which implies both Statements (i)–(ii) while Statement (iii) is a special case of Statement (ii). □

Remark 28.2.3. (i) Definitely we would prefer to have an estimate

$$\begin{aligned}\mathsf{E}(A) \ge{}& -C(1+\beta h)h^{-3}\\ &- Ch^{-2}\Big(\int |\partial A'|^2\,dx\Big)^{\frac{1}{2}} + \frac{1}{\kappa h^2}\Big(\int |\partial A'|^2\,dx\Big)\end{aligned} \tag{28.2.31}$$

from the very beginning, but we cannot prove it without some smoothness conditions to A and they will be proven only later under the same assumption (28.2.27).

[3] Magnetic Lieb–Thirring inequality (5) of E. H. Lieb, M. Loss, M. and J. P. Solovej [1]) would be sufficient for $\beta h \le 1$ but will lead to a worse estimate than we claim for $\beta h \ge 1$.

(ii) This assumption (28.2.27) in a bit stronger form (28.2.27)* will be required for our microlocal analysis in the next Section 28.3.

Remark 28.2.4. Using Proposition 28.2.2 one can prove easily the following:

(i) Proposition 27.2.2 (existence of the minimizer) remains valid;

(ii) As in Remark 27.2.3 we do not know if the minimizer is unique. From now on until further notice let A be a minimizer. We also assume that V is sufficiently smooth ($V \in \mathscr{C}^{2+\delta}$). This is be the case for magnetic Thomas-Fermi potential for sure.

(iii) Proposition 27.2.4 (namely, equation (27.2.14) to a minimizer) remains valid for both A and $A' = A - A^0$.

Proposition 28.2.5 [4]**.** *(i) Let $\beta h \le 1$ and $0 < \kappa \le (1-\epsilon_0)\kappa^*$. Assume that*

$$\mathsf{E}^*(\kappa^*, \beta, h) \ge \mathcal{E} - CM, \tag{28.2.32}$$

$$\mathsf{E}^*(\kappa, \beta, h) \le \mathcal{E} + CM \tag{28.2.33}$$

with the same number $\mathcal{E}$ and with $M \ge Ch^{-1} + C\kappa^*\beta^2$. Then

$$\int |\partial A'|^2 \, dx \le C_1 \kappa h^2 M; \tag{28.2.34}$$

(ii) Let $\beta h \ge 1$ and $\kappa^* \beta h \le c$, $0 < \kappa \le (1-\epsilon_0)\kappa^*$. Assume that (28.2.32)–(28.2.33) *are fulfilled with the same number $\mathcal{E}$ and with $M \ge C\beta + C\kappa^* h^{-2}$. Then estimate also* (28.2.34) *holds.*

Proof. Proof obviously follows the proof of Proposition 27.2.5. □

Estimates to a Minimizer: $\beta h \lesssim 1$

Consider first the simpler case $\beta h \le 1$.

[4] Cf. Proposition 27.2.5.

Proposition 28.2.6. *Let $\beta h \le 1$. Then*

$$|e(x,y,\tau)| \le C\big(1+\mu^{\frac12}h^{\frac12}\big)h^{-3} \tag{28.2.35}$$

and

$$|((hD-A)_x\cdot\sigma)e(x,y,\tau)| \le C\big(1+\mu^{\frac12}h^{\frac12}\big)h^{-3}, \tag{28.2.36}$$

where

$$\mu = \|\partial A'\|_\infty. \tag{28.2.37}$$

Proof. Without any loss of the generality one can assume that $\mu h \ge 1$. Consider $\mu^{-\frac12}h^{\frac12}$-element in $\mathbb{R}^3_x$. Without any loss of the generality one can assume that $A^0(z) = A(z) = 0$ in its center z.

Since both operators $E(\tau)$ and $((hD-A)_x\cdot\sigma)E(\tau)$ have their operator norms bounded by c in $\mathscr{L}^2$, one can prove easily that both operators $\phi D^\alpha E(\tau)$ and $\phi D^\alpha((hD-A)_x\cdot\sigma)E(\tau)$ have their operator norms bounded by $C\zeta^{|\alpha|}$ with $\zeta = \mu^{\frac12}h^{-\frac12}$ if $\alpha\in\{0,1\}^3$ and ϕ is supported in the mentioned element.

Then operator norms of both operators $\gamma_x E(\tau)$ and $\gamma_x((hD-A)_x\cdot\sigma)E(\tau)$ from $\mathscr{L}^2$ to $\mathbb{C}^q$ do not exceed $C_0\zeta_1\zeta_3^{\frac12}$ and therefore the same is true for adjoint operators; here γ_z is operator of restriction to $x=z$.

Since $E(\tau)^* = E(\tau)^2 = E(\tau)$ we conclude that the left-hand expressions in (28.2.35) and (28.2.36) do not exceed $C\zeta^3$, which is exactly the right-hand expression in both of them.

