Short Contents

Preface lxvi

Introduction lxvii

Volume I. Semiclassical Microlocal Analysis and Local and Microlocal Semiclassical Asymptotics 1

I Semiclassical Microlocal Analysis 1

1 Introduction to Microlocal Analysis 2

2 Propagation of Singularities in the Interior of the Domain 126

3 Propagation of Singularities near the Boundary 196

II Local and Microlocal Semiclassical Spectral Asymptotics in the Interior of the Domain 284

4 General Theory in the Interior of the Domain 285

5 Scalar Operators in the Interior of the Domain. Rescaling Technique 406

6 Operators in the Interior of Domain. Esoteric Theory 519

III Local and Microlocal Semiclassical Spectral Asymptotics near the Boundary 620

7 Standard Local Semiclassical Spectral Asymptotics near the Boundary 621

8 Standard Local Semiclassical Spectral Asymptotics near the Boundary. Miscellaneous 740

Volume II. Functional Methods and Eigenvalue Asymptotics 1

IV Estimates of the Spectrum 799

9 Estimates of the Negative Spectrum 800

10 Estimates of the Spectrum in the Interval 843

V Asymptotics of Spectra 892

11 Weyl Asymptotics of Spectra 893

12 Miscellaneous Asymptotics of Spectra 1060

Volume III. Magnetic Schrödinger and Dirac Operators. 1 1238

VI Smooth Theory in Dimensions 2 and 3 1238

13 Schrödinger Operator. Standard Theory Dimensions 2 and 3 1239

14 2D-Schrödinger Operator with the Strong Degenerating Magnetic Field 1419

15 2D-Schrödinger Operator with the Strong Magnetic Field near the Boundary 1553

VII Smooth Theory in Dimensions 2 and 3 (Continued) 1650

16 agnetic Schrödinger Operator: Short Loops, Pointwise Spectral Asymptotics and Asymptotics of Dirac Energy 1651

17 Dirac Operator with the Strong Magnetic Field 1799

Volume IV. Magnetic Schrödinger and Dirac Operators. 2 1

VIII Non-Smooth Theory and Higher Dimensions 1881

18 2D- And 3D-Magnetic SchrÖdinger Operator with Irregular Coefficients 1882

19 Multidimensional Magnetic Schrödinger Operator. Full-Rank Case 1984

20 Multidimensional Magnetic Schrödinger Operator. Non-Full-Rank Case 2102

IX Magnetic Schrödinger Operator in Dimension 4 2204

21 4D-Schrödinger Operator with the Strong Degenerating Magnetic Field 2205

22 Generic 4D-Schrödinger Operator with the Strong Magnetic Field 2313

X Eigenvalue Asymptotics for Schrödinger and Dirac Operators with the Strong Magnetic Field 2377

23 Eigenvalue asymptotics. 2D Case 2378

24 Eigenvalue asymptotics. 3D Case 2448

Volume V. Applications to Quantum Theory and Miscellaneous Problems 1

XI Application to Multiparticle Quantum Theory 2511

25 No Magnetic Field Case 2512

26 The Case of External Magnetic Field 2600

27 The Case of Self-Generated Magnetic Field 2742

28 The Case of Combined Magnetic Field 2819

Bibliography 2930

XII Articles 3003

Semiclassical Dirichlet to Neumann Operator 3004

Spectral Asymptotics for Fractional Laplacians 3031

Spectral Asymptotics for Dirichlet to Neumann operator in the Domains with Edges 3049

Asymptotics of the Ground State Energy in the Relativistic Settings 3076

Asymptotics of the Ground State Energy in the Relativistic Settings and with Self-Generated Magnetic Field 3095

Complete Semiclassical Spectral Asymptotics for Periodic and Almost Periodic Perturbations of Constant Operator 3118

Complete Differentiable Semiclassical Spectral Asymptotics 3142

Bethe-Sommerfeld Conjecture in Semiclassical Settings 3154

Scott and Thomas-Fermi approximations to electronic density 3175

Pointwise spectral asymptotics out of diagonal near boundary 3241

Pointwise spectral asymptotics out of diagonal near degeneration 3288

Pointwise spectral asymptotics near singularity 3315

29 Introduction 3316

30 Toy-model operator 3320

31 General case 3335

100 years of Weyl's Law 3346

Index 3437

Preface **lxvi**

Introduction **lxvii**

1. Problems to Study lxvii
2. Weyl's Law lxix
3. Methods lxx
4. Methods. II lxxiv
5. What is in the Book lxxvi

Volume I. Semiclassical Microlocal Analysis and Local and Microlocal Semiclassical Asymptotics lxxvi
Part I. Semiclassical Microlocal Analysis lxxvi
Part II. Local and Microlocal Semiclassical Spectral Asymptotics in the Interior of the Domain lxxx
Part III. Local and Microlocal Semiclassical Spectral Asymptotics near the Boundary . . lxxxiv
Volume II. Functional Methods and Eigenvalue Asymptotics lxxxvi
Part IV. Estimates of the Spectrum. lxxxvi
Part V. Asymptotics of Spectra lxxxix
Volume III. Magnetic Schrödinger and Dirac Operators. 1 xciv
Part VI. Smooth Theory in Dimensions 2 and 3 . xcv
Part VII. Smooth Theory in Dimensions 2 and 3 (Continued) xcvii
Volume IV. Magnetic Schrödinger and Dirac Operators. 2 xcviii
Part VIII. Non-smooth Theory and Higher Dimensions xcviii
Part IX. Magnetic Schrödinger Operator in Dimension 4 c

Part X. Eigenvalue Asymptotics for Schrödinger and Dirac Operators with the Strong Magnetic Field ci
Volume V. Applications to Quantum Theory and Miscellaneous Problems cii
Part XI. Asymptotics of the Ground State Energy of Heavy Atoms and Molecules cii
Part XII. Articles cvi
6. How LSSA are Applied to Classical Asymptotics cvii
7. Paths cix
8. About the Author cx
Elements of Biography cx
My Way to Spectral Asymptotics and Around cx
Weyl Conjecture (66–67 AW) cx
Aftermath (68–79 AW) cxiii
Multiparticle Quantum Theory (79 AW–88 AW) cxv
New Dawn (88–93 AW) cxv
Etc (93 AW–113 AW) cxv
Aftermath (113 AW–present time) cxvi

Volume I. Semiclassical Microlocal Analysis and Local and Microlocal Semiclassical Asymptotics 1

I Semiclassical Microlocal Analysis 1

1 Introduction to Microlocal Analysis 2
1.1 Pseudodifferential Operators 3
1.1.1 Calculus of Pseudodifferential Operators 3
h-Fourier Transform 5
h-DO Representation via h-Fourier Transform; Quantization of Different Flavors 6
Symbols and h-Pseudodifferential Operators; qp-, pq-, Weyl (Symmetric) Quantization. Double Symbols and Their Quantization 7

	Negligible Functions, Symbols, Operators. Going from one Type of Quantization to Another. Symbol and Operator classes .	9
	Algebra: Conjugate and Product of Operators. Symmetric Pseudodifferential Operators	12
	Quantization: Abstract Operator Point of View .	14
	Matrix Pseudodifferential Operators	15
	Ellipticity, Parametrix, Resolvent. Functional Calculus	15
	Traces and Hilbert-Schmidt Norms	16
	Pseudodifferential Operators Applied to an Exponent	19
1.1.2	Analysis of Pseudodifferential Operators	22
	Introduction	22
	Estimates	24
	Remainder Estimates	27
	Classes of Symbols and Pseudodifferential Operators	28
	Compactness	28
	Rescaling	29
	Gårding Inequalities	30
	Parametrix and Inverse	39
	Resolvent	41
	Analytic Functional Calculus of Pseudodifferential Operators	42
	Smooth Functional Calculus of Pseudodifferential Operators	44
	Families of Commuting Operators	47
	Norms and bBounds	47
1.1.3	Pseudodifferential Operators with Analytic Symbols and Logarithmic Uncertainty Principle . . .	48
	Pseudodifferential operators with Infinitely Smooth Symbols	50
	Pseudo-differential Operators with Analytic Symbols	51
1.1.4	Other Classes and Calculi of Pseudodifferential Operators	53
	Classical Pseudodifferential Operators	53
	Classes $\mathsf{S}^m_{\sigma,\varsigma}$ and $\mathbf{\Psi}^m_{\sigma,\varsigma}$	56
	Beals-Fefferman and Hörmander Operators	60
	Global Operators	60

h-Pseudodifferential Operators 61
1.2 Lagrangian Distributions and Fourier Integral Operators 62
1.2.1 Motivation 62
Oscillatory Solutions to Evolution Equations . . . 62
Blow-up 65
Maslov Canonical Operator 65
Propagator 67
1.2.2 Lagrangian Distributions and Manifolds 68
Definition 68
Main Properties 70
Maslov Index 75
Other Properties 76
Complex Phase 77
Coherent States 78
1.2.3 Fourier Integral Operators 79
Final Remarks 87
1.2.4 Metaplectic Operators 88
1.2.5 Germs 90
1.3 Wave Front Sets and Related Topics 93
1.3.1 Principal Notions 93
Philosophy 93
Smooth (Standard) Theory 94
Analytic Theory 96
1.3.2 Properties 96
1.3.3 Propagator 100
1.3.4 Alternative Theories 101
1.4 Elliptic Boundary Value Problems and Associated Operators 101
1.4.1 Pseudodifferential Operators with Transmission Property 101
Causality 101
Transmission Property 102
Pseudodifferential Operators in a Domain 104
1.4.2 Related Operators 105
Boundary (Poisson) Operators 105
Trace and Singular Green Operators 107
Boutet de Monvel Algebra 110
Ellipticity and Parametrices 110
Resolvent and Functional Calculus. I 112

1.4.3 Applications to Elliptic Boundary Value Problems 113
Parametrix Construction 113
Dirichlet-to-Neumann and Similar Operators . . . 116
Adjoint Operator; Self-Adjoint Operator 117
Projectors 119
Semiclassical Theory 120
1.A Appendices 121
1.A.1 Operator $e^{itQ(D)}$ 121
1.A.2 Almost Analytic Compactly Supported Symbols . 122
1.A.3 Stationary Phase Method 123
1.A.4 Function in the Box 124

2 Propagation of Singularities in the Interior of the Domain 126
2.1 Energy Estimates Approach 127
2.1.1 Main Theorem 127
2.1.2 Cauchy Problem. I 133
2.1.3 Cauchy Problem. II 136
2.1.4 Properties of Fundamental Solutions 138
2.1.5 Overdetermined Systems 143
Overdetermined Systems 143
Multi-Time Systems 143
2.2 Geometric Interpretation 145
2.2.1 Discussion of the Microhyperbolicity Condition . 145
Scalar Case 145
Cones of Directions of Microhyperbolicity 145
Examples 148
Microhyperbolicity: Algebraic Theory 149
2.2.2 Main Theorem 150
Main Theorem 150
Discussion 153
2.2.3 Examples of Propagation 154
Constant Coefficients Case 154
Scalar Principal Type (Again) 155
Operators with Completely Factorizing Characteristic Symbol: Non-Involutive Case . . 155
Operators with Completely Factorizing Characteristic Symbol: Involutive Case 159

Operators with not Factorizing Characteristic Symbol. I 160
Operators with not Factorizing Characteristic Symbol. II 161
Operators with not Factorizing Characteristic Symbol. III 163
Operators with not Factorizing Characteristic Symbol. IV 167
2.3 Operators with Rough Symbols 167
2.3.1 Main Theorem 168
Statement of the Main Theorem 168
Proof of the Main Theorem 169
2.3.2 Corollaries 175
2.4 Heisenberg Approach to Propagation of Singularities along Long Bicharacteristics 176
2.4.1 Evolution of Operators 177
Heisenberg Approach 177
Solving Heisenberg Equations. Standard Case . . 180
Discussion 181
Properties of Hamiltonian Flow 182
Solving Heisenberg Equations for Long-Time Evolution 183
2.4.2 Propagation of Singularities 187
Scalar Principal Symbol Case 187
Diagonalization 188
Heisenberg Evolution for Matrix Principal Symbols 191
Main Theorem 193

3 Propagation of Singularities near the Boundary 196
3.1 Energy Estimates Approach 197
3.1.1 Statement of the Main Theorem 197
Preliminary Notes 197
Finally, the Main Theorem 203
3.1.2 Proof of the Main Theorem 204
Reduction to a Special Case 204
Elliptic Theory 210
Main Theorem Refined 215
Proof of Theorem 3.1.13. Step 1 216

Proof of Theorem 3.1.13. Step 2 218
Proof of Theorem 3.1.13. Step 3 222
Proof of Proposition 3.1.14 223
Proof of Proposition 3.1.5 226
3.2 Geometric Interpretation 226
3.2.1 Main Theorem 226
Notations and Definitions 226
Finally, Main Theorem 229
3.2.2 Discussion and Examples 231
General Remarks 231
Constant Coefficients Case 231
Transversal Points 231
Elliptic Points 233
Bicharacteristics tangent to the boundary 234
3.3 Corollaries of Theorem 3.1.7 239
3.3.1 Finite Speed of Propagation and Related Topics . 239
Finite Speed of Propagation 239
Decomposition of the Fundamental Solution . . . 243
3.3.2 Normal Singularity Property 245
Preliminary Analysis 245
Main Results 248
3.4 Energy Estimates Approach Revisited 252
3.4.1 Theorem 3.1.7(ii) Revisited 253
Energy Estimates 253
Condition (3.4.13) 255
Examples 256
Theorems 3.1.13(ii), 3.1.7(ii) and 3.2.4(ii) Generalized 258
3.4.2 Main Theorem 258
Discussion 258
Symbol q: General Construction 261
Energy Estimates. I 262
Energy Estimates. II 263
Energy Estimates. III 264
Results: Single Glancing Point 266
Further Discussion 266
3.5 Propagation of Singularities along Long Transversally Reflecting Bicharacteristics 269

3.5.1 Evolution of Operators 269
Standard Theory 270
Reflections 271
3.5.2 Long Time Evolution 274
Main Theorem 274
Proof of the Main Theorem 276
3.5.3 Branching Billiards and Propagation 279
3.A Appendices 280
3.A.1 On Solutions to Linear Matrix Equations 280
3.A.2 Structure of Gliding Points 282

II Local and Microlocal Semiclassical Spectral Asymptotics in the Interior of the Domain 284

4 General Theory in the Interior of the Domain 285
4.1 Introduction 285
4.1.1 Main Objects 285
4.1.2 Kind of Assumptions to be Used 288
4.1.3 Plan of the Chapter 289
4.2 Preliminary Analysis and Tauberian Method 290
4.2.1 General Estimates 290
4.2.2 Semiclassical Spectral Gaps. I 293
First Standard Set of Assumptions 293
Second Standard Set of Assumptions 295
Estimates to Propagator 295
Estimates to Projector 298
Estimates without Cut-offs 302
Semiclassical Spectral Gaps under Reduced Smoothness Assumptions 304
4.2.3 Main Tauberian Estimate 309
Main Tauberian Formula 309
Asymptotics with Mollification 310
Asymptotics with Averaging 311
Operator Valued Functions 313
4.2.4 Applications 313
Scheme of Things 313

So, what We Get? 316
4.2.5 Estimates in the Hilbert Scale 317
Hilbert Scale 317
Estimates in the Hilbert Scale 319
4.3 The Method of Successive Approximations for Propagator 320
4.3.1 The Method of Successive Approximations in the Standard Ccase 320
Pilot-Construction 320
Transformation of the Successive Approximation Formula 322
Minor Modifications 324
4.3.2 Successive Approximations in the Hilbert Scale . 326
4.3.3 Calculations 331
4.3.4 Exploiting Microhyperbolicity and Increasing T . 337
Exploiting Microhyperbolicity 337
4.4 General Basic Theorems 340
4.4.1 General Theory: $T \asymp h^{\frac{1}{2}-\delta}$ 341
4.4.2 General Microhyperbolic Theory: $T \asymp 1$ 345
Asymptotics with Mollification 345
Asymptotics without Mollification 346
Improved Asymptotics without Mollification . . . 348
Useful Formulae 351
4.5 Long Term Propagation and Sharper Remainder Estimates 353
4.5.1 Preliminary Discussion 353
Increasing T 353
Synthesis 354
Sharp and Sharper 355
4.5.2 Standard Sharp Theory 356
Analysis of Wave Front Sets 356
Periodic Trajectories and Loops 358
Results 360
4.5.3 Sharper Remainder Estimates 364
Analysis as $|t| \le T_0$ 364
Successive Approximations 365
Increasing T 366
Tauberian Estimates 366
Finally, Results 367
4.5.4 Discussion 368

Local Results 368
Simple Improvements 369
Sharper Remainder Estimates 371
Matrix Case and Branching Bicharacteristics . . . 373
4.6 Operators with Rough Coefficients 373
4.6.1 Discussion: Rationale 374
4.6.2 Estimates 377
4.6.3 Successive Approximations and Calculations . . . 378
4.6.4 Main Theorems 383
4.6.5 Applications: Bracketing Method 385
4.6.6 Final Remarks 388
4.7 Operators with Irregular Coefficients 390
4.7.1 Preliminary Analysis 390
4.7.2 Tauberian Estimates 391
4.7.3 Weyl Asymptotics 394
4.7.4 Sharper Asymptotics 399
4.A Appendices 399
4.A.1 On the Traces of Almost Analytic Functions . . . 399
4.A.2 Smoothing of $\mathscr{C}^m_\vartheta$ Functions 402

5 Scalar Operators in the Interior of the Domain. Rescaling Technique 406
5.1 Introduction 406
5.1.1 Pilot: Schrödinger Operator 406
5.1.2 Plan of the Chapter 408
5.2 Spectral Asymptotics for Scalar Operators 410
5.2.1 From Condition "No Critical Point" to "$\mathsf{rank}\,\mathsf{Hess}\,a \geq 2$ at Critical Points." I 411
Standard Asymptotics 411
Sharp and Sharper Asymptotics 417
Near-Critical Zone 418
Sharp and Sharper Asymptotics (End) 422
5.2.2 From Condition "No Critical Point" to "$\mathsf{rank}\,\mathsf{Hess}\,a \geq 2$ at cCritical Points. " II 422
5.2.3 From Condition "$\mathsf{rank}\,\mathsf{Hess}\,a \geq 2$ at Critical Points" to "$\mathsf{rank}\,\mathsf{Hess}\,a \geq 1$ at Critical Points" 433
5.2.4 From Condition "$\mathsf{rank}\,\mathsf{Hess}\,a \geq 1$ at Critical Points" to a Weak Non-Degeneracy cCondition 439

5.2.5 From Microlocal to Local Spectral Asymptotics . 445
5.3 Local and Pointwise Spectral Asymptotics for the Schrödinger and Dirac Operators 445
5.3.1 Schrödinger Operator 446
Main Assumptions 446
Asymptotics with Spatial Mollification 447
Asymptotics without Spatial Mollification 451
Asymptotics without Spatial Mollification and Short Loops 452
5.3.2 Dirac Operator 461
Assumptions 461
Calculations 463
Asymptotics for $m \geq c_0$ 468
Asymptotics for $m \leq c_0$ 473
Further Improvements 479
Sharp Remainder Estimates 483
5.4 Operators with Irregular Coefficients 487
5.4.1 Preliminary Remarks 487
5.4.2 Schrödinger Operator 488
Reminder 488
Getting Rid of Condition (5.4.2) 489
From Condition (5.4.2) to Condition (5.4.3) . . . 492
Case $d \leq s+1$ Reloaded 493
Dropping Condition (5.4.3) 496
Sharp Remainder Estimates 497
Applying Results of Section 4.7 499
Applying Results of Section 4.7. II 499
5.4.3 Dirac Operator 501
Getting Rid of Condition (5.4.2) 501
From Condition (5.4.2) to Condition (5.4.3) . . . 503
Dropping Condition (5.4.3) 503
Sharp Remainder Estimate 504
5.4.4 General oOperators 504
Dropping Condition $|\nabla_\xi a| \neq 0$ 504
Case $\nu(t) = o(t)$ 507
Case $\nu(t) = o(t)$. II 509
Sharp Remainder Estimates 510
5.A Appendices 511

5.A.1 Spectral Kernel Calculations for Some Model Operators . . . 511
Case $d = 1$ . . . 511
Case $d = 2$ . . . 513
5.A.2 On Pauli Matrices . . . 514

6 Operators in the Interior of Domain. Esoteric Theory 519
6.1 Spectral Asymptotics for Families of Commuting Operators 520
6.1.1 Introduction . . . 520
6.1.2 General Theory . . . 522
Elliptic Arguments . . . 522
Successive Approximations . . . 523
Basic Results (General Case) . . . 524
The Microhyperbolicity Condition . . . 525
Exploiting Microhyperbolicity . . . 526
Tauberian Arguments . . . 528
Principal Results . . . 529
Possible Generalizations, Remarks . . . 530
6.1.3 Operators with Scalar Symbols . . . 532
Preliminary Remarks . . . 532
Asymptotics with Mollifications . . . 532
Principal Results . . . 534
6.2 Scalar Operators with Periodic Hamiltonian Flow . . . 536
6.2.1 Introduction . . . 536
6.2.2 Operator B . . . 543
Scalar Case . . . 543
Matrix Case . . . 549
6.2.3 Long Term Evolution . . . 550
Main Theorem . . . 550
Corollaries . . . 551
Spectral Gaps (the First Attempt) . . . 556
6.2.4 Exploiting Microhyperbolicity . . . 558
Extending Time Interval . . . 558
Tauberian Arguments . . . 558
Removing Cut-off ψ . . . 562
6.3 Scalar Operators with Periodic Hamiltonian Flow (End) 562
6.3.1 Scalar a and Subperiodic Trajectories . . . 562
Structure of Subperiodic Trajectories . . . 562

Propagation of Singularities near Π 564
Successive Approximations 566
Exploiting Microhyperbolicity 570
Tauberian Estimates 571
6.3.2 The case of Degenerate Scalar Operator B 572
Asymptotics with mMollification 572
Estimates without Mollification 573
6.3.3 Some Remarks 576
6.3.4 Spectral Gaps Reloaded 578
6.3.5 Families of Commuting Operators Approach . . . 579
Operators with Completely Periodic Evolution . . 579
Operators with the Global dDecomposition 582
General oOperators 584
6.3.6 Strong Perturbations 585
6.3.7 Operators with Massive set of Periodic tTrajectories 587
6.3.8 Examples 590
Laplacian 590
Harmonic Oscillator 591
Coulomb Potential 592
6.4 Asymptotics for Dirac Energy 593
6.4.1 Introduction 593
6.4.2 Estimates 595
Special Case 595
Smooth Case 597
Singular homogeneous case 599
Singular Homogeneous Case: Using ξ-Microhyperbolicity 600
6.4.3 Calculations 601
Constant Coefficients Case 601
General ξ-Microhyperbolic Case 602
6.4.4 Scalar Case 604
Smooth case. I 604
Smooth case. II 606
Singular Homogeneous Case 606
6.4.5 Rescaling Technique 609
Schrödinger Operator 609
6.5 Mollification with Respect to Non-Spectral Parameters . 612
6.5.1 Linear Dependence 612
6.5.2 Microhyperbolic Case 614

6.5.3 Averaging 616
6.A Appendices 616
6.A.1 Hamiltonian Flows of Commuting Operators . . . 616
6.A.2 One Property of Real Residues 617
6.A.3 Eigenvalues of Some Model Operators 618

III Local and Microlocal Semiclassical Spectral Asymptotics near the Boundary 620

7 Standard Local Semiclassical Spectral Asymptotics near the Boundary 621
7.1 Preliminary Analysis 622
7.1.1 General Case 622
7.1.2 Elliptic Case 627
7.1.3 Operators with Minimal Smoothness Conditions . 634
7.1.4 Estimates for the Schrödinger Operator 639
7.2 Method of Successive Approximations 643
7.2.1 Approximating the Free Space Term 643
Standard Calculations Revised 643
Calculating Restriction to the Boundary 644
7.2.2 Approximations for the Reflected Wave 648
7.2.3 Calculations 655
Starting Point 655
One Dimensional Parametrices 655
One Dimensional Parametrices (End) 657
Calculations: what We Got 664
Calculations: Taking Traces 665
Calculations: Mollification with Respect to τ . . . 666
7.2.4 Exploiting Microhyperbolicity 667
7.2.5 Conclusion 671
7.3 General Basic Theorems 671
7.3.1 Asymptotics with Mollification 672
7.3.2 Asymptotics under Microhyperbolicity Condition 673
7.3.3 Asymptotics in the Elliptic Zone 675
7.3.4 Local Asymptotics 679
7.4 Sharper Asymptotics 681
7.4.1 Discussion 681

7.4.2 General Theory 683
Sharp Asymptotics 683
Sharper Asymptotics 684
7.4.3 Billiard Flow for Schrödinger Operator 685
Definition of the Flow 685
Growth of the Billiard Flow. I 686
Growth of the Billiard Flow. II 690
Non-Periodicity Condition and Results. I 695
Non-Periodicity Condition and Results. II 697
Non-Periodicity Condition for Branching Billiards 700
7.5 Operators with Irregular Coefficients. Seeley's Method . 705
7.5.1 Discussion 706
Rescaling Technique 706
Propagation 707
What Then? 708
Mollification 709
7.5.2 $O(h^{1-d})$ Remainder Estimate for Scalar Operators 710
Inner Zone 710
Moving Closer to the Boundary 715
Boundary Strip 716
Synthesis 716
7.5.3 $O(h^{1-d})$ Remainder Estimate for Matrix Operators 719
Covering 720
Estimates 723
7.5.4 Sharp Remainder Estimate 724
Near Boundary Zone 724
Inner Zone 726
7.5.5 Less Sharp Remainder Estimates 729
7.A Appendices 731
7.A.1 Sets Associated with the Microhyperbolicity Condition 731

8 Standard Local Semiclassical Spectral Asymptotics near the Boundary. Miscellaneous 740
8.1 Pointwise Spectral Asymptotics 741
8.1.1 Preliminary Analysis 741
Discussion 741
Toy-Model 743

8.1.2 Schrödinger Operator 745
General Theory 745
Calculations and Main Theorem 748
8.1.3 Generalizations 749
8.2 Scalar operators and Rescaling 751
8.2.1 Schrödinger Operator. I 751
General Theory 751
Sharp Remainder Estimates 755
Special Case $d = 1$ 755
Generalizations 757
8.2.2 Schrödinger Operator. II 758

XI Application to Multiparticle Quantum Theory 2511

25 No Magnetic Field Case 2512
25.1 Introduction . . . 2512
25.1.1 Framework . . . 2512
25.1.2 Problems to Consider . . . 2514
25.1.3 Thomas-Fermi Theory . . . 2515
25.1.4 Main Results Sketched and Plan of the Chapter . 2517
25.2 Reduction to Semiclassical Theory . . . 2518
25.2.1 Lower Estimate . . . 2519
25.2.2 Upper Estimate . . . 2522
25.2.3 Remarks and Dirac Correction . . . 2524
25.3 Thomas-Fermi Theory . . . 2525
25.3.1 Existence . . . 2526
25.3.2 Properties . . . 2528
25.4 Application of Semiclassical Methods . . . 2534
25.4.1 Asymptotics of the Trace . . . 2534
25.4.2 Upper Estimate for E . . . 2538
Estimating $|\lambda_N - \nu|$ . . . 2538
Estimating D-Term . . . 2541
Finally, a Theorem . . . 2543
25.4.3 Improved Asymptotics . . . 2544
25.4.4 Corollaries and Discussion . . . 2547
Estimates for $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}})$ . . . 2547
Estimates for Distance between Nuclei in the Free Nuclei Model . . . 2548
25.5 Negatively Charged Systems . . . 2550
25.5.1 Estimates of the Correlation Function . . . 2550
25.5.2 Excessive Negative Charge . . . 2557
25.5.3 Estimate for Ionization Energy . . . 2561
25.6 Positively Charged Systems . . . 2562
25.6.1 Estimate from above for Ionization Energy . . . 2562
25.6.2 Estimate from below for Ionization Energy . . . 2566

25.6.3 Estimate for Excessive Positive Charge 2576
25.A Appendices 2580
25.A.1 Electrostatic Inequalities 2580
25.A.2 Hamiltonian Trajectories 2581
25.A.3 Some Spectral Function Estimates 2582
25.A.4 Calculation of Scott, Dirac and Schwinger correction terms 2583
Scott correction term 2583
Dirac correction term 2584
Schwinger correction term 2585
General case 2586
25.A.5 Baxter's Lemma 2588
25.A.6 Dependence of Thomas-Fermi energy of the nuclear coordinates 2589
Regularized Thomas-Fermi theory 2589
Proof of Theorem 25.3.8 2593
Electronic contribution to the Born-Oppenheimer energy 2596
Auxiliary statements 2597

26 The Case of External Magnetic Field **2600**
26.1 Introduction 2600
26.1.1 Framework 2600
26.1.2 Problems to Consider 2601
26.1.3 Magnetic Thomas-Fermi Theory 2603
26.1.4 Main Results Sketched and Plan of the Chapter . 2604
26.2 Magnetic Thomas-Fermi Theory 2606
26.2.1 Framework and Existence 2606
26.2.2 Properties 2608
26.2.3 Positive Ions 2614
26.3 Applying Semiclassical Methods: $M = 1$ 2619
26.3.1 Heuristics 2619
Total Charge 2620
Semiclassical D-Term 2622
$|\lambda_N - \nu|$ and another D-Term 2624
Trace 2626
Discussion 2626
26.3.2 Smooth Approximation 2627

Trivial Arguments 2627
Formal Expansion 2631
Expansion: Justification 2633
26.3.3 Rough Approximation 2635
Properties of Mollification 2635
Charge Term 2637
Trace Term 2640
Semiclassical D-Term: Local Theory 2643
Semiclassical D-Term: Global Theory 2646
26.4 Applying Semiclassical Mmethods: $M \geq 2$ 2648
26.4.1 Scaling Functions in Zone $\mathcal{X}_2$ 2648
26.4.2 Zone $\mathcal{X}_2$: Semiclassical N-Term 2653
26.4.3 Zone $\mathcal{X}_2$: Semiclassical D-Term 2657
26.4.4 Semiclassical T-Term 2660
Semiclassical T-Term: Zone $\mathcal{X}_1$ Extended 2660
Semiclassical T-Term: Zone $\mathcal{X}_2$ 2662
26.4.5 Zone $\mathcal{X}_3$ 2666
26.5 Semiclassical Analysis in the Boundary Strip for $M \geq 2$. 2666
26.5.1 Properties of W_B^{TF} if $N = Z$ 2667
26.5.2 Analysis in the Boundary Strip $\mathcal{Y}$ for $N \geq Z$ . . . 2672
26.5.3 Analysis in the Boundary Strip $\mathcal{Y}$ for $N < Z$ . . . 2675
Case $B \geq (Z-N)_+^{\frac{4}{3}}$ 2675
Case $B \leq (Z-N)_+^{\frac{4}{3}}$ 2680
26.5.4 Summary 2681
26.6 Ground State Energy 2682
26.6.1 Lower Estimates 2682
26.6.2 Upper Estimate: General Scheme 2684
26.6.3 Upper Estimate as $M = 1$ 2684
Estimate for $|\lambda_N - \nu|$ 2684
Estimate for D-Terms 2686
Summary 2687
26.6.4 Upper Estimate as $M \geq 2$ 2688
Estimate for $|\lambda_N - \nu|$ 2688
Estimate for D-Terms for Almost Neutral sSystems 2691
Estimate for D-Terms for Positively Charged sSystems 2693
Summary 2698

26.7 Negatively Charged Systems 2699
26.7.1 Estimates of the Correlation Function 2699
26.7.2 Excessive Negative Charge 2701
26.7.3 Estimate for Ionization Energy 2704
26.8 Positively Charged Systems 2710
26.8.1 Upper Estimate for Ionization Energy: $M = 1$ . . 2710
26.8.2 Lower Estimate for Ionization Energy: $M = 1$ . . 2714
26.8.3 Estimates for Ionization Energy: $M \geq 2$ 2724
26.8.4 Free Nuclei Model 2724
Preliminary Arguments 2725
Minimal Distance 2725
Estimate of Excessive Positive Charge 2730
26.A Appendices 2731
26.A.1 Electrostatic Inequalities 2731
26.A.2 Very Strong Magnetic Field Case 2736
26.A.3 Riemann Sums and Integrals 2737
26.A.4 Some Spectral Ffunction Estimates 2738
26.A.5 Zhislin's Theorem for Constant Magnetic Field . . 2739

27 The Case of Self-Generated Magnetic Field 2742
27.1 Introduction 2742
27.2 Local Semiclassical Trace Asymptotics 2744
27.2.1 Toy-Model 2744
Statement of the Pproblem 2744
Preliminary Analysis 2745
Estimates 2748
27.2.2 Microlocal Analysis Unleashed 2751
Sharp Estimates 2751
Application 2756
Classical Dynamics and Sharper Estimates 2759
27.2.3 Local Theory 2762
Localization and Estimate from above 2762
Estimate from below 2765
27.2.4 Rescaling 2767
Case $\kappa \leq 1$ 2768
Case $1 \leq \kappa \leq h^{-1}$ 2770
27.3 Global Trace Asymptotics in the Case of Coulomb-Like Singularities 2772

27.3.1 Problem 2772
27.3.2 Estimates of a Minimizer 2773
Preliminary Analysis 2773
Estimates to a Minimizer. I 2776
Estimates to a Minimizer. II 2779
Estimates to a Minimizer. III 2781
27.3.3 Basic Trace Estimates 2782
27.3.4 Improved Trace Estimates 2785
Improved Tauberian Estimates 2785
Improved Weyl Estimates 2788
27.3.5 Single Singularity 2790
Coulomb Potential 2790
Main Theorem 2795
27.3.6 Several Singularities 2796
Decoupling of Singularities 2796
Main Results 2799
Problems and rRemarks 2800
27.4 Asymptotics of the Ground State Energy 2800
27.4.1 Problem 2800
27.4.2 Lower Estimate 2802
27.4.3 Upper Estimate 2805
27.4.4 Main Theorems 2807
27.4.5 Free Nuclei Model 2809
27.5 Miscellaneous Problems 2811
27.5.1 Excessive Negative Charge 2811
27.5.2 Estimates for Ionization Energy 2812
27.5.3 Free Nuclei Model: Excessive Positive Charge . . 2813
27.A Appendices 2814
27.A.1 Minimizers and Ground States 2814
27.A.2 Zhislin's Theorem 2815
27.A.3 L. Erdös–J. P. Solovej's Lemma 2815

28 The Case of Combined Magnetic Field 2819
28.1 Introduction 2819
28.1.1 Plan of the Chapter 2820
28.1.2 Unfinished Business 2820
28.2 Local Semiclassical Trace Asymptotics: Preparation . . . 2821
28.2.1 Toy-Model 2821

28.2.2 Formal Semiclassical Theory 2821
Semiclassical Theory: $\beta h \lesssim 1$ 2821
Semiclassical Theory: $\beta h \gtrsim 1$ 2825
28.2.3 Estimate from below 2825
Basic Estimates 2825
Estimates to a Minimizer: $\beta h \lesssim 1$ 2827
Estimates to a Minimizer: $\beta h \gtrsim 1$ 2829
28.3 Microlocal Analysis Unleashed: $\beta h \lesssim 1$ 2831
28.3.1 Rough Estimate to a Minimizer 2831
28.3.2 Microlocal Analysis 2835
28.3.3 Advanced Estimate to a Minimizer 2840
Tauberian Estimate 2840
Calculating Tauberian Expression 2843
Estimating $|\partial^2 A'|$ 2846
28.3.4 Trace Term Asymptotics 2847
General Microlocal Arguments 2847
Strong Non-Degenerate cCase 2850
Non-Degenerate Case 2851
Degenerate case 2852
28.3.5 Endgame 2853
Upper Estimate 2853
Lower Estimate 2854
Weak Magnetic Field Approach. 2856
Main Theorem 2856
28.3.6 N-Term Asymptotics 2857
Introduction 2857
Strong Non-Degenerate Case 2858
Non-Degenerate Case 2859
Degenerate Case 2859
28.3.7 D-Term Estimate 2860
28.4 Microlocal Analysis: $\beta h \gtrsim 1$ 2866
28.4.1 Estimate to a Minimizer 2866
28.4.2 Trace Term Asymptotics 2867
28.4.3 Endgame 2869
28.4.4 N-Term Asymptotics and D-Term Estimates . . . 2869
28.5 Global Trace aAsymptotics in the Case of Thomas-Fermi Potential: $B \le Z^{\frac{4}{3}}$ 2870
28.5.1 Introduction 2870

28.5.2 Estimates to a Minimizer 2871
Preliminary Analysis 2871
Estimates to a Minimizer: Interior Zone 2874
Estimates to a Minimizer: Exterior Zone 2875
28.5.3 Trace aAsymptotics 2876
28.5.4 Endgame 2882
Main Theorem: $M = 1$ 2882
28.5.5 N-Term Asymptotics and D-Term Estimate 2885
Case $M = 1$ 2885
Case $M \geq 2$ 2887
28.5.6 More Estimates to a Minimizer 2889
Case $M = 1$ 2890
Case $M \geq 2$ 2892
28.5.7 Endgame: $M \geq 2$ 2894
28.6 Global Trace Asymptotics in the Case of Thomas-Fermi Potential: $Z^{\frac{4}{3}} \leq B \leq Z^3$ 2895
28.6.1 Trace Estimates 2895
28.6.2 Estimates to a Minimizer 2899
28.6.3 N-Term Asymptotics and D-Term Estimates . . . 2902
28.7 Applications to Ground State Energy 2903
28.7.1 Preliminary Remarks 2903
28.7.2 Estimate from above: $B \leq Z^{\frac{4}{3}}$ 2905
28.7.3 Main Theorems: $B \leq Z^{\frac{4}{3}}$ 2909
Ground State Energy Asymptotics 2909
Ground State Density Asymptotics 2912
28.7.4 Main Theorems: $Z^{\frac{4}{3}} \leq B \leq Z^3$ 2914
Ground State Energy Asymptotics 2914
Ground State Density Asymptotics 2915
28.A Appendices 2917
28.A.1 Generalization of Lieb-Loss-Solovej Estimate . . . 2917
28.A.2 Electrostatic Inequality 2921
28.A.3 Estimates for $(hD_{x_j} - \mu x_j)e(x, y, \tau)|_{x=y}$ for Toy-Model Operator 2922
Calculations 2922
Case $\alpha \geq \mu^2 h$ 2924
Case $\alpha \leq \mu^2 h$ 2925
Case $\mu h \geq \epsilon_0$ 2927
Tauberian Estimates 2929

Preface

The Problem of the *Spectral Asymptotics*, in particular the problem of the *Asymptotic Distribution of the Eigenvalues*, is one of the central problems in the *Spectral Theory of Partial Differential Operators*; moreover, it is very important for the *General Theory of Partial Differential Operators*.

I started working in this domain in 1979 after R. Seeley [1] justified a remainder estimate of the same order as the then hypothetical second term for the Laplacian in domains with boundary, and M. Shubin and B. M. Levitan suggested me to try to prove Weyl's conjecture. During the past almost 40 years I have not left the topic, although I had such intentions in 1985, when the methods I invented seemed to fail to provide the further progress and only a couple of not very exciting problems remained to be solved. However, at that time I made the step toward local semiclassical spectral asymptotics and rescaling, and new much wider horizons opened.

So I can say that this book is the result of 40 years of work in the Theory of Spectral Asymptotics and related domains of Microlocal Analysis and Mathematical Physics (I started analysis of *Propagation of singularities* (which plays the crucial role in my approach to the spectral asymptotics) in 1975).

Victor Ivrii,
Toronto, July 9, 2023.

Introduction

1. Problems to Study

Finding the *Spectral Asymptotics*, in particular the *Asymptotic Distribution of Eigenvalues*, is one of the central problems of the *Spectral Theory of Partial Differential Operators*, and is very important for the *General Theory of Partial Differential Operators*.

Apart from applications to Quantum Mechanics, Radio Physics, Continuum Media Mechanics (Elasticity, Acoustics, Hydrodynamics, Theory of Shells), etc., there are also applications to mathematics itself and deep though non-obvious links to Differential Geometry, Dynamical Systems Theory, Ergodic Theory and Number Theory; even the term *Spectral Geometry* was coined. All these circumstances make this topic very attractive for a mathematician.

The original problem was formulated independently by A. Sommerfeld [1] and H. A. Lorentz [1] in 1910 who stated the *Weyl's Law* as a conjecture based on the book of Lord Rayleigh "The Theory of Sound" (1887) (see in details in W. Arendt and others [1]).

This conjecture was proven in 1911 by then young mathematician, a disciple of David Hilbert, specialist in partial differential and integral equations Hermann Weyl who published several papers [1–5] devoted to eigenvalue asymptotics for the Laplace operator (and also the elasticity operator) in a bounded domain with a regular boundary. After this article a huge number of various papers devoted to spectral asymptotics were published among the authors of which were numerous prominent mathematicians.

Also, in [4] Weyl published his famous *Weyl conjecture*.

Much later, in 1950, H. Weyl in his paper [7] returned to this topic.

The theory was developed in two directions: on one hand, the theory was extended to consider more general operators, boundary conditions and

geometrical domains; on the other hand, the asymptotics were improved and more accurate remainder estimates were derived. In the latter extensions the links with differential geometry, dynamical systems theory and ergodic theory appeared. Even the theory of eigenvalue asymptotics for the Laplace (or Laplace-Beltrami) operator has a long, dramatic and still unfinished history.

Apart from asymptotics with respect to the *spectral parameter*, asymptotics with respect to other parameters appeared; the most important among them are (in my opinion) *semiclassical asymptotics*, i. e. asymptotics with respect to a small parameter h (the Planck constant in physics), tending to $+0$. For a long time these asymptotics were in the shadows: most attention was paid to the eigenvalue asymptotics for operators on compact manifolds (with or without boundary).

The results which had been obtained in that case were then reproved for operators in $\mathbb{R}^d$ such as the Schrödinger operator $h^2\Delta + V(x)$ with fixed $h > 0$ and with $V(x) \to +\infty$ as $|x| \to \infty$ where Δ is a (positive) Laplacian; less attention was paid to semiclassical asymptotics (i.e., asymptotics of the number of eigenvalues below some fixed level λ as $h \to +0$).

The asymptotics of small negative eigenvalues were considered in the case of fixed h and $V(x)$ decreasing at infinity as $|x|^{2m}$ with $m \in (-1, 0)$; under reasonable conditions in this case the discrete spectrum of the operator has accumulation point -0 and the essential spectrum coincides with $[0, +\infty)$.

The result of the development of the theory was that at a certain time there existed four parallel (though not equally developed and not equally respected)[1)] theories, the statements in each of which had to be proven separately.

This pluralism was over from ≈1985 because all other results are easily derived from the *Local Semiclassical Spectral Asymptotics* (*LSSA* in what follows)[2)].

[1)] While the achievements in the first theory were broadly known by mathematicians, the other results were familiar to the narrow circle of PDE-folk and mathematical physicists, many of whom (including myself, it is a real shame for me) even thought that only the first topic is of the prime interest.

[2)] I started to study semiclassical spectral asymptotics at the time when I foolishly assumed that the first theory was completely finished and I had nothing to do; so I decided to extend the results to semiclassical asymptotics before leaving the area. When I told my first results to M. Z. Solomyak, he asked if those results could be deduced from the results of the classical theory by the Birman-Schwinger principle. A quick check

One of the main tools here is a *rescaling technique* (see Section *6. How LSSA are Applied to Classical Asymptotics*) I invented approximately in the same time.

The semiclassical spectral asymptotics are the main object of this book, and all the other results are obtained as applications.

We also consider applications to the multiparticle quantum theory the topic I began working on in 1990 with M.I.Sigal.

Alternative introduction the reader can find in V. Ivrii [28]: "100 years of Weyl's law"; see also my talk [9].

2. Weyl's Law

Let us formulate here the Weyl's law for a non-Magnetic Schrödinger operator

$$H = h^2\Delta + V(x), \tag{0.1}$$

where $\Delta = -\partial_{x_1}^2 - ... - \partial_{x_d}^2$, $h \ll 1$ and $V(x)$ is the real valued function. Assuming that H is a self-adjoint operator, let $E(\lambda)$ is its spectral projector and $e(x, y, \lambda)$ its Schwartz kernel. Then *Weyl's law* states

$$\mathsf{N}(\lambda) \approx (2\pi h)^{-d} \iint_{\{|\xi|^2+V(x)\le\lambda\}} dxd\xi = (2\pi h)^{-d}\varpi_d \int \big(\lambda - V\big)_+^{d/2}\, dx, \tag{0.2}$$

where $N(\lambda) \coloneqq \mathsf{Tr}(E(\lambda))$ is an *eigenvalue counting function* i.e. a number of eigenvalues of H lesser than λ provided $(-\infty, \lambda) \cap \mathsf{Spec}_{\mathsf{ess}}(H) = \emptyset$, otherwise $N(\lambda) = +\infty$, ϖ_d is a volume of the unit ball in $\mathbb{R}^d$. There are also *local Weyl's law*

$$\mathsf{Tr}(E(\lambda)\psi) \approx (2\pi h)^{-d}\varpi_d \int \big(\lambda - V\big)_+^{d/2}\psi(x)\, dx \tag{0.3}$$

for $\psi \in \mathscr{C}_0^\infty$ and *pointwise Weyl's law*

$$e(x, x, \lambda) \approx (2\pi h)^{-d}\varpi_d\big(\lambda - V\big)_+^{d/2}. \tag{0.4}$$

gave a very surprising answer: using "classical" asymptotics one can prove semiclassical asymptotics only under very unnatural restrictions; but using semiclassical asymptotics one can extend "classical" asymptotics to more general operators and problems.

3. Methods

In his papers, starting from the second one, H. Weyl applied the *variational method* (*Dirichlet-Neumann bracketing*) he invented; later this method was improved in various directions by many outstanding mathematicians and mathematical physicists (R. Courant, M. Sh. Birman, and others). This method is simple and works in the general situations (even for non-semibounded operators) and seems to be the best method if one does not care about precise remainder estimates.

Later *Tauberian methods* appeared (first due to T. Carleman). The idea is to consider some function $F(H,t)$ of an operator in question H and some auxiliary parameter t. Then

$$\mathsf{Tr}(F(H,t)) = \int F(\tau,t)\, d_\tau\, \mathsf{Tr}(E(\tau)), \tag{0.5}$$

where $E(\tau)$ is the spectral projector. One then tries to construct the left-hand expression by means of PDE theory and then recover $\mathsf{Tr}(E(\tau))$ with some error by means of an appropriate Tauberian theorem. The choice of the function $F(H,t)$ is very important here. Taking $F(H,t) = \exp(-tA)$ (for a positive operator H), $F(H,t) = (t-H)^{-1}$ and $F(H,t) = H^t$ one obtains respectively the *heat equation, resolvent and ζ-function methods*, which are usually simple in their PDE part but difficult in the Tauberian part and almost always fail to provide a decent remainder estimate.

On the other hand, the *hyperbolic operator method* due to B. M. Levitan and V. G. Avakumovič is difficult in its PDE part but is almost trivial in the Tauberian part and provides accurate remainder estimates. By this method all the asymptotics with the most accurate remainder estimates were obtained. This method is based on the function $U(t) = F(H,t) = \exp(itH)$ which satisfies $(D_t - H)U = 0$, $U(0) = I$, and therefore the Schwartz kernel $u(x,y,t)$ of the operator is the fundamental solution to the Cauchy problem (or the initial-boundary value problem) for the operator $D_t - H$ (where $D_t = -i\partial_t$, etc.). The Schwartz kernel is connected to the eigenvalue counting function of the operator H by the formula

$$\int u(x,x,t)\, dx = \int \exp(it\lambda)\, d_\lambda \mathsf{N}(\lambda). \tag{0.6}$$

In the case of a matrix operator H, $u(x,y,t)$ is a matrix-valued function and should be replaced by its trace in the left-hand expression. Then by

the means of the inverse Fourier transform we can recover $\mathsf{N}(\lambda)$ provided we have constructed $u(x,y,t)$ by means of the methods of partial differential operator theory.

In fact, we are never able (excluding some very special and rare cases) to construct $u(x,y,t)$ precisely and for all the values $t \in \mathbb{R}$. Usually (now we assume that H is an elliptic first-order pseudodifferential operator) the fundamental solution is constructed approximately (modulo smooth functions) for t belonging to some interval $[-T,T]$ with $T>0$. As a consequence we obtain, modulo $O(\lambda^{-s})$ with any arbitrarily chosen exponent s, an expression for

$$F_{t\to\tau}\Big(\chi_T(t)\int u(x,x,t)\,dx\Big) = \int \hat{\chi}_T(\tau-\lambda)\,d_\lambda \mathsf{N}(\lambda), \tag{0.7}$$

where χ is a fixed smooth function supported in $[-1,1]$, $\chi_T(t)=\chi(t/T)$ and the hat as well as $F_{t\to\tau}$ mean the Fourier transform. Then, if we know the left-hand expression, we are able, by the Tauberian theorem due to B. M. Levitan, to recover $\mathsf{N}(\lambda)$ approximately by the formula

$$\mathsf{N}(\lambda) = \int_{-\infty}^{\lambda} \big(F_{t\to\tau}\chi_T(t)\sigma(t)\big)(\tau)\,d\tau + O\big(\lambda^{d-1}\big), \tag{0.8}$$

where d is the dimension of the domain and

$$\sigma(t) = \int u(x,x,t)\,dx. \tag{0.9}$$

The explicit construction of $u(x,x,t)$ in this situation leads us to the formula

$$\mathsf{N}(\lambda) = \kappa_0\lambda^d + O\big(\lambda^{d-1}\big) \tag{0.10}$$

with the leading coefficient

$$\kappa_0 = (2\pi)^{-d}\int_{H(x,\xi)<1} dx d\xi, \tag{0.11}$$

where $H(x,\xi)$ is the principal symbol of the operator H.

We see that the crucial step in this approach is the construction of the fundamental solution. This construction by means of Fourier integral operators is now standard and well known as long as we consider scalar operators or operators with the constant multiplicities of the eigenvalues of

the principal symbol. We construct $u(x,y,t)$ on a compact set K contained in the interior of our domain X (and T depends on the distance between K and ∂X).

If one of those assumptions is violated, then the construction is much more sophisticated and is possible only under some very restrictive conditions. In the presence of the boundary (but only in the case of the constant multiplicities of the eigenvalues of the principal symbol) this construction was implemented in papers due to V. M. Babich, B. M. Levitan, R. Seeley, R. Melrose, D. Vassiliev and others. But it is possible to avoid all these troubles by means of another approach suggested by V. Ivrii [8] (see also L. Hörmander [1] (vol. 4)) based on the investigation of the propagation of singularities for $u(x,y,t)$ and the construction of an "approximation" (in a rather exotic sense) for the distribution which leads to an approximation in a reasonable sense for $\sigma(t)$ for $|t| \le T$ with appropriate $T > 0$.

For the h-pseudodifferential operators, considered in this book, this approach is essentially simpler and more transparent because there is a selected parameter h; this case will be discussed below. This method allows us to prove the asymptotics (0.8) for an arbitrary self-adjoint m-th order elliptic operator with $m > 0$ and the spectral parameter λ^m on a compact manifold with or without boundary (in the former case the boundary conditions are also supposed to be elliptic), scalar or matrix, semibounded from below or not semibounded at all (in this case $\mathsf{N}(\lambda)$ is replaced by $\mathsf{N}^{\pm}(\lambda)$ which is the number of eigenvalues lying between 0 and $\pm\lambda^m$); the formula for κ_0 should be changed if necessary.

The two-term asymptotics

$$\mathsf{N}(\lambda) = \kappa_0\lambda^d + \kappa_1\lambda^{d-1} + o\big(\lambda^{d-1}\big), \tag{0.12}$$

suggested by H. Weyl [4] (who also gave a formula for κ_1) fails to be true without some additional condition. Surely this asymptotic expansion is wrong for $d = 1$ and for the Laplace-Beltrami operator on the sphere $\mathbb{S}^d$; this fact is associated with the high multiplicities of its eigenvalues. Moreover, it remains wrong in the case when this Laplace-Beltrami operator is perturbed by a potential or even by a symmetric first-order operator with small coefficients; in these cases all the eigenvalues of high multiplicities will be split into narrow eigenvalue clusters separated by spectral gaps.

On the other hand, under conditions of a global nature the asymptotics (0.12) is valid. For a scalar operator on a compact manifold without boundary the relevant condition is:

The measure of the {*set of all the points of the cotangent bundle periodic with respect to the Hamiltonian flow generated by the principal symbol*} *equals* 0

(see J. J. Duistermaat and V. Guillemin [1]). The condition is more complicated for matrix operators.

For a scalar second-order operator on a compact manifold with the boundary one needs only to consider trajectories which are transversal to the boundary and which reflect according the laws of geometrical optics. There are some points of the cotangent bundle through which infinitely long trajectories do not pass but the measure of these dead-end points vanishes and we need not take them into account.

However, for higher-order operators as well as for matrix operators the trajectories reflected from the boundary can branch and in this case it is necessary to follow every branch. This circumstance guides us to a situation which is essentially more complicated: the measure of the set of all these dead-end points does not necessarily vanish, so the following additional condition appears:

the measure of {*the set of all dead-end points*} *equals* 0*;*

this condition is not automatically fulfilled now.

Let us clarify, for scalar first-order operators on a manifold without boundary, the link between the asymptotics (0.12) and periodic Hamiltonian trajectories. It is well known that singularities of the solutions of hyperbolic equations propagate along Hamiltonian trajectories. This fact guides us to the conclusion that the singular support of $\sigma(t)$ is contained in the set of all the periods of the Hamiltonian trajectories including $t = 0$ (this is the so-called *Poisson relation*); in particular, $t = 0$ is an isolated point of the singular support (this fact remains true also in the much more general situation).

Hence, if there is no periodic trajectory with the period not exceeding T, then we know that in the interval $[-T, T]$ the distribution $\sigma(t)$ is singular only at 0 and hence we know $\sigma(t)$ in this interval modulo a smooth function. The Tauberian theorem implies that the remainder in asymptotics (0.12) does not exceed $C\lambda^{d-1}T^{-1} + O\bigl(\lambda^{d-2}\bigr)$ with a constant C, which does not depend on T; however "O" here is not necessarily uniform with respect to T. Therefore, if $t = 0$ were the only period (surely I know that it is impossible!), then we could choose T arbitrarily large and obtain the remainder estimate $o\bigl(\lambda^{d-1}\bigr)$.

In the general (realistic) case one should consider a partition of unity by means of two pseudodifferential operators Q_j ($j = 1, 2$) for every chosen T, such that the support of the first operator contains no periodic point with a period not exceeding T, and the measure of the support of the symbol of the second operator is less than ε with arbitrarily chosen $\varepsilon > 0$. Applying the Tauberian theorem to each term

$$\mathsf{N}_j(\lambda) = \int (Q_j e)(x, x, \lambda)\, dx, \tag{0.13}$$

we obtain the remainder estimate $C\lambda^{d-1}T^{-1} + O\bigl(\lambda^{d-2}\bigr)$ for $j = 1$ and $C\varepsilon\lambda^{d-1} + O\bigl(\lambda^{d-2}\bigr)$ for $j = 2$. Therefore the total remainder estimate for $\mathsf{N}(\lambda) = \mathsf{N}_1(\lambda) + \mathsf{N}_2(\lambda)$ is $C\lambda^{d-1}(\varepsilon + T^{-1}) + O\bigl(\lambda^{d-2}\bigr)$ with arbitrarily large T and arbitrarily small $\varepsilon > 0$; this estimate again implies (0.12).

Moreover, under certain more restrictive conditions to the Hamiltonian flow, one can improve the remainder estimate in (0.12) up to $O\bigl(\lambda^{d-1}(\log \lambda)^{-1}\bigr)$ or even $O\bigl(\lambda^{d-1-\delta}\bigr)$ with a small exponent $\delta > 0$.

It appeared later that the presence of periodic trajectories and, moreover, the presence of eigenvalue clusters allow two-term asymptotics of the form

$$\mathsf{N}(\lambda) = \kappa_0\lambda^d + f(\lambda)\lambda^{d-1} + o\bigl(\lambda^{d-1}\bigr) \tag{0.14}$$

with an explicitly calculable function $f(\lambda)$ which is bounded and oscillating as $\lambda \to +\infty$ with the characteristic "period" of oscillations $\asymp 1$. In particular, this fact permits us to obtain the asymptotic distribution of eigenvalues inside clusters. In addition, under some assumptions including the assumption that all the trajectories are periodic, one can obtain the asymptotics (0.14) with the remainder estimate $O\bigl(\lambda^{d-2}\bigr)$!

4. Methods. II

The theory presented above has major exceptions. First, it could happen that in some part of our domain we should not apply the semiclassical spectral asymptotics (rescaled or not) but instead we simply need to estimate the main part of the asymptotics using methods different from those explained (usually those are variational methods). So, our domain is split into two parts: a *semiclassical zone* (aka a *regular zone*) and a *singular zone*; this partition depends on the parameters. F. e., if we consider the Schrödinger operator $h^2\Delta - |x|^{-1}$, then the semiclassical zone is $\{x\colon |x| \gtrsim h^{-2}\}$ and the

singular zone is $\{x\colon |x| \lesssim h^{-2}\}$. Definitely joining results in these two zones requires some work.

Second, it may happen that (in some part of the domain) we need to split variables x and ξ to two parts: $x = (x'; x'')$, $\xi = (\xi'; \xi'')$, and only consider (x', ξ') as *Weyl variables*, which means that one should consider the operator in question as a (partial) differential operator with respect to x' with operator-valued coefficients (acting in some auxiliary Hilbert space) and apply the Weyl procedure to this operator. F.e., if we consider Laplacian in the domain has a cusp: $\{x = (x', x'')\colon x'' \in f(x')\Omega\}$, where Ω is a bounded domain in $\mathbb{R}^{d''}$ with a smooth boundary, and $f(x')$ decays as $|x'| \to \infty$, then for $|x'| \ge g(\lambda)$ we can consider x' as Weyl variables and an auxiliary space is $\mathbb{K} = \mathscr{L}^2(\Omega)$.

In the more general case one should divide the phase space into a few parts, one of which should be removed from consideration altogether while in the other parts the "Weylization" (preceded by a certain transform) should be made only with respect to certain variables.

The previous remarks are not a survey, even an incomplete one. Their purpose is only to motivate this book in general and the following part of this introduction in particular. Nor are the comments in each chapter complete.

As the best surveys I recommend the books of M. S. Birman and M. Z. Solomyak [5] and G. Rozenblioum, M. Z. Solomyak and M. Shubin [1], despite being outdated.

It also should be noted that though this book demands from the reader only a good and detailed knowledge of the theory of pseudodifferential operators and a familiarity with the theory of Fourier integral operators (see, e.g., the books of L. Hörmander [1], F. Treves [1], M. Taylor [7] and M. Shubin [3]); an elementary familiarity with the theory of spectral asymptotics (see the same books) is also very desirable. As an elementary introduction to Semiclassical analysis I recommend M. Zworski [1], A. Martinez [1], B. Helffer [2].

It should be noted that this book has few intersections with the books of S. Levendorskii [6] and Yu. Safarov and D. Vassiliev [3] which are also devoted to spectral asymptotics. I recommend both of those books, especially the second one.

Finally, I would like to mention that there are some problems in this book. There are problems the solutions of which are not known to me. There are problems the solutions of which are known to me but which cannot be published here or elsewhere by me because of lack of time due to my

efforts on *this* book. I welcome readers to solve these problems either by the method suggested or by some other method and to publish their solutions. Finally, there are problems I consider rather simple exercises.

The structure of this book and the numbering of statements and formulas is clear from the table of contents and from the Section below.

5. What is in the Book

Let us now discuss the contents and principal ideas of this book. It consists of five volumes:

Volume I covers the general microlocal and local theory.

Volume II covers the general functional-analytic theory which in combination with the microlocal theory of Volume 1 leads us to spectral asymptotics in domains with singularities. Then we apply these results to more specific problems. We also consider here some problems not covered by the general theory.

Volume III is devoted to Schrödinger and Dirac operators with the strong magnetic field.

Volume IV is also devoted to Schrödinger and Dirac operators with the strong magnetic field.

Volume V is devoted to the asymptotics of the ground state energy of heavy atoms and molecules and related topics. It also contains some latest articles, which are not included into the main body of the book.

Volume I. Semiclassical Microlocal Analysis and Local and Microlocal Semiclassical Asymptotics

Part I. Semiclassical Microlocal Analysis

There are no spectral asymptotics yet in Part I, "Semiclassical Microlocal Analysis"; we develop the apparatus (both basic notions and technique) of the semiclassical microlocal analysis here.

Chapter 1. Introduction to Microlocal Analysis. This chapter contains the necessary survey of the theory of the h-pseudodifferential operators (in *Section 1.1*), the functional calculus of these operators (in *Section 1.4*), the theory of the h-Fourier integral operators (in *Section 1.2*) and the theory of singularities (wave front sets and related topics, in *Section 1.3*). There are no new non-trivial results in this chapter but there is a rather obvious but very important new

Definition 0.1. A family of functions $u = u_h$, depending on a small parameter $h \in (0, h_0]$ (and maybe depending on some other parameters of an arbitrary nature), tempered (i.e., with $\|u\| \le Ch^{-n}$ with some constant C and exponent n where here and below $\|.\|$ means the $\mathscr{L}^2$-norm) is *negligible in the box*

$$\Pi = \{(x,\xi) : |x_j - \bar{x}_j| \le \gamma_j,\ |\xi_j - \bar{\xi}_j| \le \rho_j\ \forall j = 1,\dots,d\},$$

if there exists a function $\phi \in \mathscr{C}_0^\infty(\mathbb{R}^{2d})$, equal to 1 in the unit cube $\{(x,\xi) : |x_j| \le 1, |\xi_j| \le 1 \quad \forall j = 1,\dots,d\}$ and such that $\|\phi_\Pi^w(x, hD)u\| \le Ch^s$, where $\phi_\Pi(x,\xi) = \phi(\gamma^{-1}(x-\bar{x}), \rho^{-1}(\xi - \bar{\xi}))$; note that the exponent s enters into the definition of negligibility and here and below we use a notation $\gamma^{-1}x = (\gamma_1^{-1}x_1, \dots, \gamma_d^{-1}x_d)$ etc.

In the standard definition, leading to the notion of an *wave front set*, one takes a *fixed* box Π (i.e., with constant $(\bar{x},\bar{\xi})$ and $(\gamma_1,\dots,\gamma_d;\rho_1,\dots,\rho_d)$); this definition is too crude for our needs and we admit variable (i.e., depending on parameters) $(\bar{x},\bar{\xi})$ and $(\gamma_1,\dots,\gamma_d;\rho_1,\dots,\rho_d)$, satisfying the *microlocal uncertainty principle*

$$\gamma_j\rho_j \ge h^{1-\delta} \qquad \forall j = 1,\dots,d \tag{0.15}$$

with an arbitrarily small exponent $\delta > 0$. An important special case is $\gamma_1 = \dots = \rho_d \ge Ch^{\frac{1}{2}(1-\delta)}$ [3)]

[3)] We can weaken (0.15) to the *logarithmic uncertainty principle*

$$\gamma_j\rho_j \ge C_s h|\log h| \qquad \forall j = 1,\dots,d \tag{0.16}$$

with important special case $\gamma_1 = \dots = \rho_d \ge C(h|\log h|)^{\frac{1}{2}}$ albeit not to the *standard uncertainty principle*

$$\gamma_j\rho_j \ge h \qquad \forall j = 1,\dots,d. \tag{0.17}$$

Chapter 2. Propagation of Singularities in the Interior of the Domain. This chapter is devoted to the propagation of singularities (or, more precisely, of the negligibility) of solutions in the interior of the domain. The key definition of the *microhyperbolicity of an operator P at* the given *point z* of the cotangent bundle *in the direction* $\mathcal{T} \in T_z T^*X$ appears in *Section 2.1*, and the main theorem concerning propagation of singularities is proven there; the theorem is formulated in terms of real-valued functions ϕ_k, such that the operator P under consideration is microhyperbolic at every point $z \in \Omega$ in the directions of the Hamiltonian fields $\nabla^{\#}\phi_k$, generated by ϕ_k; here and in what follows $\Omega \subset T^*X$ is a phase domain under consideration. This theorem is proven by means of the energy estimates.

We then apply this theorem to the operator $P = hD_t - A^w(x, hD_x, h)$ and to the analysis of the fundamental solution $u(x, y, t)$ of the Cauchy problem for this operator, establishing the finite speed of propagation of singularities (in the domain $\Omega \subset T^*X$). In particular, under the microhyperbolicity condition for the operator A on the energy level λ we prove that the singularities of $u(x, y, t)$ leave the diagonal $\{x = y, \xi = \eta\}$; this statement yields the negligibility of

$$\sigma_Q(t) = \int (Q_x u)(x, x, t) dx \tag{0.18}$$

in boxes of the form $\{(t, \tau) : Ch^{1-\delta} \le \pm t \le T_0, |\tau - \lambda| \le \epsilon_0\}$ with small enough positive constants T_0 and ϵ_0 and with arbitrarily small exponent $\delta > 0$; here and in what follows Q is a cutting h-pseudodifferential operator supported in Ω.

The results of Section 2.1 are reformulated in *Section 2.2* in the terms of the *generalized bicharacteristics* of P, which, in the case of constant multiplicities of the eigenvalues $\alpha_j(x, \xi)$ of the symbol $a(x, \xi) = A(x, \xi, 0)$, are the standard bicharacteristics of the symbols $\tau - \alpha_j(x, \xi)$.

Also results of Section 2.1 are extended in *Section 2.3* to operators with rough symbols.

In *Section 2.4* the classical theorem on the propagation of singularities along bicharacteristics for operators with constant multiplicities of the characteristics is proven in a more general and refined form. Namely, for the operator $P = hD_t - A^w(x, hD_x, h)$ with self-adjoint operator $A^w(x, hD_x, h)$ and with constant multiplicities of the eigenvalues $\alpha_j(x, \xi)$ of the symbol $a(x, \xi)$ we replace the usually used negligibility in a small fixed neighborhood by negligibility in the γ-neighborhood of a Hamiltonian trajectory with

$\gamma \geq h^{\frac{1}{2}(1-\delta)}$; it is assumed that this trajectory is not too long (i.e., $T \leq ch^{-\delta'}$ with a small enough exponent $\delta' > 0$); the symbol $A(x, hD_x, h)$ and its derivatives up to large enough order K and the elements of the Jacobi matrix of the corresponding Hamiltonian flow are also assumed to be not too large (i.e., their absolute values or norms are also less than $ch^{-\delta'}$). The proof is based on the Heisenberg equation. In what follows we sometimes return to the investigation of the propagation of singularities.

Chapter 3. Propagation of Singularities near the Boundary. Here we realize approximately the same program for operators near the boundary on which boundary conditions are given. In *Section 3.1* we give the key definition of the *microhyperbolicity of the problem* (P, B) *at the point* $z \in T^*\partial X$ *in the multidirection* $\mathcal{T} = (\mathcal{T}', \zeta_1, \dots, \zeta_n) \in T_z T^*\partial X \times \mathbb{R}^n$, where n is the number of the different characteristic points z_k of the operator P, lying over z. Then we prove the main theorem concerning the propagation of singularities; this theorem is formulated in terms of real-valued functions $\phi_k(x, \xi')$, coinciding at $\{x_1 = 0\}$ and such that the problem (P, B) is microhyperbolic in the domain $\Omega \subset T^*\partial X$ under consideration in the multidirection $(\nabla^{\#}\phi, \partial_{x_1}\phi_1, \dots, \partial_{x_1}\phi_n)$, where we assume that $X = \{x_1 = 0\}$ locally and $x' = (x_2, \dots, x_d)$, $\phi = \phi_k(0, x, \xi')$.

Then in *Section 3.2* we discuss some geometrical aspects of the propagation of singularities; however the general results are not very precise.

Next, in *Section 3.3* we deduce the same corollaries as in Section 2.1 (concerning the finite speed of the propagation of singularities for the operator $P = hD_t - A^w(x, hD_x, h)$ and the negligibility of $\sigma_Q(t)$ in the same boxes as before provided (A, B) is microhyperbolic at the level λ) from this theorem.

Further, in *Section 3.4* we develop a more refined energy method and prove that there is no propagation along creeping rays.

Finally, *Section 3.5* is devoted to the propagation of singularities along "long trajectories"; here we consider only h-differential second-order operators and assume that at the point where a trajectory meets the boundary and reflects the trajectory is transversal enough to the boundary (with angle greater than $h^{\delta'}$); moreover, we assume that a certain non-degeneracy condition on the boundary operator is also fulfilled at such reflection points. It should be noted that the number of reflection points is not too large (less

than $h^{-\delta''}$ with exponent $\delta'' = \delta''(\delta') > 0$, $\delta''(\delta') \to +0$ as $\delta' \to +0$).

Part II. Local and Microlocal Semiclassical Spectral Asymptotics in the Interior of the Domain

The main goal of Part II is to obtain asymptotics as $h \to +0$ for

$$\mathcal{E}_Q(\lambda_1, \lambda_2) = \int (Q_x e)(x, x, \lambda_1, \lambda_2)\, dx \tag{0.19}$$

with

$$e(x, y, \lambda_1, \lambda_2) = e(x, y, \lambda)\big|_{\lambda=\lambda_1}^{\lambda=\lambda_2}, \tag{0.20}$$

where $e(x, y, \lambda)$ is a Schwartz kernel of $E(\lambda)$ (which is a spectral projector of A) and either $Q = Q^w(x, hD_x)$ is an h-pseudodifferential operator with compactly supported symbol or $Q = \psi(x)$ is a compactly supported function; we speak about *microlocal spectral asymptotics* and *local spectral asymptotics* respectively. Here and below the subscript "x" means that the corresponding operator acts with respect to x, etc.

We also consider the same expressions mollified with respect to the spectral parameter.

Chapter 4. General Theory in the Interior of the Domain. Here we consider the case when $\mathsf{supp}(Q)$ is disjoint from the boundary of the domain X.

Section 4.2 contains a preliminary analysis and the results obtained there are rather trivial. First of all, microlocal estimates $\|\mathcal{E}_Q(\lambda_1, \lambda_2)\| \le Ch^{-d}$ are derived in the general case and estimates $\|\mathcal{E}_Q(\lambda_1, \lambda_2)\| \le Ch^s$ are derived in the case when the interval (λ_1, λ_2) is *classically forbidden* in a neighborhood of $\mathsf{supp}(Q)$ (i.e., the interval is disjoint from the spectrum of the symbol $A(x, \xi, h)$ for the indicated (x, ξ)); one can weaken this condition provided the multiplicities of the eigenvalues of the symbol $a(x, \xi)$ are constant. We obtain similar local estimates for operators elliptic in the standard sense.

Then in *Section 4.3* we apply the *method of successive approximations* to $u(x, y, t)$; we take an unperturbed operator $\bar{A} = A(y, hD_x, 0)$ with the symbol depending only on ξ. This method turns out to be applicable in the rather short time interval $\{|t| \le h^{\frac{1}{2}+\delta}\}$ with arbitrary small exponent $\delta > 0$.

This immediately yields in *Section 4.4* complete semiclassical asymptotics for the spectral means

$$\int \phi\big(\frac{1}{L}(\lambda - \bar{\lambda})\big)\, d_\lambda \mathcal{E}_Q(\lambda_1, \lambda) \tag{0.21}$$

with any $L \ge h^{\frac12-\delta}$ and with $\phi \in \mathscr{C}_0^K(\mathbb{R})$; further, one can take $L \ge h^{1-\delta}$ provided the eigenvalues of $A(x,\xi)$ have constant multiplicities. This yields *complete asymptotics* for $\mathcal{E}_Q(\lambda_1,\lambda_2)$ in the case when both levels λ_1 and λ_2 are classically forbidden but the whole interval (λ_1,λ_2) is not; in all these cases the leading term is $\kappa_0 h^{-d}$. Then we consider the main case when $\bar\lambda$ is not a classically forbidden level and A is microhyperbolic at this level.

Combining the results of Section 4.3 with the statement from Section 2.1 concerning the negligibility of $\sigma_Q(t)$, we obtain complete asymptotics of $\sigma_Q(t)$ in the zone $\{(t,\tau) : |t| \le T_0, |\tau-\bar\lambda| \le \epsilon_0\}$ with small positive constants T_0 and ϵ_0. For $|\tau-\bar\lambda| \le \epsilon_0$ we get asymptotics in the interval $[-h^{\frac12+\delta}, h^{\frac12+\delta}]$. It was proven in Section 2.1 that $\sigma(t)$ is negligible in $[-T_0,-h^{1-\delta}]\cup[h^{1-\delta},T_0]$, and these intervals overlap! We immediately get asymptotics of (0.21) for $L \ge h^{1-\delta}$. Moreover, the Tauberian method yields the estimate

$$\|\mathcal{E}_Q(\lambda_1,\lambda_2) - \kappa_{0Q}(\lambda_1,\lambda_2)h^{-d}\| \le Ch^{1-d} \tag{0.22}$$

for $\lambda_1,\lambda_2 \in (\bar\lambda-\frac12\epsilon_0, \bar\lambda+\frac12\epsilon_0)$ and miscellaneous related asymptotics in which the possible smallness of $\mathsf{supp}(Q)$ is taken into account. The same method also yields asymptotics of the Riesz means of order $\vartheta > 0$ with remainder estimate $Ch^{1-d+\vartheta}$. However, all these asymptotics are due to the simple Tauberian estimate

$$\|\mathcal{E}_Q(\lambda_1,\lambda_2)\| \le Ch^{1-d} \qquad \forall \lambda_1,\lambda_2 \in [\bar\lambda-\epsilon_0, \bar\lambda+\epsilon_0] : |\lambda_1-\lambda_2| \le h \tag{0.23}$$

and asymptotics of (0.21) with $L \ge h$ and remainder estimate $Ch^{1-d}\big(h/L\big)^s$ with an arbitrarily large exponent s. Actually estimates of this type seem to be the most important for our internal needs.

In *Section 4.5* we derive sharper remainder estimates under assumptions of the global nature. Applying the results of Section 2.3 under a condition forbidding periodic trajectories of length not exceeding T, we obtain complete asymptotics of $\sigma_Q(t)$ in the zone indicated above with T_0 replaced by T; then the same arguments yield the estimate

$$\|\mathcal{E}_Q(\lambda_1,\lambda_2) - \kappa_{0Q}(\lambda_1,\lambda_2)h^{-d} - \kappa_{1Q}(\lambda_1,\lambda_2)h^{1-d}\| \le C\varepsilon h^{1-d} + Ch^{1-d+\delta'} \tag{0.24}$$

with $\epsilon = T^{-1}$ and small enough exponent $\delta' > 0$; under some more general and realistic conditions we obtain an estimate with a more complicated

expression for ε. Those adjustments are also achieved for Riesz means (the first term in the remainder estimate is $Ch^{1-d+\vartheta}T^{-1-\vartheta}$) and for expression (0.21) with $L \geq hT^{-1}$ (the first term of the remainder estimate is $Ch^{1-d}T^{-1}\big(h/LT\big)^{s}$).

Furthermore, in *Section 4.6* we generalize these results to operators with rough coefficients. Then for operators with irregular coefficients we construct two operators with rough coefficients, bracketing them, and close enough to provide the same principal parts of the asymptotics.

Considering $a(x,\xi)$ as the symbol of an m-th order differential operator and assuming that it is elliptic in the standard sense, we switch from microlocal to local asymptotics. It allows us in certain cases to consider operators with non-smooth ($\mathscr{C}^l$) coefficients by the bracketing method.

Finally, in Section 4.7 we consider operators with non-smooth coefficients directly by the perturbation method.

We discuss Chapters 4–6 so comprehensively because its results and methods are highly important for the parts of the book which follow. The scheme of the arguments in the main stream of these chapters is the following:

Construction (by means of the method of successive approximations) of $u(x,y,t)$ *and hence* $\sigma_Q(t)$ *in the short time-interval* $\{|t| \leq T_1\}$*—step-by-step extension of this interval by different methods—application of the Tauberian method;*

in what follows this scheme is used repeatedly. An important general idea is that

In the theory of spectral asymptotics the step-by-step approach with improvement is much better than more bold attempts to do everything in one shot.

It should be mentioned that we do not use the results of Chapter 3 in Chapters 4–6 and that the results of Sections 4.2–4.4 are obtained for standard operators as well as for operators with operator-valued symbols; however, the results for operators with operator-valued symbols are applied only in Chapter 12 (except Section 12.6).

Chapter 5. Scalar Operators in the Interior of the Domain. Rescaling Technique. Here we consider scalar operators (and sometimes operators with the similar properties).

In *Section 5.2* we analyze operators with constant multiplicities of the eigenvalues of the principal symbol. By means of *an admissible partition of unity and rescaling with respect to x with a change of h on every element of this partition* we replace the microhyperbolicity condition by another much less restrictive condition (which is void for Riesz means). The method applied here is very important and will be used very often in this book. We call it the *rescaling method* or *partition-rescaling method* in what follows. To get the best possible results one should combine this method with a refined analysis of the propagation of singularities along trajectories which are long *after* rescaling but are usually of bounded length or even short *before*: time and energy are rescaled automatically.

Section 5.3 may be summarized simply: for the Schrödinger, Schrödinger-Pauli and Dirac operators in dimension $d \geq 2$ one can simply drop the microhyperbolicity condition. Here we apply the same rescaling method as before with some simplifications and modifications.

For these operators we also consider *pointwise asymptotics*, i.e. asymptotics of $e(x,x;\lambda_1,\lambda_2)$ or $(Q_{x,y}e)(x,x;\lambda_1,\lambda_2)$ without mollification with respect to the spatial variables. In this case not only periodic trajectories but also loops play important role: namely, trajectory returns to the same point but from the different direction.

In *Section 5.4* we generalize previous results to operators with rough and irregular symbols.

Chapter 6. Operators in the Interior of Domain. Esoteric Theory. In this chapter we consider more special questions.

First, in *Section 6.1* we extend the above results to the families of commuting operators.

Further, *Sections 6.2 and 6.3* have a more special character. Here we consider scalar operators with periodic Hamiltonian flow of the principal symbol, or some weak perturbation of an operator of this type; there automatically appears an additional parameter $\eta \in [h^n, h^\delta]$ with arbitrarily large n and arbitrarily small $\delta > 0$ (this parameter equals h in the "normal" situation); for $\eta \leq \epsilon h$ with a small constant $\epsilon > 0$ there arise spectral zones of length $\leq C\eta$ separated by lacunary zones of length $\asymp h$ in the semiclassical

approximation to the spectrum; it is proven that $\mathcal{E}_Q(\lambda_1,\lambda_2)=O(h^s)$ with arbitrarily large s provided the interval (λ_1,λ_2) lies in a lacunary zone; in the case when λ_1 and λ_2 belong to different lacunary zones we obtain complete non-Weyl asymptotics for $\mathcal{E}_Q(\lambda_1,\lambda_2)$.

Turning to the long-time propagation of singularities (with $|t|\le \epsilon\eta^{-1}$) we prove that singularities propagate along Hamiltonian trajectories of the symbol $a(x,\xi)$, drifting in the direction of the Hamiltonian field generated by an auxiliary symbol $b(x,\xi)$ with drift speed $\asymp\eta$. Now turning to $\mathcal{E}_Q(\lambda_1,\lambda_2)$ we finally derive, under certain conditions, the estimate

$$\bigl|\mathcal{E}_Q(\lambda_1,\lambda_2)-\kappa_{0Q}(\lambda_1,\lambda_2)h^{-d}-\kappa_{1Q}(\lambda_1,\lambda_2)-f_Q(\lambda_1,\lambda_2)h^{1-d}\bigr|\le C(\eta+h)h^{1-d}, \tag{0.25}$$

where the quickly oscillating function f is explicitly calculated. It arises from singularities of $\sigma_Q(t)$ different from $t=0$. Nevertheless the last term in the asymptotics is of the order of the second one and its variation on the interval of length $\asymp h$ is of the same order $\asymp h^{1-d}$ as the variation of the first term[4)]. For $\eta\ge h^{1-\delta}$ we obtain asymptotics (0.24) with $\varepsilon=\eta$ under certain assumptions.

In *Section 6.4* we consider asymptotics of expression

$$I:=\iint \omega(x,y)|e(x,y,\tau)|^2\,dxdy \tag{0.26}$$

with $\omega(x,y):=\Omega(x,y;x-y)$, where function $\Omega(x,y,z)$ is smooth with respect to x and y and smooth positively homogeneous of degree κ with respect to $z\ne 0$. This expression generalize the *Dirac energy* used in Chapters 25–28 (in which case $\omega(x,y)=|x-y|^{-1}$).

Finally, in *Section 6.5* we consider improved asymptotics with mollifications with respect to some parameter, which is different from a spectral parameter.

Part III. Local and Microlocal Semiclassical Spectral Asymptotics near the Boundary

Chapter 7. Standard Local Semiclassical Spectral Asymptotics near the Boundary. This chapter is essentially parallel to Chapter 4:

[4)] As it should be because the decrease of the last term along the spectral gap should compensate for the increase of the first term; along the cluster both terms grow and if $\eta\ll h$ then the last term grows more quickly.

the content of each of *Sections 7.1–7.5* is very similar to the content of its counterpart from 4.2–4.6. We underline only the following "shortcomings":

(a) We now consider only standard operators, not operators with operator-valued symbols.

(b) We do not weaken the microhyperbolicity condition for operators with constant multiplicities of the eigenvalues of the principal symbol; we do it only for the Schrödinger operator in Section 7.4.

(c) In Section 7.4 boundary is also irregular and we cannot smooth it up by a change of coordinates because then coefficients become too irregular. Instead we use (generalized) Seeley's method.

It also should be noted that if the interval $[\lambda_1, \lambda_2]$ is classically forbidden for the symbol $a(x,\xi)$ but is not forbidden for the 1D-problem (on the semiaxis $\mathbb{R}^+ \ni t$) $\big(a(x', D_t, \xi'); b(x', D_t, \xi')\big)$ (as above we assume that $X = \{x_1 > 0\}$ locally), then in the above estimates and asymptotics one should replace d by $(d-1)$; sometimes we are even able to get two-term asymptotics.

Chapter 8. Standard Local Semiclassical Spectral Asymptotics near the Boundary. Miscellaneous. This chapter contains results similar to those of Chapters 5 and 6.

In *Section 8.1* we consider pointwise asymptotics (i.e. asymptotics of $e(x,x;\lambda_1,\lambda_2)$) near the boundary. Because there are short loops (when a trajectory, reflected from the boundary, goes in the exactly opposite direction and returns to the same point x) such asymptotics with a decent remainder estimate has an additional term of the *boundary layer type* of the width h, i.e. the term of the magnitude h^{-d} if $\operatorname{dist}(x,\partial X) \lesssim d$ and decaying away from ∂X.

In *Section 8.2* we consider scalar operators and develop a rescaling technique for them.

In *Section 8.3* we consider operators with periodic Hamiltonian flows but with a twist. First, as we know from Section 6.2 a quantum periodicity may be violated by the phase shift; now however there may be an additional phase shift at the reflections from the boundary. Second, in the case of branching billiards the periodicity could be partial: only some branches return to the original point (x,ξ) while other branches do not, so there is an energy decay along periods.

Finally, in *Section 8.4* we consider spectral asymptotics on subspaces (when the main Hilbert space is not $\mathscr{L}^2(X, \mathbb{C}^D)$ but it subspace which is defined by underdetermined elliptical boundary value problem (f.e. a space of solenoid vector fields)). Such generalization in the case without boundary is rather trivial.

Volume II. Functional Methods and Eigenvalue Asymptotics

Part IV. Estimates of the Spectrum.

The character of Part IV is essentially different from the character of the previous parts. There are only a few micro-analytical arguments in this part but there are many functional-analytical arguments.

The substance of these arguments is the following: in Parts II and III we considered $\mathcal{E}_\psi(0)$ for a function ψ supported in $B(0, \frac{1}{2})$ (where $B(y, r)$ is the ball with radius r and center y in $\mathbb{R}^d$) and all conditions (apart from the self-adjointness condition and conditions associated with Hamiltonian trajectories) were assumed to be fulfilled only in $B(0, 1)$. We had asymptotics with remainder estimates with constants depending only on the constants, used in these conditions.

Hence those estimates yield a similar estimate in the case in which ψ is supported in $B(y, \frac{1}{2}\gamma(y))$ and it is assumed that after the rescaling (an affine transformation in $\mathbb{R}^d$) transforming $B(y, \gamma(y))$ into $B(0, 1)$ and multiplication by $\varrho^{-1}(y)$ for the operator in question the conditions of Part II or III will be fulfilled with the parameter h replaced by a new parameter $h_{\text{eff}} = h\rho(y)^{-1}\gamma(y)^{-1}$ [5)].

One should assume here that $h_{\text{eff}} \le 1$ (i.e., that $\rho(y)\gamma(y) \ge h$) and one can rewrite the conditions mentioned above for the operator before rescaling. Let us assume that $\gamma(y) > 0$ and $|\nabla\gamma(y)| \le 1$; then one can take a γ-admissible partition of unity and under the condition $\rho(y)\gamma(y) \ge h$ one can sum the derived estimates and obtain an estimate of the type (0.28) or (0.29) below.

Chapter 9. Estimates of the Negative Spectrum. We assume here that the operator is semibounded from below. Then under assumption

[5)] Moreover, in Chapters 13–22 the results which also could be used in the similar arguments a parameter μ_{eff} also appears.

$\rho(y)\gamma(y) \ge h$ everywhere the partition-rescaling technique results in

$$\bigl|\mathsf{N}^-(0) - \mathcal{N}^-(0)\bigr| \le CR_1 \tag{0.27}$$

with the same (Weyl or non-Weyl) principal part $\mathcal{N}^-(0)$ as before and with some remainder estimate R_1. However, there are many important cases in which this condition $\rho(y)\gamma(y) \ge h$ is fulfilled only in a subdomain X' of the domain X (as we mentioned we call X' semiclassical or regular zone); then summing with respect to a partition of unity in X' we obtain estimates only for $\mathcal{E}_\psi(0)$ (but not for $\mathsf{N}^-(0)$) with an admissible function ψ such that $\mathsf{supp}(\psi) \subset X'$ and $\psi = 1$ outside of $X'_{3/2} = \{y\colon \rho(y)\gamma(y) \le \frac{3}{2}h\}$. Thus, in order to obtain an estimate for $\mathsf{N}^-(0) = \mathcal{E}_1(0)$, we need to derive an estimate for $\mathcal{E}_{1-\psi}(0)$.

On the other hand, if we had $X = X'' \supset \{y\colon \rho(y)\gamma(y) \le 2h\}$, then we very often would have some estimates for $\mathsf{N}^-(0)$ of a completely different (variational) origin which have the form $\mathsf{N}^-(0) \le CR_2$.

In this book we almost exclusively apply the Rozenblioum variational estimate, but one can use other estimates of this type. It appears that in the general case one can prove these estimates together and derive the estimate

$$\bigl|\mathsf{N}^-(0) - \mathcal{N}^-(0)\bigr| \le C\bigl(R_1 + R_2 + R_{12}\bigr), \tag{0.28}$$

where $\mathcal{N}^-(0)$ and R_1 (associated with $\mathcal{E}_\psi(0)$) are exactly the same as before in the zone X', the estimate R_2 is derived for a self-adjoint operator A'' defined in the domain X'' where A'' coincides with A in the zone $\{y\colon \rho(y)\gamma(y) \le \frac{7}{4}h\}$ (and the boundary conditions also coincide at the common part of the boundaries of X and $\partial X''$), and R_{12} is an additional term, depending on the auxiliary construction.

The proper construction using the *Birman-Schwinger principle* with an appropriate auxiliary function makes this term less than $C(R_1 + R_2)$. This construction is done in Chapter 9.

First of all, in *Section 9.1* the principal theorems are formulated and proven.

Next, in *Section 9.2* we illustrate these theorems in the simpler cases and in *Section 9.3* we reformulate them for quadratic forms. Here we have two important ideas:

(a) *rescaling with multiplication and a change of parameters* (we mentioned this idea in the discussion of Section 5.3) and

(b) *combining the asymptotics derived in Parts II and III with estimates of the variational origin which makes it possible to consider a domain containing not only a semiclassical zone X' but also a singular zone X''.*

This task is done in this chapter for semi-bounded operators.

Chapter 10. Estimates of the Spectrum in the Interval. Here we consider the non-semibounded case and our analysis here is essentially parallel to the analysis of Chapter 9; a very important role is played by the following form of the *Birman-Schwinger principle:*

$$\mathsf{N}\big(A;[\lambda_1,\lambda_2)\big) = \mathsf{N}\big(A-\bar t J;[\lambda_1,\lambda_2)\big) - \mathsf{N}\big(-J^{-1}(A-\lambda I);[0,\bar t)\big)\Big|_{\lambda=\lambda_1}^{\lambda=\lambda_2}, s \tag{0.29}$$

which applies (under some hypotheses) in the case of a positively defined matrix-valued function J and for $\bar t>0$ [6], where $\mathsf{N}(A;[\lambda_1,\lambda_2))$ is the number of eigenvalues of the operator A in the interval $[\lambda_1,\lambda_2)$ [7] and similarly $\mathsf{N}(-J^{-1}(A-\lambda I);[0,\bar t))$ is the number of eigenvalues of the spectral problem

$$\big((A-\lambda I)+tJ\big)u=0 \tag{0.30}$$

in the interval $[0,\bar t)$.

One can iterate this formula, at each step replacing the operator A by $A-t_1J_1-\dots-t_{k-1}J_{k-1}$, the number $\bar t$ by t_k and the function J by J_k with $k=1,\dots,n$; here $t_1,\dots,t_n$ *are not necessarily of the same sign*. As a result we obtain the following more complicated formula

$$\begin{aligned}\mathsf{N}\big(A;[\lambda_1,\lambda_2)\big) =& \mathsf{N}\big(A-t_1J_1-\dots-t_{k-1}J_{k-1};[\lambda_1,\lambda_2)\big) - \\ & \mathsf{N}\big(-J_1^{-1}(A-\lambda I);[0,t_1)\big)\Big|_{\lambda=\lambda_1}^{\lambda=\lambda_2} - \dots \\ & \mathsf{N}\big(-J_n^{-1}(A-\lambda I-t_1J_1-\dots-t_{n-1}J_{n-1});[0,t_n)\big)\Big|_{\lambda=\lambda_1}^{\lambda=\lambda_2},\end{aligned}$$

to the right-hand expression of which we apply arguments, similar to those discussed above (in the discussion of Chapter 9)[8].

---

[6] A similar form applies to the case $\bar t<0$.

[7] Provided $\mathsf{Spec}_{\mathsf{ess}}(A)\cap[\lambda_1,\lambda_2)=\emptyset$; otherwise $\mathsf{N}(A;[\lambda_1,\lambda_2))=\infty$.

[8] Actually, we multiply the last equality by $\varphi_1(t_1)\cdots\varphi_n(t_n)$ with appropriate functions φ_k and integrate on $(t_1,\dots,t_n)\in\mathbb{R}^n$ (this rather technical trick is useful).

It should be noted that the reader who is interested only in semibounded operators has no need to read Chapter 10. It should also be noted that Chapters 9 and 10 would be absolutely trivial if we assumed that the singular zone is empty; however in this case we would obtain a much more restricted series of results in Chapters 11, 23 and 24 and we would be ready for Chapter 12 neither technically nor psychologically.

Part V. Asymptotics of Spectra

In Part V we return to spectral asymptotics, now based on Parts II, III and IV.

Chapter 11. Weyl Asymptotics of Spectra. The essence of Chapter 11 is very simple: *we substitute an operator A depending on certain parameters into the assertions of Chapters 9 and 10 (and even Chapters 4–8 after partition of unity, rescaling, multiplication and change of parameters), check that the conditions of these assertions are uniformly fulfilled, and as a result we obtain asymptotics with respect to these parameters*.

The arguments of this Chapter are in terms of "arithmetics", dynamical systems theory (when we check conditions associated with the Hamiltonian trajectories) and rather simple functional analysis (when we check conditions associated with the singular zone).

So *having started with (micro)local semiclassical asymptotics we come to asymptotics with respect to quite different parameters (e.g., the spectral parameter)*. Actually, semiclassical asymptotics are also treated but our results are not the same as before and one should distinguish the actual semiclassical parameter h and the effective semiclassical parameter $h_{\mathsf{eff}} = h/(\rho\gamma)$. The latter depends on the point and arises always, no matter what parameters were in the original problem.

In *Section 11.1* we treat semiclassical asymptotics again, but now we are interested in $\mathsf{N}_h(\lambda_1, \lambda_2)$ and in situations when there are singularities in the domain and coefficients, exits to infinity of different shapes (or even the domain $\mathbb{R}^d$) and other non-regular phenomena.

In Sections 11.2–11.5 we investigate *asymptotics with respect to a large spectral parameter*. Namely, in *Sections 11.2* and *11.3* we consider cases in which a domain may have singularities on the boundary (edges, vertices, conical points, spikes, etc.), cusps (i.e., exits to infinity) which are not too massive and also cases in which coefficients may have singularities which are

not too strong (a good example is the Schrödinger operator with potential similar to $\pm|x|^{2m}$ near the origin with $m \in (-1, 0)$).

Further, in *Section 11.4* stronger singularities of coefficients are allowed but a *coercivity* condition is assumed (a good example is the Schrödinger operator with potential similar to $+|x|^{2m}$ near the origin with $m \le -1$).

Furthermore, in *Section 11.5* we consider the situation in which a domain is "essentially unbounded" or even coincides with $\mathbb{R}^d$; e.g., we consider the Schrödinger operator in $\mathbb{R}^d$ with potential similar to $+|x|^{2m}$ near infinity with $m > 0$. We are able to consider certain situations when the potential does not tend to $+\infty$ along some directions (along these directions, $V(x) = 0$ or even $V(x)$ tends to $-\infty$, for example) but the arising "canyons" are assumed to be narrow and shallow enough to provide the standard asymptotics.

Next, in *Section 11.6* we analyze eigenvalues tending to -0 which is the bottom of the essential spectrum; e.g., we consider the Schrödinger operator in $\mathbb{R}^d$ with potential similar to $-|x|^{2m}$ near infinity with $m \in (-1, 0)$; for this operator the essential spectrum is $[0, +\infty)$ and $(-\infty, 0)$ contains the discrete spectrum tending to -0, the asymptotics of which is the object of our interest.

Next, in *Section 11.7* we consider asymptotics with several parameters: when we have different semiclassical parameters with respect to different variables or when we have semiclassical and spectral parameters at the same time.

It should be noted, that in all Sections 11.1–11.7 there are three cases: when singularities are rather week and affect neither principal part nor remainder estimate, when singularities are too strong and we cannot derive any meaningful results this way, and the intermediate case, when we derive asymptotics with the same principal part albeit with deteriorated remainder estimate. Two latter cases are partially covered in Chapter 12.

In rather different *Section 11.8* the distribution of the spectra of negative-order pseudodifferential operators on compact closed manifolds is derived.

Chapter 12. Miscellaneous Asymptotics of Spectra. The character of this chapter is quite different: we improve and generalize some results of Chapter 11, but the results of Chapters 4–8 are insufficient for our purposes in this case and we are forced to repeat some arguments of Chapter 4 and even those of Chapter 2 in certain specific situations. Basically we apply the

ideas discussed above. The asymptotics obtained are more or less non-Weyl (or, more precisely, "partially Weyl").

In *Section 12.2* elliptic operators in domains with *thick cusps* are discussed: a cusp is thick if the area of its boundary is infinite, and the standard Weyl asymptotics with the remainder estimate $O\bigl(\tau^{\frac{1}{m}(d-1)}\bigr)$ fails to hold. Moreover, if the volume of the cusp is infinite, then $\mathsf{N}(\tau) = O\bigl(\tau^{\frac{d}{m}}\bigr)$ is no longer true[9)].

For simplicity let us consider the Dirichlet Laplacian in a domain which for $|x'| > c$ coincides with $\{(x', x'') : x'' \in f(x')\Omega\}$ with $\Omega \Subset \mathbb{R}^{d''}$. Here Ω and $f(x')$ describe the shape of the cusp's cross section and its thickness. Making a change of variables $(x', x'') \mapsto (x', x''/f(x'))$, which transforms the cusp into the cylinder $\mathbb{R}^{d'} \times \Omega$, one can consider the transformed operator as a Schrödinger operator in $\mathbb{R}^{d'}$ with operator-valued coefficients.

The auxiliary space is $\mathbb{H} = \mathscr{L}^2(\Omega)$. Applying the results of Chapter 4 concerning operators with operator-valued symbols we obtain non-Weyl asymptotics. However, this asymptotics is not very effective in the sense that the principal part contains a term

$$(2\pi)^{-d'} \iint \boldsymbol{n}(x', \xi'; \lambda)(1 - \psi_0(x'))\, dx' d\xi' \tag{0.31}$$

(with $\psi_0 \in \mathscr{C}_0^\infty$), thus depending on the eigenvalue counting function $\boldsymbol{n}(x', \xi')$ for the family of the auxiliary operators in $\mathbb{H}$ while we would like to have just one such operator.

Observe that one can study the propagation of singularities for the transformed operator, treated as an operator with an operator-valued symbol. We then obtain some results for the original operator as well. Namely, we obtain that for a not very remote part of the cusp in Weyl asymptotics one can take take much larger T (depending on τ, $|x'|$) and drastically improve the remainder estimate. These asymptotics are not very effective either because in addition to the Weyl principal part they contain plenty of extra terms.

On the other hand, under a stabilization condition in the remote part $\{x\colon |x'| \ge r\}$ of the cusp ($r = r(\tau) \to \infty$ as $\tau \to +\infty$) the Schrödinger operator is rather close to $\Delta' + |x'|^{2m}\Delta''$ provided $f(x') = |x'|^{-m}$; for the latter operator we can express the right-hand expression of (0.31) through

[9)] This is correct as long as we consider $\mathsf{N}(\lambda)$; for its Riesz means $\mathsf{N}_\vartheta(\lambda)$ the definition of the thickness depends on ϑ.

eigenvalue counting function $\boldsymbol{n}(.)$ for the Dirichlet Laplacian Δ'' in Ω. Then for the Schrödinger operator which we really got we have an asymptotics which is not very effective either; its main part depends only on $\boldsymbol{n}(.)$ but one needs to add plenty of extra terms.

So, we get two different asymptotics, both of which are not effective. However, combining them we obtain much more effective asymptotics because in the result most of these extra terms turn out to be superficial since they strongly depend on parameter $r(\tau)$, which we can select almost arbitrarily; comparing these terms for different choices of this parameter we can conclude that they must vanish. In the best possible case one has only one auxiliary operator instead of a family. Thus, the ideas are basically the same as in many forthcoming sections and chapters:

We take two different approaches (on one hand, we apply the theory of operators with operator-valued symbols to derive spectral asymptotics, and on the other, we apply the operator-valued theory only in order to get better propagation results) and then we combine the asymptotics obtained.

In *Section 12.3* we consider the class of elliptic operators in $\mathbb{R}^d$. A good example of such operators is the Schrödinger operator with potential V, failing to tend to $+\infty$ along directions $x \in \Lambda$, where Λ is a conical set of the "bad" directions. So, the domain $\{x\colon V(x) \le \tau\}$ contains cusps and if the "canyons" are not narrow and shallow enough the Weyl asymptotics with the standard remainder estimate fails.

Let us assume that Λ is a smooth d'-dimensional manifold and let us transform it to $\mathbb{R}^{d'}$. Then the ideas of Section 12.2 yield results of the same type (heuristically one can say that we apply the results of the Section 12.2 but the cusp depends on τ and widens when τ increases).

In *Section 12.4* we generalize the results of Section 11.6 to singular potentials, decaying at infinity in the case when singularity is strong enough; again non-Weyl correction terms appear; moreover, if singularity is strong enough the principal term in the asymptotics is non-Weyl.

In *Section 12.5 maximally hypoelliptic operators* on compact manifolds are treated. We assume that the operator uniformly degenerates on the symplectic conic manifold Λ. Microlocally $\Lambda = \{(x,\xi)\colon x'' = \xi'' = 0\}$. The same basic ideas as above are applied. We treat the operator in question as $A(x', D')$ in $\mathscr{L}^2(\mathbb{R}^{d'}, \mathbb{H})$ with $\mathbb{H} = \mathscr{L}^2(\mathbb{R}^{d''})$. Instead of the remote part of

the cusp we have now a tight (depending on the spectral parameter) vicinity of Λ: $\{(x,\xi)\colon |x'|+|\xi'|\le \varepsilon(\tau)\}$ with $\varepsilon(\tau)\to +0$ as $\tau\to+\infty$.

In *Section 12.6* we consider semiclassical asymptotics of the spectral Riesz means for operators with singularities at disjoint points. In this case the asymptotics of $\mathsf{N}^-(h)$ are Weyl as are the asymptotics of $\mathsf{N}^-_\vartheta(h)$ with $\vartheta<\bar\vartheta$ where ϑ is the order of the Riesz mean. So, we are interested in the case $\vartheta\ge\bar\vartheta$. One very early idea was to use the equality

$$\mathsf{Tr}\big(E^1_\vartheta(\tau)-E^0_\vartheta(\tau)\big)=\mathsf{const}\int_0^1 \mathsf{Tr}(A^1-A^0)E^t_{\vartheta-1}(\tau)\,d\tau, \tag{0.32}$$

where $A^t=tA^1+(1-t)A^0$ and the superscript $E^t(\tau)$ is related to A^t and $E_\vartheta(\tau)\coloneqq \Gamma(\vartheta+1)^{-1}\,\mathsf{Tr}\big((\tau-A)^\vartheta_+\big)$. Then taking appropriate partitions and applying the standard Weyl approximation to some elements and this formula (or its more sophisticated and general form) to the other elements we obtain the final answer as a sum of the Weyl expression and the term(s) associated with the model operator A^0. In comparison with purely Weyl asymptotics correction terms appear. They are similar to *Scott correction term* for $-|x|^{-1}$-like potential in dimension 3 for $\vartheta=1$.

We pick A^0 as an operator with positively homogeneous coefficients and get a more or less simple expression for the non-Weyl term(s). Actually this idea is adjusted in different ways, one of which is an investigation of the very long range (in the local scale) propagation of singularities which allows to improve significantly the remainder estimate.

In *Section 12.7* we apply the same idea as in Section 12.2 to the Neumann Laplacian in domain with cusps. However situation is very different now because the Neumann Laplacian in Ω of the cusp has the lowest eigenvalue 0 and the Schrödinger operator described there breaks into direct sum of two: one with the potential growing as in Section 12.2 in $\mathscr{L}^2(\mathbb{R}^{d'},\mathbb{H}\ominus\mathbb{K})$ and a special one in $\mathscr{L}^2(\mathbb{R}^{d'},\mathbb{K})$ coinciding here with $\mathsf{const}|\nabla\log f(x')|^2$. Here $\mathbb{K}=\mathbb{C}^1$ (or $\mathbb{C}^p$ in more general examples). This term is due to the the change of the density when we change variables.

As a result, unless the cusp is really very thin, the Neumann Laplacian has an essential spectrum $[0,\infty)$ or $[c_*,\infty)$. However if $|\log f|\asymp |x'|^m$, $|\nabla\log f|\asymp |x'|^{m-1}$ with $m>1$, then the essential spectrum is empty and we derive sharp spectral asymptotics for $\mathsf{N}(\tau)$ which may contain non-Weyl correction or even principal term.

Finally, in *Section 12.8* we consider periodic operator A^0; its spectrum consists of *spectral bands* separated by *spectral gaps*. Let λ belong to a

spectral gap (or its border). Consider perturbed operator $A^t := A^0 + tW$ with W non-negative and decaying fast enough at infinity. This operator can have discrete eigenvalues inside spectral gaps. We study asymptotics for the number $N(\tau)$ of such eigenvalues crossing λ as t changes from 0 to τ and $\tau \to \pm\infty$.

Volume III. Magnetic Schrödinger and Dirac Operators. 1

This Volume is entirely devoted to the study of the *magnetic Schrödinger operator*[10),11)]

$$H = (-ih\nabla - \mu \boldsymbol{A}(x))^2 + V(x), \tag{0.33}$$

and also Schrödinger-Pauli operator[10)]

$$H = ((-ih\nabla - \mu \boldsymbol{A}(x)) \cdot \boldsymbol{\sigma})^2 + V(x), \tag{0.34}$$

and Dirac operators[10)]

$$H = ((-ih\nabla - \mu \boldsymbol{A}(x)) \cdot \boldsymbol{\sigma}) + \sigma_0 M + V(x) \tag{0.35}$$

and

$$H = ((-ih\nabla - \mu \boldsymbol{A}(x)) \cdot \boldsymbol{\sigma}) + V(x) \tag{0.36}$$

with a small semiclassical parameter h and large *magnetic intensity parameter* (a coupling constant), responsible for the interaction of the particle with the magnetic field, μ. Here $\boldsymbol{\sigma} = (\sigma_1, \dots, \sigma_d)$ where $\sigma_1, \dots, \sigma_d$ are Pauli matrices, $\sigma_0, \sigma_1, \dots, \sigma_d$ are Dirac matrices, $\boldsymbol{A}$ is *magnetic vector potential*. Here for odd d operator (0.36) is not a special case of (0.35) with $M = 0$ since the former exists for D multiple of $2^{(d-1)/2}$ and the latter for D multiple of $2^{(d-1)/2}$; D is a dimension of matrices.

In this Volume we consider the most interesting cases $d = 2, 3$ and also assume that $\boldsymbol{A}(x)$, $V(x)$ (and metrics g) are smooth.

[10)] Actually we consider more general form.

[11)] From now we denote operator by H.

Part VI. Smooth Theory in Dimensions 2 and 3

Chapter 13. Schrödinger Operator. Standard Theory. Here we consider the Schrödinger operator, assuming that the the unit ball under consideration is entirely contained in the domain X and that the intensity of the magnetic field nowhere vanishes in this ball.

In *Section 13.2* a preliminary analysis is done and, in particular, $e(x,x,\lambda)$ is calculated explicitly in the case when the metrics and the scalar potential are constant and the vector potential is linear (so the intensity of the magnetic field is also constant) and $X = \mathbb{R}^d$; these formulae are good approximations for the general case, which we consider. We prove the estimates $|\mathcal{E}_\psi(0)| \le ch^{-d}$ in the general case and $|\mathcal{E}_\psi(0)| \le \mu^{-s}$ for $\mu h \ge C_0$; hence for the Schrödinger operator (but neither for the Schrödinger-Pauli nor for the Dirac operators!) we assume in what follows that $\mu h \le c$.

In *Section 13.3* we reduce the operator in question microlocally to canonical forms which are really different in the cases $d = 2$ and $d = 3$. For $d = 2$ we obtain, modulo $O(\mu^{-s})$, $\mu^{-1}h$-pseudodifferential operators with respect to $x' = x_1$. For $d = 3$ we obtain, also modulo $O(\mu^{-s})$, $(\mu^{-1}h, h)$-pseudodifferential operators with respect to $x' = (x_1, x_2)$. In both cases x_d enters in these forms only through the harmonic oscillator.

Based on this reduction, in *Section 13.4* we analyze the propagation of singularities with respect to x' in the case of the *weak-to-moderate magnetic field* $\mu \le h^{\delta-1}$ and, under some restrictions, we prove that on the intervals $[-T,-T_0]$ and $[T_0,T]$ the distribution $\sigma_\psi(t)$ is negligible, where either $T_0 \asymp \mu^{-1}$ or $T_0 \asymp h^{1-\delta}$, while on the interval $[-2T_0, 2T_0]$ for $\sigma_\psi(t)$ the standard formulae of Section 4.3 hold where $T \asymp 1$ for $d = 3$ and $T \asymp \mu$ or larger under *non-degeneracy* assumptions for $d = 2$; in the latter case singularities propagate along *cyclotrons* which are circles of radii $\asymp \mu^{-1}$ which however drift with a speed also $\asymp \mu^{-1}$. For $d = 3$ singularities propagate along helices of radii $\asymp \mu^{-1}$ winding around *magnetic lines*.

We always assume that there is an appropriate cutting near the energy level 0 with respect to the dual variable τ. Applying the Tauberian, method we obtain asymptotics for $\mathcal{E}_\psi(0)$ with the principal part $\asymp h^{-d}$ and the remainder term $O(h^{-2})$ for $d = 3$ and $O(\mu^{-1}h^{-1})$ or even better for $d = 2$. We also analyze less restrictive conditions in this and the following sections and obtain asymptotics in these cases with the same or worse remainder estimates. Thus, in this section *the canonical form is applied only for the study of the long-time propagation of singularities in order to extend the time*

interval and improve the remainder estimate in the Weyl-type asymptotics.

Next, in *Section 13.5* the case of the *moderate-to-strong magnetic field* $h^{-\delta} \le \mu \le C_0 h^{-1}$ is considered. Then the remainder term $O(\mu^{-s})$ in the microlocal canonical form is negligible and, after decomposition with respect to Hermitian functions of $\sqrt{\mu h^{-1}} x_d$, we obtain families of $\mu^{-1}h$-pseudodifferential operators with respect to $x' = x_1$ for $d = 2$ and $(\mu^{-1}h, h)$-pseudodifferential operators with respect to $x' = (x_1, x_2)$ for $d = 3$. These operators depend on the number n of the Hermitian function. Applying the results of Chapter 4 to these families of operators, we obtain asymptotics for $\mathcal{E}_\psi(0)$ under certain conditions with the same remainder estimates as in Section 13.4. Thus, now *the canonical form is used fully*. These asymptotics are not completely effective (i.e., one can calculate some terms only "in principle" but not "in fact").

The frameworks of this section and those of Section 13.4 overlap and under all of them both asymptotics are valid. These asymptotics are of different types, but comparing them, we can eliminate "superficial terms", obtaining effective asymptotics for $\mu \le C_0 h^{-1}$. These two ideas—*Application of the canonical form for the analysis of propagation of singularities and the extension of the interval for* $\sigma_\psi(t)$ and *comparison of the asymptotics obtained by different methods*—are very useful and we use them heavily in many chapters of the book.

Next, in *Section 13.6* we consider the case of the *strong magnetic field* $\mu \ge \epsilon_0 h^{-1}$. Then instead of V we should impose the same conditions to $V_n^* = V + (2n+1)\mu F$ for the Schrödinger operator and to $V_n^* = V + 2n\mu F$ for the Schrödinger-Pauli operator (with $n = \in \mathbb{Z}^+$ for $d = 2$, $n = 0$ for $d = 3$) and derive asymptotics with the principal part $\asymp \mu h^{1-d}$ and remainder estimates $O(1)$ for $d = 2$, $O(\mu h^{-1})$ for $d = 3$.

Further, in the case $d = 2$ it is possible that $V_n^* \le -\epsilon\mu h$ and $V_{n+1}^* \ge \epsilon\mu h$ everywhere in the ball in question; then $\tau = 0$ belongs to the *spectral gap* and in this case remainder estimate is $O(\mu^{-s})$.

Furthermore, in *Section 13.7* we improve results of Sections 13.4–13.7 under assumptions about the long-time dynamics (along *drift lines* for $d = 2$ and *magnetic lines* for $d = 3$).

Some possible generalizations (weakening or even dropping some assumptions) are discussed in *Section 13.8.*

Chapter 14. 2D-Schrödinger Operator with the Strong Degenerating Magnetic Field. In this chapter we consider the same operators in dimension 2 only albeit intensity of magnetic field F vanishes along lines with $\nabla F \neq 0$.

Section 14.1 is devoted to a preliminary analysis; in *Section 14.2* we study the classical dynamics which is rather non-trivial with short periodic trajectories appearing in $\mu^{-\frac{1}{2}}$-vicinity of these degeneration lines.

In *Section 14.3* we study related quantum dynamics and prove the remainder estimate $O(\mu^{-\frac{1}{2}}h)$. Then in *Section 14.4* we calculate asymptotics with the same magnitude of the principal part and with a correction term due to aforementioned short periodic trajectories. Further, in *Section 14.5* we formulate main theorems (all as $\mu \le h^{-1}$).

Finally, in *Sections 14.5* and *14.6* we analyze cases of the *strong magnetic field* $h^{-1} \le \mu \le h^{-2}$ and *superstrong magnetic field* $\mu \ge h^{-2}$ respectively.

Chapter 15. 2D-Schrödinger Operator with the Strong Magnetic Field near Boundary. In this chapter we consider the same 2-dimensional operators as in Chapter 13 albeit near smooth boundary which causes a significant modification of the dynamics: while inner "particles" (aka *bulk electrons*) travel along the same cyclotrons as before, near-boundary "particles" (aka *edge electrons*) "jump" along the boundary with an average speed $\asymp 1$. Drifting, bulk particles may collide with the boundary and become edge particles and edge particles may leave the boundary and become bulk particles so the global dynamics could be really complicated.

We analyze different cases (weak, moderate, strong magnetic field) in *Sections 15.2–15.4* respectively. There is a significant difference between operators with Dirichlet and Neumann boundary conditions , especially in the case of the strong magnetic field.

Also the former spectral gaps could be (at least partially) filled with *edge energy levels* in which case we need to study their distribution as well. They are less dense than eigenvalues in the *spectral bands*.

As usual, the first *Section 15.1* is devoted to the preliminary analysis and the last *Section 15.5* to some generalizations.

Part VII. Smooth Theory in Dimensions 2 and 3 (Continued)

Chapter 16. Magnetic Schrödinger Operator: Short Loops, Pointwise Spectral Asymptotics and Asymptotics of Dirac Energy. In

this chapter we study the same operators as in Chapter 13 but under different angle: we are interested in the *pointwise spectral asymptotics*, i.e. asymptotics of $e(x,x,\lambda)$ without mollification with respect to x, and also asymptotics of the expression (0.26); the results needed in Chapters 25–28.

As we know, for pointwise spectral asymptotics the important role play short loops (recall that in contrast to periodic trajectory the loop returns to the same spatial point albeit from the different direction) and for operators in question there are plenty of them for $d=2$.

The first half of the chapter is devoted to the case $d=2$: in *Section 16.2* we analyze a toy-model when explicit construction is possible and derive formulae which we would like to prove in the general case. The short loops cause either correction term if magnetic field is not too strong or even completely different asymptotics if magnetic field is sufficiently strong.

Then in *Section 6.2* we derive pointwise asymptotics, and in *Sections 16.4* and *16.5* we derive asymptotics of the expression (0.26).

In *Sections 16.6–16.9* we do the same as $d=3$; then effects of short loops is mitigated by a "free" movement along magnetic lines.

Finally, in *Section 16.9* we derive estimate of

$$\iint \bigl(e(x,x,\tau)-h^{-d}\mathcal{N}_x(\tau)\bigr)\bigl(e(y,y,\tau)-h^{-d}\mathcal{N}_x(\tau)\bigr)\omega(x,y)\,dxdy, \tag{0.37}$$

where $h^{-d}\mathcal{N}_x(\tau)$ is a Weyl expression for $e(x,x,\tau)$ for $d=2,3$.

Chapter 17. Dirac Operator with the Strong Magnetic Field. Here we consider operators (0.35) and (0.36) and our analysis is very similar to one of Chapter 13 but some significant differences and complications appear. *Sections 17.1–17.7* run in parallel with Sections 13.2–13.8.

We should mention that here as in Section 5.3 our results are proven uniformly with respect to $M\ge 0$.

Volume IV. Magnetic Schrödinger and Dirac Operators. 2

Part VIII. Non-smooth Theory and Higher Dimensions

In this Part we consider magnetic Schrödinger operator in dimensions 2, 3 and higher under rather low smoothness conditions.

Chapter 18. 2D- and 3D-magnetic Schrödinger Operator with Irregular Coefficients. Here we generalize Chapter 13 to the case when the coefficients are not very smooth. It leads us to the necessity to a microlocal canonical form, which, due to the lack of the smootness, is not only incomplete but also the lowest computed term in which is modified.

Section 18.1 contains a preliminary analysis, *Sections 18.2–18.5* cover $d = 2$ (Case of weak magnetic field, Canonical form, Tauberian theory and Calculations and main theorems–respectively).

Sections 18.6–18.9 cover $d = 3$ (exactly in the same order as for $d = 2$).

Chapter 19. Multidimensional Magnetic Schrödinger Operator. I. Full-rank case. Here we consider $d \ge 4$, assuming that $\mathsf{rank}(F_{jk})(x) = d$ at each point x, where (F_{jk}) is a skew-symmetric *magnetic intensity matrix*, $F_{jk} = (\partial_k A_j - \partial_j A_k)$ [12]. This is the main case if $d = 2r$ is even. Then this matrix has eigenvalues $\pm i f_j(x)$ with $j = 1, \dots, r$ and $f_j(x) > 0$.

This chapter does not completely generalize Chapter 18 since smoothness conditions here are higher. We also need two *non-resonance* conditions:

$$(0.38)_{2,3} \quad f_j(x) \ne f_k(x) \quad \forall j \ne k \qquad \text{and} \qquad f_j(x) \ne f_k(x) + f_l(x) \quad \forall j, k, l$$

at each point x (where the second condition covers both cases $k \ne l$ and $k = l$).

Section 19.1 contains a preliminary analysis, *Section 19.2* covers the case of the weak magnetic field.

In *Section 19.3* we reduce our operator to a microlocal canonical form, which again is incomplete but there are two obstacles: insufficient smoothness but also a lack of higher order non-resonance conditions since we do not impose them.

Sections 19.4–19.6 cover cases of the weak-to-moderate, moderate, moderate-to-strong, and strong magnetic field respectively.

In *Section 19.7* we consider the case of a simple violation of *non-degeneracy* assumption.

Chapter 20. Multidimensional Magnetic Schrödinger Operator. II. Non-full-rank Case. Here we consider $d \ge 4$, now assuming that $\mathsf{rank}(F_{jk})(x) = 2r < d$ at each point x. This is the main case if $d = 2r + 1$ is odd. Then this matrix has eigenvalues $\pm i f_j(x)$ with $j = 1, \dots, r$ and $f_j(x) > 0$ and eigenvalue 0 of the constant multiplicity $d - 2r$.

[12] For non-Euclidean metrics we need to lift one of two indices.

This chapter does not completely generalize Chapter 18 since smoothness conditions here are higher. We also need two *non-resonance* conditions $(0.38)_{2,3}$.

Section 20.1 contains a preliminary analysis, *Section 20.2* covers the case of the weak magnetic field.

In *Section 20.3* we reduce operator to a microlocal canonical form with the same caveats as in Section 19.3.

In *Sections 20.4* and *20.5* we derive remainder estimates in the cases of the moderate and strong magnetic field respectively; in *Sections 20.6* and *20.7* we calculate asymptotics and prove main theorems.

In *Section 20.8* we consider the cases of a simple violation of main assumptions.

Part IX. Magnetic Schrödinger Operator in Dimension 4

Chapter 21. 4D-Schrödinger Operator with a Strong Degenerating Magnetic Field. We start analysis of the generic operators in dimension 4. Then there are two magnetic intensities $f_1(x)$ and $f_2(x)$ and in the generic case they do not vanish simultaneously. We consider a vicinity of $\Sigma = \{x\colon f_1(x) = 0\}$ and in the generic case $\nabla f_1|_\Sigma \neq 0$. However it is not a simple lift of Chapter 14 because now $\nabla f_1|_\Sigma$ belongs to $\operatorname{Ker} F$ not in every point of Σ but only on submanifold $\Lambda \subset \Sigma$, $\dim \Lambda = 1$.

Section 21.1 contains a preliminary analysis, *Section 21.2* covers the case of the weak magnetic field.

Sections 21.3–21.5 cover the case of the stronger magnetic field: in *Section 21.3* we reduce operator to a microlocal canonical form, in *Section 21.4* we prove a remainder estimate and in *Section 21.5* we calculate asymptotics and prove main theorems.

Chapter 22. Generic 4*D*-Schrödinger Operator with the Strong Magnetic Field. In this chapter we conclude our analysis of the generic operators in dimension 4. Now we assume that neither magnetic intensity vanishes but non-resonance conditions $(0.38)_{2,3}$ are violated. More precisely, in the generic case $(0.38)_2$ can be violated on manifold of codimension 2 and $(0.38)_3$ can be violated on manifold of codimension 1 and these manifolds do not intersect.

Sections 22.1 and *22.2* contain a preliminary analysis, *Section 22.3* covers the case of the weak magnetic field.

Sections 22.4–22.5 cover the case of stronger magnetic field: in *Section 22.4* we prove a remainder estimate and in *Section 22.5* we calculate asymptotics and prove main theorems.

In *Section 22.6* we consider a case of V, vanishing somewhere.

Part X. Eigenvalue Asymptotics for Schrödinger and Dirac Operators with the Strong Magnetic Field

Chapter 23. Eigenvalue Asymptotics. 2D case and Chapter 24. Eigenvalue Asymptotics. 3D case. These chapters are devoted to the distribution of spectra for the Schrödinger and Dirac operators with the strong magnetic field. The idea is exactly the same as in Chapter 11, but now we consider the case when we apply the results of Chapters 13, 17 and 19 after the partition-rescaling-multiplication procedure. So we now have two local effective parameters: h_{eff} and μ_{eff}, and on elements with $\mu_{\mathsf{eff}} \gg 1$ we refer to the results of Chapters 13 and 17 while on elements with $\mu_{\mathsf{eff}} \le \mathsf{const}$ we refer to the results of Chapters 4 and 7.

In *Sections 23.2* and *24.2* we consider the case of a fixed spectral parameter.

In *Sections 23.3* and *24.3* we are interested in asymptotics with the spectral parameter tending to $+\infty$.

In *Sections 23.4* and *24.4* we are interested in asymptotics with the spectral parameter tending to ± 0. In particular, we consider the Schrödinger and Dirac operators in $\mathbb{R}^d$ with constant metric coefficients, vanishing scalar potential and constant non-vanishing magnetic field.

(a) Schrödinger and Dirac operators in $\mathbb{R}^2$ with constant metric coefficients, vanishing scalar potential and constant non-vanishing magnetic field have pure point spectra of infinite multiplicity. If we perturb these operators by a scalar potential, tending to 0 at $-\infty$, then each of these eigenvalues of infinite multiplicity decomposes to a sequence of eigenvalues of finite multiplicities, tending to a point of the essential spectrum (which is an eigenvalue of the unperturbed operator) and we are interested in the asymptotic distribution of eigenvalues in each sequence.

We also consider generalizations to even-dimensional full-rank case, and for magnetic field either growing, or decaying at infinity, or stabilizing to positively homogeneous of order 0.

(b) For $d = 3$ we obtain asymptotics of eigenvalues near the boundary of the essential spectrum. If the potential decreases slowly enough, the results of Chapters 13 and 17 could be applied.

(c) For $d = 3$ we obtain asymptotics of eigenvalues near the boundary of the essential spectrum. If the potential decreases quickly enough, the results of Chapters 13 and 17 fail to apply so we use the theory of spectral asymptotics for operators with operator-valued symbols: if the magnetic field is directed along x_3 we introduce an auxiliary space $\mathbb{H} = \mathscr{L}^2(\mathbb{R}_{x_3})$ and consider x' as the main variable.

(d) We reload case (b) to obtain sharper asymptotics, using the theory of spectral asymptotics for operators with operator-valued symbols as in the case (c).

In *Sections 23.5* and *24.5* we consider asymptotics with respect to all three parametrs τ, μ, h.

Volume V. Applications to Quantum Theory and Miscellaneous Problems

Part XI. Asymptotics of the Ground State Energy of Heavy Atoms and Molecules

In this Part we consider an application to Thomas-Fermi Theory. Consider a large (heavy) atom or molecule; it is described by *Multiparticle Quantum Hamiltonian*

$$\mathsf{H}_N = \sum_{1\le n\le N} H_V(x_n) + \sum_{1\le n<k\le N} \frac{1}{|x_n - x_k|}, \tag{0.39}$$

where H is *one-particle quantum Hamiltonian*, Planck constant $\hbar = 1$, electron mass $= \frac{1}{2}$, electron charge $= -1$, y_m is a location of m-th nuclei and Z_m its charge, M is fixed, but $Z_m \asymp N \to \infty$.

This operator acts on the space $\wedge_{1\le j\le N}\mathscr{L}^2(\mathbb{R}^3, \mathbb{C}^2)$ of totally antisymmetric functions $\Psi(x_1, \varsigma_1; \dots; x_N, \varsigma_N)$ because electrons are Fermions, $x_n = (x_n^1, x_n^2, x_n^3)$ is a coordinate and $\varsigma_n \in \{-\frac{1}{2}, \frac{1}{2}\}$ is a *spin* of n-th particle. We identify $\mathbb{C}^2$-valued function $\psi(x)$ on $\mathbb{R}^3$ with scalar-valued $\psi(x, \varsigma)$

If electrons were not interacting between themselves, but the field potential was $-W(x)$, then they would occupy lowest eigenvalues and ground state

wave functions would be (anti-symmetrized) $\phi_1(x_1,\varsigma_1)\phi_2(x_2,\varsigma_2)\dots\phi_N(x_N,\varsigma_N)$ where ϕ_n and λ_n are eigenfunctions and eigenvalues of H_W.

Then the local electron density would be $\rho_\Psi = \sum_{1\le n\le N} |\phi_n(x)|^2$ and according to pointwise Weyl law (if there is no magnetic field)

$$\rho_\Psi(x) \approx \frac{1}{3\pi^2}(W+\nu)_+^{\frac{3}{2}}, \tag{0.40}$$

where $\nu = \lambda_N$; here we assume that $H_V = \Delta - V(x)$ as it is in Chapter 25.

This density would generate potential $-|x|^{-1} * \rho_\Psi$ and we would have $W \approx V - |x|^{-1} * \rho_\Psi$.

Replacing all approximate equalities by strict ones we arrive to Thomas-Fermi equations:

$$V - W^{\mathsf{TF}} = |x|^{-1} * \rho^{\mathsf{TF}}, \tag{0.41}$$

$$\rho^{\mathsf{TF}} = \frac{1}{3\pi^2}(W^{\mathsf{TF}}+\nu)_+^{\frac{3}{2}}, \tag{0.42}$$

$$\int \rho^{\mathsf{TF}}\,dx = N, \tag{0.43}$$

where $\nu \le 0$ is called *chemical potential* and in fact approximates λ_N.

Thomas-Fermi theory has been rigorously justified (with pretty good error estimates).

Chapter 25. No Magnetic Field Case. In this chapter we assume that there is no magnetic field: $H_V = \Delta - V(x)$ with

$$V(x) = \sum_{1\le m\le M} \frac{Z_m}{|x-\mathsf{y}_m|}, \tag{0.44}$$

where y_m is a *position* and Z_m is a *charge* of m-th nuclei, M is fixed and $Z_1 \asymp Z_2 \asymp \dots \asymp Z_M \asymp N$.

Section 25.1 is an Introduction and in *Section 25.2* we justify a reduction of the original multiparticle problem to one-particle one. This is done mainly by methods of the classical mathematical physics (functional analysis).

In *Section 25.3* we expose *Thomas-Fermi theory* described by (0.41)–(0.43).

In *Section 25.4* we, based on previous sections and chapters, prove our main results. First of all, the *ground state energy* is given by

$$\mathsf{E}_N = 2\frac{(6\pi^2)^{\frac{5}{3}}}{15\pi^2}\int \Big(\rho^{\mathsf{TF}\,\frac{5}{3}} - V\rho^{\mathsf{TF}}\Big)\,dx - \frac{1}{2}\iint \rho^{\mathsf{TF}}(x)\rho^{\mathsf{TF}}(y)|x-y|^{-1}\,dxdy + O(Z^2). \tag{0.45}$$

Using results of Section 12.6 *Riesz Means Asymptotics for Operators Singular at a Point*, we improve the remainder estimate to $O(Z^{\frac{5}{3}})$ but we need to include the *Scott correction term*

$$\sum_{1\le m\le M} S_0 Z_m^2, \tag{0.46}$$

and even to $O(Z^{\frac{5}{3}-\delta})$ but we need to include *Dirac and Schwinger correction terms* $\sim Z^{\frac{5}{3}}$.

In *Section 25.5* we consider *negatively charged systems* (i.e. those with $Z := Z_1 + ... + Z_m < N$) and estimate *excessive negative charge* $(N - Z)$, when system is able to bind N electrons, i.e. $\mathsf{E}_N < \mathsf{E}_{N-1}$.

In *Section 25.6* we consider *positively charged systems* (i.e. those with $Z > N$) and estimate or find asymptotics $\mathsf{I}_N \approx \nu_N$ for an *ionization energy* $\mathsf{I}_N := \mathsf{E}_{N-1} - \mathsf{E}_N$.

We also consider systems with free $\mathsf{y}_1, \dots, \mathsf{y}_M$ and include in the total energy the *internuclear energy*

$$\sum_{1\le m<m'\le M} \frac{Z_m Z_{m'}}{|\mathsf{y}_m - \mathsf{y}_{m'}|}, \tag{0.47}$$

and minimize the ground state energy by $\mathsf{y}_1, \dots, \mathsf{y}_M$ and recover all aforementioned results.

We also estimate *excessive positive charge* $(Z - N)$ for which system does not disintegrate into separate atoms.

Chapter 26. The Case of External Magnetic Field. Here we assume that there is a constant magnetic field with a magnetic potential $\boldsymbol{A}(x) = B(-\frac{1}{2}x_2, \frac{1}{2}x_1, 0)$ and then one-particle Hamiltonian is Schrödinger-Pauli operator (0.34). We assume that the magnetic field is not hyperstrong:

$B \ll N^3$. Still it may be sufficiently strong to affect pointwise Weyl formula, which needs to be modified according to Chapter 13 (the results of Chapter 14 are not needed here).

Basically there are two principally cases $B \ll Z^{\frac{4}{3}}$ of a moderate magnetic field and $Z^{\frac{4}{3}} \ll B \ll Z^3$ of a strong magnetic field and a transitional case.

Section 26.1 is an Introduction (which is parallel to Sections 25.1 and 25.2, arguments and results of which require almost no modification).

Section 26.2 is parallel to Section 25.3 but instead of Section 25.4 we have four *Sections 26.3–26.6*, covering single nucleus case $M = 1$, multiple nuclei case $M \geq 2$ with analysis "inside molecule" and "near the molecule edge"and the synthesis, respectively.

Sections 26.7 and *26.8* are similar to Sections 25.5 and 25.6.

Chapter 27. The Case of Self-Generated Magnetic Field. Here we consider the same Schrödinger-Pauli operator but magnetic field is underdetermined a priory and its energy

$$\alpha^{-1} \int |\nabla \times \boldsymbol{A}|^2 \, dx \tag{0.48}$$

is included in the total energy. Here we assume that $\alpha Z_m \leq \kappa^*$ with some constant $\kappa^* > 0$. We recover the same results as in Chapter 25 but with the *Scott correction term*

$$\sum_{1 \leq m \leq M} S(\alpha Z_m) Z_m^2 \tag{0.49}$$

instead of (0.46).

Section 27.1 is an Introduction. *Sections 27.2* and *27.3* provide a replacement for Sections 12.6: while Section 27.2 treats a single singularity, Section 27.3 deals with a molecular case and the necessity to "decouple" singularities.

In *Section 27.4* as in Section 25.4 the asymptotics of the ground state energy is recovered and *Section 27.5* is similar to Sections 25.5 and *Section 25.6*.

Chapter 28. The Case of Combined Magnetic Field. This chapter combines two previous ones: there is an external constant magnetic field

$\boldsymbol{A}_0(x) = B(-\frac{1}{2}x_2, \frac{1}{2}x_1, 0)$ and an unknown self-generated magnetic field $\big(\boldsymbol{A} - \boldsymbol{A}_0\big)(x)$, and the energy of the latter

$$\alpha^{-1} \int |\nabla \times (\boldsymbol{A} - \boldsymbol{A}_0(x))|^2 \, dx \tag{0.50}$$

should be added to the total energy.

Section 28.1 is an Introduction. Since we need a lot of microlocal arguments, they spread over six sections: *Sections 28.2–28.4* cover the local theory and *Sections 28.5* and *28.6* the global theory under different assumptions.

However applications to the ground state energy, excessive negative and positive charges and ionization energy need only small modifications of our previous arguments and squeeze into a single *Section 28.7*.

Part XII. Articles

I decided to put results of the last few years in this volume as separate articles. So far those are[13)]

- Joint paper with A. Hassel [1] *Spectral asymptotics for the semiclassical Dirichlet to Neumann operator*.
- My paper [29] *Spectral asymptotics for fractional Laplacians*.
- My paper [32] *Spectral asymptotics for Dirichlet to Neumann operator in the domains with edges*.
- My paper [30] *Asymptotics of the ground state energy in the relativistic settings*.
- My paper [31] *Asymptotics of the ground state energy in the relativistic settings and with self-generated magnetic field*.
- My paper [33] *Complete semiclassical spectral asymptotics for periodic and almost periodic perturbations of constant operator*.
- My paper [34] *Complete differentiable semiclassical spectral asymptotics*.

[13)] While I do not plan to change the main body of this book, I intend to add new articles, as soon as I write them.

- My paper [34] *Bethe-Sommerfeld conjecture in semiclassical settings.*
- My paper [34] *Pointwise spectral asymptotics out of the diagonal near boundary.*
- My paper [34] *Pointwise spectral asymptotics out of the diagonal near degeneration.*
- My paper [28] *100 years of Weyl's law.*

See also the List of my presentations with links to them.

6. How LSSA are Applied to Classical Asymptotics

Finally, let us discuss three examples which illustrate Chapter 11 and show how LSSA yield asymptotics with respect to the spectral parameter. This basically explains

Example 0.2. Let X be a compact Riemannian manifold without boundary and let Δ be a (positive) Laplace-Beltrami operator. Let us consider the Schrödinger operator $A_h = h^2\Delta + V(x)$; it is well known that

$$\mathsf{N}^-(A_h) = \kappa_0 h^{-d} + O\big(h^{1-d}\big) \tag{0.51}$$

with Weyl constant κ_0 provided 0 is not a critical value of $V(x)$ [14]. The Birman-Schwinger principle implies that $\mathsf{N}^-(A_h) = \mathsf{N}(h^{-2})$ where $\mathsf{N}(\lambda)$ is the number of eigenvalues $\mu \in [0,\lambda)$ of the spectral problem $\big(\Delta + \mu V(x)\big)u = 0$ (counting their eigenvalues).

These two equalities immediately yield the asymptotics

$$\mathsf{N}(\lambda) = \kappa_0 \lambda^{\frac{d}{2}} + O\big(\lambda^{\frac{1}{2}(d-1)}\big) \tag{0.52}$$

provided 0 is not a critical value of $V(x)$ (the condition which was claimed not to be necessary).

Try to obtain this result directly in the case when $V(x)$ vanishes at some point! It is striking that nobody had observed this non-trivial new result which trivially follows from two well known facts.

[14] It is shown in this book that one can skip this condition for $d \geq 2$ and for manifolds with boundary.

Example 0.3. Let us consider the Schrödinger operator $A = \Delta + V(x)$ in $\mathbb{R}^d$ where Δ is the (positive) Laplacian and the real-valued potential $V(x)$ satisfies the following conditions:

$$\big|D^\alpha V\big| \le \langle x\rangle^{2m-\alpha} \qquad \forall \alpha : |\alpha| \le K, \tag{0.53}$$

and

$$V \ge \epsilon_0 |x|^{2m} \qquad \forall x : |x| \ge c, \tag{0.54}$$

where $\langle x\rangle = \big(|x|^2+1\big)^{\frac{1}{2}}$ here and in what follows. Let us take a γ-admissible partition of unity with $\gamma(x) = \frac{1}{4}\langle x\rangle$. If we make the rescaling transforming $B\big(\bar{x}, \gamma(\bar{x})\big)$ to $B(0,1)$ and multiply $A-\lambda$ by λ^{-1}, we obtain a Schrödinger operator for $|x| \le C\lambda^{\frac{1}{2m}}$ in $B(0,1)$ with the standard restrictions to the potential and with $h = \gamma(\bar{x})^{-1}\lambda^{-\frac{1}{2}}$.

Let us apply corresponding results of Chapter 4 [15]. Then we obtain Weyl asymptotics for spatial means of $e(x,x,\lambda)$ in $B\big(\bar{x}, \gamma(\bar{x})\big)$ with the remainder estimate $O\big(h^{1-d}\big) = O\big(\lambda^{\frac{1}{2}(d-1)}\gamma(\bar{x})^{d-1}\big)$; there is no additional factor because $e(x,x,\lambda)$ is a density rather than a function. Summing with respect to the partition of unity in $\{x\colon |x| \le C\lambda^{1/2m}\}$, we obtain the remainder estimate $O\big(\lambda^{(d-1)l}\big)$ with $l = (1+m)/2m$.

On the other hand, let us consider the ball $B\big(\bar{x}, \gamma(\bar{x})\big)$ with $|x| \ge C\lambda^{\frac{1}{2m}}$. After rescaling and multiplication of $A-\lambda$ by $\rho^{-2}(\bar{x})$ with $\rho(\bar{x}) = \langle x\rangle^m$ we obtain a Schrödinger operator with the standard restrictions to the potential $v(x) \ge \epsilon$ and with $h = \gamma(\bar{x})^{-1}\rho(\bar{x})^{-1}$; then we derive the estimate $|e(x,x,\lambda)| \le Ch^s\gamma(\bar{x})^{-d}$ with an arbitrary exponent s and hence the contribution of the domain $\{x\colon |x| \ge C\lambda^{\frac{1}{2m}}\}$ to the remainder is $O(\lambda^{-s})$ with another, also arbitrarily large, exponent s. Combining with the contribution of the previous zone, we obtain the asymptotics

$$\mathsf{N}(\lambda) = \mathsf{N}(\lambda) + O\big(\lambda^{(d-1)l}\big) \tag{0.55}$$

with

$$\mathsf{N}(\lambda) = \kappa_0 \int \big(\lambda - V(x)\big)_+^{\frac{d}{2}}\, dx \tag{0.56}$$

as $\lambda \to +\infty$ and $\mathsf{N}(\lambda) \asymp \lambda^{dl}$.

[15] In which case we are able to skip assumption that V is non-degenerate, i.e., $|\nabla V| \ge \epsilon_0 |x|^{2m-1}$ for $|x| \ge c$.

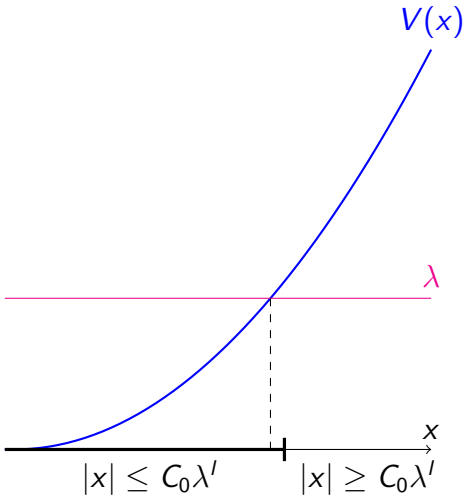
Example 0.4. Let us consider the Schrödinger operator in $\mathbb{R}^d$ with potential $V(x)$ satisfying (0.53) with $m \in (-1, 0)$ and now let $\lambda < 0$ be a small parameter. Then for the same ρ and γ as before the rescaling of $B\big(\bar{x}, \gamma(\bar{x})\big)$ into $B(0,1)$ and multiplication of $A-\lambda$ by $\rho(\bar{x})^{-2}$ produce a Schrödinger operator with standard restrictions to the potential and with $h = \gamma(\bar{x})^{-1}\rho(\bar{x})^{-1}$ provided $|x| \le C|\lambda|^{\frac{1}{2m}}$. Hence for the spatial mean of $e(x,x,\lambda)$ in $B\big(\bar{x}, \gamma(\bar{x})\big)$ the Weyl formula holds with remainder estimate $O\big(h^{1-d}\big) = O\big(\rho(\bar{x})^{d-1}\gamma(\bar{x})^{d-1}\big)$.

On the other hand, for $|x| \ge C|\lambda|^{\frac{1}{2m}}$ rescaling and multiplication by $|\lambda|^{-1}$ produce a Schrödinger operator with standard restrictions to the potential $v(x) \ge \epsilon$ and with $h = \gamma(\bar{x})^{-1}|\lambda|^{-\frac{1}{2}}$. Hence the estimate $|e(x,x,\lambda)| \le Ch^s\gamma(\bar{x})^{-d}$ again holds.

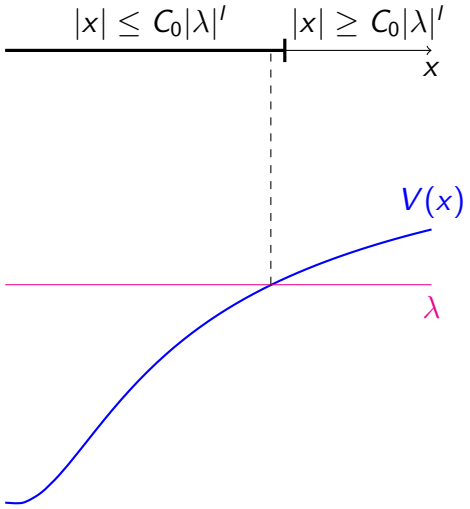
Summing with respect to a partition of unity we obtain asymptotics (0.55)–(0.56) as $\lambda \to -0$ with the same $l = (1+m)/2m$ as in Example 0.3; moreover $\mathsf{N}(\lambda) \asymp |\lambda|^{dl}$ provided

$$V \le -\epsilon|x|^{2m} \qquad \text{for} \quad x : |x| \ge c \tag{0.57}$$

in some non-empty open cone in $\mathbb{R}^d$.



(a) Illustration to Example 0.3



(b) Illustration to Example 0.4

7. Paths

For those interested in the basics of the theory I recommend the following sequence of chapters: 1 ⟶ 2 ⟶ 4 ⟶ 11 and then 1 ⟶ 2 ⟶ 4 ⟶

$9 \longrightarrow 11$; in addition, I suggest considering only the Schrödinger operator in Chapter 11 and only the standard (not the operator-valued) case in Chapters 2 and 4.

Those interested in domains with boundaries (still on a rather elementary level) should read also Chapter 3 and then Chapter 7.

Those interested in magnetic field theory should start reading Chapters 13 (and maybe 17) and 23 (but Chapters 3 and 7 are not necessary for this).

Those interested in the results of Chapter 12 should consider references to every its section.

Those interested in the results of other chapters should look at the map and read the references to each chapter they are interested in.

My Way to Spectral Asymptotics and Around

Weyl Conjecture (66–67 AW)

Background. It was Winter '78-'79 when Michael Shubin and B. M. Levitan suggested me to prove Weyl conjecture. R. Seeley just proved remainder estimate $O(\lambda^{(d-1)/2})$. He considered (as anyone would at this time) $\sigma(t) = \mathsf{Tr}(\cos(t\Delta^{\frac{1}{2}}))$ and respectively $u(x,y,t)$ was the Schwartz kernel of $\cos(t\Delta^{\frac{1}{2}})$, satisfying initial-boundary value problem

$$(D_t^2 - \Delta_x)u = 0, \tag{0.58}$$

$$u|_{t=0} = \delta(x-y), \qquad D_t u|_{t=0} = 0, \tag{0.59}$$

$$u|_{x\in\partial X} = 0, \tag{0.60}$$

where for simplicity we discuss the Dirichlet Laplacian; the Neumann Laplacian is considered in the same way. So it was the wave equation rather than the Schrödinger equation (which came later, with semiclassics).

I did not messed up with spectral asymptotics before but I was an established expert in the propagation of singularities, and here I used the energy estimates which is much more robust and general method than the explicit construction of the parametrix.

My idea was to invent a new approach because (as I thought) if Seeley's method worked for Weyl conjecture then Seeley would prove it!

I thought wrong! Couple of years later D. Vassiliev who was *a secret physicist* at that time gave the proof of Weyl conjecture using Seeley's method. And much later I combined Seeley's approach with my own.

But it was the best mistake I ever made! Because the method I invented worked in many situations Seeley' method did not, f.e. for general systems.

Normal Singularity. First, I conjectured that the singularity of $\sigma(t)$ at 0 is normal i.e. $(tD_t)^n\sigma(t)$ at 0 have the same order of singularity for any n exactly as for manifolds without boundary.

I proved this conjecture by implicit method of propagation of singularities in Spring '79. At this moment I had a powerful method of the energy estimates with the theorem stated in the form:

If Ω is a domain in the phase space and ϕ satisfies microhyperbolicity condition and Pu is smooth in $\Omega\cap\{\phi<0\}$, and u is smooth in $\partial\Omega\cap\{\phi<0\}$, then u is smooth in $\Omega\cap\{\phi<0\}$.

Sure, it looks similar to Holmgren uniqueness theorem! Using this technique plus rescaling arguments I proved that singularity of $\sigma(t)$ at $t=0$ is normal.

Successive Approximations. My next idea was rather crazy: to calculate $u(x,y,t)$, using successive approximations, first going to the coordinate system where boundary was planar and getting operator with variable coefficients even if it originally was not, then to the problem (0.58)–(0.59) and apply successive approximation method, freezing coefficients of Δ at point y.

This looks insane because such perturbation decreases smoothness by 2 while parametrix to the problem

$$\begin{aligned}&(D_t^2-\Delta)u=f,\\ &u|_{t=0}=u_t|_{t=0}=0,\\ &u|_{\partial X}=0\end{aligned}$$

increases it only by 1, so each next term in this approximation approach is more singular than the previous one! However, the perturbation contains factors (x_j-y_j) which are of magnitude t due to the finite propagation speed and each parametrix contains factor t due to the Duhamel integral, so in fact, each next term in successive approximations acquires an extra factor t^2D_t. *Big deal, so what?*

But then the same is true for $\sigma(t)$ as well, but for $\sigma(t)$ I knew already that near 0 each multiplication by t compensates one differentiation and this allowed me to justify the successive approximation method for $\sigma(t)$ near 0 without justification it for u. So, a complete asymptotics (with respect to smoothness) of $\sigma(t)$ near 0 was done. This would imply Seeley's result.

Other Singularities. It was early August '79 and I wrote to Michael Shubin about my progress. His answer came two weeks later (no email at that time!): "So what? Other singularities (at $t\neq 0$) are much more difficult!"

But at this moment I already had a solution! Actually other singularities were easier. I have proven that *if the set of periodic geodesic billiards has measure* 0 *then two-term (Weyl) asymptotics holds*.

To tackle "other" singularities of $\sigma(t)$ I analyzed Duistermaat-Guillemin method, purging all irrelevant FIO stuff.

As a result arguments became very simple: Fix arbitrary $T>0$. A set Π_T of geodesic billiards, periodic with periods $\le T$, is a closed set. Then due to our assumption it is a closed nowhere dense set of measure 0. And the set Λ_T of all dead-end billiards of the length $\le T$ is also of this type. Recall that dead-end billiards are those which become tangent to the boundary or behaving badly.

Let $I=Q_1+Q_2$, where Q_1 is a pdo with symbol in ε-vicinity of $\Pi_T\cup\Lambda_T$ and the small vicinity of the boundary and Q_2 has a symbol vanishing in the vicinity of this set. Then $\sigma(t)=\sigma_{Q_1}(t)+\sigma_{Q_2}(t)$ with $\sigma_Q(t)=\mathsf{Tr}(\cos(t\Delta^{\frac12})Q)$.

Here $\sigma_{Q_2}(t)$ has no "other" singularities on $[-T, T]$ and Tauberian methods let me to recover asymptotics of $\mathsf{Tr}(E(\lambda)Q_2)$ with the remainder estimate $CT^{-1}\lambda^{\frac{d-1}{2}} + C'_T$ with C which does not depend on T or ε.

On the other hand, I recovered asymptotics of $\mathsf{Tr}(E(\lambda)Q_1)$ with the remainder estimate $C\varepsilon\lambda^{\frac{d-1}{2}} + C'_{T,\varepsilon}$ where $\varepsilon = \mathsf{mes}(\mathsf{supp}(Q_1))$ is arbitrarily small. So, I recovered asymptotics of $N(\lambda) = \mathsf{Tr}(E(\lambda))$ with the remainder estimate

$$C\bigl(\varepsilon + \frac{1}{T}\bigr)\lambda^{\frac{d-1}{2}} + C'_{T,\varepsilon}$$

and the rest was a second-year calculus exercise!

Aftermath (68–79 AW)

Using this method I instantly proved asymptotics with the remainder estimate $O(\lambda^{\frac{d-1}{m}})$ for m-th order elliptic systems on manifolds without boundaries, and later on manifolds with the boundaries.

When I was peacefully exploiting my method and harvesting results and even published a book two events happened:

Corners, Edges Etc. I got from RZh Matematika (a Russian version of Math. Reviews, but better) a some weird paper (K. Otsuka [1]), deriving two-term Weyl asymptotics for the Euclidean Laplacian in polygons. The author was spending a lot of efforts to consider wave equation near vertices and I realized that this was a completely unnecessary job.

So I decided to do a proper job and I with my student Svetlana Fedorova proved ('84) Weyl formula for Laplace-Beltrami operators in domains with edges, vertices, conical points, cuts etc. But what is more important: rescaling technique was invented!

Going Semiclassic. I decided to go cheap and prove some semiclassic asymptotics. I said "cheap" because at this time I believed as many did that really great mathematicians like H. Weyl, R. Courant, L. Hörmander, J. J. Duistermaat, V. Guillemin, R. Seeley and myself (smile!) study the classical $\mathsf{N}(\lambda)$ on compact manifolds while less great mathematicians study $N(\lambda)$ for the Schrödinger operator with growing potential, semiclassics, etc. So I proved some semiclassical results and told M. Z. Solomyak about them.

He asked: "Why you just do not deduct it from classical asymptotics by a *cheap trick*[16)]?"

I tried to follow this advice with a rather surprising result. Semiclassical results derived this way were less general than I had already; however, working the opposite way I derived more general classical results than I had. It was an eye-opener: *Semiclassical Asymptotics are the most important!* So, I began to study semiclassical asymptotics as a prime target. And in this framework my method became not only more general, but also more natural and transparent, and it worked better with the rescaling technique.

Going Ballistic. First, I discovered that the rescaling applied to the semiclassic produces a bunch of new results. In particular, it allowed to eliminate $|V| + |\nabla V| \neq 0$ (if $d \geq 2$) as a precondition for the sharp semiclassical asymptotics for the Schrödinger operator, which using cheap trick got instantly new results for the classical asymptotics.

Further, I studied degenerations and singularities of different kinds, horns and cusps, other degenerations and singularities. I derived classical asymptotics, asymptotics of eigenvalues for operators, generalizing the Schrödinger operator with the potential growing at infinity, and for operators, generalizing the Schrödinger operator with potential slowly decaying at infinity, and these operators had their degenerations and singularities too. *It was a complete Results Explosion! And it was so damn easy!*

I was feeling like a prospector who found a place with native ores of gold lying just on the surface, ready to be picked. These results were subject of my ICM-1986 talk[17)].

But often remainder estimates were not as good as in the non-degenerate or non-singular cases and I felt that the reason was not my lack of skill but a more profound one.

Going Deeper. I modified my method to treat operators with symbols which were operators in auxiliary spaces and treated only some variables as semiclassical variables and others as non-semiclassical variables, and I reexamined some singularities and degenerations and cusps and derived more sharp asymptotics than before. But these asymptotics either contained

[16)] It was a colloquial name for the Birman-Schwinger principle.

[17)] My ICM-1978 was devoted to propagation of singularities. By Soviet bureaucracy I was not allowed to go to ICMs, further, the permission to send a talk for ICM-1978 came too late and, while this talk was published, it was not read. 8 years later I was smarter–and sent the talk without any permission. L. Hörmander read it. I visited Berkeley many times since and in 2014 I visited Helsinki the first time–36 years too late!

non-Weyl correction terms of the magnitude of the remainder estimates derived on the previous stage or even were non-Weyl in their main parts.

I also considered the Schrödinger and Dirac operators with the strong magnetic field. This was longer, slower and much more difficult process than before and its results appeared in my research monograph of '98.

Multiparticle Quantum Theory (79 AW–88 AW)

In '90 Michael Sigal suggested me to work together to justify the Scott correction term for or asymptotics of the ground state energy for molecules consisting of very large atoms (for atoms even more precise results were already justified by C. Fefferman and L. Seco, using harmonic analysis). My part was to derive sharp asymptotics for the trace of the Schrödinger operator with a Coulomb type singularity. My first attempt was a (partial) success: the remainder estimate was sufficiently sharp to justify the Scott correction, but not sharp enough to justify Dirac and Schwinger corrections or even to approach to them.

A bit later I was able to find more subtle arguments and succeeded to derive estimates, sufficiently sharp to justify Dirac and Schwinger corrections. Further, I considered this problem in the presence a strong external magnetic field.

New Dawn (88–93 AW)

Next few years I have been working on sharp spectral asymptotics for operators with not very regular coefficients. The major tool is the same kind of the analysis as before, applied to the mollified operator. Mollification scale depends on h and equals to $Ch|\log h|$ in the simplest case. This is related to the *Logarithmic Uncertainty Principle*.

These arguments were applied also to the Schrödinger operator with the strong magnetics field.

Etc (93 AW–113 AW)

I did many other things later (apart of improving my old results and writing this monograph, which I started in 96 AW). The whole Volumes III and IV (except Chapter 13) and also Chapters 27 and 28 are brand new.

Further, many sections of the "old" chapters are brand new, so chapters became much larger and the material was rearranged.

Aftermath (113 AW–present time)

As I mentioned, I decided not to change the main body of the monograph, but to add new results as separate articles (actually, I even moved two results from the main body to *Part XII. Articles*).

Microlocal Analysis, Sharp Spectral Asymptotics and Applications. I

Semiclassical Microlocal Analysis and Local and Microlocal Semiclassical Asymptotics

Part I

Semiclassical Microlocal Analysis

Chapter 1

Introduction to Microlocal Analysis

In this chapter we give a survey of the theory of h-pseudodifferential operators (in Section 1.1), h-Fourier integral operators (in Section 1.2), the notion of wave front sets and related topics (in Section 1.3). Proofs are mostly sketchy since all the results of this chapter are trivial consequences of the results proven in L. Hörmander's monograph [1] or they can be proven by trivial modifications of the arguments used in that book.

Further, (in Section 1.4) we give a concise introduction to L. Boutet de Monvel calculus and its application to elliptic boundary value problems.

What is Microlocal Analysis?

Microlocal Analysis is a theory of *Pseudo-Differential Operators* and *Fourier Integral Operators* (PDOs and FIOs). It draws on many rich traditions in mathematics including the links between analysis and geometry and has a powerful application to partial differential equations. For example, all the significant progress in linear PDEs for the last 50 years has been based on microlocal analysis and many important advances in non-linear PDEs over this period were also based on microlocal analysis.

Pseudo-differential operators are generalization of (partial) differential operators (DOs) and also appear as parametrices (almost inverse) of elliptic differential operators (and parabolic differential operators unless we stick with "classical" pseudodifferential operators). 0-order PDOs are singular in-

tegral operators. There is a very nice calculus of pseudodifferential operators which make them extremely useful tool.

Fourier integral operators appear as propagators of hyperbolic and similar equations. While from the Quantum Mechanics point of view pseudodifferential operators are observables, Fourier integral operators are canonical transformations.

Microlocal analysis comes in few flavors. One of the possible classifications is: semi-classical with explicit asymptotics with respect to a small parameter h (Plank constant or wavelength) and classical (standard or more general) where there is no explicit parameter and asymptotics is with respect to the smoothness (or something like this). However, there is still implicit small parameter and microlocal analysis is asymptotical by its nature.

We will consider semi-classical pseudodifferential operators and Fourier integral operators: one can always get from there to standard pseudodifferential operators and Fourier integral operators but semi-classical theory has more applications.

Less formal description of (semi-classical) microlocal analysis is "a semi-classical limit of quantum mechanics" or "high-frequency limit of electrodynamics" (etc). This is really difficult and exciting topic to understand how quantum mechanics yields classical mechanics as Plank constant h goes to 0 (in contrast to trivial "Special relativity yields Newton mechanics as light speed $c \to \infty$"; the fundamental difference is that quantum and corresponding classical objects are mathematically completely different while special relativity and Newton mechanics objects are exactly the same). So, *Microlocal* means local both in coordinates and momenta. There are direct and deep connections with Global Analysis.

1.1 Pseudodifferential Operators

1.1.1 Calculus of Pseudodifferential Operators

Officially Microlocal Analysis was born in 1965 after two articles of L. Hörmander [2] and J. J. Kohn and L. Nirenberg [1] were published where pseudodifferential operators were introduced by formula

$$(Au)(x) = \int a(x,\xi) e^{i\langle x,\xi\rangle} \hat{u}(\xi)\, d\xi \tag{1.1.1}$$

or by alternative formula

$$\widehat{(Au)}(\xi) = \int a(x,\xi) e^{-i\langle x,\xi\rangle} u(x)\, dx \tag{1.1.2}$$

where

$$\hat{u}(\xi) = F_{x\mapsto\xi} u = (2\pi)^{-d} \int e^{-i\langle x,\xi\rangle} u(x)\, dx \tag{1.1.3}$$

is a Fourier transform.

Formulae (1.1.1) and (1.1.2) are not exactly equivalent. Really, if $a(x,\xi) = \sum_{|\alpha|\le m} a_\alpha(x)\xi^\alpha$ is a polynomial then (1.1.1) defines a differential operator $A(x,D) = \sum_{|\alpha|\le m} a_\alpha(x) D^\alpha$ while (1.1.2) defines differential operator $A(x,D) = \sum_{|\alpha|\le m} D^\alpha a_\alpha(x)$, $D = -i\partial_x$. In the first case we differentiate first and multiply by coefficients after while in the second case we reverse this order. Following terminology originated from physics we call (1.1.1) by qp-quantization and (1.1.2) by pq-quantization.

In these articles *symbol* $a(x,\xi)$ was supposed to be either positive homogeneous of degree m or the asymptotic sum of such

$$a \sim \sum_{j=0}^{\infty} a_{m-j}(x,\xi) \tag{1.1.4}$$

with a_{m-j} positively homogeneous of degree $m-j$. Later more general classes were introduced.

However one can notice that essentially the same operators were introduced by A. Calderon-A. Zygmund and S. G. Mihlin as singular integral operators. Also quantization procedure was introduced first by H. Weyl, who used yet another formula

$$(Au)(x) = (2\pi)^{-d} \iint a(\frac{x+y}{2},\xi) e^{i\langle x-y,\xi\rangle} u(y)\, dyd\xi \tag{1.1.5}$$

which is called *symmetric* or *Weyl* quantization. The procedure $\mathsf{symbol} \mapsto \mathsf{operator}$ is called *quantization*.

Even if there are different methods of quantization we get the same classes of pseudodifferential operators. So, each pseudodifferential operator has pq-, qp- and Weyl-symbols and the navigation between different symbols will be given.

Moving from differential operators to pseudodifferential we lose property $\mathsf{supp}(Au) \subset \mathsf{supp}(u)$ but retain $\mathsf{sing\,supp}(Au) \subset \mathsf{sing\,supp}(u)$.

Microlocal Analysis of this type is not exact in the sense that we consider infinitely smooth functions and infinitely smoothing operators as negligible. Microlocal Analysis is asymptotic in the sense that we will consider (1.1.4)-type decomposition of symbols and decomposition on functions which are more and more smooth.

The most important properties of such calculus are:

Remark 1.1.1. The most important properties of such calculus are:

(i) Product of operators of orders m_1 and m_2 has degree $m_1 + m_2$ and its principal symbol is equal to the product of principal symbols.

(ii) Commutator of operators of orders m_1 and m_2 has degree $m_1 + m_2 - 1$ and its principal symbol is equal to the Poisson bracket of principal symbols.

(iii) Elliptic operator (i.e. operator with non-vanishing principal symbol) has parametrix (or almost inverse): $AB \equiv BA \equiv I$ modulo infinitely smoothing operators.

(iv) There is a functional calculus of 0-order pseudodifferential operators.

This section is devoted to the calculus of pseudodifferential operators and to major inequalities. However we will deal mainly with h-pseudodifferential operators $a(x, hD)$ with small parameter $h \to 0$ (in this case homogeneity is not assumed). This makes asymptotic nature of Microlocal Analysis more explicit. The price to pay: we have not functions or operators but families of them depending on h. Temperate function or operator (or rather the family!) is with the norm $O(h^{-l})$ for some l. Negligible function or operator (or rather the family!) is with the norm $O(h^s)$ for any s.

h-Fourier Transform

Important role in our constructions plays h-Fourier transform given by

$$F_h : u(x) \mapsto (F_h u)(\xi) = (2\pi h)^{-d} \int e^{-ih^{-1}\langle x,\xi\rangle} u(x)\, dx \tag{1.1.6}$$

and its inverse is

$$F_h^{-1} : v(\xi) \mapsto (F_h^{-1} v)(x) = \int e^{ih^{-1}\langle x,\xi\rangle} v(\xi)\, d\xi. \tag{1.1.7}$$

We could put factor $(2\pi h)^{-\frac{d}{2}}$ in both expressions (instead of $(2\pi h)^{-d}$ and 1, to get unitary operators $\mathcal{F}_h$ and $\mathcal{F}_h^*$ in $\mathscr{L}^2(\mathbb{R}^d)$.

Physicists call $u(x)$ a coordinate representation and $\mathcal{F}_h u$ a momentum representation because $\mathcal{F}(hD_{x_j})u = \xi_j \mathcal{F}_h$, $D_{x_j} = -i\partial_{x_j}$ and hD_{x_j} is momentum operator. In physics q and p is reserved for coordinates and momenta.

The only operators commuting with multiplication by $e^{ih^{-1}\langle x,\xi\rangle}$ for every ξ are operators of multiplication $u(x)$ by a function $\nu(x)$. Operator norm of such operator $\nu(x)$ in $\mathscr{L}^2(\mathbb{R}^d)$ is $\|\nu\|_\infty = \operatorname{ess\,sup} |\nu(x)|$.

Respectively, the only operators commuting with all shifts are *multiplicators* :

$$\mu(hD) = F_h^{-1}\mu(\xi)F_h. \tag{1.1.8}$$

Operator norm of such operator $\mu(hD)$ in $\mathscr{L}^2(\mathbb{R}^d)$ is $\|\mu\|_\infty = \operatorname{ess\,sup} |\mu(\xi)|$.

h-DO Representation via h-Fourier Transform; Quantization of Different Flavors

Now we will construct much broader algebra including both operators of multiplication and multiplicators (with admissible *symbols* $a(x)$, $b(\xi)$. The trouble is that these operators do not commute! So, how to quantize $a(x,\xi) = \nu(x)\mu(\xi)$?

The first way is $\nu(x)\mu(hD)$ which would be given by formula

$$\big(a(\overset{2}{x}, \overset{1}{hD})u\big)(x) = (2\pi h)^{-d} \iint e^{ih^{-1}\langle x-y,\xi\rangle} a(x,\xi)u(y)\, dyd\xi; \tag{1.1.9}$$

we can do it in the reverse order $\nu(x)\mu(hD)$:

$$\big(a(\overset{1}{x}, \overset{2}{hD})u\big)(x) = (2\pi h)^{-d} \iint e^{ih^{-1}\langle x-y,\xi\rangle} a(y,\xi)u(y)\, dyd\xi. \tag{1.1.10}$$

One can see easily that

(1.1.11) As $a(x,\xi) = \sum_\alpha a_\alpha(x)\xi^\alpha$ formulae (1.1.9) and (1.1.10) define operators $\sum_\alpha a_\alpha(x)(hD)^\alpha$ and $\sum_\alpha (hD)^\alpha a_\alpha(x)$ respectively;

(1.1.12) If $a(x,hD)$ is defined by (1.1.9) or (1.1.10) then $F_h a(x,hD)F_h^{-1} = a(-hD_\xi,\xi)$ where $a(-hD_\xi,\xi)$ is defined by method (1.1.10) or (1.1.9) respectively.

Formulae (1.1.9), (1.1.10) are called qp- and pq-quantization respectively to reflect order in which x (aka q) and hD_x (aka p) are applied.

Should we look for something more symmetric? The first guess $\frac{1}{2}\big(\nu(x)\mu(hD)+\mu(hD)\nu(x)\big)$ is not that bad but

$$\big(a^{\mathsf{w}}(x,hD)u\big)(x)=(2\pi h)^{-d}\iint e^{ih^{-1}\langle x-y,\xi\rangle}a\big(\frac{x+y}{2},\xi\big)u(y)\,dyd\xi \tag{1.1.13}$$

is way better. One can prove easily that

(1.1.14) For $a(x,\xi)=\sum a_\alpha(x)\xi^\alpha$ formula (1.1.13) gives h-DO;

$$a^{\mathsf{w}}(x,hD)=\sum_{\alpha,\beta}2^{-|\alpha|-|\beta|}\frac{(\alpha+\beta)!}{\alpha!\beta!}(hD)^\alpha a_{\alpha+\beta}(x)(hD)^\beta; \tag{1.1.15}$$

(1.1.16) If $a(x,hD)$ is defined by (1.1.13) then $F_h a(x,hD)F_h^{-1}=a(-hD_\xi,\xi)$ where $a(-hD_\xi,\xi)$ is defined by the same method (1.1.13).

Formula (1.1.13) is called *Weyl* or *symmetric quantization*. Apart of p and q equality it has yet another advantage: if $a(x,\xi)$ is real valued then $a(x,hD)$ is symmetric and often self-adjoint operator.

Symbols and h-Pseudodifferential Operators; qp-, pq-, Weyl (Symmetric) Quantization. Double Symbols and Their Quantization

Now we can define using formulae (1.1.9), (1.1.10) or (1.1.13) pseudodifferential operators for more general classes of symbols than it was before: we simply plug an (admissible) general symbol $a(x,\xi)$ in such formula. For a sake of generality and simplicity in some arguments we, however, introduce quantization *double symbols* $a(x,\xi,y)$ by formula

$$\big(a(\overset{3}{x},\overset{2}{hD},\overset{1}{x})u\big)(x)=(2\pi h)^{-d}\iint e^{ih^{-1}\langle x-y,\xi\rangle}a(x,\xi,y)u(y)\,dyd\xi \tag{1.1.17}$$

which for $a(x,\xi,y)=a(x,\xi)$, $a(x,\xi,y)=a(y,\xi)$, $a(x,\xi,y)=a(\frac{x+y}{2},\xi)$ gives $a(\overset{2}{x},\overset{1}{hD})$, $a(\overset{1}{x},\overset{2}{hD})$ and $a^{\mathsf{w}}(x,hD)$ respectively.

Surely there are two shortcomings of this way: completely lost symmetry between x and hD and very non-unique symbol $\leftrightarrow$ operator correspondence. However such symbols are technically useful.

Operator $A = a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x})$ defined by (1.1.17) has Schwartz kernel

$$\mathcal{K}_A(x,y) = (2\pi h)^{-d} \iint e^{ih^{-1}\langle x-y,\xi\rangle} a(x,\xi,y)\, d\xi \tag{1.1.18}$$

Recall that each linear operator $A : \mathscr{C}_0^\infty(Y) \to \mathscr{D}'(X)$ where $\mathscr{D}'(Y)$ is the space of distributions over $\mathscr{D}(X) = \mathscr{C}_0^\infty(X)$ has a (unique) Schwartz kernel $\mathcal{K}_A \in \mathscr{D}'(X \times Y)$ such that $\langle A\phi, \psi\rangle = \langle \mathcal{K}_A, \phi \otimes \psi\rangle$ where $(\phi \otimes \psi)(x,y) = \phi(x)\psi(y)$.

For an infinitely smooth and fast decaying with respect to ξ symbol this Schwartz kernel belongs to $\mathscr{C}^\infty(\mathbb{R}^d \times \mathbb{R}^d)$ and operator is infinitely smoothing and can be extended to operator $\mathscr{E}'(\mathbb{R}^d) \to \mathscr{C}^\infty(\mathbb{R}^d)$ where $\mathscr{E}'$ the space of distributions over $\mathscr{E} = \mathscr{C}^\infty$. However it is not uniform with respect to h and in contrast to classical theory (to follow) smoothness of the function (distribution) is not the subject of our prime interest.

Let us consider operator defined by (1.1.18) in $\mathscr{L}^2(\mathbb{R}^d)$ (our usual playground). The following very weak statements are nevertheless useful:

Proposition 1.1.2. *If*

$$|\partial_\xi^\alpha a| \le M(1+|\xi|)^{-s} \qquad \forall \alpha : |\alpha| \le K \tag{1.1.19}$$

then

$$|\mathcal{K}_A(x,y)| \le C_{s,K} M h^{-d}\big(1 + h^{-1}|x-y|\big)^{-K} \tag{1.1.20}$$

Proof. Obviously statement holds as $K = 0$.

Let us multiply $\mathcal{K}_A$ by $(x_j - y_j)$, observe that $e^{ih^{-1}\langle x-y,\xi\rangle}(x_j - y_j) = i\partial_{\xi_j} e^{ih^{-1}\langle x-y,\xi\rangle}(x_j - y_j)$ and integrate by parts with respect to ξ_j. We will get that

(1.1.21) $\mathcal{K}_A(x,y)(x_j - y_j)$ has the Schwartz kernel defined by (1.1.18) with symbol $a(x,\xi,y)$ replaced by $-ih\partial_{\xi_j} a(x,\xi,y)$.

Then (1.1.20) holds with $K = 1$. Repeating the same argument K times we will get (1.1.20) for any K. □

Obviously, $\mathcal{K}_A(x,y)(x_j-y_j)$ is the Schwartz kernel of commutator $[x_j, A]$.

Theorem 1.1.3. *If* (1.1.19) *(or* (1.1.20)*) holds for* $K > d$ *then operator norm of* A *in* $\mathscr{L}^2(\mathbb{R}^d)$ *does not exceed* CM.

Proof. There is a theorem in Real Analysis that the operator norm in $\mathscr{L}^p(\mathbb{R}^d)$ does not exceed

$$\Big(\sup_x \int |\mathcal{K}(x,y)|dy\Big)^{\frac{1}{p}} \Big(\sup_y \int |\mathcal{K}(x,y)|dx\Big)^{\frac{p-1}{p}}. \tag{1.1.22}$$

The proof of it based on the trivial proofs for $p = 1, \infty$ and then interpolation.

It follows from (1.1.20) with $K > d$ that both integrals in (1.1.22) do not exceed CM. □

Later we will replace assumption that a decays in ξ by a more natural one.

Negligible Functions, Symbols, Operators. Going from one Type of Quantization to Another. Symbol and Operator classes

Now when we noticed that factor (x_j-y_j) in the double symbol leads to extra h in the operator norm estimate, we can assuming some smoothness reduce $a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x})$ to $b'(\overset{2}{x}, \overset{1}{hD})$ or to $b''(\overset{1}{x}, \overset{2}{hD})$ or to $b^{\mathrm{w}}(x, hD)$ (modulo operators with small norms).

Namely, to go to $b'(\overset{2}{x}, \overset{1}{hD})$ we need to get rid of y. The simplest way to do this is to use the Taylor expansion

$$a(x,\xi,y) = \sum_{\alpha:|\alpha|<N} \frac{1}{\alpha!}(y-x)^\alpha(\partial_y^\alpha a)(x,\xi,y=x) + \sum_{\alpha:|\alpha|=N} (y-x)^\alpha \tilde{a}_\alpha(x,\xi,y) \tag{1.1.23}$$

and then using arguments of the proof of Proposition 1.1.2 one can replace $(y-x)^\alpha$ by $(-ih\partial_\xi)^\alpha$. Then the regular terms (with $|\alpha| < N$) in (1.1.23) will produce

$$b' = b''_N(x,\xi) = \sum_{\alpha:|\alpha|<N} \frac{(-ih)^{|\alpha|}}{\alpha!}(\partial_y^\alpha \partial_\xi^\alpha a)(x,\xi,x) \tag{1.1.24}$$

while the remainder terms (with $|\alpha| = N$) will produce operator with operator norm not exceeding CMh^N provided

$$|\partial_y^\alpha \partial_\xi^\nu a(x,y,\xi)| \le M(1+|\xi|)^{-s} \qquad \forall \alpha : |\alpha| \le N, \forall \nu : |\nu| \le N+d+1 \tag{1.1.25}$$

(with some $s > d$).

Using similar arguments (but with permuted x and y) one can reduce $a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x})$ to $b''(\overset{1}{x}, \overset{1}{hD})$ with

$$b'' = b''_N(x,\xi) = \sum_{\alpha:|\alpha|<N} \frac{(ih)^{|\alpha|}}{\alpha!} (\partial_x^\alpha \partial_\xi^\alpha a)(x,\xi,x) \tag{1.1.26}$$

provided

$$|\partial_x^\alpha \partial_\xi^\nu a(x,y,\xi)| \le M(1+|\xi|)^{-s} \qquad \forall \alpha : |\alpha| \le N, \forall \nu : |\nu| \le N+d+1. \tag{1.1.27}$$

Furthermore, decomposing in both x, y at the midpoint $\frac{1}{2}(x+y)$ one can reduce $a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x})$ to $b^{\mathrm{w}}(x, hD)$ with

$$b = b_N(x,\xi) = \sum_{\alpha,\beta:|\alpha|+|\beta|<N} \frac{i^{|\alpha|-|\beta|}(h/2)^{|\alpha|+|\beta|}}{\alpha!\beta!} (\partial_x^\alpha \partial_y^\beta \partial_\xi^{\alpha+\beta} a)(x,\xi,x) \tag{1.1.28}$$

provided

$$|\partial_x^\alpha \partial_y^\beta \partial_\xi^\nu a(x,y,\xi)| \le M(1+|\xi|)^{-s} \qquad \forall \alpha,\beta : |\alpha|+|\beta| \le N, \forall \nu : |\nu| \le N+d+1. \tag{1.1.29}$$

So we proved

Theorem 1.1.4. *(i) Let condition* (1.1.25) *be fulfilled with* $s > d$. *Then* $a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x}) \equiv b'(\overset{2}{x}, \overset{1}{hD})$ *modulo operator with operator norm*[1)] *not exceeding* $C_{N,s} M h^N$ *where* $b' = b'_N$ *is defined by* (1.1.24).

[1)] All the norms are by default $\mathscr{L}^2$-norms and all the operator norms are by default operator norms in $\mathscr{L}^2$.

(ii) Let condition (1.1.27) *be fulfilled with* $s > d$. *Then* $a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x}) \equiv b''(\overset{1}{x}, \overset{2}{hD})$ *modulo operator with operator norm not exceeding* $C_{N,s}Mh^N$ *where* $b'' = b''_N$ *is defined by* (1.1.26).

(iii) Let condition (1.1.29) *be fulfilled with* $s > d$. *Then* $a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x}) \equiv b^{\mathsf{w}}(x, hD)$ *modulo operator with operator norm not exceeding* $C_{N,s}Mh^N$ *where* $b = b_N$ *is defined by* (1.1.28).

We refer to b', b'', b as to pq-, qp- and *Weyl symbols*. .

Definition 1.1.5. (i) We call operator *negligible* if its operator norm does not exceed Ch^N with some constant C.

(ii) We call double symbol negligible if it satisfies (1.1.25) or (1.1.27) or (1.1.29) and leads to $b_N = 0$ or $c_N = 0$ or $e_N = 0$ respectively.

(iii) We call a family of functions u_h depending on parameter h *negligible* if $\|u_h\| \le Ch^N$.

(iv) We call a family of functions u_h depending on parameter h *admissible* if $\|u_h\| \le C$. Sometimes we admit the family with $\|u_h\| \le Ch^{-l}$.

Surely these definitions depend on N; we will just assume that N is large enough. Note that if a satisfies one of the conditions (1.1.25),(1.1.27),(1.1.29), it is not generally true for b', b'', b. More robust formulae will be provided later.

Definition 1.1.6. Fix s and $N \ge 1$.

(i) Denote by $\mathsf{S}^s_N(\mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d)$ the class of double symbols

$$a(x,\xi,y) = \sum_{j=0}^{N-1} a_j(x,y,\xi)h^j \tag{1.1.30}$$

with a_j satisfying condition (1.1.29) with N replaced by $(N-j)$ and with some constant M. Denote by $\mathsf{S}^s_N(\mathbb{R}^d \times \mathbb{R}^d)$ the class of corresponding ordinary symbols.

(ii) Denote by $\boldsymbol{\Psi}^s_N(\mathbb{R}^d)$ the class of operators obtained (modulo negligible) from double symbols $a \in \mathsf{S}^s_N(\mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d)$ by quantization procedure (1.1.17).

(iii) According to Theorem 1.1.3 we get the same class if we start from ordinary symbols $b \in \mathsf{S}^s_N(\mathbb{R}^d \times \mathbb{R}^d)$ and apply quantization procedures (1.1.9),(1.1.10),(1.1.13); in this case we refer to b as qp-symbol, pq-symbol and Weyl symbol respectively.

(iv) We call $a_0(x,\xi)|_{h=0}$ or $a_0(x,\xi,x)|_{h=0}$ the principal symbol. It does not depend on method of quantization.

Remark 1.1.7. Several questions arise immediately:

Can two different symbols generate the same operator (modulo negligible)? We have seen this non-uniqueness for double symbols but how about ordinary symbols? We will see later that they are uniquely determined. Note that if we allow dependence a_j on h decomposition of the symbol is not unique for sure but we are talking about symbol itself. In particular, the principal symbol is defined uniquely.

Algebra: Conjugate and Product of Operators. Symmetric Pseudodifferential Operators

There are two operations which are not completely trivial: multiplication and finding adjoint (finding resolvent and functional calculus will follow later). Since we study now bounded operators, we do not need to study the domain of the adjoint operator:

$$(Au, v) = (u, A^* v) \qquad \forall u, v \in \mathscr{L}^2(\mathbb{R}^d) \tag{1.1.31}$$

where $(.,.)$ is an inner product in $\mathscr{L}^2(\mathbb{R}^d)$. Adjoint is rather easy:

$$\bigl(a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x})\bigr)^* = a^\dagger(\overset{1}{x}, \overset{2}{hD}, \overset{3}{x}) \tag{1.1.32}$$

where $a^\dagger$ means a complex or Hermitian conjugate to a. In particular

$$\bigl(a(\overset{1}{x}, \overset{2}{hD})\bigr)^* = a^\dagger(\overset{2}{x}, \overset{1}{hD}), \tag{1.1.33}_1$$

$$\bigl(a(\overset{2}{x}, \overset{1}{hD})\bigr)^* = a^\dagger(\overset{1}{x}, \overset{2}{hD}), \tag{1.1.33}_2$$

$$\bigl(a^{\mathsf{w}}(x, hD)\bigr)^* = a^{\dagger\mathsf{w}}(x, hD), \tag{1.1.33}_3$$

(1.1.34) $a^\dagger = a$ implies that $a^{\mathsf{w}}(x, hD)$ is symmetric.

Product is more tricky but we can restrict ourselves by $a(\overset{2}{x}, \overset{1}{hD})b(\overset{1}{x}, \overset{2}{hD})$. One can see easily that

$$a(\overset{2}{x}, \overset{1}{hD})b(\overset{1}{x}, \overset{2}{hD}) = c(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x}), \qquad c(x,\xi,y) = a(x,\xi)b(y,\xi). \tag{1.1.35}$$

Further, using (1.1.35) and (1.1.24), (1.1.26) and (1.1.28) one can see easily that

$$a(x, hD)b(x, hD) \equiv (a \bullet b)(x, hD) \tag{1.1.36}$$

with the same quantization method where (with indicated quantization method)

$$a \bullet_{qp,L} b = \sum_{\alpha:|\alpha|<N} \frac{(-ih)^\alpha}{\alpha!}(\partial_\xi^\alpha a)(\partial_x^\alpha b), \tag{1.1.37}_1$$

$$a \bullet_{pq,L} b = \sum_{\alpha:|\alpha|<N} \frac{(ih)^\alpha}{\alpha!}(\partial_x^\alpha a)(\partial_\xi^\alpha b), \tag{1.1.37}_2$$

$$a \bullet_{\mathsf{w},L} b = \sum_{\alpha,\beta:|\alpha|+|\beta|<N} \frac{i^{|\beta|-|\alpha|}(h/2)^{|\beta|+|\alpha|}}{\alpha!\beta!}(\partial_\xi^\alpha \partial_x^\beta a)(\partial_x^\alpha \partial_\xi^\beta b). \tag{1.1.37}_3$$

In particular, the principal symbol of the product is equal to the product of the principal symbols:

$$a(x, hD)b(x, hD) \equiv (ab)(x, hD) \qquad \mathsf{mod}\ h\boldsymbol{\Psi}_{N-1}. \tag{1.1.38}$$

Using above formulae one can check easily that the *principal symbol of the commutator is equal to* $-ih \times$ *Poisson bracket of principal symbols*:

$$[a(x, hD), b(x, hD)] \equiv -ih\{a, b\}(x, hD) \qquad \mathsf{mod}\ h^2\boldsymbol{\Psi}_{N-2} \tag{1.1.39}$$

where

$$\{a, b\} = \langle \partial_\xi a, \partial_x b\rangle - \langle \partial_x a, \partial_\xi b\rangle. \tag{1.1.40}$$

Furthermore, using above formulae one can check easily that

$$a^{\mathsf{w}}(x, hD)b^{\mathsf{w}}(x, hD) + b^{\mathsf{w}}(x, hD)a^{\mathsf{w}}(x, hD) \equiv 2(ab)^{\mathsf{w}}(x, hD) \qquad \mathsf{mod}\ h^2\boldsymbol{\Psi}_{N-2}, \tag{1.1.41}$$

$$[a^{\mathsf{w}}(x, hD), b^{\mathsf{w}}(x, hD)] \equiv -ih\{a, b\}(x, hD) \qquad \mathsf{mod}\ h^3\boldsymbol{\Psi}_{N-3}. \tag{1.1.42}$$

Remark 1.1.8. Formulae $(1.1.33)_3$, (1.1.39) and (1.1.42) hold for Weyl quantization only.

Quantization: Abstract Operator Point of View

This approach is due to Hermann Weyl (1927) who was looking for a quantization method in the flat space. In quantum mechanics observables should be self-adjoint operators. Unfortunately, self-adjointness of unbounded operators is a very subtle thing and one can assure only symmetry of the quantization of randomly chosen real-valued symbol (classical observable).

Let $\mathscr{H}$ be a Hilbert space and Q_j, P_j $j = 1, \dots, d$ be a self-adjoint unbounded operators satisfying commutation relations

$$[P_j, P_k] = 0, \qquad [Q_j, Q_k] = 0, \qquad [P_j, Q_k] = -ih\delta_{jk} \tag{1.1.43}$$

This is how physicists usually write it but it is bizarre: for unbounded operators we need to indicate domains and even if we assume that (1.1.43) hold on everywhere dense linear subset of $\mathscr{H}$ it would not be enough. Compare:

(1.1.44) Two unbounded self-adjoint operators commute if their resolvents commute ($\Leftrightarrow$ their spectral projectors commute $\Leftrightarrow$ their generated groups commute).

To write commutation relations properly we consider unitary groups $U_j(t) = e^{itQ_j}$, $V_j(t) = e^{itP_j}$ and assume that

$$\begin{aligned} &U_j(t)U_k(s) = U_k(s)U_j(t), \qquad V_j(t)V_k(s) = V_k(s)V_j(t), \\ &\qquad\qquad V_j(t)U_k(s) = e^{i\delta_{jk}hts}U_k(s)V_j(t) \qquad \forall j,k \quad \forall t,s \in \mathbb{R}. \end{aligned} \tag{1.1.45}$$

One can prove a following

Theorem 1.1.9. *If P_j, Q_k $(j, k = 1, \dots, d)$ are self-adjoint operators satisfying* (1.1.45) *then there exists a unitary operator $F : \mathscr{H} \to \mathscr{L}^2(\mathbb{R}^d, \mathbb{H})$ with some auxiliary Hilbert space $\mathbb{H}$ such that $FP_jF^* = hD_j$, $FQ_jF^* = x_j$ (operators of multiplication by).*

Surely one can transform it to momenta representation $FP_jF^* = \xi_j$, $FQ_jF^* = -hD_{\xi_j}$. We call $Q_j = x_j$, $P_j = hD_j$ *canonical*.

Let us introduce $\boldsymbol{Q} = (Q_1, \dots, Q_d)$, $U(\boldsymbol{s}) = e^{ih\langle \boldsymbol{s}, \boldsymbol{Q}\rangle} = U_1(s_1)\cdots U_d(s_d)$, $\boldsymbol{P} = (P_1, \dots, P_d)$ $V(\boldsymbol{t}) = e^{ih\langle \boldsymbol{t}, \boldsymbol{P}\rangle} = V_1(t_1)\cdots V_d(t_d)$ as $\boldsymbol{s} = (s_1, \dots, s_d)$ and $\boldsymbol{t} = (t_1, \dots, t_d)$.

Now let us quantize symbol $a(q,p)$ which we represent as

$$a(q,p)=\iint \hat{a}(s,t)e^{i\langle s,q\rangle}e^{i\langle t,p\rangle}\,ds\,dt \tag{1.1.46}$$

where $\hat{a}$ is a Fourier transform of a with respect to all variables. We should plug into (1.1.46) P, Q instead of p, q but we need to select an order: one can replace $e^{i\langle s,q\rangle}e^{i\langle t,p\rangle}$ either by $U(s)V(t)$, or take them in the opposite order which is equivalent to taking $e^{ih\langle t,s\rangle}U(s)V(t)$, or to take a "symmetric product" $e^{\frac{i}{2}h\langle t,s\rangle}U(s)V(t)$. So, we get

$$\begin{aligned} a(Q,P)&=\iint \hat{a}(s,t)e^{ih\varsigma\langle t,s\rangle}U(s)V(t)\,ds\,dt = \\ &(2\pi)^{-2d}\iint\iint a(q,p)e^{i(h\varsigma\langle t,s\rangle-\langle p,t\rangle-\langle q,s\rangle)}U(s)V(t)\,ds\,dt\,dp\,dq. \end{aligned} \tag{1.1.47}$$

One can check easily that

(1.1.48) For canonical Q_j, P_j this formula with $\varsigma=0,1,\frac{1}{2}$ gives qp-, pq-and Weyl quantizations respectively as we introduced them before.

Matrix Pseudodifferential Operators

We can construct the same theory for matrix pseudodifferential operators (i.e. pseudodifferential operators with matrix symbols). More precisely, we can consider symbols belonging to $\mathcal{L}(\mathbb{K},\mathbb{H})$ which is the space of bounded linear operators from $\mathbb{H}$ to $\mathbb{K}$ (where $\mathbb{H}$ and $\mathbb{K}$ two auxiliary Hilbert spaces). Then all the above formulae hold albeit with Hermitian conjugate rather than complex conjugate in (1.1.32)–(1.1.33)$_3$.

All the product formulae including (1.1.38) remain true but (1.1.39)–(1.1.42) fail unless one of the factors is a scalar operator $\lambda(x,hD)\otimes I$.

One can consider also symbols which are unbounded operators with fixed domain and "strength" (and it has important applications) but it brings tons of difficulties with justification.

Ellipticity, Parametrix, Resolvent. Functional Calculus

Since symbols of the classes we considered so far decay as $|\xi|\to\infty$, they cannot be elliptic, having inverse of the same class. It does not preclude ellipticity of symbols $\big(\lambda I-a(x,\xi)\big)$ with $\lambda\in\mathbb{C}$ and therefore construction of the

resolvent and then functional calculus. However we postpone construction until the class of operators we study is extended.

Traces and Hilbert-Schmidt Norms

Let us start from the formal calculations. It is known from Real Analysis (see f.e. P. D. Lax [1]) that if operator $A \in \mathcal{L}\big(\mathscr{L}^2(\mathbb{R}^d,\mathbb{H}),\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})\big)$ belongs to the trace class then its trace is equal to

$$\mathsf{Tr}(A) = \int \mathsf{tr}(\mathcal{K}_A(x,x))\,dx \tag{1.1.49}$$

where "tr" means a "matrix trace" i.e. the trace in $\mathcal{L}(\mathbb{H},\mathbb{H})$.

One can check easily that

$$\mathsf{Tr}(a(\overset{3}{x},\overset{2}{hD},\overset{1}{x})) = (2\pi h)^{-d}\iint \mathsf{tr}(a(x,\xi,x))\,dxd\xi. \tag{1.1.50}$$

Meanwhile the Hilbert-Schmidt norm of an operator $A \in \mathcal{L}\big(\mathscr{L}^2(\mathbb{R}^{d'},\mathbb{H}'),\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})\big)$ is $\|A\|_{\mathsf{HS}} = (\mathsf{Tr}(A^*A))^{1/2} = (\mathsf{Tr}(AA^*))^{1/2}$. It is known from Real Analysis that A is a Hilbert-Schmidt operator if and only if $\mathcal{K} \in \mathscr{L}^2\big(\mathbb{R}^d\times\mathbb{R}^{d'},\mathsf{HS}(\mathbb{H}',\mathbb{H})\big)$ where $\mathsf{HS}(\mathbb{H}',\mathbb{H})$ is the space of Hilbert-Schmidt operators from $\mathbb{H}$ to $\mathbb{H}'$ equipped with the corresponding norm; further

$$\|A\|^2_{\mathsf{HS}} = \iint \mathsf{tr}(\mathcal{K}_A(x,y)^\dagger \mathcal{K}_A(x,y))\,dxdy. \tag{1.1.51}$$

Let us prove

Proposition 1.1.10. *For any quantization of symbol* $a(x,\xi)$

$$\|a(x,hD)\|^2_{\mathsf{HS}} = (2\pi h)^{-d}\iint \mathsf{tr}((a^\dagger a))(x,\xi)\,dxd\xi \tag{1.1.52}$$

Proof. This is obvious for pq- and qp-quantizations but holds also for Weyl quantization; even more generally for any $\varsigma\in\mathbb{R}$ and $\varsigma' = 1-\varsigma$

$$\begin{aligned}&\iint \mathsf{tr}(\mathcal{K}_A(x,y)^\dagger\mathcal{K}_A(x,y))\,dxdy = \\ &(2\pi h)^{-2d}\iint\iint \mathsf{tr}(a^\dagger(\varsigma x+\varsigma' y,\xi)a(\varsigma x+\varsigma' y,\eta))e^{ih^{-1}\langle x-y,\eta-\xi\rangle}\,dxdy\,d\xi d\eta = \\ &\qquad (2\pi h)^{-2d}\iint\iint \mathsf{tr}(a^\dagger(z,\xi)a(z,\eta))e^{ih^{-1}\langle z',\eta-\xi\rangle}\,dzdz'\,d\xi d\eta\end{aligned}$$

(after obvious change of variables) which obviously equals to the right-hand expression of (1.1.52). □

To justify all these formulae we need

Proposition 1.1.11. *Let us consider operator A with a double symbol $a = a(x,y,\xi)$ such that*

$$\|D_x^\alpha D_y^\beta D_\xi^\nu a\| \le M\Phi(\xi)^{-m}\phi(x)^{-l} \qquad \forall \alpha,\beta,\nu : |\alpha|+|\beta| \le N+K, |\nu| \le N+K \qquad \forall (x,y,\xi) \in \mathbb{R}^d\times\mathbb{R}^d\times\mathbb{R}^d \tag{1.1.53}$$

where $\phi(x) = (1+\sum_j x_j^2/\bar\gamma_j^2)^{\frac12}$, $\Phi(\xi) = (1+\sum_j \xi_j^2/\bar\rho_j^2)^{\frac12}$ with $\bar\rho_j \ge 1$, $\bar\gamma_j \ge 1$ and $N \ge 0$. Alternatively, let us consider operator A with a symbol $a(x,\xi)$ which satisfies (1.1.53) *and apply any method of quantization.*

Then its Schwartz kernel satisfies

$$\int \|\mathcal{K}_A(x,y)\|^2 dy \le CM^2\bar\rho_1\cdots\bar\rho_d h^{-d} \qquad \forall x\in\mathbb{R}^d \tag{1.1.54}$$

provided $m > d/2$, $l = 0$ and

$$\iint \|\mathcal{K}_A(x,y)\|^2\, dxdy \le CM^2\bar\rho_1\cdots\bar\rho_j\bar\gamma_1\cdots\bar\gamma_d h^{-d} \tag{1.1.55}$$

provided $m > d/2$, $l > d/2$.

Proof. The conditions on $\bar\gamma_j, \rho_j$ and $\bar\rho_j$ imply that the weight functions $\Phi(\xi)^m$ and $\phi(x)^l$ are tempered with respect to the metrics $\sum_j dx_j^2 + h^2 d\xi_j^2$. Then Theorem 18.5.5 of [1] implies that the operator $\Phi(hD)^m A^* A \Phi(hD)^m$ is a scalar h-pseudodifferential operator with a symbol satisfying (1.1.27) with M replaced by CM^2; hence it is a bounded operator from $\mathscr{L}^2(\mathbb{R}^d)$ to $\mathscr{L}^2(\mathbb{R}^d)$ and its norm does not exceed CM^2.

Then Sobolev embedding theorem implies that the norm of the operator $A^*A\Phi(hD)^m$ from $\mathscr{L}^2(\mathbb{R}^d)$ to $\mathscr{L}^\infty(\mathbb{R}^d,\mathbb{H})$ does not exceed $CM^2\bar\rho_1^{\frac12}\cdots\bar\rho_d^{\frac12}h^{-\frac{d}{2}}$ and therefore

$$\int |\mathcal{K}_{A^*A\Phi(hD)^m}(x,y)|^2\, dy \le CM^4\bar\rho_1\cdots\bar\rho_d h^{-d} \qquad \forall x\in\mathbb{R}^d.$$

But the left-hand expression is equal to

$$\int |\Phi(hD_y)^m \mathcal{K}_{A^*A}(x,y)|^2\, dy$$

and the same arguments imply that

$$|\mathcal{K}_{A^*A}(x,y)| \le CM^2 \bar\rho_1 \cdots \bar\rho_d h^{-d} \qquad \forall x,y \in \mathbb{R}^d. \tag{1.1.56}$$

On the other hand,

$$\mathcal{K}_{A^*A}(x,x) = \int \mathcal{K}_A^\dagger(x,y)\mathcal{K}_A(x,y)\, dy = \int \|\mathcal{K}_A(x,y)\|^2\, dy \tag{1.1.57}$$

since the range of $\mathcal{K}_A(x,y)$ is a matrix-column. This equality and (1.1.56) imply (1.1.54).

Moreover, (1.1.56) holds with A replaced by $A\phi(x)^l$ and hence the inequality for A remains true if we integrate with respect to $x \in \mathbb{R}^d$ provided $l < d/2$. This inequality and (1.1.57) imply (1.1.55). □

Theorem 1.1.12. *(i) Let A operator be an operator with a symbol a (simple or double) satisfying* (1.1.29) *with Hilbert-Schmidt rather than operator norm. Let $m > d/2$, $l > d/2$. Then A is Hilbert-Schmidt operator and its Hilbert-Schmidt norm does not exceed $CM(\bar\rho_1 \cdots \bar\rho_d \bar\gamma_1 \cdots \bar\gamma_d)^{1/2} h^{-d/2}$;*

(ii) Let A operator be an operator with a symbol a (simple or double) satisfying (1.1.53) *with trace norm rather than operator norm. Let $m > d$, $l > d$. Then A is trace class operator and its trace norm does not exceed $CM(\bar\rho_1 \cdots \bar\rho_d \bar\gamma_1 \cdots \bar\gamma_d) h^{-d}$.*

Proof. Assume first that $\min(\dim \mathbb{H}, \dim \mathbb{H}') = 1$. Then there is no difference between Hilbert-Schmidt, trace or operator norms for $\mathcal{L}(\mathbb{H}', \mathbb{H})$ operators.

Without any loss of the generality one can assume that $m = l$. Obviously (i) and (ii) hold as m is large enough. Further, both (i) and (ii) hold for $\Lambda_m = (1 + |x|^2 + h^2 D^2)^{-m/2}$. One can see easily that $A = B\Lambda_m + C$ where B is an operator with the symbol $a(1 + |x|^2 + |\xi|^2)^{m/2}$ and C is an operator with the symbol satisfying (1.1.53) with m, K replaced by $m+1, K-1$. Then "induction" with respect to m proves the Theorem in this restricted case.

The general case can be forced to the restricted one considering operators A_w with symbols $a(x,\xi)w$ with $w \in \mathbb{H}$, $\|w\| = 1$. □

Remark 1.1.13. All the conclusions of Proposition 1.1.11 and this Theorem remain true with constants not depending on $\bar{x}$, $\bar{\xi}$ if we replace $\Phi(\xi)$ and $\phi(x)$ by $\Phi(\xi-\bar{\xi})$ and $\phi(x-\bar{x})$ respectively, with arbitrary $(\bar{x},\bar{\xi})\in\mathbb{R}^{2d}$.

Note that the shift $x\to x-\bar{x}$, $\xi\to\xi-\bar{\xi}$ is equivalent to the transformation $A\in T^*AT$ with the operator T: $(Tu)(x)=e^{-i\langle x,\bar{\xi}\rangle}u(x+\bar{x})$ which preserves all the $\mathscr{L}^p$-norms.

Pseudodifferential Operators Applied to an Exponent

We need to study pseudodifferential operators applied to an exponent $u=f(x)e^{ih^{-1}\phi(x)}$ where currently

(1.1.58) *phase* $\phi(x)$ is a real-valued function,

$\phi(x)$ and *amplitude* $f(x)$ satisfy

$$|\partial^\alpha\phi|\le c\quad\forall\alpha:|\alpha|\le N+1,\quad |\partial^\alpha f|\le M_1\qquad\forall\alpha:|\alpha|\le N \tag{1.1.59}$$

where for f it is a norm in the auxiliary space $\mathbb{H}$.

Let us consider

$$\begin{aligned}a(\overset{2}{x},h\overset{1}{D})\bigl(f(x)e^{ih^{-1}\phi(x)}\bigr)=&\\ (2\pi h)^{-d}\iint a(x,\xi)f(y)e^{ih^{-1}[\langle x-y,\xi\rangle+\phi(y)]}\,d\xi dy=&\\ (2\pi h)^{-d}e^{ih^{-1}\phi(x)}\iint a(x,\xi)f(y)e^{ih^{-1}[\langle x-y,\xi\rangle+\phi(y)-\phi(x)]}\,d\xi dy&\end{aligned} \tag{1.1.60}$$

which after substitution $\xi\mapsto\nabla\phi(x)+\xi$ becomes

$$\begin{aligned}(2\pi h)^{-d}e^{ih^{-1}\phi(x)}\iint a(x,\nabla\phi(x)+\xi)f(y)e^{ih^{-1}[\langle x-y,\xi\rangle+\varphi(x,y)]}\,d\xi dy=&\\ e^{ih^{-1}\phi(x)}a(\overset{2}{x},\nabla\phi(x)+h\overset{1}{D}_y)e^{ih^{-1}\varphi(x,y)}\Big|_{y=x}&\end{aligned}$$

with

$$\varphi(y,x)=\phi(y)-\phi(x)-\langle y-x,\nabla\phi(x)\rangle. \tag{1.1.61}$$

If an original operator was h-differential operator of order m the last expression would be $e^{ih^{-1}\phi(x)}\sum_{n\le m} b_n(x)h^n$ where differentiating $e^{ih^{-1}\varphi(x,y)}$ ones we would need to differentiate factor $\big(\nabla\phi(y)-\nabla\phi(x)\big)$ at least ones to prevent getting 0 as $y=x$; so, at least one factor h would not be compensated by h^{-1} arising from the differentiation of exponent.

We can apply *stationary phase method*. We will learn it later in full but now we need its poor man's approach.

Step 1. Let us replace $\varphi(y,x)$ by

$$\varphi_N(x,y)=\sum_{\alpha:2\le|\alpha|\le N}\frac{1}{\alpha!}(y-x)^\alpha\partial_x^\alpha\phi(x). \tag{1.1.62}$$

Note that

$$e^{ih^{-1}\varphi(x,y)}-e^{ih^{-1}\varphi_N(x,y)}= ih^{-1}[\varphi(y)-\varphi_N(x,y)]\int_0^1 e^{ih^{-1}[t\varphi(y)+(1-t)\varphi_N(x,y)]} \tag{1.1.63}$$

and one can decompose $\phi(y)-\phi_N(x,y)$ into the sum $(y-x)^\alpha b_\alpha(x,y)$ with $|\alpha|=N+1$. Then replacing $(y-x)^\alpha$ by $(ih\partial_\xi)^\alpha$ applied to $e^{ih^{-1}\langle x-y,\xi\rangle}$ and integrating $N+1$ times by parts we will obviously get that this error is $O(h^{N-d})$.

Similarly, one can replace f by

$$f_{N-1}(x,y)=\sum_{\alpha:|\alpha|\le N-1}\frac{1}{\alpha!}(y-x)^\alpha\partial_x^\alpha f(x). \tag{1.1.64}$$

One can skip Step 1 assuming extra smoothness of ϕ and f.

Step 2. Now let us assume that ϕ and f are smooth enough (or we plug ϕ_N and f_{N-1} instead) and let us replace $f(y)e^{ih^{-1}\varphi(a,y)}$ by its Taylor decomposition

$$\sum_{\alpha:|\alpha|<L}\frac{1}{\alpha!}(y-x)^\alpha\partial_y^\alpha\big(f(y)e^{ih^{-1}\varphi(x,y)}\big)\Big|_{y=x}$$

with an error of the similar form but $|\alpha|=L$. Then the error will be

$$\sum_{\substack{k,\alpha:k\le L,\\ |\alpha|\ge N+(2k-L)_+}} c_{k\alpha}(x,y)(x-y)^\alpha h^{-k}e^{ih^{-1}\varphi(x,y)}$$

where L is large enough and $k_+ = \max(k,0)$. Replacing $(y-x)^\alpha$ by $(ih\partial_\xi)^\alpha$ applied to $e^{ih^{-1}\langle x-y,\xi\rangle}$ and integrating $|\alpha|$ times by parts we will obviously get that this error is $O(h^{|\alpha|-d-k})$ which is $O(h^{N-k})$ as $|\alpha| = L = 2N$.

Consider now "regular terms": $\partial_y^\alpha \big(f(y)e^{ih^{-1}\varphi(x,y)}\big)\big|_{y=x}$ which contain no exponent and lead to the answer

$$\sum_{\alpha:|\alpha|<2N} \frac{1}{\alpha!}(2\pi h)^{-d} \iint a(x,\nabla\phi(x)+\xi)(y-x)^\alpha e^{ih^{-1}\langle x-y,\xi\rangle}\times \big(\partial_y^\alpha f(y)e^{ih^{-1}\varphi(x,y)}\big)\big|_{y=x} d\xi\, dy = \sum_{\alpha:|\alpha|<2N} \frac{(-ih)^{|\alpha|}}{\alpha!} a^{(\alpha)}\big(x,\nabla\phi(x)\big)\big(\partial_y^\alpha f(y)e^{ih^{-1}\varphi(x,y)}\big)\big|_{y=x} e^{ih^{-1}\phi(x)} \tag{1.1.65}$$

where here and below

$$a^{(\alpha)} = \partial_\xi^\alpha a, \quad a_{(\beta)} = \partial_x^\beta a, \quad a_{(\beta)}^{(\alpha)} = \partial_\xi^\alpha \partial_x^\beta a.$$

So we arrive to

Theorem 1.1.14. *Let a satisfy* (1.1.25) *and ϕ, f satisfy* (1.1.58) *and* (1.1.59). *Then*

$$\|a(x, \overset{2}{h}D, \overset{1}{h}D)\big(f(x)e^{ih^{-1}\phi(x)}\big) - g(x)e^{ih^{-1}\phi(x)}\| \le CM_1 h^{N-d} \tag{1.1.66}$$

with

$$g(x) = \frac{(-ih)^{|\alpha|}}{\alpha!} a^{(\alpha)}(x,\nabla\phi(x))\,\partial_y^\alpha\big(f_N(y)e^{ih^{-1}\varphi_N(x,y)}\big)\big|_{y=x} \tag{1.1.67}$$

where for smooth enough f, ϕ one does not need to replace f, φ by f_N, φ_N.

Remark 1.1.15. Assuming instead of (1.1.58) that

$$\operatorname{Im}\phi(x) \ge 0 \tag{1.1.68}$$

one would be able to prove the same statement provided $a(x,\xi)$ is analytic with respect to ξ; otherwise one needs to make sense of $a(x,\nabla\phi(x))$. One can do it replacing $a(x,\xi)$ by its *quasianalytic* continuation from $\mathbb{R}^d$:

$$\tilde a(x,\xi) = \sum_{\beta:|\beta|\le M} \frac{1}{\beta!} a^{(\beta)}(x,\operatorname{Re}\xi)(\operatorname{Im}\xi)^\beta \tag{1.1.69}$$

and using fact that $|\nabla \operatorname{Im}\phi| \le c_0 |\operatorname{Im}\phi|^{1/2}$. Then (1.1.67) is preserved with $a^{(\alpha)}(x,\nabla\phi(x))$ replaced by $\tilde a^{(\alpha)}(x,\nabla\phi(x))$.

Remark 1.1.16. Note that

$$\partial_y^\alpha \bigl(f_N(y)e^{ih^{-1}\varphi_N(x,y)}\bigr)\big|_{y=x} = \sum_{\substack{m,\alpha_1:|\alpha_1|\ge 2,\dots,\alpha_m:|\alpha_m|\ge 2,\\ \beta:\alpha_1+\dots+\alpha_m+\beta=\alpha}} \kappa_{\alpha_1,\dots,\alpha_m,\beta}(\nabla_1^\alpha\phi)\cdots(\nabla_m^\alpha\phi)\nabla^\beta f\cdot h^{-m} \tag{1.1.70}$$

with absolute constants $\kappa_{\alpha_1,\dots,\alpha_m,\beta}$ and therefore in (1.1.66) one can take

$$g=\sum_{n<N} h^n \mathcal{L}_n f \tag{1.1.71}$$

where

$$\mathcal{L}_n=\sum \kappa_{\alpha_1,\dots,\alpha_m,\beta}\frac{i^{-|\alpha|}}{\alpha!}a_l^{(\alpha)}(x,\nabla\phi)(\nabla_1^\alpha\phi)\cdots(\nabla_m^\alpha\phi)\nabla^\beta \tag{1.1.72}$$

with the sum over set

$$\bigl\{l,\alpha,m,\alpha_1,\dots,\alpha_m,\beta:|\alpha_1|\ge 2,\dots,|\alpha_m|\ge 2,\ \alpha_1+\dots+\alpha_m+\beta=\alpha,|\alpha|=m+n+l\bigr\} \tag{1.1.73}$$

(which implies that $\frac{1}{2}|\alpha|+|\beta|\le n-l$). In particular

$$\mathcal{L}_0 = a_0(x,\nabla\phi), \tag{1.1.74}$$

$$\begin{aligned}\mathcal{L}_1 &= -i\sum_j a_0^{(j)}(x,\nabla\phi)\partial_j - \frac{i}{2}\sum_{j,k} a_0^{(jk)}(x,\nabla\phi)(\partial_j\partial_k\phi)+a_1(x,\nabla\phi)\\ &= -i\sum_j a_0^{(j)}(x,\nabla\phi)\partial_j - \frac{i}{2}\sum_j\bigl(\partial_j a_0^{(j)}(x,\nabla\phi)\bigr)+a^s(x,\nabla\phi)\end{aligned} \tag{1.1.75}$$

(recall that a^s is subprincipal symbol of operator).

For ϕ satisfying (1.1.68) rather than (1.1.58) one should replace a by $\tilde{a}$.

1.1.2 Analysis of Pseudodifferential Operators

Introduction

We need to generalize our results to symbols which do not satisfy any decay as $|\xi|\to\infty$ conditions. Namely we assume that (1.1.29) in the matrix sense

is satisfied with $s = 0$:

$$\|\partial_x^\alpha \partial_y^\beta \partial_\xi^\nu a(x,\xi,y)\| \le M \qquad \forall \alpha,\beta,\nu : |\alpha|+|\beta| \le N+K, |\nu| \le N+K \tag{1.1.76}$$

where $\|.\|$ is the norm in $\mathcal{L}(\mathbb{H}', \mathbb{H})$ and define operators $a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x})$ by (1.1.17) while for ordinary symbols satisfying (1.1.76)

$$\|\partial_x^\alpha \partial_\xi^\nu a(x,y,\xi)\| \le M \qquad \forall \alpha,\nu : |\alpha| \le N+K, |\nu| \le N+K \tag{1.1.77}$$

we define $a(\overset{2}{x}, \overset{1}{hD})$, $a(\overset{1}{x}, \overset{2}{hD})$ and $a^{\mathsf{w}}(x, hD)$ by (1.1.9), (1.1.10) and (1.1.13) respectively. Here $K = K(d)$ is large enough.

In principle, according to Section 18.4 of L. Hörmander [1], the different types of quantization are unnecessary; namely an operator $a = a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x})$ can be rewritten in each form $a_{(1)}(\overset{2}{x}, \overset{1}{hD})$, $a_{(2)}(\overset{1}{x}, \overset{2}{hD})$, $a^{\mathsf{w}}_{(3)}(x, hD)$ with the symbols $a_{(j)}$ are given by formulas

$$a_{(1)}(x,\xi) = \Gamma_x e^{ih\langle D_y, D_\xi\rangle} a(x,\xi,y), \tag{1.1.78$_1$}$$

$$a_{(2)}(x,\xi) = \Gamma_x e^{-ih\langle D_x, D_\xi\rangle} a(x,\xi,y), \tag{1.1.78$_2$}$$

$$a_{(3)}(x,\xi) = \Gamma_x e^{\frac{ih}{2}\langle D_y - D_x, D_\xi\rangle} a(x,\xi,y), \tag{1.1.78$_3$}$$

where $e^{ih\langle D_y, D_\xi\rangle}$ etc are defined explicitly through corresponding Fourier transforms and Γ_x is the operator of restriction to the diagonal $\{x = y\}$.

Moreover, due to the similar arguments it is not necessary to introduce operators with multiple symbols:

$$A = \int \cdots \int \hat{a}(\alpha_{(1)}, \dots, \alpha_{(n+1)}, \beta_{(1)}, \dots, \beta_{(n)}) \times e^{i\langle \alpha_{(1)}, x\rangle} e^{i\langle \beta_{(1)}, hD\rangle} \cdots e^{i\langle \beta_{(n)}, hD\rangle} e^{i\langle \alpha_{(n+1)}, x\rangle} d\alpha_{(1)} \dots d\alpha_{(n+1)} d\beta_{(1)} \dots d\beta_{(n)} \tag{1.1.79}$$

where $a(x_{(1)}, \dots, x_{(n+1)}, \xi_{(1)}, \dots, \xi_{(n)})$ is a multiple symbol, $\hat{a}$ its complete Fourier transform (with respect to all variables) and $x_{(j)}, \xi_{(j)}, \alpha_{(j)}, \beta_{(j)} \in \mathbb{R}^d$.

The following simple exact formulae are useful:

Lemma 1.1.17. *(i) Let $b(x,\xi)$ be a linear scalar symbol. Then for an arbitrary symbol a and any type of quantization*

$$[\mathsf{Op}(a), \mathsf{Op}(b)] = -ih\,\mathsf{Op}(\{a,b\}) \tag{1.1.80}$$

where $[.,.]$ is the commutator and $\{.,.\}$ is Poisson bracket.

(ii) Moreover, for Weyl quantization

$$\mathsf{Op}^{\mathrm{w}}(a)\,\mathsf{Op}^{\mathrm{w}}(b)+\mathsf{Op}^{\mathrm{w}}(b)\,\mathsf{Op}^{\mathrm{w}}(a)=\mathsf{Op}^{\mathrm{w}}(ab+ba) \tag{1.1.81}$$

for a linear symbol b; further (1.1.80) *holds even for a quadratic scalar symbol b.*

Proof. By direct calculation. □

Expressions $(1.1.78)_1$–$(1.1.78)_3$ are precise but non-local with respect to the corresponding variables. To remedy this we need

Proposition 1.1.18. *Suppose that $a(x,y,\xi)$ satisfies* (1.1.76)*. Then*

(i) For $h\in(0,1]$ symbols $a_{(j)}$ defined by $(1.1.78)_1$-$(1.1.78)_3$ satisfy (1.1.77) *with M replaced by CM with $C=C(d)$ and K replaced by $K/2$.*

(ii) Further, as in Theorem 1.1.4 for every $L\le N-1$ symbols $\bigl(a_{(j)}-a_{(j,L)}\bigr)$ satisfy (1.1.77) *with N, M, and K replaced by $(N-L)$, CMh^L with $C=C(L,d)$ and $K/2$ respectively where $a_{(j,L)}$ are b'_L, b''_L and b_L defined by* (1.1.24), (1.1.26) *and* (1.1.28) *respectively.*

Proof. Proof follows immediately from Theorem 18.4.10 and formula (18.4.8) of L. Hörmander [1] or alternatively from (1.A.5). Note that expressions for $a_{(j),L}$ are just Taylor decompositions (without remainder terms) for corresponding exponents. □

Estimates

Now we need to prove the estimates for operator norms:

Theorem 1.1.19. *Let* (1.1.76) *be fulfilled with $N=0$, $K>2d$. Then for $h\in(0,1]$ the $\mathcal{L}\bigl(\mathscr{L}^2(\mathbb{R}^d,\mathbb{H}'),\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})\bigr)$-norm of operator $A=a(\overset{3}{x},\overset{2}{hD},\overset{1}{x})$ does not exceed CM.*

Proof. Proof follows immediately Theorem 18.6.2 of L. Hörmander [1]. However let us sketch it. While it is sufficient to cover only case $h=1$ (otherwise one can apply rescaling $x\mapsto xh$ [2].) Let us conduct proof for any $h\in(0,1]$.

[2] I.e. $x_{\mathsf{new}}=x_{\mathsf{old}}h^{-1}$.

Let us consider partition of unity in $\mathbb{R}^d_\xi$:

$$\sum_\mu \psi_\mu^2 = 1 \tag{1.1.82}$$

where

(1.1.83) ψ_μ are real-valued, supported in $B_\mu = \{|\xi - \xi_\mu| \le 1\}$ and such that $|\partial^\alpha \psi_\mu| \le c_\alpha \ \forall \alpha, \mu$

and moreover

(1.1.84) Multiplicity of covering $\mathbb{R}^d$ by $\bar{B}_\mu = \{|\xi - \xi_\mu| \le 2\}$ does not exceed $C = C(d)$ [3)].

Then

$$\|Au\|^2 = \sum_\mu \|\psi_\mu(hD)Au\|^2 = \sum_\mu \|\psi_\mu(hD)\sum_{\nu,\lambda} A_\nu \phi_\lambda(hD)u\|^2 \tag{1.1.85}$$

with $\phi_\lambda = \psi_\lambda^2$ and $A_\nu = (a\phi_\nu)(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x})$; so in fact we quantize symbol $a(x,\xi,y)\phi_\nu(\xi)$.

Note first that the operator norm of A_ν does not exceed CM because its symbol satisfies (1.1.76) and is supported in $\{(x,\xi) : \xi \in B_\nu\}$; if $\xi_\nu = 0$ it would be in the framework of Theorem 1.1.3 but one can either notice that all arguments of the proof of this theorem remain valid or just notice that

$$e^{-ih^{-1}\langle x,\eta\rangle} b(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x}) e^{ih^{-1}\langle x,\eta\rangle} = b(\overset{3}{x}, \overset{2}{hD} + \eta, \overset{1}{x}) \tag{1.1.86}$$

(so one can shift support to $\{|\xi| \le 1\}$).

Let us prove that

(1.1.87) Operator norm of $\psi_\mu A_\nu$ does not exceed $CM(1 + |\xi_\mu - \xi_\nu|)^{-K}$.

[3)] That means that no point belongs to more than L of these sets. One can prove existence of such partition easily.

Really, let for simplicity $\bar{\xi} = \xi_\mu$, $\bar{\eta} = \xi_\nu$ and subscript denote coordinate. Note that

$$(\bar{\xi}_j - \bar{\eta}_j)\psi_\mu(hD)A_\nu = \psi'_\mu(hD)A_\nu + \psi_\mu(hD)A'_\nu \tag{1.1.88}$$

where $\psi'_\mu(\xi) = (\bar{\xi}_j - \xi_j)\psi_\mu(\xi)$ and A'_ν is a quantization of

$$\Big(a(x,\xi,y)(\xi_j - \bar{\eta}_j) - ih\partial_{x_j}a(x,\xi,y)\Big)\phi_\lambda(\xi)$$

and therefore operator norm of each term in the right-hand expression of (1.1.88) does not exceed CM. Thus (1.1.87) is proven for $K = 1$. Repeating these arguments we can prove it for any K.

Similarly,

(1.1.89) Operator norm of $\psi_\mu A_\nu \psi_\lambda$ does not exceed

$$CM(1 + |\xi_\mu - \xi_\nu| + |\xi_\nu - \xi_\lambda|)^{-K}.$$

Then as $K > d$

$$\begin{aligned}\sum_\nu \|\psi_\mu(hD)A_\nu\phi_\lambda(hD)u\| \le{}& \\ CM\sum_\nu \big(1 + |\xi_\mu - \xi_\nu| + |\xi_\nu - \xi_\lambda|\big)^{-K}&\|\psi_\lambda(hD)u\| \le \\ CM\big(1 + |\xi_\mu - \xi_\lambda|\big)^{d-K}&\|\psi_\lambda(hD)u\|\end{aligned} \tag{1.1.90}$$

and plugging into (1.1.85) we get

$$\begin{aligned}\|Au\|^2 \le C^2M^2\sum_\mu\Big(\sum_\lambda (1 + |\xi_\mu - \xi_\lambda|)^{d-K}\|\psi_\lambda(hD)u\|\Big)^2 \le& \\ \sum_{\lambda,\mu,\nu}\big(1 + |\xi_\mu - \xi_\lambda|\big)^{d-K}\big(1 + |\xi_\mu - \xi_\nu|\big)^{d-K}\|\psi_\lambda(hD)u\|\cdot\|\psi_\nu(hD)u\| \le& \\ C^2M^2\sum_{\lambda,\nu}\big(1 + |\xi_\nu - \xi_\lambda|\big)^{d-K}\|\psi_\lambda(hD)u\|^2 \le& \\ C^2M^2\sum_\lambda \|\psi_\lambda(hD)u\|^2 = C^2M^2\|u\|^2&\end{aligned} \tag{1.1.91}$$

provided $K > 2d$; between the second and the third lines we summed with respect to μ and estimated $\|\psi_\lambda(hD)u\|\cdot\|\psi_\nu(hD)u\|$ by the half-sum of squares; then in one part we permuted λ and ν.

So, we proved that $\|Au\| \le CM\|u\|$ for any u. □

Remark 1.1.20. Actually we need a bit weaker assumption than (1.1.76) with $N = 0$, $K > 2d$; it is enough to assume that the corresponding estimate holds as $|\alpha| \le K$, $|\beta| \le K$, $|\nu| \le K$ with $K > d$. Then in (1.1.89) we get

$$CM(1 + |\xi_\mu - \xi_\nu|)^{-K}(1 + |\xi_\nu - \xi_\lambda|)^{-K}.$$

This remark holds for all statements of this section.

Remainder Estimates

Theorem 1.1.19 and Proposition 1.1.18(ii) immediately imply

Theorem 1.1.21. *Let* (1.1.76) *be fulfilled with* $K > 2d$. *Then for* $h \in (0, h_0]$ *and* $L \le N - 1$ *the* $\mathcal{L}\big(\mathscr{L}^2(\mathbb{R}^d, \mathbb{H}'), \mathscr{L}^2(\mathbb{R}^d, \mathbb{H})\big)$*-norm of operator* $\mathsf{Op}\big(a_{(j)} - a_{(j,L)}\big)$ *with* $a_{(j,L)}$ *defined by* (1.1.24), (1.1.26) *and* (1.1.28) *does not exceed* CMh^L.

Theorem 1.1.22. *Let* a *and* b *be* $\mathcal{L}(\mathbb{H}'', \mathbb{H}')$*- and* $\mathcal{L}(\mathbb{H}', \mathbb{H})$*-valued ordinary symbols satisfying* (1.1.77) *with* $M = M_a$ *and* $M = M_b$ *respectively. Let* $a(x, hD)$, $b(x, hD)$ *and* $(a \bullet_L b)(x, hD)$ *be quantizations of symbols* a, b *and* $a \bullet_L b$ *where* $L \le N - 1$ *and here and in what follows* $a \bullet_{pq,L} b$, $a \bullet_{qp,L} b$, $a \bullet_{\mathsf{w},L} b$ *are defined by* $(1.1.37)_1$–$(1.1.37)_3$ *for* qp*-,* pq*- and Weyl quantization respectively.*

Then the $\mathcal{L}\big(\mathscr{L}^2(\mathbb{R}^d, \mathbb{H}''), \mathscr{L}^2(\mathbb{R}^d, \mathbb{H})\big)$*-norm of the operator*

$$a(x, hD)b(x, hD) - (a \bullet_L b)(x, hD)$$

does not exceed $Ch^L M_a M_b$.

Proof. Proof follows immediately from Proposition 1.1.18(ii) and Theorem 1.1.16. □

Remark 1.1.23. Again there are sharp but non-local formulae

$$(1.1.92)_1 \qquad a \bullet_{qp} b = \Gamma_{x,\xi} e^{ih\langle D_y, D_\xi\rangle}\big(a(x, \xi)b(y, \eta)\big),$$

$$(1.1.92)_2 \qquad a \bullet_{pq} b = \Gamma_{x,\xi} e^{-ih\langle D_x, D_\eta\rangle}\big(a(x, \xi)b(y, \eta)\big),$$

$$(1.1.92)_3 \qquad a \bullet_{\mathsf{w}} b = \Gamma_{x,\xi} e^{\frac{ih}{2}\langle D_y, D_\xi\rangle - \frac{ih}{2}\langle D_x, D_\eta\rangle}\big(a(x, \xi)b(y, \eta)\big),$$

with $\Gamma_{x,\xi}$ is the operator of restriction to the diagonal $\{x = y, \xi = \eta\}$.

Classes of Symbols and Pseudodifferential Operators

From now on we in use

Definition 1.1.24. (i) Denote by $\mathsf{S}_{h,N}(\mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}', \mathbb{H})$ and $\mathsf{S}_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}', \mathbb{H})$ classes of double and ordinary symbols in the form (1.1.30)

$$a(x,\xi,y) = \sum_{j=0}^{N-1} a_j(x,y,\xi)h^j$$

with a_j satisfying condition (1.1.76) with N replaced by $(N-j)$ and with some constant M.

(ii) Denote by $\mathbf{\Psi}_{h,N}(\mathbb{R}^d, \mathbb{H}', \mathbb{H})$ the class of operators obtained from double symbols $a \in \mathsf{S}_{h,N}(\mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d)$ by quantization; operators of this class are defined modulo negligible i.e. with the operator norm not exceeding Mh^N.

(iii) The smallest M such that (1.1.76) with N replaced by $(N-j)$ holds for all $j = 0, \dots, N$ and (ii) also holds, the norm of A: $\|\!|A|\!\| = \|A\|_{\mathbf{\Psi}}$.

We preserve the notions of the principal and subprincipal symbol.

Remark 1.1.25. Discussing trace or Hilbert-Schmidt operators we need to use trace or Hilbert-Schmidt norms both in (1.1.76) and for negligible operator estimate as well. Discussing compact operators (see below) we need to assume that both symbols and negligible operator are compact.

Compactness

Theorem 1.1.26. *Let A operator be an operator with a symbol a (simple or double) satisfying* (1.1.76) *and*

$$\|D_x^\alpha D_y^\beta D_\xi^\nu a(x,\xi,y)\| \le \epsilon(R) \qquad \forall (x,\xi,y) \in \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d : |x| + |y| + |\xi| \ge R \qquad \forall \alpha, \beta, \nu : |\alpha| \le K, |\beta| \le K, |\nu| \le K \tag{1.1.93}$$

$\epsilon(R) \to 0$ *as* $R \to \infty$, $N \ge 0$.

Further, let us assume that $a(x,\xi,y)$ is a compact operator for each (x,y,ξ).

Then A is compact operator.

Proof. We need to prove that one can approximate A by compact operators (in operator norm).

Let A_R be an operator with the symbol $a\varphi_R$ with

$$\varphi_R = \chi\big(\frac{1}{R^2}(|x|^2+|y|^2+|\xi|^2)\big),$$

$\chi \in \mathscr{C}_0^\infty(\mathbb{R})$ equal 1 on $(-1,1)$. Note that $(A-A_R)$ is a quantization of the symbol $a(1-\varphi_R)$ which satisfies (1.1.76) with M replaced by $C\epsilon(R)$. Therefore its operator norm does not exceed $C\epsilon(R)$.

Let P_n be a sequence of finite-dimensional projectors in $\mathbb{H}$ converging to I strongly (i.e. $P_n w \to w$ for each $w \in \mathbb{H}$. Then $a(x,y,\xi)P_n \to a(x,y,\xi)$ in operator norm for each (x,y,ξ) and due to (1.1.76)

$$\|D_x^\alpha D_y^\beta D_\xi^\nu a(x,\xi,y)(I-P_n)\| \le \epsilon_R(n) \qquad \forall (x,\xi,y)\in \mathbb{R}^d\times\mathbb{R}^d\times\mathbb{R}^d : |x|+|y|+|\xi|\le R \qquad \forall \alpha,\beta,\nu : |\alpha|\le K/2, |\beta|\le K/2, |\nu|\le K/2$$

with $\epsilon_R(n)\to 0$ as $n\to\infty$. Similar inequalities then hold for $a\varphi_R$. Therefore operator norm of $A_R(I-P_n)$ does not exceed $C\epsilon_R(n)$.

On $A_R P_n$ is Hilbert-Schmidt (and even the trace class) operator due to Theorem 1.1.12.

Therefore operator A can be approximated in operator norm by compact operators $A_R P_n$ and therefore is compact as well. □

Rescaling

We will need to consider operators with symbols which could be reduced to those considered before by rescaling $x \mapsto x\boldsymbol{\gamma}^{-1}$, $\xi \mapsto \xi\boldsymbol{\rho}^{-1}$ with $\boldsymbol{\rho} = (\rho_1,\dots,\rho_d)$ and $\boldsymbol{\gamma} = (\gamma_1,\dots,\gamma_d)$ which means $x_j \mapsto x_j\gamma_j^{-1}$, $\xi_j \mapsto \xi_j\rho_j^{-1}$ and $h \mapsto \boldsymbol{h} = (h_1,\dots,h_d)$ with $h_j = h/(\rho_j\gamma_j)$ [4]. To reach after this rescaling (1.1.76) or (1.1.77) with $h\le 1$ we need to assume that

$$\|D_x^\alpha D_y^\beta D_\xi^\nu a\| \le M\boldsymbol{\rho}^{-\nu}\boldsymbol{\gamma}^{-\alpha-\beta} \quad \forall (x,y,\xi)\in\mathbb{R}^d\times\mathbb{R}^d\times\mathbb{R}^d \qquad \forall \alpha,\beta,\nu : |\alpha|+|\beta|\le N+K, |\nu|\le N+K \tag{1.1.94}$$

or

$$\|\partial_x^\alpha\partial_\xi^\nu a(x,y,\xi)\| \le M\boldsymbol{\rho}^{-\nu}\boldsymbol{\gamma}^{-\alpha} \qquad \forall \alpha,\nu : |\alpha|\le N+K, |\nu|\le N+K \tag{1.1.95}$$

[4] I.e. $x_{j,\mathsf{new}} = x_{j,\mathsf{old}}\gamma_j^{-1}$ etc.

respectively with

$$\hbar = \max_j h/(\rho_j\gamma_j) \le 1 \qquad (\iff \rho_j\gamma_j \ge h). \tag{1.1.96}$$

Remark 1.1.27. (i) Under these assumptions Theorems 1.1.21, 1.1.22 remain true with the remainder estimate $CM\hbar^L$. Condition (1.1.96) is known as *an uncertainty principle*.

(ii) To get negligible remainder estimate $O(h^s)$ one should assume that $\hbar = O(h^\delta)$ with an arbitrarily small exponent $\delta > 0$ i.e.

$$\rho_j\gamma_j \ge h^{1-\delta}. \tag{1.1.97}$$

Condition (1.1.97) is known as *a (standard) microlocal uncertainty principle*. Later we will introduce *a logarithmic uncertainty principle*.

Remark 1.1.28. Using the same methods one can generalize Theorem 1.1.22 to the case when a, b satisfy (1.1.95) with M_a, ρ_a, γ_a and M_b, ρ_b, γ_b respectively such that $\rho_{a,j}\gamma_{a,j} \ge h$, $\rho_{b,j}\gamma_{b,j} \ge h$ $\forall j$ and with exactly the same methods of quantizations of all symbols; in this case an operator norm of the remainder does not exceed $C\hbar^L M_a M_b$ with

$$\hbar = h \max_{1\le j\le d} \frac{1}{\rho_{a,j}\gamma_{b,j}}, \tag{1.1.98}_1$$

$$\hbar = h \max_{1\le j\le d} \frac{1}{\rho_{b,j}\gamma_{a,j}}, \tag{1.1.98}_2$$

$$\hbar = h \max_{1\le j\le d} \Big(\frac{1}{\rho_{a,j}\gamma_{b,j}} + \frac{1}{\rho_{b,j}\gamma_{a,j}}\Big) \tag{1.1.98}_3$$

for qp-, pq- and Weyl quantizations respectively.

Gårding Inequalities

By *Gårding inequalities* we call statements of the type "if symbol is positive then operator is (almost) positive". The following theorem will be our workhorse:

Theorem 1.1.29. *Let a be an $\mathcal{L}(\mathbb{H},\mathbb{H})$-valued Hermitian symbol satisfying* (1.1.77) *with $N = 0$ and such that*

$$\langle a(x,\xi)w, w\rangle \ge 0 \qquad \forall (x,\xi) \in \mathbb{R}^d \times \mathbb{R}^d \quad \forall w \in \mathbb{H} \tag{1.1.99}$$

where here $\langle .,. \rangle$ *means the inner product in* $\mathbb{H}$. *Then for* $h \in (0, h_0]$

$$(a^{\mathsf{w}}(x, hD)u, u) \geq -CMh\|u\|^2 \qquad \forall u \in \mathscr{L}^2(\mathbb{R}^d, \mathbb{H}) \tag{1.1.100}$$

where here and below $(.,.)$ *and* $\|.\|$ *mean the inner product and the norm in* $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H})$ *and* $h_0 = \mathsf{min}_{1\leq j\leq d}\, \rho_j\gamma_j$.

Proof. This is an adapted proof of Theorem 18.6.4 L. Hörmander [1]. Without any loss of the generality one can assume that $M = 1$.

First of all we need a really fine partitions of unity. Consider

$$1 = \sum_{\nu} \phi_\nu^2(x), \quad 1 = \sum_{\mu} \psi_\mu^2(\xi) \tag{1.1.101}$$

where all functions are real, supported in $B(x_\nu, 1)$ or $B(\xi_\mu, 1)$ which are balls of radius 1 with the centers at the lattice points x_ν, ξ_μ and such that

$$|\partial_x^\alpha \phi_\nu| \leq c_\alpha, \quad |\partial^\alpha \psi_\mu| \leq c_\alpha \qquad \forall \alpha, \nu, \mu \tag{1.1.102}$$

uniformly with respect to x, ξ, ν, μ.

Let us introduce $\hat{\phi}_\nu = \phi_\nu(h^{-\frac{1}{2}}x)$, $\hat{\psi}_\mu = \psi_\mu(h^{\frac{1}{2}}D)$, and consider equality

$$\begin{aligned}(Au, u) = \sum_{\nu} \big(\hat{\phi}_\nu^2 Au, u\big) = \\ \sum_{\nu} \big(\hat{\phi}_\nu Au, \hat{\phi}_\nu u\big) = \sum_{\nu} \big(A\hat{\phi}_\nu u, \hat{\phi}_\nu u\big) - \sum_{\nu} \big(\hat{\phi}_\nu [A, \hat{\phi}_\nu]u, u\big).\end{aligned} \tag{1.1.103}$$

Note that operator $[A, \hat{\phi}_\nu]$ is skew-symmetric, and therefore

$$\big(\hat{\phi}_\nu [A, \hat{\phi}_\nu]\big)^* + \hat{\phi}_\nu [A, \hat{\phi}_\nu] = -\frac{1}{2}\big[[A, \hat{\phi}_\nu], \hat{\phi}_\nu\big] \tag{1.1.104}$$

and (1.1.103) becomes

$$(Au, u) = \sum_{\nu} \big(A\hat{\phi}_\nu u, \hat{\phi}_\nu u\big) + \frac{1}{2}\sum_{\nu} \big(\big[[A, \hat{\phi}_\nu], \hat{\phi}_\nu\big]u, u\big). \tag{1.1.105}$$

We claim that

(1.1.106) *Operator norm of* $\sum_\nu \big[[A, \hat{\phi}_\nu], \hat{\phi}_\nu\big]$ *does not exceed* Ch.

On the heuristic level, calculating commutators formally, one can notice that every time a factor $h^{\frac12}$ appears, so the second commutator has an extra factor h.

To justify (1.1.106) if $a(x,\xi)$ is fast-decaying with respect to ξ one can notice that the Schwartz kernel of the second commutator is

$$\mathcal{K}_{[[A,\hat\phi_\nu],\hat\phi_\nu]}(x,y) = \mathcal{K}_A(x,y)\bigl(\phi_\nu(h^{-\frac12}x) - \phi_\nu(h^{-\frac12}y)\bigr)^2 \tag{1.1.107}$$

and therefore for $K \ge 2$

$$\sum_\nu |\mathcal{K}_{[[A,\phi_\nu],\phi_\nu]}(x,y)| \le \\ C(1+h^{-1}|x-y|)^{-d-3}\times h^{-1}|x-y|^2 \le Ch(1+h^{-1}|x-y|)^{-d-1}.$$

The proof in the general situation repeats one of Theorem 1.1.9.

After (1.1.106) is proven, (1.1.105) implies

$$(Au,u) \ge \sum_\nu (A\hat\phi_\nu u, \hat\phi_\nu u) - Ch\|u\|^2 \tag{1.1.108}$$

and therefore it is sufficient to prove (1.1.100) for u replaced by $\hat\phi_\nu u$. The same arguments work for the second partition. Therefore it is sufficient to prove (1.1.100) for u replaced by $\hat\psi_\mu\hat\phi_\nu u$.

Remark 1.1.30. We used the finest x- and ξ- partitions for which (1.1.106) is still valid.

Furthermore, now one can replace $a(x,hD)$ by its approximation on support of $\hat\psi_\mu\hat\phi_\nu$:

$$\bar a(x,hD) = \\ a(\bar x,\bar\xi) + \sum_j \bigl(\partial_{x_j}a\bigr)(\bar x,\bar\xi)(x_j-\bar x_j) + \bigl(\partial_{\xi_j}a\bigr)(\bar x,\bar\xi)(hD_j-\bar\xi_j) + \\ C_0|x-\bar x|^2 + C_0|hD-\bar\xi|^2 \tag{1.1.109}$$

where overbar replaces index $_{\mu\nu}$. Really, the quadratic term of the Taylor decomposition is $O(h)$ on the support of $\hat\phi_\nu$, $\hat\psi_\mu$. To justify it we can freeze $x = x_\nu$ first (before introduction ψ_μ), and $hD = \xi_\mu$ after it. Proofs repeat one of Theorem 1.1.19.

Consider first the case of the scalar operator a. Then one can rewrite quadratic operator $\bar{a}(x, hD)$ as

$$\bar{a}(x, hD) = C_0|hD - \eta - \bar{\xi}|^2 + C_0|x - y - \bar{x}|^2 + b$$

with

$$\eta = -\frac{1}{2C_0}\nabla_\xi a, \quad y = -\frac{1}{2C_0}\nabla_x a, \quad b = a - \frac{1}{4C_0}(|\nabla_x a|^2 + |\nabla_x a|^2)$$

calculated at $x = \bar{x}$, $\xi = \bar{\xi}$.

Now without any loss of the generality one can assume that $\bar{x} + y = \bar{\xi} + \eta = 0$ (otherwise we can make a shift). So, we have a harmonic oscillator $C_0(|x|^2 + |hD|^2)$ plus b. Here $b \ge 0$ (provided we picked up a large enough constant C_0) due to the known fact that if the second derivatives of f are bounded and f is nonnegative then $f \ge C_0|\nabla f|^2$.

On the other hand, harmonic oscillator is non-negative operator; in fact its lower bound is Cdh; we will analyze it later. So, our reduced operator $\bar{a}(x, hD)$ satisfies (1.1.100) and thus our operator a satisfies it as well. Later we reexamine scalar case to improve sharp Gårding inequality.

Consider general (matrix) case now. Then

$$\bigl\langle \bigl(a(\bar{x}, \bar{\xi}) + L(\bar{x}, \bar{\xi}; y, \eta)\bigr)v, v\bigr\rangle + c(|y|^2 + |\eta|^2)\|v\|^2 \ge 0 \qquad \forall v \in \mathbb{H} \quad \forall y, \eta \in \mathbb{R}^d \tag{1.1.110}$$

where

$$L(\bar{x}, \bar{\xi}; y, \eta) = \langle (\nabla_x a)(\bar{x}, \bar{\xi}), y\rangle + \langle (\nabla_\xi a)(\bar{x}, \bar{\xi}), \eta\rangle.$$

We can plug $2y, 0$ instead of y, ξ. Then we L becomes an operator of multiplication and then

$$\bigl(\bigl(a(\bar{x}, \bar{\xi}) + 2L(\bar{x}, \bar{\xi}; x - \bar{x}, 0)\bigr)u, u\bigr) + 4c\|xu\|^2 \ge 0;$$

here u is an arbitrary $\mathbb{H}$-valued function. Plugging in (1.1.110) $0, 2\eta$ instead of y, η and making h-Fourier transform (recall that such transform does not break Weyl quantization) we will get

$$\bigl(\bigl(a(\bar{x}, \bar{\xi}) + 2L(\bar{x}, \bar{\xi}; 0, hD - \bar{\xi})\bigr)u, u\bigr) + 4c\|hDu\|^2 \ge 0.$$

Adding two last inequalities we will arrive to

$$(\bar{a}(x, hD)u, u) \ge 0$$

as long as $C \ge 4c$. It concludes the proof. □

In the scalar case (i.e., for $\mathbb{H} = \mathbb{C}$) one can prove a better estimate.

Theorem 1.1.31. *Let a be a scalar real valued symbol satisfying* (1.1.77) *with $N = 0$ and such that*

$$a(x,\xi) \ge 0. \tag{1.1.111}$$

Then

$$(a^{\mathrm{w}}(x,hD)u,u) \ge -CMh^2\|u\|^2 \qquad \forall u \in \mathscr{L}^2(\mathbb{R}^d). \tag{1.1.112}$$

Proof. This is very precise result and it looks like no tight partition of unity can save us because if we take scale h^δ the double commutator has the norm $\asymp h^{2-2\delta}$ which will be too large for any $\delta > 0$. However, we will run rescaling method. The proof is really difficult and idea rich.

We will follow the proof of Theorem 18.6.8 of L. Hörmander [1]. We will run induction with respect to d.

Step 1. Non-degenerate case. First, let us consider ball $B(\bar z,\epsilon)$ of radius ϵ with the center 0 in $\mathbb{R}^{2d}$ where $\epsilon > 0$ is a small enough constant. If $a(\bar z) \ge \kappa$ then $a(z) \ge \kappa/2$ in $B(\bar z,\epsilon)$ where $\kappa > 0$ is an arbitrarily small constant and $\epsilon = \epsilon(\kappa) > 0$ and then

$$(a^{\mathrm{w}}(x,hD)\phi(x,hD)u, \phi(x,hD)u) \ge -C_0h^2\|u\|^2 \tag{1.1.113}$$

provided

$$\operatorname{supp}(\phi) \subset B(\bar z,r), \qquad |\nabla^\alpha\phi| \le c_\alpha r^{-|\alpha|} \qquad \forall \alpha \tag{1.1.114}$$

with $r = \epsilon$.

Assume now that $|\nabla^2 a|(\bar z) = 1$ and $a(\bar z) < \kappa$ with a small enough constant $\kappa > 0$. Then without any loss of the generality one can assume that

$$\partial^2_{\xi_1} a(\bar z) \ge \kappa. \tag{1.1.115}$$

Really, if one of the second derivatives with respect to ξ_j is greater than κ by absolute value we can reach our inequality by rotation (and multiplication of a by some constant); if it is true for one of the second derivatives with respect to x_j can reach the previous case by rotation and h-Fourier transform; if one of the mixed x,ξ-derivatives we can reach the previous case by gauge transformation:

$$a^{\mathrm{w}}(x,hD) \mapsto e^{-\frac{i}{2}h^{-1}\langle Qx,x\rangle} a^{\mathrm{w}}(x,hD) e^{\frac{i}{2}h^{-1}\langle Qx,x\rangle}$$

with symmetric real matrix Q, transforming the symbol $a(x,\xi)$ to $a(x,\xi+Qx)$. One can prove easily that

$$e^{-\frac{i}{2}h^{-1}\langle Qx,x\rangle}a^{\mathrm{w}}(x,hD)e^{\frac{i}{2}h^{-1}\langle Qx,x\rangle} = b^{\mathrm{w}}(x,hD), \qquad b(x,\xi)=a(x,\xi+Qx). \tag{1.1.116}$$

Then under assumption (1.1.115) in $B(\bar{z},\epsilon)$

$$a(x,\xi) = b(x,\xi)^2 + a_1(x,\xi'), \qquad x'=(x_2,\dots,x_d),\ \xi'=(\xi_2,\dots,\xi_d) \tag{1.1.117}$$

where $a_1 = a(x,t(x,\xi'),\xi') \ge 0$ and $\xi_1 = t(x,\xi')$ is a solution to equation $\partial_{\xi_1} a = 0$ and a, b are real-valued. Further, one can prove easily that derivatives of a_1, b up to order k are estimated by derivatives of a up to order $k+2$ (multiplied by a some constant).

Then

$$a^{\mathrm{w}}(x,hD) \equiv b^{\mathrm{w}}(x,hD)^* b^{\mathrm{w}}(x,hD) + a_1^{\mathrm{w}}(x,hD') + h^2\boldsymbol{\Psi} \tag{1.1.118}$$

where $\boldsymbol{\Psi}$ denotes the class of bounded h-pseudodifferential operators. Therefore inequality (1.1.112) for $a^{\mathrm{w}}(x,hD)$ is reduced to the same inequality for $a_1^{\mathrm{w}}(x,hD')$; this is an operator-valued function and one needs to prove (1.1.112) for each x_1 with an inner product in $\mathscr{L}^2(\mathbb{R}^{d-1})$. Reduction is done.

Step 2. Rescaling. Assume now that

$$|\nabla^\alpha a| \le c_\alpha r^{4-|\alpha|} \qquad \forall \alpha : |\alpha| \le K \tag{1.1.119}$$

and that

$$\text{Either } a(\bar{z}) \asymp r^4 \text{ or } |\nabla^2 a(\bar{z})| \asymp r^2 \text{ with } r \ge Ch^{\frac{1}{2}}. \tag{1.1.120}$$

In this case we can rescale: $x \mapsto x_{\mathrm{new}} = r^{-1}x$, $\xi \mapsto \xi_{\mathrm{new}} = r^{-1}\xi$ and thus $B(\bar{z},\epsilon r) \mapsto B(r^{-1}\bar{z},\epsilon))$, $h \mapsto h_{\mathrm{new}} = r^{-2}h$ and $a(x,\xi) \mapsto a_{\mathrm{new}}(x,\xi) = r^{-4}a(rx,r\xi)$. Then we get $-Cr^4h_{\mathrm{new}}^2 = -Ch^2$ in the right-hand side of our target inequality.

Step 3. Choice of scale. Let us introduce *scaling function*

$$r(z) = \epsilon_0\big(a(z) + |\nabla^2 a(z)|^2\big)^{\frac{1}{4}} + Ch^{\frac{1}{2}} \tag{1.1.121}$$

in $\mathbb{R}^{2d}$. Furthermore

(1.1.122) If $f(z) \ge 0$ and $|\nabla^4 f| \le c$ in $\mathbb{R}^n$ then in each point

$$|\nabla f(z)| \le C f(z)^{\frac12} |\nabla^2 f|^{\frac12} + C f^{\frac34}, \tag{1.1.123}$$

$$|\nabla^3 f(z)| \le C |\nabla^2 f|^{\frac12} + C f^{\frac14} \tag{1.1.124}$$

with an appropriate constant C.

One can prove (1.1.123), (1.1.124) basing on Taylor decomposition up to fourth order terms. Further, one can prove then that for an appropriate constant $\epsilon_0 > 0$

$$|\nabla_z r| \le \frac{1}{2}, \tag{1.1.125}$$

(1.1.119) holds and either (1.1.120) holds or $r \le 2Ch^{\frac12}$.

Then we conclude that

(1.1.126) Inequality (1.1.112) holds for symbol a replaced by $a_\phi = a\phi$ where ϕ satisfies (1.1.120) for some $\bar z$ and $r = r(\bar z)$.

Indeed, if $r(\bar z) \ge 2Ch^{\frac12}$ it follows from Step 2. If $r(\bar z) \le 2Ch^{\frac12}$ then $h_{\mathsf{new}} \asymp 1$ and our inequality is trivial (after rescaling).

Step 4. Partition. Now we need an *r-admissible partition*. Namely, as *scaling function* $r(z)$ satisfies (1.1.125), there is a partition of unity $1 = \sum_\nu \psi_\nu^2$, such that

(1.1.127) Each ψ_ν satisfies (1.1.114), is supported in the ball $B(z_\nu, \frac12 r(z_\nu))$ and balls $B(z_\nu, r(z_\nu))$ cover $\mathbb{R}^n$ with multiplicity not exceeding $C(d)$.

To construct such partition one needs to construct first covering of $\mathbb{R}^n$ by balls $B(z_\nu, \frac13 r(z_\nu))$ with the distance $|z_\nu - z_\mu| \ge \frac14 \max\big(r(z_\nu), r(z_\mu)\big)$; then we have multiplicity condition fulfilled. Let $\psi'_\nu(z) = \chi((z - z_\nu)/r(z_\nu))$ with smooth function χ, supported in $B(0, \frac12)$ and equal 1 in $B(0, \frac13)$. Then $\phi = \sum_\nu \psi_\nu(z)^2$ is a smooth function, satisfying (1.1.114) in $B(z_\nu, \frac23 r(z_\nu))$ for each ν and disjoint from 0. Finally $\psi_\nu = \phi^{-\frac12}\psi'_\nu$ satisfy (1.1.127).

More general scaling should reflect the different scales with respect to x, ξ and even more general scaling can be introduced by *temperate metric* (see Definition 18.5.1 in L. Hörmander [1], Vol. III).

Now one can quantize ψ'_ν and construct instead operators $\hat{\psi}'_\nu = {\psi'_\nu}^{\mathsf{w}}$, $\hat{\phi} = \sum_\nu \hat{\psi}'_\nu \hat{\psi}'_\nu$ and $\hat{\psi}_\nu = \hat{\psi}'_\nu \hat{\phi}^{-\frac{1}{2}}$. One can see easily that $\hat{\psi}'_\nu$ and $\hat{\phi}$ are Hermitian operators, $h_\nu^{-1}(\hat{\psi}^*_\nu - \hat{\psi}_\nu)$ satisfies (1.1.114) with $h_\nu = h/r(z_\nu)^2$ and

$$I = \sum \hat{\psi}^*_\nu \hat{\psi}_\nu. \tag{1.1.128}$$

Then we arrive to decomposition

$$(Au, u) = \sum_\nu (\hat{\psi}^*_\nu \hat{\psi}_\nu Au, Au) = \sum_\nu (A_\nu \hat{\psi}_\nu u, \hat{\psi}_\nu u) - \frac{1}{2}(Tu, u) + (Ru, u)$$

with

$$T = \hat{\psi}^*_\nu [A_\nu, \hat{\psi}_n] \; - \; [A_\nu, \hat{\psi}^*_\nu]\hat{\psi}_\nu, \qquad R = \sum_\nu \psi^*_\nu \psi_\nu (A - A_\nu)$$

where $A_\nu = (A\phi_\nu)^{\mathsf{w}}(x, hD)$, ϕ_ν satisfies (1.1.114), is supported in $B(z_\nu, \frac{3}{4}r(z_\nu))$ and equal 1 in $B(z_\nu, \frac{2}{3}r(z_\nu))$.

One can see easily that operator norms of each term in the sum defining T, R does not exceed $r(z_\nu)^4 h_\nu^2 = h^2$. Then using arguments of the proofs of Theorems 1.1.9, 1.1.22 one can prove easily that both (Tu, u) and (Ru, u) do not exceed $Ch^2\|u\|^2$ (surely we have a more tricky partition but it is not a grave problem. We are skipping this part).

On the other hand, due to Step 2 $(A_\nu \hat{\psi}_\nu u, \hat{\psi}_\nu u) \ge -Ch^2 \|\hat{\psi}_\nu u\|^2$ and $\sum_\nu \|\hat{\psi}_\nu u\|^2 = \|u\|^2$ due to (1.1.128).

Combining these inequalities we arrive to (1.1.112). □

It looks like Theorem 1.1.31 is very sharp. Surely it is. But in many cases it gives a wrong lower bound! Namely, let us look in $d = 1$ at Harmonic oscillator $H = x^2 + (hD)^2$. Its spectrum is $\{h, 3h, 5h, ...\}$ and $(Hu, u) \ge h\|u\|^2$ while Theorem 1.1.31 claims that $(Hu, u) \ge -Ch^2\|u\|^2$. Actually formally this theorem is not applicable since H has unbounded symbol and is unbounded operator but one can overcome this easily. Let us discuss another inequality for scalar operators which covers this gap even in general it is less sharp than Theorem 1.1.31. It also involves some *symplectic* notions.

Theorem 1.1.32. *Let $a(x,\xi)$ be scalar, real-valued and satisfy* (1.1.77). *Let*

$$a(x,\xi) + h\,\mathsf{Tr}^+(\mathsf{Hess}^{\#}\, a)(x,\xi) \ge 0 \tag{1.1.129}$$

where

$$\mathsf{Hess}\, a = \begin{pmatrix} a_{xx} & a_{x\xi} \\ a_{\xi x} & a_{\xi\xi}\end{pmatrix}, \tag{1.1.130}$$

$$\mathsf{Hess}^{\#}\, a = \begin{pmatrix} a_{\xi x} & a_{\xi\xi} \\ -a_{xx} & -a_{x\xi}\end{pmatrix} = \begin{pmatrix} 0 & I \\ -I & 0\end{pmatrix} \mathsf{Hess}\, a$$

are $2d\times 2d$-matrices called <u>Hessian</u> and <u>skew-Hessian</u> of a respectively, $\mathsf{Tr}^+(\mathsf{Hess}^{\#})a$ is a half-sum of absolute values of eigenvalues of $\mathsf{Hess}^{\#}\, a$. Then for any $\epsilon>0$

$$(a^{\mathsf{w}}(x,hD)u,u) \ge -(\epsilon h - C_\epsilon h^2)\|u\|^2 \tag{1.1.131}$$

for all u, $h\le 1$.

Proof. Let sketch the proof. First of all we can always make ε-partition of unity in $\mathbb{R}^{2d}$ with arbitrarily small constant $\epsilon>0$ (actually since our remainder estimate is $o(h)$ we can take even $L_\epsilon h^{\frac12}$-partition with large enough L_ϵ).

Let us look at Step 1 of the proof of Theorem 1.1.31. Repeating it as long as $|\nabla^2 a|$ or $|\nabla^2 a_1|$ etc are disjoint from 0 we will get that we can reduce symbol to $b_1^2+\ldots+b_I^2+a_I$ where $|\nabla^2 a_I|$ is small enough and then it would be sufficient to prove (1.1.131) for symbol $a'=g-h\,\mathsf{Tr}^+\,\mathsf{Hess}^{\sigma}\, g$, $g=b_1^2+\cdots+b_I^2$. Furthermore, in this construction $\nabla b_1,\ldots\nabla b_I$ are linearly independent.

Now it would be sufficient to check (1.1.129) on manifold $\Sigma=\{(x,\xi): b_1=\ldots=b_I=0\}$ and one can check easily that on Σ non-zero eigenvalues of $\mathsf{Hess}^{\#}\, g$ are those of skew-symmetric matrix $(\{b_j,b_k\})_{j,k=1,\ldots,I}$ (and thus these eigenvalues are purely imaginary).

Further, one can replace system $b_1,\ldots,b_I$ by $b_1',\ldots,b_I'$, $b_j'=\sum_k \alpha_{jk}b_k$ with orthogonal real matrix (α_{jk}) in the way that at some point $\bar z\in\Sigma$ matrix $(\{b_j',b_k'\})$ is in the canonical form: $\{b_j',b_k'\}=\rho_m$ as $j=2m-1, k=2m$, $m=1,\ldots,r$, $\{b_j',b_k'\}=-\rho_m$ as $j=2m, k=2m-1$, $m=1,\ldots,r$ and $\{b_j',b_k'\}=0$ otherwise where $\pm i\rho_m$ $(m=1,\ldots,r)$ are non-zero eigenvalues of

$(\{b_j, b_k\})$ and $\rho_m > 0$. Therefore it is sufficient to prove (1.1.131) as $I = 2$. Now it is reduced to

$$\|B_1 u\|^2 + \|B_2 u\|^2 + i([B_1, B_2]u) \geq -Ch^2\|u\|^2 \tag{1.1.132}$$

because replacing B_j by $B_j + \frac{h}{2}\mu_j$ we can always get rid of terms $(h\mu_j B_j u, u)$ with pseudodifferential operators μ_1, μ_2. However the left-hand expression of (1.1.132) is exactly $\|(B_1 + iB_2)u\|^2$ as long as B_j are symmetric. □

Inequality (1.1.131) (Melin's inequality) gives a correct lower bound of the spectrum of $a(x, hD)$. Really, for quadratic symbol

$$a(x,\xi) = \sum_{\alpha,\beta:|\alpha|+|\beta|=2} c_{\alpha\beta} x^\alpha \xi^\beta$$

which is non-negative, the bottom of the spectrum of $a^{\mathrm{w}}(x, hD)$ is exactly $h\,\mathsf{Tr}^+(a)$.

There is more limited but more precise statement which we will not prove:

Theorem 1.1.33. *Let $b_1, \dots, b_k$ be real valued symbols with $\nabla b_1, \dots, \nabla b_I$ linearly independent at $\Sigma = \{b_1 = \dots = b_I = 0\}$. Furthermore, let matrix $\beta = (\{b_j, b_k\})$ have a constant rank on Σ and let $a = b_1^2 + \dots + b_I^2 + hb_0$ with $b_0 = -h\,\mathsf{Tr}^+(\beta)$ on Σ. Then* (1.1.131) *holds.*

Remark 1.1.34. (i) Theorems 1.1.31–1.1.33 remain true even if only the principal symbol a_0 is scalar.

(ii) A generalization of Melin's inequality to 2×2-matrix case is known. See f.e. R. Brummelhuis [2].

Parametrix and Inverse

Now let us consider parametrix construction.

Theorem 1.1.35. *Let $a \in \mathsf{S}_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}', \mathbb{H})$. Assume that $\|\!|a|\!\| \leq c$ and its principal symbol a_0 is left invertible or right invertible at every point $(x,\xi) \in \Omega \subset \mathbb{R}^d \times \mathbb{R}^d$:*

$$b_0(x,\xi)a_0(x,\xi) = I \qquad \text{or} \qquad a_0(x,\xi)b_0(x,\xi) = I \tag{1.1.133}$$

with

$$\|\!|b_0|\!\| \le c. \tag{1.1.134}$$

Then there exists a symbol $b \in \mathsf{S}_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}, \mathbb{H}')$ *with* $\|\!|b|\!\| \le C = C(d, N, c)$ *such that respectively*

$$b \bullet_N a = I \qquad or \qquad a \bullet_N b = I \quad in \ \ \Omega. \tag{1.1.135}$$

Proof. One can define b_n recursively by

$$b_n = -\Big(\sum_{m<n} b_m h^m \bullet a\Big)_n b_0, \qquad b_n = -b_0\Big(a \bullet \sum_{m<n} b_m h^m\Big)_n \tag{1.1.136}$$

in the case of left (right) invertible symbol a_0. Note that in this construction b_n depends only on $D_x^\alpha D_\xi^\nu a_k$ with $|\alpha| \le n-k, |\nu| \le n-k$ at this point. In particular, if $\mathbb{H}' = \mathbb{H}$, $a_0 = I, a_1 = ... = a_n = 0$ in Ω then in this construction $b_0 = I, b_1 = ... = b_n = 0$ in Ω as well. □

Remark 1.1.36. (i) If $a_0(x,\xi)$ is invertible (i.e. both left and right invertible) then $a_0 b_0 = b_0 a_0 = I$ with $b_0 = a_0^{-1}$. Condition (1.1.134) is then replaced by

$$\|a_0^{-1}(x,\xi)\| \le c. \tag{1.1.137}$$

(ii) Further, both recursive formulae in (1.1.136) are equivalent. Really, let b and b' be left and right inverse symbols in the sense of (1.1.135). Then $b \equiv b \bullet Na \bullet_N b' \equiv b'$ implies that $b_n = b'_n$ for all n which is not obvious from (1.1.136). Furthermore one can see easily that in this case b is defined uniquely in Ω.

We would call operator $\mathsf{Op}(a)$ *left elliptic*, *right elliptic* or *elliptic* in the corresponding cases and we will call operator $\mathsf{Op}(b)$ a *left parametrix*, *right parametrix* or *parametrix* in Ω of operator $\mathsf{Op}(a)$.

Corollary 1.1.37. *If* a_0 *is either left invertible, or right invertible, or invertible in* $\mathbb{R}^d \times \mathbb{R}^d$ *and* (1.1.134) *holds then for* $h \le h_1$ *operator* $\mathsf{Op}(a)$ *is either left invertible, or right invertible, or invertible and the corresponding inverse belongs to the same class.*

We know that if the principal symbol of inverse operator is inverse to the principal symbol. We leave to the reader an easy proof of the following useful formula:

$$\begin{aligned}(1.1.138)\quad \bigl(A^{-1}\bigr)^s = -a_0^{-1}a^s a_0^{-1} - \\ \frac{i}{2}\sum_j a_0^{-1}\Bigl((\partial_{\xi_j}a_0)a_0^{-1}(\partial_{x_j}a_0) - (\partial_{x_j}a_0)a_0^{-1}(\partial_{\xi_j}a_0)\Bigr)a_0^{-1};\end{aligned}$$

further, if a_0 is a scalar symbol the last line vanishes and

$$(1.1.139)\qquad \bigl((\lambda - A)^{-1}\bigr)^s = -a^s a_0^{-2}.$$

Resolvent

As $\mathbb{H}' = \mathbb{H}$ we can apply these arguments to the resolvent construction. Let A be a quantization of $a \in \mathsf{S}_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}, \mathbb{H})$. The we define

$$(1.1.140)\qquad \Sigma(a) = \overline{\bigcup_{(x,\xi)} \mathsf{Spec}\bigl(a_0(x,\xi)\bigr)}.$$

In other words, $\Sigma(a)$ is a minimal closed subset in $\mathbb{C}$ such that $\bigl(\lambda - a_0(x,\xi)\bigr)$ is invertible as $\lambda \notin \Sigma(a)$ and $\bigl\|\bigl(\lambda - a_0(x,\xi)\bigr)^{-1}\bigr\| \le C = C(\lambda)$ for all $(x,\xi) \in \mathbb{R}^d \times \mathbb{R}^d$. Obviously

(1.1.141) Let $a \in \mathsf{S}_{h,N}$. Then $\Sigma(a) \subset \{\lambda \in \mathbb{C}, |\lambda| \le C_0\}$ and also $\bigl\|\bigl(\lambda - a_0(x,\xi)\bigr)^{-1}\bigr\| \le C_0|\lambda|^{-1}$ as $|\lambda| \ge C_0$;

(1.1.142) Let $a(x_0,\xi)$ be Hermitian for all (x,ξ). Then $\Sigma(a) \subset \mathbb{R}$ and also $\bigl\|\bigl(\lambda - a_0(x,\xi)\bigr)^{-1}\bigr\| \le C_0|\operatorname{Im}\lambda|^{-1}$.

Now it follows immediately from Theorem 1.1.35, Remark 1.1.36 and Corollary 1.1.37 that

Theorem 1.1.38. *Let A be a pseudodifferential operator with symbol $a \in \mathsf{S}_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}, \mathbb{H})$. Then*

(i) For arbitrarily small $\epsilon > 0$ $\mathsf{Spec}(A)$ is contained in ϵ-vicinity of $\Sigma(a)$ as $h \le h_0(\epsilon)$;

(ii) Let $r(\lambda) = r_{(N)}(\lambda, h)$ *be a result of standard parametrix construction (truncated modulo* $O(h^N)$*). Then as* λ *does not belong* ϵ*-vicinity of* $\Sigma(a)$

$$\|(A-\lambda)^{-1} - \mathsf{Op}\big(r(\lambda)\big)\| \le C|\lambda|^{-N-1}h^N. \tag{1.1.143}$$

We will consider a more precise statement in (1.1.152).

Remark 1.1.39. (i) The kind of inverse statement follows from (1.1.164).

(ii) Furthermore, as operator A is Hermitian (i.e. $A = a^{\mathsf{w}}(x, hD)$ with Hermitian $a(x,\xi)$) all such statements are really about the distance to the spectrum).

Analytic Functional Calculus of Pseudodifferential Operators

Let f be an analytic in $\mathcal{G} \supset \mathsf{Spec}(A)$ function and ℓ a closed contour in $\mathcal{G}$ going around spectrum of A exactly once in counter-clock-wise direction (ℓ is not necessarily connected). Then according to Real Analysis

$$f(A) = \frac{1}{2\pi i}\oint_{\ell} f(\lambda)(\lambda - A)^{-1}\,d\lambda. \tag{1.1.144}$$

Plugging into Theorem 1.1.38 we arrive to

Theorem 1.1.40. *Let* $A = \mathsf{Op}(a)$, $a \in \mathsf{S}_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}, \mathbb{H}, \mathbb{H})$ *and* $\Sigma(a)$ *be defined by* (1.1.140)*. Further, let* $\mathcal{G}$ *be a vicinity of* $\Sigma(a)$ *and* $f(\lambda)$ *analytic in* $\mathcal{G}$*. Then for* $h \le h_1$ *(with small enough constant* $h_1 > 0$*)* $f(A) \in \mathbf{\Psi}_{h,N}$ *and coincides modulo* $O(h^N)$ *with*

$$f^{\bullet}(a) = \frac{1}{2\pi i}\oint_{\ell} f(\lambda) r_{(N)}(\lambda, h)\,d\lambda \tag{1.1.145}$$

with $r_{(N)}(\lambda, h)$ *defined in Theorem 1.1.38(ii).*

Furthermore, the principal symbol of $f(a)$ *is* $f(a_0)$*.*

Formula (1.1.139) implies that if a_0 is a scalar symbol then

$$\big(f(A)\big)^s = -a^s f'(a_0). \tag{1.1.146}$$

Remark 1.1.41. (i) Assume instead that $\Sigma(a) \subset \mathcal{G} \cup \mathcal{G}'$ where $\mathcal{G} \cap \mathcal{G} = \emptyset$. Then (1.1.144) defines $f(A)\Pi_{\mathcal{G}}$ where $\Pi_{\mathcal{G}} = \chi_{\mathcal{G}}(A)$ is also defined by (1.1.144) with $f = 1$ is a projector, $\chi_{\mathcal{G}}$ is a characteristic function of $\mathcal{G}$. In particular, as a_0 is Hermitian elliptic symbol we conclude that $|A|^t$ and $\theta(\pm A)|A|^t$ are pseudodifferential operators where θ is a Heaviside function and $t \in \mathbb{C}$.

(ii) One can define $\Sigma(a,\Omega)$ and run the whole construction on the (full) symbol rather than operator level.

We need however to consider a more delicate case and to be more precise. Namely let us now assume that

$$\|(\tau - a_0(x,\xi))^{-1}\| \le c\,\mathsf{dist}(\tau,\Sigma)^{-p} \qquad \forall (x,\xi)\in \mathbb{R}^d\times\mathbb{R}^d\ \forall \lambda\in\mathbb{C} : |\lambda|\le C_0 \tag{1.1.147}$$

with an exponent $p\ge 1$ where $\Sigma(a)\subset\Sigma\subset\{|\lambda|<C_0\}$.

Remark 1.1.42. Condition (1.1.147) is satisfied with $\Sigma=\Sigma(a)$ provided either

$$\mathbb{H}=\mathbb{C}^r\otimes\mathbb{H}_0,\quad a_0(x,\xi)=b(x,\xi)\otimes I,\quad p=r \tag{1.1.148}$$

or

$$a_0(x,\xi)^\dagger = a_0(x,\xi)\quad \forall (x,\xi),\quad p=1. \tag{1.1.149}$$

Note that in the resolvent construction each new term norm gains factor $O(h\|(\tau-a_0(x,\xi))^{-1}\|^2)$. Therefore as $\mathsf{dist}(x,\Sigma)\ge\eta^{1/p}$ with

$$\eta \ge h^{\frac12-\delta} \tag{1.1.150}$$

with an arbitrarily small exponent $\delta>0$ the resolvent construction is justified and the error is $O(h^N\eta^{-(2N+1)})$. Further, after rescaling $x\mapsto x/\eta$, $\xi\mapsto\xi/\eta$, $h\mapsto\hbar=h/\eta^{2p}$ $\quad j$-th term satisfies (1.1.77) with $M_j=h^j\eta^{-2j-1}$.

In particular

$$\|(\tau-A)^{-1}\|\le C\eta^{-1},\quad \|(\tau-A)^{-1}-\mathsf{Op}\big((\tau-a_0)^{-1}\big)\|\le Ch\eta^{-3}. \tag{1.1.151}$$

Also we conclude that

(1.1.152) $\mathsf{Spec}(A)$ is contained in $Ch^{1/2p}$ vicinity of Σ.

Combining with (1.1.144) we arrive to

Theorem 1.1.43. *Let* (1.1.47) *be fulfilled. Let f be analytic in $\mathcal{G}$ and ℓ be a closed contour in $\mathcal{G}$ going around spectrum of A exactly once in counter-clock-wise direction on the distance no less than $\epsilon_0\eta^{1/p}$ from Σ. Then*

$$\|f(A)-\mathsf{Op}\big(f^\bullet(a)\big)\|\le Ch^N\eta^{-2N-1}\|f\|_{\mathscr{L}^1(\ell)} \tag{1.1.153}$$

where symbol $f^\bullet$ is defined by (1.1.145) *and each term in its decomposition does not exceed $Ch^j\eta^{-2j-1}\|f\|_{\mathscr{L}^1(\ell)}$.*

Further,

$$\|f(A)\| \le C\eta^{-1}\|f\|_{\mathscr{L}^1(\ell)}, \quad \|f(A) - \mathsf{Op}\big(f(a_0)\big)\| \le CMh\eta^{-3}. \tag{1.1.154}$$

Smooth Functional Calculus of Pseudodifferential Operators

As operator A is Hermitian (or unbounded self-adjoint) one can construct $f(A)$ with smooth function f. Let us look for a smooth function of a Hermitian pseudodifferential operator. Since one can define $f(A)$ through propagator e^{itA} let us consider such operators first but we need to consider them for large $t \in \mathbb{R}$ as well.

Let us apply analytic theory to $\varphi_t(\tau) = e^{it\tau}$ under condition (1.1.49) (we do not need a stronger condition at this moment). Then $p = 1$. To avoid exponential growth with respect to t we must bound $|t\,\mathsf{Im}\,\tau|$; so let ℓ be a boundary of the rectangle $\{|\,\mathsf{Re}\,\tau| \le c, |\,\mathsf{Im}\,\tau| \le |t|^{-1}\}$, where we assume that $\Sigma(a) \subset [-\frac{1}{2}c, \frac{1}{2}c]$. Then $\|\varphi_t\|_{\mathscr{L}^1(\ell)} \asymp 1$ and therefore

$$\|e^{itA} - \mathsf{Op}(\varphi_t^\bullet(a))\| \le Ch^s \tag{1.1.155}$$

and

$$\|\,\mathsf{Op}(\varphi_t^\bullet(a))\| \le C|t|, \qquad \|\,\mathsf{Op}(\varphi_t^\bullet(a)) - \mathsf{Op}(e^{ita_0})\| \le Ch|t|^3 \tag{1.1.156}$$

provided $t \in \mathbb{R}, 1 \le |t| \le h^{(\delta-1)/2}$.

Moreover, note that the terms $r_n(\tau)$ in the decomposition of the symbol $r(\tau)$ are sums of terms of the form

$$(\tau - a_0)^{-1} b_1 (\tau - a_0)^{-1} \cdots (\tau - a_0)^{-1} b_{j-1} (\tau - a_0)^{-1} h^n$$

with $j \le 2n+1$, $b_k = b_{njk} \in \mathsf{S}_{h,N-(2n+1)+j}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}, \mathbb{H})$ do not depend on τ and the number of these terms does not exceed $K_0(n)$.

Then we conclude that the terms $\varphi_{tn}^\bullet$ in the decomposition of the symbol $\varphi_t^\bullet$ are sums of terms of the form $g(t) * b_1 g(t) * \cdots * b_{j-1} g(t) h^n$ where "$*$" means convolution and

$$g(t) = \frac{1}{2\pi i} \oint_\ell (\tau - a_0)^{-1} e^{it\tau}\, d\tau = e^{ita_0};$$

hence $\varphi_{tn}^\bullet$ is a sum of terms of the form

$$t^{j-1} h^n \int \cdots \int_{\Delta_{j-1}} e^{itz_1 a_0} b_1 e^{itz_2 a_0} \cdots b_{j-1} e^{itz_j a_0}\, dz' \tag{1.1.157}$$

with $z_j = 1 - z_1 - ... - z_{j-1}$, $dz' = dz_1 \cdots dz_{j-1}$ and
$\Delta_{j-1} = \{z' \in \mathbb{R}^{j-1} : z_k > 0 \quad \forall k, z_1 + ... z_{j-1} < 1\}$. Recall that $j \le 2n+1$.

Note that for any first-order differentiation ∂ the following formula holds:

$$\partial e^{ita_0} = \int_0^t e^{it'a_0}(i\partial a_0)e^{i(t-t')a_0}\, dt'. \tag{1.1.158}$$

Applying this formula to (1.1.157) we conclude easily that

$$\| \mathsf{Op}(\varphi_t^\bullet(a))\| \le C, \qquad \| \mathsf{Op}(\varphi_t^\bullet(a)) - \mathsf{Op}(e^{ita_0})\| \le Ch\gamma^{-2} \tag{1.1.159}$$

provided $|t| \le h^{(\delta-1)/2}$. So we have improved estimates (1.1.156).

Therefore we arrive to

Theorem 1.1.44. *Under condition* (1.1.149) e^{itA} *is a pseudodifferential operator with the symbol satisfying* (1.1.95) *with* $\boldsymbol{\rho} = \boldsymbol{\gamma} = |t|^{-1}\mathbf{1}$ *provided* $|t| \le ch^{(\delta-1)/2}$, $\mathbf{1} = (1, 1, ..., 1)$.

Remark 1.1.45. (i) One can see easily that symbol e^{ita_0} satisfies (1.1.95) with $\boldsymbol{\rho} = \boldsymbol{\gamma} = |t|^{-1}\mathbf{1}$ provided $|t| \le ch^{(\delta-1)/2}$ and one cannot improve this statement;

(ii) Note that for a scalar symbol a_0 the symbol $\varphi_{tn}^\bullet$ is a symbol of the form

$$e^{ita_0} \sum_{0\le n\le N,\, j\le 2n} b_{nj} h^n t^j. \tag{1.1.160}$$

Now we can consider smooth functions of Hermitian operator. Assume that $A^* = A$ and $f \in \mathscr{C}^N(\mathbb{R})$ satisfies

$$\langle\tau\rangle^2 |D_\tau^j f(\tau)| \le M\eta^{-j} \quad \forall j \le N \qquad \text{for } \eta \in [h^{\frac{1}{2}(1-\delta)}, 1],\ \delta > 0 \tag{1.1.161}$$

with $\langle\tau\rangle = (1 + |\tau|^2)^{1/2}$. Then $f(A)$ is given by the formula

$$f(A) = \int_{\mathbb{R}} \hat f(t) e^{itA}\, dt \tag{1.1.162}$$

where (1.1.161) implies that

$$|\hat f(t)| \le CM(1 + \eta|t|)^{-N}. \tag{1.1.163}$$

Consider integral (1.1.162) separately on $[-h^{(\delta'-1)/2}, h^{(\delta'-1)/2}]$ and on the remaining part of $\mathbb{R}$ where $\delta' > 0$ is a small enough exponent; then (1.1.163) implies that the operator norm of the second integral does not exceed

$$C\big(h^{(\delta'-1)/2}\eta\big)^{1-N}\eta^{-1} = O(h^s)$$

while in the first integral we can replace e^{itA} by $\mathsf{Op}(\varphi_t^\bullet(a))$. One can consider $\hat f(t)\varphi_t^\bullet(a))$ for $|t| \ge h^{(\delta'-1)/2}$ as a small and thus quantizable (generating a negligible operator); so one can take the integral on $\mathbb{R}$ again; the operator norm of the new error also is $O(h^s)$. We obtain then the sum of terms of the form

$$h^n \int_{\mathbb{R}} \mathcal{J}_{nj}(\tau) f(\tau)\, d\tau \tag{1.1.164}$$

where

$$\mathcal{J}_{nj}(\tau) = \mathsf{Res}_{\mathbb{R}}\, J_{nj} = \frac{1}{2\pi i}\big(J_{nj}(\tau + i0) - J_{nj}(\tau - i0)\big)$$

and $J_{nj}(\tau)$ are operator-valued functions of the form (1.1.157). Therefore $\mathcal{J}_{nj}(\tau)$ are distributions supported in $\mathcal{C} = \big\{(\tau, x, \xi) : \tau \in \mathsf{Spec}\big(a_0(x,\xi)\big)\big\}$; so $\mathsf{supp}(\mathcal{J}_{nj}) \subset \{|\tau| \le C_0\}$. Moreover, $|J_{nj}(\tau)| \le C|\,\mathsf{Im}\,\tau|^{-j} \quad \forall \tau \in \mathbb{C}$ and hence

$$\Big|\int J_{nj}(\tau \pm i0) f(\tau)\, d\tau\Big| \le C\|f\|_{\mathscr{C}^j} \tag{1.1.165}$$

for every $f \in \mathscr{C}_0^j([-2c, 2c])$. Therefore (1.1.158) implies that the term (1.1.164) does not exceed $Ch^n\eta^{-j}$. Moreover, applying $D^\alpha_{x,\xi}$ to (1.1.157) we obtain a function of the same type with $j + |\alpha|$ instead of j. So we obtain the first assertion of the following statement:

Theorem 1.1.46. *(i) Let conditions* (1.1.149) *and* (1.1.161) *be satisfied. Then the described procedure leads to a construction of quantizable symbol* $f^\bullet(a)$ *such that*

$$\|\,\mathsf{Op}(f^\bullet(a)) - \mathsf{Op}(f(a_0))\| \le CMh\eta^{-3}.$$

In particular as A *is Hermitian (f.e.* $a^\dagger = a$ *and we use Weyl quantization)* (1.1.153) *and* (1.1.154) *hold.*

(ii) Moreover, for scalar symbol a_0

$$\|f(A) - \mathsf{Op}\big(f(a_0)\big)\| \le CMh\eta^{-2}. \tag{1.1.166}$$

The proof of the second assertion is based on the fact that in this case

$$\int_{-2c}^{2c} |J_{nj}(\tau \pm i\eta)|\, d\tau \le C\eta^{1-j}$$

provided $j > 1$ and hence in the right-hand expression in (1.1.165) one can replace j by $(j-1)$.

Finally, for a scalar symbol a_0 formula (1.1.146) remains true.

Remark 1.1.47. Instead of (1.1.161) we can assume that $f_1 = \langle\tau\rangle^{-2l} f \in \mathscr{C}_b^K$ and derive Theorem 1.1.46 with $M = \|f_1\|_{\mathscr{C}_b^K}$ where

$$\mathscr{C}_b^K = \{g : \|g\|_K = \sum_{|\alpha|\le K} \sup |D^\alpha g| < \infty\};$$

surely in this case K and C depend on l also. In fact, $f(A) = (A^2 + I)^l f_1(A)$ where f_1 satisfies (1.1.161) with $\eta = 1$.

Families of Commuting Operators

One can easily derive results similar to those obtained in two previous sections for a family $A^1, \dots, A^n$ of commuting operators; these operators have commuting principal symbols; instead of spectrum one should consider a joint spectrum and introduce $\Sigma(a^1, \dots, a^n) \subset \mathbb{C}^n$; respectively one should consider $f(A^1, \dots, A^n)$ where either f is analytic in the vicinity of $\Sigma(a^1, \dots, a^n)$ or all operators $A^1, \dots, A^n$ are Hermitian.

We leave details to the reader.

Norms and bBounds

Gårding inequalities imply that for Hermitian operator its lower bound is not less than $\inf \Sigma(a_0) - CMh$ and its upper bound is not greater than $\sup \Sigma(a_0) + CMh$; this is a better result than $Ch^{1/2}$ error due to (1.1.152).

On the other hand, one can easily generalize Theorem 1.1.14 to operators of the type considered here: using arguments of the proof of Theorem 1.1.19 one can prove easily that $a(x, hD)\big(e^{ih^{-1}\phi} f\big)$ is negligible as $\operatorname{supp}(a)$ is disjoint from the set $\{x, \nabla\phi(x)\}$.

Let us consider $u = (2\pi h)^{-d/4} e^{ih^{-1}\phi} w$ with $\phi = \langle x, \bar\xi\rangle + i|x - \bar x|^2/2$ and $w \in \mathbb{H}$; one can prove easily that

$$(a^{\mathrm{w}}(x, hD)u, u) = \langle a(\bar x, \bar\xi) w, w\rangle + O(h)$$

and therefore we arrive to

Theorem 1.1.48. *For Hermitian operator operator*

$$|\inf \mathsf{Spec}(A) - \inf \Sigma(a)| \le CMh \tag{1.1.167}$$

and

$$|\sup \mathsf{Spec}(A) - \sup \Sigma(a)| \le CMh. \tag{1.1.168}$$

Remark 1.1.49. (i) In the general case one can apply Theorem 1.1.48 to operator $B = \frac{1}{2}(A + A^*)$;

(ii) If $\dim \mathbb{H} \ge 2$ it may happen that $\Sigma(a)$ is not connected. Let $\mathcal{G}$ be an open set in $\mathbb{C}$ such that $\Sigma(a) \cup \mathcal{G} \ne \emptyset$ and $\mathsf{dist}(\mathcal{G}, \Sigma(a) \setminus \mathcal{G}) \ge \epsilon_0$. Then one can apply (i) to $A\Pi_{\mathcal{G}}$ with projector $\Pi_{\mathcal{G}}$ introduced in Remark 1.1.41(i). This generalization makes sense for Hermitian operators as well as general ones.

(iii) Further, we can apply Theorem 1.1.46 to A^*A resulting in

$$|\, \|A\| - \sup_{(x,\xi)} \|a_0(x,\xi)\| \,| \le CMh. \tag{1.1.169}$$

1.1.3 Pseudodifferential Operators with Analytic Symbols and Logarithmic Uncertainty Principle

So far we considered pseudodifferential operators with finitely smooth symbols $N < \infty$. How one needs to modify results as $N = \infty$? Surely it concerns only results with the remainder estimates depending on N (unlike Gårding inequalities). The first answer is rather easy: all sums became asymptotic and all such remainder estimates are "$L_N h^N$ for all $N < \infty$".

The next question is "how L_N depend on N?" The answer we got already f.e. for the product of $a^w(x, hD)$ and $b^w(x, hD)$ is

$$L_N \le C_N \sum_{|\alpha|+|\beta|\le N} \|D_x^\alpha D_\xi^\beta a\|_{\mathscr{L}^\infty} \times \sum_{|\alpha|+|\beta|\le N} \|D_x^\alpha D_\xi^\beta b\|_{\mathscr{L}^\infty}$$

and if we look at the regular terms containing $\frac{1}{\alpha!\beta!}$ etc we can think that $C_N = C_0^N (N!)^{-1}$. Inequality (1.A.5) and formulae $(1.1.92)_1$–$(1.1.92)_3$ immediately prove this remainder estimate for all types of quantization.

To exploit this observation we need to consider operators with ultra-smooth symbols: those whose derivatives derivatives grow with the controlled rate: f.e. with

$$\|D_x^\alpha D_\xi^\beta a\|_{\mathscr{L}^\infty} \le M\varrho^{|\alpha|+|\beta|}(|\alpha|!)^\sigma(|\beta|!)^\varsigma \tag{1.1.170}$$

with $\sigma \ge 1$, $\varsigma \ge 1$ and ϱ independent on N. To be consistent we should assume that junior terms satisfy

$$\|D_x^\alpha D_\xi^\beta a_n\|_{\mathscr{L}^\infty} \le M\varrho^{|\alpha|+|\beta|+2n}(|\alpha|!)^\sigma(|\beta|!)^\varsigma(n!)^{\sigma+\varsigma-1} \tag{1.1.171}$$

Then the remainder estimate is $c^N h^N (N!)^{\sigma+\varsigma-1}$. One can see easily that there is a minimal value $N = N_h = \epsilon_0 h^{-1/(\sigma+\varsigma-1)}$ when estimate hits the minimum

$$\exp\bigl(-\epsilon h^{-1/(\sigma+\varsigma-1)}\bigr) \tag{1.1.172}$$

and this is "supersmall" remainder estimate.

We will reconstruct the theory of two previous subsections for such symbols and remainder estimates and with this notion of negligible. Obviously the best possible case is $\sigma = \varsigma = 1$ which corresponds to analytic symbols. One can object that there are no compactly supported symbols and therefore there is no microlocalization. However M. Bronstein observed that we need to satisfy estimates only as $|\alpha| + n \le N_h$, $|\beta| + n \le N_h$ and there are very regular families of symbols satisfying a bit weaker but still allowing quantization condition (see Proposition 1.A.2).

Further, this theory brings fruits even for the old notion of negligible $O(h^s)$. Namely, if estimate (1.1.171) holds only after rescaling $x_j \mapsto x_j/\gamma_j$, $\xi_j \mapsto \xi_j/\rho_j$, then the remainder estimate would be $O(\exp(-\epsilon\hbar^{1/(\sigma+\varsigma-1)})) = O(h^s)$ as $\hbar \le \epsilon s^{-1}|\log h|^{-(\sigma+\varsigma-1)}$.

Recall that $\hbar = \sup_j h/(\rho_j\gamma_j)$; so the previous condition becomes

$$\rho_j\gamma_j \ge C_s h|\log h|^{\sigma+\varsigma-1}. \tag{1.1.173}$$

As $\sigma = \varsigma = 1$ we arrive to the most important case

$$\rho_j\gamma_j \ge C_s h|\log h| \tag{1.1.174}$$

which we call *logarithmic uncertainty principle*.

Pseudodifferential operators with Infinitely Smooth Symbols

Definition 1.1.50. Let $\mathsf{S}_{h,\infty}$ be a class of the symbols satisfying (1.1.77) for all N (with constant depending on N). Denote by $\mathbf{\Psi}_{h,\infty}$ the corresponding class of pseudodifferential operators.

We immediately arrive to

Theorem 1.1.51. *Let $a_j \in \mathsf{S}_{h,\infty}$. Then there exist $a \in \mathsf{S}_{h,\infty}$ such that*

$$a \sim \sum_j h^j a_j \tag{1.1.175}$$

which means that for any N

$$a - \sum_{0\le j\le N-1} h^j a_j \in h^N \mathsf{S}_{h,\infty}. \tag{1.1.176}$$

Proof. Proof is the standard asymptotic exercise (very similar to the proof that for any sequence of numbers c_k there exists a function f such that $f^{(k)}(0) = c_k$). Namely let ϕ be a smooth function, supported in $(-2,2)$ and equal 1 in $(-1,1)$. Let us consider

$$a = \sum_j h^j a_j \phi(hl_j)$$

with $l_j \to \infty$ as $j \to \infty$. Then a is defined properly for each $h > 0$ (the sum is finite). We leave to the reader to prove that a is a proper symbol in the following steps: prove that the first of inequalities holds

$$|\partial^\alpha \sum_{j\ge N} h^j a_j \phi(hl_j)| \le C_N h^N \qquad \forall \alpha : |\alpha| \le N \tag{1.1.177}$$

$$|\partial^\alpha \sum_{j< N} h^j a_j (\phi(hl_j) - 1)| \le C_N h^N \qquad \forall \alpha : |\alpha| \le N \tag{1.1.178}$$

with proper constants C_N provided l_j grow fast enough; then one can prove easily that the second inequality holds with proper constants C_N. □

Then all the constructions of this chapter are valid with $N = \infty$ as well.

Pseudo-differential Operators with Analytic Symbols

We are interested *only* in the case of analytic symbols with $\sigma = \varsigma = 1$ leaving more general case of Gevrey symbols to the reader; the standard theory was developed by L. Boutet de Monvel and P. Krée [1], pp. 302–306 and semiclassical theory does not differ much. We follow this article here for analysis of symbols.

We introduce class $\mathsf{S}_{h,\mathsf{an}}$ of symbols

$$a(x,\xi,h) = \sum_{n:\le N} a_n(x,\xi,h)h^n, \quad N = N(C,h) = \epsilon_0 C^{-1}h^{-1}, \tag{1.1.179}$$

$$\|D^\alpha_{x,\xi} a_n\| \le MC^{|\alpha|+2n}|\alpha|!n! \qquad \forall \alpha, n : 2|\alpha| + n \le N + 2K, n \le N \tag{1.1.180}$$

where C, M could be arbitrarily large and ϵ_0, K depend only on d.

Equivalent but more technically convenient is

Definition 1.1.52. $\mathsf{S}_{h,\mathsf{an}} = \bigcup_{\varrho>0} \mathsf{S}_{h,\mathsf{an}}(\varrho)$ where $a \in \mathsf{S}_{h,\mathsf{an}}(\varrho)$ if *the formal norm* defined by *a formal power series* (1.1.80) converges for $|\zeta| < \varrho$:

$$P(a,\zeta) = \sum_{\alpha,n} \frac{\epsilon_1^{-1}\epsilon_0^{-n}}{(2n+|\alpha|)!}\zeta^{2n+|\alpha|} \sup_z \|\nabla^\alpha_z a(z)\| \tag{1.1.181}$$

where $z = (x,\xi)$ and we select $\epsilon_0, \epsilon_1 > 0$ later.

Proposition 1.1.53. *For small enough ϵ_0, ϵ_1 norm $P(a,\zeta)$ has following properties:*

$$P(a+b,\zeta) \lll P(a,\zeta) + P(b,\zeta), \tag{1.1.182}$$

$$P(a \bullet b,\zeta) \lll P(a,\zeta)\cdot P(b,\zeta), \tag{1.1.183}$$

where $\bullet$ is calculated for $N = \infty$ and we consider here formal symbols i.e. sum $\sum a_n h^n$ etc and $\sum_n A_n\zeta^n \lll \sum_n B_n\zeta^n$ means that $A_n \le B_n$ for all n.

Proof. We prove the second estimate. From obvious

$$\|\nabla^\alpha (a\bullet b)_n\| \le \sum_{\substack{l+m+|\gamma|=n,\,\gamma,\,\alpha'\ge\gamma,\,\alpha''\ge\gamma,\\ \alpha'+\alpha''=\alpha+2\gamma}} \frac{\alpha!}{(\alpha'-\gamma)!(\alpha''-\gamma)!\gamma!}\|\nabla^{\alpha'} a_l\|\cdot\|\nabla^{\alpha''} b_m\|$$

we conclude that

$$P(a\bullet b,\zeta)\lll \sum_{l,m,\gamma,\alpha',\alpha''} \frac{(\alpha'+\alpha''-2\gamma)!}{(\alpha'-\gamma)!(\alpha''-\gamma)!(2m+2l+|\alpha'|+|\alpha''|)!\gamma!}\times \\ \|\nabla^{\alpha'}a_l\|\cdot\|\nabla^{\alpha''}b_m\|\times \epsilon_1^{-1}\epsilon_0^{l+m+|\gamma|}\zeta^{2l+2m+|\alpha'|+|\alpha''|}$$

which equals

$$\sum_{l,m,\gamma,\alpha',\alpha''} \frac{(\alpha'+\alpha''-2\gamma)!}{(\alpha'-\gamma)!(\alpha''-\gamma)!}\cdot\frac{(2l+|\alpha'|)!(2m+|\alpha''|)!}{(2m+2l+|\alpha'|+|\alpha''|)!}\cdot\frac{\epsilon_1\epsilon_0^{|\gamma|}}{\gamma!}\times \\ \frac{\epsilon_1^{-1}\epsilon_0^{l}}{(2l+|\alpha'|)!}\|\nabla^{\alpha'}a_l\|\zeta^{2l+|\alpha'|}\cdot\frac{\epsilon_1^{-1}\epsilon_0^{m}}{(2m+|\alpha''|)!}\|\nabla^{\alpha''}b_m\|\zeta^{2m+|\alpha''|}$$

where in the first line the first and the second factor do not decrease if we replace γ by 0 and l,m by 0 as well; meanwhile $\sum_\gamma \frac{1}{\gamma!}\epsilon_0^{|\gamma|}\le e^{2d\epsilon_0}$ and Proposition 1.1.53 follows from estimate[5)]

$$\frac{(\alpha'+\alpha'')!}{\alpha'!\alpha''!}\le\frac{(|\alpha'|+|\alpha''|)!}{|\alpha'|!(|\alpha''|)!}\impliedby \frac{|\alpha'|!}{\alpha'!}\cdot\frac{|\alpha''|!}{\alpha''!}\le\frac{|\alpha'+\alpha''|!}{(\alpha'+\alpha'')!}$$

with the trivial from the combinatorial point of view last inequality. □

Then we arrive immediately to

Theorem 1.1.54. *Let $a,b\in \mathsf{S}_{h,\mathsf{an}}(\varrho)$. Then $a\bullet b\in \mathsf{S}_{h,\mathsf{an}}(\varrho)$ and with $N=N(\varrho^{-1},h)$)*

$$\|\operatorname{Op}(a)\operatorname{Op}(b)-\operatorname{Op}(a\bullet_N b)\|\le C_0\bar{P}(a,\varrho)\bar{P}(b,\varrho)\exp(-\epsilon_2\varrho h^{-1}) \tag{1.1.184}$$

where C_0 depends only on d and $\bar{P}(a,\varrho)$ is an actual sum of $P(a,\varrho)$.

Finally, consider two-sided parametrix.

Theorem 1.1.55. *Let $a\in \mathsf{S}_{h,\mathsf{an}}$ satisfy* (1.1.137)*. Then there exist $b\in \mathsf{S}_{h,\mathsf{an}}$ such that $a\bullet b=b\bullet a=I$.*

Proof. Note first that the following statement holds:

[5)] In [1] more general inequality is considered to be "easy". Still We prove this one (1.A.5).

(1.1.185) Let $a \in \mathsf{S}_{h,\mathsf{an}}(\varrho)$ with $\varrho > 0$. Assume that $\mathsf{sup}_{(x,\xi)} \|a_0(x,\xi)\| \le c$ and $\mathsf{sup}_{(x,\xi)} \|a_0(x,\xi)^{-1}\| \le c$. Then $a_0^{-1} \in \mathsf{S}_{h,\mathsf{an}}(\varrho')$ with some $\varrho' > 0$.

Then $a \bullet a_0^{-1} = I - hr$ with $r \in \mathsf{S}_{h,\mathsf{an}}(\varrho'')$ and $b = r' \bullet a$ with

$$r' \sim I + \sum_{n\ge 1} h^n \underbrace{r \bullet r \bullet \cdots \bullet r}_{n \text{ factors}}$$

and one can see easily that

$$P(r',\zeta) \lll 1 + \sum_{n\ge 1} \bigl(\zeta P(r,\zeta)\bigr)^n \tag{1.1.186}$$

which converges as $|\zeta| < \varrho'''$ with $\varrho''' \bar{P}(r,\varrho''') < 1$. □

1.1.4 Other Classes and Calculi of Pseudodifferential Operators

Let us describe now more traditional classes and calculi of pseudodifferential operators without visible parameter h. Instead of it a hidden parameter $\hbar = h_{\mathsf{eff}}$ appears. Now the notion of *order* appears; in semiclassical theory it was masked: instead of m-th order operator we used 0-th order one multiplied by h^{-m}. Another new property which comes with certain classes is invariance with respect to change of coordinates.

Classical Pseudodifferential Operators

Classical pseudodifferential operators were the first to be introduced historically:

Definition 1.1.56. (i) Symbol $a \in \mathscr{C}^\infty(\mathbb{R}^d \times \mathbb{R}^d)$ belongs to $\mathsf{S}^m_{\mathsf{cl}}$ with $m \in \mathbb{R}$ if

$$|D_x^\alpha D_\xi^\beta a(x,\xi)| \le C_{\alpha\beta} \langle \xi \rangle^{m-|\beta|} \qquad \forall \alpha, \beta \tag{1.1.187}$$

and

$$a \sim \sum_{j\ge 0} a_j \tag{1.1.188}$$

with symbols $a_j \in \mathscr{C}^\infty\big(\mathbb{R}^d \times (\mathbb{R}^d \setminus 0)\big)$ positively homogeneous of degrees $(m-j)$ in the sense that

$$|D_x^\alpha D_\xi^\beta \big(a(x,\xi) - \sum_{j\le n} a_j(x,\xi)\big)| \le C_{n\alpha\beta}\langle\xi\rangle^{m-n=|\beta|} \qquad \forall n,\alpha,\beta. \tag{1.1.189}$$

(ii) Meanwhile $\mathsf{S}^{-\infty}$ is a class of symbols satisfying (1.1.86) for all m and such symbols are *negligible*[6)].

(iii) Class $\boldsymbol{\Psi}^m_{\mathsf{cl}}$ consists of pseudodifferential operators of the form $\mathsf{Op}(a)$ with $h=1$ and $a \in \mathsf{S}^m_{\mathsf{cl}}$. Such operators are defined modulo negligible operators where negligible means *infinitely smoothing* operator i.e. continuous from $\mathscr{H}^t$ to $\mathscr{H}^r$ for all $t, r \in \mathbb{R}$.

Here $a^0 = a_0$ is *principal symbol* and with Weyl quantization $a^s = a_1$ is *subprincipal symbol*. Here and below $\mathscr{H}^r$ are equipped with the standard norms $\|u\|_{\mathscr{H}^r} = \|(I+|D|^2)^{r/2}u\|_{\mathscr{L}^2}$.

One can consider $m \in \mathbb{C}$; then one needs to replace m by $\mathsf{Re}\, m$ in the right-hand expressions of (1.1.187) and (1.1.189). We do not list any properties of them except that

Theorem 1.1.57. *(i) Let $A \in \boldsymbol{\Psi}^{m_1}_{\mathsf{cl}}$, $B \in \boldsymbol{\Psi}^{m_2}_{\mathsf{cl}}$. Then $AB \in \boldsymbol{\Psi}^{m_1+m_2}_{\mathsf{cl}}$; if one of operators is scalar then $[A,B] \in \boldsymbol{\Psi}^{m_1+m_2-1}_{\mathsf{cl}}$.*

(ii) Let $A \in \boldsymbol{\Psi}^m_{\mathsf{cl}}$ with principal symbol a_0 and $|a_0^{-1}(x,\xi)| \le c$ for all (x,ξ). Then there exists a parametrix $B \in \boldsymbol{\Psi}^{-m}_{\mathsf{cl}}$: $AB \equiv BA \equiv I$ (modulo negligible); similar statements hold for left and right parametrices.

(iii) Let $m=0$ and either f be analytic in the vicinity of $\mathsf{Spec}(A)$ or f be smooth and A be Hermitian. Then $f(A) \in \boldsymbol{\Psi}^0_{\mathsf{cl}}$. Moreover let $m<0$ be an integer; then $f(A) - f(0) \in \boldsymbol{\Psi}^m_{\mathsf{cl}}$ (as m not being integer powers $ml-k$ with $l,k \in \mathbb{Z}^+$ will appear in decomposition (1.1.188).

*(iv) $\boldsymbol{\Psi}^m_{\mathsf{cl}}$ is invariant with respect to change of coordinates (*see *Teorem 1.1.62 below for more details).*

Remark 1.1.58. Since "negligible" now means "infinitely smoothing" then parametrix does not mean exact invertibility and $\mathsf{Spec}(A)$ does not shrink to $\Sigma(a)$ defined by (1.1.40) as $m=0$ or to 0 as $m<0$.

[6)] So actually symbol classes S^m_{cl} and $S^m_{\sigma,\varsigma}$ defined below are considered modulo $\mathsf{S}^{-\infty}$.

Theorem 1.1.59. *(i) Let* $A \in \boldsymbol{\Psi}^m_{\mathsf{cl}}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *be self-adjoint and moreover*

$$A - \epsilon(I + |D|^2)^{m/2} \geq 0 \tag{1.1.190}$$

in operator sense. Then $A^l \in\in \boldsymbol{\Psi}^{ml}_{\mathsf{cl}}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *for any* $l \in \mathbb{R}$ *(and even* $l \in \mathbb{C}$*); further, its principal symbol is* a_0^l *and if* a_0 *is scalar, its subprincipal symbol is* $l a^s a_0^{l-1}$.

(ii) Let $A \in \boldsymbol{\Psi}^m_{\mathsf{cl}}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *be self-adjoint and moreover*

$$\|Au\| \geq \epsilon \|(I + |D|^2)^{m/2} u\| \qquad \forall u \in \mathscr{L}(\mathbb{R}^d, \mathbb{H}); \tag{1.1.191}$$

Consider orthogonal (in $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H})$*) projectors* $\Pi^{\pm}$ *on positive and negative subspaces of* A*. Then* $\Pi^{\pm} \in\in \boldsymbol{\Psi}^0_{\mathsf{cl}}$*; their principal symbols are* $\pi^{\pm}(x, \xi)$ *(orthogonal projectors to positive and negative subspaces of* $a_0(x, \xi)$*.*

Proof. Note first that assumptions (1.1.190) and (1.1.191) imply respectively that $a_0(x, \xi) - \epsilon|\xi|^m \geq 0$ and $\|a_0^{-1}(x, \xi)\| \leq c|\xi|^{-m}$.

(i) Without any loss of the generality one can assume that $\mathsf{Re}\, m \geq 0$ (otherwise we substitute A by A^{-1} and l by $-l$) and $-1 < \mathsf{Re}\, l < 0$ (otherwise $l = l'n' + n$ with l' satisfying this assumption and $n, n' \in \mathbb{Z}$). Then

$$A^l = -\frac{1}{2\pi i} \int_{-\infty i}^{+\infty i} \zeta^l (\zeta - A)^{-1}\, d\zeta \tag{1.1.192}$$

along $i\mathbb{R}$. One can see easily that operator $(|\zeta| + 1)(\zeta - A)^{-1}$ belongs to $\boldsymbol{\Psi}^0_{1,0}$ uniformly with respect to $\zeta \in i\mathbb{R}$ (see discussion of $\mathsf{S}^m_{\sigma,\varsigma}$ in the next two subsubsections) and therefore $A^l \in \boldsymbol{\Psi}^0_{1,0}$.

Decomposing symbol of $(\zeta - A)^{-1}$ into asymptotic series

$$r(x, \xi, \zeta) \sim \sum_{n \geq 0} r_n(x, \xi, \zeta)$$

with $r_n(x, \lambda\xi, \lambda^m\zeta) = \lambda^{-m-1} r_n(x, \xi, \zeta)$, $r_0 = \big(\zeta - a_0(x, \xi)\big)^{-1}$ and r_n a finite sum terms in the form

$$\big(\zeta - a_0(x, \xi)\big)^{-1} b_1(x, \xi) \big(\zeta - a_0(x, \xi)\big)^{-1} b_2(x, \xi) \cdots b_j(x, \xi) \big(\zeta - a_0(x, \xi)\big)^{-1}$$

with $(j+1)$ factors $\bigl(\zeta - a_0(x,\xi)\bigr)^{-1}$ we calculate easily that symbol of A^l belongs to $\mathsf{S}^{ml}_{\mathsf{cl}}$; furthermore its principal and subprincipal symbols equal

$$a^0_{(l)} = -\frac{1}{2\pi i}\int_{-\infty i}^{+\infty i} \zeta^l(\zeta - a_0)^{-1}\,d\zeta, \tag{1.1.193}$$

$$a^s_{(l)} = -\frac{1}{2\pi i}\int_{-\infty i}^{+\infty i} \zeta^l(\zeta - a_0)^{-1}a^s\zeta^l(\zeta - a_0)^{-1}\,d\zeta, \tag{1.1.194}$$

which implies the rest of Statement (i).

(ii) Observe that orthogonal projectors $\Pi^{\pm}$ for A and $A(A^2)^{-1/2}$ coincide and $A(A^2)^{-1/2} \in \boldsymbol{\Psi}^0_{\mathsf{cl}}$ due to (i). Then Statement (ii) follows from the functional calculus (Theorem 1.1.57(iii)). □

Classes $\mathsf{S}^m_{\sigma,\varsigma}$ and $\boldsymbol{\Psi}^m_{\sigma,\varsigma}$

If we consider symbols satisfying only (1.1.187) we get classes of symbols and operators denoted by $\mathsf{S}^m_{1,0}$ and $\boldsymbol{\Psi}^m_{1,0}$; all other properties remain. Next generalization is given by

Definition 1.1.60. (i) Symbol $a \in \mathscr{C}^\infty(\mathbb{R}^d \times \mathbb{R}^d)$ belongs to $\mathsf{S}^m_{\sigma,\varsigma}$ with $m \in \mathbb{R}$, $0 \le \varsigma < \sigma \le 1$ if

$$|D_x^\alpha D_\xi^\beta a(x,\xi)| \le C_{\alpha\beta}\langle\xi\rangle^{m-\sigma|\beta|+\varsigma|\alpha|} \qquad \forall \alpha,\beta. \tag{1.1.195}$$

(ii) Class $\boldsymbol{\Psi}^m_{\sigma,\varsigma}$ consists of pseudodifferential operators of the form $\mathsf{Op}(a)$ with $h = 1$ and $a \in \mathsf{S}^m_{\mathsf{cl}}$. Such operators are defined modulo negligible operators where negligible means infinitely smoothing operator.

If we consider $|\xi| \asymp \rho \gg 1$ and rescale $x \mapsto x\rho^\varsigma$, $\xi \mapsto \xi\rho^\sigma$ we get $\hbar$-pseudodifferential operator with $\hbar = \rho^{\sigma-\varsigma}$ and to have it small for $\rho \gg 1$ one needs to set $\varsigma < \sigma$.

We state only few most important results here:

Theorem 1.1.61. *(i) Let $a \in \mathsf{S}^{m_1}_{\sigma,\varsigma}$, $b \in \mathsf{S}^{m_2}_{\sigma,\varsigma}$. Then $a \bullet b \in \mathsf{S}^{m_1+m_2}_{\sigma,\varsigma}$ and*

$$a \bullet b \equiv ab \qquad \mathsf{mod}\ \mathsf{S}^{m_1+m_2-\sigma+\varsigma}_{\sigma,\varsigma}. \tag{1.1.196}$$

(ii) If one of symbols a, b *is scalar then* $(a \bullet b - b \bullet a) \in \mathsf{S}^{m_1+m_2-\sigma+\varsigma}_{\sigma,\varsigma}$ *and*

$$a \bullet b - b \bullet a \equiv \{a, b\} \qquad \mathsf{mod}\ \mathsf{S}^{m_1+m_2-\sigma+\varsigma}_{\sigma,\varsigma}. \tag{1.1.197}$$

(iii) Further, if one of symbols a, b *is scalar then*

$$a \bullet_{\mathsf{w}} b + b \bullet_{w} a \equiv 2ab \qquad \mathsf{mod}\ \mathsf{S}^{m_1+m_2-2\sigma+2\varsigma}_{\sigma,\varsigma}, \tag{1.1.198}$$

$$a \bullet_{\mathsf{w}} b - b \bullet_{w} a \equiv -i\{a, b\} \qquad \mathsf{mod}\ \mathsf{S}^{m_1+m_2-3\sigma+3\varsigma}_{\sigma,\varsigma}. \tag{1.1.199}$$

(iv) Let $A \in \boldsymbol{\Psi}^m_{\sigma,\varsigma}$ *with principal symbol* a_0 *and* $|a^{-1}(x,\xi)| \le c$ *for all* $(x,\xi) : |\xi| \ge c$. *Then there exists a parametrix* $B \in \boldsymbol{\Psi}^{-m}_{\sigma,\varsigma}$: $AB \equiv BA \equiv I$ *(modulo negligible); similar statements hold for left and right parametrices.*

(v) Let $m = 0$ *and either* f *be analytic in the vicinity of* $\mathsf{Spec}(A)$ *or* f *be smooth and* A *be Hermitian. Then* $f(A) \in \boldsymbol{\Psi}^0_{\sigma,\varsigma}$. *Moreover, let* $m < 0$. *Then* $f(A) - f(0) \in \boldsymbol{\Psi}^m_{\sigma,\varsigma}$.

Until now we did not discuss change of variables with a good reason: semiclassical pseudodifferential operators of subsection 1.1.2 did not possess this property (but those of Subsection 1.1.1 did).

Theorem 1.1.62. *(i) Let* $a \in \mathsf{S}^m_{\sigma,\varsigma}$ *with*

$$0 \le 1 - \sigma \le \varsigma < \sigma \le 1. \tag{1.1.200}$$

Let G *and* G' *be open domains in* $\mathbb{R}^d$ *and let* $\varkappa : G \to G'$ *be a diffeomorphism (onto* G'*). Then there exists a symbol* $a_{(\varkappa)} \in \mathsf{S}^m_{\sigma,\varsigma}$ *such that for every pair of functions* $f, g \in \mathscr{C}^\infty_0(G')$

$$\varkappa^* f a(x, hD) g \varkappa^{*-1} \equiv f' a_{(\varkappa)}(x, D) g' \tag{1.1.201}$$

modulo negligible where $\varkappa^*$ *is the induced map:* $\varkappa^* u = u \circ \varkappa$, $f' = f \circ \varkappa^{-1}, g' = g \circ \varkappa$.

(ii) Moreover, in T^*G' *the symbol* $a_{(\varkappa)}$ *is defined uniquely modulo negligible: in particular for* qp*-quantization*

$$a_{(\varkappa)}(x,\xi) \sim \Gamma_x \sum_\alpha \frac{1}{\alpha!} a^{(\alpha)}\bigl(\varkappa(x),\, {}^{\mathsf{t}}\varkappa'^{-1}(x)\xi\bigr) \times \\ (hD_y)^\alpha \exp\bigl(i\langle \varkappa(y) - \varkappa(x) - \varkappa'(x)(y-x), \xi\rangle\bigr) \tag{1.1.202}$$

where $\varkappa'(x)$ *is the Jacobi matrix of* $\varkappa$ *at* x *and* ${}^{\mathsf{t}}$ *means matrix transposition here,* $a^{(\alpha)}(x,\xi) = \partial^\alpha_\xi a(x,\xi)$.

Proof. Note that we need $1-\sigma \le \varsigma$ in order to have $a\bigl(\varphi(x),\, \check{\varkappa}'(x)\xi\bigr)$ belonging to $\mathsf{S}^m_{\sigma,\varsigma}$. Really, differentiating this symbol with respect to x through ξ we gain factor $\langle\xi\rangle^{-\sigma}$ because of definition of the class but also $\check{\varkappa}'(x)\xi$ i.e. we get factor $\langle\xi\rangle^{1-\sigma}$ which should not exceed $\langle\xi\rangle^{\varsigma}$.

Consider in qp-quantization

$$\varkappa^*(A\varkappa^{*-1}u)(x) = (2\pi)^{-d}\int a\bigl(\varkappa(x),\xi\bigr)e^{i\langle\varkappa(x)-y,\xi\rangle}u\bigl(\varkappa^{-1}(y)\bigr)\,dyd\xi$$

where we accommodated f and g' in $a(x,\xi)$ and u respectively. To be closer to the semiclassical arguments let us consider integral over zone $\{|\xi| \asymp h^{-1}\}$ only and change $\xi \mapsto \xi h$ arriving to

$$(2\pi h)^{-d}\int a\bigl(\varkappa(x),\xi\bigr)e^{ih^{-1}\langle\varkappa(x)-\varkappa(y),\xi\rangle}|\det\varkappa'(y)|u(y)\,dyd\xi$$

where we also changed variables of integration $y_{\mathsf{old}} = \varkappa(y)$. Plugging $\varkappa(x)-\varkappa(y) = \varkappa'(x)(x-y)-\varphi(x,y)$ we get $\exp\bigl(ih^{-1}\langle x-y-\varphi_1(x,y),\, \check{\varkappa}(x)\xi\rangle\bigr)$ with $\varphi_1(x,y) = \varkappa'^{-1}\varphi(x,y)$ and changing variables $\xi_{\mathsf{old}} = \varkappa'(x)\xi$ we get

$$(2\pi h)^{-d}\int a\bigl(\varkappa(x),\, \check{\varkappa}'^{-1}(x)\xi\bigr)e^{ih^{-1}\langle x-y+\varphi_1(x,y),\xi\rangle}\times \\ |\det\varkappa'(y)|\cdot|\det\varkappa'(x)|^{-1}u(y)\,dyd\xi.$$

Note that

$$e^{ih^{-1}\langle\varphi_1(x,y),\xi\rangle} \sim \sum_n \frac{1}{n!}h^{-n}\langle\varphi_1(x,y),\xi\rangle^n$$

with each term $O(|x-y|^{2n}h^{-n})$ and the similar error estimate and then integrating $2n$ times by parts with respect to ξ we get also factor h^{2n}; however these $2n$ derivatives could be applied to a symbol which leads to the factor $h^{2n(\sigma-1)}$ in the estimates[7]; so the total factor in estimates is $h^{n(2\sigma-1)}$. Noting that $\sigma > 1/2$ we prove that what we got is an asymptotic expansion.

Further, these arguments imply that it is sufficient to prove (1.1.202) for operators D^β only; however for them this formula is obvious. □

Corollary 1.1.63. *Let $a \in \mathsf{S}^m_{\mathsf{cl}}$. Then*

[7] Differentiating power of $\langle\varphi_1(x,y),\xi\rangle$ causes no extra powers of h.

(i) For pq-quantization

$$a_{(\varkappa)n} = \sum_{0\le k\le n} (\mathcal{L}_{n-k} a_k)\circ \Psi \tag{1.1.203}$$

where $\Psi : T^*G \to T^*G'$ is a symplectomorphism, induced by $\varkappa$:

$$\Psi(x,\xi) = (\varkappa(x), {}^t\varkappa'^{-1}(x)\xi), \tag{1.1.204}$$

$\mathcal{L}_k$ are linear $2k$-th degree differential operators with respect to ξ only, depending on $\varkappa$; in particular

$$\mathcal{L}_0 = I, \qquad \mathcal{L}_k 1 = 0 \quad \forall k \ge 1. \tag{1.1.205}$$

(ii) For any method of quantization $\mathcal{L}_0 = I$ and

$$\mathcal{L}_k = \sum_{|\beta|<|\alpha|,\, 1\le|\alpha|+|\beta|\le 2k} l_{k\alpha\beta}\partial_\xi^\alpha \partial_x^\beta \quad \forall k \ge 1. \tag{1.1.206}$$

(iii) Moreover, for Weyl quantization operators are of order not exceeding $(2k-1)$.

Proof. Statement (i) is trivial, (ii) follows from (i) and formulae describing transitions between quantizations.

To prove (iii) one needs to consider only differential operators; moreover, one needs to consider only operators with symbols $a(x,\xi) = b(x)\langle \ell,\xi\rangle^m$ with $\ell \in \mathbb{R}^d$. Then $a^{\mathrm{w}}(x,D)$ is a symmetric product of $\langle \ell, D_x\rangle$ (m copies) and $b(x)$. Therefore $\varkappa^* a^{\mathrm{w}}(x,D)\varkappa^{*-1}$ is a symmetric product of

$$\varkappa^*\langle \ell, D_x\rangle \varkappa^{*-1} = \langle \varkappa'^{-1}(x)\ell, D_x\rangle = j(x)^{-1/2} L^{\mathrm{w}}(x,D) j(x)^{1/2}$$

(m copies) and $\varkappa^* b \varkappa^{*-1} = b(\varkappa(x))$ with $L(x,\xi) = \langle \ell, {}^t\varkappa'^{-1}(x)\xi\rangle$ and $j(x) = |\det \varkappa'|$. Then (1.1.198) implies (iii). □

Remark 1.1.64. (i) In particular, above arguments imply that

$$a^0_{(\varkappa)} \circ \Psi, \tag{1.1.207}$$

$$a^s_{(\varkappa)} = \bigl(a^s - \frac{i}{2}\sum_j \partial_{\xi_j} a^0 \cdot \partial_{x_j} \log|\det \varkappa' \circ \varkappa^{-1}|\bigr)\circ \Psi \tag{1.1.208}$$

(ii) With the change of variables comes the theory of pseudodifferential operators on manifolds, and acting on sections of the bundles (with finite or infinite-dimensional fibers) over these manifolds rather than functions.

Beals-Fefferman and Hörmander Operators

Even more general classes of symbols (and operators associated with them) are due to R. Beals and R. Beals–C. Fefferman and are described by

$$\|D_x^\alpha D_\xi^\beta a(x,\xi)| \le C_{\alpha\beta}\mu(x,\xi)\Phi(x,\xi)^{-|\beta|}\phi(x,\xi)^{-|\alpha|} \tag{1.1.209}$$

two scaling functions $\Phi(x,\xi)$, $\phi(x,\xi)$ and a weight function $\mu(x,\xi)$ such that

$$c^{-1} \le \frac{\Phi(x,\xi)}{\Phi(y,\eta)} \le c,\ c^{-1} \le \frac{\phi(x,\xi)}{\phi(y,\eta)} \le c,\ c^{-1} \le \frac{\mu(x,\xi)}{\mu(y,\eta)} \le c \tag{1.1.210}$$
$$\Longleftarrow\ |x-y| \le c^{-1}\phi(x,\xi),\ |\xi-\eta| \le \Phi(x,\xi).$$

In this case effective semiclassical parameter is $\hbar = 1/(\Phi\phi)(x,\xi)$ and we need condition $\Phi\phi \ge 1$.

Assume that weight function μ is identically 1. It is proven that $\mathsf{Op}^{\mathsf{w}}(a)$ is a bounded operator in $\mathscr{L}^2(\mathbb{R}^d)$ (or from in $\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})$ to $\mathscr{L}^2(\mathbb{R}^d,\mathbb{H}')$ in case of operator valued symbols). Further, if we want negligible operators to be infinitely smoothing we need a condition

$$(\Phi\phi)(x,\xi) \ge (1+|\xi|^2)^{\delta/2}, \qquad \delta > 0; \tag{1.1.211}$$

further, if we want negligible operators to act from $\mathscr{S}'(\mathbb{R}^d)$ to $\mathscr{S}(\mathbb{R}^d)$ we need a condition

$$(\Phi\phi)(x,\xi) \ge (1+|\xi|^2+|x|^2)^{\delta/2}, \qquad \delta > 0. \tag{1.1.212}$$

Taking $\mu(x,\xi) = (\Phi\phi)(x,\xi)^m$ we get operators of order m; then principles "$\mathsf{ord}(ab) = \mathsf{ord}(a) + \mathsf{ord}(b)$" and "$\mathsf{ord}(\{a,b\}) = \mathsf{ord}(a) + \mathsf{ord}(b) - 1$" hold.

Without any loss of the generality we can assume that each of functions $a = \Phi$, $a = \phi$ and $a = \mu$ satisfies (1.1.209) with a weight function in the right-hand expression Φ, ϕ and μ respectively; otherwise one can replace them with equivalent functions satisfying this condition. Then one can introduce corresponding spaces $\mathscr{H}^s = \mathscr{H}^s_{\Phi\phi,\mu}$ with norms $\|u\|_{\mathscr{H}^s} = \|\,\mathsf{Op}(\Phi\phi)^s\,\mathsf{Op}(\mu)u\|_{\mathscr{L}^2}$.

The most general classes due to L. Hörmander use temperate metrics instead of temperate scaling functions L. Hörmander [1].

Global Operators

In particular one can select $\Phi(x,\xi) = \phi(x,\xi) = (1+|x|^2+|\xi|^2)^{1/2}$ and consider *global symbols* of order m:

$$\|D_x^\alpha D_\xi^\beta a(x,\xi)| \le C_{\alpha\beta}(1+|x|^2+|\xi|^2)^{m-(|\alpha|+|\beta|)/2} \qquad \forall \alpha,\beta. \tag{1.1.213}$$

Operators of this class are invariant with respect to Fourier transform.

One can consider classical version of such symbols: they should admit decomposition (1.1.188) with a_j positively homogeneous of degrees $2(m-j)$ with respect to (x,ξ); operators of this class are invariant with respect to Fourier transform.

The simplest example is harmonic oscillator $|D|^2+|x|^2$; in the framework of this calculus it has an order 1.

Slightly more general class of operators is described by scaling functions $\Phi(x,\xi)=(1+|\xi|^2+|x|^{2\nu})^{1/2}$, $\phi(x,\xi)=(1+|\xi|^2+|x|^{2\nu})^{1/2\nu}$:

$$\|D_x^\alpha D_\xi^\beta a(x,\xi)|\le C_{\alpha\beta}(1+|x|^{2\nu}+|\xi|^2)^{m(1+1/\nu)-|\alpha|/(2\nu)-|\beta|/2}\quad \forall\alpha,\beta. \tag{1.1.214}$$

One can consider classical version of such symbols: the should admit decomposition (1.1.188) with a_j positively $(1,\nu)$-quasihomogeneous of degrees $(m-j)(\nu+1)$ with respect to (x,ξ): $a_j(\lambda x,\lambda^\nu\xi)=\lambda^{(m-j)(\nu+1)}a_j(x,\xi)$ as $\lambda>0$. The simplest example is an anharmonic oscillator $|D|^2+|x|^{2\nu}$; in the framework of this calculus it has an order $2\nu/(\nu+1)$. In this case one can prove statements similar to Theorems 1.1.57 and 1.1.59.

Both propagation of singularities and spectral asymptotics demonstrate that discussed operators behave like operators of prescribed orders on compact manifolds.

Furthermore, one can consider symbols and operators "global" with respect to some variables and ordinary with respect to others or with vector $\nu\in\mathbb{R}^{+d}$.

h-Pseudodifferential Operators

One can consider classes of operators described in this subsection and introduce semiclassical parameter h: i.e. replace operator $a(x,D)$ by $a(x,hD)$. Surely it affects the spaces as well: f.e. standard $\mathscr{H}^s$ should be replaced by spaces with the norm $\|u\|_s=\|(1+h^2|D|^2)^{s/2}u\|_{\mathscr{L}^2}$.

Then effective semiclassical parameter would be $\hbar=h/(\Phi\phi)(x,\xi)$ (for Beals-Fefferman operators). h-pseudodifferential operators with $\mathsf{S}^m_{\sigma,\varsigma}$ symbols admit a smooth change of coordinates provided $0\le 1-\sigma\le\varsigma<\sigma\le 1$; h-pseudodifferential operators with classical symbols also admit a smooth change of coordinates.

1.2 Lagrangian Distributions and Fourier Integral Operators

1.2.1 Motivation

Oscillatory Solutions to Evolution Equations

Let us consider evolution equation

$$hD_t u + a(x,t,hD_x)u = 0 \tag{1.2.1}$$

with the scalar symbol a and a real-valued a_0 and let us find oscillatory solutions

$$u(x,t) = e^{ih^{-1}\phi(x,t)} f(x,t). \tag{1.2.2}$$

Plugging (1.2.2) into (1.2.1) and applying Theorem 1.1.14 and Remark 1.1.16 we find that

$$\big(hD_t + a(x,t,hD_x)\big)u \sim \Big(\big(a_0(x,\nabla\phi) + \phi_t\big) + \sum_{n\ge 1} h^n \mathcal{L}_n\Big) f \times e^{ih^{-1}\phi(x,t)} \tag{1.2.3}$$

where $\mathcal{L}_n$ are differential operators of order n; in particular,

$$\mathcal{L}_1 = -i\partial_t - i\sum_j (\partial_{\xi_j} a_0)(x,\nabla\phi)\partial_{x_j} + K, \tag{1.2.4}$$

where for qp-quantization

$$K = \frac{i}{2}\sum_{j,k} (\partial^2_{\xi_j\xi_k} a_0)(x,\nabla\phi)\partial^2_{x_j x_k}\phi + a_1(x,\nabla\phi) = -\frac{i}{2}\sum_j \partial_{x_j} a_0^{(j)}(x,\nabla\phi)\big) + a^s(x,\nabla\phi) \tag{1.2.5}$$

where only in the last sum we first plug $\xi = \nabla\phi(x,t)$ and differentiate after; recall that $a_0^{(j)} = \partial_{\xi_j} a_0$.

