[5)] As we assume that $\mu = 1$; otherwise $\bar\rho = \mu\beta^{-1}$.

Let us take $\alpha = \alpha'$, $\varphi_1 = \varphi_2$ and $\rho_1 = \rho_2$. Since in this case expression

$$p_x^{\alpha} p_y^{\alpha'} \varphi_1(\rho_1^{-1} p_{3x}) \varphi_2(\rho_2^{-1} p_{3y}) e(.,.,\tau)|_{x=y} \tag{28.3.30}$$

is a monotone function with respect to τ, then the standard Tauberian arguments (part I–estimates; we leave easy details to the reader) imply that

$$\begin{aligned} |p_x^{\alpha} p_y^{\alpha} \varphi_1(\rho^{-1} p_{3x}) \varphi_1(\rho^{-1} p_{3y}) \big[e(.,.,\tau) - e(.,.,\tau')\big]|_{x=y}| \\ \le C S(\rho, T) \big(T^{-1} + |\tau - \tau'| h^{-1}\big) \end{aligned} \tag{28.3.31}$$

for all $\tau' \le \tau \le c$ and therefore

$$\begin{aligned} &|p_x^{\alpha} p_y^{\alpha'} \varphi_1(\rho_1^{-1} p_{3x}) \varphi_2(\rho_2^{-1} p_{3y}) \big[e(.,.,\tau) - e(.,.,\tau')\big]|_{x=y}| \\ &\le C \big(S(\rho_1, T_1) S(\rho_2, T_2)\big)^{\frac{1}{2}} \Big(T_1^{-\frac{1}{2}} T_2^{-\frac{1}{2}} + |\tau - \tau'|^{\frac{1}{2}} \big(T_1^{-\frac{1}{2}} + T_2^{-\frac{1}{2}}\big) h^{-\frac{1}{2}} + |\tau - \tau'| h^{-1} \Big). \end{aligned} \tag{28.3.32}$$

Then the standard Tauberian arguments (part II–asymptotics, with the minor modifications; again we leave easy details to the reader) imply that expression (28.3.30) is given by the standard Tauberian formula with an error, not exceeding the right-hand expression of (28.3.32) with $|\tau - \tau'|$ replaced by hT^{-1}, which is

$$C \big(S(\rho_1, T_1) S(\rho_2, T_2)\big)^{\frac{1}{2}} \Big(T_1^{-\frac{1}{2}} T_2^{-\frac{1}{2}} + \big(T_1^{-\frac{1}{2}} + T_2^{-\frac{1}{2}}\big) T^{-\frac{1}{2}} + T^{-1} \Big). \tag{28.3.33}$$

Note that for $T \ge \max(T_1, T_2)$ the second factor in (28.3.33) is $\asymp T_1^{-\frac{1}{2}} T_2^{-\frac{1}{2}}$.

In other words, a contribution of the pair (ρ_1, ρ_2) to the Tauberian error does not exceed a square root of $S(\rho_1, T_1) T_1^{-1} \times S(\rho_2, T_2) T_2^{-1}$ with

$$\begin{aligned} S(\rho, T) T^{-1} &= \beta h^{-1} \Big(\rho^{-1} T^{-1} + h^{-2} \rho \nu T \big(T^4 + \rho^2 T^2 + h^2 \rho^{-2}\big) \Big) \\ &\asymp \beta h^{-1} \Big(\rho^{-1} T^{-1} + h^{-2} \nu \rho^3 T^3 + h^{-2} \nu \rho T^5 + \nu \rho^{-1} T \Big) \\ &\qquad \text{for } \ \bar{\rho} \le \rho \le \rho^*. \end{aligned} \tag{28.3.34}$$

Minimizing this expression by $h \le T \lesssim 1$ we get

$$\begin{aligned} &\beta h^{-1} \Big(\rho^{-\frac{3}{4}} (h^{-2} \nu \rho^3)^{\frac{1}{4}} + \rho^{-\frac{5}{6}} (h^{-2} \nu \rho)^{\frac{1}{6}} + \rho^{-1} \nu^{\frac{1}{2}} \Big) \\ &\qquad \asymp \beta h^{-1} \Big(h^{-\frac{1}{2}} \nu^{\frac{1}{4}} + h^{-\frac{1}{3}} \nu^{\frac{1}{6}} \rho^{-\frac{2}{3}} + \nu^{\frac{1}{2}} \rho^{-1} \Big); \end{aligned}$$

then the summation by $\rho \in [\rho', \rho^*]$ returns

$$\beta h^{-1}\Big(h^{-\frac{1}{2}}\nu^{\frac{1}{4}}|\log h| + h^{-\frac{1}{3}}\nu^{\frac{1}{6}}\rho^{-\frac{2}{3}} + \nu^{\frac{1}{2}}\rho^{-1}\Big) \tag{28.3.35}$$

with $\rho = \rho'$ to be selected later.

Zone $\{\rho^* \lesssim |p_3| \lesssim 1\}$. Further, we claim that

(28.3.36) For $h^{\frac{1}{3}} \le \rho \le C_0$, $h \le T \le \epsilon_0\rho$ we can take $\gamma = h\rho^{-1}$.

Indeed, observe that if we use ε-approximation with $\varepsilon = (\rho^{-1}h)^{1-\delta}$ then the contribution of time intervals $\{t\colon T_* \le |t| \le T^*\}$ with $T_* = \rho^{-1}(\rho^{-1}h)^{1-\delta}$, $T^* = \epsilon_0\rho$ is negligible and the transition from $\varepsilon = (\rho^{-1}h)^{1-\delta}$ to $\varepsilon = (\rho^{-1}h)$ is done like in the previous Chapter 26. Again we leave easy details to the reader.

Then

$$S(\rho, T)T^{-1} \asymp \rho h^{-2}\big(T^{-1} + \nu T\big); \tag{28.3.37}$$

minimizing by $T\colon h \le T \le \epsilon\rho$ we get

$$\rho h^{-2}\big(\nu^{\frac{1}{2}} + \rho^{-1} + \nu h\big);$$

then summation by $\rho \in [\rho^*, C_0]$ returns

$$h^{-2}\big(\nu^{\frac{1}{2}} + (1+\nu h)|\log h|\big). \tag{28.3.38}$$

Observe that $\rho^* = (\beta h)^{\frac{1}{2}} \ge h^{\frac{1}{3}}$ as $\beta \ge h^{-\frac{1}{3}}$.

Zone $\{|p_3| \lesssim \rho'\}$. Finally, the remaining zone $\{|p_3| \lesssim \rho'\}$ is covered by a single element $\varphi(\rho^{-1}p_3)$ with $\varphi \in \mathscr{C}_0^\infty([-2,2])$, $\rho = \rho'$.

Then instead of minimized $S(\rho, T)T^{-1}$ we can take $\rho\beta h^{-2}$ which should be added to the sum of expressions (28.3.38) and (28.3.35) which estimate contributions of two other zones resulting in

$$\begin{aligned} &h^{-2}\big(\nu^{\frac{1}{2}} + (1+\nu h)|\log h|\big) \\ &\qquad + \beta h^{-1}\Big[h^{-\frac{1}{2}}\nu^{\frac{1}{4}}|\log h| + \underbrace{h^{-\frac{1}{3}}\nu^{\frac{1}{6}}\rho^{-\frac{2}{3}} + \nu^{\frac{1}{2}}\rho^{-1} + \rho h^{-1}}\Big]. \end{aligned} \tag{28.3.39}$$

Obviously the second term in (28.3.39) should be minimized by $\rho = \rho' \in [\bar{\rho}, \rho^*]$, resulting in

$$\beta h^{-1}\Big[h^{-\frac{1}{2}}\nu^{\frac{1}{4}}|\log h| + h^{-\frac{2}{5}}(h^{-\frac{1}{3}}\nu^{\frac{1}{6}})^{\frac{3}{5}} + h^{-\frac{1}{2}}(\nu^{\frac{1}{2}})^{\frac{1}{2}}\Big] \asymp \beta h^{-1}\Big[h^{-\frac{1}{2}}\nu^{\frac{1}{4}}|\log h| + h^{-\frac{3}{5}}\nu^{\frac{1}{10}} + h^{-\frac{1}{2}}\nu^{\frac{1}{4}})\Big];$$

two terms arising when we set $\rho = \rho^*$ in the terms with negative power of ρ and one term arising when we set $\rho = \bar{\rho}$ in the term with positive power of ρ are absorbed by other terms in (28.3.39), which becomes

$$h^{-2}\big(\nu^{\frac{1}{2}} + (1+\nu h)|\log h|\big) + \beta h^{-1}\Big[h^{-\frac{1}{2}}\nu^{\frac{1}{4}}|\log h| + h^{-\frac{3}{5}}\nu^{\frac{1}{10}} + h^{-\frac{1}{2}}\nu^{\frac{1}{4}}\Big]. \tag{28.3.40}$$

This is an estimate for the whole Tauberian error (with variable $T = T(\rho)$).