Then from equation (27.2.14), which remains valid (see Remark 28.2.4(iii)) we conclude that

$$\|\Delta A'\|_{\mathscr{L}^\infty} \le C\kappa\big(1+\mu^{\frac12}h^{\frac12}\big)h^{-1} \tag{28.2.38}$$

and therefore

$$\|\partial^2 A'\|_{\mathscr{L}^\infty} \le C\kappa|\log h|\big(1+\mu^{\frac12}h^{\frac12}\big)h^{-1}. \tag{28.2.39}$$

Further, combining (28.2.39) with (28.2.24), the standard inequality $\|\partial A'\|_{\mathscr{L}^\infty} \le \|\partial^2 A'\|^{\frac35}_{\mathscr{L}^\infty}\cdot\|\partial A'\|^{\frac25}$ and (28.2.37), we conclude that

$$\mu \le C(\kappa|\log h|)^{\frac45}\big(1+\mu^{\frac12}h^{\frac12}\big)^{\frac45}h^{-\frac45}$$

and therefore $\mu h \ll 1$. Then

$$\|\partial A'\|_{\mathscr{L}^\infty} \le C(\kappa|\log h|)^{\frac45}h^{-\frac45} \tag{28.2.40}$$

and therefore due to (28.2.39)

$$\|\partial A'\|_{\mathscr{L}^\infty} \le C\kappa|\log h|h^{-1} \tag{28.2.41}$$

(where for a sake of simplicity we slightly increase power of logarithm) thus arriving to

Proposition 28.2.7. *Let $\beta h \le 1$ and $\kappa \le \kappa^*$. Let A be a minimizer. Then estimates* (28.2.40) *and* (28.2.41) *hold.*

Furthermore, the standard scaling arguments applied to the results of Section 27.2 imply that in fact the left-hand expressions of estimates (28.2.36) and (28.2.24) do not exceed $C(1+\beta+\mu)h^{-2}$ and $C(1+\beta+\mu)^2h^{-1}$ respectively.

Therefore $\|\partial^2 A'\|_{\mathscr{L}^\infty}$ does not exceed $C\kappa|\log h|(1+\beta+\mu)$ and $\|\partial A'\|$ does not exceed $C\kappa^{\frac12}(1+\beta+\mu)h^{\frac12}$, and then $\mu \le C(\kappa|\log h|)^{\frac45}(1+\beta+\mu)^{\frac45}h^{\frac15}$ which implies $\mu \le C(\kappa|\log h|)^{\frac45}(1+\beta)^{\frac45}h^{\frac15}$ and finally we arrive to

Proposition 28.2.8. *Let $\beta h \le 1$ and $\kappa \le \kappa^*$. Then*

$$\|\partial A'\|_{\mathscr{L}^\infty} \le C(\kappa|\log h|)^{\frac45}(1+\beta)^{\frac45}h^{\frac15} \tag{28.2.42}$$

and

$$\|\partial^2 A'\|_{\mathscr{L}^\infty} \le C\kappa|\log h|(1+\beta). \tag{28.2.43}$$

Estimates to a Minimizer: $\beta h \gtrsim 1$

Consider now more complicated case $\beta h \ge 1$.

Proposition 28.2.9. *Let $\beta h \ge 1$. Then the following estimates hold with $\mu = \|\partial A'\|_\infty$:*

$$|e(x,y,\tau)| \le C\big(\beta+\mu\big)\big(1+\mu^{\frac12}h^{\frac12}\big)h^{-2} \tag{28.2.44}$$

and

$$|((hD-A)_x\cdot\sigma)e(x,y,\tau)| \le C\big(\beta+\mu\big)\big(1+\mu^{\frac12}h^{\frac12}\big)h^{-2} \tag{28.2.45}$$

Proof. Without any loss of the generality one can assume that $\mu \le \beta$; otherwise we simply replace β by μ. Consider $(\beta^{-\frac12}h^{\frac12}, \beta^{-\frac12}h^{\frac12}, (\mu+1)^{-\frac12}h^{\frac12})$-box in $\mathbb{R}^3_x$, where recall that $\nabla\times A^0$ is directed along x_3. Without any loss of the generality one can assume that $A^0(z) = A'(z) = 0$ in its center z.

Since both operators $E(\tau)$ and $((hD-A)_x\cdot\boldsymbol{\sigma})E(\tau)$ have their operator norms bounded by c in $\mathscr{L}^2$, one can prove easily that both operators $\phi D^\alpha E(\tau)$ and $\phi D^\alpha((hD-A)_x\cdot\boldsymbol{\sigma})E(\tau)$ have their operator norms bounded by $C\zeta^\alpha$ with $\zeta_1=\zeta_2=\beta^{\frac12}h^{-\frac12}$ and $\zeta_3=(h^{-1}+\mu^{\frac12}h^{-\frac12})$ for $\alpha\in\{0,1\}^3$ and ϕ, supported in the mentioned cube.

Then operator norms of both operators $\gamma_x E(\tau)$ and $\gamma_x((hD-A)_x\cdot\boldsymbol{\sigma})E(\tau)$ from $\mathscr{L}^2$ to $\mathbb{C}^q$ do not exceed $C_0\zeta_1\zeta_3^{\frac12}$ and therefore the same is true for adjoint operators; recall that γ_z is operator of restriction to $x=z$.

Since $E(\tau)^*=E(\tau)^2=E(\tau)$ we conclude that the left-hand expressions in (28.2.44) and (28.2.45) do not exceed $C\zeta_1^2\zeta_3$ which is exactly the right-hand expressions in both of them. □

Then from equation (27.2.14), which remains valid (see Remark 28.2.4(iii)), we conclude that

$$\|\Delta A'\|_{\mathscr{L}^\infty}\le C\kappa\big(\beta+\mu\big)\big(1+\mu^{\frac12}h^{\frac12}\big) \tag{28.2.46}$$

and therefore

$$\|\partial^2 A'\|_{\mathscr{L}^\infty}\le C\kappa|\log\beta|\big(\beta+\mu\big)\big(1+\mu^{\frac12}h^{\frac12}\big). \tag{28.2.47}$$