To eliminate the first term in the right hand expression of (1.2.3) we need to impose condition to ϕ:

$$\phi_t + a_0(x,\nabla\phi) = 0 \tag{1.2.6}$$

which is called *eikonal equation* as ϕ is called *eikonal*. For a simplicity of the terminology we assume that

(1.2.7) a does not depend on t.

Note that this is *Hamilton-Jacobi equation* for *classical Hamiltonian dynamics*

$$\frac{d}{dt}(x,\xi) = \nabla^{\#} a_0(x,\xi) \iff \begin{cases} \dfrac{dx}{dt} = \nabla_\xi a_0(x,\xi), \\ \dfrac{d\xi}{dt} = -\nabla_x a_0(x,\xi), \end{cases} \tag{1.2.8}$$

where $\nabla^{\#} b = (\nabla_\xi b, -\nabla_x b)$ is a *Hamiltonian field* generated by b. We refer to V. I. Arnold [2] for details. For such equations

$$\frac{d}{dt}\phi = \langle \xi, a'_{0\xi}(x,\xi)\rangle, \qquad \nabla\phi = \xi \tag{1.2.9}$$

along trajectories of (1.2.8).

Equation (1.2.8) defines a *Hamiltonian flow* Ψ_t on the *phase space* $T^*X \ni (x,\xi)$ ($X = \mathbb{R}^d$); however after ϕ is selected we have a flow Φ_t on the *configuration space* $X \ni x$:

$$\frac{dx}{dt} = \nabla_\xi a_0(x, \nabla\phi(x,t)). \tag{1.2.10}$$

Remark 1.2.1. It is known that Ψ_t is a *symplectomorphism* and so preserves the volume form on the phase space; however the similar statement is not true for Φ_t and $\sum_j \partial_{x_j} a_0^{(j)}(x, \nabla\phi)$ is a divergence of this flow:

$$\sum_j \partial_{x_j} a_0^{(j)}(x,\nabla\phi) = \frac{d}{dt} \log |\det d\Phi_t|. \tag{1.2.11}$$

To eliminate the second term in the right hand expression of (1.2.3) we need to impose condition to f:

$$\bigl(\partial_t + \sum_j (\partial_{\xi_j} a_0)(x,\nabla\phi) + iK\bigr) f = 0 \tag{1.2.12}$$

which is equivalent to equation along trajectories of Φ_t

$$\Big(\frac{d}{dt} + iK\Big) f = 0 \tag{1.2.13}$$

and its called *transport equation*. Together with (1.2.11) it implies that

$$\Big(\frac{d}{dt} - 2\operatorname{Im} ia^s\Big)\big(|f|^2 \cdot |\det d\Phi_t|\big) = 0; \tag{1.2.14}$$

in particular for real a^s we get a kind of *energy conservation*

$$\frac{d}{dt}\big(|f|^2 \cdot |\det d\Phi_t|\big) = 0. \tag{1.2.15}$$

To eliminate all other term in (1.2.3) we pick up

$$f \sim \sum_{n\ge 0} f_n h^n \tag{1.2.16}$$

where f_0 we already defined and all other terms are defined recursively from transport equations

$$\Big(\frac{d}{dt} + iK\Big) f_n = -i \sum_{r\ge 2} \mathcal{L}_r f_{n+1-r}. \tag{1.2.17}$$

Remark 1.2.2. This construction is obviously extended to the matrix operators provided a_0 is scalar. Furthermore, this construction is extended even to more general matrix operators provided

$$\dim\ker\big(\phi_t + a_0(x, \nabla\phi)\big) = \text{const}. \tag{1.2.18}$$

So, we found asymptotic solutions to a equation (1.2.1) with initial condition

$$u|_{t=0} = e^{ih^{-1}\phi_0} f_0(x). \tag{1.2.19}$$

However *this solution is only local* because of the blow-up.

Blow-up

The trouble is that solution to eikonal equation (1.2.6) is only local. The geometric reason is very transparent: while Ψ_t is a symplectomorphism,

$$\Phi_t : x \to \pi_x \Psi_t(x, \nabla\phi_0(x)) \tag{1.2.20}$$

is a smooth map but may cease to be a diffeomorphism for $|t| \ge t_0$; here $\pi_x : (x,\xi) \to x$ is a projection map.

At the moment when Φ_t ceases to be a diffeomorphism the energy density $|f|^2$ surges due to (1.2.14) and this is the reason why propagators fail to be bounded operators from $\mathscr{L}^p(\mathbb{R}^d)$ to $\mathscr{L}^p(\mathbb{R}^d)$ for $p \ne 2$.

One can describe it in a different way:

$$\Lambda_0 = \{(x, \nabla\phi_0(x)),\ x \in X\} \subset T^*X \tag{1.2.21}$$

is a *Lagrangian submanifold*, i.e. submanifold of the maximal dimension (thus d) on which *symplectic form*

$$\sigma = \sum_j (d\xi_j \wedge dx_j) \tag{1.2.22}$$

identically vanishes. Then since Ψ_t is a symplectomorphism $\Lambda_t = \Psi_t\Lambda_0$ is a Lagrangian manifold as well. If $\pi_x : \Lambda_t \to \mathbb{R}^d$ is a local diffeomorphism one can (locally) describe Λ_t by (1.2.21) with ϕ_0 replaced by ϕ_t. Blow-up happens when $\mathsf{rank}(d\pi_x|_{\Lambda_t}) < d$.

Very geometrical discussion of blow-up (caustics, focussing) the reader can find in V. I. Arnold [3]. Extensive analytic theory could be found in V. M. Babich [1].

Maslov Canonical Operator

To tackle blow-ups V. Maslov [1] (see also M. Fedoryuk, V. Maslov [1]) suggested *Maslov canonical operator* method. Idea of this method is to pass to the different representation near the blow-up. While we do not use this method in our book, we sketch it here.

So, let us go to p-representations of (1.2.2):

$$\mathcal{F}(u)(\xi) = (2\pi h)^{-d/2} \int e^{ih^{-1}(-\langle x,\xi\rangle + \phi(x))} f(x)\, dx \tag{1.2.23}$$

where we ignore t-dependence. To calculate oscillatory integral (1.2.23) we need to apply *stationary phase formula* (see Appendix 1.A.3):

$$\nabla_x\big(-\langle x,\xi\rangle+\phi(x)\big)=0 \iff \xi=\nabla_x\phi(x) \tag{1.2.24}$$

and under the nondegeneracy assumption

$$\det \mathsf{Hess}\,\phi\neq 0 \tag{1.2.25}$$

we get

$$\mathcal{F}(u)(\xi)\sim e^{ih^{-1}\tilde\phi(\xi)}\big(\tilde f(\xi)+h\tilde f_1(\xi)+\dots\big) \tag{1.2.26}$$

with $x(\xi)$ defined by (1.2.24) (locally) uniquely under assumption (1.2.25); if there are several solutions to (1.2.24) we arrive to the sum of several expressions of (1.2.26) type; further

$$\tilde\phi(\xi)=-\langle\xi,x(\xi)\rangle+\phi\big(x(\xi)\big), \tag{1.2.27}$$

and

$$\tilde f_0(\xi)=e^{\frac{\pi i}{4}\,\mathsf{sgn}\,\mathsf{Hess}\,\phi}|\det \mathsf{Hess}\,\phi|^{-1/2}f_0\big|_{x=x(\xi)}. \tag{1.2.28}$$

Transition from $(x,\phi(x))$ to $(\xi,\tilde\phi(\xi))$ described above is called *Legendre transformation*.

Remark 1.2.3. The meaning of the second factor in (1.2.28) is also obvious in virtue of $|\det \mathsf{Hess}\,\phi|=|\det(\xi'(x))|$ where ξ' is a Jacobi matrix of $x\to\xi=\nabla_x\phi$. Due to this factor when we pass from x to ξ coordinates amplitude behaves as a *half-density* rather than a function: $|\tilde f|^2\,d\xi=|f|^2\,dx$ in the corresponding points where $d\xi$ and dx are Euclidean measures on $\mathbb{R}^d_x$ and $\mathbb{R}^d_\xi$ respectively.

Finally, in the first factor of (1.2.28) $\mathsf{sgn}\,b$ is a *signature* of a real symmetric matrix b, which is the number of its positive eigenvalues minus number of its negative ones. This factor manifests itself prominently when we return back to x after blow-up.

Similar formulae hold for partial h-Fourier transform and for (partial) inverse h-Fourier transform. Furthermore, locally on every Lagrange manifold Λ one can introduce coordinates $(x_{\mathcal{J}},\xi_{\mathcal{J}'})$ where $x_{\mathcal{J}}=(x_{j_1},\dots,x_{j_r})$, $\{j_1,\dots,j_r\}=\mathcal{J}\subset\{1,\dots,d\}$, $\mathcal{J}'=\{1,\dots,d\}\setminus\mathcal{J}$ and therefore we can always find an appropriate representation. To every such representation we

attribute locally a phase function and also an amplitude; moreover, modulo factor i^p (with $p \in \mathbb{Z}/4\mathbb{Z}$) this amplitude can be considered as half-density on Λ.

To understand the role of the first factor in (1.2.28) let us consider case $d = 1$. Then this factor is $\pm i$ if $\pm\frac{d\xi}{dx} > 0$. F.e. if Λ is as on picture below.

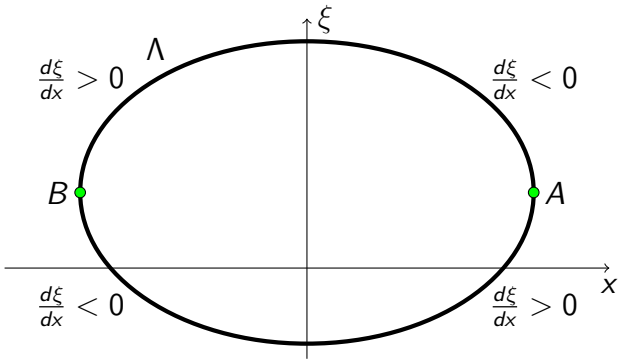

Figure 1.1: Maslov index

Here A and B are blow-up points, so signature when passing from $\{\frac{d\xi}{dx} > 0\}$ to $\{\frac{d\xi}{dx} < 0\}$ increases by -2 and thus factor $e^{-\frac{\pi i}{2}} = -i$ is acquired. Therefore after going counter-clockwise around Λ factor -1 is acquired.

More generally: consider multidimensional case. Let Λ be a Lagrangian submanifold in T^*X and $z, z' \in \Lambda$ such that $\operatorname{rank} d\pi_x(z) = \operatorname{rank} d\pi_x(z') = d$. Consider path $\ell(z', z)$ from z to z'. One can prove that this path could be deformed to the path along which $\operatorname{rank} d\pi_x = d$ in all but a discrete set of points $z_1, \dots, z_r$ and $\operatorname{rank} d\pi_x(z_j) = d - 1$.

Near point z_j one can select k such that $\operatorname{rank} d\pi_{x_{\hat{k}},\xi_k}(z_j) = d$; here $x_{\hat{k}}$ means "all coordinates but k-th". At this points *Maslov index* of the path grows (decreases) by 2 if we pass from $\{\frac{d\xi_k}{dx_k} < 0\}$ to $\{\frac{d\xi_k}{dx_k} > 0\}$ (in the opposite direction, respectively). This procedure introduces Maslov index of the path $\ell(z', z)$ and allows to introduce Maslov index of the closed path ℓ which does not depend on the choice of initial point.

The most important conclusion we carry from this construction, that solution for any time is expected to be (a sum of terms)

$$(2\pi h)^{-m} \int e^{ih^{-1}\varphi(x,\theta)} f(x,\theta,h)\, d\theta \tag{1.2.29}$$

with $\theta = \xi_{\mathcal{J}'}$, $\varphi(x,\theta) = \langle x_{\mathcal{J}'}, \theta\rangle + \phi(x_{\mathcal{J}}, \theta)$, $m = \#\mathcal{J}'$.

Propagator

Another approach is to consider initial phase $\langle x - y, \xi\rangle$ and initial function $(2\pi h)^{-d}$ and construct local solution in the form

$$\mathcal{K}(x,y,t) = (2\pi h)^{-d} e^{ih^{-1}(\phi(x,\xi,t) - \langle y,\xi\rangle)} b(x,\xi,t,h) \tag{1.2.30}$$

and this would be a Schwartz kernel of the propagator $e^{-ih^{-1}tA}$.

Then for any $t = t_1 + t_2 + ... + t_m$ we can construct a Schwartz kernel of propagator $e^{-ih^{-1}tA} = e^{-ih^{-1}t_1A} \cdots e^{-ih^{-1}t_mA}$

$$\mathcal{K}(x,y,t) = (2\pi h)^{-dm} \int e^{ih^{-1}\varphi(x,\theta,y,t)} b(x,\theta,y,t,h)\, d\theta \tag{1.2.31}$$

where we dumped all intermediate variables into $\theta = (\xi, x_{(1)}, \xi_{(1)}, \dots, x_{(m-1)}, \xi_{(m-1)})$ and $\varphi = \phi(x,\xi,t_1) - \langle x_{(1)}, \xi\rangle + \phi(x_{(1)}, \xi_{(1)}) - \langle x_{(2)}, \xi_{(1)}\rangle + ... - \langle y, \xi_{(m-1)}\rangle$.

Further, applying it to initial function $e^{ih^{-1}\psi} f_0$ we get a solution in the form

$$u(x,t) = (2\pi h)^{-dm} \int e^{ih^{-1}\varphi(x,\theta,t)} f(x,\theta,t,h)\, d\theta \tag{1.2.32}$$

where here we dumped y into θ as well and included $\psi(y)$ into φ. Expressions (1.2.32) and (1.2.31) will be used to define Lagrangian distributions and Schwartz kernels of Fourier integral operators.

Remark 1.2.4. There is a disparity between Lagrangian distributions and Lagrangian distributions which are Schwartz kernels of operators in $\mathscr{L}^2(X)$: the former with m-dimensional parameter $theta$ have factor $h^{-m/2}$ while the latter have factor $h^{-(m+d)/2}$ where $d = \dim(X)$.

Later we will consider Lagrangian distributions which are Schwartz kernels of operators $\mathscr{L}^2(X)$ to $\mathscr{L}^2(Y)$ and those will have factor $h^{-(m+d_X)/2}$ where $d_X = \dim(X)$ and $d_Y = \dim(Y)$.

1.2.2 Lagrangian Distributions and Manifolds

Definition

We start with the theory of Lagrangian distributions which are given by (1.2.32) without t and with ϕ satisfying non-degeneracy condition below.

Definition 1.2.5. A smooth real-valued function $\phi(x,\theta)$ defined for $(x,\theta) \in G \Subset \mathbb{R}^d \times \mathbb{R}^r$ is called *non-degenerate* if

$$(x,\theta) \in \bar{G}, \phi'_\theta(x,\theta) = 0 \implies \operatorname{rank}(\phi''_{\theta x}, \phi''_{\theta\theta}) = r \tag{1.2.33}$$

where $\phi''_{\theta x}$, $\phi''_{\theta\theta}$ are $d \times r$ and $r \times r$ matrices of the second derivatives, so $(\phi''_{\theta x}, \phi''_{\theta\theta})$ is $(d+r) \times r$ matrix.

The quantified version of (1.2.33) is

(1.2.34) If $|\phi'_\theta(x,\theta)| \le \epsilon$, then the matrix $(\phi''_{\theta x}, \phi''_{\theta\theta})$ has a minor (determinant) of dimension r, the absolute value of which is not less than ϵ with a small enough constant $\epsilon > 0$.

Let $\mathbb{H}$ be an auxiliary Hilbert space as before.

Definition 1.2.6. An $\mathbb{H}$-*valued Lagrangian distribution* is a distribution of the form

$$u(x) = (2\pi h)^{-\frac{r}{2}} \int a(x,\theta) e^{ih^{-1}\phi(x,\theta)}\, d\theta \tag{1.2.35}$$

with the smooth, real-valued and nondegenerate phase function $\phi \in \mathscr{C}^{N+K}(\bar{G})$ and smooth *amplitude* $a \in \mathscr{C}_0^{N+K}(G,\mathbb{H})$.

The quantitative versions of these conditions are:

$$\operatorname{diam} G \le c, \quad \operatorname{dist}(\operatorname{supp}(a), \partial G) \ge \epsilon, \tag{1.2.36}$$

$$|D_x^\alpha D_\theta^\nu \phi| \le L \quad \forall \alpha,\nu : |\alpha| \le N+K, |\nu| \le N+K \quad \forall (x,\theta) \in G, \tag{1.2.37}$$

$$\|D_x^\alpha D_\theta^\nu a\| \le M \quad \forall \alpha,\theta : |\alpha| \le N+K, |\nu| \le N+K \quad \forall (x,\theta). \tag{1.2.38}$$

Definition 1.2.7. More generally, let us consider amplitudes of the form (1.1.30) where a_j satisfy the previous conditions with N replaced by $(N-j)$. The class of these amplitudes we denote by $\dot{S}_{h,N}(G,\mathbb{H})$ and the least M for which these estimates hold we denote by $|||a|||$.

It is rather obvious that the same Lagrangian distribution could be defined (modulo $O(h^\infty)$) by different phase functions and amplitudes and the first question to answer is "How one can characterize phase functions defining the same Lagrangian distributions"?

Definition 1.2.8. *Lagrangian manifold generated by a phase function* ϕ is

$$\Lambda_\phi = \{(x, \phi'_x(x,\theta)) : (x,\theta) \in \Sigma_\phi\} \subset T^*\mathbb{R}^d \tag{1.2.39}$$

where

$$\Sigma_\phi = \{(x,\theta) \in G, \phi'_\theta(x,\theta) = 0\}. \tag{1.2.40}$$

Then $\Lambda = \Lambda_\phi$ and Σ_ϕ are respectively $\mathscr{C}^{N+K-2}$ and $\mathscr{C}^{N+K-1}$ manifolds of dimension d. Furthermore

(1.2.41) Λ_ϕ is a *Lagrangian manifold* which means that $\dim(\Lambda) = d$ and the restriction of the symplectic form $\sigma = \sum_j d\xi_j \wedge dx_j$ to Λ equals 0,

(1.2.42) The map $\iota : \Sigma_\phi \ni (x,\theta) \to (x, \phi'_x(x,\theta)) \in \Lambda_\phi$ is a local diffeomorphism.

One can prove easily that

$$r - \operatorname{rank} \phi''_{\theta\theta}(x,\theta) = d - \operatorname{rank} \pi'_{\Lambda,x}(\iota(x,\theta)), \tag{1.2.43}$$

where $\pi_{\Lambda,x} : \Lambda \ni (x,\xi) \to x \in \mathbb{R}^d$ and $\pi'_{\Lambda,x}$ is its differential.

Main Properties

For a justification of all our future calculations we need

Proposition 1.2.9. *Let conditions* (1.2.34) *and* (1.2.36)–(1.2.38) *be fulfilled with* $K = K_0(d,r)$, $N = 0$. *Then the* $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H})$*-norm of* u *does not exceed* $C\|\!|a|\!\|$ *with* $C = C(d,r,c,\epsilon)$.

Proof. The proof of this proposition follows from the arguments of Chapter 21.1 of L. Hörmander [1]. Namely, consider

$$\|u\|^2 = (2\pi h)^{-r} \iiint \langle a(x,\theta),\, a(x,\theta')\rangle e^{ih^{-1}(\phi(x,\theta)-\phi(x,\theta'))}\, dx d\theta d\theta' \tag{1.2.44}$$

which is an oscillatory integral with the phase function $\varphi(z) = \phi(x,\theta) - \phi(x,\theta')$, $z = (\theta,\theta',x)$ (and with the "deficient" power of $(2\pi h)$). One can see easily that the (quantified) nondegeneracy condition for ϕ implies (quantified) condition $\varphi'_z = 0 \implies \operatorname{rank} \varphi''_{zz} \ge 2r$. Then sthe tationary phase method reduces this integral to the finite sum of (oscillatory) integrals with d variables and 0-th power of $(2\pi h)$. □

Remark 1.2.10. Since $(hD)^\alpha u$ is a distribution of the same form again we obtain that its $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H})$-norm also does not exceed $C\|\!|a|\!\|$ with $C = C(d,r,N,c,\epsilon)$ provided $|\alpha| \le N$ in the conditions.

Then the stationary phase method immediately implies

Proposition 1.2.11. *Let ι be a one-to-one map, and let $\pi_{\Lambda,x}$ be a diffeomorphism*[8)]*. Then for $K = K(d,r)$ a distribution u of the form* (1.2.35) *can be rewritten in the following form:*

$$u(x) = \tilde{a}(x)e^{ih^{-1}\tilde{\phi}(x)} + U(x) \tag{1.2.45}$$

where

$$\tilde{\phi}(x) = \phi(\iota^{-1}\pi'^{-1}_{\Lambda,x}(x)), \tag{1.2.46}$$

$\tilde{a} \in \dot{S}_{h,N}(\pi'_{\Lambda,x}\iota G)$ *with* $K = K(d,0)$, $\|\tilde{a}\| \le C\|a\|$ *where the norms are calculated in the corresponding classes,*

$$\tilde{a}_0(x) = e^{\frac{\pi i}{4}\operatorname{sgn}(\phi''_{\theta\theta})}|\det(\phi''_{\theta\theta})|^{-\frac{1}{2}}a_0\big|_{(x,\theta)=\iota^{-1}\pi'^{-1}_{\Lambda,x}(x)}, \tag{1.2.47}$$

and the $\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})$-norm of U does not exceed $Ch^N\|a\|$ with $C = C(d,r,N,c,\epsilon)$; moreover the same is true for $(hD)^\alpha U$ provided $|\alpha| \le k$ and we add k to K and take C also depending on k[9)]*.*

Remark 1.2.12. One can see easily that $\Lambda = \{(x,\tilde{\phi}'_x(x)) : x \in \pi'_{\Lambda,x}\iota G\}$ in this case.

Definition 1.2.13. A point $z \in \Lambda$ is called *regular* provided

$$\operatorname{rank}\pi'_{\Lambda,x}(z) = d.$$

Therefore Proposition 1.2.11 states that if all points of a Lagrangian manifold are regular then one can take $r = 0$ in (1.2.35) (we assume that ι is a one-to-one map and that $K = K(d,r)$).

Let us consider the case when $\operatorname{rank}\pi'_{\Lambda,x}(z) = k$ with $0 \le k \le d-1$. Then there exists a partition of variables $x = (x',x'') \in \mathbb{R}^k \times \mathbb{R}^{d-k}$ (preceded by a change of enumeration of the coordinates if necessary) such that if $\xi = (\xi',\xi'')$ is the corresponding partition of the dual variables in $T^*_x\mathbb{R}^d$ then

$$\operatorname{rank}\pi'_{\Lambda,(x',\xi'')}(z) = d \tag{1.2.48}$$

[8)] I.e., let $\pi_{\Lambda,x}$ be a one-to-one map with $\operatorname{rank}\pi'_{\Lambda,x} = d$ at every point of Λ; then $|\det\pi'_{\Lambda,x}| \ge \epsilon$ at every point of Λ.

[9)] Such functions we call (k,N)-negligible or simply negligible.

where $\pi'_{\Lambda,(x',\xi'')} : \Lambda \ni (x,\xi) \to (x',\xi'')$ and the prime means differential (i.e. we assume that the absolute value of the determinant of this matrix is not less than ϵ).

Then one can prove easily that the $r^* \times r^*$ matrix

$$\Phi = \begin{pmatrix} \phi''_{\theta\theta} & \phi''_{\theta x''} \\ \phi''_{x''\theta} & \phi''_{x''x''} \end{pmatrix} \tag{1.2.49}$$

with $r^* = r + d - k$ is non-degenerate. Let us consider function

$$v(x',\xi'') = (2\pi h)^{\frac{k-d}{2}} \int e^{ih^{-1}\langle x'',\xi''\rangle} u(x)\, d\xi''$$

which is a partial h^{-1}-Fourier transform according to Maslov's terminology. Then v is a distribution of the form (1.2.35) with $r, x, \theta, a(x,\theta)$ and $\phi(x,\theta)$ replaced by $r^*, y = (x',\xi'')$, $\theta^* = (\theta, x'')$, $a^*(y,\theta^*) = a(x,\theta)$ and $\phi^*(y,\theta^*) = \phi(x,\theta) - \langle x'',\xi''\rangle$ respectively.

Surely the new amplitude is not compactly supported with respect to ξ'' but it can easily be improved by multiplying by the cutting function $\zeta(\xi'')$ with a fixed $\zeta \in \mathscr{C}_0^\infty(\mathbb{R}^{d-k})$ supported in the ball of appropriate radius R and equal to 1 in the ball of radius $\frac{1}{2}R$; one can prove easily by the stationary phase method that the error function V as well as $\langle\xi\rangle^k V$ are negligible.

Applying Proposition 1.2.11 one can rewrite v in the form (1.2.45) with the phase function

$$S(x',\xi'') = \phi\big(\iota^{-1}\pi^{-1}_{\Lambda,(x',\xi'')}(x',\xi'')\big) - \langle x'',\xi''\rangle \tag{1.2.50}$$

with x'' calculated at the point $x = \pi_{\Lambda,x}\pi^{-1}_{\Lambda,(x',\xi'')}(x',\xi'')$ instead of the phase function $\tilde\phi$. Hence we obtain

Proposition 1.2.14. *Let conditions* (1.2.36)–(1.2.38) *be satisfied with* $K = K(d,r)$*; let* ι *be a one-to-one map and for all* $z \in \Lambda_\phi$*. Finally. let condition* (1.2.48) *be fulfilled.*

Then one can rewrite (modulo negligible functions) a distribution u *of the form* (1.2.35) *in the same form with* θ *replaced by* ξ''*, with the phase function*

$$\psi(x,\xi'') = S(x,\xi'') + \langle x'',\xi''\rangle \tag{1.2.51}$$

and with a new amplitude b *satisfying the same inequality for amplitude norms, with the same constants here and in the negligibility condition as before.*

One can see easily that

$$\Lambda_\phi = \Lambda_\psi = \{(x,\xi) : x'' = -S'_{\xi''}(x',\xi''), \xi' = S'_{x'}(x'',\xi'')\}; \tag{1.2.52}$$

so despite ever changing phase function, corresponding set $\Sigma_.$ and dimension of θ, Lagrangian manifold Λ_ϕ stays the same.

Also any distribution of the form (1.2.35) can be rewritten modulo negligible functions as the sum of distributions of the same form with $r \le d$; recall that amplitudes can be chosen compactly supported. Here assumption that ι is one-to-one is no more needed.

The arguments used in the proofs of Propositions 1.2.11 and 1.2.14 imply that the terms in the decomposition of the amplitude $b(x',\xi'')$ are defined by the formula

$$b_n = \sum_{0\le j\le n} (\mathcal{L}_{n-j} a_j) \circ \iota^{-1} \pi^{-1}_{\Lambda,(x',\xi'')} \tag{1.2.53}$$

where $\mathcal{L}_j$ are $(2j)$-th order linear differential operators depending on ϕ. In particular,

$$b_0 = e^{\frac{\pi i}{4}\operatorname{sgn}\Phi} |\det \Phi|^{-\frac12} a_0 \circ \iota^{-1} \pi^{-1}_{\Lambda,(x',\xi'')}. \tag{1.2.54}$$

This implies that

Corollary 1.2.15. *Classes of distributions defined by different phase functions coincide modulo negligible functions provided these functions generate the same Lagrangian manifold and we take appropriate K.*

On the other hand, it is well known[10)] that if Λ is a Lagrangian manifold and if condition (1.2.48) is fulfilled at $z \in \Lambda$ then Λ is generated in a neighborhood of z by the phase function (1.2.51) with S defined uniquely modulo an additive constant.

Therefore we conclude that

Corollary 1.2.16. *For a compact subset Λ_0 of the Lagrangian $\mathscr{C}^M$ manifold Λ, the spaces $I_{h,N,k}(\mathbb{R}^d, \Lambda_0, \mathbb{H})$ of Lagrangian distributions are well defined.*

[10)] L. Hörmander [1], Chapter XXV and Fedoryuk-Maslov [1].

Here we assume that in the ϵ-neighborhood of each point $z \in \Lambda_0$ the Lagrangian manifold coincides with $\{l_j(x,\xi) = 0 \quad \forall j = 1, \dots, d\}$ with all the derivatives up to order $K+N$ of the functions l_j not exceeding c and with the absolute value of some d-dimensional minor of the $d \times 2d$ matrix $(l_{jx_k}, l_{j\xi_k})_{j,k=1,\dots,d}$ greater than or equal to ϵ; then locally after an appropriate partition of coordinates in $\mathbb{R}^d \times \mathbb{R}^d$ Lagrangian manifold Λ is defined by (1.2.52) with appropriate function S.

Let us consider the density δ_Σ on the manifold $\Sigma = \Sigma_\phi$ which is the push-forward of the Dirac measure δ in $\mathbb{R}^r$ under the map $(x,\theta) \to \phi'_\theta(x,\theta)$; then

$$\delta_\Sigma = \frac{|dz|}{\left|\frac{D(\lambda,\phi'_{\theta'})}{D(x,\theta)}\right|}$$

where $z = (z_1, \dots, z_d)$ is an arbitrary local coordinate system on Λ continued as $\mathscr{C}^1$ functions in a neighborhood of Λ and $|dz|$ is the Lebesgue measure on Λ. Then (1.2.54) implies that

$$a_0 \delta_\Sigma^{\frac{1}{2}} \circ \iota^{-1} = \tilde{a}_0 \delta_{\tilde{\Sigma}}^{\frac{1}{2}} \circ \tilde{\iota}^{-1}$$

provided the manifold Λ in a neighborhood of z is generated by two phase functions ϕ and $\tilde{\phi}$ with coinciding r, $\operatorname{sgn}\Phi$ and with the coinciding values on Λ [11)] and a_0 and $\tilde{a}_0$ are the leading terms of the symbols a and $\tilde{a}$ and (a,ϕ) and $(\tilde{a},\tilde{\phi})$ define the same Lagrangian distribution (modulo negligible functions).

More generally, (1.2.54) implies that the half-density

$$a^0 = e^{\frac{\pi i}{4}\operatorname{sgn}\Phi} a_0 \delta_\Sigma^{\frac{1}{2}} \circ \iota^{-1} \tag{1.2.55}$$

does not depend (modulo a factor i^p with $p \in \mathbb{Z}/4\mathbb{Z}$) on the choice of ϕ generating Λ where here

$$\Phi = \begin{pmatrix} \phi''_{\theta\theta} & \phi''_{\theta x} \\ \phi''_{x\theta} & \phi''_{xx} \end{pmatrix}$$

is a $(d+r) \times (d+r)$ matrix (see Proposition 25.1.5 of L. Hörmander [1]).

Definition 1.2.17. $\mathbb{H}$-valued half-density a^0 defined on Λ modulo factor i^p with $p \in \mathbb{Z}/4\mathbb{Z}$ is called *principal symbol of the Lagrangian distribution* u.

[11)] The values of the functions at Λ are well defined since Λ and Σ are identified by means of ι; one can prove easily that two phase functions with coinciding r, $\operatorname{sgn}\Phi$ and Λ coincide at Λ provided they coincide at z.

Maslov Index

Locally on Λ a branch of i^p can be chosen uniquely; however it is not always possible globally (see below). To avoid this "modulo factor" one can use *Maslov bundle* $\mathcal{M}$ defined on Λ; so principal symbol is actually $\mathbb{H}\otimes\mathcal{M}$-valued (see L. Hörmander [1], Definition 21.6.5). However notion of Maslov index seems to be more transparent.

Namely, assume that $\iota : \Sigma \to \Lambda$ one-to-one map. Let us consider some path ℓ without self-intersections; consider two regular points z_1 and z_2. Then

$$\operatorname{sgn} \phi''_{\theta\theta}\big|_{\iota^{-1}z_1}^{\iota^{-1}z_2} = 2\operatorname{ind}_{\mathsf{M}} \ell(z_1, z_2) \tag{1.2.56}$$

where $\operatorname{ind}_{\mathsf{M}}$ is the Maslov index and $\ell(z_1, z_2)$ is any curve from z_1 to z_2.

In the general case one can define Maslov index of any path and then one can select branch i^p globally if and only if

$$\operatorname{ind}_{\mathsf{M}} \ell \equiv 0 \qquad \operatorname{mod} 4\mathbb{Z} \tag{1.2.57}$$

for every closed curve ℓ on Λ (more precisely, for every class $[\ell]$ of homotopic closed curves since Maslov indices of homotopic closed curves coincide). This condition means exactly that Maslov bundle is trivial.

Since $d\phi = \langle \xi, dx\rangle$ on Λ [12] it follows that the global unique continuous definition of a^0 is impossible unless

$$\int_\ell \langle \xi, dx\rangle = 0 \tag{1.2.58}$$

for every closed curve ℓ on Λ (more precisely, for every class $[\ell]$ of homotopic closed curves since these integrals for homotopic closed curves coincide): for a Lagrangian manifold the exterior form $\langle \xi, dx\rangle|_\Lambda$ is closed[13].

Definition 1.2.18. On the other hand, under quantization conditions (1.2.57) and (1.2.58) the symbol a^0 can be chosen globally uniquely for u and conversely starting from a^0 one can define $u \in I_{h,N,k}(\mathbb{R}^d, \Lambda, \mathbb{H})$ with principal symbol a^0. The isomorphic map $a^0 \mapsto u$ is called the *Maslov canonical operator*.

---

[12] In fact, $d\phi = \langle \phi'_x, dx\rangle + \langle \phi'_\theta, d\theta\rangle = \langle \xi, dx\rangle$.

[13] In fact, $d\langle \xi, dx\rangle = -\sigma$.

Remark 1.2.19. The same arguments imply that if we want to consider not all the values of $h \in (0, h_0]$ but only a certain sequence tending to $+0$ then we can replace conditions (1.2.57) and (1.2.58) by one quantization condition

$$\frac{1}{4}\,\mathsf{ind}_M[\ell] + (2\pi h)^{-1}\int_{[\ell]} \langle \xi, dx\rangle \equiv 0 \qquad \mathsf{mod}\ \mathbb{Z} \tag{1.2.59}$$

for every class $[\ell]$ of homotopic closed curves and for every h from this sequence.

Condition (1.2.59) is called *Bohr-Sommerfeld quantization condition*. This condition plays a crucial role in calculation of eigenvalues of one-dimensional operators.

Other Properties

In conclusion we give some other properties of Lagrangian distributions:

Theorem 1.2.20. *Let u be a distribution of the form* (1.2.35) *and ϕ, a satisfy conditions* (1.2.36)–(1.2.38) *with $M = K + N$, $a \in \dot{S}_{h,N}(G, \mathbb{H})$ with $K = K(d, r, k)$. Moreover, let us assume that for every $n \le s$ the amplitude a_n has a $(2s - 2n + 1)$-th order zero at Σ_ϕ. Then*

(i) There exists an amplitude $a' \in \dot{S}_{h,N}(G, \mathbb{H})$ with $a'_n = 0$ for $n \le s$ such that $\|a'\| \le C\|a\|$ and a' defines u modulo negligible functions[14]*.*

(ii) The terms in the decomposition of a' are defined by the formula

$$a'_n = \sum_{0\le j\le n-s-1} \mathcal{L}_j a_{n-s-j} \tag{1.2.60}$$

where $\mathcal{L}_j$ are $2j$-th order linear differential operators.

Proof. Obviously $a_n \sim \sum_{|\alpha|\ge(2s-2n+1)} b_{n\alpha}(\nabla_\theta\phi)^\alpha$ with $b_{n\alpha}$ being $|\alpha|$-th order differential operators applied to a_n. Integration $|\alpha|$ times by parts concludes the proof. □

Theorem 1.2.21. *Let u bes a distribution of the form* (1.2.35) *and ϕ satisfy condition* (1.2.37) *with $M = K + N$. Let $a \in \dot{S}_{h,N}(G, \mathbb{H})$ with $K = K(d, r, k)$.*

Let $P \in S_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}', \mathbb{H})$. Then

[14] More precisely, the $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H}')$-norm of $(hD)^\alpha(u - v)$ does not exceed $C_\alpha\|a\| \cdot h^{N+1}$ for $|\alpha| \le k$.

(i) There exists a symbol $b \in \dot{S}_{h,N}(G, \mathbb{H}')$ *such that* $|||b||| \le C|||a||| \cdot |||P|||$ *(we recall that all norms are calculated in the corresponding classes) and* b *defines a Lagrangian distribution* v *with the same phase function coinciding modulo negligible functions with* $P(x, hD, h)u$ [15]*. Moreover,*

$$b_0(x,\theta) = P_0(x, \phi'_x(x,\theta))a_0(x,\theta) \tag{1.2.61}$$

and therefore

$$b^0(x,\xi) = P^0(x,\xi)a^0(x,\xi) \quad \text{on } \Lambda. \tag{1.2.61}'$$

(ii) Finally, if $P^0(x,\xi) = 0$ *on* Λ *then* $v = hw$ *where* w *is also a Lagrangian distribution with the principal symbol*

$$c^0 = -i\{P^0, a^0\} + Ka^0 \quad \text{on } \Lambda \tag{1.2.62}$$

where the Poisson bracket does not depend on a smooth continuation of a^0 *from* Λ *and* K *is a symbol depending on* P^0 *and* Λ*.*

Proof. (i) Statement (i) follows immediately from Theorem 1.1.14.

(ii) Since all objects engaged in (1.2.62) are invariant with respect to action of unitary Fourier integral operator $u \mapsto \mathcal{F}^* u, P \mapsto \mathcal{F}^* P \mathcal{F}$ (see next subsection) then one can assume without any loss of the generality that $u = b(x)$ and $\Lambda = \{\xi = 0\}$. In this case formula (1.2.62) becomes trivial. □

Remark 1.2.22. Obviously all these statementss remain true if we replace $\mathbb{H}$-valued distributions and symbols (amplitudes) by $\mathcal{L}(\mathbb{H}, \mathbb{H}_0)$-valued ones where $\mathbb{H}_0$ is also an auxiliary Hilbert space.

Complex Phase

The similar construction works provided ϕ is complex-valued function satisfying condition $\operatorname{Im}\phi \ge 0$. Then one should redefine

$$\Sigma_\phi = \{(x,\theta) : \phi'_\theta(x,\theta) = 0,\ \operatorname{Im}\phi(x,\theta) = 0\} \tag{1.2.63}$$

[15] More precisely, the $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H}')$-norm of $(hD)^\alpha(P(x, hD, h)u - v)$ does not exceed $C|||a||| \cdot |||P|||h^{N+1}$ for $|\alpha| \le k$.

(instead of (1.2.40)), while preserving (1.2.39) for Λ. However Λ is not a Lagrangian manifold anymore, but a "real part" of a *positive Lagrangian ideal* (Section 25.2 of L. Hörmander [1]). In this case all non-degeneracy conditions are supposed to be fulfilled at the real points (i.e. of Σ and Λ).

We only mention that such distributions allow to generalize construction of the oscillatory solutions for operators with scalar principal symbols with $\operatorname{Im} a^0(x,\xi) \le 0$ and with initial data of the same type as before. Then Hamiltonian trajectories while going into complex domain where $\operatorname{Im}\phi > 0$ would never become real again and they do not contribute in Λ_t.

Coherent States

Out of all such Lagrangian distributions a special role is played by those with $\phi(x,\theta) = \phi(x)$ with

$$\operatorname{Im}\phi(x) \ge \epsilon|x-y|^2 \tag{1.2.64}$$

(i.e. $\phi = 0 \iff x = y$ and moreover $\operatorname{Im}\phi''(y) > 0$). In this case

$$\Lambda = \{(y, \nabla\phi(y))\} \tag{1.2.65}$$

consists of a single point.

The simplest example of such distribution is the one with quadratic phase functions

$$\phi(x) = \bar{\phi} + \langle x-y, \eta\rangle + \frac{1}{2}\langle Q(x-y), (x-y)\rangle \tag{1.2.66}$$

where Q is symmetric matrix and $\operatorname{Im} Q$ is positive.

Lagrangian distribution with the general phase function $\phi(x)$ satisfying (1.2.64) could be reduced to one with the quadratic phase function and with amplitudes

$$f_h(x) \sim \sum_{\alpha, n \le |\alpha|/3} c_{\alpha n}(x-y)^\alpha h^{-n} \tag{1.2.67}$$

where here $n \in \mathbb{Z}$ may be negative.

Such functions are called *Gaussian beams* (due to the obvious reason) or *coherent states* (not sure why). However, we add an extra factor $h^{-d/4}$ since

$$\|e^{ih^{-1}\phi} f\| \le C h^{d/4} \tag{1.2.68}$$

provided ϕ satisfies (1.2.64).

The remarkable property of such distributions is that such form is preserved in the propagation with the scalar real-valued a^0 for arbitrarily long time (despite all the caustics). In this case $y(t), \eta(t)$ and $\bar{\phi}(t)$ evolve according to the Hamiltonian equation (1.2.8) (with (y,η) instead of (x,ξ)) and $d\bar{\phi}(t) = \langle \eta(t), dy(t)\rangle$ and $Q(t)$ evolves according to

$$\frac{d}{dt}Q(t) = -Q(t)A(t)Q(t) - B(t)Q(t) - Q(t)B^T(t) - C(t), \tag{1.2.69}$$

with

$$A(t) = a^{0\prime\prime}_{\eta\eta}(y(t),\eta(t)), \quad B(t) = a^{0\prime\prime}_{y\eta}(y(t),\eta(t)), \quad C(t) = a^{0\prime\prime}_{yy}(y(t)\eta(t)), \tag{1.2.70}$$

where $B^T(t) = a^{0\prime\prime}_{y\eta}(y(t),\eta(t))$ means transposed matrix.

The proof of (1.2.69)–(1.2.70) is based on the linearization of the Hamiltonian system at $(y(t),\eta(t))$

$$\frac{d}{dt}\delta x = A(t)\delta x + B(t)\delta\xi, \qquad \frac{d}{dt}\delta\xi = -B^T(t)\delta x - C(t)\delta\xi, \tag{1.2.71}$$

which preserves both forms

$$\sum_j \delta\xi_j \wedge \delta x_j \qquad \text{and} \qquad \mathsf{Im}\sum_j \delta\xi_j \cdot \delta x_j^\dagger; \tag{1.2.72}$$

and therefore on the tangent plane to Λ_t the first one is 0 and the second one is positive definite and therefore this plane is given by $\delta\xi = Q(t)\delta x$ with symmetric $Q(t)$, $\mathsf{Im}\, Q(t) > 0$.

Coherent states surely look more like particles than waves.

Another (closely related) property is that $\mathcal{T}u$ is a coherent state for any Fourier integral operator $\mathcal{T}$ (see next subsection).

1.2.3 Fourier Integral Operators

Let us now proceed to the theory of h-Fourier integral operators. Generally speaking (see Section 25.2 of L. Hörmander [1]) Fourier integral operators are operators whose Schwartz kernels are Lagrangian distributions in $\mathbb{R}^d \times \mathbb{R}^m$ corresponding to Lagrangian manifold Λ^T with respect to symplectic form

$\sigma = \sigma_X + \sigma_Y$. However we consider a slightly more narrow but far the most important (and the only one we need in this book) case of Λ being a *canonical graph*. In this case automatically $m = d$.

Definition 1.2.23. A Lagrangian manifold Λ in $X \times Y = \mathbb{R}^d \times \mathbb{R}^d$ equipped with a symplectic form

$$\sigma_X - \sigma_Y = \sum_j d\xi_j \wedge dx_j - \sum_j d\eta_j \wedge dy_j \tag{1.2.73}$$

is a *canonical graph*, if projectors $\pi_X : \Lambda \to T^*X$ and $\pi_Y : \Lambda \to T^*Y$ are local diffeomorphisms and therefore $\Psi\pi_X\pi_Y^{-1} : T^*Y \to T^*X$ is a local diffeomorphism (and then $\Lambda = \mathsf{graph}(\Psi)$ is its graph).

On the other hand, let $\mathcal{X}$ and $\mathcal{Y}$ be domains in phase spaces T^*X and T^*Y equipped with symplectic forms $\sigma_X = \sum_j d\xi_j \wedge dx_j$ and $\sigma_Y = \sum_j d\eta_j \wedge dy_j$ respectively; here $X = \mathbb{R}^d \ni x$ and $Y = \mathbb{R}^d \ni y$.

Let $\Psi : \mathcal{Y} \to \mathcal{X}$ be a diffeomorphism such that

$$|D^\alpha_{y,\eta}\Psi(y,\eta)| \le c \qquad \forall \alpha : |\alpha| \le M \quad \forall (y,\eta) \in \mathcal{Y} \tag{1.2.74}$$

and the same inequalities remain true for the inverse diffeomorphism Ψ^{-1} and $(x,\xi) \in \mathcal{X}$.

Remark 1.2.24. Then the following statements are equivalent:

(i) Ψ is a symplectomorphism, i.e., Ψ preserves the symplectic structure ($\Psi_*\sigma_Y = \sigma_X$) or (what is the same) Ψ preserves Poisson brackets ($\{f \circ \Psi, g \circ \Psi\} = \{f,g\} \circ \Psi$ for all functions f, g on Ω_X; one need check only $f, g \in \{x_1, \dots, x_d, \xi_1, \dots, \xi_d\}$).

(ii) $\Lambda = \mathsf{graph}(\Psi)$ is a Lagrangian manifold with respect to the symplectic form $\sigma = \sigma_X - \sigma_Y$ or (what is the same) $\Lambda^T = \{(x,\xi,y,\eta) : (x,\xi,y,-\eta) \in \Lambda\}$ is a Lagrangian manifold with respect to the symplectic form $\sigma^T = \sigma_X + \sigma_Y$.

Definition 1.2.25. Let $\Psi : \mathcal{Y} \to \mathcal{X}$ be a symplectomorphism, Λ its graph, Λ_0 a compact subset of Λ with $\mathsf{dist}(\Lambda_0, \bar{\Lambda} \setminus \Lambda) \ge \epsilon > 0$. A *Fourier integral operator* is an operator A with Schwartz kernel $\mathcal{K}_A(x,y)$ such that $(2\pi h)^{d/2}\mathcal{K}_A(x,y) \in I_{h,N,k}\big(\mathbb{R}^d \times \mathbb{R}^d, \Lambda_0^T, \mathcal{L}(\mathbb{H}', \mathbb{H})\big)$.

On the other hand, consider $\phi(x,y,\theta)$ is a phase function satisfying (1.2.36)–(1.2.37) with (x,y) instead of x and generating Lagrangian manifold Λ^T then

$$\mathcal{K}_A(x,y) = (2\pi h)^{-\frac{r+d}{2}} \int a(x,y,\theta) e^{ih^{-1}\phi(x,y,\theta)}\, d\theta \tag{1.2.75}$$

with $a \in \dot{S}_{h,N}(G_0, \mathcal{L}(\mathbb{H}', \mathbb{H}))$ where G_0 is an admissible domain in $\mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^r$.

Then locally

$$\Lambda = \big\{(x, \phi'_x(x,y,\theta), y, -\phi'_y(x,y,\theta)) : \phi'_\theta(x,y,\theta) = 0\big\}. \tag{1.2.76}$$

Example 1.2.26. (i) If the differential of the map $\Lambda \ni (x,\xi,y,\eta) \to (x,\eta)$ is non-degenerate then we can take $\phi(x,y,\theta) = S(x,\eta) - \langle y,\eta\rangle$ with $\theta = \eta$ and then

$$\mathcal{K}_A(x,y) = (2\pi h)^{-\frac{d}{2}} \int a(x,y,\eta) e^{ih^{-1}(S(x,\eta) - \langle y,\eta\rangle)}\, d\eta \tag{1.2.77}$$

and in this case $\Lambda = \{(x, S'_x(x,\eta), S'_\eta(x,\eta), \eta)\}$.

(ii) In particular, for $S(x,\eta) = \langle y,\eta\rangle$ we obtain an h-pseudodifferential operator with compactly supported symbol.

(iii) The map $\Psi : (y,\eta) = (y', y'', \eta', \eta'') \to (y', \eta', \eta', -y'')$ with $y' \in \mathbb{R}^k$, $y'' \in \mathbb{R}^{d-k}$ corresponds to the phase function

$$\phi(x,y,\eta') = \langle x' - y', \eta'\rangle - \langle x'', y''\rangle$$

and for a symbol equal to 1 we obtain the operator which is the partial h-Fourier transform:

$$(\mathcal{F}'' u)(x) = (2\pi h)^{(k-d)/2} \int e^{-ih^{-1}\langle x'', y'\rangle} u(x', y'')\, dy'' \tag{1.2.78}$$

(surely 1 is not a compactly supported function but we can save this by multiplying F'' on the left or right by an h-pseudodifferential operator with compactly supported symbol (see Theorem 1.2.29(ii) below)). With this choice of the scalar factor $\mathcal{F}''$ is an unitary operator.

(iv) Suppose $\mathcal{U}$ and $\mathcal{V}$ are domains in X and Y respectively and $\psi : \mathcal{V} \to \mathcal{U}$ is a diffeomorphism; let us introduce the operator $A : u \to P(fug \circ \psi^{-1})$ with $f, g \in C_0^M(\mathcal{V})$ and an h-pseudodifferential operator P with compactly supported symbol. Then A corresponds to the symplectomorphism $\Psi : (y,\eta) \to (\psi(y), {}^t\psi'^{-1}(y)\eta)$ where the notation of Section 1.1 is used.

(v) The special case of a symplectomorphism described in (i) is a map $(y,\eta)\to(y,\eta-\psi')$ with a real-valued scalar function ψ; the corresponding Fourier integral operator is of the form $Pe^{ih^{-1}\psi}$ (or $e^{ih^{-1}\psi}P$) where P is an h-pseudodifferential operator with compactly supported symbol.

Remark 1.2.27. Egorov's theorem (see L. Hörmander [1] states that every symplectomorphism locally is a composition of those described in Example 1.2.26(i), (iii) and (iv); moreover, microlocally (see the next Subsection) every Fourier integral operator is a product of those described in (i), (iii) and (iv).

Theorem 1.2.28. *Let $\phi(x,y,\theta)$ be a phase function which satisfies conditions* (1.2.36)–(1.2.37) *and suppose Λ is the Lagrangian manifold given by* (1.2.76). *Assume that Λ is a canonical graph, i.e.*

(1.2.79) *At every point $(x,\xi,y,\eta)\in\Lambda$ the differentials of the maps $\pi_X:\Lambda\ni(x,\xi,y,\eta)\to(x,\xi)$ and $\pi_Y:\Lambda\ni(x,\xi,y,\eta)\to(y,\eta)$ have rank $2d$* [16].

Further, let $a\in\dot{\mathsf{S}}_{h,N}(G,\mathcal{L}(\mathbb{H}',\mathbb{H}))$ with $N=0$, $K=K(d,r)$ and A is an operator with Schwartz kernel defined by (1.2.75).

Then $\|A\|\le C\|\!|a|\!\|$ where $\|.\|$ means the $\mathcal{L}\bigl(\mathscr{L}^2(\mathbb{R}^d,\mathbb{H}'),\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})\bigr)$-norm and $C=C(d,r,c,\epsilon)$ [17].

Proof. By the arguments of Section 25.2 of L. Hörmander [1]. First, due to Theorem 1.2.29(i),(ii) below A^*A is an h-Fourier integral operator with the identical canonical map, i.e. pseudodifferential operator. Applying Theorem 1.1.19 we arrive to the statement. □

Applying this Theorem one can prove easily that all the statements of Proposition 1.2.14, Corollaries 1.2.15 and 1.2.16 and Theorems 1.2.20 and 1.2.21 (with P staying either to the left or to the right of A) remain true for Fourier integral operators; one should only replace (1.2.35) by (1.2.74) and the $\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})$-norm by the $\mathcal{L}\bigl(\mathscr{L}^2(\mathbb{R}^d,\mathbb{H}'),\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})\bigr)$-norm and in (1.2.61)

---

[16] Equivalently, at every point $(x,y,\theta)\in\Sigma_\phi$ the matrix $\begin{pmatrix}\phi''_{\theta\theta}&\phi''_{\theta x}\\ \phi''_{x\theta}&\phi''_{xx}\end{pmatrix}$ is non-degenerate. In quantitative terms: $|\det\begin{pmatrix}\phi''_{\theta\theta}&\phi''_{\theta x}\\ \phi''_{x\theta}&\phi''_{xx}\end{pmatrix}|\ge\epsilon>0\quad\forall(x,y,\theta)\in\Sigma_\phi$.

[17] Moreover, the same is true for the operator $(hD)^\alpha A(hD)^\beta$ provided $|\alpha|+|\beta|\le k$ and K is replaced by $K+k$; in the conditions and C depends on k now.

one should replace $P_0(x,\phi'_x)$ by $P_0(y,-\phi'_y)$ in the case when P is to the right of A; formulas (1.2.61)$'$ and (1.2.62) should be changed in the same manner.

Moreover, we obtain the following statements which one can prove in the same manner

Theorem 1.2.29. *(i) Let A be a Fourier integral operator with the phase function $\phi(x,y,\theta)$ and symbol $a(x,y,\theta)$. Then the adjoint operator A^* is also a Fourier integral operator with the phase function $-\phi(y,x,\theta)$ and symbol $a^\dagger(y,x,\theta)$ and*

$$\Psi_{A^*} = \Psi_A^{-1} \tag{1.2.80}$$

where here and below Ψ_A is the symplectomorphism corresponding to A.

(ii) Let A and B be Fourier integral operators with the phase functions $\phi_A(x,y,\theta')$ and $\phi_B(y,z,\theta'')$ and symbols $a(x,y,\theta')$ and $b(y,z,\theta'')$ respectively. Then AB is also a Fourier integral operator with phase function $\phi_A(x,z,\theta')+\phi_B(z,y,\theta'')$ and symbol $a(x,z,\theta')b(z,y,\theta'')$, where now $\theta=(\theta',z,\theta'')\in\mathbb{R}^r$, $r=r'+d+r''$.

Moreover, if ϕ_A and ϕ_B satisfy (1.2.36), (1.2.37) *and* (1.2.79) *then the new phase function also satisfies those conditions (maybe with other constants c and ϵ) and*

$$\Psi_{AB} = \Psi_A \circ \Psi_B. \tag{1.2.81}$$

Further, if $a\in \dot{S}_{h,N}(G'',\mathbb{H}'',\mathbb{H}')$ and $b\in \dot{S}_{h,N}(G',\mathbb{H}',\mathbb{H})$ respectively and we remove from the product ab all terms with degree of h greater than N then the $\mathcal{L}\big(\mathscr{L}^2(\mathbb{R}^d,\mathbb{H}''),\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})\big)$-norm of the error does not exceed $C\|\!|a|\!\|\cdot\|\!|b|\!\|h^{N+1}$; moreover, footnote [17)] remains true.

Furthermore,

$$c^0(x,\xi,z,\zeta) = a^0(x,\xi,y,\eta)b^0(y,\eta,z,\zeta) \tag{1.2.82}$$

for $(x,\xi)=\Psi_A(y,\eta)$, $(y,\eta)=\Psi_B(z,\zeta)$.

(iii) Let A be a Fourier integral operator with phase function $\phi(x,y,\theta')$ which satisfies (1.2.36), (1.2.37) *and* (1.2.79) *and with symbol $a(x,y,\theta')$ and let u be a Lagrangian distribution with phase function $\psi(y,\theta'')$ which satisfies* (1.2.36), (1.2.37) *and* (1.2.33) *and with amplitude $b(y,\theta'')$.*

Then Au *is a Lagrangian distribution with phase function* $\psi'(x,\theta) = \phi(x,y,\theta') + \psi(y,\theta'')$ *and amplitude* $b(x,\theta) = a(x,y,\theta')b(y,\theta'')$*, where* $\theta = (\theta', y, \theta'') \in \mathbb{R}^r$*,* $r = r' + d + r''$*. Moreover,* $\psi'(x,\theta)$ *satisfies* (1.2.36)*,* (1.2.37) *and* (1.2.33) *and*

$$\Lambda_{Au} = \Psi_A(\Lambda_u) \tag{1.2.83}$$

where here Λ_u *is the Lagrangian manifold corresponding to the Lagrangian distribution* u*.*

Further, if $a \in \dot{S}_{h,N}(G'', \mathbb{H}', \mathbb{H})$ *and* $b \in \dot{S}_{h,N}(G', \mathbb{H})$ *and we remove from the product* ab *all terms with degree of* h *greater than* N *then the* $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H}')$*-norm of the error does not exceed* $C\|a\| \cdot \|b\| h^{N+1}$*; moreover, the natural modification of footnote* [17] *remains true.*

Furthermore

$$d^0(x,\xi) = a^0(x,\xi,y,\eta)b^0(y,\eta) \tag{1.2.82}'$$

for $(x,\xi) = \Psi_A(y,\eta)$ *where* c^0 *and* d^0 *are the principal symbols of* AB *and* Au *respectively.*

Theorem 1.2.30. *Let* A *be a Fourier integral operator with phase function* ϕ *satisfying* (1.2.36)*,* (1.2.37) *and* (1.2.79) *with* $K = K(d,r)$ *and with symbol* $a \in \dot{S}_{h,N}(G, \mathbb{H}', \mathbb{H})$ *with* $K = K(d,r)$*.*

Moreover, let $p \in S_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}'', \mathbb{H}')$ *and* $q \in S_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}, \mathbb{H}'')$*.*

Then there exist symbols $b \in \dot{S}_{h,N}(G, \mathbb{H}'', \mathbb{H})$ *and* $b' \in \dot{S}_{h,N}(G, \mathbb{H}', \mathbb{H}')$ *with* $\|b\| \le C\|P\| \cdot \|a\|$ *and* $\|b'\| \le C\|P\| \cdot \|a\|$ *such that the* $\mathcal{L}\big(\mathscr{L}^2(\mathbb{R}^d, \mathbb{H}''), \mathscr{L}^2(\mathbb{R}^d, \mathbb{H})\big)$*-norm of the operator* $p(x, hD, h)A - B$ *and the* $\mathcal{L}\big(\mathscr{L}^2(\mathbb{R}^d, \mathbb{H}'), \mathscr{L}^2(\mathbb{R}^d, \mathbb{H}'')\big)$*-norm of the operator* $Aq(x, hD, h) - B'$ *do not exceed* $C\|P\| \cdot \|a\| h^{N+1}$ *and, moreover, footnote* [17] *remains true. Here* B *and* B' *are Fourier integral operators with phase function* ϕ *and symbols* b *and* b' *respectively.*

Moreover,

$$b_0(x,y,\theta) = p_0(x, \phi'_x(x,\theta)) \cdot a_0(x,y,\theta), \tag{1.2.84}$$

$$b'_0(x,y,\theta) = a_0(x,y,\theta) \cdot q_0(x, -\phi'_y(x,\theta)) \tag{1.2.84}'$$

and hence

$$b^0(x,\xi,y,\eta) = p_0(x,\xi) \cdot a^0(x,\xi,y,\eta), \tag{1.2.85}$$

$$b'^0(x,\xi,y,\eta) = a^0(x,\xi,y,\eta) \cdot q_0(y,\eta) \tag{1.2.85}'$$

where the principal symbol of a Fourier integral operator equals the principal symbol of its Schwartz kernel at the ^{T}-transposed point.

In what follows we assume that the domains and ranges of all symbols and operators agree.

Corollary 1.2.31. *(i) Let A and B be Fourier integral operators with symplectomorphisms Ψ and Ψ^{-1} respectively and let $p(x, hD, h)$ be an h-pseudodifferential operator.*

Then modulo negligible operators $q(x, hD, h) \equiv Bp(x, hD, h)A$ is also an h-pseudodifferential operator and

$$q_n = \sum_{0\le j\le n} \mathcal{L}_{n-j}(p_j)\circ\Psi \tag{1.2.86}$$

where $\mathcal{L}_j$ are $(2j)$-th degree linear differential operators of the form

$$\mathcal{L}_j(q) = \sum_{k,|\alpha|\le 2j} c_{jk\alpha}(D^\alpha_{x,\xi}q)c'_{jk\alpha}$$

with operator-valued coefficients $c_{jk\alpha}$ and $c'_{jk\alpha}$ (for scalar A and B we obtain scalar differential operators); in particular,

$$q_0(x,\xi) = b^0((x,\xi),\Psi(x,\xi))\cdot p_0(\Psi(x,\xi))\cdot a^0(\Psi(x,\xi),(x,\xi)). \tag{1.2.87}$$

(ii) Assume that the operator A is elliptic for (x,ξ,y,η) with $(x,\xi) = \Psi_A(y,\eta)$ and $(y,\eta)\in\mathcal{Y}'\Subset\mathcal{Y}$, i.e., $a^0(x,\xi,y,\eta)$ is invertible and the norm of the inverse symbol does not exceed c (as well as $|||a|||$).

Then there exists a Fourier integral operator B corresponding to the symplectomorphism Ψ_A^{-1} such that $BA\equiv I$ in $\mathcal{Y}'$ (i.e., the equality is true modulo the sum of an h-pseudodifferential operator with symbol vanishing in this neighborhood and a negligible operator) and $AB\equiv I$ in $\mathcal{X}' = \Psi_A(\mathcal{Y}')$.

In particular, if A is a scalar operator and $P = p(x, hD, h)$ is an h-pseudodifferential operator then in $\mathcal{Y}$ for the principal symbol of $Q\equiv BPA$ the following equality holds:

$$q_0 = p_0\circ\Psi. \tag{1.2.88}$$

Let us note that for a given symplectomorphism Ψ and domain $\mathcal{Y}'$ an elliptic symbol does not necessarily exist because of obstacles of a topological nature. However, such symbols certainly exist (even in the scalar case) provided quantization conditions (1.2.57) and (1.2.58) are fulfilled; in particular, such symbols exist provided $\mathcal{Y}'$ is simply connected. In this case A^*A is an h-pseudodifferential operator with a Hermitian symbol and with the positive definite principal symbol in the vicinity of $\mathcal{Y}'$. Then we arrive to

Theorem 1.2.32. *Let $\Psi : \mathcal{Y} \to \mathcal{X}$ be a local symplectomorphism satisfying condition* (1.2.74) *with graph satisfying* (1.2.57) *and* (1.2.58). *Suppose $\mathcal{Y}' \Subset \mathcal{Y}$ and let $\mathcal{X}' = \Psi(\mathcal{Y}')$. Then there exists a scalar Fourier integral operator A corresponding to Ψ such that $A^*A \equiv I$ and $AA^* \equiv I$ in neighborhoods of $\mathcal{Y}'$ and $\mathcal{X}'$ respectively.*

One can easily rewrite all these assertions in the uniform form which we used before. Using a partition of unity in $\mathbb{R}^d \times \mathbb{R}^d$ and Corollary 1.2.31 one can prove

Theorem 1.2.33. *Let A and B be scalar Fourier integral operators with symplectomorphisms Ψ and Ψ^{-1} respectively and let p be a symbol supported in $G \Subset \mathbb{R}^d \times \mathbb{R}^d$ belonging to $\mathsf{S}_{h,N}(\mathbb{R}^d, \mathbb{H}', \mathbb{H})$ after rescaling $x \mapsto x/\rho$, $\xi \mapsto \xi/\rho$, $\rho \in (0,1]$. Let $\hbar = h\rho^{-2} \in (0,1]$.*

Then there exists symbol supported in $G' = \Psi(G)$ and belonging to $\mathsf{S}_{h,N}(G', \mathbb{H}', \mathbb{H})$ after the same rescaling such that $\|\!|q|\!\|_\rho \le C\|\!|p|\!\|_\rho$ (where $\|\!|.|\!\|_\rho$ denotes the norm of the rescaled symbol)

$$\|q(x, hD, h) - Bp(x, hD, h)A\| \le C\rho^{-4d}\hbar^{N+1}\|\!|p|\!\| \tag{1.2.89}$$

with $C = C(d, c, N, G, A, B)$ and $K = K(d)$ in the conditions to Ψ, A, B. Moreover, footnote[17] *remains true.*

Remark 1.2.34. (i) One can easily replace in (1.2.89) factor ρ^{-4d} by the factor $(\rho^{-2d}\,\mathsf{mes}\,\mathsf{supp}(P)+1)$. I do not know whether it is possible to replace the factor ρ^{-4d} by 1 here. However we have no need of these improvements.

(ii) Since when transforming pseudodifferential operators by Fourier integral operators we mess x and ξ, in this and similar theorems one needs to replace in the definition of $\mathsf{S}_{h,\dots,N}$ range $|\alpha| \le N + K$, $|\beta| \le N + K$ by $|\alpha| + |\beta| \le 2N + K$.

However we are not concerned about N and we will skip N in notations at all (or assume $N = \infty$).

The following statement is well known (see, e.g., L. Hörmander [1]):

Theorem 1.2.35. *Let $A \in \boldsymbol{\Psi}_{h,N}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ and suppose its principal symbol a_0 is real-valued and scalar. Let $P \in \boldsymbol{\Psi}_{h,N}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ be an operator with compactly supported symbol. Then $e^{ith^{-1}A}P$ and $Pe^{ith^{-1}A}$ are Fourier integral operators (for any $t \in \mathbb{R}$) with symplectomorphism $\Psi = \Phi_t$ where $\Phi_t = \exp(tH_{a_0})$ is the Hamiltonian flow generated by the Hamiltonian field $-\nabla^{\#}a_0$; recall that $\nabla^{\#}a_0 = (\nabla_\xi a_0, -\nabla_x a_0)$.*

In conclusion let us note that the notations for negligible functions and negligible operators do not agree completely: if $h^{d/2}\mathcal{K}_A$ is an (N,k)-negligible function then A is an $(N - \frac{d}{2}, k)$-negligible operator; conversely, if A is an (N,k)-negligible operator then $h^{d/2}\mathcal{K}_A$ is an $(N, k - \lfloor \frac{d}{2} \rfloor - 1)$-negligible function. However this fact should not lead to confusion.

Final Remarks

Remark 1.2.36. (i) So far we constructed propagator $U(t) = e^{-ih^{-1}tA}$ of operator A which does not depend on t. Construction of propagator $U(t,t')$ instead of $U(t-t')$ of t-dependent A is done by a similar way.

(ii) As in Subsection 1.2.2 we considered Lagrangian distributions with the complex phase, we can construct h-Fourier integral operators with the complex phase. They appear as parametrix for operators with scalar principal symbol a with $\operatorname{Im} a \le 0$.

(iii) Since any function could be decomposed into coherent states due to

$$\delta(x) = (2\pi h)^{-3d/2} \iint e^{ih^{-1}\langle x,\xi\rangle - \frac{1}{2}h^{-1}|x-z|^2}\, d\xi dz \tag{1.2.90}$$

one can construct propagator constructing solutions with the initial data $e^{ih^{-1}\langle x-y,\xi\rangle - \frac{1}{2}h^{-1}|x-y-z|^2}$ (instead of the usual procedure of plane waves decomposition.

(iv) One can construct the theory for "analytic" phase functions and symbols using Fourier-Bros-Iagolnitzer transform (see f.e. A. Martinez [1]).

(v) Non semiclassical theory is well known.

1.2.4 Metaplectic Operators

Let us consider operators with quadratic symbols:

$$(1.2.91)_1 \quad A = \sigma(FZ, Z) = \frac{1}{2}\sum_{i,j}\bigl(\alpha_{ij}x_ix_j + \alpha'_{ij}(x_ihD_j + hD_ja_i) + \alpha''_{ij}h^2D_iD_j\bigr)$$

$$(1.2.92)_1 \qquad a = \sigma(Fz, z) = \frac{1}{2}\sum_{i,j}\bigl(\alpha a_{ij}x_ix_j + 2\alpha'_{ij}x_i\xi_j + \alpha''_{ij}\xi_i\xi_j\bigr)$$

where $\sigma(z,z') = \langle\xi, x'\rangle - \langle x, \xi'\rangle$ for $z = (x,\xi)$ and $z' = (x',\xi')$ is the skew-symmetric bilinear *symplectic form*, $Z = (x, hD)$ is a vector-valued operator from $\mathscr{H}^1(\mathbb{R}^d) := \{u\colon u, x_ju, D_ju \in \mathscr{L}^2(\mathbb{R}^d, \mathbb{C}^{2d})\ \forall j = 1, \dots, d\}$ to $\mathscr{L}^2(\mathbb{R}^d, \mathbb{C}^{2d})$, $F = \begin{pmatrix} -{}^t\alpha' & -\alpha'' \\ \alpha & \alpha' \end{pmatrix}$ is the *skew-Hessian* of a, $\alpha = (\alpha_{ij})$, $\alpha' = (\alpha'_{ij})$, $\alpha'' = (\alpha''_{ij})$ are $d \times d$ matrices and (α), (α'') are assumed to be symmetric and all the coefficients here and below are assumed to be real.

Moreover, let us consider operators with linear symbols:

$$(1.2.91)_{\frac12} \qquad A = \sigma(\ell, Z) = \sum_j(\alpha_jx_j + \alpha'_jhD_j),,$$

$$(1.2.92)_{\frac12} \qquad a = \sigma(\ell, z) = \sum_j(\alpha_jx_j + \alpha'_j\xi_j),$$

where $\ell = (-\alpha, \alpha')$, $\alpha = (\alpha_1, \dots, \alpha_d)$, $\alpha' = (\alpha'_1, \dots, \alpha'_d)$ and the subscript means the genuine order of the operator in the framework of the "correct" calculus.

One can see easily that

$$(1.2.93) \qquad \sigma(Fz, z') = -\sigma(z, Fz'), \qquad \forall z, z'$$

$$(1.2.94) \qquad \sigma(\nabla^\# f, \nabla^\# g) = \{f, g\}$$

and

(1.2.95) $\nabla^\# a = -Fz$, $\nabla^\# a = -\ell$ for quadratic and linear symbols respectively.

Let $\mathfrak{A}_1$ and $\mathfrak{A}_{\frac12}$ be the spaces of operators with real-valued quadratic and real-valued linear symbols respectively and let $\mathfrak{A}_0 = \mathbb{R}$. Then

(1.2.96) $\mathfrak{A} = \mathfrak{A}_1$ and $\tilde{\mathfrak{A}} = \mathfrak{A}_1 \oplus \mathfrak{A}_{\frac12} \oplus \mathfrak{A}_0$ are Lie algebras with Lie operation $A, B \mapsto ih^{-1}[A, B]$ (moreover, $\tilde{\mathfrak{A}}$ is a graded Lie algebra)

and

$$\dim \mathfrak{A} = d(2d+1), \qquad \dim \tilde{\mathfrak{A}} = (d+1)(2d+1). \tag{1.2.97}$$

On the other hand, there are the natural isomorphisms $\mathfrak{A}_j \simeq \mathfrak{B}_j$, etc., where $\mathfrak{B}_1$ is the space of all real $2d \times 2d$ matrices satisfying (1.2.93), $\mathfrak{B}_{\frac12} = \mathbb{R}^d$, $\mathfrak{B}_0 = \mathbb{R}$ equipped by induced Lie operations $F, F' \mapsto -[F, F']$ and $(F; \ell; c), (F'; \ell'; c') \mapsto (-[F, F']; -Fl' + F'l; \sigma(l, l'))$ on $\mathfrak{B}$ and $\tilde{\mathfrak{B}}$ respectively.

The following statements are either well known or easy (see, e.g., Leray [1]):

Proposition 1.2.37. *(i) Let $A \in \tilde{\mathfrak{A}}$ and $\mathfrak{D}(A) = \{u \in \mathscr{L}^2(\mathbb{R}^d)\colon Au \in \mathscr{L}^2(\mathbb{R}^d)\}$. Then A is a self-adjoint operator.*

(ii) The sets $\mathfrak{G}$ and $\tilde{\mathfrak{G}}$ of all operators of the form $e^{ih^{-1}A}$ with $A \in \mathfrak{A}$, $A \in \tilde{\mathfrak{A}}$ are Lie groups and $\dim \mathfrak{G} = d(2d+1)$, $\dim \tilde{\mathfrak{G}} = (d+1)(2d+1)$.

(iii) The set $\mathscr{G}$ of all matrices of the form $\exp(-F)$ with $F \in \mathfrak{B}$ coincides with the Lie group of all symplectic matrices (i.e., matrices S such that $\sigma(Sz, Sz') = \sigma(z, \zeta')$); further $\dim \mathscr{G} = d(2d+1)$.

Moreover, the set $\tilde{\mathscr{G}}$ of all transformations of the form $\exp(-\tilde{F})|_{\mathbb{R}^{2d}}$ with $\tilde{F} \in \tilde{\mathfrak{B}}$ coincides with the Lie group of all symplectic affine transformations of $\mathbb{R}^{2d}$ (i.e., transformations of the form $z \to Sz + L$ with $S \in \mathscr{G}$, $L \in \mathbb{R}^{2d}$). For $\tilde{F} = (F; \ell; c)$ we have

$$S = exp(-F), \quad L = \int_0^1 \exp(-tF)\ell \, dt;$$

further, $\dim \tilde{\mathscr{G}} = d(2d+3)$.

(iv) The isomorphisms $\mathfrak{A} \simeq \mathfrak{B}$ and $\tilde{\mathfrak{A}} \simeq \tilde{\mathfrak{B}}$ generate natural maps $\theta : \mathfrak{G} \to \mathscr{G}$ and $\tilde{\theta} : \tilde{\mathfrak{G}} \to \tilde{\mathscr{G}}$ where θ is two-sheeted covering and for any $g \in \tilde{\mathscr{G}}$, $\tilde{\theta}^{-1} g \simeq \mathbb{S}^1 \subset \mathbb{C}$.

(v) Suppose $G \in \mathfrak{G}$ or $G \in \tilde{\mathfrak{G}}$ and let $P = p^{\mathrm{w}}(x, D)$ be a pseudodifferential operator. Then

$$G^* P G = q^{\mathrm{w}}(x, D), \qquad q(x, \xi) = q(S(x, \xi)) \tag{1.2.98}$$

where $S = \theta(G) \in \mathscr{G}$ or $S = \tilde{\theta}(G) \in \tilde{\mathscr{G}}$ respectively.

One can find the complete description of spectra of such operators in M. Zaretskaya [1].

Proposition 1.2.38. *(i) Let $G \in \mathfrak{G}$ (or $G \in \tilde{\mathfrak{G}}$) and let P be an h-pseudodifferential operator with compactly supported symbol. Then PG and GP are Fourier integral operators with symplectomorphism $S = \theta(G)$ (or $S = \tilde{\theta}(G)$ respectively). They can be defined by a quadratic phase function (with linear part in the second case). Moreover,*

$$GZ = (SZ)G. \tag{1.2.99}$$

(ii) On the other hand, (1.2.99) *with linear (or affine) transformation S yields that $G \in \mathfrak{G}$, $S = \theta(G)$ (or $G \in \tilde{\mathfrak{G}}$, $S = \tilde{\theta}(G)$ respectively).*

Definition 1.2.39. (i) Elements of $\mathfrak{G}$ are *metaplectic operators*.

(ii) Elements of $\tilde{\mathfrak{G}}$ are *generalized metaplectic operators*.

Example 1.2.40. (i) Partial h-Fourier transforms (with an appropriate numerical factor) are metaplectic operators.

Further, operators of the form $(Gu)(x) = |\det \beta|^{1/2} u(\beta x)$ with non-degenerate matrix β are metaplectic operators.

Finally, operators of the form $(Gu)(x) = e^{\frac{1}{2} ih^{-1}\langle Wx, x\rangle} u(x)$ with symmetric matrix W are metaplectic operators.

Conversely, all metaplectic operators are products of operators of these three types.

(ii) Operators of the form $(Gu)(x) = e^{ih^{-1}(\langle bx\rangle + \phi)} u(x-a)$ are (all) generalized metaplectic operators with linear phase functions.

(iii) All generalized metaplectic operators are products of operators of form (i) and (ii).

1.2.5 Germs

Lemma 1.1.17 yields the following

Proposition 1.2.41. *Let $X = \mathbb{R}^d$ and $p_j(x,\xi)$ with $j = 1, \dots, s-1$ be scalar linear functions on T^*X. Then*

$$(p_1 \cdots p_s)^{\mathrm{w}}(x, hD) = \frac{1}{s!} \sum_{|J|=s} p_{j_1}^{\mathrm{w}}(x, hD) \cdots p_{j_s}^{\mathrm{w}}(x, hD) \tag{1.2.100}$$

where the summation is taken over all the permutations J.

Definition 1.2.42. The right-hand expression of (1.2.100) is a *symmetric product* of (operators) $p_1^{\mathrm{w}}(x, hD), \dots, p_s^{\mathrm{w}}(x, hD)$.

Moreover $(1.1.37)_3$ implies

Proposition 1.2.43. *Let $p_j(x,\xi,h)$, $j = 1, \dots, s > 1$ be scalar symbols and suppose $p_{j0}(x,\xi)$ vanish at $(\bar{x},\bar{\xi}) \in T^*\mathbb{R}^d$. Let q be the Weyl symbol of the symmetric product of $p_1^{\mathrm{w}}(x, hD, h), \dots, p_s^{\mathrm{w}}(x, hD, h)$. Then*

$$D^{\alpha}_{x,\xi} q_n(\bar{x},\bar{\xi}) = 0 \qquad \forall n \ge 1,\ \alpha : |\alpha| + 2n \le s. \tag{1.2.101}$$

Remark 1.2.44. These equalities remain true for other types of quantization only provided $|\alpha| + 2n < s$.

Let $p_j(x,\xi,h)$ be the symbols described in Proposition 1.2.43 and let $\tilde{p}_j(x,\xi,h)$ be Weyl symbols of $Bp_j^{\mathrm{w}}(x, hD, h)A$ where A and B are Fourier integral operators corresponding to symplectomorphisms Ψ and Ψ^{-1} respectively such that $AB \equiv I$ and $BA \equiv I$ in $\mathcal{X} \ni (\bar{x},\bar{\xi})$ and $\mathcal{Y} \ni (\bar{y},\bar{\eta}) = \Psi^{-1}(\bar{x},\bar{\xi})$ respectively.

Then symbols $\tilde{p}_{j0} = p_{j0} \circ \Psi$ vanish at $(\bar{y},\bar{\eta})$. On the other hand,

$$\prod_{0\le j\le s} \bigl(Bp_j^{\mathrm{w}}(x, hD, h)A\bigr) \equiv B\Bigl(\prod_{0\le j\le s} p_j^{\mathrm{w}}(x, hD, h)\Bigr)A$$

and the same is also true for a symmetric product.

Applying Corollary 1.2.31(i) and Pproposition 1.2.43 to both sides of the latter equality we obtain that the degrees of the operators $\mathcal{L}_j$ in (1.2.86) do not exceed $(2j-1)$ for $j \ge 1$. Moreover, the general case of Corollary 1.2.31(i) can be easily reduced to the case considered (when A and B are scalar and mutually inverse in the indicated sense) by replacing A and B by $A' = AR_1$ and $B' = R_2B$ respectively with h-pseudodifferential operators R_1 and R_2. So we arrive to

Proposition 1.2.45. *For Weyl quantization* $\mathcal{L}_j$ *in* (1.2.86) *(and hence in* (1.2.74) *also) are* $(2j-1)$*-th degree operators for* $j \ge 1$*.*

Remark 1.2.46. One can observe easily that this assertion fails for other types of the quantization (it fails even for $j = 1$).

Definition 1.2.47. (i) Let $P = p(x, hD, h)$ be an operator with symbol p such that

$$\partial_x^\alpha \partial_\xi^\beta p_n(\bar{x}, \bar{\xi}) = 0 \qquad \forall \alpha, \beta, n : l|\alpha| + r|\beta| + n(l+r) < m \tag{1.2.102}$$

in $\mathbb{R}^d$ where $l > 0, r > 0, (\bar{x}, \bar{\xi}) \in T^*\mathbb{R}^d$ [18]. Then the operator

$$q(z, hD_z, h) \coloneqq \sum_{\alpha,\beta,n: l|\alpha|+r|\beta|+n(l+r)=m} \frac{1}{\alpha!\beta!} \big(\partial_x^\alpha \partial_\xi^\beta p_n\big)(\bar{x}, \bar{\xi}) \ell_{\alpha\beta}(z, hD_z) h^n \tag{1.2.103}$$

is called an (l, r)*-germ of operator* P *at the point* $(\bar{x}, \bar{\xi})$*;* here $\ell_{\alpha\beta}(z, \zeta) = z^\alpha \zeta^\beta$ and we use the same type of quantization for p and $z^\alpha \zeta^\beta$.

(ii) This procedure is called *microlocalization*.

One can show easily that

(1.2.104) The microlocalization does not depend on the type of quantization.

Remark 1.2.48. (i) One can also introduce *anisotropic microlocalizations* (with vector l and r); moreover it is possible to consider the case in which some components of l and r vanish, but we have no need of it.

(ii) One can see easily that the product of operators corresponds to the product of their microlocalizations; (l, r) are supposed to be the same and then degrees (m) sum.

Corollary 1.2.31, Theorem 1.1.35 and Proposition 1.2.43 imply

Proposition 1.2.49. *Let* (1.2.102) *be fulfilled. Then*

[18] Without any loss of generality one can assume that $l + r = 1$.

(i) Let A and B be scalar Fourier integral operators corresponding to symplectomorphisms Ψ and Ψ^{-1} respectively such that $BA \equiv I$ on $\mathcal{Y}$ and $AB \equiv I$ on $\mathcal{X} \ni (\bar{x}, \bar{\xi})$.

Then for $l = r$ the operator $\tilde{P} = BPA$ satisfies (1.2.102) *at $(\bar{y}, \bar{\eta}) = \Psi(\bar{x}, \bar{\xi})$ and the germ of operator $\tilde{P}$ at point $(\bar{y}, \bar{\eta})$ is linked to the the germ of operator P at point $(\bar{x}, \bar{\xi})$ by the equality*

$$\tilde{q}(z, hD_z, h) = (q \circ \Psi'_{(\bar{y},\bar{\eta})})(z, hD_z, h) = G^* q(z, hD_z, h) G \tag{1.2.105}$$

where $\Psi'_{(\bar{y},\bar{\eta})}$ is the differential of Ψ at $(\bar{y}, \bar{\eta})$ (so $\Psi'_{(\bar{y},\bar{\eta})}$ is a linear symplectomorphism in $\mathbb{R}^d \times \mathbb{R}^d$) and G is the corresponding metaplectic operator.

(ii) The above statement remains true provided $l < r$ and $Au = u \circ \varkappa$, $Bu = u \circ \varkappa^{-1}$ where $\varkappa$ is a diffeomorphism[19]*.*

1.3 Wave Front Sets and Related Topics

1.3.1 Principal Notions

Philosophy

In this book we consider various objects depending on a parameter (or parameters) $\mathfrak{m} \in \mathfrak{M}$ of an arbitrary nature (i.e., we consider *families* of the individual objects); one of these parameters is the *semiclassical parameter* $h \in (0, 1]$[20] and the exact nature of other parameters is as a rule unessential[21].

Objects not depending on the parameters (i.e., individual objects) are called *fixed* while numbers depending on parameters are also called *parameters*[22].

If $\mathscr{B}$ is a Banach space of individual objects then $\underline{\mathscr{B}}$ is the Banach space of these objects uniformly bounded (in which case $\|u\|_{\underline{\mathscr{B}}} = \sup_{\mathfrak{m}\in\mathfrak{M}} \|u_{\mathfrak{m}}\|_{\mathscr{B}}$

[19] In this case $(Gu)(x) = |\det \beta|^{\frac{1}{2}} u(\beta x)$ with $\beta = \varkappa'(\bar{y})$.

[20] Surely, h can run over a certain subset of $(0, 1]$ with an accumulation point 0.

[21] For example, for h-differential operators one can treat coefficients as parameters belonging to certain functional spaces. On the other hand, we can consider coefficients also depending on h via other parameters.

[22] There is no room for any confusion: fixed numbers are called *constants* and some of these constants are called *exponents.*

for $u = (u_{\mathtt{m}})_{\mathtt{m}}$); if $\lambda = (\lambda_{\mathtt{m}})$ is a (numerical) parameter then $\lambda\underline{\mathscr{B}}$ is the space of families of the form λu with $u \in \underline{\mathscr{B}}$ and $\|v\|_{\lambda\underline{\mathscr{B}}} = \|\lambda^{-1}u\|_{\underline{\mathscr{B}}}$.

In what follows we speak of *objects but mean families of these objects* [23].

In this book as *admissible* we consider *tempered* functions, i.e., functions $u \in h^{-L}\underline{\mathscr{L}}^2(\mathbb{R}^d, \mathbb{H})$ where $\mathbb{H}$, $\mathbb{H}'$, etc., are auxiliary Hilbert spaces. Sometimes we replace $\mathbb{H}$ in this definition by $\mathcal{L}(\mathbb{H}, \mathbb{H}')$ [24].

Similarly, as *admissible* we consider *tempered* operators, i.e., operators $A \in h^{-L}\underline{\mathcal{L}}\big(\mathscr{L}^2(\mathbb{R}^d, \mathbb{H}), \mathscr{L}^2(\mathbb{R}^{d'}, \mathbb{H}')\big)$.

Functions $u \in h^s\underline{\mathscr{L}}^2(\mathbb{R}^d, \mathbb{H})$ or $u \in h^s\underline{\mathscr{L}}^2\big(\mathbb{R}^d, \mathcal{L}(\mathbb{H}, \mathbb{H}')\big)$ and operators $A \in h^s\underline{\mathcal{L}}\big(\mathscr{L}^2(\mathbb{R}^d, \mathbb{H}), \mathscr{L}^2(\mathbb{R}^{d'}, \mathbb{H}')\big)$ are called *negligible;* in these cases we write $u \equiv 0$ and $A \equiv 0$ respectively. Exponents l and s enter into these definitions (so in fact we speak about l-admissible or s-negligible functions, etc.).

Smooth (Standard) Theory

As an *admissible box* we consider a parallelepiped

$$B = \big\{(x,\xi) : \ |x_j - \bar{x}_j| \le \gamma_j, \ |\xi_j - \bar{\xi}_j| \le \rho_j \ \forall j = 1, \dots, d\big\} \tag{1.3.1}$$

where $(\bar{x}, \bar{\xi})$, $\boldsymbol{\rho} = (\rho_1, \dots, \rho_d)$, $\boldsymbol{\gamma} = (\gamma_1, \dots, \gamma_d)$ are parameters such that

$$\infty \ge \gamma_j > 0, \quad \infty \ge \rho_j > 0, \quad \rho_j\gamma_j \ge h^{1-\delta} \qquad \forall j = 1, \dots, d \tag{1.3.2}$$

where here and in what follows $\delta > 0$ is always an arbitrarily small positive exponent; so an admissible box is not necessarily fixed.

Definition 1.3.1. (i) Let u be an admissible function and B an admissible box. Then u *is negligible in* B ($u \equiv 0$ in B) if there exists a symbol $\varphi \in \mathsf{S}_{h,\rho,\gamma,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{C})$ with $K = K(d, l, s, \delta)$ in the definition of the class such that $\varphi = 1$ in B and $\varphi(x, hD, h)u \equiv 0$ (this agrees with the definition given in the introduction)[25].

(ii) Similarly, let A be an admissible operator and $B = B \times B''$ an admissible box. Then A is *negligible in* B ($A \equiv 0$ in B) if there exist symbols $\varphi' \in$

[23] This casualness does not lead to any confusion because we use the word *fixed* for individual objects.

[24] In what follows we use plain letters instead of bold.

[25] Here and below extra indices $\boldsymbol{\rho}, \boldsymbol{\gamma}$ mean that φ would belong to the standard class $\mathsf{S}_{h,N}$ after rescaling $x_j \mapsto x_j/\gamma_j$, $\xi_j \mapsto \xi_j/\rho_j$.

$\mathsf{S}_{h,\rho',\gamma',N}(\mathbb{R}^{d'}\times\mathbb{R}^{d'},\mathbb{C})$ and $\varphi''\in \mathsf{S}_{h,\rho'',\gamma'',N}(\mathbb{R}^{d''}\times\mathbb{R}^{d''},\mathbb{C})$ with $K=K(d,I,s,\delta)$ in the definition of the class such that $\varphi'=1$ in B', $\varphi''=I$ in B'' and $\mathsf{Op}(\varphi'')A\,\mathsf{Op}(\varphi')\equiv 0$.

(iii) On the other hand, we call an admissible function u *essentially supported in* B if $\varphi(x,hD,h)u\equiv u$ for some ϕ with a symbol, supported in B.

Also we call an operator A *essentially supported in* B if $\mathsf{Op}(\phi')A\,\mathsf{Op}(\phi'')\equiv A$ for some ϕ', ϕ'' with symbols, supported in B' and B'' respectively.

Remark 1.3.2. (i) Surely these definitions depend on exponents I and s; the results of Section 1.1 imply that these definitions do not depend on the choice of K large enough;

(ii) Though all admissible (negligible) functions are Schwartz kernels of admissible (negligible) operators the converse assertion fails to be true.

Definition 1.3.3. (i) Let u be an admissible function. Let us introduce the set $\mathsf{WF}^s(u)\subset T^*\mathbb{R}^d$: $(\bar{x},\bar{\xi})\notin \mathsf{WF}^s(u)$ if and only if $u\equiv 0$ in some fixed box centered at $(\bar{x},\bar{\xi})$ (so, the point $(\bar{x},\bar{\xi})$ is also fixed);

(ii) Similarly, let A be an admissible operator. Let us introduce $\mathsf{WF}^s(A)\subset T^*(\mathbb{R}^{d'}\times\mathbb{R}^{d''}) : (\bar{x},\bar{\xi},\bar{y},\bar{\eta})\notin \mathsf{WF}^s(A)$ iff $A\equiv 0$ in some fixed box centered in $(\bar{x},\bar{\xi},\bar{y},\bar{\eta})$.

(iii) In both cases $\mathsf{WF}^s(.)$ are called *wave front sets*.

Remark 1.3.4. (i) In the previous book I called these sets *oscillation front sets* and denote them as OF^s to avoid confusion with the standard wave front sets. Here on the contrary I would like to emphasize similarity and I use the standard term wave front set and notation WF^s.

(ii) Still, there is a very essential difference: negligible functions are not smooth anymore. This leads to certain problems, usually related to the restrictions of functions. Therefore we can consider as a main space

$$\mathscr{H}^m=\bigl\{u : \|u\|_m=\|(1+h|D|)^{m/2}u\|<\infty\bigr\} \tag{1.3.3}$$

where $m\in\mathbb{R}$. This leads to the modification of all our definitions and to sets $\mathsf{WF}^{s,m}(u)$.

(iii) Respectively for operators we consider $\mathcal{L}(\mathscr{H}^m, \mathscr{H}^k)$ of (uniformly with respect to h) bounded operators from $\mathscr{H}^k$ to $\mathscr{H}^m$ and to wave front sets $\mathsf{WF}^{s,m,k}(A)$.

(iv) The notion of wave (oscillation) front set is rather rough and it would be desirable to give a more refined and sophisticated definition also based on Definition 1.3.1 and leading to no difficulty in the advanced development of the theory. Maybe non-standard analysis will be useful? However we simply use Definition 1.3.1 instead of Definition 1.3.3 if the latter is too rough for our needs.

Analytic Theory

In the framework of the theory of operators with analytic symbols we replace the standard microlocal uncertainty principle $\rho_j\gamma_j \ge h^{1-\delta}$ by the logarithmic uncertainty principle $\rho_j\gamma_j \ge C_s h|\log h|$ and thus we replace (1.3.2) by

$$\infty \ge \gamma_j > 0, \quad \infty \ge \rho_j > 0, \quad \rho_j\gamma_j \ge Ch|\log h| \qquad \forall j = 1, \dots, d \tag{1.3.4}$$

Remark 1.3.5. This leads to the question: can we go further? The answer is *No. Microlocal Analysis starts from logarithmic uncertainty principle*; see Appendix 1.A.4.

1.3.2 Properties

The results of Sections 1.1 and 1.2 imply immediately

Theorem 1.3.6. *(i) Let $p \in \mathsf{S}_{h,\rho,\gamma,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}', \mathbb{H})$ with $K = K(d, s, \delta)$. Then $P = p(x, hD, h)$ is negligible in every box $B = B' \times B''$ with*

$$\begin{aligned} B' &= \{(x,\xi) : |x_j - \bar{x}_j| \le \gamma'_j,\ |\xi_j - \bar{\xi}_j| \le \rho'_j \qquad \forall j = 1, \dots, d\}, \\ B'' &= \{(y,\eta) : |y_j - \bar{y}_j| \le \gamma''_j,\ |\eta_j - \bar{\eta}_j| \le \rho''_j \qquad \forall j = 1, \dots, d\} \end{aligned} \tag{1.3.5}$$

provided there exist γ_j, ρ_j such that

$$\gamma'_j \asymp \gamma''_j, \quad \rho'_j \asymp \rho''_j, \tag{1.3.6}$$

$$\min(\rho'_j, \rho_j) \cdot \min(\gamma'_j, \gamma_j) \ge h^{1-\delta} \quad \forall j \tag{1.3.7}$$

and

$$\sum_{1\le j\le d}\big(\frac{1}{\gamma_j}(|x_j-y_j|+|x_j-z_j|)+\frac{1}{\rho_j}(|\xi_j-\eta_j|+|\xi_j-\zeta_j|)\big)\ge\epsilon \tag{1.3.8}$$
$$\forall(x,\xi)\in B',\quad \forall(y,\eta)\in B'',\quad \forall(z,\zeta)\in \mathsf{supp}(p);$$

recall that ϵ is an arbitrary positive constant.

(ii) Further, if $p\in \mathsf{S}_{h,\rho,\gamma,\mathsf{an}}(\mathbb{R}^d\times\mathbb{R}^d,\mathbb{H}',\mathbb{H})$ [26] *one can replace* (1.3.7) *by*

$$\min(\rho_j',\rho_j)\cdot\min(\gamma_j',\gamma_j)\ge Ch|\log h|\quad\forall j. \tag{1.3.9}$$

Theorem 1.3.7. *(i) Let A be a Fourier integral operator corresponding to the symplectomorphism Ψ and let all the conditions on phase functions and symbols be fulfilled with $M=K=K(d,r,s,\delta)$ uniformly with respect to all the parameters. Then A is negligible in every box $B'\times B''$ of the form* (1.3.5) *such that*

$$\gamma_j'\asymp\gamma_j''\asymp\gamma,\quad \rho_j'\asymp\rho_j''\asymp\rho,\quad \gamma=\rho\ge\epsilon h^{(1-\delta)/2}, \tag{1.3.10}$$

$$\mathsf{dist}\big((x,\xi),\Psi(y,\eta)\big)+\mathsf{dist}\big((x,\xi),(z,\phi_z'(z,z',\theta)\big)\ge\epsilon\rho \tag{1.3.11}$$
$$\forall(x,\xi)\in B',\quad\forall(y,\eta)\in B'',$$
$$\forall(z,z',\theta)\in\mathsf{supp}(a)\cap\{|\phi_\theta'(z,z',\theta)|\le\epsilon\rho\}.$$

(ii) Let $Au=(fu)\circ\varkappa^{-1}$ where $\varkappa$ is a $\mathscr{C}^K$ diffeomorphism from $Y\subset\mathbb{R}^d$ to $X\subset\mathbb{R}^d$ and $f\in\mathscr{C}_0^K(Y)$ uniformly with respect to all the parameters, $K=K(d,s,\delta)$. Then A is negligible in every box $B'\times B''$ of the form (1.3.5) *such that*

$$\gamma_j'\asymp\gamma_j''\asymp\gamma,\ \rho_j'\asymp\rho_j''\asymp\rho,\ \gamma\le\rho,\ \min(\gamma,1)\cdot\min(\rho,1)\ge h^{1-\delta}, \tag{1.3.12}$$

$$\frac{1}{\gamma}\big(|x-\varkappa(y)|+|y-z|\big)+\frac{1}{\rho}|{}^t\varkappa'\xi-\eta|\ge\epsilon \tag{1.3.13}$$
$$\forall(x,\xi)\in B',\quad\forall(y,\eta)\in B'',\quad\forall z\in\mathsf{supp}(f).$$

[26] We define these classes in the manner similar to [25].

(iii) Let u be a Lagrangian distribution with Lagrangian manifold Λ and let all the conditions on Λ, phase functions and amplitudes be fulfilled with $K = K(d, r, s, \delta)$ uniformly with respect to all the parameters. Then u is negligible in every box B of the form (1.3.5) *provided*

$$\gamma_j' \asymp \gamma, \quad \rho_j' \asymp \rho \quad \forall j, \quad \gamma = \rho \ge \epsilon h^{(1-\delta)/2}, \tag{1.3.14}$$

$$\begin{aligned} \operatorname{dist}\big((x,\xi),(z,\phi_z'(z,\theta)\big) \ge \epsilon\rho \\ \forall (x,\xi) \in \Pi \quad \forall (z,\theta) \in \operatorname{supp}(a) \cap \{|\phi_\theta'(z,\theta)| \le \epsilon\rho\}. \end{aligned} \tag{1.3.15}$$

(iv) Moreover, let $\Lambda = \{x' = \xi'' = 0\}$ be a model Lagrangian manifold where $x = (x'; x'') = (x_1, \dots, x_{d'}; x_{d'+1}, \dots, x_d)$, etc., with $0 \le d' \le d$. Then u is negligible in every box of the form (1.3.5) *such that*

$$\min(\rho_j, 1) \cdot \min(\gamma_j, 1) \ge \epsilon h^{1-\delta} \quad \forall j, \tag{1.3.16}$$

$$\sum_{1 \le j \le d'} \frac{1}{\gamma_j}|x_j| + \sum_{d'+1 \le j \le d} \frac{1}{\rho_j}|\xi_j| \ge \epsilon. \tag{1.3.17}$$

Using statement (iv) one can easily find boxes in which operators A: $(Au)(x') = (f(hD)u)(x', 0)$ and B: $(Bu)(x') = \int f(x)u(x)|_{x=(x',x'')}\, dx''$ with compactly supported smooth function f are negligible (see also Theorem 1.3.13. It is also easy to prove that wave front sets introduced here have the following properties similar to properties of the standard wave front sets:

Theorem 1.3.8. *$\mathsf{WF}^s(.)$ is a closed set; conversely, if $M \subset T^*\mathbb{R}^d$ is a closed set and $s > 0$ then there exists $u \in \mathscr{L}^2(\mathbb{R}^d)$ such that $\mathsf{WF}^s(u) = M$.*

Theorem 1.3.9. *Let u, v etc be admissible with $l = 0$ functions and A, B etc be admissible with $l = 0$ operators. Further, let $Q \in \boldsymbol{\Psi}_{h,N}$ be an operator with symbol supported in $\{|x| + |\xi| \le C_0\}$. Then for $s > 0$*

$$\begin{aligned} \mathsf{WF}^s(AQu) \subset \mathsf{WF}^s(A) \circ \mathsf{WF}^s(u) = \\ \big\{(x,\xi : \exists (y,\eta) \in \mathsf{WF}^s(u) : (x,\xi,y,\eta) \in \mathsf{WF}^s(A)\big\}, \end{aligned} \tag{1.3.18}$$

$$\begin{aligned} \mathsf{WF}^s(AQB) \subset \mathsf{WF}^s(A) \circ \mathsf{WF}^s(B) = \\ \big\{(x,\xi,z,\zeta) : \exists (y,\eta) : (x,\xi,y,\eta) \in \mathsf{WF}^s(A), (y,\eta,z,\zeta) \in \mathsf{WF}^s(B)\big\}; \end{aligned} \tag{1.3.19}$$

$$\mathsf{WF}^s(u \otimes v) = \mathsf{WF}^s(u) \times \mathsf{WF}^s(v). \tag{1.3.20}$$

Theorem 1.3.10. *Let* $P = p(x, hD, h)$ *with* $p \in \mathsf{S}_{h,\rho,\gamma,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}', \mathbb{H})$ *with* $K = K(d, s, \delta)$ *such that*

$$\min(1, \rho_j) \cdot \min(1, \gamma_j) \geq \epsilon h^{1-\delta} \qquad \forall j. \tag{1.3.21}$$

Then

$$\mathsf{WF}^s(P) = \{(x, \xi, x, \xi) : (x, \xi) \in \mathsf{supp}(p)\} \tag{1.3.22}$$

and for every admissible function u

$$\mathsf{WF}^s(Pu) \subset \mathsf{WF}^s(u) \subset \mathsf{WF}^s(Pu) \cup \mathsf{Char}(P) \tag{1.3.23}$$

provided K *also depends on* I *and* $\mathsf{Char}(P)$ *is the set of all the points* (x, ξ) *at which the symbol* $p(x, \xi, 0)$ *is not invertible with the norm of the inverse symbol not exceeding* C*.*

Theorem 1.3.11. *Let* A *be an admissible operator with Schwartz kernel* $\mathcal{K}_A$*. Then the following inclusions hold:*

$$\mathsf{WF}^s(A) \subset \mathsf{WF}^s(\mathcal{K}_A)^T \tag{1.3.24}$$

and for admissible $\mathcal{K}_A$

$$\mathsf{WF}^s(\mathcal{K}_A)^T \subset \mathsf{WF}^{s+\frac{d}{4}}(A) \tag{1.3.25}$$

with $d = d' + d''$ *provided* $\mathcal{K}_A \in h^{-I}\mathscr{L}^2$*.*

Theorem 1.3.12. *(i) Let* u *be a Lagrangian distribution with Lagrangian manifold* $\Lambda \subset T^*\mathbb{R}^d$*. Then*

$$\mathsf{WF}^s(u) \subset \Lambda \tag{1.3.26}$$

provided $K = K(d, r, s)$*;*

(ii) Let A *be a Fourier integral operator with Lagrangian manifold* $\Lambda \subset T^*\mathbb{R}^{2d}$*. Then*

$$\mathsf{WF}^s(u) \subset \Lambda^T. \tag{1.3.27}$$

Theorem 1.3.13. *(i) Let* $a \in \mathsf{S}_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}', \mathbb{H})$ *with* $K = K(d, I, s)$ *and* $\mathsf{supp}(a) \subset \{|\xi''| \leq c\}$*. Let*

$$v(x') = \big(a(x, hD, h)u\big)(x', 0). \tag{1.3.28}$$

Then

$$\mathsf{WF}^s(v) \subset \big\{(x', \xi') : \exists \xi'' : (x', 0, \xi', \xi'') \in \mathsf{WF}^{s+\frac{d''}{2}}(u)\big\}; \tag{1.3.29}$$

(ii) Further, let $a \in \mathsf{S}_{h,N}(\mathbb{R}^d \times \mathbb{R}^d, \mathbb{H}', \mathbb{H})$ *with* $K = K(d, l, s)$ *and* $\mathsf{supp}(a) \subset \{|x''| \le c\}$. *Let*

$$v(x') = \int_{\mathbb{R}^{d''}} (a(x, hD, h)u)(x', x'')dx''. \tag{1.3.30}$$

Then

$$\mathsf{WF}^s(v) \subset \big\{(x', \xi') : \exists x'' : (x', x'', \xi', 0) \in \mathsf{WF}^s(u)\big\}. \tag{1.3.31}$$

Remark 1.3.14. (i) Let $u \in \mathscr{L}^2(X, \mathbb{H})$ with $X \subset \mathbb{R}^d$. Then Definition 1.3.1(i) remains reasonable provided

$$B_{\epsilon x} = \{|x_j - \bar{x}_j| \le (1+\epsilon)\gamma_j \quad \forall j = 1, \dots, d\} \subset X$$

with some small positive constant ϵ; in this case one should replace the cutting operator $\varphi(x, hD, h)$ by $\varphi(x, hD, h)\psi(x)$ where $\psi = 1$ in Π, ψ is supported in $\Pi_{\epsilon x}$ and belongs to the same symbol class.

Therefore Definition 1.3.3(i) remains reasonable provided $\mathsf{dist}(\bar{x}, \complement X) \ge \epsilon$.

(ii) Let $A \in \mathcal{L}\big(\mathscr{L}^2(Y, \mathbb{H}'), \mathscr{L}^2(X, \mathbb{H})\big)$ with $X \subset \mathbb{R}^d$ and $Y \subset \mathbb{R}^{d'}$ then Definition 1.3.1(ii) remains reasonable provided $B'_{\epsilon x} \subset X$ and $B''_{\epsilon y} \subset Y$; one should only take cutting operators of the form $\mathsf{Op}(\varphi')\psi'$ and $\psi''\,\mathsf{Op}(\varphi'')$.

So Definition 1.3.3(ii) remains reasonable provided $\mathsf{dist}(\bar{x}, \complement X) \ge \epsilon$ and $\mathsf{dist}(\bar{y}, \complement Y) \ge \epsilon$.

(iii) Let $v \in \mathscr{L}^2(X, \mathbb{H})$ be a fixed function. Let $u = u_h = \phi(h|D|)v$ be a family of functions where $\phi \in \mathscr{C}_0^\infty(\mathbb{R}^+)$, $\phi \ne 0$. Then $(\mathsf{WF}(u))_{\mathsf{cone}} = \mathsf{WF}(v)$ where M_{cone} is the cone hull (with respect to ξ) of the set M and $\mathsf{WF}_{\mathsf{cl}}(v)$ is a standard wave front set.

1.3.3 Propagator

Theorem 1.3.12(ii) and the construction of propagator as a Fourier integral operator imply immediately

Theorem 1.3.15. *Let* $A \in \boldsymbol{\Psi}_{h,N}$ *with a scalar principal symbol* a^0, *which is real. Then*

$$\mathsf{WF}^s(e^{-ith^{-1}A}) = \big\{(x, \xi; y, \eta) : \ (x, \xi) = \Psi_t(y, \eta)\big\} \tag{1.3.32}$$

where Ψ_t *is a forward Hamiltonian flow described by* (1.2.8).

In particular,

$$\mathsf{WF}^s(e^{-ith^{-1}A}f) = \Psi_t \circ \mathsf{WF}^s(f). \tag{1.3.33}$$

1.3.4 Alternative Theories

We are sending the reader to any Microlocal Analysis textbook for the theory of wave front sets associated with the classical pseudodifferential operators. In this case $h = 1$ and $A \in \boldsymbol{\Psi}^1_{\mathsf{cl}}$.

Further, one can con construct the theory of global operators (whose symbols satisfy (1.1.213) or (1.1.214) with $m = 1$: order of operator *must* be 1. In this case we assume that modulo 0-th order symbol a is positively quasihomogeneous as $|x| + |\xi| \ge C$. Then Hamiltonian flow generated by quasihomogeneous principal symbol acts on $\mathbb{R}^{2d}/R$ where R means a group $(x, \xi) \mapsto (\lambda x, \lambda^\nu \xi)$ with any $\lambda > 0$; see V. Ivrii, [12].

1.4 Elliptic Boundary Value Problems and Associated Operators

1.4.1 Pseudodifferential Operators with Transmission Property

The purpose of this Subsection is to introduce pseudodifferential operators in the half-space and then in the domains with the smooth boundaries.

Causality

Consider classical double symbol $a(x, y, \xi)$ such that

$$\|\partial_x^\alpha \partial_y^\beta \partial_\xi^\gamma a(x, y, \xi)\| \le M(1 + |\xi|)^m \qquad \forall \alpha, \beta, \gamma : |\alpha| + |\beta| \le N + K, |\gamma| \le N + K \tag{1.4.1}$$

and a vector $\nu \in \mathbb{R}^d \setminus 0$. Assume that

(1.4.2) $a(x, y, \xi + \tau\nu)$ has an analytic continuation to $\tau \in \mathbb{C}_+$ [27] such that

$$\|\partial_x^\alpha \partial_y^\beta \partial_\xi^\gamma a(x, y, \xi + \tau\nu)\| \le M(1 + |\xi| + |\tau|)^m \qquad \forall \alpha, \beta, \gamma : |\alpha| + |\beta| \le N + K, |\gamma| \le N + K. \tag{1.4.3}$$

[27] Where we here and in what follows use notations $\mathbb{C}_\pm := \{\tau \in \mathbb{C} : \pm\tau > 0\}$.

We arrive immediately to

Proposition 1.4.1. *Let symbol a satisfy* (1.4.1)–(1.4.2) *and let $\mathcal{K}_A(x,y)$ be a Schwartz kernel of operator $A = a(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x})$. Then*

$$\operatorname{supp}(\mathcal{K}_A(x,y)) \subset \bigl\{(x,y) : \langle x-y, \nu\rangle \le 0\bigr\}. \tag{1.4.4}$$

Proof. Without any loss of the generality one can assume that $\nu = (1,0,\dots,0)$. Then the proof follows from deforming the contour of integration with respect to ξ_1 in expression (1.1.18) for $K_A(x,y)$. □

We refer to property (1.4.4) as a*causality*. One can prove easily that

Proposition 1.4.2. *(i) If a double symbol a satisfies* (1.4.1)–(1.4.2) *then the same is true for all three ordinary symbols (pq-, qp- and Weyl) of operator A.*

(ii) If ordinary symbols a, b satisfy (1.4.1)–(1.4.2) *then the same is true for $a \bullet b$ for any method of quantization;*

(iii) If an ordinary symbol a satisfies (1.4.1)–(1.4.2) *then the same is true for $a^\dagger$ and vector $-\nu$ instead of ν.*

Transmission Property

While causality is a useful and deserving study property, it is too restrictive for our needs. Instead we introduce *transmission property* essentially following L. Boutet de Monvel [1]:

Definition 1.4.3. (i) Symbol $a \in \mathsf{S}^m_{\sigma,\varsigma}$ with $1 \ge \sigma > \varsigma \ge 0$ has a *transmission property* with respect to half-space $\dot{\mathbb{R}}^+ \times \mathbb{R}^{d-1} = \{x_+ \ge 0\}$ if one can decompose a and all its derivatives in $\{|\xi_1| \ge C|\xi'| + C\}$:

$$a \sim \sum_{k\ge 1} a_k(x',\xi')(\xi_1 + i0)^{m-k} \tag{1.4.5}$$

with $a_k \in \mathsf{S}^{-k}_{\sigma,\varsigma}(\mathbb{R}^d \times \mathbb{R}^{d-1}, \mathbb{H}', \mathbb{H})$ where asymptotic decomposition (1.4.5) means that

$$\|\partial_x^\alpha \partial_\xi^\gamma \bigl(a - \sum_{1\le k\le r-1} a_k(x',\xi')(\xi_1+i0)^{m-k}\bigr)\big|_{x_1=0}\| \le M_{r\alpha\gamma}(1+|\xi'|)^{r+\varsigma|\alpha|}|\xi_1|^{m-r-\sigma|\gamma|} \tag{1.4.6}$$

for all r, α, γ.

Class of such symbols is denoted by $\mathsf{S}^m_{\sigma,\varsigma,\mathsf{trans}}(X\times\mathbb{R}^d,\mathbb{H}',\mathbb{H})$ where here $X=\dot{\mathbb{R}}^+\times\mathbb{R}^{d-1}:=\{x\colon x_1>0\}$.

(ii) Operator $A\in\boldsymbol{\Psi}^m_{\sigma,\varsigma}$ with $1\ge\sigma>\varsigma\ge 0$ has a *transmission property* with respect to a half-space $X=\dot{\mathbb{R}}^+\times\mathbb{R}^{d-1}$ if $A\equiv\mathsf{Op}(a)$ modulo infinitely smoothing operator where $a\in\mathsf{S}^m_{\sigma,\varsigma}$ satisfies (i).

Class of such operators is denoted by $\boldsymbol{\Psi}^m_{\sigma,\varsigma,\mathsf{trans}}(X,\mathbb{H}',\mathbb{H})$.

(iii) Finally, $\mathsf{S}^m_{\mathsf{cl},\mathsf{trans}}$ and $\boldsymbol{\Psi}^m_{\mathsf{cl},\mathsf{trans}}$ denote classes of classical symbols and operators with transmission property.

Remark 1.4.4. (i) Surely one can introduce similar classes with r, $|\alpha|$, ν bounded by $N+K$.

(ii) Obviously transmission property is preserved under affine changes of variables preserving half-space $\mathbb{R}^+\times\mathbb{R}^{d-1}$. Therefore one can introduce transmission property with respect to any half-space $X=\{x:\langle x,\nu\rangle>c\}$.

One can prove easily that

Proposition 1.4.5. *For $X=\{x:\langle x,\nu\rangle>c\}$ the following properties hold:*

(i) If $A_1\in\boldsymbol{\Psi}^{m_1}_{\sigma,\varsigma,\mathsf{trans}}(X,\mathbb{H}'',\mathbb{H}')$ and $A_2\in\boldsymbol{\Psi}^{m_2}_{\sigma,\varsigma,\mathsf{trans}}(X,\mathbb{H}',\mathbb{H})$ then $A_1A_2\in\boldsymbol{\Psi}^{m_1+m_2}_{\sigma,\varsigma,\mathsf{trans}}(X,\mathbb{H}',\mathbb{H})$.

(ii) If $A\in\boldsymbol{\Psi}^m_{\sigma,\varsigma,\mathsf{trans}}(X,\mathbb{H}',\mathbb{H})$ is elliptic and $m\in\mathbb{Z}$ then it has a parametrix $A'\in\boldsymbol{\Psi}^{-m}_{\sigma,\varsigma,\mathsf{trans}}(X,\mathbb{H}',\mathbb{H})$.

(iii) Therefore if $A\in\boldsymbol{\Psi}^m_{\sigma,\varsigma,\mathsf{trans}}(X,\mathbb{H},\mathbb{H})$ and $m\le 0$ then $f(A)-f(0)\in\boldsymbol{\Psi}^m_{\sigma,\varsigma,\mathsf{trans}}(X,\mathbb{H},\mathbb{H})$ as well for all "admissible" functions f (in the sense of the functional calculus of Section 1.1.

(iv) If $A\in\boldsymbol{\Psi}^m_{\sigma,\varsigma,\mathsf{trans}}(X,\mathbb{H}'',\mathbb{H}')$ and $\varkappa$ is a diffeomorphism preserving X then $A_\varkappa=\varkappa_*^{-1}A\varkappa_*$ also belongs to this class;

(v) If $A\in\boldsymbol{\Psi}^m_{\sigma,\varsigma,\mathsf{trans}}(X,\mathbb{H}',\mathbb{H})$ with then $A^*\in\boldsymbol{\Psi}^m_{\sigma,\varsigma,\mathsf{trans}}(X',\mathbb{H},\mathbb{H}')$ with an opposite half-space $X'=\{\langle x,\nu\rangle\le c\}$.

(vi) Classes S^m and $\boldsymbol{\Psi}^m$ for half-space X' coincide with those for X if and only if $m\in\mathbb{Z}$.

Remark 1.4.6. Statement (ii) and a pseudo-locality allow us to extend the notion of transmission property to any bounded open domain $X \subset \mathbb{R}^d$ with a smooth boundary in such way that all statements of Proposition 1.4.5 still hold. We need to assume that either X is a half-space or ∂X is bounded or to assume that ∂X is "uniformly $\mathscr{C}^\infty$" (the notion we do not want to exploit).

Pseudodifferential Operators in a Domain

However we need to explain how actually one applies such operators to functions defined in such domain (or in an open half-space). The main idea is to introduce action of operator A by

(1.4.7) $A_X = \eth_X A F_X$ where F_X is an operator of extension from X to $\mathbb{R}^d$ by 0 and $\eth_X$ is an operator of restriction from $\mathbb{R}^d$ to X.

This formula would definitely brake composition and related operations. We can take different extension operators F_X but since we develop mainly $\mathscr{L}^2$-theory we will take $F_X = \eth_X^*$ which is continuation by 0.

(1.4.8) For $s \ge 0$ let us introduce $\mathscr{H}^s(X) = \{u : \exists v \in \mathscr{H}^s(\mathbb{R}^d) : \ \eth_X v = u\}$ with $\|u\|_{\mathscr{H}^s(X)} = \inf_{v:\eth_X v = u} \|v\|_{\mathscr{H}^s(\mathbb{R}^d)}$.

As $u = \eth_X v$ with $v \in \mathscr{H}^s(\mathbb{R}^d)$ we get $F_X u = v^+ = v - v^-$ with $v^+ = v\theta_X(x)$ and $v^- = v\theta_{\complement X}(x)$ where $\theta_Y(x)$ denotes characteristic function of Y and therefore $A_X u = \eth_X v^+ = \eth_X A v - \eth_X A v^-$.

Let us consider first the case of half-space.

Proposition 1.4.7. *Let $X = \{x\colon x_1 > 0\}$ and $A \in \boldsymbol{\Psi}^m_{\sigma,\varsigma,\mathsf{trans}}(X, \mathbb{H}', \mathbb{H})$.*

Then for any $j \in \mathbb{Z}^+$ operator $D_1^j \eth_X A$ is a bounded operator from $\mathscr{L}^2\big(\mathbb{R}^-, \mathscr{H}^s(\mathbb{R}^{d-1}, \mathbb{H})\big)$ to $\mathscr{L}^2\big(\mathbb{R}^+, \mathscr{H}^{s-m+j}(\mathbb{R}^{d-1}, \mathbb{H}')\big)$.

Proof. Obviously $D_1^j A$ would be a bounded operator from $\mathscr{L}^2\big(\mathbb{R}, \mathscr{H}^s(\mathbb{H})\big)$ to $\mathscr{L}^2\big(\mathbb{R}^-, \mathscr{H}^{s-m+j}(\mathbb{R}^{d-1}, \mathbb{H}')\big)$ if we cut of it in zone $\{|\xi_1| \ge C|\xi'|\}$ replacing $a(x,\xi)$ by $a(x,\xi)\varphi(\xi_1/|\xi'|)$ with $\varphi \in \mathscr{C}_0^\infty(\mathbb{R})$. Therefore we need to consider only $a(x,\xi) = a_k(x,\xi')(\xi_1 + i0)^{m-k}$.

On the other hand, operator A with such symbol has a causality property and therefore $\eth_X A$ restricted to $\mathscr{L}^2\big(\dot{\mathbb{R}}^-, \mathscr{H}^s(\mathbb{H})\big)$ is simply 0. □

Observing that

$$\bigcap_{j\ge 0} \mathscr{H}^{j}(\mathbb{R}^{+}, \mathscr{H}^{s-j}(\mathbb{R}^{d-1}, \mathbb{H}')) \subset \mathscr{H}^{s}(X, \mathbb{H}') \qquad \text{as} \quad s \ge 0 \tag{1.4.9}$$

we conclude that the following statement holds for half-space $X = \{x\colon x_1 > 0\}$ and therefore for any bounded domain with a smooth boundary.

Proposition 1.4.8. *Let $A \in \mathbf{\Psi}^{m}_{\sigma,\varsigma,\mathsf{trans}}(X, \mathbb{H}', \mathbb{H})$. Then for any $s \ge \max(m, 0)$ A_X is a bounded operator from $\mathscr{H}^{s}(X, \mathbb{H}))$ to $\mathscr{H}^{s-m}(X, \mathbb{H}))$.*

Now we want to consider product a $A_X B_X$. According to (1.4.7)

$$A_X B_X = \eth_X A F_X \eth_X B F_X = (AB)_X - \eth_X A (I - F_X \eth_X) B F_X. \tag{1.4.10}$$

One can apply proposition 1.4.7 to such operator. We investigate it later.

1.4.2 Related Operators

Boundary (Poisson) Operators

Let us start from equation

$$A(x, D)u = f \qquad \text{in } X \tag{1.4.11}$$

where A is a differential operator of order m. To apply a pseudodifferential parametrix to it we need to rewrite it first as an equation in $\mathbb{R}^d$. Consider continuation $F_X u$ to $\mathbb{R}^d$ by 0. Then

$$A F_X u = F_X f + \sum_{j\le m-1} \delta^{(j)}_{\partial X}(x) g_j(x) \tag{1.4.12}$$

with $g_j = A_j(x, D)u$ where $A_j(x, D)$ are differential operators of order $(m - j - 1)$, $j = 0, \dots, m-1$.

More precisely, if X coincides locally with a half-space $\{x\colon x_1 > 0\}$ then $\delta^{(j)}_{\partial X}(x) = \delta^{(j)}(x_1)$ and $A_j(x, \xi) = \frac{1}{(j+1)!} D^{j+1}_{\xi_1} P(x, \xi)$ provided we use qp-quantization. Then

$$\sum_{j\le m-1} \delta^{(j)}(x_1) g_j(x) = \sum_{k\le j\le m-1} \delta^{(j-k)}(x_1) \eth_0 \partial^{k}_{x_1} g_j (-1)^k = \sum_{k\le j\le m-1} \delta^{(j-k)}(x_1) \eth_0 \partial^{k}_{x_1} \bigl(A_j(x, D) u_j\bigr) (-1)^k$$

where $\mathfrak{d}_0$ is an operator of restriction to ∂X.

Assume that A is elliptic; let A' be its parametrix. Then $A' \in \boldsymbol{\Psi}^{-m}_{\mathsf{cl},\mathsf{trans}}$. Applying $\mathfrak{d}_X A'$ to (1.4.12) we arrive to

$$u \equiv \mathfrak{d}_X A' F_X f + \sum_{j\le m-1} \mathfrak{d}_X A'\bigl(\delta^{(j)}_{\partial X}(x) g_j(x)\bigr) \tag{1.4.13}$$

where the first term is exactly $A'_X f$. Consider other terms. To do this we need to analyze $\mathfrak{d}_X A' \delta^{(j)}(x_1) g'_j(x')$ where $g'_j = \mathfrak{d}_0 L_j(x,D)u$ and L_j are differential operators of order $(m-1-j)$.

Departing from the previous considerations and notations we need to study operators of the type $P : g \to A(\delta^{(j)} \otimes g)$ where $g = g(x')$ and A is operator of order $(m-j)$. This operator has a Schwartz kernel

$$\mathcal{K}_P(x,y') = (2\pi)^{-d} \int b_j(x,y',\xi) e^{i\langle x'-y',\xi'\rangle + i x_1\xi_1}\, d\xi \tag{1.4.14}$$

where $b_j = (-\partial_{y_1} + i\xi_1)^j a(x,y,\xi)$; one can rewrite it as

$$\mathcal{K}_P(x,y') = (2\pi)^{1-d} \int k(\langle\xi'\rangle x_1, x', y', \xi') e^{i\langle x'-y',\xi'\rangle}\, d\xi' \tag{1.4.15}$$

with

$$k(t,x',y',\xi') = (2\pi)^{-1} \int b_j(x,y',\xi) e^{it\xi_1/\langle\xi'\rangle}\, d\xi_1. \tag{1.4.16}$$

Remark 1.4.9. While this construction works for any symbol a, for symbols with transmission property resulting function $k(t,x',y',\xi')$ is "nice"; one can prove easily that for $a \in \boldsymbol{\Psi}^{m-1}_{\sigma,\varsigma,\mathsf{trans}}$ with $m \in \mathbb{Z}$

$$\begin{aligned}\|D^\alpha_{x'} D^\beta_{y'} D^\gamma_{\xi'} D^j_t k(t,x',y',\xi')\| \le \\ C_{\alpha\beta\gamma jr}(1+t)^{-s}(1+|\xi'|)^{m+\varsigma(|\alpha|+|\beta|)-\sigma|\gamma|} \qquad \forall \alpha,\beta,\gamma,j,r.\end{aligned} \tag{1.4.17}$$

Definition 1.4.10. (i) Operator with the Schwartz kernel $\mathcal{K}_P(x,y')$ given modulo $\mathscr{C}^\infty(\bar X \times \partial X)$ by (1.4.15) with $k(t,x',y',\xi')$ satisfying (1.4.17) is called *Poisson operator of order* m.

Let $\boldsymbol{P}^m_{\sigma,\varsigma}$ denote the class of such operators. Further, by $\boldsymbol{P}^m_{\mathsf{cl}}$ we denote class of operators with functions $k \sim \sum k_s$ where k_s are positively homogeneous of degrees $(m-s)$ with respect to ξ'.

(ii) One can define $\boldsymbol{P}^m_{\sigma,\varsigma}$ and $\boldsymbol{P}^m_{\mathsf{cl}}$ for any half-space and for any domain X with the smooth compact boundary in the natural way.

Trace and Singular Green Operators

Let us introduce other classes of operators:

Definition 1.4.11. (i) Operator with the Schwartz kernel $K_T(x', y)$ defined modulo $\mathscr{C}^\infty(\partial X \times \bar{X})$ by (1.4.15) with x_1 replaced by y_1 and with $k(t, x', y', \xi')$ satisfying (1.4.17) with m replaced by $(m+1)$ is called *trace operator of order* m.

Let $\boldsymbol{T}^m_{\sigma,\varsigma}$ denote the class of such operators. Further, by $\boldsymbol{T}^m_{\mathsf{cl}}$ we denote class of operators with functions $k \sim \sum k_s$ where k_s are positively homogeneous of degrees $(m+1-s)$ with respect to ξ'.

(ii) One can define $\boldsymbol{T}^m_{\sigma,\varsigma}$ and $\boldsymbol{T}^m_{\mathsf{cl}}$ for any half-space and for any domain X with the smooth compact boundary.

Sometimes Poisson operators are called *coboundary operators* and trace operators are called *boundary operators*.

Definition 1.4.12. (i) Operator with the Schwartz kernel $\mathcal{K}_G(x, y)$ given modulo $\mathscr{C}^\infty(\bar{X} \times \bar{X})$ by

$$\mathcal{K}_G(x, y) = (2\pi)^{1-d} \int k(\langle\xi'\rangle x_1, x', \langle\xi'\rangle y_1, y', \xi') e^{i\langle x'-y', \xi'\rangle} d\xi' \tag{1.4.18}$$

with $k(t, x', t', y', \xi')$ satisfying

$$\begin{aligned} &\|D^\alpha_{x'} D^\beta_{y'} D^\gamma_{\xi'} D^j_{t,t'} k(t, x', t', y', \xi')\| \le \\ &\qquad C_{\alpha\beta\gamma jr}(1+t+t')^{-s}(1+|\xi'|)^{m+1+\varsigma(|\alpha|+|\beta|)-\sigma|\gamma|} \qquad \forall \alpha, \beta, \gamma, j, r. \end{aligned} \tag{1.4.19}$$

is called *singular Green operator of order* m.

Let $\boldsymbol{G}^m_{\sigma,\varsigma}$ denote the class of such operators. Further, by $\boldsymbol{G}^m_{\mathsf{cl}}$ we denote class of operators with functions $k \sim \sum k_s$ where k_s are positively homogeneous of degrees $(m+1-s)$ with respect to ξ'.

(ii) One can define $\boldsymbol{G}^m_{\sigma,\varsigma}$ and $\boldsymbol{G}^m_{\mathsf{cl}}$ for any half-space and for any bounded domain X with the smooth boundary.

One can prove (see L. Boutet de Monvel [1]) the following statements:

Proposition 1.4.13. *Let $P \in \boldsymbol{P}_{\mathsf{cl}}(X)$, $T \in \boldsymbol{T}_{\mathsf{cl}}(X)$, $G, G' \in \boldsymbol{G}_{\mathsf{cl}}(X)$. Then $\mathcal{K}_P$, $\mathcal{K}_T$ and $\mathcal{K}_G$ are smooth in $\partial X \times \bar{X}$, $\bar{X} \times \partial X$ and $\bar{X} \times \bar{X}$ respectively with the exception of the diagonal of $\partial X \times \partial X$ (i.e. the set $\{(x,x),\ x \in \partial X\}$).*

Proposition 1.4.14. *(i) Let $P \in \boldsymbol{P}^m_{\mathsf{cl}}(X, \mathbb{H}', \mathbb{H})$. Then P is a bounded operator from $\mathscr{H}^{s-1/2}(\partial X, \mathbb{H})$ to $\mathscr{H}^{s-m}(X, \mathbb{H}')$.*

Further, as $X = \{x\colon x_1 > 0\}$ P is a bounded operator from $\mathscr{H}^{s-1/2}(\partial X, \mathbb{H})$ to

$$\bigcap_{j\ge 0} \mathscr{H}^{j}\bigl(\mathbb{R}^+, \mathscr{H}^{s-m-j}(\mathbb{R}^{d-1}, \mathbb{H}')\bigr). \tag{1.4.20}$$

(ii) Let $T \in \boldsymbol{T}^m_{\mathsf{cl}}(X, \mathbb{H}', \mathbb{H})$. Then T is a bounded operator from $\mathscr{H}^{s}(X, \mathbb{H})$ to $\mathscr{H}^{s-m-1/2}(\partial X, \mathbb{H}')$.

(iii) Let $G \in \boldsymbol{G}^m_{\mathsf{cl}}(X, \mathbb{H}', \mathbb{H})$. Then G is a bounded operator from $\mathscr{H}^{s}(X, \mathbb{H})$ to $\mathscr{H}^{s-m}(X, \mathbb{H}')$.

Further, as $X = \{x\colon x_1 > 0\}$ P is a bounded operator from $\mathscr{H}^{s}(X, \mathbb{H})$ to (1.4.20).

Proposition 1.4.15. *(i) $P \in \boldsymbol{P}^m_{\mathsf{cl}}(X, \mathbb{H}', \mathbb{H})$ if and only if $P^* \in \boldsymbol{T}^{m+1}_{\mathsf{cl}}(X, \mathbb{H}, \mathbb{H}')$.*

(ii) $G \in \boldsymbol{G}^m_{\mathsf{cl}}(X, \mathbb{H}'\mathbb{H})$ if and only if $G^* \in \boldsymbol{G}^m_{\mathsf{cl}}(X, \mathbb{H}, \mathbb{H}')$.

Proposition 1.4.16. *Let $P \in \boldsymbol{P}_{\mathsf{cl}}(X)$, $T \in \boldsymbol{T}_{\mathsf{cl}}(X)$, $G, G' \in \boldsymbol{G}_{\mathsf{cl}}(X)$ and let $A, A' \in \boldsymbol{\Psi}_{\mathsf{cl},\mathsf{trans}}(X)$ with $\mathsf{ord}(A), \mathsf{ord}(A') \in \mathbb{Z}$, $B \in \boldsymbol{\Psi}_{\mathsf{cl}}(\partial X)$* [28].

(i) Then as $\mathsf{ord}A' \le 0$

$$A_X P, GP, PB \in \boldsymbol{P}_{\mathsf{cl}}(X), \tag{1.4.21}$$

$$TA'_X, TG, BT \in \boldsymbol{T}_{\mathsf{cl}}(X), \tag{1.4.22}$$

$$A_X G, GA'_X, GG', PT \in \boldsymbol{G}_{\mathsf{cl}}(X), \tag{1.4.23}$$

$$TP \in \boldsymbol{\Psi}_{\mathsf{cl}}(\partial X) \tag{1.4.24}$$

and

$$A_X A'_X - (AA')_X \in \boldsymbol{G}_{\mathsf{cl}}(X) \tag{1.4.25}$$

and in each statement the rule "the order of the product equals to the sum of the orders" holds;

[28] Here and below we deliberately skip $\mathbb{H}$, $\mathbb{H}'$ and $\mathbb{H}''$ in our notations as otherwise it would be too tedious.

(ii) On the other hand, as $m' = \mathsf{ord}A' \ge 1$

$$TA'_X = \sum_{0\le j\le m'-1} B_j \eth_{\partial X} D_1^j + T', \tag{1.4.26}$$

$$GA'_X - (GA')_X = \sum_{0\le j\le m'-1} T''_j \eth_{\partial X} D_1^j + G', \tag{1.4.27}$$

$$A_X A'_X - (AA')_X = \sum_{0\le j\le m'-1} T'''_j \eth_{\partial X} D_1^j + G' \tag{1.4.28}$$

with operators $B_j \in \boldsymbol{\Psi}_{\mathsf{cl}}^{m+m'-1-j}(\partial X)$ *and* T''_j, $T'''_j \in \boldsymbol{T}_{\mathsf{cl}}^{m+m'-1-j}(X)$ *and* T', G' *belonging to the corresponding classes.*

Proposition 1.4.17. *Let conditions of proposition 1.4.16 be fulfilled. Assume that locally* $X = \{x_1 > 0\}$.

(i) Let $F_j : v \to (\delta^{(j)} \otimes v)$. *Then* $\eth_X A F_j, G F_j \in \boldsymbol{P}_{\mathsf{cl}}(X)$ *and* $T F_j \in \boldsymbol{\Psi}_{\mathsf{cl}}(\partial X)$ *and the rule "the order of the product equals to the sum of the orders" holds if we assign an order* $(j+1)$ *to operator* F_j.

(ii) Let $\eth_{\partial X}$ *be an operator of restriction to* ∂X. *Then* $\eth_{\partial X} G \in \boldsymbol{T}_{\mathsf{cl}}(X)$ *and* $\eth_{\partial X} A_X \in \boldsymbol{T}_{\mathsf{cl}}(X)$ *provided* $\mathsf{ord}(A) < 0$.

On the other hand, for $m = \mathsf{ord}(A) \ge 0$

$$\eth_{\partial X} A_X = \sum_{0\le j\le m} Q_j \eth_{\partial X} D_1^j + T, \qquad Q_j \in \boldsymbol{\Psi}_{\mathsf{cl}}^{m-j}(\partial X),\ T \in \boldsymbol{T}_{\mathsf{cl}}^m(X). \tag{1.4.29}$$

The rule "the order of the product equals to the sum of the orders" holds in both cases if we assign an order 0 *to* $\eth_{\partial X}$.

(iii) $x_1 G, G x_1 \in \boldsymbol{G}_{\mathsf{cl}}(X)$, $x_1 P \in \boldsymbol{P}_{\mathsf{cl}}(X)$ *and* $T x_1 \in \boldsymbol{T}_{\mathsf{cl}}(X)$ *and the rule "the order of the product equals to the sum of the orders" holds if we assign an order* -1 *to an operator of multiplication by* x_1.

Theorem 1.4.18. *Let* $\kappa : X \to X'$ *be a diffeomorphism of* $U \ni 0$ *to* $V \ni 0$ *such that* $\kappa(X) = X'$ *with* $X = U \cap \{x_1 > 0\}$, $X = V \cap \{x_1 > 0\}$. *Then induced map* $A \to \kappa_*^{-1} A \kappa_*$ *transforms* $\boldsymbol{P}_{\mathsf{cl}}^m(X)$, $\boldsymbol{T}_{\mathsf{cl}}^m(X)$ *and* $\boldsymbol{G}_{\mathsf{cl}}^m(X)$ *to* $\boldsymbol{P}_{\mathsf{cl}}^m(X')$, $\boldsymbol{T}_{\mathsf{cl}}^m(X')$ *and* $\boldsymbol{G}_{\mathsf{cl}}^m(X')$ *respectively.*

Remark 1.4.19. Similar statements (may be with some modifications) hold for $\boldsymbol{\Psi}_{\sigma,\varsigma}^m$, $\boldsymbol{P}_{\sigma,\varsigma}^m$, $\boldsymbol{T}_{\sigma,\varsigma}^m$ and $\boldsymbol{G}_{\sigma,\varsigma}^m$.

Boutet de Monvel Algebra

In L. Boutet de Monvel [1] the notion of trace and singular Green operator are extended to include operators as in the right hand expressions of (1.4.26) and (1.4.27) respectively. Further, operators of the type $A+G$ are called *Green operators* in contrast to singular Green operators with $A=0$.

Furthermore, the matrix operators of the form $\mathcal{A}=\begin{pmatrix} A_X+G & P\\ T & B\end{pmatrix}$ from $\mathbb{H}\oplus\mathbb{H}_b$ to $\mathbb{H}'\oplus\mathbb{H}'_b$ are introduced where $\mathbb{H}_b$ and $\mathbb{H}'_b$ are also axillary Hilbert spaces.Recall that $B\in \boldsymbol{\Psi}_{\mathsf{cl}}(\partial X, \mathbb{H}', \mathbb{H}_b)$; T is a trace operator of extended type.

This leads to *Boutet de Monvel algebra* $\mathfrak{B}(X)$ of such operators.

Moreover, the notion of ellipticity is introduced and parametrices for elliptic Boutet de Monvel operators are constructed; these parametrices are also Boutet de Monvel operators; the usual rule $\mathsf{ord}(\mathcal{A}^{-1})=-\mathsf{ord}(\mathcal{A})$ holds.

There are easy and natural generalizations to manifolds and to sections of the Hilbert bundles over such manifolds.

We refer to L. Boutet de Monvel [1] for the further reading; the only things we am interested are Green operators of order 0 (see next Subsubsection) and applications to elliptic boundary problems (see Subsection 1.4.3).

One can also prove similar results for operators of (σ,ς)-type.

Ellipticity and Parametrices

Consider $\mathcal{A}=A_X+G$ operators with $A\in \boldsymbol{\Psi}^0_{\mathsf{cl},\mathsf{trans}}(X,\mathbb{H}',\mathbb{H})$ and $G\in \boldsymbol{G}^0_{\mathsf{cl}}(X,\mathbb{H}',\mathbb{H})$. We want to construct parametrix of the same type. Obviously ellipticity of A is necessary (but not sufficient):

(1.4.30) For each $(x,\xi)\in S^*X$ symbol $a_0(x,\xi)$ is invertible and satisfies $\|a_0(x,\xi)^{-1}\|\le c$.

On the other hand if condition (1.4.30) is fulfilled what we need is to construct parametrix locally in the vicinity of every point $\bar{x}\in\partial X$ and therefore we can assume that $X=\{x\colon x_1>0\}$.

Consider first the "constant" and homogeneous case when $a=a_0(\xi)$ and in definition (1.4.18) of $\mathcal{K}_G$ one can take $k(x_1|\xi'|,y_1|\xi'|,\xi')$ and this function is positively homogeneous of order 1 with respect to the third argument: $|\xi'|\kappa(x_1|\xi'|,y_1|\xi'|,\xi'/|\xi'|)$.

In this case we can make a Fourier transform with respect to $x' \to \xi'$ and the analysis of $A_X + G$ is reduced to the analysis of 1-dimensional operator $a_0(D_1; \xi')_{\mathbb{R}^+} + g_0(\xi')$ where $g_0(\xi')$ is one dimensional integral operator on $\mathbb{R}^+$ with Schwartz kernel $\kappa(x_1, y_1; \xi')$; we need to consider only $|\xi'| = 1$ because the general case is reduced by an obvious change of variables x_1 and y_1.

Obviously we need to assume that $a_0(D_1; \xi')_{\mathbb{R}^+} + g_0(\xi') : \mathscr{L}^2(\mathbb{R}^+, \mathbb{H}) \to \mathscr{L}^2(\mathbb{R}^+, \mathbb{H}')$ is invertible for all ξ'.

Definition 1.4.20. Green operator $A_X + G$ with $A \in \boldsymbol{\Psi}^0_{\mathsf{cl},\mathsf{trans}}(X, \mathbb{H}', \mathbb{H})$ and $G \in \boldsymbol{G}^0_{\mathsf{cl}}(X, \mathbb{H}', \mathbb{H})$ is *elliptic* if

(i) a is elliptic in the sense of (1.4.30) and

(ii) For each $(x', \xi') \in S^*\partial X$ operator

$$a_0(D_1; x', \xi')_{\mathbb{R}^+} + g_0(x', \xi') : \mathscr{L}^2(\mathbb{R}^+, \mathbb{H}) \to \mathscr{L}^2(\mathbb{R}^+, \mathbb{H}')$$

is invertible and $\|\big(a_0(D_1; x', \xi') + g_0(x', \xi')\big)^{-1}\| \le c$ where to construct $g_0(x', \xi')$ we locally make $X = \{x\colon x_1 > 0\}$, take principal symbol of k (i.e. remove all the terms with an order of homogeneity less than 1) and freeze $y' = x'$.

Definition 1.4.21. One-dimensional integral operator g_0 is *principal symbol* of G.

One can see easily that under these assumptions an inverse operator is of the same type as the original one

$$\big(a_0(D_1; x', \xi')_{\mathbb{R}^+} + g_0(x', \xi')\big)^{-1} = a_0^{-1}(D_1; x', \xi')_{\mathbb{R}^+} + g_0'(x', \xi')$$

and smoothly depends on (x', ξ'). This leads to an obvious construction of the singular Green operator $G' \in \boldsymbol{G}^0_{\mathsf{cl}}(X)$ with the principal symbol g_0'. One can see easily that operator $(A'_X + G')$ where A' is the parametrix of A satisfies

$$(A_X + G)(A'_X + G') \equiv (A'_X + G')(A_X + G) \equiv I \tag{1.4.31}$$

modulo $\boldsymbol{G}^{-1}_{\mathsf{cl}}(X)$. Therefore one can adjust G' (by $\boldsymbol{G}^{-1}_{\mathsf{cl}}(X)$ operator) so that (1.4.31) holds modulo operators with smooth in $\bar{X} \times \bar{X}$ symbol.

Therefore we have proved

Theorem 1.4.22. *Operator* $(A_X + G)$ *with* $A \in \boldsymbol{\Psi}^0_{\mathsf{cl},\mathsf{trans}}(X, \mathbb{H}', \mathbb{H})$ *and* $G \in \boldsymbol{G}^0_{\mathsf{cl}}(X, \mathbb{H}', \mathbb{H})$ *has a parametrix* $(A'_X + G')$ *with* $A' \in \boldsymbol{\Psi}^0_{\mathsf{cl},\mathsf{trans}}(X, \mathbb{H}, \mathbb{H}')$ *and* $G' \in \boldsymbol{G}^0_{\mathsf{cl}}(X, \mathbb{H}, \mathbb{H}')$ *if and only if* $(A_X + G)$ *is elliptic in the sense of Definition 1.4.20.*

Resolvent and Functional Calculus. I

Now one can consider resolvent $R(\zeta)$ of operator of this type. Similarly to arguments for classical pseudodifferential and h-pseudodifferential operators we have:

Theorem 1.4.23. *Consider operator* $(A_X + G)$ *with* $A \in \boldsymbol{\Psi}^0_{\mathsf{cl}}(X, \mathbb{H}, \mathbb{H})$ *and* $G \in \boldsymbol{G}^0_{\mathsf{cl}}(X)$. *Let*

$$\Sigma(a) = \overline{\bigcup_{(x,\xi)\in S^*X} \mathsf{Spec}\big(a_0(x,\xi)\big)} \tag{1.4.32}$$

and

$$\Sigma_b(a_0, g_0) = \overline{\bigcup_{(x,\xi)\in S^*\partial X} \mathsf{Spec}\big(a_0(D_1; x', \xi')_{\mathbb{R}^+} + g_0(x', \xi')\big)}. \tag{1.4.33}$$

Then for any vicinity Ω *of* $\Sigma(a_0, g_0) = \Sigma(a) \cup \Sigma_b(a_0, g_0)$ *one can adjust* $(A_X + G)$ *by an operator with infinitely smooth Schwartz kernel so that the spectrum of the new* $(A_X + G)$ *would be contained in* Ω.

Theorem 1.4.24. *Consider operator* $(A_X + G)$ *with* $A \in \boldsymbol{\Psi}^0_{\mathsf{cl}}(X, \mathbb{H}, \mathbb{H})$ *and* $G \in \boldsymbol{G}^0_{\mathsf{cl}}(X)$. *Let* $f(z)$ *be analytic function in the vicinity* Ω *of* $\mathsf{Spec}(A_X + G)$. *Then*

(i) $f(A_X + G)$ *also is operator of this type. Further, pseudodifferential part of it could be constructed as a (formal)* $f(A)$ *and thus principal pseudodifferential symbol is* $f(a_0)$.

(ii) Furthermore, its principal singular Green symbol (in the sense of definition 1.4.21) is a singular Green part of $f\big(a_0(D_1; x', \xi')_{\mathbb{R}^+} + g_0(x', \xi')\big)$;

(iii) In particular, as $A = 0$ *pseudodifferential part of* $f(A_X + G)$ *is* $f(0)$ *and* $f(G) - f(0) \in \boldsymbol{G}^0_{\mathsf{cl}}(X)$.

Further, the resolvent based construction leads to

Theorem 1.4.25. *Consider operator* $(A_X + G)$ *with* $A \in \boldsymbol{\Psi}^0_{\mathsf{cl}}(X, \mathbb{H}, \mathbb{H})$ *and* $G \in \boldsymbol{G}^0_{\mathsf{cl}}(X, \mathbb{H}.\mathbb{H})$.

(i) Assume that it is Hermitian, positive and disjoint from 0 *in operator sense operator.*

Then $(A_X + G)^l$ *is operator of the same type for any* $l \in \mathbb{R}$ *(and even* $l \in \mathbb{C}$*); further, its principal pseudodifferential symbol is* a_0^l *and its principal singular Green symbol is a singular Green part of* $\bigl(a_0(D_1; x', \xi')_{\mathbb{R}^+} + g_0(x', \xi')\bigr)^l$.

(ii) Assume that it is Hermitian and disjoint from 0 in the operator sense operator.

Consider orthogonal (in $\mathscr{L}^2(X, \mathbb{H})$*) projectors* $\Pi^{\pm}$ *on positive and negative subspaces of* A. *Then* $\Pi^{\pm}$ *are operators of the same type; their principal pseudodifferential symbols are* $\pi^{\pm}(x, \xi)$ *(orthogonal projectors to positive and negative subspaces of* $a_0(x, \xi)$*) and their singular Green principal symbols are singular Green parts of the corresponding projectors for* $\bigl(a_0(D_1; x', \xi')_{\mathbb{R}^+} + g_0(x', \xi')\bigr)$.

(iii) In particular, $\Pi^{\pm} \in \boldsymbol{G}^0_{\mathsf{cl}}(X, \mathbb{H}, \mathbb{H})$ *(i.e. pseudodifferential part is* 0*) if and only if* $\pm a_0(x, \xi) < 0$ *for all* (x, ξ).

Remark 1.4.26. Arguments leading to the proof of Theorem 1.1.46 allows us to construct $f(A_X + G)$ as $(A_X + G)$ is Hermitian and f is smooth in the vicinity of $\mathsf{Spec}(A_X + G)$.

1.4.3 Applications to Elliptic Boundary Value Problems

Parametrix Construction

Let us consider $m = \mathsf{ord}A > 0$. In this case $(A_X + G)$ is not necessarily elliptic (i.e. $(A_X + G) : \mathscr{H}^s(X, \mathbb{H}) \to \mathscr{H}^{s-m}(X, \mathbb{H}')$ fails to be invertible) and one needs to consider in addition to $(A_X + G)u = f$ boundary value problem $Tu = g$ where $T : \mathscr{H}^s(X, \mathbb{H}) \to \mathscr{H}^{s-\mu-1/2}(X, \mathbb{H}_b)$ is a trace operator of extended type.

Remark 1.4.27. (i) We are interested only in the case when A is a differential operator, $G = 0$ and $T = B$ with

$$B = \sum_{0\le j\le m-1} B_j \eth_{\partial X} D_1^j \qquad \text{with} \quad B_j \in \boldsymbol{\Psi}^{\mu-j}_{\mathsf{cl}}(\partial X). \tag{1.4.34}$$

(ii) There could be more than one boundary conditions of different orders but one can always make them of the same order (say $\mu = (m-1)$) by multiplying by elliptic pseudodifferential operators on the boundary and then join then by taking $\mathbb{H}_b = \mathbb{H}_{b1} \oplus ... \oplus \mathbb{H}_{bk}$.

Assume that A is elliptic in the sense that $\|a_0(x,\xi)^{-1}\| \le c|\xi|^{-m}$. Let us consider in $(x',\xi') \in T^*\partial X$; without any loss of the generality one can assume that locally $X = \{x_1 > 0\}$.

Consider space $\mathsf{Ker}\, a_0(D_1; x', \xi')_{\mathbb{R}^+}$ of exponentially decaying solutions of $a_0(D_1; x', \xi')$. Alternatively one can consider $\mathcal{Y}(x',\xi') = \eth_{(m-1)} \mathsf{Ker}\, a_0(D_1; x', \xi')_{\mathbb{R}^+}$ where $\eth_{(m-1)} v = (v, D_1 v, ..., D_1^{m-1} v)$.

Definition 1.4.28. We call (A, B) *elliptic boundary value problem* if

(i) A is elliptic in the sense that $\|a_0(x,\xi)^{-1}\| \le c|\xi|^{-m}$;

(ii) Map $(b_j(x',\xi), ... b_{m-1}(x',\xi') : \mathcal{Y}(x',\xi') \to \mathbb{H}_b$ is invertible with uniformly bounded inverse for all (x',ξ') where b_j are principal symbols of B_j are positively homogeneous with respect to ξ' of degrees $\mu - j$.

Assume that (A, B) is elliptic. Let

$$\beta(x',\xi) : \mathbb{H}_b \to \mathcal{Y}(x',\xi') \subset \mathbb{H}^m = \underbrace{\mathbb{H} \oplus ... \mathbb{H}}_{m \text{ copies}} \tag{1.4.35}$$

be an inverse map and $\beta_j(x',\xi')$ $(j = 0, ..., m-1)$ be its components; then $\beta_j(x',\xi')$ are positively homogeneous of degrees $(j-\mu)$ with respect to ξ'.

Consider also maps

$$\kappa_j(x',\xi') : \mathbb{H} \to \mathsf{Ker}\, a_0(D_1; x', \xi') : D_t^k \kappa_j(t, x', \xi')|_{t=0} = \delta_{jk} \qquad j, k = 0, ..., m-1 \tag{1.4.36}$$

which has a Schwartz kernel $k_j(x_1|\xi'|, x', \xi')$ with $k_j(t, x', \xi')$ positively homogeneous of degree $-j$ with respect to ξ' and satisfying (1.4.17) as $|\xi'| = 1$.

Then operator

$$\kappa(x',\xi') = \sum_j \kappa_j(x',\xi')\beta_j(x',\xi') : \mathbb{H}_b \to \mathsf{Ker}\, a_0(D_1; x',\xi') \tag{1.4.37}$$

has a Schwartz kernel $k(|\xi'|x_1, x', \xi') = \sum_j \kappa_j(|\xi'|x_1, x', \xi')\beta_j(x',\xi')$ with $k(t, x', \xi')$ positively homogeneous of degree $-j$ with respect to ξ' and satisfying (1.4.17) as $|\xi'| = 1$.

Consider $P \in \boldsymbol{P}^{-\mu}_{\mathsf{cl}}(X, \mathbb{H}_b, \mathbb{H})$ with the principal symbol $k(|\xi'|x_1, x', \xi')$. Then

$$A_X P \equiv 0 \qquad \mathsf{mod}\ \boldsymbol{P}^{m-\mu-1}_{\mathsf{cl}}(X, \mathbb{H}', \mathbb{H}_b), \tag{1.4.38}$$

$$BP \equiv I \qquad \mathsf{mod}\ \boldsymbol{\Psi}^{-1}_{\mathsf{cl}}(\partial X, \mathbb{H}_b, \mathbb{H}_b). \tag{1.4.39}$$

Meanwhile let $A' \in \boldsymbol{\Psi}^{-m}_{\mathsf{cl}}(X, \mathbb{H}, \mathbb{H}')$ be a parametrix of A. Then $A_X A'_X \equiv I$ modulo infinitely smoothing operator because A is a differential operator. On the other hand, $BA'_X \in \boldsymbol{T}^{\mu-m}_{\mathsf{cl}}(X, \mathbb{H}_b, \mathbb{H}')$ and therefore $G = -PBA'_X \in \boldsymbol{G}^{-m}_{\mathsf{cl}}(X, \mathbb{H}', \mathbb{H}')$ and $R = A'_X + G$ satisfies

$$A_X R \equiv I \qquad \mathsf{mod}\ \boldsymbol{\Psi}^{-\infty}_{\mathsf{cl}}(X, \mathbb{H}', \mathbb{H}'), \tag{1.4.40}$$

$$BR \equiv 0 \qquad \mathsf{mod}\ \boldsymbol{T}^{\mu-m-1}_{\mathsf{cl}}(X, \mathbb{H}_b, \mathbb{H}'). \tag{1.4.41}$$

Therefore

(1.4.42) One can adjust R by element of $\boldsymbol{G}^{-m-1}_{\mathsf{cl}}(X, \mathbb{H}, \mathbb{H}')$ and P by element of $\boldsymbol{P}^{-\mu-1}_{\mathsf{cl}}(X, \mathbb{H}, \mathbb{H}_b)$ so that (1.4.38)–(1.4.41) hold modulo operators with infinitely smooth Schwartz kernels.

In other words,

$$\begin{pmatrix} A \\ B \end{pmatrix} \begin{pmatrix} R & P \end{pmatrix} \equiv \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \tag{1.4.43}$$

and $\mathfrak{R} = (R, B)$ is a *left parametrix of boundary value problem* (A, B).

On the other hand, if $Au \equiv f$ then due to (1.4.12) and consequent analysis

$$A\digamma_X u \equiv \digamma_X f + \sum_{j\le m-1} \delta^{(j)}_{\partial X}(x) g_j$$

modulo $F_X\mathscr{C}^\infty(\bar{X},\mathbb{H}',\mathbb{H})$ where $g_j = \eth_{\partial X,j}u$. Applying $\eth_X A'$ we arrive to

$$u \equiv A'_X f + \eth_X A' \sum_{j\le m-1} \delta^{(j)}_{\partial X}(x) g_j \equiv A'_X f + \sum_j P'_j g_j \tag{1.4.44}$$

modulo $\mathscr{C}^\infty(\bar{X},\mathbb{H})$ where $P'_j \in \boldsymbol{P}^{-j}_{\mathsf{cl}}(X,\mathbb{H},\mathbb{H})$. Further,

$$g_k = \eth_{\partial X,k}u \equiv T_k f + \sum_j Q_{kj} g_j \tag{1.4.45}$$

where $T_k \in \boldsymbol{T}^{-m+k}_{\mathsf{cl}}(X,\mathbb{H},\mathbb{H}')$ and $Q_{kj} \in \boldsymbol{\Psi}^{k-j}_{\mathsf{cl}}(\partial X,\mathbb{H},\mathbb{H})$. Furthermore

$$Bu \equiv \sum_k B_k g_k. \tag{1.4.46}$$

One can prove easily that ellipticity as in Definition 1.4.28 implies that if $f\equiv 0$, $Bu\equiv 0$ then (1.4.45)–(1.4.46) imply that $g_k \equiv 0$. Therefore $\mathfrak{R} = (R,B)$ is a *right parametrix of boundary value problem* as well: $RA+PB \equiv I$ and therefore

(1.4.47) $\mathfrak{R}$ is a *parametrix of boundary value problem*.

Meanwhile

(1.4.48) $R = A'_X + G$ is a *parametrix of* A *under boundary condition* $Bu\equiv 0$.

Dirichlet-to-Neumann and Similar Operators

On the other hand, as $Au\equiv 0$ we get

$$\eth_{\partial X,j}u \equiv \eth_{\partial X,j}PBu \equiv L_j Bu \qquad \text{with } \ L_j \in \boldsymbol{\Psi}^{-\mu+j}(\partial X,\mathbb{H},\mathbb{H}_b) \tag{1.4.49}$$

Example 1.4.29. Consider Laplace-Beltrami operator $\Delta_X = \sum_{j,k} D_j g^{jk} D_k$ with symmetric real positive definite matrix (g^{jk}) (considered as a Riemannian metrics). Then $\Delta_X u \equiv 0$ implies that $\sum g^{jk} n_j D_k u|_{\partial X} = i\Delta^{1/2}_{\partial X} u|_{\partial X}$ where n_j are elements on the unit normal to ∂X (with respect to this metrics) directed into X, $\Delta_{\partial X}$ is defined in the same way according to induced metrics on ∂X.

The properly defined Laplace-Beltrami operator (which is self-adjoint in $\mathscr{L}^2(X)$ with Riemannian density) differs from this one by lower order terms.

Adjoint Operator; Self-Adjoint Operator

Consider operator A_B which is operator A with the domain

$$\mathscr{D}(A_B) = \{u \in \mathscr{H}^m(X, \mathbb{H}) : Bu = 0\}. \tag{1.4.50}$$

We can introduce adjoint operator A_B^* in the standard functional analysis way and we would say that A_B is self-adjoint if $A_B^* = A_B$ (as $\mathbb{H}' = \mathbb{H}$). However we will give a slightly more restrictive definition. As far as we know, nobody explored the gap.

So, for elliptic differential operator A let us consider

$$(Au, v)_X - (u, A^*v)_X = (\mathcal{B}\eth_{(m-1),\partial X}u, \eth_{(m-1),\partial X}v)_{\partial X} = \sum_{j+k\le m-1} (\mathcal{B}_{jk}\eth_{j,\partial X}u, \eth_{k,\partial X}v)_{\partial X} \tag{1.4.51}$$

where A^* is a *formally adjoint* differential operator, we pass from the left-hand expression to the middle one by integration by parts and $\mathcal{B}_{jk}$ are differential operators of order $(m-1-j-k)$ on ∂X. Recall that $\eth_{(m-1),\partial X}u = (\eth_{0,\partial X}u, \dots, \eth_{m-1,\partial X})$ is a function with values in $\mathbb{H}^m$.

Consider the middle expression of (1.4.51). It is a bilinear form of $\eth_{(m-1),\partial X}u$ and $\eth_{(m-1),\partial X}v$. Let us consider boundary value problem $Bu = 0$ for A; Recall that actually

$$Bu = B\eth_{(m-1),\partial X}u = \sum_{0\le j\le m-1} B_j\eth_{j,\partial X}u \qquad \text{with } B_j \in \boldsymbol{\Psi}^{\mu-j}_{\mathsf{cl}}(\partial X, \mathbb{H}_b, \mathbb{H}); \tag{1.4.52}$$

there should be no confusion that we excluded $\eth_{(m-1),\partial X}$ from B.

Further, let us consider for A^* the boundary conditions $B'v = 0$ of the same type (1.4.52).

Definition 1.4.30. Let us consider boundary conditions $Bu = 0$ for operator A and $B'u = 0$ for A^*; both conditions are of (1.4.52) type. Then $B' = 0$ is an *adjoined boundary value problem* for A^* if

$$BU = 0, B'V = 0 \implies (\mathcal{B}U, V)_{\partial X} = 0, \tag{1.4.53}$$

$$(\mathcal{B}U, V)_{\partial X} = 0 \qquad \forall U : BU = 0 \implies B'V = 0 \tag{1.4.54}$$

$$(\mathcal{B}U, V)_{\partial X} = 0 \qquad \forall V : B'V = 0 \implies BU = 0 \tag{1.4.55}$$

and moreover

$$\mathcal{B} = \beta B + (\beta' B')^* \qquad (1.4.56)$$
$$\text{with } \beta \in \boldsymbol{\Psi}^{m-1-\mu}_{\mathsf{cl}}(\partial X, \mathbb{H}'^{m}, \mathbb{H}_b),\ \beta' \in \boldsymbol{\Psi}^{m-1-\mu}_{\mathsf{cl}}(\partial X, \mathbb{H}^{m}, \mathbb{H}'_b).$$

One can prove easily that principal symbols of both β and β' should satisfy

$$\operatorname{Ker} \beta_0(x', \xi') = 0, \qquad \operatorname{Ker} \beta'_0(x', \xi') = 0. \qquad (1.4.57)$$

Definition 1.4.31. Let $A = A^*$, $\mathbb{H}' = \mathbb{H}$. Then $\mathcal{B}$ is skew-self-adjoint. We call $Bu = 0$ *self-adjoint boundary value problem* for A if $B' = B$ satisfies definition 1.4.30.

Example 1.4.32. Let $A = \sum_{j,k}(D_j - V_j)g^{jk}(D_k = V_k) + V$ with symmetric real positive definite matrix $(g^{jk}(x))$ (considered as a Riemannian metrics) and real-valued $V_j(x)$, $V(x)$. Then $A^* = A$. On the other hand,

$$(Au, v)_X - (u, Av)_X = i(Lu, v)_{\partial X} + i(u, Lv)_{\partial X} \qquad (1.4.58)$$
$$\text{with } Lu = \sum_{j,k} \nu_j g^{jk}(D_k - A_k)$$

where $\nu = (\nu_1, \dots, \nu_d)$ is an inner unit normal to ∂X. Therefore

(i) Dirichlet boundary condition $u|_{\partial X} = 0$ is self-adjoint;

(ii) Neumann boundary condition $Lu|_{\partial X} = 0$ is self-adjoint;

(iii) Adjoint to boundary condition $(L - iM)u|_{\partial X} = 0$ with $M \in \boldsymbol{\Psi}^1_{\mathsf{cl}}(\partial X)$ is $(L - iM^*)v|_{\partial X} = 0$; in particular it is self-adjoint if and only if $M = M^*$.

One can see easily that this problem is elliptic if and only if

$$|\big(\sum_{j,k} \tilde{g}^{jk}\xi_j\xi_k\big)^{1/2} + M_1(x', \xi')| \ge \epsilon \qquad (x', \xi') \in S^*\partial X \qquad (1.4.59)$$

where $\tilde{g}^{jk}$ is an induced metrics on ∂X.

Further, one can prove easily that (under condition (1.4.59)) A_B is semi-bounded from below if and only if

$$\big(\sum_{j,k} \tilde{g}^{jk}\xi_j\xi_k\big)^{1/2} + M_1(x', \xi') \ge \epsilon \qquad (x', \xi') \in S^*\partial X. \qquad (1.4.60)$$

As $d = 2$ one can satisfy (1.4.59) and fail (1.4.60) even with differential operator M.

Projectors

Standard resolvent construction (like in the proof of Theorem 1.1.59) yields two following theorems (as $\mathbb{H} = \mathbb{H}'$):

Theorem 1.4.33. *Let A be an elliptic differential operator and B an elliptic boundary value problem for it. Let X be compact. Then for arbitrarily small $\epsilon > 0$ $\operatorname{Spec}(A_B)$ with the exception of finite subset is contained in ϵ-vicinity of $\Sigma(a) \cup \Sigma(a_b)$ where as before*

$$\Sigma(a) = \overline{\bigcup_{(x,\xi)\in T^*X} \operatorname{Spec} a_0(x,\xi)}$$

and

$$\Sigma(a_b) = \overline{\bigcup_{(x',\xi')\in T^*\partial X} \operatorname{Spec} a_0(D_1,x',\xi')_{b_0(D_1,x',x')}} \tag{1.4.61}$$

where a_0 and b_0 are principal symbols of A and B and $a_0(D_1,x',\xi')_{b_0(D_1,x',\xi')}$ is boundary-value problem on $\mathbb{R}^+$;

Theorem 1.4.34. *Let A be an elliptic formally self-adjoint differential operator and B an elliptic boundary value problem for it. Let A_B be self-adjoint.*

Let $\Pi^\pm$ be orthogonal projectors onto positive and negative invariant subspaces of A_B. Then

(i) $\Pi^\pm \equiv \pi^\pm(x,D)_X \mod \boldsymbol{G}^0_{\mathsf{cl}}(X,\mathbb{H},\mathbb{H})$ where $\pi^\pm(x,D) \in \boldsymbol{\Psi}^0_{\mathsf{cl},\mathsf{trans}}(X,\mathbb{H},\mathbb{H})$ and their principal symbols $\pi_0^\pm(x,\xi)$ are projectors onto positive and negative subspaces of $a_0(x,\xi)$.

(ii) $\pi^\pm = 0$ if and only if $\pm a_0(x,\xi)$ is negative definite at every $(x,\xi) \in T^*X \setminus 0$. This condition is equivalent to $\Sigma(a) \subset \mathbb{R}^\mp$. In this case $\Pi^\pm \in \boldsymbol{G}^0_{\mathsf{cl}}(X,\mathbb{H},\mathbb{H})$ and its Schwartz kernel is

$$\mathcal{K}_{\Pi^\pm}(x,y) = (2\pi)^{1-d} \int e^{i\langle x'-y',\xi'\rangle} \kappa^\pm(x_1|\xi'|, \frac{1}{2}(x'+y'),\xi')\, d\xi' \tag{1.4.62}$$

where modulo lower order symbol $\kappa^\pm(x_1|\xi'|,x',\xi')$ is the Schwartz kernel of the spectral projector $\pi^\pm(x',\xi)$ of $a_0(D_1,x',\xi')_{b_0(D_1,x',\xi')}$.

(iii) $\Pi^{\pm} \equiv 0$ *modulo infinitely smoothing operator is and only if* $\pm a_0(x,\xi)$ *is negative definite at every* $(x,\xi) \in T^*X \setminus 0$ *and* $a_0(D_1, x', xi')_{b_0(D_1,x',\xi')}$ *is negative definite at every* $(x',\xi') \in T^*\partial X \setminus 0$. *This condition is equivalent to* $\Sigma(a) \cup \Sigma(a_b) \subset \mathbb{R}^{\mp}$.

Note however that $|A|$ does not have a transmission property unless m is even and $|A|^l$ does not have a transmission property unless ml is even.

Example 1.4.35. Consider operator A_B from Example 1.4.32(iii) with violated condition (1.4.62). Without any loss of the generality one can assume that $g^{1k} = \delta_{1k}$ as $x \in \partial X$ [29]. Then modulo Schwartz kernel of operator G_{cl}^{-1} one can define $\mathcal{K}_{\Pi^{\pm}}(x,y)$ by (1.4.62) with

$$\kappa^{-}(x_1|\xi'|, x', \xi') \equiv 2\lambda(x',\xi) e^{-\lambda(x',\xi')x_1} \theta\big(-M_1(x',\xi') - \lambda(x',\xi)\big) \tag{1.4.63}$$

with $\lambda(x',\xi) = \big(\sum_{j,k} \tilde{g}^{jk}\xi_j\xi_k\big)^{1/2}$.

Semiclassical Theory

Remark 1.4.36. Obviously all things stay the same for differential and pseudodifferential operators with D replaced by hD (and multiplied by h^{-s} if it was operator belonging to Ψ^s_{cl}). Then in the right-hand expressions of (1.4.15) of $\mathcal{K}_P(x,y')$ and $\mathcal{K}_T(x',y)$ and (1.4.15) of $\mathcal{K}_G(x,y)$ one should

(i) Replace x_1 and y_1 by $h^{-1}x_1$ and $h^{-1}y_1$ respectively,

(ii) Replace $e^{i\langle x'-y',\xi'\rangle}$ by $e^{ih^{-1}\langle x'-y',\xi'\rangle}$ and $d\xi'$ by $h^{1-d}d\xi'$ and

(iii) Multiply them by h^{-s} as $\mathcal{K}_P(x,y')$ is defined and by h^{-s-1} as $\mathcal{K}_T(x',y)$ and $\mathcal{G}_T(x,y)$ are defined.

Example 1.4.37. Consider operator A_B from example 1.4.32(iii). Then in the semiclassical theory $a_0 = \sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k) + V$ and positivity of a_0 condition means that also $V \ge \epsilon$.

Ellipticity condition (1.4.59) and positivity condition (1.4.62) are replaced by

$$|\lambda(x',\xi') + M_1(x',\xi')| \ge \epsilon \qquad \forall (x',\xi') \in T^*\partial X \tag{1.4.64}$$

[29] One can always achieve it by taking $x_1 = \mathsf{dist}(x, \partial X)$ in the vicinity of ∂X where dist means the Riemannian distance.

and

$$\lambda(x',\xi') + M_1(x',\xi') \ge \epsilon \qquad \forall (x',\xi') \in T^*\partial X \tag{1.4.65}$$

respectively and (1.4.63) is replaced by

$$\kappa^-(h^{-1}x_1|\xi'|, x', \xi') \equiv 2h^{-1}\lambda(x',\xi)e^{-h^{-1}\lambda(x',\xi')x_1}\theta\big(-M_1(x',\xi') - \lambda(x',\xi)\big) \tag{1.4.66}$$

with

$$\lambda(x',\xi') = \big(\sum_{j,k} \tilde{g}^{jk}(\xi_j - V_j)(\xi_k - V_k) + V\big)^{1/2}. \tag{1.4.67}$$

1.A Appendices

1.A.1 Operator $e^{itQ(D)}$

Let $q(D) = \langle QD, D\rangle$ be a nondegenerate real quadratic form in $\mathbb{R}^d$ with real symmetric matrix Q; then

$$k(x,y) = \mathcal{K}_{e^{iq(D)}}(x,y) = (2\pi)^{d/2}|\det Q'|^{1/2} e^{\frac{\pi i d}{4} - \frac{i}{4}q'(x-y)} \tag{1.A.1}$$

is the Schwartz kernel of $e^{iq(D)}$ where $q'(z) = \langle Q^{-1}z, z\rangle$.

We claim first that

$$\|e^{iq(D)}f\|_{\mathscr{L}^\infty} \le C \sum_{|\alpha|\le (d+2)/2} \|D^\alpha f\|_{\mathscr{L}^\infty}. \tag{1.A.2}$$

Indeed, an estimate for $\|\int_{B(x,1)} k(x,y)f(y)\,dy\|$ is obvious; to estimate a similar integral over $\mathbb{R}^d\backslash B(x,1)$ we note that $\nabla_y k(x,y) = \frac{i}{2}Q^{-1}(y-x)k(x,y)$; then $k(x,y) = \omega_{-1}(x-y)\nabla_y k(x,y)$ with positive homogeneous of degree s functions ω_s; then after integration by parts

$$\int_{|x-y|\ge 1} k(x,y)f(y)\,dy = \int \omega_{-2}(x-y)k(x,y)f(y)\,dy + \int \omega_{-1}(x-y)k(x,y)\nabla f(y)\,dy$$

and we continue repeating this procedure until we get ω_{-d-1} in every term.

Estimate (1.A.2) after rescaling $x \mapsto |t|^{-1/2}x$, $D \mapsto |t|^{1/2}D$ implies immediately

$$\|e^{tiq(D)}f\|_{\mathscr{L}^\infty} \le C \sum_{|\alpha|\le(d+2)/2} |t|^{|\alpha|/2}\|D^\alpha f\|_{\mathscr{L}^\infty}. \tag{1.A.3}$$

Using Taylor decomposition (with respect to t at $t=0$) and applying (1.A.3) to the remainder estimate we arrive to

$$\|\Big(e^{tiq(D)} - \sum_{n\le N-1} \frac{1}{n!}\big(itQ(D)\big)^n\Big)f\| \le C|t|^N \frac{1}{N!} \sum_{|\alpha|\le(d+2)/2} |t|^{|\alpha|/2}\|D^\alpha Q(D)^N f\|_{\mathscr{L}^\infty}. \tag{1.A.4}$$

Finally, we get immediately

$$\sum_{|\beta|=K} \|D^\beta\Big(e^{tiq(D)} - \sum_{n\le N-1} \frac{1}{n!}\big(itq(D)\big)^n\Big)f\| \le C|t|^N \frac{1}{N!} \sum_{|\beta|=K,|\alpha|\le(d+2)/2} |t|^{|\alpha|/2}\|D^{\alpha+\beta} q(D)^N f\|_{\mathscr{L}^\infty}. \tag{1.A.5}$$

1.A.2 Almost Analytic Compactly Supported Symbols

Proposition 1.A.1. *For any n there exists a function ϕ_n, such that*

$$\operatorname{supp}(\phi_n) \subset [0,1], \tag{1.A.6}$$

$$\phi_n \ge 0\ , \quad \int_{-\infty}^{\infty} \phi_n\, dx = 1, \tag{1.A.7}$$

$$|\partial^k \phi_n| \le c(cn)^k \qquad \forall k \le n \tag{1.A.8}$$

with c which does not depend on n.

Proof. Let us fix $\phi = \phi_1$ supported in $[0, \frac{1}{2}]$ and satisfying (1.A.7). Then

$$\phi_n(t) = \underbrace{n\phi(nt) * n\phi(nt) * \cdots * n\phi(nt)}_{n \text{ times}} * \phi(t) \tag{1.A.9}$$

is a proper function. □

1.A.3 Stationary Phase Method

Let us consider

$$\mathcal{I}(x) = e^{ih^{-1}\phi(\theta)} f(\theta) d\theta \tag{1.A.10}$$

with smooth and real-valued ϕ, smooth and compactly supported f and $\theta \in \mathbb{R}^N$. Then under assumption

$$|\nabla \phi| \ge \epsilon_0 \qquad \text{on} \quad \mathsf{supp}(f) \tag{1.A.11}$$

$\mathcal{I} = O(h^s)$ for any s. Proof is trivial: decomposing $f = f_1 + ... + f_N$ with $|\partial_{\theta_k}\phi| \ge \epsilon_1$ on $\mathsf{supp}(f_k)$ and integrating by parts.

Therefore in the general case we need to consider f supported in the vicinity of the set

$$\mathcal{C} = \{\theta : \nabla \phi(\theta) = 0\} \tag{1.A.12}$$

of stationary points of ϕ.

Assume now that

$$|\nabla \phi| \le \epsilon_0 \implies |\det \mathsf{Hess}\, \phi| \ge \epsilon_0 \qquad \text{on} \quad \mathsf{supp}(f) \tag{1.A.13}$$

which is a quantitative version of $\mathsf{rank}\, \mathsf{Hess}\, \phi = N$ on $\mathcal{C} \cap \mathsf{supp}(f)$. Then $\mathcal{C} \cap \mathsf{supp}(f) = \{\theta^1, ..., \theta^r\}$ is a finite set. So we can consider f supported in the vicinity a single non-degenerate stationary point $\bar{\theta}$. Without any loss of the generality we can assume that $\bar{\theta} = 0$. Changing variables we can achieve $\phi(\theta) = \frac{1}{2}\varsigma_1\theta_1^2 + ... + \frac{1}{2}\varsigma_N\theta_N^2$ where ς_j are eigenvalues of $\mathsf{Hess}\, \phi(0)$; then $f(0)$ is preserved. Note that

(1.A.14) If $f = O(|\nabla\phi|^l)$ then one can rewrite $\mathcal{I} = h^l \mathcal{I}'$ where $\mathcal{I}'$ is given by the same formula (1.A.10) with $f' = \mathcal{L}_l f$ with depending on ϕ linear differential operator $\mathcal{L}_l$ of order l.

One can prove it using integration by parts.

Decomposing f into Taylor series at $\theta = 0$ we arrive to need to consider only case $f = 1$; then applying formula

$$\int e^{\frac{i}{2}h\langle Q\theta,\theta\rangle}\, d\theta = (2\pi h)^{N/2} |\det Q|^{-1/2} e^{\frac{\pi i\, \mathsf{sgn}\, Q}{4}} \tag{1.A.15}$$

we arrive to the *stationary phase principle*

Proposition 1.A.2. *Consider* (1.A.10) *with smooth and real-valued* ϕ*, smooth and compactly supported* f *and* $\theta \in \mathbb{R}^N$*. Then under assumption* (1.A.13)

$$\mathcal{I} \asymp \sum_{z_k \in \mathcal{C}_k} e^{ih^{-1}\phi(\theta_k)} \times |\det \mathsf{Hess}\, \phi(\theta_k)|^{-1/2} e^{\frac{\pi i}{4}\operatorname{sgn} \mathsf{Hess}\, \phi(\theta_k)} \Big(\sum_{n\ge 0} f_{k,n} h^n\Big) \tag{1.A.16}$$

with $f_{k,0} = f(\theta_k)$ *and* $f_{k,n} = (\mathcal{L}_n f)(\theta_k)$.

Proof. Proof of (1.A.10) is trivial: first, as Q is diagonal it is a product of one-dimensional integrals; further, changing $z = |\lambda_j|^{1/2} h^{-1/2}\theta$ we reduce it to $\int_{-\infty}^{\infty} e^{\pm iz^2/2}\, dz$. The contour of integration of the latter could be deformed to $e^{\pm i\pi/4}\mathbb{R}$; so we get $e^{\pm i\pi/4}\int_{-\infty}^{\infty} e^{-z^2/2}\, dz$ and the latter integral is well-known.□

1.A.4 Function in the Box

Consider function u such that

(1.A.17) $\|u\| \asymp 1$ such that is negligible in $\{|x| \ge \gamma\}$ and $F_{x\to h^{-1}}u$ is negligible in $\{|\xi| \ge \rho\}$.

Does such function exists?

Obviously the same answer remains if instead of "$F_{x\to h^{-1}\xi}u$ is negligible in $\{|\xi| \ge \rho\}$" we request "$\mathsf{supp}\big(F_{x\to h^{-1}}u\big) \subset \{|x| \le \rho\}$".

However then (see f.e. (3.3) of B. Paneah [2] and the references there):

$$\|u\|_{\{|x|\ge\gamma\}} \ge \epsilon e^{-\epsilon h^{-1}\rho\gamma}\|u\| \tag{1.A.18}$$

with $\epsilon = \epsilon(d)$. Therefore

(1.A.19) $\|u\| \asymp 1$ and $\|u\|_{\{|x|\ge\gamma\}} \le Ch^s$ imply $e^{-\epsilon h^{-1}\rho\gamma} \le Ch^s$ which is equivalent to $h^{-1}\rho\gamma \ge \epsilon s|\log h|$; so we must assume $\rho\gamma \ge \epsilon sh|\log h|$.

On the other hand,

(1.A.20) Consider a coherent state $u = (2\pi\alpha)^{-d/2}e^{-|x|^2/2\alpha^2}$. Then $F_{x\to h^{-1}\xi} = (2\pi\beta)^{-d/2}e^{-|\xi|^2/2\beta^2}$ with $\beta = h/\alpha$. Picking $\alpha = \gamma(s|\log h|)^{-1/2}$ we get that u satisfies (1.A.17) as long as $\beta \le \rho(s|\log h|)^{-1/2}$ which holds as $\rho\gamma \ge Cs|\log h|$.

Comments

We have sent the reader to the book of L. Hörmander [1] for details, proofs and advanced results. One can find relatively easy exposition in the monographs of F. Treves [1] and M. Taylor [7].

One can find interesting approaches in the monograph of M. Shubin [3]. Unfortunately there seem to be no comprehensive and comprehensible book, covering relation between pseudodifferential operators and *singular integral operators* due to Calderon-Zygmund-Mihlin.

Chapter 2

Propagation of Singularities in the Interior of the Domain

In this chapter we consider microlocal propagation of singularities (i.e., wave front sets) in the interior of a domain. In general in this book we consider two types of microlocal operator, namely, microelliptic and microhyperbolic. For microelliptic operators[1)] there is no propagation of singularities at all and we prove the different variants of this fact which we need by means of either a parametrix construction or the Gårding inequality; sometimes we combine both methods.

In this chapter we treat microhyperbolic operators. There are different approaches. One based on Fourier integral operators we already considered. While delivering the most information about solutions it also imposes the most conditions to operator. We will apply different approaches instead.

In Sections 2.1–2.3 we use the most general approach based on the energy estimates. First of all, in Section 2.1 we prove the main general Theorem 2.1.2 and certain of its corollaries which will be necessary for our study of spectral asymptotics; this Theorem is formulated in the terms of auxiliary real-valued functions $\phi_j(x,\xi)$ with $j = 1, \dots, J$.

Next, in Section 2.2 we reformulate this Theorem in more geometric terms, namely, in the terms of bicharacteristics and generalized bicharacteristics and consider a host of different examples.

Finally, in Section 2.4 we generalize this Theorem to the case of the

[1)] I.e. operators elliptic in the vicinity of the point in question; so all operators are microelliptic everywhere except their characteristic varieties.

"rough" symbols.

In Section 2.4 we consider Heisenberg approach for the propagation of singularities for scalar and related operators. It will allow us to consider a large time interval.

We will use not only results but also the methods of this chapter to prove different type of propagation later; in particular in perturbed case of the periodic Hamiltonian flow the very long-time propagation results will be obtained by the same and other methods.

2.1 Energy Estimates Approach

2.1.1 Main Theorem

Let us start with the key notion and key statement of this chapter:

Definition 2.1.1. Let $p \in \mathsf{S}_{h,1}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ be a Hermitian symbol. Then p is *microhyperbolic at the point* $z = (x, \xi) \in T^*\mathbb{R}^d$ *in the direction* $\ell = (\ell_x, \ell_\xi) \in T_z T^*\mathbb{R}^d$ iff

$$-\langle (\ell p)(z)w, w\rangle \ge \epsilon_0 \|w\|^2 - c_1 \|p(z)w\|^2 \qquad \forall w \in \mathbb{H} \tag{2.1.1}$$

where $\ell p = (\langle \ell_x \partial_x\rangle + \langle \ell_\xi, \partial_\xi\rangle)p$ and $\epsilon_0 > 0$ and c_1 are appropriate constants.

Using this definition we are going to prove the following main Theorem:

Theorem 2.1.2. *Suppose* $P \in \mathbf{\Psi}_h(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *and assume that*

$$p(z) = P_0(z) \quad \text{is a Hermitian symbol.} \tag{2.1.2}$$

Let $\Omega \Subset T^*\mathbb{R}^d$ *and let* $\phi_1, \dots, \phi_J$ *be real-valued* $\mathscr{C}^N_b$ *functions in* $T^*\mathbb{R}^d$ *such that at every point* $z \in \bar{\Omega}$ *the symbol* p *is microhyperbolic in the directions* $\nabla^\# \phi_1, \dots, \nabla^\# \phi_J$ *where* $\nabla^\# \phi = \langle (\nabla_\xi \phi), \nabla_x\rangle - \langle (\nabla_x \phi), \nabla_\xi\rangle$ *is the Hamiltonian field generated by* ϕ.

Let u *be tempered, i.e.,*

$$\|u\| \le h^{-I}, \tag{2.1.3}$$

and

$$\mathsf{WF}^{s+1}(Pu) \cap \Omega \cap \{\phi_1 \le 0\} \cap \dots \cap \{\phi_J \le 0\} = \emptyset, \tag{2.1.4}$$

$$\mathsf{WF}^{s}(u) \cap \partial\Omega \cap \{\phi_1 \le 0\} \cap \dots \cap \{\phi_J \le 0\} = \emptyset. \tag{2.1.5}$$

Then

$$\mathsf{WF}^s(u) \cap \Omega \cap \{\phi_1 \le 0\} \cap \dots \cap \{\phi_J \le 0\} = \emptyset. \tag{2.1.6}$$

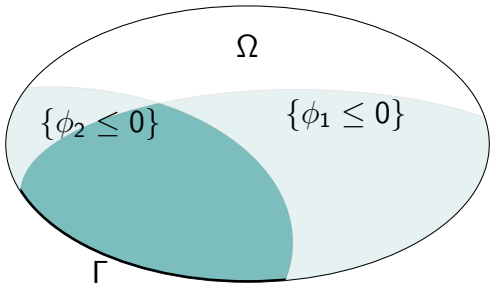

Figure 2.1: Domains to Theorem 2.1.2

This picture shows domains Ω and $\{\phi_j \le 0\}$: so the dark shaded area is where we assume that Pu is negligible and we deduct that u is negligible while we also assume that u is negligible in the small vicinity of the thick line $\Gamma = \partial\Omega \cap \{\phi_1 \le 0\} \cap \{\phi_2 \le 0\}$.

It looks like Holmgren uniqueness Theorem but now Ω resides in the phase space rather than configuration space and "$u \equiv 0$" replaces "$u = 0$" which does not have sense with the relation to phase space.

Proof. Let $q_1, q_2, q_3 \in \mathsf{S}_h(\mathbb{R}^d, \mathbb{C})$ be arbitrary symbols such that $q_1 = 1$ in $\Omega_\epsilon \cap \{\phi_1 \le \epsilon\} \cap \dots \cap \{\phi_J \le \epsilon\}$, $q_2 = 1$ in $(\partial\Omega)_\epsilon \cap \{\phi_1 \le \epsilon\} \cap \dots \cap \{\phi_J \le \epsilon\}$ and $\mathsf{supp}(q_3) \subset \Omega_{\frac{1}{2}\epsilon} \cap \{\phi_1 \le \frac{1}{2}\epsilon\} \cap \dots \cap \{\phi_J \le \frac{1}{2}\epsilon\}$.

Let $Q_k = \mathsf{Op}^{\mathsf{w}}(q_k)$ and $N = N(s, l)$ in the definition of the symbol classes, etc.

One can easily see that in order to prove the Theorem it is sufficient to prove that (2.1.3) and

$$\|Q_1 P u\| \le h^{s+1}, \qquad \|Q_2 u\| \le h^s \tag{2.1.7}_{1,2}$$

yield

$$\|Q_3 u\| \le C h^s \tag{2.1.8}$$

where $\|.\|$ as usual means the $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H})$-norm and C depends on $d, s, l, \epsilon_0, c_1, \epsilon$,

$$c_2 = \|\!|P|\!\| + \sum_k \|\!|q_k|\!\| + \sum_j \|\phi_j\|_{\mathscr{C}^\infty};$$

however,

(2.1.9) C depends neither on Ω nor even its diameter.

We prove (2.1.8) under the additional assumption

$$\|Q_1 u\| \le h^{s-\delta}; \tag{2.1.10}$$

with any exponent $\delta > 0$ which does not depend s; we can take $\delta = \frac{1}{2}$ here; obviously, the general case is reduced to this one by "induction" on s in (2.1.8).

Let $\chi \in \mathscr{C}^\infty(\mathbb{R})$ be a fixed real-valued function such that

$$\begin{aligned}\mathsf{supp}(\chi) \subset (-\infty, 0],\ \chi > 0 \text{ on } \quad (-\infty, 0),\ \chi' \ge c_3\chi \text{ and}\\ \chi_1 = \chi^{\frac{1}{2}},\ \chi_2 = (-\chi')^{\frac{1}{2}} \in \mathscr{C}^\infty(\mathbb{R})\end{aligned} \tag{2.1.11}$$

where the prime means derivative and the constant c_3 can be chosen later (such a function χ exists for every c_3).

We can replace ϕ_j by $(\phi_j - \frac{1}{4}\epsilon)$ and ϵ by $\frac{3}{4}\epsilon$; hence it is sufficient to prove (2.1.8) only for $Q_3 = \mathsf{Op}^{\mathsf{w}}(q_3)$ with

$$q_3(z) = \zeta(z) \prod_{1\le k\le J} \chi(\phi_k(z)) \tag{2.1.12}$$

where $\zeta \in \mathscr{C}_0^N(\Omega_\epsilon)$, $0 \le \zeta \le 1$, $\zeta = 1$ in $\Omega_{\frac{2}{3}\epsilon}$; there exists such a function with $\mathscr{C}^\infty$-norm not exceeding $C_1 = C_1(d, N, \epsilon)$.

Let us consider the main identity of the energy estimate method

$$\begin{aligned}-\mathsf{Re}\ i([P, Q]u, u) =\\ \mathsf{Re}\, i((Q + Q^*)Pu, u) + \mathsf{Re}\, i((P^* - P)Qu, u).\end{aligned} \tag{2.1.13}$$

Let us plug $Q = Q_3^2$; then $Q = Q^*$ and the absolute value of the first term in the right hand expression in (2.1.13) does not exceed $\|Q_3 Pu\| \cdot \|Q_3 u\|$.

Then (2.1.3) and (2.1.6) imply that $\|Q_3 Pu\| \le 2h^{s+1}$: indeed, $q_1 = 1$ in the ϵ_1-neighborhood of $\mathsf{supp}(q_3)$ with $\epsilon_1 = \epsilon_1(d, \epsilon_0, c_1, J, \epsilon) > 0$). Therefore the absolute value of the first term in the right hand expression in (2.1.13) does not exceed $2h^{s+1}\|Q_3 u\|^2$.

Meanwhile the second term in the right hand expression in (2.1.13) equals

$$\mathsf{Re}\, i((P^* - P)Q_3 u, Q_3 u) + \mathsf{Re}\, i([P^* - P, Q_3]Q_3 u, u). \tag{2.1.14}$$

Then (2.1.2) yields that the absolute value of the first term here does not exceed $C_2 h\|Q_3 u\|$ where C_2 does not depend on c_3. Further, (2.1.2), (2.1.3)

and (2.1.10) imply that the absolute value of the second term does not exceed $Ch^{s+\frac{3}{2}}\|Q_3u\|^2$ where C depends on c_3. Thus (2.1.13) implies that

$$|-\operatorname{Re} ih^{-1}([P,Q]u,u)| \le C_2\|Q_3u\|^2 + Ch^{2s}. \tag{2.1.15}$$

Now our goal is to estimate $-\operatorname{Re} ih^{-1}([P,Q]u,u)$ from below. Let us note that the principal symbol of the operator $-ih^{-1}[P,Q]$ is equal to

$$\sum_{1\le j\le J} 2\{p,\phi_j\}r_j^2 - \{p,\zeta^2\}\prod_{1\le k\le J}\chi^2(\phi_k) \tag{2.1.16}$$

where

$$r_j = \zeta\chi_1(\phi_j)\chi_2(\phi_j)\prod_{k\ne j}\chi(\phi_k)$$

and χ_1, χ_2 are defined by (2.1.11).

Since $q_2 = 1$ in the ϵ_1-neighborhood of the support of the second term in (2.1.16) we conclude from (2.1.3), $(2.1.7)_{1,2}$, (2.1.10) and (2.1.15) that

$$|\sum_{1\le j\le J}(S_jR_ju,R_ju)| \le C_2\|Q_3u\|^2 + Ch^{2s} \tag{2.1.17}$$

where $R_j = \operatorname{Op}^{\mathrm{w}}(r_j)$, $S_j = \operatorname{Op}^{\mathrm{w}}(\{p,\phi_j\})$.

The microhyperbolicity of p in the directions $\nabla^{\#}\phi_j$ yields that there exists a symbol q_4 vanishing in the ϵ_1-neighborhood of the supports of r_j for all j such that $\|\!|q_4|\!\| \le C$ and the following inequalities are fulfilled:

$$\langle(\{p,\phi_j\} + cp^{\dagger}p + (q_4-\epsilon_0)I)w,w\rangle \ge 0 \qquad \forall w\in\mathbb{H}\quad \forall z\in T^*\mathbb{R}^d\quad \forall j = 1,\dots,J. \tag{2.1.18}$$

Then passing from symbols to operators we obtain by means of the Gårding inequality (Theorem 1.1.29) that

$$\operatorname{Re}(S_jv,v) + c_1\|Pv\|^2 + \operatorname{Re}(Q_4v,v) \ge (\epsilon_0 - Ch)\|v\|^2. \tag{2.1.19}$$

Let us plug $v = R_ju$ here. Observe that (2.1.3), (2.1.6) and (2.1.10) yield that

$$\|Pv\| \le \|R_jPu\| + \|[R_j,P]u\| \le Ch^s. \tag{2.1.20}$$

Moreover, observe that $|(Q_4v, v)| \le Ch^{2s}$ because the supports of Q_4 and R_j are disjoint and that $\|v\| \le Ch^{s-\frac{1}{2}}$ in virtue of (2.1.10) and (2.1.3). Therefore

$$\mathsf{Re}(S_jR_ju, R_ju) \ge \epsilon_0\|R_ju\|^2 - Ch^{2s}. \tag{2.1.21}$$

This inequality and (2.1.17) yield that

$$\sum_{1\le j\le J} \|R_ju\| \le C_2\|Q_3u\|^2 + Ch^{2s}. \tag{2.1.22}$$

Moreover, (2.1.11) yields that $q_3^2 \le \epsilon_3^{-1}r_j^2$ with $\epsilon_3 = c_3^{-1}$. Therefore the Gårding inequality yields that

$$\|Q_3v\|^2 \le \epsilon_3\|R_jv\|^2 + Ch\|v\|^2.$$

Let us plug $v = Q_5u$ here where $q_5 = 1$ in the ϵ_1-neighborhood of $\mathsf{supp}(q_5)$; then this estimate and (2.1.3) and (2.1.6) yield that

$$\|Q_3u\|^2 \le c_3^{-1}\|R_ju\|^2 + Ch^{2s}.$$

This estimate, (2.1.6) again, the possibility of choosing ϵ_3 arbitrarily small and the fact that C_2 does not depend on c_3 (and ϵ_3) together imply (2.1.8).□

Remark 2.1.3. (i) In fact, we could prove this Theorem for $J = 1$ from which the general case follows. Indeed, one can reduce $J \ge 2$ to $J = 1$ considering $\phi = f(\phi_1, \dots, \phi_J)$ where $f = f_\varepsilon \in \mathscr{C}^\infty$ such that $\partial_{t_j}f(t) > 0$ $\forall j$ $\forall t = (t_1, \dots, t_J)$ and

$$\{t : f(t) \le -\varepsilon\} \subset \{t_1 \le 0, \dots, t_J \le 0\} \subset \{t : f(t) \le \varepsilon\}$$

with arbitrarily small constant $\varepsilon > 0$.

(ii) We can replace "$\phi_j \le 0$" by "$\phi_j < 0$" in (2.1.4)–(2.1.6). We can use one type of inequalities for some indices j and another type fo other indices.

(iii) The Theorem and Statement (ii) here remain true if we assume that p is microhyperbolic in $\bar\Omega$ in the direction $\nabla^\#\psi$ with a real-valued function ψ with $\|\psi\|_{\mathscr{C}^\infty} \le c_2$ and that p is *non-strictly microhyperbolic* in $\bar\Omega$ in the directions $\nabla^\#\phi_j$ for $j = 1, \dots, J$; the non-strict microhyperbolicity means that for $\ell = \nabla^\#\phi_j$

$$-\langle((\ell p)(z)w, w\rangle \ge -c_1\|p(z)w\|^2 \qquad \forall w \in \mathbb{H}; \tag{2.1.23}$$

we reduce this case to one considered above replacing ϕ_j by $(\phi_j + \varepsilon\psi)$ with small enough $\varepsilon > 0$.

We need however to assume that sets $\{\phi_j \le t\}$ depend continuously on t at $t = 0$ i.e.

$$\overline{\{z, \phi_j(z) < 0\}} = \{z, \phi_j(z) \le 0\}$$

and

$$\overline{\{z, \phi_j(z) > 0\}} = \{z, \phi_j(z) \ge 0\}.$$

In what follows we need

Proposition 2.1.4. *Statement "*$(2.1.7)_{1,2}$ & $(2.1.3) \implies (2.1.8)$*" remains true if in the definition of* c_2 *and hence in the definition of* C *we replace* $\|\!|P|\!\|$ *by* $\|\!|P - \bar{P}|\!\|$ *with an arbitrary Hermitian matrix* $\bar{P} \in \mathcal{L}(\mathbb{H}, \mathbb{H})$.

Proof. Let $P = \bar{P} + P'$, $\|\!|P'|\!\| \le c_2 - 1$. Without any loss of the generality one can assume that $\mathbb{H} = \mathbb{H}_1 \otimes \mathbb{H}_2$, $\bar{P}\mathbb{H}_j \subset \mathbb{H}_j$ and $\|\bar{P}w_1\| \le c_2\|w_1\|$, $\|\bar{P}w_2\| \ge c_2\|w_2\| \quad \forall w_j \in \mathbb{H}_j$. Then

$$P = \begin{pmatrix} P_1 & P_{12} \\ P_{21} & P_2 \end{pmatrix}$$

and the principal symbol p_2 of P_2 is invertible and the norm of the inverse symbol does not exceed 1; then its parametrix $R_2 \in \mathbf{\Psi}_h(\mathbb{R}^d, \mathbb{H}_2, \mathbb{H}_2)$ exists with $\|\!|R_2|\!\| \le C_0 = C_0(d, N, c, c_1, c_2)$. Thus the treatment of the propagation of singularities for P is reduced to that for $P'' = P_1 - P_{12}R_2P_{21} \in \mathbf{\Psi}_h(\mathbb{R}^d, \mathbb{H}_1, \mathbb{H}_1)$ with $\|\!|P''|\!\| \le C_0$.

The principal symbol $p'' = p_1 - p_{12}p_2^{-1}p_{21}$ of P'' is Hermitian because $p_{12} = p_{21}^{\dagger}$. Moreover, the equality

$$\langle \{p'', \phi\} w_1, w_1 \rangle = \langle \{p, \phi\} w, w \rangle$$

holds for $w = (w_1, w_2) = (w_1, -p_2^{-1}p_{21}w_1)$ and hence condition (2.1.1) for p implies the same condition for p'' with the constants c_1 and ϵ_0 replaced by C_0c_1 and $C_0^{-1}\epsilon_0$. □

2.1.2 Cauchy Problem. I

Let us now consider the Cauchy problem for the operator

$$P = hD_t + A \tag{2.1.24}$$

with $A \in \mathscr{C}^1\big([0,\,T], \mathbf{\Psi}_h(\mathbb{R}^d, \mathbb{H}, \mathbb{H})\big)$ where

(2.1.25) $a(t,x,\xi) = A_0(t,x,\xi)$ is a Hermitian symbol for all (t,x,ξ).

We assume that $\Omega \Subset \mathbb{R} \times T^*\mathbb{R}^d$ and $\phi_j \in \mathscr{C}^1\big([0,\,T], \mathscr{C}^N_b(T^*\mathbb{R}^d)\big)$ are real-valued functions such that

$$\langle \{p, \phi_j\}(t,z)w, w\rangle \geq \epsilon_0 \|w\|^2 \quad \forall w \in \mathbb{H}. \tag{2.1.26}$$

Then we replace (2.1.13) by the identity

$$\begin{aligned} h\,\mathsf{Re}(Qu,u)_T - \mathsf{Re}\, i([P,Q]u,u)_{[0,T]} = \\ h\,\mathsf{Re}(Qu,u)_0 + \mathsf{Re}\, i((Q+Q^*)u,u)_{[0,T]} + \mathsf{Re}\, i((P-P^*)Qu,u)_{[0,T]} \end{aligned} \tag{2.1.27}$$

where $(.,.)_{[0,T]}$ and $(.,.)_t$ are inner products in $\mathscr{L}^2((0,\,T)\times\mathbb{R}^d, \mathbb{H})$ and in $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H})$ for the indicated t respectively; for the norms similar notation will be used. Repeating the proof of Theorem 2.1.2 with the obvious modifications we obtain

Theorem 2.1.5. *Let conditions* (2.1.24) *and* (2.1.25) *be fulfilled and suppose* $\Omega \Subset \mathbb{R}\times T^*\mathbb{R}^d$. *Let* $\phi_j \in \mathscr{C}^1([0,\,T], \mathscr{C}^\infty_b(T^*\mathbb{R}^d))$ *be real-valued functions satisfying* (2.1.26) *in* Ω_ϵ *where* M_ϵ *denotes* ϵ*-vicinity of* M.

Let $q_1, q_2, q_3 \in \mathscr{C}([0,\,T], \mathsf{S}_h(T^*\mathbb{R}^d, \mathbb{C}))$ *be symbols such that*

$$\begin{aligned} &q_1 = 1 \quad \textit{in} \qquad \Omega_\epsilon \cap \{\phi_1 \leq \epsilon\} \cap \dots \cap \{\phi_J \leq \epsilon\},\\ &q_2 = 1 \quad \textit{in} \quad (\partial\Omega)_\epsilon \cap \{\phi_1 \leq \epsilon\} \cap \dots \cap \{\phi_J \leq \epsilon\} \end{aligned}$$

and

$$\mathsf{supp}(q_3) \subset \Omega_{\frac{\epsilon}{2}} \cap \{\phi_1 \leq \frac{\epsilon}{2}\} \cap \dots \cap \{\phi_J \leq \frac{\epsilon}{2}\}.$$

Let $Q_k = \mathsf{Op}^{\mathsf{w}}(q_k)$ *and* $N = N(s,l)$ *in the definition of symbol classes, etc. Then*

$$\sup_{t\in[0,T]} \|u\|_t \leq 1, \qquad \|Q_1 u\|_0 \leq h^s, \tag{2.1.28}$$

$$\int_0^T (\|Q_1 Pu\|_t + h\|Q_2 u\|_t)\,dt \leq h^{s+1} \tag{2.1.29}$$

imply that

$$\sup_{t\in[0,T]} \|Q_3 u\|_t \le Ch^s \tag{2.1.30}$$

with the same type constant C as in Theorem 2.1.2[2)].

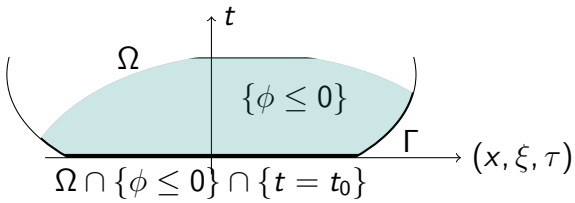

Figure 2.2: Domains to Theorem 2.1.5 $\Gamma = \partial\Omega \cap \{\phi \le 0\} \cap \{t_0 \le t \le T\}$ $\Omega \cap \{\phi \le 0\} \cap \{t_0 \le t \le T\}$.

Here instead of Ω we consider strip $\Omega \cap \{t_0 \le t \le T\}$ and initial condition are on the bottom lid $\{t = t_0\}$ while the top lid $\{t = T\}$ is free. So, we assume that $Pu \equiv 0$ at $\Omega \cap \{\phi \le 0\} \cap \{t_0 \le t \le T\}$ and conclude that $u \equiv 0$ there, assuming also that $u \equiv 0$ at and also that $u|_{t=0} \equiv 0$ at

Remark 2.1.6. (i) Theorem 2.1.5 remains true if we in the conditions and in the conclusion replace $\sup_{t\in[0,T]} \|.\|_t$ by $\frac{1}{\sqrt{T}}\|.\|_{[0,T]}$.

(ii) Moreover, Proposition 2.1.4 remains true[3)].

Let us note that if

$$\|\nabla_z a\| \le c \qquad \forall (t,z) \in [0,T]\times T^*\mathbb{R}^d \tag{2.1.31}$$

then (2.1.26) holds for a function $\phi = t + \psi(z)$ provided $\|\nabla_z \psi\| \le c^{-1}(1-\epsilon)$.

Corollary 2.1.7. *Let conditions* (2.1.24), (2.1.25) *and* (2.1.31) *be fulfilled. Then the statements of Theorem 2.1.5 and Remark 2.1.6 hold for $\Omega = [0,T]\times T^*\mathbb{R}^d$, $q_k = q_k(z)$ $(k = 1,3)$, $q_2 = 0$ provided*

$$\operatorname{dist}(\operatorname{supp}(1-q_1), \operatorname{supp}(q_3)) \ge CT + \epsilon$$

with an arbitrarily small constant $\epsilon > 0$.

[2)] Surely with $\|P\|$ replaced by $\|A\|$ in the definition of c_2.

[3)] Surely with $\|P - \bar{P}\|$ replaced by $\|A - \bar{A}\|$ in the definition of c_2.

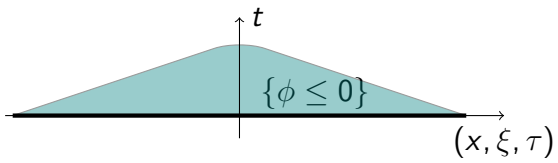

Figure 2.3: To the proof of Corollary 2.1.7

One can prove this Corollary using $\psi = -\epsilon\big(|x-\bar{x}|^2+|\xi-\bar{\xi}|^2+\varepsilon^2\big)^{1/2}$ with an arbitrarily small constant ϵ and the domain $\{t+\psi\le 0\}$ is drawn here.

We will need the following

Definition 2.1.8. Let $x=(x',x'')\in\mathbb{R}^{d'}\times\mathbb{R}^{d''}$ be a partition of variables, $d=d'+d''$. Let u be an admissible (in the previous sense) function. Let us introduce $\mathsf{WF}^{s'}(u)\subset T^*\mathbb{R}^{d'}\times\mathbb{R}^{d''}$. Namely, $(\bar{x},\bar{\xi}')\notin\mathsf{WF}^{s'}(u)$ iff there exists a symbol $q(x,\xi')\in\mathscr{C}^1(\mathbb{R}^{d''},\mathsf{S}_h(T^*\mathbb{R}^{d'},\mathbb{C}))$ such that $q(\bar{x},\bar{\xi}')\ne 0$ and $\|q(x,hD')u\|\le Ch^s$ where $\|.\|$ means the $\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})$-norm.

We will call $\mathsf{WF}^{s'}(u)$ *partial wave front set*.

Partial wave front sets are useful when studying boundary value problems, including those in the domains with edges or conical points.

Using the natural partition (t,x) and in the definition replacing the $\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})$-norm by the $\mathscr{L}^2([0,T]\times\mathbb{R}^d,\mathbb{H})$-norm we obtain

Corollary 2.1.9. *Under the assumptions of Corollary 2.1.7*

$$\begin{aligned}\mathsf{WF}^{s'}(u)\subset\big\{(t,x,\xi):\exists(t',y,\eta)\in\mathsf{WF}^{(s+1)\prime}(Pu)\quad\text{with}\quad \pm t'\in[0,\pm t]\\ \text{and}\quad \mathsf{dist}((x,\xi),(y,\eta))\le c|t-t'|\}\cup\\ \{(t,x,\xi):\exists(y,\eta)\in\mathsf{WF}^{s}((u|_{t=0})\quad\text{with}\quad \mathsf{dist}((x,\xi),(y,\eta))\le c|t|\big\};\end{aligned}$$

this assertion holds for intervals $[0,T]$, $[-T,0]$, $[-T,T]$*; in particular in the last case we obtain that*

$$\pi'\,\mathsf{WF}^{s}(u)\big|_{t=0}\subset\mathsf{WF}^{s'}(u)\big|_{t=0}\subset\mathsf{WF}^{s}(u\big|_{t=0})\cup\mathsf{WF}^{(s+1)\prime}(Pu)\big|_{t=0}\tag{2.1.32}$$

where $\pi':(t,x,\tau,\xi)\to(t,x,\xi)$ *is a natural map.*

Corollary 2.1.9 states the finite speed of propagation of singularities. The second of its assertions also is useful: it justifies the application of Theorem 2.1.2 for the propagation of singularities of solutions to the Cauchy problem without loss in the order of "smallness".

2.1.3 Cauchy Problem. II

Let us now consider the Cauchy problem for the operator

$$P = B^{-1}hD_t + A \tag{2.1.33}$$

where $A \in \boldsymbol{\Psi}_h(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ satisfying (2.1.25) and

(2.1.34) B is a self-adjoint operator in $\mathbb{H}$ such that

$$\langle Bw, w\rangle \geq \|w\|^2 \qquad \forall w \in \mathfrak{D}(B).$$

Let $u^{\pm} = \theta(\pm t)u$ where here and in what follows θ is the Heaviside function. Then

$$Pu^{\pm} = (Pu)^{\pm} \mp ih\delta(t)B^{-1}u_0, \qquad u_0 = \eth_0 u \tag{2.1.35}$$

where $\eth_0$ is the operator of restriction to $\{t = 0\}$. Then we obtain easily

Proposition 2.1.10. *Let conditions* (2.1.33), (2.1.25) *and* (2.1.34) *be fulfilled and* $N = N(s, l)$. *Then*

$$\mathsf{WF}^{s+1}(Pu^{\pm}) \subset \mathsf{WF}^{s+1}(Pu) \cap \{\pm t \geq 0\} \cup \pi_0^{-1}(\mathsf{WF}^{(s+1)\prime}(Pu)\big|_{t=0} \cup \mathsf{WF}^{s+\frac{1}{2}}(\eth_0 u)) \tag{2.1.36}$$

where $\pi_0 : (0, x, \tau, \xi) \to (x, \xi)$ *is a natural map.*

Remark 2.1.11. (i) Obviously function $\phi = t$ satisfies the microhyperbolicity condition in the domain $\Omega' \times \{|\tau| \leq 2c'\}$ if and only if

$$\|B^{-\frac{1}{2}}w\| + \|a(x, \xi)w\| \geq \epsilon_0\|w\| \qquad \forall w \in \mathbb{H} \quad \forall (x, \xi) \in \Omega'. \tag{2.1.37}$$

More precisely, the microhyperbolicity condition (for $\phi = t$) at some energy level $\tau \in [-2c', 2c']$ [4)] yields (2.1.37) while (2.1.37) yields the microhyperbolicity condition at every level $\tau \in [-2c', 2c']$; without any loss of generality we assume that $c' = c$ here.

(ii) One can check easily that replacing in (2.1.37) $B^{-\frac{1}{2}}$ by $B^{-\delta}$ with an exponent $\delta > 0$ we obtain exactly the same condition (2.1.37).

[4)] I.e., the standard microhyperbolicity condition for the operator $A - B^{-1}\tau I$.

Observe that if conditions (2.1.37) and (2.1.31) are fulfilled then microhyperbolicity condition (2.1.1) is fulfilled for $\phi = t + \psi(x,\xi)$ with any real-valued function ψ such that $|\nabla_{x,\xi}\psi| \le \epsilon_2$ with $\epsilon_2 = \epsilon_2(\epsilon_0, c) > 0$. This observation, the uniform version of Proposition 2.1.10, Theorem 2.1.2 and the fact that operators P and $\varphi(hD_t)$ commute imply

Proposition 2.1.12. *Let conditions* (2.1.31), (2.1.33), (2.1.34), (2.1.25) *and* (2.1.37) *be fulfilled. Let* $T \in [\epsilon, c_1]$, $T' = (1+\epsilon)T$ *and* $Q_j = \mathsf{Op}(q_j)$ *with* $q_j \in \mathsf{S}_h(T^*\mathbb{R}, \mathbb{C})$ *such that*

$$\mathsf{dist}(\complement\Omega', \mathsf{supp}(1-q_1), \mathsf{supp}(q_2)) \ge C_0 T \tag{2.1.38}$$

with $C_0 = C_0(c, \epsilon_0)$. *Let* $\chi \in \mathscr{C}_0^N([-1,1])$ *and* $\varphi \in C_0^N([-c,c])$ *be fixed functions,* $\chi_T(t) = \chi(\frac{t}{T})$. *Then*

(i) The inequalities

$$\|u\|_{[-T',T']} \le h^{-l}, \qquad \|Q_1 P u\|_{[-T',T']} \le h^{s+1}, \tag{2.1.39}$$

$$\|B^{-\frac{1}{2}} Q_1 u\|_0 \le h^{s+\frac{1}{2}} \tag{2.1.40}$$

imply that

$$\|\varphi(hD_t)\chi_T(t) Q_2 u\| \le C h^s \tag{2.1.41}$$

where C *depends on* d, s, l, c, ϵ_0, c_1, c_2, *and* ϵ, $c_2 = \|\!|A - \bar{A}|\!\| + \sum_k \|\!|q_k|\!\|$, $\bar{A}$ *is an arbitrarily chosen (constant) Hermitian operator in* $\mathbb{H}$ *and* $N = N(s,l)$ *in the conditions.*

(ii) In particular, for $\|u\| \le 1$ *we obtain that*

$$\begin{aligned} &\mathsf{WF}^s(u) \cap \big\{|t| \le T, |\tau| \le c, (x,\xi) \in \Omega'\big\} \\ &\quad \subset \big\{(t,x,\xi) : \exists (t',y,\eta) \in \mathsf{WF}^{s+1}(Pu) \quad \textit{with} \quad \pm t' \in [0, \pm t] \\ &\qquad\qquad \textit{and} \ \ \mathsf{dist}((x,\xi),(y,\eta)) \le C_0|t-t'|\big\} \cup \\ &\quad \big\{(t,x,\xi) : \exists (y,\eta) \in \mathsf{WF}^{s+\frac{1}{2}}(B^{-\frac{1}{2}} u\big|_{t=0}) \cup \partial\Omega' \\ &\qquad\qquad \textit{with} \ \ \mathsf{dist}((x,\xi),(y,\eta)) \le C_0|t|\big\}. \end{aligned} \tag{2.1.42}$$

So we state here the finite speed of propagation of singularities for energy levels $\tau \in [-c, c]$.

2.1.4 Properties of Fundamental Solutions

Now let us treat the (approximate) fundamental solution to the Cauchy problem for operator (2.1.33).

Let us consider $\mathcal{L}(\mathbb{H},\mathbb{H})$-valued distribution $U(t,x,y)$ such that an operator $\boldsymbol{U}:\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})\to\mathscr{L}^2(\mathbb{R}^{d+1},\mathbb{H})$ with Schwartz kernel $U(t,x,y)$ satisfies the following estimates in the $\mathcal{L}\bigl(\mathscr{L}^2(\mathbb{R}^{d+1},\mathbb{H}),\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})\bigr)$

$$\|\boldsymbol{U}\|\le M, \tag{2.1.43}$$

$$\|\bar\chi_{T_0}(t)\,\mathsf{Op}(\zeta)P\boldsymbol{U}\|\le Mh^{s+1} \tag{2.1.44}$$

and the estimate in the $\mathcal{L}\bigl(\mathscr{L}^2(\mathbb{R}^d,\mathbb{H}),\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})\bigr)$-norm

$$\|\,\mathsf{Op}(\zeta)(\bar\partial_0\boldsymbol{U}-I)\|\le Mh^{s+\frac12} \tag{2.1.45}$$

where $\zeta=1$ in $\Omega'_\epsilon\Subset T^*\mathbb{R}^d$, here and below $\bar\chi$ (and χ as well) is a fixed function

$$\bar\chi\in\mathscr{C}_0^\infty(\mathbb{R}),\qquad \bar\chi=1\quad\text{on}\quad(-\frac12,\frac12),\qquad \bar\chi_T(t)=\bar\chi(t/T) \tag{2.1.46}$$

$\epsilon\le T_0\le c_1$, $|\!|\!|\zeta|\!|\!|\le c_1$ and the constant M will be discussed later.

In particular, the Schwartz kernel $u(x,y,t)$ of $e^{ih^{-1}BA}$ cut outside of $\{|t|\le T,|\xi|\le C_0\}$ satisfies these assumptions. Then Proposition 2.1.12 yields

Proposition 2.1.13. *Let conditions* (2.1.31)–(2.1.34), (2.1.25), (2.1.37) *and* (2.1.43)–(2.1.45) *be fulfilled with* $M\ge1$, $N=N(s,l)$.

Let $\varphi\in\mathscr{C}_0^N([-c,c])$ *be a fixed function and* $Q_k=\mathsf{Op}(q_k)$ *where* $q_k\in \mathsf{S}_h(T^*\mathbb{R}^d,\mathbb{H},\mathbb{H})$ *satisfy condition*

$$\mathsf{dist}\bigl(\mathsf{supp}(q_1),\mathsf{supp}(q_2)\cup\complement\Omega'\bigr)\ge C_0T \tag{2.1.47}$$

with $C_0=C_0(c)$ *and* $T=T_0/2$. *Then*

$$\|\varphi(hD_t)\bar\chi_{T/2}(t)Q_1\boldsymbol{U}Q_2\|\le CMh^s. \tag{2.1.48}$$

This Proposition and Proposition 1.1.11 yield

Corollary 2.1.14. *Let conditions* (2.1.31)–(2.1.34), (2.1.25), (2.1.37) *and* (2.1.43)–(2.1.45) *be fulfilled with* $M\ge1$, $N=N(s,l)$. *Let* $q_k\in\mathsf{S}_h(T^*\mathbb{R}^d,\mathbb{H},\mathbb{H})$ *and* $\mathsf{diam}(\mathsf{supp}(q_k))\le c$, $k=1,2$. *Then*

(i) If (2.1.43) *holds then for* $T \in [\epsilon, T_0]$ *estimate*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}U\,{}^tQ_{2y}\| \le CMh^{-d} \qquad \forall \tau : |\tau| \le c \quad \forall x, y \in \mathbb{R}^d \tag{2.1.49}$$

holds where here and in what follows ${}^tQ$ *is a dual operator to* Q *defined by* ${}^tQu = (Q^*u^\dagger)^\dagger$, *"†" is a natural antilinear map from* $\mathbb{H}$ *to the dual space* $\mathbb{H}^\dagger$ *and inversely, and operators with respect to* y *are written to the right of the function*[5]*.*

(ii) Further, under assumption (2.1.47) *the following estimate holds:*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}U\,{}^tQ_{2y}\| \le CMh^{s} \qquad \forall \tau : |\tau| \le c \quad \forall x, y \in \mathbb{R}^d \tag{2.1.50}$$

Remark 2.1.15. (i) If $Q = q(\overset{3}{x}, \overset{2}{hD}, \overset{1}{x})$ then ${}^tQ = q(\overset{1}{x}, \overset{2}{-hD}, \overset{3}{x})$;

(ii) C is the same type of constant as before.

Let us assume that a is microhyperbolic in Ω' with respect to $\nabla^\# \phi$. Let us apply Theorem 2.1.2 with $\phi_1 = \pm t$ and $\phi_2 = \pm(\phi - \epsilon_1 t)$ with a small enough constant ϵ_1 to $u^\pm$ and equation (2.1.35) replacing P by $\pm P$. We then obtain immediately

Proposition 2.1.16. *Let conditions* (2.1.31)–(2.1.34), (2.1.25), (2.1.37) *and* (2.1.43)–(2.1.45) *be fulfilled with* $M \ge 1$, $N = N(s, l)$. *Let* $\phi \in \mathscr{C}_b^N(T^*\mathbb{R}^d)$ *be a real-valued function such that* $\|\phi\|_{\mathscr{C}^\infty} \le c_1$ *and* a *is microhyperbolic in* Ω' *with respect to* $\nabla^\# \phi$.[6]

Let $q_k \in S_h(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *satisfy the conditions*

$$\pm\phi(x,\xi) \le \pm\phi(y,\eta) + \epsilon_1 T - \epsilon \qquad \forall (x,\xi) \in \operatorname{supp}(q_1)\ \forall (y,\eta) \in \operatorname{supp}(q_2) \tag{2.1.51}$$

and

$$\operatorname{dist}\big(\operatorname{supp}(q_1), \complement\Omega'\big) \ge C_0 T + \epsilon \tag{2.1.52}$$

[5] This is a convenient notation because it agrees with the matrix theory notation even if it contradicts to the standard operator theory notation.

[6] Then p is also microhyperbolic in $\Omega = \{(t, x, \tau, \xi) : (x, \xi) \in \Omega', |\tau| \le 2\epsilon_1\}$ with respect to $\nabla^\# \phi$ where $\epsilon_1 = \epsilon_1(\epsilon_0, c, c_1)$.

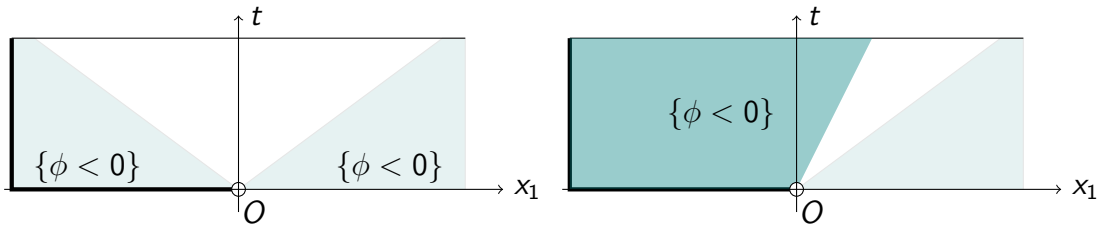
where $T \in [\epsilon, T_0]$ *is arbitrary and* $T_0 = T_0(c) > 0$ *is a small enough constant,* $\epsilon > 0$ *is an arbitrarily small constant.*

Moreover, let $\chi^{\pm}$ *and* $\varphi \in \mathscr{C}_0^N((-2\epsilon_1, 2\epsilon_1))$ *be fixed functions where here and below*

$$\chi^+ \in \mathscr{C}_0^\infty([\frac{1}{2}, 1]), \qquad \chi^-(t) = \chi(-t), \qquad \chi = \chi^+ + \chi^-. \tag{2.1.53}$$

Then

$$\|\varphi(hD_t)\chi_T^{\pm}(t)Q_1 U Q_2\| \le CMh^s. \tag{2.1.54}$$



(a) teal shaded zone is free of WFs (b) now dark-shaded zone is also free of WFs

Figure 2.4: Illustration to the proof of Proposition 2.1.16 and Corollary 2.1.17; (x', ξ, τ) are not shown. All zones are open.

Representing q_1 and q_2 as sums of symbols with small enough supports and applying Proposition 1.1.11 we obtain immediately

Corollary 2.1.17. *Let conditions* (2.1.31)–(2.1.34), (2.1.25), (2.1.37) *and* (2.1.43)–(2.1.45) *be fulfilled with* $M \ge 1$, $N = N(s, l)$.

Let $\phi \in \mathscr{C}_b^N(T^*\mathbb{R}^d)$ *be a real-valued function such that* $\|\phi\|_{\mathscr{C}^\infty} \le c_1$ *and* a *is microhyperbolic in* Ω' *with respect to* $\nabla^{\#}\phi$. *Let* $\operatorname{diam}(\operatorname{supp}(q_k)) \le c$, $k = 1, 2$. *Then*

(i) The estimate

$$\|F_{t\to h^{-1}\tau}\chi_T^{\pm}(t)\Gamma(Q_{1x}U\,{}^tQ_{2y})\| \le CMh^s \qquad \forall \tau : |\tau| \le \varepsilon_0 \tag{2.1.55}$$

holds where here and in what follows

$$(\Gamma_x u)(x) = u(x, x) \qquad \textit{and} \qquad (\Gamma u) = \int (\Gamma_x u)(x)dx. \tag{2.1.56}$$

(ii) Moreover, if $\phi = \phi(x)$ *and* $\mathsf{supp}(q_k) \subset \{|\xi| \le c_1\}$ $\forall k = 1, 2$ *then the following estimate holds:*

$$\|F_{t\to h^{-1}\tau}\chi_T^{\pm}(t)\Gamma_x(Q_{1x}U\,{}^tQ_{2y})\| \le CMh^s \quad \forall \tau : |\tau| \le \varepsilon_0 \quad \forall x \in \mathbb{R}^d. \tag{2.1.57}$$

Remark 2.1.18. Since condition to sign $\pm$ disappeared when we passed from Proposition 2.1.16 to Corollary 2.1.17, estimates (2.1.55) and (2.1.57) hold for both signs $\pm$ and thus for function χ instead of $\chi^{\pm}$.

Actually this Corollary easily implies a much stronger version of itself:

Theorem 2.1.19. *Let conditions* (2.1.31)–(2.1.34), (2.1.25), (2.1.37) *and* (2.1.43)–(2.1.45) *be fulfilled with* $M \ge 1$, $N = N(s, l)$.

Let $\phi \in \mathscr{C}_b^N(T^*\mathbb{R}^d)$ *be a real-valued function such that* $\|\phi\|_{\mathscr{C}^\infty} \le c_1$ *and assume* a *is microhyperbolic in* Ω' *with respect to* $\nabla^{\#}\phi$.

Let $q_k \in \mathsf{S}_h(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *satisfy* (2.1.52), *and let* $\mathsf{diam}(\mathsf{supp}(q_k)) \le c$, $k = 1, 2$. *Let* $T_0 = T_0(c, \epsilon_0) > 0$ *be a small enough constant. Then*

(i) For $T \in [h, T_0]$ *the following estimate holds:*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(Q_{1x}U\,{}^tQ_{2y})\| \le CMh^{1-d}\Big(\frac{h}{T}\Big)^s \qquad \forall \tau : |\tau| \le \varepsilon_0. \tag{2.1.58}$$

(ii) Moreover, if $\phi = \phi(x)$ *and* $\mathsf{supp}(q_k) \subset \{|\xi| \le c_1\}$ $\forall k = 1, 2$ *then the following estimate following holds:*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma_x(Q_{1x}U\,{}^tQ_{2y})\| \le CMh^{1-d}\Big(\frac{h}{T}\Big)^s \qquad \forall \tau : |\tau| \le \varepsilon_0 \quad \forall x \in \mathbb{R}^d \tag{2.1.59}$$

Proof. Let us observe that we need to prove estimates (2.1.58) and (2.1.59) only provided $\mathsf{diam}(\mathsf{supp}(q_k)) \le \epsilon_2$, $k = 1, 2$ with a small enough constant $\epsilon_2 = \epsilon_2(d, \epsilon_0, c, c_1) > 0$ (otherwise one can make a partition of unity).

Then without any loss of generality one can assume that $\phi = x_1$: in fact, we can reduce the case $\phi = \phi(x)$ to this one by a change of the coordinate system (and (2.1.59) remains true); meanwhile we can reduce the most general case to this one by replacing U by $U' = \mathcal{T}_x U\,{}^t\mathcal{T}_y$ where $\mathcal{T}$ is a scalar Fourier integral operator such that $\mathcal{T}^*\mathcal{T} \equiv I$ in a neighborhood of $\mathsf{supp}(q_1)$,

$\mathcal{T}\mathcal{T}^* \equiv I$ in a neighborhood of $\Psi_{\mathcal{T}}(\mathsf{supp}(q_1))$ and $\phi = x_1 \circ \Psi_{\mathcal{T}}$ where $\Psi_{\mathcal{T}}$ is the corresponding symplectomorphism.

For a parameter $r \in [h,1]$ let us consider a real-valued r-admissible partition of unity $\sum_k \psi_k^2$ in the vicinity Ω'' of $\mathsf{supp}(q_1)$ [7]. Obviously, for $c_3 = c_3(d,c)$ such functions exist.

Let us replace Q_1 and Q_2 by $\psi_k Q_1$ and $\psi_k Q_2$ respectively and make the *rescaling* (dilatation) $t' = t/r$, $x' = x/r$, $h' = h/r$ (in which case $h'D_{x'} = hD_x$ and $h'D_{t'} = hD_t$).

Now we are in precisely the framework of Corollary 2.1.17 and therefore we obtain the estimate (2.1.57) in the new variables. Then in the old variables we obtain the estimate

$$\|F_{t\to h^{-1}\tau}\chi_{\pm r\mathcal{T}_0}(t)\Gamma_x(\psi_k^2(x)Q_{1x}U\,{}^tQ_{2y})\| \le CMr^{1-d}\bigl(\frac{h}{r}\bigr)^s \qquad \forall \tau : |\tau| \le \varepsilon_0 \quad \forall x \in \mathbb{R}^d \quad \forall k = 1,\dots,K. \tag{2.1.60}$$

Remark 2.1.20. (i) The factor r^{-d} in the right hand expression appears because

(2.1.61) The Schwartz kernel is a function with respect to x and a density with respect to y and therefore the restriction of the Schwartz kernel to the diagonal is also a density.

(ii) The factor r in the right hand expression appears because

$$F_{t\to h^{-1}\tau} = rF_{t'\to h'^{-1}\tau}. \tag{2.1.62}$$

These two simple observations are very important because the rescaling technique will be used very often.

Finally, let us sum with respect to k and pick $r = T/\mathcal{T}_0$. We get estimate (2.1.59). □

Moreover, we need

Remark 2.1.21. In addition to conditions of Theorem 2.1.19 let us assume that

$$\|B_1^{2j}\varphi(hD_t)\chi_{\mathcal{T}}(t)\boldsymbol{U}(t)B_1^{2j}\| \le M \tag{2.1.63}$$

[7] As usual this means that $\psi_k(x)$ $(k = 1,\dots,K)$ are real-valued functions such that $\sum_k \psi_k^2(x) = 1$ in Ω'', $\mathsf{diam}(\mathsf{supp}(\psi_k)) \le r$, $|D_x^\alpha \psi_k| \le c_3 r^{-|\alpha|}$ $\forall \alpha : |\alpha| \le K$; $K = c_3(1+r^{-d})$ and the multiplicity of the covering by $\mathsf{supp}(\psi_k)$ is less than c_3.

where $\varphi = 1$ at $(-c, c)$ and B_1 is an operator satisfying (2.1.34). Then the standard interpolation arguments imply that every estimate obtained remains true if we multiply the left-hand expression by B_1^j on both sides and replace the s-degree of h or $\frac{h}{T}$ in the right hand expression by the corresponding $s/2$-degree.

2.1.5 Overdetermined Systems

Overdetermined Systems

In certain cases we have an extra conditions to solutions of the evolution equation: f.e. for the standard Maxwell system $\partial_t E = \nabla \times H, \partial_t H = -\nabla \times E$ there are extra conditions $\nabla \cdot E = \nabla \cdot H = 0$. To cover this case we consider original system with such extra conditions.

Remark 2.1.22. Let us note that if in Theorem 2.1.2 we know that

$$\|Q_1 P' u\| \le h^s \tag{2.1.64}$$

then one can weaken microhyperbolicity condition (2.1.1):

$$-\langle((\ell p)(z)w, w\rangle \ge \epsilon_0\|w\|^2 - c_1\|p(z)w\|^2 - \|p'(z)w\|^2 \qquad \forall w \in \mathbb{H} \tag{2.1.1}'$$

where p' is the principal symbol of $P' \in \mathbf{\Psi}_h(T^*X, \mathbb{H}', \mathbb{H})$.

Indeed, replacement of (2.1.1) by (2.1.1)$'$ leads to the additional term $C\|q_1 p' w\|^2$ in the left-hand expression of (2.1.18) and then to the additional term $C\|Q_1 P' v\|^2$ in the left-hand expression of (2.1.21). Other details of the proof do not change.

Multi-Time Systems

We will need to consider such systems to analyze systems of commuting operators. Namely let us consider the solution of the *multi-time Cauchy problem*

$$hD_{t_j} U \equiv -A_j \mathbf{U} \qquad \text{in } \Omega \quad (j = 1, \dots, m), \tag{2.1.65}$$

$$\mathbf{U}\big|_{t_1 = \dots = t_m = 0} \equiv I \tag{2.1.66}$$

where $A_j = A_j(x, hD, h)$ commute modulo negligible operators:

$$[A_j, A_k] \equiv 0 \qquad \forall j, k = 1, \dots, m. \tag{2.1.67}$$

Then Proposition 2.1.13 and Corollary 2.1.14 remain true with $\bar{\chi}(t)$ and $\chi(t)$ understood as the products of the corresponding one-dimensional functions with $t = (t_1, \dots, t_m)$, $\tau = (\tau_1, \dots, \tau_m)$.

Moreover, Proposition 2.1.16 remains true under microhyperbolicity condition $(2.1.1)'$ with $P = A_\beta = \beta_1 A_1 + \dots + \beta_m A_m$, $P'_j = A_j$ for some $\beta \in \mathbb{R}^m$ with $|\beta| = 1$ and χ supported in the vicinity of β.

Repeating the proof of Theorem 2.1.19 with rescaling rule

$$F_{t \to h^{-1}\tau} = r^m F_{t' \to h'^{-1}\tau} \tag{2.1.62}'$$

instead of (2.1.62) we arrive to

Theorem 2.1.23. *Let conditions* (2.1.31), (2.1.25), (2.1.43) *and* (2.1.65)–(2.1.65) *be fulfilled for* $j = 1, \dots, m$ *with* $M \ge 1$, $N = N(s, l)$.

Suppose $\phi \in \mathscr{C}^N_b(T^*\mathbb{R}^d)$ *is a real-valued function such that* $\|\phi\|_{\mathscr{C}^\infty} \le c_1$ *and the microhyperbolicity condition* $(2.1.1)'$ *is fulfilled in* Ω' *with* $\mathcal{T} = \nabla^\# \phi$, $p = a_\beta = \beta_1 a_1 + \dots + \beta_m a_m$ *and* $p'_j = a_j$.

Let $q_k \in \mathsf{S}_h(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *satisfy* (2.1.52) *and let* $\operatorname{diam}(\operatorname{supp}(q_k)) \le c$, $k = 1, 2$. *Let* $\chi \in \mathscr{C}^\infty$ *be a fixed function supported in the neighborhood of* β *and* $T_0 = T_0(c, \epsilon_0) > 0$ *be a small enough constant. Then*

(i) For $T \in [h, T_0]$ *the estimate*

$$\|F_{t \to h^{-1}\tau} \chi_{\pm T}(t) \Gamma(Q_{1x} U\, {}^t Q_{2y})\| \le C M h^{m-d} \Big(\frac{h}{T}\Big)^s \qquad \forall \tau : |\tau| \le \varepsilon_0 \tag{2.1.58}'$$

holds for a sufficiently small constant $\epsilon_0 = \epsilon_0(c, 0)$.

(ii) Moreover, if $\phi = \phi(x)$ *and* $\operatorname{supp}(q_k) \subset \{|\xi| \le c_1\}$ $\forall k = 1, 2$ *then the estimate*

$$\|F_{t \to h^{-1}\tau} \chi_{\pm T}(t) \Gamma_x(Q_{1x} U\, {}^t Q_{2y})\| \le C M h^{m-d} \Big(\frac{h}{T}\Big)^s \qquad \forall \tau : |\tau| \le \varepsilon_0 \quad \forall x \in \mathbb{R}^d \tag{2.1.59}'$$

holds.

(iii) If an appropriate function $\phi = \phi_\beta$ *exists for every* $\beta \in \mathbb{S}^{m-1}$ *then the corresponding estimate* $(2.1.58)'$ *or* $(2.1.59)'$ *holds for every function* $\chi \in \mathscr{C}^\infty_0\big(B(0,1) \setminus B(0, \frac{1}{2})\big)$.

2.2 Geometric Interpretation

2.2.1 Discussion of the Microhyperbolicity Condition

Scalar Case

In this Section we consider a more geometrical version of Theorem 2.1.2, the main Theorem of the previous section. Then we will discuss various special cases of this main Theorem. We assume throughout this section that $\Omega \Subset T^*\mathbb{R}^d$ and

(2.2.1) Symbol $p \in \mathscr{C}^1_b\big(\bar{\Omega}, \mathcal{L}(\mathbb{H},\mathbb{H})\big)$ is Hermitian and microhyperbolic at each point $z = (x,\xi) \in \Omega$ in the direction $\nabla^{\#}x_1$.

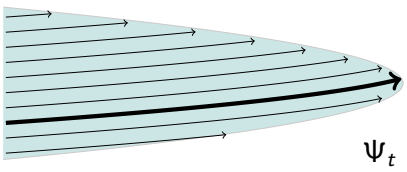


Figure 2.5: Scalar principal type; colored zone is $\{\phi < 0\}$

So x_1 will play a role of time. In the simplest case of scalar principal symbol $p \in \mathscr{C}^2$ microhyperbolicity condition $\{p,\phi\} > 0$ means exactly that $\frac{d}{dt}\phi > 0$ along Hamiltonian trajectories (as $p = 0$) and then Theorem 2.1.2 immediately implies that wave fronts propagate along such trajectories as shown on the picture to the left: one can find ϕ strongly increasing along Hamiltonian trajectories such that $\{\phi < 0\}$ is an arbitrarily narrow "finger" there.

Now we want to provide a similar geometric description in the case of the matrix[8)] symbol p.

Cones of Directions of Microhyperbolicity

Let us introduce the closed invariant subspace $\mathbb{H}_\rho(p,z) \subset \mathbb{H}$ of the matrix $p(z)$ corresponding to the interval $[-\rho,\rho]$ of its spectrum where $\rho > 0$ and $z \in \omega$; recall that $p(z)$ is Hermitian.

Let us define for $\rho > 0$, $\varepsilon > 0$ the sets

$$K_{\rho\varepsilon}(p,z) = \{\ell \in T_z\Omega \setminus 0 : -\langle((\ell^0 p)(z)w, w\rangle \ge \varepsilon\|w\|^2 \quad \forall w \in \mathbb{H}_\rho(p,z)\} \tag{2.2.2}$$

[8)] It is more convenient to use term "matrix" for an operator acting in the auxiliary spaces.

where $\ell^0 = \ell/|\ell|$. Moreover, let us introduce the set

$$K(p,z) = \bigcup_{\rho>0,\varepsilon>0} K_{\rho\varepsilon}(p,z) = \bigcup_{\rho>0} K_{\rho 0}(p,z) \tag{2.2.3}$$

where the second equality is due to (2.2.1) (and we temporarily extended (2.2.2) to $\varepsilon = 0$). Then the following assertion is obvious:

Lemma 2.2.1. *(i) If $|\ell| \le c$ satisfies* (2.1.1) *then $\ell \in K_{\rho\varepsilon}(p,z)$ with $\varepsilon = \rho = \rho(\epsilon_0, c_1) > 0$. On the other hand, if $|\ell| \ge \rho$ and $\ell \in K_{\rho\varepsilon}(p,z)$ then* (2.1.1) *holds with $\epsilon_0 = \epsilon_0(\rho,\varepsilon) > 0$ and $c_1 = c_1(\rho,\varepsilon)$.*

(ii) $K_{\rho\varepsilon}(p,z)$ is a conical strictly convex respectively closed subset of $T_z\Omega \setminus 0$ where here and below 0 means the 0-section of this bundle.

(iii) For $\rho' < \rho$ and $\varepsilon' < \varepsilon$ the set $K_{\rho',\varepsilon'}(p,z)$ contains the ε''-neighborhood of $K_{\rho\varepsilon}(p,z) \cap \{|\ell| = 1\}$ with $\varepsilon'' = \varepsilon''(\epsilon_0, c_1, \rho, \rho', \varepsilon, \varepsilon')$.

(iv) Hence $K(p,z)$ is a conical convex open subset of $T_z\Omega \setminus 0$;

(v) $\ell \in \partial K(p,z)$ if and only if

$$\lim_{\rho\to+0} \inf_{w\in\mathbb{H}_\rho(p,z),\, \|w\|=1} \langle (\ell p)(z)w, w\rangle = 0.$$

Definition 2.2.2. Let $M(z)$ be *set-valued function*; then

(i) As $z_n \to z$ we define for such functions limits

$$\lim_{z_n\to z} M(z_n) := \bigcap_{\varepsilon>0} \bigcap_n \big(M(z_n)\big)_\varepsilon$$

where M_ε is ε-vicinity of M; for conical set we set $M_\varepsilon = \big((M\cap\{|\zeta| = 1\})_\varepsilon\big)_{\mathsf{cone}}$ instead where $M_{\mathsf{cone}} = \{t\zeta, \zeta \in M, t > 0\}$ is a conical hull of M;

(ii) We say that $M(z)$ is *upper semicontinuous*, *lower semicontinuous* and *continuous* at z if for any sequence $z_n \to z$ $\lim_{z_n\to z} M(z_n) \subset M(z)$, $\lim_{z_n\to z} M(z_n) \supset M(z)$ and $\lim_{z_n\to z} M(z_n) = M(z)$ respectively.

Obviously, $K(p,z)$ introduced by (2.2.2)–(2.2.2) is lower semicontinuous; moreover

Lemma 2.2.3. *(i)*[9] $\{(z,\ell) \in T\Omega : \ell \in K_{\rho\varepsilon}(p,z)\}$ *is a respectively closed subset of* $T\Omega \setminus 0$ *where* 0 *means the* 0*-section of this bundle.*

Furthermore, let the index set $\mathfrak{M}$ *be a Hausdorff topological space and assume that for all* $\mathfrak{m} \in \mathfrak{M}$ *the symbol* $p_{\mathfrak{m}}$ *satisfies* (2.2.1) *and that the map* $\mathfrak{M} \ni \mathfrak{m} \to p_{\mathfrak{m}} \in \mathscr{C}^1_b(T^*\mathbb{R}^d)$ *is continuous; then the set* $\{(\mathfrak{m},z,\ell) \in \mathfrak{M} \times T\Omega : \ell \in K_{\rho\varepsilon}(p,z)\}$ *is a respectively closed subset of* $\mathfrak{M} \times (T\Omega \setminus 0)$.

(ii) Statement (iii) of Lemma 2.2.1 remains true if we replace $K_{\rho'\varepsilon'}(p,z)$ *by* $\{(z,\ell) \in T\Omega : \ell \in K_{\rho\varepsilon}(p,z)\}$ *and even by* $\{(\mathfrak{m},z,\ell) \in \mathfrak{M} \times T\Omega : \ell \in K_{\rho\varepsilon}(p,z)\}$ *provided the index set is a metric space, and for all* $\mathfrak{m} \in \mathfrak{M}$ *the symbol* $p_{\mathfrak{m}}$ *satisfies* (2.2.1) *and the map* $\mathfrak{M} \ni \mathfrak{m} \to p_{\mathfrak{m}} \in \mathscr{C}^1_b(T^*\mathbb{R}^d)$ *is uniformly continuous (surely in this case* ϵ *depends on this map also).*

(iii)[10] $\{(\mathfrak{m},z,\ell) \in \mathfrak{M} \times T\Omega : \ell \in K(p,z)\}$ *is an open subset of* $\mathfrak{M} \times (T\Omega \setminus 0)$ *provided the additional conditions at the end of Statement (ii) are fulfilled.*

(iv)[11] $(z,\ell) \in \partial\{(z,\ell) \in T\Omega : \ell \in K(p,z)\}$ *iff*

$$\lim_{\rho\to+0,z'\to z} \inf_{w\in\mathbb{H}_\rho(p,z'),\,\|w\|=1} \langle (\ell p)(z')w, w\rangle = 0.$$

Definition 2.2.4. (i) We call $K(p,z)$ *microhyperbolicity cones*.

(ii) Furthermore, let us introduce the *propagation cones* $K^{\#}_{\rho\varepsilon}(p,z)$ and

$$K^{\#}(p,z) = \bigcap_{\rho>0,\varepsilon>0} K^{\#}_{\rho\varepsilon}(p,z) = \bigcap_{\rho>0} K^{\#}_{\rho 0}(p,z) \tag{2.2.4}$$

where for any set $G \subset T^*\mathbb{R}^d$ the dual cone $G^{\#}$ is defined by

$$G^{\#} = \{\zeta \in T^*\mathbb{R}^d \setminus 0, \sigma(\zeta,\zeta') \le 0 \quad \forall \zeta' \in G\}$$

and $\sigma(.,.)$ is a bilinear symplectic form[12].

Since $K(p,z)$ is lower semicontinuous (see definition 2.2.2) we conclude that

(2.2.5) $K^{\#}(p,z)$ is upper semicontinuous.

[9] Cf. Lemma 2.2.1(ii).
[10] Cf. Lemma 2.2.1(iv).
[11] Cf. Lemma 2.2.1(v).
[12] Surely, $G^{\#}$ is always conic convex closed set in $T^*\mathbb{R}^d$.

Examples

Example 2.2.5. (i) If p is elliptic at z, i.e., if

$$\|p(z)w\| \ge \epsilon\|w\| \qquad \forall w \in \mathbb{H} \tag{2.2.6}$$

then $K(p,z) = T^*\mathbb{R}^d \setminus 0$ and $K^{\#}(p,z) = 0$.

(ii) Suppose that for $z \in \Omega$ the symbol $p(z)$ is unitarily equivalent to

$$\begin{pmatrix} q(z)(\xi_1 - \lambda(z')) & 0 \\ 0 & p''(z) \end{pmatrix}, \qquad \mathbb{H} = \mathbb{H}' \oplus \mathbb{H}'' \tag{2.2.7}$$

where the symbols q and p'' are bounded and Hermitian, λ is a real-valued function with $z' = (x,\xi')$, $\xi' = (\xi_2, \dots, \xi_d)$ in this example and p'' is elliptic i.e. satisfies (2.2.6) on $\mathbb{H}''$,

$$\langle q(z)w, w\rangle \ge \epsilon\|w\|^2 \qquad \forall w \in \mathbb{H}'. \tag{2.2.8}$$

Then in a neighborhood of $\Sigma = \{\xi_1 = \lambda(z')\}$ all those symbols and functions (including the symbol of the operator effecting the unitary equivalence) can be chosen as smooth as p; moreover, for $z \in \Sigma$

$$K(p,z) = \{(\ell', \eta_1) \in T^*\mathbb{R}^d : \eta_1 > (\ell'\lambda)(z')\} \tag{2.2.9}$$

and

$$K^{\#}(p,z) = (\nabla^{\#}(\xi_1 - \lambda))_{\mathsf{cone}}. \tag{2.2.10}$$

(iii) Suppose that for $z \in \Omega$, $p(z)$ is unitarily equivalent to the symbol

$$\begin{pmatrix} p_1(z)\otimes I_1 & \cdots & 0 & 0 \\ \vdots & \ddots & \vdots & 0 \\ 0 & \cdots & p_n(z)\otimes I_n & 0 \\ 0 & \cdots & 0 & p''(z) \end{pmatrix} \tag{2.2.11}$$

where $\mathbb{H} = \mathbb{H}'_1 \oplus \dots \oplus \mathbb{H}'_n \oplus \mathbb{H}''$, $\mathbb{H}'_j = \mathbb{H}_j \otimes \mathbb{H}^0_j$, $\mathbb{H}_j$ are finite-dimensional spaces, $p_j(z)$ are matrices in $\mathbb{H}_j$ and I_j are the identity operators in $\mathbb{H}^0_j$. Let us assume that all the symbols are Hermitian and smooth, the symbol effecting the unitary equivalence is smooth too and p'' satisfies (2.2.6) at $\mathbb{H}''$. Then

$$K(p,z) = \bigcap_{1\le j\le n} K(p_j, z) \tag{2.2.12}$$

and

$$K^{\#}(p,z) = \text{convex hull}\Big(\bigcup_{1\le j\le n} K^{\#}(p_j,z)\Big) = \sum_{1\le j\le n} K^{\#}(p_j,z) \tag{2.2.13}$$

where $\sum G_j \coloneqq \{\zeta = \zeta_1 ... + \zeta_n \colon z_1 \in G_1, ..., z_n \in G_n\}$ is an *arithmetical sum of sets*.

Microhyperbolicity: Algebraic Theory

In the framework of (2.2.1) and (2.2.11) let us consider the *characteristic symbol*

$$g(z) = \prod_{1\le j\le n} \det p_j(z). \tag{2.2.14}$$

Proposition 2.2.6. *Let g have a zero of order exactly r at $\bar z \in \Omega$.*

(i) Then[13)]

$$(H^r_{x_1} g)(\bar z) \ne 0 \tag{2.2.15}$$

and $\ell \in K(p,\bar z)$ if and only if

$$(\ell^j H^{r-j}_{x_1} g)(\bar z)\cdot (H^r_{x_1} g)^{-1}(\bar z) > 0 \qquad \forall j = 1, ..., r. \tag{2.2.16}$$

Moreover, $\ell \in \overline{K(p,\bar z)}$ if and only if the corresponding non-strict inequalities are fulfilled.

(ii) Further, $K(p,\bar z)$ coincides with the connected component of the set $\{\zeta \colon g_{\bar z}(\zeta) \ne 0\}$ where $g_{\bar z}(\zeta)$ is a germ of g at $\bar z$:

$$g_{\bar z}(\zeta) = \sum_{|\alpha|=r} \frac{1}{\alpha!}(\partial^\alpha_z g)(\bar z)\zeta^\alpha \tag{2.2.17}$$

(iii) Furthermore, $g_{\bar z}(\zeta)$ is a hyperbolic polynomial of ζ with respect to $\nabla^{\#} x_1$.

[13)] Here and below sometimes we use notation $H_f g \coloneqq (\nabla^{\#} f)(g) = \{f, g\}$.

Proof. Let us first consider the special case $r = r_1 + ... + r_n$ where $r_j = \dim \mathbb{H}_j$. Then (2.2.1) easily implies that $p_1(\bar z) = ... = p_n(\bar z) = 0$ and (2.2.15) holds. In this case $\ell \in K(p, z)$ iff $-(\ell p)(\bar z)$ is a positive definite matrix, i.e., iff $\big((-\ell - tH_{x_1})p\big)(\bar z)$ is a positive definite matrix for every $t \ge 0$ and that is obviously equivalent to (2.2.16). Moreover, Statements (ii) and (iii) are also obvious in this case.

On the other hand, if $r < r_1 + ... + r_n$ then in a neighborhood of $\bar z$ the finite-dimensional symbol

$$p' = \begin{pmatrix} p_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & p_n \end{pmatrix}$$

is unitarily equivalent to the matrix $\begin{pmatrix} p''' & 0 \\ 0 & p^{IV} \end{pmatrix}$ where p^{IV} satisfies (2.2.6) on the corresponding space and the dimension of the first component of the decomposition is r. It is obvious that condition (2.2.15) or (2.2.16) for $g = \det p'$ is fulfilled if and only if the same condition is fulfilled for $g''' = \det p'''$. Moreover, the germs of g and g''' in $\bar z$ coincide modulo of a constant factor. Finally, it is obvious that the microhyperbolicity conditions for p and p''' are equivalent. □

2.2.2 Main Theorem

Main Theorem

To prove the main result of this section Theorem 2.2.10 we need first to reformulate Theorem 2.1.2 in the following way:

Proposition 2.2.7. *Let conditions* (2.1.2) *and* (2.2.1) *be fulfilled. Consider* $\bar z = (\bar x, \bar \xi) \in \Omega$, *a proper convex closed cone* $G \subset \{(x, \xi) \in T^*\mathbb{R}^d, x_1 > 0\} \cup 0$ *and* $\bar t < x_1$. *Assume that for some* $\rho > 0$, $\varepsilon > 0$

$$K^{\#}_{\rho\varepsilon}(p, z) \subset G \qquad \forall z \in (\bar z - G) \cap \{\bar t \le x_1 \le \bar x_1\} \tag{2.2.18}$$

where $\bar z - G := \{\bar z - z, z \in G\}$.

Let u *be temperate and let*

$$\mathsf{WF}^{s+1}(Pu) \cap (\bar z - G) \cap \{t \le x_1 \le \bar x_1\} \cap \Omega = \emptyset, \tag{2.2.19}$$

$$\mathsf{WF}^{s}(u) \cap (\bar z - G) \cap \{t \le x_1 \le \bar x_1\} \cap \partial\Omega = \emptyset, \tag{2.2.20}$$

$$\mathsf{WF}^{s}(u) \cap (\bar z - G) \cap \{x_1 = t\} \cap \Omega = \emptyset. \tag{2.2.21}$$

Then

$$\mathsf{WF}^s(u) \cap (\bar z - G) \cap \{t \le x_1 \le \bar x_1\} \cap \Omega = \emptyset. \tag{2.2.22}$$

Proof. Due to our conditions $G = \{(x,\xi) : x_1 \ge \psi(x',\xi)\}$ with continuous positive homogeneous of degree 1 convex function ψ. One can smoothen ψ replacing it by $\psi_\eta = \psi * \eta^{-2d}\omega(z/\eta)$ with the smooth nonnegative $\omega \in \mathscr{C}_0^\infty$ such that $\int \omega\, dz' = 1$.

Then $\{x_1 \ge \psi_\eta(x',\xi) + \beta\} \subset G \subset \{x_1 \ge \psi_\eta(x',\xi) - \beta\}$ for arbitrarily small $\beta > 0$ and small enough $\eta = \eta(\beta) > 0$. Furthermore, due to (2.2.18) and properties of cones $K_{\rho\varepsilon}(p,z)$ we conclude that $\nabla^\# \phi \in K_{\rho'\varepsilon'}(p,z)$ for all $z \in \{\phi \le \beta\} \cap \{x_1 \ge \bar t\}$ where $\phi(x,\xi) = x_1 - \bar x_1 + \psi(x',\xi)$, $\rho' = \rho/2$, $\varepsilon' = \varepsilon/2$ and $\beta > 0$ is small enough.

Then Theorem 2.1.2 yields the Proposition. □

We are going to take $G = K^\#_{\rho\varepsilon}(p,\bar z)$ and apply Proposition 2.2.7 for $\bar t = \bar x_1 - \eta$ with $\eta = \eta(\rho,\varepsilon)$ so small that (2.2.18) holds with ρ,ε replaced by $\rho/2, \varepsilon/2$. Furthermore, we are going to repeat this procedure for any $z \in (\bar z - G) \cap \{x_1 = \bar t\}$ and so on, getting the domain $\mathcal{G}_{\rho\varepsilon}$ which is the union of small cut-off cones. Finally, we are going to consider its limit as $\rho \to +0, \varepsilon \to +0$. To codify this construction let us give the key

Definition 2.2.8. (i) *A generalized bicharacteristics (generalized (ρ,ε)-bicharacteristics)* of p is a Lipschitz curve $\{z = z(t)\}$ such that for a.a. t, $z(t)$ is differentiable and

$$\frac{dz}{dt} \in K^\#(p,z), \tag{2.2.23}$$

$$\frac{dz}{dt} \in K^\#_{\rho\varepsilon}(p,z) \tag{2.2.24}$$

respectively.

Since $K^\#_{\rho\varepsilon}(p,z) \subset \{|z'| \le Cx_1\}$ then one can take x_1 as a parameter t (let us recall that $z = (x,\xi)$).

(ii) Let $\mathcal{K}^\pm(p,z,\Omega)$ ($\mathcal{K}^\pm_{\rho\varepsilon}(p,z,\Omega)$) be the union of all the generalized bicharacteristics (generalized (ρ,ε)-bicharacteristics) of p lying in $\bar\Omega$ and going out from the point $z \in \bar\Omega$ in the direction of increasing $\pm t$.

Lemma 2.2.9. *The introduced sets have the following properties:*

(i) $\mathcal{K}^{\pm}(p,z,\Omega) \subset \mathcal{K}^{\pm}_{\rho\varepsilon}(p,z,\Omega) \subset \mathcal{K}^{\pm}_{\rho'\varepsilon'}(p,z,\Omega)$ *for* $0<\rho<\rho', 0<\varepsilon<\varepsilon'$*; moreover,* $\mathcal{K}^{\pm}_{\rho'\varepsilon'}(p,\bar z,\Omega)$ *contains the* $\eta|x_1-\bar x_1|$*-vicinity of every point* $z=(x,\xi)\in\mathcal{K}^{\pm}_{\rho\varepsilon}(p,\bar z,\Omega)$ *intersected with* Ω *where* $\eta=\eta(\epsilon_0,c_1,c_2,\rho,\rho',\varepsilon,\varepsilon')>0$.

(ii) $z'\in\mathcal{K}^{\pm}(p,z,\Omega)$ *if and only if* $z\in\mathcal{K}^{\mp}(p,z',\Omega)$.

(iii) If $z''\in\mathcal{K}^{\pm}(p,z',\Omega)$ *and* $z'\in\mathcal{K}^{\pm}(p,z,\Omega)$ *then* $z''\in\mathcal{K}^{\pm}(p,z,\Omega)$*; Statements (ii) and (iii) remain true for* $\mathcal{K}^{\pm}_{\rho\varepsilon}$ *as well.*

(iv) $\mathcal{K}^{\pm}(p,z,\Omega)$ *and* $\mathcal{K}^{\pm}_{\rho\varepsilon}(p,z,\Omega)$ *are closed sets.*

(v) $\mathcal{K}^{\pm}(p,z,\Omega)=\bigcap\limits_{\rho>0,\varepsilon>0}\mathcal{K}^{\pm}_{\rho\varepsilon}(p,z,\Omega)$.

(vi) If $z_n\to z$, $z'_n\to z'$ *and* $p_n\to p$ *in* $\mathscr{C}^1_b$ *as* $n\to+\infty$ *and if* $z'_n\in\mathcal{K}^{\pm}(p_n,z_n,\Omega)$ *then* $z'\in\mathcal{K}^{\pm}(p,z,\Omega)$ [14].

Proof. Statements (i)–(iii) are obvious; we prove (v); and (iv) and (vi) are proven in the same way. Let us consider $\mathcal{K}^{+}(p,z,\Omega)$. Then (i) implies that $\mathcal{K}^{+}(p,z,\Omega)$ is contained in $\bigcap_{\rho>0,\varepsilon>0}\mathcal{K}_{\rho\varepsilon}(p,z,\Omega)$.

Let us prove the reverse inclusion. If $z'\in\bigcap_{\rho>0,\varepsilon>0}\mathcal{K}^{+}_{\rho\varepsilon}(p,z,\Omega)$ then there exist sequences $\rho_n\to+0,\varepsilon_n\to+0$ and generalized (ρ_n,ε_n)-bicharacteristics $z=z_n(t)$ such that $z_n(0)=z$, $z_n(t_n)=z'$; since one can take $t=x_1+\mathsf{const}$ then one can assume that $t_n=t_0$.

Since $|\frac{dz_n(t)}{dt}|$ is uniformly bounded for all n and $t\in[0,t_0]$ then by the Ascoli-Arzelà Theorem one can assume that $z_n(t)\to z(t)$ as $n\to+\infty$ uniformly with respect to $t\in[0,t_0]$ where $z=z(t)$ is a Lipschitz curve; since $z(t)$ is a function with bounded variation, by the Lebesgue Theorem (f.e. A. N. Kolmogorov, S. V. Fomin [1]) it is differentiable a.e. and we need only to prove that $\frac{dz}{dt}\in K^{\#}(p,z(t))$ for a.a. t.

It is obvious that for every $\rho>0,\varepsilon>0$ there exist $\epsilon>0$ and n_0 such that $z_n-z_n(t')\in\pm K^{\#}_{\rho\varepsilon}(p,z(t'))$ for all $n\ge n_0$ and $t\in[t'-\epsilon,t'+\epsilon]\cap[0,t_0]$ with $\pm(t-t')>0$. Then after the limit transition we obtain that $z-z(t')\in\pm K^{\#}_{\rho\varepsilon}(p,z(t'))$ for every $\rho>0,\varepsilon>0$ and indicated t,t'. This yields that if $z(t)$ is differentiable at $t=t'$ then $\frac{dz}{dt}\in K^{\#}_{\rho\varepsilon}(p,z(t))$ for $t=t'$ and for all $\rho>0,\varepsilon>0$ and hence $\frac{dz}{dt}\in K^{\#}(p,z(t))$ for $t=t'$. □

[14] However, even for $p_n=p$ it is possible that the set $\mathcal{K}^{\pm}(p,z,\Omega)$ is larger than the set of such limits.

Now we can prove the central Theorem of this section:

Theorem 2.2.10. *Suppose* $\Omega \Subset T^*\mathbb{R}^d$ *and conditions* (2.1.2) *and* (2.2.1) *are fulfilled. Moreover, let* $\bar z \in \Omega$. *Then if* u *is temperate and*

$$\mathsf{WF}^{s+1}(Pu) \cap \mathcal{K}^{\mp}(p, \bar z, \Omega) = \emptyset \tag{2.2.25}$$

and

$$\mathsf{WF}^{s}(u) \cap \mathcal{K}^{\mp}(p, \bar z, \Omega) \cap \partial\Omega = \emptyset \tag{2.2.26}$$

then

$$\mathsf{WF}^{s}(u) \cap \mathcal{K}^{\mp}(p, \bar z, \Omega) = \emptyset. \tag{2.2.27}$$

Proof. Let us prove this statement with $\mathcal{K}^{\mp}_{\rho\varepsilon}$ instead of $\mathcal{K}^{\mp}$. Then assertions (v) and (i) of Lemma 2.2.9 yield the statement in its original form. Let us consider $\mathcal{K}^{-}_{\rho\varepsilon}$; replacing t, P by $-t, -P$ one can reduce the $\mathcal{K}^{+}_{\rho\varepsilon}$ case to this one.

It is easy to see that if $\rho' > \rho > \rho'', \varepsilon' > \varepsilon > \varepsilon''$ then for $\bar z = (\bar x, \bar\xi) \in \Omega$ and $\bar t = \bar x_1 - \eta$ with small enough $\eta = \eta(\epsilon_0, \rho, \rho', \rho'', \varepsilon, \varepsilon', \varepsilon'', c, c_1, c_2) > 0$ the following inclusions hold:

$$\mathcal{K}^{-}_{\rho'\varepsilon'}(p, \bar z, \Omega) \supset (\bar z - K^{\#}_{\rho\varepsilon}(p, \bar z)) \cap \{x_1 \ge \bar t\} \supset \mathcal{K}^{-}_{\rho''\varepsilon''}(p, \bar z, \Omega) \cap \{x_1 \ge \bar t\}.$$

Then the assertions of the Theorem for the domain $\Omega_n = \{z \in \Omega, -c_4 + \eta n > x_1\}$ instead of Ω are proven easily for an appropriate constant c_4 by means of induction with respect to n: for $n = 0$ the assertion is trivial since $\Omega_0 = \emptyset$ for appropriate c_4, and the induction step is provided by Proposition 2.2.7. Therefore this assertion holds for Ω as well. □

Discussion

Remark 2.2.11. (i) It is easy to see that in the assumptions of Theorem 2.1.2 the function ϕ_j increase along the generalized (ρ, ε)-bicharacteristics provided $\rho > 0, \varepsilon > 0$ are small enough; hence if $\phi(\bar z) < 0$ and $z \in \mathcal{K}^{-}_{\rho\varepsilon}(p, \bar z, \Omega)$ then $\phi(z) < 0$. Therefore Theorem 2.1.2 and Theorem 2.2.10 are equivalent.

(ii) One can generalize Theorem 2.2.10 to overdetermined systems. Assume that $\mathbb{H}' = \mathbb{H}^m$ and $P' = (P'_1, \dots, P'_m)$ where P'_j are self-adjoint and commute between themselves and with P. Then one should define $\mathbb{H}_\rho(z)$ as an invariant subspace of $\mathbb{H}$ corresponding to joint spectrum of $p(z), p'_1(z), \dots, p'_m$ residing in $[-\rho, \rho]^{m+1}$.

Remark 2.2.12. (i) "Equations" of (2.2.23) type are called *ordinary differential inclusions*. They are very well known in the control theory. However our case is rather special: one can see easily that either in the generic point $\nabla^{\#} g \neq 0$ and then in such points $K^{\#}$ are 1-dimensional or at least $g = g_1^{r_1} g_2^{r_2} \cdots g^k r_k$ and again g redefined as $g_1 g_2 \cdots g_k$ has the above property. So in our case in in generic points we have (up to parametrization[15)]) ordinary differential equations.

(ii) Let $\Sigma^{(r)}(p)$ be a set of points in which $g(z)$ has a zero exactly of order not exceeding r. One can see easily that $K(p,z)$ and $K^{\#}(p,z)$ are continuous functions of $z \in \Sigma^{(r)}(p) \setminus \Sigma^{(r-1)}(p)$.

(iii) Let us define $L(p,z)$ for $z \in \Sigma^{(r)}(p)$ recurrently in the following way:

$$z \in \Sigma^{(1)}(p) \implies L(p) = K^{\#}(p,z), \tag{2.2.28}$$

$$z \in \Sigma^{(r)}(p) \setminus \Sigma^{(r-1)}(p) \implies L(p,z) = \bigcup_{\{z_n\} \subset \Sigma^{(r-1)},\ z_n \to z} \lim_{z_n \to z} L(p, z_n) \cup \left(K^{\sigma}(p,z) \cap T_z \Sigma^{(r)}\right) \tag{2.2.29}$$

where for any set $M \ni z$ we define a conical subset in $T_z\Omega$:

$$\zeta \notin T_z M \iff \exists \varepsilon > 0 \text{ such that } \operatorname{dist}(z + t\zeta, M) \geq \varepsilon t \ \forall t \in (0, \varepsilon). \tag{2.2.30}$$

Due to (2.2.5) $L(p,z) \subset K^{\#}(p,z)$. Obviously, $L(p,z)$ is conic but not necessarily convex set. One can prove that actually generalized bicharacteristics satisfy a.e.

$$\frac{dz}{dt} \in L(p,z). \tag{2.2.31}$$

2.2.3 Examples of Propagation

We consider $\mathcal{K}^{-}(p,z)$ in different cases.

Constant Coefficients Case

Example 2.2.13. Let $p = p(\xi)$; then $K(x,\xi) = K(\xi) = \mathbb{R}^d_x \oplus \Gamma(\xi)$ with a conic set $\Gamma(\xi) \subset \mathbb{R}^d_\xi$ and $K^{\#}(\xi) = \Gamma'(\xi) \oplus \{0\}$ where $\mathbb{R}^d_x \supset \Gamma'(\xi)$ is a dual cone to $\Gamma(\xi)$.

[15)] And we can take x_1 as a parameter due to (2.2.1).

Finally, $\mathcal{K}^{\pm}(x,\xi) = \big(x \pm \Gamma'(\xi)\big) \times \{\xi\}$. One can look at the phenomena of *conical refraction* (especially in Crystal Optics and Magnetic Hydrodynamics in R. Courant & D. Hilbert [2]. General theory is exposed in M F. Atiyah, R. Bott & L. Gårding [1]

Scalar Principal Type (Again)

Example 2.2.14. (i) If p satisfies (2.2.6) then $\mathcal{K}^{\pm}(p,z,\Omega) = z$;

(ii) If in Ω

$$p(z) = \begin{pmatrix} g(z)q(z) & 0 \\ 0 & p''(z) \end{pmatrix},$$

$p''(z)$ and $q(z)$ satisfy (2.2.6) and (2.2.8) respectively on the corresponding subspaces, $g(z)$ is a real-valued scalar function with $dg \neq 0$ and if $g(\bar{z}) = 0$ then $\mathcal{K}^{\pm}(p,\bar{z},\Omega) = \gamma^{\pm}(p,\bar{z})$ is an interval of the *semibicharacteristics* of g lying in $\bar{\Omega}$, i.e., of the curve $z = z(t)$ with

$$\frac{dz}{dt} = \nabla^{\#} g(z), \qquad z(0) = \bar{z} \qquad (\pm t \geq 0). \tag{2.2.32}$$

In particular, if $g = \tau + a(x,\xi)$ where a is a scalar real-valued symbol and (x,ξ) is replaced by (t,x,τ,ξ) we obtain the system

$$\frac{dz}{dt} = \nabla^{\#} a(z), \qquad z = (x,\xi), \qquad \tau = -a(z) = \mathsf{const}. \tag{2.2.33}$$

This case will be analyzed very carefully in Section 2.4.

Until the end of subsection we are dealing in the framework of Example 2.2.5(iii).

Operators with Completely Factorizing Characteristic Symbol: Non-Involutive Case

We assume that characteristic symbol $g(z)$ defined by (2.2.14) completely factorizes:

$$g = \prod_{1\leq j\leq n} g_j(z), \qquad g_j = 0 \implies H_{g_j} \neq 0. \tag{2.2.34}$$

In this case

$$\Sigma := \mathsf{Char}\, p = \bigcup_{1\le j\le n} \Sigma_j, \quad \Sigma_j = \{z : g_j(z) = 0\}.$$

Then at $\Sigma_j \setminus \bigcup_{k\neq j} \Sigma_k$ wave front sets propagate along bicharacteristics of g_j and the question is what happens at $\Sigma_j \cap \Sigma_k$ with $j \neq k$. Obviously

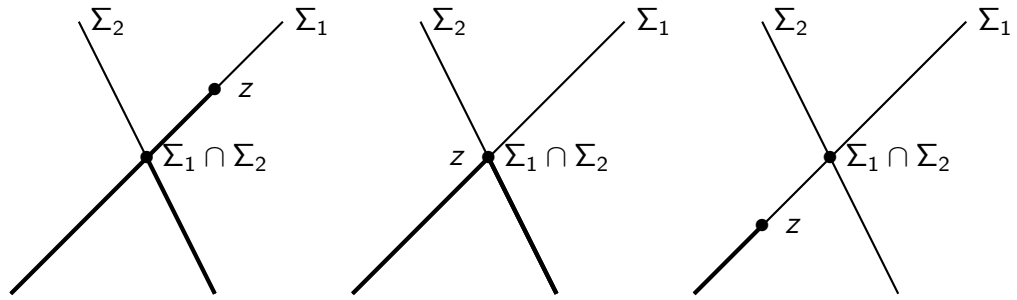
$$\begin{aligned} &(2.2.35)\quad g_1 = ... = g_n = 0 \implies \\ &\qquad K^{\#}(z) = \{\alpha_1 \nabla^{\#} g_1 + \alpha_2 \nabla^{\#} g_2(z) + ... + \alpha_n \nabla^{\#} g_n(z), \quad \alpha \in \mathbb{R}^{+\,n}\}. \end{aligned}$$

Let us consider the series of *microlocal examples*. So all statements below are true for guaranteed small time.

Example 2.2.15. Let $n = 2$ and

$$(2.2.36)\qquad g_j = g_k = 0 \implies \{g_j, g_k\} \neq 0 \qquad (j \neq k).$$

Then as $z \in \Sigma_1 \cap \Sigma_2$ $L(z) = \{\alpha_1 \nabla^{\#} g_1 + \alpha_2 \nabla^{\#} g_2, \quad \alpha \in \mathbb{R}^+ \times 0 \cup 0 \times \mathbb{R}^+\}$ and $\mathcal{K}^-(g, z) = \gamma_1^-(z) \cup \gamma_2^-(z)$ where $\gamma_j^-(z)$ are semibicharacteristics of g_j. The case of $z \in \Sigma_1 \setminus \Sigma_2$ is shown at pictures:



(a) $\gamma_1^-(z)$ hits $\Sigma_1 \cap \Sigma_2$ (b) $z \in \Sigma_1 \cap \Sigma_2$ (c) $\gamma_1^-(z) \cap \Sigma_1 \cap \Sigma_2 = \emptyset$

Figure 2.6: Thick lines show $\mathcal{K}^-(z)$

However Theorem 2.2.10 fails to notice that while branching at $\Sigma_1 \cap \Sigma_2$ the singularity loses its power by $1/2$: let $z^* \in \Sigma_1 \cap \Sigma^2$, $z_j^{\pm} \in \gamma_j^+(z^*)$ and different from z^*. Let $\gamma_j(z, z')$ be a segment of the bicharacteristics with the ends z and z'.

Proposition 2.2.16. *In the framework of Example 2.2.15*

$$\begin{aligned}(2.2.37)\quad &\gamma_1(z_1^-, z_1^+)\cap \mathsf{WF}^{s+1}(Pu)=\emptyset,\quad z_1^-\notin \mathsf{WF}^{s}(u),\\ &\gamma_2(z_2^-, z^*)\cap \mathsf{WF}^{s+1/2}(Pu)=\emptyset, z_2^-\notin \mathsf{WF}^{s-1/2}(u)\implies\\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad z_1^+\notin \mathsf{WF}^{s}(u).\end{aligned}$$

Proof. To prove this let us notice first that due to (2.2.36)

(2.2.38) $g_j=g_k=0=0 \implies H_{g_j}$ and $\nabla^{\#}g_k$ are linearly independent for all $j\neq k$

and then that multiplying p by elliptic symbols from the left and right one can achieve p in the form (2.2.11) with $n=2$ and $p_j=g_j$. Then $P=\begin{pmatrix} P_1 & hB_1\\ hB_2 & P_2\end{pmatrix}$ where $P_j\in \mathbf{\Psi}_h$ are operators with the principal parts g_j and $B_j\in\mathbf{\Psi}_h$. Let R_j be parametrices of P_j with the properly directed propagation; then one can run method of successive approximations and thus needs to consider terms Q^nR where $Q=\begin{pmatrix} 0 & hR_1B_1\\ hR_2B_2 & 0\end{pmatrix}$ and $R=\begin{pmatrix} R_1 & 0\\ 0 & R_2\end{pmatrix}$.

Notice that Q^2 is diagonal with diagonal elements $h^2R_1B_1R_2B_2$ and $h^2R_2B_2R_1B_1$ and QR has diagonal elements 0 and non-diagonal ones $hR_1B_1R_2$ and $hR_2B_2R_1$. So one should consider two these later operators.

Further, due to (2.2.36) one can assume without any loss of the generality that $P_1=\xi_1$ and $P_2=\xi_1-x_1$ and then one can take

$$(2.2.39)\qquad (R_ju)(x)=h^{-1}\int^{x_1} e^{ih^{-1}(\phi_j(x_1)-\phi_j(y_1))}u(y_1,x')\,dy_1$$

with $\phi_1=0$ and $\phi_2=\frac{1}{2}x_1^2$. Then stationary phase method imply that $\|R_1B_1R_2\|\asymp h^{-3/2}$ which easily implies (2.2.37). □

Remark 2.2.17. (i) Arguments of the above proof imply that if $n\geq 3$, condition (2.2.36) is fulfilled and p is diagonal, then singularities propagate along branching bicharacteristics and while switching the branch magnitude acquires factor $h^{1/2}$; so as l (in the condition $\|u\|=O(h^{-l})$) and s (in the WF) are fixed, only $\lfloor 2(l+s)\rfloor$ switches should be allowed.

See V. Kucherenko [1] for the original proof (where $n\geq 2$ was considered).

(ii) $\mathcal{K}^-$ is a different matter. Note that

(2.2.40) If $J \subset \{1, \dots, n\}$ and $g_j(z) = 0 \iff j \in J$ then

$$L(z) = \Big\{ \sum_{j \in J} \alpha_j \nabla^{\#} g_j, \quad \alpha = (\alpha_k)_{k \in J} \in \operatorname{Ker} \mathcal{C}_J \cap \mathbb{R}^{+\#J} \Big\}$$

where $\mathcal{C}_J = (\{g_j, g_k\})_{j,k \in J}$.

If we know that

(2.2.41) For each $J \subset \{1, \dots, n\}$ $L(z) = 0$ where $L(z)$ is now defined by (2.2.40)

then every generalized bicharacteristics is also a branching bicharacteristics. However, if assumption (2.2.41) [16] fails and one can chose non-vanishing $\alpha \in \mathscr{C}^1$ such that $\alpha(z) \in L(z)$ then bicharacteristics of $g' = \sum_{j \in J} \alpha_j g_j$ on $\Sigma_J = \{g_j = 0 \ j \in J\}$ are generalized bicharacteristics of p but not branching bicharacteristics of $\{g_j\}_{j \in J}$.

Example 2.2.18. Let $n = 2$, (2.2.38) holds but $\{g_1, g_2\}$ vanishes at some points. Note that $L(z) = K(z)$ as $g_1 = g_2 = \omega = 0$. Further, assume that

(2.2.42) $g_1 = g_2 = \omega = 0 \implies \{g_1, \omega\} \cdot \{g_2, \omega\} > 0$ with $\omega = \{g_1, g_2\}$.

Then while Σ_1 and Σ_2 intersect transversally due to (2.2.34), bicharacteristics of g_j are tangent to Σ_{3-j} as $g_1 = g_2 = \omega = 0$. Note due to (2.2.42) one can consider ω as a "time" parameter along bicharacteristics as ω is close to 0; one can see easily that generalized bicharacteristics are ordinary bicharacteristics with branching at $\Sigma_1 \cup \Sigma_2$ and that there are no more than two branching on each of bicharacteristics. More precisely, every maximally extended bicharacteristics passing near but not through $\Lambda = \Sigma_1 \cap \Sigma_2 \cap \{\omega = 0\}$ has either two (as on Figure 2.7(a)) or none (as on Figure 2.7(b)) branching points and each time trajectory switches branches the magnitude of solution acquires factor $h^{1/2}$. On the other hand, such trajectory passing through Λ has exactly one branching point (as on Figure 2.7(c)).

Model: $g_1 = \xi_1$, $g_2 = \xi_1 - \xi_2 - x_1^2/2$.

Conjecture 2.2.19. *As trajectory switches branches on Λ the magnitude of solution acquires factor $h^{1/3}$.*

[16] As $n = 3$ (2.2.41) fails iff $\{g_1, g_2\} \cdot \{g_2, g_3\} > 0$ and $\{g_2, g_3\} \cdot \{g_3, g_1\} > 0$ (then the third inequality of this sort holds as well).

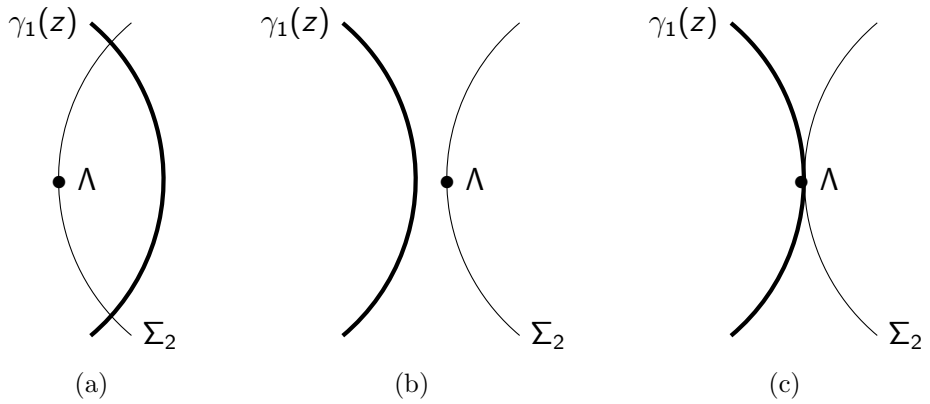


Figure 2.7: Thick lines show $\mathcal{K}^-(z)$

Proof of this conjecture would require a study of oscillatory integrals with degenerate phase functions.

Example 2.2.20. Let $n = 2$, (2.2.38) holds and

$$g_1 = g_2 = \omega = 0 \implies \{g_1, \omega\} \cdot \{g_2, \omega\} < 0 \quad \text{with } \omega = \{g_1, g_2\}. \tag{2.2.43}$$

In this case bicharacteristics of g_j passing through Λ do not hit Σ_{3-j} again. On the other hand if branching on $\Sigma_1 \cap \Sigma_2 \setminus \Lambda$ occurs then due to Proposition 2.2.16 factor $O(h^{1/2})$ is acquired. Therefore again singularities propagate along branching bicharacteristics.

However again as in Remark 2.2.17(ii) bicharacteristics of $g' = \sum_j \alpha_j g_j$ (with $\alpha_j > 0$ defined from $\sum_j \alpha_j \{g_j, \omega\} = 0$) are generalized bicharacteristics of p but not a branching bicharacteristics of $\{g_1, g_2\}$.

Operators with Completely Factorizing Characteristic Symbol: Involutive Case

Example 2.2.21. Assume that

(2.2.44) For each $J \subset \{1, \dots, n\}$ $\nabla^{\#} g_j$, $j \in J$ are linearly independent on $\Sigma_J = \{g_j = 0 \ \forall j \in J\}$.

and

$$g_j = g_k = 0 \implies \{g_j, g_k\} = 0 \qquad \forall j \neq k. \tag{2.2.45}$$

Then Σ_J are involutive manifolds of codimensions $r = \#J$:

$$\nabla^{\#} g_j \in T_z \Sigma_J \qquad \forall z \in \Sigma_J \ \forall j \in J. \tag{2.2.46}$$

Therefore due to Frobenius Theorem Σ_J is locally stratified into submanifolds of dimension r:

$$\Lambda_J(z) = \bigl\{ e^{\sum_{j\in J} t_j \nabla^{\#} g_j},\ t \in B(0,\epsilon) \subset \mathbb{R}^r \bigr\}. \tag{2.2.47}$$

Let

$$\Lambda^-_J(z) = \bigl\{ e^{\sum_{j\in J} t_j \nabla^{\#} g_j},\ t \in B(0,\epsilon) \cap \mathbb{R}^{-r} \bigr\} \tag{2.2.48}$$

which is diffeomorphic locally to $\mathbb{R}^r$.

Then $\mathcal{K}^-(p,z) = \Lambda^-_{J(z)}(z)$ with $J(z) = \{j : g_j(z) = 0\}$. In particular, if $J' = \{j\}$ and $r \geq 2$ we get *limiting bicharacteristics* $\gamma_j(z) \subset \Sigma_J$.

In particular, if $\Sigma_{J'} \ni z' \to z \in \Sigma_J$ and $J' = J(z') \subsetneq J$ then $\mathcal{K}^-(z') \to \Lambda^-_{J'}(z)$.

Operators with not Factorizing Characteristic Symbol. I

Consider case when g has a double characteristic point but is not completely factorizing in its vicinity. Then due to microhyperbolicity condition (2.2.1) microlocally

$$g = -g_1^2 + \sum_{2\leq j\leq n} g_j^2 \tag{2.2.49}$$

with smooth functions g_j and $n = 3, 4$ [17]. Let $\Sigma = \{g = 0\}$ and

$$\Sigma^0 = \{g = \nabla^{\#} g = 0\} = \{g_j = 0 \quad \forall j = 1, \dots, n\}. \tag{2.2.50}$$

Then the eigenvalues of $\mathsf{Hess}^{\#} g$ calculated at Σ^0 play the crucial role in the behavior of bicharacteristics and propagation of singularities[18]. As $z \in \Sigma^0$ consider the second order germ $g(z;\zeta)$ of g; then due to (2.2.1)

(2.2.51) At each point $z \in \Sigma^0$ germ $g(z;\zeta)$ is a hyperbolic polynomial with respect to $\nabla^{\#} x_1$

---

[17] $n = 3, 4$ in the generic case of real or complex matrix symbol p, respectively.

[18] Some eigenvalues could be 0; the rest is coming in pairs belonging to $(\mathbb{R} \cup i\mathbb{R}) \setminus 0$, and quartets belonging to $\mathbb{C} \setminus (\mathbb{R} \cup i\mathbb{R})$ and eigenvalues λ, $-\lambda$, $\lambda^\dagger$ and $-\lambda^\dagger$ have the same Jordan structure.

and therefore

(2.2.52) At each point $z \in \Sigma^0$ germ $\mathsf{Hess}^{\#}(z)$ either has only purely imaginary eigenvalues or it has two simple real eigenvalues $\pm\lambda(z)$ and all other eigenvalues are purely imaginary; further, all non-zero purely imaginary eigenvalues $\pm i\lambda_j$ come in pairs (so the multiplicity of $i\lambda_j$ and $-i\lambda_j$ coincide and associated Jordan cells have height 1 while Jordan cells associated with eigenvalue 0 "normally" have heights at most 2; as there are no real eigenvalues there always is at least one Jordan cell of height 2 associated with eigenvalue 0 and even one cell of the height 4 may appear.

One can deduct the proof from Williamson Theorem (see V. Arnold [2]) or find it in V. Ivrii & V. Petkov [1] or L. Hörmander [6] where the crucial role of this distinction in the Cauchy problem is uncovered.

We just note that non-zero eigenvalues of $\mathsf{Hess}^{\#} g$ coincide with those of the product $\mathsf{diag}(1,-1,\dots,-1)(\{g_j,g_k\})_{j,k=1,\dots,n}$.

Let us assume that

(2.2.53) $\nabla^{\#} g_1,\dots,\nabla^{\#} g_n$ are linearly independent on Σ^0,

which is equivalent to

(2.2.54) Σ^0 is $\mathscr{C}^\infty$-submanifold and $T_z(\Sigma^0) = \mathsf{Ker}\,\mathsf{Hess}^{\#}(z)$ at each point $z \in \Sigma^0$.

Operators with not Factorizing Characteristic Symbol. II

In this subsubsection we assume that

(2.2.55) At no point $z \in \Sigma^0$ matrix $\mathsf{Hess}^{\#}(z)$ has real non-zero eigenvalues.

Then without any loss of the generality one can assume that

(2.2.56) $g(x,\xi) = -\xi_1^2 + B(x,\xi') \quad$ with $\quad B(x,\xi') \ge 0, \qquad \xi' = (\xi_2,\dots,\xi_d)$

and

(2.2.57) $$|\partial_{x_1} B| \le cB.$$

Indeed, we can achieve (2.2.56) by multiplying g by disjoint from 0 symbol and symplectic change of variables. Observe that if $\partial_{x_1}^2 B > 0$ at some point

$z \in \Sigma^0$ then $\mathsf{Hess}^{\#} g(z)$ would have non-zero real eigenvalues; therefore $\partial^2_{x_1} B = 0$ on Σ_0 and then in virtue (2.2.53) $\Sigma^0 = \{\xi_1 = h_2(x', \xi') = ... = h_n(x', \xi') = 0\}$ which implies (2.2.57).

Observe that at level 0 (i.e. as $g(x, \xi) = 0$), $|\xi_1| = B^{\frac{1}{2}}$ and along bicharacteristics $|d\xi_1/dx_1| \le C$ and therefore we arrive to Statement (i) below. Then generalized bicharacteristics cannot enter or leave Σ^0 and therefore $dz/dt \in T_z\Sigma^0$ along generalized bicharacteristics residing on Σ^0; further, $dz/dt \in \mathsf{Ran}\, \mathsf{Hess}^{\#}(z) = (T_z\Sigma^0)$ at point $z \in \Sigma^0$. Then we arrive to Statement (ii) below.

Proposition 2.2.22. *Let conditions* (2.1.2), (2.2.1), (2.2.54) *and*(2.2.55) *be fulfilled. Then*

(i) Let $z \in \Sigma = \{g = 0\}$ *and* $\mathsf{dist}(z, \Sigma^0) = \rho > 0$*; consider* $z(t)$ *bicharacteristics of* g *with* $z(0) = z$*. Then*

$$c^{-1}\rho \le \mathsf{dist}(z(t), \Sigma^0) \le c\rho \quad \text{and} \quad c^{-1}\rho|t| \le \mathsf{dist}(z, z(t)) \le c\rho|t| \tag{2.2.58}$$

as $|t| \le \epsilon\rho^{-1}$.

(ii) On Σ^0 *generalized bicharacteristics of* p *are defined by*

$$\frac{dz}{dt} \in K^{\#}(p, z) \cap T_z\Sigma^0 \cap (T_z\Sigma^0)^{\perp} \tag{2.2.59}$$

which is (2.2.31).

Assume now that

$\sigma|_{\Sigma^0}$ has a constant rank. (2.2.60)

Then there exists foliation of Σ^0 into isotropic submanifolds[19] $\Lambda(z)$:

$$T_z\Lambda(z) = T_z\Sigma^0 \cap (T_z\Sigma^0)^{\perp} \qquad \forall z \in \Sigma^0 \tag{2.2.61}$$

and generalized bicharacteristics reside inside the leaves of this foliation.

Consider one leaf $\Lambda(z)$. Without any loss of the generality one can assume that

$$\Lambda(z) = \{\xi'' = \xi''' = x''' = 0\} \quad \text{with} \quad \xi' = (\xi''; \xi''') = (\xi_1, ..., \xi_k; \xi_{k+1}, ..., \xi_d). \tag{2.2.62}$$

[19] I.e. manifolds such that $\sigma|_{\Lambda} = 0$.

Let us consider symbol $g_2(x'';\xi'',x''',\xi''')$ which is a 2-germ of $g(x,\xi)$ at Σ^0; obviously $g_2(x'';\xi'',x''',\xi''')$ is a second order homogeneous polynomial with respect to (ξ'',x''',ξ''') and let us set $x'''=\xi'''=0$; we get $g'(x'',\xi'')=g_2(x'';\xi'',0,0)$ a second order homogeneous polynomial with respect to ξ''. Obviously all these polynomials are strictly hyperbolic.

Then

(2.2.63) $\mathcal{K}^-(z)\subset\Lambda(z)$ and is the *dependence conoid* for $g'(x',\xi')$ [20)]

Problem 2.2.23. We leave to the reader

(i) To prove that the generic case is $k=1,2$; so $k=1$ only if $n=k+2m$ is odd (and thus equals 3).

(ii) Investigate limiting bicharacteristics (residing on Σ^0) in the cases of Σ^0 involutive submanifold (i.e. $\mathsf{rank}\,\sigma|_{\Sigma^0}=2d-2n$ which is equivalent $\{g_j,g_k\}|_{\Sigma^0}=0\ \forall j,k$) and Σ^0 not involutive submanifold (i.e. $\mathsf{rank}\,\sigma|_{\sigma^0}>2d-2n$); in particular, consider the case of Σ^0 symplectic submanifold (i.e. $\mathsf{rank}\,\sigma|_{\Sigma^0}=2d-n$).

(iii) For each limiting bicharacteristics $\gamma(z)$ prove existence of solution u with $\mathsf{WF}(Pu)=\emptyset$, $WF(u)=\gamma(z)$ (in the vicinity of a given point $z\in\Sigma^0$).

For detail see V. Ivrii [4].

Example 2.2.24. The toy-model symbol with such properties is

$$\frac{1}{2}\Big(-\xi_1^2+\sum_{2\le j\le k}\xi_j^2+\sum_{k+1\le j\le k+m}\omega_j^2(x_j^2+\xi_j^2)\Big) \tag{2.2.64}$$

with $k\ge 1$, $m\ge 0$ and $\omega_j>0$; then $n=k+2m$.

Operators with not Factorizing Characteristic Symbol. III

In this subsubsection in addition to (2.2.53) we assume that

(2.2.65) At each point $z\in\Sigma^0$ matrix $\mathsf{Hess}^{\#}(z)$ has two real non-zero eigenvalues $\pm\lambda$, $\lambda=1$ [21)];

[20)] See any course in partial differential equations; R. Courant and D. Hilbert [2] is my favorite.

[21)] Obviously the latter could be achieved by multiplying g by λ^{-1}.

Then we can assume without any loss of the generality that

$$g(x,\xi) = x_1\xi_1 + B(x',\xi') + \mathcal{O}_n(\Sigma_0) \tag{2.2.66}_n$$

with $x' = (x_2,\dots,x_d)$ etc, $\Sigma^0 = \{(x,xi)\colon x_1 = \xi_1 = 0, (x',\xi') \in \Sigma'\}$, Σ' a smooth manifold,

$$B(x'\xi') = \mathcal{O}_2(\Sigma'), \qquad B(z') \asymp \mathsf{dist}(z',\Sigma')^2 \tag{2.2.67}$$

$\mathcal{O}_n(\Lambda)$ denotes a space of $\mathscr{C}^\infty$-functions vanishing on Λ with all their derivatives of order less than n and so far $n = 3$.

One can prove it easily from microhyperbolicity (in this case in the direction $\nabla^\#(x_1+\xi_1)$) and conditions (2.2.53) and (2.2.65).

Proposition 2.2.25. *In appropriate symplectic coordinates* $(2.2.66)_n$ *and* (2.2.67) *hold with arbitrarily large* $n = \infty$.

Proof. Let us make induction with respect to n. Assume that $(2.2.66)_n$ has been proven and let us prove it with n replaced by $(n+1)$. Consider undesirable terms in the right-hand expression of $(2.2.66)_n$:

$$\sum_{j,k:j+k=l} b_{jk}(x',\xi')x_1^j\xi_1^k, \qquad b_{jk} = O_{n-l}(\Sigma') \tag{2.2.68}$$

with $l = 1,\dots,n$. We do not care about $l = 0$ as we include this term in $B(x'\xi')$.

Let us make almost symplectomorphism $x_j \mapsto x_j + \partial_{\xi_j}S$, $\xi_j \mapsto \xi_j - \partial_{x_j}S$ with

$$S = \sum_{j,k:j+k=l} s_{jk}(x',\xi')x_1^j\xi_1^k, \qquad s_{jk} = O_{n-l}(\Sigma'). \tag{2.2.69}$$

Then canonical relations will be fulfilled modulo $\mathcal{O}_{2n-4}$ and they could be fixed by a symplectomorfism $(x,\xi) \mapsto (x,\xi) + \mathcal{O}_{2n-3}(\Sigma^0))$ which does not spoil $(2.2.66)_{n+1}$ as $2n-3 \ge n$.

One can prove easily that by such transformation one can eliminate all terms in (2.2.68) except those with $j = k$: $b_{jj}(x',\xi')(x_1\xi_1)^j$ and those latter terms could be eliminated by multiplying $g(x,\xi)$ by $\bigl(1+\mathcal{O}_{n-2}(\Sigma^0)\bigr)$. Thus we can escalate l from $l = 1$ to $l = n+1$ but then we get $\mathcal{O}_{n+1}(\Sigma^0)$.

Therefore we can achieve $(2.2.66)_n$ for any n and since transition from n to $n+1$ is achieved by $(x,\xi) \mapsto (x,\xi)+\mathcal{O}_{n-1}(\Sigma^0))$ we can take an asymptotic limit and achieve $(2.2.66)_\infty$. □

Assume for a moment that instead of $(2.2.66)_\infty$ we have an exact equality

$$g(x,\xi) = x_1\xi_1 + B(x',\xi'). \tag{2.2.70}$$

Then $B'(x',\xi')$ is a movement integral and we have the following picture

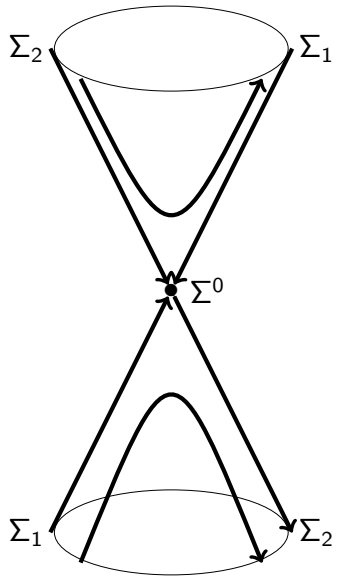

Figure 2.8: Bicharacteristics

Therefore bicharacteristics with $B(x',\xi') \neq 0$ miss Σ^0 while bicharacteristics with $B(x',\xi') = 0$ and thus with $x_1\xi_1 = 0$ have limiting points on Σ^0 as $t \to +\infty$ (for $x_1 = 0$) and as $t \to -\infty$ (for $\xi_1 = 0$) and on $\{B(x',\xi') = 0\}$ picture of $K^-(z)$ is as on Figure 2.6.

More precisely: consider a toy-model (2.2.71). One can look at section of the circular cone by planes parallel to its axis (as on Figure 2.8 as $k = 2$, $m = 0$); as $m \geq 1$ one needs to remember about extra circular motions in (x_j,ξ_j)-planes ($j = k+1,\dots,k+m$) which was present in the previous subsubsection as well.

Example 2.2.26. The toy-model symbol with such properties is

$$\frac{1}{2}\Big(\lambda x_1\xi_1 + \sum_{2\leq j\leq k} \xi_j^2 + \sum_{k+1\leq j\leq k+m} \omega_j^2(x_j^2+\xi_j^2)\Big) \tag{2.2.71}$$

with $k \geq 1$, $m \geq 0$ and $\omega_j > 0$; then $n = k + 2m$. In this case

$$\Sigma^0 = \{x_1 = \xi_1 = \xi' = \xi'' = x'' = 0\}, \tag{2.2.72}$$
$$x = (x_1; x'; x''; x''') = (x_1; x_2 \dots, x_k; x_{k+1}, \dots, x_{k+2m}; x_{k+2m+1}, \dots, x_n), \text{ etc}$$

Σ^0 has codimension $k+2m+1$ and $\operatorname{rank}\sigma|_{\Sigma^0} = 2m$. Then ξ_j ($j = 2,\dots,k$), $(x_j^2+\xi_j^2)$ ($j = k+1,\dots,k+m$) and x_j,ξ_j ($j \geq k+m+1$) are motion integrals while x_1 and ξ_1 are exponents $e^{\pm\lambda t}$.

Let us prove that this happens in the general case as well:

Proposition 2.2.27. *Let conditions* (2.1.2), (2.2.1), (2.2.53), *and* (2.2.65) *be fulfilled. Then*

(i) There exist $(\dim \Sigma^0 + 1)$*-dimensional smooth submanifolds* $\Sigma_j \subset \Sigma = \{g = 0\}$ *and real valued smooth symbols* $\eta_j (j = 1, 2)$ *such that* $\Sigma^0 = \Sigma_1 \cap \Sigma_2$,

$$d\eta_j \notin T_z\Sigma^0 \qquad \text{for} \quad z \in \Sigma^0, \tag{2.2.73}$$

$$\{\eta_1, \eta_2\} = 1 \qquad \text{on} \quad \Sigma^0 \tag{2.2.74}$$

and

$$\eta_j = 0 \quad \text{and} \quad \nabla^{\#} g = \big(\eta_{3-j} + O(|B|^{\infty})\big)\nabla^{\#}\eta_j \qquad \text{on} \quad \Sigma_j \tag{2.2.75}$$

and moreover,

- *(a) as* $z \in \Sigma_j$ *bicharacteristics of* g *have limiting points on* Σ^0 *as* $t \to (-1)^j\infty$*;*
- *(b) These bicharacteristics (modulo parametrization) coincide with bicharacteristics of* η_j*;*
- *(c) further, for* $z \in \Sigma_j$ $\mathcal{K}^-(z)$ *consists of bicharacteristics of* η_j *and* η_{3-j} *with branching on* Σ^0 *exactly as on Figure 2.6.*

(ii) Let $z \in \{g = 0\} \setminus (\Sigma_1 \cup \Sigma_2)$. *Then* $\mathcal{K}^-(z) = \gamma_g^-(z)$ *and it does not have limiting points on* Σ^0.

Proof. We sketch the proof; for details see Proposition 3.8 in V. Ivrii [1].

Consider bicharacteristics which start as $t = 0$ at $z \in \Sigma \cap \{x_1 + \xi_1 = 0\}$, $B(z) = \rho^2$. Using (2.2.53) and canonical form $(2.2.66)_\infty$ one can prove easily that for $0 < t < |\log \rho| - C_0$

$$|x_1| \asymp \rho e^t, \qquad C_0^{-1}\rho e^{-t} - C_0(\rho e^t)^n \le |\xi_1| \le C_0\rho e^{-t} + C_0(\rho e^t)^n,$$

and

$$C_0^{-1}\rho^2 - C_0(\rho e^t)^n \le B(x', \xi') \le C_0\rho^2 + C_0(\rho e^t)^n$$

and then that

$$|D_z^\alpha \Phi_t(z)| \le C_\alpha \qquad \forall z \in \Sigma \cap \{x_1 + \xi_1 = 0\} \setminus \Sigma^0, \quad 0 < t < \frac{1}{2}|\log B(z)| - C.$$

Then as $B(z) \to 0$ we get in the limit $\gamma_1^{\pm}(z)$ for $z \in \Sigma^0$ with signs $\pm$ corresponding two possible signs of x_1. Further, one can prove easily that

$\gamma_1(z) = \gamma_1^+(z) \cup \gamma_2^-(z)$ is a smooth curve and that $\Sigma_1 := \bigcup_{z\in\Sigma^0} \gamma_1(z)$ is a smooth manifold.

Similarly, but with t replaced by $-t$ we get $\gamma_2^\pm(z)$, $\gamma_2(z)$ and Σ_2. The proof of other statements is rather trivial. □

Remark 2.2.28. Observe that limiting bicharacteristics are of the form $\gamma_1^\pm(z) \cup \gamma_2^\mp(z)$ with $z \in \Sigma^0$.

Problem 2.2.29. It would be interesting to investigate if one always can achieve (2.2.70) rather than just $(2.2.66)_\infty$.

Operators with not Factorizing Characteristic Symbol. IV

Problem 2.2.30. (i) It would be interesting to consider symbols satisfying condition

(2.2.76) At each point $z \in \Sigma^0$ germ $\mathsf{Hess}^\#(z)$ has a Jordan cell of the height 4 associated with eigenvalue 0

with the toy-model

$$\frac{1}{2}\Big(-2\xi_1\xi_2 - \alpha\xi_2^2 + x_2^2 + \sum_{3\le j\le k} \xi_j^2 + \sum_{k+1\le j\le k+m} \omega_j^2(x_j^2+\xi_j^2)\Big) \tag{2.2.77}$$

with $\alpha = 0$, $k \ge 3$. Note that at $\xi_1 = \xi_2 = x_2 = 0$ non-zero eigenvalues of $\mathsf{Hess}^\#(g)$ are $\pm\alpha^{1/2}$ and $\pm i\omega_j$ so as $\alpha < 0$ we are in the framework of Proposition 2.2.22 and as $\alpha > 0$ we are in the framework of Proposition 2.2.27. One can analyze pretty easily bicharacteristics of (2.2.77) in all three cases of $\alpha = \mathsf{const}$.

(ii) Further, it would be really interesting to consider variable α f.e. $\alpha = kx_1$ with $k \ne 0$ when type is changed on Σ^0.

2.3 Operators with Rough Symbols

Our goal now is to generalize Theorem 2.1.2 and then some of its corollaries to the case when instead of belonging to $\boldsymbol{\Psi}_h$ operator under consideration

belongs to $\boldsymbol{\Psi}_{h,\boldsymbol{\rho},\boldsymbol{\gamma},N}$ or $\boldsymbol{\Psi}_{h,\boldsymbol{\rho},\boldsymbol{\gamma},\mathsf{an}}$ with $\boldsymbol{\rho} \le \mathbf{1}$, $\gamma \le \mathbf{1}$ satisfying an appropriate form of the uncertainty principle.

Operators with rough symbols serve as proxies (or approximations) for operators with irregular symbols and some rather limited results we derive for those later in Section 27.2.

2.3.1 Main Theorem

Statement of the Main Theorem

Let us analyze assumptions of Theorem 2.1.2 and look at its proof and applications. We do not need to have ϕ_j "rough", and smooth and even analytic functions work well for applications. On the other hand, we consider there $[P, Q_j]$ and we need to assume that these operators also belong to $\boldsymbol{\Psi}_{h,\boldsymbol{\rho},\boldsymbol{\gamma}}$ or $\boldsymbol{\Psi}_{h,\boldsymbol{\rho},\boldsymbol{\gamma},\mathsf{an}}$, i.e. in the smooth case we need to assume that

$$\|\partial_\xi^\alpha \partial_x^\beta \partial_{x,\xi}^\gamma p_m(x,\xi)\| \le c_{m\alpha\beta} \boldsymbol{\rho}^{-\alpha} \boldsymbol{\gamma}^{-\beta} \varepsilon^{-m} \qquad \forall m, \alpha, \beta : |\alpha| + |\beta| + 2m \le N \ \forall \gamma : |\gamma| \le 1 \tag{2.3.1}$$

with $\boldsymbol{\rho}, \boldsymbol{\gamma}$ satisfying uncertainty principle (1.1.97):

$$\varepsilon = \min_j \rho_j \gamma_j \ge h^{1-\delta}. \tag{2.3.2}$$

In the proof we need also assume that $h^{-1}(P - P^*)$ belongs to the same class, i.e. in addition to (2.1.2) we need to assume that

$$\|\partial_\xi^\alpha \partial_x^\beta (p_m - p_m^\dagger)(x,\xi)\| \le c_{m\alpha\beta} \boldsymbol{\rho}^{-\alpha} \boldsymbol{\gamma}^{-\beta} \varepsilon^{1-m} \qquad \forall m, \alpha, \beta : m \ge 1, |\alpha| + |\beta| + 2m \le N \tag{2.3.3}$$

Then the proof of Theorem 2.1.2 implies

Theorem 2.3.1. *Suppose* $P \in \boldsymbol{\Psi}_{h,\boldsymbol{\rho},\boldsymbol{\gamma}}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *satisfying* (2.1.2), (2.3.1) *and* (2.3.3) *with* $\boldsymbol{\rho}, \boldsymbol{\gamma}$ *satisfying uncertainty principle* (2.3.2).

Let $\Omega \Subset T^*\mathbb{R}^d$ *and let* $\phi_1, \dots, \phi_J$ *be real-valued* $\mathscr{C}_b^N$ *functions in* $T^*\mathbb{R}^d$ *such that at every point* $z \in \Omega_\epsilon$ *the symbol* p *is microhyperbolic in the directions* $H_{\phi_1}, \dots, H_{\phi_J}$ *Let* u *be tempered, i.e.,* $\|u\| \le h^{-I}$.

Then (2.1.4) *and* (2.1.5) *imply* (2.1.6).

Skipping easy details, instead let us go to a more difficult task: case of $\boldsymbol{\Psi}_{h,\boldsymbol{\rho},\boldsymbol{\gamma},\mathsf{an}}$ and logarithmic uncertainty principle (1.1.174). Then we need to replace (2.3.1) and (2.3.2) respectively by

$$\|\partial_\xi^\alpha \partial_x^\beta \partial_{x,\xi}^\gamma p_m(x,\xi)\| \le c(m!|\alpha|!|\beta|!)^\sigma \boldsymbol{\rho}^{-\alpha}\boldsymbol{\gamma}^{-\beta}\varepsilon^{-m} \qquad \forall m,\alpha,\beta : |\alpha|+|\beta|+2m \le N\ \forall \gamma : |\gamma| \le 1 \tag{2.3.4}$$

and

$$\|\partial_\xi^\alpha \partial_x^\beta (p_m - p_m^\dagger)(x,\xi)\| \le c(m!|\alpha|!|\beta|!)^\sigma \boldsymbol{\rho}^{-\alpha-m}\boldsymbol{\gamma}^{-\beta}\varepsilon^{-m+1} \qquad \forall m,\alpha,\beta : m \ge 1, |\alpha|+|\beta|+2m \le N \tag{2.3.5}$$

with $N = \epsilon\hbar^{-1}$, $\hbar = h/\varepsilon$ and

$$\min_j \rho_j\gamma_j \ge \varepsilon = Ch|\log h|^\sigma \qquad \sigma \ge 1. \tag{2.3.6}$$

Theorem 2.3.2. *Suppose* $P \in \boldsymbol{\Psi}_{h,\boldsymbol{\rho},\boldsymbol{\gamma}}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *satisfying* (2.1.2), (2.3.4) *and* (2.3.5) *with* $\boldsymbol{\rho}, \boldsymbol{\gamma}$ *satisfying logarithmic uncertainty principle* (2.3.6) *with* $\sigma \ge 1$ *and large enough* C [22].

Let $\Omega \Subset T^*\mathbb{R}^d$ *and let* $\phi_1, \dots, \phi_J$ *be real-valued* $\mathscr{C}_b^N$ *functions in* $T^*\mathbb{R}^d$ *such that at every point* $z \in \Omega_\epsilon$ *the symbol* p *is microhyperbolic in the directions* $H_{\phi_1}, \dots, H_{\phi_J}$ *Let* u *be tempered, i.e.,* $\|u\| \le h^{-l}$. *Then* (2.1.4), (2.1.5) *imply* (2.1.6).

Proof of the Main Theorem

Remark 2.3.3. (i) Recall that assumptions (2.1.4), (2.1.5) mean that for appropriate scalar symbols q_1 and q_2 equal to 1 in the vicinities of $\bar\Omega \cap \{\phi_1 \le \epsilon\} \cap \dots \cap \{\phi_J \le \epsilon\}$ and $\partial\Omega \cap \{\phi_1 \le \epsilon\} \cap \dots \cap \{\phi_J \le \epsilon\}$ respectively and for Q_1, Q_2 their Weyl quantizations

$$\|\bar Q_1 Pu\| \le Ch^{s+1}, \quad \|\bar Q_2 u\| \le Ch^s. \tag{2.3.7}$$

(ii) Without any loss of the generality one can assume that

$$\|\bar Q_1 u\| \le Ch^{s-\delta} \tag{2.3.8}$$

with any fixed exponent $\delta > 0$. Otherwise we will be able to prove Theorem in steps reducing ϵ and shrinking $\mathsf{supp}(q_1)$.

[22] C must depend on all other constants including ϵ in the definition of WF when we are looking at "ϵ-vicinity."

(iii) Without any loss of the generality one can assume $J = 1$: one can always find ϕ satisfying microhyperbolicity condition such that

$$\bar{\Omega} \cap \{\phi_1 \le 0\} \cap \dots \cap \{\phi_J \le 0\} \subset \bar{\Omega} \cap \{\phi < 0\}$$

and

$$\bar{\Omega} \cap \{\phi < \epsilon\} \subset \bar{\Omega} \cap \{\phi_1 \le \epsilon\} \cap \dots \cap \{\phi_J \le \epsilon\}.$$

(iv) Without any loss of the generality one can assume that ϕ is analytic and symbols $\bar{q}_j$ introduced in (i) satisfy

$$|\partial_x^\alpha \partial_\xi^\beta \phi| \le c^{|\alpha|+|\beta|+1}(|\alpha+\beta|)! \tag{2.3.9}$$

$$|\partial_x^\alpha \partial_\xi^\beta f| \le c(cN)^{(|\alpha|+|\beta|-K)_+} \qquad \forall \alpha, \beta : |\alpha| + |\beta| \le N \tag{2.3.10}$$

with arbitrarily large fixed K [23) 24)].

With $Q = Q^*$ of the same type let us repeat (2.1.13):

$$\begin{aligned} -\operatorname{Re} i([P,Q]u,u) = \\ \operatorname{Re} i((Q+Q^*)Pu,u) + \operatorname{Re} i((P^*-P)Qu,u). \end{aligned} \tag{2.3.11}$$

As in the proof of Theorem 2.1.2 we pick up $Q = q^{\mathsf{w}}(x, hD)$ with

$$q = \zeta(x,\xi)^2 \chi\big(\phi(x,\xi)\big) \tag{2.3.12}$$

where

$$\zeta = 1 \text{ in } \Omega \cap \Big\{\phi < \frac{\epsilon}{2}\Big\} \quad \text{and} \quad \operatorname{supp}(\zeta) \subset \Omega_\epsilon \cap \big\{\phi < \epsilon\big\}. \tag{2.3.13}$$

Let $\chi(t) = 0$ for $t \ge \epsilon/4$, both χ and ζ satisfy (2.3.10). One can prove easily that

(2.3.14) Let both χ and ζ satisfy (2.3.10). Then q also satisfies (2.3.10) (with different constants).

[23)] I.e. (2.3.10) holds for $f = \bar{q}_j$.

[24)] Symbols q_j satisfying (2.3.10) and supported in arbitrary small constant vicinities of the corresponding sets exist due to Proposition 1.A.2; however as $\sigma = 1$ such symbols depend on h but conditions are satisfied in the uniform manner.

Let us consider $[P,Q]$ first. With $O(h^K)$ error in (2.3.11) one can replace $[P,Q]$ by $\zeta^{\mathsf{w}} r^{\mathsf{w}} \zeta^{\mathsf{w}}$ with

$$r = \zeta_1 \big(p \bullet \chi(\phi) - \chi(\phi) \bullet p\big)\zeta_1 \tag{2.3.15}$$

with ζ_1 of the same type (2.3.13) as ζ but with ϵ replaced by 3ϵ.

Really, the error would not exceed $C_0^{N+1} N^N h^N \bar{\varepsilon}^{-N} h^{-I}$ with

$$\bar{\varepsilon} = \min_j \min(\rho_j, \gamma_j) \ge \varepsilon$$

and with fixed I and this expression does not exceed $C_0(C_0 N\hbar)^N h^{-I}$ with $\hbar = h/\varepsilon$ and with $N = \epsilon_1 \hbar^{-1/\sigma}$ it does not exceed $e^{-\epsilon_2 \hbar^{-1/\sigma}} h^{-I} = O(h^K)$ as $\hbar \le C|\log h|^{-1}$ with large enough constant C which follows from the logarithmic uncertainty principle (2.3.6).

Consider

$$p \bullet q - q \bullet p + ih\{p,q\} = \sum_{\substack{\alpha,\beta:|\alpha+\beta|\ge 2,\\ |\alpha|-|\beta|\in 2\mathbb{Z}+1}} \frac{2}{\alpha!\beta!}(-i)^{|\alpha|-|\beta|}\big(\frac{h}{2}\big)h^{|\alpha+\beta|}\big(D_\xi^\alpha D_x^\beta p\big)\cdot\big(D_x^\alpha D_\xi^\beta q\big) \tag{2.3.16}$$

and plug $q = \chi(\phi)$. Note that

$$\frac{1}{\nu!}D^\nu \chi(\phi) = \sum_{k\le|\nu|} \sum_{\substack{\nu_1,\dots,\nu_k:\\ |\nu_1|\ge 1,\dots,|\nu_k|\ge 1,\\ \nu_1+\dots+\nu_k=\nu}} \chi^{(k)}(\phi) \prod_{1\le j\le k} \frac{1}{\nu_j!} D^{\nu_j}\phi \tag{2.3.17}$$

where $\chi^{(k)}(t) = \partial_t^k \chi(t)$. Therefore

(2.3.18) Let χ satisfy (2.3.10). Then modulo negligible one can rewrite the right hand expression of (2.3.16) as

$$\sum_{1\le l+n\le N} \chi^{(l+1)}(\phi) r_{ln}(x,\xi)\hbar^{n+l} h \tag{2.3.19}$$

with $\phi = \phi(x,\xi)$ and

$$\|\partial_\xi^\alpha \partial_x^\beta r_{ln}\| \le c_1^{l+n+|\alpha|+|\beta|}(l!)^{\sigma-1}(n!\alpha!\beta!)^\sigma \boldsymbol{\rho}^{-\alpha}\boldsymbol{\gamma}^{-\beta} \qquad \forall l,n,\alpha,\beta : l+n+|\alpha|+|\beta| \le N. \tag{2.3.20}$$

We will be very particular choosing χ. Namely, we consider χ satisfying (2.3.10) and then replace in the formulae above $\chi(t)$ by

$$\chi_j(t) = \hbar^{2j} \int_t^\infty \bigl(\chi^{(j)}(t')\bigr)^2 \, dt'; \tag{2.3.21}$$

one can see easily that

(2.3.22) $\hbar^{-2j} N^{-2j} \chi_j(\phi)$ and $N^{-j}\chi^{(j)}(\phi)$ satisfy (2.3.10) uniformly with respect to $j \le N = \epsilon_1 \hbar^{-1/\sigma}$;

therefore every formula above holds uniformly as well.

Then (2.3.18) implies that

(2.3.23) Modulo negligible one can rewrite the right hand expression of (2.3.16) with $q = \chi_j(\phi)$ as

$$\sum_{1\le l_1+l_2+n\le N} \chi^{(l_1+j)}(\phi)\chi^{(l_2+j)}(\phi) r_{l_1 l_2 n}(x,\xi)\hbar^{2j+l_1+l_2+n} h \tag{2.3.24}$$

with

$$\|\partial_\xi^\alpha \partial_x^\beta r_{l_1 l_2 n}\| \le c_1^{l_1+l_2+n+|\alpha|+|\beta|} (l_1! l_2!)^{\sigma-1} (n!\alpha!\beta!)^\sigma \cdot \boldsymbol{\rho}^{-\alpha}\boldsymbol{\gamma}^{-\beta} \qquad \forall l, n, \alpha, \beta : l_1 + l_2 + n + |\alpha| + |\beta| \le N. \tag{2.3.25}$$

Now using "revert" formula

$$pq \equiv \sum_{\alpha,\beta:} \frac{2}{\alpha!\beta!} i^{|\alpha|-|\beta|} \bigl(\frac{h}{2}\bigr) h^{|\alpha|+|\beta|} \bigl(D_\xi^\alpha D_x^\beta p\bigr) \bullet \bigl(D_x^\alpha D_\xi^\beta q\bigr) \tag{2.3.26}$$

one can rewrite (2.3.24) as

$$\sum_{1\le l_1+l_2+n\le N} \hbar^{l_1+j}\chi^{(l_1+j)}(\phi) \bullet r'_{l_1 l_2 n}(x,\xi) h^n \bullet \hbar^{l_2+j}\chi^{(l_2+j)}(\phi) \tag{2.3.27}$$

where $r'_{l_1 l_2 n}$ also satisfy (2.3.25).

Then

$$\ell_j \coloneqq h^{-1}\Bigl(p \bullet \chi_j(\phi) - \chi_j(\phi) \bullet p + ih\{p, \chi_j(\phi)\}\Bigr)\zeta^2 \equiv \sum_{1\le l_1+l_2+n\le N} t_{l_1+1} \bullet r'_{l_1 l_2 n}(x,\xi) h^n \bullet t_{l_2+j} + \ell'_j \tag{2.3.28}$$

with $t_m = \chi^{(m)}(\phi)\zeta\hbar^m$ and

$$\ell'_j = \zeta^2\Big(\sum_{1\le l_1+l_2+n\le N} \hbar^{l_1+j}\chi^{(l_1+j)}(\phi)\bullet r'_{l_1l_2n}(x,\xi)h^n\bullet\hbar^{l_2+j}\chi^{(l_2+j)}(\phi)\Big)- \sum_{1\le l_1+l_2+n\le N} \zeta\hbar^{l_1+j}\chi^{(l_1+j)}(\phi)\bullet r'_{l_1l_2n}(x,\xi)h^n\bullet\zeta\hbar^{l_2+j}\chi^{(l_2+j)}(\phi) \tag{2.3.29}$$

and therefore

$$|(L_ju,u)| \le c_2\|T_ju\|\cdot\Big(\sum_{1\le l\le N-j} c_2^l(l!)^{\sigma-1}\cdot\|T_{j+l}u\|\Big)+ c_2\Big(\sum_{1\le l\le N-j} c_2^l(l!)^{\sigma-1}\cdot\|T_{j+l}u\|\Big)^2 + C_2\hbar\|T_ju\|^2 + |(L'_ju,u)| \tag{2.3.30}$$

with $T_m = \mathsf{Op}^{\mathsf{w}}(t_m)$, $L_j = \mathsf{Op}^{\mathsf{w}}(\ell_j)$ and $L'_j = \mathsf{Op}^{\mathsf{w}}(\ell'_j)$.

One can prove easily that due to (2.3.8) and (2.3.22)

$$|(L'_ju,u)| \le C_3h^s\hbar^jN^j\Big(\sum_{0\le l\le N-j} c_3^l(l!)^{\sigma-1}\cdot\|T_{j+l}u\|\Big) + C_3h^{2s}\hbar^{2j}N^{2j}. \tag{2.3.31}$$

Meanwhile

$$\{p,\chi_j(\phi)\} = -\chi^{(j)}(\phi)^2\hbar^{2j}\{p,\phi\} \tag{2.3.32}$$

and due to microhyperbolicity condition

$$\{p,\phi\} = b^2 + f^\dagger p + pf \tag{2.3.33}$$

where

(2.3.34) both b, f satisfy (2.3.4) type estimates and b is Hermitian and elliptic.

Therefore modulo (2.3.27)-type expression one can rewrite (2.3.32) as

$$\hbar^j\chi^{(j)}(\phi)\bullet b\bullet b\bullet\hbar^j\chi^{(j)} + \chi^{(j)}\bullet f^\dagger\bullet p + p\bullet f\bullet\hbar^j\chi^{(j)}. \tag{2.3.35}$$

Repeating arguments leading to (2.3.30)–(2.3.30) we conclude that

$$-ih^{-1}([P,Q']\,\mathsf{Op}^{\mathsf{w}}(\zeta^2)u,u) \ge \epsilon_1\|T_ju\|^2 - (2.3.30) - (2.3.31). \tag{2.3.36}$$

Here we used the (2.3.8) and the first of estimates (2.3.7) exactly as in the proof of Theorem 2.1.2.

Also, without any loss of the generality we can assume that

$$-ih^{-1}(p_1^\dagger - p_1) = \tilde{b}^2 + f^\dagger p + pf \tag{2.3.37}$$

where both b, f satisfy (2.3.4) type estimates and $\tilde{b}$ is Hermitian and elliptic. Really, due to (2.3.33) we can achieve this by multiplying operator P by an equivalent operator $e^{k\phi}Pe^{-k\phi}$ with large enough $k \in \mathbb{R}^+$.

Then the second term in the right hand expression of (2.3.11) multiplied by h^{-1} is less than $-\epsilon_1(Q_j u, u) + Ch^{2s+\delta}$ due to Gårding inequality with the semiclassical parameter $\hbar$.

Then (2.3.11) implies

$$\epsilon_1\|T_j u\|^2 + \epsilon_1(Q_j u, u) \le (2.3.30) + (2.3.31) + ch^s\|Q_j u\| + Ch^{2s}\hbar^{2j}N^{2j}. \tag{2.3.38}$$

Note, that $q_j^2 \le (c\hbar N)^j q_j$ and using to Gårding inequality with the semiclassical parameter h we conclude that

$$\|Q_j u\|^2 \le C(cN\hbar)^j(Q_j u, u) + Ch^{2s+\delta} \tag{2.3.39}$$

again due to (2.3.8).

Then (2.3.38) implies that

$$\mu_j := \epsilon_1\|T_j u\| + \epsilon_1(Q_j u, u)^{1/2} \tag{2.3.40}$$

satisfy inequalities

$$\mu_j \le \sum_{1\le l\le N-j} \mu_l c_3^l (l!)^{\sigma-1} + f_n \qquad \text{with} \quad f_n = C_2(cN\hbar)^j h^s \tag{2.3.41}$$

where the last term is greater than $Ch^{s+\delta}$. Then[25)]

$$\mu_j \le C_4 \sum_{0\le l\le N-j} c_4^l (l!)^{\sigma-1} f_{j+l}. \tag{2.3.42}$$

Plugging f_{j+l} and $N = \epsilon_1\hbar^{1/\sigma}$ one can see easily that $\mu_j \le Ch^s$; picking up $j = 0$ we conclude that (2.1.6) holds. Theorem 2.3.2 is proven.

[25)] Really, solving (2.3.41) for $f_j = 0$ and for $j < k$ only one can prove by induction with respect to $j = k, \dots, 0$ that $\mu_j \le C_4 c_4^{k-j}((k-j)!)^{\sigma-1}\mu_k$, which implies (2.3.42) for the original inhomogeneous system.

2.3.2 Corollaries

After propagation of singularities Theorem is proven, it implies few corollaries similar to those of Theorem 2.1.2.

Remark 2.3.4. In the regularity conditions of Theorem 2.3.2 assertions of Remark 2.1.3 and Proposition 2.1.4 remain true.

Theorem 2.3.5. *For operator $P = hD_t + A$ with the regularity of A as in Theorem 2.3.2 rather than of 2.1.2*

(i) Assertion of Theorem 2.1.5 remains true: (2.1.28) *and* (2.1.29) *imply* (2.1.30)*; Remark 2.1.6 also remains true.*

(ii) Assertions of Corollaries 2.1.7 and 2.1.9 (finite speed of propagation) remain true.

(iii) Assertions of Propositions 2.1.10 and 2.1.12 remain true.

(iv) Assertions of Proposition 2.1.13 and Corollary 2.1.14 remain true.

(v) Assertions of Proposition 2.1.16, Corollary 2.1.17 and Remark 2.1.18 remain true.

(vi) Furthermore, as $\rho = 1$ assertions of Theorem 2.1.19 and Remark 2.1.21 remain true. Moreover, if $\rho \le 1$ then estimate (2.1.59) *is replaced by*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma_x(Q_{1x}U\,{}^tQ_{2y})\| \le CMh^{1-d}\Big(\frac{h}{\rho T}\Big)^s \qquad \forall \tau : |\tau| \le \varepsilon_0 \quad \forall x \in \mathbb{R}^d \tag{2.3.43}$$

where $\rho = \min_j \rho_j$.

(vii) Assertions of Remark 2.1.22 remains true.

(viii) Finally, as $\rho = 1$ assertion of Theorem 2.1.23(ii) with the same modification as in (vi) remains true. Moreover, if $\rho \le 1$ then estimate $(2.1.59)'$ *is replaced by*

$$\|F_{t\to h^{-1}\tau}\chi_{\pm T}(t)\Gamma_x(Q_{1x}U\,{}^tQ_{2y})\| \le CMh^{m-d}\Big(\frac{h}{\rho T}\Big)^s \qquad \forall \tau : |\tau| \le \varepsilon_0 \quad \forall x \in \mathbb{R}^d \tag{2.3.43$'$}$$

where $\rho = \min_j \rho_j$.

(ix) Further, if $\phi = \phi(x')$ *wuth* $\xi' = (\xi_1, \dots, \xi_k)$ *then in (vi), (viii) one can take* $\rho = \min_{j\le k} \rho_j$.

(x) Meanwhile modified in the same way Statements Theorems 2.1.19(i) and 2.1.23(i) remain true as $\rho \le \gamma$.

Proofs of all these statements just repeats those of those we refer to.