Calculating Tauberian Expression

Now we need to consider the Tauberian expression for $p_x^\alpha p_y^{\alpha'} e(.,.,0)|_{x=y=z}$ and estimate an error made when we replace it by the Tauberian expression for $p_x^\alpha p_y^{\alpha'} e_z(.,.,0)|_{x=y=z}$; we will call it the *second error* in contrast to the first (Tauberian) error. Note that we are interested only in the case $|\alpha| + |\alpha'| = 1$.

Let us again consider contribution of pair (ρ_1, ρ_2). First, observe that for $\rho_1 \asymp \rho_2$ this error does not exceed $CS(\rho_2, T)T^{-1}$ due to our standard arguments and therefore we get for such pairs the same contribution to the total error as we already got for the Tauberian error.

Second, consider pairs with $\rho_1 \gg \rho_2$ and in this case redoing previous arguments we observe that the contribution to the first error does not exceed $CS(\rho_1, T)^{\frac{1}{2}} S(\rho_2, T)^{\frac{1}{2}} T^{-1}$ and the contribution to the second error does not exceed

$$C\beta h^{-1} \times \rho_1^{\frac{1}{2}}\rho_2^{\frac{1}{2}} h^{-2}\nu T^3 (T+\rho_2)^2, \tag{28.3.41}$$

where the first term which was $C\beta h^{-1}\rho^{-1}T^{-1}$ in the former case $\rho_1 \asymp \rho_2$ simply disappear. Indeed, it appears only due to the contribution of the time interval $\{|t| \le \rho\}$ where we should take $\rho = \max(\rho_1, \rho_2) = \rho_1$ and estimate an error due to the propagation of singularities.

Similarly, the second term leading to expression (28.3.41) would also disappear unless $\rho_1 \lesssim T$ again due to the propagation of singularities. Therefore the combined contribution of any pair to both errors does not exceed

$$\begin{aligned}(28.3.42)\quad &\Bigl(\rho_1^{-1}T^{-1}+\rho_1^3h^{-2}\nu T^3+\rho_1h^{-2}\nu T^5+\rho_1^{-1}\nu T\Bigr)^{\frac12}\\ &\qquad\times\Bigl(\rho_2^{-1}T^{-1}+\rho_2^3h^{-2}\nu T^3+\rho_2h^{-2}\nu T^5+\rho_2^{-1}\nu T\Bigr)^{\frac12}+\rho_1^{\frac12}\rho_2^{\frac12}h^{-2}\nu T^5,\end{aligned}$$

multiplied by $C\beta h^{-1}$ since we consider at this moment the case of $\rho'\le\rho_2\ll\rho_1\le\rho^*$ while all other cases (namely, $\rho_2\le\rho'\le\rho_1\le\rho^*$; $\rho_2\le\rho'\le\rho^*\le\rho_1$; $\rho'\le\rho_2\le\rho^*\le\rho_1$; and $\rho^*\le\rho_2\ll\rho_1$) are easier and left to the reader.

Opening parenthesis in (28.3.42) and eliminating all smaller terms we arrive to

$$\begin{aligned}&\rho_1^{-\frac12}\rho_2^{-\frac12}T^{-1}+\rho_1^{\frac12}\rho_2^{\frac12}h^{-2}\nu T^5+\rho_1^{\frac32}\rho_2^{\frac12}h^{-2}\nu T^4\\ &\quad+\bigl(\rho_1^{\frac32}\rho_2^{\frac32}h^{-2}\nu+\rho_1^{\frac12}\rho_2^{-\frac12}h^{-1}\nu\bigr)T^3+\bigl(\rho_1^{\frac12}\rho_2^{-\frac12}(h^{-2}\nu)^{\frac12}+\rho_1^{\frac32}\rho_2^{-\frac12}h^{-1}\nu\bigr)T^2\\ &\qquad+\bigl(\rho_1^{-\frac12}\rho_2^{-\frac12}\nu+\rho_1^{\frac32}\rho_2^{-\frac12}(h^{-2}\nu)^{\frac12}\bigr)T+\rho_1^{-\frac12}\rho_2^{-\frac12}\nu^{\frac12};\end{aligned}$$

minimizing by T we get

$$\begin{aligned}&\rho_1^{-\frac13}\rho_2^{-\frac13}(h^{-2}\nu)^{\frac16}+\rho_1^{-\frac{1}{10}}\rho_2^{-\frac{3}{10}}(h^{-2}\nu)^{\frac15}+(h^{-2}\nu)^{\frac14}+\rho_1^{-\frac14}\rho_2^{-\frac12}(h^{-1}\nu)^{\frac14}\\ &\qquad+\rho_1^{-\frac16}\rho_2^{-\frac12}(h^{-1}\nu)^{\frac16}+\rho_1^{-\frac12}\rho_2^{-\frac12}\nu^{\frac12}+\rho_1^{\frac12}\rho_2^{-\frac12}(h^{-2}\nu)^{\frac14}+\underbrace{\rho_1^{-\frac12}\rho_2^{-\frac12}\nu^{\frac12}}.\end{aligned}$$

Observe, that only the last term has ρ_1 in the positive degree. Also observe, that the optimal $T=T(\rho)$ in the Tauberian error is a decreasing function of ρ, so $T_1\le T_2$ where $T_j:=T(\rho_j)$; therefore we consider the Tauberian expression for $T\le T_2$ and thus for $\rho_1\le T\lesssim T_2$.

Therefore T_2 must be an upper bound for ρ_1 and therefore the summation by $\rho_1:\rho_2\le\rho_1\le T_2$ results in all the terms with negative power of ρ_1 in the value as $\rho_1=\rho_2$ and in the exceptional (last) term with $\rho_1=T_2$:

$$\begin{aligned}(28.3.43)\quad &\rho_2^{-\frac23}(h^{-2}\nu)^{\frac16}+\rho_2^{-\frac25}(h^{-2}\nu)^{\frac15}+(h^{-2}\nu)^{\frac14}|\log\rho_2(\rho_2^{-2}h^2\nu^{-1})^{-\frac16}|\\ &\qquad+\rho_2^{-\frac34}(h^{-1}\nu)^{\frac14}+\rho_2^{-1}\nu^{\frac12}+(\rho_2^{-2}h^2\nu^{-1})^{\frac{1}{12}}\rho_2^{-\frac12}(h^{-2}\nu)^{\frac14}\end{aligned}$$

(where we used inequality $T_2 \le (\rho_2^{-2}h^2\nu^{-1})^{\frac16}$) with the last term equal to the first one.

Then the summation by $\rho_2 \ge \rho'$ results in the same expression (28.3.43) calculated for $\rho_2 = \rho'$; adding as usual $\rho' h^{-1}$ (asince $\rho'\beta h^{-2}$ estimates the contribution of zone $\{\rho_2 \le \rho'\}$) and minimizing by $\rho' \ge \bar\rho$, we get, after we multiply by βh^{-1} and add contributions of all other zones and also Tauberian estimate (28.3.40), the following expression:

$$h^{-2}\bigl(\nu^{\frac12} + (\mu+\nu h)|\log h|\bigr) + \beta h^{-1}\Bigl[h^{-\frac12}\nu^{\frac14}|\log h| + h^{-\frac35}\nu^{\frac{1}{10}} + h^{-\frac47}\nu^{\frac17} + h^{-\frac12}\nu^{\frac14}\Bigr]. \tag{28.3.44}$$

Recall that we derived estimate for the difference between $p_x^\alpha p_y^{\alpha'} e(.,.,0)|_{x=y=z}$ and $p_x^\alpha p_y^{\alpha'} e_z(.,.,0)|_{x=y=z}$ and thus for $\mu = 1$ we arrive to Statement (i) of Proposition 28.3.8 below for $\mu = 1$.

Observe, however, that in virtue of Subsection 28.3.1 the same estimate holds for $\beta \le h^{-\frac13}$. Then, if $1 \le \mu \le \beta$, one can scale $x \mapsto \mu x$, $h \mapsto \mu h$, $\nu \mapsto \mu^2\nu$, $\kappa \mapsto \mu\kappa$ and we arrive to the same statement without assumption $\mu = 1$.