Let (28.2.27)) be fulfilled. Then combining (28.2.47) with (28.2.29) and $\|\partial A'\|_{\mathscr{L}^\infty}\le \|\partial^2 A'\|_{\mathscr{L}^\infty}^{\frac35}\cdot\|\partial A'\|^{\frac25}$ we conclude that

$$\mu\le C(\kappa|\log\beta|)^{\frac35}\big(\beta+\mu\big)^{\frac35}\big(1+h^{\frac12}\mu^{\frac12}\big)^{\frac35}\times\kappa^{\frac15}\beta^{\frac15}$$

and then <u>either</u>

$$1\le\mu h\le C(\kappa\beta h|\log\beta|)^{\frac67}(\kappa\beta h^2)^{\frac27} \tag{28.2.48}$$

<u>or</u> $\mu h\le 1$. In the former case of (28.2.48)

$$\|\partial A'\|_{\mathscr{L}^\infty}\le C(\kappa\beta|\log\beta|)^{\frac87}h^{\frac37} \tag{28.2.49}$$

and

$$\|\partial^2 A'\|_{\mathscr{L}^\infty}\le C(\kappa\beta|\log\beta|)^{\frac{11}{7}}h^{\frac57}. \tag{28.2.50}$$

Observe that the right-hand expression of (28.2.49) is less than $C\beta$ under assumption

$$\kappa\beta h^2|\log\beta|^K\le c \tag{28.2.27)*}$$

with sufficiently large K; however the right-hand expression of (28.2.50) is not necessarily less than $C\beta$ under this assumption and we need more delicate arguments.

Without any loss of the generality we can assume that $\partial_3 A_3(z) = 0$ (we can reach it by a gauge transformation).

Then considering $(\beta^{-\frac{1}{2}}h^{\frac{1}{2}}, \beta^{-\frac{1}{2}}h^{\frac{1}{2}}, \nu^{-\frac{1}{3}}h^{\frac{1}{3}})$-box in $\mathbb{R}^3$ we can replace factor $(1+\mu^{\frac{1}{2}}h^{\frac{1}{2}})h^{-1}$ by $(1+\nu^{\frac{1}{3}}h^{\frac{2}{3}})h^{-1}$ in all above estimates with $\nu = \|\partial^2 A'\|_{\mathscr{L}^\infty}$ and therefore (28.2.47) is replaced by

$$\nu \le C\kappa|\log\beta|\beta\big(1+\nu^{\frac{1}{3}}h^{\frac{2}{3}}\big)$$

and then under assumption (28.2.27)*

$$\nu = \|\partial^2 A'\|_{\mathscr{L}^\infty} \le C\kappa|\log\beta|\beta \tag{28.2.51}$$

which implies

$$\|\partial A'\|_{\mathscr{L}^\infty} \le C(\kappa|\log\beta|\beta)^{\frac{4}{5}}. \tag{28.2.52}$$

Obviously, if $\mu h \le 1$ we arrive to the same conclusion in easier way. Thus we have proven

Proposition 28.2.10. *Let $\beta h \ge 1$, $\kappa \le \kappa^*$ and (28.2.27)* be fulfilled. Then estimates (28.2.51)–(28.2.52) hold.*

28.3 Microlocal Analysis Unleashed: $\beta h \lesssim 1$

28.3.1 Rough Estimate to a Minimizer

Recall equation (27.2.14) to a minimizer A of $\mathsf{E}(A)$:

$$\frac{2}{\kappa h^2}\Delta A_j(x) = \Phi_j(x) := \tag{27.2.14}$$
$$-\operatorname{Re}\operatorname{tr}\Big[\sigma_j\Big(\big((hD-A)_x\cdot\boldsymbol{\sigma}e(x,y,\tau) + e(x,y,\tau)\,{}^t(hD-A)_y\cdot\boldsymbol{\sigma}\big)\Big)\Big]|_{y=x},$$

where $e(x,y,\tau)$ is the Schwartz kernel of the spectral projector $\theta(\tau - H_{A,V})$. In the current framework this equation should be replaced by

$$\frac{2}{\kappa h^2}\Delta\big(A_j(x) - A_j^0(x)\big) = \Phi_j(x) \tag{28.3.1}$$

with $\Phi_j(x)$ defined above but since $\Delta A_j^0 = 0$ these two equations are equivalent. We assume in this section that $\beta h \lesssim 1$.

Proposition 28.3.1. *Let $\beta h \lesssim 1$ and let*

$$\|\partial A'\|_{\mathscr{L}^\infty} \le \mu \le h^{-1}. \tag{28.3.2}$$

Then for $\theta \in [1,2]$

$$\begin{aligned}\|\Phi_j\|_{\mathscr{L}^\infty} + \|h\partial\Phi_j\|_{\mathscr{L}^\infty} \\ \le Ch^{-2}\Big(1+\beta^{\frac{3}{2}}h^{\frac{1}{2}} + |\log h| + (\beta h)^{\frac{\theta-1}{\theta+1}}\|\partial A'\|_{\mathscr{C}^\theta}^{\frac{1}{\theta+1}} + (\beta h)^{\frac{\theta-1}{\theta+1}}\|\partial V\|_{\mathscr{C}^\theta}^{\frac{1}{\theta+1}}\Big).\end{aligned} \tag{28.3.3}$$

Proof. (i) Assume first that $V \asymp 1$,

$$\beta h^{\frac{1}{3}} \lesssim 1 \qquad \text{and} \qquad \mu = 1. \tag{28.3.4}$$