Moreover, let us assume that as $h \to +0$ symbol $p(x, \xi, h)$ tends to some limit which we denote also by p. Let us define $K(p, z)$, $K^{\#}(p, z)$ and $\mathcal{K}^{\pm}(p, z)$ for this limiting symbol. Then

Theorem 2.3.6. *For operator* A *with the regularity as in Theorem 2.3.2 rather than of 2.1.2*

(i) Assertions of Lemma 2.2.1, Proposition 2.2.7 remain true; further, Definition 2.2.8 make sense and assertions of Lemma2.2.9 remain true.

(ii) Moreover, assertion of Theorem 2.2.10 remains true: (2.2.25) *and* (2.2.26) *imply* (2.2.27).

Again, proofs of all these statements just repeats those of those we refer to.

2.4 Heisenberg Approach to Propagation of Singularities along Long Bicharacteristics

The results of Section 2.2 imply the well known fact that singularities for operators with scalar principal symbols propagate along bicharacteristics. In this section we improve and generalize this result in two directions: namely, we treat large time intervals depending on h and we replace the description of the singularities by means of wave front sets with a more refined description related to boxes depending on h.

2.4.1 Evolution of Operators

Heisenberg Approach

We start with the Cauchy problem for the operator

$$P = hD_t + A \tag{2.4.1}$$

where

(2.4.2) $A = A^w(x, hD_x, h)$ is an operator with a Hermitian Weyl symbol and hence A is a self-adjoint operator.

Solution to $Pu = 0$ is given by $u_t = e^{-ih^{-1}tA}u_0$ where $u_t = u(., t)$; then

$$e^{-ih^{-1}tA}Qu_0 = e^{-ih^{-1}tA}Qe^{ih^{-1}tA} \cdot e^{-ih^{-1}tA}u_0 = Q^t u_t \tag{2.4.3}$$

with

$$Q^t = e^{-ih^{-1}tA}Q^0 e^{ih^{-1}tA}. \tag{2.4.4}$$

Therefore one can apply observable $Q^0 = Q$ to the initial state or alternatively apply evolved observable Q^t to the evolved state u_t and the result would be the same. Equivalently one can apply observable $Q^0 = Q$ to the evolved state u_t or alternatively apply evolved observable Q^{-t} to the initial state u_0 and the result would be the same. In the latter case physicists would say that we use the *Heisenberg representation*.

Since WF are intimately related to pseudodifferential operators, it is obvious that the investigation of the propagation of singularities of solutions to this Cauchy problem can be reduced to the treatment of the operator Q^t where $Q^0 = \mathsf{Op}^w(q^0)$ is a pseudodifferential operator. The crucial question is if Q^t is a pseudodifferential operator.

We already know that for a standard pseudodifferential operator A such that and

(2.4.5) $a = A_0$ is a scalar real-valued symbol.

and Q and finite time t the *propagators* $e^{\pm ih^{-1}tA}$ are Fourier integral operators corresponding to the symplectomorphisms $\varphi_{\pm t}$ where $\varphi_t : z(0) \to z(t)$ and $z(t)$ is a solution of the Hamiltonian system (2.2.33).

This implies that Q^t is also a pseudodifferential operator. However, we use these results only as a heuristic preliminary.

Definition (2.4.4) implies that Q^t is a solution of the Cauchy problem

$$\partial_t Q^t = -ih^{-1}[A, Q^t], \tag{2.4.6}$$

$$Q^t\big|_{t=0} = Q^0. \tag{2.4.7}$$

Let us *assume* that Q^t is a pseudodifferential operator with Weyl symbol q^t where for now we treat symbols as formal power series; we will *justify* this assumption later.

Then the Cauchy problem (2.4.6)–(2.4.7) implies the similar Cauchy problem for symbols; namely, for a term q_n^t in the decomposition of q^t we obtain the equation

$$\partial_t q_n^t + \{a, q_n^t\} + i[a^s, q_n^t] = \sum_{\substack{0\le k\le n-1\\ j+|\alpha|+|\beta|=n-k}} \frac{1}{2^{|\alpha|+|\beta|}\alpha!\beta!}\big((-i)^{|\alpha|-|\beta|}A^{(\alpha)}_{j(\beta)}q^{t(\beta)}_{k(\alpha)} - i^{|\alpha|-|\beta|}q^{t(\beta)}_{k(\alpha)}A^{(\alpha)}_{j(\beta)}\big) \tag{2.4.8$_n$}$$

with initial condition

$$q_n^t\big|_{t=0} = q_n^0. \tag{2.4.9$_n$}$$

Recall that $\{.,.\}$ are Poisson brackets, $[.,.]$ is the commutator in $\mathcal{L}(\mathbb{H},\mathbb{H})$, a^s is the subprincipal symbol of A (i.e., $a^s = A_1$), A_n are terms in the decomposition of the Weyl symbol of A and $b^{(\alpha)}_{(\beta)} = \partial_x^\beta \partial_\xi^\alpha b$.

Now we throw of our assumption that Q^t is an h-pseudodifferential operator. We needed this assumption *only* to derive problems (2.4.8)$_n$–(2.4.9)$_n$. So, let us consider this problem, where for now "symbol" means "function" rather than "symbol of an operator."

Let us start with the principal symbol q_0^t which satisfies the following *transport equation*

$$\partial_t q_0^t + \{a, q_0^t\} + i[a^s, q_0^t] = 0 \tag{2.4.8$_0$}$$

where $[.,.]$ means the matrix (i.e., operator in the auxiliary space $\mathbb{H}$) commutator.

Moreover, if

(2.4.10) a^s is also a scalar symbol

we obtain the following equation:

$$\partial_t q_0^t + \{a, q_0^t\} = 0 \tag{2.4.11}$$

which can be rewritten in the form

$$\partial_t (q_0^t \circ \Psi_t) = 0 \tag{2.4.12}$$

where $\Psi_t : T^*\mathbb{R}^d \to T^*\mathbb{R}^d$ is a symplectomorphism; namely, $\Psi_t : z(0) \to z(t)$ where $z(t)$ is a solution of the dynamical system

$$\frac{dz(t)}{dt} = H_a(z(t)) \tag{2.4.13}$$

and hence

$$q_0^t = q_0^0 \circ \Psi_{-t}. \tag{2.4.14}$$

Definition 2.4.1. The family Ψ_t is called the *Hamiltonian flow generated by the Hamiltonian* a.

In the general case (i.e. without assumption (2.4.10)) one can rewrite equation $(2.4.8)_0$ in the form

$$\partial_t \big(R_t^{-1}(q_0^t \circ \Psi_t)R_t\big) = 0 \tag{2.4.15}$$

where R_t is a differentiable matrix family in $\mathbb{H}$ satisfying the Cauchy problem

$$\partial_t R_t = -i(a^s \circ \Psi_t)R_t, \qquad R_0 = I. \tag{2.4.16}$$

These matrices are unitary since a^s is Hermitian. Therefore $R_t^\dagger(q_0^t \circ \Psi_t)R_t = q_0^0$ and

$$q_0^t = (R_t q_0^0 R_t^\dagger) \circ \Psi_{-t}. \tag{2.4.17}$$

Note that

$$R_{t,t'} = R_t R_{t'}^\dagger \tag{2.4.18}$$

satisfies the Cauchy problem

$$\partial_{t'} R_{t,t'} = -i(a^s \circ \Psi_t)R_{t,t'}, \qquad R_{t,t'} = I. \tag{2.4.19}$$

Solving Heisenberg Equations. Standard Case

As long as T is bounded, and $a^{(\alpha)}_{(\beta)} \circ \Psi_t$ are bounded at (x,ξ) for $\pm t \in [0,\, T]$ so are derivatives of $\Psi_t(x,\xi)$ with respect to (x,ξ). Further, since $d\Psi_t$ is a linear symplectomorphism and therefore $\det d\Psi_t = 1$, derivatives of $\Psi_{-t'}$ remain bounded at $\Psi_t(x,\xi)$ as $0 \le \pm t' \le \pm t \le T$.

Assume that these properties hold for all $z \in \Omega = B(\bar z, \varepsilon)$ and that $a^{(\alpha)}_{n(\beta)} \circ \Psi_t$ are bounded at (x,ξ) for $\pm t \in [0,\, T]$. Further, assume that

$$q^0 \in \mathsf{S}_{h,\varepsilon,\varepsilon}, \qquad \mathsf{supp}(q^0) \subset \Omega. \tag{2.4.20}$$

Then it immediately follows from $(2.4.8)_n$ that

$$q^t \in \mathsf{S}_{h,\varepsilon,\varepsilon}, \qquad \mathsf{supp}(q^0) \subset \Omega_t = \Psi_t\Omega. \tag{2.4.21}$$

Moreover, $B(\bar z_t,\, C_0^{-1}\varepsilon) \subset \Omega_t \subset B(\bar z_t,\, C_0\varepsilon)$ where $\bar z_t = \Psi_t(\bar z)$.

Then as ε satisfies microlocal uncertainty principle

$$\varepsilon \ge h^{(1-\delta)/2} \tag{2.4.22}$$

one can quantize q^t.

Thus $Q^t = q^{t\,\mathsf{w}}(x, hD)$ satisfies (2.4.6)–(2.4.7) modulo $O(h^N)$ [26] operators. Therefore

$$\partial_t\Big(e^{ih^{-1}tA} Q^t e^{-ih^{-1}tA}\Big) \equiv 0 \tag{2.4.23}$$

also modulo $O(h^N)$ [26] operators. Then

$$e^{ih^{-1}tA} Q^t e^{-ih^{-1}tA} \equiv Q^0 \tag{2.4.24}$$

and finally

$$Q^t \equiv e^{-ih^{-1}tA} Q^0 e^{ih^{-1}tA}. \tag{2.4.25}$$

This proves that $Q^t = q^{t\,\mathsf{w}}$ differs from Q^t defined by (2.4.4) by $O(h^N)$ and therefore

Theorem 2.4.2. *Let $A \in \boldsymbol{\Psi}_h$ be an operator with the Hermitian and scalar principal symbol. Let Ψ_t be a corresponding Hamiltonian flow.*

Furthermore, let $Q^0 \in \boldsymbol{\Psi}_{h,\varepsilon,\varepsilon}$ where $\varepsilon \in (0,1]$ satisfies (2.4.22)*. Then*

[26] In the operator norm.

(i) For $\pm t \in [0, T]$ *with bounded* T *operator* Q^t *defined by* (2.4.4) *belongs to* $\boldsymbol{\Psi}_{h,\varepsilon,\varepsilon}$ *and is defined by the procedure described in the previous section.*

(ii) In particular, $\mathsf{supp}(q^t) = \Psi_t(\mathsf{supp}(q^0))$.

In the same way one can prove

Theorem 2.4.3. *Let* $A \in \boldsymbol{\Psi}_{h,\mathsf{an}}$ *be an operator with the Hermitian and scalar principal symbol. Let* Ψ_t *be a corresponding Hamiltonian flow.*

Furthermore, let $Q^0 \in \boldsymbol{\Psi}_{h,\varepsilon,\varepsilon,\mathsf{an}}$ *where* $\varepsilon \in (0, 1]$ *satisfies logarithmic uncertainty principle*

$$\varepsilon \geq C(h|\log h|)^{1/2}. \tag{2.4.26}$$

Then

(i) For $\pm t \in [0, T]$ *with bounded* T *operator* Q^t *defined by* (2.4.4) *belongs to* $\boldsymbol{\Psi}_{h,\varepsilon,\varepsilon,\mathsf{an}}$ *and is defined by the procedure described in the previous section.*

(ii) In particular $\mathsf{supp}(q^t) = \Psi_t(\mathsf{supp}(q^0))$.

Remark 2.4.4. Actually in the symbol construction we need only that conditions to q^0 be fulfilled only in Ω and conditions to symbol of A in $\bigcup_{\pm t\in[0,T]} \boldsymbol{\Psi}_t(\Omega)$.

Discussion

Now we want to extend the results of the previous subsubsection to the case of unbounded (but not too large) T. Then derivatives of Ψ_t may cease to be bounded. Usually in applications they have either exponential (general case) or polynomial (completely integrable case) growth with respect to t. Also in the applications it is more natural to assume that A belongs to $\boldsymbol{\Psi}_{h,\rho,\rho}$ with unbounded but not to large ρ. In this theory since different components of (x, ξ) are messed up during Hamiltonian motion, one needs to assume that all components of $\boldsymbol{\rho}$ and $\boldsymbol{\gamma}$ are equal.

For the sake of simplicity we consider $t \in [0, T]$ but exactly the same results hold as $-t \in [0, T]$.

Properties of Hamiltonian Flow

First we need to establish the growth properties of the Hamiltonian flow. It appears that everything is defined by the growth of $d\Psi_t$ and by the growth of F along trajectories.

Lemma 2.4.5. *Let $\Psi_t : \mathbb{R}^d \to \mathbb{R}^d$ be a flow defined by the dynamical system*

$$\frac{dz}{dt} = F(z). \tag{2.4.27}$$

Let $\bar{z} \in \mathbb{R}^d$, $T > 0$ and $z(t) = \Psi_t(\bar{z})$. Let us assume that

$$|(\partial_z^\alpha F)(z(t))| \le c\mu\rho^{-|\alpha|} \qquad \forall t \in [0, T] \quad \forall \alpha : 1 \le |\alpha| \tag{2.4.28}$$

and

$$|d\Psi_{t-t'}(z(t'))| \le c\omega \qquad \forall t, t' \in [0, T] \tag{2.4.29}$$

where $d\Psi_t$ is a differential of Ψ_t (with respect to z) and μ, ρ, ω are (positive) parameters such that

$$\mu\rho T\omega \ge 1, \qquad \omega \ge 1. \tag{2.4.30}$$

Then

$$|(\partial_z^\alpha \Psi_t)| \le C_\alpha \omega \eta^{1-|\alpha|} \qquad \forall t \in [0, T] \; \forall \alpha : 1 \le |\alpha| \tag{2.4.31}$$

with

$$\eta = \rho^2\omega^{-2}\mu^{-1}T^{-1}. \tag{2.4.32}$$

Proof. Let us use induction with respect to $n \ge 1$; for $n = 1$ the estimate (2.4.31) coincides with (2.4.29). Let us assume that (2.4.31) holds for all α with $|\alpha| < n$ and let us consider $z(t, u) = \Psi_t(u)$.

Differentiating the initial system n times with respect to u we obtain that

$$\frac{dz_k^{(\alpha)}}{dt} = \sum_{1 \le j \le d} F'_{kj}(z) z_j^{(\alpha)} + f_{k,\alpha} \tag{2.4.33}$$

where F_k and z_k are components of F and z respectively and $F'_{kj} = \partial_{z_j} F_k$, $z_k^{(\alpha)} = \partial_u^\alpha z$,

$$f_{k,\alpha} = \sum_{2 \le |I| \le r} \sum_{\substack{\alpha_1, \dots, \alpha_s : s = |I|, \\ |\alpha_i| \ge 1, \alpha_1 + \dots + \alpha_s = \alpha}} \bar{c}_{d, I, \alpha_1, \dots, \alpha_s} F_I(z(t)) z_{i_1}^{(\alpha_1)} \cdots z_{i_s}^{(\alpha_s)},$$

where $I = (i_1, \dots, i_s) \in \{1, \dots, d\}^s$, $F_I = \partial_{z_{i_1}} \dots \partial_{z_{i_s}} F$, and $\bar{c}_\dots$ are absolute constants.

Then (2.4.28), (2.4.30), and the induction assumption imply that

$$|f_{k,\alpha}| \le C\mu(\mu T)^{n-2}\omega^{2n-2}\rho^{2-2n} \tag{2.4.34}$$

On the other hand, (2.4.33) and the equality $z_k^{(\alpha)} = 0$ for $t = 0$ and $|\alpha| \ge 2$ imply that

$$z^{(\alpha)}(t) = \int_0^t (d\Psi)_{t-t'}(z(t'))f_\alpha(t')dt'$$

where $z^{(\alpha)}$ and f_α are vectors with components $z_k^{(\alpha)}$ and $f_{k,\alpha}$ respectively; this formula, (2.4.29) and (2.4.34) imply (2.4.31) for $|\alpha| = n$ where we change the constant C if necessary. □

Remark 2.4.6. (i) For Hamiltonian system (2.4.13) condition (2.4.28) means precisely that

$$|a_{(\beta)}^{(\alpha)}\big(z(t)\big)| \le c\mu\rho^{1-|\alpha|-|\beta|} \tag{2.4.35}$$
$$\forall t : [0, T] \quad \forall \alpha, \beta : 2 \le |\alpha| + |\beta| \le n + 1.$$

(ii) If for system (2.4.13) condition (2.4.29) is fulfilled for $t' = 0$ then this condition is fulfilled for all $t' \in [0, t]$ with ω replaced by ω^{2d}; in fact,

$$d\Psi_{t-t'}(z(t')) = d\Psi_t(z(0))\big(d\Psi_{t'}(z(0))\big)^{-1}$$

and since $\det d\Psi_t = 1$ we conclude that $(d\Psi_t)^{-1}$ is a cofactor matrix.

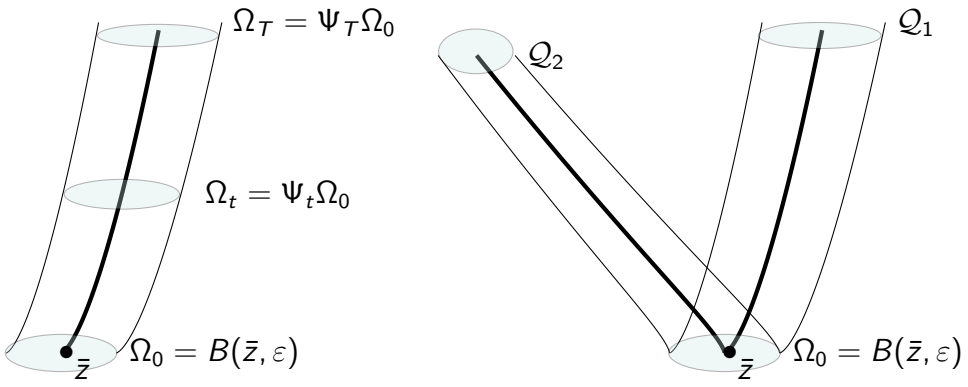
Solving Heisenberg Equations for Long-Time Evolution

Let us consider Hamiltonian trajectory $z(t)$ with $z(0) = \bar{z}$ and the evolution of $\Omega_0 = B(0, \varepsilon)$. Our analysis will deal only with the Hamiltonian tube

$$\mathcal{Q} := \bigcup_{0 \le t \le T} \Psi_t \Omega_0$$

where $\Omega_0 = B(\bar{z}, \varepsilon)$. We want to estimate q_n^t and their derivatives as $z \in \Omega_t$ but we are going to deal with $r_n^t := q_n^t \circ \Psi_t$ in Ω_0.

We assume that Hamiltonian flow Ψ_t satisfies (2.4.27)–(2.4.30). As a^s is scalar we have $r_0^t = q_0^0$. In the general case however formula is (2.4.18) and



(a) (b)

Figure 2.9: Hamiltonian tubes: in (a) for $D_t - \lambda(x, D_x)$, and in (b) for $D_t - A(x, D_x)$ with eigenvalues of $a(x, \xi)$ of constant mutiplicities.

we need to estimate derivatives of $R_{t,t}$; Recall that since a^s is Hermitian, $R_{t,t'}$ is unitary. Assuming that

$$\|D^\alpha_{x,\xi} a^s\| \le C\mu\omega\rho^{-1-|\alpha|} \qquad \forall \alpha : 1 \le |\alpha| \tag{2.4.36}$$

and

$$\mu T \ge 1, \quad \omega \ge 1, \quad \rho \le 1 \tag{2.4.37}$$

we conclude that

$$\|D^\alpha_{x,\xi}(a^s \circ \Psi_t)\| \le C\mu\rho^{-2}\omega^2\eta^{1-|\alpha|} \qquad \forall \alpha : 1 \le |\alpha| \tag{2.4.38}$$

and then repeating in the simplified way proof of Lemma 2.4.5 we arrive to

Lemma 2.4.7. *In the framework of Lemma 2.4.5 assume that* (2.4.35) *and* (2.4.37) *are fulfilled. Further, let a^s be a Hermitian symbol satisfying* (2.4.36) *(in the Hamiltonian tube $\mathcal{Q}$). Then*

$$\|D^\alpha_{x,\xi} R_{t,t'}\| \le C\eta^{-|\alpha|} \qquad \forall (x,\xi) \in \Omega_{t'}\ \forall t, t' \in [0, T]\ \forall \alpha. \tag{2.4.39}$$

Therefore we arrive to

Corollary 2.4.8. *In the framework of Lemma 2.4.7 $q_0^t \circ \Psi_t$ satisfies*

$$\|D^\gamma_{x,\xi}(q_0^t \circ \Psi_t)\| \le C\varepsilon^{-1}\varsigma^{1-|\gamma|} \tag{2.4.40}$$
$$\forall (x,\xi) \in \Omega_0\ \forall t \in [0, T]\ \forall \gamma : 1 \le |\gamma|$$

with

$$\varsigma = \min(\varepsilon, \eta). \tag{2.4.41}$$

Consider now equation $(2.4.8)_n$ defining q_n with $n \ge 1$; one can rewrite it as

$$\partial_t r_n^t + i[a^s \circ \Psi_t, r_n^t] = f_n^t := \sum_{\substack{0\le k\le n-1\\ j+|\alpha|+|\beta|=n-k}} \frac{1}{2^{|\alpha|+|\beta|}\alpha!\beta!}\bigl((-i)^{|\alpha|-|\beta|}A_{j(\beta)}^{(\alpha)}q_{k(\alpha)}^{t(\beta)} - i^{|\alpha|-|\beta|}q_{k(\alpha)}^{t(\beta)}A_{j(\beta)}^{(\alpha)}\bigr)\circ\Psi_t \tag{2.4.42}$$

with the initial condition $r_n^0 = q_n^0$; observe that we can rewrite (2.4.42) as

$$\partial_t\bigl(R_t^{-1}(q_n^t\circ\Psi_t)R_t\bigr) = R_t^{-1}f_n^tR_t. \tag{2.4.43}$$

Further, we can rewrite $q_{k(\beta)}^{t(\alpha)}\circ\Psi_t$ as the sum of $b_{\alpha,\beta;\alpha',\beta'}D_{x,\xi}^{\alpha',\beta'}(q_k^t\circ\Psi_t)$ with $1\le|\alpha'|+|\beta'|\le|\alpha|+|\beta|$ and with the the coefficients satisfying

$$\|D_{x,\xi}^{\gamma}b_{\alpha,\beta;\alpha',\beta'}\| \le C\omega^{|\alpha|+|\beta|+|\gamma|}\eta^{-|\gamma|-|\alpha|-|\beta|+|\alpha'|+|\beta'|}. \tag{2.4.44}$$

Meanwhile

$$\|D_{x,\xi}^{\gamma}\bigl(A_{k(\beta)}^{(\alpha)}\circ\Psi_t\bigr)\| \le C\mu\omega^k\eta^{-|\gamma|}\rho^{-k-|\alpha|-|\beta|} \tag{2.4.45}$$

provided we assumed that

$$\|A_{k(\beta)}^{(\alpha)}\| \le C\mu\omega^k\rho^{-k-|\alpha|-|\beta|} \tag{2.4.46}$$

in the respective range of α,β,γ,k. Then the induction with respect to n yields

Proposition 2.4.9. *Let $\Psi_t:\mathbb{R}^d\to\mathbb{R}^d$ be a Hamiltonian flow defined by a. Let us assume that in the Hamiltonian tube $\mathcal{Q}$ conditions* (2.4.35) *and* (2.4.29) *are fulfilled with ρ and $\omega\ge 1$ satisfying* (2.4.30) *and* (2.4.37).

Further, let us assume that in the Hamiltonian tube $\mathcal{Q}$ all terms of Weyl symbol of A satisfy (2.4.46) *and that $q^0\in \mathsf{S}_{h,\varepsilon,\varepsilon}$. Then for all n*

$$\|D_{x,\xi}^{\gamma}(q_n^t\circ\Psi_t)\| \le C(\mu T\rho^{-2})^n\varsigma^{-2n-|\gamma|} \qquad \forall(x,\xi)\in\Omega_0\ \forall t\in[0,T]\ \forall k,\gamma. \tag{2.4.47}$$

Proof. Assuming that (2.4.47) is fulfilled for $k < n$ we conclude that

$$\|D^{\gamma}_{x,\xi} f^t_n\| \le C\mu\rho^{-2}\varsigma^{-2n-|\gamma|} \tag{2.4.48}$$

which due to Lemma 2.4.7 implies (2.4.47). □

It follows from (2.4.47) and Lemma 2.4.5 that

$$\|D^{\gamma}_{x,\xi} q^t_n\| \le C(\mu T\rho^{-2})^n \varsigma^{-2n-|\gamma|}\omega^{|\gamma|} \qquad \forall (x,\xi)\in\Omega_t\ \forall t\in[0,T]\ \forall k,\gamma. \tag{2.4.49}$$

To have $\sum_n q^t_n h^n$ decaying we need to assume

$$\varsigma \ge (\mu T)^{1/2}\rho^{-1}h^{(1-\delta)/2} \tag{2.4.50}$$

and to perform quantization we need

$$\varsigma \ge \omega h^{(1-\delta)/2}; \tag{2.4.51}$$

plugging $\varsigma = \varepsilon$ and $\varsigma = \eta$ in both we get

$$\varepsilon \ge \max\bigl((\mu T)^{1/2}\rho^{-1},\omega\bigr)h^{(1-\delta)/2} \tag{2.4.52}$$

and

$$\rho \ge (\mu T)^{1/2}\max\bigl(\omega^{2/3}h^{(1-\delta)/6}, \omega^{3/2}h^{(1-\delta)/4}\bigr); \tag{2.4.53}$$

Thus we (almost) proved

Theorem 2.4.10. *Let $A \in \mu\rho\boldsymbol{\Psi}_{h,\cdot,\cdot}(\mathbb{R}^d,\mathbb{H},\mathbb{H})$ be a self-adjoint operator with the scalar principal symbol satisfying in the Hamiltonian tube $\mathcal{Q}$ conditions* (2.4.29), (2.4.35), (2.4.46) *with ρ and $\omega \ge 1$ satisfying* (2.4.30), (2.4.37) *and* (2.4.53).

Let $q^0 \in \mathsf{S}_{h,\varepsilon,\varepsilon}$ be supported in Ω_0 with ε satisfying (2.4.52). *Let q^t be a symbol described in Proposition 2.4.9.*

Then for $t\in[0,T]$ operator $Q^t = \mathsf{Op}^{\mathsf{w}}(q^t)$ satisfies

$$\|Q^t - e^{-ih^{-1}tA}Q^0 e^{ih^{-1}tA}\| \le C\mu T h^s. \tag{2.4.54}$$

Remark 2.4.11. As we consider $\mathsf{S}_{h,\cdot,\cdot,N}$ and $\boldsymbol{\Psi}_{h,\cdot,N}$ with finite N one should take $s = \delta'(\delta)N$ where $\delta' > 0$ as $\delta > 0$.

Proof of Theorem 2.4.10. Obviously

$$\|\partial_t Q^t + ih^{-1}[A, Q^t]\| \le C\mu h^s$$

which is equivalent to

$$\|\partial_t(e^{ih^{-1}tA} Q^t e^{-ih^{-1}tA})\| \le C\mu h^s$$

because the operator A is self-adjoint.

On the other hand, $\|Q^0 - Q\| \le Ch^s$. Then

$$\|e^{ih^{-1}tA} Q^t e^{-ih^{-1}tA} - Q^0\| \le C\mu T h^s$$

(note that $\mu T \ge 1$) which is equivalent to (2.4.54). □

2.4.2 Propagation of Singularities

Scalar Principal Symbol Case

Theorem 2.4.10 immediately implies

Theorem 2.4.12. *Let $A \in \mu\rho \boldsymbol{\Psi}_{h,.,.}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ be a self-adjoint operator with the scalar principal symbol satisfying in the Hamiltonian tube $\mathcal{Q}$ conditions* (2.4.29), (2.4.35), (2.4.46) *with ρ and $\omega \ge 1$ satisfying* (2.4.30), (2.4.37) *and* (2.4.53). *Let ε satisfy* (2.4.52).

Let us assume that <u>*either*</u>

(a) $q \in \mathsf{S}_{h,\varepsilon,\varepsilon}$ is supported in Ω_0, $q' \in \mathsf{S}_{h,\varsigma/\omega,\varsigma/\omega}$ and for some $t = t^* \in [0, T]$

$$\mathsf{dist}(z', \Psi_t(z)) \ge \epsilon\varsigma/\omega \qquad \forall z \in \mathsf{supp}(q)\ \forall z' \in \mathsf{supp}(q') \tag{2.4.55}$$

<u>*or*</u>

(b) The assumptions of (a) are fulfilled with permuted q and q' and Ψ_t replaced by Ψ_{-t}.

Then

(i) For for $t = t^* \in [0, T]$, $Q = \mathsf{Op}(q)$ and $Q' = \mathsf{Op}(q')$ the following inequality holds:

$$\|Qe^{ih^{-1}tA} Q'\| \le C\mu T h^s \tag{2.4.56}$$

(ii) Moreover, let $U(x, y, t)$ be the Schwartz kernel of $e^{ih^{-1}tA}$ and $\mathsf{supp}(q) \cup \mathsf{supp}(q') \subset \{|\xi| \le c\}$. Then the following estimate holds:

$$\|Q_x U(., ., t^*)^t Q'_y\| \le C' h^{s-d} T \qquad \forall x, y \in \mathbb{R}^d. \tag{2.4.57}$$

Diagonalization

We need to generalize this Theorem 2.4.12. Namely, we consider operator whose principal symbol is not scalar but whose spectrum in some interval consists of few rather disjoint eigenvalues

$$\mathsf{Spec}\, a(z) \cap [-\tau_1 - \varrho, -\tau_2 + \varrho] = \{\lambda_1(z), \dots, \lambda_m(z)\} \cap [-\tau_1, -\tau_2] \qquad \forall z \in \Omega \tag{2.4.58}$$

and for every j

$$\mathsf{Spec}\, a(z) \cap [\lambda_j(z) - \varrho, \lambda_j(z) + \varrho] = \lambda_j(z) \qquad \forall z \in \mathcal{Q}_j \tag{2.4.59}$$

where λ_j are assumed to be uniformly continuous and $\mathcal{Q}_j = \bigcup_{t\in[0,T]} \Psi_{\lambda_j,t}\Omega_0$ is a Hamiltonian tube generated by λ_j and the lower bound to ϱ will be defined later.

We want to reduce this case to one of Theorem 2.4.12. To do this we need a series of axillary statements.

Proposition 2.4.13. *Let $a \in \mathsf{S}_{h,\gamma,\gamma}$ be Hermitian symbol and the conditions* (2.4.58) *and* (2.4.59) *be fulfilled. Let Ω be simple connected. Then there exist unitary symbols $r(z), r_1(t,z), \dots, r_m(t,z)$ defined in $\Omega, \Omega_1(t), \dots, \Omega_m(t)$ respectively where $\Omega_j(t) = \Psi_{\lambda_j,t}\Omega$ such that*

(i) In Ω

$$r_j(0,z) = r(z) \qquad \forall j = 1, \dots, m, \tag{2.4.60}$$

$$r^\dagger(z)a(z)r(z) = a^0 = \begin{pmatrix} \lambda_1(z)I & \cdots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & \lambda_m(z)I & 0 \\ 0 & \cdots & 0 & a'(z) \end{pmatrix}, \tag{2.4.61}$$

and

$$\mathsf{Spec}\, a'(z) \cap [\lambda_j(z) - \frac{\varrho}{2}, \lambda_j(z) + \frac{\varrho}{2}] = \emptyset \qquad \forall j = 1, \dots, m \tag{2.4.62}$$

(ii) and, moreover, for every j in $\Omega_j(t)$

$$r_j^\dagger(t,z)a(z)r_j(t,z) = a^0_{j,t} = \begin{pmatrix} b_j'(t,z) & 0 & b_j''(t,z) \\ 0 & \lambda_j(z) & 0 \\ b_j'''(t,z) & 0 & b_j^{IV}(t,z) \end{pmatrix}, \tag{2.4.63}$$

$$\mathsf{Spec}\, a_j'(t,z) \cap [\lambda_j(z) - \frac{\varrho}{2}, \lambda_j(z) + \frac{\varrho}{2}] = \emptyset \tag{2.4.64}$$

with

$$a'_j(t,z) = \begin{pmatrix} b'_j(t,z) & b''_j(t,z) \\ b'''_j(t,z) & b^{IV}_j(t,z) \end{pmatrix}$$

and

$$\|\partial_t^k r^{(\alpha)}_{j(\beta)}\| \le C\varrho^{-|\alpha|-|\beta|-k}\gamma^{-|\alpha|-|\beta|-2k} \qquad \forall \alpha,\beta,k. \tag{2.4.65}$$

Proof. Let us define

$$\pi_j(z) = \frac{1}{2\pi i}\int_{\ell_j} (\zeta - a(z))^{-1}\, d\zeta \tag{2.4.66}$$

for $z \in \Omega_j(t)$ where ℓ_j is a closed smooth curve contained in the ring $\{\frac{1}{8}\gamma \le |\zeta - \lambda_j(z)| \le \frac{1}{4}\gamma\} \subset \mathbb{C}$ and going one time around $\lambda_j(z)$ in the counter-clockwise direction; then $\pi_j(z)$ is the orthogonal projector to the eigenspace of $a(z)$ corresponding to the eigenvalue $\lambda_j(z)$. Here we used condition (2.4.59).

Then in $\Omega_j(t)$ symbol $\pi(z)$ satisfies (2.4.65); here we used conditions (2.4.59) again and an assumption that $a \in \mathsf{S}_{h,\gamma,\gamma}$. Then one can find $r, r_j(t)$ satisfying (2.4.65) with $k = 0$.

It should be noted that the periodicity or approximate periodicity of some trajectories of the Hamiltonian flows would make $\mathcal{Q}_j$ not simple connected possibly prevent the existence of r_j not depending on t. However it would not happen during time $T \asymp \gamma^2\varrho$. Indeed, we can replace Ω by its $\gamma\varrho$-vicinity and note that the speed does not exceed $c\gamma^{-1}$.

This implies statement of Proposition. □

So, we proved that symbols $r, r_j \in \mathsf{S}_{h,\rho,\rho}$ with $\rho = \gamma\varrho$; therefore we need to assume that

$$\rho = \gamma\varrho \ge h^{(1-\delta)/2}. \tag{2.4.67}$$

Proposition 2.4.14. *In the framework of Proposition 2.4.13 assume that condition* (2.4.67) *is fulfilled. Further, let* $a' \in \nu\mathsf{S}_{h,\gamma,\gamma}$ *with*

$$h(\gamma\varrho)^{-2} \le \nu \le \varrho h^{\delta}. \tag{2.4.68}$$

Then there exist symbols $r, r_{1t}, \dots, r_{mt} \in \mathsf{S}_{h,\rho,\rho}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *satisfying* (2.4.60) *and such that* $\gamma^{2k}\varrho^k\partial_t^k r_{j,t} \in \mathsf{S}_{h,\rho,\rho}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$, $\forall k$, *with* $\rho = \gamma\varrho$ *and the corresponding norms of these operators do not exceed* C, *and*

(i) Modulo operators with symbols vanishing in Ω

$$R^*R \equiv RR^* \equiv I, \tag{2.4.69}$$

$$R^*AR \equiv \begin{pmatrix} A_1 I & \dots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \dots & A_m I & 0 \\ 0 & \dots & 0 & A' \end{pmatrix} \tag{2.4.70}$$

(ii) and modulo operators with symbols vanishing in $\Omega_j(t)$

$$R^*_{j,t}R_{j,t} \equiv R_{j,t}R^*_{j,t} \equiv I, \tag{2.4.71}$$

$$-ihR^*_{j,t}(\partial_t R_{j,t}) + R^*_{j,t}AR_{j,t} \equiv \begin{pmatrix} B'_{j,t} & 0 & B''_{j,t} \\ 0 & A_{j,t} & 0 \\ B'''_{j,t} & 0 & B^{IV}_{j,t} \end{pmatrix} \tag{2.4.72}$$

where $R_{j,t} = \mathsf{Op}(r_{j,t})$, $R = \mathsf{Op}(r)$ *and*

(2.4.73) *Symbols of operators* $A_{j,t}, A', B'_{j,t}, \dots, B^{IV}_{j,t}$ *are equal to* $\lambda_j I, a', b'_{j,t}, \dots, b^{IV}_{j,t}$ *modulo* $\nu S_{h,\rho,\rho}$.

Proof. Let us use induction with respect to n:

$$V \in \nu^n \varrho^{1-n} \mathsf{S}_{h,\rho,\rho}(\Omega, \mathbb{H}, \mathbb{H}) \tag{2.4.74}$$

and

$$\partial_t^k V_{j,t} \in \gamma^{-2k}\gamma^{-2k}\nu^n \varrho^{1-n-k} \mathsf{S}_{h,\rho,\rho}(\Omega_j(t), \mathbb{H}, \mathbb{H}) \tag{2.4.75}$$

where V and $V_{j,t}$ are the differences between the symbols of the left-hand and right hand expressions in (2.4.70) and (2.4.72) respectively while (2.4.69) and (2.4.71) are assumed to be fulfilled with much higher precision.

Proposition 2.4.13 implies this assertion for $n = 1$ as long as $\nu \ge h/(\gamma\varrho)^2$.

In order to make the induction step it is sufficient to construct Hermitian symbols I and $I_{j,t}$ satisfying (2.4.60), (2.4.74), (2.4.75) [27], and

$$[I, a^0] = -iV \qquad \text{in } \Omega, \tag{2.4.76}$$

[27] So we plug $r = I$ etc in these equations.

and

$$[I_{j,t}, a^0_{j,t}] = -iV_{j,t} \qquad \text{in } \Omega_j(t) \tag{2.4.77}$$

where a^0 and $a^0_{j,t}$ are defined by (2.4.61) and (2.4.63) respectively.

Indeed, let us replace $R_{j,t}$ by $R_{j,t}(I + iL_{j,t})(I + L'_{j,t})$ with $L_{j,t} = \mathsf{Op}(l_{j,t})$, $L'_{j,t} = \mathsf{Op}(l'_{j,t})$ with Hermitian symbols $l'_{j,t}$ satisfying (2.4.63) with n replaced by $(n+1)$ and providing (2.4.71) after the induction step; then one needs to pick up $L'_{j,t} = -\frac{1}{2}L^*_{j,t}L_{j,t}$.

Moreover, let us replace R by $R(I + iL)(I + L')$ with $L' = -\frac{1}{2}L^*L$; then the induction step will be made obviously.

On the other hand, the construction of I and $I_{j,t}$ satisfying (2.4.76) and (2.4.77) is obvious and, moreover, Hermitian symbols I with diagonal blocks equal to 0 and $I_{j,t}$ of the form

$$I_{j,t} = \begin{pmatrix} 0 & * & 0 \\ * & 0 & * \\ 0 & * & 0 \end{pmatrix}$$

are uniquely defined from (2.4.76) and (2.4.77). □

Heisenberg Evolution for Matrix Principal Symbols

Let us introduce the operators $\tilde{R}_{j,t} = R_{j,t}\pi_j$, $\tilde{R}_j = R\pi_j$ where π_j are projectors corresponding to the block decomposition in (2.4.61) and $j = 1, \dots, m+1$. Then (2.4.69) and (2.4.70) imply that

$$\tilde{R}^*_j \tilde{R}_k \equiv \delta_{jk} I \qquad \text{in } \Omega \quad (j, k = 1, \dots, m+1), \tag{2.4.78}$$

$$\tilde{R}^*_{j,t} \tilde{R}_{j,t} \equiv I \qquad \text{in } \Omega_j(t) \quad (j = 1, \dots, m+1), \tag{2.4.79}$$

$$A\tilde{R}_j \equiv A_j \tilde{R}_j \qquad \text{in } \Omega \quad (j = 1, \dots, m+1), \tag{2.4.80}$$

and

$$A\tilde{R}_{j,t} - ih^{-1}[A_{j,t}, Q_{j,t}] \equiv \tilde{R}_{j,t} A_{j,t} \qquad \text{in } \Omega_j(t) \quad (j = 1, \dots, m) \tag{2.4.81}$$

with $A_{m+1} = A'$ and $Q_{j,t} = e^{-ih^{-1}tA_j} Q^0 e^{ih^{-1}tA_j}$.

Let us consider Cauchy problem (2.4.6)–(2.4.7) for A_j. Then in order to fit into theory of the previous Subsection 2.4.1, conditions (2.4.30), (2.4.32),

(2.4.37), (2.4.41), (2.4.52) and (2.4.53) must be fulfilled with $\mu = \rho^{-1}$ and $\rho = \gamma\varrho$:

$$T \ge \max(\omega^{-1}, \varrho\gamma), \quad \omega \ge 1, \quad \varrho\gamma \le 1, \tag{2.4.82}$$

$$\eta = \varrho^3\gamma^3\omega^{-2}T^{-1}, \quad \varsigma = \min(\varepsilon, \eta), \tag{2.4.83}$$

$$\varepsilon \ge \max\bigl((\varrho^{-3}\gamma^{-3}T)^{1/2}, \omega\bigr)h^{(1-\delta)/2}, \tag{2.4.84}$$

$$\varrho\gamma \ge T^{1/3}\max\bigl(\omega^{4/9}h^{(1-\delta)/9}, \omega h^{(1-\delta)/6}\bigr) \tag{2.4.85}$$

while ν satisfies (2.4.68) and also the following version of (2.4.38)

$$\nu \le \min\bigl(\varrho h^{\delta}, \omega\varrho^{-1}\gamma^{-1}h\bigr), \tag{2.4.86}$$

$\nu = h(\gamma\varrho)^{-2}$ shouls also fit into this last inequality

$$\omega\gamma\varrho \ge 1, \quad \gamma^2\varrho^3 \ge h^{1-\delta}. \tag{2.4.87}$$

Then Theorem 2.4.10 yields the following

Proposition 2.4.15. *Let $a \in \mathsf{S}_{h,\gamma,\gamma}$* [28] *be Hermitian symbol and the conditions* (2.4.58), (2.4.59) *be fulfilled. Let A be a self-adjoint operator and $A - \mathsf{Op}^w(a) \in \nu\mathsf{S}_{h,\gamma,\gamma}$. Let domain Ω be simple connected. Further, let conditions* (2.4.29) *and* (2.4.82)–(2.4.87) *be fulfilled. Finally, let*

$$Q_j = \tilde{R}_j Q \tilde{R}_j^* \qquad (j = 1, \dots, m) \tag{2.4.88}$$

and let $Q_{j,t}$ be a solution of (2.4.81) *with initial data $Q_{j,0} = Q_j$. Then*

$$\|Q_j^t - e^{-ih^{-1}tA}Qe^{ih^{-1}tA}\| \le Ch^s T \tag{2.4.89}$$

for $Q_j^t = \tilde{R}_{j,t}Q_{j,t}\tilde{R}_{j,t}^*$.

As $m = 1$ and we are interested in the left-hand expression of (2.4.90) only we get

Corollary 2.4.16. *Let conditions of Proposition 2.4.15 be fulfilled with $m = 1$. Then*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\bigl(Q^t e^{-ih^{-1}tA} - e^{-ih^{-1}tA}Q\bigr)\| \le Ch^s \qquad \forall \tau \in [\tau_1, \tau_2] \tag{2.4.90}$$

where χ is our standard function supported in <u>either</u> $[-1, 1]$ <u>or</u> $[-1, 0]$ <u>or</u> $[0, -1]$ as conditions of Proposition 2.4.15 are fulfilled <u>either</u> for all $t \in [-T, T]$ <u>or</u> for all $t \in [-T, 0]$ <u>or</u> for all $t \in [0, T]$ respectively and $Q^t = Q_1^t = \tilde{R}_{1,t}Q_{1,t}\tilde{R}_{1,t}^*$.

[28] All conditions need to be fulfilled only in $\mathcal{Q}_j$.

Main Theorem

Theorem 2.4.17. *Let* $a \in \mathsf{S}_{h,\gamma,\gamma}$ [28] *be Hermitian symbol and the conditions* (2.4.58), (2.4.59) *be fulfilled. Let* A *be a self-adjoint operator and* $A - \mathsf{Op}^w(a) \in \nu \mathsf{S}_{h,\gamma,\gamma}$ [28]. *Let domain* Ω *be simple connected. Further, let conditions* (2.4.29) *and* (2.4.82)–(2.4.87) *be fulfilled.*

Furthermore let us assume that <u>*either*</u>

(a) $q \in \mathsf{S}_{h,\varepsilon,\varepsilon}$ *is supported in* Ω_0, $q' \in \mathsf{S}_{h,\varsigma/\omega,\varsigma/\omega}$ *and for* $t \in [t^* - \kappa, t^* + \kappa] \subset [0, T]$ *condition*

$$\mathsf{dist}(z', \Psi_t(z)) \geq \varsigma/\omega \qquad \forall z \in \mathsf{supp}(q)\ \forall z' \in \mathsf{supp}(q') \tag{2.4.91}$$

is fulfilled for Hamiltonian flows generated by λ_j *for all* $j = 1, \dots, m$ <u>*or*</u>

(b) The assumptions of (a) are fulfilled with permuted q *and* q' *and* $\Psi_{\lambda_j,t}$ *replaced by* $\Psi_{\lambda_j,-t}$.

Finally, let $U(x, y, t)$ *be the Schwartz kernel of* $e^{ih^{-1}tA}$; *assume that* $\mathsf{supp}(q) \cup \mathsf{supp}(q') \subset \{|\xi| \leq c\}$, $\chi \in \mathscr{C}^\infty([-1, 1])$ *and*

$$\kappa\varrho \geq h^{1-\delta}. \tag{2.4.92}$$

Then the following estimate holds:

$$\|F_{t\to h^{-1}\tau}\chi_{\kappa/2}(t - t^*)Q_x U(t, ., .)\, {}^tQ'_y\| \leq C' h^s \qquad \forall x, y \in \mathbb{R}^d \quad \forall \tau \in [\tau_1, \tau_2] \tag{2.4.93}$$

Proof. Assume that we are in the framework of assumption (a) (the other case is considered similarly).

Theorem 2.4.12 microlocalizes $e^{ih^{-1}tA_j}Q$ in $\Psi_{\lambda_j,t}(\mathsf{supp}(q))$ and equality (2.4.80) is fulfilled in its vicinity. Therefore modulo negligible

$$e^{ih^{-1}tA}\tilde{R}_j Q'' \equiv e^{ih^{-1}tA_j}\tilde{R}_j Q'' \qquad \forall j = 1, \dots, m \tag{2.4.94}$$

as long as $0 \leq t \leq T$ and Q'' has a symbol supported in vicinity of $\mathsf{supp}(q)$. Recall that if we are looking for energy levels $\tau \in [\tau_1, \tau_2]$

$$\Psi_t(z) = \bigcup_{j=1,\dots,m} \Psi_{\lambda_j,t}(z) \tag{2.4.95}$$

Therefore in virtue of Theorem 2.4.12 estimate (2.4.93) holds for $U_j(x,y,t)$, the Schwartz kernels of $e^{ih^{-1}tA}\tilde{R}_j$ with $1 \le j \le m$.

Next, using ellipticity of A_{m+1} on energy levels $\tau \in [\tau_1, \tau_2]$ in the vicinity of $\mathsf{supp}(q)$ we conclude that (2.4.93) holds $j = m+1$ as well.

Finally these results combined with

$$\sum_{j=1,\dots,m+1} \tilde{R}_j \tilde{R}_j^* Q \equiv Q \tag{2.4.96}$$

imply (2.4.93). □

Comments

Theorem 2.1.2 was first proven for wave front sets in V. Ivrii [1]. Theorem 2.3.2 was first proven under steally more restrictive conditions in M. Bronstein, V. Ivrii [1].

The description of propagation of singularities in terms of generalized bicharacteristics is due to S. Wakabayashi [2].

Similar and also different results for equations with multiple characteristics could be found in V. Ivrii [4], [5]. Pseudoconvexity method based on the second commutators to study propagation of singularities was used in V. Ivrii [9].

For wave front sets there is a paper due to A. Volovoi [1] where a parametrix construction by means of Fourier integral operators for long bicharacteristics was examined very carefully; his approach is essentially more complicated. Moreover in standard microlocal analysis (when there is no exterior parameter such as h or a frequency) these results are senseless.

D. Robert [5], D. Robert and M. Combescure [1] used coherent states to describe a long term propagation.

The more detailed description of singularities can be made using polarization wave front sets:

Definition 2.4.18. Let $\|u\| = O(h^{s-\delta})$. Then

$$\mathsf{PWF}^s(u) = \Big\{(x,\xi;v) \in T^*\mathbb{R}^d \times \mathbb{H} : v \in \mathsf{Ker}\, q_0(x,\xi) \\ \forall q \in \mathbf{\Psi}_h \ \text{ such that } \ \|qu\| = O(h^s)\Big\}$$

is called *polarization wave front set*.

Description of polarization wave front sets for systems with constant multiplicities of characteristics follows from our results: their (x, ξ) components travel along bicharacteristics and their v components belongs to $\mathsf{Ker}\, P_0(x, \xi)$ and "rotates". The definition of polarization wave front set is due to N. Dencker, who also investigated propagation of them not only in the case of characteristics of constant multiplicities, but also in the framework of conical refraction [1] and [3], [4].

Chapter 3

Propagation of Singularities near the Boundary

In this chapter we perform the same task as in the previous Chapter 2 but near the smooth boundary. In Section 3.1 we prove Theorem 3.1.7 which is the main theorem of the energy estimates method and is formulated in the terms of some auxiliary functions exactly as Theorem 2.1.2 was. However the phase space T^*X is "glued" at the boundary ∂X and we really need several such auxiliary functions and the notion of the microhyperbolicity of the operator in the direction is replaced by the notion of the microhyperbolicity of the boundary value problem in the multidirection.

In Section 3.2 we prove Theorem 3.2.4 which is the geometric reincarnation of Theorem 3.1.7 exactly like Theorem 2.2.10 was the the geometric reincarnation of Theorem 2.1.2. However geometric picture becomes much more complicated even in the case of the scalar operators.

In Section 3.3 we prove some statements similar to those of the second part of sSection 2.1.

Theorem 3.2.4 is not very precise: for example it cannot exclude creeping rays even in the case of wave equation. So, in sSection 3.4 we reinvent the energy estimates method and prove (under much more restrictive assumptions) Theorems 3.4.4 and 3.4.5 which improve Theorem 3.1.7 and in combination with it provide in some cases more precise description of the propagation.

Finally, in Section 3.5 we study propagation of singularities along long bicharacteristic billiards which are "almost transversal to the boundary" and may contain large number of reflections (even with branching); this section is similar to Section 2.4.

3.1 Energy Estimates Approach

3.1.1 Statement of the Main Theorem

Preliminary Notes

In this section our geometric domain is $X = \mathbb{R}^+ \times X' = \mathbb{R}^+ \times \mathbb{R}^{d-1} \ni (x_1; x') = (x_1; x_2, \dots, x_d)$ with the boundary $\partial X = 0 \times X'$ and interior $\dot{X} = X \setminus \partial X$. We consider the operator

$$P = \sum_{0 \le k \le m} A_k(x, hD')(hD_1)^{m-k} \tag{3.1.1}$$

where

$$A_k \in \mathbf{\Psi}'_{h,N}(X, \mathbb{H}, \mathbb{H}) = \bigcap_{0 \le j \le N} \mathscr{C}^j_b\big(\mathbb{R}^+, \mathbf{\Psi}_{h,N-j}(X', \mathbb{H}, \mathbb{H})\big). \tag{3.1.2}$$

Let $a_k(x, \xi')$ and

$$p(x, \xi) = \sum_{0 \le k \le m} a_k(x, \xi')\xi_1^{m-k} \tag{3.1.3}$$

be the principal symbols of A_k and P respectively. We assume that

(3.1.4) $p(z)$ is a Hermitian matrix for every $z \in T^*X$,

i.e., that the system in question is *symmetric in the principal*.

Let $\Omega \Subset T^*X$, $\Omega' \Subset T^*\partial X$, $\Omega|_{\partial X} = \iota^{-1}\Omega'$ [1] and let us assume further that

$$\|a_0(z)w\| \ge \epsilon_0 \|w\| \qquad \forall w \in \mathbb{H} \quad \forall z \in \Omega, \tag{3.1.5}$$

i.e., that *the boundary is not characteristic* in Ω.

Then (3.1.4) yields the equality

$$\langle p(z, D_1)u, v\rangle_+ - \langle u, p(z, D_1)v\rangle_+ = i\langle T(z)\eth u, \eth v\rangle_m \tag{3.1.6}$$
$$\forall z \in T^*\partial X \qquad \forall u, v \in \mathscr{S}(\mathbb{R}^+, \mathbb{H})$$

where $\langle ., . \rangle_+$ and $\langle ., . \rangle_m$ are inner products in $\mathscr{L}^2(\mathbb{R}^+, \mathbb{H})$ and $\mathbb{H}^m$ respectively, $\eth u = \eth_{(m)} u = (u, D_1 u, \dots, D_1^{m-1}u)|_{x_1=0}$ is the m-trace of u at ∂X and $T(z) \in$

[1] Recall that $\iota : T^*X|_{\partial x} \to T^*\partial X$ is a natural map.

$\mathcal{L}(\mathbb{H}^m, \mathbb{H}^m)$ is a matrix with blocks

$$T_{jk}(z) = \begin{cases} a_{m-j-k-1} & \text{for } j+k \le m+1 \\ 0 & \text{for } j+k \ge m+2 \end{cases} \qquad j,k = 1,\dots,m \tag{3.1.7}$$

i.e.,

$$T(z) = \begin{pmatrix} a_{m-1} & a_{m-2} & \dots & a_1 & a_0 \\ a_{m-2} & a_{m-3} & \dots & a_0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ a_1 & a_0 & \dots & 0 & 0 \\ a_0 & 0 & \dots & 0 & 0 \end{pmatrix}.$$

Then equality (3.1.6) implies the estimate

$$\|T(z)\underline{w}\| \ge \epsilon \|\underline{w}\| \qquad \forall \underline{w} \in \mathbb{H}^m \quad \forall z \in \Omega' \tag{3.1.8}$$

with a constant $\epsilon = \epsilon(m, c, \epsilon_0, c_2) > 0$, $c_2 = \max_{1\le k\le m} \sup_{z\in\Omega} \|a_k(z)\|$. Without any loss of the generality we may replace ϵ by ϵ_0.

Let $B = (B_1, \dots, B_m)$ be a boundary operator, $B_k \in \mathbf{\Psi}_{h,N-k}(\partial X, \mathbb{H}_b, \mathbb{H})$ where $\mathbb{H}_b$ is another auxiliary Hilbert space with an inner product $\langle .,. \rangle_b$ and a norm $\|.\|_b$.

Let us assume that there exist symbols $\beta_k \in \mathscr{C}_b^N(\partial X, \mathcal{L}(\mathbb{H}_b, \mathbb{H}))$ and $\beta = (\beta_1, \dots, \beta_m)$ such that

$$\langle T(z)\underline{w}, \underline{w}\rangle_m + 2\,\mathrm{Re}\,\langle b(z)\underline{w}, \beta(z)\underline{w}\rangle_b \le 0 \qquad \forall \underline{w} \in \mathbb{H}^m \quad \forall z \in \Omega' \tag{3.1.9}$$

where b_k and b are the principal symbols of B_k and B respectively; in this case the boundary value problem (P, B) is called *dissipative* in Ω'. Moreover, if

$$\langle T(z)\underline{w}, \underline{w}\rangle_m + 2\,\mathrm{Re}\,\langle b(z)\underline{w}, \beta(z)\underline{w}\rangle_b \le -\epsilon_0\|\underline{w}\|^2 \qquad \forall \underline{w} \in \mathbb{H}^m \quad \forall z \in \Omega' \tag{3.1.9}^*$$

then the boundary value problem (P, B) is called *strictly dissipative* in Ω'.

In what follows the most important case is $\mathbb{H} = \mathbb{C}^{\mathsf{D}}$; one can easily prove then that if $\mathsf{D}_\pm$ and $\bar{\mathsf{D}}_\pm$ are the numbers of positive (negative) eigenvalues of the matrices a_0 and T respectively then equality (3.1.6) yields that

$$\bar{\mathsf{D}}_\pm = \begin{cases} \dfrac{1}{2} m\mathsf{D} & \text{for even } m, \\ \dfrac{1}{2}(m-1)\mathsf{D} + \mathsf{D}_\pm & \text{for odd } m. \end{cases} \tag{3.1.10}$$

Moreover, the most important case is $\mathbb{H}_b = \mathbb{C}^{\bar{\mathsf{D}}_+}$ when condition (3.1.9) is equivalent to the pair of conditions

$$\operatorname{rank} b(z) = \bar{\mathsf{D}}_+ \qquad \forall z \in \bar{\Omega}' \tag{3.1.11}$$

and

$$\langle T(z)\underline{w}, \underline{w}\rangle_m \le 0 \qquad \forall \underline{w} \in \operatorname{Ker} b(z) \quad \forall z \in \bar{\Omega}'. \tag{3.1.12}$$

Furthermore, condition (3.1.9)* is equivalent to (3.1.11) and

$$\langle T(z)\underline{w}, \underline{w}\rangle_m \le -\epsilon_0\|\underline{w}\|^2 \qquad \forall \underline{w} \in \operatorname{Ker} b(z) \quad \forall z \in \bar{\Omega}'. \tag{3.1.12*}$$

Let us notice that (3.1.6) implies that

$$|\eta|^m\|w\| \le C(\|p(z,\eta)w\| + \|w\|) \qquad \forall w \in \mathbb{H} \quad \forall z \in \Omega' \quad \forall \eta \in \mathbb{R}. \tag{3.1.13}$$

Let $\Sigma_\rho = \Sigma_\rho(P)$ be the set of all the points $z \in T^*X$ at which the ellipticity condition

$$\|p(z)w\| \ge \rho\|w\| \qquad \forall w \in \mathbb{H} \tag{3.1.14}$$

is violated; here and below $\rho > 0$ is an arbitrarily small constant.

Further, let $\Sigma'_\rho = \iota\Sigma_\rho|_{\partial X}$ be the set of all the points $z \in \Omega'$ at which the ellipticity condition

$$\|p(z,\eta)w\| \ge \rho\|w\| \qquad \forall w \in \mathbb{H} \quad \forall \eta \in \mathbb{R} \tag{3.1.14$'$}$$

is violated.

For $z = (x', \xi')$ let us introduce the linear space

$$\mathbb{H}'(z) = \{v \in \mathscr{L}^2(\mathbb{R}^+, \mathbb{H}) : p(z, D_1)v = 0\}. \tag{3.1.15}$$

Then for $z \notin \Sigma'_\rho$ the following estimates hold:

$$\|e^{\varkappa x_1} D_1^j v\|_+ \le C_j\|v\|_+ \qquad \forall j \ge 0 \quad \forall v \in \mathbb{H}'(z) \tag{3.1.16}$$

with an appropriate exponent $\varkappa = \varkappa(m, c, c_1, \epsilon_0, \rho) > 0$ and constants $C_j = C_j(m, c, c_1, \epsilon_0, \rho)$.

Furthermore, let us introduce the sets $\Sigma_{b,\rho} = \Sigma_{b,\rho}(P, B)$: $z \in \Sigma_{b,\rho}$ if *either* $z \in \Sigma'_\rho$ *or* the following condition

$$\|b(z)\eth_m v\|_{\mathbb{H}'} \ge \rho\|v\|_+^2 \qquad \forall v \in \mathbb{H}'(z) \tag{3.1.17}$$

is violated.

Finally, let

$$\Sigma = \Sigma(P) = \bigcap_{\rho>0} \Sigma_\rho, \quad \text{and} \quad \Sigma_b = \Sigma_b(P,B) = \bigcap_{\rho>0} \Sigma_{b,\rho}\,; \tag{3.1.18}$$

it is obvious that

(3.1.19) Σ and Σ_b are closed sets and that the space $\mathbb{H}'(z)$ depends continuously (in the natural sense) on $z \in \Omega' \setminus \Sigma'$ where $\Sigma' = \iota\Sigma|_{\partial X}$.

Definition 3.1.1. A point $z \in \Sigma \subset T^*X$ ($z \in T^*X \setminus \Sigma$) is called a *characteristic* (*elliptic* respectively) point of the operator P.

A point $z \in \Sigma_b \subset \Omega'$ ($z \in \Omega' \setminus \Sigma_b$) is called a *characteristic* (*elliptic* respectively) point of the problem (P,B).

By means of standard elliptic arguments of Section 1.4 one can easily prove the following semiclassical result

Theorem 3.1.2. *Let condition* (3.1.6) *be fulfilled,* $N = N(d,s,M,l)$ *and let* u *be temperate in the sense*

$$\|D_1^j u\|_X \le h^{-M} \qquad \forall j = 1,\dots,m+l. \tag{3.1.20}$$

Then

$$\mathsf{WF}_b^{s,m+l}(u) \cap \Omega' \subset \mathsf{WF}_b^{s,l}(Pu) \cup \mathsf{WF}^{s-\frac12}(B\eth_h u) \cup \Sigma_b \tag{3.1.21}$$

where here and in what follows

$$\mathsf{WF}_b^{s,l}(u) \coloneqq \bigcup_{0\le j\le l} \mathsf{WF}^{s-j\,\prime}(D_1^j u)|_{\partial X} \tag{3.1.22}$$

is called the boundary wave front set of order (s,l) of u *and* $\eth_h u = \eth_{h(m)} u = (u, hD_1 u, \dots, (hD_1)^{m-1}u)|_{\partial X}$.

Let us recall that $\mathsf{WF}^{t\,\prime}$ denotes a partial wave front set (see Definition 2.1.8). Later we will prove this theorem. Let us now assume that

$$\begin{aligned} \mathbb{H} =& \mathbb{C}^{\mathsf{D}_1}\otimes\mathbb{H}^0_1 \oplus \dots \oplus \mathbb{C}^{\mathsf{D}_M}\otimes\mathbb{H}^0_M \oplus \mathbb{H}_0 \\ p =& \quad p_1\otimes I_{\mathbb{H}^0_1} \oplus \dots \oplus p_M \otimes \quad I_{\mathbb{H}^0_M} \oplus p_0 \end{aligned} \tag{3.1.23}$$

and

(3.1.24) p_0 on $\mathbb{H}_0$ satisfies condition (3.1.14)$'$ with $\epsilon = \epsilon_0$

where $\mathbb{H}^0_1, \dots, \mathbb{H}^0_M, \mathbb{H}_0$ are auxiliary Hilbert spaces and $p_1, \dots, p_M, p_0$ are symbols on $\mathbb{C}^{D_1}, \dots, \mathbb{C}^{D_M}, \mathbb{H}_0$ respectively.

Then at every point $z \in \Omega'$ the estimate (3.1.16) holds with an appropriate exponent $\varkappa > 0$ and constants C_j depending on $p(z, .)$. Moreover, the space $\mathbb{H}'(z)$ is a lower semicontinuous function of z in the sense of Definition 2.2.2.

Let us introduce the *characteristic polynomial*

$$g(z, \eta) = \det p_1(z, \eta) \cdots \det p_M(z, \eta). \tag{3.1.25}$$

Definition 3.1.3. For $z \in \Omega' \subset T^*\partial X$ let us denote by $\eta_1(z), \dots, \eta_n(z)$ all the real distinct roots of $g(z, \eta)$ where also $n = n(z)$. Then $\mathcal{T} = (\ell', \nu_1, \dots, \nu_n) \in T_z T^*\partial X \times \mathbb{R}^n$ is called *multidirection*.

Definition 3.1.4. Let conditions (3.1.1)–(3.1.6), (3.1.23) and (3.1.9) be fulfilled.

Then the problem (P, B) is *microhyperbolic at the point* $z \in \Omega' \subset T^*\partial X$ *in the multidirection* $\mathcal{T} = (\ell', \nu_1, \dots, \nu_n)$ if the following two conditions are fulfilled:

(i) For every $k = 1, \dots, n$ the operator P is microhyperbolic at the point $z_k = (z, \eta_k)$ in the direction $\ell_k = (\ell, \nu_k, 0) \in T_{z_k}(T^*X|_{\partial X}) \subset (T_{z_k} T^*X)|_{\partial X}$;

(ii) The following estimate holds

$$\begin{aligned} -\operatorname{Re} \langle (\mathcal{T}' p)(z, D_1) v, v \rangle_+ + \operatorname{Re} i \langle (\mathcal{T}' b)(z) \eth v, \beta(z) \eth v \rangle_b \geq \\ \epsilon \|v\|^2_+ - c_1 (c_1 \|b(z) \eth v\|'^2 - \langle T(z) \eth v, \eth v \rangle_m) \qquad \forall v \in \mathbb{H}'(z) \end{aligned} \tag{3.1.26}$$

(compare with estimate (2.1.1) in Definition 2.1.1).

In what follows we will prove the following

Proposition 3.1.5. *Let the problem* (P, B) *be microhyperbolic at the point* z *in the multidirection* $\mathcal{T}$. *Further, let the problem* $(\tilde{P}, \tilde{B})$ *also satisfy conditions* (3.1.1)–(3.1.6), (3.1.23) *and* (3.1.9) *and suppose that*

$$\|\tilde{p} - p\|_{\mathscr{C}^1_b} \leq \varepsilon, \quad \|\tilde{b} - b\|_{\mathscr{C}^1_b} \leq \varepsilon, \quad |\tilde{z} - z| \leq \varepsilon, \ |\tilde{\mathcal{T}} - \mathcal{T}| \leq \varepsilon$$

with a small enough constant $\varepsilon > 0$.

Then the problem $(\tilde{P}, \tilde{B})$ *is also microhyperbolic at the point* $\tilde{z}$ *in the multidirection* $\tilde{\mathcal{T}}$.

Remark 3.1.6. Obviously the structure of $\iota^{-1}\tilde{z}\cap\Sigma(\tilde{P})$ does not necessarily coincide with that of $\iota^{-1}z\cap\Sigma(P)$ and it can happen that $\tilde{n}(\tilde{z})>n(z)$. However one can avoid this difficulty by either of two methods:

(i) If z_{ki} with $i=1,\dots,t_k$ $(t_k\ge 0)$ are points of $\iota^{-1}\tilde{z}\cap\Sigma(\tilde{P})$ close to z_k then the condition $|\tilde{\mathcal{T}}-\mathcal{T}|\le\varepsilon$ is understood in the sense that
$|\tilde{\ell}_{ki}-\ell_k|\le\varepsilon\quad\forall i=1,\dots,l_k\quad\forall k=1,\dots,n$ [2)];

(ii) The condition that η_k $(k=1,\dots,n)$ are all the real roots of $g(z,\eta)$ is replaced by the condition that the set $\{\eta:(z,\eta)\in\Sigma_\epsilon\}$ is contained in the union of the intervals $(\eta_k-\mu,\eta_k+\mu)$ $(k=1,\dots,n)$ where $|\eta_k-\eta_j|\ge 3\mu$ $\forall j\ne k$ and $0<\mu\le\bar{\mu}=\bar{\mu}(c,\epsilon_0,c_1,c_3)$ where ϵ_0 and c_1 are constants from the microhyperbolicity conditions (2.1.1) with z,ℓ replaced by z_k,ℓ_k (with $k=1,\dots,n$), (3.1.6) and (3.1.26), and $c_3=\max_j\|a_j\|_{\mathscr{C}^2_b}+\max_j\|b_j\|_{\mathscr{C}^2_b}$.

In this case $\varepsilon=\varepsilon(d,m,M,\mathrm{D}^*,c,\epsilon_0,c_1,c_2,\epsilon)$, $\mathrm{D}^*=m\max_j\mathrm{D}_j$.

[2)] I.e. $|\tilde{\ell}-\ell|\le\varepsilon$ and $|\tilde{\nu}_{ki}-\nu_k|\le\varepsilon\quad\forall i=1,\dots,l_k\quad\forall k=1,\dots,n$.

Finally, the Main Theorem

Now we can formulate the main result of this section:

Theorem 3.1.7. *Let conditions* (3.1.1)–(3.1.6), (3.1.23), (3.1.9) *be fulfilled and let* $N = N(d, m, s, M, l, \mathsf{D}^*)$.

Further, let $z^* \in \Omega' \subset T^*\partial X$ *and* $\phi_j \in \mathscr{C}^N(T^*\partial X)$, $\phi_{kj} \in \mathscr{C}^N(T^*X' \times \mathbb{R}^+)$ *with* $j = 1, \dots, J$, $k = 1, \dots, n$ *be real-valued functions such that*

$$\phi_{1j} = \dots = \phi_{nj} = \phi_j \qquad \text{at} \quad T^*\partial X \quad \forall j \tag{3.1.27}$$

and for every $j = 1, \dots, J$ *the problem* (P, B) *is microhyperbolic at the point* z^* *in the multidirection* $\mathcal{T}_j = (\nabla^{\#}\phi_j, -\partial_{x_1}\phi_{1j}, \dots, -\partial_{x_1}\phi_{nj})(z^*)$.

Furthermore, let u *satisfy* (3.1.20) *and*

$$\bigl(\mathsf{WF}_b^{s+1,l}(Pu) \cup \mathsf{WF}^{s+\frac{1}{2}}(B\mathfrak{d}_h u)\bigr) \cap \Omega' \cap \{\phi_1 \le t_1\} \cap \dots \cap \{\phi_J \le t_J\} = \emptyset, \tag{3.1.28}$$

$$\mathsf{WF}^{s+1}(Pu) \cap \Omega'_k \cap \{\phi_{k1} \le t_1\} \cap \dots \cap \{\phi_{kJ} \le t_J\} = \emptyset \quad \forall k = 1, \dots, n, \tag{3.1.29}$$

$$\mathsf{WF}_b^{s,0}(u) \cap \partial\Omega' \cap \{\phi_1 \le t_1\} \cap \dots \cap \{\phi_J \le t_J\} = \emptyset \tag{3.1.30}$$

and

$$\mathsf{WF}^{s}(u) \cap \partial\Omega_k \cap \{\phi_{k1} \le t_1\} \cap \dots \cap \{\phi_{kJ} \le t_J\} = \emptyset \quad \forall k = 1, \dots, n \tag{3.1.31}$$

where Ω' *and* Ω_k *are small enough neighborhoods of* z *and* z_k *in* $T^*\partial X$ *and* T^*X *respectively not depending on* $u, t_1, \dots, t_J$ *such that*

$$\iota\Omega_k|_{\partial X} = \Omega' \qquad \forall k = 1, \dots, n. \tag{3.1.32}$$

(i) Then

$$\mathsf{WF}_b^{s,m+l}(u) \cap \Omega' \cap \{\phi_1 \le t_1\} \cap \dots \cap \{\phi_J \le t_J\} = \emptyset\,. \tag{3.1.33}$$

(ii) Moreover, if condition $(3.1.9)^*$ *is fulfilled then one can weaken condition* (3.1.28) *replacing in it* $\mathsf{WF}^{s+\frac{1}{2}}(B\mathfrak{d}_h u)$ *by* $\mathsf{WF}^{s}(B\mathfrak{d}_h u)$*:*

$$\bigl(\mathsf{WF}_b^{s+1,l}(Pu) \cup \mathsf{WF}^{s}(B\mathfrak{d}_h u)\bigr) \cap \Omega' \cap \{\phi_1 \le t_1\} \cap \dots \cap \{\phi_J \le t_J\} = \emptyset \tag{3.1.28}'$$

and at same time obtain in addition that

$$\mathsf{WF}^{s-i}(D_1^i u|_{\partial X}) \cap \Omega' \cap \{\phi_1 \le t_1\} \cap \dots \cap \{\phi_J \le t_J\} = \emptyset \qquad \forall i = 0, \dots, m+l-1. \tag{3.1.34}$$

Remark 3.1.8. (i) Assumption (3.1.29) is referring to points of $T^*\dot{X}$.

(ii) Assumptions (3.1.6), (3.1.20), (3.1.28) and (3.1.30) imply (3.1.30) again with $\mathsf{WF}^{s,0}(u)$ replaced by $\mathsf{WF}^{s,m+l}(u)$.

(iii) The uniform version of Theorem 3.1.7 (such as was proven in the proof of Theorem 2.1.2) is obvious but very long and tedious to formulate.

3.1.2 Proof of the Main Theorem

In order to prove Theorems 3.1.2 and 3.1.7 and Proposition 3.1.5 we first of all reduce the general case to a special one: first to $m = 1$ and then to the block-diagonal form with each block corresponding to a single point $\iota^{-1}z^*$ and an elliptic block of the special type.

Reduction to a Special Case

Step 1. Reduction to $m = 1$. First of all, *one can assume that* $m = 1$. Indeed, let us set $\underline{u} = (u_j)_{j=1,\dots,m}$ with $u_j = (hD_1)^{j-1}u$. Then in the intersection with the vicinities of $\iota^{-1}z^*$ or z^*

$$\mathsf{WF}^s(u) = \mathsf{WF}^s(\underline{u}), \qquad \mathsf{WF}^{s,m+l\,\prime}(u) = \mathsf{WF}^{s,l+1\,\prime}(\underline{u}),$$
$$\mathsf{WF}^t(Pu) = \mathsf{WF}^t(\underline{P}\,\underline{u}), \qquad \mathsf{WF}^{s,l\,\prime}(Pu) = \mathsf{WF}^{s,l\,\prime}(\underline{P}\,\underline{u})$$

provided $|s-t| \le 1$ where $\underline{P} = \underline{A}_0 hD_1 + \underline{A}_1$,

$$\underline{A}_0 = (A_{m-j-k+1})_{j,k=1,\dots,m} \tag{3.1.35}$$

is an operator with principal symbol $T(z)$, $\underline{A}_1 = -\underline{A}_0 L$,

$$L = (L_{jk})_{j,k=1,\dots,m}, \qquad L_{jk} = \delta_{j+1,k} - A_0' A_{m-k+1}\delta_{j,m} \tag{3.1.36}$$

where A_0' is a parametrix of A_0 here (condition (3.1.6) guarantees its existence) and $\delta_{j,k}$ is the Kronecker symbol as usual. Then modulo operators with symbols vanishing in the vicinity of z^*

$$\underline{A}_1 = (-A_{m-j-k+2} + A_{m-j+1}\delta_{k,1} + A_{m-k+1}\delta_{j,1})_{j,k=1,\dots,m}. \tag{3.1.37}$$

Observe that condition (3.1.6) for P implies the same condition for $\underline{P}$. Moreover, condition (3.1.4) for P is equivalent to the same condition for $\underline{P}$. Furthermore, condition (3.1.23) for P is equivalent to to the same condition for $\underline{P}$ with D_j replaced by $m\mathsf{D}_j$.

One can prove easily that

$$\Sigma_{C_1^{-1}\rho}(P) \subset \Sigma_\rho(\underline{P}) \subset \Sigma_{C_1\rho}(P)$$

for appropriate $C_1 = C_1(c, \epsilon_0, c_1, m)$ and arbitrary $\rho > 0$.

Moreover, $B\eth_{h(m)}u = B\eth_{h(1)}\underline{u}$ and hence

(3.1.38) Condition (3.1.9) or $(3.1.9)^*$ for (P, B) is equivalent to to the same condition for $(\underline{P}, B)$;

from this one can prove easily that

$$\Sigma_{C_1^{-1}\rho}(P, B) \subset \Sigma_\rho(\underline{P}, B) \subset \Sigma_{C_1\rho}(P, B)$$

for appropriate $C_1 = C_1(c, \epsilon_0, c_1, c_2, m)$ and arbitrary $\rho > 0$.

Finally, one can prove easily the following inequalities

$$|\langle(\ell p)(z)w, w\rangle - \langle(\ell \underline{p})(z)\underline{w}, \underline{w}\rangle_m| \le C|\ell| \cdot \|\underline{p}(z)\underline{w}\|\|\underline{w}\| \qquad \forall \underline{w} \in \mathbb{H}^m : w = w_1$$

and

$$|\langle(\ell' p)(z, D_1)v, v\rangle_+ - \langle(\ell' \underline{p})(z, D_1)\underline{v}, \underline{v}\rangle_+| \le C|\ell'| \cdot \|\underline{p}(z, D_1)\underline{v}\|_+ \cdot \|\underline{v}\|_+ \qquad \forall \underline{v} \in \mathscr{S}(\mathbb{R}^+, \mathbb{H}^m) : v = v_1$$

where as usual $\|.\|_+$ and $\langle ., .\rangle$ is a norm and an inner product in $\mathscr{L}^2(\mathbb{R}^+, .)$.

Hence

(3.1.39) $\underline{P}$ is microhyperbolic at z in the direction ℓ if and only if P has the same property; moreover, $(\underline{P}, B)$ is microhyperbolic at z in the multidirection $\mathcal{T}$ if and only if (P, B) has the same property.

The reduction step is complete:

Proposition 3.1.9. *Under reduction* (3.1.35)–(3.1.37) *conditions* (3.1.6), (3.1.4), (3.1.23), (3.1.9) *or* $(3.1.9)^*$, *and microhyperbolicity conditions are preserved.*

Furthermore all wave front sets and Σ_* *are are essentially preserved as described above.*

Step 2. Isolation of characteristic roots. Let us now show that

Proposition 3.1.10. *(i) In the proofs of Theorem 3.1.7 and Proposition 3.1.5 one can assume without any loss of the generality that*

$$|\det p_j(z^*,\eta)| \ge \epsilon \qquad \forall \eta \in \mathbb{C} : |\eta-\eta_j| \ge \mu \tag{3.1.40}$$

where $\mu > 0$ is arbitrarily small, $\epsilon > 0$ depends on μ, η_j are not necessarily distinct anymore and

$$p_0 = \begin{pmatrix} 0 & p_0' \\ p_0'' & 0 \end{pmatrix}, \qquad p_0' = \rho(\eta-\alpha), \quad p_0'' = (\eta-\alpha^\dagger)\rho^\dagger \tag{3.1.41}$$

with the matrix symbols α and ρ such that

$$\|(\eta-\alpha)w\| \ge \epsilon\|w\|, \quad \|\rho w\| \ge \epsilon\|w\| \qquad \forall w \in \mathbb{H} \quad \forall \eta \in \mathbb{C} : \operatorname{Im}\eta \le \mu. \tag{3.1.42}$$

(ii) In the proof of Theorem 3.1.2 one can assume without any loss of the generality that

$$p_0 = \begin{pmatrix} 0 & p_0' \\ p_0'' & 0 \end{pmatrix}, \quad p_0' = \eta-\alpha', \quad p_0'' = \eta-\alpha'' \tag{3.1.41$'$}$$

and (3.1.42) *holds for $\alpha = \alpha'$ and $\alpha = -\alpha''$.*

(iii) Also in this reduction D^* does not increase.

In order to make the reduction step let us first consider the separate symbols $p_j(z,\eta)$ with $j = 1,\dots,J$. Let η_{jk} be all the real distinct roots of $\det p_j(z^*,\eta)$, $k = 1,\dots,n_j$. Then η_{jk} are all the real distinct eigenvalues of $L_j(z^*)$ where $L_j(z) = -a_{0j}(z)^{-1}a_{1j}(z)$ [3)].

Hence there exist symbols $r_j(z)$ defined, smooth and invertible such that in Ω''

$$r_j^{-1}L_j r_j = \tilde{L}_j = \begin{pmatrix} \tilde{L}_{j1} & \dots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \dots & \tilde{L}_{jn_j} & 0 \\ 0 & \dots & 0 & \tilde{L}_{j0} \end{pmatrix},$$

where

[3)] Let us recall that $p_j(z,\eta) = a_{0j}(z)\eta + a_{1j}(z)$) and $z \in \Omega''$ where Ω'' is a small enough neighborhood of z^* in $T^*X' \times \mathbb{R}^+$ which we shrink if necessary.

(3.1.43) For $k \ge 1$ all the eigenvalues of $\tilde{L}_{jk}$ are equal to η_{jk} and all the eigenvalues of $\tilde{L}_{j0}$ are non-real.

Then

$$r_j^\dagger a_{1j} r_j = r_j^\dagger a_{0j} r_j \tilde{L}_j$$

and taking the Hermitian conjugate we obtain that

$$(r_j^\dagger a_{0j} r_j)\tilde{L}_j = \tilde{L}_j^\dagger (r_j^\dagger a_{0j} r_j).$$

Since $\tilde{L}_j$ is of the block-diagonal type and since $\eta \ne \zeta^\dagger$ if η and ζ belong to the spectra of different blocks (where $\zeta^\dagger$ is a complex conjugate number) we conclude that $r_j^\dagger a_{0j} r_j$ is also of the block-diagonal type and hence $r_j^\dagger a_{1j} r_j$ is also of this type.

Therefore multiplying $p(z,\eta)$ on the left and on the right by $r^\dagger(z)$ and $r(z)$ respectively we obtain

$$p = \oplus \sum_{1\le j\le M, 1\le k\le n_j} p_{jk} \otimes I_{\mathbb{H}_j^0} \ \oplus p_0 \tag{3.1.44}$$

provided

$$r = \begin{pmatrix} r_1 \otimes I_{\mathbb{H}_j^0} & \dots & 0 & 0 \\ \vdots & \ddots & r_M \otimes I_{\mathbb{H}_M^0} & \\ 0 & \dots & 0 & I \end{pmatrix};$$

here $\det p_{jk}(z^*,\eta)$ has no complex root except $\eta_{jk} \in \mathbb{R}$ and p_0 satisfies (3.1.14)$'$; after this reduction step the space $\mathbb{H}_0$ can be larger than before.

Similarly, let us consider $L_0(z) = -a_{00}(z)^{-1} a_{10}(z)$ [4]; then the spectrum of $L_0(z)$ resides in $\{\eta \in \mathbb{C}, |\operatorname{Im}\eta| \ge \epsilon\}$ and hence there exists a smooth and invertible symbol $r_0(z)$ such that in Ω''

$$r_0^{-1} L_0 r_0 = \tilde{L}_0 = \begin{pmatrix} L_0' & 0 \\ 0 & L_0'' \end{pmatrix}$$

where the spectrum of L_0' resides in $\{\eta \in \mathbb{C}, \operatorname{Im}\eta \ge \epsilon\}$ and the spectrum of L_0'' resides in $\{\eta \in \mathbb{C}, \operatorname{Im}\eta \le -\epsilon\}$.

Then using the same arguments as before (but taking into account that $\eta \ne \zeta^\dagger$ provided η and ζ belong to the spectrum of the same block) we obtain that both symbols $r_0^\dagger a_{00} r_0$ and $r_0^\dagger a_{10} r_0$ are of the form $\begin{pmatrix} 0 & * \\ * & 0 \end{pmatrix}$.

[4] Let us recall that $p_0(z,\eta) = a_{00}(z)\eta + a_{10}(z)$.

Then multiplying (3.1.44) on the left and on the right by $r^\dagger$ and r respectively with

$$r = \begin{pmatrix} I & \dots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \dots & I & 0 \\ 0 & \dots & 0 & r_0 \end{pmatrix},$$

we obtain p_0 of the form (3.1.41).

Thus, the second step of the reduction is provided by multiplying P on the left and on the right by $\mathsf{Op}(r)^*$ and $\mathsf{Op}(r)$ respectively where r is now the product of the two matrices constructed in the two sub-steps of this step.

Step 3. Reduction of Lower Order Terms. In the final reduction step we obtain

$$P = \begin{pmatrix} P_1 & \dots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \dots & P_n & 0 \\ 0 & \dots & 0 & P_0 \end{pmatrix}, \qquad P_0 = \begin{pmatrix} 0 & P_0' \\ P_0'' & 0 \end{pmatrix} \tag{3.1.45}$$

with $P_0'' = P_0'^*$ where for $k = 1, \dots, n$ the principal symbols of P_k are of the form

$$p_k = \oplus \sum_{1 \le k \le K_j} p_{kj} \otimes I_{\mathbb{H}^0_{jk}}, \tag{3.1.46}$$

p_{jk} are the same as in (3.1.44), and p_0' and p_0'' (the principal symbols of P_0' and P_0'' respectively) are of the same type as in (3.1.41).

In order to make this reduction step we assume that (3.1.45) is fulfilled modulo operators with symbol $h^n(F_0\eta + F_1)$; we then apply induction on n. For $n = 1$ these approximate equalities are fulfilled.

In order to make the induction step we multiply P on the right and on the left by $(I + h^n Q^*)$ and $(I + h^n Q)$ respectively; then the step in the first equality (3.1.45) will be made provided for $j \neq k$

$$q_{kj}^\dagger a_{0k} + a_{0j} q_{jk} = F_{0jk}, \tag{3.1.47}_1$$

$$q_{kj}^\dagger a_{1k} + a_{1j} q_{jk} = F_{1jk} \tag{3.1.47}_2$$

where a_{0k}, a_{1k} are diagonal blocks and q_{jk}, F_{0jk}, F_{1jk} are blocks of the corresponding symbols, $Q = \mathsf{Op}(q)$.

Since both F_0 and F_1 are Hermitian matrices we need to fulfill these equalities only for $j < k$; for $j > k$ they will then be fulfilled automatically. Finding $q_{kj}^\dagger$ from the first equality and substituting into the second one we obtain after multiplication by a_{0j}^{-1} that we need only to solve the equation

$$-q_{jk}L_k + L_j q_{jk} = F'_{jk} \tag{3.1.48}$$

for $j < k$ where $L_k = -a_{0k}^{-1}a_{1k}$ and F'_{jk} is obtained from F_{0jk} and F_{1jk}. This equation is solvable since the spectra of L_j and L_k are disjoint (see Appendix 3.A.1). The choice of q_{jk} for $j = k$ is arbitrary.

In order to make the induction step in the second equality in (3.1.45) we need to solve the equations

$$q_{(21)}^\dagger \rho^\dagger + \rho q_{(21)} = F_{0(11)}, \tag{3.1.49}_1$$

$$q_{(21)}^\dagger \alpha^\dagger \rho^\dagger + \rho\alpha q_{(21)} = F_{1(11)} \tag{3.1.49}_2$$

and similar equations for q_{12} where $\rho = p'_0$, $q_{(jk)}$ are blocks of

$$q_{00} = \begin{pmatrix} q_{(11)} & q_{(12)} \\ q_{(21)} & q_{(22)} \end{pmatrix},$$

$F_{0(jk)}$ and $F_{1(jk)}$ are similar blocks of the matrices F_{000} and F_{100}, and these blocks are Hermitian for $j = k$. The solution of the first equation is of the form

$$q_{(21)} = \rho^{-1}(\frac{1}{2}F_{0(11)} + i\Lambda)$$

where Λ is an arbitrary Hermitian symbol. Substituting this equality to the second equation we obtain that

$$\Lambda\alpha'^\dagger - \alpha'\Lambda = iF'_{(11)} \tag{3.1.50}$$

where $\alpha' = \rho\alpha'\rho^{-1}$ and $F'_{(11)}$ is some given Hermitian symbol. We can solve this equation because the spectra of α' and $\alpha'^\dagger$ are disjoint (see Appendix 3.A.1 again). Moreover, one can choose $q_{(11)}$ and $q_{(22)}$ arbitrarily. The induction step is done.

The reduction is complete.

Elliptic Theory

The following series of assertions is crucial in the proof of Theorem 3.1.2 and is important in the proof of Theorem 3.1.7:

Proposition 3.1.11. *Let $\alpha \in \mathscr{C}^{l}_{b}\big(\mathbb{R}, \mathbf{\Psi}_h(\mathbb{R}^d, \mathbb{H}, \mathbb{H})\big)$ be an operator with the principal symbol α_0 such that*

$$\|(\eta - \alpha_0(z))w\| \geq \epsilon\|w\| \qquad \forall w \in \mathbb{H} \quad \forall \eta \in \mathbb{C} : \operatorname{Im}\eta \leq \epsilon \quad \forall z \in \mathbb{R} \times T^*\mathbb{R}^d \tag{3.1.51}$$

and let $l \geq 1$. Then for $h \in (0, h_0]$ with $h_0 = h_0(d, c, \epsilon, c_2) > 0$, $c_2 = \|\alpha\|$ there exists an operator family

$$G \in \mathscr{C}^{l+1}\big(\Delta, \mathcal{L}(\mathscr{L}^2(\mathbb{R}^d, \mathbb{H}), \mathscr{L}^2(\mathbb{R}^d, \mathbb{H}))\big)$$

with $\Delta = \{(x_1, y_1) \in \mathbb{R}^2, x_1 \geq y_1\}$ such that

(i) The following relations hold:

$$G(x_1, x_1) = I, \tag{3.1.52}$$

$$\|D^j_{x_1} D^k_{y_1} G(x_1, y_1)\| \leq Ch^{-j-k} e^{-\epsilon h^{-1}(x_1 - y_1)} \qquad \forall j, k : j + k \leq q + 1 \tag{3.1.53}$$

where here and below $C = C(d, s, M, l, \epsilon, c_2)$.

(ii) If the operators $G_\pm : \mathscr{L}^2(\mathbb{R}^{d+1}, \mathbb{H}) \to \mathscr{L}^2(\mathbb{R}^{d+1}, \mathbb{H})$ are given by the formulae

$$(G_+ f)(x_1) = +ih^{-1} \int_{-\infty}^{x_1} G(x_1, y_1) f(y_1)\, dy_1, \tag{3.1.54}$$

$$(G_- f)(x_1) = -ih^{-1} \int_{x_1}^{\infty} G(y_1, x_1) f(y_1)\, dy_1 \tag{3.1.54}$$

then $G_+^* = G_-$ and

$$\|G_\pm\| \leq C, \tag{3.1.55}$$

$$PG_+ = G_+ P = I, \tag{3.1.56}$$

$$P^* G_- = G_- P^* = I \tag{3.1.56}$$

where $P = hD_1 - \alpha$ and then $P^* = hD_1 - \alpha^*$.

Moreover, if f is tempered (i.e., $\|D_1^j f\| \leq h^{-M} \ \ \forall j = 0, \dots, l$) then

$$\mathsf{WF}^{s,l+1\prime}(G_\pm f) = \mathsf{WF}^{s,l\prime}(f). \tag{3.1.57}$$

(iii) If the operator family $G_t : \mathscr{L}^2(\mathbb{R}^d, \mathbb{H}) \to \mathscr{L}^2(\mathbb{R}^+_t \times \mathbb{R}^d, \mathbb{H})$ *with* $\mathbb{R}^+_t = \{x_1, x_1 \ge t\}$ *is given by the formula*

$$(G_t f)(x_1) = G(x_1, t) f, \tag{3.1.58}$$

then

$$\|G_t\| \le C h^{\frac{1}{2}}, \tag{3.1.59}$$

$$PG_t = 0, \qquad \eth_t G_t = I \tag{3.1.60}$$

where $\eth_t u = u|_{x_1 = t}$ *and, moreover, if* f' *is tempered then*

$$\mathsf{WF}^{s, l+1\prime}(G_t f') = \{t\} \times \mathsf{WF}^{s-\frac{1}{2}}(f'). \tag{3.1.61}$$

Proof. Let us note that for $h \in (0, h_0]$ with an appropriate constant $h_0 > 0$ the following estimate holds:

$$\|(\eta - \alpha)v\| \ge \frac{1}{2}\epsilon \|v\| \qquad \forall v \in \mathscr{L}^2(\mathbb{R}^d, \mathbb{H}) \quad \forall \eta \in \mathbb{C} : \mathsf{Im}\, \eta \le \frac{1}{2}\epsilon \quad \forall x_1 \in \mathbb{R}.$$

Then for operators

$$G_{(1)}(x_1, y_1) = e^{ih^{-1}(x_1 - y_1)\alpha_{y_1}} \qquad \text{with} \quad \alpha_{y_1} = \alpha|_{x_1 = y_1}$$

and

$$G_{(2)}(x_1, y_1) = e^{ih^{-1}(x_1 - y_1)\alpha_{x_1}}$$

(3.1.52) and (3.1.53) with $j = k = 0$ are fulfilled. Hence if we define $G'_\pm$ by formulae $(3.1.54)_\pm$ with $G_{(1)}$ and $G_{(2)}$ respectively instead of G then (3.1.55) would be fulfilled while $(3.1.56)_\pm$ would be fulfilled only partially and approximately:

$$PG'_+ = I + R_+, \quad P^* G'_- = I + R_-, \quad \|R_\pm\| \le Ch.$$

Then for $h \in (0, h_0]$ with an appropriate constant $h_0 > 0$ the operators $G_\pm = G'_\pm (I + R_\pm)^{-1}$ satisfy $(3.1.56)_\pm$ partially

$$PG_+ = P^* G_- = I \tag{3.1.56}'$$

and are of the form $(3.1.54)_\pm$ with appropriate functions $G = G_\pm(x_1, y_1)$ satisfying (3.1.52)–(3.1.53); however these functions may be different for different indices $\pm$.

But then $(3.1.56)'$ yields that $G_+^* P^* = G_-^* P = I$ and these equalities and $(3.1.56)'$ again imply that $G_+ = G_-^*$ and then $(3.1.56)_\pm$ hold; therefore the functions $G_\pm$ in formulae $(3.1.54)_\pm$ coincide. This implies (3.1.60) and (3.1.53).

It remains to prove (3.1.57) and (3.1.61). In fact, it is sufficient to prove that $\mathsf{WF}^{s\prime}(G_\pm f)$ and $\mathsf{WF}^{s\prime}(G_t f')$ are contained in the right-hand sets of (3.1.57) and (3.1.61) respectively; these inclusions and (3.1.56) and (3.1.60) imply (3.1.57) and (3.1.61).

Furthermore, one can see easily that it is sufficient to prove these inclusions for $G'_\pm f$ and $G'_t f'$ where G'_t is given by (3.1.58) with G replaced by $G_{(1)}$.

Note that

$$e^{ih^{-1}\tau\alpha} Q = \sum_{0\le k\le n} \frac{1}{k!}\partial_\lambda^k \bigl(e^{ih^{-1}\tau\lambda\alpha} Q e^{ih^{-1}\tau(1-\lambda)\alpha}\bigr)\big|_{\lambda=0} + \frac{1}{n!}\int_0^1 (1-\lambda)^n \partial_\lambda^{n+1}\bigl(e^{ih^{-1}\tau\lambda\alpha} Q e^{ih^{-1}\tau(1-\lambda)\alpha}\bigr)\, d\lambda = \sum_{0\le k\le n} \frac{1}{k!}(\mathsf{Ad}^k_{ih^{-1}\alpha} Q)\tau^k e^{ih^{-1}\tau\alpha} + \frac{1}{n!}\int_0^1 (1-\lambda)^n (\mathsf{Ad}^{n+1}_{ih^{-1}\alpha} Q)\tau^{n+1} e^{ih^{-1}\tau(1-\lambda)\alpha}\, d\lambda$$

where Ad_M is an operator of commutation with M and Ad^k_M are defined by $(\mathsf{Ad}^0_M Q) = Q$, $(\mathsf{Ad}^1_M Q) = [M, Q]$ and $(\mathsf{Ad}^k_M Q) = [M, (\mathsf{Ad}^{k-1}_M Q)]$ for $k \ge 1$.

It is easy to deduce from (3.1.53) that if Q is a scalar pseudodifferential operator then the norm of the last term does not exceed $C_n h^n e^{-\frac{1}{2}\epsilon\tau h^{-1}}$ and hence modulo negligible operators

$$e^{ih^{-1}\tau\alpha} Q \equiv \sum_{0\le k\le n} \frac{1}{k!}(\mathsf{Ad}^k_{ih^{-1}\alpha} Q)\tau^k e^{ih^{-1}\tau\alpha}$$

with large enough $n = n(s)$. This equality obviously implies the inclusions in question. □

Theorem 3.1.12. *Let Ω be a domain in $\mathbb{R}\times T^*\mathbb{R}^{d-1}$ and $\tilde\Omega$ its ϵ-vicinity. Further, let $\Omega' = \Omega\cap\{x_1 = 0\}$, $\Omega_+ = \Omega\cap\{x_1 \ge 0\}$, $\tilde\Omega' = \tilde\Omega\cap\{x_1 = 0\}$ and $\tilde\Omega_+ = \tilde\Omega\cap\{x_1 \ge 0\}$.*

Furthermore, let $\alpha \in \mathscr{C}^l(\mathbb{R}, \mathbf{\Psi}_h(\mathbb{R}^d, \mathbb{H}, \mathbb{H}))$ *satisfy* (3.1.51) *for all* $z \in \tilde{\Omega}$ *and let* $l \ge 1$.

Then there exist operators

$$G_0 \in \mathcal{L}\big(\mathscr{L}^2(\partial X, \mathbb{H}), \mathscr{L}^2(X, \mathbb{H})\big) \quad \text{with} \quad \|G_0\| \le Ch^{1/2}$$

and

$$G \in \mathcal{L}\big(\mathscr{L}^2(X, \mathbb{H}), \mathscr{L}^2(X, \mathbb{H})\big) \quad \text{with} \quad \|G_0\| \le C$$

with the same type of constant C *as before such that for tempered* u_0, f *(i.e., with* $\|u_0\|_{\partial X} \le h^{-M}, \|D_1^j f\|_X \le h^{-M}\ \forall j \le l$*) the following relations hold:*

$$\mathsf{WF}^{s,l+1\,\prime}(G_0 u_0) \subset \mathsf{WF}^{s-\frac{1}{2}}(u_0) \cap \tilde{\Omega}, \tag{3.1.62}$$

$$\mathsf{WF}^{s,l+1\,\prime}(Gf) \subset \mathsf{WF}^{s,l\,\prime}(f) \cap \tilde{\Omega}_+, \tag{3.1.63}$$

$$\mathsf{WF}^{s,l\,\prime}(PG_0 u_0) \cap \Omega_+ = \emptyset, \tag{3.1.64}$$

$$\mathsf{WF}^{s-\frac{1}{2}}(\eth G_0 u_0 - u_0) \cap \Omega = \emptyset, \tag{3.1.65}$$

$$\mathsf{WF}^{s,l\,\prime}(PGf - f) \cap \Omega_+ = \emptyset, \tag{3.1.66}$$

$$\mathsf{WF}^{s-\frac{1}{2}}(\eth Gf) = \emptyset, \tag{3.1.67}$$

and

$$\mathsf{WF}^{s,l+1\,\prime}(G^* f) \subset \mathsf{WF}^{s,l\,\prime}(f) \cap \tilde{\Omega}_+, \tag{3.1.62}'$$

$$\mathsf{WF}^{s,l\,\prime}(P^* G^* f - f) \cap \Omega_+ = \emptyset. \tag{3.1.64}'$$

Moreover, if $\|D_1^j u\|_X \le h^{-M}$ *for all* $j \le l+1$ *then the following relations hold:*

$$\mathsf{WF}^{s,l+1\,\prime}(u - GPu - G_0 \eth u) \cap \Omega_+ = \emptyset, \tag{3.1.68}$$

$$\mathsf{WF}^{s,l+1\,\prime}(u - G^* P^* u) \cap \Omega_+ = \emptyset. \tag{3.1.68}'$$

Proof. Without any loss of the generality one can assume that (3.1.51) is satisfied in $\mathbb{R} \times T^*\mathbb{R}^d$. Indeed, (3.1.51) is satisfied in $\tilde{\Omega}'$ for a small enough constant $\epsilon > 0$ and hence $\bar{\alpha}(z) = \alpha(z)\varphi(z) + i(1 - \varphi(z))I$ satisfies (3.1.51) in $\mathbb{R} \times T^*\mathbb{R}^d$ provided φ is a smooth scalar function equal to 1 in the $\frac{1}{3}\epsilon$-neighborhood of Ω' and vanishing outside of the $\frac{2}{3}\epsilon$-neighborhood of Ω' and such that $0 \le \varphi \le 1$.

Let us define $\bar{G}_{\pm}$ and $\bar{G}_0$ according to the Proposition 3.1.11[5)] and let us set $\bar{G} = R\bar{G}_+T$ where here R and T are the operators of restriction from $\mathbb{R}^{d+1}$ to X and extension from X to $\mathbb{R}^{d+1}$ by 0 in $\mathbb{R}^{d+1}\setminus X$ respectively.

Then $\bar{G}^* = R\bar{G}_-T$ and operators $\bar{G}$ and $\bar{G}_0$ obviously satisfy (3.1.62)–(3.1.64)$'$ with $\Omega = \tilde{\Omega} = T^*\mathbb{R}^d$ and with $\Omega_+ = \tilde{\Omega}_+ = \mathbb{R}^+ \times T^*\mathbb{R}^d$. Moreover, the obvious equalities

$$\begin{aligned} PTu &= TPu - ih(\eth u)\delta(x_1),\\ P^*Tu &= TP^*u - ih(\eth u)\delta(x_1) \end{aligned}$$

combined with $(3.1.56)_{\pm}$ and $(3.1.54)_{\pm}$ imply the equalities

$$u = \bar{G}Pu + \bar{G}_0\eth u, \qquad u = \bar{G}^*P^*u;$$

these equalities combined with (3.1.57) and (3.1.60) imply (3.1.68) and (3.1.68)$'$ with $\Omega_+ = \mathbb{R}^+ \times T^*\mathbb{R}^d$.

Finally, $G = \mathsf{Op}(\varphi)\bar{G}\,\mathsf{Op}(\varphi)$ and $G_0 = \mathsf{Op}(\varphi)\bar{G}_0\,\mathsf{Op}(\varphi_0)$ are the operators in question provided $\varphi_0 = \varphi|_{x_1=0}$. □

Proof of Theorem 3.1.2. The simplifying reduction of Subsubsection *3.1.2.1 Reduction to a Special Case* implies that without any loss of the generality one can assume that $\Sigma(P) = \emptyset$ and

$$P = \begin{pmatrix} P_1 & 0\\ 0 & P_2\end{pmatrix}, \qquad \mathbb{H} = \mathbb{H}_1 \oplus \mathbb{H}_2$$

where $P_j = hD_1 - \alpha_j$ and α_1 and $\alpha_2^\dagger$ satisfy (3.1.51).

Therefore if $\Omega' \supset \omega$ and ω does not intersect $\mathsf{WF}_b^{s,l}(Pu)$ then Theorem 3.1.12 yields that

$$\omega \cap \mathsf{WF}_b^{s,l+1}(u_2) = \emptyset, \qquad \omega \cap \mathsf{WF}_b^{s,l+1}(u_1 - G_0v) = \emptyset,$$
$$\omega \cap \mathsf{WF}_b^{s,l+1}(u_1) \subset \mathsf{WF}^{s-\frac{1}{2}}(v)$$

where G_0 is constructed for P_1 and $v = \eth u_1$. Then

$$\omega \cap \mathsf{WF}^{s-\frac{1}{2}}(B\eth u) = \omega \cap \mathsf{WF}^{s-\frac{1}{2}}(B'v) \supset \omega \cap \mathsf{WF}^{s-\frac{1}{2}}(B'^*B'v)$$

where B' is the restriction of B to $\mathbb{H}_1$.

One can see easily that $\mathbb{H}'(z) = \mathbb{H}_1$ and hence the set of characteristic points of operator B'^*B' is exactly $\Sigma_b(P,B)$. Hence if $\omega \cap \mathsf{WF}^{s-1/2}(B\eth u) = \emptyset$ then $\omega \cap \mathsf{WF}^{s-1/2}(v) \subset \Sigma_b(P,B)$. Therefore $\omega \cap \mathsf{WF}_b^{s,l+1}(u) \subset \Sigma_b(P,B)$. □

[5)] We now use a bar for the operators constructed in that proposition, with $t = 0$ now in (3.1.60) and (3.1.61).

Main Theorem Refined

The rest of this section is almost entirely devoted to the proof of the following assertion which is slightly more precise than Theorem 3.1.7:

Theorem 3.1.13. *Let P be a reduced operator satisfying the conditions of Theorem 3.1.7, i.e., we suppose that conditions* (3.1.1) *with* $m=1$, (3.1.4), (3.1.6), (3.1.41), (3.1.42), (3.1.45) *and* (3.1.46) *are satisfied.*

Further, let $z^*\in \Omega' \Subset T^*\partial X$ and let us assume that each polynomial $\det p_k(z^*,\eta)$ with $k=1,\dots,n$ has only one complex root and this root is real (namely $\eta_k\in\mathbb{R}$).

Further, let boundary operator B satisfy condition (3.1.9).

Finally, let $\phi_j\in \mathscr{C}^N(T^*\partial X)$, $\phi_{kj}\in \mathscr{C}^N(\mathbb{R}^+\times T^*X')$ be real-valued functions satisfying (3.1.27) *($j=1,\dots,J$, $k=1,\dots,n$).*

Let us assume that for every $j=1,\dots,J$ the problem (P,B) is microhyperbolic at the point z^* in the multidirection $\mathcal{T}_j=(\nabla^{\#}\phi_j, -\partial_{x_1}\phi_{1j},\dots,-\partial_{x_1}\phi_{nj})(z^*)$. Let $N=N(d,s,M,l)$ and $l\ge 2\mathrm{D}^*-2$, $\mathrm{D}^*=\max_k \mathrm{D}_k$ where D_k are the dimensions of $\mathbb{H}_k$. Then

(i) Let u satisfy (3.1.20) *and*

$$\bigl(\mathsf{WF}_b^{s+1,l}(P_0u_0)\cup \mathsf{WF}^{s+\frac12}(B\eth u)\bigr)\cap \Omega'\cap\{\phi_1\le t_1\}\cap\dots\cap\{\phi_J\le t_J\}=\emptyset, \tag{3.1.69}$$

$$\mathsf{WF}^{s+1,l\,\prime}(P_ku_k)\cap\Omega_k''\cap\{\phi_{k1}\le t_1\}\cap\dots\cap\{\phi_{kJ}\le t_J\}=\emptyset \quad \forall k=1,\dots,n, \tag{3.1.70}$$

$$\mathsf{WF}^{s-\frac12}(\eth u_0)\cap\partial\Omega'\cap\{\phi_1\le t_1\}\cap\dots\cap\{\phi_J\le t_J\}=\emptyset \tag{3.1.71}$$

and

$$\mathsf{WF}^{s\,\prime}(u_k)\cap\partial\Omega_k''\cap\{\phi_{k1}\le t_1\}\cap\dots\cap\{\phi_{kJ}\le t_J\}=\emptyset \quad \forall k=1,\dots,n \tag{3.1.72}$$

where $u=(u_1,\dots,u_n,u_0)$, Ω' and Ω_k'' are small enough neighborhoods of z^* in $T^*\partial X$ and $\mathbb{R}^+\times T^*X'$ respectively such that $\Omega'=\Omega_k''|_{\partial X}$ $\forall k=1,\dots n$. Then

$$\mathsf{WF}^{s-\frac12}(\eth u_0)\cap\Omega'\cap\{\phi_1\le t_1\}\cap\dots\cap\{\phi_J\le t_J\}=\emptyset \tag{3.1.73}$$

and

$$\mathsf{WF}^{s,l+1\prime}(u_k)\cap\Omega_k''\cap\{\phi_{k1}\le t_1\}\cap\dots\cap\{\phi_{kJ}\le t_J\}=\emptyset \qquad \forall k=1,\dots,n. \tag{3.1.74}$$

(ii) Moreover, if condition $(3.1.9)^*$ *is satisfied then one can weaken condition* (3.1.69)*, replacing in it* $\mathsf{WF}_b^{s+1,l}(P_0u_0)$ *and* $\mathsf{WF}^{s+1/2}(B\eth u)$ *by* $\mathsf{WF}_b^{s+1/2,l}(P_0u_0)$ *and* $\mathsf{WF}^{s}(B\eth u)$ *respectively:*

$$\bigl(\mathsf{WF}_b^{s+\frac12,l}(P_0u_0)\cup\mathsf{WF}^{s}(B\eth u)\bigr)\cap \Omega'\cap\{\phi_1\le t_1\}\cap\dots\cap\{\phi_J\le t_J\}=\emptyset, \tag{3.1.69}'$$

and skip condition (3.1.71) *completely, while getting statement* (3.1.34) *in addition to* (3.1.73) *and* (3.1.74)*.*

Proof of Theorem 3.1.7. Let conditions (3.1.20) and (3.1.28)–(3.1.31) be fulfilled. Then there obviously exists $\varepsilon>0$ depending on $u, t_1,\dots,t_J$ such that if $\psi=\psi(x_1)$ is a smooth function equal to 1 for $x_1\le\frac12\varepsilon$ and vanishing for $x_1\ge\varepsilon$ and if Q is a scalar h-pseudodifferential operator with symbol equal to 1 in the $\frac12\varepsilon$-neighborhood of $\Sigma(P)$ and vanishing outside of the ε-neighborhood of $\Sigma(P)$ then $U=\psi u+Q(1-\psi)u$ satisfies (3.1.69)–(3.1.72) with $\Omega_k''=\tilde\imath\Omega_k$ where $\tilde\imath: T^*X\to\mathbb{R}^+\times T^*X'$ is a natural map.

Then Theorem 3.1.13 applied to U yields (3.1.33) and even (3.1.34) (under condition $(3.1.9)^*$) for u. □

Proof of Theorem 3.1.13. Step 1

In this proof we can assume without any loss of the generality that (3.1.73) and (3.1.74) hold with s replaced by $s-\frac12$, i.e., that

$$\mathsf{WF}^{s-1}(\eth u_0)\cap\Omega'\cap\{\phi_1\le t_1\}\cap\dots\cap\{\phi_J\le t_J\}=\emptyset, \tag{3.1.75}$$

$$\mathsf{WF}^{s-\frac12,l+1\prime}(u_k)\cap\Omega_k''\cap\{\phi_{k1}\le t_1\}\cap\dots\cap\{\phi_{kJ}\le t_J\}=\emptyset \qquad \forall k=1,\dots,n. \tag{3.1.76}$$

Let us construct operators $Q_k\in\boldsymbol{\Psi}_{h,N}(X,\mathbb{C})$ in the same manner as Q_3 in the proof of Theorem 2.1.2, i.e., let us set

$$Q_k=\mathsf{Op}^{\mathsf{w}}\bigl(\zeta_k(x,\xi')\prod_{1\le j\le J}\chi(\phi_{kj}(x,\xi'))\bigr) \tag{3.1.77}$$

where the real-valued function χ satisfies (2.1.8); for the sake of simplicity we assume that $t_1 = ... = t_J = 0$, ϕ_{kj} are replaced everywhere by $\phi_{kj} - \frac{1}{4}\varepsilon$, $\varepsilon > 0$ is small enough, $\zeta_k \in \mathscr{C}_0^N(\mathbb{R}^+ \times T^*X')$, $0 \le \zeta_k \le 1$, ζ_k are supported in the $\frac{1}{2}\varepsilon$-neighborhood of Ω_k'' and $\zeta_k = 1$ in the $\frac{1}{3}\varepsilon$-neighborhood of Ω_k'', and $\zeta_1 = ... = \zeta_n = \zeta$ on $T^*\partial X$.

Let us consider the following identities similar to (2.1.10):

$$-\operatorname{Re} i([P_k, Q_k']u_k, u_k) = \operatorname{Re} i((Q_k' + Q_k'^*)P_k u_k, u_k) + \operatorname{Re} i((P_k - P_k^*)Q_k' u_k, u_k) + \operatorname{Re} h(Q'^* T_k u_k, u_k)_{\partial X} \tag{3.1.78}$$

where $T_k = A_{0k}|_{\partial X}$ (now T is an operator with the principal symbol T_0 given by (3.1.5), so we have changed notation slightly), $Q_k' = Q_k^2$ and the index k in the last term is skipped because all the operators Q_k coincide at ∂X due to condition (3.1.27).

Repeating the arguments of the proof of Theorem 2.1.2 with the obvious modifications we obtain the following inequalities similar to (2.1.11):

$$|-\operatorname{Re} i([P_k, Q_k']u_k, u_k) - \operatorname{Re}(Q'^* T_k u_k, u_k)_{\partial X}| \le C_2 \|Q_k u_k\|^2 + Ch^{2s}. \tag{3.1.79}$$

Let us note that the principal symbol of the operator $-ih^{-1}[P_k, Q_k']$ equals

$$\sum_{1\le j\le J} 2\{p_k, \phi_{kj}\} r_{kj}^2 - \{p_k, \zeta_k\} \prod_{1\le j\le J} \chi(\phi_{kj})^2$$

where $r_{kj} = \zeta\chi_1(\phi_{kj})\chi_2(\phi_{kj}) \prod_{i\ne j} \chi(\phi_{ki})^2$ and the functions χ_1, χ_2 are defined in (2.1.11).

Then similarly to (2.1.17) we obtain the inequalities

$$\Big|\sum_{1\le j\le J} 2(S_{kj}R_{kj}u_k, R_{kj}u_k) - \operatorname{Re}(Q'^* T_k u_k, u_k)_{\partial X}\Big| \le C_2\|Q_k u_k\|^2 + C_2 h \|Q_k u_k\|_{\partial X}^2 + Ch^{2s} \tag{3.1.80}$$

where $R_{kj} = \operatorname{Op}(r_{kj})$, $S_{kj} = \operatorname{Op}^{\mathrm{w}}(\{p_k, \phi_{kj}\})$ and a boundary term (the second term) in the right-hand expression appears because the symbols $\{p_k, \phi_{kj}\}$ depend on ξ_1.

The microhyperbolicity of the symbols p_k in the directions $\nabla^{\#}\phi_{kj}$ yields the existence of symbols q_k'' vanishing in the ε-neighborhoods of the supports

of r_{kj} for all k, j such that

$$\begin{aligned}(3.1.81)\quad &\langle(\{p_k,\phi_{kj}\}+cp_k^\dagger p_k+(q_k''-\epsilon_0)I)w,w\rangle\ge 0\\ &\forall w\in\mathbb{H}_k\quad \forall(x,\xi')\in\mathbb{R}^+\times T^*X'\qquad \forall j=1,\dots,J\quad \forall k=1,\dots,n.\end{aligned}$$

Then passing from symbols to operators and applying the Gårding inequality we obtain an inequality similar to (2.1.19):

$$(3.1.82)\quad \mathsf{Re}(S_{kj}v,v)+c\|P_kv\|^2+\mathsf{Re}(Q_k''v,v)\ge\epsilon_0\|v\|^2-C_2h\|v\|^2_{\partial X}-Ch\|v\|^2.$$

More precisely, we obtain this inequality first only for v with $\eth v=0$; in order to get rid of this restriction we substitute $v-e^{-h^{-1}x_1}\eth v$ for v in (3.1.82) to derive (3.1.82) in the general case.

Substituting $v=R_{kj}u_k$ into (3.1.82) and repeating the arguments of the proof of Theorem 2.1.2 we obtain the inequalities

$$(3.1.83)\qquad \mathsf{Re}(S_{kj}R_{kj}u_k,R_{kj}u_k)\ge\epsilon_0\|R_{kj}u_k\|^2-C_2h\|R_ju_k\|^2_{\partial X}-Ch^{2s}$$

where the index k is omitted in the second term in the right-hand expression since R_{kj} on ∂X do not depend on k.

Proof of Theorem 3.1.13. Step 2

So far we have been just repeating the arguments of the proof of Theorem 2.1.2. However now we need some new ideas:

Proposition 3.1.14. *Let conditions* (3.1.1)–(3.1.6) *with* $m=1$ *and* (3.1.46) *be fulfilled and let us assume that* $\det p_{kj}(z^*,\eta)$ *has only one complex root and this root is real (namely,* $\eta_k\in\mathbb{R}$*). Then*

(i) For every $\epsilon>0$ *there exists a neighborhood* Ω''' *of* z^* *such that if* $\mathcal{Q}$ *is an operator with principal symbol* $\mathcal{Q}^0$ *supported in* Ω''' *and satisfying the inequality* $|\mathcal{Q}^0|\le 1$ *then the following estimate holds:*

$$(3.1.84)\qquad h\|\mathcal{Q}v\|^2_{\partial X}\le\epsilon\|w\|^2+C_\epsilon\sum_{0\le i\le\bar l}\|D_1^iP_kv\|^2+Ch\sum_{0\le i\le\bar l+1}\|D_1^lv\|^2$$

where we omit the subscript "X*" as before and* $\bar l=2\mathsf{D}^*-1$ *where* D^* *is the maximal dimension of the Jordan cell in the Jordan normal form of* $L_{kj}(z^*)$*,* $L_{kj}=-a_{0kj}^{-1}a_{1kj}$*; the maximum is taken for all* $j=1,\dots,J_k$ *and all the Jordan cells.*

(ii) Moreover,

$$\|v(0)\|^2 \le 2\epsilon\|v\|_+^2 + C_\epsilon \sum_{0\le l\le \bar l} \|D_1^l p_k(z, D_1)v\|_+^2 \qquad \forall v \in \mathscr{S}(\mathbb{R}^+, \mathbb{H}_k) \qquad \forall z \in \Omega'''. \tag{3.1.85}$$

This proposition[6)] will be proven later (see Subsubsection *3.1.2.7 Proof of Proposition 3.1.14*). Let us now finish the proof of Theorem 3.1.13. Taking in (3.1.84) $\mathcal{Q}$ with symbol equal to 1 in a neighborhood of the support of the symbol of Q_k and using (3.1.70), (3.1.75) and (3.1.76) we upgrade (3.1.83) to the estimate

$$\operatorname{Re}(S_{kj}R_{kj}u_k, R_{kj}u_k) \ge \frac{1}{2}\epsilon_0\|R_{kj}u_k\|^2 + c_4 h\|R_j u_k\|_{\partial X}^2 - Ch^{2s} \tag{3.1.86}$$

with an arbitrarily constant c_4 which will be chosen later.

So the final estimate at this step in the proof is

$$-\operatorname{Re} ih^{-1}([P_k, Q_k']u_k, u_k) \ge \frac{1}{2}\epsilon_0 \sum_{1\le j\le J} \|R_{kj}u_k\|^2 + c_4 h \sum_{1\le j\le J} \|R_j u_k\|_{\partial X}^2 - Ch^{2s} \quad \forall k = 1, \dots, n; \tag{3.1.87}$$

thus we estimated from below the left hand expression of (3.1.78).

Let us now consider the fourth term in the right hand expression of (3.1.78) and sum with respect to $k = 0, \dots, n$; we obtain

$$-\sum_{0\le k\le n} \operatorname{Re}(Q'^* T_k u_k, u_k)_{\partial X}. \tag{3.1.88}$$

Definitions of Q and Q' and (3.1.76) imply immediately that modulo terms with absolute values not exceeding $C_2 h\|Qu\|_{\partial X}^2 + Ch^{2s}$ (where C_2 does not depend on the choice of c_3 and c_4) this expression equals

$$-\sum_{0\le k\le n} \operatorname{Re}(T_k Qu_k, Qu_k)_{\partial X} = -\operatorname{Re}(TQu, Qu)_{\partial X} + \operatorname{Re}(T_0 Qu_0, Qu_0)_{\partial X}. \tag{3.1.89}$$

[6)] Which implies that the boundary operator enters into microhyperbolicity condition only through nonreal roots.

Let us transform (3.1.89) modulo terms with absolute values not exceeding $C_2 h\|Qu\|^2_{\partial X} + Ch^{2s}$ [7]; in these transformations we will use assumption (3.1.76) repeatedly. Let us recall that in a neighborhood of z^*

$$S_0 = -T_0 - \beta^\dagger b - b^\dagger \beta$$

is a non-negatively defined symbol due to assumption (3.1.9). Hence

$$-\operatorname{Re}(TQu, Qu)_{\partial X} \equiv \operatorname{Re}(SQu, Qu)_{\partial X} + 2\operatorname{Re}(BQu, \mathcal{B}Qu)_{\partial X} \equiv \\ -\operatorname{Re}(SQu, Qu)_{\partial X} + 2\operatorname{Re}(Q[B, Q]u, \mathcal{B}u)_{\partial X}$$

because (3.1.69) implies $\operatorname{Re}(QBu, \mathcal{B}Qu) \equiv 0$ where $S = \operatorname{Op}^{\mathrm{w}}(S_0)$ and $\mathcal{B} = \operatorname{Op}^{\mathrm{w}}(\beta)$.

On the other hand, the structure of P_0 (see (3.1.45)) yields that

$$|(T_0 Qu_0, Qu_0)_{\partial X}| \le C_2 \|Qu_0'\|_{\partial X} \cdot \|Qu_0''\|_{\partial X};$$

moreover, (3.1.69) and Proposition 3.1.11 imply that $\|Qu_0''\|_{\partial X} \le Ch^{s+\frac{1}{2}}$ and therefore this expression is equivalent to 0. Thus

$$-\sum_{0\le k\le n} \operatorname{Re}(T_k Qu_k, Qu_k)_{\partial X} \equiv \\ \operatorname{Re}(SQu, Qu)_{\partial X} + 2\operatorname{Re}(Q[B, Q]u, \mathcal{B}u)_{\partial X}. \tag{3.1.90}$$

Let S' be an h-pseudodifferential operator on ∂X with a non-negatively defined Weyl symbol coinciding with that of S in the neighborhood of z^*; then the Gårding inequality yields that

$$\operatorname{Re}(S'v, v)_{\partial X} \ge -C_2\|v\|^2_{\partial X} \tag{3.1.91}$$

and hence

$$\operatorname{Re}(SQu, Qu)_{\partial X} \ge -C_2\|Qu\|^2_{\partial X} - Ch^{2s} \tag{3.1.92}$$

where we again have used the fact that the symbol of Q is supported in a small neighborhood of z^*.

Let us now consider the second term in the right-hand expression in (3.1.90). Calculating the principal symbol of the operator $Q[B, Q]$ we see that this term is equivalent to

$$\sum_{1\le j\le J} h(L_j R_j u, R_j u)_{\partial X}$$

[7] Where C_2 does not depend on the choice of c_3 and c_4.

where the operators R_j are defined above and L_j are operators with principal symbols

$$L_{j0} = i\beta^\dagger\{b, \phi_j\} - i\{b^\dagger, \phi_j\}\beta.$$

Then (3.1.26) implies that in a neighborhood of z^* the symbols

$$L_{j0} + c(S_0 + b^\dagger b + \Pi) - 2\epsilon_0 I$$

are non-negative definite where

(3.1.93) Π is the projector to the orthogonal complement of $\mathbb{H}'(z^*)$.

Therefore Gårding inequality again implies that

$$\operatorname{Re}(L_j v, v)_{\partial X} = c\operatorname{Re}(Sv, v)_{\partial X} + c\|Bv\|^2_{\partial X} + c\|\Pi v\|^2_{\partial X} \geq (2\epsilon_0 - Ch)\|v\|^2_{\partial X} - \|\mathcal{Q}' v\|^2_{\partial X}$$

where the symbol of $\mathcal{Q}'$ vanishes in some neighborhood of z^*.

Setting $v = R_j u$ and multiplying by h we obtain that

$$h\operatorname{Re}(L_j R_j u, R_j u)_{\partial X} + ch\operatorname{Re}(SR_j u, R_j u)_{\partial X} + ch\|BR_j u\|^2_{\partial X} + ch\|\Pi R_j u\|^2_{\partial X} \geq \epsilon_0 h\|R_j u\|^2_{\partial X} - Ch^{2s}. \tag{3.1.94}$$

Moreover, condition (3.1.69) implies that the third term in the left-hand expression is equivalent to 0 and the second term is equivalent to $ch\operatorname{Re}(S''Qu, R_j' u)_{\partial X}$ where $S'' = S' + C_2 h$ and R_j' is an operator with principal symbol $\zeta\chi_4(\phi_j)\prod_{k\neq j}\chi(\phi_k)$; here $\chi_4 = (\chi')^2/\chi = (2\chi_1')^2$ is a smooth function because of (2.1.8).

Then (3.1.91) and the Cauchy inequality yield that

$$h|(S''Qu, R_j' u)_{\partial X}| \leq h(S''Qu, Qu)^{1/2}_{\partial X} \cdot (S'' R_j' u, R_j' u)^{1/2}_{\partial X} \leq \frac{1}{2}\epsilon_0 \operatorname{Re} h(SQu, Qu)_{\partial X} + C_2 h\|Qu\|^2_{\partial X} + Ch^{2s}. \tag{3.1.95}$$

On the other hand, (3.1.69) and Proposition 3.1.11 yield that $\|R_j u_0''\|^2 \leq Ch^{2s}$ and hence

$$\|\Pi R_j u\|^2_{\partial X} \leq C_2 \sum_{1\leq k\leq n} \|R_j u_k\|^2_{\partial X} + \varepsilon\|R_j u_0'\|^2_{\partial X} + C_\varepsilon h^{2s}$$

with arbitrary small $\varepsilon > 0$ provided $\Omega' = \Omega'_\varepsilon$ is narrow enough.

Then (3.1.90), (3.1.92) and (3.1.94) imply that

$$(3.1.96)\quad -\sum_{1\le k\le n} \mathsf{Re}(Q'^{*}T_k u_k, u_k) \ge \epsilon_0 h \sum_{\le j\le J} \|R_j u_0'\|^2_{\partial X} - C_2 h \sum_{1\le j\le J,\, 1\le k\le n} \|R_j u_k\|^2_{\partial X} - C_2 h\|Qu\|^2_{\partial X} - Ch^{2s}.$$

This inequality combined with (3.1.79), (3.1.87) and (3.1.95) yields after an appropriate choice of constant c_4 that

$$(3.1.97)\quad \sum_{1\le j\le J}\Big(h\|R_j u\|^2_{\partial X} + \sum_{1\le k\le n}\|R_{jk}u_k\|^2\Big) \le C_2\Big(h\|Qu\|^2_{\partial X} + \sum_{1\le k\le n}\|Q_k u_k\|^2\Big) + Ch^{2s}.$$

This estimate is similar to estimate (2.1.18) in the proof of Theorem 2.1.2. Repeating the remaining arguments of the proof of Theorem 2.1.2 together with the choice of constant c_3 in (2.1.8) we finally obtain that (3.1.73) and (3.1.74) with $l = -1$ hold. Then (3.1.70) implies (3.1.74) in the general form.

Theorem 3.1.13(i) has beens proven.

Proof of Theorem 3.1.13. Step 3

Let us assume now that condition $(3.1.9)^*$ is fulfilled. Then one can replace inequality (3.1.92) by

$$(3.1.92)^*\qquad \mathsf{Re}(SQu, Qu) \ge (\epsilon_0 - Ch)\|Qu\|^2_{\partial X} - Ch^{2s}$$

(we assume that (3.1.34) holds with $(s - \frac{1}{2})$ instead of s). Moreover, we know that $\|Qu_0''\|_{\partial X} \le Ch^s$ because of Proposition 3.1.11 and we can weaken condition (3.1.69) to $(3.1.69)'$.

But in this case with no analysis of the principal symbols of the commutators we obtain instead of (3.1.95) the following stronger inequality:

$$(3.1.96)^*\qquad -\sum_{1\le k\le n} \mathsf{Re}(Q'^{*}T_k u_k, u_k) \ge \frac{1}{2}\epsilon_0\|Qu\|^2_{\partial X} - Ch^{2s}.$$

This inequality combined with (3.1.79) and (3.1.87) implies that

$$\|Qu\|^2_{\partial X} + \sum_{1\le j\le J,\ 1\le k\le n} \|R_{jk}u_k\|^2 \le C \sum_{1\le k\le n} \|Q_k u_k\|^2 + Ch^{2s}$$

and repeating the remaining arguments of the proof of Theorem 2.1.2 we obtain (3.1.73), (3.1.74) and (3.1.34).

Theorem 3.1.13(ii) has beens proven.

Proof of Proposition 3.1.14

Proof of Proposition 3.1.14. Obviously, it is sufficient to prove this proposition for $P = hD_1 - L$ with $L \in \boldsymbol{\Psi}'_h(X, \mathbb{H}, \mathbb{H})$ where $\mathbb{H} = \mathbb{C}^r$ and $L_0(z^*)$ has exactly one complex eigenvalue (namely, $\eta \in \mathbb{R}$); now L_0 (the principal symbol of L) is not necessarily Hermitian. Obviously, estimates (3.1.84) and (3.1.85) do not depend on the lower order terms; moreover, these estimates are stable with respect to small perturbations of L_0 for every fixed $\epsilon > 0$. Therefore it is sufficient to prove them only in the case of constant $L = L_0(z^*)$.

Then (3.1.84) is reduced to (3.1.85) by a change of variables $x_{1\mathsf{new}} = h^{-1}x_1$. So we need to prove only (3.1.85) for $z = z^*$. Moreover, one can assume that $\eta = 0$; the general case is reduced to this one by the substitution $v = v_{\mathsf{new}} e^{i\eta x_1}$. We will apply the following

Lemma 3.1.15. *Let L be an $r \times r$ matrix such that $L^r = 0$. Then for every $\mu > 0$ there exist $r \times r$ matrices ρ_j with $j = 0, \dots, 2r-2$ such that*

$$\rho_j^\dagger = \rho_j \qquad \forall j, \tag{3.1.98}$$

$$-\sum_{0\le j\le 2r-2} \operatorname{Re}\langle \rho_j L^{j+1} w, w\rangle \ge \|Lw\|^2 - \mu\|w\|^2 \tag{3.1.99}$$

and

$$-\sum_{0\le k\le j\le 2r-2} \operatorname{Re}\langle i\rho_j L^{j-k} w, L^k w\rangle \le \mu\|w\|^2 \qquad \forall w \in \mathbb{H}. \tag{3.1.100}$$

This lemma will be proven later; now let us prove Proposition 3.1.14 in the reduced form. Let

$$P = D_1 - L, \qquad Q = \sum_{0\le k\le j\le 2r-2} \rho_j D_1^k L^{j-k};$$

then

$$PQ = \sum_{0\le j\le 2r-2} \rho_j (D_1^{j+1} - L^{j+1})$$

and hence

$$\operatorname{Re}\langle QPv, v\rangle_+ = -\sum_{0\le j\le 2r-2} \langle \rho_j L^{j+1} v, v\rangle_+ + \sum_{0\le j\le 2r-2} \langle \rho_j D_1^{j+1} v, v\rangle_+ =$$

$$-\sum_{0\le j\le 2r-2} \langle \rho_j L^{j+1} v, v\rangle_+ + \frac{1}{2} \sum_{0\le k\le j\le 2r-2} \operatorname{Re}\langle i\rho_j (D_1^{j-k} v)(0), (D_1^k v)(0)\rangle$$

where we have applied (3.1.98). Let us replace D_1^k and D_1^{j-k} in the last term by L^k and L^{j-k} respectively; then the absolute value of the error will not exceed

$$C\Big(\sum_{1\le j\le 2r-2} \|(D_1^{j-1} Pv)(0)\|^2 + \|v(0)\|^2\Big) \le \mu \|v\|_+^2 + C \sum_{0\le j\le 2r-2} \|D_1^j Pv\|_+^2$$

where the last inequality is due to the obvious estimates

$$\|v(0)\|^2 \le \|v\|_+ \cdot \|D_1 v\|_+ \quad \text{and} \qquad \|D_1 v\|_+ \le \|Pv\|_+ + C\|v\|_+.$$

Hence for every $\mu > 0$ the following estimate holds:

$$\sum_{0\le j\le 2r-2} \operatorname{Re}\langle -\rho_j L^{j+1} v, v\rangle_+ + \frac{1}{2} \sum_{0\le k\le j\le 2r-2} \operatorname{Re}\langle i\rho_j L^{j-k} v(0), L^k v(0)\rangle \le$$

$$\mu \|v\|_+^2 + C \sum_{0\le j\le r-2} \|D_1^j Pv\|_+^2.$$

These estimates combined with (3.1.100) imply (3.1.85). □

Proof of Lemma 3.1.15. By induction on $l = 1, \dots, r$ we will prove that for every l there exist Hermitian matrices ρ_j with $j = 0, \dots, 2l-2$ such that

$$(3.1.101)_l \quad -\sum_{0\le j\le 2l-2} \operatorname{Re}\langle \rho_j L^{j+1} w, w\rangle \ge \epsilon_l \|Lw\|^2 - \mu \|w\|^2 - C_{l\mu} \|L^l w\|^2$$

and

$$(3.1.102)_l \quad -\sum_{0\le k\le j\le 2l-2} \operatorname{Re}\langle i\rho_j L^{j-k} w, L^k w\rangle \le \mu \|w\|^2 + C_{l\mu} \|L^l w\|^2$$

$$\forall w \in \mathbb{H}$$

where $\epsilon_l > 0$ do not depend on arbitrarily small $\mu > 0$.

Then for $l = r$ we obtain the assertion of the lemma. On the other hand, $(3.1.101)_1$ with $\mu = 0$ and $(3.1.102)_1$ with arbitrarily small $\mu > 0$ hold for $\rho_0 = L - L^\dagger$.

Let $l = 1, \dots, r-1$; let us assume that $(3.1.101)_l$ and $(3.1.102)_l$ are fulfilled with some $\epsilon_l > 0$ and matrices ρ_j $(j = 0, \dots, 2l-2)$. Then $(3.1.101)_{l+1}$ and $(3.1.102)_{l+1}$ will be fulfilled with 2μ instead of μ and with $\epsilon_{l+1} = \frac{1}{2}\epsilon$ provided

$$(3.1.103)_{l+1} \quad \operatorname{Re}\langle -\rho_{2l-1}L^{2l} - \rho_{2l}L^{2l+1})w, w\rangle \geq \\ -\frac{1}{2}\epsilon_l\|Lw\|^2 - \mu\|w\|^2 + C_{l,\mu}\|L^{2l}w\|^2 - C'_{l+1,\mu}\|L^{2l+2}w\|^2$$

and

$$(3.1.104)_{l+1} \quad \operatorname{Re}\langle(-\rho_{2l}L^l w, L^l w\rangle \leq \mu\|w\|^2 - C_{l,\mu}\|L^l w\|^2 + C'_{l+1,\mu}\|L^{l+1}w\|^2 \\ \forall w \in \mathbb{H}.$$

Indeed, let us consider all the terms in the left hand expression in $(3.1.102)_{l+1}$ which are both new in comparison with $(3.1.102)_l$ and different from $(3.1.104)_{l+1}$; obviously the absolute values of these terms do not exceed $\varepsilon\|w\|^2 + C''_{;+1,\mu,\varepsilon}\|L^{l+1}w\|^2$ where $\varepsilon > 0$ is arbitrarily small, and the constant $C_{l,\mu}$ is fixed but the constant $C'_{l+1,\mu}$ is not fixed yet.

Therefore we need to prove only that for every $\varepsilon > 0$ and $l < r$ there exist matrices $\alpha = -\alpha^\dagger$ and $\beta = -\beta^\dagger$ such that

$$-\operatorname{Re}\langle\alpha L^{2l}w, w\rangle - \operatorname{Re}\langle\beta L^{2l+1}w, w\rangle \geq -\varepsilon\|w\|^2 + \|L^{2l}w\|^2 - C_\varepsilon\|L^{2l+2}w\|^2$$

and

$$\operatorname{Re}\langle i\beta L^l w, L^l w\rangle \geq -\varepsilon\|w\|^2 + \|L^l w\|^2 - C_\varepsilon\|L^{l+1}w\|^2 \qquad \forall w \in \mathbb{H}.$$

Finally, let us note that matrices $\alpha = L^{2l} - L^{\dagger 2l}$ and

$$\beta = 4\varepsilon^{-1}(L^{2l+1} - L^{\dagger 2l+1}) - i(I - L^\dagger L)$$

satisfy these inequalities. □

Proof of Proposition 3.1.5

Obviously it is sufficient to prove this proposition for the reduced operator. Moreover, it is sufficient to check only condition (ii) in Definition 3.1.4.

The arguments of the proof of Theorem 3.1.7 imply that if the operator P_k is microhyperbolic at (every) point $z_k \in \iota^{-1}z^*$ in the direction (ℓ', ν_k) then for every $t > 0$ the following estimate holds

$$-\operatorname{Re}\langle((\ell' p_k)(z^*, D_1)v, v\rangle_+ \geq \epsilon_0\|v\|_+^2 + t\|v(0)\|^2 - C_t \sum_{0\leq j\leq l} \|D_1^j p_k(z^*, D_1)v\|_+^2 \qquad \forall v \in \mathscr{S}(\mathbb{R}^+, \mathbb{H}).$$

Hence the same estimate holds for all $z : |z - z^*| \leq \varepsilon(t)$. Then the estimate

$$-\operatorname{Re}\langle((\ell' p_k)(z^*, D_1)v, v\rangle_+ \geq \epsilon_0\|v\|_+^2 + t\|v(0)\|^2 \qquad \forall v \in \mathbb{H}'_k(z)$$

holds where $\mathbb{H}'_k(z)$ is the space of all solutions of the equation $p_k(z, D_1)v = 0$ decreasing at $+\infty$.

Therefore for large enough $t > 0$ and small enough $\varepsilon > 0$ estimate (3.1.26) at the point $z = z^*$ implies the same estimate at points $z : |z - z^*| \leq \varepsilon$. Furthermore, $\mathbb{H}'(z^*) = \mathbb{H}'_0$ in our decomposition and $\mathbb{H}'(z) = \mathbb{H}'_0 \oplus \mathbb{H}'_1(z) \oplus \cdots \oplus \mathbb{H}'_n(z)$.

Hence condition (ii) is stable with respect to perturbations of z and hence it is stable with respect to perturbations of P, B also. Moreover, this condition is obviously stable with respect to ℓ' as well.

3.2 Geometric Interpretation

3.2.1 Main Theorem

Notations and Definitions

This section is similar to Section 2.2. Let us remind that the set

$$\mathfrak{N}(p, b) = \big\{(z', \mathcal{T}) : z' \in T^*\partial X, \text{ and the problem } (P, B) \text{ is microhyperbolic at the point } z' \text{ in the multidirection } \mathcal{T}\big\} \tag{3.2.1}$$

is open in the sense of Proposition 3.1.5 and Remark 3.1.6. Moreover, obviously

(3.2.2) The set $\mathfrak{K}(p,b,z') = \{\mathcal{T} : (z',\mathcal{T}) \in \mathfrak{N}(p,b)\}$ is convex for any $z' \in T^*\partial X$.

Let us introduce the set

(3.2.3) $K'(p,b,z') = \boldsymbol{\iota}\mathfrak{K}(p,b,z') =$
$\{\ell', \exists(\nu_1,...,\nu_n)$ such that $(\ell',\nu_1,...,\nu_M) \in \mathfrak{K}(p,b,z')\} \subset T_{z'}T^*\partial X$

where $\boldsymbol{\iota} : \mathcal{T} = (\ell,\nu_1,...,\nu_n) \to \ell$ is a natural map.

Since microhyperbolicity condition in Definition 3.1.4 consists of two conditions (i) and (ii) and the first condition does not include B while the second one does not contain $(\nu_1,...,\nu_n)$ we conclude that

$$K'(p,b,z') = K'(p,z') \cap K''(p,b,z') \tag{3.2.4}$$

where

(3.2.5) $K'(p,z') = \boldsymbol{\iota}\mathfrak{K}(p,z')$ and $\mathfrak{K}(p,z')$ is defined by (3.2.1) and (3.2.2) with the full microhyperbolicity condition replaced by condition (i) in Definition 3.1.4

while

(3.2.6) $K''(p,b,z')$ is the set of all directions $\ell' \in T_{z'}T^*\partial X$ satisfying condition (3.1.26).

Then

(3.2.7) $K''(p,b,z')$ is an open convex cone

and

$$K'(p,z') = \bigcap_{z_k \in \iota^{-1}z' \cap \Sigma} \pi K(p,z_k) \tag{3.2.8}$$

$$K'(p,b,z') = \bigcap_{z_k \in \iota^{-1}z' \cap \Sigma} \pi K(p,z_k) \cap K''(p,b,z') \tag{3.2.9}$$

where $\pi : T_{\iota^{-1}z'}T^*X \to T_{z'}T^*\partial X$ is a natural map.

Thus, $K''(p,b,z')$, $K'(p,z')$ and $K'(p,b,z')$ are subsets of $T_{z'}T^*\partial X$ while $K(p,z_k) \subset T_{z_k}T^*X$.

Now we can introduce the dual (with respect to bilinear form σ) cones $K''^{\#}(p,b,z')$, $K'^{\#}(p,z')$ and $K'^{\#}(p,b,z')$, all subsets of $T_{z'}T^*\partial X$ as well. Obviously

$$K'^{\#}(p,z') = \oplus \sum_{z_k \in \iota^{-1}z' \cap \Sigma} (K^{\#}(p,z_k) \cap T_{z'}T^*\partial X), \tag{3.2.10}$$

$$K'^{\#}(p,b,z') = \oplus \sum_{z_k \in \iota^{-1}\iota z' \cap \Sigma} (K^{\#}(p,z_k) \cap T_{z'}T^*\partial X) \oplus K'^{\#}(p,b,z'). \tag{3.2.11}$$

Finally, let

$$K^{\#}(p,b,z') = \oplus \sum_{z_k \in \iota^{-1}z' \cap \Sigma} K^{\#}(p,z_k) \oplus K'^{\#}(p,b,z') \tag{3.2.12}$$

(and one can introduce $K^{\#}(p,z')$ in the same way but without the last term).

Remark 3.2.1. (i) $K^{\#}(p,z_k)$, $K^{\#}(p,z')$ and $K^{\#}(p,b,z')$ are subsets of $T_{\iota^{-1}z'}T^*X$ while $K'^{\#}(p,z')$ and $K''^{\#}(p,z')$ are subsets of $T_{z'}T^*\partial X$.

(ii) Obviously these sets have the properties described in Lemma 2.2.3.

Without any loss of generality we can assume that $X = \{x_1 \geq 0\}$ locally. Further, let us assume that

(3.2.13) $\nabla^{\#}x_2 \in K^{\#}(p,z) \quad \forall z \in \bar{\Omega}$ such that $z \notin T^*X|_{\partial X}$ and
$\nabla^{\#}x_2 \in K^{\#}(p,b,z') \quad \forall z' \in \iota\bar{\Omega} \cap T^*\partial X$ where $\Omega \subset T^*X$ such that

$$z \in \Omega \cap T^*X|_{\partial X} \implies \iota^{-1}\iota z \in \Omega \tag{3.2.14}$$

This assumption is similar to (2.2.1).

Definition 3.2.2. Let $\Omega \subset T^*X$ be a domain satisfying (3.2.14). A *generalized bicharacteristic billiard* is a curve $\{z = z(t)\}$ in $\bar{\Omega} \cap T^*X$ (where $\bar{\Omega}$ is a closure of Ω) such that

(i) If $z(t) \notin T^*X|_{\partial X}$ for some t then $|z(t') - z(t'')| \leq C_0|t' - t''|$ for all $t', t'' : |t' - t| + |t'' - t| \leq \epsilon_0 \mathsf{dist}(z(t), T^*X|_{\partial X})$ where the constants $\epsilon_0 > 0$ and C_0 do not depend on $t, z(t)$;

(ii) In the general case $|z'(t') - z'(t'')| \le C_0|t' - t''|$ for all t', t'' where $z' = (x, \xi')$, $\xi' = (\xi_2, \dots, \xi_d)$;

(iii) For a.e. t if $z(t) \notin T^*X|_{\partial X}$ then the function $z(t)$ is differentiable at t and

$$\frac{dz}{dt} \in K^{\#}(p, z); \tag{3.2.15}$$

(iv) For a.e. t if $z(t) \in T^*X|_{\partial X}$ then the function $z'(t)$ is differentiable at t and

$$\frac{dz}{dt} \in K'^{\#}(p, b, z'). \tag{3.2.16}$$

We consider examples later. Here let us notice that generalized bicharacteristic billiards are the generalized bicharacteristics inside the domain (equation (3.2.15) coincides with (2.2.23)) but on the boundary they can jump along $\iota^{-1}\iota z$ and also experience other effects. Equivalent definition would be if we considered T^*X with points z_1, z_2 glued together iff $z_1, z_2 \in T^*X|_{\partial X}$ and $\iota z_1 = \iota z_2$.

Then one could rewrite (3.2.15), (3.2.16) as

$$\frac{dz}{dt} \in K^{\#}a(p, b, z). \tag{3.2.17}$$

where $K^{\#}(p, b, z) = K^{\#}(p, z)$ as $z \notin T^*X|_{\partial X}$ and $K^{\#}(p, b, z) = K^{\#}(p, b, \iota z)$ as $z \in T^*X|_{\partial X}$.

Definition 3.2.3. Let $\mathcal{K}^{\pm}(p, b, z, \Omega)$ be the union of all the generalized bicharacteristic billiards residing in $\bar{\Omega}$ and going out from the point $z \in \bar{\Omega}$ in the direction of increasing $\pm t$.

Finally, Main Theorem

Theorem 3.2.4. *Let $\Omega \Subset T^*X$, $\Omega' \Subset T^*\partial X$ and $\Omega|_{\partial X} = \iota^{-1}\Omega'$. Let (P, B) satisfy the conditions of Theorem 3.1.7 in Ω' and let p be symmetric in Ω.*

Further, let condition (3.2.13) *be fulfilled.*

(i) Let u *be admissible (i.e., satisfy* (3.1.20)*) and*

$$\mathsf{WF}^{s+1}(Pu) \cap \mathcal{K}^-(p,b,z,\Omega) = \emptyset, \tag{3.2.18}$$

$$\bigl(\mathsf{WF}_b^{s+1,l}(Pu) \cup \mathsf{WF}^{s+\frac12}(B\mathring{\partial}_h u)\bigr) \cap \iota\mathcal{K}^-(p,b,z,\Omega) = \emptyset, \tag{3.2.19}$$

and

$$\mathsf{WF}^{s}(u) \cap \partial\Omega \cap \mathcal{K}^-(p,b,z,\Omega) = \emptyset, \tag{3.2.20}$$

$$\mathsf{WF}_b^{s,0}(u) \cap \partial\Omega' \cap \iota\mathcal{K}^-(p,b,z,\Omega) = \emptyset. \tag{3.2.21}$$

Then

$$\mathsf{WF}^{s}(u) \cap \mathcal{K}^-(p,b,z,\Omega) = \emptyset, \tag{3.2.22}$$

$$\mathsf{WF}_b^{s,l+m}(u) \cap \iota\mathcal{K}^-(p,b,z,\Omega) = \emptyset. \tag{3.2.23}$$

(ii) Moreover, let condition $(3.1.9)^*$ *be fulfilled in* Ω'*. Then one can weaken the condition* (3.2.19) *replacing* $\mathsf{WF}^{s+\frac12}(B\mathring{\partial}_h u)$ *by* $\mathsf{WF}^{s}(B\mathring{\partial}_h u)$*:*

$$\bigl(\mathsf{WF}_b^{s+1,l}(Pu) \cup \mathsf{WF}^{s+\frac12}(B\mathring{\partial}_h u)\bigr) \cap \iota\mathcal{K}^-(p,b,z,\Omega) = \emptyset \tag{3.2.19}'$$

and skip condition (3.2.21) *completely and at the same time obtain in addition that*

$$\mathsf{WF}^{s-j}(D_1^j u|_{\partial X}) \cap \iota\mathcal{K}^-(p,b,z,\Omega) = \emptyset \qquad \forall j = 0,\dots,m+l-1. \tag{3.2.24}$$

Proof. The proof repeats without any essential modifications the proof of Theorem 2.2.10: first, we introduce $K^{\cdots}_{\rho\varepsilon}(\dots)$ versions of all sets $K^{\cdots}(\dots)$ introduced before and study their properties.

Further, using Theorem 3.1.7 we prove the counterpart of Proposition 2.2.7: namely, we consider point $z' \in \Omega$, and for arbitrarily small ρ,ε we establish Statements (i) and (ii) similar to those of Theorem 3.1.7 but with Ω' and Ω replaced by narrow vicinities of z' and $\iota^{-1}z'$ respectively and with $\{\phi_1 \le t_1\}\cap\dots\cap\{\phi_J \le t_J\}$ and $\{\phi_{k1} \le t_1\}\cap\dots\cap\{\phi_{kJ} \le t_J\}$ replaced by $\bigl(z' - K'^{\#}_{\rho\varepsilon}(p,b,z')\bigr)$ and $\bigl(\iota^{-1}z' - K^{\#}_{\rho\varepsilon}(p,b,z')\bigr)$ respectively.

Furthermore, we introduce $\mathcal{K}^{\pm}_{\rho\varepsilon}(p,b,z')$ and study their properties. We prove the counterpart of Lemma 2.2.9 and based on the above counterpart of Proposition 2.2.7 and on Proposition 2.2.7 itself we establish Theorem 3.2.4 but with $\mathcal{K}^-(p,b,z)$ replaced by $\mathcal{K}^-_{\rho\varepsilon}(p,b,z)$.

Finally, taking $\rho \to +0$, $\varepsilon \to +0$ we prove that $\mathcal{K}^-_{\rho\varepsilon}(p,b,z,\Omega)$ tends to $\mathcal{K}^-(p,b,z,\Omega)$ which concludes the proof. We leave all obvious but tedious details to the reader. □

3.2.2 Discussion and Examples

General Remarks

Propagation of singularities near boundary is very complicated. Even analysis of the scalar operators of the principal type becomes really complicated due to jumping along $\iota^{-1}(z')$ and especially due to bicharacteristics tangent to the boundary. Even case of elliptic P is as complicated as the general boundaryless case case (see Subsubsection *3.2.2.4 Elliptic Points* below).

Remark 3.2.5. (i) Under condition $(3.1.9)^*$ $K''(p,b,z) = \mathbb{R}^{2d-2}$ and hence there is no propagation linked with the boundary conditions. One can prove it easily following the proof of Theorem 3.1.13. This would make results marginally simpler.

However in this book we are interested in the symmetric, not strictly dissipative boundary conditions. In Section 3.4 we will show that one can replace $(3.1.9)^*$ by a weaker condition (3.4.18) which dallows symmetric boundary conditions and has the same effect.

(ii) To ensure that boundary value problem is not overdetermined, we assume that

(3.2.25) B is $\bar{\mathsf{D}}_+ \times$ D-matrix operator.

Constant Coefficients Case

Example 3.2.6. As $X = \{x \in \mathbb{R}^d, x_1 \ge 0\}$ and $p = p(\xi)$, $b = b(\xi)$ we have that

$$\mathcal{K}^-(p,b,z) = \big(z - K^{\#}(p,b,z)\big) \cap T^*X \qquad \text{as } z \in T^*X|_{\partial X} \tag{3.2.26}$$

$$\mathcal{K}^-(p,b,z) = \big(z - K^{\sigma}(p,z)\big) \cap T^*X \ \cup \bigcup_{z' \in (z - K^{\sigma}(p,z))} \mathcal{K}^-(p,b,z') \qquad \text{as } z \in T^*X|_{X\setminus\partial X} \tag{3.2.27}$$

where $K(p,b,z) \subset 0 \times \mathbb{R}^d_\xi$ and $K^{\#}(p,b,z) \subset \mathbb{R}^d_x \times \iota^{-1}\iota z$.

Transversal Points

Let $z' \in T^*\partial X$ and $z_k \in \iota^{-1}z'$. Consider two very special cases:

$$K^{\sigma}(p,z_k) \setminus 0 \subset \{\pm x_1 > 0\}. \tag{3.2.28}_{\pm}$$

Definition 3.2.7. (i) As $(3.2.28)_+$ is fulfilled z_k is *outgoing point* ;

(ii) As $(3.2.28)_-$ is fulfilled z_k is *incoming point* .

(iii) As $m = 1$ (i.e. $P = A_0(x, hD')hD_1 + A_1(x, hD')$) and P has a block-diagonal form (3.1.45), the corresponding component of u is called *outgoing and incoming components* respectively.

Obviously,

(3.2.29) As $m = 1$ and P has a block-diagonal form (3.1.45), condition $(3.2.28)_\pm$ is equivalent to

$(3.2.30)_\pm$ $\qquad \pm a_k(z')$ is positive definite.

Let us denote by u', u'' and u''' collections of all outgoing, incoming and other components respectively. Let $\mathsf{D}', \mathsf{D}'', \mathsf{D}'''$ be dimensions of u', u'', u'''. Let us rewrite boundary operator B in the form $B = \begin{pmatrix} B' & B'' & B''' \end{pmatrix}$. Then (3.2.10) and $(3.2.30)_+$ imply that

$$\operatorname{rank} b' = \mathsf{D}' \tag{3.2.31}$$

and therefore one can assume without any loss of the generality that

$$B = \begin{pmatrix} I & B_1'' & B_1''' \\ 0 & B_2'' & B_2''' \end{pmatrix} \tag{3.2.32}$$

(otherwise we multiply it by an elliptic operator from the left). Then microlocally one can exclude outgoing components, consider reduced operator P and boundary operator B:

$$P = \begin{pmatrix} P' & 0 & 0 \\ 0 & P'' & 0 \\ 0 & 0 & P''' \end{pmatrix}, \qquad B = \begin{pmatrix} I & B_1'' & B_1''' \\ 0 & B_2'' & B_2''' \end{pmatrix} \tag{3.2.33}$$

where removed components are dimmed.

One can see easily that all conditions are fulfilled including (3.1.11), (3.2.25) and $(3.1.9)^{8)}$. As we determine (u'', u''') from the reduced problem,

[8)] Which may even become $(3.1.9)^*$; we leave to the reader to find out when it happens.

we can find $\eth u'$ from the remaining boundary conditions and then find u' for $x_1 > 0$ solving Cauchy problem for P' with the initial data as $\{x_1 = 0\}$.

Consider now incoming component u''. Assume that we know u'' as $\{x_2 \le t - \varepsilon, x_1 \ge \epsilon\varepsilon\}$ while $x_2(z') = t$; recall that we assume that P is microhyperbolic in direction $\nabla^{\#} x_2$ where $\epsilon > 0$ and $\varepsilon > 0$ are small enough constants. Then u' is determined in the small vicinity of $\iota^{-1} z'$ from the "Cauchy" problem with data at $\{x_2 \le t - \varepsilon\}$. Thus, we can exclude incoming trajectories as well:

$$P = \begin{pmatrix} P'' & 0 \\ 0 & P''' \end{pmatrix}, \qquad B = \begin{pmatrix} B_2'' & B_2''' \end{pmatrix} \tag{3.2.34}$$

(but due to the different reason).

One can see easily that all conditions are fulfilled including (3.1.11), (3.2.25) and (3.1.9).

Elliptic Points

Consider now *elliptic component* u_0 of u; in accordance with (3.1.45) we denote it by (u', u'') where $p_0'' = (p_0')^{\dagger}$ and without any loss of the generality one can assume that

$$a_0(z') = \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix}, \qquad a_1(z') = \begin{pmatrix} 0 & -\alpha \\ -\alpha^{\dagger} & 0 \end{pmatrix} \tag{3.2.35}$$

where α satisfies (3.1.51).

Then due to Theorem 3.1.12 the equation $P_0'' u'' \equiv f''$ alone determines u'' (modulo $O(h^s)$). In a certain sense u'' is similar to incoming component of the previous subsubsection. However, while we can remove it from B, we cannot remove it from P without removing u' because then assumption $p^{\dagger} = p$ would be violated. Let us rewrite B as $B = \begin{pmatrix} B' & B'' & B''' \end{pmatrix}$ again where again u''' denotes remaining components and $\mathsf{D}', \mathsf{D}'', \mathsf{D}'''$ are dimensions of components. Assuming that

$$\operatorname{rank} b' = \mathsf{D}' \tag{3.2.36}$$

we can assume without any loss of the generality that B has form (3.2.32) and then we can determine $\eth u'$ from $\eth u'''$ and then we can remove both u'' and u' from P and from B reducing them to P''' and B_2'''. One can see easily that all conditions are fulfilled including (3.1.11), (3.2.25) and (3.1.9).

Knowing u''' we can find $\eth u'$ from the boundary conditions and then u' according to Theorem 3.1.12 solving Cauchy problem.

However, this reduction requires condition (3.2.36). Assume now that $\mathsf{D}''' = 0$. Then what we have is $B'\eth u' = 0$. Due to Theorem 3.1.12 equation $P'u \equiv f'$ has no effect on $\eth u'$ and therefore in this case analysis of propagation for (P, B) is reduced to the analysis of propagation for B'.

Condition (3.3.17) below implies that $\beta' b'$ is symmetric while (3.1.9) implies that $\beta' b'$ is dissipative[9]; here β' is an elliptic symbol. Further, condition (3.1.9)* clearly implies that $\beta' B'$ is strictly dissipative and thus elliptic.

Finally microhyperbolicity condition for (P, B) is equivalent to microhyperbolicity condition for $\beta' b'$.

Remark 3.2.8. The boundary waves are often called surface waves and they are $O(h^s)$ on the distances $\geq C_s h^{-1}|\log h|$ from the boundary.

Example 3.2.9. The most famous example of the boundary waves in the elliptic zone are Rayleigh waves in the elasticity; see f.e. M. Taylor [4].

Bicharacteristics tangent to the boundary

Let us consider the simplest and the most interesting case. Assume that $\mathsf{D} = 2$, $\mathsf{D}_+ = 1$ (may be after removal transversal and removable elliptic components) . One can prove easily that in this case one can reduce p to

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \xi_1 \pm \begin{pmatrix} I & 0 \\ 0 & r(x,\xi') \end{pmatrix} \tag{3.2.37}$$

with a scalar real-valued symbol $r(x,\xi')$ and then

$$g(x,\xi) = -\xi_1^2 + r(x,\xi'). \tag{3.2.38}$$

Further, let us assume that $g(x,\xi) = \det p(x,\xi)$ is of the real principal type (i.e. $g = 0 \implies |\nabla g| \geq \epsilon$) which now is equivalent to

$$|r(x,\xi') = 0| \leq \epsilon_0 \implies |\nabla_{x,\xi'} r(x,\xi')| \geq \epsilon_0 \tag{3.2.39}$$

[9] We call symbol ε *dissipative* if $i(\varepsilon - \varepsilon^\dagger)$ is nonnegative matrix and *strictly dissipative* if it is strictly positive matrix.

and also microhyperbolic with respect $\nabla^{\#}x_2$ which is equivalent to

$$|r(x,\xi')=0| \le \epsilon_0 \implies \pm\partial_{\xi_2} r(x,\xi') \ge \epsilon_0. \tag{3.2.40}_{\pm}$$

Then

$$\begin{aligned} T^*\partial X = \{(0,x',\xi')\} = \mathcal{H}\cup\mathcal{G}\cup\mathcal{G} \coloneqq \\ \{(x',\xi') : r(0,x',\xi')>0\}\cup\{(x',\xi') : r(0,x',\xi')=0\}\cup \\ \{(x',\xi') : r(0,x',\xi')<0\} \end{aligned} \tag{3.2.41}$$

where $\mathcal{H}$, $\mathcal{E}$ and $\mathcal{G}$ are called respectively *hyperbolic, elliptic, glancing zones*.

Analysis in the Hyperbolic Zone. In the hyperbolic zone $\mathcal{H}$ we have two transversal trajectories: an incoming trajectory with $\xi_2 = \pm r^{1/2}(x',\xi')$ and an outgoing trajectory with $\xi_2 = \mp r^{1/2}(x',\xi')$ (in the framework of $(3.2.40)_{\pm}$); reflection goes according to "incident angle = reflection angle" law.

Analysis in the Elliptic Zone. In the elliptic zone $\mathcal{E}$ propagation can happen only along boundary bicharacteristics. Namely, assuming that the boundary problem satisfies conditions (3.2.25) and (3.3.17) we have (after multiplication by an elliptic symbol) either

$$b(x'\xi') = \begin{pmatrix} i & \beta(x',\xi') \end{pmatrix} \tag{3.2.42}$$

or

$$b(x'\xi') = \begin{pmatrix} i\tilde{\beta}(x',\xi') & 1 \end{pmatrix} \tag{3.2.43}$$

where $\beta(x',\xi')$ and $\tilde{\beta}(x',\xi')$ are scalar real-valued symbols and the second case is not reduced to the first one near $\{\tilde{\beta}=0\}$.

Then in the elliptic zone the decaying (for $x_1>0$) solution of $p(0,x',D_1,\xi')u = 0$ is $u = e^{-(-r)^{1/2}x_1}(-i(-r)^{1/2},1)^T$ (up to a constant factor) with $r = r(0,x',\xi')$; so a prorogation of singularities for (P,B) is reduced there to a propagation for operator $Q(x',hD')$ on the boundary (applied to $v=\eth u_2$) and the principal symbol of Q is

$$q(x',\xi') = -(-r(0,x',\xi'))^{1/2} - \beta(x',\xi') \tag{3.2.44}$$

in the case (3.2.42). In the case (3.2.43)

$$q(x',\xi') = \tilde{\beta}(x',\xi')(-r(0,x',\xi'))^{1/2} + 1$$

and since we consider this case only near $\{\tilde{\beta} = 0\}$, operator Q is elliptic.

Therefore, in the case (3.2.42) the characteristic manifold of Q is

$$\Sigma_b \coloneqq \{(x',\xi') : \ \lambda(x',\xi') \coloneqq r(0,\xi,\xi) - \beta^2(x',\xi) = 0,\ \beta(x',\xi) > 0\} \tag{3.2.45}$$

and the propagation is going in the elliptic zone along the boundary along trajectories of $\lambda(x',\xi')$.

Analysis in the Glancing Zone. Consider now $(x',\xi') \in \mathcal{G}$. One can see easily that at such points

$$K^{\#}(p,b,(x',\xi')) \cap T^*X = \{\nabla^{\#} r(0,x',\xi')\}_{\mathsf{cone}}; \tag{3.2.46}$$

so we get generalized bicharacteristics going along the boundary: namely, bicharacteristics of $r(0,x',\xi')$ going along $\mathcal{G}$. We call them *boundary bicharacteristics*

The generalized bicharacteristic billiards of (P,B) thus should consist of those bicharacteristics and bicharacteristics of $r(x,\xi) - \xi_1^2$ and here we have two principally different cases:

Bicharacteristically Strongly Convex dDomain means that

$$x_1 = 0,\ g = 0,\ \{g,x_1\} = 0 \implies \{g,\{g,x_1\}\} < 0 \tag{3.2.47}$$

which is equivalent to

$$x_1 = 0,\ r(0,x',\xi') = 0 \implies \partial_{x_1} r(0,x',\xi') < 0. \tag{3.2.48}$$

In this case no bicharacteristic of g can pass through points of $\mathcal{G}$ and thus only boundary bicharacteristics are passing through $\mathcal{G}$. Further, along bicharacteristic billiards passing through points of $\mathcal{H}$ close to $\mathcal{G}$ symbol

$$\rho(x,\xi') \coloneqq r(x,\xi') - x_1 \cdot \partial_{x_1} r(0,x',\xi) = \xi_1^2 - x_1 \cdot \partial_{x_1} r(0,x',\xi) \tag{3.2.49}$$

preserves its magnitude (at any finite time interval); so these billiards make short jumps; the height (maximal value of the jump) is $\asymp \rho$, the length of

each jump and the incidence/reflection angles are $\asymp \rho^{1/2}$; thus the number of jumps during the finite time is $\asymp \rho^{-1/2}$.

There is a huge literature (see *Comments*). Let us mention only that it is referred as *whispering gallery* case and boundary bicharacteristics are called *gliding rays*.

Example 3.2.10. Consider

$$g(x,\xi) = \xi_2^2 - \xi_1^2 - x_1. \tag{3.2.50}$$

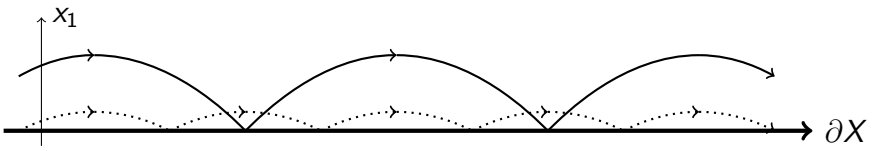


Figure 3.1: Bicharacteristically convex case: Example 3.2.10.

Bicharacteristically Strongly Concave Domain means that

$$x_1 = 0,\ g = 0,\ \{g, x_1\} = 0 \implies \{g, \{g, x_1\}\} > 0 \tag{3.2.51}$$

which is equivalent to

$$x_1 = 0,\ r(0, x', \xi') = 0 \implies \partial_{x_1} r(0, x', \xi') > 0. \tag{3.2.52}$$

In this case through each point $(x', \xi') \in \mathcal{G}$ passes both bicharacteristics of g and boundary bicharacteristics as well. The x-projection of bicharacteristic of g is tangent to ∂X; such bicharacteristics are called *grazing rays*.

Since boundary bicharacteristics resides in $\mathcal{G}$, we get that at every its point the generalized bicharacteristic billiard can leave the boundary along grazing ray. Such trajectories consisting of boundary bicharacteristics and may be grazing rays are called *creeping rays*.

Remark 3.2.11. (i) The truth is however that our results in this case are not sharp: singularities as we understand them (which are equivalent to smooth singularities) *do not* propagate along creeping rays. However analytic singularities *do* propagate along boundary bicharacteristics and creeping rays.

(ii) Further, Gevrey singularities with index $\kappa \le 3$ propagate along creeping rays while Gevrey singularities with index $\kappa > 3$ don't.

Namely, consider propagator $U(x,y,t)$ and assume that no other ray but a creeping ray only reaches x from y for time t; then $|U(x,y,t) = O(h^{\infty})$ and moreover $|\log u| \asymp sh^{-1/3}$ where $s \le t$ is a time spent by this ray creeping along boundary bicharacteristic. For more details see 3.5.3.

(iii) We will improve Theorems 3.1.7, 3.1.13 and thus 3.2.4 to exclude creeping rays.

Example 3.2.12. Consider

$$g(x,\xi) = \xi_2^2 - \xi_1^2 + x_1. \tag{3.2.53}$$

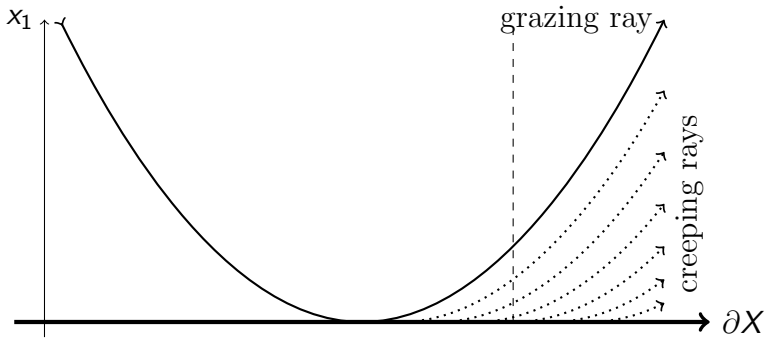

Figure 3.2: Bicharacteristically concave case: Example 3.2.10. Dotted lines show creeping rays and the dashed line shows the front of them at some moment

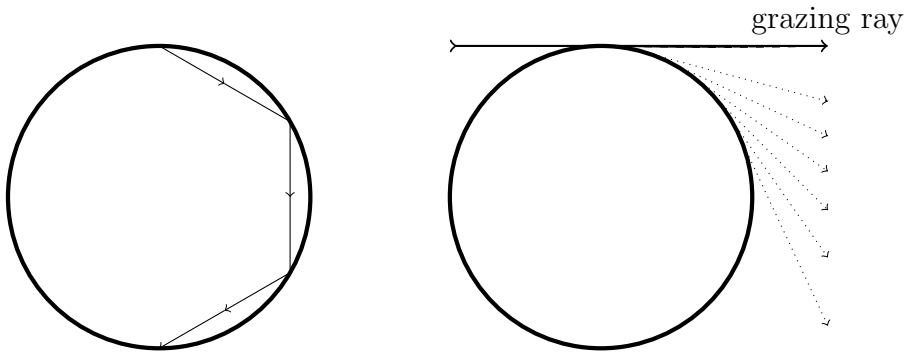
Remark 3.2.13. Consider $P = -\tau^2 + |\xi|^2$ in $X \times \mathbb{R}_t$ where $X \subset \mathbb{R}^d$ is a domain with the smooth boundary and (ξ,τ) are dual variables. Then notions of (strong) convexity and concavity coincide with ordinary geometric notions. On Figure 3.3 we consider interior (a) and exterior (b) of the circle; on (b) we also show front of the creeping rays "in the development".

We, however, distinguish *strong* and *strict* convexity and concavity; strong is a bit more restrictive as the boundaries of strictly convex and concave domains may be flat at some points (like $x_2 = x_1^4$).



(a) Convex case (b) Concave case

Figure 3.3: Straight rays and non-straight boundary

Domain which is neither Bicharacteristically Concave nor Bicharacteristically Convex. This is when the real troubles come. In this case bicharacteristic billiards can branch even if domain is just convex and the curvature $\{g,\{g,x_1\}\}$ vanishes at some points with all its derivatives.

3.3 Corollaries of Theorem 3.1.7

In this section we consider the following issues: the immediate corollaries of Theorem 3.1.7 like the finite speed of the propagation of singularities and the decomposition of a solution into two components (the free space solution and the reflected wave) and the structure in a neighborhood of $t=0$ of the restriction of the fundamental solution to the diagonal and the structure of some related functions (we are mainly interested in the *normality of the singularity*.

3.3.1 Finite Speed of Propagation and Related Topics

Finite Speed of Propagation

In this section we consider the operators

$$
\begin{aligned}
&P = hD_t + A, && B = (B_j)_{j=1,\dots,m},\\
&A \in \boldsymbol{\Psi}'^{m}_{h}(X,\mathbb{H},\mathbb{H}), && B_j \in \boldsymbol{\Psi}_h(\partial X,\mathbb{H}',\mathbb{H})
\end{aligned}
\tag{3.3.1}
$$

where $\boldsymbol{\Psi}'^{m}_{h,N}(X,\mathbb{H},\mathbb{H})$ is the class of operators of the form (3.1.1) with $A_k \in \boldsymbol{\Psi}'_{h,N}(X,\mathbb{H},\mathbb{H})$.

Surely Theorem 3.1.7 immediately yields an assertion about the finite speed of the propagation of singularities, but condition (3.1.23) of that theorem is not necessary for this special consequence, so we want to get rid of it and to prove the assertion directly.

Theorem 3.3.1. *Let P, B be operators of type* (3.3.1) *and let conditions* (3.1.4), (3.1.6) *and* (3.1.9) *be fulfilled in the domains $\Omega_+ \subset T^*(X'\times\mathbb{R}_t)\times\mathbb{R}^+_{x_1}$ and $\Omega \subset T^*(\partial X\times\mathbb{R}_t)$ respectively where $\Omega = \Omega_+ \cap \{x_1 = 0\}$; the matrix T is now defined by the operator A. Let us assume that*

$$(3.3.2)_1 \quad \|a_k(x,\xi')\| + \|\nabla_{x,\xi'}a_k(x,\xi')\| \le c \qquad \forall (t,x,\tau,\xi') \in \Omega_+ \quad \forall k = 0,\dots,m,$$

$$(3.3.2)_2 \quad \|\beta_k(x',\xi')\| + \|b_k(x,\xi')\| + \|\nabla_{x',\xi'}b_k(x,\xi')\| \le c \qquad \forall (t,x',\tau,\xi') \in \Omega \quad \forall k = 1,\dots,m$$

and

$$(3.3.2)_3 \quad |\tau| \le c \qquad \text{in } \Omega_+$$

where $a_k(x,\xi')$ are the principal symbols of A_k, $A = \Sigma_{0\le k\le m}A_k(hD_1)^k$. Let $N = N(d,m,s,M,l)$ and let u be temperate (i.e. satisfy condition (3.1.20)*). Then*

(i) If $\bar z = (\bar t,\bar x,\bar\tau,\bar\xi') \in \Omega_+$, $\bar t > 0$ and

$$(3.3.3) \qquad \mathrm{WF}^{s+1,l\prime}(Pu) \cap K_-(\bar z) \cap \Omega_+ = \emptyset,$$

$$(3.3.4) \qquad \mathrm{WF}^{s+\frac12}(B\eth_h u) \cap K_-(\bar z) \cap \Omega = \emptyset,$$

$$(3.3.5) \qquad \mathrm{WF}^{s,m+l\prime}(u) \cap K_-(\bar z) \cap \partial\Omega_+ = \emptyset$$

and if $K_-(\bar z)\cap\Omega_+$ is a bounded domain where

$$(3.3.6) \quad K_\pm(\bar z) = \{(t,x,\tau,\xi') \in T^*(X'\times\mathbb{R})\times\mathbb{R}^+ : \tau = \bar\tau, |x-\bar x| + |\xi'-\bar\xi'| \le \pm C_0(t-\bar t)\},$$

$C_0 = C_0(m,c)$, then

$$(3.3.7) \qquad \mathrm{WF}^{s,l\prime} \cap K_-(\bar z) \cap \Omega_+ = \emptyset.$$

(ii) Moreover, if condition $(3.1.9)^*$ *is fulfilled then one can replace superscript* $s+\frac{1}{2}$ *in* (3.3.4) *by* s *(see f.e.* $(3.1.28)'$*) and obtain at the same time that*

$$\mathsf{WF}^{s-j}(D_1^j u|_{\partial X}) \cap K_-(\bar z) \cap \Omega = \emptyset \qquad \forall j = 0, \dots, q+m-1. \tag{3.3.8}$$

Proof. It is sufficient to prove this theorem with $K_-(\bar z)$ replaced by $\{\phi \le 0\}$ for $\phi = t + \psi(x, \tau, \xi')$ for every smooth real-valued function ψ with

$$|\nabla_{x,\xi'}\psi| \le \varepsilon = \varepsilon(m, c) > 0; \tag{3.3.9}$$

the assertion modified in this way will be indicated by a prime.

Moreover, it is sufficient to consider the case $l = 0$ and one can assume that

$$\mathsf{WF}^{s-\frac{1}{2},m\prime} \cap \{\phi \le 0\} \cap \Omega_+ = \emptyset \tag{3.3.10}$$

and in the proof of (3.3.8) one can assume in addition that

$$\mathsf{WF}^{s-j-\frac{1}{2}}(D_1^j u|_{\partial X}) \cap \{\phi \le 0\} \cap \Omega = \emptyset \qquad \forall j = 0, \dots, m-1. \tag{3.3.11}$$

Let $q(t, x, \tau, \xi') = \zeta\chi(\phi - \delta)$ where $\zeta \in \mathscr{C}_0^\infty(\Omega_+)$ equals 1 in Ω_+ outside of the μ-neighborhood of $\partial\Omega_+$, χ is a function satisfying (2.1.8) and $\mu > 0$ is small enough. Let $Q = \mathsf{Op}^{\mathsf{w}}(q)$ and $Q' = Q^2$.

Let us apply the identity

$$\begin{aligned} -\operatorname{Re} i([P, Q']u, u) = \operatorname{Re} i((Q' + Q'^*)Pu, u) + \\ \operatorname{Re} i((P^* - P)Q'u, u) + \operatorname{Re} h(Q'^* T\eth_h u, \eth_h u)_{\partial X\times\mathbb{R}} \end{aligned} \tag{3.3.12}$$

(compare with (3.1.70)) where now the inner product $(.,.)$ is taken on $X \times \mathbb{R}$ and the matrix T is defined by (3.1.5); then after routine estimates we obtain the following inequality:

$$\begin{aligned} \|Q''u\|^2 \le \mathsf{Re}([A, \Psi]Q''u, Q''u) - \\ \mathsf{Re}\, ih(\mathcal{B}[B, \Psi]Q''\eth_h u, Q''\eth_h u)_{\partial X\times\mathbb{R}} + Ch^{2s} \end{aligned} \tag{3.3.13}$$

where Q'' and Ψ are pseudodifferentials operators with the principal symbols $q'' = \zeta\chi_1(\phi-\delta)\chi_2(\phi-\delta)$ and ψ respectively, χ_1 and χ_2 are defined in (2.1.8); moreover, under condition $(3.1.9)^*$ one can add the term $\epsilon_1\|Q''\gamma_h u\|^2_{\partial X\times\mathbb{R}}$ to

the left-hand expression in (3.3.13) where here and below $\epsilon_1 = \epsilon_1(m, c)$ and $C_1 = C_1(m, c)$.

On the other hand, (3.3.9) yields that the right-hand expression in (3.3.13) does not exceed

$$C\varepsilon \sum_{0\le j\le m} \|(hD_1)^j Q'' u\|^2 + Ch^{2s}$$

hence the theorem in question will be proven provided we prove the inequality

$$\sum_{0\le j\le m} \|(hD_1)^j Q'' u\| \le C_1 \|Q'' u\| + Ch^s.$$

This inequality follows from $(3.3.2)_3$ and the estimate

$$\sum_{0\le j\le m} \|(hD_1)^j v\| \le C_1\big(\|v\| + \|Av\| + \|\mathcal{Q}v\|\big) \tag{3.3.14}$$

where $\mathcal{Q} = \mathcal{Q}(x, D_x) \in \boldsymbol{\Psi}'^m_h(X, \mathbb{H}, \mathbb{H})$ is some operator with symbol vanishing in $\pi\Omega_+ \times \mathbb{R}_{\xi_1}$ where π is the map $(t, x, \tau, \xi) \to (x, \xi)$ and the norms are taken on X instead of $X \times \mathbb{R}$.

Estimate (3.3.14) is stable with respect to small variations of the principal symbol of A and arbitrary variations of the lower order terms and hence it is sufficient to prove the estimate

$$\sum_{0\le j\le m} \|(hD_1)^j v\|_+ \le C_1\big(\|v\|_+ + \|a(z, hD_1)v\|_+\big) \tag{3.3.15}$$
$$\forall z \in \pi\Omega_+ \quad \forall v \in \mathscr{S}(\mathbb{R}^+, \mathbb{H});$$

the previous estimate follows from this one by a partition of unity in $\pi\Omega_+$. In order to prove (3.3.15) we use the well known inequality

$$\|D_1^j v\|_+ \le C_{mj} \|D_1^m v\|_+^{\frac{j}{m}} \cdot \|v\|_+^{1-\frac{j}{m}} \qquad \forall j = 0, \dots, m; \tag{3.3.16}$$

this inequality yields that for every $\delta > 0$

$$\|\big(a(z, hD_1) - a_0(z)(hD_1)^m\big)v\|_+ \le \delta \|(hD_1)^m v\|_+ + C_\delta \|v\|_+$$

and hence condition (3.1.6) implies that

$$\|(hD_1)^m v\|_+ \le C_1\delta \|(hD_1)^m v\|_+ + C_\delta \|v\|_+ + C_\delta \|a(z, hD_1)v\|_+.$$

This inequality and (3.3.16) obviously imply (3.3.15). □

Let us replace condition (3.1.9) by the condition

$$\langle T(z)\underline{w},\underline{w}\rangle_m + 2\,\mathrm{Re}\,\langle \beta(z)b(z)\underline{w},\underline{w}\rangle = 0 \qquad \forall \underline{w}\in \mathbb{H}^m. \tag{3.3.17}$$

Such boundary problems are called *symmetric*.

Then one can replace t by $-t$, P by $-P$ and $K_-(\bar z)$ by $K_+(\bar z)$. Let us apply Theorem 3.3.1 to $u^{\pm} = \theta(\pm t)u$ instead of u and let us use the obvious analogue of Proposition 2.1.10; we then obtain

Theorem 3.3.2. *Let conditions* (3.3.1), (3.1.4), (3.1.6), (3.3.2) *and* (3.3.17) *be fulfilled and let u be temperate. Then if $\bar z = (\bar t, \bar x, \bar\tau, \bar\xi') \in \Omega_+$ and $\bar t > 0$,*

$$\mathsf{WF}^{s+1,l\prime}(Pu)\cap K_-(\bar z)\cap\{t\ge 0\}\cap\Omega_+ = \emptyset, \tag{3.3.18}$$

$$\mathsf{WF}^{s+\frac12,l\prime}(B\eth_h u)\cap K_-(\bar z)\cap\{t\ge 0\}\cap\Omega = \emptyset, \tag{3.3.19}$$

$$\mathsf{WF}^{s,m+l\prime}(u)\cap K_-(\bar z)\cap\{t\ge 0\}\cap\partial\Omega_+ = \emptyset \tag{3.3.20}$$

and

$$\mathsf{WF}^{s+1,l\prime}(Pu)\cap \pi(K_-(\bar z)\cap\{t=0\}\cap\Omega_+) = \emptyset, \tag{3.3.21}$$

$$\mathsf{WF}^{s+\frac12\prime}(B\eth_h u)\cap (\pi K_-(\bar z)\cap\{t=0\}\cap\Omega) = \emptyset, \tag{3.3.22}$$

$$\mathsf{WF}^{s,m+l\prime}(u|_{t=0})\cap \pi(K_-(\bar z)\cap\{t=0\}\cap\partial\Omega_+) = \emptyset \tag{3.3.23}$$

where in (3.3.21) *and* (3.3.22) *the wave front sets are calculated as wave front sets of functions on $X'\times(\mathbb{R}_t\times\mathbb{R}^+)$ and $\partial X\times\mathbb{R}_t$ respectively; then*

$$\mathsf{WF}^{s,m+l\prime}(u)\cap K_-(\bar z)\cap\{t\ge 0\}\cap\Omega_+ = \emptyset \tag{3.3.24}$$

This assertion remains true if we take $\bar t < 0$ and replace $K_-(\bar z)$ by $K_+(\bar z)$ and $\{t\ge 0\}$ by $\{t\le 0\}$.

Decomposition of the Fundamental Solution

At this point we assume that conditions (3.1.6) and $(3.3.2)_{1-3}$ are fulfilled for all $z\in T^*\mathbb{R}^d$. Let us assume that

(3.3.25) The operator A with domain

$$\mathfrak{D}(A) = \big\{u : D_1^j u\in \mathscr{L}^2(X,\mathbb{H}) \quad \forall j = 0,\dots,m \ \text{ and } \ B\eth_h u = 0\big\}$$

is a self-adjoint operator in $\mathscr{L}^2(X,\mathbb{H})$.

Let $U(t,x,y)$ be the Schwartz kernel of the operator $e^{-ith^{-1}A}$. Then

$$P_x U = 0, \tag{3.3.26}$$

$$B_x \eth_{hx} U = 0, \tag{3.3.27}$$

$$U\, {}^tP_y = 0, \tag{3.3.26)†}$$

$$U\, {}^t(B_y \eth_{hy}) = 0, \tag{3.3.27)†}$$

$$U|_{t=0} = \delta(x-y)I, \tag{3.3.28}$$

$$U(t,x,y) = U^\dagger(-t,y,x). \tag{3.3.29}$$

Then Theorem 3.3.2 immediately implies

Theorem 3.3.3. *Let conditions* (3.3.1), (3.1.4), (3.1.6), (3.3.17) *and* (3.3.25) *be fulfilled and* $N = N(d,m,M,s,l)$. *Then*

$$\mathsf{WF}^{s,l\prime}(U) \cap \{|\tau| \le c\} \subset \{|x-y| + |\xi' + \eta'| \le C_0|t|\} \tag{3.3.30}$$

where in the calculation of the wave front set U *is treated as a distribution on* $(\mathbb{R}_t \times X' \times X') \times \mathbb{R}^{+2}_{x_1,y_1}$.

Let us now assume that

(3.3.31) The operator A^0 with domain

$$\mathfrak{D}(A^0) = \bigl\{u : D_1^j u \in \mathscr{L}^2(X^0, \mathbb{H}) \quad \forall j = 0, \dots, m\bigr\}$$

is a self-adjoint operator[10)] in $\mathscr{L}^2(X^0,\mathbb{H})$, $X^0 = \mathbb{R}^d$ and coincides with A on X.

Let $U^0(t,x,y)$ be the Schwartz kernel of the operator $e^{-ith^{-1}A^0}$; then U^0 satisfies (3.3.26), (3.3.26)†, (3.3.28) and (3.3.29) with X replaced by X^0.

Then $U^1 = U - U^0$ satisfies equations (3.3.26), (3.3.26)†, (3.3.29) and

$$B_x \eth_{hx} U^1 = -B_x \eth_{hx} U^0, \tag{3.3.32}$$

$$U^1(\, {}^tB_y \eth_{hy}) = -U^0(\, {}^t(B_y \eth_{hy}), \tag{3.3.32)†}$$

$$U^1|_{t=0} = 0. \tag{3.3.33}$$

Hence $U^{1\pm} = \theta(\pm t)U^1$ satisfies (3.3.26), (3.3.26)† and (3.3.32), (3.3.32)† with U^0 replaced by $U^{0\pm}$. In particular, (3.3.26) and (3.3.26)† imply that

[10)] If condition (3.1.6) is fulfilled in the whole space X^0 then the operator is self-adjoint provided it is symmetric, i.e., provided its Weyl symbol is Hermitian.

(3.3.34) $U^{1\pm}$ is many times differentiable with respect to x_1, y_1.

Theorem 2.1.2 implies that for $y_1 > 0$

$$\mathsf{WF}^{s,l\prime}(\bar{\partial}_{hx} U^{0\pm}) \cap \{|\tau| \le c\} \subset \{|x'-y'| + |\xi'+\eta'| + y_1 \le \pm C_0 t\} \tag{3.3.35}$$

and hence Theorem 3.3.2 implies that

$$\mathsf{WF}^{s,l\prime}(U^{1\pm}) \cap \{|\tau| \le c\} \subset \{|x'-y'| + |\xi'+\eta'| + x_1 + y_1 \le \pm C_0 t\}; \tag{3.3.36}$$

moreover

(3.3.37) (3.3.36) holds as $y_1 \ge 0$.

Really, the only reason why we need this assumption is that otherwise $D_1^{m-1} U^{0\pm}$ has a jump as $x_1 = y_1$ and thus $\bar{\partial}_{hx} U^{0\pm}$ is not defined; however we can consider (3.3.28) with $\delta(x_1 - y_1)$ replaced by $\theta(x_1 - y_1)$ and get for modified $U^{1\pm}$ (3.3.36) with $l = 0$; then for modified $U^{1\pm}$ we get (3.3.36) with arbitrarily large l due to (3.3.26) and (3.3.26)†. Differentiating with respect to y_1 we return to original $U^{1\pm}$.

3.3.2 Normal Singularity Property

Preliminary Analysis

In this subsection we investigate the structure near $t = 0$ of the functions $\Gamma_x Q_{1x} U\, {}^t Q_{2y}$ and $\Gamma Q_{1x} U\, {}^t Q_{2y}$ [11] and some related functions where $Q_1, Q_2 \in \boldsymbol{\Psi}_h'^{m-1}(X \times \mathbb{R}, \mathbb{H}, \mathbb{H})$ are operators with symbols supported in a small neighborhood of $z^* \in T^*(\partial X \times 0)$. We now assume that condition (3.1.23) is fulfilled.

Let $\mathcal{R} \in \boldsymbol{\Psi}_h'^{m-1}(X \times \mathbb{R}, \mathbb{H}^m, \mathbb{H})$ be an operator implementing all the reductions of Subsubsection *3.1.2.1 Reduction to a Special Case*. Let us introduce $\underline{U} = \mathcal{R}_x U\, {}^t\mathcal{R}_y$ and let us consider its blocks $\underline{U}_{jk}$ with $j, k = 0, \dots, n$. Moreover, let us subdivide $\underline{U}_{00}$ into four subblocks

$$\underline{U}_{00} = \begin{pmatrix} \underline{U}_{00}^{(11)} & \underline{U}_{00}^{(12)} \\ \underline{U}_{00}^{(21)} & \underline{U}_{00}^{(22)} \end{pmatrix},$$

[11] Recall that $(\Gamma_x V)(x,t) = V(x,t)$ and $(\Gamma V)(t) = \int V(x,x,t)dx$.

and subdivide $\underline{U}_{0k}$ and $\underline{U}_{j0}$ with $j, k = 1, \dots, n$ into two subblocks

$$\underline{U}_{0k} = \begin{pmatrix} \underline{U}^{(1)}_{0k} \\ \underline{U}^{(2)}_{0k} \end{pmatrix}, \qquad \underline{U}_{j0} = \begin{pmatrix} \underline{U}^{(1)}_{j0} & \underline{U}^{(2)}_{j0} \end{pmatrix}.$$

Then

$$\Gamma_x Q_{1x} U\, {}^t Q_{2y} \equiv \sum_{0\le j,k\le n} \Gamma_x Q_{1,jx} \underline{U}_{jk}\, {}^t Q_{2,ky} \tag{3.3.38}$$

where $Q_{1,j}, Q_{2,j} \in \boldsymbol{\Psi}'_h(X \times \mathbb{R}, \mathbb{H}, \mathbb{H}_j)$ are operators with symbols supported in a small neighborhood of z^*.

Theorem 3.1.2, (3.3.26) and (3.3.26)† imply that

$$\mathsf{WF}^{s,l\prime\prime}(\underline{U}^{(2)}_{0k})^{\mathsf{T}} \cap z^* \times X'_y \times \mathbb{R}^{+2}_{x_1,y_1} = \emptyset, \tag{3.3.39}$$

$$\mathsf{WF}^{s,l\prime\prime}(\underline{U}^{(1)}_{j0})^{\mathsf{T}} \cap X'_x \times z^* \times \mathbb{R}^{+2}_{x_1,y_1} = \emptyset \tag{3.3.39}^*$$

where ${}^{\mathsf{T}}$ means that η is replaced by $-\eta$.

Therefore

(3.3.40) Assertion (3.3.36) remains true for $Q_{1,0x}\underline{U}_{0k}$, $\underline{U}_{j0}\, {}^t Q_{2,0y}$ and $Q_{1,0x}\underline{U}_{00}\, {}^t Q_{2,0y}$ replaced by $Q^{(1)}_{1,0x}\underline{U}_{0k}$, $\underline{U}^{(2)}_{j0}\, {}^t Q^{(2)}_{2,0y}$ and $Q^{(1)}_{1,0x}\underline{U}^{(12)}_{00}\, {}^t Q^{(2)}_{2,0y}$ respectively (where we use the obvious notation).

We need

Proposition 3.3.4. *The following formula holds:*

$$\Gamma'' Q_{1,x} U\, {}^t Q_{2,y} \equiv \sum_{1\le j\le n} \Gamma'' Q_{1,jx} \underline{U}_{jj}\, {}^t Q_{2,jy} + \sum_{0\le j,k\le n} h\Gamma_{x'} \mathcal{Q}_{jk}(V_{jk}), \tag{3.3.41}$$

where

$$V = \underline{U}|_{x_1=y_1=0}, \tag{3.3.42}$$

$$(\Gamma'_{x'} V)(x', t) = V(x', x', t), \qquad (\Gamma'' V)(x', t) = \int_{\mathbb{R}^+} V(x, x, t)\, dx_1. \tag{3.3.43}$$

and $\mathcal{Q}_{jk} \in \boldsymbol{\Psi}_h\big(\partial X \times \partial X \times \mathbb{R}^+, \mathcal{L}(\mathbb{H}, \mathbb{H}), \mathcal{L}(\mathbb{H}_j, \mathbb{H}_k)\big)$ *are operators with symbols supported in a small neighborhood of point* $z^{**} = (x^*, y^*, t^*, \xi^*, -\eta^*, \tau^*)$.

Proof. It is sufficient to prove that for $j \neq k$

$$\Gamma'' Q_{1,jx} \underline{U}_{jk}\, {}^t Q_{2,ky} \equiv h\mathcal{Q}_{jk}(V_{jk}); \tag{3.3.44}$$

the equality

$$\Gamma'' Q^{(1)}_{1,jx} \underline{U}^{(12)}_{00}\, {}^t Q_{2,ky} \equiv h\mathcal{Q}_{00}(V^{(12)}_{00}) \tag{3.3.45}$$

is proven in the same way.

Let us note that modulo functions negligible in the vicinity of z^{**} the following equalities are due to (3.3.26) and (3.3.26)†:

$$(hD_{x_1} - L_{jx})\underline{U}_{jk} \equiv 0, \tag{3.3.46}$$

$$\underline{U}_{jk}(-hD_{y_1} - {}^t L_{ky}) \equiv 0 \tag{3.3.47}$$

where $L_{jx} = L_j(x, hD'_x, hD_t) = -\underline{A}^{-1}_{0j}\underline{A}_{1j}$, $\underline{P}_j = \underline{A}_{0j} hD_1 + \underline{A}_{1j}$ are the diagonal blocks of the reduced operator and here M^{-1} means a parametrix of M in the neighborhood of z^* or z^{**}. Hence

$$h(D_{x_1} + D_{y_1})\underline{U}_{jk} \equiv L_{jx}\underline{U}_{jk} - \underline{U}_{jk}\, {}^t L_{ky} \tag{3.3.48}$$

and setting $W = \underline{U}_{jk}|_{x_1=y_1}$ we obtain that

$$hD_1 W \equiv \mathcal{N}_{jk}(W) \coloneqq L_{jx} W - W\, {}^t L_{ky}. \tag{3.3.49}$$

Let us consider operator $\mathcal{N}_{jk} = \mathcal{N}(x_1, x', y', hD_{x'}, hD_{y'})$ as an element of $\boldsymbol{\Psi}'_h\bigl(\mathbb{R}^+ \times X' \times X', \mathcal{L}(\mathbb{H}_j, \mathbb{H}_k), \mathcal{L}(\mathbb{H}_j, \mathbb{H}_k)\bigr)$.

Let us note that if λ_j and λ_k belong to the spectra of the principal symbols of L_j and L_k respectively with $j \neq k$ then $|\lambda_j - \lambda_k| \geq \epsilon > 0$ at z^{**}.

Therefore due to Appendix 3.A.1 the principal symbol of the operator $\mathcal{N}_{jk}$ is invertible at z^{**} and thus this operator is elliptic in a neighborhood of the point in question[12)]. Then (3.3.49) yields that

$$W \equiv {\mathcal{N}_{jk}}^{-1}(hD_1 W). \tag{3.3.50}$$

Hence

$$Q_{1,jx} W\, {}^t Q_{2,ky} \equiv -i\mathcal{Q}'_{jk}(hD_1 W).$$

[12)] The same remains true if we replace L_j and L_k by $L^{(1)}_0$ and $L^{(2)}_0$ respectively and hence all the forthcoming analysis also remains true.

Let us permute $\mathcal{Q}'_{jk} \in \boldsymbol{\Psi}'_h\bigl(X' \times X' \times \mathbb{R}^+, \mathcal{L}(\mathbb{H},\mathbb{H}), \mathcal{L}(\mathbb{H}_j,\mathbb{H}_k)\bigr)$ with hD_1 and substitute the right-hand expression of (3.3.40) instead of W into the term with the commutator. Moreover, let us repeat this procedure many times; we then obtain

$$Q_{1,jx} W\, {}^tQ_{2,ky} \equiv -ihD_1 \mathcal{Q}''_{jk}(W).$$

Integration on $x_1 \in \mathbb{R}^+$ and substitution $y' = x'$ gives us (3.3.44) with $\mathcal{Q}_{jk} = \mathcal{Q}''_{jk}|_{x_1=0}$. □

Main Results

Theorem 3.3.5. *Let P and B satisfy conditions* (3.3.1), (3.1.4), (3.1.6), (3.1.23), (3.3.17), (3.3.25) *and* (3.3.31). *Let us assume that the problem (P,B) is microhyperbolic at the point $z^* \in T^*(\partial X \times \mathbb{R})$, $t(z^*) = 0$ in the multidirection $\mathcal{T} = (\ell'_x, \ell'_\xi, \nu_1, \dots, \nu_n)$.*

Further, let $Q_1, Q_2 \in \boldsymbol{\Psi}'_h(X \times \mathbb{R}, \mathbb{H}, \mathbb{H})$ have symbols supported in a small enough neighborhood of point z^*. Finally, let $\chi \in \mathscr{C}_0^N([\frac12, 1])$ and $T > 0$ be a small enough constant, $N = N(d, m, l, s, \mathsf{D}^*)$ and let $|\alpha| \le l$, $|\beta| \le l$. Then

(i) If $\ell'_x = 0, \nu_1 = \dots = \nu_n = \nu$ then

$$\|\Gamma_x \chi_T(t) D_x^\alpha D_y^\beta Q_{1,x} U\, {}^tQ_{2,y}\| \le C' h^s \tag{3.3.51}$$

where here and below in this theorem C' depends on T.

(ii) If $\ell'_x = 0$ then

$$\|\Gamma'' \chi_T(t) D_x^\alpha D_y^\beta Q_{1,x} U\, {}^tQ_{2,y}\| \le C' h^s \tag{3.3.52}$$

and

$$\|\Gamma'_{x'} \eth_x \eth_y \chi_T(t) D_x^\alpha D_y^\beta Q_{1,x} U\, {}^tQ_{2,y}\| \le C' h^s. \tag{3.3.53}$$

(iii) If $\nu_1 = \dots = \nu_n = \nu$ then

$$\|\Gamma''' \chi_T(t) D_x^\alpha D_y^\beta Q_{1,x} U\, {}^tQ_{2,y}\| \le C' h^s \tag{3.3.54}$$

where $(\Gamma''' V)(x_1, t) := \int_{X'} (\Gamma_x V)(x_1, x', t)\, dx'$.

(iv) If $\ell'_x = \ell'_\xi = 0$ then

$$\|\eth_x \eth_y \chi_T(t) D_x^\alpha D_y^\beta Q_{1,x} U\, {}^tQ_{2,y}\| \le C' h^s. \tag{3.3.55}$$

(v) In the general case

$$\|\Gamma\chi_T(t)D_x^\alpha D_y^\beta Q_{1,x}U\,{}^tQ_{2,y}\| \le C'h^s \tag{3.3.56}$$

and

$$\|\Gamma'\eth_x\eth_y\chi_T(t)D_x^\alpha D_y^\beta Q_{1,x}U\,{}^tQ_{2,y}\| \le C'h^s. \tag{3.3.57}$$

Proof. Let us note that (iii) and (v) follow from (i) and (ii) respectively by means of the Fourier integral operator on x' with linear canonical transformation $\Psi : (x',\xi') \to \Psi(x',\xi')$ such that $(\Psi\ell')_\xi = 0$. Let us prove (i), (ii) and (iv).

Let $\underline{P}$ be a reduced operator and $\mathcal{R}$ an operator implementing this reduction. Let

$$\underline{U} = \mathcal{R}_x U\,{}^t\mathcal{R}_y, \quad \underline{U}^0 = \mathcal{R}_x U^0\,{}^t\mathcal{R}_y \quad \text{and} \quad \underline{U}^1 = \mathcal{R}_x U^1\,{}^t\mathcal{R}_y.$$

Then (3.3.26), (3.3.26)† and the ellipticity of P_0 yield that

$$\mathsf{WF}^{s,l'}(\underline{U}^0_{0k}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega_+^T) = \emptyset \qquad \forall k = 0,\dots,n, \tag{3.3.58}$$

$$\mathsf{WF}^{s,l'}(\underline{U}^0_{j0}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega_+^T) = \emptyset \qquad \forall j = 0,\dots,n, \tag{3.3.58†}$$

and

$$\mathsf{WF}^{s,l'}(\underline{U}^1_{0k}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega_+^T) \subset \{x_1 = 0\} \qquad \forall k = 0,\dots,n, \tag{3.3.59}$$

$$\mathsf{WF}^{s,l'}(\underline{U}^1_{j0}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega_+^T) \subset \{y_1 = 0\} \qquad \forall j = 0,\dots,n \tag{3.3.59†}$$

where Ω and Ω_+ are small enough neighborhoods of z^* in $T^*(\partial X \times \mathbb{R})$ and $T^*(X' \times \mathbb{R}) \times \mathbb{R}^+$ respectively and $\boldsymbol{\pi}$ is the map deleting the second copy of (t,τ) in $\Omega_+ \times \Omega_+^T$, etc.

Moreover, Theorem 3.1.2 yields that

$$\mathsf{WF}^{s,l'}(\underline{U}^{1(2)}_{0k}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega_+^T) = \emptyset \qquad \forall k = 0,\dots,n, \tag{3.3.60}$$

$$\mathsf{WF}^{s,l'}(\underline{U}^{1(1)}_{j0}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega_+^T) = \emptyset \qquad \forall j = 0,\dots,n. \tag{3.3.60†}$$

Let us note that Corollary 2.1.14 implies that the set

$$\mathsf{WF}^s(\underline{U}^0_{jk}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega_+^T) \times \mathbb{R}^2_{\xi_1,\eta_1} \cap \{|t| \le T\} \tag{3.3.61}$$

is contained in the C_0T-neighborhood of $\xi_1 = -\eta_1$. Furthermore, (3.3.26) and (3.3.26)† imply that this set is contained in a small neighborhood of

$\{\xi_1 = \zeta_j, \eta_1 = -\zeta_k\}$ (recall that ζ_j are characteristic roots) and hence this set(3.3.61) is empty for small $T > 0$:

$$\mathsf{WF}^s(\underline{U}^0_{jk}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega^T_+) \times \mathbb{R}^2_{\xi_1,\eta_1} \cap \{|t| \le T\} = \emptyset \qquad \forall j \ne k. \tag{3.3.62}$$

Moreover, Theorem 2.1.2 with $J = 2$ and $\phi_1 = t$ and

$$\phi_2 = \langle \ell'_\xi, x' - y' \rangle + \nu_k(x_1 - y_1) - \varepsilon t \tag{3.3.63}$$

with a small enough constant $\varepsilon > 0$ and Corollary 2.1.14 imply that

$$\begin{aligned} &\mathsf{WF}^s(\underline{U}^0_{kk}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega^T_+) \times \mathbb{R}^2_{\xi_1,\eta_1} \cap \\ &\qquad \bigl\{0 \le t \le T, \langle \ell'_\xi, x' - y' \rangle + \nu_k(x_1 - y_1) < \varepsilon t\bigr\} = \emptyset \quad \forall k = 1, \dots, n. \end{aligned} \tag{3.3.64}$$

Furthermore, (3.3.26), (3.3.26)† and the ellipticity of $\underline{P}_{jx}$ and ${}^t\underline{P}_{ky}$ for $|\xi_1| \ge c, |\eta_1| \ge c$ [13] combined with (3.3.62) and (3.3.64) imply that

$$\mathsf{WF}^{s,l\,\prime}(\underline{U}^0_{jk}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega^T_+) \cap \{|t| \le T\} = \emptyset \qquad \forall j \ne k \tag{3.3.62}'$$

and

$$\begin{aligned} &\mathsf{WF}^{s,l\,\prime}(\underline{U}^0_{kk}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega^T_+) \cap \\ &\qquad \bigl\{0 \le t \le T, \langle \ell'_\xi, x' - y' \rangle + \nu_k(x_1 - y_1) < \varepsilon t\bigr\} = \emptyset \quad \forall k = 1, \dots, n. \end{aligned} \tag{3.3.64}'$$

Therefore

$$\mathsf{WF}^{s,l\,\prime}(\eth_x \underline{U}^0_{jk}) \cap \boldsymbol{\pi}(\Omega \times \Omega^T_+) \cap \{|t| \le T\} = \emptyset \qquad \forall j \ne k, \tag{3.3.65}$$

and

$$\begin{aligned} &\mathsf{WF}^{s,l\,\prime}(\eth_x \underline{U}^0_{kk}) \cap \Omega \times \Omega^T_+ \cap \\ &\qquad \bigl\{0 \le t \le T, \langle \ell'_\xi, x' - y' \rangle - \nu_k y_1 < \varepsilon t\bigr\} = \emptyset \qquad \forall k = 1, \dots, n. \end{aligned} \tag{3.3.66}$$

Let us apply Theorem 3.1.13 with $J = 2$, $\phi_{j1} = \phi_1 = t$ and

$$\phi_{j2} = \langle \ell'_\xi, x' - y' \rangle + \nu_j x_1 - \varepsilon t, \qquad \phi_2 = \langle \ell'_\xi, x' - y' \rangle - \varepsilon t. \tag{3.3.67}$$

[13] Which is due to (3.1.6).

Then (3.3.65), (3.3.66), (3.3.26), (3.3.27) and (3.3.36) yield that

$$\mathsf{WF}^{s,l'}(\underline{U}^1_{jk}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega^T_+) \cap \bigl\{\{0 \le t \le T, \langle \ell'_\xi, x'-y'\rangle - \nu_k y_1 + \nu_j x_1 < \varepsilon t\bigr\} = \emptyset \quad \forall j,k = 1,\dots,n \tag{3.3.68}$$

and

$$\mathsf{WF}^{s,l'}(\underline{U}^1_{0k}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega^T_+) \cap \bigl\{0 \le t \le T, \langle \ell'_\xi, x'-y'\rangle - \nu_k y_1 < \varepsilon t\bigr\} = \emptyset \qquad \forall k = 1,\dots,n. \tag{3.3.69}$$

Similarly, (3.3.58)†, (3.3.26), (3.3.27) and (3.3.36) imply that

$$\mathsf{WF}^{s,l'}(\underline{U}^1_{j0}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega^T_+) \cap \bigl\{0 \le t \le T, \langle \ell'_\xi, x'-y'\rangle + \nu_j x_1 < \varepsilon t\bigr\} = \emptyset \qquad \forall j = 1,\dots,n \tag{3.3.70}$$

and

$$\mathsf{WF}^{s,l'}(\underline{U}^1_{00}) \cap \boldsymbol{\pi}(\Omega_+ \times \Omega^T_+) \cap \bigl\{0 \le t \le T, \langle \ell'_\xi, x'-y'\rangle < \varepsilon t\bigr\} = \emptyset. \tag{3.3.71}$$

These four relations combined with relations (3.3.62), (3.3.64) and (3.3.58) yield Statements (i), (ii) and (iv); moreover, in the proof of (3.3.52) we also use Proposition 3.3.4 which reduces contribution of the non-diagonal blocks to (3.3.53)-type expression. □

The arguments used in the proof of Theorem 2.1.19 yield immediately

Theorem 3.3.6. *Let conditions of assertions (i), (ii), (iii), (iv) or (v) of Theorem 3.3.5 be fulfilled. Then the left-hand expressions in* (3.3.51)*,* (3.3.52) *and* (3.3.53)*,* (3.3.54)*,* (3.3.55)*,* (3.3.56) *and* (3.3.57) *respectively do not exceed*

$$Ch^{1-d-|\alpha|-|\beta|}\bigl(\frac{h}{T}\bigr)^s \tag{3.3.72}$$

with constant C not depending on $T \in [h, T_0]$, where $T_0 > 0$ is a small constant.

For the forthcoming applications inequality (3.3.56) and its sidekick in Theorem 3.3.6 are the most important. Note that according to Proposition 3.3.4 the contributions of non-diagonal blocks to (3.3.52) and (3.3.56)

is given by (3.3.53) and (3.3.57)-type expressions respectively with an extra factor h. On the other hand, we do not need to integrate with respect to x_1 the contributions of the diagonal blocks but if we plug into these expressions U^1 instead of U and integrate we recover an extra factor T due to (3.3.36). Then we get immediately

Theorem 3.3.7. *Let conditions of assertions (ii) or (v) of Theorem 3.3.5 be fulfilled. Then the left-hand expressions in* (3.3.52), (3.3.56) *respectively with U replaced by U^1 do not exceed*

$$Ch^{2-d-|\alpha|-|\beta|}\bigl(\frac{h}{T}\bigr)^s \tag{3.3.73}$$

with constant C not depending on $T \in [h, T_0]$, where $T_0 > 0$ is a small constant.

In particular we get

Corollary 3.3.8. *Let conditions of assertions (ii) or (v) of Theorem 3.3.5 be fulfilled. Assume that P is elliptic at $\iota^{-1}z^*$. Then the left-hand expressions in* (3.3.52), (3.3.56) *respectively do not exceed* (3.3.73) *with constant C not depending on $T \in [h, T_0]$, where $T_0 > 0$ is a small constant.*

Really, due to the ellipticity of P U^0 is negligible in the vicinity in question. However it is not true for U^1 unless (P, B) is elliptic as well.

3.4 Energy Estimates Approach Revisited

The main purpose of this section is to prove theorem similar to Theorem 3.1.7 but showing that there is no propagation along creeping ways. In such theorem one needs to have function ϕ depending on ξ_1; in this case having separate function ϕ_j for each component does not make sense.

Then $\chi(\phi)$ would also depend on ξ_1; to avoid dealing with pseudodifferential operators containing hD_1 we however use Weierstrass theorem and rewrite this and other symbols as polynomials with respect to ξ_1 modulo $g(x,\xi)$; namely $\chi(\phi) = q(x,\xi)+g(x,\xi)\mu(x,\xi)$ where $g(x,\xi)$ is a determinant as usual and $q(x,\xi)$ is a polynomial with respect to ξ_1.

Since $g(x,\xi)I = \nu(x,\xi)p(x,\xi)$ then after quantization term an operator which applied to u we can properly bound. So we need to consider case when operator $Q(x,hD')$ we used before is replaced by

$$Q(x,hD) = \sum_{0\le j\le m} Q_k(x,hD')(hD_1)^j \tag{3.4.1}$$

which is a scalar symmetric operator as before.

Actually to a certain degree we did it before in Proposition 3.1.14.

Remark 3.4.1. Assume that in the vicinity of $(\bar{x}',\bar{\xi}') \in T^*\partial X$ operator P has a block form with different blocks corresponding to disjoint groups of characteristic roots $\xi_1 = \zeta_*(x,\xi')$ of $g(x,\xi_1,\xi')$; let $g_j(x,\xi)$ be corresponding characteristic polynomials; $j = 1,\dots,J$. Then

$$\phi(x,\xi) = \sum_{1\le j\le J} G_j(x,\xi)\phi_j(x,\xi), \qquad G_j(x,\xi) \coloneqq \prod_{k\ne j} g_k(x,\xi) \tag{3.4.2}$$

would deliver for each group its own function ϕ_j and therefore, at least in principle, we need just one function ϕ if we allow it to depend on ξ_1; conversely, if each group has just one real characteristic root $\xi_1 = \zeta_j(x,\xi')$ then our new approach does not deliver anything ne.

On the contrary, if $g_j(x,\xi)$ has several characteristic roots which cannot be separated (so, they coincide at $(\bar{x}',\bar{\xi}')$) our new approach separates them "mildly".

3.4.1 Theorem 3.1.7(ii) Revisited

To test this method we first prove statements (ii) of Theorems 3.1.7 and 3.1.13 under more general condition than (3.1.9)*.

Energy Estimates

To do this we replace our old $Q_k(x,hD')$ by $Q_{k,\mathsf{new}} = \alpha_k(x,hD)Q_k(x,hD')$ where an extra factor $\alpha(x,hD)$ is a polynomial with respect to hD_1

$$\alpha_k(x,hD) = \sum_{0\le j\le m} \bigl(\delta_{j0} + \alpha_{kj}(x,hD')\bigr)(hD_1)^j \tag{3.4.3}$$

and $\alpha_{kj}(x,\xi')$ are real-valued and $\mathsf{S}_{h,N}$-norms of α_{kj} do not exceed ε (which is a sufficiently small constant).

Then $Q_{kj,\mathsf{new}} \equiv \big(\delta_{j0} + \alpha_{kj}\big) Q_k \mod O(h)$ (with Q_k as in the proof of Theorem 3.1.13) and one can see easily that all the terms along the proof of Theorem 3.1.13 produce exactly the same result as in the proof of Statement (i) with the singular exception of the boundary term

$$h(A_{0k} Q_{k,\mathsf{new}} u_k, u_k)_{\partial X} \tag{3.4.4}$$

where index k indicate diagonal blocks of the corresponding operators and their symbols or components of u.

Really, the principal symbol of the commutator term is still $-\{p_k, q_k\}$ which is now replaced by

$$-\{p_k, \alpha_k q_k\} = -\alpha_k \{p_k, q_k\} - \{p_k, \alpha_k\} q_k. \tag{3.4.5}$$

Let us recall that in this proof $-\{p_k, q_k\}$ was basically replaced by $\chi_2^2(\phi_k)\{p_k, \phi_k\}$ with $\chi_2 = (-\chi')^{1/2}$ (all other terms were properly estimated) and then $\{p_k, \phi_k\}$ was replaced by a positive symbol plus a symbol of the form $\rho_k^\dagger p_k + p_k \rho_k$. This still is the case after multiplication by α_k because we can rewrite

$$\alpha_k(x, \xi) = \alpha'_k(x, \xi') + \tau_k(x, \xi) p_k(x, \xi), \tag{3.4.6}$$

$$\alpha'_k(x', \xi') = \sum_{0 \le j \le m} \alpha_{kj} (-a_{0k}^{-1} a_{1k})^j \tag{3.4.7}$$

and τ_k and $(\alpha'_k - I)$ are both small. On the other hand, rewriting $-\{p_k, \alpha_k\}$ in the form (3.4.6) we see that the only suspicious term is $-\alpha''_k q_k = -\alpha''_k \chi_1^2(\phi_k)$ where $\alpha''_k = \alpha''(x, \xi')$, $\chi_1 = \chi^{1/2}$ and we already know how to suppress such terms.

Further, boundary terms appearing from expression

$$(Q_{k,\mathsf{new}} u_k, P_k u) - (u_k, Q^*_{k,\mathsf{new}} P u_k) \tag{3.4.8}$$

are easy to estimate as well.

Therefore let us consider the mentioned above boundary term (3.4.4) and plug (3.4.6), (3.4.7) there; then obviously we need to consider only $h(T_k Q_k u_k, u_k)_{\partial X}$ where $T_k = T_k(x', hD')$ is an operator with the symbol

$$T_k(x', \xi') = \sum_{0 \le j \le m} \big(\delta_{j0} + \alpha_{kj}\big) a_{0k} (-a_{0k}^{-1} a_{1k})^j. \tag{3.4.9}$$

Further we can replace Q_k by $Q_k'^* Q_k'$ where Q_k' is an operator with the symbol $\chi_1(\phi)$. Then the boundary term becomes $h(T_k Q' u_k, Q' u_k)_{\partial X}$ (modulo terms we can easily estimate); we skip index k because we assume that functions ϕ_k (and thus operators Q_k, Q_k') as well) restricted to ∂X do not depend on k.

In virtue of arguments of Subsubsection *3.1.2.6 Proof of Theorem 3.1.13. Step 3* we conclude that

(3.4.10) Statements (ii) of Theorems 3.1.7 and 3.1.13 remain true provided

$$\langle Tw, w\rangle \le -\epsilon \|w\|^2 \qquad \forall w \in \operatorname{Ker} b \tag{3.4.11}$$

where T is a block-diagonal symbol with blocks defined by (3.4.9).

Obviously (3.1.9)* coincides with (3.4.11) with $\alpha_{kj} = 0$ $\forall j \ge 1$. Let us assume that the weaker condition (3.1.9) holds; then

$$a_0 = a_0^- + \beta^\dagger b + b^\dagger \beta \tag{3.4.12}$$

where a_0^- is non-positive definite matrix. So we want to construct small α_{kj} such that

$$\langle T'w, w\rangle \le -\epsilon \|w\|^2 \qquad \forall w \in \operatorname{Ker} b \cap \mathbb{K}_\epsilon \tag{3.4.13}$$

where T' is a block-diagonal symbol with blocks

$$T_k'(x', \xi') = \sum_{0\le j\le m} \alpha_{kj} a_{0k} (-a_{0k}^{-1} a_{1k})^j. \tag{3.4.14}$$

and $\mathbb{K}_\epsilon$ is an invariant subspace of a_0^- corresponding to eigenvalues in $[-\epsilon, 0]$.

Condition (3.4.13)

Obviously it is sufficient to establish (3.4.13) at one point; then it will be fulfilled in its vicinity. Further, one can skip assumption that α_{kj} are small since we can always can replace α_{kj} by $\varepsilon\alpha_{kj}$.

Note that

(3.4.15) One needs to satisfy (3.4.13) only for w with all incoming and outgoing components of w equal 0.

Indeed, for such components $\mp a_{0k} > 0$ and one can replace α_{0k} by $\alpha_{0k} \pm \epsilon$ without changing anything else.

Further, note that (3.4.13) implies (3.2.36) where $b = \begin{pmatrix} b' & b'' & b''' \end{pmatrix}$ with the reference to (3.2.35), (3.1.51). Really, if (3.2.36) is not satisfied one can pick up $w = \begin{pmatrix} w' & 0 & 0 \end{pmatrix}^T \in \mathsf{Ker}\, b$ and then $\langle Tw, w\rangle = 0$.

On the other hand, if condition (3.2.36) is satisfied we can exclude both components u', u'' as described in Subsubsection 3.2.2 and condition (3.4.13) will be fulfilled for the reduced problem (P, B) if it was fulfilled for the original one but only under extra assumption with $w' = w'' = 0$. Further, one can see easily that Statement (ii) of Theorem 3.1.13 holds for original problem (P, B) provided it holds for the reduced one.

Meanwhile, (3.4.13) for the original system fails unless in addition to (3.2.36) $\mathsf{rank}\, b'' = \mathsf{D}''$ (where we recall that $\mathsf{D}'' = \mathsf{D}'$) due to the same arguments as above. However, since our purpose is Statement (ii) of Theorem 3.1.13 rather than (3.4.13) itself, we do not need to add this twin of (3.2.36). Thus

(3.4.16) Only w with components corresponding to roots with $|\mathsf{Im}\, \zeta| \le \epsilon'$ equal 0 need to be considered.

Furthermore,

(3.4.17) One can replace in (3.4.9) $a_{0k}^{-1}a_{1k}$ by $(a_{0k}^{-1}a_{1k} - \eta_k)$ with any real (bounded) η_k.

Then adjusting α_{kj} one can fulfil (3.4.13). Thus, what we need is

(3.4.18) There exist real α_{kj} such that (3.4.11) is fulfilled for all $w \in \mathsf{Ker}\, b \cap \mathbb{K} \cap \mathsf{Ker}\, \pi$ where π is the a spectral projector for $a_0^{-1}a_1$ to subspace corresponding to non-real eigenvalues.

Examples

Example 3.4.2. Let us consider D-matrices of the form

$$a_0 = -\begin{pmatrix} 0 & 0 & \dots & 0 & 1 \\ 0 & 0 & \dots & 1 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 1 & \dots & 0 & 0 \\ 1 & 0 & \dots & 0 & 0 \end{pmatrix} \quad \text{and} \quad a_1 = \begin{pmatrix} 0 & \dots & 0 & 1 & 0 \\ 0 & \dots & 1 & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots \\ 1 & \dots & 0 & 0 & 0 \\ 0 & \dots & 0 & 0 & 0 \end{pmatrix}; \tag{3.4.19}$$

i.e. $a_{0kl} = \delta_{\mathsf{D}+1-k-l}$, $a_{1kl} = \delta_{\mathsf{D}-k-l}$ [14].

One can see easily that elements of $a_0(-a_0^{-1}a_1)^j$ are $a_{jkl} = -\delta_{\mathsf{D}+1-j-k-l}$. Then

(i) Let $\mathsf{D} = 2n$. Then both positive and negative spectral subspaces of a_0 have dimension n and thus b should be $n \times \mathsf{D}$ matrix. Let us prove that

(3.4.20) (3.1.14) is fulfilled provided $\mathsf{rank}\, b_{II} = n$ with $b = \begin{pmatrix} b_I & b_{II}\end{pmatrix}$.

Indeed, selecting recurrently α_{2j+1} (from $j = 0$) and picking up $\alpha_{2j} = 0$ one can achieve

$$\langle T'w, w\rangle \le -\|w_I\|^2 - \varepsilon\|w_{II}\|^2 \tag{3.4.21}$$

with arbitrarily small $\varepsilon > 0$ where $w_I = (w_1, \dots, w_n)$, $w_{II} = (w_{n+1}, \dots, w_{\mathsf{D}})$ and thus we achieve (3.1.14) under condition $\mathsf{rank}\, b_{II} = n$.

On the other hand, since for any choice of α_j

$$\langle Tw, w\rangle = 0 \qquad \forall w : w_I = 0 \tag{3.4.22}$$

condition $\mathsf{rank}\, b_{II} = n$ is also necessary for (3.1.14).

(ii) Let $\mathsf{D} = 2n + 1$. Then positive and negative spectral subspaces of a_0 have dimensions n and $(n + 1)$ respectively and thus b should be $n \times \mathsf{D}$ matrix. Selecting recurrently α_{2j} (from $j = 0$) and picking up $\alpha_{2j+1} = 0$ one can achieve (3.4.21) where now $w_I = (w_1, \dots, w_{n+1})$, $w_{II} = (w_{n+2}, \dots, w_{\mathsf{D}})$. On the other hand, (3.4.22) holds. Therefore claim (3.4.20) holds in this case as well.

(iii) Let $\mathsf{D} = 2n + 1$ but a_0 is replaced by $-a_0$. Then positive and negative spectral subspaces of a_0 have dimensions $(n+1)$ and n respectively and thus b should be $(n + 1) \times \mathsf{D}$ matrix. Selecting recurrently α_{2j} (from $j = 0$) and picking up $\alpha_{2j+1} = 0$ one can achieve (3.4.21) in the same notations as in (ii). On the other hand, (3.4.22) holds. Therefore claim (3.4.20) holds in this case as well.

Example 3.4.3. In particular let $n = 1$, $\mathsf{D} = 2$. Then (3.1.9) and (3.4.18) together are equivalent to $b = (b_1\ 1)$ (or could be reduced to this form) with $\mathsf{Re}\, b_1 \le 0$.

[14] We use notation $\delta_l := \delta_{l,0}$.

One can easily consider the case when a_0 and a_1 are block-diagonal with blocks a_{0k} and $(a_{1k} + \eta_k a_{0k})$ of the types covered by example 3.4.2(i)–(iii).

Theorems 3.1.13(ii), 3.1.7(ii) and 3.2.4(ii) Generalized

So, we arrive to following generalization of Theorems 3.1.13(ii) and 3.1.7(ii):

Theorem 3.4.4. *Let conditions of Theorem 3.1.13 be fulfilled. Further, let boundary operator B satisfy* (3.1.9), (3.2.36) *and* (3.4.18).

Finally, let $\phi_j \in \mathscr{C}^N(T^*\partial X)$, $\phi_{kj} \in \mathscr{C}^N(\mathbb{R}^+ \times T^*X')$ be real-valued functions satisfying (3.1.27) *($j = 1, \dots, J$, $k = 1, \dots, n$). Let us assume that for every $j = 1, \dots, J$ the problem (P, B) is microhyperbolic at the point z^* in the multidirection $\mathcal{T}_j = (\nabla^{\#}\phi_j, -\partial_{x_1}\phi_{1j}, \dots, -\partial_{x_1}\phi_{nj})(z^*)$. Let $N = N(d, M, s, l)$ and $l \geq 2\mathsf{D}^* - 2$, $\mathsf{D}^* = \max_k \mathsf{D}_k$ where D_k are the dimensions of $\mathbb{H}_k$.*

Let u satisfy (3.1.20), (3.1.69)$'$, (3.1.70), (3.1.71), (3.1.72) *where $u = (u_1, \dots, u_n, u_0)$, Ω' and Ω''_k are small enough neighborhoods of z^* in $T^*\partial X$ and $\mathbb{R}^+ \times T^*X'$ respectively such that $\Omega' = \Omega''_k|_{\partial X}$ $\forall k = 1, \dots, n$.*

Then (3.1.34), (3.1.73) *and* (3.1.74) *hold.*

Theorem 3.4.5. *Let conditions of Theorem 3.1.13 be fulfilled. Further, let boundary operator B satisfy* (3.1.9), (3.2.36) *and* (3.4.18).

Furthermore, let u satisfy (3.1.20), (3.1.28)$'$ (3.1.29), (3.1.30) *and* (3.1.31) *where Ω' and Ω_k are small enough neighborhoods of z and z_k in $T^*\partial X$ and T^*X respectively not depending on $u, t_1, \dots, t_J$ such that $\Omega' = \Omega''_k|_{\partial X}$ $\forall k = 1, \dots n$.*

Then (3.1.33) *and* (3.1.34) *hold.*

Theorem 3.4.6. *Let conditions of Theorem 3.2.4 be fulfilled. Further, let boundary operator B satisfy* (3.1.9), (3.2.36) *and* (3.4.18). *Furthermore, let u satisfy* (3.2.18), (3.2.19)$'$ (3.2.20), *and* (3.2.21).

Then (3.2.22) *and* (3.2.24) *hold.*

3.4.2 Main Theorem

Discussion

We are interested in te case when $g = \det p$ is of the real principal type or more generally when p is block-diagonal with $p_k \otimes I$ blocks and $g_k = \det p_k$ of the real principal type. Then points where $\pm\{g_k, x_1\}(z_k) > 0$ are outgoing

and incoming points respectively and the corresponding components could be excluded from the analysis, we are interested in the tangent points z_k where $\{g_k, x_1\}$ vanishes. Then $(a_{0k}^{-1}a_{1k})(z)$ has Jordan cells of the height D_k as $z = \iota z_k$. We will prove (see Appendix 3.A.2) then that symbols a_{0k} and a_{1k} calculated at such points could be reduced to the types covered by example 3.4.2(i)–(iii).

This is still pretty complicated due to the interaction of the different components; so we start from the simplest case $n = 1$, $\mathsf{D} = 2$. Then modulo positive factor

$$g(x,\xi) = -\bigl(\xi_1 - \eta(x,\xi')\bigr)^2 + r(x,\xi'); \tag{3.4.23}$$

we have sign "$-$" since a_0 has two eigenvalues of different signs. Without any loss of the generality one can assume that $\eta = 0$ i.e.

$$g(x,\xi) = -\xi_1^2 + r(x,\xi'). \tag{3.4.24}$$

Anyway, points $(x'\xi') \in T^*\partial X$ with $r(0,x',\xi') > 0$, $r(0,x',\xi') = 0$ and $r(0,x',\xi') < 0$ are called *hyperbolic*, *elliptic* and *glancing* points respectively, and we are interested in the small vicinities of the glancing points. Microhyperbolicity with respect to $\nabla^{\#}x_2$ means exactly that

$$\varsigma\partial_{\xi_2} r(x,\xi') > 0 \tag{3.4.25}$$

with $\varsigma = \pm 1$ (depending on the structure of the system; see more precisely in Appendix 3.A.2.

Further, glancing points (i.e. those with $g = x_1 = \{g, x_1\} = 0$) could be of three types: *gliding* with $H_g^2 x_1 = -2\partial_{x_1} r < 0$ (recall that $H_g f = \{g, f\}$, see footnote [13)] from Chapter 2), *grazing* or *diffractive* with

$$H_g^2 x_1 = 2\partial_{x_1} r > 0, \tag{3.4.26}$$

and *degenerate* with $H_g^2 x_1 = -2\partial_{x_1} r = 0$.

We do not need any extra analysis in the gliding points but for diffractive points we need to prove that there is no propagation along boundary bicharacteristics. The results for degenerate points will follow.

So, we consider now only diffractive points.

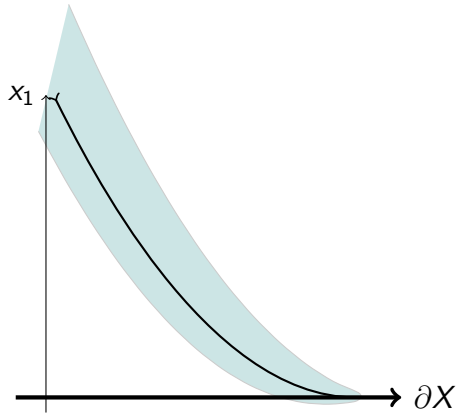


Figure 3.4: Diffractive case: $\{\phi \le 0\}$

To prove that singularities do not propagate along boundary bicharacteristics one needs to consider incoming bicharacteristics to a boundary point and chose function $\phi(x,\xi)$ such that $\{\phi < 0\}$ would be a narrow tongue around it and in the same time $\varsigma\{g,\phi\} > 0$. We already noticed that this is impossible if $\phi(x,\xi)$ does not depend on ξ_1 [15] So we need to take $\phi(x,\xi)$ depending on ξ_1. Due to Weierstrass theorem one needs to check ϕ as a linear function with respect to ξ_1 and from the heuristic point of view ϕ should not decrease at reflections from the boundary. However $\varsigma\xi_1 > 0$ at incoming and $\varsigma\xi_1 < 0$ at outgoing bicharacteristics; so we need to have

$$\varsigma\partial_{\xi_1}\phi < 0; \tag{3.4.27}$$

therefore adding $\phi_1(x,\xi')\xi_1$ to $\phi(x,\xi)$ with negative $\varsigma\phi_0$ helps to inequality $\varsigma\{g,\phi\} > 0$ by increasing $\varsigma\{g,\phi\}$ iff $\{g,\xi_1\} < 0$ which is exactly (3.4.26).

What actually we would like to prove in general is the following

Conjecture 3.4.7. *Let P be an operator with the Hermitean principal symbol p microhyperbolic in direction $\nabla^{\#}\xi_2$. Assume that*

$$p = \begin{pmatrix} p' & 0 \\ 0 & p'' \end{pmatrix} \tag{3.4.28}$$

Let $z' \in T^*\partial X$ and let $z_k \in \iota^{-1}z' \cap \mathsf{Char}(p')$, $k = 1,\dots,J$. Assume that

$$\mathcal{K}^-(p,z_k) \cap T^*X|_{\partial X} \cap \Omega_k = \{z_k\} \qquad \forall k = 1,\dots J. \tag{3.4.29}$$

Further, let boundary operator B satisfy (3.1.9), (3.2.36) *and* (3.4.18).

Furthermore, let u satisfy (3.1.20) *and*

$$z' \notin \mathsf{WF}^{s+1,l'}(Pu) \cup \mathsf{WF}^{s}(B\mathfrak{d}_h u), \tag{3.4.30}$$

$$\bigl(\mathcal{K}^-(p',z_k) \setminus z_k\bigr) \cap \mathsf{WF}^s(u) \cap \Omega_k = \emptyset \qquad \forall k = 1,\dots,J, \tag{3.4.31}$$

$$\mathcal{K}^-(p'',z') \cap T^*X|_{X\setminus\partial X} \cap \mathsf{WF}^s(u) \cap \Omega = \emptyset, \tag{3.4.32}$$

$$\bigl(\mathcal{K}^-(p'',z') \setminus \iota^{-1}z\bigr) \cap \bigl(\mathsf{WF}^{s,0\,\prime}(u) \cup \mathsf{WF}^s(u|_{\partial X})\bigr) \cap \Omega' = \emptyset \tag{3.4.33}$$

[15] Or under weaker condition "$\phi(0,x',\xi)$ does not depend on ξ_1".

where Ω' *and* Ω_k *are small enough neighborhoods of* z *and* z_k *in* $T^*\partial X$ *and* T^*X *respectively such that* $\Omega' = \Omega_k|_{\partial X}$ $\forall k = 1, \dots, J$.

Then

$$\bigl(\mathcal{K}^-(p'', z') \setminus \iota^{-1}z\bigr) \cap \bigl(\mathsf{WF}^{s,0\,\prime}(u) \cup \mathsf{WF}^s(u|_{\partial X})\bigr) \cap \Omega' = \emptyset. \tag{3.4.34}$$

We will be able to prove this conjecture under certain restrictions.

Symbol q: General Construction

In this subsubsection we consider the case $n = 1$ and Jordan cell of an arbitrary order m. Let us consider $\phi(x, \xi)$ which is the smooth and real-valued function as usual. We are interested only in ϕ on $\Sigma = \{g(x, \xi) = 0\}$; then due to Weierstrass theorem we can assume without any loss of the generality that

(3.4.35) $\phi(x, \xi)$ is a polynomial of degree $(m - 1)$ with respect to ξ_1.

Let consider $q(x, \xi) = \chi\bigl(\phi(x, \xi)\bigr)$. Again due to Weierstrass theorem we rewrite it as polynomial of degree $m - 1$ with respect to ξ_1 (modulo $g(x, \xi)$). Then slightly redefining $q(x, \xi)$ we get

$$q(x, \xi) = \sum_{0 \le j \le m-1} q_j(x, \xi')\xi_1^j = \chi\bigl(\phi(x, \xi)\bigr) + \mu(x, \xi)g(x, \xi). \tag{3.4.36}$$

Equality (3.4.36) reflects two "faces" of $q(x, \xi)$: the second one will be used to calculate commutator $\{p, q\}$.

$$\begin{aligned} -\{p, \chi(\phi)\}(x, \xi) = \chi_2^2\bigl(\phi(x, \xi)\bigr)\{p, \phi\}(x, \xi) + \mu'(x, \xi)g(x, \xi) = \\ \bigl(q''(x, \xi)\bigr)^2\{p, \phi\}(x, \xi) + \mu''(x, \xi)g(x, \xi) \end{aligned} \tag{3.4.37}$$

where $\chi_2 = (-\chi')^{1/2}$, $\chi_1 = \chi^{1/2}$ and here and below $q'(x, \xi)$, $q''(x, \xi)$ are polynomials of degree $(m - 1)$ with respect to ξ_1 constructed according to Weierstrass theorem from $\chi_1\bigl(\phi(x, \xi)\bigr)$ and $\chi_2\bigl(\phi(x, \xi)\bigr)$ respectively.

On the other, hand $g = Gp = pG$ where G is a matrix of cofactors and therefore

$$\{p, g\} = \{p, G\}p + \sum_j \bigl(p^{(j)}Gp_{(j)} - p_{(j)}Gp^{(j)}\bigr) \tag{3.4.38}$$

and

$$\{p,g\} = \frac{1}{2}\bigl(\{p,G\}p + p\{p,G\}\bigr) \tag{3.4.39}$$

with the matrix Poisson brackets are defined by usual formula $\{p,G\} = \sum_j \bigl(p^{(j)}G_{(j)} - p_{(j)}G^{(j)}\bigr)$ (in this multiplication order; as usual $^{(j)}$ and $_{(j)}$ denote derivatives with respect to ξ_j and x_j respectively) and thus

$$\begin{aligned} -\{p,q\} = \bigl(q'''(x,\xi')\bigr)^{\dagger}\{p,\phi\}(x,\xi')q'''(x,\xi')+ \\ \nu(x,\xi)p(x,\xi) + p(x,\xi)\nu^{\dagger}(x,\xi) \end{aligned} \tag{3.4.40}$$

with matrix symbols q''' and μ'''.

Energy Estimates. I

Actually we will need to make some minor adjustments multiplying q by cut-off functions $\zeta^2(x,\xi')$ equal 1 in vicinity $z' \in T^*\partial X$ and slightly shifting argument of χ; so finally we take

$$q = \chi\bigl(\phi(x,\xi) - \varepsilon\bigr)\zeta^2(x,\xi') \tag{3.4.41}$$

with arbitrarily small constant $\varepsilon > 0$. Then we arrive to the following inequality provided p is microhyperbolic in the direction $\nabla^{\#}\phi$:

$$\begin{aligned} -h^{-1}\operatorname{Re} i([P,Q]u,u)_X \ge \\ \epsilon_0\|Q'''u\|^2 - Ch\|Q^{IV}u\|^2 - C\|Q^{IV}Pu\|^2 - C\|Q^{V}u\|^2 - Ch\|Q'''u\|^2_{\partial X} \end{aligned} \tag{3.4.42}$$

where Q^{IV} and Q^{V} are operators with symbols $q^{IV}(x,\xi)$ and $q^{V}(x,\xi)$ which are produced by the Weierstrass theorem from $\chi(\phi - 2\varepsilon)$ and $\chi(\phi - 2\varepsilon)\zeta_1$ respectively with ζ_1 supported in ε-vicinity of $\operatorname{supp}(\nabla\zeta)$. We can also replace here Q^{IV} and Q^{V} by matrix operators not containing hD_1.

Let us assume that p is microhyperbolic in direction $\nabla^{\#}x_2$ and that $g(x,\xi)$ is of principal type in $\iota^{-1}z' \cap \{g = 0\} = z$ (which consists of just one point). Then (3.4.25) holds in vicinity of z with $\varsigma = \pm 1$.

Let us consider incoming bicharacteristics $\gamma^{-}(z)$; this bicharacteristics is a bicharacteristics of ςg issued from z into direction of $t < 0$. Assume that (3.4.29) holds, i.e.

$$\gamma^{-}(z) \cap T^*X|_{\partial X} \cap \Omega = z \tag{3.4.43}$$

where Ω is vicinity of z. This assumption follows from concavity condition (3.4.26) but is definitely weaker; however this assumption would be incompatible with the convexity condition.

Also assume that (3.4.30)–(3.4.33) and a weaker assumption of (3.4.34) hold

$$\bigl(\mathcal{K}^-(p'',z')\setminus \iota^{-1}z\bigr)\cap \bigl(\mathsf{WF}^{s-\delta,0\,\prime}(u)\cup \mathsf{WF}^{s-\delta}(u|_{\partial X})\bigr)\cap \Omega' = \emptyset \tag{3.4.44}$$

with small exponent $\delta > 0$.

Let ϕ be a real-valued function such that p is microhyperbolic in direction of $\nabla^{\#}\phi$ and

(3.4.45) $\{\phi < 0\}\cap\{g = 0\}\cap\Omega$ contains $\gamma^-(z)\cap\Omega$ and is contained in the small enough vicinity of $\gamma^{-1}(z)\cap\Omega$

Proposition 3.4.8. *Let p be microhyperbolic in direction $\nabla^{\#}\phi$ at point z_k and q be defined by* (3.4.41)*. Then under assumptions* (3.4.30)–(3.4.33) *and* (3.4.44) *all the terms but the first one in the right-hand expression of* (3.4.42) *do not exceed Ch^{2s}.*

Proof. Proof is obvious. Actually we do not need conditions to $B\bar{\partial}u$ or $\bar{\partial}u$ here. □

Energy Estimates. II

Now we need to consider boundary term (3.4.4) which is after division by h

$$\mathsf{Re}(A_0Qu,u)_{\partial X} = \mathsf{Re}\sum_{0\le j\le m-1} A_0(Q_j(hD_1)^j u,u)_{\partial X}\equiv \mathsf{Re}\sum_{0\le j\le m-1}(Q_jA_0(A_0^{-1}A_1)^j u,u)_{\partial X} \tag{3.4.46}$$

modulo terms not exceeding

$$\sum_{0\le j\le m-} \|Q^{VI}D_1^jPu\|_{\partial X}\cdot\|QVI\|_{\partial X}\le Ch^{2s}$$

where $Q^{VI} = q^{VI}(x',hD')$ with q^{VI} supported in the small vicinity of z' and the second inequality is due to $z'\notin \mathsf{WF}^{s+1/2-j}(\bar{\partial}D_1^jPu)$ (which is due to (3.4.30)) and (3.4.44).

Energy Estimates. III

Let us consider the most important case $m = 2$ first. Without any loss of the generality one can assume that g is given by (3.4.24). Note that under condition (3.4.25) microhyperbolicity condition is equivalent to

$$\varsigma\{g, \phi\} > 0. \tag{3.4.47}$$

Then there are only two terms in (3.4.46). Let us assume that in vicinity of z'

$$\varsigma^j q_j \ge 0 \tag{3.4.48}_j$$

where q_j are defined in (3.4.36) and also that

$$\varsigma^j \langle a_j w, w\rangle \le -\epsilon \|w\|^2 \qquad \forall w \in \mathsf{Ker}\, b. \tag{3.4.49}_j$$

Then Gårding inequality and $(3.4.48)_j$, $(3.4.49)_j$ imply that

$$\begin{aligned} -\mathsf{Re}(Q_j A_j u, u)_{\partial X} \ge \\ \epsilon\, \mathsf{Re}\, \varsigma^j (Q_j u, u)_{\partial X} - \mu \|Q_j u\|^2_{\partial X} - C\mu^{-1}\|Q^{VI} B u\|^2_{\partial X} - Ch^{2s} \end{aligned} \tag{3.4.50}$$

with arbitrarily small constant $\mu > 0$.

We can skip the third term in the right-hand expression due to $z' \notin \mathsf{WF}^s(B\eth u)$.

Further, since $\varsigma^j q_j \ge 2\varepsilon q_j^2$ Gårding inequality and $(3.4.48)_j$ imply that

$$\varsigma^j (Q_j u, u)_{\partial X} \ge 2\varepsilon \|Q_j u\|^2 - Ch^{2s}$$

and and we can skip the second term in the right-hand expression of (3.4.50) as well.

Then the arguments of the proof of Theorem 3.1.13(ii) imply that

$$\|Q''' u\| \le Ch^s \qquad \text{and} \qquad \varsigma^j (Q_j u, u)_{\partial X} \le Ch^{2s} \tag{3.4.51}$$

which implies $z' \notin \mathsf{WF}^s(\eth u)$ since at least one of operators Q_j is elliptic in z'. The latter statement is trivial because $q_0(z') = \chi(\phi(z) - \varepsilon)$ and $q_1 = \chi'(\phi(z))(\partial_{\xi_1}\phi(z))$ with $z = \iota^{-1} z' \cap \{g = 0\}$.

Then $Pu^0 = -ih\delta(x_1) A_0 u|_{\partial X} + (Pu)^0$ where u^0 is a continuation of u by 0 to $\{x_1 < 0\}$ and ellipticity of the "scalar version" of Q''' (which is different

from "matrix version" by multiple of P and has a symbol $\chi_2(\phi(z)-\varepsilon))$ implies that $z' \notin \mathsf{WF}^{s,0\,\prime}(u)$.

Let us consider $(3.4.49)_j$. Obviously $(3.4.49)_0$ is exactly $(3.1.9)^*$.

On the other hand, without any loss of the generality under (3.4.24) one can assume that at z'

$$a_0 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad a_1 = \begin{pmatrix} \varsigma & 0 \\ 0 & 0 \end{pmatrix} \tag{3.4.52}$$

and condition $(3.4.49)_1$ is nothing but (3.4.18) (assuming that (3.1.9) holds).

Furthermore, we actually do not need $(3.1.9)^*$: as (3.1.9) and (3.4.18) are fulfilled we can add to Q operator $\alpha_1 Q_0 h D_1$ which would lead to an extra boundary term as in the proof of Theorem 3.4.4.

Let us prove $(3.4.48)_j$. As $R > 0$

$$q_0 = \frac{1}{2}\bigl(\chi(\phi^+ - \varepsilon) + \chi(\phi^+ - \varepsilon)\bigr), \tag{3.4.53}$$

$$q_1 = \frac{1}{2R^{1/2}}\bigl(\chi(\phi^+ - \varepsilon) - \chi(\phi^+ - \varepsilon)\bigr) \tag{3.4.54}$$

where

$$\phi^{\pm} = \phi_0 \mp \varsigma\phi_1 R^{1/2} \tag{3.4.55}$$

and we assume that

$$-\varsigma\phi_1(z') > 0. \tag{3.4.56}$$

Moreover, as $R < 0$ one can prove easily that for all n

$$|q_0 - \chi(\phi_0 - \varepsilon)| \le C_n|R|^n, \qquad |q_1 - \chi'(\phi_0 - \varepsilon)\phi_1| \le C_n|R|^n$$

provided $|\chi^{(m)}| \le C_{m\delta}\chi^{1-\delta}$ for any m and $\delta > 0$ and $-\chi'$ has the same property.

Then redefining $q_0 := q_0 + C|r|^n$, $q_1 := q_1 + C\varsigma|r|^n$ for $r < 0$ we achieve $(3.4.48)_j$ without violating (3.4.36). Here functions q_0, q_1 and μ in (3.4.36) are very smooth and we do not infinite smoothness (but actually we can construct infinitely smooth correction).

Note that $\chi(t) = e^{1/t}$ as $t < 0$ and $\chi(t) = 0$ as $t > 0$ has all the properties we need.

Results: Single Glancing Point

So, we have proven

Theorem 3.4.9. *Under assumptions*[16] $\mathsf{D}=2$ *and* (3.4.26) *Conjecture 3.4.7 holds.*

Note that for systems with $\mathsf{D}=2$ satisfying (3.4.23) and (3.4.25) generalized bicharacteristic billiards are a.e. described by

$$\frac{dz}{dt} = \nabla^{\#} g + \kappa \nabla^{\#} x_1 \qquad \text{with} \quad \kappa = 0 \text{ as } \quad x_1 > 0. \tag{3.4.57}$$

Then along boundary bicharacteristics

$$\kappa = H_g^2 x_1 \cdot \left(H_{x_1}^2 g\right)^{-1} \tag{3.4.58}$$

(this formula is invariant if we replace g by eg with non-vanishing e).

Combing Theorems 3.4.9 and 3.4.6 we arrive to

Theorem 3.4.10. *Let* $\mathsf{D}=2$ *and* (3.4.23), (3.4.25) *be fulfilled. Then Theorem 3.4.4 remains true if in the definition* (3.4.57) *of the generalized bicharacteristic billiard we add an extra condition* $\kappa \le 0$ *thus replacing it by*

$$\frac{dz}{dt} = \nabla^{\#} g + \kappa \nabla^{\#} x_1 \qquad \text{with} \quad \kappa = 0 \text{ as } \quad x_1 > 0 \text{ and } \quad \kappa \le 0 \text{ as } \quad x_1 = 0. \tag{3.4.57}^*$$

Remark 3.4.11. Theorem 3.4.10 remain true with the obvious modification: p has a block diagonal form with the single block described there and all other blocks corresponding to transversal or elliptic components.

Further Discussion

Unfortunately Theorem 3.4.9 is almost everything we managed to prove by this energy estimate method. We were unable to cover multiple tangent points belonging to $\iota^{-1}z$ or higher multiplicity of ξ_1-root (with the exception of the special case). Neither it works for Neumann boundary conditions for wave operator and one needs to use direct parametrix construction (see *Comments*).

The real power of Theorem 3.4.9 comes when it works together with Theorem 3.2.4. Let us consider several examples:

[16] And all other assumptions listed in Conjecture 3.4.7.

Violation of Assumptions (3.2.36), (3.4.18). Assume that z' is a grazing point with $\mathsf{D}=2$ but (3.2.36) and (3.4.18) do not necessarily hold.

Consider in the vicinity of z' manifold $\mathcal{G}=\{z', r(z')=0\}$ where we assume that $g(z)$ is of the form (3.4.24) and (3.4.25), (3.4.26) are fulfilled. Further, assume that in the vicinity of z'

$$a_0=\begin{pmatrix}0&1\\1&0\end{pmatrix}, \qquad a_1=\begin{pmatrix}\varsigma&0\\0&\varsigma r\end{pmatrix}. \tag{3.4.59}$$

Then boundary operator could be reduced to form $\begin{pmatrix}1 & b_2\end{pmatrix}$ with real-valued b_2 which vanishes in z' (otherwise we can apply Theorem 3.4.10 directly).

Then condition (3.2.15) is fulfilled at points of $\mathcal{G}$ with $b_2\neq 0$. Therefore Theorem 3.4.9 and thus Theorem 3.4.10 could be directly used there. On the other hand, Theorem 3.2.4 does allow propagation along boundary bicharacteristic of g (i.e. bicharacteristic of r) and also propagation in the elliptic zone along bicharacteristics of $\bigl((-r)^{1/2}+b_2\bigr)$ or those of

$$\varsigma(r+b_2^2), \qquad b_2<0. \tag{3.4.60}$$

However if we assume that $\gamma^-_{\varsigma r}(z')$ which is (boundary) bicharacteristics of ςr issued from z' in the direction $t<0$ leaves $\Lambda=\{b_2=0\}$ immediately, which is the case provided

$$x_1=r=b_2=0 \implies \{r,b_2\}(z')\neq 0 \tag{3.4.61}$$

then there is no propagation along it and thus Theorem 3.4.9 could be extended to this case:

Theorem 3.4.12. *Let in vicinity of z'* (3.4.59) *and* (3.4.24)–(3.4.26) *be fulfilled. Let boundary operator $b=\begin{pmatrix}1 & b_2\end{pmatrix}$ with real-valued b_2, $b_2(z')=0$. Let*

$$\bigl(\gamma^-_{\varsigma r}(z')\setminus z'\bigr)\cap\{b_2=0\}\cap\Omega'=\emptyset, \tag{3.4.62}$$

$$z'\notin \mathsf{WF}^{s+1,l'}(Pu)\cup \mathsf{WF}^{s+1/2}(B\eth u), \tag{3.4.63}$$

$$\bigl(\gamma^-_{\varsigma g}(z)\setminus z\bigr)\cap \mathsf{WF}^{s}(u)\cap\Omega=\emptyset, \qquad z=\iota^{-1}z'\cap\{g=0\} \tag{3.4.64}$$

$$\bigl(\gamma^-_{\beta}(z')\setminus z'\bigr)\cap \mathsf{WF}^{s-1/2}(\eth u)\cap\Omega'=\emptyset. \tag{3.4.65}$$

Then

$$z'\notin \mathsf{WF}^{s,l+1'}(u)\cup \mathsf{WF}^{s-1/2}(\eth u). \tag{3.4.66}$$

Further one can prove more global statement where (3.4.61) ensures (3.4.62) at every point of Λ.

Several Grazing Points. Let us assume that $\iota^{-1}z'$ consists of n grazing points, $n \ge 2$, each of them satisfying (3.4.23), (3.4.25), (3.4.26). Then we have $\varsigma_k = \pm$ and g_k, r_k, $\mathcal{G}_k$ with $k = 1, \dots, n$. Let

$$\Lambda^{(m)} = \bigcup_{\{J\subset\{1,\dots,n\},\#J=m\}} \Big(\bigcap_{k\in J} \mathcal{G}_k.\Big). \tag{3.4.67}$$

Let us assume that (3.4.63), (3.4.64) are replaced by

$$z' \notin \mathsf{WF}^{s+1,l'}(Pu) \cup \mathsf{WF}^s(B\eth u), \tag{3.4.63)*}$$

and

$$\big(\gamma^-_{\varsigma_k g_k}(z_k) \setminus z_k\big) \cap \mathsf{WF}^s(u) \cap \Omega_k = \emptyset, \qquad z_k = \iota^{-1}z' \cap \{g_k = 0\} \quad \forall k = 1, \dots, n. \tag{3.4.64)*}$$

respectively.

Assuming (3.2.36), (3.4.18) we conclude from Theorem 3.4.9 that

$$\big(\Lambda^{(m)} \setminus \Lambda^{(m+1)}\big) \cap \big(\mathsf{WF}^s \cup \mathsf{WF}^s(\eth u)\big) \cap \Omega' = \emptyset. \tag{3.4.68)$_m$}$$

holds with $m = 1$.

Let us apply Theorem 3.4.4. Let us consider a generalized bicharacteristics of p issued from z' in the direction $t < 0$. It consists of a boundary bicharacteristics defined by

$$\frac{dz''}{dt} \in K_b(z'') \tag{3.4.69}$$

where

$$K_b(z'') = \mathsf{convex\ hall}\big\{\nabla^{\#}\varsigma_j r_j(z'),\ j \in J\big\} \quad \text{as } z'' \in \Lambda^{(m)} \setminus \Lambda^{(m+1)} \text{ and } r_j(z'') = 0 \iff j \in J. \tag{3.4.70}$$

Then $z'' \notin \big(\mathsf{WF}^s \cup \mathsf{WF}^s(\eth u)\big)$ for every $z'' \in \Omega'$ such that z'' has a vicinity Ω'' such that $\mathcal{K}_b^-(z'') \cap \Omega'' \cap \big(\Lambda^{(m)} \setminus \Lambda^{(m+1)}\big) = \emptyset$ with $m = 1$.

But then $(3.4.68)_1$ implies $(3.4.68)_2$ provided $r_j = r_k = 0 \implies \{r_j, r_k\} \ne 0$ etc until $(3.4.68)_n$ under condition (2.2.41) for g_k replaced by $\varsigma_k r_k$.

Meet a Gliding Component. Let situation described in the previous paragraph hold for all points $z_k \in \iota^{-1}z'$ with the exception of z_1 such that $\mathsf{D}_1 = 2$ but it is gliding point i.e. $H_{g_1}x_1 < 0$ at z_1. Let g_1 be of the form (3.2.20) and let conditions (3.4.63)* and (3.4.64)* with $k = 2, \dots, n$ be fulfilled.

Let us assume that

$$\bigl(\gamma^-_{\varsigma_1 r_1}(z') \setminus z'\bigr) \cap \bigl(\mathsf{WF}^{s,l'}(u) \cup \mathsf{WF}^s(\eth u)\bigr) \cap \Omega' = \emptyset. \tag{3.4.71}$$

Then the previous arguments yield that

$$\{r_1 \neq 0\} \cap \bigl(\mathsf{WF}^{s,l'}(u) \cup \mathsf{WF}^s(\eth u)\bigr) \cap \Omega'' = \emptyset \tag{3.4.72}$$

where Ω'' is small enough vicinity of z'. Applying Theorem 3.2.4 again we conclude that $z' \notin \mathsf{WF}^{s,l'}(u) \cup \mathsf{WF}^s(\eth u)$ under condition (2.2.41) for g_k replaced by $\varsigma_k r_k$ $(k = 1, \dots, n)$.

On the other hand, two gliding components create a real mess in billiards due to jumps in different directions and after jump to some direction the length of the jump to other direction can change drastically.

3.5 Propagation of Singularities along Long Transversally Reflecting Bicharacteristics

In this section we obtain results similar to those of Section 2.4. However, the presence of the boundary makes things much more complicated and we need to assume that in the zone under analysis not only $a(x,\xi)$ has eigenvalues of the constant multiplicities but also that bicharacteristic billiards are transversal to the boundary. Further, we need to assume not only that symbol $A(x,\xi)$ is regular but it is also true for the function defining the boundary and coefficients of the boundary operator. More precisely, we assume that operator "incoming components $\to$ outgoing components" is a pseudodifferential operator with a regular symbol.

3.5.1 Evolution of Operators

So, as in Subsection 2.4.1 we are interested in operator (2.4.4)

$$Q^t = e^{-ih^{-1}tA} Q^0 e^{ih^{-1}tA} \tag{3.5.1}$$

where we assume that

(3.5.2) $A = A_B$ i.e. operator with domain

$$\mathfrak{D}(A_B) = \{u : u \in \mathscr{L}^2(X, \mathbb{H}),\ Au \in \mathscr{L}^2(X, \mathbb{H}),\ B\eth_{m-1}u = 0\} \tag{3.5.3}$$

is a self-adjoint in $\mathscr{L}^2(X, \mathbb{H})$ operator.

Standard Theory

Here we need to assume that $Q = Q(x, hD)$ is a pseudodifferential operator with the symbol $q(x, \xi)$ and to avoid boundary operators in domain with the boundary we assume that

$$\mathsf{dist}(\pi_x \mathsf{supp}(q), \partial X) \ge \varrho. \tag{3.5.4}$$

To describe a classical evolution of A we need to consider generalized bicharacteristic billiards; we need to assume that the free space evolution is according to Section 2.4; so we repeat assumptions (2.4.58) and (2.4.59):

$$\mathsf{Spec}\, a(z) = \{\lambda_1(z), \dots, \lambda_m(z)\} \qquad \forall z \in \Omega \tag{3.5.5}$$

and for every $j = 1, \dots, m$

$$\mathsf{Spec}\, a(z) \cap [\lambda_j(z) - \varrho, \lambda_j(z) + \varrho] = \lambda_j(z) \qquad \forall z \in \Omega \tag{3.5.6}$$

where λ_j are assumed to be uniformly continuous and $\Omega = \mathcal{K}^+_{[0,T]}(p, \Omega_0)$ with Ω_0 a ϱ-vicinity of $\mathsf{supp}(q)$. Here we parametrize bicharacteristics billiards by t and subscript means the range of t.

Moreover we need to assume that the reflection is transversal:

$$|\{\lambda_j, \phi\}(z)| \ge \rho \qquad \forall z = (x, \xi) :\ \phi(x) \le \varrho \tag{3.5.7}$$

where

$$X = \{x,\ \phi(x) > 0\}, \quad \partial X = \{x,\ \phi(x) = 0\}, \tag{3.5.8}$$
$$\phi(x) \le \varrho \implies |\nabla\phi| \ge \rho.$$

If there is no branching of billiards i.e. if

$$\#\big\{k : \exists z_k \in \iota^{-1}z',\ \lambda_k(z_k) = 0,\ \{\lambda_k, \phi\}(z_k) > 0\big\} = 1 \tag{3.5.9}$$
$$\forall z' \in \iota\mathcal{K}^+_{[0,T]}(p, \Omega_0) \cap T^*X|_{\partial X}$$

then

$$\mathcal{K}_t^+(p,z) = \Psi_t(z) \quad \text{for} \quad z \in \Omega_0 \tag{3.5.10}$$

where Ψ_t is a *Hamiltonian dynamics with the reflections at* ∂X. Otherwise this formula holds but now Ψ_t is a *Hamiltonian dynamics with the reflections and branching at* ∂X:

$$\Psi_t(z) = \{\Psi_{t,j}(z),\ j = 1, \dots, N(t)\} \tag{3.5.11}$$

where $\Psi_{t,j}$ are Hamiltonian maps.

We expect (correctly) that Q^t is pseudodifferential operators with the symbol supported in $\mathcal{K}_t^+$ but again we need to assume that

$$\mathsf{dist}(\pi_x \mathcal{K}_{\bar t}^+(p, \mathsf{supp}(q)), \partial X) \ge \varrho \tag{3.5.12}$$

for this particular $t = \bar t$; however we cannot assume that this is true on the whole interval $[0, \bar t]$.

Therefore the evolution would consist of alternating free space evolution along Hamiltonian trajectories where we apply results of Section 2.4 and reflections. These reflections happen when $\phi \circ \Psi_t(z) \le \varrho$.

If billiards branch then different branches have different reflection times and we consider different branches separately replacing operator Q^t by the sum of operators supported in different components of $\Psi_t(\Omega_0)$.

Reflections

Let us consider vicinity of the boundary: $\{x, \phi(x) \le \varrho\}$. Without any loss of the generality one can introduce coordinate system with $x_1 = \phi(x)$.

Let us consider point $(z', 0, \tau) \in T^*(\partial X \times \mathbb{R}_t)$ and $z_j = \iota^{-1} z' \cap \{\lambda_j = -\tau\}$. Let us consider a single incoming component with index j ignoring all other. So we consider trajectory of $\big(\tau + \lambda_j(z)\big)$ with $\{\lambda_j, \phi\} \le -\rho$. Let us consider all outgoing trajectories (those of $\big(\tau + \lambda_k(z)\big)$ with $\{\lambda_k, \phi\} \ge \rho$ where $k = 1, \dots, m$).

Let us consider point $(z^-, -T', \tau)$ belonging to the incoming trajectory such that $x_1 \asymp \varrho$ at z^- and let us consider operator $Q^- = Q^-(x, hD_x)$ with the symbol q^- supported in $\epsilon\varrho$-vicinity of z^-. Our goal is to consider evolution of this operator during time $T' \asymp \varrho/\rho$; this will be a short time evolution in the case of small parameters ρ and $\varrho \ll \rho$. There are three steps:

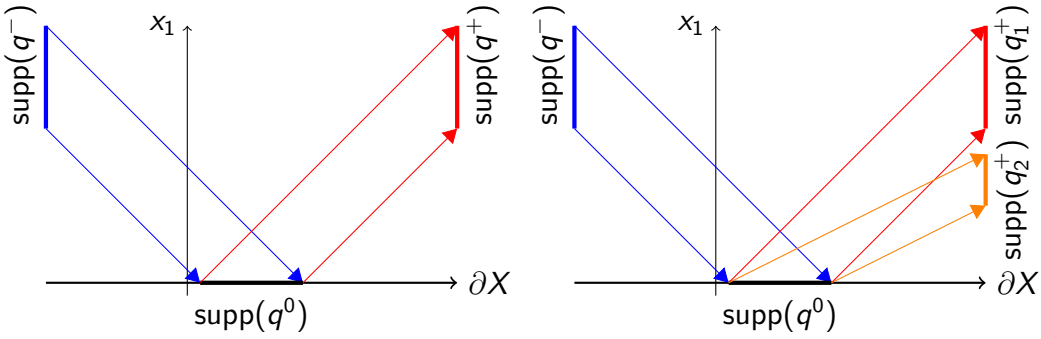
(i) We construct G_j^+ which transforms Cauchy data for u_j as $t = -T'$ to solution u_j of $P_j u_j \equiv 0$ as $t > 0$ and to prove that

(3.5.13) $\eth G_j^+ Q^- = Q^0 \eth G_j^+$ where $Q^0 = Q^0(x', t, hD'_x, hD_t)$ is an operator with symbol q^0 and

(3.5.14) $$\mathsf{supp}(q^0) = \big\{(z', t, \tau) : z' \in \iota\Psi_{t+T',j}(\mathsf{supp}(q^-) \cap \{\lambda_j = -\tau\})\big\};$$

(ii) Then we construct operators Q_k^0 such that $B\eth u \equiv 0$ implies $Q^0 u_j \equiv \sum_k Q_k^0 u_k$ where u_k are outgoing components of u as $k \geq 1$ and u_0 is an elliptic component and

(3.5.15) $$\bigcup_k \mathsf{supp}(q_k^0) = \mathsf{supp}(q^0).$$



(a) Simple reflection (b) Branching reflection

Figure 3.5: Reflections as $\eth G_j^+ Q^- = Q^0 \eth G_j^+$ and $G_k^+ Q_k^0 = \sum_k Q_k^+ G_k^+$

(iii) Finally, we construct parametrices G_k^+ corresponding to outgoing components and solving Cauchy problems $P_k u_k \equiv 0$ with Cauchy data on ∂X (with x_1 considered as "time") and prove that as $t \geq T'$

(3.5.16) $\gamma_{T'} G_k^+ Q_k^0 = Q_k^+ \gamma_{T'} G_k^+$ where γ_t is operation of fixing t, and $Q_k^+ = Q_k^+(x, hD_x)$ is an operator with the symbol q_k^+ and

(3.5.17) $$\mathsf{supp}(q_k^+) \cap \{t = T'\} = \{z : \exists t' \in [0, T'],\ \tau = -\lambda_k(z),$$
$$z' \in \mathsf{supp}(q_k^0) : z' \in \iota\Psi_{-T'+t',k}(z)\}.$$

To implement Steps (i) and (iii) we can consider Cauchy problems with respect to x_1 and note that one can always rewrite operator $Q_j^{\pm}(x, hD_x)$ as $Q_j^{\pm}(x, \pm T', hD_x)$ where $Q_j^{\pm}(x, t, hD_x)$ commutes with P_j and one can always rewrite $Q_j^{\pm}(x, t, hD_x)$ as

$$Q_j^0(x, t, hD_x', hD_t) + R_j(x, t, hD_x, hD_t)P_j(x, hD_x, hD_t).$$

Obviously

(3.5.18) As ρ, ϱ, T' are (small) constants, both operators G_j^+ and $\gamma_t G_k^+$ (with $t \in [T', T'']$) are Fourier integral operators with the symplectomorphisms $z \in T^*X \to (z', t, \tau) \in T^*(\partial X \times \mathbb{R}_t)$ and $(z', t, \tau) \in T^*(\partial X \times \mathbb{R}_t) \to z \in T^*X$ described above.

Note also that due to symmetry assumption

(3.5.19) Operator $\mathcal{B}$: "incoming components $\to$ outgoing components" is unitary modulo lower order terms.

This statement is true even if there are elliptic components. Now combining free propagation and reflection we arrive to

Theorem 3.5.1. *Let conditions* (3.5.2), (3.5.4)–(3.5.8) *be fulfilled with constants* ρ, ϱ, T. *Let* $t \in (0, T]$ *and* (3.5.12) *be fulfilled as well. Also assume that*

(3.5.20) $K^+_{[0,T]}(p, z)$ *consists of one non-branching billiard.*

Then for any $\tau_1 < \tau_2$ *with small enough* $|\tau_2 - \tau_1|$ *there exists pseudodifferential operator* Q^t *such that*

$$\|F_{t\to h^{-1}\tau}\bar{\chi}_{T'}(t-\bar{t})\big(e^{-ih^{-1}tA}Q - Q^t e^{-ih^{-1}tA}\big)\| \le Ch^s \qquad \forall \tau \in [\tau_1, \tau_2] \tag{3.5.21}$$

with small enough constant T' *and symbol of* Q^t *is supported in*

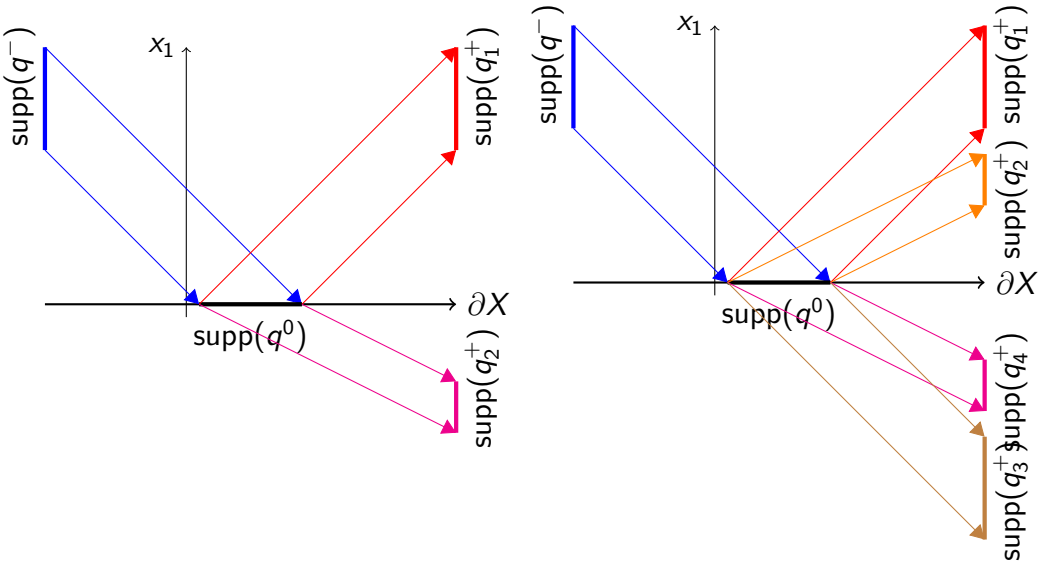
$$\bigcup_{\tau\in[\tau_1',\tau_2']} \mathcal{K}_t^+(a+\tau, \mathsf{supp}(q)) : \tag{3.5.22}$$

where $\tau_1' < \tau_1 < \tau_2 < \tau_2'$ *are arbitrary constants.*

Since we did not assume that A has a scalar principal symbol we cannot use the same operator Q^t for all τ but since λ_j are separated according to (3.5.5)–(3.5.6) we can exclude hD_t from Q^t in (3.5.21).

Remark 3.5.2. One can consider problems when operator is defined as $x_1 > 0$ and as $x_1 < 0$ with *transition conditions* at $x_1 = 0$. We refer to it as *reflection-refraction*.

We show it on Figure 3.6 below. The numbers of *reflected waves* and *refracted waves* do not necessarily coincide.



(a) Simple reflection-refraction (b) Branching reflection-refraction

Figure 3.6: Reflections and refractions

3.5.2 Long Time Evolution

Main Theorem

Now we want to take ρ, ϱ to be small parameters and T be a large parameter. Actually there are plenty of parameters here: large parameters time T, the bounds to derivatives of coefficients of operators A, B (which is natural to assume to be h-differential operators) and the bounds to number of reflections

along one billiard, the total number of billiards (due to branching) and the bounds to elements of $D\Psi_{t,j}$. Further, there are also upper bounds to derivatives of ϕ defining ∂X and the lower bounds to $|\nabla\phi|$, incidence and reflection angles. Furthermore, here are bounds to derivatives of the symbol of pseudodifferential operator $\mathcal{B}$: "$\mathsf{incoming\ components} \to \mathsf{outgoing\ components}$". Finally, there is a scaling parameter ε for operator Q.

To avoid an orgy of parameters we just assume (with no implications to applications) that $\varepsilon \ge h^{1/2-\delta}$ with an arbitrarily small exponent $\delta > 0$ while all other small parameters are not less than $h^{\delta'}$ and all large parameters are not larger than $h^{-\delta'}$ with $\delta' = \delta'(\delta) > 0$.

So, we assume that all the coefficients of A and B satisfy the inequalities in $\mathcal{K}^+_{[0,T]}(p, \mathsf{supp}(q))$

$$\|D^\alpha A_\beta\| \le c\rho^{-|\alpha|-1} \tag{3.5.23)$_1$}$$

$$\|D^\alpha B_\beta\| \le c_\alpha \rho^{-|\alpha|-1} \qquad \forall \alpha, \tag{3.5.23)$_2$}$$

and

$$|D^\alpha \phi| \le c_\alpha \rho^{-|\alpha|-1} \qquad \forall \alpha, \tag{3.5.24)$_1$}$$

$$|\phi(x)| \le \epsilon_0 \rho \implies |\nabla_x \phi(x)| \ge \epsilon_0, \tag{3.5.24)$_2$}$$

$$|\phi(x)| \le \epsilon_0 \rho \implies |\frac{d}{dt}\phi(x)| \ge \epsilon_0 \rho, \tag{3.5.24)$_3$}$$

along Hamiltonian trajectories comprising $\mathcal{K}^+_{[0,T]}(p, \mathsf{supp}(q))$, symbol of $\mathcal{B}$ satisfies

$$\|D^\alpha_{x',\xi',\tau} \mathcal{B}_n\| \le c_\alpha \rho^{-2n-|\alpha|-1} \qquad \forall \alpha. \tag{3.5.23)$_3$}$$

Finally we assume that

$$|D\Psi_{t,j}| \le c\rho^{-1} \tag{3.5.25}$$

again along trajectories comprising $\mathcal{K}^+_{[0,T]}(p, \mathsf{supp}(q))$.

Our goal is to prove

Theorem 3.5.3. *Let A, B be differential operators of orders m and not exceeding $(m-1)$ respectively. Let A_B be a self-adjoint operator.*

Let $Q \in \boldsymbol{\Psi}_{h,\varepsilon,\varepsilon}(X, \mathbb{H}, \mathbb{H})$ with $\varepsilon \ge h^{1/2-\delta}$. Let us assume that $T \le \rho^{-1}$ and in $\mathcal{K}^+_{[0,T]}(p, \mathsf{supp}(q))$ conditions (3.5.5), (3.5.6), $(3.5.23)_{1-3}$, $(3.5.24)_{1-3}$, (3.5.25) *be fulfilled with $\rho = h^{\delta'}$, $\delta' = \delta'(\delta) > 0$.*

Further, assume that

$$\mathsf{dist}(\pi_x \operatorname{supp}(q), \partial X) \ge \epsilon_0 \varepsilon, \tag{3.5.26)$_1$}$$

$$\mathsf{dist}(\pi_x \mathcal{K}_t^+(p, \operatorname{supp}(q)), \partial X) \ge \epsilon_0 \varepsilon. \tag{3.5.26)$_2$}$$

Finally, assume that (3.5.20) *is fulfilled.*

Then for any $\tau_1 < \tau_2$ *with* $|\tau_2 - \tau_1| \le \epsilon\rho$ *there exists operator* $Q^t \in \mathbf{\Psi}_{h,\varepsilon',\varepsilon'}(X, \mathbb{H}, \mathbb{H})$ *with* $\varepsilon' = \rho^r \varepsilon$ *such that* (3.5.21) *holds with* $T' = \epsilon_0 \rho^r$ *where* r *is large enough (but not depending on* δ*).*

Symbol of Q^t *is supported in* $\bigcup_{\tau\in[\tau_1,\tau_2]} \mathcal{K}_t^+(a+\tau, \operatorname{supp}(q))$.

Proof of the Main Theorem

First of all we note that the case of billiard not hitting the boundary is covered by Theorem 2.4.10. So we need to consider the case of the billiard hitting boundary at least once and possibly branching there. Each branch of such billiard consists of *hops* between boundary points but the first and the last hops are not complete: the former does not start at the boundary and the latter does not end here. Note that the length of every hop could be rather small: if everything but the angle with the boundary is bounded by a constant rather than a parameter, and angle is still bounded from below by ρ then the length of the hop could be as small as $\asymp \rho$ (for the bicharacteristically strongly convex domain as in the Figure 3.1. So the number of hops in such case would be $\asymp T\rho^{-1}$.

In the general case the length of the hop is bounded from below by ρ^3 and the number of hops is bounded from above by $T\rho^{-1} \asymp \rho^4$ (here exact fixed power is of no importance).

Let us consider first the Hamiltonian map Ψ_t along such billiard. Let $0 < t_1 < ... < t_N < t$ be moments when billiard hits the boundary and let us set $t_n' = t_n - \varsigma$, $t_n'' = t_n + \varsigma$ be moments "just before" and "just after" the hit. Then near z

$$\Psi_t = \Psi_{t,t_N''} \circ \Psi_{t_N'',t_N'} \circ \Psi_{t_N',t_{N-1}''} \circ \cdots \Psi_{t_1'',t_1'} \circ \Psi_{t_0',0} \tag{3.5.27}$$

where we use $\Psi_{t,t'}$ instead of $\Psi_{t-t'}$ to emphasize the moments on the billiards and

$$D\Psi_t = D\Psi_{t,t_N''} \cdot D\Psi_{t_N'',t_N'} \cdot D\Psi_{t_N',t_{N-1}''} \cdots D\Psi_{t_1'',t_1'} \cdot D\Psi_{t_0',0} \tag{3.5.28}$$

and we claim that

Proposition 3.5.4. $(m+1)$*-th order derivatives of* $\Psi_{t,0}$ *do not exceed* $C\rho^{-1-9m}$.

Proof. We apply induction with respect to m; as $m=0$ this just assumption (3.5.25). Let us consider $m \ge 1$.

Differentiating $(m+1)$-times $\Psi_{t,0} = \Psi_{t,s}\circ\Psi_{s,0}$ we get the following terms:

(i) Just one term when $\Psi_{t,s}$ is differentiated $(m+1)$ times.

(ii) No more than c_m terms when $\Psi_{t,s}$ is differentiated k times, $2 \le k \le m$. Such terms do not exceed

$$|D^k\Psi_{t,s}|\cdot|D^{r_1}\Psi_{s,0}|\cdot|D^{r_2}\Psi_{s,0}|\cdots|D^{r_k}\Psi_{s,0}|$$

with $r_1+...+r_k = m+1$, $r_i \ge 1$. However as time interval between s and t contains no hits the first factor due to Lemma 2.4.5 does not exceed $c\rho^{2-3k}$ and by induction assumption all $(i+1)$-th factor does not exceed $C\rho^{-8+9r_i}$ so the whole product does not exceed $C\rho^{2-3k-(9r_1-8)-\dots-(9r_k-8)} = C\rho^{2+5k-9(m+1)} = C\rho^{3-9m}$.

(iii) One term when $\Psi_{t,s}$ is differentiated just one time and $\Psi_{s,0}$ is differentiated $(m+1)$ times.

Repeating this procedure again and again we realize that there will be no more $2n+2 \le \rho^{-4}$ (ii)-type terms and their total contribution would not exceed $C\rho^{-1-9m}$. Therefore only terms when one of the factors gets all $(m+1)$ derivatives and all other factors get one derivative each need to be considered. So we get n terms of the type

$$|D\Psi_{t,s}|\cdot|D^{m+1}\Psi_{s,t}|\cdot|D\Psi_{s,0}| \tag{3.5.29}$$

where we used $D\Psi_{t,s} = D\Psi_{t,\tau}\cdot D\Psi_{\tau,s}$. Note that in (3.5.29) the first and the third factors do not exceed $c\rho^{-1}$ each and in the second factor either $t=t''_n$, $s=t'_n$ or $t=t'_{n+1}$, $s=t''_n$ and we set $t'_{N+1}=t$, $t''_0=0$.

So, we need to prove only that in this framework $|D^{m+1}\Psi_{s,t}|$ does not exceed $C\rho^{4-9m}$.

As $t=t'_{n+1}$, $s=t''_n$ the time interval between them contains no hits and due to Lemma 2.4.5 $|D^{m+1}\Psi_{s,t}|$ does not exceed $C\rho^{-1-3m}$.

Consider $t=t''_n$, $s=t'_n$. We can take $\varsigma>0$ arbitrarily small here; thus $t''_n = t_n+0$, $t'_n = t_n-0$. Then $\Psi_{t_n+0,t_n-0} = \Psi^+_k\Psi^-_j$ where Ψ^+_k :

$(x', \xi', t, \tau) \to (x, \xi)$ and $\Psi_j^- : (x, \xi) \to (x', \xi', t, \tau)$ correspond to outgoing and incoming bicharacteristic respectively. So we can study both of these symplectomorphisms separately.

Scaling ρ times with respect to x and ξ and changing coordinates so X locally is defined as $\{x_1 > 0\}$ we arrive to the standard situation with the sole exception that $-\{\lambda_j, x_1\} \asymp \zeta_j$ and $\{\lambda_k, x_1\} \asymp \zeta_k$ with $\zeta_j, \zeta_k \in [\rho, 1]$. Then rescaling with respect to x_1, ξ_1 only we arrive to the standard situation. One can prove easily that the inverse change of the coordinates provide the required estimate. □

Now consider point $\bar{z}$ and operator Q with the symbol supported in ε-vicinity of $\bar{z}$. By assumption $\tau_{1,2} = \bar{\tau} \mp \epsilon\rho$ for some $\bar{\tau}$. Without any loss of the generality one can assume that $|\lambda_j(\bar{z}) + \bar{\tau}| \le 2\epsilon\rho$ for some j [17].

Let us repeat arguments of Subsubsection *Heisenberg Evolution for Matrix Principal Symbols.3 Heisenberg Evolution for Matrix Principal Symbols.* In ρ^3-vicinity of $\bar{z}$ one can reduce A to the form

$$A \equiv \begin{pmatrix} A_j & 0 \\ 0 & A_{\hat{j}} \end{pmatrix}, \qquad Q \equiv \begin{pmatrix} Q_{jj} & Q_{j\hat{j}} \\ Q_{\hat{j}j} & Q_{\hat{j}\hat{j}} \end{pmatrix} \tag{3.5.30}$$

where the principal symbol of A_j is λ_j and eigenvalues of the principal symbol of $A_{\hat{j}}$ differ from $\bar{\tau}$ by $3\epsilon\rho$ at least.

Then one can redefine Q replacing two lower blocks by 0 [18] and then one can redefine A replacing A_j by whatever we want[19] (and we want it to be equal to λ_j^{w}):

$$A := A_{(j)} = \begin{pmatrix} A_j & 0 \\ 0 & \lambda_j^{\mathsf{w}} \end{pmatrix}, \qquad Q := Q_{(j)} = \begin{pmatrix} Q_{jj} & Q_{j\hat{j}}, \\ 0 & 0 \end{pmatrix}. \tag{3.5.31}$$

So we replaced A, Q by

$$A_{(j)} = \pi_j A + (I - \pi_j)\lambda_j^{\mathsf{w}}, \qquad Q_{(j)} = \pi_j Q \tag{3.5.32}$$

where π_j is the corresponding projector. While the global[20] reduction of A, Q to form (3.5.30) and definition (3.5.31) is a murky business, pseudodifferential operator π_j and thus $A_{(j)}$, $Q_{(j)}$ are well defined globally[20].

[17] Otherwise $F_{t\to h^{-1}\tau}\bar{\chi}_T(t)UQ \equiv 0$ for $\tau \in [\tau_1, \tau_2]$.

[18] Then $F_{t\to h^{-1}\tau}U(t)Q$ changes negligibly as $\tau \in [\tau_1, \tau_2]$.

[19] Then $e^{-ih^{-1}tA}Q$ changes negligibly.

[20] In the zone $\Sigma_j = \{|\lambda_j + \bar{\tau}| \le 3\epsilon\rho\}$.

However since $A_{(j)}$ has a scalar principal symbol, operator Q^t defined by (2.4.4) with A, Q replaced by $A_{(j)}$ and $Q_{(j)}$ respectively is a pseudodifferential operator as long as we do not hit the boundary. Therefore, Theorem 3.5.3 is proven as long there are no reflection points.

Now consider the act of reflection. Since we can push the free propagation almost until the boundary we can rescale as we did in the proof of Proposition 3.5.4. After this rescaling we have bicharacteristic transversal to the boundary and therefore we arrive to

$$\eth_{\partial X}\bigl(e^{-ih^{-1}(t-t')A_{(j)}}Q_j^{t'}\bigr) \equiv Q_j'\eth_{\partial X}e^{-ih^{-1}(t-t')A_{(j)}} \qquad \text{for } \ t\in[t_n-\epsilon\rho^2, t_n+\epsilon\rho^2] \tag{3.5.33}$$

where $Q_j' = Q_j'(x', hD', t, hD_t)$.

As $\mathsf{D}_j = 1$ its principal symbol is $\bigl(q_j^{t'}\circ \Psi_j^{-}{}^{-1}\bigr)$ and all other symbols are given by

$$Q_{jm}' = \sum_{|\alpha|+2l\le 2m} \ell_{m-m',\alpha} D_{x,\xi}^{\alpha}\bigl(Q_j^{t'}\circ\Psi_j^{-}{}^{-1}\bigr) \tag{3.5.34}$$

with

$$\|D_{x,\xi}^{\beta} b_{l,\alpha}\| \le c_{l,\beta}\rho^{-6l-3|\beta|}. \tag{3.5.35}$$

However as $\mathsf{D}_j \ge 2$ ℓ_j are linear maps from the space of $\mathsf{D}_j\times\mathsf{D}_j$-matrices to itself; in particular $q_j' = T_j^{\dagger}\bigl(q_j^{t'}\circ\Psi_j^{-}{}^{-1}\bigr)T_j$ with unitary matrix T_j.

In the same manner solving Cauchy problem with the initial data on ∂X we get the similar statement with the reverse time and j corresponding to the incoming bicharacteristics replaced by k corresponding to the outgoing one (which is an incoming bicharacteristics in the reverse time). Finally, as $\mathcal{B}$ mapping incoming component u_j to outgoing one u_k is a unitary operator (modulo negligible) we can rewrite $\mathcal{B}Q_j' \equiv Q_{kj}''\mathcal{B}$ and therefore as $t' = t_n-\epsilon\rho^2$, $\mathsf{supp}(\chi)\subset[t_n+\epsilon\rho^2, t_n+\epsilon\rho^2]$ (3.5.21) holds.

Combining with free space propagation we arrive to Theorem 3.5.1 as long as there is just one reflection point. However combining with Proposition 3.5.4 we arrive to Theorem 3.5.1 in the general case.

3.5.3 Branching Billiards and Propagation

Theorem 3.5.5. *Let A, B be differential operators of orders m and not exceeding $(m-1)$ respectively. Let $A_{\mathcal{B}}$ be a self-adjoint operator.*

Let $Q \in \mathbf{\Psi}_{h,\varepsilon,\varepsilon}(X, \mathbb{H}, \mathbb{H})$ *with* $\varepsilon \ge h^{1/2-\delta}$. *Let us assume that* $T \le \rho^{-1}$ *and in* $\mathcal{K}^+_{[0,T]}(p, \mathsf{supp}(q))$ *conditions* (3.5.5), (3.5.6), $(3.5.23)_{1-3}$, $(3.5.24)_{1-3}$ *and* (3.5.25) *be fulfilled with* $\rho = h^{\delta'}$, $\delta' = \delta'(\delta) > 0$.

Further assume that conditions $(3.5.26)_1$, $(3.5.26)_2$ *are fulfilled and*

(3.5.36) $K^+_{[0,T]}(p,z)$ *consists of no more than* $C\rho^{-l}$ *non-branching billiards.*

Let $Q \in \mathbf{\Psi}_{h,\varepsilon,\varepsilon}$ *with the symbol supported in* $\mathcal{V}$ *which is* ε*-vicinity of* z *and* $Q' \in \mathbf{\Psi}_{h,\varepsilon',\varepsilon'}$ *with the symbol equal* 1 *in* $\Psi_{\bar t}(\mathcal{V}')$ *where* $\mathcal{V}'$ *is* $(1+\rho^3)\varepsilon$*-vicinity of* z. *Then*

$$|F_{t\to h^{-1}\tau}\chi_{T'}(t-\bar t(1-Q')e^{-ih^{-1}tA}Q| \le Ch^s \qquad \forall t \in [\tau_1,\tau_2]. \tag{3.5.37}$$

Proof. Since each non-branching billiard has no more than $C\rho^{-2}$ reflection points it is sufficient to prove theorem as

(3.5.38) Each of non-branching billiards comprising $K^+_{[0,T]}(p,z)$ has no more than 1 reflection point each.

Indeed, in the general case we can select points t'_j such that condition $(3.5.26)_2$ is fulfilled with t'_j instead of $\bar t$ and on interval $[t'_j, t''_j]$ each billiard has no more than 1 reflection point. Then statement of the theorem in the general case follows from it under restriction (3.5.38).

Then due to finite speed of propagation it is sufficient to prove this theorem as $t_1 < \bar t$ and $t_1, \bar t - t_1 \asymp \rho^3$. But then the rescaling brings us to the standard case. □

3.A Appendices

3.A.1 On Solutions to Linear Matrix Equations

Let $\mathbb{H}$ and $\mathbb{H}'$ be Hilbert spaces and let us consider the equation

$$AX - XB = C \tag{3.A.1}$$

with respect to $X \in \mathcal{L}(\mathbb{H}, \mathbb{H}')$ with given $A \in \mathcal{L}(\mathbb{H}, \mathbb{H})$, $B \in \mathcal{L}(\mathbb{H}', \mathbb{H}')$, $C \in \mathcal{L}(\mathbb{H}, \mathbb{H}')$.

Let us assume that the

(3.A.2) spectra of A and B are disjoint

and let $\mathbb{C} \supset \gamma$ be a closed counter-clockwise oriented curve, $\gamma = \partial G$ where G is a bounded domain in $\mathbb{C}$, $\mathsf{Spec}(A) \subset G$, $\mathsf{Spec}(B) \subset \complement \bar{G}$. Then

$$X = \frac{1}{2\pi i} \int_\gamma (z - A)^{-1} C (z - B)^{-1} dz \tag{3.A.3}$$

is the (unique) solution of equation (3.A.1).

Further, if $\mathbb{C} \supset \gamma'$ is a closed counter-clockwise oriented curve, $\gamma' = \partial G'$, G' is a bounded domain in $\mathbb{C}$, $\mathsf{Spec}(B) \subset G'$, $\mathsf{Spec}(A) \subset \complement \bar{G}'$ then

$$X = -\frac{1}{2\pi i} \int_{\gamma'} (z - A)^{-1} C (z - B)^{-1} dz. \tag{3.A.3}'$$

Moreover,

(3.A.4) formula (3.A.3) ((3.A.3)$'$ respectively) remains true also in the case when B (A respectively) is an unbounded operator.

If $A \geq \epsilon I, B \leq -\epsilon I$ with $\epsilon > 0$ then the (unique) solution of (3.A.1) is also given by the formula

$$X = \int_0^{+\infty} e^{-At} C e^{Bt} dt \tag{3.A.5}$$

and if $B \geq \epsilon I, A \leq -\epsilon I$ then

$$X = \int_{-\infty}^0 e^{-At} C e^{Bt} dt;. \tag{3.A.5}'$$

Furthermore,

(3.A.6) formula (3.A.5) ((3.A.5)$'$ respectively) remains true if $-A$ and B (A and $-B$ respectively) are unbounded operators which generate semigroups tending to 0 quickly enough as t tends to $+\infty$.

Let us note that if X is a solution of (3.A.1) then $X^\dagger$ is a solution of

$$X^\dagger A^\dagger - B^\dagger X^\dagger = C^\dagger. \tag{3.A.1}^\dagger$$

and hence if $\mathbb{H} = \mathbb{H}'$ and $A^\dagger = B$, $C^\dagger = -C$ then the uniqueness of solutions implies that $X^\dagger = X$.

Similarly, if $\mathbb{H}$ and $\mathbb{H}'$ are complexifications of the real spaces then the operation of complex conjugation is defined and if A, B, C are real then X is also real; moreover, if $\mathbb{H} = \mathbb{H}'$ and $A^T = B$, $C^T = -C$ then $X^T = X$.

Let us emphasize that the fundamental condition is (3.A.2).

3.A.2 Structure of Gliding Points

Assume that a and b are two Hermitean $m \times m$-matrices, a is non-degenerate and $a^{-1}b$ has the only eigenvalue 0 and $\operatorname{rank} a^{-1}b = m-1$. Let f_k ($k = 1, \dots, m$) be the corresponding (associated) eigenvectors:

$$bf_k = af_{k-1} \qquad k = 1, \dots, m;\ f_0 = 0. \tag{3.A.7}$$

Then

$$\langle af_k, f_j\rangle = \langle bf_{k+1}, f_j\rangle = \langle f_{k+1}, bf_j\rangle = \langle af_{k+1}, f_{j-1}\rangle$$

which implies that

$$\langle af_k, f_j\rangle = \rho_{j+k} \qquad \text{with } \rho_l = 0 \text{ as } l = 2, \dots, m; \tag{3.A.8}$$

however since a is non-degenerate $\rho = \rho_{m+1} \neq 0$. Then replacing f_j by $\lambda f_j + \sum_{k<j} \lambda_{j-k} f_k$ we can achieve $\rho_l = 0$ as $l = m+2, \dots, 2m$ and $\rho_{m+1} = \pm 1$.

Let ρ be a linear transformation mapping k-th coordinate vector to f_k; then $\rho^\dagger a \rho$ is of the form of a_0 in (3.1.15) (modulo factor $\varsigma = \pm 1$). Then (3.A.7) implies that modulo the same factor b is of the form of a_1 there.

Let now a and b be variable matrices being of form (3.1.15) only at point z^*. Then $g = \det(\eta - a^{-1}b)$ coincides with $r = b_{mm}$ modulo term vanishing with its first order derivatives at $z = z^*$ and $\eta = 0$.

Comments

There are many papers devoted to the propagation of singularities near the boundary.

Theorems 3.1.7 and 3.1.12 were first proven for wave front sets in V. Ivrii [2] in the less general form. We already explained that these theorems, in contrast to Theorem 2.1.2, are not very precise.

A certain analog of Theorem 3.3.6 for the wave equation was first proven in V. Ivrii [8], which was the first proof of this type of theorem without an explicit parametrix construction.

In order to exclude boundary bicharacteristics for a bicharacteristically concave domain one needs to prove results similar to those of Theorems 3.4.9, 3.4.10 etc. Energy estimates based proof was published first in V. Ivrii [7]. see also L. Hörmander [1]. Alternatively one can use explicit parametrix construction; see R. Melrose [1], G Eskin [1,2], M. Taylor [2,3,5]

where the theorem was proved by an explicit parametrix construction. Idea to combine two types of results (general but not excluding bicharacteristics for a bicharacteristically concave domain and one which excludes them at strictly concave points was used first by R. Melrose and J. Sjöstrand in [1].

Otherwise only analytic or Gevrey (with Gevrey index ≤ 3) singularities propagate along boundary bicharacteristics J. Sjöstrand [3–6], G. Lebeau [1, 2].

Propagation near edges and vertices was studied in G. Lebeau [3, 4] and in P. Gérard and G. Leabeau [1].

Propagation near conical points was studied in M. E. Taylor [6] and in J. Cheeger and M. E. Taylor [1, 2].

All this propagation results are of no importance for integrated spectral asymptotics and we do not cover them here.

One should be note that there is a huge literature devoted to diffraction partially predating microlocal analysis and coexisting with it. I just mention fundamental monographs with a richness of the material and references; we highly recommend V. A. Borovikov [1], V. A. Borovikov and B. Ye. Kinber [1] and especially V. M. Babich and V. S. Buldyrev [1].

In particular in V. A. Borovikov [1] was treated the propagation of the plane waves for constant coefficients near angles (in dimension 2), vertices and edges (in dimension 3). In addition to several plane waves appearing due to (possibly multiple) reflections from all illuminated sides or faces, there appear circular waves generated by vertices with amplitudes acquiring factor $h^{\frac{1}{2}}$ (in dimension 2) and cylindrical waves generated by edges with amplitudes acquiring factor $h^{\frac{1}{2}}$ and spherical waves generated by vertices with amplitudes acquiring factor h (in comparison to incidental plane waves).

Part II

Local and Microlocal Semiclassical Spectral Asymptotics in the Interior of the Domain

Chapter 4

General Theory in the Interior of the Domain

4.1 Introduction

4.1.1 Main Objects

In this chapter we begin the treatment of the *local and microlocal semiclassical spectral asymptotics*. At this stage we are interested in the *standard* spectral asymptotics, i.e., in asymptotics with respect to the Planck constant $h \to +0$ only; namely, in this chapter we are interested in the asymptotics of the *spectral function* $e(x,x,\tau)$ which is the restriction to the diagonal of the Schwartz kernel of the spectral projector, and the spatial means of $e(x,x,\tau)$. Further, we are interested in the *microlocal spectral asymptotics*; so our main object is either

$$\mathsf{N}_x := \Gamma_x\bigl(Q_{1x}\psi(x)e(.,.,\tau)\psi(y)\,{}^tQ_{2y}\bigr) \tag{4.1.1}$$

and

$$\mathsf{N} := \Gamma\bigl(Q_{1x}\psi(x)e(.,.,\tau)\psi(y)\,{}^tQ_{2y}\bigr) \tag{4.1.2}$$

where Qj are h-pseudodifferential operators with compactly supported symbols and $\psi_j(x)$ are compactly supported functions. We also consider averaging with respect to the spectral parameter i.e. we consider

$$\mathsf{N}_{x,\varphi,L} := \int \varphi\bigl(\frac{h}{L}\bigr)\,d_\tau\Gamma_x\bigl(Q_{1x}\psi(x)e(.,.,\tau)\psi(y)\,{}^tQ_{2y}\bigr) \tag{4.1.3}$$

and

$$\mathsf{N}_{\varphi,L} \coloneqq \int \varphi\big(\frac{h}{L}\big)\, d_\tau \Gamma\big(Q_{1x}\psi(x)e(.,.,\tau)\psi(y)\,{}^tQ_{2y}\big) \tag{4.1.4}$$

where φ is an *averaging function* and L is an *averaging parameter*. What kind of averaging functions we use we discuss later.

Let be clear: the most interesting case is (4.1.2) with $Q_1 = Q_2 = I$ and $\psi_1 = \psi_2 = 1$ and microlocalized expressions will be used in the future as building blocks for localized expressions i.e. with $Q_1 = Q_2 = I$ and those in turn will be used as building blocks for those with $\psi_1 = \psi_2 = 1$.

As an approximation to $e(x,y,\tau)$ to be used in expressions (4.1.1)–(4.1.4) we pick up first the *Tauberian approximation*

$$e^{\mathsf{T}}(x,y,\tau) \coloneqq h^{-1}\int_{-\infty}^{\tau} \Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)u(x,y,t)\Big)\, d\tau \tag{4.1.5}$$

where $u(x,y,t)$ is the corresponding propagator i.e. the Schwartz kernel of $e^{ih^{-1}tA}$, $\bar{\chi} \in \mathscr{C}_0^\infty([-1,1])$ equal to 1 on $[-\frac{1}{2},\frac{1}{2}]$ and $\bar{\chi}_T(t) = \bar{\chi}(t/T)$ and *usually* T will be a small constant here. Plugging $e^{\mathsf{T}}(x,y,\tau)$ into (4.1.1)–(4.1.4) we get corresponding *Tauberian approximations* $\mathsf{N}_*^{\mathsf{T}}$ and the difference between N_* and $\mathsf{N}_*^{\mathsf{T}}$ we denote by $\mathsf{R}_*^{\mathsf{T}}$ which will be called *Tauberian error*.

So, our first goal is to estimate $\mathsf{R}_*^{\mathsf{T}}$ either in the general case or under microhyperbolicity assumption. In the most papers devoted to sharp spectral asymptotics this step is masked but we prefer to make it explicit.

Surely, $u(x,y,t)$ and thus $e^{\mathsf{T}}(x,y,\tau)$ is no more implicit object than $e(x,y,\tau)$ was but actually we can calculate $\mathsf{N}_*^{\mathsf{T}}$ it with a high precision: in the standard papers it is made by constructing $u(x,y,t)$ as an oscillatory integral but this imposes very strong assumptions on operator we consider.

Instead here we use completely different approach: first using our propagation results we show that under microhyperbolicity condition one can replace in the Tauberian expressions $T \gtrsim 1$ by much smaller value $T = h^{1-\delta}$ with an arbitrarily small exponent $\delta > 0$.

On such small time interval we can construct $u(x,y,t)$ by the *successive approximation method* picking up as unperturbed operator $A(y, hD_x, 0)$. This construction is much more robust and universal than construction as an oscillatory integral.

Actually this construction does not use microhyperbolicity at all and we need to assume only that $T \le h^{\frac{1}{2}+\delta}$ with an arbitrarily small exponent

$\delta > 0$. However without microhyperbolicity it is useful only for $\mathsf{N}_{\varphi,L}$ and $\mathsf{N}_{x,\varphi,L}$ and only as $L \ge h^{\frac{1}{2}-\delta}$.

Plugging $u(x,y,t)$ into Tauberian approximations N_*^{T} we will be able to prove that with a certain precision

$$\mathsf{N}_x^{\mathsf{T}} \sim \mathsf{N}_x^{\mathsf{W}} := \sum_{0\le n\le m} \kappa_{nx}(\tau) h^{-d+n}, \tag{4.1.6}$$

or

$$\mathsf{N}^{\mathsf{T}} \sim \mathsf{N}_x^{\mathsf{W}} := \sum_{0\le n\le m} \kappa_{n}(\tau) h^{-d+n} \tag{4.1.7}$$

with

$$\kappa_n(\tau) = \int \kappa_{nx}(\tau)\, dx \tag{4.1.8}$$

and the corresponding equalities for $\mathsf{N}^{\mathsf{T}}_{x,\varphi,L}$ and $\mathsf{N}^{\mathsf{T}}_{\varphi,L}$.

Here κ_{nx} and κ_n depend on Q_1, Q_2, ψ_1, ψ_2; in particular

$$\kappa_{0x}(\tau) = (2\pi)^{-d} \int q_1^0(x,\xi)\psi_1(x) e(x,\xi,\tau)\psi_2(x) q_2^0(x,\xi)\, d\xi \tag{4.1.9}$$

where q_j are principal symbols of Q_j and

$$e(x,\xi,\tau) = \theta\big(\tau - a(x,\xi)\big) \tag{4.1.10}$$

is the spectral projector of the principal symbol $a(x,\xi)$ of operator A; as usual θ is the Heaviside function.

Expressions for next coefficients are much more complicated but they could be also calculated explicitly. These coefficients could be defined formally but without microhyperbolicity condition they could be rather irregular.

We call $\mathsf{N}_*^{\mathsf{W}}$ *Weyl approximation* and Weyl approximation is our final goal. We denote by $\mathsf{R}_*^{\mathsf{W}}$ the difference between N_* and $\mathsf{N}_*^{\mathsf{W}}$ and call it *Weyl error*.

So, on the second step we estimate $(\mathsf{N}_*^{T} - \mathsf{N}_*^{\mathsf{W}})$. Since $\mathsf{R}_x^{\mathsf{T}}$ and R^{T} usually are estimated by $O(h^{1-d})$ (but under assumptions of the global nature one can improve them marginally) it would be sufficient to pick up in $\mathsf{N}_x^{\mathsf{W}}$ and N^{W} usually $m = 0$ but sometimes $m = 1$. However estimates of $\mathsf{R}^{\mathsf{T}}_{x,\varphi,L}$ and $\mathsf{R}^{\mathsf{T}}_{\varphi,L}$ could be (much) better than $O(h^{1-d})$ and we need (much) more terms.

Remark 4.1.1. If we consider operators acting on sections then all the symbols and thus κ_{nx} are sections as well; then Γ and κ_n are not defined. However, $\Gamma\,\mathsf{tr}$ is defined and we should use instead

$$\kappa_n(\tau) = \int \mathsf{tr}(\kappa_{nx}(\tau))\,dx$$

in this case as well.

4.1.2 Kind of Assumptions to be Used

The only global condition we assume is that the operator A is self-adjoint.

All other conditions will be local or even microlocal: we derive asymptotics for $\mathsf{N}_{x,*}$ or N_* with x belonging and symbols of q_j supported in the ball $B(0,\frac{1}{2})$ under the assumption that the ball $B(0,1)$ is contained in the domain and all conditions are imposed in this ball.

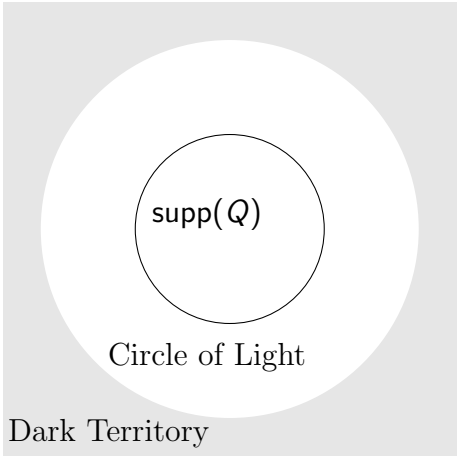


Figure 4.1: We impose condition in the "Circle of Light"; the only global condition is self-adjointness.

This is exactly true only if we want to derive asymptotics of N_x or N with an error estimate $O(h^{1-d})$; then we pick up T as a small constant.

However if we want to derive (marginally) better remainder estimates we need to pick up large T and impose some conditions at the points which we can touch by some generalized Hamiltonian trajectory of the length T starting in $B(0,\frac{1}{2})$.

Finally, there are two microhyperbolicity conditions: microhyperbolicity and ξ-microhyperbolicity:

Definition 4.1.2. We say that

(i) Symbol $a(x,\xi)$ is *microhyperbolic* at energy level τ in Ω if at each point $z\in\Omega$ symbol $(\tau - a(x,\xi))$ is microhyperbolic at z in some direction $\ell=\ell(z)$ ($|\ell(z)|\le 1$) in the sense of Definition 2.1.1;

(ii) Symbol $a(x,\xi)$ is *ξ-microhyperbolic* at energy level τ in Ω if in the framework of (i) one can select $\ell((z) = (0,\ell_\xi(z))$ at each point.

Normally microhyperbolicity is used to derive asymptotics with the spatial averaging (i.e. of N and $\mathsf{N}_{\varphi,L}$ while ξ-microhyperbolicity is used to derive asymptotics without spatial averaging (i.e. of N_x and $\mathsf{N}_{x,\varphi,L}$ but in Section 4.6 we will always need ξ-microhyperbolicity.

4.1.3 Plan of the Chapter

In Section 4.2 we introduce the basic notions, obtain the first rough estimates and under microhyperbolicity or ξ-microhyperbolicity conditions estimate

$$\Gamma\Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)Q_{1x}u(x,y,t)\,{}^tQ_{2y}\Big) \tag{4.1.11}$$

and

$$\Gamma_x\Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)Q_{1x}u(x,y,t)\,{}^tQ_{2y}\Big) \tag{4.1.12}$$

by Ch^{1-d} as $T \asymp 1$; we also derive certain estimates for larger T under non-periodicity or no-loop condition. Then using Tauberian technique we derive from (4.1.11) or (4.1.12) estimates respectively $\mathsf{R}^{\mathsf{T}} \le Ch^{1-d}$ and $\mathsf{R}^{\mathsf{T}}_x \le Ch^{1-d}$ and certain estimates for $\mathsf{R}^{\mathsf{T}}_{\varphi,L}$ and $\mathsf{R}_{x,\varphi,L}$.

Then in Section 4.3 by means of the successive approximations we construct $u(t,x,y)$ in a bounded domain in phase space for $|t| \le h^{\frac12+\delta}$ with an arbitrarily small exponent $\delta > 0$ and then we construct $(\Gamma u)(t)$ and $(\Gamma_x u)(t,x,x)$ and related functions.

Next, in Section 4.4 we prove the main general theorems. Namely, the construction of Section 4.3 immediately yields the complete asymptotic decomposition of $\mathsf{N}_{x,\varphi,L}$ as $\varphi \in \mathscr{C}_0^\infty(\mathbb{R})$ and $L \ge h^{\frac12-\delta}$. Further, under microhyperbolicity or ξ-microhyperbolicity condition respectively we prove that coefficients κ_n or κ_{nx} are smooth as $\tau \in [-\epsilon,\epsilon]$. Moreover, the same condition allows us in the Tauberian approximation (4.1.5) for N_* and $\mathsf{N}_{x,*}$ to replace small constant T by any lesser $T \ge h^{1-\delta}$ and thus we can apply construction of Section 4.3 and pass from Tauberian to Weyl approximations.

In Section 4.5 we using the long time propagation theorems increase T from small constant T_0 either to arbitrarily large constant or even to larger $T \le h^{-\delta}$ and derive even sharper remainder estimates; actually we apply these estimates not everywhere but with exception of sets of small measure (not exceeding ε). Combining with estimates there we arrive to remainder estimates

$$C_0(T^{-1}+\varepsilon)h^{1-d} + C'h^{1-d+\delta}$$

for errors R^{W} or $\mathsf{R}^{\mathsf{W}}_x$ and improved estimates with averaging.

Further, in Section 4.6 we partially generalize the results of the previous sections to operators with "rough" with respect to x symbols. As an application we derive spectral asymptotics for number of negative eigenvalues for operators with non-smooth coefficients on compact closed manifolds; here we combine results for "rough" operators with variational ideas. This is a first taste of things to come much later.

Finally, in Section 4.7 we consider operators with non-smooth ($\mathscr{C}^l$) coefficients directly by the perturbation method.

In Appendix 4.A.1 we consider the boundary values of almost-analytic functions (which are useful for the calculation of successive approximations via the Fourier transform) and in Appendix 4.A.2 we study approximations of non-smooth functions by "rough" functions.

Remark 4.1.3. (i) During the whole chapter we consider pseudodifferential operators cut-offs Q_j of different classes; we include ψ_j into them: $Q_j := Q_j\psi_j$ and thus ${}^{t}Q_j := \psi_j\, {}^{t}Q_j$.

(ii) Further, we assume by default that

$$\sup_{(x,\xi)} \|q_j^0(x,\xi)\| \le 1 \qquad \forall j \tag{4.1.13}$$

which simplifies some statements; obviously there is no loss of the generality.

4.2 Preliminary Analysis and Tauberian Method

4.2.1 General Estimates

In this chapter we consider the differential operator

$$A = \mathsf{Op}^{\mathsf{w}}(A(x,\xi,h)) = \sum_{|\alpha|+|\beta|\le m} \frac{(\alpha+\beta)!}{\alpha!\beta!}(hD)^{\alpha} a_{\alpha+\beta}(x,h)(hD)^{\beta} \tag{4.2.1}$$

with the full symbol

$$A(x,\xi,h) = \sum_{|\alpha|\le m} a_{\alpha}\xi^{\alpha} \tag{4.2.2}$$

and $h \in (0,1]$, given on the manifold X some part of which is identified with the ball $B(0,1)$ where the coefficients $a_\alpha(x,h)$ are linear (not necessarily bounded) symmetric operators in some auxiliary Hilbert space $\mathbb{H}$.

Alternatively, we consider pseudodifferential operators $A \in \boldsymbol{\Psi}_h(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ and $A \in \tilde{\boldsymbol{\Psi}}_h^{(m)}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ and more general operators; at this moment we need only to assume that

(4.2.3) A with the given domain $\mathfrak{D}(A)$ is a self-adjoint operator in $\mathscr{L}^2(X, \mathbb{H})$

(this condition will be formulated more precisely later). Then there are Hermitean spectral projectors and an unitary propagator.

Let $E(\tau)$ be the spectral projector of A corresponding to the interval $(-\infty, \tau)$; then $E(\tau_1, \tau_2) = E(\tau_1) - E(\tau_2)$ for $\tau_1 < \tau_2$ is the spectral projector corresponding to the interval $[\tau_1, \tau_2)$. Our goal is to derive asymptotics as $h \to +0$ for various functions associated with $e(x, y, \tau_1, \tau_2)$, the Schwartz kernel of $E(\tau_1, \tau_2)$.

Our main tool is the analysis of $u(x, y, t)$, the Schwartz kernel of the propagator $U(t) := e^{ih^{-1}tA}$. Obviously,

$$u(x,y,t) = \int e^{ith^{-1}\tau} d_\tau e(x,y,\tau_1,\tau) \tag{4.2.4}$$

with an arbitrary $\tau_1 \in [-\infty, +\infty]$.

Equality (4.2.1) is understood in the sense of distributions and in the general case we cannot set $x = y$ here.

However, Proposition 1.1.11 and Theorem 1.1.12 yield that we can set $x = y$ if we first apply operators Q_{1x} and ${}^tQ_{2y}$ on the left and right respectively provided the symbols of Q_1 and Q_2 are compactly supported. Namely, since the operator norms of $U(t)$ and $E(\tau_1, \tau_2)$ do not exceed 1 Theorem 1.1.12 yields the following

Proposition 4.2.1. *Let A be an operator self-adjoint in $\mathscr{L}^2(X, \mathbb{H})$ and let functions $\psi_1, \psi_2 \in \mathscr{L}^\infty$ be supported in $B(0,1)$ and $|\psi_j| \le 1$.*

Moreover, let $q_1, q_2 \in \mathsf{S}_{h,\rho,1,K}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ be supported in $\{|\xi| \le \rho\}$ and $Q_i = \mathsf{Op}^{\mathsf{w}}(q_i)$ $(i = 1, 2)$, with $\rho \ge h$. Then

$$\|Q_{1x}\psi_1(x) e(x,y,\tau_1,\tau_2)\psi_2(y)\, {}^tQ_{2y}\| \le C'\Big(\frac{\rho}{h}\Big)^d \tag{4.2.5}$$

$$\forall x, y \in \mathbb{R}^d \quad \forall \tau_1, \tau_2 \in \mathbb{R}$$

and

$$\|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)\big(Q_{1x}\psi_1(x)u(t,x,y)\psi_2(y)\,{}^tQ_{2y}\big)\| \le C'T\big(\frac{\rho}{h}\big)^d \qquad \forall x,y\in\mathbb{R}^d \quad \forall T\ge h,\ T'\in\mathbb{R} \tag{4.2.6}$$

where here and below $C'=C\|\!|q_1|\!|\cdot|\!|q_2|\!|$, $|\!|\!|\cdot|\!|\!|$ *means the* $\mathsf{S}_{h,\rho,1,K}$*-norm; further* $K=K(d)$, $C=C(d)$ *here,* $\chi\in\mathscr{C}_0([-1,1])$ *and* $\chi_{T,T'}(t)=\chi(\frac{t-T'}{T})$.

In the case of $\dim H=\infty$ we need to obtain a more refined assertion. Let us assume that B_1 is a (self-adjoint) operator in $\mathbb{H}$ such that

$$B_1^\dagger = B_1, \qquad B_1\ge I \tag{4.2.7}$$

where $\ge$ and $\le$ denote the standard order of symmetric operators; furthermore, assume tat the estimate

$$\|B_1^l u\|_{\mathscr{L}^2(B(0,1),\mathbb{H})} \le c\big(\|A^l u\|_{\mathscr{L}^2(X,\mathbb{H})}+\|u\|_{\mathscr{L}^2(X,\mathbb{H})}\big) \qquad \forall u\in\mathfrak{D}(A^l) \tag{4.2.8}_l$$

holds with some $l>0$.

Proposition 4.2.2. *Let the assumptions of Proposition 4.2.1 and conditions* (4.2.7) *and* $(4.2.8)_l$ *be fulfilled.*

(i) Then

$$\|Q_{1x}\psi_1(x)B_1^j e(x,y,\tau_1,\tau_2)B_1^k\psi_2(y)\,{}^tQ_{2y}\| \le C'\big(\frac{\rho}{h}\big)^d(|\tau_1|+|\tau_2|+1)^{j+k} \qquad \forall x,y\in\mathbb{R}^d \quad \forall\tau_1,\tau_2\in\mathbb{R} \quad \forall j,k\in[0,l] \tag{4.2.9}_l$$

where here and below K *and* C *also depend on* l *and* C *also depends on* c *in condition* $(4.2.8)_l$.

(ii) Moreover, if $\chi\in\mathscr{C}_0^{k+j}([-1,1])$ *and* $T\ge h$, $T'\in\mathbb{R}$ *then*

$$\|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_{1x}\psi_1(x)B_1^j u(t,x,y)B_1^k\psi_2(y)\,{}^tQ_{2y}\| \le C'T|\!|\!|\chi|\!|\!|\big(\frac{\rho}{h}\big)^d(|\tau|+1)^{j+k} \qquad \forall x,y\in\mathbb{R}^d \quad \forall\tau\in\mathbb{R} \quad \forall j,k\in[0,l] \tag{4.2.10}_l$$

where $|\!|\!|\chi|\!|\!|$ *means the* $\mathscr{C}^{k+j}$*-norm of* χ.

In particular, in the framework of Proposition 4.2.1 this estimate holds for $j=k=0$.

Proof. Let us note that the interpolation theorems of J. L. Lions, and E. Magenes [1] imply that (4.2.8) holds for l replaced by arbitrary $j \in [0, l]$ and hence

$$\|B_1^j(A \pm i)^{-j}\| \le c, \qquad \|(A \mp i)^{-j} B_1^j\| \le c \tag{4.2.11}$$

where we derived the second inequality just taking an adjoint operator. Therefore

$$\|B_1^j E(\tau_1, \tau_2) B_1^k\| \le c^2 \|(A+i)^j E(\tau_1, \tau_2)(A+i)^k\| \le C(|\tau_1| + |\tau_2| + 1)^{j+k};$$

the resulting inequality combined with Theorem 1.1.12 implies $(4.2.9)_l$.

Similarly

$$\|F_{t\to h^{-1}\tau} \chi_{T,T'}(t) B_1^j U(t) B_1^k\| \le C\|F_{t\to h^{-1}\tau}(A+i)^j \chi_{T,T'}(t) U(t)(A+i)^k\| =$$
$$C\|F_{t\to h^{-1}\tau}((-hD_t + i + \tau)^{j+k} \chi_{T,T'}) U(t)\| \le CT(|\tau|+1)^{j+k} \|\!|\chi|\!\|$$

where the inequality $T \ge h$ was also used. Applying Theorem 1.1.12 again we obtain (4.2.10). □

4.2.2 Semiclassical Spectral Gaps. I

Now we are interested in the spectral gaps (of the simplest nature) appearing because some interval in $\mathbb{R}$ is free of $\mathsf{Spec}\, a(x,\xi)$ for all $(x,\xi) \in \mathsf{supp}(q)$ [1)]. To do so let us now investigate the equations

$$(hD_t - A_x)u = 0, \tag{4.2.12}$$

$$u(hD_t - {}^tA_y) = 0. \tag{4.2.12}^\dagger$$

from the elliptic point of view.

Since it is relatively simple, we do it in the general case of $\mathcal{L}(\mathbb{H}, \mathbb{H})$ valued symbols.

First Standard Set of Assumptions

Let us assume that

$$\|D_x^\beta a_\alpha(x,h) B^{-(1-\frac{|\alpha|}{m})}\| \le c \tag{4.2.13}_1$$
$$\forall x \in B(0,1) \quad \forall \beta : |\beta| \le K \quad \forall \alpha : |\alpha| \le m$$

[1)] More complicated smaller gaps of the different nature will be examined much later.

and

$$(4.2.14)_1 \quad \|a_0(x,h)w\| \ge \epsilon_0\|Bw\| - c\|w\| \qquad \forall x \in B(0,1) \quad \forall w \in \mathfrak{D}(B)$$

where

(4.2.15) B is an operator in $\mathbb{H}$ satisfying (4.2.7) [2)]

and the meaning of the subscript "1" will be clear later (see $(4.2.13)_l$, $(4.2.14)_l$ below). Moreover, let us assume that

(4.2.16) A is a self-adjoint operator in $\mathscr{L}^2(X,\mathbb{H})$ and $\mathfrak{D}(A) \supset \mathscr{C}_0^m(B(0,1),\mathfrak{D}(B))$

and

(4.2.17) $a_0(x,h)$ with $\mathfrak{D}(a_0) = \mathfrak{D}(B)$ is a self-adjoint operator in $\mathbb{H}$.

Then

(4.2.18) $a_\alpha(x,h)$ with $\mathfrak{D}(a_\alpha) = \mathfrak{D}(B)$ are symmetric operators in $\mathbb{H}$ for all $x \in B(0,1), h$ and $\alpha : |\alpha| \le m$

and

(4.2.19) $A(x,\xi,h)$ with the domain $\mathfrak{D}(B)$ is a self-adjoint operator in $\mathbb{H}$ for all $x \in B(0,1), \xi \in \mathbb{R}^d, h$

and, moreover, the conditions

$$(4.2.13)_l \quad \|D_x^\beta B^{-(1-\frac{|\alpha|}{m})(1-l)} a_\alpha(x,h) B^{-(1-\frac{|\alpha|}{m})l}\| \le c \qquad \forall x \in B(0,1) \quad \forall \beta : |\beta| \le K \quad \forall \alpha : |\alpha| \le m,$$

$$(4.2.14)_l \quad \|B^{l-1}a_0(x,h)w\| \ge \epsilon_0\|B^l w\| - c\|B^{l-1}w\| \qquad \forall x \in B(0,1) \quad \forall w \in \mathfrak{D}(B)$$

are fulfilled for all $l \in [0,1]$.

[2)] But not necessarily coinciding with B_1; in what follows $B_1 \le B$. In Remark 4.2.22 we explain why we need B_1 different from B.

In fact, (4.2.18) follows from (4.2.16), while $(4.2.13)_l$ and $(4.2.14)_l$ follow from $(4.2.13)_1$ and $(4.2.14)_1$ by means of transition to the adjoint operator, (44.2.18) and interpolation. Finally, (4.2.19) follows from $(4.2.13)_1$ with $K = 0$, $(4.2.14)_1$ and (4.2.17).

Finally, let us assume that $(4.2.20)_1$ Condition $(4.2.8)_1$ is fulfilled with $B_1 = B$.

Conditions $(4.2.13)_1$, $(4.2.14)_1$, (4.2.15)–(4.2.17) and $(4.2.20)_1$ form *the first standard set of assumptions*.

Second Standard Set of Assumptions

However, we can also deal with *the second standard set of assumptions* obtained by replacing in the previous set conditions $(4.2.13)_1$, $(4.2.14)_1$, (4.2.16) and $(4.2.20)_1$ respectively by $(4.2.13)_{\frac12}$,

$$(4.2.14)_{\pm} \qquad \pm\langle a_0(x,h)w,w\rangle \ge \epsilon_0\|B^{\frac12}w\|^2 - c\|w\|^2 \qquad \forall w \in \mathfrak{D}(B),$$

(4.2.21) $\pm A$ is a self-adjoint semibounded from below operator in $\mathscr{L}^2(X,\mathbb{H})$ and $\mathfrak{D}(A^{\frac12}) \supset \mathscr{C}_0^m(B(0,1),\mathfrak{D}(B^{\frac12}))$.

and $(4.2.20)_{\frac12}$ Condition $(4.2.8)_{\frac12}$ is fulfilled with $B_1 = B$ and preserving (4.2.15).

Obviously, then (4.2.17) and (4.2.18) hold and, moreover, (4.2.19) is replaced by $(4.2.19)_{\pm}$ $\pm A(x,\xi,h)$ is a self-adjoint semibounded from below operator in $\mathbb{H}$ with $\mathfrak{D}(A(x,\xi,h)^{\frac12}) = \mathfrak{D}(B^{\frac12})$ for all $x \in B(0,1)$, $\xi \in \mathbb{R}^d$, h; in particular, it holds for $a_0(x,h)$.

Estimates to Propagator

(i) If the first standard set of assumptions is fulfilled then multiplying the operator $(hD_t - A)$ by B^{-1} on the left or on the right we see that the parametrices G_1 and G_0 of the operators $P_1 = B^{-1}(hD_t - A)$ and $P_0 = (hD_t - A)B^{-1}$ can be constructed on $\mathsf{supp}(q) \times \mathbb{R}_t \times [\tau_1,\tau_2]$ provided

$$(4.2.22) \qquad \|(\tau - A(x,\xi,h))B^{-1}w\| \ge \epsilon_0\nu\|w\|$$

and

$$\|A^{(\alpha)}_{(\beta)}(x,\xi,h)(\tau - A(x,\xi,h))^{-1}\| \le c\rho^{-|\alpha|}\gamma^{-|\beta|} \tag{4.2.23}$$
$$\forall (x,\xi) \in \mathsf{supp}(q) \quad \forall \tau \in [\tau_1,\tau_2] \quad \forall w \in \mathbb{H} \quad \forall \alpha,\beta : |\alpha|+|\beta| \le K$$

where

$$\gamma \le 1, \quad \rho\gamma \ge h^{1-\delta}\omega^{\delta}, \quad \omega \ge 1, \quad \tau_2 - \tau_1 \ge \nu \ge \big(\frac{h}{\omega}\big)^n \tag{4.2.24}$$

with an arbitrarily small exponent $\delta > 0$ and arbitrary n (surely, K depends on n).

(ii) Similarly, if the second standard set of assumptions is fulfilled then multiplying the operator $(hD_t - A)$ by $B^{-\frac12}$ on the left and right we see that the parametrix of the operator $P_{\frac12} = B^{-\frac12}(hD_t - A)B^{-\frac12}$ can be constructed on $\mathsf{supp}(q) \times \mathbb{R}_t \times [\tau_1,\tau_2]$ provided

$$\pm\langle (A(x,\xi,h) - \tau)w, w\rangle \ge \epsilon_0\nu\|B^{\frac12}w\|^2 \qquad \forall w \in \mathfrak{D}(B) \tag{4.2.22}_{\pm}$$

and

$$\|(A(x,\xi,h) - \tau)^{-\frac12} A^{(\alpha)}_{(\beta)}(x,\xi,h)(A(x,\xi,h) - \tau)^{-\frac12}\| \le c\rho^{-|\alpha|}\gamma^{-|\beta|} \tag{4.2.23}'$$
$$\forall (x,\xi) \in \mathsf{supp}(q) \quad \forall \tau \in [\tau_1,\tau_2] \quad \forall w \in \mathbb{H} \quad \forall \alpha,\beta : |\alpha|+|\beta| \le K$$

where condition (4.2.24) is assumed to be fulfilled in this case also.