Furthermore, in virtue of Propositions 28.A.4 and 28.A.5, expression $|p_x^\alpha p_y^{\alpha'} e_z(.,.,0)|_{x=y=z}|$ does not exceed $C\beta^{\frac12}h^{-2}\|\partial V\|_{\mathscr{L}^\infty}$ if $|\alpha| + |\alpha'| = 1$ [6]. Therefore we arrive to Statement (ii) below:

Proposition 28.3.8. *Let $\beta \le h^{-1}$ and* (28.3.14) *and* (28.3.15) *be fulfilled. Then*

(i) $|p_x^\alpha p_y^{\alpha'}\bigl[e(.,.,0) - e_z(.,.,0)\bigr]|_{x=y=z}|$ does not exceed expression (28.3.44) *for $|\alpha| \le 2$, $|\alpha'| \le 2$.*

(ii) Consider $|\alpha| + |\alpha'| = 1$; then $|p_x^\alpha p_y^{\alpha'} e(.,.,0)|_{x=y=z}|$ does not exceed expression (28.3.44) *plus $C\omega h^{-2}$ with*

$$\omega = \begin{cases} 1 & \text{if } \beta \le h^{-\frac13}, \\ \beta^{\frac32}h^{\frac12} & \text{if } h^{-\frac13} \le \beta \le h^{-\frac12}, \\ \beta^{\frac12} & \text{if } h^{-\frac12} \le \beta \le h^{-1}. \end{cases} \tag{28.3.45}$$

[6] Actually Proposition 28.A.4 provides better estimate for $\|\partial V\|_{\mathscr{L}^\infty} \le \beta^2 h$.

Remark 28.3.9. (i) Observe that for $\beta \le h^{-\frac12}$ we got no improvement over results of Subsection 28.3.1.

(ii) One can replace μ in the definition of $\bar\rho$ by $\nu^{\frac12}$. Indeed, we can assume that $\partial A'(z) = 0$. Then γ-vicinity of z we have $\mu = O(\nu\gamma)$ and scaling we should be concerned only abut this vicinity. We select $\gamma = \nu^{-\frac12}$.

Estimating $|\partial^2 A'|$

Recall that if A' is a minimizer, then it must satisfy (27.2.14) and then for $h^{-\frac12} \le \beta \le h^{-1}$ due to Proposition 28.3.8(ii) $\|\Delta A'\|_{\mathscr{L}^\infty}$ does not exceed $Ch^2\bigl((28.3.44)+\beta^{\frac12}h^{-2}\bigr)$ and then $\|\partial^2 A'\|_{\mathscr{L}^\infty}$ must not exceed this expression multiplied by $C|\log h|$ plus $\|\partial A'\|_{\mathscr{L}^\infty}$ [7]:

$$\begin{aligned}(28.3.46)\quad \|\partial^2 A'\|_{\mathscr{L}^\infty} &\le C\kappa|\log h|\bigl(\nu^{\frac12} + (\mu+\nu h)|\log h|\bigr)\\ &+ C\kappa\beta h|\log h|\bigl(h^{-\frac35}\nu^{\frac{1}{10}} + h^{-\frac47}\nu^{\frac17} + h^{-\frac12}\nu^{\frac14}|\log h|^2\bigr) + C\kappa|\log h|\beta^{\frac12}\|\partial V\|_{\mathscr{L}^\infty}\\ &+ C\|\partial A'\|_{\mathscr{L}^\infty}.\end{aligned}$$

Also recall that we can define $\nu := \max\bigl(\|\partial^2 A'\|_{\mathscr{L}^\infty}, 1\bigr)$; then we arrive to

Proposition 28.3.10. *Let $1 \le \beta \lesssim h^{-1}$ and* (28.3.14) *be fulfilled. Let A' be a minimizer satisfying* (28.3.15).

Then one of the following two cases holds: <u>either</u>

$$\begin{aligned}(28.3.47)\quad \|\partial^2 A'\|_{\mathscr{L}^\infty} &\le C\mu(\kappa|\log h|^2+1)\\ &+ C(\kappa\beta|\log h|)^{\frac{10}{9}}h^{\frac49} + C(\kappa\beta|\log h|)^{\frac76}h^{\frac12} + C(\kappa\beta|\log h|^3)^{\frac43}h^{\frac23}\\ &+ C\kappa|\log h|\omega + C\|\partial A'\|_{\mathscr{L}^\infty}\end{aligned}$$

with the right-hand expressions $\ge C$ <u>or</u>

$$\begin{aligned}(28.3.48)\quad \|\partial^2 A'\|_{\mathscr{L}^\infty} &\le C\mu(\kappa|\log h|^2+1)\\ &+ C\kappa\beta|\log h|h^{\frac25} + C\kappa\beta|\log h|h^{\frac37} + C\kappa\beta|\log h|^3h^{\frac12}\\ &+ C\kappa|\log h|\omega + C\|\partial A'\|_{\mathscr{L}^\infty}\end{aligned}$$

with the right-hand expression $\le C$. Recall that ω is defined by (28.3.45).

[7] Which can be replaced by a different norm, say, $\|\partial A'\|$.

Proof. Indeed, if $\nu \ge C$ we have

$$\nu \le C\kappa\mu|\log h| + C\big(\kappa\beta|\log h|h^{\frac{2}{5}}\big)^{\frac{10}{9}} + C\big(\kappa\beta|\log h|h^{\frac{3}{7}}\big)^{\frac{7}{6}} + C\big(\kappa\beta|\log h|^3h^{\frac{1}{2}}\big)^{\frac{4}{3}} + C\kappa\beta^{\frac{1}{2}}\|\partial V\|_{\mathscr{L}^\infty} + C\|\partial A'\|_{\mathscr{L}^\infty},$$

which leads to (28.3.47); if $\nu \asymp 1$ we have (28.3.48). □

Remark 28.3.11. (i) Observe that the right-hand expressions of (28.3.47) and (28.3.48) are either $\lesssim 1$ or $\gtrsim 1$ simultaneously.

(ii) The second term in the right-hand expression of (28.3.47) (i.e. with the power $\frac{10}{9}$) is always greater than the third and the fourth terms unless $\kappa\beta h \ge |\log h|^{-K}$). Because of this we just take power K of $|\log h|$ in this term and skip two other terms. One can find easily that $K = 4$ is sufficient;

(iii) The second term in the right-hand expression of (28.3.47) is less than the last one as $\beta \le h^{-\frac{8}{11}}(\kappa|\log h|)^{-\frac{20}{11}}$.

(iv) Obviously, in (28.3.48) we can take $\mu = 1$; however we are missing estimate of μ in (28.3.47). For sure, we know that $\mu \le C\nu$ but we will be able to do a better work after we estimate $\|\partial A'\|^2$ in Subsubsection *28.3.5.3. Weak Magnetic Field Approach.*.

28.3.4 Trace Term Asymptotics

General Microlocal Arguments

Now let us consider the trace term. We are not assuming anymore that A' is a minimizer but that it satisfies

$$(28.3.49)_{1,2} \qquad \|\partial A'\|_{\mathscr{L}^\infty} \le \mu, \qquad \|\partial^2 A'\|_{\mathscr{L}^\infty} \le \nu \qquad \text{with } 1 \le \mu \le \nu \le \epsilon.$$

We assume that $V \in \mathscr{C}^2$ uniformly. Later we will impose on V different non-degeneracy assumptions; from now on small constant $\epsilon > 0$ in conditions (28.3.15) and $(28.3.49)_{1,2}$ depends also on the constants in the non-degeneracy assumption.

Let us introduce the scaling function

$$\ell(x) \coloneqq \epsilon_0\big(\min_j |V - 2j\beta h| + |\partial V|^2\big)^{\frac{1}{2}} + \bar{\ell} \tag{28.3.50}$$

with

$$\bar{\ell} \coloneqq C_0 \max\bigl(\nu\beta^{-1},\, \mu\beta^{-1},\, h^{\frac{1}{2}}\bigr). \tag{28.3.51}$$

We need the following

Proposition 28.3.12. *Let $\beta h \lesssim 1$ and $(28.3.49)_{1,2}$ be fulfilled. Consider (γ,ρ)-element with respect to (x,p_3) with $\gamma\rho \ge h$, $\gamma \le \max(\ell,\rho)$ and*

$$\rho \ge \bar{\rho} \coloneqq C_0 \max\bigl(\mu\beta^{-1},\, h^{\frac{1}{2}}\bigr). \tag{28.3.52}$$

Then for

$$T_* \coloneqq h\rho^{-2} \le T \le T^* \coloneqq \epsilon_0 \min(1, \rho\ell^{-1}) \tag{28.3.53}$$

for (γ,ρ)-element $\{(x,\xi_3)\colon x \in B(z,\gamma), |\xi_3 - A_3(z)| \asymp \rho\}$ the following estimate

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\bigl(p_x^{\alpha}p_y^{\alpha'}\varphi_1(\rho^{-1}p_{3x})\varphi_2(\rho^{-1}p_{3y})\psi_1(\gamma^{-1}x)\psi_2(\gamma^{-1}y)U\bigr)| \le CS(\rho,T)\gamma^3 \tag{28.3.54}$$

holds with

$$S(\rho,T) = \bigl(\beta h^{-1} + \rho^2 h^{-2}\bigr)\bigl(\rho^{-1} + \rho^{-3}h\nu^2\varepsilon^4 T^3\bigr), \tag{28.3.55}$$

where $\varepsilon = h\rho^{-1}$.