Note that we need to consider only case $\beta \ge 2$ because otherwise estimate has been proven in Section 27.2 (see Proposition 27.2.16). Then the contribution of the zone $\mathscr{Z}'_\rho := \{|\xi_3 - A_3(x)| \le \rho\}$ with $\rho \ge \rho_* := C_0\beta^{-1}$ to the Tauberian remainder with $T = T_* := \epsilon\beta^{-1}$ does not exceed

$$Ch^{-2}\rho\Big(\beta + h^{\frac{1}{2}(\theta-1)}\|\partial A'\|_{\mathscr{C}^\theta}^{\frac{1}{2}} + h^{\frac{1}{2}(\theta-1)}\|\partial V\|_{\mathscr{C}^\theta}^{\frac{1}{2}}\Big). \tag{28.3.5}$$

Indeed, if Q is h-pseudodifferential operator supported in this zone then exactly as in the proof of (27.2.48) for $T \le T_*$

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma_x\big((hD)^k Q_x U_\varepsilon\big)| \le C\rho h^{-2}$$

and

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma_x\big((hD)^k Q_x (U-U_\varepsilon)\big)| \le C\rho h^{-4}\vartheta T^2,$$

where U and U_ε are Schwartz kernels of $e^{-ih^{-1}tH_{A,V}}$ and $e^{-ih^{-1}tH_{A_\varepsilon,V_\varepsilon}}$ respectively and ϑ is an operator norm of perturbation $\big(H_{A_\varepsilon,V_\varepsilon} - H_{A,V}\big)$, A_ε and V_ε are ε-mollification of A and V respectively and $\varepsilon \ge h$; then

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma_x\big((hD)^k Q_x U\big)| \le C\rho(h^{-2} + h^{-4}\vartheta T^2)$$

and therefore the Tauberian error does not exceed $C\rho(h^{-2}T^{-1} + h^{-4}\vartheta T)$.

Optimizing by $T \le T_*$ we get $C\rho(h^{-2}\rho^{-1} + h^{-3}\vartheta^{\frac{1}{2}})$ with $\varepsilon = h$ and $\vartheta = \varepsilon^{\theta+1}\|\partial A'\|_{\mathscr{C}^\vartheta}$, which is exactly the (28.3.5).

Further, following arguments of Section 27.2 we conclude that an error when we pass from the Tauberian expression to the Weyl expression does not exceed

$$C\rho h^{-2}\Big(1 + h^{\frac{1}{2}(\theta-1)}\|\partial A'\|_{\mathscr{C}^\theta}^{\frac{1}{2}} + h^{\frac{1}{2}(\theta-1)}\|\partial V\|_{\mathscr{C}^\theta}^{\frac{1}{2}}\Big). \tag{28.3.6}$$

(ii) On the other hand, the contribution of zone $\mathcal{Z}_\rho = \{|\xi_3 - A_3(x)| \asymp \rho\}$ with $\rho \ge \rho_* = C_0\beta^{-1}$ to the Tauberian remainder with $T = T^* := \epsilon\rho$ does not exceed

$$Ch^{-2}\Big(1 + \rho^{\frac{1}{2}(1-\theta)}h^{\frac{1}{2}(\theta-1)}\|\partial A'\|^{\frac{1}{2}}_{\mathscr{C}^\theta} + \rho^{\frac{1}{2}(1-\theta)}h^{\frac{1}{2}(\theta-1)}\|\partial V\|^{\frac{1}{2}}_{\mathscr{C}^\theta}\Big). \tag{28.3.7}$$

Indeed, if Q is h-pseudodifferential operator, supported in this zone, then for $T \le T^*$

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma_x\big((hD)^k Q_x U_\varepsilon\big)| \le C\rho h^{-2},$$

and for $T_* \le T \le T^*$

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma_x\big((hD)^k Q_x U_\varepsilon\big)| \le C\rho h^{-2}(h/T\rho^2)^s,$$

and then

$$|F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t) - \bar{\chi}_{T_*}(t)\big)\Gamma_x\big((hD)^k Q_x U_\varepsilon\big)| \le C\rho h^{-2}(\beta h/\rho^2)^s$$

and

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma_x\big((hD)^k Q_x U_\varepsilon\big)| \le C\rho h^{-2},$$

while approximation error is estimated in the same way as before but with $\varepsilon = h\rho^{-1}$ and thus ϑ acquires factor $\rho^{-1-\theta}$.

Then the Tauberian error is estimated and optimized by $T \le T^*$ and it does not exceed (28.3.7).

Following arguments of Section 27.2 we conclude that an error when we pass from the Tauberian expression to the Weyl expression does not exceed (28.3.6).

Then the summation of the Tauberian error with respect to ρ ranging from $\rho = \rho'$ to $\rho = 1$ (where in what follows we use ρ instead of ρ' notation) returns

$$Ch^{-2}\Big(1 + |\log\rho| + \rho^{-\frac{1}{2}(\theta-1)}h^{\frac{1}{2}(\theta-1)}\|\partial A'\|^{\frac{1}{2}}_{\mathscr{C}^\theta} + \rho^{-\frac{1}{2}(\theta-1)}h^{\frac{1}{2}(\theta-1)}\|\partial V\|^{\frac{1}{2}}_{\mathscr{C}^\theta}\Big) \tag{28.3.8}$$

and adding contribution of zone $\mathcal{Z}'_\rho$ we conclude that the total Tauberian remainder does not exceed

$$Ch^{-2}\Big(\beta\rho + |\log\rho| + \rho^{-\frac{1}{2}(\theta-1)}h^{\frac{1}{2}(\theta-1)}\|\partial A'\|^{\frac{1}{2}}_{\mathscr{C}^\theta} + \rho^{-\frac{1}{2}(\theta-1)}h^{\frac{1}{2}(\theta-1)}\|\partial V\|^{\frac{1}{2}}_{\mathscr{C}^\theta}\Big). \tag{28.3.9}$$