Let $q \in \mathsf{S}_{h,\rho,\gamma,K}(\mathbb{R}^d,\mathbb{H},\mathbb{H})$ and $Q = \mathsf{Op}^{\mathsf{w}}(q)$. Then in all three cases ($l = 0, 1, \frac12$) the operator norm of $Q(G_lP_l - I)$ does not exceed $C'\|\!|Q|\!\|(h\omega^{-1})^s$ where here and in what follows s is arbitrarily large and K, C depend on d, m, δ, n, s and C' also depends on c. Until further notice $l = 1$ or $l = \frac12$.

Then Theorem 1.1.12 immediately implies

Proposition 4.2.3. *(i) Let conditions* $(4.2.13)_1$, $(4.2.14)_1$, (4.2.15), (4.2.16), (4.2.17), $(4.2.20)_1$ *and* (4.2.22)–(4.2.24) *be fulfilled with either* $q = q_1$ *or* $q = q_2$ *and let us assume that*

$$|\xi| \le c\omega \qquad \forall (x,\xi) \in \mathsf{supp}(q_1) \cup \mathsf{supp}(q_2) \tag{4.2.25}$$

where $q_1, q_2 \in \mathsf{S}_{h,\rho,\gamma,K}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *and* $Q = \mathsf{Op}^{\mathsf{w}}(q)$ *and* $Q_i = \mathsf{Op}^{\mathsf{w}}(q_i)$. *Let* $\psi_1, \psi_2 \in \mathscr{C}_0^K(B(0, 1-\epsilon))$, $\epsilon > 0$ *be an arbitrarily small constant,*

$$T \geq h^{1-\delta}\omega^{\delta} \tag{4.2.26}$$

and $\chi \in \mathscr{C}_0^K([-1,1])$. *Then*

$$\|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_{1x}B^j\psi_1(x)u(t,x,y)B^k\psi_2(y)\,{}^tQ_{2y}\| \leq C'T(|\tau|+1)^{j+k}\Big(\frac{h}{\omega}\Big)^s \tag{4.2.27}_l$$

$$\forall x, y \in \mathbb{R}^d \quad \forall \tau \in [\tau_1, \tau_2] \quad \forall j, k \in [0, l]$$

with $l = 1$ *where here* $C' = C\|\!|q_1|\!\| \cdot \|\!|q_2|\!\| \cdot \|\!|\psi_1|\!\| \cdot \|\!|\psi_2|\!\| \cdot \|\!|\chi|\!\|$, *all the norms are calculated in the spaces indicated above, and* C *also depends on* ϵ.

(ii) Let conditions $(4.2.13)_{\frac12}$, $(4.2.14)_{\pm}$, (4.2.15), (4.2.21), $(4.2.20)_{\frac12}$ *and* $(4.2.22)_{\pm}$, $(4.2.23)'$, (4.2.24), (4.2.25) *be fulfilled with either* $q = q_1$ *or* $q = q_2$ *as well as the conditions of (ii) on* $Q_1, Q_2, \psi_1, \psi_2, \chi$. *Then estimate* $(4.2.27)_l$ *holds with* $l = \frac12$.

(iii) In particular, conditions (4.2.22)–(4.2.23) *are automatically fulfilled in the* γ*-neighborhood of* $(\bar{x}, \bar{\xi})$ *with* $\gamma = h^{\frac12-\delta}$ *provided* (4.2.22) *is fulfilled at this point with* $\nu = h^{\frac12-\delta}$.

On the other hand, one can use the sharp Gårding inequality (Theorem 1.1.29) and its sharpest form for scalar operators (Theorem 1.1.31) combined with the fact that $B^{-\frac12}[A,\psi]B^{-\frac12}$ is a skew-self-adjoint operator modulo $O(h^2)$) instead of the parametrix construction and easily obtain

Proposition 4.2.4. *Let conditions* $(4.2.13)_{\frac12}$, $(4.2.14)_{\pm}$, (4.2.15), $(4.2.19)_{\pm}$ (4.2.21), *be fulfilled for* $\tau = \bar{\tau}$ *and let condition* $(4.2.22)_{\pm}$ *be fulfilled in the* ϵ*-neighborhood of* $\mathsf{supp}(q_2)$ *where* $\epsilon > 0$ *is an arbitrarily small constant. Then*

(i) Estimate $(4.2.27)_l$ *holds with* $l = \frac12$ *provided* $\nu = Ch$ *with a large enough constant* C *and* $\tau \in [\tau_1, \tau_2]$ *with* $[\tau_1, \tau_2] = [\bar{\tau}, \infty)$ *respectively.*

(ii) Further, if $a(x,\xi) = \lambda(x,\xi)$ *is a scalar-valued symbol this estimate remain true provided* $\nu = Ch^{2-\delta}$ *with a large enough constant* C.

(iii) Furthermore, reducing A *to the block-diagonal matrix* $\begin{pmatrix} A_I & 0 \\ 0 & A_{II} \end{pmatrix}$ *where* $\operatorname{Spec} A_{II}(x,\xi)$ *does not intersect* $[\tau_1-\epsilon, \tau_2+\epsilon]$ *we obtain the same assertion as in (ii) provided*

$$\operatorname{Spec} a(x,\xi) \cap [\tau_1-\epsilon, \tau_2+\epsilon] = \{\lambda(x,\xi)\}. \tag{4.2.28}$$

Finally, if $B = I$ and if in the ϵ-neighborhood of $(\bar{x}, \bar{\xi})$ either

$$\operatorname{Spec} A(x,\xi,h) \cap [\bar{\tau}-\epsilon, \bar{\tau}+\nu] = \emptyset \tag{4.2.29}_+$$

or

$$\operatorname{Spec} A(x,\xi,h) \cap [\bar{\tau}-\nu, \bar{\tau}+\epsilon] = \emptyset \tag{4.2.29}_-$$

then reducing the operator to the block structure $\begin{pmatrix} A_+ & 0 \\ 0 & A_- \end{pmatrix}$ with positively defined $\pm(A_\pm - \bar{\tau})$ and applying the same arguments as above we obtain

Proposition 4.2.5. *Let condition* $(4.2.13)_1$, $(4.2.14)_1$, (4.2.15), (4.2.16) *and* (4.2.17), $(4.2.20)_1$ *be fulfilled with* $B = I$. *Furthermore, let condition* $(4.2.29)_\pm$ *be fulfilled with* $\nu = Ch$ *in the general case and with* $\nu = h^{2-\delta}$ *in the case of condition* (4.2.28).

Then for τ *residing in the indicated interval estimate* $(4.2.27)_I$ *holds with* $I = \frac{1}{2}$.

Estimates to Projector

In order to pass from estimates of $u(\cdot,\cdot,\cdot)$ to estimates of $e(\cdot,\cdot,\cdot,\cdot)$ we apply a *simplified Tauberian technique.*[3)].

Proposition 4.2.6. *(i) In the frameworks of Proposition 4.2.3(i) or (ii) the estimate*

$$\begin{aligned} \|Q_{1x}\psi_1(x) B^j e(x,y,\tau',\tau'') B^k \psi_2(y)\, {}^tQ_{2y}\| \le \\ C'\bigl(\frac{h}{\omega}\bigr)^s (|\tau'|+|\tau''|+1)^{j+k}(|\tau''-\tau'|+1) \\ \forall x,y \in \mathbb{R}^d \quad \forall \tau',\tau'' \in [\tau_1,\tau_2] \quad \forall j,k \in [0,I] \end{aligned} \tag{4.2.30}$$

holds with $I = 1$ *and* $I = \frac{1}{2}$ *respectively with the same* K *and* C *as before and with* $C' = C\|\!|q_1|\!\| \cdot \|\!|q_2|\!\| \cdot \|\!|\psi_1|\!\| \cdot \|\!|\psi_2|\!\|$.

[3)] In what follows using these words we refer to the proof of Proposition 4.2.6 below.

(ii) Moreover, the estimate holds in the frameworks of Propositions 4.2.4 and 4.2.5.

Proof. We apply Tauberian arguments. Namely, equality (4.2.4) implies the equality

$$F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\psi_1(x)B^j u(t,x,y)B^k\psi_2(y)\,{}^tQ_{2y} = T\int \hat\chi(\frac{(\tau-\lambda)T}{h})\,d_\lambda \mathsf{N}_{x,y}(\lambda) \tag{4.2.31}$$

with

$$\mathsf{N}_{x,y}(\lambda) = Q_{1x}\psi_1(x)B^j e(x,y,\lambda_1,\lambda)B^k\psi_2(y)\,{}^tQ_{2y}. \tag{4.2.32}$$

Let us pick $j=k$, $Q_2=Q_1^*$, $\psi_2=\psi_1^\dagger$ (where † means complex conjugation) and $x=y$; then we get

$$\Gamma_x F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\psi_1(x)B^j u(t,x,y)B^k\psi_2(y)\,{}^tQ_{2y} = T\int \hat\chi(\frac{(\tau-\lambda)T}{h})\,d_\lambda \mathsf{N}_{x}(\lambda) \tag{4.2.33}$$

with the $\mathcal{L}(\mathbb{H},\mathbb{H})$-valued function $\mathsf{N}_x(\lambda)=\Gamma_x\mathsf{N}_{x,y}(\lambda)$.

Note that in this special case $\mathsf{N}_x(\lambda)$ is monotone[4)] with respect to λ because in this case $\mathsf{N}_x(\lambda)$ is a restriction to the diagonal of the Schwartz kernel of the monotone operator-valued function $RE(\lambda_1,\lambda)R^*$ with $R=Q_1\psi_1B^j$ and $A\le B \implies \mathcal{K}_A(x,x)\le \mathcal{K}_B(x,x)$ where in the second case we talk about natural partial order in $\mathcal{L}(\mathbb{H},\mathbb{H})$ and that that operator, trace and Hilbert-Schmidt are monotone with respect to this partial order on the space of self-adjoint operators.

Let us pick a *Hörmander function* χ [5)].

Lemma 4.2.7. *(i) Let f be monotone increasing function, χ Hörmander function and*

$$\int \hat\chi(\frac{(\tau-\lambda)}{\hbar})\,d_\lambda f(\lambda)\le g(\tau) \tag{4.2.34}$$

[4)] Recall that Hermitian operators on Hilbert space are partially ordered.

[5)] That means that $\chi\in \mathscr{C}_0^\infty([-1,1])$ is even and satisfies $\chi(0)=1$, $\hat\chi(\tau)>0\ \ \forall\tau\in\mathbb{R}$ where the hat means Fourier transform. Such a function exists (see, e.g., Shubin [3]).

Then

$$|f(\tau'')-f(\tau')|\le g^*(\tau,\tau',\tau'') := C_0\hbar^{-1}\int_{\tau'}^{\tau''} g(\tau)\,d\tau + g(\tau) \qquad \forall \tau',\tau'',\tau : \tau'-\hbar\le\tau\le\tau'+\hbar, \tau'\le\tau'' \tag{4.2.35}$$

where C_0 depends only on the choice of Hörmander function.

(ii) Above assertion remains true for symmetric operator-valued functions as well.

Proof. Note first that $g(\tau)\ge 0$. Observe that the right-hand expression of (4.2.34) will not increase if we take the integral only on the interval $[\tau-\hbar,\tau+\hbar]\ni\lambda$ and replace after this $\hat\chi(\frac{(\tau-\lambda)}{\hbar})$ by $\epsilon_0=\min_{\tau\in[-1,1]}\hat\chi(\tau)>0$; then we obtain in the right-hand expression $\epsilon_0 f(\tau-\hbar,\tau+\hbar)$. Therefore

$$|f(\tau'')-f(\tau')|\le C_0 g(\tau) \qquad \forall \tau'',\tau' : |\tau'-\tau|\le\hbar, |\tau''-\tau|\le\hbar. \tag{4.2.36}$$

Then (4.2.35) is proven as $|\tau''-\tau'|\le 2\hbar$ and moreover, as $|\tau''-\tau'|=2\hbar$ we can skip the second term in the right-hand expression. This immediately yields (4.2.35) without the second term in the right-hand expression as $|\tau''-\tau'|\ge 2\hbar$. Combining with (4.2.36) we arrive to (4.2.35) without this assumption. □

This Lemma 4.2.7 with $\hbar = hT^{-1}$ and $f(\tau)=\mathsf{N}_x(\tau)$ combined with estimate $(4.2.27)_l$ yield that

$$\mathsf{N}_x(\tau-\frac{h}{T},\tau+\frac{h}{T})\le C'\big(\frac{h}{\omega}\big)^s(|\tau|+1)^{2j}I_{\mathbb{H}} \qquad \forall \tau\in[\tau_1,\tau_2]$$

where $I_{\mathbb{H}}$ is the identity operator. This inequality generalizes immediately to

$$\mathsf{N}_x(\tau',\tau'')\le C'\big(\frac{h}{\omega}\big)^s\big(\frac{|\tau''-\tau'|T}{h}+1\big)\big(|\tau'|+|\tau''|+1\big)^{2j}I_{\mathbb{H}}. \tag{4.2.37}$$

where here and in what follows $\mathsf{N}_*(\tau',\tau'')=\mathsf{N}_*(\tau'')-\mathsf{N}_*(\tau')$.

Taking an appropriate constant T we obtain (4.2.30) in the special case $Q_2=Q_1^*$, $\psi_2=\psi_1^\dagger$ and $k=j$ provided the conditions of the proposition are fulfilled with $q=q_1$.

But in this case the left-hand expression in (4.2.30) equals RR^* where for fixed x we define operator R from $\mathscr{L}^2(X,\mathbb{H})$ to $\mathbb{H}$ by

$$Rv = \big(Q_1\psi_1 B^j E(\tau',\tau'')v\big)(x) \tag{4.2.38}$$

and hence R^* acts in the opposite direction. Therefore the already proven version of (4.2.30) implies that

$$\|R\| = \|R^*\| \le C'\big(\frac{h}{\omega}\big)^s(|\tau'|+|\tau''|+1)^j(|\tau''-\tau'|+1)^{\frac12}. \tag{4.2.39}$$

On the other hand, Proposition 4.2.2 and the same arguments as before yield the estimate

$$\|S\| = \|S^*\| \le C'\big(\frac{h}{\omega}\big)^{-\frac{d}{2}}(|\tau'|+|\tau''|+1)^k(|\tau''-\tau'|+1)^{\frac12} \tag{4.2.40}$$

where S is defined in the same way as R was defined but with Q_1,ψ_1,x replaced by Q_2,ψ_2,y. Since the left-hand expression in (4.2.30) equals the norm of RS^* we obtain (4.2.30) in complete form; recall that exponent s is chosen arbitrarily. □

Let us consider explicitly the case in which the second standard set of assumptions holds. Then $(4.2.14)_\pm$ implies that if

$$\pm\tau \le -C_0\langle\xi\rangle^m \tag{4.2.41}_\pm$$

with $C_0 = C_0(d,m,c)$ [6] then conditions $(4.2.22)_\pm$ and $(4.2.23)'$ are fulfilled with $\nu=1$, $\rho = |\tau|^{\frac1m}$, $\gamma=1$ and moreover

$$\|(\tau - A(x,\xi,h))^{-1}\| \le C|\tau|^{-1}. \tag{4.2.42}$$

In fact, $(4.2.13)_{\frac12}$ implies that

$$|\langle (A(x,\xi,h)-a_0(x,h))w,w\rangle| \le C_0|\xi|^m\|w\|^2 + C_0|\xi|\cdot\|B^{\frac{m-1}{2m}}w\|^2$$

and then $(4.2.14)_\pm$ and $(4.2.41)_\pm$ yield that

$$\pm\langle (A(x,\xi,h)-\tau)w,w\rangle \ge C_0^{-1}(|\tau|\cdot\|w\|^2 + \|B^{\frac12}w\|^2)$$

[6] We use the notation C_0 instead of C in the case when in its definition c can be calculated for K replaced by $K_0 = 1,2,3$ where the definition of K_0 in every case we leave to the reader.

and this inequality yields $(4.2.22)_{\pm}$, (4.2.42) and $(4.2.23)'$.

Therefore if $q_i \in \mathsf{S}_{h,\rho,\gamma,K}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$, $Q_i = \mathsf{Op}^{\mathsf{w}}(q_i)$ and (4.2.24), (4.2.25) hold and if $\pm\tau \le -C_0\omega^m$, then (4.2.30) holds for $\tau' = \tau$, $\tau'' = 2\tau$; hence the estimate

$$\|Q_{1x}\psi_1(x)B^j e(x,y,\tau,2\tau)B^k\psi_2(y)\,{}^tQ_{2y}\| \le C' h^s|\tau|^{-s} \quad \forall x,y\in\mathbb{R}^d \quad \forall j,k\in[0,l] \tag{4.2.43}$$

holds with $Q_1 = \zeta(\bar\omega^{-1}hD)$ where $\bar\omega = C_0^{-1}|\tau|^{\frac{1}{m}}$, $\zeta \in \mathscr{C}_0^K(B(0,1))$.

It easily follows that this estimate holds for $Q_1 = \mathsf{Op}^{\mathsf{w}}(q_1)$ provided $q_1 \in \mathsf{S}_{h,\rho,\gamma,K}$ is supported in $\{|\xi| \le C_0^{-1}|\tau|^{\frac{1}{m}}\}$, $\pm\tau \le -C_0$ and condition (4.2.24) is fulfilled; here $l = \frac{1}{2}$.

Moreover, if conditions $(4.2.13)_1$, $(4.2.14)_1$ and $(4.2.20)_1$ are fulfilled then one can take $l = 1$. Replacing τ by $2^p\tau$ and summing with respect to $p = 0, 1, 2, \ldots$ we obtain

Proposition 4.2.8. *Let conditions* $(4.2.13)_{\frac{1}{2}}$, $(4.2.14)_{\pm}$, (4.2.15), (4.2.21) *and* $(4.2.20)_{\frac{1}{2}}$ *be fulfilled and let* $q_i \in \mathsf{S}_{h,\rho,1,K}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ *satisfy* (4.2.25) *and* ρ *and* $\gamma = 1$ *satisfy* (4.2.24). *Let* $\psi_{1,2}$ *be as in Proposition 4.2.3. Then*

$$\|Q_{1x}\psi_1(x)B^j e(x,y,\mp\infty,\tau)B^k\psi_2(y)\,{}^tQ_{2y}\| \le C' h^s|\tau|^{-s} \quad \forall x,y\in\mathbb{R}^d \quad \forall \tau : \pm\tau \le -C_0\omega^m \quad \forall j,k\in[0,l] \tag{4.2.44}$$

with $l = \frac{1}{2}$*; moreover, if conditions* $(4.2.13)_1$, $(4.2.14)_1$ *and* $(4.2.20)_1$ *are fulfilled then one can take* $l = 1$.

Estimates without Cut-offs

The following two assertions show how one can set $x = y$ without multiplication by cutting operators.

Proposition 4.2.9. *Let conditions* $(4.2.13)_1$ *and* $(4.2.14)_1$ *be fulfilled and let*

$$|\xi|^m\|w\| + \|Bw\| \le c(\|A(x,\xi,h)w\| + \|w\|) \quad \forall x\in B(0,1) \quad \forall \xi\in\mathbb{R}^d \quad \forall w\in\mathfrak{D}(B). \tag{4.2.45}$$

(i) Then $(4.2.20)_1$ *holds.*

Further let us assume that $q_1, q_2 \in \tilde{\mathsf{S}}^0_{h,\rho,\gamma,K}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$, $Q_i = \mathsf{Op}^{\mathsf{w}}(q_i)$, (2.1.25) *holds and* ψ_1, ψ_2 *are as in Proposition 4.2.3. Then*

(ii) If either q_1 *or* q_2 *is supported in* $\{|\xi| \ge \omega\}$ *with* $\omega \ge C_0$ *then*

$$\|D_x^\alpha D_y^\beta Q_{1x}\psi_1(x)B^j e(x,y,\tau',\tau'')B^k\psi_2(y)\,{}^tQ_{2y}\| \le C'\Big(\frac{h}{\omega}\Big)^s \tag{4.2.46}$$
$$\forall x, y \in \mathbb{R}^d\ \forall \tau', \tau'' : |\tau'| \le C_0^{-1}\omega,\ |\tau''| \le C_0^{-1}\omega$$
$$\forall j, k \in [0, l]\ \forall \alpha, \beta : |\alpha| + |\beta| \le r$$

where K *and* C' *now also depend on* r, r *arbitrarily large, and the* $\tilde{\mathsf{S}}$*-norms of* $q_{1,2}$ *are now used in the definition of* C'*, and* $l = 1$ *here.*

(iii) In the general case

$$\|D_x^\alpha D_y^\beta Q_{1x}\psi_1(x)B^j e(x,y,\tau',\tau'')B^k\psi_2(y)\,{}^tQ_{2y}\| \le \tag{4.2.47}$$
$$C' h^{-d-|\alpha|-|\beta|}(|\tau'| + |\tau''| + 1)^{\frac{1}{m}(d+|\alpha|+|\beta|)+j+k}$$
$$\forall x, y \in \mathbb{R}^d \quad \forall \tau', \tau'' \quad \forall j, k \in [0, l] \quad \forall \alpha, \beta : |\alpha| + |\beta| \le r.$$

Proof. (i) We will prove our claim that $(4.2.20)_1$ is fulfilled later (see Subsection 4.2.3).

(ii) Proposition 4.2.6 implies estimate (4.2.46) under the additional assumption that q_1 and q_2 are supported in $\{|\xi| \le 4\omega\}$ and either q_1 or q_2 is supported in $\{|\xi| \ge \omega\}$ where as usual $Q_j = \mathsf{Op}(q_j)$.

Replacing ω by 2ω and summing over a partition of unity by means of pseudodifferential operators with symbols supported in $\{2^p\omega \le |\xi| \le 2^{p+2}\omega\}$, $p = 0, 1, 2, \dots$ we obtain (ii); more precisely, we can take two partitions (one to the left of Q_1 and another to the right of Q_2, and p means the largest index).

(iii) Assertion (iii) follows from (i) and Proposition 4.2.3. □

Proposition 4.2.10. *Let conditions* $(4.2.13)_{\frac12}$, $(4.2.14)_\pm$, (4.2.15), (4.2.21) *be fulfilled and let*

$$\pm\langle A(x,\xi,h)w, w\rangle \ge \epsilon_0(|\xi|^m\|w\|^2 + \|B^{\frac12}w\|^2) - c\|w\|^2 \tag{4.2.48}_\pm$$
$$\forall x \in B(0,1) \quad \forall \xi \in \mathbb{R}^d \quad \forall w \in \mathfrak{D}(B).$$

(i) Then $(4.2.20)_{\frac12}$ *holds.*

Further, let us assume that $q_1, q_2 \in \tilde{\mathsf{S}}^0_{h,\rho,\gamma,K}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$, $Q_i = \mathsf{Op}^{\mathsf{w}}(q_i)$, (4.2.24) *holds and* $\psi_{1,2}$ *are as in Proposition 4.2.3. Then*

(ii) The estimate

$$(4.2.49)_{\pm} \quad \|D_x^\alpha D_y^\beta Q_{1x}\psi_1(x)B^j e(x,y,\mp\infty,\tau)B^k\psi_2(y)\,{}^tQ_{2y}\| \le C' h^s|\tau|^{-s} \qquad \forall x,y\in\mathbb{R}^d \quad \forall \pm\tau \le -C_0 \quad \forall j,k\in[0,l]$$

holds with $l = \frac12$*; moreover, if either the symbol of* Q_1 *or the symbol of* Q_2 *is supported in* $\{|\xi| \ge \omega\}$ *then this estimate remains true with the additional factor* ω^{-s} *in the right-hand expression.*

(iii) In the general case the following estimate holds:

$$(4.2.50)_{\pm} \quad \|D_x^\alpha D_y^\beta Q_{1x}\psi_1(x)B^j e(x,y,\mp\infty,\tau)B^k\psi_2(y)\,{}^tQ_{2y}\| \le C' h^{-d-|\alpha|-|\beta|}(|\tau|+1)^{\frac1m(d+|\alpha|+|\beta|)+j+k} \qquad \forall x,y\in\mathbb{R}^d \quad \forall j,k\in[0,l]$$

with $l = \frac12$.

(iv) Moreover, if conditions $(4.2.13)_1$, $(4.2.14)_1$ *are fulfilled then all these estimates hold with* $l = 1$.

Proof. The proof is similar to that of Proposition 4.2.9 but also uses Proposition 4.2.8. □

Semiclassical Spectral Gaps under Reduced Smoothness Assumptions

The following assertions follow from Propositions 4.2.6–4.2.10 under smoothness conditions which are too restrictive; here we give an independent proof.

Proposition 4.2.11. *Let conditions* $(4.2.13)_1$, $(4.2.14)_1$, (4.2.15), (4.2.16) *and* (4.2.17) *be fulfilled with* $K = \mathsf{max}(1+\frac{d}{2}, m) + r$. *Then*

(i) If condition (4.2.45) *is fulfilled then*

$$\|D_x^\alpha D_y^\beta B^j e(x,y,\tau',\tau'')B^k\| \le C' h^{-d-|\alpha|-|\beta|}(|\tau'|+|\tau''|+1)^{\frac{1}{m}(d+|\alpha|+|\beta|)+j+k} \tag{4.2.51}$$
$$\forall x,y \in B(0,1-\epsilon) \quad \forall \tau',\tau'' \quad \forall \alpha,\beta : |\alpha| \le r, |\beta| \le r \quad \forall j,k \in [0,l]$$

with $l = 1$ *where here and below* C' *equals* $C(d,m,r,c,\epsilon)$ *multiplied by norm of all auxiliary symbols and functions.*

(ii) If the following condition

$$\|(A(x,\xi,h)-\tau)w\| \ge \epsilon((\omega+|\xi|^m)\|w\| + \|Bw\|) \tag{4.2.52}$$
$$\forall x \in B(0,1) \quad \forall \xi \in \mathbb{R}^d \quad \forall \tau \in [\tau_1,\tau_2] \quad \forall w \in \mathfrak{D}(B)$$

is fulfilled with $\omega \ge 1$ *then*

$$\|D_x^\alpha D_y^\beta B^j e(x,y,\tau',\tau'')B^k\| \le C'\bigl(\frac{h}{\omega}\bigr)^s(|\tau'|+|\tau''|+1)^{j+k} \tag{4.2.53}$$
$$\forall x,y \in B(0,1-\epsilon) \quad \forall \tau',\tau'' \in [\tau_1,\tau_2] \quad \forall \alpha,\beta : |\alpha| \le r, |\beta| \le r \quad \forall j,k \in [0,l]$$

with $l = 1$ *where* s *is arbitrary and* C *depending also on* s.

Proposition 4.2.12. *Let conditions* $(4.2.13)_{\frac12}$, $(4.2.14)_\pm$, (4.2.15), (4.2.21) *and* $(4.2.48)_\pm$ *be fulfilled with* $K = \max(1+\frac{d}{2}, m) + r$. *Then*

$$\|D_x^\alpha D_y^\beta B^j e(x,y,\mp\infty,\tau)B^k\| \le \begin{cases} C' h^s(|\tau|+1)^{-s} & \forall \tau \le -C_0 \\ C' h^{-d-|\alpha|-|\beta|}(|\tau|+1)^{\frac{1}{m}(d+|\alpha|+|\beta|)+j+k} & \forall \tau \end{cases} \tag{4.2.54}$$
$$\forall x,y \in B(0,1-\epsilon) \quad \forall \alpha,\beta : |\alpha| \le r, |\beta| \le r \quad \forall j,k \in [0,l]$$

with $l = \frac12$.

Moreover, if conditions $(4.2.13)_1$ *and* $(4.2.14)_1$ *are fulfilled then this estimate holds with* $l = 1$.

Proof of propositions 4.2.11 and 4.2.12. Let us note that if (4.2.45) is fulfilled, $v \in \mathscr{C}_0^m(B(0,1), \mathfrak{D}(B))$ and

$$Av = \sum_{|\beta|\le m-l} (hD)^\beta w_\beta$$

with $k = 0, \dots, m$ then

$$\sum_{|\alpha|\le k} \|(hD)^\alpha B^{\frac{1}{m}(l-|\alpha|)} v\| \le \sum_{|\beta|\le m-k} C\|B^{\frac{1}{m}(-m+k+|\beta|)} w_\beta\| + C\|v\|. \tag{4.2.55}$$

In fact, one can easily prove this estimate in the constant coefficient case by means of the Fourier transform. In the general case let ψ_n be a partition of unity in a neighborhood of $B(0,1)$ with small enough supports and let A_n be obtained from A by freezing coefficients at the point $x^n \in B(0,1) \cap \mathsf{supp}(\psi_n)$. Then

$$A_n \psi_n v = \sum_{|\beta|\le m-k} \psi_n (hD)^\beta w_\beta + (A_n - A)\psi_n v + [A, \psi_n] v;$$

representing the last two terms in the form

$$\sum_{|\alpha|\le k, |\beta|\le m-k} (hD)^\beta b_{\beta\alpha} (hD)^\alpha v$$

with small coefficients $b_{\beta\alpha}$ for $|\alpha| = k$, $|\beta| = m-k$ and applying estimate (4.2.55) to A_n we obtain that $M_1 \le \nu M_1 + C_\nu M_2$ where M_1 and M_2 are the left-hand and right-hand expressions respectively in (4.2.55) and one can choose $\nu > 0$ arbitrarily small (before choosing the partition of unity). Hence (4.2.55) holds in the general case.

Similarly one can prove that for $k = m+1, \dots, K$ the estimate

$$\sum_{l-m\le|\alpha|\le k} \|(hD)^\alpha B^{\frac{1}{m}(k-|\alpha|)} v\| \le C \sum_{|\beta|\le m-k} C\|(hD)^\beta Av\| + C\|v\| \tag{4.2.56}$$

holds for $v \in \mathscr{C}_0^m(B(0,1), \mathfrak{D}(B))$; one should use in this deduction estimate (4.2.55).

Repeatedly substituting ψv for v where $\psi \in \mathscr{C}_0^\infty(B(0, 1-\epsilon))$ in (4.2.55) and (4.2.56) we obtain that both these estimates remain true for $v \in \mathscr{C}^p(B(0,1), \mathfrak{D}(B))$ with $p = \max(m,k)$ if in the left-hand and right-hand expressions we take the norms in the balls $B(0, 1-\epsilon)$ and $B(0, 1-\frac{\epsilon}{2})$ respectively; here C also depends on $\epsilon > 0$.

Further, iterating if necessary we obtain that for $|\alpha| \le k, j \in [0,1]$ and $\frac{1}{m}|\alpha| + j \in \mathbb{Z}$

$$\|(hD)^\alpha B^j v\|_{B(0,1-\epsilon)} \le C(\|A^{\frac{1}{m}|\alpha|+j} v\| + \|v\|).$$

Substituting $E(\tau', \tau'')v$ for v we conclude that

(4.2.57) The operator norm of the operator $(hD)^\alpha B^j E(\tau', \tau'') : \mathscr{L}^2(X, \mathbb{H}) \to \mathscr{L}^2(B(0, 1-\epsilon), \mathbb{H})$ does not exceed $C(|\tau'| + |\tau''| + 1)^{\frac{1}{m}|\alpha|+j}$;

interpolation and estimate (4.2.56) again yield that this estimate remains true without restriction $\frac{1}{m}|\alpha| + j \in \mathbb{Z}$.

Then the embedding inequalities imply that

(4.2.58) The operator norm of the operator

$$R : \mathscr{L}^2(X, \mathbb{H}) \ni v \to ((hD)^\alpha B^j E(\tau', \tau'')v)(x) \in \mathbb{H}$$

with $x \in B(0, 1-\epsilon)$ does not exceed $Ch^{-\frac{d}{2}-|\alpha|}(|\tau'| + |\tau''| + 1)^{\frac{d}{2m}+\frac{1}{m}|\alpha|+j}$.

Obviously, $D_x^\alpha(-D_y^\beta)B^j e(x, y, \tau', \tau'')B^i = RS^*$ where S is defined in the same way as R but with β, i, y instead of α, j, x. Therefore we obtain (4.2.51).

In a similar way one can prove two estimates below:

$$\|D_x^\alpha D_y^\beta F_{t\to h^{-1}\tau}\chi_T(t)B^j U(t)B^i\| \le C' T h^{-|\alpha|-|\beta|}(|\tau|+1)^{\frac{1}{m}(|\alpha|+|\beta|)+j+i} \quad \forall \tau \quad \forall \alpha, \beta : |\alpha| \le k, |\beta| \le k \quad \forall j, i \in [0,1] \tag{4.2.59}$$

where $T \ge h^{-1}$, $\chi \in \mathscr{C}_0^\infty([-1,1])$ is a fixed function, $\|\cdot\|$ means the operator $\mathcal{L}(\mathscr{L}^2(B(0,1-\epsilon), \mathbb{H}), \mathscr{L}^2(B(0,1-\epsilon), \mathbb{H}))$-norm and the operator is applied only to functions supported in $B(0, 1-\epsilon)$; and also

$$\|D_x^\alpha D_y^\beta F_{t\to h^{-1}\tau}\chi_T(t)B^j u(t,x,y)B^i\| \le C' T h^{-d-|\alpha|-|\beta|}(|\tau|+1)^{\frac{1}{m}(d+|\alpha|+|\beta|)+j+i} \quad \forall x, y \in B(0,1-\epsilon) \quad \forall \tau \quad \forall \alpha, \beta : |\alpha| \le k, |\beta| \le k \quad \forall j, i \in [0,1] \tag{4.2.60}$$

where $\|\cdot\|$ means the $\mathcal{L}(\mathbb{H}, \mathbb{H})$-norm.

In this deduction we use (4.2.56), (4.2.12), (4.2.12)† and (4.2.59) with $\alpha = \beta = 0$, $j = i = 0$ which follows from the fact that $U(t)$ is an unitary operator.

On the other hand, if condition (4.2.52) is fulfilled then the arguments used to deduce (4.2.55) and (4.2.56) yield that these estimates remain true if in them as well as in their conditions A is replaced by $A - \tau$ with $\tau \in [\tau_1, \tau_2]$ and the last term in their right-hand expressions (namely $C\|v\|$) is replaced by $'(\frac{h}{\omega})^s\|v\|$.

These modified estimates, (4.2.12), (4.2.12)† and (4.2.59) imply that for $T \ge h^{1-\delta}\omega^{-\delta}$, $\tau \in [\tau_1, \tau_2]$ the left-hand expressions in (4.2.59) and (4.2.60) do not exceed

$$C'\big(\frac{h}{\omega}\big)^s\big(|\tau|+1\big)^{\frac{1}{m}(|\alpha|+|\beta|)+j+k-1} \quad \text{and} \quad C'\big(\frac{h}{\omega}\big)^s\big(|\tau|+1\big)^{\frac{1}{m}(d+|\alpha|+|\beta|)+j+k-1}$$

respectively.

Then the Tauberian arguments used in the proof of Proposition 4.2.6 yield estimate (4.2.53). So Proposition 4.2.11 is proven.

Let us assume that $(4.2.48)_\pm$ is fulfilled. Then the arguments used to derive estimates (4.2.55) and (4.2.56) imply that

(i) If

$$Av = \sum_{|\beta|\le m-k} (hD)^\beta w_\beta,$$

$k = 0, 1, \dots, \frac{m}{2}$ (obviously m is even in this case) then

$$\sum_{|\alpha|\le k} \|(hD)^\alpha B^{\frac{1}{m}(k-|\alpha|)}v\| \le \sum_{|\beta|\le m-k} C\|B^{-\frac{1}{2}+\frac{1}{m}(-\frac{m}{2}+k+|\beta|)_+}w_\beta\| + C\|B^{\frac{1}{2}}v\| \tag{4.2.61}$$

for $v \in \mathscr{C}_0^m(B(0,1), \mathfrak{D}(B^{1/2}))$.

(ii) For $k \ge \frac{m}{2}$

$$\sum_{\frac{m}{2}\le|\alpha|\le k} \|(hD)^\alpha B^{\frac{1}{m}(k-|\alpha|)}v\| \le \sum_{|\beta|\le k-\frac{m}{2}-i} C\|B^{\frac{i}{m}-\frac{1}{2}}Av\| + C\|B^{\frac{1}{2}}v\| \tag{4.2.62}$$

where $v \in \mathscr{C}_0^p(B(0,1), \mathfrak{D}(B^{\frac{1}{2}}))$, $i = 0, 1, \dots, \min(\frac{m}{2}, k - \frac{m}{2})$, $p = \max(m, k)$ is arbitrary.

(iii) Moreover, these estimates remain true if we replace A by $A-\tau$ with $\pm\tau \le -C_0$, add

$$|\tau| \sum_{|\alpha|\le k-\frac{m}{2}-\frac{i}{2}} \|(hD)^{\alpha} B^{-\frac{1}{2}+\frac{i}{m}} v\|$$

to the left-hand expression and in the right-hand expression replace $C\|B^{\frac{1}{2}}v\|$ by $Ch^{s}|\tau|^{-s}\|B^{\frac{1}{2}}v\|$.

(iv) Finally, all these estimates remain true for $v \in \mathscr{C}^{p}(B(0,1), \mathfrak{D}(B^{\frac{1}{2}}))$ if in their left-hand and right-hand expressions we take norms on $B(0,1-\epsilon)$ and $B(0,1-\frac{\epsilon}{2})$ respectively.

Then the arguments used in the proof of Proposition 4.2.11 yield Proposition 4.2.12. □

4.2.3 Main Tauberian Estimate

Now we are going to discuss the main scheme used to derive spectral asymptotics. We will use the series of different abstract statements. Because of the fundamental importance of these statements we will discuss them in all details.

Main Tauberian Formula

Lemma 4.2.13. *Assume that f satisfies* (4.2.35). *Let $\chi \in \mathscr{C}_0^{\infty}([-1,1])$ and $\chi(0)=1$. Then*

$$|\big(f(\tau'')-f(\tau')-f^{\mathsf{T}}(\tau'',\tau')\big)| \le C_1\mathcal{R}(\tau')+C_1\mathcal{R}(\tau'') \tag{4.2.63}$$

with the Tauberian expression

$$f^{\mathsf{T}}(\tau'',\tau') := \hbar^{-1}\int_{\tau'}^{\tau''}\Big(\int \hat{\chi}\Big(\frac{(\tau-\lambda)}{\hbar}\Big)\,d_{\lambda}f(\lambda)\Big)\,d\tau, \tag{4.2.64}$$

$$\mathcal{R}(\tau) := g(\tau)+\int g(\tau+\hbar z)(1+|z|^2)^{-m}\,dz \tag{4.2.65}$$

and $C_0^{-1}C_1$ depending only on χ and arbitrarily large m.

Proof. Let us rewrite the left-hand expression in (4.2.34) as

$$\frac{d}{d\tau}\int \hat{\chi}\Big(\frac{(\tau-\lambda)}{\hbar}\Big)f(\lambda)\,d\lambda.$$

Integrating from τ' to τ'' we get that

$$f^{\mathsf{T}}(\tau'',\tau') = f^{\mathsf{T}}(\tau'') - f^{\mathsf{T}}(\tau') \tag{4.2.66}$$

where

$$f^{\mathsf{T}}(\tau) \coloneqq \hbar^{-1}\int \hat{\chi}\Big(\frac{(\tau-\lambda)}{\hbar}\Big)f(\lambda)\,d\lambda. \tag{4.2.67}$$

Then $\chi(0)=1$ implies that

$$f^{\mathsf{T}}(\tau) - f(\tau) = \hbar^{-1}\int \hat{\chi}\Big(\frac{(\tau-\lambda)}{\hbar}\Big)\big(f(\lambda)-f(\tau)\big)\,d\lambda;$$

then inequalities $|\hat{\chi}(\eta)|\le C(|\eta|+1)^{-2m-1}$ and (4.2.35) imply that

$$|f^{\mathsf{T}}(\tau)-f(\tau)| \le C_0\hbar^{-1}\int (|\tau-\lambda|\hbar^{-1}+1)^{-2m-1}\Big(\hbar^{-1}\Big|\int_\tau^\lambda g(\tau')\,d\tau'\Big| + g(\tau)\Big)\,d\lambda.$$

Opening parenthesis, changing order of integration in the double integral and calculating the simple integrals we arrive to

$$C_1\hbar^{-1}\int g(\tau')\,d\tau'(|\tau'-\lambda|\hbar^{-1}+1)^{-2m} + C_1 g(\tau);$$

this expression is obviously equal to $C_1\mathcal{R}(\tau)$. This estimate combined with (4.2.66) implies (4.2.63)–(4.2.65). □

We will call (4.2.63)–(4.2.65) *main Tauberian formula*. (with an error estimate).

Asymptotics with Mollification

We consider now mollifications with kernel $L^{-1}\varphi_L(\tau)$ where $\varphi\in \mathscr{C}_0^\infty([-1,1])$ and

$$\varepsilon \coloneqq \hbar/L \le 1. \tag{4.2.68}$$

Let us consider

$$\int L^{-1}\varphi_L(\tau-\bar\tau)\big(f(\tau)-f^{\mathsf T}(\tau)\big)\,d\tau=\int L^{-1}\tilde\varphi_L(\tau-\bar\tau)f(\tau)\,d\tau \tag{4.2.69}$$

with $\tilde\varphi := \varphi * \varepsilon^{-1}\hat\chi_\varepsilon - \varphi$. Assuming that

$$\chi(0)=1,\qquad \chi^{(k)}(0)=0\quad \forall k=1,2,... \tag{4.2.70}$$

we note that $\varepsilon^{-n}\tilde\varphi$ is an uniformly $\mathscr{C}_0^\infty$ function for all n and then repeating arguments of the proof of Lemma 4.2.13 one can prove easily

Lemma 4.2.14. *Let f satisfy* (4.2.35). *Let* (4.2.68), (4.2.70) *be fulfilled. Let $\varphi\in\mathscr{C}_0^\infty([-1,1])$.*

Then

$$\Big|\int \varphi_L(\tau-\bar\tau)\big(f(\tau)-f^{\mathsf T}(\tau)\big)\,d\tau\Big|\le C\mathcal{R}(\bar\tau)\big(\frac{\hbar}{L}\big)^s \tag{4.2.71}$$

where s is arbitrarily large and $C_0^{-1}C$ depends on χ,φ,s, and m.

Moreover

$$\Big|\int \varphi_L(\tau-\bar\tau)\big(f(\tau,\bar\tau)-f^{\mathsf T}(\tau,\bar\tau)\big)\,d\tau\Big|\le C\mathcal{R}(\bar\tau). \tag{4.2.72}$$

Formula (4.2.71) is a *mollified Tauberian formula*, and (4.2.72) is an *alternative Tauberian formula*. The advantage of the latter is that it invokes only one energy level.

Asymptotics with Averaging

Let us consider *averaging functions* with singularities[7]. Let us assume that

(4.2.73) $\vartheta\in\mathscr{C}(\mathbb{R}^+)$ is a positive monotone function on $\mathbb{R}^+$, such that

$$\vartheta(2z)\le c\vartheta(z)\qquad \forall z\in(0,1) \tag{4.2.74}$$

and $\varphi\in\mathscr{C}^\infty(\dot{\mathbb{R}}^+)$, compactly supported in $[0,\infty]$ such that its derivatives $\varphi^{(m)}$ satisfy

$$|\varphi^{(m)}(z)|\le c_m\vartheta(z)z^{-m}\qquad \forall z>0\ \forall m\ge 0. \tag{4.2.75}$$

[7] The term "mollifying" is reserved for smooth functions.

Lemma 4.2.15. *Let f satisfy* (4.2.35) *and let* (4.2.68) *and* (4.2.70) *be fulfilled. Further, assume that φ satisfies* (4.2.73)–(4.2.75).

Then

$$|\int \varphi_L(\tau-\bar\tau)\bigl(f(\tau)-f^{\mathsf T}(\tau)\bigr)\,d\tau| \le C\mathcal{R}(\bar\tau)\vartheta\bigl(\frac{\hbar}{L}\bigr) \tag{4.2.76}$$

where $C_0^{-1}C$ depends on χ,φ,ϑ, and m.

Moreover as $\varphi_i,\vartheta_i,L_i$ satisfy (4.2.73)–(4.2.75), (4.2.68) *then*

$$|\iint \varphi_{1L_1}(\tau-\bar\tau_1)\varphi_{2L_2}(\tau'-\bar\tau_2)\bigl(f(\tau,\tau')-f^{\mathsf T}(\tau,\tau')\bigr)\,d\tau d\tau'| \le C\sum_{i=1,2}\mathcal{R}(\bar\tau_i)\vartheta_i\bigl(\frac{\hbar}{L_i}\bigr) \tag{4.2.77}$$

Proof. It is sufficient to prove only estimate (4.2.76) since (4.2.77) follows from it due to the same arguments as before. Without any loss of the generality one can assume that as $L=1$; otherwise we can make a rescaling.

One can find $\psi\in\mathscr{C}_0^\infty([\frac13,1])$ such that $\sum_{n\ge1}\psi(2^{-n}z)=1$ on $(0,1)$. Then

$$\varphi(z)=\sum_{n\ge0,L_n\ge h}\vartheta(L_n)\phi_n(zL_n^{-1})+\vartheta(h)\bar\phi(z/h)$$

where $\phi_n\in\mathscr{C}_0^\infty([\frac13,1])$ uniformly and $L_n=2^{-n}$ and $\bar\phi\in\mathscr{L}^\infty$ is supported in $[0,2]$.

Then according to estimates with mollification contribution of each term $\vartheta(L_n)\phi_n(zL_n^{-1})$ to (4.2.76) does not exceed $C\mathcal{R}(\bar\tau)(hL_n^{-1})^m\vartheta(L_n)$ with arbitrarily large m.

One can see easily that $L^{-m/2}\vartheta(L)\le ch^{-m/2}\vartheta(h)$ for large enough m and therefore the total contributions of these terms does not exceed the same expression as $L_n=h$ which is exactly the right-hand expression of (4.2.76). On the other hand, estimate without mollification implies that contribution of the last term $\vartheta(h)\bar\phi(zh^{-1})$ does not exceed the same result. □

Remark 4.2.16. (i) The most prominent application are asymptotics of Riesz means with $\varphi(z)=\vartheta(z)=z_+^s/\Gamma(s+1)$.

(ii) Obviously Lemma 4.2.15 extends to functions

$$\varphi(z) = \int \phi(z - z'; z')\, df(z'), \qquad \text{with} \quad \int |d\mu(z')| \le c \tag{4.2.78}$$

where $\phi(z; z')$ satisfy (4.2.75) with respect to z uniformly with respect to z' and μ is a function of the bounded variation.

One may try to find an alternative description of functions of this type.

Operator Valued Functions

Remark 4.2.17. Obviously all these results hold when f and g are functions with the values in the space of symmetric operators. In this case each inequality of the type $|F| \le G$ is replaced by $F' \prec G$ which is a short notation for

$$|(Fw, w)| \le (Gw, w) \qquad \forall w \in \mathfrak{D}(G)$$

where G is self-adjoint operator. We say that G *dominates* F.

4.2.4 Applications

Scheme of Things

Let us consider some applications to the spectral asymptotics. From now again $\chi \in \mathscr{C}_0^\infty([-1, -\frac{1}{2}] \cup [\frac{1}{2}, 1])$ and $\bar\chi \in \mathscr{C}_0^\infty([-1, 1])$, $\bar\chi = 1$ on $[-\frac{2}{3}, \frac{2}{3}]$.

Let $Q_k = \mathsf{Op}^{\mathsf{w}}(q_k)$ be a fixed h-pseudodifferential operators with symbols $q_k \in \mathsf{S}_{h,K}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$, $\mathsf{supp}(q_k) \Subset \Omega$ and let us assume that A is microhyperbolic on Ω on energy level 0. This is a crucial assumption.

Then one can apply Theorem 2.1.19 estimates

$$\|F_{t\to h^{-1}\tau}\chi_{T'}(t)\Gamma(Q_{1x}u\,{}^tQ_{2y})\| \le Ch^{1-d}\bigl(\frac{h}{T}\bigr)^s \tag{2.1.58}$$

and

$$\|F_{t\to h^{-1}\tau}\chi_{T}(t)\Gamma_x(Q_{1x}u\,{}^tQ_{2y})\| \le Ch^{1-d}\bigl(\frac{h}{T}\bigr)^s \quad \forall x \in \mathbb{R}^d \tag{2.1.59}$$

hold for all $\tau : |\tau| \le \varepsilon_0$, where for the second estimate we need ξ-microhyperbolicity. Due to self-adjoint properties of A we have $M = 1$ in (2.1.43)–(2.1.45) and therefore in (2.1.58), (2.1.59). Recall that in these estimates $T \in [\bar T, T_0]$ is arbitrary where $\bar T = h$ and T_0 is a small constant.

Then making t-admissible partition on $[\bar{T}, T_0]$ we derive that

$$\|F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T_0}(t) - \bar{\chi}_{\bar{T}}(t)\big)\Gamma(Q_{1x}u\,{}^tQ_{2y})\| \le Ch^{1-d} \tag{4.2.79}$$

and

$$\|F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T_0}(t) - \bar{\chi}_{\bar{T}}(t)\big)\Gamma_x(Q_{1x}u\,{}^tQ_{2y})\| \le Ch^{1-d} \quad \forall x \in \mathbb{R}^d \tag{4.2.80}$$

respectively.

On the other hand, there are "dumb" estimates without any microhyperbolicity condition

$$\|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(Q_{1x}u\,{}^tQ_{2y})\| \le CTh^{-d} \tag{4.2.81}$$

and

$$\|F_{t\to h^{-1}\tau}\bar{\chi}_T\Gamma_x(Q_{1x}u\,{}^tQ_{2y})\| \le CTh^{-d} \quad \forall x \in \mathbb{R}^d. \tag{4.2.82}$$

Here $T \ge h$ is arbitrary. Plugging $T = \bar{T} = h$ we get

$$\|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(Q_{1x}u\,{}^tQ_{2y})\| \le CM_Th^{1-d} \tag{4.2.83}$$

and

$$\|F_{t\to h^{-1}\tau}\bar{\chi}_T\Gamma_x(Q_{1x}u\,{}^tQ_{2y})\| \le CM_Th^{1-d} \quad \forall x \in \mathbb{R}^d \tag{4.2.84}$$

as $T = \bar{T}$. Then *by virtue of* (4.2.79), (4.2.80) *these estimates hold with* $T = T_0$ where actually $M_T = 1$, $T = T_0$ but we do not need to make these assumptions if just assume that either (4.2.83) or (4.2.84) hold.

Note that all these estimates (2.1.58), (2.1.59), (4.2.83), (4.2.84) remain valid if we substitute $\bar{\chi}_T(t)$ by $\chi_{T_0}(t)\bar{\chi}_T(t)$. Therefore estimate (4.2.83) or (4.2.84) hold with $\chi_{T_0}(t)$ instead of $\bar{\chi}_{T_0}(t)$.

In particular, it holds with Hörmander function $\chi_T(t)$ where from now we use T instead of T_0.

Let us recall that $U(t) = \int e^{ih^{-1}\tau t}\, d_\tau E(\tau)$ and thus we are dealing with

$$f(\tau) = \langle \Gamma Q_{1x} e(.,.,\tau)\, {}^tQ_{2y} w, w\rangle \tag{4.2.85}$$

and

$$f_x(\tau) = \langle \Gamma_x Q_{1x} e(.,.,\tau)\, {}^tQ_{2y} w, w\rangle \tag{4.2.86}$$

respectively which are monotone functions as $Q_1 = Q_2^*$; here $w \in \mathbb{H}$ is arbitrary with $\|w\| = 1$.

Thus we conclude that (4.2.34) holds with

$$g(\tau) = \begin{cases} CM_T h^{1-d} & \text{as } |\tau| \le \epsilon_0 \\ Ch^{-d} T(|\tau+1|)^{2l} & \text{as } |\tau| \ge \epsilon_0 \end{cases} \tag{4.2.87}$$

Further, plugging $Q_2 = Q_1^*$ and $j = k$ we have monotone function $f(\tau)$ and due to virtue of Lemma 4.2.7 we conclude that in this case $f(\tau)$ satisfies (4.2.35).

Now it is time to drop this restriction. Since

$$Q_1 E(\tau,\tau') Q_2^* = Q_1 E(\tau,\tau') \cdot E(\tau,\tau') Q_1^* = (E(\tau,\tau') Q_1^*)^* E(\tau,\tau') Q_1^* \tag{4.2.88}$$

we conclude that

Proposition 4.2.18. *Under microhyperbolicity condition*

$$\|R(\tau,\tau')\|_{\mathsf{HS}} \le C(g^*(\tau,\tau',\tau))^{\frac12} \tag{4.2.89}$$

and under ξ-microhyperbolicity condition

$$\|R_x(\tau,\tau')\|_{\mathsf{HS}} \le C(g^*(\tau,\tau',\tau))^{\frac12} \tag{4.2.90}$$

with g^* defined by (4.2.35) *and g defined by* (4.2.87) *where*

$$R(\tau,\tau') \coloneqq R_w(\tau,\tau') : \mathscr{L}^2(X,\mathbb{H}) \ni f \to \langle Q_1 E(\tau,\tau') f, w\rangle \in \mathscr{L}^2(X,\mathbb{C})$$

and

$$R_x(\tau,\tau') \coloneqq R_{w,x}(\tau,\tau') : \mathscr{L}^2(X,\mathbb{H}) \ni f \to \langle Q_1 E(\tau,\tau') f, w\rangle(x) \in \mathbb{C}.$$

However the same is true for operator S defined as R but with Q_2, w' instead of Q_1, w; further, in the second case one may substitute x by y.

Then the trace norm (and thus the trace) of operator RS^* does not exceed the right-hand expression of (4.2.35). One can see easily that the trace of $(RS^*)(\tau',\tau'')$ is exactly

$$f(\tau,\tau') = \langle \Gamma Q_{1x} e(.,.,\tau,\tau')\, {}^t Q_{2y} w', w\rangle \tag{4.2.91}$$

and

$$f_{x,y}(\tau,\tau') = \langle Q_{1x} e(.,.,\tau)\, {}^t Q_{2y} w', w\rangle \tag{4.2.92}$$

where in the second case we have f depending not only on w, w' but on x, y as well. Let us recall that $w, w' \in \mathbb{H}$ are arbitrary with $\|w\| = \|w'\| = 1$. Thus we can junk w, w' and estimate $\mathcal{L}(\mathbb{H},\mathbb{H})$ norms of operators rather than their "bra-kets" with w, w'.

Therefore we arrive to the following

Proposition 4.2.19. *(i) Under microhyperbolicity assumption* f *satisfies* (4.2.35) *with* g *defined by* (4.2.87).

(ii) Under ξ*-microhyperbolicity assumption* $f_{x,y}$ *satisfies* (4.2.35) *with* g *defined by* (4.2.87).

So, what We Get?

Now we can apply Lemmas 4.2.13, 4.2.13 and 4.2.15; plugging $T = T_0$ and calculating g^* and $\mathcal{R}$ according to (4.2.35), (4.2.65) and (4.2.87) we get immediately

Proposition 4.2.20. *(i) Under microhyperbolicity assumption on energy levels* $\bar\tau$ *and* $\bar\tau'$ *on* $\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)$

$$\|\mathsf{N}(\bar\tau, \bar\tau') - \mathsf{N}^{\mathsf{T}}(\bar\tau, \bar\tau')\| \le Ch^{1-d} \tag{4.2.93}$$

and

$$\|\mathsf{N}_{\varphi,L}(\bar\tau) - \mathsf{N}^{\mathsf{T}}_{\varphi,L}(\bar\tau)\| \le Ch^{1-d}\vartheta\big(\frac{h}{L}\big); \tag{4.2.94}$$

(ii) Under ξ*-microhyperbolicity assumption on energy levels* $\bar\tau$ *and* $\bar\tau'$ *on* $\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)$

$$\|\mathsf{N}_{x,y}(\bar\tau, \bar\tau') - \mathsf{N}^{\mathsf{T}}_{x,y}(\bar\tau, \bar\tau')\| \le Ch^{1-d} \tag{4.2.95}$$

and

$$\|\mathsf{N}_{x,y,\varphi,L}(\bar\tau) - \mathsf{N}^{\mathsf{T}}_{x,y,\varphi,L}(\bar\tau)\| \le Ch^{1-d}\vartheta\big(\frac{h}{L}\big). \tag{4.2.96}$$

Remark 4.2.21. (i) In Statement (i) we need microhyperbolicity only on $\mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$ since this expression change negligibly as we replace Q_1 and Q_2 by $Q_1' \equiv Q_1$ and $Q_2 \equiv Q_2$ in the vicinity of $\mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$.

(ii) From Proposition 4.2.18 it follows that

$$\|\mathsf{N}_{x,y}(\tau', \tau'')w\|_{\mathscr{H}} \le Ch^{-\frac{d}{2}}\big(|\tau' - \tau''| + h\big)^{\frac{1}{2}} \tag{4.2.97}$$

as both $\tau;, \tau''$ are close to $\bar\tau$ and $w \in \mathbb{H}$, $\|w\| = 1$ where $\mathscr{H} = \mathscr{L}^2(\mathbb{R}^{2d}_{x,y}, \mathbb{H})$ under microhyperbolicity assumption and $\mathscr{H} = \mathscr{L}^2(\mathbb{R}^{d}_{y}, \mathbb{H})$ under ξ microhyperbolicity assumption. Then repeating arguments of the proofs of Lemmas 4.2.13–4.2.15 we arrive to

$$\|\big(\mathsf{N}_{x,y}(\bar\tau, \bar\tau') - \mathsf{N}^{\mathsf{T}}_{x,y}(\bar\tau, \bar\tau')\big)w\|_{\mathscr{H}} \le Ch^{-\frac{d-1}{2}} \tag{4.2.98}$$

and

$$\|\big(\mathsf{N}_{x,y,\varphi,L}(\bar\tau)-\mathsf{N}^{\mathsf{T}}_{x,y,\varphi,L}(\bar\tau)\big)w\|_{\mathscr{H}}\le Ch^{-\frac{d-1}{2}}. \tag{4.2.99}$$

(iii) We also get the same array of formulae with Q_{1x} and ${}^tQ_{2y}$ replaced by $Q_{1x}B_1^j$ and $B_1^k\,{}^tQ_{2y}$ respectively (thus Q_2 is replaced by $Q_2B_1^k$).

It looks that instead of difficult to calculate expressions N_* we got equally difficult to calculate expressions $\mathsf{N}_*^{\mathsf{T}}$. However it is not completely true. First of all in some special cases we can construct $u(x,y,t)$ as an oscillatory integral and calculate corresponding Tauberian expressions.

However for N^{T}, $\mathsf{N}^{\mathsf{T}}_{\varphi,L}$ or $\mathsf{N}^{\mathsf{T}}_{x}$, $\mathsf{N}^{\mathsf{T}}_{x,\varphi,L}$ under microhyperbolicity or ξ-microhyperbolicity condition respectively we can apply Theorem 2.1.19 again and replace $T=T_0$ by *any* $T\in[h^{1-\delta},T_0]$. So, we need to be able to calculate these expressions with really small T. Thus we need to be able to construct $u(x,y,t)$ for $|t|\le T$. We will do it in sSection 4.3 by the successive approximation method.

On the other hand, there is no Theorem 2.1.19 for expressions with $x\ne y$; it is just plain false. Still we will be able to get some less sharp results.

We would be able to derive better estimates if we increased T without significant increase M_T. Everything is left for Sections 4.4, 4.5 after calculations of Section 4.3.

4.2.5 Estimates in the Hilbert Scale

Hilbert Scale

In conclusion we return to the scale of Hilbert spaces $\mathbb{H}_j=\mathfrak{D}(B_1^j)$ with norms $\|u\|_j=\|B_1^ju\|$, $j\in[0,l]$ where B_1 satisfies $(4.2.8)_l$. Moreover, we introduce the spaces $\mathbb{H}_j=\mathbb{H}^\dagger_{-j}$ for $j\in[-l,0]$. So far we used sometimes Hilbert scale associated with B and with $l=\bar l$ where $\bar l=1$ or $\bar l=\frac12$ depending on assumptions[8)].

Let us assume that

$$\|(a_0(x,h)+i)^{-1}w\|_j\le c\|w\|_{j-1}\qquad\forall w\in\mathbb{H}_{j-1}, \tag{4.2.100}$$

[8)] We use l as notation for "new" l and adopt $\bar l$ as a value of "old" $l=1,\frac12$.

$$(4.2.101)\quad \|(a_0(x,h)+i)^{-1}D^\beta a_\alpha(x,h)w\|_j \le c\|w\|_{j-\frac{|\alpha|}{m}}$$
$$\forall w\in \mathbb{H}_{j-\frac{|\alpha|}{m}}\cap \mathfrak{D}(B^l)\quad \forall x\in B(0,1)\quad \forall \beta:|\beta|\le K\quad \forall j\in[0,l]$$

and let us also assume that

$$(4.2.102)_l\qquad \|B_1^{\bar l}w\|\le c\|B^{\bar l}w\|\qquad \forall w\in\mathfrak{D}(B^{\bar l}).$$

Remark 4.2.22. Let us explain why we need to have different operators B and B_1. Consider for example applications to asymptotics of number of eigenvalues of the elliptic operator in domain with thick cusps[9]. After rescaling cusp is replaced by a cylinder $X\times Y$ where X and Y are the base and cross-section of the cusp respectively and instead of the old spatial variable we have (x,y). We replace $\mathscr{L}^2(X\times Y)$ by $\mathscr{L}^2(X,\mathbb{H})$ with $\mathbb{H}=\mathscr{L}^2(Y)$; actually there will be weight but it is not important at the moment.

However we are interested in the genuine trace $\mathsf{Tr}(E(\tau))=\Gamma\,\mathsf{tr}(e(.,.,\tau))$ where $e(x,z,\tau)$ is a "matrix" operator (i. e. operator in $\mathscr{L}(\mathbb{H},\mathbb{H})$) and tr is a "matrix trace" (i.e. trace in $\mathscr{L}(\mathbb{H},\mathbb{H})$). In this example $B=(h^2\Delta_Y+I)^{m/2}$ with the Dirichlet boundary conditions where Δ_Y is positive Laplacian in Y, so associated Hilbert scale would be $\mathbb{H}_j=\mathscr{H}^{jm}_0(Y)$ (we consider Dirichlet boundary condition on the border of the cusp $X\times\partial Y$ [10].

There will be a problem since we need to increase $\bar l=1$ (or $\bar l=\frac12$) to l large enough to have operator of imbedding $I:\mathbb{H}_{l/2}\to\mathbb{H}_{-l/2}$ of the trace class but increasing l in the above scale would not be possible. However it will be possible in the scale $\mathbb{H}_j=\mathscr{H}^{jm}(Y)$. So as B_1 we will take operator generating this scale.

Remark 4.2.23. Note that in our estimates B_1^j and B_1^k appear inside, between Q_{1x} and $e(.,.,\tau)$ and between $e(.,.,\tau)$ and ${}^tQ_{y2}$ respectively and thus in order to estimate trace we need to move them outside. Thus we need to assume that $B_1^jQ_1B_1^{-j}$ and $B_1^{-k}Q_2B_1^k$ are (uniformly) bounded operators. However usually Q_1 and Q_2 are scalar h-pseudodifferential operators.

Further, let us assume that $K=K(d,m,s)$ is large enough. Then

(4.2.103) $u\in\mathscr{H}^s_{\mathsf{loc}}(B(0,1),\mathbb{H}_k\cap\mathfrak{D}(B^{1-\bar l}))$, $Au\in\mathscr{H}^s_{\mathsf{loc}}(B(0,1),\mathbb{H}_j)$ imply that $u\in\mathscr{H}^{s'}_{\mathsf{loc}}(B(0,1),\mathbb{H}_{j+1})$ with $k=j$, $s'=s-m$, $s\in\mathbb{R}$

[9] See in details in Section 12.2. Cusp is *thick* if the standard Weyl asymptotics either fails or does not provide good remainder estimate.

[10] Neumann Laplacian there is a completely different animal; see Section 12.7.

This deduction remains true for $k = 0$, $s' = s - (j+1)m$. Therefore

(4.2.104) $u \in \mathscr{H}^s_{\mathsf{loc}}(B(0,1), \mathfrak{D}(B^{1-\bar{l}}))$ and $A^l u \in \mathscr{H}^s_{\mathsf{loc}}(B(0,1), \mathbb{H})$, $l \in \mathbb{Z}^+$ imply $u \in \mathscr{H}^{s'}_{\mathsf{loc}}(B(0,1), \mathbb{H}_l)$ with an admissible s'.

Then these statements imply the inequality

$$\|\psi B_1^l u\|_{(s)} \le C'(\|A^l u\| + \|u\|) \tag{4.2.105}$$

where $\psi \in \mathscr{C}_0^\infty(B(0,1-\epsilon))$; here $\|\cdot\|_{(s)}$ means the Sobolev $\mathscr{H}^s(\mathbb{R}^d, \mathbb{H})$-norm, and $s = s(m,l) < 0$, $C' = C\|\psi\|_{\mathscr{C}^K}$, $C = C(d,m,l,c,\epsilon)$.

On the other hand, let us assume that inequality (4.2.105) is fulfilled for all $\psi \in \mathscr{C}_0^K(B(0,1-\frac{\epsilon}{2}))$ and that under certain conditions we have proven either estimate (4.2.61) or estimate (4.2.62) for some q_1 and q_2 and for all $\psi_1, \psi_2 \in \mathscr{C}_0^K(B(0,1-\frac{\epsilon}{2}))$ with $q_1 = l$, $q_2 = l$ in neighborhoods of $\mathsf{supp}(q_1')$, $\mathsf{supp}(q_2')$ respectively.

Then one can see easily that this estimate ((4.2.61) or (4.2.62)) will also be fulfilled for q_1', q_2', B_1^j, B_1^k with $j,k \in [0,l]$ instead of q_1, q_2, B^j, B^k with $j,k \in [0,\bar{l}]$ respectively; however, one should replace in the modified estimate T, ϵ, s by $T(1-\epsilon)$, 2ϵ, $s - K_0(m,l)$ respectively.

Estimates in the Hilbert Scale

In particular, we arrive to

Proposition 4.2.24. *Let conditions* (4.2.100)–(4.2.102)$_l$ *be fulfilled. Then one can enhance Propositions 4.2.6, 4.2.8–4.2.12, 4.2.18–4.2.20 to 4.2.6*, 4.2.8*–4.2.12*, 4.2.18*–4.2.20* where * means the following modification:*

(4.2.106) *we replace B^j, B^k with $j,k \in [0,\bar{l}]$ by B_1^j, B_1^k with $j,k \in [0,l]$. One can enhance* (4.2.97)–(4.2.99) *in the same way.*

Moreover, let us assume that

$$\|(A(x,\xi,h)+i)^{-1}w\|_j + |\xi|^m \cdot \|(A(x,\xi,h)+i)^{-1}w\|_{j-1} \le c\|w\|_{j-1} \qquad \forall w \in \mathbb{H}_{j-1} \tag{4.2.107}$$

and

$$\|(A(x,\xi,h)+i)^{-1}D^\beta a_\alpha(x)w\|_j \le c\|w\|_{j-\frac{|\alpha|}{m}} \qquad \forall w \in \mathbb{H}_{j-\frac{|\alpha|}{m}} \cap \mathfrak{D}(B^l) \quad \forall x \in B(0,1) \quad \forall \xi \in \mathbb{R}^d. \tag{4.2.108}$$

Then one can easily prove by the standard elliptic methods that for $B(0,1-\epsilon)$ estimate $(4.2.8)_l$ holds instead of (4.2.105) and then it is easy to prove by the same methods

Proposition 4.2.25. *Under conditions* (4.2.100)–$(4.2.102)_l$ *and* (4.2.107)–(4.2.108) *one can enhance propositions 4.2.9–4.2.11 to propositions 4.2.9*–4.2.11* where * means the same modification* (4.2.106)*.*

We leave trivial details to the reader. Again all final statements will come in Section 4.4. Here we are more interested in the scheme of things.

4.3 The Method of Successive Approximations for Propagator

Now our purpose is to construct propagator $u(x,y,t)$ on a rather short interval $[-T,T]$ with $T \ge h^{1-\delta}$. We will do it for $T = h^{\frac{1}{2}-\delta}$.

4.3.1 The Method of Successive Approximations in the Standard Ccase

Pilot-Construction

Let us temporarily assume that $X = \mathbb{R}^d$ and that $A \in \mathbf{\Psi}_{h,K}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ (so we consider neither operator B nor Hilbert scale $\mathbb{H}_j$). We also assume that K is large enough (a non-smooth case will be treated separately in Section 4.6).

Moreover, let us assume that A is a self-adjoint operator in $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H})$ and let $u(t,x,y)$ be the Schwartz kernel of the operator $U(t) = e^{ih^{-1}tA}$.

Then (4.2.12) (namely, $(hD_t - A_x)u = 0$) and the initial condition $u|_{t=0} = \delta(x-y)I$ imply the equations

$$(hD_t - A)u^{\pm} = \mp ih\delta(x-y)\delta(t)I \tag{4.3.1}$$

where $u^{\pm} = \theta(\pm t)u$, $\theta(.)$ is the Heaviside function, $I = I_{\mathbb{H}}$ is the identity operator in $\mathbb{H}$ and here and in what follows *all the operators without index y act on x and t.*

Let

$$\bar{A} = a(y, hD_x) \tag{4.3.2}$$ so the operator $\bar{A}$ is the principal part of operator A frozen at the point $x = y$;

then

$$A = \bar{A} + R \tag{4.3.3}$$

where

$$R = \sum_{1\le|\alpha|+p\le N} (x-y)^{\alpha} h^{j} A_{\alpha,p}, \tag{4.3.4}$$

(4.3.5) Operators $A_{\alpha,p} = A_{\alpha,p}(y, hD_x)$ for $|\alpha|+p < N$ and $A_{\alpha,p} = A_{\alpha,p}(x, y, hD_x, h)$ for $|\alpha| + p = N$ belong to $\boldsymbol{\Psi}_{h,K-N}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$.

Then (4.3.1) yields the equality

$$(hD_t - \bar{A})u^{\pm} = \mp ih\delta(x-y)\delta(t)I + Ru^{\pm} \tag{4.3.6}$$

and hence

$$u^{\pm} = \mp ih\bar{G}^{\pm}\delta(x-y)\delta(t)I + \bar{G}^{\pm}Ru^{\pm} \tag{4.3.7}$$

where $\bar{G}^{\pm}$ and $G^{\pm}$ are parametrices of the problems

$$(hD_t - \bar{A})v = f, \qquad \mathsf{supp}(v) \subset \{\pm(t-t_0) \ge 0\}, \tag{4.3.8}_{\pm}$$

$$(hD_t - A)v = f, \qquad \mathsf{supp}(v) \subset \{\pm(t-t_0) \ge 0\} \tag{4.3.8}'_{\pm}$$

respectively with $\mathsf{supp}(f) \subset \{\pm(t-t_0) \ge 0\}$ for some $t_0 \in \mathbb{R}$.

Moreover, equation (4.3.1) yields that

$$u^{\pm} = \mp ihG^{\pm}\delta(x-y)\delta(t)I. \tag{4.3.9}$$

Iterating (4.3.7) N times and then substituting (4.3.9) we obtain the equality

$$u^{\pm} = \mp ih \sum_{0\le n\le N-1} (\bar{G}^{\pm}R)^n \bar{G}^{\pm}\delta(x-y)\delta(t) \mp ih(\bar{G}^{\pm}R)^n G^{\pm}\delta(x-y)\delta(t). \tag{4.3.10}$$

Therefore the method of the successive approximations works provided

(4.3.11) An operator norm of $\bar{G}^{\pm}R$ does not exceed $h^{\delta'}$ with an arbitrarily small exponent $\delta' > 0$;

then one needs to take $N = N(s, \delta')$ to get $O(h^{-d+s})$ error.

Observe that on the time interval $[0, T]$ the operator norms of the parametrices $\bar{G}^{\pm}$ do not exceed CTh^{-1} (due to the Duhamel principle; see below) and $R = O(|x-y|+h) = O(T)$ for $T \geq h$ due to the finite speed of propagation property and normally one cannot improve this.

Therefore the restriction to T is $T^2 \leq h^{1+\delta'}$ or

$$T \leq h^{\frac{1}{2}+\delta} \qquad \text{with } \delta > 0. \tag{4.3.12}$$

This is the heuristic idea but the actual implementation will be slightly different.

Transformation of the Successive Approximation Formula

Namely, let us consider the factors $(x_j - y_j)$ entering into all the copies of R defined by (4.3.4) and let us transfer them from the left to the right (to $\delta(x-y)$). If some factor reaches $\delta(x-y)$ then the corresponding term vanishes and so only those terms survive in which all factors $(x_j - y_j)$ are killed. There are two possibilities for killing $(x_j - y_j)$:

(i) Commuting it with a pseudodifferential operator; then there arises a pseudodifferential operator again and an additional factor h;

(ii) Commuting it with either $\bar{G}^{\pm}$ or $G^{\pm}$. Let us note that for $\bar{P} = hD_t - \bar{A}$

$$\bar{P}(x_j - y_j)v = (x_j - y_j)\bar{P}v - [\bar{A}, (x_j - y_j)]v$$

and $\operatorname{supp}((x_j - y_j)v)$ is contained in $\{\pm(t - t_0) \geq 0\}$ provided $\operatorname{supp}(v)$ is contained here; therefore

$$(x_j - y_j)v = \bar{G}^{\pm}(x_j - y_j)\bar{P}v - \bar{G}^{\pm}[\bar{A}, (x_j - y_j)]v$$

and we finally obtain the equality

$$(x_j - y_j)\bar{G}^{\pm} = \bar{G}^{\pm}(x_j - y_j) - \bar{G}^{\pm}[\bar{A}, (x_j - y_j)]\bar{G}^{\pm}; \tag{4.3.13}$$

similarly

$$(x_j - y_j)G^{\pm} = G^{\pm}(x_j - y_j) - G^{\pm}[A, (x_j - y_j)]G^{\pm}. \tag{4.3.13$'$}$$

Therefore as a result of commuting of $(x_j - y_j)$ with $\bar{G}^{\pm}$ there appear a pseudodifferential operator, a factor h and an additional factor $\bar{G}^{\pm}$; the same is also true for $G^{\pm}$.

Now our goal is to prove that

(4.3.14) All the terms in (4.3.10) containing more than $(N-1)$ factors h and $(x_j - y_j)$ are negligible in some appropriate sense; in particular, one can then drop the last term in (4.3.10) and in all the remaining terms in R (defined by (4.3.4)) we can drop all terms with $|\alpha| + p = N$; all the remaining terms we call *regular*.

Recall that we consider the case $X = \mathbb{R}^d$, $A \in \boldsymbol{\Psi}_{h,N}(X, \mathbb{H}, \mathbb{H})$; later we will justify the same procedure in other situations. Then the Duhamel equality

$$(\bar{G}^{\pm} v)(t, .) = ih^{-1} \int_{\pm t' \le \pm t} \bar{U}(t - t') v(t', .)\, dt' \tag{4.3.15}$$

with the unitary operator $\bar{U}(t) = e^{ih^{-1} t \bar{A}}$ and a similar formula for $G^{\pm}$ imply that

(4.3.16) $\mathcal{L}\big(\mathscr{L}^2([-T, T] \times X, \mathbb{H}), \mathscr{L}^2([-T, T] \times X, \mathbb{H})\big)$-norms of $\bar{G}^{\pm}$ and $G^{\pm}$ do not exceed $2Th^{-1}$.

Moreover, the equality

$$\bar{G}^{\pm}(\delta(t) v) = \pm ih^{-1} \theta(\pm t) \bar{U}(t) v \tag{4.3.17}$$

and a similar equality for $G^{\pm}$ imply that the

(4.3.18) $\mathcal{L}\big(\mathscr{L}^2([-T, T] \times X, \mathbb{H}), \mathscr{L}^2(X, \mathbb{H})\big)$-norms of the operators $v \to \bar{G}^{\pm}(\delta(t) v)$ and $v \to G^{\pm}(\delta(t) v)$ do not exceed $T^{1/2} h^{-1}$.

Hence we conclude that

(4.3.19) $\mathcal{L}\big(\mathscr{L}^2([-T, T] \times X, \mathbb{H}), \mathscr{L}^2([-T, T] \times X, \mathbb{H})\big)$-norm[11] of every term of decomposition (4.3.10) does not exceed $C' h^{r-k} T^{p+k+\frac{1}{2}}$ where r, p and $k+1$ are the original numbers of factors h, $(x_j - y_j)$, $\bar{G}^{\pm}$ (or $G^{\pm}$) respectively.

Obviously $k \le p + r$ and therefore the norm in question does not exceed $C' h^{\sigma(p+r)}$ with $\sigma = \sigma(\delta) > 0$ provided T satisfies (4.3.12) with an arbitrarily small exponent $\delta > 0$. Therefore (4.3.14) is proven.

Applying Theorem 1.1.12 we arrive to

[11] One can consider this term as the Schwartz kernel of an operator and calculate its operator norm.

Proposition 4.3.1. *Let $A \in \boldsymbol{\Psi}_{h,K}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$, $q_1, q_2 \in \mathsf{S}_{h,K}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ be supported in $\{|\xi| \le c\}$, $Q_i = \mathsf{Op}^{\mathsf{w}}(q_i)$, $i = 1, 2$, $\chi \in \mathscr{C}_0^K([-1, 1])$ and $T \in [h^{1-\delta}, h^{\frac{1}{2}+\delta}]$ with $\delta > 0$. Then*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\big(u^{\pm}\pm ih\sum_{0\le n\le N-1}(\bar{G}^{\pm}R')^n\delta(x-y)\delta(t)\big)^tQ_{2y}\| \le C'h^s \quad \forall x, y \in \mathbb{R}^d \quad \forall \tau \in \mathbb{R} \tag{4.3.20}$$

where

$$R' = \sum_{1\le|\alpha|+p\le N-1}(x-y)^\alpha h^j A_{\alpha,p}(y, hD_x), \tag{4.3.4}'$$

$\delta > 0$ and s are arbitrary, $N = N(d, s, \delta)$ and $K = K(d, s, \delta, N)$ are large enough, $C = C(d, s, \delta, N, c)$, $C' = C\|\!|q_1|\!\| \cdot \|\!|q_2|\!\| \cdot \|\!|\chi|\!\|$ and all the norms are calculated in the corresponding spaces.

Minor Modifications

Let us make minor modifications to the standard case. Namely, let us replace condition $A \in \boldsymbol{\Psi}_{h,K}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ by one one of the following conditions: $(4.3.21)_1$ $\zeta A \in \boldsymbol{\Psi}_{h,\rho,\gamma,K}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ with $\rho, \gamma \in [0, 1]$, $\zeta \ge h^s$, $\rho\gamma \ge h^{1-\delta}$; $(4.3.21)_2$ $A \in \tilde{\boldsymbol{\Psi}}^m_{h,K}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$; $(4.3.21)_3$ A is a differential operator with coefficients satisfying (4.2.13) with $B = I$. Now we consider the domain $\Omega \subset T^*X$ (or $\Omega \subset T^*B(0, 1-\epsilon_0)$ in the third case) and we assume that

(4.3.22) In Ω the symbol of A coincides with that of $A' \in \boldsymbol{\Psi}_{h,K}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$.

Moreover, let us assume that

$$\|\nabla_{x,\xi}A(x, \xi, h)\| \le c_0 \qquad \forall (x, \xi) \in \Omega \tag{4.3.23}$$

Then Corollary 2.1.7 yields that if $q_1, q_2 \in \mathsf{S}_{h,\rho,\gamma,K}(\mathbb{R}^d, \mathbb{H}, \mathbb{H})$ with $\rho, \gamma \in [0, 1]$, $\rho\gamma \ge h^{1-\delta}$ are supported in $\Omega_{(\epsilon_0)}$ and $Q_1 = \mathsf{Op}^{\mathsf{w}}(q_1)$, $Q_2 = \mathsf{Op}^{\mathsf{w}}(q_2)$, then

(4.3.24) For $t \in [-T_0, T_0]$ with $T_0 = T_0(c_0, \epsilon_0) > 0$ $u(t,x,y)\,{}^tQ_{2y}$ [12] is negligible outside of $\Omega_{\frac{1}{2}\epsilon_0}$ where $\Omega_\varepsilon = \{(x,\xi) : \mathsf{dist}((x,\xi), \complement\Omega) \ge \varepsilon\}$ and ϵ_0 is arbitrarily small.

Hence (4.3.1) yields that

$$(4.3.1)' \quad (hD_t - A')u^{\pm}\,{}^tQ_{2y} \equiv \mp ih\delta(t)\mathcal{K}(x,y) \qquad \text{in } [-T_0, T_0]\times\mathbb{R}^d\times\mathbb{R}^d$$

modulo negligible functions where $\mathcal{K}(x,y) = \mathcal{K}_{Q_2}(x,y) = \delta(x-y)\,{}^tQ_{2y}$ is the Schwartz kernel of Q_2; hence one can replace (4.3.10) by

$$(4.3.10)' \quad u^{\pm}\,{}^tQ_{2y} \equiv \mp ih \sum_{0\le n\le N-1} (\bar G^{\pm}R)^n \bar G^{\pm}\mathcal{K}(x,y)\delta(t) \mp ih(\bar G^{\pm}R)^n G^{\pm}\mathcal{K}(x,y)\delta(t)$$

where $\bar A$, R, $\bar G^{\pm}$ and $G^{\pm}$ are constructed for A' instead of A [13].

Let us apply the previous procedure of the transfer of the factors $(x_j - y_j)$ to the right; now these factors can be also killed in the commutator with ${}^tQ_{2y}$ but it is still in consistent with the case (i) in the beginning of the previous subsubsection. So we obtain the following estimate

$$(4.3.20)' \quad \|F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\big(u^{\pm}\,{}^tQ_{2y} \pm ih^{-1}\sum_{0\le n\le N-1} (\bar G^{\pm}R')^n\bar G^{\pm}\delta(t)(\delta(x-y)\,{}^tQ_{2y})\| \le C'h^s.$$

Remark 4.3.2. (i) This estimate differs from (4.3.20) only by position of ${}^tQ_{2y}$; let us remember that while operator A does not depend on y, operators $\bar A$ and R do;

(ii) Moreover, let us replace here ϵ_0 by $\frac{1}{3}\epsilon_0$ and q_2 by q_2' equal to 1 in $\Omega_{\frac{2}{3}\epsilon_0}$; let us multiply the function inside the norm by ${}^tQ_{2y}$; then Corollary 2.1.7 yields that the obtained function will not change modulo negligible terms if we replace the operator ${}^tQ'_{2y}$ by I.

So we have proven

---

[12] In the case $(4.3.21)_3$ one should replace Q_i by $Q_i\psi_i$ with ψ_i supported in $B(0, 1-\epsilon_0)$; usually we do it without special mention.

[13] Later we will see that in the final answer this replacement is not necessary.

Proposition 4.3.3. *(i) The assertion of Proposition 4.3.1 remains true for operators A of the type $(4.3.21)_j$–(4.3.22), $j = 1, 2$, with K, C' depending on m and C' also depending on c_0, ϵ_0, $c = \|R\| + \|A\|$ where all the norms are calculated in the corresponding spaces.*

(ii) Moreover, for operators A of the type $(4.3.21)_3$–(4.3.22) this assertion remains true if we replace Q_1, Q_2 by $Q_1\psi_1, Q_2\psi_2$ respectively with $\psi_i \in \mathscr{C}_0^K(B(0, 1-\epsilon_0))$; i.e., the estimate

$$(4.3.20)'' \quad \|F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\psi_1(x)\big(u^{\pm}\pm ih\sum_{0\le n\le N-1}(\bar{G}^{\pm}R')^n\delta(x-y)\delta(t)\big)\psi_2(y)\,{}^tQ_{2y}\| \le C'h^s \quad \forall x, y \in \mathbb{R}^d \quad \forall \tau \in \mathbb{R}$$

holds, where now $C' = C\|q_1\| \cdot \|q_2\| \cdot \|\psi_1\| \cdot \|\psi_2\|$.

4.3.2 Successive Approximations in the Hilbert Scale

Let us consider the general case of a differential operator with the coefficients which are unbounded operators with the coefficients satisfying $(4.2.13)_l$–$(4.2.14)_l$.

We will use the successive approximations method with the operator A replaced by the operator

$$A' = a_0(x, h) + \zeta(D)\psi_3(x)\big(A - a_0(x, h)\big)\psi_3(x)\zeta(D) \tag{4.3.25}$$

where $a_0(x, h)$ is a coefficient in A without derivatives extended to $\mathbb{R}^d$ preserving properties $(4.2.13)_l$–$(4.2.14)_l$ (for this coefficient) and here and in what follows $\psi_3, \psi_4, \psi_5 \in \mathscr{C}_0^K$ are real-valued functions supported in $B(0, 1-\frac{7}{9}\epsilon_0)$, $B(0, 1-\frac{5}{9}\epsilon_0)$, $B(0, 1-\frac{3}{9}\epsilon_0)$ and are equal to 1 in $B(0, 1-\frac{8}{9}\epsilon_0)$, $B(0, 1-\frac{2}{9}\epsilon_0)$, $B(0, 1-\frac{4}{9}\epsilon_0)$ respectively (recall that ψ_1 and ψ_2 are supported in $B(0, 1-\epsilon_0)$), $\zeta \in \mathscr{C}^\infty(\mathbb{R}^d)$ equal 1 as $|\xi| \le c$. Then due to finite speed of propagation $u\,{}^tQ_2$ satisfies propagation equation $(hD_t - A')u\,{}^tQ_2 \equiv 0$ modulo negligible f.

Recall that $a_0(x, hD)$ is "the most powerful" coefficient in A as operator in $\mathbb{H}$ and we do not cut it of because we want

$$(a_0 \pm i I_{\mathbb{H}})^{-1} \in \mathcal{L}\big(\mathscr{L}^2(X, \mathbb{H}_j), \mathscr{L}^2(X, \mathbb{H}_{j-1})\big)$$

uniformly.

Such an extension for "potential" $a_0(x,h)$ can be easily chosen provided in the case (i) we replace $B(0,1)$ by any ball from its ϵ-covering (if necessary).

The *principal difficulty now is that the coefficients of* A' *and thus perturbation* $R = A' - \bar{A}$, $\bar{A}' = A'(y,0,hD)$ *are unbounded operators and parametrices* $G^{\pm}$ *and* $\bar{G}^{\pm}$ *do not compensate this unboundedness in an explicit way*[14)].

To tackle this unboundedness we apply the *sandwich procedure*. Namely, let us note that

$$\bar{G}^{\pm} = -(\bar{A}'+i)^{-1} + \bar{G}^{\pm}(hD_t+i)(\bar{A}'+i)^{-1} \tag{4.3.26}$$

and that all three operators $\bar{G}^{\pm}$, $(\bar{A}'+i)^{-1}$ and (hD_t+i) commute.

Let us transform in this way all the terms in the right-hand expression in $(4.3.10)'$ and let us move all the copies of the factor (hD_t+i) to the left; in this way we can replace $\bar{G}^{\pm}$ in the original version of the right-hand expression in $(4.3.10)'$ either by $-(\bar{A}'+i)^{-1}$ or $(\bar{A}'+i)^{-2}$ or $(\bar{A}'+i)^{-1}\bar{G}^{\pm}(\bar{A}'+i)^{-1}$ (with the additional factor $(hD_t+i)^k$ with $k=0,1,2$ respectively).

One can easily see that for $k \ge 1$ the $\mathcal{L}\bigl(\mathscr{L}^2(\mathbb{R}^d,\mathbb{H}),\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})\bigr)$-norms of the operators $B^{1-j}(\bar{A}'+i)^{-k}B^j$ do not exceed C where here and what follows $j\in[0,1]$ is arbitrary in the case of the first standard set of assumptions and $j=\frac{1}{2}$ in the case of the second standard set of assumptions.

Therefore

(4.3.27) $\mathcal{L}\bigl(\mathscr{L}^2([-T,T]\times\mathbb{R}^d,\mathbb{H}),\mathscr{L}^2([-T,T]\times\mathbb{R}^d,\mathbb{H})\bigr)$-norm of the operator $B^{1-j}(\bar{A}'+i)^{-1}\bar{G}^{\pm}(\bar{A}'+i)^{-1}B^j$ does not exceed CTh^{-1}.

Similarly we can deal with $G^{\pm}$ or $\hat{G}^{\pm}$. Hence we conclude that

(4.3.28) Let us consider a term (in the right-hand expression in $(4.3.10)'$ which was negligible in the context of Subsection 4.3.1. Then after multiplication from the left by $F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\psi_1(x)$ with $Q_1=\mathsf{Op}^{\mathsf{w}}(q_1)$, q_1 supported in $\{|\xi|\le c\}$ we obtain an expression with $\mathcal{L}(\mathbb{H},\mathbb{H})$-norm not exceeding $C'h^s(|\tau|+1)^{\mu}$ with $\mu=\mu(d,m,s,\delta)$ for all $x,y\in\mathbb{R}^d$.

Moreover, this assertion remains true if we replace Q_{1x} and ${}^tQ_{2y}$ by $Q_{1x}B^j$ and $B^k\,{}^tQ_{2y}$ respectively where $j,k\in[0,1]$, $j+k\le 1$ in the case

[14)] Actually, there is unboundedness with respect to ξ and the failure of the coefficients to be $\mathcal{L}(\mathbb{H},\mathbb{H})$-operators: they are only $\mathcal{L}(\mathbb{H},B^{-1}\mathbb{H})$-operators. The unboundedness with respect to ξ will be compensated by cutting of A by $\zeta(D)$.

of the first standard set of assumptions and $j, k \in [0, \frac{1}{2}]$ in the case of the second standard set of assumptions.

However, we should remember that instead of equation $(4.3.1)'$ we now have

$(4.3.1)''$ $\quad (hD_t - R)u^{\pm}B^k\psi_2(y)\,{}^tQ_{2y} = \mp ih\delta(t)\delta(x-y)B^k\psi_2(y)\,{}^tQ_{2y} + f^{\pm}$

where

$$f^{\pm} = (A - A')u^{\pm}B^k\psi_2(y)\,{}^tQ_{2y}$$

and hence we need to examine corresponding terms which were automatically negligible in the context of Subsection 4.3.1.

Let us note that if we replace $u^{\pm}$ by its cut-offs $u_1^{\pm} = \psi_4(x)u^{\pm}$ then $(4.3.1)''$ remains true with $f^{\pm}$ given now by formula

$$f^{\pm} = \psi_4(x)(A - A')\psi_5 u^{\pm}B^k\psi_2(y)\,{}^tQ_{2y}$$

where

$$u^{\pm} = \mp ih\hat{G}^{\pm}\delta(t)\delta(x-y)I_{\mathbb{H}}$$

and $\hat{G}^{\pm}$ is a parametrix of the problem $(4.3.8)_{\pm}$ (for the operator $hD_t - A$ while $G^{\pm}$ are reserved for parametrices of $hD_t - A'$).

One can apply the sandwich procedure to the parametrices $\hat{G}^{\pm}$ as well; then we obtain terms in which $\hat{G}^{\pm}$ is sandwiched between $\psi_5(A+i)^{-1}$ on the left and $(A+i)^{-1}\psi_4$ from the right and also we obtain the terms containing no factor $\hat{G}^{\pm}$ at all.

Condition $(4.2.20)_l$ [15] yields that

(4.3.29) For $\psi \in \mathscr{C}_0^K(B(0,1-\varepsilon))$ operator $\psi(A \pm i)^{-1}$ acts from $\mathscr{H}^r(X, \mathbb{H}_{j-1})$ to $\mathscr{H}^{r-m}(X, \mathbb{H}_j)$ where $\mathscr{H}^r$ is a Sobolev space and r is arbitrary (but K depends on r)[16]. Then the same is true for the adjoint operator $(A \pm i)^{-1}\psi$ [17].

Further, let us consider the commutator of $(A \pm i)^{-1}$ with an operator of the form $\psi Q\psi$ where Q is a quantization of a compactly supported scalar symbol. Then

$$[(A \pm i)^{-1}, \psi Q\psi] = -(A \pm i)^{-1}[A, \psi Q'\psi](A \pm i)^{-1}$$

[15] Namely, either $(4.2.20)_1$ or $(4.2.20)_{\frac{1}{2}}$ in the cases of the first or second standard set of assumptions.

[16] And $j, 1-j \in [-l, l]$.

[17] Condition $(4.2.13)_l$ is assumed to be fulfilled for given l and for $1-l$ simultaneously.

and hence (4.3.29) yields that its operator norm from $\mathscr{L}^2(X,\mathbb{H}_{j-1})$ to $\mathscr{L}^2(X,\mathbb{H}_j)$ [16)] does not exceed Ch.

This assertion immediately yields that if $q_1, q_2 \in \mathsf{S}_{h,K}(T^*\mathbb{R}^d,\mathbb{H},\mathbb{H})$, q_2 is compactly supported with respect to (x,ξ) and its support does not intersect that of q_1 then the operator norms from $\mathscr{L}^2(X,\mathbb{H}_{j-1})$ to $\mathscr{L}^2(X,\mathbb{H}_j)$ [16)] of the operator $\psi Q_1\psi(A\pm i)^{-1}\psi Q_2\psi$ do not exceed $C'h^s$ and the same is true for $(1-\psi')(A\pm i)^{-1}\psi Q_2\psi$ provided $\psi'=1$ in the neighborhood of $\mathsf{supp}\,\psi$; here $Q_i=\mathsf{Op}^{\mathsf{w}}(q_i)$.

This assertion and Corollary 2.1.7 imply that

$$\|F_{t\to h^{-1}\tau}B^{-j}\chi_{2T}(t)f^{\pm}w\|\le C'h^s\|w\| \qquad \forall y\in\mathbb{R}^d \quad \forall\tau:|\tau|\le 2c \quad \forall w\in\mathbb{H} \tag{4.3.30}$$

where $\chi\in\mathscr{C}_0^K([-1,1])$ is arbitrary and we estimate the $\mathscr{L}^2(\mathbb{R}^d,\mathbb{H})$-norm with respect to x.

Therefore the extra terms arising in $(4.3.10)'$ in connection with $f^{\pm}$ after multiplication by $F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\psi_1(x)B^j$ with $|\tau|\le c$ have $\mathcal{L}(\mathbb{H},\mathbb{H})$-norms not exceeding $C'h^s$. So we have proven

Proposition 4.3.4. *(i) Let conditions* $(4.2.13)_1$, $(4.2.14)_1$, (4.2.15), (4.2.16), (4.2.17) *and* $(4.2.20)_1$ *be fulfilled and let* $T,\chi,\psi_1,\psi_2,Q_1,Q_2,N$ *be as in Proposition 4.3.1; further, let* Q_1 *and* Q_2 *be scalar operators. Then the estimates*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\psi_1(x)B^j\bigl(u^{\pm}\pm ih\sum_{0\le n\le N-1}(\bar G^{\pm}R')^n\bar G^{\pm}\delta(t)\delta(x-y)\bigr)B^k\psi_2(y)\,{}^tQ_{2y}\|\le C'h^s \qquad \forall x,y\in\mathbb{R}^d \quad \forall\tau:|\tau|\le c \quad \forall j,k\in[0,\bar l], j+k\le 1 \tag{4.3.31}$$

hold with $\bar l=1$ [8)].

(ii) Let conditions $(4.2.13)_{\frac12}$, $(4.2.14)_{\pm}$, (4.2.15), (4.2.21), (4.2.17), $(4.2.20)_{\frac12}$ *be fulfilled and let* $T,\chi,\psi_1,\psi_2,Q_1,Q_2,N$ *be as in Proposition 4.3.1. Then estimates* $(4.3.31)_{\pm}$ *hold with* $\bar l=\frac12$.

Furthermore, let us assume that conditions (4.2.100)–$(4.2.102)_l$ are fulfilled.

Consider first terms which do not contain $\hat G^{\pm}$. Then (4.3.26) yields that every copy of $\bar G^{\pm}$ can either be sandwiched between two copies of $(\bar A+i)^{-p}$

with arbitrarily large p or replaced by $(\bar{A}+i)^{-q}$ with $q = 1, \dots, 2p$, and the same is true for $G^{\pm}$. Let us perform this procedure for the leftmost and the rightmost copies of $\bar{G}^{\pm}$ or $G^{\pm}$. If after this a factor $\bar{G}^{\pm}$ or $G^{\pm}$ disappears we go to the next factor of this type. Then two final outcomes are possible:

(a) The term contains a factor $(\bar{A}+i)^{-p}$ or a factor $(A'+i)^{-p}$ with no factor $\bar{G}^{\pm}$, $G^{\pm}$ to the left of it, and the term contains a factor $(\bar{A}+i)^{-p}$ or a factor $(A'+i)^{-p}$ or a factor $(A+i)^{-p}$ with no factor $\bar{G}^{\pm}$, $G^{\pm}$ to the right of it;

(b) The term contains no factor $\bar{G}^{\pm}$, $G^{\pm}$.

In the case (a) (with large enough p) after multiplication on the left by an operator $F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\psi_1(x)B_1^j$ and replacing B^k with $k \in [0, \bar{l}]$ by B_1^k with $k \in [0, l]$ we conclude that the $\mathcal{L}(\mathbb{H}, \mathbb{H})$-norm of the term obtained does not exceed $C'h^s$ provided this term was negligible under the assumptions of Subsection 4.3.1.

In the case (b) it is true only if $j + k \le 1$ but *if we consider* $u = u^+ + u^-$ *then two copies of this term will be annihilated* because they are equal but of the opposite sign.

Further, let us consider terms containing $\hat{G}^{\pm}$ (and hence originating from $f^{\pm}$). Let us note that

$$(A+i)^{-1} = (a_0+i)^{-1} \sum_{0\le n\le N-1} ((a_0-A)(a_0+i)^{-1})^n + ((a_0-A)(a_0+i)^{-1})^N (A+i)^{-1};$$

therefore the arguments used in the proof of Proposition 4.3.4 and conditions (4.2.100)–(4.2.102)$_{\bar{l}}$ imply that if q_2 is compactly supported with respect to (x, ξ) then the operator norm from $\mathscr{L}^2(X, \mathbb{H}_{j-1})$ to $\mathscr{L}^2(X, \mathbb{H}_j)$ [16)] of the operator $(A \pm i)^{-1}\psi Q_2 \psi$ does not exceed $C\|\!|q_1|\!\| \cdot \|\!|q_2|\!\| \cdot \|\!|\psi_1|\!\| \cdot \|\!|\psi_2|\!\|$.

Moreover, if the support of q_2 does not intersect the support of q_1 then the operator norms from $\mathscr{L}^2(X, \mathbb{H}_{j-1})$ to $\mathscr{L}^2(X, \mathbb{H}_j)$ of the operators $\psi Q_1 \psi (A \pm i)^{-1}\psi Q_2 \psi$ do not exceed $C'h^s$, and the same is true for $(1-\psi')(A\pm i)^{-1}\psi Q_2\psi$ provided $\psi' = 1$ in a neighborhood of $\operatorname{supp}\psi$; here $Q_i = \mathsf{Op}(q_i)$ and $\nu \in [0, l]$ is arbitrary.

Then applying the sandwich procedure in the recently modified form and referring in case (a) to Corollary 2.1.7 we obtain that terms of type (a) satisfy the same estimate as before and terms of type (b) annihilate when we add u^+ and u^-. So we have proven

Proposition 4.3.5. *Suppose that* either *conditions* $(4.2.13)_1$, $(4.2.14)_1$, (4.2.15), (4.2.16), (4.2.17), $(4.2.20)_1$ or *conditions* $(4.2.13)_{\frac12}$, $(4.2.14)_{\pm}$, (4.2.15), (4.2.21), (4.2.17), $(4.2.20)_{\frac12}$ *are fulfilled and let* $T, \chi, \psi_1, \psi_2, Q_1, Q_2, N$ *be as in Proposition 4.3.1.*

Moreover, let (4.2.100)–$(4.2.102)_l$ *be fulfilled (surely* N, K *and* C *now also depend on* l*). Then*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\psi_1(x)B^j\big(u+ ih\sum_{\varsigma=\pm}\sum_{0\le n\le N-1}\varsigma\big(\bar G^\varsigma R'\big)^n\bar G^\varsigma\delta(t)\delta(x-y)\big)B^k\psi_2(y)\,{}^tQ_{2y}\|\le C'h^s \quad \forall x,y\in\mathbb{R}^d \quad \forall\tau:|\tau|\le c \quad \forall j,k\in[0,l]. \tag{4.3.32}$$

4.3.3 Calculations

Let us go from estimates to calculations. For a sake of simplicity we include now powers of B_1 into Q_1 and Q_2 if needed.

Since $\bar A = a(y, hD_x)$ is an operator with symbol which does not depend on x, an obvious method is a Fourier transform $x \to h^{-1}\xi$ with $\xi\in\mathbb{R}^d$ and the Fourier-Laplace transform $t\to h^{-1}\tau$ with $\tau\in\mathbb{C}_\mp\setminus\mathbb{R}$.

Then the following table of transformations is valid:

$\delta(x-y)\psi_2(y)\,{}^tQ_{2y}$	$e^{ih^{-1}\langle x-y,\xi\rangle}q_2(y,\xi,h)$
$\delta(t)$	1
$\bar G^\pm$	$(\tau-a(y,\xi))^{-1}$ as $\pm\operatorname{Im}\tau<0$
$b(y,hD_x,h)$	$b(y,\xi,h)$
(x_j-y_j)	$ih\partial_{\xi_j}$

Table 4.1: Table of transformations

Namely, $\delta(x-y)\psi_2(y)\,{}^tQ_{2y}$ is transformed into $e^{ih^{-1}\langle x-y,\xi\rangle}q_2(y,\xi,h)$ where $q_2(y,\xi,h)$ is the pq-symbol of operator Q_2 (replaced by $\psi_2 Q_2$ in the formulas and in this definition if necessary)[18], and $\delta(t)$ is transformed into 1; parametrices $\bar G^{\pm}$ are transformed into operators of multiplication by $(\tau - a(y,\xi))^{-1}$ [19]; let us recall that $a(x,\xi)=A(x,\xi,0)$ is a principal symbol of A. Finally, operators $b(y,hD_x,h)$ and (x_j-y_j) are transformed into $b(y,\xi,h)$ and $ih\partial_{\xi_j}$ respectively.

Therefore for $\tau\in\mathbb{C}_{\mp}\setminus\mathbb{R}$

$$(4.3.33)\quad F_{t\to h^{-1}\tau}\sum_{0\le n\le N-1}\bigl(\bar G^{\pm}R'\bigr)^n\bar G^{\pm}\delta(t)\delta(x-y)\bigr)\,{}^tQ_{2y}= \mp i\sum_{0\le n\le N'}(2\pi)^{-d-1}h^{-d+n}\int e^{ih^{-1}\langle x-y,\xi\rangle}F_n(y,\xi,\tau)[q_2(y,\xi,h)]\,d\xi$$

where

(4.3.34) F_n are differential operators[20] with respect to ξ of degree not exceeding n with $\mathcal{L}(\mathbb{H},\mathbb{H})$-valued coefficients which are holomorphic with respect to $\tau\in\mathbb{C}\setminus\mathbb{R}$ and $\mathscr{C}^s$ with respect (x,ξ) where s is arbitrarily large.

(4.3.35) $q_2=\mathsf{symb}_{qp}(Q_2)$ (and $q_1=\mathsf{symb}_{qp}(Q_1)$ later).

Moreover

(4.3.36) Under the assumptions of Propositions 4.3.1, 4.3.3 the $\mathcal{L}(\mathbb{H},\mathbb{H})$-norms of these coefficients[21] do not exceed $C|\operatorname{Im}\tau|^{-2n-1-|\beta|}$.

The sandwich procedure yields that

(4.3.37) Under the assumptions of Proposition 4.2.3 the $\mathcal{L}(\mathbb{H},\mathbb{H})$-norms (with the same j as in this proposition) of these coefficients[21] do not exceed $C(|\tau|+1)^{2r}|\operatorname{Im}\tau|^{-r}$ with large enough r depending on n.

Finally, the modified sandwich procedure yields that

---

[18] In the previous analysis the method of quantization was not essential.

[19] With $\tau\in\mathbb{C}_{\mp}\setminus\mathbb{R}$; so the only difference here is the range of τ.

[20] Applied to q_2.

[21] And their derivatives of degree β, $|\beta|\le s$ with respect to $(x,\xi)\in\Omega$.

(4.3.38) Under the assumptions of Proposition 4.3.5 these estimates hold for Q_1, Q_2 incorporating B_1^j and B_1^k with $j, k \in [0, l]$.

Finally, $F_n(y, \xi, \tau)$ depend only on the values of $A(., ., h)$ in a neighborhood of (y, ξ) and hence the replacement of A by A' was not essential from the formal point of view.

Remark 4.3.6. The way in which we obtained formula (4.3.33) yields that its right-hand expression is approximately equal[22)] to

$$\mp i(2\pi)^{-d-1}h^{-d}\int e^{ih^{-1}\langle x-y,\xi\rangle}\,\mathsf{symb}_{pq(N')}\big((\tau-A)^{-1}\psi_2 Q_2\big)\,d\xi \tag{4.3.39}$$

where $(\tau - A)^{-1}$ means a parametrix *formally constructed in terms of the symbol calculus* (or in terms of the formal calculus of pseudodifferential operators), "symb" means symbol, the subscript pq means the type of the symbol and the subscript (N') means that we cut of the decomposition at $h^{N'}$; this subscript is not written in what follows.

In fact, for every fixed $\tau \in \mathbb{C} \setminus \mathbb{R}$ the construction of this parametrix by the method of successive approximations gives exactly the same formulas (without the factor $\pm(2\pi i)^{-1}$).

Therefore

(i) Expression (4.3.39) is the Schwartz kernel of the operator $\mp\frac{1}{2\pi i}(\tau - A)^{-1}\psi_2 Q_2$;

(ii) In particular,

$$F_0(y, \tau, \xi) = \big(\tau - a(y, \xi)\big)^{-1} \tag{4.3.40}$$

and

$$\begin{aligned} F_1(y, \tau, \xi)[q_2] = \big(\tau - a(y, \xi)\big)^{-1}\cdot \\ \big(a^s(y, \xi) + \frac{i}{2}\sum_j a^{(j)}_{(j)}(y, \xi) + \sum_j a_{(j)}(y, \xi)(i\partial_{\xi_j})\big)\big[\big(\tau - a(y, \xi)\big)^{-1} q_2\big] \end{aligned} \tag{4.3.41}$$

where a^s is the subprincipal symbol of A.

[22)] Errors will be only in terms with $n \ge s + d$.

Formula (4.3.33) yields that

$$(4.3.42)\quad F_{t\to h^{-1}\tau}\sum_{0\le n\le N-1} Q_{1x}\big(\bar G^{\pm}R')^n\bar G^{\pm}\delta(t)\delta(x-y)\big)\,{}^tQ_{2y}=$$

$$\mp i\sum_{0\le n\le N'}(2\pi)^{-d-1}h^{-d+n}\int e^{ih^{-1}\langle x-y,\xi\rangle}q_1(x,\xi,h)F_n(y,\xi,\tau)[q_2(y,\xi,h)]\,d\xi$$

where q_1 is the qp-symbol of Q_1 (replaced by $Q_1\psi_1$ in the formulas and in this definition if necessary).

On the other hand, Appendix 4.A.1 yields that one can set $\tau\in\mathbb{R}$ in formulas (4.3.33) and (4.3.42) and then one should replace the τ-analytic functions $F_n(y,\xi,\tau)$ by distributions

$$(4.3.43)\qquad F_n^{\mp}(y,\xi,\tau)=F_n(y,\xi,\tau\mp i0)\in\mathscr{S}'\big(\mathbb{R}_\tau,\mathscr{C}^s(\Omega,\mathcal{L}(\mathbb{H}_{\bar l},\mathbb{H}_{\bar l-1}))\big).$$

More precisely, the coefficients of $F_n^{\mp}$ belong to this space; recall that F_n and hence $F_n^{\mp}$ and $\mathcal{F}_n$ (see below) are differential operators.

Thus the left-hand expression of (4.3.42) equals as $\tau\in\mathbb{R}$ (in the sense of distributions) to

$$(4.3.44)\quad \mp i\sum_{0\le n\le N'}(2\pi)^{-d-1}h^{-d+n}\times$$

$$\int e^{ih^{-1}\langle x-y,\xi\rangle}q_1(x,\xi,h)F_n^{\mp}(y,\tau,\xi)[q_2(y,\xi,h)]\,d\xi$$

and therefore

$$(4.3.45)\quad F_{t\to h^{-1}\tau}\sum_{\varsigma=\pm}\sum_{0\le n\le N-1} Q_{1x}\varsigma\big(\bar G^{\varsigma}R')^n\bar G^{\varsigma}\delta(t)\delta(x-y)\big)\,{}^tQ_{2y}=$$

$$\sum_{0\le n\le N'}(2\pi)^{-d}h^{-d+n}\int e^{ih^{-1}\langle x-y,\xi\rangle}q_1(x,\xi,h)\mathcal{F}_n(y,\xi,\tau)[q_2(y,\xi,h)]\,d\xi$$

with

$$(4.3.46)\qquad \mathcal{F}_n=\mathsf{Res}_{\mathbb{R}}(F_n)=\frac{1}{2\pi i}(F_n^{-}-F_n^{+}).$$

Obviously

$$(4.3.47)\qquad \mathsf{supp}\,\mathcal{F}_n=\{(x,\xi,\tau):\ \tau\in\mathsf{Spec}\,a(x,\xi)\}.$$

Moreover,

(4.3.48) Under the assumptions of Proposition 4.3.5

$$\mathcal{F}_n = \mathsf{Res}_{\mathbb{R}}(F_n) = \frac{1}{2\pi i}(F_n^- - F_n^+) \in \mathscr{S}'\big(\mathbb{R}_\tau, \mathscr{C}^s(\Omega, \mathcal{L}(\mathbb{H}_l, \mathbb{H}_{-l}))\big). \tag{4.3.49}$$

Therefore Propositions 4.3.1–4.3.5 yield the following

Proposition 4.3.7. *Let $T \in [h^{1-\delta}, h^{\frac{1}{2}+\delta}]$ with an arbitrarily small exponent $\delta > 0$. Then*

(i) Under the assumptions of Proposition 4.3.1 the following estimates hold $\forall x, y \in \mathbb{R}^d$ $\forall \tau \in \mathbb{R}$:

$$\|F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}u^{\pm}\,{}^tQ_{2y} \pm i\sum_{0\le n\le N'}(2\pi)^{-d-1}h^{-d+n+1}\times \iint T\hat{\chi}(\frac{(\tau-\tau')T}{h})e^{ih^{-1}\langle x-y,\xi\rangle}q_1(x,\xi,h)F_n^{\mp}(y,\xi,\tau')[q_2(y,\xi,h]\,d\tau' d\xi\| \le C'h^s \tag{4.3.50}$$

and

$$\|F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}u\,{}^tQ_{2y} - \sum_{0\le n\le N'}(2\pi)^{-d}h^{-d+n+1}\times \iint T\hat{\chi}(\frac{(\tau-\tau')T}{h})e^{ih^{-1}\langle x-y,\xi\rangle}q_1(x,\xi,h)\mathcal{F}_n(y,\xi,\tau')[q_2(y,\xi,h]\,d\tau' d\xi\| \le C'h^s. \tag{4.3.51}$$

(ii) Under the assumptions of Proposition 4.3.3 this estimate also remains true; in terms of condition $(4.3.21)_3$ one should replace Q_1 and Q_2 by $Q_1\psi_1$ and $\psi_2 Q_2$ respectively.

(iii) Under the assumptions of Proposition 4.3.4 this estimate also holds with Q_1, Q_2 and q_1, q_2 replaced by $Q_1\psi_1 B^j$, $\psi_2 B^k Q_2$ and $q_1 B^j$, $B^k q_2$ respectively (with $j, k \in [0, \bar{l}]$, $j + k \le 1$) and with $\tau \in [-2c, 2c]$;

(iv) Under the assumptions of Proposition 4.3.5 the following estimate holds $\forall x, y \in \mathbb{R}^d\ \forall \tau \in [-2c, 2c]\ \forall j, k \in [0, l]$*:*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)Q_{1x}\psi_1(x)B_1^j u B_1^k \psi_2(y)\,{}^tQ_{2y} - \sum_{0\le n\le N'}(2\pi)^{-d}h^{-d+n+1}\iint T\hat{\chi}\Big(\frac{(\tau-\tau')T}{h}\Big)e^{ih^{-1}\langle x-y,\xi\rangle}q_1(x,\xi,h)\times B_1^j\mathcal{F}_n(y,\tau',\xi)[B_1^k q_2(y,\xi,h)]\,d\tau' d\xi\| \le C'h^s; \tag{4.3.52}$$

further, in this case $\mathcal{F}_n$ *is* $\mathcal{L}(\mathbb{H}_l, \mathbb{H}_{-l})$*-valued distribution.*

Remark 4.3.8. (i) Surely, Remark 4.3.6 remains true with the obvious modifications for the further formulas. In particular, the sum of the left-hand expressions in (4.3.33) (with both signs) is approximately equal[22] to

$$(2\pi)^{-d}h^{-d}\int e^{ih^{-1}\langle x-y,\xi\rangle}\,\mathsf{Res}_{\mathbb{R}}\,\mathsf{symb}_{qp(N')}\big((\tau-A)^{-1}\psi_2 Q_2\big)\,d\xi \tag{4.3.53}$$

which is the Schwartz kernel of the operator $\mathsf{Res}_{\mathbb{R}}\big((\tau-A)^{-1}\psi_2 Q_2\big)$.

(ii) We also have the important formula

$$\mathcal{F}_0(y,\xi,\tau) = \delta\big(\tau - a(y,\xi)\big) = \partial_\tau\theta\big(\tau - a(y,\xi)\big) \tag{4.3.54}$$

(where $\theta(.)$ is the Heaviside function) and

$$\mathcal{F}_1[q_2] = \mathsf{Res}_{\mathbb{R}}\Big\{(\tau-a)^{-1}\Big(a^s + \frac{i}{2}\sum_j\Big(a_{(j)}(\tau-a)^{-1}a^{(j)} - a^{(j)}(\tau-a)^{-1}a_{(j)}\Big)\Big)(\tau-a)^{-1}q_2 + \frac{i}{2}\sum_j\Big((\tau-a)^{-1}a_{(j)}(\tau-a)^{-1}q_2^{(j)} - \big((\tau-a)^{-1}a_{(j)}(\tau-a)^{-1}q_2\big)^{(j)}\Big)\Big\}. \tag{4.3.55}$$

(iii) In particular, as a is scalar

$$\mathcal{F}_1[q_2] = -\delta'(\tau-a)a^s q_2 + \frac{i}{2}\sum_j\Big(-\delta'(\tau-a)a_{(j)}q_2^{(j)} + \big(\delta'(\tau-a)a_{(j)}q_2\big)^{(j)}\Big). \tag{4.3.56}$$

4.3.4 Exploiting Microhyperbolicity and Increasing T

Proposition 4.3.7 holds with any $T \in [h^{1-\delta}, h^{\frac12+\delta}]$ and without microhyperbolicity condition. Let us consider the possibility to increase T in the corollaries of estimates (4.3.51) and (4.3.52) to T which is a small constant and may be beyond; as we know it is very important for the Tauberian method. We also discuss the property of coefficients under microhyperbolicity condition.

Exploiting Microhyperbolicity

Let us set $x = y$ in (4.3.51)

$$F_{t\to h^{-1}\tau}\chi_T(t)\Gamma_x\bigl(Q_{1x}u\,{}^tQ_{2y}\bigr) \equiv \sum_{0\le n\le N'} (2\pi)^{-d}h^{-d+n+1}\times \iint T\hat\chi\Bigl(\frac{(\tau-\tau')T}{h}\Bigr)q_1(x,\xi,h)\mathcal{F}_n(y,\xi,\tau')[q_2(y,\xi,h]\,d\xi d\tau' \tag{4.3.57}$$

and integrate with respect to x

$$F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\bigl(Q_{1x}u\,{}^tQ_{2y}\bigr) \equiv \sum_{0\le n\le N'} (2\pi)^{-d}h^{-d+n+1}\times \iint T\hat\chi\Bigl(\frac{(\tau-\tau')T}{h}\Bigr)q_1(x,\xi,h)\mathcal{F}_n(y,\xi,\tau')[q_2(y,\xi,h]\,dxd\xi d\tau'; \tag{4.3.58}$$

these formulae hold modulo matrices with $\mathcal{L}(\mathbb{H},\mathbb{H})$ or even $\mathcal{L}(\mathbb{H}_l,\mathbb{H}_l)$ norms[23] bounded by Ch^s.

Proposition 4.3.9. *Let the operator A be ξ-microhyperbolic on energy level 0 on $\operatorname{supp} q_1 \cup \operatorname{supp} q_2$ where $q_1, q_2 \in \mathsf{S}_{h,K}(T^*\mathbb{R}^d,\mathbb{H},\mathbb{H})$. Then*

(i) For $T \in [h^{1-\delta}, T_0]$ and $\tau \in [\bar\tau-\epsilon, \bar\tau+\epsilon]$ with small constants $T_0 > 0$, $\epsilon > 0$ equality (4.3.57) holds modulo matrices with $\mathcal{L}(\mathbb{H},\mathbb{H})$ norms bounded by Ch^s.

(ii) Further, then

$$\kappa'_{nx}(\tau) = (2\pi)^{-d}\int q_1(x,\xi,h)\mathcal{F}_n(x,\xi,\tau)[q_2(x,\xi,h)]\,d\xi \tag{4.3.59}$$

belong to $\mathscr{C}_0^s\bigl(\mathbb{R}^d\times[\bar\tau-\epsilon,\bar\tau+\epsilon],\mathcal{L}(\mathbb{H},\mathbb{H})\bigr)$.

[23] In the framework of the corresponding statement of Proposition 4.3.7.

(iii) Moreover, in the framework of Proposition 4.3.5[23)] *equality* (4.3.57) *holds with* Q_1, Q_2 *and* q_1, q_2 *replaced by* $Q_1B_1^j$, Q_2B^k *and* $q_1B_1^j$, $q_2B_1^k$ *with* $j,k \in [0,l]$.

Proposition 4.3.10. *Let the operator* A *be microhyperbolic on energy level* 0 *on* $\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)$ *where* $q_1, q_2 \in \mathsf{S}_{h,K}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$. *Then*

(i) For $T \in [h^{1-\delta}, T_0]$ *and* $\tau \in [\bar\tau - \epsilon, \bar\tau + \epsilon]$ *with small constants* $T_0 > 0$, $\epsilon > 0$ *equality* (4.3.57) *holds modulo matrices with* $\mathcal{L}(\mathbb{H},\mathbb{H})$ *norms bounded by* $C'h^s$.

(ii) Further, then

$$\kappa'_n(\tau) = (2\pi)^{-d} \int q_1(x,\xi,h)\mathcal{F}_n(x,\xi,\tau)[q_2(x,\xi,h)]\,dxd\xi \tag{4.3.60}$$

belong to $\mathscr{C}_0^s\bigl([\bar\tau - \epsilon, \bar\tau + \epsilon], \mathcal{L}(\mathbb{H},\mathbb{H})\bigr)$.

(iii) Moreover, in the framework of Proposition 4.3.5[23)] *equality* (4.3.58) *holds with* Q_1, Q_2 *and* q_1, q_2 *replaced by* $Q_1B_1^j$, Q_2B^k *and* $q_1B_1^j$, $q_2B_1^k$ *with* $j,k \in [0,l]$.

Proof of Propositions 4.3.9, 4.3.10. Let us note that under the microhyperbolicity condition the assertions on the regularity properties of κ'_{nx} and κ_n follow from Appendix 4.A.1.

As we mentioned, for $T \in [h^{1-\delta}, h^{\frac12}+\delta]$ asymptotics (4.3.57) and (4.3.58) are due to (4.3.51), (4.3.52). Let us take $\chi = \bar\chi$ where here we assume that $\bar\chi \in \mathscr{C}_0^K([-1,1])$ equals 1 on $[-\frac34, \frac34]$.

Then Corollary 2.1.17 yields that under corresponding microhyperbolicity condition in the left-hand expressions of (4.3.57) and (4.3.58) one can replace $\bar\chi_T$ by $\bar\chi_{T'}$ with arbitrary $T' \in [h^{1-\delta}, T_0]$; moreover, in the framework of Proposition 4.3.5 we also use the arguments of Subsection 4.2.4.

Further, Proposition 4.3.11 below implies that under corresponding microhyperbolicity condition in the right-hand expressions of (4.3.57) and (4.3.58) one can replace $\bar\chi_T$ by $\bar\chi_{T'}$ with arbitrary $T' \in [h^{1-\delta}, \infty]$. Therefore for $\chi = \bar\chi$ all statements are proven.

Since replacing a factor $\bar\chi$ by a factor $\chi = \chi\bar\chi$ (with χ supported in $[-1,1]$) is equivalent to convoluting the Fourier transform with $2\pi i T\hat\chi(\tau T h^{-1})$ we conclude that the proposition has also been proven for χ. □

Proposition 4.3.11. *(i) Let $\chi = \bar{\chi}$ (equal 1 on $[-\frac{3}{4}, \frac{3}{4}]$). Then under ξ-microhyperbolicity condition or microhyperbolicity condition one can replace in the right-hand expression of* (4.3.57) *or* (4.3.58) *respectively $\bar{\chi}_T$ by $\bar{\chi}_{T'}$ with arbitrary $T' \in [h^{1-\delta}, \infty]$; then $\mathcal{L}(\mathbb{H}, \mathbb{H})$-norm of error does not exceed $C' h^s$.*

(ii) Moreover, in the framework of Proposition 4.3.5 Statement (i) remains true with Q_1, Q_2 and q_1, q_2 replaced by $Q_1 B_1^j$, $Q_2 B^k$ and $q_1 B_1^j$, $q_2 B_1^k$ with $j, k \in [0, l]$.

Remark 4.3.12. As $T = \infty$ and $\chi = \bar{\chi}$ the right-hand expressions of (4.3.57) and (4.3.58) become

$$\sum_{0 \le n \le N'} h^{-d+n+1} \kappa'_{nx}(\tau), \tag{4.3.61}$$

$$\sum_{0 \le n \le N'} h^{-d+n+1} \kappa'_{n}(\tau) \tag{4.3.62}$$

respectively.

Proof of Proposition 4.3.11. Since $\hat{\chi} \in \mathcal{S}$ then in the right-hand expressions of (4.3.57) and (4.3.58) for $\tau \in [\bar{\tau} - \epsilon, \bar{\tau} + \epsilon]$ we can insert an additional factor $\phi(\tau')$ with $\phi \in \mathscr{C}_0^K([\bar{\tau} - 2\epsilon, \bar{\tau} + 2\epsilon]$ equal to 1 on $[\bar{\tau} - \frac{3}{2}\epsilon, \bar{\tau} + \frac{3}{2}\epsilon]$.

Let us note that if $\chi(t)$ is replaced by $t\chi(t)$ then $\hat{\chi}((\tau - \tau')Th^{-1})$ should be replaced by $-ihT^{-1}\partial_{\tau'}\hat{\chi}((\tau - \tau')Th^{-1})$ and integration by parts moves $\partial_{\tau'}$ from $\hat{\chi}((\tau - \tau')Th^{-1})$ to $\phi(\tau')\kappa_{nx}(\tau')$ or $\phi(\tau')\kappa_n(\tau')$.

Repeating this procedure we conclude from the regularity properties of κ_{nx} or κ_n that if we replace $\chi_T(t)$ by $t^r\chi_T(t)$ then we obtain in the right-hand expressions of (4.3.57) and (4.3.58) negligible terms. Taking $\chi(t) = t^{-r}(\bar{\chi}(t\zeta^{-1}) - \bar{\chi}(t))$ we conclude that we can replace T by ζT in the right-hand expression of (4.3.57) and (4.3.58) provided $\chi = \bar{\chi}, \zeta \in [1, 2]$.

Repeating this procedure $\lfloor \log_2(\frac{T'}{T}) \rfloor + 1$ times we conclude that we can replace T by T' provided $\chi = \bar{\chi}$; obviously, we can skip $\phi(\tau')$ now. □

While the previous arguments used microhyperbolicity indirectly through smoothness of κ'_{nx} and κ'_n with respect to τ, the following arguments use it directly through propagation:

Alternative proof of Proposition 4.3.11. Note that without any loss of the generality one can assume ξ-microhyperbolicity; otherwise we can apply metaplectic transformation (exactly as in the proof of Theorem 2.1.19). Let us remember that the right-hand expressions of (4.3.57) came from parametrices $\bar{G}^{\mp}$ and one can apply the same propagation results to them but with any $T \ge h^{1-\delta}$ (since those are parametrices of operators with symbols $A(hD)$ in $\mathbb{R}^d$ scaling brings any $T \ge T_0$ to $T = T_0$). □

Remark 4.3.13. (i) Therefore the microhyperbolicity condition works many times: it allows us to derive Tauberian formula with a sharp remainder estimate; further, it allows us to replace in the Tauberian formula T by $h^{1-\delta}$ without spoiling the remainder estimate and, finally, it implies regularity of the coefficients in the decompositions (4.3.61) or (4.3.62).

(ii) We will discuss if it is possible to increase T further in Section 4.5.

4.4 General Basic Theorems

In this section we obtain and improve local and microlocal semiclassical spectral asymptotics. We consider here the most important and sophisticated case of partial differential operators (possibly with unbounded coefficients). Moreover, the results obtained here remain true for both classes of pseudodifferential operators introduced in Section 4.3[24)] in which case a cutting function ψ_i is not necessary. We assume that

$$Q_i = \mathsf{Op}(q_i)\psi_i,\ \mathsf{supp}(q_i) \subset \Omega \subset \{|\xi| \le c\}, \tag{4.4.1}$$
$$\mathsf{dist}(\mathsf{supp}(q_i), \complement\Omega) \ge \epsilon_0, \psi_i \in \mathscr{C}_0^\infty\big(B(0, \frac{1}{2})\big)$$

while our conditions are fulfilled in $B(0,1)$.

We start from the general case in which no microhyperbolicity condition is assumed, then treat the microhyperbolic case. In both these cases we consider microlocal spectral asymptotics with no global condition (save self-adjointness of operator) assumed.

Then the most special case when conditions on Hamiltonian trajectories are assumed. These conditions are semi-global i.e. imposed where these trajectories reach.

[24)] See conditions $(4.3.21)_1$ and $(4.3.21)_2$.

4.4.1 General Theory: $T \asymp h^{\frac12-\delta}$

Let us start with the most general case. In this case we can derive only asymptotics for (smooth) spectral means:

Theorem 4.4.1. *Let either conditions* $(4.2.13)_1$, $(4.2.14)_1$, (4.2.15), (4.2.16), (4.2.17), $(4.2.20)_1$ *or* $(4.2.13)_{\frac12}$, $(4.2.14)_{\pm}$, (4.2.15), (4.2.21), (4.2.17), $(4.2.20)_{\frac12}$ *be fulfilled.*

Moreover, let conditions (4.4.1) *and* (4.2.100)–$(4.2.102)_l$ *be fulfilled. Let* $q_i \in \mathsf{S}_{h,K}(T^*\mathbb{R}^d, \mathbb{H}, \mathbb{H})$, $|\bar\tau| \le c$ *where as usual* $_*$ *means any subscript (including an empty one).*

Let $\varphi, \varphi_1, \varphi_2 \in \mathscr{C}_0^\infty(\mathbb{R})$ *and*

$$L_* \ge h^{\frac12-\delta}. \tag{4.4.2}$$

Then

(i) The following estimates hold:

$$\mathsf{R}^{\mathsf{W}}_{x,y,\varphi,L}(\bar\tau) := \int \varphi\big(\frac{\tau-\bar\tau}{L}\big)\Big(d_\tau\big(Q_{1x}B_1^j e(x,y,\tau_1,\tau)B_1^k\, {}^tQ_{2y}\big) - \sum_{0\le n\le N-1} h^{-d+n}\int \mathcal{K}'_n(x,y,\tau)\,d\tau\Big) \prec C'h^s \tag{4.4.3}$$

and

$$\mathsf{R}^{\mathsf{W}}_{x,y,\varphi_1,\varphi_2,L_1,L_2}(\bar\tau_1,\bar\tau_2) := \frac{1}{L_1L_2}\iint \Big(Q_{1x}B_1^j e(x,y,\tau',\tau'')B_1^k\, {}^tQ_{2y} - \sum_{0\le n\le N-1} h^{-d+n}\mathcal{K}_n(x,y,\tau',\tau'')\Big)\varphi_1\big(\frac{\tau'-\bar\tau_1}{L_1}\big)\varphi_2\big(\frac{\tau''-\bar\tau_2}{L_2}\big)\,d\tau' d\tau'' \prec C'h^s \qquad \forall x,y\in\mathbb{R}^d \quad \forall j,k\in[0,l] \tag{4.4.4}$$

where s *and* $\delta>0$ *are arbitrary,* $N = N(d,m,s,\delta)$, $K = K(d,m,s,N,\delta)$, $C' = C\|q_1\|\cdot\|q_2\|\cdot\|\psi_1\|\cdot\|\psi_2\|\cdot\|\varphi\|$ *or* $C' = C\|q_1\|\cdot\|q_2\|\cdot\|\psi_1\|\cdot\|\psi_2\|\cdot\|\varphi_1\|\cdot\|\varphi_2\|$,

$$\mathcal{K}'_n(x,y,\tau) = \int e^{ih^{-1}\langle x-y,\xi\rangle} q_1(x,\xi,h)B_1^j\mathcal{F}_n(y,\tau,\xi)B_1^k[q_2(y,\xi,h)]\,d\xi, \tag{4.4.5}$$

and

$$\mathcal{K}_n(.,.,\tau',\tau'') = \int_{\tau'}^{\tau''} \mathcal{K}'_n(.,.,\tau)\,d\tau; \tag{4.4.6}$$

$\mathsf{R}^{\mathsf{W}}_{\dots}$ *with various subscripts means Weyl remainder estimate* [25].

(ii) Without conditions (4.2.100)–(4.2.102)$_\prime$*estimates* (4.4.3) *and* (4.4.4) *remain true with* B^j_1, B^k_1 *replaced by* B^j, B^k, $j,k \in [0,\bar{l}]$;

(iii) Moreover, estimates (4.4.3) *and* (4.4.4) *remain true for* $|\bar{\tau}_*| \le c(L_*+1)$.

Furthermore in the case $B = I$ *one can take arbitrary* $\bar{\tau}_* \in \mathbb{R}$.

Proof. (a) Let us pick $T \in [h^{1-\delta}, h^{\frac12+\delta}]$ such that

$$TL \ge h^{1-\delta} \tag{4.4.7}$$

(which can be done due to condition (4.4.2); we decrease $\delta > 0$ if necessary). Applying (4.2.31) and (4.3.52) we obtain that estimate (4.4.3) holds with $T\hat{\chi}\big((\tau'-\tau)Th^{-1}\big)$ instead of $\varphi\big((\tau-\bar{\tau})L^{-1}\big)$ and with $\tau' \in [-c,c]$.

Let us multiply this estimate by $h^{-1}\varphi\big((\tau-\bar{\tau})L^{-1}\big)$ and integrate over $\tau \in \mathbb{R}$ [26]. Then (4.4.3) holds with the function $\varphi(\lambda)$ replaced by

$$\varphi_\varepsilon(\lambda) = \varepsilon^{-1}\int \varphi(\lambda')\hat{\chi}\big((\lambda-\lambda')\varepsilon^{-1}\big)\,d\lambda', \qquad \varepsilon = \frac{h}{LT}.$$

Let us pick $\chi = \bar{\chi}$. Recall that $\bar{\chi} = 1$ on $[-\frac12, \frac12]$. Then one can easily prove that

$$\varphi_\varepsilon(\lambda) = \varphi(\lambda) + O\big(\varepsilon^s(1+|\lambda|)^{-s}\big).$$

Therefore it is sufficient to estimate the norm of

$$\varepsilon^s \int \big(1+\frac{|\tau-\bar{\tau}|\,T}{h}\big)^{-s} d_\tau \mathsf{N}_{x,y}(\tau) \tag{4.4.8}$$

with $\mathsf{N}_{x,y}$ defined by modified (4.2.32):

$$\mathsf{N}_{x,y}(\tau) := Q_{1x}B^j_1 e(x,y,\tau_1,\tau)B^k_1\ {}^tQ_{2y}. \tag{4.4.9}$$

Dividing this integral into a sum of integrals over intervals $[n,n+1]$ with $n \in \mathbb{Z}$ and applying Proposition 4.2.1 we obtain that the norm of the n-th integral does not exceed $Ch^s(|n|+1)^{-s}$ (recall that $\varepsilon \le h^\delta$) and hence estimate (4.4.3) is proven.

---

[25] Let us recall that $\mathcal{K}'_n$ are distributions with respect to τ; so $\mathcal{K}_n$ are distributions with respect to (τ',τ).

[26] This means exactly that we apply operator $\varphi\big((hD_t-\bar{\tau})L^{-1}\big)$ to $Q_{1x}B^j_1 u B^k_1\ {}^tQ_{2y}$ and to its approximation obtained in the previous section and set $t=0$ afterwards.

(b) Let us prove (4.4.4). Integrating by parts in (4.4.3) and replacing $\partial_\tau\varphi(\tau)$ by $\varphi(\tau)$ we obtain that under the additional restriction

$$\int_{-\infty}^{\infty} \varphi(\tau)d\tau = 0 \tag{4.4.10}$$

the following estimate holds:

$$\mathsf{R}^{\mathsf{W}}_{x,y,\varphi_2,L_2}(\bar\tau_1,\bar\tau_2) \coloneqq L_2^{-1}\int \Big(Q_{1x}B_1^j e(x,y,\bar\tau_1,\tau)B_1^k\, {}^tQ_{2y}\,d\tau - \sum_{0\le n\le N-1} h^{-d+n}\mathcal{K}_n(x,y,\bar\tau_1,\tau)\Big)\varphi\big(\frac{\tau-\bar\tau_2}{L_2}\big)\,d\tau \prec C'h^s \qquad \forall x,y\in\mathbb{R}^d \quad \forall j,k\in[0,l] \tag{4.4.11}$$

where under condition (4.4.10) $\mathsf{R}^{\mathsf{W}}_{x,y,\varphi_2,L_2}$ does not depend on $\bar\tau_1$. It implies (4.4.4) as one of functions φ_1,φ_2 satisfies (4.4.10).

Let us note that the function

$$\varphi(\tau) = \varphi_2(\tau)\int_{-\infty}^{\infty}\varphi_1(\tau''')\,d\tau''' - \varphi_1(\tau)\int_{-\infty}^{\infty}\varphi_2(\tau''')\,d\tau'''$$

satisfies condition (4.4.10); substituting it into (4.4.11) we obtain the difference of two double integrals; let us replace (τ,τ''') in the first integral by (τ'',τ') and in the second one by (τ',τ''); then using the equality $e(.,.,\tau_1,\tau'') - e(.,.,\tau_1,\tau') = e(.,.,\tau',\tau'')$ and similar equalities for $\mathcal{K}_n$ we obtain (4.4.4) as $L = L_1 = L_2$ and $\bar\tau_1 = \bar\tau_2$.

Consider $L = L_1 \le L_2$ (which is not any loss of the generality); then (4.4.4) for $L_2 = L$ implies it for $L_2 \ge L$ with $\varphi_2 \coloneqq \varphi_2 * \varphi_{L/L_2}$ with $\varphi\in\mathscr{C}_0^\infty(\mathbb{R})$ and $\varphi_\varepsilon(\tau) = \varepsilon\varphi(\tau\varepsilon^{-1})$. However, picking φ such that $\int_{\mathbb{R}}\varphi(\tau)\,d\tau = 1$ we note that $\varphi_2 - \varphi_2 * \varphi_{L/L_2}$ satisfies (4.4.10) and thus φ_2 is decomposed into the sum of two functions for which (4.4.4) has been proven. So, we can drop condition $L_1 = L_2$.

Note that

$$e(x,y,\tau_1,\tau_2) = \sum_{i=1,2}(-1)^i\int e(x,y,\tau',\tau_i)\varphi_i(\tau')\,d\tau' \qquad \text{as} \quad \int_{\mathbb{R}}\varphi_i(\tau')\,d\tau' = 1. \tag{4.4.12}$$

Therefore it is sufficient to consider the case $L_2 = 1$. In this case shifting φ_2 we can remove assumption $\bar\tau_2 = \bar\tau_1$.

As $L_* \ge 1$ shifting φ_* replace assumption $|\bar\tau_*| \le c$ in (4.4.33), (4.4.34) by $|\bar\tau_*| \le cL_* + c$

Let us first note that in the case $B = I$, $L \in [h^{\frac12-\delta}, 1]$ one can choose $\bar\tau_i$ arbitrarily (because $\tau : |\tau| \ge C_0$ falls into the semiclassical spectral gap; recall that q_i are compactly supported). □

This theorem combined with Propositions 4.2.3–4.2.5 immediately yields

Theorem 4.4.2. *Let the conditions of Theorem 4.4.1 be fulfilled.*

(i) Moreover, let either conditions of Proposition 4.2.3 be fulfilled in an interval of the length $\ge h^{\frac12-\delta}$ containing $\bar\tau_1$ or let the conditions of one of Propositions 4.2.4, 4.2.5 be fulfilled with $\bar\tau$ replaced by $\bar\tau_1 \in \mathbb{R}$. Finally, let $|\bar\tau_1| \le cL + c$. Then

$$\mathsf{R}^{\mathsf{W}}_{x,y,\varphi_2,L_2}(\bar\tau_1,\bar\tau_2) \prec C'h^s; \tag{4.4.13}$$

here $\mathsf{R}^{\mathsf{W}}_{x,y,\varphi_2,L_2}(\bar\tau_1,\bar\tau_2)$ does not depend (modulo $O(h^s)$) on $\bar\tau_1$ lying in the indicated interval.

(ii) Further, let the assumptions of (i) be fulfilled for $\bar\tau = \bar\tau_1$ as well as for $\bar\tau = \bar\tau_2$. Then

$$\mathsf{R}^{\mathsf{W}}_{x,y}(\bar\tau_1,\bar\tau_2) \coloneqq \mathsf{N}_{x,y}(\bar\tau_1,\bar\tau_2) - \sum_{0\le n\le N-1} h^{-d+n}\mathcal{K}_n(x,y,\bar\tau_1,\bar\tau_2) \prec C'h^s; \tag{4.4.14}$$

here $\mathsf{R}^{\mathsf{W}}_{x,y}(\bar\tau_1,\bar\tau_2)$ does not depend (modulo $O(h^s)$) on $\bar\tau_1,\bar\tau_2$ residing in the indicated intervals.

(iii) Moreover, if conditions $(4.2.14)_\pm$, (4.2.21) *are fulfilled then in Statements (i) and (ii) one can take $\bar\tau_1 = \mp\infty$.*

(iv) If $B = I$ then in in Statements (i) and (ii) one can take $\bar\tau_1 \le -C_0$ (or $\bar\tau_1 = -\infty$ and $\bar\tau_2 \ge C_0$ (or $\bar\tau_2 = \infty$) with sufficiently large C_0.

(v) Assertions (ii) and (iii) of Theorem 4.4.1 remain true for the estimates of this theorem.

Proof. The corresponding proposition of Subsection 4.2.2 yields that in the function to be estimated one can replace τ_1 and (or) τ_2 by any other value from the neighborhood indicated above and hence by the mean value on this interval. On the other hand, for the spectral mean the corresponding estimate is obvious. □

Remark 4.4.3. One can prove easily that if an averaging function φ is not infinitely smooth but merely satisfies (4.2.73)–(4.2.75) then the statements above hold with the remainder estimate $C'h^{-d}\vartheta(h^{\frac{1}{2}-\delta}L^{-1})$.

4.4.2 General Microhyperbolic Theory: $T \asymp 1$

In the previous subsection we found the complete Weyl asymptotics of $\mathsf{N}_{x,y}(\tau_1,\tau_2)$ but with a twist: either τ_* falls into semiclassical spectral gap or it is "tamed" by mollification with $L_* \ge h^{\frac{1}{2}-\delta}$. Now we consider the main theory when at least one of energy levels τ_* neither falls into semiclassical spectral gap nor is "tamed".

Remark 4.4.4. Actually we can assume that only one τ_i is of this type; the general case is reduced to this due to (4.4.12).

Asymptotics with Mollification

Still let us explore first asymptotics with mollification. We know that under ξ-microhyperbolicity (microhyperbolicity) condition complete asymptotics of $F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma_x(Q_{1x}B_1^j uB_1^k\, {}^tQ_{2y})$ ($F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(Q_{1x}B_1^j uB_1^k\, {}^tQ_{2y})$ respectively) was holds for $T \asymp 1$ rather than $T = h^{\frac{1}{2}+\delta}$. Then in virtue of the same arguments as in the previous subsection all the results with applied Γ_x or Γ hold as condition (4.4.2) (which was $L_* \ge h^{\frac{1}{2}-\delta}$)is replaced by

$$L_* \ge h^{1-\delta}. \tag{4.4.15}$$

Theorem 4.4.5. *Let assumptions of Theorem 4.4.1 be fulfilled with* (4.4.2) *replaced by* (4.4.15).

Further, let A be ξ-microhyperbolic on $\mathsf{supp}(q_1)\cap\mathsf{supp}(q_2)$ on the energy level $\bar{\tau}_*$. Then

(i) The following estimates hold

$$\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}(\bar\tau) \coloneqq \int \varphi\big(\frac{\tau-\bar\tau}{L}\big)\Big(d_\tau \Gamma_x\big(Q_{1x}B_1^j e(x,y,\tau_1,\tau)B_1^k\, {}^tQ_{2y}\big) - \sum_{0\le n\le N-1} h^{-d+n}\int \kappa'_{nx}(\tau)\,d\tau\Big) \prec C'h^s \tag{4.4.16}$$

and

$$\mathsf{R}^{\mathsf{W}}_{x,\varphi_1,\varphi_2,L_1,L_2}(\bar\tau_1,\bar\tau_2) \coloneqq \frac{1}{L_1L_2}\iint \Gamma_x\Big(Q_{1x}B_1^j e(x,y,\tau',\tau'')B_1^k\, {}^tQ_{2y} - \sum_{0\le n\le N-1} h^{-d+n}\kappa_{nx}(\tau',\tau'')\Big)\varphi_1\big(\frac{\tau'-\bar\tau}{L_1}\big)\varphi_2\big(\frac{\tau''-\bar\tau}{L_2}\big)\,d\tau' d\tau'' \prec C'h^s \qquad \forall x,y\in\mathbb{R}^d \quad \forall j,k\in[0,l] \tag{4.4.17}$$

with the same s, $\delta>0$, N, K, C' *as before.*

(ii)–(iii) Statements (ii)–(iii) of Theorem 4.4.1 remain true with (4.4.16), (4.4.17) *instead of* (4.4.3), (4.4.4).

Theorem 4.4.6. *Let assumptions of Theorem 4.4.1 be fulfilled with* (4.4.2) *replaced by* (4.4.15).

Further, let A *be microhyperbolic on* $\mathsf{supp}(q_1)\cap\mathsf{supp}(q_2)$ *on the energy level* $\bar\tau_*$. *Then all the results of Theorem 4.4.5 remain true with* Γ_x *replaced by* Γ *and* κ_{nx}, κ'_{nx} *replaced by* κ_n, κ'_n *respectively.*

One can modify Theorem 4.4.2 in the same way as well.

Remark 4.4.7. Usually in asymptotics of N_{x*} one needs to assume ξ-microhyperbolicity at $\mathsf{supp}(q_1)\cup\mathsf{supp}(q_2)$ but in this section due to the finite speed of propagation we can to assume ξ-microhyperbolicity at $\mathsf{supp}(q_1)\cap\mathsf{supp}(q_2)$ instead.

Asymptotics without Mollification

The following statement immediately follows from the Tauberian estimates of Section 4.2 and calculations of Section 4.3:

Theorem 4.4.8. *Let assumptions of Theorem 4.4.1 be fulfilled with* (4.4.2) *replaced by*

$$L_* \ge h. \tag{4.4.18}$$

Further, let A be ξ-microhyperbolic on $\mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$ on the energy level $\bar\tau_*$. Then

(i) The following estimate holds:

$$\mathsf{R}^{\mathsf{W}}_x(\bar\tau_1,\bar\tau_2) \coloneqq \Gamma_x\big(Q_{1x}B_1^j e(x,y,\bar\tau_1,\bar\tau_2)B_1^k\, {}^tQ_{2y} - \sum_{0\le n\le N-1} h^{-d+n}\kappa_{nx}(\bar\tau_1,\bar\tau_2)\big) \prec C'h^{1-d} \tag{4.4.19}$$

(ii) As φ_* satisfy (4.2.73)–(4.2.75) *the following estimates hold:*

$$\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}(\bar\tau) \prec C'h^{1-d}\vartheta\big(\frac{h}{L}\big), \tag{4.4.20}$$

$$\mathsf{R}^{\mathsf{W}}_{x,\varphi_1,L_1,\varphi_2,L_2}(\bar\tau_1,\bar\tau_2) \prec C'h^{1-d}\vartheta_1\big(\frac{h}{L_1}\big) + C'h^{1-d}\vartheta_2\big(\frac{h}{L_2}\big) \tag{4.4.21}$$

with the left-hand expressions defined by (4.4.16) *and* (4.4.17).

Theorem 4.4.9. *Let assumptions of Theorem 4.4.1 be fulfilled with* (4.4.2) *replaced by* (4.4.18). *Further, let A be microhyperbolic on $\mathsf{supp}(q_1)\cap\mathsf{supp}(q_2)$ on the energy level $\bar\tau_*$. Then all the results of Theorem 4.4.8 remain true with $\mathsf{R}^{\mathsf{W}}_{x*}$ replaced by $\mathsf{R}^{\mathsf{W}}_*$ and κ_{nx}, κ'_{nx} replaced by κ_n, κ'_n respectively.*

Remark 4.4.10. (i) In Theorem 4.4.8 one can skip ξ-microhyperbolicity condition on some level $\bar\tau_i$ by making mollification with $\varphi_i \in \mathscr{C}_0^\infty(\mathbb{R})$ and $L_* \ge h^{1-\delta}$ in then (4.4.19) or just assuming that $\varphi_* \in \mathscr{C}_0^\infty(\mathbb{R})$ and $L_* \ge h^{1-\delta}$ in (4.4.21). The similar statement in the framework of Theorem 4.4.9 also holds.

(ii) In asymptotics without averaging only one term $\kappa_{0x}h^{-d}$ or $\kappa_0 h^{-d}$ is needed. In the asymptotics with averaging one can skip all the terms such that $t^{n-1} \lesssim \vartheta(t)$ for all $t \ll 1$ (obviously this is true as $L \lesssim 1$; as $L \gtrsim 1$ we apply Statement (iii) below). One can skip even more terms as $L \ll 1$.

(iii) One can prove easily that under ξ-microhyperbolicity condition

$$(\kappa'_{nx} * \varphi_L)(\bar\tau) = O(L^{-n}) \qquad \text{as} \quad L \ge 1 \tag{4.4.22}$$

and under microhyperbolicity condition this is true for κ'_n.

(iv) One can easily improve asymptotics derived in the previous subsections to $O(h^s L^{-s})$ as $L \ge h^{-M}$.

Improved Asymptotics without Mollification

Here we will improve asymptotics without mollification. Actually this improvement will be probably superficial in the current settings but it will open the door for the real improvement under conditions of the semi-global nature in the next section. Let us observe that we know now (4.1.12)- or (4.1.11)-like expressions with far better precision than before and therefore as $Q_2 = Q_1^*$ and $j = k$ we have estimates

$$\Gamma_x\Big(F_{t\to h^{-1}\tau}\chi_T(t) Q_{1x} B_1^j u(x,y,t) B_1^k\, {}^t Q_{2y}\Big) \prec C_0 J_x(q_1^0 B_1^j, \tau) h^{1-d} + C' h^{2-d} \tag{4.4.23}$$

and

$$\Gamma\Big(F_{t\to h^{-1}\tau}\chi_T(t) Q_{1x} B_1^j u(x,y,t) B_1^k\, {}^t Q_{2y}\Big) \prec C_0 J(q_1^0 B_1^j, \tau) h^{1-d} + C' h^{2-d} \tag{4.4.24}$$

as $|\tau - \bar\tau| \le \epsilon$ under ξ-microhyperbolicity and microhyperbolicity assumptions respectively where

$$J_x(q_1^0 B_1^j, \tau) \coloneqq \int q_1^0 B_1^j \, d_\xi \mu_{\tau x}\, B_1^j q_1^0 \tag{4.4.25}$$

$$J(q_1^0 B_1^j, \tau) \coloneqq \int q_1^0 B_1^j \, d_{(x,\xi)} \mu_\tau\, B_1^j q_1^0 \tag{4.4.26}$$

q_i^0 is the principal symbol of Q_i,

$$\mu_\tau = \delta\big(\tau - a(x,\xi)\big) = \partial_\tau \theta\big(\tau - a(x,\xi)\big) \tag{4.4.27}$$

is a non-negative $\mathcal{L}(\mathbb{H},\mathbb{H})$-valued measure and $\mu_{\tau x}$ is the same measure for given x.

Finally, here and below $C_0 = C_0(d, \vartheta, \varphi)$ is an absolute constant; so $C_0 = C_0(d)$ in the most important case $\vartheta = \varphi = 1$.

Indeed, the leading coefficients in the asymptotics of the left-hand expressions are $\kappa'_{0x}(\tau)$ and $\kappa'_0(\tau)$ which due to (4.3.52), (4.3.54), (4.3.60) and (4.3.59) are exactly

$$\kappa'_{0x}(\tau) \coloneqq (2\pi)^{-d} \int q_1^0 B_1^j \, \delta\big(\tau - a(x,\xi)\big)\, B_1^j q_2^0 \, d\xi \tag{4.4.28}$$

and

$$\kappa'_0(\tau) \coloneqq (2\pi)^{-d} \int q_1^0 B_1^j \, \delta\big(\tau - a(x,\xi)\big)\, B_1^j q_2^0 \, dx d\xi \tag{4.4.29}$$

respectively and coincide with J_{0x}, J_0 as $q_2^0 = q_1^{0\dagger}$ and $j = k$.

Estimates (4.4.23), (4.4.24) replace previously used estimates with $C'h^{1-d}$ right-hand expressions. Let us recall that

(4.4.30) Under ξ-microhyperbolicity condition $J_x(q_1^0 B_1^j, \tau)$ is a smooth function of (x, τ). Under microhyperbolicity condition $J(q_1^0 B_1^j, \tau)$ is a smooth function of τ.

Taking Hörmander function χ and applying Lemma 4.2.7) we derive easily from (4.4.24) that for $j = k$ and $Q_2 = Q_1^*$ under microhyperbolicity or ξ-microhyperbolicity on the energy level 0

$$\mathsf{N}(\tau', \tau'') \prec C_0 g^*(\tau', \tau''), \tag{4.4.31}$$

$$\mathsf{N}_x(\tau', \tau'') \prec C_0 g_x^*(\tau', \tau'') \tag{4.4.32}$$

with g^*, g_x^* defined by (4.2.35) where g, g_x are right-hand expressions of (4.4.24), (4.4.23) respectively as $|\tau - \bar\tau| \le \epsilon_0$; we do not change definition (4.2.87) of $g(\tau) = g_x(\tau) = C'T(|\tau| + 1)^{2l}$ as $|\tau - \bar\tau| \ge \epsilon_0$.

Now again we want to get rid of assumption $j = k$, $Q_2 = Q_1^*$. For this purpose we still under this assumption rewrite (4.4.31) or (4.4.32) respectively as

$$|(\mathsf{N}(\tau', \tau'')w, w)| \le C_0 (g^*(\tau', \tau'')w, w),$$
$$|(\mathsf{N}_x(\tau', \tau'')w, w)| \le C_0 (g_x^*(\tau', \tau'')w, w)$$

for all $w \in \mathbb{H}$.

Then arguments of the proof of Proposition 4.2.19 imply that without assumption $j = k$, $Q_2 = Q_1^*$

$$|(\mathsf{N}(\tau',\tau'')w,w)| \le C_0(g_1^*(\tau',\tau'')w,w)^{\frac12}(g_2^*(\tau',\tau'')w,w)^{\frac12}, \tag{4.4.33}$$

$$|(\mathsf{N}_x(\tau',\tau'')w,w)| \le C_0(g_{x1}^*(\tau',\tau'')w,w)^{\frac12}(g_{x2}^*(\tau',\tau'')w,w)^{\frac12} \tag{4.4.34}$$

respectively where subscript $_1$, $_2$ refers to g, g^* defined with $Q_1B_1^j$ and $Q_2B_2^k$.

Then

$$\begin{aligned}&|(\mathsf{N}(\tau',\tau'')w,w)| \le C_0(g_1^*(\tau',\tau'')w,w) + C_0(g_2^*(\tau',\tau'')w,w),\\ &|(\mathsf{N}_x(\tau',\tau'')w,w)| \le C_0(g_{x1}^*(\tau',\tau'')w,w) + C_0(g_{x2}^*(\tau',\tau'')w,w)\end{aligned}$$

respectively and we do not need w anymore.

Now we can apply Lemmas 4.2.13, 4.2.15; we need to calculate $\mathcal{R}(\bar\tau)$ according to (4.2.65). Since due to (4.4.30)

$$g(\tau) = g(\bar\tau) + O\big(h^{1-d}|\tau-\bar\tau| + h^{2-d}\big)$$

we conclude that $\mathcal{R}(\bar\tau) = g(\bar\tau) + O(T^{-1}h^{2-d} + h^{2-d})$.

Therefore we arrive to estimates with the right hand expressions defined by these calculations:

$$\mathsf{R}^{\mathsf{T}}_{\varphi_2,L_2}(\bar\tau,\bar\tau_2) \prec \frac{h^{1-d}}{T}\Big(C_0J(q_1^0B_1^j,\bar\tau) + C_0J(q_2^0B_1^k,\bar\tau) + C'\frac{h}{T} + C'h\Big) \tag{4.4.35}$$

and

$$\begin{aligned}&\mathsf{R}^{\mathsf{T}}_{\varphi,L,\varphi_2,L_2}(\bar\tau,\bar\tau_2) \prec\\ &\qquad \frac{h^{1-d}}{T}\Big(C_0J(q_1^0B_1^j,\bar\tau) + C_0J(q_2^0B_1^k,\bar\tau) + C'\frac{h}{T} + C'h\Big)\vartheta\big(\frac{h}{LT}\big)\end{aligned} \tag{4.4.36}$$

provided $\bar\tau_2 = \bar\tau$ and $\varphi_2 \in \mathscr{C}_0^\infty(\mathbb{R})$ while φ satisfies (4.2.73)–(4.2.75).

These estimates hold under microhyperbolicity condition; the similar estimates (with J_x, R^{T}_{x*}) hold under ξ-microhyperbolicity condition.

Let us recall that $T \asymp 1$ in the current settings. Also in virtue of the calculations of the Section 4.3 we can replace $\mathsf{R}^{\mathsf{T}}_*$ by $\mathsf{W}^{\mathsf{T}}_*$. Then we arrive to estimates (4.4.38) and (4.4.39) below but only as $\bar\tau_2 = \bar\tau_1$ and $\varphi_2 \in \mathscr{C}_0^\infty(\mathbb{R})$. However in virtue of (4.4.12) we can remove these restrictions arriving to the improved versions of Theorems 4.4.8 and 4.4.9:

Theorem 4.4.11. *Let assumptions of Theorem 4.4.1 be fulfilled with* (4.4.2) *replaced by* (4.4.18). *Further, let* A *be* ξ*-microhyperbolic on* $\mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$ *on the energy level* $\bar\tau_*$. *Then for* $j, k \le l$

$$\mathsf{R}^{\mathsf{W}}_x(\bar\tau_1, \bar\tau_2) \prec \sum_{*=1,2} C_0 \frac{h^{1-d}}{T_0}\Big(J_x(q_1^0 B_1^j, \bar\tau_*) + J_x(q_2^0 B_1^k, \bar\tau_*) + C'h\Big), \tag{4.4.37}$$

$$\begin{aligned}\mathsf{R}^{\mathsf{W}}_{x,\varphi_2,L_2}(\bar\tau_1, \bar\tau_2) \prec\ & C_0 \frac{h^{1-d}}{T_0}\Big(J_x(q_1^0 B_1^j, \bar\tau_1) + J_x(q_2^0 B_1^k, \bar\tau_1) + C'h\Big) + \\ & C_0 \frac{h^{1-d}}{T_0}\Big(J_x(q_1^0 B_1^j, \bar\tau_2) + J_x(q_2^0 B_1^k, \bar\tau_2) + C'h\Big)\vartheta_2\big(\frac{h}{L_2 T_0}\big)\end{aligned} \tag{4.4.38}$$

and

$$\begin{aligned}&\mathsf{R}^{\mathsf{W}}_{x,\varphi_1,L_1,\varphi_2,L_2}(\bar\tau_1, \bar\tau_2) \prec \\ &\qquad \sum_{*=1,2} C_0 \frac{h^{1-d}}{T_0}\Big(J_x(q_1^0 B_1^j, \bar\tau_*) + J_x(q_2^0 B_1^k, \bar\tau_*) + C'h\Big)\vartheta_*\big(\frac{h}{L_* T_0}\big)\end{aligned} \tag{4.4.39}$$

with the left-hand expressions defined respectively by (4.4.19), (4.4.16) *and* (4.4.17).

Theorem 4.4.12. *Let assumptions of Theorem 4.4.1 be fulfilled with* (4.4.2) *replaced by* (4.4.18). *Further, let* A *be microhyperbolic on* $\mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$ *on the energy level* $\bar\tau_*$. *Then all the results of Theorem 4.4.11 remain true with* $\mathsf{R}^{\mathsf{W}}_{x*}$ *replaced by* $\mathsf{R}^{\mathsf{W}}_*$ *and* κ_{nx}, κ'_{nx} *replaced by* κ_n, κ'_n *respectively.*

Useful Formulae

Remark 4.4.13. (i) Due to (4.4.28), (4.4.29)

$$\kappa_{0x}(\tau) := (2\pi)^{-d} \int q_1^0 B_1^j\, \theta\big(\tau - a(x,\xi)\big)\, B_1^j q_2^0\, d\xi \tag{4.4.40}$$

and

$$\kappa_0(\tau) := (2\pi)^{-d} \int q_1^0 B_1^j\, \theta\big(\tau - a(x,\xi)\big)\, B_1^j q_2^0\, dx d\xi. \tag{4.4.41}$$

(ii) Formulae for the next coefficients are rather complicated. Formulae for κ_{1x}, κ_1 are due to (4.3.52), (4.3.55), (4.3.60) and (4.3.59). In particular, in the case of scalar a (4.3.56) implies that

$$\kappa_{1x} = (2\pi)^{-d} \int \delta(\tau - a)\Big(-q_1^0 a^s q_2^0 - \frac{i}{2}\{a, q_1^0 q_2^0\}\Big)\, d\xi + (2\pi)^{-d} \int \theta(\tau - a)(q_1 q_2)^s \, d\xi \tag{4.4.42}$$

where $(q_1 q_2)^s$ is subprincipal symbol of $Q_1 Q_2$. Important is that as $Q_1 = Q_2 = I$ (we can set it only formally now)

$$\kappa_{1x} = -(2\pi)^{-d} \int \delta(\tau - a) a^s \, d\xi. \tag{4.4.43}$$

Similar formulae hold for κ_1.

(iii) Again, as $Q_1 = Q_2 = I$ but in the matrix case there is an extra term due to the second line in (4.3.55). The explicit formula and geometric interpretation of this term see in O. Chervova, R. J. Downes and D. Vassiliev [1, 2].

Problem 4.4.14. Consider (magnetic) Schrödinger operator

$$H = (-ih\nabla - \boldsymbol{A}(x))^2 + V(x)$$

and take $Q_1 = -ih\partial_j - A_j(x)$, $Q_2 = I$. Then obviously $\kappa_{0x} = 0$ and we leave to the reader to prove that $\kappa_{1x} = \mathsf{const}\, \partial_j (\tau - V(x))^{d/2}$ and calculate the constant.

Remark 4.4.15. Assume that Q_1, Q_2 are scalar operators. Then one can set $j = k = I$ in (4.4.37) and multiplying by B_1^{-I} from both sides one can rewrite it as

$$\mathsf{R}^{\mathsf{W}}_x(\bar\tau_1, \bar\tau_2) \prec h^{1-d} \sum_{*=1,2} \Big(C_0 \int (|q_1^0|^2 + |q_2^0|^2)\, d_\xi \mu_{x\bar\tau_*} + C' h B_1^{-2I} \Big) \tag{4.4.44}$$

where now the left-hand expression is defined by (4.4.19) with $j = k = 0$. Then

$$|\,\mathsf{tr}\big(\mathsf{R}^{\mathsf{W}}_x(\bar\tau_1, \bar\tau_2)\big)| \le h^{1-d} \sum_{*=1,2} \Big(C_0 \int (|q_1^0|^2 + |q_2^0|^2)\, d_\xi(\mathsf{tr}(\mu_{x\bar\tau_*})) + C' h\, \mathsf{tr}(B_1^{-2I}) \Big). \tag{4.4.45}$$

One can modify all other estimates in the same way.

4.5 Long Term Propagation and Sharper Remainder Estimates

4.5.1 Preliminary Discussion

Increasing T

In the previous section we under microhyperbolicity (or ξ-microhyperbolicity) condition increased T to a small constant T_0. Now we want to increase it further but in a such way that expression

$$F_{t\to h^{-1}\tau}\Big(\bar{\chi}_T(t)\Gamma\big(Q_{1x}u\,{}^tQ_{2y}\big)\Big) \tag{4.5.1}$$

or

$$F_{t\to h^{-1}\tau}\Big(\bar{\chi}_T(t)\Gamma_x\big(Q_{1x}u\,{}^tQ_{2y}\big)\Big) \tag{4.5.2}$$

would change negligibly for τ in the vicinity of $\bar{\tau}$. Then (almost) the same estimate for this expression with this new T would have place as it was for $T = T_0$ which would allow us to estimate the Tauberian error by

$$\frac{h^{1-d}}{T}\Big(C_0J(q_1^0B_1^j,\bar{\tau}) + C_0J(q_2^0B_1^k,\bar{\tau}) + C'\frac{h}{T} + C'h\Big)\vartheta\big(\frac{h}{LT}\big) \tag{4.5.3}$$

or

$$\frac{h^{1-d}}{T}\Big(C_0J_x(q_1^0B_1^j,\bar{\tau}) + C_0J_x(q_2^0B_1^k,\bar{\tau}) + C'\frac{h}{T} + C'h\Big)\vartheta\big(\frac{h}{LT}\big) \tag{4.5.4}$$

where $\vartheta = 1$ if there is no averaging (but then we take mollification with respect to the second energy level) where now T means "new" T.

However then the Tauberian expressions should change by

$$F_{t\to h^{-1}\tau}\Big(\big(\bar{\chi}_T(t) - \bar{\chi}_{T_0}(t)\big)\Gamma\big(Q_{1x}u\,{}^tQ_{2y}\big)\Big) \tag{4.5.5}$$

or

$$F_{t\to h^{-1}\tau}\Big(\big(\bar{\chi}_T(t) - \bar{\chi}_{T_0}(t)\big)\Gamma_x\big(Q_{1x}u\,{}^tQ_{2y}\big)\Big) \tag{4.5.6}$$

integrated from $-\infty$ to $\bar{\tau}$. We know that this operation is equivalent to the substitution

$$\big(\bar{\chi}_T(t) - \bar{\chi}_{T_0}(t)\big) \ \mapsto\ iht^{-1}\big(\bar{\chi}_T(t) - \bar{\chi}_{T_0}(t)\big) \tag{4.5.7}$$

and pinning $\tau = \bar{\tau}$. The same *no-periodicity* or *no-loop* condition which ensures respectively the negligibility of (4.5.5) or (4.5.6) also ensures the negligibility of these side-kicks.

Since we know that under microhyperbolicity or ξ-microhyperbolicity condition one can replace Tauberian expression for $T = T_0$ by Weyl expression, it is now true for new T as well. Therefore *Weyl error will be also estimated by* (4.5.3) *or* (4.5.4).

Synthesis

However it is not realistic to expect that no-periodicity or no-loop condition we use to derive such improved remainder estimates is fulfilled in every point of $\mathsf{supp}(q_1)$ or $\mathsf{supp}(q_2)$. To overcome this problem we will use different approaches in he cases of Γ- and Γ_x-related expressions.

In the former (Γ) case we replace our *original* operators Q_1 and Q_2 by $Q_{1i} = R_i Q_1$ and $Q_2 = R_i^* Q_2$ where

(4.5.8) R_i are *scalar pseudodifferential operators*

and assume the non-periodicity condition with time T_i on $\mathsf{supp}(r_i) \cap \mathsf{supp}(q_1)$ or $\mathsf{supp}(r_i) \cap \mathsf{supp}(q_2)$ for $i = 1, \dots, m$ while for $i = 0$ we pick up T_0 as a small constant. Then we estimate the error in question by

$$C_0 \frac{h^{1-d}}{T_i} \vartheta\Big(\frac{h}{LT_i}\Big)\big(J(r_i^0 q_1^0 B_1^j, \bar{\tau}) + J(r_i^0 q_2^0 B_1^k, \bar{\tau}) + C'h\Big). \tag{4.5.9}$$

Now we select R_i such that

$$\sum_{0\le i\le m} R_i^* R_i \equiv I, , \tag{4.5.10}$$

and thus

$$\sum_{0\le i\le m} |r_i^0|^2 = 1, . \tag{4.5.11}$$

Note that due to (4.5.8)

$$\Gamma\big(R_i Q_{1x} v(x,y)\, {}^t Q_{2y}\big) = \Gamma\big(Q_{1x} e(\dots)\, {}^t(R_i Q_2)_y\big). \tag{4.5.12}$$

Plugging $Q_2 \coloneqq R_i^* Q_2$ we arrive due to (4.5.10) to

$$\Gamma\big(Q_{1x} v(x,y)\, {}^t Q_{2y}\big) \equiv \sum_{0\le i\le m} \Gamma\big(R_i Q_{1x} v(x,y)\, {}^t(R_i^* Q_2)_y\big) \tag{4.5.13}$$

and also to

$$\kappa_n = \sum_{0\le i\le m} \kappa_{ni} \tag{4.5.14}$$

where κ_{ni} is coefficient κ_n calculated for pair $Q_{1i} = R_i Q_1$ and $Q_2 = R_i^* Q_2$. Then

$$\mathsf{N} = \sum_{0\le i\le m} \mathsf{N}_i,\ \mathsf{N}^{\mathsf{W}} = \sum_{0\le i\le m} \mathsf{N}_i^{\mathsf{W}}\ (\implies)\ \mathsf{R}^{\mathsf{W}} = \sum_{0\le i\le m} \mathsf{R}_i \tag{4.5.15}$$

in the obvious notations.

Therefore $\mathsf{R}_*^{\mathsf{W}}$ will be estimated by the sum of expressions (4.5.9) which is

$$C_0 \sum_{0\le i\le m} \frac{h^{1-d}}{T_i}\vartheta\big(\frac{h}{LT_i}\big)\Big(J(r_i^0 q_1 B_1^j, \bar\tau) + J(r_i^0 q_2 B_1^k, \bar\tau) + C'h\Big). \tag{4.5.16}$$

Note that due to (4.5.11), (4.5.8)

$$\sum_{0\le i\le m} J(r_i^0 q_1^0 B_1^j, \bar\tau) = J(q_1^0 B_1^j, \bar\tau) \tag{4.5.17}$$

which shows that inserting r_i^0 into $J(.,.)$ does not hurt.

On the other hand, as far as Γ_x-expressions are concerned the bulk of our arguments will not work; instead we simply decompose Q_1 and Q_2 into sums of operators. Then estimate would depend on m in a more explicit way. However in applications usually $m = 2$ in this case.

Later we will apply these improved (no double summation) versions of (4.5.9) and (4.5.10) in the following context: $T_1, \dots, T_m$ are large, T_0 is a fixed small constant.

Sharp and Sharper

So, to increase T we need to prove that (4.5.5)- or (4.5.6)-like expressions are negligible. For this purpose we will use propagation results of Chapters 2 and 3. However, there are *two* kinds of results: first there are standard results of Sections 2.1, 2.2 and 3.1–3.4 when we can take T as an arbitrarily large constant and long-term results of Sections 2.4 and 3.5 when depending on conditions we can take T up to $h^{-\delta}$ with sufficiently small exponent $\delta > 0$.

The results of the first kind allow us to acquire an arbitrarily small constant factor ε in the estimate of the contribution of the corresponding element Q_i with $i \geq 1$ [27)] to Weyl error basically going from "O"-type estimates to "o"-type estimates. However contribution of Q_0 is not improved this way and so not to lose the improvement we achieved we need to take Q_0 with an arbitrarily small but fixed support; "small" means here that $J_*(q_0^0 B_1^j, \bar\tau)$ is small (less than ε). Actually we cannot do better in the framework of the standard theory. In this case C' depends also on T. We will do it in Subsection 4.5.2.

The results of the second kind allow us to acquire a smaller factor ε in the estimate of the contribution of the corresponding element Q_i with $i \geq 1$ [27)] to Weyl error; now ε is a small but not very small parameter $\varepsilon \geq h^\delta$. Then not to lose this improvement we need to take Q_0 with a really small support; "small" means again that $J_*(q_0^0 B_1^j, \bar\tau) \leq \varepsilon$ but "really" indicates that ε is a parameter now. We can accommodate this only with Q with variable size support and in this case the theory of the previous Section 4.4 needs to be rebuilt. We will do it in Subsection 4.5.3.

Finally, Subsection 4.5.4 is devoted to simplest applications, examples and discussions.

4.5.2 Standard Sharp Theory

Analysis of Wave Front Sets

Let us recall that according to Theorem 1.3.13

$$\begin{aligned}(4.5.18)\quad &\mathsf{WF}(\Gamma_x Q_{1x} u\, {}^t Q_{2y}) \subset \big\{(x,\zeta,t,\tau):\ \exists \xi,\eta \text{ s.t. } \zeta = \xi - \eta\\ &\qquad \text{and } (x,\xi,x,-\eta,t,\tau) \in \mathsf{WF}(u),\ (x,\xi)\in \mathsf{supp}(q_1),\ (y,\eta)\in \mathsf{supp}(q_2)\big\}\end{aligned}$$

and

$$\begin{aligned}(4.5.19)\quad &\mathsf{WF}(\Gamma Q_{1x} u\, {}^t Q_{2y}) \subset \big\{(t,\tau):\ \exists x,\xi \text{ s.t.}\\ &\qquad (x,\xi,x,-\xi,t,\tau) \in \mathsf{WF}(u),\ (x,\xi)\in \mathsf{supp}(q_1)\cap \mathsf{supp}(q_2)\big\}.\end{aligned}$$

Meanwhile

$$(4.5.20)\quad (x,\xi,y,-\eta,t,\tau)\notin \mathsf{WF}(u) \implies \tau \in \mathsf{Spec}\, a(x,\xi)\cap \mathsf{Spec}\, a(y,\eta)$$

[27)] We ignore double summation and even the presence of the second factor in this discussion.

and according to Theorem 2.2.10 for bounded T

(4.5.21) $(x,\xi,y,-\eta,t,\tau)\notin \mathsf{WF}(u)$ provided *either*

(i) There exists a complete Hamiltonian flow $\Psi_{\tau,t'}(y,\eta)$ for $t'/t\in[0,1]$ which stays where symbol $A(.,.)$ is smooth and does not hit the boundary[28)] and $(x,\xi)\notin \Psi_{\tau,t}(y,\eta)$ *or*

(ii) There exists a complete Hamiltonian flow $\Psi_{\tau,-t'}(y,\eta)$ for $t'/t\in[0,1]$ which stays where symbol $A(.,.)$ is smooth and does not hit the boundary[28)] and $(y,\eta)\notin \Psi_{\tau,t}(x,\xi)$.

where $\Psi_{\tau,-t'}$ is a generalized Hamiltonian flow (possibly multivalued) on the energy level τ generated by symbol $-a$ [29)].

Then combining this claim with (4.5.18) we arrive to

(4.5.22) $(x,\zeta,t,\tau)\notin \mathsf{WF}(\Gamma_x Q_{1x}u\,{}^tQ_{2y})$ provided *either*

(i) For each $(y,\eta)\in \mathsf{supp}\, q_2$ s.t. $\tau\in a(y,\eta)$ there exists complete Hamiltonian flow $\Psi_{\tau,t'}(y,\eta)$ for $t'/t\in[0,1]$ which stays where symbol $A(.,.i)$ is smooth and does not hit the boundary[28)] and for each $(x,\xi)\in\Psi_t(y,\eta)$ either $x\neq y$ or $\zeta\neq\xi-\eta$ *or*

(ii) For each $(x,\xi)\in \mathsf{supp}\, q_1$ s.t. $\tau\in a(x,\xi)$ there exists complete Hamiltonian flow $\Psi_{\tau,-t'}(x,\xi)$ for $t'/t\in[0,1]$ which stays where symbol $A(.,.)$ is smooth and does not hit the boundary[28)] and for each $(y,\eta)\in\Psi_{-t}(x,\xi)$ either $x\neq y$ or $\zeta\neq\xi-\eta$.

Moreover, combining claim (4.5.21) with (4.5.19) we arrive to

(4.5.23) $(t,\tau)\notin \mathsf{WF}(\Gamma Q_{1x}u\,{}^tQ_{2y})$ provided *either*

(i) For each $(x,\xi)\in \mathsf{supp}(q_2)\cap\mathsf{supp}(q_1)$ s.t. $\tau\in a(x,\xi)$ there exists complete Hamiltonian flow $\Psi_{\tau,t'}(x,xi)$ for $t'/t\in[0,1]$ which stays where symbol $A(.,.i)$ is smooth and does not hit the boundary[28)] and $(x,\xi)\notin\Psi_t(x,\xi)$ *or*

(ii) Above condition (i) is fulfilled for t replaced by $-t$.

[28)] If we consider differential operators in domain with the boundary.

[29)] Where $z\in\Psi_{\tau,\pm t}(z')$ with $t>0$ simply means by definition that $(z;\pm t,\tau)\in \mathcal{K}_t^{\pm}(\tau-a,(z;0,\tau))$. We prefer to use terminology of the Hamiltonian flows.

Periodic Trajectories and Loops

Let us discuss what conditions of (4.5.22) and (4.5.23) actually mean.

Assume first that the complete Hamiltonian flow exists and is a single-valued. Then condition (4.5.22)(i) is equivalent to (4.5.22)(ii) and if we are not interested in ζ this condition simply means that

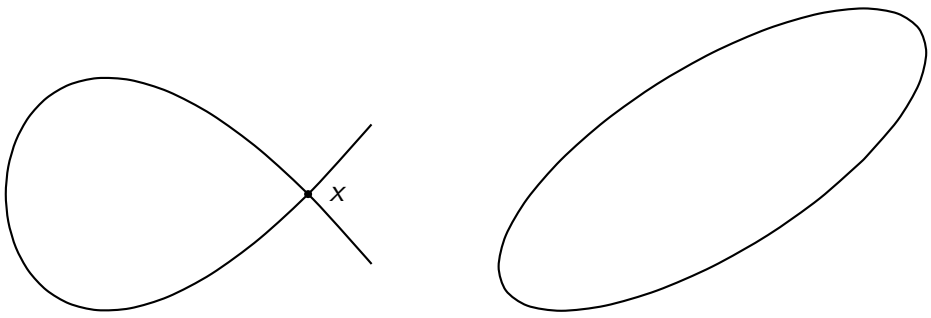
$$x \neq \pi_x \Psi_{\tau,t}(x,\xi); \tag{4.5.24}$$

simply flow does not return to point x at moment t (even from another direction). This means *absence of bicharacteristic loops*.

In the same framework condition (4.5.23)(i) is equivalent to (4.5.23)(ii) and means that

$$(x,\xi) \neq \Psi_{\tau,t}(x,\xi); \tag{4.5.25}$$

simply flow does not return to point (x,ξ) at moment t. This means *absence of periodic bicharacteristics*.



(a) Bicharacteristic loop (b) Periodic bicharacteristics

Figure 4.2: The case of a simple hamiltonian flow

Note that the looping trajectory (unless it is also a periodic trajectory) does not intersect itself, only its x projection (as shown on Figure 4.2(a)) does. Also note that x-projection of the loop could look differently from the one shown on Figure 4.2(a): it can be periodic[30] or be the same curve ran twice (in one and then in the opposite direction)[31].

[30] F.e. as $a = (\xi_1 - x_2)^2 + (\xi_2 + x_1)^2 - x_3$.

[31] F.e. as $a(x,\xi) = |\xi|^2 - x_1$.

Another difference is the *time direction* which manifests itself in more general settings. While in (4.5.23) we can choose time direction as we want, it is not the case in (4.5.22) since then we need to permute $\mathsf{supp}(q_1)$ and $\mathsf{supp}(q_2)$ as well. Moreover, to employ Tauberian technique we need a symmetric interval $[-T, T]$ and to extend $[-T_0, T_0]$ to it we need to verify our conditions for $t \in [-T, -T_0] \cup [T_0, T]$. In the case of (4.5.23) we should do it either for $t \in [-T, -T_0]$ or for $t \in [T_0, T]$ but in the case of (4.5.22) we should do it for $t \in [-T, -T_0]$ and for $t \in [T_0, T]$. For example, let (x, ξ) and (x, η) be such that $\Psi_{\tau,-t}(x, \xi)$ and $\Psi_{\tau,t}(x, \eta)$ hit "Dark Territory" as $t > 0$ and $t \asymp T_1$ and $(x, \xi) \in \mathsf{supp}(q_1)$, $(x, \eta) \in \mathsf{supp}(q_2)$; then in (4.5.22) we cannot go beyond time interval $[-T_1, T_1]$ (and we need to check no-loop condition).

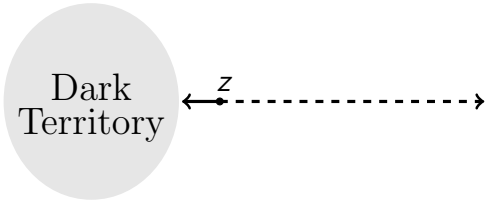


Figure 4.3: In (4.5.22) analysis we must follow both directions; in (4.5.23) analysis we can chose direction and we choose the dashed one.

On the other hand, if $\Psi_{\tau,-t}(x, \xi)$ neither hits "Dark Territory" nor comes back as $-T_2 < t < 0$ (for all $(x, \xi) \in \mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$) then (4.5.23) we can extend a time interval to $[-T_2, T_2]$.

In the current settings a "Dark Territory" could mean even a smooth boundary. However applying results of Chapter 3 we would not consider a smooth transversally met boundary as a "Dark Territory" but as a possible source of looping. For example, for a geodesic billiard flow the trajectory which hits the boundary normally goes back the same way and we need either to take $T_1 < 2\mathsf{dist}(x, \partial X)$ which is not an improvement over $T_1 < \mathsf{dist}(x, \partial X)$ or to analyze the contribution of this loop explicitly getting a boundary layer type correction to $e(x, x, .)$; this would have no affect on $\int e(x, x, .)\psi(x)\,dx$ as $\mathsf{supp}(\psi) \cap \partial X = \emptyset$. For details see Section 8.1.

For branching flow one should replace (4.5.24) and (4.5.25) by

$$x \notin \pi_x \Psi_{\tau,t}(x, \xi), \tag{4.5.26}$$

$$(x, \xi) \notin \Psi_{\tau,t}(x, \xi) \tag{4.5.27}$$

respectively.

Results

Remark 4.5.1. (i) Instead of Theorem 2.2.10 which does not allow bicharacteristic trajectory to hit the boundary, we can refer to Theorem 3.2.4 or geometric versions of Theorems 3.4.6 and 3.4.14.

item We definitely need to use the quantitate conditions: instead "trajectory does not hit the boundary" we need to assume that

$$\mathsf{dist}\big(\Psi_{t,\tau}(x,\xi),\partial X\big)\ge \gamma \tag{4.5.28}$$

and instead of (4.5.26), (4.5.27) we need to assume respectively that

$$\mathsf{dist}\big(x,\pi_x\Psi_{\tau,t}(x,\xi)\big)\ge \begin{cases}\epsilon|t| & \text{as } |t|\le T_0,\\ \gamma & \text{as } T_0\le |t|\le T,\end{cases}' \tag{4.5.29}$$

$$\mathsf{dist}\big((x,\xi),\Psi_{\tau,t}(x,\xi)\big)\ge \begin{cases}\epsilon|t| & \text{as } |t|\le T_0,\\ \gamma & \text{as } T_0\le |t|\le T,\end{cases} \tag{4.5.30}$$

where γ is a small constant. Conditions in this form are fulfilled automatically for $|t|\le T_0$ due to microhyperbolicity and ξ-microhyperbolicity respectively. Assuming that these conditions are fulfilled for all t (may be of a selected sign) with $|t|\le T$ completely removes implicit T_0 from the final estimates.

So, our analysis leads us to the following results:

Theorem 4.5.2. *Let assumptions of Theorem 4.4.1 be fulfilled with* (4.4.2) *replaced by* (4.4.18).

(i) Let A be microhyperbolic on $\mathsf{supp}(q_1)\cup\mathsf{supp}(q_2)$ on the energy level $\bar\tau$. Consider a generalized Hamiltonian flow $\Psi_{t,\bar\tau}$ issued from γ-vicinity $\mathcal{U}$ of $\mathsf{supp}(q_1)\cap\mathsf{supp}(q_2)$. Assume that as $\varsigma t>0$ [32] *and $|t|\le T$ conditions* (4.5.28), (4.5.30) *are fulfilled and also*

(4.5.31) *In γ-vicinity of $\pi_x\Psi_{t,\bar\tau}(\mathcal{U})$ assumptions of Theorem 4.4.1 are fulfilled.*

Then formula (4.3.58) *and all its derivative formulae remain valid for indicated T (rather than $T=T_0$) modulo terms not exceeding $C'h^s$ where here and in what follows constant C' depends also on T and γ.*

[32] Where we can select $\varsigma=\pm1$.

(ii) Let A be ξ-microhyperbolic on $\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)$. Consider a generalized Hamiltonian flow $\Psi_{t,\bar\tau}$ issued from $\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)$. Assume that as $|t| \le T$ conditions (4.5.28), (4.5.29) *and* (4.5.31) *are fulfilled. Then formula* (4.3.57) *and all its derivative formulae remain valid for indicated T (rather than $T = T_0$) modulo terms not exceeding $C'h^s$.*

Remark 4.5.3. Under additional assumptions of Proposition 4.3.5 statements of Theorem 4.5.2 hold with Q_1, Q_2 and q_1, q_2 replaced by $Q_1B_1^j$, $Q_2B_1^k$ and $q_1B_1^j, q_2B_1^k$ respectively with $j, k \in [0, l]$.

Now combining with arguments of Subsubsection *4.4.2.2 Improved Asymptotics without Mollification* we arrive to the sharp[33)] Theorems 4.4.12 and 4.4.11. Before doing it just note

Theorem 4.5.4. *Let assumptions of Theorem 4.4.1 be fulfilled with* (4.4.2) *replaced by* (4.4.18). *Then*

(i) In the framework of Theorem 4.5.2(i) and Remark 4.5.3 for both energy levels $\bar\tau_1$ and $\bar\tau_2$ sharp[3)] estimates (4.4.37)–(4.4.39) *hold (in "without $_x$" version).*

(ii) In the framework of Theorem 4.5.2(ii) and Remark 4.5.3 for both energy levels $\bar\tau_1$ and $\bar\tau_2$ sharp[33)] estimates (4.4.37)–(4.4.39) *hold.*

Now we are ready to the synthesis as described in Subsubsection *4.5.1.2 Synthesis*.

Theorem 4.5.5. *Let assumptions of Theorem 4.4.1 be fulfilled with* (4.4.2) *replaced by* (4.4.18). *Let A be microhyperbolic on $\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)$ on energy levels $\bar\tau_*$, $* = 1, 2$. Let $r_i^0 \in \mathsf{S}_{h,\gamma,\gamma,K}(T^*X)$ [34)] be scalar symbols satisfying* (4.5.11) .

Consider generalized Hamiltonian flow $\Psi_{t,\bar\tau_*}$ issued from γ-vicinity $\mathcal{U}_i$ of $\mathsf{supp}(r_i^0) \cap \mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$. Assume that as $\varsigma t > 0$ with $\varsigma := \varsigma_{*i}$ [32)] *and $|t| \le T_{*i}$ conditions* (4.5.28), (4.5.30) *and* (4.5.31) *are fulfilled with $\mathcal{U} := \mathcal{U}_i$.*

[33)] Where "sharp" means "with T instead of T_0" and with C' depending on γ, T.

[34)] With an arbitrarily small constant γ.

Then

$$\mathsf{R}^{\mathsf{W}}(\bar\tau_1,\bar\tau_2) \prec \sum_{*=1,2}\ \sum_{0\le i\le m} C_0\frac{h^{1-d}}{T_{*i}}\Big(J(r_i^0q_1^0B_1^j,\bar\tau_*)+J(r_i^0q_2^0B_1^k,\bar\tau_*)+C'h\Big), \tag{4.5.32}$$

$$\mathsf{R}^{\mathsf{W}}_{\varphi_2,L_2}(\bar\tau_1,\bar\tau_2) \prec \sum_{0\le i\le m} C_0\frac{h^{1-d}}{T_{*i}}\Big\{\Big(J(r_i^0q_1^0B_1^j,\bar\tau_1)+J(r_i^0q_2^0B_1^k,\bar\tau_1)+C'h\Big)+ \Big(J(r_i^0q_1^0B_1^j,\bar\tau_2)+J(r_i^0q_2^0B_1^k,\bar\tau_2)+C'h\Big)\vartheta_2\big(\frac{h}{L_2T_{*i}}\big)\Big\} \tag{4.5.33}$$

and

$$\mathsf{R}^{\mathsf{W}}_{\varphi_1,L_1,\varphi_2,L_2}(\bar\tau_1,\bar\tau_2) \prec \sum_{*=1,2}\ \sum_{0\le i\le m} C_0\frac{h^{1-d}}{T_{*i}}\Big(J(r_i^0q_1^0B_1^j,\bar\tau_*)+J(r_i^0q_2^0B_1^k,\bar\tau_*)+C'h\Big)\vartheta_*\big(\frac{h}{L_*T_{*i}}\big) \tag{4.5.34}$$

with the left-hand expressions defined respectively by (4.4.19), (4.4.16) *and* (4.4.17) *(without subscript "$_x$") with* $J(q^0B^j,\bar\tau)$ *defined by* (4.4.26). *Here* C' *depends on* γ, m, $\max_i T_{*i}$.

Theorem 4.5.6. *Let assumptions of Theorem 4.4.1 be fulfilled without* (4.4.2). *Let* A *be* ξ*-microhyperbolic on* $\operatorname{supp}(q_1)\cup\operatorname{supp}(q_2)$ *on energy levels* $\bar\tau_*$, $*=1,2$. *Let* $r_i^0\in \mathsf{S}_{h,\gamma,\gamma,K}(T^*X)$ [34] *be scalar symbols satisfying*

$$\sum r_i^0 = 1. \tag{4.5.35}$$

Consider generalized Hamiltonian flow $\Psi_{t,\bar\tau_*}$ *issued from* γ*-vicinity* $\mathcal{U}_i$ *of* $\operatorname{supp}(r_i^0)\cap(\operatorname{supp}(q_1)\cup\operatorname{supp}(q_2))$. *Assume that as* $|t|\le T_{*i}$ *conditions* (4.5.28), (4.5.29) *and* (4.5.31) *are fulfilled with* $\mathcal{U}:=\mathcal{U}_i$. *Then*

$$\mathsf{R}^{\mathsf{W}}_x(\bar\tau_1,\bar\tau_2) \prec \sum_{*=1,2}\ \sum_{0\le i\le m} C_0(m+1)\frac{h^{1-d}}{T_{*i}}\Big(J_x(r_i^0q_1^0B_1^j,\bar\tau_*)+J_x(r_i^0q_2^0B_1^k,\bar\tau_*)+C'h\Big), \tag{4.5.36}$$

(4.5.37) $\mathsf{R}^{\mathsf{W}}_{x,\varphi_2,L_2}(\bar\tau_1,\bar\tau_2) \prec$
$$\sum_{0\le i\le m} C_0(m+1)\frac{h^{1-d}}{T_{*i}}\Big\{\Big(J_x(r_i^0 q_1^0 B_1^j,\bar\tau_1)+J_x(r_i^0 q_2^0 B_1^k,\bar\tau_1)+C'h\Big)+ \Big(J_x(r_i^0 q_1^0 B_1^j,\bar\tau_2)+J_x(r_i^0 q_2^0 B_1^k,\bar\tau_2)+C'h\Big)\vartheta_2\big(\frac{h}{L_2 T_{*i}}\big)\Big\}$$

and

(4.5.38) $\mathsf{R}^{\mathsf{W}}_{x,\varphi_1,L_1,\varphi_2,L_2}(\bar\tau_1,\bar\tau_2) \prec$
$$\sum_{*=1,2} C_0(m+1)\sum_{0\le i\le m}\frac{h^{1-d}}{T_{*i}}\Big(J_x(r_i^0 q_1^0 B_1^j,\bar\tau_*)+J_x(r_i^0 q_2^0 B_1^k,\bar\tau_*)+C'h\Big)\vartheta_*\big(\frac{h}{L_* T_{*i}}\big)$$

with left-hand expressions defined respectively by (4.4.19), (4.4.16) *and* (4.4.17) *with* $J_x(q^0,\bar\tau)$ *defined by* (4.4.25).

Proof. Consider scalar operators R_i with principal symbols r_i^0 such that $\sum_i R_i = I$. Then plugging $Q_1 := R_{i_1}Q_1$, $Q_2 := Q_2 R_{i_2}^*$ and $T = \min(T_{i_1}, T_{i_2})$ we see that now we need to analyze not $\mathsf{N}_{xi}(\tau',\tau'')$ but $\mathsf{N}_{xi_1i_2}(\tau',\tau'')$ and the problem is that we have now T_{i_1} and T_{i_2}. We do not indicate which of two energy levels is considered because due to (4.4.12) they are treated independently.

Still as $Q_1 = Q_2^*$, $j = k$ and $i_1 = i_2 = i$ we using Lemma 4.2.7 estimate $\mathsf{N}_{xii}(\tau',\tau'')$ as before:

$$\mathsf{N}_{xii}(\tau',\tau'') \prec C_0 J_x(r_i^0 q_1^0 B_1^j,\bar\tau)\cdot\big(|\tau'-\tau''|+\frac{h}{T_i}\big)h^{-d}+\dots$$

where dots denote

$$C'\big(|\tau'-\tau''|+h\big)\cdot\big(|\tau'-\bar\tau|+|\tau''-\bar\tau|+h\big)$$

and therefore in the general case

$$\mathsf{N}_{xi_1i_2}(\tau',\tau'') \prec C_0 J_x(r_{i_1}^0 q_1^0 B_1^j,\bar\tau)\cdot\big(|\tau'-\tau''|+\frac{h}{T_{i_1}}\big)h^{-d}+ C_0 J_x(r_{i_2}^0 q_2^0 B_1^k,\bar\tau)\cdot\big(|\tau'-\tau''|+\frac{h}{T_{i_2}}\big)h^{-d}+\dots$$

which again leads to Tauberian and Weyl errors

$$C_0\frac{h^{1-d}}{T_{i_1}}\vartheta\big(\frac{h}{LT_{i_1}}\big)J(r^0_{i_1}q^0_1B^j_1,\bar\tau)+C_0\frac{h^{1-d}}{T_{i_2}}\vartheta\big(\frac{h}{LT_{i_2}}\big)J(r^0_{i_2}q^0_2B^k_1,\bar\tau)+C'h^{2-d}.$$

Now summation with respect i_1, i_2 delivers announced estimates. □

Note that if $r^0=\big(\sum_i|r^0_i|^2\big)^{\frac12}\le 1$ (which is easy to satisfy in the framework of (4.5.35)) then

$$\sum_i J_x(r^0_iq_0,\bar\tau)=J_x(r^0q_0,\bar\tau)\le J_x(q_0,\bar\tau). \tag{4.5.39}$$

4.5.3 Sharper Remainder Estimates

To establish truly sharper remainder estimates we need to work simultaneously in two directions: to increase T up to $h^{-\delta}$ (depending on assumptions) and to decrease γ. While it is sufficient to decrease γ to h^δ we will go here further, up to $\gamma=h^{\frac12-\delta'}$ where δ' and δ are related.

Analysis as $|t|\le T_0$

We need to reexamine first results which are due to propagation.

Proposition 4.5.7. *Let A satisfy all the assumptions of Theorem 4.4.1. Let $q_1,q_2\in \mathsf{S}_{h,\rho,\gamma,K}(T^*X,\mathbb{H},bH)$ with $\rho\gamma\ge h^{1-\delta}$. Then*

(i) If A is ξ-microhyperbolic on $\mathsf{supp}(q_1)$ on the energy level τ then

$$F_{t\to h^{-1}\tau}\chi_T(t)\Gamma_x\big(Q_{1x}B^j_1uB^k_1{}^tQ_{2y}\big)\equiv 0 \tag{4.5.40}$$

as

$$h^{1-\delta}\rho^{-1}\le T\le T_0 \tag{4.5.41}$$

where as usual $\chi\in \mathscr{C}_0^\infty([-1,-\frac13]\cup[\frac13,1])$ and T_0 is a small constant, $j,k\in[0,l]$.

(ii) If $\rho=\gamma$ and A is microhyperbolic on $\mathsf{supp}(q_1)$ on the energy level τ then instead

$$F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(Q_{1x}B^j_1uB^k_1{}^tQ_{2y}\big)\equiv 0 \tag{4.5.42}$$

as

$$h^{1-\delta}\rho^{-1}\le T\le T_0. \tag{4.5.43}$$

Proof. Let A be ξ-microhyperbolic on $\mathsf{supp}\,\bar{q}_1$ and $\bar{q}_1, \bar{q}_2 \in \mathsf{S}_{h,1,1,K}(T^*X, \mathbb{H}.bH)$. Let $\psi \in \mathscr{C}_0^\infty(\mathbb{R}^d)$, supported in $\{|x-y| \le \epsilon\}$ with small enough $\epsilon > 0$. Then ξ-microhyperbolicity and the standard propagation results imply that

$$F_{t\to h^{-1}\tau}\chi_T(t)\big(\bar{Q}_{1x}B_1^j u\psi_T(x-y)B_1^k\,{}^t\bar{Q}_{2y}\big) \equiv 0$$

as $T \ge h^{1-\delta}$.

Applying Q_{1x} and ${}^tQ_{2y}$ from the left and right-respectively we derive (4.5.40) under (4.5.41) immediately. Statement (i) is proven.

Finally, (i) follows from (i). □

Successive Approximations

Let us look at successive approximation method of Section 4.3 with $q_2 \in \mathsf{S}_{h,\rho,\gamma,K}(T^*X, \mathbb{H}, bH)$. The only difference appears as $(x_j - y_j)$ commutes with Q_2. In this case factor $[x_j - y_j, Q_2]$ of magnitude $\rho^{-1}h$ appears (instead of h) and since $(x_j - y_j)$ may be accompanied by a single parametrix $G^\pm$ or $\bar{G}^\pm$ with the norm $\lesssim Th^{-1}$, we gain a factor $Ch\rho^{-1}\cdot Th^{-1} = CT\rho^{-1}$ in the estimate of the norm. Then for the method of successive approximations to work we need in addition to condition $T \le h^{\frac12+\delta}$ also condition $T \le \rho h^\delta$; so we need

$$T \le \min\big(h^{\frac12+\delta}, \rho h^\delta\big). \tag{4.5.44}$$

Under this condition we get asymptotic expansions

$$F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma_x\big(Q_{1x}B_1^j uB_1^k\,{}^tQ_{2y}\big) \sim \sum_{n\ge 0}\kappa'_{nx}(\tau)h^{-d+n+1} \tag{4.5.45}$$

and

$$F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\big(Q_{1x}B_1^j uB_1^k\,{}^tQ_{2y}\big) \sim \sum_{n\ge 0}\kappa'_{n}(\tau)h^{-d+n+1} \tag{4.5.46}$$

Actually we get a similar asymptotic expansion (with $\mathcal{K}'_n(x,y,\tau)$) even without Γ_x. However, we want to increase T and we can do it only if we apply Γ_x. In this case we get expansion for $T = T_0$ (where T_0 is again a small constant) provided upper bound (4.5.44) to T is larger than the lower bound (4.5.41); this condition is equivalent to

$$\rho \ge h^{\frac12-\delta} \tag{4.5.47}$$

where we adjust an arbitrarily small exponent $\delta > 0$ if needed.

Thus we arrive to

Proposition 4.5.8. *(i) In the framework of Proposition 4.5.7(i) and* (4.5.47) *asymptotic expansion* (4.5.45) *holds with* $T = T_0$.

(ii) In the framework of Proposition 4.5.7(ii) asymptotic expansion (4.5.46) *holds with* $T = T_0$.

Further, one can prove easily

Proposition 4.5.9. *In the framework of Proposition 4.5.8(i) and (ii) respectively*

$$\|\partial_\tau^p \kappa_{nx}\| \le C_{np}\rho^{-n-p}\gamma^{-n} \tag{4.5.48}$$

and

$$\|\partial_\tau^p \kappa_n\| \le C_{np}\gamma^{-2n-p} \tag{4.5.49}$$

Increasing T

Now the long-range propagation results of Sections 2.4 and 3.5 allow us to increase T with negligible error in (4.5.45), (4.5.46) under no-loop and no-periodicity conditions (4.5.29), (4.5.30) respectively where $\gamma \ge h^{\frac{1}{2}-\delta}$ now is a small parameter. Those are assumptions of Theorem 2.4.17 if there is no boundary or Theorem 3.5.3 otherwise. Let us mention that due to the nature of these theorems we *must* assume that $\rho = \gamma$ even if we consider asymptotics without spatial averaging.

Tauberian Estimates

Now due to Proposition 4.5.9 estimates (4.4.23), (4.5.25) are replaced by the same estimates but with $C'h^{2-d}$ replaced by $C'h^{2-d}\gamma^{-2}$. Then the right-hand expression of (4.5.32) is replaced by

$$C_0\Big(J(q_1^0 B_1^j, \tau) + C'h\gamma^{-2}\Big)\frac{h^{1-d}}{T}$$

which due to Proposition 4.5.9 does not exceed

$$C_0\Big(J(q_1^0 B_1^j, \bar\tau) + C'\gamma^{-1}|\tau-\bar\tau| + C'h\gamma^{-2}\Big)\frac{h^{1-d}}{T}.$$

Then the right-hand expression of (4.5.33) is replaced by

$$C_0\Big(J(q_1^0 B_1^j, \bar\tau) + C'\gamma^{-1}|\tau'-\bar\tau| + C'\gamma^{-1}|\tau''-\bar\tau| + C'h\gamma^{-2}\Big)\cdot\big(|\tau'-\tau''| + \frac{h}{T}\big)$$

as $Q_2 = Q_1^*$, $j = k$ which yields the similar estimate

$$C_0\Big(J(q_1^0 B_1^j, \bar\tau) + J(q_2^0 B_1^k, \bar\tau) + C'\gamma^{-1}|\tau' - \bar\tau| + C'\gamma^{-1}|\tau'' - \bar\tau| + C'h\gamma^{-2}\Big)\times \Big(|\tau' - \tau''| + \frac{h}{T}\Big)$$

in the general case.

Therefore in the end of the day we arrive to the remainder estimate

$$C_0\frac{h^{1-d}}{T}\vartheta\big(\frac{h}{LT}\big)\Big(J(q_1^0 B_1^j, \bar\tau) + J(q_2^0 B_1^k, \bar\tau) + C'h\gamma^{-2}\Big) \tag{4.5.50}$$

which is obtained from the previous one by transformation $|\tau' - \bar\tau| \mapsto hT^{-1}$, $|\tau'' - \bar\tau| \mapsto hT^{-1}$.

First we get estimate (4.5.50) for Tauberian and then for Weyl errors. Similar estimates holds without spatial averaging.

So, *the only difference in comparison with the earlier estimates is the replacement of the term $C'h$ by $C'h\gamma^{-2}$ where C' does not depend on γ, T.*

The synthesis stage repeats one for $\gamma \asymp 1$.

Remark 4.5.10. (i) As $q_1, q_2 \in \mathsf{S}_{h,\gamma,\gamma,K}$ we may need to take more terms in the Weyl expansion than we used to have because junior terms are larger; however on the synthesis stage we return to our original $q_1, q_2 \in \mathsf{S}_{h,K}$ and in the Weyl expansions for them we can drop all these extra terms.

(ii) Probably one can improve term $C'h\gamma^{-2}$ to $C'h\gamma^{-1}$ but this term seems to be rather superficial.

Finally, Results

Theorem 4.5.11. *Let assumptions of Theorem 4.4.1 be fulfilled with* (4.4.2) *replaced by* (4.4.18). *Let A be microhyperbolic on $\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)$ on the energy levels $\bar\tau_*$, $* = 1, 2$. Let $r_i^0 \in \mathsf{S}_{h,\gamma,\gamma,K}(T^*X)$* [35] *be scalar symbols satisfying* (4.5.11).

Consider generalized Hamiltonian flow $\Psi_{t,\bar\tau_*}$ issued from γ-vicinity $\mathcal{U}_i$ of $\mathsf{supp}(r_i^0) \cap \mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$. Assume that as $\varsigma t > 0$ with $\varsigma := \varsigma_{*i}$ [32] *and $|t| \le T_{*i}$ conditions* (4.5.28), (4.5.30) *and* (4.5.31) *are fulfilled and moreover*

[35] With $h^{\frac12-\delta} \le \gamma \le 1$.

as $i = 1, \dots, m$ *along* $\Psi_{t,\tau}(\mathcal{U})$ *conditions of Theorem 2.4.17 or Theorem 3.5.3 are fulfilled with* $\mathcal{U} := \mathcal{U}_i$.

Then estimates (4.5.32)–(4.5.34) *hold with term* $C'h$ *in the factor replaced by* $C'h\gamma^{-2}$ *with the left-hand expressions defined respectively by* (4.4.19), (4.4.16) *and* (4.4.17) *(without* $_x$*) with* $J(q^0 B^j, \bar\tau)$ *defined by* (4.4.26). *Here* C' *does not depend on* γ, T_{*i}.

Theorem 4.5.12. *Let all assumptions of Theorem 4.4.1 be fulfilled except may be* (4.4.2). *Let* A *be* ξ*-microhyperbolic on* $\operatorname{supp}(q_1) \cup \operatorname{supp}(q_2)$ *on the energy levels* $\bar\tau_*$, $* = 1, 2$. *Let* $r_i^0 \in \mathsf{S}_{h,\gamma,\gamma,K}(T^*X)$ *be scalar symbols satisfying* (4.5.35).

Consider generalized Hamiltonian flow $\Psi_{t,\bar\tau_*}$ *issued from* γ*-vicinity* $\mathcal{U}_i$ *of* $\operatorname{supp}(r_i^0) \cap (\operatorname{supp}(q_1) \cup \operatorname{supp}(q_2))$. *Assume that as* $|t| \le T_{*i}$ *conditions* (4.5.28), (4.5.29) *and* (4.5.31) *are fulfilled and moreover as* $i = 1, \dots, m$ *along* $\Psi_{t,\tau}(\mathcal{U})$ *conditions of Theorem 2.4.17 or Theorem 3.5.3 are fulfilled with* $\mathcal{U} := \mathcal{U}_i$.

Then estimates (4.5.36)–(4.5.38) *hold with term* $C'h$ *in the factor replaced by* $C'h\gamma^{-2}$ *with the left-hand expressions defined respectively by* (4.4.19), (4.4.16) *and* (4.4.17) *(without* $_x$*) with* $J(q^0 B^j, \bar\tau)$ *defined by* (4.4.26). *Here* C' *does not depend on* γ, T_{*i}.

4.5.4 Discussion

Local Results

We already achieved rather general results as far as $O(h^{1-d})$ remainder estimate is concerned.

Let $A(x, D)$ be an elliptic operator on the closed manifold and we are interested in its spectral asymptotics for a large spectral parameter $\lambda \gg 1$. So, we are looking at its spectrum in $(0, \lambda)$ [36]. Alternatively we can consider operator $\lambda^{-1}A(x, D)$ and look at its spectrum at $(0, 1)$.

Further, we can rewrite the latter operator as $a(x, hD, h)$ where $h = \lambda^{-1/m}$, m is an order of $A(x, D)$. Obviously the principal symbol $a(x, \xi, 0)$ of h-differential operator $a(x, hD, h)$ and the principal symbol $A_m(x, \xi)$ of the differential operator $A(x, D)$ coincide. One can see easily that 0 is a

[36] Negative eigenvalues are covered in the same manner.

lacunar value unless we are looking at $\xi = 0$ [37]. All the details are left for Sections 11.2 and 11.3.

On the other hand, in this case $a(x, hD, 0)$ is microhyperbolic on the energy level 1 in the direction $\ell = (\ell_\xi, 0) = (\xi, 0)$. Therefore asymptotics

$$e(x, x, 0, \lambda) = \kappa_0(x)\lambda^{d/m} + O(\lambda^{(d-1)/m}) \qquad \text{as} \quad \lambda \to +\infty \tag{4.5.51}$$

holds where we used the trick described in [37]. Also we get a host of asymptotics for spectral mollifications. These results hold for matrix operators and for operators acting on the Hermitean (or even Hilbert) sections of the bundles. All details are left for Chapter 11 and for elliptic operators on manifolds with boundaries as long as x is disjoint from the boundary.

Simple Improvements

However the completely local nature of the above results (where the only global condition is the self-adjointness of A) is lost if we want marginally improve the remainder estimate. Let us start from $o(\lambda^{(d-1)/m})$. Then we need to consider Hamiltonian dynamics Ψ_t on $\Sigma_\tau = \{\tau \in \operatorname{Spec} a(x, \xi)\}$; the concrete value of the energy level > 0 here is of no importance due to homogeneity.

As $A_m(x, \xi)$ is the scalar symbol this is the ordinary Hamiltonian dynamics of it; further, if $\operatorname{Spec} A_m(x, \xi)$ consists of eigenvalues $\rho_1(x, \xi), \dots, \rho_r(x, \xi)$ of the constant multiplicities we get a bunch of dynamics generated by these eigenvalues; finally, in the general case this is the generalized Hamiltonian dynamics as described in Chapter 2.

Then the result depends strongly on what we are looking for: if we want remainder estimate $o(\lambda^{(d-1)/m})$ in (4.5.51) upgraded to

$$e(x, x, 0, \lambda) = \kappa_0(x)\lambda^{d/m} + \kappa_1(x)\lambda^{(d-1)/m} + o(\lambda^{(d-1)/m}) \qquad \text{as} \quad \lambda \to +\infty \tag{4.5.52}$$

we need to fight bicharacteristic loops as on Figure 4.2(a), if we want this remainder estimate in

[37] To avoid this little problem we can consider spectrum of $A(x, D)$ in $(\frac{1}{2}\lambda, \lambda)$ and thus the spectrum of $a(x, hD, h)$ in $(\frac{1}{2}, 1)$ and then plug $2^{-n}\lambda$ instead of λ and finally to sum what we got with respect to $n = 0, \dots, \lfloor \log_2 \lambda \rfloor$.

$$\int e(x,x,0,\lambda)\psi(x)\,dx = \int \Big(\kappa_0(x)\lambda^{d/m} + \kappa_1(x)\lambda^{(d-1)/m}\Big)\psi(x)\,dx + o\big(\lambda^{(d-1)/m}\big) \qquad \text{as } \lambda \to +\infty \tag{4.5.53}$$

we need to fight periodic bicharacteristics as on Figure 4.2(b). Recall that the bicharacteristic loops and periodic bicharacteristics are defined by (4.5.24), (4.5.25).

Let Π denote the set of all periodic points (x,ξ) and Π_T denote the set of periodic points with periods $t \le T$. The latter set is closed, the former is the union of the sequence of closed sets. For a sake of simplicity we assume that $\dim \mathbb{H} < \infty$.

Assume that

$$\mu_\tau(\Pi) = 0. \tag{4.5.54}$$

Then $\mu_\tau(\Pi_T) = 0$ for any T. However Π_T is a closed set[38]. Then if we consider its ε-vicinity $\Pi_{T,\varepsilon}$

$$\mu_\tau(\Pi_{T,\varepsilon}) \to +0 \qquad \text{as } \varepsilon \to +0. \tag{4.5.55}$$

Applying Theorem 4.5.5 with $\mathcal{U}_0 = \Pi_{T,\varepsilon}$ we arrive to asymptotics (4.5.53) with the remainder

$$C\big(T^{-1} + \mu_\tau(\Pi_{T,\varepsilon})\big)\lambda^{(d-1)/m} + C'_{T,\varepsilon}\lambda^{(d-2)/m} \tag{4.5.56}$$

with arbitrary T, ε and thus (4.5.56) is actually $o\big(\lambda^{(d-2)/m}\big)$ due to (4.5.55). Therefore

(4.5.57) Asymptotics (4.5.53) holds provided assumption (4.5.54) is fulfilled.

On the other hand, without assumption (4.5.54) asymptotics (4.5.53) could fail as for Laplace-Beltrami operator on $\mathbb{S}^d$ or on other manifolds with all periodic bicharacteristics. We will consider such operators in Section 6.2.

Meanwhile the same arguments and Theorem 4.5.6 show that asymptotics (4.5.52) holds provided

$$\mu_{\tau,x}(\Lambda) = 0. \tag{4.5.58}$$

[38] Therefore due to $\mu_\tau(\Pi_T) = 0$ it is of measure 0 and thus Π is of the first Baire category.

where Λ is the set of loop points (x,ξ).

For example, on the surface of ellipsoid in $\mathbb{R}^3$ with the semi-axis (a_1, a_2, a_3) condition (4.5.58) is fulfilled if x is not an umbilic point[39].

Similarly, considering an ellipse we arrive to asymptotic (4.5.52) in all interior points which are not focal (we need to consider billiards but Chapter 3 provides all the necessary tools).

The further analysis can go in two directions: sharper reminder estimates and more general operators.

Sharper Remainder Estimates

In this case we need to apply the long-term propagation which involves an analysis how fast $D\Psi_t$ grows as $t\to\infty$ and how fast $\mu_\tau(\Pi_{T,\varepsilon})$ tends to 0 as $\varepsilon\to+0$. There are two cases:

Example 4.5.13 (Exponential case). It is the case when one can prove that

$$|D\Psi_t|\le ce^{c|t|} \tag{4.5.59}$$

and

$$\mu_\tau(\Pi_{T,\varepsilon})\le CT^{-1}\qquad \text{as } \varepsilon\le c^{-1}e^{-cT}. \tag{4.5.60}$$

Then taking $T=\epsilon\log\lambda$ one can derive (4.5.53) with the remainder estimate $O\bigl(\lambda^{(d-1)/m}(\log\lambda)^{-1}\bigr)$.

This happens f.e. on the manifolds on of the negative sectional curvature or on 2-dimensional manifolds without conjugate points P. Bérard [1].

Similarly, under condition (4.5.60) replaced by

$$\mu_{\tau,x}(\Lambda_{T,\varepsilon})\le CT^{-1}\qquad \text{as } \varepsilon\le c^{-1}e^{-cT}. \tag{4.5.61}$$

one can derive (4.5.52) with the remainder estimate $O\bigl(\lambda^{(d-1)/m}(\log\lambda)^{-1}\bigr)$.

Example 4.5.14 (Power case). It is the case when one can prove that

$$|D\Psi_t|\le c(|t|+1)^c \tag{4.5.62}$$

and

$$\mu_\tau(\Pi_{T,\varepsilon})\le CT^{-\delta}\qquad \text{as } \varepsilon\le c^{-1}T^{-c}. \tag{4.5.63}$$

---

[39] There are four of such points located at $x_2=0$ as $a_1>a_2>a_3$ and there are two of them at $(0,0,\pm a_3)$ if $a_1=a_2\ne a_3$.

Then taking $T = \epsilon\lambda^{\delta'}$ one can derive (4.5.53) with the remainder estimate $O\bigl(\lambda^{(d-1-\delta'')/m}\bigr)$ with unspecified small exponent $\delta'' > 0$.

This happens for example in some Euclidean domains (ellipse, ball, domain between two confocal ellipses or between two spheres with the same center), on the surface of 3-dimensional ellipsoids which are not spheres. In this examples dynamics is completely integrable.

It happens also in Euclidean polyhedra which is not completely integrable case.

Similarly, under condition (4.5.63) replaced by

$$\mu_{\tau,x}(\Lambda_{T,\varepsilon}) \le CT^{-1} \qquad \text{as } \varepsilon \le c^{-1}T^{-c}. \tag{4.5.64}$$

one can derive (4.5.52) with the remainder estimate $O\bigl(\lambda^{(d-1-\delta'')/m}\bigr)$.

This happens for example in some Euclidean domains (ellipse, ball, domain between two confocal ellipses or between two spheres with the same center), on the surface of 3-dimensional ellipsoids which are not spheres, as long as we keep away from some special points:

$$\operatorname{dist}(x, \mathcal{L}) \ge \lambda^{-\delta''} \tag{4.5.65}$$

where $\mathcal{L}$ is the set of umbilical points for the surface of the ellipsoid, $\mathcal{L}$ is the set of foci for elliptical domain, $\mathcal{L}$ is the center for a ball.

All details are left for Chapter 11.

Remark 4.5.15. Bringing polygons and polyhedra into consideration brings also the question what to do with billiards which hit the "bad" points which are in this case corners or edges. One can decide that they branch here[40)] or simply dynamics breaks.

In the second case we define dynamics not on the whole Σ_τ but on $\Sigma_\tau \setminus \Xi$ where Ξ is the set of points for which global dynamics does not exists. Then not Π_T or Λ_T are not necessarily closed sets, but but Ξ_T, $\Pi_T \cup \Xi_T$ and $\Lambda_T \cup \Xi_T$ are where Ξ_T is the set of points for which dynamics breaks for time $t, |t| \le T$. The second approach leaves us with the simple dynamics and in all above arguments we replace Π_T or Λ_T by their unions with Ξ_T.

This is the case for billiards even in the smooth domains due to appearance of the pathological billiards which either touch the boundary or make an infinite number of jumps in the finite time.

[40)] F.e. if we consider an incoming ray close to one which hits a vertex of the polygon the direction of the outgoing ray is defined by which side was encountered first, so for the ray which hits the vertex there will be two outgoing rays. For polyhedra there will be many rays leaving vertex.

Matrix Case and Branching Bicharacteristics

There we are again with the case described in Remark 4.5.15: the billiards are branching when they hit the sets $\Theta_{jk} = \{(x,\xi) : \rho_j = \rho_k\}$ $(j \neq k)$ where ρ_j are eigenvalues of $A_m(x,\xi)$ and we do not distinguish eigenvalues which coincide everywhere. However now the set Ξ_{jk} (points starting from which dynamics eventually hits the point of Θ_{jk}) could be rather large. F.e. if λ_j are smooth and $\{\lambda_j, \lambda_k\} \neq 0$ then the set Ξ_{jk} has a positive measure (unless $\Theta_{jk} = \emptyset$). Does it mean that we are doomed to consider branching bicharacteristics?

Not necessarily. In the example just considered we know that the dynamics of ρ_j changes to those of $\rho_k = 0$ the singularity loses order by $\frac{1}{2}$ (see Proposition 2.2.16). Consider more general case assuming that ρ_j are analytic. Then any given trajectory of ρ_j either belongs to Θ_{jk} completely or hits Θ_{jk} only in some locally finite number of points. However again due to analyticity $\mu_\tau(\Theta_{jk}) = 0$ and the first case could be ignored.

Along trajectories of the second type the order of the singularity also decays by $\delta > 0$ as the dynamics of $\rho_j = 0$ changes to those of ρ_k. This should allow us to ignore branching.

Further, if only $A_m(x,\xi)$ is analytic then there is a set $\hat{\Theta}_j$ consisting of points in vicinity of which ρ_j fails to be analytic but this should be very small and the set of points $\hat{\Xi}_j$ such that the generalized Hamiltonian dynamics originated from them hits $\hat{\Theta}_j$ should have measure 0.

Conjecture 4.5.16. *(i) As $A_m(x,\xi)$ is analytic and there is no boundary, it is sufficient to consider only points of $\{\rho_j = \tau\}$ such that the Hamiltonian dynamics of ρ_j originated in these points remains in the domain where ρ_j is analytic and ignore branching.*

(ii) As there is a boundary only branching at the boundary needs to be addressed.

We will discuss the affect of the branching on the boundary later.

4.6 Operators with Rough Coefficients

In this section we establish results similar to those we obtained earlier, for operators with symbols satisfying (2.3.4)–(2.3.6):

$$\|\partial_\xi^\alpha \partial_x^\beta \partial_{x,\xi}^\gamma A_m(x,\xi)\| \le c(m!|\alpha|!|\beta|!)^\sigma \boldsymbol{\rho}^{-\alpha}\boldsymbol{\gamma}^{-\beta}\varepsilon^{-m} \quad \forall m,\alpha,\beta : |\alpha|+|\beta|+2m \le N\ \forall \gamma : |\gamma| \le 1 \tag{4.6.1}$$

with $N = \epsilon\hbar^{-1}$, $\hbar = h/\varepsilon$ and

$$\min_j \rho_j\gamma_j \ge \varepsilon = Ch|\log h|^\sigma \qquad \sigma \ge 1. \tag{4.6.2}$$

Actually we need $\sigma = 1$.

The "pedestrian way" is to consider operators satisfying

$$\|\partial_\xi^\alpha \partial_x^\beta \partial_{x,\xi}^\gamma A_m(x,\xi)\| \le c_{m\alpha\beta}\boldsymbol{\rho}^{-\alpha}\boldsymbol{\gamma}^{-\beta}\varepsilon^{-m} \quad \forall m,\alpha,\beta : |\alpha|+|\beta|+2m \le N\ \forall \gamma : |\gamma| \le 1 \tag{4.6.3}$$

with $\boldsymbol{\rho},\boldsymbol{\gamma}$ satisfying (2.3.2):

$$\min_j \rho_j\gamma_j \ge h^{1-\delta}. \tag{4.6.4}$$

We will be mainly interested in the case of $\rho_j = 1$ and $\gamma_j = \gamma \ll 1$ briefly mentioning other cases too.

4.6.1 Discussion: Rationale

Actually we are interested in the operators with irregular coefficients. F.e. let us consider elliptic self-adjoint semiclassical (matrix) operator in the divergent form

$$A(x,hD) = \sum_{\alpha,\beta:|\alpha|\le m,|\beta|\le m} (hD)^\alpha a_{\alpha\beta}(x)(hD)^\beta \tag{4.6.5}$$

on compact closed manifold X, defined by quadratic form (then it must be of even order $2m$ and semibounded). We can also consider first order (matrix) operator

$$A(x,hD) = \frac{1}{2}\sum_j \bigl(hD_j a_j(x) + a_j(x) hD_j\bigr) + a_0(x). \tag{4.6.6}$$

We assume that the coefficients belong to $\mathscr{C}_\nu^l(X,.)$ where

(4.6.7) $\nu \in \mathscr{C}(0,\infty)$ is a positive as $t \ge 0$ function, $\nu(t)t^{-l}$ and $\nu(t)t^{-l-1}$ are respectively non-decreasing and non-increasing functions on $(0,\infty)$, $l \in \mathbb{Z}^+$

and

Definition 4.6.1. $\mathscr{C}^l_\nu(X)$ is a subspace of $\mathscr{C}^l(X)$ consisting of functions with l-th order derivatives *continuous with continuity modulus*

$$|\partial^\alpha f(x) - \partial^\alpha a(y)| \le C\nu(|x-y|)\cdot |x-y|^{-l}, \qquad \text{as } \ |\alpha| = l. \tag{4.6.8}$$

Remark 4.6.2. Surely this definition would hold for vector- or matrix- valued functions and one can generalize it easily to sections of vector bundles.

So we are looking for the dimension $\mathsf{N}_A(\tau_1,\tau_2)$ of the spectral projector $E_A(\tau_1,\tau_2)$ of operator A corresponding to interval $[\tau_1,\tau_2)$ with $\tau_1<\tau_2$. Since we cannot apply microlocal analysis to such operators we approximate them by operators with symbols satisfying (4.6.1)–(4.6.2). The most obvious approach is to *bracket* such operators. Namely in the case of operator A semibounded from below we can assume without any loss of the generality that $\tau_1=-\infty$ and $\tau_2=0$ and we are interested in $\mathsf{N}^-_A := \mathsf{N}_A(-\infty,0)$. Let us bracket A between A_- and A_+:

$$A_- \le A \le A_+. \tag{4.6.9}$$

Then

$$\mathsf{N}^-_{A^+} \le \mathsf{N}^-_A \le N^-_{A^-}. \tag{4.6.10}$$

In the case of non-semibounded A we can either modify this method or just to notice that

$$\mathsf{N}_A(\tau_1,\tau_2) = \mathsf{N}^-\bigl(\bigl(A-\frac{1}{2}(\tau_1+\tau_2)\bigr)^2 - \frac{1}{4}(\tau_1-\tau_2)^2\bigr). \tag{4.6.11}$$

We want $A_\pm$ satisfy (4.6.1)–(4.6.4). If we manage to derive remainder estimates for such operators

$$|\mathsf{N}^-_{A_-} - \mathsf{N}^{\mathsf{W}\,-}_{A_-}| \le R_-, \tag{4.6.12}_-$$

$$|\mathsf{N}^-_{A_+} - \mathsf{N}^{\mathsf{W}\,-}_{A_+}| \le R_+ \tag{4.6.12}_+$$

and

$$|\mathsf{N}^{\mathsf{W}\,-}_{A_-} - \mathsf{N}^{\mathsf{W}\,-}_{A}| \le R'_-, \tag{4.6.13}_-$$

$$|\mathsf{N}^{\mathsf{W}\,-}_{A_+} - \mathsf{N}^{\mathsf{W}\,-}_{A}| \le R'_+, \tag{4.6.13}_+$$

where $\mathsf{N}_A^{\mathsf{W}-}$ are Weyl approximations for N_A^- etc, then

$$|\mathsf{N}_A^- - \mathsf{N}_A^{\mathsf{W}-}| \le \max(R_- + R'_-, R_+ + R'_+). \tag{4.6.14}$$

So, remainder estimate for operator with irregular coefficients consists of two parts: remainder estimates $R_\pm$ for approximate operators and *approximation error* $R'_\pm$. While $R_\pm$ is the subject of this section, $R'_\pm$ is much more simple object. Let us approximate coefficients a_α by $a_{\alpha\varepsilon}$ according to Proposition 4.A.2. As A is defined by (4.6.5) or (4.6.6) let A_ε be defined in the same way but with a_α replaced by $a_{\alpha\varepsilon}$.

Remark 4.6.3. From the heuristic point of view would like to take $A_\pm := A_\varepsilon \pm C\nu(\varepsilon)$ but it is not exactly possible since $A - A_\varepsilon$ is an unbounded operator. However we can fix it.

Namely, assume that A given by (4.6.5) is a semi-bounded from below elliptic operator $A \ge -C_0 + 1$ and $\tau_1 = -\infty$. Then the following sequence

$$A \mapsto A + C_0 \mapsto \bigl(A_\varepsilon \pm C\nu(\varepsilon)\bigr)\cdot\bigl(1 \pm C_1\nu(\varepsilon)\bigr) \mapsto A_\pm := \bigl(A_\varepsilon \pm +C\nu(\varepsilon)\bigr)\cdot\bigl(1 \pm C_1\nu(\varepsilon)\bigr) - C_0$$

takes care of this issue.

One can prove then easily that

Lemma 4.6.4. *Let A be ξ-microhyperbolic on energy levels 0. Then as $\varepsilon \ge h$ an approximation error does not exceed $Ch^{-d}\nu(\varepsilon)$.*

So we are interested to take ε as small as possible. Since our symbol is analytic with respect to ξ we can take the smallest ε satisfying logarithmic uncertainty principle:

$$\varepsilon = Ch|\log h|. \tag{4.6.15}$$

So, in this case an approximation error is $Ch^{-d}\nu(Ch|\log h|)$ and it is $O(h^{1-d})$ or $o(h^{1-d})$ provided

$$\nu(t) = O(t|\log t|^{-1}), \tag{4.6.16}$$

$$\nu(t) = o(t|\log t|^{-1}) \tag{4.6.17}$$

respectively.

We will prove in this section that under assumption (4.6.16) the remainder estimate is $O(h^{1-d})$. Moreover under appropriate condition to the dynamic system we will prove in this section that under assumption (4.6.17) remainder estimate is $o(h^{1-d})$.

Further we will prove that under assumption $\nu(t) \ge t|\log t|^{-1}$ for all $t \in (0,1)$ the remainder estimate is $O\big(h^{-d}\nu(Ch|\log h|)\big)$.

Thus spectral asymptotics for operators with symbols satisfying (4.6.1)–(4.6.4) are instrumental for spectral asymptotics for operators with $\mathscr{C}^{l}_{\nu}$-coefficients.

Remark 4.6.5. (i) We will assume that $\rho_1 = ... = \rho_d = \rho$ and $\gamma_1 = ... = \gamma_d = \gamma$.

(ii) We can see that the most important case is

$$\rho = 1, \qquad \gamma = \varepsilon. \tag{4.6.18}$$

Actually one can reduce more general case $\rho \ge \gamma$ to it by rescaling. So we assume that (4.6.18) holds.

(iii) In Section 4.7 we replace the bracketing method by perturbation method which allows us to improve remainder estimates in asymptotics for Riesz means N^{-}_{φ} (as ϑ is sufficiently large) and consider asymptotics of $\mathsf{N}_x(\tau_1,\tau_2)$ and $\mathsf{N}^{-}_{x,\varphi}$.

4.6.2 Estimates

The simplest thing to try would be to scale $x \mapsto x\varepsilon^{-1}$, $t \mapsto t\varepsilon^{-1}$, $\xi \mapsto \xi\varepsilon^{-1}$ and $h \mapsto h\varepsilon^{-1}$. However then scaling back we have estimate

$$\mathsf{R} \prec C\big(\frac{h}{\varepsilon}\big)^{1-d}\varepsilon^{-d} \asymp C\varepsilon^{-1}h^{1-d} \tag{4.6.19}$$

where R denotes both Tauberian R^{T} and Weyl R^{W} errors. Thus we got an extra factor ε^{-1} which is really bad. For errors in averaged expressions we would get even worse factor ε^{-1-s} where an extra factor ε^{-s} comes from $\vartheta\big(h/L\varepsilon\big) : \vartheta\big(h/L\big)$.

These bad factors are no surprise: actually we use usual Tauberian estimate but with time $T \asymp \varepsilon$ instead of $T \asymp 1$. Fortunately we have Theorem 2.3.5(vi) which implies that

Proposition 4.6.6. *Let $\varepsilon \ge Ch|\log h|$. Then under ξ-microhyperbolicity condition on the energy level 0 estimate* (2.1.59) *remains true as $T \in [h, T_0]$ with small constant T_0 and then*

$$\|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma_x\big(Q_{1x}u\,{}^tQ_{2y}\big)\| \le Ch^{1-d} \qquad \forall \tau : |\tau| \le \epsilon_0 \tag{4.6.20}$$

Then our standard Tauberian technique implies the standard estimate

$$\mathsf{R}^{\mathsf{T}}_{\varphi} \prec Ch^{1-d}\vartheta\big(\frac{h}{L}\big) \tag{4.6.21}$$

where ϑ is a continuity modulus of φ.

4.6.3 Successive Approximations and Calculations

Now we need to pass from Tauberian expression

$$\mathsf{N}^{\mathsf{T}}_x = \int_{-\infty}^{\tau} \Big(F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma_x\big(Q_{1x}u(x,y,t)\,{}^tQ_{2y}\big)\Big)\,d\tau \tag{4.6.22}$$

to Weyl expression.

As in Sections 4.3–4.5 Q_1 and Q_2 are fixed operators, $\bar\chi$ is a fixed $\mathscr{C}_0^\infty([-1,1])$ function, $\bar\chi = 1$ on $[-\frac{2}{3}, \frac{2}{3}]$ and T is a small enough constant.

Remark 4.6.7. In order to deal with operators of (4.6.1)–(4.6.4) type we assume that $Q_j \in \boldsymbol{\Psi}_{h,\mathsf{an}}$.

Since we know from (2.1.59) that $F_{t\to h^{-1}\tau}\chi_T(t)\Gamma_x Q_{1x}u\,{}^tQ_{2y}$ is negligible as $T \in [h^{1-\delta}, T_0]$ we conclude that

(4.6.23) In the Tauberian expression we can take any $T \in [h^{1-\delta}, T_0]$.

Remark 4.6.8. (i) Minor improvement of the propagation technique implies that actually one can take any $T \in [Ch|\log h|, T_0]$; we will not need this improvement for a very long time and we will make it much later.

(ii) Improvements connected with our ability to chose T_0 as an arbitrarily large constant will be discussed later.

We will apply successive approximation method. Almost as in Section 4.3 we introduce operators $\bar{A} = A(y, hD_x)$ and $R = A - \bar{A}$ and arrive to the same formula (4.3.10)′:

$$(4.3.10)' \quad u^{\pm}\, {}^{t}Q_{2y} \equiv \mp ih \sum_{0\le n\le N-1} (\bar{G}^{\pm}R)^n \bar{G}^{\pm}\mathcal{K}(x,y)\delta(t) \mp ih(\bar{G}^{\pm}R)^n G^{\pm}\mathcal{K}(x,y)\delta(t).$$

Plugging it into (4.6.23) we conclude that

(4.6.24) n-th term (with $n = 0, 1, ...$) in the resulting formula does not exceed

$$(4.6.25) \qquad Ch^{-d}T\big(\frac{T^2}{h}\big)^n$$

where we can take $T = h^{1-\delta}$ with arbitrarily small exponent $\delta > 0$ [41].

(4.6.26) In particular, as we are looking for R^{W} it is sufficient to take 2 terms and as we are looking for $\mathsf{R}^{\mathsf{W}}_{\varphi}$ with $L \le 1$ it is sufficient to take $2 + \lfloor s \rfloor$ terms provided $\vartheta(z) \ge \epsilon_0 z^s \quad \forall z \in (0,1)$.

Let us prove

Proposition 4.6.9. *Under ξ-microhyperbolicity condition n-th term does not exceed* (4.6.24) *with $T = h$, i.e. Ch^{1-d+n}.*

Proof. It is sufficient to consider n-th term with $\bar{\chi}_T(t)$ replaced by $\chi_T(t)$ with "new" T running from h to "old" T and to estimate this term by (4.6.25) multiplied by $(hT^{-1})^M$ with sufficiently large exponent M; here and below $h \le T \le \epsilon_0$.

Scaling $x \mapsto (x-y)T^{-1}$, $t \mapsto tT^{-1}$, $h \mapsto hT^{-1}$ we conclude that it is sufficient to consider $T = \epsilon_0$ only. Let us recall that n-th term could be rewritten as a "sandwich" u_n with operators $\bar{G}^{\pm}$ interlaced with h-pseudodifferential operators; the latter now are of $\boldsymbol{\Psi}_{\varepsilon T^{-1},1,hT^{-1},\mathsf{an}}$ class.

[41] Actually according to Remark 4.6.7 we can take $T = Ch|\log h|$.

However Theorem 2.3.2 and ξ-microhyperbolicity condition on the energy level 0 which is preserved under rescaling imply that

$$\mathsf{WF}(Q_{1x}u_n^{\pm}\,{}^tQ_{2y})\cap\{|\tau|\le\epsilon\}\cap\{\epsilon\le\pm t\le\epsilon_0\}\subset \{\pm\langle\ell_\xi, y-x\rangle\ge\pm\epsilon_0 t\} \tag{4.6.27}$$

where $(0,\ell_\xi)$ is the direction of microhyperbolicity and therefore

$$\mathsf{WF}\big(\Gamma_x(Q_{1x}u_n^{\pm}\,{}^tQ_{2y})\big)\cap\{|\tau|\le\epsilon\}\cap\{\epsilon\le\pm t\le\epsilon_0\}=\emptyset \tag{4.6.28}$$

and the required estimate is proven. □

Thus, if we are interested just in $O(h^{1-d})$ estimate i.e. we are looking for $s=0$, we are done: we need to consider just one term, i.e. we can take $N=1$ in (4.3.10)′; to be able to take $A_0(y,hD_x)$ instead of $A(y,hD_x)$ we will need to make assumption that their difference is $O(h)$ (see assumption (4.6.33) below with $l=1$).

If we are interested in estimate better than $O(h^{1-d})$ but not better than $O(h^{2-d})$ we should take $N=2$ and consider a new term

$$\mp ih\bar{G}^{\pm}R\bar{G}^{\pm}\mathcal{K}(x,y)\delta(t), \tag{4.6.29}$$

plug here

$$\bar{R}=\sum_{1\le|\alpha|+k\le l}\frac{1}{\alpha!}(x-y)^{\alpha}A_{k(\alpha)}(y,hD_x)h^k \tag{4.6.30}$$

with $l=1$ instead of R, getting again the standard term

$$\mp ih\bar{G}^{\pm}\bar{R}\bar{G}^{\pm}\mathcal{K}(x,y)\delta(t), \tag{4.6.31}$$

(and plugging it to expression we need to calculate) and find estimate for the error due to

$$\mp ih\bar{G}^{\pm}R'\bar{G}^{\pm}\mathcal{K}(x,y)\delta(t), \tag{4.6.32}$$

with $R'=R-\bar{R}$. For remainder estimate better than $O(h^{1-d})$ we will need more regularity assumptions than (4.6.1)–(2.3.6).

Further, if we are interested in the remainder estimate $O(h^{l-d})$ with $l>1$ we need to assume more regularity conditions: namely that (4.6.1) holds for all γ with $|\gamma|\le m$ and modify (4.6.2) in the similar way to keep $A_{k(\alpha)}$

with $k+|\alpha|\le l$ bounded. Then expression due to (4.6.32) will be obviously $O(h^{l-d})$. We need to consider higher order successive approximation terms in (4.3.10)$'$, replace R by $\bar{R}$ in each of them and estimate an error. However these terms will be easier and we will be able even to shorten $\bar{R}$ in them.

Finally, for remainder estimates between $O(h^{l-d})$ and $O(h^{l+1-d})$ we will need intermediate regularity conditions. So, let us assume that

$$\|A^{(\alpha)}_{i+k(\beta+\gamma)}(x,\xi)\| \le c(i!|\alpha|!|\beta|!)\varepsilon^{-|\beta|-i} \qquad \forall i,\alpha,\beta : |\alpha|+|\beta|+2i\le N\ \forall \gamma, k : |\gamma|+k\le l \tag{4.6.33}$$

and

$$\|A^{(\alpha)}_{i+k(\beta+\gamma)}(x,\xi) - A^{(\alpha)}_{i+k(\beta+\gamma)}(y,\xi)\| \le c(i!|\alpha|!|\beta|!)\varepsilon^{-|\beta|-i}\nu(|x-y|)|x-y|^{-l} \qquad \forall i,\alpha,\beta : |\alpha|+|\beta|+2i\le N\ \forall \gamma, k : |\gamma|+k=m \tag{4.6.34}$$

with $N=\epsilon\hbar^{-1}$, $\hbar=h/\varepsilon$ where ν satisfies (4.6.7).

Proposition 4.6.10. *Let ξ-microhyperbolicity condition,* (4.6.33) *and* (4.6.34) *be fulfilled with ν satisfying* (4.6.7). *Then replacing in* (4.3.10)$'$ R *by* $\bar{R}$ *defined by* (4.6.30) *leads to* $O\big(h^{-d}\nu(h)\big)$ *error.*

Proof. So, we need to consider sandwiches

$$\bar{G}^{\pm}R_1\bar{G}^{\pm}R_2\bar{G}^{\pm}\cdots R_{n-1}\bar{G}^{\pm}\mathcal{K}(x,y)\delta(t)$$

with n factors $\bar{G}^{\pm}$ and $(n-1)$ factors R_k where each R_k is either $\bar{R}$ or $(R-\bar{R})$ and there is at least one latter factor. Then acting as before we can estimate the contribution of each sandwich by $Ch^i(h/T)^{-M}$ with $i=n_1+ln_2$ and $M\le Ci$ where n_1, n_2 is the number of factors of each type, $n_1+n_2=n$ and $n_2\ge 1$.

Then the contribution of each sandwich does not exceed $Ch^{-d+i-\delta}$ while $\nu(h)\ge h^{l+1}$. Obviously $i\ge l+2$ unless $n\le 3$ and the contribution of the sandwich is properly estimated.

Further, we can apply the same procedure as in the proof of Proposition 4.6.9: let us pick up $T=h$ and then the contribution of sandwich does not exceed Ch^{-d+l}; then let us plug $\chi_T(t)$ instead of $\bar{\chi}_T(t)$ with "new" T running from h to "old" T and basing on Theorem 2.3.2 estimate this

contribution by $Ch^{-d+l}(h/\mathsf{T})^{M'-M}$ where we can take M' arbitrarily large, say $M' = M+1$ and then summation with respect to partition results in Ch^{-d+l}. Obviously $i \ge l+1$ unless $n=2$ and the contribution of the sandwich is properly estimated.

So, only case $n=2$ needs a special consideration and only in the case when $\nu(h) \asymp h^l$ fails. Then we have "a simple sandwich"

$$\bar{G}^{\pm}(R-\bar{R})\bar{G}^{\pm}\mathcal{K}(x,y)\delta(t);$$

let us insert factor ψ_r in the middle:

$$\bar{G}^{\pm}\psi_r(R-\bar{R})\bar{G}^{\pm}\mathcal{K}(x,y)\delta(t);$$

where $\psi_r = \psi\big((x-y)r^{-1}\big)$ and we consider three cases:

(i) $r = CT$, $\psi \in \mathsf{S}^0_{h,\mathsf{an}}$ is supported in $\{|x-y| \le 1\}$, $T = h$. Then since norm of $\psi_r(R-\bar{R})$ does not exceed $C\nu(r)$ [42] and and as $T \asymp h$ we estimate the contribution of such modified sandwich by $Ch^{-d}\nu(r)$ which is $O\big(h^{-d}\nu(h)\big)$.

(ii) $r = CT$, $\psi \in \mathsf{S}^0_{h,\mathsf{an}}$ is supported in $\{|x-y| \le 1, |\xi| \le c\}$, $T \ge h$ and $\bar{\chi}$ is replace by χ. Then we estimate the contribution of such modified sandwich by

$$Ch^{-d}\nu(r)\big(\frac{h}{T}\big)^{M-M'} \lesssim Ch^{-d}\nu(T)\big(\frac{h}{T}\big)^{M'-M} \lesssim Ch^{-d}\nu(h)\big(\frac{h}{T}\big)^{M-M'-l-1}$$

and summation with respect to t-partition results in $Ch^{-d}\nu(h)$ since M' is arbitrarily large. I remind that we apply Theorem 2.3.2 after rescaling $x \mapsto (x-y)T^{-1}$, $t \mapsto tT^{-1}$ and $h \mapsto hT^{-1}$. We again used estimate of $\psi_r(R-\bar{R})$ with footnote [42].

(iii) $r \ge CT$, $\psi \in \mathsf{S}^0_{h,\mathsf{an}}$ is supported in $\{|x-y| \le 1, |\xi| \le c\}$, $T \ge h$. Then we estimate the contribution of such modified sandwich by

$$Ch^{-d}\nu(r)\big(\frac{h}{T}\big)^{M-M'} \lesssim Ch^{-d}\nu(r)\big(\frac{h}{T}\big)^{-M}\big(\frac{h}{R}\big)^{M'} \lesssim Ch^{-d}\nu(h)\big(\frac{h}{r}\big)^{M-M'-l-1}$$

where we use the same procedure as before but we apply Theorem 2.3.2 after rescaling $x \mapsto (x-y)r^{-1}$, $t \mapsto tr^{-1}$ and $h \mapsto hr^{-1}$. We again used estimate of $\psi_r(R-\bar{R})$ with footnote [42]. Again summation with respect to r results in $Ch^{-d}\nu(h)$ since M' is arbitrarily large. □

[42] Actually it may be true only if we multiply this operator by $\bar{Q} = \bar{q}(hD)$ with compactly supported symbol but we can insert such factor with the negligible error.

Thus we constructed "Weyl approximation" with $O\big(h^{-d}\nu(h)\big)$ error for Tauberian expressions (4.6.23) and also for

$$\mathsf{N}_{x,\varphi,L} = \int \varphi_L(\tau)\Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma_x\big(Q_{1x}u(x,y,t)\,{}^tQ_{2y}\big)\Big)\,d\tau \tag{4.6.35}$$

(with small constant T). Let us recall that according to Tauberian arguments $\mathsf{N}_x^{\mathsf{T}}(0)$ defined by (4.6.22) and $\mathsf{N}_{x,\varphi,L}(0)$ defined by (4.6.35) approximate $\mathsf{N}_x(0)$ and

$$\mathsf{N}_{x,\varphi,L}(0) = \int \varphi_L(\tau) d_\tau\Big(\Gamma_x\big(Q_{1x}e(.,.,0)\,{}^tQ_{2y}\big)\Big) \tag{4.6.36}$$

with $O(h^{1-d})$ and $O(h^{1-d}\vartheta(h/L))$ errors.

So, we arrive to

Corollary 4.6.11. *(i) For N_x Weyl approximation is as good as the Tauberian one provided $\nu(t) = O(t)$ as $t \to +0$ (which we assumed).*

(ii) For $\mathsf{N}_{x,\varphi,L}$ Weyl approximation is as good as the Tauberian one as $L \le 1$ and $\nu(t) = O\big(t\vartheta(t)\big)$ as $t \to +0$.

(iii) In both cases the difference between Weyl and Tauberian approximations is "o" in comparison with the remainder estimate provided $\nu(t) = o(t)$ as $t \to +0$ or $\nu(t) = o\big(t\vartheta(t)\big)$ as $t \to +0$ respectively.

Proof. These statements are clearly true for N_x and for $\mathsf{N}_{x,\varphi,L}$ with $L \lesssim 1$. Then for $\mathsf{N}_{x,\varphi,L}$ with $L \gtrsim 1$ we can apply arguments of Remark 4.4.10. □

4.6.4 Main Theorems

Now we arrive immediately to the following

Theorem 4.6.12. *Let A be a self-adjoint operator with the symbol satisfying (4.6.34) where ν satisfies (4.6.7) and $l \ge 1$. Assume that ξ-microhyperbolicity condition on the energy level 0 at each point of $\pi_x\big(\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)\big)$.*

Then

$$\mathsf{R}^{\mathsf{W}}_{x,\varphi,L} \prec Ch^{1-d}\Big(\vartheta\big(\frac{h}{L}\big) + \nu(h)h^{-1}\Big); \tag{4.6.37}$$

in particular

$$\mathsf{R}^{\mathsf{W}}_{x} \prec Ch^{1-d}\Big(1 + \nu(h)h^{-1}\Big). \tag{4.6.38}$$

Corollary 4.6.13. *The same estimates hold for* $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$, R^{W}.

Now let us slightly improve remainder estimates using long term propagation.

Theorem 4.6.14. *Let conditions of Theorem 4.6.12 be fulfilled. Let* $r_i^0 \in \mathsf{S}_{h,\gamma,\gamma,K}(T^*X)$ [34] *be scalar symbols satisfying* (4.5.11).

Consider generalized Hamiltonian flow $\Psi_{t,0}$ *issued from* γ*-vicinity* $\mathcal{U}_i$ *of* $\mathsf{supp}(r_i^0) \cap \mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$. *Assume that as* $\varsigma t > 0$ *with* $\varsigma := \varsigma_{*i}$ [32] *and* $|t| \le T_i$ *conditions* (4.5.28), (4.5.30) *and* (4.5.31) *are fulfilled with* $\mathcal{U} := \mathcal{U}_i$.

(i) Then

$$\mathsf{R}^{\mathsf{T}}(0) \prec \sum_{0\le i\le m} C_0 \frac{h^{1-d}}{T_i}\Big(J(r_i^0 q_1^0, 0) + J(r_i^0 q_2^0, 0) + C'h\Big), \tag{4.6.39}$$

$$\mathsf{R}^{\mathsf{T}}_{\varphi,L} \prec \sum_{0\le i\le m} C_0 \frac{h^{1-d}}{T_i}\Big(J(r_i^0 q_1^0, 0) + J(r_i^0 q_2^0, 0) + C'h\Big)\vartheta\big(\frac{h}{LT_i}\big). \tag{4.6.40}$$

Here C' *depends on* γ, m, $\max_i T_i$.

(ii) Further, the same estimates with an extra term $Ch^{-d}\nu(h)$ *in the right-hand expressions hold for* $\mathsf{R}^{\mathsf{W}}(0)$ *and* $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$.

Theorem 4.6.15. *Let conditions of Theorem 4.6.12 be fulfilled. Consider generalized Hamiltonian flow* $\Psi_{t,\bar\tau_*}$ *issued from* γ*-vicinity* $\mathcal{U}_i$ *of* $\mathsf{supp}(r_i^0) \cap (\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2))$. *Assume that as* $|t| \le T_i$ *conditions* (4.5.28), (4.5.29) *and* (4.5.31) *are fulfilled with* $\mathcal{U} := \mathcal{U}_i$.

(i) Then

$$\mathsf{R}^{\mathsf{T}}_x(0) \prec \sum_{0\le i\le m} C_1 \frac{h^{1-d}}{T_i}\Big(J_x(r_i^0 q_1^0, 0) + J_x(r_i^0 q_2^0, 0) + C'h\Big), \tag{4.6.41}$$

$$\mathsf{R}^{\mathsf{T}}_{x,\varphi,L} \prec \sum_{0\le i\le m} C_1 \frac{h^{1-d}}{T_i}\Big(J_x(r_i^0 q_1^0, 0) + J_x(r_i^0 q_2^0, 0) + C'h\Big)\vartheta\big(\frac{h}{LT_i}\big). \tag{4.6.42}$$

Here $C_1 = C_0(l+1)$ *and* C' *depends on* γ, m, $\max_i T_i$.

(ii) Further, the same estimates with an extra term $Ch^{-d}\nu(h)$ *in the right-hand expressions hold for* $\mathsf{R}^{\mathsf{W}}(0)$ *and* $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$.

4.6.5 Applications: Bracketing Method

At this moment we want to demonstrate technique rather than achieve the most general results. In particular we want to use only the simplest variational arguments. Therefore we assume that operator A defined by consider operator (4.6.5) is elliptic with the positively defined senior symbol:

$$\langle a^0(x,\xi)w,\ w\rangle \ge \epsilon_0|\xi|^{2m}\|w\|^2 \qquad \forall \xi \in \mathbb{R}^d\ \forall w \tag{4.6.43}$$

with

$$a^0(x,\xi) \coloneqq \sum_{\alpha:|\alpha|+|\beta|=2m} .a_{\alpha\beta}(x)\xi^{\alpha+\beta} \tag{4.6.44}$$

Then provided $a_{\alpha\beta} \in \mathscr{C}$ (as $|\alpha| = |\beta| = m$)

$$(Au, u) \ge \epsilon_0 h^{2m}\|u\|_{\mathscr{H}^m} - C_0\|u\|^2 \qquad \forall u \in \mathscr{H}^m \tag{4.6.45}$$

First of all, applying Theorem 4.6.12 and Corollary 4.6.13 we immediately arrive to

Theorem 4.6.16. *Let A be an partial differential operator in the divergent form* (4.6.5) *on compact closed manifold with the coefficients belonging to $\mathscr{C}^l_\nu$ with ν satisfying* (4.6.7) *and $l \ge 1$. Let* (4.6.43) *be fulfilled. Assume that ξ-microhyperbolicity condition on energy level 0 is fulfilled at each point. Let $Q_1 = Q_2 = I$, $\psi_1 = \psi_2 = 1$.*

Then

$$|\operatorname{tr}(\mathsf{R}^{\mathsf{W}}_{\varphi,L})| \le Ch^{1-d}\Big(\vartheta(\frac{h}{L}) + \nu(\varepsilon)h^{-1}\Big)\operatorname{dim}\mathbb{H} \tag{4.6.46}$$

with $\varepsilon = h|\log h|$; in particular

$$|\operatorname{tr}(\mathsf{R}^{\mathsf{W}})| \le Ch^{1-d}\Big(1 + \nu(\varepsilon)h^{-1}\Big)\operatorname{dim}\mathbb{H}. \tag{4.6.47}$$

Proof. Indeed, we can bracket A between two operators with the rough coefficients, different from those of A by $O(\nu(\varepsilon))$. We leave easy details to the reader. □

Corollary 4.6.17. *In the framework of Theorem 4.6.16 with fixed $\operatorname{dim}\mathbb{H} < \infty$ the usual remainder estimate $|\operatorname{tr}(\mathsf{R}^{\mathsf{W}}_{\varphi,L})| \le Ch^{1-d}\vartheta(h/L)$ holds as $L \le 1$ provided continuity modulus ν satisfies*

$$\nu(\varepsilon) \lesssim \vartheta(\varepsilon|\log\varepsilon|^{-1})\cdot\varepsilon|\log\varepsilon|^{-1}; \tag{4.6.48}$$

in particular, the usual remainder estimate $|\mathsf{tr}(\mathsf{R}^{\mathsf{W}})| \le Ch^{1-d}$ *holds provided*

$$\nu(\varepsilon) \lesssim \varepsilon |\log \varepsilon|^{-1}. \tag{4.6.49}$$

Now let us combine Theorem 4.6.14 with the approximation arguments. We will get an approximation error $O(h^{-d}\nu(\varepsilon))$ but there is a problem: in this theorem non-periodicity condition is supposed to be fulfilled with the generalized Hamiltonian flow generated by a_ε while it is natural to consider generalized Hamiltonian flow generated by the original symbol a. The good news are that

(4.6.50) As $\varepsilon \to +0$ the generalized bicharacteristics of $(\tau - a_\varepsilon)$ converge to those of $(\tau - a)$

and therefore

$$\Psi_{t,a}(\mathcal{U}) \supset \lim_{\varepsilon \to +0} \Psi_{t,a_\varepsilon}(\mathcal{U}). \tag{4.6.51}$$

Thus non-periodicity condition (4.5.30) for $\Psi_{t,a}$ implies the same condition for Ψ_{t,a_ε} with γ replaced by $\frac{1}{2}\gamma$ and Theorem 4.6.14 implies

Theorem 4.6.18. *Let conditions of Theorem 4.6.16 be fulfilled.*

Consider generalized Hamiltonian flow $\Psi_{t,0}$ *issued from* γ*-vicinity* $\mathcal{U}_i$ *of* $\mathsf{supp}(r_i^0) \cap \mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$*. Assume that as* $\varsigma t > 0$ *with* $\varsigma := \varsigma_{*i}$ [32] *and* $|t| \le T_i$ *conditions* (4.5.28), (4.5.30) *and* (4.5.31) *are fulfilled with* $\mathcal{U} := \mathcal{U}_i$*.*

Then

$$\mathsf{R}^{\mathsf{W}}(0) \prec \sum_{0\le i\le m} C_0 \frac{h^{1-d}}{T_i}\Big(J(r_i^0 q_1^0, 0) + J(r_i^0 q_2^0, 0) + C'h\Big) + C_0 h^{-d}\nu(\varepsilon), \tag{4.6.52}$$

$$\mathsf{R}^{\mathsf{T}}_{\varphi,L} \prec \sum_{0\le i\le m} C_0 \frac{h^{1-d}}{T_i}\Big(J(r_i^0 q_1^0, 0) + J(r_i^0 q_2^0, 0) + C'h\Big)\vartheta\big(\frac{h}{LT_i}\big) + C_0 h^{-d}\nu(\varepsilon) \tag{4.6.53}$$

hold with $\varepsilon = Ch|\log h|$.

Corollary 4.6.19. *Assume that one can select T_i as arbitrarily large constants for $i \ge 1$ and simultaneously $\mu_0(\mathcal{U}_0)$ to be arbitrarily small then*

$$\mathsf{R}^{\mathsf{W}} = o\big(h^{1-d}\big), \tag{4.6.54}$$

$$\mathsf{R}^{\mathsf{W}}_{\varphi,L} = o\big(h^{1-d}\vartheta\big(\frac{h}{L}\big)\big), \tag{4.6.55}$$

provided $\nu(\varepsilon) = o\big(h^{1-d}\big)$ and $\nu(\varepsilon) = o\big(h^{1-d}\vartheta(h/L)\big)$ respectively (with $\varepsilon = h|\log h|$) i.e.

$$\nu(\varepsilon) = o\big(\varepsilon|\log\varepsilon|^{-1}\big), \tag{4.6.56}$$

$$\nu(\varepsilon) = o\big(\vartheta(\varepsilon|\log\varepsilon|^{-1})\cdot\varepsilon|\log\varepsilon|^{-1}\big). \tag{4.6.57}$$

Remark 4.6.20. (i) It is not clear if sets in both sides of (4.6.51) coincide; so may be non-periodicity assumption for a is more restrictive than for a_ε.

(ii) Even in the scalar case when equation of the generalized bicharacteristics becomes

$$\frac{dz}{dt} = -\nabla^{\#}a(z)$$

those could branch unless the right-hand expression satisfies Lipshitz condition i.e. $l \ge 2$ and $\nu(\varepsilon) = O(\varepsilon^2)$.

Finally, let us consider less regular case of $l = 0$. Let us apply the same approximation as before. However we can apply Theorem 4.6.12 only after rescaling $x \mapsto x/T$, $t \mapsto t/T$ with

$$T = T(\varepsilon) = \varepsilon\nu(\varepsilon)^{-1} \tag{4.6.58}$$

which leads to the remainder estimates

$$\mathsf{R}^{\mathsf{T}}_x \prec Ch^{1-d}\frac{1}{T(\varepsilon)} = Ch^{1-d}\varepsilon^{-1}\nu(\varepsilon). \tag{4.6.59}$$

One can see easily that this is less then the approximation error $Ch^{-d}\nu(\varepsilon)$ and therefore

Theorem 4.6.21. *Let conditions of Theorem 4.6.16 be fulfilled but with $l = 0$. Then*

$$\mathsf{R}^{\mathsf{W}}_x \prec C\nu(\varepsilon)h^{-d}. \tag{4.6.60}$$

Since approximation error dominates, mollification with respect to the spectral parameter would not improve this estimate.

4.6.6 Final Remarks

The following problem may be easy, or not:

Problem 4.6.22. (i) Replace assumption (4.6.43) by

$$\|a_0(x,\xi)w\| \ge \epsilon_0|\xi|^2 m\|w\| \qquad \forall \xi \in \mathbb{R}^d\ \forall w. \tag{4.6.61}$$

Then as $a_{\alpha\beta} \in \mathscr{C}$ (as $|\alpha| = |\beta| = m$)

$$\|(1+h^2|D|^2)^{-m/2}Au\| \ge \epsilon_0\|(1+h^2|D|^2)^{m/2}u\| - C_0\|u\| \qquad \forall u \in \mathscr{H}^m. \tag{4.6.62}$$

(ii) Instead of operators (4.6.5) consider

$$A(x,hD) = \sum_{\substack{\alpha,\beta:|\alpha|\le m+1,\,|\beta|\le m+1,\\ |\alpha|+|\beta|\le 2m+1}} (hD)^\alpha a_{\alpha\beta}(x)(hD)^\beta \tag{4.6.63}$$

under assumption (4.6.61) with

$$a^0(x,\xi) \coloneqq \sum_{\alpha:|\alpha|+|\beta|=2m+1} a_{\alpha\beta}\xi^{\alpha+\beta}. \tag{4.6.64}$$

Then as $a_{\alpha\beta} \in \mathscr{C}^1$ as $|\alpha|+|\beta| = 2m+1$

$$\|(1+h^2|D|^2)^{-\bar m/2}Au\| \ge \epsilon_0\|(1+h^2|D|^2)^{\bar m/2}u\| - C_0\|u\| \qquad \forall u \in \mathscr{H}^{\bar m} \tag{4.6.65}$$

where here and below $\bar m = m$ for for operators (4.6.5) and $\bar m = m + \frac{1}{2}$ for operators (4.6.63).

Remark 4.6.23. (i) We did not consider in this section operators with unbounded coefficients. Most likely that this two generalizations of the standard case do not mix well together.

(ii) We did not consider in this section sharper remainder estimates. While they are possible the conditions of theorems (especially in applications) become too exotic.

Remark 4.6.24. Can we replace ξ-microhyperbolicity by microhyperbolicity retaining our results for $\mathsf{N}^{\mathsf{T}}, \mathsf{N}^{\mathsf{T}}_{\varphi,L}, \mathsf{N}^{\mathsf{W}}, \mathsf{N}^{\mathsf{W}}_{\varphi,L}$? The answer is positive but with a lot of caveats.

(i) First of all, in Subsection 4.6.2 we need to replace $\bar{T} = h^{1-\delta}$ by $\bar{T} = h^{1-\delta}\varepsilon^{-1}$. Really, as we go to ξ-microhyperbolic case applying metaplectic transformation, we get operator belonging to $\mathbf{\Psi}_{h,\varepsilon,\varepsilon,\mathsf{an}}$. Then shift $\asymp T$ is observable as microlocal uncertainty principle $T\cdot\varepsilon \ge h^{1-\delta}$ is fulfilled; improvements as we apply logarithmic uncertainty principle are superficial.

It looks really bad because then we should estimate expression (4.1.11)

$$F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\big(Q_{1x}u\,{}^tQ_{2y}\big)$$

by $Ch^{1-d}\varepsilon^{-1}$ which would lead to remainder estimates with an extra factor ε^{-1} but actually we can repair this after calculations.

(ii) Still the method of the successive approximations requires $T \le h^{\frac12+\delta}$ and $\bar{T}$ satisfies this if and only if

$$\varepsilon \ge h^{\frac12-\delta} \tag{4.6.66}$$

where we change an arbitrarily small exponent $\delta > 0$ if needed. Under this condition and microhyperbolicity one can prove easily that

$$|\kappa_n^{(i)}| \le C\,\mathsf{max}\big(\varepsilon^{-n-i}\nu(\varepsilon),1\big). \tag{4.6.67}$$

Then as $l \ge 1$ and ε satisfies (4.6.66) we can estimate (4.1.11) by Ch^{1-d} and therefore no factor ε^{-1} actually appears. Note that we must assume that $l \ge 1$; otherwise we cannot differentiate with respect to x in applications and microhyperbolicity does not make sense (while ξ-microhyperbolicity does not require such differentiation).

(iii) Much larger ε given by (4.6.66) increases an approximation error and to achieve the proper remainder estimates we must assume that $h^{-d}\nu(\varepsilon) \le h^{1-d}\vartheta(h)$ (as $L = 1$) which means now

$$\nu(\varepsilon) = O\big(\vartheta\big(\varepsilon^{2+2\delta}\big)\varepsilon^{2+2\delta}\big); \tag{4.6.68}$$

in particular, as $\vartheta = 1$ we get

$$\nu(\varepsilon) = O\big(\varepsilon^{2+2\delta}\big). \tag{4.6.69}$$

Further to recover sharp remainder estimates we need to replace in these conditions "O" by "o".

4.7 Operators with Irregular Coefficients

4.7.1 Preliminary Analysis

Our goal is to derive spectral asymptotics for operators (4.6.5) and (4.6.63) satisfying ellipticity condition (4.6.61).

For brevity of statements we consider

(4.7.1) operator A of the type either (4.6.5) or (4.6.63), with $a_{\alpha\beta} \in \mathscr{C}^l$ for all α, β and with $a_{\alpha\beta} \in \mathscr{C}^{l+1}$ as $|\alpha| + |\beta| = 2m + 1$. Let $\bar{m} = \frac{1}{2}\mathsf{ord}A$.

Proposition 4.7.1. *Let us consider operator A of the type* (4.7.1).

(i) Then the following estimate holds

$$\|(1+h^2|D|^2)^{(-\bar{m}+s)/2}Au\| \le C_0\|(1+h^2|D|^2)^{(\bar{m}+s)/2}u\| \qquad \forall u \in \mathscr{H}^{\bar{m}}\ \forall s : |s| \le l. \tag{4.7.2}$$

(ii) If ellipticity condition (4.6.61) *is fulfilled then*

$$\|(1+h^2|D|^2)^{(-\bar{m}+s)/2}Au\| \ge \epsilon_0\|(1+h^2|D|^2)^{(\bar{m}+s)/2}u\| - C_0\|(1+h^2|D|^2)^{s}u\| \qquad \forall u \in \mathscr{H}^{\bar{m}+s}\ \forall s : |s| \le l. \tag{4.7.3}$$

Proof. Easy proof is left to the reader. □

Then in virtue of embedding theorem we immediately arrive to

Corollary 4.7.2. *In the framework of Proposition 4.7.1(ii) with*

$$m^* := l + m' - d/2 > 0 \tag{4.7.4}$$

the following estimate holds

$$|(hD_x)^\alpha (hD_y)^\beta e(x,y,\tau_1,\tau_2)| \le Ch^{-d} \tag{4.7.5}$$

for all $\alpha : |\alpha| < m^*$, $\beta : |\beta| < m^*$, for $|\tau_1| \le c$, $|\tau_2| \le c$.

4.7.2 Tauberian Estimates

Now we can unleash the full power of microlocal analysis but we need to extend it to our framework.

Proposition 4.7.3. *For a commutator of a pseudodifferential operator with a smooth compactly supported symbol and $\mathscr{C}^l$-function $b(x)$ a usual commutator formula holds modulo $O(h^l \|\partial b\|_{l-1})$ for any $l > 0$ where*

$$\|b\|_l := \begin{cases} \sum_{\alpha:|\alpha|=l} \sup_x |\partial^\alpha f(x)| & l \in \mathbb{Z}^+, \\ \sum_{\alpha:|\alpha|=\lfloor l \rfloor} \sup_{x\neq y} |x-y|^{\lfloor l \rfloor - l} \cdot |\partial^\alpha f(x) - \partial^\alpha f(y)| & l \notin \mathbb{Z}^+. \end{cases} \tag{4.7.6}$$

Proof. Easy proof is left to the reader. □

For operator A of type (4.7.1) let

$$\|A\|_l := \sum_{\alpha,\beta} \|a_{\alpha\beta}\|_l + \sum_{\alpha,\beta:|\alpha|+|\beta|=2m+1} \|a_{\alpha\beta}\|_{l+1}. \tag{4.7.7}$$

Proposition 4.7.4. *Let us consider operator A of the type* (4.7.1) *satisfying ellipticity condition* (4.6.61). *Let $u(x,y,t)$ be the Schwartz kernel of $e^{ih^{-1}tH_{A,V}}$. Then for $T \asymp 1$*

(i) Estimate

$$\|F_{t\to h^{-1}\tau}\chi_T(t)(hD_x)^\alpha (hD_y)^\beta \psi_1(x)\psi_2(y)u\| \le Ch^s \tag{4.7.8}$$

for all $\alpha : |\alpha| < \bar{m} + l$, $\beta : |\beta| < \bar{m} + l$, s and all $\psi_1, \psi_2 \in \mathscr{C}_0^\infty(B(0,1))$, such that $\operatorname{dist}(\operatorname{supp}(\psi_1), \operatorname{supp}(\psi_2)) \ge C_0 T$, $\chi \in \mathscr{C}_0^\infty([-1,1])$ and $\tau : |\tau| \le c_0$; in this Proposition $\|.\|$ means an operator norm from $\mathscr{L}^2$ to $\mathscr{L}^2$.

(ii) As $l \ge 1$ estimate

$$\|F_{t\to h^{-1}\tau}\chi_T(t)(hD_x)^\alpha (hD_y)^\beta \varphi_1(hD_x)\varphi_2(hD_y)u\| \le Ch^s + Ch^{l-1}\|\partial A\|_{l-1} \tag{4.7.9}$$

holds for all $\alpha : |\alpha| < \bar{m} + l$, $\beta : |\beta| < \bar{m} + l$, s and all $\varphi_1, \varphi_2 \in \mathscr{C}_0^\infty$, such that $\operatorname{dist}(\operatorname{supp}(\varphi_1), \operatorname{supp}(\varphi_2)) \ge C_0 T$, $\chi \in \mathscr{C}_0^\infty([-1,1])$ and $\tau : |\tau| \le c_0$.

(iii) If also $l > 1$ *and in* $B(0,2)$ *operator* A *is* ξ*-microhyperbolic on the energy level* $\tau : |\tau| \le c$ *then then for a small constant* $T = \epsilon$ *estimate* (4.7.9) *holds for all* $\alpha : |\alpha| \le \bar{m} + l$, $\beta : |\beta| \le \bar{m} + l$, s *and all* $\psi_1, \psi_2 \in \mathscr{C}_0^\infty(B(0,1))$, *such that* $\operatorname{diam}(\operatorname{supp}(\psi_1) \cup \operatorname{supp}(\psi_2)) \le \epsilon_0 T$ *and* $\chi \in \mathscr{C}_0^\infty([-1,-\frac{1}{2}] \cup [\frac{1}{2}, 1])$.

Proof. Let $v = e^{ith^{-1}H} f$ with arbitrary f.

(i) Statement (i)[43] is easily proven by the same arguments as in the proof of Theorem 2.1.2: we consider just usual function $\phi(x)$ and operators of multiplication like $\chi(\phi(x))$ so there are no "bad" commutators due to non-smoothness of the coefficients.

(ii) Statement (ii)[44] is also proven by the same arguments; however in this case $\phi = \phi(x,\xi)$ so we need to involve "bad" commutators but their contributions are bounded by

$$C\|Q_1 u\| \cdot \Bigl(h^l \|\!| A |\!\|_l + \|u\| + h^{1+\delta} \|Q' u\| \Bigr)$$

in the right-hand expression while the left-hand expression is $\epsilon h \|Q_1 u\|^2$ where Q, Q_1, and Q' are operators with symbols $\chi(\phi(x,\xi))$, $\chi_1(\phi(x,\xi))$, and $\chi_1(\phi(x,\xi) - \eta)$ respectively, $\eta > 0$ is an arbitrarily small constant (so the latter symbol has a bit larger support than the former one), $\delta > 0$ is a small exponent, $\chi_1(t) = (-\chi'(t))^{\frac{1}{2}}$, and f.e. $\chi(t) = e^{-|t|^{-1}}$ as $t < 0$, $\chi(t) = 0$ as $t \ge 0$.

Therefore we conclude that

$$\|Qu\| \le Ch^{l-1} \|\!| A |\!\|_l + \|u\| + Ch^\delta \|Q' u\|$$

and similarly we can estimate $\|Q'u\|$ with $\|Q''u\|$ in the right-hand expression etc and thus we conclude that

$$\|Qu\| \le Ch^{l-1} \|\!| A |\!\|_l + Ch^s \|u\|$$

which is what we need.

---

[43] Finite speed of propagation with respect to x.

[44] Finite speed of propagation with respect to ξ.

(iii) Statement (iii) is easily proven also by the same arguments: we consider just usual function $\phi(x)$ and operators of multiplication like $\chi(\phi(x))$ so there are no "bad" commutators due to non-smoothness of the coefficients. However we need to consider a contribution of u which is not confined to the small vicinity of (y,η) and we need Statement (ii) for this so the last term in the right-hand expression of (4.7.9) is inherited. We leave easy details to the reader. □

Proposition 4.7.5. *In the framework of Proposition 4.7.4(iii) with however $T : h \le T \le \epsilon$ estimates*

$$|F_{t\to h^{-1}\tau}\chi_T(t)\big((hD_x)^\alpha (hD_y)^\beta u(x,y,t)\big)\big|_{x=y}| \le Ch^{1-d+s}T^{-s} + Ch^{l-1}T^{2-d-l}\Big(\sum_{1\le k\le \lfloor l\rfloor} T^k \|\partial A\|_{k-1} + T^l \|\partial A\|_{l-1}\Big) \tag{4.7.10}$$

and as $l+d>2$

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\big((hD_x)^\alpha (hD_y)^\beta u(x,y,t)\big)\big|_{x=y}| \le Ch^{1-d} \tag{4.7.11}$$

hold for all $\alpha : |\alpha| < \bar m + l - d/2$, $\beta : |\beta| < \bar m + l - d/2$, s as $T=\epsilon$ and $|\tau| \le \epsilon$ where as usual $\chi \in \mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1])$, $\bar\chi \in \mathscr{C}_0^\infty([-1,1])$.

Proof. Observe first that estimate (4.7.10) holds as $T \asymp 1$ in virtue of embedding theorem.

Let us consider $T \in [C_0 h, \epsilon]$; then we apply the standard rescaling $t \mapsto tT^{-1}$, $x \mapsto xT^{-1}$, $h \mapsto hT^{-1}$. Then we need to add factor $T^{-d}\times T$ to the right-hand expression where the first factor appears since $u(x,y,t)$ is a density with respect to y and the second one appears since there is an integral with respect to t in the left-hand expression.

Observation how $\|.\|_l$ scales concludes the proof of (4.7.10).

To prove (4.7.11) observe first that it holds for $T=2h$. To prove it for $h\le T\le\epsilon$ we use t-admissible partition on $[-1,1]\setminus[-h,h]$ and apply (4.7.10) for each element of the partition. The result is Ch^{1-d} unless $l=d=1$ when the result is $O(|\log h|)$. □

Then for $\mathsf{R}^{\mathsf{T}}_x(\tau_1,\tau_2)$ and its averages the standard estimates hold: $\mathsf{R}^{\mathsf{T}}_x \prec Ch^{1-d}$ etc.

4.7.3 Weyl Asymptotics

Now let us pass from Tauberian expression $\mathsf{N}_x^{\mathsf{T}}(\tau_1,\tau_2)$ to Weyl expression $\mathsf{N}_x^{\mathsf{W}}(\tau_1,\tau_2)$.

Theorem 4.7.6. *Let A be operator* (4.7.1) *with $l \ge 1$ satisfying ellipticity condition* (4.6.61) *and* (4.7.4). *Let on the energy levels τ_1 and τ_2 ξ-microhyperbolicity condition is fulfilled.*

(i) Then

$$\Gamma_x(hD_x)^\alpha(hD_y)^\beta e(x,y;\tau_1,\tau_2) - \mathsf{N}_x^{\mathsf{W}}(x;\tau_1,\tau_2) \prec C\bigl(h^{1-d}+h^{-d}\varsigma^{1/2}\bigr) \tag{4.7.12}$$

as $|\alpha| < m^* = m + l - d/2$, $|\beta| < m^*$ and $\varsigma = h^l$ where $\mathsf{N}_x^{\mathsf{W}}(x,\tau)$ means corresponding Weyl expression.

(ii) Further, for φ supported in the small vicinity of $\bar\tau_i$ such that $\partial^\alpha\varphi$ is continuous with the modulus of continuity $\tau^{r-\lceil r\rceil+1}$

$$\int \varphi(\tau)\,d_\tau\Bigl(\Gamma_x(hD_x)^\alpha(hD_y)^\beta e(x,y;\tau,\tau_i) - \mathsf{N}_x^{\mathsf{W}}(x;\tau,\tau_i)\Bigr) \prec C\bigl(h^{1+r-d}+h^{-d}\varsigma^{(r+1)/2}+\delta_{r1}h^{-d}\varsigma|\log\varsigma|\bigr) \tag{4.7.13}$$

as $|\alpha| < m^*$, $|\beta| < m^*$ and $\varsigma = h^l$ where $\mathsf{N}_x^{\mathsf{W}}(x,\tau)$ means corresponding Weyl expression including the second term (if needed).

Remark 4.7.7. It is definitely not as good as $C\bigl(h^{1-d}+h^{-d}\varsigma\bigr)$ estimate we got in the previous section but it is a different object (pointwise vs global), we consider a larger class of operators and it really does not matter provided $\nu(\varepsilon) = O(h^2)$ which is the case as $l \ge 2$ (at least if we set $\varepsilon = h$).

Proof of Theorem 4.7.6. (a) We will use the method of successive approximations but in two steps and the first step will be different. As unperturbed operator we consider A_ε with the coefficients $a_{\alpha\beta\varepsilon} = a_{\alpha\beta} * \phi_\varepsilon$ where $\phi_\varepsilon(x) = \varepsilon^{-d}\phi(\varepsilon^{-1}x)$. Then $|a_{\alpha\beta\varepsilon} - a_{\alpha\beta}| \le \varsigma := \nu(\varepsilon)$ where $\nu(\varepsilon) = C_0\varepsilon^l$ under assumption that coefficients belong to $\mathscr{C}^l$.

Therefore on the energy level $\tau : |\tau| \le C$ the error norm does not exceed $C_0\varsigma$ and then according to calculations of Section 4.4 Tauberian expressions

on intervals $[-T,-T/2]\cup[T/2,T]$ for A and A_ε differ by $Ch^{-d-1}\varsigma T$ and then this is true for Tauberian expressions on interval $[-T,T]$: in the obvious notations

$$\mathsf{N}^{\mathsf{T}}_x(\tau_1,\tau_2;T;A)-\mathsf{N}^{\mathsf{T}}_x(\tau_1,\tau_2;T;A_\varepsilon)\prec Ch^{-d-1}\varsigma T \tag{4.7.14}$$

while Tauberian errors do not exceed $Ch^{1-d}T^{-1}$.

Let us set $\varepsilon = C_0h|\log h|$ [45]. Then according to previous Section 4.6

$$\mathsf{N}^{\mathsf{T}}_x(\tau_1,\tau_2;T;A_\varepsilon)-\mathsf{N}^{\mathsf{W}}_x(\tau_1,\tau_2;A_\varepsilon)\prec Ch^{1-d} \tag{4.7.15}$$

and due to microhyperbolicity one can prove easily that

$$\mathsf{N}^{\mathsf{W}}_x(\tau_1,\tau_2;A_\varepsilon)-\mathsf{N}^{\mathsf{W}}_x(\tau_1,\tau_2;A)\prec Ch^{-d}\varsigma. \tag{4.7.16}$$

Combining, we arrive to

$$\mathsf{R}^{\mathsf{W}}_x(\tau_1,\tau_2;A)\prec C\bigl(h^{1-d}T^{-1}+h^{-d-1}\varsigma T\bigr). \tag{4.7.17}$$

Minimizing by $T\in[C_0h,\epsilon]$ we get

$$\mathsf{R}^{\mathsf{W}}_x(\tau_1,\tau_2;A)\prec C\bigl(h^{1-d}+h^{-d}\varsigma^{\frac12}\bigr). \tag{4.7.18}$$

(b) Similarly, let us consider $\mathsf{N}^{\mathsf{W}}_{x,\varphi}$, with φ supported in the small vicinity of τ_i such that $\partial^\alpha\varphi$ is continuous with the modulus of continuity $\tau^{r-\lceil r\rceil+1}$ as $|\alpha|\le\lceil r\rceil-1$ as $r>0$. Then the Tauberian error is $Ch^{1+r-d}T^{-1-r}$, Tauberian expressions on intervals $[-T,-T/2]\cup[T/2,T]$ for A and A_ε differ by $Ch^{-d-1}\varsigma T\times(h/T)^r$ and therefore this is also true for Tauberian expressions on interval $[-T,T]$ provided $r<1$ while for $r=1$ we obtain $Ch^{-d}\varsigma(1+|\log T/h|)$:

$$\mathsf{N}^{\mathsf{T}}_{x,\varphi}(T;A)-\mathsf{N}^{\mathsf{T}}_{x,\varphi}(T;A_\varepsilon)\prec Ch^{-d-1+r}\varsigma\bigl(T^{1-r}+C\delta_{r1}|\log T/h|\bigr). \tag{4.7.14}'$$

Similarly, the right-hand expression in (4.7.15) becomes Ch^{1+r-d} but one needs to include in Weyl expressions the second term here and below (unless it is 0), the right-hand expression in (4.7.15) remains and combining we get $Ch^{-d}\varsigma$:

$$\mathsf{R}^{\mathsf{W}}_{x,\varphi}(A)\prec C\Bigl(h^{1+r-d}T^{-r-1}+Ch^{-d-1+r}\varsigma\bigl(T^{1-r}+C\delta_{r1}|\log T/h|\bigr)\Bigr). \tag{4.7.17}'$$

[45] Later we will set $\varepsilon=C_0h$.

Minimizing by $T \in [C_0 h, \epsilon]$ we get

$$\mathsf{R}^{\mathsf{W}}_{x,\varphi}(A) \prec C\big(h^{1+r-d} + h^{-d}\varsigma^{(r+1)/2} + \delta_{r1} h^{-d}\varsigma |\log \varsigma|\big). \tag{4.7.18}'$$

(c) We need to prove that we can set $\varepsilon = C_0 h$. Let us apply the previous arguments to $A_{2\varepsilon}$ and A_ε instead of A_ε and A respectively, and set $\varsigma = \nu(\varepsilon)$, $\varepsilon \ge C_0 h$.

One can observe easily that for operator A_ε rather than A all our previous results could be improved. Namely, in Proposition 4.7.3 a usual commutator formula holds modulo $O\big(h^l(h/\varepsilon)^s \|\partial b\|_{l-1}\big)$ with arbitrarily large exponent s and therefore this factor $(h/\varepsilon)^s$ pops-up in some other estimates in the correct places: in Proposition 4.7.4 it appears alongside factor h^{l-1} in the last term of the right-hand expression in (4.7.9).

Consider now (4.7.14)′. Interval $[-T, -T/2] \cup [T/2, T]$ contributes now $Ch^{-d-1}(h/T)^r \varsigma T\big((h/\varepsilon)^s + (h/T)^s\big]$. Indeed, it follows from the fact that rescaling $x \mapsto x/T$ we have not only $h \mapsto h/T$ but also $\varepsilon \mapsto \min(\varepsilon/T, 1)$. Then summation with respect to partition with respect to tT results in $Ch^{-d-1}(h/T)^r \varsigma T(h/\varepsilon)^s + Ch^{-d}\varsigma$ which is now the new right-hand expression in (4.7.14)′. Plugging $\varepsilon = \varepsilon_n := 2^n h$ and taking a sum with respect to $n = 0, 1, \dots \bar{n} = \lceil \log_2(\varepsilon/h)\rceil$ we conclude that

$$\mathsf{N}_{x,\varphi}(A) - \mathsf{N}^{\mathsf{T}}_{x,\varphi}(T, A_\varepsilon) \prec Ch^{-d}(h/T)^r + Ch^{-d-1}(h/T)^r \varsigma(h) T + Ch^{-d}\varsigma(\varepsilon) \tag{4.7.19}$$

where the first term estimates the Tauberian error, the second term estimates an error when we replace A by A_h in the Tauberian expression, and it and the third term estimate together an error when we replace A_h by A_ε. Here $0 \le r \le 1$ where for $r = 0$ we consider instead N_x and $\mathsf{N}^{\mathsf{T}}_x$ and for $r = 1$ we need to replace the second term by $Ch^{-d}\varsigma(h)|\log h|$.

Next in virtue of Section 4.6 we can replace here $\mathsf{N}^{\mathsf{T}}_{x,\varphi}(T, A_\varepsilon)$ by $\mathsf{N}^{\mathsf{W}}_{x,\varphi}(T, A_\varepsilon)$ as long as $\varepsilon \ge C_0 h|\log h|$ and, finally, we can replace $\mathsf{N}^{\mathsf{W}}_{x,\varphi}(T, A_\varepsilon)$ by $\mathsf{N}^{\mathsf{W}}_{x,\varphi}(T, A)$.

Minimizing with respect to $T \in [C_0 h, \epsilon]$ we conclude that the left-hand expression in (4.7.19) is estimated by the right-hand expression of (4.7.18)′ with $\varsigma = \varsigma(h)$ plus $Ch^{-d}\varsigma(\varepsilon)$. One can see easily that the latter term is smaller than the right-hand expression of (4.7.18)′ as long as $\varepsilon \le h^{1-\delta}$ for $r < 1$ and $\varepsilon \le C_0 h|\log h|$ for $r = 1$. This concludes the proof. □

Theorem 4.7.8. *In the framework of Theorem 4.7.6(i) and (ii) respectively*

(i) Estimate

$$|\Gamma\,\mathsf{tr}\big(b(x)(hD_x)^\alpha(hD_y)^\beta e(x,y;\tau_1,\tau_2)\big) - \mathsf{N}^{\mathsf{W}}(\tau_1,\tau_2)| \le C\big(h^{1-d}+h^{-d}\varsigma^{2/3}\big)\,\mathsf{dim}\,\mathbb{H} \tag{4.7.20}$$

holds where $\mathsf{N}^{\mathsf{W}}(\tau_1,\tau_2)$ *means corresponding Weyl expression and* $b\in \mathscr{C}_0^\infty$ *is a matrix-valued function.*

(ii) Estimate

$$|\int \varphi(\tau)\,d_\tau\Big(\Gamma\,\mathsf{tr}\big(b(x)(hD_x)^\alpha(hD_y)^\beta e(x,y;\tau,\tau_i)\big) - \mathsf{N}^{\mathsf{W}}(\tau,\tau_i)\Big)| \le C\big(h^{1+r-d}+h^{-d}\varsigma^{2(r+1)/3}+\delta_{r2}h^{-d}\varsigma|\log\varsigma|\big)\,\mathsf{dim}\,\mathbb{H} \tag{4.7.21}$$

holds where $\mathsf{N}^{\mathsf{W}}(\tau,\tau_i)$ *means corresponding Weyl expression including the second term.*

Proof. (a) Let us apply a two term approximation rather than one term. Then the error will be the third rather than the second term; then the error estimate will be $Ch^{-d-2}\varsigma^2T^2$ rather than $Ch^{-d-1}\varsigma T$ and we get expression

$$C\Big(h^{1+r-d}T^{-r-1}+h^{-d-2+r}\varsigma\big(T^{2-r}+\delta_{r2}|\log T/h|\big)\Big) \tag{4.7.22}$$

instead of the right-hand expression in (4.7.17)′. Minimizing by $T\in[C_0h,\epsilon]$ we get the right hand expression in (4.7.21) but without $\mathsf{dim}\,\mathbb{H}$ which appears after we take trace. Here $\varsigma=\nu(\varepsilon)$, $\varepsilon=C_0h|\log h|$ at the moment.

Consider the second term; it appears from

$$\mathsf{Tr}\big(BG_\varepsilon^{\pm}(A-A_\varepsilon)G_\varepsilon^{\pm}\big)=\mathsf{Tr}\big((A-A_\varepsilon)G_\varepsilon^{\pm}BG_\varepsilon^{\pm}\big) \tag{4.7.23}$$

with $B=(-hD)^\beta b(hD)^\alpha$ and since in $G_\varepsilon^{\pm}BG_\varepsilon^{\pm}$ operator B has smooth coefficients and $\varepsilon=C_0h|\log h|$ we conclude that due to propagation of singularities results contribution of time intervals $[-T,-\bar T]\cup[\bar T,T]$ with $\bar T=Ch|\log h|$ is negligible.

Meanwhile on time interval $[-\bar T,\bar T]$ we apply our standard successive approximation method with freezing symbol at point y etc resulting in

$$\mathsf{tr}\big((a-a_\varepsilon)(\tau-a_\varepsilon)^{-1}b(\tau-a_\varepsilon)^{-1}\big)=\mathsf{tr}\big(b(\tau-a_\varepsilon)^{-1}(a-a_\varepsilon)(\tau-a_\varepsilon)^{-1}\big)$$

calculated at point (y,ξ).

To this expression one needs to apply $\mathsf{Res}_{\mathbb{R}}$, multiply by $(2\pi h)^{-d}$, integrate by $(y,\xi)\in\mathbb{R}^{2d}$ and by $\tau\in[\tau_1,\tau_2]$ [46]. Due to microhyperbolicity of a on the energy level s τ_1,τ_2 and estimate $|a-a_\varepsilon|\le C_0\varsigma$ the result is equal to the result of the same procedure applied to

$$\mathsf{tr}\big(b(\tau-a_\varepsilon)^{-1}-b(\tau-a)^{-1}\big)$$

with an error, not exceeding $Ch^{-d}\varsigma^2$. However the latter result is equal to the difference between $\mathsf{N}^{\mathsf{W}}(\tau_1,\tau_2;A)$ and $\mathsf{N}^{\mathsf{W}}(\tau_1,\tau_2;A_\varepsilon)$ and therefore Statement (i) is proven albeit with $\varsigma=\nu(\varepsilon)$.

(b) To improve this statement to one with $\varsigma=\nu(h)$ we apply the same procedure as in Part (c) of the proof of Theorem 4.7.6. Then estimate of the third (error) term in the successive approximation is trivial and is left to the reader, let us consider the second term which now is due to the following modification of (4.7.23):

$$\sum_{0\le n\le \bar n}\mathsf{Tr}\Big((A_{\varepsilon_n}-A_{\varepsilon_{n+1}})G^{\pm}_{\varepsilon_{n+1}}BG^{\pm}_{\varepsilon_{n+1}}\Big) \tag{4.7.24}$$

where $h\le\varepsilon_n\le\varepsilon=C_0h|\log h|$. We want to convert both factors $G^{\pm}_{\varepsilon_{n+1}}$ to $G^{\pm}_{\varepsilon}$. To do this properly observe that $G^{\pm}_{\varepsilon_m}BG^{\pm}_{\varepsilon_m}-G^{\pm}_{\varepsilon_{m+1}}BG^{\pm}_{\varepsilon_{m+1}}$ contains one factor $(A_{\varepsilon_m}-A_{\varepsilon_{m+1}})$ and three factors $G^{\pm}_{\varepsilon_{m+1}}$ and $G^{\pm}_{\varepsilon_m}$ (together). Then applying arguments Part (c) of the proof of Theorem 4.7.6 we estimate the error in (4.7.24) by

$$T^3h^{-3}\sum_{0\le n\le m\le\bar n}\nu(\varepsilon_n)\nu(\varepsilon_m)h^{l-1}\big[(h/\varepsilon_m)^s+(h/T)^s\big]$$

and we estimate the resulting error in the second term properly.

So, instead of (4.7.24) we have $\mathsf{Tr}\Big((A-A_\varepsilon)G^{\pm}_{\varepsilon}BG^{\pm}_{\varepsilon}\Big)$ and we are be able to pass to Weyl expression as in Part (a). □

Remark 4.7.9. (i) As $r\ge\frac12$ and $1\le l\le 1+r$ we have a better estimate than one delivered by the bracketing.

(ii) One can generalize our arguments for more general ν, in paricular, for $\nu(s)=s^l(\log|s|)^\sigma$.

[46] If we consider Statement (i); Statement (ii) is proven the same way.

4.7.4 Sharper Asymptotics

Observe that under assumption

$$\nu(s) = o(s^{\frac{2}{3}}) \qquad \text{as } s \to +0. \tag{4.7.25}$$

the second terms in the right-hand expressions of (4.7.20) and (4.7.21)are "o" in comparison with the first terms.

Theorem 4.7.10. *In the framework of Theorem 4.7.8 let* (4.7.25) *be fulfilled.*

Further, let the standard non-periodicity condition

$$z \notin \Phi_{(}z) \qquad \forall t \neq 0\, \forall z \tag{4.7.26}$$

(where Φ_t means the generalized (multivalued) Hamiltonian flow) be fulfilled. Then estimates (4.7.20) *and* (4.7.21) *hold with the right-hand expressions $o(h^{1-d})$ and $o(h^{1-d+r})$ respectively.*

Proof. Under assumption (4.7.26) for A_ε one can take T arbitrarily large (so in all estimates $Ch^{1-d+r}T^{-1-r}$ with $h \le T \le \epsilon$ is replaced by $Ch^{1-d+r}T^{-1-r} + o_T(h^{1-d+r})$ for any $T \ge \epsilon$.

Then under assumption (4.7.26) proof of Theorem 4.7.8 delivers improved estimates. □

4.A Appendices

4.A.1 On the Traces of Almost Analytic Functions

Let $\Omega \subset \mathbb{R}^d$ be an open domain, Γ an open convex domain with a vertex at 0 and let $\tilde\Omega = \Omega + i\Gamma z \subset \mathbb{C}^d$. Let $\mathbb{B}$ be a Banach space. A function $F(.) \in \mathscr{C}^1(\tilde\Omega, B)$ is called *r-almost analytic* if

$$\|F(z)\| \le M|\operatorname{Im} z|^{-l+\delta} \qquad \forall z \in \tilde\Omega, \tag{4.A.1}$$

and

$$\|\bar\partial_{z_j} F(z)\| \le M|\operatorname{Im} z|^{r-1+\delta} \qquad \forall z \in \tilde\Omega \quad \forall j = 1, \dots, d \tag{4.A.2}$$

where $\bar\partial_{z_j} = \frac{1}{2}(\partial_{x_j} + i\partial_{y_j})$ and $\delta > 0$, $l \in \mathbb{N}$.

Proposition 4.A.1. *Let conditions* (4.A.1) *and* (4.A.2) *with* $r = 0$ *be fulfilled. Then*

For every $y \in \Gamma$ *with* $|y| = 1$ *there exists a limit*

$$f(x) = F(x + i0y) = \lim_{t \to +0} F(x + ity) \tag{4.A.3}$$

in the space of $\mathbb{B}$*-valued distributions* $\mathscr{D}'(\Omega, \mathbb{B})$*;*

Moreover $f = \sum_{0 \le k \le l} \mathcal{M}^k f_k$ *where* $f_k \in \mathscr{C}(\Omega, \mathbb{B})$ *and* $\|f_k\| \le CM$ *with* $C = C(l, \delta)$, $\mathcal{M} = \langle y, \bar\partial_x \rangle$.

$f(x)$ *does not depend on the choice of* y.

Proof. For $l = 0$ this assertion is obvious. Let us note that

$$\partial_t F(x + ity) = -\mathcal{M} F(x + ity) + 2\langle y, \bar\partial_z \rangle F(x + ity)$$

and hence

$$F(x + ity) = F(x + iy) + 2\int_1^t \langle y, \bar\partial_z \rangle F(x + it'y) dt' - \int_1^t \mathcal{M} F(x + it'y)\, dt'. \tag{4.A.4}$$

Then (4.A.1) and (4.A.1) yield that the first and the second terms in the right hand expression belong to $\mathscr{C}(\Omega_x \times J_t \times \Gamma_y, \mathbb{B})$, $J = [0, 1]$; the same is also true for the "shortened" third term $\int_1^t F(x + it'y) dt'$ provided $l = 1$. On the other hand, for $l \ge 2$ we replace $F(x + it'y) dt'$ in (4.A.4) by the right-hand expression of (4.A.4) with t, t' replaced by t', t'' respectively. Repeating this procedure $l - 1$ times we obtain that

$$F(x + ity) = \sum_{0 \le k \le l-1} \mathcal{M}^k F_k(x) + \frac{1}{(l-1)!}(-\mathcal{M})^l \int_1^t (t - t')^{l-1} F(x + it'y)\, dt' \tag{4.A.5}$$

where F_k with $k = 0, \dots, l - 1$ as well as

$$F_l(x) = \frac{1}{(l-1)!}(-\mathcal{M})^l \int_1^t (t - t')^{l-1} F(x + it'y)\, dt'$$

obviously belong to $\mathscr{C}(\Omega_x \times J_t \times \Gamma_y, B)$. Therefore the limit $F(x+i0y)$ exists in the distribution sense and is the sum of $\mathcal{M}^k f_k$ with $f_k(x) = F_k(x+i0y)$. So Statements 4.A.1 and 4.A.1, are proven.

In order to prove 4.A.1 let us note that

$$\partial_s F(x+iy^0-is\omega) = \mathcal{M}'F(x+iy^0-is\omega) - 2\langle\omega,\bar\partial_z\rangle F(x+iy^0-is\omega)$$

with $\mathcal{M}' = -\langle\omega,\partial_x\rangle$; setting $y, y^0 \in \Gamma$, $s, t \in [0,1]$ and $\omega = y^0 - ty$ we obtain a formula similar to (4.A.4) with $F(x+ity)$, $\mathcal{M}$, $\langle y,\bar\partial_z\rangle$, $t, t', 1$ replaced by $F(x+iy^0-is\omega)$, $-\mathcal{M}'$, $-\langle\omega,\bar\partial_z\rangle$, $s, s', 0$ respectively. Then formula (4.A.5) also holds modified in the same way:

$$F(x+ity) = \sum_{0\le k\le l-1} (-\mathcal{M}')^k F_k(x,y^0,\omega,t) + \frac{1}{(l-1)!}\mathcal{M}'^l \int_0^1 (1-s')^{l-1} F(x+iy^0-is'\omega)\,ds';$$

moreover, in this sum we can take the limit as $t \to +0$ (and $\omega \to y^0$, $\mathcal{M}' \to -\mathcal{M}$), and this limit obviously does not depend on y. □

Let us consider a symbol $a \in \mathscr{C}^k(\Omega, \mathbb{H}, \mathbb{H})$ (where $\mathbb{H}$ is an auxiliary Hilbert space) such that

(4.A.6) $a^\dagger(x) = a(x) \qquad$ in Ω,

and

(4.A.7) $\langle(\ell a)(x)w, w\rangle \ge \epsilon_0\|w\|^2 - c\|(a(x)-\tau)w\|^2 \qquad \forall x\in\Omega \quad \forall w \in \mathbb{H}$

where we write now x instead of (x,ξ) and $\ell \in T\Omega$. Let $\tilde a(x+iy)$ be the q-analytic extension of $a(x)$:

$$\tilde a(x+iy) = \sum_{|\alpha|\le q} \frac{1}{\alpha!}(\partial_x^\alpha a)(x)(iy)^\alpha. \tag{4.A.8}$$

We assert that for small enough $\epsilon \ge 0$, $\nu \ge 0$

$$\|\tilde P w\| \ge \epsilon_1(\varepsilon+\nu)\|w\| \tag{4.A.9}$$

where here and below $\tilde P = \tilde a(x+i\varepsilon\ell) - \tau + i\nu I$ and $P = a(x) - \tau$. In fact,

$$\tilde P(x)w = P(x)w + i(\varepsilon(\ell a)(x) + \nu)w + O(\varepsilon^2\|w\|)$$

and hence (4.A.6) and (4.A.7) yield that

$$\|\tilde{P}(x)w\| \cdot \|w\| \ge \mathsf{Im}\langle \tilde{P}(x)w, w\rangle \ge \epsilon_0(\varepsilon+\nu)\|w\|^2 - C_0\varepsilon^2\|w\|^2 - c\|P(x)w\|^2 \ge (\frac{1}{2}(\varepsilon+\nu) - C\varepsilon^2 - C\nu^2)\|w\|^2 - c\|\tilde{P}(x)w\|^2,$$

and (4.A.9) trivially follows from this inequality.

Therefore $F(z) = (\tilde{a}(z') - z_0)^{-1}$ satisfies (4.A.1) and (4.A.2) with $I = 2$, $\delta = 1$, $r = q-2$, $z = (z_0, z')$ and $\Gamma = \{y_0 \le 0, y' = t\ell, t \ge 0, y_0 - t < 0\}$. Moreover,

$$\big(a(x) - \tau \pm i0\big)^{-1} = \big(\tilde{a}(x \pm i0\ell) - \tau\big)^{-1} \tag{4.A.10}$$

(we have analyzed the "+" case; the "−" case can be analyzed in the same way) and the same is true for all products of the factors $(\tilde{a}(z') - z_0)^{-1}$ (the number of which should not exceed j) and regular[47] q-almost analytic factors, $q = q(j)$.

We will use these properties in the forthcoming sections and chapters.

4.A.2 Smoothing of $\mathscr{C}^m_\vartheta$ Functions

Proposition 4.A.2. *Let $f \in \mathscr{C}^m_\vartheta(X, .)$ where ϑ satisfies* (4.6.7).

Then for every $\varepsilon > 0$ there exits f_ε such that

$$|\partial^\alpha f_\varepsilon(x) - \partial^\alpha f(x)| \le C\vartheta(\varepsilon)\varepsilon^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le m, \tag{4.A.11}$$

$$|\partial^\alpha f_\varepsilon(x)| \le C\vartheta(\varepsilon)\varepsilon^{-|\alpha|} \qquad \forall \alpha : |\alpha| > m; \tag{4.A.12}$$

here C does not depend on α.

Proof. Let ϕ be a function such that

$$\hat{\phi} \in \mathscr{C}_0^\infty\big(B(0, \tfrac{1}{2})\big),\ \partial^\alpha\hat{\phi}(0) = \delta_{\alpha 0} \text{ where } \hat{\phi} \text{ denotes Fourier transform of } \phi. \tag{4.A.13}$$

Then $|\partial^\alpha\phi| \le C_n(1+|x|)^{-n}$ for any fixed n and every α. Let $f_\varepsilon := f * \phi_\varepsilon$ with $\phi_\varepsilon = \varepsilon^{-d}\phi(x/\varepsilon)$.

[47] I.e., of the class C^q up to $\Omega \subset \mathbb{R}^d$.

Then for $|\alpha| \le m$

$$\partial^\alpha f_\varepsilon(x) - \partial^\alpha f(x) = \int \phi(y)\big(\partial^\alpha f(x-\varepsilon y) - \partial^\alpha f(x)\big)\,dy.$$

Taking Taylor expansion

$$\partial^\alpha f(x-\varepsilon y) = \sum_{\beta:|\beta|\le m-|\alpha|} \frac{1}{\beta!}(-\varepsilon y)^\beta \partial^{\alpha+\beta} f(x) + R_\alpha$$

with

$$R_\alpha \le C(\varepsilon|y|)^{-|\alpha|}\vartheta(\varepsilon|y|)$$

we see that the left hand expansion in (4.A.11) does not exceed

$$C\varepsilon^{-|\alpha|}\int |y|^{-|\alpha|}\vartheta(\varepsilon|y|)(1+|y|)^{-n}\,dy$$

and the integrand does not exceed $\vartheta(\varepsilon)(1+|y|)^{1-n}$ for both $|y| \le 1$ and $|y| \ge 1$ due to assumption $f \in \mathscr{C}^m_\vartheta$; so we get (4.A.11).

For $|\alpha| > m$ we have

$$\partial^\alpha f_\varepsilon = \varepsilon^{m-|\alpha|}\int \partial^\beta\phi(y)(\partial^{\alpha-\beta}f)(x-\varepsilon y)\,dy$$

with $|\beta| = |\alpha| - m$; replacing $(\partial^{\alpha-\beta}f)(x-\varepsilon y)$ by $(\partial^{\alpha-\beta}f)(x)$ we get 0 and the difference does not exceed

$$C\varepsilon^{-|\alpha|}\int \vartheta(\varepsilon|y|)(|y|+1)^{-n}\,dy$$

which leads to (4.A.12). □

Comments

The number of papers devoted to spectral asymptotics is huge. Apart of the Tauberian approach developed by T. Carleman in [1, 2] and used here, and variational approach we will use later to cover singular zones, we should mention a method of almost spectral projector due to M. Shubin and V. Tulovsky [1].

Depending which function $f(t, A)$ is used and what Tauberian theorem is applied we talk about resolvent method ($f = (z - A)^{-1}$), complex power method ($f = A^z$), heat kernel method ($f = e^{-tA}$) or hyperbolic operator method ($f = e^{itA}$, $f = \cos(t\sqrt{A})$ or $f = \sin(t\sqrt{A})$ applied here.

The absolute majority of the papers using the latter use explicit construction of the hyperbolic kernel and we refer to Yu. Safarov and D. Vassiliev [3]. Here we comment only on the constructions of this Chapter.

The whole construction of Sections 4.3–4.4 appeared first in paper of V. Ivrii [8] in the standard rather than semi-classical situation: first propagation results and rescaling were used to prove that singularity at $t = 0$ of $\sigma(t) = \Gamma(Qu)$ was of the *normal type* i.e. $(tD_t)^n\sigma(t)$ had the same order of singularity in the vicinity of 0:

$$t^n D_t^n \sigma(t) \in \mathscr{H}^{-M}[-T_0, T_0] \qquad \forall n \in \mathbb{Z}^+.$$

Then the successive approximation was used and each next term contained an extra factor of $t^2 D_t$ type:

$$\sigma_m(t) \in t^{2m}\mathscr{H}^{-M-m}[-T_0, T_0] \qquad \forall m \in \mathbb{Z}^+.$$

Then combining these two statements it was proven that actually

$$\sigma_m(t) \in \mathscr{H}^{M-m}[-T_0, T_0] \qquad \forall m \in \mathbb{Z}^+.$$

Long term propagation to prove a "sharp" remainder estimate was first used by J. J. Duistermaat and V. Guillemin [1] and without Fourier integral operators again by V. Ivrii [8]. These allowed to prove Weyl conjecture: two-term asymptotics of eigenvalue counting function under assumption that measure of the set of all periodic billiards is 0.

These arguments were repeated in V. Ivrii [10] to study matrix operators with characteristic roots of variable multiplicity.

"Sharper" remainder estimates were first derived by P. Bérard [1] and then by A. Volovoy [1] and later repeated by V. Ivrii [23] in the general settings.

The sharp remainder estimates without smoothness conditions appeared first in L. Zielinski [1–4], followed by V. Ivrii [26] and M. Bronstein and V.Ivrii [1]. While L. Zielinski was able to develop microlocal analysis as $\varepsilon = h^{\frac{1}{2}}$ and in V.Ivrii [26] it was done as $\varepsilon = h^{1-\delta}$ with arbitrarily small $\delta > 0$; then it was improved to $\varepsilon = h|\log h|^{1+\delta}$ (unpublished) and in M. Bronstein–V.Ivrii [1] envelope was pushed further to the limit $\varepsilon = Ch|\log h|$; this

improvement leads to smaller approximation errors as regularity is fixed and to weaker regularity condition as approximation error is fixed.

Direct approach to operators with non-smooth coefficients was developed first by V. Ivrii while researching for Chapter 27 of this book.

Chapter 5

Scalar Operators in the Interior of the Domain. Rescaling Technique

5.1 Introduction

5.1.1 Pilot: Schrödinger Operator

In this chapter we consider scalar and similar operators and weaken microhyperbolicity conditions while trying to retain sharp remainder estimates. Note that for such operators we can rewrite ellipticity, microhyperbolicity and ξ-microhyperbolicity on energy level τ conditions respectively as

$$|a(x,\xi) - \bar{\tau}| \ge \epsilon_0, \tag{5.1.1}$$

$$|a(x,\xi) - \bar{\tau}| + |\nabla_{x,\xi} a(x,\xi)| \ge \epsilon_0, \tag{5.1.2}$$

$$|a(x,\xi) - \bar{\tau}| + |\nabla_{\xi} a(x,\xi)| \ge \epsilon_0. \tag{5.1.3}$$

To illustrate, for Schrödinger operator

$$h^2|D|^2 + V(x) \tag{5.1.4}$$

and $Q_1 = Q_2 = I$ these conditions become

$$V \le \bar{\tau} - \epsilon_0, \tag{5.1.5}$$

$$|V(x)| + |\nabla V(x)| \ge \epsilon_0, \tag{5.1.6}$$

$$|V(x)| \ge \epsilon_0 \tag{5.1.7}$$

respectively. These conditions are assumed to be fulfilled in $B(0,1)$ and then respectively

$$|e(x,y,\bar\tau)| \le C'h^s, \qquad e^{\mathsf{W}}(x,y,\bar\tau) = 0 \tag{5.1.8}$$

with arbitrarily large s,

$$|\int \mathsf{R}^{\mathsf{W}}_x(\bar\tau)\psi(x)\,dx| \le Ch^{1-d} \tag{5.1.9}$$

$$|R^{\mathsf{W}}_x(\bar\tau)| \le Ch^{1-d}. \tag{5.1.10}$$

as $x, y \in B(0,\frac12)$ or $\psi \in \mathscr{C}_0^\infty(B(0,\frac12))$

To weaken these conditions we apply *rescaling with variable scale parameters*.

First, however, consider constant parameters ρ, γ such that

$$\rho\gamma \ge h \tag{5.1.11}$$

and that V is $\lesssim \rho^2$ in an appropriate sense and our playground is $B(0,\gamma)$. Then we scale $x \mapsto x\gamma^{-1}$, divide operator by ρ^2 [1)] and arrive to operator (5.1.4) but with $h \mapsto \hbar = h\rho^{-1}\gamma^{-1}$ and potential $V' = \rho^{-2}V(x\gamma)$ now satisfying all the assumptions of Chapter 4.

In order our new operator to be elliptic, microhyperbolic or ξ-microhyperbolic on the energy level 0 we must assume that *originally*

$$V \le -\epsilon_0\rho^2, \tag{5.1.12}$$

$$|V(x)| + \gamma|\nabla V(x)| \ge \epsilon_0\rho^2, \tag{5.1.13}$$

$$|V(x)| \ge \epsilon_0\rho^2 \tag{5.1.14}$$

respectively and then we get estimates

$$|e(x,y,0)| \le C'h^l\rho^{-l}\gamma^{-l-d}, \quad e^{\mathsf{W}}(x,y,\bar\tau) = 0, \tag{5.1.15}$$

$$\gamma^{-d}|\int \mathsf{R}^{\mathsf{W}}_x(0)\psi(x)\,dx| \le Ch^{1-d}\rho^{d-1}\gamma^{-1} \tag{5.1.16}$$

$$|R^{\mathsf{W}}_x(0)| \le Ch^{1-d}\rho^{d-1}\gamma^{-1}. \tag{5.1.17}$$

[1)] Without any loss of the generality we can assume that $\bar\tau = 0$.

Now, if we want to get rid of assumptions (5.1.6) or (5.1.7) in the original standard problem we need to introduce *scaling functions*

$$\gamma(x) = \epsilon\big(|V(x)| + |\nabla V(x)|^2\big)^{\frac{1}{2}} + \bar{\gamma}, \qquad \rho(x) = \gamma(x), \tag{5.1.18}$$

or

$$\gamma(x) = \epsilon|V(x)| + \bar{\gamma}, \qquad \rho(x) = \gamma(x)^{\frac{1}{2}} \tag{5.1.19}$$

where $\bar{\gamma} = h^{\frac{1}{2}}$, $\bar{\gamma} = h^{\frac{2}{3}}$ respectively in order to fulfill (5.1.11).

Then $|\nabla\gamma| \le \frac{1}{2}$ and therefore both γ and ρ have constant magnitudes in balls $B(x,\gamma(x))$. Further, as $\gamma \ge 2\bar{\gamma}$ in $B(x,\gamma(x))$ condition (5.1.13) (or (5.1.14)) is fulfilled. On the other hand, as $\gamma \asymp \bar{\gamma}$ these conditions are of no importance since $\hbar \asymp 1$ then.

So, we arrive to estimates

$$|\int \mathsf{R}^{\mathsf{W}}_x(0)\psi(x)\,dx| \le Ch^{-d}\int \rho(x)^{d-1}\gamma^{-1}\,dx \tag{5.1.20}$$

or

$$|\mathsf{R}^{\mathsf{W}}_x(0)| \le Ch^{-d}\rho(x)^{d-1}\gamma^{-1}. \tag{5.1.21}$$

Plugging $\rho = \gamma$ or $\rho = \gamma^{\frac{1}{2}}$ we arrive to

$$|\int \mathsf{R}^{\mathsf{W}}_x(0)\psi(x)\,dx| \le Ch^{-d}\int \gamma(x)^{d-2}\,dx \tag{5.1.22}$$

or

$$|\mathsf{R}^{\mathsf{W}}_x(0)| \le Ch^{-d}\rho(x)^{d-1}\gamma^{(d-3)/2}. \tag{5.1.23}$$

Observe that the right-hand expression in (5.1.22) is $O(h^{1-d})$ as $d \ge 2$ and $O(h^{-\frac{1}{2}})$ as $d = 1$ while the right-hand expression in (5.1.23) is $O(h^{1-d})$ as $d \ge 2$, $O(h^{-\frac{4}{3}})$ as $d = 2$ and $O(h^{-\frac{2}{3}})$ as $d = 1$.

Therefore we can remove in some cases microhyperbolicity or ξ-microhyperbolicity condition either without any punishment at all or with some punishment.

5.1.2 Plan of the Chapter

The goal of this Chapter is to develop this approach further.

In Section 5.2 we consider operators with scalar principal symbols as well as operators with eigenvalues of the principal symbols having constant multiplicities. First, we prove results similar to those for the Schrödinger

operator we discussed above; the role of the dimension is played by $\mathsf{rank}\,\mathsf{Hess}\,a$ in stationary points. Then for asymptotics with spatial mollification we step by step weaken these non-degeneracy conditions until the become really weak. We also explore sharp and sharper asymptotics.

In Section 5.3 we apply these results to the Schrödinger and Dirac operators. For the Schrödinger operator the conditions of these theorems are fulfilled automatically for any dimension d (if we are interested in spatial means) but for the Dirac operator some additional treatment is necessary because we want asymptotics uniform with respect to the mass which can be not only finite but also very large or very small parameter; in the latter case eigenvalues of the principal symbols are not disjoint but it happens only at one point. We also derive improved asymptotics without spatial mollification for 1- and 2-dimensional Schrödinger operator as operator is not ξ-microhyperbolic; then asymptotics contains a correction term due to short bicharacteristic loops.

In Section 5.4 we generalize some of the results of the previous two sections to non-smooth operators. While we start from ξ-microhyperbolicity condition, at some moment we weaken it and microhyperbolicity condition also plays a role and we observe that results with or without spatial mollification become different. For example, if $d = 1, 2$ and we consider Schrödinger operator then in the framework of Subsection 5.1.1 remainder estimate is

$$|\mathsf{R}^{\mathsf{W}}| = |\int R^{\mathsf{W}}_x \psi(x)\,dx| \le Ch^{1-d}\int \gamma^{(d-3)/2}(x)\,dx; \tag{5.1.24}$$

and under microhyperbolicity condition

$$\gamma(x) + |\nabla\gamma(x)| \ge \epsilon_0. \tag{5.1.25}$$

Then as $d = 2, 1$ we arrive to the remainder estimates $|\mathsf{R}^{\mathsf{W}}| = O(h^{-1})$ and $|\mathsf{R}^{\mathsf{W}}| = O(|\log h|)$ respectively and in the latter case additional arguments lead to the remainder estimate $|\mathsf{R}^{\mathsf{W}}| = O(1)$. Thus we replaced ξ-microhyperbolicity by microhyperbolicity.

Rescaling again, we arrive to certain estimates without microhyperbolicity condition.

Furthermore, in some proofs we use not only rescaling but also long-term propagation (where long-term refers to time scale after rescaling) and ability to choose time direction arbitrarily is very handy (but this is possible only for asymptotics with spatial mollification).

Finally, in Appendix 5.A.1 we calculate spectral kernels for Schrödinger operator with potential $V(x) = x_1$ and in Appendix 5.A.2 we list some properties of the Pauli matrices.

5.2 Spectral Asymptotics for Scalar Operators

In this Section we consider operators with scalar principal symbols[2)] for which we weaken the restrictions on averaging parameter L of Subsection 4.4.1 and the microhyperbolicity condition we had in Subsection 4.4.2. Our main tool is rescaling applied to the results of the previous Chapter 4.

This theory is applied to more general operators as well. Namely, all the results remain true for operators such that

$$\mathsf{Spec}\, A^0(x,\xi) \cap [-\epsilon_0, \epsilon_0] = \{a(x,\xi)\} \qquad \text{in } \Omega \tag{5.2.1}$$

where here $A^0(x,\xi)$ is the principal symbol of A and $a(x,\xi)$ is the scalar function. Then in a fixed neighborhood of $\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)$ the operator A can be reduced[3)] to the block-diagonal form $A \equiv \begin{pmatrix} A_I & 0 \\ 0 & A_{II} \end{pmatrix}$ where the principal symbol of A_I equals $a(x,\xi)$ and $\mathsf{Spec}\, a_{II} \cap [-\epsilon_0, \epsilon_0] = \emptyset$; let Ω be this neighborhood.

If $u = \begin{pmatrix} u_{I,I} & u_{I,II} \\ u_{II,I} & u_{II,II} \end{pmatrix}$ corresponds to this reduction then the standard ellipticity arguments yield that

(5.2.2) All the components of u apart from $u_{I,I}$ are negligible in $\Omega \times \Omega^T \times [-\epsilon_0, \epsilon_0] \ni (x, y, \tau)$;

in what follows we will consider only $\tau \in [-\epsilon_0, \epsilon_0]$. Thus we can assume without any loss of the generality that

(5.2.3) $B = I$ and A is an operator with the scalar principal symbol a.

[2)] Later when we consider more degenerate operators we will need to include more terms in the analysis and assume that these terms are scalar.

[3)] By means of multiplication on the right and left by G^* and G respectively where G is a pseudodifferential operator with $G^*G \equiv GG^* \equiv I$.

For operators satisfying assumption (5.2.3) the ellipticity, microhyperbolicity and ξ-microhyperbolicity conditions on the energy level $\bar\tau$ are exactly (5.1.1), (5.1.2) and (5.1.3) meaning respectively that $\bar\tau$ is not a value of $a(x,\xi)$ at all, and $\bar\tau$ is not a *critical value of* a, $\bar\tau$ is not a critical value as $a(x,\xi)$ is considered to be function of ξ only.

One can easily see that

$$d\mu_\tau = I_{\mathbb{H}}\, dxd\xi : da\big|_{\Sigma_\tau} \tag{5.2.4}$$

in the sense of exterior forms.

5.2.1 From Condition "No Critical Point" to "$\operatorname{rank}\operatorname{Hess} a \ge 2$ at Critical Points." I

Standard Asymptotics

Let us introduce the *scaling functions*

$$\gamma(x,\xi) = \epsilon_1\big(|a(x,\xi)-\tau| + |\nabla_{(x,\xi)}a|^2\big)^{\frac12} + \bar\gamma, \qquad \rho(x,\xi) = \gamma(x,\xi) \tag{5.2.5}$$

with $\bar\gamma = h^{\frac12}$; this choice of $\bar\gamma$ is due to the fact that at this step γ will be scale with respect x and ξ.

One can easily check that γ is an *admissible scaling function*

$$|\nabla_{(x,\xi)}\gamma(x,\xi)| \le \frac12 \tag{5.2.6}$$

provided $\epsilon_1 > 0$ is a small enough constant.

Let us consider a γ-admissible partition of unity by pseudodifferential operators Q'_l [4)] Let $Q''_l = \operatorname{Op}(q''_l)$ where q''_l is the symbol of the same type as q'_l. Then one can easily see that

$$\rho_l^{-2} Q'_l A_l \in \Psi_{h,\gamma_l,\gamma_l,K}(T^*\mathbb{R}^d,\mathbb{H},\mathbb{H}) \text{ uniformly with respect to } l. \tag{5.2.7}$$

Then one needs to consider the separate elements of the partition and to treat two cases:

[4)] That means that $Q'_l = \operatorname{Op}(q'_l)$ where $q_l \in \mathsf{S}_{h,\gamma(z^l),\gamma(z^l),K}(T^*\mathbb{R}^d)$ are supported in the balls $B(z^l, \frac12\gamma_l)$ with $\gamma_l = \gamma(z^l)$ and the multiplicity of the covering by balls $B(z^l,\gamma_l)$ does not exceed $K_0 = K_0(d)$. Such a partition exists (see Hörmander [1], for example).

(i) *Regular case* when $\gamma := \gamma_l \ge c_0\bar{\gamma}$; then for this element all the conditions including the microhyperbolicity condition will be fulfilled after the rescaling

$$x \mapsto x_{\text{new}} = (x - x^l)\gamma^{-1},\ \xi \mapsto \xi_{\text{new}} = (\xi - \xi^l)\gamma^{-1}, \tag{5.2.8}$$
$$h \mapsto h_{\text{new}} = h\gamma^{-1}\rho^{-1},\ A \mapsto A_{\text{new}} = \rho^{-2}A_l$$

and the gauge transformation $A_l \mapsto e^{ih^{-1}\langle x,\xi_l\rangle}A_l e^{-ih^{-1}\langle x,\xi_l\rangle}$.

So, there are (apart from inessential shifts with respect to (x,ξ)) rescalings with respect to (x,ξ) and the rescaling with respect to the spectral parameter τ as well

$$\tau \mapsto \tau_{\text{new}} = \tau\varrho^{-1} \tag{5.2.9}$$

with $\varrho = \rho^2$ here. We can assume that $\bar{\tau} = 0$ to keep this energy level unaffected by rescaling. We selected $\bar{\gamma} = h^{\frac{1}{2}}$ to keep $h_{\text{new}} \le 1$ (because $\rho = \gamma$ at this moment).

Therefore one can apply all the results of Subsection 4.4.2.

Thus, let us apply all the results of Subsubsection 4.4.2.3 *Improved Asymptotics without Mollification* and then return back to the original variables. At this moment we consider *only* estimates of $\mathsf{R}^{\mathsf{W}}(\tau)$ and $\mathsf{R}^{\mathsf{W}}_{\varphi,L}(\tau)$.

We need to plug there $L_{\text{new}} = L\varrho^{-1}$. Moreover we can apply the results of Section 4.5 as well noticing that *on this step* no rescaling on t is necessary because $h_{\text{new}}^{-1}A_{\text{new}} = h^{-1}A$ modulo an inessential shift and thus $T_{\text{new}} = T$ here.

Note that

$$h_{\text{new}}L_{\text{new}}^{-1} = hL^{-1} \ \text{ and } \ h_{\text{new}}(L_{\text{new}}T)^{-1} = h(LT)^{-1} \tag{5.2.10}$$

and therefore

$$\frac{h_{\text{new}}^{1-d}}{T_{\text{new}}}\int_{(\mathcal{U}\cap\Sigma_\tau)} dx_{\text{new}}d\xi_{\text{new}} : da_{\text{new}} = \frac{h^{1-d}}{T}\int_{\mathcal{U}\cap\Sigma_\tau} dxd\xi : da \tag{5.2.11}$$

(surely in the left-hand expression not $(x_{\text{new}},\xi_{\text{new}})$ but (x,ξ) belongs to $\mathcal{U}\cap\Sigma_\tau$) and

$$h_{\text{new}}^{1-d+\delta}\vartheta\Big(\frac{h_{\text{new}}}{L_{\text{new}}T}\Big) = \Big(\frac{h}{\gamma^2}\Big)^{1-d+\delta}\vartheta\Big(\frac{h}{L}\Big). \tag{5.2.12}$$

We obtain that

(5.2.13) For this element of the partition all the estimates of Subsubsection 4.4.2.3 *Improved Asymptotics without Mollification* and Section 4.5 remain true with an additional term

$$C' h^{1-d+\delta} \vartheta\big(\frac{h}{L}\big) \int_{\mathcal{U}} \gamma^{-2-2\delta}\, dxd\xi \tag{5.2.14}$$

in the right-hand expression where $\mathcal{U} = B(z', \gamma_l)$ now.

(ii) *Irregular case* when $\gamma := \gamma_l \le c_0\bar{\gamma}$; then for this element all the conditions apart from the microhyperbolicity condition will be fulfilled after the same change of variables as before. However, the microhyperbolicity condition provides no advantage because $h_{\mathsf{new}} \asymp 1$ now.

Therefore one can apply Proposition 4.2.1 and Theorem 4.4.12. Returning to the original variables and operator we see that the contribution of this element to the remainder does not exceed

$$C_0 h^{1-d}\Big(\int_{\mathcal{U}'\cap\Sigma_\tau} dxd\xi : da + C' h^{\delta} \int_{\mathcal{U}'} \gamma^{-2-2\delta}\, dxd\xi\Big)\vartheta\big(\frac{h}{L}\big) \tag{5.2.15}$$

where $\mathcal{U}' = B(z', \gamma_l)$ now and

$$\int_{\mathcal{U}'\cap\Sigma_\tau} dxd\xi : da = O\Big(\int \gamma^{-2}\, dxd\xi\Big); \tag{5.2.16}$$

moreover one can replace "$= O$" by "$\asymp$" if in $B(z', \frac{1}{2}\gamma_l)$ ellipticity $a \asymp \gamma^2$ fails.

Note that

(5.2.17) Contribution[5)] of each irregular element does not exceed $C_0\vartheta(h/L)$

(5.2.18) Contribution[5)] of each regular elliptic element does not exceed $C_k h^{-d+k}\gamma^{-2d-2k}\vartheta(h/L)$ with an arbitrarily large exponent k.

[5)] Both to the remainder and to the main term.

Now let us sum the contributions of all the elements of this partition:

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L}(\tau)| \le C_0 h^{1-d}\vartheta\Big(\frac{h}{L}\Big)\Big(\int_{\mathcal{U}\cap\Sigma_\tau\cap\{\gamma\ge c_0\bar\gamma\}} dxd\xi : da + C' h^{\delta}\int_{\mathcal{U}\cap\{|a-\tau|\le\epsilon\gamma^2\}} \gamma^{-2-2\delta}\, dxd\xi + C' h^{k}\int_{\mathcal{U}} \gamma^{-2-2k}\, dxd\xi\Big) \tag{5.2.19}$$

where $\mathcal{U}$ is a fixed vicinity of $\mathsf{supp}(q)$. Here the last term in the right-hand expression is the contribution of all elliptic and of all irregular elements.

We need to consider only one level asymptotics and $\mathsf{R}^{\mathsf{W}}(\tau)$ is also covered since we can always set the second energy level to $-C$ since $B = I$.

First of all we obtain immediately

Theorem 5.2.1. $\mathsf{R}^{\mathsf{W}}(\tau) = O(h^s)$ *with arbitrarily large* s *provided* $L \ge h^{1-\delta}$ *and* $\varphi \in \mathscr{C}_0^\infty(\mathbb{R})$.