Observe that we redefined $\bar{\rho}$ possibly increasing it.

Proof. The proof is similar to one of Theorem 27.2.17 and is based on $h\rho^{-1}$-approximation. Note first that the propagation speed with respect to x_3 is $\asymp \rho$, the propagation speed with respect to p_3 is $O(\ell)$ and all other propagation speeds are bounded by $\bar{\rho}$. Therefore the shift with respect to x_3 is $\asymp \rho T \lesssim \ell$ as $T \le T^*$ and it is observable for $T \ge T_* = h|\log h|\rho^{-2}$ [8].

Let us apply the three-term approximation. Then since the first term does not includes any error, we can estimate it by

$$C\bigl(\beta h^{-1} + \rho^2 h^{-2}\bigr)\rho\gamma^3 h^{-1} T_* \asymp C\bigl(\beta h^{-1} + \rho^2 h^{-2}\bigr)\rho^{-1}\gamma^3,$$

[8] But in estimates we can skip the logarithmic factor using our standard scaling arguments.

which delivers the first term in $S(\rho, T)\ell^3$.

The second term is linear with respect to the perturbation $(A - A_\varepsilon)$ and asince we consider a shift by x_3 in the estimate of this term, we also can take $T = T_*$. Indeed, contributions of intervals $|t| \asymp T'$ with $T_* \le T' \le T^*$ to this term are negligible if we include a logarithmic factor in T_* [8]. Then this term does not exceed $C\bigl(\beta h^{-1} + \rho^2 h^{-2}\bigr)\rho\ell^3\nu\gamma^2 T_*^2 h^{-2}$ and it is less than the first term in $S(\rho, T)\gamma^3$.

Finally, the third term does not exceed the second term in $S(\rho, T)\gamma^3$.□

After estimate (28.3.54) has been proven we can estimate the contribution of the given element to the Tauberian error by $CS(\rho, T)\gamma^3\rho^2h^2T^{-2}$ [9] which is

$$C\bigl(\beta + \rho^2h^{-1}\bigr)\bigl(\rho T^{-2} + \rho^{-1}\nu^2hT\bigr)\gamma^3. \tag{28.3.56}$$

Consider an error appearing when we replace in the Tauberian expression T by T_*. The first two terms are negligible on intervals $|t| \asymp T'$ with $T_* \le T' \le T^*$ and the third term contributes here

$$C(\beta + \rho^2h^{-1})\rho^{-1}\nu^2hT'\gamma^3,$$

which sums to its value for $T' = T$. Therefore this error does not exceed (28.3.56) as well.

Minimizing expression (28.3.56) by $T \le T^*$ we get

$$\begin{aligned} &C\bigl(\beta + \rho^2h^{-1}\bigr)\bigl(\rho T^{*-2} + \rho^{-\frac13}\nu^{\frac43}h^{\frac23}\bigr)\gamma^3 \\ &\qquad\qquad \asymp C\bigl(\beta + \rho^2h^{-1}\bigr)\bigl(\rho + \rho^{-1}\ell^2 + \rho^{-\frac13}\nu^{\frac43}h^{\frac23}\bigr)\gamma^3, \end{aligned} \tag{28.3.57}$$

where we do not include the last term with $T = T_*$ since then the first term would be larger than $C\beta h^{-2}\rho^3\gamma^3$, which is the trivial estimate.

Now let us sum over the partition. Observe first that

(28.3.58) The contribution of the zone $\{\rho\colon \rho \ge (\beta h)^{\frac12}\}$ does not exceed

$$Q_0 := Ch^{-1} + Ch^{-\frac13}\nu^{\frac43} \tag{28.3.59}$$

since ρ here would be in the positive degree. Consider now the contribution of the zone $\{\rho\colon \rho \le (\beta h)^{\frac12}\}$.

[9] Factors ρ^2 and h^2T^{-2} (rather than hT^{-1}) appear because we consider the trace term.

Strong Non-Degenerate cCase

Here ρ is in the negative degree but we can help it under *strong non-degeneracy assumption*

$$\min_j |V - 2j\beta h| + |\partial V| \ge \epsilon_0 \qquad \text{in } B(0,1), \tag{28.3.60}$$

which later will be relaxed. Indeed, the relative measure of those x-balls with $\gamma = \rho^2$, where operator is non-elliptic is $\rho^2(\beta h)^{-1}$ as $\rho \ge h^{\frac{1}{3}}$. Then the total contribution of such elements does not exceed $\rho^2 h^{-1}\big(\rho^{-1}\ell^2 + \rho^{-\frac{1}{3}}\nu^{\frac{4}{3}}h^{\frac{2}{3}}\big)$ and the summation over ρ results in (28.3.59). Meanwhile, the total contribution of balls with $|\xi_3 - A'_3| \le \bar\rho = h^{\frac{1}{3}}$ does not exceed $C\bar\rho^5 h^{-3}$, which is smaller[10)].

However we have another restriction, namely, $\bar\rho \ge C_0\mu\beta^{-1}$ [11)]. Because of this we need to increase the remainder estimate by $C\bar\rho\beta^2 h^{-1} \times \bar\rho^2(\beta h)^{-1}$ i.e. by

$$Q' = \mu^3\beta^{-2}h^{-2}. \tag{28.3.61}$$

We should not be concerned about the zone $\{\rho\colon \bar\rho \ge \rho \ge (\beta h)^{\frac{1}{2}}\}$ since here we can always use $T \asymp \beta^{-1}$ and its contribution to the remainder will be the same $\mu^3\beta^{-2}h^{-2}$.

Now we need to pass from the Tauberian expression with $T = T_*$ to the magnetic Weyl expression and we need to consider only two first terms in the successive approximations. We can involve our standard methods of Section 18.9: note that $|x-y| \le c\rho T_* = C\varepsilon$ in the propagation and then we consider another unperturbed operator with $V = V(y)$ and $A'_j = A'(y) + \langle \nabla A_j(y), x-y\rangle$ frozen at point y (when we later set $x = y$). Then one can see that these terms modulo an error, not exceeding Q_0, are respectively

$$-h^{-3}\int P_{B_\varepsilon h}(V)\psi\, dx \tag{28.3.62)$_1$}$$

and

$$-h^{-3}\int \big(P_B(V) - P_{B_\varepsilon h}(V)\big)\psi\, dx \tag{28.3.62)$_2$}$$

[10)] These arguments work even if $\beta \le h^{-\frac{1}{3}}$ (and therefore $(\beta h)^{\frac{1}{2}} \le h^{\frac{1}{3}}$): we just set $\gamma = h\rho^{-1}$ for $(\beta h)^{\frac{1}{2}} \le \beta \le h^{\frac{1}{3}}$.

[11)] Here we can take $\mu = \|\partial A'\|_{\mathscr{L}^\infty}$ without resetting it to 1 if the former is smaller.

with $B_\varepsilon = |\nabla \times (A^0 + A'_\varepsilon)|$. Then we arrive to estimate (28.3.64) below.

Observe that non-degeneracy condition (28.3.60) was used only to estimate by $\rho^2(\beta h)^{-1}$ a relative measure of some set. However the same estimate would be achieved under slightly weaker non-degeneracy condition

$$\min_j |V - 2j\beta h| + |\partial V| + |\det(\operatorname{Hess} V)| \ge \epsilon_0 \qquad \text{in } B(0,1); \tag{28.3.63}$$

all arguments including transition to the magnetic Weyl expression work. Therefore under this assumption the same estimate holds and we arrive to

Proposition 28.3.13. *Let $\beta h \lesssim 1$ and conditions $(28.3.49)_{1,2}$ be fulfilled. Then under non-degeneracy assumptions (28.3.60) or (28.3.63) estimate*

$$|\operatorname{Tr}(H^-_{A,V}\psi) + h^{-3}\int P_{Bh}(V)\psi\,dx| \le CQ \tag{28.3.64}$$

holds with $Q = Q_0 + Q'$ with Q_0 and Q' defined by (28.3.59) and (28.3.61).