Meanwhile, the summation of the Tauberian-to-Weyl error with respect to ρ returns (28.3.9) albeit without logarithmic term. Optimizing with respect to $\rho \ge \rho_*$ we arrive to

$$Ch^{-2}\Big(1+|\log h|+(\beta h)^{\frac{\theta-1}{\theta+1}}\|\partial A'\|_{\mathscr{C}^\theta}^{\frac{1}{\theta+1}}+(\beta h)^{\frac{\theta-1}{\theta+1}}\|\partial V\|_{\mathscr{C}^\theta}^{\frac{1}{\theta+1}}\Big). \tag{28.3.10}$$

Furthermore, observe that

(28.3.11) If in ϵ-vicinity of x inequality $|\nabla V|\le \zeta$ holds (with $\zeta \ge |\log h|^{-1}$), then we can pick up $T^* = \epsilon \min(\zeta^{-1}\rho, 1)$.

Indeed, we can introduce

$$p_3' := \xi_3 - A_3 - \beta^{-1}\alpha_1(\xi_1 - A_1) - \beta^{-1}\alpha_2(\xi_2 - A_2)$$

such that $\{H, p_3'\} = V_{\xi_3} + O(\nu\beta^{-1})$ with $\nu := \|\partial^2 A\|_{\mathscr{C}^\infty}$.

Therefore, in this case the remainder does not exceed

$$Ch^{-2}\Big(1+\zeta|\log h|+(\beta h)^{\frac{\theta-1}{\theta+1}}\|\partial A'\|_{\mathscr{C}^\theta}^{\frac{1}{\theta+1}}+(\beta h)^{\frac{\theta-1}{\theta+1}}\|\partial V\|_{\mathscr{C}^\theta}^{\frac{1}{\theta+1}}\Big). \tag{28.3.12}$$

(iii) Finally, observe that the Weyl expression for Φ_j is just 0. Therefore under assumption (28.3.4) slightly improved estimate (28.3.3) has been proven: $\|\Phi_j\|_{\mathscr{L}^\infty} + \|h\partial\Phi_j\|_{\mathscr{L}^\infty}$ does not exceed expression (28.3.12).

(iv) To get rid of assumption (28.3.4) we scale $x \mapsto x\gamma^{-1}$, $h \mapsto h\gamma^{-1}$, $\beta \mapsto \beta\gamma$ and pick up $\gamma = \min\big((\beta h^{\frac13})^{-\frac32}, \mu^{-1}\big)$; then $\beta h \mapsto \beta h$, and $Ch^{-2} \mapsto Ch^{-2}\gamma^{-1} = C\beta^{\frac32}h^{-\frac32} + C\mu h^{-2}$ (as we need to multiply by γ^{-3}) and both $\|\partial A'\|_{\mathscr{C}^\theta}^{\frac{1}{\theta+1}}$ and $\|\partial V\|_{\mathscr{C}^\theta}^{\frac{1}{\theta+1}}$ acquire factor γ.

Observing that we can take $\zeta = C\gamma$ and that factor γ also pops up in all other terms (except 1) in (28.3.12) we arrive to estimate (28.3.3).

Furthermore, to get rid of assumption $V \asymp 1$ we also can scale with $\gamma = \epsilon|V| + h^{\frac23}$ and multiply operator by γ^{-1}; then $h \mapsto h\gamma^{-\frac32}$, $\beta \mapsto \beta\gamma^{\frac12}$ and estimate (28.3.3) does not deteriorate; we need to multiply by $\gamma^{\frac12}$ which does not hurt. □

Remark 28.3.2. (i) We can use $\theta' \neq \theta$ for norm of V.

(ii) If V is smooth enough we can skip the related term (details later).

(iii) We can take $\theta = 1$ but in this case factor $\rho^{-\frac{1}{2}(\theta-1)}h^{\frac{1}{2}(\theta-1)}$ in (28.3.8) (i.e. after summation) and in (28.3.9) is replaced by $|\log\rho|$; then taking into account (i) we replace (28.3.10) by

$$(28.3.10)' \qquad Ch^{-2}\Big(1+|\log h|+|\log h|\cdot \|\partial A'\|^{\frac{1}{2}}_{\mathscr{C}^1} + (\beta h)^{\frac{\theta'-1}{\theta'+1}}\|\partial V\|^{\frac{1}{\theta'+1}}_{\mathscr{C}^{\theta'}}\Big)$$

and similarly we deal with (28.3.12) and (28.3.3):

$$(28.3.3)' \quad \|\Phi_j\|_{\mathscr{L}^\infty} + \|h\partial\Phi_j\|_{\mathscr{L}^\infty} \leq Ch^{-2}\Big(1+\beta^{\frac{3}{2}}h^{\frac{1}{2}}+|\log h|+|\log h|\|\partial A'\|^{\frac{1}{2}}_{\mathscr{C}^1} + (\beta h)^{\frac{\theta'-1}{\theta'+1}}\|\partial V\|^{\frac{1}{\theta'+1}}_{\mathscr{C}^{\theta'}}\Big).$$

(iv) From the very beginning we could assume that $\mu \leq \beta$; otherwise we could rescale as above with $\gamma = \beta^{-1}$ and apply arguments of Section 27.2 simply ignoring external field.