To cover more interesting case we need to impose some non-degeneracy condition; namely let us assume that (5.2.20)$_r$ $|a(x,\xi)-\tau| + |\nabla_{x,\xi} a(x,\xi)| \le \epsilon_0 \implies \mathsf{Hess}\, a(x,\xi)$ has r eigenvalues (counting multiplicities) $f_1, \dots, f_r$ such that $|f_1| \ge \epsilon_0, \dots, |f_r| \ge \epsilon_0$ [6].

Then in the vicinity of every point $z = (x,\xi)$ with

$$|a(z)-\tau| + |\nabla_z a(z)| \le \epsilon_0 \tag{5.2.21}$$

one can choose a coordinate system[7] $z = (z'; z'') = (z_1, \dots, z_r; z_{r+1}, \dots, z_{2d})$ such that

$$a(z) = \sum_{1\le j\le r} \varsigma_j z_j^2 + V(z'') \qquad \text{with } \varsigma_j = \pm 1. \tag{5.2.22}$$

Then in a smaller vicinity

$$\gamma(z) \asymp |z'| + \gamma'(z''), \quad \gamma'(z'') \coloneqq \epsilon_2\big(|V(z'')-\tau| + |\nabla V(z'')|^2\big)^{\frac12} + \bar\gamma. \tag{5.2.23}$$

One can see easily that then

$$\int_{\Sigma_\tau\cap\mathcal{U}\cap\{\varepsilon\le\gamma(x,\xi)\le 2\varepsilon\}} dxd\xi : da \le C\varepsilon^{r-2}; \tag{5.2.24}$$

[6] The other eigenvalues are arbitrary.

[7] This system is not assumed to be symplectic.

then for $r \ge 3$

$$\int_{\Sigma_\tau \cap \Omega} dxd\xi : da < \infty, \tag{5.2.25}$$

and

$$\int_{\Sigma_\tau \cap \Omega \cap \{\gamma(x,\xi)<\varepsilon\}} dxd\xi : da = O(\varepsilon^{(r-2)}) \tag{5.2.26}$$

and, moreover, all the additional terms are $O\big(h^{1-d+\delta'}\vartheta(h/L)\big)$ with a small enough exponent $\delta' > 0$.

Meanwhile for $r = 2$ we get a logarithmic divergence in (5.2.25).

On the other hand, assume instead that $(5.2.20)_2^+$ $|a(x,\xi) - \tau| + |\nabla_{x,\xi} a(x,\xi)| \le \epsilon_0 \implies \mathsf{Hess}\, a(x,\xi)$ has 2 eigenvalues (counting multiplicities) f_1, f_2 of the same sign such that $|f_1| \ge \epsilon_0, |f_2| \ge \epsilon_0$ [6].

Then (5.2.25), (5.2.26) hold. Really, in this case for each z'' on Σ_τ magnitude of $|z'|$ is defined which prevents logarithmic divergence. So, in this case $\int_{\Sigma_\tau} dxd\xi : da$ is uniformly bounded[8].

Finally, under condition $(5.2.20)_2$ the additional terms are $O\big(h^{1-d}\vartheta(h/L)\big)$.

Thus we arrive to the remainder estimate $O\big(h^{1-d}\vartheta(h/L)\big)$ under condition $(5.2.20)_2^+$.

Now look what happens to the coefficients. They are given by the "regularized" formulae in which Q_2 is replaced by $Q_2(I - \zeta(x, hD))$ where

$$\mathsf{supp}(\zeta) \subset \{\gamma(x,\xi) \le c_0\bar\gamma\}, \qquad \zeta = 1 \quad \text{as} \quad \gamma(x,\xi) \ge \bar\gamma, \tag{5.2.27}$$
$$|D^\alpha \zeta| \le c_\alpha \gamma^{-|\alpha|} \qquad \forall \alpha;$$

so these regularized coefficients are given by

$$\kappa'_{n\,\mathsf{reg}}(\tau, h) = \tag{5.2.28}$$
$$(2\pi)^{-d} \int q_1(x,\xi,h)\mathcal{F}_n(x,\tau,\xi)[q_2(x,\xi,h)]\big(1 - \zeta(x,\xi)\big)\, dxd\xi$$

instead of (4.3.60); exact choice of ζ is not important. Meanwhile integral in (4.3.60) may lead to distribution with respect to τ because there is no microhyperbolicity anymore.

So, we arrive immediately to

[8] However, as example $a = z_1^2 + z_2^2$ shows, this integral is not necessarily uniformly convergent.

Theorem 5.2.2. *(i) Under condition* $(5.2.20)_3$

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L,\mathsf{reg}}(\bar\tau)| \le C_0 h^{1-d}\vartheta\big(\frac{h}{L}\big)\Big(\int_{\Sigma_{\bar\tau}\cap\mathcal{U}} dxd\xi : da + C'h^{\delta'}\Big) \tag{5.2.29}$$

where

$$\mathsf{R}^{\mathsf{W}}_{\varphi,L,\mathsf{reg}}(\bar\tau) \coloneqq \int \varphi\big(\frac{\tau-\bar\tau}{L}\big)\Big(d_\tau\big(\Gamma Q_{1x} Be(.,.,\tau',\tau)\,{}^t Q_{2y}\big) - \sum_{0\le n\le N'-1} h^{-d+n}\kappa'_{n,\mathsf{reg}}(\tau,h)\,d\tau\Big) \tag{5.2.30}$$

with regularized coefficients $\kappa'_{n,\mathsf{reg}}$.

(ii) Under condition $(5.2.20)^+_2$

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L,\mathsf{reg}}(\bar\tau)| \le Ch^{1-d}\vartheta\big(\frac{h}{L}\big). \tag{5.2.31}$$

(iii) Under condition $(5.2.20)_2$

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L,\mathsf{reg}}(\bar\tau)| \le Ch^{1-d}\vartheta\big(\frac{h}{L}\big)\cdot\big(|\log h|+1\big). \tag{5.2.32}$$

(iv) Under condition $(5.2.20)_1$

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L,\mathsf{reg}}(\bar\tau)| \le Ch^{\frac12-d}\vartheta\big(\frac{h}{L}\big). \tag{5.2.33}$$

Proof. We proved Statements (i) and (ii) already. Proof of Statements (iii) and (iv) follows the same scheme but as we integrate with respect to z' we note that this integral becomes

$$\int |\log\big(|V(z'')-\bar\tau|+h\big)|\,dz'' \tag{5.2.34}$$

and

$$\int \big(|V(z'')-\bar\tau|+h\big)^{-\frac12}\,dz'' \tag{5.2.35}$$

as $r=2$, $a=z_1^2-z_2^2+V(z'')$ and as $r=1$, $a=\pm z_1^2+V(z'')$ respectively. In the worst case $V(z'')=0$ these expressions become $|\log h|$ and $h^{-\frac12}$ factors.

We will use improved remainder estimates later. □

Remark 5.2.3. (i) We do not need to include terms such that $\vartheta(h) \ge C^{-1}h^{n-1}$ for all $h \in (0, h_0)$;

(ii) Under condition $(5.2.20)^+_r$ we do not need to regularize coefficients in the terms such that $\vartheta(L)L^{-n}$ is a monotone non-decreasing function on $(0, h_0)$.

Sharp and Sharper Asymptotics

Let us leave analysis of Statements (iii) and (iv) of Theorem 5.2.2 for coming subsections and consider improvements of (i) and (ii) under condition to long-term dynamics.

If we assume that a is scalar globally we have just Hamiltonian flow (not the generalized Hamiltonian flow) and we do not need to consider sharp asymptotics separately; however we do not make such assumption.

We will use ν instead of γ of Section 4.5 because γ is in use.

Then we can apply Theorems 4.5.5 and 4.5.12 in the following settings. Let $\mathcal{U}_i$ denote $\mathsf{supp}(r_i^0)$ and Ω denote $\mathsf{supp}(q_1) \cap \mathsf{supp}(q_2)$ (from these theorems). Assume that

$$\mathcal{U}_i \subset \Omega^+_\varepsilon := \{z \in \Omega : \gamma(z) \ge \varepsilon\} \qquad \forall i = 1, \dots, m \tag{5.2.36}$$

with ν either a small constant (for sharp asymptotics) or a small parameter $\nu \in [h^\delta\epsilon, \epsilon]$ (for sharper asymptotics). Then in the zone Ω^+_ε we can use Theorems 4.5.5 and 4.5.12 with condition (4.5.30) replaced by

$$\mathsf{dist}\big((x,\xi), \Psi_{\tau,t}(x,\xi)\big) \ge \begin{cases} \epsilon\gamma|t| & \text{as } |t| \le T_0, \\ \gamma\nu & \text{as } T_0 \le |t| \le T. \end{cases} \tag{5.2.37}$$

In particular, we arrive to

Proposition 5.2.4. *Let condition* $(5.2.20)^+_2$ *be fulfilled. Further, assume that* $\mu_\tau(\Pi \cap \Omega^+) = 0$ *where* Π *is the set of all periodic trajectories and* $\Omega^+ := \{z \in \Omega : \gamma(z) > 0\}$. *Then for any* $\varepsilon > 0$ *contribution of* Ω^+_ε *to the remainder estimate is* $o\big(h^{1-d}\vartheta(h/L)\big)$ *uniformly with respect to* $h \ge L$.

We leave to the reader to formulate theorems. However it would be completely futile unless we can properly estimate contribution to the remainder of *near-critical zone*

$$\Omega_\varepsilon := \{z \in \Omega : \gamma(x,\xi) < \varepsilon\}. \tag{5.2.38}$$

Near-Critical Zone

Observe first that due to (5.2.26) as $r \ge 3$ contribution of Ω_ε to the remainder does no exceed $C\varepsilon h^{1-d}$ and thus is small. In particular, Proposition 5.2.4 immediately implies the final Theorem 5.2.9(i).

However under condition $(5.2.20)_2^+$ situation is more complicated. Due to (5.2.23)

$$\mu_\tau(\Omega_\varepsilon) \lesssim \mathsf{mes}(\Omega''_\varepsilon), \quad \Omega''_\varepsilon := \{z'' \in \Omega'' : \gamma'(z'') < \varepsilon\} \tag{5.2.39}$$

where we assigned $\mu_\tau(\Omega_0) = 0$ because μ_τ is not defined on $\Omega_0 = \{z \in: \gamma(z) = 0\}$, and $\Omega_\varepsilon = B(0,\varepsilon) \times \Omega''$.

Proof of Theorem 5.2.2(ii) immediately implies

Proposition 5.2.5. *Let condition* $(5.2.20)_2^+$ *be fulfilled. Then contribution of* Ω_ε *to the remainder estimate does not exceed* $Ch^{1-d}\vartheta(h/L)\,\mathsf{mes}(\Omega''_\varepsilon)$.

In particular, Proposition 5.2.4 immediately implies the final Theorem 5.2.9(ii) under assumption $\mathsf{mes}(\{V = \bar\tau\}) = 0$. However we can do better than this. Let us introduce the set

$$\Sigma'_\tau = \{(x,\xi) : \ \tau \text{ is an eigenvalue of } \ a(x,\xi) + ha^s(x,\xi)\} \tag{5.2.40}$$

and the $\mathcal{L}(\mathbb{H},\mathbb{H})$-valued[9] measure

$$d\mu'_\tau = \partial_\tau \theta\big(\tau - a(x,\xi) - a^s(x,\xi)h\big) \tag{5.2.41}$$

supported on Σ'_τ.

Proposition 5.2.6. *Let condition* $(5.2.20)_2^+$ *be fulfilled. Then* $\mathsf{R}^{\mathsf{T}}_{\varphi,L}(\tau)$ *is dominated by*

$$\Big(Ch^{1-d}\int_{\Sigma'_\tau\cap\Omega\cap\{\gamma\ge\varepsilon\}} d\mu'_\tau + Ch^{1-d}\int_{\Sigma'_\tau\cap\Omega\cap\{\gamma\le\varepsilon\}} |\{z_1,z_2\}|\, d\mu'_\tau + C''h^{1-d+\delta'}\Big)\vartheta\big(\frac{h}{L}\big) \tag{5.2.42}$$

where $\varepsilon = h^\delta$ *with arbitrarily small* $\delta > 0$.

[9] We do not assume here that the subprincipal symbol a^s is scalar.

Proof. It is sufficient to prove (5.2.42) as

$$\mathsf{supp}(q_1) \cap \mathsf{supp}(q_2) \subset \Omega_\varepsilon. \tag{5.2.43}$$

Without any loss of the generality we can assume that two disjoint from 0 eigenvalues of $\mathsf{Hess}\, a$ are positive. Introducing appropriate local coordinates $z = (z'; z'') = (z_1, z_2; z'')$ in $\mathbb{R}^{2d}$ we obtain that $a - \tau = (z_1^2 + z_2^2 + V(z''))$ and then (5.2.23) holds for γ defined by (5.2.5); let us take $\bar\gamma = h^{\frac12-\delta}$ and consider a γ-admissible partition of unity. Then the arguments of the proof of Theorem 5.2.2 provide us with an appropriate estimate in the zone $\{\gamma \ge c_0\varepsilon\}$ and we need to consider only the zone $\{|z'| \le \varepsilon\} \times \Omega''$.

Let us cover Ω'' with balls of radius $\gamma_1 = h^{\delta_1}$ with $\delta_1 < \delta$ and consider balls of different types:

(i) Let $|\mathsf{Hess}\, V| \ge c_0\gamma_1$ at some point $z'' \in \Omega$. Then this remains true in $B(z'', \gamma_1)$ (with c_0 replaced by $\frac12 c_0$) and

$$\mathsf{mes}\big(\Omega''_\varepsilon \cap B(z'', \gamma_1)\big) \le \mathsf{mes}\big(B(z'', \gamma_1)\big)h^{\delta'}, \quad \delta' > 0. \tag{5.2.44}$$

Then the total contribution of these balls to the remainder does not exceed $C'h^{1-d+\delta'}\vartheta\big(h/L\big)$; thus we need to consider only balls with $|\mathsf{Hess}\, V| \le \gamma_1$.

Moreover, the same arguments combined with the induction with respect to m yield that one need only treat balls with $\sum_{2\le|\alpha|\le m} |D^\alpha V| \le c_0\gamma_1$ with arbitrarily large m.

Now as V is almost constant in the balls in question we need to consider $\{z_1, z_2\}$ which is either rather small (less than ω) or has a constant magnitude ω in balls in question; then in both cases classical dynamics could be periodic but its period is $\gtrsim \omega^{-1}$. We exploit this in a bit different way.

(ii) Let us consider a ball with $|\{z_1, z_2\}| \le c\omega$ where $\omega \ge h^{\delta_0}$. This inequality holds at all points of this ball simultaneously. Then in the appropriate *symplectic* coordinates

$$(a - \bar\tau) = \xi_1^2 + (\xi_2 + b_1(x,\xi))^2 + b_2(x,\xi) \tag{5.2.45}$$

where $|\nabla b_1| \le c\omega$ and $|\mathsf{Hess}\, b| \le c\omega^2$ in this ball.

Let us redefine the scaling functions γ and ρ in the ball $B(z'', \gamma_1)$. Namely, pick

$$\begin{aligned} &\rho := \epsilon\Big(|\xi_1| + |\xi_2 + b_1| + \big(|b_2 - \tau| + \omega^{-2}|\nabla b_2|^2\big)^{\frac12}\Big) + \bar\rho', \\ &\gamma := \rho\omega^{-1}, \qquad \bar\rho' = h^{\frac12}\omega^{\frac12}. \end{aligned} \tag{5.2.46}$$

Then $|\nabla\rho| \le \frac{1}{2}$ (due to the condition on the Hessian) and $\rho\gamma \ge h$.

Moreover, one can check that

$$\mathsf{dist}_x(z',z'') \le \gamma(z''),\ \mathsf{dist}_\xi(z,z'') \le \rho(z'') \implies \rho(z') \asymp \rho(z''),\ \gamma(z') \asymp \rho(z''). \tag{5.2.47}$$

Let us rescale $x_{\mathsf{new}} = x\gamma^{-1}$, $\xi_{\mathsf{new}} = \xi\rho^{-1}$. Then we should replace h by $h_{\mathsf{new}} = h\rho^{-1}\gamma^{-1}$ and L by $L_{\mathsf{new}} = L\rho^{-2}$ because we divide A by ρ^2 now. Obviously,

$$\frac{h_{\mathsf{new}}}{L_{\mathsf{new}}} = \frac{h}{L}\omega. \tag{5.2.48}$$

One can easily check that after this rescaling the derivatives (up to order K) of the symbol of the operator are bounded.

Surely, the symbol itself is not necessary bounded because of the term $a^s h\rho^{-2}$ but in this case one can introduce operator $B = a^s(\bar z)h\rho^{-2}$ where $\bar z$ is a fixed point in the original ball of radius γ_1.

For a scalar symbol a^s one can avoid this difficulty simply by replacing a with $a + ha^s$ in the definitions of γ and ρ.

Moreover, the microhyperbolicity condition is fulfilled for $\rho \ge c_0\bar\rho'$ [10)].

Then Theorem 4.5.12 provides all the necessary estimates in this zone and its total contribution to $\mathsf{R}_{\varphi,L}$ surely does not exceed the right-hand expression of estimate (5.2.41) with ω instead of $|\{z_1,z_2\}|$.

Further, Theorem 5.2.2 [11)] applies in the domain $\rho \le \bar\rho'$, the total contribution to $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ of which does not exceed

$$C'\bar\rho'^{2-d}\bar\gamma'^{-d}\vartheta\Big(\frac{h}{L}\Big) \le C'h^{1-d}\omega\vartheta\Big(\frac{h}{L}\Big).$$

Therefore the contribution of balls with $\omega \le h^{\delta_0}$ is estimated properly.

[10)] According to our procedures, one should check this condition for the symbol $a + a^s h$ after rescaling, but the derivatives of $a^s h$ are negligible, so one may check the condition for the scalar symbol a instead.

[11)] With obvious modifications for matrix a^s.

(iii) Finally, let us consider balls of radius $\gamma_2 = h^{\frac{1}{2}-\delta_2}$ where $|\mathsf{Hess}\, V| \le c_0\gamma_1$ and $|\{z_1, z_2\}| \asymp \omega \ge h^{\delta_0}$. In these balls the variation of b_2 is less than $h^{1+\delta_3}$ and we simply include $h^{-1}b_2$ in a^s. Without any loss of the generality one can assume that in the ball, $h^{-1}b_2 + a^s - \tau = \begin{pmatrix} B_+ & 0 \\ 0 & B_- \end{pmatrix}$ where $B_+ \ge \nu I$, $B_- < (1-\epsilon)\nu I$ and $\epsilon''\omega \le \nu \le \epsilon'\omega$ with small enough positive constants $\epsilon, \epsilon', \epsilon''$. Then one can easily see that

$$\int_{\Sigma'_\tau \cap B(z,\gamma_2)} d\mu'_\tau \succ \pi_- \gamma_2^{2-2d}$$

where $\pi_- = \begin{pmatrix} 0 & 0 \\ 0 & I \end{pmatrix}$.

Let us consider $A_+ = Z_1^2 + Z_2^2 + B_+$. Then Gårding inequality yields that

$$\begin{aligned}(A_+u, u) \ge \|Z_1u\|^2 + \|Z_2u\|^2 - C_0h^{1+2\delta_0}\|u\|^2 - C\|\mathcal{Q}u\|^2 \ge \\ \frac{1}{2}(\|Z_1u\|^2 + \|Z_2u\|^2 + |([Z_1, Z_2]u, u)|) - C_0h^{1+2\delta_0}\|u\|^2 - C\|\mathcal{Q}u\|^2 \ge \\ \epsilon(\|Z_1u\|^2 + \|Z_2u\|^2 + \omega h\|u\|^2) - C\|\mathcal{Q}u\|^2\end{aligned}$$

where $\mathcal{Q}$ is negligible in the ball in question. Therefore for $\tau' \le \tau$ the operator $A_+ - \tau'$ is invertible in this ball and the norm of the inverse does not exceed $Ch^{-1}\omega^{-1}$.

Therefore $F_{t\to h^{-1}\tau}\chi_\tau(t)(Q_1u^{++})$ is negligible for $\tau \le \epsilon\omega h$, $T \ge h^{-1-\delta'''}\omega^{-1}$ with an arbitrarily small exponent $\delta''' > 0$ and simplified Tauberian arguments yield that $Q_1E(\tau', \tau)$ is negligible for $\tau', \tau'' \le \tau + \epsilon\omega h$. This and estimates from below of the right-hand expressions of (5.2.42) yield that (5.2.42) holds. □

From the proof above immediately follows

Theorem 5.2.7. *Let condition* $(5.2.20)_2^+$ *be fulfilled. Then* $\mathsf{R}^{\mathsf{W}}_{\varphi,L,\mathsf{reg}}$ *is dominated by* (5.2.42) *where now regularization also means that* $a^s h$ *is included in the principal symbol while calculating coefficients.*

Remark 5.2.8. (i) Obviously $\mu_\tau(U)$ may be not continuous function; in particular, it has no-zero jump at $\bar\tau$ as $a = z_1^2 + z_2^2 + \bar\tau$; however in the case (iii) which is the only case when this really matters the bottom of the spectrum is actually pushed up and it helps; otherwise we would need to replace in the right-hand expression τ by $\tau + C_h$.

(ii) Theorem 5.2.7 clearly provides improvement for example for 2-dimensional Schrödinger operator without magnetic field but it provides improvement neither for 2-dimensional magnetic Schrödinger operator

$$h^2D_1^2 + h^2(D_2 - x_1)^2 \tag{5.2.49}$$

nor for 1-dimensional Schrödinger operator

$$h^2D_1^2 + h^2x_1^2; \tag{5.2.50}$$

these operators are actually equivalent.

In particular, Proposition 5.2.4 immediately implies the final Theorem 5.2.9(ii) in the full generality.

Sharp and Sharper Asymptotics (End)

So, we can apply Theorem 5.2.7 in the near-critical zone. In particular we get

Theorem 5.2.9. *Assume that* $\mu_{\bar\tau}(\Pi \cap \Omega^+) = 0$. *Then*

(i) Under condition $(5.2.20)_3$

$$\mathsf{R}^{\mathsf{W}}_{\varphi,L,\mathsf{reg}}(\bar\tau) = o\Big(h^{1-d}\vartheta\big(\frac{h}{L}\big)\Big). \tag{5.2.51}$$

(ii) Let condition $(5.2.20)_2^+$ *be fulfilled. Then as as*

$$\mathsf{mes}(\{V = \bar\tau,\ \{z_1, z_2\} \neq 0\}) = 0 \tag{5.2.52}$$

estimate (5.2.51) *holds.*

5.2.2 From Condition "No Critical Point" to "rank Hess $a \geq 2$ at cCritical Points. " II

Now we begin treating the more complicated case in which condition $(5.2.20)_2$ is fulfilled but condition $(5.2.20)_2^+$ fails. We want to obtain remainder estimate $O(h^{1-d}\vartheta(h/L))$ in this case. Without any loss of the generality one can assume that $(5.2.20)_2^-$ $|a(x,\xi) - \tau| + |\nabla_{x,\xi}a(x,\xi)| \leq \epsilon_0 \implies \mathsf{Hess}\, a(x,\xi)$

has two eigenvalues (counting multiplicities) f_1, f_2 such that $f_1 \ge \epsilon_0, -f_2 \ge \epsilon_0$ [6]. Then in the appropriate coordinates locally

$$a - \tau = z_1 z_2 + V(z'') \tag{5.2.53}$$

with $z'' = (z_3, \dots, z_{2d})$.

The goal of this Subsection is

Theorem 5.2.10. *Let condition and* $(5.2.20)_2^-$ *be fulfilled. Let* $\operatorname{diam} \Omega \le c$. *Then* $\mathsf{R}^{\mathsf{W}}_{\varphi,L,\mathsf{reg}}$ *is dominated by* $Ch^{1-d}\vartheta(h/L)$.

Proof. Let us observe first that for fixed z'' hyperbole $\Sigma_{\tau,z''} = \{(z_1, z_2) : (z_1, z_2, z'') \in \Sigma_\tau\}$ is parametrized by $z_1 \pm z_2$ as $\pm V(z'') < 0$ and

$$\int_{\Sigma_{\tau,z''} \cap \{|z'| \ge h^{\frac12}\}} d\mu_{\tau,z''} \lesssim |\log\bigl(|V(0)| + h\bigr)|; \tag{5.2.54}$$

after integration with respect to z'' this may lead to the factor $|\log h|$ in the final estimate and our purpose is to fight it.

(a) First we consider zone where V is "variable enough".

Let us introduce the scaling functions

$$\zeta_l(z'') = \epsilon\Bigl(\sum_{|\alpha|\le l} |D^\alpha V|^{\frac{l+1}{l+1-|\alpha|}}\Bigr)^{\frac{1}{l+1}} + \bar\zeta_l, \qquad \bar\zeta_l = h^{\frac{2}{l+3}} \tag{5.2.55}$$

with $l \ge 1$. Then

$$|\nabla \zeta_l| \le \frac12 \tag{5.2.56}$$

as $\epsilon > 0$ is small enough constant and

$$\gamma(z) \asymp |z_1| + |z_2| + \zeta_1(z'') \tag{5.2.57}$$

and it trivially follows from the arguments of the previous Subsection 5.2.1 [12] that

(5.2.58) The contribution of the zone $\Omega \cap \{\gamma(z) \le C_0 h^{\frac12}\}$ to the remainder does not exceed $Ch^{1-d} \operatorname{mes}\bigl(\{z'' \in \Omega'' : \zeta_1(z'') \le C_1 h^{\frac12}\}\bigr)\vartheta(h/L)$

[12] One needs to consider balls in $\mathbb{R}^{2d}$ of radius $\zeta_1(z)$ for each z.

and

(5.2.59) The contribution of the zone $\Omega\cap\{\gamma(z) \le C_0\zeta_1(z'')\}$ to the remainder estimate does not exceed $Ch^{1-d}\vartheta(h/L)$

where $\Omega = \{(z', z'') : |z'| \le \epsilon, z'' \in \Omega''\}$ and domain Ω'' is fixed.

Moreover, the same arguments yield that

(5.2.60) The contribution of the zone $\Omega \cap \{\gamma(z) \le \varrho(z'')\}$ to the remainder estimate does not exceed

$$Ch^{1-d}\vartheta\big(\frac{h}{L}\big) \int_\Omega \big(\log \frac{\varrho(z'')}{\zeta_1(z'')} + 1\big)\, dz'' \tag{5.2.61}$$

provided $\varrho(z'')$ satisfies conditions $\varrho(z'') \ge \zeta_1(z'')$ and $|\nabla\varrho| \le 1$.

Denote by J_l the integral in (5.2.61) with

$$\varrho_l := \sum_{1\le k\le l} \zeta_k^{p_k}, \qquad p_k = 2^{k-1}. \tag{5.2.62}$$

Let us prove by induction with respect to $l \ge 1$ that

(5.2.63) J_l does not exceed C_l.

For $l = 1$ this is obvious. Let us assume that it is true for some l; to make an induction in (5.2.63) we should prove that

$$J'_l := \int \log\big(\frac{\varrho_l(z'')}{\varrho_{l-1}(z'')}\big)\, dz'' \tag{5.2.64}$$

is bounded.

Let us consider a ζ-admissible covering of Ω'' (with $\zeta = \zeta_l$) and let us consider the contribution of each element to J'_l. Surely, one needs to consider only elements $B\big(z'', \zeta(z'')\big)$ with $\varrho_l \ge C_2\varrho_{l-1}$ with arbitrarily large constant C_2. The latter inequality means that $\zeta_k \le \epsilon\zeta^{p_l/p_k}$ i. e.

$$|D^\alpha V| \le \epsilon_2\zeta^{2^{l-k}(k-|\alpha|+1)} \qquad \forall k : |\alpha| \le k \le l-1 \tag{5.2.65}$$

with arbitrarily small constant $\epsilon_2 > 0$. On the other hand,

$$|D^\alpha V| \le c\zeta^{l-|\alpha|+1} \qquad \forall \alpha : |\alpha| \le l \tag{5.2.66}$$

and for some $\alpha = \bar\alpha$ with $|\alpha| \le l$ the opposite inequality holds

$$|D^\alpha V| \ge \epsilon_0 \zeta^{l-|\alpha|+1} \qquad \text{as} \quad \alpha = \bar\alpha. \tag{5.2.67}$$

Picking in (5.2.65) $k = l-1$ we get inequality

$$|D^\alpha V| \le \epsilon_2 \zeta^{2(l-|\alpha|)} \qquad \forall \alpha : |\alpha| \le l-1$$

which is stronger than (5.2.66) and incompatible with (5.2.67) since ϵ_0 is fixed and ϵ_2 is arbitrarily small; thus (5.2.67) holds with some $\alpha = \bar\alpha : |\bar\alpha| = l$.

Meanwhile (5.2.64) can only increase if we replace ϱ_{l-1} by the lesser value $\zeta_{l-1}^{p_{l-1}}$ where ζ_{l-1} in turn is greater than

$$\eta \coloneqq \sum_{\alpha:|\alpha|=l-1} |D^\alpha V| \tag{5.2.68}$$

while $\varrho_l \varrho_{l-1} \asymp 1 + \zeta^{p_l} \varrho_{l-1}^{-1}$.

Thus contribution of $B(z', \zeta(z'))$ to (5.2.64) does not exceed

$$C_0 \int_{B(z',\zeta(z'))} \log\bigl(\frac{\zeta^l}{\eta}\bigr)\, dz'. \tag{5.2.69}$$

Rescaling $y = z'/\zeta$ and introducing function $W(y) = V(\zeta y)\zeta^{-l}$ we see that (5.2.69) does not exceed $C\zeta^{2d-2} \int |\log \phi(y)|\, dy$ with $\phi(y) = \sum_{\alpha:|\alpha|=l-1} |D_y^\alpha W|$ and

(5.2.70) For some β with $|\beta| = l$, $|D_y^\beta W| \ge \epsilon_0$.

Therefore it is sufficient to prove that $\int |\log \phi(y)|\, dy \le C$ but this is obvious because in the appropriate coordinate system $\phi(y) \ge |y_1|$ (due to (5.2.70)). Thus, inequality $J_l' \le C$ is proven, the induction step is complete and (5.2.63) is also proven.

As a corollary we obtain that

(5.2.71) The contribution of the zone

$$\{z=(z',z''):\, z''\in\Omega, \gamma(z)\le \varrho_l(z')=\sum_{1\le k\le l}\zeta_k^{p_k},\quad p_k=2^{k-1}\}$$

to the remainder does not exceed $Ch^{1-d}\vartheta(h/L)$.

Thus, we have estimated properly the contribution of the zone $\{\varrho_l\ge\epsilon\gamma\}$; so far the non-covered zone is $\{\zeta_k\le\gamma^{1/p_k}\ \forall k\le l\}$ or equivalently

$$\{|D^\alpha V|\le \gamma^{(k-|\alpha|+1)/2^{k-1}}\quad \forall\alpha,k:|\alpha|\le k\le l\}.$$

Picking the optimal value $k=|\alpha|$ we get this zone

$$\{(z_1,z_2,z''):|D^\alpha V|\le c\gamma^{2^{1-|\alpha|}}\ \forall\alpha:|\alpha|\le l,\ \gamma\asymp |z_1|+|z_2|\} \tag{5.2.72}$$

with arbitrarily large l.

(b) Now we want to estimate the contribution of the larger (than (5.2.72)) zone defined by

$$|D^\alpha V|\le c\gamma^\delta\quad \forall\alpha:|\alpha|=2,\qquad \gamma\asymp |z_1|+|z_2| \tag{5.2.73}$$

with arbitrarily small $\delta>0$ (as $l=2$ we need to do it for $\delta=\frac12$).

First of all we consider the part of this zone with

$$|\nabla V|\ge \gamma^{1+\delta_1} \tag{5.2.74}$$

with $\delta_1<\delta$. Let us consider a point $\bar z''$ satisfying both inequalities (5.2.73) and (5.2.74). Without any loss of the generality one can assume that all the components of $\nabla V(\bar z'')$ vanish excluding $\sigma=\partial_{z_3}V$. Then in the ν-vicinity $\mathcal{U}$ of $(0,\bar z'')$

$$c^{-1}\le|\nabla V|\le c\sigma,\quad V(z)=V(\bar z'')+\sigma(z_3-\bar z_3)+O(\nu^2\gamma^\delta) \tag{5.2.75}$$

provided $\nu\le\min(\sigma\gamma^{-\delta},\gamma^\delta)$.

Let $\mathcal{V}_1=\mathcal{V}\cap\{z'':|V(z'')|\le c\gamma^2\}$. One can see easily that due to (5.2.75)

$$\mathsf{mes}(\mathcal{V}_1)\nu^{2-2d}\le\gamma^2\sigma^{-1}\nu^{-1}\le\gamma^{\delta_2} \tag{5.2.76}$$

with $\delta_2>0$ provided $\nu\sigma\ge\gamma^{2+\delta_2}$, $\nu\ge\gamma^{1-\delta_2}$. Obviously conditions to ν are not contradictory for small enough $\delta_2>0$, $\delta_1>0$.

Therefore

(5.2.77) For any ε the contribution of the zone

$$\{z : \frac{1}{2}\varepsilon \le \gamma(z) \le 2\varepsilon,\ |\nabla^2 V| \le \gamma^{\delta},\ |\nabla V| \ge \gamma^{1+\delta'}\}$$

to the remainder does not exceed $Ch^{1-d}\varepsilon^{\delta_2}\vartheta(h/L)$ and therefore the total contribution of the zone in question does not exceed $Ch^{1-d}\vartheta(h/L)$.

So, we should consider only zone where inequalities (5.2.73) and

$$|\nabla V| \le \gamma^{1+\delta} \tag{5.2.78}$$

hold.

In this zone we apply Theorem 4.5.12 after rescaling: so we use the long term propagation of singularities.

(c) In this part of the proof we establish that

(5.2.79) Contribution of γ-admissible element on which

$$\omega := |\{z_1, z_2\}| \le \gamma^{\delta_1} \tag{5.2.80}$$

to $\mathsf{R}^{\mathsf{W}}_{\varphi,L,\mathsf{reg}}$ does not exceed

$$Ch^{1-d}\gamma^{2d-2}\Big(\gamma^{\delta_2} + h^{\delta_2}\gamma^{-2\delta_2}\Big)\vartheta\big(\frac{h}{L}\big). \tag{5.2.81}$$

To prove (5.2.79) let us consider $\mathcal{V}$ which is $\epsilon_0\gamma$-vicinity with respect to z' and $\gamma^{1-\delta_3}$-vicinity with respect to z''.

Due to (5.2.77) we can assume that both (5.2.78) and (5.2.80) hold. Then in $\mathcal{V}$ the propagation speed with respect to z' does not exceed $c\omega\gamma + c\gamma^{1+\delta} \le c\gamma^{1+\delta_1}$ while the propagation speed with respect to z'' does not exceed $c\gamma$. Therefore for time $T = \gamma^{-\delta_2}$ Hamiltonian trajectories remain in $\mathcal{V}$.

Moreover, for infinitesimal variations we obtain the inequality $|\frac{d}{dt}\mathfrak{d}z| \le C\gamma^{\delta}|\mathfrak{d}z|$ and therefore $|\mathfrak{d}z(t)| \le C|\mathfrak{d}z(0)|$. Hence, $|D\Psi_t| \le C$.

Finally, let us check the non-periodicity condition for $|t| \le T$. One should consider only initial points with $|\bar{z}_1| \ge \gamma$ (or with the same inequality for $\bar{z}_2$). Obviously there exists a linear function ψ such that $\{\psi, z_1\} = \{\psi, V\} = 0$

and $\{\psi, z_2\} = 1$ at $\bar{z}$ in which case $\frac{d}{dt}\psi = z_1 + O(\gamma^{1+\delta})$ and therefore $\psi(z(t)) = \psi(z(0)) + z_1(0)t + O(\gamma^{1+\delta_1})$ and the non-periodicity condition is fulfilled as well.

Thus (5.2.79) is proven. It immediately implies that the total contribution of zone defined by (5.2.80) and (5.2.78) to the remainder does not exceed $Ch^{1-d}\vartheta(h/L)$ and we arrive to

(5.2.82) The total contribution of zone defined by (5.2.80) to the remainder does not exceed $Ch^{1-d}\vartheta(h/L)$.

(d) So, we should now consider only points satisfying (5.2.72), (5.2.73) and

$$\omega = |\{z_1, z_2\}| \ge \gamma^{\delta_2} \tag{5.2.83}$$

where one can choose $\delta_2 > 0$ arbitrarily.

Consider $\epsilon\omega(0, z'') + h^{\frac{1}{2}}$ as a scaling function and a corresponding partition. Now we need to prove that

(5.2.84) As $\hat{z} = (0, \hat{z}'')$ contribution to $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ of η admissible element $B(\hat{z}, \eta)$ does not exceed $Ch^{1-d}\eta^{2d-2}\vartheta(h/L)$ with $\eta := \epsilon\omega(\hat{z})$.

Let us again consider the Hamiltonian flow (which will be hyperbolic here); to be definite we assume that $\{z_1, z_2\} > 0$. We consider point $\bar{z}$ and trace the trajectory $z(t)$ with $z(0) = \bar{z}$ as long as it remains in $\mathcal{V}$ which is η vicinity of $\hat{z}$ with respect to z'' and $\epsilon_1\eta^2$ vicinity with respect to z'; due to (5.2.83) $\bar{z} \in \mathcal{V}$.

Recall that one can choose the time direction arbitrarily. Therefore without any loss of the generality one can assume that $|\bar{z}_2| \asymp \gamma \gg \bar{z}_1$ because $|z_1| \asymp |z_2|$ implies that $\gamma \asymp \zeta_1$ of Part (a). Note that due to (5.2.83) $\gamma \le \omega^M$ with arbitrarily large M and that $|\nabla V| \le \gamma^{1+\delta} \le \omega\gamma^{1+\delta_4}$.

So, consider Hamiltonian equation; then under extra assumptions just imposed, for time

$$T := \epsilon\omega^{-1}|\log\gamma| \ge C\omega^{-1}|\log\omega| \tag{5.2.85}$$

this trajectory remains in $\mathcal{V}$; and for positive time $T^* \le C\omega^{-1}|\log\gamma|$ it leaves $\mathcal{V}$ for sure through $|z_2| \asymp \omega^2$.

Let us try to look at this trajectory in the positive time direction; then considering equation to variations we conclude that $|\frac{d}{dt}\mathfrak{d}z| \le c\omega|\mathfrak{d}z|$ and therefore $|\mathfrak{d}z(t)| \le Ce^{c\omega|t|}|\mathfrak{d}z(0)|$. Hence, $|D\Psi_t| \le Ce^{c\omega|t|}$.

Finally, since $|z_2(t) - z_2(0)| \ge \epsilon_1\omega te^{\epsilon_1\omega t}$ we conclude that the non-periodicity condition is fulfilled as well. Thus we can take T defined by (5.2.85). Then the total contribution of the element in question to the remainder does not exceed $Ch^{1-d}J\omega^{2d-1}\vartheta(h/L)$ with

$$J = \int \gamma^{-1}|\log\gamma|^{-1}\,d\gamma; \tag{5.2.86}$$

this integral has loglog divergence and we can avoid it considering only $\gamma \le h^{\delta'}$ with arbitrarily small $\delta' > 0$; to be on the safe side we also assume that $\gamma \ge h^{\frac12-\delta'}$. So we arrive to

(5.2.87) Contribution of subzone described in (5.2.84) with extra condition $\{h^{\frac12-\delta'} \le \gamma \le h^{\delta'}\}$ does not exceed $Ch^{1-d}\omega^{2d-1}\vartheta(h/L)$.

Thus we need to reconsider two subzones: *outer subzone* $\{h^{\delta'} \le \gamma \le \omega^M\}$ and *inner core* $\{h^{\frac12} \le \gamma \le h^{\frac12-\delta'}\}$.

(e) To tackle the former subzone let us consider trajectories issued from $\bar z$ in the negative time direction (while before we considered positive time direction) as long as it remains in $\mathcal{V}$ but capping T by $\epsilon|\log h|$. Then it remains in the zone $\{|z_2| \ge h^{2\delta'}\}$ and $|d\Psi_t| \le h^{-3\delta'}$ and non-periodicity condition is fulfilled as well. Then the contribution of subzone in question does not exceed

$$\Big(Ch^{1-d}\int_{\Sigma_\tau\cap\mathcal{U}}\big(T_-(x,\xi)^{-1} + |\log h|^{-1}\big)\,dxd\xi : da + C''h^{1-d+\delta''}\omega^{2d-2}\Big)\vartheta\big(\frac{h}{L}\big) \tag{5.2.88}$$

where $\mathcal{U}$ is an element in question and we do not cap $T_-(z)$ anymore so $T_-(z) = \infty$ if the trajectory in question does not leave $\mathcal{V}$ for time $\ge \epsilon|\log h|$. Obviously $|\log h|^{-1}\int dxd\xi : da| \le C$ and we are left with

$$\int_{\Sigma_\tau} T_-(x,\xi)^{-1}dxd\xi : da; \tag{5.2.89}$$

and trajectories counted can leave $\mathcal{V}$ only through $|z_1| \asymp \omega^2$.

Since the measure $dxd\xi : da$ is invariant we conclude that integral (5.2.89) is of the same magnitude as if it was restricted to $\{\frac{1}{2}\omega^2 \le \gamma \le \omega^2\}$ and T_- was replaced by the time T' spent by the trajectory in this zone; this removes logarithmic divergency. So we arrive to

(5.2.90) Contribution of subzone described in (5.2.84) with extra condition $\{h^{\delta'} \le \gamma \le \omega^M\}$ does not exceed $Ch^{1-d}\omega^{2d-1}\vartheta(h/L)$.

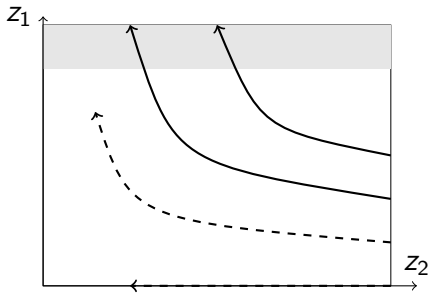

Figure 5.1: Solid trajectories leave $\mathcal{V}$ for a capped time; dashed trajectories do not and are not considered in (5.2.89); the shadow indicate zone $\gamma \asymp \omega^2$.

(f) In order to treat the remaining zone let us apply the routine rescaling $x_{\mathsf{new}} = (x - \bar{x})\bar{\gamma}^{-1}$ and $h_{\mathsf{new}} = \hbar := h\bar{\gamma}^{-2}$ with $\bar{\gamma} = h^{\frac{1}{2}-\delta'}$. We get an operator of the same type but with complete symbol $a = z_1z_2 + \bar{V} + ...$ where $\{z_1, z_2\} = \omega + ...$ where the dots denote symbols all the derivatives of which do not exceed $\hbar^M$ with arbitrarily large M and are therefore negligible, $\bar{V}$ and ω are constant and $\bar{V}$ is not necessarily a scalar; here $\omega \ge \hbar^{\delta_1}$ (otherwise we can apply rescaling and arrive into case already considered in Part (c) and only the contribution of the zone $h^{\frac{1}{2}}\gamma \le \hbar^{\frac{1}{2}-\delta''}$ needs to be treated (with $\gamma = \gamma_{\mathsf{new}} = \gamma_{\mathsf{old}}/\bar{\gamma}$ as well and δ_1 and δ_2 are new but still arbitrarily small). Now $\delta_0 = 0$.

Without any loss of the generality one can assume that $z_1 = hD_1$ and either $z_2 = \omega x_1$ or $z_2 = \omega x_1 + x_2$ (which can be arranged otherwise by an appropriate symplectic change of variables). Moreover, changing coordinates $x_{1\mathsf{new}} = x_1 + \omega^{-1}x_2$, $x'_{\mathsf{new}} = x'$ if necessary and multiplying the operator by ω^{-1} we get exactly the operator $x_1\hbar D_1 + \frac{i\hbar}{2} + \bar{V}_{\mathsf{new}}$ (modulo negligible) with $\bar{V}_{\mathsf{new}} = \omega^{-1}\bar{V}$.

All that remains to do is to consider points $(\bar{x}, \bar{\xi})$ with $\bar{\gamma} = |\bar{x}_1| \ge |\bar{\xi}_1|$ (points with the opposite inequality are treated similarly with the negative time direction) and to prove that one can take $T = \epsilon|\log\hbar|$. But for this very specific operator the proof is direct: one can consider operators of multiplication; then $e^{-it\hbar^{-1}A}\phi e^{it\hbar^{-1}A} \equiv \phi_t$ with $\phi_t(x) = \phi(e^{-t}x)$ and for the indicated $t \ge \epsilon$ we obtain that $\phi_t\phi = 0$ provided $\operatorname{supp}\phi$ is small enough.

This proves that the contribution of the element of the partition in question to the remainder estimate is $O\big(h^{1-d}\omega\gamma^{2d-2}|\log h|^{-1}\vartheta(h/L)\big)$ and the total contribution of such elements is $O\big(h^{1-d}\omega^{2d-1}\vartheta(h/L)\big)$ as well because factor $|\log h|^{-1}$ compensate for logarithmic divergence of the integral. Thus we arrive to

(5.2.91) Contribution to the remainder of the subzone described in (5.2.84) with extra condition $\{h^{\frac12} \le \gamma \le h^{1/2-\delta''}\}$ does not exceed $Ch^{1-d}\omega^{2d-1}\vartheta(h/L)$.

Now combining (5.2.87), (5.2.90) and (5.2.91) we obtain (5.2.84) which implies the proper estimate $Ch^{1-d}\vartheta(h/L)$ of the remaining zone.

Finally, Theorem 5.2.10 has been proven. □

Remark 5.2.11. (i) Thus in the inner zone $\{\gamma \le h^{\delta'}\}$ we considered trajectories moving from degeneration while in the outer zone we considered trajectories moving to degeneration.

(ii) We did not exploit that actually instead of factor $\vartheta(h/L)$ we had factor $\vartheta(h/LT)$.

(iii) Now regularization means that $a^s h$ must be included in the principal part; otherwise generally remainder estimate would contain logarithmic factor.

(iv) Assuming that $V = 0$ identically, one can use the canonical form of such operators. Namely, it was proven (for similar proofs see, e. g., Section 13.3) that in the framework of the current analysis with $\{z_1, z_2\} \asymp 1$

$$\mathcal{F}^*A\mathcal{F} \equiv \sum_{m,n:m+n\ge 1} a_{mn}(x', hD')(x_1 hD_1 - \frac{1}{2}ih)^m h^n \tag{5.2.92}$$

for an appropriate Fourier integral operator $\mathcal{F}$ such that in the vicinity of the point in question $\mathcal{F}^*\mathcal{F} \equiv I$.

(v) The most reasonable example is 1-dimensional Schrödinger operator

$$h^2D_1^2 - h^2x_1^2. \tag{5.2.93}$$

Actually we proved even more precise

Theorem 5.2.12. *Let condition* $(5.2.20)_2^-$ *be fulfilled. Then contribution of* Ω_ε *to the remainder does not exceed*

$$Ch^{1-d}\Big(\eta + \int_{\{\zeta_m<\eta\}} |\{z_1,z_2\}|\,dz'' + C'h^\delta\Big)\vartheta\big(\frac{h}{L}\big) \tag{5.2.94}$$

with $\eta = O(\varepsilon^\delta)$ *as* $\varepsilon \to +0$*, arbitrarily large* m *and* $\delta = \delta_m > 0$*.*

Proof. Consider ζ_m-admissible covering. Arguments of the proof of Theorem 5.2.10 imply that the total contribution of zone $\{\zeta_m \ge \varepsilon_1\}$ does not exceed $\big(\eta h^{1-d} + C''h^{1-d+\delta''}\big)\vartheta(h/L)$; therefore only zone $\{\zeta_m \le \varepsilon_1\}$ needs to be reexamined. Here ε_1 is an arbitrarily small constant.

Further, reexaming this proof one can notice that then only zone where $\{\omega > \varepsilon_1\}$ needs to be reconsidered and contribution of the latter zone does not exceed (5.2.94). □

This opens the door to more precise remainder estimates. In particular, we have

Theorem 5.2.13. *Assume that*

$$\mu_{\bar\tau}(\Pi \cap \Omega^+) = 0 \tag{5.2.95}$$

and

$$\mathsf{mes}(\{V = \bar\tau, \{z_1,z_2\} \ne 0\}) = 0. \tag{5.2.96}$$

Then estimate (5.2.51)

$$\mathsf{R}^{\mathsf{W}}_{\varphi,L,\mathsf{reg}}(\bar\tau) = o\Big(h^{1-d}\vartheta\big(\frac{h}{L}\big)\Big)$$

holds.

So, despite very essential differences between $(5.2.20)_2^+$ and $(5.2.20)_2^-$ cases, both estimates $O\big(h^{-d}\vartheta(h/L)\big)$ and $o\big(h^{-d}\vartheta(h/L)\big)$ are proven in the both of them; the latter under assumptions (5.2.95) and (5.2.96).

Our analysis under assumption $(5.2.20)_2$ is complete.

5.2.3 From Condition "rank Hess $a \geq 2$ at Critical Points" to "rank Hess $a \geq 1$ at Critical Points"

Now we will consider operators with stronger degenerations and we consider only scalar operators. We will indicate later what order of matrix symbol can be added. So, let us assume that

(5.2.97) A is a scalar operator[13].

In this subsection we assume that condition $(5.2.20)_1$ is fulfilled. Then locally in the appropriate coordinate system

$$a = \pm\bigl(z_1^2 + V(z')\bigr), \qquad z' = (z_2, \dots, z_{2d}) \tag{5.2.98}$$

where here and below a means the complete symbol of A [13]. However we need to pass to symplectic coordinates with $z_1 = \xi_1$.

Without any loss of the generality we can assume that $|\partial_{\xi_1} z_1| \geq \epsilon_0$ (locally) and then by Malgrange preparation theorem (Malgrange [1]) we rewrite (5.2.98) as

$$a = b(x,\xi)\bigl(\bigl(\xi_1 - \alpha(x,\xi')\bigr)^2 + V(x,\xi')\bigr).$$

Then after the symplectic transformation

$$\xi_{1\mathsf{new}} = \xi_1 - \alpha(x,\xi'),\ (x,\xi')_{\mathsf{new}} = \psi(x,\xi')$$

we obtain the same formula with $\alpha = 0$. Thus, without any loss of the generality one can assume that

$$a(x,\xi) = b(x,\xi)\bigl(\xi_1^2 + V(x,\xi')\bigr), \qquad b(x,\xi) \geq \epsilon_0 \tag{5.2.99}$$

where we changed the sign if needed. In what follows $z' = (x,\xi')$.

Theorem 5.2.14. *Let conditions* (5.2.98) *and* $(5.2.20)_1$ *be fulfilled. Then*

(i) If

$$\sum_{|\alpha|\leq m} |D^\alpha V| \geq \epsilon \tag{5.2.100}_m$$

with some $m \geq 2$ *then* $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ *is dominated by* $Ch^{1-d}\vartheta\bigl(h/L\bigr)$.

[13] In fact, in this subsection one needs to assume that this condition is fulfilled only modulo $O(h^2)$.

(ii) If

(5.2.101) $\vartheta(\tau)\tau^{-s}$ *is a monotone increasing function with some* $s>0$

then $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ *is dominated by* $Ch^{1-d}\vartheta\big(h/L\big)$ *as well.*

(iii) In the general case estimate

$$\mathsf{R}^{\mathsf{W}}_{\varphi,L}\le Ch^{1-d-\delta}\vartheta\big(\frac{h}{L}\big) \tag{5.2.102}$$

holds for arbitrarily small $\delta>0$.

In the smoothness conditions K *depends on* m, ϑ *and* $\delta>0$.

Proof, Part I. First of all, this theorem is proven under condition $(5.2.100)_m$ for $m=2$ (see Theorems 5.2.2 and 5.2.10). Let us assume that Statements (i), (ii) are proven for given $m=\bar m-1\ge 2$ and let us prove it for $m=\bar m$.

Let us introduce the function $\gamma=\zeta_{m-1}$ by formula (5.2.55):

$$\gamma\coloneqq\epsilon\Big(\sum_{|\alpha|\le m-1}|D^\alpha V|^{\frac{l}{m-|\alpha|}}\Big)^{\frac{1}{l+1}}+\bar\gamma_m,\qquad \bar\gamma_m=h^{\frac{2}{m+2}} \tag{5.2.103}$$

then $|\nabla\gamma|\le\frac12$ (so γ is a scaling function) and

$$|D^\alpha V|\le C\rho^2\gamma^{-|\alpha|}\qquad\forall\alpha:|\alpha|\le K \tag{5.2.104}$$

with

$$\rho=\gamma^{\frac{m}{2}}. \tag{5.2.105}$$

Let us consider the point $(\bar x,\bar\xi')$. Let $\mathcal{U}'$ be its γ-vicinity (with respect to (x,ξ')) with $\gamma=\gamma(\bar x,\bar\xi')\ge h^{2/(m+2)}$.

(a) Let us consider zone $\{|\xi_1|\ge C_0\rho\}$ with ρ defined by (5.2.105) and let

$$\mathcal{U}=\{(x,\xi):(x,\xi')\in\mathcal{U}',|\xi_1-\bar\xi_1|\le\frac12|\bar\xi_1|\}$$

with $|\bar\xi_1|\ge C_O\rho$.

Let us rescale $x_{\mathsf{new}} = (x - \bar{x})\gamma^{-1}$, multiply the operator by ρ^{-2} and introduce $h_{\mathsf{new}} = h\rho^{-1}\gamma^{-1}$ with redefined temporarily $\rho := |\bar{\xi}_1|$. Let us note that the ellipticity condition is fulfilled and

$$\hbar \le 1, \qquad h\gamma^{-2} \le h^{1-\frac{2}{m}} \tag{5.2.106}$$

due to our choice of $\bar{\gamma}$. Therefore contribution of $\mathcal{U}$ to the remainder does not exceed

$$R(\gamma,\rho,h) := C\vartheta\Big(\frac{h\rho}{L\gamma}\Big)\Big(\frac{h}{\rho\gamma}\Big)^{r-d+1}\Big(\frac{\gamma}{\rho}\Big)^{d-1} = Ch^{1-d}\vartheta\Big(\frac{h\rho}{L\gamma}\Big)\Big(\frac{h}{\rho\gamma}\Big)^{r}\gamma^{2d-2} \tag{5.2.107}$$

with arbitrarily large r; here factor $(\gamma/\rho)^{d-1}$ appears since $\mathcal{U}'$ is covered by this number of balls of radius ρ with ξ' and we plugged $L_{\mathsf{new}} = L\rho^{-2}$ and $h_{\mathsf{new}}/L_{\mathsf{new}} = h\rho/L\gamma$ into $\vartheta(.)$.

Observe that $R(\gamma,\rho,h)\rho^{r/2}$ is decaying function of ρ provided r is large enough. Therefore after summation on a $|\xi_1|$-admissible partition of unity in $\{(x,\xi) : (x,\xi') \in \mathcal{U}', |\xi_1| \ge c\rho\}$ we obtain that the contribution of this zone to the remainder estimate does not exceed CR as well with ρ restored to its (5.2.105) definition. Note that

$$\vartheta\Big(\frac{h\rho}{L\gamma}\Big) \le \vartheta\Big(\frac{h}{L}\Big)\Big(\frac{\rho}{\gamma}\Big)^{s} \tag{5.2.108}$$

with $s > 0$ under assumption (5.2.101) and $s = 0$ otherwise. Using (5.2.108) and (5.2.105) we arrive to

$$R \le Ch^{1-d}\vartheta\Big(\frac{h}{L}\Big)\Big(\frac{h}{\gamma^{\frac{1}{2}(m+2)}}\Big)^{r}\gamma^{\frac{1}{2}(m-2)s+2d-2}. \tag{5.2.109}$$

Summation with respect to $(2d-1)$-dimensional γ-admissible partition results in

$$Ch^{1-d}\vartheta\Big(\frac{h}{L}\Big)\int \Big(\frac{h}{\gamma^{\frac{1}{2}(m+2)}}\Big)^{r}\gamma^{\frac{1}{2}(m-2)s-1}\,dz'. \tag{5.2.110}$$

Note that under condition $(5.2.100)_m$ this integral is converging as $r > 0$.

(b) Now let us consider zone

$$\mathcal{U} = \{(x,\xi) : (x,\xi') \in \mathcal{U}', |\xi_1| \le c\rho|\}.$$

Let us rescale and multiply the operator in the same way as above. Let us note that if $\gamma \ge c\bar{\gamma}$ then condition $(5.2.100)_{m-1}$ is fulfilled[14] and the contribution of $\mathcal{U}$ to the remainder does not exceed (5.2.107) with $r = 0$; this we estimate by (5.2.109) with $r = 0$ and summation with respect to partition results in (5.2.110) with $r = 0$, and this integral is bounded under condition $(5.2.100)_m$ as $s > 0$.

(c) proof-5-2-14-c If $\gamma \le c\bar{\gamma}$ then $h_{\mathsf{new}} \asymp 1$ and one does not need to check condition $(5.2.100)_{m-1}$ and therefore the same arguments hold.

(d) So, under assumption $s > 0$ we can make the step of induction and $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ is properly estimated under condition $(5.2.100)_m$. Further, as $(m-2)s > 2$ integral (5.2.109) is bounded even without condition $(5.2.100)_m$ and therefore Statement (ii) of theorem is proven.

On the other hand, if $s = 0$ with each step of induction factor $|\log h|$ appears and we arrive to estimate (5.2.102) but with an extra factor $|\log h|^{m-3}$. Further, on the step without condition $(5.2.100)_m$ with large enough m factor γ^{-1} appears with $\gamma = h^{2/(m+2)}$. Therefore statement (iii) of theorem is proven as well. □

Proof, Part II. Now, our goal is to get rid of logarithmic factor for $s = 0$ under condition $(5.2.100)_m$. We will follow the proof of Theorem 5.2.10 with some modifications; to make comparison more clear we restart numeration of the parts of the proof.

(a) First of all, without any loss of the generality one can assume that

$$|\partial_{z_2}^m V| \ge \epsilon_0 \qquad (5.2.111)_m$$

[14] More precisely, this condition is fulfilled if $\gamma' \ge \epsilon\gamma$ where γ' is introduced by the same formula (5.2.103) with differentiation only on x. However before rescaling one can apply the symplectic transformation $(x_j,\xi_j) \to (\xi_j,-x_j)$ with some $j = 2,\dots,d$ if necessary and fulfill this condition.

(condition $(5.2.100)_m$ yields this condition after ϵ-partition and appropriate choice of coordinate system). Then Malgrange preparation theorem yields that

$$V = \beta(z')\big(z_2^m + W_1(z'')z_2^{m-1} + ... + W_m(z'')\big) \tag{5.2.112}$$

with $|\beta(z'')| \ge \epsilon$, $z'' = (z_3, ..., z_{2d})$. Without any loss of the generality one can assume that $W_1 = 0$; really we can achieve it by $z_2 \mapsto z_2 + \frac{1}{m}W_1$. Then on the induction step $\gamma_{m-1} = \epsilon_1|z_2| + \gamma'_{m-1}(z'')$ where

$$\gamma'_{m-1} = \epsilon\Big(\sum_{2\le k\le m}\ \sum_{|\alpha|\le(k-1)} |D^\alpha W_k|^{\frac{m}{k-|\alpha|}}\Big)^{\frac{1}{m}} \tag{5.2.113}_m$$

with $|\nabla\gamma'_m| \le \frac{1}{2}$ and one can see easily that due to the induction assumption

(5.2.114) Contribution of zone $\{|z_2| \le C_0\gamma'_m\}$ to $\mathcal{R}_{2\vartheta}$ does not exceed $Ch^{1-d}\vartheta(h/L)$.

Thus we need to consider only zone $\{|z_2| \ge C_0\gamma'_m\}$ which was the source of the logarithmic factor.

Now let us introduce

$$\zeta_{m-1,j} = \epsilon\Big(\sum_{2\le k\le m}\ \sum_{|\alpha|\le j(k-1)/m} |D^\alpha W_k|^{\frac{mj}{kj-|\alpha|m}}\Big)^{\frac{1}{j}} \tag{5.2.115}_{m,l}$$

with $j \ge m$; it coincides with $(5.2.113)_m$ as $j = m$. Here $j \in \mathbb{R}$, $j > 0$. Note that

(5.2.116) Conditions

$$\zeta_{m-1,j} \ge \epsilon \tag{5.2.117}_{m,j}$$

are essentially different for given m only for a monotone sequence $j_i \in \mathbb{Q}$ (which denotes the set of rational numbers), $j_i \to \infty$, $j_{i+1} - j_i \le 1$ $\forall i$.

Introducing ϱ_j in the same way as in the proof of Theorem 5.2.10, Part (a) and repeating relevant arguments we arrive to the proper estimate of zone $\{|z_2| \le C\rho_{m,l}\}$ with redefined

$$\gamma \coloneqq \big(|z_2|^m + |z_1|^2\big)^{1/m} \ge ch^{2/(m+2)} \tag{5.2.118}$$

and in particular of zone defined by

$$\sum_{|\alpha|+k=m} |D^\alpha W_k| \ge \epsilon\gamma^\delta$$

with some $\delta > 0$. Easy details are left to the reader.

(b) So, we need to consider zone where opposite inequality

$$\sum_{|\alpha|+k=m} |D^\alpha W_k| \le \epsilon\gamma^\delta \tag{5.2.119}$$

holds; this inequality is a new incarnation of (5.2.73) and repeating arguments of the proof of Theorem 5.2.10, Part (b) we reduce it to zone defined by

$$|D^\alpha W_k| \le C\gamma^{m+\delta-k-|\alpha|} \qquad \forall \alpha, k : |\alpha| + k \le m; \tag{5.2.120}$$

this is a new incarnation of (5.2.78); we use induction with respect to j to prove that if (5.2.120) is fulfilled for all α, k with $|\alpha| + k > m - j$ and some $\delta > 0$ and if (5.2.120) fails for some α, k with $|\alpha| + k = m - j$ and any $\delta > 0$ then (5.2.76) holds with $\mathcal{V}_1 = \mathcal{V} \cap \{z'' : |V(z'')| \le c\gamma^{(m+2)/2}\}$. So, $\delta = \delta_j$ is decreasing but we take the smallest one in the end.

(c) So, we need to consider zone where (5.2.120) and (5.2.80) hold. Recall that

$$a = \pm\big(z_1^2 + \beta(z')z_2^m + W(z')\big) \tag{5.2.121}$$

where

$$|D^\alpha W| \le c\gamma^{m+\delta-|\alpha|}. \tag{5.2.122}$$

As $\beta > 0$ and m is even proof is no different from one under condition $(5.2.20)_2^+$. As m is odd this is true for subzone where $\beta z_2^m > 0$.

So we need to consider the remaining cases: <u>either</u> even m and $\beta < 0$ <u>or</u> odd m, $\beta < 0$ and $z_2 > 0$ [15)]. Consider

$$w_1 = z_1 - (-\beta)^{1/2} z_2^{m/2}, \ w_1 = z_2 + (-\beta)^{1/2} z_2^{m/2} \tag{5.2.123}$$

[15)] One can reduce the case of odd m, $\beta > 0$ and $z_2 < 0$ to this one replacing z_2, β by $-z_2$, $-\beta$.

which will play role of z_1 and z_2. Then

$$|w_1| + |w_2| \asymp \gamma^{m/2}, \tag{5.2.124}$$

$$\{w_1, w_2\} = 2\omega(-\beta)^{1/2} z_2^{(m-2)/2} + O(z_2^{m/2}), \qquad \omega = \{z_1, z_2\} \tag{5.2.125}$$

and we need to rescale time $t = t_{\mathsf{new}} = t_{\mathsf{old}}\gamma^{(2-m)/2}$.

Then analysis in zone $\{|\omega| \le \gamma^{\delta_2}\}$ is exactly as it was in the proof of Theorem 5.2.10(c); as before $\omega = \{z_1, z_2\}$.

(d) Finally analysis in zone where $|\omega| \ge \gamma^{\delta_2}$ repeats arguments of the proof of Theorem 5.2.10 (d)–(f) but with a twist: we always consider trajectory launched in the direction of decreasing $\gamma(z(t))$.

Indeed, because propagation slows down near $w = 0$ faster than before we can cap time by $T = \epsilon(\gamma/\bar\gamma)^{\delta_2}$ with $\delta_2 > 0$ rather than by $T = \epsilon|\log\gamma/\bar\gamma|$ as we did then; now $\int_{\Sigma_\tau} T^{-1}dxd\xi$ is bounded (instead of possible loglog divergence) and the same arguments of that proof Part (e) work in the whole zone $\{\bar\gamma \le \gamma \le \epsilon\}$. □

In the case $V = \mathsf{const}$ (treated as a parameter) one can divide the operator by $\rho^2 = \max(|V|, h^2)$ and introduce $h_{\mathsf{new}} = h\rho^{-1}$ (no rescaling with respect to x is necessary). Then the remainder estimate $O\big(h^{1-d}\vartheta(h/L)\big)$ holds. Therefore we arrive to

Conjecture 5.2.15. *For operators with analytic symbols the remainder estimate $O\big(h^{1-d}\vartheta(h/L)\big)$ holds under condition $(5.2.20)_1$ even without condition (5.2.101).*

5.2.4 From Condition "rank Hess $a \ge 1$ at Critical Points" to a Weak Non-Degeneracy cCondition

Now even condition "$\mathsf{rank}\,\mathsf{Hess}\, a \ge 1$" seems to be too restrictive for us and we are going to get rid of it.

Theorem 5.2.16. *Let A be a scalar operator. Then*

(i) Under assumption

$$\sum_{|\alpha|\le n} |D^\alpha a| \ge \epsilon_0 \tag{5.2.126}_n$$

$\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ *is dominated by $C\vartheta(h/L)h^{1-d-\delta}$ with arbitrarily small $\delta > 0$.*

(ii) Under condition (5.2.101) *with* $s > 0$ $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ *is dominated by* $C\vartheta(h/L)h^{1-d}$.

Proof. To prove both Statements (i) and (ii) we apply induction on n. Note that for $n = 2$ theorem is already proven.

(a) So suppose that under condition $(5.2.126)_{n-1}$ both Statements (i) and (ii) are already proven and let us consider some point $\bar{z}$ at which condition $(5.2.126)_n$ holds but $(5.2.126)_{n-1}$ fails.

Then in the appropriate symplectic coordinates $|\partial^n_{\xi_1} a(\bar{z})| \ge \epsilon_0$ and then according to Malgrange preparatory theorem in the vicinity of $\bar{z}$

$$a(x,\xi) = b(x,\xi)\Big(\sum_{0\le j\le n} \xi_1^{n-j} V_j(x,\xi')\Big) \qquad \text{with} \quad |b(x,\xi)| \ge \epsilon_0 \tag{5.2.127}$$

and with

$$V_0 = 1, \qquad V_1 = 0. \tag{5.2.128}$$

Now instead of a single function V we have several functions V_j and we want to prove remainder estimate (5.2.126) under an extra condition

$$\sum_{2\le j\le n,\ |\alpha|\le lj/n} |D^\alpha V_j| \ge \epsilon_0 \tag{5.2.129}_{n,l}$$

with $l \ge n$; later we will drop it for large ν.

First let us treat the case $l = n$. Let us introduce the functions

$$\gamma := \gamma_n = \epsilon\Big(\sum_{2\le j\le n,\ |\alpha|\le j-1} |D^\alpha V_j|^{\frac{n}{j-|\alpha|}}\Big)^{\frac{1}{n}} + \bar{\gamma} \qquad \text{with} \quad \bar{\gamma} = h^{\frac{1}{2}} \tag{5.2.130}_n$$

and $\rho = \gamma$. Then $|\nabla\gamma| \le \frac{1}{2}$ for small enough $\epsilon > 0$ (so γ is a scaling function) and

$$|D^\beta V_j| \le c\rho^j \gamma^{-|\beta|} \qquad \forall j, \beta. \tag{5.2.131}$$

Let us rescale as usual $x_{\mathsf{new}} = (x - \bar{x})\gamma^{-1}$, multiply the operator by ρ^{-n} and introduce $h_{\mathsf{new}} = h\rho^{-1}\gamma^{-1}$. Then for $\gamma \ge c_0\bar{\gamma}$ after this procedure the smoothness conditions and condition $(5.2.126)_{n-1}$ are fulfilled and hence the contribution of the zone $\{z :\ z' \in B\big(\bar{z}', \gamma_n(\bar{z}')\big), |\xi_1| \le c\rho\}$ to the remainder does not exceed

$$C\Big(\frac{h}{\rho\gamma}\Big)^{-d+1-\delta} \vartheta\Big(\frac{h\rho^{n-1}}{L\gamma}\Big) \tag{5.2.132}$$

where $\delta = 0$ under condition (5.2.101) with $s > 0$ and $\delta = 0$ otherwise; later ρ will be different from γ. We used the fact that $L_{\mathsf{new}} = L\rho^{-n}$ due to multiplication of operator and therefore

$$\frac{h_{\mathsf{new}}}{L_{\mathsf{new}}} = \frac{h\rho^{n-1}}{L\gamma} \tag{5.2.133}$$

Therefore the total contribution of the zone $\{z : |\xi_1| \le c\rho, \rho\gamma \ge h\}$ to the remainder does not exceed

$$Ch^{1-d-\delta} \int \gamma^{-1+\delta} \vartheta\big(\frac{h\rho^{n-1}}{L\gamma}\big)\, dz'. \tag{5.2.134}$$

Meanwhile for $\rho\gamma \asymp h, |\xi_1| \le c\rho$ (i. e. for $\rho \asymp \bar\rho$ and $\gamma \asymp \bar\gamma$) we obtain $h_{\mathsf{new}} = 1$ and the contribution of the corresponding element of the partition to the remainder estimate does not exceed $C\vartheta(h\rho^{n-1}/L\gamma)$ and the total contribution of zone $\{\rho\gamma \asymp h, |z_1| \le c\rho\}$ to the remainder does not exceed (5.2.134) with integral restricted to his zone.

Finally, in the zone $\{|\xi_1| \ge c\rho\}$ we apply an $\epsilon|\xi_1|$-admissible partition and standard elliptic arguments and then the contribution of each element does not exceed $C(h/\xi_1^2)^r \vartheta(h\xi_1^{n-2}/L)$ with arbitrarily large r and therefore the total contribution does not exceed (5.2.134).

(b) Let us notice that under condition $(5.2.129)_{n,n}$ in the appropriate coordinate system $\gamma \ge \epsilon'|z_2|$ and then (5.2.134) with $\rho = \gamma$ does not exceed $Ch^{1-d-\delta}\vartheta(h/L)$. This is trivial as $\delta > 0$; as $\delta = 0$ and (5.2.101) is fulfilled we use estimate

$$\vartheta\big(\frac{h\rho^{n-1}}{L\gamma}\big) \le \vartheta\big(\frac{h}{L}\big) \cdot \big(\frac{\rho^{n-1}}{\gamma}\big)^s \tag{5.2.135}$$

with $s > 0$.

Therefore we proved that

(5.2.136) Assuming that under condition $(5.2.126)_{n-1}$ a proper remainder estimate is proven, we prove it also under conditions conditions $(5.2.126)_n$ and $(5.2.129)_{n,n}$.

It is not a complete induction; in the next step we apply induction with respect to l as well.

Moreover, let us notice that

(5.2.137) Under condition (5.2.101) we obtain a proper remainder estimate even without condition $(5.2.129)_{n,n}$ for $(n-2)s \ge 1$.

So, under condition (5.2.101) the estimate will be proven for any n if it was proven for $n \le 2 + s^{-1}$.

(c) Let us assume that Statements (i) and (ii) are proven under condition $(5.2.126)_{n-1}$ and also under conditions $(5.2.126)_n$ and $(5.2.129)_{n,l}$. Now our goal is to prove them under conditions $(5.2.126)_n$ and $(5.2.129)_{n,l'}$ with some $l' > 0$ and to get rid of the latter condition for l' large enough.

Obviously statement similar to (5.2.116) holds.

Let us introduce the scaling function

$$\gamma \coloneqq \gamma_{n,l}(z') = \epsilon\Big(\sum_{2\le j\le n,\ |\alpha|\le jl/n} |D^\alpha V_j|^{\frac{nl}{jl-|\alpha|n}}\Big)^{\frac{1}{nl}} + \bar\gamma_{nl}, \quad \bar\gamma_{nl} = h^{\frac{n}{n+l}} \tag{5.2.138}$$

with small enough $\epsilon > 0$. Further, let $\rho = \gamma^{l/n}$. One can easily see that $|\nabla\gamma| \le \frac12$ and that (5.2.131) holds.

Moreover, for some j and $\alpha : |\alpha| < jl/n$ the opposite inequality holds (with $\epsilon_1 > 0$ instead of c) provided $\gamma \ge c\bar\gamma$.

Therefore, after the routine rescaling procedure with $x_{\mathsf{new}} = (x - \bar x)\gamma^{-1}$, $h_{\mathsf{new}} = h\rho^{-1}\gamma^{-1}$ and with multiplication operator ρ^{-n} we obtain the routine smoothness conditions and either condition $(5.2.129)_{n,l}$ or $h_{\mathsf{new}} \asymp 1$; we consider now the zone $\{|\xi_1| \le c\rho\}$ and if necessary apply a linear symplectic transformation for (x', ξ'). In both cases the contributions of the corresponding balls was described above and the contributions of the corresponding zones are given by (5.2.134).

In the zone $\{|\xi_1| \ge c\rho\}$ elliptic arguments are applicable and taking into account that $\gamma^2 \ge h^{1-\sigma}$ for $l > n$ we easily obtain that the contribution of this zone does not exceed the (5.2.134) as well. So, the total remainder estimate is given by (5.2.134). Recall that this deduction holds under the assumption that for given $l \ge 1$ condition $(5.2.129)_{n,l}$ yields the proper remainder estimate.

(d) Let us assume now that condition $(5.2.129)_{n,l'}$ is fulfilled. Then there exist α and j with $|\alpha| \le l'j/n$ such that

$$|D^\alpha V_j| \ge \epsilon.$$

Then in the appropriate coordinates

$$|D^\beta V_j| \ge \epsilon |z_2|$$

for some $\beta : |\beta| = |\alpha| - 1$ and picking $l = (|\alpha| - 1)j/n$ we obtain that $\gamma \ge \epsilon |z_2|$. Then integral in (5.2.134) is bounded.

Therefore remainder estimate (5.2.126) under condition $(5.2.129)_{n,l'}$ holds provided it holds under condition $(5.2.129)_{n,l}$. We can restrict ourselves to numbers $l = m/(n-1)!$ with integers $m \ge n$ and apply induction on m.

Moreover, under condition (5.2.101) with $s > 0$ and $l > l(n,s)$ none of the final estimates linked with z_2 and condition $(5.2.129)_{n,l}$ are necessary. These estimates can also be avoided in the case $s = 0$ as well (for $m \ge m_{n,\delta}$) by doubling δ. Therefore the induction step from $n-1$ to n is complete.

So, Statements (i) and (ii) are proven under condition $(5.2.126)_n$ with arbitrarily large n.

(e) Finally we need to get rid of condition $(5.2.126)_n$ in Statement (ii). Let us introduce the scaling functions

$$\gamma_n = \epsilon \Big(\sum_{\alpha : |\alpha| \le n-1} |D^\alpha a|^{\frac{n}{n-|\alpha|}} \Big)^{\frac{1}{n}} + \bar\gamma_n, \qquad \bar\gamma_n = h^{\frac12}. \tag{5.2.139}$$

Then $|\nabla \gamma| \le \frac12$ and

$$|D^\alpha a| \le c\gamma^{n-|\alpha|} \qquad \forall \alpha : |\alpha| < n$$

and either $\gamma \le ch^{\frac12}$ or the opposite estimate holds for some α with $|\alpha| < n$.

Then applying the rescaling procedure $x_{\mathsf{new}} = (x - \bar x)\gamma^{-1}$, $h_{\mathsf{new}} = h\gamma^{-2}$ and multiplying the operator by γ^{-n} we get into the situation of $(5.2.126)_{n-1}$ or $h \asymp 1$ respectively and applying an estimate $Ch^{1-d}\vartheta(h/L)$ we obtain that the contribution of γ-element to the remainder does not exceed

$$Ch^{1-d}\gamma^{2d-2}\vartheta\Big(\frac{h\gamma^{n-2}}{L}\Big) \le Ch^{1-d}\gamma^{2d-2+(n-2)s}\vartheta\Big(\frac{h}{L}\Big) \le Ch^{1-d}\gamma^{2d}\vartheta\Big(\frac{h}{L}\Big)$$

as $(n-2)s \ge 2$.

In this case summation with respect to partition yields the required remainder estimate. □

Remark 5.2.17. (i) Without condition (5.2.101) with $s > 0$ we obtain the unpleasant factor $h^{-\delta}$ only when we get rid of condition $(5.2.129)_{n,l}$. All other steps of our analysis give only additional factors $|\log h|^M$. However, we cannot go from conditions $(5.2.126)_{n-1}$, $(5.2.129)_{n-1,l}$ to $(5.2.126)_n$, $(5.2.129)_{n,n}$ without dropping condition $(5.2.129)_{n-1,l}$ first unless we assume that the condition

$$(5.2.140)_r \qquad \sum_{2\le j\le n-r,\ |\alpha|\le j} |D^\alpha V_j| \ge \epsilon$$

holds with $r = n-2$.

Indeed, this jump invokes γ_n defined by $(5.2.130)_n$ and we need to check that for some $k \le n-1$ and β

$$|D^\beta V_k| \asymp \gamma_n^{(k-1-|\beta|(n-1)/l)} \asymp \sum_{2\le j\le n, |\alpha|\le j-1} |D^\alpha V_j|^{\frac{k-1-|\beta|(n-1)/l}{j-|\alpha|}};$$

one can rewrite this condition as

$$\sum_{2\le j\le n-1,\ \alpha\le j} |D^\alpha V_j|^{1/(j-1-|\alpha|(n-1)/l)} \asymp \sum_{2\le j\le n,\ |\alpha|\le j-1} |D^\alpha V_j|^{1/(j-|\alpha|)};$$

and this is not guaranteed unless $|D^\alpha V_j| \asymp 1$ for some $\alpha : |\alpha| = 1$ and $j = 2$; let us recall that $V_1 = 0$.

So in order to provide the remainder estimate $O(h^{1-d}|\log h|^M)$ one should assume that condition $(5.2.140)_r$ is fulfilled for $r = n-2$; under this condition one can prove the estimate easily.

(ii) On the other hand, if we assume that $V_2, \dots, V_{n-r-1}$ vanish identically while condition $(5.2.140)_r$ holds, we observe that the problem is reduced (after a few steps of the induction described above) to the problem with $a = b\xi_1^r$ with $r = n-r-1$ and non-vanishing symbol b. Then the same partition arguments yield the remainder estimate $O(h^{1-d})$ because the zone $\{|\xi_1| \ge h\}$ is elliptic. Therefore a proper remainder estimate remains true but we do not know whether it is uniform with respect to the spectral parameter.

(iii) In certain cases (under some additional conditions) propagation of singularities arguments provide the remainder estimate $O(h^{1-d})$ but I never investigated it.

The remark above leads us to

Conjecture 5.2.18. *For operators with analytic symbols $R^{\mathsf{W}}_{\varphi,L}$ is dominated by $O\big(h^{1-d}\vartheta(h/L)\big)$.*

5.2.5 From Microlocal to Local Spectral Asymptotics

Let us go from microlocal to local spectral asymptotics. Then the results of the previous subsections combined with the results of Section 4.2 imply

Theorem 5.2.19. *(i) Let condition* (4.2.45) *be fulfilled. Then the assertions of all the above statements remain true for $Q_1 = Q_2 = I$ provided their conditions are fulfilled for $\Omega = T^*B(0,1)$* [16].

(ii) Moreover if condition $(4.2.48)_{\pm}$ *is fulfilled then in every estimate without mollification with respect to τ_1 one can take $\tau_1 = \mp\infty$ and in every estimate with mollification one can drop the mollification and take $\tau_1 = \mp\infty$.*

5.3 Local and Pointwise Spectral Asymptotics for the Schrödinger and Dirac Operators

In this section we treat the Schrödinger operator

$$A = \sum_{j,k} P_j g^{jk} P_k + V, \qquad P_j = hD_j - V_j \tag{5.3.1}$$

and Dirac operator

$$A = \sum_{j,l} \frac{1}{2}\sigma_l(\omega^{jl}P_j + P_j\omega^{jl}) + \sigma_0 m + V\cdot I \tag{5.3.2}$$

where *the components g^{jk} of the inverse metric tensor, coefficients ω^{jl}, the components of the vector-potential V_j* and *the scalar potential V* are real-valued functions, σ_l are *Pauli matrices* (see Subsection 5.3.2 and Appendix 5.A.2), $m = \mathsf{const} \ge 0$ is a *mass parameter*, and $h \in (0,1)$. Constants in conditions and in estimates depend neither on h nor m.

[16] In fact, it is necessary to check them only for $\Omega = B(0,1)\times B(0,C_0)$ with a large enough C_0.

Remark 5.3.1. As $d \ge 2$ one can consider also the Schrödinger-Pauli operator

$$A = \Big(\sum_{j,l} \frac{1}{2}\sigma_l(\omega^{jl}P_j + P_j\omega^{jl})\Big)^2 + V \tag{5.3.3}$$

which differs from (5.3.1) only by matrix lower order terms, but in the current framework (without strong magnetic field as in Volumes III and IV) it does not make any difference.

We assume that

(5.3.4) A is self-adjoint operator in $\mathscr{L}^2(X, \mathbb{H})$, $\mathbb{H} = \mathbb{C}^{\mathsf{D}}$, $\mathsf{D} = 1$ for the Schrödinger operator.

5.3.1 Schrödinger Operator

Main Assumptions

Let us start with the Schrödinger operator assuming that

$$B(0,1) \subset X, \tag{5.3.5}$$

$$|D^\alpha g^{jk}| \le c, \quad |D^\alpha V_j| \le c, \quad |D^\alpha V| \le c \quad \forall \alpha : |\alpha| \le K, \tag{5.3.6}_{1-3}$$

and

$$\epsilon_0 \le \sum_{j,k} g^{jk}(x)\xi_j\xi_k|\xi|^{-2} \le c \quad \forall x \in B(0,1) \quad \forall \xi \in \mathbb{R}^d \setminus 0. \tag{5.3.7}$$

Remark 5.3.2. A (unitary) *gauge transformation* $u \to e^{ih^{-1}\varphi(x)}u$ with a real-valued function φ can be applied which for the Schrödinger and Dirac operators is equivalent to the transformation $V_j \mapsto V_j + \partial_j\varphi$. Hence one can weaken condition $(5.3.6)_2$, replacing it with

$$|D^\alpha F_{jk}| \le c \quad \forall \alpha : |\alpha| \le K \tag{5.3.6}'_2$$

where

$$F_{jk} = \partial_k V_j - \partial_j V_k \tag{5.3.8}$$

are *components of the tensor magnetic intensity.*

Here the principal symbol of A equals

$$a(x,\xi) = \sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k) + V \tag{5.3.9}$$

and the subprincipal symbol vanishes and hence the coefficients in the spectral asymptotics are

$$\kappa_0(x,\tau) = (2\pi)^{-d}\varpi_d(\tau - V)_+^{d/2}\sqrt{g} \tag{5.3.10}$$

and

$$\kappa_1(x,\tau) = 0 \tag{5.3.11}$$

where $\tau_1 = -\infty$, $\tau_2 = \tau$, ϖ_d is the volume of the unit ball in $\mathbb{R}^d$ and $g = \det(g^{jk})^{-1}$. We prefer to use notation $\kappa_n(x,\tau)$ rather than $\kappa_{xn}(\tau)$ [17].

Asymptotics with Spatial Mollification

Then the results of the previous Section 5.2 immediately yield the following assertions:

Theorem 5.3.3. *Let conditions* (5.3.1), (5.3.4), (5.3.5), $(5.3.6)_{1-3}$ *and* (5.3.7) *be fulfilled and* $d \geq 2$. *Let* φ *satisfy* (4.2.73)–(4.2.75). *Then as* $Q_1 = I$, $Q_2 = \psi(x)$

(i) The following estimate holds:

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L}| \leq \bigl(Ch^{1-d} + C'h^{1-d+\delta''}\bigr)\vartheta\bigl(\frac{h}{L}\bigr) \tag{5.3.12}$$

where here and below $C = C(d,c)$, $K = K(d)$, $\delta'' = \delta''(d) > 0$ *is small enough and* $\sup_x |\psi(x)| \leq 1$, $C' = C\|\psi\|_{\mathscr{C}^K}$.

(ii) Let $\Lambda_1, \dots, \Lambda_n$ *be closed subsets of* $\Sigma_\tau = \{(x,\xi) \in T^*B(0,1), a(x,\xi) = \tau\}$ *and let* $\Lambda_j \subset \{\gamma^2 = |\tau - V| + |\nabla_x V|^2 \geq h^{1-\delta}\}$ *with* $\delta > 0$.

Further, let us assume that through each point of Λ_j *there passes a Hamiltonian trajectory of* $a(x,\xi)$ *with* $t \in \mathcal{J}_j$, $\mathcal{J}_j = [0, T_j]$ *or* $\mathcal{J}_j = [-T_j, 0]$, $T_j \in [1, h^{-\delta}]$ *along which*

$$|D^\alpha g^{jk}| \leq ch^{-\delta'}, \quad |D^\alpha V_j| \leq ch^{-\delta'}, \quad |D^\alpha V| \leq ch^{-\delta'} \quad \forall \alpha : |\alpha| \leq K' \tag{5.3.13}$$

[17] For Schrödinger-Pauli operator (5.3.3) κ_0 acquires factor D and $\kappa_1 = 0$ because $\mathsf{tr}(a^s) = 0$.

and

$$\mathsf{dist}\big(x(t), \partial X\big) \ge \epsilon h^{\delta'}, \tag{5.3.14}$$

$$\mathsf{dist}\big((x(t), \xi(t)), (x, \xi)\big) \ge \epsilon |t| h^{\frac{1}{2}-\delta} \tag{5.3.15}$$

and condition (2.4.29) *holds with* $\omega = h^{-\delta'}$ *with small enough exponent* $\delta' = \delta'(d, \delta) > 0$.

Furthermore, let (5.2.101) *be fulfilled with* $s \ge 0$. *Then*

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L}| \le C\Big(\sum_{0\le j\le n} \frac{h^{1-d}}{T_j^{1+s}} \int_{\Lambda_j} dx d\xi : da + C'' h^{1-d+\delta''}\Big)\vartheta\big(\frac{h}{L}\big) \tag{5.3.16}$$

where $T_0 = 1$, $\Lambda_0 = \Sigma_\tau \setminus (\Lambda_1 \cup \dots \cup \Lambda_n)$, $K' = K'(d, s, \delta)$, $C'' = \|\psi\|_{\mathscr{C}^{K'}}$.

Proof. Indeed, condition $(5.2.20)^+_d$ is fulfilled and therefore Statement (i) as $d \ge 2$ and (ii) as $d \ge 3$ follow automatically.

Further, as $d = 2$ for Statement (ii) we need to apply Proposition 5.2.6 but since $a^s = 0$ we have $\mu'_\tau = \mu_\tau$. Note that in this case condition $\mathsf{mes}(\{V = \bar\tau, \{z_1, z_2\} \ne 0\}) = 0$ of Theorem 5.2.9(ii) translates into

$$\mathsf{mes}(\{V = \bar\tau, F_{12} \ne 0\}) = 0 \tag{5.3.17}$$

with F_{jk} defined by (5.3.8). □

Alternative proof. Alternatively, one can repeat more rigorously arguments of Subsection 5.1.1. Let us start from estimate (5.3.12), (5.3.16) which hold under microhyperbolicity condition

$$|V| + |\nabla V| \ge \epsilon_0 \qquad \text{in } B(0,1), \tag{5.3.18}$$

estimate

$$|e(x, x, 0)| \le C h^r \qquad \text{in } B(0, \frac{1}{2}) \tag{5.3.19}$$

which holds with arbitrarily large exponent r under assumption

$$V(x) \ge \epsilon_0 \qquad \text{in } B(0,1) \tag{5.3.20}$$

and generic estimate

$$|e(x, x, 0)| \le C h^{-d} \qquad \text{in } B(0, \frac{1}{2}) \tag{5.3.21}$$

which holds with no extra condition.

Rescaling them $x \mapsto x\gamma^{-1}$, $hD \to \hbar D$ and $h \to \hbar = h\rho^{-1}\gamma^{-1}$ we get estimate

$$|\mathsf{R}^{\mathsf{W}}| \le Ch^{1-d}\rho^{d-1}\gamma^{-1} \tag{5.3.22}$$

under condition

$$|V| + \gamma|\nabla V| \ge \epsilon_0\rho^2 \qquad \text{in } B(0,\gamma), \tag{5.3.18)*}$$

estimate

$$|e(x,x,0)| \le Ch^r\rho^{-s}\gamma^{-d-r} \qquad \text{in } B(0,\frac{1}{2}\gamma) \tag{5.3.19)*}$$

which holds with arbitrarily large exponent r under assumption

$$V(x) \ge \epsilon_0\rho^2 \qquad \text{in } B(0,\gamma) \tag{5.3.20)*}$$

and generic estimate

$$|e(x,x,0)| \le Ch^{-d}\rho^d \qquad \text{in } B(0,\frac{1}{2}) \tag{5.3.21)*}$$

which holds with no extra condition; here we assume that

$$\rho\gamma \ge h \tag{5.3.23}$$

and replace $(5.3.6)_{1-3}$ by

$$|D^\alpha g^{jk}| \le c\gamma^{-|\alpha|}, \quad |D^\alpha V_j| \le c\rho\gamma^{-|\alpha|}, \quad |D^\alpha V| \le c\rho^2\gamma^{-|\alpha|} \quad \forall x \in B(0,\gamma),\ \forall \alpha : |\alpha| \le K \tag{5.3.6)$^*_{1-3}$}$$

and (5.3.5) by

$$B(0,\gamma) \subset X. \tag{5.3.5)*}$$

Further, assuming (5.2.101) with $s \ge 0$ and also $\rho \le \gamma$ we get estimate

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L}| \le Ch^{1-d}\rho^{d-1+s}\gamma^{-s}\vartheta\big(\frac{h}{L}\big). \tag{5.3.24}$$

Let us introduce scaling functions

$$\gamma(x) = \epsilon\big(|V| + |\nabla V|^2\big)^{\frac{1}{2}} + \frac{1}{2}\bar\gamma, \qquad \rho = \gamma \qquad \text{with } \bar\gamma = h^{\frac{1}{2}} \tag{5.3.25}$$

with small enough constant ϵ and observe that conditions $(5.3.6)^*_{1-3}$ are fulfilled[18], as $\gamma \ge h^{\frac12}$ condition $(5.3.18)^*$ is fulfilled and as $\gamma \asymp h^{\frac12}$ all estimates are equally good (actually generic estimate even does not need spatial mollification).

After summation over γ-admissible partition we arrive to Statement (i).

Proof of Statement (ii) follows the same scheme but with the use of long time propagation results. □

Remark 5.3.4. Statement (i) as $d \ge 2$ and Statement (ii) as $d \ge 3$ remain true for Schrödinger-Pauli operator as well. As $d = 2$ (5.3.16) should be replaced by while for $d = 2$

$$|\mathcal{R}^{\mathsf{W}}_{\varphi,L}| \le C_0 h^{-1}\Big(\sum_{0\le j\le n} \frac{1}{T_j^{1+s}} \int_{\Lambda_j^{\pm}} dx d\xi : da + \int_{\{\varrho\le h^{\delta}\}} |F_{12}|\, dx + C'' h^{\delta''}\Big)\vartheta\big(\frac{h}{L}\big) \tag{5.3.26}$$

where we assume that

$$\Lambda_j^{\pm} \subset \big\{\varrho^2 \coloneqq |V| + |\nabla V|^2 \ge h^{1-\delta}\big\}.$$

For the proof we refer to the proof of the Statement (ii) of Theorem 5.3.25 below where it is done for Dirac operator.

Theorem 5.3.5. *Let conditions* (5.3.1), (5.3.4)–(5.3.7) *be fulfilled and* $d = 1$. *Then*

(i) The following estimate holds

$$|\mathsf{R}^{\mathsf{W}}| \le C h^{-\delta}. \tag{5.3.27}$$

(ii) Moreover, if either

$$\sum_{|\alpha|\le n} |D^{\alpha} V| \ge \epsilon_0 \tag{5.3.28}$$

or (5.2.101) *holds with* $s > 0$ *then Statements (i) and (ii) of Theorem 5.3.3 remain true. However, for* $s \in \mathbb{N}$ *one should regularize the coefficient* κ_{1+s} *and take it depending on* h *(and it is* $O(|\log h|^M)$ *in virtue of the analysis of the previous Section 5.2).*

[18] Actually condition to V_j may fail as $\alpha = 0$ but we need to check it only as $|\alpha| \ge 1$ due to Remark 5.3.2.

Proof. Proof follows arguments to the previous section but with essential simplification. We leave details to the reader. □

Remark 5.3.6. Conditions $(5.2.20)^{\pm}_2$ in this case mean exactly that V has non-degenerate minimum (maximum) in the point in question.

Asymptotics without Spatial Mollification

Let us consider spectral asymptotics without spatial mollification. First of all, let us check ξ-microhyperbolicity condition; it is

$$|V| \ge \epsilon_0 \qquad \forall x \in B(0,1) \tag{5.3.29}$$

and we immediately arrive to

Theorem 5.3.7. *Let conditions* (5.3.1), (5.3.4), (5.3.5), (5.3.6), (5.3.7) *and* (5.3.29) *be fulfilled. Then*

$$|\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}| \le C_0 h^{1-d}\vartheta\Big(\frac{h}{L}\Big) \qquad \forall x \in B(0,\frac{1}{2}). \tag{5.3.30}$$

Now let us use the same rescaling scheme as in the alternative proof of Theorem 5.3.3. Then we should replace $(5.3.18)^*$ by

$$|V| \ge \epsilon_0\rho^2 \qquad \forall x \in B(0,\gamma) \tag{5.3.29}^*$$

and therefore we need to pick up the scaling functions

$$\gamma = \epsilon|V| + \bar\gamma, \qquad \rho = \gamma^{\frac12} \qquad \text{with } \bar\gamma = \frac{1}{2}h^{\frac23} \text{ and } \bar\rho = h^{\frac13}; \tag{5.3.31}$$

we select the $\bar\gamma$ equal $h^{\frac23}$ to keep $\rho\gamma \ge h$. Obviously $|\nabla_x\gamma| \le \frac12$.

We immediately arrive to the estimate

$$|\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}| \le Ch^{1-d}\rho^{d-1}\gamma^{-1}\vartheta\Big(\frac{h\rho}{L\gamma}\Big) \asymeq \begin{cases} Ch^{1-d}|V|^{(d-3)/2}\vartheta\Big(\frac{h}{L}|V|^{-\frac12}\Big) & \text{as } |V| \ge h^{\frac23},\\ Ch^{-\frac23 d}\vartheta\Big(\frac{h^{2/3}}{L}\Big) & \text{as } |V| \le h^{\frac23}. \end{cases} \tag{5.3.32}$$

So, we proved

Theorem 5.3.8. *Let conditions* (5.3.1), (5.3.4), (5.3.5), (5.3.6) *and* (5.3.7) *be fulfilled. Then estimate* (5.3.32) *holds.*

Corollary 5.3.9. *Let conditions of Theorem 5.3.8 be fulfilled. Let us assume that*

(5.3.33) $\vartheta(\tau)\tau^{-s}$ *is a monotone decreasing function*[19] *with some* $s \ge 0$.

Then as $d-3 \ge s$ *estimate* (5.3.30) *holds and as* $d-3 < s$ *estimate*

$$|\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}| \le C_0 h^{-\frac{2}{3}(d+s)} \vartheta\Big(\frac{h}{L}\Big) \qquad \forall x \in B(0,\frac{1}{2}) \tag{5.3.34}$$

holds.

The reader can reformulate Theorem 5.2.14 for the Schrödinger operator and improved asymptotics with the "no loop" condition. Finally the results of Section 5.2 yield

Theorem 5.3.10. *Let conditions* (5.3.1), (5.3.4), (5.3.5), (5.3.6) *and* (5.3.7) *be fulfilled. Then for* $\tau \le V_* = \inf_{B(0,1)} V$ *the following estimate holds*

$$|e(x,y,\tau)| \le C' h^{-d}\big(1+\frac{|V_*-\tau|}{h}\big)^{-l} \quad \forall x,y \in B(0,1-\epsilon) \tag{5.3.35}$$

where $C' = C'(d,c,l,\epsilon)$ *and* $l,\epsilon > 0$ *are arbitrary.*

Here we use that $|\nabla V| \le C|V-V_*|^{\frac{1}{2}}$.

Asymptotics without Spatial Mollification and Short Loops

In this subsubsection we consider very special case $\vartheta = 1$ and $d = 1,2$ when estimate $|\mathsf{R}^{\mathsf{W}}_x| \le Ch^{1-d}$ fails replaced by $|\mathsf{R}^{\mathsf{W}}_x| \le Ch^{-\frac{2}{3}}$ and $\mathcal{R}_x \le Ch^{-\frac{4}{3}}$ as $d = 1,2$. More precisely, as $|V| \ge h^{\frac{2}{3}}$ estimates $|\mathsf{R}^{\mathsf{W}}_x|| \le Ch^{1-d}|V|^{(d-3)/2}$ holds.

Our purpose is to improve these estimates, possibly adding a *correction term* associated with the short loop. As $|\nabla_x V|$ is our foe rather than our friend here, we assume that condition (5.3.18) holds. Later we will get rid of it by scaling.

Our goal is to prove

[19] Before we assumed that it is increasing function.

Theorem 5.3.11. *Let conditions* (5.3.1), (5.3.4), (5.3.5), (5.3.6), (5.3.7) *and* (5.3.18) *be fulfilled. Then*

$$|e(x,x,0) - \kappa_0(x)h^{-d} - h^{-\frac{2}{3}d}|\nabla V(x)|_g^{\frac{1}{3}d}\mathcal{Q}\big(W(x)h^{-\frac{2}{3}}\big)g| \le Ch^{1-d}\gamma(x)^{\frac{1}{2}(d-2)} \tag{5.3.36}$$

where in the correction term $W(x) \asymp V(x)$ *and* $\mathcal{Q}$ *will be defined by* (5.3.62), *and* (5.A.11) *respectively and*

$$\mathcal{Q}(\lambda) = O(\lambda^{-\frac{1}{4}(d+3)}) \quad \text{as} \quad \lambda \to \infty \tag{5.3.37}$$

(see (5.A.12) *for its asymptotics as* $\lambda \to +\infty$*) and* $\gamma(x) \asymp |W(x)| + h^{\frac{2}{3}}$,

$$|\nabla V|_g = \big(\sum_{j,k} g^{jk}\partial_j V \cdot \partial_k V\big)^{\frac{1}{2}}. \tag{5.3.38}$$

The crucial step in the proof is

Proposition 5.3.12. *Let* $u(x,y,t)$ *be the Schwartz kernel of* $e^{ih^{-1}A}$. *In the framework of Theorem 5.3.11*

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma_x u| \le Ch^{1-d}\gamma(x)^{\frac{1}{2}(d-2)} \qquad \forall \tau : |\tau| \le \epsilon\gamma(x) \tag{5.3.39}$$

where T *is the small constant.*

Note that the rescaling arguments yield (5.3.39) with $T = \epsilon_0\gamma(x)^{\frac{1}{2}}$ and this would yield estimates $O\big(h^{1-d}\gamma^{(d-3)/2}\big)$. Generalizing it to $T = \epsilon_0$ leads to remainder estimates $O\big(h^{1-d}\gamma^{(d-2)/2}\big)$ which are announced in Theorem 5.3.11, but with Tauberian main part. This Tauberian expression would have two contributors: one equal $h^{-d}\kappa_0(x)$ which is the main term from $t = 0$ and another equal to the correction term which from the loop and also collects all other terms from $t = 0$.

Proof of Proposition 5.3.12. Consider first the left-hand expression of (5.3.39) with $\bar{\chi}_T(t)$ replaced with $\chi_T(t)$ supported in $\frac{1}{2}T \le |t| \le T$ with $T = T_0$ which is a small constant and with $\gamma(x) \le \epsilon_1 T$; then it would be less than Ch^s.

Rescaling $x \mapsto x_{\mathsf{new}} = xT^{-2}$, $t \mapsto t_{\mathsf{new}} = tT^{-1}$, $h \mapsto h_{\mathsf{new}} = hT^{-3}$ and multiplying operator by T^{-2} we reduce the general case of $T \ge \gamma(x)^{\frac{1}{2}}$ to the

previous one; so now the left-hand expression of (5.3.39) with $\chi_T(t)$ instead of $\bar{\chi}_T(t)$ does not exceed

$$CT^{-2d}\Big(\frac{h}{T^3}\Big)^s$$

where $T^{1-2d} = T \times T^{-2d}$ and the first factor T appears from Fourier transform while T^{-2d} appears because we have a density.

Summation with respect to $T \in [C_0\gamma^{\frac12}, T_0]$ results in the same expression as $T = \gamma^{\frac12}$ i. e.

$$C\gamma^{-\frac12-d}\Big(\frac{h}{\gamma^{\frac32}}\Big)^s$$

which does not exceed the right-hand expression of (5.3.39).

Therefore we need to prove (5.3.39) with $T = C_0\gamma^{\frac12}$. Rescaling $x \mapsto x_{\text{new}} = x\gamma^{-1}$, $t \mapsto t_{\text{new}} = t\gamma^{-\frac12}$, $h \mapsto h_{\text{new}} = h\gamma^{-\frac32}$ and multiplying operator by γ^{-1} we reduce (5.3.39) to the case $\gamma \asymp 1$.

However, if originally $\gamma(x) \ge C_0h^{\frac23}$ then condition (5.3.29) is fulfilled after rescaling this estimate follows from (4.2.82). On the other hand, if originally $\gamma \asymp h^{\frac23}$ then after rescaling $h_{\text{new}} \asymp 1$ and this estimate holds as well. □

Therefore due to Tauberian theorem we arrive to

Corollary 5.3.13. *In the framework of Theorem 5.3.11*

$$|\mathsf{R}^{\mathsf{T}}_{x,\varphi,L}| \le Ch^{1-d}\gamma(x)^{\frac12(d-2)}\vartheta\Big(\frac{h}{L}\Big) \tag{5.3.40}$$

as $\mathsf{N}^{\mathsf{T}}_{x,\varphi,L}$ *is defined with* $T = T_0$ *which is a small constant.*

Now our goal is to calculate $\mathsf{N}^{\mathsf{T}}_x$ with the indicated error. Due to the same arguments as in the proof of Proposition 5.3.12

(5.3.41) Estimate (5.3.40) remains true as $\mathsf{N}^{\mathsf{T}}_{x,\varphi,L}$ is defined with $T = \max\big(C\gamma^{\frac12}, h^{\frac13-\delta}\big)$.

Now let us calculate. We will do first the general calculations in the case of $\gamma(x) \asymp 1$ and then we rescale. To do this we need to prove

Theorem 5.3.14. *Let* $\bar{x}$, $\bar{y}$ *be fixed points and let* $t_1 < t_2$ *be of the same sign and* $t_1 \asymp t_2 \asymp (t_2 - t_1) \asymp 1$. *Assume that*

(5.3.42) *There exist only one Hamiltonian trajectory* $(x(t),\xi(t))$ *such that* $x(0)=\bar y$, $x(t)=\bar x$ *and* $t\in[t_1,t_2]$; *let it happen as* $t=\bar t$, $\xi(0)=\bar\eta$ *and* $(\bar t-t_1)\asymp(t_2-\bar t)\asymp 1$,

$$\frac{dx}{dt}\Big|_{t=\bar t}\asymp \frac{dx}{dt}\Big|_{t=\bar t}\asymp 1 \tag{5.3.43}$$

and

(5.3.44) *Map* $\Sigma_0\cap T^*_{\bar y}X\ni\eta\to\pi_x\Psi_t(y,\eta)$ *is nondegenerate in* $(\bar y,\bar\eta)$.

Then as $t_1\le\bar t-\epsilon$, $t_2\ge\bar t+\epsilon$, $x=\bar x$, $y=\bar y$

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar\chi_\epsilon(t-T^*)u\Big)\,d\tau\equiv e^{ih^{-1}\phi(x,y)}\sum_{n\ge0}b_n(x,y)h^{\frac{1-d}{2}+n} \tag{5.3.45}$$

where

$$\phi(x,y)=\int_0^{\bar t}\ell(x(t),\xi(t))\,dt,\qquad \ell(x,\xi)\coloneqq\langle\partial_\xi a,\xi\rangle. \tag{5.3.46}$$

Proof. First, let us rewrite the left-hand expression of (5.3.45) as

$$i\Big(F_{t\to h^{-1}\tau}t^{-1}\bar\chi_\epsilon(t-\bar t)\Big)\Big|_{\tau=0}. \tag{5.3.47}$$

On the other hand we know that

$$u(x,y,t)\equiv(2\pi h)^{-\frac12(d+m)}\int e^{ih^{-1}\varphi(x,y,\theta,t)}\sum_{n\ge0}b'_n(x,y,t,\theta)\,d\theta \tag{5.3.48}$$

where θ is m-dimensional variable and $\varphi(x,y,t,\vartheta)$ is defined in the corresponding way. For example, one can take $m=d$, $\theta=\eta$,

$$\varphi(x,y,t,\eta)=-\langle y,\eta\rangle+\psi(x,t,\eta) \tag{5.3.49}$$

where

$$\partial_t\psi=-a(x,\partial_x\psi),\qquad \psi(x,0,\eta)=\langle x,\eta\rangle. \tag{5.3.50}$$

Let us apply stationary phase method with respect to θ,t; condition (5.3.42) and $\partial_t\psi=-a(x,\xi)$ imply that there is only one stationary point and it is $(\bar\eta,\bar t)$. Further, conditions (5.3.43) and (5.3.44) imply that this is nondegenerate point. Thus we gain a factor $h^{\frac12(d+1)}$ and (5.3.45)–(5.3.46) are proven. □

Proof of Theorem 5.3.11. To apply Theorem 5.3.14 to our case we need just rescale $x \mapsto x\gamma^{-1}$, $h \mapsto \hbar = h\gamma^{-\frac{3}{2}}$; then as $\hbar \le h^{\delta}$ i. e.

$$\gamma \ge h^{\frac{2}{3}(1-\delta)} \tag{5.3.51}$$

we conclude that

$$\mathsf{N}_{x,\mathsf{corr}} := \mathsf{N}_x^{\mathsf{T}} - \mathsf{N}_x^{\mathsf{W}} \equiv e^{i\phi(x,x)} \sum_{n\ge 0} b_n(x,x)\gamma^{\frac{1}{4}(-d-3-6n)} h^{\frac{1-d}{2}+n} \tag{5.3.52}$$

where we also multiplied by γ^{-d} since we are dealing with densities.

Thus

(5.3.53) Correction term $\mathsf{N}_{x,\mathsf{corr}}$ is of magnitude $h^{\frac{1}{2}(1-d)}\gamma^{-\frac{1}{4}(d+3)}$.

This implies a drastic difference between $d = 1$ when the correction term is below remainder estimate $h^{1-d}\gamma(x)^{\frac{1}{2}(d-2)}$ of (5.3.40) only as $\gamma \asymp 1$ and $d \ge 2$ it is always so as

$$\gamma \ge \bar{\gamma}_1 := h^{(2d-2)/(3d-1)}. \tag{5.3.54}$$

Let us introduce

$$X^- = \{x :\ V(x) < 0\}, \qquad X^0 = \partial X^- = \{x :\ V(x) = 0\}, \tag{5.3.55}$$

Without any loss of the generality one can assume that $X^- = \{x_1 < 0\}$.

Case $d = 1$. We can assume without any loss of the generality that $a(x,\xi) = \beta(x)\big(\xi_1^2 - V_0(x)\big)$ (we can always get rid of V_1 by gradient transform); then

$$W(x_1) = \Big(\frac{3}{2}\int_0^{x_1} V_0(y_1)^{\frac{1}{2}}\, dy_1\Big)^{\frac{2}{3}} \tag{5.3.56}$$

is a travel time from $x_1 \in X^-$ to X^0 (on energy level 0, if we replace β by 1) and one can see easily that then

(5.3.57) Under assumption (5.3.18) $W(x)/V_0(x)$ is a smooth and disjoint from 0 function on $X^- \cup X^0$.

We redefine $x_1 = W(x)$ and then $a(x,\xi)$ will be in the same form as before but with different β and with $W(x_1) = x_1$:

$$a(x,\xi) = \beta(x)\big(\xi_1^2 - x_1\big) \tag{5.3.58}$$

Let us prove that *in calculations one can replace* $\beta(x)$ *by* $\beta(x) = 1$ *and assume that*

$$A = h^2 D_1^2 - x_1 \qquad \text{on } \mathbb{R}. \tag{5.3.59}$$

Really, let $\bar{x}$ be a point where calculations are done, while x be a "running" point. Without any loss of the generality one can assume that $\beta(\bar{x}) = 1$. Let us rescale as before. Then we can assume that we are at he point with $\gamma(x)$ but on $[-c, c]$

$$|D_1^j \beta(x)| \le c_j \varepsilon^j \tag{5.3.60}$$

where ε is an original $\gamma(\bar{x})$.

Let us apply Theorem 5.3.14. Note that phase functions for the original operator and for the model operator coincide identically while amplitudes differ by $O(\varepsilon)$ (where $\varepsilon = \gamma$); so an error is $O(h^{1-d}\varepsilon)$ and scaling back we get an error estimate $Ch^{1-d}\gamma^{\frac{1}{2}(d-3)}\varepsilon = Ch^{1-d}\gamma^{\frac{1}{2}(d-1)}$ which is actually better by factor $\gamma^{\frac{1}{2}}$ than we need. Calculations for model operator (5.3.59) are produced in Appendix 5.A.1. Theorem 5.3.11 is proven as $d = 1$.

Case $d \ge 2$. Again without any loss of the generally one can assume that $V(x) = -k(x)x_1$ with $k(x) > 0$ disjoint from 0.

Let

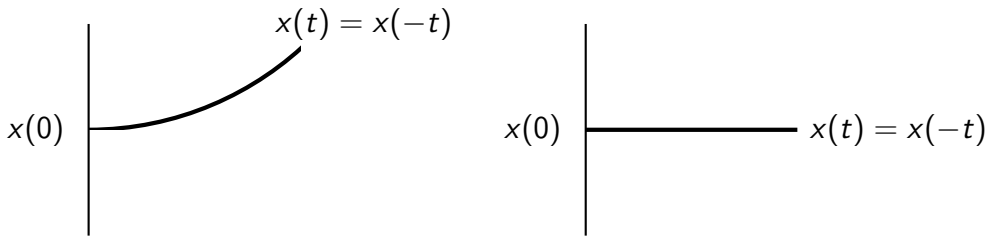
$$\Theta = \{(x,\xi) : V(x) = 0\} \cap \Sigma_0 = \{(x,\xi) : \ x_1 = 0, \xi_j = V_j(x)\} \tag{5.3.61}$$

parametrized by $x' = (x_2, \dots, x_d)$.

Consider Hamiltonian trajectory passing through $(0, x') \in \Theta$. One can select ξ_1 as a natural parameter along this trajectory, so we get a d-dimensional manifold $\Lambda \subset \Sigma_0$; since Σ_0 is $(2d-1)$-dimensional, there exists $(d-1)$-dimensional variable η: $\Lambda = \Sigma_0 \cap \{\eta = 0\}$.

Assume first that

(5.3.62) There is no magnetic field, i. e. $V_1 = V_2 = \dots = V_d = 0$.



(a) Original coordinates (b) Straighten coordinates

Figure 5.2: : Short loops

Then trajectory passing through Θ as $t = 0$ is symmetric: $x(-t) = x(t)$ and $\xi(-t) = \xi(t)$. Then the set of loops coincides with Λ and x-projection of the loop is exactly as on the left picture below

If we introduce new coordinates replacing x' by $x'(0)$ we get picture as on the right. Note that due to the same arguments as for $d = 1$ one can assume that

$$a(x,\xi) = \beta(x)\Big(\xi_1^2 - x_1 + \sum_{j,k\geq 2} g'^{jk}(x)\big(\xi_j - \alpha_j(x)\xi_1\big)\big(\xi_k - \alpha_k(x)\xi_1\big)\Big) \tag{5.3.63}$$

with positive definite matrix (g'^{jk}). Then $\eta = 0$ if and only if $\xi_j - \alpha_j(x)\xi_1 = 0$ $\forall j = 2, \dots, d$. Also note that on Σ_0 we must have $\eta = 0 \implies \{a, \eta\} = 0$ i. e. $\{\xi_1^2 - x_1, \xi_j - \alpha_j(x)\xi_1\} = 0$ which easily yields that $\alpha_j(x) = 0$ $\forall j = 2, \dots, d$ i. e.

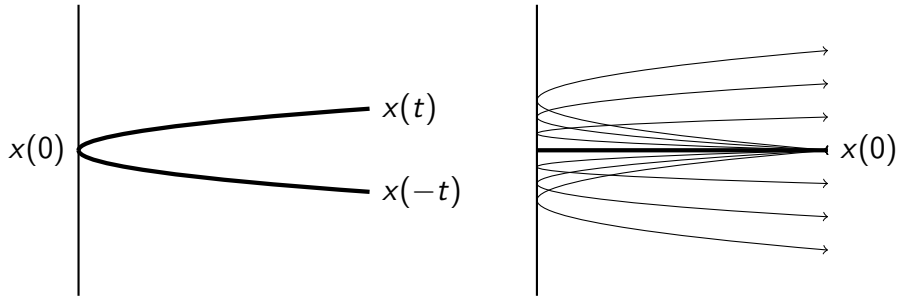
$$a(x,\xi) = \beta(x)\Big(\xi_1^2 - x_1 + \sum_{j,k\geq 2} g'^{jk}(x)\xi_j\xi_k\Big) \tag{5.3.64}$$

and $\eta = \xi'$.

One can see easily that in the special case $g'^{jk}(x) = \delta_{jk}$ trajectories are parabolas

$$\begin{aligned} &\xi_1 = t, && x_1 = t^2,\\ &\xi' = \mathrm{const}, && x' = \mathrm{const} + \xi' t \ (j \geq 2) \end{aligned}$$

and similarly looking in more general case.



(a) (b)

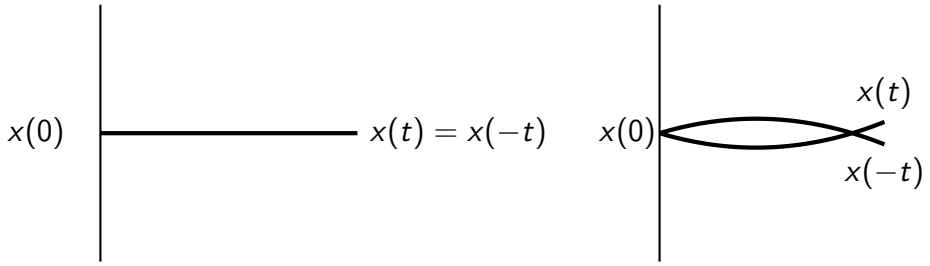
Figure 5.3: Selecting $\xi' \neq 0$ destroys the loop

Again, as $\gamma \asymp 1$ we can estimate contribution of the loop by $Ch^{1-d} \times h^{\frac{1}{2}(d-1)} = h^{-\frac{1}{2}(d-1)}$ where extra factor $h^{\frac{1}{2}(d-1)}$ is due to Theorem 5.3.14. Scaling procedure leads to estimate (5.3.53).

As $g'^{jk} = \delta_{jk}$ Appendix 5.A.1 implies that estimate (5.3.36) holds. Thus it holds for $g'^{jk} = \mathsf{const}$. For variable g'^{jk} we get instead of phase $|\xi'|^2$ another phase $|\xi'|^2 + \omega(x, \xi')$ with $\omega = O(\gamma|\xi'|^2)$ which leads to an error with an extra factor γ in the error estimate which becomes $h^{-\frac{1}{2}(d-1)}\gamma^{-\frac{1}{4}(d-1)}$ and is less than the right hand expression of (5.3.36).

Therefore *under assumption (5.3.62) Theorem 5.3.11 is proven*.

We can consider operator (5.3.64) and add magnetic field to it.



(a) No magnetic field case (b) Magnetic field case

Figure 5.4: Short loop without and with magnetic field

In this case equalities $\xi(-t) = -\xi(t)$ and $x(-t) = x(t)$ along trajectories passing through Θ fail, Λ loses is value and picture on Figure 5.2(b) is replaced by the picture on the left where actually the arcs are symmetric only asymptotically. However as before for each x (with $0 < x_1 < \epsilon$) there

exists $\xi = \xi(x)$ such that $(x,\xi) \in \Sigma_0$ and Hamiltonian trajectory passing through (x,ξ) comes back to x. So, instead of few looping trajectories and each such trajectory being a loop for each of its points, we have now many looping trajectories but each of them serves only one point.

Further, one can prove that then the phase is changed by $O(\varepsilon)$ where $\varepsilon = \gamma$ and scaling back we get an extra term $O(h^{-1}\gamma^{\frac{3}{2}} \times \varepsilon) = O(h^{-1}\gamma^{\frac{5}{2}})$ in the exponent which leads to the error not exceeding $Ch^{-\frac{1}{2}(d+1)}\gamma^{-\frac{1}{4}(d-7)}$ which does not exceed the right-hand expression of (5.3.36) as $h^{\frac{2}{3}} \le \gamma \le \bar{\gamma}_1$.

Theorem 5.3.11 proven completely. □

Remark 5.3.15. Obviously

$$W(x) = \mathsf{const}\, \varrho^{\frac{4}{3}}(x), \qquad \mathsf{const} = \big(\frac{3}{2}\big)^{\frac{2}{3}} \tag{5.3.65}$$

where $\varrho(x)$ is the distance in the metrics $g^{jk}V(x)^{-1}$ from x to X^0. Thus one can rewrite the correction term as

$$h^{-\frac{2}{3}d}|\nabla V(x)|^{\frac{d}{3}}\mathcal{Q}\Big(\mathsf{const}\, h^{-\frac{2}{3}}\varrho^{\frac{4}{3}}(x)\Big). \tag{5.3.66}$$

Finally, let us get rid of condition $|\nabla V(x)| \ge \epsilon$. To do this let us rewrite first the right-hand expression of (5.3.36) as

$$Ch^{-\frac{1}{2}(d-1)}\big(\max(|V|, h^{\frac{2}{3}})\big)^{\frac{1}{2}(d-2)} \tag{5.3.67}$$

thus releasing notation γ.

Let us introduce a standard scale $\gamma = \big(|V| + |\nabla V|^2\big)^{\frac{1}{2}} + h^{\frac{1}{2}}$ but exclusively at point $\bar{x}$ in question. Then applying the standard rescaling $x \to x\gamma^{-1}$, $h \to \hbar = h\gamma^{-2}$, $V \to V\gamma^{-2}$, $\nabla V \to \nabla V\gamma^{-1}$ we get instead of (5.3.67) expression

$$Ch^{1-d}\gamma^{d-2}\big(\max(|V|\gamma^{-2}, h^{\frac{2}{3}}\gamma^{-\frac{4}{3}})\big)^{\frac{1}{2}(d-2)} = Ch^{1-d}\big(\max(|V|, h^{\frac{2}{3}}\gamma^{\frac{2}{3}})\big)^{\frac{1}{2}(d-2)}.$$

As $d \ge 2$ the latter expression can only increase as γ is replaced by 1. However as $d = 1$ situation is different and we arrive to

$$C\min(|V|^{-\frac{1}{2}}, h^{-\frac{1}{3}}\gamma^{-\frac{1}{3}})\big). \tag{5.3.68}$$

Thus we proved

Theorem 5.3.16. *Let conditions* (5.3.1), (5.3.4), (5.3.5), (5.3.6) *and* (5.3.7) *be fulfilled. Then*

(i) As $d = 2$ *asymptotics* (5.3.36) *holds; furthermore one can skip the correction term without penalty as* $h^{d-1}|\nabla V|^{d+1} \le |V|^{3d-1}$.

(ii) As $d = 1$ *the left-hand expression of* (5.3.36) *does not exceed*

$$C\begin{cases} |V(x)|^{-\frac12} & \text{as } \ h^{\frac23}|\nabla V(x)|^{\frac23} \le |V(x)| \le |\nabla V(x)|^2 \\ & \text{or as } \ |V(x)| \ge \max\bigl(|\nabla V(x)|^2, h\bigr), \\ h^{-\frac13}|\nabla V(x)|^{-\frac13} & \text{as } \ |V(x)| \le h^{\frac23}|\nabla V(x)|^{\frac23},\ |\nabla V(x)| \ge h^{\frac12}, \\ h^{-\frac12} & \text{as } \ |V(x)| \le h, |\nabla V(x)| \le h^{\frac12}; \end{cases} \tag{5.3.69}$$

further, as $|V(x)| \ge \max\bigl(|\nabla V(x)|^2, h\bigr)$ *one can skip the correction term without penalty.*

Problem 5.3.17. Consider averaged with respect to the spectral parameter correction term with $s > 0$ and, respectively, as $d > s + 3$ and generalize results we derived as $s = 0$, $d = 1, 2$.

5.3.2 Dirac Operator

Assumptions

So, we consider Dirac operator (5.3.2)

$$A = \sum_{j,l} \frac{1}{2}\sigma_l(\omega^{jl}P_j + P_j\omega^{jl}) + \sigma_0 m + V \cdot I$$

where coefficients ω^{jl}, the components of the vector-potential V_j and the scalar potential V are real-valued functions, σ_l are $\mathsf{D} \times \mathsf{D}$-dimensional Pauli matrices (see Appendix 5.A.2), $\mathsf{D} \ge 2$, $m = \mathsf{const} \ge 0$ is a mass parameter, and $h \in (0, 1)$.

We can also consider *massless Dirac operator*

$$A = \sum_{j,l} \frac{1}{2}\sigma_l(\omega^{jl}P_j + P_j\omega^{jl}) + V \cdot I \tag{5.3.70}$$

which is not necessarily a special case of (5.3.2) because for a given dimension D there may be only d rather than $(d + 1)$ of $\mathsf{D} \times \mathsf{D}$-dimensional Pauli

matrices[20]; however unless otherwise specified we consider it under $m = 0$ blanket as well.

Moreover, for the future applications we also consider the *generalized Dirac operator*

$$\boldsymbol{A} = J^{-\frac{1}{2}}(A + W\sigma_0)J^{-\frac{1}{2}} \tag{5.3.71}$$

with

$$J = \frac{1}{2}J_+(I + \sigma_0) + \frac{1}{2}J_-(I - \sigma_0) \tag{5.3.72}$$

where $J_\pm$ are positive-valued functions.

Let us discuss operator (5.3.2) in the simple case of $\omega^{jl} = \delta_{jl}$, $V_j = V = 0$:

$$a(x,\xi) = \sum_j \sigma_j \xi_j + m\sigma_0 + V(x). \tag{5.3.73}$$

Then $a(x,\xi)$ has eigenvalues

$$\lambda_\pm = \pm(m^2 + |\xi|^2)^{\frac{1}{2}} + V(x) \tag{5.3.74}$$

and observe that

(5.3.75) For given x there is a spectral gap $(-m + V(x), m + V(x))$ which is empty as $m = 0$.

As $m \lesssim 1$ we get rather standard case of the matrix operator and actually we will improve results getting rid of the microhyperbolicity condition.

On the other hand, as $m \gg 1$ we get a huge spectral gap and to avoid it we need to take energy level close to its end; alternatively we can pick up energy level 0 but replace $V(x)$ by $\mp m + V_0(x)$. Then the "interesting" eigenvalue of $a(x,\xi)$ becomes

$$\lambda_\pm = \pm(m^2 + |\xi|^2)^{\frac{1}{2}} \mp m + V(x) \approx \pm \frac{1}{2m}|\xi|^2 + V(x) = \pm\frac{1}{2m}\Big(|\xi|^2 \pm 2mV(x)\Big) \tag{5.3.76}$$

as $|\xi| \lesssim 1$ and we arrive basically to the Schrödinger operator with the potential $\pm 2mV(x)$ and we want it to be of the type we considered before.

[20] This can happen only for odd d.

The following array of assumptions codifies these two different situations for the generalized Dirac operator (5.3.71)–(5.3.72). Let us assume that

$$(5.3.77)_{1-2} \qquad |D^\alpha \omega^{jl}| \le c, \quad |D^\alpha V_j| \le c \qquad \forall \alpha : |\alpha| \le K,$$

$$(5.3.77)_3 \qquad |D^\alpha V| \le c \min(1, \frac{1}{m}) \qquad \forall \alpha : 1 \le |\alpha| \le K,$$

$$(5.3.77)_4^- \qquad (\tau_j - m - V)_- \le c \min(1, \frac{1}{m}),$$

$$(5.3.77)_4^+ \qquad (\tau_j + m - V)_+ \le c \min(1, \frac{1}{m}),$$

$$(5.3.77)_5 \qquad |D^\alpha W| \le c \min(1, \frac{1}{m}) \qquad \forall \alpha : |\alpha| \le K$$

and

$$(5.3.77)_6 \qquad |D^\alpha J_\varsigma| \le c \quad \forall \alpha : |\alpha| \le K, \quad \varsigma = \pm,$$

$$(5.3.77)_7 \qquad \epsilon_0 \le J_\varsigma \le c$$

where $\tau_1 < \tau_2$ are the energy levels in question.

Moreover let us assume that

(5.3.78) The metric tensor

$$(5.3.79) \qquad g^{jk} = \sum_{l,r} \omega^{jl}\omega^{kr}\delta_{lr}$$

satisfies $(5.3.6)_1$ and (5.3.7).

Let us recall that

$$(5.3.80) \qquad \sigma_l^\dagger = \sigma_l,$$

$$(5.3.81) \qquad \sigma_l\sigma_k + \sigma_k\sigma_l = 2\delta_{kl}I \qquad (k, l = 0, \dots, d),$$

i. e., that σ_l are Hermitian, unitary and anti-commuting. The properties of Pauli matrices are presented more explicitly in Appendix 5.A.2.

Calculations

Lemma 5.3.18. *For $d \ge 1$ the principal symbol (of the Dirac operator)*

$$(5.3.82) \qquad a(x, \xi) = \sum_{j,l} \sigma_l \omega^{jl}(\xi_j - V_j) + \sigma_0 m + V \cdot I$$

has two eigenvalues

$$\lambda_{\mp} = V \mp (g^{jk}(\xi_j - V_j)(\xi_k - V_k) + m^2)^{\frac{1}{2}} \tag{5.3.83}$$

of multiplicity $\frac{1}{2}\mathsf{D}$.

Proof. Obviously it is sufficient to treat the case $V = V_1 = ... = V_d = 0$. Then (5.3.81) implies that $a(x,\xi)^2 = g^{jk}\xi_j\xi_k + m^2$ and hence there is no eigenvalue of a different from $\lambda_{\pm}$.

Since $\lambda_{\pm}$ coincide only if $\xi = 0, m = 0$ then in the calculation of multiplicities one can assume that $\xi = 0, m > 0$. But in this case the multiplicities of $\lambda_{\pm}$ are equal to $\frac{1}{2}\mathsf{D}$ since $\sigma_1^{-1}\sigma_0\sigma_1 = -\sigma_0$; for the massless Dirac operator we can consider instead $\xi = (1, 0, ..., 0)$. □

Remark 5.3.19. (i) Let $d = 1$; this is possible only for massless Dirac operator $A = \omega(D_1 - V_1) + V$ and the conclusion fails; however it is still valid for $d \geq 2$ and

$$a(x,\xi) = \sum_{j,l} \sigma_l \omega^{jl}(\xi_j - V_j) + V \cdot I. \tag{5.3.84}$$

(ii) Without any loss of the generality one can assume that $\mathsf{D} = \bar{\mathsf{D}} := 2^{\lfloor \frac{d+1}{2} \rfloor}$ because $\sigma_k = q^{\dagger}(\bar{\sigma}_k \otimes I_{\mathsf{D}'})q$ with the unitary matrix q, $\bar{\mathsf{D}} \times \bar{\mathsf{D}}$ matrices $\bar{\sigma}_k$ and $\mathsf{D}' = \mathsf{D}\bar{\mathsf{D}}^{-1}$. In particular, for $d = 1, 2$ we get $\bar{\mathsf{D}} = 2$ and the eigenvalues of $a(x,\xi)$ are simple.

(iii) Similarly for massless Dirac operator without any loss of the generality one can assume that $\mathsf{D} = \bar{\mathsf{D}} := 2^{\lfloor \frac{d}{2} \rfloor}$. In particular, for $d = 3$ we get $\bar{\mathsf{D}} = 2$ and the eigenvalues of $a(x,\xi)$ are simple.

As a corollary we obtain that for the Dirac operator

$$\mathsf{tr}(\kappa_0(x,\tau_1,\tau_2)) = \frac{\mathsf{D}}{2}(2\pi)^{-d} \sum_{\varepsilon=\pm} \int_{\tau_1<\lambda_\varepsilon<\tau_2} d\xi \tag{5.3.85}$$

and for the generalized Dirac operator

$$\mathsf{tr}(\kappa_0(x,\tau_1,\tau_2)) = (2\pi)^{-d} \int \boldsymbol{n}(x,\xi,\tau_1,\tau_2) d\xi \tag{5.3.86}$$

where $\boldsymbol{n}(x,\xi,\tau_1,\tau_2)$ is the eigenvalue counting function for the symbol

$$\boldsymbol{a}(x,\xi) = J(x)^{-\frac{1}{2}}\big(a(x,\xi)+\sigma_0 W(x)\big)J(x)^{-\frac{1}{2}} \tag{5.3.87}$$

and $\boldsymbol{a}$ is defined by (5.3.82).

Let us calculate $\kappa_1'(y,\tau)$. The arguments of Section 4.3 imply that $\kappa_1'(y,\tau)$ depends only on the values of ω^{jl}, V_j, V, $m+W$, J_+, J_- and their first-degree derivatives at the point y and the dependence on the derivatives is linear.

Since the gauge transformation is equivalent to multiplying the spectral function $e(x,y,\tau_1,\tau_2)$ by $\exp ih^{-1}(\varphi(x)-\varphi(y))$ and hence it does not change $e(y,y,\tau_1,\tau_2)$ then it does not change $\kappa_1'(y,\tau)$ either. Then $\kappa_1'(y,\tau)$ depends on V_j only through $F_{jk}(y)$. Therefore it is sufficient to be able to calculate $\kappa_1'(y,\tau)$ in two cases:

(a) $V_j=0$ and ω^{jl}, V, W, J_+ and J_- are linear functions;

(b) V_j are linear functions and ω^{jl}, V, W, J_1 and J_2 are constants.

and then add the results.

But in the case (a) the substitution $A\mapsto \sigma_0 A\sigma_0$, $x_j\mapsto 2y_j-x_j$ (which obviously does not change $\mathsf{tr}(e(y,y,\tau_1,\tau_2))$) is equivalent to reversing the signs of the coefficients at (x_j-y_j) in ω^{kl}, V, W, J_+ and J_- and therefore $\mathsf{tr}(e(y,y,\tau_1,\tau_2))$ does not depend on the derivatives of these functions.

In the case (b) we reach $g^{jk}=\delta_{jk}$ after an appropriate linear change of variables; then one can assume that $\omega^{jl}=\delta_{jl}$ (otherwise we obtain these equalities by replacing σ_l with $\sigma_l'=\sum_k \omega^{lk}\sigma_k$ as $l=1,\dots,d$ and $\sigma_0'=\sigma_0$; one can check that these new matrices also satisfy (5.3.80) and (5.3.81).

Let us now apply an explicit calculation based on (4.3.39). Taking into account that $\boldsymbol{a}^s=0$ and J is constant we obtain that

$$\mathsf{tr}(\kappa_1'(y,\tau)) = \frac{1}{2}(2\pi)^{-d-1}\int \mathsf{Res}_{\mathbb{R}}\,\mathcal{F}_1\,d\xi \tag{5.3.88}$$

with

$$\mathcal{F}_1 = \sum_j \mathsf{tr}\big(J(J\tau-\boldsymbol{a})^{-1}\boldsymbol{a}_{(j)}(J\tau-\boldsymbol{a})^{-1}\boldsymbol{a}^{(j)}(J\tau-\boldsymbol{a})^{-1}\big). \tag{5.3.89}$$

Including for the sake of simplicity $-\frac{1}{2}(J_++J_-)\tau$ in V and $\frac{1}{2}(J_--J_+)\tau+W$ in m; then taking into account that $\boldsymbol{a}^s=0$ we obtain that

$$\mathcal{F}_1 = \mathsf{tr}\big(J(\tau-\boldsymbol{a})^{-1}\boldsymbol{a}_{(j)}(\tau-\boldsymbol{a})^{-1}\boldsymbol{a}^{(j)}(\tau-\boldsymbol{a})^{-1}\big) \tag{5.3.90}$$

where $a_{(j)}$ and $a^{(j)}$ are the derivatives of a with respect to x_j and ξ_j respectively and after calculations we need to take $\tau = 0$ and finally substitute $V \mapsto V - \frac{1}{2}(J_+ + J_-)\tau$ and $m \mapsto m + \frac{1}{2}(J_- - J_+)\tau + W$.

Let us note that

$$\bigl(\alpha I + \sum_j \alpha_j \sigma_j\bigr)^{-1} = \bigl(\alpha^2 - \sum_k \alpha_k^2\bigr)^{-1}\bigl(\alpha I - \sum_j \alpha_j \sigma_j\bigr)$$

for $\alpha, \alpha^1, \dots, \alpha^d \in \mathbb{C}$; therefore

$$\mathcal{F}_1 = -\Delta^{-3}\,\mathrm{tr}\Bigl(J(\tau + a' - V)\sum_{j,k}\sigma_k V_{k(j)}(\tau + a' - V)\sigma_j \cdot (\tau + a' - V)\Bigr)$$

where

$$\Delta = (\tau - V)^2 - |\xi|^2 - m^2, \qquad a' = \sum_l \sigma_l \xi_l + \sigma_0 m, \qquad V_{k(j)} = \partial_j V_k$$

and we have taken into account that $a^{(j)} = \sigma_j$, $a_{(j)} = -\sigma_k V_{k(j)}$ because of simplifying assumptions. Since

$$(\tau + a' - V)\sigma_k = \sigma_k(\tau + a' - V) + 2\xi_k I$$

and $(\tau + a' - V)(\tau - a' - V) = \Delta I$ and these two factors commute we conclude that

$$\begin{aligned}(5.3.91)\quad \mathcal{F}_1 = -\Delta^{-2}\,\mathrm{tr}\Bigl(\sum_{j,k} J\sigma_k\sigma_j(\tau + a' - V)V_{k(j)}\Bigr) - \\ 2\Delta^{-2}\,\mathrm{tr}\Bigl(\sum_{j,k} J\sigma_j\xi_k V_{k(j)}\Bigr) - 2\Delta^{-2}\,\mathrm{tr}\Bigl(\sum_{j,k} J(\tau + a' - V)V_{k(j)}\xi_k\xi_j\Bigr).\end{aligned}$$

The properties of Pauli matrices (see Appendix 5.A.2) yield that the second term vanishes. Without any loss of the generality one can assume that $V_{k(j)} = -V_{j(k)} = -\frac{1}{2}F_{kj}$; we can always arrange this by a gauge transformation. Then the third term also vanishes and (5.3.91) becomes

$$\mathcal{F}_1 = \frac{1}{2}\Delta^{-2}\,\mathrm{tr}\Bigl(\sum_{j,k}\sigma_k\sigma_j F_{kj} J(\tau + a' - V)\Bigr).$$

Then the properties of Pauli matrices yield that $\mathcal{F}_1$ vanishes unless $d=2$, in which case only terms of type $f\sigma_0$ with scalar f in the product $J(\tau+a'-V)$ are essential and hence

$$\mathcal{F}_1 = \frac{1}{2}\Delta^{-2}\operatorname{tr}\Big((\sigma_1\sigma_2\sigma_0)F_{12}\big((J_+ + J_-)m + (J_+ - J_-)(\tau - V)\big)\Big). \tag{5.3.92}$$

Explicit calculation in polar coordinates in $\mathbb{R}^2_\xi$ yields that

$$\int \Delta^{-2} d\xi = \pi\big((\tau - V)^2 - m^2\big)^{-1}$$

and the real residue of this function is equal to

$$\frac{\pi^2 i}{m}\big(\delta(\tau - V - m) - \delta(\tau - V + m)\big)$$

and therefore

$$\operatorname{tr}\kappa_1'(x,\tau) = \frac{1}{8\pi}F_{12}\operatorname{tr}(i\sigma_1\sigma_2\sigma_0)\big(\delta(\tau - V - m) - \delta(\tau - V + m)\big) \tag{5.3.93}$$

which implies

$$\operatorname{tr}(\kappa_1(x,\tau_1,\tau_2)) = \frac{1}{8\pi}F_{12}\operatorname{tr}(i\sigma_1\sigma_2\sigma_0)\Big(\theta(\tau - V - m) - \theta(\tau - V + m)\Big)\Big|_{\tau=\tau_1}^{\tau=\tau_2}. \tag{5.3.94}$$

Recalling that some terms were "hidden" in V and m we conclude that

$$\operatorname{tr}(\kappa_1'(x,\tau)) = \frac{1}{8\pi}F_{12}\operatorname{tr}(i\sigma_1\sigma_2\sigma_0)\sum_{\varsigma=\pm}\varsigma J_\varsigma \delta\big(J_\varsigma\tau - \varsigma(m+W) - V\big) \tag{5.3.95}$$

and thus finally

$$\operatorname{tr}(\kappa_1(x,\tau_1,\tau_2)) = \frac{1}{8\pi}F_{12}\operatorname{tr}(i\sigma_1\sigma_2\sigma_0)\sum_{\varsigma=\pm}\varsigma\theta\big(J_\varsigma\tau - \varsigma(m+W) - V\big)\big|_{\tau=\tau_1}^{\tau=\tau_2}. \tag{5.3.96}$$

These arguments with necessary modifications work for the massless Dirac operator as well resulting the answer which is 0. So we have proven

Lemma 5.3.20. *(i) For the generalized Dirac operator* (5.3.71)–(5.3.72) $\operatorname{tr}(\kappa_1(x,\tau_1,\tau_2))$ *vanishes for* $d\neq 2$ *and* $\operatorname{tr}(\kappa_1(x,\tau_1,\tau_2))$ *is given by* (5.3.96) *for* $d=2$*; this formula becomes* (5.3.94) *for Dirac operator.*

(ii) For the massless Dirac operator $\operatorname{tr}(\kappa_1(x,\tau_1,\tau_2))=0$.

All calculations are modulo gradient.

Asymptotics for $m \ge c_0$

Let us pass from calculations to asymptotics. We assume that $\tau_2 = 0$, which is not a restriction for Dirac operator (5.3.2) but is a restriction for the more general operator (5.3.71). In this subsubsection we consider the case

$$m \ge c_0. \tag{5.3.97}$$

Then at least one of the two conditions

$$W + m \mp V \ge \epsilon_0 m \tag{5.3.98}_{\pm}$$

is fulfilled. Moreover let us assume that

$$m + W \ge |V - \tau_1| + \epsilon_0 m; \tag{5.3.99}$$

under assumption (5.3.97) we can always satisfy this condition by an appropriate choice of τ_1 but we cannot guarantee that $\tau_1 < \tau_2$. So, we select τ_1 belonging to the semiclassical spectral gap which is here for sure under assumption (5.3.97).

Without any loss of generality one can assume that

$$\sigma_0 = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} \tag{5.3.100}$$

(see Appendix 5.A.2). Separating the $\mathbb{C}^{\mathsf{D}}$-valued functions into two components $\begin{pmatrix} v_+ \\ v_- \end{pmatrix}$ and the $\mathbb{C}^{\mathsf{D}} \times \mathbb{C}^{\mathsf{D}}$-valued functions into four blocks $\begin{pmatrix} u_{++} & u_{+-} \\ u_{-+} & u_{--} \end{pmatrix}$ we obtain that the non-stationary generalized Dirac equation

$$(JhD_t - A)J^{-\frac{1}{2}}u = 0 \tag{5.3.101}$$

is equivalent to two equations

$$(J_+ hD_t - m - W - V)u^+ - \mathcal{M}u^- = 0, \tag{5.3.102}_+$$

and

$$-\mathcal{M}^\dagger u^+ + (J_- hD_t + m + W - V)u^- = 0 \tag{5.3.102}_-$$

where

$$\mathcal{M} = \frac{1}{2}\sum_{j,l} \sigma'_l(\omega^{jl}P_j + P_j\omega^{jl}), \tag{5.3.103}$$

$$\mathcal{M}^\dagger = \frac{1}{2}\sum_{j,l} \sigma'^\dagger_l(\omega^{jl}P_j + P_j\omega^{jl}) \tag{5.3.103}^\dagger$$

and due to (5.3.100) $\sigma_l = \begin{pmatrix} 0 & \sigma_l' \\ \sigma_l'^{\dagger} & 0 \end{pmatrix}$.

In this case if condition $(5.3.98)_{\pm}$ is fulfilled then the second (the first respectively) of these equations is elliptic for $|\tau| \le \epsilon_0 m$ and hence we can exclude the corresponding component. Let us assume that condition $(5.3.98)_{-}$ is fulfilled. Then plugging

$$u^- \equiv (J_- hD_t + m + W - V)^{-1} \mathcal{M}^{\dagger} u^+ \tag{5.3.104}$$

into $(5.3.101)_{+}$ we obtain that

$$m\Big((J_+ hD_t - m - W - V) - \mathcal{M}(J_- hD_t + m + W - V)^{-1}\mathcal{M}^{\dagger}\Big)u^+ \equiv 0 \tag{5.3.105}$$

where $(J_- hD_t + m + W - V)^{-1}$ is a parametrix of $(J_- hD_t + m + W - V)$ in the zone $\{|\tau| \le \epsilon_0 m\}$ and the norms of the errors in (5.3.104) and (5.3.105) do not exceed $C' m^{-1} h^s$.

Let us consider the operator

$$m\mathcal{M}(J_- hD_t + m + W - V)^{-1}\mathcal{M}^{\dagger}; \tag{5.3.106}$$

the properties of Pauli matrices yield that

(5.3.107) The principal symbol of operator (5.3.106) is equal to

$$m(J_-\tau + m + W - V)^{-1} \sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k).$$

Rescaling the time $t_{\mathsf{new}} = m^{-1}t$ we rewrite (5.3.105) as

$$(J_+ hD_t - \mathcal{A})u^+ \equiv 0 \tag{5.3.108}$$

with

$$\mathcal{A} = m(m + W + V) + m\mathcal{M}(J_- hD_t + m + W - V)^{-1}\mathcal{M}^{\dagger} \tag{5.3.109}$$

which due to (5.3.107) would be Schrödinger operator (modulo lower order terms) if not hD_t in the parametrix:

(5.3.110) The principal symbol of $\mathcal{A}$ is equal to

$$m(m + W - V)^{-1} b + O(\tau) \tag{5.3.111}$$

with

$$b \coloneqq \sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k) + (m + W)^2 - V^2. \tag{5.3.112}$$

Note that due to $(5.3.77)_{3-5}$ the potential

$$V^* := (m+W)^2 - V^2 \tag{5.3.113}$$

satisfies $(5.3.6)_3$.

One can prove easily the following

Proposition 5.3.21. *(Uniform) ellipticity, ξ-microhyperbolicity or microhyperbolicity conditions for operator $\boldsymbol{A}$ on the energy level 0 are equivalent to those for the Schrödinger operator with potential* (5.3.113) *also on the energy level 0 i. e. respectively to*

$$(m+W)^2 - V^2 \ge \epsilon_0, \tag{5.3.114}$$

$$|(m+W)^2 - V^2| \ge \epsilon_0, \tag{5.3.115}$$

$$|(m+W)^2 - V^2 + |\nabla\big((m+W)^2 - V^2\big)| \ge \epsilon_0. \tag{5.3.116}$$

All the arguments for operators scalar in principal and all the arguments for the Schrödinger operator remain true excluding arguments linked with the subprincipal symbol. First of all we have the standard elliptic statement[21)]

Proposition 5.3.22. *(i) Let conditions* (5.3.71), (5.3.71), $(5.3.77)_{1-7}$, (5.3.7), (5.3.97) *and* $(5.3.98)_{\pm}$ *be fulfilled and let*

$$m + W \pm V \ge \epsilon \frac{r}{m} \qquad \forall x \in B(0,1), \tag{5.3.117}_{\pm}$$

with $\epsilon > 0$, $m^2 \ge r \ge 1$. Then

$$|F_{t\to h^{-1}\tau}\chi_T(t)u| \le C'\big(\frac{h}{r}\big)^s T \tag{5.3.118}$$
$$\forall x, y \in B(0, 1-\epsilon) \quad \forall \tau \in [-\epsilon' r, \epsilon' r]$$

where $\epsilon' = \epsilon'(d, c, \epsilon_0, \epsilon) > 0$ is a small constant and $C' = C'(d, s, c, \epsilon_0, \epsilon)$.

(ii) Moreover, the same estimate with an additional factor m^{-1}, m^{-1}, m^{-2} in the right-hand expression holds for the blocks $u^{\mp,\cdot}(.,.,.)$, $u^{\cdot,\mp}(.,.,.)$ and $u^{\mp,\mp}(.,.,.)$ respectively.

[21)] Under assumptions already made condition $(5.3.117)_{\pm}$ below is equivalent to (5.3.114) with the right-hand expression $\epsilon_0 r$.

Then the standard Tauberian arguments yield

Corollary 5.3.23. *(i) In the framework of Proposition 5.3.22*

$$|e(x,y,\tau',\tau'')| \le C'\bigl(\frac{h}{r}\bigr)^s \qquad \forall x,y \in B(0,1-\epsilon)] \quad \forall \tau',\tau'' \in [-\epsilon' r, \epsilon' r]. \tag{5.3.119}$$

(ii) Moreover, the same estimate with a factor m^{-1}, m^{-1}, m^{-2} in the right-hand expression holds for the blocks $e^{\mp,\cdot}(x,y,\tau',\tau'')$, $e^{\cdot,\mp}(x,y,\tau',\tau'')$ and $e^{\mp,\mp}(x,y,\tau',\tau'')$ respectively.

Remark 5.3.24. Corollary 5.3.23 yields that we can assume in what follows that

$$m + W \pm V \le \frac{c}{m}. \tag{5.3.120}_{\pm}$$

Then the following assertions similar to those for the Schrödinger operator are proven easily:

Theorem 5.3.25 [22]**.** *Let assumptions* (5.3.71)–(5.3.71), $(5.3.77)_{1-7}$, (5.3.78), (5.3.97) *and* $(5.3.98)_{\pm}$, $(5.3.120)_{\pm}$ *be fulfilled and let* $d \ge 2$.

Let $\psi \in \mathscr{C}_0^K(B(0,\frac{1}{2}))$, $|\psi| \le 1$ *and let* (4.2.73)–(4.2.75) *be fulfilled and* $L \ge m^{-1}h$. *Then*

(i) The following estimate holds

$$|\mathcal{R}^{\mathsf{W}}_{\varphi,L}| \le \bigl(Ch^{1-d} + C'h^{1-d+\delta'}\bigr)\vartheta\bigl(\frac{h}{mL}\bigr). \tag{5.3.121}$$

(ii) Moreover, let $\Lambda_1^{\pm},\dots,\Lambda_n^{\pm}$ be closed subsets of $\Sigma^{\pm} = \{(x,\xi) : \lambda_{\pm} = 0\}$ where $\lambda_{\pm}$ are given by (5.3.83),

$$\Lambda_j^{\pm} \subset \bigl\{\varrho_{\pm}^2 := m| \pm V + m + W| + m^2|\nabla(V \pm W)|^2 \ge h^{1-\delta}\bigr\}$$

and suppose that through each point of the $h^{\frac{1}{2}-\delta}$-neighborhood of $\Lambda_j^{\pm}$ there passes a Hamiltonian trajectory generated by $mJ_{\pm}(x)^{-1}\lambda_{\pm}(x,\xi)$ with $t \in \mathcal{J}_j = [0,T_j]$ or $\mathcal{J}_j = [-T_j,0]$, $T_j \in [1,h^{-\delta'}]$, along which

[22] Cf. Theorem 5.3.3.

$$(5.3.122)_{1,2} \quad |D^{\alpha}\omega^{jl}| \le c_1 h^{-\delta'}, \quad |D^{\alpha}V_j| \le c_1 h^{-\delta'},$$

$$(5.3.122)_3 \quad |D^{\alpha}V| \le c_1 h^{-\delta'} \min(1, \frac{1}{m}) \quad (|\alpha| \ge 1)$$

$$(5.3.122)_4 \quad |D^{\alpha}W| \le c_1 h^{-\delta'} \min(1, \frac{1}{m}), \quad |D^{\alpha}J_{\varepsilon}| \le c_1 h^{-\delta'} \quad \forall \alpha : |\alpha| \le K',$$

$$(5.3.122)_5 \quad \epsilon_1 h^{\delta'} \le J_{\varepsilon} \le c_1 h^{-\delta'}$$

and conditions (2.4.29), (5.3.14), (5.3.15) *are fulfilled. Further, let* (5.2.101) *with* $s \ge 0$ *be fulfilled.*

Then for $d \ge 3$, $d = 2$ *respectively estimates* (5.3.16) *and* (5.3.26) *hold with* $\vartheta(h/L)$ *replaced by* $\vartheta(h/Lm)$ *and* $a = \lambda_{\pm}$ *and* $\gamma = \varrho_{\pm}$ *in the right-hand expressions.*

Proof. In this modification only the proof of Statement (ii) with $d = 2$ must be changed, only the part at which we consider a ball $B(z', \gamma_1)$ with $|\operatorname{Hess} V^*| \le \gamma_1$, $|\{z_1, z_2\}| \asymp \gamma_3$ where $V^* = (m + W \pm V)m$, $\gamma_3 \ge h^{\delta_3}$ with arbitrarily small $\delta_3 > 0$ and we refer to the proof of Theorem 5.2.7. The difference between magnetic Schrödinger and Schrödinger-Pauli or Dirac operators will be explored later.

Let us consider Dirac operator in the ball of radius $\gamma_4 = h^{\frac{1}{2}-\delta_4}$ with respect to x with a small enough exponent $\delta_4 > 0$. Let us introduce new coordinates $x_{\mathsf{new}} = x\gamma_4^{-1}$, divide the Dirac operator by $\gamma_4\gamma_3$ and replace h, m by $h_{\mathsf{new}} = h/(\gamma_4^2\gamma_3) < h^{\delta_5}$, $m_{\mathsf{new}} = m/(\gamma_3\gamma_4)$. One can easily check that we remain consistent with all the assumptions of this subsection provided $V^* \ge -c_0\gamma_3^2\gamma_4^2$ in the ball in question and in this case the contribution of this ball to the remainder estimate does not exceed

$$C_0 h_{\mathsf{new}}^{-1} + C' h_{\mathsf{new}}^{\delta'-1} \le C_0 h^{-1}\gamma_4^2 |F_{12}| + C' h_{\mathsf{new}}^{\delta'-1}$$

where exponents and constants are changed if necessary; after summation with respect to all the balls of this type we obtain the second and the fourth terms of the right-hand expression in (5.2.26).

On the other hand, balls with $V^* \le -c_0\gamma_3^2\gamma_4^2$ are consistent with the proof of Theorem 5.2.7: after rescaling we divide by $(-V^*)^{\frac{1}{2}}$ and obtain the case in which the microhyperbolicity condition is fulfilled; so the total contribution of the balls of this type does not exceed the sum of the first and the fourth terms of the right-hand expression in (5.3.26).

The similar proof works also for Schrödinger-Pauli operators as mentioned in Remark 5.3.4. □

Also one can prove easily

Theorem 5.3.26 [23]**.** *In the framework of Theorem 5.3.25 but with* $d = 1$ *estimate* (5.3.27) *holds.*

Moreover, if either V^* *satisfies* (5.3.28) *or* (5.2.101) *holds with* $s > 0$ *then Statements (i) and (ii) of Theorem 5.3.25 remain true.*

Also one can explore asymptotics without spatial mollification:

Problem 5.3.27. (i) Prove statements similar to those of Theorems 5.3.7, 5.3.8, 5.3.10, Corollary 5.3.9, with the only difference that not L but Lm should be greater than h and $\vartheta(h/L)$ needs to be replaced by $\vartheta(h/Lm)$ in the right-hand expressions of estimates.

(ii) Prove the statements similar to those of Theorems 5.3.11, 5.3.16.

We believe that the complete proofs of these statements are worth to be published.

Asymptotics for $m \le c_0$

Let us now consider the opposite case

$$m \le c_0. \tag{5.3.123}$$

Remark 5.3.28. Actually in the previous Subsubsection 5.3.2.4 *Asymptotics for* $m \le c_0$ we used only ellipticity of one of the equations $(5.3.102)_\pm$ and one can achieve this by ϵ'-partition provided

$$m + W \ge \epsilon_0 \tag{5.3.124}$$

with the only difference that in sharp or sharper asymptotics both signs $\pm$ may contribute to the remainder estimate; so in (5.3.26) one needs to sum with respect to sign $\pm$. So our main interest is when $m + W \ll 1$. In this case the eigenvalues $\lambda_\pm$ of $a(x,\xi)$ are not necessarily disjoint.

[23] Cf. Theorem 5.3.5.

One can prove easily

Proposition 5.3.29. *(i) Operator* (5.3.71)–(5.3.72) *is microhyperbolic at energy level* 0 *in* ξ*-directions if and only if*

$$|m + W \pm V| \ge \epsilon_0 \tag{5.3.125}$$

for both signs;

(ii) Operator (5.3.71)–(5.3.72) *is microhyperbolic at energy level* 0 *if and only if*

$$|m + W \pm V| + |\nabla(W \pm V)| \ge \epsilon_0 \tag{5.3.126}$$

for both signs and also

$$|m + W| \le \epsilon_0 \implies \exists \ell : \ |\ell_x| = 1,\ \ell_x(V \pm W) \ge \epsilon_0 \tag{5.3.127}$$

for both signs.

Then the general results of Section 4.4 imply

Corollary 5.3.30. *Let conditions* (5.3.71)–(5.3.71), $(5.3.77)_{1-7}$, (5.3.78), *and* (5.3.123), (4.2.73)–(4.2.75) *be fulfilled.*

(i) Further, let (5.3.126)–(5.3.127) *be fulfilled. Then*

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L}| \le Ch^{1-d}\vartheta\big(\frac{h}{L}\big).$$

(ii) On the other hand, let (5.3.125) *be fulfilled. Then*

$$|\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}| \le Ch^{1-d}\vartheta\big(\frac{h}{L}\big).$$

We will discuss sharp and sharper estimates later. If we want to rescale our main obstacle is condition (5.2.128). The good news is that in our applications we can assume that either (5.2.135) holds or

$$W = 0 \tag{5.3.128}$$

and since the first case is already covered we assume that (5.2.129) holds. Then condition (5.2.128) is equivalent to (5.2.127).

As long we remain in the framework of $m \le \epsilon_0$ there are two modes of rescaling:

(a) If we are interested in estimates with the spatial averaging and magnetic field is 0, i.e.

$$V_1 = ... = V_d = 0 \tag{5.3.129}$$

we can take

$$\gamma = \epsilon\big(|V| + |\nabla V|^2\big)^{\frac{1}{2}} + \bar{\gamma}, \qquad \rho = \gamma^2, \qquad \bar{\gamma} = \max\big(h^{\frac{1}{3}}, m^{\frac{1}{2}}\big) \tag{5.3.130}$$

(b) If we are interested in estimates without the spatial averaging or magnetic field is 0 we should take

$$\gamma = \epsilon|V| + \bar{\gamma}, \qquad \rho = \gamma, \qquad \bar{\gamma} = \max\big(h^{\frac{1}{2}}, m\big). \tag{5.3.131}$$

Then rescaling $x \mapsto x\gamma^{-1}$ and dividing by ρ we get to $h \mapsto h\rho^{-1}\gamma^{-1}$, $m \mapsto m\rho^{-1}$, $L \mapsto L\rho^{-1}$; here we want $m_{\mathsf{new}} = m\rho^{-1} \le 1$ i. e. $\gamma \gtrsim m^{\frac{1}{2}}$ in the case (a) and $\gamma \gtrsim m$ in the case (b).

We also want $L_{\mathsf{new}} = L\rho^{-1} \ge h_{\mathsf{new}} = h\rho^{-1}\gamma^{-1}$ i. e. $\gamma \ge hL^{-1}$ but we will ignore it since estimates hold without this condition as well.

As a result the right-hand expressions with or without spatial averaging become

$$Ch^{1-d} \int \rho^{d-1} \vartheta\big(\frac{h}{L\gamma}\big)\, dx, \tag{5.3.132}$$

where dimmed elements are present only if there is a spatial averaging. Under assumption (5.3.33) we can estimate (5.3.132) by

$$Ch^{1-d}\vartheta\big(\frac{h}{L}\big) \int \rho^{d-1}\gamma^{-s}\, dx, \tag{5.3.133}$$

and it is where all our cases finally separate:

Proposition 5.3.31. *Let conditions* (5.3.71)–(5.3.71), $(5.3.77)_{1-7}$, (5.3.78), *and* (5.3.123), (5.3.128), (4.2.73)–(4.2.75) *be fulfilled. Then*

(i) If condition (5.3.129) *is fulfilled*[24] *the contribution of zone* $\{\gamma \ge 2\bar{\gamma}\}$ *with* γ *and* $\bar{\gamma}$ *defined by* (5.3.130) *to* $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ *does not exceed*

$$Ch^{1-d}\big(\frac{h}{L}\big) \cdot \begin{cases} 1 & \text{if either } 2d-3-s \ge 0 \\ & \quad \text{or } 2d-2-s+r > 0, \\ |\log \bar{\gamma}| & \text{if } 2d-3-s+r = 0, \\ \bar{\gamma}^{2d-3-s+r} & \text{if } 2d-3-s+r < 0. \end{cases} \tag{5.3.134}$$

[24] Then we plug $\rho = \gamma^2$.

Here and below r is defined by assumption

(5.3.135)$_r$ $\mathsf{Hess}\, V$ *has at least r eigenvalues disjoint from 0 as* $|\nabla V| \le \epsilon$.

(ii) Otherwise[25] *the contribution of zone* $\{\gamma \ge 2\bar\gamma\}$ *with* γ *and* $\bar\gamma$ *defined by* (5.3.131) *to* $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ *does not exceed*

$$Ch^{1-d}\bigl(\frac{h}{L}\bigr)\cdot \begin{cases} 1 & \text{if either } d-2-s\ge 0 \\ & \quad \text{or } d-2-s+r>0, \\ |\log\bar\gamma| & \text{if } d-2-s+r=0, \\ \bar\gamma^{d-2-s+r} & \text{if } d-2-s+r<0. \end{cases} \tag{5.3.136}$$

(iii) If $|V(x)^2-m^2|\ge \bar\gamma^2$ *with* $\bar\gamma$ *defined by* (5.3.131) *then*

$$|\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}| \le Ch^{1-d}\vartheta\bigl(\frac{h}{L}\bigr)|V(x)|^{d-1-s}. \tag{5.3.137}$$

Now we need to consider zone $\{2\bar\gamma_0 \le \gamma \le 2\bar\gamma\}$ and either calculate its contribution to $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ or to $\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}$ as $\bar\gamma_0 \le |V(x)| \le \bar\gamma$. There we need to distinguish between $\bar\gamma$ defined by h or by m. In the former case $h_{\mathsf{new}} \asymp 1$ and we skip this step completely and define $\bar\gamma_0 := \bar\gamma$.

In the latter case after rescaling we have $m_{\mathsf{new}} \asymp 1$ and $h\le 1$. It means that we can apply directly results of the previous Subsubsection 5.3.2.3 *Asymptotics for* $m\ge c_0$. However let us explain what this actually means. If we consider asymptotics with the spatial averaging we need to pick up here

$$\gamma = \epsilon\bigl(|V^*| + |\nabla V^*|^2\bigr)^{\frac12} + \bar\gamma_0, \qquad \rho=\gamma, \qquad \bar\gamma_0 = h^{\frac12}$$

with $V^* = V^2-m^2$ and get

$$h_{\mathsf{new}} = h\rho^{-1}\gamma^{-1}, \qquad L_{\mathsf{new}} = L\rho^{-2}.$$

But this would be true after original rescaling; so if we want to make proper definitions in the original settings we need to replace in these equations γ, ρ, V, m, $\bar\gamma_0$, L and h by $\gamma\bar\gamma^{-1}$, $\rho\bar\rho^{-1}$, $V\bar\rho^{-1}$, $m\bar\rho^{-1}$, $\bar\gamma_0\bar\gamma^{-1}$, $L\bar\rho^{-1}$ and $h\bar\gamma^{-1}\bar\rho^{-1}$ respectively thus arriving to

$$\gamma = \epsilon\bar\gamma\bigl(\bar\rho^{-2}|V^*| + \bar\rho^{-4}\bar\gamma^4|\nabla V^*|^2\bigr)^{\frac12} + \bar\gamma_0, \qquad \rho=\bar\rho\bar\gamma^{-1}\gamma, \tag{5.3.138}$$

$$\bar\gamma_0 = h^{\frac12}\bar\gamma^{\frac12}\bar\rho^{-\frac12}, \qquad h_{\mathsf{new}} = h\bar\gamma\bar\rho^{-1}\gamma^{-2}, \qquad L_{\mathsf{new}} = L\bar\rho^{-1}\bar\gamma^2\gamma^{-2}.$$

[25] Then we plug $\rho=\gamma$.

(i) Let us recall that in the case (a) we need to check if $m \ge h^{\frac{2}{3}}$ and plug $\bar\gamma = m^{\frac12}$, $\bar\rho = m$ thus arriving to

$$\gamma = \epsilon\big(m^{-1}|V^2 - m^2| + m|\nabla V|^2\big)^{\frac12} + \bar\gamma_0, \qquad \rho = m^{\frac12}\gamma, \tag{5.3.139}$$
$$\bar\gamma_0 = h^{\frac12} m^{-\frac14}, \qquad h_{\mathsf{new}} = hm^{-\frac12}\gamma^{-2}, \qquad L_{\mathsf{new}} = L\gamma^{-2}$$

where we actually slightly modified γ (without changing its magnitude).

Therefore contribution of the zone $\{2\bar\gamma_0 \le \gamma \le 2\bar\gamma\}$ to $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ does not exceed

$$Ch^{1-d}m^{d-1-\frac12 s}\vartheta\big(\frac{h}{L}\big)\int_{\{\gamma(x)\le 2\bar\gamma\}} \gamma^{d-2}\,dx \le Ch^{1-d}m^{\frac12(2d-3+r-s)}\vartheta\big(\frac{h}{L}\big) \tag{5.3.140}$$

provided $d \ge 2$ [26) 27)].

(ii) Meanwhile in the case (b) we need check if $m \ge h^{\frac12}$ and to plug into (5.3.138) $\bar\gamma = \bar\rho = m$ thus replacing (5.3.139) by

$$\gamma = \epsilon\big(|V^2 - m^2| + m^4|\nabla V|^2\big)^{\frac12} + \bar\gamma_0, \qquad \rho = \gamma, \tag{5.3.141}$$
$$\bar\gamma_0 = h^{\frac12}, \qquad h_{\mathsf{new}} = h\gamma^{-2}, \qquad L_{\mathsf{new}} = Lm\gamma^{-2}.$$

and (5.3.140) by

$$Ch^{1-d}\vartheta\big(\frac{h}{Lm}\big)\int_{\{\gamma(x)\le 2\bar\gamma\}} \gamma^{d-2}\,dx \le Ch^{1-d}m^{d-2+r-s}\vartheta\big(\frac{h}{L}\big) \tag{5.3.142}$$

as $d \ge 2$ [26)].

(iii) Finally, in the asymptotics without spatial mollification we need to check again if $m \ge h^{\frac12}$ and then take

$$\gamma = \epsilon|V^*| + \bar\gamma_0, \qquad \rho = \gamma^{\frac12}, \qquad \bar\gamma_0 = h^{\frac23}, \qquad h_{\mathsf{new}} = h\gamma^{-\frac32}, \qquad L_{\mathsf{new}} = L\gamma^{-1}$$

after the first rescaling; to derive these relations in the original coordinates one needs the same replacement as in (ii) thus arriving to

$$\gamma = \epsilon m^{-1}|V^2 - m^2| + \bar\gamma_0, \qquad \rho = \gamma^{\frac12}m^{\frac12}, \qquad \bar\gamma_0 = h^{\frac23}m^{-\frac13}, \tag{5.3.143}$$
$$h_{\mathsf{new}} = h\gamma^{-\frac32}m^{-\frac12}, \qquad L_{\mathsf{new}} = L\gamma^{-1}$$

[26)] It was proven that for $d = 2$ for Schrödinger operator there is no logarithmic factor.

[27)] Case $d = 1$ needs to be reexamined anyway.

and deriving estimate

$$|\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}| \le Ch^{1-d}\gamma^{\frac{1}{2}(d-3)}\vartheta\Big(\frac{h}{L\gamma^{\frac{1}{2}}m^{\frac{1}{2}}}\Big) \le Ch^{1-d}|V^2-m^2|^{\frac{1}{2}(d-3-s)}m^{-\frac{1}{2}(d-3)}\vartheta\Big(\frac{h}{L}\Big). \tag{5.3.144}$$

Let us recall that there is also zone $\{\gamma \le 2\bar\gamma_0\}$ but in this zone $h_{\mathsf{new}} \asymp 1$ and one can prove easily that contribution of this zone to the remainder does not exceed the estimate we derived for the first zone as $\bar\gamma_0 = \bar\gamma$ and for the second zone as $\bar\gamma_0 \le \bar\gamma$ (the second statement was actually proven as $m \ge \epsilon_0$.

Thus we arrive to

Theorem 5.3.32. *Let conditions* (5.3.71)–(5.3.71), $(5.3.77)_{1-7}$, (5.3.78), (5.3.123), (5.3.128) *and* (4.2.73)–(4.2.75) *be fulfilled.*

(i) Moreover let $d \ge 2$ *and* (5.3.129) *be fulfilled. Then* $|\mathsf{R}^{\mathsf{W}}_{\varphi,L}|$ *does not exceed* (5.3.134) *with* $\bar\gamma = \mathsf{max}(m^{\frac{1}{2}}, h^{\frac{1}{3}})$.

(ii) In the general case $d \ge 2$ $|\mathsf{R}^{\mathsf{W}}_{\varphi,L}|$ *does not exceed* (5.3.136) *with* $\bar\gamma = \mathsf{max}(m, h^{\frac{1}{2}})$. *In particular,* $|\mathsf{R}^{\mathsf{W}}| \le Ch^{1-d}$ *as* $d \ge 2$.

(iii) $\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}$ *satisfies* (5.3.137) *as* $|V(x)^2-m^2| \ge \bar\gamma^2$ *and* (5.3.144) *as* $m \ge h^{\frac{1}{2}}$, $m^2 \ge |V(x)^2-m^2| \ge h^{\frac{2}{3}}m^{\frac{2}{3}}$. *Furthermore*

$$|\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}| \le Ch^{\frac{1}{2}(1-d-s)}\vartheta\Big(\frac{h}{L}\Big) \tag{5.3.145}$$

as $m + |V(x)| \le h^{\frac{1}{2}}$, *and*

$$|\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}| \le Ch^{\frac{1}{3}(-2d-s)}m^{-\frac{1}{6}(d-3+2s)}\vartheta\Big(\frac{h}{L}\Big) \tag{5.3.146}$$

as $m \ge h^{\frac{1}{2}}$, $|V(x)^2-m^2| \le h^{\frac{2}{3}}m^{\frac{2}{3}}$.

Remark 5.3.33. We did not formulate Theorem 5.3.32(i) as $d = 1$ only because as we know contribution of zone $\{\gamma(x) \le cm^{\frac{1}{2}}\}$ is not necessarily estimated by $C\vartheta(h/L)$.

Further Improvements

Now our goal is to improve Theorem 5.3.32(i) especially as $d = 1$, $s = 0$.

Theorem 5.3.34. *Let conditions* (5.3.71)–(5.3.71), $(5.3.77)_{1-7}$, (5.3.78), *and* (5.3.123), (5.3.128), (5.3.129) *and* (4.2.73)–(4.2.75) *be fulfilled. Then*

(i) Estimate $|\mathsf{R}^{\mathsf{W}}_{\varphi,L}| \le Ch^{1-d}\vartheta(h/L)$ *holds as* $2d > s+2$.

(ii) Estimate

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L}| \le Ch^{1-d}\vartheta\Big(\frac{h}{L}\Big)\,|\log(h+m)| \tag{5.3.147}$$

holds as $2d = s+2$, $d \ge 2$.

(iii) Estimate

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L}| \le C\vartheta\Big(\frac{h}{L}\Big)\,|\log(h+m)|^{n-1} \tag{5.3.148}$$

holds as $d = 1$, $s = 0$ *and and both functions* $V \pm m$ *satisfy non-degeneracy condition* $(5.2.100)_n$.

(iv) Estimate

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L}| \le C\vartheta\Big(\frac{h}{L}\Big)h^{-\delta} \tag{5.3.149}$$

holds as $d = 1$, $s = 0$.

(v) Estimate

$$|\mathsf{R}^{\mathsf{W}}_{\varphi,L}| \le Ch^{1-d}\vartheta\Big(\frac{h}{L}\Big)\big(\max(h^2, m^3)\big)^{\frac{1}{6}(2d-2-s)} \tag{5.3.150}$$

holds as $2d < s+2$.

Proof. Let us introduce scaling functions

$$\gamma_n(x) = \epsilon\Big(\sum_{\alpha:|\alpha|\le n-1} |\nabla^\alpha V|^{\frac{n}{(n-|\alpha|)}}\Big)^{\frac{1}{n}} + \bar\gamma_n, \qquad \rho_n = \gamma_n^n, \tag{5.3.151}$$

$$\bar\gamma_n = \max\big(h^{\frac{1}{n+1}}, m^{\frac{1}{n}}\big).$$

(i) Assume that under assumption $\gamma_n \asymp 1$ Statement (i) is proven. This is the case as $n = 2$ because then the microhyperbolicity condition holds as $m \le \epsilon$ and as $m \ge \epsilon$ we are in the framework of the previous Subsubsection 5.3.2.4 *Asymptotics for* $m \le c_0$.

Let us consider ball $B(x, \gamma_n(x))$ with $\gamma_n(x) \ge C_0\bar{\gamma}_n$. Rescaling it to $B(0,1)$ and simultaneously multiplying operator by ρ_n^{-1} we find ourselves in the framework of $\gamma_n \asymp 1$ with $h \mapsto h\rho_n^{-1}\gamma_n^{-1}$, $L \mapsto L\rho_n^{-1}$ and therefore the contribution of such ball to $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ does not exceed

$$C\big(\frac{h}{\rho_n\gamma_n}\big)^{1-d}\vartheta\big(\frac{h}{L\gamma_n}\big) \le Ch^{1-d}\rho_n^{d-1}\gamma_n^{d-1-s}\vartheta\big(\frac{h}{L}\big);$$

then the total contribution of all such balls does not exceed

$$Ch^{1-d}\vartheta\big(\frac{h}{L}\big)\int \rho_n^{d-1}\gamma_n^{-1-s}\,dx = Ch^{1-d}\vartheta\big(\frac{h}{L}\big)\int \gamma_n^{(d-1)n-1-s}\,dx. \tag{5.3.152}$$

Meanwhile as $m \ge h^{n/(n+1)}$ consider $B(x, \gamma_n(x))$ with $\gamma_n(x) \asymp \bar{\gamma}_n \asymp m^{1/n}$; rescaling as before we arrive to $m \asymp 1$ and $h \mapsto h\bar{\rho}_n^{-1}\bar{\gamma}_n^{-1}$, $L \mapsto L\bar{\rho}_n^{-1}$. Applying results of the previous Subsubsection we conclude that the contribution of such ball to the remainder does not exceed the same expression as before and again the contribution of all such balls does not exceed

$$Ch^{1-d}\bar{\gamma}_n^{(d-1)n-s-1}\vartheta\big(\frac{h}{L}\big)\,\mathsf{mes}(\{\gamma(x) \le \bar{\gamma}_n\}). \tag{5.3.153}$$

Finally, as $m \le h^{n/(n+1)}$ consider $B(x, \gamma_n(x))$ with $\gamma_n(x) \asymp \bar{\gamma}_n \asymp h^{1/(n+1)}$; rescaling as before we arrive to $m \le 1$ and $h \mapsto 1$ and again estimate (5.3.153) is achieved.

Note that as $(d-1)n > s$ under condition that $\gamma_{n+1} \asymp 1$ an integral in the right-hand expression of (5.3.152) converges and we estimate the right-hand expression of (5.3.152) by $Ch^{1-d}\vartheta(h/L)$. In this case $\mathsf{mes}(\{\gamma(x) \le \bar{\gamma}_n\}) \lesssim \bar{\gamma}_n$ and we estimate (5.3.153) by $Ch^{1-d}\vartheta(h/L)$ as well.

So, we made the step of induction. This inequality $(d-1)n > s$ is fulfilled for $n \ge 3$ provided it is fulfilled for $n = 2$ and $d \ge 2$. So, everything works well and as $(d-1)n \ge s+1$ integrand in (5.3.152) is bounded and we do not even need assumption $\gamma_{n+1} \asymp 1$ to get the proper estimate.

Statement (i) is proven.

(ii)–(iv) As $d = s + 1$ integral in (5.3.152) is logarithmically diverging for $n = 2$ only as $d \ge 2$ and for every n as $d = 1$, $s = 0$; furthermore as $d \ge 2$ for large enough n this integral converges even without condition $\gamma_{n+1} \asymp 1$ and thus Statements (ii) and (iii) are also proven.

On the other hand, as $d = 1$ dropping condition $\gamma_{n+1} \asymp 1$ leads to an extra factor $\bar{\gamma}_n^{-1} \le h^{-\delta}$ with $\delta = 1/(n+1)$. This proves Statement (iv).

Surely, one needs to consider also contribution of the zone $\{\gamma_n \asymp \bar{\gamma}_n\}$; as $m \ge h^{n/(n+1)}$ we get (5.3.153) as $d \ge 2$, or as $d = 1$ and non-degeneracy condition is fulfilled and we get

$$C\bar{\gamma}_n^{-1}\bigl(\frac{h}{\bar{\gamma}_n^{n+1}}\bigr)^{-\delta}\vartheta\bigl(\frac{h}{L}\bigr)$$

as $d = 1$ and we assume no non-degeneracy condition.

Finally, as $m \le h^{n/(n+1)}$ the analysis of zone $\{\gamma_n \asymp \bar{\gamma}_n\}$ is also trivial. So, Statements (ii)–(iv) are proven completely.

(v) As $d < s + 1$, $n = 2$ expression (5.3.152) has the same magnitude as (5.3.153) which is exactly the right-hand expression of (5.3.150). So, as $\gamma_3 \asymp 1$ estimate (5.3.150) is proven even for $d = 1$. Let us scale the right-hand expression of (5.3.150): i. e. plug $m \mapsto m\gamma^{-n}$, $h \mapsto h\gamma^{-(n+1)}$ and multiply by γ^{-d}; we get

$$C\bigl(h\gamma^{-n-1}\bigr)^{1-d}\gamma^{-d}\vartheta\bigl(\frac{h}{L\gamma}\bigr)\bigl(\max\bigl(h^2\gamma^{-2(n+1)}, m^3\gamma^{-3n}\bigr)\bigr)^{\frac{1}{6}(2d-2-s)} \le$$
$$Ch^{1-d}\gamma^{-1+\frac{1}{3}(d+s-1)(n-2)}\vartheta\bigl(\frac{h}{L}\bigr)\bigl(\max\bigl(h^2, m^3\gamma^{-n-2}\bigr)\bigr)^{\frac{1}{6}(2d-2-s)}$$

and then integrating with respect to dx we get the same right-hand expression of (5.3.150) provided either $\gamma_{n+1} \asymp 1$ or n is large enough. This takes care of Statement (v). □

Let us improve Statement (iii) of Theorem 5.3.34:

Theorem 5.3.35. *Let $d = 1$ and conditions* (5.3.71)–(5.3.71)$'$, $(5.3.77)_{1-7}$, (5.3.78)$'$, *and* (5.3.123), (5.3.128) (4.2.73)–(4.2.75) *be fulfilled.*

Furthermore, let both $V \pm m$ satisfy non-degeneracy condition $(5.2.100)_n$. *Then estimate $|\mathsf{R}^{\mathsf{W}}| \le C$ holds.*

Proof. Let us repeat the proof of the previous theorem and treat the behavior of the Hamiltonian trajectories in the zone $\{\rho \ge C_0 m\}$ (the only zone which yields the logarithmic factor)[28)].

Note that on each step of induction $\gamma(x) \asymp \varepsilon + |x_1 - \hat{x}_1|$ with $\varepsilon \ge 0$ where without any loss of the generality one can assume that $\hat{x}_1 = 0$. Then on each step of the induction a logarithmic factor appears only due to the zone $\{|x_1| \ge C_0 \bar{\gamma}_n\}$ with $\bar{\gamma}_n$ increased to

$$\bar{\gamma}_n := \mathsf{max}\big(\varepsilon, m^{\frac{1}{n}}, h^{\frac{1}{n+1}}\big) \tag{5.3.154}$$

and an arbitrarily large constant C_0. But in this zone one should not apply the induction assumption but only the microhyperbolic theorem; so the power of logarithm in the right-hand expression of (5.3.148) is always 1.

Moreover, let us note that after rescaling $t_{\mathsf{new}} = t\gamma^{-1}$ and therefore the only term to be treated is

$$\int_{\{|x_1|\ge C_0\bar{\gamma}_n\}} \frac{1}{T(x_1)}\, dx_1 \tag{5.3.155}$$

and a logarithmic factor appears if we take $T = \epsilon_0\gamma$. Here on the energy level 0

$$\xi_1 = \pm\big(V^2 - m^2\big)^{\frac{1}{2}}. \tag{5.3.156}$$

Let us consider the trajectory of the Hamiltonian system (after ξ_1 is excluded)

$$\frac{dx_1}{dt} = \pm\frac{\big(V^2 - m^2\big)^{\frac{1}{2}}}{V} \tag{5.3.157}$$

starting from the point $\bar{x}_1$ in the time direction in which $|x_1|$ increases.

Then the time until x_1 remains in $\{|x_1| \le \epsilon_0\}$ is disjoint from 0 and one can see easily that in this time interval $|x_1(t)| \asymp |x_1(0)| + |t|$ because as $|x_1|$ increases $|V(x)|$ also increases and stays larger than $2m$.

Then non-periodicity condition is fulfilled trivially. Further, one can prove easily that

$$|\mathfrak{d}x_1(t)| \le C|\mathfrak{d}x_1(0)| + C(|x_1(0)| + |t|)^r |x_1(0)|^{-r-n+1}|\mathfrak{d}\tau|$$

with large enough r and so in order to fulfill condition on the Jacobi matrix we should take $T(x_1) = \epsilon_1 \min(1, |x_1|^{1+\delta}\bar{\gamma}_n^{-\delta})$ with sufficiently small exponent $\delta > 0$; we replaced here $x_1(0)$ by x_1. But then integral (5.3.155) is bounded.□

[28)] Surely, these trajectories coincide geometrically with the trajectories of the Schrödinger operator (depending on the energy level) but dynamically there is an essential difference.

Sharp Remainder Estimates

Now our goal is to derive sharp spectral asymptotics. Let us first formulate them in microhyperbolic case; the following statement is due to Section 4.4:

Theorem 5.3.36. *Let conditions of Corollary 5.3.30 be fulfilled.*

Further, let $\Lambda_j^{\pm}$ *be closed subsets of* $\Sigma^{\pm}$ *and suppose that through every point of* $\Lambda_j^{\pm}$ *there passes a Hamiltonian trajectory generated by* $J_{\pm}^{-1}\lambda_{\pm}$ *with* $t \in \mathcal{J}_j$, $\mathcal{J}_j = [0, T_j]$ *or* $\mathcal{J}_j = [-T_j, 0]$, $T_j \in [1, h^{-\delta'}]$ *in the* $h^{\frac{1}{2}-\delta}$*-neighborhood for which conditions* $(5.3.122)_{1-7}$, (2.4.29), (5.3.14) *are fulfilled and*

$$(m+W)^2 + g^{jk}(\xi_j - V_j)(\xi_k - V_k) \ge \epsilon_1 h^{2\delta'}. \tag{5.3.158}$$

(i) Moreover, let microhyperbolicity condition (5.3.126)-(5.3.127) *be fulfilled and along trajectories non-periodicity condition* (5.3.15) *be fulfilled.*

Then estimate

$$|\operatorname{tr}(\mathsf{R}^{\mathsf{W}}_{\varphi,L})| \le C\Big(\sum_{0\le j\le n} \frac{h^{1-d}}{T_j^{1+s}} \int_{\Lambda_j} d\mu + C' h^{1-d+\delta''}\Big)\vartheta\big(\frac{h}{L}\big) \tag{5.3.159}$$

holds with $\Lambda_j = \Lambda_j^+ \cup \Lambda_j^-$, $d\mu := J dx d\xi : d\lambda_{\pm}$ *on* $\Sigma^{\pm}$.

(ii) Moreover, let microhyperbolicity condition (5.3.125) *be fulfilled and along trajectories non-looping condition*

$$\operatorname{dist}\big(x(t), x\big) \ge \epsilon |t| h^{\frac{1}{2}-\delta} \tag{5.3.160}$$

be fulfilled.

Then estimate (5.3.159) *holds with* $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$, Λ_j *and* $d\mu$ *replaced by* $\mathsf{R}^{\mathsf{W}}_{x,\varphi,L}$, Λ_{xj}, $d\mu_x = J d\xi : d\lambda_{\pm}$ *respectively.*

Remark 5.3.37. (i) Here condition (5.3.158) prevents eigenvalues $\lambda_{\pm}(x,\xi)$ from meeting one another. One can see easily that with $\mu_x = dx : d\lambda$

$$\mu_x(\{|\xi - \boldsymbol{V}(x)|_g \le \varepsilon\}) \le C(m + W(x) + \varepsilon)\varepsilon^{d-2} \tag{5.3.161}$$

where $|.|_g$ is associated with matrix g^{jk} and $\boldsymbol{V} = (V_1, \dots, V_d)$.

(ii) Further, $J_+ \asymp J_-$ and we can skip index here.

(iii) We took the trace to avoid dealing with matrices.

Proposition 5.3.38. *Let $W = 0$ and $d \geq 2$ and suppose the condition*

$$\sum_{j,k} g^{jk}\eta_j\eta_k \geq h^{\delta''}|\eta|^2 \qquad \forall \eta \in \mathbb{R}^d \tag{5.3.162}$$

holds along trajectories. Then in Theorem 5.3.36(i) one can drop condition (5.3.158).

Proof. It is sufficient to prove that $\mu(\mathcal{Z}) \leq Ch^{\delta''}$ with small exponent $\delta'' > 0$. Here $\mathcal{Z}$ is the set of all points $(x,\xi) \in \Lambda$ (we skip index j for the sake of simplicity) such that (5.3.158) is violated somewhere along trajectory.

Let us first note that because of (5.3.161) this estimate holds for the measure of the set of all points of $\Sigma^{\pm} \subset T^*B(0,1)$ at which $|V(x)| \leq \rho_1 := h^{\delta''}$. Hence we should consider points in which $|V(x)| \geq h^{\delta_1}$ and therefore condition (5.3.158) holds but is violated somewhere along the trajectory. Let $\mathcal{Z}'$ be the set of these points. Without any loss of the generality we can assume that $T \leq h^{-\delta_1}$ and all inequalities along trajectories are fulfilled with δ_1 instead of δ'; so δ' which is arbitrarily small but much larger than δ_j is invoked only in definition of $\mathcal{Z}$.

Let X' be the union of x-projections of all the Hamiltonian trajectories of length not exceeding T passing through $\mathcal{Z}'$. Then every such trajectory intersects $\mathcal{Y}_1$ where

$$\mathcal{Y}_\nu = \{(x,\xi) \in \Sigma, 2^{-\nu}\rho \leq |V| \leq 2^{\nu}\rho\}, \quad \rho = h^{\delta'}$$

and one can assume that $m \leq \frac{1}{8}\rho$. Along these trajectories

$$|\frac{dz}{dt}| \leq c_1 h^{-\delta_2}; \tag{5.3.163}$$

hence $\mathcal{X}' \subset B(0, h^{-\delta_3})$ and the trajectory intersecting $\mathcal{Y}_1$ belongs to $\mathcal{Y}_2$ in a time interval of length $t_0 = h^{\delta_4}\rho$. Hence due to ability to select invariant measure equivalent to μ

$$\mu(\mathcal{Z}') \leq \frac{T}{t_0}\mu(\mathcal{Y}_2) \leq C'h^{-\delta_5}\rho^{d-2}\,\mathsf{mes}(\{x \in X', |V| \leq 4\rho\}) \leq C'h^{-\delta_6}\rho^{d-2}$$

because $\mu(\mathcal{Y}_2) \leq C\rho^{d-1}h^{-\delta_5}$ due to (5.3.161), (5.3.162) and $T \leq h^{-\delta_1}$. Then for $d \geq 3$ we obtain the estimate in question as $\delta' > 2\delta_6$.

For $d = 2$ a more sophisticated analysis is necessary. Let

$$\mathcal{Y}'_\nu = \{z \in \mathcal{Y}_\nu, |\nabla V| \le 2^\nu \rho_1\}, \qquad \mathcal{Y}''_\nu = \{z \in \mathcal{Y}_\nu, |\nabla V| \ge 2^{-\nu}\rho_1\}.$$

with small enough $\delta_1 > 0$.

Then the previous arguments are applicable to $\mathcal{Y}'_\nu$, $t'_0 = h^{\delta_4}\rho\rho_1^{-1}$, $\mathcal{Y}''_\nu$ and $t''_0 = h^{\delta_4}\rho$ and hence

$$\mu(\mathcal{Z}') \le C'h^{-\delta_5}\rho^{d-2}\Big(\rho_1 \operatorname{mes}(\{x \in X', |V| \le 4\rho\}) + \operatorname{mes}(\{x \in X', |V| \le 4\rho, |\nabla V| \ge \rho_1\})\Big) \le C'h^{-\delta_6}\rho^{d-\frac{3}{2}}$$

where we estimated the second measure by $Ch^{-\delta_5}\rho\rho_1^{-1}$ and picked up $\rho_1 = \rho^{\frac{1}{2}}$.□

Theorem 5.3.39. *Let conditions of Corollary 5.3.30 be fulfilled.*

Moreover, let $\Lambda_1^\pm, \dots, \Lambda_n^\pm$ *be closed subsets of* $\Sigma^\pm = \{(x,\xi) : \lambda_\pm = 0\}$ *where* $\lambda_\pm$ *are given by* (5.3.83)*,*

$$\Lambda_j^\pm \subset \{\gamma = |\nabla V| + \min\big(|V|, \frac{|V|^2}{m}\big) \ge h^{\frac{1}{2}-\delta}\}$$

and through every point of $\Lambda_j^\pm$ *there passes a Hamiltonian trajectory generated by* $J_\pm^{-1}\lambda_\pm$ *with* $t \in \mathcal{J}_j$, $\mathcal{J}_= [0, T_j]$ *or* $\mathcal{J}_= [-T_j, 0]$, $T_j \in [1, h^{-\delta'}]$ *in the* $h^{\frac{1}{2}-\delta}$*-neighborhood for which conditions* $(5.3.122)_{1-5}$ *and conditions* (2.4.29), (5.3.14), (5.3.15) *are fulfilled. Further, let* (5.2.101) *with* $s \ge 0$ *be fulfilled.*

(i) Let <u>*either*</u> $d > s + 2$ <u>*or*</u> $V_j = 0$ *and* $2d > s + 2$*. Then estimate* (5.3.16) *with* $\Lambda_j = \Lambda_j^+ \cup \Lambda_j^-$, $da = d\lambda_\pm$ *at* $\Sigma^\pm$ *remains true.*

(ii) Let $d = 2$, $s = 0$*. Then estimate* (5.3.26) *holds where the notation of Theorem 5.3.3 is used.*

Proof. Proof of Statement (i) is trivial. Let us prove Statement (ii). We need to consider only balls of radius $\gamma_1 = h^{\frac{1}{2}-\delta}$ in which

$$(5.3.164)_{1,2,3} \qquad |V| \le c_0 h^{\frac{1}{2}-\delta'}, \quad |\nabla V| \le c_0 h^{\frac{1}{2}-\delta'}, \quad m \le c_0 h^{\frac{1}{2}-\frac{1}{4}\delta'};$$

the last condition follows from the fact that $\gamma \ge \epsilon_0 m$ in this proof. Let us consider various cases:

(a) If $|F_{12}(x')| = \mu \ge h^{\frac{1}{4}\delta'}$ and $v = |V(x')| \le \mu\gamma_1$ then $|F_{12}| \asymp \mu$ and $|V| \le c\mu\gamma_1$ in the ball $B(x', \gamma_1)$. Let us change variables $x_{\mathsf{new}} = x\gamma_1^{-1}$, divide A by $\mu\gamma_1$ and set $h_{\mathsf{new}} = h(\mu\gamma_1^2)^{-1}$, $m_{\mathsf{new}} = m(\mu\gamma_1)^{-1}$; then we remain in the framework of our theorem and the same arguments as in the proof of Theorem 5.3.25 yield that the contribution of this ball to the remainder does not exceed

$$C\gamma_1^2\mu h^{-1} + C''\gamma_1^2 h^{\delta''-1} + C''h^r.$$

(b) Let $|F_{12}(x')| = \mu \ge h^{\frac{1}{4}\delta'}$ and $v = |V(x')| \ge \mu\gamma_1$. Let us change variables $x_{\mathsf{new}} = x\gamma_1^{-1}$, divide A by v and set $h_{\mathsf{new}} = h(v\gamma_1)^{-1}$, $m_{\mathsf{new}} = mv^{-1}$; then we remain in the framework of this theorem and the microhyperbolicity condition is fulfilled; applying Theorem 5.3.25 we obtain that the contribution of this ball to the remainder does not exceed

$$C\gamma_1 vh^{-1} + C'\gamma_1^2 h^{\delta''-1} + C''h^r.$$

(c) If $|F_{12}(x')| \le \mu = h^{\frac{1}{2}\delta'}$ then the analysis of Parts (a) and (b) is applicable for $v = |V(x')| \le \mu\gamma_1$ and $v = |V(x')| \ge \mu\gamma_1$ respectively and we obtain that the estimate of (b) remains true.

Calculating the total contribution of all balls of this type we obtain (5.3.26). □

Remark 5.3.40. Thus again we can easily derive asymptotics with the remainder estimate $o\big(h^{1-d}\vartheta(h/L)\big)$ under assumption that the set of all periodic trajectories has measure 0; as $m = 0$ we should consider only trajectories which do not hit

$$\Theta_\tau = \{(x,\xi) :\ \xi_1 - V_1(x) = ... = \xi_d - V_d(x) = 0, V(x) = \tau\}.$$

As $d = 2$ we need an extra condition

$$\mathsf{mes}(\{x : V(x) = \pm m, |F(x)| > 0\}) = 0. \tag{5.3.165}$$

Remark 5.3.41. (i) Similar results could be proven for asymptotics without spatial mollification; however in this case we cannot get rid of condition (5.3.158) along trajectories but one could check that actual assumption should be with δ' replaced by $\frac{1}{2} - \delta'$.

(ii) It would be rather interesting to improve asymptotics without averaging as $V_1 = ... = V_d = 0$ with addition of correction term, especially in the case of $m = 0$. However condition (5.3.158) seem to be an obstacle.

5.4 Operators with Irregular Coefficients

5.4.1 Preliminary Remarks

Now we consider operators with irregular coefficients (as in Sections 4.6 and 4.7) and for such scalar operators we are going to extend to a certain degree results of the previous sections of this chapter. We consider only asymptotics with the spatial averaging due to the following reason:

Analysis of asymptotics without spatial averaging is much more straightforward and thus simpler. Really, our base points for rescaling procedure used to be results of Sections 4.4 and 4.5 for microhyperbolic and ξ-microhyperbolic operators respectively as we consider asymptotics with or without spatial averaging. However the results Sections 4.6 and 4.7 require ξ-microhyperbolicity and only in the case of ridiculously large roughness parameter[29)] we could derive them under microhyperbolicity condition. So our first goal is to recover these results under microhyperbolicity condition (plus some extra assumptions).

On the other hand, as analysis of Section 5.3 shows, for a Schrödinger operator $h^2|D|^2+V(x)$ exactly points with $V=0$ and $|\nabla V| \asymp 1$ are the main obstacle for pointwise spectral asymptotics. Still, it is not that simple: as this analysis shows the remainder estimate obtained just by rescaling is not necessary optimal even if we consider only asymptotics without correction term. Therefore we formulate the following problem which we consider really challenging, especially its second part:

Problem 5.4.1. (i) Extend results of Subsection 5.3.1 (i.e. only for Schrödinger operator) partially (i.e. without correction term and respectively with the remainder at least of the same magnitude as a correction term) to operators with irregular coefficients.

(ii) Extend results of Subsection 5.3.1 completely (i.e. with correction term) to operators with irregular coefficients.

Recall that our goal are operators with irregular coefficients rather than the "rough" operators which are our main objects of study and we either bracket irregular operators between rough ones but this bracketing has implications only for asymptotics of the number of eigenvalues which will

[29)] $\varepsilon = C(h|\log h|)^{\frac{1}{2}}$ as opposed to $\varepsilon = Ch|\log h|$.

be assembled from (micro)local asymptotics with the spatial averaging or use the method of perturbation as in Sections 4.6 and 4.7 respectively.

Let us discuss in more detail bracketing method. Recall that applying our rescaling technique we have two scaling functions $\gamma(x)$ and $\rho(x)$. However, applying results of Section 4.6 we need to remember about *roughness parameter* ε which becomes a *roughness function* which is (much) smaller than $\gamma(x)$ and usually is defined to satisfy logarithmic uncertainty principle (see (5.4.14)).

Applications: we construct approximations which provide a rather small error in Weyl expressions and also rather small remainder estimate. Further, for semi-bounded operators we can select two approximations of this type $A_\varepsilon^{\pm}$ [30] such that $A_\varepsilon^- \le A \le A_\varepsilon^+$ and thus numbers of negative eigenvalues have opposite order: $\mathsf{N}^-(A_\varepsilon^-) \ge \mathsf{N}^-(A) \ge \mathsf{N}^-(A_\varepsilon^+)$.

For non-semibounded operators we are looking for number of eigenvalues between τ_1 and τ_2 and thus for number of negative eigenvalues of

$$B = \bigl(A - \frac{1}{2}(\tau_2+\tau_1)\bigr)^2 - \frac{2}{4}(\tau_2-\tau_1)^2 \tag{5.4.1}$$

and one can construct two operators $A_\varepsilon^{\pm}$ such that $B_\varepsilon^- \le A \le B_\varepsilon^+$. We will do it when we consider applications (so much later).

5.4.2 Schrödinger Operator

Reminder

We start from the Schrödinger operator as a toy-model but we consider the general one (5.3.1). Our first goal is to replace ξ-microhyperbolicity condition

$$|V(x)| \ge \epsilon_0, \tag{5.4.2}$$

by microhyperbolicity ocondition

$$|V(x)| + |\nabla V(x)| \ge \epsilon_0, \tag{5.4.3}$$

where $V(x)$ is the potential.

Since such condition makes sense only as original operator had at least $\mathscr{C}^1$-coefficients we assume this. In fact we assume that

[30] Where subscript ε means not the actual selection of the parameter function but simply fact that we are talking about approximations

(5.4.4) g^{jk}, V_j, V are $\mathscr{C}^l_\nu$-functions with $t^l \le \nu(t) \le t^{l+1}$, $l = 1, 2, ...$ (see Definition 4.6.1).

Consider operator A_ε with g^{jk}, V_j, V replaced by g^{jk}_ε, $V_{j\varepsilon}$, V_ε which are their ε-mollifications.

Then under condition (5.4.2) we derived asymptotics

$$|\mathsf{R}^{\mathsf{W}}_{x,\varphi,L,\varepsilon}| \le Ch^{1-d}\vartheta\Big(\frac{h}{L}\Big) \tag{5.4.5}$$

and exactly the same estimate for $\mathsf{R}^{\mathsf{W}}_{\varphi,L,\varepsilon}$. Let us recall that approximation error was $Ch^{-d}\nu(\varepsilon)$.

Let us recall that we could take ε pretty small:

$$\varepsilon = Ch|\log h|. \tag{5.4.6}$$

Getting Rid of Condition (5.4.2)

First we consider the case of low smoothness:

(5.4.7) Let $\nu(t)$ be monotone increasing function such that $\nu(0) = 0$

and

$$\nu(t) \ge t, \qquad \frac{d}{dt}(\nu(t)t^{-1}) \le 0 \tag{5.4.8}$$

and also

$$\nu(C_1 t) \ge c_1\nu(t) \quad \forall t \in (0,1) \qquad \text{with} \quad c_1 > 1,\ C_1 > 1. \tag{5.4.9}$$

Here if (5.4.9) holds for some $c_1 > 1$ and $C_1 > 1$ then it holds for every $c_1 > 1$ and $C_1 = C_1(c_1)$.

Then $\gamma(x)$ defined from

$$\nu(\gamma(x)) = \max\big(\epsilon|V(x)|, \nu(\bar\gamma)\big) \tag{5.4.10}$$

satisfies

$$|x-y| \le \epsilon\gamma(x) \implies C^{-1}\gamma(x) \le \gamma(y) \le C\gamma(x) \tag{5.4.11}$$

and thus is a proper scaling function.

Really, $|x-y| \le \epsilon\gamma$ implies $|V(x)-V(y)| \le \nu(\epsilon\gamma)$. Then $|x-y| \le \epsilon\gamma(x)$ implies that $|V(y)-V(x)| \le \epsilon_1 \max(|V(x)|, \nu(\bar\gamma)$ which due to (5.4.9)–(5.4.10) implies that $|\gamma(x)-\gamma(y)| \le \epsilon_2\gamma(x)$.

Further, let

$$\rho(x) = \nu(\gamma(x))^{\frac{1}{2}} \tag{5.4.12}$$

and therefore we should define $\bar{\gamma}$, $\bar{\rho}$ from

$$\bar{\gamma}\nu(\bar{\gamma})^{\frac{1}{2}} = 2h, \qquad \bar{\rho} = \nu(\bar{\gamma})^{\frac{1}{2}}. \tag{5.4.13}$$

Let us consider an element $B(y,\gamma)$ with $\gamma = \gamma(y)$ etc and let us scale $x \mapsto x\gamma^{-1}$, $\xi \mapsto \xi\rho^{-1}$, $h \mapsto h\rho^{-1}\gamma^{-1}$. This also scales $\varepsilon \mapsto \varepsilon\gamma^{-1}$ and we need to satisfy $\varepsilon = Ch|\log h|$ after rescaling; thus we need to pick up

$$\varepsilon = C\frac{h}{\rho}|\log \frac{h}{\rho\gamma}| \tag{5.4.14}$$

Now let us notice that $\nu(t)$ scales as well:

$$\nu_{\mathsf{new}}(t) = \rho^{-2}\nu(\gamma t) = \nu(\gamma)^{-1}\nu(\gamma t) \tag{5.4.15}$$

which satisfies (5.4.7).

We know (see Theorem 4.6.21) that under condition (5.4.2)

$$|\mathsf{R}^{\mathsf{W}}_{x,\varepsilon}| \le Ch^{-d}\nu(\varepsilon); \tag{5.4.16}$$

there $\varepsilon = Ch|\log h|$.

Then (5.4.16) scales to

$$|\mathsf{R}^{\mathsf{W}}_{x,\varepsilon}| \le Ch^{-d}\rho^{d-2}\nu\big(\frac{h}{\rho}|\log \frac{h}{\rho\gamma}|\big)\big|_{\rho=\nu(\gamma)^{\frac{1}{2}}}. \tag{5.4.17}$$

Let us consider the right-hand expression of (5.4.17) as a function of ρ (so $\gamma = \gamma(\rho)$ is defined from $\nu(\gamma) = \rho^2$). As $d \le 2$ it is clearly monotone decreasing and therefore it does not exceed its value as $\rho = \bar{\rho}$ which is

$$|\mathsf{R}^{\mathsf{W}}_{x,\varepsilon}| \le Ch^{-d}\nu\big(\bar{\gamma}\big)^{\frac{1}{2}d} \asymp C\bar{\gamma}^{-d}. \tag{5.4.18}$$

On the other hand, the right-hand expression of (5.4.17) does not exceed $Ch^{-d}\rho^{d-2}\nu\big(h\rho^{-1}|\log h|\big)$ which for $d \ge 3$ is a monotone increasing function of ρ due to (5.4.8) and therefore the right-hand expression of (5.4.17) does not exceed its value as $\rho = 1$.

Thus we arrive to

Theorem 5.4.2. *Let* (5.4.7)–(5.4.9) *be fulfilled and let us drop condition* (5.4.2). *Then for described above operator* A_ε *estimate* (5.4.17) *holds.*

In particular, as $d \ge 3$ *estimate* $|\mathsf{R}^{\mathsf{W}}_{x,\varepsilon}| \le Ch^{-d}\nu(h|\log h|)$ *still holds and as* $d = 1, 2$ *estimate* $|\mathsf{R}^{\mathsf{W}}_{x,\varepsilon}| \le C\bar\gamma^{-d}$ *holds with* $\bar\gamma$ *defined from* (5.4.13).

Remark 5.4.3. We conclude immediately that in the framework of Theorem 5.4.2 for ψ with compact support[31)].

(i) As $d \ge 3$ estimate (5.4.16) holds for $\mathsf{R}^{\mathsf{W}}_\varepsilon$ with $\varepsilon = Ch|\log h|$;

(ii) As $d = 1, 2$ estimate

$$|\mathsf{R}^{\mathsf{W}}_\varepsilon| \le c\bar\gamma^{-d} \tag{5.4.19}$$

holds with $\bar\gamma$ defined by (5.4.13).

(iii) One can easily improve (5.4.19) under assumption $\mathsf{mes}(Z(t)) \le \sigma(t)$ where $Z(t) = \{x : |V(x)| \le t\}$;

(iv) So far the same estimates hold for bracketing-approximation errors (actually estimates for $|\mathsf{R}^{\mathsf{W}}_\varepsilon|$, $|\mathsf{R}^{\mathsf{W}}_{x,\varepsilon}|$ are marginally better). Indeed, we take $A^\pm_\varepsilon = A_\varepsilon + C_0\nu(\varepsilon)$. Thus we got estimates for the combined error.

(v) Due to low smoothness we did not apply results of Section 4.7.

Example 5.4.4. Let $\nu(t) = t^r|\log t|^\sigma$ where

$$r \in [0, 1], \qquad r = 0 \implies \sigma < 0, \qquad r = 1 \implies \sigma \ge 0. \tag{5.4.20}$$

Then

(i) If either (5.4.2) is fulfilled or $d \ge 3$ then

$$|\mathsf{R}^{\mathsf{W}}_\varepsilon| \le Ch^{-d+r}|\log h|^{r+\sigma}; \tag{5.4.21}$$

(ii) If $d = 1, 2$ and (5.4.2) fails then

$$|\mathsf{R}^{\mathsf{W}}_\varepsilon| \le Ch^{-\frac{2d}{r+2}}|\log h|^{\frac{\sigma d}{r+2}}. \tag{5.4.22}$$

We leave to the reader

Problem 5.4.5. Generalize these results to the spectral means averages.

[31)] One can easily get rid of this assumption and take $\psi = 1$ in $\mathbb{R}^d$ provided $\{x : V(x) \le \epsilon_0\}$ is compact.

From Condition (5.4.2) to Condition (5.4.3)

Now we change our assumptions: in addition to (5.4.7) we assume that and

$$\nu(t)\le t,\qquad \frac{d}{dt}(\nu(t)t^{-1})\ge 0,\qquad \nu(t)t^{-1}\to 0 \quad \text{as} \quad t\to +0. \tag{5.4.23}$$

Let us recall that then under condition (5.4.2) $|\mathsf{R}^{\mathsf{W}}_{x,\varepsilon}|\le Ch^{1-d}$ and we are not talking about approximation error now.

Then we can introduce scaling functions as they were introduced in the smooth case when we wanted to get rid of condition (5.4.2):

$$\gamma(x):=\epsilon\,\mathsf{max}(|V(x)|,\bar\gamma),\qquad \rho(x):=\gamma(x)^{\frac12},\qquad \bar\gamma=C_1h^{\frac23} \tag{5.4.24}$$

(which coincides with the definition of the previous subsubsection as $\nu(t)=t$) and rescale as we used to; then $h\mapsto h_{\mathsf{new}}=h\rho^{-1}\gamma^{-1}$ and $\varepsilon\mapsto\varepsilon\gamma^{-1}$; we define ε by (5.4.14). Then after rescaling $\nu_{\mathsf{new}}(t)$ satisfies $\nu_{\mathsf{new}}(t)\le t$.

Then remainder estimate scales to

$$|\mathsf{R}^{\mathsf{W}}_{x,s,\varepsilon}|\le C(h/\rho\gamma)^{1-d+s}\gamma^{-d}\times\rho^{2s}=Ch^{1-d+s}\rho^{d-1+s}\gamma^{-1-s}= Ch^{1-d+s}\gamma^{\frac12(d-s-3)} \tag{5.4.25}$$

because $\rho^2=\gamma$ and $\mathsf{R}^{\mathsf{W}}_{x,s,\varepsilon}$ is a spectral averaging with $\varphi(\tau)=\tau_+^s$, $s\ge 0$ (in particular, $\mathsf{R}^{\mathsf{W}}_{x,0,\varepsilon}=\mathsf{R}^{\mathsf{W}}_{x,\varepsilon}$). So far all as it used to be in the smooth case when we study local spectral asymptotics without averaging.

Therefore

$$|\mathsf{R}^{\mathsf{W}}_{x,s,\varepsilon}|\le Ch^{1-d+s}\int \gamma^{\frac12(d-s-3)}\,dx \tag{5.4.26}$$

and now condition (5.4.3) changes the rules of the game:

Proposition 5.4.6. *For Schrödinger operator under conditions* (5.4.3), (5.4.7) *and* (5.4.23)

$$|\mathsf{R}^{\mathsf{W}}_{x,s,\varepsilon}|\le C\begin{cases} h^{1-d+s} & \text{as}\quad d>s+1,\\ h^{1-d+s}|\log h| & \text{as}\quad d=s+1,\\ h^{\frac23(-d+s+1)} & \text{as}\quad d<s+1.\end{cases} \tag{5.4.27}$$

So, a proper remainder estimate is recovered for $d > s+1$; while for $d = s+1$ logarithmic factor appears. Meanwhile due to (5.4.3) bracketing-approximation error does not exceed

$$Ch^{-d}\int \rho^{d-2+2s}\nu(\varepsilon(\rho))\,dx \asymp Ch^{-d}\int \rho^{d-1+2s}\nu(\varepsilon(\rho))\,d\rho. \tag{5.4.28}$$

Therefore

Theorem 5.4.7. *Let conditions* (5.4.3), (5.4.7) *and* (5.4.23) *be fulfilled. Then for appropriate bracketing operators* $A_\varepsilon^{\pm}$ [30] ($A_\varepsilon^+ \ge A \ge A_\varepsilon^-$) *the combined Weyl and bracketing-approximation error does not exceed* (5.4.27) + (5.4.28) [32] *with* $\varepsilon(\rho) = C\rho^{-1}h|\log(h\rho^{-3})$ *and* ρ *running from* $\bar\rho = Ch^{\frac13}$ *to a small constant.*

Remark 5.4.8. (i) (5.4.28) is $O(h^{1-d+s})$ provided <u>either</u> $d+s \ge 2$ and $\nu(t) = t^{s+1}|\log t|^{-s-1}$ <u>or</u> $d=1$, $s=0$ and $\nu(t) = t|\log t|^{-2-\delta}$.

(ii) As $d \le s+1$ we are rather unhappy with Weyl error because in arguments leading to Proposition 5.4.6 no smoothness requirement can produce such remainder $O(h^{1-d+s})$.

Case $d \le s+1$ Reloaded

Now our goal is to improve arguments leading to Theorem 5.4.7 and to prove $|\mathsf{R}^{\mathsf{W}}_{s,\varepsilon}| \le Ch^{1-d}$ as $d \le s+1$ without significantly increasing ε. We need to better estimate the contribution of $B\big(y,\gamma(y)\big)$ to the remainder.

To do so we need to study a long term propagation of wave front sets. For simplicity of notations we assume that $\boldsymbol{V}=0$, $g^{jk}=\delta_{jk}$. Let us introduce

$$\gamma(y) = \epsilon_0|V(y)| + C_0(h|\log h|)^{\frac23}, \qquad \rho(y) = C_0\gamma(x)^{\frac12}, \qquad \varepsilon(y) = Ch|\log h|\rho^{-1}. \tag{5.4.29}$$

Let us consider point y and operator Q with the symbol supported in

$$\{(x,\xi):\ |x-y|\le \epsilon\gamma,\ \pm\langle\xi,\nabla V(y)\rangle \ge -\epsilon\rho\}$$

with γ,ρ calculated at x and sufficiently small constant ϵ.

[32] Here and in what follows (5.4.28) denotes the right-hand expression only.

Then

$$\mathsf{WF}(u_\varepsilon\, {}^{t}Q)\cap\{|\tau|\le \epsilon'\rho^2\}\cap\{C_0\epsilon\gamma^{\frac12}\le \mp t\le \epsilon_0\gamma^{\frac12}\}\subset \tag{5.4.30}$$
$$\{(x,\xi):\ |x-y|\le C\epsilon_0\gamma,\ \pm\langle\xi,\nabla V(y)\rangle\ge C\epsilon\rho,\ \langle x-y,\nabla V(y)\rangle\ge C_0\epsilon^2\gamma\}.$$

Indeed, it follows after rescaling due from standard propagation results. Here t is an "absolute time", after rescaling it is divided by $\gamma^{\frac12}$. Here and below u_ε is the Schwartz kernel of $U_\varepsilon(t)=e^{ih^{-1}tA_\varepsilon}$.

Then one can extend it for larger t:

$$\mathsf{WF}(u_\varepsilon\, {}^{t}Q)\cap\{|\tau|\le \epsilon'\rho^2\}\cap\{T\le \mp t\le 2T\}\subset \tag{5.4.31}$$
$$\{(x,\xi):\ |x-y|\le C\epsilon_0 T^2,\ \pm\langle\xi,\nabla V(y)\rangle\ge \epsilon_1 T,\ \langle x-y,\nabla V(y)\rangle\ge \epsilon_1^2\gamma\}$$

as $\epsilon_0\gamma^{\frac12}\le T\le\epsilon_0$. Indeed, one can prove it easily by recursion $T\mapsto 2T$.

Then, using property of Γ we conclude

(5.4.32) Let ψ be supported in $\{|V(x)|\le\gamma\}$. Then $F_{t\mapsto h^{-1}\tau}\chi_T(t)\Gamma\big(u_\varepsilon\psi\big)$ is negligible for $T_*\le T\le T^*$ with $T_*=\epsilon\gamma^{\frac12}$ and $T^*=\epsilon$, as $|\tau|\le\epsilon'\gamma$.

As usual $\chi\in\mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1])$ and therefore in the Tauberian estimates we can replace $T\asymp\gamma^{\frac12}$ by $T\asymp 1$. This works not only as $\gamma\ge 2C_0(h|\log h|)^{\frac12}$ where we use ξ-microhyperbolicity but also as $\gamma\le 2C_0(h|\log h|)^{\frac12}$ where we use microhyperbolicity (5.4.3) which is possible because there $\varepsilon\asymp\gamma$ and after rescaling $h\mapsto\hbar=C_0^{-1}|\log h|^{-1}$.

So, contribution of $B(x,\gamma(x))$ to $\mathsf{R}^{\mathsf{T}}_{s,\varepsilon}$ does not exceed

$$C\big(\frac{h}{\rho\gamma}\big)^{1-d+s}\times\big(\frac{T_*}{T^*}\big)^{1+s}\times\rho^{2s}\asymp Ch^{1-d+s}\rho^{d-2}\gamma^d \tag{5.4.33}$$

which sums to $Ch^{1-d+s}\int\rho^{d-2}\,dx$ which is does not exceed Ch^{1-d+s} even as $d=1$ in virtue of (5.4.3).

So, in the current framework $|\mathsf{R}^{\mathsf{T}}_{s,\varepsilon}|\le Ch^{1-d+s}$.

Remark 5.4.9. Now we need to pass from Tauberian to Weyl expression and there is a twist: we need to take sufficiently many terms.

(i) If $d=s+1$ there was only logarithmic divergence and we need to take only terms with h^{-d+n} with $0\le n\le s+1$ (the term where logarithmic divergence was because "out of the box" this term does not exceed $C\int\gamma^{-1}\,dx\asymp C|\log h|$ and remainder estimate should be $O(1)$; next term does not exceed $Ch\int\gamma^{-\frac52}\,dx=o(1)$.

(ii) If $d < s+1$ there was a power divergence and we need to take many terms, and only if

$$(5.4.29)^* \quad \gamma(y) = \epsilon_0 |V(y)| + C_0 h^{\frac{2}{3}-\delta}, \qquad \rho(y) = C_0 \gamma(x)^{\frac{1}{2}}, \qquad \varepsilon(y) = Ch|\log h|\rho^{-1}.$$

Recall that the bracketig error is delivered by (5.4.28). Thus we arrive to

Theorem 5.4.10. *Let $d \le s+1$ and conditions* (5.4.3), (5.4.7) *and* (5.4.23) *be fulfilled. Then for appropriate bracketing operators $A_\varepsilon^{\pm}$ [30] ($A_\varepsilon^+ \ge A \ge A_\varepsilon^-$) the combined Weyl and bracketing-approximation error does not exceed*

(i) Ch^{-d+s+1} + (5.4.28) [32] *with ρ running from $\bar\rho = (h|\log h|)^{\frac{1}{3}}$ to a small constant as $d = s+1$.*

(ii) Ch^{-d+s+1} + (5.4.28) + (5.4.34) *with the third term*

$$(5.4.34) \qquad Ch^{-d}\bar\rho^{d+2s}\nu(\bar\varepsilon)$$

and ρ running from $\bar\rho = h^{\frac{1}{3}-\delta}$ to a small constant and and $\bar\varepsilon = \bar\rho^2$ as $d < s+1$.

Example 5.4.11. In the framework of Theorem 5.4.10 let $\nu(t) = t^l|\log t|^{-\sigma}$.

(i) Then the combined error is $O(h^{-d+s+1})$ provided $l = s+1$ and either $d+s > 1$, $\sigma = s+1$ or $= 1$, $s = 0$, $\sigma = 2$. Recall that $l = s+1$, $\sigma = -1$ needed for this remainder estimate to work under condition (5.4.2).

(ii) Other cases are left to the reader as well as $\nu(t) = t^l|\log t|^{\sigma}$.

The following problem seems to be challenging, at least Part (ii):

Problem 5.4.12. (i) Prove that in the framework of Theorem 5.4.10 one can preserve in the Weyl expression $\mathsf{N}^{\mathsf{W}}_{s,\varepsilon}$ only terms containing h to the power lesser than $-d+s+1$, and then one can replace Weyl expression for approximation $\mathsf{N}^{\mathsf{W}}_{s,\varepsilon}$ by Weyl expression for the operator itself $\mathsf{N}^{\mathsf{W}}_{s}$. Recall that Weyl coefficients appear first as distributions with respect to τ.

(ii) Prove that Statement (i) of Theorem 5.4.10 holds even as $d < s+1$.

Dropping Condition (5.4.3)

Recall that as $d \ge s+3$ we simply dropped condition (4.5.2) but as $d < s+3$ we traded it to (4.5.3). Now we want to get rid of the latter. So, let $d < s+3$. Let $\nu(t)$ satisfy (5.4.7), (5.4.23) as before and let us replace (5.4.9) by a stronger assumption

$$\nu(C_1 t) \ge C_1 c_1 \nu(t) \quad \forall t \in (0,1) \qquad \text{with } \ c_1 > 1,\ C_1 > 1 \tag{5.4.35}$$

which means exactly that $\nu(t)t^{-1}$ also satisfies (5.4.9). We also assume that

$$t^{-2}\nu(t) \text{ is a monotone decreasing function} \tag{5.4.36}$$

so that we do not assume more smoothness than $\mathscr{C}^2$. Let us introduce γ, ρ by the following formula similar to (5.4.10)

$$\gamma = \max(\gamma', \bar\gamma), \quad \gamma' = \epsilon \min\{t : |V| \le \nu(t), |\nabla V| \le t^{-1}\nu(t)\}, \tag{5.4.37}$$
$$\text{with } \bar\gamma \ \text{ defined from } \ \bar\gamma \nu(\bar\gamma)^{\frac12} = h$$

Then γ is a scaling function i.e. (5.4.11) holds. Indeed, if $|x-y| \le \epsilon\gamma$ then

$$|\nabla V(x) - \nabla V(y)| \le \nu(|x-y|)|x-y|^{-1} \le \epsilon_1 \nu(\gamma)\gamma^{-1}$$

and therefore $|\nabla V(y)| \le 2\nu(\gamma)\gamma^{-1}$. Then

$$|V(x) - V(y)| \le 2\nu(\gamma)\gamma^{-1}|x-y| + \nu(|x-y|) \le \epsilon_1 \nu(\gamma).$$

Combining these two inequalities and using (5.4.9), (5.4.35) we conclude that $\gamma(x)$ satisfies (5.4.11).

Let us define $\rho, \bar\gamma$ by (5.4.12), (5.4.13). Then after our usual rescaling, we obtain an operator satisfying (5.4.3) as $\gamma \ge 2\bar\gamma$. Then h^{-d+s+1} is replaced by $Ch^{-d+s+1}\int \nu(\gamma)^{\frac12(d+s-1)}\gamma^{-s-1}\,dx$ which in the current framework we cannot estimate by anything better than

$$Ch^{-d+s+1} \sup_{\gamma:\gamma\nu(\gamma)^{1/2}\ge h} \nu(\gamma)^{\frac12(d+s-1)}\gamma^{-s-1}. \tag{5.4.38}$$

One can observe easily that in this scaling procedure $h \mapsto h/(\rho\gamma)$, $\nu(\varepsilon) \mapsto \nu(\varepsilon\gamma)/\rho^2$ with $\rho = \nu(\gamma)^{1/2}$ and terms (5.4.28) and (5.4.34) (in the framework of Theorem 5.4.10(ii)) do not increase.

Also one can observe that the contribution of zone $\{\gamma\nu(\gamma)^{1/2} \le C_0 h\}$ does not exceed (5.4.28).

Therefore we arrive to

Theorem 5.4.13. *Let* $d \le s+3$ *and conditions* (5.4.7) *and* (5.4.23), (5.4.35), (5.4.36) *be fulfilled. Then for appropriate bracketing operators* $A_\varepsilon^{\pm}$ [30] ($A_\varepsilon^+ \ge A \ge A_\varepsilon^-$) *the combined Weyl and bracketing-approximation error does not exceed*

(i) (5.4.38) + (5.4.28) [32] *with* ρ *running from* $\bar\rho = (h|\log h|)^{\frac13}$ *to a small constant as* $d = s+1$.

(ii) (5.4.38) + (5.4.28) + (5.4.34) *with* ρ *running from* $\bar\rho = h^{\frac13-\delta}$ *to a small constant and and* $\bar\varepsilon = \bar\rho^2$ *as* $d < s+1$.

Remark 5.4.14. (i) Let $d \ge 2$ and $\nu(\gamma) \le \gamma^l$ with $l = l(s) = 2(s+1)/(d+s-1)$. Then expression (5.4.38) is $\asymeq Ch^{-d+s+1}$). Here $l(s) = 2$ as $d = 2$ and $l(s) < 2$ as $d \ge 3$.

(ii) Let $d = 1$, $l = 2$ expression (5.4.38) is $\asymeq Ch^{-d+s+\frac12}$). Assuming that $\nu(t) = o(t^l)$ and $\nu(t) \ge t^{l+1}$ with $l = 2, 3, \dots$, one can introduce a scaling function

$$(5.4.37)' \quad \gamma = \max(\gamma', \bar\gamma), \quad \gamma' = \epsilon \min\{t : |\nabla^j V| \le t^{-j}\nu(t)\ \forall j = 1, \dots, l\}$$
$$\text{with } \bar\gamma \text{ defined from } \bar\gamma\nu(\bar\gamma)^{\frac12} = h$$

and as $l = 2$ recover remainder estimate $O(1)$ or $O(|\log h|)$ provided V has a single non-degenerate minimum or maximum. One can even recover remainder estimate $O(1)$ if either V has a single non-degenerate minimum or $s > 0$, $\nu(t) = O(t^2|\log t|^{-\sigma}$, $\sigma > 2$. The one can continue as in Subsection 5.2.3.

Sharp Remainder Estimates

So far the best possible combined remainder estimate we derived is $O(h^{-d+1+s})$:

Theorem 5.4.15. *(a) In the framework of Theorem 5.4.7 assume that* $d > s+1$ *and expression* (5.4.28) *is* $O(h^{1-d+s})$.

(b) In the framework of Theorem 5.4.10(i) assume that expression (5.4.28) *is* $O(h^{1-d+s})$.

(c) In the framework of Theorem 5.4.10(ii) assume that expressions (5.4.28) *and* (5.4.34) *are* $O(h^{s+1})$.

(d) In the framework of Theorem 5.4.13(i) assume that expressions (5.4.28) *and* (5.4.38) *are* $O(h^{1-d+s})$.

(e) In the framework of Theorem 5.4.13(ii) assume that expressions (5.4.28), (5.4.34) *and* (5.4.38) *are* $O(h^{1-d+s})$.

Here all terms are calculated in the frameworks of the corresponding theorems.

Then the combined error is $O(h^{-d+1})$

Could we do better than this? Observe that all terms in the estimates we derived which contain ν estimate approximating-bracketing errors while Ch^{1-d+s} estimates semiclassical error[33)]. Only the latter could be improved. Therefore

Theorem 5.4.16. *(a) In the framework of Theorem 5.4.7 assume that* $d > s+1$ *and expression* (5.4.28) *is* $o(h^{1-d+s})$.

(b) In the framework of Theorem 5.4.10(i) assume that expression (5.4.28) *is* $o(h^{1-d+s})$.

(c) In the framework of Theorem 5.4.10(ii) assume that expression (5.4.28) *is* $o(h^{s+1})$ *and*

$$\sup_{\gamma<t:\gamma\nu(\gamma)^{1/2}\ge h} \nu(\gamma)^{\frac{1}{2}(d+s-1)}\gamma^{-s-1} = o(1) \qquad \text{as } h\to+0, t\to+0. \tag{5.4.39}$$

(d) In the framework of Theorem 5.4.13(i) assume that expressions (5.4.28) *and* (5.4.38) *are* $o(h^{1-d+s})$.

(e) In the framework of Theorem 5.4.13(ii) assume that expressions (5.4.28), (5.4.34) *are* $o(h^{1-d+s})$ *and* (5.4.39) *holds.*

Here all terms are calculated in the frameworks of the corresponding theorems.

Further, let $d\ge 2$. *Assume that the measure of the set of all dead-end*[34)] *or periodic points*[35)] *is* 0.

Then the combined error is $o(h^{-d+1})$.

[33)] The only exception is (5.4.38) which we discuss later.

[34)] Let us recall we call point z dead-end if dynamics $\Psi_t(z)$ leaves our domain for some $t : \pm t > 0$.

[35)] Let us recall we call point z periodic if $z\in\Psi_t(z)$ for some $t : \pm t > 0$. Let us recall that to dismiss point as dead-end or periodic we are free to chose (the same) sign $\pm$.

Proof. The easy proof is left to the reader. □

Applying Results of Section 4.7

We know from Section 4.7 that under assumption (5.4.2)

$$|\mathsf{R}^{\mathsf{W}}_{x,s}| \le Ch^{1-d+s} + Ch^{-d}\nu(\varepsilon)^{\frac{1}{2}(s+1)} \tag{5.4.40}$$

and

$$|\mathsf{R}^{\mathsf{W}}_{s}| \le Ch^{1-d+s} + Ch^{-d}\nu(\varepsilon)^{\frac{2}{3}(s+1)} \tag{5.4.41}$$

with $\varepsilon = h$. Then applying the arguments of the proof of Theorem 5.4.7 we arrive to

Therefore

Theorem 5.4.17. *Let conditions* (5.4.3), (5.4.7) *and* (5.4.23) *be fulfilled. Then* $|\mathsf{R}^{\mathsf{W}}_{s}|$ *does not exceed* (5.4.27) + (5.4.42) *with the second term*

$$Ch^{-d}\int \rho^{d-\frac{1}{3}+\frac{2}{3}s}\nu(\varepsilon(\rho))^{\frac{2}{3}(s+1)}\,d\rho, \tag{5.4.42}$$

$\varepsilon(\rho) = C\rho^{-1}h$ *and* ρ *running from* $\bar\rho = Ch^{\frac{1}{3}}$ *to a small constant.*

Applying Results of Section 4.7. II

To improve (5.4.27) as $d \le s+1$ we can apply arguments of the proof of Theorem 5.4.10 but we need to recall how estimate (5.4.41) was derived to understand how term (5.4.42) should be modified. However this improvement would not make any sense if $T := (h\nu(\varepsilon(\rho))^{-\frac{2}{3}} < \rho$, i.e. $\nu(\varepsilon) \ge \varepsilon^{\frac{3}{2}}$.

So we assume that

$$\nu(\varepsilon) = \varepsilon^{l}, \qquad l > \frac{3}{2}. \tag{5.4.43}$$

The trouble is that we consider propagation for time larger than ρ and then the magnitude $\varepsilon(\rho)$ (and $\nu(\varepsilon(\rho))$ changes) and it may increase or decrease. So

$$Ch^{-d}\rho^{d-s-1}\gamma^{d-s-1}\times\rho^{2s}\times\rho^{-2s-1}T^3\nu(\varepsilon(\rho))^2 \asymp Ch^{-d}\rho^{d-s-3}\gamma^{d-s-1}\times T^3\nu(\varepsilon(\rho))^2 \tag{5.4.44}$$

is not necessarily the correct estimate of the third term in the successive approximation (on the given γ-element, $\rho^2 \asymp \gamma$) an it seems that we need to replace here $\varepsilon(\rho)$ by $\bar{\varepsilon} = h^{\frac{2}{3}}|\log h|$ but it would be too bad in the end. While we cannot completely cure it, we can actually do significantly better.

Recall that for each h-pseudodifferential partition element Q we need to consider $\mathsf{Tr}(G^{\pm}Q)$ which for the third term translates into $\mathsf{Tr}(G^{\pm}A'_{\varepsilon}G_{\varepsilon}^{\pm}A'_{\varepsilon}G_{\varepsilon}^{\pm}Q)$ where $G^{\pm}$ and $G_{\varepsilon}^{\pm}$ are parametrices for perturbed (original) and unperturbed (mollified) operators and A'_{ε} is a perturbation.

If for given Q propagator $G_{\varepsilon}^{\pm}$ increases ρ and thus decreases $\varepsilon(\rho)$ we can indeed preserve one copy of $\nu(\varepsilon(\rho))$. Furthermore, since we actually have $\int \nu(\varepsilon(\rho(t)))\,dt$ in virtue of (5.4.43) we can replace here T by $\rho < T$. Application of A'_{ε} forces propagator to "lose direction". However in front of A'_{ε} we can insert $Q_1^{\pm}$ of the same nature as $Q^{\pm}$ and in the case "$Q^{\pm}$ meets $Q_1^{\pm}$" we can do the same, but in the case "$Q^{\pm}$ meets $Q_1^{\mp}$" we need to take $\bar{\rho}\nu(\bar{\varepsilon})$ instead.

Now we need to understand what to do in the opposite case, $Q = Q^{\mp}$. Observe that in successive approximation we can put $G^{\pm}$ to the left as we did or to the right as we will do now and the choice is ours. But because of the trace we can move $Q^{\mp}$ to the left. And finally, because the result is real we can complex conjugate the result, thus take adjoint operator under the trace which restores this term to its original form but with a twist: while $Q^{\pm}$ and A'_{ε} are preserved, $G^{\pm}$ and $G_{\varepsilon}^{\pm}$ are replaced by $G^{\mp}$ and $G_{\varepsilon}^{\mp}$ and are now in the accordance with $Q^{\mp}$ and the same estimate as before holds. Further, instead of three term approximation we can make many term approximation, each time gaining factor $h^{-1}\bar{\rho}\nu(\bar{\varepsilon}) \le h^{\delta}$ due to (5.4.3).

Therefore we can consider only "regular terms" with only $G_{\varepsilon}^{\pm}$ and therefore the last copy of T could be replaced by ρ since we need to return to ρ^2-vicinity of $\mathsf{supp}(\psi)$.

Thus we estimate the total error on the element Q by

$$Ch^{-d+s+1}\rho^{d-2}\gamma^d + Ch^{-d-2}\rho^{d+2s}\gamma^d(\rho\nu(\varepsilon(\rho)))(\bar{\rho}\nu(\bar{\varepsilon})) \tag{5.4.45}$$

and summation over partition in $\rho \le r\}$ returns

$$Ch^{-d+s+1} + Ch^{-d+\frac{5}{3}(l-1)-\delta}r^{d+2s+3-l} \tag{5.4.46}$$

because to avoid troubles with Weyl terms we may need to take $\bar{\varepsilon} = h^{\frac{2}{3}-\delta}$. Here the first term is actually smaller but it would not make any difference.

However taking $r = 1$ we get rather poor estimate as the last term usually would exceed both the first term and $Ch^{-d+\frac{2}{3}(s+1)l}$ whicjh is the second term in (5.4.41). Therefore we apply arguments of the previous subsubsection in $\{r \le \rho \lesssim 1\}$ and estimate its contribution by the second line in the following expression

$$Ch^{-d+\frac{5}{3}(l-1)-\delta} r^{d+2s+3-l} + Ch^{-d+s+1} r^{d-s-1} + Ch^{-d+\frac{2}{3}(s+1)l} r^{d-\frac{2}{3}l+\frac{2}{3}s-2sl} \tag{5.4.47}$$

and optimizing by $r : h^{\frac{1}{3}} \le r \le 1$ we arrive to

Theorem 5.4.18. *Let $d \le s+1$ and conditions* (5.4.3), (5.4.7) *and* (5.4.43) *be fulfilled. Then the total error does not exceed espression* (5.4.47) *minimized over $r : h^{\frac{1}{3}} \le r \le 1$.*

We leave to the reader

Problem 5.4.19. (i) Get rid of condition (5.4.3) like in Subsubsection 5.4.2.5.

(ii) Analyze separately $d = 1$ as in this dimension there $\{V = 0\}$ is a point and the movement could be either to it or from it which probably allows to replace one factor ρ by a factor $\rho^{-2}h|\log h|$.

(iii) Consider case of more regular V and irregular magnetic potential (the case we will deal in Chapters 27 and 28 and use the fact that a factor ρ pops-up in $\nu(\varepsilon(\rho))$.

5.4.3 Dirac Operator

Let us consider Dirac operator now. We assume that $m \le 1$; otherwise it brings nothing new in comparison with Schrödinger operator. As $|V(x)| \ge 2m$ we can apply the same approach as before but with the obvious modifications described below.

Getting Rid of Condition (5.4.2)

Assume that (5.4.7)–(5.4.9) hold and define $\gamma(x)$ by (5.4.10). Then (5.4.11) holds but now (5.4.12)–(5.4.13) are replaced respectively by

$$\rho(x) = \nu(\gamma(x)) \tag{5.4.48}$$

and

$$\bar{\gamma}\nu(\bar{\gamma}) = h. \tag{5.4.49}$$

This is a correct definition as long as $\nu(\bar{\gamma}) \ge 2m$ which is equivalent to

$$\nu\big(\frac{h}{m}\big) \ge 2m. \tag{5.4.50}$$

Let us define ε by (5.4.14).

Let us recall that the combined error does not exceed $Ch^{-d}\nu(h|\log h|)$ under condition (5.4.2). Let us scale $x \mapsto x\gamma^{-1}$, $\xi \mapsto \xi\rho^{-1}$, $h \mapsto h\rho^{-1}\gamma^{-1}$, $\varepsilon \mapsto \varepsilon\gamma^{-1}$ and $\nu(t) \mapsto \nu_{\mathsf{new}}(t) \coloneqq \rho^{-1}\nu(\gamma t)$. Then we conclude that

$$|R_x^{\mathsf{W}}| \le Ch^{-d}\rho^{d-1}\nu\big(\frac{h}{\rho}|\log\frac{h}{\rho\gamma}|\big) \tag{5.4.51}$$

and this expression reaches its maximum as $\rho \asymp 1$ as $d \ge 2$ and as $\rho = \bar{\rho}$ as $d = 1$. Thus we arrive to

Theorem 5.4.20. *Let* (5.4.7)–(5.4.9) *and* (5.4.50) *be fulfilled and let us drop condition* (5.4.2). *Then*

(i) For $d \ge 2$ the combined error still does not exceed $Ch^{-d}\nu(h|\log h|)$.

(ii) For $d = 1$ estimate $|\mathsf{R}_x^{\mathsf{W}}| \le C\bar{\gamma}^{-1}$ holds with $\bar{\gamma}$ defined from (5.4.49).

On the other hand if (5.4.50) fails, i. e. if

$$\nu\big(\frac{h}{m}\big) \le 2m \tag{5.4.52}$$

then in the zone $\{\gamma(x) \le \bar{\gamma}_1\}$ we find ourselves in the framework of the Schrödinger operator with $V(x)$ replaced by $V(x)/2m$ and therefore with $\nu(t)$ replaced by $m^{-1}\nu(\bar{\gamma}_1 t)$; here $\bar{\gamma}_1$ is defined defined by

$$\nu(\bar{\gamma}_1) = 2m. \tag{5.4.53}$$

Then as $d \ge 3$ we have still the same estimates rescaled; in particular, $|\mathsf{R}_x^{\mathsf{W}}| \le Ch^{-d}\nu(h|\log h|)$.

However for $d = 1, 2$ we need to rescale estimate $C|\mathsf{R}_x^{\mathsf{W}}| \le \bar{t}^{-d}$ with $\bar{t}$ defined after rescaling by (5.4.13); the latter equation after rescaling is

$\bar{t}\big(m^{-1}\nu(\bar{\gamma}_1\bar{t})\big)^{\frac{1}{2}} = h(m\bar{\gamma}_1)^{-1}$. Thus we arrive to estimate $|\mathsf{R}^{\mathsf{W}}_x| \le C\bar{\gamma}_1^{-d}\bar{t}^{-d}$. Denoting $\bar{\gamma}_1\bar{t}$ by $\bar{\gamma}$ we arrive to $|\mathsf{R}^{\mathsf{W}}_x| \le C\bar{\gamma}^{-d}$ with $\bar{\gamma}$ defined by

$$\bar{\gamma}\nu(\bar{\gamma})^{\frac{1}{2}} = hm^{-\frac{1}{2}}. \tag{5.4.54}$$

Thus we proved

Theorem 5.4.21. *Let* (5.4.7)–(5.4.9) *and* (5.4.52) *be fulfilled and let us drop condition* (5.4.2). *Then*

(i) For $d \ge 3$ *the combined error still does not exceed* $Ch^{-d}\nu(h|\log h|)$;

(ii) For $d \ge 1, 2$ *estimate* $|\mathsf{R}^{\mathsf{W}}_x| \le C\bar{\gamma}^{-d}$ *holds with* $\bar{\gamma}$ *defined from* (5.4.54).

From Condition (5.4.2) to Condition (5.4.3)

Let (5.4.7), (5.4.23) be fulfilled. Define $\gamma(x)$ by (5.4.37). Then we need to define $\bar{\gamma}_1 = m$ and replace (5.4.50), (5.4.52) by $m \le h^{\frac{1}{2}}$ and $m \ge h^{\frac{1}{2}}$ respectively. However in both cases we arrive to

Theorem 5.4.22. *Let* (5.4.7), (5.4.23) *be fulfilled and let us drop condition* (5.4.2). *Let* <u>*either*</u> $d \ge 3$ <u>*or*</u> $d = 2$ *and* $m \le h^{\frac{1}{2}}$ <u>*or*</u> *condition* (5.4.3) *be fulfilled. Then* $|\mathsf{R}^{\mathsf{W}}| \le Ch^{1-d}$ *while an approximation error does not exceed* $Ch^{-d}\nu(h|\log h|)$ *as* $d \ge 2$ *and* (5.4.27) *as* $d = 1$ *(and* $s = 0$*).*

Dropping Condition (5.4.3)

We are left with the case $d = 1, 2$ and $m \ge h^{\frac{1}{2}}$ only. Otherwise we arrive to estimate Ch^{1-d} for the combined error with a single exception of $d = 1$ when this estimate is replaced by $C\bar{\gamma}^{-1}$ with $\bar{\gamma}$ defined by (5.4.49).

Using scaling defined by (5.4.37) we arrive to

Theorem 5.4.23. *Let* $d = 1, 2$*; let* (5.4.7), (5.4.23), (5.4.35) *and* (5.4.36) *be fulfilled and let us drop condition* (5.4.3). *Let* <u>*either*</u> $d = 2$ *and* $m \ge h^{\frac{1}{2}}$ <u>*or*</u> $d = 1$.

Then the combined error does not exceed $C\bar{\gamma}^{-d}$ *where* $\bar{\gamma}$ *is defined by* (5.4.54) *as* $m \ge h^{\frac{1}{2}}$ *and by* (5.4.49) *otherwise (which happens only as* $d = 1$*).*

Sharp Remainder Estimate

Obviously we arrive

Theorem 5.4.24. *Let* (5.4.7) *and* (5.4.23) *be fulfilled. Further, let* $d \geq 3$.

Alternatively let $d = 2$, $\mathsf{mes}(Z(0)) = 0$ *and either* (5.4.3) *be fulfilled or* $m \leq h^{\frac{1}{2}}$ *or* $\nu(t) = t^2$.

Assume that the measure of the set of all dead-end[34] *or periodic points*[35] *is* 0.

Then $|\mathsf{R}^{\mathsf{W}}| = o(h^{1-d})$ *and the same is true for approximation error provided* (5.4.28) *holds.*

We leave details to the reader. Let us observe that if $m \to \bar{m}$ we need to investigate Hamiltonian system corresponding to $\bar{m}$ only.

We leave to the reader

Problem 5.4.25. (i) Consider $\mathsf{R}^{\mathsf{W}}_s$ (see also Subsubsection 5.3.2.4).

(ii) Consider Riesz means using also methods and results of Section 4.7.

5.4.4 General oOperators

In this subsection we consider general differential operators with irregular coefficients. We approximate them by operators with the "rough" coefficients and estimate both Weyl remainder estimate and the approximation error in Weyl expression. The applications to asymptotics will come later.

Dropping Condition $|\nabla_\xi a| \neq 0$

Again, instead of the microhyperbolicity condition

$$|a| + |\nabla_{x,\xi} a| \geq \epsilon_0 \tag{5.4.55}$$

as in the smooth case our "reference theorem" requires a stronger ξ-microhyperbolicity condition

$$|a| + |\nabla_{\xi} a| \geq \epsilon_0 \tag{5.4.56}$$

which also works for asymptotics without spatial mollification.

Assume first that $\nu(t)$ satisfies (5.4.7)–(5.4.9) and define scaling functions from equations

$$\nu(\gamma) = \epsilon \max\bigl(|a| + |\nabla_\xi a|^2, \nu(\bar\gamma)\bigr), \qquad \rho = \nu(\gamma)^{\frac12}, \qquad h_{\text{new}} = \frac{h}{\rho\gamma} \tag{5.4.57}$$

with $\bar\gamma$ defined from equation (5.4.13) and a roughness function

$$\varepsilon = C\frac{h}{\rho}|\log\frac{h}{\rho\gamma}|. \tag{5.4.58}$$

Then instead of (5.4.11) we have

$$|x-y| \le \epsilon\gamma(x), \qquad |\xi-\eta| \le \epsilon\rho \implies \tag{5.4.59}$$
$$C^{-1}\gamma(x,\xi) \le \gamma(y,\eta) \le C\gamma(x,\xi), \qquad C^{-1}\rho(x,\xi) \le \rho(y,\eta) \le C\rho(x,\xi).$$

Indeed,

$$|a_\eta(y,\eta) - a_\xi(x,\xi)| \le |a_\eta(y,\eta) - a_\eta(x,\eta)| + |a_\eta(x,\eta) - a_\xi(x,\xi)| \le \\ C_0\nu(|x-y|) + C_0|\xi-\eta|$$

(where $a_\xi = \nabla_\xi a$ etc) which implies that

$$|a_\eta(y,\eta) - a_\xi(x,\xi)| \le \epsilon\rho$$

and also

$$|\eta(y,\eta) - a(x,\xi)| \le |a(y,\eta) - a(x,\eta)| + |a(x,\eta) - a(x,\xi)| \le \\ C_0\nu(|x-y|) + C_0|a_\xi(x,\xi)|\cdot|\xi-\eta| + C_0|\xi-\eta|^2 \le \epsilon\rho^2.$$

These two inequalities imply (5.4.59). So, (γ,ρ) is a scaling vector-function.

Consider first asymptotics *without* spatial mollification. Scaling estimate $Ch^{-d}\nu(h|\log h|)$ of the combined error we estimate the contribution of (γ,ρ) element by

$$Ch^{-d}\rho^{d-2}\nu\bigl(\frac{h}{\rho}|\log\frac{h}{\rho\gamma}|\bigr)$$

(let us recall that $\nu_{\text{new}}(t) = \rho^{-2}\nu(\gamma t)$)) and the total combined error by

$$Ch^{-d}\int \rho^{-2}\nu\bigl(\frac{h}{\rho}|\log\frac{h}{\rho\gamma}|\bigr)\,d\xi. \tag{5.4.60}$$

Let us assume that one of two following conditions holds: $(5.4.61)^+_r$ $a_{\xi\xi}$ has r eigenvalues of the same sign with absolute values larger than ϵ_1; $(5.4.61)_r$ $a_{\xi\xi}$ has r eigenvalues with absolute values larger than ϵ_1 where here and below $a_{\xi\xi}$, $a_{\xi x}$, $a_{x\xi}$ and a_{xx} denote the matrices of the second derivatives (we don't use the last one since it does not necessarily exist).

Observe that under assumption $(5.4.61)_r$

$$a = Q(z;\xi' - \mu(z)) + W(z), \qquad \xi' = (\xi_1, \dots, \xi_r),\ z = (x, \xi''),\quad \xi'' = (x_{r+1}, \dots, \xi_d) \tag{5.4.62}$$

where is Q a non-degenerate quadratic form with respect to $\xi' - \mu(z)$; further, under condition $(5.4.61)^+_r$ this form is either positive or negative definite.

Then $\rho \gtrsim |\xi' - \mu(z)| + |V(z)|$ and (5.4.60) equals

$$Ch^{-d} \int \Big(\int \rho^{-2} \nu\big(\frac{h}{\rho} |\log \frac{h}{\rho\gamma}\big)\, d\xi' \Big)\, d\xi'' \tag{5.4.63}$$

where the integrand does not exceed $C\rho^{-3}\nu(h|\log h|)$.

Then the inner integral in expression (5.4.63) and thus the whole expression (5.4.63) do not exceed $Ch^{-d}\nu(h|\log h|)$ as either $(5.4.61)_4$ or $(5.4.61)^+_3$ is fulfilled. The same is true under condition $(5.4.61)_3$ provided $\nu(r)r^{-l}$ is monotone decreasing with some $l < 1$.

Really, the inner integral does not exceed $\int \rho^{-l-2}\, d\rho^r$ with integral generally taken over $\bar\rho \le \rho \le c$ and with $l = 1$; hence we need $r = 4$ to have this integral bounded; $l < 1$ relaxes it to $r = 3$; finally, under condition $(5.4.61)^+_r$ integration is taken over set $|\xi' - \mu(z)| \asymp |W(z)|^{\frac12}$ and therefore as $r = 3$ this integral is also bounded.

On the other hand, under weaker assumptions we get weaker estimates:

Theorem 5.4.26. *Let ν satisfy* (5.4.7)–(5.4.9).

(i) Let <u>*either*</u> $(5.4.61)_4$ <u>*or*</u> $(5.4.61)^+_3$ *be fulfilled* <u>*or*</u> $(5.4.61)_3$ *be fulfilled and $\nu(r)r^{-l}$ be monotone decreasing with some $l < 1$. Then the combined error (for both N and N_x) does not exceed $Ch^{-d}\nu(h|\log h|)$.*

(ii) Let $(5.4.61)_3$ be fulfilled. Then the combined error (for both N and N_x) does not exceed $Ch^{-d}\nu(h|\log h|)$.

(iii) Let condition $(5.4.61)_r$ with $r = 1, 2$ be fulfilled. Then the combined error (for both N and N_x) does not exceed $Ch^{-d}\nu(h|\log h|)$ does not exceed $Ch^{-d}\bar\rho^r$ with $\bar\rho$, $\bar\gamma$ defined by (5.4.13).

Case $\nu(t)=o(t)$

Assuming instead that $\nu(t)$ satisfies (5.4.7), (5.4.23) and using scaling (5.4.57) associated with $\nu(t)=t$, i. e.

$$\gamma=\epsilon\max\bigl(|a|+|\nabla_\xi a|^2,\bar\gamma\bigr),\qquad \rho=\gamma^{\frac12},\qquad h_{\mathsf{new}}=h\gamma^{-\frac32} \tag{5.4.64}$$

one arrives instantly to the following

Theorem 5.4.27. *Let ν satisfy* (5.4.7), (5.4.23).

(i) Let <u>*either*</u> $(5.4.61)_3^+$ <u>*or*</u> $(5.4.61)_4$ *be fulfilled. Then the combined error (for both* N *and* N_x*) does not exceed* $Ch^{-d}\bigl(\nu(h|\log h|)+h\bigr)$*;*

(ii) Let $(5.4.61)_3$ *be fulfilled. Then the combined error (for both* N *and* N_x*) does not exceed* $Ch^{-d}\bigl(\nu(h|\log h|)+h|\log h|\bigr)$*;*

(iii) Let (5.4.55) *and* $(5.4.61)_2$ *be fulfilled. Then the combined error (for* N *only) does not exceed* $Ch^{-d}\bigl(\nu(h|\log h|)+h|\log h|\bigr)$*;*

(iv) Let (5.4.55) *and* $(5.4.61)_1$ *be fulfilled. Then the combined error (for* N *only) does not exceed* $Ch^{-d}\bigl(\tilde\nu(h|\log h|)+h^{\frac13}|\log h|\bigr)$ *where*

$$\tilde\nu=\int_{h^{1/3}}^1 \nu(\rho^{-1}|\log\rho^{-3}h|)\rho^{-1}\,d\rho. \tag{5.4.65}$$

Problem 5.4.28. Following the proof of Theorem 5.4.10 one can prove that in the framework of Statement (iv) estimate is actually $Ch^{-d}\bigl(\tilde\nu(h|\log h|)+h\bigr)$.

Now we encounter strange new possibilities not available for Schrödinger operator. First, it may happen that (5.4.55) holds but (5.4.56) and $(5.4.61)_1$ fail.

Second, it may happen that (5.4.55) also fails and $\mathsf{rank}(a_{\xi\xi})$ is not large enough, but $\mathsf{rank}(a_{\xi\xi}\ a_{\xi x})$ helps. Therefore let us assume that

$(5.4.66)_m$ The following $(d+1)\times 2d$-matrix has rank at least m [36]:

$$\begin{pmatrix} da \\ da_{\xi_1} \\ \vdots \\ da_{\xi_d} \end{pmatrix} = \begin{pmatrix} a_{\xi_1} & \dots & a_{\xi_d} & a_{x_1} & \dots & a_{x_d} \\ a_{\xi_1\xi_1} & \dots & a_{\xi_1\xi_d} & a_{\xi_1 x_1} & \dots & a_{\xi_1 x_d} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ a_{\xi_d\xi_1} & \dots & a_{\xi_d\xi_d} & a_{\xi_d x_1} & \dots & a_{\xi_d x_d} \end{pmatrix} \tag{5.4.67}$$

Then we can prove easily

Theorem 5.4.29. *Let ν satisfy* (5.4.7) *and* (5.4.23).

(i) Let <u>either</u> (5.4.55) *and* $(5.4.66)_2$ *<u>or</u>* $(5.4.66)_4$ *be fulfilled; then the combined error does not exceed* $Ch^{-d}\big(\nu(h|\log h|+h\big)$.

(ii) Let <u>either</u> (5.4.55) *and* $(5.4.66)_1$ *<u>or</u>* $(5.4.66)_3$ *be fulfilled; then the combined error does not exceed* $Ch^{-d}\big(\nu(h|\log h|+h\big)|\log h|$.

(iii) Let <u>either</u> (5.4.55) *<u>or</u>* $(5.4.66)_2$ *be fulfilled; then the combined error does not exceed* $Ch^{-d+\frac{2}{3}}$.

(iv) Let $(5.4.66)_1$ *be fulfilled; then the combined error does not exceed* $Ch^{-d+\frac{1}{3}}$.

Proof. Let us introduce γ and ρ by (5.4.64) again (only in the vicinity of $\{\nabla a_x = 0\}$). Then the total combined error does not exceed again

$$Ch^{-d}\int \Big(\gamma^{-1}\nu\big(\frac{h}{\gamma^{\frac{1}{2}}}|\log\frac{h}{\gamma^{\frac{3}{2}}}|\big) + Ch\gamma^{-\frac{3}{2}}\Big)\,dxd\xi \tag{5.4.68}$$

where we divided the previous expression by $\rho^d\gamma^d$ and plugged $\rho=\gamma^{\frac{1}{2}}$.

Note that under condition $\big((5.4.66)\big)_m$ in an appropriate non-symplectic coordinates

$$\gamma \gtrsim \sum_{1\le j\le m} z_j^2 + \bar\gamma$$

and under conditions (5.4.55) and $\big((5.4.66)\big)_m$

$$\gamma \gtrsim |z_1| + \sum_{2\le j\le m} z_j^2 + \bar\gamma$$

which leads to the corresponding estimates of integral (5.4.68). □

[36] Which means that there exists m-minor with an absolute value not less than ϵ_1.

Case $\nu(t)=o(t)$. II

Basically we are left with the cases when (5.4.55) or $(5.4.66)_2$ or $(5.4.66)_1$ is fulfilled and we hope to improve remainder estimate as $\nu(t)\le t^l$ with $l\in(1,2]$.

Problem 5.4.30. Following the proof of Theorem 5.2.14 prove that under condition (5.4.55) the combined error does not exceed $Ch^{-d}\bigl(\tilde\nu(h^{1-\delta})+h^{1-\delta}\bigr)$ with arbitrarily small $\delta>0$.

Now we need to cover case when only $(5.4.66)_m$ with $m=1,2$ is fulfilled. Assuming that (5.4.35), (5.4.36) are fulfilled we can introduce γ, ρ by the following formula similar to (5.4.37)

$$\gamma=\mathsf{max}(\gamma',\bar\gamma),\quad \gamma'=\epsilon\,\mathsf{min}\{t:|a|+|a_\xi|^2\le\nu(t),|a_x|\le t^{-1}\nu(t)\}. \tag{5.4.69}$$

with ρ, $\bar\gamma$ defined by (5.4.12) and (5.4.13).

One can prove easily that (5.4.59) holds.

Theorem 5.4.31. *Let continuity modulus ν satisfy* (5.4.7), (5.4.23), (5.4.35), (5.4.36) *and* $(5.4.66)_m$ *be fulfilled with $m=1,2$. Then the combined error is $O(h^{-d}\bar\rho^m+h^{1-\delta-d})$ with $\bar\gamma$, $\bar\rho$ defined by* (5.4.13).

Proof. Let us consider (ρ,γ)-element.

(a) As $\gamma\ge c_0\bar\gamma$ and $|a|+|\nabla_\xi a|^2\asymp\rho^2$ there its contribution to the remainder does not exceed $Ch^{1-d}\rho^{d-1}\gamma^{d-1}$ and contribution of all these elements does not exceed

$$Ch^{1-d}\int\rho^{-1}\gamma^{-1}\,dxd\xi.$$

(b) As $\gamma\ge c_0\bar\gamma$ and $|\nabla_x a|\asymp\nu(\gamma)\gamma^{-1}$ there its contribution to the remainder does not exceed due to problem 5.4.30 $Ch^{1-\delta-d}\rho^{d-1+\delta}\gamma^{d-1+\delta}$ and contribution of all these elements does not exceed

$$Ch^{1-\delta-d}\int\rho^{\delta-1}\gamma^{\delta-1}\,dxd\xi.$$

Thus, we got the second integral anyway. Then due to condition $(5.4.66)_m$ $\mathsf{mes}(\{z:\rho(z)\asymp\rho\})\lesssim\rho^m$ and this integral does not exceed

$$Ch^{1-\delta-d}\int\rho^{m+\delta-2}\gamma(\rho)^{\delta-1}\,d\rho \tag{5.4.70}$$

and if

(5.4.71) $M(\rho) = \rho^{m+\delta-1}\gamma(\rho)^{\delta-1}$ satisfies $M(k\rho) \ge k^{-\sigma}M(\rho)$ with $\sigma > 0$ as $k \le 1$

we conclude that this integral does not exceed $Ch^{1-\delta-d}\bar\rho^{m+\delta-1}\bar\gamma^{\delta-1} = Ch^{-d}\bar\rho^{m}$.

Obviously (5.4.71) holds as $m = 1$, $\delta = \frac{1}{3}$ for sure, we do not need even Problem 5.4.30 but can refer to Theorem 5.4.29(ii). If $m = 2$ situation becomes more complicated and slightly varying δ we can achieve either (5.4.71) or $M(k\rho) \le k^{\sigma}M(\rho)$; in the latter case (5.4.70) does not exceed $Ch^{1-d+\delta}$. □

Problem 5.4.32. (i) Assuming that $\nu(t) = o(t^2)$ introduce a_{xx} into consideration and replace assumption $(5.4.66)_m$ by a weaker assumption

$(5.4.72)_m$ The following $(2d+1)\times 2d$-matrix has rank at least m[36]:

$$(5.4.73)\qquad \begin{pmatrix} da \\ da_{\xi_1} \\ \vdots \\ da_{x_d}\end{pmatrix} = \begin{pmatrix} a_{\xi_1} & \dots & a_{\xi_d} & a_{x_1} & \dots & a_{x_d} \\ a_{\xi_1\xi_1} & \dots & a_{\xi_1\xi_d} & a_{\xi_1 x_1} & \dots & a_{\xi_1 x_d} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ a_{x_d\xi_1} & \dots & a_{x_d\xi_d} & a_{x_d x_1} & \dots & a_{x_d x_d}\end{pmatrix}.$$

(ii) Alternatively introduce $\varepsilon = C(h|\log h|)^{\frac{1}{2}}$, derive the combined estimate $Ch^{-d}\big(\nu((h|\log h|)^{\frac{1}{2}}) + h\big)$ under microhyperbolicity condition and scale it.

Problem 5.4.33. (i) Consider $\mathsf{R}^{\mathsf{W}}_s$ (see also Subsubsection 5.3.2.4).

(ii) Consider Riesz means using also methods and results of Section 4.7.

Sharp Remainder Estimates

As long as the contribution of $\{z : \gamma(z) \le \eta\}$ to the remainder estimate does not exceed $\big(\mu(\eta) + o_\eta(1)\big)h^{1-d}$ as $h \to +0$ with $\mu(\eta) = o(1)$ as $\eta \to +0$, under standard non-periodicity condition one can derive remainder estimate $\mathsf{R}^{\mathsf{W}} = o(h^{1-d})$. Moreover if an approximation error is $o(h^{1-d})$ then the combined error is $o(h^{1-d})$ as well.

5.A Appendices

5.A.1 Spectral Kernel Calculations for Some Model Operators

Case $d = 1$

Consider operator (5.3.59).

Note first that

$$B = -x_1 \implies \partial_\tau e_B(x, y, \tau) = \delta(x_1 - y_1)\delta(x_1 + \tau). \tag{5.A.1}$$

Then making unitary h-Fourier transform we conclude that for

$$B = hD_{\xi_1} \implies \partial_\tau e_B(\xi_1, \eta_1, \tau) = (2\pi h)^{-1} \exp\bigl(ih^{-1}(\xi_1 - \eta_1)\tau\bigr). \tag{5.A.2}$$

Therefore since $\mathcal{T}^* hD_{\xi_1}\mathcal{T} = hD_{\xi_1} + \xi_1^2$ for $\mathcal{T} = \exp(ih^{-1}\frac{1}{3}\xi_1^3)$ we conclude that

$$\begin{aligned} &B = hD_{\xi_1} + \xi_1^2 \implies \\ &\qquad \partial_\tau e_B(\xi_1, \eta_1, \tau) = (2\pi h)^{-1} \exp\bigl(ih^{-1}\bigl[(\xi_1 - \eta_1)\tau - \frac{1}{3}(\xi_1^3 - \eta_1^3)\bigr]\bigr). \end{aligned} \tag{5.A.3}$$

Finally making inverse Fourier transform we conclude that for A defined by (5.3.59)

$$\begin{aligned} &\partial_\tau e(x_1, y_1, \tau) = \\ &\qquad (2\pi h)^{-2} \iint \exp\bigl(ih^{-1}\bigl[(\xi_1 - \eta_1)\tau + x_1\xi_1 - y_1\eta_1 - \frac{1}{3}(\xi_1^3 - \eta_1^3)\bigr]\bigr)\, d\xi_1\, d\eta_1 \end{aligned} \tag{5.A.4}$$

and therefore

$$\begin{aligned} &\partial_\tau e(x_1, x_1, \tau) = \\ &\qquad (2\pi h)^{-2} \iint \exp\bigl(ih^{-1}\bigl[(\xi_1 - \eta_1)(\tau + x_1) - \frac{1}{3}(\xi_1^3 - \eta_1^3)\bigr]\bigr)\, d\xi_1\, d\eta_1. \end{aligned} \tag{5.A.5}$$

One can rewrite it as

$$e(x_1, x_1, \tau) = h^{-\frac{2}{3}} \int_{-\infty}^{(x_1+\tau)h^{-\frac{2}{3}}} F(\tau)\, d\tau, \tag{5.A.6}$$

with

$$F(t) = (2\pi)^{-2} \iint \exp\bigl(i\bigl[(\xi_1 - \eta_1)t - \frac{1}{3}(\xi_1^3 - \eta_1^3)\bigr]\bigr)\, d\xi_1\, d\eta_1 = \tag{5.A.7}$$
$$2(2\pi)^{-2} \iint \exp\bigl(i\bigl[2\beta t - \frac{2}{3}\beta^3 - 2\beta\alpha^2\bigr]\bigr)\, d\alpha\, d\beta =$$
$$(2\pi)^{-\frac{3}{2}} \int |\beta|^{-\frac{1}{2}} \exp\bigl(-i\frac{\pi}{4}\operatorname{sgn}\beta + i\bigl[2\beta t - \frac{2}{3}\beta^3\bigr]\bigr)\, d\beta$$

where we first substituted $\xi_1 = \alpha + \beta$, $\eta_1 = \alpha - \beta$ and then integrated with respect to α.

The remaining integral has stationary points $\beta = \pm t^{\frac{1}{2}}$ and a singular point $\beta = 0$. Decomposing for $t > 0$ $F(t) = F_1(t) + F_2(t)$,

$$F_1(t) = (2\pi)^{-\frac{3}{2}} \int |\beta|^{-\frac{1}{2}} \exp\bigl(-i\frac{\pi}{4}\operatorname{sgn}\beta + 2i\beta t\bigr)\, d\beta = \frac{1}{2}\kappa t^{-\frac{1}{2}} \tag{5.A.8}$$

with

$$\kappa = 2(2\pi)^{-\frac{3}{2}} \int_0^\infty \beta^{-\frac{1}{2}} \cos(2\beta - \frac{\pi}{4})\, d\beta, \tag{5.A.9}$$

and

$$F_2(t) = \tag{5.A.10}$$
$$(2\pi)^{-\frac{3}{2}} \int |\beta|^{-\frac{1}{2}} \exp\bigl(-i\frac{\pi}{4}\operatorname{sgn}\beta + 2i\beta t\bigr)\Bigl(\exp\bigl(-\frac{2}{3}i\beta^3\bigr) - 1\Bigr) d\beta.$$

Then primitives of $F_1(t)$ and $F_2(t)$ produce exactly main term and correction term in (5.3.36):

$$\mathcal{Q}(t) = \int_\infty^t F_2(t')\, dt' = \tag{5.A.11}$$
$$-\,2^{-2}(2\pi)^{-\frac{3}{2}} \int |\beta|^{-\frac{3}{2}} \bigl(i\frac{\pi}{4}\operatorname{sgn}\beta + 2i\beta t\bigr)\Bigl(\exp\bigl(-\frac{2}{3}i\beta^3\bigr) - 1\Bigr)\, d\beta.$$

In this integral singularity at $\beta = 0$ gives a relatively small contribution (one can prove it is $O(t^{-\frac{3}{2}})$ as $t \to \infty$); the main contribution comes from the stationary points $\beta = \pm t^{\frac{1}{2}}$ and modulo $O(t^{-\frac{3}{2}})$

$$\mathcal{Q}(t) \equiv -2^{-1}(2\pi)^{-1} \sum_{\beta = \pm t^{\frac{1}{2}}} |\beta|^{-2} \exp\bigl(i\frac{\pi}{2}\operatorname{sgn}\beta + \frac{4}{3}i\beta t\bigr) = \tag{5.A.12}$$
$$(2\pi)^{-1} t^{-1} \sin\bigl(\frac{4}{3}t^{\frac{3}{2}}\bigr).$$

Case $d = 2$

Now we consider operator

$$A = h^2 D_{x_1}^2 + h^2 D_{x_2}^2 - x_1$$

leading to $B = \xi_1^2 + \xi_2^2 + hD_{\xi_1}$ and then instead of (5.A.5) we have

(5.A.13) $\partial_\tau e(x_1, x_1, \tau) =$

$$(2\pi h)^{-3} \iint \exp\bigl(ih^{-1}\bigl[(\xi_1 - \eta_1)(\tau + x_1 - \xi_2^2) - \frac{1}{3}(\xi_1^3 - \eta_1^3)\bigr]\bigr)\, d\xi_1 d\xi_2 d\eta_1.$$

and all previous formulae are adjusting accordingly. Then (5.A.6)–(5.A.7) are replaced by

(5.A.14) $e(x_1, x_1, \tau) = h^{-\frac{4}{3}} \int_{-\infty}^{(x_1+\tau)h^{-\frac{2}{3}}} F(\tau)\, d\tau,$

with

(5.A.15) $F(t) = 2(2\pi)^{-3} \iint \exp\bigl(i\bigl[2\beta(t + \gamma^2) - \frac{2}{3}\beta^3 - 2\beta\alpha^2\bigr]\bigr) d\alpha d\beta d\gamma =$

$$(2\pi)^{-2} \int |\beta|^{-1} \exp\bigl(i\bigl[2\beta t - \frac{2}{3}\beta^3\bigr]\bigr)\, d\beta$$

and (5.A.8)–(5.A.10) are replaced by

(5.A.16) $$F_1(t) = (2\pi)^{-2} \int |\beta|^{-1} \exp\bigl(2i\beta t\bigr)\, d\beta = \kappa + \kappa_1 t^{-3}$$

with

(5.A.17) $$\kappa = 2(2\pi)^{-\frac{3}{2}} \int_0^\infty \beta^{-\frac{1}{2}} \cos(2\beta - \frac{\pi}{4})\, d\beta,$$

where integral was understood in the sense of distributions and

(5.A.18) $$F_2(t) = (2\pi)^{-2} i^{-1} \int |\beta|^{-1} \exp\bigl(2i\beta t\bigr)\Bigl(\exp\bigl(-\frac{2}{3}i\beta^3\bigr) - 1\Bigr) d\beta.$$

Then (5.A.11) is replaced by

(5.A.19) $\mathcal{Q}(t) = \int_\infty^t F_2(t')\, dt' =$

$$-\, 2^{-1}(2\pi)^{-2} \int |\beta|^{-2} \operatorname{sgn}\beta \exp\bigl(2i\beta t\bigr)\Bigl(\exp\bigl(-\frac{2}{3}i\beta^3\bigr) - 1\Bigr)\, d\beta.$$

In this integral singularity at $\beta = 0$ gives a small contribution; really, decomposing $\exp\bigl(-\frac{2}{3}i\beta^3\bigr) - 1$ into powers of β^3 we get that he leading term is $O(t^{-2})$. The main contribution comes from the stationary points $\beta = \pm t^{\frac{1}{2}}$ and modulo $O(t^{-\frac{3}{2}})$

$$\mathcal{Q}(t) \equiv (2\pi)^{-1} t^{-\frac{5}{4}} \sin\bigl(\frac{4}{3} t^{\frac{3}{2}}\bigr). \tag{5.A.20}$$

5.A.2 On Pauli Matrices

The results of this appendix are important for Section 4.6 and for later applications.

Definition 5.A.1. *Pauli matrices*[37] are $\mathsf{D} \times \mathsf{D}$ matrices $\sigma_0, \dots, \sigma_d$ such that

$$\sigma_j^\dagger = \sigma_j, \tag{5.A.21}$$

and

$$\sigma_j \sigma_k + \sigma_k \sigma_j = 2\delta_{jk} I \qquad j, k = 0, \dots, d. \tag{5.A.22}$$

We have the key statement

Theorem 5.A.2. *(i) A set $\sigma_0, \dots, \sigma_d$ of $\mathsf{D} \times \mathsf{D}$ Pauli matrices exists if and only if $\mathsf{D} \in \bar{\mathsf{D}}\mathbb{Z}$ where $\bar{\mathsf{D}} = 2^{\lfloor \frac{d+1}{2} \rfloor}$.*

(ii) Moreover, if $\mathsf{D} = \bar{\mathsf{D}}$ and d is odd then all sets of Pauli matrices are unitarily equivalent[38] *On the other hand, for $\mathsf{D} = \bar{\mathsf{D}}$ and even d there exist precisely two sets of Pauli matrices which are not unitarily equivalent.*

(iii) If $\mathsf{D} = \bar{\mathsf{D}}$ and d is even then

$$\sigma_0 \cdots \sigma_d = \varsigma i^{\frac{d}{2}} I \quad \text{with } \varsigma = \pm 1 \tag{5.A.23}$$

and two sets are equivalent if and only if $\varsigma = \varsigma'$. If $\mathsf{D} = \bar{\mathsf{D}}$ and d is odd then $\sigma_0, \dots, \sigma_d, \sigma_{d+1}$ with

$$\sigma_{d+1} = \varsigma(-i)^{\frac{d+1}{2}} \tag{5.A.24}$$

are also Pauli matrices.

---

[37] As $\mathsf{D} = 4$ they are also called Dirac matrices.

[38] The sets $\sigma_0, \dots, \sigma_d$ and $\sigma'_0, \dots, \sigma'_d$ are unitarily equivalent if $\sigma'_j = q^\dagger \sigma'_j q \quad \forall j = 0, \dots, d$ with appropriate unitary matrix q. Obviously the transition to a unitarily equivalent set preserves properties (5.A.21) and (5.A.22).

(iv) If $p = \mathsf{D}/\bar{\mathsf{D}} \in \mathbb{Z}$ *and* d *is odd then every set of Pauli matrices is unitarily equivalent to the set* $\sigma_j = \bar{\sigma}_j \otimes I_p$ $j = 0, \dots, d$ *where* $\{\bar{\sigma}_j \quad j = 0, \dots, d\}$ *is a standard set in dimension* $\bar{\mathsf{D}}$*.*

Further, if $p = \mathsf{D}/\bar{\mathsf{D}} \in \mathbb{Z}$ *and* d *is even then every set of Pauli matrices is unitarily equivalent to the set* $\sigma_j = \bar{\sigma}_j \otimes J_{p,q}$ $j = 0, \dots, d$ *where* $J_{p,q} = \mathsf{diag}(1, \dots, 1, -1, \dots, -1)$ *is a diagonal* $p \times p$ *matrix,* $q = 0, \dots, p$*. Here sets with different* q *are not unitarily equivalent.*

So a set of Pauli matrices is irreducible if and only if $\mathsf{D} = \bar{\mathsf{D}}$*;*

(v) The property "Every matrix commuting with all the Pauli matrices is scalar" is fulfilled if and only if $\mathsf{D} = \bar{\mathsf{D}}$*.*

Proof. Property (5.A.22) yields that $\sigma_j^2 = I$ and hence $\mathsf{Spec}\,\sigma_j \subset \{-1, 1\}$. Let us reduce σ_0 to the diagonal form; then for $d = 0$ a set of Pauli matrices is unitarily equivalent to the set consisting of one matrix

$$\sigma_0 = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} \tag{5.A.25}$$

and hence for $d = 0$ we obtain all the statements of the theorem and $\bar{\mathsf{D}} = 1$ and for $\mathsf{D} = 1$ $\sigma_0 = \varepsilon = \pm 1$.

Thus without any loss of the generality one can assume that (5.A.25) holds and for $d \geq 1$ (5.A.21) and (5.A.22) yield that $-\sigma_0 = \sigma_1^{-1}\sigma_0\sigma_1$ and hence the multiplicities of the eigenvalues ± 1 are equal to $\frac{1}{2}\mathsf{D}$.

Moreover, (5.A.21) and (5.A.22) yield that

$$\sigma_j = \begin{pmatrix} 0 & \alpha_j \\ \alpha_j^\dagger & 0 \end{pmatrix} \qquad \text{for} \quad j = 1, \dots, d \tag{5.A.26}$$

where α_j are unitary. Let $q = \begin{pmatrix} I & 0 \\ 0 & q' \end{pmatrix}$ where q' is a unitary $\frac{1}{2}\mathsf{D} \times \frac{1}{2}\mathsf{D}$ matrix; then $q^\dagger \sigma_0 q = \sigma_0$ and $\sigma'_j = q^\dagger \sigma_j q$ $(j \geq 1)$ have the same form as σ_j but with α_j replaced by $\alpha'_j = \alpha_j q$. Hence without loss of generality one can assume that $\alpha_1 = iI$, i. e. , that

$$\sigma_1 = \begin{pmatrix} 0 & iI \\ -iI & 0 \end{pmatrix}. \tag{5.A.27}$$

So we obtain Statements (i) and (ii) for $d = 1$ with $\bar{\mathsf{D}} = 2$.

Moreover, (5.A.21) and (5.A.22) yield that if σ_0 and σ_1 have the indicated form then the matrices α_j with $j = 2, \dots, d$ also satisfy (5.A.21) and (5.A.22). The proof is complete. □

Lemma 5.A.3. *If $d \ge 2$ and conditions* (5.A.21) *and* (5.A.22) *are fulfilled then by a unitary transformation the set $\sigma_0, \dots, \sigma_d$ can be reduced to the form*

$$\sigma_0 = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}, \quad \sigma_1 = \begin{pmatrix} 0 & iI \\ -iI & 0 \end{pmatrix}, \quad \sigma_j = \begin{pmatrix} 0 & \alpha_j \\ \alpha_j & 0 \end{pmatrix} \tag{5.A.28}$$

$(j = 2, \dots, d)$ *where $\alpha_2, \dots, \alpha_d$ are $\frac{1}{2}\mathsf{D} \times \frac{1}{2}\mathsf{D}$ matrices satisfying* (5.A.21) *and* (5.A.22) *also.*

Conversely, if $\alpha_2, \dots, \alpha_d$ are $\frac{1}{2}\mathsf{D} \times \frac{1}{2}\mathsf{D}$ matrices satisfying (5.A.21) *and* (5.A.22) *then the $\mathsf{D} \times \mathsf{D}$ matrices $\sigma_0, \dots, \sigma_d$ introduced by* (5.A.28) *way also satisfy* (5.A.21) *and* (5.A.22).

Moreover if $\sigma_0, \dots, \sigma_d$ satisfy (5.A.23) *if and only if $\alpha_2, \dots, \alpha_d$ do with the same ς and with d replaced by $d - 2$.*

Theorem 5.A.2 can be easily proven by induction with respect to d with step 2.

We have obtained in particular that for $d = 2$ $\bar{\mathsf{D}} = 2$ and

$$\sigma_0 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \sigma_1 = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}, \quad \sigma_j = \varsigma \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \tag{5.A.29}$$

modulo unitary equivalence; we have obtained the *Pauli matrices;* moreover,

$$[\sigma_j, \sigma_k] = 2i\varsigma \bar{\varepsilon}^{jkl} \sigma_l \tag{5.A.30}$$

where $\bar{\varepsilon}^{jkl}$ is an absolutely skew-symmetric tensor with $\bar{\varepsilon}^{123} = 1$ (we do not discuss the change of coordinates) and we write σ_3 instead of σ_0 here. We have also obtained that for $d = 3, 4$ $\bar{\mathsf{D}} = 4$ and we have a method to construct the corresponding sets. In particular, for $d = 3$ one can assume that

$$\sigma_0 = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}, \quad \sigma_j = \begin{pmatrix} 0 & \alpha_j \\ \alpha_j & 0 \end{pmatrix} \quad j = 1, 2, 3 \tag{5.A.31}$$

where $\alpha_3 = \alpha_0, \alpha_1, \alpha_2$ are Pauli matrices.

We do not prove the two following simple assertions here:

Proposition 5.A.4. *Let $\sigma_0, \dots, \sigma_d$ be Pauli matrices with $d \geq 2$. Let $\mathbb{K}^{\pm} = \mathsf{Ker}(\sigma_1 \pm i\sigma_2)$. Then*

(i) $\dim \mathbb{K}^{\pm} = \frac{1}{2}\mathsf{D}$, *$\mathbb{K}^+$ and $\mathbb{K}^-$ are orthogonal, and $\mathbb{K}^+ \oplus \mathbb{K}^- = \mathbb{H}$;*

(ii) $\sigma_j \mathbb{K}^{\pm} = \mathbb{K}^{\pm}$ *for $j \neq 1, 2$ and $\sigma_j \mathbb{K}^{\pm} = \mathbb{K}^{\mp}$ for $j = 1, 2$.*

(iii) If (5.A.23) *is fulfilled then*

$$\sigma_0 \cdots \sigma_d|_{\mathbb{K}^{\pm}} = \pm\varsigma i^{\frac{d-2}{2}} I. \tag{5.A.32}$$

Proposition 5.A.5. *Let $\sigma_0, \dots, \sigma_d$ be Pauli matrices and $(\omega^{jk})_{j,k=0,\dots,d}$ be a real orthogonal matrix. Then*

$$\sigma'_j = \sum_{0 \leq k \leq d} \omega^{jk} \sigma_k \quad j = 0, \dots, d$$

are also Pauli matrices. Moreover, (5.A.23) *for $\sigma_0, \dots, \sigma_d$ yields the same equality for $\sigma'_0, \dots, \sigma'_d$ with $\varsigma' = \varsigma \operatorname{sgn} \det(\omega^{jk})$.*

Moreover the following assertion is useful:

Proposition 5.A.6. *Let $\sigma_0, \dots, \sigma_d$ be Pauli matrices. Let us introduce Hermitian matrices $\beta_j = \frac{1}{2i}[\sigma_{2j-2}, \sigma_{2j-1}]$ with $j = 1, \dots, r \leq q = \lfloor \frac{d+1}{2} \rfloor$. Then*

(i) $\beta_j^2 = I$, $\quad \beta_1, \dots, \beta_r$ *commute.*

(ii) For every set $(\varepsilon_1, \dots, \varepsilon_r) \in \{-1, 1\}^r$

$$\dim\Big(\bigcap_{1 \leq j \leq r} \mathsf{Ker}(\beta_j - \varepsilon_j) \Big) = 2^{-r}\mathsf{D}. \tag{5.A.33}$$

Proof. Statement (i) is obvious; Statement (ii) is easily proven by induction with respect to r with a constant $d - 2r$ where the inductive construction of the proof of Theorem 5.A.2 is used. □

Propositions 5.A.5 and 5.A.5 yield

Corollary 5.A.7. *Let $\sigma_0, \dots, \sigma_d$ be Dirac matrices, $(F_{jk})_{j,k=0,\dots,d}$ be a skew-symmetric real matrix and $\pm i f_j$, $j = 1, \dots, q$ be its non-zero eigenvalues (we take multiplicities into account), $f_j > 0$. Then*

$$\mathsf{Spec}\Big(\sum_{j,k} F_{jk}[\sigma_j, \sigma_k]\Big) = \Big\{\nu_\varepsilon = \sum_{1\le j\le r} \varepsilon_j f_j, \quad \varepsilon \in \{-1,1\}^r\Big\}. \tag{5.A.34}$$

Further, the multiplicity of each eigenvalue on the left coincides with the multiplicity of each number on the right multiplied by $2^{-r}\mathsf{D}$, assuming that if ν_ε and $\nu_{\varepsilon'}$ coincide then their multiplicities are combined.

Chapter 6

Operators in the Interior of Domain. Esoteric Theory

This chapter is devoted to even more specialized results than the previous one.

In Section 6.1 we extend some of the above results to conjoint spectral asymptotics for families of commuting operators (general or scalar).

Then in Section 6.2 we consider scalar operators with periodic Hamiltonian flow of the principal symbol (or some perturbations of such operators) and under certain conditions we obtain spectral asymptotics with highly accurate remainder estimates; these asymptotics are not necessarily completely Weyl-type. In the case of the cluster character of the spectrum we get the asymptotic distribution of the eigenvalues inside the clusters. Our main tools here are very long term propagation of singularities (the main result is that singularities propagate along periodic trajectories which drift along the Hamiltonian field of some auxiliary symbol) and conjoint spectral asymptotics of two commuting operators (namely, the operator in question can be represented as the sum of an operator A_0 with spectrum $\{2\pi h T_0^{-1} n, n \in \mathbb{Z}\}$ and a perturbing operator μB commuting with A_0, where μ is a small parameter).

Next, in Section 6.4 we consider asymptotics of

$$\int \omega(x,y)|e(x,y,0)|^2\,dxdy$$

with $\omega(x,y)$ singular at the diagonal $x=y$.

Finally, in Section 6.5 we consider mollification with respect to non-spectral parameters and establish that under corresponding microhyperbolicity condition it would lead to the same effect as mollification with respect to spectral parameter; we will need it much later.

As usual we have few appendices.

6.1 Spectral Asymptotics for Families of Commuting Operators

In this section we generalize the results of the previous sections to the case of families of commuting operators.

6.1.1 Introduction

Let $A_j = A_j(x, hD, h)$ ($j = 1, \dots, I$) be h-pseudodifferential operators on a manifold X. We assume that

(6.1.1) Either $X = \mathbb{R}^d$ or X is a compact closed $\mathscr{C}^K$ manifold or X is a compact $\mathscr{C}^K$ manifold with boundary $\partial X \in \mathscr{C}^K$ with large enough $K = K(d)$, $d = \mathsf{dim}\, X$. In the third case A_j are differential operators and their original domains are given by some boundary value conditions.

Moreover, let us assume that

(6.1.2) The operators A_j are self-adjoint operators in $\mathscr{L}^2(X, \mathbb{H})$ where $\mathbb{H}$ is a Hermitian space[1)] and commute.

Let us recall that

Definition 6.1.1. Unbounded self-adjoint operators $A_1, \dots, A_I$ commute if[2)]

(i) Their spectral projectors $E_1(\tau_1), \dots, E_I(\tau_I)$ commute;

(ii) Their propagators $U_1(t_1), \dots, U_I(t_I)$ commute;

[1)] Surely, one can consider operators acting in the Hermitian bundles.

[2)] These conditions are equivalent.

(iii) Their resolvents $(z_1 - A_1)^{-1}, \dots, (z_l - A_l)^{-1}$ commute.

Then

$$A_j = \int_{\mathbb{R}^l} \tau_j \, d_\tau E(\boldsymbol{\tau}) \tag{6.1.3}$$

where $\boldsymbol{\tau} = (\tau_1, \cdots, \tau_l) \in \mathbb{R}^l$, $E(\tau) = E_1(\tau_1) \dots E_l(\tau_l)$ is the *spectral projector of the family of commuting operators* $\{A_1, \dots, A_l\}$ and $E_j(\tau_j)$ is the spectral projector of A_j.

The standard question is how to get the semiclassical asymptotics of the number of conjoint eigenvalues τ lying in the (compact) domain $\Lambda \subset \mathbb{R}^l$. Usually, however, the case of a domain with the smooth boundary is treated when $\Lambda = \{\boldsymbol{\tau}, \phi(\boldsymbol{\tau}) \le 0\}$ with $\phi \in \mathscr{C}^K$ and $|\phi| + |\nabla\phi|$ disjoint from 0. But results of this type are due to the standard theory applied to the operator $A = \phi(A_1, \dots, A_l)$.

The real problem arises when $\partial\Lambda$ is not smooth. These settings are too general to get a meaningful answer. We assume that

$$\Lambda = [\lambda_1, \tau_1] \times [\lambda_2, \tau_2] \times \cdots \times [\lambda_l, \tau_l] \qquad \text{with} \quad \tau'_j < \tau_j. \tag{6.1.4}$$

Remark 6.1.2. Then we immediately will be able to generalize to the case when $\Lambda = \{\boldsymbol{\tau} : \phi(\boldsymbol{\tau}) \in \Lambda'\}$ where Λ' rather than λ is defined by (6.1.4) with l replaced by m and $\phi : \mathbb{R}^l \to \mathbb{R}^m \supset \Lambda'$ is a smooth map (dimensions of Λ' and Λ do not necessarily coincide. Really, if $\phi = (\phi_1, \dots, \phi_m)$ one can consider family $(A'_1, \dots, A'_m) = \phi_1(A_1, \dots, A_l), \dots, \phi_m(A_1, \dots, A_l)$.

However conditions we will use may be not preserved when we pass from family $(A_1, \dots, A_l)$ to $(A'_1, \dots, A'_m)$ unless $m = l$ and ϕ is a diffeomorphism.

Therefore we assume that (6.1.4) is fulfilled i.e. that Λ is the box. In this case one can consider the dimensions of this box as parameters as well. Thus we are going to treat the semiclassical asymptotics of $\mathsf{Tr}(E(\boldsymbol{\tau}'; \boldsymbol{\tau}))Q$ where

$$E(\boldsymbol{\lambda}; \boldsymbol{\tau}) = \big(E_1(\tau_1) - E_1(\lambda_1)\big) \cdots \big(E_l(\tau_l) - E_l(\lambda_l)\big)$$

and Q is an appropriate h-pseudodifferential operator.

To give a more precise description of the operators in question we assume that

(6.1.5) Either A_j are h-differential operators of orders m_j or $A_j \in \tilde{\boldsymbol{\Psi}}^{(m_j)}_{h,\rho,\gamma,h}$ where the classes of h-pseudodifferential operators $\boldsymbol{\Psi}_{h,\rho,\gamma}$ and $\tilde{\boldsymbol{\Psi}}^{(m)}_{h,\rho,\gamma}$ were introduced in Subsection 6.4.2 for $\rho, \gamma \in (0,1]$, $\rho\gamma \ge h^{1-\delta}$, $\delta > 0$ is arbitrarily small.

To attack this problem let us consider the *propagator of the family of commuting operators* $\{A_1, \dots, A_l\}$

$$U(\boldsymbol{t}) = \exp ih^{-1}(t_1A_1 + \cdots + t_lA_l) = \exp(ih^{-1}t_1A_1)\cdots\exp(ih^{-1}t_lA_l) \tag{6.1.6}$$

with $\boldsymbol{t} = (t_1, \dots, t_l) \in \mathbb{R}^l$. Then

$$U(\boldsymbol{t}) = \int_{\mathbb{R}^l} e^{ih^{-1}\langle \boldsymbol{t},\boldsymbol{\tau}\rangle}\, d_{\boldsymbol{\tau}}E(\boldsymbol{\tau}) \tag{6.1.7}$$

and its Schwartz kernel $u(x, y, \boldsymbol{t})$ satisfies the "Cauchy" problem

$$(hD_{t_j} - A_j)u = 0 \quad (j = 1, \dots, l), \qquad u|_{\boldsymbol{t}=0} = \delta(x-y)I. \tag{6.1.8}$$

Since A_j commute we conclude that

(6.1.9) The principal symbols of A_j commute as well: $[a_j, a_k] = 0$.

6.1.2 General Theory

Elliptic Arguments

Applying routine elliptic arguments one can easily prove the following

Proposition 6.1.3. *Let $(A_1, \dots, A_l)$ be a system of commuting operators of* (6.1.5) *type and let the ellipticity condition*

$$\sum_{1\le j\le l} |a_j(z)v| \ge 2\varrho|v| \qquad \forall v \in \mathbb{H} \tag{6.1.10}$$

be fulfilled in the γ-neighborhood $\mathcal{U}$ of $\bar{z} \in T^*\mathbb{R}^d$ with $\gamma \ge h^{\frac12-\delta}$, $\varrho \ge \gamma^2$ where a_j are the principal symbols of A_j. Let $Q_k \in \boldsymbol{\Psi}_{h,\gamma,\gamma}$ and their symbols be supported in $\mathcal{U}$. Then

$$|F_{\boldsymbol{t}\to h^{-1}\boldsymbol{\tau}}\chi_T(\boldsymbol{t})Q_{1x}u\,{}^tQ_{2y}| \le Ch^s T_1\cdots T_l \tag{6.1.11}$$
$$\forall \boldsymbol{\tau} : |\boldsymbol{\tau}| \le \varrho \quad \forall x, y \in \mathbb{R}^d$$

provided $T_j\varrho \ge h^{1-\delta}$ $\forall j$ where $\chi \in \mathscr{C}_0^K(B_l(0,1))$ is any fixed function, subscript l means dimension here, $T = \operatorname{diag}(T_1, \dots, T_l)$, $\chi_T(\boldsymbol{t}) = \chi(T^{-1}\boldsymbol{t})$.

Successive Approximations

As in Section 4.3 let us first construct

$$F_{t\to h^{-1}\tau}\chi_T(\boldsymbol{t})\,\mathsf{Tr}(U(\boldsymbol{t})Q) \tag{6.1.12}$$

with $\chi_T(\boldsymbol{t}) = \chi_{1T_1}(t_1)\cdots\chi_{lT_l}(t_l)$ and $h^{1-\delta} \le T \le h^{\frac12+\delta}$ by the successive approximation method. To do it we do not need to repeat the construction of that section. An easy induction on l with Proposition 4.3.7 at each step gives us the following

Proposition 6.1.4. *Let $(A_1,\dots,A_l)$ be a system of commuting operators of* (6.1.5) *type and let $\chi_j \in \mathscr{C}_0^K[-1,1]$ and*

$$T_j \in [h^{1-\delta}, h^{\frac12+\delta}] \qquad \forall j. \tag{6.1.13}$$

Let $Q_k \in \boldsymbol{\Psi}_h(\mathbb{R}^d)$ be operators with compactly supported symbols[3)]*. Then*

$$\|F_{\boldsymbol{t}\to h^{-1}\boldsymbol{\tau}}\chi_T(\boldsymbol{t})Q_{1x}u(x,y,\boldsymbol{t})\,{}^tQ_y - h^{-d}T_1\cdots T_l\iint e^{ih^{-1}\langle x-y,\xi\rangle}\hat\chi(h^{-1}T(\boldsymbol{\tau}-\boldsymbol{\tau}'))\mathcal{F}(y,\xi,\boldsymbol{\tau}',h)\,d\xi d\tau'\| \le Ch^s \tag{6.1.14}$$

where

$$\mathcal{F}(y,\xi,\tau',h) = \mathsf{Res}_{\mathbb{R}}\,F(y,\xi,\tau',h) \tag{6.1.15}$$

with l-dimensional operation $\mathsf{Res}_{\mathbb{R}}$ and

(6.1.16) *F is the symbol of the operator $(2\pi)^{-d}Q_1(\tau_1-A_1)^{-1}\cdots(\tau_l-A_l)^{-1}Q_2$ constructed in the framework of the formal symbol calculus*

and s is arbitrarily large.

Therefore

$$F = \sum_{0\le n\le M} F_n(y,\xi,\tau) \tag{6.1.17}$$

where $M = M(s)$ and F_n are sums of terms of the sandwich type

$$b_{j_0}(y,\xi)\big(\tau_{j_1}-a_{j_1}(y,\xi)\big)^{-1}b_{j_1}(y,\xi)\big(\tau_{j_2}-a_{j_2}(y,\xi)\big)^{-1}\cdots b_{j_{r-1}}(y,\xi)\big(\tau_{j_r}-a_{j_r}(y,\xi)\big)^{-1}b_{j_r}(y,\xi) \tag{6.1.18}$$

[3)] If $X\ne\mathbb{R}^d$ we replace Q_k by $Q_k\psi_k$ with $\psi\in\mathscr{C}_0^K(B(\bar x,\frac12))$ where $B(\bar x,1)\subset X$.

and b_* *are pseudodifferential symbols supported in* $\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)$ *as* $l+1 \le r \le l+2n$ *for* $n \ge 1$.

In particular,

$$F_0 = q_1^0(\tau_1 - a_1)^{-1} \cdots (\tau_l - a_l)^{-1} q_2^0 \tag{6.1.19}$$

and

$$\mathcal{F}_0 = (2\pi)^{-d} q_1^0 \delta(\tau_1 - a_1) \cdots \delta(\tau_l - a_l) q_2^0 = \partial_{\tau_1} \cdots \partial_{\tau_l} (2\pi)^{-d} q_1^0 \theta(\tau_1 - a_1) \cdots \theta(\tau_l - a_l) q_2^0 \tag{6.1.20}$$

where q_k *are symbols of* Q_k.

Basic Results (General Case)

Let us start from the really rough estimates:

Theorem 6.1.5. *Let* $(A_1, \dots, A_l)$ *be a system of commuting operators of* (6.1.5) *type and let* Q_k *be operators with compactly supported symbols. Then*

(i) The following estimate holds:

$$|(Q_{1x} e\, {}^t Q_{2y})(x, y, \boldsymbol{\tau})| \le C h^{-d}. \tag{6.1.21}$$

(ii) In the framework of Proposition 6.1.3 (i.e. if system $(A_1, \dots, A_l)$ *is elliptic on either* $\mathsf{supp}(q_1)$ *or* $\mathsf{supp}(q_2)$*) the following estimate holds:*

$$|(Q_{1x} e\, {}^t Q_{2y})(x, y, \boldsymbol{\tau}', \boldsymbol{\tau})| \le C h^s \qquad \forall \tau', \tau : |\tau| \le \rho, |\tau'| \le \rho. \tag{6.1.22}$$

Proof. Let us recall that $e(x, y, \boldsymbol{\lambda}, \boldsymbol{\tau})$ is a Schwartz kernel of operator $E(\boldsymbol{\lambda}, \boldsymbol{\tau}) = \prod_j (E(\tau_j) - E(\lambda_j))$ (which is a projector as $\boldsymbol{\tau} \ge \boldsymbol{\lambda}$ where $\boldsymbol{\tau} \ge \boldsymbol{\lambda}$ means exactly that $\tau_j \ge \lambda_j$ for $j = 1, \dots, l$.

Then estimates (6.1.21), (6.1.22) follow from the similar estimates for $\Gamma_x (Q_{1x} e\, {}^t Q_{2y})(\boldsymbol{\tau}, \boldsymbol{\lambda})$ replaced by $F_{\boldsymbol{t} \to h^{-1}\boldsymbol{\tau}} \phi_T(\boldsymbol{t}) \Gamma_x (Q_{1x} u\, {}^t Q_{2y})$ (where the first esxtimate is obvious and the second one is due to Proposition 6.1.3) as we pick $T \asymp 1$ and l*-dimensional Hörmander function* ϕ (which can be taken as a product of l ordinary Hörmander functions: $\phi(\boldsymbol{\tau}) = \prod_j \phi(\tau_j)$).

We get rid of Γ_x and assumption that $Q_1 = Q_2^*$ following the same scheme as in Section 4.2. □

Theorem 6.1.6. *Let* $(A_1, \dots, A_l)$ *be a system of commuting operators of* (6.1.5) *type and let* Q_k *be operators with compactly supported symbols. Let* $\varphi \in \mathscr{C}_0^K(\mathbb{R})$. *Then estimate*

$$\Big|\int \varphi(hL^{-1}(\bar{\tau}-\tau))\big(d_\tau \int (Q_{1x}e^{\,t}Q_{2y})(x,x,\tau)dx - h^{-d}\iint \mathcal{F}(x,\xi,\tau)dxd\xi d\tau\big)\Big| \le Ch^s \tag{6.1.23}$$

holds provided $L = \mathsf{diag}(L_1, \dots, L_l)$ *with* $h^{\frac{1}{2}-\delta} \le L_j \le h^{-n} \quad \forall j$.

Proof. We just apply $\varphi(L^{-1}(hD_{\boldsymbol{t}} - \bar{\tau}))$ to (6.1.14) (inside absolute value) and then take $\boldsymbol{t} = 0$. □

The Microhyperbolicity Condition

Let us replace our standard microhyperbolicity condition by the similar condition for a system $(a_1, \dots, a_l)$:

Definition 6.1.7. We call system $(a_1, \dots, a_l)$ microhyperbolic (or ξ-microhyperbolic) in Ω if for each $\zeta \in \mathbb{S}^l$ symbol $a_\zeta = \sum_{1\le j\le l} \zeta_j a_j(x,\xi)$ is microhyperbolic (or ξ-microhyperbolic respectively) in Ω.

Note that in this definition direction of (ξ-)microhyperbolicity of a_ζ may depend on ζ.

Let us repeat arguments of Section 2.1.5. The routine propagation of singularities arguments (combined with elliptic arguments) yield

Proposition 6.1.8. *Let* $(A_1, \dots, A_l)$ *be a system of commuting operators of* (6.1.5) *type.*

(i) Let symbol a_ζ *be* ξ*-microhyperbolic at the point* $\bar{z}$ *as* $\zeta = \bar{\zeta}$ *and let* $\chi \in \mathscr{C}_0^K$ *be supported in the* ϵ*-vicinity of* $\bar{\zeta}$ *with sufficiently small* $\epsilon > 0$. *Then*

$$\|F_{\boldsymbol{t}\to h^{-1}\tau}\chi_T(\boldsymbol{t})\Gamma_x(Q_{1x}u\,{}^tQ_{2y})\| \le Ch^s \qquad \forall x \quad \forall \boldsymbol{\tau} : |\boldsymbol{\tau}| \le \epsilon \tag{6.1.24}$$

with any scalar $T \in [\epsilon_1, T_0]$ *and with* $Q_j \in \boldsymbol{\Psi}_h$ *with symbols supported in the* ϵ*-neighborhood of* $\bar{z}$ *where* $\epsilon_1 > 0$ *is arbitrarily small, and* T_0 *is a sufficiently small constant which does not depend on* ϵ_1 *or the choice of* χ.

(ii) Let $J \subset \{1, \dots, l\}$ *and let system* $(a_j)_{j\in J}$ *be* ξ*-microhyperbolic at point* $\bar{z}$*. Let* $\chi \in \mathscr{C}_0^K\big(B_r(0,1) \setminus B_r(0, \frac{1}{2})\big)$ *where* $r = \#J$*,* $T \in [\epsilon_1, T_0]$*. Further, let* $\phi \in \mathscr{C}_0^K\big(B_{l-r}(0,1)\big)$*,* $T'' \in [h^{1-\delta}, \epsilon_0 T]$*.*

Then (6.1.24) *holds with* $\chi_T(t)$ *replaced by* $\chi_T(t')\phi_{T''}(t'')$*,* $t' := (t_j)_{j\in J}$*,* $t'' := (t_j)_{j\notin J}$*.*

Then we immediately arrive to

Corollary 6.1.9. *Let* $(A_1, \dots, A_l)$ *be a system of commuting operators of* (6.1.5) *type. Let* $J \subset \{1, \dots, l\}$ *and let system* $(a_j)_{j\in J}$ *be* ξ*-microhyperbolic at point* $\bar{z}$*. Let* Q_k *be operators with symbols supported in vicinity of* $\bar{z}$*. Then*

(i) Estimate (6.1.14) *holds provided*

$$T_j \in [h^{1-\delta}, T_0] \quad \forall j \in J, \qquad T_j \in [h^{1-\delta}, h^{\frac{1}{2}+\delta}] \quad \forall j \notin J. \tag{6.1.25}$$

(ii) Estimate (6.1.23) *holds provided*

$$L_j \in [h^{1-\delta}, h^{-n}] \quad \forall j \in J, \qquad L_j \in [h^{\frac{1}{2}-\delta}, h^{-n}] \quad \forall j \notin J. \tag{6.1.26}$$

Exploiting Microhyperbolicity

Repeating rescaling arguments of Theorem 2.1.19 and remembering that in scaling $t \to T^{-1}t$ brings factor T^l rather than T as it was then (when $l = 1$) we arrive to

Proposition 6.1.10. *In the framework of Proposition 6.1.8(ii)*

$$\|F_{t\to h^{-1}\tau}\chi_T(t')\phi_{T''}(t'')\Gamma_x(Q_{1x}u\,{}^tQ_{2y})\| \le Ch^{l-d}\big(\frac{h}{T}\big)^s \qquad \forall x \quad \forall \tau : |\tau| \le \epsilon \quad \forall T \in [h, T_0]. \tag{6.1.27}$$

Proposition 6.1.11. *Let* $(A_1, \dots, A_l)$ *be a system of commuting operators of* (6.1.5) *type. Let* $(a_1, \dots, a_l)$ *be* ξ*-microhyperbolic at point* $\bar{z}$ *and let* Q_k *be operators with symbols supported in vicinity of* $\bar{z}$*. Then*

(i) Estimate

$$\|F_{t\to h^{-1}\tau}\phi_T(t)\Gamma_x(Q_{1x}u\,{}^tQ_{2y})\| \le Ch^{l-d}\prod_{1\le j\le l}\big(\frac{T_j}{T_0}+1\big) \qquad \forall x \quad \forall \tau : |\tau| \le \epsilon \quad \forall T_j \ge h \tag{6.1.28}$$

holds as $\phi \in \mathscr{C}_0^K(B(0,1))$*.*

(ii) the following estimate holds:

$$\|\Gamma_x(Q_{1x}e^{\,t}Q_{2y})(\boldsymbol{\tau}',\boldsymbol{\tau})\| \le Ch^{l-d}T_0^{-l}\prod_{1\le j\le l}\bigl(1+\frac{T_0}{h}|\tau_j-\lambda_j|\bigr) \tag{6.1.29}$$
$$\forall \boldsymbol{\tau}',\boldsymbol{\tau} : |\boldsymbol{\tau}'|\le \epsilon_0, |\boldsymbol{\tau}|\le \epsilon_0.$$

Proof. (a) Statement (i) for $T_j \in [h, T_0]$ follows from Proposition 6.1.10 after we pick up an appropriate partition of unity with respect to $\boldsymbol{\tau}$.

(b) Let us pick up $T = T_0$ and multidimensional Hörmander function ϕ. Then we derive immediately from Proposition 6.1.10 the following estimate

$$\|\Gamma_x(e^{\,t}Q_y)(\boldsymbol{\tau}',\boldsymbol{\tau})\| \le Ch^{l-d}T_0^{-l} \qquad \forall \boldsymbol{\tau}',\boldsymbol{\tau} : |\boldsymbol{\tau}|\le \epsilon_0,\ |\boldsymbol{\tau}-\boldsymbol{\lambda}|\le C\frac{h}{T_0}$$

which immediately implies (6.1.29). We can get rid of Γ_x and assumption that $Q_1 = Q_2^*$ following the same scheme as in Section 4.2.

(c) After (6.1.29) is proven we can get prove (6.1.28) in the full generality as it was done in Section 4.2. □

Remark 6.1.12. (i) Let us recall that $T_0 \asymp 1$ but in certain settings this could change.

(ii) One can replace ξ-microhyperbolicity condition by microhyperbolicity condition and Γ_x by Γ.

(iii) Finally, if we know only that $(a_j)_{j\in J}$ is ξ-microhyperbolic where $J \subset \{1,\dots,l\}$, $\#J = r$ then we conclude that

$$\|F_{\boldsymbol{t}\to h^{-1}\boldsymbol{\tau}}\phi_T(\boldsymbol{t})\Gamma_x(Q_{1x}u\,{}^tQ_{2y}\| \le Ch^{r-d}\prod_{j\in J}\bigl(\frac{T_j}{T_0}+1\bigr)\cdot\prod_{j\notin J}(T_j+1) \tag{6.1.30}$$
$$\forall x \quad \forall \boldsymbol{\tau} : |\boldsymbol{\tau}|\le \epsilon \quad \forall T_j \ge h$$

and

$$\|\Gamma_x(Q_{1x}e^{\,t}Q_{2y})(\boldsymbol{\tau}',\boldsymbol{\tau})\| \le Ch^{r-d}T_0^{-r}\prod_{j\in J}\bigl(1+\frac{T_0}{h}|\tau_j-\lambda_j|\bigr) \tag{6.1.31}$$
$$\forall \boldsymbol{\tau}',\boldsymbol{\tau} : |\boldsymbol{\tau}'|\le \epsilon_0, |\boldsymbol{\tau}|\le \epsilon_0.$$

Tauberian Arguments

Let

$$\mathsf{N}_{x,y}(\boldsymbol{\lambda},\boldsymbol{\tau}) \coloneqq Q_{1x}e(x,y,\boldsymbol{\lambda},\boldsymbol{\tau})\,{}^{t}Q_{2y} \tag{6.1.32}$$

and

$$\mathsf{N}_{x,y,\varphi_1,\dots,\varphi_l;L_1,\dots,L_l}(\boldsymbol{\tau}) \coloneqq \int \prod_{1\le j\le l} \varphi_j(L_j^{-1}(\tau_j-\lambda_j))d_{\boldsymbol{\lambda}}\mathsf{N}_{x,y}(\boldsymbol{\lambda}) \tag{6.1.33}$$

(where $\mathsf{N}_{x,y}(\boldsymbol{\tau}) = \mathsf{N}_{x,y}(-\boldsymbol{\infty},\boldsymbol{\tau})$ etc).

Now we want to approximate $e(x,y,\boldsymbol{\tau})$ by

$$e^{\mathsf{T}}(x,y,\boldsymbol{\tau}) \coloneqq h^{-l}\int_{\boldsymbol{\tau}+\mathbb{R}^{-,l}} \Big(F_{\boldsymbol{t}\to h^{-1}\boldsymbol{\lambda}}\bar{\chi}(T^{-1}\boldsymbol{t})u(x,y,\boldsymbol{t})\Big)d\boldsymbol{\lambda} \tag{6.1.34}$$

with matrix $T = \mathsf{diag}(T_1,\dots,T_l)$. Namely,

(6.1.35) Let $\mathsf{N}^{\mathsf{T}}_{x,y}(\boldsymbol{\lambda},\boldsymbol{\tau})$ and $\mathsf{N}^{\mathsf{T}}_{x,y,\varphi_1,\dots,\varphi_l;L_1,\dots,L_l}$ be defined by (6.1.32) and (6.1.33) with $e(x,y,\boldsymbol{\tau})$ replaced by $e^{\mathsf{T}}(x,y,\boldsymbol{\tau})$.

Let $\mathsf{R}_* \coloneqq \mathsf{N}_* - \mathsf{N}^{\mathsf{T}}_*$ denote the Tauberian error.

Theorem 6.1.13. *Let $(A_1,\dots,A_l)$ be a system of commuting operators of* (6.1.5) *type.*

(i) Assume that the following modification of condition (6.1.29)

$$\|(Q_{1x}e\,{}^{t}Q_{2y})(\boldsymbol{\tau}',\boldsymbol{\tau})\| \le Ch^{l-d}\prod_{1\le j\le l}\big(\frac{1}{T_j}+\frac{1}{h}|\tau_j-\lambda_j|\big) \tag{6.1.36}$$
$$\forall \boldsymbol{\tau}',\boldsymbol{\tau} : |\boldsymbol{\tau}'|\le\epsilon_0, |\boldsymbol{\tau}|\le\epsilon_0$$

holds where $T_j \ge h$.

Then

$$\mathsf{R}^{T}_{x,y}(\boldsymbol{\lambda},\boldsymbol{\tau}) \prec Ch^{-d}\sum_{1\le k\le l}\frac{h}{T_k}\prod_{1\le j\le k: j\ne k}\big(|\tau_j-\lambda_j|+\frac{h}{T_j}\big) \tag{6.1.37}$$

and if φ_k satisfy (4.2.73)–(4.2.75) *and $L_jT_j \ge h$ for all j*

$$\mathsf{R}_{x,y,\varphi_1,\dots,\varphi_l;L_1,\dots,L_l} \prec Ch^{-d}L_1\cdots L_l\sum_{1\le k\le l}\frac{h}{L_kT_k}\vartheta_k\big(\frac{h}{L_kT_k}\big) \tag{6.1.38}$$

(ii) Further, if (6.1.36) *holds (only) after application of* Γ_x *or* Γ *then the same is true for* (6.1.37) *and* (6.1.38).

Note that (6.1.37) is a special case of (6.1.38) with φ_k which are characteristic functions of $[0,1]$.

Proof. Proof is trivial: we just apply l times Tauberian Lemma 4.2.13 with respect to variable τ_j with j running from 1 to l. □

Principal Results

Now assuming that system $(a_1,\dots,a_l)$ is ξ-microhyperbolic we can apply Theorem 6.1.13 with $T_j \asymp 1$. However due to ξ-microhyperbolicity with the negligible error we can replace in the Tauberian expressions $\mathsf{N}^{\mathsf{T}}_{x,x,*}$ (as $x=y$) $T_j \asymp 1$ by any $T_j \ge h^{1-\delta}$ thus arriving to Weyl expression

$$e^{\mathsf{W}}(x,y,\boldsymbol{\tau}) = (2\pi)^{-d}\int\int_{\boldsymbol{\tau}+\mathbb{R}^{-l}} \mathcal{F}(x,y,\boldsymbol{\lambda}) e^{i\langle x-y,\xi\rangle}\, d\boldsymbol{\lambda} d\xi. \tag{6.1.39}$$

Thus we proved

Theorem 6.1.14. *Let* $(A_1,\dots,A_l)$ *be a system of commuting operators of* (6.1.5) *type and let* Q_1, Q_2 *be operators with symbols compactly supported in* Ω.

(i) Let system $(a_1,\dots,a_l)$ *be* ξ*-microhyperbolic in* Ω. *Then*

$$\begin{aligned}\mathsf{R}^{\mathsf{W}}_x(\boldsymbol{\tau},\boldsymbol{\lambda}) \coloneqq \mathsf{N}_x(\boldsymbol{\tau},\boldsymbol{\lambda}) - {}& \\ (2\pi h)^{-d}\int q_1^0(x,\xi)\mathsf{e}(\boldsymbol{\tau},\boldsymbol{\lambda},x,\xi) q_2^0(x,\xi)\, d\xi \prec {}& \\ Ch^{1-d}\sum_{1\le k\le l}\ \prod_{1\le j\le l: j\ne k} \bigl(|\tau_j-\lambda_j|+h\bigr)&\end{aligned} \tag{6.1.40}$$

where

$$\mathsf{e}(\boldsymbol{\tau},\boldsymbol{\lambda},x,\xi) = \bigl(\theta(\tau_1 - a_1(x,\xi))\cdots(\tau_l - a_l(x,\xi)\bigr) \tag{6.1.41}$$

and skipped subscript y *as usual means that* $y=x$.

Further, assume that φ_k *satisfy* (4.2.73)–(4.2.75) *and* $L_k \ge h$*; then*

$$\mathsf{R}^{\mathsf{W}}_{x,\varphi_1,L_1,\dots,\varphi_l,L_l} \prec Ch^{-d}L_1\cdots L_l \sum_{1\le k\le l} \frac{h}{L_k}\vartheta_k\bigl(\frac{h}{L_k}\bigr) \tag{6.1.42}$$

where the left-hand expression is the difference between $\mathsf{N}_{x,\varphi_1,L_1,\dots,\varphi_l,L_l}$ *and* $\mathsf{N}^{\mathsf{W}}_{x,\varphi_1,L_1,\dots,\varphi_l,L_l}$ *obtained by plugging* $e^{\mathsf{W}}(x,y,\boldsymbol{\tau})$ *instead of* $e(x,y,\boldsymbol{\tau})$ *in the definition of* $\mathsf{N}_{x,\varphi_1,L_1,\dots,\varphi_l,L_l}$*.*

(ii) Let system $(a_1,\dots,a_l)$ *be microhyperbolic in* Ω*. Then all above estimates hold after integration with respect to* x*. In particular*

$$\mathsf{R}^{\mathsf{W}}(\boldsymbol{\tau},\boldsymbol{\lambda}) \coloneqq \mathsf{N}(\boldsymbol{\tau},\boldsymbol{\lambda}) - (2\pi h)^{-d}\int q_1^0(x,\xi)e(\boldsymbol{\tau},\boldsymbol{\lambda},x,\xi)q_2^0(x,\xi)\,dxd\xi \prec Ch^{1-d}\sum_{1\le k\le l}\ \prod_{1\le j\le k: j\ne k}\bigl(|\tau_j-\lambda_j|+h\bigr). \tag{6.1.43}$$

Possible Generalizations, Remarks

One can easily generalize Theorem 6.1.14 to the case when only subsystem is (ξ-)microhyperbolic:

Theorem 6.1.15. *Let* $(A_1,\dots,A_l)$ *be a system of commuting operators of* (6.1.5) *type and let* Q_1, Q_2 *be operators with symbols compactly supported in* Ω*. Let* $\varphi_j \in \mathscr{C}_0^K$*,* $L_j \ge h^{\frac12-\delta}$ *for all* $j\notin J$ *where* $J\subset\{1,\dots,l\}$*.*

(i) Let system $(a_j)_{j\in J}$ *be* ξ*-microhyperbolic in* Ω*. Then*

$$\mathsf{R}^{\mathsf{W}}_{x,(\varphi_j,L_j)_{j\notin J}}(\boldsymbol{\tau}',\boldsymbol{\lambda}') \coloneqq \int \prod_{j\notin J}\varphi_{jL_j}(\tau_j)\,d_{\boldsymbol{\tau}''}\mathsf{R}^{\mathsf{W}}_x(\boldsymbol{\tau},\boldsymbol{\lambda}) \prec Ch^{1-d}\sum_{k\in J}\ \prod_{j\in J: j\ne k}\bigl(|\tau_j-\lambda_j|+h\bigr) + Ch^s \tag{6.1.44}$$

with arbitrarily large exponent s*.*

Further, assume that φ_k *satisfy* (4.2.73)–(4.2.75) *and* $L_k \ge h$ *for all* $k\in J$*; then*

$$\mathsf{R}^{\mathsf{W}}_{x,\varphi_1,L_1,\dots,\varphi_l,L_l} \prec Ch^{-d}\prod_{k\in J}L_j\sum_{k\in J}\frac{h}{L_k}\vartheta_k\bigl(\frac{h}{L_k}\bigr) + Ch^s. \tag{6.1.45}$$

(ii) Let system $(a_j)_{j\in J}$ be microhyperbolic in Ω. Then all above estimates hold after integration with respect to x. In particular,

$$\mathsf{R}^{\mathsf{W}}_{(\varphi_j,L_j)_{j\notin J}}(\boldsymbol{\tau}',\boldsymbol{\lambda}') \coloneqq \int \prod_{j\notin J} \varphi_{jL_j}(\tau_j)\, d_{\tau''}\mathsf{R}^{\mathsf{W}}(\boldsymbol{\tau},\boldsymbol{\lambda}) \prec Ch^{1-d}\sum_{k\in J}\ \prod_{j\in J: j\neq k} \bigl(|\tau_j-\lambda_j|+h\bigr) + Ch^s. \tag{6.1.46}$$

Problem 6.1.16. Get sharp remainder estimates (namely with right-hand expressions (6.1.37) or (6.1.38) with $T_j \geq 1$. To do this one needs to introduce *multitime generalized Hamiltonian flow* exactly as we introduced in Section 2.2 generalized Hamiltonian flow and then to define loop or periodic points for such flow. However since $a_1,\dots,a_l$ commute one can introduce such flow as a product of generalized Hamiltonian flows:

$$\Psi_{\boldsymbol{t},a_1,\dots,a_l} = \Psi_{t_1,a_1}\circ\Psi_{t_2,a_2}\circ\cdots\circ\Psi_{t_l,a_l} \tag{6.1.47}$$

(but one needs to show that these flows commute).

We will do it only in the case of scalar symbols $a_1,\dots,a_l$ in the next subsection. The general construction is left to the reader and we believe that full exposition deserves to be published.

Remark 6.1.17. We do not need large smoothness; in particular we can assume that operators $A_1,\dots,A_l$ satisfy regularity conditions of Section 4.6 (but then we need ξ-microhyperbolicity). However our main target are operators with irregular coefficients rather than rough operators. So if we have commuting irregular operators $A_1,\dots,A_l$ one should be able to approximate them by rough operators $A_{1\varepsilon},\dots,A_{l\varepsilon}$ in such way that these operators also commute. While in some special cases it is possible but there is no general theory and it even does not seem to be possible.

Remark 6.1.18. Let $a_1,\dots,a_m$, $m\leq l$ be scalar symbols. Then $(a_1,\dots,a_l)$ is microhyperbolic if and only if for all $J\subset\{1,\dots,m\}$

(a) $(da_j)_{j\in J}$ are linearly independent at $(a_j)_{j\in J}=0$ and therefore $\Sigma_J \coloneqq \{(a_j)_{j\in J}=0\}$ is a smooth manifold in T^*X and

(b) as $m<l$ $(a_{m+1},\dots,a_l)$ restricted to Σ_m is microhyperbolic.

One can describe ξ-microhyperbolicity as microhyperbolicity for fixed x and therefore the above description works (with fixed x) for ξ-microhyperbolicity.

6.1.3 Operators with Scalar Symbols

Preliminary Remarks

Let us assume now that

(6.1.48) All the symbols $a_1, \dots, a_l$ are scalar.

Then since $(A_1, \dots, A_l)$ is a system of commuting operators

$$\{a_j, a_k\} = 0 \qquad \forall j, k = 1, \dots, l \tag{6.1.49}$$

and assuming that at $\bar{z}$ a subsystem $(a_1, \dots, a_r)$ is microhyperbolic and no its subsystem is elliptic one can introduce symplectic coordinates in the vicinity of $\bar{z}$ such that $a_j = \xi_j$ for $j = 1, \dots, m$ there.

Furthermore one can prove easily

Proposition 6.1.19. *Let $(A_1, \dots, A_l)$ be a system of commuting operators. Assuming that at $\bar{z}$ a subsystem $(a_1, \dots, a_m)$ is microhyperbolic and no its subsystem is elliptic one can find a h-Fourier integral operator $\mathcal{F}$ such that $\mathcal{F}\mathcal{F}^* \equiv I$ in vicinity of $\bar{z}$ and*

$$\mathcal{F}^*\mathcal{F} \equiv I, \qquad \mathcal{F}^* A_j \mathcal{F} \equiv hD_j \quad \forall j = 1, \dots, m \qquad \text{in vicinity of } 0. \tag{6.1.50}$$

Furthermore

$$\mathcal{F}^* A_j \mathcal{F} \equiv A_j'(x', hD, h) \quad \forall j = m+1, \dots, l \qquad \text{in vicinity of } 0 \tag{6.1.51}$$

with $(x'; x'') = (x_1, \dots, x_m; x_{m+1}, \dots, x_l)$ etc.

Asymptotics with Mollifications

Our first task is to replace condition $L_j \ge h^{\frac{1}{2}-\delta}$ by the condition $L_j \ge h^{1-\delta}$ in Theorems 6.1.6 and 6.1.15.

Theorem 6.1.20. *Theorems 6.1.6 (with mollification with respect to x) and 6.1.15(ii) hold under extra condition* (6.1.48) *if we relax conditions to L_j to $L_j \ge h^{1-\delta}$ for all $j = 1, \dots, l$ (in Theorem 6.1.6) and or all $j = m+1, \dots, l$ (in Theorem 6.1.15) respectively.*

Proof. Let us apply induction with respect to (r,m) where r is the number of $j=1,\dots,l$ such that $L_j \le h^{1-\delta}$. Note that as $r=0$ condition $L_j \asymp 1$ is fulfilled for all j and we can apply Theorems 6.1.6 and 6.1.15; meanwhile as $m=l$ system $(a_1,\dots,a_l)$ is microhyperbolic and we can apply Theorem 6.1.15.

Due to Proposition 6.1.19 one can assume without any loss of the generality that $\bar{z}=0$ and in its vicinity $A_j = hD_j$ for $j=1,\dots,m$ and $A_j = A_j(x'', hD', hD'')$ for $j=m+1,\dots,l$.

Let us introduce the scaling function

$$\gamma = \epsilon\Big(\sum_{m+1\le j\le l} (|b_j| + |\nabla b_j|^2) + |\xi'|\Big)^{\frac{1}{2}} + \bar{\gamma} \tag{6.1.52}$$

with $b_j = a_j(x'',0,\xi'')$ and

$$\bar{\gamma} = |L|^{\frac{1}{2}}, \qquad |L| = \max_{1\le j\le l} L_j \tag{6.1.53}$$

and a small constant $\epsilon>0$. Let us recall that $|L| \ge h^{\frac{1}{2}-\delta'}$ unless $m=l$.

Then $|\nabla\gamma| \le \frac{1}{2}$. Let us make a $(\epsilon,\gamma,\gamma,\gamma^2)$-admissible partition with respect to (x',x'',ξ',ξ'') and consider the contribution of one element of this partition. Obviously, we need to rescale $x'' \mapsto x''_{\mathsf{new}} = x''\gamma^{-1}$ and introduce $h_{\mathsf{new}} = h\gamma^{-2}$. This yields the rescaling $\xi' \mapsto \xi'_{\mathsf{new}} = \xi'\gamma^{-2}$, $\xi'' \mapsto \xi''_{\mathsf{new}} = \xi''\gamma^{-1}$. Moreover, let us divide the operators A_j by γ^2 for all $j=1,\dots,l$; so, $L_j \mapsto L_{j,\mathsf{new}} = L_j\gamma^{-2}$ and h/L_j are preserved.

First, let us consider elements of the partition with $|\xi'| \ge \epsilon_0\gamma^2$ and $\gamma \ge C_1\bar{\gamma}$.

Then system is elliptic near 0 and Theorem 6.1.5(ii) yields that the contribution of such elements to the principal part is 0 and the contribution to the remainder is $O(h^s)$ provided C_1 is large enough.

Now, if $|L| \ge \epsilon_0\gamma^2$ then after this rescaling procedure we are in the case $(r-1,m)$ [4] and due to induction assumption we obtain that the contribution of such an element does not exceed the rescaled right-hand expression of estimate (6.1.45) which is

$$C\gamma^{2d-2m}\Big(h^{-d}\prod_{k=1,\dots,m} L_j \sum_{k=1,\dots,m} \frac{h}{L_k}\vartheta_k\big(\frac{h}{L_k}\big) + h^{s'}\Big) \tag{6.1.54}$$

[4] Really, $L_{j\mathsf{new}} \asymp 1$ for at least one number j.

where s' is another but still arbitrarily large exponent.

On the remaining elements with $\gamma \ge C\bar{\gamma}$ microhyperbolicity condition is fulfilled for a subsystem with $(m+1)$ elements after rescaling and permutation of A_j with $j = m+1, \dots, l$. Therefore we can also apply the induction hypothesis. We obtain that the contribution of such element to the remainder also does not exceed the rescaled right-hand expression of estimate (6.1.45) which is (6.1.54).

Now let us restrict γ to $\Lambda := \{x' = \xi' = 0\}$ and consider contribution of $B(z'', \gamma(z'')) \times \mathbb{R}^{2m} \cap \Omega$ where $z'' = (x'', \xi'')$; due to the previous arguments it does not exceed (6.1.54) and therefore the total contribution of such balls does not exceed (6.1.54) multiplied by γ^{-2d+2m} (since $\dim \Lambda = 2d - 2m$) and integrated over Λ; this is exactly (6.1.45). □

Principal Results

Now we can get rid of the mollification.

Theorem 6.1.21. *Let $(A_1, \dots, A_l)$ be a system of commuting operators of* (6.1.5) *type and condition* (6.1.48) *be fulfilled. Moreover, let $(a_1, \dots, a_{l-1})$ be microhyperbolic in the vicinity of $\bar{z}$ (in which case $\Sigma := \{a_1 = \dots = a_{l-1} = 0\}$ is a smooth manifold). Assume that φ_j satisfy* (4.2.73)–(4.2.75) *and $L_j \ge h$.*

(i) Let $b = a_l|_\Sigma$ satisfy condition $(5.2.20)_r$

$(6.1.55)_r$ $|b(x'', \xi'') - \tau_l| + |\nabla_{x'',\xi''} b(x'', \xi'')| \le \epsilon_0 \implies \operatorname{Hess} b(x'', \xi'')$ *has r eigenvalues (counting multiplicities) $f_1, \dots, f_r$ such that $|f_1| \ge \epsilon_0, \dots, |f_r| \ge \epsilon_0$* [5] *with $r \ge 3$ or*

$(6.1.55)_2^+$ $|b(x'', \xi'') - \tau_l| + |\nabla_{x'',\xi''} b(x'', \xi'')| \le \epsilon_0 \implies \operatorname{Hess} b(x'', \xi'')$ *has 2 eigenvalues (counting multiplicities) f_1, f_2 of the same sign such that $|f_1| \ge \epsilon_0, |f_2| \ge \epsilon_0$* [5].