Remark 28.3.14. We will show that for a minimizer $Q \asymp Q_0$ in both cases (and even under even weaker non-degeneracy assumption (28.3.65)).

Non-Degenerate Case

Assume now that even weaker non-degeneracy condition is fulfilled:

$$\min_j |V - 2j\beta h| + |\partial V| + |\partial^2 V| \ge \epsilon_0 \qquad \text{in } B(0,1). \tag{28.3.65}$$

Then the measure of the degenerate set is $\rho(\beta h)^{-\frac{1}{2}}$ but even this is sufficient to obtain the same sum from the second term. In the first term we get however extra $C\beta|\log h|$ (which is $O(h^{-1})$ provided $\beta \le (h|\log h|)^{-1}$) but we can help with this too: indeed, if we fix $\ell \ge 2\bar\ell$, then the relative measure does not exceed $\rho^2(\beta h\ell)$ and summation results in $O(h^{-1})$. We still need to consider set $\{x\colon \ell(x) \le 2\bar\ell\}$, but its contribution is obviously less than $C\beta\bar\ell|\log h|$ which in turn is $O(h^{-1} + \nu|\log h|)$ (and this is $O(h^{-1})$ for a minimizer).

However contribution of the degenerate set becomes $C\beta h^{-2}\bar\rho^3\bar\ell$ which boils down to the same expression Q'. Then we arrive to

Proposition 28.3.15. *Let $\beta h \lesssim 1$ and conditions $(28.3.49)_{1,2}$ be fulfilled. Then under non-degeneracy assumption (28.3.65) estimate (28.3.63) holds with $Q = Q_0 + Q''$, $Q'' = Q' + \nu|\log h|$ with Q_0 and Q' defined by (28.3.59) and (28.3.61) respectively.*

We leave easy details to the reader.

Degenerate case

Let us derive a remainder estimate without any non-degeneracy assumptions. In comparison with the non-degenerate case we need to sum $\beta\rho^{-\frac{1}{3}}\nu^{\frac{4}{3}}h^{\frac{2}{3}}$ and we sum it over $\rho \ge \rho_*$, resulting in the same expression with ρ replaced by ρ_*; adding the contribution of the degenerate zone, equal to $\beta\rho_*^3$, we get $\beta\rho_*^{-\frac{1}{3}}\nu^{\frac{4}{3}}h^{\frac{2}{3}} + \beta h^{-2}\rho_*^3$, which should be minimized by $\rho_* \ge \bar{\rho}$, resulting in $\beta\nu^{\frac{6}{5}}h^{\frac{2}{5}} + \beta\bar{\rho}^3$ i.e.

$$Q''' = \beta\nu^{\frac{6}{5}}h^{\frac{2}{5}} + \beta h^{-\frac{1}{2}} + \mu^3\beta^{-2}h^{-2} + \nu|\log h|. \tag{28.3.66}$$

Thus we arrive to

Proposition 28.3.16. *Let $\beta h \lesssim 1$ and conditions* (28.3.49)$_{1,2}$ *be fulfilled. Then estimate* (28.3.63) *holds with Q replaced by $Q = Q_0 + Q'''$ with Q_0 and Q''' are defined by* (28.3.59) *and* (28.3.66) *respectively.*

Remark 28.3.17. We are going to apply our results to $V = W_B^{\mathsf{TF}} + \lambda$ with chemical potential λ. We know that

(i) For $M = 1$ (single nucleus case) after rescalings the non-degeneracy condition (28.3.60) is fulfilled everywhere including the *boundary zone* $\{x\colon \epsilon_0\bar{r} \le r(x) \le C_0\bar{r}\}$.

(ii) For $M \ge 2$ (multiple nuclei case) after rescalings the non-degeneracy condition (28.3.60) is fulfilled if $r(x) \le \epsilon d$ where d is the minimal distance between nuclei.

(iii) Further, for $M \ge 2$ and $B \le Z^{\frac{4}{3}}$ after rescalings the non-degeneracy condition (28.3.65) is fulfilled in the zone $\{x\colon Z^{-\frac{1}{3}} \le r(x) \le \epsilon_0\bar{r}\}$ where $r(x)$ is the distance to the closest nuclei and $\bar{r} = \min\bigl(B^{-\frac{1}{4}}, (Z-N)_+^{-\frac{1}{3}}\bigr)$.

(iv) On the other hand, the non-degeneracy condition (28.3.63) is uncalled: while we believe that that this condition is often fulfilled while (28.3.60) fails we have no proof of this.

(v) For $M \ge 2$ in the boundary zone a more delicate scaling needs to be applied to improve remainder estimate which is possible not only because W_B^{TF} is more regular than just $\mathscr{C}^2$ but also has some special properties.

28.3.5 Endgame

Until now in this Section we assumed only that A' satisfies equation to the minimizer locally (and assumptions (28.3.14)–(28.3.15)) but now we assume that A' is a minimizer.

Upper Estimate

Let us first derive an upper estimate for E^*_κ and for this we need to pick-up some A'. First of all, we try $A' = 0$ resulting in

$$\mathsf{E}^*_\kappa \le \mathcal{E}^*_0 + Ch^{-1} \le \mathcal{E}^*_\kappa + Ch^{-1} + C\kappa\beta^2$$

which is a good estimate for $\kappa\beta^2 \lesssim h^{-1}$:

$$\mathsf{E}^*_\kappa \le \mathcal{E}^*_\kappa + Ch^{-1}. \tag{28.3.67}$$

However for $\kappa\beta^2 \gtrsim h^{-1}$ we need to be more subtle. Namely, we pick up a mollified minimizer for the modified functional $\bar{\mathcal{E}}_\kappa(A')$, defined by (28.2.8). More precisely, let A' be the minimizer for $\bar{\mathcal{E}}_\kappa(A')$; then $\mathcal{E}_\kappa(A') = \mathcal{E}^*_\kappa + O(h^{-1})$.

Still it is not a good choice since our approach relies upon $\mathscr{C}^2$-smoothness but A' is only $\mathscr{C}^{\frac{3}{2}}$-smooth.

Proposition 28.3.18. *Let $\beta h \lesssim 1$ and $\kappa\beta^2 h \gtrsim 1$; let A' be a minimizer for the modified functional $\bar{\mathcal{E}}_\kappa(A')$ and let A'_ε be its ε-mollification. Then there exists $\varepsilon > 0$ such that*

$$|\partial A'_\varepsilon| \le C\mu = \kappa\beta h, \quad |\partial^2 A'_\varepsilon| \le C\nu = C\bigl(1 + (\kappa\beta)^{\frac{4}{3}} h^{\frac{2}{3}}\bigr)|\log h| \tag{28.3.68}_{1,2}$$

and

$$\mathcal{E}_\kappa(A'_\varepsilon) = \mathcal{E}^*_\kappa + O(h^{-1}). \tag{28.3.69}$$

Proof. From equation to A' we observe that

$$|\partial(A' - A'_\varepsilon)| \le C\kappa(\varepsilon + \beta h\varepsilon^{\frac{1}{2}}), \quad |\partial^2 A'_\varepsilon| \le C\kappa(1 + \beta h\varepsilon^{-\frac{1}{2}})|\log h| \tag{28.3.70}$$

and

$$|\mathcal{E}_\kappa(A') - \mathcal{E}_\kappa(A'_\varepsilon)| \le C(\varepsilon^2 + \beta h\varepsilon^{\frac{3}{2}})\kappa h^{-3} + C\kappa(\varepsilon + \beta h\varepsilon^{\frac{1}{2}})^2 h^{-2} \tag{28.3.71}$$

because linear with respect to $\partial(A' - A'_\varepsilon)$ terms disappear due to equation to a minimizer. Then for $\varepsilon \ge h$ the right-hand expression of (28.3.71)

is $O(h^{-1}+\kappa\beta h^{-2}\varepsilon^{\frac{3}{2}})$ and we take $\varepsilon = \min\bigl(1, (\kappa\beta)^{-\frac{2}{3}}h^{\frac{2}{3}}\bigr)$ [12], resulting in $(28.3.68)_{1,2}$ and (28.3.69) since $|\partial A'| \le C\kappa\beta h$. □

Then applying Propositions 28.3.12, 28.3.15 and 28.3.16 to operator $H_{A_\varepsilon,V}$ with $A_\varepsilon = A^0 + A'_\varepsilon$ we arrive to

Proposition 28.3.19. *(i) For $\beta h \lesssim 1$ and $\kappa\beta^2 h \lesssim 1$ estimate* (28.3.67) *holds.*

(ii) For $\beta h \lesssim 1$ and $\kappa\beta^2 h \gtrsim 1$ estimate $\mathsf{E}^*_\kappa \le \mathcal{E}^*_\kappa + CQ$ holds with $Q = Q_0$ under non-degeneracy assumption (28.3.65) *and with $Q = Q_0 + Q'''$ in the general case, calculated with $\nu = \bigl(1+(\kappa\beta)^{\frac{4}{3}}h^{\frac{2}{3}}\bigr)|\log h|$, $\bar\rho = h^{\frac{1}{2}}$, and $\bar\ell = \max(h^{\frac{1}{2}}, \beta^{-1}\nu)$.*

Indeed, for A' selected above $\mu \le \kappa\beta h$ and one can check easily that $Q' \le Q_0$. Since ν here is lesser than one derived for a minimizer of $\mathsf{E}^*_\kappa(A')$, we are happy and skip calculation of Q'''.