Corollary 28.3.3. *Let in the framework of Proposition 28.3.1 A' be a minimizer. Then for $\theta, \theta' \in [1,2]$*

$$(28.3.13) \quad |\log h|^{-1}\|\partial A'\|_{\mathscr{C}^1} + h^{\theta-1}\|\partial A'\|_{\mathscr{C}^\theta} \leq C\kappa\Big(\beta^{\frac{3}{2}}h^{\frac{1}{2}}+|\log h|+\mu+(\beta h)^{\frac{1}{2}(\theta'-1)}\|V\|^{\frac{1}{2}}_{\mathscr{C}^{\theta'+1}}\Big) + C\kappa^2|\log h||\log h|^2 + C\|\partial A'\|.$$

Proof. Indeed, the left-hand expression of (28.3.13) does not exceed

$$\|\Delta A'\|_{\mathscr{L}^\infty} + \|h\partial\Delta A'|_{\mathscr{L}^\infty} + C\|\partial A'\|$$

while for a minimizer $\|\Delta A'\|_{\mathscr{L}^\infty} + \|h\partial\Delta A'|_{\mathscr{L}^\infty}$ does not exceed the right-hand expression of (28.3.3) multiplied by $C\kappa h^2$. □

28.3.2 Microlocal Analysis

As long as $\beta \leq C_0 h^{-\frac{1}{3}}$ we are rather happy with our result here, but we want to improve it otherwise. First we will prove that singularities propagate along magnetic lines; however since we do not know a self-generated magnetic field we just consider all possible lines which will be in the cone $\{(x,y)\colon |x'-y'| \leq C_0\mu\beta^{-1}T\}$ where $1 \leq \mu \leq \beta$.

Proposition 28.3.4. *Assume that* $\beta h \lesssim 1$,

$$\|V\|_{\mathscr{C}^1(B(0,2))} \le C_0 \tag{28.3.14}$$

and

$$\|\partial A'\|_{\mathscr{C}(B(0,2))} \le \mu \qquad (1 \le \mu \le \epsilon\beta) \tag{28.3.15}$$

with sufficiently small constant $\epsilon > 0$.

Let $U(x,y,t)$ *be the Schwartz kernel of* $e^{ih^{-1}tH_{A,V}}$. *Then*

(i) For $T \asymp 1$ *estimate*

$$\|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\psi_1(x)\psi_2(y)U\| \le Ch^s \tag{28.3.16}$$

holds for all $\psi_1, \psi_2 \in \mathscr{C}_0^\infty(B(0,1))$, *such that* $\mathsf{dist}(\mathsf{supp}(\psi_1), \mathsf{supp}(\psi_2)) \ge C_0 T$ *and* $\tau \le c_0$; *here* $\|.\|$ *means an operator norm from* $\mathscr{L}^2$ *to* $\mathscr{L}^2$ *and* s *is arbitrarily large.*

(ii) For $\bar{\rho} \le \rho \lesssim 1$ *with* $\bar{\rho} := C_0\mu\beta^{-1}$ *and* $T \asymp \rho$ *estimate*

$$\begin{aligned}\|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\varphi_1(\rho^{-1}p_{3x})\varphi_2(\rho^{-1}p_{3y})\psi_1(x)\psi_2(y)U\| \\ \le C\rho^{1-3s}h^s + C\rho^{2-\theta}h^\theta\big(\|\!|A'|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big)\end{aligned} \tag{28.3.17}$$

holds for all all $\varphi_1, \varphi_2 \in \mathscr{C}_0^\infty$, $\psi_1, \psi_2 \in \mathscr{C}_0^\infty(B(0,1))$, *such that* $\mathsf{dist}(\mathsf{supp}(\varphi_1), \mathsf{supp}(\varphi_2)) \ge C_0$, *and* $\tau \le c_0$; *here and below* $p_j = hD_j - A_j$, $p_j^0 = hD_j - A_j^0$.

(iii) For $\bar{\rho} \le \rho \lesssim 1$ *and* $T \asymp \rho \lesssim 1$ *estimate*

$$\begin{aligned}\|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\varphi_1(\rho^{-1}p_{3x})\varphi_2(\rho^{-1}p_{3y})\psi_1(\gamma^{-1}x)\psi_2(\gamma^{-1}y)U\| \\ \le C\rho^{1-s}\gamma^{-s}h^s + Ch^\theta\gamma\rho^{-\theta}\big(\|\!|A'|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big)\end{aligned} \tag{28.3.18}$$

holds for all $\varphi_1, \varphi_2 \in \mathscr{C}_0^\infty$, $\psi_1, \psi_2 \in \mathscr{C}_0^\infty$, *such that* $\mathsf{dist}(\mathsf{supp}(\psi_1), \mathsf{supp}(\psi_2)) \ge C_0$, $\gamma = \rho T \ge \beta^{-1}$, $\rho\gamma \ge h$ *and* $\tau \le c_0$.

Proof. Statement (i) claims that the general propagation speed with respect to x is bounded by C_0. Further, Statement (ii) claims that the on distances $\ge C_0\bar{\rho}$ the propagation speed with respect to p_3 is also bounded by C_0. Finally, Statement (iii) claims that on distances $\ge C_0\bar{\rho}$ the propagation speed with respect to x is bounded by $C_0\rho$. Note that from Corollary 28.3.3 we know that $\mu \lesssim \beta$.

(a) Proof follows the proof of Proposition 27.2.11 in the framework of the strong magnetic field. Namely, proof of Statement (i) is a straightforward repetition of the proof of Proposition 27.2.11(i). Since here we do not apply at this stage operators $(hD_x)^\alpha$ and $(hD_y)^{\alpha'}$, no assumption to the smoothness of A is needed.