Then estimates (6.1.43) *and*

$$\mathsf{R}^{\mathsf{W}}_{\varphi_1, L_1, \dots, \varphi_l, L_l} \prec Ch^{-d} L_1 \cdots L_l \sum_{1 \le k \le l} \frac{h}{L_k} \vartheta_k\Big(\frac{h}{L_k}\Big) \tag{6.1.56}$$

hold.

[5] The other eigenvalues are arbitrary.

(ii) Let b *satisfy condition* $(6.1.55)_2$. *Then estimates*

$$\mathsf{R}^{\mathsf{W}} \prec Ch^{1-d} \sum_{1\le k\le l} \prod_{1\le j\le k: j\ne k} \bigl(|\tau_j-\lambda_j|+h\bigr)\,|\log h| \tag{6.1.57}$$

and

$$\mathsf{R}^{\mathsf{W}}_{\varphi_1,L_1,\dots,\varphi_l,L_l} \prec Ch^{-d}L_1\cdots L_l \sum_{1\le k\le l} \frac{h}{L_k}\vartheta_k\bigl(\frac{h}{L_k}\bigr)\,|\log h| \tag{6.1.58}$$

hold.

(iii) Let b *satisfy condition* $(6.1.55)_1$. *Then estimates*

$$\mathsf{R}^{\mathsf{W}} \prec Ch^{\frac12-d} \sum_{1\le k\le l} \prod_{1\le j\le k: j\ne k} \bigl(|\tau_j-\lambda_j|+h\bigr) \tag{6.1.59}$$

and

$$\mathsf{R}^{\mathsf{W}}_{\varphi_1,L_1,\dots,\varphi_l,L_l} \prec Ch^{-\frac12-d}L_1\cdots L_l \sum_{1\le k\le l} \frac{h}{L_k}\vartheta_k\bigl(\frac{h}{L_k}\bigr) \tag{6.1.60}$$

hold.

Proof. Let us introduce scaling function $\gamma(z)$ by (6.1.52) with $\bar\gamma = h^{\frac12}$. Let us rescale as in the proof of Theorem 6.1.20. Then the right-hand expressions of (6.1.43) and (6.1.57) scale to the same expressions but with an extra factor γ^{2d-2l} and therefore the contribution of $B(z',\gamma(z'))\times\mathbb{R}^{2m}\cap\Omega$ to the remainder does not exceed $\gamma^{2d-2l}R$ where R denotes the original expression, $z''\in\Sigma$, $\dim\Sigma = 2d-2l+2$ and we again restricted γ to Σ.

Then the total contribution to the remainder does not exceed $\int \gamma^{-2}\,dz''\times R$ and we arrive to all estimates; under condition $(6.1.55)_2^+$ we introduce coordinates $z''=(z_1,z_2;z''')$ on Σ such that $\gamma(z'')\gtrsim |z_1|+|z_2|$ and $|z_1|+|z_2|$ has a constant magnitude as z''' is constant and ellipticity is violated (as we did in the proof of Theorem 5.2.2). □

Problem 6.1.22. (i) It would be very interesting to carry out the analysis of Section 5.2 but it requires large t_l which is impossible due to terms with $|\alpha|=1$ in the decomposition $b\sim\sum b_\alpha(x'',\xi'')\xi'^\alpha$. Really, these terms mean the propagation with respect to x' with the speed $b_\alpha(x,\xi'')$.

On the other hand, if $b_\alpha=\mathsf{const}$ we would be able to replace A_l by $A_l' := A_l - \sum_\alpha b_\alpha A^\alpha$ where $\alpha\in\mathbb{Z}^{+\,l-1}$ and $A^\alpha := A_1^{\alpha_1}\cdot A_{l-1}A^{\alpha_{l-1}}$ and analysis of this new system $(A_1,\dots,A_{l-1},A_l)$ would lead us to the desired results. However b_α are variable and this is a difficulty we could not tackle.

(ii) It would be even more challenging to consider few degenerating symbols $a_1, \dots, a_l$.

We strongly believe that solution of any of these two problems deserves to be published.

Example 6.1.23. We leave to the reader the hosts of examples related to spherically symmetric operators: e. g. $A_1 = h^2\Delta$ on $\mathbb{S}^d$ ($d \geq 3$) or $A_1 = h^2\Delta + V(|x|)$ in $\mathbb{R}^d$ while $A_2 = x_2 hD_1 - x_1 hD_2$ is a component of the angular momentum.

6.2 Scalar Operators with Periodic Hamiltonian Flow

In this section we treat scalar operators with the periodic Hamiltonian flow and weak perturbations of such operators. We consider very long-time propagation of the singularities. Then under some restrictions we prove a microlocal version of a theorem concerning spectral gaps (i.e. lacunas in the spectrum), and under other restrictions we obtain highly accurate semiclassical spectral asymptotics which may contain a non-Weyl term. Thus periodic trajectories which were so far the worst enemy of sharp spectral asymptotics are tamed and become their best friend.

6.2.1 Introduction

Let us assume that

(6.2.1) $A \in \boldsymbol{\Psi}_h(X, \mathbb{K})$ is a self-adjoint operator with principal symbol $a(x,\xi)$.

Assume for a while that a is a scalar symbol; later we abandon this condition but then we will return to it. Let $\bar\tau$ be a fixed energy level (usually for a sake of simplicity $\bar\tau = 0$), and let Ω be a connected domain in $T^*\mathbb{R}^d$. Let us assume that

(6.2.2) a is microhyperbolic in Ω on the energy level $\bar\tau$

which for scalar symbol means that

$$|\nabla_{(x,\xi)} a(x,\xi)| + |a(x,\xi) - \bar\tau| \geq \epsilon_0 \quad \text{in } \Omega, \tag{6.2.3}$$

and that all Hamiltonian trajectories are periodic in Ω i.e.

$$\Psi_{a,T}(x,\xi) = (x,\xi) \quad \forall (x,\xi) \in \Omega \qquad \text{for} \quad T = T(x,\xi) \tag{6.2.4}$$

where $\Psi_{a,t}$ is a Hamiltonian flow generated by a. Then one can replace Ω by

$$\bigcup_{(x,\xi)\in\Omega} \quad \bigcup_{t\in[0,T(x,\xi)]} \Psi_{a,t}(x,\xi)$$

and hence without any loss of the generality we can assume that

$$\Psi_{a,t}(\Omega) = \Omega \qquad \forall t. \tag{6.2.5}$$

It is well known that (6.2.4) then holds with $T(x,\xi) = T(a(x,\xi))$ (i.e., the period depends only on the energy level) with a smooth function $T(\tau)$ as $\tau \in [\tau_1, \tau_2]$ provided this interval is contained in the set of values of $a(x,\xi)$ at Ω [6)].

Remark 6.2.1. (i) There can be *subperiodic points* (x,ξ) with $T(x,\xi) = \frac{1}{m}T(a(x,\xi))$, $m \in \mathbb{Z}^+$ but condition (6.2.2) forbids stationary points of $\Psi_{a,t}$. Further, the set of subperiodic points is always a symplectic submanifold (see Proposition 6.3.1).

(ii) This conclusion would be wrong if we assume only that all the trajectories on the given energy level $\bar\tau$ are periodic. Really, let $\bar\tau = 0$; then replacing

[6)] More precisely, if we can select $T = T(z)$ as $\mathscr{C}^1$ function then $T(z)$ is constant on each connected component of $\{a(z) = \tau\}$ provided $\nabla a(z)$ is disjoint from 0 here.

Indeed, let us consider $\iint dH(z) \wedge dt(z)$ over

$$\Sigma = \{z = \Phi_t(x(s)), 0 \le s \le 1, 0 \le t \le t(x(s))\}$$

where $x(s)$ $(0 \le s \le 1)$ is a $\mathscr{C}^1$-curve $\{a(z) = E\}$. Then with an arbitrary constant c

$$0 = \iint da(z) \wedge dT(z) = \int (a+c)dT|_{s=0}^{s=1} = (E+c)\big(T(x(1)) - T(x(0))\big) \implies$$
$$T(x(1)) = T(x(0)).$$

Obviously, if $da \ne 0$ and $T(z)$ is bounded in the neighbourhood of some point $\bar z$, then one can select T such that $\Phi_{T(z)}(z) = z$; however at some points $T(z)$ could be the multiple of the shortest period.

$a(x,\xi)$ by $a'(x,\xi) = b(x,\xi)a(x,\xi)$ with $b \neq 0$ we do not change trajectories on $\{a(x,\xi) = 0\}$, so they remain periodic but their periods are now

$$T'(x,\xi) = \int_0^{T(x,\xi)} b^{-1}(\Psi_{a,t}(x,\xi))\, dt$$

which is not necessarily constant on Σ_τ.

Further, it is well known that the quantity

$$\frac{1}{T}\kappa_1 = \frac{1}{T}\int_0^T (-\xi dx + a dt) \tag{6.2.6}$$

(where the integral is taken along the Hamiltonian trajectory $(x(t),\xi(t)) = \Psi_{a,t}(x,\xi)$) is a constant. Here κ_1 is a (classical) *action*.

Furthermore, we assume that

$$T(\tau) = T_0, \quad \text{i.e.} \quad \Psi_{a,T_0} = I; \quad \text{in } \Omega \tag{6.2.7}$$

then κ_1 will also is a constant.

Remark 6.2.2. Starting from (6.2.4) one can always reach (6.2.7) with $T_0 = 1$ replacing A by $f(A)$ with

$$f(\tau) = \int^\tau T(\tau')\, d\tau'. \tag{6.2.8}$$

However we will formulate main theorems with general T_0.

So, we assumed that *the classical dynamics is periodic* (with period T_0). What can we say about quantum dynamics? We know that $e^{ih^{-1}tA}$ is an h-Fourier integral operator (uniformly with respect to $t : |t| \le c$). The corresponding symplectomorphism is $\Psi_{a,-t}$ which is an identity as $t = T_0$ due to (6.2.7). Therefore we conclude that it is actually h-pseudodifferential operator (at least in Ω). More precisely

Theorem 6.2.3. *(i) Let conditions* (6.2.1), (6.2.2) *and* (6.2.7) *be fulfilled. Then*

$$e^{ih^{-1}T_0A} \equiv e^{ih^{-1}\kappa} G \qquad \textit{in } \Omega \tag{6.2.9}$$

where $G \in \mathbf{\Psi}_h(X, \mathbb{K})$ *is an operator with the principal symbol* $V(x, \xi, T_0)$ *where* $V(x, \xi, t) \in S(X, \mathbb{K})$ *is a solution to Cauchy problem*

$$\frac{d}{dt} V(z, t) = i a^s \circ \Psi_{a,-t}(z) V(z), \qquad V(z, 0) = I, \tag{6.2.10}$$

a^s *is subprincipal symbol of* A *and* $\kappa = \kappa_1 - \frac{1}{2}\pi\kappa_0 h$ *is the* Maslov constant*,* κ_0 *is the* Maslov index *of the periodic trajectory* $\Psi_{t,a}(x, \xi)$ *(which is also a constant and* κ_1 *is an action.*

(ii) In particular, if a^s *is also a scalar symbol*

$$e^{ih^{-1}T_0 A} \equiv e^{ih^{-1}\kappa + iB} \tag{6.2.11}$$

where B *is an operator with the principal symbol*

$$b := \int_0^{T_0} a^s \circ \Psi_{a,-t}(z)\, dt. \tag{6.2.12}$$

Proof. Proof easily follows from the construction of Subsection 1.2.2. Also one can find the proof at Y. Colin de Verdiere [2]. □

Now for the purpose of introduction assume that $\Omega = T^*X$.

First of all, assume that $G = e^{i\kappa_2}$ and (6.2.9) holds precisely rather than modulo negligible operator

$$e^{ih^{-1}T_0 A} = e^{i\kappa'}, \qquad \kappa' = h^{-1}\kappa_1 + \kappa_2 - \frac{1}{2}\pi\kappa_0, \quad \kappa' \in \mathbb{R}; \tag{6.2.13}$$

then we conclude that $\mathsf{Spec}(h^{-1}T_0 A) \subset 2\pi\mathbb{Z} + \kappa'$ and equivalently

$$\mathsf{Spec}(A) \subset \frac{2\pi h}{T_0}\mathbb{Z} + \frac{h}{T_0}\kappa'; \tag{6.2.14}$$

let us recall that T_0 is a period. This ratio hT_0^{-1} plays important role in all statements.

In this case we get pure point spectrum; if X is not compact manifold it could be of the infinite multiplicity. So, there are *spectral gaps* of the length $2\pi h T_0^{-1}$.

Further, the results of Chapter 4 imply that if X is a compact manifold and then for "typical" $n \in \mathbb{Z}$ such that

$$\tau_n = \frac{2\pi h}{T_0} n + \frac{h}{T_0}\kappa' \tag{6.2.15}$$

belongs to $[-\epsilon_0, \epsilon_0]$ multiplicity of τ_n as an eigenvalue of A is $\asymp h^{1-d}$ (provided a is not elliptic).

This in turn implies that we cannot reasonably expect asymptotics with the remainder estimate better than $O(h^{1-d})$, however we can reformulate the problem in this case in the opposite way: *Calculate precisely multiplicity* N_n *of* τ_n. This problem we will be able to solve.

If T_0 is not a minimal period then replacing T_0 by mT_0 we conclude that for $n \in \mathbb{Z} \setminus m\mathbb{Z}$ formula (6.2.15) gives us fake possible eigenvalues. So it is crucial to assume during this section that

(6.2.16) T_0 is a minimal period of the Hamiltonian flow $\Psi_{a,t}$;

then we will prove that every τ_n given by (6.2.15) is actually an eigenvalue and its multiplicity is actually $\asymp h^{1-d}$.

It would not preclude from subperiodic points but their contribution to τ_n would be of magnitude h^{1-d+2r} where $2r$ is a codimension of the manifold of subperiodic points. Their effect would be basically to shift some eigenvalues from τ_n with $n \notin m\mathbb{Z}$ to τ_n with $n \in m\mathbb{Z}$.

More generally, instead of (6.2.13) let us assume that (6.2.11) holds with the bounded Hermitean operator B; then instead of (6.2.14) we conclude that

$$\mathsf{Spec}(A) \subset \frac{2\pi h}{T_0}\mathbb{Z} + \frac{h}{T_0}\kappa' + \frac{h}{T_0}\,\mathsf{Spec}(B). \tag{6.2.17}$$

in particular if $\mathsf{Spec}\, B \subset [-\eta\pi, \eta\pi]$ with $\eta < 1$ we conclude that $\mathsf{Spec}(A)$ is consisting in *spectral clusters* contained in η-vicinities of τ_n defined by (6.2.15).

So, a single eigenvalue τ_n of large multiplicity N_n would be split into eigenvalues of the total multiplicity of N_n and our calculation of N_n will be still useful. However the new and more challenging question arrises: *How eigenvalues are distributed inside the cluster?* which boils down to asymptotics of $\mathsf{N}(\tau, h)$ again; under certain assumptions we will be able to give an answer with the remainder estimate $O(h^{2-d})$. In this case η may be a constant or a small parameter ($h' \le \eta < 1$), in the latter case the spectral clusters will be narrow.

The task to find sharp asymptotics of $\mathsf{N}(\tau, h)$ is not restricted to the case of $\eta < 1$ even if otherwise the spectral gaps disappear and clusters overlap.

We will add some twist replacing A by $A+\varepsilon A'$ with $\varepsilon \ll 1$ we will arrive to (6.2.17) with B replaced by $\varepsilon' h^{-1}B$ where typically $\varepsilon' = \varepsilon$.

Note that $\varepsilon' h^{-1}$ could be a large parameter. In this case under certain assumptions we will be able to give an answer with the remainder estimate $O(\varepsilon h^{1-d})$.

Let us describe the method. Let us replace (6.2.11) by

$$e^{ih^{-1}T_0 A} = e^{i\varepsilon h^{-1}B} \tag{6.2.18}$$

where

(6.2.19) A and B commute.

We reached $\kappa = 0$ by replacing A by $A - hT_0^{-1}\kappa$ and included εh^{-1} in B explicitly. We will justify these assumptions later (modulo negligible). Then

$$e^{ih^{-1}nT_0 A} = e^{inh^{-1}\varepsilon B} \qquad n\in\mathbb{Z},\ |n|\le h^{-l'}$$

and therefore

$$e^{ih^{-1}tA} = e^{ih^{-1}t'A}e^{ih^{-1}nT_0 A} = e^{ih^{-1}t'A}e^{ih^{-1}\varepsilon nB} = e^{ih^{-1}(t'A+t''B)} \qquad \text{as}\ \ t = nT_0 + t',\ t'' = n\varepsilon. \tag{6.2.20}$$

Here the right-hand expression is h-Fourier integral operator uniformly with respect to $|t'|\le c$, $|t''|\le c$; picking up $n = \lfloor tT_0^{-1}\rfloor$ we rewrite this assumption as

$$|t| \le T := c\varepsilon^{-1}. \tag{6.2.21}$$

Therefore instead of one-parameter long time evolution we get two-parameter normal time evolution described by Hamiltonian flow $\Psi_{a,b,t',t''} := \Psi_{a,t'}\Psi_{b,t''}$ provided B has a scalar principal symbol b; in the general case $\Psi_{b,t''}$ would be generalized Hamiltonian flow. Instead of one time t we have a *normal time* t' and a *slow time* t''. Our classical dynamics contains periodic movement and a *drift* controlled by b.

So, if the drift breaks periodicity instantly we get Weyl asymptotics with the remainder estimate $CT^{-1}h^{1-d} \asymp C\varepsilon h^{1-d}$ where T is defined by (6.2.21) with c replaced by ϵ_0. Periodicity is broken instantly in the classical dynamics provided (a,b) satisfies microhyperbolicity condition (see Definition 6.1.7). We will deal with a more degenerate scenario of Subsection 6.1.3 later.

However, situation is more complicated for a quantum dynamics: the drift for time t'' shifts trajectory by $\asymp |t''|$ and therefore the shift is observable only as $|t''| \ge Ch|\log h|$ (due to logarithmic uncertainty principle) or as $|n|\varepsilon \ge Ch|\log h|$.

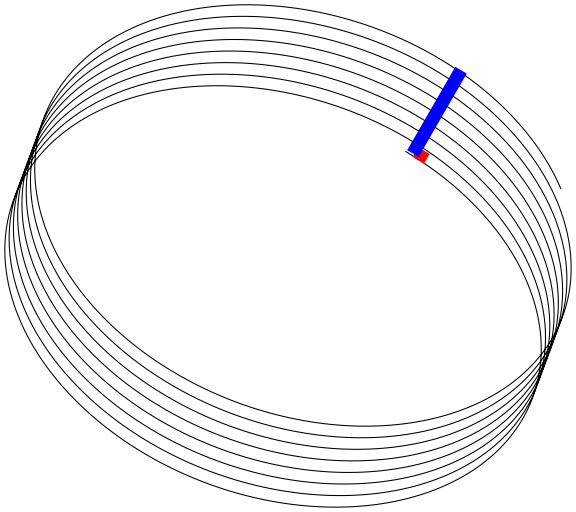


Figure 6.1: Periodicity classical and quantum: the shift between two consecutive windings may be quantum observable only after many windings.

So, the shift is observable instantly (i.e. after the first period) only as $\varepsilon \ge Ch|\log h|$ (or $\varepsilon \ge C|\log h|$) and our conclusion stays only then. Otherwise we need to wait time $T' := Ch\varepsilon^{-1}|\log h|$ and then

$$\|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(u\,{}^tQ)| \le CT'h^{1-d} = C\varepsilon^{-1}h^{2-d}|\log h|. \tag{6.2.22}$$

In fact, a more accurate analysis allows us to prove a better estimate

$$\|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(u\,{}^tQ)| \le C(\varepsilon^{-1}+h^{-1})h^{2-d} \tag{6.2.23}$$

valid for $\varepsilon \le 1$; so as $\varepsilon \le h$ effectively $T' \asymp \varepsilon^{-1}h$ which corresponds to the standard uncertainty principle.

Then (6.2.23) leads to the Tauberian estimate

$$\mathsf{R}^{\mathsf{T}} \prec CT^{-1}(\varepsilon^{-1}+h^{-1})h^{2-d} \asymp C(\varepsilon+h)h^{1-d}. \tag{6.2.24}$$

Remark 6.2.4. (i) We can apply logarithmic uncertainty principle only under analyticity assumption; in the general case one needs to replace $|\log h|$ by $h^{-\delta}$ but we are getting rid of both factors anyway.

(ii) However instant transition from Tauberian asymptotics to the Weyl one is possible only as $\varepsilon \ge Ch|\log h|$ (or $\varepsilon \ge h^{1-\delta}$); in the general case one needs to calculate the correction term which is due to contribution of the windings with $1 \le |n| \le \varepsilon^{-1}T'$.

6.2.2 Operator B

Let us analyze the *crucial assumption* (6.2.18)–(6.2.19). In fact, it is the only assumption we made so far which we really need. We do not need even assumptions that a is scalar and Hamiltonian flow periodic as long as (6.2.18)–(6.2.19) hold. However we need to discover how realistic this assumption is.

So, let us assume that a is a scalar symbol and it generates the Hamiltonian flow which is 1-periodic in Ω.

Scalar Case

Let a^s be a scalar symbol as well. Then (6.2.11) holds (at least modulo $O(h)$) with operator B with the scalar principal symbol b defined in Ω by (6.2.12); this symbol obviously is $\Psi_{a,t}$-invariant and therefore $\{a,b\} = 0$ there. We can always extend it to the smooth real-valued symbol.

Consider $B = \mathsf{Op}^{\mathrm{w}}(b)$; this operator commutes with A modulo $O(h)$ and (6.2.11) holds modulo $O(h)$. However we can fix it due to the following procedure described in more general settings.

Assume first that (6.2.18) holds. Let $R \in \mathbf{\Psi}_h(X,\mathbb{K})$. Consider averaging of R over period equal 1:

$$\bar{R} := \int_0^1 e^{-ih^{-1}t'A} R e^{ih^{-1}t'A}\, dt'. \tag{6.2.25}$$

Consider $\bar{R}_t := e^{-ih^{-1}tA} R e^{ih^{-1}tA}$; it is also given by (6.2.25) but with an integral taken from t to $1+t$ and thus

$$\begin{aligned}\bar{R}_t - \bar{R} = {}& \\ & \int_0^t \Big(e^{-ih^{-1}(t'+1)A} R e^{ih^{-1}(t'+1)A} - e^{-ih^{-1}tA} R e^{ih^{-1}tA}\Big)\, dt' = \\ & \qquad \int_0^t e^{-ih^{-1}t'A}\Big(e^{-ih^{-1}A} R e^{ih^{-1}A} - R\Big) e^{ih^{-1}t'A}\, dt'\end{aligned} \tag{6.2.26}$$

and the latter expression vanishes as $R = B$. So, $\bar{B}$ commutes with A modulo an operator negligible in Ω.

Let us compare B and $\bar{B}$. Due to Theorem 6.2.3 their principal symbols coincide and $B - \bar{B} \in h\boldsymbol{\Psi}_h(X, \mathbb{K})$. Then in Ω

$$e^{ih^{-1}A} \equiv e^{iB} \equiv e^{i\bar{B}+i(B-\bar{B})} \equiv e^{i\bar{B}} + ie^{i\bar{B}}(B-\bar{B}) + R, \qquad R \in h^2\boldsymbol{\Psi}_h(X, \mathbb{K}).$$

Since $e^{ih^{-1}A}$ and $\bar{B}$ commute with A, after averaging according to (6.2.26) we arrive to

$$e^{ih^{-1}A} \equiv e^{i\bar{B}} + \bar{R}, \qquad \bar{R} \in h^k\boldsymbol{\Psi}_h(X, \mathbb{K}) \tag{6.2.27}$$

with $k = 2$. Let us assume that (6.2.27) holds with some $\bar{B}$ and $\bar{R}$ which commute with A (modulo negligible in Ω). Then replacing $\bar{B}$ by $\bar{B}' := \bar{B} + e^{-i\bar{B}}\bar{R}$ we get the same (6.2.27) but with k replaced by $k+1$. Here again all operators commute with A.

Iterating and adjusting $\bar{B}$ we can achieve (6.2.18)–(6.2.19). Therefore we arrive to

Proposition 6.2.5. *Let conditions* (6.2.1)–(6.2.4) *and* (6.2.7) *be fulfilled and let a^s be scalar symbol. Then one can find operator $B \in \boldsymbol{\Psi}_h(X, \mathbb{K})$ with the scalar principal symbol b defined by* (6.2.12) *and satisfying* (6.2.18)–(6.2.19)*.*

Then we conclude that

Corollary 6.2.6. *In the framework of Proposition 6.2.5 operator $A_0 := A - hB$ commutes (modulo negligible) with A and B and*

$$e^{ih^{-1}T_0A_0} \equiv I \tag{6.2.28}$$

modulo an operator which is negligible in Ω.

So A could be considered as perturbation of A_0 by εB with $\varepsilon = h$. Let us forget about (6.2.18)–(6.2.19), consider scalar *unperturbed operator* $A_0 \in \boldsymbol{\Psi}_h(X)$ satisfying (6.2.28) and perturb it by operator εP where $P \in \boldsymbol{\Psi}_h(X, \mathbb{K})$ and it does not necessarily commute with A_0 anymore.

Proposition 6.2.7. *Let conditions* (6.2.1)–(6.2.4) *and* (6.2.7) *be fulfilled and let* $A_0 \in \mathbf{\Psi}_h(X)$ *be an operator with the principal symbol* a *satisfying* (6.2.28). *Let* $P \in \mathbf{\Psi}_h(X)$ *and*

$$A(\varepsilon) = A_0 + \varepsilon P, \qquad \varepsilon \in [h^l, h^\delta]. \tag{6.2.29}$$

Then there exists an operator

$$B(\varepsilon) \sim \sum_{k\ge 0} B_k \varepsilon^k \tag{6.2.30}$$

commuting with $A(\varepsilon)$ *and satisfying*

$$e^{ih^{-1}T_0 A(\varepsilon)} \equiv e^{ih^{-1}\varepsilon B(\varepsilon)} \tag{6.2.31}$$

in Ω. *Furthermore the principal symbol of* B_0 *is defined by*

$$b_0' = (x,\xi) = \int_0^{T_0} b\circ \Psi_{a,-t}(z)\,dt. \tag{6.2.32}$$

Proof. Let $U_0(t) = e^{ith^{-1}A_0}$ and $U(t) = e^{ith^{-1}A}$; so in fact objects we study depend on ε. Let us consider operator $V(t) = U(t)U_0(-t)$; then

$$D_t V(t) = h^{-1}U(t)PU_0(-t) = \varepsilon h^{-1} V(t)L(t), \qquad V(0) = I \tag{6.2.33}$$

with

$$L(t) \coloneqq U_0(t)PU_0(-t). \tag{6.2.34}$$

Our purpose is to construct $V(t)$.

Let us construct a self-adjoint operator $R(t) \in \mathbf{\Psi}_h(X)$ such that

$$V(t) \equiv \exp\bigl(i\varepsilon h^{-1}\int_0^t R(t')\,dt'\bigr) \qquad \text{in } \Omega. \tag{6.2.35}$$

To construct $R(t)$ let us consider

$$W(\sigma,t) \coloneqq \exp\bigl(i\varepsilon h^{-1}\sigma\int_0^t R(t')\,dt'\bigr). \tag{6.2.36}$$

Then

$$\partial_\sigma W - i\varepsilon h^{-1}\int_0^t R(t')dt'\cdot W = 0$$

and differentiating with respect to t we obtain that

$$\Big(\partial_\sigma - i\varepsilon h^{-1}\int_0^t R(t')\,dt'\Big)(\partial_t W) = i\varepsilon h^{-1}R(t)W.$$

Then

$$\partial_t W(\sigma,t) = i\varepsilon h^{-1}\int_0^\sigma W(\sigma-\sigma',t)R(t)W(\sigma',t)\,d\sigma' = i\varepsilon h^{-1}R'(\sigma,t)W(\sigma,t)$$

due to definition (6.2.36) and equality $\partial_t W = 0$ as $\sigma = 0$; here we define

$$R'(\sigma,t) = \int_0^\sigma W(\sigma',t)R(t)W(-\sigma',t)\,d\sigma'.$$

Setting $\sigma = 1$ we obtain that

$$\partial_t W_1(t) = i\varepsilon h^{-1}R'(1,t)W_1(t) \tag{6.2.37}$$

for $W_1(t) = W(1,t)$ and

$$R'(1,t) = \int_0^1 W(\sigma,t)R(t)W(-\sigma,t)d\sigma. \tag{6.2.38}$$

Comparing (6.2.35) and (6.2.37)–(6.2.38) and recalling that $V(0) = W_1(0) = I$ we conclude that (6.2.35) is fulfilled provided $R'(1,t) \equiv L(t)\ \forall t \in [-T_0, T_0]$ modulo negligible operators in a fixed neighborhood of $\bar\Omega$. Thus we need to construct $R(t)$ such that

$$R'(t) \coloneqq \int_0^1 W(\sigma,t)R(t)W(-\sigma,t)\,d\sigma \equiv L(t) \qquad \text{in } \Omega \quad \forall t \in [-T_0, T_0] \tag{6.2.39}$$

where we denote this neighborhood by Ω again.

Theorem 2.4.10 yields that R' and L belong to $\boldsymbol{\Psi}_h(X)$ provided R and P belong to this class; moreover $R'(t) \equiv R(t) \mod \varepsilon\boldsymbol{\Psi}_h(X)$.

Further, (6.2.39) is equivalent to

$$\sum_{m\ge 0}\frac{1}{(m+1)!}\big(i\varepsilon h^{-1}\operatorname{Ad}_{\int_0^t R(t)\,dt}\big)^m R(t) \equiv L(t) \qquad \text{in } \Omega \quad \forall t \in [-T_0, T_0]. \tag{6.2.40}$$

Really, the left-hand expressions of (6.2.39) and (6.2.40) coincide as $\varepsilon \le h^{\delta}$. This allows to fulfill (6.2.40) and in the end of the day (6.2.35) recurrently by

$$R(t,\varepsilon) = \sum_{n\ge 1} R_n(t)\varepsilon^{n-1}. \tag{6.2.41}$$

Namely, as $R_1(t), \dots, R_{n-1}(t)$ are defined we can calculate the corresponding partial sum $R_{(n-1)}(t,\varepsilon)$ of (6.2.41), plug it instead of $R(t)$ in any term with $m \ge 1$ in (6.2.40) and drop all the terms with power of ε greater than $(n-1)$; finally we plug $R(t) = R_{(n-1)}(t,\varepsilon) + R_n(t)\varepsilon^{n-1}$ to the term with $m = 0$. Then terms with the power of ε less than $(n-1)$ will be reduced and we get

$$R_n(t) = \mathfrak{R}\big[R_1(t), \dots, \mathcal{R}_{n-1}(t)\big] + \delta_{n1} L(t)$$

where $\mathfrak{R}$ is non-linear operator, differential with respect to (x,ξ) but containing integrations with respect to t. One can see easily that all operators $R_k(t)$ are self-adjoint.

In particular

$$R_1(t) = L(t) = U_0(t) P U_0(-t), \tag{6.2.42}$$

$$R_2(t) = -\frac{1}{2} i h^{-1} \int_0^t [U_0(t') P U_0(-t'), U_0(t) P U_0(-t)]\, dt'. \tag{6.2.43}$$

Finally, setting $t = T_0$ in (6.2.35) we arrive to $U(t)U_0(-1) = V(T_0) \equiv \exp(i\varepsilon h^{-1} B)$ and therefore since $U_0(-T_0) \equiv I$ in Ω we arrive to (6.2.31) with

$$B(\varepsilon) = \sum_{n\ge 0} B_n \varepsilon^{n-1}, \tag{6.2.44}$$

$$B_n = \int_0^{T_0} R_n(t)\, dt. \tag{6.2.45}$$

In particular, (6.2.42), (6.2.43) yield

$$B_1 = \int_0^{T_0} U_0(t) P U_0(-t)\, dt, \tag{6.2.46}$$

$$B_2 = -\frac{1}{2} i h^{-1} \int_{0\le t'\le t\le T_0} \big[U_0(t') P U_0(-t'), U_0(t) P U_0(-t)\big]\, dt' dt \tag{6.2.47}$$

with the principal symbols

$$b_1' = \int_0^{T_0} b \circ \Psi_{a,t}\, dt \tag{6.2.48}$$

$$b_2' = -\frac{1}{2} \int_{0\le t'\le t\le T_0} \bigl\{ b \circ \Psi_{a,t'}, b \circ \Psi_{a,t} \bigr\}\, dt' dt. \tag{6.2.49}$$

Proposition 6.2.8. *In the framework of Proposition 6.2.7*

$$[A, B] \equiv 0 \quad \textit{in } \Omega. \tag{6.2.50}$$

Proof. Let us assume that $C = ih^{-1}[A, B] \in h^p \mathbf{\Psi}_h(X)$ in Ω, $p \ge 0$. Let us apply formula

$$e^{-i\varepsilon h^{-1}tB} A e^{i\varepsilon h^{-1}tB} = A + i\varepsilon h^{-1} \int_0^t e^{-i\varepsilon h^{-1}t'B} [A, B] e^{i\varepsilon h^{-1}t'B}\, dt' \tag{6.2.51}$$

to C_1 instead of A. We then obtain that (in Ω)

$$e^{-i\varepsilon h^{-1}tB} C_1 e^{i\varepsilon h^{-1}tB} \equiv C_1 + \varepsilon t C_2$$

with $C_2 = ih^{-1}[C_1, B] \in h^p \mathbf{\Psi}_h(X)$.

Applying (6.2.51) to A we then obtain that

$$e^{-i\varepsilon h^{-1}tB} A e^{i\varepsilon h^{-1}tB} = \equiv A + \varepsilon t C_1 \mod \varepsilon^2 \mathbf{\Psi}_h(X).$$

Taking $t = T_0$ and replacing $e^{\pm i\varepsilon h^{-1}B}$ by $e^{\pm ih^{-1}T_0 A}$ we obtain that $C_1 \equiv 0 \mod \varepsilon \mathbf{\Psi}_h(X)$ and hence p can be replaced by $p+\delta$ because $\varepsilon \le h^\delta$; meanwhile division by ε is justified by $\varepsilon \ge h^l$. Induction with respect to p concludes this analysis. □

Remark 6.2.9. (i) Surely if the right-hand expression in (6.2.48) vanishes then $B(\varepsilon) = \max(\varepsilon, h) B'$ with $B' \mathbf{\Psi}_h(X)$ and therefore effectively ε is redefined as $\varepsilon_{\mathsf{new}} = \varepsilon \max(\varepsilon, h)$ etc.

(ii) Most likely Propositions 6.2.7–6.2.8 hold for $\varepsilon \in [h^\delta, \varepsilon_0]$ with small constant ε_0 and the proof would be very interesting.

(iii) However we will investigate the case $\varepsilon \in [h^\delta, \varepsilon_0]$ by using results of Section 4.5.

Matrix Case

The case of matrix operator P is more complicated. However in this case we need to assume that $\varepsilon \le ch$ because otherwise the nature of operator $e^{ih^{-1}(A_0+\varepsilon P)}$ is not clear unless we assume that b has eigenvalues of constant multiplicities.

Unfortunately we were unable to prove existence of $B(\varepsilon)$ with desired properties unless a bit stronger assumption is made:

Proposition 6.2.10. *Let conditions* (6.2.1)–(6.2.4) *and* (6.2.7) *be fulfilled and let* $A_0 \in \boldsymbol{\Psi}_h(X)$ *be an operator with the principal symbol* a *satisfying* (6.2.28). *Let* $P \in \boldsymbol{\Psi}_h(X, \mathbb{K})$ *and*

$$A(\varepsilon) = A_0 + \varepsilon P, \qquad \varepsilon \in [h', \epsilon_0 h] \tag{6.2.52}$$

Then there exists an operator

$$B(\varepsilon) \sim \sum_{k\ge 0} B_k (h^{-1}\varepsilon)^k \tag{6.2.53}$$

commuting with $A(\varepsilon)$ *and satisfying* (6.2.31) *in* Ω.

Proof. Consider operator $e^{ih^{-1}t(A_0+\eta hP)}$. According to Subsection 1.2.2 its parametrix is a h-Fourier integral operator with a phase function independent on η and a symbol analytic with respect to η. Therefore $F(\eta) := e^{ih^{-1}t(A_0+\eta hP)}$ is (in Ω) unitary h-pseudodifferential operator with the symbol analytic with respect to η. Also it is I as $\eta = 0$. Then as $\|F(\eta) - I\| \le 1 - \epsilon$ (which is fulfilled as $\eta \le \epsilon_0$) one can define

$$\log F(\eta) = \sum_{n\ge 1} \frac{1}{n}(-1)^{n-1}\big(F(\eta) - I\big)^n$$

analytic with respect to η; further this function is skew-symmetric, vanishes as $\eta = 0$ (again, modulo negligible in Ω) and thus $B := -i\eta^{-1}F(\eta)$ is a required operator. □

Problem 6.2.11. Extend the statement above to $\epsilon_0 h \le \epsilon \le ch$.

Example 6.2.12. (i) Operator

$$A = \sum_{1\le i<j\le} \sigma_{ij}(x_i hD_j - x_j hD_i) + m\sigma_0 \tag{6.2.54}$$

on $\mathbb{R}^d$ where $\{\sigma_0, \sigma_{ij}, 1 \le i < j \le d\}$ is a set of Pauli matrices; one can skip $m\sigma_0$. This operator satisfies (6.2.7). It could be considered also on the positively homogeneous of degree 0 functions. One can "fix" it to operator satisfying (6.2.28).

(ii) Let a be as above and $A_k = A(S_k x, S_k^{*-1} hD)$ where S_k are nondegenerate matrices. Then $a_1 \oplus a_2 \oplus \cdots \oplus a_m$ may have characteristics of variable multiplicity and satisfies (6.2.7) if we ignore branching of the generalized Hamiltonian flow; it satisfies (6.2.28). So case of truly matrix a in the current framework is reasonable.

6.2.3 Long Term Evolution

At this step we need assume neither that a, b are scalar symbols nor that $\varepsilon \le h^\delta$ ($\varepsilon \le \epsilon$ is enough). However some of the statements below require such assumptions; then these assumptions are mentioned explicitly.

Main Theorem

Now we consider the long-range evolution:

Proposition 6.2.13. *Let conditions* (6.2.1), (6.2.4), (6.2.7), (6.2.18) *and* (6.2.19) *be fulfilled in* Ω. *Further let* $\Omega_0 \subset \Omega$ *also satisfy* (6.2.4) *and*

$$\Psi_{b,t}\Omega_0 \subset \Omega \qquad \forall t : |t| \le T'' \tag{6.2.55}$$

where T'' *is a constant. Let*

$$\varepsilon \in [h', \epsilon_0]. \tag{6.2.56}$$

Then for all t, $|t| \le T^* = \varepsilon^{-1} T'' T_0$ *the uniform equality*

$$e^{ih^{-1}tA} \equiv e^{it''B} e^{ih^{-1}t'A} \qquad \text{in } \Omega_0 \tag{6.2.57}$$

holds with $t'' = \varepsilon n$, $t' = t - n$ *provided* $n \in \mathbb{Z}$, $|n - tT_0^{-1}| \le c$.

Proof. Let us first note that $e^{i\varepsilon h^{-1} nB} = e^{ih^{-1}t''B}$ with $t'' = \varepsilon n$ is a standard propagator for operator B as $|t''| \le \mathsf{const}$. Then the standard theory of propagation of singularities (see Theorem 2.2.10) yields that due to condition (6.2.55) $(I - Q')e^{i\varepsilon nB} Q \equiv 0$ as $|t''| \le T''$ (i.e. $|n| \le \varepsilon^{-1} T''$, and $Q = \mathsf{Op}(q)$, $Q' = \mathsf{Op}(q')$, $\mathsf{supp}(q) \subset \Omega_0$, $q' = 1$ in Ω.

Then as $0 \le \pm n \le \varepsilon^{-1}T''$

$$e^{i\varepsilon h^{-1}nB}Q \equiv e^{\pm ih^{-1}T_0A}e^{i\varepsilon h^{-1}(n\mp 1)B}Q \equiv e^{ih^{-1}mT_0A}e^{i\varepsilon h^{-1}(n\mp m)B}Q \equiv e^{ih^{-1}nT_0A}Q \tag{6.2.58}$$

modulo negligible operator; we used the fact that the number of transitions is $O(h^{-l})$ and therefore accumulated error is $O(h^{-l+K})$ as $O(h^K)$ error is made each time. Then

$$e^{ih^{-1}tA}Q \equiv e^{ih^{-1}(nT_0+t')A}Q \equiv e^{ih^{-1}nT_0A}e^{ih^{-1}t'A}Q \equiv e^{ih^{-1}\varepsilon nB}e^{ih^{-1}t'A}Q \tag{6.2.59}$$

because we can use identity (6.2.58) with Q replaced by $e^{ih^{-1}t'A}Qe^{-ih^{-1}t'A}$ which is h-pseudodifferential operator with the symbol supported in Ω_0. □

This proposition combined with different versions of propagation results (Theorems 2.2.10, 2.3.6, 2.4.17 etc) yields the following "metastatement":

Corollary 6.2.14. *In the framework of Proposition 6.2.13 singularities of $e^{ih^{-1}tA}$ with $|t| \le \varepsilon^{-1}T''T_0$ propagate along the (periodic) flow $\Psi_{a,t'}$ drifting along the flow $\Psi_{b,t''}$ where $t'' = t - nT_0$ and $t'' = \varepsilon n$ are quick and slow times respectively.*

Corollaries

Proposition 6.2.13 allows us to apply results of successive approximations of Subsubsection *6.1.2.2 Successive Approximations* on the series of isolated time intervals

$$\mathcal{J}_n := (n-\nu, n+\nu), \qquad |n| \le \varepsilon^{-1}T \tag{6.2.60}$$

where *currently* $\nu = h^{\frac{1}{2}+\delta}$ and $T = \varepsilon h^{\frac{1}{2}+\delta}$ but later we will increase them. Indeed, according to successive approximations

$$U(x,y,t',t'')\,{}^tQ_{2y} \equiv \sum_{m\ge 0} h^{-d+m}\iiint \mathcal{F}_m(y,\xi,\tau',\tau'')e^{ih^{-1}(\langle x-y,\xi\rangle+t'\tau'+t''\tau'')}\,d\xi\,d\tau'd\tau''$$

where $U(x,y,t',t'')$ is the Schwartz kernel of $e^{ih^{-1}(t'A+t''B)}$. Plugging $t''=\varepsilon n$, $t'=t-nT_0$ we arrive to

$$u(x,y,t)\,{}^tQ_{2y}\equiv \sum_{m\ge 0} h^{-d+m}\iiint \mathcal{F}_m(y,\xi,\tau',\tau'')e^{ih^{-1}(\langle x-y,\xi\rangle+t\tau'+n(\varepsilon\tau''-T_0\tau'))}\,d\xi\,d\tau' d\tau''$$

as $|t'|\le h^{\frac12+\delta}$, $|t''|\le h^{\frac12+\delta}$. Then, as $\phi\in \mathscr{C}_0^\infty([-1,1])$, multiplying by $\phi_\nu((t-nT_0))$, making h-Fourier transform and applying Γ we arrive to

$$\Gamma_{t\to h^{-1}\tau}\phi_\nu(t-nT_0)\Gamma\big(Q_{1x}u(x,y,t)\,{}^tQ_{2y}\big)\equiv \tag{6.2.61}$$
$$\sum_{m\ge 0} h^{1-d+m}\iiint \nu\hat\phi\big(\frac{(\tau-\tau')\nu}{h}\big)\mathcal{F}_m(y,\xi,\tau',\tau'')e^{ih^{-1}n(\varepsilon\tau''-T_0\tau)}\,dyd\xi\,d\tau' d\tau''.$$

In particular, as $\mathcal{F}_0=(2\pi)^{-d}q_1^0\delta(\tau'-a)\delta(\tau''-b)q_2^0$ the main part of the right-hand expression is a convolution of

$$(2\pi)^{-d}h^{1-d}\iint q_1 e^{ih^{-1}n(\varepsilon b-T_0 a)}q_2\,dyd\xi \tag{6.2.62}$$

with $\nu h^{-1}\hat\phi(\nu h^{-1}\tau)$.

Proposition 6.2.15. *Let conditions* (6.2.1), (6.2.4), (6.2.7), (6.2.18) *and* (6.2.19) *be fulfilled in* Ω. *Further, let* a *be microhyperbolic in* Ω *on energy level* $\bar\tau$ *and let* (6.2.55) *be fulfilled. Let* $Q_1,Q_2\in \boldsymbol{\Psi}_{h,\gamma,\gamma,K}(x,\mathbb{K})$ *be supported in* Ω_0, $\gamma\ge h^{\frac12-\delta}$.

Then (6.2.61) *holds with a small constant* ν.

Proof. We constructed successive approximations as $|t'|\le \epsilon^{-1}T'$ and $|t''|\le \epsilon^{-1}T'$ where $T'=h^{\frac12+\delta}$ and ϵ is an arbitrarily small constant. However if a is microhyperbolic, so is $a+\alpha b$ as $|\alpha|\le\epsilon$ and therefore due to arguments of Subsubsection *6.1.2.4 The Microhyperbolicity Condition* intervals with $|t''|\le T'$, $\epsilon^{-1}T'\le |t'|\le \epsilon$ provide negligible contribution to the trace. □

So, as far as trace is concerned we slightly extended interval system (6.2.55). These intervals still do not overlap and cannot overlap due to possible subperiodic trajectories. We ban them temporarily.

Let $\mathcal{U}$ be an open subset in Ω such that

$$\mathsf{dist}\big(\Psi_{a,t}(z), z\big) \ge \epsilon_0\gamma \sin\frac{\pi t}{T_0} \qquad \forall t \in [0, T_0] \quad \forall z \in \mathcal{U} \quad \text{with} \ \ \gamma \ge h^{\frac{1}{2}-\delta}. \tag{6.2.63}$$

This condition excludes subperiodic trajectories, starting from $\mathcal{U}$. Later we will modify our arguments in order to permit them. However, the latter makes sense only as a is scalar. In the matrix case we must assume that $\gamma = \epsilon'$ and we will not be able to allow subperiodic trajectories.

If (6.2.63) is fulfilled for $\mathcal{U}$, then it is also fulfilled for $\epsilon_1\gamma$-neighborhood of $\mathcal{U}$.

Proposition 6.2.16. *Let conditions of Proposition 6.2.15 be fulfilled. Further, let* (6.2.63) *be fulfilled where* $\gamma \ge h^{\frac{1}{2}-\delta}$ *as* a *is scalar and* $\gamma \asymp 1$ *in the general case. Let* $Q_1, Q_2 \in \mathbf{\Psi}_{h,\gamma,\gamma,K}(X, \mathbb{K})$ *be supported in the* $\epsilon_1\gamma$*-neighborhood of* $\mathcal{U}$*. Then*

(i) (6.2.61) *holds with any constant* $\nu < T_0$*.*

(ii) Moreover, as $\chi \in \mathscr{C}_0^K([-1,1])$ *and* $T \in [\frac{1}{2}T_0, \varepsilon^{-1}h^{\frac{1}{2}+2\delta}]$, $N = \lfloor TT_0^{-1}\rfloor$

$$F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(Q_{1x}u(x,y,t)\,{}^tQ_{2y}\big) \equiv \sum_{m\ge 0}\sum_{n:|n|\le T} h^{1-d+m}\iiiint T\hat{\chi}\big(\frac{(\tau-\tau')T}{h}\big)\mathcal{F}_m(y,\xi,\tau',\tau'')e^{ih^{-1}n(\varepsilon\tau''-T_0\tau')}\times dyd\xi\, d\tau' d\tau''. \tag{6.2.64}$$

Proof. (i) Statement (i) follows from the simple fact that under condition (6.2.63) the contribution of time intervals $\big((n-1)T_0+\epsilon, nT_0-\epsilon\big)$ is negligible.

Really, consider first $\gamma \asymp 1$. Then as $|t'| \ge \epsilon$ the right-hand expression of (6.2.63) is disjoint from 0; this is not broken by perturbation of $t'A$ by $t''B$ with $|t''| \le h^{\frac{1}{2}+\delta}$. Applying results of Section 2.3 we arrive to the required conclusion.

Consider the case of $\gamma \ge h^{\frac{1}{2}-\delta}$ and scalar a. In this case we can assume with no loss of the generality that $\mathsf{diam}(\mathsf{supp}(Q_1)\cup\mathsf{supp}(Q_2)) \le \epsilon''\gamma$. Then

$$Q_1 e^{ih^{-1}t''B}e^{ih^{-1}t'A}Q_2 \equiv Q_1 e^{ih^{-1}t''B}Q_{2t'}e^{ih^{-1}t'A} \equiv 0$$

where $Q_{2t'} = e^{ih^{-1}t'A}Q_2e^{-ih^{-1}t'A} \in \mathbf{\Psi}_{h,\gamma,\gamma}(X,\mathbb{K})$ and $\mathsf{dist}(\mathsf{supp}(Q_1),\mathsf{supp}(Q_{2t'})) \ge \epsilon_2\gamma$ due to (6.2.63). Due to the finite speed of propagation for B and $|t''| \le h^{\frac12+\delta} \le \epsilon_2\gamma$ we conclude that $Q_1e^{ih^{-1}t''B}Q_{2t'} \equiv 0$ which proves the second identity above.

(ii) Then representing $\chi_T(t) = \chi_T(t)\sum_n \phi(t-nT_0)$ with some ϕ and applying Statement (i) we arrive to (6.2.64). One should notice that τ in the exponent in (6.2.61) is replaced by τ' in (6.2.64) because ϕ_ν is shifted by nT_0 in the first term while χ_T is not. □

Let $\chi = 1$ at $[-\frac12 T_0, \frac12 T_0]$ and $\varphi \in \mathscr{C}_0^K([-c,c])$; let $L \ge T^{-1}h^{1-\delta}$. In this case we know that modulo $O(h^s)$ with arbitrarily large s

$$\int \varphi\Big(\frac{\tau}{L}\Big)\, d_\tau \Gamma Q_{1x} e(.,.,\tau_1,\tau)\, {}^tQ_{2y} - h^{-1}\int \varphi\Big(\frac{\tau}{L}\Big)\big(F_{t\to h^{-1}\tau}\chi_T \Gamma Q_{1x}u(.,.,t)\, {}^tQ_{2y}\big)\, d\tau \equiv 0. \tag{6.2.65}$$

Combining with (6.2.64) we arrive to

$$\int \varphi\Big(\frac{\tau}{L}\Big)\Big(d_\tau \Gamma Q_{1x} e(.,.,\tau_1,\tau)\, {}^tQ_{2y} - \sum_{m\ge 0}\sum_{n:|n|\le T} h^{-d+m}\iiint \mathcal{F}_m(y,\xi,\tau,\tau'') e^{ih^{-1}n(\varepsilon\tau''-T_0\tau)} \times dyd\xi\, d\tau'' d\tau\Big) \equiv 0 \tag{6.2.66}$$

where we have applied estimate

$$|\varphi\Big(\frac{\tau'}{L}\Big) - \frac{T}{h}\int \hat\chi\Big(\frac{(\tau-\tau')T}{h}\Big)\varphi\Big(\frac{\tau'}{L}\Big)\, d\tau| \le C'h^s \tag{6.2.67}$$

and then after τ was removed we renamed τ' by τ.

In fact, replacing $\varphi(\tau L^{-1})$ by

$$\sum_{0\le k\le K-1} \varphi^{(k)}\Big(\frac{\tau'}{L}\Big)\frac{1}{k!}(\tau-\tau')^k L^{-k} + O\big((\tau'-\tau)^K L^{-K}\big),$$

estimating $\hat\chi(t)$ by $C(|t|+1)^{-2K}$ and recalling that $\chi(0)=1$, $\chi'(0)=\chi''(0)=\ldots=0$ and that $LT \ge h^{1-\delta}$ we obtain inequality (6.2.67).

Note that actually in (6.2.66) we can extend summation over $n \in \mathbb{Z}$. Indeed, the norm of m-th term of successive approximations on $[-T,T]$

does not exceed $CT^{l(m)}h^{-l(m)}$ and multiplying by $\phi_T(t)$ with $\phi \in \mathscr{C}_0^\infty(\mathbb{R})$, then applying $\varphi(hL^{-1}D_t)$ with $LT \ge h^{1-\delta}$ and finally setting $t=0$ makes it $O(h^s)$.

Then using formula

$$\sum_{n\in\mathbb{Z}} e^{-int} = 2\pi \sum_{p\in\mathbb{Z}} \delta(t-2\pi p) = \partial_t \Upsilon(t) \tag{6.2.68}$$

with

$$\Upsilon(t) \coloneqq 2\pi \sum_{p\in\mathbb{Z}} \theta(t-2\pi p) = 2\pi \lceil \frac{t}{2\pi} \rceil \tag{6.2.69}$$

we conclude that

$$\sum_{n\in\mathbb{Z}} e^{inh^{-1}(\varepsilon\tau''-T_0\tau)} = hT_0^{-1}\partial_\tau \Upsilon\big(h^{-1}(T_0\tau-\varepsilon\tau'')\big)$$

thus rewriting (6.2.66) as

$$\int \varphi\big(\frac{\tau}{L}\big)\Big(d_\tau \Gamma Q_{1x} e(.,.,\tau_1,\tau)\, {}^tQ_{2y} - \sum_{m\ge 0} h^{1-d+m} T_0^{-1} \iiint \mathcal{F}_m(y,\xi,\tau,\tau'') d_\tau \Upsilon\big(h^{-1}(T_0\tau-\varepsilon\tau'')\big)\, dy d\xi\, d\tau''\Big) \equiv 0. \tag{6.2.70}$$

In particular, the main part is

$$(2\pi)^{-d} h^{1-d} T_0^{-1} \int_{\Sigma_\tau} q_1^0 \Upsilon\big(h^{-1}(T_0 a - \varepsilon b)\big)\, d\mu_\tau q_2^0 \tag{6.2.71}$$

(multiplied by $-\partial_\tau \varphi(\tau/L)$ and integrated over τ) where

(6.2.72) $\Sigma_\tau = \{(x,\xi) : \tau \in \mathsf{Spec}(a(x,\xi))\}$ and $\mu_\tau = \delta(\tau - a)$ is a measure there as usual.

So, we arrive to

Theorem 6.2.17. *Let conditions* (6.2.1), (6.2.4), (6.2.7), (6.2.18) *and* (6.2.19) *be fulfilled in* Ω. *Further, let* a *be microhyperbolic in* Ω *on energy level* $\bar\tau$ *and let* (6.2.55) *be fulfilled.*

Furthermore, let (6.2.63) *be fulfilled where* $\gamma \ge h^{\frac12-\delta}$ *as* a *is scalar and* $\gamma \asymp 1$ *in the general case. Let* $Q_1, Q_2 \in \mathbf{\Psi}_{h,\gamma,\gamma,K}(X, \mathbb{K})$ *be supported in the* $\epsilon_1\gamma$*-neighborhood of* $\mathcal{U}$*. Then as*

$$L \ge \varepsilon h^{\frac12-\delta} \tag{6.2.73}$$

formula (6.2.70) *holds.*

Here we took $T = \varepsilon^{-1}h^{\frac12-\delta}$, defined bound to L from $LT \ge h^{1-\delta}$ and denoted 2δ by δ.

Spectral Gaps (the First Attempt)

We conclude that if $\Omega = T^*X$ and (6.2.28) holds precisely rather than modulo negligible then $\mathsf{Spec}(A_0) \subset 2\pi h T_0^{-1}\mathbb{Z}$; otherwise it is contained in h^s-vicinity of $2\pi h T_0^{-1}\mathbb{Z}$.

Further, if A_0 and B commute precisely rather than modulo negligible then $\mathsf{Spec}(A_0 + \varepsilon B) \subset \mathsf{Spec}(A_0) + \varepsilon\,\mathsf{Spec}(B)$; otherwise it is contained in h^s-vicinity of the latter set.

Therefore as $\varepsilon \le \epsilon_0 h$ spectrum is split into *spectral bands* of the width $\asymp \varepsilon$ (there may be degenerations) separated by *spectral gaps*. As $\varepsilon \le \mathsf{ch}$ there may be spectral gaps (but as ε grows from $\epsilon_0 h$ to ch spectral bands start overlap and spectral gaps start disappear (barring degenerations), and as $\varepsilon \ge \mathsf{ch}$ one should not expect them at all.

Criteria of τ belonging to the spectral gap (in Ω) is

$$\begin{aligned} &|\tau - 2\pi p\frac{h}{T_0} - \varepsilon\lambda| \ge L \\ &\qquad \forall p \in \mathbb{Z} \quad \forall \lambda \in \mathsf{Spec}(b(x,\xi)) \quad \forall (x,\xi) \in \Omega : |a(x,\xi) - \tau| \le \mathsf{ch} \end{aligned} \tag{6.2.74}$$

where *currently* L is defined by (6.2.73). Later in the dedicated Subsection 6.4 we using elliptic arguments weaken condition to L.

We say that

(6.2.75) τ' and τ'' belong to the same spectral gap if (6.2.74) holds for all $\tau \in [\mathsf{min}(\tau', \tau''), \mathsf{max}(\tau', \tau'')]$.

Corollary 6.2.18. *Let conditions of Theorem 6.2.17 be fulfilled. Then*

(i) If τ_1, τ_2 belong to spectral gaps in Ω then estimate (6.2.70) *holds without mollification:*

$$\Gamma Q_{1x} e(.,.,\tau_1,\tau_2)\, {}^t Q_{2y} \equiv \sum_{m\ge 0} h^{-d+m} T_0 \iiint \int_{\tau_1}^{\tau_2} \mathcal{F}_m(y,\xi,\tau,\tau'') d_\tau \Upsilon\big(h^{-1}(T_0\tau - \varepsilon\tau'')\big)\, dy d\xi\, d\tau''. \tag{6.2.76}$$

(ii) In particular, if τ_1, τ_2 belong to the same spectral gap in Ω then

$$\Gamma Q_{1x} e(.,.,\tau_1,\tau_2)\, {}^t Q_{2y} \equiv 0. \tag{6.2.77}$$

Proof. (a) Note first that since due to Section 6.1

$$\operatorname{supp}\big(\mathcal{F}_m(x,\xi,\tau,\lambda)\big) \subset \{\tau \in \operatorname{Spec}(a(x,\xi)),\ \lambda \in \operatorname{Spec}(b(x,\xi))\} \tag{6.2.78}$$

we conclude that

$$\operatorname{supp}\big(\mathcal{F}_m(x,\xi,\tau,\lambda)\delta(h^{-1}(T_0\tau - \varepsilon\lambda - 2\pi p h))\big) \subset \{\tau \in \operatorname{Spec}(a(x,\xi)),\ \lambda \in \operatorname{Spec}(b(x,\xi)), \tau = 2\pi p \frac{h}{T_0} + \lambda\}. \tag{6.2.79}$$

Therefore if $\operatorname{supp}(\varphi) \subset (-1,1)$ and $[-L, L]$ belongs to the spectral gap we conclude that

$$\int \varphi(\tau/L) d_\tau \Gamma Q_{1x} e(.,.,\tau_1,\tau_2)\, {}^t Q_{2y} \equiv 0.$$

Taking $\varphi \ge 0$ and disjoint from 0 on $(-\frac12, \frac12)$ and $Q_2 = Q_1^*$ we arrive to (6.2.77) for $\tau_1, \tau_2 \in (-\frac12 L, \frac12 L)$; then we can get rid of condition $Q_2 = Q_1^*$. Shifting with respect to spectral parameter we get Statement (ii) in the full generality. Moreover Statement (i) is proven as τ_1, τ_2 belong to the same spectral gap.

(b) Let τ_1, τ_2 belong to different spectral gaps; we can assume without any loss of the generality that $\tau_2 \ge \tau_1 + L$. We can apply (6.2.70) with $\varphi(\tau/L)$ replaced by $\varphi_j((\tau - \tau_j')/L)$ and thus with $\varphi(\tau/L)$ replaced by their sum $\omega(\tau)$ containing no more than h^{-l} terms. However we can always make $\omega(\tau)$ supported in $[\tau_1, \tau_2]$ and equal 1 on $[\tau_1 + \frac12 L, \tau_2 - \frac12]$. Applying Statement (i) to both spectral gaps we can replace $\int \omega(\tau)(\dots)$ by $\int_{\tau_1}^{\tau_2}(\dots)$ with the negligible error and therefore Statement (i) is proven in the full generality. □

6.2.4 Exploiting Microhyperbolicity

In this subsection we assume that

(6.2.80) System (A, B) is microhyperbolic in Ω on energy level $(\bar{\tau}, \bar{\lambda})$ (see Definition 6.1.7)

and derive asymptotics without mollification and with mollification with a smaller parameter L; as usual $\bar{\tau} = 0$.

Extending Time Interval

Let us recall that the successive approximation delivers $U(x, y, t', t'')$ as $|t'| \le T' = h^{\frac{1}{2}+\delta}$ and $|t''| \le T'' = h^{\frac{1}{2}+\delta}$. Then microhyperbolicity of A allowed us to increase T' to ϵ without affecting T'' and then (6.2.63) allowed us to increase T' so time intervals for $t = t' + nT_0$ began overlap provided $\gamma \ge CT'' = C\varepsilon T$ which was automatically fulfilled under assumptions there.

On the other hand, microhyperbolicity of (A, B) combined with the results of Subsubsection *6.1.2.5 Exploiting Microhyperbolicity* allow to increase T', T'' to $T' = T'' = \epsilon$ then (6.2.63) allowed us to increase T' so time intervals for $t = t' + nT_0$ began overlap provided $\gamma \ge CT'' = C\varepsilon T$. This condition is automatically fulfilled as $\gamma \asymp 1$ but may be a problem otherwise. We need to allow γ small if we want to approach subperiodic points.

Therefore we immediately arrive to

Theorem 6.2.19. *Let condition* (6.2.80) *be fulfilled. Then if we replace* $e(., y, \tau)$ *by* $\psi(B)_x e(., y, \tau)$ *with* $\psi \in \mathscr{C}_0^\infty([\bar{\lambda} - \epsilon, \bar{\lambda} + \epsilon])$ *with small enough* ϵ

(i) Proposition 6.2.15 extends to $n : |n| \le TT_0^{-1} \le \epsilon\varepsilon^{-1}$.

(ii) Proposition 6.2.16 extends to n, T*:* $|n| \le TT_0^{-1} = \epsilon\varepsilon^{-1}\gamma$.

(iii) Theorem 6.2.17 extends to L *satisfying*

$$L \ge \varepsilon\gamma^{-1}h^{1-\delta}. \tag{6.2.81}$$

Tauberian Arguments

To apply Tauberian arguments we need to estimate

$$M(\phi) := F_{t\to h^{-1}\tau}\phi_T(t)\Gamma\big(\psi(B)_x Q_{1x} u(., ., t)\, {}^t Q_{2y}\big). \tag{6.2.82}$$

Theorem 6.2.20. *Let conditions* (6.2.1), (6.2.4), (6.2.7), (6.2.18), (6.2.19) *and* (6.2.80) *be fulfilled in* Ω. *Further, let* (6.2.55) *be fulfilled.*

Furthermore, let (6.2.63) *be fulfilled with* $\gamma \asymp 1$. *Let* $Q_1, Q_2 \in \mathbf{\Psi}_{h,\gamma,\gamma,K}(X, \mathbb{K})$ *be supported in the* $\epsilon_1\gamma$*-neighborhood of* $\mathcal{U}$. *Let* $\chi \in \mathscr{C}_0^\infty([-1, -\frac{1}{2}] \cup [\frac{1}{2}, 1])$, $\bar{\chi} \in \mathscr{C}_0^\infty([-1, 1])$. *Then with the arbitrarily large exponent* I

(i) As $|n| \le T^* T_0^{-1} := \epsilon\varepsilon^{-1}$, $\phi(t) = \bar{\chi}(t - nT_0)$

$$|M(\phi)| \le Ch^{1-d}(1 + \varepsilon h^{-1}|n|)^{-I}. \tag{6.2.83}$$

(ii) As $1 \le T \le T^*$

$$|M(\chi_T)| \le Ch^{1-d} T(1 + \varepsilon h^{-1} T)^{-I} \tag{6.2.84}$$

and

$$|M(\bar{\chi}_T)| \le Ch^{1-d}(\varepsilon^{-1}h + 1). \tag{6.2.85}$$

We took $\gamma \asymp 1$ because we will study subperiodic points later.

Proof. We need a following statement:

(6.2.86) Consider system $(A_1, \dots, A_m)$ microhyperbolic at $(\bar{\tau}_1, \dots, \bar{\tau}_m)$. Let $\varphi_j \in \mathscr{C}_0^\infty([\bar{\tau}_j - \epsilon, \bar{\tau}_j + \epsilon])$. Then

$$|\Gamma\big(Q_{1x}\varphi_1(A_1)_x\varphi_2(A_2)_x \cdots \varphi_m(A_m)_x U(., ., \boldsymbol{t})\, {}^tQ_{2y}\big)| \le Ch^{-d}\big(1 + h^{-1}|\boldsymbol{t}|\big)^{-I} \qquad \text{as} \quad |\boldsymbol{t}| \le \epsilon. \tag{6.2.87}$$

Really, due to propagation theory the left-hand expression is $O(h^s)$ as $\frac{1}{2}\epsilon \le |\boldsymbol{t}| \le \epsilon$. Scaling as usual we arrive to (6.2.87) as $h \le |\boldsymbol{t}| \le \epsilon$. Finally, combining with the trivial estimate $O(h^{-d})$ we get (6.2.87) as $|\boldsymbol{t}| \le h$. Here $\phi_j(A_j)$ replace $\phi_j(\tau_j)$.

This estimate immediately implies that

$$|F_{\boldsymbol{t}' \to h^{-1}\boldsymbol{\tau}'}\phi_1(t_1) \cdots \phi_{m'}(t_{m'})\Gamma\big(Q_{1x}\varphi_{m'+1}(A_{m'+1})_x \cdots \varphi_m(A_m)_x \times U(., ., \boldsymbol{t})\, {}^tQ_{2y}\big)| \le Ch^{-d+m'}\big(1 + h^{-1}|\boldsymbol{t}|\big)^{-I} \qquad \text{as} \quad |\boldsymbol{t}'| \le \epsilon, \tag{6.2.88}$$

$\mathsf{supp}(\phi_j) \subset [-\epsilon, \epsilon]$ and $\boldsymbol{t}' = (t_1, \dots, t_{m'})$.

Applying (6.2.88) with $m'=1$ to microhyperbolic system (A,B) and picking up $|t_2|=\varepsilon n$ we derive (6.2.83) as $\mathsf{supp}(\phi)\subset [nT_0-\epsilon, nT_0+\epsilon]$.

However assumption (6.2.63) with $\gamma\asymp 1$ implies that the contribution of time intervals $[(n-1)T_0+\epsilon, nT_0-\epsilon]$ is negligible and we arrive to (6.2.83) in its full generality.

It immediately implies (6.2.84), which in turn implies (6.2.85). □

Now Tauberian theorem implies the Tauberian estimate

$$|\mathsf{R}^{\mathsf{T}}_{\psi}|\le Ch^{1-d}T^{-1}(\varepsilon^{-1}h+1)=Ch^{1-d}(\varepsilon+h) \tag{6.2.89}$$

and more generally

$$|\mathsf{R}^{\mathsf{T}}_{\psi,\varphi,L}|\le Ch^{1-d}(\varepsilon+h)\vartheta\Big(\frac{\varepsilon h}{L}\Big)\qquad \text{as}\quad L\ge \varepsilon h \tag{6.2.90}$$

where we plugged $T=\epsilon\varepsilon^{-1}$ and subscript ψ means that we replaced $e(.,.,\tau)$ by $\psi(B)_x e(.,.,\tau)$.

So, we have proven

Theorem 6.2.21. *Let conditions of Theorem 6.2.20 be fulfilled and let φ satisfy* (4.2.73)–(4.2.75). *Then estimates* (6.2.89), (6.2.90) *hold as $\mathsf{R}^{\mathsf{T}}_{\psi}$ is the difference between $\mathsf{N}^{\mathsf{T}}_{\psi}$ and Tauberian expression, which is the right-hand expression of* (6.2.64) *or equivalently* (6.2.76), *and $\mathsf{N}^{\mathsf{T}}_{\psi,\varphi,L}$ is the same expression mollified.*

Let us analyze the contribution of the different terms in (6.2.64) into the final answer. Here we need to distinguish terms with $n=0$ which deliver Weyl expression (probably with many terms) and terms with $n\ne 0$ which deliver *correction terms*.

Then Theorem 6.2.20 yields that

(6.2.91) The contribution of term with $n\ne 0$ to $\mathsf{R}^{\mathsf{T}}_{\psi,\varphi,L}$ does not exceed

$$Ch^{1-d+m}|n|^{-1}\big(1+h^{-1}\varepsilon|n|\big)^{-l}\vartheta\Big(\frac{h}{L|n|}\Big). \tag{6.2.92}$$

In particular we arrive to

Theorem 6.2.22. *In the framework of Theorem 6.2.21 as* $\varepsilon \ge h^{1-\delta}$ *the same estimates* (6.2.89), (6.2.90) *hold for* $\mathsf{R}^{\mathsf{W}}_{\psi}$ *and* $\mathsf{R}^{\mathsf{W}}_{\psi,\varphi,L}$.

Further trivially we have

Proposition 6.2.23. *In the framework of Theorem 6.2.21 the total contribution of all terms with* $m \ge 1$, $n \ne 0$ *to the Tauberian expression* $\mathsf{N}^{\mathsf{T}}_{\psi,\varphi,L}$ *does not exceed*

$$Ch^{2-d}\bigl(\frac{h}{\varepsilon}\bigr)^{l}\vartheta\bigl(\frac{h}{\max(h,L)}\bigr) \tag{6.2.93}$$

as $\varepsilon \ge h$ *and*

$$Ch^{2-d}\sum_{1\le n\le \varepsilon^{-1}h} n^{-1}\vartheta\bigl(\frac{h}{\max(h,Ln)}\bigr) \tag{6.2.94}$$

as $\varepsilon \ge h$. *In particular, this contribution to the Tauberian expression* N^{T} *does not exceed* Ch^{2-d} *and* $Ch^{2-d}\bigl(|\log \varepsilon^{-1}h|+1\bigr)$ *respectively.*

Consider now terms with $m=0$, $n\ne 0$. According to (6.2.71) their contribution is

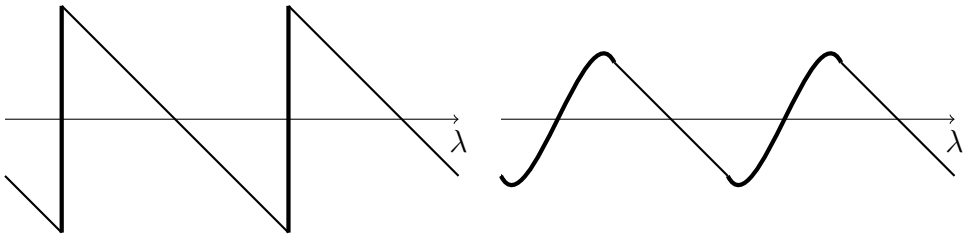
$$\mathsf{N}_{\mathsf{corr},\psi} := (2\pi)^{-d}h^{1-d}T_0^{-1}\int_{\Sigma_\tau} q_1^0\psi(x)\Upsilon_1\bigl(h^{-1}(aT_0-\varepsilon b)\bigr)\,d\mu_\tau q_2^0 \tag{6.2.95}$$

where $\Upsilon_1(t)=\Upsilon(t)-t+\frac{1}{2}$. So, we have proven

Theorem 6.2.24. *In the framework of Theorem 6.2.21 with an error not exceeding* (6.2.93) *as* $\varepsilon \ge h$ *and* (6.2.94) *as* $\varepsilon \le h$ *one can replace* $\mathsf{N}^{\mathsf{T}}_{\psi}$ *or* $\mathsf{N}^{\mathsf{T}}_{\psi,\varphi,L}$ *in Theorem 6.2.21 by* $\mathsf{N}^{\mathsf{W}}_{\psi}+\mathsf{N}_{\mathsf{corr},\psi}$ *or* $\mathsf{N}^{\mathsf{W}}_{\psi,\varphi,L}+\mathsf{N}_{\mathsf{corr},\psi,\varphi,L}$ *respectively.*

Using approach of Section 6.3.1 in the scalar case one can eliminate logarithm.

Problem 6.2.25. Prove that in the case of operators belonging to $\boldsymbol{\Psi}_{h,\mathsf{an}}(X,\mathbb{K})$ one can replace in the estimates above $(1+\varepsilon h^{-1}|n|)^{-l}$ by $\exp(-\epsilon h^{-1}|n|)$; in particular, prove that $\mathsf{N}^{\mathsf{T}}_{\psi}\equiv \mathsf{N}^{\mathsf{W}}_{\psi}$ as $\varepsilon \ge Ch|\log h|$.



(a) $\Upsilon_1(t)$ (b) $\int \Upsilon_1(t-\varepsilon b(x,\xi))d\mu_\tau$

Figure 6.2: Mollified with respect to $d\mu_\tau$ "a sharp saw" becomes a "dull saw"; bold curved parts correspond to the spectral bands.

Removing Cut-off ψ

Remark 6.2.26. Theorems 6.2.19, 6.2.21, 6.2.22, 6.2.24 and Proposition 6.2.23 hold with $\psi(B) = I$ provided

(i) Either $\varepsilon \gg h$ and microhyperbolicity condition (6.2.80) holds for every $\bar\lambda$ (and we cannot do better in this case).

(ii) Or $\varepsilon \lesssim h$, we interested in asymptotics at $\tau : |\tau - \bar\tau| \le \epsilon\varepsilon$ and microhyperbolicity condition (6.2.80) holds for all $\bar\lambda_p = \varepsilon^{-1}(\bar\tau - 2\pi p h)$.

(iii) As $\varepsilon \ll h$ and $\bar\tau$ does not belong to spectral gap microhyperbolicity condition should be checked exactly for one p (such that $|\bar\tau - 2p\pi h T_0^{-1}| \ll h$.

Proof is trivial because values in the spectral gaps are already eliminated.

Remark 6.2.27. Obviously wit is sufficient to fulfill microhyperbolicity of spectral gap condition on $\mathsf{supp}\, Q_1 \cap \mathsf{supp}\, Q_2$ only.

6.3 Scalar Operators with Periodic Hamiltonian Flow (End)

6.3.1 Scalar a and Subperiodic Trajectories

Structure of Subperiodic Trajectories

Let a be a scalar symbol. Let Π be the set of all the subperiodic points. Due to Colin de Verdiere [2], Proposition 1.3, we have the following

Proposition 6.3.1. *(i) The set of all subperiodic points* Π *is a union of a finite number of symplectic submanifolds* $\Pi_{p,r}$ *of codimension* $2r$ *consisting of* $p^{-1}T_0$*-periodic points*

$$\Pi = \bigcup_{(p,r)\in\mathcal{J}} \Pi_{p,r} \tag{6.3.1}$$

$\mathcal{J}$ *is a finite subset of* $\{2,3,...\}\times\{1,...,(d-1)\}$.

(ii) Moreover $\Psi_{a,t}(\Pi_{p,r}) = \Pi_{p,r}$ *and for all* t *and*

$$z\in\Omega_0,\ z'\in\Psi_{a,t}(z) \implies \operatorname{dist}(z',\Pi_{p,r}) \asymp \operatorname{dist}(z',\Pi_{p,r}) \qquad \forall t. \tag{6.3.2}$$

(iii) As $z\in\Pi_{p,r}$

$$T_z\Pi_{p,r} = \operatorname{Ker}(D\Psi_{a,p^{-1}T_0}(z) - I) \tag{6.3.3}$$

and

$$(D\Psi_{a,p^{-1}T_0}(z))^p = I; \tag{6.3.4}$$

hence

$$\operatorname{Spec}(D\Psi_{a,p^{-1}T_0}(z)) \subset \{e^{2\pi i\frac{q}{p}}, q = 0,...,p-1\} \tag{6.3.5}$$

and all the Jordan cells of $D\Psi_{a,p^{-1}T_0}(z)$ *are* 1*-dimensional.*

(iv) Further, $\Pi_{p,r}$ *and* $\Pi_{p,r'}$ *are disjoint for* $r\neq r'$, $\Pi_{p'}\subset\Pi_p$ *if and only if* p *divides* p' *and* $\Pi_{p'}\cap\Pi_{p''} = \Pi_p$ *where* p *is the greatest common divisor of* p' *and* p''*. Moreover, this intersection is clean*[7)]*.*

(v) Furthermore, the intersection of $\Pi_{p,r}$ *and* Σ_τ *is clean and* $\operatorname{codim}\Pi_{p,r}\cap\Sigma_\tau = 2r+1$.

Proof. Note first that (6.3.4) follows from $\Psi^p_{a,p^{-1}T_0} = I$; (6.3.5) and the lack of adjoint eigenvectors follow from this. The other statements follow obviously. □

Further, due to $\{a,b\}=0$ (recall that a is scalar) $\Psi_{a,t'}$ and $\Psi_{b,t''}$ commute (an easy proof is left to the reader),

$$\Psi_{a,t}\Psi_{b,t''}(\Pi_{p,r}\cap\Omega_0)\subset\Pi_{p,r} \tag{6.3.6}$$

[7)] See J. J. Duistermaat & V. Guillemin [1] for the definition.

and

$$(6.3.7)\quad z \in \Omega_0,\ z' \in \Psi_{a,t}\Psi_{b,t''}(z) \implies \mathsf{dist}(z', \Pi_{p,r}) \asymp \mathsf{dist}(z', \Pi_{p,r}) \qquad \forall |t''| \le T'',\ \forall t$$

where T'' is the same constant as in condition (6.2.55).

We currently assume neither that b is scalar no microhyperbolicity of (a, b).

Propagation of Singularities near Π

In the previous analysis we using condition (6.2.63) were able to reduce the analysis of $\chi_T(t)\Gamma(Q_1 e^{ih^{-1}At}Q_2)$ to the analysis of $\phi(t - nT_0)\Gamma(Q_1 e^{ih^{-1}At}Q_2)$ with $|n| \le T$ and ϕ supported in $[-\epsilon, \epsilon]$. Now we have condition (6.2.63) as $\mathsf{dist}(z, \Pi) \ge \gamma$ and condition

$$(6.3.8)\quad \mathsf{dist}\big(\Psi_{a,t}(z), z\big) \ge \epsilon_0\big(|\sin \frac{\pi p t}{T_0}| + \gamma |\sin \frac{\pi t}{T_0}|\big) \qquad \forall t \in [0, T_0] \quad \forall z \in \mathcal{U}$$

as z is near Π_p, but disjoint from $\Pi_{p'}$ with p' not multiple of p, $\gamma \asymp \mathsf{dist}(z, \Pi_p)$.

Anyway we need to consider additionally $\phi(t - nT_0 - t_{p,q})\Gamma(Q_1 e^{ih^{-1}At}Q_2)$ where $t_{p,q} = qp^{-1}T_0$, $q = 1, \dots, p-1$ and p, q are coprimes.

The following statement will be needed only if (a, b) is microhyperbolic but does not require microhyperbolicity by itself:

Proposition 6.3.2. *Let $Q_1, Q_2 \in \mathbf{\Psi}_{h,\gamma,\gamma}(X, K)$ be supported respectively in $\{\mathsf{dist}(z, \Pi_p) \ge C_0\gamma\}$ and $\{\mathsf{dist}(z, \Pi_p) \le \gamma\} \cap \Omega_0$ with large enough constant C_0 and $\gamma \ge h^{\frac{1}{2}-\delta}$.*

Then $Q_1 e^{ih^{-1}tB}Q_2 \equiv 0$ as $|t| \le T''$ where T'' is a constant from (6.2.55).

Proof. If b is scalar this statement follows immediately from Section 2.4. Let us prove it in the general case. Obviously it is sufficient to provide proof for small constant T''; then without any loss of the generality one can assume that

(6.3.9) $\Pi_p = \{f_1 = \dots = f_m = 0\}$ with smooth real-valued functions $f_1, \dots, f_m$ such that $df_1, \dots, df_m$ are linearly independent on Π_p.

Actually one can even assume that $f_j = x_j$ for $j = 1, \dots, r$ and $f_j = \xi_{j-r}$ for $j = r+1, \dots, 2r = m$ because Π_p is symplectic but this is immaterial now. We need however the following consequence of (6.3.7):

$$\{b, f_j\} = \sum_k b_{jk} f_k \tag{6.3.10}$$

Then $\pm\{\tau - b, e^{\pm Ct}|f|^2\}e^{\pm Ct} \ge |f|^2$ and one can apply the energy estimate method with

$$Q_\alpha = \mathsf{Op}^{\mathsf{w}}\big(\chi(\gamma^{-2}e^{\pm Ct}|f - \bar f|^2 - \alpha)\big) \tag{6.3.11}$$

with $\bar f = 0$ here where χ is a function as in the proof of Theorem 2.1.2 (i.e. described by (2.1.11)) and to prove the following

Proposition 6.3.3. *Assume that v is temperate and*

$$\|Q_\alpha v|_{t=0}\| \le Ch^s, \tag{6.3.12}$$

$$\|Q_\alpha(hD_t - B)v^\pm\| \le Ch^{s+1}, \tag{6.3.13}$$

then for $\beta < \alpha$

$$\|Q_\beta v^\pm\| \le Ch^s \tag{6.3.14}$$

where $\beta < \alpha$ are arbitrary constants.

First (6.3.14) is proved under additional assumption $\|Q_\alpha v^\pm\| \le Ch^{s-\delta}$ with arbitrarily small exponent $\delta > 0$ which can be easily dropped.

An easy proof of Proposition 6.3.3 following exactly the same scheme as in Theorem 2.1.2 is left to the reader. This completes the proof of Proposition 6.3.2. □

Proposition 6.3.4. *Let $Q_1, Q_2 \in \mathbf{\Psi}_{h,\gamma,\gamma}(X, K)$ be supported in $\{f \in \mathcal{V}_1\}$ and $\{f \in \mathcal{V}_2\} \cap \Omega_0$ respectively where $f = (f_1, \dots, f_m)$. Let T'' be a constant and $\mathcal{V}_j \subset \{|f| \le \gamma\}$ for $j = 1, 2$, $\mathsf{dist}(\mathcal{V}_1, \mathcal{V}_2) \ge C_0 T''\gamma$.*

Then $Q_1 e^{ih^{-1}tB} Q_2 \equiv 0$ as $|t| \le T''$. Here C_0 does not depend on T''.

Proof. Without any loss of the generality one can assume that $\mathcal{V}_1 = \{|f - \bar f| \le \epsilon\gamma\}$, $\mathcal{V}_2 = \{|f - \bar f| \ge (2\epsilon + CT'')\gamma\}$ with $|\bar f| \le \gamma$.

An easy proof following exactly the same scheme as in Theorem 2.1.2 with Q_α defined by (6.3.11). It is left to the reader. □

Corollary 6.3.5. *Assume that* $Q_1, Q_2 \in \mathbf{\Psi}_{h,\gamma,\gamma}(X, K)$ *are supported in* $\{z\colon \mathsf{dist}(z, \Pi_p) \asymp \gamma\} \cap \Omega_0$ *with* $\gamma \ge h^{\frac{1}{2}-\delta}$.

Then $\Gamma Q_1 e^{ih^{-1}tA} Q_2 \equiv 0$ *as* $|t - t_{p,q} - nT_0| \le \epsilon$ *with* $q = 1, \dots, p-1$.

Proof. Without any loss of the generality one can assume that Q_1, Q_2 are supported in $\{|f - \bar{f}| \le \epsilon'\gamma\}$ with the same $\bar{f}$ and arbitrarily small constant ϵ', $|\bar{f}| \asymp \gamma$. Note that

$$e^{ih^{-1}tA} Q_2 \equiv e^{ih^{-1}(t-nT_0)A} e^{ih^{-1}\varepsilon nB} Q_2 \equiv e^{ih^{-1}(t-nT_0)A_0} e^{ih^{-1}\varepsilon tB} Q_2. \tag{6.3.15}$$

Due to Proposition 6.3.4

$$e^{ih^{-1}\varepsilon tB} Q_2 \equiv Q_3 e^{ih^{-1}\varepsilon tB} Q_2$$

where planted operator $Q_3 \in \mathbf{\Psi}_{h,\gamma,\gamma}(X, \mathbb{K})$ is supported in $\{|f - \bar{f}| \le 3\epsilon'\gamma\} \cap \Omega$ and $Q_3 \equiv I$ in $\{|f - \bar{f}| \le 3\epsilon'\gamma\}$. However then $Q_1 e^{ih^{-1}(t-n)A_0} Q_3 \equiv 0$ as $|t - t_{p,q} - n| \le \epsilon$ due to (6.3.8) and the theory of Section 2.4. □

Therefore in what follows we need to consider only

$$\phi(t - nT_0 - t_{p,q}) \Gamma \big(Q_{1x} u(., ., t) Q^{t}{}_{2y}$$

with Q_j supported in $\{z\colon \mathsf{dist}(z, \Pi_p) \le \gamma = h^{\frac{1}{2}-\delta}\}$.

Successive Approximations

At this moment we do not assume that (a, b) is microhyperbolic; therefore we need to take $T = \varepsilon h^{\frac{1}{2}+2\delta}$ and $T'' = h^{\frac{1}{2}+2\delta}$.

Since Π_p is symplectic manifold we can assume without any loss of the generality that $\Pi_p = \{x'' = \xi'' = 0\}$ with $x = (x'; x'') = (x_1, \dots, x_{d-r}; x_{d-r+1}, \dots, x_d)$, $\xi = (\xi'; \xi'') = (\xi_1, \dots, \xi_{d-r}; \xi_{d-r+1}, \dots, \xi_d)$.

Let us run successive approximations to construct $e^{it''h^{-1}B} Q_2$ only; and let us freeze not $x = y$ but $x = (y', 0)$ and also replace hD'' by 0; so if $B = B(x', x'', hD_{x'}, hD_{x''}, h)$ we pick up $\bar{B} = b(y', 0, hD_{x'}, 0)$ where $b(x, \xi)$ is the principal symbol of B. We can do it because x'' and ξ'' are confined to $\{|x''| \le \gamma, |\xi''| \le \gamma\}$ with $\gamma = h^{\frac{1}{2}-\delta}$ since due to the previous subsubsection we should consider Q_j supported in γ-vicinity of Π_p. Note that we selected exponents in such way that $T''\gamma = h^{1+\delta}$.

Then the Schwartz kernel of $e^{it''h^{-1}B} Q_2$ is given by

$$\sum_{m\ge 0} h^{-d+m} \iint \mathcal{G}_m(y,\xi,\lambda) e^{ih^{-1}(t''\lambda+\langle x-y,\xi\rangle)}\, d\xi d\lambda \tag{6.3.16}$$

where $\mathcal{G}_m$ are functions described in Section 4.3 as $\mathcal{F}_m$ but they are constructed with $(\lambda - b(x',\xi'))^{-1}$ and they are polynomials with respect to (x'',ξ''). Note that since $\{b,x''\} = \{b,\xi''\} = 0$ as $x'' = \xi'' = 0$ each perturbation of this new type brings factor $\gamma^2 T'' h^{-1}$ so actually we need only $T'' \le \min\bigl(h^{\frac12+\delta}, h^{1+\delta}\gamma^{-2}\bigr)$.

Meanwhile $e^{ih^{-1}t'A_0}$ is h-Fourier integral operator corresponding to symplectomorphism $\Psi_{a,t}$ and one can write it as

$$\sum_{m\ge 0} h^{-\frac12(d+N)+k} \int f_k(x,y,t',\theta) e^{ih^{-1}S(x,y,t',\theta)}\, d\theta \tag{6.3.17}$$

where $\theta \in \mathbb{R}^N$, $S(x,y,t',\theta)$ and $f_k(x,y,t',\theta)$ are phase functions and amplitudes respectively. Therefore

$$\begin{aligned}\Gamma(Q_1 e^{ih^{-1}t'A_0} e^{it''h^{-1}B} Q_2) \equiv \sum_{m\ge 0} h^{-\frac12(3d+N)+m}\times \\ \iint\iiint \mathcal{G}_m(y,\xi,\lambda,t',\theta) e^{ih^{-1}(t''\lambda+\langle x-y,\xi\rangle+S(x,y,t',\theta))}\, d\theta d\xi d\lambda\, dxdy\end{aligned} \tag{6.3.18}$$

where we collected together equal powers of h and functions $\mathcal{G}_m(y,\xi,\lambda,\theta)$ are polynomials with respect to x'', ξ'' and are smooth with respect to t',θ (but there are also cut-off factors like $q(x''\gamma^{-1},\xi''\gamma^{-1})$ if we assume that symbols of Q_j are products of $q_j'(x',\xi')$ and such symbols.)

Consider an oscillatory integral

$$\begin{aligned}h^{-\frac12(3d+N)+m}\times \\ \iiiint \mathcal{G}_m(y,\xi,\lambda,t',\theta) e^{ih^{-1}(t''\lambda+\langle x-y,\xi\rangle+S(x,y,t',\theta))}\, d\theta dxdy''d\xi''.\end{aligned} \tag{6.3.19}$$

One can prove easily based on (6.3.7) that

(6.3.20) As x',y',λ,ξ',t' are fixed with $|t'-t_{p,q}| \le \epsilon$ the phase function $\langle x-y,\xi\rangle + S(x,y,t',\theta)$ has just one stationary point defined by

$$\{x''=y''=\xi''=0,\ \xi' = -\partial_{x'}S_0(x',y',t',\theta),\ \partial_\theta S_0(x',y',t',\theta)=0\}$$

with $S_0(x',y',t',\theta) \coloneqq S(x',0,y',0,t',\theta)$ and this point is non-degenerate.

Then due to the stationary phase principle one can eliminate integration with respect to (x'', y'', ξ'') (without any interference of $q(x''\gamma^{-1}, \xi''\gamma^{-1})$ factors if $q = 1$ in the vicinity of $\{x'' = \xi'' = 0\}$) resulting in (6.3.19) becoming the sum of

$$h^{-\frac{1}{2}(3d-3r+N)+m+k}\times \iint \mathcal{G}_{m,k}(y', \xi', \lambda, t', \theta) e^{ih^{-1}(t''\lambda+\langle x'-y', \xi\rangle+S_0(x', y', t', \theta))}\, d\theta dx'. \tag{6.3.21}$$

Let us recall that $S_0(x', y', t', \theta)$ corresponds to symplectomorphism $\Psi_{a,t}|_{\Pi_p}$ which is I as $t = t_{p,q}$; further, without any loss of the generality one can assume that locally $a = \xi_1$. Therefore without any loss of the generality one can assume that $N = d - r$ and $S(x', y', t', \theta) = -\langle x' - y', \theta\rangle + (t' - t_{p,q})\theta_1$ and (6.3.18) becomes

$$\sum_{m\ge 0} h^{-2(d-r)+m}\times \iint \iiint \mathcal{G}_m(y', \xi', \lambda, \theta) e^{ih^{-1}(t''\lambda+\langle x'-y', \xi'-\theta\rangle+(t'-t_{p,q})\theta_1)}\, d\theta d\xi' d\lambda\, dx' dy'. \tag{6.3.22}$$

This is exactly (but with the different functions) would look like

$$\Gamma\big(Q_{1x} e^{ih^{-1}(t'-t'_{p,q})A_0} e^{-ih^{-1}t''B_0} Q_2\big)$$

with $(d-r)$ dimensional operators $A_0 = a(x', 0, hD', 0)$ and $B_0 = b(x', 0, hD', 0)$. It invokes $\big(\tau' - a(x', \xi')\big)^{-1}$ and $\big(\lambda - b(x', \xi')\big)^{-1}$. Therefore in view (6.3.15) formula (6.2.64) should be corrected to

$$\begin{aligned} &F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(Q_{1x} u(x, y, t)\, {}^tQ_{2y}\big) \equiv \\ &\sum_{m\ge 0}\sum_{n:|n|\le T} h^{1-d+m} \iiiint T\hat{\chi}\big(\tfrac{(\tau-\tau')T}{h}\big)\mathcal{F}_m(y, \xi, \tau', \tau'') e^{ih^{-1}n(\varepsilon\tau''-T_0\tau')}\times \\ &\qquad dyd\xi\, d\tau' d\tau'' + \\ &\sum_{p,r}\sum_{\Lambda}\sum_{m\ge 0}\sum_{n:|n|\le T} h^{1-d+r+m} \iiiint T\hat{\chi}\big(\tfrac{(\tau-\tau')T}{h}\big)\times \\ &\qquad \mathcal{F}_{p,r,m}(y', \xi', \tau', \tau'') e^{ih^{-1}np^{-1}(\varepsilon\tau''-T_0\tau'+2\pi q(\Lambda))}\, dy' d\xi'\, d\tau' d\tau''. \end{aligned} \tag{6.3.23}$$

where we sum with respect to connected components Λ of $\Pi_{p,r}$, use $dy'd\xi'$ to denote natural measure on $\Pi_{p,r}$ and we also replaced T_0 and ε by $T_0' = T_0 p^{-1}$ and $\varepsilon' = \varepsilon p^{-1}$.

Since we can only be sure that $e^{ih^{-1}T_0'A_0'} = e^{2\pi p^{-1}qi}$ with $q(\Lambda) = 0, \dots, p-1$ rather than with $q(\Lambda) = 0$, we get the last term in the exponent in the second part of (6.3.23).

Similarly (6.2.70) should be corrected to

$$\begin{aligned}(6.3.24)\quad &\int \varphi\big(\frac{\tau}{L}\big)\Big(d_\tau \Gamma Q_{1x} e(.,.,\tau_1,\tau)\,{}^tQ_{2y} - \\ &\sum_{m\ge 0} h^{1-d+m}\iiint \mathcal{F}_m(y,\xi,\tau,\tau'')d_\tau \Upsilon\big(h^{-1}(T_0\tau - \varepsilon\tau'')\big)\,dyd\xi\,d\tau'' - \\ &\sum_{p,r} p \sum_{\Lambda}\sum_{m\ge 0} h^{1-d+r+m}\iiint \mathcal{F}_{p,r,m}(y',\xi',\tau,\tau'')\times \\ &\qquad d_\tau \Upsilon\big(h^{-1}p^{-1}(T_0\tau - \varepsilon\tau'' - q(\Lambda))\big)\,dy'd\xi'\,d\tau''\Big) \equiv 0\end{aligned}$$

and similarly (6.2.76) should be corrected to

$$\begin{aligned}(6.3.25)\quad &\Gamma Q_{1x} e(.,.,\tau_1,\tau_2)\,{}^tQ_{2y} \equiv \\ &\sum_{m\ge 0} h^{-d+m}\iiint \int_{\tau_1}^{\tau_2} \mathcal{F}_m(y,\xi,\tau,\tau'')d_\tau \Upsilon\big(h^{-1}(T_0\tau - \varepsilon\tau'')\big)\,dyd\xi\,d\tau'' + \\ &\qquad \sum_{p,r} p \sum_{m\ge 0} h^{1-d+r+m}\iiint \int_{\tau_1}^{\tau_2} \mathcal{F}_{p,r,m}(y',\xi',\tau,\tau'')\times \\ &\qquad\qquad d_\tau \Upsilon\big(h^{-1}p^{-1}(T_0\tau - \varepsilon\tau'' - q(\Lambda))\big)\,dyd\xi\,d\tau''.\end{aligned}$$

Thus we arrive to the following statement

Theorem 6.3.6. *Let a be scalar symbol. Let conditions* (6.2.1), (6.2.4), (6.2.7), (6.2.18) *and* (6.2.19) *be fulfilled in Ω. Further, let a be microhyperbolic in Ω on the energy level $\bar\tau$ and let* (6.2.55) *be fulfilled.*

Then

(i) As $L \ge \varepsilon h^{\frac12-\delta}$ formula (6.3.24) *holds (cf. Theorem 6.2.17).*

(ii) If τ_1, τ_2 belong to spectral gaps in Ω then formula (6.3.25) *holds (cf. Corollary 6.2.18).*

Exploiting Microhyperbolicity

Now we assume that (a,b) is microhyperbolic on the level $(\bar\tau,\bar\lambda)$ and discuss the consequences of this assumption. First of all we prove that we can take $T\asymp \varepsilon^{-1}$. To do this we should consider

$$\Gamma\big(Q_1\psi(B)\varphi(A_0)e^{ih^{-1}t''B}e^{ih^{-1}t'A_0}Q_2\big) \tag{6.3.26}$$

with φ,ψ supported in ϵ-vicinities of $\bar\tau$ and $\bar\lambda$ but this time as $|t'-t_{p,q}|\le\epsilon$, $|t''|\le T''=\epsilon$.

The key to extend constriction of the previous Subsubsection 6.3.1.4 to increased time interval is

Proposition 6.3.7. *Let a be scalar symbol and (a,b) be microhyperbolic on level $(\bar\tau,\bar\lambda)$. Then expression* (6.3.26) *is negligible as $|t'-t_{p,q}|+|t''|\asymp T$ with $\bar T:=h^{1-\delta}\le T\le\epsilon$ (this is a temporary notation).*

Proof. Consider instead

$$\Gamma\big(Q_1\psi(B)\varphi(A_0)e^{ih^{-1}t''B}e^{ih^{-1}t'A_0}e^{ih^{-1}t_{p,q}A_0}Q_2\big) \tag{6.3.27}$$

but with $|t'|+|t''|\asymp T$. Without any loss of the generality we can assume that near $\mathsf{supp}(Q_j)$ system (a,b) is ξ'-microhyperbolic on the level $(\bar\tau,\bar\lambda)$ where as before we need to consider only γ-vicinity of $\Xi_{p,r}=\{x''=\xi''=0\}$ and

$$\{a,x''\}=\{a,\xi''\}=\{b,x''\}=\{b,\xi''\}=0 \qquad \text{as } x''=\xi''=0. \tag{6.3.28}$$

Let us scale $x'\mapsto x'T^{-1}$, $x''\mapsto x''T^{-\frac12}$, leading to $\xi'\mapsto\xi'$, $\xi''\mapsto\xi''T^{-\frac12}$, $h\mapsto h_{\mathsf{new}}:=hT^{-1}$, $\gamma\mapsto\gamma_{\mathsf{new}}:=\gamma T^{-\frac12}$. Then again $\gamma\asymp h^{\frac12-\delta'}$ leads to $\gamma_{\mathsf{new}}\asymp h_{\mathsf{new}}^{\frac12-\delta''}$ but there is a new question: how scales $v(x,y)$ which is the Schwartz kernel of $e^{ih^{-1}t_{p,q}A_0}Q_2$? In the definition of $v(x,y)$ parameters h, $t_{p,q}$ are not scaled.

However $e^{ih^{-1}t_{p,q}A_0}$ is h-Fourier integral operator and with the scaling of x, y it becomes h_{new}-Fourier integral operator with

$$\mathsf{WF}(v)\subset\{|x'-y'|\lesssim(|x''|+|\xi''|)\asymp(|y''|+|\eta''|)\}.$$

Now we apply cut-off Q_2 (rescaled) and conclude that

$$\mathsf{WF}(v)\subset\{x'=y',x''=y''=\xi''=\eta''=0\}$$

and due to propagation of singularities and ξ'-microhyperbolicity we conclude that

$$\mathsf{WF}(U) \subset \{|x'-y'| \ge \epsilon, x''=y''=\xi''=\eta''=0\}$$

where $U(x,y,t',t'')$ is a Schwartz kernel of $\psi(B)\varphi(A_0)e^{ih^{-1}t''B}e^{ih^{-1}t'A_0}v$ after this rescaling. Then $\Gamma(U)\equiv 0$ as $|t'|+|t''|\asymp 1$ and (6.3.27) is negligible as $|t'|+|t''|\asymp T$ and therefore (6.3.26) is negligible as $|t'-t_{p,q}|+|t''|\asymp T$.□

Proposition 6.3.7 immediately implies

Theorem 6.3.8. *(cf. Theorem 6.2.19) Let a be scalar symbol and microhyperbolicity condition* (6.2.80) *be fulfilled. Then*

(i) Expression (6.2.15) *is negligible outside of zone where it was constructed by the method of successive approximations.*

(ii) Let us replace $\mathsf{e}(.,y,\tau)$ by $\psi(B)_x\mathsf{e}(.,y,\tau)$ with $\psi\in \mathscr{C}_0^\infty([\bar\lambda-\epsilon,\bar\lambda+\epsilon])$ with small enough ϵ; then the statement of Theorem 6.3.6 extends to L satisfying $L\ge \varepsilon h^{1-\delta}$.

Tauberian Estimates

Analysis of subsubsections *6.3.1.2 Propagation of Singularities near* Π and *6.3.1.4 Exploiting Microhyperbolicity* immediately implies that

(6.3.29) Contribution of $\Pi_{p,r}$ and including its subperiodical points to $F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma\big(Q_1\psi(B)e^{ih^{-1}tA}Q_2\big)$ does not exceed

$$Ch^{-d}\gamma^{2r}\bar T(\varepsilon^{-1}\bar T+1)\le Ch^{1-d+r-\delta'}(\varepsilon^{-1}h+1) \tag{6.3.30}$$

where factor γ^{2r} is a volume of γ-vicinity of $\Pi_{p,r}$, factor $\bar T$ comes as a length of the time interval on one period which contributes non-negligibly (recall that $|t'-t_{p,q}|\le \bar T$ then) and factor $(\varepsilon^{-1}\bar T+1)$ is a number of periods to be counted (since as $|t''|\ge \bar T$ contribution is negligible).

Probably this statement holds with $\delta'=0$ but we do not need this improvement since it is less anyway than estimate $Ch^{1-d}(\varepsilon^{-1}h+1)$ we got earlier and therefore Tauberian estimates (6.2.89) and (6.2.90) do not change.

Consider corrected Weyl expressions. One can see easily that the corrections look exactly as main oscillatory terms but with integration with respect to Λ and with an extra factor h^r where $2r=\mathsf{codim}\,\Lambda$. Therefore we arrive to two statements below:

Theorem 6.3.9 [8]**.** *In the framework of Theorem 6.2.24 with an error not exceeding* (6.2.93) *as* $\varepsilon \ge h$ *and* (6.2.94) *as* $\varepsilon \le h$ *one can replace* $\mathsf{N}^{\mathsf{T}}_{\psi}$ *or* $\mathsf{N}^{\mathsf{T}}_{\psi,\varphi,L}$ *in Theorem 6.2.21 by* $\mathsf{N}^{\mathsf{W}}_{\psi} + \mathsf{N}_{\mathsf{corr},\psi}$ *or* $\mathsf{N}^{\mathsf{W}}_{\psi,\varphi,L} + \mathsf{N}_{\mathsf{corr},\psi,\varphi,L}$ *respectively where correction term now contains also contributions of subperiodic trajectories.*

Proposition 6.3.10 [9]**.** *Contributions of* $\Pi_{p,r}$ *to the Tauberian expression* $\mathsf{N}^{\mathsf{T}}_{\psi,\varphi,L}$ *does not exceed expression* (6.2.93) *multiplied by* h^{r-1} *as* $\varepsilon \ge h$ *and expression* (6.2.94) *multiplied by* h^{r-1} *as* $\varepsilon \ge h$.

In particular, this contribution to the Tauberian expression N^{T} *does not exceed* Ch^{2-d} *and* $Ch^{2-d}\bigl(|\log \varepsilon^{-1}h| + 1\bigr)$ *as* $\varepsilon \ge h$ *and* $\varepsilon \le h$ *respectively.*

6.3.2 The case of Degenerate Scalar Operator B

Now we assume that not only a but also b is scalar symbol. In this case microhyperbolicity condition of (a, b) means exactly that

$$|\nabla_{\Sigma} b| + |b - \bar\lambda| \ge \epsilon_0 \qquad \text{on } \ \Sigma := \{a = \bar\tau\}. \tag{6.3.31}$$

Now we want to tackle degenerating symbol b. Without any loss of the generality one can assume that locally $a = \xi_1$, $\bar\tau = 0$.

Asymptotics with mMollification

Let introduce scaling function ρ by

$$\rho = \epsilon_1\bigl(|\nabla_{x',\xi'} b|^2 + |b - \bar\lambda|\bigr)^{\frac12} + \bar\rho \tag{6.3.32}$$

with

$$\bar\rho = h^{\frac12 - \delta'} \tag{6.3.33}$$

here; $(x', \xi') = (x_2, \dots, x_d; \xi_2, \dots, \xi_d)$. Then this is an admissible function on Σ. Consider $\rho = \bar\rho$ vicinity of point $\bar z$ with respect to (x', ξ') and $(\epsilon, \epsilon\rho^2)$ vicinity with respect to (x_1, ξ_1). Then in this vicinity

$$b = \bar\lambda + \rho^2 b' + \mu a + O(\rho^2), \quad b' = \rho^{-2}\bigl(b(x', 0, \xi') - \bar\lambda\bigr) \tag{6.3.34}$$

[8] Cf. Theorem 6.2.24.

[9] Cf. Theorem 6.2.23.

with , $\mu = \mathsf{const}$. Then for $Q \in \mathbf{\Psi}_{h,\boldsymbol{\rho},\boldsymbol{\gamma}}(X,\mathbb{K})$ supported in this vicinity, $\boldsymbol{\rho} = (\rho^2, \rho, \dots, \rho)$, $\boldsymbol{\gamma} = (1, \rho, \dots, \rho)$

$$e^{ih^{-1}T_0 A} Q \equiv e^{i\varepsilon h^{-1} B} Q \equiv e^{i\varepsilon h^{-1}(\bar{\lambda}+\rho^2 B'+\mu A_0)} Q \equiv e^{i\varepsilon h^{-1}(\bar{\lambda}+\rho^2 B'+\mu A_0)} Q \tag{6.3.35}$$

where B' is an operator with the principal symbol b'.

Then after rescaling $x' \mapsto x'\rho^{-1}$, $\xi' \mapsto \xi'\rho^{-1}$, $x_1 \mapsto x_1$, $\xi_1 \mapsto \xi_1\rho^{-2}$, $h \mapsto h_{\mathsf{new}} = h\rho^{-2}$, $\varepsilon \mapsto \varepsilon_{\mathsf{new}} := \varepsilon\rho^2$ we are in the framework of the previous theory (at least if there are no subperiodic trajectories). Further, as $\rho \ge c\bar{\rho}$ we are in the framework of the microhyperbolic theory and are allowed to use mollification parameter $L = \varepsilon_{\mathsf{new}} h_{\mathsf{new}}^{1-\delta'} \le \varepsilon h^{1-\delta'}$. On the other hand, as $\rho \le c\bar{\rho}$ we are allowed to use mollification parameter $L = \varepsilon_{\mathsf{new}} h_{\mathsf{new}}^{\frac{1}{2}-\delta'} \le \varepsilon h^{1-2\delta}$.

Consider subperiodic trajectories. Then also nothing changes because cases $\mathsf{dist}(z,\Pi) \ge h^{\frac{1}{2}-\delta}$ and $\mathsf{dist}(z,\Pi) \le h^{\frac{1}{2}-\delta}$ are transformed to the similar cases after rescaling.

Therefore we arrive to

Theorem 6.3.11 [10]**.** *Let a and b be scalar symbols. Let conditions* (6.2.1), (6.2.4), (6.2.7), (6.2.18) *and* (6.2.19) *be fulfilled in Ω. Further, let a be microhyperbolic in Ω on the energy level $\bar{\tau}$ and let* (6.2.55) *be fulfilled.*

Then

(i) As $L \ge \varepsilon h^{1-\delta}$ formula (6.3.24) *holds (cf. Theorem 6.2.17).*

(ii) If τ_1, τ_2 belong to spectral gaps in Ω then estimate (6.3.25) *holds (cf. Theorem 6.2.18). Here we use the same definition* (6.2.74) *of the spectral gap but with $L = h^{1-\delta}$ rather than $L = h^{\frac{1}{2}-\delta}$.*

Estimates without Mollification

Let us consider the same partition. Note that one should take $T \asymp \varepsilon^{-1}$ again (since evolution remains in zone $\{\rho \asymp \rho(\bar{z})\}$ for this time) but estimate for $M(\pi)$ defined by (6.2.82) would be different from (6.2.83):

$$|M(\phi)| \le Ch^{1-d}(1 + \varepsilon\rho^2 h^{-1}|n|)^{-l}\rho^{2d-2} \tag{6.3.36}$$

and therefore

$$|M(\bar{\chi}_T)| \le Ch^{1-d}\big(1 + \varepsilon^{-1}\rho^{-2}h\big)\rho^{2d} \tag{6.3.37}$$

[10] Cf. Theorem 6.3.6.

and therefore contribution of this element to the remainder estimate does not exceed

$$Ch^{1-d}\bigl(\varepsilon+\rho^{-2}h\bigr)\rho^{2d-2}\vartheta\bigl(\frac{\varepsilon h}{L}\bigr) \tag{6.3.38}$$

and thus summation over partition elements with $\rho \ge c\bar\rho$ results in

$$Ch^{1-d}\vartheta\bigl(\frac{\varepsilon h}{L}\bigr)\int_{\Sigma_{\bar\tau}\cap\{\rho\ge\bar\rho\}}\bigl(\varepsilon+\rho^{-2}h\bigr)\,dx'd\xi' \le Ch^{1-d}\Bigl(\varepsilon+h\int_{\Sigma_{\bar\tau}\cap\{\rho\ge\bar\rho\}}\rho^{-2}\,dx'd\xi'\Bigr)\vartheta\bigl(\frac{\varepsilon h}{L}\bigr). \tag{6.3.39}$$

where we again consider locally $a=\xi_1$.

Meanwhile contribution of the balls with $\rho\asymp\bar\rho$ does not exceed

$$Ch^{1-d}\Bigl(\int_{\Sigma_{\bar\tau}\cap\{\rho\le\bar\rho\}}dx'd\xi'\Bigr)\vartheta\bigl(\frac{\varepsilon h}{L}\bigr). \tag{6.3.40}$$

Really, we apply here the Tauberian estimates with $T\asymp\varepsilon^{-1}$ but here we have

$$M(\bar\chi_T)\le Ch^{1-d}\varepsilon^{-1}\rho^{2d-2} \tag{6.3.41}$$

since number of windings is $O(\varepsilon^{-1})$.

Combining estimates (6.3.39) and (6.3.40) we arrive to

Theorem 6.3.12 [11]**.** *Let a and b be scalar symbols. Let conditions* (6.2.1), (6.2.4), (6.2.7), (6.2.18) *and* (6.2.19) *be fulfilled in Ω. Further, let a be microhyperbolic in Ω on energy level $\bar\tau$ and let* (6.2.55) *be fulfilled.*

(i) Then

$$|\mathsf{R}^{\mathsf{T}}_{\varphi,\psi,L}|\le Ch^{1-d}\Bigl(\varepsilon+h\int_{\Sigma_{\bar\tau}\cap\{\rho\ge\bar\rho\}}\rho^{-2}\,dx'd\xi'+\int_{\Sigma_{\bar\tau}\cap\{\rho\le\bar\rho\}}dx'd\xi'\Bigr)\vartheta\bigl(\frac{\varepsilon h}{L}\bigr). \tag{6.3.42}$$

[11] Cf. Theorem 6.3.6.

(ii) In particular, if

$(6.3.43)_k$ $|a-\bar\tau|+|b-\bar\lambda|+|\nabla_{x',\xi'}b| \le \epsilon$ *implies that* $\mathsf{Hess}_{x',\xi'}\, b$ *has* k *eigenvalues disjoint from* 0

then as $k \ge 3$ *estimate*

$$|\mathsf{R}^{\mathsf{T}}_{\varphi,\psi,L}| \le Ch^{1-d}(\varepsilon + h)\vartheta\big(\varepsilon\frac{h}{L}\big) \tag{6.3.44}$$

holds as if there was no degeneration, as $k = 2$ *estimate*

$$|\mathsf{R}^{\mathsf{T}}_{\varphi,\psi,L}| \le Ch^{1-d-\delta}(\varepsilon + h)\big(\frac{\varepsilon h}{L}\big) \tag{6.3.45}$$

holds and as $k = 1$ *estimate*

$$|\mathsf{R}^{\mathsf{T}}_{\varphi,\psi,L}| \le Ch^{\frac12-d}(\varepsilon + h^{1-\delta})\big(\frac{\varepsilon h}{L}\big) \tag{6.3.46}$$

holds.

This result is not completely satisfactory as $k = 1, 2$; in this case we need to be able to take $\bar\rho = h^{\frac12}$. It is possible despite the fact that condition $\varepsilon_{\mathsf{new}} \ge h^l_{\mathsf{new}}$ breaks because we need condition $\varepsilon \ge h^l$ only because error is $O(h^r)$ in the original equations. However in fact error is this with the original h and we need only "$\varepsilon_{\mathsf{new}} \ge h^l$" rather than "$\varepsilon_{\mathsf{new}} \ge h^l_{\mathsf{new}}$". Therefore we arrive to

Theorem 6.3.13. *(i) In the framework of Theorem 6.3.12 estimate* (6.3.42) *holds with* $\bar\rho = h^{\frac12}$.

(ii) In particular, if condition

$(6.3.43)^+_2$ $|a-\bar\tau| + |b-\bar\lambda| + |\nabla_{x',\xi'}b| \le \epsilon$ *implies that* $\mathsf{Hess}_{x',\xi'}\, b$ *has* 2 *eigenvalues disjoint from* 0 *and both of the same sign*

then estimate (6.3.44) *holds as if there was no degeneration.*

(iii) Under condition $(6.3.43)_2$ *estimate*

$$|\mathsf{R}^{\mathsf{T}}_{\varphi,\psi,L}| \le Ch^{1-d-\delta}(\varepsilon + h|\log h|)\big(\frac{\varepsilon h}{L}\big) \tag{6.3.47}$$

holds.

(iv) Under condition $(6.3.43)_1$ *estimate*

$$|\mathsf{R}^{\mathsf{T}}_{\varphi,\psi,L}| \le Ch^{\frac{1}{2}-d}(\varepsilon + h^{\frac{1}{2}})(\frac{\varepsilon h}{L}) \tag{6.3.48}$$

holds.

6.3.3 Some Remarks

Remark 6.3.14. (i) The following question arises naturally: can we improve estimate (6.3.44), surely including if necessary the next terms into the left-hand expression. The answer will be affirmative if we manage to increase T. It is not a difficult task and the additional arguments are completely in terms of the Tauberian method provided the following conditions are fulfilled:

$$\Psi_{b,t''}(\Omega') \subset \Omega \qquad \forall t'' \in [-T'', T''], \tag{6.3.49}$$

$$|D_{x,\xi}\Psi_{b,t''}| \le h^{-\delta'} \qquad \forall (x,\xi) \in \Omega' \quad \forall t'' \in [-T'', T''] \tag{6.3.50}$$

and

$$\mathsf{dist}(\Psi_{a,t} \circ \Psi_{b,t'}(x,\xi), (x,\xi) \ge \epsilon_0 \gamma |t'| t(1-t) \tag{6.3.51}$$
$$\forall (x,\xi) \in \mathcal{U} \quad \forall t \in (0,1) \quad \forall t'' \in [-T'', T'']$$

where Ω' contains the ϵ_1-neighborhood of Ω_0, $\Psi_{a,t}(\Omega_0) = \Omega_0$ and $1 \le T'' \le h^{-\delta'}$, $\delta' > 0$ is a small enough exponent. Then in the corresponding estimates one can replace T by $\varepsilon^{-1}T''$ and insert factor T''^{-1} in the right hand expression of (6.3.44) In this case $d \ge 3$ automatically.

(ii) In particular if one can take T'' as an arbitrarily large constant, then one can insert factor $o(1)$.

(iii) On the other hand, one can investigate the case when the flow $\Psi_{b,t''}$ on $\tilde{\Omega} = \Omega/\sim$ is T_1-periodic where $\sim$ is the equivalence relation given by $z \sim z'$ if $\Psi_{a,t}(z) = z'$ for some t, and if $\tilde{\Omega}$ contains the ϵ-neighborhood of $\tilde{\Omega}_0 = \Omega_0/\sim$; in this case the arguments of this section work; moreover this chain could be prolonged but these conditions seem rather insane (but possible to fulfill).

Let $\varepsilon \ll h$ and $\varepsilon' \ll h$ where now $B = B_0 + \varepsilon' B'$ and quantum evolution for B_0 is periodic i.e. $e^{ih^{-1}T_1 B_0} \equiv I$. Then spectral bands of the width $\asymp \varepsilon$

separated by spectral gaps of the width h in turn consist of spectral subbands of the width $\asymp \varepsilon\varepsilon'$ separated by spectral gaps of the width εh (we assume that perturbations are generic).

Remark 6.3.15. (i) Let us recall that in the case of one operator formally[12)]

$$\partial_\tau E(\tau) \approx (2\pi h)^{-d} \operatorname{Res}_{\mathbb{R}} (\tau - A)^{-1} \tag{6.3.52}$$

Similarly in the case of I commuting operators

$$\partial_{\tau_1}\cdots\partial_{\tau_I} E_1(\tau_1)\cdots E_I(\tau_I) \approx (2\pi h)^{-d} \operatorname{Res}_{\mathbb{R}} (\tau_1 - A_1)^{-1}\cdots \operatorname{Res}_{\mathbb{R}} (\tau_I - A_I)^{-1} \tag{6.3.53}$$

we have now

$$\partial_\tau E(\tau) \approx (2\pi h)^{-d} \sum_{p\in\mathbb{Z}} \operatorname{Res}_{\mathbb{R}} (\tau' - A_0)^{-1}\big|_{\tau'=2\pi ph T_0^{-1}} \theta(\lambda - B)\big|_{\lambda=\varepsilon^{-1}(\tau-2\pi ph T_0^{-1})}. \tag{6.3.54}$$

In particular, as τ_1 and τ_2 are two gap values we have

$$Q_1 E(\tau) Q_2 \equiv (2\pi h)^{-d} \sum_{p\in\mathbb{Z}} Q_1 \theta(\tau' - A_0)\big|_{\tau'=2\pi ph} \theta(\lambda - B)\big|_{\lambda=\varepsilon^{-1}(\tau-2\pi ph)} Q_2 \Big|_{\tau=\tau_1}^{\tau=\tau_2} \tag{6.3.55}$$

with here $\theta(\tau - A)$ etc is understood as $\int^\tau \operatorname{Res}_{\mathbb{R}} (\tau - A)^{-1}\, d\tau$ with $(z - A)^{-1}$ constructed as formal pseudodifferential operators.

(ii) We know that as $\varepsilon \ll h$ there are spectral gaps of the width $\asymp h$; however as b is matrix-valued there could be spectral gaps of the width $\asymp \varepsilon$. Let us ignore them. Then as $\tau_1 < \tau_2$ are adjacent gap values; define $p \in \mathbb{Z}$ by

$$\varepsilon \operatorname{Spec}(b) \subset (\tau_2 - \frac{2\pi(p+1)h}{T_0}, \tau_2 - \frac{2\pi ph}{T_0}) \tag{6.3.56}$$

then

$$Q_1 E(\tau) Q_2 \equiv (2\pi h)^{-d} Q_1 \theta(\tau' - A_0)^{-1}\big|_{\tau'=\frac{2\pi ph}{T_0}} \tag{6.3.57}$$

expression which does not depend on ε (as long as ε is small enough not to destroy spectral gaps).

[12)] So, it makes sense after substitution in the various "taming" expressions.

6.3.4 Spectral Gaps Reloaded

Let us try a bit different approach. Assume that a is a scalar symbol and consider operator

$$G \equiv e^{ih^{-1}T_0A} \tag{6.3.58}$$

This is h-pseudodifferential operator. Without any loss of the generality one can assume that

$$G = \mathsf{const}\cdot I + \eta G', \quad G' \in \boldsymbol{\Psi}_{h,K}(\mathbb{R}^d, \mathbb{H}), \quad \eta \in [h^r, h]; \tag{6.3.59}$$

for $r = 1$ this condition can be checked effectively because we know G modulo $h\boldsymbol{\Psi}$.

Let us consider the self-adjoint operators $G_1 = \frac{1}{2}(G + G^*)$ and $G_2 = -\frac{1}{2}i(G - G^*)$. Then (6.3.58) remains true for $\exp(ih^{-1}T_0A)$ and G replaced by either $\cos(ih^{-1}T_0A)$ and G_1 or $\sin(ih^{-1}T_0A)$ and G_2 respectively.

Proposition 6.3.16. *(i) If for $j = 1$ or $j = 2$*

$$|G_j(x,\xi,h) - \mu_j| \ge \zeta \qquad \forall (x,\xi) \in \Omega, \tag{6.3.60}$$

where $\zeta \in [C_0h\eta, 1]$ and $G_j(x,\xi,h)$ and $G(x,\xi,h)$ are Weyl symbols of G_j G respectively, then

$$E_j'(\mu_j - \frac{1}{2}\eta\zeta, \mu_j + \frac{1}{2}\eta\zeta) \equiv 0 \qquad \textit{in } \Omega \tag{6.3.61}$$

where E_1' and E_2' are the spectral projectors of $\cos(h^{-1}A)$ and $\sin(h^{-1}A)$ respectively.

(ii) Let

$$|G(x,\xi,h) - \exp(ih^{-1}T_0\tau)| \ge \eta\zeta \qquad \forall (x,\xi) \in \Omega \quad \forall \tau \in [\tau_1, \tau_2] \tag{6.3.62}$$

where $\zeta \in [C_0h\eta, 1]$. Then

$$E(\tau_1, \tau_2) \equiv 0 \qquad \textit{in } \Omega. \tag{6.3.63}$$

(iii) For scalar G one can assume that $\zeta \in [C_0h^2\eta, 1]$.

Proof. (i) An easy proof is based on sharp Gårding inequality combined with the simplified Tauberian arguments.

(ii) Taking into account the link between these spectral projectors and the spectral projector E of A we obtain that

$$E(\tau - \frac{1}{2}h\zeta, \tau + \frac{1}{2}h\zeta) \equiv 0 \quad \text{in} \quad \Omega$$

provided $\cos(h^{-1}T_0\tau) = \mu_1$ or $\sin(h^{-1}T_0\tau) = \mu_2$.

(iii) To prove Statement (iii) one should apply Melin inequality instead of sharp Gårding inequality.

Easy details are left to the reader. □

We call intervals $[\tau_1, \tau_2]$ satisfying (6.3.62) *(semiclassical) spectral gaps*. We already obtained complete asymptotics in the case when the spectral parameters belong to different spectral gaps. However now we just defined border of such gaps with a better precision.

6.3.5 Families of Commuting Operators Approach

Operators with Completely Periodic Evolution

Now let us consider a bit different approach. However, the first step of the new approach is based on the previous ideas. Let us consider in this subsubsection operator $A = A_0$ satisfying (6.2.28) (i.e. $e^{ih^{-1}T_0A_0} \equiv I$).

Proposition 6.3.16 immediately yields that the spectral zones in Ω lie in very narrow vicinities of the points $2\pi mhT_0^{-1}$ with $m \in \mathbb{Z}$.

Let $\bar\tau = 2\pi mhT_0^{-1}$; further, let $\tau_1 \in (2\pi(m-1)\pi hT_0^{-1}, 2\pi mhT_0^{-1})$ and $\tau_2 \in (2\pi mhT_0^{-1}, 2\pi(m+1)hT_0^{-1})$ be lacunar values, and let $\phi \in \mathscr{C}_0^K([-1,1])$ equal 1 on $[-\frac{1}{3}, \frac{1}{3}]$. Then

$$QE(\tau_1, \tau_2) \equiv \int \varphi\bigl(\frac{\tau - \bar\tau}{L}\bigr) Q\, d_\tau E(*, \tau) \equiv \varphi\bigl(\frac{1}{L}(hD_t - \bar\tau)\bigr)\bar\chi_T QU|_{t=0} \tag{6.3.64}$$

for $L = \frac{1}{2}h$, φ and $\bar\chi$ the same type of function as ϕ, and $LT \ge h^{1-\delta}$.

One can replace $\bar\chi_T(t)$ here by $\sum_{|n|\le T} \bar\chi(t - nT_0)$ for $\bar\chi \in \mathscr{C}_0^K([-\frac{2}{3}, \frac{2}{3}])$ such that the last sum with n running over $\mathbb{Z}$ equals 1. Then applying (6.2.28) we obtain that the right-hand expression of (6.2.52) is equal to

$$\int_{\mathbb{R}} \varphi\bigl(\frac{\tau - \bar\tau}{L}\bigr) \sum_{|n|\le T} e^{ih^{-1}T_0n\tau} F_{t\to h^{-1}\tau}\bar\chi(t) QU\, d\tau \tag{6.3.65}$$

provided $T \le h^{-l}$ with arbitrarily large l.

Recall that QU is a Fourier integral operator. Let us write its Schwartz kernel in the form of a Lagrangian distribution of the class $I_{h,M}$ [13] where temporarily

$$M := \{(x,\xi,y,\eta,t,\tau) : (x,\xi) = \Psi_{a,t}(y,-\eta), \tau = a(x,\xi)\}.$$

Then one can easily see that the Schwartz kernel of $F_{t\to h^{-1}\tau}\bar{\chi}(t)QU$ is a Lagrangian distribution of the class $I_{h,\Lambda}$ with the Lagrangian manifold

$$\Lambda_\tau = \{(x,\xi;y,\eta),\ a(x,\xi)=\tau,\ \exists t : (y,-\eta) = \Psi_{a,t}(x,\xi)\} \tag{6.3.66}$$

depending smoothly on $h^{-1}\tau$ provided there are no subperiodic trajectories[14].

Then one can take the sum with respect to n running over $\mathbb{Z}$ in (6.3.65); the error will be negligible. Recall that the sum of the exponents then equals $\sum_m \delta(\tau - 2\pi m h T_0^{-1}) h T_0^{-1}$.

Moreover, one can take here only $m = 0$ (other terms vanish because of the choice of φ and L). Then the right-hand expression of (6.3.65) is a Lagrangian distribution of the class hI_{h,Λ_τ} depending smoothly on τ with Lagrangian manifold Λ_τ [15].

So, the following statement is proven:

Theorem 6.3.17. *Let A be an operator with a scalar symbol a and let conditions* (6.2.1), (6.2.2), (6.2.5), (6.2.7) *and* (6.2.28) *be fulfilled. Then*

(i) Let there be no subperiodic trajectories. Then for all $\tau = 2\pi m h T_0^{-1}$ with $|\tau| \le \epsilon$ the Schwartz kernel of $E_A(\tau-\zeta;\tau+\zeta)$ is a Lagrangian distribution with Lagrangian manifold Λ_τ; $\zeta = C_0 h^s$ here [16].

(ii) In the general case Λ_τ is (locally) the union of a finite number of Lagrangian manifolds and the distribution in question is microlocally the sum of the corresponding Lagrangian distributions.

---

[13] Recall that this means that it is defined by $h^{-m}\int b(x,y,t,\theta)e^{ih^{-1}\varphi(x,y,t,\theta)}\,d\theta$ with m-dimensional variable θ and phase function φ satisfying standard conditions.

[14] If there are subperiodic trajectories then Λ_τ is a locally finite union of Lagrangian manifolds and we obtain a sum of the corresponding Lagrangian distributions.

[15] By definition $\tau = \bar{\tau}$ which runs over a lattice; nevertheless we can obviously extend the phase functions and amplitudes to the interval.

[16] However, $E(\tau-\zeta;\tau+\zeta)$ surely is not a Fourier integral operator because $\dim \operatorname{Ker} d\pi_X = \dim \operatorname{Ker} d\pi_Y = 1 (\ne 0)$ for projectors $\pi_X : \Lambda \to T^*X$, $\pi_Y : \Lambda \to T^*Y$, $Y = X$ here.

Now let us consider $\mathsf{Tr}\, QE(\tau_1,\tau_2)$. The same techniques are applicable (it seems to be more convenient to go from $F_{t\to h^{-1}\tau}(\chi_T(t)QU)$ than from QE).

First of all, let us assume that there are no subperiodic trajectories. Then one can take $\bar\chi$ supported in a small vicinity of 0. Then in virtue of the calculations of Subsection 4.3.3 we immediately obtain that modulo $O(h^s)$ the answer is

$$\sum_{m\ge 0} h^{-d+m+1}\, T_0^{-1} \iiint \mathcal{F}_m(y,\xi,\tau)\, d\mu_\tau \tag{6.3.67}$$

for $\tau=\bar\tau$ where $d\mu_\tau$ is a density on Σ_τ.

On the other hand, let us assume now that there are subperiodic trajectories with the (minimal) subperiod $T=p^{-1}$, $p=2,3,...$ (then one should also take into account subperiods np^{-1}, $n\in\mathbb{Z}$).

Therefore in order to take into account subperiodic trajectories one should in addition treat

$$\int \varphi\big(\frac{\tau-\bar\tau}{L}\big) F_{t\to h^{-1}\tau}\chi_T(t-T')\,\mathsf{Tr}\big(QU(t)\big)\, d\tau \tag{6.3.68}$$

with $T'=(k+qp^{-1})T_0$, $k\in\mathbb{Z}$, $|k|\le N$ and coprimes p and q, $1\le q\le p-1$. The easy calculations of oscillatory integrals give us an answer of the form

$$\int \varphi\big(\frac{\tau-\bar\tau}{L}\big) h^{-d+r} \int_{\Pi_{p,r}\cap\Sigma_\tau} F_{p,q}(x,\xi,\tau,h) e^{ih^{-1}T'\tau}\, d\mu_{p,r,\tau} d\tau \tag{6.3.69}$$

with smooth functions F_* where $d\mu=d\mu_\tau$ is a smooth density on $\Pi_{p,r}\cap\Sigma_\tau$.

One can see easily that the error will be negligible if we sum over $k\in\mathbb{Z}$ instead of $|k|\le N$ with $N=h^{-K}$ with large enough K. After summation with respect to $k\in\mathbb{Z}$ we get a sum of $hT_0^{-1}\delta(\tau-2\pi pkhT_0^{-1})$ and only $k=m$ gives a contribution to the final answer which at this step is equal to

$$h^{1-d+r} \int_{\Pi_{p,r}\cap\Sigma_\tau} F_{p,q}(x,\xi,\tau,h) e^{2\pi i h^{-1}T_0 qp^{-1}}\, d\mu_{p,r,\tau}. \tag{6.3.70}$$

So, the following statement has been proven:

Theorem 6.3.18. *Let A be an operator with a scalar symbol a and let conditions* (6.2.1), (6.2.2), (6.2.5), (6.2.7) *and* (6.2.28) *be fulfilled.*

Then $\mathsf{Tr}\big(QE(2\pi mh-\zeta, 2\pi mh+\zeta)\big)$ *is the sum of the terms* (6.3.67) *and* (6.3.70) *where* (p,r) *runs over the set of the admissible indices and* q *runs over* $(0),\dots,p-1$ [17].

Operators with the Global dDecomposition

In this subsubsection we treat operators of the form

(6.3.71) $A = A_0 + \varepsilon B$ where $e^{ih^{-1}A_0} = I$ and $B \in \mathbf{\Psi}_h$ and A_0 commute.

Then (6.2.18) holds with the same operator B. Later we will show that the general case can be reduced to this one. Therefore

$$E_A\big(\tau',\tau''\big) = \sum_m \boldsymbol{\pi}_n E_B\big(\varepsilon^{-1}(\tau' - 2\pi m\frac{h}{T_0}), \varepsilon^{-1}(\tau'' - 2\pi m\frac{h}{T_0})\big) \tag{6.3.72}$$

where

$$\boldsymbol{\pi}_m = E_{A_0}(2\pi m\frac{h}{T_0} - 0, 2\pi m\frac{h}{T_0} + 0) \tag{6.3.73}$$

is the spectral projector of A_0 to the eigenspace corresponding to eigenvalue $2\pi mhT_0^{-1}$.

We are interested in the spectrum of A close to $\bar\tau = 2\pi nhT_0^{-1}$. Note that for $\varepsilon \le \epsilon_2 h$ only the term with $m = n$ is essential in the right-hand expression of (6.3.72). Without any loss of the generality one can assume that microlocally $a = \xi_1$.

Let us consider a $(\rho,\rho,\varepsilon,\rho^2)$-admissible partition of unity with respect to $(x',\xi';x_1,\xi_1)$ with $\rho = \rho(x',\xi')$ given by (6.3.32) with $\bar\rho = h^{\frac12}$. For $\rho^2\varepsilon \le \epsilon_2 h$ only the term with $m = n$ is essential in the right-hand expression of (6.3.71) after application of the operator Q with the corresponding support. We treat only this case below. One can treat the opposite case by the same method but the results of the previous subsections are sufficient for our needs in this case.

Let us consider the two-parameter group $\boldsymbol{U}(t',t'') = e^{ih^{-1}(t'A+t''B)}$. This group is 1-periodic with respect to t'. The following statement is due to the results of Section 6.1:

---

[17] One can easily see that the character of the answer does not change if we include $q = 0$ and (or) q with reducible ratio qp^{-1}.

Proposition 6.3.19. *In the previous assumptions for small enough positive constants T', T''*

$$F_{(t',t'')\to h^{-1}(\tau',\tau'')}\bigl(\bar\chi_{T'}(t')\bar\phi_{T''}(t'')\,\mathsf{Tr}\,QU\bigr) \tag{6.3.74}$$

is given modulo $O(\hbar^s)$ by the successive approximations method where $\hbar = \rho^{-2}h$ and the absolute value of this expression does not exceed Ch^{-d}.

Then the same answer with an additional factor $e^{inh^{-1}T_0\tau}$ holds for this expression with $\bar\chi_T(t-nT_0)$ instead of $\bar\chi$. Therefore in absence of subperiodic trajectories

$$\int \varphi\bigl(\frac{\tau-\bar\tau}{L}\bigr)F_{(t,t')\to h^{-1}(\tau,\tau')}\bigl(\bar\chi_T(t)\,\mathsf{Tr}(QU)\bigr)\,d\tau \tag{6.3.75}$$

is given modulo $O(\hbar^s)$ by the successive approximations method and further calculations: it is equal to

$$\int \mathsf{Res}_{\mathbb{R}^2}\,\mathsf{Tr}\bigl(Q(\tau-A)^{-1}(\tau'-B)^{-1}\bigr)\varphi\bigl(\frac{\tau-\bar\tau}{L}\bigr)\,d\Upsilon(h^{-1}\tau) \tag{6.3.76}$$

provided $TL \ge h^{1-\delta}$; here $\mathsf{Res}_{\mathbb{R}^2}$ is taken with respect to (τ,τ').

For $L \le h$ the absolute value of the last expression does not exceed Ch^{2-d}. Applying the Tauberian method we obtain then that for a function φ satisfying (4.2.73)–(4.2.75)

$$\int \varphi\bigl(\frac{\tau'}{L}\bigr)\,d_{\tau'}QE_B(*,\tau')\boldsymbol{\pi}_n \equiv \int \varphi\bigl(\frac{\tau'}{L}\bigr)\,\mathsf{Res}_{\mathbb{R}^2}\,\mathsf{Tr}\bigl(Q(\bar\tau-A)^{-1}(\tau'-B)^{-1}\bigr)\,d\tau'$$

modulo $O(\hbar^{2-d}\vartheta(\varepsilon h/L)$.

This immediately yields (after summation with respect to the partition) all statements of Theorem 6.3.12 (under assumptions made).

Now let us consider the contribution of the subperiodic trajectories. Direct calculation based on Proposition 6.3.1 yields that the contribution of such trajectories to $F_{t\to h^{-1}\tau}\chi_T(t)QU$ does not exceed $Ch^{2-d}T$ (which does not exceed the standard estimate of this Fourier transform) and therefore their contribution to the remainder does not exceed $Ch^{2-d}\vartheta(\varepsilon h/L)$ which does not exceed the final remainder estimate. Furthermore, their contributions to the principal parts are also known and we again recover all statements of Theorem 6.3.12 (under assumptions made).

General oOperators

Let us consider the general scalar operator A satisfying conditions (6.2.1), (6.2.2), (6.2.5) and (6.2.7). Then condition (6.2.18) is also fulfilled and without any loss of generality one can assume that B is a self-adjoint operator. Let $A_0 = A - \varepsilon B$. Then

$$e^{ih^{-1}T_0A_0} \equiv I, \qquad [A_0, B] \equiv 0 \qquad \text{in } \Omega_1 \tag{6.3.77}$$

where Ω_1 is the intermediate domain between Ω and Ω_0. Then for the operator A_0 the results of Subsubsection *6.2.3.3 Spectral Gaps (the First Attempt)* hold. Let us set

$$\bar{A}_0 = \sum_n \tau_n E(\tau_n - \zeta, \tau_n + \zeta) \tag{6.3.78}$$

with $\epsilon h \ge \zeta \ge h^l$ and $\tau_n = 2\pi nh T_0^{-1}$, thus replacing eigenvalues of A_0 close to τ_n by τ_n. Then

$$\bar{A}_0 \equiv A_0 \qquad \text{in } \Omega_1, \qquad e^{ih^{-1}T_0\bar{A}_0} = I. \tag{6.3.79}$$

Furthermore, let us set

$$\bar{B} = \frac{1}{T_0}\int_0^{T_0} e^{-ih^{-1}t\bar{A}_0} B e^{ih^{-1}t\bar{A}_0}\, dt. \tag{6.3.80}$$

Then

$$\bar{B} \equiv B \qquad \text{in } \Omega_1, \qquad [\bar{A}_0, \bar{B}] = 0 \tag{6.3.81}$$

and all the operators are self-adjoint.

Then the operator $\bar{A} = \bar{A}_0 + \bar{B}$ satisfies the assumptions of the previous subsubsection and we can apply those results to it.

On the other hand, $A \equiv \bar{A}$ in Ω_1. Then propagation of singularities results of Subsection 6.2.3 yield that $e^{ith^{-1}tA}Q \equiv e^{ith^{-1}t\bar{A}}Q$ for $|t| \le T = \epsilon\varepsilon^{-1}$ and therefore

$$\int \hat{\chi}\big(\frac{(\tau-\lambda)T}{h}\big)\, d_\lambda \nu(\tau') \equiv \int \hat{\chi}\big(\frac{(\tau-\tau')T}{h}\big)\, d_{\tau'}\bar{\nu}(\tau') \tag{6.3.82}$$

with $\nu(\tau) = \mathsf{Tr}\big(QE_A(-\infty,\tau)\big)$ and $\bar{\nu}(\tau) = \mathsf{Tr}\big(QE_{\bar{A}}(-\infty,\tau)\big)$. Picking up a Hörmander function for χ we obtain by the Tauberian method that

$$|\nu(\tau + \frac{h}{T}) - \nu(\tau)| \le C \sup_\tau |\bar{\nu}(\tau + \frac{h}{T}) - \bar{\nu}(\tau)| + Ch^s \tag{6.3.83}$$

and one can easily estimate the right-hand expression.

Then applying Tauberian arguments in the full one can estimate

$$|\int \varphi\big(\frac{\tau-\bar{\tau}}{L}\big)\, d_\tau\big(\nu(\tau)-\bar{\tau}(\tau)\big)|$$

and recover Theorem 6.3.12 in the current assumptions.

6.3.6 Strong Perturbations

Consider now the case of

$$\varepsilon \in [h^\delta, 1] \tag{6.3.84}$$

with arbitrarily small exponent $\delta > 0$. For a sake of simplicity we assume that $T_0 = 1$; it will not enter into our final results anyway.

We assume that A_0 and B are scalar operators. The problem here is that our construction of $\bar{B}$ such that

$$e^{ih^{-1}(A_0+\varepsilon B)} \equiv e^{ih^{-1}\varepsilon \bar{B}}, \qquad [A_0, \bar{B}] \equiv 0$$

leads to these equalities modulo $O(\varepsilon^K)$ with arbitrarily large K; however in view of (6.3.84) this is not negligible. Thus arguments of the current section fail. Instead we apply results of Section 4.5 and here (6.3.84) is our ally rather than foe. Still we can assume without any loss of the generality that above relations are *almost fulfilled for* b *in its classical variant*[18)], namely

$$\exp(\nabla^{\#}(a+\varepsilon b)) \equiv \exp(\varepsilon \nabla^{\#} b), \qquad \{a, b\} \equiv 0 \qquad \mathsf{mod}\ O(\varepsilon^{K+1}) \tag{6.3.85}$$

with large $K = K(I, d)$ where I is defined below. Here the first identity obviously follows from the second one and from $\exp(\nabla^{\#} a) = I$.

Therefore we can follow classical dynamics until $T \asymp \varepsilon^{-1}$. Indeed,

$$\exp(t\nabla^{\#}(a+\varepsilon b)) \equiv \exp(t''\nabla^{\#} b)\cdot \exp(t', \nabla^{\#}(a+\varepsilon b)) \qquad \text{with}\ \ t' = t-n,\ t'' = \varepsilon n,\ |n-t| \le c. \tag{6.3.86}$$

Now let us consider $\mathsf{dist}\big(z, \exp(t\nabla^{\#}(a+\varepsilon b))z\big)$. First of all, one can see easily that

[18)] I.e. for Hamiltonian fields.

(6.3.87) If $\epsilon_1 \le |t| \le T = \epsilon_0\varepsilon^{-1}$ and $\rho := |\nabla_{\Sigma} b(z)| \ge C_0\varepsilon$ with small enough constants ϵ_0 and C_0^{-1} then

$$\operatorname{dist}\bigl(z, \exp(t\nabla^{\#}(a+\varepsilon b))z\bigr) \ge \epsilon_2\varepsilon\rho.$$

We recall that locally $a = \xi_1$ and then $b \equiv b(x', \xi) \mod O(\varepsilon^K)$; then we consider derivatives of b with respect to (x', ξ').

Then due to results of Section 4.5 we arrive to the following

Proposition 6.3.20. *(i) Contribution of the zone* $\{|\nabla_{\Sigma} b| \ge C_0\varepsilon\}$ *to* $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ *does not exceed* $C\varepsilon h^{1-d}\vartheta(\varepsilon h/L)$*; in particular, its contribution to* R^{W} *does not exceed* $C\varepsilon h^{1-d}$*.*

(ii) Contribution of the zone $\{|\nabla_{\Sigma} b| \le C_0\varepsilon\}$ *to* $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ *does not exceed*

$$C\varepsilon h^{1-d}\vartheta\bigl(\frac{h}{L}\bigr)\mu\bigl(\{|\nabla_{\Sigma} b| \le C_0\varepsilon\}\bigr); \tag{6.3.88}$$

in particular, its contribution to R^{W} *does not exceed* $C\varepsilon h^{1-d}\mu\bigl(\{|\nabla_{\Sigma} b| \le C_0\varepsilon\}\bigr)$*.*

(iii) In particular, under condition $(6.3.43)_1$ $\mathsf{R}^{\mathsf{W}} \le C\varepsilon h^{1-d}$*.*

Problem 6.3.21. Prove that (6.3.88) holds with $\vartheta(\varepsilon h/L)$ rather than $\vartheta(h/L)$.

Instead we consider R^{W} and weaken condition $(6.3.43)_1$.

Theorem 6.3.22. *Let* A, B *be scalar self-adjoint operators,* a *microhyperbolic and* $\exp(\nabla^{\#}) = I$*. Assume that conditions* (6.3.84) *and* (6.3.85) *are fulfilled and*

$$\sum_{\alpha:|\alpha|\le I} |\nabla_{\Sigma}^{\alpha} b| \ge \epsilon_0. \tag{6.3.89}_I$$

Then $\mathsf{R}^{\mathsf{W}} \le C\varepsilon h^{1-d}$ *provided* $\delta = \delta(I, d)$*.*

Proof. We leave to the reader a standard proof based on induction with respect to I and scaling $(x_1, x'; \xi_1, \xi') \mapsto (x_1, \rho^{-1}x'; \rho^{-1}\xi_1, \rho^{-2}\xi')$, $h \mapsto \rho^{-2}h$ with the scaling function

$$\rho_I := \Bigl(\sum_{\alpha:|\alpha|\le I-1} |\nabla_{\Sigma}^{\alpha} b|^{\frac{I}{(I-|\alpha)}}\Bigr)^{\frac{1}{I}} + \bar{\rho} \tag{6.3.90}_I$$

with $\bar{\rho} = h^{\delta'}$. □

6.3.7 Operators with Massive set of Periodic tTrajectories

Let us reproduce some results of Yu. Safarov (the monograph Yu. Safarov & D. Vassiliev [2] and series of articles) concerning the case when Hamiltonian flow is not periodic but $\mu_\tau(\Pi) > 0$ where Π is the set of periodic trajectories. Here we cannot expect any remainder estimate better than $o(h^{1-d})$. So, let A be an operator with a scalar principal symbol a microhyperbolic at energy level τ. For the simplicity of statements (but not arguments) we assume that symbols are infinitely smooth.

Let $z \in \Sigma = \Sigma_\tau$ be periodic point with the minimum period $T(z)$. Consider some surface $\Theta \ni z$, $\Sigma \supset \Theta$, transversal to the Hamiltonian flow at z, and measure μ'_τ generated by μ_τ on Θ. Consider map $\Phi : \Theta \to \Theta$, mapping point $\Theta \ni w \to \Psi_{t(w)}(w)$ where $t(w)$ is a time when Ψ_t hits Θ the next time.

Definition 6.3.23. Let locally $a = \xi_1$, $\theta = \{x_1 = 0\}$ and $x' = (x_2, \dots, x_d)$, $\xi' = (\xi_2, \dots, \xi_d)$.

Periodic point z is called *absolutely periodic* if $\nabla_{(x'',\xi'')}\big(\Phi - I\big)(x,\xi) = 0$ $\forall \alpha$ for some $t \neq 0$.

Obviously,

(6.3.91) Definition of the absolute periodicity does not depend on the choice of $\Theta \ni z$.

Let Π_T be a set of all periodic points with periods not exceeding T. Let Π^∞ be the set of all absolutely periodic points and Π^∞_T be the set of all absolutely periodic points with periods not exceeding T.

Obviously

(6.3.92) Π_T and Π^∞_T are closed sets and $\Pi = \bigcup_T \Pi_T$, $\Pi^\infty = \bigcup_T \Pi^\infty_T$;

(6.3.93) Π, Π^∞, Π_T and Π^∞_T are $\exp\big(t\nabla^\# a\big)$-invariant;

(6.3.94) If $z \in \Sigma_\tau$ but $z \notin \Pi^\infty$ then for each $T > 0$ there exists $\varepsilon > 0$ such that $\mu_\tau\big(\Pi_T \cap B(z,\varepsilon)\big) = 0$.

Also obviously we arrive to

Proposition 6.3.24. *(i) Let $z \in \Pi_T^\infty \cap \Sigma_{\bar\tau}$ with $\bar\tau = 0$ and the minimal period in z be exactly $T_0 := T_0(z) \le T$. Let $\gamma = h^\delta$ with arbitrarily small $\delta > 0$. Let us extend $t(w)$ from $\Theta \ni z$ to vicinity of z so that it remains constant along Ψ_t* [19] *Let $t^{\mathsf w}$ denote operator with t as a principal symbol, we can construct it locally so that $[A, t^{\mathsf w}] = 0$.*

Then in $B(z,\gamma)$

$$e^{ih^{-1}t^{\mathsf w}A} \equiv G + \mathcal{F}(A - \bar\tau) \tag{6.3.95}$$

with $G \in \mathbf{\Psi}_{h,\gamma,\gamma,\infty}(X, \mathbb{K})$ such that $G^*G \equiv GG^* \equiv I$ and 0-th order h-Fourier integral operator $\mathcal{F}$.

(ii) Principal symbol of G is uniquely defined at z.

(iii) In particular, if a^s is scalar then the principal symbol of G (at z) is given by (6.2.12).

Then modulo $o_T(h^{1-d})$

$$F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(Q_{1,x}u\,{}^tQ_{2y}\big) \equiv \tag{6.3.96}$$
$$(2\pi h)^{-d}\int T\hat\chi\big((\tau-\tau')Th^{-1}\big)\sum_n q_1(x,\xi)G(x,\xi)^n e^{ih^{-1}nT_0(x,\xi)\tau'}q_2(x,\xi)\,d\mu_{\tau'}$$
$$\text{as}\quad |\tau-\bar\tau| = o(1)$$

where sum is actually taken over $n : |n| \le TT_0(x,\xi)^{-1}$ and we use the same symbol G for operator and its principal symbol. Here we do not need to assume that $\bar\tau = 0$ anymore: we can get rid of this assumption in the standard way. We used here that

$$\liminf_{z'\to z} T_0(z') = T_0(z). \tag{6.3.97}$$

Further,

(6.3.98) With the same error one can replace $\mu_{\tau'}$ by μ_τ in (6.3.96).

Then obviously

[19] We cannot extend it globaly this way unless all trajectories are periodic.

(6.3.99) The absolute value of the right-hand expression of (6.3.96) does not exceed

$$\Big(C_\varepsilon + CTJ(T',\varepsilon) + CTT'^{-1} + o_{T,T',\varepsilon}(1)\Big)h^{1-d} \tag{6.3.100}$$

with

$$J(T',\varepsilon) \coloneqq \int_{\{\mathsf{dist}(\mathsf{Spec}(G(z)e^{ih^{-1}T_0(z)\tau}),1)<\varepsilon,\ T_0(z)\le T'\}} T_0^{-1}\,d\mu_\tau, \tag{6.3.101}$$

arbitrarily small $\varepsilon>0$, arbitrarily large $T'\le T$ and $o_{T,T',\varepsilon}(1)$ with respect to $h\to 0$ but not uniform with respect to T, T', ε.

Multiplying by $h^{d-1}T^{-1}$ and tending $h\to +0$ and *only then* $T\to\infty$ we get $CJ(T',\varepsilon)+CT'^{-1}$. After this tending $\varepsilon\to +0$ and *only then* $T'\to\infty$ we get $C\mu_\tau\big(\Pi^\infty\cap\Sigma_\tau\cap\{1\in\mathsf{Spec}(G(z)e^{ih^{-1}T_0(z)\tau})\}\big)$.

Applying Tauberian theorem we arrive to

$$\mathsf{R}^T_{\varphi,L;\tau} = o\big(h^{1-d}\vartheta(hL^{-1})\big) \tag{6.3.102}$$

provided

$$\mu_\tau\Big(\Pi^\infty\cap\Sigma_\tau\cap\big\{e^{-ih^{-1}T_0(z)\tau}\in\mathsf{Spec}\big(G(z)\big)\big\}\Big)=0; \tag{6.3.103}$$

Denoting by $e^{i\lambda_j(z)}$ eigenvalues of $G(z)$ one can rewrite this condition as

$$\mu_\tau\Big(\Pi^\infty\cap\Sigma_\tau\cap\big\{\tau\in -\frac{h}{T_0(z)}\lambda_j(z)+\frac{2\pi h}{T_0(z)}\mathbb{Z}\big\}\Big)=0\qquad \forall j. \tag{6.3.104}$$

In the condition (6.3.104) choice of τ is important. In the Tauberian expression we need to take $T\to\infty$ slowly.

Theorem 6.3.25. *Let $A\in\boldsymbol{\Psi}_h$ be a self-adjoint operator with a scalar principal symbol a microhyperbolic at energy level τ. Let condition* (6.3.104) *be fulfilled with $G(z)$ introduced on $\Pi^\infty\cap\Sigma_\tau$ by Proposition 6.3.24. Let φ satisfy* (4.2.73)–(4.2.75).

Then

$$\mathsf{N}_{\varphi,L}(\tau) = \mathsf{N}^{\mathsf{W}}_{\varphi,L}(\tau) + \mathsf{N}_{\mathsf{corr},\varphi,L} + o\big(h^{1-d}\vartheta(hL^{-1})\big) \tag{6.3.105}$$

with

$$\mathsf{N}_{\mathsf{corr}} \coloneqq (2\pi)^{-d}h^{1-d}\int_{\Pi^\infty\cap\Sigma_\tau} q_1^0\,T_0^{-1}\Upsilon_1\big(T_0h^{-1}(a-hb)\big)q_2^0\,d\mu_\tau \tag{6.3.106}$$

$b\coloneqq -iT_0^{-1}\log G$ *and* $\Upsilon_1(t)=\Upsilon(t)-t+\frac12$, Υ *defined by* (6.2.69).

In particular as conditions are fulfilled on both levels τ_1 and τ_2 we recover asymptotics of $\mathsf{N}(\tau_1,\tau_2)$ with an error estimate $o(h^{1-d})$.

Let us recall that here T_0 depends on the point of Π^∞.

6.3.8 Examples

Laplacian

As the first example let us consider Laplace-Beltrami operators on the manifolds with all closed geodesics. One can find the theory of such manifolds in A. Besse [1]. Instead of Hamiltonian flow one can consider geodesic flow on $\mathbb{S}^*X$ and there could be subperiods. Let us recall that for spectral asymptotics of such operators one should multiply it by h^{-2} with $h := \lambda^{-\frac{1}{2}}$ and consider energy level 1.

Then the general theory claims that $\mathsf{N} = \mathsf{N}^{\mathsf{W}} + O(\lambda^{\frac{1}{2}(d-1)})$ with $\mathsf{N}^{\mathsf{W}} = \kappa_0 \lambda^{\frac{1}{2}d}$. Now with the generic lower order terms $\varepsilon = h$ and therefore correction is of the type $\lambda^{\frac{1}{2}(d-1)}\mathcal{Q}(\lambda^{\frac{1}{2}})$ with bounded but oscillating function $\mathcal{Q}$. Later we consider even the case when such manifolds have isolated singularities (see Example 11.3.28).

Symbol b is defined on $\mathbb{S}^*X/\sim$ where "$\sim$" means equivalence along geodesic flow.

In particular,

(6.3.107) (see Appendix 6.A.3) As $X = \mathbb{S}^d$ eigenvalues of Laplacian are

$$\lambda_n = n\big(n+d-1\big) = \big(n+\frac{1}{2}(d-1)\big)^2 - \frac{1}{4}(d-1)^2 \tag{6.3.108}$$

of multiplicity

$$N_n = \frac{(n+d-2)!(2n+d-1)}{(d-1)!n!}, \qquad n = 0,1,... \tag{6.3.109}$$

General perturbations of Laplacian are of the form $A'(x,D)$ where A' is a first order operator and then $\varepsilon = h$. In this case the width of the spectral cluster is generically $\asymp \lambda\varepsilon \asymp \lambda^{\frac{1}{2}}$ while the distance between eigenvalues is $\asymp \lambda h \asymp \lambda^{\frac{1}{2}}$ (actually $\lambda_n - \lambda_{n-1} = 2n + \frac{1}{2}(d-3)$); so spectral gaps could disappear.

There is an exceptional case when the principal symbol of A' is odd: $A'(x,\xi) = -A'(-x,-\xi)$. Then the the principal symbol of b which is an average of a' along Hamiltonian trajectories is identically 0. Really these trajectories are circles and $\exp(\frac{1}{2}\pi\nabla^{\#}a) = -I$ so antipodal points contribute

equally. Therefore in this case we can take $\varepsilon = h^2 = \lambda^{-\frac{1}{2}}$. In this case the width of the eigenvalue cluster is generically $\asymp \lambda\varepsilon \asymp 1$.

More generally, if perturbation is an operator of order k, $k \le 1$ then generically $\varepsilon = h^{2-k} \asymp \lambda^{\frac{k}{2}-1}$ and the width of the spectral cluster is generically $\asymp \lambda\varepsilon \asymp \lambda^{\frac{k}{2}}$. However for odd perturbations $\varepsilon = h^{2-2k} \asymp \lambda^{-k}$.

The most interesting example in this case is "Laplacian plus potential" with $k = 0$.

Harmonic Oscillator

Consider harmonic oscillator $\Delta + |x|^2$ on $\mathbb{R}^d$.

(6.3.110) Eigenvalues of harmonic oscillator $\Delta + |x|^2$ on $\mathbb{R}^d$

$$\lambda_n = 2n + d \tag{6.3.111}$$

of multiplicity

$$N_n = \frac{(n+d-1)!}{(d-1)!n!}, \qquad n = 0, 1, ... \tag{6.3.112}$$

which follows from the similar fact as $d = 1$.

Dividing by λ and rescaling $x \mapsto x\lambda^{-1}$ we get into framework of our theory with $h = \lambda^{-1}$; the domain is basically $X = \{|x| \le 2\}$ since $\{|x| > 1\}$ is classically forbidden. So standard theory yields $\mathsf{N} = \mathsf{N}^{\mathsf{W}} + O(\lambda^{d-1})$ with $\mathsf{N}^{\mathsf{W}} = \kappa_0\lambda^d$. This is completely consistent with the theory of global operators (see Subsubsection *1.1.4.4 Global Operators*) in which harmonic oscillator has degree 1 while operators x_j and D_j have degree $\frac{1}{2}$.

Note that x-projections of Hamiltonian trajectories are ellipses with center at the origin. Let us perturb such operator by a weak constant magnetic field:

$$A = \sum_k \big(D_k - \mu F_k(x)\big)^2, \qquad F_k = \sum_j f_{kj} x_j D_k \tag{6.3.113}$$

with $\mu \ll 1$. Then

$$b(x,\xi) = -\frac{2}{\pi}\mu \int_0^\pi \sum_{j,k} f_{kj} x_j \xi_k \, dt = -\frac{1}{\pi}\mu \int_\ell \sum_{j,k} f_{kj} x_j dx_k = \\ -\frac{1}{\pi}\mu \int_{\mathcal{D}(\ell)} \sum_{j,k} f_{kj} dx_j \wedge dx_k \tag{6.3.114}$$

where $\mathcal{D}(\ell)$ is a planar elliptical domain "inside" ellipse ℓ.

Thus $\varepsilon = \mu$ and as $\mu\lambda \le \epsilon_0$ spectral gaps separate clusters.

Problem 6.3.26. It should be easy to prove that b has only non-degenerate critical points on $\Sigma/\sim$ where $\Sigma = \{|\xi|^2 + |x|^2 = 1\} = \mathbb{S}^{2d-1}$ and "$\sim$" means equivalence along Hamiltonian flow.

Remark 6.3.27. A related, but a special and separate example is a Schrödinger operator on $\mathbb{R}^2$ with a constant magnetic and 0 electric field (see Volumes III and IV).

Coulomb Potential

Consider Schrödinger operator with Coulomb potential $\Delta - |x|^{-1}$ on $\mathbb{R}^d$. Surely it is singular in origin; so we consider more formal theory. The justification will be given much later in Sections 11.2, 11.3 and 11.4.

(6.3.115) (see Appendix 6.A.3) Eigenvalues of such operator

$$-\lambda_n = -(2n + d - 1)^{-2} \tag{6.3.116}$$

of multiplicity

$$\nu_n = \sum_{0\le m\le n} \frac{(m + d - 3)!(2m + d - 2)}{(d - 2)!m!}, \qquad n = 0, 1, \dots \tag{6.3.117}$$

Dividing by λ and rescaling $x \mapsto x\lambda$ we get into framework of our theory with $h = \lambda^{\frac12}$; the domain is basically $X = \{|x| \le 2\}$ since $\{|x| > 1\}$ is classically forbidden. However part with $|x| \le \epsilon$ would be a problem.

So the standard theory yields $\mathsf{N} = \mathsf{N}^{\mathsf{W}} + O(\lambda^{-\frac{d-1}{2}})$ with $\mathsf{N}^{\mathsf{W}} = \kappa_0\lambda^{-\frac{d}{2}}$.

Note that x-projections of Hamiltonian trajectories are Kepler ellipses with focus at the origin. Let us perturb such operator by a weak constant magnetic field:

$$A = \sum_k \big(D_k - \mu F_k(x)\big)^2 - |x|^{-1}, \qquad F_k = \sum_j f_{kj}x_jD_k \tag{6.3.118}$$

with $\mu \ll \lambda^{\frac32}$. Then (6.3.114) holds.

Thus $\varepsilon = \mu\lambda^{-\frac32}$ and as $\mu\lambda \le \epsilon_0\lambda^2$ spectral gaps may be separating clusters.

Problem 6.3.28. Prove that b has only non-degenerate critical points on $\Sigma/\sim$ where $\Sigma = \{|\xi|^2 - |x|^{-1} = -1\}$ and "$\sim$" means equivalence along Hamiltonian flow.

6.4 Asymptotics for Dirac Energy

6.4.1 Introduction

In *Part XI Application to Multiparticle Quantum Theory* devoted to the *sharp asymptotics of the ground state energy of heavy atoms and molecules* it was needed to calculate*Dirac correction term*[20)] which in that approximation was equal to

$$\mathsf{I} := \iint |x-y|^{-1} \cdot |e(x,y,\tau)|^2 \, dxdy \tag{6.4.1}$$

where $e(x,y,\tau)$ is the Schwartz kernel of the spectral projector $E(\tau)$ of the (magnetic) Schrödinger operator

$$A = \frac{1}{2}\Big(\sum_{j,k} P_j g^{jk}(x) P_k - V\Big), \qquad P_j = hD_j - \mu V_j \tag{6.4.2}$$

$\tau \approx 0$ and $h \to +0$ (while either $\mu \to +\infty$ or remains constant). Actually the corresponding parts of Chapters 25–28 was originally more complicated but it was reduced to the problem above.

Then $\mathsf{I} \asymp h^{-d-1}$ (where $d = 3$ in the above papers) and it is needed to prove that $\mathsf{I} = \mathsf{I}^{\mathsf{W}} + O(h^{-d-1+\delta})$ with I^{W} defined by the same formula but with $e(x,y,\tau)$ replaced by

$$\mathsf{N}^{\mathsf{W}}_y(x,y,\tau) := (2\pi h)^{-d} \int_{g(y,\xi)\le V(y)+2\tau} e^{ih^{-1}\langle x-y,\xi\rangle} \, d\xi \tag{6.4.3}$$

and with a small exponent $\delta > 0$; for Magnetic Schrödinger it was needed to prove as binding parameter $\mu \le h^{-\delta}$ only. Expression (6.4.3) is a *Weyl expression* for $e(x,y,\tau)$ for operator with coefficients frozen at point y.

[20)] Representing Coulomb interaction of electrons with themselves which should not to be counted in the energy calculation and should be subtracted from the Thomas-Fermi expression.

However we believe that the asymptotics of expression (6.4.1) or more general ones are interesting by themselves and that there are sharp asymptotics. Still our attempts to derive it were not very successful. Let us bring some degree of the order to this matter.

Let us consider a matrix h-differential operator $A(x, hD)$ and find asymptotics of

$$\mathsf{I} := \iint \omega(x,y) e(x,y,\tau)\psi_2(x) e(y,x,\tau)\psi_1(y)\,dx\,dy \tag{6.4.4}$$

with a matrix-valued function $\omega(x,y)$ such that

(6.4.5) $\omega(x,y) := \Omega(x,y;x-y)$ where function Ω is smooth in $B(0,1)\times B(0,1)\times B(\mathbb{R}^d\setminus 0)$ and positively homogeneous of degree $-\kappa$ ($0<\kappa<d$) with respect to its third argument[21)]

and with smooth cut-off functions ψ_1, ψ_2.

The main part of asymptotics should have a magnitude of $h^{-d-\kappa}$ and our goal is to get a remainder estimate $O(h^{1-d-\kappa})$.

One can also consider a more general expression

$$\begin{aligned}\mathsf{I}_m := \iint \omega(x^1,\dots,x^m)\times \\ e(x^1,x^2,\tau)\psi_2(x^1)e(x^2,x^3,\tau)\cdots e(x^m,x^1,\tau)\psi_{m+1}(x^0)\,dx^1\cdots dx^m\end{aligned} \tag{6.4.6}$$

with $x^{m+1}=x^1$, $\psi_{m+1}:=\psi_1$ etc and

(6.4.7) $\omega(x^1,\dots,x^m) := \Omega(x^1,\dots,x^m;\{x^j-x^{j+1}\}_{1\le j\le m})$ where function Ω is smooth in $B(0,1)^m\times B(\mathbb{R}^d\setminus 0)^m$ and homogeneous of degree $-(m-1)\kappa$ with respect to $\{x^j-x^k\}_{1\le j<k\le m}$. Moreover,

$$|D_z^\beta D_x^\alpha \Omega| \le C_{\beta,\alpha}|z^1|^{-\kappa-|\beta^1|}\cdots|z^m|^{-\kappa-|\beta^m|} \qquad \text{as} \quad \sum_k |z^k|^2=1, \sum_k z^k=0$$

where $\boldsymbol{x}=(x^1,\dots,x^m)$, $\boldsymbol{z}=(z^1,\dots,z^m)$, etc.

[21)] In other words it is Michlin-Calderon-Zygmund kernel.

However we are able to implement in this case only some of our arguments.

The main part of asymptotics should have a magnitude of $h^{-d-(m-1)\kappa}$ (see Theorem 6.4.7) and we would like to get a remainder estimate $O(h^{1-d-(m-1)\kappa})$.

We are leaving for Chapter 16 book the similar but much more delicate and difficult analysis for a 2- and 3-dimensional Magnetic Schrödinger operator(6.4.2) with the trajectories having many loops.

Remark 6.4.1. (i) To avoid the necessity to cut-off with respect to hD one needs to assume that its symbol satisfies

$$\|a(x,\xi)^{-1}\| \le C|\xi|^{-m} \qquad \text{as } |\xi| \ge C_0 \tag{6.4.8}$$

as $a \in \mathbf{\Psi}^m_h$ (one can weaken this condition but we leave it to the reader).

(ii) One needs to assume that a is semibounded from below which under assumption (6.4.8) is equivalent to

$$\langle a(x,\xi)v, v\rangle \ge c^{-1}\|v\|^2 \qquad \text{as } |\xi| \ge C_0; \tag{6.4.9}$$

otherwise instead of $E(\tau)$ one should consider $E(\tau_1,\tau_2) \coloneqq E(\tau_2) - E(\tau_1)$; we leave it to the reader as well.

This section consist of four more subsections: in Subsection 6.4.2 we derive asymptotics with the sharp remainder estimate but with the implicit Tauberian approximation for $e(x,y,0)$. In Subsections 6.4.4 and 6.4.3 we replace it by expression (6.4.3) without deteriorating remainder estimate for scalar operators and for certain matrix operators and with some not sharp remainder estimates for other matrix operators. Finally, in Subsection 6.4.5 we apply a rescaling technique to the Schrödinger operator.

Let us mention that for larger κ we need less restrictive conditions to operator.

6.4.2 Estimates

Special Case

Let us assume first that $\omega = 1$ but relax conditions to $\psi_1,\dots,\psi_m$, assuming only that $\psi_1,\dots,\psi_m \in \mathscr{L}^\infty$. This is definitely not the case we are interested in but one needs to make few clarifications first. Then

$$\mathsf{I}_m \coloneqq \Gamma\big(E(\tau)\psi_2 E(\tau)\psi_3 E(\tau)\psi_4 \cdots \psi_m E(\tau)\psi_{m+1}\big) \tag{6.4.10}$$

containing m factors $E(\tau)$.

Under condition (6.4.9) we know (see f.e. Proposition 4.2.1) that if $\mathscr{L}^\infty$ norms and the diameters of supports ψ, ψ_1 are bounded, then

$$\|\psi E(\tau)\psi_1\|_1 \le Ch^{-d} \qquad \text{as } |\tau| \le c \tag{6.4.11}$$

where $\|.\|_\infty$ and $\|.\|_1$ denote operator and trace norms respectively. Then since an operator norm of $E(\tau)$ does not exceed 1 we conclude that $|\mathsf{I}_m| \le Ch^{-d}$. Therefore

(6.4.12) If $\psi_j \in \mathscr{L}^\infty$ and I_m is given by (6.4.10) then $|\mathsf{I}_m| \le Ch^{-d}$.

Further, let us assume that

(6.4.13) $a(x,\xi)$ is microhyperbolic on energy level 0.

Then as (6.4.13) is fulfilled on supports of ψ, ψ_1 it is known (see Section 4.2) that

$$\|\psi\big(E(\tau)-E(\lambda)\big)\psi_1\| \le C(|\tau-\lambda|+hT^{-1})h^{-d} \qquad \text{as } |\tau|\le\epsilon_1,\ |\lambda|\le c. \tag{6.4.14}$$

Here and for a while $T \asymp 1$ but we want to keep a track of it.

Since this property holds under wider assumptions than microhyperbolicity, we will assume so far only that (6.4.14) holds. On the other hand, if we want to be able to take $T \ll 1$ microhyperbolicity is not enough; in this case we assume that

(6.4.15) $a(x,\xi)$ is ξ-microhyperbolic on energy level 0.

Anyway, under condition (6.4.14)

$$|\Gamma\Big(\big(E(\tau)-E(\lambda)\big)\psi_2E(\tau_2)\psi_3E(\tau_3)\psi_4\cdots\psi_mE(\tau_m)\psi_{m+1}\Big)| \tag{6.4.16}$$

also does not exceed the right hand expression of (6.4.14) as $|\tau| \le \epsilon_1$ and therefore due to the standard Tauberian arguments (second part, see again Section 4.2) the following inequality holds:

$$|\Gamma\Big(\Big(E(0)-h^{-1}\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\big(\bar\chi_T(t)U(t)\big)\,d\tau\Big)\times \psi_2E(\tau_2)\psi_3E(\tau_3)\psi_4\cdots\psi_mE(\tau_m)\psi_{m+1}\Big)| \le CT^{-1}h^{1-d} \tag{6.4.17}$$

where we use our standard notations $\bar{\chi}$ and χ in the future and $\bar{\chi}_T(t) = \bar{\chi}(t/T)$ and as usual Γ is the "scalar trace" of the operator, and does not include taking matrix trace tr.

Here and below $U(t) = e^{ih^{-1}tA}$ is the propagator of A and $u(x,y,t)$ is its Schwartz kernel.

So with $O(T^{-1}h^{1-d})$ error we can replace one copy of $E(0)$ in I_m by its standard implicit Tauberian approximation

$$h^{-1}\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_T(t)U(t)\bigr)\,d\tau \tag{6.4.18}$$

and in by the virtue of the same arguments we can do it with another copy of $E(0)$. Therefore

Proposition 6.4.2. *Under conditions* (6.4.14) *with an error* $O(T^{-1}h^{1-d})$ I_m *is equal to*

(6.4.19)
$$h^{-m}\Gamma\int_{\boldsymbol{\tau}\in\mathbb{R}^{-,m}} F_{\boldsymbol{t}\to h^{-1}\boldsymbol{\tau}}\Bigl(\bar{\chi}_T(t_1)U(t_1)\psi_2\bar{\chi}_T(t_2)U(t_2)\psi_3\cdots\psi_m U(t_m)\psi_{m+1})\Bigr)\,d\boldsymbol{\tau}$$

with $\boldsymbol{t} = (t_1,\dots,t_m)$, $\boldsymbol{\tau} = (\tau_1,\dots,\tau_m)$.

Note that here one can take any $T\in[h^{1-\delta},c]$ (but then an error depends on T). Further, note that as $\mathsf{dist}(\mathsf{supp}\,\psi_j,\mathsf{supp}\,\psi_{j+1})\ge(c_0+\epsilon)T$ where c_0 here and below is the upper bound of the propagation speed on energy level 0 and $x^{m+1}:=x^1$, expression (6.4.19) as $m=2$ or the similar expression as $m\ge 3$ become negligible and we arrive to

Corollary 6.4.3. *If in framework of Proposition 6.4.2*

$$\mathsf{dist}(\mathsf{supp}(\psi_j),\mathsf{supp}(\psi_{j+1}))\ge(c_0+\epsilon)T$$

for some $j=1,\dots,m$ *then* $|\mathsf{I}_m|$ *does not exceed* $CT^{-1}h^{1-d}$.

Smooth Case

The next step is to assume that ω is a general smooth function rather than the product as before. Without any loss of the generality one can assume

that ω is also compactly supported (since ψ, ψ_1 are). Then from

$$\omega(x^1,\dots,x^m) = \int \omega(y^1,\dots,y^m)\cdot \delta(y^1-x^1)\cdots\delta(y^m-x^m)\,dy = \int \omega'(y^1,\dots,y^m)\cdot \theta(y^1-x^1)\cdots\theta(y^m-x^m)\,dy^1\cdots dy^m \tag{6.4.20}$$

one arrives to

$$\mathsf{I}_m = \int \omega'(y^1,\dots,y^m)\cdot J_m(y^1,\dots,y^m)\,dy^1\cdots dy^m \tag{6.4.21}$$

with $J_m(y^1,\dots,y^m)$ defined by (6.4.6) with $\omega = 1$ and $\psi_j(x)$ redefined as $\psi_j(x)\theta(y^j - x)$ where

$$\omega'(y^1,\dots,y^m) = (-1)^{md} \prod_{1\le j\le m}\prod_{1\le k\le d} \partial_{y_k^j}\omega(y^1,\dots,y^m)$$

and here and below $\theta(x) = \theta(x_1)\cdots\theta(x_d)$. Then we immediately arrive to

Proposition 6.4.4. *Let ω and $\psi_1,\dots,\psi_m$ be smooth functions and let condition* (6.4.9) *be fulfilled. Then $|\mathsf{I}_m| \le Ch^{-d}$.*

Problem 6.4.5. As $m = 2$ and $\omega, \psi_1, \psi_2 \in \mathscr{L}^\infty$ $|\mathsf{I}_2| \le Ch^{-d}$ obviously (it follows from the estimate $\|\psi E\psi\|_2 \le Ch^{-d/2}$ where $\|.\|_2$ is the Hilbert-Schmidt norm). Is it possible prove the similar result for $m \ge 3$?

Proposition 6.4.6. *Let ω and $\psi_1,\dots,\psi_m$ be smooth functions and let conditions* (6.4.9) *and* (6.4.14) *be fulfilled. Then*

(i) With an error $O(T^{-1}h^{1-d})$ I_m is equal to

$$\mathsf{I}_m^{\mathsf{T}} = h^{-m}\int\int_{\tau\in\mathbb{R}^{-,m}} \omega(x^1,\dots,x^m)\times F_{t\to h^{-1}\tau}\Big(\bar\chi_T(t_1)u(x^1,x^2,t_1)\psi_2(x^2)\bar\chi_T(t_2)u(x^2,x^3,t_2)\psi_3(x^3)\cdots \psi_m(x^m)u(x^m,x^{m+1},t_m)\psi_{m+1}(x^{m+1})\Big)\,d\tau\,dx^1\cdots dx^m \tag{6.4.22}$$

with $x^{m+1} := x^1$.

(ii) Further, if $\operatorname{dist}(\operatorname{supp}(\psi_j),\operatorname{supp}(\psi_{j+1})) \ge (c_0+\epsilon)T$ for some $j = 1,\dots,m$ then $|\mathsf{I}_m|$ does not exceed $CT^{-1}h^{1-d}$ where so far $T \asymp 1$.

Proof. Proof follows immediately from Proposition 6.4.2 and representation (6.4.20)–(6.4.21). □

Singular homogeneous case

Theorem 6.4.7. *Let conditions* (6.4.9) *and* (6.4.7) *be fulfilled.*
Then $|\mathsf{I}_m| \le Ch^{-d-(m-1)\kappa}$.

Proof. Let us replace $\Omega(x,z)$ by $\Omega(x,z)\beta(z^1\gamma_1^{-1})\cdots\beta(z^m\gamma_m^{-1})$ where $\gamma_j \ge h$ and $\beta, \bar\beta$ are functions (on $\mathbb{R}^d$) similar to $\chi, \bar\chi$ respectively i.e. $\beta, \bar\beta \in \mathscr{C}_0^\infty(B(0,1))$ and $\beta = 0$, $\bar\beta = 1$ in $B(0,\frac12)$.

Then similarly to the analysis of the smooth case one can estimate the contribution of such partition element to I_m by

$$Ch^{-d}\bigl(\gamma_1\cdots\gamma_m\bigr)^{-1}(\gamma_1+\cdots+\gamma_m)^{1-\kappa}; \tag{6.4.23}$$

then summation with respect to all such elements with $\gamma_j \ge \bar\gamma = h$ results in the value of this expression as $\gamma_j = \bar\gamma$ which is exactly $Ch^{-d-(m-1)\kappa}$.

However one needs to consider the other partition elements when some (or all) of $\beta(z^j\gamma_j^{-1})$ are replaced by $\bar\beta(z^j\bar\gamma^{-1})$. So we get "sandwiches" consisting of the factors

$$e(x^k, x^{k+1}, \tau)\beta(z^{k+1}\gamma_{k+1}^{-1})\cdots e(x^{j-1}, x^j, \tau)\beta(z^j\gamma_j^{-1})e(x^j, x^{j+1}, \tau)$$

with $j \ge k$ and in between them factors $\bar\beta(z^k\bar\gamma^{-1})$.

Let J be the set of indices appearing in $\bar\beta(z^k\bar\gamma^{-1})$ (for a given type of a "sandwich"). One can see easily that the contribution of each "sandwich" to I_m does not exceed

$$Ch^{-dr}\prod_{j\notin J}\gamma_j^{-\kappa}\times\Bigl(\int_{\{|z|\le\bar\gamma\}}|z|^{-\kappa}\,dz\Bigr)^{r-1} \asymp Ch^{-dr}\prod_{j\notin J}\gamma_j^{-\kappa}\times\bar\gamma^{(d-\kappa)(r-1)}$$

where $r = \#J$. Then after summation with respect to $\gamma_j \ge \bar\gamma$ one gets the same expression with $\gamma_j = \bar\gamma$ i.e.

$$Ch^{-dr}\bar\gamma^{\kappa(m-r)+(d-\kappa)(r-1)} = Ch^{-dr}\bar\gamma^{-\kappa(m-1)+d(r-1)}$$

which is exactly what we want as $\bar\gamma \asymp h$. □

The following statement immediately follows from the proof:

Proposition 6.4.8. *Let conditions* (6.4.9) *and* (6.4.7) *be fulfilled. Then replacing* $\Omega(x,z)$ *by* $\Omega(x,z)\bar\beta(z^1\gamma^{-1})\cdots\bar\beta(z^m\gamma^{-1})$ *with* $\gamma \ge h$ *results in the error not exceeding*

$$Ch^{-d-(m-2)\kappa}\gamma^{-\kappa}. \tag{6.4.24}$$

Singular Homogeneous Case: Using ξ-Microhyperbolicity

Now let assume instead of condition (6.4.14) that ξ-microhyperbolicity condition (6.4.15) is fulfilled. Then we can improve estimate (6.4.24):

Proposition 6.4.9. *Let conditions* (6.4.9), (6.4.7) *and* (6.4.15) *be fulfilled. Then replacing* $\Omega(x,z)$ *by* $\Omega(x,z)\bar{\beta}(z^1\gamma^{-1})\cdots\bar{\beta}(z^m\gamma^{-1})$ *with* $\gamma\ge h$ *results in the error not exceeding*

$$Ch^{1-d-(m-2)\kappa}\gamma^{-1-\kappa}. \tag{6.4.25}$$

This is equivalent to taking $T\asymp\gamma$ *in* (6.4.18) *and plugging Schwartz kernel of it instead of* $e(x,y,0)$ *in the definition of* I_m.

Proof. Proof follows from the combined arguments of the proofs of Theorem 6.4.7 and Proposition 6.4.2; in this case one needs to consider only "sandwiches" containing at least one factor $\beta(x^j\gamma_j^{-1})$ with $\gamma_j\ge\gamma$ which accounts for an extra factor $h\gamma_j^{-1}$ and summation with respect to partition results in an extra factor $h\gamma^{-1}$. □

So one needs to study expression (6.4.22) with some $T=T^*$; let us recall that the remainder estimate contains factor T^{*-1}. One can decompose $\bar{\chi}_{T^*}(t)$ into the sum of $\bar{\chi}_{\bar{T}}(t)$ and $\chi_T(t)$ with T running between $\bar{T}$ and T^* and also one can take $\bar{T}=Ch$. Then expression (6.4.22) becomes the sum of the similar expressions with $\bar{\chi}_T(t)$ (with $T=T^*$) replaced by $\phi_{jT_j}(t)$ where <u>either</u> $\phi_j=\chi_j$ and $\bar{T}\le T_j\le T^*$ <u>or</u> $\phi_j=\bar{\chi}$ and $T_j=\bar{T}$.

In this expression as $\phi_j=\chi_j$ one can replace $\int_{-\infty}^0(\dots)\,d\tau_j$ by $(\dots)|_{\tau_j=0}$ simultaneously replacing $h^{-1}\chi_{j,T_j}(t_j)$ by $it^{-1}\chi_{j,T_j}(t)=T_j^{-1}\phi_{j,T_j}(t)$ with redefined $\phi_j(t)=it^{-1}\chi_j(t)$.

So we get a modified expression (6.4.22) with

(a) r factors $\bar{\chi}_{\bar{T}}(t_j)$ and integration over $\mathbb{R}^{-r}\ni\tau_J$, $r=\#J$ and

(b) $(m-r)$ factors $\phi_{k,T_k}(t_k)$ and with τ_k snapped to 0 (instead of integration) as $k\notin J$

(c) furthermore, factor h^{-m} is replaced by $h^{-r}\prod_{k\notin J}T_k^{-1}$.

Finally we will need

Proposition 6.4.10. *Let conditions* (6.4.9) *and* (6.4.15) *be fulfilled and let* ω *be a smooth function,*

$$\omega = O\big((|x^1 - x^2| + \cdots + |x^m - x^1|)^K\big). \tag{6.4.26}$$

Then $\mathsf{I}_m = O(h^{1-d})$ *as* $K > 1$ *and* $\mathsf{I}_m = O(h^{1-d}|\log h|)$ *as* $K = 1$.

Proof. Proof follows from the combined arguments of the proofs of Theorem 6.4.7 and Proposition 6.4.2 exactly as in the proof of Proposition 6.4.9.

Here however the main contribution (as $K \geq 1$) is delivered by zone $\{|x^1 - x^2| + \cdots + |x^m - x^1| \asymp 1\}$. □

One can consider certain generalizations but we will do them later.

6.4.3 Calculations

Now our purpose is to go from implicit Tauberian expression (6.4.22) to more explicit one.

Constant Coefficients Case

Let us first consider case $A(x,\xi) = A(\xi)$. In this case

$$e(x,y,\tau) = (2\pi h)^{-d} \int e^{ih^{-1}\langle x-y,\xi\rangle} E(\xi)\, d\xi \tag{6.4.27}$$

where $E(\xi,\tau)$ is the matrix projector corresponding to $A(\xi)$. Then

$$\mathsf{I}_m = (2\pi h)^{-dm} \int\int \omega(x^1,\dots,x^m) E(\xi^1,0)\cdots E(\xi^m,0)\times \tag{6.4.28}$$
$$e^{ih^{-1}\left(\langle x^1-x^2,\xi^1\rangle + \langle x^2-x^3,\xi^2\rangle + \cdots + \langle x^m-x^1,\xi^m\rangle\right)}\, dx^1\cdots dx^m\, d\xi^1\cdots d\xi^m.$$

(6.4.29) From now and until the end of the paper we are assuming that $m = 2$.

Without any loss of the generality one can assume that either $\omega(x,y)$ is of the form

$$\omega(x,y) = \Omega\big(\frac{1}{2}(x+y), x-y\big). \tag{6.4.30}$$

or it is of the same singular type as before but multiplied by $(x_k - y_k)$. However in the latter case (under microhyperbolicity condition) one can apply a Tauberian approximation for $e(x, y, \tau)$ equal 0 with the remainder estimate $O(h^{1-d}|x-y|^{-1})$ (in the same trace class as before) which leads to $\mathsf{I} \approx 0$ with the sought remainder estimate $O(h^{1-d-\kappa})$.

In the former case (6.4.30) we get

$$\mathsf{I} := \mathsf{I}_2 = \int \mathcal{J}(x)\, dx, \tag{6.4.31}$$

where

$$\mathcal{J}(x) = 2(2\pi h)^{-2d} \iiint \Omega(x,z) E(\xi,0) E(\eta,0) e^{ih^{-1}\langle z, \xi-\eta\rangle}\, dz d\xi d\eta = G(x) h^{-d-\kappa}, \tag{6.4.32}$$

with

$$G(x) = \iint \widehat{\Omega}(x, \xi-\eta) E(\xi,0) E(\eta,0)\, d\xi d\eta, \tag{6.4.33}$$

and

$$\widehat{\Omega}(x,\zeta) = 2(2\pi)^{-2d} \int \Omega(x,z) e^{i\langle z,\zeta\rangle}\, dz. \tag{6.4.34}$$

One always can take Ω having a compact support with respect to x (since we had originally cutoffs $\psi_1(x^1), \dots, \psi_m(x^m)$.

Remark 6.4.11. (i) One can easily generalize (6.4.31)–(6.4.34) to $m > 2$.

(ii) Integral (6.4.34) converges as $|z| \le 1$ since $\kappa < d$. On the other hand it defines a distribution with respect to ζ which is positively homogeneous of degree $\kappa - d$ and also is smooth as $\zeta \ne 0$; thus $\widehat{\Omega} \in \mathscr{L}^1_{\mathsf{loc}}$ and (6.4.33) is well-defined. However generalization to $m > 2$ is not that easy.

General ξ-Microhyperbolic Case

Note first that due to the ξ-microhyperbolicity condition (6.4.15) one should take $T \asymp \gamma$ as $m = 2$ [22]. Otherwise as $T \in [h^{1-\delta}, T^*]$, T^* is the small constant, the contribution of $[-\frac{1}{2}T, -T] \cup [T, \frac{1}{2}T]$ would be negligible.

[22] And $T_j \asymp |x^j - x^{j+1}|$ in the general case.

To calculate u let us apply the successive approximation method on the time interval $[-T, T]$ with $h^{1-\delta} \le T$. Then plugging the successive approximation into any copy on that interval we arrive to an error in u in the trace norm equal to $O\big(h^{-d}(T^2h^{-1})^n\big)$ where n is the number of the first dropped term (starting from 0). This leads to the error in I $O\big(h^{-d-\kappa}(T^2h^{-1})^n\gamma^{-\kappa}\big)$ as $T \ge \gamma$. Since under ξ-microhyperbolicity assumption (6.4.15) we need to consider only $T \asymp \gamma$, the error does not exceed

$$Ch^{-d}(T^2h^{-1})^n T^{-\kappa}. \tag{6.4.35}$$

On the other hand if we just take $u = 0$ then we get an error not exceeding

$$Ch^{1-d}T^{-1-\kappa}. \tag{6.4.36}$$

Let us minimize the sum of (6.4.35) and (6.4.36). Finding T from the equation $h^{-d}(T^2h^{-1})^n = h^{1-d}T^{-1}$ we get

$$T = h^{(n+1)/(2n+1)} \tag{6.4.37}$$

(which is greater than $h^{1-\delta}$ with $\delta > 0$) and this leads to an error not exceeding

$$Ch^{1-d-(n+1)(\kappa+1)/(2n+1)}. \tag{6.4.38}$$

Proposition 6.4.12. *Let conditions* (6.4.9), (6.4.7) *and* (6.4.15) *be fulfilled. Then*

(i) Using successive approximation as $|t| \le T$ *given by* (6.4.28) *and taking* $u = 0$ *otherwise we get* I *with an error given by* (6.4.38).

(ii) In particular, this is the sharp remainder estimate $O(h^{1-d-\kappa})$ *as*

$$\kappa \ge (n+1)/n; \tag{6.4.39}$$

in particular, as $\kappa \ge 2$ *one can skip all perturbation terms and get the same answer* (6.4.30)–(6.4.33).

On the other hand, if we cannot skip some term, then this is given by the same formulae (6.4.30)–(6.4.33) as before but with the factor $h^{-d-\kappa+s}$ instead of $h^{-d-\kappa}$ and with Ω replaced by Ω_s positively homogeneous of degree $-\kappa+s$ [23]. Then as long as $s < \kappa$ one can see that these terms are less than the remainder estimate and we arrive to

[23] Provided these formulae have sense!

Proposition 6.4.13. *Let conditions* (6.4.9), (6.4.7) *and* (6.4.15) *be fulfilled. Then*

(i) As $\kappa > 1$ *formulae* (6.4.30)–(6.4.33) *provide an answer with the remainder estimate* $O(h^{1-d-\kappa})$.

(ii) As $\kappa \le 1$ *formulae* (6.4.30)–(6.4.33) *provide an answer with the remainder estimate* $O\bigl(h^{\frac{1}{2}(1+\kappa)-d-\kappa-\delta}\bigr)$ *with arbitrarily small exponent* $\delta > 0$.

6.4.4 Scalar Case

Let us completely analyze the case of the scalar ξ-microhyperbolic operator.

Smooth case. I

Assume first that $\omega = 1$ and ψ_1, ψ_2 are smooth functions. Then one can rewrite (6.4.19) with $m = 2$

$$h^{-2}\Gamma \int_{(\tau_1,\tau_2)\in\mathbb{R}^{-,2}} F_{t_1\to h^{-1}\tau_1, t_2\to h^{-1}\tau_2}\times \Bigl(\bar{\chi}_T(t_1)\bar{\chi}_T(t_2)\psi_1 U(t_1)\psi_2 U(t_2)\Bigr)\, d\tau \tag{6.4.40}$$

with $T = T^*$ which is the largest value for which remainder estimate $O(T^{-1}h^{1-d})$ for the standard asymptotics was derived; here $T^* \asymp 1$.

Let us recall that if we replace some copies of $\bar{\chi}_T(t_k)$ by $\chi_{T_k}(t_k)$ with $Ch \le T_k \le T^*$ then one can replace also operator $h^{-1}\int_{-\infty}^0 (\dots)\, d\tau_k$ by $T^{-1}(\dots)|_{\tau_k=0}$ and χ by $it^{-1}\chi$.

If we do it with both $k = 1, 2$ then we get a term $O(h^{-d})$ (the better estimate is actually possible) and the summation with respect to all partitions with respect to T_1, T_2 results in $O(h^{-d}|\log h|^2)$ which differs from the proper estimate by $|\log h|^2$ factor.

If we replace some copies of $\bar{\chi}_T(t_k)$ by $\bar{\chi}_h(t_k)$ then we do not make a transformation with respect to these factors but we gain a factor h due to the size of the support. So after summation with respect to partition we arrive to estimate $O(h^{-d}|\log h|^{2-r})$ for I where r is the number of $\bar{\chi}_h(t_k)$ factors.

On the other hand, expression (6.4.40) is equal to

$$h^{-2}\Gamma \int_{(\tau_1,\tau_2)\in\mathbb{R}^{-,2}} F_{t_1\to h^{-1}\tau_1, t_2\to h^{-1}\tau_2}\times \Big(\bar{\chi}_T(t_1)\bar{\chi}_T(t_2)\psi_1\psi_{2,t_1}U(t_1+t_2))\Big)\, d\tau \tag{6.4.41}$$

with $\psi_t = U(t)\psi U(-t)$.

Applying our standard approach we arrive to

$$\mathsf{I}^{\mathsf{T}} \sim \sum_{n\ge 0} \varkappa_n h^{-d+n} \tag{6.4.42}$$

where $\mathsf{I}^{\mathsf{T}} = \mathsf{I}^{\mathsf{T}}_2$ is defined by (6.4.22).

Let us replace in (6.4.41) ψ_{2,t_1} by ψ_2. Plugging $t_{1,2} = \frac{1}{2}t \pm z$, $\tau_{1,2} = \tau \pm \lambda$ we arrive to

$$h^{-1}\Gamma \int_{\infty}^{0} \Big(\int_{\mathbb{R}} \rho_T(t,\tau)\psi_1\psi_2 U(t) e^{-ih^{-1}t\tau}\, dt\Big)\, d\tau \tag{6.4.43}$$

where $\rho_T(t,\tau) = \rho(tT^{-1},\tau)$, $\tau < 0$

$$\rho(t,\tau) = -\pi^{-1}h^{-1}\int_{\mathbb{R}} \bar{\chi}_T(\frac{1}{2}t+z)\bar{\chi}_T(\frac{1}{2}t-z)z^{-1}\sin(h^{-1}Tz\tau)\, dz \tag{6.4.44}$$

belongs to $\mathscr{C}_0^{\infty}([-2,2])$ and one can prove easily that

$$|\partial_t^n(\rho(t,\tau) \mp \bar{\chi}^2(\frac{1}{2}t))| \le C_{nm}(1+|\tau|\,Th^{-1})^{-m} \qquad \forall m,n\ \forall \tau \leqslant 0. \tag{6.4.45}$$

Then due to (6.4.45) only zone $\{|\tau| \le h^{1-\delta}\}$ gives a non-negligible contribution to this error and due to the microhyperbolicity condition there $|\Gamma\psi_1\psi_2 U(t)| \le Ch^{-d}(1+|t|h^{-1})^{-m}$ which together with (6.4.45) implies

(6.4.46) Under microhyperbolicity condition (6.4.13) expression (6.4.43) is equal modulo $O(h^{1-d})$ to the same expression with ρ replaced by $\bar{\chi}^2(\frac{1}{2}t)$.

On the other hand, if we replace ψ_{2,t_1} by $\psi_{2,t_1} - \psi_2 = t_1\psi'_{2,t_1}$ then we can apply the same transformation as before just getting rid of one factor h^{-1} and integration with respect to τ_1, which simply snaps to 0, resulting in the expression, similar to (6.4.43) but with $\rho\psi_2$ replaced by

$$\rho'(t,\tau,x) = (2\pi)^{-1} i \int_{\mathbb{R}} \bar{\chi}_T(z)\bar{\chi}_T(t-z)e^{ih^{-1}\tau z}\psi'_{2,z}\, dz \tag{6.4.47}$$

which satisfies inequality similar to (6.4.45)

$$|\partial_t^n \rho(t,\tau)| \le C_{nm}(1+|\tau|\,Th^{-1})^{-m} \qquad \forall m,n\ \forall \tau \lessgtr 0. \tag{6.4.48}$$

and therefore we arrive to

(6.4.49) Under microhyperbolicity condition (6.4.13) this new (6.4.43)-type expression is $O(h^{1-d})$.

So, we are left with expression (6.4.43) with $\rho(t) = \bar{\chi}^2(\frac{1}{2}t)$ but due to the standard theory we get modulo $O(h^{1-d})$ expression

$$\Gamma\psi_1\psi_2 E(0) \equiv (2\pi h)^{-d} \iint_{\{a(x,\xi)<0\}} \psi_1\psi_2\, dx\, d\xi. \tag{6.4.50}$$

So, I^{T} is given by (6.4.50) modulo $O(h^{1-d})$ and therefore

$$\varkappa_0 = (2\pi)^{-d} \int \iint_{\{a(x,\xi)<0\}} \psi_1\psi_2\, dx\, d\xi \qquad \text{in (6.4.42)}. \tag{6.4.51}$$

Smooth case. II

Then in the general smooth case we get

Proposition 6.4.14. *Let ω and $\psi_1,\dots,\psi_m$ be smooth functions and let* (6.4.9) *and microhyperbolicity condition* (6.4.13) *be fulfilled. Then with an error $O(T^{-1}h^{1-d})$ where $T \asymp 1$ here decomposition* (6.4.42) *holds with*

$$\varkappa_0 = (2\pi)^{-d} \iint_{\{a(x,\xi)<0\}} \omega(x,x)\psi_1(x)\psi_2(x)\, dx\, d\xi. \tag{6.4.52}$$

Proof. Follows from the standard decomposition (6.4.20)–(6.4.21). □

Singular Homogeneous Case

Consider now the case of singular homogeneous ω. However, let us consider first $\mathsf{I}^{\mathsf{T}}_\gamma$ defined by (6.4.22) with $\omega = 1$ and ψ_1,ψ_2 replaced by $\psi_{1,\gamma},\psi_{2,\gamma}$ which are some smooth functions scaled at some point z with the scaling parameter $\gamma \in (h^{1-\delta}, h^{\delta})$. To have microhyperbolicity condition sustain

scaling we replace it by ξ-microhyperbolicity condition (6.4.15). Then (6.4.42) implies

$$\mathsf{I}^{\mathsf{T}}_{\gamma} \sim \sum_{n,m\ge 0} \varkappa_{nm} h^{-d+n}\gamma^{m-n+d} \tag{6.4.53}$$

and obviously

$$(2\pi)^{-d}\iint_{\{a(x,\xi)<0\}} \psi_{1,\gamma}(x)\psi_{2,\gamma}(x)\,dx\,d\xi \sim \sum_{m\ge 0} \varkappa'_m \gamma^{m+d}. \tag{6.4.54}$$

One can see easily that in (6.4.53) terms with $m=0$ would be the same for operator $A^0_z = a_0(z, hD)$ where $a_0(x,\xi)$ is the principal symbol of A; this z is not necessarily the original one, but distance between them should not exceed $c\gamma$; similarly in (6.4.54) term with $m=0$ coincides with the left-hand expression with $a(x,\xi)$ replaced by $a(z,\xi)$.

What is more, under ξ-microhyperbolicity condition (6.4.15) integration with respect to x is not needed, so all these results would hold (without factor γ^d in the decomposition and estimates) without it; thus one can take $z=x$ (or y, does not matter).

Thus we arrive to

Proposition 6.4.15. *Let $\mathsf{I}^{\mathsf{T}}_{\gamma}$ be defined by* (6.4.22) *with $\omega=1$ and ψ_1,ψ_2 replaced by $\psi_{1,\gamma},\psi_{2,\gamma}$ which are the same smooth functions scaled at some point z with the parameter $\gamma\in(h^{1-\delta},h^{\delta})$.*

Further, let $\mathsf{I}^{\mathsf{T}\,0}_{\gamma}$ be defined the same way but with $U(t)$ replaced by $U^0(t) = e^{ih^{-1}tA^0}$ where $A^0 = a(z,hD)$ and later z is set to x. Then

$$\mathsf{I}^{\mathsf{T}}_{\gamma} - \mathsf{I}^{\mathsf{T}\,0}_{\gamma} = O(h^{1-d}\gamma^d).$$

Now we can calculate I^{T} in the scalar case:

Proposition 6.4.16. *In the framework of Proposition 6.4.15 as ω satisfies* (6.4.17) *and $\kappa>0$*

$$\mathsf{I}^{\mathsf{T}} - \mathsf{I}^{\mathsf{T}\,0} = O(h^{1-d-\kappa}) \tag{6.4.55}$$

where $\mathsf{I}^{\mathsf{T}\,0}$ is defined for constant-coefficient operator obtained by freezing coefficients of A at point x (or y, does not matter).

Proof. Consider three zones: $\{|x-y| \gtrsim \gamma_1\}$ with $\gamma_1 \asymp h^{\delta}$, $\{\gamma \lesssim |x-y| \lesssim \gamma_1\}$ with $\gamma_0 \asymp h^{1-\delta}$ and $\{|x-y| \lesssim \gamma\}$.

Then the contribution of the first zone to the reminder for I^{T} and $\mathsf{I}^{\mathsf{T}\,0}$ does not exceed $Ch^{1-d}\gamma_1^{-1-\kappa} = O(h^{1-d-\kappa})$ (while main parts are 0); in virtue of proposition 6.4.15 and decomposition (6.4.20)–(6.4.21) the contribution of the second zone to (6.4.55) does not exceed $O(h^{1-d}\gamma^{-\kappa}) = o(h^{1-d-\kappa})$.

In the third zone one can apply the method of successive approximations resulting in

$$\mathsf{I}^{\mathsf{T}} - \mathsf{I}^{\mathsf{T}\,0} \sim h^{-d} \sum_{m+n+k\ge 1} \varkappa''_{mnk} h^{-d+n-m+k-\kappa}\gamma^{2m-n}.$$

However since the final answer does not depend on γ only terms with $2m = n$ are posed to survive just resulting in $\bigl(\varkappa + o(1)\bigr)h^{-d+1-\kappa}$. □

Summarizing results of Subsection 6.4.2, Proposition 6.4.16 and formulae (6.4.31)–(6.4.34) we arrive to

Theorem 6.4.17. *Let A be a scalar operator satisfying conditions* (6.4.9) *and* (6.4.15). *Then*

$$\mathsf{I} = \int \mathsf{J}(x)\psi_1(x)\psi_2(x)\,dx + O(h^{1-d-\kappa}), \tag{6.4.56}$$

where

$$\begin{aligned}\mathsf{J}(x) = G(x)h^{-d-\kappa} = {}& \\ 2(2\pi h)^{-2d} \iiint E(x,\xi,0)\Omega(x,z)E(x,\eta,0)e^{ih^{-1}\langle z,\xi-\eta\rangle}\,dzd\xi d\eta = {}& \\ 2(2\pi h)^{-2d} \iiint_{\{a(x,\xi)<0,\ a(x,\eta)<0\}} \Omega(x,z)e^{ih^{-1}\langle z,\xi-\eta\rangle}\,dzd\xi d\eta & \end{aligned} \tag{6.4.57}$$

with

$$\begin{aligned} G(x) = \iint E(x,\xi,0)\widehat{\Omega}(x,\xi-\eta)E(x,\eta,0)\,d\xi & \\ \iint_{\{a(x,\xi)<0,\ a(x,\eta)<0\}} \hat{\Omega}(x,\xi-\eta)\,d\xi d\eta, & \end{aligned} \tag{6.4.58}$$

and $\hat{\Omega}$ is defined by (6.4.34).

Remark 6.4.18. (i) Alternatively one can prove this theorem using oscillatory integral representation of $u(x,y,t)$ as $|t| \le T = \epsilon$.

(ii) Alternatively one can replace one or both copies of x in $E(x,.,.)$ or in $a(x,0)$ by y.

Definition 6.4.19. We will refer to formulae (6.4.56)–(6.4.58), (6.4.34) as to *standard Weyl expression* even in the matrix case. However in this case the the last parts of (6.4.56), (6.4.57) containing $a < 0$ should be skipped.

6.4.5 Rescaling Technique

Now our goal is to weaken and eventually to get rid of (ξ-)microhyperbolicity condition for the Schrödinger operator.

Schrödinger Operator

Let us recall that for a Schrödinger operator condition of ξ-microhyperbolicity (6.4.15) means that

$$V \ge \epsilon_0. \tag{6.4.59}$$

If this condition is violated let us introduce scaling functions $\rho(x)$, $\gamma(x)$ in the usual way $\gamma = \epsilon|V|$ and $\rho = \gamma^{\frac12}$.

Then, as $\rho\gamma \ge h$, due to ξ-microhyperbolicity of the rescaled operator, the contribution of $B(\bar{x},\gamma(\bar{x})) \times B(\bar{x},\gamma(\bar{x}))$ to the remainder does not exceed

$$C\big(\frac{h}{\rho\gamma}\big)^{1-d-\kappa}\gamma^{-\kappa} \asymp Ch^{1-d-\kappa}\rho^{d-1-\kappa}\gamma^{d-1} \tag{6.4.60}$$

with $\rho = \rho(\bar{x})$ and $\gamma = \gamma(\bar{x})$. Therefore the total contribution of the zone

$$\big\{(x,y) : |x-y| \le \epsilon\gamma(x)\big\} \tag{6.4.61}$$

(where automatically $\gamma(x) \asymp \gamma(y)$) to the remainder does not exceed

$$Ch^{1-d-\kappa}\int \rho^{d-1+\kappa}\gamma^{-1}\,dx \tag{6.4.62}$$

and with $\rho = \gamma^{\frac12}$ here it becomes $Ch^{1-d-\kappa}M$ with

$$M := \int \gamma^{\frac12(d-3+\kappa)}\,dx + 1; \tag{6.4.63}$$

obviously, $M = O(1)$ provided *either* $d + \kappa \ge 3$ *or*

$$|V| + |\nabla V| \ge \epsilon_0. \tag{6.4.64}$$

and $d + \kappa > 1$ (which is surely the case).

Remark 6.4.20. (i) Note that (6.4.64) is microhyperbolicity condition (6.4.13).

(ii) As usual, one should take $\rho\gamma \ge Ch$ and thus to add $Ch^{\frac{1}{3}}$ and $Ch^{\frac{2}{3}}$ to ρ, γ respectively. However it does not affect our conclusion due to the standard fact that if $\rho\gamma \asymp h$ then $h_{\mathsf{eff}} \asymp 1$ and condition (6.4.64) is not needed.

Consider now the complement of the zone (6.4.61). Let us consider γ-admissible partitions $\phi_\alpha(x)$ and $\phi_\beta(y)$. We say that elements are adjacent $\alpha \sim \beta$ if $|x-y| \le \max(\gamma(x), \gamma(y))$ as $x \in \operatorname{supp}\phi_\alpha$, $y \in \operatorname{supp}\phi_\beta$; then $\gamma(x) \asymp \gamma(y)$ and we already calculated the contribution of all pairs of adjacent elements. Now we need to consider contribution of all pairs of not adjacent elements with $|x-y| \asymp \nu$.

Due to our previous analysis the contribution of such group does not exceed

$$C\nu^{-\kappa} \| \sum_{\alpha \not\sim \beta} \phi_\alpha E(0) \phi_\beta \|_1 \tag{6.4.65}$$

where summation is taken over elements belonging to the given group.

Due to the standard theory of Subsubsection *5.3.1.3 Asymptotics without Spatial Mollification* for such elements $e^{\mathsf{W}}(x,y,0) = 0$ and therefore

$$|e(x,y,0)| \le R_x^{\frac{1}{2}} R_y^{\frac{1}{2}} \le Ch^{1-d} \big(\rho(x)^{d-1}\gamma(x)^{-1}\big)^{\frac{1}{2}} \big(\rho(y)^{d-1}\gamma(y)^{-1}\big)^{\frac{1}{2}}. \tag{6.4.66}$$

There are two cases: $d \ge 3$ and $d = 1, 2$. In the former case we do not need ξ-microhyperbolicity condition at all, so we can increase γ, ρ to $\nu^{\frac{1}{2}}$, ν respectively. Then the norm in (6.4.66) does not exceed $Ch^{1-d}\nu^{\frac{1}{2}(d-3)} \times \nu^d$; the contribution of each ν-group does not exceed $Ch^{1-d}\nu^{\frac{1}{2}(3d-3)-\kappa}$ and contribution of all ν-groups does not exceed $Ch^{1-d}\nu^{\frac{1}{2}(d-3)-\kappa}$.

Finally, summation with respect to ν results in Ch^{1-d} as $d-3 > 2\kappa$, $Ch^{1-d}|\log h|$ as $d-3 = 2\kappa$ and $Ch^{1-d} \times h^{\frac{2}{3}(\frac{1}{2}(d-3)-\kappa)}$ as $d-3 < 2\kappa$ (since the least value of ν is $h^{\frac{2}{3}}$; each of these expressions does not exceed $Ch^{1-d-\kappa}$).

Consider now case $d = 1, 2, 3$ (so $d = 3$ fits both analysis). Observe that

$$\sup \big(\rho(x)^{d-1}\gamma(x)^{-1}\big)^{\frac{1}{2}} \le Ch^{\frac{1}{3}(d-3)}$$

and therefore

$$\|\sum_{\alpha\gamma\beta}\phi_\alpha E(0)\phi_\beta\|_1 \le Ch^{-\frac{2}{3}d}\int \bigl(\rho(x)^{d-1}\gamma(x)^{-1}\bigr)^{\frac{1}{2}}\,dx$$

and then contribution of each ν-group does not exceed

$$Ch^{-\frac{2}{3}d}\nu^{-\kappa}\int \bigl(\rho(x)^{d-1}\gamma(x)^{-1}\bigr)^{\frac{1}{2}}\,dx$$

with integral over $B(z,\nu)$. Then the total contribution of all ν-groups does not exceed the same expression with integral taken over $\{\gamma(x)\le\nu\}$. Finally summation with respect ν results in

$$Ch^{-\frac{2}{3}d}\int \gamma(x)^{\frac{1}{4}(d-3)-4\kappa}\,dx$$

which is less than $Ch^{1-d-\kappa}M$ because $\gamma\ge h^{\frac{2}{3}}$.

So, we arrive to

Proposition 6.4.21. *Consider Schrödinger operator. Then the the standard Weyl asymptotics* (6.4.56)–(6.4.58), (6.4.34) *holds with the remainder estimate* $Ch^{1-d-\kappa}$ *provided* <u>*either*</u> $d+\kappa>3$ <u>*or*</u> *condition* (6.4.64) *is fulfilled.*

This completely covers the case $d\ge 3$. Furthermore, after Proposition 6.4.21 is proven, we can introduce scaling functions

$$\gamma=\rho=\epsilon\bigl(|V|+|\nabla V|^2\bigr)^{\frac{1}{2}}+Ch^{\frac{1}{2}} \tag{6.4.67}$$

and then applying the same arguments we arrive to

Proposition 6.4.22. *Consider Schrödinger operator. Then the the standard Weyl asymptotics* (6.4.56)–(6.4.58), (6.4.34) *holds with the remainder estimate* $Ch^{1-d-\kappa}$ *provided* <u>*either*</u> $d+\kappa>2$ <u>*or*</u> *condition*

$$|V|+|\nabla V|+|\nabla^2 V|\ge\epsilon \tag{6.4.68}$$

is fulfilled.

This completely covers the case $d=2$. As $d=1$ we get the required remainder estimate under condition (6.4.68).

Now, combining this with the arguments of the proof of Theorem 5.2.14 we arrive to

Proposition 6.4.23. *Consider Schrödinger operator with* $d = 1$, $\kappa > 0$. *Then the standard Weyl asymptotics* (6.4.56)–(6.4.58), (6.4.34) *holds with the remainder estimate* $O(h^{1-d-\kappa})$.

We are leaving easy details of both proofs to the reader; see also the proofs of the next subsection.

Remark 6.4.24. Actually all above results hold as $\kappa = 0$ as well with the singular exception of $d = 1$ when the remainder estimate $O(1)$ is recovered under condition

$$\sum_{|\beta|\le K} |\nabla_x^\beta V| \ge \epsilon; \tag{6.4.69}$$

without it the remainder estimate is $O(h^{-\delta})$ with arbitrarily small $\delta > 0$.

6.5 Mollification with Respect to Non-Spectral Parameters

6.5.1 Linear Dependence

Let operator $A = A_\zeta$ depend on parameter $\zeta \in (-1, 1)$ smoothly and microhyperbolically, i.e.,

$$\operatorname{Re} \langle \partial_\zeta a v, v\rangle \ge \epsilon_0 \|v\|^2 - c\|av\|^2 \qquad \forall \zeta \quad \forall (x,\xi) \in \Omega \quad \forall v \in \mathbb{H} \tag{6.5.1}$$

where a is the principal symbol of A.

Then the propagation of singularities theory yields that $u_\zeta(x, y, t)$ is negligible in zones $\{|t| \le T_0, \pm t > 0, \pm z \le \pm\epsilon_1 t - T, |\tau| \le \epsilon_2\}$ with appropriate constants $\epsilon_j > 0$ and $T_0 > 0$ where z is dual to the ζ variable and $T > h^{1-\delta}$ is a parameter, $\delta > 0$.

In particular, $u_\zeta(x, y, t)$ is negligible for $t = \pm T_0$, $\pm z \le \epsilon_3$. Moreover, let us assume that

(6.5.2) A_ζ is a linear function of ζ,

$$\operatorname{Re} \langle \partial_\zeta A_\zeta u, u\rangle \ge 0 \quad \forall u. \tag{6.5.3}$$

Then using the standard energy estimates technique with $\psi = \psi(z)$ one can prove easily that U is negligible in zones $\{T_0 \le \pm t \le h^{-l} = T_1, \pm z \le \frac{1}{2}\epsilon_3\}$ with an arbitrary exponent l.

In the z-representation, let us apply the operator $\phi_1(hL^{-1}D_z)$ where $\phi_1 \in \mathscr{C}_0^K([-\frac{1}{2}, \frac{1}{2}])$ and set $z = 0$; in the ζ-representation this procedure means multiplication by $\phi_1(\zeta L^{-1})$ and integration with respect to $\zeta \in \mathbb{R}$. The resulting function is negligible for $T_1 \ge |t| \ge T, \tau \in [-\epsilon_2, \epsilon_2]$ and for $|t| \le h^{\frac{1}{2}+\delta}$ this function was constructed by a successive approximation method. Thus, for $\tau, \tau' \in [-\frac{1}{2}\epsilon_2, \frac{1}{2}\epsilon_2]$ we obtain the complete asymptotic expansion for

$$\frac{1}{L}\int \phi_1\bigl(\frac{\zeta}{L}\bigr)(\Gamma Q_x'^{\,t} Q_y'' e)(\tau', \tau; \zeta)\, d\zeta \tag{6.5.4}$$

and therefore for $\tau \in [-\frac{1}{2}\epsilon_2, \frac{1}{2}\epsilon_2]$ we obtain the complete asymptotic expansion for

$$\frac{1}{LL_1}\iint \phi\bigl(\frac{\tau'}{L_1}\bigr)\phi_1\bigl(\frac{\zeta}{L}\bigr)(\Gamma Q_x'^{\,t} Q_y'' e)(\tau', \tau; \zeta)\, d\zeta d\tau'. \tag{6.5.5}$$

We assume in these expansions that L and L_1 are such that $1 \ge L \ge h^{\frac{1}{2}-\delta}$ (because the only condition on L is $LT \ge h^{1-\delta}$ and we can take $T = h^{\frac{1}{2}+\delta}$) and $1 \ge L_1 \ge 0$.

Moreover, if a has only one eigenvalue in the interval $[-h^{\delta'}, h^{\delta'}]$ with a small enough exponent $\delta' > 0$ (in which case this eigenvalue is of constant multiplicity) then the same arguments as for mollification on the spectral parameter in Theorem 5.2.1 yield that we can weaken the restrictions on L and obtain the condition $1 \ge L \ge h^{1-\delta}$.

Furthermore, later for the two-dimensional Schrödinger and Dirac operators with strong magnetic field we will be able to weaken this condition also, replacing it by the same condition as for mollification with respect to spectral parameter. So the following statement has been proven:

Proposition 6.5.1. *(i) Under conditions* (6.5.1)–(6.5.3) *all the theorems and complete asymptotics for mollification with respect to spectral parameter remain true if we replace mollification with respect to spectral parameter by mollification with respect to ζ with the same restrictions on L; here we assume that $\tau', \tau \in [-\epsilon, \epsilon]$ with a small constant $\epsilon > 0$.*

(ii) Moreover, these theorems and asymptotics remain true if we also include mollification with respect to the spectral parameter τ' with $L_1 \in [0,1]$ where we take $e(\lambda,\tau,\zeta)\,d\lambda d\zeta$ instead of $d_\tau(.,\tau)$ in the original mollification.

On the other hand, if we drop conditions (6.5.2) and (6.5.3) then we are forced to take $T_1 = T_0$ [24]. Then the Tauberian method provides the following

Proposition 6.5.2. *Under condition* (6.5.1) *in the theorems on asymptotics without mollification we can drop the microhyperbolicity condition provided we mollify with respect to ζ and take $\tau', \tau \in [-\epsilon,\epsilon]$ (we can mollify also with respect to ζ, τ' and take $\tau \in [-\epsilon,\epsilon]$). Here we have the same restrictions on L and L_1 as before (recall that in the scalar and similar cases these restrictions are weaker than in the general case).*

Let us observe that applying the same energy estimates technique as before in the framework of (6.5.1) and (6.5.2) we can reach $T_1 = \epsilon h^{-2}$ and so we can improve the remainder estimate in Proposition 6.5.2 under the additional condition (6.5.2).

6.5.2 Microhyperbolic Case

Let us treat the general case and assume that

(6.5.6) At level 0 the operator A is microhyperbolic with respect to (x,ξ) in Ω for every $\zeta \in (-1,1)$.

Then taking into account that under this condition for $T = T_0$ and $\tau_1, \tau_2 \in [-\epsilon,\epsilon]$ with $|\tau_2 - \tau_1| \le hT^{-1}$ the trace norm of the operator $Q'E(\tau_1,\tau_2)Q''$ does not exceed Ch^{1-d} and that this norm does not exceed $Ch^{-m}(|\tau_1|+|\tau_2|+1)^m$ for general $\tau_1, \tau_2 \in \mathbb{R}$ with appropriate m, we obtain from the formula

$$F_{t\to h^{-1}\tau}\chi_T(t)u = \int \hat{\chi}_T((\tau-\tau')h)\, d_{\tau'}e(\tau_1,\tau')$$

that (after multiplication by Q'_x and ${}^tQ''_y$) the trace norm of the left-hand expression does not exceed Ch^{1-d} for $T = T_0$ and $\tau \in [-\frac{1}{2}\epsilon, \frac{1}{2}\epsilon]$.

[24] But we can increase T_1 under standard conditions on the Hamiltonian flow or under the conditions of Section 6.2.

This and the previous arguments easily yield that for $|T| \ge 2T_0$ and $|\tau| \le \frac{1}{2}\epsilon$ the trace norm of

$$F_{t\to h^{-1}\tau}\chi_{T_0,T}(t)MQ'_x u\, {}^tQ''_y$$

does not exceed $CTh^{1-d}(hL^{-1})^{3s}$ where $L \in [h,1]$ is arbitrary, $M = M_L$: $Mv = L^{-1}\int \phi(\zeta L^{-1})v_\zeta\, d\zeta$. Moreover, for $|T| \le 2T_0$ this norm does not exceed Ch^{1-d}. But then the trace norm of

$$F_{t\to h^{-1}\tau}\chi_{T}(t)MQ'_x u\, {}^tQ''_y$$

does not exceed $Ch^{1-d} + CT^2h^{1-d}(hL^{-1})^{3s}$ and therefore the standard Tauberian arguments with $T_1 = (\frac{h}{L})^{-s}$ yield that

$$|M\Gamma Q'_x\Big(e - \frac{1}{h}\int_{\tau_1}^{\tau_2} F_{t\to h^{-1}\tau}\bar\chi_{T_1}(t)u\, {}^tQ''_y\, d\tau\Big)| \tag{6.5.7}$$

does not exceed $Ch^{1-d}(hL^{-1})^s$.

Let us now consider

$$|M\Gamma Q'_x\frac{1}{h}\int_{\tau_1}^{\tau_2} F_{t\to h^{-1}\tau}\big(\bar\chi_{T_1}(t) - \bar\chi_{T_0}(t)\big)u\, {}^tQ''_y\, d\tau| = |M\Gamma Q'_x F_{t\to h^{-1}\tau}\frac{1}{t}\big(\bar\chi_{T_1}(t) - \bar\chi_{T_0}(t)\big)u\, {}^tQ''_y\Big|_{\tau=\tau_1}^{\tau=\tau_2}|.$$

The previous analysis yields that the right-hand expression of this equality does not exceed $CT_1^2h^{1-d}(hL^{-1})^{3s} = Ch^{1-d}(hL^{-1})^s$ and therefore we can replace T_1 by T_0 in (6.5.7) without increasing the error. However, under condition (6.5.6) for $T = T_0$ we have complete asymptotics for $\Gamma Q'_x F_{t\to h^{-1}\tau}\bar\chi_T(t)u\, {}^tQ''_y$ and hence we have obtained *complete asymptotics for* $M\Gamma Q'_x e\, {}^tQ''_y$ *with remainder estimate* $Ch^{1-d}(hL^{-1})^s$.

Remark 6.5.3. (i) Without condition (6.5.6) we would obtain remainder estimate $Ch^{-d}(hL^{-1})^s$.

(ii) Let us assume that condition (6.5.1) is fulfilled for all $\zeta \in (-1,1)$. Using a partition of unity and the arguments of Section 5.2 we obtain that under conditions $(5.2.20)_1$ the remainder estimate is $O\big(h^{\frac{1}{2}-d}(hL^{-1})^s\big)$; under condition $(5.2.20)_2^+$ the remainder estimate is $O\big(h^{1-d}(hL^{-1})^s\big)$ and under condition $(5.2.20)_2$ the remainder estimate is $O\big(h^{1-d}(hL^{-1})^s|\log h|\big)$.

Moreover, the more advanced arguments of Section 5.2 yield that under condition $(5.2.20)_2$ the remainder estimate is $O\big(h^{1-d}(hL^{-1})^s\big)$ as well and, moreover, we get the same remainder estimate under conditions $(5.2.20)_1$ and $(5.2.100)_m$.

Furthermore, under condition $(5.2.20)_1$ only the remainder estimate is $O\big(h^{1-d-\delta}(hL^{-1})^s\big)$ with an arbitrarily small exponent $\delta > 0$ and the same estimate holds under condition (5.2.126).

(iii) Similarly, under conditions of a global nature linked to the Hamiltonian trajectories the remainder estimate can be improved; now in the remainder estimates $T_1 = (hL^{-1})^{-s}T_2$ where T_2 is the time controlled by the Hamiltonian trajectories.

(iv) For Schrödinger and Dirac operators with strong magnetic field we will be able to obtain similar results.

6.5.3 Averaging

Starting from the previous results and applying a partition of unity with respect to ζ we obtain that if condition $\varphi \in \mathscr{C}_0^K([-\frac{1}{2},\frac{1}{2}])$ is replaced by the condition (4.2.73)–(4.2.75) then in general under condition (6.5.6) the remainder estimate is $O\big(h^{1-d}\vartheta(hL^{-1})\big)$, etc.: in all cases the remainder estimates are as good as those we obtained for similar averaging with respect to τ.

Therefore under conditions (6.5.1)–(6.5.3) the estimates for averaging remain true if they are taken with respect to ζ (instead of the spectral parameter).

6.A Appendices

6.A.1 Hamiltonian Flows of Commuting Operators

Proposition 6.A.1. *Let a be scalar and*

$$\{a,b\} = 0 \tag{6.A.1}$$

Then as long as we do not leave domain where (6.A.1) *holds*

$$\Psi_{b,t}(\{a=\tau\}) \subset \{a=\tau\}; \tag{6.A.2}$$

$$\Psi_{b,t}\circ\Psi_{a,t'} = \Psi_{a,t'}\circ\Psi_{b,t} = \Psi_{at'+bt,1} \tag{6.A.3}$$

Proof. Since a is scalar $\Psi_{a,t} = e^{t\nabla^{\#}a}$ is single-valued. Due to (6.A.1) $\nabla^{\#}a(b) = 0$ and $\Psi_{a,t'}$ preserves b: $b \circ \Psi_{a,t'} = b$. Then $\Psi_{a,t'}$ also preserves $K_b(z)$ and $K_b^{\sigma}(z)$ and therefore $\Psi_{a,t'}$ also preserves $\Psi_{b,t}$. The first of two equalities (6.A.3) is proven.

Then

$$\Psi_{a,t'} \circ \Psi_{b,t} = \bigl(\Psi_{a,n^{-1}t'}\bigr)^n \circ \bigl(\Psi_{b,n^{-1}t}\bigr)^n = \bigl(\Psi_{a,n^{-1}t'}\Psi_{b,n^{-1}t}\bigr)^n$$

and due to the fact that $\Psi_{a,t'}$ preserves $\Psi_{b,t}$ the latter expression is

$$\bigl(\Psi_{n^{-1}(at'+bt),1} + O(n^{-2})\bigr)^n$$

which tends to $\Psi_{at'+bt,1}$ as $n \to \infty$.

Finally, by definition

$$K_b(z) = \{\ell : \langle \ell(b)v, v\rangle > 0 \ \forall v \in \operatorname{Ker} b\}$$

and thus $\ell \in K_b(z)$ implies that $\ell + \alpha\nabla^{\#}a(z) \in K_b(z)$ for any $\alpha \in \mathbb{R}$. Then $\zeta \in K_z^{\sigma}(b)$ implies that $\sigma(\zeta, \nabla^{\#}a) = 0$ i.e. $\zeta(a) = 0$. Therefore $K_z^{\sigma}(b) \subset T\{a = \tau\}$ as $a(z) = \tau$. This implies (6.A.2). □

Problem 6.A.2. Does (6.A.3) hold as both a and b are matrix symbols of two commuting operators so $[a, b] = 0$ and

$$-i\{a, b\} + [a', b] + [a, b'] = 0$$

with

$$\{a, b\} \coloneqq \frac{1}{2}\sum_j \bigl(a^{(j)}b_{(j)} + b_{(j)}a^{(j)} - a_{(j)}b^{(j)} - b^{(j)}a_{(j)}\bigr),$$

a', b' are subprincipal symbols (so we actually have a standard formula for Poisson brackets but including symmetrized products of $a^{(j)}$ and $b_{(j)}$ and $b^{(j)}$ and $a_{(j)}$?

6.A.2 One Property of Real Residues

Proposition 6.A.3. *Let $F(z)$ be analytic in $\mathbb{C} \setminus [\tau_1, \tau_2]$ with $[\tau_1, \tau_2] \subset \mathbb{R}$ and $-\infty < \tau_1 \le \tau_2 < \infty$. Then*

$$\int_{\tau_1'}^{\tau_2'} (\operatorname{Res}_{\mathbb{R}} F)(\tau)\, d\tau = 2\pi i \operatorname{Res}_{\infty} F \tag{6.A.4}$$

as $-\infty < \tau_1' < \tau_1$, $\tau_2 < \tau_2' < \infty$. In particular,

$$\operatorname{Res}_{\mathbb{R}} F(\tau) = \partial_\tau\bigl(k\tau + g(\tau)\bigr), \quad k = 2\pi i \operatorname{Res}_{\infty} F, \quad \operatorname{supp}(g) \subset [\tau_1, \tau_2]. \tag{6.A.5}$$

Proof. Obviously the left hand expression in (6.A.4) equals to $-\int_\gamma F(z)\,dz$ where γ is any contour winding once in the counter-clock-wise direction around $[\tau_1,\tau_2]$ and in turn equals to the right-hand expression. □

6.A.3 Eigenvalues of Some Model Operators

Proof of (6.3.105). Indeed, eigenfunctions of Laplacian on the sphere $\mathbb{S}^d$ are closely connected to homogeneous harmonic polynomials in $\mathbb{R}^{d+1} \ni x$: $P(x) = |x|^n\phi(x/|x|)$ and denoting $|x| = r$, $x/|x| = y$ we arrive to

$$0 = \Delta_x P(x) = \bigl(-\partial_r^2 - dr^{-1}\partial_r + r^{-2}\Delta_y\bigr)\bigl(r^n\phi(y)\bigr) = r^{n-2}\bigl(-n(n-1) - nd + \Delta_y\bigr)\phi(y)$$

which results in (6.3.106) in the statement "N_n is equal to the dimensional of the space of all harmonic polynomials of degree n in $\mathbb{R}^{d+1}$". However such polynomial $P(x)$ is uniquely defined by $P(0,x')$ and $\partial_{x_1}P(0,x')$ which are arbitrary homogeneous polynomials of degrees n and $(n-1)$ respectively on $\mathbb{R}^d \ni x' = (x_2,\dots,x_{d+1})$. Since dimension of the space of homogeneous polynomials of degree n polynomials on $\mathbb{R}^d$ is equal to $\frac{(n+d-1)!}{n!(d-1)!}$ we get (6.3.107). □

Proof of (6.3.113). Let $A = \Delta - r^{-1}$; let us rewrite it as

$$A = -\partial_r^2 - (d-1)r^{-1} + r^{-2}\Lambda - r^{-1} \tag{6.A.6}$$

where Λ is Laplacian on $\mathbb{S}^{d-1}$. Then plugging $m(m+d-2)$ as its eigenvalues we get for eigenvalues $-\lambda$ of A

$$\Bigl(\partial_r^2 + (d-1)r^{-1}\partial_r - m(m+d-2)r^{-2} + r^{-1} - \lambda\Bigr)u = 0;$$

plugging $u = r^m v$ we get

$$\Bigl(\partial_r^2 + (d-1+2m)r^{-1}\partial_r + r^{-1} - \lambda\Bigr)v = 0.$$

Plugging $v = e^{-\sqrt{\lambda}r}w$ to compensate the last term we get after multiplication by r

$$\Bigl(r\partial_r^2 - 2\sqrt{\lambda}r\partial_r + (d-1+2m)\partial_r + \bigl(1-(d-1+2m)\sqrt{\lambda}\bigr)\Bigr)w = 0.$$

This equation scales to

$$\Big(r\partial_r^2 - 2\sqrt{\lambda}\beta r\partial_r + (d-1+2m)\partial_r + \beta\big(1-(d-1+2m)\sqrt{\lambda}\big)\Big)w = 0.$$

and picking up $\beta = 1/2\sqrt{\lambda}$ we arrive to

$$\Big(r\partial_r^2 - r\partial_r + (d-1+2m)\partial_r + \big(1-(d-1+2m)\sqrt{\lambda}\big)/2\sqrt{\lambda}\Big)w = 0 \tag{6.A.7}$$

which is the equation defining associated Laguerre polynomial $L_k^{(\alpha)}$ as

$$\begin{aligned}(d-1+2m) &= \alpha+1\\ \big(1-(d-1+2m)\sqrt{\lambda}\big)/2\sqrt{\lambda} &= k\end{aligned} \tag{6.A.8}$$

with $\alpha = 0, \dots, k$. The second equation here is

$$1/\sqrt{\lambda} = d-1+2m+2k$$

or

$$\lambda = \lambda_n := (2n+d-1)^{-2}, \qquad n = m+k. \tag{6.A.9}$$

This proves (6.3.114). To calculate ν_n we need to sum (6.3.107) with d replaced by $(d-1)$ and n by m from $m=0$ to $m=n$. This proves (6.3.115).□

Part III

Local and Microlocal Semiclassical Spectral Asymptotics near the Boundary

Chapter 7

Standard Local Semiclassical Spectral Asymptotics near the Boundary

In this chapter we continue the treatment of local and microlocal semiclassical spectral asymptotics. Now with the singular exception of Section 7.5 we consider the case when our (unit) "Ball of Light" intersects the boundary of the domain in a part of the boundary which is smooth. This chapter consists of five sections mainly matching to the corresponding sections of Chapter 4.

Namely, Section 7.1 is devoted to the preliminary analysis; here we obtain rough estimates of the spectral function. More precisely, we find that there are three different cases; two of them (when the spectral function on a fixed interval has order h^{-d} and $O(h^{\infty})$ respectively) we have met before; in the third case the operator A is elliptic (on the given energy level) but the boundary value problem $(A, \eth B)$ is not, and the spectral function has order h^{1-d}–exactly as in the case of elliptic operator on the closed manifold of dimension $(d-1)$. This is not a coincidence.

In Section 7.2 we find successive approximations, which are now essentially more complicated because we need to consider the boundary value problem. The good news is that if the operator A is not elliptic we have already constructed free-space propagator and we need to consider only the part of propagator generated by the boundary; if the operator A is elliptic the "free space" propagator is negligible.

In Sections 7.3 and 7.4 we prove the basic theorems of this chapter. Again

in the former we derive asymptotics with the remainder estimate $O(h^{1-d})$ (if $(A, \partial B)$ is microhyperbolic and A is not elliptic on the energy level in question) or $O(h^{2-d})$ (if $(A, \partial B)$ is microhyperbolic but not elliptic and A is elliptic on the energy level in question). In the latter section we improve estimates $O(h^{1-d})$ to $o(h^{1-d})$ or even slightly better under non-periodicity condition of the global nature.

In Section 7.5 as in Section 4.6 we study operators with the irregular coefficients and reimplement method of R. Seeley; in conjugation with our own technique it works extremely nicely. In particular the microhyperbolicity condition for $(A, \partial B)$ disappears leaving us with the microhyperbolicity condition for A only which is a nice development even in the smooth case.

Finally, in Appendix 7.A we prove that the set of "bad" energy levels where the microhyperbolicity property is violated has measure 0; this result is reasonable even if there is no boundary.

7.1 Preliminary Analysis

7.1.1 General Case

In this chapter we treat the operator

$$A = \sum_{|\alpha|\le m} a_\alpha(x,h)(hD)^\alpha \tag{7.1.1}$$

in the domain $X \subset \mathbb{R}^d$ assuming that

$$X \cap B(0,1) = \mathbb{R}^d_+ \cap B(0,1) \tag{7.1.2}$$

where $\mathbb{R}^d_+ = \mathbb{R}_+ \times \mathbb{R}^{d-1}$ [1)] the slightly more general case

$$X \cap B(0,1) = \{x_1 \ge \phi(x')\} \cap B(0,1), \quad |D^\beta \phi| \le c \quad \forall \beta, |\beta| \le K \tag{7.1.3}$$

is reduced to the former after a regular change of coordinates which preserves (in particular) the smoothness condition

$$\|D^\beta a_\alpha\| \le c \qquad \forall \alpha : |\alpha| \le m, \quad \forall \beta : |\beta| \le K; \tag{7.1.4}_1$$

we assume that

[1)] Except the last Section 7.5 describing irregular operators and domains with irregular boundary.

(7.1.5) $\mathbb{H} = \mathbb{C}^D$ and so a_α are $D \times D$ matrices.

We also assume that the boundary operator B on $Y = \partial X$ is given; more precisely we assume that

(7.1.6) $u \in \mathscr{C}_0^m(B(0,1), \mathbb{H})$ belongs to $\mathfrak{D}(A)$ if and only if

$$B_k u|_Y = 0 \qquad k = 1, \dots, l \tag{7.1.7}$$

where

$$B_k = \sum_{|\alpha| \le m_k} b_{k\alpha}(x', h)(hD)^\alpha \tag{7.1.8}$$

where $0 \le m_1 < m_2 < \dots < m_l \le m-1$, $b_{k\alpha}$ are $\mathsf{D}_k \times \mathsf{D}$ matrices and

$$\|D^\beta b_{k\alpha}\| \le c \qquad \forall \alpha, |\alpha| \le m_k, \quad \forall \beta, |\beta| \le K \quad \forall k = 1, \dots, l. \tag{7.1.4)$_2$}$$

Moreover, we assume that the boundary is not characteristic, i.e., we assume that

$$\|a_{(m,0,\dots,0)}(x)^{-1}\| \le c \qquad \forall x \in B(0,1). \tag{7.1.9}$$

Finally we assume that

(7.1.10) A is a self-adjoint operator in $\mathscr{L}^2(X, \mathbb{H})$ where $\mathfrak{D}(A)$ satisfies condition (7.1.6).

One can then prove that then

$$\mathsf{D}_1 + \dots + \mathsf{D}_l = \frac{m\mathsf{D}}{2}. \tag{7.1.11}$$

Let us introduce a condition similar to (3.1.9): there exist symbols $\beta_j(z)$ with $j = 1, \dots, m$ and $\beta = (\beta_1, \dots, \beta_m)$ such that

$$T(z) + (\beta^\dagger b)(z) + (b^\dagger \beta)(z) = 0 \qquad \forall z \in T^*(Y \cap B(0,1)) \tag{7.1.12}$$

where $T(z)$ is written in the form (3.1.7) after A has been written in the form (3.1.1) and operators A_k have been defined, with principal symbols a_k,

and b is the principal symbol of the boundary operator $B = (B_{(1)}, \dots, B_{(m)})$ where the boundary conditions (7.1.7) have been rewritten in the form

$$Bu = \sum_{1 \le j \le m} B_{(j)} (hD_1)^{j-1} u|_Y = 0. \tag{7.1.13}$$

Condition (7.1.12) follows from the equality

$$(Au, v)_X + \sum_{1 \le k \le l} (B_k u, B'_k v)_Y = (u, Av)_X + \sum_{1 \le k \le l} (B'_k u, B_k v)_Y \qquad \forall u, v \in \mathscr{C}_0^m(B(0,1), \mathbb{H}) \tag{7.1.14}$$

where B'_k are h-differential operators of orders $(m - m_k - 1)$ with the coefficients satisfying condition $(7.1.4)_2$. Let us note that conditions (7.1.14), (7.1.9) and (7.1.11) yield that

$$\operatorname{rank} b(z) = \frac{m\mathsf{D}}{2} \qquad \forall z \in T^*(Y \cap B(0,1)) \tag{7.1.15}$$

and

$$\operatorname{rank} b_{k(m_k,0,\dots,0)}(x) = \mathsf{D}_k \qquad \forall x \in Y \cap B(0,1) \tag{7.1.16}$$

where these conditions are satisfied uniformly (i.e., there exits a minor of the corresponding dimension the absolute value of which is not less than ϵ_0).

Let $e(x, y, \tau)$ be the Schwartz kernel of the spectral projector of A and let $e(x, y, \tau_1, \tau_2) = e(x, y, \tau)|_{\tau=\tau_1}^{\tau=\tau_2}$.

We start from a statement similar to Proposition 4.2.1:

Theorem 7.1.1. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_1$, (7.1.9) *and* (7.1.10) *be fulfilled. Let* $\psi_1, \psi_2 \in \mathscr{C}_0^K(B(0, 1-\epsilon))$, $\epsilon > 0$ *and let* $q_1, q_2 \in \mathsf{S}'_{h,K}$ *be supported in* $\{|\xi'| \le c_1\}$, $Q_i = \mathsf{Op}(q_i)$. *Then*

$$\|Q_{1x}\psi_1(x)e(.,.,\tau_1,\tau_2)\psi_2(y)^t Q_{2y}\| \le C' h^{-d} \big(1 + |\tau_1| + |\tau_2|\big)^{\frac{1}{m}} \qquad \forall x, y \in \mathbb{R}^d \quad \forall \tau_1, \tau_2 \in \mathbb{R} \tag{7.1.17}$$

with $K = K(d, m)$, $C' = C'(d, m, c, c_1, \epsilon)$ *defined in the same way as in Proposition 4.2.1 (with the corresponding norms of* q_i*).*

Proof. Let us note first of all that the conditions of this theorem imply the very rough estimate

$$\|D_1^j \psi u\|_{(-n)} \le C' h^{-n}(\|Au\| + \|u\|) \qquad \forall j = 0, \dots, m-1 \tag{7.1.18}$$

where in the left-hand expression the $\mathscr{L}^2$-norm with respect to x_1 and the $\mathscr{H}^{(-n)}$-norm with respect to x' is calculated, $\psi \in \mathscr{C}_0^K(B(0, 1-\epsilon'))$, C' also depends on $\epsilon' > 0$ and ψ, and $n = n(d, m)$.

In fact, (7.1.9) yields that

$$(hD_1)^m \psi u = \psi Au + \sum_{|\alpha| \le m, \alpha_1 \le m-1} (hD)^\alpha a'_\alpha u \tag{7.1.19}$$

where $a'_\alpha \in \mathscr{C}_0^K(B(0, 1-\epsilon'))$ and hence

$$\begin{aligned}(7.1.20)_j \quad (hD_1)^j \psi u = \mathcal{K}^{m-j} \psi Au + \\ \sum_{|\alpha| \le m, m-j \le \alpha_1 \le m-1} (hD')^{\alpha'} (hD_1)^{\alpha_1 - m + j} a'_\alpha u + \\ \sum_{|\alpha| \le m, \alpha_1 \le m-j} \mathcal{K}^{m-j-\alpha_1} (hD')^{\alpha'} a'_\alpha u\end{aligned}$$

where $(\mathcal{K}u)(x) = ih^{-1} \int_\infty^{x_1} u(t, x')dt$.

Substituting $(7.1.20)_1$ into $(7.1.20)_2$ and continuing this process we remove from the right-hand expression of $(7.1.20)_m$ every degree of hD_1; in this expression there will only be multiple compositions of operators of multiplication by smooth compactly supported functions, hD' and $\mathcal{K}$; this representation yields (7.1.18) with $n = n(m)$.

Let $u \in \mathscr{C}_0^m(B(0, 1), \mathbb{H})$. Then (7.1.9) yields that

$$\begin{aligned}\|(hD_1)^m u\| \le C\|Au\| + C \sum_{|\alpha| \le m,\, \alpha_1 \le m-1} \|(hD)^\alpha u\| \le \\ C\|Au\| + C \sum_{|\alpha| \le m,\, \alpha_1 = 0} \|(hD)^\alpha u\|\end{aligned}$$

where we have applied the inequality

$$\sum_{|\alpha| \le m,\, \alpha_1 \le m-1} \|(hD)^\alpha u\| \le \epsilon \|(hD_1)^m u\| + C_\epsilon \sum_{|\alpha| \le m,\, \alpha_1 = 0} \|(hD)^\alpha u\|$$

with arbitrarily small $\epsilon > 0$. Then substituting $u = Q_1\psi_1 v$ we again obtain by means of (7.1.18) that

$$\sum_{j\le m} \|(hD_1)^j Q_1\psi_1 v\| \le C(\|Av\| + \|v\|) + \sum_{j\le m-1} Ch\|(hD_1)^j Q_1'\psi_1' v\|$$

where Q_1' and ψ_1' are an operator and function of the same type as Q_1 and ψ_1 but with c_1 and ϵ replaced by $2c_1$ and $\frac{1}{2}\epsilon$. Applying the same arguments to Q_1' and ψ_1' repeatedly we finally obtain estimate

$$\sum_{j\le m} \|(hD_1)^j Q_1\psi_1 v\| \le C(\|Av\| + \|v\|). \tag{7.1.21}$$

Next, applying inequality

$$\|v(x_1,.)\|' \le Ch^{-\frac{1}{2}}\|v\|^{\frac{2m-1}{2m}} \sum_{j\le m} \|(hD_1)^j v\|^{\frac{1}{2m}} \tag{7.1.22}$$

with the $\mathscr{L}^2$-norm with respect to x' in the left-hand expression we conclude that

$$\|(Q_1\psi_1 v)(x_1,.)\|' \le Ch^{-\frac{1}{2}}\big(\|v\| + \|Av\|^{\frac{1}{2m}}\|v\|^{\frac{2m-1}{2m}}\big).$$

Observing that instead of Q_1 we could take in this analysis $(hD)^\alpha Q_1$ with any fixed α we obtain from the Sobolev embedding theorems that

$$\|(Q_1\psi_1 v)(x)\| \le Ch^{-\frac{d}{2}}\Big(\|v\| + \|Au\|^{\frac{1}{2m}}\|v\|^{1-\frac{1}{2m}}\Big). \tag{7.1.23}$$

Substituting $v = Q_1\psi_1 E(\tau_1,\tau_2)w$ we conclude that

(7.1.24) The operator norm of operator $M = Q_1\psi_1 E(\tau_1,\tau_2) : \mathscr{L}^2(X,\mathbb{H}) \to \mathbb{H}$ does not exceed $Ch^{-\frac{d}{2}}(1+|\tau_1|+|\tau_2|)^{\frac{1}{2m}}$,

and since $Q_{1x}\psi_1(x)e(.,.,\tau_1,\tau_2)\psi_2^t Q_2 = MN^*$ where $N = Q_2^*\bar\psi_2 E(\tau_1,\tau_2)$ is an operator of the same type as M we obtain (7.1.17). □

Remark 7.1.2. Our proof implies the estimate

$$\|D_{x_1}^j D_{y_1}^k Q_{1x}\psi_1(x)e(.,.,\tau_1,\tau_2)\psi_2(y)^t Q_{2y}\| \le C'h^{-d-j-k}\big(1+|\tau_1|+|\tau_2|\big)^{\frac{j+k+1}{m}} \tag{7.1.17}'$$

for $j \le m-1, k \le m-1$. If we apply our analysis to the powers of the operator A instead of A itself we obtain this estimate for arbitrary j,k but now K and C' also depend on j,k.

7.1.2 Elliptic Case

Our next step is to treat the zone where A is elliptic:

Theorem 7.1.3. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_1$, (7.1.9) *and* (7.1.10) *be fulfilled and let* Q_i *and* ψ_i *be the same as in Theorem 7.1.1*[2)]. *Let us assume that*

$$\|(\tau - a(x,\xi))^{-1}\| \le c \qquad \forall (x,\xi') \in \operatorname{supp}(q_1) \cup \operatorname{supp}(q_2) \quad \forall \xi_1 \in \mathbb{R} \quad \forall \tau \in [\tau_1, \tau_2]. \tag{7.1.25}$$

Then for $\tau_1', \tau_2' \in [\tau_1, \tau_2]$ *the following estimates hold:*

$$\|D_{x_1}^j D_{y_1}^k Q_{1x} \psi_1(x) e(.,.,\tau_1',\tau_2') \psi_2(y)^t Q_{2y}\| \le C' h^{-d-j-k} (1 + |\tau_1'| + |\tau_2'|)^{\frac{j+k+1}{m}} \big(1 + \frac{1}{h}(x_1 + y_1)\big)^{-s} \tag{7.1.26}$$

and

$$\|\Gamma'' Q_{1x} \psi_1(x) e(.,.,\tau_1',\tau_2') \psi_2(y)^t Q_{2y}\| \le C' h^{1-d} (1 + |\tau_1'| + |\tau_2'|)^{\frac{j+k+1}{m}} \tag{7.1.27}$$

where Γ'' *is introduced by* (3.3.43).

Proof. Let $\chi \in \mathscr{C}_0^K([-1,1]$ be fixed. Then partially repeating arguments of the proof of Theorem 7.1.1 (see also the proof of Proposition 4.2.2) we obtain that

$$\|F_{t \to h^{-1}\tau} \chi_{T,T'}(t)_x D_{x_1}^j Q_1' \psi_1' u\| \le C' T h^{-\frac{1}{2}-j} (1 + |\tau|)^{\frac{1}{m}(j+\frac{1}{2})} \|v\| \tag{7.1.28}$$

where $v \in \mathscr{L}^2(X, \mathbb{H})$ is arbitrary, $u = \exp(ih^{-1}tA)v$, $T \ge h$, $T' \in \mathbb{R}$ and $\tau \in \mathbb{R}$ are arbitrary, Q_i' and ψ_i' are operators and functions of the same type as Q_i and ψ_i, equal to 1 in the neighborhoods of the supports of Q_i and ψ_i respectively, and $\mathfrak{d}$ is the operator of restriction to $Y = \partial X$.

Now let $\mathfrak{C}$ be the operator realizing the reduction of Subsubsection *3.1.2.1 Reduction to a Special Case* in a neighborhood of $\operatorname{supp} Q_1' \times [\tau_1, \tau_2]$; then estimate (7.1.28) also holds for u, v replaced by $\tilde{u} = \mathfrak{C}u, \tilde{v} = \mathfrak{C}v$.

Moreover, $\tilde{u}$ is divided into two blocks $(\tilde{u}', \tilde{u}'')$ and Subsubsection *3.1.2.2 Elliptic Theory* yields that one of them $(\tilde{u}'')$ is negligible while the second

[2)] Including condition $\operatorname{supp}(q_i) \subset \{|\xi'| \le c_1\}$.

satisfies the estimate

$$\|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)D^j_{x_1}Q_1\psi_1\tilde{u}'\|' \le C'Th^{-\frac12-j}(1+|\tau|)^{\frac1m(j+\frac12)}\|v\|\big(1+\frac{x_1}{h}\big)^{-s} \quad \forall\tau\in[\tau_1,\tau_2] \tag{7.1.29}$$

where in the left-hand expression the $\mathscr{L}^2$-norm with respect to x' is calculated; then the same estimate holds also for $\tilde{u}'$ replaced either by $\tilde{u}=\mathfrak{C}v$ or by u itself.

Further, here we can replace Q_1 by $(hD')^\alpha Q_1$ and hence the embedding theorems yield that

$$\|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_1\psi_1 u\| \le C'Th^{-\frac d2}(1+|\tau|)^{\frac{1}{2m}}\big(1+\frac{x_1}{h}\big)^{-s}\|v\| \quad \forall x\in\bar{\mathbb{R}}^+\times\mathbb{R}^{d-1} \quad \forall\tau\in[\tau_1,\tau_2].$$

Taking into account the connection between u, v and propagator $U = U(x,y,t)$ we conclude that

$$\|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_{1x}\psi_1(x)f^\dagger U\| \le C'T^{-\frac d2}(1+|\tau|)^{\frac{1}{2m}}(1+\frac{x_1}{h})^{-s} \quad \forall x\in\bar{\mathbb{R}}^+\times\mathbb{R}^{d-1} \quad \forall\tau\in[\tau_1,\tau_2] \quad \forall f\in\mathbb{H}$$

where in the left-hand expression the $\mathscr{L}^2$-norm with respect to y is calculated. Repeating the same arguments with x replaced by y we obtain from this estimate and from the rough estimate with $s=0$ (which holds for all $\tau\in\mathbb{R}$) estimate

$$\|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_{1x}\psi_1(x)U\psi_2(y)^tQ_{2y}\| \le C'T^{-d}(1+|\tau|)^{\frac12}\big(1+\frac{1}{h}(x_1+y_1)\big)^{-s} \quad \forall x,y\in\bar{\mathbb{R}}^+\times\mathbb{R}^{d-1} \quad \forall\tau\in[\tau_1,\tau_2].$$

Obviously, one can assume that $|\tau_2-\tau_1|\ge 1$. Applying the standard simplified Tauberian arguments we obtain estimate (7.1.26) from which estimate (7.1.27) follows. □

Let us now treat the completely elliptic zone:

Theorem 7.1.4. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9), (7.1.10) *and* (7.1.12) *be fulfilled. Let Q_i and ψ_i be the same as in Theorem 7.1.1.*

Let us assume that condition (7.1.18) *is fulfilled and that boundary problem is elliptic at the domain in question:*

$$\|\eth b(x', D_{x_1}, \xi')v\| \ge \epsilon_0\|v\|_+ \quad \forall v \in \mathscr{S}(\bar{\mathbb{R}}^+): \quad \big(a(0, x', D_{x_1}, \xi')v - \tau\big) = 0 \quad \forall (x', \xi') \in (\mathrm{supp}(q_1) \cup \mathrm{supp}(q_2)) \cap Y \quad \forall \tau \in [\tau_1, \tau_2]. \tag{7.1.30}$$

Then the following estimate holds for $\tau_1', \tau_2' \in [\tau_1, \tau_2]$*:*

$$\|D_{x_1}^j D_{y_1}^k Q_{1x}\psi_1(x)e(., ., \tau_1', \tau_2')\psi_2(y)^t Q_{2y}\| \le C' h^s \big(1 + |\tau_1'| + |\tau_2'|\big)^{\frac{j+k+1}{m}}. \tag{7.1.31}$$

Proof. The proof is similar to the proof of Proposition 4.2.6 but also uses Theorem 3.1.2 (see also the end of the proof of the next Theorem 7.1.5). We leave easy details to the reader. □

Theorem 7.1.5. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9), (7.1.10) *and* (7.1.12) *be fulfilled. Let us assume that*

$$\langle a(x, \xi_1, \xi')v, v\rangle \ge (\epsilon_0|\xi|^m - c)\|v\|^2 \quad \forall x \in B(0,1) \cap X \quad \forall \xi_1 \in \mathbb{R}, \xi' = 0 \quad \forall v \in \mathbb{H} \tag{7.1.32}$$

and that

$$\sum_{1\le j\le m} |\tau|^{-\frac{1}{m}(m_j+\frac{1}{2})}\|\eth b_j(x', D_1, \xi')v\| \ge \epsilon_0\|v\|_+^2 \quad \forall x' \in B(0,1) \cap Y,\ \xi' = 0 \quad \forall \tau \le -c \quad \forall v \in \mathscr{S}(\bar{\mathbb{R}}^+, H):\ (a(0, x', D_1, \xi') - \tau)v = 0. \tag{7.1.33}$$

Assume that Q_i *and* ψ_i *are the same as in Theorem 7.1.1. Then for* $\tau \le -C_1 = C_1(d, c, c_1)$ *the following estimate holds:*

$$\|D_{x_1}^j D_{y_1}^k Q_{1x}\psi_1(x)e(., ., -\infty, \tau)\psi_2(y)^t Q_{2y}\| \le C' h^s |\tau|^{-s}. \tag{7.1.34}$$

Proof. Obviously (7.1.32) and (7.1.33) imply the same conditions for symbols a and b_j from which all the terms not containing ξ_1^m and $\xi_1^{m_j}$ respectively are excluded. Then for these symbols the following estimate holds:

$$\sum_j |\tau|^{\frac{1}{m}(2m-2m_j-1)}\|\bar{\eth} b_j(x', D_1, \xi')v\|^2 + \|(a(0, x', D_1, \xi') - \tau)v\|_+^2 \geq \epsilon_0 \sum_{0\leq k\leq m} |\tau|^{\frac{2(m-k)}{m}}\|D_1^k v\|_+^2 - c|\xi'|^m\|v\|_+^2 \tag{7.1.35}$$

and hence the same estimate holds also for the original symbols a and b_j where now $\xi' \in \mathbb{R}^d$, $\tau \leq -C_1$ and $v \in \mathscr{S}(\bar{\mathbb{R}}^+, \mathbb{H})$ are arbitrary and c, C_1 are increased if necessary. Therefore h-Fourier transform with respect to x' and rescaling with respect to x_1 yield that if a and b_j do not depend on x and $A = a(hD)$, $B = b(hD)$ then

$$\sum_j |\tau|^{\frac{2m-2m_j-1}{m}}\|\bar{\eth} B_j u\|_Y^2 + \|(A-\tau)u\|^2 \geq \epsilon_0 \sum_{0\leq k\leq m} |\tau|^{\frac{2(m-k)}{m}}\|(hD_1)^k u\|_+^2 - c\sum_{|\alpha|\leq m}\|(hD')^\alpha u\|^2 \tag{7.1.36}$$

for $u \in \mathscr{C}_0^K(B(0,1), \mathbb{H})$.

This estimate is obviously preserved when we perturb operators A and B_j by arbitrary bounded lower order terms; moreover, it is preserved when we perturb these operators by operators of the same orders with small coefficients (i.e., with small maxima of the $\mathcal{L}(\mathbb{H}, \mathbb{H})$-norms of the coefficients).

Hence for general operators A and B_j estimate (7.1.36) remains true provided we replace u by $\psi_\nu u$ where $\psi_\nu \in \mathscr{C}_0^K(B(y_\nu, \epsilon))$, $y_\nu \in B(0,1)$ and $\epsilon > 0$ is a small constant. Taking real-valued functions ψ_ν such that $\sum_\nu \psi_\nu^2 = 1$ in $B(0, 1+\frac{\epsilon}{2})$ and summing estimates (7.1.36) for $\psi_\nu u$ with respect to ν we obtain inequality (7.1.36) for u in the general case.

Let us substitute

$$u = \phi\big(\frac{\tau}{L}\big) F_{t\to h^{-1}\tau}\chi_T(t)\bar{\psi}_1 Q_1 \psi_1 v$$

into (7.1.36) where $v = \exp(ih^{-1}tA)w$, $\chi \in \mathscr{C}_0^K([-1,1])$, $\phi \in \mathscr{C}_0^K([-c, -\epsilon_1,])$, $Q_1 = \mathsf{Op}(q_1)$, $q_1 \in \mathsf{S}_{h,\rho,1,K}(\mathbb{R}^{d-1}, \mathbb{C})$ is supported in $\{|\xi'| \leq c_2^{-1}\rho\}$, and $\rho = L^{\frac{1}{M}}$ with an appropriate constant c_2.

Let $\bar{\psi}_1$, $\bar{q}_1$, $\bar{\phi}$ and $\bar{\chi}$ be functions of the same type as ψ_1, q_1, ϕ and χ, equal to 1 in the neighborhoods of the respective supports of the latter functions. Then (7.1.36) yields that for $L \le -C_1$, $TL \ge h$

$$\sum_{0\le k\le m} \|(hD_1)^k \phi\big(\frac{h}{L}D_t\big)\chi_T(t)Q_1\psi_1 v\| \le$$
$$C'hL^{-1}\sum_{0\le k\le m} \|(hD_1)^k \bar{\phi}\big(\frac{h}{L}D_t\big)\bar{\chi}_T(t)\bar{Q}_1\bar{\psi}_1 v\| +$$
$$C'h^sL^{-s}\sum_{0\le k\le m-1} \|(hD_1)^k \bar{\phi}\big(\frac{h}{L}D_t\big)\bar{\chi}_T(t)v\|_{(-m)}$$

where we calculate the $\mathscr{L}^2$-norm with respect to (x,t) everywhere but the last term in which we calculate the $\mathscr{L}^2$-norm with respect to (x_1,t) and the $\mathscr{H}^{(-m)}$-norm with respect to x', which obviously does not exceed

$$C'h^sL^{-s}\Big(\|\bar{\phi}\big(\frac{h}{L}D_t\big)\chi_T(t)v\| + \|A\bar{\phi}\big(\frac{h}{L}D_t\big)\bar{\chi}_T(t)v\|\Big);$$

replacing Av by hD_tv and permuting hD_t with $\bar{\chi}_T(t)$ we obtain that none of these expressions exceeds $C'h^sL^{-s}\|v_0\|$. Thus,

$$\sum_{0\le k\le m} \|(hD_1)^k \phi\big(\frac{h}{L}D_t\big)\chi_T(t)Q_1\psi_1 v\| \le$$
$$C'hL^{-1}\sum_{0\le k\le m} \|(hD_1)^k \bar{\phi}\big(\frac{h}{L}D_t\big)\bar{\chi}_T(t)\bar{Q}_1\bar{\psi}_1 v\| + C'h^sL^{-s}\|w\|.$$

Then a repeated argument yields that

$$\|(hD_1)^j \phi\big(\frac{h}{L}D_t\big)\chi_T(t)Q_1\psi_1 v\| \le C'h^sL^{-s}\|w\|$$

for $j = 0,\dots,m-1$. Then the non-characteristic property of $\partial X = \{x_1 = 0\}$ yields that this estimate holds for all $j \in \mathbb{Z}^+$. Therefore the embedding theorems yield that

$$\|(hD_1)^j \phi\big(\frac{h}{L}D_t\big)\chi_T(t)Q_1\psi_1 v\| \le C'h^sL^{-s}\|w\| \qquad \forall x \in B(0,1).$$

Further, this inequality and the relation between v, w and propagator U imply that

$$\|(hD_{x_1})^j\phi\big(\frac{h}{L}D_t\big)\chi_T(t)Q_{1x}\psi_1(x)f^\dagger U\| \le C'h^sL^{-s}\|f\| \qquad \forall x\in B(0,1)\quad \forall f\in\mathbb{H}$$

where in the left-hand expression the $\mathscr{L}^2$-norm with respect to (y,t) is calculated.

Repeating all these arguments for y instead of x we easily obtain inequality

$$\|(hD_{x_1})^j(hD_{y_2})^k\phi\big(\frac{h}{L}D_t\big)\chi_T(t)Q_{1x}\psi_1(x)f^\dagger U\psi_2(y)^tQ_{2y}\| \le C'h^sL^{-s}\|f\| \qquad \forall x,y\in B(0,1)\quad \forall f\in\mathbb{H}.$$

where in the left-hand expression the $\mathscr{L}^2$-norm with respect to t is calculated. Therefore we arrive to estimate

$$\|F_{t\to h^{-1}\tau}(hD_{x_1})^j(hD_{y_2})^k\chi_T(t)Q_{1x}\psi_1(x)U\psi_2(y)^tQ_{2y}\| \le C'h^s|\tau|^{-s} \qquad \forall x,y\in B(0,1)\quad \forall \tau\le -C_1.$$

The rest of the proof coincides with the end of the proof of Proposition 4.2.8. □

Remark 7.1.6. Note that we have proven this theorem under the restriction $\mathsf{supp}(q_i)\subset\{|\xi'|\le C_0^{-1}|\tau|^{\frac{1}{m}}\}$ which is weaker than $\mathsf{supp}(q_i)\subset\{|\xi'|\le c_1\}$.

The following two statements are similar to Propositions 4.2.9 and 4.2.10 and are proven in the same way (taking into account the proof of Theorem 7.1.5).

Theorem 7.1.7. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9), (7.1.10) *and* (7.1.12) *be fulfilled and let*

$$|\xi|^m\|v\| \le c(\|a(x,\xi)v\|+\|v\|) \qquad \forall x\in B(0,1)\cap X\quad \forall \xi\in\mathbb{R}^d\quad \forall v\in\mathbb{H} \tag{7.1.37}$$

and

$$|\xi'|^m\|v\|_+ \le c(\|a(0,x',D_1,\xi')v\|_+ + \sum_j |\xi'|^{m-m_j-\frac12}\|\mathring{\partial} b_j(x',D_1,\xi')v\| + \|v\|_+) \quad \forall x' \in B(0,1)\cap Y \quad \forall \xi' \in \mathbb{R}^{d-1} \quad \forall v \in \mathscr{S}(\bar{\mathbb{R}}^+,\mathbb{H}). \tag{7.1.38}$$

Let us assume that $Q_i = \mathsf{Op}(q_i)$, $q_i \in \tilde{\mathsf{S}}^{0\prime}_{h,\rho,\gamma,K}$,

$$\rho\gamma \ge h^{1-\delta}\omega^\delta, \qquad \omega \ge 1, \quad \gamma \le 1 \tag{7.1.39}$$

where $\delta > 0$ *is arbitrarily small; let* ψ_1 *and* ψ_2 *be the same as above. Then*

(i) If the symbol q_i *is supported in* $\{|\xi'| \ge \omega\}$ *for some* $i = 1,2$ *then for* $\omega \ge C_0$, $|\tau_1'| + |\tau_2'| \le \epsilon_2\omega^m$, $x, y \in \mathbb{R}^+ \times \mathbb{R}^{d-1}$,

$$\|D^j_{x_1} D^k_{y_1} Q_{1x}\psi_1(x) e(.,.,\tau_1',\tau_2')\psi_2(y)^t Q_{2y}\| \le C' h^s \omega^{-s} \tag{7.1.40}$$

where C *and* C' *include products of the norms of* ψ_i, q_i *(*$i = 1,2$*) in the corresponding spaces and in the case of* C' *these spaces and* C' *itself depend on* s.

(ii) In the general case

$$\|D^j_{x_1} D^k_{y_1} Q_{1x}\psi_1(x) e(.,.,\tau_1',\tau_2')\psi_2(y)^t Q_{2y}\| \le C' h^{-d-j-k}\big(|\tau_1'| + |\tau_2'| + 1\big)^{\frac{d+j+k}{m}}. \tag{7.1.41}$$

(iii) If condition (7.1.32) *is fulfilled then*

$$\|D^j_{x_1} D^k_{y_1} Q_{1x}\psi_1(x) e(.,.,\tau_1',\tau_2')\psi_2(y)^t Q_{2y}\| \le Ch^{1-d-j-k}\big(|\tau_1'| + |\tau_2'| + 1\big)^{\frac{d+j+k-1}{m}} \quad \forall \tau_1' \le -C_0, \tau_2' \le -C_0. \tag{7.1.42}$$

Remark 7.1.8. Obviously, under condition (7.1.37) it is sufficient to check condition (7.1.38) only for $v \in \mathscr{S}(\bar{\mathbb{R}}^+,\mathbb{H})$ such that $a(0,x'D_1,\xi')v = 0$.

Theorem 7.1.9. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9), (7.1.10), (7.1.12), (7.1.37) *and* (7.1.38) *be fulfilled.*

Further let conditions (7.1.32) *and* (7.1.33) *be fulfilled for all* $\xi \in \mathbb{R}^d$ *and* $\xi' \in \mathbb{R}^{d-1}$ *respectively*[3]. *Furthermore, let* Q_i *and* ψ_i *be the same as in Theorem 7.1.7. Then*

(i) For $\tau \le -C_0$ *estimate* (7.1.28) *holds.*

(ii) Moreover, if q_i *is supported in* $\{|\xi'| \ge \omega\}$ *for some* $i = 1, 2$ *then estimate* (7.1.28) *remains true with an additional factor* ω^{-s} *in the right-hand expression.*

(iii) In the general case

$$\|D^j_{x_1} D^k_{y_1} Q_{1x}\psi_1(x) e(.,.,-\infty,\tau)\psi_2(y)^t Q_{2y}\| \le Ch^{d-j-k}(|\tau|+1)^{\frac{d+j+k}{m}}. \tag{7.1.43}$$

Remark 7.1.10. (i) Condition (7.1.37) means exactly that the senior symbol[4] of a is elliptic and condition (7.1.38) means exactly that the senior symbols of a, $b_1, \dots, b_l$ satisfy the Shapiro-Lopatinskii condition.

(ii) If (7.1.38) holds then condition (7.1.33) for all ξ' means exactly that the bottom of the spectrum of the operator $a(0, x', D_1, \xi')$ on $\mathscr{L}^2(\mathbb{R}^+, \mathbb{H})$ with the boundary condition $b(x', D_1, \xi')v = 0$ is not less than $\bigl(\epsilon_0^{-1}|\xi'|^m - C_0\bigr)$.

7.1.3 Operators with Minimal Smoothness Conditions

On the following step of our analysis we will prove assertions similar to Propositions 4.2.11 and 4.2.12, i.e., obtain estimates under minimal restrictions[5] on smoothness:

Theorem 7.1.11. *Assume that conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$ *with* $K = \max(\frac{d}{2}+1, m) + n$, (7.1.9), (7.1.10), (7.1.14), (7.1.37) *and* (7.1.38) *are fulfilled. Then*

[3] That means exactly that the operator $a(0, x', D_1, \xi')$ in $\mathscr{L}^2(\bar{\mathbb{R}}^+, \mathbb{H})$ with the boundary condition $\eth b(x', D_1, \xi')v = 0$ is semibounded from below uniformly with respect to (x', ξ').

[4] I.e., the higher degree homogeneous symbol.

[5] Later in Section 7.5 we will apply different approaches (partly similar to those of Section 4.7) to consider even far less regular case.

(i) The following estimate holds:

$$\|D_x^\alpha D_y^\beta e(x,y,\tau_1',\tau_2')\| \le C'' h^{-d-|\alpha|-|\beta|}\big(1+|\tau_1'|+|\tau_2'|\big)^{\frac{1}{m}(d+|\alpha|+|\beta|)} \quad \forall x,y\in B(0,1-\epsilon) \quad \forall \alpha,\beta : |\alpha|\le n, |\beta|\le n. \tag{7.1.44}$$

(ii) Moreover, if condition

$$\|(a(x,\xi)-\tau)v\| \ge \epsilon_0\big(|\xi|^m+\omega\big)\|v\| \quad \forall x\in B(0,1)\cap X \quad \forall \xi\in\mathbb{R}^d \quad \forall v\in\mathbb{H} \quad \forall \tau\in[\tau_1,\tau_2] \tag{7.1.45}$$

is fulfilled with $\omega = |\tau|+1$ then estimate

$$\|D_x^\alpha D_y^\beta e(x,y,\tau_1',\tau_2')\| \le C'' h^{-d-|\alpha|-|\beta|}\big(1+|\tau_1'|+|\tau_2'|\big)^{\frac{1}{m}(d+|\alpha|+|\beta|-1)}\big(1+\frac{1}{h}(x_1+y_1)\big)^{-s} \tag{7.1.46}$$

holds with the same x, y, α, β as before and with $\tau_1',\tau_2'\in[\tau_1,\tau_2]$;

(iii) Moreover, if condition (7.1.45) *is fulfilled and*

$$\|(a(0,x',D_1,\xi')-\tau)v\|_+ + \sum_j \big(|\xi'|+\omega^{\frac{1}{m}}\big)^{m-m_j-\frac{1}{2}}\|\mathfrak{d}b_j(x',D_1,\xi')v\| \ge \epsilon_0(|\xi'|^m+\omega)\|v\|_+ \quad \forall x'\in B(0,1)\cap Y \quad \forall \xi'\in\mathbb{R}^{d-1} \quad \forall v\in\mathscr{S}(\bar{\mathbb{R}}^+,\mathbb{H}) \quad \forall \tau\in[\tau_1,\tau_2] \tag{7.1.47}$$

then estimate

$$\|D_x^\alpha D_y^\beta e(x,y,\tau_1',\tau_2')\| \le C' h^s \omega^{-s} \tag{7.1.48}$$

holds with the same x, y, α, β as before and with $\tau_1',\tau_2'\in[\tau_1,\tau_2]$.

Theorem 7.1.12. *Assume that conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$ *with $K=\max(\frac{d}{2}+1,m)+n$,* (7.1.9), (7.1.10) *and* (7.1.14) *are fulfilled. Further, let the following conditions be fulfilled:*

$$\epsilon_0|\xi|^m\|v\|^2 \le \big(\langle a(x,\xi)v,v\rangle + c\|v\|^2\big) \quad \forall x\in B(0,1)\cap X \quad \forall \xi\in\mathbb{R}^d \quad \forall v\in\mathbb{H} \tag{7.1.49}$$

and

$$\epsilon_0|\xi'|^m\|v\|^2_+ \le \big(\langle a(0,x',D_1\xi')v,v\rangle_+ + c\|v\|^2_+\big) \tag{7.1.50}$$
$$\forall x'\in B(0,1)\cap Y \quad \forall \xi'\in\mathbb{R}^{d-1} \quad \forall v\in \mathscr{S}(\bar{\mathbb{R}}^+,\mathbb{H})\colon\ \eth b(x'D_1,\xi')v=0.$$

Then estimate

$$\|D_x^\alpha D_y^\beta e(x,y,-\infty,\tau)\| \le \begin{cases} C''h^s(1+|\tau|)^{-s} & \forall \tau\le -C_0\\ C''h^{-d-|\alpha|-|\beta|}(1+|\tau|)^{\frac{1}{m}(d+|\alpha|+|\beta|)} \end{cases} \tag{7.1.51}$$

holds with the same x, y, α, β as before.

Proof of Theorems 7.1.11 and 7.1.12. Let us note first of all that in the framework of Theorem 7.1.11(i)

$$\sum_{|\alpha|\le n}\|(hD)^\alpha v\| \le \tag{7.1.52}$$
$$C\Big(\sum_{|\beta|\le n-m}\|(hD)^\beta Av\| + \|v\| + \sum_j \sum_{|\beta|\le n-m_j-1} h^{\frac12}\|(hD')^\beta B_j v\|_{Y,\frac12}\Big)$$
$$\forall v\in \mathscr{C}_0^K(B(0,1),\mathbb{H})$$

where

$$\|v\|_{Y,\frac12} \coloneqq \inf\{\sum_{1\le k\le d}\|hD_k w\| :\quad \eth w = v\} \tag{7.1.53}$$

and $m\le n\le K$; this estimate is similar to (4.2.54).

Estimate (7.1.52) can be proven in the constant coefficient case by means of the Fourier transform with respect to x' and then it could be extended to the general case by means of a partition of unity. Then we easily obtain (see the proof of Proposition 4.2.11) that estimate (7.1.52) remains true for $v\in \mathscr{C}^n(B(0,1),\mathbb{H})$ provided that in the left and right-hand expressions the norms on $B(0,1-\epsilon)\cap X$ and $B(0,1-\frac{\epsilon}{2})\cap X$, $B(0,1-\frac{\epsilon}{2})\cap Y$ are calculated.

Iterating if necessary we obtain for $n\in m\mathbb{Z}^+$, $n\le K$ estimate

$$\sum_{|\alpha|\le n}\|(hD)^\alpha v\|_{B(0,1-\epsilon)} \le C\big(\|A^{\frac{n}{m}}v\|_{B(0,1-\epsilon')} + \|v\|_{B(0,1-\epsilon')}\big) \tag{7.1.54}$$
$$\forall v\in \mathfrak{D}(A^{\frac{n}{m}}).$$

On the other hand, for $0 \le n \le m$, (7.1.52) yields the inequality

$$\sum_{|\alpha|\le n} \|(hD)^\alpha v\|_{B(0,1-\epsilon)} \le \tag{7.1.55}$$
$$C\|v\|^{1-\frac{n}{m}}_{B(0,1-\frac{\epsilon}{2})} \cdot \|Av\|^{\frac{n}{m}}_{B(0,1-\frac{\epsilon}{2})} + C\|v\|_{B(0,1-\frac{\epsilon}{2})} \qquad \forall v \in \mathfrak{D}(A).$$

Substituting $E(\tau_1', \tau_2')v$ for v we obtain from (7.1.54) and (7.1.55) that the norm of the operator

$$(hD)^\alpha E(\tau_1', \tau_2') : \mathscr{L}^2(X, \mathbb{H}) \to \mathscr{L}^2(B(0, 1-\epsilon) \cap X, \mathbb{H})$$

does not exceed $C(|\tau_1'| + |\tau_2'| + 1)^{\frac{|\alpha|}{m}}$ for all $\alpha : |\alpha| \le K$. The rest of proof of Theorem 7.1.11(i) repeats the end of the proof of Proposition 4.2.11.

In a similar way the estimate

$$\|(hD)^\alpha F_{t\to h^{-1}\tau}\chi_T(t)v\|_{B(0,1-\epsilon)} \le C''T(|\tau|+1)^{\frac{|\alpha|}{m}}\|w\| \tag{7.1.56}$$

can be proven for $v = e^{ih^{-1}tA}w$, $w \in \mathfrak{D}(A^{\frac{n}{m}})$, $|\alpha| \le n$ with $n \in m\mathbb{Z}^+$, $n \le K$ where $T \ge h^{-1}$ and $\chi \in \mathscr{C}_0^\infty([-1,1])$ is fixed.

Starting from this estimate one can prove Theorems 7.1.11(iii) and 7.1.12 in the same way as we proved Propositio 4.2.11(ii). Namely, in estimates (7.1.52) and (7.1.54) for $\tau \in [\tau_1, \tau_2]$, the term $\|v\|$ in the right hand expression is replaced by $(1+|\tau|)^{-s}h^s\|v\|$ and A is replaced by $A - \tau$; all the other arguments repeat those of the proof of Proposition 4.2.11(ii).

Let us now prove Theorem 7.1.11(ii). Let us first note that without any loss of the generality we can assume that $|\tau_1| + |\tau_2| \le c$. In fact, for $d \ge 2$ it is sufficient to prove estimate (7.1.45) under this restriction or the restriction $c\epsilon_0 \le \tau_1/\tau_2 \le c$, $|\tau_j| \ge 1$; the general case can be reduced to these special cases by division of the interval $[\tau_1, \tau_2]$ into intervals $[-2^l, -2^{l-1}]$ and two other intervals, the first of which satisfies the first restriction and the second of which satisfies the second restriction.

However if $\epsilon_0\omega \le \pm\tau_j \le c\omega \quad \forall j = 1, 2$ with $\omega \ge 1$ then dividing A by ω and replacing τ_j and h by $\tau_j\omega^{-1}$ and $h\omega^{-\frac{1}{m}}$ respectively we reduce the second case to the first one. On the other hand, one can easily see that if $d = 1$, $|\tau| \ge C_0$ and (7.1.45) holds then (7.1.47) also holds and hence it is sufficient for us to treat the case $|\tau_1| + |\tau_2| \le c$.

But if condition (7.1.45) is fulfilled then

$$\sum_{|\alpha|\le n} \|(hD)^{\alpha} u\| \le C \sum_{|\beta|\le n-m} \|(hD)^{\beta}(A-\tau)u\| + Ch^{s}\|u\| \qquad \forall \tau \in [\tau_1,\tau_2] \quad \forall u \in \mathscr{C}_0^{n}\big(B(0,1)\cap\{x_1 \ge -\epsilon\},\mathbb{H}\big) \tag{7.1.57}$$

where here (and only here) we calculate the $\mathscr{L}^2$-norms on $B(0,1)$ instead of its intersection with X. Let us substitute here u by $\phi(x_1\nu^{-1})u$ where $\phi \in \mathscr{C}^{\infty}(\mathbb{R})$, $\phi(t)=1$ for $t \ge 1$, $\phi(t)=0$ for $t \le 1-\epsilon$ and $\nu \in [h,1]$ is arbitrary; we then obtain inequality

$$\sum_{|\alpha|\le n} \|(hD)^{\alpha} u\|_{X_\nu} \le C \sum_{|\beta|\le n-m} \|(hD)^{\beta}(A-\tau)u\|_{X_{\nu(1-\epsilon)}} + Ch\nu^{-1} \sum_{|\beta|\le n-1} \|(hD)^{\beta} u\|_{X_{\nu(1-\epsilon)}}$$

where $X_\eta = \{x, x_1 \ge \eta\}$. Since $\epsilon > 0$ is arbitrary, then iterating this inequality we obtain another one:

$$\sum_{|\alpha|\le n} \|(hD)^{\alpha} u\|_{X_\nu} \le C \sum_{|\beta|\le n-m} \|(hD)^{\beta}(A-\tau)u\|_{X_{\nu(1-\epsilon)}} + Ch^{s}\nu^{-s} \sum_{|\beta|\le n-1} \|(hD)^{\beta} u\|_{X_{\nu(1-\epsilon)}}; \tag{7.1.58}$$

moreover, standard arguments yield that we can take $u \in \mathscr{C}^{n}((B(0,1),\mathbb{H})$ but in this case the norms in the left and right-hand expressions should be calculated on $B(0,1-\epsilon)\cap X_\nu$ and $B(0,1-\frac{\epsilon}{2})\cap X_{\nu(1-\epsilon)}$ respectively.

Further, let us substitute into this inequality $u = F_{t\to h^{-1}\tau}\chi_T(t)v$ with $v = e^{ih^{-1}t}Aw$ and let us note that $(A-\tau)u = ihT^{-1}u_1$ with $u_1 = F_{t\to h^{-1}\tau}\chi_T'(t)v$ where χ' is the derivative of χ. Applying this inequality to u_1, etc., we finally obtain that

$$\sum_{|\alpha|\le n} \|(hD)^{\alpha} F_{t\to h^{-1}\tau}\chi_T(t)v\|_{B(0,1-\epsilon)\cap X_\nu} \le Ch^{s}\nu^{-s} \sum_{|\beta|\le n-1} \|(hD)^{\beta} F_{t\to h^{-1}\tau}\bar{\chi}_T(t)v\|_{B(0,1-\frac{\epsilon}{2})\cap X_{\frac{\nu}{2}}} \le Ch^{s}\nu^{-s}T\|w\|$$

where $\bar{\chi} \in \mathscr{C}_0^\infty([-2,2])$ is equal to 1 on $[-\frac{3}{2}, \frac{3}{2}]$ and we used (7.1.57). Then embedding theorems imply that

$$\|(hD)^\alpha F_{t\to h^{-1}\tau}\chi_T(t)v\| \le Ch^{-\frac{d}{2}+s}T\nu^{-s}\|w\| \\ \forall x \in B(0,1-\epsilon) : x_1 \ge \nu \quad \forall \tau \in [\tau_1,\tau_2] \quad \forall \alpha : |\alpha| \le n \quad \forall T \ge \nu$$

where in the left-hand expression the norms in $\mathbb{H}$ are calculated. Since w is arbitrary we obtain the following estimate

$$\|(hD_x)^\alpha F_{t\to h^{-1}\tau}\chi_T(t)f^\dagger U(x,y,t)\| \le Ch^{-\frac{d}{2}+s}T\nu^{-s}\|f\| \\ \forall x \in B(0,1-\epsilon) : x_1 \ge \nu \\ \forall \tau \in [\tau_1,\tau_2] \quad \forall \alpha : |\alpha| \le n \quad \forall T \ge \nu \quad \forall f \in \mathbb{H} \tag{7.1.59}$$

where in the left-hand expression the $\mathscr{L}^2$-norm with respect to y is calculated.

Starting with estimates (7.1.59) and

$$\sum_{|\alpha|\le n, |\beta|\le k} \|(hD_x)^\alpha (hD_y)^\beta F_{t\to h^{-1}\tau}\chi_T(t)f^\dagger U(x,y,t)\| \le \\ Ch^{-\frac{d}{2}}(|\tau|+1)^{\frac{1}{m}(d+|\alpha|+|\beta|)}\|f\| \\ \forall x \in B(0,1-\epsilon) : x_1 \ge \nu \quad \forall \tau \in \mathbb{R} \quad \forall T \ge \nu \quad \forall f \in \mathbb{H} \tag{7.1.60}$$

(where again in the left-hand expression the $\mathscr{L}^2$-norm with respect to y is calculated) and repeating the same arguments with y instead of x we obtain that

$$\|(hD_x)^\alpha (hD_y)^\beta F_{t\to h^{-1}\tau}\chi_T(t)U(x,y,t)\| \le Ch^{-d+s}T\nu^{-s} \\ \forall x,y \in B(0,1-\epsilon) : x_1 \ge \nu, y_1 \ge \nu \quad \forall \tau \in [\tau_1,\tau_2] \quad \forall T \ge \nu \\ \forall \alpha,\beta : |\alpha| \le n, |\beta| \le n.$$

Restricting to $x = y$ and $\alpha = \beta$ and applying the standard Tauberian arguments we obtain estimate (7.1.46) in this case; then the estimate also holds without the restriction due to the arguments used in the proof of estimate (4.2.53). □

7.1.4 Estimates for the Schrödinger Operator

One of the most important assertions of Subsection 7.1.2 from the point of view of applications is Theorem 7.1.7 which permits cutting with respect to

ξ' (for $|\tau| \le c$) taking into account only the zone $\{|\xi'| \le C_0\}$. For this we were forced to assume that the operator and the boundary value problem are elliptic in the classical sense. Let us demonstrate that in a certain special case one can weaken this restriction. Let us treat the Schrödinger operator (5.3.1) satisfying $(5.3.6)_{1-3}$ and (5.3.7).

Let us choose a coordinate system in a neighborhood of ∂X in which x_1 is the Riemannian distance in X from x to Y corresponding to the Riemannian metric g^{jk}; in this system $g^{1k} = \delta_{1k}$. Using gradient transform we can reduce the general case to $V_1 = 0$. So we treat operator

$$A = (hD_1)^2 + A'(x', hD', h) = (hD_1)^2 + \sum_{2\le j,k\le d} (hD_j - V_j) g^{jk} (hD_k - V_k) + V; \tag{7.1.61}$$

and assumption (5.3.7) becomes

$$\sum_{2\le j,k\le d} g^{jk}\xi'_j\xi'_k \ge \epsilon_0 |\xi'|^2. \tag{7.1.62}$$

Let us consider the boundary operator

$$B = -i\alpha(x')hD_1 + M(x', hD') + \beta(x') + h\beta'(x'), \qquad M(x',\xi') = \sum_{2\le j\le d} m^j(x')(\xi_j - V_j). \tag{7.1.63}$$

One can see easily that the self-adjointness of A (with the boundary condition $Bu = 0$) yields that functions $\alpha^{-1}m^j$ and $\alpha^{-1}\beta$ are real-valued (at points where $\alpha \ne 0$). Let us assume that

(7.1.64) α, β, m^j are real-valued functions.

Proposition 3.1.11 yields that if $(A-\tau)v = 0$ and $Q = \mathsf{Op}(q)$, $q \in \mathsf{S}'_{h,\rho,1,K}$ with $\rho \ge C_0$ and if q is supported in $\{\epsilon_0\rho \le |\xi'| + |\tau|^{\frac12} \le c\rho\}$ and if *either* $|\xi'| \ge C_0|\tau|^{\frac12}$ on $\mathsf{supp}(q)$ *or* $\tau \le 0$ then

$$\|Q\eth(ihD_1 + L)v\| \le C'\rho^{-s}h^s\|v\|$$

where $L = \mathsf{Op}(\ell)$, $\ell \in \tilde{\mathsf{S}}^{1\prime}_{h,K}$ does not depend on Q and its principal symbol equals

$$\ell_0 = (a'(x',\xi') - \tau)^{\frac12}, \qquad a'(x',\xi') = \sum_{2\le j,k\le d} g^{jk}(\xi_j - V_j)(\xi_k - V_k). \tag{7.1.65}$$

Therefore in the zone $\Omega = \{|\xi'| \ge C_0(|\tau|+1)\} \cup \{\tau \le -C_0\}$ the boundary condition $\mathfrak{d}Bv = 0$ is equivalent to the condition $\tilde{B}\mathfrak{d}v = 0$ where

$$\tilde{B} = \alpha L + M + \beta + h\beta'. \tag{7.1.66}$$

It is easy to see that for $d \ge 3$ the Shapiro-Lopatinskii condition means exactly that

$$|\alpha| \ge \Big(\sum_{2\le j,k\le d} g_{jk} m^j m^k\Big)^{\frac{1}{2}} + \epsilon_0 \tag{7.1.67}$$

where (g_{jk}) is the tensor inverse to (g^{jk}).

However in the case $d = 2$ this condition is stronger than the Shapiro-Lopatinskii condition which in this case means exactly that

$$|\alpha \pm \sqrt{g}_{22} m^2| \ge \epsilon_0 \tag{7.1.68}$$

for both signs $\pm$; moreover, speaking about this condition we assume that $|\alpha| \ge \epsilon_0$. We replace condition (7.1.67) or (7.1.68) by the pair of conditions

$$\alpha \ge (1+\epsilon_0)\Big(\sum_{2\le j,k\le 2} g_{jk} m^j m^k\Big)^{\frac{1}{2}}, \tag{7.1.69}_1$$

and

$$\beta \ge \epsilon_0. \tag{7.1.69}_2$$

Let us note that $(7.1.69)_2$ and (7.1.64) provide (7.1.11). Moreover, $(7.1.69)_{1,2}$ and (7.1.64) imply that in Ω

$$\tilde{B}_0(x',\xi',\tau) \ge \epsilon_1 \alpha(x')\big(|\xi'| + |\tau|^{\frac{1}{2}}\big) + \epsilon_1$$

with $\epsilon_1 = \epsilon_1(d, c, \epsilon_0) > 0$.

We need the following assertion:

Lemma 7.1.13. *Let conditions* (7.1.61)–(7.1.64), $(7.1.69)_{1,2}$ *and* $(7.1.4)_{1,2}$ *be fulfilled. Let* $Q = q(hD')$ *with* $q \in \mathsf{S}'_{h,\rho,1,K}$ *supported in*

$$\{\epsilon_0\rho \le |\xi'| + |\tau|^{\frac{1}{2}} \le c\rho\} \cap \Omega;$$

moreover, let Q' *and* q' *be an operator and symbol of the same nature, with* $q' = 1$ *in the* $\epsilon\rho$*-neighborhood of* $\mathsf{supp}(q)$*. Finally let* $\psi, \psi' \in \mathscr{C}_0^K(B(0,1))$ *and assume* ψ' *equals* 1 *in the* ϵ*-neighborhood of* $\mathsf{supp}\,\psi$*. Then*

$$\|Q\psi v\|_Y \le C(\|Q'\tilde{B}\psi' v\|_Y + \rho^{-s}h^s\|\psi' v\|). \tag{7.1.70}$$

where $Y = \partial X$.

Proof. Obviously it is sufficient to prove estimate

$$\|Q\psi v\|_Y \le C\big(\|Q'\tilde{B}\psi' v\|_Y + \rho^{-\frac12}h^{\frac12}\|Q'\psi' v\|_Y + \rho^{-s}h^s\|\psi' v\|\big). \tag{7.1.71}$$

Applying this estimate to Q', ψ' instead of Q, ψ and repeating this process we obtain (7.1.70). We can assume without loss of generality that ψ, ψ', Q, Q' are real-valued.

Then (7.1.64), $(7.1.69)_{1,2}$ and the sharp Gårding inequality yield that

$$\mathsf{Re}(\tilde{B}Q\psi v, Q\psi v)_Y \ge \epsilon_0\|Q\psi v\|_Y^2 - C\rho^{-s}h^s\|\psi' v\|_Y^2$$

and we need to consider

$$\begin{aligned}\mathsf{Re}(\tilde{B}Q\psi v, Q\psi v)_Y = \mathsf{Re}(Q\psi\tilde{B}\psi' v, Q\psi v)_Y + \\ \mathsf{Re}([\tilde{B}, Q]\psi v, Q\psi v)_Y + \mathsf{Re}(Q[\tilde{B}, \psi]\psi' v, Q\psi v)_Y.\end{aligned} \tag{7.1.72}$$

The absolute value of the first term in the right-hand expression does not exceed

$$\|Q\psi v\|_Y \cdot \|Q'\tilde{B}\psi' v\|_Y + C\rho^{-s}h^s\|\psi' v\|_Y^2.$$

One can rewrite the second term in the right-hand expression of (7.1.72) in the form $\frac12\,\mathsf{Re}(\mathcal{K}_1\psi v, \psi v)_Y$ with

$$\mathcal{K}_1 = [Q, [\tilde{B}, Q]] - [\tilde{B}^* - B, Q]Q \in \rho^{-1}h\boldsymbol{\Psi}'_{h,\rho,1,K}$$

uniformly with respect to ρ and hence the absolute value of this term does not exceed

$$C\rho^{-1}h\|Q'\psi' v\|_Y^2 + \rho^{-s}h^s\|\psi' v\|_Y^2. \tag{7.1.73}$$

Finally, the third term in the right-hand expression of (7.1.72) is equal to $\mathsf{Re}(\mathcal{K}_2\psi' v, \psi' v)_Y$ where

$$\mathcal{K}_2 = \psi Q^2[B, \psi] = Q\psi[\tilde{B}, \psi]Q + [\psi, Q][\tilde{B}, \psi]Q + Q\psi[Q, [\tilde{B}, \psi]];$$

here the second and the third terms obviously belong to $\rho^{-1}h\boldsymbol{\Psi}'_{h,\rho,1,K}$ and hence modulo an expression with absolute value not exceeding (7.1.73) the third term in the right-hand expression of (7.1.72) is equal to

$$\mathsf{Re}(\psi[\tilde{B}, \psi]Q\psi' v, Q\psi' v)_Y = \frac12\,\mathsf{Re}(\mathcal{K}_3\psi' v, \psi' v)_Y$$

where

$$\mathcal{K}_3 = [\psi, [\tilde{B}, \psi]] - [\tilde{B}^* - \tilde{B}, \psi] \in \rho^{-1} h \mathbf{\Psi}'_{h,\rho,1,K}.$$

Therefore the absolute value of the third term in the right-hand expression of (7.1.72) also does not exceed (7.1.73). These estimates clearly yield (7.1.71). □

This Lemma 7.1.13, Proposition 3.1.11 and the standard Tauberian technique obviously yield

Theorem 7.1.14. *Let conditions* (7.1.61)–(7.1.64), $((7.1.69)_1)_{1,2}$, $(7.1.4)_{1,2}$ *and* (7.1.5) *be fulfilled. Then statements (i)–(iii) of Theorem 7.1.9 remain true with* $\omega = \rho$.

7.2 Method of Successive Approximations

The goal of this section is the same as the goal of Section 4.3. There is an additional difficulty arising from the fact that there is no mollification with respect to x_1 and y_1 because there is no cutting with respect to ξ_1 and η_1 (so smoothness with respect to x_1 and y_1 should be treated carefully).

7.2.1 Approximating the Free Space Term

It will be convenient for us to represent propagator $U = U(x, y, t)$ as a sum $U = U^0 + U^1$ as was done in Section 3.3; to construct $U^0 = U^0(x, y, t)$ we continue operator A into the domain $\{x_1 \geq -\epsilon\} \cap B(0, 1 - \epsilon)$ with a small enough constant $\epsilon > 0$. Then for U^0 the construction of Subsection 4.3.1 is applicable with the modifications indicated in Subsection 4.3.2 (but the coefficients are bounded operators now) and with the calculations of Subsection 4.3.3. Namely, for U^0 a slightly modified form of Proposition 4.3.7 holds:

Standard Calculations Revised

Proposition 7.2.1. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_1$, (7.1.9) *and* (7.1.10) *be fulfilled. Let* $Q_i = \mathsf{Op}(q_i)$, $q_i \in \mathsf{S}'_{h,K}$ *be supported in* $\{|\xi'| \leq c\}$ *for*

$i = 1, 2$, *and let* $\psi_i \in \mathscr{C}_0^K(B(0, 1-\epsilon))$. *Then*

$$\mathcal{R} := \|D_x^\alpha D_y^\beta \Big(F_{t\to h^{-1}\tau}\chi_T(t) Q'_{1x}\psi_1(x) U^0 \psi_2(y)^t Q'_{2y} - \sum_{0\le n\le N'} h^{-d+n} \iint T\hat{\chi}(\frac{(\tau-\tau')T}{h}) e^{ih^{-1}\times\langle x-y,\xi\rangle} q'_1(x,\xi')\times \mathcal{F}^0_n(y,\tau',\xi)[q'_2(y,\xi')]d\tau' d\xi' \Big)\| \le C' h^s \tag{7.2.1}$$

$$\forall x, y \in \mathbb{R}^d \quad \forall \tau : |\tau| \le c \quad \forall \alpha, \beta : |\alpha| \le r, |\beta| \le r$$

where we recall that

$$\mathcal{F}^0_n(y,\tau',\xi) = \mathsf{Res}_{\mathbb{R}}\, F^0_n(y,\tau',\xi), \tag{7.2.2}$$

$T \in [h^{1-\delta}, h^{\frac12+\delta}]$, $\delta > 0$ *is an arbitrarily small exponent,* r *is arbitrary, and* K *and the constants depend on* r *also.*

Proof. Proposition 4.3.7(ii) yields this estimate for Q'_{1x} and Q'_{2y} replaced by $Q_{1x} = Q'_{1x}Q''_{1x}$ and $Q_{2y} = Q'_{2y}Q''_{2y}$ respectively where $Q''_{1x} = q''_1(hD_{x_1})$, $Q''_{2y} = q''_2(hD_{y_1})$ with $q''_1, q''_2 \in \mathsf{S}_{h,\rho,1,K}(\mathbb{R})$, q'_1 supported in $\{|\xi_1| \le c_1\}$ and with similar q''_2; the constant c_1 will be chosen later. Surely $q'_1(x,\xi')$, $q'_2(x,\xi')$ should be replaced by $q_1(x,\xi)$, $q_2(y,\xi)$ respectively.

On the other hand, the standard elliptic arguments yield that

$$\|D_x^\alpha D_y^\beta \big(F_{t\to h^{-1}\tau}\chi_T(t) Q_{1x}\psi_1(x) U^0 \psi_2(y)^t Q_{2y}\big)\| \le C' h^s \rho^{-s}$$

provided Q_1 and Q_2 have the same structure as before and $q''_i \in \mathsf{S}_{h,K}(\mathbb{R})$ are supported in $\{|\xi_1| \le c\rho\}$ for $i = 1, 2$ and $q''_i \in \mathsf{S}_{h,\rho,1,K}(T^*\mathbb{R})$ is supported in $\{|\xi_1| \ge \epsilon_0\rho\}$ for some $i = 1, 2$ where $\rho \ge c_1$ with an appropriate constant c_1.

Moreover, the regularity property of F^0_n for $|\tau| \le c$, $|\xi_1| \ge c_1\epsilon_0$ and $|\xi'| \le c$ yields that all the other terms in $\mathcal{R}$ vanish.

Summing with respect to an admissible partition of unity on $\mathbb{R}_{\xi_1}$, we obtain estimate (7.2.1). □

Calculating Restriction to the Boundary

Now our goal is to obtain a decomposition for U^1. The first step is to obtain a decomposition for $\eth_x D^j_{x_1} U^{0\pm}$ for $j = 0, \dots, m-1$. For this purpose let us use Proposition 4.3.7(ii) again. However, now we modify the construction of Subsection 4.3.1.

First of all, since we are looking at restriction as $x_1 = 0$ let us freeze the symbol of A at the point $(0, y')$ instead of y as we did before. Then the factor $(x_1 - y_1)$ will be replaced by the factor x_1 which we now move to the left (to $\bar{\partial}_x$) instead of moving it to the right (to $\delta(x-y)$) as was done before with the factor $(x_1 - y_1)$. However the final result remains the same: if the factor x_1 reaches $\bar{\partial}_x$ then the corresponding term vanishes.

Further, now we cut only with respect to ξ', we do not cut with respect to ξ_1. In order to control the smoothness with respect to x_1 and y_1 we apply the construction of Subsection 4.3.2 with $B^{\frac{1}{m}}$ replaced by hD_1 (therefore we need to assume that the extended operator A' satisfies condition (7.1.9) at every point). All other details of the construction are preserved without any change and then the calculations of Subsection 4.3.3 yield the following estimate

$$\begin{aligned}(7.2.3)\quad \mathcal{R}'_{\pm} = \|\bar{\partial}_x D_x^{\alpha} D_y^{\beta}\Big(F_{t\to h^{-1}\tau}\chi_T(t)Q'_{1x}\psi_1(x)U^0\psi_2(y)^t Q'_{2y}\pm \\ \sum_{0\le n\le N'} h^{-d+n}\iint T\hat{\chi}(\frac{\tau' T}{h})e^{ih^{-1}\langle x-y,\xi\rangle}q'_1(x,\xi')\times \\ F_n^1(y,\tau-\tau',\xi)[q'_2(y,\xi')]d\tau' d\xi'\Big)\| \le C' h^s(1+|\tau|)^N\end{aligned}$$

$$\forall x', y' \in \mathbb{R}^{d-1} \quad \forall \tau : \pm \operatorname{Im}\tau < 0 \quad \forall \alpha, \beta : |\alpha| \le r, |\beta| \le r, \alpha_1 + \beta_1 \le m-1$$

where F_n^1 are $2n$-th order differential operators with respect to ξ' with coefficients analytic in $\mathbb{C}_{\mp} \setminus \mathbb{R}$ and $F_0^1 = F_0^0$; the norm in the left-hand expression is the operator norm from $\mathscr{L}^2(\mathbb{R}_{y_1}, \mathbb{H})$ to $\mathbb{H}$ and we assume that $Q'_i = \mathsf{Op}(q'_i)$ with $q'_i \in \mathsf{S}'_{h,K}$ supported in $\{|\xi| \le c\}$ for $i = 1, 2$.

Proposition 7.2.2. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_1$, (7.1.9) *and* (7.1.10) *be fulfilled and let* Q_i, ψ_i *be the same as in Proposition 7.2.1.*

Then estimate (7.2.3) *remains true under the restriction* $\alpha_1 \le m-1$ *instead of the previous restriction* $\alpha_1 + \beta_1 \le m-1$ *provided* $y_1 > 0$ *and in the left-hand expression the operator norm from* $\mathbb{H}$ *to* $\mathbb{H}$ *is calculated.*

Proof. Obviously it is sufficient to prove that this estimate holds for the $\mathcal{L}(\mathbb{H}, \mathscr{L}^2(\mathbb{R}^+, \mathbb{H}))$-norm with the condition $\alpha_1 + \beta_1 \le m-1$ replaced by $\alpha_1 \le m-1$.

If we perform the sandwich procedure of Subsection 4.3.2 then we see that the only terms preventing us from obtaining this estimate are terms which

contain no factor $\bar{G}^{\pm}$, $G^{\pm}$, $\hat{G}^{\pm}$ which are parametrices of $(4.3.8)_{\pm}$-problems for $(hD_t - \bar{A})$, $(hD_t - A')$, $(hD_t - A)$ respectively.

Therefore each of these terms may contain only factors $(\bar{A}+i)^{-1}$, $(A'+i)^{-1}$, $(A+i)^{-p}$ and it must contain at least one copy of the factor $(\bar{A}+i)^{-1}$ and no more than one copy of the factor $(\bar{A}+i)^{-p}$. Further, every factor $(\bar{A}+i)^{-1}$ is to the left of every factor $(A'+i)^{-1}$ and $(A+i)^{-p}$ is to the right of every factor $(A'+i)^{-1}$. Furthermore, these terms contain h-pseudodifferential operators with compact supports with respect to (x,ξ'), functions with compact supports with respect to x and operators hD_t and hD_{x_1}, hD_{y_1}.

One can see easily that all these terms vanish if we sum U^{0+} and U^{0-}. However we need to consider U^{0+} and U^{0-} separately.

Let us replace all copies of the operator D_{y_1} applied to $\delta(x-y)$ by $-D_{x_1}$.

(i) Let us first treat all terms which do not contain $(A+i)^{-1}$. Let us move all the copies of hD_{x_1} from the left to the right by applying the commutation formula

$$[(A'+i)^{-1}, T] = -(A'+i)^{-1}[A', T](A'+i)^{-1};$$

we know that $(\bar{A}+i)^{-1}$ and hD_1 commute. Moreover, if there is a copy of $(hD_1)^k$ with $k \ge m$ near either $(A'+i)^{-1}$ or $(\bar{A}+i)^{-1}$ then (7.1.9) yields that this term equals a sum of terms one of which does not contain a copy of $(A'+i)^{-1}$ or $(\bar{A}+i)^{-1}$ while the other contains hD_1 to a degree not exceeding $m-1$. Therefore we obtain terms of two types as the result of these transformations:

(a) Terms which are products of factors $(hD_1)^j(\bar{A}+i)^{-1}$, $(hD_1)^j(A'+i)^{-1}$ with $j \le m-1$, operators belonging to $\boldsymbol{\Psi}'_{h,K}$, smooth functions and hD_t;

(b) Terms which contain neither $(\bar{A}+i)^{-1}$ nor $(A'+i)^{-1}$.

Furthermore, terms originating from terms which we threw away before contain a factor h^L with arbitrary large L. Then the norms of *these* terms of type (a) do not exceed $C'h^s(1+|\tau|)^N$ because of (7.1.9) and terms of type (b) will vanish for $x_1 \ne y_1$ because they are differential operators with respect to x_1, y_1.

(ii) Let us now treat terms containing $(A+i)^{-p}$; these terms necessarily contain a factor $(A-A')$ as well. Let us recall that there is operator $\psi(x)Q_x\psi(x)$ applied to $\delta(x-y)$; the symbol of this operator is supported

in the vicinity of $(\bar{y}, \bar{\xi}')$. Let us drag this operator to the left; if it meets $(A - A')$ whose symbol is 0 in the vicinity of this point, we get a high degree of h. Thus applying the commutation formula for $(A + i)^{-1}$ and $\psi Q \psi$ we can reduce our analysis to the case in which there is no factor $(A - A')$ but there is a high degree of h. Really, we need a lot of commutations since on each step we get h-pseudodifferential operators (with respect to (x', t)) with symbols supported in vicinity of $(\bar{y}, \bar{\xi}')$.

Let us recall that there are also factors hD_1, hD_t, operators belonging to $\boldsymbol{\Psi}'_{h,K}$ with compactly supported symbols and compactly supported functions. If we consider the commutators of $(A + i)^{-1}$ with ψD_1^q and apply division of ψD_1^q by $(A + i)$ with remainder (we have $\psi \in \mathscr{C}_0^K(B(0, 1 - \epsilon))$ decreasing $\epsilon > 0$ if necessary) we obtain as before three types of terms:

(a) Terms which are products of factors $(hD_1)^j(\bar{A} + i)^{-1}$, $(hD_1)^j(A' + i)^{-1}$, $\psi(hD_1)^j(A + i)^{-1}$ with $j \le m - 1$, operators belonging to $\boldsymbol{\Psi}'_{h,K}$, smooth functions and hD_t;

(b) Terms which are products of factors $(hD_1)^j(\bar{A} + i)^{-1}$, $(hD_1)^j(A' + i)^{-1}$ with $j \le m - 1$, $(A + i)^{-p}$ (only one copy), operators belonging to $\boldsymbol{\Psi}'_{h,K}$, smooth functions and hD_t;

(c) Terms which contain neither $(\bar{A} + i)^{-1}$, nor $(A' + i)^{-1}$, nor $(A + i)^{-1}$.

All these terms contain factor h^L with large L. Let us note that for $0 \le j \le m$ operators $(hD_1)^j(\bar{A} + i)^{-1}$, $(hD_1)^j(A' + i)^{-1}$ and $\psi(hD_1)^j(A + i)^{-1}$ act from $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H})$ ($\mathscr{L}^2(B(0, 1), \mathbb{H})$ in the third case) into $\mathscr{L}^2(\mathbb{R}^d, \mathbb{H})$. Then we can estimate terms of types (a) and (b) while terms of type (c) vanish. □

Remark 7.2.3. Surely one could refer to the theory of h-pseudodifferential operators with the transmission property and prove that $\psi(A + i)^{-p}\psi$ is an operator of this type, but one should first develop this theory!

Corollary 7.2.4. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_1$, (7.1.9) *and* (7.1.10) *be fulfilled; let* Q'_i, ψ'_i *be the same as in Proposition 7.2.1. Then*

$$\mathcal{R}''_{\pm} := \|D_x^{\alpha} D_y^{\beta}\Big(F_{t\to h^{-1}\tau}\chi_T(t)Q'_{1x}\psi_1(x)V^{\pm}\psi_2(y)^t Q'_{2y} - \sum_{0\le n\le N'} h^{-d+n}\iint T\hat{\chi}(\frac{\tau\tau' T}{h})e^{ih^{-1}\langle x-y,\xi\rangle}q'_1(x,\xi')\times F_n^2(y,\tau-\tau',\xi)[q'_2(y,\xi')]\,d\tau' d\xi'\Big)\| \le C' h^s(|\tau|+1)^{N''} \tag{7.2.4}$$

$$\forall x', y' \in \mathbb{R}^{d-1} \quad \forall y_1 > 0 \quad \forall \tau : \pm\tau < 0 \quad \forall \alpha, \beta : |\alpha| \le r, |\beta| \le r$$

where $T \in [h^{1-\delta}, h^{\frac{1}{2}+\delta}]$ *as before,* $V^{\pm} = -\mathfrak{d}_x B(x, hD_x)U^{0\pm}$, *and* F_n^k *are functions of the same type as before; here they are sums of terms*

$$\Big(\prod_{1\le j\le l_n}\big(\tau - a(0,y',\xi)\big)^{-1} p_j(y',\xi)\Big)\cdot\big(\tau - a(0,y',\xi)\big)^{-1} \tag{7.2.5}$$

where p_j *are polynomials with respect to* ξ *the degrees of which with respect to* ξ_1 *do not exceed* $m-1$.

7.2.2 Approximations for the Reflected Wave

Let us calculate $U^{1\pm}$ by the method of successive approximations. For this purpose we write the problem (3.3.26), (3.3.32)–(3.3.33) in the previous notations:

$$(hD_t - A)U^{1\pm} = 0, \tag{7.2.6}$$

$$\mathfrak{d}BU^{1\pm} = -\mathfrak{d}BU^{0\pm}, \tag{7.2.7}$$

$$U^{1\pm}|_{\pm t<0} = 0; \tag{7.2.8}$$

hence

$$(hD_t - A')U^{1\pm} = F^{\pm}, \tag{7.2.9}$$

$$\mathfrak{d}B'U^{1\pm} = -\mathfrak{d}B'U^{0\pm} + f^{\pm} \tag{7.2.10}$$

with

$$F^{\pm} = (A - A')U^{1\pm}, \tag{7.2.11}$$

$$f^{\pm} = -\mathfrak{d}(B - B')(U^{0\pm} + U^{1\pm}). \tag{7.2.12}$$

Therefore

$$(hD_t - \bar{A})U^{1\pm} = F^{\pm} + RU^{1\pm}, \tag{7.2.13}$$

$$\eth\bar{B}U^{1\pm} = -V^{\pm} + \eth R_1 U^{1\pm} + f^{\pm} \tag{7.2.14}$$

where exactly as in Subsubsection *7.2.1.2 Calculating Restriction to the Boundary* $R = A' - \bar{A}$, $R_1 = B' - \bar{B}$, $\bar{A}$ and $\bar{B}$ are operators A' and B' with symbols frozen at the point $(0, y')$, A' and B' are obtained from A and B by cutting outside of a neighborhood of $\mathsf{supp}(q_2')$, and all the operators act with respect to x.

Then (7.2.13), (7.2.14) and (7.2.8) yield that

$$U^{1\pm} = \bigl(\bar{G}^{\pm}R + \bar{G}'^{\pm}\eth R_1\bigr)U^{1\pm} + \bar{G}^{\pm}F^{\pm} + \bar{G}'^{\pm}\bigl(-V^{\pm} + f^{\pm}\bigr). \tag{7.2.15}$$

Furthermore, (7.2.9), (7.2.10), (7.2.8) yield that

$$U^{1\pm} = G^{\pm}F^{\pm} + G'^{\pm}(-V^{\pm} + f^{\pm}) \tag{7.2.16}$$

where $\bar{G}^{\pm}$ and $\bar{G}'^{\pm}$ are parametrices of the problems

$$(hD_t - \bar{A})u = f, \quad \mathsf{supp}\, f \subset \{\pm(t - t_0) \ge 0\}, \tag{7.2.17}$$

$$\eth\bar{B}u = 0, \tag{7.2.18}$$

$$u|_{\pm(t-t_0)<0} = 0 \tag{7.2.19}$$

and

$$(hD_t - \bar{A})u = 0, \tag{7.2.17}$$

$$\eth\bar{B}u = f, \quad \mathsf{supp}\, f \subset \{\pm(t - t_0) \ge 0\}, \tag{7.2.18}$$

$$u|_{\pm(t-t_0)<0} = 0 \tag{7.2.19}$$

respectively, $G^{\pm}$ and $G'^{\pm}$ are defined in the same way for A' and B' instead of $\bar{A}$ and $\bar{B}$ and in what follows we will use $\hat{G}^{\pm}$ and $\hat{G}'^{\pm}$ defined in the same way for A and B.

Iterating (7.2.15) and applying (7.2.16) we obtain that

$$\begin{aligned} U^{1\pm} = -\sum_{0\le n\le N'-1} \bigl(\bar{G}^{\pm}R + \bar{G}'^{\pm}\eth R_1\bigr)^n \bar{G}'^{\pm}\eth B' U^{0\pm} - \\ \bigl(\bar{G}^{\pm}R + \bar{G}'^{\pm}\eth R_1\bigr)^{N'} G'^{\pm}\eth U^{0\pm} + \\ \sum_{0\le n\le N'-1} \bigl(\bar{G}^{\pm}R + \bar{G}'^{\pm}\eth R_1\bigr)^n \bigl(\bar{G}^{\pm}F^{\pm} + \bar{G}'^{\pm}f^{\pm}\bigr) + \\ \bigl(\bar{G}^{\pm}R + \bar{G}'^{\pm}\eth R_1\bigr)^{N'} \bigl(G^{\pm} + G'^{\pm}f^{\pm}\bigr). \end{aligned} \tag{7.2.20}$$

Our goal is to prove that as $|t| \le h^{\frac12+\delta}$ only the first line matters for the final answer.

Let us first treat the first and second lines (the third and fourth lines will be called "extra terms").

For this task we need the commutation relations for $\bar G^{\pm}$ and $\bar G'^{\pm}$ with $(x_j - y_j)$ $(j = 2, \dots, d)$ and x_1 and similar relations for $G^{\pm}$, $G'^{\pm}$. Let us take u supported in $\{t : \pm(t - t_0) \ge 0\}$ and let us consider the equalities

$$\bar P x_j u = x_j \bar P u - [\bar A, x_j]u,$$
$$\eth \bar B x_j u = \eth [\bar B, x_j]u + x_j \eth \bar B u$$

where $\bar P = hD_t - \bar A$ and for $j = 1$ the last term should be skipped; then

$$x_j u = \bar G^{\pm} x_j \bar P u - \bar G [\bar A, x_j]u + \bar P'^{\pm}[\bar B, x_j]u + \bar G'^{\pm} x_j \eth \bar B u$$

where for $j = 1$ the last term should be skipped.

Substituting $u = \bar G^{\pm} v$ or $u = \bar G'^{\pm} w$ with arbitrary v, w supported in $\{t : \pm(t - t_0) \ge 0\}$ we obtain that

$$x_j \bar G^{\pm} = \bar G^{\pm} x_j - \bar G^{\pm}[\bar A, x_j]\bar G^{\pm} + \bar G'^{\pm}\eth[\bar B, x_j]\bar G^{\pm}, \tag{7.2.21}$$

$$x_j \bar G'^{\pm} = -\bar G^{\pm}[\bar A, x_j]\bar G'^{\pm} + \bar G'^{\pm}\eth[\bar B, x_j]\bar G'^{\pm} + \bar G'^{\pm} x_j \tag{7.2.22}$$

where for $j = 2$ one can replace x_j by $x_j - y_j$ and for for $j = 1$ the last term in (7.2.22) should be skipped:

$$x_1 \bar G'^{\pm} = -\bar G^{\pm}[\bar A, x_1]\bar G'^{\pm} + \bar G'^{\pm}\eth[\bar B, x_1]\bar G'^{\pm}. \tag{7.2.23}$$

The same relations hold for $G^{\pm}$ and $G'^{\pm}$.

Let us recall that

$$\begin{aligned}\eth B' U^{0\pm} = \mp i \sum_{0\le n\le N'-1} & \eth B' (\bar G_0^{\pm} R)^n \bar G_0^{\pm} \delta(t)\delta(x-y) \mp \\ & ih \eth B' (\bar G_0^{\pm} R)^{N'} G_0^{\pm} \delta(t)\delta(x-y) + \\ & \sum_{0\le n\le N'-1} \eth B' (\bar G_0^{\pm} R)^n \bar G_0^{\pm} F_0^{\pm} + \eth B' (\bar G_0^{\pm} R)^{N'} \bar G_0^{\pm} F_0^{\pm}\end{aligned} \tag{7.2.24}$$

where $\bar G_0^{\mp}$ and $G_0^{\mp}$ are parametrices of the Cauchy problems (i.e., of problems $(4.3.8)_{\pm}$, $(4.3.8)'_{\pm}$) and $F_0^{\pm} = (A - A')U^{0\pm}$.

Further, let us recall that for $\bar{G}_0^{\mp}$ and $G_0^{\mp}$ the commutation relations (4.3.13) and (4.3.13)$'$ hold. Let us apply commutation relations (4.3.13), (4.3.13)$'$, (7.2.21) and (7.2.22) to the first and second lines in the right-hand expression of (7.2.20); we transfer $(x_j - y_j)$ with $j \ge 2$ and x_1 to the right, i.e. to $B'U^{0\pm}$. When x_1 reaches it the corresponding term vanishes (which is equivalent to the absence of the last term in in (7.2.22) for $j = 1$).

Meanwhile in (7.2.24) we transfer x_1 to the left (i.e., to $\eth$); when x_1 reaches it the corresponding term vanishes; in (7.2.20) and (7.2.24) we transfer $(x_j - y_j)$ with $j \ge 2$ to the right (i.e., to $\delta(x - y)$) with the same result.

Therefore each such factor should be killed this way, and then a factor h arises.

Let us substitute (7.2.24) into (7.2.20) and let us omit all terms containing $F^{\pm}$, $f^{\pm}$, $F_0^{\pm}$ which will be analyzed later (so we include the terms generated by the third line in (7.2.24) in "extra terms").

Let us transfer all factors $(x_j - y_j)$ with $j \ge 2$ and x_1 (or large number of them) in the same way as described above. In addition, let us apply sandwiching procedure to all operators $G^{\pm}$, $\bar{G}^{\pm}$, $G_0^{\pm}$, $\bar{G}_0^{\pm}$; for $G^{\pm}$ and $\bar{G}^{\pm}$ the sandwiching procedure is the same as for $G_0^{\pm}$ and $\bar{G}_0^{\pm}$. Moreover, we can "sandwich" the operators $\bar{G}'^{\pm}$ and $G'^{\pm}$ on their left. In fact, equalities

$$(\bar{A} + i)\bar{G}'^{\pm} = (-hD_t + \bar{A})\bar{G}'^{\pm} + (hD_t + i)\bar{G}'^{\pm} = (hD_t + i)\bar{G}'^{\pm}$$

and $\eth\bar{B}\bar{G}'^{\pm} = I$ yield that

$$\bar{G}'^{\pm} = (hD_t + i)(\bar{A} + i)^{-1}\bar{G}'^{\pm} + \bar{E}' \tag{7.2.25}$$

where $\bar{E}'$ is a parametrix of the problem

$$(\bar{A} + i)u = 0, \qquad \eth\bar{B}u = f$$

and $(\bar{A} + i)^{-1}$ means a parametrix of the problem

$$(\bar{A} + i)u = f, \qquad \eth\bar{B}u = 0$$

as it was in the sandwiching procedure for $\bar{G}^{\pm}$. The same method is also applicable to $G'^{\pm}$.

Furthermore, we also have the procedure of division by $\bar{A}$ (or A) with the remainder which we apply to $(hD_1)^k$ with $k \ge m$. Namely, if we have a factor $(hD_1)^k\bar{G}_0^{\pm}$ then we can transform this factor into a sum of factors of

the same type with $k \le m-1$ and an operator which is h-differential with respect to x_1 and h-pseudodifferential with respect to x'. The same is true for $\bar{G}^{\pm}$, $\bar{G}_0^{\pm}$, $G^{\pm}$ and for operators $\bar{G}_0^{\pm}$, $G_0^{\pm}$ staying to the left of $(hD_1)^k$.

Moreover, we can transform operator $(hD_1)^k \bar{G}'^{\pm}$ into a sum of operators of the same type with $k \le m-1$ multiplied on the left by operators belonging to $\boldsymbol{\Psi}'_{h,K}$.

Let us note that if between the rightmost copy of $\eth$ and $\delta(x-y)$ there is no parametrix[6)] then the corresponding term vanishes for $y_1 > 0$. Therefore treating the commutators of $(hD_1)^k$ with $(A'+i)_0^{-1}$ in the same way as before we conclude that to the right of the rightmost copy of $\eth$ we can obtain a product of operators $(hD_1)^k(A'+i)_0^{-1}$, $(hD_1)^k(\bar{A}+i)_0^{-1}$ with $k \le m-1$, $G_0^{\pm}$, $\bar{G}_0^{\pm}$, h-pseudodifferential operators with respect to x' with symbols compactly supported with respect to (x,ξ'), and compactly supported functions (even if we have applied $(hD_{y_1})^k$ with arbitrarily large k before this procedure).

Similarly, if we apply $(hD_{x_1})^k$ with arbitrarily large k we can provide that to the left of the rightmost copy of $\eth$ there is a product of operators $(hD_1)^k(A'+i)^{-1}$, $(hD_1)^k(\bar{A}+i)^{-1}$ with $k \le m-1$, $h^{\frac12}\eth(hD_1)^k(A'+i)^{-1}$, $h^{\frac12}\eth(hD_1)^k(\bar{A}+i)^{-1}$, $h^{-\frac12}(hD_1)^k E'$, $h^{-\frac12}(hD_1)^k \bar{E}'$, $\eth(hD_1)^k \bar{E}'$, $\eth(hD_1)^k E'$ with $k \le m-1$, $\bar{G}^{\pm}$, $G^{\pm}$, hD_t, h-pseudodifferential operators with respect to x' with symbols compactly supported with respect to (x,ξ') and compactly supported functions.

Further, the total quantity of copies of $\bar{G}^{\pm}$, $G^{\pm}$, $\bar{G}_0^{\pm}$ and $G_0^{\pm}$ in every product does not exceed $(2\nu+1)$ where ν is the degree of h gained in the commutation process. All these operators, excluding hD_t, $\bar{G}^{\pm}$, $G^{\pm}$, $\bar{G}_0^{\pm}$ and $G_0^{\pm}$, have operator norms from $\mathscr{L}^2(Z,.)$ to $\mathscr{L}^2(Z',.)$ not exceeding C' where Z and Z' are corresponding domains from the following list: $\mathbb{R}^d$, $\mathbb{R}^{d-1}$, $\bar{\mathbb{R}}^+ \times \mathbb{R}^{d-1}$.

Moreover, the operator norms of $\bar{G}^{\pm}$, $G^{\pm}$, $\bar{G}_0^{\pm}$ and $G_0^{\pm}$ in $\mathscr{L}^2([-T,T]\times Z)$ do not exceed $C'h^{-1}T$. Therefore the norm of the term with gained h^{ν} does not exceed $Ch^{-d+\nu}(h^{-1}T)^{2\nu+1}$ and in particular

(7.2.26) All terms which contain neither $F_0^{\pm}$ nor $F^{\pm}$ nor $f^{\pm}$ and contain either $G^{\pm}$ or $G'^{\pm}$ or terms of the decomposition of $\bar{A}-A'$ or $\bar{B}-B'$ with $x_1^{\alpha_1}(x'-y')^{\alpha'}h^{\nu}$ with $|\alpha|+\nu \ge N$ are negligible as $T \in [h^{1-\delta}, h^{-\frac12}]$;

[6)] I.e., no operator $G_0^{\pm}$, $\bar{G}^{\pm}$, $(A'+i)_0^{-1}$, $(\bar{A}+i)_0^{-1}$; there can be no other parametrix at this place and the index "0" means that the parametrix is constructed in $\mathbb{R}^d$.

we say that *a term is negligible* if after applying $Q'_{1x}\psi_1(x)(hD_{x_1})^j$ and $Q'_{2y}\psi_2(y)(hD_{y_1})^j$ to it with $j,k\le s$ the corresponding norms will be less than $C'h^s$ where s is arbitrarily large and $N'=N'(d,m,s)$.

Let us consider terms originating from $F_0^{\pm}$, $F^{\pm}$ and $f^{\pm}$ (we called them "extra terms" and skipped so far). However, we change the first step of our construction slightly. Namely, we write the problems for $U^{0\pm}$ and $U^{1\pm}$ in the form

$$(hD_t-A')\psi_4U^{0\prime\pm}=\mp ih\delta(t)\delta(x-y)\psi_4(x)+F_0^{\pm},$$
$$(hD_t-A')\psi_4U^{1\prime\pm}=F^{\pm},$$
$$\eth B'\psi_4U^{1\prime\pm}=-\eth B'\psi_4U^{0\prime\pm}+f^{\pm}$$

where now

$$F_0^{\pm}=\psi_4(A-A')\psi_5U^{0\pm}-[A,\psi_4]\psi_5U^{0\pm},$$
$$F^{\pm}=\psi_4(A-A')\psi_5U^{1\pm}-[A,\psi_4]\psi_5U^{1\pm},$$
$$f^{\pm}=\eth\psi_4(B-B')\psi_5(U^{0\pm}+U^{1\pm})+\eth[B,\psi_4](U^{0\pm}+U^{1\pm}).$$

Then when we commute h-pseudodifferential operators with $\bar G^{\pm}$ and $G^{\pm}$, sandwich and divide with the remainder operators $(hD_1)^k$ with $k\ge m$ by A' (or $\bar A$) we obtain[7] from $F_0^{\pm}$, $F^{\pm}$ and $f^{\pm}$ terms which after multiplication by $Q'_{1x}\psi_1(x)$ [8] are of one of the following forms:

(a) $(hD_t)^{N'''}\mathcal{K}^{\pm}(hD_1)^j\psi_5U^{1\pm}$ with $j\le m-1$;

(b) $(hD_t)^{N'''}\mathcal{K}'^{\pm}\eth(hD_1)^j\psi_5U^{i\pm}$ with $i=0,1$ and $j\le m-1$

where the operator norms of the operators

$$\left.\begin{aligned}&\mathcal{K}^{\pm}:\mathscr{L}^2\bigl(\mathbb{R}^+\times[-T,T],\mathscr{H}^{-\mu}(\mathbb{R}^{d-1},.)\bigr)\\ &\mathcal{K}'^{\pm}:\qquad\mathscr{L}^2\bigl([-T,T],\mathscr{H}^{-\mu}(\mathbb{R}^{d-1},.)\bigr)\end{aligned}\right\}\to\mathscr{L}^2\bigl(\mathbb{R}^+\times[-T,T],\mathscr{H}^{\mu}(\mathbb{R}^{d-1},.)\bigr)$$

will be less than $C'h^{\mu}$ where μ is arbitrary and does not depend on N' (but now K and N''' depend on N' and μ).