Lower Estimate

Estimate (28.3.63) implies that

$$\underbrace{\mathsf{Tr}(H^-_{A,V}\psi) + \kappa^{-1}h^2\|\partial A'\|^2}_{=\mathsf{E}_\kappa(A')} \ge \underbrace{-h^{-3}\int P_{Bh}(V)\psi\,dx + \kappa^{-1}h^{-2}\|\partial A'\|^2}_{=\mathcal{E}_\kappa(A')} - CQ$$

and therefore

$$\mathsf{E}^*_\kappa \ge \mathcal{E}^*_\kappa - CQ \qquad \text{with } \mathsf{E}^*_\kappa = \inf_{A'}\mathsf{E}_\kappa(A'),\quad \mathcal{E}^*_\kappa = \inf_{A'}\mathcal{E}_\kappa(A'), \tag{28.3.72}$$

where $A' = A'_\kappa$ is a minimizer of $\mathsf{E}_\kappa(A')$ and Q is defined in Propositions 28.3.12, 28.3.15 and 28.3.16 and ν is a right-hand expression of (28.3.47) or 1 whatever is larger. For a sake of simplicity we replace it by a marginally larger expression

$$\nu = (\mu+1)(\kappa|\log h|^2+1) + (\kappa\beta)^{\frac{10}{9}}h^{\frac{4}{9}}|\log h|^K + \kappa\beta^{\frac{1}{2}}|\log h|; \tag{28.3.47}^*$$

recall that in "old" (28.3.47) $\mu = \|\partial A'\|_{\mathcal{L}^\infty}$ or $\mu = 1$, whatever is larger, so we modified the first term here accordingly.

[12] Then $\varepsilon \gtrsim h$ due to $\kappa\beta^2 h \gtrsim 1$.

Our problem is that so far we know neither $\|\partial A'\|_{\mathcal{L}^\infty}$ nor $\|\partial A'\|$. Observe however that

$$\begin{aligned}\mathsf{E}^*_\kappa = \mathsf{E}_\kappa(A') \ge \mathsf{E}_{2\kappa}(A') + (2\kappa)^{-1}\|\partial A'\|^2 \ge \mathcal{E}^*_{2\kappa} + (2\kappa)^{-1}\|\partial A'\|^2 - CQ\\ \ge \mathcal{E}^*_\kappa(A') - C\kappa\beta^2(2\kappa)^{-1}\|\partial A'\|^2 - CQ\end{aligned}$$

and therefore combining this with an upper estimate we arrive to estimate

$$\|\partial A'\| \le C(\kappa h^2 Q)^{\frac{1}{2}} + C\kappa\beta h, \tag{28.3.73}$$

and we have also

$$\|\partial A'\|_{\mathcal{L}^\infty} \le C\|\partial A'\|^{\frac{2}{5}} \cdot \|\partial^2 A'\|^{\frac{3}{5}}_{\mathcal{L}^\infty}. \tag{28.3.74}$$

We are going to explore what happens if

$$\nu \asymp \mu(\kappa|\log h|^2 + 1), \tag{28.3.75}$$

where the right-hand expression is the sum of all terms in (28.3.47)* containing μ.

Remark 28.3.20. (i) Observe first that remainder estimate $Q = O(\beta^2 h^{-1})$ is guaranteed and therefore $\|\partial A'\| \le C\beta h^{\frac{1}{2}}$. Then $\mu \le C\beta^{\frac{2}{5}} h^{\frac{1}{5}} \nu^{\frac{3}{5}}$ due to (28.3.74).

(ii) Further, if (28.3.75) is fulfilled, then $\mu \le \beta h^{\frac{1}{2}}|\log h|^K$ and the same estimate holds for ν and then $Q_0 \asymp h^{-1}$, $Q''' \le C\beta h^{-\frac{1}{2}}|\log h|^K$; then the rough estimate to Q is improved, and then $\mu \ll \beta h^{\frac{1}{2}}$, $\nu \ll \beta h^{\frac{1}{2}}$ and, finally, $Q \asymp h^{-1}$ under assumption (28.3.65) and $Q \asymp h^{-1} + \beta h^{-\frac{1}{2}}$ in the general case, and we also have nice estimates to μ, ν.

Therefore we can assume that (28.3.75) is not fulfilled, but then ν is defined by the remaining terms and then

$$\nu = \kappa|\log h| + \kappa \min(\beta^{\frac{3}{2}} h^{-\frac{1}{2}},\, \beta^{\frac{1}{2}})|\log h| + (\kappa\beta)^{\frac{10}{9}} h^{\frac{4}{9}}|\log h|^K \tag{28.3.76}$$

(and from now we do not reset to 1 if this expression is smaller).

We *almost* proved the following estimates for Q:

(28.3.77) $Q = Q_0$ under non-degeneracy assumption (28.3.65) and $Q = Q_0 + \beta h^{-\frac{1}{2}} \asymp h^{-1} + \beta h^{-\frac{1}{2}}$ in the general case.

However we need still explore what happens if $Q \asymp \mu^3\beta^{-2}h^{-2}$. In this case $\mu \le (\mu^3\beta^{-2})^{\frac{1}{5}}\nu^{\frac{3}{5}}$ and then $\mu^{\frac{2}{5}} \le \beta^{-\frac{2}{5}}\nu^{\frac{3}{5}}$, and using (28.3.76) one can prove easily (28.3.77) unless $\beta \le h^{-\frac{1}{5}}|\log h|^K$ in which case $\nu = (\kappa|\log h| + 1)$.

Weak Magnetic Field Approach.

Consider now case $\beta \lesssim h^{-\frac{1}{3}}$. Recall that then $\nu \le C\kappa|\log h|$ and $\mu \ll 1$. Then as we study propagation with respect to p_3 we do not need to correct it to p_3' and then we do not need $\bar{\rho}$.

Then we can apply *weak magnetic field approach* (see Section 13.4). Now contribution of a partition element with $\rho \ge C_0\beta^{-1}$ does not exceed $\rho^3 h^{-1} \times \rho^{-2}$ as we use $T \le \epsilon_0\rho$ and the total contribution of such elements does not exceed Ch^{-1}; meanwhile the total contribution of elements with $\rho = C_0\beta^{-1}$ does not exceed $C\beta^2 h^{-1} \times \beta^{-3} \le Ch^{-1}$ as we use $T = \epsilon_0\beta^{-1}$.

Main Theorem

Therefore after we plug ν into Q_0 we have proven our estimate from below and also the main theorem of this Section:

Theorem 28.3.21. *Let $\beta h \lesssim 1$ and $\kappa \le \kappa^*$. Then*

(i) Estimate

$$|\mathsf{E}^*_\kappa - \mathcal{E}^*_\kappa| \le CQ \tag{28.3.78}$$

holds where under non-degeneracy assumption (28.3.65)

$$Q := h^{-1} + \kappa^{\frac{40}{27}}\beta^{\frac{40}{27}}h^{\frac{7}{27}}|\log h|^K, \tag{28.3.79}$$

and in the general case

$$Q := h^{-1} + \beta h^{-\frac{1}{2}}. \tag{28.3.80}$$

(ii) For a minimizer the following estimate holds: $\|\partial^2 A'\|_{\mathscr{L}^\infty} \le C\nu$ with ν, defined by (28.3.76).