(b) Assume that $A_3 \equiv 0$ (we will get rid of this assumption on the next step). After Statement (i) has been proven we rescale $t \mapsto t/T$, $x_3 \mapsto x_3/\gamma$ with $\gamma = \rho T$ (since φ_l depend only on ξ_3, all other coordinates are rather irrelevant), $h \mapsto \hbar = h/(\rho\gamma)$, $T \mapsto 1$. Then we apply the arguments used in the proof of Proposition 27.2.11(ii) and conclude that the left-hand expression of (28.3.17) does not exceed

$$T\Big(\hbar^s + C\hbar^\theta \gamma^{\theta+1}\big(\|\!|A'|\!\|_{\theta+1} + \|\!|V|\!\|_{\theta+1}\big)\Big),$$

where factor T is due to the scaling in the Fourier transform and $\gamma^{\theta+1}$ is due to the scaling in $\|\!|\cdot|\!\|$-norms. Plugging $\hbar$, T, and $\gamma = \rho^2$ we get the right-hand expression of (28.3.17).

Then if ψ_l depend only on x_3, y_3 we can follow the proof of Proposition 27.2.11(iii) and prove Statement (iii).

(c) Let A_3 be not necessarily identically 0. To consider ψ_l depending only on x_1 or x_2 we should introduce (in the standard magnetic Schrödinger manner) $x_1' := x_1 + \beta^{-1}p_2^0$ or $x_2' := x_2 - \beta^{-1}p_1^0$ respectively; recall that $p_j^0 = hD_j - A_j^0$ and $p_j = hD_j - A_j$, $j = 1,2,3$.

Then $[p_1^0, p_2^0] = ih\beta^{-1}$, $[p_j^0, x_k] = -ih\delta_{jk}$, $[p_j^0, x_k'] = 0$ and one can see easily that $[p_j, x_k'] = O(\beta^{-1}\mu h)$ (for any $\mu : 1 \le \mu \le \beta$) for $j = 1,2,3$ and $k = 1,2$. Now we can apply the same arguments as above as long as $\rho \ge \bar\rho$.

(d) Next we need to recover Statement (ii) in the general case. Without any loss of the generality we may consider a vicinity of point z where $A'(z) = 0$ and also $\partial A'(z) = 0$. Indeed we can achieve the former by the gauge transformation and the latter by a rotation of coordinates in which case increment of p_3^0 will be $O(\bar\rho)$.

In this case we just repeat the same arguments of Part (b) of our proof.

(e) Finally, the proof of Statement (iii) as ψ_l depend only on x_3 follows from Statement (ii).

We leave all easy details to the reader. □

Proposition 28.3.5. *Let $\beta h \lesssim 1$ and assumptions* (28.3.14) *and* (28.3.15) *be fulfilled. Then*

(i) For $h \le T \le 1$ estimate

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)p_x^{\alpha}p_y^{\alpha'}U| \le CT^{-s}h^{-3+s} \tag{28.3.19}$$

holds for all $\alpha : |\alpha| \le 2$, $\alpha' : |\alpha'| \le 2$, and all $x, y \in B(0,1)$, such that $|x-y| \ge C_0T$ and $\tau \le c_0$.

(ii) In the framework of Proposition 28.3.4(ii) the following estimate holds for all $\alpha : |\alpha| \le 2$, $\alpha' : |\alpha'| \le 2$, and $\tau \le c$:

$$\begin{aligned}|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)p_x^{\alpha}p_y^{\alpha'}\varphi_1(\rho^{-1}p_{3x})\varphi_2(\rho^{-1}p_{3y})\psi_1(x)\psi_2(y)U| \\ \le C\rho h^{-1}\bigl(\beta h^{-1}+\rho^2h^{-2}\bigr)\Bigl(\rho^{1-3s}h^s+\rho^{2-\theta}h^{\theta}\bigl(\|A'\|_{\theta+1}+\|V\|_{\theta+1}\bigr)\Bigr);\end{aligned} \tag{28.3.20}$$

(iii) In the framework of Proposition 28.3.4(iii) the following estimate holds for all $\alpha : |\alpha| \le 2$, $\alpha' : |\alpha'| \le 2$, and $\tau \le c$:

$$\begin{aligned}|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)p_x^{\alpha}p_y^{\alpha'}\varphi_1(\rho^{-1}p_{3x})\varphi_2(\rho^{-1}p_{3y})\psi_1(\gamma^{-1}x)\psi_2(\gamma^{-1}y)U| \\ \le C\rho h^{-1}\bigl(\beta h^{-1}+\rho^2h^{-2}\bigr)\Bigl(\rho^{1-s}\gamma^{-s}h^s+h^{\theta}\gamma\rho^{-\theta}\bigl(\|A'\|_{\theta+1}+\|V\|_{\theta+1}\bigr)\Bigr).\end{aligned} \tag{28.3.21}$$

Proof. Observe that estimates (28.3.16)–(28.3.18) hold if one applies operator $p_x^{\alpha}p_y^{\alpha'}$ under the norm (this follows from equations for U by (x,t) and dual equations by (y,t)). Then estimates (28.3.19)–(28.3.21) hold with $\alpha = \alpha' = 0$.

Really, without any loss of the generality one can assume that $A' = 0$ at some point of $\operatorname{supp}(\psi_1)$; then estimates (28.3.16)–(28.3.18) hold if one applies operator $p_x^{0\alpha}p_y^{0\alpha'}$ instead. Then estimate (28.3.19) holds with $\alpha = \alpha' = 0$; further, estimates (28.3.20)–(28.3.21) also hold with $\alpha = \alpha' = 0$ if one applies an extra factor $\bar{\varphi}_1(\rho^{-1}p_{3x}^0)\bar{\varphi}_2(\rho^{-1}p_{3y}^0)$ under the norm (this follows from the properties of p_j^0, $j = 1,2,3$, in particular, canonical form). However if $\bar{\varphi}_l = 1$ in ϵ-vicinity of $\operatorname{supp}(\varphi_l)$ then we can skip this factor.