On the other hand, the following lemma is a consequence of the proof of Theorem 7.1.1.

---

[7] Even if we apply $(hD_{x_1})^k$ with arbitrarily large k before this procedure.

[8] Let us recall that $Q'_1=\mathsf{Op}(q'_1)$ where $\mathsf{supp}\,q'_1$ does not intersect the support of $(A'-A)$.

Lemma 7.2.5. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_1$, (7.1.9) *and* (7.1.10) *be fulfilled and let ψ_i be the same as before. Then*

$$\|\psi_1(x)(hD_{x_1})^j(hD_{y_1})^k\psi_2(y)U^{1\pm}\| \le C'h^{-L},$$
$$\|\eth_x\psi_1(x)(hD_{x_1})^j(hD_{y_1})^k\psi_2(y)U^{0\pm}\| \le C'h^{-L},$$

where j and k are arbitrary (less than L), in the left-hand expression the operator norms

$$\mathscr{L}^2(\mathbb{R}^+\times[-T,T],\mathscr{H}^L(\mathbb{R}^{d-1},.)) \to \begin{cases}\mathscr{L}^2\big(\mathbb{R}^+\times[-T,T],H_{-L}(\mathbb{R}^{d-1},.)\big)\\ \qquad\mathscr{L}^2\big([-T,T],\mathscr{H}^{\mu}(\mathbb{R}^{d-1},.)\big)\end{cases}$$

respectively are calculated, and $L = L(d,m,j,k)$.

Proof. The proof is very simple and is based on the equalities

$$(hD_t - A_x)U^{i\pm} = 0, \quad U^{i\pm t}(hD_t - A_y) = 0$$

(provided $x_1 \ne y_1$ for $i = 0$). □

Therefore

(7.2.27) All terms originating from $F_0^{\pm}$, $F^{\pm}$ and $f^{\pm}$ are negligible.

Combining this with (7.2.26) we arrive to

Proposition 7.2.6. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$–(7.1.10) *be fulfilled and let the operators Q_i and functions ψ_i be the same as before. Finally, let $\chi \in \mathscr{C}_0^K([-1,1])$ and $T \in [h^{1-\delta}, h^{\frac12+\delta}]$. Then*

$$(7.2.28)\quad \|(hD_x)^{\alpha}(hD_y)^{\beta}Q'_{1x}\psi_1(x)F_{t\to h^{-1}\tau}\chi_T(t)\times \Big(U^{1\pm} - \sum_{n\le N'-1}\big(\bar G^{\pm}R' + \bar G'^{\pm}\eth R'_1\big)^n\bar G'^{\pm}V^{\pm}\Big)\psi_2(y)^tQ'_{2y}\| \le C'h^s(1+|\tau|)^{N'''}$$

with

$$(7.2.29)\quad V^{\pm} = \mp ih\eth(\bar B + R'_1)\sum_{k\le N'-1}(\bar G_0^{\pm}R')^k\delta(t)\delta(x-y)$$
$$\forall x,y\in\bar{\mathbb{R}}^+\times\mathbb{R}^{d-1}\quad \forall\tau : \pm\operatorname{Im}\tau<0\quad \forall\alpha,\beta : |\alpha|\le s, |\beta|\le s$$

where $N' \ge N'(d,m,s,\delta)$, $K' = K = K(d,m,s,\delta,N')$, and R', R'_1 are obtained from R, R_1 by dropping terms containing $x_1^{\alpha_1}(x'-y')^{\alpha'}h^{\nu}$ with $|\alpha|+\nu \ge N'$; all operators without the index "y" act with respect to x.

7.2.3 Calculations

Starting Point

Let us go from estimates to calculations. Let us recall that according to Corollary 7.2.4

$$F_{(t,x')\to h^{-1}(\tau,\xi')}V^{\pm} = \pm\sum h^{-d+k}\int_{-\infty}^{\infty} F_k^2(y',\eta_1,\xi',\tau)e^{-ih^{-1}y_1\eta_1}\,d\eta_1 \tag{7.2.30}$$

where F_k^* are functions smooth with respect to (y',ξ') and holomorphic with respect to (η_1,τ) in the domain containing $\mathbb{R}\times\mathbb{C}_{\mp}$; these functions tend to 0 in this domain as $|\eta_1|\to\infty$.

One Dimensional Parametrices

Let us construct parametrices $\bar{G}'^{\pm}$ and $\bar{G}^{\pm}$. Let us note that

$$F_{(t,x')\to h^{-1}(\tau,\xi')}\bar{G}'^{\pm} = \mathcal{G}'(z,h^{-1}x_1,\tau)F_{(t,x')\to h^{-1}(\tau,\xi')} \qquad (\pm\operatorname{Im}\tau<0) \tag{7.2.31}$$

where $z=(y',\xi')$ and $\mathcal{G}'$ is a solution of the problem

$$\bigl(\tau-\bar{A}(z,D_1)\bigr)\mathcal{G}'=0, \tag{7.2.32}$$

$$\eth\bar{B}(z,D_1)\mathcal{G}'=0, \tag{7.2.33}$$

$$\mathcal{G}'\in\mathscr{S}(\mathbb{R}^+,.) \tag{7.2.34}$$

and for $z\in\operatorname{supp}q_2$ (as will be assumed without being specially mentioned) we can replace $\bar{A}$ and $\bar{B}$ by a and b respectively.

Using $\bar{G}'^{\pm}$ and parametrices in the whole space $\mathbb{R}^d$ for the same operator $(\tau-\bar{A})$ we can construct the parametrices $\bar{G}^{\pm}$. Namely, let $\mathcal{G}(z,\tau)$ be the one-dimensional (on $\mathbb{R}^+$) integral operator with Schwartz kernel

$$\begin{aligned}\mathcal{K}_{\mathcal{G}}(x_1,y_1;z,\tau) = {}& (2\pi)^{-1}\text{v.p.}\int_{-\infty}^{\infty}\bigl(e^{i(x_1-y_1)\xi_1}-\mathcal{G}'(z,x_1,\tau)\bar{B}(z,\xi_1)e^{-iy_1\xi_1}\bigr)\times\\ &\bigl(\tau-\bar{A}(z,x_1,\xi_1)\bigr)^{-1}\,d\xi_1\end{aligned} \tag{7.2.35}$$

where the principal value of the integral is calculated; then

$$F_{(t,x')\to h^{-1}(\tau,\xi')}\mathcal{L}\bar{G}^{\pm} = \mathcal{G}(z,\tau)\mathcal{L}F_{(t,x')\to h^{-1}(\tau,\xi')} \qquad (\pm\operatorname{Im}\tau<0) \tag{7.2.36}$$

where $(\mathcal{L}v)(x_1) = v(x_1 h)$.

It is easy to see that for $\eta_1 \in \mathbb{R}$

$$\mathcal{G}(e^{ix_1\eta_1}v) = \bigl(e^{ix_1\eta_1} - \mathcal{G}(z,x_1,\tau)\bar{B}(z,\eta_1)\bigr)\bigl(\tau - \bar{A}(z,\eta_1)\bigr)^{-1}v. \tag{7.2.37}$$

We need to establish certain properties of $\mathcal{G}'$ and $\mathcal{G}$ for $z \in \mathsf{supp}(q_2)$.

Lemma 7.2.7. *(i) Functions* $W_j(z,\tau) = \eth D_1^j \mathcal{G}'(z,x_1,\tau)$ *are regular on* $\mathbb{R}^{2d-2} \times (\mathbb{C}\setminus\mathbb{R}) \ni (z,\tau)$ *and satisfy inequalities*

$$\|D_z^\alpha D_\tau^\beta W_j\| \le C|\operatorname{Im}\tau|^{-N}(1+|\tau|)^N \qquad \forall \alpha,\beta,j : |\alpha|+\beta+j \le s \tag{7.2.38}$$

where $N = N(d,m,s)$ *and* s *is arbitrary.*

(ii) Further, $\eth_y (D_{y_1})^j \mathcal{K}_{\mathcal{G}} = \mathcal{G}' W_j'$ *where the functions* $W_j'(z,\tau)$ *have the same properties as* W_j*.*

Proof. Since $\mathcal{G}$ is a parametrix for $\bigl(\tau - a(z,D_1)\bigr)$ with the boundary condition $\eth b(z,D_1)u = 0$ and since the operator $a(z,D_1)$ with this condition is self-adjoint we conclude that the operator norm in $\mathscr{L}^2(\mathbb{R}^+,\mathbb{H})$ of the operator $\mathcal{G}$ does not exceed $|\operatorname{Im}\tau|^{-1}$. On the other hand, (7.1.9) and the definition of $\mathcal{G}$ as a parametrix yield that

$$\|D_1^m \mathcal{G}\| \le C\Bigl(\sum_{0\le j\le m-1} \|D_1^j \mathcal{G}\| + |\tau|\cdot\|\mathcal{G}\| + 1\Bigr);$$

this inequality, the inequality $\|\mathcal{G}\| \le C|\operatorname{Im}\tau|^{-1}$ and interpolation yield that

$$\|D_1^j \mathcal{G}\| \le C|\operatorname{Im}\tau|^{-1}(|\tau|+1)^{\frac{j}{m}} \qquad (j = 0,\dots,m) \tag{7.2.39}$$

which implies

$$\|\eth_y D_{y_1}^j \mathcal{K}_{\mathcal{G}}\| \le C|\operatorname{Im}\tau|^{-1}(|\tau|+1)^{\frac{j+1}{m}} \qquad (j = 0,\dots,m-1) \tag{7.2.40}$$

where in the left-hand expression the operator norm from $\mathbb{H}$ to $\mathscr{L}^2(\mathbb{R}^+,\mathbb{H})$ is calculated. Then the equality $\bigl(\tau - a(z,D_{y_1})\bigr)\mathcal{K}_{\mathcal{G}}^\dagger = 0$ for $y_1 \ne x_1$ yields that

(7.2.41) Estimate (7.2.40) holds for all j with constant $C = C_j$.

Starting from (7.2.40)–(7.2.41) and treating equation

$$\big(\tau - a(z, D_{x_1})\big)\eth_y D_{y_1}^j \mathcal{K}_{\mathcal{G}} = 0 \tag{7.2.42}$$

for $x_1 > 0$ we obtain that

$$\|D_{x_1}^k \eth_y D_{y_1}^j \mathcal{K}_{\mathcal{G}}\| \le C_{jk} |\operatorname{Im}\tau|^{-1} (|\tau| + 1)^{\frac{j+k+1}{m}} \tag{7.2.43}$$

and

$$\|\eth_x D_{x_1}^k \eth_y D_{y_1}^j \mathcal{K}_{\mathcal{G}}\| \le C_{jk} |\operatorname{Im}\tau|^{-1} (|\tau| + 1)^{\frac{j+k+2}{m}} \tag{7.2.44}$$

for all j, k.

Moreover, equation (7.2.42) yields the equality $\eth_y D_{y_1}^j \mathcal{K}_{\mathcal{G}} = \mathcal{G}' W_j'$ with $W_j' = \eth_x b(z, D_{x_1}) \eth_y D_{y_1}^j \mathcal{K}_{\mathcal{G}}$; therefore Statement (ii) holds with (7.2.38) proven only for $\alpha = \beta = 0$ so far.

Furthermore, equality

$$\mathcal{G}'(z, \tau) = \mathcal{R} - \mathcal{G}(z, \tau)\big(\tau - a(z, D_1)\big)\mathcal{R}$$

holds for every operator $\mathcal{R}$ from $\mathbb{H}'$ to $\mathscr{S}(\bar{\mathbb{R}}^+, \mathbb{H})$ such that $\eth b(z, D_1)\mathcal{R} = I$ (e.g., for $\mathcal{R} = \mathcal{G}'(z, i)$). Therefore Statement (i) also holds holds (but with (7.2.38) proven only for $\alpha = \beta = 0$ so far).

For arbitrary α and β (7.2.38) follows from the following formulas similar to (7.2.21) and (7.2.22):

$$\partial \mathcal{G} = -\mathcal{G}(\partial(\tau - a))\mathcal{G} - \mathcal{G}' \eth(\partial b)\mathcal{G},$$
$$\partial \mathcal{G}' = -\mathcal{G}(\partial(\tau - a))\mathcal{G}' - \mathcal{G}' \eth(\partial b)\mathcal{G}'$$

where $\partial = \partial_{x_j}, \partial_{\xi_j}$ with $j = 2, \dots, d$ or $\partial = \partial_\tau$; in the last case the last terms in these equalities vanish. □

One Dimensional Parametrices (End)

Let us investigate regularity of $\mathcal{G}'(z, \tau)$ and $\mathcal{G}(z, \tau)$ with respect to (z, τ). Let us start from the obvious

Remark 7.2.8. Operator $\mathcal{G}$ is bounded in a neighborhood of (z^*, τ^*) if and only if the problem $\big(\tau - a(z, D_1), \eth b(z, D_1)\big)$ is elliptic, i.e., if $z^* \notin \Sigma_{\tau^*, b}$. In this case the functions W_j and W_j' are regular in a neighborhood of (z^*, τ^*).

Let us assume that the problem $\bigl(\tau - a(z, D_1), \eth b(z, D_1)\bigr)$ is microhyperbolic at (z^*, τ^*) in the multidirection $\mathcal{T} = (\ell', \nu_1, \dots, \nu_n)$; in particular, in this case (3.1.25) is fulfilled. Without any loss of the generality one can assume that either

(a) $\ell = \partial_{z_1}$ or

(b) $\ell' = 0$

(otherwise we can arrange this by a uniformly non-degenerate change of coordinates in $\mathbb{R}^{2d-2}$).

In the former case let us treat the almost analytic (with respect to z_1) extensions of $a(z, D_1)$ and $b(z, D_1)$ to the neighborhood $\tilde{\Omega} \subset \mathbb{C} \times \mathbb{R}^{2d-3} \times \mathbb{C}$ of the point (z^*, τ^*). Let us make the reduction of Subsection 3.1.2 but now the coefficients at powers of hD_1 are functions of (z, τ) rather than h-pseudodifferential operators. Let $\mathfrak{C} = (\mathfrak{C}_j) = (\mathfrak{C}_j(z, D_1, \tau))_{j=0,\dots,n}$ be the operator realizing this reduction.

Proposition 7.2.9. *Let the problem $(\tau - a, \eth b)$ be microhyperbolic at (z^*, τ^*) in the multidirection $\mathcal{T} = (\ell', \nu_1, \dots, \nu_n)$. Then*

(i) If $\ell' = 0$ then W_j and W_j' are regular in a neighborhood of (z^*, τ^*), i.e., (7.2.38) *holds with $N = 0$;*

(ii) If $\ell' = \partial_{z_1}$ then there are almost analytic (with respect to z_1) extensions of W_j and W_j' in $\tilde{\Omega}_\pm = \tilde{\Omega} \cap \{\pm \operatorname{Im} \tau < 0, \mp \operatorname{Im} z_1 < 0\}$ and here

$$\|D_z^\alpha D_\tau^\beta W_j\| \le C(|\operatorname{Im} \tau| + |\operatorname{Im} z_1|)^{-N} \qquad \forall \alpha, \beta, j \tag{7.2.45}$$

with $C = C_{\alpha\beta j}$, $N = N_{\alpha\beta j}$.

Proof of proposition 7.2.9, Part I. Let us note that case (b) is reduced to (a) by introducing an additional variable z_1 (on which symbols a and b do not depend); therefore let us treat case (a).

Let us consider almost analytic extension of $\mathcal{G}'(z, \tau)$; it should satisfy (7.2.32) and (7.2.33) but (7.2.34) does not necessarily remain true.

Let us recall that we reduce operator $p(z, D_1, \tau) = \bigl(\tau - a(z, D_1)\bigr)$ to operator $\underline{p}(z, D_1, \tau)$ in the block-diagonal form as in Subsubsection *3.2.1.1 Notations and Definitions*.

Let us note that the microhyperbolicity condition of $p(z, \tau, D_1)$ at (z, τ, ν_l) yields that

(7.2.46) $g_l(z,\xi_1,\tau)=\det \underline{p}_l(z,\xi_1,\tau)$ has no root ξ_1 in the strip

$$\{|\operatorname{Im}\xi_1-\nu_l\operatorname{Im}z_1|\le \epsilon(|\operatorname{Im}\tau|+|\operatorname{Im}z_1|)\}$$

provided $(z,\tau)\in\tilde{\Omega}_{\pm}$.

Therefore we can replace (7.2.34) by condition

$$e^{\nu_l\sigma x_1}\boldsymbol{\pi}_l\mathcal{G}'\in \mathscr{S}(\mathbb{R}^+,.)\qquad \forall l=0,\dots,n \tag{7.2.47}$$

where $\sigma=\operatorname{Im}z_1$, $\nu_0=0$; here and below $\boldsymbol{\pi}_l$ means projection to l-th block and $l=0$ means an elliptic block.

Introducing $u=(u_0,\dots,u_n)$ with $u_l=e^{-\nu_j z_1 x_1}\boldsymbol{\pi}_l\mathcal{G}'$ we obtain the problem

$$\underline{p}_l(z,D_1-\nu_l z_1,\tau)u_l=0, \tag{7.2.48}$$

$$\eth\underline{b}(z,\tau)u=I, \tag{7.2.49}$$

$$u\in\mathscr{S}(\mathbb{R}^+,.); \tag{7.2.50}$$

let us recall that for $z_1\in\mathbb{R}$, $\operatorname{Im}\tau\ne 0$ this problem is solvable. □

Let us prove

Lemma 7.2.10. *Problem* (7.2.48)–(7.2.50) *is solvable for* $(z,\tau)\in\tilde{\Omega}_{\pm}$*; its solution is almost analytic with respect to* z_1 *and satisfies estimates*

$$\|D_1^k u\|_+\le C_k\big(|\operatorname{Im}\tau|+|\operatorname{Im}z_1|\big)^{-1}\qquad \forall k \tag{7.2.51}$$

Proof. Since this problem is solvable for $\operatorname{Im}z_1=0$, $\operatorname{Im}\tau\ne 0$, its solubility in the general case follows from (7.2.51). The deduction of the inequality in the proof of Theorem 3.1.12 implies that for $\omega:=(z,\tau)\in\mathbb{R}^{2d-2}\times\mathbb{R}$

$$\begin{aligned} M:=&-\operatorname{Re}\big(\langle \ell'\underline{p}(\omega,D_1)\underline{v},\underline{v}\rangle_+\\ &+\sum_{1\le l\le n}\nu_l\langle \ell'\underline{p}'_l(\omega,D_1)\underline{v}_l,\underline{v}_l\rangle_+ - i\langle \ell'\underline{b}(\omega)\eth\underline{v},\underline{b}'(\omega)\eth\underline{v}\rangle_b\big)\ge\\ &C^{-1}\|\underline{v}\|_+^2-C\|\underline{p}(\omega,D_1)\underline{v}\|_{(r)+}-C\|\underline{b}(\omega)\eth\underline{v}\|^2\\ &\forall \underline{v}\in\mathscr{S}(\bar{\mathbb{R}}^+,\mathbb{H}^m) \end{aligned} \tag{7.2.52}$$

with some r and C where $\underline{p}'_l=\partial_{\xi_1}\underline{p}_l$, $\underline{v}_l$ are the components of $\underline{v}$ after the reduction and

$$\|w\|_{(r)+}=\sum_{0\le k\le r}\|D_1^k w\|_+.$$

Let us take into account that for $\omega \in \mathbb{R}^{2d-2} \times \mathbb{R}$ expression

$$\langle \underline{p}(\omega, D_1)\underline{v}, \underline{v}\rangle_+ - i\langle \underline{b}(\omega)\eth\underline{v}, \underline{b}'(\omega)\eth\underline{v}\rangle_b$$

is real-valued due to (7.1.12). Further, let us take into account the following inequality

$$|\operatorname{Im}\big(\langle \underline{p}_\sigma(\omega, D_1)\underline{v}, \underline{v}\rangle_+ - i\langle \underline{b}_\sigma(\omega)\eth\underline{v}, \underline{b}'_\sigma(\omega)\eth\underline{v}\rangle_b\big) - M\sigma - M_0 \operatorname{Im}\tau| \le$$
$$C|\sigma| \cdot \|\underline{b}_\sigma(\omega)\eth\underline{v}\|_b \cdot \|\eth\underline{v}\|_b + C\big(|\sigma| + |\operatorname{Im}\tau|\big)^2\|\underline{v}\|^2_{(r)+}$$

where $\omega \in \mathbb{R}^{2d-2} \times \mathbb{C}$,

$$\underline{p}_\sigma(\omega, D_1) = \big(\underline{p}_{jl}(\omega + i\sigma\ell', D_1 - i\sigma\nu_l)\big)_{l=0,\dots,n},$$
$$\underline{b}'_\sigma(\omega) = \underline{b}'(\omega + i\sigma\ell'),$$

M_0 is defined as M by (7.2.52) with ℓ' and ν_l replaced by ∂_τ and 0 respectively; these inequality is due to microhyperbolicity of $(\underline{p}, \eth\underline{b})$ in multidirection $\mathcal{T}$. It yields an estimate

$$\big(|\sigma| + |\operatorname{Im}\tau|\big)\|\underline{v}\|_+ \le C\big(\epsilon|\sigma|\big)^{-1}\big(\|\underline{p}_\sigma(\omega, D_1)\underline{v}\|^2_{(r)+} + \|\underline{b}_\sigma(\omega)\eth\underline{v}\|^2_b\big) +$$
$$C\big((|\sigma| + |\operatorname{Im}\tau|)^2 + \epsilon(|\sigma| + |\operatorname{Im}\tau|)\big)\|\underline{v}\|_{(r+1)+}$$

with an arbitrarily small constant $\epsilon > 0$. Note that in the left-hand expression of this estimate one can replace $\|\underline{v}\|_+$ by $\|\underline{v}\|_{(r+1)+}$ because the coefficient of hD_1 in $\underline{p}_\sigma(z, D_1)$ is non-degenerate and so for small $|\sigma| + |\operatorname{Im}\tau|$ one can drop the last term in the right-hand expression. Then we arrive to

$$\|\underline{v}\|_{(r+1)+} \le \big(|\sigma| + |\operatorname{Im}\tau|\big)^{-1}\big(\|\underline{p}_\sigma(\omega, D_1)\underline{v}\|_{(r)+1} + \|\underline{b}_\sigma(z)\eth\underline{v}\|_b\big). \tag{7.2.53}$$

This inequality yields (7.2.51). Moreover, (7.2.53) and the equalities

$$(\partial\underline{p}_\sigma)u + \underline{p}_\sigma(\partial u) = 0,$$
$$\eth(\partial\underline{b}_\sigma)u + \eth\underline{b}_\sigma(\partial u) = 0$$

for every vector field ∂ yield that u is almost analytic with respect to τ and z_1 and that the estimate

$$\|D_z^\alpha D_\tau^\beta D_1^j u\| \le C\big(|\operatorname{Im} z_1| + |\operatorname{Im}\tau|\big)^{-N} \tag{7.2.54}$$

holds for $|\alpha| + \beta = 1$. If we make a few differentiations we can easily obtain the same estimate arbitrary α, β with $C = C_{\alpha\beta}$, $N = N_{\alpha\beta}$. □

Proof of proposition 7.2.9 (end). Lemma 7.2.10, estimate (7.2.54) and the definition of W_j immediately imply that for W_j of Proposition 7.2.9 holds.

Let us prove Proposition 7.2.9 for W_j'. Formula (7.2.35) yields that for real z, $\operatorname{Im}\tau \neq 0$ and $x_1 + y_1 > 0$ the following formula holds:

$$\mathcal{K}_{\mathcal{G}}(x_1, y_1; z, \tau) = (2\pi)^{-1} \int_{\gamma_+} e^{i(x_1-y_1)\xi_1} \big(\tau - a(z,\xi_1)\big)^{-1} d\xi_1 + \mathcal{G}'(z, x_1, \tau) \times (2\pi)^{-1} \int_{\gamma_-} b(z,\xi_1) e^{-iy_1\xi_1} \big(\tau - a(z,\xi_1)\big)^{-1} d\xi_1 \tag{7.2.55}$$

where

(7.2.56) $\gamma_\pm$ are closed contours in $\mathbb{C}$ passing once around the poles of $\big(\tau - a(z,\xi_1)\big)^{-1}$ lying in $\mathbb{C}_\pm$ and not passing around the poles lying in $\mathbb{C}_\mp$; for real z and $\operatorname{Im}\tau \neq 0$ there is no real pole.

Note that the factor to the right of $\mathcal{G}'$ in the second term in the right-hand expression is a sum of terms of the form

$$\int_{\gamma_-} \xi_1^k e^{-iy_1\xi_1} \big(\tau - a(z,\xi_1)\big)^{-1} d\xi_1$$

with regular coefficients and with $k \leq m-1$. Differentiating j times with respect to y_1 and setting $y_1 = 0$ we obtain terms of the form

$$W_k''(z,\tau) = \int_{\gamma_-} \xi_1^k \big(\tau - a(z,\xi_1)\big)^{-1} d\xi_1$$

with coefficients regular with respect to z, τ. In order to treat $\operatorname{Im} z_1 \neq 0$ let us replace the contours $\gamma_\pm$ by homotopic contours $\gamma_\pm^\sigma$ such that for $0 \leq \pm\sigma' \leq \pm\sigma$ there is no pole of $(\tau - a(z,\xi_1))^{-1}$ in $\gamma_\pm^\sigma$ where $\sigma = \operatorname{Im}\zeta$.

Property (7.2.46) implies that one can assume without any loss of the generality that in the intersection with the ϵ-neighborhood of ζ_j the contour $\gamma_\pm^\sigma$ coincides with $\{\operatorname{Im}\xi_1 = \nu_j \operatorname{Im} z_1\}$; then the microhyperbolicity condition yields that on $\gamma_\pm^\sigma$

$$\big\|\big(\tau - a(z,\xi_1)\big)^{-1}\big\| \leq C(|\operatorname{Im}\tau| + |\operatorname{Im} z_1|)^{-1}$$

and hence W_k'' also satisfies the statement of Proposition 7.2.9. Hence we need to treat only the first term in $\mathcal{K}_{\mathcal{G}}$. Applying $\partial D_{y_1}^j$ we obtain a sum of terms of the form

$$v_j := (2\pi)^{-1} \int_{\gamma_+} e^{ix_1\xi_1} \xi_1^j \big(\tau - a(z,\xi_1)\big)^{-1} d\xi_1.$$

These terms satisfy equation $\bigl(\tau - a(z,D_1)\bigr)v = 0$ for $x_1 > 0$ and hence $v_j = \mathcal{G}'(z,x_1,\tau)\eth b(z,D_1)v_j$. Repeating the same arguments as before we see that $W_k''' = \eth b(z,D_1)v$ satisfy statement of Proposition 7.2.9; therefore this statement holds for W_k' also. □

Let us represent $\mathcal{G}'$ as an oscillatory integral:

Lemma 7.2.11. *(i) The following formula holds:*

$$\mathcal{G}'(z,x_1,\tau) = \mathsf{v.p.}\int_{-\infty}^{\infty} \sum_{0\le j\le m-1} \xi_1^{m-j-1}\bigl(\tau - a(z,\xi_1)\bigr)^{-1}\,d\xi_1 \cdot W_j''(z,\tau) \tag{7.2.57}$$

where W_j'' satisfy (7.2.38).

(ii) In this formula one can replace integration along $\mathbb{R}$ by integration along γ_+.

(iii) Hence the same representation holds for $D_1^k\mathcal{G}'(z,x_1,\tau)$ for all $k \ge 0$.

(iv) Under the microhyperbolicity condition for W_j'' the statement of Proposition 7.2.9 holds.

Proof. Starting from the equality

$$\bigl(\tau - a(z,D_1)\bigr)\bigl(\mathcal{G}'\theta(x_1)\bigr) = \sum_{j+k\le m-1} \delta^{(k)}(x_1)a_{kj}(z)\eth D_1^j\mathcal{G}'$$

with regular coefficients a_{kj} and applying the Fourier transform with respect to x_1, multiplication by $(\tau - a(z,\xi_1))^{-1}$, and the inverse Fourier transform we obtain (7.2.56); estimate (7.2.38) follows from Lemma 7.2.7.

Further, Statement (iv) follows from Proposition 7.2.9 while Statement (iii) is obvious. Applying D_1^k to (7.2.56) with γ_+ instead of $\mathbb{R}$ and dividing with the remainder by $(\tau - a(z,\xi_1))$ we obtain the same representation for $D_1^k\mathcal{G}'$, and at the last moment we can replace γ_+ by $\mathbb{R}$ again; so, Statement (ii) is proven. □

Now we can prove

Proposition 7.2.12. *(i) For $\mathsf{Im}\,\tau \ne 0$ one-dimensional operator*

$$\mathcal{A}(z,D_1) = c_1(z)D_1^{j_1}\mathcal{G}\cdot c_2(z)D_1^{j_2}\mathcal{G}\cdots c_{\mu-1}(z)D_1^{j_{\mu-1}}\mathcal{G}\cdot c_\mu(z)D_1^{j_\mu}\mathcal{G}'$$

containing $(\mu-1)$ *factors* $\mathcal{G}$ *is a sum of terms of the form*

$$\int_{\gamma_+} e^{ix_1\xi_1}\xi_1^k F_{kl}(z,\xi_1,\tau)d\xi_1 \cdot W_{lk}(z,\tau) \tag{7.2.58}$$

where

$$F_{kl} = c'_{kl1}(z,\tau)\big(\tau - a(z,\xi_1)\big)^{-1}\cdots c'_{kll}(z,\tau)\big(\tau - a(z,\xi_1)\big)^{-1}$$

$k=0,\dots,m-1$, $l\le\mu$, *and* W_{lk} *satisfy* (7.2.38) *(there could be many terms with the same* (k,l) *but different coefficients* c_{lk*}*).*

(ii) Moreover, $\mathfrak{d}\mathcal{A} = W(z,\tau)$ *satisfies* (7.2.38)*.*

(iii) Under the microhyperbolicity condition W_{lk} *and* W *satisfy the statement of Proposition 7.2.9.*

Proof. Let us prove by induction with respect to μ. For $\mu=1$ this proposition follows from Lemma 7.2.10 and Proposition 7.2.9. Let us rewrite (7.2.58) as the principal value of an integral along $\mathbb{R}$ and apply (7.2.37); we then obtain terms of the same form with F_{lk} replaced by $(\tau-a(z,\xi_1))^{-1}F_{lk}$ and terms of the form $\mathcal{G}(z,\xi_1,\tau)W'_{lk}$ with

$$W'_{lk} = \mathsf{v.p.}\int_{-\infty}^{\infty} b(z,\xi_1)\xi_1^k\big(\tau-a(z,\xi_1)\big)^{-1}F_{lk}(z,\xi_1,\tau)\,d\xi_1.$$

In this integral we can take integration over the contour γ_+ coinciding with the real axis in the ϵ-neighborhood of ζ_j and therefore W'_{lk} satisfy (7.2.38); moreover, under the microhyperbolicity condition taking $\mathsf{Im}\, z_1\ne 0$ we can deform this contour into γ_+^σ (see the proof of Proposition 7.2.9) and obtain that W'_{lk} satisfy the assertion of Proposition 7.2.9.

We rewrite $\mathcal{G}'$ in the form (7.2.56), pass to integration along γ_+, apply the operator $c_1(z)D_1^{j_1}$ and divide by $(\tau-a(z,\xi_1))$ with the remainder any factor ξ_1^k with k exceeding $(m-1)$. Since the quotient contains no pole its integral is 0, so only the remainder matters and we finish the induction step.

Then Statement (i) and the first part of Statement (iii) are proven (in fact, Statement (iii) consists of two parts corresponding to the two parts of Proposition 7.2.9).

Applying operator $\mathfrak{d}$ to (7.2.58) and estimating $\int_{\gamma_+}\xi_1^k F_{kl}(z,\xi_1,\tau)d\xi_1$ (and its derivatives) in a manner similar to the previous arguments (and with $\mathsf{Im}\, z_1\ne 0$ under the microhyperbolicity condition) we prove Statement (ii) and the second part of Statement (iii). □

Calculations: what We Got

Now we can finish our calculations. Starting from Proposition 7.2.6 we can eliminate all the degrees of x_1 and $(x'-y')$ by commutation; we can use formulae (7.2.31) and (7.2.36) to pass from operators $\bar{G}^{\pm}$ and $\bar{G}'^{\pm}$ to $\mathcal{G}$ and $\mathcal{G}'$ in $\mathbb{C}_{\mp}\setminus\mathbb{R}$ and Proposition 7.2.12; we can also use formulae for $\bar{G}_0^{\pm}$. Thus we arrive to

Theorem 7.2.13. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9) *and* (7.1.10) *be fulfilled.*

Further, let $Q_i'=\mathsf{Op}(q_i')$ *with symbols* $q_i'\in \mathsf{S}'_{h,K}$ *supported in* $\{|\xi'|\le c\}$ *and* $\psi_i\in \mathscr{C}_0^K(B(0,1-\epsilon))$. *Finally, let* $\chi\in\mathscr{C}_0^K([-1,1])$ *and* $T\in[h^{1-\delta},h^{\frac12+\delta}]$.

(i) Then

$$
\begin{aligned}
(7.2.59)\quad \|D_x^{\alpha}D_y^{\beta}\Big(F_{t\to h^{-1}\tau}\chi_T(t)Q'_{1x}\psi_1(x)U^{1\pm}\psi_2(y)^{t}Q'_{2y}\mp\\
\sum_{0\le n\le N'-1}h^{-d+n}\int T\hat{\chi}(\frac{\tau' T}{h})d\tau'\int d\xi'\int_{\gamma_+}d\xi_1\int_{\gamma_-}d\eta_1\times\\
e^{ih^{-1}(x_1\xi_1-y_1\eta_1+\langle x'-y',\xi'\rangle)}q_1'(x,\xi')F_n(y',\xi',\xi_1,\eta_1,\tau-\tau')[q_2'(y,\xi')]\Big)\|\le\\
C'h^{s}(|\tau|+1)^{N''}\\
\forall\alpha,\beta:|\alpha|\le s,|\beta|\le s\quad\forall\tau\in\mathbb{C}_{\mp}\quad\forall x,y\in\bar{\mathbb{R}}^{+}\times\mathbb{R}^{d-1}
\end{aligned}
$$

provided $N'=N'(d,m,s,\delta)$, $N''=N''(d,m,s,\delta,N')$, $K=K(d,m,s,\delta,N')$ *where* F_n *are sums of terms of the form*

$$
\begin{aligned}
(7.2.60)\quad \xi_1^{j}\eta_1^{k}\prod_{1\le\mu\le M}\big(\tau-a(y',\xi_1,\xi')\big)^{-1}c_{\mu}(y',\xi')\times\\
W(y',\xi',\tau)\prod_{1\le\nu\le M'}c'_{\nu}(y',\xi')\big(\tau-a(y',\eta_1,\xi')\big)^{-1}
\end{aligned}
$$

with $j,k\le m-1$, $M+M'\le M_0(n)=2n+2$, *and functions* W *satisfying* (7.2.38)*; here* q_1' *and* q_2' *are symbols of* $Q_1'\psi_1$ *and* $Q_2'\psi_2$ *respectively and there are no more than* $M_0(n)$ *differentiations with respect to* (ξ',x_1).

(ii) Moreover, under the microhyperbolicity condition the functions W *satisfy the assertion of Proposition 7.2.9.*

Remark 7.2.14. (i) In formula (7.2.59) we have replaced integration with respect to ξ_1 along $\mathbb{R}$ by integration along γ_-.

(ii) Multiplication of all the terms of decomposition (7.2.59) by x_1 or y_1 is equivalent (after integration by parts) to the application to F_n of the operator $ih\partial_{\xi_1}$ or $-ih\partial_{\eta_1}$ respectively.

(iii) Further, note that application of ∂_{ξ_1} or ∂_{η_1} increases the singularity of F_n at $\xi_1, \eta_1 \in \mathbb{R}$ and $\tau \to \mathbb{R} \pm i0$ by no more than an extra factor $(\operatorname{Im}\tau)^{-1}$ and hence the singularity of the distribution $F_n(y', \xi', \xi_1, \eta_1, \tau \pm i0)$ increases by no more than by 1. Hence when we estimate the corresponding integral we should replace the $\mathscr{C}^N$-norm of $\hat{\chi}(\tau' Th^{-1})$ by its $\mathscr{C}^{N+1}$-norm, i.e., there arises an extra factor Th^{-1}. Also multiplication by x_1 or y_1 essentially multiplies the corresponding integral by T. Therefore for $(x_1 + y_1) \geq Th^{-\delta}$ with $\delta > 0$ all terms in the decomposition are negligible.

Calculations: Taking Traces

Let us set $x_1 = y_1$ and integrate over x_1 along $\mathbb{R}^+$; let us take the Taylor decomposition of q_i' with respect to x_1 and y_1 and apply Remark 7.2.14(ii),7.2.14-iii; then we can drop all the remainder terms and eliminate factors x_1 and y_1 by means of integration by parts. As a result there arises inside the exterior integrals with respect to τ' and ξ' a term

$$W_n'(z, \tau - \tau') = ih \int_{\gamma_+} \int_{\gamma_-} F_n(y', \xi', \xi_1, \eta_1, \tau - \tau')(\xi_1 - \eta_1)^{-1} d\xi_1 d\eta_1$$

where we have taken non-intersecting contours γ_+ and γ_- and we do not write factors q_1' and q_2' and $z = (x', \xi')$. Moreover, we can choose γ_+ and γ_- (depending on τ) such that

$$\operatorname{dist}(\gamma_+, \gamma_-) \geq \epsilon |\operatorname{Im}\tau| \tag{7.2.61}$$

and at these contours

$$|\big(\tau - a(y', \xi', \xi_1)\big)^{-1}| \leq C |\operatorname{Im}\tau|^{-1}. \tag{7.2.62}$$

Hence functions W_n' satisfy (7.2.38).

Furthermore, under microhyperbolicity condition we can pass to non-real variable z_1 and choose γ_+ and γ_- such that in the preceding inequalities

(7.2.61), (7.2.62) $|\operatorname{Im}\tau|$ will be replaced by $(|\operatorname{Im}\tau| + |\operatorname{Im} z_1|)$ (let us recall the that signs of $\operatorname{Im}\tau$ and $\operatorname{Im} z_1$ should be opposite). But then for W'_n the statement of Proposition 7.2.9 holds. So we have proven

Theorem 7.2.15. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9) *and* (7.1.10) *be fulfilled.*

Further, let $Q'_i = \mathsf{Op}(q'_i)$ *with symbols* $q'_i \in \mathsf{S}'_{h,K}$ *supported in* $\{|\xi'| \le c\}$ *and* $\psi_i \in \mathscr{C}_0^K(B(0,1-\epsilon))$. *Finally, let* $\chi \in \mathscr{C}_0^K([-1,1])$ *and* $T \in [h^{1-\delta}, h^{\frac12+\delta}]$.

(i) Then

$$
\begin{aligned}
(7.2.63)\quad \|D^\alpha_{x'} D^\beta_{y'} \Big(F_{t\to h^{-1}\tau}\chi_T(t) \int_0^\infty \big(Q'_{1x}\psi_1(x) U^{1\pm}\psi_2(y)^t Q'_{2y}\big)\big|_{x_1=y_1} dy_1 \mp \\
\sum_{0\le n\le N'-1} h^{-d+n+1} \int T\hat\chi\big(\frac{\tau' T}{h}\big)\, d\tau' \int d\xi' \times \\
e^{ih^{-1}\langle x'-y',\xi'\rangle} q'_1(x,\xi') W'_n(y',\xi',\tau-\tau')[q'_2(y,\xi')]\Big)\| \le C' h^s (|\tau|+1)^{N''} \\
\forall \alpha,\beta : |\alpha|\le s, |\beta|\le s \quad \forall \tau \in \mathbb{C}_\mp \quad \forall x', y' \in \mathbb{R}^{d-1}
\end{aligned}
$$

with the same N', N'' *and* K *as before and with* W'_n *satisfying* (7.2.38).

(ii) Moreover, under microhyperbolicity condition for W'_n *the statement of Proposition 7.2.9 holds.*

(iii) Furthermore, the same Statements (i), (ii) remain true if we replace ψ_1 *and (or)* ψ_2 *by* $\psi_1\psi'_1$ *and (or)* $\psi_2\psi'_2$ *with* $\psi'_i(x_1) = \psi''_i(x_1 h^{-\delta} T^{-1})$, $\psi''_i \in \mathscr{C}_0^K([-1,1])$ *equal to* 1 *on* $[-\frac12, \frac12]$*; moreover by virtue of Remark 7.2.14 doing this we change none of the terms in the decomposition.*

Calculations: Mollification with Respect to τ

On the other hand, applying the operator $\phi(hL^{-1}D_t)$ and taking $t = 0$ we obtain

Theorem 7.2.16. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9) *and* (7.1.10) *be fulfilled.*

Further, let $Q'_i = \mathsf{Op}(q'_i)$ *with symbols* $q'_i \in \mathsf{S}'_{h,K}$ *supported in* $\{|\xi'| \le c\}$ *and* $\psi_i \in \mathscr{C}_0^K(B(0,1-\epsilon))$. *Finally, let* $\chi \in \mathscr{C}_0^K([-1,1])$, $\chi = 1$ *at* $[-\frac12, \frac12]$,

$T \in [h^{1-\delta}, h^{\frac12+\delta}]$ *and* $L \ge h^{1-\delta'}T^{-1}$. *Then*

$$\|D_x^\alpha D_y^\beta \Big(\phi(L^{-1}hD_t)\chi_T(t)\big(Q'_{1x}\psi_1(x)U^{1\pm}\psi_2(y)^t Q'_{2y}\big)\big|_{t=0}\mp \sum_{0\le n\le N'-1} h^{-d+n+1}\int \phi\big(\frac{\tau'}{L}\big)\,d\tau' \int d\xi' \int_{\gamma_+} d\xi_1 \int_{\gamma_-} d\eta_1 \times e^{ih^{-1}(x_1\xi_1-y_1\eta_1+\langle x'-y',\xi'\rangle}q'_1(x,\xi')F_n(y',\xi',\xi_1,\eta_1,\tau'\mp i0)[q'_2(y,\xi')]\Big)\| \le C'h^s \quad \forall \alpha,\beta : |\alpha|\le s, |\beta|\le s \quad \forall x,y \in \bar R^+ \times \mathbb{R}^{d-1} \tag{7.2.64}$$

and

$$\|D_{x'}^\alpha D_{y'}^\beta \Big(\phi(L^{-1}hD_t)\chi_T(t)\int_0^\infty \big(Q'_{1x}U^{1\pm}(y)^t Q'_{2y})|_{x_1=y_1}\big)\,dy_1\big|_{t=0}\mp \sum_{0\le n\le N'-1} h^{-d+n+2}\int \phi\big(\frac{\tau'}{L}\big)\,d\tau' \int d\xi' \times e^{ih^{-1}\langle x'-y',\xi'\rangle}q'_1(x,\xi')W'_n(y',\xi',\tau'\mp i0)[q'_2(y,\xi')]\Big)\| \le C'h^s \quad \forall \alpha,\beta : |\alpha|\le s, |\beta|\le s \quad \forall x',y' \in \mathbb{R}^{d-1} \tag{7.2.65}$$

with the same N', N'', K, δ, δ' *as before*[9)].

7.2.4 Exploiting Microhyperbolicity

Now let us apply the microhyperbolicity condition and try to prove that inequalities (7.2.59) and (7.2.63) remain true (under some assumptions) for $T \in [h^{1-\delta}, T_0]$ with a small enough constant $T_0 > 0$; then the same will be true for (7.2.64) and (7.2.65) as well.

Theorem 7.2.17. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9) *and* (7.1.10) *be fulfilled.*

Further, let $Q'_i = \mathsf{Op}(q'_i)$ *with symbols* $q'_i \in \mathsf{S}'_{h,K}$ *supported in* $\{|\xi'| \le c\}$ *and* $\psi_i \in \mathscr{C}_0^K(B(0,1-\epsilon))$.

Furthermore, let us assume that the problem $(\tau - A, \eth B)$ *is microhyperbolic on* $\mathsf{supp}(q'_2)$ *in the multidirection* $\mathcal{T} = (\ell', \nu_1, \dots, \nu_n)$ *for every* $\tau \in [\tau_1, \tau_2]$.

Finally, let $\chi \in \mathscr{C}_0^K([-1,1])$ *and* $T \in [h^{1-\delta}, T_0]$, $T_0 = T_0(d, m, D, c, \epsilon)$. *Then for* $\tau \in [\tau_1, \tau_2]$, $|\alpha| \le s$, $|\beta| \le s$, *the following estimates hold:*

[9)] We assume for the sake of simplicity that Q'_i and ψ'_i do not depend on x_1 for $x_1 \le Th^{-\delta'}$.

(i) If $\ell'_x = 0$, $\nu_1 = ... = \nu_n = \nu$ *then*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma_x\big(D_x^\alpha D_y^\beta Q'_{1x}\psi_1(x)U^{1\pm}\psi_2(y)^t Q'_{2y}\big)\big|_{t=0}\mp \sum_{0\le n\le N'-1} h^{-d+n-|\alpha|-|\beta|}\int T\hat\chi\big(\frac{\tau' T}{h}\big)d\tau'\int_{\gamma_+}d\xi_1\int_{\gamma_-}d\eta_1\times e^{ih^{-1}y_1(\xi_1-\eta_1)}F^1_{n,\alpha,\beta}(y',\xi_1,\eta_1,\tau-\tau'\mp i0)\| \le C'h^s \quad \forall y\in \bar{\mathbb{R}}^+\times\mathbb{R}^{d-1}, \tag{7.2.66}$$

where (as $\tau\in[\tau_1,\tau_2]$*)* $F^1_{n,\alpha,\beta}(y',\xi_1,\eta_1,\tau\mp i0)$ *are regular functions with respect to all variables and analytic with respect to* ξ_1 *and* η_1 *such that*

$$F^1_{n,\alpha,\beta}(y',\xi_1,\eta_1,\tau\mp i0)\sim\sum_{0\le k} c_{nk\alpha\beta}(y',\eta_1,\tau\mp i0)\xi_1^{-k-1} \tag{7.2.67}$$

as $|\xi_1|\to\infty$ *(and a similar decomposition holds as* $|\eta_1|\to\infty$*), coefficients* $c_{nk\alpha\beta}$ *are regular and for them similar decompositions hold as* $|\xi_1|\to\infty$ *or* $|\eta_1|\to\infty$.

Moreover, functions $F^1_{n,\alpha,\beta}(y',\xi_1,\eta_1,\tau+i0)$ *and* $F^1_{n,\alpha,\beta}(y',\xi_1,\eta_1,\tau-i0)$ *coincide provided* $(y',\xi')\notin\Sigma_{\tau,b}\cap\operatorname{supp}(q'_1)\cap\operatorname{supp}(q'_2)$ *for every* $\xi'\in\mathbb{R}^{d-1}$.

(ii) If $\ell'_x = 0$ *then*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma''\big(D_x^\alpha D_y^\beta Q'_{1x}\psi_1(x)U^{1\pm}\psi_2(y)^t Q'_{2y}\big)\big|_{t=0}\mp \sum_{0\le n\le N'-1} h^{-d+n-|\alpha|-|\beta|+1}\int T\hat\chi\big(\frac{\tau' T}{h}\big)\,d\tau'\times W_{n,\alpha,\beta}(y',\tau-\tau'\mp i0)\| \le C'h^s \tag{7.2.68}$$

and

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma'_{x'}\big(\eth_x\eth_y D_x^\alpha D_y^\beta Q'_{1x}\psi_1(x)U^{1\pm}\psi_2(y)^t Q'_{2y}\big)\big|_{t=0}\mp \sum_{0\le n\le N'-1} h^{-d+n-|\alpha|-|\beta|}\int T\hat\chi\big(\frac{\tau' T}{h}\big)\,d\tau'\times W'_{n,\alpha,\beta}(y',\tau-\tau'\mp i0)\| \le C'h^s \quad \forall y'\in\mathbb{R}^{d-1} \tag{7.2.69}$$

where (as $\tau\in[\tau_1,\tau_2]$*)* $W_{n,\alpha,\beta}(y',\tau\mp i0)$ *and* $W'_{n,\alpha,\beta}(y',\tau\mp i0)$ *are regular functions which*[10] *coincide provided* $(y',\xi')\notin\Sigma_{\tau,b}\cap\operatorname{supp}(q'_1)\cap\operatorname{supp}(q'_2)$ *for every* $\xi'\in\mathbb{R}^{d-1}$.

[10] With the signs "+" and "−".

(iii) If $\nu_1 = ... = \nu_n = \nu$, *then*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma'''\big(D_x^\alpha D_y^\beta Q'_{1x}\psi_1(x)U^{1\pm}\psi_2(y)^t Q'_{2y}\big)\big|_{t=0}\mp \sum_{0\le n\le N'-1} h^{-d+n-|\alpha|-|\beta|}\int T\hat\chi\big(\frac{\tau' T}{h}\big)d\tau'\int_{\gamma_+} d\xi_1\int_{\gamma_-} d\eta_1\times e^{ih^{-1}y_1(\xi_1-\eta_1)}F^2_{n,\alpha,\beta}(\xi_1,\eta_1,\tau-\tau'\mp i0)\| \le C'h^s \quad \forall y_1\in\bar{\mathbb{R}}^+ \tag{7.2.70}$$

where $F^2_{n,\alpha,\beta}(\xi_1,\eta_1,\tau-\tau'\mp i0)$ *are functions of the same type as in (i) which*[10] *coincide provided* $(y',\xi')\notin \Sigma_{\tau,b}\cap\mathrm{supp}(q'_1)\cap\mathrm{supp}(q'_2)$ *for every* $(y',\xi')\in T^*Y$.

(iv) If $\ell'=0$ *then*

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\big(\eth_x\eth_y D_x^\alpha D_y^\beta Q'_{1x}\psi_1(x)U^{1\pm}\psi_2(y)^t Q'_{2y}\big)\big|_{t=0}\mp \sum_{0\le n\le N'-1} h^{-d+n-|\alpha|-|\beta|}\int T\hat\chi\big(\frac{\tau' T}{h}\big)\,d\tau'\times e^{ih^{-1}\langle x'-y',\xi'\rangle}W''_{n,\alpha,\beta}(y',\tau-\tau'\mp i0)d\xi'\| \le C'h^s \quad \forall x',y'\in\mathbb{R}^{d-1} \tag{7.2.71}$$

where $W''_{n,\alpha,\beta}(y',\tau\mp i0)$ *are functions of the same type as in (ii) which*[10] *coincide provided* $(y',\xi')\notin\Sigma_{\tau,b}\cap\mathrm{supp}(q'_1)\cap\mathrm{supp}(q'_2)$.

(v) In the general case

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(D_x^\alpha D_y^\beta Q'_{1x}\psi_1(x)U^{1\pm}\psi_2(y)^t Q'_{2y}\big)\big|_{t=0}\mp \sum_{0\le n\le N'-1} h^{-d+n-|\alpha|-|\beta|+1}\int T\hat\chi\big(\frac{\tau' T}{h}\big)d\tau'\times e^{ih^{-1}\langle x'-y',\xi'\rangle}W'''_{n,\alpha,\beta}(\tau-\tau'\mp i0)\,d\xi'\| \le C'h^s \tag{7.2.72}$$

and

$$\|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma'\big(\eth_x\eth_y D_x^\alpha D_y^\beta Q'_{1x}\psi_1(x)U^{1\pm}\psi_2(y)^t Q'_{2y}\big)\big|_{t=0}\mp \sum_{0\le n\le N'-1} h^{-d+n-|\alpha|-|\beta|}\int T\hat\chi\big(\frac{\tau' T}{h}\big)\,d\tau'\times e^{ih^{-1}\langle x'-y',\xi'\rangle}W^{IV}_{n,\alpha,\beta}(y',\tau-\tau'\mp i0)\,d\xi'\| \le C'h^s \tag{7.2.73}$$

where $W'''_{n,\alpha,\beta}(\tau \mp i0)$ *and* $W^{IV}_{n,\alpha,\beta}(\tau \mp i0)$ *are functions of the same type as in (ii) which*[10] *coincide provided* $(y',\xi') \notin \Sigma_{\tau,b} \cap \mathsf{supp}(q'_1) \cap \mathsf{supp}(q'_2)$ *for every* $(y',\xi') \in T^*Y$.

(vi) Moreover, for $n = 0$ *all the functions* $F^{\cdots}_{\cdots}$, $W^{\cdots}_{\cdots}$ *contain* q^0_1, q^0_2, ψ_1 *and* ψ_2 *as factors.*

(vii) Finally, in (ii), (iv) and (v) one can replace ψ_1 *and* ψ_2 *by* $\psi_1\psi'_1(x_1 h^{\delta'} T^{-1})$ *and* $\psi_2\psi'_2(y_1 h^{\delta'} T^{-1})$ *respectively.*

Proof. The proof evidently follows from Theorems 7.2.13, 7.2.13 and 3.3.5 if we prove that for χ supported in $[-1,-\epsilon'] \cup [\epsilon',1]$ with arbitrarily small $\epsilon' > 0$ all the terms of the decomposition are $O(h^s)$ and also prove that the functions $F^{\cdots}_{\cdots}$, $W^{\cdots}_{\cdots}$ are as regular as is announced in the corresponding statements. Repeating the arguments of the proof of Proposition 4.3.9 we obtain that it is sufficient to prove only the statements concerning regularity.

Further, all the statements concerning regularity of the functions $W^{\cdots}_{\cdots}$ follow from the corresponding assertions of Theorems 7.2.13 and 7.2.15 and from Appendix 4.A.1. Therefore it is sufficient to prove regularity properties of $F^{\cdots}_{\cdots}$ in the cases (i) and (iii). We treat case (i) and case (iii) which is treated in the same way is left to the reader.

Let us replace the contour γ_+ by the union of contours $\gamma_{+,j}$ with $\gamma_{+,j}$ located near $\xi_1 = \zeta_j$ for $j \ge 1$ and $\gamma_{+,0}$ located in $\mathsf{Im}\,\xi_1 \ge \epsilon''$; similarly we replace γ_- where now $\gamma_{-,0}$ is located in $\mathsf{Im}\,\xi_1 \le -\epsilon$; as a result we obtain the sum of terms

$$\int_{\gamma_{+,j}} d\xi_1 \int_{\gamma_{-,k}} d\eta_1 \times \xi_1^p \eta_1^r e^{ix_1(\xi_1-\eta_1)} f_1(\xi_1,\xi',\tau) W(\xi',\tau) f_2(\eta_1,\xi',\tau) \coloneqq \Phi(\xi',\tau)$$

where f_1 is a product of $(\tau - a(\xi_1,\xi'))^{-1}$ separated by regular functions of ξ' and f_2 has a similar form, $p \le m-1$, $r \le m-1$ and for the sake of simplicity we do not indicate here dependence on y' and do not write the exterior integral with respect to ξ'.

Without any loss of the generality one can assume that $\ell' = \partial_{\xi_2}$ (if $\ell' = 0$ we can introduce an additional variable). Then in W the replacement of $\tau \in \mathbb{R}$ by $\tau \mp i0$ is equivalent to the replacement of $\xi_2 \in \mathbb{R}$ by $\xi_2 \pm i0$ and in f_1 and f_2 the replacement of $\tau \in \mathbb{R}$ by $\tau \mp i0$ is equivalent to the replacement

$$\xi_2 \to \xi_2 \pm i0, \quad \xi_1 \to \xi_1 + i\nu\,\mathsf{Im}\,\xi_2, \quad \eta_1 \to \eta_1 + i\nu\,\mathsf{Im}\,\xi_2$$

(let us recall that $\nu_1 = ... = \nu_n = \nu$ in the case (i) and ν_0 can be chosen arbitrarily). Therefore the replacement of $\tau \in \mathbb{R}$ by $\tau \mp i0$ is equivalent to the replacement of $\xi_2 \in \mathbb{R}$ by $\xi_2 \pm i0$ with the deformation of contours $\gamma_\pm \to \gamma_\pm + i\nu \operatorname{Im} \xi_2$ and without any loss of the generality one can assume that $\gamma_\pm \subset \mathbb{C}_\pm \cup \mathbb{R}$; then the absolute value of the exponent does not exceed 1 and on the deformed contours $\|(\tau - a(\xi', \xi_1))^{-1}\| \le C|\operatorname{Im} \xi_2|^{-1}$.

Therefore we obtain that there exists an almost analytic (with respect to ξ_2) extension of $\Phi(y', \xi', \tau \mp i0)$ to the domain $\{\pm \operatorname{Im} \xi_2 > 0\}$ such that

$$\|D_{y'}^\alpha D_\tau^\beta \Phi n(y', \xi', \tau \mp i0)\| \le C'|\operatorname{Im} \xi_2|^{-N} \qquad \forall \alpha, \beta : |\alpha| + \beta \le s.$$

Therefore after multiplication by functions compactly supported with respect to ξ' and integration with respect to ξ_2 we obtain functions $F_{...}^{...}(y', \tau \mp i0)$ which are smooth due to Appendix 4.A.2. □

7.2.5 Conclusion

We leave to the reader to write down corollaries of Theorems 7.2.13 and 7.2.15 in which $U^{1\pm}$ are replaced by their sum $U^1 = U^{1+} + U^{1-}$ and $\mp F_{...}^{...}(\tau)$, $\mp W_{...}^{...}(\tau)$ with $\tau \in \mathbb{C}_\mp$ are replaced by

$$\begin{aligned} \mathcal{F}_{...}^{...}(\tau) &= F_{...}^{...}(\tau - i0) - F_{...}^{...}(\tau + i0), \\ \mathcal{W}_{...}^{...}(\tau) &= W_{...}^{...}(\tau - i0) - W_{...}^{...}(\tau + i0) \end{aligned}$$

with $\tau \in \mathbb{R}$ where we skip all other arguments.

Similarly, in Theorems 7.2.16 and 7.2.17 one can do the similar modifications except here we replace $\tau - \tau' \mp i0$ in the arguments just by $\tau - \tau'$.

Finally, we leave to the reader to write down decompositions when U^1 (or $U^{1\pm}$) is replaced by $U = U^0 + U^1$ (or $U^\pm = U^{0\pm} + U^{1\pm}$) and decompositions of this section are added to decomposition of Section 4.3.

We will use all these decompositions in the next section as needed.

7.3 General Basic Theorems

In this section we obtain the principal microlocal and local asymptotics. Proofs which are completely similar to those of Section 4.4 are usually left to the reader.

7.3.1 Asymptotics with Mollification

We begin with microlocal asymptotics with mollification with respect to the spectral parameter.

Theorem 7.3.1. [11] *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9) *and* (7.1.10) *be fulfilled and let* $Q_i = \mathsf{Op}(q_i)$, $q_i \in \mathsf{S}_{h,K}$ *be supported in* $\{|\xi'| \le c\}$, $\psi_i \in \mathscr{C}_0^K(B(0,1-\epsilon))$*; let* $\phi \in \mathscr{C}_0^K([-c,c])$ *and* $\bar\tau \in [-c,c]$. *Then*

(i) For $L \in [h^{\frac12-\delta}, 1]$ *the following estimates hold:*

$$\frac{1}{L}\Big\|\int \phi\big(\frac{\tau-\bar\tau}{L}\big)\Big(d_\tau Q'_{1x}\psi_1(x)e(x,y,\tau_1,\tau)\psi_2(y)^t Q'_{2y} - \sum_{0\le n\le N'-1} h^{-d+n}\mathcal{K}'_n(x,y,\tau)\,d\tau\Big)\Big\| \le C'h^s \quad \forall x,y \in \bar{\mathbb{R}}^+\times\mathbb{R}^{d-1}, \tag{7.3.1}$$

$$\frac{1}{L}\Big\|\int \phi\big(\frac{\tau-\bar\tau}{L}\big)\Big(d_\tau \Gamma_x Q'_{1x}\psi_1(x)e(x,y,\tau_1,\tau)\psi_2(y)^t Q'_{2y} - \sum_{0\le n\le N'-1} h^{-d+n}\kappa'_n(x,\tau)\,d\tau\Big)\Big\| \le C'h^s \quad \forall x \in \bar{\mathbb{R}}^+\times\mathbb{R}^{d-1}, \tag{7.3.2}$$

$$\frac{1}{L}\Big\|\int \phi\big(\frac{\tau-\bar\tau}{L}\big)\Big(d_\tau \Gamma Q'_{1x}\psi_1(x)e(x,y,\tau_1,\tau)\psi_2(y)^t Q'_{2y} - \sum_{0\le n\le N'-1} h^{-d+n}\varkappa'_n(x,y,\tau)\,d\tau\Big)\Big\| \le C'h^s \tag{7.3.3}$$

where $\mathcal{K}'_n = \mathcal{K}^{0\prime}_n + \mathcal{K}^{1\prime}_n$, $\mathcal{K}^{0\prime}_n$ *and* $\mathcal{K}^0_n$ *are defined by* (4.4.5) *and* (4.4.6) *respectively,* $\kappa'_n = \kappa^{0\prime}_n + \kappa^{1\prime}_n$ *and* $\kappa^{\cdots}_{\cdots} = \mathcal{K}^{\cdots}_{\cdots}|_{x=y}$, $\varkappa'_n = \varkappa^{0\prime}_n + \varkappa^{1\prime}_n$ *and* $\varkappa^{\cdots}_{\cdots} = \int \kappa^{\cdots}_{\cdots}\,dx$ *while*

$$\mathcal{K}^{1\prime}_n(x,y,\tau) = -2\pi i \int d\xi' \int_{\gamma_+} d\xi_1 \int_{\gamma_-} d\eta_1 \times e^{ih^{-1}(x_1\xi_1 - y_1\eta_1 + \langle x'-y',\xi'\rangle)}\,\mathsf{Res}_{\mathbb{R}}\, F^1_{n,0,0}(x',\xi_1,\eta_1,\xi',\tau), \tag{7.3.4}$$

[11] Compare with Theorem 4.4.1.

$$\kappa_n^{1\prime}(x,\tau)=\Gamma_x\mathcal{K}_n^{1\prime}(x,y,\tau)=-2\pi i\int d\xi'\int_{\gamma_+}d\xi_1\int_{\gamma_-}d\eta_1\times e^{ih^{-1}x_1(\xi_1-\eta_1)}\operatorname{Res}_{\mathbb{R}}F^1_{n,0,0}(x',\xi_1,\eta_1,\xi',\tau), \tag{7.3.5}$$

$$\varkappa_n^{1\prime}(\tau)=\Gamma\mathcal{K}_n^{1\prime}(x,y,\tau)=-2\pi i\operatorname{Res}_{\mathbb{R}}W_{n-1,0,0}(\tau),\quad \varkappa_0^{1\prime}(\tau)=0, \tag{7.3.6}$$

and functions $F^1_{n,0,0}(x',\xi_1,\eta_1,\xi',\tau)$ *and* $W_{n,0,0}$ *are defined in Theorem 7.2.17.*

(ii) Assume that the operator $(\tau-A)$ *is microhyperbolic for* $\tau=\bar\tau$ *at* $\operatorname{supp}(q_1')\cap\operatorname{supp}(q_2')\cap T^*(X\cap B(0,1))$ *in some direction* ℓ *and that the problem* $(\tau-A,\eth B)$ *is microhyperbolic for* $\tau=\bar\tau$ *at* $\operatorname{supp}(q_1')\cap\operatorname{supp}(q_2')\cap T^*(Y\cap B(0,1))$ *in some multidirection* $\mathcal{T}=(\ell',\nu_1,\dots,\nu_N)$*. Then* (7.3.3) *remains true for* $L\in[h^{1-\delta},1]$*.*

Moreover, if $\ell_x=\ell'_x=0$ *then the same is true for asymptotics* (7.3.2)*.*

7.3.2 Asymptotics under Microhyperbolicity Condition

Assuming that the problem is microhyperbolic let us now consider non-mollified asymptotics and asymptotics with smaller L.

Theorem 7.3.2. [12] *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9) *and* (7.1.10) *be fulfilled and let* $Q_i=\operatorname{Op}(q_i)$, $q_i\in\mathsf{S}_{h,K}$ *be supported in* $\{|\xi'|\le c\}$, $\psi_i\in\mathscr{C}_0^K(B(0,\frac12))$.

Let us assume that the problem $(\tau-A,\eth B)$ *is microhyperbolic for* $\tau=\bar\tau$ *at* $(\operatorname{supp}(q_1')\cup\operatorname{supp}(q_2'))\cap T^*(Y\cap B(0,1))$ *in some multidirection* $\mathcal{T}$*. Then*

(i) Estimates

$$\mathsf{R}^{\mathsf{W}}=\|\Gamma\big(Q'_{1x}\psi_1(x)e(x,y,\tau_1,\tau_2)\psi_2(y)^tQ'_{2y}\big)-h^{-d}\varkappa_0(\tau_1,\tau_2)-h^{1-d}\varkappa_1(\tau_1,\tau_2)\|\le C\big(M_0(\tau_1)+M_0(\tau_2)\big)h^{1-d}+Ch^{2-d}\quad\forall\tau_1,\tau_2\in[\bar\tau-\epsilon_0,\bar\tau+\epsilon_0], \tag{7.3.7}$$

[12] Compare with Theorems 4.4.5, 4.4.6, 4.4.8, 4.4.11 and 4.4.12.

$$\mathsf{R}_1^{\mathsf{W}} = \frac{1}{L}\| \int \varphi\big(\frac{\tau'-\bar\tau}{L}\big)\Big(\Gamma\big(Q'_{1x}\psi_1(x)e(x,y,\tau',\tau)\psi_2(y)^t Q'_{2y}\big) - h^{-d}\varkappa_0(\tau',\tau) - h^{1-d}\varkappa_1(\tau',\tau)\Big)d\tau'\| \le M_0(\tau)h^{1-d} + Ch^{2-d} \quad \forall \tau \in [\bar\tau-\epsilon_0, \bar\tau+\epsilon_0] \tag{7.3.8}$$

hold where $\epsilon_0 = \epsilon_0(d, m, D, c) > 0$ *is small enough,* $\varphi \in \mathscr{C}_0^K([-c, c])$, $L \in [h^{1-\delta}, 1]$ *is arbitrary,*

$$M_0(\tau) = \|\varkappa'_{0,q_1}(\tau)\| + \|\varkappa'_{0,q_2}(\tau)\| \tag{7.3.9}$$

and

$$\varkappa_n(\tau_1,\tau_2) = \int_{\tau_1}^{\tau_2} \varkappa'_n(\tau)d\tau \tag{7.3.10}$$

and other notations of Section 4.4 are used.

(ii) Assume instead that φ *satisfies* (4.2.73)–(4.2.75). *Then*

$$\mathsf{R}^{\mathsf{W}}_{\varphi,L} = \| \int \varphi\big(\frac{\tau'-\bar\tau}{L}\big)d_\tau\Big(\Gamma\big(Q'_{1x}\psi_1(x)e(x,y,\tau_1,\tau)\psi_2(y)^t Q'_{2y}\big) - h^{-d}\varkappa_0(\tau_1,\tau) - h^{1-d}\varkappa_1(\tau_1,\tau)\Big)\| \le C\big(M_0(\bar\tau)h^{1-d} + Ch^{2-d}\big)\vartheta\big(\frac{h}{L}\big). \tag{7.3.11}$$

Remark 7.3.3. (i) Obviously, the list of statements could be extended in the correspondence with the statements of Theorem 7.2.17.

(ii) In particular, in the same assumptions as above one can replace Γ by $\Gamma'\eth_x\eth_y$ i.e. with integration over ∂X after restriction to $x = y \in \partial X$; In this case $\varkappa_n$, $\varkappa'_n$ are replaced by $\int \eth\kappa_n dx'$ and $\int \eth\kappa'_n dx'$ both in asymptotics (7.3.7), (7.3.8), (7.3.11) and in definition (7.3.9) of M_0; note that zone where $(\tau - a)$ is elliptic may contribute to thus redefined M_0.

(iii) Further, if $\ell'_x = 0$ both in Theorem 7.3.2 and in the Statement (ii) above we can skip integration with respect to x' (but not with respect to x_1).

(iv) On the other hand, if $\nu_1 = ... = \nu_m = \nu$ in Theorem 7.3.2 we can skip integration with respect to x_1.

(v) Finally, if both $\ell'_x = 0$ and $\nu_1 = ... = \nu_m = \nu$ in Theorem 7.3.2 we can skip integration with respect to x.

7.3.3 Asymptotics in the Elliptic Zone

Let us now treat the case in which A is elliptic for $\tau \in [\tau_1, \tau_2]$ on $\mathsf{supp}(q_2')$. In this case $\varkappa_0(\tau', \tau'') = 0$ for $\tau', \tau'' \in [\tau_1, \tau_2]$.

Remark 7.3.4. Ellipticity of the operator yields that $U^0\, {}^tQ_{2y} \equiv 0$; however it is not true for $U^{0\pm}\, {}^tQ_{2y}$ which are given by

$$U^{0\pm}\, {}^tQ_{2y} \equiv \mp iG\delta(t)\delta(x-y)\, {}^tQ_{2y} \tag{7.3.12}$$

where G is a parametrix of elliptic in this zone operator $(hD_t - A)$ (and due to ellipticity we do have separate $G^{\pm}$.

Let us calculate $\varkappa_1'(\tau)$, $\varkappa_1(\tau', \tau'')$ and $\mathcal{K}_0'(x, y, \tau)$, $\mathcal{K}_0(x, y, \tau', \tau'')$ for these τ, τ', τ''. Here we skip superscript ^{1} since U^0 does not contribute into these functions.

Construction of these functions yields that in our case it is sufficient to do the special case $A = a(hD_1)$, $B = b(hD_1)$; this easily yields

Lemma 7.3.5. *Let the conditions of Theorem 7.3.1 be fulfilled and let A be elliptic for $\tau \in [\tau_1, \tau_2]$ on $\mathsf{supp}(q_2')$. Then for $\tau', \tau'' \in [\tau_1, \tau_2]$*

$$\mathcal{K}_0(x, y, \tau', \tau'') = (2\pi)^{1-d} \int e^{ih^{-1}\langle x'-y', \xi'\rangle} q_1^0(x', \xi') \times \mathsf{e}(h^{-1}x_1, h^{-1}y_1; y', \xi', \tau', \tau'') q_2^0(x', \xi')\, d\xi' \tag{7.3.13}$$

and

$$\mathcal{K}_0'(x, y, \tau) = (2\pi)^{1-d} \int e^{ih^{-1}\langle x'-y', \xi'\rangle} q_1^0(x', \xi') \times \partial_\tau \mathsf{e}(h^{-1}x_1, h^{-1}y_1; y', \xi', \tau, \tau'') q_2^0(x', \xi')\, d\xi' \tag{7.3.14}$$

where τ', τ'' are spectral parameters, $\mathsf{e}(x_1, y_1; y', \xi', \tau', \tau'')$ is the Schwartz kernel of the spectral projector of one-dimensional operator

$$\mathsf{a} := a(0, y', D_1, \xi'), \tag{7.3.15}$$

on $\mathscr{L}^2(\mathbb{R}^+, \mathbb{H})$ with the domain

$$\mathfrak{D}(\mathsf{a}) = \{v \in \mathscr{H}^1(\mathbb{R}^+, \mathbb{H}) : \eth b(y', D_1, \xi')v = 0\} \tag{7.3.16}$$

Proof. Easy calculations are left to the reader. □

Corollary 7.3.6. *Therefore in the framework of Lemma 7.3.5*

$$\varkappa_1 := \Gamma\mathcal{K}_0(.,,,\tau',\tau'') = (2\pi)^{1-d}\int q_1^0(x',\xi')\upsilon(x',\xi',\tau',\tau'')q_2^0(x',\xi')\,dx'd\xi' \tag{7.3.17}$$

where

$$\upsilon = \int_0^\infty \mathsf{e}(x_1,x',x_1,x')\,dx_1. \tag{7.3.18}$$

Theorem 7.3.7. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9) *and* (7.1.10) *be fulfilled and let* $Q_i = \mathsf{Op}(q_i)$, $q_i \in \mathsf{S}_{h,K}$ *be supported in* $\{|\xi'| \le c\}$, $\psi_i \in \mathscr{C}_0^K(B(0,\frac12))$.

Further, let us assume that the operator $(\tau - A)$ *is elliptic for* $\tau = \bar\tau$ *at* $(\mathsf{supp}(q_1') \cup \mathsf{supp}(q_2')) \cap T^*(X \cap B(0,1))$ *and that the problem* $(\tau - A, \eth B)$ *is microhyperbolic for* $\tau = \bar\tau$ *at* $(\mathsf{supp}(q_1') \cup \mathsf{supp}(q_2')) \cap T^*(Y \cap B(0,1))$ *in some multidirection* $\mathcal{T}$ [13].

(i) Then

$$\mathsf{R}_b^{\mathsf{W}} := \|\Gamma\big(Q_{1x}'\psi_1(x)e(x,y,\tau_1,\tau_2)\psi_2(y)\,{}^tQ_{2y}'\big) - h^{1-d}\varkappa_1(\tau_1,\tau_2) - h^{2-d}\varkappa_2(\tau_1,\tau_2)\| \le C\big(M_1(\tau_1)+M_1(\tau_2)\big)h^{2-d} + Ch^{3-d} \quad \forall \tau_1,\tau_2 \in [\bar\tau-\epsilon_0,\bar\tau+\epsilon_0], \tag{7.3.19}$$

and

$$\mathsf{R}_{b,1}^{\mathsf{W}} := \frac{1}{L}\|\int \phi\big(\frac{\tau'-\bar\tau}{L}\big)\Big(\Gamma\big(Q_{1x}'\psi_1(x)e(x,y,\tau',\tau)\psi_2(y)^tQ_{2y}'\big) - h^{1-d}\varkappa_1(\tau',\tau) - h^{2-d}\varkappa_2(\tau',\tau)\Big)\,d\tau'\| \le CM_1(\tau)h^{2-d} + Ch^{3-d} \quad \forall,\tau \in [\tau-\epsilon_0,\bar\tau+\epsilon_0]; \tag{7.3.20}$$

where ϵ_0, ϕ, L *are the same as in Theorem 7.3.2(i) and*

$$M_1(\tau) = \|\varkappa_{1q_1}'(\tau)\| + \|\varkappa_{1q_2}'(\tau)\|. \tag{7.3.21}$$

[13] Due to ellipticity of $(\tau - A)$ $\mathcal{T} = \ell' \in T^*Y$.

(ii) Assume instead that φ satisfies (4.2.73)–(4.2.75). *Then*

$$\mathcal{R}^{\mathsf{W}}_{\varphi,L} \le C\big(M_1(\bar\tau)+h\big)h^{2-d}\vartheta\big(\frac{h}{L}\big). \tag{7.3.22}$$

(iii) If $\ell'_x = 0$ then

$$\begin{aligned}\mathsf{R}^{\mathsf{W}}_x = \|\Gamma_{x'}\big(Q'_{1x}\psi_1(x)e(x,y,\tau_1,\tau_2)\psi_2(y)\,{}^{t}Q'_{2y}\big)- \\ h^{-d}\mathcal{K}_0(x,x,\tau_1,\tau_2)\| \le C'h^{1-d}\big(1+\frac{(x_1+y_1)}{h}\big)^{-s} \\ \forall x_1,y_1\in[0,1]\quad \forall x'\in\mathbb{R}^{d-1}\quad \forall \tau_1,\tau_2\in[\bar\tau-\epsilon_0,\bar\tau+\epsilon_0].\end{aligned} \tag{7.3.23}$$

Proof. Proof follows from arguments of the proof of Theorem 4.4.2. Microhyperbolicity of the boundary value problem provides smoothness with respect to τ all expressions involved (after corresponding integrations).

In the proof of Statement (iii) we also use the estimate

$$\|\Gamma_{x'}\mathcal{K}_n(x,y,\tau)\| \le C'\big(1+\frac{(x_1+y_1)}{h}\big)^{-s} \qquad \forall n\le s \tag{7.3.24}$$

for $\tau\in[\bar\tau-\epsilon_0,\bar\tau+\epsilon_0]$. This latter estimate follows from the fact that contours $\gamma_\pm$ can be chosen (due to the ellipticity condition) lying in the zone $\{\pm\operatorname{Im}\xi_1\ge\epsilon>0\}$. □

Remark 7.3.8. In all estimates of this section, involving two energy levels one can take one of them equal to $-\infty$ provided the following conditions are fulfilled:

$$\begin{aligned}&\langle a(x,\xi)v,v\rangle \ge -c\|v\|^2 \qquad \forall v\in\mathbb{H}\\ &\forall (x,\xi')\in(\operatorname{supp}(q'_1)\cup\operatorname{supp}(q'_2))\cap(X\cap B(0,1))\times\mathbb{R}^{d-1}\quad\forall\xi_1\in\mathbb{R}\end{aligned} \tag{7.3.25}$$

and

$$\begin{aligned}&\langle a(0,x',D_1,\xi')v,v\rangle_+ \ge -c\|v\|^2_+\\ &\qquad\forall v\in\mathscr{S}(\bar{\mathbb{R}}^+,\mathbb{H}):\mathfrak{d}b(x',D_1,\xi')v=0\\ &\forall (x',\xi')\in(\operatorname{supp}(q'_1)\cup\operatorname{supp}(q'_2))\cap(Y\cap B(0,1))\times\mathbb{R}^{d-1};\end{aligned} \tag{7.3.26}$$

moreover, these conditions imply the same inequalities (7.3.25) and (7.3.26) with the additional terms $\epsilon_0|\xi_1|^m\|v\|^2$ and $\epsilon_0\|D_1^{\frac{m}{2}}v\|_+^2$ respectively in their right-hand expressions (because $a(0,x',D_1,\xi')$ is elliptic as a one-dimensional differential operator; we assume that either (7.1.12) or the conditions of Lemma 7.1.13 are fulfilled).

Furthermore, in all the other estimates mollification with respect to τ' can be replaced by setting $\tau'=-\infty$ in this situation.

Example 7.3.9. Consider Schrödinger operator with the principal symbol

$$a=\sum_{j,k} g^{jk}(x)\bigl(\xi_j-V_j(x)\bigr)\bigl(\xi_k-V_k(x)\bigr)+V(x) \quad \text{with} \quad g^{1j}=\delta_{1j} \tag{7.3.27}$$

with the boundary condition

$$\mathfrak{d}\bigl(hD_1-i\beta(x,hD')\bigr)u=0. \tag{7.3.28}$$

We consider elliptic energy level

$$\tau<a'(x',\xi') \coloneqq \sum_{2\le j,k\le d} g^{jk}(x')\bigl(\xi_j-V_j(x')\bigr)\bigl(\xi_k-V_k(x')\bigr)+V(x') \tag{7.3.29}$$

as $x=(0,x')$ and then

$$\partial_\tau e(x_1,y_1,x',\xi',\tau,-\infty)= 2\beta(x',\xi')^{\frac12}e^{-\beta(x',\xi')(x_1+y_1)}\delta\bigl(\tau-a'(x',\xi')+\beta(x',\xi')^2\bigr)\theta\bigl(\beta(x',\xi')\bigr); \tag{7.3.30}$$

and therefore as τ satisfies (7.3.29)

$$\varkappa_1(\tau_2,\tau_1)=(2\pi)^{1-d}\iint \theta\bigl(\tau-a'(x',\xi')+\beta(x',\xi')^2\bigr)\Big|_{\tau=\tau_1}^{\tau=\tau_2}\times \theta\bigl(\beta(x',\xi')\bigr)q_1^0(x',\xi')q_2^0(x',\xi')\,dx'd\xi' \tag{7.3.31}$$

and microhyperbolicity condition is the one for $\bigl(\tau-a'(x',\xi')+\beta(x',\xi')^2\bigr)$ as $\beta(x',\xi')>0$.

7.3.4 Local Asymptotics

Let us proceed from microlocal asymptotics derived above to the local asymptotics. This transition is based on the results of Section 7.1 that in the zones $\{|\xi'| \ge C_0\}$ problem is elliptic and therefore contributions of these zones into asymptotics are negligible. The easy details are left to the reader.

Theorem 7.3.10. *Let conditions* (7.1.1), (7.1.2), $(7.1.4)_{1,2}$, (7.1.9), (7.1.10) *and* (7.1.37), (7.1.38) *be fulfilled and let* $\phi \in \mathscr{C}_0^K([-c,c])$, $\bar\tau \in [-c,c]$ *and* $L \in [h^{\frac12-\delta},1]$. *Then*

(i) The following estimate holds:

$$\frac{1}{L}\Big\| \int \phi\big(\frac{\tau-\bar\tau}{L}\big)\Big(d_\tau e(x,y,\tau_1,\tau)- \sum_{0\le n\le N'-1} h^{-d+n}\mathcal{K}'_n(x,y,\tau)\,d\tau\Big)\Big\| \le C'h^s \qquad \forall x,y \in B(0,1-\epsilon) \tag{7.3.32}$$

where $\mathcal{K}'_n$, $\mathcal{K}_n$ *are defined above for* $q_1 = q_2 = \psi_1 = \psi_2 = 1$.

(ii) Moreover, if symbol $a(x,\xi)$ *is semi-bounded from below uniformly with respect to* $(x,\xi) \in T^*(X \cap B(0,1))$ *and if operator* $a(0,x',D_1,\xi')$ *is semi-bounded from below uniformly with respect to* $(x',\xi') \in T^*(Y \cap B(0,1))$ *then*

$$\frac{1}{L}\Big\| \int \big(\phi\big(\frac{\tau-\bar\tau}{L}\big)\Big(e(x,y,-\infty,\tau)- \sum_{0\le n\le N'-1} h^{-d+n}\mathcal{K}_n(x,y,-\infty,\tau)\Big)\,d\tau\Big\| \le C'h^s \qquad \forall x,y \in B(0,1-\epsilon). \tag{7.3.33}$$

Theorem 7.3.11. *Let the conditions of the previous Theorem 7.3.10 be fulfilled and let us assume that the operator* $(\tau - A)$ *is microhyperbolic for* $\tau = \bar\tau$ *at* $T^*(X \cap B(0,1))$ *and that the problem* $(\tau - A, \eth B)$ *is microhyperbolic for* $\tau = \bar\tau$ *at* $T^*(Y \cap B(0,1))$. *Then*

(i) The following estimate holds:

$$\|\Gamma\big(\psi_1(x)e(.,.,\tau_1,\tau_2)\big) - h^{-d}\varkappa_0(\tau_1,\tau_2) - h^{1-d}\varkappa_1(\tau_1,\tau_2)\| \le C\big(M_0(\tau_1)+M_0(\tau_2)\big)h^{1-d} + Ch^{2-d} \quad \forall \tau_1,\tau_2 \in [\bar\tau-\epsilon_0,\bar\tau+\epsilon_0] \tag{7.3.34}$$

and

$$\frac{1}{L}\|\int \phi\big(\frac{\tau-\bar\tau}{L}\big)\Big(\Gamma\big(\psi_1(x)e(.,.,\tau',\tau)\big) - h^{-d}\varkappa_0(\tau',\tau) - h^{1-d}\varkappa_1(\tau',\tau)\Big)\,d\tau'\| \le M_0(\tau)h^{1-d} + CMh^{2-d} \quad \forall \tau \in [\bar\tau-\epsilon_0,\bar\tau+\epsilon_0] \tag{7.3.35}$$

where $\epsilon_0 = \epsilon_0(d,m,D,c) > 0$ is small enough, $\phi \in \mathscr{C}_0^K([-c,c])$ is fixed, $L \in [h^{1-\delta},1]$ is arbitrary, $M_0(\tau)$ and $\varkappa_n$ were defined above for $q_1 = q_2 = 1$; moreover, estimates for $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ defined by (7.3.11) *with proper modifications remain true as well.*

(ii) If the operator $(\tau - A)$ is elliptic for $\tau = \bar\tau$ at $T^*(X \cap B(0,1))$ then

$$\|\Gamma\big(\psi_1(x)e(.,.,\tau_1,\tau_2)\big) - h^{1-d}\varkappa_1(\tau_1,\tau_2) - h^{2-d}\varkappa_2(\tau_1,\tau_2)\| \le C\big(M_1(\tau_1)+M_1(\tau_2)\big)h^{2-d} + Ch^{3-d} \quad \forall \tau_1,\tau_2 \in [\bar\tau-\epsilon_0,\bar\tau+\epsilon_0] \tag{7.3.36}$$

and

$$\frac{1}{L}\|\int \phi\big(\frac{\tau-\bar\tau}{L}\big)\Big(\Gamma\big(\psi_1(x)e(.,.,\tau',\tau)\big) - h^{1-d}\varkappa_1(\tau',\tau) - h^{2-d}\varkappa_2(\tau',\tau)\Big)\,d\tau'\| \le M_1(\tau)h^{2-d} + Ch^{3-d} \quad \forall \tau \in [\bar\tau-\epsilon_0,\bar\tau+\epsilon_0] \tag{7.3.37}$$

where $M_1(\tau)$ is defined above for $q_1 = q_2 = 1$; moreover, estimates for $\mathsf{R}^{\mathsf{W}}_{\varphi,L}$ with proper modifications remain true as well.

(iii) In the framework of Statement (ii) of the previous Theorem 7.3.10 estimates (7.3.34) *and* (7.2.37) *remain true for $\tau_1 = -\infty$.*

(iv) Statements (i) and (ii) of the previous Theorem 7.3.10 remain true for $L \in [h^{1-\delta}, 1]$.

Remark 7.3.12. If we assume that the conditions of some theorem (or some part of a theorem) are fulfilled for $\tau = \bar{\tau}_i$, $i = 1, 2$, then the corresponding estimates (without mollification) remain for τ_i belonging to the ϵ_0-neighborhoods of $\bar{\tau}_i$.

7.4 Sharper Asymptotics

7.4.1 Discussion

The purpose of this section is similar to the purpose of Section 4.5: using long term propagation we want to make sharper asymptotics. However the answer strongly depends what asymptotics we are talking about:

(i) sect-7-4-1-i If our goal are asymptotics of

$$\int e(x, x, \tau)\psi(x)\, dx \tag{7.4.1}$$

(and the similar) then it follows from the previous Section 7.3 that (under microhyperbolicity assumption) contribution of the boundary strip $Y_\varepsilon := \{x \in X, \mathsf{dist}(x, \partial X) \le \varepsilon\}$ to the remainder does not exceed $C(\varepsilon + h)h^{1-d}$ and therefore we need to impose conditions of the global nature only at inner points; so basically all results of Section 4.5 remains valid but now generalized Hamiltonian flow is defined as in Chapter 3 rather than Chapter 2.

Thus even in the simplest case of the Schrödinger operator we should consider Hamiltonian billiards rather than just Hamiltonian trajectories (we will prove that the generalized Hamiltonian billiards which are not Hamiltonian billiards form set of measure zero here). Still checking non-periodicity conditions for billiards is an extremely difficult task[14)].

Situations becomes even more complicated if there is a branching on the boundary which will be the case for example for few Schrödinger operators intertwined through boundary conditions, in particular in the case when X is a "layered" domain so in each layer we have its own Schrödinger

[14)] We are talking about "classical" rather than "quantum" dynamics here.

operator which are tied through conditions on the smooth "inner boundaries"; then branching happens when incoming ray generates two outgoing rays: reflected and refracted. Another meaningful example comes from elasticity (in isotropic media) when we have compression waves and sheer waves and at reflection incoming wave of one type may generate outgoing waves of both types. Analysis of branching billiards is an incredibly difficult task and there is very little known[14]. This revives the question "what is a periodic branching billiard"?

(ii) Situation is rather different if we are discussing either

$$\int_{\partial X} e(x,x,\tau)\psi(x)\,dx' \tag{7.4.2}$$

or we are still discussing asymptotics of (7.4.1) but operator $(\tau - A)$ is elliptic (but the boundary value problem is microhyperbolic). In the former case the contribution of the inner points is missing and in the latter it is negligible. So in both cases we have a measure concentrated on $\Sigma_{\tau,b}$. One can easily generalize the results of Section 4.5 to these cases–with the obvious modifications.

(iii) And analysis of $e(x,x,\tau)$ just changes the game completely. At this moment here the previous section just does not provide complete results because the corresponding microhyperbolicity condition requires $\nu_1 = ... = \nu_N$ and cannot be satisfied at some points: for Schrödinger operator it fails near points $(x',\xi') \in T^*\partial X$ such that the reflected ray has the direction opposite to direction of the incoming ray (and repeats it if there is no magnetic field). Situation is similar to those considered in Subsubsection *5.3.1.4 Asymptotics without Spatial Mollification and Short Loops*. Namely: we have short loops (of the length $\asymp \gamma(x) := \mathsf{dist}(x,\partial X)$) and the standard rescaling technique gives us that their contribution is $O(\gamma^{-1}h^{-d})$.

However under certain assumptions we can construct $U(x,x,t)$ using oscillatory integrals and we arrive to the terms of the boundary layer type $h^{-d}\Upsilon(x',h^{-1}\gamma(x))$ with $\Upsilon(x,s) = O(s^{-\frac{1}{2}(d+1)})$. While results are similar to those for degenerating Schrödinger operator there is a difference: this term is of magnitude $O(h^{-d})$ at the boundary no matter how large dimension is. We will do it in Section 8.1.

After this difficulty is tackled (or simply avoided assuming that x is disjoint from ∂X) there are no other obstacles to get sharper remainder

estimates except that we should assume no loop condition which is very difficult to check[14)].

7.4.2 General Theory

Sharp Asymptotics

The proof of the following statements is trivial in view of the results of the previous section and propagation results of Section 3.2:

Theorem 7.4.1. *Let conditions of Theorem 7.3.2 be fulfilled. Assume that there exists set $\Xi_\tau \subset \Sigma_\tau$ such that*

$$(x,\xi) \notin \Psi_t(x,\xi) \qquad \forall (x,\xi) \in \Sigma_\tau \Xi_\tau \quad \forall t : \varsigma t > 0 \tag{7.4.3}$$

where $\Psi_t(z)$ is a generalized Hamiltonian billiard flow in the sense of Definitions 3.2.2–3.2.3[15)] *where $\varsigma = \pm$ may depend on (x,ξ).*

Further, assume that $Q_1, Q_2 \in \mathbf{\Psi}_{h,K}(X \setminus \partial X, \mathbb{H})$ have symbols q_1, q_2 with the compact supports

$$\mu_\tau\big(\Xi_\tau \cap \operatorname{supp}(q_1^0) \cap \operatorname{supp}(q_2^0)\big) = 0 \tag{7.4.4}$$

as $\tau = \tau_1$, $\tau = \tau_2$ and $\tau = \bar\tau$ where $\mu_\tau = \delta(\tau - a)$ is the same measure as in Section 4.5. Then

(i) The left-hand expressions of (7.3.7) *and* (7.3.8) *are $o(h^{1-d})$.*

(ii) Moreover, in the framework of Theorem 7.3.2(ii) the left-hand expression of (7.3.11) *is $o\big(h^{1-d}\vartheta(hL^{-1})\big)$.*

Corollary 7.4.2. *Let conditions of Theorem 7.3.11(i) be also fulfilled. Then Theorem 7.4.1 remains true as $Q_j = \psi_j(x) \in \mathscr{C}_0^K(X \setminus \partial X, \mathbb{H})$.*

Remark 7.4.3. If (7.4.3) is fulfilled for measure μ'_τ which is the restriction of μ_τ to ∂X then all the statements above remain true for $Q_1, Q_2 \in \mathbf{\Psi}_{h,K}(\partial X, \mathbb{H})$, $\psi_j(x) \in \mathscr{C}_0^K(\partial X, \mathbb{H})$ and Γ replaced by $\Gamma' \eth_x \eth_y$ (see Remark 7.3.3(ii)).

[15)] I.e. it is an intersection of $\mathcal{K}^\varsigma(z, \tau - a, b)$ with $\{x_0 = t\}$.

Theorem 7.4.4. *Let conditions of Theorem 7.3.7 be fulfilled. Assume that there exists set* $\Xi_{\tau,b} \subset \Sigma_{\tau,b}$ *such that* (7.4.3) *is fulfilled.*

Further, assume that $Q_1, Q_2 \in \mathbf{\Psi}_{h,K}(X, \mathbb{H})$ *have symbols* q_1, q_2 *with the compact supports and condition* (7.4.3) *is fulfilled as* $\tau = \tau_1$, $\tau = \tau_2$ *and* $\tau = \bar{\tau}$ *with* $\mu_{\tau,b} = \delta(\tau - a)$ *which is the similar measure but now it is concentrated on* ∂X *and* $\mathbb{H}$ *is replaced by* $\mathscr{S}(\mathbb{R}^+, \mathbb{H})$. *Then*

(i) The left-hand expressions of (7.3.19) *and* (7.3.20) *are* $o(h^{2-d})$.

(ii) Moreover, in the framework of Theorem 7.3.7(ii) the left-hand expression of (7.3.22) *is* $o\big(h^{2-d}\vartheta(hL^{-1})\big)$.

Corollary 7.4.5. *Let conditions of Theorem 7.3.11(ii) be fulfilled. Then Theorem 7.4.4 remains true as* $Q_j = \psi_j(x) \in \mathscr{C}_0^K(\partial X, \mathbb{H})$.

Sharper Asymptotics

Our goal is to establish either remainder estimate $O(h^{1-d-\delta})$ with unspecified exponent $\delta > 0$ or $O(h^{1-d}|\log h|^{-1})$.

Theorem 7.4.6 [16]**.** *Let assumptions of Theorem 7.3.2 be fulfilled. Let* $r_i^0 \in \mathsf{S}_{h,\gamma,\gamma,K}(T^*X)$ [17] *be scalar symbols satisfying* (4.5.11).

Consider generalized Hamiltonian flow $\Psi_{t,\bar{\tau}_*}$ *issued from* γ*-vicinity* $\mathcal{U}_i$ *of* $\operatorname{supp}(r_i^0) \cap \operatorname{supp}(q_1 \cap) \operatorname{supp}(q_2)$. *Assume that as* $\varsigma t > 0$ *with* $\varsigma := \varsigma_{*i}$ [32] *and* $|t| \le T_{*i}$ *conditions* (4.5.28), (4.5.30) *and* (4.5.31) *are fulfilled and, moreover, as* $i = 1, \dots, m$ *along* $\Psi_{t,\tau}(\mathcal{U})$ *conditions of either Theorem 2.4.17 or Theorem 3.5.3 are fulfilled with* $\mathcal{U} := \mathcal{U}_i$.

Then estimates (4.5.32)–(4.5.34) *hold with term* $C'h$ *in the factor replaced by* $C'h\gamma^{-2}$ *with the left-hand expressions defined respectively by* (4.4.19), (4.4.16) *and* (4.4.17) *(without* $_x$*) with* $J(q^0 B^j, \bar{\tau})$ *defined by* (4.4.26). *Here* C' *does not depend on* γ, T_{*i}.

Theorem 7.4.7 [18]**.** *Let assumptions of Theorem 7.3.2 be fulfilled. Let* A *be* ξ*-microhyperbolic on* $\operatorname{supp}(q_1) \cup \operatorname{supp}(q_2)$ *on the energy levels* $\bar{\tau}_*$, $* = 1, 2$. *Let* $r_i^0 \in \mathsf{S}_{h,\gamma,\gamma,K}(T^*X)$ *be scalar symbols satisfying* (4.5.35).

---

[16] Cf. Theorem 4.5.11.

[17] With $h^{\frac{1}{2}-\delta} \le \gamma \le 1$.

[18] Cf. Theorem 4.5.12.

Consider generalized Hamiltonian flow $\Psi_{t,\bar\tau_*}$ *issued from* γ*-vicinity* $\mathcal{U}_i$ *of* $\mathsf{supp}(r_i^0) \cap (\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2))$. *Assume that as* $|t| \le T_{*i}$ *conditions* (4.5.28), (4.5.29) *and* (4.5.31) *are fulfilled and, moreover, as* $i = 1, \dots, m$ *along* $\Psi_{t,\tau}(\mathcal{U})$ *conditions of either Theorem 2.4.17 or Theorem 3.5.3 are fulfilled with* $\mathcal{U} := \mathcal{U}_i$.

Then estimates (4.5.36)–(4.5.38) *hold with term* $C'h$ *in the factor replaced by* $C'h\gamma^{-2}$ *with the left-hand expressions defined respectively by* (4.4.19), (4.4.16) *and* (4.4.17) *(without* $_x$*) with* $J(q^0 B^j, \bar\tau)$ *defined by* (4.4.26). *Here* C' *does not depend on* γ, T_{*i}.

7.4.3 Billiard Flow for Schrödinger Operator

We need to tackle Hamiltonian billiard flow in different domains and manifolds with the boundary.

Definition of the Flow

Consider Schrödinger operator with the symbol

$$a = \sum_{j,k} g^{jk}(x)\bigl(\xi_j - V_j(x)\bigr)\bigl(\xi_k - V_k(x)\bigr) + V(x) \tag{7.4.5}$$

and instead of generalized Hamiltonian billiards we consider ordinary Hamiltonian billiards composed of Hamiltonian trajectories

$$\frac{dz}{dt} = \nabla^{\#} a(z) \tag{7.4.6}$$

which must hit boundary transversally:

$$|\phi| + |\{a, \phi\}| > 0 \tag{7.4.7}$$

where $X = \{\phi > 0\}$ and $|\phi| + |\nabla\phi| \ge \epsilon_0$.

Then Hamiltonian billiard flow is not necessarily defined on Σ_τ but on the set of the full measure:

Theorem 7.4.8. *Let* X *be a smooth manifold with the boundary and let* a *be microhyperbolic on level* τ. *Assume that* g^{jk} *and* V *are uniformly bounded and* (g^{jk}) *is uniformly elliptic.*

Then there exists Ξ_τ *the set of measure* 0 *and of the first Baire category on* Σ_τ *such that through each point of* $\Sigma_\tau \setminus \Xi_\tau$ *there passes an (unique)*

infinitely long in both directions Hamiltonian billiard and thus a (single-valued) Hamiltonian billiard flow Ψ_t *is defined on* $\Sigma_\tau \setminus \Xi_\tau$*; this set is* Ψ_t*-invariant.*

This flow conserves the natural measure $dxd\xi : da$ *on* Σ*.*

Proof. The proof coincides with the arguments of Chapter 6 in the book of Cornfeld, Sinai, Fomin [1]. Consider set $\Xi_{\tau,T} \subset$ of points on Σ_τ such that Ψ_t cannot be defined on interval $[0, T]$. Then as T_1, T_2 have the same sign

$$\Xi_{\tau,T_1+T_2} \subset \Xi_{\tau,T_1} \cup \Psi_{-T_1}(\Xi_{\tau,T_2}).$$

Therefore since Ψ_t preserves measure $d\mu = dxd\xi : da$ on Σ we conclude that

$$\mu_\tau(\Xi_{\tau,T_1+T_2}) \le \mu_\tau(\Xi_{\tau,T_1}) + \mu_\tau(\Xi_{\tau,T_2})$$

as $T > 0$, $\Delta > 0$; thus $\mu_\tau(\Xi_{\tau,T}) \le T\Delta^{-1}\mu_\tau(\Xi_{\tau,\Delta})$. However

$$\Xi_{\tau,\Delta} \subset \{\phi \le c\Delta, |\{H,\phi\}| \le \varepsilon(\Delta)\}$$

with $\varepsilon(\Delta) = o(1)$ as $\Delta \to 0$. Hence $\mu_\tau(\Xi_{\tau,\Delta}) \le C\varepsilon(\Delta)\Delta$ and thus $\mu_\tau(\Xi_{\tau,T}) \le C\varepsilon(\Delta)$; therefore $\mu_\tau(\Xi_{\tau,T}) = 0$ for any $T > 0$ and thus $\mu_\tau(\Xi_\tau) = 0$.

The same arguments work in domain with corners, edges and vertices (see Chapter 11). □

Remark 7.4.9. If we are interested only in trajectories of length not exceeding T then in the statement of this lemma one can replace Ξ by a closed nowhere dense subset Ξ_T. However then we have no invariancy.

Growth of the Billiard Flow. I

We need to study how this flow grows.

Let $J_t(x,\xi) = D\Psi_t(x,\xi)$ be the Jacobi matrix of Ψ_t calculated at the point (x,ξ); then $\det J_t(x,\xi) = 1$. We need the following statements concerning the Hamiltonian flows on various manifolds:

Let us treat different classes of strongly convex compact Riemannian manifolds with boundary.

We assume that uniformly $\phi \in \mathscr{C}^3$,

$$\phi > 0 \quad \text{on} \quad X, \qquad \phi = 0 \text{on} \quad \partial X \tag{7.4.8}$$

and

$$|\nabla\phi| + |\phi| \ge \epsilon. \tag{7.4.9}$$

Further, we assume that X is uniformly *strongly convex* i.e. we assume the uniform version of

$$\phi(x) = 0,\ \{a,\phi\}(x,\xi) = 0 \implies \{a,\{a,\phi\}\}(x,\xi) < 0 \qquad \forall (x,\xi) \in \Sigma_\tau. \tag{7.4.10}$$

Thus we assume

$$\phi(x) \le \epsilon,\ |a(x,\xi) - \tau| \le \epsilon,\ |\{a,\phi\}(x,\xi)| \le \epsilon \implies \{a,\{a,\phi\}\}(x,\xi) \le -\epsilon. \tag{7.4.11}$$

Recall that $\{.,.\}$ are Poisson brackets. In this case

$$\Xi_\tau = \big\{(x,\xi)\colon a = \tau, \phi = \{a,\phi\} = 0\big\} \tag{7.4.12}$$

is a manifold of codimension 2 in Σ_τ. Define

$$\rho(x,\xi) = \frac{1}{2}\{a,\phi\}^2 - \{a,\{a,\phi\}\}\phi \tag{7.4.13}$$

in a small enough neighborhood of Ξ_τ (on Σ_τ).

Then due to strict convexity $\rho(x,\xi) = 0 \iff (x,\xi) \in \Xi_\tau$ and $\rho \asymp 1$ outside of this neighborhood in Σ_τ. Moreover,

$$\rho \asymp \{a,\phi\}^2 + \phi \qquad \text{on } \Sigma_\tau. \tag{7.4.14}$$

Theorem 7.4.10. *Let X be a smooth manifold with the boundary. Let $g^{jk}, V_j, V \in \mathscr{C}^3$ uniformly. Under the assumptions made above (most notably strong convexity) the following estimates hold:*

$$C^{-1}e^{-C|t|} \le \frac{\rho(\Psi_t(x,\xi))}{\rho(x,\xi)} \le Ce^{C|t|}, \tag{7.4.15}$$

$$|J_t(x,\xi)| \le Ce^{C|t|}\rho(x,\xi)^{-M} \tag{7.4.16}$$

for all $(x,\xi) \in \Sigma_\tau \setminus \Xi_\tau$, $t \in \mathbb{R}$ where C does not depend on (x,ξ,t).

Proof. Note that due to (7.4.14) $|\{a,\rho\}| \le C_0\rho$. Therefore along Hamiltonian trajectories $|\frac{d}{dt}\rho| \le C_0\rho$. Note that

(7.4.17) ρ does not change at the moment of reflection at ∂X.

This yields (7.4.15) with $C = C_0$. Let $\Sigma' = T^*X|_{\partial X}$. Important: we use coordinates (x', ξ) rather than (x', ξ', τ) on Σ'.

Let us prove (7.4.16). Let us consider the map $\Phi : \Sigma' \to \Sigma'$ transforming the point $z' \in \Sigma'$ to the point $\varsigma\Psi_{t_1(z')}(z')$ where $t_1(z') > 0$ is the time of the first return of the trajectory passing through z' to ∂X and $\varsigma : \Sigma' \to \Sigma'$ is the reflection map; if a trajectory never hits ∂X again then $t_1(z') = +\infty$ and $\Psi(z')$ is not defined.

One can see easily that

(7.4.18) Map Φ preserves measure ν_τ on $\Sigma'_\tau = \Sigma_\tau|_Y$ with the density

$$d\nu_\tau = |\eta| dx d\xi : (da \wedge d\phi) \tag{7.4.19}$$

with $\eta = \{a, \phi\} = \pm(2\rho)^{\frac{1}{2}}$ on Σ'; obviously ν does not depend on the choice of ϕ.

Further, one can easily see that (7.4.16) holds if the trajectory $\Psi_{t'}(z)$ does not hit ∂X for $0 \le t' \le t$ or $0 \ge t' \ge t$. On the other hand, one can easily see that

$$t_1(z') \asymp |\eta(z')|, \tag{7.4.20}$$

and

$$D\Phi(z') = I + O\big(t_1(z')\big) \tag{7.4.21}$$

in the local coordinates provided $\rho(z') \le \epsilon_1$ (where $\epsilon_1 > 0$ is small enough) and therefore

$$|D\Phi^n(z')| \le e^{C_1 t_n(z')} \tag{7.4.22}$$

for $n = 1$ under the same assumption. On the other hand, if $\rho(z') \ge \epsilon_1$ we conclude that (7.4.22) for $n = 1$ holds as well. So, (7.4.22) for $n = 1$ always holds.

Let us consider the map Φ^n. Then (7.4.15), (7.4.20) and (7.4.21) yield that

$$n \le C_1 e^{C|t_n|} |\eta(z')|^{-1} \tag{7.4.23}$$

with an appropriate constant C_1 and that (7.4.22) holds for arbitrary $n \in \mathbb{Z}^+$. Here $t_n(z') > 0$ is the time of the n-th return of the billiard Hamiltonian trajectory to ∂X (it is possible that $t_n(z') = +\infty$ in which case $\Phi^n(z')$ is not defined). Inverting time in our arguments we obtain that (7.4.22) holds for arbitrary $n \in \mathbb{Z}^+$.

Now we should finish the proof of (7.4.16). Let us consider an arbitrary point $z \in T^*X$ and let us rewrite $\Psi_t(z)$ in the form

$$\Psi_t(z) = \Psi_{t-t_{n+1}(z)} \circ \Phi^n \circ \Psi_{t_1(z)}(z) \tag{7.4.24}$$

where $t_j(z) > 0$ is the time of the j-th return of the billiard Hamiltonian trajectory to ∂X and we assume that $t_{n+1}(z) \le t < t_{n+2}(z)$ and $n \ge 0$.

Our purpose now is to estimate the differential of this product. Consider $\Psi_{t_1(z)}(z)$ mapping T^*X to $T^*X|_{\partial X}$. Note that

$$e^{-C_0|t_k|}\rho^{\frac{1}{2}}(z) \le |\eta(\Psi_{t_k(z)}(z))| \le e^{C_0|t_k|}\rho^{\frac{1}{2}}(z) \tag{7.4.25}$$

and

$$|dt_k(z)| + |d\Psi_{t_k(z)}(z)| \le C_0 e^{C_0 t_1(z)}\rho(z)^{-\frac{1}{2}} \tag{7.4.26}$$

hold as $k = 1$ while

$$|D\Psi_{t'}(z')| \le C_0 e^{C_0 t'} \qquad \text{as } \ 0 \le t' \le t_1(z'),\ z' \in T^*X|_Y. \tag{7.4.27}$$

So we need to understand how t_1, t_{n+1} depend on z. One can easily see that for $z' \in \Sigma'$ the inequality $|dt_1(z')| \le C_1 e^{C_1 t_1(z')}|dz'|$ holds and therefore

$$|dt_k(z')| \le |dt_{k-1}(z')| + C_1 e^{C_1|t_{k+1}-t_k|}|d\Phi^{n-1}(z')| \le |dt_{k-1}(z')| + C_2 e^{C_2|t_k|}|dz'|$$

and finally we obtain by induction by k (using the above inequalities) that

$$|dt_k(z')| \le Ce^{C|t_k|(z')}|\eta|^{-1} \cdot |dz'|. \tag{7.4.28}$$

Combining with (7.4.26) for $k = 1$ we arrive to (7.4.25) and (7.4.26) for arbitrary $k \in \mathbb{Z}^+$; combining with (7.4.27) we arrive to (7.4.16) as $t > 0$. Reverting time we arrive to (7.4.16) as $t < 0$. □

Growth of the Billiard Flow. II

Now let us consider cases with a power growth.

Theorem 7.4.11 (Polyhedra). *Let X be a compact polyhedral domain in $\mathbb{R}^d$ with $g^{jk} = \delta_{jk}$. Let $V_j = V = 0$. Then*

$$|J_t(x,\xi)| \le C(|t|+1) \tag{7.4.29}$$

uniformly with respect to $(x,\xi) \in S^*\bar{X} \setminus \Xi$.

Proof. One can prove easily that the measure of rays hitting the corners and perishing there is 0. We will prove it later anyway.

Note that Ψ_t consists of linear movements $(x,\xi) \to (x + t_j\xi, \xi)$ and reflections from various faces:

(7.4.30) The reflection from the face Z at point $y_Z \in Z$ is

$$(x,\xi) \to (\varsigma_Z(x - y_Z) + y_Z, \varsigma_Z\xi)$$

with $\varsigma_Z \in \mathcal{G}$ where $\mathcal{G}$ is a group of reflections in $\mathbb{R}^d$ (i.e., linear orthogonal maps ς such that $\varsigma^* = \varsigma$ and $\varsigma^2 = I$).

Therefore

(7.4.31) If $(\bar{x},\bar{\xi}) \notin \xi_{\bar{t}}$ and $(\bar{x},\bar{\xi}), \Psi_{\bar{t}}(\bar{x},\bar{\xi}) \notin S^*\bar{X}|_{\partial X}$ then in a neighborhood of $(\bar{x},\bar{\xi},\bar{t})$

$$\Psi_t(x,\xi) = (\bar{\varsigma}(x + \xi t) + \bar{y}, \bar{\varsigma}\xi)$$

with $\bar{y} \in \mathbb{R}^d$ and $\bar{\varsigma} \in \mathcal{G}$ depending on $(\bar{x},\bar{\xi},\bar{t})$.

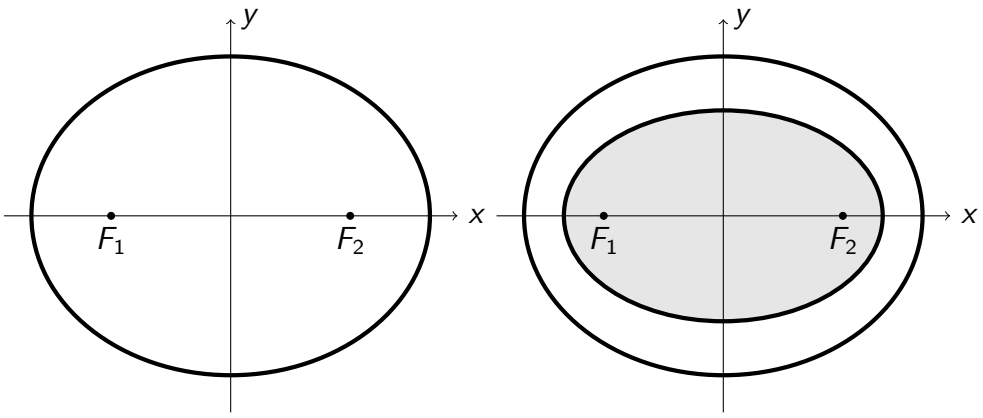
This immediately yields (7.4.29). □

Theorem 7.4.12 (Elliptical domains). *(i) Let X be the interior of an ellipse in $\mathbb{R}^2$ or, more generally, an elliptic annulus, i.e. domain lying between two confocal ellipses where the standard Euclidean metric is given on $\mathbb{R}^2$.*

Then there exists a continuous non-negative function $\rho(z)$ on $\Sigma = S^*X$ such that

$$\rho(\Psi_t(z)) = \rho(z), \tag{7.4.32}$$

$$|D\Psi_t(z)| \le C\rho^{-L}(z)(|t|+1)^{L'} \qquad \forall z \in \Sigma \setminus \Xi \quad \forall t \in \mathbb{R} \tag{7.4.33}$$



(a) Ellipse (b) Elliptical annulus

Figure 7.1: Elliptical domains

with $\Xi = \{z, \rho(z) = 0\}$ *and*

$$\mathsf{mes}_\Sigma(\{z : \rho(z) < h\}) = O(h^\sigma) \qquad \text{as } h \to +0 \tag{7.4.34}$$

with $\sigma > 0$ *and* $L' = 1$. *Here* mes_Σ *is the standard measure on* Σ.

(ii) The same is true for a ball in $\mathbb{R}^d$ *and for a domain lying between two spheres with the same center (where the standard Euclidean metric is given on* $\mathbb{R}^d$*).*

Proof. (i) Let us consider first a more difficult case of an elliptical domain or a domain lying between two ellipses with the same foci $F_1 \neq F_2$; let Y_2 be an outer and Y_1 an inner ellipses.

In the first case ($Y_1 = \emptyset$) let us define $\Xi = S^* Y$. In the second case let us introduce $\Xi_2 = S^* Y_2$ and $\Xi'_1 = S^* Y_1$ for Y_2 and Y_1 respectively and let us set

$$\Xi_1 = \big\{(x + t\xi, \xi) \colon (x, \xi) \in \Xi'_1, t \in \mathbb{R}, x + t\xi \in \bar{X}\big\} \tag{7.4.35}$$

(thus, the definitions of Ξ_1 and Ξ_2 and are different; moreover, $\mathsf{dim}\, \Xi_1 = 2$, $\mathsf{dim}\, \Xi_2 = 1$). Then let $\Xi = \Xi_2 \cup \Xi_1$. Note that $\Xi_2 \cap \Xi_1 = \emptyset$.

In the domains of this type every billiard belongs to one of the following three classes:

(a) All the straight lines containing at least one segment of this billiard do not pass between foci and are tangent to an ellipse Y which has the same foci F_1 and F_2 and is smaller than Y_2 (although not necessarily larger than Y_1).

(b) All the straight lines containing at least one segment of this billiard pass between foci and are tangent to the same hyperbola Y which has the same foci F_1 and F_2.

(c) All the straight lines containing at least one segment of this billiard pass through the foci (either by turns or simultaneously). Then Y is the straight segment between foci.

For elliptical domains it is well known[19]. However this property (preserving Y) holds for an internal reflection from an ellipse Y_k then it holds also for an external reflection from it since in this case extensions of rays reflect internally from Y_k (see Figure 7.2(d)). So Y is preserved both at reflections from Y_2 and Y_1.

Then

(7.4.36) $\beta := +b^2, -b^2, 0$ in the cases (a), (b) and (c) respectively is an invariant of the Hamiltonian flow. Here a_k and b_k are semiaxes of Y_k ($k = 1, 2$) directed along the axes x_1 and x_2 respectively, $a_k > b_k$ and a and b are are semiaxes of Y; $a_k^2 - b_k^2 = a^2 - y^2 = c^2$ where $c = \frac{1}{2}\mathsf{dist}(F_1, F_2)$.

Direct calculation shows that[20]

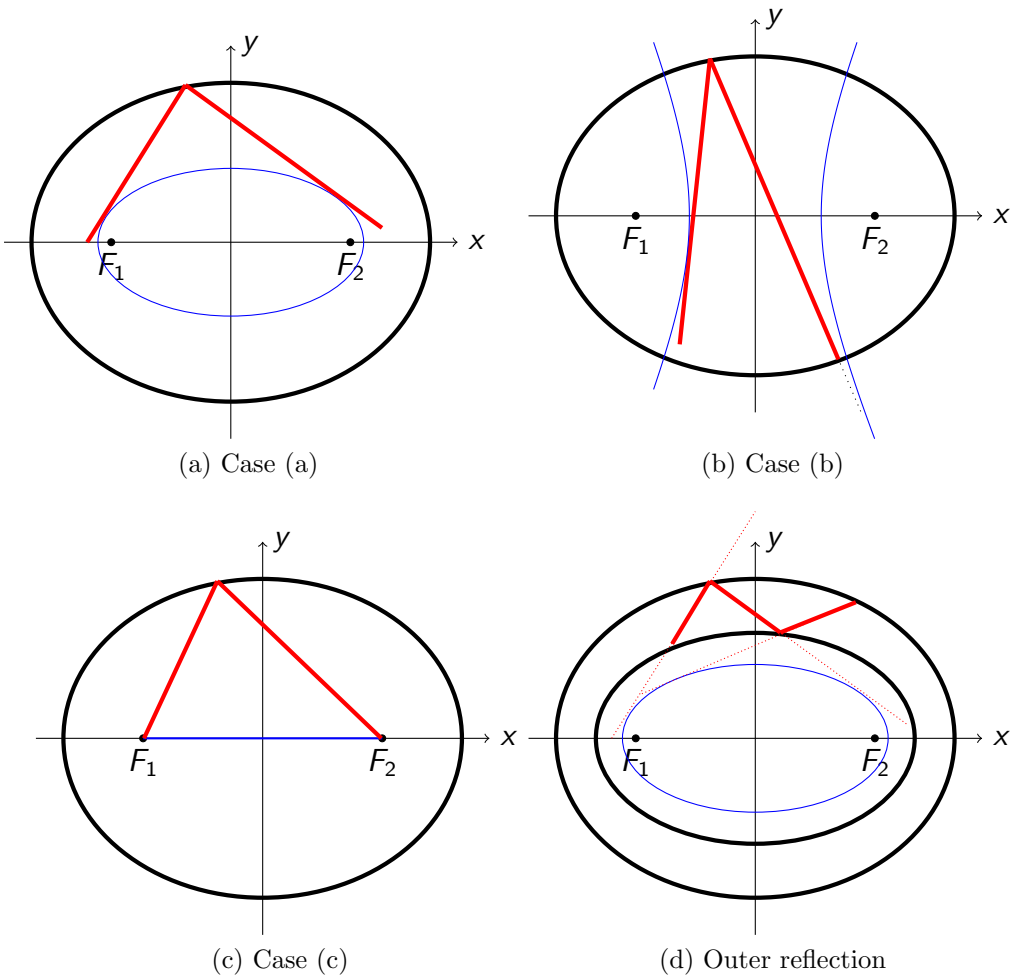
$$\beta = b_k^2 - a_k^2 b_k^2 \Big(\frac{x_1\xi_1}{a_k^2} + \frac{x_2\xi_2}{b_k^2}\Big)^2 = (x_1\xi_2 - x_2\xi_1)^2 - c^2\xi_2^2 \qquad \text{for } x \in Y_k,\ |\xi| = 1. \tag{7.4.37}$$

Let us introduce $\Sigma_2' = \Sigma|_{Y_2} = B^* Y_2$ and the map $\Phi : \Sigma_2' \to \Sigma_2'$: we launch ray from $\iota^{-1}z \cap S^*X$ and then $\Phi(z)$ and $t_1(z)$ are the point and the time of its first return to Σ_2' (maybe after one reflection from Y_1); so

$$\Phi(z) = \iota \Psi_{t_1(z)}(\iota^{-1}z \cap S^*X). \tag{7.4.38}$$

[19] See, e.g., V. M. Babich & V. S. Buldyrev [1], section 4.5 and the beautiful pictures there. See also Figure 7.2(a)–(c)

[20] One can see easily that the middle and the right-hand expression coincide, that the latter is invariant along rays while $(x_1 x_1 a_1^2 + x_2\xi_2 a_2^2)$ acquires factor (-1) at reflections. Then it is sufficient to calculate β at point of the tangency with Y.



(a) Case (a) (b) Case (b)

(c) Case (c) (d) Outer reflection

Figure 7.2: Cases (a), (b), (c) in ellipse and (d) in annulus. Red lines are rays, dotted lines their extensions, Y is drawn in blue; cases (b), (c) in an annulus a similar

Then

$$t_1(z') \asymp \rho_2(z')^{\frac{1}{2}} = \Big|\frac{x_1\xi_1}{a_2^2} + \frac{x_2\xi_2}{b_2^2}\Big|. \tag{7.4.39}$$

Here the right-hand expression is an invariant of the map Φ and therefore in what follows

$$n \le C(|t_n(z')| + 1)\rho_2(z')^{-\frac{1}{2}} \tag{7.4.40}$$

with the obvious definition of $t_n(z')$. Let us introduce the function

$$\eta = \frac{x_1\xi_1}{a_2^2} + \frac{x_2\xi_2}{b_2^2} \tag{7.4.41}$$

on Σ_2'. Then

$$|\nabla_{\Sigma_2'}\eta| \asymp \rho_3(z') := (|x_1| + |\xi_1|)\cdot(|x_2| + |\xi_2|). \tag{7.4.42}$$

One can prove it easily introducing coordinates $(u, v) : x_1 = a_2 \cos u$, $x_2 = b_2 \sin u$, $\xi_1 = \cos v$, $\xi_2 = \sin v$ on Σ_2'; in what follows $z' = (u, v)$.

Let us calculate the density $d\nu : d\eta$ on the lines $\{\eta = \mathsf{const}\}$ by different methods where $d\nu$ is the density on Σ_2' corresponding to

$$\phi = \frac{1}{2}\big(1 - \frac{x_1^2}{a_2^2} - \frac{x_2^2}{b_2^2}\big).$$

Then under constrain $\eta = \mathsf{const}$ we obtain equality

$$|\frac{du}{U}| = |\frac{dv}{V}| \quad \text{with} \quad U = U(z') = -\frac{x_1\xi_2}{a_2^2} + \frac{x_2\xi_1}{b_2^2},\ V = V(z') = -\frac{x_2\xi_1}{a_2^2} + \frac{x_1\xi_2}{b_2^2},$$

and obviously[21)]

$$|U| + |V| \asymp \rho_3 \tag{7.4.43}$$

Taking into account that $d\nu$ and $|\eta|$ are invariants of Φ we see that $|d\nu : d\eta|$ is also an invariant and therefore the middle equality in this chain holds:

$$|\frac{du}{U}| = |\frac{dv}{V}| = |\frac{du'}{U'}| = |\frac{dv'}{V'}|$$

under the constrain $d\eta = 0$ where $(u', v') = \Phi(u, v)$ and $U' = U(u', v')$, $V' = V(u', v')$. One can easily see that $\rho_3(u, v) \asymp \rho_3(u', v')$.

Starting with this chain of equalities one can easily prove that without the constrain the following equivalence chain holds:

$$|\frac{du}{U}| \equiv |\frac{dv}{V}| \equiv |\frac{du'}{U'}| \equiv |\frac{dv'}{V'}|$$

[21)] As $a_2 \neq b_2$; as $a_2 \approx b_2$ $\rho_3 \gtrsim |U| + |V| \gtrsim (a_2 - b_2)/a_2 b_2$.

modulo terms with absolute values no greater than $C\bigl(\rho_3^{-L}+\rho_1^{-L}|d\eta|\bigr)$ where

$$\rho_1(z')=\mathsf{dist}(z',\Xi)\asymp \min\bigl(|\beta-b_1^2|,|\beta-b_2^2|\bigr).$$

Here ρ_3 is not Φ-invariant but we know that

$$\rho_3\ge \epsilon\min\bigl(|\beta|,|\beta+a_2^2-b_2^2|\bigr)$$

and β is invariant. Therefore for (u',v') the previous chain of equivalences holds modulo terms with absolute values not exceeding $Cn\rho^{-L}|d\eta|$ with

$$\rho=\min\bigl(|\beta|,|\beta+a_2^2-b_2^2|,|\beta-b_1^2|,|\beta-b_2|^2\bigr).$$

Increasing L if necessary we obtain the inequality $|D\Phi^n|\le Cn\rho^{-L}$. The remainder of the proof repeats the final arguments of the proof of the Theorem 7.4.10 with (7.4.16) replaced by (7.4.40). This yields (7.4.33). The proof of (7.4.34) is trivial.

(ii) If $a_2=b_2$ and $a_1=b_1$ then the proof is trivial, Φ is just a rotation of (x,ξ) by an angle 2β which is constant along billiards.

In this case from the beginning we use $\rho(z)$ instead of $\rho_3(z)$. The case of a ball or of a spherical shell can be reduced to case $d=2$ because every billiard lies in some two-dimensional plane passing through the center and the Hamiltonian flow commutes with the map $(x,\xi)\to(Gx,G\xi)$ for every orthogonal matrix G. Therefore one can consider only billiards and their variations in the plane (x_1,x_2). Singularities related to this reduction near the manifold $\{(x,\xi),x=t\xi,t\in\mathbb{R}\}=\{(x,\xi),\beta=0\}$ are taken into account because $|\beta|\ge\epsilon\rho$. □

Remark 7.4.13. For elliptic annulus we were lucky that if ray is tangent to Y_1 it remains tangent all the time and thus Ξ_1 cuts Σ into two connected components. For more general domains (f.e. disk with a round hole, but with shifted center) $\Xi_1=\bigcup_{n\in\mathbb{Z}}\Xi_{1(n)}$ where $\Xi_{1(n)}$ is a set of rays tangent to Y_1 on its n-th segment; then Ξ_1 cuts Σ into infinite number of components.

Non-Periodicity Condition and Results. I

Let us discuss first the "sharp" asymptotics. Then results of Subsubsection *7.4.2.1 Sharp Asymptotics* imply immediately

Theorem 7.4.14. *Consider Schrödinger operator and assume that τ is microhyperbolicity level*[22]*. Assume that*

$$\mu_\tau(\Pi_\tau) = 0 \tag{7.4.44}$$

where Π_τ denotes the set of points on Σ_τ periodic with respect to billiard Hamiltonian flow. Then Weyl asymptotics holds with the remainder estimate $o(h^{1-d})$.

Remark 7.4.15. (i) Theorem 7.4.6 immediately implies that $\mu'_\tau(\iota(\Xi_\tau|_{\partial X})) = 0$ where $\iota : T^*X|_Y \to T^*Y$ is a standard map and μ'_τ is a measure on T^*Y; first we define $dx'd\xi : da$ on $\Sigma_\tau|_Y$ and then ι pushes it to T^*Y, where as usual $Y = \partial X$. This measure is absolutely continuous with respect to $dx'd\xi'$ and concentrated where $\tau - a' > 0$.

(ii) Further, condition (7.4.44) implies that

$$\mu'_\tau(\iota\Pi_\tau)_Y) = 0 \tag{7.4.45}$$

Then (modulo condition in the elliptic zone, i.e. zone where $\tau - a' < 0$) asymptotics with integration only over ∂X holds with the remainder estimate $o(h^{1-d})$.

While (7.4.44) fails say for hemisphere everybody believes in so-called *Ivrii's conjecture* (1980):

Conjecture 7.4.16. *For standard Euclidean billiards in Euclidean domain* (7.4.44) *holds.*

Considered to be an easy game in 1980 it turned to be really hard even in the case of $d = 2$ (see f.e. E. Gutkin [1]); the sketch of the proof of E. Gutkin [2] contained unpatchable holes. For *generic* domains in $\mathbb{R}^d$ conjecture 7.4.16 was proven by V. Petkov, L. Stoyanov in [2] (see also their book V. Petkov, L. Stoyanov [4]).

The following theorem is due to D. Vassiliev

Theorem 7.4.17. *Consider manifold and operator described in Theorem 7.4.10. Further, assume that g^{jk}, V_j, V and ϕ are analytic functions. Then* (7.4.45) *and*

$$\mu_\tau(\Pi_\tau \setminus \Pi_\tau^0) = 0 \tag{7.4.46}$$

[22] Currently for both a and $(A, \eth B)$; see Section 7.5 for generalizations.

hold where Π^0_τ is the set of periodic points but with trajectories never hitting Y.

Proof. All we need to prove is that $\mu'(\Pi_{n,\tau}) = 0$ for all $n \in \mathbb{Z}^+$, $n \neq 0$ where $\Pi_{n,\tau} = \{z' \in \Sigma'_\tau, \Phi^n(z) = z\}$. Due to analyticity Φ is also analytic and it is sufficient to prove that $\Phi^n \neq I$ on Σ_τ. However this is true since due to microhyperbolicity $|\{a, \phi\}| \asymp \varepsilon \le \epsilon n^{-1}$ $\mathsf{dist}(\Phi^n(z), z) \asymp \varepsilon n$. □

Remark 7.4.18. Note that for domains in $\mathbb{R}^d$, with $g^{jk} = \delta_{jk}$, $V_j = V = 0$ $\Pi^0_\tau = \emptyset$.

Non-Periodicity Condition and Results. II

Theorem 7.4.19. *Consider operator $A = h^2\Delta - 1$ in X which is an ellipse, elliptic annulus, ball or spherical annulus. Then Weyl asymptotic holds with the remainder estimate $O(h^{1-d+\delta})$ with (unspecified) $\delta > 0$.*

Proof. (i) Let us apply Theorems 7.4.6 and 7.4.7; we know already that $D\Psi_t$ has a power growth but we need to check that

$$\mathsf{mes}(\Pi_{T,\varepsilon}) \le h^\delta \tag{7.4.47}$$

where

$$\Pi_{T,\varepsilon} := \{z : \exists t : \epsilon_0 < t \le T : \ \mathsf{dist}(z, \Psi_t(z)) \le \epsilon\} \tag{7.4.48}$$

as we pick up $T = h^{-\delta_1}$, $\varepsilon = h^{\delta_2}$ and consider billiard flow on $\Sigma_0 = S^*X$ and μ_0 is the usual measure. Really, due to Theorem 7.4.12 we estimate $|D\Psi_t|$ by $CT^{-1}\varepsilon^{-N}$ as $|t| \le T$ everywhere with the exception of $\Lambda = \{\rho_3 \le \varepsilon\}$. Therefore taking exponents δ_1 and δ_2 small enough we conclude that the contributions of $\Lambda_\varepsilon \cup \Pi_{T,\varepsilon}$ and $\Sigma_0 \setminus (\Lambda_\varepsilon \cup \Pi_{T,\varepsilon})$ to the remainder estimate do not exceed $C\,\mathsf{mes}(\Lambda_\varepsilon \cup \Pi_{T,\varepsilon})h^{1-d}$ and $CT^{-1}h^{1-d}$ respectively. However one can see easily that $\mathsf{mes}(\Lambda_\varepsilon) \le \varepsilon^{\delta''}$ and (7.4.47) is all we need to check. We will use notations of the proof of Theorem 7.4.12.

Obviously (7.4.47) is equivalent to

$$\mathsf{mes}\big\{z' \in \Sigma'_2 : \exists k = 1, \dots, n : \mathsf{dist}(z', \Phi^k z') \le \varepsilon = n^{-M}\big\} = O(n^{-\sigma}) \quad \text{as } n \to +\infty \tag{7.4.49}$$

for appropriate M and $\sigma > 0$. Let us recall that $\Sigma'_2 = B^*Y_2$ and $\Phi : \Sigma'_2 \to \Sigma'_2$ is a map.

(ii) Let us first consider the zone $\{(x,\xi),\beta > 0\}$. Let us consider the lines $\{\eta = \mathsf{const}\}$. These lines are analytically parameterized by a cyclic parameter $u \in \mathbb{R}/2\pi\mathbb{Z}$ [23].

Let $w \in \mathbb{R}/\mathbb{Z}$ be a new cyclic coordinate: $w = w_\eta(u) = \nu_\eta((0,u))m_\eta^{-1}$ for $u \in [0,2\pi]$ and then by periodicity. Here $m_\eta = \nu_\eta([0,2\pi])$. One can easily see that $m_\eta \asymp \log|\beta|$ as $\beta \to +0$ for $a_2 > b_2$ and $m_\eta \asymp \beta^{-1}$ as $\beta \to +0$ for $a_2 = b_2$.

For every fixed η the map Φ_η of this line is analytic and preserves the measure $dw_\eta = m_\eta^{-1} d\nu_\eta$ and the orientation[24] and therefore Φ_η is a shift $\Phi_\eta : w_\eta \to w_\eta + f(\eta)$. Then to prove (7.4.49) for $\Sigma_2' \cap \{\beta > 0\}$ one needs and suffices to prove that

$$\mathsf{C}n\,\mathsf{mes}\big(\{\eta : \exists k, l = 1,\dots,n : |f(\eta) - \frac{k}{l}| \le \varepsilon = n^{-L}\}\big) = O(n^{-\sigma}) \quad \text{as } n \to +\infty \tag{7.4.50}$$

for admissible L and $\sigma > 0$; here mes means Lebesgue measure.

Obviously, $f(\eta)$ is a continuous function. One can easily prove that

$$\epsilon\beta^p \le |\frac{df}{d\eta}| \le c\beta^{-p} \qquad \text{for } |\eta| \le a_2 - \epsilon_0, \tag{7.4.51}$$

i.e., for $\beta \in (0,\beta_0)$ with small enough $\epsilon_0 > 0, \beta_0 > 0$. Let us recall that $\beta = b_2^2 - a_2^2 b_2^2 \eta^2$. Therefore (7.4.50) holds for values of η indicated here.

On the other hand, Φ is an analytic map for $\beta \ne b_1^2$ (the case when rays are tangent to the inner ellipse Y_1). Therefore the function $f(\eta)$ is analytic for $|\eta| < \eta_1 = a_2^{-1}b_2^{-1}(b_2^2 - b_1^2)^{\frac12}$ and for $\eta_1 < |\eta| \le a_2^{-1}$. Obviously, $f(\eta)$ is not constant in each of these three intervals. One can easily see that $f_\pm(\zeta) = f(\bar\eta \pm \zeta^2)$ is an analytic function for $|\zeta| \le \epsilon_0$ and $\bar\eta = +\eta_1, -\eta_1$.

But one can easily see that

$$\mathsf{mes}(\{\eta : |f(\eta)| \le \varepsilon\}) \le C\varepsilon^\delta \tag{7.4.52}$$

[23] More precisely, this line consists of two connected components. Φ transforms every component into itself and the x-projection is an analytic diffeomorphism of this component to the ellipse Y_2. Every component is parameterized by u. Permutation of these components is equivalent to replacing Φ by Φ^{-1}.

[24] Moreover, it is well known from Cornfeld, Sinai, Fomin [1] that for generic η, Φ_η is an ergodic map.

for every $\mathscr{C}^K$ function on the closed segment provided

$$\sum_{1\le j\le K-1} |f^{(j)}| \ge \epsilon_0. \tag{7.4.53}$$

Therefore (7.4.50) holds.

(iii) Let us treat the zone $\{(x,\xi) : 0 > \beta > b_2^2 - a_2^2\}$. In this case every line $\{\eta = \mathsf{const}\}$ consists of two connected components and every component is equivalent to $\mathbb{S}^1$ and the x-projection maps every component to one of two segments on the ellipse Y_2 describing by the inequality $x_2^2 \ge -\beta b_2^2(a_2^2 - b_2^2)^{-1}$. The inverse map is two-valued. Let us introduce on this connected component the cyclic coordinate u' which can be done in the following way: let us consider the confocal hyperbola described by the equation

$$\frac{x_1^2}{a'^2} - \frac{x_2^2}{b'^2} = 1$$

with $a'^2 + b'^2 = a_2^2 - b_2^2$. This hyperbola intersects Y_2 in four points $(\bar{x}_1, \bar{x}_2)$ with

$$\bar{x}_1^2 = a_2^2(a_2^2 - b_2^2 + \beta)(a_2^2 - b_2^2)^{-1},\ \bar{x}_2^2 = -b_2^2\beta(a_2^2 - b_2^2)^{-1}.$$

Let us introduce the parameter $u' \in \mathbb{S}^1$ on this hyperbola: $x_1 = a' \sec u'$, $x_2 = b' \tan u'$. Through every point of the hyperbola corresponding to this parameter there passes a tangent straight line hitting the corresponding segment of the ellipse. Then (x_1, x_2) is an intersection point and (ξ_1, ξ_2) is a unit vector along this tangent line, directed inside and outside for $\eta < 0$ and $\eta > 0$ respectively.

Further, let us introduce the parameter $w' \in \mathbb{R}/\mathbb{Z}$ in the same way as before. Again we take $dw' = m_\eta^{-1} d\nu_\eta$ with $m_\eta \asymp \log|\beta|$ as $\beta \to -0$ and $m_\eta \asymp 1$ as $\beta \to b_2^2 - a_2^2$. Moreover, in the latter case m_η is an analytic function of $\zeta' = (\beta + a_2^2 - b_2^2)^{\frac{1}{2}}$.

One can easily see that if there is no inner ellipse Y_2 then Φ transforms one connected component of every line $\{\eta = \mathsf{const}\}$ to another and therefore for $\beta < -n^{-\sigma}$ the inequality $\mathsf{dist}(z', \Psi^k(z')) < \epsilon$ is impossible for odd k and the measure of the set $\{|\beta| \le n^{-\sigma}\}$ is $O(n^{-\delta})$.

On the other hand, if there is an inner ellipse Y_1 then the map Φ preserves both connected components of $\eta = \mathsf{const}$ but changes their orientations, i.e., the map is of the form $w_\eta \to \frac{1}{2} f(\eta) - w_\eta$ and therefore for odd k the

$d\nu_\eta$-measure of points with $\mathsf{dist}(z', \Phi^k z') \le \varepsilon$ is $O(n^p\varepsilon)$. Therefore *in both cases only even* k *should be treated*.

Furthermore, on every connected component Φ^2 is of the form $w_\eta \to w_\eta + f(\eta)$ where the function f is again continuous and (7.4.51) holds this time for $|\eta| \ge (a_2^{-1} + \epsilon_0)$, i.e., $\beta \in (-\beta_0, 0)$ with small enough ϵ_0 and β_0. This function is analytic for $a_2^{-1} < |\eta| < b_2^{-1}$, i.e., for $\beta \in (0, b_2^2 - a_2^2)$, and the functions $f(\pm(b_2^{-1} - \zeta^2))$ are analytic with respect to ζ with $|\zeta| \le \epsilon_0$. Therefore we obtain that (7.4.53) and (7.4.50) remain true in this case. □

Non-Periodicity Condition for Branching Billiards

Let us consider the case when several Schrödinger operators are intertwined on the boundary through boundary conditions; in this case Hamiltonian billiard flow (in contrast to generalized Hamiltonian billiard flow) may not even be defined on the set of the full measure and non-periodicity is a very long shot. However we consider a very special case.

Case 1. Let us consider first Hamiltonian billiard flow in the ball $X = B(0,1)$ assuming that

(7.4.54) The metrics (g^{jk}) and potential V are spherically symmetric and $V_j = 0$.

Then each billiard stays in the same plane and we can assume without any loss of the generality that $d = 2$. Introducing polar coordinates $(r, \theta) \in (0,1) \times \mathbb{R}/2\pi\mathbb{Z}$ we can rewrite our Hamiltonian as

$$a(r, \xi_r, \xi_\theta) = \frac{1}{2}\lambda(r)^2\Big(\xi_r^2 + \mu(r)^2 r^{-2}\xi_\theta - V(r)\Big) \tag{7.4.55}$$

with $\epsilon \le \lambda, \mu \le c$. Then $\xi_\theta = \eta$ is a movement integral. Obviously

$$\Sigma_0 := \big\{(r, \xi_r, \eta) \in (0,1] \times \mathbb{R}^2 :\ a(r, \xi_r, \eta) = 0\big\} = \big\{(r, \xi_r, \eta) :\ \xi_r = \big(V(r) - \mu(r)^2 r^{-2}\eta^2\big)^{\frac{1}{2}}\big\}. \tag{7.4.56}$$

We are interested only in level 0 trajectories which hit the boundary $\partial X = Y = \{r = 1\}$. Let us denote by $\mathcal{X} \subset \Sigma_0$ the set of points such that

trajectories passing through them hit Y; then

$$\mathcal{X} = \big\{(r,\xi_r,\eta)\in \Sigma_0,\ \eta : |\eta|\le \eta_0 := (V(1)/\mu(1))^{-\frac{1}{2}}, \ r_1(\eta)\le r\le 1\big\} \tag{7.4.57}$$

where $r = r_1(\eta) < 1$ is the largest root of the equation $V(r)-\mu(r)^2r^{-2}\eta^2 = 0$.

Studying trajectories one can assume without any loss of the generality that $\lambda(r) = 1$; then along trajectories

$$\frac{dr}{dt} = \xi_r = \big(V(r)-\mu(r)^2r^{-2}\eta^2\big)^{\frac{1}{2}}, \qquad \frac{d\theta}{dt} = \mu(r)^2\eta \tag{7.4.58}$$

and therefore increment of θ between two consecutive hits is equal to

$$f(\eta) = 2\int_{r_1(\eta)}^1 \big(V(r)-\mu(r)^2r^{-2}\eta^2\big)^{-\frac{1}{2}}\mu(r)^2r^{-2}\eta\, dr \tag{7.4.59}$$

One can see easily that Ψ_t satisfies power-growth condition

$$|D\Psi_t| \le C(|t|+1)\rho^{-M}, \qquad \rho = \eta_0^2-\eta^2 \tag{7.4.60}$$

and the strong non-periodicity condition is due to (7.4.52) which in turn follows from condition (7.4.53) i.e.

$$\sum_{1\le k\le K-1} |f^{(k)}(\eta)| \ge \epsilon_0 \qquad \forall \eta : 0<\eta\le\eta_0. \tag{7.4.61}$$

Thus we arrive to

Proposition 7.4.20. *Let problem $(A,\eth B)$ be self-adjoint and microhyperbolic on the energy level 0 where A is an operator with the principal symbol* (7.4.55)*; let conditions* (7.4.54) *and* (7.4.60) *be fulfilled. Then the contribution of the small vicinity of $\mathcal{X}$ to the remainder in the Weyl asymptotics is $O(h^{1-d+\delta})$.*

Case 2. Consider now several operators of the same type (albeit with its own s and potential) linked through boundary conditions; so $A = \mathsf{diag}(A_1,\dots,A_m)$. We consider each operator A_j in its own copy X_j of ball $B(0,1)$ which are glued along Y.

Theorem 7.4.21. *Let problem* $(A, \eth B)$ *be self-adjoint and microhyperbolic on the energy level* 0 *where* $A = \mathsf{diag}(A_1, \dots, A_m)$ *and each* A_j *is an operator with the principal symbol* (7.4.55) *with* $\lambda = \lambda_j$, $\mu = \mu_j$, $V = V_j$ *satisfying* (7.4.54).

Assume that <u>*either*</u>

$$\sum_{0\le k\le K-1} |\sum_j \bigl(n_j f_j(\eta) - 2\pi q\bigr)| \ge q^{-K} \qquad \forall n = (n_1, \dots, n_m) \in \mathbb{Z}^{+\,m} \tag{7.4.62}$$

$$\text{with} \quad n_j = 0 \quad \text{as} \quad \eta_j \ge \eta_{j0} \quad \text{and} \quad q \in \mathbb{Z}^+ \setminus 0$$

provided $N \le \varepsilon^{-\delta}$ <u>*or*</u> *for all* j *functions* f_j *satisfy* (7.4.61) *and also*

$$\pm \frac{d}{d\eta} f_j(\eta) \le 0 \qquad \forall \eta : 0 < \eta \le \eta_{0j} \tag{7.4.63}_{\pm}$$

(with the same sign). Then the contribution of small vicinity of $\bigcup_j \mathcal{X}_j$ *to the remainder in the Weyl asymptotics is* $O(h^{1-d+\delta})$.

Proof. We need to prove that

$$\mathsf{mes}(\Pi_{\varepsilon,N}) = O(\varepsilon^{\delta}) \qquad \text{as} \quad \varepsilon \to +0 \tag{7.4.64}$$

where

$$\Pi_{\varepsilon,N}\bigl(\{\eta > 0,\ \exists n = (n_j, \dots, n_m) \in \mathbb{Z}^{+\,m} \ \text{ with } \ n_j = 0 \ \text{ as } \ \eta_j \ge \eta_{j0},$$
$$\text{and } \ q = 1, \dots, N \ \text{ such that } \ |\sum_{1\le j\le m} n_j f_j(\eta) - 2\pi q| \le \varepsilon\} \tag{7.4.65}$$

provided $N \le \varepsilon^{-\delta}$.

However (7.4.61), (7.4.63) imply (7.4.64). □

Example 7.4.22. (i) (flat disk) As $\mu = \mathsf{const}$, $V = \alpha^2 = \mathsf{const}$ we see that $r_1(\eta) = \alpha^{-1}\mu\eta$ and

$$f(\eta) = 2\int_{\alpha^{-1}\mu\eta}^{1} \bigl(\alpha^2 - \mu^2 r^{-2}\eta^2\bigr)^{-\frac{1}{2}} \mu^2 r^{-2}\eta \, dr = \mu\pi - 2\mu \arcsin(\alpha^{-1}\mu\eta)$$

satisfies (7.4.61) and $(7.4.63)_+$.

(ii) (spherical cut) As $\mu(r) = \beta r \sin^{-1}(\beta r)$, $V = \alpha^2 = \mathsf{const}$ we see that $r_1 = \beta^{-1} \arcsin(\alpha^{-1}\beta\eta)$ and

$$f(\eta) = 2\int_{\beta^{-1}\arcsin(\alpha^{-1}\beta\eta)}^{1} \bigl(\alpha^2 - \beta^2 \sin^{-2}(\beta r)\eta^2\bigr)^{-\frac{1}{2}} \beta^2 \sin^{-2}(\beta r)\eta \, dr = \pi - 2\arcsin\Bigl(\beta\eta(\alpha^2 - \beta^2\eta^2)^{-\frac{1}{2}} \cot\beta\Bigr)$$

satisfies $(7.4.63)_+$ as $\beta \in (0, \frac{\pi}{2})$ (less than semi-sphere) and $(7.4.63)_-$ as $\beta \in (0, \frac{\pi}{2})$ (more than semi-sphere).

Case 3. Alternatively consider a cylinder $X = (-1, 1) \times \mathbb{R}/2\pi\mathbb{Z} \ni (z, \theta)$ with

$$\mathsf{a}(r, \xi_r, \xi_\theta) = \frac{1}{2}\lambda(z)^2\Bigl(\xi_z^2 + \mu(z)^2\xi_\theta^2 - V(z)\Bigr) \tag{7.4.66}$$

with $\mu = \mathsf{const}$, $\alpha = \mathsf{const}$. Then $\partial X = Y_- \cup Y_+$, $Y_\pm = \{z = \pm 1\}$ and increment of θ between consecutive hits of Y_j and Y_{-j} is

$$f(\eta) = 2\int_0^1 \bigl(V(z) - \mu^2(z)\eta^2\bigr)^{-\frac{1}{2}} \mu^2(z)\eta \, dz \tag{7.4.67}$$

provided $|\eta| \le \inf_z \mu^{-1}(z)V(z)^{\frac{1}{2}}$; otherwise trajectory returns to Y_j and

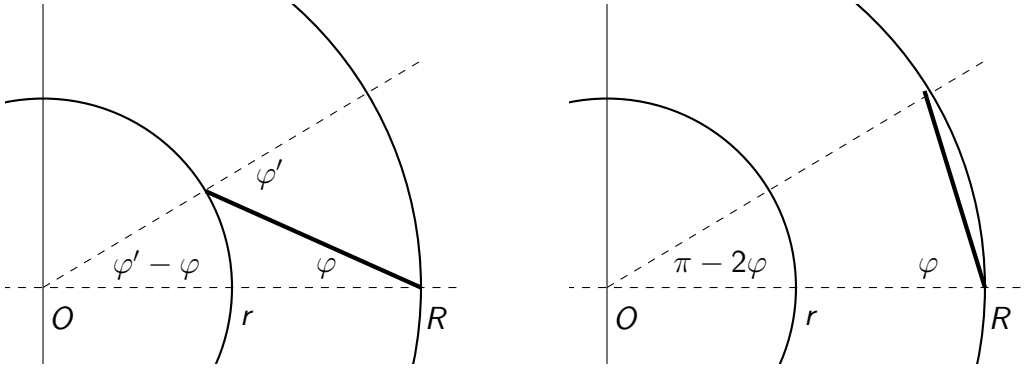
$$f(\eta) = 2\int_{z_1(\eta)}^1 \bigl(V(z) - \mu^2(z)\eta^2\bigr)^{-\frac{1}{2}} \mu^2(z)\eta \, dz. \tag{7.4.68}$$

Example 7.4.23. As $\mu(z) = \mathsf{const}$, $V = \alpha^2 = \mathsf{const}$, $f(\eta) = 2\mu^2\eta(1-\mu^2\eta^2)^{-\frac{1}{2}}$ satisfies $(7.4.63)_-$.

Remark 7.4.24. (i) Theorem 7.4.21 holds also in the case of $X_1, \dots, X_{m_1}$ balls with the common boundary Y_-, $X_{m_1+1}, \dots, X_{m_1+m_2}$ balls with the common boundary Y_+, and $X_{m_1+m_2+1}, \dots X_m$ cylinders with the common boundary $Y_- \cup Y_+$ (so $X_1, \dots, X_{m_1}$ and $X_{m_1+m_2+1}, \dots X_m$ are glued together along Y_- and $X_{m_1+1}, \dots, X_{m_1+m_2}$ and $X_{m_1+m_2+1}, \dots X_m$ are glued together along Y_+) provided f_j satisfy either (7.4.62) or $(7.4.63)_\pm$ with the same sign.

(ii) We avoided to discuss boundary conditions; we need to assume that for almost all billiards boundary bicharacteristics do not appear (see assumption (8.3.34) below).

Example 7.4.25. Consider $X_1, \dots, X_m$ circular annuli with the outer and inner radii R_k and r_k and if $R_k = r_j$ or $R_k = R_k$ or $R_j = r_j$ we consider the corresponding boundaries to be identified and operators to be intertwined there.



(a) Ray hits inner boundary (b) Ray does not hit inner boundary

Figure 7.3: Circular annulus: dashed lines are normals to the boundary

Then if φ_k is an incidence angle[25)] of the ray at the outer boundary and φ'_k is an incidence angle of the same ray at the inner boundary then as an easy geometrical exercise shows $r_k \sin \phi'_k = R_k \sin \phi_k$. Furthermore if $R_k = R_j$, $R_k = r_j$, $r_k = R_j$, $r_k = r_j$, then according to the Snell's law $c_k \sin \varphi_k = c_j \sin \varphi_j$, $c_k \sin \varphi_k = c_j \sin \varphi'_j$, $c_k \sin \varphi'_k = c_j \sin \varphi_j$, $c_k \sin \varphi'_k = c_j \sin \varphi'_j$ respectively, and therefore $R_k c_k \sin \varphi_k$ and $r_k c_k \sin \varphi'_k$ are preserved along rays and at reflections and they are equal (if the ray hits inner boundary). Let us denote this value by η.

Further, if the ray hits an inner boundary, the increment of the central angle along the ray segment (between hitting the outer and then inner or inner and then outer boundaries) is $\varphi'_k - \varphi_k$. On the other hand, if the ray does not hit the inner boundary the increment between two consecutive hits of the outer boundary is $\pi - 2\varphi_k$.

Therefore the total increment of the central angle is

$$F(\eta, n_1, \dots, n_m) = \sum_{k:|\eta|\le c_k r_k} n_k \Big(\arcsin\big(\frac{\eta}{r_k c_k}\big) - \arcsin\big(\frac{\eta}{R_k c_k}\big) \Big) + \sum_{k:c_k r_k < |\eta| \le c_k R_k} n_k \Big(\pi - 2 \arcsin\big(\frac{\eta}{R_k c_k}\big) \Big)$$

[25)] Incidence angle is an angle between the ray and the normal to the boundary.

where n_k denotes the number of segments of the billiard residing in X_k.

Then

$$\partial_\eta F(\eta, n_1, \dots, n_m) = \sum_{k:|\eta|\le c_k r_k} n_k\Big(\big(r_k^2c_k^2-\eta^2\big)^{-\frac12}-\big(R_k^2c_k^2-\eta^2\big)^{-\frac12}\Big)-\sum_{k:c_kr_k<|\eta|\le c_kR_k} n_k\big(R_k^2c_k^2-\eta^2\big)^{-\frac12}$$

and one can justify strong non-periodicity provided

$$c_kR_k \ne c_jr_j \qquad \forall j,k. \tag{7.4.69}$$

Really, $F(\eta, n_1, \dots, n_m)$ is analytic outside of points $\{\pm\eta_k, \eta_k = c_kR_k\}$ and $\{\pm\eta'_k, \eta'_k = c_kr_k\}$ and condition (7.4.69) ensures that $\partial_\eta F(\eta, n_1, \dots, n_m)$ tends to infinity as $\eta \to \eta_k - 0$ (and $\eta \to -\eta_k + 0$) which implies necessary diophantine condition.

7.5 Operators with Irregular Coefficients. Seeley's Method

In this section we consider operators with irregular coefficients in the domain with the irregular boundary. As usual we want smoothness slightly greater than $\mathscr{C}^1$. Observe, that we need to reject an idea to straighten the boundary we heavily used before. Indeed only if $\partial X \in \mathscr{C}^2$ we will get after an operator with $\mathscr{C}^1$-coefficients (assuming that original coefficients were smooth enough).

To avoid this difficulty we apply method originally due to R.Seeley [1] which with the minor modifications could be used for operators with the smooth coefficients but in the domains with the irregular boundary.

To accomodate also operators with irregular coefficients we need to modify it more and to accomodate matrix operators we need to modify it even more. We cover differential operators considered in Section 4.6 assuming that they have semi-bounded and elliptic principal symbols. If the principal symbol is not semi-bounded we will just need to consider two energy levels and only obvious modification is required (except boundary strip).

Let us consider ball $B(0,1)$ with $B(0,1) \cap \partial X \ne \emptyset$; otherwise either $B(0,1) \subset X$ and one can apply results of Chapters 4–5 or $B(0,1) \cap X = \emptyset$.

7.5.1 Discussion

Rescaling Technique

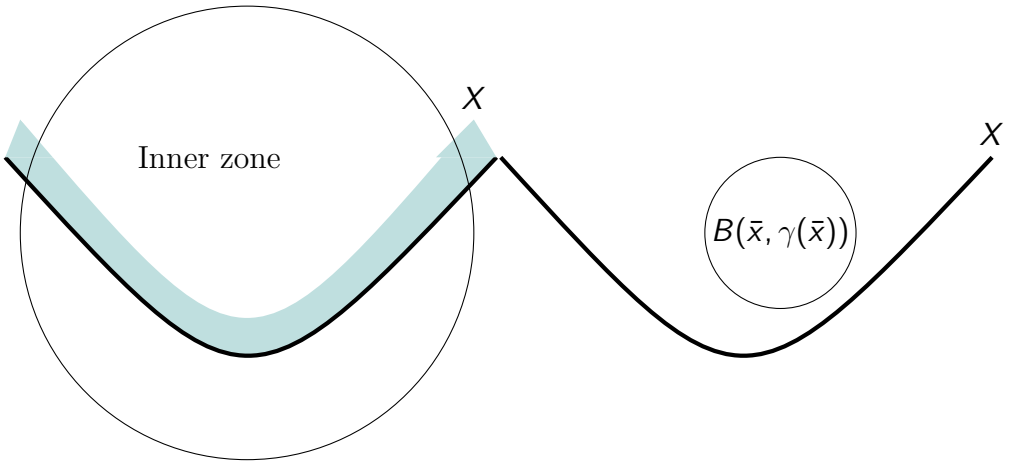
We consider contribution of the *inner zone*

$$\{x \in X \cap B(0,1) : \ \mathsf{dist}(x, \partial X) \geq \bar{\gamma}\} \tag{7.5.1}$$

to asymptotics and to the remainder estimate; we estimate contribution of the *boundary strip*

$$\{x \in X \cap B(0,1) : \ \mathsf{dist}(x, \partial X) \leq \bar{\gamma}\} \tag{7.5.2}$$

later. Usually $\bar{\gamma} \asymp h$ but we commit only to an assumption that $\bar{\gamma} \geq h$.



(a) Inner zone and boundary strip (b) $B(\bar{x}, \gamma(\bar{x}))$ to be rescaled

Figure 7.4: Rescaling settings

Let us introduce

$$\gamma(x) = \frac{1}{2}\mathsf{dist}(x, \partial X) \tag{7.5.3}$$

which is obviously scaling function and consider $B(\bar{x}, \gamma)) \subset X \cap B(0,1)$ with $\gamma = \gamma(\bar{x})$ here.

We rescale it $x \mapsto x\gamma^{-1}$, $h \mapsto \hbar = h\gamma^{-1}$. We want that

(7.5.4) Contribution of $B(\bar{x}, \gamma(\bar{x}))$ to the remainder does not exceed $\hbar^{1-d}$.

This happens for example if operator is ξ-microhyperbolic or scalar and satisfies certain non-degeneracy assumptions (which should survive rescaling; we will discuss them later in Section 8.1). Due to Sections 4.6 and 5.4 we do not need restrictive smoothness conditions.

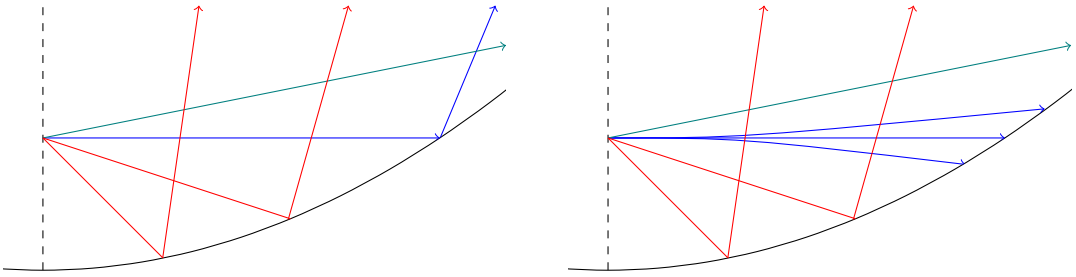
Then the total contribution of inner zone (7.5.1) to the remainder does not exceed

$$Ch^{1-d}\int \gamma(x)^{-1}\,dx. \tag{7.5.5}$$

Really, contribution of each ball does not exceed $C\hbar^{1-d} = Ch^{1-d}\gamma^{-1}\times\gamma^{d}$.

The bad news are that even in the smooth case integral in (7.5.5) is unbounded; the good news are that this divergence is only logarithmic.

Propagation



(a) Geometry of rays (b) Approximate geometry of rays

Figure 7.5: Green rays are outgoing, red are incoming and blue are almost parallel to the boundary

The idea of R. Seeley was to consider rays (only wave equation in the domain with the smooth boundary was analyzed then). In the smooth case almost parallel rays (with an angle no more than $\hbar^{\delta}$) do not meet the boundary for a time $T \asymp \min\bigl(\gamma^{\frac{1}{2}}, \hbar^{-\delta}\gamma\bigr)$, while outgoing rays require even larger time. Incoming rays meet boundary once during this time, they are not tangent to the boundary and one can use oscillatory integrals to calculate their contribution. However here we are interested only in the asymptotics of $e(x,x,0)$ integrated with respect to x and therefore we can select time direction along each ray bundle as we want; so we do not need to consider incoming rays at all.

Thus at least heuristically we can replace $T(x) \asymp \gamma(x)$ by larger value which in the R. Seeley settings was

$$T(x) \asymp \min\bigl(\gamma(x)^{\frac{1}{2}}, \hbar^{-\delta}\gamma(x)\bigr). \tag{7.5.6}$$

Then the contribution of $B(\bar{x}, \gamma)$ to the remainder does not exceed

$$CT^{-1}h^{1-d} \tag{7.5.7}$$

and the total contribution of zone (7.5.1) does not exceed

$$Ch^{1-d}\int T(x)^{-1}\,dx \asymp Ch^{1-d}\int \bigl(\gamma^{-\frac{1}{2}} + h^{\delta}\gamma^{-1-\delta}\bigr)\,dx. \tag{7.5.8}$$

Remark 7.5.1. (i) One can see easily that in the smooth settings integral in (7.5.8) is bounded. What is more: obviously it work for less smooth boundaries as well: if $\partial X \in \mathscr{C}_{\nu}$ with the continuity modulus $\nu(t) = o(t)$ all we need is to replace $\gamma^{\frac{1}{2}}$ in (7.5.6) by $\check{\nu}(\gamma)$ where $\check{\nu}$ is an inverse function. In particular, integral in (7.5.8) is bounded provided $\nu(t) = O(t|\log t|^{1+\delta})$ with $\delta > 0$.

(ii) Contribution of zone (7.5.2) is easy to estimate: in the current (smooth boundary) settings $e(x, x, 0) \le Ch^{-d}$ and the total measure of this zone is $O(\bar{\gamma})$; so the total contribution of this zone does not exceed $Ch^{-d}\bar{\gamma} \asymp Ch^{1-d}$. In the case of irregular boundary we will discuss this later in the different settings (Dirichlet boundary conditions being the most favourable).

What Then?

However we want to deal not only with irregular boundary but also with irregular coefficients. In this section we mainly

(i) Generalize this analysis (and justify propagation) to general ξ-microhyperbolic scalar operators (including rough ones);

(ii) Generalize this analysis (and justify propagation) to general ξ-microhyperbolic matrix operators (including rough ones);

(iii) Using rescaling consider degenerating scalar operators (including rough ones);

(iv) Improve the remainder estimate to $o(h^{1-d})$ under conditions of the global nature;

(v) Describe construction of mollification for irregular operators.

Mollification

To recover $O(h^{1-d})$ and $o(h^{1-d})$ remainder estimate in the case of irregular operators we will select smoothing parameter ε in a special way (assuming ξ-microhyperbolicity): again as in Section 5.4 we can take *variable smoothing parameter*. Namely we take

$$\varepsilon(x) = \eta\gamma(x)^{\delta_0-1} \tag{7.5.9}$$

with $\gamma(x) = \frac{1}{2}\mathsf{dist}(x, \partial X)$ and arbitrarily small exponent $\delta_0 > 0$; here η denotes the *original smoothing parameter* which was

$$\eta = Ch|\log h|, \quad \eta = C'(h)h|\log h| \tag{7.5.10}$$

in the proof of remainder estimates $O(h^{1-d})$ and $o(h^{1-d})$ respectively where C is a large enough constant and $C'(h) \to \infty$ slowly enough: $C'(h)\nu(\eta)\eta^{-1} \to 0$ where $\nu(t)t^{-1}$ is the continuity modulus of the first derivatives of the coefficients.

However, we define $\varepsilon(x)$ by (7.5.9) only as $\gamma(x) \geq C\varepsilon(x)$ i.e only in the interior domain

$$X_{\hat\gamma} := \{x \in X, \gamma(x) \geq \hat\gamma\} \qquad \text{with } \hat\gamma_1 = C(h|\log h|)^{1/(2-\delta_0)} \tag{7.5.11}$$

while in

$$Y_{\hat\gamma} := \{\gamma(x) \leq \hat\gamma\} \tag{7.5.12}$$

we pick

$$\varepsilon(x) = \epsilon_0\gamma(x) \tag{7.5.13}$$

with an appropriate constant ϵ_0; then in this zone

$$\hat\gamma \leq \varepsilon(x) \leq \epsilon\gamma(x). \tag{7.5.14}$$

We mollify operator in question; namely we replace it's coefficients $a_*(x)$ by

$$\tilde a_*(x) = \int a_*\big(x + \varepsilon(x)y\big)\phi(y)dy$$

where ϕ is a mollifying function of the same type as in Section 5.4.

Remark 7.5.2. (i) Again *in what follows we skip "˜" over mollified symbol a and over its level surfaces "Σ_τ"* .

(ii) Note that near the boundary we favor mollification over precision (and we will see that there is a good reason for this); however one can see easily that the differences for the Weyl expressions for mollified and original operators are $O(h^{1-d})$, $o(h^{1-d})$ as soon as operator is ξ-microhyperbolic, domain satisfies condition (7.5.28) below and also

(7.5.15) First derivatives of the coefficients are continuous with the continuity modulus $O\big(\nu(t)t^{-1}\big)$ in the vicinity of $\bar{X}$ with $\nu(t) = O\big(t|\log t|^{-1}\big)$ or $\nu(t) = o\big(t|\log t|^{-1}\big)$ respectively.

7.5.2 $O(h^{1-d})$ Remainder Estimate for Scalar Operators

Let us consider a point $\bar{x}$ and γ-vicinity of it with $\gamma = \gamma(\bar{x})$. Rescaling it to $B(0,1)$ by $x \mapsto (x-\bar{x})\gamma^{-1}$ we get the operator of the same type with $\hbar = h\gamma^{-1}$ instead of h.

Inner Zone

Now let us start our real arguments. Namely, let us consider a point $\bar{x} \in Y_\mu$ and a $\frac{1}{4}\zeta$-vicinity of it with parameter $\zeta \le \gamma := \gamma(\bar{x})$ defined later and an (arbitrarily) small constant μ. We consider also $\bar{\xi}$ and $\frac{1}{4}\rho$-vicinity of it with parameter ρ defined later.

Let us consider generalized Hamiltonian trajectories of $a(x,\xi)$ with $|t| \le T$,

$$T \le T_0(\gamma) := \gamma^{1-\delta_1}. \tag{7.5.16}$$

These trajectories remain in $(\frac{1}{2}\rho, \frac{1}{2}\zeta)$-vicinity of $(y(t), \bar{\xi})$ with $y(t) := \bar{x} + \ell t$, $\ell = \nabla_\xi a(\bar{x}, \bar{\xi})$ as long as they do not hit the boundary provided

$$\rho \ge CT, \qquad \zeta \ge C\rho T. \tag{7.5.17}_{1,2}$$

Let us recall that $|\nabla_{x,\xi}\nabla_\xi a| \le c$. Therefore

(7.5.18) Assumption $\gamma(y(t)) \ge \zeta$ for all $t : 0 \le \pm t \le T$ implies that $\gamma(x(t)) \ge \frac{1}{2}\zeta$ at every trajectory of this "beam" (of the trajectories).

To pass from the "classical" to "quantum" dynamics we need to request the logarithmic uncertainty principle $\zeta\rho \ge Ch|\log h|$ and $\varepsilon(x(t))\rho \ge Ch|\log h|$ at each point of the trajectory. So let us assume that

$$\zeta\rho \ge Ch|\log h|, \qquad \rho \ge CT^{1-\delta_0} \tag{7.5.19}_{1,2}$$

where the second condition assures the second of the uncertainty principles due to observation $\gamma(x(t)) \le CT$ and definition of $\varepsilon(x)$.

Note, that the only condition bounding ρ from above is $(7.5.17)_2$; plugging $\rho = \epsilon\zeta T(\gamma)^{-1}$ into all other conditions and selecting appropriate exponents δ_0, δ_1 we observe that we can satisfy all of them if and only if $\gamma \ge \bar\gamma_1 := h^{1-\delta_2}$ and $\zeta = \max\bigl(\gamma^{\frac12(1-\delta)}h^{\frac12}, \gamma^{2-\delta}\bigr)$ with arbitrarily small exponents $\delta > 0$ and $\delta_2 = \delta(1+\delta)^{-1}$.

Remark 7.5.3. Observe that we could take $\varepsilon(x) = Ch|\log h|\gamma^{-1}|\log\gamma|^{-1-\delta_0}$ and $T_0(\gamma) = \gamma|\log\gamma|^{1+\delta_0}$ and push $\bar\gamma_0$ to $h|\log h|^\sigma$ with large enough σ.

These assumptions enable us to prove

Proposition 7.5.4. *The singularity of $v = e^{ih^{-1}tA}v_0$ contained at $t = 0$ in $B(\bar x, \frac14\zeta)\times B(\bar\xi, \frac14\rho)$ is contained in $B(y(t), \frac12\zeta)\times B(\bar\xi, \frac12\rho)$ as long as*

$$0 \le \pm t \le T^*_\pm(x,\xi) = \min\bigl(T_\pm(x,\xi), T_0(\gamma)\bigr) \tag{7.5.20}$$

where

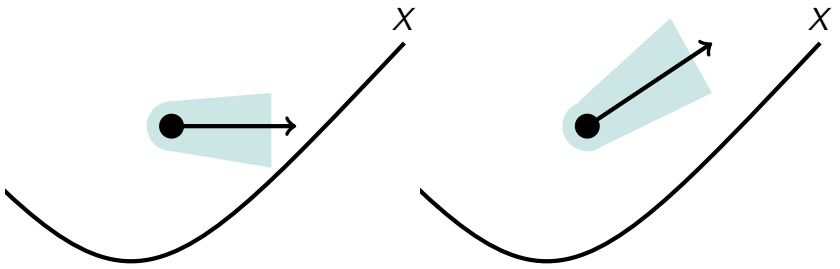
$$T_\pm(x,\xi) := \max\{T : x(t) \in X_\zeta \quad \forall t : 0 \le \pm t \le T\}. \tag{7.5.21}$$

See Figure 7.6 below for illustration of the assertion of this proposition.

Remark 7.5.5. (i) So $T^*_\pm(x,\xi)$ is $T_\pm(x,\xi)$ *capped* by $T_0(x)$.

(ii) Let us recall that $x(t)$ could be a multi-valued function because the Hamiltonian flow could be multi-valued due to the irregularity of the right-hand expressions in the Hamiltonian equations. Note however that defining $T_\pm$ we can take *either* multivalued Hamiltonian trajectories *or* single-valued Hamiltonian trajectories of the mollified symbol *or* just a straight lines $y(t)$ tangent to $x(t)$ at $t = 0$.

Proof of Proposition 7.5.4. Without any loss of the generality one can assume that $(\bar x, \bar\xi) = (0,0)$. Rescaling $t \mapsto t_{\text{new}} = tT^{-1}$, $x \mapsto x_{\text{new}} = (x - \ell t)\zeta^{-1}$, $\xi \mapsto \xi_{\text{new}} = \xi\rho^{-1}$ we find ourselves in the framework of Theorem 2.3.2 with $\Omega = [0,1]\times B(0,1)\times B(0,1)$, $h_{\text{new}} = h(\rho\zeta)^{-1} \le h^\delta$ and $\varepsilon_{\text{new}} = \varepsilon_0 T^{\delta_0-1}\zeta^{-1}$ which satisfy condition $\varepsilon_{\text{new}} \ge Ch_{\text{new}}|\log h_{\text{new}}|$. □



(a) (b)

Figure 7.6: Singularity initially confined in black disk with initial direction indicated by arrow remains in the colored zone for time T.

Without any loss of the generality one can assume that

(7.5.22) operator is ξ_1-microhyperbolic (i.e. microhyperbolic in the direction $\ell_\xi = (1, 0, \dots, 0)$);

then we can take operators $Q_j = Q_j(x, hD')$ with $\xi' = (\xi_2, \dots, \xi_d)$.

Then

$$F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t) - \bar\chi_{T'}(t)\bigr)\Gamma\bigl(Q_{1x}u\,{}^tQ_{2y}\bigr) \equiv 0 \tag{7.5.23}$$

as Q_2 is supported in $B(\bar x, \frac{1}{4}\zeta)\times B(\bar\xi', \frac{1}{4}\rho)$ and $T' = h^{1-\delta'}$ with arbitrarily small exponent $\delta' > 0$.

Therefore

(7.5.24) the contribution of $\Omega'(\bar x, \bar\xi') := B(\bar x, \frac{1}{4}\zeta)\times B(\bar\xi', \frac{1}{4}\rho)$ to the remainder does not exceed $Ch^{1-d}\zeta^d T^{*-1}$ with $T^* = \max(T^*_+, T^*_-)$.

Really, if $T_-(x,\xi) > T_+(x,\xi)$ one can always revert time.

Plugging $T^*_\pm$ defined by (7.5.20) we can rewrite this expression as

$$Ch^{1-d}\int_{\Omega'(\bar x,\bar\xi)\cap\Sigma_\tau} T(x,\xi)^{-1}dx\,d\xi : da + Ch^{1-d}\zeta^d T_0(\gamma) \tag{7.5.25}$$

where

$$T(x,\xi) = T_+(x,\xi) + T_-(x,\xi) \tag{7.5.26}$$

and $\Sigma_\tau = \{(x,\xi) : a(x,\xi) = \tau\}$.

Then the contribution of the strip $\mathcal{X}_{(\beta)} = \{x \in X : \beta \le \gamma(x) \le 2\beta\}$ with $\beta \in (\bar\gamma_1, \mu)$ to the remainder does not exceed

$$Ch^{1-d} \int_{\mathcal{X}_{(\beta)}\times\mathbb{R}^d\cap\Sigma_\tau} T(x,\xi)^{-1} dx\, d\xi : da + Ch^{1-d} T_0(\beta)^{-1} \cdot \mathsf{mes}(\mathcal{X}_{(\beta)}). \tag{7.5.27}$$

The second term does not exceed $C\beta^\delta h^{1-d}$ provided

$$\mathsf{mes}(\mathcal{X}_{(\beta)}) \le c\beta \tag{7.5.28}$$

which is a very weak regularity condition to ∂X (intersected with $B(0,1)$); we will deal with even with less regular boundaries in Subsection 7.5.5.

Then estimate (7.5.27) for contribution of $\mathcal{X}_{(\beta)}$ implies that the contribution of the strip

$$Y_\beta \cap X_{\beta'} = \{x \in X : \beta' \le \gamma(x) \le \beta\} \tag{7.5.29}$$

to the remainder does not exceed

$$Ch^{1-d} \int_{(Y_\beta\cap X_{\beta'})\times\mathbb{R}^d\cap\Sigma_\tau} T(x,\xi)^{-1} dx\, d\xi : da + Ch^{1-d}\beta^\delta \tag{7.5.30}$$

provided $\frac{1}{2}\beta > \beta' > \bar\gamma_1$.

Let us recall definition of $T(x,\xi)$: according to (7.5.21) and (7.5.26)

(7.5.31) $T(x,\xi)$ is the maximal time such that any trajectory passing through (x,ξ) remains in X_β: i.e. if $x(t) \in X_\beta$ as $t \in [-T_-(x,\xi), T_+(x,\xi)]$, then $T(x,\xi) = T_+(x,\xi) + T_-(x,\xi)$.

Observe that increasing ζ, we decrease $T(x,\xi)$ and thus increase the first term in (7.5.30); so we are interested to pick up the smallest possible ζ. Further, note that $(7.5.17)_{1,2}$ is the only restriction to ρ from above; selecting $\rho = \epsilon\zeta T^{-1}$ and plugging into $(7.5.17)_{1,2}$ and $(7.5.19)_{1,2}$ we get

$$\zeta \ge C\max\bigl((h|\log h|\,T)^{\frac{1}{2}}, T^{2-\delta_0}\bigr).$$

Recalling that $T_0 = \gamma^{1-\delta_1}$ and taking $T = T_0$, we pick up

$$\zeta = \max\bigl(h^{\frac{1}{2}-\delta}\beta^{\frac{1}{2}+\delta}, \beta^{2-\delta}\bigr) \tag{7.5.32}$$

with (arbitrarily) small $\delta > 0$ (with all previous exponents δ_j depending on it). Furthermore, for any given β let us define $\beta' = \zeta$ by (7.5.32). Let us recall that $\zeta \le \gamma$ and thus β' is the lowest value of γ we can afford for given ζ.

So, let us take β and define $\beta' = \zeta(\beta) \le \beta$ by (7.5.32) and then pick up this ζ in the whole strip (7.5.29). Therefore the contribution of this strip (7.5.29) to the remainder is given by (7.5.30) where now $T(x,\xi)$ is a time for which Hamiltonian trajectory of the mollified symbol $a(x,\xi)$ remains in (7.5.29).

Since the corresponding Hamiltonian flow preserves both Σ_τ and measure $dx\,d\xi : da$ on it, we conclude that thus interpreted (7.5.30) does not exceed

$$Ch^{1-d}\int_{(\mathcal{X}_{(\beta')}\cup\mathcal{X}_{(\beta')})\times\mathbb{R}^d\cap\Sigma_\tau} t(x,\xi)^{-1}dx\,d\xi : da + Ch^{1-d}\beta^{\delta} \tag{7.5.33}$$

where $t(x,\xi)$ is the time spent by trajectory in $\mathcal{X}_{(\gamma)}$ as $x \in \mathcal{X}_{(\gamma)}$; however $t(x,\xi) \ge \epsilon\gamma(x,\xi)$ and the first term in (7.5.33) does not exceed $Ch^{1-d}\gamma^{-1}\operatorname{vol}\mathcal{X}_{(\gamma)}$ and in virtue of condition (7.5.28) it does not exceed Ch^{1-d}. Therefore

(7.5.34) Contribution of the strip (7.5.29) with $\beta \ge h^{1-\delta}$ and $\beta' = \zeta$ defined by (7.5.32) to the remainder does not exceed Ch^{1-d}.

Since zones

$$\mathcal{X}'' := \{x : h^{1-\delta} \le \gamma(x) \le h^{\delta}\} \tag{7.5.35}$$

and

$$\mathcal{X}' := \{x : h^{\delta} \le \gamma(x) \le \mu\} \tag{7.5.36}$$

can be covered by no more than C_δ and $C\log|\log h|$ respectively of such stripes, we have proven

Proposition 7.5.6. *Let coefficients be $\mathscr{C}^1(\bar{X})$ and mollification parameter is selected as above. Let condition* (7.5.28) *be fulfilled. Then*

(i) The contribution of zone $\mathcal{X}''$ defined by (7.5.35) *to the remainder does not exceed $C_\delta h^{1-d}$.*

(ii) The contribution of zone $\mathcal{X}'$ defined by (7.5.36) *to the remainder does not exceed*

$$Ch^{1-d}\int_{(X_{h^\delta}\cap Y_\mu)\times\mathbb{R}^d\cap\Sigma_\tau} T(x,\xi)^{-1}dx\,d\xi : da + Ch^{1-d}\mu^\delta \tag{7.5.37}$$

with $T(x,\xi)$ defined by (7.5.31) *with*

$$\zeta = \beta^{2-\delta}. \tag{7.5.38}$$

(iii) In particular, it does not exceed $Ch^{1-d}\log|\log h|$.

(iv) If

$$\int_{Y_1} T(x,\xi)^{-1}dx\,d\xi : da < \infty \tag{7.5.39}$$

then the contributions of both zones $\mathcal{X}'$, $\mathcal{X}''$ to the remainder do not exceed $C_\mu h^{1-d}$ with $C_\mu = o(1)$ as $\mu \to +0$.

Moving Closer to the Boundary

Let us consider zone

$$\mathcal{X}''' := \{x : \mu^{-1}h \le \gamma(x) \le h^{1-\delta}\} \tag{7.5.40}$$

with $\mu \le 1$.

We can repeat our analysis leading to Proposition 7.5.6 but we must replace conditions $(7.5.19)_{1,2}$ by a single condition

$$\zeta\rho \ge Ch|\log\hbar| \qquad \text{with} \quad \hbar = \frac{h}{\gamma}; \tag{7.5.19}'_1$$

we do not need the second condition since trajectory is contained in the zone where $\varepsilon(x) = \gamma(x)$ and we need only $|\log\hbar|$ because $\hbar$ is our effective semiclassical parameter. Therefore we can define ζ by (7.5.38) and take $T_0(\gamma) = \gamma^{1+\delta'}h^{-\delta'}$ with small exponents $\delta, \delta' > 0$.

Then the contribution of the strip $\mathcal{X}_{(\beta)}$ to the remainder does not exceed (7.5.27) and repeating the rest of arguments leading to Proposition 7.5.6 we arrive to

Proposition 7.5.7. *(i) Contribution of zone $\mathcal{X}'''$ with to the remainder does not exceed*

$$Ch^{1-d}\int_{(X_{\mu^{-1}h}\bigcap Y_{h^{1-\delta}})\times\mathbb{R}^d\cap\Sigma_\tau} T(x,\xi)^{-1}dx\,d\xi : da + Ch^{1-d}\mu^{\delta''}; \tag{7.5.41}$$

(ii) In particular, it does not exceed $Ch^{1-d}\log|\log h|$.

(iii) Under condition (7.5.39) *it does not exceed $C_\mu h^{1-d}$ with $C_\mu = o(1)$ as $\mu\to+0$.*

Boundary Strip

Simple rescaling $x\mapsto x\gamma^{-1}$ with $\gamma = h$ implies

Proposition 7.5.8. *Under extra condition*

$$X\cap B(0,1) = \{x_1 > \phi(x')\} \qquad \text{with} \qquad |D^\beta\phi|\le ch^{1-|\alpha|} \qquad \forall \alpha : 1\le|\beta|\le K \tag{7.5.42}$$

contributions of zone Y_β with $\beta\ge h$ to the main part of the asymptotics and to the remainder do not exceed $Ch^{-d}\beta$.

Currently we do not have good tools to estimate contribution of zone Y_β as $\beta\asymp h$ and ∂X is very irregular. So, instead of inventing a special proof (which is not very difficult) we refer to the results of Chapter 9 which imply

Remark 7.5.9. (i) With the Dirichlet boundary conditions contributions of zone Y_β with $\beta\ge h$ to the main part of the asymptotics and to the remainder do not exceed $Ch^{-d}\operatorname{vol} Y_\beta$; in particular, under condition (7.5.28) these contributions do not exceed $Ch^{-d}\beta$.

(ii) We will discuss other boundary conditions as well.

Synthesis

Thus after summation of contribution of these four zones ($\mathcal{X}', \mathcal{X}'', \mathcal{X}'''$ and Y_h) and adding the contribution of the interior zone X_μ with (arbitrarily) small constant $\mu > 0$ which is $O(h^{1-d})$ due to results of Section 4.6, we arrive to

Theorem 7.5.10. *Let A be a scalar h-differential operator of* (4.6.5) *type with coefficients belonging to $\mathscr{C}^{l}_{\nu}(\bar{X})$ with $l = 1$ and $\nu(t) = t|\log t|^{-1}$ (see Definition 4.6.1).*

Assume that the principal symbol of A is elliptic and semi-bounded from below and the Dirichlet boundary conditions are imposed on ∂X. Further, assume that condition (7.5.28) *is fulfilled. Let X be a bounded domain. Then under ξ-microhyperbolicity condition on level τ*

(i) The following remainder estimate holds:

$$|\mathsf{N}(\tau) - \mathsf{N}^{\mathsf{W}}(\tau)| \le Ch^{1-d} \int_{(\mathcal{X}'\cup\mathcal{X}''')\times\mathbb{R}^d\cap\Sigma_\tau} T(x,\xi)^{-1} dx\, d\xi : da + Ch^{1-d} \tag{7.5.43}$$

with $\mathcal{X}'$ and $\mathcal{X}'''$ defined by (7.5.36) *and* (7.5.40) *respectively and $T(x,\xi)$ defined by* (7.5.31), (7.5.23) *with ζ given by* (7.5.38) *(namely, $\zeta(x) = \gamma(x)^{2-\delta}$).*

(ii) Moreover, if also condition (7.5.39) *is fulfilled then*

$$|\mathsf{N}(\tau) - \mathsf{N}^{\mathsf{W}}| \le Ch^{1-d}. \tag{7.5.44}$$

Remark 7.5.11. If domain X is unbounded then the statement remains true after we replace A by its regularization with ε given by (7.5.13) and include cut-off with $\psi \in \mathscr{C}^1_0(B(0,\frac{1}{2}))$.

Corollary 7.5.12. *In the framework of Theorem 7.5.10*

(i) Remainder (i.e. the left hand expression in (7.5.43)*) does not exceed $Ch^{1-d}\log|\log h|$.*

(ii) If ∂X is more regular, namely, if

$$\partial X = \bigcup_k \{x_k = \phi_k(x_{\hat{k}})\} \qquad \text{with} \quad \phi_k \in \mathscr{C}^1_{\nu_1} \tag{7.5.45}$$

then the remainder does not exceed

$$Ch^{1-d} + Ch^{1-d} \int_J \nu_1(t)\, \frac{dt}{t^2} dt \tag{7.5.46}$$

with $J = [h, h^{1-\delta}] \cup [h^{\delta}, 1]$*; in particular, it does not exceed* Ch^{1-d} *provided*

$$\int_0^1 \nu_1(t)\,\frac{dt}{t^2} < \infty \tag{7.5.47}$$

which happens f.e. as $\nu_1(t) = t|\log t|^{-1-\delta}$ *with* $\delta > 0$.

(iii) For the Schrödinger operator the remainder does not exceed

$$Ch^{1-d} + Ch^{1-d}\int_J \nu_1(t)^2\,\frac{dt}{t^3}; \tag{7.5.48}$$

in particular, it does not exceed Ch^{1-d} *provided*

$$\int_0^1 \nu_1(t)^2\,\frac{dt}{t^3} < \infty. \tag{7.5.49}$$

(iv) Under assumption (7.5.39)[26] *contribution of zone* $\{x, \mu^{-1} \le \gamma(x) \le \mu\}$ *to the remainder does not exceed* $C_\mu h^{1-d}$ *with* $C_\mu = o(1)$ *as* $\mu \to +0$.

Proof. (i) Proof of Statement (i) is trivial.

(ii) Under condition (7.5.45) one can see easily that $T(x,\xi) \ge \epsilon_0 \tilde{\nu}_1(\gamma(x,\xi))$ and $\tilde{\nu}_1$ is the corresponding inverse function; we will improve these arguments later to cover more general case. Then

$$h^{1-d}\int T^{-1}(x,\xi)\,dxd\xi : da \le Ch^{1-d}\int_J \tilde{\nu}_1(\gamma)^{-1}d\gamma$$

which does not exceed (7.5.46).

(iii) Further, note that for the Schrödinger operator under condition (7.5.45) $T(x,\xi) \ge \epsilon_0 \max\bigl(\tilde{\nu}_1(\gamma), \tilde{\nu}_0(\varrho)\bigr)$ where ϱ is a slope (an angle between trajectory and the boundary), $\nu_0(t) = \nu_1(t)t^{-1}$ and $\tilde{\nu}_0$ is the corresponding inverse function. Then

$$h^{1-d}\int T^{-1}(x,\xi)\,dxd\xi : da \le$$
$$Ch^{1-d}\int_J \frac{1}{t}d_t\,\mathsf{mes}\bigl(\{(x,\xi) : \gamma(x) \le \nu_1(t), \varrho(x,\xi) \le \nu_0(t)\}\bigr) \le$$
$$Ch^{1-d}\int \frac{1}{t}\,d_t\bigl(t^{-1}\nu_1^2(t)\bigr)$$

which does not exceed (7.5.48).

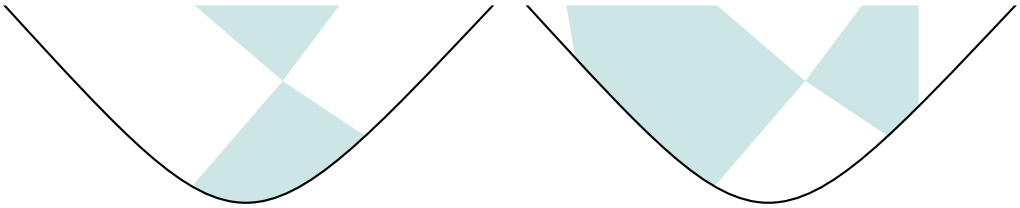
[26] In particular, in the framework either of Statement (ii) and (7.5.47) or Statement (iii) and (7.5.49).

(iv) Finally, Statement (iv) trivially follows from the proofs of Statements (ii) and (iii). □

Remark 7.5.13. If the first derivatives of the coefficients of a are Hölder continuous (i.e. $\nu(t) = t^{1+\delta}$), then one can pick up $\varepsilon = h^{1-\delta}$ as $\gamma > h^{\delta}$ with small exponent $\delta > 0$ and with an approximation error $o(h^{1-d})$; then for $\gamma > h^{\delta}$ we can pick up $\zeta = h^{\delta}$ and then contribution of $\mathcal{X}'$ to the remainder would not exceed $C_{\mu}h^{1-d}$ with $C_{\mu} = o(1)$ as $\mu \to +0$; then in estimate (7.5.43) we can skip $\mathcal{X}'$ and therefore estimates (7.5.46), (7.5.48) hold with $J = [h, h^{1-\delta}]$.

7.5.3 $O(h^{1-d})$ Remainder Estimate for Matrix Operators

Let us consider the general matrix case; we define $\gamma(x)$, η, $\varepsilon(x)$, $\bar{\gamma}_1$ in the same way as before.



(a) (b)

Figure 7.7: Matrix case: massive propagation

We have a major problem now: in the general matrix case some singularities propagate along "massive" propagation cones rather than along "thin" Hamiltonian trajectories (even if Hamiltonian flow is multivalued due to non-smoothness the corresponding cones were thin enough in the previous subsection). And we have issue not with the case of incoming and outgoing cones as on the Subfigure (a), but with what is now instead of parallels rays as on Subfigure (b).

However we will show that arguments of the previous Subsection 7.5.2 remain true because such massive propagation happens in rather small number of points. Heuristically if $\dim \ker a(\bar{x}, \bar{\xi}) = l$ at some point, then one can assume that a is $l \times l$-matrix and two cases are possible: *either*

$\mathsf{dim}\,\mathsf{span}_{j,k}\,\nabla_\xi a_{jk} = 1$ and then $\partial_{\xi_i} a_{jk}(\bar{x},\bar{\xi}) = b_{jk}\ell_i$ for all j,k,i and therefore the x-projection of the propagation direction at $(\bar{x},\bar{\xi})$ is proportional to ℓ and arguments of the previous subsection work *or* $\mathsf{dim}\,\mathsf{span}_{j,k}\,\nabla_\xi a_{jk} \ge 2$ and then in majority of points $(x,\xi)\in\Sigma$ in the vicinity of $(\bar{x},\bar{\xi})$ $\mathsf{dim}\,\mathsf{ker}\,a(x,\xi) < l$; let us recall that $\Sigma = \{(x,\xi) :\ \mathsf{ker}\,a(x,\xi)\neq\{0\}\}$. Let us formalize this idea.

As in the previous subsection we should consider zones $\mathcal{X}'\cup\mathcal{X}''$ defined by (7.5.36), (7.5.35) and $\mathcal{X}'''$ defined by (7.5.40) separately; boundary strip Y_β does not require any modification in comparison with the scalar case.

Let us introduce small parameter

(7.5.50) $\eta=\gamma$ and $\eta = h\gamma^{-1}$ in $\mathcal{X}'\cup\mathcal{X}''$ and $\mathcal{X}'''$ respectively.

Covering

Let $(\bar{x},\bar{\xi})\in\Omega\subset\bigl(\mathcal{X}'\cup\mathcal{X}''\cup\mathcal{X}'''\bigr)\times\mathbb{R}^d$. As in the scalar case we want to analyze our operator in $\gamma\eta^{-\delta}$-vicinity of $(\bar{x},\bar{\xi})$ because for time t with $|t|\le c_0^{-1}\gamma\eta^{-\delta}$ we do not expect singularities to leave it. However, with respect to ξ we will take ρ-vicinity with $\rho=\eta^\delta$ for a sake of uncertainty principle.

More precisely, as before we assume that a is ξ_1-microhyperbolic in the whole domain in question and we consider ρ-vicinity with respect to ξ' and thus use operators $Q_j = Q_j(x,hD')$.

Further, without any loss of the generality one can assume that

$$\|a(\bar{x},\bar{\xi})\|\le\epsilon\eta^{\delta_1} \tag{7.5.51}$$

with some small exponent $\delta_1>0$.

Indeed, otherwise in η^{δ_1}-vicinity of $(\bar{x},\bar{\xi})$ we can transform our operator A [27] into the direct sum of an operator, satisfying this condition, and an elliptic operator with the following explanations:

(a) The transformation and resulting operators are h-pseudodifferential operators which is fine as long as we stay away from the boundary. So actually we can take only $B(\bar{x},\gamma)\times B(\bar{\xi}',\epsilon\eta^{\delta_1})$ but then after we consider propagation we can take the similar vicinity of another point and so on as long as propagation keeps away from ∂X in the same way as it was in the scalar case. Then propagation is reduced to propagation of operator A_0-type;

[27] We use the same notation for operator with mollified coefficients.

(b) Actually the resulting operator is block-diagonal $\mathsf{diag}(A_0; A_1, \dots, A_k)$ where A_0 satisfies (7.5.51) and $\varrho_j^{-1} A_j$ are regular elliptic operators with $\nu^{\delta_1} < \varrho_1 < \dots < \varrho_k$.

After rescaling $x \mapsto x\eta^{-\delta_1}$, $\xi \mapsto \xi\eta^{-\delta_1}$, $t \mapsto t\eta^{-\delta_1}$, $h \mapsto h\eta^{-2\delta_1}$ this operator would satisfy the proper regularity conditions.

Note that due to assumption of ξ_1-microhyperbolicity $b := a_{\xi_1}(\bar{x}, \bar{\xi})$ is a positive matrix. Then for $\xi \in B(\bar{\xi}, \rho)$

$$a'(\xi) := b^{-\frac{1}{2}} a(\bar{x}, \xi) b^{-\frac{1}{2}} = (\xi_1 - \bar{\xi}_1) + a''(\xi' - \bar{\xi}') + O(\rho^2) \qquad (7.5.52)$$

$$\text{with} \quad a''(\zeta') = \sum_{2 \le k \le d} a'_{\xi_k}(\bar{x}, \bar{\xi}) \zeta_k,$$

$$a'_{\xi_k}(\bar{x}, \xi) = a_{\xi_k}(\bar{x}, \xi) + O(\rho). \qquad (7.5.53)$$

Now let us consider for $|\zeta'| = 1$ the top $\lambda_{\mathsf{max}}(\zeta')$ and the bottom $\lambda_{\mathsf{min}}(\zeta')$ eigenvalues of the matrix $a''(\zeta')$. Two cases are possible

$$\forall \zeta' : |\zeta'| = 1 \qquad \lambda_{\mathsf{max}}(\zeta') - \lambda_{\mathsf{min}}(\zeta') \le \eta^{\delta_2}, \qquad (7.5.54)$$

$$\exists \zeta' : |\zeta'| = 1 \qquad \lambda_{\mathsf{max}}(\zeta') - \lambda_{\mathsf{min}}(\zeta') \ge \eta^{\delta_2} \qquad (7.5.55)$$

with some exponent $\delta_2 \in (0, \frac{1}{8}\delta_1)$.

One can prove easily that in the former case $a''(\xi') = \sum_k \lambda_k \xi_k + O(\eta^{\delta_2})$ for all $\xi' : |\xi'| = 1$ and therefore

$$a'(\xi) = \sum_{1 \le k \le d} \lambda_k \xi_k + O(\rho\eta^{\delta_2}) \qquad (7.5.56)$$

and

$$a'_{\xi_k}(\xi) = \lambda_k + O(\eta^{\delta_2}) \qquad \forall \xi \in B(\bar{\xi}, \rho) \qquad (7.5.57)$$

with $\lambda_1 = 1$; for our needs it will be effectively scalar operator with the principal symbol $g = \mathsf{tr}(a_0)$ (alternatively with $g = \sum_k \lambda_k(\xi_k - \bar{\xi}_k)$).

In the latter case (7.5.55) one can find the covering of the sphere $\mathbb{S}^{d-2}(0,1)$ by the union of balls $\bigcup_{j \in \mathcal{I}' \cup \mathcal{I}''} B(\zeta'_j, \eta^{\delta_3})$ such that

$$\lambda_{\mathsf{max}}(\zeta') - \lambda_{\mathsf{min}}(\zeta') \ge \eta^{2\delta_2} \qquad \forall \xi' \in B(\zeta'_j, \eta^{\delta_3}), \quad j \in \mathcal{I}',$$

$$\mathsf{mes}'\Big(\bigcup_{j \in I''} B(\zeta'_j, \eta^{\delta_3}) \cap \mathbb{S}^{d-2}(0,1) \Big) \le \eta^{\delta_4}$$

where mes' is a standard measure on $\mathbb{S}^{d-2}(0,1)$. Here $\delta_3>0$ and $\delta_4>0$ are small exponents.

Then we will be able to cover $B(\bar\xi', \eta^{\delta_1-3\delta_2})$ by by the union of balls $\bigcup_{j\in\mathcal{J}'\cup\mathcal{J}''} B(\xi'_j, \eta^{\delta_5})$ such that

$$\lambda_{\mathsf{max}}(\xi') - \lambda_{\mathsf{min}}(\xi') \ge \eta^{\delta_1-\delta_6} \qquad \forall \xi' \in B(\xi'_j, 2\eta^{\delta_5}), \quad j\in\mathcal{J}', \tag{7.5.58}$$

$$\mathsf{mes}\Big(\bigcup_{j\in\mathcal{J}''} B(\xi'_j,\eta^{\delta_5})\Big) \le \eta^{\delta_6}\,\mathsf{mes}\, B(\bar\xi, \eta^{\delta_1-3\delta_2}). \tag{7.5.59}$$

Thus, there will be "not very many" balls of the second type (with $j\in\mathcal{J}''$) and in each ball of the first type (with $j\in\mathcal{J}'$) one can reduce our operator to direct sum of two operators of lesser (matrix) dimension. Continuing this process with the balls of the first type we arrive to

Proposition 7.5.14. *One can cover $B(\bar\xi,\rho)$ with $\rho=\eta^\delta$ by the union of balls $\bigcup_{j\in\mathcal{J}'\cup\mathcal{J}''} B(\xi_j,\rho_1)$ with $\rho_1=\rho\eta^{\delta'}$ such that*

(i) For each $\bar x$ and each $j\in\mathcal{J}'$ in the domain

$$\big(B(\bar x, 2\gamma_1)\cap\{\frac{1}{2}\gamma\eta^\delta \le \mathsf{dist}(x,\partial X)\le 2\gamma\eta^{-\delta}\}\big)\times B(\xi_j, 2\rho_1)$$

with $\gamma_1=\gamma\eta^{-\delta}$, $j\in\mathcal{J}'$ and ξ_j, $\mathcal{J}'$ depending on $\bar x$ one can transform operator A into block-diagonal matrix operator $\mathsf{diag}(A_1,\dots,A_p)$ with $p=p(\bar x, j)$ with symbols a_l of blocks such that

$$|\partial_x^\beta\partial_\xi^\alpha a_l(x,\xi)| \le N^{|\alpha|+|\beta|-1}\eta^{-2(|\alpha|+|\beta|-1)\delta'}\varepsilon^{-|\beta|} \qquad \forall \alpha,\beta: 1\le|\alpha|+|\beta|\le N,$$

and the same estimates hold for a transforming matrix; furthermore, for each block

$$|\partial_{\xi_k} a_l - \lambda_{l,k}(j) b_l| \le C\eta^{\delta''}$$

with some numbers $\lambda_{l,k}(j)$, $\lambda_{l,1}=1$, and some exponent $\delta''>0$.

(ii) prop-7-5-14-ii The total $(d-1)$-dimensional measure of $\pi\big(\bigcup_{j\in\mathcal{J}''} B(\xi_j,\rho')\big)$ does not exceed $C\rho^{d-1}\eta^{\delta''}$ where π denotes projection $(\xi_1,\xi')\to\xi'$.

One can choose δ, δ' and δ'' to be arbitrarily small.

This proposition allows us to estimate properly contribution to the remainder of the domains of each type.

Estimates

Indeed, in each domain

$$\bigl(B(\bar{x},\gamma_1)\cap\{\gamma\eta^{\delta}\le \mathsf{dist}(x,\partial X)\le \gamma\eta^{-\delta}\}\bigr)\times B(\xi_j,\rho_1)$$

of the first type (with $j\in\mathcal{J}'$) we can apply arguments of Subsection 7.5.2 and get the same estimate of their contribution to the remainder. Namely, the total contribution of these domains to the remainder does not exceed

$$Ch^{1-d}\int_{(\mathcal{X}'\bigcup\mathcal{X}''')\times\mathbb{R}^d\bigcap\Sigma_0\bigcap\Xi'} T(x,\xi)^{-1}dx\,d\xi : dg + Ch^{1-d} \tag{7.5.60}$$

where $T(x,\xi)$ is defined by Hamiltonians flows with appropriate scalar Hamiltonians[28)].

Further, applying arguments of Remark 7.5.13 we can skip $\mathcal{X}'$ in (7.5.60) if the first derivatives of coefficients are Hölder continuous.

On the other hand, the contribution to the remainder of the union Ξ'' of the boxes of the second type ($j\in\mathcal{J}''$) does not exceed $Ch^{1-d}\int \eta(x)^{\delta''}\gamma(x)^{-1}dx$ which in turn does not exceed Ch^{1-d} due to condition (7.5.28) and definition (7.5.50).

Furthermore, the contributions to the remainder of X_1 and Y_h do not exceed Ch^{1-d}. Thus we had proven

Theorem 7.5.15. *Let A be a h-differential operator of* (4.6.5) *type with coefficients belonging to $\mathscr{C}^l_\eta(\bar{X})$ with $l=1$ and $\eta(t)=t|\log t|^{-1}$ (see Definition 4.6.1) and assume that the principal symbol of A is elliptic and semi-bounded from below and the Dirichlet boundary conditions are imposed on ∂Y. Assume that* (7.5.28) *is fulfilled. Let X be a bounded domain. Then under ξ-microhyperbolicity condition on level τ*

(i) The remainder for $\tau=0$ does not exceed (7.5.60).

(ii) Further, under condition (7.5.39) *the remainder is $O(h^{1-d})$.*

(iii) Furthermore, Remark 7.5.13 also remains true.

Similarly, one can prove

[28)] One can pick up these Hamiltonians in different ways leading to the same result: as affine with respect to ξ functions or as $g(x,\xi)$ where $\{g(x,\xi)=0\}$ coincides in these boxes with Σ_0 and $c^{-1}\le|\nabla g|\le c$.

Corollary 7.5.16. *(i) Statements (i), (ii) and (iv) of Corollary 7.5.12 remain true in the matrix case.*

(ii) Statement (iii) of Corollary 7.5.12 also remains true in the matrix case for operators such that near boundary $\det a(x,\xi) = \prod_{1\le k\le m} q_k(x,\xi)$ *with elliptic quadratic forms (with respect to* ξ*)* $q_k(x,\xi)$.

In the proof of Statement (ii) one should apply the same arguments as in the proof of Proposition 7.5.14: either $\{(x,\xi') : \exists \xi_1 : q_k(x,\xi) = q_l(x,\xi) = 0\}$ is a "thin set" or q_k and q_l do not differ much and one can ignore q_l in the propagation arguments.

7.5.4 Sharp Remainder Estimate

If we want to derive a sharp remainder estimate $o(h^{1-d})$ we need first to improve handling of two zones: *boundary strip* $\{x\colon \gamma(x) \le \mu^{-1}h\}$ and *inner zone* $\{x\colon \gamma(x) \ge \mu\}$ where μ should be an arbitrarily small constant; we already proved that under appropriate conditions (ensuring remainder estimate $O(h^{1-d})$) the contribution of the *intermediate strip* $\{x : \mu^{-1}h \le \gamma(x) \le \mu\}$ to the remainder does not exceed $(C_\mu + o(1))h^{1-d}$ with $C_\mu = o(1)$ as $\mu \to +0$.

Near Boundary Zone

The better handling of the boundary strip $\{x : \gamma(x) \le \mu^{-1}h\}$ does not require assumptions of the global nature but slightly improved smoothness condition (7.5.28). The reason is that in our assumptions[29] the contribution of this zone to N does not exceed $C\mu h^{1-d}$. We will assume that the boundary is rather regular with the exception of the thinner set:

(7.5.61) There exists a closed set $Z \subset \partial X$ such that

$$\mathsf{vol}(\mathcal{X}_{(\beta)} \cap Z_\alpha) \le f_\alpha \beta \qquad \text{with} \quad f_\alpha = o(1) \quad \text{as} \quad \alpha \to +0 \tag{7.5.62}$$

where $Z_\alpha = \{x, \mathsf{dist}(x,Z) < \alpha\}$ and for each $\alpha > 0$

$$\partial X \setminus Z_\alpha = \bigcup_k \{x_k = \phi_k(x_{\hat{k}})\} \qquad \text{with} \quad \phi_k \in \mathscr{C}^1.$$

[29] Including Dirichlet boundary conditions.

Let us apply ε_1-mollification of ∂X. Then there exist two domains $X^{\pm}(\varepsilon_1)$ with mollified boundaries, such that

$$X^{+}(\varepsilon_1) \supset X \supset X^{-}(\varepsilon_1) \tag{7.5.63}$$

and

$$\mathsf{vol}\big(X^{+}(\varepsilon_1) \setminus X^{-}(\varepsilon_1)\big) = o(\varepsilon_1) \ \text{ as } \ \varepsilon_1 \to 0. \tag{7.5.64}$$

Then we can select $\varepsilon_1 = \varepsilon_1(h)$ such that $h\varepsilon_1^{-1} = o(1)$ and the approximation error in N^{W} due to the mollification of the boundary is $o(h^{1-d})$.

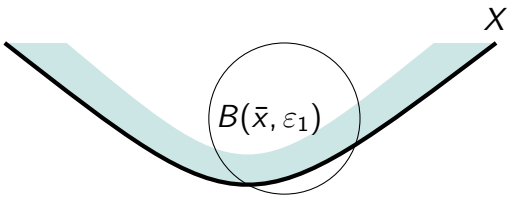


Figure 7.8: Boundary strip; $\varepsilon_1 \gg \mu^{-1}h$

Let us consider ball $B(x, \varepsilon_1)$ with $x \in Y_{\mu^{-1}h}$ and rescaling it to $B(0,1)$ we have that the problem is uniformly smooth and microhyperbolic in an appropriate multidirection provided condition (7.5.65) below is fulfilled and we can apply smooth theory to calculate contribution of $Y_{\mu^{-1}h} \cap B(x, \varepsilon_1)$; namely, its contribution to the remainder does not exceed $o(1)(h\varepsilon_1^{-1})^{1-d}$. We assume that

(7.5.65) Boundary value problem is microhyperbolic on energy level τ in an appropriate multidirection $(\ell_\xi, 0, \nu_1, \dots, \nu_M)$ at each point.

taking sum over all the balls covering $Y_{\mu^{-1}h} \setminus Z_\alpha$ we get a total estimate

$$o(1)(h\varepsilon_1^{-1})^{1-d} \times \varepsilon_1^{1-d} = o(h^{1-d})$$

because due to (7.5.28) we need to consider $M(\varepsilon_1)$ of such balls with $M(\varepsilon_1) = C\,\mathsf{mes}(\{x\colon \gamma(x) \le \varepsilon_1\})\varepsilon_1^{-d} = O(\varepsilon_1^{1-d})$.

On the other hand, the total contribution of all the balls with non-empty intersection with Z_α does not exceed $Cf_\alpha h^{1-d}$. So, we have proven

Proposition 7.5.17. *Under additional conditions* (7.5.61)–(7.5.62), (7.5.65) *contribution of the strip $Y_{\mu^{-1}h}$ to the principal part of asymptotics is*

$$\int_{Y_{\mu^{-1}h}} \mathsf{N}^{\mathsf{W}}(x)\psi(x)dx + \kappa' h^{1-d} \tag{7.5.66}$$

where $\psi(x) = 1$ in $Y_{\mu^{-1}h}$ and supported in $Y_{2\mu^{-1}h}$ and its contribution to the remainder is $o(h^{1-d})$ for each small fixed $\mu > 0$.

Remark 7.5.18. (i) With more general than Dirichlet boundary condition we do not have a monotone dependence of N on the domain and thus we cannot approximate ∂X at all; this leaves us with no other option but to flatten the boundary by changing a coordinate $x_{k,\mathsf{new}} = x_k - \phi_k(x_{\hat{k}})$. This looks rather unappealing since then the principal symbol includes the first derivatives of ϕ_k but it is not that bad since (in contrast to Remark 7.5.1) we do it only in a very marrow strip and here we we can take ε_2-approximation of the coefficients and since first derivatives of ϕ_k are uniformly bounded an approximation error does not exceed $o(\mu^{-1}h^{1-d})$ as $\varepsilon_2 \to +0$.

(ii) Further, since the only difference is that between $O(h^{1-d})$ and $o(h^{1-d})$ and we rescale $x \mapsto x\mu h^{-1}$ one can very easily weaken condition (7.5.65) to

(7.5.67) Boundary value problem is (non-uniformly) microhyperbolic in an appropriate multidirection $(\ell_\xi, 0, \nu_1, \dots, \nu_M)$ on the energy level τ at each point $(x', \xi) \in T^*Y_k \setminus \mathcal{Z}_k$ and $\mathsf{mes}_{T^*Y_k}(\mathcal{Z}_k) = 0$, where $Y_k = \{x_k = \phi_k(x_{\hat{k}})$ and $\mathsf{mes}_{T^*Y_k}$ is a natural measure there.

Inner Zone

To get remainder estimate $o(h^{1-d})$ we need also to improve the remainder estimate for $\int \psi(x)e(x,x,\tau)dx$ with ψ supported in X_μ with any fixed $\mu > 0$. This involves the analysis of the propagation of singularities starting from X_μ.

To do this we need to assume in condition (7.5.61)–(7.5.62) that $\phi_k \in \mathscr{C}^1_{\nu_1}$ with $\nu_1(t) = o(t|\log t|^{-1})$. Then taking ε_1-mollification of the boundary we get approximation error in N^{W} as $o(h^{1-d})$ provided $\varepsilon_1(h|\log h|)^{-1} \to +\infty$ slowly enough as $h \to +0$.

Theorem 7.5.19. *Let A be a Schrödinger operator with $\mathscr{C}^1_\nu$ coefficients, $\nu(t) = o\big(t|\log t|^{-1}\big)$. Let condition* (7.5.39) *be fulfilled and conditions* (7.5.61)–(7.5.62) *hold with $\phi_k \in \mathscr{C}^1_{\nu_1}$, $\nu_1(t) = o(t|\log t|^{-1})$. Let us consider mollified domain and mollified operator.*

Further, let $(\bar{x}, \bar{\xi}) \in T^*\overset{\circ}{X} := X \setminus \partial X$. Let us consider $\Psi_t(\bar{x}, \bar{\xi})$, the (multivalued) Hamiltonian flow with reflections from $\partial X = \{x_k = \phi_k(x_{\hat{k}})\}$ (where k depends on position of point near $\partial X \setminus Z$. Assume that

(7.5.68) *For all* $t \in [0, T]$ *and for all* $(x(t), \xi(t)) \in \Psi_t(\bar{x}, \bar{\xi})$

$$x(t) \in \overset{\circ}{X} \cup \partial X \setminus Z\,, \tag{7.5.69}$$

$$|\phi(x(t))| + |\frac{d}{dt}\phi(x(t))| \geq \epsilon. \tag{7.5.70}$$

(i) Furthermore, let $(\bar{x}', \bar{\xi}') \in T^*\overset{\circ}{X} \setminus \Psi_T(\bar{x}, \bar{\xi})$. *Then for pseudodifferential operators* Q_1 *and* Q_2 *with symbols supported in the small vicinities of* $(\bar{x}, \bar{\xi})$ *and* $(\bar{x}', \bar{\xi}')$ *respectively we have that* $Q_2 e^{ih^{-1}tA} Q_1 \equiv 0$ *for* t *in the small vicinity of* T.

(ii) On the other hand, let $\bar{x}' \in \bar{X}$ *and* $\bar{x}' \notin \pi_x \Psi_T(\bar{x}, \bar{\xi})$ *where* π_x *is an* x*-projection. Then for a pseudodifferential operator* Q_1 *with symbol supported in the small vicinity of* $(\bar{x}, \bar{\xi})$ *and function* ψ *supported in the small vicinity of* $\bar{x}'$ *we have that* $\psi e^{ih^{-1}tA} Q_1 \equiv 0$ *for* t *in the small vicinity of* T.

Proof. Note first, that due to Section 2.3 Statement (i) holds in the case of the free propagation

$$\pi_x \Psi_t(\bar{x}, \bar{\xi}) \cap \partial X = \emptyset \qquad \forall t \in [0, t]. \tag{7.5.71}$$

Then it is sufficient to prove theorem assuming that

(7.5.72) $\bar{x}, \bar{x}' \in Y_\beta$ and $T \leq c\beta$ with (arbitrarily) small constant $\beta > 0$ and large enough constant c which does not depend on β.

Really, let us apply induction with respect to maximal number n trajectories from $\Psi_T(\bar{x}, \bar{\xi})$ hit the boundary. Then for each n we employ induction with respect to $m = \lfloor CT/\beta \rfloor$ with large constant C, also β-independent. But then if either $\bar{x} \notin Y_\beta$ or $\bar{x}' \notin Y_\beta$ one can reduce the problem to one with lesser m due to free propagation. Now, if $\bar{x} \in Y_\beta$ and as we assumed along trajectory (7.5.70) holds (with $\epsilon \gg \beta$) and also $\pi_x \Phi_t(\bar{x}, \bar{\xi}) \in \partial X$ for some $t = c\beta$ then we will be able to reduce problem to one with lesser m, n unless $n = 1$ and $T \leq c\beta$.

Under assumption (7.5.72) $\xi(t)$ are concentrated in the ball of radius not exceeding $C\beta$ and $x(t)$ are concentrated in the ball of radius not exceeding $C\beta^2$ for all Hamiltonian trajectories $(x(t), \xi(t))$ issued from $(\bar{x}, \bar{\xi})$ as long as $|t| \leq c\beta$. Then it is sufficient to prove theorem assuming also that $\gamma(\bar{x}) = \beta$ and $\gamma(\bar{x}') = \beta$ in Statement (i).

From now on we will consider β as a small parameter rather than as a constant; $1 \gg \beta \ge h^{1-\delta}$. Further, instead of small constant vicinity of $(\bar{x}, \bar{\xi})$ we will consider (ζ, ρ)-vicinity of it with ζ given by (7.5.30) and $\rho = c\beta^{-1}\zeta$.

Then applying arguments of the proof of Proposition 7.5.4 with $T \asymp \beta$ we can reduce this problem to the problem with β replaced by $\beta' = \zeta$ and correspondingly replaced ρ. We continue this process as long as $\beta \ge h^{1-\delta}$. There will be no more than $L = C \log |\log h|$ steps. On some of these steps ρ decays and on each step we should go to the partition containing however no more than

$$\bigl(1 + \rho_n \rho_{n+1}^{-1}\bigr)^d \bigl(1 + \beta_n \beta_{n+1}^{-1}\bigr)^d$$

elements ending in the end with no more than $L(\rho_0 \rho_n^{-1})^d \le h^{-2d}$ elements but an error on each element is $O(h^s)$ and the total error is $O(h^{s-d})$ with arbitrarily large s.

So, the proof of our theorem is reduced to the case $\beta = h^{1-\delta}$.

However, then $\varepsilon \asymp \beta$ and since we used analytic mollifications of the coefficients we find ourselves in the framework of (uniformly) analytic theory of free propagation after we rescale[30]. In this theory propagation error is $O(e^{-\epsilon \hbar^{-1}})$ where $\hbar = h\beta^{-1}$ is effective semiclassical parameter. Then we can apply the same arguments as above as long as $\beta \ge Ch|\log h|$ and therefore the proof of our theorem is reduced to the case $\beta = Ch|\log h|$.

But now rescaling we find that the boundary is (uniformly) analytic as well and we just apply analytic theory of the propagation of singularities near the boundary when rays are transversal, see f.e. S. Wakabayashi [1], J. Sjostrand [1,3] to the boundary.

So our theorem has been proven. □

Immediately we have

Theorem 7.5.20. *Let A be a Schrödinger operator with $\mathscr{C}^1_\nu$ coefficients, $\nu(t) = o\bigl(t|\log t|^{-1}\bigr)$. Let condition* (7.5.39) *be fulfilled and conditions* (7.5.61)–(7.5.62) *hold with $\phi_k \in \mathscr{C}^1_{\nu_1}$, $\nu_1(t) = o(|\log t|^{-1})$. Let*

$$|a(x,\xi) - \tau| + |\nabla_\xi a(x,\xi)| \ne 0. \tag{7.5.73}$$

Let us assume that

[30] Actually because mollification scale is near boundary so close to 1 we find ourselves in the framework of small analytic perturbation of the constant coefficient operator.

(7.5.74) $dxd\xi : da$*-measure of the set of "bad" points* $z \in T^*X$ *is 0; we call* z *a "bad" point if for some* t *either* $z \in \Psi_t(z)$ *(periodicity) or* $\Psi_t(z) \cap \bigl(\pi^{-1}(Z) \cup \bigcup_k \iota_k^{-1}(\bigcup_k \mathcal{Z})\bigr) \neq \emptyset$ *(hitting bad or non-hyperbolic point on the boundary, here* $\pi : T^*X \ni (x,\xi) \to x$ *and* $\iota_k : T^*X|_{Y_k} \ni (x,\xi) \to (x',\xi') \in T^*Y_k$*) or* $\phi(z') = \frac{d}{dt}\phi(z'(t)) = 0$ *for some* $z' \in \Psi_t(z)$ *(tangency).*

Then the following asymptotics holds:

$$\mathsf{N}(\tau) = \mathsf{N}^{\mathsf{W}} + \kappa_1' h^{1-d} + o(h^{1-d}) \qquad \text{as} \quad h \to 0. \tag{7.5.75}$$

Problem 7.5.21. We leave to the reader operators more general than the Schrödinger operator.

7.5.5 Less Sharp Remainder Estimates

There are two sources of abnormally large remainder estimate

(i) Irregularity of the coefficients. Let us assume that either $\nu(t) \geq t|\log t|^{-1}$ i.e. either $\nu(t) \leq t$ and coefficients belong to $\mathscr{C}^1_\nu$ or $\nu(t) \geq t$ and coefficients belong to $\mathscr{C}^0_\nu$. In this case even if there is no boundary the remainder estimate is $R_1 = Ch^{-d}\nu\bigl(h|\log \nu(h)|\bigr)$ which is $\asymp h^{-d}\nu(h|\log h|)$ provided $\nu(h) \leq h^\delta$ with $\delta > 0$ (see Theorem 4.6.16).

(ii) Irregularity of the boundary which leads to the remainder estimate at least $R_2 = Ch^{-d}\nu(h)$ with $\nu(t) = \mathsf{mes}(Y_t)$ even for a constant coefficients.

Our goal is to recover in the general case the remainder estimate $R_1 + R_2$ or close to it. We will assume that

(7.5.76) $\nu(t)t^{-1}$ is monotonically decreasing function of t.

Then using constant scale ε-approximation with $\varepsilon \geq \eta = Ch|\log h|$ we get that the total approximation error is $h^{-d}\vartheta(\varepsilon)$ and the contribution of $B\bigl(x,\gamma(x)\bigr)$ to the semiclassical error after rescaling $x \mapsto x\varrho^{-1}$,

$$\varrho = \mathsf{min}\bigl(\gamma(x), \frac{\varepsilon}{\nu(\varepsilon)}\bigr) \tag{7.5.77}$$

(see Subsection 4.6.5 for analysis inside domain) does not exceed

$$Ch^{1-d}\gamma^d\bigl(\varepsilon^{-1}\nu(\varepsilon) + \gamma^{-1}\bigr) \tag{7.5.78}$$

and then the contribution of X_h to the semiclassical error does not exceed

$$Ch^{1-d}\varepsilon^{-1}\nu(\varepsilon) + Ch^{1-d}\int_h^1 t^{-1}d_t\nu(t) \tag{7.5.79}$$

while the total contribution of the strip Y_h does not exceed $R_2 = Ch^{-d}\nu(h)$ according to Chapter 9.

The first term in (7.5.79) is less than R_1 as $\varepsilon = \eta$ and only the second term could be a problem. However, if the boundary is quite irregular, namely $\nu(t) \ge t^\sigma$ with $\sigma < 1$, then

$$\int_s^1 t^{-1}d_t\nu(t) \le Cs^{-1}\nu(s)$$

and then this term does not exceed R_2. Therefore we have proven

Theorem 7.5.22. *(i) Remainder does not exceed $R_1 + R_2$ unless*

$$\nu(t) \coloneqq \mathsf{mes}(Y_t) \le C_\delta t^{1-\delta} \tag{7.5.80}$$

with some exponent $\delta > 0$.

(ii) If (7.5.80) *holds, then the remainder does not exceed $R_1 + R_2 + R_2'$ where R_2' is the second term in* (7.5.79)*.*

Therefore we need to reconsider only case when (7.5.80) holds and we need to assume that

(7.5.81) ν satisfies condition (7.5.80) as well: $\nu(t) \le Ct^{1-\delta}$;

otherwise R_1 will be larger than R_2' and then we pick up $\varepsilon = \eta$ again.

We will apply then our more sophisticated variable scale ε-approximation with $\varepsilon = \mathsf{min}\bigl(\eta\gamma^{-\sigma}, \hat{\gamma}\bigr)$ as in Subsections 7.5.1–7.5.3. In this case approximation error does not exceed

$$Ch^{-d}\int \nu(\eta_0 t^{-\sigma})\, d_t\nu(t) \le Ch^{-d}\int \nu(\eta)t^{-\delta}\, d_t\nu(t) = R_1\int t^{-\sigma'}\, d_t\nu(t)$$

provided

(7.5.82) $\nu(\varepsilon)\varepsilon^{-1-\sigma_1}$ is decreasing function of ε

and $\sigma' = \sigma(1+\sigma_1)$. Assuming that exponents σ and σ_1 are small enough, we see that this integral does not exceed

$$C\nu(s)s^{-\sigma'} + C\int \nu(t)t^{-\sigma'-1}dt \le C$$

and so an approximation error does not exceed R_1.

To estimate a semiclassical error we apply the same arguments as in the proof of Proposition 7.5.6 and find that the contribution of the strip $\mathcal{X}'_{(\beta)} := \{x : \beta \le \gamma(x) \le \beta^{1-\delta'}\}$ to the semiclassical error does not exceed

$$Ch^{1-d}\int_{\mathcal{X}'_{(\beta)}} \gamma^{\delta-1}\,dx + Ch^{1-d}\int_{\mathcal{X}'_{(\beta)}\times\mathbb{R}^d \bigcap \Sigma_\tau} d\mu_\tau$$

with the standard measure μ_τ on Σ_τ. One can see easily that the second integral does not exceed $d\nu(\beta)/d\beta$ and then the total semiclassical error does not exceed

$$Ch^{1-d}\int_{X_h} \gamma^{\delta-1}dx + Ch^{1-d}\sum_{k:0\le k\le C\log|\log h|} \frac{d\nu(\beta)}{d\beta}\Big|_{\beta=e^{-\epsilon e^{\epsilon k}}}. \tag{7.5.83}$$

Replacing this sum by an integral and changing variable in the integral we arrive to

$$Ch^{1-d}\int_h^1 \frac{1}{t|\log t|}\,d_t\nu(t)$$

which is larger than the first term in (7.5.83). Therefore we proved

Theorem 7.5.23. *Let ν, ν satisfy* (7.5.49)*. Then the remainder does not exceed $R_1 + R_2 + R_2''$ with*

$$R_2'' = Ch^{1-d}\int_{X_h} \gamma^{-1}|\log\gamma|^{-1}\,dx. \tag{7.5.84}$$

7.A Appendices

7.A.1 Sets Associated with the Microhyperbolicity Condition

In this section we study the structure of certain sets associated with the microhyperbolicity condition; namely let

$$\sigma(x,\xi) = \mathsf{Spec}\big(J^{-1}(x)a(x,\xi)\big) \tag{7.A.1}$$

be the set of all the eigenvalues of $J^{-1}(x)a(x,\xi)$,

$$\Sigma_\tau = \{(x,\xi) \in T^*\bar{X}, \tau \in \sigma(x,\xi)\}, \tag{7.A.2}$$

$$\Sigma'_{\tau b} = \iota\Sigma_\tau \tag{7.A.3}$$

where $\iota : T^*\bar{X}|_Y \to T^*Y$ is a natural map. Let

$$\Xi_0 = \overline{\bigcup_{T^*\bar{X}} \sigma(x,\xi)}. \tag{7.A.4}$$

Further, let $(x',\xi') \in T^*Y$ and let $\sigma_d(x',\xi')$ be the discrete spectrum of the problem

$$(a(x',D_1,\xi') - \tau J(x'))v = 0,) \tag{7.A.5}$$

$$\mathfrak{d}b(x',D_1,\xi')v = 0, \tag{7.A.6}$$

$$v = o(1) \qquad \text{as } x_1 \to +\infty; \tag{7.A.7}$$

and let

$$\Sigma''_{\tau b} = \{(x',\xi') \in T^*Y, \tau \in \sigma_d(x',\xi')\}, \qquad \Xi_1 = \overline{\bigcup_{T^*Y} \sigma_d(x,\xi)} \tag{7.A.8}$$

where we skip $x_1 = 0$ in the notation for a and J. Let $\Sigma_{\tau b} = \Sigma'_{\tau b} \cup \Sigma''_{\tau b}$.

Moreover, let us introduce the sets

(7.A.9) $\mathcal{Y}_0 = \big\{\tau \in \mathbb{R}, \Sigma_\tau$ contains at least one point at which the symbol $\tau J(x) - a(x,\xi)$ is microhyperbolic in no direction $\ell \in T\big(T^*\bar{X}\big)\big\}$,

and

(7.A.10) $\mathcal{Y}_1 = \big\{\tau \in \mathbb{R}$ and $\Sigma_{\tau b}$ contains at least one point at which the problem $\big(\tau J(x') - a(x',D_1,\xi'), \mathfrak{d}b(x',D_1,\xi')\big)$ is microhyperbolic in no multidirection$\big\}$.

Finally, let

(7.A.11) $\mathcal{Z}_0$ be the set of the points $(x,\tau) \in \overset{\circ}{X} \times \mathbb{R}$ such that for some $\xi \in T^*_x\overset{\circ}{X}$ the symbol $\tau J(x) - a(x,\xi)$ is microhyperbolic at (x,ξ) in no direction ℓ with $\ell_x = 0$;

and

(7.A.12) $\mathcal{Z}_1$ be the set of points $(x',\tau)\in Y\times\mathbb{R}$ such that for some $\xi'\in T^*_{x'}Y$ the problem $\bigl(\tau J(x')-a(x',D_1,\xi'),\eth b(x',D_1,\xi')\bigr)$ is microhyperbolic at (x',ξ') in no multidirection $\mathcal{T}=(\ell',\nu_1,\dots,\nu_M)$ with $\ell'_x=0$.

We assume that

(7.A.13) $J(x)$ and $a(x,\xi)$ are Hermitian (matrix-valued) symbols and $J(x)$ is non-degenerate,

(7.A.14) Either $J(x)$ or $a(x,\xi)$ is positive definite,

(7.A.15) Operator $a(x',D_1,\xi')$ with the boundary condition $\eth b(x',D_1,\xi')v=0$ is self-adjoint on $\mathscr{L}^2(\mathbb{R}^+,\mathbb{H})$,

(7.A.16) Either $J(x')$ or operator $a(x',D_1,\xi')$ (with the indicated boundary condition) is positive definite,

and

(7.A.17) The coefficient of D_1^m in $a(x',D_1,\xi')$ is non-degenerate.

Here and in what follows $\overset{\circ}{X}$, Y and $\bar{X}$ mean the the previous domain, its boundary and its closure respectively intersected with $\overline{B(0,1)}$.

Obviously,

(7.A.18) Ξ_0 and Ξ_1 are closed sets.

Let us recall that

(7.A.19) If a symbol is microhyperbolic at some point in some direction then it is microhyperbolic in a neighborhood of this point in all the directions close to original one.

Similarly

(7.A.20) If the problem is microhyperbolic at some point in some multidirection then it is microhyperbolic in a neighborhood of this point in all multidirections close to original one (see Proposition 3.1.5).

Hence

(7.A.21) $\mathcal{Y}_0$, $\mathcal{Y}_1$ are closed subsets of $\mathbb{R}$, $\mathcal{Z}_0$ is a closed subset of $\overset{\circ}{X} \times \mathbb{R}$, and $\mathcal{Z}_0 \cap (Y \times \mathbb{R})$, $\mathcal{Z}_1$ are closed subsets of $Y \times \mathbb{R}$; obviously $\mathcal{Z}_0 \cap (Y \times \mathbb{R}) \subset \mathcal{Z}_1$.

Our main goal is

Theorem 7.A.1. *Let conditions* (7.A.13)–(7.A.17) *be fulfilled and let* $K = K(d, m, \mathsf{D})$ *in the smoothness conditions where* D *is the dimension of the matrices and* m *is an order of symbols with respect to* ξ_1. *Then*

(i) The Lebesgue measures of the sets $\mathcal{Y}_0$ *and* $\mathcal{Y}_1$ *equal* 0.

(ii) For every $x \in \overset{\circ}{X}$, $y \in Y$ *the Lebesgue measure of the set* $\{\tau, (x, \tau) \in \mathcal{Z}_0\}$ *equals* 0.

(iii) The Lebesgue measures of the sets $\mathcal{Z}_0$ *and* $\mathcal{Z}_1$ [31] *equal* 0

(iv) The Lebesgue measure of the set $\Sigma''_{\tau b}$ *(in* T^*Y*) equals* 0 *provided* $\tau \notin \mathcal{Y} = \mathcal{Y}_0 \cup \mathcal{Y}_1$.

Proof. We will prove Statement (i) here; Statement (ii) can be proven similarly.

Obviously $\mathcal{Z}_0$ and $\mathcal{Z}_1$ are measurable sets and hence Statement (iii) follows from Statement (ii). In the proof of Statement (iv) one can assume that $(\partial_{x_2}, \nu_1, \dots, \nu_M)$ is the multidirection of microhyperbolicity; then it follows from the proof below that for every $x'' = (x_3, \dots, x_d)$ and ξ' the Lebesgue measure of the set $\{x_2, (x_2, x'', \xi') \in S''_{\tau b}\}$ equals 0; this fact and the obvious fact that $\Sigma''_{\tau b}$ is measurable imply Statement (iv).

So let us prove that $\mathsf{mes}(\mathcal{Y}_1) = 0$ (the equality $\mathsf{mes}(\mathcal{Y}_0) = 0$ can be proven in the same way but without any preliminary analysis; this equality follows directly from Lemma 7.A.2).

Let $\varepsilon > 0$ and let Ω be an open subset in $T^*Y \times \mathbb{R}$. Let us introduce set $\mathcal{Y}_1(\Omega, \varepsilon)$ as we defined $\mathcal{Y}_1$ but with $(z, \tau) \in \Omega$, $z = (x', \xi')$ and with condition (7.A.7) in the problem (7.A.5)–(7.A.7) replaced by

$$u = O(e^{-\varepsilon x_1}) \quad \text{as } x_1 \to +\infty; \tag{7.A.22}$$

then it is sufficient to prove that

[31] In $\overset{\circ}{X} \times \mathbb{R}$ and $Y \times \mathbb{R}$ respectively.

(7.A.23) Every point (z^*, τ^*) has a neighborhood $\Omega = \Omega(\varepsilon)$ such that $\mathsf{mes}\big(\mathcal{Y}_1(\Omega, \varepsilon)\big) = 0$.

Without any loss of the generality one can assume that the polynomial $g(z, \zeta, \tau)$ has no root with the imaginary part equal to ε for $(z, \tau) \in \Omega$.

Let us reduce problem (7.A.5), (7.A.6) to a first-order problem and let us replace $\underline{u}$ by $\underline{u}_{\mathsf{new}} = Q\underline{u}$ as we did in Subsection 3.1.2; then we obtain problem $(\underline{p}, \eth\underline{b})$ where

$$\underline{p} = \begin{pmatrix} \underline{p}_I & 0 & 0 \\ 0 & 0 & \underline{p}_{II} \\ 0 & \underline{p}^*_{II} & 0 \end{pmatrix}, \quad \underline{b} = (\underline{b}_I, \underline{b}_{II}, \underline{p}_{III}) \tag{7.A.24}$$

and all the roots of the polynomials $\det \underline{p}_I(z, \zeta, \tau)$ and $\det \underline{p}_{II}(z, \zeta, \tau)$ lie in the domains $\{|\operatorname{Im}\zeta| \le \varepsilon\}$, $\{|\operatorname{Im}\zeta| \ge \varepsilon\}$ of $\mathbb{C}$ respectively. Moreover, let $\underline{b}' = (\underline{b}'_I, \underline{b}'_{II}, \underline{b}'_{III})$ be defined by the equality

$$\begin{aligned} \langle \underline{p}(z, D_1, \tau)U, V\rangle_+ - \langle U, \underline{p}(z, D_1, \tau)V\rangle_+ = \\ \langle \underline{b}'(z, \tau)U(0), \underline{b}(z, \tau)V(0)\rangle - \langle \underline{b}(z, \tau)U(0), \underline{b}'(z, \tau)V(0)\rangle; \end{aligned} \tag{7.A.25}$$

then

(7.A.26) $R = \underline{b}'^*_{II}\underline{b}_{II}$ is a Hermitian matrix.

The microhyperbolicity of $\big(\tau J(x') - a(x', D_1, \xi'), \eth b(x', D_1, \xi')\big)$ means exactly that

$$\begin{aligned} \langle (\ell + \nu_k\partial_\zeta)\underline{p}_I(z, \zeta, \tau)V, V\rangle < 0 \\ \forall V \in \operatorname{Ker} \underline{p}_I(z, \zeta_k, \tau) \setminus 0 \quad \forall k = 1, \dots, M \end{aligned} \tag{7.A.27}$$

and

$$\langle \ell R(z, \tau)V, V\rangle \ < 0 \qquad \forall V \in \operatorname{Ker} \underline{b}(z, \tau) \setminus 0. \tag{7.A.28}$$

Moreover,

(7.A.29) Conditions (7.A.27) and (7.A.28) are fulfilled for $\ell' = \partial_\tau$ and $\nu_1 = \dots = \nu_M = 0$.

Let us introduce

$$S(z,\zeta_1,\dots,\zeta_M,\tau)=\begin{pmatrix}\underline{p}_I(z,\zeta_1,\tau) & \dots & 0 & 0\\ \vdots & \ddots & \vdots & \vdots\\ 0 & \dots & \underline{p}_I(z,\zeta_M,\tau) & 0\\ 0 & \dots & 0 & \underline{b}_{II}(z,\tau)\end{pmatrix}, \tag{7.A.30}$$

$$T(z,\tau)=\begin{pmatrix}I & \dots & 0 & 0\\ \vdots & \ddots & \vdots & \vdots\\ 0 & \dots & I & 0\\ 0 & \dots & 0 & \underline{b}'^{*}_{II}(z,\tau)\end{pmatrix}; \tag{7.A.31}$$

then the equality $\mathsf{mes}\big(\mathcal{Y}_1(\Omega(\varepsilon),\varepsilon)\big)=0$ follows from Lemma 7.A.2 below.□

Lemma 7.A.2. *Let $S(z,\tau)$ and $T(z,\tau)$ be $\mathscr{C}^K$ matrices of dimensions $N\times D$ and $D\times N$ respectively for $(z,\tau)\in\Omega$ where $\Omega\subset\Omega_x\times\mathbb{R}$ and Ω_x are open domains and $K=K(d,N,D)$. Let us assume that*

(7.A.32) *ST is a Hermitian matrix*

and that for $\ell=\partial_\tau$ the following condition holds

$$\langle \ell(ST(z,\tau)v,v\rangle<0 \qquad \forall v\in \mathsf{Ker}\,S(z,\tau)\setminus 0 \quad \forall (z,\tau)\in\Omega. \tag{7.A.33}$$

Let

(7.A.34) $\mathcal{N}=\{(z,\tau)$: *there exists no vector field $\ell=\ell_z\in T_x\Omega_x$ satisfying condition* (7.A.33)$\}$.

Then

$$\mathsf{mes}\big(\{\tau,\exists z:(z,\tau)\in\mathcal{N}\}\big)=0. \tag{7.A.35}$$

Proof. Let $\mathcal{X}_s=\{(z,\tau):\mathsf{rank}\,S(z,\tau)\le s\}$. Then it is sufficient to prove that

$$\mathsf{mes}\big(\{\tau,\exists z:(z,\tau)\in\mathcal{N}\cap(\mathcal{X}_s\setminus\mathcal{X}_{s-1}\}\big)=0. \tag{7.A.36}$$

Moreover, it is sufficient to treat the case $s=0$. In fact, in the proof of (7.A.36) we can assume without any loss of the generality that $S=\begin{pmatrix}S' & 0\\ 0 & S''\end{pmatrix}$

where S'' is an invertible $s \times s$ matrix. This case can obviously be reduced to the case $s = 0$.

Let $t(z,\tau) = \mathsf{tr}(TS)(z,\tau)$; then condition (7.A.33) with $\ell = \partial_\tau$ yields that

$$t(z,\tau) = 0, \quad \partial_\tau t(z,\tau) > 0 \qquad \text{for } (z,\tau) \in \mathcal{X}_0.$$

Then without any loss of the generality one can assume that $\tau = \lambda(z)$ for $(z,\tau) \in \mathcal{X}_0$ where λ is a real-valued $\mathscr{C}^K$ function.

Let $\alpha_1(z), \dots, \alpha_p(z)$ be elements of matrix $R(z) = (TS)(z,\lambda(z))$ arbitrarily enumerated. Then

$$\mathcal{X}_0 = \{(z,\tau) : \tau = \lambda(z),\ \alpha_1(z) = \dots = \alpha_p(z) = 0\}.$$

Let us note that

(7.A.37) Let $(z,\tau) \in \mathcal{N} \cap \mathcal{X}_0$. Then for arbitrary dz, $d\lambda$ is a linear combination of $d\alpha_1, \dots, d\alpha_p$.

In fact, if that is not the case then there exists a direction $\ell \in T_x\Omega_x$ such that $\ell\lambda < 0$ and $\ell\alpha_1 = \dots = \ell\alpha_p = 0$. Then

$$\ell(TS)(z,\tau) = -\partial_\tau(TS)(z,\tau) \cdot \ell\lambda(z)$$

and hence (7.A.33) holds for this direction because it holds for ∂_τ.

Therefore $\mathcal{N} \cap \mathcal{X}_0$ is contained in the union of sets $\mathcal{N}_\mathcal{K}$ for $\mathcal{K} \subset \{1, \dots, p\}$ where

(7.A.38) $\mathcal{N}_\mathcal{K} = \{\tau = \lambda(z), \alpha_j(z) = 0 \quad \forall j \in \mathcal{K},\ d\alpha_j\ (j \in \mathcal{K})$ are linearly independent and $d\lambda$ is their linear combination$\}$.

Then Sard's theorem yields that

$$\mathsf{mes}\big(\{\tau, \exists z, (z,\tau) \in \mathcal{N}_\mathcal{K}\}\big) = 0$$

and this equality yields (7.A.36) with $s = 0$. □

The following assertion also seems to be of interest:

Proposition 7.A.3. *Let conditions* (7.A.13)–(7.A.17) *be fulfilled. Then*

(i) If $\tau^* \in \partial\Xi_0$ and $z^* \in \Sigma_{\tau^*}$ then the symbol $(\tau^* J - a)$ is microhyperbolic in no direction at (z^*, τ^*).

(ii) If $\tau^* \in (\partial\Xi_1)\backslash\Xi_0$ *and* $z^* \in \Sigma''_{\tau^* b}$ *then the problem* $\big(\tau^* J - a(x', D_1, \xi'), \eth b\big)$ *is microhyperbolic in no multidirection at* (z^*, τ^*).

Proof. In the proof of Statement (i) or (ii) let $\tau_1, \dots, \tau_M$ be continuous eigenvalues of the matrix $J^{-1}(x)a(x,\xi)$ (or those of the problem (7.A.5)–(7.A.7)) depending on $z \in T^*X$ or $z \in T^*Y$ equal to τ^* for $z = z^*$. Let $\Pi = \Pi(z)$ be the corresponding spectral projector in $\mathbb{H}$ or in the weighted space $\mathscr{L}^2(\mathbb{R}^+, \mathbb{H}, Jdx)$ respectively. Then both statements will be proven if we prove Statement (i) under the additional restriction $\tau^* J(z^*) - a(z^*) = 0$.

Conditions (7.A.5)–(7.A.13) yield that τ_j are one time differentiable at z^* in every direction (K. O. Friedrichs [1], e.g.) and hence it is sufficient to prove that if ℓ is a microhyperbolicity direction then $\ell\tau_j(z^*) \neq 0$ and therefore Ξ_0 contains a neighborhood of τ^*. But the equalities

$$\ell(\tau_1 + \dots + \tau_M)(z^*) = \operatorname{tr} \ell(J^{-1}a)(z^*) = -\operatorname{tr} J^{-1}\big(\ell(\tau^* J - a)\big)(z^*)$$

yield that if the matrix $\big(\ell(\tau^* J - a)\big)(z^*)$ is either positive or negative definite then $\ell(\tau_1 + \dots + \tau_M) \neq 0$ provided J is positive definite; if a is positive definite we can permute a and J and use the same arguments. □

Comments

The results of Section 7.1 are trivial enough, but the proofs given here were developed specially for this book.

The construction of Section 7.2 (the method of successive approximations) in its present form was suggested first in V. Ivrii [8, 10] for differential and pseudodifferential operators (in fact in [8] the more complicated case of a domain with boundary was treated and namely the presence of the boundary was the reason that the traditional method did not work properly); the more sophisticated and general form which was used here was suggested in V. Ivrii [11]; for h-(pseudo)-differential operators this construction and its justification is more transparent.

The results of Section 7.3 were well known in certain special cases: for scalar operators for which $h = 1$ and the large spectral parameter τ is considered (then this problem can be reduced to a semiclassical one with $h = |\tau|^{-1/m}$ where m is the degree of the operator), asymptotics with the remainder estimate $O(|\tau|^{(d-1)/m})$ are due to R. Seeley [1, 2]; later by other methods they were obtained by V. Ivrii [8, 11]; for scalar operators with $m > 2$ and for matrix operators with constant multiplicities of the eigenvalues of the principal symbol these asymptotics were first obtained by

D. Vassiliev [1–3] and in the general case by V. Ivrii [11]; we do not discuss asymptotics with less precise remainder estimate because they are outside of the domain of the method of hyperbolic operators and we only mention that in the paper of V. M. Babich & B. M. Levitan [2] this estimate was obtained under the very restrictive condition that the domain is strictly concave in the corresponding metrics (which is fulfilled for no domain in $\mathbb{R}^d$ for the standard Laplacian) before it was obtained by R. Seeley in the general case.

More precise asymptotics of Section 7.4 with the remainder estimate $o(|\tau|^{(d-1)/m})$ were first obtained (under conditions on the Hamiltonian flow) by V. Ivrii [8, 11] and in all the papers mentioned above excluding those of R. Seeley such asymptotics were also obtained; this estimate was obtained by R. Melrose R. Melrose [8] in the case $m = 2$ simultaneously with V. Ivrii [8] but under the condition that the domain is strictly concave in the corresponding metric.

Results of Section 7.5 were first published in V. Ivrii [27], I should mention less precise results of L. Zielinski [1–4].

One can find a lot of beautiful billiard pictures in many places, in particular on Wolfram MathWorld http://mathworld.wolfram.com/Billiards.html

I am aware that these comments are very poor and inadequate. I send the reader to the excellent (but not very modern) survey of G. Rozenblioum, M. Z. Solomyak & M. Shubin [1] for more information. It is a real shame that nobody came with more modern exposition.

Chapter 8

Standard Local Semiclassical Spectral Asymptotics near the Boundary. Miscellaneous

In this chapter we continue the treatment of local and microlocal semiclassical spectral asymptotics near the boundary.

In Section 8.1 we consider asymptotics of $e(x,x,\tau)$ near boundary and derive it with a remainder estimate $O(h^{1-d})$ and a boundary layer correction term $h^{-d}\Upsilon(x', h^{-1}x_1)$.

In Section 8.2 we consider rescaling technique near the boundary; here we have two scales: one comes from the principal symbol of operator and another is the distance to the boundary.

Section 8.3 is devoted to operators with (partially) periodic Hamiltonian flow: for example we consider two manifolds with the common boundary and Hamiltonian flow is periodic only in one of them. Then asymptotics with the remainder estimate $o(h^{1-d})$ and a correction term $h^{1-d}\Upsilon(\tau h^{-1})$ appears not only due to "interference" when phase shifted differently along different trajectories, but also "dissipation" when at reflection some part of energy goes to manifold with non-periodic Hamiltonian flow and does not return to the original point. We consider also the case when Hamiltonian flows in both manifolds are periodic.

Furthermore, in Section 8.4 we consider asymptotics when operator A is restricted to its invariant subspace, projector to which is either a pseudodifferential operator (away from the boundary), or sum of a pseudodifferential operator with the transmission property and a singular Green operator.

8.1 Pointwise Spectral Asymptotics

In this section we consider boundary layer type term in $e(x,x,\tau)$ appearing near boundary. Let us recall that due to rescaling technique

$$e(x,x,\tau) = \mathsf{N}^{\mathsf{w}}_x + O\big(h^{1-d}\gamma^{-1}(x)\big) \tag{8.1.1}$$

where $\gamma(x) = \mathsf{dist}(x,\partial X)$ and this remainder estimate generated after integration $O(h^{1-d}|\log h|)$ and basically the whole Chapter 7 we spent to eliminate logarithmic factor.

Now we would like to consider $e(x,x,\tau)$ without integration with respect to x.

8.1.1 Preliminary Analysis

Discussion

Let us recall that in the previous chapter we derived asymptotics of

$$\mathsf{N} := \Gamma\big(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\big) \tag{8.1.2}$$

and

$$\mathsf{N}' := \Gamma'\eth_x\eth_y\big(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\big) \tag{8.1.3}$$

with the remainder $O(h^{1-d})$ provided problem $(A,\eth B)$ is microhyperbolic in multidirection $\mathcal{T} = (\ell',\nu_1,\dots,\nu_M)$; further, we derived asymptotics of

$$\mathsf{N}'_x := \Gamma_x\eth_x\eth_y\big(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\big) \tag{8.1.4}$$

and

$$\mathsf{N}_x := \Gamma_x\big(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\big) \tag{8.1.5}$$

with the remainder $O(h^{1-d})$ provided $\ell' = (\ell'_\xi,0)$ and for (8.1.5) we also need to assume that $\nu_1 = \dots = \nu_M$ in the microhyperbolicity condition; this asymptotics had a boundary layer type term $h^{1-d}\Upsilon(x',x_1h^{-1})$ with $D^\alpha\Upsilon(x',r) = O(r^{-\infty})$ as $r\to+\infty$.

Let us discuss this microhyperbolicity condition. Consider first the case of the Laplace operator; without any loss of the generality one can assume that $a(x,\xi) = a'(x,\xi') + \xi_1^2$ where $a(x,\xi')$ is a positive definite quadratic form. Then microhyperbolicity means that

$$\langle \ell'_\xi, \nabla'_\xi a'\rangle + 2\nu_\pm\xi_1 > 0 \qquad \text{as} \quad \xi_1 = \pm\big(\tau - a(x,\xi')\big)^{\frac12} \tag{8.1.6}$$

and we can always take $\ell'_\xi = \xi'$, $\nu_+ = \nu_- = 0$ as long as $a'(x,\xi') > 0$ (i.e. $\xi' \neq 0$).

So, with the exception of the case $\xi' = 0$ both microhyperbolicity conditions hold. In this exceptional case however $\nabla'_\xi a'(x,\xi') = 0$ and the first term in (8.1.6) is 0 no matter what ℓ'_ξ we pick up; so (8.1.6) boils up to

$$\pm\nu_\pm\big(\tau - a(x,\xi')\big)^{\frac{1}{2}} > 0$$

and for microhyperbolicity we just take $\nu_\pm = \pm 1$ provided $\tau > 0$; this is the standard ξ'-microhyperbolicity condition (we deliberately take $\ell' = (\ell'_\xi, 0)$).

However it is not the case as we assume that $\nu_+ = \nu_-$; then condition is impossible to satisfy. So, the previous section fails to find asymptotics of $e(x,x,\tau)$ but not because of the rays tangent to the boundary but on the contrary, because of the rays orthogonal to it (in the corresponding metrics).

This is a pleasant surprise because then we can find the solution of non-stationary problem in the form of the standard oscillatory integrals as we did in Subsubsection *5.3.1.4 Asymptotics without Spatial Mollification and Short Loops*. The analogy does not stop here: the exceptional rays hit the boundary orthogonally, reflect and follow the same path as before forming the short loops of the length $2\mathsf{dist}(x,\partial X)$ where distance is measured in the corresponding Riemannian metrics.

Remark 8.1.1. (i) However there is a difference: in the former case loop appeared because trajectory went "uphill", lost velocity and rolled back "downhill' repeating the path while now it reflects without losing velocity.

(ii) Another difference is that in the former case the leading term in the asymptotics of $e(x,x,\tau)$ at points where $|V(x) - \tau| \ll 1$ was smaller, of magnitude $(\tau - V(x))_+^{d/2}$, than in the generic points and therefore the remainder estimate without correction term in higher dimensions ($d \geq 3$) could be taken uniform. Now, however the leading terms is everywhere of the same magnitude and the correction term is needed in any dimension, however in the higher dimensions it matters in the smaller vicinities of the boundary (under appropriate assumptions) because the measure of "observable short loops" is smaller (see Remark 8.1.2).

Toy-Model

Consider $X = \mathbb{R}^+ \times \mathbb{R}^{d-1}$, $a(\xi) = |\xi|^2$ and either Dirichlet or Neumann boundary conditions. Then propagator is defined by

$$U(x,y,t) = U^0(x,y,t) + U^1(x,y,t) \tag{8.1.7}$$

with free space solution

$$U^0(x,y,t) = (2\pi h)^{-d} \int e^{ih^{-1}(|\xi|^2 t + \langle x-y,\xi\rangle)}\, d\xi \tag{8.1.8}$$

and reflected wave

$$U^1(x,y,t) = \varsigma(2\pi h)^{-d} \int e^{ih^{-1}(|\xi|^2 t + \langle x-\tilde{y},\xi\rangle)}\, d\xi \tag{8.1.9}$$

where $\tilde{y} = (-y_1, y_2, \dots, y_d)$ and $\varsigma = \mp 1$ for Dirichlet or Neumann boundary conditions respectively.

Since U^1 is responsible to the difference $e^1(x,y,\tau)$ between $e(x,y,\tau)$ and its free space counterpart $e^0(x,y,\tau)$ we manipulate only with it. Taking $y = x$ we get $\langle x - \tilde{x}, \xi\rangle = 2x_1\xi_1$ while $F_{t\to h^{-1}\tau}$ replaces $e^{ih^{-1}\tau}$ by $h\delta\big(\tau - |\xi|^2\big)$; so

$$F_{t\to h^{-1}\tau}\Gamma_x U^1 = \varsigma(2\pi h)^{1-d} \int \delta\big(\tau - |\xi|^2\big) e^{2ih^{-1}x_1\xi_1}\, d\xi = \tag{8.1.10}$$

$$\mathsf{const}\cdot \varsigma h^{1-d}\tau^{\frac{d}{2}-1}\cdot \begin{cases} \displaystyle\int_0^\pi \cos\big(2h^{-1}\tau^{\frac12}x_1\cos\phi\big)\sin^{d-2}\phi\, d\phi & d\ge 2,\\ \cos\big(2h^{-1}\tau^{\frac12}x_1\big) & d=1 \end{cases}$$

where we introduced spherical coordinates $(\phi, \zeta\sin\phi)$ on $\mathbb{S}^{d-1}$, $\phi \in (0,\pi)$, $\zeta \in \mathbb{S}^{d-2}$.

It leads to

$$e^1(x,x,1) \;=\; h^{-1}\int_{-\infty}^1 \Big(F_{t\to h^{-1}\tau}\Gamma_x U^1\Big)\, d\tau \;=\; h^{-d}\Upsilon_\varsigma(h^{-1}x_1) \tag{8.1.11}$$

with

$$\Upsilon_\varsigma(r) = \tag{8.1.12}$$

$$\mathsf{const}\cdot\varsigma\begin{cases} \displaystyle\int_0^1 z^{d-1}\int_0^\pi \cos\big(2zr\cos\phi\big)\sin^{d-2}\phi\, d\phi dz & d\ge 2,\\ \displaystyle\int_0^1 \cos\big(2zr\big) & d=1 \end{cases}$$

where we plugged $\tau = z^2$.

Here we took $\tau = 1$ since any other value could be reduced to this one by rescaling $h \mapsto h\tau^{-\frac{1}{2}}$.

One can find the constant so that for Dirichlet/Neumann problem $e^1(x,x,\tau) = \varsigma e^0(x,x,\tau)$ as $x_1 = 0$.

Stationary phase method implies that

$$\Upsilon(r) = \mathsf{const}\cdot r^{-(d+1)/2}\cos(2r) + O(r^{-(d+3)/2}) \qquad \text{as} \quad r \to +\infty. \tag{8.1.13}$$

Therefore

(8.1.14) With an error not exceeding

$$Ch^{-d}(x_1h^{-1}+1)^{-\frac{1}{2}(d+1)} + Ch^{1-d} \tag{8.1.15}$$

the standard Weyl expression for $e(x,x,\tau)$ holds;

this error is better than $O\big(h^{-d}(x_1h^{-1}+1)^{-1}\big)$ which was due to rescaling but it is only because critical points of $a(\xi') = |\xi'|^2$ are non-degenerate.

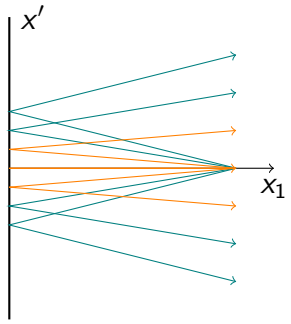

Figure 8.1: Reflection and short loops.

Remark 8.1.2. We can interpret (8.1.13) in the following way: as $|\xi'| \asymp \rho$ the point after reflection deviates from the original point (on the same distance from the boundary) by $|x'| \asymp \rho x_1$ (see Figure 8.1) and therefore this difference is quantum observable only if $\rho^2 x_1 \gg h$; then "short loops" are formed by $\{\xi' \colon |\xi'| \lesssim x_1^{-1/2}h^{1/2}\}$ and their measure is $\asymp x_1^{-(d-1)/2}h^{(d-1)/2}$ and their contribution to the asymptotics is of magnitude $h^{1-d}x_1^{-1}\cdot x_1^{-(d-1)/2}h^{(d-1)/2}$ which is exactly the first term in (8.1.13).

For second order operators this works automatically but in the general case it requires condition $(8.1.49)_r$ with $r = d-1$.

8.1.2 Schrödinger Operator

Let us consider Schrödinger operator with the symbol

$$a(x,\xi)=\sum_{j,k} g^{jk}(\xi_j-V_j)(\xi_k-V_k)+V \tag{8.1.16}$$

assuming that $\tau - V \asymp 1$ and positive. We want to study trajectories on the energy level τ only and we can assume without any loss of the generality that

$$\tau=0,\qquad V(x)\le -\epsilon,\qquad V(x)=-1 \tag{8.1.17}$$

where the last assumption is achieved by division $a(x,\xi)$ by $-V(x)$ which does not affect trajectories on energy level 0.

General Theory

We can assume without any loss of the generality that $V_1 = 0$. Let us introduce coordinates $x_1 = \mathsf{dist}(x, \partial X)$ in the metrics (g^{jk}) [1)] and x' which are constant along trajectories of $a(x,\theta)$ on level 0 which are orthogonal to the boundary, i.e. such that

$$g^{j1}=\delta_{j1}. \tag{8.1.18}$$

We are interested in the construction of parametrix in

$$\mathcal{U}=\{|\xi_j-V_j|\le\epsilon \qquad j=2,\dots,d\}. \tag{8.1.19}$$

It is be much simpler to consider this problem with the "time" x_1 and with t as one of spatial variables. Then as $l = 0$

$$u^l(x,y,t)\equiv \int \sum_{\varsigma=\pm} e^{ih^{-1}(\phi^0_\varsigma(x,y,\eta)+t\eta_0)}\sum_{n\ge 0} f^l_{\varsigma n}(x,y,\eta)h^{n-d}\,d\eta, \tag{8.1.20}$$

where $\eta=(\eta',\eta_0)=(\eta_2,\dots,\eta_d,\eta_0)$ and phase functions ϕ^0_ς are defined from

$$\partial_{x_1}\phi^l_\varsigma=\lambda_\varsigma(x,\nabla_{x'}\phi_\varsigma,\eta_0), \tag{8.1.21}$$

$$\phi^0_\varsigma(x,y,\eta,\eta_0)|_{x_1=y_1}=\langle x'-y',\eta'\rangle, \tag{8.1.22}$$

$$\lambda_\varsigma(x,\xi',\eta_0)=\varsigma\big(\eta_0-a(x,\xi')\big)^{\frac12}. \tag{8.1.23}$$

[1)] I.e. in the final run in $(g^{jk}(-V(x))^{-1})$.

Here amplitudes $f^0_{\varsigma n}(x,y,\eta)$ are smooth, satisfy transport equations and some initial conditions as $x_1 = y_1$ but we do not need to calculate them.

Then we can calculate u^0, hD_1u^0 as $x_1 = 0$ and define $u^1(x,y,t)$ in the same way (8.1.20) but with ϕ^1_ς satisfying (8.1.21) and

$$\phi^1_\varsigma = -\phi^0_{-\varsigma} \qquad \text{as} \quad x_1 = 0. \tag{8.1.24}$$

Here amplitudes $f^1_{\varsigma n}(x,y,\eta)$ are smooth, satisfy transport equations and some initial conditions as $x_1 = 0$ but we do not need to calculate them.

Obviously

$$\phi^1_\varsigma(y,y,\eta) = y_1\psi_\varsigma(y,\eta) \qquad \text{as} \quad x_1 = y_1, \tag{8.1.25}$$

$$\psi_\varsigma(y,\eta) = \lambda_\varsigma(0,y',\eta) - \lambda_{-\varsigma}(0,y',\eta) + O(y_1). \tag{8.1.26}$$

Therefore (as $|t| \le T$)

$$\Gamma_y\big(Q_{1x}u^1(x,y,t)\,{}^tQ_{2y}\big) \equiv \int \sum_{\varsigma=\pm} e^{ih^{-1}(y_1\psi_\varsigma(y,\eta)+t\eta_0)} \sum_{n\ge 0} f^2_{\varsigma n}(y,\eta)h^{n-d}\,d\eta, \tag{8.1.27}$$

where $Q_j = Q(x, hD', hD_t)$ are cut-offs with respect to ξ', τ and finally

$$F_{t\to h^{-1}\tau}\bar\chi_T(t)\Big(\Gamma_y\big(Q_{1x}u^1(x,y,t)\,{}^tQ_{2y}\big)\Big) \equiv \sum_{\varsigma=\pm}\int e^{ih^{-1}y_1\psi_\varsigma(y,\eta',\tau)} \sum_{n\ge 0} f^3_{\varsigma n}(y,\eta',\tau)h^{1+n-d}\,d\eta'. \tag{8.1.28}$$

Obviously, representation (8.1.28) implies that

(8.1.29) For small constant T expression (8.1.28) does not exceed Ch^{1-d}.

Since (8.1.29) is true for u^0 under ξ-microhyperbolicity condition

$$|\tau - V(y)| \ge \epsilon_0 \tag{8.1.30}$$

due to free space results, this statement is true also for u and therefore due to Tauberian arguments

Proposition 8.1.3. *Let* (8.1.30) *be fulfilled and* $Q_1 = Q_1(x, hD')$, $Q_2(x, hD')$ *be operators with symbols supported in* $\mathcal{U}$. *Then* $\Gamma_y\big(Q_{1x}e^1(x,y,\tau)\,{}^tQ_{2y}\big)$ *equals modulo* $O(h^{1-d})$ *Tauberian expression*

$$h^{-1}\int_{-\infty}^{\tau}\Big(F_{t\to h^{-1}\tau'}\bar\chi_T(t)\big(\Gamma_y\big(Q_{1x}u^1(x,y,t)\,{}^tQ_{2y}\big)\big)\Big)\,d\tau'. \tag{8.1.31}$$

Due to results of Subsection 7.3.1 we need to calculate only (8.1.31) with an extra factor $\chi(\tau-\tau')$ with χ supported in the small vicinity of 0:

$$\int_{-\infty}^{\tau}\chi(\tau-\tau')\sum_{\varsigma=\pm}\int e^{ih^{-1}y_1\psi_\varsigma(y,\eta',\tau')}\sum_{n\ge 0}f^3_{\varsigma n}(y,\eta',\tau')h^{n-d}\,d\eta'd\tau'. \tag{8.1.32}$$

Obviously modulo $O(h^{1-d})$ we can skip in the right-hand expression of (8.1.32) all the terms with $n\ge 1$; so we get $h^{-d}J$ with obviously defined J:

$$J := \sum_{\varsigma=\pm}\int_{-\infty}^{\tau}\chi(\tau-\tau')\int e^{i\hbar^{-1}\psi_\varsigma(y,\eta',\tau')}f^3_{\varsigma 0}(y,\eta',\tau')\,d\eta'd\tau' \tag{8.1.33}$$

with $\hbar = hy_1^{-1}$.

Further, for $y_1\ge h^{-1}$ one can consider J as an oscillatory integral with a semiclassical parameter $\hbar$. One can see easily that due to (8.1.25)–(8.1.26) in this oscillatory integral the phase function $\psi_\varsigma(y,\eta,\tau')$ satisfies $|\partial_{\tau'}\psi_\varsigma(y,\eta',\tau')|\ge\epsilon_1$ and has non-degenerate critical points with respect to η'; we denote these points by $\eta'_\varsigma(y,\tau')$. Therefore

$$J_\hbar \sim \sum_{\varsigma=\pm}\sum_{k\ge 0}e^{i\hbar^{-1}\varphi_\varsigma(y,\tau)}f^4_{\varsigma 0}(y,\tau)\hbar^{\frac12(1+d)+k}\qquad \text{as}\quad \hbar\ll 1 \tag{8.1.34}$$

where

$$\varphi_\varsigma(y,\tau)=\psi_\varsigma(y,\eta'(y,\tau),\tau). \tag{8.1.35}$$

Then

(8.1.36) $J_\hbar = J^0_\hbar + O(h)$ where $J^0_\hbar$ is also given by (8.1.33) but with y replaced by $(0,y')$.

Also the fact that f^l_0 are defined through transport equations along trajectories implies then

Proposition 8.1.4. *Modulo* $O(h^{1-d})$ *term* (8.1.31) *coincides with the same term but calculated for* $(\bar A,\eth\bar B) = (a(0,y',hD_x),\eth b(0,y',hD_x))$.

Calculations and Main Theorem

Now in virtue of Propositions 8.1.3, 8.1.4 we need only to recalculate $\Upsilon(r)$ in the case of more general boundary conditions than Dirichlet and Neumann, and then make change of variables.

Repeating arguments of Subsubsection *8.1.1.2 Toy-Model* one can prove easily that

Proposition 8.1.5. *Consider Schrödinger operator with $g^{jk} = \delta_{jk}$, $V = -1$, $\tau = 0$ and the boundary condition*

$$\big(B_0(x, hD')hD_1 + iB_1(x, hD')\big)u|_{x_1=0} = 0 \tag{8.1.37}$$

with

$$|b_0(x', \xi') + |b_1(x', \xi')| \geq \epsilon. \tag{8.1.38}$$

Assume that $\mathsf{supp}(q_j) \subset \mathcal{U}$ defined by (8.1.19)*. Then*

(i) The boundary layer term is $h^{-d}\Upsilon\big(h^{-1}x_1\big)$ with

$$\Upsilon(r) = \tag{8.1.39}$$
$$(2\pi)^{-d} \int \Big(\int_{\lambda_-(\xi',\tau)}^{\lambda_+(\xi',\tau)} \big(\xi_1 + i\beta(\xi')\big)\big(\xi_1 - i\beta(\xi')\big)^{-1} e^{2ir\xi_1}\, d\xi_1 \Big) q_1(\xi') q_2(\xi')\, d\xi'$$

where b_j are principal symbols of B_j and due to self-adjointness assumption $\beta = -ib_1 : b_0$ is real-valued.

(ii) Here function $\Upsilon(r)$ admits decomposition

$$\Upsilon(r) \sim \sum_{\varsigma=\pm} e^{2ir\varsigma} \sum_{n\geq 0} \varkappa_{\varsigma n} r^{-\frac{1}{2}(d+1)-n} \qquad \text{as} \quad r \to +\infty. \tag{8.1.40}$$

Therefore changing variables and using asymptotics in the zone where Theorems 7.3.10 and 7.3.11 work we arrive to

Theorem 8.1.6. *Let us consider Schrödinger operator with self-adjoint boundary condition* (8.1.37) *and let condition $V(x) \leq -\epsilon$, be fulfilled. Further, let ellipticity condition*

$$|b_0(x', \xi')\lambda(x', \xi') + b_1(x', \xi')| \neq 0 \qquad \text{on} \quad \mathsf{supp}(q_1) \cup \mathsf{supp}(q_2) \tag{8.1.41}$$

be fulfilled where $\lambda(x',\xi')$ *is a root of* $a(x,\xi_1,\xi')=0$ *with* $\operatorname{Im}\lambda>0$ [2)].

Then

$$\Gamma_x\big(Q_{1x}e(x,y,0)\,{}^tQ_{2y}\big)-\kappa_0(x)h^{-d}-h^{-d}\Upsilon(x',h^{-1}x_1)\sqrt{g}|\le Ch^{1-d} \tag{8.1.42}$$

with Weyl coefficient κ_0 *and with* $g=\det(g^{jk})^{-1}$ *where* x_1 *is the distance from* x *to* ∂X *in the metrics* $g^{jk}V^{-1}$ *and* $\Upsilon(r)$ *is defined by* (8.1.38) *and satisfies* (8.1.40).

Remark 8.1.7. (i) Due to Theorems 8.1.6 and 8.1.8 below the above theorem but with $\Upsilon(r)$ replaced by $\Upsilon(r)+\Upsilon_b(r)$ remains true if ellipticity condition (8.1.41) is replaced by microhyperbolicity condition

$$\begin{aligned}&|b_0(x',\xi')\lambda(x',\xi')+b_1(x',\xi')|+\\ &\qquad|\nabla_{\xi'}\big(b_0(x',\xi')\lambda(x',\xi')+b_1(x',\xi')\big)|\ne 0 \qquad \text{on}\quad \operatorname{supp}(q_1)\cup\operatorname{supp}(q_2)\end{aligned} \tag{8.1.43}$$

where $\Upsilon_b(r)\in\mathscr{S}(\mathbb{R}^+)$.

(ii) Standard Weyl asymptotics holds with the remainder estimate $O(h^{1-d})$ for $e(x,x,\tau)$ as $x_1\ge h^{(d-1)/(d+1)}$.

8.1.3 Generalizations

Now we need to consider the generalizations to the systems. We consider only Q_j with symbols supported in $\mathcal{U}$. The same approach leads to the following

Theorem 8.1.8. *Let* $(A,\eth B)$ *be self-adjoint and let* $\mathcal{U}\subset T^*\partial X$. *Assume that*

(8.1.44) *As* $(x,\xi',\tau)\in[0,\epsilon]\times\mathcal{U}\times[-\epsilon,\epsilon]$ *all the roots* ξ_1 *of equation*

$$\det\big(\tau-a(x,\xi)\big)=0 \tag{8.1.45}$$

are $\lambda_j^{\pm}(x,\xi',\tau)$ *with* $j=1,\dots,M^{\pm}$ *which are real-valued, smooth and of constant multiplicities and*

$$\pm\partial_\tau\lambda_j^{\pm}>0. \tag{8.1.46}$$

[2)] So, this is the condition only in the complement of $\pi\Sigma|_{\partial X}$; recall that $\Sigma=\{(x,\xi)\in T^*X, a(x,\xi)=0\}$.

Then

(i) Reflected solution has decomposition

$$(8.1.47)\quad F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Big(\Gamma_x\big(Q_{1x}u^1(x,y,t)\,{}^tQ_{2y}\big)\Big)\equiv \sum_{1\le j\le M^+,1\le k\le M^-}\int e^{ih^{-1}x_1\psi_{jk}(x,\eta',\tau)}\sum_{n\ge 0} f_{jkn}(x,\eta',\tau)h^{1+n-d}\,d\eta'.$$

with real phase functions ψ_{jk} and does not exceed $Ch^{1-d}(1+h^{-1}y_1)^{-\frac12(r-1)}$.

(ii) Asymptotics (8.1.42) *holds with $h^{-d}\Upsilon(x,h^{-1}x_1)$ constructed from* (8.1.47) *in the usual Tauberian way; thus*

$$(8.1.48)\quad \Upsilon(x,h^{-1}x_1)\equiv \sum_{1\le j\le M^+,1\le k\le M^-}\int^\tau\int e^{ih^{-1}x_1\psi_{jk}(y,\eta',\tau')}\sum_{n\ge 0} f_{jkn}(y,\eta',\tau')\,d\eta' d\tau'.$$

(iii) Under assumption

$$(8.1.49)_r\quad \nabla'_\xi\big(\lambda_j^+(x,\xi',\tau)-\lambda_k^-(x,\xi',\tau)\big)=0 \implies \operatorname{rank}\operatorname{Hess}_{\xi'}\big(\lambda_j^+(x,\xi',\tau)-\lambda_k^-(x,\xi',\tau)\big)\ge r$$

expressions (8.1.47) *and* (8.1.48) *do not exceed $Ch^{1-d}(1+h^{-1}x_1)^{-\frac12(r-1)}$ and $C(1+h^{-1}x_1)^{-\frac12(r+1)}$ respectively.*

(iv) Under condition $(8.1.49)_3$ *one can replace x by x' in the phase functions and amplitudes in* (8.1.48)*; then $\Upsilon(y',h^{-1}y_1)$ is constructed for the problem $\big(a(0,y',hD_x),\eth b(y',hD_x)\big)$.*

(v) As $r=d-1$ $h^{-d}\Upsilon(h^{-1}x_1)$ admits stationary phase decompositions

$$(8.1.50)\quad \sum_{j,k} e^{ix_1h^{-1}\mu_{jk}(x',\tau)}\sum_n f'_{jkn}(x',\tau)(x_1h^{-1})^{-\frac12(d+1)-n}\qquad \operatorname{mod} O(h^{1-d}).$$

Remark 8.1.9. (i) An easy proof is left to the reader.

(ii) In contrast to the Schrödinger operator we do not define x_1 as the distance to the boundary; eliminating x_1 from the phases ψ_{jk} without deteriorating estimate is possible as $r\ge 3$ while eliminating x_1 from amplitudes is possible as $r\ge 1$.

8.2 Scalar operators and Rescaling

Now our purpose is to consider scalar operators and apply to them rescaling technique. The bad news is that we do not have the all freedom of transformations we enjoyed in the smooth case since we need to preserve a boundary and also we need to look how boundary operator scales. The good news is that this restriction applies only in the boundary partition elements while in the inner partition elements we can apply the results of Chapter 5. Further, let us recall that in Section 5.4 we studied operators with irregular coefficients and did not have a freedom of transformations by means of Fourier integral operators at all.

The important question is what we study:

(a) $\Gamma\bigl(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\bigr)$,

(b) $\Gamma\bigl(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\bigr)$ as $\tau < \inf V$ or $\Gamma'\bigl(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\bigr)$,

(c) $\Gamma_x\bigl(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\bigr)$.

In the first case R. Seeley's method of Section 7.5 is our very powerful instrument to tackle balls close to the boundary. In two latter cases this method does not work very well. We consider only Schrödinger operator.

8.2.1 Schrödinger Operator. I

General Theory

As usual let us start from the Schrödinger operator with the principal symbol

$$a = \sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k) + V \tag{8.2.1}$$

(or any matrix operator with the principal symbol aI) looking for asymptotics of $\Gamma\bigl(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\bigr)$ (where Q_j are h-differential operators, usually just cut-off functions).

We consider boundary problem

$$\Bigl(\sum_j hb^j(hD_k - V_k) + b_0\Bigr)u|_{\partial X} = 0; \tag{8.2.2}$$

we assume that it is either Dirichlet boundary problem (i. e. $b^1 = ... = b^d = 0$, $b_0 = 1$) or

$$\sum_{1\le j\le d} |b^j| \ge \epsilon. \tag{8.2.3}$$

Without any loss of the generality one can assume[3)] that $X = \{x_1 > 0\}$ locally and

$$g^{jk} = \delta_{jk} \tag{8.2.4}$$

in which case self-adjointness of the problem implies that (modulo non-vanishing factor)

(8.2.5) ib^1, b^2,...,b^d and b_0 are real-valued functions

and the standard ellipticity of the problem means exactly that

$$|ib^1\big(\sum_{2\le j,k\le d} g^{jk}\xi_j\xi_k\big)^{\frac{1}{2}} + \sum_{2\le d} b^j\xi_j| \asymp |\xi'| \qquad \forall \xi' \in \mathbb{R}^d. \tag{8.2.6}$$

We know that with appropriate boundary conditions remainder estimate $O(h^{1-d})$ is achieved under ξ-microhyperbolicity condition

$$|V| \ge \epsilon_0. \tag{8.2.7}$$

To get rid of this condition (as coefficients belong to $\mathscr{C}^1$) we applied scaling functions

$$\gamma(x) = \epsilon|V(x)| + h^{\frac{2}{3}}, \qquad \rho(x) = \gamma(x)^{\frac{1}{2}}. \tag{8.2.8}$$

Let us do the same; then as $\gamma(x) \le \ell(x)$,

$$\ell(x) = \frac{1}{2}\mathsf{dist}(x, \partial X) \tag{8.2.9}$$

everything works as before in Section 5.4 and the total contribution of these balls to the remainder is $O(h^{1-d})$ as *either* $d \ge 3$ *or* $d = 2$ and

$$|V| + |\nabla V| \ge \epsilon_0; \tag{8.2.10}$$

[3)] Surely it may affect smoothness but we need this assumption only to write down conditions to B in more compact form

as $d = 1$ under condition (8.2.10) we concluded that the total contribution of these balls to the remainder is $O(|\log h|)$; we needed to examine a propagation of singularities to fix this and we will do it later.

On the other hand, as $\ell(x) \le \gamma(x)$ we have two choices: first, we can snap $\gamma(x)$ to $\ell(x)$ but leave $\rho(x) = |V(x)|^{\frac{1}{2}}$ (as it was before for $\gamma(x) \ge 2h^{\frac{2}{3}}$):

$$\gamma(x) = \ell(x), \quad \rho(x) = |V(x)|^{\frac{1}{2}} + h\ell(x)^{-1} \quad \text{as} \quad \epsilon|V(x)| \ge \ell(x) \ge h; \tag{8.2.11}$$

then the total contribution of such balls does not exceed

$$Ch^{1-d} \int \rho(x)^{d-1}\ell(x)^{-1} \le Ch^{1-d}|\log h|$$

and we cannot generally improve this while contribution of the zone $\{x\colon \ell(x) \le Ch\}$ to the remainder is $O(h^{1-d})$. So we get remainder estimate $O(h^{1-d}|\log h|)$ under condition (8.2.10) and $d \ge 1$; then rescaling arguments of Chapter 5 continue to work and we get remainder estimate $O(h^{1-d}|\log h|)$ as *either* $d \ge 2$ *or* as $d = 1$ and non-degeneracy condition $(5.2.100)_m$ is fulfilled and the remainder estimate $O(h^{-\delta})$ as $d = 1$ without non-degeneracy condition (in the latter case we should be happy as we got the same result as in the case without boundary).

Alternatively we should not replace $\gamma(x)$ by $\ell(x)$ but then we need to analyze boundary ball $B(\bar{x}, \gamma(\bar{x}))$ in which case we need to look how boundary condition scales. As before we can assume that $V_j(\bar{x}) = 0$ as $d \ge 2$ or $V_1 = 0$ as $d = 1$.

Obviously the Dirichlet boundary condition $u|_{\partial X} = 0$ scales well. Condition (8.2.2) also scales well as $b_0 = 0$ identically otherwise assumptions (8.2.3), (8.2.6) may be in trouble. In fact, this condition scales to

$$\Big(\sum_j \hbar b^j(hD_k - V_k) + \beta b_0'\Big)u|_{\partial X} = 0. \tag{8.2.12}$$

where $\beta = 1$, $b_0' = \rho^{-1}b_0$ as $|b_0(x)| \le C\rho$ at some and thus in any point of partition element and $\beta = \rho^{-1}b_0(\bar{x})$, $b_0' = b_0 b_0(\bar{x})^{-1}$ if $|b_0(x)| \ge C\rho$ at some and thus in any point of the partition element. So, we get a system with an additional large parameter β. However we use Seeley's method of Section 7.5 and we need only estimate here (in the boundary strip $\{x_1' \le \hbar\}$ after rescaling). Therefore we can allow operators with a parameter as long

the boundary condition remains elliptic with a parameter i.e.

$$|ib_0\big(\sum_{2\le j,k\le d} g^{jk}\xi_j\xi_k\big)^{\frac{1}{2}} + \sum_{2\le j\le d} b^j\xi_j + b_0\beta| \asymp |\xi'| + \beta \qquad \forall \xi' \in \mathbb{R}^d,\ \forall \beta \ge 0. \tag{8.2.13}$$

This condition scales well.

So we assume that

(8.2.14) One of the following condition is fulfilled:

(a) $b^1 = ... = b^d = 0$, $b_0 = 1$,

(b) $b_0 = 0$ and (8.2.6) is fulfilled,

(c) (8.2.13) is fulfilled.

Thus, the contribution of ball $B(\bar{x}, \gamma(\bar{x}))$ to the remainder is $O(\hbar^{1-d}) = O(h^{1-d}\gamma^{d-1}\rho^{d-1})$. Then the contribution of all such balls to the remainder does not exceed $Ch^{1-d}\int \rho^{d-1}(x)\,dx' = O(h^{1-d})$ without any extra assumption.

Therefore we get the total remainder estimate $O(h^{1-d})$ as *either* $d \ge 3$ *or* as $d = 2$ and condition (8.2.10) is fulfilled. Then using scaling with

$$\gamma(x) = \rho(x) = \epsilon(|V(x)| + |\nabla V(x)|^2)^{\frac{1}{2}} + h^{\frac{1}{2}} \tag{8.2.15}$$

and applying the same arguments we recover remainder estimate $O(h^{-1})$ as $d = 2$ even without assumption (8.2.10).

Thus we arrive to

Theorem 8.2.1. *Consider Schrödinger operator. Assume that the boundary problem is self-adjoint and condition* (8.2.14) *is fulfilled.*

Let either $d \ge 3$ and coefficients belong to $\mathscr{C}^{1,1}$ or $d = 2$ and coefficients belong to $\mathscr{C}^2$. Then

(i) The remainder estimate is $O(h^{1-d})$.

(ii) Moreover, the contribution of the zone $\{x : \mathsf{dist}(x, \partial X) \le \varepsilon\}$ with $\varepsilon \ge h$ to the remainder does not exceed $C\varepsilon h^{1-d}$.

Sharp Remainder Estimates

We can combine Theorem 8.2.1(ii) with Theorem 5.3.3. Note that for Schrödinger operator the problem $(A-\tau, \eth B)$ is automatically microhyperbolic at points where billiards hit the boundary.

Details are left to the reader. Just to remind that as $d=2$ the remainder estimate includes the term

$$Ch^{-1}\int_{\{|V-\tau|+|\nabla V|^2\le h^{1-\delta}\}} |F_{12}|\,dx$$

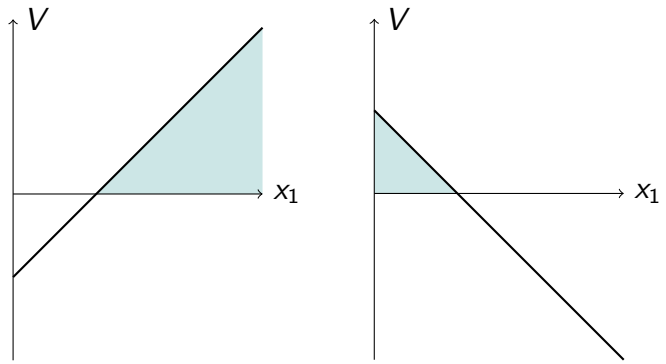
where $F_{12}=(\partial_{x_1}V_2-\partial_{x_2}V_1)$.

Special Case $d=1$

As $d=1$ we still need to get rid of $|\log h|$. Under assumption (8.2.10) it is easy. Without any loss of the generality one can assume that $|V(0)|\le\epsilon$ and then consider two cases:

(a) $\partial_{x_1}V(0)\ge\epsilon_0$;

(b) $-\partial_{x_1}V(0)\le-\epsilon_0$:



(a) $V'>0$ (b) $V'<0$

Figure 8.2: Case $d=1$ under condition (8.2.10); teal!20 gray covers classically forbidden zones.

In the former case the slope goes to the boundary and *after rescaling* $x_1\mapsto x_1\gamma^{-1}$, $\xi_1\mapsto\xi_1\gamma^{-\frac12}$, $h\mapsto\hbar=h\gamma^{-\frac32}$ with $\gamma=\frac12 x_1\ge\bar\gamma:=\big(|V(0)|+h^{\frac23}\big)$

the zone $\{x\colon x_{1\mathsf{new}} \ge C\}$ is classically forbidden and its contribution to the remainder is $O(\hbar^s) = O\big(h^s\gamma^{-\frac{2}{3}s}\big)$ and the total contribution of the zone $\{x\colon x_1 \ge C\bar\gamma\}$ does not exceed $C\int h^s\gamma^{-\frac{2}{3}s}\gamma^{-1}\,d\gamma \asymp 1$ exactly as in the proof of Theorem 5.2.7.

In the latter case the slope goes away from the boundary and therefore launching trajectory in this direction we extend $T \asymp \gamma(x)\rho(x)^{-1} \asymp x_1^{\frac12}$ to $T \asymp 1$. Then the contribution of interval $x_1 \asymp \gamma$ to the remainder improves from $O(1)$ to $O(\gamma^{\frac12})$. Therefore the total contribution of the zone $\{x\colon |x_1| \ge C(|V(0)| + h^{\frac23})\}$ improves from $\int \gamma^{-1}\,d\gamma \le |\log h|$ to $\int \gamma^{\frac12}\times\gamma^{-1}\,d\gamma \asymp 1$ exactly as in the proof of Theorem 5.2.10.

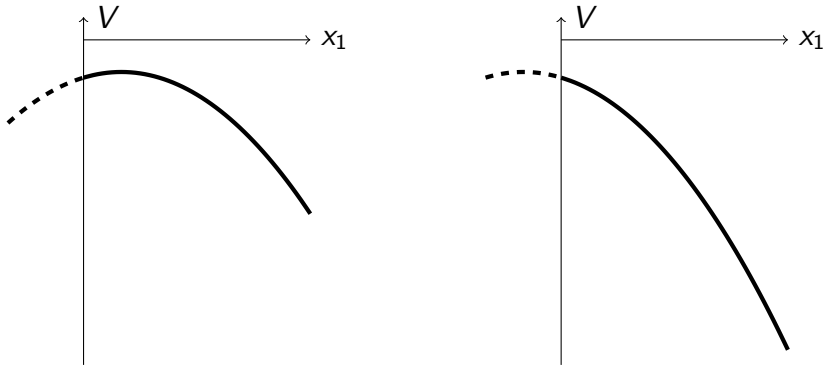
In both cases we can estimate contribution to the remainder of the zone $\{x\colon x_1 \le \bar\gamma\}$ by $O(1)$. Therefore in both cases under condition (8.2.10) we reached the remainder estimate $O(1)$.

Now we can use $\gamma = \epsilon\big(|V| + |\partial_{x_1}V|^2\big)^{\frac12} + h^{\frac12}$ and exactly as before we need to consider the case $|V(0)| + |\partial_{x_1}V(0)| \le \epsilon$ and then two cases:

(a) $\partial_{x_1}^2 V(0) > \epsilon_0$;

(b) $-\partial_{x_1}^2 V(0) < -\epsilon_0$.

Again in the former case $\int_{\Sigma_\tau} d\mu_\tau \le C$ leading us to the same remainder estimate $O(1)$; so only case (b) needs to be addressed. Again, there are two subcases: $V'(0) > 0$ and $V'(0) < 0$.



(a) $V'(0) > 0$ (b) $V'(0) < 0$

Figure 8.3: Case $d = 1$ under condition (b); sign $V(x_1^*)$ does not really matter.

Let us introduce

$$\bar{\gamma} = |V'(0)| + \bigl(|V(0)| + h\bigr)^{\frac{1}{2}}. \tag{8.2.16}$$

Then the zone $\{x\colon x_1 < C\bar{\gamma}\}$ is rescaled $x_1 \mapsto x_1\bar{\gamma}^{-1}$, $\xi_1 \mapsto \xi_1\bar{\gamma}^{-1}$, $h \mapsto \hbar = h\bar{\gamma}^{-2}$ and either $\bar{\gamma} \ge 2h^{\frac{1}{2}}$ in which case (8.2.10) is fulfilled after rescaling, or $\bar{\gamma} \asymp h^{\frac{1}{2}}$ in which case $\hbar \asymp 1$; in both cases contribution of this zone to the remainder is $O(1)$.

Assume that function $V(x)$ extended to negative x_1 reaches its maximum on $\{x\colon |x_1| \le \bar{\gamma}\}$ at x_1^*. Then in virtue of the above arguments we need to consider contribution of the zone $\{x\colon x_1 \ge C\bar{\gamma}\}$. Let us recall the proof of Theorem 5.2.10; adapting it to our case one can see easily that we considered there classical trajectories going "downhill" away from x_1^* unless $x_1 - x_1^* > h^\delta$ in which case we considered classical trajectories going "uphill" towards x_1^*. The boundary $x_1 = 0$ does not affect our arguments in the former case and affects our arguments only in the latter case and only if $x_1^* < 0$ and $V(0) < 0$; sign $V(x_1^*)$ does not matter.

However we can repeat the same arguments as in the proof of Theorem 5.2.10 but with $\bar{\gamma}$ defined by (8.2.16) rather than with $\bar{\gamma} = (|V(x_1^*)| + h)^{\frac{1}{2}}$ as we used there.

Now we can go from condition $(5.2.100)_2$ to $(5.2.100)_m$ by induction with respect to m. Note that in the proof of Theorem 5.2.14 in this case we always are moving "uphill" towards point x^* where $\gamma(x)$ reaches its minimum and

$$T \asymp \max\bigl(x_1^\delta \bar{\gamma}^{-\delta}, 1\bigr) \tag{8.2.17}$$

with $\bar{\gamma}$ introduced there by (5.2.103) as γ reaches its minimum at $x_1^* > 0$ and with $\bar{\gamma}$ replaced by $\gamma(0)$ as γ reaches its minimum at $x_1^* < 0$.

This leads us to

Theorem 8.2.2. *Consider Schrödinger operator in dimension $d = 1$ with sufficiently smooth coefficients. Assume that boundary problem is self-adjoint and satisfies condition* (8.2.14) [4]*. Then the remainder estimate is $O(1)$ under condition* $(5.2.100)_m$ *and $O(h^{-\delta})$ without it.*

Generalizations

Consider any scalar operator assuming that the classically principal part of it is (uniformly) elliptic and also classically principal part of boundary

[4] Which as $d = 1$ boils down to $|b_0| + |b^1| \asymp 1$

value problem is (uniformly) elliptic. Then in the smooth case we can apply arguments of Section 5.2 and in irregular case arguments of Section 5.4; in the latter case we either assume that the boundary is smooth or just satisfies regularity conditions of Section 7.5 and in the latter case we assume that there are Dirichlet boundary conditions.

Then under these assumptions we recover in full results of Section 5.2 or Section 5.4 respectively.

8.2.2 Schrödinger Operator. II

Preliminaries

Now we consider asymptotics either of $\Gamma\big(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\big)$ as $\tau < \inf V$ or $\Gamma'\big(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\big)$. In this case we cannot get rid of the microhyperbolicity assumption of $(A-\tau, \eth B)$ as easily as we did before. Also we assume that coefficients are smooth enough.

Remark 8.2.3. (i) Ellipticity condition[5)] (8.2.6) has different implications for different dimensions:

(i)′ As $d \ge 3$ it is equivalent to

$$g'(b') := \sum_{2\le j,k\le d} g_{jk} b^j b^k \le (1-\epsilon)|b^1|^2 \tag{8.2.18}$$

where $(g_{jk}) = (g^{jk})^{-1}$;

(i)″ As $d = 2$ it is equivalent to *either* (8.2.7) *or*

$$g_{22}|b^2|^2 \ge (1+\epsilon)|b^1|^2; \tag{8.2.19}$$

(ii) Under condition (8.2.18) operator A with boundary condition $\eth Bu = 0$ is semi-bounded from below and under condition (8.2.19) it is not.

(iii) Condition (8.2.13) is (8.2.6) in dimension dv rather than $(d-1)$ with $\xi_0 = \beta$ and $g^{0j} = \delta_{j0}$.

[5)] As $g^{jk} = \delta_{jk}$.

Microhyperbolicity Conditions

Let us recall that the microhyperbolicity condition at the interior point (x,ξ) is

$$|\tau - V(x)| - \sum_{1\le j\le d} |\xi_j - V_j(x)| + |\nabla_x V(x)| \ge \epsilon_0; \tag{8.2.20}$$

the microhyperbolicity condition for $(A-\tau)$ at the boundary point (x,ξ') is

$$|\tau - V(x)| - \sum_{2\le j\le d} |\xi_j - V_j(x)| + |\nabla_{x'} V(x)| \ge \epsilon_0 \quad (x_1 = 0); \tag{8.2.21}$$

moreover, ξ-microhyperbolicity in the interior and boundary point is

$$|\tau - V(x)| - \sum_{1\le j\le d} |\xi_j - V_j(x)| \ge \epsilon_0 \tag{8.2.22}$$

and

$$|\tau - V(x)| - \sum_{2\le j\le d} |\xi_j - V_j(x)| \ge \epsilon_0 \quad (x_1 = 0); \tag{8.2.23}$$

respectively.

Furthermore, if $(A-\tau)$ is ξ-microhyperbolic in the boundary point, problem $(\tau - A, \eth B)$ is ξ-microhyperbolic if and only if one of the following four conditions is fulfilled:

(8.2.24) The point (x',ξ') is either hyperbolic or "almost hyperbolic", i.e.

$$\tau \ge \sum_{2\le j,k\le d} g^{jk}(x)(\xi_j - V_j)(\xi_k - V_k) + V - \epsilon'$$

with $\epsilon' = \epsilon'(d, c, \epsilon_0) > 0$;

$$ib_1 b_0 \ge -\epsilon', \tag{8.2.25}$$

$$|\tau - W(x)| \ge \epsilon_0 \tag{8.2.26}$$

where

$$W = V - \beta^2(|b^1|^2 - g'(b')^{-1} \tag{8.2.27}$$

with $g'(b')$ defined by (8.2.18),

$$\sum_{2\le j\le d} \bigl|\xi_j - V_j + (\tau - V)\frac{b_j}{b_0}\bigr| \ge \epsilon_0, \quad b_j = \sum_{2\le k\le d} g_{jk}b^k; \tag{8.2.28}$$

in cases (8.2.25)–(8.2.27) the operator $\tilde{B}$ with the principal symbol

$$ib^1\Bigl(\sum_{2\le j,k\le d} g^{jk}\xi_j\xi_k\Bigr)^{\frac12} + \sum_{2\le d} b^j\xi_j \tag{8.2.29}$$

and the problem $(A-\tau, \eth B)$ are both either elliptic at this point or microhyperbolic in the multidirection $(0, \xi_j - V_j)_{j=2,\dots d})$; we assume that condition (8.2.24) is violated and hence operator $A-\tau$ is elliptic at this point.

Finally, if all four conditions (8.2.24)–(8.2.27) are violated then the microhyperbolicity condition is fulfilled if and only if

$$|\nabla_{x'} W| \ge \epsilon_0; \tag{8.2.30}$$

however $\ell'_x \ne 0$ in this case.

Analysis in the "Elliptic" Zone

Let us now consider the elliptic zone of the operator $(A-\tau)$. Here it is sufficient to consider only $\Gamma'\bigl(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\bigr)$ as $\Gamma\bigl(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\bigr)$ in this zone can be reduced to it (with modified operators Q_{1x} and Q_{2y} and) with an extra factor h.

In the zone in question case the ellipticity or microhyperbolicity of problem $(A-\tau, \eth B)$ is equivalent to the same property of the symbol

$$\tilde{b} = ib^1(x')\bigl(a'(x',\xi') - \tau\bigr)^{\frac12} + b'(x',\xi') + b_0(x') \tag{8.2.31}$$

where

$$a'(x',\xi') = \sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k) + V, \tag{8.2.32}$$

$b' = \sum_j b^j\xi_j$, we sum with respect to $j,k = 2,\dots,d$ and as before we assume that $g^{1k} = \delta_{1k}$; let us recall that the elliptic zone is given by the inequality

$$a'(x',\xi') \ge \tau + \epsilon \tag{8.2.33}$$

with a constant $\epsilon > 0$.

In turn symbol $\tilde{b}$ is elliptic in zone defined by

$$ib^1(x')^{-1}\big(b'(x',\xi')+b_0(x')\big)\ge 0 \tag{8.2.34}$$

and in zone

$$ib^1(x')^{-1}\big(b'(x',\xi')+b_0(x')\big)< 0 \tag{8.2.35}$$

the ellipticity or microhyperbolicity of $\tilde{b}$ is equivalent to those of

$$p=-\big(b^1(x')\big)^2\big(a'(x',\xi')-\tau\big)+\big(b'(x',\xi')+b_0(x')\big)^2, \tag{8.2.36}$$

Due to assumption (8.2.18) or (8.2.19) quadratic form

$$-\big(ib^1(x')\big)^2\sum_{j,k} g^{jk}(x')\xi_j\xi_k+\big(\sum_j b^j\xi_j\big)^2 \tag{8.2.37}$$

is non-degenerate and thus we basically arrive to the Schrödinger operator on the boundary; here we can assume that ib^1 is disjoint from 0; otherwise $\sum_j |b^j|^2$ is disjoint from 0 and as ib^1 is sufficiently small, the symbol p is ξ-microhyperbolic.

For this Schrödinger operator we can invoke the full power of Subsection 5.3.1 and arrive to

Theorem 8.2.4. *Consider Schrödinger operator in dimension $d\ge 2$. Assume that boundary problem is self-adjoint and satisfies condition* (8.2.14). *Let $Q_j=q_j(x,hD'_x)$ be operators with symbols supported in the zone defined by* (8.2.33). *Then*

(i) As $d\ge 3$ the following estimates hold

$$|\Gamma'\big(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\big)-\kappa_0 h^{-d}|\le Ch^{1-d} \tag{8.2.38}$$

and

$$|\Gamma\big(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\big)-\kappa_1 h^{1-d}|\le Ch^{2-d}. \tag{8.2.39}$$

(ii) As $d\ge 2$ and nondegeneracy condition $(5.2.100)_m$ is fulfilled for symbol

$$W(x')=-\big(ib^1(x')\big)^2\big(V(x')-\tau\big)+\big(b_0(x')\big)^2, \tag{8.2.40}$$

estimates (8.2.38) *and* (8.2.39) *hold as well.*

(iii) As $d = 2$

$$|\Gamma'\big(Q_{1x} e(.,.,\tau)\, {}^t Q_{2y}\big) - \kappa_0 h^{-2}| \le C h^{-1-\delta} \tag{8.2.41}$$

and

$$|\Gamma\big(Q_{1x} e(.,.,\tau)\, {}^t Q_{2y}\big) - \kappa_1 h^{1-d}| \le C h^{-\delta} \tag{8.2.42}$$

hold with arbitrarily small exponent $\delta > 0$.

Remark 8.2.5. (i) Under some conditions on the Hamiltonian trajectories of p one can obtain two-term asymptotics; however one should keep in mind that these trajectories can leave the elliptic zone, so it is necessary either to forbid this or to use the complete analysis of propagation of singularities in the hyperbolic zone.

(ii) Surely one can also consider averaging with respect to spectral parameter.

Asymptotics as $V \approx 0$

To cover this zone we introduce

$$\gamma = \epsilon |V| + h^{\frac{2}{3}}, \qquad \rho = \gamma^{\frac{1}{2}} \tag{8.2.43}$$

and after rescaling $V \approx 1$ or $\hbar \asymp 1$. We do not need to care then about microhyperbolicity condition in the elliptic zone (unless $d = 2$). Then we arrive immediately to

Theorem 8.2.6. *Consider Schrödinger operator in dimension* $d \ge 2$. *Assume that boundary problem is self-adjoint and satisfies condition* (8.2.14). *Then*

(i) Asymptotics (8.2.38) *holds as* $d \ge 3$.

(ii) Asymptotics

$$|\Gamma'\big(Q_{1x} e(.,.,\tau)\, {}^t Q_{2y}\big) - \kappa_0 h^{-d}| \le C h^{-1} \int \gamma^{-1}\, dx' \tag{8.2.44}$$

holds as $d = 2$ *and the boundary condition is either Dirichlet or Neumann or non-degeneracy condition* $(5.2.100)_m$ *is fulfilled for symbol* $W(x')$ *defined by* (8.2.40).

(iii) Asymptotics

$$|\Gamma'\big(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\big) - \kappa_0 h^{-d}| \le Ch^{-1-\delta}\int \gamma^{-1+\frac{3}{2}\delta}\,dx' \tag{8.2.45}$$

holds as $d = 2$.

Proof. Really, in the frameworks of Statements (i) or (ii) the rescaling leads to the remainder estimate $Ch^{1-d}\int \rho^{d-1}\gamma^{-1}\,dx'$ which implies (8.2.38) and (8.2.44) respectively.

In the framework of Statement (iii) we get the remainder estimate

$$Ch^{1-d}\int \rho\gamma^{-1}\big(|h\gamma^{-1}\rho^{-1}|\big)^{-\delta}\,dx'$$

which leads to (8.2.45). □

Corollary 8.2.7. *Let* $d = 2$. *Then*

(i) Asymptotics with remainder estimate $O(h^{-1-\delta})$ *holds under microhyperbolicity condition*

$$|V-\tau| + |\nabla_{x'}V| + |\nabla^2_{x'}V| \ge \epsilon. \tag{8.2.46}$$

(ii) Moreover, for Dirichlet or Neumann boundary condition asymptotics with remainder estimate $O(h^{-1}|\log h|)$ *holds under condition* (8.2.46).

(iii) Asymptotics with remainder estimate $O(h^{-\frac{4}{3}})$ *in the general case.*

Remark 8.2.8. We cannot control $\partial_{x_1}V$ so we can neither scale microhyperbolicity condition $|V-\tau| + |\nabla_{x'}V| \ge \epsilon$ properly. This prevents us from getting better results as $d = 2$.

Problem 8.2.9. (i) Derive uniform with respect to $\tau \approx 0$ remainder estimates (the best possible) for toy-model operators

$$h^2\big(D_1^2 + D_2^2\big) \pm x_1 \tag{8.2.47}$$

under Dirichlet or Neumann boundary condition.

(ii) Generalize these estimates.

8.2.3 Schrödinger Operator. III

Consider now asymptotics of $\Gamma_x\bigl(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\bigr)$. Assume for simplicity that either Dirichlet or Neumann boundary condition is imposed. Then the same scaling as before brings the remainder estimate $O(h^{1-d})$ as $d\ge 3$ and the remainder estimate $O(h^{-1}\gamma^{-\frac12})$ as $d=2$; in particular as $d=2$ the remainder estimate $O(h^{-\frac43})$ holds.

Consider case $d=2$ in more details. As $\ell(x)=\mathsf{dist}(x,\partial X)\ge\gamma(x)$ we consider a ball $B(x,\ell(x))$ and in this ball we replace $\gamma(x)$ and $\rho(x)$ by $\ell(x)$ and $\ell(x)^{\frac12}$ respectively; we can do it because we have "free space asymptotics" without assumption that $V(x)$ is disjoint from 0. This asymptotics was derived in Subsubsection *5.3.1.4 Asymptotics without Spatial Mollification and Short Loops*. Let us recall that this asymptotics had remainder estimate $O(h^{-1})$ and contained correction term described in (5.3.36) and (5.3.62) and concentrated near $V=0$.

Scaling this ball leads us to the remainder estimate $O(h^{-1}\rho^{\frac12}\gamma^{-1})$ where we plug $\gamma=\ell$ and $\rho=\ell^{\frac12}$ and arrive to the remainder estimate $O(h^{-1}\ell(x)^{-\frac12})$.

Therefore in both cases the remainder does not exceed

$$Ch^{-1}\gamma_1(x)^{-\frac12},\qquad \gamma_1(x)=\mathsf{max}\bigl(|V(x)|,\ell(x),h^{\frac23}\bigr) \tag{8.2.48}$$

but the correction term is different depending on which of $\ell(x),|V(x)$ is larger:

Theorem 8.2.10. *Consider Schrödinger operator in dimension $d=2$ under Dirichlet or Neumann boundary condition. Then asymptotics of $\Gamma_x\bigl(Q_{1x}e(.,.,\tau)\,{}^tQ_{2y}\bigr)$ holds with the remainder estimate $O\bigl(h^{-1}\gamma_1(x)^{-\frac12}\bigr)$ with the Weyl principal part and correction term $h^{-2}\Upsilon(h^{-1}x_1)$ with function Υ constructed in Section 8.1 as $|V(x)|\ge\mathsf{max}(\ell(x),h^{\frac23})$ and with the correction term described by Theorem 5.3.16 as $\ell(x)\ge\mathsf{max}(|V(x)|,h^{\frac23})$.*

Problem 8.2.11. In dimension $d=2$ assuming that $|\nabla_{x'}V(x)|\ge\epsilon$ derive asymptotics with the remainder $O(h^{-1})$ or at least which is $o(h^{-1}\gamma_1^{-\frac13})$ as $\gamma_1\ll 1$. This correction term is expected to contain a "circular wave" term corresponding to the "vertex" $\{x\in\partial X, V(x)=0\}$.

Related is the following

Problem 8.2.12. (i) In dimension $d \geq 2$ consider non-degenerate Schrödinger operator in domain with edges and derive asymptotics with the remainder estimate $O(h^{1-d})$ or at least with $o(h^{1-d}\gamma_1^{-1}(x))$ as $\gamma_1(x) \ll 1$ where γ_1 is the distance to the nearest edge.

(ii) Derive similar results in domains with edges, vertices of any dimension.

(iii) Derive similar results in domains with conical points.

Those are difficult problems solution of which clearly would deserve publication.

Remark 8.2.13. Surely we can restore results of Section 5.2 for spectral mollifications.

8.3 Operators with Periodic Hamiltonian Flows

In Section 6.2 we considered the case when there was no boundary and the Hamiltonian flow was periodic and derived very sharp spectral asymptotics. Now we want to achieve similar results when there is a boundary. We do not expect asymptotics to be that sharp, but better than $O(h^{1-d})$ and have non-Weyl correction term. However the presence of the boundary, more precisely, branching of the rays on the boundary brings the new possibilities. For simplicity we consider only Schrödinger operators.

8.3.1 Discussion and Plan

We start our analysis in Subsection 8.3.2 from the case when there is no branching and the Hamiltonian flow (with reflections) is periodic. Then if period is T_0, $\Psi_{T_0} = I$ we have the same equality

$$e^{ih^{-1}T_0A}Q = e^{iT_0L}Q \tag{8.3.1}$$

as before where $\mathsf{supp}(q)$ is disjoint from the boundary and only transversal to the boundary trajectories originate at $\mathsf{supp}(q)$ and L is h-pseudodifferential operator. Then

$$F_{t\to h^{-1}\tau}\bar{\chi}\Big(\frac{t}{T_0} - n\Big)\Gamma\big(Q_{1x}u\,{}^tQ_{2y}\big) = (2\pi h)^{1-d}J(n) + O(h^{1-d+\delta}) \tag{8.3.2}$$

with

$$J(n) = \int_{\Sigma_\tau} e^{in\ell} q_1 q_2 \, d\mu_\tau \tag{8.3.3}$$

as $\bar{\chi}$ is supported in $(-\frac{2}{3}, \frac{2}{3})$ and equals 1 in $(-\frac{1}{3}, \frac{1}{3})$ and $n \in \mathbb{Z}$, $|n| \le h^{-\delta}$. Here as before $\Sigma_\tau = \{a(x,\xi) = \tau\}$ and $\mu_\tau = dxd\xi : da$ is the measure there, ℓ is the principal symbol of L.

If ℓ is "variable enough" on Σ_τ so the right-hand expression is decaying as $n \to \infty$ we can improve remainder estimate $O(h^{1-d})$ (to what degree depends on the rate of the decay). Recall that in Section 6.2 essentially ℓ was defined by integral of the subprincipal symbol along periodic trajectories. Now however ℓ can pick up extra terms at the moment of the reflection: for example, for Schrödinger operator increment of ℓ is 0 and π for Neumann and Dirichlet boundary condition respectively; however more general boundary condition brings increment which depends on the point $(x', \xi') \in T^*Y$ of the reflection.

Then in Subsection 8.3.3 we consider a more complicated case when two operators are intertwined through the boundary conditions and all Hamiltonian trajectories of one of them are periodic but of another are not and, moreover, if the generic Hamiltonian billiard is periodic, it is in fact some Hamiltonian billiard of the first operator. Then (8.3.1) fails but (8.3.2)–(8.3.3) is replaced by (8.3.2), (8.3.4)

$$J(n) = \int_{\Sigma_{1,\tau}} e^{in\ell - |n|\ell'} q_1 q_2 \, d\mu_{1,\tau} \tag{8.3.4}$$

where $\Sigma_{1,\tau}$ and $\mu_{1,\tau}$ correspond to the first operator and $\ell' \ge 0$ depends on the portion of the energy which was whisked away along trajectory of the second operator at the reflection point. Then if

$$\mu_{1,\tau}\big(\{(x,\xi) \in \Sigma_{1,\tau}, \ell' = 0, \nabla\ell = 0\}\big) = 0 \tag{8.3.5}$$

we conclude that $J(n) = o(1)$ as $n \to \infty$ and we will be able to improve remainder estimate $O(h^{1-d})$ to $o(h^{1-d})$ and again there will be a non-Weyl correction term but it will depend also on both ℓ and ℓ'.

Finally, in Subsection 8.3.3 we consider even more complicated case when two operators are intertwined through boundary condition and the Hamiltonian trajectories of both of them are periodic and, moreover, after a while all trajectories issued from some point at T^*Y assemble there. Then we can construct a matrix symbol and its eigenvalues play a role formerly played by ℓ.

8.3.2 Simple Hamiltonian Flow

Inner Asymptotics

Let $\mathcal{U}$ be an open connected subset in T^*X disjoint from ∂X. Consider Hamiltonian billiards issued from $\mathcal{U}$, let Φ_t denote the generalized Hamiltonian flow. Assume that

$$|\nabla_{x,\xi} a(x,\xi)| \ge \epsilon \qquad \forall t \ \ \forall (x,\xi) \in \Phi_t(\mathcal{U}), \tag{8.3.6}$$

$$|\phi(x)| + |\{a,\phi\}(x,\xi)| \ge \epsilon \qquad \forall t \ \ \forall (x,\xi) \in \Phi_t(\mathcal{U}), \tag{8.3.7}$$

$$\Phi_t(x,\xi) = (x,\xi) \qquad \text{with} \ \ t = t(x,\xi) > 0 \ \ \forall (x,\xi) \in \mathcal{U}, \tag{8.3.8}$$

where $\phi \in \mathscr{C}^\infty(\bar{X})$, $\phi > 0$ in X and $\phi = 0$ on ∂X and

(8.3.9) Along $\Phi_t(\mathcal{U})$ reflections are simple without branching, which means that $\iota^{-1}\iota(y,\eta) \cap \{a(y,\eta) = \tau\}$ consists of two (disjoint) points $(y,\eta^{\pm})$ such that $\pm\{a,\phi\} > 0$ as $(y,\eta) \in \Phi_t(\mathcal{U})$, $y \in \partial X$ and $\tau = a(y,\eta)$.

Let us recall that $\iota : T^*X|_{\partial X} \to T^*\partial X$ is a natural map.

Then exactly as in the case without boundary

(8.3.10) One can select $t(x,\xi) = T(a(x,\xi))$ in $\mathcal{U}$ with $T \in \mathscr{C}^\infty$ (so period depends on the energy level only[6),7)]

and

(8.3.11) As $(x,\xi) \in \mathcal{U}$ and $0 < t < T(x,\xi)$ $\Phi_t(x,\xi)$ meets ∂X exactly $(N-1)$ times with $N = \mathsf{const}$; so as $N \ge 1$ billiard consists of N segments with the ends on the boundary.

We can consider instead of the operator A with the domain

$$\mathfrak{D}(A) = \{u \in \mathscr{H}^m(X), \eth Bu = 0\} \tag{8.3.12}$$

an operator $f(A)$ with

$$f(\tau) = \int T^{-1}(\tau)\, d\tau \tag{8.3.13}$$

[6)] See clarification in footnote [6)] in Chapter 6.

[7)] But there could be subperiodic trajectories with periods $n^{-1}T(a(x,\xi))$, $n = 2,3,\ldots$. The structure of subperiodic trajectories described in Subsection 6.3.1.

and introduce the corresponding propagator $e^{ih^{-1}tf(A)}$ so that the corresponding Hamiltonian flow Ψ_t of $f(A)$ is periodic with period 1.

However now structure of $f(A)$ near ∂X is a bit murky; but it is not really serious obstacle since we can consider problem

$$\bigl(\check{f}(hD_t)-A\bigr)e^{ih^{-1}tf(A)}=0, \tag{8.3.14}$$

$$\mathring{\partial} B e^{ih^{-1}tf(A)}=0 \tag{8.3.15}$$

where $\check{f}$ is an inverse function. Therefore its Schwartz kernel $U(x,y,t)$ satisfies problem (8.3.14)–(8.3.15) with respect to x and transposed problem with respect to y.

Note that due to assumptions (8.3.6)–(8.3.7) $e^{ih^{-1}tf(A)}Q$ is a Fourier integral operator with the symplectomorphism Ψ_t provided Q is h-pseudodifferential operator with the symbol supported in $\mathcal{U}$. Further, due to (8.3.8), (8.3.13) $\Psi_1=I$ and therefore $e^{ih^{-1}f(A)}Q$ is h-pseudodifferential operator. Therefore, we arrive to

Proposition 8.3.1. *Let A be a Schrödinger operator with the scalar principal symbol $a(x,\xi)$ satisfying* (8.3.6)–(8.3.8) *and* (8.3.13)*. Then*

$$e^{ih^{-1}f(A)-i\kappa}\equiv e^{ih^{-1}\varepsilon L} \qquad \text{in } \mathcal{U} \tag{8.3.16}$$

with $\varepsilon=h$ and h-pseudodifferential operator L; here κ is Maslov's constant and the principal symbol ℓ of L is defined by

$$e^{i\ell}=\prod_{1\le k\le N} e^{i\ell_k}e^{i\ell'_k} \tag{8.3.17}$$

where ℓ_k corresponds to k-th segment (see Theorem 6.2.3) and ℓ'_k corresponds to the k-th reflection.

Example 8.3.2. Consider Schrödinger operator. Assume that at the reflection point $a(x,\xi)=\xi_1^2+a(x',\xi')$, $b=\xi_1+i\beta(\xi')$. Then

$$e^{i\ell'_k}=-\bigl((\tau-a')^{\frac12}-i\beta\bigr)^{-1}\bigl((\tau-a')^{\frac12}+\imath\beta\bigr) \tag{8.3.18}$$

with the right-hand expression calculated in the corresponding reflection point.

Taking $\beta=0$ or $\beta=\infty$ (formally) we get $\ell'_k=0$ and $\ell'_k=\pi$ for Neumann and Dirichlet boundary conditions respectively.

Then we can use all the local results of Section 6.2, assuming that (8.3.16) holds with $h^l \le \varepsilon \le h$ and derive local spectral asymptotics with the same precision (up to $O(h^{2-d})$) as there.

Corollary 8.3.3. *(i) Let conditions of Proposition 8.3.1 be fulfilled. Then asymptotics with the remainder $o(h^{1-d})$ holds provided*

$$\mu_\tau\bigl(\{(x,\xi)\in \Sigma_\tau, \nabla_{\Sigma_\tau}\ell(x,\xi)=0\}\bigr)=0 \tag{8.3.19}$$

where ∇_{Σ_τ} means a gradient along Σ_τ.

(ii) Asymptotics with the remainder $O(h^{1-d+\delta})$ with small exponent $\delta>0$ holds provided

$$\mu_\tau\bigl(\{(x,\xi)\in \Sigma_\tau, |\nabla'\ell(x,\xi)|\le \varepsilon\}\bigr)=o(\varepsilon^{\delta'}) \tag{8.3.20}$$

with the small exponent $\delta'>0$.

(iii) Furthermore asymptotics with the remainder $o(h^{1-d})$ holds as (8.3.6)–(8.3.7) *are replaced by their non-uniform versions*

$$|\phi(x)|+|\{a,\phi\}(x,\xi)|>0 \qquad \forall t\ \ \forall (x,\xi)\in \Phi_t(\mathcal{U}\cap\Sigma_\tau\setminus\Lambda_\tau), \tag{8.3.7}'$$

where $\mu_\tau(\Lambda_\tau)=0$.

We leave to the reader to formulate statement similar to Statement (iii) but with the remainder estimate $O(h^{1-d+\delta})$.

Usually our purpose is the asymptotics with $Q_{1x}=\psi_1(x)$, $Q_{2y}=\psi_2(y)$ where ψ_j are smooth functions but not vanishing near the ∂X.

Corollary 8.3.4. *Asymptotics with the remainder estimate $o(h^{1-d})$ holds provided conditions* (8.3.6), (8.3.7)′, (8.3.8) *and* (8.3.19) *are fulfilled in $\mathcal{U}=T^*X$, $Q_j=\psi_j\in \mathscr{C}^\infty(\bar X)$ compactly supported.*

Proof. Due to corollary 8.3.3(iii) a contribution of the zone $\{x\colon x_1>\varepsilon\}$ to the remainder is $o_\varepsilon(h^{1-d})$ while a contribution of the zone $\{x\colon x_1\le\varepsilon\}$ to the remainder does not exceed $O(\varepsilon h^{1-d})$ as $\varepsilon\ge h$. □

These arguments could be improved to $\varepsilon=h^\delta$ and the remainder estimate could be improved to $O(h^{1-d+\delta})$. We leave both precise statements and precise arguments to the reader. Our goal is to derive even more sharp remainder estimate.

Asymptotics near Boundary

Let us consider $X = \{x\colon x_1 > 0\}$ and $\mathcal{U}$ open subset in $T^*\mathbb{R}^{d-1}_{x'} \times [0,\varepsilon]_{x_1} \times \mathbb{R}_\tau$ where $\varepsilon > 0$ is a very small constant. We are interested in

$$F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\,\mathsf{Tr}\big(e^{ih^{-1}tf(A)}Q\big) \tag{8.3.21}$$

with $Q = Q(x, hD'_x, hD_t)$ with symbol supported in $\mathcal{U}$; let us rewrite it as

$$F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\,\mathsf{Tr}\big(e^{ih^{-1}(t-\bar{t})f(A)}Q'e^{ih^{-1}\bar{t}f(A)}\big) = F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\,\mathsf{Tr}\big(e^{ih^{-1}tf(A)}Q'\big)$$

with $Q' = e^{ih^{-1}\bar{t}f(A)}Qe^{-ih^{-1}\bar{t}f(A)}$.

Note that if (8.3.6), (8.3.7) are fulfilled, $\varepsilon > 0$ and $\bar{t} \ge C\varepsilon$ are small enough then $Q' = Q'(x, hD_x, hD_t)$ is h-pseudodifferential operator with the symbol supported in $\{\epsilon'\bar{t} \le x_1 \le C'\bar{t}\}$ and we can rewrite

$$Q' = Q''(x, hD_x) + Q'''(x, hD_x, hD_t)\big(hD_t - f(A)\big);$$

therefore we can rewrite (8.3.21) in the same form but with Q replaced by Q''.

Now we can apply all the arguments of the previous Subsubsection *8.3.2.2 Asymptotics near Boundary* and of Section 6.2 and derive asymptotics with the remainder estimate as sharp as $O(h^{2-d})$ provided conditions (8.3.6)–(8.3.8) are fulfilled in the full measure as well as corresponding conditions of Section 6.2 to ℓ. Here as usual we lift the points of $(y', \eta', \tau) \in T^*\partial X$ to $(y', \eta^\pm) \in \Sigma_\tau$.

So, we need to analyze only a near tangent zone $\{x\colon x_1 \le \varepsilon, |\{a, x_1\}| \le \varepsilon\}$.

Let us assume that conditions (8.3.6), (8.3.7)$'$ and (8.3.8) are fulfilled for all $(x,\xi) \in T^*X : \tau_1 \le a(x,\xi) \le \tau_2$ with $\tau_1 < \tau_2$. In all examples we know (see Subsubsection *8.2.2.3 Analysis in the "Elliptic" Zone* below ∂X is *bicharacteristically flat*

$$x_1 = 0, \tau_1 \le a'(x,\xi') \le \tau_2 \implies a'_{x_1}(x,\xi) = 0; \tag{8.3.22}$$

so we assume in this section that this is the case.

Then (8.3.8) and (8.3.22) imply that

(8.3.23) All solutions of equation

$$z'' + b(\Psi_t(x',\xi'))z = 0 \qquad \text{with} \quad b(x',\xi) = \frac{1}{2}a'_{x_1x_1}(0,x',\xi') \tag{8.3.24}$$

are T_0-periodic for any $(x',\xi') \in T^*\partial X$, $\tau_1 \le a'(x,\xi') \le \tau_2$.

Therefore (8.3.8) and (8.3.22) imply that

$$\rho(x,\xi)\circ \Psi_t \asymp \rho \quad \text{with} \quad \rho = x_1 + |\{a, x_1\}| \quad \text{as} \quad \tau_1 \le a(x,\xi) \le \tau_2. \tag{8.3.25}$$

Consider zone $\mathcal{U}_\varepsilon = \{(x,\xi)\colon \rho(x,\xi) \asymp \varepsilon\}$. Blowing up $(x_1,\xi_1) \to \varepsilon^{-1}(x_1,\xi_1)$ we can prove easily that after this

$$\Psi_t(x,\xi) = \bigl(\Psi'_{t,\varepsilon}(x,\xi),\ \Psi''_{(x',\xi',t),\varepsilon}(x_1,\xi_1)\bigr), \tag{8.3.26}$$

with

$$\Psi'_{t,\varepsilon}(x,\xi) \sim \Psi'_{t,0}(x',\xi') + \sum_{n\ge 2} \varepsilon^n \Psi'_{t,(n)}(x,\xi) \tag{8.3.27}$$

and

$$\Psi''_{(x',\xi',t),\varepsilon}(x_1,\xi_1) \sim \sum_{n\ge 1} \varepsilon^n \Psi''_{(x',\xi',t),(n)}(x_1,\xi_1) \tag{8.3.28}$$

where $\Psi'_{t,0}$ is the Hamiltonian flow on $T^*\partial X$ and $\Psi''_{t,(1)}$ is the linearized with respect to (x_1,ξ_1) billiard flow (described by (8.3.24)). One can prove easily that $\Psi'_{t,(n)}$ and $\Psi''_{(x',\xi',t),(n)}$ are uniformly smooth.

Then in the blown-up coordinates (8.3.16) holds provided $\varepsilon \ge h^{\frac12-\delta}$ because $\hbar = \varepsilon^{-2}h$ and then we can apply all the previous arguments and derive asymptotics; the remainder estimate is as sharp as $O(h^{2-d})$ provided (in the original coordinates)

$$|\nabla_{(x,\xi)}\ell(x,\xi)| \ge \epsilon_0 \qquad \text{as} \quad x_1 \asymp \rho(x,\xi) \le \epsilon_1; \tag{8.3.29}$$

$x_1 \asymp \rho(x,\xi)$ means exactly that $x_1 \ge \epsilon|\xi_1|$.

Therefore we arrive to

Proposition 8.3.5. *Let A be a Schrödinger operator with the principal symbol $a(x,\xi)$ satisfying* (8.3.6)–(8.3.8) *and* (8.3.22)–(8.3.23). *Let the subprincipal symbol and the boundary condition be such that* (8.3.29) *is fulfilled. All these conditions are supposed to be fulfilled in $\{(x,\xi)\colon \rho(x,\xi)\le \epsilon_0\}$.*

Then the contribution of the zone $\{(x,\xi)\colon h^{\frac12-\delta} \le \rho(x,\xi) \le \epsilon_2\}$ to the remainder is $O(h^{2-d})$.

Since the contribution of the zone $\{(x,\xi)\colon \rho(x,\xi)\le\varepsilon\}$ to the remainder does not exceed $C\varepsilon^2 h^{1-d}$ and we can take $\varepsilon = h^{\frac12-\delta}$ we conclude that the contribution of the zone $\{(x,\xi)\colon \rho(x,\xi)\le\epsilon_2\}$ to the remainder is $O(h^{2-d-\delta})$. One can also estimate this way the contribution of the subperiodic trajectories. Thus we arrive (details are left to the reader) to

Theorem 8.3.6. *Let A be a Schrödinger operator with the principal symbol $a(x,\xi)$ satisfying* (8.3.6)–(8.3.8) *and* (8.3.22)–(8.3.23)*. Let the subprincipal symbol and the boundary condition be such that* (8.3.29) *is fulfilled. All these conditions are supposed to be fulfilled in the zone $\{(x,\xi)\colon \rho(x,\xi)\le \epsilon_0\}$.*

Then contribution of the zone $\{(x,\xi)\colon \rho(x,\xi)\le \epsilon_2\}$ to the remainder is $O(h^{2-d-\delta})$ while its contribution to the principal part of the asymptotics is given by the standard two term Weyl formula plus a correction term constructed according to Section 6.3 for symbol ℓ.