We leave as an easy exercise to the reader

Problem 28.3.22. (i) Starting from estimate $\|\partial^2 A'\|_{\mathscr{L}^\infty} \le C\nu$ derive from (28.3.73)–(28.3.74) estimate for $\|\partial A'\|_{\mathscr{L}^\infty}$; consider separately three cases: $1 \le \beta \le h^{-\frac{1}{3}}$, $h^{-\frac{1}{3}} \le \beta \le h^{-\frac{1}{2}}$ and $h^{-\frac{1}{2}} \le \beta \le 1$.

(ii) Prove that for $\kappa\beta^2 h \gtrsim 1$

$$\|\partial(A' - A'')\| \le C(\kappa Q h^2)^{\frac{1}{2}}, \tag{28.3.81}$$

where A' and A'' are minimizers for E_κ and $\bar{\mathcal{E}}_\kappa$ respectively; in particular, observe that $\|\partial(A' - A'')\| \ll \|\partial A'\|$ for $\kappa\beta^2 h \gg 1$;

(iii) Since (28.3.81) holds for A'' replaced by A''_ε as well and since we have estimate $\|\partial^2 A''_\varepsilon\|_{\mathscr{L}^\infty} \le C\nu$, derive from (28.3.81) estimate for $\|\partial(A' - A''_\varepsilon)\|_{\mathscr{L}^\infty}$ and then the same estimate for $\|\partial A'\|_{\mathscr{L}^\infty}$.

Remark 28.3.23. In the following observations we use simpler but less sharp upper estimates to critical β:

(i) Under non-degeneracy assumption (28.3.65) we conclude that $Q \le Ch^{-1}$ and $\nu \le C\beta^{\frac{1}{2}}|\log h|$ for $\beta \le h^{-\frac{2}{3}}$ and therefore $\mu \le 1$ for $\beta \le h^{-\frac{2}{3}}|\log h|^{-K}$.

(ii) In the general case we see that $Q \le Ch^{-1} + C\beta h^{-\frac{1}{2}}$ and $\nu \le C\beta^{\frac{1}{2}}|\log h|$ for $\beta \le h^{-\frac{2}{3}}$ and therefore $\mu \le 1$ fors $\beta \le h^{-\frac{3}{5}}|\log h|^{-K}$; we used here estimate $\mu \le C(\kappa h^2 Q)^{\frac{1}{5}}\nu^{\frac{3}{5}}$.

28.3.6 N-Term Asymptotics

Introduction

In the application to the ground state energy one needs to consider also N-term asymptotics and D-term estimates. Let us start from the former: we consider N-term

$$\int e(x,x,0)\psi(x)\,dx. \tag{28.3.82}$$

Again we consider this asymptotics in the more broad content of assumptions $V \in \mathscr{C}^2$ and $(28.3.49)_{1,2}$ and we will follow arguments employed for a trace term using the same notations. Then the Tauberian error does not exceed $CS(\rho, T)\gamma^3 h T^{-1}$ [13], which is

$$C(\beta + \rho^2 h^{-1})h^{-1}\big(\rho^{-1}T^{-1} + \rho^{-3}\nu^2 h T^{-2}\big)\gamma^3. \tag{28.3.56}'$$

[13] With $S(\rho, T)$ defined by (28.3.28).

Minimizing by $T \le T^*$ we get

$$C(\beta+\rho^2 h^{-1})h^{-1}\bigl(\rho^{-1}+\rho^{-2}\ell+\rho^{-\frac{5}{3}}\nu^{\frac{2}{3}}h^{\frac{1}{3}}\bigr)\gamma^3. \tag{28.3.57}'$$

Then summation over zone $\{\rho\colon \rho^2 \ge \beta h\}$ results in

$$R_0 = C\bigl(h^{-2}+h^{-\frac{5}{3}}\nu^{\frac{2}{3}}\bigr) \tag{28.3.59}'$$

and we need to consider only contributions of elements belonging to the zone $\{\rho\colon \rho^2 \le \beta h\}$

$$\beta h^{-1}\bigl(\rho^{-1}+\rho^{-2}\ell+\rho^{-\frac{5}{3}}\nu^{\frac{2}{3}}h^{\frac{1}{3}}\bigr)\gamma^3. \tag{28.3.83}$$

Strong Non-Degenerate Case

Under non-degeneracy conditions (28.3.60) or (28.3.63) expression (28.3.83) should be multiplied by $\rho^2(\beta h)^{-1}\gamma^{-3}$ and after summation by ρ we get an extra term $Ch^{-2}|\log h|$.

However we can get rid of the logarithmic factor by the standard trick: in one direction time could be improved to $\rho^{1-\delta}\ell^{\delta}$. We leave easy details to the reader.

Further, adding $R' = C\beta h^{-2}\bar\rho\times\bar\rho^2(\beta h)^{-1}$ with $\bar\rho = C_0\max(\mu\beta^{-1},\, h^{\frac{1}{2}})$ [11] i.e.

$$R' = \mu^3\beta^{-3}h^{-3}, \tag{28.3.61}'$$

which is a contribution of the zone $\{\rho\colon \rho\le\bar\rho\}$, we arrive to

Proposition 28.3.24. *Let $\beta h \lesssim 1$ and conditions $(28.3.49)_{1,2}$ be fulfilled. Then under non-degeneracy assumption* (28.3.60) *or* (28.3.63) *estimate*

$$\Bigl|\int \bigl(\operatorname{tr} e(x,x,0) - h^{-3}\int P'_{Bh}(V)\bigr)\psi(x)\,dx\Bigr| \le CR \tag{28.3.84}$$

holds with $R = R_0 + R'$, R_0, R' defined by $(28.3.59)'$ *and* $(28.3.61)'$.

Remark 28.3.25. The above estimate is sufficiently good since the weak magnetic field approach brings remainder estimate $C\mu h^{-2}$ even without any non-degeneracy assumption. We leave easy details to the reader.

Non-Degenerate Case

Under non-degeneracy assumption (28.3.65) we need to apply more subtle arguments than before. Consider first subelements[14] with $\rho \ge \ell$; for them we need to multiply expression (28.3.83) by $\rho\gamma^{-3}$ and sum by $\rho \ge \rho_*$, resulting in $C\beta h^{-1}|\log h| + C\beta h^{-\frac{2}{3}}\nu^{\frac{2}{3}}\rho_*^{-\frac{2}{3}}$.

On the other hand, for subelements with $\rho \le \ell$ we need to multiply (28.3.83) by $\rho^2(\beta h)^{-1}\gamma^{-3}$ and sum by $\rho_* \le \rho \le \ell$ and then by $\ell \ge \rho_*$, resulting in the same expression albeit with a factor $|\log h|^2$ instead of $|\log h|$. Here we get also $Ch^{-2}|\log h|$ term but we deal with it exactly as in the previous Subsubsection *28.3.6.2 Strong Non-Degenerate Case*.

We need also to add contributions of subelements with $\rho_* \le \rho \le \ell \le \bar{\ell}$ and with $\rho \le \rho_*$. For the former subelements we need to consider only term $\beta h^{-1}\rho^{-2}\bar{\ell}\gamma^3$ in (28.3.83) and only if $\bar{\ell} = \nu\beta^{-1}$, resulting in $\beta h^{-1}\rho_*^{-1}\bar{\ell}\gamma^3$ and contribution of the latter subelements we estimate by $\beta h^{-2}\rho_*^2$. So we get

$$C\beta\big(h^{-1}|\log h| + h^{-1}\rho_*^{-1}\bar{\ell} + h^{-\frac{2}{3}}\nu^{\frac{2}{3}}\rho_*^{-\frac{2}{3}} + h^{-2}\rho_*^2\big), \tag{28.3.85}$$

which should be minimized by $\rho_* \ge \bar{\rho}$, resulting in

$$C\beta\big(h^{-1}|\log h|^2 + h^{-\frac{4}{3}}\bar{\ell}^{\frac{2}{3}} + h^{-1}\nu^{\frac{1}{2}} + h^{-2}\bar{\rho}^2\big).$$

Then plugging $\bar{\rho}$ and $\bar{\ell} = \nu\beta^{-1}$ we arrive to

$$R'' = C\beta\big(h^{-1}|\log h|^2 + h^{-\frac{4}{3}}\nu^{\frac{2}{3}}\beta^{-\frac{2}{3}} + h^{-1}\nu^{\frac{1}{2}}\big) + C\mu^2\beta^{-1}h^{-2} \tag{28.3.86}$$

thus proving Proposition 28.3.26(i) below.