Finally, appealing to equations for U by (x,t) and (y,t) again we recover estimates (28.3.19)–(28.3.21) with $|\alpha| \le 2$, $|\alpha'| \le 2$. □

Proposition 28.3.6. *Let* $\beta h \lesssim 1$ *and* (28.3.14) *and* (28.3.15) *be fulfilled. Let* $z \in B(0,1)$. *Then:*

(i) The following estimate

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)p_x^{\alpha}p_y^{\alpha'}\varphi_1(\rho^{-1}p_{3x})\varphi_2(\rho^{-1}p_{3y})U|_{x=y=z}| \leq C\rho T h^{-1}\bigl(\beta h^{-1}+\rho^2h^{-2}\bigr) \tag{28.3.22}$$

holds for all $\alpha : |\alpha| \le 2$, $\alpha' : |\alpha'| \le 2$, *and* $\tau \le c$.

(ii) Let $A_z(x) = A(z) + \langle x-z, \nabla_z\rangle A(z)$, $V_z(x) = V(z) + \langle x-z, \nabla_z\rangle V(z)$ *be linear approximations to* A *and* V *at* z; *let* $H_z = H_{A_z,V_z}$, $U_z(x,y,t)$ *be its Schwartz kernel. Then for* $h^{1-\delta} \le T \le C_0$, $\rho \le C_0$ *estimate*

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)p_x^{\alpha}p_y^{\alpha'}\varphi_1(\rho^{-1}p_{3x})\varphi_2(\rho^{-1}p_{3y})(U-U_z)|_{x=y=z}| \leq C\rho T^2h^{-2}\bigl(\beta h^{-1}+\rho^2h^{-2}\bigr)\nu\gamma^2 \tag{28.3.23}$$

holds with

$$\gamma = \gamma(\rho,T) \coloneqq C_0(\rho+T)T + C_0h\rho^{-1}, \tag{28.3.24}$$

and

$$\nu = \bigl(\|A'\|_2 + \|V\|_2\bigr) + \mu^2. \tag{28.3.25}$$

Proof. (i) Proof of Statement (i) is easy and left to the reader.

(ii) To prove Statement (ii) observe that

$$e^{ith^{-1}H} = e^{ith^{-1}H_z} + ih^{-1}\int_0^t e^{i(t-t')h^{-1}H}(H-H_z)e^{it'h^{-1}H_z}\,dt' = e^{ith^{-1}H_z} + \sum_{0\le k\le K} \underbrace{ih^{-1}\int_0^t e^{i(t-t')h^{-1}H}(H-H_z)\psi_k e^{it'h^{-1}H_z}\,dt'}, \tag{28.3.26}$$

where ψ_0 is a γ-admissible function supported in $B(z,2\gamma)$ and ψ_k are γ_k-admissible functions supported in $B(z,\gamma_k)\setminus B(z,\frac12\gamma_k)$ with $\gamma_k = 2^k\gamma$. Plugging (28.3.26) into the left-hand expression of (28.3.23) we note that the first term is cancelled and we have the sum with respect to $k : 0 \le k \le K$ obtained from this expression when we replace $(U-U_z)$ by the Schwartz kernel of the selected above term.

Further, observe that the term with $k = 0$ does not exceed the right-hand expression of (28.3.23).

Furthermore, terms with $k : 1 \le k \le K$ do not exceed the right-hand expression of (28.3.21) multiplied by $CTh^{-1}\min(\nu\gamma_k^2, 1)$; indeed, we just replace ρ by T if needed. After summation with respect to $k : 0 \le k \le K$ we get

$$C\rho h^{-1}T\big(\beta h^{-1} + \rho^2 h^{-2}\big) \times \Big(\rho^{-s}\gamma^{-s}h^s \min(\nu\gamma^2, 1) + h^2\rho^{-2}\nu \min(\nu, 1)\Big)$$

which again does not exceed the right-hand expression of (28.3.23). □

Remark 28.3.7. Actually Statement (ii) is better than Statement (i) only if $\nu\gamma^2 Th^{-1} \le 1$.

28.3.3 Advanced Estimate to a Minimizer

Now we are going to apply the results of the previous Subsection 28.3.2 to the right-hand expression of (27.2.14).

Tauberian Estimate

Consider different zones (based on the magnitude of $|p_3|$). Recall that $\bar\rho = \beta^{-1}$ [5)] and $\rho^* = (\beta h)^{\frac12}$.

Zone $\{\rho' \lesssim |p_3| \lesssim \rho^*\}$. Observe that Proposition 28.3.6(ii) implies that for $\varphi_j \in \mathscr{C}_0^\infty([-2, -\frac12] \cup [\frac12, 2])$ estimate

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)p_x^\alpha p_y^{\alpha'}\varphi_1(\rho^{-1}p_{3x})\varphi_2(\rho^{-1}p_{3y})U|_{x=y=z}| \le CS(\rho, T) \tag{28.3.27}$$

holds with

$$S(\rho, T) = \big(\beta h^{-1} + \rho^2 h^{-2}\big)\big(\rho^{-1} + \rho h^{-2}\nu\gamma^2 T^2\big), \tag{28.3.28}$$

where $\gamma = \gamma(\rho, T)$ is defined by (28.3.24).

Indeed, one can prove easily that

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)p_x^\alpha p_y^{\alpha'}\varphi_1(\rho^{-1}p_{3x})\varphi_2(\rho^{-1}p_{3y})U_z|_{x=y=z}| \le C(\beta h^{-1}\rho^{-1} + \rho^2 h^{-2}). \tag{28.3.29}$$