Problem 8.3.7. Recover $O(h^{2-d})$ remainder estimate. This should not be extremely hard especially if there are no subperiodic trajectories but definitely worth of publishing.

Example 8.3.8. Consider Laplacian $h^2\Delta$ on the standard hemisphere $\mathbb{S}^d_+ := \{x\colon |x|=1, x_1>0\}$ in $\mathbb{R}^{d+1}$ or harmonic oscillator $h^2\Delta+|x|^2$ on the standard half-space $\mathbb{R}^d_+ = \{x\colon x_1>0\}$.

(i) Consider a boundary operator of Example 8.3.2. Then $N=2$ and $\ell(z,\tau)=\ell'(z,\tau)+\ell'(\varrho(z),\tau)$ where $z=(x',\xi')$, $\varrho(z)$ is the *antipodal point* and ℓ' is defined by (8.3.18). Then one can express conditions to ℓ as conditions to β; we leave exact statements to the reader.

(ii) Consider Dirichlet or Neumann boundary conditions. Then if a perturbation is hx_1 one can calculate easily that $\ell=\kappa\rho+O(\rho^2)$ where ρ is the incidence angle of trajectory and $\kappa>0$. Then condition (8.3.29) is fulfilled.

Discussion

Unfortunately almost nothing is known about manifolds with the boundaries and all billiards closed; we are discussing geodesic billiards but one can ask the same questions about Hamiltonian billiards associated with the Schrödinger operator; in the last case the phase space S^*X is replaced by the portion of the phase space $\{\tau_1\le a(x,\xi)\le\tau_2\}$. We assume that the phase space is connected.

Example 8.3.9. Consider the standard Laplacian $h^2\Delta$ on one of the following manifolds:

(i) The standard hemisphere $\mathbb{S}^d_+ = \{x\in\mathbb{S}^d\,|x|=1, x_1>0\}$ is the most obvious example.

(ii) Starting from this let $\mathcal{X}$ be a connected closed manifold with all geodesics periodic and let G be a finite group of isometries of X. Then $\{x\colon j(x)=x\}$ are surfaces in $\mathcal{X}$ for any $j\in G$ (except $j=I$); all this surfaces together break $\mathcal{X}$ into several cells. Let one of them be X. Unless $\#G=2$ ∂X can have edges and other singularities but dealing with them is easy; see Sections 11.2 and 11.3.

(iii) In particular, consider Zoll-Tannery manifolds with the rotational symmetry $\mathcal{X}:=\{x=(x_1,x')\in [-L_1,L_2]\times \mathbb{S}^{d-1}\}$ with $g^{11}=1$, $g^{jk}=f(x_1)^2\delta_{jk}$ for $j=1,\dots,d$, $k=2,\dots,d$ and function f such that all geodesics are periodic[8)].

Then we can use $j(x)=(x_1,j'(x'))$ where $j'\in G'$ where G' is a finite group of isometries of $\mathbb{S}^{d-1}$.

(iv) Further, in the framework of (iii) if f is an even function[9)], we can also use $j(x)=(-x_1,x')$ alone or in conjugation with G'.

Example 8.3.10. Consider Schrödinger operator $h^2\Delta+V(|x|)$ where

(i) We consider harmonic oscillator $V(r)=r^2$.

(ii) We consider Coulomb Hamiltonian $V(r)=-r^{-1}$ on the negative energy levels.

Let G be a finite group of the isometries of $\mathbb{S}^{d-1}$. These isometries are extended to rotational isometries of $\mathbb{R}^d$ and $\{x\colon j(x)=x\}$ are surfaces in $\mathbb{R}^d$ for any $j\in\Gamma$ (except $j=I$); all this surfaces together break $\mathbb{R}^d$ into several cells. Let one of them be X. Unless $\#G=2$ ∂X can have edges and other singularities but dealing with them is easy; see Sections 11.2 and 11.3.

Problem 8.3.11. Either prove that if all billiards are closed then ∂X must be bicharacteristically flat or to construct counter-example

(i) For Laplacians only.

[8)] These manifolds are isometric (up to a factor) to a sphere $\mathbb{S}^d$ with the metrics $(r+h(\cos(s)))^2\,ds^2+\sin^2(s)\,d\theta^2$ with $s\in[0,\pi]$, $r=p/q$, $p,q\in\mathbb{N}$, $\gcd(p,q)=1$ and odd function $h:(-1,1)\to(-r,r)$. Then the length of equator is 2π, the length of meridian $2\pi r$ and the length of general geodesics $2\pi p$. See A. Besse [1], Theorem 4.13.

[9)] Which happens only as $h=0$ in footnote [8)].

(ii) For general Schrödinger operators without magnetic field.

(iii) For general Schrödinger operators with magnetic field.

8.3.3 Branching Hamiltonian Flow with "Scattering"

Let us consider two manifolds X_1 and X_2 glued along the connected component Y of the boundary. We consider Schrödinger operators A_j on X_j and these operators are intertwined through the boundary conditions. We assume that Hamiltonian flows have simple (no branching) reflections on each of them, so branching comes from "reflection-refraction". Further we are interested in the case when Hamiltonian flow on X_1 is periodic while on X_2 majority of trajectories are not periodic and, moreover, when majority of the branching billiards in $X_1 \cup X_2$ containing trajectories in X_2 are not periodic.

Analysis in X_2

Since we want to consider examples in which we can indeed analyze the long-term behavior of billiards rather than just postulate it, we will make rather restrictive assumptions about billiards. First we assume that billiard flow on X_1 satisfy all assumptions of the previous Subsection 8.3.2; in particular

$$\Phi_{1,\tau}(z)^N = I \text{ [10]}. \tag{8.3.30}$$

We also assume that $\Phi_{1,\tau}$ and $\Phi_{2,\tau}$ commute

$$\Phi_{1,\tau} \circ \Phi_{2,\tau} = \Phi_{2,\tau} \circ \Phi_{1,\tau}. \tag{8.3.31}$$

Then for points of $\Sigma_{2,\tau}$ periodicity properties of the branching Hamiltonian flow with reflections Ψ_t coincide with those of $\Psi_{2,t}$,[11].

Now we need to impose condition to the boundary operator in addition to $\{A, B\}$ being self-adjoint. Namely, consider a point $z = (x', \xi') \in T^*Y$,

[10] We define $\Phi_{j,\tau}$ in the following way: first, we lift $z \in T^*Y$ to $z \in T^*X_j|_Y \cap \Sigma_{j,\tau}$ with $\{a_j, x_1\}(z) > 0$, then launch a trajectory forward until it hits the boundary at $(y', \eta) \in T^*X_j|_Y$ and, finally, project it back to T^*Y.

[11] Indeed, it is sufficient to analyze such properties of $\Phi_{2,\tau}$ and a corresponding branching map Φ_τ which is $\Phi_{2,\tau}^k \Phi_{2,\tau}^l$ due to (8.3.30), (8.3.31). But if $\Phi_{2,\tau}^k \Phi_{2,\tau}^l(z) = z$ then $\Phi_{2,\tau}^{rl}(z) = \Phi_{2,\tau}^{rk} \Phi_{2,\tau}^{rl}(z) = z$.

and consider an auxiliary problem

$$a_j(x', D_1, \xi')u_j = 0 \qquad j = 1, 2, \tag{8.3.32}$$

$$\eth b(x', D_1, \xi')u = 0 \tag{8.3.33}$$

(where $u = (u_1, u_2)$) and consider solutions which are combinations of the exponents $e^{i\lambda_j x_1}$ where for each j either $\operatorname{Im}\lambda_j > 0$ or $\operatorname{Im}\lambda_j = 0$ and $\{a_j, x_1\}(x', \lambda_j, \xi') > 0$ [12]. Denote by Λ the set of points for which such non-trivial solutions exist. We assume that

$$\operatorname{mes}_{T^*Y}(\Lambda) = 0. \tag{8.3.34}$$

Then we arrive to the following

Proposition 8.3.12. *Let in the described setup conditions* (8.3.30), (8.3.31) *and* (8.3.34) *be fulfilled.*

Let Q_1, Q_2 be h-pseudodifferential operators with the symbols supported in T^*X_2 and

$$\mu_{2,\tau}(\Pi_{2,\tau} \cap \operatorname{supp}(q_1) \cap \operatorname{supp}(q_2)) = 0 \tag{8.3.35}$$

where $\Pi_{2,\tau}$ is the set of point $(y, \eta) \in \Sigma_{2,\tau}$ periodic with respect to $\Psi_{2,t}$.

Then for $\Gamma(Q_{1x}e(., ., \tau)\,{}^tQ_{1y})$ the standard Weyl two-term asymptotics holds with the remainder estimate $o(h^{1-d})$.

Remark 8.3.13. (i) Note that

$$\mu_{j,\tau}(\Lambda_{j,\tau}) = 0 \tag{8.3.36}$$

where $\Lambda_{j,\tau} = \Lambda'_{j,\tau} \cup \Lambda''_{j,\tau}$, $\Lambda'_{j,\tau}$ is the set of dead-end points of billiard (not generalized billiard) flow and $\Lambda''_{j,\tau}$ is the set of points $(y, \eta) \in \Sigma_{j,\tau}$ such that $\iota_j \Psi_{j,t}(y, \eta) \in \Xi_{3-j,\tau}$ where $\Xi_{k,\tau} = \iota_k\{(x, \xi) \in \Sigma_{k,\tau}, \{a_k, x_1\} = 0\}$.

(ii) Note that the grows properties of the branching Hamiltonian flow with reflections Ψ_t coincide with those of $\Psi_{2,t}$ as long as we ensure that along billiards we do not approach to glancing rays on X_1:

$$\{a_1, x_1\}(x, \xi) \ge h^{\delta_1} \qquad \forall (x, \xi) \in \iota_1^{-1}\iota_2 \Psi_{2,t}(y, \eta) \cap \Sigma_{1,\tau} \tag{8.3.37}$$

$$\forall (y, \eta) \in \operatorname{supp}(q_2) \ \ \forall t : \pm t \in [0, T] \ \ \Psi_{2,t}(y, \eta) \in T^*X_2|_Y$$

[12] As we assume that $x_1 > 0$ on both X_1 and X_2 and $x_1 = 0$ on Y, it means that we consider solutions which either are of boundary-layer type or outgoing.

where $T = T(h)$. Then in the framework of Section 7.4 one can recover similar results: namely that two-term Weyl asymptotics holds with the remainder estimate $O(T(h)^{-1}h^{1-d})$ which is usually $O(h^{1-d}|\log h|^{-1})$ or $O(h^{1-d+\delta})$ (depending on the growth and non-periodicity conditions to $\Psi_{2,t}$. Exact statement and proof are left to the reader (which is a relatively easy problem).

(iii) In Statement (ii) we need also to assume a more sharp version of (8.3.34): namely if we consider approximate solutions to (8.3.32)–(8.3.33) with precision ε we get set $\Lambda_{\tau,\varepsilon}$ and we need to impose either condition $\mathsf{mes}(\Lambda_{\tau,\varepsilon}) = o(\varepsilon^{\delta})$ or condition $\mathsf{mes}(\Lambda_{\tau,\varepsilon}) = o(|\log\varepsilon|^{-1})$ as $\varepsilon \to +0$.

(iv) In Subsubsection *7.4.3.6 Non-Periodicity Condition for Branching Billiards* we did not consider points $z \in T^*Y$ where some of operators a_j are elliptic on $\iota^{-1}z$ rather than hyperbolic. If we want to consider such points we need to assume condition (8.3.34) or more sharp version of it described in Statement (iii).

(v) Property (8.3.37) is guaranteed if either a_2 is cylindrically symmetric on T^*X_2 or if there no complete internal reflection for billiards from X_2 at all:

$$|\{a_1, x_1\}(x,\xi)| \ge \epsilon|\{a_2, x_1\}(x,\eta)|' \tag{8.3.38}$$
$$\forall (x,\xi) \in T^*X_1|_Y \cap \Sigma_{1,\tau}\ \forall (x,\eta) \in T^*X_2|_Y \cap \Sigma_{2,\tau} : \iota_1(x,\xi) = \iota_2(x,\eta).$$

Analysis in X_1

However if operators Q_1 and Q_2 have symbols supported in X_1 situation is very different: trajectories of a_1 are periodic but the typical closed branching billiard is the one which does not contain segments of Hamiltonian trajectories of a_2. More precisely, due to conditions

$$\mu_{2,\tau}(\Pi_{2,\tau}) = 0 \tag{8.3.39}$$

and (8.3.36) we conclude that

$$\mu_{1,\tau}(\Pi'_{1,\tau}) = 0 \tag{8.3.40}$$

where $\Pi'_{1,\tau}$ is the set of points $z \in \Sigma_{1,\tau}$ such that there exists a billiard trajectory of Ψ_t starting and ending in z and which is not entirely billiard of $\Psi_{1,t}$.

Then for arbitrarily large $T > 0$ and arbitrarily small $\varepsilon > 0$ there exists a set $\mathcal{U} = \mathcal{U}_{T,\varepsilon} \subset T^*X$ such that

$$\mu_{1,\tau}(\Sigma_{1,\tau} \setminus \mathcal{U}) \le \varepsilon, \tag{8.3.41}$$

$$\operatorname{dist}(\mathcal{U}, \Pi'_{1,\tau,T} \cup \Lambda_{1,\tau,T}) \ge \gamma, \tag{8.3.42}$$

$$\operatorname{dist}(Y, \pi_x \mathcal{U}) \ge \gamma \tag{8.3.43}$$

with $\gamma = \gamma(T, \varepsilon) > 0$ were $\Pi'_{1,\tau,T}$ s the set of points $z \in \Sigma_{1,\tau}$ such that there exists a billiard trajectory of Ψ_t of the length not exceeding T, starting and ending in z and which is not entirely billiard of $\Psi_{1,t}$ and $\Lambda_{1,\tau,T}$ is the set of points $z \in \Sigma_{1,\tau}$ such that billiard trajectory of a_1 hits the boundary at point of $\Lambda_{2,T,\tau}$. As usual, these sets increase as T increases, their unions (with respect to T) coincide with $\Pi'_{1,\tau}$ and $\Lambda_{1,\tau}$ respectively and $\Lambda_{1,\tau,T}$ and $\Lambda_{1,\tau,T} \cap \Pi'_{1,\tau,T}$ are closed sets.

Therefore there exists operator $Q = Q_{T,\varepsilon}$ such that $\operatorname{supp}(q) \subset \mathcal{U}$ and

$$|\Gamma\big(Q_{1x} e(.,.,\tau)\, {}^t((I-Q)Q_2)_y\big) - \kappa'_0 h^{-d} - \kappa'_1 h^{1-d}| \le C_0 \varepsilon h^{1-d} \tag{8.3.44}$$

with $\kappa'_j = \kappa'_{j,Q_1,Q_2,Q}(\tau)$.

This estimate holds for any fixed τ satisfying (8.3.39). Therefore we need to consider $\Gamma\big(Q_{1x} e(.,.,\tau)\, {}^t Q_{2y}\big)$ with $\operatorname{supp}(q_2) \subset \mathcal{U}$.

We can assume without any loss of the generality that (8.3.42), (8.3.43) are fulfilled for all τ. Then for $\epsilon \le |t| \le T$

$$\Gamma\big(Q_{1x} U(.,.,t)\, {}^t Q_{2y}\big) \equiv \Gamma\big(Q_{1x} Z(.,.,t)\, {}^t Q_{2y}\big) \tag{8.3.45}$$

where as $\pm t > 0$ $Z(x,y,t)$ is the Schwartz kernel of "the approximate propagation with the scattering semigroup" $\boldsymbol{Z}(t)$ constructed in the following way (for a sake of simplicity in notations we consider only $t > 0$:

(i) We represent $Q_2 = Q_{2,1} + ... + Q_{2,N}$ where symbols $Q_{2,\nu}$ have small supports;

(ii) For each ν we select $0 = t_{0,\nu} < ... < t_{M,\nu} = t$ in such a way that for any $z \in \operatorname{supp}(q_{2,\nu})$ $\Psi_{t'}(z)$ is disjoint from Y as $t' = t_{j,\nu}$ and $\Psi_{t'}(z)$ hits Y no more than once as $t_{j,\nu} \le t' \le t_{j+1,\nu}$;

(iii) We set

$$\boldsymbol{Z}(t) Q_{2,\nu} = \Big(\prod_{0 \le j \le M-1} \psi e^{ih^{-1}(t_{j+1,\nu} - t_{j,\nu}) f(A)} \Big) \cdot Q_{2,\nu} \tag{8.3.46}$$

where $\psi \in \mathscr{C}^\infty$ is supported in $\{x \in X_1, \mathsf{dist}(x, Y) \ge \gamma'\}$ and equals 1 in $\{x \in X_1, \mathsf{dist}(x, Y) \ge 2\gamma'\}$.

Then

$$Z(t_1 + t_2)Q_2 \equiv Z(t_2)Z(t_1)Q_2 \qquad \text{as} \quad \pm t_1 > 0, \pm t_2 > 0 \tag{8.3.47}$$

and

$$Z(t)^* \equiv Z(-t) \tag{8.3.48}$$

and due to periodicity of $\Psi_{1,t}$ with period T_0 $Z(\pm T_0)$ are h-pseudodifferential operators.

Remark 8.3.14. In contrast to what we had before they are not necessarily unitary because *reflection coefficients* are not unitary anymore. More precisely,

(i) If $\Psi_{1,t}$ hits $T^*X|_Y$ at points (x', ξ) with $(x', \xi') \notin \iota_2 \Sigma_{2,\tau}$ [13)] the reflection coefficient $\varkappa_{11}(x', \xi', \tau)$ still satisfies $|\varkappa_{11}(x', \xi', \tau)| = 1$.

(ii) However if $\Psi_{1,t}$ hits $T^*X|_Y$ at points (x', ξ) with $(x', \xi') \in \iota_2 \Sigma_{2,\tau}$ then the reflection-refraction matrix $\varkappa(x', \xi', \tau) = \big(\varkappa_{jk}(x', \xi', \tau)\big)_{j,k=1,2}$ is unitary but the reflection coefficient $\varkappa_{11}(x', \xi', \tau)$ satisfies only $|\varkappa_{11}(x', \xi', \tau)| \le 1$ and the equality means exactly that $\varkappa_{12}(x', \xi', \tau) = \varkappa_{21}(x', \xi', \tau) = 0$ (then $|\varkappa_{22}(x', \xi', \tau)| = 1$ as well).

So the principal symbol of $Z(T_0)$ is the product of $e^{i\ell_0(x,\xi)}$ where $\ell_0(x, \xi)$ is given by the usual formula for manifolds without boundary (but with trajectories replaced by billiards) and also of reflection coefficients coefficients in the point of reflection. If the reflection coefficients do not vanish we can rewrite the answer in the form

$$Z(T_0) \equiv e^{i\varepsilon h^{-1} L} \tag{8.3.49}$$

with h-pseudodifferential operator L, $L + L^* \le 0$ and $\varepsilon = h$ (but in calculations below we are not assuming this).

We will use this formula even if the coefficients vanish: in this case we simply formally allow $\mathsf{Im}\, \ell = +\infty$.

[13)] I.e. at the point of the complete internal reflection.

Then as $\bar{\chi} \in \mathscr{C}_0^\infty[\epsilon - 1, 1 - \epsilon]$

$$F_{t\to h^{-1}\tau}\bar{\chi}_{T_0}(t - nT_0)\Gamma\big(Q_{1x}Z(.,.,t)\,{}^tQ_{2y}\big) = h^{1-d}J(h,\varepsilon,n,\tau)\cdot\widehat{\bar{\chi}}\big(\frac{\tau}{h}\big) + O\big(h^{2-d}\big), \tag{8.3.50}$$

with

$$J(h,\varepsilon,n,\tau) = (2\pi)^{1-d}\int_{\Sigma_{1,\tau}} e^{ih^{-1}((\varepsilon\,\mathrm{Re}\,\ell-\tau)n+\varepsilon\,\mathrm{Im}\,\ell|n|)}\,d\mu_{1,\tau}. \tag{8.3.51}$$

We can see easily that

(8.3.52) $J(h,\varepsilon,n,\tau) = o(1)$ as $n\to\infty$ provided

$$\mu_\tau\big(\big\{(x,\xi)\in\Sigma_\tau:\ \mathrm{Im}\,\ell(x,\xi) = \nabla\,\mathrm{Re}\,\ell(x,\xi) = 0\big\}\big) = 0. \tag{8.3.53}$$

On the other hand, note that

$$\sum_{n\in\mathbb{Z}\setminus 0} e^{ih^{-1}(n\alpha-|n|\beta)} = \frac{2e^{-\beta}\cos\alpha - 2e^{-2\beta}}{1 - 2e^{-\beta}\cos\alpha + e^{-2\beta}} \qquad \text{as}\ \ \beta > 0 \tag{8.3.54}$$

and formally we can extend this for $\beta = 0$ as well.

Then after summation with respect to n for $\beta = 0$ we get exactly $\partial_\alpha\Upsilon(\alpha)$ with Υ defined by (6.2.68) and for $\beta > 0$ we get that the expression (8.3.54) is equal to $\partial_\beta\Upsilon *_\alpha (2\pi)^{-1}G(\alpha,\beta)$ where $G(\alpha,\beta) = 2\beta\big(\alpha^2+\beta^2\big)^{-1}$ and as usual $*_\alpha$ means a convolution with respect to α.

Note that

(8.3.55) Function

$$\Upsilon(\alpha,\beta) \coloneqq \Upsilon *_\alpha G(\alpha,\beta) \tag{8.3.56}$$

is harmonic function as $\beta > 0$, coincides with $\Upsilon(\alpha)$ as $\beta = 0$, is $o(1)$ as $\beta\to+\infty$ and is periodic with respect to α.

Therefore taking in account results of this subsection we arrive to the following

Theorem 8.3.15. *Let in the described setup conditions* (8.3.30), (8.3.31), (8.3.34), (8.3.39) *and* (8.3.53) *be fulfilled.*

Then asymptotics

$$\mathsf{\Gamma e}(.,.,\tau) = \kappa_0(\tau)h^{-d}+ \Big(\kappa_1(\tau) + \int_{\Sigma_\tau} \Upsilon\big(h^{-1}(\varepsilon\,\mathsf{Re}\,\ell-\tau), -h^{-1}\varepsilon\,\mathsf{Im}\,\ell\big)\,d\mu_\tau\Big)\,d\mu_\tau\Big) + o(h^{1-d}) \tag{8.3.57}$$

holds.

Problem 8.3.16. Calculate all coefficients $\varkappa_{jk}$ for two Schrödinger operators A_1 and A_2.

We will solve this problem in the very special case:

Example 8.3.17. Assume that (at the given point $z \in T^*Y$) $a_j = c_j^2|\xi|^2$ and the boundary condition is

$$u_2 = \alpha u_1, \tag{8.3.58}$$

$$D_1 u_2 = -\beta D_1 u_1 \tag{8.3.59}$$

(recall that $x_1 > 0$ in both X_1, X_2; in more standard notations of $x_1 < 0$ in X_2 one needs to skip "$-$"). Then $\{A, B\}$ to be self-adjoint requires $\alpha\beta^\dagger = c_1^2 c_2^{-2}$. We do not consider gliding points since their measure is 0.

(i) Consider point ξ' with $c_1^2|\xi'|^2 < \tau < c_2^2|\xi'|^2$. One can prove easily that

$$\varkappa_{11}(\xi',\tau) = e^{2i\varphi} \tag{8.3.60}$$

with

$$\varphi(\xi',\tau) = \mathsf{arctan}\Big(|\beta|^{-2}c_2^{-2}c_1^2\big(c_2^2|\xi'|^2-\tau\big)^{\frac{1}{2}}\big(\tau - c_1^2|\xi'|\big)^{-\frac{1}{2}}\Big) \tag{8.3.61}$$

and therefore assumption (8.3.53) is fulfilled provided $c_1 \neq c_2$, c_j, α, β are symmetric (i.e. $c_j\varrho = c_j$) and the subprincipal symbol is 0. If $c_1 > c_2$ this case does not appear.

(ii) Consider point ξ' with $c_j^2|\xi'|^2 < \tau$ for both $j = 1, 2$. One can prove easily that

$$\varkappa_{11}(\xi',\tau) = \big(\omega-1\big)\big(\omega+1\big)^{-1} \tag{8.3.62}$$

with

$$\omega(\xi',\tau) = |\beta|^{-2}c_2^{-2}c_1^2\big(\tau - c_2^2|\xi'|^2\big)^{\frac{1}{2}}\big(\tau - c_1^2|\xi'|\big)^{-\frac{1}{2}} \tag{8.3.63}$$

and $|\varkappa_{11}| < 1$ so assumption (8.3.53) is fulfilled.

The following problems seem to be rather straightforward but not easy and worth publishing:

Problem 8.3.18. Under stronger conditions to $\Psi_{2,t}$ and ℓ (see (8.3.20)) prove remainder estimate $O(h^{1-d+\delta})$.

Problem 8.3.19. Prove the same results as Hamiltonian billiards of a_1 are assumed to be periodic only on one energy level τ rather than on neighboring levels.

8.3.4 Two Periodic Flows

Now we consider the case of both flows Ψ_{1t} and Ψ_{2t} generated by $f(a_1)$ and $f(a_2)$ both satisfying (8.3.31) and (8.3.30) which becomes

(8.3.64) $\Phi_{j,\tau}^{N_j} = I$ for $j = 1, 2$ where N_1 and N_2 are not necessarily equal.

Remark 8.3.20. (i) Here as in the previous Subsection 8.3.3 we can consider several manifolds attached to one another: X_j is a connected manifold, $\partial X_j = Y_j \cup Y_j'$ with disjoint $Y_j \cup Y_j' = \emptyset$ and Y_j' and Y_{j+1} are glued together ($j = 1, \dots, m$) while Y_1 and Y_m' may be or may be not or may be only partially glued together.

(ii) Further, we can consider cases when along (some part of) Y more than two manifolds are glued together etc

We leave such generalization to the reader.

Examples and Discussion

Let us start from examples:

Example 8.3.21. (i) In the framework of Example 8.3.9(ii) we again consider partition of $\mathcal{X}$ into cells and on each cell X_j we define operator as either Laplacian $h^2 c_j^2 \Delta$ or more generally as a Schrödinger operator $h^2 c_j^2 \Delta - E_j$.

(ii) In the framework of Example 8.3.9(iv) we consider $X_1 = \{(x_1, x_2) \in (-1, 0) \times (0, 2\pi)\}$ and $X_1 = \{(x_1, x_2) \in (0, 1) \times (0, 2\pi)\}$ and we glue them along $x_1 = 0$ identifying $(+0, x_2)$ with $(-0, x_2)$. Observe that $N_j = p_j$.

(iii) In Example 8.3.9(iv) with $p_1 = 1$ we have $N_1 = 1$ and we can glue it with anything else as (8.3.31) is fulfilled automatically then.

Example 8.3.22. Consider two Schrödinger operators in $\mathbb{R}^d_+ = \mathbb{R}^+ \times \mathbb{R}^{d-1}$

$$A_j = \frac{1}{2}\omega_j^2\big(h^2\Delta + |x|^2 - E_j\big) \tag{8.3.65}$$

intertwined through boundary conditions.

Our idea was to make all flows periodic with the common period. It works with Example 8.3.22 where $T_j = 2\pi\omega_j^{-2}$. Indeed, we want to find asymptotics of $\mathsf{N}_h^-(0)$ which is the maximal dimension of the *negative subspace* of the operator A which does not change if we replace A by $J^{-\frac{1}{2}}AJ^{-\frac{1}{2}}$ with the positive self-adjoint operator J. Picking up $J = J(x)$ equal ω_j^2 in X_j we arrive to the case of $\omega_j = 1$ and $T_j = 2\pi$. Therefore in this example one can make periods equal $T_1 = T_2$.

However this approach does not seem work with the Example 8.3.21 (unless some unnatural conditions to ω_j, E_j are imposed). The main obstacle here is that multiplying operator by $J^{-\frac{1}{2}}$ from both sides and calculating $f(A)$ do not play well together.

Reduction to the Boundary

First of all observe that the contribution to the remainder of the domain $\{z, \mathsf{dist}(z, T^*Y) \le \varepsilon_0\}$ does not exceed $C_0\epsilon_0^2 h^{1-d}$ and therefore one needs to consider the contribution of $\{z, \mathsf{dist}(z, T^*Y) \ge \varepsilon_0\}$ with arbitrarily small but fixed ε_0 [14)].

In this zone one can consider $U(x, y, t)$ as the solution of the Cauchy problem with respect to x_1 (or y_1) with the data at $\{x_1 = 0\}$ (or $\{y_1 = 0\}$). Rewriting therefore $U = R_x U\, {}^tR_y$ where R is an operator resolving this Cauchy problem is given by an oscillatory integral we can rewrite

$$\Gamma\big(U(.,.,t)\, {}^tQ_y\big) \equiv \Gamma'\big(\mathcal{Q}(x', hD'_x, hD_t, h)V\big) \tag{8.3.66}$$

with h-pseudodifferential operator R and $V = \eth_{x,m-1}\eth_{y,m-1}U$ the Cauchy data for U (assuming that m is an order of A).

One can see easily that as Q is an operator with the symbol supported in T^*X_j, the principal symbol of $\mathcal{Q}$ at (x', ξ, τ) is defined as an averaging of Q along $\Psi_{jt}(z_j)$ with $t \in [0, t_j(z_j)]$ where $z_j = \iota^{-1}(x', \xi') \cap \Sigma_{j\tau}$ and $t_j(z_j)$ is the time of the next hit of the boundary.

[14)] If our target is $o(h^{1-d})$ remainder estimate.

Then instead of continuous family of Fourier integral operators $e^{ih^{-1}tA}$ we can consider a discrete family $\mathcal{F}^n$ defined by the following way: consider $v_j = \mathfrak{d}_{m-1}u_j = (v_j^-, v_j^+)$ with $v_j^{\mp}$ corresponding to incoming and outgoing solutions.

We have two types of trajectories: those in $\Sigma_{j\tau}$ which hit $T^*X|_Y$ at points elliptic for $(a_{3-j} - \tau)$ where $j = 1, 2$ and those which hit $T^*X|_Y$ at points hyperbolic for $(a_k - \tau)$ for both $k = 1, 2$. The analysis of the former is of no different from what we have seen in the previous subsection: we just consider Ψ_{jt} and construct the (real-valued) symbol ℓ as long as we assume that $(x', \xi) \notin \Lambda$ where Λ is defined in the paragraph preceding (8.3.34).

The analysis of the latter is more interesting. Here as before we have a matrix of reflection-refraction $(\varkappa_{jk})_{j,k=1,2}$ which is a symbol defined on $\mathcal{U} \times (\tau - \varepsilon', \tau + \varepsilon')$ where $\mathcal{U}$ is a a zone described above.

We need to construct a transformation along trajectories matrix L but it will be of the different type. Consider generic point $z \in T^*Y$, and collection of $\{\Phi_{1,\tau}^j \Phi_{2,\tau}^k\}_{i=0,\dots,N_1-1;k=0,\dots N_2-1}$. Not all points here are necessarily distinct; let us numerate distinct points by greek indices: z_α with $\alpha \in \{1, \dots, N\}$ [15]. Let $\phi_j : \{1, \dots, N\} \to \{1, \dots, N\}$ be permutations: $\beta = \phi_j(\alpha) \iff z_\beta = \Phi_{j,\tau}(z_\alpha)$.

We consider $2N$-vectors $v_{j\alpha}$ with norms

$$\|v\| = \Big(\sum_{\alpha=1,\dots,N} \sum_{j=1,2} |v_{\alpha j}|^2 \cdot |\{a_j, x_1\}(z_\alpha)| \Big)^{\frac{1}{2}}. \tag{8.3.67}$$

Then we introduce a sparse matrix $2N \times 2N$-matrix L in the following way:

$$L_{\beta k, \alpha j} = |\{a_j, x_1\}(z_\beta)|^{-\frac{1}{2}} |\{a_j, x_1\}(z_\alpha)|^{\frac{1}{2}} e^{i\ell_{\alpha j}} \tag{8.3.68}$$

if $k = j$ and $\beta = \phi_j(\alpha)$ and 0 otherwise; here $\ell_{\alpha j}$ is an integral of the subprincipal symbol along trajectory of Ψ_{jt} from z_α to z_β. Obviously matrix L is unitary[16].

Finally let us consider a matrix $M = \tilde{\varkappa} L$ where $\tilde{\varkappa}$ is a matrix κ raised to $2N \times 2N$-matrix: $\tilde{\varkappa}_{\beta k, \alpha j} = \kappa_{jk}(z_\alpha)$ as $\beta = \alpha$ and 0 otherwise. Matrix M shows how data on Y is transformed after a single "step" (propagation followed by reflection-refraction). One can see easily that

(8.3.69) Matrices $\tilde{\varkappa}$ and M are unitary[16].

[15] Then N divides $N_1 N_2$ and is divisible by N_1 and N_2.

[16] In the norm (8.3.67).

Analysis of the Evolution

One can prove easily that modulo $O_T(h^{2-d})$

$$(8.3.70)\quad F_{t\to h^{-1}\tau}\chi_T(t)\Gamma'\big(\mathcal{Q}(x', hD'_x, hD_t, h)V\big) \equiv$$
$$(2\pi h)^{1-d}\chi_T(T_{j_1}+\dots+T_{j_K})\iint \sum_{K\neq 1}\ \sum_{(j_1,\dots,j_K)\in\{1,2\}^K}\ \sum_{(\alpha_1,\dots,\alpha_K)\in\{1,\dots,N\}^K}$$
$$M_{\alpha_1 j_1,\alpha_2 j_2}M_{\alpha_2 j_2,\alpha_3 j_3}\cdots M_{\alpha_{K-1}j_{K-1},\alpha_K j_K}e^{-ih^{-1}\tau(T_{j_1}+\dots+T_{j_N})}\mathcal{Q}_{\alpha_K j_K,\alpha_1 j_1}\,dx'd\xi'$$

where $\chi\in\mathscr{C}_0^\infty$ is supported in $[\frac12,1]$ and symbols M_{jk} and $\mathcal{Q}$ and T_j are calculated at (x',ξ',τ) [17] and since we consider only trajectories which are periodic on the energy levels (close to) τ in this sum $\mathcal{Q}_{\alpha_K j_K,\alpha_1 j_1}=0$ unless $\alpha_K=\alpha_1$.

One can rewrite terms with equal K as

$$(2\pi h)^{1-d}\int \hat\chi(\lambda)e^{iT^{-1}\lambda(T_{j_1}+\dots+T_{j_K})}\iint \sum_{j=(j_1,\dots,j_K)\in\{1,2\}^K}\ \sum_{(\alpha_1,\dots,\alpha_K)\in\{1,\dots,N\}^K}$$
$$M_{\alpha_1 j_1,\alpha_2 j_2}M_{\alpha_2 j_2,\alpha_3 j_3}\cdots M_{\alpha_{K-1}j_{K-1},\alpha_K j_K}e^{-ih^{-1}\tau(T_{j_1}+\dots+T_{j_K})}\mathcal{Q}_{\alpha_K j_K,\alpha_1 j_1}\,dx'd\xi'\,d\lambda$$

which in turn equals

$$(8.3.71)\qquad (2\pi h)^{1-d}\int\hat\chi(\lambda)\iint \mathsf{tr}\big(S(\lambda,\tau,x',\xi')^K\mathcal{Q}\big)\,dx'd\xi'\,d\lambda$$

where S is $2N\times 2N$ unitary [16] matrix

$$(8.3.72)\qquad S(\lambda T^{-1},\tau,x',\xi')=\big(e^{i(\lambda T^{-1}+\tau h^{-1})T_j}M_{\beta k,\alpha_j}\big)_{\beta k,\alpha j}.$$

Consider eigenvalues of this matrix; as $T\to\infty$ they tend to eigenvalues of the same matrix with $\lambda=0$:

$$(8.3.73)\qquad S(0,\tau,x',\xi')=\big(e^{i\tau h^{-1}T_j}M_{jk}\big)_{j,k=0,\dots,L-1}.$$

Therefore if

$$(8.3.74)\qquad \mathsf{mes}\big(\big\{(x',\xi'):\rho\in\mathsf{Spec}\big(S(0,0,x',\xi')\big)\big\}\big)=0)\qquad \forall\rho\in\mathbb{R}$$

[17] Where $T_j=T_j^*(\tau)/N_j$ is the time to run one leg and T_j^* is a full period.

then this term (8.3.73) is $o(h^{1-d})$ and therefore we estimated expression (8.3.70) by $o(Th^{1-d})$ (as $\tau = o(1)$) which in the end of the day returns remainder estimate $o(h^{1-d})$ with the Tauberian main part.

Consider correction to the main part; so we integrate (8.3.70) with $\chi = 1$ from $\tau = -\infty$ to $\tau = \tau$ resulting in (after multiplication by h^{-1} and modulo $o(h^{1-d})$) after taking trace we get

$$\begin{aligned}(8.3.75)\quad \Omega(\tau) \coloneqq (2\pi h)^{1-d} \iint \sum_{K\neq 1} \sum_{j=(j_1,\dots,j_K)\in\{1,2\}^K} \sum_{(\alpha_1,\dots,\alpha_K)\in\{1,\dots,N\}^K} \\ (T_{j_1}+\dots+T_{j_K})^{-1} e^{-ih^{-1}\tau(T_{j_1}+\dots+T_{j_K})} \\ \times \mathsf{tr}\big(M_{\alpha_1 j_1,\alpha_2 j_2} M_{\alpha_2 j_2,\alpha_3 j_3}\cdots M_{\alpha_{K-1} j_{K-1},\alpha_K j_K}\mathcal{Q}_{\alpha_K j_K,\alpha_1 j_1}\, dx'd\xi'\big).\end{aligned}$$

Therefore we have proven

Theorem 8.3.23. *Consider two Schrödinger operators A_1 and A_2 with all periodic trajectories on levels close to τ, satisfying* (8.3.30) *and* (8.3.31). *Further, let* (8.3.34) *and* (8.3.74) *be fulfilled. Then asymptotics*

$$(8.3.76)\qquad \mathsf{N}_h(\tau) = \kappa_0(\tau)h^{-d} + \big(\kappa_1(\tau)+\Omega(\tau)\big)h^{1-d} + o(h^{1-d})$$

holds as $h\to +0$ and $\tau = o(1)$ with the standard coefficients κ_0, κ_1 and $\Omega(\tau)$ defined by (8.3.75).

Example 8.3.24. Consider Example 8.3.17 in the new conditions to Hamiltonian flows. We can use results of that example immediately to treat billiards with complete internal reflections (thus non-branching).

To treat branching billiards we need to calculate eigenvalues of the matrix M. If $\Phi_{1,\tau} = \Phi_{2,\tau}$ and therefore $N_1 = N_2$ it is easy as $M = C\otimes \varkappa$ where C is a cyclic matrix of order M and condition (8.3.74) for M is equivalent to the same condition for $\varkappa$. It follows from calculations of Example 8.3.17 that $\varkappa_{22} = -\varkappa_{11}$; thus we arrive to

$$(8.3.77)\qquad \lambda = e^{\pm i\varphi},\qquad \varphi = \arccos \varkappa_{11} = \arccos\big((\omega-1)(\omega+1)^{-1}\big);$$

then obviously (8.3.74) is fulfilled and asymptotics (8.3.76) holds.

Problem 8.3.25. (i) In the framework of Example 8.3.24 derive formula for Ω through function Υ defined by (6.2.68).

(ii) In the framework of Example 8.3.24 consider the case when $\Phi_{1,\tau} = \Phi_{2,\tau}$ is not fulfilled. In this case calculation of eigenvalues of M could be really challenging.

Remark 8.3.26. On the contrary, assume that condition (8.3.74) is not fulfilled. Then there will be eigenvalues of high multiplicity or clusters of eigenvalues located in $o(h)$-vicinities of solutions τ of equation $\det(M-1) = 0$. Assuming that $\Phi_{1,\tau} = \Phi_{2,\tau}$ one can rewrite this equation as

$$\cos\bigl(-\varphi + \frac{1}{2}\tau h^{-1}(T_1 + T_2)\bigr) = \cos\alpha \cdot \cos\bigl(-\psi + \frac{1}{2}\tau h^{-1}(T_1 - T_2)\bigr) \tag{8.3.78}$$

as $\varkappa = \begin{pmatrix} e^{i(\phi+\psi)}\cos\alpha & e^{i(\phi+\chi)}\sin\alpha \\ -e^{i(\phi-\chi)}\sin\alpha & e^{i(\phi-\psi)}\cos\alpha \end{pmatrix}$ which is the general form of the unitary matrix.

The following problems seem to be a difficult one and worth of publication:

Problem 8.3.27. Prove the same results as flows $\Psi_{j,t}$ are assumed to be periodic only on one energy level τ rather than on neighboring levels.

Problem 8.3.28. Consider two manifolds satisfying the same assumptions as before albeit with the measure 0 of periodic billiards on each of them. Assume that $\Phi_{1,\tau}^p \Phi_{2,\tau}^q = I$ for some $p, q \in \mathbb{N}$ (recall that we assume that $\Phi_{1,\tau}$ and $\Phi_{2,\tau}$ commute.

Results should be similar to those of Subsection 8.3.3.

Example 8.3.29. Consider manifolds X_1 and X_2 with metrics $r_i^2\, ds^2 + \sin^2(s)\, d\theta^2$ and $s \in [o, \pi/2]$ and $s \in [\pi/2, pi]$ respectively albeit with r_1, r_2 which are irrational but such that $q_1 r_1 + q_2 r_2 = p$ with $q_1, q_2, p \in \mathbb{N}$.

On the contrary, the following problem seems to be relatively easy:

Problem 8.3.30. (i) Prove the same results as before when there are more than two manifolds X_j $j = 1, \dots, m'$ with the all billiards periodic.

(ii) Incorporate in this scheme Problem 8.3.28.

(iii) Extend these results to the case when there are also manifolds X_j $j = m'+1, \dots, m$ with almost all billiards non-periodic.

8.4 Spectral Asymptotics on Subspaces

So far we have considered operators with domain which is dense in $\mathscr{L}^2(X,\mathbb{H})$. We need to consider also spectral problems when eigenfunctions are restricted to a certain subspace $\mathcal{H}\subset \mathscr{L}^2(X,\mathbb{H})$ such that orthogonal projector Π to $\mathcal{H}$ is either a pseudodifferential operator (inside the domain), or a singular Green operator or sum of pseudodifferential operator with transmission property and singular Green operator.

8.4.1 Examples and Discussion

Let X be a connected Riemannian manifold (possibly) with the boundary ∂X, $\Lambda^{(p)}_x$ the space of p-forms at point x, $\Lambda^{(p)}=\Lambda^{(p)}(X)$ be the corresponding bundle over X.

Let $\mathsf{d}:\mathscr{C}^\infty(X,\Lambda^{(p)})\to\mathscr{C}^\infty(X,\Lambda^{(p+1)})$ be an operator of external differentiation, $\mathsf{d}^*:=*\mathsf{d}*:\mathscr{C}^\infty(X,\Lambda^{(p)})\to\mathscr{C}^\infty(X,\Lambda^{(p-1)})$ an operator formally adjoint to it.

Indeed, due to the Riemannian structure we have an antilinear operator $*:\mathscr{C}^\infty(X,\Lambda^{(p)})\ni u\to *u\in\mathscr{C}^\infty(X,\Lambda^{(d-p)})$ which provides an inner product $(u,v)=\varsigma\int_X u\wedge *v$ and a norm $\|u\|=\bigl(\int_X u\wedge *u\bigr)^{\frac{1}{2}}$ as $**=1$ [18].

Now we can consider operator $\Delta=\mathsf{d}\mathsf{d}^*+\mathsf{d}^*\mathsf{d}$ with the domain $\mathscr{H}^2(X,\Lambda^{(p)})$; at this moment we do not specify boundary conditions.

Example 8.4.1. (i) Consider subspace

$$\mathcal{H}:=\{u\in\mathscr{L}^2(X,\Lambda^{(p)}):\mathsf{d}^*u=0\} \tag{8.4.1}$$

with $p<d$ [19]. On this subspace consider quadratic form

$$\mathcal{Q}(u)=(\mathsf{d}u,\mathsf{d}u)+(\mathsf{d}^*u,\mathsf{d}^*u) \tag{8.4.2}$$

with domain

$$\mathfrak{D}(\mathcal{Q})=\{u\in\mathscr{L}^2(X,\Lambda^{(p)}):\ \mathsf{d}u\in\mathscr{L}^2(X,\Lambda^{(p+1)}),\ \mathsf{d}^*u\in\mathscr{L}^2(X,\Lambda^{(p-1)})\} \tag{8.4.3}$$

[18] In contrast to most of textbooks where $**=(-1)^{p(d-p-1)}$.

[19] Then $\dim\mathcal{H}=\infty$; as $d=p$ $\dim\mathcal{H}=1$.

and an operator $A = \Delta$ generated by this form; it is given by a desired differential expression

$$\Delta = \mathsf{d}^*\mathsf{d} = \mathsf{d}^*\mathsf{d} + \mathsf{d}\mathsf{d}^* \tag{8.4.4}$$

with the domain

$$\mathfrak{D}(A) = \{u \in \mathcal{H} \cap \mathscr{H}^2(X, \Lambda^{(p)}),\ \eth_n \mathsf{d}u = 0\} \tag{8.4.5}$$

where $\eth_n = \eth - \eth_t$, $\eth_t$ is an operator of the restriction to ∂X; so if $w = w_0 + w_1 \wedge dx_1$ where u_k are $(p-k)$-forms with respect to x' depending on x_1, then

$$\eth w = w_0|_{x_1=0} + w_1|_{x_1=0} \wedge dx_1, \tag{8.4.6}$$

$$\eth_t w = w_0|_{x_1=0}, \quad \eth_n w = w_1|_{x_1=0} \wedge dx_1; \tag{8.4.7}$$

We call $\eth_t w$ and $\eth_n w$ *tangential* and *normal components* of $\eth w$ respectively.

However unless either $p = 0$ or $\partial X = \emptyset$ the quadratic form and operator have infinite-dimensional kernel

$$\mathcal{K} = \{u \in \mathscr{L}^2(X, \Lambda^{(p)}) :\ \mathsf{d}u = \mathsf{d}^*u = 0\} \tag{8.4.8}$$

and we need to restrict both form and operator to

$$\mathcal{H}_0 = \mathcal{H} \ominus \mathcal{K} = \{u \in \mathscr{L}^2(X, \Lambda^{(p)}) :\ \mathsf{d}u = 0,\ \eth_n u = 0\}. \tag{8.4.9}$$

(ii) We can add to (8.4.3) condition

$$\eth_t u = 0 \tag{8.4.10}$$

and get operator $A = \Delta$ with domain

$$\mathfrak{D}(A) = \{u \in \mathcal{H} \cap \mathscr{H}^2(X, \Lambda^{(p)}),\ \eth_t u = 0\} \tag{8.4.11}$$

(iii) Using duality operator $*$ we can simultaneously permute d and d^*, $\eth_t$ and $\eth_n$, $p = 0$ and $p = d$.

(iv) Let $0 < p < d$. Then we can consider quadratic form (8.4.2) on $\mathcal{H}_1 := \mathscr{L}^2(X, \Lambda^{(p)}) \ominus \mathcal{K}$ and get an operator $A = \Delta$ with the domain

$$\mathfrak{D}(A) = \{u \in \mathcal{H} \cap \mathscr{H}^2(X, \Lambda^{(p)}),\ \eth_t \mathsf{d}u = \eth_n d^*u = 0\} \tag{8.4.12}$$

Remark 8.4.2. (i) Note that the boundary conditions for A are equivalent to equality

$$(\mathsf{d}u, \mathsf{d}v) = (\mathsf{d}^*\mathsf{d}u, v) \qquad \forall v \in \mathfrak{D}(\mathcal{Q}). \tag{8.4.13}$$

(ii) Also note that in Example 8.4.1(i),(ii) there is a "hidden" boundary condition

$$\eth_t \mathsf{d}^* u = 0 \tag{8.4.14}$$

due to $\mathsf{d}^* u = 0$; with the boundary conditions (8.4.5), (8.4.14) or (8.4.10), (8.4.14) operator $A = \Delta$ given by differential equation (8.4.4) is self-adjoint;

(iii) One can see easily that

(8.4.15) A_B and Π commute[20)].

We leave to the reader

Problem 8.4.3. Describe operators Π, Π_0 and Π_1 (projectors onto $\mathcal{H}$, $\mathcal{H}_0$ and $\mathcal{H}_1$ in example 8.4.1;

Example 8.4.4. Consider operator in $\mathcal{L}^2(X, \Lambda^{(p)}) \oplus \mathcal{L}^2(X, \Lambda^{(p-1)}) \ni \begin{pmatrix} u \\ v \end{pmatrix}$

$$A = \begin{pmatrix} 0 & \alpha \mathsf{d} \beta \\ \beta^\dagger \mathsf{d}^* \alpha^\dagger & 0 \end{pmatrix} \tag{8.4.16}$$

restricted to kernel $\mathcal{H}$ of operator

$$R = \begin{pmatrix} \mathsf{d}\alpha^{-1} \\ \mathsf{d}^* \beta^{\dagger -1} \end{pmatrix} \tag{8.4.17}$$

under boundary condition

$$\eth_t \beta v = 0 \tag{8.4.18}$$

or, alternatively,

$$\eth_n \alpha^\dagger u = 0 \tag{8.4.19}$$

[20)] Which means that spectral projectors of A_B and Π commute.

where $\alpha : \Lambda_x^{(p)} \to \Lambda_x^{(p)}$, $\beta : \Lambda_x^{(p-1)} \to \Lambda_x^{(p-1)}$ are non-degenerate matrices smoothly depending on x.

Then we can make the same conclusions as before with the corresponding subspace $\mathcal{H}$.

Maxwell equations in anisotropic media (crystals) fit the example above as $\alpha = \varepsilon^{-\frac{1}{2}}$, $\beta = \mu^{-\frac{1}{2}}$ where ε, μ are positive Hermitian matrices; for scalar such matrices we get Maxwell equations in isotropic media.

Example 8.4.5. (i) Consider $\mathcal{H} = \{u : \Delta u = 0\} \subset \mathscr{L}^2(X, \Lambda^{(p)})$ and operator generated by the quadratic form $\mathcal{Q}(u) = \|\nabla u\|^2$. Expressing $u = Rv$ with $v = \eth u$ we get quadratic form $\mathcal{Q}'(v) = \mathcal{Q}(Rv)$ on $\mathscr{H}^{-\frac{1}{2}}(Y, \mathcal{E})$ where $\mathcal{E} = \Lambda^{(p)}(Y) \oplus \Lambda^{(p-1)}(Y)$, $Y = \partial X$.

Then

$$\mathcal{Q}'(v) = (B\Delta_Y^{-\frac{1}{2}} v, \Delta_Y^{-\frac{1}{2}} v)_Y, \qquad \|u\|^2 = \|\Delta_Y^{-\frac{1}{2}}\|_Y^2 \tag{8.4.20}$$

with the pseudodifferential operator B on ∂X, acting on $\mathscr{C}^\infty(Y, \mathcal{E})$ and self-adjoint in $\mathcal{H}' = \mathscr{L}^2(Y, \mathcal{E})$. Thus the problem is reduced to study of spectral properties of B.

(ii) Consider $\mathcal{H} = \{u : \mathsf{d}u = \mathsf{d}^* u = 0\} \subset \mathscr{L}^2(X, \Lambda^{(p)})$ and operator generated by quadratic form $\mathcal{Q}(u)$. Expressing $u = Rv$ with $v = \eth u$ and the same operator R as before, we get

$$\mathcal{H}' = \{w \in \mathscr{L}^2(Y, \mathcal{E}) : \mathsf{d}R\Delta_Y^{\frac{1}{2}} w = \mathsf{d}^* R\Delta_Y^{\frac{1}{2}} w = 0\}. \tag{8.4.21}$$

Thus the problem is reduced to study of spectral properties of B' defined by a quadratic form $\mathcal{Q}'(v)$ on $\mathcal{H}'$.

(iii) In (i) and (ii) we can also impose certain conditions to v thus further reducing the space $\mathcal{H}'$.

We leave to the reader the following

Problem 8.4.6. (i) Describe projector Π in $\mathscr{L}^2(X, \Lambda^{(p)})$ which is a singular Green operator and operator B in Example 8.4.5(i).

(ii) Describe projector Π in $\mathscr{L}^2(X, \Lambda^{(p)})$ which is a singular Green operator, projector $\Pi' = \Delta_Y^{\frac{1}{2}} R^* \Pi R \Delta_Y^{\frac{1}{2}}$ which is a pseudodifferential operator on Y and B' in Example 8.4.5(ii).

8.4.2 Analysis away from the Boundary

If X is a closed manifold or at least $B(0,1) \subset X$ there is an already developed theory: projector on $\mathcal{H}$ we are interested in is (locally) a pseudodifferential operator and asymptotics of $\Gamma\big(\Pi_x e(.,.,\tau)\big)$ we already defined. However there is a twist:

Theorem 8.4.7. *Let Π be an h-pseudodifferential projector commuting with A. Then all results of Chapters 4–6 remain true if we redefine microhyperbolicity according to Definition 8.4.8 below (with $r = I - \pi$) and for sharp results consider only trajectories on manifold*

$$\Sigma_\tau := \{\mathsf{Ker}\, a(x,\xi) \cap \mathsf{Ker}(1-\pi(x,\xi)) \neq \{0\}\} \tag{8.4.22}$$

where π is the principal symbol of Π.

Definition 8.4.8. We say that operator A is microhyperbolic at point z in direction ℓ at energy level τ under restriction $Ru = 0$ if

$$\langle((\ell a(z))v, v\rangle \geq \epsilon\|v\|^2 - C\|(a(z)-\tau)v\|^2 - C\|r(z)v\|^2 \qquad \forall v \tag{8.4.23}$$

with small enough constant $\epsilon > 0$; here R is a pseudodifferential operator (not necessary a projector) with the principal symbol $r(x,\xi)$ such that $\mathsf{Ker}\, r(x,\xi)$ is invariant with respect to $a(x,\xi)$.

Proof of Theorem 8.4.7. The easiest way to recover all local results is to note that one can find pseudodifferential $\mathsf{D} \times \mathsf{D}'$-matrix operator E (where $\mathsf{D}' = \mathsf{rank}\,\pi$ and A is $\mathsf{D} \times \mathsf{D}$-matrix operator) such that $(I-\Pi)u \equiv 0$ near $z \in T^*X$ if and only if there exists v such that $u \equiv Ev$ near z. Then the problem locally becomes $\mathsf{D}' \times \mathsf{D}'$-matrix and microhyperbolic in the ordinary sense. Here D' is constant on each connected component of modified Σ_τ. The easy details are left to the reader.

Sharper results propagation are also easy: we just remember that condition $(I-\Pi)u = 0$ makes some points of old Σ_τ elliptic and thus removes them from propagation. Since so far we did not discuss in details propagation near boundary we simply announce that at this moment all propagation near boundary remains the same as without restriction (but at moment when the boundary is not considered Σ_τ is "trimmed"). We will modify this in the next subsections.

Finally, results for operators with the periodic Hamiltonian flows and based on equality $e^{ih^{-1}A} \equiv e^{i\varepsilon h^{-1}B}$ are now based on

$$e^{ih^{-1}A}\Pi \equiv e^{i\varepsilon h^{-1}B}\Pi, \tag{8.4.24}$$

$$(I-\Pi)e^{ih^{-1}A}\Pi \equiv (I-\Pi)e^{i\varepsilon h^{-1}B}\Pi \equiv 0, \tag{8.4.25}$$

$$\Pi e^{ih^{-1}A}(I-\Pi) \equiv \Pi e^{i\varepsilon h^{-1}B}(I-\Pi) \equiv 0. \tag{8.4.26}$$

Again, the easy details are left to the reader. □

Remark 8.4.9. (i) If Π does not commute with A defining quadratic form. situation here does not change drastically: this quadratic form defines operator $\Pi A = \Pi A \Pi$ on $\mathcal{H} = \mathsf{Ran}\,\Pi$ and all we need is to replace in the definitions (8.4.22) of Σ_τ and (8.4.23) of microhyperbolicity principal symbol a of A by the principal symbol $a' = \pi a \pi$ of A' where π is the principal symbol of Π.

(ii) In particular, if a and π commute, (8.4.22) and (8.4.23) do not need to be modified.

(iii) This would not be the case near the border since then ΠA would not be operator of the type we have studied.

8.4.3 Analysis near the Boundary. I

This theory is much more delicate partially because it involves not only pseudodifferential operators but also Boutet-de-Monvel operators and we do not have semi-classical theory here and development of this theory is rather tedious. Luckily we do not need a full theory but a limited one and it is rather obvious:

Problem 8.4.10. Develop semi-classical theory parallel to one of Section 1.4. In particular prove that operators described there–pseudodifferential operators with transmission property (see Definition 1.4.3), boundary, trace and singular Green operators (see Definitions 1.4.10–1.4.12) and also h-pseudodifferential operators on the boundary have the property that if symbols of two such operators R_1 and R_2 of different but "matching" types have disjoint supports then R_1R_2 is a negligible operator.

We assume that (8.4.15) holds (i.e. A_B and Π commute). Then we need to study $U_\Pi(x,y,t)$ the Schwartz kernel of $e^{ih^{-1}tA_B}\Pi$ and thus we can apply the theory of Chapter 7 with the only difference that now $Q_2=\Pi$ is the sum of pseudodifferential operator with the transmission property and a singular Green operator (with respect to (x,t)) while before it was of the type

$$Q_j(x,t,hD_x,hD_t)=\sum_{0\le k\le l} Q_{j,k}(x,t,hD'_x,D'_t)(hD_{x_1})^k. \tag{8.4.27}$$

Remark 8.4.11. One can rewrite operator $Q_j=Q_j(x,t,hD_x,hD_t)$ in the form

$$Q_j=Q_j''(x,t,hD_x,hD_t)(hD_t-A)+Q_j'+hP\eth_{\min(l,m)}+G \tag{8.4.28}$$

where $\eth_l u=\eth(u,hD_1u,\dots,(hD_1)^{l-1}u)$, Q_j' is an operator of (8.4.27) type, P, G are Poisson and singular Green operators respectively. But (hD_t-A) annihilates U, so one needs to consider only $Q_j=Q_j'+P\eth_{\min(l,m)}+G$.

Repeating arguments of Sections 3.1–3.3 we get immediately that

Proposition 8.4.12. *All statements of Theorem 7.2.17 remain true as Q_1,Q_2 are sums of h-pseudodifferential operators with the transmission property and h-singular Green operators.*

Proof. The only not completely trivial part of the proof is the Proposition 3.3.4 reinvented: then additionally appear terms of the same type $\Gamma''\bigl(Q_{1x}U_{jk}(.,.,t)\,{}^tQ_{2y}\bigr)$ but in virtue of Remark 8.4.11 with at least one of operators Q_1 and Q_2 being the sum of $P\eth_l$ and G.

As Q_1 is operator of this type, it effectively confines x_1 to $\{x_1\le h^{1-\delta'}\}$ and then there is no difference if we take $\nu_j x_1$ or $\nu_k x_1$ in the application of the propagation theorem, so we get terms of the type we deal in another parts of the proof.

Details and the rest of arguments are left to the reader. □

Now we immediately arrive to

Theorem 8.4.13. *All statements of Theorems 7.3.1 and 7.3.2 remain true as Q_1,Q_2 are sums of h-pseudodifferential operators with the transmission property and h-singular Green operators.*

Remark 8.4.14. The leading term in the asymptotics is $\kappa_0(\tau,\tau')h^{-d}$. Consider $Q_2 = Q_1^*$ and $\tau > \tau'$. Then $\kappa_0 = 0$ if and only if

$$q_1\big(\theta(a-\tau') - \theta(a-\tau)\big)q_2 = 0; \tag{8.4.29}$$

recall that $I - \theta(a-\tau)$ is a spectral projector of symbol a.

As $q_2 = \pi$ is the projector-valued symbol the latter condition becomes

$$\big(\theta(a-\tau') - \theta(a-\tau')\big)\big|_{\operatorname{Ran}\pi} = 0. \tag{8.4.30}$$

One can also prove easily the following

Theorem 8.4.15. *All statements of Theorem 7.3.7 remain true as Q_1, Q_2 are sums of h-pseudodifferential operators with the transmission property and h-singular Green operators and principal symbol of Q_1 is $q_2 = \pi$, the projector-valued symbol satisfying* (8.4.30).

Problem 8.4.16. Investigate if theorems 7.3.10, 7.3.11 also remain true.

Then one can prove rather easily

Theorem 8.4.17. *All statements of Theorems 7.4.1, 7.4.4, 7.4.6, 7.4.7, 7.4.8 and 7.4.21 remain true as Q_1, Q_2 are sums of h-pseudodifferential operators with the transmission property and h-singular Green operators and principal symbol of Q_1 is $q_2 = \pi$, the projector-valued symbol satisfying* (8.4.30).

Problem 8.4.18. (i) Investigate if statements Theorems 8.1.6 and 8.1.8 also remain true.

(ii) Investigate if statements of Theorems 8.2.1, 8.2.2, 8.2.4 and 8.2.6 also remain true.

(iii) Investigate if statements of Theorems 8.3.6, 8.3.15, 8.3.23 and 8.2.6 also remain true.

Much more difficult problem would be to weaken notion of "microhyperbolic in multidirection" and still recover the same results:

Definition 8.4.19. Let conditions (3.1.1)–(3.1.6), (3.1.23), (3.1.9) be fulfilled. Let Π be a sum of the h-pseudodifferential operator with the transmission property and singular Green operator.

Then the problem (P,B) is *microhyperbolic at the point* $z \in \Omega' \subset T^*\partial X$ *in the multidirection* $\mathcal{T} = (\ell', \nu_1, \dots, \nu_n)$ under constrain $(I-\Pi)u = 0$ if the following two conditions are fulfilled:

(i) For every $k = 1, \dots, n$ the operator P is microhyperbolic at the point $z_k = (z, \eta_k)$ in the direction $\ell_k = (\ell, \nu_k, 0) \in T_{z_k}(T^*X|_{\partial X}) \subset (T_{z_k}T^*X)|_{\partial X}$ under restrain π_0 where π_0 is the principal symbol of the pseudodifferential part of Π;

(ii) The following estimate holds

$$
\begin{aligned}
&(8.4.31)\quad -\operatorname{Re}\langle(\mathcal{T}'p)(z,D_1)v, v\rangle_+ + \operatorname{Re} i\langle(\mathcal{T}'b)(z)\eth v, \beta(z)\eth v\rangle_b \geq \\
&\epsilon\|v\|^2_+ - c_1(c_1\|b(z)\eth v\|'^2 - \langle T(z)\eth v, \eth v\rangle_m) \qquad \forall v \in \mathbb{H}'(z) \cap \operatorname{Ker}(I-\pi(z))
\end{aligned}
$$

where $\pi(z) = \pi_0(z, hD_1) + \pi'(z)$ and $\pi'(z)$ is a principal symbol of singular Green part of Π; $\pi(z)$ is a projector in $\mathscr{S}(\mathbb{R}^+, \mathbb{C}^{\mathsf{D}})$.

We leave to the reader

Problem 8.4.20. Correspondingly redefine Σ and Σ_b, modify definitions 3.1.1, 3.1.3, 3.1.4, 3.2.2, 3.2.3, 3.2.7.

Here as we weaken notion of microhyperbolicity, we increase the cone of microhyperbolic multidirections and reduce the dual cones and the propagation "conoids".

The really challenging task would be to

Problem 8.4.21. (i) Prove Theorems 3.1.2, 3.1.7 3.1.12 3.1.13, 3.2.4, 3.3.1, 3.3.2, 3.3.3, 3.3.5, 3.3.6 and 3.3.7 under new definition of microhyperbolicity as we consider only solutions satisfying $(I-\Pi)u = 0$ where Π and A_B commute.

(ii) Prove Theorems 8.4.13, 8.4.15 and 8.4.17 under new definition of microhyperbolicity as we consider only solutions satisfying $(I-\Pi)u = 0$ where Π and A_B commute.

8.4.4 Analysis near the Boundary. II. Seeley's Approach

Seeley's approach works especially well (as long as (8.4.30) is violates). In this approach we analyze zone without actually considering boundary. Let us recall this approach in the simplified version as ∂X is smooth.

(a) We consider first zone $X' = \{x : \ \gamma(x) := \mathsf{dist}(x, \partial X) \ge h^{1-\delta}\}$, take $T(x) = \gamma(x)^{1-\delta'}$ which confines propagation (in appropriate direction) to

$$Z(x) := \{y : \ (\frac{h}{\gamma(x)})^{1+\delta''} \le (\frac{h}{\gamma(y)}) \le (\frac{h}{\gamma(x)})^{1-\delta''}\}. \tag{8.4.32}$$

However in this zone A is just a regular h-pseudodifferential operator with the principal symbol a and all we need is its microhyperbolicity with the restriction $(I-\pi)u = 0$. Further, if π and a commute we need to check microhyperbolicity of a with the restriction $(I-\pi)u = 0$.

So, the same arguments as before bring us that the contribution of the strip $\{x : \gamma(x) \asymp \gamma\}$ to the remainder is $O(h^{1-d}\gamma^{\delta'})$ and the total contribution of X' is $O(h^{1-d})$.

(b) Then we consider zone $X'' = \{x : \ h \le \gamma(x) \le h^{1-\delta}\}$ and rescale it $x \mapsto x/\gamma_1$, $h \mapsto \hbar = h/\gamma_1$, $\gamma \mapsto \gamma' = \gamma/\gamma_1$ selecting $\gamma_1 = (\gamma/h)^s h$ so that $\gamma' = \hbar^{1-\delta}$; then $\gamma' = (h/\gamma)^{s-1}$.

Therefore in virtue of (a) contribution of the strip $\{x : \ \gamma(x) \asymp \gamma\}$ to the remainder does not exceed $C\hbar^{1-d}\gamma'^{\delta'}\gamma_1^{1-d} \le Ch^{1-d}(h/\gamma)^{\delta'})$ and the total contribution of this zone to the remainder is $O(h^{1-d})$. This part of arguments does not require any modification.

(c) Furthermore, we consider zone $x'' = \{x : \gamma(x) \le h\}$ and we use the rough estimate similar to those of Section 7.1 we estimate contribution of this zone also by $O(h^{1-d})$. Easy details are left to the reader.

(d) Further, these arguments prove that the contribution of the zone $\{x : \ \mu^{-1}h \le \gamma(x) \le \mu\}$ to the remainder does not exceed $\varepsilon(\mu)h^{1-d}$ with $\varepsilon(\mu) = o(1)$ as $\mu \to 0$. Improved analysis in zone $\{x : \ \gamma(x) \le \mu^{-1}h\}$ (see Section 7.5) proves that its contribution to the remainder is $o(h^{1-d})$ for any fixed $\mu > 0$. Finally, propagation arguments prove that under non-periodicity billiard conditions contribution of the zone $\{x : \ \gamma(x) \le \mu\}$ to the remainder is $o(h^{1-d})$. So we arrive to Theorem below:

Theorem 8.4.22. *Let ∂X be smooth. Then all statements of Theorems 7.5.10, 7.5.15, 7.5.19 and 7.5.20 remain true as Q_1, Q_2 are sums of h-pseudodifferential operators with the transmission property and singular Green operators.*

Example 8.4.23. Consider $\mathcal{H}$ defined by (8.4.1) and operator $\mathcal{A}$ with boundary condition $\mathcal{B}$ defined by arbitrary elliptic m-th order quadratic form $\mathcal{Q}(u)$.

Then

$$\mathcal{A} = A + G + hP\eth_{2m}, \tag{8.4.33}$$

with the domain

$$\mathfrak{D}(\mathcal{A}_{\mathcal{B}}) = \{u \in \mathscr{H}^2(X, \Lambda^{(p)}),\ \mathcal{B}u = 0\}, \tag{8.4.34}$$

$$\mathcal{B} = B\eth_{2m} + T \tag{8.4.35}$$

where $\eth_m u = (\eth u, \eth hD_1 u, \dots, \eth(hD_1)^{m-1}u)$, m is an order of $\mathcal{Q}$ and A is a pseudodifferential operator of order $2m$ with transmission property, B is a pseudodifferential operator on ∂X, G, P and T are singular Green, Poisson and trace operators respectively.

We leave to the reader the following

Problem 8.4.24. Describe operators $\mathcal{A}$, $\mathcal{B}$.

Repeating arguments above[21)] we arrive to

Theorem 8.4.25. *Let ∂X be smooth. Then*

(i) Statements of Theorems 7.5.10 and 7.5.15 remain true as Q_1, Q_2 are sums of h-pseudodifferential operators with the transmission property and singular Green operators and $\mathcal{A}_{\mathcal{B}}$ is of the type described above.

(ii) As operator $\mathcal{A}$ and generalized boundary operator $\mathcal{B}$ differ from differential operator A and operator B by lower order terms only, statement of Theorems 7.5.19 and 7.5.20 also remain true.

The following problem seems to be extremely challenging:

Problem 8.4.26. To derive asymptotics with remainder estimate $o(h^{1-d})$ for general operators of (8.4.33)–(8.4.35)-type.

Here treatment of both zones $\{x\colon \gamma(x) \le \mu^{-1}h\}$ and $\{x\colon \gamma(x) \ge \mu\}$ seems to be difficult since propagation near boundary is not clear.

[21)] In part (c) correct scaling of all terms of the operator is essential.

Comments

The systematic theory outlined in Section 8.4 even without Problem 8.4.26 would be definitely worth publications.

Part IV

Estimates of the Spectrum

Chapter 9

Estimates of the Negative Spectrum

This short chapter plays a crucial role in the whole book bridging Parts II, III and Part V. Namely here we combine the results of Parts II and III devoted to local semiclassical spectral asymptotics with the variational estimates of Rozenblioum type (upper estimates for $\mathsf{N}^-(A)$) in order to derive upper and lower estimates for $\mathsf{N}^-(A) = \mathsf{N}(-\infty, A)$ where $\mathsf{N}^-(A)$ is the number of negative eigenvalues of the self-adjoint operator A (counting their multiplicities) provided $(-\infty, 0)$ does not intersect with the essential spectrum of A and $\mathsf{N}^-(A) = \infty$ otherwise.

More precisely, the idea is that the geometric domain X consists of two overlapping zones: the *regular zone* where local semiclassical spectral asymptotics are applied and the *singular zone* where formally variational estimates are applied. We use only the regular zone and semiclassical asymptotics there to derive a lower estimate of $\mathsf{N}^-(A)$. However we use both the regular zone with its semiclassical asymptotics and the singular zone with variational estimates to derive upper estimates of $\mathsf{N}^-(A)$. Both these estimate have the same main part derived somewhere in Parts II and III.

On the *inner boundary* of the singular zone we can introduce boundary conditions of our choice and Dirichlet boundary conditions are usually the best. In the justification of this procedure (decoupling of asymptotics) the results of Chapters 2 and 3 concerning the finite speed of propagation of singularities in the intersection of these zones play an important role.

In Section 9.1 we formulate the main statements, discuss and prove them. Actually there is just one main Theorem 9.1.7 and its sidekick Theorem 9.1.13

for spectral Riesz means.

Section 9.2 is devoted to the series of initial examples; each of them could be formulated as a theorem.

In Section 9.3 we transfer the results of Section 9.2 to quadratic forms.

In Appendix 9.A we survey variational estimates and discuss some their consequences.

Later (in Part 4) we treat the case when the operator A depends on parameter(s) and we derive asymptotics of $\mathsf{N}^-(A)$ with respect to the parameters. These parameters may be of different nature but even if one of them is a semiclassical parameter h it is not the same as used here effective semiclassical parameter h which depends on partition element in the regular zone.

Surely, the results of Part II and III provide some of the asymptotics of Part V but without the additional analysis of this part we cannot cover many important cases.

9.1 Main Theorem

9.1.1 Discussion

As a preliminary example let us consider operator $\Delta - \lambda$ in the domain having singularities of different types in the domain on Figure 9.1. This domain has singularities of the type "angle" or "spike" and of the type "cusp". Later we consider many other examples of singularities of the boundary (including the case when the whole boundary itself is a singularity) or/and of the operator.

Consider *spatial scaling function* $\gamma(x)$ such that ∂X intersected with $B(\bar{x}, \gamma(\bar{x}))$ after scaling $x \mapsto (x - \bar{x})\gamma(\bar{x})^{-1}$ is uniformly smooth. After this scaling and division by λ we have Schrödinger operator $h^2\Delta - 1$ with $h = \lambda^{-\frac{1}{2}}\gamma(\bar{x})^{-1}$.

Therefore contribution of $B(\bar{x}, \gamma(\bar{x}))$ to the remainder does not exceed $Ch^{1-d} = C\lambda^{\frac{1}{2}(d-1)}\gamma(\bar{x})^{d-1}$ as long as $h \le 1$. So we can introduce a *regular zone* $X_{\mathsf{reg}} = \{x : \ \gamma(x) \ge \lambda^{-\frac{1}{2}}\}$ and its contribution to the remainder does not exceed

$$C\lambda^{\frac{1}{2}(d-1)} \int_{X_{\mathsf{reg}}} \gamma(x)^{-1}\, dx \tag{9.1.1}$$

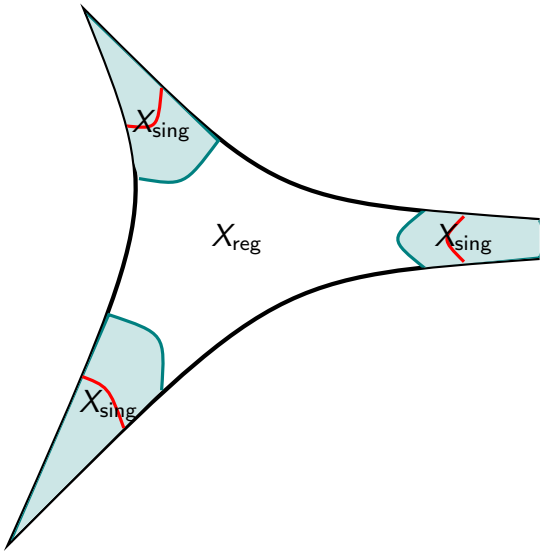

Figure 9.1: Black lines bound domain X, regular zone X_{reg} is bounded by red and black lines, singular zone X_{sing} is colored (both zones overlap).

while the principal part of asymptotics is given by the Weyl formula (with the integration over X_{reg})

$$\text{const} \cdot \lambda^{\frac{1}{2}d} \int_{X_{\text{reg}}} dx \tag{9.1.2}$$

with the standard constant.

Therefore we need to consider zone $X'_{\text{sing}} = \{x : \ \gamma(x) \le 2\lambda^{-\frac{1}{2}}\}$ which is part of the *singular zone* $X_{\text{sing}} = \{x : \ \gamma(x) \le 3\lambda^{-\frac{1}{2}}\}$. These zones shrink as $\lambda \to \infty$.

Assume that operator Δ was defined with the Dirichlet boundary conditions on ∂X. Let us formally add Dirichlet boundary conditions on the *inner boundary of singular zone* $\partial X_{\text{sing}} \setminus \partial X$ (i.e. thick lines on Figure 9.1). In this case contribution of X_{sing} and X'_{sing} to asymptotics does not exceed as $d \ge 3$

$$C\lambda^{\frac{1}{2}d} \int_{X_{\text{sing}}} dx. \tag{9.1.3}$$

So,

(9.1.4) The main part of asymptotics is (9.1.2) while the remainder estimate is given by the sum of (9.1.1) and (9.1.3).

Remark 9.1.1. (i) Obviously, the are no Dirichlet boundary condition on part of $\partial X_{\mathsf{sing}}$ and therefore this claim so far is justified only in the very special case when X is the union of infinitely many connected components, some of them completely belonging to X_{reg} and the rest to X_{sing}. However as we mentioned we will justify it.

(ii) The main part of the asymptotics is given by cut Weyl formula (9.1.2). Sure, we can always complete it, making integral over X since integral over X_{sing} is part of the error estimate. However, in the certain cases (f.e. in domains with cusps of the infinite volume) we will be able to get better estimate than (9.1.3).

(iii) Under some assumptions we are able to use sharp asymptotics[1)] in X_{reg} thus replacing (9.1.1) by a smaller expression; however in certain general cases we do not have even $O(h^{1-d})$ estimate thus replacing (9.1.1) by a larger expression.

(iv) Neumann boundary problem could be treated under certain assumptions as well but those are really restrictive assumptions due to very special nature of the Neumann boundary condition.

(v) In the discussed case the meaning of the *reference theorem* was obvious; in the general case we can use different reference theorems in the different parts of the regular zone.

In what follows by the *reference theorem* we mean the local semiclassical asymptotics we used.

9.1.2 Main Theorem Setup

Scaling Functions

Let us cover our domain X into two overlapping subdomains X_{reg} and X_{sing} in which specific conditions are assumed to be fulfilled.

Let us assume that

$$X \subset \mathbb{R}^d/(\bar{\gamma}_1\mathbb{Z} \times \bar{\gamma}_2\mathbb{Z} \times ... \times \bar{\gamma}_d\mathbb{Z}), \qquad 0 < \bar{\gamma}_j \le \infty \quad (j = 1, ..., d) \tag{9.1.5}$$

[1)] With remainder estimate $o(h^{1-d})$ or better.

and $X = X_{\mathsf{reg}} \cup X_{\mathsf{sing}}$.

Remark 9.1.2. Surely one can treat more general manifolds and in specific cases we will do it.

Let us assume that on X_{reg} a function $\gamma = \gamma(x)$ is given such that

$$0 < \gamma(x) \le \min_j \bar{\gamma}_j, \quad |\nabla\gamma(x)| \le \frac{1}{2}. \tag{9.1.6)$_1$}$$

We say that $\gamma(x)$ is a *spatial scaling function*. We also assume that on X_{reg} a *momentum scaling function* $\rho(x)$ [2)] is given such that[3)]

$$x \in \mathcal{B}(y, \gamma(y), X) \implies \rho_k(x) > 0, \quad \epsilon_0 \le \frac{\rho_k(x)}{\rho_k(y)} \le c, \quad |\nabla\rho_k(x)| \le c\rho_k(y)\gamma^{-1}(y) \tag{9.1.6)$_2$}$$

and also scaling functions ϱ and ϱ_0 are given satisfying

$$x \in \mathcal{B}(y, \gamma(y), X) \implies \varrho_j(x) > 0, \quad \epsilon_0 \le \frac{\varrho_j(x)}{\varrho_j(y)} \le c, \quad |\nabla\varrho_j(x)| \le c\varrho_j(y)\gamma^{-1}(y) \tag{9.1.6)$_3$}$$

where here and below

(9.1.7) $\mathcal{B}(y, \gamma(y), X)$ denotes a connected component of $B(y, \gamma(y)) \cap \bar{X}$ containing y.

Remark 9.1.3. Obviously

$$\mathcal{B}(y, \gamma(y), X) \supset \{x \in \bar{X} : \mathsf{dist}(x, y) < \gamma(y)\}$$

where $\mathsf{dist}(x, y) = \mathsf{dist}_X(x, y)$ is a *path-distance* in X.

Further, let us assume that

$$\rho(y)\gamma(y) \ge 1 \qquad \forall y \in X_{\mathsf{reg}}. \tag{9.1.6)$_4$}$$

Finally, X_{reg} and X_{sing} be properly overlapping: let $X_{\mathsf{reg},0} \subset X_{\mathsf{reg}}$ and

$$X = X_{\mathsf{sing}} \cup X_{\mathsf{reg},0}; \quad y \in X_{\mathsf{reg},0} \implies \mathcal{B}(y, \gamma(y), X) \subset X_{\mathsf{reg}}. \tag{9.1.8}$$

[2)] In principle one can take this function also depending on ξ.

[3)] Later other scaling functions ρ_k and ϱ_j may be introduced which should all satisfy condition (9.1.6)$_2$.

Definition 9.1.4. In what follows X_{reg} is the *zone of semiclassical asymptotics* or the *regular zone* and X_{sing} is the *zone of variational estimates* or the *singular zone*.

Operators

Let us consider the operator A defined on X_{reg} by the formula

$$A = \sum_{\alpha:|\alpha|\le m} a_\alpha(x) D^\alpha \tag{9.1.9}$$

with boundary conditions

$$B_j u = \sum_{\alpha:|\alpha|\le m_j} b_{j\alpha}(x) D^\alpha u = 0 \quad (j = 1, \dots, \mu) \qquad \text{on} \quad \partial X \cap \bar{X}_{\mathsf{reg}} \tag{9.1.10}$$

where a_α, $b_{j\alpha}$ are $\mathsf{D} \times \mathsf{D}$ matrices and $m_j \le m - 1$.

That means that A is an operator in $\mathscr{L}^2(X, \mathbb{H})$, $\mathbb{H} = \mathbb{C}^{\mathsf{D}}$ [4)] with domain $\mathfrak{D}(A)$ but $Au(x)$ is given by (9.1.9) for $u \in \mathfrak{D}(A)$, $x \in X_{\mathsf{reg}}$. Moreover, it means that if $u \in \mathscr{H}^m(X, \mathbb{H})$ is compactly supported in X_{reg} then $u \in \mathfrak{D}(A)$ if and only if $Bu|_{\partial X} = 0$.

In our analysis we replace the operator A by the operator

$$\boldsymbol{A} = J^{-1} A \tag{9.1.11}$$

in $\mathcal{H}$ where

(9.1.12) J is a Hermitian positive definite matrix depending on x

and here and below $\mathcal{H} = \mathcal{H}_J$ is a Hilbert space with inner product $(u, v)_{\mathcal{H}} = (Ju, v)$ and $(.,.)$ is the standard $\mathscr{L}^2(X, \mathbb{H})$-inner product.

We assume that

(9.1.13) $\boldsymbol{A}$ is a self-adjoint operator in $\mathcal{H}$.

Our goal is to derive upper and lower estimates for

$$\mathsf{N}^-(\boldsymbol{A}) = \int \mathsf{tr}\big(e(x, x, -\infty, 0)\big)\, dx \tag{9.1.14}$$

where $e(.,.,.,.)$ is the Schwartz kernel of the spectral projector $E(\tau)$ of $\boldsymbol{A}$.

[4)] One can also treat the case when $\mathbb{H}$ is an infinite dimensional auxiliary Hilbert space.

Remark 9.1.5. Let us note that

(i) $\boldsymbol{A}$ is unitarily equivalent to the operator $J^{-\frac{1}{2}}AJ^{-\frac{1}{2}}$ in $\mathcal{H} = \mathscr{L}^2(X, \mathbb{H})$. In what follows we use the notation $\boldsymbol{A}$ for the operator $J^{-\frac{1}{2}}AJ^{-\frac{1}{2}}$ as well. We hope that there will be no confusion.

(ii) Usually $\mathsf{N}^-(\boldsymbol{A}) = \mathsf{N}^-(A)$. It is the case, f.e. if smooth functions u satisfying boundary conditions and such that $\|J\|$ and $\|J^{-1}\|$ are bounded by $C(u)$ on $\mathsf{supp}(u)$ are dense in $\mathcal{H}$. We will discuss this with more details in Section 9.3.

(iii) Equality $\mathsf{N}^-(A) = \mathsf{N}^-(\boldsymbol{A})$ is an example of the *Birman-Schwinger* principle (see Subsection 10.1.2 for more details).

Let us describe assumptions to A, B and J.

Regular Zone

First of all, let us describe assumptions in regular zone X_{reg}. Namely, assume that uniformly with respect to $y \in X_{\mathsf{reg}}$ assumptions (9.1.15)–(9.1.18) are fulfilled:

(9.1.15) If $y \in X_{\mathsf{reg}}$ then either $B(y, \gamma(y)) \subset X$ or there exist a number $k = k(y) \in \{1, \dots, d\}$, $\varsigma = \pm 1$ and a real-valued function $\phi(x_{\hat{k}})$ such that $|\nabla\phi| \le c$ and

$$\mathcal{B}(y, \gamma(y), X) = \{\varsigma(x_k - \phi(x_{\hat{k}})) > 0\} \cap B(y, \gamma(y)) \tag{9.1.16}$$

where $x_{\hat{k}} = (x_1, \dots, x_{k-1}, x_{k+1}, \dots, x_d)$;

(9.1.17) $X_{\mathsf{reg}} = \bigcup_l X_{\mathsf{reg}(l)}$ and if $y \in X_{\mathsf{reg}(l)}$ then rescaling[5)] $\mathcal{B}(y, \gamma(y), X)$ by $x \mapsto (x-y)\gamma^{-1}$, $\xi \mapsto \xi\rho^{-1}$, $\tau \mapsto \tau\varrho^{-1}\varrho_0$ and multiplying $\boldsymbol{A}$ by $\varrho^{-1}\varrho_0$ we find ourselves in the framework of one of the theorems of Chapters 4–8 which providing estimate

$$\mathsf{R}_{h,\psi} := \Big| \int \mathsf{tr}\big(e(x,x,0)\big)\psi(x)\,dx - \mathcal{N}_{h,\psi}\Big| \le h^{-d}\vartheta_l(h) \tag{9.1.18}$$

[5)] All scaling functions are calculated at y.

where $\mathcal{N}_\psi$ denotes main part of semiclassical asymptotics, $h = (\rho\gamma)^{-1}$ is an *effective semiclassical parameter* and $\psi \in \mathscr{C}^\infty(\bar{X})$ supported in $\mathcal{B}(y, \frac{1}{2}\gamma(y))$ such that

$$|D^\beta \psi| \le c_\beta \gamma^{-|\beta|} \qquad \forall \beta : |\beta| \le K \tag{9.1.19}$$

and in (9.1.19) we already scaled back to original coordinates.

Later we list the most important cases. One can prove easily

(9.1.20) There exist real-valued functions $\psi_\nu \in \mathscr{C}^\infty(\bar{X})$, supported in $\mathcal{B}(y_\nu, \frac{1}{2}\gamma(y_\nu), X)$ such that $\psi_{\mathsf{reg}} := \sum_\nu \psi_\nu^2$ equals 1 in $X_{\mathsf{reg},\frac{7}{16}}$ and no more than $L(d)$ of different balls $\mathcal{B}(y_\nu, \frac{3}{4}\gamma(y_\nu), X)$ can have non-empty intersection.

Here and below γ'-vicinity of set M is a set $\bigcup_{y\in M} \mathcal{B}(y, \gamma'(y), X)$ and $X_{\mathsf{reg},\sigma}$ denotes $\sigma\gamma$-vicinity of $X_{\mathsf{reg},0}$, $0 \le \sigma \le 1$. Condition (9.1.8) means that $X_{\mathsf{reg}} \supset X_{\mathsf{reg},1}$.

Then we instantly arrive to

Proposition 9.1.6. *Let all the above assumptions be fulfilled and let ψ satisfy* (9.1.19) *and be supported in $X_{\mathsf{reg},\frac{1}{2}}$. Then*

$$\mathsf{R}_\psi \le R_1 := C_0 \sum_l \int_{X_{\mathsf{reg}(l)}} \rho^d \vartheta_l\big((\rho\gamma)^{-1}\big)\, dx \tag{9.1.21}$$

with $C_0 = C_0(d, c, m)$.

Singular Zone

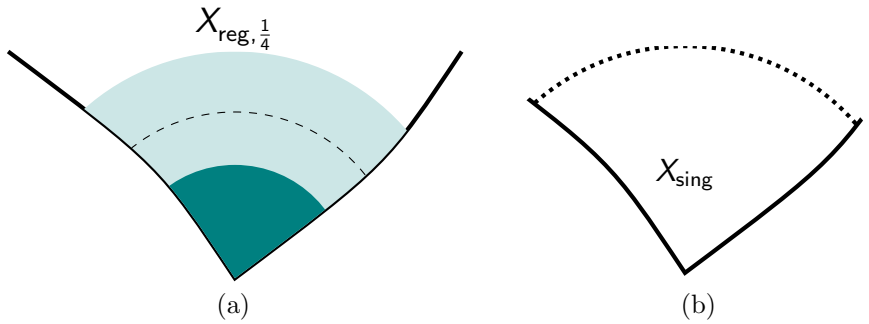
To estimate $\mathsf{N}^-(\boldsymbol{A})$ from above we need to consider $\psi = \psi_{\mathsf{sing}}$ satisfying (9.1.19) and supported in $\bar{X} \setminus \bar{X}_{\mathsf{reg},\frac{6}{16}}$.

Let us assume that

(9.1.22) There exist an operator $\boldsymbol{A}'$ in $\mathscr{L}^2(X_{\mathsf{sing}}, \mathbb{H})$ and boundary operators B_j' coinciding with $\boldsymbol{A}$ and B_j respectively on functions supported in $\bar{X}_{\mathsf{sing}} \setminus \bar{X}_{\mathsf{reg},\frac{1}{4}}$ such that under the boundary conditions $B_j' u|_{\partial X_{\mathsf{sing}}} = 0$ $(j = 1, \dots, \mu)$ this operator $\boldsymbol{A}'$ is self-adjoint and the estimate

$$\mathsf{N}^-(\boldsymbol{A}' - t) \le R_0(t+1)^p \qquad \forall t \ge 0 \tag{9.1.23}$$

holds.



(a) (b)

Figure 9.2: On (a) dark colored zone denotes $\mathsf{supp}(\psi_{\mathsf{sing}})$, together with light colored zone making X_{sing}; dashed line is the border of $X_{\mathsf{reg},\frac14}$. On (b) X_{sing} is considered alone; dotted line is $\partial X_{\mathsf{sing}} \setminus \partial X$.

Finally, let us assume that

$$\varrho_0\rho\gamma \ge \epsilon_0\varrho \quad \text{in} \quad \bigl(X_{\mathsf{reg},\frac14} \setminus X_{\mathsf{reg,ell}}\bigr) \cap X_{\mathsf{sing}} \cap \{\rho\gamma \ge c\}, \tag{9.1.24}$$

$$\epsilon_0\varrho(\rho\gamma)^{-p} \le \varrho_0 \le c\varrho(\rho\gamma)^{p} \quad \text{in} \quad X_{\mathsf{reg}} \cap X_{\mathsf{sing}} \tag{9.1.25}$$

where $X_{\mathsf{reg,ell}}$ denotes a part of X_{reg} where $\{A, B\}$ is elliptic in the semiclassical sense (after described rescaling).

The first assumption is assumed to provide the following statement:

(9.1.26) As $0 \le \sigma_1 < \sigma \le 1$ singularities starting at $X \setminus X_{\mathsf{reg},\sigma}$ reach $X_{\mathsf{reg},\sigma_1}$ only after a time no less than $\epsilon(\sigma - \sigma_1)$.

In fact, as $\rho\gamma \le c$ the propagation of singularities is absent because $h = (\rho\gamma)^{-1} \asymp 1$ and hence the notion of the singularity is empty. Further, there is no propagation in the elliptic zone either.

On the other hand, the results of Chapters 2 and 3 obviously yield that the spatial velocity of propagation of singularities for the operator $D_t - A$ in $X_{\mathsf{reg},\frac14} \cap X_{\mathsf{sing}}$ does not exceed $C_0\varrho\varrho_0^{-1}\rho^{-1}$ while the distance between $y \in X \setminus X_{\mathsf{reg},\sigma}$ and $x \in X_{\mathsf{reg},\sigma_1}$ is not less than $(\sigma - \sigma_1)\gamma(x)$. Therefore the time is not less than $\epsilon_2(\sigma - \sigma_1)\varrho^{-1}\varrho_0\rho\gamma$.

Meanwhile assumption (9.1.25) guarantees that $\varrho\varrho_0^{-1}$ is neither too large nor too small in this zone.

Finally, assume that

(9.1.27) In $X_{\mathsf{reg}} \cap X_{\mathsf{sing}}$ after rescaling $\mathcal{B}(y, \gamma(y), X)$ by $x \mapsto (x-y)\gamma^{-1}$, $\xi \mapsto \xi\rho^{-1}$, $\tau \mapsto \tau\varrho^{-1}\varrho_0$ and multiplying $\boldsymbol{A}$ by $\varrho^{-1}\varrho_0$ we find that problem $\{A, B\}$ is uniformly elliptic and positive in the classical sense[6)].

Our major result is the following

Theorem 9.1.7. *Let conditions* (9.1.5)–(9.1.13) *and* (9.1.15)–(9.1.18) *be fulfilled.*

(i) Then estimate

$$\mathsf{N}^-(\boldsymbol{A}) \ge \mathcal{N} - C_0 R_1 \tag{9.1.28}$$

holds with $\mathcal{N} = \mathcal{N}_{1,\psi}$ *defined as a sum of main parts of asymptotics in* (9.1.17)–(9.1.18) *and* R_1 *defined by* (9.1.21) *as a sum of remainder estimates there.*

(ii) Moreover, if conditions (9.1.22)–(9.1.25) *and* (9.1.27) *are fulfilled then estimate*

$$\mathsf{N}^-(\boldsymbol{A}) \le \mathcal{N} + C_0 R_1 + C_1 R_0 + C R_2 \tag{9.1.29}$$

holds with R_0 *appearing in* (9.1.23) *and*

$$R_2 = \int_{X_{\mathsf{reg},\frac{1}{4}} \cap X_{\mathsf{sing}}} \rho^{d-s}\gamma^{-s}\,dx, \tag{9.1.30}$$

$C_0 = C_0(d, c)$, $C_1 = C_1(d, p, c)$, $C = C(d, \mathsf{D}, c, s)$.

9.1.3 Proof of the Main Theorem

Let us note first that the lower estimate (9.1.23) for $\mathsf{N}^-(\boldsymbol{A})$ follows immediately from Proposition 9.1.6 since $\mathsf{N}^-(\boldsymbol{A}) \ge \mathsf{Tr}\big(E(0)\psi_{\mathsf{reg}}\big)$ as $0 \le \psi_{\mathsf{reg}} \le 1$. Further note that the upper estimate for $\mathsf{N}^-(\boldsymbol{A})$ also follows from Proposition 9.1.6 in the special case when $X_{\mathsf{sing}} = \emptyset$. Meanwhile in the general case we obtained an upper estimate for $\mathsf{Tr}\big(E(0)\psi_{\mathsf{reg}}\big)$ provided

[6)] Which means that selecting only homogeneous main parts of A, B_j with coefficients fixed in y we get a problem in the whole or half-space which is elliptic uniformly with respect to y and non-negative.

(9.1.31) $\mathsf{supp}(\psi_{\mathsf{reg}}) \subset X_{\mathsf{reg},\frac{1}{4}}$, $\psi_{\mathsf{reg}} = 1$ in $\mathsf{supp}(\psi) \subset X_{\mathsf{reg},\frac{1}{3}}$ and ψ_{reg} satisfies (9.1.19).

To derive an upper estimate for $\mathsf{N}^-(\boldsymbol{A})$ we need an upper estimate for $\mathsf{Tr}(E(0)(1-\psi_{\mathsf{reg}}))$. Let $U(x,y,t)$ be the Schwartz kernel of the operator $\exp(it\boldsymbol{A})$; recall that $\boldsymbol{A} = J^{-\frac{1}{2}} A J^{-\frac{1}{2}}$. We need some additional analysis in the zone $X_{\mathsf{reg},\mathsf{ell}} \cap X_{\mathsf{sing}} \cap \{\rho\gamma \ge c\}$.

Proposition 9.1.8. *Let conditions* (9.1.5)–(9.1.13), (9.1.15)–(9.1.18), (9.1.24)–(9.1.25) *and* (9.1.27) *be fulfilled.*

Let $\epsilon_0 > 0$ and $T_0 = T_0(d,c,\epsilon_0) > 0$ be small enough constants. Then the following estimates hold uniformly with respect to $x \in X_{\mathsf{reg},\frac{2}{7}}$:

$$\|D_x^\alpha F_{t\to h^{-1}\tau}\chi_T(t)U^{\pm}\psi'(y)\| \le C_1' h^s (|\tau|+1)^{-s}\gamma(x)^{-\frac{d}{2}-|\alpha|} \qquad \forall \tau \le c \qquad \forall \alpha : |\alpha| \le s, \tag{9.1.32}$$

and

$$\|D_x^\alpha F_{t\to h^{-1}\tau}\chi_T(t)U^{\pm}\psi'(y)\| \le C_1' h^{-M} (|\tau|+1)^{M}\gamma(x)^{-\frac{d}{2}-|\alpha|} \qquad \forall \tau \ge c \qquad \forall \alpha : |\alpha| \le s \tag{9.1.33}$$

where $\mathscr{L}^2$-norms with respect to y are calculated in the left-hand expression and here and below $\psi' \in \mathscr{L}^\infty$ is an arbitrary function such that

$$|\psi'| \le 1,\ \mathsf{supp}(\psi') \cap \mathcal{B}(x, \epsilon_0\gamma(x), X) = \emptyset \tag{9.1.34}$$

with $M = M(d,m,s)$, $C_1' = C_1'(d,m,s,c)$ and $h := \big(\rho(x)\gamma(x)\big)^{-1}$.

Proof. (a) Let us consider point $\bar{x}$ instead of x and operator $P = hD_t - \zeta\boldsymbol{A}$ with $h = (\bar\rho\bar\gamma)^{-1}$, $\zeta = h\bar\varrho^{-1}\bar\varrho_0$ where $\bar\gamma = \gamma(\bar{x})$ etc. Without any loss of the generality one can assume that $\bar\gamma = 1$ (otherwise we rescale).

Consider $f \in \mathscr{L}^2(X, \mathbb{H})$ with $\mathsf{supp}\, f \cap \mathcal{B}(\bar{x}, \epsilon_0\bar\gamma, X)$. Let us set

$$u(x,t) = \int U(x,y,t)(y)f(y)dy. \tag{9.1.35}$$

Then

$$Pu^{\pm} = 0 \quad \text{in} \quad \mathcal{B}(\bar{x}, \epsilon_0\bar\gamma, X), \tag{9.1.36}$$

$$B_j u^{\pm} = 0 \quad \text{at} \quad \partial X \cap \mathcal{B}(\bar{x}, \bar\gamma, X) \qquad (j = 1, \dots, \mu). \tag{9.1.37}$$

(b) Let us first assume that $\zeta \le c$. Then one can apply the theorem about the finite speed of propagation of singularities[7)] and therefore the following estimate holds:

$$\|F_{t\to h^{-1}\tau}\chi_T(t)u^{\pm}\| \le C_1' h^s \|f\| \qquad \forall x \in \mathcal{B}(\bar{x}, \frac{1}{2}\epsilon_0\bar{\gamma}, X) \qquad \forall \tau : |\tau| \le c \tag{9.1.38}$$

where we have also used the estimate

$$\|u^{\pm}\| \le \|f\| \tag{9.1.39}$$

which follows from the fact that the operator $\exp(itA)$ is unitary in $\mathcal{H}_0$; here $\mathscr{L}^2(X, \mathbb{H})$-norms (with respect to x) are calculated.

(c) Now let us apply the following *additional arguments:* the classical ellipticity of the rescaled problem as stated in (9.1.27), the inequality $\zeta \ge h^{\rho}$ due to (9.1.25) and the standard embedding inequality; then we obtain estimate

$$|D^{\alpha}F_{t\to h^{-1}\tau}\chi_T(t)u^{\pm}| \le C_1' h^s \|f\| \qquad \forall x \in \mathcal{B}(\bar{x}, \frac{1}{2}\epsilon_0\bar{\gamma}, X) \quad \forall \alpha : |\alpha| \le s \quad \forall \tau : |\tau| \le c. \tag{9.1.40}$$

Furthermore, the same *additional arguments* and the classical ellipticity and positivity of the rescaled problem as stated in (9.1.27) easily yield estimate

$$|D^{\alpha}F_{t\to h^{-1}\tau}\chi_T(t)u^{\pm}| \le C_1' h^s (|\tau|+1)^{-s}\|f\| \qquad \forall x \in \mathcal{B}(\bar{x}, \frac{1}{2}\epsilon_0\bar{\gamma}, X) \quad \forall \alpha : |\alpha| \le s \quad \forall \tau \le -C_0. \tag{9.1.41}$$

(d) On the other hand, let $\zeta \ge c$. Then as $\rho\gamma \ge c$ the problem is elliptic in the semiclassical sense in $\mathcal{B}(\bar{x}, \epsilon_0\bar{\gamma})$ due to assumption (9.1.24) and the semiclassical elliptic arguments and the above *additional arguments* yield estimate (9.1.41) for all $\tau \le \epsilon_2\zeta$. Therefore estimate (9.1.41) remains true in this case as well.

[7)] Let us recall that we assumed not just estimate in (9.1.18) but also being in the frameworks of one of the theorems of Part sII and III in X_{reg} and it implies the finite speed of propagation and all other results involved.

(e) Finally, the *additional arguments* alone easily yield the estimate

$$|D^{\alpha}F_{t\to h^{-1}\tau}\chi_T(t)u^{\pm}| \le C_1' h^{-M}(|\tau|+1)^M \|f\| \quad \forall x \in \mathcal{B}(\bar{x}, \frac{1}{2}\epsilon_0\bar{\gamma}, X) \quad \forall \alpha : |\alpha| \le s \quad \forall \tau. \tag{9.1.42}$$

Since $f \in \mathscr{L}^2(X, \mathbb{H})$ is an arbitrary function such that $\mathsf{supp}(f) \cap \mathcal{B}(\bar{x}, \epsilon_0\bar{\gamma}, X) = \emptyset$, estimates (9.1.40)–(9.1.42) yield estimates (9.1.32) and (9.1.33). □

Remark 9.1.9. The same proof implies that estimates (9.1.32) and (9.1.33) remain true for $U'^{\pm}(x, y, t)$ where $U'(x, y, t)$ is the Schwartz kernel of the operator $\exp(it\boldsymbol{A}')$ as long as $x \in X \setminus X_{\mathsf{reg}, \frac{1}{4}}$.

Indeed, in $X \setminus X_{\mathsf{reg}, \frac{1}{4}}$ operator $\boldsymbol{A}'$ coincides with $\boldsymbol{A}$.

Proposition 9.1.10. *In the framework of Proposition 9.1.8 estimates*

$$\|F_{t\to\tau}\chi_T(t) \int \psi_{\mathsf{sing}}(x)\big(U^{\pm} - U'^{\pm}\big)(x, x, t)\, dx\| \le C_1'(|\tau|+1)^{-s} R_2 \tag{9.1.43}$$

and

$$\|F_{t\to\tau}\psi_{\mathsf{sing}}\chi_T(t)\big(\exp(it\boldsymbol{A}) - \exp(it\boldsymbol{A}')\big)\psi_{\mathsf{sing}}\|_1 \le C'(|\tau|+1)^{-s} R_2 \tag{9.1.44}$$

hold for all $\tau \le \frac{1}{2}c$. Recall that $\|.\|_1$ means the trace norm and C_1' does not depend on D but C' does.

Proof. Let ψ satisfy (9.1.19), $\psi = 1$ in $\bar{X} \setminus \bar{X}_{\mathsf{reg}, \frac{6}{16}}$ and $\mathsf{supp}(\psi) \subset \bar{X} \setminus \bar{X}_{\mathsf{reg}, \frac{5}{16}}$. Let us recall that $\mathsf{supp}(\psi_{\mathsf{sing}}) \subset \bar{X} \setminus \bar{X}_{\mathsf{reg}, \frac{7}{16}}$.

Let us consider

$$V^{\pm}(x, y, t) = \psi(x)(U^{\pm} - U'^{\pm})(x, y, t)\psi'(y) \tag{9.1.45}$$

where here and below ψ' is a cut-off function similar to ψ_{sing}. Then

$$PV^{\pm} = F^{\pm}, \quad B_k V^{\pm} = G_k^{\pm}$$

with $P = D_t - \boldsymbol{A}$, $F^{\pm}$ and $G_k^{\pm}$ supported in $\mathcal{X} := \bar{X}_{\mathsf{reg},\frac{6}{16}} \setminus \bar{X}_{\mathsf{reg},\frac{5}{16}}$ and therefore by the Duhamel principle

$$V^+(x,y,t) = \int_0^t dt' \Big(\int U^+(x,z,t') F^+(z,y,t-t')\, dz + \sum_{1\le k\le \mu} \int_{\partial X} \big(\beta_k(z,D_z) U^+(x,z,t')\big)\, G_k^+(z,y,t-t')\, dz' \Big) \tag{9.1.46}$$

where β_k are differential operators on z.

Therefore $V^+ = \sum_n V_n^+$ where V_n^+ are given by formula (9.1.46) with additional factors $\psi_n^2(z)$ in the integrands and $\{\psi_n^2\}$ is a γ-admissible partition of unity in $\mathcal{X}$.

Then Proposition 9.1.8 and Remark 9.1.9 yield that $\mathscr{L}^2$-norms with respect to y of $F_{t\to h^{-1}\tau}\chi_T(t)F^+$ and $F_{t\to h^{-1}\tau}\chi_T(t)G_k^+$ do not exceed

$$C_0 h^{-M}\big(|\tau|+1\big)^M \bar{\gamma}^{-\frac{d}{2}}$$

and

$$C_0 h^{-M} \bar{\varrho}_k \big(|\tau|+1\big)^M \bar{\gamma}^{-\frac{d}{2}}$$

respectively for all $z \in \mathsf{supp}(\psi_n)$ where $h = \bar{\rho}^{-1}\bar{\gamma}^{-1}$ and $\bar{\rho}, \bar{\gamma}, \bar{\varrho}_k$ are ρ, γ, ϱ_k calculated at some point of $\mathsf{supp}(\psi_n)$; all of these and the following estimates hold for all n.

Further, Proposition 9.1.8 and Remark 9.1.9 yield that the $\mathscr{L}^2$-norms with respect to x of

$$\psi'(x) F_{t\to h^{-1}\tau}\chi_T(t) U^+(x,z,t)$$

and

$$\psi'(x) F_{t\to h^{-1}\tau}\chi_T(t) B_k'(z,D_z) U^+(x,z,t)\psi_n(z)$$

do not exceed

$$C_0 h^{-M}\big(|\tau|+1\big)^M \bar{\gamma}^{-\frac{d}{2}}$$

and

$$C_0 h^{-M} \bar{\varrho}_k^{-1} \big(|\tau|+1\big)^M \bar{\gamma}^{1-\frac{d}{2}}$$

respectively. Recall that $z \in \mathsf{supp}(\psi_n)$ and

$$U(x,y,t) = U^{\dagger}(y,x,-t) \tag{9.1.47}$$

because $\boldsymbol{A}$ is a self-adjoint operator in $\mathcal{H}_0$.

Furthermore, Proposition 9.1.8 and Remark 9.1.9 also imply that for $\tau \le \frac{1}{2}c$ these four estimates hold with the exponent M replaced by $-s$ in the right-hand expressions and with constant C_0 replaced by C_1'. Since $\dim \mathbb{H} = \mathsf{D} < \infty$ all these inequalities hold (with constants depending also on D) not only $\mathscr{L}^2$-norms with respect to x or y but also for Hilbert-Schmidt norms of the corresponding operators.

Therefore we conclude that

(9.1.48) Let $W_n^+(x,y,t)$ be given by formula (9.1.46) with the additional factor $\psi_n^2(z)\chi_T(t')\chi_T(t-t')$ in the integrand. Then the trace norm of operator with the Schwartz kernel $F_{t\to h^{-1}\tau} W_n^+ \psi'(x)\psi'(y)$ does not exceed

$$\begin{cases} C'\bar\gamma^{-d} h^s (|\tau|+1)^{-s} & \text{as } \tau \le c, \\ C\bar\gamma^{-d} h^{-M} (|\tau|+1)^{M} & \text{as } \tau \ge c. \end{cases} \tag{9.1.49}$$

Therefore

(9.1.50) The trace norm of the operator with the Schwartz kernel

$$F_{t\to h^{-1}\tau}\chi_{\frac{1}{2}T}(t) W_n^+ \psi'(x)\psi'(y)$$

does not exceed $C'\bar\gamma^{-d} h^s (|\tau|+1)^{-s}$ as $\tau \le \frac{1}{2}c$.

Let us replace in the previous analysis and definitions function χ by $\bar\chi$ equal to 1 on $\operatorname{supp}(\chi)$. Then $\chi_T(t)\big(V_n^+ - W_n^+\big) = 0$ and therefore one can replace W_n^+ by V_n^+ in the statement (9.1.50).

Surely one can replace $h^{-1}\tau$ by τ in this statement as well. Replacing h by $\rho^{-1}\gamma^{-1}$ and summing with respect to n we obtain estimate (9.1.44); (9.1.43) follows from it. Finally, these estimates for sign "+" imply themselves for sign "−". □

Proof of Theorem 9.1.7. Let Π be an arbitrary r-dimensional self-adjoint projector in $\mathcal{H}_0$. Then (9.1.44) yields that

$$|F_{t\to\tau}\chi_T(t)\operatorname{Tr}\Big(\Pi\psi_{\mathsf{sing}}\big(\exp(it\boldsymbol{A}) - \exp(it\boldsymbol{A}')\big)\psi_{\mathsf{sing}}\Big)| \le C'R_2\big(|\tau|+1\big)^{-s} \tag{9.1.51}$$

where here and below we assume that $\tau \le \frac{1}{2}c$.

Observe that the left-hand expression of (9.1.51) equals the left-hand expression of

$$|\int \widehat{\chi_T}(\tau-\lambda)\, d_\lambda\, \mathsf{Tr}\Big(\Pi\psi_{\mathsf{sing}}\big(E(\lambda)-E'(\lambda)\big)\psi_{\mathsf{sing}}\Big)| \le C'R_2\big(|\tau|+1\big)^{-s}$$

where $E'(\lambda)$ is the spectral projector of $\boldsymbol{A}'$. The latter estimate holds ince the trace norm of Π does not exceed Cr. Therefore

$$|\int \widehat{\chi_T}(\tau-\lambda)\, d_\lambda\, \mathsf{Tr}\Big(\Pi\psi_{\mathsf{sing}}E(\lambda)\psi_{\mathsf{sing}}\Big)| \le$$
$$|\int \widehat{\chi_T}(\tau-\lambda)\, d_\lambda\, \mathsf{Tr}\Big(\Pi\psi_{\mathsf{sing}}E'(\lambda)\psi_{\mathsf{sing}}\Big)| + C'R_2\big(|\tau|+1\big)^{-s}.$$

Let us take a Hörmander function χ (and so χ_T is of the same type). Then the standard Tauberian arguments yield that

$$\mathsf{Tr}\Big(\Pi\psi_{\mathsf{sing}}\big(E(\tau)-E(\tau-1)\big)\psi_{\mathsf{sing}}\Big) \le$$
$$C\int \widehat{\chi_T}(\tau-\lambda)\, \mathsf{Tr}\Big(\Pi\psi_{\mathsf{sing}}\, d_\lambda E'(\lambda)\psi_{\mathsf{sing}}\Big) + C'R_2\big(|\tau|+1\big)^{-s}.$$

The right-hand expression of this estimate does not decrease if we replace Π by I and ψ_{sing} by 1. Since $\mathsf{Tr}(E'(\lambda)) = \mathsf{N}^-(\boldsymbol{A}'-\lambda)$ we conclude that

$$\mathsf{Tr}\Big(\Pi\psi_{\mathsf{sing}}\big(E(\tau)-E(\tau-1)\big)\psi_{\mathsf{sing}}\Big) \le$$
$$C\int \widehat{\chi_T}(\tau-\lambda)\, d_\lambda \mathsf{N}^-(\boldsymbol{A}'-\lambda) + C'R_2\big(|\tau|+1\big)^{-s}.$$

Since this estimate is true for all the self-adjoint finite-dimensional projectors in $\mathcal{H}_0$ it is true for Π replaced by I:

$$\mathsf{Tr}\Big(\psi_{\mathsf{sing}}\big(E(\tau)-E(\tau-1)\big)\psi_{\mathsf{sing}}\Big) \le \tag{9.1.52}$$
$$C\int \widehat{\chi_T}(\tau-\lambda)\, d_\lambda \mathsf{N}^-(\boldsymbol{A}'-\lambda) + C'R_2\big(|\tau|+1\big)^{-s}.$$

Thus we got rid of projector Π which we used only to justify the Fourier transform and the replacement of the left-hand expression in (9.1.51).

Picking up $\tau = -n$ in (9.1.52), after summation with respect to $n = 0, 1, 2, \dots$ we obtain estimate

$$\mathsf{Tr}\Big(\psi_{\mathsf{sing}} E(0) \psi_{\mathsf{sing}}\Big)) \le C \sum_{n\ge 0} \int \widehat{\chi_T}(-n-\lambda)\, d_\lambda \mathsf{N}^-(\boldsymbol{A}' - \lambda) + C' R_2. \tag{9.1.53}$$

Let us note that $\sum_{n\ge 0} \widehat{\chi_T}(-n-\lambda)$ does not exceed C_1 and $C_1'(|\lambda|+1)^{-s}$ for $\lambda \ge 0$ and $\lambda \le 0$ respectively.

Therefore the first term in the right-hand expression of (9.1.53) does not exceed

$$C_1' \int_0^\infty (|\lambda|+1)^{-s}\, d_\lambda \mathsf{N}^-(\boldsymbol{A}' - \lambda) + C_1 \int_{-\infty}^0 d_\lambda \mathsf{N}^-(\boldsymbol{A}' - \lambda) \le$$
$$C_1' \int_0^\infty (|\lambda|+1)^{-s}\, d_\lambda \mathsf{N}^-(\boldsymbol{A}' - \lambda) + C_1 \mathsf{N}^-(\boldsymbol{A}')$$

where we have integrated by parts. Then condition (9.1.23) yields that the first term in the right-hand expression in (9.1.53) does not exceed $C_1 R_0$ and therefore

$$\mathsf{Tr}\big(\psi_{\mathsf{sing}} E(0) \psi_{\mathsf{sing}}\big) \le C_1 R_0 + C' R_2. \tag{9.1.54}$$

Namely this estimate was lacking for the proof of Theorem 9.1.7. □

The following problem does not seem to be too hard but still worth publishing:

Problem 9.1.11. As $\mathbb{H}$ is infinite-dimensional space prove the similar results involving auxiliary operators B and B_1 (not to be confused with boundary operators) and Hilbert scale $\mathbb{H}_j$ (see Chapters 2 and 4 for details.

9.1.4 Riesz Means Estimates

Let us instead of $\mathsf{N}^-(A)$ consider Riesz means, namely

$$\mathsf{N}^-_\omega(A) = \int \tau_+^{\omega-1} \mathsf{N}^-(A-\tau)\, d\tau, \qquad \omega > 0. \tag{9.1.55}$$

Then one can apply local asymptotics for Riesz means. However, it would be more convenient for us to write $\mathsf{N}^-_\omega(A)$ in the form

$$\mathsf{N}^-_\omega(A) = \int \tau_+^{\omega-1} \mathsf{N}^-(J^{-\frac12}(A-\tau)J^{-\frac12})\, d\tau \tag{9.1.56}$$

with the same function J as before in order to get better estimates in the singular zone. In this case one can apply the results of Section 6.5.

As before contribution of the partition element ψ of the the regular zone to the main part of the asymptotics is given by $\mathcal{N}_{\psi,\omega}$ prescribed by Section 6.5 while its contribution to the remainder does not exceed $h^{-d}\varrho^{\omega}\nu_{l,\omega}(h)$ as this element is supported in $X_{\mathsf{reg},(l)}$. So the total main part of asymptotics is $\mathcal{N}_{\psi_{\mathsf{reg}},\omega}$ while contribution of the regular zone to the remainder is

$$\mathsf{R}_{\psi,\omega} \le R_{1,\omega} \coloneqq C\sum_{l}\int_{X_{\mathsf{reg}(l)}} \rho^{d}\varrho^{\omega}\vartheta_{l,\omega}\bigl((\rho\gamma)^{-1}\bigr)\,dx. \tag{9.1.57}$$

As in (9.1.21) the standard case was h^{1-d} but now it is $h^{1-d+\omega}\varrho^{\omega}$; so the standard remainder estimate is

$$C\int_{X_{\mathsf{reg}}} \rho^{d-1-\omega}\gamma^{-1-\omega}\varrho^{\omega}\,dx. \tag{9.1.58}$$

Remark 9.1.12. One can easily prove that application of (9.1.56) instead of (9.1.55) does not lead to a different local expression.

Further, the same arguments as in the proof of Theorem 9.1.7 imply

Theorem 9.1.13. *Let conditions* (9.1.5)–(9.1.13) *and* (9.1.15)–(9.1.18) *be fulfilled.*

(i) Then estimate

$$\mathsf{N}^{-}_{\omega}(\boldsymbol{A}) \ge \mathcal{N}_{\omega} - C_0 R_{1,\omega} \tag{9.1.59}$$

holds.

(ii) Moreover, if conditions

$$\mathsf{N}^{-}_{\omega}(\boldsymbol{A}'-t) \le R_{0,\omega}(t+1)^{p} \qquad \forall t\ge 0, \tag{9.1.60}$$

(9.1.24), (9.1.25) *and* (9.1.27) *are fulfilled then the estimate*

$$\mathsf{N}^{-}_{\omega}(\boldsymbol{A}) \le \mathcal{N}_{\omega} + C_0 R_{1,\omega} + C_1 R_{0,\omega} + C' R_{2,\omega} \tag{9.1.61}$$

holds with

$$R_{2,\omega} = \int_{X_{\mathsf{reg},\frac{1}{4}}\cap X_{\mathsf{sing}}} \rho^{d-s}\gamma^{-s}\varrho^{\omega}\,dx, \tag{9.1.62}$$

$C_0 = C_0(d,c,\omega)$, $C_1 = C_1(d,c,p,\omega)$, $C' = C'(d,\mathsf{D},c,M,\omega)$.

Proof. Easy details are left to the reader. □

Problem 9.1.14. Derive similar results for averaging functions φ satisfying (4.2.73)–(4.2.75) rather than $\varphi(\tau) = \tau_+^\omega$.

9.2 Examples to Main Theorems

In this section we consider some rather general examples of contributions of X_{reg} and X_{sing} to the remainder.

9.2.1 Regular Zone: Standard Remainder Estimate

Let us consider the first regular zone. In virtue of Parts II and III one can set

$$\mathcal{N} = \mathcal{N}^{\mathsf{W}} := (2\pi)^{-d} \iint \boldsymbol{n}^-(x,\xi)\, dxd\xi \tag{9.2.1}$$

where $\boldsymbol{n}^-(x,\xi)$ is a number of negative eigenvalues of $a(x,\xi)$ and

$$R_1 = C \int_{X_{\mathsf{reg}} \setminus X_{\mathsf{reg,ell}}} \rho^{d-1}\gamma^{-1}\, dx + C' \int_{X_{\mathsf{reg,ell}}} \rho^{d-s}\gamma^{-s}\, dx \tag{9.2.2}$$

with C' depending on s in the cases described in Examples 9.2.1–9.2.5 below. We assume that $\mathsf{D} < \infty$ is fixed.

Example 9.2.1. Assume that the regularity conditions

$$|D^\beta a_\alpha| \le c\varrho\rho^{-|\alpha|}\gamma^{-|\beta|} \qquad \forall \alpha : |\alpha| \le m, \tag{9.2.3}_1$$

$$|D^\beta b_{j\alpha}| \le c\varrho_j\rho^{-|\alpha|}\gamma^{-|\beta|} \qquad \forall j = 1,\dots,\mu \qquad \forall \alpha : |\alpha| \le m_j, \tag{9.2.3}_2$$

$$|D^\beta J| \le c\varrho_0\gamma^{-|\beta|}, \qquad \forall \beta : |\beta| \le K \tag{9.2.3}_3$$

and

$$|D^\beta \phi| \le c\gamma^{1-|\beta|} \qquad \forall \beta : 1 \le |\beta| \le K \tag{9.2.3}_4$$

are fulfilled; recall that a_α and $b_{j\alpha}$ are coefficients of A and B_j and ϕ appears in (9.1.15)–(9.1.16). Moreover assume that

$$|J^{-1}| \le c\varrho_0^{-1} \tag{9.2.4}$$

and operator $\varrho^{-1}A$ is microhyperbolic at energy level 0 (uniformly, after rescaling $x \mapsto x\gamma^{-1}$, $\xi \mapsto \xi\rho^{-1}$).

Further let us assume that operator $\varrho^{-1}A$ and boundary value problem $\{\varrho^{-1}A, \varrho_1^{-1}B_1, \dots, \varrho_\mu^{-1}B_\mu\}$ are uniformly elliptic in the classical sense. Recall that in virtue of Theorem 7.5.15 we do not need to assume microhyperbolicity of the boundary value problem.

Example 9.2.2. Consider in dimension $d \ge 2$ Schrödinger operator (possibly with magnetic field)

$$A = \sum_{j,k} (D_j - V_j) g^{jk} (D_k - V_k) + V \tag{9.2.5}$$

with real-valued $g^{jk} = g^{kj}$, V_j, V such that

$$c^{-1}|\eta|^2 \le \sum_{j,k} g^{jk}\eta_j\eta_k \le c|\eta|^2 \qquad \forall \eta \in \mathbb{R}^d \tag{9.2.6}$$

and

$$|D^\beta g^{jk}| \le c\gamma^{-|\beta|} \qquad \forall j,k, \tag{9.2.7}_1$$

$$|D^\beta F_{jk}| \le c\rho\gamma^{-|\beta|-1} \qquad \forall j,k, \tag{9.2.7}_2$$

$$|D^\beta V| \le c\rho^2\gamma^{-|\beta|}, \qquad \forall \beta : |\beta| \le K \tag{9.2.7}_3$$

where $F_{jk} = \partial_k V_j - \partial_j V_k$ is the tensor of magnetic field intensity.

Recall that due to results of Section 8.2 we do not need microhyperbolicity.

Furthermore, due to Sections 4.6, 7.5 and 8.2 we can relax smoothness conditions in Examples 9.2.1 and 9.2.2:

Example 9.2.3. Assume ξ-microhyperbolicity in example 9.2.1. Then one can replace condition $(9.2.3)_1$ by

$$|D^\beta a_\alpha| \le c\varrho\beta!\rho^{-|\alpha|}\gamma^{-|\beta|}(1+\varepsilon^{1-|\beta|}) \qquad \text{with } \varepsilon = C(\rho\gamma|\log\rho\gamma|)^{-1} \quad \forall \alpha : |\alpha| \le m, \forall \beta : |\beta| \le \epsilon\rho\gamma; \tag{9.2.8}_1$$

we leave to the reader to rewrite the smoothness conditions to ϕ, $b_{j,\alpha}$ (starting from (7.5.42)) according to Section 7.5 [8)].

[8)] One can relax smoothness conditions to J as well but this is not important since it is an auxiliary weight we introduce as needed and can smoothen it.

Example 9.2.4. Assume that either $d \ge 3$ or that $d = 2$ and

$$|V| + |\nabla V|^{\gamma} \ge \epsilon\rho^2 \tag{9.2.9}$$

in Example 9.2.2. Then we can relax conditions $(9.2.7)_1$–$(9.2.7)_3$ in the similar way.

Example 9.2.5. Furthermore, again due to Sections refsect-4-6, 7.5 and 8.2 we can relax smoothness conditions even further: instead of $(9.2.8)_1$ we can assume $(9.2.3)_1$ with $K = 1$ and

$$|\nabla a_\alpha(x) - \nabla a_\alpha(y)| \le C|\log \mathsf{dist}(x,y)|^{-1}. \tag{9.2.10}$$

Then we can find operators A^+ and A^- bracketing A [9], both satisfying $(9.2.8)_1$ and such that

$$\mathcal{N}^{\mathsf{W}}(A^-) - CR_1 \le \mathcal{N}^{\mathsf{W}}(A) \le \mathcal{N}^{\mathsf{W}}(A^+) \le CR_1. \tag{9.2.11}$$

Other such examples following immediately from Parts II and III we leave to the reader.

9.2.2 Regular Zone: Sharper Asymptotics

In Parts II and III we also derived sharper asymptotics. Their main parts contained next terms some of which were expressed as integrals of functions supported in

$$\Sigma_\tau = \mathsf{supp}\big(\partial_\tau \boldsymbol{n}(x,\xi,\tau)\big) \tag{9.2.12}$$

and others as integrals over

$$\iota\big(\mathsf{supp}\big(\boldsymbol{n}(x,\xi,\tau)\big) \cap T^*X|_Y\big); \tag{9.2.13}$$

recall that $\iota : T^*X|_Y \to T^*Y$. We recall the exact expressions of them in Part V as needed.

Meanwhile the remainder estimate contains two terms:

$$\frac{C}{T_j}\partial_\tau \iint_{\Lambda_j} \boldsymbol{n}(x,\xi,\tau)\, dxd\xi \tag{9.2.14}$$

[9] I.e. such that $A^+ \ge A \ge A^-$ and therefore $\boldsymbol{A}^+ \ge \boldsymbol{A} \ge \boldsymbol{A}^-$ as we use the same matrix J satisfying $(9.2.3)_3$ for all three operators.

and

$$C'' \int_{X_{\mathrm{reg}}} \rho^{d-1-\delta}\gamma^{-1-\delta}\,dx \tag{9.2.15}$$

where (generalized) Hamiltonian trajectories (or billiards) issued from Λ_j in an appropriate time direction should satisfy certain assumptions of Parts II and III. Again we leave exact form of those assumptions to more concrete Part V but we need to mention that while the geometric shape of these trajectories on the energy level 0 does not depend on J, the temp of movement depends on ϱ_0. Really, consider just the case of scalar symbols $a(x,\xi)$ and $J(x)$. Then trajectory is given by equation

$$\begin{cases} \dfrac{dx}{dt} = \quad \varrho_0(x)^{-1}\kappa\partial_\xi a(x,\xi) \\ \dfrac{d\xi}{dt} = -\varrho_0(x)^{-1}\kappa\partial_x a(x,\xi) \end{cases} \tag{9.2.16}$$

where

$$\kappa = \varrho^{-1}\varrho_0\rho\gamma\big|_{x=x(0)} \tag{9.2.17}$$

is a normalization factor, so that initial ball $B(x,\gamma)$ is passed with time $T_0 \asymp 1$. Here we renormalized time with our usual scaling. So, these conditions and estimates are affected by the choice of ϱ_0.

9.2.3 Singular Zone

All results in the singular zone are due to Appendix 9.A.1. We mention only few of them.

Example 9.2.6. Let us assume that

$$(Au,u) \ge \epsilon\|u\|_r^2 - \|\rho^r u\|^2 \qquad \forall u \in \mathfrak{D}(A_B) : \mathsf{supp}(u) \subset \bar{X}_{\mathsf{sing}} \tag{9.2.18}$$

where $m = 2r$ is an order of operator. Therefore due to the Rozenblioum estimate (9.A.11) if on $\partial X_{\mathsf{sing}}$ $\mathfrak{D}(A_B)$ is defined by Dirichlet boundary conditions and if $d > m$ then

$$R_0 = C\int \left(\rho^d + \varrho_0^{d/m}\right) dx. \tag{9.2.19}$$

Meanwhile R_2 is less than R_0, so R_0 estimates the total contribution of X_{sing} to the remainder. Let us recall that the standard remainder estimate in the

regular zone is given by (9.2.2) but the first term may be sharpened; then the total remainder estimate is given by the sum of (9.2.2) and (9.2.19):

$$C\int_{X_{\mathsf{reg}}\setminus X_{\mathsf{reg,ell}}} \rho^{d-1}\gamma^{-1}\,dx + C'\int_{X_{\mathsf{reg,ell}}} \rho^{d-s}\gamma^{-s}\,dx + C\int_{X_{\mathsf{sing}}} \bigl(\rho^d + \varrho_0^{d/m}\bigr)\,dx. \tag{9.2.20}$$

Since the answer should not depend on J we can select $\varrho_0 \le \rho^m$ thus arriving to

$$C\int_{X_{\mathsf{reg}}\setminus X_{\mathsf{reg,ell}}} \rho^{d-1}\gamma^{-1}\,dx + C'\int_{X_{\mathsf{reg,ell}}} \rho^{d-s}\gamma^{-s}\,dx + C\int_{X_{\mathsf{sing}}} \rho^d\,dx. \tag{9.2.21}$$

Note however that selection of J affects sharper asymptotics.

Example 9.2.7. Let all assumptions of the previous example are fulfilled with the exception that on part Y_{N} of $(\partial X)\cap \bar{X}_{\mathsf{sing}}$ $\mathfrak{D}(A_B)$ is defined by some other boundary condition, which does not violate (9.2.18).

Assume that the cone condition (9.A.23)–(9.A.26) is satisfied with the cone of some fixed angle ϕ and height h_j (depending on $X_{\mathsf{sing},j}$). Then in virtue of (9.A.32) remainder estimate is still valid with an extra term

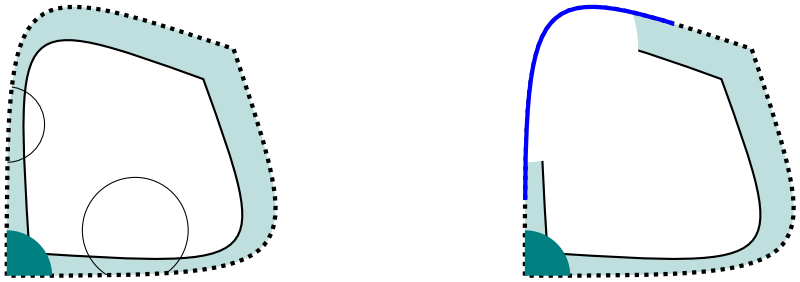
$$C\sum_j h_j^{-d}\,\mathsf{mes}(X_j). \tag{9.2.22}$$

Example 9.2.8. Consider *quasiregular zone* X_{qreg} in which all assumptions of the regular zone are fulfilled with the exception of those to the boundary which may be rather irregular there (see Figure 9.3).

Let us include the *inner zone* $\mathcal{X} = \{x \in X_{\mathsf{qreg}},\ \mathsf{dist}(x,\partial X) \ge \rho^{-1}(x)\}$ into X_{reg} and the *boundary strip* $\mathcal{Y} = \{x \in X_{\mathsf{qreg}},\ \mathsf{dist}(x,\partial X) \le 2\rho^{-1}(x)\}$ into X_{sing}.

Assume that

(9.2.23) After rescaling $x \mapsto (x-y)\gamma(y)^{-1}$ in (rescaled) $\mathcal{B}(y,\gamma(y),X)$ condition (7.5.28) is fulfilled uniformly with respect to y.



(a) (b)

Figure 9.3: On both pictures dotted line shows the part of $\partial X \cap \bar{X}_{\mathsf{qreg}}$ while solid blue line shows the smooth part of the boundary; dark color indicates $X_{\mathsf{sing}} \setminus X_{\mathsf{qreg}}$ and light color indicates $\mathcal{Y}$. Finally, on (a) two balls $\mathcal{B}(y, \gamma(y), X)$ are drawn.

Then due to Theorem 7.5.10 and Proposition 7.5.6(iii) contribution of $\mathcal{B}(y, \gamma(y), X) \cap \mathcal{X}$ to the remainder does not exceed $C\rho^{d-1}\gamma^{d-1}|\log\log(\rho\gamma)|$ [10]. Therefore the total contribution of $\mathcal{X}$ to the remainder does not exceed

$$C \int_{X_{\mathsf{qreg}}} \rho^{d-1}\gamma^{-1} |\log\log(\rho\gamma)|\, dx. \tag{9.2.24}$$

Assume that the Dirichlet boundary conditions are fulfilled there. Then as $d > m$ we can apply Rozenblioum estimate (9.2.12) and conclude that the contribution of X_{sing} to the remainder does not exceed contribution of $X_{\mathsf{sing}} \setminus X_{\mathsf{qreg}}$ plus

$$C \int_{\{x \in X_{\mathsf{qreg}},\ \mathsf{dist}(x, \partial X) \le 2\rho^{-1}(x)\}} \rho^{d}\, dx \tag{9.2.25}$$

(provided $\varrho_0 \le \rho^d$ there). Due to (9.2.23) contribution of $\mathcal{B}(y, \gamma(y), X)$ to this expression does not exceed $C\rho^{d-1}\gamma^{d-1}$ and therefore (9.2.25) does not exceed

$$C \int_{X_{\mathsf{qreg}}} \rho^{d-1}\gamma^{-1}\, dx. \tag{9.2.26}$$

[10]. Really, as $\gamma(y) = 1$, $\rho(y) = h^{-1}$ we are exactly in the framework of this section. General case is reduced to this by rescaling. Obviously γ at this moment is the radius of the ball rather then scaling function inside it.

On the other hand, if $d \le m$ we can apply the boxing described in Subsubsection *9.A.1.2 Bracketing* and since ρ has a constant magnitude in $\mathcal{B}(y,\gamma(y),X)$ we again recover the same remainder estimate.

So, instead of the assumption $X = X_{\mathsf{reg}} \cap X_{\mathsf{sing}}$ we can assume that $X = X_{\mathsf{reg}} \cap X_{\mathsf{qreg}} \cap X_{\mathsf{sing}}$ and calculate contribution of X_{reg} and X_{sing} to the remainder in the usual way and of X_{qreg} by (9.2.24).

Example 9.2.9. (i) If after rescaling $x \mapsto x\gamma^{-1}$ we find ourselves in the framework of condition (7.5.39) uniform with respect to y, we can skip factor $|\log\log(\rho\gamma)|$ in (9.2.24).

(ii) Further, assume that in X_{qreg} cone condition (9.A.23)–(9.A.26) is satisfied with the cone of fixed angle ϕ and height $h = \epsilon\gamma(x)$. Then condition (9.2.23) is fulfilled automatically. In this case we do not need to assume that we have Dirichlet boundary condition but only that (9.2.18) holds.

(iii) Therefore under certain assumptions contribution of X_{qreg} to the remainder does not exceed (9.2.24).

Example 9.2.10. On the other hand, assume that the boundary is less regular; namely we assume only that

$$\mathsf{mes}\big(\{x \in X_{\mathsf{qreg}} \cap \mathcal{B}(y,\gamma(y),X), \mathsf{dist}(x,\partial X) \le t\}\big) \le ct^{\sigma}\gamma(y)^{d-\sigma} \qquad \forall t : \rho(y)^{-1} \le t \le \gamma(y) \tag{9.2.27}$$

is fulfilled uniformly with respect to $y \in X_{\mathsf{qreg}}$ with $\sigma \in (0,1)$ [11].

In this case we can relax smoothness conditions to coefficients as well and due to Theorem 7.5.22 the contribution of $\mathcal{X}$ to the remainder does not exceed

$$C\int_{X_{\mathsf{qreg}}} \rho^{d-\sigma}\gamma^{-\sigma}\,dx. \tag{9.2.28}$$

On the other hand, expression (9.2.25) in this case does not exceed (9.2.28) as well and so the contribution of X_{qreg} to the remainder is estimated by (9.2.28).

This allows us to treat fractal boundaries in Chapter 11.

[11] As $\sigma = 1$ this condition coincides with (9.2.23).

Remark 9.2.11. (i) So far we considered operators which in the regular zone X_{reg} are either regular or "rough". However bracketing operator with the irregular coefficients A between two rough operators $A^- \le A \le A^+$ we conclude that $\mathsf{N}^-(A^+) \le \mathsf{N}(A)\mathsf{N}(A^-)$ and estimating difference $\mathsf{N}^-(A^-) - \mathsf{N}^-(A^+)$ we get remainder estimate for $\mathsf{N}^-(A)$ as well. Actually since $\mathsf{N}^-(A^-)$ and $\mathsf{N}^-(A^+)$ have the same remainder estimates we need to estimate $\mathcal{N}(A^-) - \mathcal{N}(A^+)$.

(ii) The similar approach works for Riesz means as well; we can also apply results of Section 4.7.

9.2.4 Riesz Means

Example 9.2.12. In the framework of Example 9.2.6 remainder estimate (9.2.21) is replaced by

$$C\int_{X_{\mathsf{reg}}\setminus X_{\mathsf{reg,ell}}} \varrho^{\omega}\rho^{d-1-\omega}\gamma^{-1-\omega}\,dx + C'\int_{X_{\mathsf{reg,ell}}} \varrho^{\omega}\rho^{d-s}\gamma^{-s}\,dx + C\int_{X_{\mathsf{sing}}} \varrho^{\omega}\rho^{d}\,dx. \tag{9.2.29}$$

Note however that selection of J affects sharper asymptotics.

Example 9.2.13. In the framework of Example 9.2.7 an extra term (9.2.22) is replaced by

$$C\sum_j h_j^{-d}\int_{X_j} \varrho^{\omega}\,dx. \tag{9.2.30}$$

Example 9.2.14. In the framework of Example 9.2.8 the contributions of X_{qreg} to both the remainder and the principal part are estimated by

$$C\int_{X_{\mathsf{qreg}}} \varrho^{\omega}\rho^{d-1}\gamma^{-1}\,dx. \tag{9.2.31}$$

Remark 9.2.15. In Section 12.6 we discuss Riesz means in domains with corners, angles and critical points and discover that those singularities can produce non-Weyl correction terms in the main part of asymptotics.

9.3 Estimates for Quadratic Forms

Let us prove another version of the basic theorems of this chapter. These new theorems deal with the quadratic forms instead of operators and N^- is now the maximal dimension of the negative subspace lying in $\mathscr{C}_0^K(\mathbb{R}^d, \mathbb{H}) \cap \mathfrak{D}(Q)$. The advantage is that conditions to J become more transparent and we are able to select it properly in X_{sing}.

So, we have two quadratic forms, namely $Q(u) = (Au, u)$ and $Q_0(u) = (Ju, u)$, but we are interested in the negative subspaces of $Q(u)$, and the answer cannot depend on $Q_0(u)$ [12)].

Let us introduce space $\mathcal{H} = \mathcal{H}_{Q_0}$ which is the closure of $\mathscr{C}_0^K(\mathbb{R}^d, \mathbb{H}) \cap \mathfrak{D}(Q)$ in the norm $\|u\|_0 = Q_0(u)^{\frac{1}{2}}$. If the form $Q(u)$ generates a self-adjoint operator $\boldsymbol{A}$ in this space then

$$\mathsf{N}^-(\boldsymbol{A}) = \mathsf{N}^-(Q) \tag{9.3.1}$$

and under appropriate conditions we can apply Theorems 9.1.7 and 9.1.13.

Let us discuss how the answer depends on J. Let us observe first that if we do not consider trajectories then neither conditions nor estimates depend on the choice of J outside of X_{sing}. Surely, if we were to assume that $\boldsymbol{A}$ has a scalar principal symbol (or something like this) then we should take J satisfying this condition because then we have special theorems; so, let us assume that if A has a scalar principal symbol then J is a scalar matrix.

Note that existence of self-adjoint operator requires that

(9.3.2) $\mathfrak{D}(Q)$ is a dense subset of $\mathcal{H}$.

We try to take J in X_{sing} as small as possible (in order to decrease R_0 in estimate (9.1.23)) but we need to fulfill $(9.2.3)_3$ and (9.1.24)–(9.1.25). Note that if we assume that

$$\varrho = \varrho_0 \rho\gamma \qquad \text{in } \ X_{\mathsf{reg}} \setminus X_{\mathsf{reg,ell}} \tag{9.3.3}$$

then in the equations of trajectories (9.2.16) $\kappa = 1$ and therefore these equations and conditions will be more natural. Despite these simplifications the constant R_0 has not yet been calculated and whether the quadratic form $Q(u)$ generates a self-adjoint operator in $\mathcal{H}$ is not yet clear.

[12)] Nevertheless the estimates we will derive can depend on J.

However, in the lower bounds of $\mathsf{N}^-(Q)$ the latter condition is not necessary. Really, these estimates are non-trivial only if $\mathsf{N}^-(Q)<\infty$ but in this case the quadratic form Q is semibounded from below on $\mathcal{H}$ and due (9.3.3) this form really generates an operator on $\mathcal{H}$ which is semibounded from below. Therefore the lower and the upper estimates are provided and in the upper estimates the constant R_0 is deduced from the quadratic form $Q_t(u)=Q(u)-tQ_0(u)$, i.e., conditions (9.1.23) and (9.1.60) should be replaced by

$$\mathsf{N}^-(Q-tQ_0)\le R_0(t+1)^p \qquad \forall t\ge 0 \tag{9.3.4}$$

with Q here restricted to the domain X_{sing}.

Let us consider upper estimates. Namely, let us assume that Q is given by the formula

$$Q(u)= \int_X \sum_{|\alpha|,|\beta|\le r} \langle a_{\alpha\beta}D^\beta u, D^\alpha u\rangle\,dx + \int_{\partial X}\sum_{|\alpha|,|\beta|\le r-1}\langle b_{\alpha\beta}D^\beta u, D^\alpha u\rangle\,dx' \tag{9.3.5}$$

with coefficients satisfying

$$a_{\alpha\beta}=a^\dagger_{\beta\alpha},\quad b_{\alpha\beta}=b^\dagger_{\beta\alpha}\qquad \forall \alpha,\beta, \tag{9.3.6}$$

and

$$\sum_{\alpha,\beta:|\alpha|=|\beta|=r}\langle a_{\alpha\beta}\xi^{\alpha+\beta}v,v\rangle \ge \epsilon_0\varrho\rho^{-2r}|\xi|^{2r}\|v\|^2 \qquad \forall \xi\in\mathbb{R}^d\quad \forall v\in\mathbb{H}. \tag{9.3.7}$$

Further, let us also assume that

(9.3.8) Function $u\in \mathscr{C}_0^K(\mathcal{X},\mathbb{H})$ belongs to $\mathfrak{D}(Q)$ if and only if $B_ju|_{\partial X}=0$ $\forall j=1,\dots,\mu'$ where B_j are differential operators of orders $m_j\le r-1$ (where $m=2r$) and that Q is originally defined on these functions and is expanded to $\mathcal{H}$ as a closure.

Thus the boundary conditions for operator $\boldsymbol{A}$ are $B_ju|_{\partial X}=0$ with $j=1,\dots,\mu$ of two types: original conditions (imposed to the domain of the quadratic form) with $j=1,\dots,\mu'$ and $m_j\le r-1$ and additional conditions with $j=\mu'+1,\dots,\mu$ and $m_j\ge r$ which follow from the variational problem.

Furthermore, let us assume that

(9.3.9) $J, J^{-1} \in \mathscr{L}^{\infty}_{\mathsf{loc}}(\mathcal{X})$ where $\mathcal{X} \supset \bar{X}_{\mathsf{reg}}$ and $\mathcal{X}$ is dense in X.

Then

(9.3.10) The subspaces in which we test whether Q is negative definite are the same for the chosen J and for $J = I$.

All these conditions should be assumed from the beginning which we will do in the statements of theorems. To proceed further, let us first note that under the assumptions of our theorems the contribution of every ball $\mathcal{B}(x, \gamma(x), X)$ with $x \in X_{\mathsf{reg}}$ to $\mathcal{N} + \mathsf{R}$ is either larger than a constant ϵ_1 or is $O(h^s)$ where h means $h_{\mathsf{eff}} = (\rho\gamma)^{-1}$.

We will call these balls *balls of the first type* and *balls of the second type* respectively. Therefore

(9.3.11) If the right-hand expression is finite then the number of balls of the first type is finite and $\rho, \gamma, \varrho, \varrho_0, J$ on the union of these balls are disjoint from 0 and ∞.

Thus, in order to obtain a theorem similar to Theorems 9.1.7 and 9.1.13 but with $\mathsf{N}^-(Q)$ instead of $\mathsf{N}^-(A)$ we need only to prove that Q generates a self-adjoint operator in $\mathcal{H}$. Surely it is sufficient to prove that $\mathsf{N}^-(Q_T) < \infty$ for some $T > 0$ with $Q_T(u) = Q(u) + T(Ju, u)$.

Moreover, note that estimate $N^-(Q) \le M$ is due to the uniform estimate $N^-(Q_t) \le M$ for $Q_t(u) = Q(u) + t(J_1 u, u)$ and for all $t > 0$ and for some function J_1 satisfying the same assumptions as J [13)].

Further, if Q_t generates a self-adjoint operator A_t then one can apply the Theorems 9.1.7 and 9.1.13 to this operator.

Let us note that in balls of the first type for small enough $t > 0$ the same conditions are fulfilled[14)] which were assumed to be fulfilled for $t = 0$. Estimates in balls of the second type and in the singular zone are obvious. Therefore we get the estimate $N^-(Q_t) \le M + \varepsilon(t)$ for $t > 0$, $\varepsilon = 0(1)$ as $t \to +0$, which yields the estimates in question.

Thus, it is sufficient to assume that

[13)] With another weight function ϱ_0' instead of ϱ_0 and with a non-essential constant c' instead of c.

[14)] With constants $2c$ and $\frac{1}{2}\epsilon_0$ instead of c and ϵ.

(9.3.12) Form $Q_{t,T}(u) = Q(u) + t(J_1 u, u) + T(Ju, u)$ is non-negative-definite for every $t > 0$ and sufficiently large $T = T_t$.

But this assumption holds provided

(9.3.13) The quadratic form $Q_T(u) = Q(u) + (J_0 u, u)$ is non-negative definite for some function J_0 satisfying the same assumptions as J [13)].

Really, under this condition one can pick $J_1 = J_0^2 J^{-1}$ and $T = t^{-1}$. Therefore,

(9.3.14) Under condition (9.3.13) one can pass from operators to quadratic forms.

There are many situations in which condition (9.3.13) is obviously fulfilled. Let us list some of them. Assume that

(9.3.15) $\{\psi_n^2\}_{n\ge 0}$ is a partition of unity such that ψ_n satisfy (9.1.19) in X_{reg} uniformly on n, $\mathsf{supp}(\psi_0) \subset X_{\mathsf{sing}} \setminus Y_{\mathsf{reg},\epsilon}$, $\mathsf{supp}(\psi_n) \subset X_{\mathsf{reg}} \setminus Y_{\mathsf{sing},\epsilon}$ where $Y_{\mathsf{reg},\epsilon}$ is $\epsilon\gamma$-neighborhood of $X \setminus X_{\mathsf{sing}}$ and $Y_{\mathsf{sing},\epsilon}$ is $\epsilon\gamma$-neighborhood of $X \setminus X_{\mathsf{reg}}$, $\mathsf{diam}\,\mathsf{supp}(\psi_n) \le \epsilon_2\gamma$ for $n \ge 1$ and the multiplicity of this partition does not exceed $C_0 = C_0(d)$.

Then

$$(9.3.16)\quad Q(u) = \sum_{n\ge 0}\Big(\int_X \psi_n^2 \sum \langle a_{\alpha\beta} D^\beta u, D^\alpha u\rangle \, dx + \int_{\partial X} \psi_n^2 \sum \langle b_{\alpha\beta} D^\beta u, D^\alpha u\rangle \, dx\Big)$$

which in turn equals

$$\begin{aligned}\sum_{n\ge 0}\Big(Q(\psi_n u) &- 2\,\mathsf{Re}\int_X \sum \langle a_{\alpha\beta}[D^\beta, \psi_n]u, D^\alpha \psi_n u\rangle \, dx + \\ &\mathsf{Re}\int_X \sum \langle a_{\alpha\beta}[D^\beta, \psi_n]u, [D^\alpha, \psi_n]u\rangle dx - \\ &2\,\mathsf{Re}\int_{\partial X} \sum \langle b_{\alpha\beta}[D^\beta, \psi_n]u, D^\alpha \psi_n u\rangle \, dx' + \\ &\mathsf{Re}\int_{\partial X} \sum \langle b_{\alpha\beta}[D^\beta, \psi_n],\ [D^\alpha \psi_n]u\rangle \, dx'\Big)\end{aligned}$$

where we sum on α, β inside. Therefore (9.3.16) yields that

$$(9.3.17)\quad Q(u) \geq \sum_{n\geq 0} Q(\psi_n u) - \sum_{|\alpha|\leq r-1} C \int_X \chi\varrho(\rho\gamma)^{-2}\rho^{-2|\alpha|}|D^\alpha u|^2\,dx - \sum_{|\alpha|\leq r-1} C\int_{\partial X} \chi\varrho\rho^{-2|\alpha|-1}|D^\alpha u|^2\,dx' \geq \sum_{n\geq 0}\tilde{Q}(\psi_n u)$$

where

$$(9.3.18)\quad \tilde{Q}(v) = Q(v) - \sum_{|\alpha|\leq r-1} C \int_X \chi\varrho(\rho\gamma)^{-2}\rho^{-2|\alpha|}|D^\alpha v|^2\,dx - \sum_{|\alpha|\leq r-1} C\int_{\partial X} \chi\varrho\rho^{-2|\alpha|-1}|D^\alpha v|^2\,dx',$$

χ is the characteristic function of $X \setminus (2\epsilon\gamma$-neighborhood of $(X_{\mathsf{reg}} \setminus X_{\mathsf{sing}}))$ and we assume from the beginning that

$$(9.3.19)\qquad |D^\sigma a_{\alpha\beta}| \leq c\varrho\rho^{-|\alpha|-|\beta|}\gamma^{1-|\sigma|},$$

$$(9.3.20)\qquad |D^\sigma b_{\alpha\beta}| \leq c\varrho\rho^{-|\alpha|-|\beta|}\gamma^{1-|\sigma|} \qquad \forall\sigma : |\sigma|\leq 1 \quad \forall\alpha,\beta.$$

One can easily see that under conditions (9.3.8)

$$(9.3.21)\qquad \tilde{Q}(u) + 2(J_0 u, u) \geq \frac{1}{2}Q(u) + (J_0 u, u)$$

for appropriate function J_0.

Let us consider $\tilde{Q}(\psi_n u)$ with $n \geq 1$ first. In the case of balls of the first type we consider quadratic forms without boundary conditions and one can see easily that for a large enough T the corresponding quadratic form is positive definite.

Let us consider balls of the second type. The following new difficulty arises: $\psi_n u$ does not necessarily satisfy the boundary conditions defining the domain of the quadratic form Q.

However, this difficulty does not arise provided one of the following conditions is fulfilled:

$$(9.3.22)_1\qquad B(\bar{x}, \gamma(\bar{x})) \subset X \qquad \forall \bar{x} \in X_{\mathsf{reg}};$$

$$(9.3.22)_2\qquad m_j \leq \frac{m}{2} - 1 \implies m_j = 0;$$

in particular, this condition is fulfilled if $m = 2$;

$(9.3.22)_3$ $$B_j = D_1^{j-1} \qquad \forall j = 1, \dots, \mu'.$$

Moreover, this difficulty does not arise in some other cases. Finally, one can avoid this difficulty provided

$(9.3.22)_4$ $\forall j$ with $m_j \le \frac{m}{2} - 1$ operator B_j is a $\mathsf{D}_j \times \mathsf{D}$ matrix operator with $\mathsf{D}_j \le \mathsf{D}$ and the coefficient of $D_1^{m_j}$ has rank D_j at any point of ∂X (where in the local coordinates $X = \{x_1 > 0\}$). Further, (9.3.20) holds for all $\sigma : |\sigma| \le K$ (in contrast to original (9.3.20) with $K = 1$).

Indeed, one can prove easily that under this condition there exists an operator $\mathcal{L}$ such that

(9.3.23) $$\mathsf{supp}(v) \subset \mathcal{B}\big(\bar{x}, (1-2\epsilon)\gamma(\bar{x}), X\big) \implies \mathsf{supp}(\mathcal{L}v) \subset \mathcal{B}\big(\bar{x}, (1-\epsilon)\gamma(\bar{x}), X\big),$$

(9.3.24) $$\sum_{|\alpha|\le q} \rho^{-|\alpha|} \|D^\alpha \mathcal{L} v\| \le C_q \sum_{|\alpha|\le q-1} \rho^{-|\alpha|-1}\gamma^{-1} \|D^\alpha v\|$$

where K in (9.3.20) also depends on q and $q \ge p$ is arbitrary,

(9.3.25) $$B_j(I + \mathcal{L})v|_{\partial X} = 0 \qquad \forall j : m_j \le \frac{m}{2} - 1$$

and

(9.3.26) $$(I + \mathcal{L})v = 0,\ \mathsf{supp}(v) \subset \mathcal{B}\big(\bar{x}, (1-\epsilon)\gamma(\bar{x}), X\big) \implies v = 0.$$

An easy proof is left to the reader.

Further, a similar operator $\mathcal{L}$ is also defined for $n = 0$ with

(9.3.27) $$\mathsf{supp}(v) \subset \mathcal{Z}_2 \implies \mathsf{supp}(\mathcal{L}v) \subset \mathcal{Z}_1, \qquad v = \mathcal{L}v \quad \text{in} \quad \mathcal{Z}_4,$$

(9.3.28) $$\sum_{|\alpha|\le q} \|\varrho^{\frac{1}{2}} \rho^{-|\alpha|} D^\alpha \mathcal{L} v\| \le C_q \sum_{|\alpha|\le q-1} \|\varrho^{\frac{1}{2}} \rho^{-|\alpha|-1}\gamma^{-1} D^\alpha v\|$$

(9.3.29) $$B_j(I + \mathcal{L})v|_{\partial X} = 0 \quad \forall j : m_j \le \frac{m}{2} - 1 \quad \text{provided} \quad B_j v|_{\partial X \cap \mathcal{Z}_3} = 0 \quad \forall j : m_j \le \frac{m}{2} - 1,$$

$$(I+\mathcal{L})v=0,\ \operatorname{supp}(v)\subset \mathcal{Z}_1 \implies v=0 \tag{9.3.30}$$

where $\mathcal{Z}_k$ is $\bar{X}\setminus(k\epsilon\gamma$-neighborhood of $X\setminus X'_{\mathrm{reg},0})$ and $\epsilon>0$ is a small enough constant. This construction is also left to the reader. Recall that ψ_0 differs from 1 only in the regular zone.

Finally, we obtain estimate

$$Q(u)\geq \sum_{n\geq 0}\tilde{Q}\big((I+\mathcal{L})\psi_n u\big). \tag{9.3.31}$$

Therefore in all the cases $(9.3.22)_{1-4}$ the following estimate

$$\mathsf{N}^-(Q)\leq \sum_{n\geq 1}\mathsf{N}^-\big(\tilde{Q};\mathcal{B}(x^n(1-\epsilon)\gamma^n,X\big)+\mathsf{N}^-\big(\tilde{Q},\bar{X}_{\mathsf{sing}}\big) \tag{9.3.32}$$

holds where Z denotes the geometrical domain on which the quadratic form Q is defined (i.e., all the test functions are supported) in the definition of $\mathsf{N}^-(\tilde{Q},Z)$, $x^n\in\operatorname{supp}(\psi_n)$ and $\gamma^n=\gamma(x^n)$ as $n\geq 1$.

Let us recall that under the above conditions estimate

$$\mathsf{N}^-(\tilde{Q},\mathcal{B}(x^n,(1-\epsilon)\gamma^n,X)\leq M(\mathcal{N}_n^-+R_n)$$

holds where $\mathcal{N}_n^-$ and R_n are the contributions of the ball $\mathcal{B}(x^n,\gamma^n,X)$ to the principal part and the remainder estimate of the corresponding asymptotics. To prove this one should consider balls of the first and second type separately. Recall that there is only a finite number of balls of the first type.

Therefore the total contributions of these elements is finite provided the right-hand expression in the upper estimate is finite. Furthermore, condition (9.3.4) yields that the contribution of $n=0$ is finite as well. Therefore,

(9.3.33) In the framework of our assumptions for appropriate function J_0 the number $N^-(Q_1)$ is finite and therefore $Q_T(u)=Q(u)+T(J_0u,u)$ is positive definite for some T.

Thus we arrive to

Theorem 9.3.1. *In the framework of our assumptions Theorems 9.1.7 and 9.1.13 hold for quadratic forms as well.*

9.A Appendices

9.A.1 Variational Estimates

Rozenblioum Estimates

Rozenblioum estimates are far the most important variational estimates we use. Let us consider the following two quadratic forms defined on scalar functions:

$$Q_1(u) = \sum_{|\alpha|=m} \bigl(a(x)D^\alpha u, D^\alpha u\bigr), \tag{9.A.1}$$

and

$$Q_0(u) = \sum_{|\alpha_1|\le m, |\alpha_2|\le m, |\alpha_1|+|\alpha_2|=2r} \bigl(V_{\alpha_1,\alpha_2}(x)D^{\alpha_1}u, D^{\alpha_2}u\bigr) \tag{9.A.2}$$

where

$$m > r \ge 0, \quad m \in \mathbb{Z}, \quad r \in \frac{1}{2}\mathbb{Z}, \tag{9.A.3}$$

$$a \ge 0, \quad V_{\alpha_1,\alpha_2} = V^\dagger_{\alpha_2,\alpha_1}. \tag{9.A.4}$$

Let us assume that

$$a^{-1} \in \mathscr{L}^p, \quad V_{\alpha_1,\alpha_2} \in \mathscr{L}^q, \tag{9.A.5}$$

$$1 \le p \le \infty, \quad 1 \le q \le \infty, \quad \frac{1}{p} + \frac{1}{q} = \frac{1}{\theta} = \frac{2}{d}(m-r), \tag{9.A.6}$$

$$m - r \le d,\ p \ge 1; \quad \theta > 1 \implies q > 1. \tag{9.A.7}$$

Moreover, let us assume that

(9.A.8) Q_0 contains only terms with

$$\begin{aligned} &2(m-|\alpha_i|) < d(1+\frac{1}{p}) && \text{for} \quad p > 1,\\ &m - |\alpha_i| \le d && \text{for} \quad p = 1. \end{aligned}$$

Let us introduce main objects of the study:

(9.A.9) Let $\mathsf{N}_0^-(Q,X)$ be a maximal dimension of Q-negative subspace of $\mathscr{C}_0^\infty(X)$

and

(9.A.10) Let $\mathsf{N}^-(Q,X)$ be a maximal dimension of Q-negative subspace of $\mathscr{C}^\infty(\bar{X})$ having compact support where integration is taken over X in definition of Q.

Then the following is estimate due to G. Rozenblioum [5]:

Theorem 9.A.1. *In assumptions* (9.A.1)–(9.A.8) *estimate*

$$\mathsf{N}^-(Q_1-Q_0,\mathbb{R}^d)\le C\|a^{-1}\|^\theta_{\mathscr{L}^p}\cdot\|V\|^\theta_{\mathscr{L}^q} \tag{9.A.11}$$

holds where

$$\|V\|_*:=\sum_{\alpha_1,\alpha_2}\|V_{\alpha_1,\alpha_2}\|_*$$

and $C=C(d,m,r,p,q)$.

Example 9.A.2. The most well known case is $m=1, r=0$ when for $d\ge 3$ one can take $p=\infty, q=\frac12 d$. This is the famous Cwikel-Lieb-Rozenblioum estimate (CLR) (see M. Reed & B. Simon [1] and for $d=2$ one can take arbitrary $q>1$ and $p=q/(q-1)$.

Corollary 9.A.3. *Estimate* (9.A.11) *holds for* $\mathsf{N}^-_0(Q_1-Q_0,X)$ *as* $X\subset\mathbb{R}^d$.

Other estimates of this type are discussed in survey M. S. Birman & M. Z. Solomyak [5].

Bracketing

Let γ be a scaling function on X, and X be covered by balls $\mathcal{B}(x_n,\gamma(x_n),X)$ of multiplicity not exceeding c. Let $\sum_n\psi_n^2=1$ where ψ_n be real-valued functions supported in $\mathcal{B}(x_n,\gamma(x_n),X)$ and satisfy

$$|D^\beta\psi_n|\le c\gamma_n^{-|\beta|} \tag{9.A.12}$$

Note that

$$Q_1(u)\ge\sum_n\Big(\frac12 Q_1(\psi_n u)-Q_1'(\psi_n u)\Big)$$

with

$$Q_1'(u) = C(a\gamma^{-2m}u, u)$$

and as $r = 0$

$$Q_0(u) = \sum_n Q_0(\psi_n u).$$

Then

$$\mathsf{N}_0^-(Q_1 - Q_0, X) \le \sum_n \mathsf{N}_0^-\big(Q_1 - 2Q' - 2Q_0, \mathcal{B}(x_n, \gamma(x_n), X)\big). \tag{9.A.13}$$

Similar inequalities hold for $\mathsf{N}^(Q_1 - Q_0, X)$

$$\mathsf{N}^-(Q_1 - Q_0, X) \le \sum_n \mathsf{N}^-\big(Q_1 - 2Q' - 2Q_0, X; \mathcal{B}(x_n, \gamma(x_n), X)\big) \tag{9.A.14}$$

where $\mathsf{N}^-(Q, X; Y_n)$ denotes Q-negative subspace of $\mathscr{C}^\infty(Y_n)$ supported in Y_n where integration is taken over X in definition of Q.

Neumann Type Problems

Let us now consider these quadratic forms on the space $\mathcal{V} \subset \mathscr{C}^m(\bar{X})$. Let us assume that $X = \bigcup_{j\in\mathcal{J}} X_j$ and $X_j \subset \mathcal{X}_j$ where X_j and $\mathcal{X}_j$ are open domains such that for every j there exists a linear operator $\mathcal{L}_j : \mathcal{V} \to \mathscr{C}_0^m(\mathcal{X}_j)$ satisfying

$$\mathcal{L}_j u = u \qquad \text{in} \quad X_j \quad \forall u \in \mathcal{V}, \tag{9.A.15}$$

with

$$Q_{1j}(\mathcal{L}_j u) \le Q_{1j}'(u) + Q_{2j}'(u) \qquad \forall u \in \mathcal{V} \qquad \forall j \tag{9.A.16}$$

where Q_{1j} and Q_{1j}' are forms of (9.A.1)-type with a replaced by $a_j \ge 0$, $a_j' \ge 0$ respectively and Q_{2j}' are forms of (9.A.2)-type.

Then summing (9.A.16) over j we obtain from (9.A.15) that if the quadratic form $Q - Q_0$ is negative definite on the subspace $\mathcal{W} \subset \mathcal{V}$ then on this subspace

$$\sum_j Q_{1j}(\mathcal{L}_j u) \le Q_1(u) + \sum_j Q_{2j}'(u) \le \\ Q_0(u) + \sum_j Q_{2j}'(u) \le \sum_j Q_0'(\mathcal{L}_j u) \tag{9.A.17}$$

provided

$$\sum_j a'_j = a, \tag{9.A.18}$$

and

(9.A.19) Forms Q_0, Q'_{2j} contain only terms with $\alpha_1 = \alpha_2$, $|\alpha_1| = r$ and $V_{\alpha_1,\alpha_1} \ge 0$ (and the same is true for the coefficients of Q'_{2j}) and

$$Q'_0 = Q_0 + \sum_k Q'_{2k}. \tag{9.A.20}$$

Therefore $\mathsf{N}^-(Q_1 - Q_0, \mathcal{V})$ does not exceed the maximal dimension of the subspace $\mathcal{W} \subset \bigoplus_j \mathscr{C}_0^m(\mathcal{X}_j)$ with the following property:

(9.A.21) For every $w = (w_j)_{j\in\mathcal{J}} \in \mathcal{W}$ there exists $u \in V$ with $w_j = \mathcal{L}_j u$ for all j on which the quadratic form $\sum_j (Q_{1j} - Q'_{0j})(w_j)$ is negative definite.

Dropping the condition $\mathcal{L}_j u = w_j$ on w_j we obtain that

$$\mathsf{N}^-(Q_1 - Q_0, \mathcal{V}) \le \sum_j \mathsf{N}^-(Q_{1j} - Q'_{0j}, \mathcal{W}_j) \tag{9.A.22}$$

with $\mathcal{W}_j = \mathscr{C}_0^m(\mathcal{X}_j)$.

Now one can apply Rozenblioum estimate (9.A.11) in order to estimate every term in the right-hand expression. One should take $\mathscr{L}^p$- and $\mathscr{L}^q$-norms on $\mathcal{X}_j$ in these estimates.

In particular, let $\mathcal{V}$ be the space of all compactly supported $\mathscr{C}^{m+1}$ functions satisfying the Dirichlet condition of order $(m+1)$ on $Y_{\mathsf{D}} \subset \partial X$. Let us assume that

$$Y_{\mathsf{N}} = \partial X \setminus Y_{\mathsf{D}}, \tag{9.A.23}$$

$$X = \bigcup_{j\ge 0} X_j, \tag{9.A.24}$$

$$Z_j = Y_{\mathsf{N}} \cap \bar{X}_j, \qquad Y_{\mathsf{N}} \cap \bar{X}_0 = \emptyset. \tag{9.A.25}$$

Let Γ_j be open cones with vertex 0 in $\mathbb{R}^d$ with angle $\phi > 0$ and altitudes h_j such that the following *cone condition* is fulfilled:

(9.A.26) For every point $\bar{x} \in X : \mathsf{dist}(x, X_j) \le \epsilon_0 h_j$ the connected component of $(\bar{x} + \Gamma_j) \setminus Y_{\mathsf{D}}$ containing $\bar{x}$ does not intersect Y_N.

Recall that $\mathsf{dist}(x, y)$ is a path distance in X.

Then taking the Sobolev extension operators $\mathcal{L}_j$ (see f.e. S. L. Sobolev [1]) associated with cones $\epsilon\Gamma_j$ with a small enough constant $\epsilon > 0$ and cutting of on the distances exceeding $\epsilon_1 h_j$ from X we see that for $j \ge 1$

$$\sum_{|\alpha|=m} \|D^\alpha \mathcal{L}_j u\| \le C \sum_{|\alpha|=m} \|D^\alpha u\|_{X'_j} + C h_j^{-m} \|u\|_{X'_j} \tag{9.A.27}$$

where X'_j is a connected component of $(X_j + 2\epsilon\Gamma_j) \setminus Y_{\mathsf{D}}$, containing $\bar{x}$.

Assuming that

(9.A.28) X'_j form no more than a c-multiple covering of $X \setminus X_0$

one can take $Q_1 \asymp \|.\|^2_m$, $Q'_{1j} \asymp \|.\|^2_m$, $Q_{1j} \asymp \|.\|^2_m$ in the domains X, X'_j and $\mathbb{R}^d$ respectively and $Q'_{2j} = C h_j^{-2m} \|.\|^2_{X'_j}$.

Moreover, assume that

(9.A.29) $X''_j = \{x \in X, \mathsf{dist}(x, Z_j) < h_j\}$ form no more than a c-multiple covering of $X \setminus \mathcal{X}_0$.

Then as $\mathcal{L}_0$ one can take the operator of multiplication by a function ψ such that $\psi = 1$ in X_0, $\psi = 0$ in the ϵh_j-neighborhood of Z_j (for every $j \ge 1$) satisfying the inequalities $|D^\alpha \psi| \le c\gamma^{-|\alpha|} \quad \forall \alpha : |\alpha| \le m$ with $\gamma = \mathsf{dist}(x, Z)$.

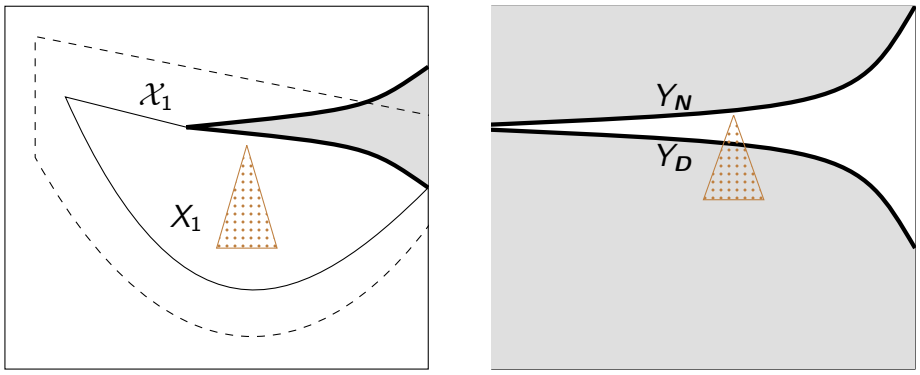
In this case one can take $Q_1(u) \asymp \sum_{|\alpha|=m} (a D^\alpha u, D^\alpha u)$, Q'_{10} and Q_{10} given by the same formula in X, X_0 and $\mathbb{R}^d$ respectively and $Q'_{20} = C \sum_j h_j^{-2m} \|.\|^2_{X''_j}$ provided

$$\epsilon_0 \le a \le c \qquad \text{in} \quad Y'_j \quad \forall j \ge 1. \tag{9.A.30}$$

So, we obtain that $Q'_{0j}(v) = Q_0(v) + (W_j v, v)$ with $W_j = h_j^{-2m} \chi_{X''_j}$ for $j \ge 1$ and $W_0 = \sum_{j \ge 1} h_j^{-2m} \chi_{X''_j}$ where χ_M is the characteristic function of the set M. In fact, without any loss of the generality one can assume that X_j are contained in the $\frac{2}{3} h_j$-neighborhoods of Z_j.

Let us apply the following inequality

$$\mathsf{N}^-(Q_{(1)} + Q_{(2)}) \le \mathsf{N}^-(Q_{(1)}) + \mathsf{N}^-(Q_{(2)}) \tag{9.A.31}$$



(a) (b)

Figure 9.4: Domain X is white, cone is covered by dots. On (a) this cone serves X_1; flipping vertically we get X_2 and corresponding cone. On (b) pretty large cone serves thin domain because of Y_D making the lower part of the cone irrelevant.

(on the same functional spaces) with $Q_{(1)} = \frac{1}{2}Q_{1j} - Q_0$ and $Q_{(2)} = \frac{1}{2}Q_{1j} - Q'_{2j}$.

First of all, let us apply Rozenblioum estimate (9.A.11) to $\mathsf{N}^-(Q_{(1)})$.

(i) Assume that $d > 2m$. Then we can apply the same estimate (9.A.11) to $\mathsf{N}^-(Q_{(2)})$ with $p = \infty$, $\theta = q = d/2m$. After summation over j we end up with estimate

$$\mathsf{N}^-(Q_1 - Q_0) \le C\|a^{-1}\|^\theta_{\mathscr{L}^p}\|V\|^\theta_{\mathscr{L}^q} + C\sum_j h_j^{-d}\,\mathsf{mes}(X''_j). \tag{9.A.32}$$

(ii) For $d \le 2m$ let us assume that

$$j = 0, \dots, J < \infty \quad \text{in the covering in question.} \tag{9.A.33}$$

In this case let us again apply (9.A.31) and take a covering of X''_j by h_j-cubes of multiplicity less than C_0. Furthermore, let us apply estimate $\mathsf{N}^-_(Q_1 - 2Q_0) \le C_1$ in every cube. Then we again obtain estimate (9.A.32) with a constant C depending on J.

So the following statement has been proven:

Proposition 9.A.4. *(i) Under the above conditions estimate* (9.A.32) *holds for* $d > 2m$.

(ii) For $d \le 2m$ *this estimate holds under additional assumption* (9.A.33) *with* C *depending on* J.

Some Useful Estimate

In the end of this subsection let us assume that $a \ge \epsilon_0$ in X_{sing} and let us estimate $\mathsf{N}^-(Q_1 - Jt + J_3)$ in the domain X_{sing} with $J = J_1 + J_2$ where $J_1 = \chi_{X_{\mathsf{reg}} \cap X_{\mathsf{sing}}} \rho^{-2s} \gamma^{-2s-2m}$ $(s \in \mathbb{R})$, $J_2 \ge 0$, $J_3 \ge 0$, with thea Dirichlet condition on $\partial X_{\mathsf{sing}} \cap X$. Here ρ and γ satisfy all assumptions of Section 9.1.

Let us apply estimate (9.A.31). Then in order to estimate $\mathsf{N}^-(Q_1 - 2J_1 t)$ one can use a covering of $X_{\mathsf{reg}} \cap X_{\mathsf{sing}}$ by balls $\mathcal{B}(x, \gamma(x), X)$ with multiplicity less than C_0.

Then in every ball without boundary conditions (because ∂X is regular in the intersection with this ball)

$$\mathsf{N}^-(Q_1 - 2J_1 t + J_3) \le C(t\rho^{-2s}\gamma^{-2s})^{\frac{d}{2m}} + C_0 \tag{9.A.34}$$

in the general case and the last term is absent provided

$$x \in X_{\mathsf{reg},+} = \{x \in X_{\mathsf{reg}}, J_3 \ge \epsilon \rho^{2m} \text{ in } \quad B(x, \bar{\gamma}(x))\}. \tag{9.A.35}$$

Therefore their sum does not exceed

$$Ct^{\frac{d}{2m}} \int_{X_{\mathsf{reg}} \cap X_{\mathsf{sing}}} \rho^{-\frac{ds}{m}} \gamma^{-\frac{ds}{m} - d} \, dx + C \int_{X_{\mathsf{reg},-} \cap X_{\mathsf{sing}}} \gamma^{-d} \, dx \tag{9.A.36}$$

where $X_{\mathsf{reg},-} = X_{\mathsf{reg}} \setminus X_{\mathsf{reg},+}$.

Moreover, the contribution of $X_{\mathsf{sing}} \setminus X_{\mathsf{reg}}$ is equal to 0 (because the form $Q_1 - 2J_1 t + J_3$ is non-negative definite on functions supported there). So in this case we obtain the estimate

$$\mathsf{N}^-(Q_1 - Jt + J_3) \le \tag{9.A.37}$$

$$\mathsf{N}^-(Q_1 - 2J_2 t + J_3) + Ct^{\frac{d}{2m}} \int_{X_{\mathsf{reg}} \cap X_{\mathsf{sing}}} \rho^{\frac{ds}{m}} \gamma^{\frac{ds}{m} - d} \, dx + C \int_{X_{\mathsf{reg},-} - \cap X_{\mathsf{sing}}} \gamma^{-d} \, dx.$$

9.A.2 Riesz Means Estimates

Assume that $r = 0$, $Q_0 = (Wu, u)$ with $W \ge 0$ and $\bar{Q} = \|u\|^2$. Let us consider

$$\mathsf{N}^-_\omega := \int_{-\infty}^0 t_-^\omega \, d_t \mathsf{N}^-(Q_1 - Q_0 - t\bar{Q}) = \omega \int_{-\infty}^0 t_-^{\omega-1} \mathsf{N}^-(Q_1 - Q_0 - t\bar{Q})\, dt. \tag{9.A.38}$$

Then, according to Rozenblioum estimate (9.A.11)

$$\mathsf{N}^-_\omega \le C\|a^{-1}\|^\theta_{\mathscr{L}^p} \int_0^\infty \|(V-t)_+\|^\theta_{\mathscr{L}^q} \cdot t^{\omega-1}\, dt. \tag{9.A.39}$$

In the case $p = \infty$, $q = \theta$ [15)] we immediately obtain estimate

$$\mathsf{N}^-_\omega \le C\|a^{-1}\|^{\frac{d}{2m}}_{\mathscr{L}^\infty} \int W^{\frac{d}{2m}+\omega}\, dx. \tag{9.A.40}$$

On the other hand, let $p < \infty$; then $q > \theta$. Applying the Hölder inequality to the right-hand expression of estimate (9.A.11) we get estimate

$$\mathsf{N}^-_\omega \le C\|a^{-1}\|^\theta_{\mathscr{L}^p} \cdot \Big(\int \phi(t)\, dt\Big)^{1-\frac{\theta}{q}} \Big(\iint t^{\frac{q}{\theta}(\omega-1)} (W-t)_+^q \phi(t)^{\frac{1-q}{\theta}}\, dxdt\Big)^{\frac{\theta}{q}}$$

with arbitrary function $\phi(t) \ge 0$; here we integrate with respect to $t \in (0, \infty]$. Picking up $\phi(t) = t^{-1+\delta}(t+\tau)^{-\delta-\delta'}$ with $\delta > 0, \delta' > 0$ and parameter $\tau \ge 0$ we then obtain that

$$\mathsf{N}^-_\omega \le C\|a^{-1}\|^\theta_{\mathscr{L}^p} \Big[\Big(\int W^{l_1} dx\Big)^{\frac{\theta}{q}} \tau^{-\delta'(1-\frac{\theta}{q})} + \Big(\int W^{l_2} dx\Big)^{\frac{\theta}{q}} \tau^{\delta(1-\frac{\theta}{q})}\Big]$$

with

$$l_1 = q(1+\frac{\omega}{\theta}) + \delta'(\frac{q}{\theta}-1),\ l_2 = q(1+\frac{\omega}{\theta}) - \delta(\frac{q}{\theta}-1).$$

Minimizing with respect to τ and denoting $\rho = (\delta+\delta')(\frac{q}{\theta}-1)$, $\nu = \delta(\delta+\delta')^{-1}$ we obtain the following

Proposition 9.A.5. *(i) As $d > 2m$ estimate* (9.A.40) *holds.*

[15)] This is possible if and only if $d > 2m$.

(ii) As $d \le 2m$ estimate

$$\mathsf{N}_\omega^- \le C\|a^{-1}\|_{\mathscr{L}^p}^\theta \Big(\int W^{l_1}\,dx\Big)^{\frac{\nu\theta}{q}} \Big(\int W^{l_2}\,dx\Big)^{\frac{(1-\nu)\theta}{q}} \tag{9.A.41}$$

holds with arbitrary $\nu \in (0,1)$, $\rho > 0$

$$l_1 = q(1+\frac{\omega}{\theta}) + (1-\nu)\rho, \quad l_2 = q(1+\frac{\omega}{\theta}) - \nu\rho.$$

(iii) In particular, as $d = 2m$ estimate

$$\mathsf{N}_\omega^- \le C_q\|a^{-1}\|_{\mathscr{L}^\infty} \big(\mathsf{mes}(X)\big)^{1-\frac{1}{q}} \Big(\int W^{(\omega+1)q}\,dx\Big)^{\frac{1}{q}} \tag{9.A.42}$$

holds with arbitrarily chosen $q > 1$.

We leave to the reader the following

Problem 9.A.6. Investigate averaging with function φ satisfying (4.2.73)–(4.2.75).

The following problem is really hard (see Comments).

Problem 9.A.7. Investigate if estimate (9.A.40) holds for some $q > 0$ even if $d \le 2m$.

Comments

The principal idea of this chapter was first used in the papers V. Ivrii [13] and V. Ivrii & S. Fedorova [1] where a second order operator was treated via the wave equation, and the finite spatial velocity of the propagation of supports was used instead of the finite spatial velocity of propagation of singularities. The next paper V. Ivrii [14] and all consecutive papers were using semiclassical asymptotics in the regular zone and variational estimates in the singular zone and were based on the slightly more complicated (and essentially more universal and flexible) proof presented here.

In all my papers and in Part V just the Rozenblioum spectral estimate (see G. Rozenblioum [2]) was used. Sometimes even the earlier Birman–Solomyak estimate (see M. S. Birman & M. Z. Solomyak [3–6]) is sufficient.

But we do not want to "close the door" to using other estimates and hence a more abstract form of the basic theorems is presented.

Note that in the special case of the Schrödinger operator the Rozenblioum estimate is the famous Lieb–Cwikel–Rozenblioum estimate, at least five different proofs of which are known (J. Conlon [1], M. Cwikel [1], E. Lieb [1], P. Li & S. T. Yau [1], G. Rozenblioum [2].

Essential in these estimates are Dirichlet boundary conditions. It is well known that Neumann Laplacian could differ drastically from Dirichlet Laplacian in the domains which are not "bounded domains with smooth boundaries". This difference will be exploited in Section 12.7. But in more general setting not just asymptotics and estimates but the whole character of the spectrum could be different. What we have in Appendix 9.A.1 is the only patch. We can think about more systematic use of the methods and results of Yu. Netrusov & Yu. Safarov [1, 2].

Estimates to Riesz means were investigated in many papers, see f.e. E. H. Lieb & W. Thirring [1], L. Erdös [1], A. Laptev & T. Weidl [1], Y. Netrusov & T. Weidl [1].

Surely, in applications in which an operator depends on parameters, the auxiliary functions $\rho, \varrho, \dots$ (and maybe γ) also depend on the parameters, and thus regular and singular zones, etc., also depend on the parameters but constants do not.

Chapter 10

Estimates of the Spectrum in the Interval

In this chapter we obtain upper and lower estimates for

$$\mathsf{N}(A;\tau_1,\tau_2) \coloneqq \mathsf{Tr}\, E(A;\tau_1,\tau_2) \tag{10.0.1}$$

with $-\infty < \tau_1 < \tau_2 < \infty$.

Here $E(A;\tau_1,\tau_2)$ is the spectral projector corresponding to the *open interval* (τ_1,τ_2) rather than to more standard semi-open interval $[\tau_1,\tau_2)$ as before[1)] and $\mathsf{N}(A;\tau_1,\tau_2)$ is number of eigenvalues in (τ_1,τ_2) counting their multiplicities, unless $(\tau_1,\tau_2)\cap \mathsf{Spec}_{\mathsf{ess}}(A)\neq\emptyset$ in which case $\mathsf{N}(A;\tau_1,\tau_2)=\infty$.

These results are useful in the case when $\mathsf{N}^-(A-\tau_1)=\infty$ and also $\mathsf{N}^-(-A+\tau_2)=\infty$. Our analysis is very similar to the analysis of Chapter 9 but here an important role is played by Birman-Schwinger principle. It is rather strange that this extremely powerful and simple tool has been used much less than it should be in the papers devoted to spectral asymptotics.

Further, in this chapter we do not consider Riesz means-like mollifications with respect to spectral parameters[2)].

[1)] This adjustment allows us to cover the case $\tau_1\in \mathsf{Spec}_{\mathsf{ess}}(A)$.

[2)] Riesz means themselves are usually infinite.

10.1 Statement of the Main Theorems

10.1.1 Preliminary Remarks

First of all let us just mention a series of results which follows trivially from the results of the previous chapter applied to operators $A-(\tau_1+0)$ and $A-\tau_2$ with corresponding functions J_1 and J_2, and from the formula

$$\mathsf{N}(A;\tau_1,\tau_2)=\mathsf{N}^-(A-\tau_2)-\mathsf{N}^-(A-(\tau_1+0)). \tag{10.1.1}$$

These results do not work, however, in the numerous cases when there is an indefiniteness of the form "$\infty-\infty$" in the right-hand expression.

Similarly, replacing A, τ_1 and τ_2 by $-A$, $-\tau_2$ and $-\tau_1$ respectively we could apply formula

$$\mathsf{N}(A;\tau_1,\tau_2)=\mathsf{N}^-(-A+\tau_1)-\mathsf{N}^-(-A+(\tau_2-0)) \tag{10.1.2}$$

but again these results do not work, however, in the numerous cases when there is an indefiniteness of the form "$\infty-\infty$" in the right-hand expression.

Formula

$$\mathsf{N}\big(A;\tau_1,\tau_2\big)=\mathsf{N}^-\big((2A-(\tau_2+\tau_1))^2-(\tau_2-\tau_1)^2\big) \tag{10.1.3}$$

may be more useful than both (10.1.1) and (10.1.2) but it may ignore that levels τ_1 and τ_2 are not "of equal rights".

Further, let us mention some results which follow trivially from Parts II and III: if operators $A-\tau_1$ and $A-\tau_2$ satisfy assumptions of the previous chapter with $J_1=J_2=I$ (this is essential only in the restrictions to trajectories) and with the auxiliary functions $\gamma_{(1)}$, $\rho_{(1)}$, $\varrho_{(1)1}$, ... and $\gamma_{(2)}$, $\rho_{(2)}$, $\varrho_{(2)1}$, ... respectively and if in both cases $X_{\mathsf{sing}(1)}=X_{\mathsf{sing}(2)}=\emptyset$ then under additional restriction $\gamma_{(1)}=\gamma_{(2)}=\gamma$, $\rho_{(1)}=\rho_{(2)}=\rho$, ... we can apply a γ-admissible partition of unity for

$$\mathsf{N}(A;\tau_1,\tau_2)=\int \mathsf{tr}\big(e(x,x,\tau_1,\tau_2)\big)\,dx \tag{10.1.4}$$

and obtain estimate

$$|\mathsf{N}(A;\tau_1,\tau_2)-\mathcal{N}(\tau_1,\tau_2)|\le C\big(R_{(1)}+R_{(2)}\big) \tag{10.1.5}$$

where $R_{(i)}$ are remainder estimates for operators $(A-\tau_i)$ while $\mathcal{N}$ is a main part of asymptotics due to Part II; writing $\mathcal{N}(\tau_1,\tau_2)=\mathcal{N}_{(2)}-\mathcal{N}_{(1)}$ we may

get indefiniteness of the form "$\infty - \infty$". Recall that remainder estimates were corresponding to the energy levels rather than to the error $|\mathsf{N} - \mathcal{N}|$ itself.

Note that again $e(.,.,\tau_1,\tau_2)$ is a Schwartz kernel of the modified spectral projector $E(A;\tau_1,\tau_2)$ but as one can notice easily the results of Parts II and III are equally valid for intervals (τ_1,τ_2), $(\tau_1,\tau_2]$, $[\tau_1,\tau_2)$ and $[\tau_1,\tau_2]$.

Furthermore, restriction $\gamma_{(1)} = \gamma_{(2)} = \gamma$, $\rho_{(1)} = \rho_{(2)} = \rho$, ... in this analysis is not necessary.

Indeed, let us take a γ-admissible partition of unity with $\gamma = \max(\gamma_{(1)}, \gamma_{(2)})$. Then for every element of this partition we have an estimate like

$$|\int \frac{1}{L}\phi\big(\frac{\tau-\tau_i}{L}\big)\Big(\int_X \mathsf{tr}\big(e(x,x,\tau,\tau_i)\big)\psi(x)\,dx - \tilde{\mathcal{N}}_\psi(\tau,\tau_i)\Big)\,d\tau| \le CR_{(i),\psi} \tag{10.1.6}$$

where $\tilde{\mathcal{N}}_\psi$ may also contain extra terms in comparison with $\mathcal{N}_\psi$ as L is large enough.

Estimate (10.1.6) is definitely correct as $\gamma_{(i)} \ge \epsilon_0\gamma$ on the given element; if this condition is violated there one can make an additional $\gamma_{(i)}$-admissible subpartition on this element, apply on every element of this subpartition results of Parts II and III and then sum.

Note that as $L \ge |\tau_2 - \tau_1|$ we can replace there τ_i by $\bar\tau = \frac{1}{2}(\tau_1+\tau_2)$. Then adding these estimates with the subtraction of the estimated quantities we arrive to

$$\begin{aligned}|\int_X \mathsf{tr}\big(e(x,x,\tau_1,\tau_2)\big)\psi(x)\,dx - \\ \int \frac{1}{L}\phi\big(\frac{\tau-\bar\tau}{L}\big)\Big(\tilde{\mathcal{N}}_\psi(\tau_1,\tau) - \tilde{\mathcal{N}}_\psi(\tau_2,\tau)\Big)\,d\tau| \le CR_{(1),\psi} + CR_{(2),\psi}\end{aligned} \tag{10.1.7}$$

where we assumed that $\int \phi(\tau)\,d\tau = 1$ and used equality $E(\tau_1,\tau) - E(\tau_2,\tau) = E(\tau_1,\tau_2)$.

Note that

$$\tilde{\mathcal{N}}_\psi(\tau_1,\tau) - \tilde{\mathcal{N}}_\psi(\tau_2,\tau) = \tilde{\mathcal{N}}_\psi(\tau_1,\tau_2) = \mathcal{N}_\psi(\tau_1,\tau_2). \tag{10.1.8}$$

Really, the first equality is due to construction of $\tilde{\mathcal{N}}$. The second equality is true since if $|\tau_2 - \tau_1| \ge C_0 \max(\varrho_{(1)} + \varrho_{(2)})$ then $\tilde{\mathcal{N}}_\psi(\tau_1',\tau_2') = 0$ as

$$\tau_1 + C_0\varrho_{(1)} \le \tau_1' \le \tau_2' \le \tau_2 - C_0\varrho_{(2)}$$

for sufficiently large C_0.

Now (10.1.5) follows from (10.1.7), (10.1.8) after summation over partition.

The results of this type are not very exciting because in the real situations condition $X_{\mathsf{sing}(1)} = X_{\mathsf{sing}(2)} = \emptyset$ is not necessarily fulfilled and that in the conditions on Hamiltonian trajectories restriction $J_1 = J_2 = I$ is not necessarily natural.

In order to circumvent the first restriction we can apply the arguments of Section 9.1 (assuming that $X_{\mathsf{reg}(1)} = X_{\mathsf{reg}(2)} = X_{\mathsf{reg}}$ and $X_{\mathsf{sing}(1)} = X_{\mathsf{sing}(2)} = X_{\mathsf{sing}}$ in the upper estimates; one picks up $J_1 = J_2 = I$). Therefore the following statement holds:

Theorem 10.1.1. *Let the operators $(A - \tau_i)$ satisfy assumptions of Theorem 9.1.7 in $X_{\mathsf{reg}(i)}$ with $J_i = \lambda I$ (where λ is a constant parameter) and with auxiliary functions $\gamma_{(i)}$, $\rho_{(i)}$, ... instead of γ, ρ, ...; conditions depending on j should be fulfilled for both $i = 1$ and $i = 2$.*

Let $\tau_1 < \tau_2$ and $X_{\mathsf{reg}(1)} = X_{\mathsf{reg}(2)} = X_{\mathsf{reg}}$. Then

(i) Estimate

$$\mathsf{N}(A; \tau_1, \tau_2) \ge \mathcal{N}(A; \tau_1, \tau_2) - C\big(R_{*(1)} + R_{*(2)}\big) \tag{10.1.9}$$

holds where $\mathcal{N}(A; \tau_1, \tau_2)$ is prescribed by Parts II and III and $R_{*(1)}$ and $R_{*(2)}$ are taken from the lower estimates for $\mathsf{N}^-(A-\tau_1)$ and $\mathsf{N}^-(A-\tau_2)$ respectively, obtained in the Theorem 9.1.7 in which the conditions were fulfilled.

(ii) Moreover, let $X_{\mathsf{sing}(1)} = X_{\mathsf{sing}(2)} = X_{\mathsf{sing}}$ and let assumptions (9.1.24)–(9.1.25) *be fulfilled in $X_{\mathsf{reg}} \cap X_{\mathsf{sing}}$ with $\varrho_{(i)0} = \lambda$; further, let condition* (9.1.22) *be fulfilled with inequality* (9.1.23) *replaced by inequality*

$$\mathsf{N}(A'; \tau_1 - t\lambda, \tau_2 + t\lambda) \le R_0(1+t)^l \qquad \forall t \ge 0 \tag{10.1.10}$$

with some (arbitrarily large) exponent l [3]*. Then estimate*

$$\mathsf{N}(A; \tau_1, \tau_2) \le \mathcal{N}(A; \tau_1, \tau_2) + C\big(R^*_{(1)} + R^*_{(2)}\big) \tag{10.1.11}$$

holds with $R^*_{(1)}$ and $R^*_{(2)}$ taken from the upper estimates for $\mathsf{N}^-(A - \tau_1)$ and $\mathsf{N}^-(A - \tau_2)$ respectively, and these estimates are not less than CR_0.

[3] We denote the auxiliary operator coinciding with A in the $\epsilon\gamma$-vicinity of $X_{\mathsf{reg}} \setminus X_{\mathsf{sing}}$ by A' instead of $\boldsymbol{A}'$ because $J = I$.

Remark 10.1.2. This theorem does not follow from Theorem 9.1.7 because $\mathcal{N}(A;\tau_1,\tau_2)$, $R_{(1)}$ and $R_{(2)}$ can be finite and $\mathcal{N}^-(A-\tau_i)$ can be infinite at the same time. Usually this occurs in the case when $\tau_1<\tau_2$ belong to the same gap in the semiclassical approximation to the spectrum for $|x|\ge C_0$; examples provided by the Dirac operator be given in Subsection 11.1.3.

Similar examples for the Schrödinger and Dirac operators with constant magnetic field in dimension 2 and higher even dimensions will be provided in Parts VI–X.

10.1.2 Birman-Schwinger Principle

Main Formula

In order to obtain less trivial results let us apply the following identity which is trivial due to *Birman-Schwinger principle:*

$$\mathsf{N}(A;\tau_1,\tau_2)=\mathsf{N}(A-tJ;\tau_1,\tau_2)+ \mathsf{N}\bigl(J^{-1}(A-\tau_1);0,t\bigr)-\mathsf{N}\bigl(J^{-1}(A-\tau_2);0,t\bigr) \tag{10.1.12}$$

provided $\tau_1<\tau_2$, $t>0$ and J is a positive definite operator such that

$$J^{-1}(A-\tau_i) \text{ are self-adjoint operators in the space } \mathcal{H}=\mathcal{H}_J. \tag{10.1.13}$$

As we will prove in Section 10.2 it is sufficient to assume that J is a symmetric, positive[4], bounded and A-compact[5] operator. We will justify formula (10.1.12) in Section 10.2. Then this formula (10.1.12) is also valid for $t<0$ where we define

$$\mathsf{N}(B;0,t):=-\mathsf{N}(B;0,-t) \qquad \text{as} \quad t<0. \tag{10.1.15}$$

Then formula (10.1.12) yields more general formula

$$\mathsf{N}(A;\tau_1,\tau_2)=\mathsf{N}(A-t_1J_1-\ldots-t_nJ_n;\tau_1,\tau_2)- \sum_{1\le k\le n}\mathsf{N}\bigl(J_k^{-1}(A-t_1J_1-\ldots-t_{k-1}J_{k-1}-\tau);0,t_k\bigr)\Big|_{\tau=\tau_1}^{\tau=\tau_2} \tag{10.1.16}$$

---

[4] I.e. $(Jv,v)>0 \quad \forall u\ne 0$.

[5] I.e. $J(A+i)^{-1}$ is a compact operator. This condition is stronger than the standard definition

$$\|Jv\|\le\epsilon\|Av\|+C_\epsilon\|v\| \qquad \forall v\in\mathfrak{D}(A) \qquad \forall\epsilon>0 \tag{10.1.14}$$

which will be also useful.

where we assume that

(10.1.17) All operators J_k ($k = 1, \dots, n$) are symmetric, positive definite, bounded and A-compact.

Artificial energy levels in (10.1.16) may spoil our estimate; to overcome this we will mollify with respect to them arriving to the following final formula which will be used:

$$\begin{aligned}(10.1.18)\quad \mathsf{N}(A;\tau_1,\tau_2) = {}& \\ & \int_{\mathbb{R}^n} \mathsf{N}(A - t_1J_1 - \dots - t_nJ_n;\tau_1,\tau_2)\phi_1(t_1)\cdots\phi_n(t_n)\,dt_1\cdots dt_n - \\ & \sum_{1\le k\le n}\int_{\mathbb{R}^k} \mathsf{N}\big(J_k^{-1}(A - t_1J_1 - \dots - t_{k-1}J_{k-1} - \tau);0,t_k\big)\Big|_{\tau=\tau_1}^{\tau=\tau_2}\times \\ & \qquad\qquad \phi_1(t_1)\cdots\phi_k(t_k)\,dt_1\cdots dt_k\end{aligned}$$

provided

$$(10.1.19)\qquad \phi_k \in \mathscr{C}_0^K(\mathbb{R}),\quad \int_{\mathbb{R}}\phi_k(t)dt = 1 \qquad \forall k.$$

Partition and Scaling

Let $\{\psi_j^2\}_{j\ge 0}$ be a partition of unity of the same type as in Chapter 9; then the right-hand expression of (10.1.18) is a sum of terms of the type

$$(10.1.20)_{n+1}\qquad \int_{\mathbb{R}^n} \mathsf{tr}\big(\Gamma\psi^2 e_{A-t_1J_1-\dots-t_nJ_n}\big)(\tau_1,\tau_2)\phi_1(t_1)\cdots\phi_n(t_n)\,dt_1\cdots dt_n$$

and

$$\begin{aligned}(10.1.21)_k\quad \mp\int_{\mathbb{R}^k} \mathsf{tr}\big(\Gamma\psi^2 e_{J_k^{-1}(A-t_1J_1-\dots-t_{k-1}J_{k-1}-\tau)}\big)(0,t_k)\times & \\ \phi_1(t_1)\cdots\phi_k(t_k)\,dt_1\dots dt_k & \end{aligned}$$

with $k = 1, \dots, n$.

Remark 10.1.3. (i) In these expressions for the sake of simplicity we skip the subscript j of ψ and also the subscript $i = 1, 2$ of τ in terms with $k \le n$; in these terms $\tau = \tau_{1,2}$ correspond to signs $\mp$.

(ii) Obviously we can take different partitions of unity for different $k = 1, \dots, n+1$ and for different $i = 1, 2$ if $k \le n$.

Let us assume that J_k are Hermitian positive definite matrices (bounded and A-compact as operators) and that in $\mathcal{B}(y, \gamma(y), X)$

$$|D^\alpha J_k| \le \varrho_k' \gamma^{-|\alpha|}, \qquad |J_k^{-1}| \le {\varrho_k'}^{-1} \qquad \forall \alpha : |\alpha| \le K \tag{10.1.22}$$

with appropriate ϱ_k' and $\gamma = \gamma_{(i)}$, $i = 1, 2$. Later ϱ_k' will be scaling functions. These conditions must be fulfilled in addition to all "standard" conditions which will be formulated later and invoking $\gamma = \gamma_{(i)}$, $\rho = \rho_{(i)}$, $\varrho = \varrho_{(i)}$ and possibly $\varrho_l = \varrho_{l(i)}$, associated with the boundary conditions.

General Operators. Consider first term $(10.1.20)_{n+1}$. Then $h_{\mathsf{eff}} = (\rho\gamma)^{-1}$ is an effective semiclassical parameter. Let us note first of all that after rescaling we get the mollification parameter $L_{\mathsf{eff}} = \varrho_k' \varrho^{-1}$ for t_k and our results of Section 6.5 on spectral asymptotics with the mollification[6] yield that we have a complete[7] asymptotics of term in question provided $L_{\mathsf{eff}} \ge h_{\mathsf{eff}}^{\kappa-\delta}$ i.e.

$$\max_{r \le k} \varrho_r' \ge \varrho h^{\kappa-\delta}, \qquad h = (\rho\gamma)^{-1}, \qquad \text{with } \kappa = \frac{1}{2} \tag{10.1.23}_k$$

where *here* $k = n$ and arbitrarily small exponent $\delta > 0$. Further, in the scalar case we can replace exponent $(\frac{1}{2} - \delta)$ by $(1 - \delta)$ i.e. take $\kappa = 1$ in condition $(10.1.23)_k$.

Moreover, for $k \ge 2$ we have a complete asymptotics of $(10.1.21)_k$ provided condition $(10.1.23)_{k-1}$ is fulfilled; here do not need microhyperbolicity assumption with respect to (x, ξ) because these problems are automatically microhyperbolic with respect to $t_1, \dots, t_k$ and condition $(10.1.23)_k$ means that there is sufficient mollification with respect to t_r with appropriate $r \le k-1$ is necessary.

Finally, consider term $(10.1.21)_1$. Then under condition $(10.1.23)_1$ we need microhyperbolicity condition[8] as $t_1 = 0$ and we do not have complete asymptotics. So let us now assume that

(10.1.24) For $\tau = \tau_i$ $(i = 1, 2)$ microhyperbolicity condition[8] is fulfilled for the original problem $(A - \tau_i, B)$.

---

[6] Which obviously hold near boundary as well.

[7] I.e., modulo $O(h^s)$ with arbitrary s.

[8] Or ξ-microhyperbolicity for "rough" operators in the sense of Sections 4.6 and 7.5.

Then modulo $O(h^{1-d})$ we have asymptotics of the term in question.

On the other hand, if condition $(10.1.23)_1$ is violated then this microhyperbolicity condition is fulfilled for the problem $(A - t_1 J_1 - \tau_i, B)$ $(i = 1, 2)$ and we have asymptotics of the term $(10.1.21)_2$ modulo $O(h^{1-d})$ also. Repeating these arguments we conclude that under the microhyperbolicity condition we have asymptotics modulo $O(h^{1-d})$ of all the terms $(10.1.21)_k$ with $k = 1, \dots, n$ (and we have no need to check conditions $(10.1.23)_k$.

Furthermore, the same is true for the modified term $(10.1.20)_{n+1}$ now defined by

$$(10.1.25)_{n+1} \quad \frac{1}{L}\int_{\mathbb{R}^{n+1}} \mathsf{tr}\big(\Gamma \psi^2 e_{A-t_1J_1-\dots-t_nJ_n}\big)(\tau', \tau_i)\times \phi_0\big(\frac{1}{L}(\tau' - \tau_i)\big)\phi_1(t_1)\cdots\phi_n(t_n)\, d\tau' dt_1 \cdots dt_n$$

with $L \ge h^{\frac{1}{2}-\delta}$ (or $L \ge h^{1-\delta}$ in the scalar case).

Moreover, the same assertion is true if the microhyperbolicity condition for $(A-\tau_i, B)$ is replaced by the ellipticity condition for the operator $(A-\tau_i)$; this condition does not include the assumption that the boundary value problem is elliptic (or microhyperbolic).

Finally, if we assume that the boundary value problem $(A - \tau_i, B)$ is also elliptic then we can obtain all the terms $(10.1.21)_k$ $(k = 1, \dots, n)$ and $(10.1.25)_{n+1}$ modulo $O(h^s)$.

Dirac Operator. Let us now treat the Dirac operator. Let us recall that according to Subsections 5.3.2 (smooth case) and 5.4.3 ("rough case") Dirac operator

$$(10.1.26) \qquad A = \sum_{j,l} \frac{1}{2}\sigma_l(\omega^{jl}P_j + P_j\omega^{jl}) + \sigma_0 m + V\cdot I, \qquad P_j = D_j - V_j$$

the usual smoothness (or "roughness") conditions are fulfilled but with

$$(10.1.27) \qquad \varrho = \mathsf{min}\big(\frac{\rho^2}{m}, \rho\big)$$

$V \pm m$ instead of V and weakened condition to V_j:

$$(10.1.28) \qquad |F_{jl}| \le c\rho\gamma^{-1}, \qquad F_{jl} = F_{jk} = \partial_l V_j - \partial_j V_l$$

instead of $|V_j| \le c\rho$. Corresponding conditions should be fulfilled for their derivatives.

Also Dirac operator is accessible to the scaling technique and one does not need any microhyperbolicity condition as $d \ge 3$, or even $d = 2$ but under some smoothness or weakened nondegeneracy conditions, and similarly for $d = 1$.

Remark 10.1.4. We need matrix functions J_k such that operators

$$J_k^{-\frac{1}{2}}\bigl(A - t_1J_1 - ... - t_{k-1}J_{k-1} - \tau_i\bigr)J_k^{-\frac{1}{2}} \tag{10.1.29}$$

are generalized Dirac operators (5.3.71) i.e. that matrices

$$W_k = -t_1J_1 - ... - t_{k-1}J_{k-1} \tag{10.1.30}$$

satisfy after rescaling $(5.3.77)_5$ in the smooth case or similar condition in the "rough" case.

Scalar-Like Operators. Finally, let us treat the arbitrary matrix operator and let us assume that (after normalization, i.e., multiplication by an appropriate number if necessary) this operator satisfies the following condition:

(10.1.31) Interval $[\tau_1 - \epsilon_0, \tau_2 + \epsilon_0]$ contains no eigenvalues of the principal symbol of A different from the eigenvalue $\lambda(x,\xi)$ of constant multiplicity.

Then this condition is also fulfilled for operator $J_k^{-1}A$ provided one of the following three conditions is fulfilled:

$(10.1.32)_1$ λ is a simple eigenvalue of the principal symbol of A;

$(10.1.32)_2$ J_k is scalar;

$(10.1.32)_3$ The restriction of J_k to $\mathsf{Ker}(a^0 - \lambda)$ is scalar (a^0 is the principal symbol of A).

Remark 10.1.5. (i) Condition $(10.1.32)_3$ is more general than $(10.1.32)_{1,2}$ but it is difficult to fulfill $(10.1.32)_3$ outside of the framework of $(10.1.32)_{1,2}$ because J_k does not depend on ξ and $(a^0 - \lambda)$ depends on ξ.

(ii) Application of the matrix J_k which does not satisfy one of the conditions $(10.1.32)_{1-3}$ is possible only if before there was mollification with parameter $L_{\text{eff}} \ge h_{\text{eff}}^{\frac12-\delta}$.

Thus, let us assume that one of conditions $(10.1.32)_{1-3}$ is fulfilled. Assume that second derivatives of coefficients are bounded (after rescaling); then it is true for λ as well. Let us make a γ-admissible partition of unity with

$$\gamma = \epsilon_0\bigl(|\lambda-\tau_i| + |\nabla\lambda|^2\bigr)^{\frac12} + h^{\frac12}. \tag{10.1.33}$$

Then for $\gamma \ge 2h^{\frac12}$ microhyperbolicity condition is fulfilled for the original operator after the rescaling-multiplication procedure; therefore in this case our remainder estimate is justified. For $\gamma \le h^{\frac12-\delta'}$ the condition $L' \ge h'^{\frac12-\delta'}$ is fulfilled where $\delta' = \delta'(\delta) > 0$ is small enough, h' and L' are effective values of h and L after the dilatation-multiplication procedure and we assume that $L \ge h^{1-\delta}$. So in this we can replace condition $L \ge h^{\frac12-\delta}$ by $L \ge h^{1-\delta}$ and thus we can take $\kappa = 1$ in $(10.1.23)_k$.

On the other hand, for rough operators one needs ξ-microhyperbolicity and thus

$$\gamma = \epsilon_0\bigl(|\lambda-\tau_i| + |\nabla_\xi\lambda|^2\bigr)^{\frac12} + h^{\frac12}. \tag{10.1.34}$$

which leads us to $\kappa = \frac23$ in $(10.1.23)_k$. In a more regular case we need some $\kappa \in \bigl(\frac23, 1\bigr)$ depending on regularity.

Finally, we obtain that in the general case the microhyperbolicity condition can be replaced by some non-degeneracy condition of Sections 5.2, 5.4 and

$(10.1.35)_p$ For every $k = 1, \dots, p$ the matrix J_k satisfies one of conditions $(10.1.32)_{1-3}$ and there exists $k \le p$ such that $(10.1.23)_k$ holds with $\kappa \in [\frac23, 1]$ defined by regularity

with some $p \le n+1$.

Moreover, let conditions (9.1.31) and $(9.1.32)_1$ be fulfilled. Then $(10.1.35)_p$ is reduced to the condition

$(10.1.36)_p$ There exists $k \le p$ such that $\varrho'_k \ge \varrho h^{\kappa-\delta} = \varrho(\rho\gamma)^{\delta-\kappa}$.

So far contribution of the ball $\mathcal{B}(y,\gamma(y),X)$ to the remainder is $O(h_{\mathsf{eff}}^{1-d})$. Furthermore, under appropriate conditions to the trajectories contribution of the ball $\mathcal{B}(y,\gamma(y),X)$ to the remainder estimate is $O(h_{\mathsf{eff}}^{1-d+\delta})$ with some small exponent $\delta>0$.

Recall that while geometry of trajectories do not depend on the choice of J_k but the temp of movement depends on it. Not to invoke multiple matrices we should assume that condition $(10.1.23)_1$ is fulfilled.

Remark 10.1.6. In the lacunary zone, which appears in the case of periodic trajectories, restrictions of the type $\varrho_k'\le\eta$ and $\varrho_k'\ge\eta h^{1-\delta}$ are also possible; here $\eta\in(h',h)$ is a width of the spectral gap.

Calculations in the Regular Zone

Let us now treat the terms of the derived asymptotics. For the sake of the notational simplicity we do not write the mollification on $t_1,\dots,t_k$. Then expression $(10.1.21)_k$ with $k=1,\dots,n$ generates

$$(10.1.37)_k\qquad \int_0^{t_k}\mathsf{Tr}\bigl(\mathsf{Res}_{\mathbb{R}}\bigl(z-J_k^{-1}(A-t_1J_1-\dots-t_{k-1}J_{k-1}-\tau)\bigr)^{-1}\psi\bigr)\,dz$$

with $\tau=\tau_1,\tau_2$ and expression $(10.1.20)_{n+1}$ generates

$$(10.1.38)_{n+1}\qquad \int_{\tau_1}^{\tau_2}\mathsf{Tr}\bigl(\mathsf{Res}_{\mathbb{R}}(z-A+t_1J_1+\dots+t_nJ_n)^{-1}\psi\bigr)\,dz$$

where $\mathsf{Res}_{\mathbb{R}}$ is the difference of the limits from the upper and lower complex half-planes with respect to z, we skip numerical factors depending on d only and G^{-1} means the formal resolvent of G (in the context of the formal calculus of pseudodifferential operators) derived according to the rules of Parts II and III.

We need to treat the case $n=1$ only: the general case can be reduced to this case if we replace A by $A-t_1J_1-\dots-t_{k-1}J_{k-1}$ and sum with respect to k. Therefore we can skip the subscript "1" of t and J.

Then term $(10.1.37)_1$ is replaced by

$$(10.1.39)_1\qquad \int_0^{t}\mathsf{Tr}\bigl(\mathsf{Res}_{\mathbb{R}}(Jz-A+\tau)^{-1}J\psi\bigr)\,dz$$

(it is easy to see that the equality $(z - J^{-1}A)^{-1} = (Jz - A)^{-1}J$ holds for formal resolvents also) and term $(10.1.38)_2$ is replaced by

$$(10.1.40)_2 \qquad \int_{\tau_1}^{\tau_2} \mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}(z - A + tJ)^{-1}\psi\big)\, dz.$$

Denote by $\Theta(t)$ and $\Theta'_i(t)$ be expressions $(10.1.40)_2$ and $(10.1.39)_1$ at $\tau = \tau_i$ respectively. We claim that

$$\begin{aligned}(10.1.41)\quad \Theta(0) - \Theta(t) - \Theta'_2(t) + \Theta'_1(t) = \\ - \int_0^t \int_{\tau_1}^{\tau_2} \mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}(z - A + tJ)^{-2} J (z - A + tJ)^{-1}[A, \psi]\big)\, dz\end{aligned}$$

Indeed, the derivative with respect to t of the left-hand expression is equal to

$$- \int_{\tau_1}^{\tau_2} \mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}(z - A + tJ)^{-2} J (z - A + tJ)^{-1}[A, \psi]\big)\, dz$$

because of the chain of equalities

$$\begin{aligned}\partial_t \,\mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}(z - A + tJ)^{-1}\psi\big) = \\ - \mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}(z - A + tJ)^{-1} J (z - A + tJ)^{-1}\psi\big) = \\ - \mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}(z - A + tJ)^{-2} J\psi\big) - \mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}(z - A + tJ)^{-2} J (z - A + tJ)^{-1}[A, \psi]\big)\end{aligned}$$

which follow from the properties of the trace and from the fact that J and ψ commute. The first term in the right-hand expression is equal to

$$\partial_z \,\mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}(z - A + tJ)^{-1} J\psi\big)$$

and after integration with respect to z it reduces with $\partial_t(-\Theta'_2(t) + \Theta'_1(t))$. So, derivatives with respect to t of both sides of (10.1.41) and for $t = 0$ both expressions vanish.

In the framework of condition $(10.1.35)_1$ these calculations are justified by microhyperbolicity for small ϱ'_1 and by microhyperbolicity and mollifications otherwise; justifications in the frameworks of other conditions are similarly.

Finally, after adding all terms due to $(10.1.21)_k$ $(k = 1, \dots, n)$ and $(10.1.20)_{n+1}$ we obtain that the right-hand expression of (10.1.18) contains main parts of asymptotics of $(\Gamma\psi e_A)(\tau_1, \tau_2)$ described in Parts II and III plus a remainder estimate also described there plus extra terms of the form

$$\sum_{1 \le r \le s} h^{r-d} \int (\mathcal{L}_r \psi)\, dx.$$

Here $\mathcal{L}_r$ are differential operators such that $\mathcal{L}_r 1 = 0$. Let us note that these operators $\mathcal{L}_r$ depend uniquely on A, $J_1, \dots, J_n$, $\phi_1, \dots, \phi_n$ and hence after summation with respect to partition of unity all these extra terms disappear.

All these assertions have been proven provided $\varrho'_k \le \varrho$ for all $k = 1, \dots, n$. On the other hand, as it is true for $k < k_0$ only and $\varrho'_k \ge \varrho$, one can replace in all the terms with $k \ge k_0 + 1$ h by $h' = h\bigl(\varrho/\varrho'_k\bigr)^{\frac{1}{m}}$, etc.

Therefore after summation with respect to partition of unity we obtain that only terms supported in $X_{\mathsf{reg}} \cap X_{\mathsf{sing}}$ are not completely reduced, and the remaining terms do not exceed

$$Ch^{1-d}\Bigl(1 + \frac{(\varrho'_1 + \dots + \varrho'_n)}{\varrho}\Bigr)^{\frac{(d-1)}{m}}. \tag{10.1.42}$$

Finally, let us note that if in some ball $\mathcal{B}(y, \gamma(y), X)$ condition

(10.1.43) τ_i lies in the spectral gap of the problem $(A - t'_1 J_1 - \dots - t'_k J_k, B)$ for all $t'_k \in [0, t_k]$ (or $t'_k \in [t_k, 0]$ for $t_k < 0$) for all $k = 1, \dots, n$ and for all $t_k \in \mathsf{supp}(\phi_k)$

is fulfilled then all the operators $\mathcal{L}_r$ vanish in this ball.

Analysis in the Singular Zone

Let us now treat the zone X_{sing}. First of all we must assume that in every ball in $X_{\mathsf{reg}} \cap X_{\mathsf{sing}} \cap \{\rho\gamma \ge c\}$ [9] either an ellipticity condition or condition

$$\varrho'_1 \ge \varrho h \tag{10.1.44}$$

are fulfilled.

Furthermore, we need to introduce condition similar to (9.1.22). Namely, let us assume that

(10.1.45) There exist a self-adjoint operator A' and symmetric operators J'_k coinciding with A and J_k respectively in X_{sing} and such that for all k the operators J'_k are A'-compact and

$$\mathsf{N}\bigl({J'_k}^{-1}(A' - \tau_i - t_1 J'_1 - \dots - t_{k-1} J'_{k-1}); -t, t\bigr) \le R_0(|t|+1)^{l} \qquad \forall k \quad \forall t_j \in \mathsf{supp}(\phi_j) \quad (j = 1, \dots, k-1) \quad \forall t \in \mathbb{R}. \tag{10.1.46}$$

[9] In the general case; modifications will be given below for the Schrödinger and Dirac operators.

Moreover, we assume that

(10.1.46)* condition (10.1.46) is fulfilled for some sequences $\tau_{i,n} \to \tau_i$ with $\tau_{i,n} \in [\tau_1, \tau_2] \setminus \mathsf{Spec}_{\mathsf{ess}}(A)$.

Finally, let us assume that

$$\int_{X_{\mathsf{sing}}} \mathsf{tr}\big(e_{A-t_1J_1-\dots-t_nJ_n}(x,x,\tau_1,\tau_2)\big)\,dx \le R_0 \qquad \forall t_j \in \mathsf{supp}(\phi_j) \quad (j=1,\dots,n). \tag{10.1.47}$$

Instead of this condition we will usually use the condition

$$\mathsf{N}(A - t_1J_1 - \dots - t_nJ_n; \tau_1, \tau_2) \le R_0 \qquad \forall t_j \in \mathsf{supp}(\phi_j) \quad (j=1,\dots,n). \tag{10.1.48}$$

This condition may seem to be too restrictive because it is associated with X instead of X_{sing}, but in fact this is not so.

10.1.3 Main Theorems

Now we can formulate and prove our main theorems.

General Operators

We start from the general operators.

Theorem 10.1.7. *Let X, X_{reg}, X_{sing}, $\gamma_{(i)}$, $\rho_{(i)}$, $\varrho_{(i)j}$ and ϱ'_k satisfy conditions* (9.1.5)–(9.1.8) *for both $i = 1, 2$* [10]*.*

Let operators A and B be of the forms (9.1.9) *and* (9.1.10) *respectively. Let us assume that in X_{reg}*

(10.1.49)$_1$ *Operators $\rho^m_{(i)}\varrho^{-1}_{(i)1}A$ are classically uniformly elliptic for $i = 1, 2$* [11]*;*

(10.1.49)$_2$ *Boundary value problems*

$$\big(\rho^m_{(i)}\varrho^{-1}_{(i)1}A,\ \rho^{m_j}_{(i)}\varrho^{-1}_{(i)j}B_j,\ j=1,\dots,\mu\big)$$

are classically uniformly elliptic for $i = 1, 2$.

[10] Here X_{reg}, X_{sing} and ϱ'_k do not depend on i.

[11] In which case $\rho^m_{(1)}\varrho^{-1}_{(1)1} \asymp \rho^m_{(2)}\varrho^{-1}_{(2)1}$ and a similar conclusion holds for the next assumption (10.1.49)$_2$.

Further, let us assume that $\tau_1 < \tau_2$ *and*

(10.1.50) *For both* $i = 1, 2$, *for every ball* $\mathcal{B}(x, \gamma^{(i)}(x), X)$ *in*

$$X_{\mathsf{reg}} \cap X_{\mathsf{sing}} \cap \{\rho_{(i)}\gamma_{(i)} \ge c\}$$

either the boundary value problem $\bigl(\varrho_{(i)1}^{-1}(A - \tau_i),\ \varrho_{(i)j}^{-1}B_j,\ j = 1, \dots, \mu\bigr)$ *is elliptic (as an* $h_{(i)}$*-boundary value problem with* $h_{(i)} = \bigl(\rho_{(i)}\gamma_{(i)}\bigr)^{-1}$*) or condition* $(10.1.36)_1$ *is fulfilled*[12]*.*

Furthermore, let us assume that J_k *are bounded and* A*-compact operators. Finally, let us assume that there exist operator* $A'_{(i)}$ *coinciding with* A *in* $X_{(i)\mathsf{sing}}$*, self-adjoint and such that for all* k *the operators* J_k *are* A'*-compact and conditions* $(10.1.46)^*$*,* $(10.1.48)$ *are fulfilled.*

Then

(i) The following estimate holds:

$$\mathsf{N}(A; \tau_1, \tau_2) \ge \mathcal{N}(A; \tau_1, \tau_2) - C \sum_{i=1,2} \bigl(R_{(i)1} + R_{(i)2} + R_{(i)3}\bigr) - CR_0 \tag{10.1.51}$$

where $\mathcal{N}$ *is derived as a semiclassical approximation in construction in* X_{reg} *for the sum of* $\mathsf{N}\bigl(J_k^{-1}(A - t_1J_1 - \dots - t_{k-1}J_{k-1}, 0, t_k\bigr)$ *with mollification, according to rules of the Part II,* $R_{(i)1}$ *is the corresponding remainder estimate,* $R_{(i)2}$ *is given by* (9.1.30) *i.e. one can define*

$$R_{(i)2} = \int_{X_{\mathsf{reg}} \cap X_{\mathsf{sing}}} \rho_{(i)}^{d-s}\gamma_{(i)}^{-s}\, dx, \tag{10.1.52}$$

$$R_{(i)3} = \int_{X_{\mathsf{reg}} \cap X_{\mathsf{sing}}} \bigl(\varrho'_1 + \dots + \varrho'_n\bigr)^{\frac{(d-1)}{m}} \varrho^{-\frac{(d-1)}{m}} \rho_{(i)}^{d-1}\gamma_{(i)}^{-1}\, dx, \tag{10.1.53}$$

(ii) On the other hand, if also condition (10.1.47) *is fulfilled then*

$$\mathsf{N}(A; \tau_1, \tau_2) \le \mathcal{N}(A; \tau_1, \tau_2) + C \sum_{i=1,2} \bigl(R_{(i)1} + R_{(i)2} + R_{(i)3}\bigr) + CR_0. \tag{10.1.54}$$

The proof which, after (10.1.12) is established, repeats almost exactly the proofs of Theorems 9.1.7 and 9.1.13 will be presented in Subsection 10.2.3.

[12] I.e., $\varrho'_1 \ge \varrho_{(i)1}h_{(i)}^{1-\delta}$ with $\delta > 0$.

Dirac Operator

In the case of the Dirac operator one can get effective expressions for $R_{j(i)}$ and deduce the following statements:

Theorem 10.1.8. *Let X, X_{reg}, X_{sing}, γ and ρ satisfy conditions* (9.1.5)–(9.1.8). *Let operator A be of the form* (10.1.26), *$d \geq 2$, $\tau_1 < \tau_2$. Let in X_{reg} let the following conditions be fulfilled:*

$$|D^\alpha \omega^{jk}| \leq c\gamma^{-|\alpha|}, \tag{10.1.55}$$

$$|D^\alpha F_{jk}| \leq c\rho\gamma^{-|\alpha|-1}, \tag{10.1.56}$$

$$|D^\alpha V| \leq c\min(\rho, \frac{1}{m}\rho^2)\gamma^{-|\alpha|} \qquad (\alpha \neq 0) \qquad \forall \alpha : |\alpha| \leq K, \tag{10.1.57}$$

and

$$(V - \tau_2 - m)_+ \leq c\min(\rho, \frac{1}{m}\rho^2), \tag{10.1.58$)_2$}$$

$$(V - \tau_1 + m)_- \leq c\min(\rho, \frac{1}{m}\rho^2), \tag{10.1.58$)_1$}$$

$$|\det(\omega^{jk})| \geq \epsilon_0, \tag{10.1.59}$$

$$B\big(x, \gamma(x)\big) \subset X. \tag{10.1.60}$$

Then

(i) Estimate

$$\mathsf{N}(A, \tau_1, \tau_2) \geq \mathsf{N}^{\mathsf{W}}(A; \tau_1, \tau_2) - C\big(R_1 + R_2\big) \tag{10.1.61}$$

holds with

$$R_1 = \int_{X_{\mathsf{reg}} \setminus X_{\mathsf{reg,ell}}} \rho^{d-1}\gamma^{-1}\, dx, \tag{10.1.62}$$

$$R_2 = \int_{X_{\mathsf{reg,ell}}} \rho^{d-s}\gamma^{-s}\, dx, \tag{10.1.63}$$

with arbitrarily large exponent s where $X_{\mathsf{reg,ell}}$ consists of points X_{reg} satisfying both of the following conditions

$$V - \tau_2 - m \leq -\epsilon_0 \min\big(\rho, \frac{1}{m}\rho^2\big), \tag{10.1.64$)_2$}$$

$$-V + \tau_1 - m \leq -\epsilon_0 \min\big(\rho, \frac{1}{m}\rho^2\big). \tag{10.1.64$)_1$}$$

(ii) Estimate

$$\mathsf{N}(A;\tau_1,\tau_2) \le \mathsf{N}^{\mathsf{W}}(A;\tau_1,\tau_2) + C\big(R_1+R_2+R_3+R_4+R_5\big) \tag{10.1.65}$$

holds with R_1, R_2 *defined above,*

$$R_3 = \int_{X_{\mathsf{reg}}\cap X_{\mathsf{sing}}} \rho^d\,dx + \begin{cases} C\displaystyle\int_{X_{\mathsf{sing}}} \tilde\rho^d\,dx & \text{for } d\ge 3,\\ C_p\big(\displaystyle\int_{X_{\mathsf{sing}}} \tilde\rho^{2p}\,dx\big)^{\frac{1}{p}}(\mathsf{mes}(X_{\mathsf{sing}}))^{1-\frac{1}{p}} & \\ \qquad\qquad \text{for } d=2,\ p>1, & \end{cases} \tag{10.1.66}$$

$$R_4 = \Big(\int (\rho+m)^{\delta}\chi_Y\gamma^{-d}\,dx\Big)^{\frac{1}{2}}\Big(\int (\rho+m)^{-\delta}\chi_Y\gamma^{-d}\,dx\Big)^{\frac{1}{2}} \tag{10.1.67}$$

with arbitrarily small $\delta>0$ *and we assume that*

$$\bar X_{\mathsf{sing}}\cap \partial X = \emptyset, \tag{10.1.68}$$

and in X_{sing} *conditions* $(10.1.58)_{1,2}$ *with* ρ *replaced by* $\tilde\rho$ *and* (10.1.59) *are fulfilled and also there*

$$|V_j| \le c\tilde\rho, \tag{10.1.69}$$

$$|D_j\omega^{kl}| \le c\tilde\rho. \tag{10.1.70}$$

Finally,

$$R_5 = \min\Big(\frac{Mm^{\frac{d}{2}}}{|\tau_2-\tau_1|}, M^{\frac12}m^{\frac{d}{2}}(\mathsf{mes}(X_{\mathsf{reg}}\cap X_{\mathsf{sing}}))^{\frac12}\Big), \tag{10.1.71}$$

$$M = \int_{X_{\mathsf{reg}}\cap X_{\mathsf{sing}}} \gamma^{-d}\,dx \tag{10.1.72}$$

and only those connected components of X_{sing} *where condition* $\rho\le cm$ *is violated are taken into account.*

The proof of this theorem will be given in Subsection 10.2.4.

Remark 10.1.9. (i) For $d \ge 3$ estimates (10.1.61), (10.1.65) hold with

$$R_1 = \sum_{\pm} \int_{\Sigma_\pm \cap T^* X_{\mathsf{reg}}} dx d\xi : dH_\pm + R_1', \tag{10.1.73}$$

$$R_1' = \int_{X_{\mathsf{reg}} \setminus X_{\mathsf{reg,ell}}} \rho^{d-1-\delta} \gamma^{-1-\delta}\, dx, \tag{10.1.74}$$

$$H_\pm = V \pm \bigl(m^2 + g^{jk}(\xi_j - V_j)(\xi_k - V_k)\bigr)^{\frac{1}{2}}, \tag{10.1.75}$$

$\Sigma_\pm = \{H_\pm = 0\}$. Moreover, thus modified estimate remains true for $d = 2$ provided either $V_j = 0$ or microhyperbolicity condition is fulfilled. Finally, under appropriate modifications (see Section 5.3.2) this estimate remains true for $d = 2$ in the general case.

(ii) One can improve R_1 in the standard way under assumptions for trajectories. While ϱ_1' defining temp along trajectories could be selected in different ways, it affects contribution of $X_{\mathsf{reg}} \cap X_{\mathsf{sing}}$.

(iii) All these results hold for "rough" Dirac operator (see Subsection 5.4.3) as long as contribution of X_{reg} to the remainder estimate does not change.

(iv) Moreover, in the case when $X_{\mathsf{reg}} \cap X_{\mathsf{sing}}$ contains few connected components one can calculate R_4 and R_5 for every component and then sum the results. As $d = 2$ the same statement holds for R_3.

(v) There will be some improvement for R_4 (see the second term in (10.2.73)).

(vi) Dirac and Schrödinger operators with the strong magnetic field will be covered later.

(vii) The method of this chapter and the previous chapters provide estimates for $\mathsf{N}(A; \tau_1, \tau_2)$ averaged with respect to τ_1 or (and) τ_2 with improved contribution of X_{reg} to the remainder estimate.

(viii) For principally massless Dirac operator one can just take $J = I$.

Consider principally massless operator

$$A = \sum_{j,l} \frac{1}{2} \sigma_l (\omega^{jl} P_j + P_j \omega^{jl}) + V \cdot I, \qquad P_j = D_j - V_j \tag{10.1.76}$$

which is not necessarily of the form (10.1.26) with $m = 0$ since matrix σ_0 may not exist.

It is not necessarily of the type (10.1.26) since σ_0 does not necessarily exist. However we can always extend σ_j by $\begin{pmatrix} \sigma_j & 0 \\ 0 & \sigma_j \end{pmatrix}$ and $\sigma_0 = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}$ fits the bill. Therefore we arrive to

Corollary 10.1.10. *Let all assumptions of Theorem 10.1.8 be fulfilled with* $m = 0$. *Then estimates* (10.1.61) *and* (10.1.65) *hold with* $R_5 = 0$.

10.2 Functional-Analytic Arguments and Proofs of the Main Theorems

10.2.1 Self-Adjointness of the Dirac Operator

Let us begin with the self-adjointness of the (generalized) Dirac operator. First of all let us prove

Theorem 10.2.1. *Let us assume that* A *is an operator of the form* (10.1.26) *or* (10.1.76) *with real-valued coefficients* ω^{jl}, V_j *and* V. *Let us assume that* (10.1.59) *holds and*

(10.2.1) $\omega^{jl} \in \mathscr{C}(X)$, $D_j\omega^{jl}, V_j, V \in \mathscr{L}^p_{\mathsf{loc}}(X)$ *with* $p = d$ *for* $d \geq 3$ *and with some* $p > 2$ *for* $d = 2$.

Then the operator A *with the domain*

$$\mathfrak{D}(A) = \bigl\{u \in \mathscr{L}^2(X, \mathbb{H}) \cap \mathscr{H}^1_{\mathsf{loc}}(X, \mathbb{H}) : Au \in \mathscr{L}^2(X, \mathbb{H})\bigr\} \tag{10.2.2}$$

is self-adjoint in $\mathscr{L}^2(X, \mathbb{H})$.

Proof. (a) Let us first observe that if $u \in \mathscr{H}^1_{\mathsf{loc}}$ then Sobolev embedding theorem yields that $u \in \mathscr{L}^q_{\mathsf{loc}}$ and

$$\|u\|_{\mathscr{L}^q(Y)} \leq C_Y \|u\|_{\mathscr{H}^1(Y)} \tag{10.2.3}$$

on every compact Y where here and below $q = d/(d-2)$ for $d \geq 3$ and $q = p/(p-2)$ with arbitrary $p > 2$ for $d = 2$. Therefore (10.2.1) yields that $V_j u, Vu, \omega^l u \in \mathscr{L}^2_{\mathsf{loc}}(x, \mathbb{H})$ where $\omega^l = i\sum_j D_j\omega^{jl}$.

(b) Next let us prove that the operator A with the indicated domain is closed. Let us first assume that $\max_j \bar\gamma_j < \infty$ [13)].

Let us rewrite V, V_j in the form $V = V' + V''$ with $\|V''\|_{\mathscr{L}^p} \le \varepsilon$, $\|V'\|_{\mathscr{L}^\infty} \le C_\varepsilon$, etc., and let us rewrite ω^{jl} in the form $\omega^{jl} = \omega^{jl\prime} + \omega^{jl\prime\prime}$ with $\|\omega^{jl\prime\prime}\|_{\mathscr{L}^\infty} \le \varepsilon$, $\|\omega^{jl\prime}\|_{\mathscr{C}^2} \le C_\varepsilon$ with arbitrarily small $\varepsilon > 0$. Then

$$\|Au - A_1 u\| \le C_0\varepsilon\|u\|_{\mathscr{H}^1} + C'_\varepsilon\|u\| \qquad \forall u \in \mathfrak{D}(A) \tag{10.2.4}$$

where $A_1 = \sum_{j,l} \omega^{jl\prime}\sigma_l h D_j$ and C_0 does not depend on ε. Moreover, properties of $\omega^{jl\prime}$ and σ_l yield that

$$\left|\|A_1 u\|^2 - \int \sum_{j,k} g^{jk\prime}(D_k u)^\dagger (D_j u)\, dx\right| \le C'_\varepsilon\varepsilon'\|u\|^2_{\mathscr{H}^1} + C''_{\varepsilon\varepsilon'}\|u\|^2 \qquad \forall u \in \mathfrak{D}(A)$$

where $g^{jk\prime} = \sum_l \omega^{jl\prime}\omega^{kl\prime}$ and therefore $|g^{jk} - g^{jk\prime}| \le C_0\epsilon$; here $\varepsilon' > 0$ is arbitrarily small and C'_ε does not depend on ε'. This inequality and (10.2.4) yield inequality

$$\left|\|Au\|^2 - \int \sum_{j,k} g^{jk}(D_k u)^\dagger (D_j u)\, dx\right| \le C_0\varepsilon\|u\|^2_{\mathscr{H}^1} + C'_\varepsilon\|u\|^2 \qquad \forall u \in \mathfrak{D}(A)$$

and then (10.1.59) yields estimate

$$\|u\|_{\mathscr{H}^1} \le C\big(\|Au\| + \|u\|\big) \qquad \forall u \in \mathfrak{D}(A). \tag{10.2.5}$$

This estimate immediately yields that the operator A is closed provided $\max_j \bar\gamma_j < \infty$.

Now let us consider the case $\max_j \bar\gamma_j = \infty$. Let $\psi \in \mathscr{C}_0^1(X)$ be a scalar function. Then $A\psi u = \psi Au + \psi' u$ with a matrix-valued function $\psi' \in \mathscr{C}_0(X)$. Then the above arguments yield the estimate

$$\|\psi u\|_{\mathscr{H}^1} \le C\big(\|Au\| + \|u\|\big) \qquad \forall u \in \mathfrak{D}(A) \tag{10.2.6}$$

where C depends on ψ. But then A is again obviously closed.

(c) Let us prove that the operator A is symmetric. This is obvious for $\max_j \bar\gamma_j < \infty$. For $\max_j \bar\gamma_j = \infty$ equality

$$(Au, v) = (u, Av) \qquad u, v \in fD(A) \tag{10.2.7}$$

[13)] Recall that $X = \mathbb{R}^d/(\bar\gamma_1\mathbb{Z} \times ... \times \bar\gamma_d\mathbb{Z})$.

holds for compactly supported v. Let us replace v by $\psi(x't^{-1})v$ where $\psi \in \mathscr{C}_0^1(X')$ equals 1 in a neighborhood of 0 and $X' \ni x' = (x_j)_{j\in J}$ with $J = \{j, \bar\gamma_j = \infty\}$. For t tending to $+\infty$ we obtain the same equality (10.2.7) for arbitrary $v \in \mathfrak{D}(A)$.

(d) To prove that A is self-adjoint let us consider the problem

$$D_t u = Au, \qquad u|_{t=0} = f. \tag{10.2.8}$$

We are going to prove that for every $f \in \mathfrak{D}(A)$ there exists a solution $u \in \mathscr{C}(\mathbb{R}, \mathscr{L}^2(X, \mathbb{H})) \cap \mathscr{L}^\infty(\mathbb{R}, \mathfrak{D}(A))$ of this problem.

Let us assume first that $\max_j \bar\gamma_j < \infty$. Then problem (10.2.8) is obviously well-posed provided $\omega^{jl}, V_j, V \in \mathscr{C}^2$. In this case $\mathfrak{D}(A) = \mathscr{H}^1(X, \mathbb{H})$.

Let $\omega^{jl}_\delta, V_{j\delta}, V_\delta$ be sequences of mollifications of ω^{jl}, V_j, V respectively with mollifying function $\psi_\delta(x) = \delta^{-d}\psi(x\delta^{-1})$ where $\psi \in \mathscr{C}_0^\infty(\mathbb{R}^d)$ is a real-valued non-negative function with $\int \psi\, dx = 1$. Then for $\delta \to +0$, ω^{jl}_δ tends to ω^{jl} in $\mathscr{C}$ and ω^{l}_δ, $V_{j\delta}$, V_δ tend to ω^{l}, V_j, V respectively in $\mathscr{L}^p$. Moreover, $\|V''_\delta\|_{\mathscr{L}^p} \le C_0\varepsilon$ and $\|V'_\delta\|_{\mathscr{L}^\infty} \le C_\varepsilon$, etc., where V' and V'' were introduced in part (b).

Let u_δ be a sequence of solutions of problem (10.2.8) with the operator A_δ instead of A. Then the arguments of part (b) and the equalities $\|u_\delta\| = \|f\|$, $\|A_\delta u_\delta\| = \|A_\delta f\|$ $\forall t$ yield that for all $\delta > 0$ small enough,

$$\|D_t u_\delta\| + \|u_\delta\|_{\mathscr{H}^1} \le C(\|Af\| + \|f\|) \qquad \forall t \in \mathbb{R}$$

where the constant C does not depend on δ. Then the standard compactness arguments yield that one can choose a subsequence u_δ tending to a function u in $\mathscr{C}(\mathbb{R}, \mathscr{L}^2(X, \mathbb{H}))$ which lies in the required solution space and, moreover, $A_\delta u_\delta \to Au$ in $\mathscr{D}'(\mathbb{R}\times X, \mathbb{H})$ and therefore u is a solution of (10.2.8). The symmetry of A yields that this solution is unique and

$$\|u\| = \|f\|, \ \|Au\| = \|Af\| \qquad \forall t \in \mathbb{R}. \tag{10.2.9}$$

Now let $\max_j \bar\gamma_j = \infty$. Let us first take f supported in the domain $\{x\colon |x'| \le R\}$. Let us replace $\bar\gamma_j = \infty$ by $\bar\gamma_j = CR^2$ and let us solve problem (10.2.8). Then $|\omega^{jl}| \le c$ yields that the propagation speed for operators A_δ does not exceed C_0 and therefore the same is true for the operator A. Then u is supported in $\{|x'| \le \frac12 CR^2\}$ for $|t| \le R$ and sufficiently large R;

moreover, $u(.,t)$ does not depend on $R \geq |t|$. Letting R tend to $+\infty$ we conclude that problem (10.2.8) has a solution in the required space for every compactly supported $f \in \mathfrak{D}(A)$ and the propagation speed does not exceed C_0 and estimate (10.2.9) holds. But then the compactness condition is not necessary.

Now Theorem 10.2.1 is due to Proposition 10.2.2 below. □

Proposition 10.2.2. *Let A be a symmetric closed operator with the dense domain in the Hilbert space $\mathcal{H}$ and let $U(t)$ be a group of unitary operators in $\mathcal{H}$ such that for $f \in \mathfrak{D}(A)$*

(a) $U(t)f \in \mathfrak{D}(A) \quad \forall t \in \mathbb{R}$ and $\|AU(t)f\| \leq M_f e^{ct}$ with some constant $M = M_f$;

(b) $U(t)f \to f$ as $t \to 0$;

(c) $D_t U(t)f = AU(t)f$ in the weak sense.

Then A is a self-adjoint generator of $U(t)$.

Proof. Let us set

$$R_\pm = \mp i \int_0^\infty U(\pm t) e^{-\lambda t} dt$$

with $\lambda > c$. Obviously, the operator norm of $R_\pm$ in $\mathcal{H}$ does not exceed λ^{-1} and for $f \in \mathfrak{D}(A) \quad R_\pm f \in \mathfrak{D}(A)$ and $(A \pm i\lambda)R_\pm f = f$. Then $R_\pm f \in \mathfrak{D}(A)$ $\forall f \in \mathcal{H}$ and both defect indices vanish; here we used that A is closed and $\mathfrak{D}(A)$ is dense. Therefore A is self-adjoint. But then a generator of $U(t)$ coincides with A. □

Remark 10.2.3. (i) Obviously, symmetric operator A is defined under conditions weaker than in Theorem 10.2.1. For example, one can take its domain $\mathfrak{D}(A) = \mathscr{C}_0^1(X)$ provided $\omega^{jl}, \omega^l, V_j, V \in \mathscr{L}^2_{\mathsf{loc}}(X)$.

Moreover, let Y be a measure zero closed subset of X. Assume that $\omega^{jl}, \omega^l, V_j, V \in \mathscr{D}'(X) \cap \mathscr{L}^2_{\mathsf{loc}}(X \setminus Y)$. Then one can take $\mathfrak{D}(A) = \mathscr{C}_0^1(X \setminus Y)$. Obviously, A is a symmetric operator with domain dense in $\mathscr{L}^2(X, \mathbb{H})$.

(ii) Further, if $V_j = 0$ and <u>either</u> d is odd <u>or</u> d is even and $m = 0$ then operator (10.1.66) has a self-adjoint extension. In fact, there exists a unitary matrix β such that $\beta^\dagger \bar{\sigma}_j \beta = \sigma_j$ with $j = 0, \dots, d$ as d is odd and with

$j = 1, \dots, d$ as d is even where the bar means a complex conjugation[14]. But then $\beta^\dagger \bar{A} \beta = A$ and therefore both defect indices of A coincide.

(iii) Similarly, if $V = 0$, $m = 0$, then $\beta^\dagger A \beta = -A$ with $\beta = \sigma_0$ and therefore both defect indices of A again coincide[14].

On the other hand, if $V = 0$ and $m > 0$ then

$$\|Au\|^2 = \|(A - m\sigma_0)u\|^2 + m^2\|u\|^2$$

and inequality

$$\|Au\| \geq m\|u\| \qquad \forall u \in \mathfrak{D}(A) \tag{10.2.10}$$

holds. Therefore both defect indices of A coincide in this case also; moreover, there exists a self-adjoint extension of A satisfying (10.2.10).

Thus, if $V = 0$ then there exists a self-adjoint extension of A satisfying (10.2.10) [13].

(iv) For $d = 2$ let us consider an operator A of the form

$$A_1 = \sigma_1(D_r + \frac{i}{2}r^{-1}) + \sigma_2 r^{-1}(D_\phi + \alpha) + \sigma_0 m \tag{10.2.11}$$

in the polar coordinates with $\mathfrak{D}(A) = \{u \in \mathscr{H}^1(\mathbb{R}^2, \mathbb{H}), r^{-1}u \in \mathscr{L}^2(\mathbb{R}^2, \mathbb{H})\}$. One can see easily that A is self-adjoint for $\alpha \notin \mathbb{Z}$ and that

$$q^\dagger(\sigma_1 \cos\phi - \sigma_2 \sin\phi)q = \sigma_1, \quad q^\dagger(\sigma_1 \sin\phi + \sigma_2 \cos\phi)q = \sigma_2, \quad q^\dagger \sigma_0 q = \sigma_0$$

for the unitary matrix-valued function $q = \operatorname{diag}(e^{i\zeta\phi}, 1)$ and σ_0, σ_1, σ_2 defined by (5.A.28). Moreover,

$$A_2 = q^\dagger A_1 q = \sigma_1(D_1 - \alpha x_2|x|^{-2}) + \sigma_2(D_2 + \alpha x_1|x|^{-2}) + \sigma_0 m. \tag{10.2.12}$$

Then for $\alpha \notin \mathbb{Z}$ the operator A_2 (with the same domain as A_1) is self-adjoint. Moreover, magnetic intensity $F = 0$ for $x \neq 0$ but for $\alpha \notin \mathbb{Z}$ one can remove the vector potential by means the of a gradient transform only in a simply connected subdomain in $\mathbb{R}^2 \setminus 0$.

Furthermore, one can easily see that $A_2(\alpha')$ and $A_2(\alpha)$ are unitarily equivalent if and only if $\alpha' - \alpha \in \mathbb{Z}$.

(v) Other examples of self-adjoint Dirac operators with the magnetic field will be given in Parts VI–X.

---

[14] These arguments however do not work as d is odd but operator A is principally massless operator (10.1.76).

10.2.2 Abstract Theory

Let us now consider the abstract theory. We will use the following definition:

Definition 10.2.4. Let A be a self-adjoint operator and J a symmetric operator in the separable Hilbert space $\mathcal{H}$ such that $\mathfrak{D}(J) \supset \mathfrak{D}(A)$. Then

(i) Operator J is A-*bounded* if

$$\|Ju\| \le C\|Au\| + C'\|u\| \quad \forall u \in \mathfrak{D}(A). \tag{10.2.13}$$

The smallest C_0 such that (10.2.13) holds with $C = C + \epsilon$ and $C' = C'_\epsilon$ for arbitrarily small $\epsilon > 0$ is called A-*bound* of J.

(ii) Operator J is A-*compact* if $J(A+i)^{-1}$ is a compact operator.

Proposition 10.2.5. *Let A be a self-adjoint operator and J_k be symmetric operators in the separable Hilbert space $\mathcal{H}$. Assume that operator J_1 is A-compact and A-bound of J_2 is less than 1. Then*

(i) A-bound of J_1 equals 0 and therefore operators $A + J_k$ are self-adjoint.

(ii) Operator $J_1(A + J_2 + i)^{-1}$ is compact.

(iii) $\mathsf{Spec}_{\mathsf{ess}}(A + J_1) = \mathsf{Spec}_{\mathsf{ess}}(A)$.

Proof. Recall that operator J_1 is A-compact if $J_1(A+i)^{-1}$ is compact; then for every $\epsilon > 0$ there exists a finite-dimensional operator $K = K_\epsilon$ such that $\|J_1(A+i)^{-1} - K\| \le \epsilon$. This operator is of the form

$$Ku = \sum_{1 \le j \le N} f_j \langle u, g_j \rangle$$

and without any loss of the generality one can assume that $g_j \in \mathfrak{D}(A)$ (otherwise they can be replaced by nearby elements of $\mathfrak{D}(A)$). But then $K(A+i)$ is a bounded operator and therefore

$$\|J_1 u\| \le \|K(A+i)u\| + \epsilon\|(A+i)u\| \le \epsilon\|Au\| + C'_\epsilon\|u\| \qquad \forall u \in \mathfrak{D}(A)$$

and therefore A-bound of J_1 equals 0. Statement (i) is proven.

Statement (ii) is due to equality

$$J_1(A+i)^{-1} - J_1(A+J_2+i)^{-1} = J_1(A+i)^{-1} \cdot J_2(A+J_2+i)^{-1}$$

with compact operator $J_1(A+i)^{-1}$ and bounded operator $J_2(A+J_2+i)^{-1}$ (because the A-bound of J_2 is less than 1).

Let us prove that if $\tau \in \mathsf{Spec}_{\mathsf{ess}}(A)$ then $\tau \in \mathsf{Spec}_{\mathsf{ess}}(A+J_1)$; this assertion combined with Statements (i) and (ii) with $J_2 = J_1$ yield the inverse implication and thus Statement (iii). If $\tau \in \mathsf{Spec}_{\mathsf{ess}}(A)$ then there exists a sequence $u_n \in \mathfrak{D}(A)$ such that $\|u_n\| = 1$, $u_n \overset{w}{\to} 0$ and $\|(A-\tau)u_n\| \to 0$. Let $v_n = (A+i)u_n$. Then $1 \le \|v_n\| \le M$ obviously and

$$\langle v_n, f\rangle = \langle u_n, (A-i)f\rangle \to 0 \qquad \text{as} \quad f \in \mathfrak{D}(A).$$

Then $v_n \overset{w}{\to} 0$ and then $J_1 u_n = J_1(A+i)^{-1} v_n \overset{s}{\to} 0$ because operator $J_1(A+i)^{-1}$ is compact. Hence $\|(A+J_1-\tau)u_n\| \to 0$ and therefore $\tau \in \mathsf{Spec}_{\mathsf{ess}}(A+J_1)$.□

Proposition 10.2.6. *Let A be a self-adjoint operator and let J be a symmetric operator in the separable Hilbert space $\mathcal{H}$. Assume that J is A-bounded. Then*

(i) Let $\mathsf{dist}\big(\tau_0, \mathsf{Spec}(A)\big) \ge \epsilon > 0$. *Then* $\mathsf{dist}\big(\tau_0, \mathsf{Spec}(A+tJ)\big) \ge \frac{1}{2}\epsilon$ *for* $|t| \le \delta = \delta(\epsilon) > 0$.

(ii) If $\mathsf{dist}\big(\tau_0, \mathsf{Spec}(A) \setminus \tau_0\big) \ge \epsilon > 0$ *then*

$$\mathsf{Spec}(A+tJ) \cap [\tau_0 - \frac{1}{2}\epsilon, \tau_0 + \frac{1}{2}\epsilon] \subset [\tau_0 - C|t|, \tau_0 + C|t|]$$

for $|t| \le \delta = \delta(\epsilon) > 0$.

(iii) Moreover, in the framework of (ii) the spectral projector of the operator $A+tJ$ corresponding to the interval $[\tau_0 - \frac{1}{2}\epsilon, \tau_0 + \frac{1}{2}\epsilon]$ depends analytically on t.

(iv) In particular, if τ_0 is an eigenvalue of A with multiplicity $n < \infty$ then for $|t| \le \delta$

$$\mathsf{Spec}(A+tJ) \cap [\tau_0 - \frac{1}{2}\epsilon, \tau_0 + \frac{1}{2}\epsilon] = \big\{\tau_1(t), \dots, \tau_n(t)\big\}$$

where $\tau_k(t)$ are Lipschitz functions and the number of eigenvalues of $A+tJ$ in the interval $[\tau_0 - \frac{1}{2}\epsilon, \tau_0 + \frac{1}{2}\epsilon]$ (counting multiplicities) is equal to n.

Proof. Both Statements (i) and (ii) immediately follow from the inequality

$$\|(A-\tau)u\| \ge \mathsf{dist}\big(\tau, \mathsf{Spec}(A)\big) \cdot \|u\| \qquad \forall u \in \mathfrak{D}(A)$$

for self-adjoint operators.

Rewriting the spectral projector in question in the form

$$\Pi(t) = \frac{1}{2\pi i}\int_{\Gamma}(z - A - tJ)^{-1}dz$$

where $\Gamma = \{z \in \mathbb{C}, |z - \tau_0| = \frac{3}{4}\epsilon\}$ is a counter-clockwise oriented contour we obtain Statement (iii) and the assertion concerning the number of eigenvalues in Statement (iv). Moreover, we conclude that

$$\mathsf{Spec}_{\mathsf{ess}}(A + tJ) \cap [\tau_0 - \frac{1}{2}\epsilon, \tau_0 + \frac{1}{2}\epsilon] = \emptyset.$$

Finally, the Lipschitz property of τ_k easily follows from the arguments of the proof of Statements (i) and (ii). □

Proposition 10.2.7. *In the framework of Proposition 10.2.6(iv) assume that*

$$\langle Jv, v\rangle \ge \epsilon\|v\|^2 \qquad \forall u \in \mathsf{Ker}(A - \tau_0). \tag{10.2.14}$$

Then

$$\tau_k(t') \ge \tau_k(t) + \delta_1(t' - t) \qquad \forall k = 1, \dots, n \quad \forall t, t' \in [-\delta, \delta] : t' > t \tag{10.2.15}$$

with $\delta_1 = \delta_1(\epsilon) > 0$.

Proof. Obviously it is sufficient to prove (10.2.15) under additional condition $t' < t + \delta_2(t)$ with $\delta_2(t) > 0$.

Consider $t = \bar{t}$. Let $\bar{\tau}$ be an eigenvalue of $A + \bar{t}J$ of multiplicity r and let $\bar{\Pi}$ be the corresponding spectral projector.

Let τ' be an eigenvalue of $A + t'J$ close to $\bar{\tau}$ and let $|t' - \bar{t}|$ be small enough; then Proposition 10.2.6(iii) yields that

$$\|(I - \bar{\Pi})u\| \le M|t' - \bar{t}| \cdot \|u\| \qquad \text{with} \quad M = M(\bar{t}). \tag{10.2.16}$$

We know that $|\tau' - \bar{\tau}| \le C|t' - \bar{t}|$. This inequality combined with (10.2.16), equalities

$$(A + t'J - \tau')v = 0, \quad (A + \bar{t}J - \bar{\tau})\bar{\Pi}v = 0 \quad \text{for} \quad v \in \mathsf{Ker}(A + t'J - \tau')$$

and the A-boundedness of the operator J yield that

$$\|A(I-\bar\Pi)v\| \le M|t'-\bar t|\cdot\|v\| \quad \text{for} \quad v\in \mathsf{Ker}(A+t'J-\tau'). \tag{10.2.17}$$

Then the same inequality (10.2.17) holds for J instead of A (we increase M if necessary). These inequalities and the equality $(A+\bar tJ-\bar\tau)\bar\Pi=0$ yield that

$$\begin{aligned}\big|(t'-\bar t)\langle Jv,v\rangle+(\tau'-\bar\tau)\|v\|^2\big| = \\ |\langle (A+\bar tJ-\bar\tau)v,v\rangle| \le M|t'-t|^2\|v\|^2.\end{aligned} \tag{10.2.18}$$

On the other hand, inequality (10.2.14) remains true (with $\frac12\epsilon$ instead of ϵ) for $u\in\mathsf{Ker}(A+t'J-\tau')$ also with $|t'|\le\delta$, $|\tau'-\bar\tau|\le\delta$. This inequality, (10.2.18) and Proposition 10.2.6(iii) yield that

$$\mathsf{Spec}(A+t'J)\cap[\tau_0-\delta_3,\tau_0+\delta_1(t'-\bar t)]=\emptyset \qquad \text{for}\quad t'\in[\bar t,\bar t+\delta_2(\bar t)]$$

where $\delta_3=\delta_3(\bar t)>0$ while $\delta_1>0$ does not depend on $\bar t$. So (10.2.15) is proven for $t'<\bar t+\delta_2(\bar t)$. □

Now we are ready to prove the main statement:

Theorem 10.2.8 (Birman-Schwinger principle). *Let A be self-adjoint operator and let J be a symmetric operator in the separable Hilbert space $\mathcal{H}$. Assume that J is A-compact operator.*

Let us assume that $\bar\tau_1,\bar\tau_2\in\mathbb{R}$, $\bar\tau_1<\bar\tau_2$, $\bar t>0$ and

$$(A+tJ-\bar\tau_i)u=0 \implies \varsigma_i\langle Ju,u\rangle\ge\epsilon\|u\|^2 \qquad \forall i=1,2\quad \forall t\in[0,\bar t] \tag{10.2.19}$$

with $\varsigma_i=\pm1$, $\epsilon>0$. Then

(i) The following equality holds:

$$\begin{aligned}\mathsf{N}\big(A;[\bar\tau_1,\bar\tau_2]\big)=\mathsf{N}\big(A+\bar tJ;[\bar\tau_1,\bar\tau_2]\big)+ \\ \varsigma_2\tilde{\mathsf{N}}\big((A-\bar\tau_2),-J;[0,\bar t]\big)-\varsigma_1\tilde{\mathsf{N}}\big((A-\bar\tau_1),-J;[0,\bar t]\big)\end{aligned} \tag{10.2.20}$$

where $\tilde{\mathsf{N}}(B,-J;\mathcal{J})$ is the number of eigenvalues $t\in\mathcal{J}$ of the problem

$$(B+tJ)u=0 \qquad u\in\mathfrak{D}(B)\setminus 0 \tag{10.2.21}$$

counting their multiplicities[15)].

On the other hand, $\mathsf{N}(B,\mathcal{J})$ *is the cardinality of the spectrum of* B *in* $\mathcal{J}$ *and* $\mathsf{N}(B,\mathcal{J})=\infty$ *if* $\mathsf{Spec}_{\mathsf{ess}}(B)\cap\mathcal{J}\neq\emptyset$.

(ii) Further, equality (10.2.20) *remains true if one replaces the interval* $\mathcal{J}$ *in the left-hand and right-hand expressions: one removes* $\bar\tau_1$ *and (or)* $\bar\tau_2$ *from* $\mathcal{J}$ *and replaces* $[0,\bar t]$ *by* $(0,\bar t)$ *in the third and (or) second terms in the right-hand expression; however, in order to avoid complications with the domain of* u*, one should assume that* $\bar\tau_i\notin\mathsf{Spec}_{\mathsf{ess}}(A)$.

(iii) Furthermore, $\tilde{\mathsf{N}}\bigl(A-\bar\tau_i,-J;[0,\bar t]\bigr)<\infty$ *provided* $\bar\tau_i\notin\mathsf{Spec}_{\mathsf{ess}}(A)$.

Remark 10.2.9. If $\mathsf{Spec}_{\mathsf{ess}}(A)\cap[\bar\tau_1,\bar\tau_2]\neq\emptyset$ then $\mathsf{Spec}_{\mathsf{ess}}(A+tJ)\cap[\bar\tau_1,\bar\tau_2]\neq\emptyset$ due to Proposition 10.2.5(iii) and both sides of (10.2.20) are infinite: indeed, it will follow from Statement (iii) of the Theorem that $\tilde{\mathsf{N}}\bigl((A-\bar\tau_i),-J;[0,\bar t]\bigr)<\infty$ for $i=1,2$ and therefore there is no indefiniteness in the right-hand expression).

Proof of Theorem 10.2.8. In virtue of Remark 10.2.9 in the proof of Statements (i) and (i) we can assume without any loss of the generality that

$$\mathsf{Spec}_{\mathsf{ess}}(A)\cap[\bar\tau_1,\bar\tau_2]=\emptyset. \tag{10.2.22}$$

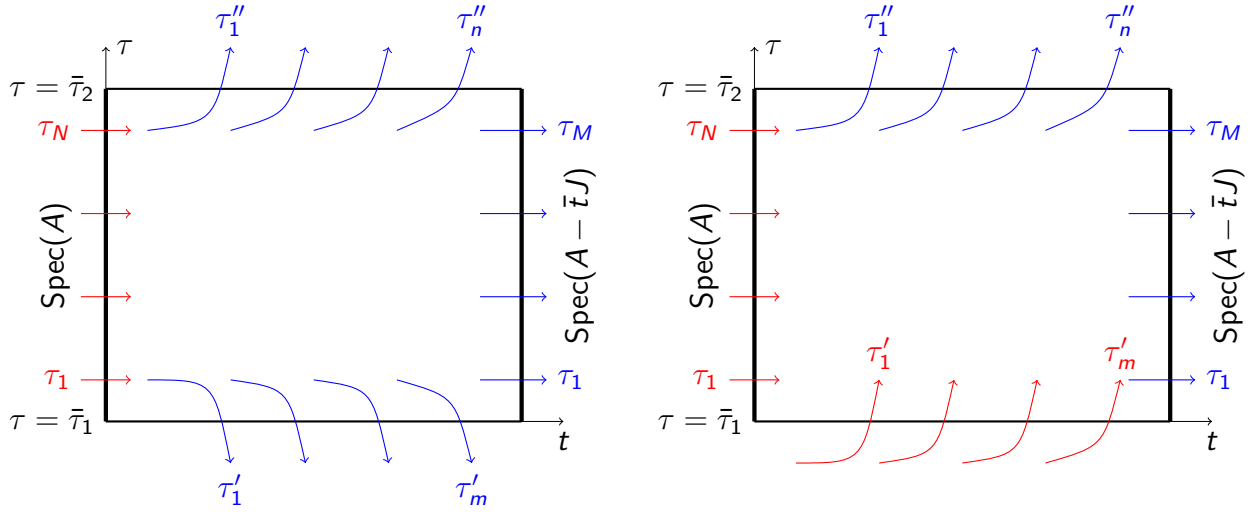
Then

$$\mathsf{Spec}(A+tJ)\cap[\bar\tau_1,\bar\tau_2]=\bigl\{\tau_k(t),\,t\in[t'_k,t''_k],\,k=0,\dots,N\bigr\}$$

where $N\le\infty$ and for each $\tau\in[\bar\tau_1,\bar\tau_2]$ $\#\{k\colon\tau_k(t)=\tau\}$ is equal to the multiplicity of τ as an eigenvalue of $(A+tJ)$.

Furthermore, due to Propositions 10.2.5 and 10.2.5 $0\le t'_k<t''_k\le\bar t$ and $\tau_k(t)$ are Lipschitz functions on the intervals $(\tilde t'_k,\tilde t''_k)\supset[t'_k,t''_k]$ such that for $t\in(\tilde t'_k,\tilde t''_k)$ $\tau_k(t)\in[\bar\tau_1,\bar\tau_2]$ if and only if $t\in[t'_k,t''_k]$. Finally, $\varkappa_i\tau_k(t)$ are monotone increasing function of t in neighborhoods of $t_{ik}\in[t'_k,t''_k]$ with $\tau_k(t_{ik})=\bar\tau_i$.

Then the various terms in (10.2.20) are the numbers of graphs $\{\tau=\tau_k(t)\}$ intersecting respectively the upper, lower, right and left sides of the rectangle $\{0\le t\le\bar t,\ \bar\tau_1\le\tau\le\bar\tau_1\}$ on Figure 10.1, taken with the correct signs and



(a) $\varsigma_2 > 0, \varsigma_1 < 0$; $N = M + m + n$ (b) $\varsigma_2 > 0, \varsigma_1 > 0$; $N + m = M + n$

Figure 10.1: : As $\varsigma_2 \gtrless 0$ eigenvalues exit/enter $[\bar\tau_1, \bar\tau_2]$ through $\tau = \bar\tau_2$ and as $\varsigma_1 \lessgtr 0$ eigenvalues exit/enter $[\bar\tau_1, \bar\tau_2]$ through $\tau = \bar\tau_1$ as t grows. As $\varsigma_2 < 0$ pictures should be modified in the obvious way.

equality (10.2.20) and its modifications in Statement (ii) are due to obvious geometric arguments.

Statements (i) and (ii) are proven; let us prove Statements (iii). If $\tilde{\mathsf{N}}(A - \bar\tau, -J; [0, \bar t]) = \infty$ then there would exist sequences $t_n \in [0, \bar t]$ and $u_n \in \mathfrak{D}(A)$ such that $(A - \bar\tau + t_n J)u_n = 0$ and $\langle Ju_n, u_m\rangle = \delta_{nm}$. Then $\|u_n\| \le C$ by (10.2.19) and then the equality $(A + t_n J - \bar\tau)u_n = 0$ and the fact that the A-bound of J is 0 imply that $\|Au_n\| \le C_1$. Then the compactness of the operator $J(A + i)^{-1}$ yields that the sequence Ju_n is strongly convergent (we take a subsequence if necessary) but this contradicts the equality $\langle Ju_n, u_m\rangle = \delta_{nm}$. □

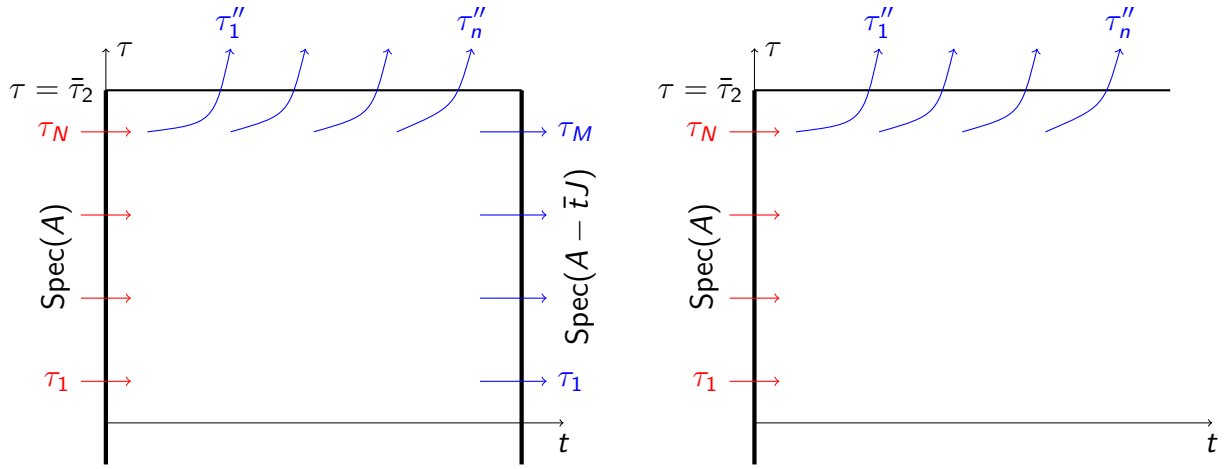
Remark 10.2.10. (i) As A is semi-bounded from below we are in the framework of Chapter 9 and Birman-Schwinger principle is illustrated on Figure 10.2(a); we can take $\bar\tau_1 = -\infty$ resulting in

$$(10.2.20)' \quad \mathsf{N}\big(A; [\bar\tau_1, \bar\tau_2]\big) = \mathsf{N}\big(A + \bar t J; [\bar\tau_1, \bar\tau_2]\big) + \varsigma_2 \tilde{\mathsf{N}}\big((A - \bar\tau_2), -J; [0, \bar t]\big).$$

[15] I.e., the dimensions of the subspaces of $\mathcal{H}$ on which (10.2.21) holds with given t; in this definition neither continuous nor fancier types of the spectrum are discussed, just the bare dimension of the null space.

(ii) And then we can take $\bar{t} = \infty$ important subcase is of $\bar{t} = \infty$ as illustrated on Figure 10.2(b):

$$\mathsf{N}\big(A; [\bar{\tau}_1, \bar{\tau}_2]\big) = \varsigma_2 \tilde{\mathsf{N}}\big((A - \bar{\tau}_2), -J; [0, \bar{t}]\big). \tag{10.2.20}''$$



(a) $\varsigma_2 > 0, N = M + n$ (b) $\varsigma_2 > 0, N = n, \bar{t} = \infty$

Figure 10.2: : Case of A bounded from below.

Remark 10.2.11. Let A be a self-adjoint operator and J be a symmetric operator in the separable Hilbert space $\mathcal{H}$. Let $\mathfrak{D}(J) \supset \mathfrak{D}(A)$ and $J(A+i)^{-1}$ be a compact operator. Moreover, let us assume that $J \geq 0$, $\mathsf{Ker}\, J = 0$ and

$$\|(A - \bar{\tau}_i)u\| + \|Ju\| \geq \epsilon_1 \|u\| \qquad \forall u \in \mathfrak{D}(A) \tag{10.2.23}$$

with $\epsilon_1 > 0$. Then (10.2.19) holds.

In fact, otherwise there exist sequences $t_n \in [0, \bar{t}]$ and $u_n \in \mathfrak{D}(A)$ such that $Au_n = -t_n Ju_n$ (we assume for the sake of simplicity that $\bar{\tau}_i = 0$), $\|u_n\| = 1$, $\langle Ju_n, u_n\rangle \to 0$. Then estimate $\|Ju\| \leq \delta\|Au\| + C_\delta\|u\|$ (with arbitrarily chosen $\delta > 0$) yields that $\|Au_n\| \leq C$ and since $\|u\|_n = 1$ we obtain that the sequence Ju_n is strongly convergent (we take a subsequence if necessary). Then the sequence Au_n is also strongly convergent. Then (10.2.23) yields that the sequence u_n is also strongly convergent (because a Cauchy sequence is a converging sequence and conversely).

Let $u = \lim u_n$. Then $u \in \mathfrak{D}(A)$, $\|u\| = 1$ and $\langle Ju, u\rangle = \lim\langle Ju_n, u_n\rangle = 0$; this contradicts the conditions $J \geq 0$ and $\operatorname{Ker} J = 0$.

Proposition 10.2.12. *Let assumptions of Remark 10.2.11 be fulfilled. Let us replace assumption* (10.2.23) *by assumption*

$$\|(A - \bar\tau_i)u\| + \|J^{\frac12}u\| \geq \epsilon_1\|u\| \qquad \forall u \in \mathfrak{D}(A); \tag{10.2.24}$$

one can easily see that this condition is stronger. Then for small enough $\delta > 0$ operators $((A-\bar\tau_i)\pm i\delta J)^{-1}$, $(A-\bar\tau_i)((A-\bar\tau_i)\pm i\delta J)^{-1}$ and $J((A-\bar\tau_i)\pm i\delta J)^{-1}$ are bounded (their norms depend on δ) and therefore operator $J((A-\bar\tau_i)\pm i\delta J)^{-1}$ is compact.

Moreover, one can take arbitrarily large $\delta > 0$ provided J is a bounded operator.

Proof. Without any loss of the generality one can assume that $\bar\tau_i = 0$. If $(A + i\delta J)u = f$ then

$$\|J^{\frac12}u\|^2 \leq \delta^{-1}\|u\| \cdot \|f\|, \quad \|Au\| \leq \delta\|Ju\| + \|f\| \leq C\delta(\|Au\| + \|u\|) + \|f\|$$

and hence $\|u\| + \|Au\| \leq C_\delta\|f\|$. This inequality yields the boundedness of the indicated operators. Moreover, if J is a bounded operator then $\|Ju\| \leq C\|J^{\frac12}u\|$ and therefore $\|Au\| \leq C\delta\|J^{\frac12}u\| + \|f\|$; this inequality combined with the inequalities $\|J^{\frac12}u\|^2 \leq \delta^{-1}\|u\| \cdot \|f\|$ and (10.2.24) yield that $\|u\| + \|Au\| \leq C_\delta\|f\|$ for arbitrary $\delta > 0$. □

Proposition 10.2.13. *Let assumptions of Remark 10.2.11 be fulfilled and let J be a bounded operator (one can easily check that conditions* (10.2.23) *and* (10.2.24) *are equivalent in this case). Then*

(i) Operator $B = J^{-\frac12}(A - \bar\tau_i)J^{-\frac12}$ with domain

$$\mathfrak{D}(B) = \big\{u \in \mathfrak{D}(J^{-\frac12}) : \ J^{-\frac12}u \in \mathfrak{D}(A) \ \text{ and } \ (A - \bar\tau_i)J^{-\frac12}u \in \mathfrak{D}(J^{-\frac12})\big\}$$

is self-adjoint.

(ii) Operators $(B \pm i)^{-1}$ are compact.

(iii) Eigenvalues of the operator $-B$ and those of the problem

$$(A - \bar\tau_i)u + tJu = 0 \qquad u \in \mathfrak{D}(A) \tag{10.2.25}$$

coincide (counting multiplicities) and

$$\mathsf{Ker}(B+tJ) = J^{\frac12}\,\mathsf{Ker}((A-\bar\tau_i)+tJ). \tag{10.2.26}$$

Proof. The obvious proof is left to the reader. □

10.2.3 Proof of Theorem 10.1.7

Thus *Theorem 10.1.7 has been proven under additional condition* (10.2.23) *which should be checked for operator* A *replaced by*

$$A'_k := A - t_1J_1 - ... - t_{k-1}J_{k-1},$$

$J = J_k$ *and* $\bar\tau_i = \tau_i$ *for every* $k = 1, ..., n$*:*

$$\|(A-\tau_i - t_1J_1 - ... - t_{k-1}J_{k-1})u\| + \|J_ku\| \ge \epsilon_1\|u\| \qquad u\in\mathfrak{D}(A)\quad \forall k = 1, ..., n. \tag{10.2.27}$$

Really, by the construction operators $J_k \ge 0$ are bounded[16] operators with $\mathsf{Ker}\, J_k = 0$ and therefore in virtue of Proposition 10.2.11

$$\tilde{\mathsf{N}}\big((A-\tau_2), -J; [0,\bar t]\big) = \mathsf{N}\big(-J^{-\frac12}(A-\tau_2)J^{-\frac12}; [0,\bar t]\big) = \mathsf{N}\big(-J^{-1}(A-\tau_2); [0,\bar t]\big) \tag{10.2.28}$$

and formula (10.2.20) becomes

$$\mathsf{N}\big(A; [\tau_1,\tau_2]\big) = \mathsf{N}\big(A+\bar tJ; [\tau_1,\tau_2]\big) + \varsigma_2\mathsf{N}\big(-J^{-\frac12}(A-\tau_2)J^{-\frac12}; [0,\bar t]\big) - \varsigma_1\mathsf{N}\big(J^{-\frac12}(A-\tau_1)J^{-\frac12}; [0,\bar t]\big). \tag{10.2.29}$$

Due to (10.2.27) we can replace here A by A'_k and J_1 by J_k and $\bar t$ by $-t_k$.

Therefore we justified (10.1.12) and thus (10.1.18) and then the arguments of Subsection 10.1.2 prove the statement of Theorem 10.1.7.

One can easily check that

(10.2.30) Condition (10.2.23) is fulfilled provided

$$\tau_1, \tau_2 \notin \mathsf{Spec}_{\mathsf{ess}}(A). \tag{10.2.31}$$

[16] One can see easily that otherwise $R_{(i)1} = \infty$ and then the statement of the theorem is empty.

Moreover, Proposition 10.2.5(iii) yields that in this case condition (10.2.27) is fulfilled as well. Therefore *Theorem 10.1.7 has been proven under additional condition* (10.2.31).

Finally, let us consider the general case. Let us replace condition (10.2.31) by condition

(10.2.32) There exist sequences $\tau_{1,n} \to \tau_1 + 0$ and $\tau_{2,n} \to \tau_2 - 0$ with $\tau_{1,n}, \tau_{2,n} \notin \mathsf{Spec}_{\mathsf{ess}}(A)$;

this condition is fulfilled in virtue of (10.2.24). Under this condition we can apply Theorem 10.1.7 to intervals $(\tau_{1,n}, \tau_{2,n})$.

Let us note that $\mathsf{Spec}\, a^0(x,\xi) = \{\lambda_1(x,\xi), \dots, \lambda_D(x,\xi)\}$ with Lipschitz functions λ_j such that $|\lambda_j(x,\xi)| \to \infty$ as $|\xi| \to \infty$ and therefore

$$x \in X_{(1)\mathsf{reg},\mathsf{ell}} \cap X_{(2)\mathsf{reg},\mathsf{ell}} \implies \mathsf{Spec}\, a^0(x,\xi) \cap [\tau_1, \tau_2] = \emptyset. \tag{10.2.33}$$

On the other hand, it is easy to check (e.g., see the next Subsection 10.2.4) that if $R_{(1)1}+R_{(2)1} < \infty$ (otherwise the statement of Theorem 10.1.7 is empty) then $X_{(1)\mathsf{reg}} \setminus X_{(1)\mathsf{reg},\mathsf{ell}}$ and $X_{(2)\mathsf{reg}} \setminus X_{(2)\mathsf{reg},\mathsf{ell}}$ are compact sets. Therefore all conditions in $X_{(i)\mathsf{reg}} \setminus X_{(i)\mathsf{reg},\mathsf{ell}}$ (i.e., the microhyperbolicity condition, etc.) remain true (with $\gamma' = \frac{1}{2}\gamma$ and the same $\rho, \dots$) for $\tau_{i,n}$ instead of τ_i provided n is large enough.

Moreover, the ellipticity condition which defines $X_{(i)\mathsf{reg},\mathsf{ell}}$ remains true (with $\gamma' = \frac{1}{2}\gamma$ and $\rho' \ge \rho$ and appropriately changed other parameters) for τ_i' instead of τ_i provided $|\tau_i' - \tau_i|$ is small enough.

Therefore every term of the remainder estimate in the zone $X_{(i)\mathsf{reg}}$ for the interval $(\tau_{1,n}, \tau_{2,n})$ tends to the corresponding term of the remainder estimate for the interval (τ_1, τ_2) and $\mathcal{N}(\tau_{1,n}, \tau_{2,n})$ tends to $\mathcal{N}(\tau_1, \tau_2)$ (even if it is infinite).

Moreover, we can take the same R_0 for the interval $(\tau_{1,n}, \tau_{2,n})$ as for the original interval (τ_1, τ_2) (see conditions (10.1.44)–(10.1.46)). Therefore *Theorem 10.1.7 has been proven in the full generality.*

10.2.4 Proof of Theorem 10.1.8

Functional-Analytic Arguments

Let us return to the Dirac operator. In order to prove Theorem 10.1.8 one should derive some estimates of (10.1.46)- and (10.1.48)-type and construct the admissible matrix functions J_k.

Let us first consider the Dirac operator in the context of Theorem 10.1.7. Let us note first of all that if $R_1 < \infty$ (otherwise all the statements of this theorem are void) then $X_{\mathsf{reg}} \setminus X_{\mathsf{reg,ell}}$ are compact sets and on these sets ρ and γ are bounded and disjoint from 0. Really, otherwise there exists a family of non-intersecting balls $B(x^n, \gamma(x^n))$ with $n = 1, 2, \dots$, lying in this set, the contribution of each of these balls to R_1 is larger than $\epsilon > 0$.

On the other hand, the definition of $X_{\mathsf{reg,ell}}$ immediately yields that $\rho \le c'm$ on this set. So we can assume that

$$\rho \le M,\ \gamma \ge \epsilon \qquad \text{at} \quad X_{\mathsf{reg,ell}} \tag{10.2.34}$$

and

$$\varepsilon \le \rho \le M,\ \epsilon \le \gamma \le M \qquad \text{at} \quad X_{\mathsf{reg}} \tag{10.2.35}$$

where ε, M should not enter in the estimates.

Now we need to prove the A-compactness property.

Proposition 10.2.14. *Let all the conditions of Theorem 10.1.8 associated with the zone X_{reg} be fulfilled. Let us assume that the operator A is self-adjoint. Moreover, let $\rho \le M$ at X_{reg} and $J \in \mathscr{L}^\infty(X)$ be supported in X_{reg}. Let*

$$\forall \delta > 0 \qquad \mathsf{mes}(\{x, |J(x)| > \delta\}) < \infty. \tag{10.2.36}$$

Then operator $J(A+i)^{-1}$ is compact in $\mathscr{L}^2(X, \mathbb{H})$.

Proof. The results of Subsection 5.3.2 and the boundedness of ρ yield the estimate

$$|e(x, x, 0, \tau)| \le M(|\tau|^d + 1) \qquad \forall x \in X_{\mathsf{reg}} \quad \forall \tau \in \mathbb{R} \tag{10.2.37}$$

where the constant M is increased if necessary and e assumed without losing generality that $\tau_1 = -\tau_2$.

Therefore $Q := J^{\frac12}\big(E(\tau) - E(0)\big)J^{\frac12}$ is a trace operator with the trace norm not exceeding $M(|\tau|^d + 1)$ provided $J \in \mathscr{L}^1 \cap \mathscr{L}^\infty$ where $E(\tau)$ is the spectral projector of A; recall that J is supposed to be supported in X_{reg} here.

This operator is of the form $Q = SS^*$ and therefore $S = J^{\frac12}\big(E(\tau) - E(0)\big)$ is a Hilbert-Schmidt operator with the Hilbert-Schmidt norm not exceeding $M(|\tau|^d + 1)$. Then equalities

$$(A+i)^{-p} = \int_{-\infty}^{\infty} (\tau+i)^{-p} d_\tau E(\tau) = \int_{-\infty}^{\infty} p(\tau+i)^{-p-1}\big(E(\tau) - E(0)\big)\, d\tau$$

yield that

(10.2.38) For $p > d$ operator $J(A+i)^{-p}$ is also a Hilbert-Schmidt operator.

Let us note that for $\varepsilon > 0$

$$J(A+i)^{-1} = J(A+i)^{-1}(I+i\varepsilon A)^{-d} + JB_\varepsilon \tag{10.2.39}$$

with

$$B_\varepsilon = (A+i)^{-1}(I+i\varepsilon A)^{-d}\big((I+i\varepsilon A)^d - I\big); \tag{10.2.40}$$

then due to (10.2.38) the first term in the right-hand expression of (10.2.39) is a Hilbert-Schmidt operator and B_ε is a product of $\varepsilon A(A+i)^{-1}$ and an operator with the uniformly bounded operator norm. Hence the operator norm of B_ε does not exceed $C\varepsilon$. Therefore $J(A+i)^{-1}$ is approximated in the operator norm by compact operators and therefore is also compact. *Thus, for $J \in \mathscr{L}^1 \cap \mathscr{L}^\infty$ the proposition is proven.*

In the general case, for every $\varepsilon > 0$ there exists a representation $J = J' + J''$ with $J' \in \mathscr{L}^1 \cap \mathscr{L}^\infty$ and $\|J''\|_{\mathscr{L}^\infty} \le \varepsilon$. Then $J'(A+i)^{-1}$ is a compact operator and $\|J''(A+i)^{-1}\| \le \varepsilon$ and so $J(A+i)^{-1}$ is approximated by compact operators and so is also compact. □

Proposition 10.2.15. *Let all the conditions of Theorem 10.1.8 associated with the zone X_{sing} be fulfilled. Let $R_3 < \infty$ and $\gamma \ge \epsilon$ on $X_{\mathsf{reg}} \cap X_{\mathsf{sing}}$. Let $J \in \mathscr{L}^p(X)$ with $p = d$ for $d \ge 3$ and with $p > 2$ for $d = 2$* [17]*.*

Suppose $\mathsf{supp}(J) \subset X_{\mathsf{sing}}$ *and* $\mathsf{dist}(\mathsf{supp}(J), \partial X_{\mathsf{sing}} \setminus X_{\mathsf{reg}}) \ge \epsilon$. *Then operator $J(A+i)^{-1}$ is compact.*

Proof. Conditions of this proposition yield that there exists a function ϕ supported in the $\frac{2}{3}\epsilon$-neighborhood of $\mathsf{supp}(J)$ and equal 1 in the $\frac{1}{3}\epsilon$-neighborhood of $\mathsf{supp}(J)$ such that $0 \le \psi \le 1$ and $|D^\alpha \phi| \le C \quad \forall \alpha : |\alpha| \le K$.

Let us consider equation $(A+i)v = f \in \mathscr{L}^2(X, \mathbb{H})$ with v supported in X_{sing}. Let us apply the arguments used in the proof of Theorem 10.2.1, and also condition $R_3 < \infty$. One can prove easily that if $v \in \mathscr{H}^1$ then

$$\|Dv\| \le M(\|f\| + \|v\|). \tag{10.2.41}$$

Let us consider $v \in \mathscr{H}^1_{\mathsf{loc}} \cap \mathscr{L}^2(X, \mathbb{H})$ and take a function ψ with $|\psi| + |\nabla\psi| \le C$. Then $(A+i)\psi v = \psi f + [A, \psi]v$ and (10.2.41) yields

[17] Let us recall that for $d = 2$ the condition $R_3 < \infty$ also means that $\mathsf{mes}(X_{\mathsf{sing}}) < \infty$.

estimate $\|D\psi v\| \le M(\|f\| + \|v\|)$. Since this estimate holds for every ψ described above we obtain that $v \in \mathscr{H}^1$ and estimate (10.2.41) holds.

Similarly, if $u \in \mathfrak{D}(A)$ and $(A+i)u = f$ then

$$\|\phi u\|_{\mathscr{H}^1} \le M(\|f\| + \|u\|) \le (M+1)\|f\|$$

and therefore the operator $\phi(A+i)^{-1} : \mathscr{L}^2(X, \mathbb{H}) \to \mathscr{H}^1(X, \mathbb{H})$ is bounded. On the other hand, it is well known that if $J \in \mathscr{L}^p$ with p indicated above (and $\mathsf{mes}(X_{\mathsf{sing}}) < \infty$ for $d = 2$) then the operator $J : \mathscr{H}^1(X_{\mathsf{sing}}, \mathbb{H}) \to \mathscr{L}^2(X, \mathbb{H})$ is compact. □

The final arguments of the proof of Proposition 10.2.14 obviously yield

Corollary 10.2.16. *The assertion of Proposition 10.2.15 remains true if condition $J \in \mathscr{L}^p$ is replaced by condition*

(10.2.42) $V = V' + V''$, $V \in \mathscr{L}^p$, $V'' \in \mathscr{L}^\infty$ *and satisfies*(10.2.36).

Estimates for a Number of Crossing Eigenvalues

Let us start from the construction of matrices J_k. One can see easily that there exists a function ζ' on X_{reg} such that $\zeta'(x) > 0$, $c^{-1} \le \zeta'(x)/\zeta'(y) \le c$ for $y \in B\big(x, \epsilon_1\gamma(x)\big)$, $x \in X'_{\mathsf{reg}}$ where X'_{reg} is a domain intermediate between X_{reg} and $X_{\mathsf{reg}} \setminus X_{\mathsf{sing}}$, $\zeta' \asymp \min(\rho, \frac{1}{m}\rho^2)$. Let us set $\zeta = \zeta'$ in X_{reg} and $\zeta = \eta\zeta''$ in $X_{\mathsf{sing}} \setminus X_{\mathsf{reg}}$ where $\zeta'' \in \mathscr{S}(X)$ is a fixed function, $\zeta''(x) > 0$ and $\mathbb{R} \ni \eta \to +0$ in what follows. Let us note that $\zeta \in \mathscr{L}^\infty$ provided $R_1 < \infty$.

Let us choose

$$J_1 = \begin{pmatrix} \zeta I & 0 \\ 0 & \epsilon_2\zeta I \end{pmatrix}, \qquad J_2 = \begin{pmatrix} \epsilon_2\zeta I & 0 \\ 0 & \zeta I \end{pmatrix}$$

and let us take ϕ_1 supported in $[c_0, 2c_0]$ and ϕ_2 supported in $[-2c_0, -c_0]$, where $\epsilon_2 > 0$ is small enough and c_0 is large enough constants, such that

$$(10.2.43)_2 \qquad m - V - \tau_2 + t_1 j + \epsilon_2 t_2 \zeta \ge \frac{\epsilon}{2}\min(\rho, \frac{1}{m}\rho^2),$$

$$(10.2.43)_1 \qquad -m + V - \tau_1 + t_1\epsilon_2 j + t_2\zeta \le -\frac{\epsilon}{2}\min(\rho, \frac{1}{m}\rho^2)$$

$$\text{in } X_{\mathsf{reg}} \qquad \forall t_k \in \mathsf{supp}(\phi_k).$$

Let us apply the arguments of Section 10.1. Then in order to estimate $\mathsf{N}(A, \tau_1, \tau_2)$ from below we need to estimate R_0 in condition (10.1.46); the compactness of the operator $J(A+i)^{-1}$ obviously follows from $R_1 < \infty$ and Proposition 10.2.14.

Further, in order to estimate R_0 we need to estimate $\mathsf{N}(\tilde{A}-\tau_i, -\tilde{J}_1, (-t, t))$ and $\mathsf{N}(\tilde{A}+t\tilde{J}_1-\tau_i, -J_2, (-t, t))$ where Proposition 10.2.13(iii) yields that we can replace $\tilde{\mathsf{N}}$ by N. Here $\tilde{A}$ and $\tilde{J}_k$ mean corresponding operators extended from X_{sing} [18]. Let us consider the first number; one can analyze the second number in the same way. Let us assume for the sake of simplicity that $\tau_i = 0$ (otherwise we replace V by $V - \tau_i$).

We know that $\mathsf{N}(\tilde{A}, -\tilde{J}_1; (-t, t))$ for $t \ge 0$ is the maximal dimension of the subspace $\mathcal{L}' \subset \mathscr{C}_0^1(X, \mathbb{H})$ on which inequality

$$\|\tilde{J}_1^{-\frac{1}{2}}\tilde{A}u\|^2 \le t^2\|\tilde{J}_1^{\frac{1}{2}}u\|^2 \tag{10.2.44}$$

holds. Therefore we should estimate the maximal dimension of the subspace $\mathcal{L} \subset \mathscr{C}_0^1(X, \mathbb{H})$ on which inequality

$$\|\tilde{\zeta}^{-\frac{1}{2}}\tilde{A}u\|^2 \le C_0 t^2\|\tilde{\zeta}^{\frac{1}{2}}u\|^2 \tag{10.2.45}$$

holds where $\tilde{\zeta}$ is an admissible continuation of ζ from X''_{sing} (which is a domain intermediate between X_{sing} and $X_{\mathsf{sing}} \setminus X'_{\mathsf{reg}}$) to $\mathbb{R}^d$ and none of the constants below depend on η.

Let $\tilde{A}$ be an operator of (5.3.71) type:

$$\tilde{A} = \tilde{A}_0 + \tilde{V}, \qquad \tilde{A}_0 = \sum \frac{1}{2}\sigma_l(\omega^{kl}\tilde{P}_j + \tilde{P}_k\omega^{kl}) + \sigma_0(m+W) \tag{10.2.46}$$

where the coefficients ω^{kl} are the same as in A,

$$\tilde{P}_k = D_k - \tilde{V}_k, \quad |\tilde{V}_k| \le c\tilde{\rho}, \quad |\tilde{V}| \le m + c\min(\rho, \frac{1}{m}\rho^2) \tag{10.2.47}$$

and $\tilde{V}_k$, $\tilde{V}$ are supported in X_{sing},

$$W \ge 0, \qquad |D^\alpha W| \le c\rho\gamma^{-|\alpha|} \quad \forall \alpha : |\alpha| \le K, \tag{10.2.48}$$

$W \asymp \rho$ for $\rho \ge cm$ outside of X_{sing} and W vanishes in X'_{sing} and also W vanishes for $\rho \le \epsilon_1 m$.

[18] Or rather from its connected component, and later we sum the results obtained for these components.

(10.2.49) *For notational simplicity in what follows we skip tilde writing* A, P, W *instead of* $\tilde{A}$, $\tilde{P}$, $\tilde{V}$.

Let us consider a partition of unity $1 = \sum_{\nu\ge 0} \psi_\nu^2$ in X_{sing} where ψ_ν are supported in the $\epsilon\gamma$-vicinity of X_{reg} and γ-admissible for $\nu \ge 1$, and where ψ_0 is supported in X_{sing}. Then the left-hand expression in (10.2.45) is equal to

$$2\|\zeta^{-\frac{1}{2}} Au\|^2 \ge 2\sum_{\nu\ge 0} \lambda_\nu \|\psi_\nu Au\|^2 \ge \sum_{\nu\ge 0} \lambda_\nu \|A\psi_\nu u\|^2 - 2\sum_{\nu\ge 0} \lambda_\nu^2 \|[A,\psi_\nu]u\|^2 \tag{10.2.50}$$

provided

$$\zeta\lambda_\nu^2 \le 1 \qquad \text{on} \quad \mathsf{supp}(\psi_\nu). \tag{10.2.51}$$

Note that

$$[A,\psi_\nu] = \sum_{k,l} \sigma_l \omega^{kl} [P_j,\psi_\nu]$$

and therefore

$$[A,\psi_\nu]^*[A,\psi_\nu] \asymp \sum_l |[P_l,\psi_\nu]|^2 \le C|\nabla\psi_\nu|^2$$

and

$$\sum_{\nu\ge 0} \lambda_\nu^2 \|[A,\psi_\nu]u\|^2 \le C\sum_{\nu\ge 0} \lambda_\nu^2 \|(\nabla\psi_\nu)u\|^2 = C\sum_{\mu,\nu\ge 0} \lambda_\mu^2 \|(\nabla\psi_\mu)\psi_\nu u\|^2. \tag{10.2.52}$$

Using the finite multiplicity of the covering we can estimate the sum of terms with $\mu \ge 1, \nu \ge 1$ and $\nu = \mu = 0$ by

$$C\sum_{\nu\ge 0} \lambda_\nu^2 \|\chi_Y \gamma^{-1}\psi_\nu u\|^2 \tag{10.2.53}$$

provided

$$\mathsf{supp}(\psi_\nu) \cap \mathsf{supp}(\psi_\mu) \ne \emptyset \implies \lambda_\nu \le c\lambda_\mu \qquad \forall \mu \ge 1, \nu \ge 1 \tag{10.2.54}$$

where Y is $\epsilon\gamma$-vicinity of X_{reg} intersected with X_{sing} and χ_Y is its characteristic function. However the sum in the right-hand expression of (10.2.52) contains also terms with $\nu = 0$ and $\mu \ge 1$ and inversely and we want to "untangle" these indices. We assume that

$$|\nabla\psi_\nu| \le \bigl(\alpha + \Phi(\alpha)\psi_\nu\bigr)\gamma^{-1} \qquad \text{for } \alpha \in (0,1), \tag{10.2.55}$$

with slowly growing to $+\infty$ function $\Phi(\alpha) \ge 1$ as $\alpha \to +0$. We discuss the possible choice of Φ and its implication later.

Then the sums of the terms with $\nu = 0, \mu \ge 1$ and with $\nu \ge 1, \mu = 0$ in the right-hand expression of (10.2.52) do not exceed

$$C\sum_{\nu\ge 1}\bigl(\lambda_\nu\Phi(\alpha_\nu) + \lambda_0\beta_\nu\bigr)^2\|\chi_Y\gamma^{-1}\psi_\nu u\|^2 + C\sum_{\nu\ge 1}\bigl(\lambda_0\Phi(\beta_\nu) + \lambda_\nu\alpha_\nu\bigr)^2\|\chi_Y\gamma^{-1}\bar\psi_\nu\psi_0 u\|^2 \tag{10.2.56}$$

where $\bar\psi_\nu$ is a characteristic function of $\mathsf{supp}(\psi_\nu)$.

This expression is greater than (10.2.53). Combining with (10.2.50) we conclude that

$$\sum_{\nu\ge 0}\lambda_\nu^2\|A\psi_\nu u\|^2 \le 2\|\zeta^{-\frac12}Au\|^2 + C\sum_{\nu\ge 1}\bigl(\lambda_\nu\Phi(\alpha_\nu) + \lambda_0\beta_\nu\bigr)^2\|\chi_Y\gamma^{-1}\psi_\nu u\|^2 + C\sum_{\nu\ge 1}\bigl(\lambda_0\Phi(\beta_\nu) + \lambda_\nu\alpha_\nu\bigr)^2\|\chi_Y\gamma^{-1}\bar\psi_\nu\psi_0 u\|^2. \tag{10.2.57}$$

This conclusion allows us to "localize" variational problem. Note that

$$\|A_0\psi_\nu u\|^2 = \|A\psi_\nu u\|^2 + \|V\psi_\nu u\|^2 - 2\,\mathsf{Re}(\psi_\nu Au, V\psi_\nu u), \tag{10.2.58}$$

because $[A, \psi_\nu]$ is a skew-Hermitian matrix valued function and V, ψ_ν are real-valued and scalar. Then

$$\|A_0\psi_\nu u\|^2 \le 2\|A\psi_\nu u\|^2 + \|V\psi_\nu u\|^2 + \lambda_\nu^{-2}\|\zeta^{-\frac12}\psi_\nu Au\|^2 + \lambda_\nu^2\|\zeta^{\frac12}V\psi_\nu u\|^2. \tag{10.2.59}$$

Multiplying by λ_ν^2, summing on ν and applying (10.2.57) we conclude that

$$\sum_{\nu\ge 0}\lambda_\nu^2\|A_0\psi_\nu u\|^2 \le 2\|\zeta^{-\frac12}Au\|^2+\sum_{\nu\ge0}\lambda_\nu^2\|V\psi_\nu u\|^2+ C\sum_{\nu\ge0}\lambda_\nu^4\|\zeta^{\frac12}V\psi_\nu u\|^2+C\sum_{\nu\ge1}\bigl(\lambda_\nu\Phi(\alpha_\nu)+\lambda_0\beta_\nu\bigr)^2\|\chi_Y\gamma^{-1}\psi_\nu u\|^2+ C\sum_{\nu\ge1}\bigl(\lambda_0\Phi(\beta_\nu)+\lambda_\nu\alpha_\nu\bigr)^2\|\chi_Y\gamma^{-1}\bar\psi_\nu\psi_0 u\|^2. \tag{10.2.60}$$

and we can replace in the right-hand expression $\|\zeta^{-\frac12}Au\|^2$ by $t^2\sum_{\nu\ge0}\|\zeta^{\frac12}\psi_\nu u\|^2$ provided $\|\zeta^{-\frac12}Au\|\le t\|\zeta^{\frac12}u\|$.

Therefore

(10.2.61) Maximal dimension $\mathsf{N}(t)$ of subspace $\mathcal{L}\subset \mathscr{C}_0^1(X_{\mathsf{sing}})$ on which $\|\zeta^{-\frac12}Au\|\le t\|u\|$ does not exceed the sum of maximal dimensions $\mathsf{N}_\nu(t)$ of subspaces $\mathcal{L}_\nu\subset\mathscr{C}_0^1(\mathsf{supp}(\psi_\nu))$ on which

$$\|A_0u_\nu\|^2\le 2t^2\lambda_\nu^{-2}\|\zeta^{\frac12}u_\nu\|^2+\|V\psi_\nu u\|^2+C\lambda_\nu^2\|\zeta^{\frac12}Vu_\nu\|^2+ C\bigl(\Phi(\alpha_\nu)+\lambda_\nu^{-1}\lambda_0\beta_\nu\bigr)^2\|\chi_Y\gamma^{-1}u_\nu\|^2 \qquad \text{as}\ \ \nu\ge1 \tag{10.2.62}$$

and

$$\|A_0u_0\|^2\le 2t^2\lambda_0^{-2}\|\zeta^{\frac12}u_0\|^2+\|Vu_0\|^2+ C\lambda_0^2\|\zeta^{\frac12}Vu_0\|^2+C\sum_{\nu\ge1}\bigl(\Phi(\beta_\nu)+\lambda_\nu\lambda_0^{-1}\alpha_\nu\bigr)^2\|\chi_Y\gamma^{-1}\bar\psi_\nu u_0\|^2. \tag{10.2.63}$$

One can see easily that

$$A_0^2=\sum_{l,k}P_lg^{lk}P_k+(m+W)^2+\sum_l(\theta^lP_l+P_l\theta^l)+\theta \tag{10.2.64}$$

where θ^l,θ are Hermitian matrices such that $|\theta^l|\le C\rho$, $|\theta|\le C\tilde\rho^2+C\rho\gamma^{-1}\chi_Y$. Therefore

$$\|A_0v\|^2\ge \epsilon_1\sum\|P_jv\|^2+\|(m+W)v\|^2-C\|\tilde\rho v\|^2-C\|\rho^{\frac12}\gamma^{-\frac12}\chi_Yv\|^2 \tag{10.2.65}$$

with $\tilde\rho$ supported in X_{sing} and due to (10.2.47)

(10.2.66) Estimate (10.2.65) remains true with P_j replaced by D_j in the right-hand expression.

Then on $\mathcal{L}_\nu$ with $\nu \ge 1$

$$\epsilon_1\|\nabla v\|^2 \le 2t^2\lambda_\nu^{-2}\|\zeta^{\frac12}v\|^2 + C\big(\Phi(\alpha_\nu)+\lambda_\nu^{-1}\lambda_0\beta_\nu\big)^2\|\chi_Y\gamma^{-1}v\|^2 + C\lambda_\nu^2\|\zeta^{\frac12}Vv\|^2 + C\|\tilde\rho v\|^2 + C\|\chi_Y\rho^{\frac12}\gamma^{-\frac12}v\|^2 \tag{10.2.67}$$

where originally we had $\|(m+W)u_\nu\|^2$ and $\|Vu\|^2$ in the left- and right-hand expressions respectively and used that $V^2 \le m^2 + c\tilde\rho^2$, $W \ge 0$.

Let us apply Rozenblioum variational estimate (9.A.11) . As $d \ge 3$ we conclude that for $\nu \ge 1$

$$\mathsf{N}_\nu(t) \le C\int \Big(t^d\lambda_\nu^{-d}\zeta^{\frac d2} + \lambda_\nu^d\zeta^{\frac d2}|V|^d + \tilde\rho^d + \rho^{\frac d2}\gamma^{-\frac d2} + \big(\Phi(\alpha_\nu)+\lambda_\nu^{-1}\lambda_0\beta_\nu\big)^d\gamma^{-d}\Big)\bar\psi_\nu\,dx. \tag{10.2.68}$$

Similarly starting from (10.2.63) instead of (10.2.62) we conclude that

$$\mathsf{N}_0(t) \le C\int \Big(t^d\lambda_0^{-d}\zeta^{\frac d2} + \lambda_0^d\zeta^{\frac d2}|V|^d + \tilde\rho^d + \rho^{\frac d2}\gamma^{-\frac d2}\chi_Y\Big)\bar\psi_0\,dx + C\sum_{\nu\ge1}\int \big(\Phi(\beta_\nu)+\lambda_0^{-1}\lambda_\nu\alpha_\nu\big)^d\gamma^{-d}\bar\psi_\nu\bar\psi_0\,dx. \tag{10.2.69}$$

Then

$$\mathsf{N}(t) \le \sum_{\nu\ge0}\mathsf{N}_\nu \le C(t^d+1)R \tag{10.2.70}$$

with

$$R = \int \Big(\lambda_0^{-d}\zeta^{\frac d2} + \lambda_0^d\zeta^{\frac d2}|V|^d + \tilde\rho^d + \rho^{\frac d2}\gamma^{-\frac d2}\chi_Y\Big)\bar\psi_0\,dx + \sum_{\nu\ge1}\int \Big(\lambda_\nu^{-d}\zeta^{\frac d2} + \lambda_\nu^d\zeta^{\frac d2}|V|^d + \tilde\rho^d + \rho^{\frac d2}\gamma^{-\frac d2}\chi_Y + \big(\Phi(\alpha_\nu)+\lambda_\nu^{-1}\lambda_0\beta_\nu + \Phi(\beta_\nu)+\lambda_0^{-1}\lambda_\nu\alpha_\nu\big)^d\gamma^{-d}\Big)\bar\psi_\nu\,dx. \tag{10.2.71}$$

Our purpose now is to make (10.2.71) as small as possible in the framework of our construction. First of all recall that we can make ζ on $\bar\psi_0$ arbitrarily small function without affecting estimates; so we can skip first two terms in the first line. Since Φ is slowly growing at 0 almost optimal choice is $\alpha_\nu = \min(\lambda_0\lambda_\nu^{-1}, 1)$ and $\beta_\nu = \min(\lambda_0^{-1}\lambda_\nu, 1)$ and (10.2.71) becomes

$$R = \int \Big(\tilde\rho^d + \rho^{\frac{d}{2}}\gamma^{-\frac{d}{2}}\chi_Y\Big)\,dx + \sum_{\nu\ge 1}\int \Big(\lambda_\nu^{-d}\zeta^{\frac{d}{2}} + \lambda_\nu^d\zeta^{\frac{d}{2}}|V|^d + \bar\Phi(\lambda_0^{-1}\lambda_\nu)^d\gamma^{-d}\Big)\bar\psi_\nu\,dx$$

with

$$\bar\Phi(t) = \Phi\big(\min(t, t^{-1})\big). \tag{10.2.72}$$

Estimating $|V| \le c(m+\rho)$, $\zeta \le c\rho^2(m+\rho)^{-1}$ and selecting $\lambda_\nu \asymp (m+\rho)^{-\frac12}$ on $\operatorname{supp}(\psi_\nu)$ to optimize two first terms in the second line here we arrive to

$$R = \int \big(\tilde\rho^d + \rho^d\chi_Y\big)\,dx + \int \bar\Phi\big(\lambda_0(\rho+m)^{\frac12}\big)^d\gamma^{-d}\chi_Y\,dx. \tag{10.2.73}$$

Estimates for a Number of Crossing Eigenvalues (End)

Let us discuss the possible choice of Φ. Note that if ϕ_ν^2 is some partition then partition ψ_ν^2 with $\psi_\nu = \varphi(\phi_\nu)\big(\sum\varphi(\phi_\nu)^2\big)^{-\frac12}$ satisfies (10.2.55) provided

$$\varphi(t) = 0 \text{ for } t<0, \quad \varphi>0 \text{ for } t>0, \quad |\frac{d}{dt}\varphi(t)| \le c \tag{10.2.74}$$

and

$$|\frac{d}{dt}\varphi(t)| \le \alpha + \Phi(\alpha)\varphi(t) \qquad \forall \alpha, t\in(0,1). \tag{10.2.75}$$

Remark 10.2.17. One can prove easily that function φ satisfying (10.2.74)–(10.2.75) exists provided

$$\int_0^1 \frac{d\beta}{\min_{\alpha>0}(\alpha+\Phi(\alpha)\beta)} < \infty. \tag{10.2.76}$$

Therefore one can take $\Phi(\alpha) = C_\delta\alpha^{-2\delta}$ with arbitrarily small exponent $\delta>0$ in which case the second term in (10.2.73) becomes

$$\lambda_0^{2\delta}\int(\rho+m)^\delta\chi_Y\gamma^{-d}\,dx + \lambda_0^{-2\delta}\int(\rho+m)^{-\delta}\chi_Y\gamma^{-d}\,dx.$$

Optimizing by λ_0 we arrive to term R_4 defined by (10.1.67).

However, one can pick $\Phi(\alpha)$ $\Phi(\alpha) = \log^{1+\delta}\alpha^{-1}$ or even

$$\Phi(\alpha) = \log\alpha^{-1}\cdot \log_{(2)}\alpha^{-1}\cdots \log_{(n)}\alpha^{-1}\cdot \log^{1+\delta}_{(n+1)}\alpha^{-1}$$

with arbitrarily small exponent $\delta > 0$, arbitrary n and $\log_{(n)}$ denoting the n-tuple logarithm (as $\alpha \ll 1$) which implies

Remark 10.2.18. If

$$c^{-1}\lambda \le \rho + m \le c\lambda \qquad \text{in } \ X_{\mathsf{reg}}\cap X_{\mathsf{sing}} \tag{10.2.77}$$

with some parameter λ then the second term optimizes to $C\int \chi_Y \gamma^{-d}\,dx$ which is less than the first term.

Further, if X_{sing} consists of several connected components $X_{\mathsf{sing},l}$ then one can use different parameters $\lambda = \lambda_l$ in $X_{\mathsf{reg}}\cap X_{\mathsf{sing},l}$.

Remark 10.2.19. For $d = 2$ we should slightly modify Rozenblioum estimate; however this modification affects only term with $\nu = 0$ and only contribution of $X_{\mathsf{sing}}\setminus X_{\mathsf{reg}}$. However, applying the same arguments as in Appendix *9.A.1.2 Bracketing* we see that one needs only to replace the first term in (10.2.73) by (10.1.66).

Further, if $d = 2$ and X_{sing} consists of several connected components one can instead calculate R_3 for each of them and then add results.

Remark 10.2.20. Let us recall that deriving (10.2.67) we used estimate $(m+W)^2 - V^2 \le c\rho^2$ in X_{reg}. However in $X_{\mathsf{reg,ell}}$ one can replace estimate by $(m+W)^2 - V^2 \le c - \epsilon\rho^2$ and, moreover, from the very beginning one can take $\zeta = \rho\gamma^{-1}m^{-1}$ here and therefore one can get slightly better remainder estimate than (10.2.73): from integral of ρ^d is excluded $X_{\mathsf{reg,ell}}\cap\{\rho\gamma \ge C_\epsilon\}$ and from integral of $\bar{\Phi}\big(\lambda_0(\rho+m)^{\frac12}\big)^d\gamma^{-d}$ is excluded $X_{\mathsf{reg,ell}}\cap\{\rho\gamma \ge C_\epsilon\}$ where $\bar{\Phi}\big(\lambda_0(\rho+m)^{\frac12}\big) \le \epsilon\rho\gamma$.

Estimates for a Number of Remaining Eigenvalues

Thus, we derived asymptotics for terms counting eigenvalues crossing τ_1 and τ_2 i.e. the last line in the right-hand expression of (10.1.18). The main part of the result is given by Weyl formula (cut outside of X_{reg}) and the remainder is estimated.

In order to prove the upper estimate (10.1.65) we need also to derive an upper estimate for $\mathsf{N}(B;\tau_1,\tau_2)$ which is the second line in (10.1.18) where here and in what follows

$$B = A - t_1 J_1 - \dots - t_n J_n. \tag{10.2.78}$$

So B is a generalized Dirac operator (5.3.71) with $J = I$ satisfying all the conditions of Subsection 5.3.2 with the following modifications: in conditions on $D^\alpha V$, $D^\alpha W$ with $|\alpha| \ge 1$ there is an additional factor $\bar{t}$ in the right-hand expression, conditions on V (without derivatives) remain true and

$$|V| \le \bigl(m - \bar{t}\,\mathsf{min}(\rho, \frac{1}{m}\rho^2)\bigr)_+ + \mathsf{min}(\rho, \frac{1}{m}\rho^2) \qquad \text{in } X'_{\mathsf{reg}} \tag{10.2.79}$$

$$\bar{t}\,\mathsf{min}(\rho, \frac{1}{m}\rho^2) > m \implies W \ge \bar{t}\,\mathsf{min}(\rho, \frac{1}{m}\rho^2) \qquad \text{in } X'_{\mathsf{reg}}, \tag{10.2.80}$$

$$c\bar{t}\,\mathsf{min}(\rho, \frac{1}{m}\rho^2) \ge W \ge 0 \qquad \text{in } X \tag{10.2.81}$$

where $\bar{t}$ is arbitrarily large and c does not depend on $\bar{t}$, X'_{reg} is the $\epsilon\gamma$-neighborhood of $X_{\mathsf{reg}} \setminus X_{\mathsf{sing}}$; however we can still denote it by X_{reg} without breaking estimates. All these conditions are provided by an appropriate choice of $J_1, \dots, J_n$ and $\phi_1, \dots, \phi_n$. Also in X_{sing} one should replace ρ by $\tilde{\rho}$.

Note that conditions (10.2.79)–(10.2.79) mean that ellipticity condition in X_{reg} is fulfilled. More precisely:

$$\tau_1 - \frac{k}{m}\rho^2 + m \ge V \ge \tau_2 - m + \frac{k}{m}\rho^2 \qquad \text{as } \ m \ge k_1\rho, \tag{10.2.82}$$

$$W \ge k\rho \qquad \text{as } \ m \le k_1\rho, \tag{10.2.83}$$

and thus in both cases

$$\tau_1 - k\,\mathsf{min}(\rho, \frac{1}{m}\rho^2) + m + W \ge V \ge \tau_2 - m - W + k\,\mathsf{min}(\rho, \frac{1}{m}\rho^2). \tag{10.2.84}$$

Let us divide connected components of X_{sing} into two types. Components with $\tilde{\rho} \le cm$ at every point are components of the first type.

Remark 10.2.21. Note that we could choose $J_1, \dots, J_n$ such that conditions (10.2.79)–(10.2.81) are also fulfilled on components of the first type but with ρ replaced by $\tilde{\rho}$ and all estimates of the previous subsubsection remain true.

One can see easily that $\mathsf{N}(B;(\tau_1,\tau_2))$ equals the maximal dimension of the subspace $\mathcal{L}\subset \mathscr{C}_0^1(X,\mathbb{H})$ on which

$$\|(B-\bar\tau)u\|^2 < \tau^2\|u\|^2 \qquad (u\neq 0) \tag{10.2.85}$$

where $\bar\tau = \frac{1}{2}(\tau_2+\tau_1)$, $\tau = \frac{1}{2}(\tau_2-\tau_1)$.

Let $\{\psi_\nu^2\}_{k=1,2}$ be a partition of unity such that $|\nabla\psi_\nu|\le c\gamma^{-1}$ and ψ_ν be supported in X_ν where X_1 is the union of X_{reg} and all components of X_{sing} the first type and X_2 is the union of all components of X_{sing} of the second type.

Then one can see easily that

$$\sum_\nu \|(B-\bar\tau)\psi_\nu u\|^2 = \|(B-\bar\tau)u\|^2 + \sum_\nu \|[B,\psi_\nu]u\|^2, \tag{10.2.86}$$

$$\|[B,\psi_\nu]u\| \le C_0\|\gamma^{-1}\chi_Y u\| \tag{10.2.87}$$

where χ_Y is the characteristic function of $Y = X_{\mathsf{reg}}\cap X_{\mathsf{sing}}$.

Therefore

(10.2.88) $\dim\mathcal{L}$ does not exceed $\max\dim\mathcal{L}_1 + \max\dim\mathcal{L}_2$ where $\mathcal{L}_\nu$ is a subspace of $\mathscr{C}_0^1(X_\nu,\mathbb{H})$ on which inequality

$$\|(B-\bar\tau)u\|^2 < \tau^2\|u\|^2 + C_0\|\gamma^{-1}\chi_Y u\|^2 \quad (u\neq 0) \tag{10.2.89}$$

is fulfilled.

Obviously there exists an extension B' of B from X_1 to X such that conditions (10.2.79)–(10.2.81) are fulfilled on X. Then $\dim\mathcal{L}_1$ does not exceed the cardinality of the spectrum of the problem

$$(B'-\bar\tau)v + \lambda Jv = 0 \qquad v\in\mathfrak{D}(B') \tag{10.2.90}$$

in the interval $(-1,1)$ where $J = (\tau^2 + c\gamma^{-2}\chi_Y)^{\frac{1}{2}}$ and $J\in\mathscr{L}^\infty$ provided the right-hand expression of the estimate in question is finite.

Dividing v into $\frac{1}{2}\mathsf{D}$-dimensional components v_1 and v_2 we can rewrite operator $B'-\bar\tau+\tau J$ in the form

$$B'-\bar\tau+\tau J = \begin{pmatrix} \zeta_1 & T\\ T^* & -\zeta_2\end{pmatrix}$$

where conditions (10.2.79)–(10.2.81) fulfilled in X yield that

$$\zeta_j > \epsilon_0(1-|\tau|),\ |\tau|\le 1 \qquad \forall j = 1,2$$

provided $\bar{t}$ is large enough. Then $(-1,1)$ does not intersect the spectrum of the problem (10.2.90) and therefore $\mathsf{dim}\,\mathcal{L}_1 = 0$.

Let us estimate $\mathsf{dim}\,\mathcal{L}_2$. Let us note that the conditions on V can be rewritten in the form

$$\tau - m - c\,\mathsf{min}(\tilde{\rho}, \frac{1}{m}\tilde{\rho}^2) \le V - \bar{\tau} \le m - \tau + c\,\mathsf{min}(\tilde{\rho}, \frac{1}{m}\tilde{\rho}^2). \tag{10.2.91}$$

In particular

$$\tau \ge m \implies |V-\tau| + |\tau - m| \le c\,\mathsf{min}(\tilde{\rho}, \frac{1}{m}\tilde{\rho}^2). \tag{10.2.92}$$

Let us consider operator $B_0 = B - V\cdot I - \sigma_0 W$. Standard arguments and assumptions (10.1.69), (10.1.70) easily yield that

$$\|B_0 u\|^2 \ge \epsilon_1 \|Du\|^2 + m^2\|u\|^2 - C\|\tilde{\rho}u\|^2 \tag{10.2.93}$$

On the other hand, on $\mathcal{L}_2$ estimates

$$\begin{aligned}\|B_0u\|^2 \le (1+\varepsilon^{-2})\|(B-\bar{\tau})u\|^2 + (1+\varepsilon^2)\|(V+\sigma_0 W - \bar{\tau})u\|^2 \le \\ \big((1+\varepsilon^{-2})\tau^2 + (1+\varepsilon^2)(m-\tau)^2\big)\|u\|^2 + \\ C(1+\varepsilon^{-2})\|\chi\gamma^{-1}u\|^2 + C(1+\varepsilon^2)\|\tilde{\rho}u\|^2\end{aligned}$$

are fulfilled where we have applied (10.2.91) and the restrictions on W. These inequalities, (10.2.93) and (10.1.69) yield that

$$\|Du\|^2 \le C(\mathcal{K}u, u) \qquad \text{on} \quad \mathcal{L}_2 \tag{10.2.94}$$

where

$$\mathcal{K} = 9\big((m-\tau)\varepsilon - \varepsilon^{-1}\tau\big)^2 + \tilde{\rho}^2(1+\varepsilon^2) + \chi\gamma^{-2}(1+\varepsilon^{-2}). \tag{10.2.95}$$

If $\tau \ge 2m$ then (10.2.91) yield that $m+\tau \le c\tilde{\rho}$ in X_2 and therefore for $\varepsilon = 1$ one can skip the first and the third terms in $\mathcal{K}$; then Rozenblioum estimate yields that $\mathsf{dim}\,\mathcal{L}_2$ does not exceed CR_3 defined by (10.1.66); as $d=2$ a standard trick with an extra partition is needed to get $\int \rho^d\,dx$ rather than the same expression as with $\tilde{\rho}$.

Let us consider the case $\tau \le 2m$. One can assume without any loss of the generality that $\tau_2 - \tau_1 \le \frac{1}{2}m$; otherwise one can divide the interval (τ_1, τ_2) into fewer than 10 intervals (τ_1', τ_2') with $\frac{1}{4}m \le |\tau_1' - \tau_2'| \le \frac{1}{2}m$. Moreover, if $\tau_2 - \tau_1 \ge \frac{1}{4}m$ then the value of $\varepsilon > 0$ for which the first term in $\mathcal{K}$ vanishes is disjoint from 0 and ∞ and in this case estimate $\mathsf{dim}\, \mathcal{L}_2 \le CR_3$ remains true.

Let us now consider the case $\tau \le \frac{1}{4}m$. Then Rozenblioum estimate yields

$$\mathsf{dim}\, \mathcal{L}_2 \le C\Big(\big((m-\tau)\varepsilon - \varepsilon^{-1}\tau\big)^2 + a^2\varepsilon^2 + b^2\varepsilon^{-2}\Big)^{\frac{d}{2}}(\mathsf{mes}(X_2)) + CR_3 \tag{10.2.96}$$

with

$$a = \begin{cases} \Big(\dfrac{1}{\mathsf{mes}(X_2)}\displaystyle\int_{X_2} \rho^d\, dx\Big)^{\frac{1}{d}} & (d \ge 3), \\ \Big(\dfrac{1}{\mathsf{mes}(X_2)}\displaystyle\int_{X_2} \rho^{2p}\, dx\Big)^{\frac{1}{2p}} & (d = 2, p > 1), \end{cases} \tag{10.2.97}$$

$$b = \Big(\frac{1}{\mathsf{mes}(X_2)}\int_{X_2} \chi\gamma^{-d}\, dx\Big)^{\frac{1}{d}} \qquad (d \ge 2) \tag{10.2.98}$$

(for $d = 2$ the procedure of covering of $X_1 \cap X_2$ by balls $B(x_n, \epsilon\gamma(x_n))$ is applied; see above).

Optimizing with respect to ε we obtain from (10.2.96) the final estimate

$$\mathsf{dim}\, \mathcal{L}_2 \le CR_3 + CR_5 \tag{10.2.99}$$

with R_5 defined by (10.1.68).

For $\tau \ge \epsilon_0 m$ this estimate coincides with (10.2.96).

Theorem 10.1.8 has been proven.

Remark 10.2.22. The contribution of X_2 to the remainder in Theorem 10.1.8 is estimated reasonably as $\tilde\rho \ge cm$ everywhere on X_2. One can get better estimates using Birman-Schwinger principle while reducing $\tilde\rho$ and estimating number of "escaping" eigenvalues. Further development in this direction is left to the reader.

10.2.5 From Rough to Irregular Operators

Remark 10.2.23. (i) While we formulated our results for smooth operators, the same results hold for rough operators (in the assumptions of the corresponding theorems).

(ii) Approximation of operators with irregular coefficients by rough operators is more subtle in the case when we calculate $\mathsf{N}(A, \tau_1, \tau_2)$ because in contrast to the case $\mathsf{N}^-(A-\tau)$ simple bracketing does not work here.

However if we know that $A' - \eta < A < A' + \eta$ [19] we conclude that

$$\mathsf{N}(A', \tau_1 + \eta, \tau_2 - \eta) \le \mathsf{N}(A, \tau_1, \tau_2) \le \mathsf{N}(A', \tau_1 - \eta, \tau_2 + \eta) \tag{10.2.100}$$

and therefore

$$\begin{aligned} -\mathsf{N}(A', \tau_1, \tau_1 + \eta) - \mathsf{N}(A', \tau_2 - \eta, \tau_2) \le \\ \mathsf{N}(A, \tau_1, \tau_2) - \mathsf{N}(A', \tau_1, \tau_2) \le \\ \mathsf{N}(A', \tau_1 - \eta, \tau_1) + \mathsf{N}(A', \tau_2, \tau_2 + \eta) \end{aligned} \tag{10.2.101}$$

and this conclusion could be applied either directly or through Birman-Schwinger principle.

Comments

Due to its nature and to the fact that M. Sh. Birman for many years has the leader of the school using variational approach to eigenvalue asymptotics Birman-Schwinger principle has been used mainly in such papers. One should mention many papers of M. Sh. Birman and M. Z. Solomyak and their students: G. Rozenblioum, Yu. Safarov, A. Sobolev and many others.

Extremely surprising is that this powerful method had not find its way to the papers studying sharp asymptotics much sooner; at least the author is not aware of any such papers prior to his own. Furthermore, it took some time and advice of M. Z. Solomyak to realize the tremendous power of Birman-Schwinger principle which allows to analyze often very easily many asymptotics which either could not be analyzed directly or at least require some difficult and ingenious arguments. With Birman-Schwinger principle

[19] Here A is an original operator with the irregular coefficients, A' is its rough approximation and $\eta > 0$ is a small parameter.

we just reduce asymptotics with respect to some parameters (f.e. spectral parameter) to asymptotics with respect to others, most notably semiclassical parameter.

In the framework of this chapter this method was first used by V.Ivrii [17]. We will use Birman-Schwinger principle systematically either directly or through Chapters 9 and 10.

Part V

Asymptotics of Spectra

Chapter 11

Weyl Asymptotics of Spectra

This chapter is devoted to applications of the results of Parts II, III and IV to the eigenvalue asymptotics. Now we consider operator A depending on parameters; then all the functions $\rho, \tilde{\rho}, \varrho,$ and γ with different indices and zones X_{reg} and X_{sing} depend on these parameters as well. Further, the main part of the asymptotics N^{W} (given by Weyl formula but may be with corrections) and the remainder R depend on this parameter as well; both of them tend to infinity but under appropriate assumptions $R \ll \mathsf{N}^{\mathsf{W}}$. Further, as parameters tend to their limits X_{sing} shrinks.

In Section 11.1 we treat semiclassical asymptotics. In this case we consider operator $A_h = A(x, hD, h)$ and select $\rho_h = h^{-1}\rho$, $\gamma_h = \gamma$ and $h_{\mathsf{eff}} = (\rho_h\gamma_h)^{-1} = h\rho^{-1}\gamma^{-1}$; then $X_{\mathsf{reg},h} = \{\rho_h\gamma_h \ge 1\} = \{x : \rho\gamma \ge h\}$ and $X_{\mathsf{sing}} = \{\rho\gamma \le 2h\}$.

In Sections 11.2–11.6 we consider asymptotics with respect to the spectral parameter τ; in this case $A_\tau = A - \tau$ and usually $\rho_\tau = |\tau|^{1/m} + \rho$, $\gamma_\tau = \gamma$ as we assume that A satisfies some conditions with functions ρ, γ and $\varrho = \rho^m$. Then $h_{\mathsf{eff}} = \big(|\tau|^{1/m} + \rho\big)^{-1}\gamma^{-1}$ and $X_{\mathsf{reg},\tau} = \{\big(|\tau|^{1/m} + \rho\big)\gamma \ge 1\}$ and $X_{\mathsf{sing},\tau} = \{\big(|\tau|^{1/m} + \rho\big)\gamma \le 2\}$.

More precisely, in Sections 11.2–11.5 we consider asymptotics of the eigenvalues tending to infinity, then $\tau \to +\infty$ but there are different scenarios:

- in Section 11.2 domain X is "essentially" bounded (i.e., exits to infinity are thin enough) and the coefficients are weakly singular;
- in Section 11.4 the coefficients are strongly singular and the coercivity condition is fulfilled but the domain is still "essentially" bounded;