Degenerate Case

In the general case we arrive to (28.3.85) albeit with factor ρ_*^{-1}

$$C\beta\big(h^{-1}\rho_*^{-1} + h^{-1}\rho_*^{-2}\bar{\ell} + h^{-\frac{2}{3}}\nu^{\frac{2}{3}}\rho_*^{-\frac{5}{3}} + h^{-2}\rho_*\big), \tag{28.3.87}$$

which should be minimized by $\rho_* \ge \bar{\rho}$, resulting in

$$C\beta\big(h^{-\frac{3}{2}} + h^{-\frac{5}{3}}\bar{\ell}^{\frac{1}{3}} + h^{-\frac{4}{3}}\nu^{\frac{1}{4}} + h^{-2}\bar{\rho}\big).$$

[14] We call them "subelements" but they live in the phase spaces in contrast to elements which live in the coordinate spaces.

Then plugging $\bar{\rho}$ and $\bar{\ell}$ we arrive to

$$R''' = C\beta\big(h^{-\frac{3}{2}} + h^{-\frac{5}{3}}\nu^{\frac{1}{3}}\beta^{-\frac{1}{3}} + h^{-\frac{4}{3}}\nu^{\frac{1}{4}}\big) + C\mu h^{-2} \tag{28.3.88}$$

thus proving Proposition 28.3.26(ii):

Proposition 28.3.26. *Let $\beta h \lesssim 1$ and conditions $(28.3.49)_{1,2}$ be fulfilled. Then*

(i) Under non-degeneracy assumption (28.3.65) *estimate* (28.3.63) *holds with $R = R_0 + R''$, R_0, R'' defined by $(28.3.59)'$ and* (28.3.86).

(ii) In the general case estimate (28.3.63) *holds with $R = R_0 + R'''$, R_0, R''' defined by $(28.3.59)'$ and* (28.3.88).

28.3.7 D-Term Estimate

Consider now D-term

$$\mathsf{D}\big([e(x,x,0) - h^{-3}P'_{Bh}(V)]\psi,\, [e(x,x,0) - h^{-3}P'_{Bh}(V)]\psi\big) \tag{28.3.89}$$

with $\psi \in \mathscr{C}_0^\infty((B(0,1))$.

Proposition 28.3.27. *Let $\beta h \lesssim 1$ and A' satisfy $(28.3.49)_{1,2}$. Then under non-degeneracy assumption* (28.3.60) *D-term* (28.3.89) *does not exceed CR^2 with $R = R_0 + R'$, R_0 and R' defined by $(28.3.59)'$ and $(28.3.61)'$.*

Proof. *Step 1.* Let us apply Fefferman-de Llave decomposition (16.4.1); then we need to consider pairs of elements $B(\bar{x}, r)$ and $B(\bar{y}, r)$ such that $3r \le |\bar{x} - \bar{y}| \le 4r$. If $r \ge \bar{\rho}$, then on each of these elements we should consider (γ, ρ) subelements (we call them "subelements" but they live in the phase spaces in contrast to the elements which live in the coordinate spaces). Then we have three parameters, namely (r, ρ_x, ρ_y).

Observe that for each $\bar{y}$ the number of matching x-elements is $\asymp 1$ and that the summation with respect to $\rho_x \ge \rho^* = (\beta h)^{\frac{1}{2}}$ results in $R_0 r^2$ multiplied by a contribution of (γ, ρ_y)-subelement; after summation by r and then by these (γ, ρ_y)-subelements we get CR_0R. Similarly we are dealing with $\rho_y \ge \rho^*$.

Therefore we need to consider only the case when both ρ_x and ρ_y do not exceed ρ^*. If $r \ge c\rho^*$, then "the relative measure trick" allows us to add factors $\rho_x^2(\beta h)^{-1}$ and $\rho_y^2(\beta h)^{-1}$ even if $\rho_x^2 \ge r$ or $\rho_y^2 \ge r$ and then the total contribution of such subelements also does not exceed CR^2.

Step 2. Consider next $h \le r \le \rho^*$ [15)] and we should look only at $\rho_x \le \rho^*$, $\rho_y \le \rho^*$. Further, if $\rho_x^2 \ge \epsilon r$ or $\rho_y^2 \ge \epsilon r$ we can always inject factor $c\rho_x^2 r^{-1}$ or $c\rho_y^2 r^{-1}$ ending up again with CR^2.

On the other hand, if both $\rho_x^2 \le \epsilon r$ and $\rho_y^2 \le \epsilon r$ but $r \ge c\bar{\rho}$ we can apply the same "relative measure trick" but comparing the measure of ρ_x^2- or ρ_y^2-elements with violated ellipticity assumption to the total measure of $B(z,r)$; then we can inject factors $(\rho_x^2/r)^\theta$ and $(\rho_y^2/r)^\theta$ with arbitrary $0 \le \theta \le 1$ and we select any $\theta : \frac{5}{6} < \theta < 1$ to have positive powers of ρ_x and ρ_y and power of r (counting r^{-1}) greater than -3. We end up again with CR^2.

Observe that these arguments cover also cases $\rho_x \le \bar{\rho}$ or $\rho_y \le \bar{\rho}$.

Step 3. To estimate the contribution of zone $\{(x,y)\colon r \le h\}$ we just estimate $|e(x,x,\tau)| \le Ch^{-3}$. □

For $M \ge 2$ we will need to estimate D-term under non-degeneracy assumptions (28.3.63), or (28.3.65), or without any non-degeneracy assumption.

Proposition 28.3.28. *Let $\beta h \lesssim 1$ and A' satisfy* $(28.3.49)_{1,2}$. *Then* D*-term* (28.3.89) *does not exceed CR^2 where*

(i) Under non-degeneracy assumption (28.3.63) $R = R_0 + R'$, R_0 *and* R' *defined by* $(28.3.59)'$ *and* $(28.3.61)'$.

(ii) Under non-degeneracy assumption (28.3.65) $R = R_0 + R''$, R_0 *and* R'' *defined by* $(28.3.59)'$ *and* (28.3.86).

(iii) In the general case $R = R_0 + R'''$, R_0 and R''' defined by $(28.3.59)'$ *and* (28.3.88).

Proof. Let us use ideas used in the proofs of Proposition 28.3.26, 28.3.24 and 28.3.26. Let us apply Fefferman-de Llave decomposition (16.4.1); then we need to consider pairs of elements $B(\bar{x},r)$ and $B(\bar{y},r)$ with $3r \le |\bar{x}-\bar{y}| \le 4r$. If $r \ge \bar{\rho}$ on each of these elements we should consider (γ,ρ) subelements[14)]. Then again we have three parameters, namely (r,ρ_x,ρ_y). On the other hand, there is a scaling function $\ell(x)$ and covering of $B(0,1)$ by ℓ-elements.

[15)] Observe that we do not need to keep $t \ge \bar{\rho}$ but we need to keep $\rho r \ge h$.

Part 1. Consider case of $\ell_x \lesssim r$ (and therefore $\ell_y \lesssim r$). Then we must assume that $\rho_x\ell_x \gtrsim h$, $\rho_y\ell_y \gtrsim h$. Observe as in *Step 1* of the previous proof that if $\rho_x \gtrsim \rho^* = (\beta h)^{\frac{1}{2}}$, then the relative density of such subelements is $\rho_x^2/(\beta h)$ and therefore the summation over such subelements of the given x-element results in $CR_0\ell_x^3$. Therefore the double summation over corresponding subelements of x- and y-elements results in $CR_0^2\ell_x^3\ell_y^3 r^{-1}$. Finally, after the double summation over x- and y-elements we get $CR_0^2\int |x-y|^{-1}\,dxdy$, which does not exceed CR_0^2.

Therefore in what follows we need to consider only subelements with $\rho_x \lesssim \rho^*$, $\rho_y \lesssim \rho^*$ [16]. Further, observe that the same arguments are applicable if $\ell_x \gtrsim \rho^*$, $\ell_y \gtrsim \rho^*$ and we are left with the pairs of elements with $\ell_x \lesssim \rho^*$, $\ell_y \lesssim \rho^*$ and their subelements with $\rho_x \lesssim \rho^*$, $\rho_y \lesssim \rho^*$ since we will always keep $\ell_x \ge \bar{\rho}$, $\ell_y \ge \bar{\rho}$.

Observe that the summation of (28.3.83) over subelements with $\rho \ge \ell$ of the given element results in

$$C\beta h^{-1}\bigl(\ell^{-1} + \ell^{-\frac{5}{3}}\nu^{\frac{2}{3}}h^{\frac{1}{3}}\bigr)\ell^3. \tag{28.3.90}$$

On the other hand, for $\rho \le \ell$ the relative density of ρ-subelements of the given ℓ-element does not exceed $C\rho^2\ell^{-2}$ and therefore summation over such subelements results in (28.3.90) again.

However in (28.3.83) if $\ell \le \bar{\ell}$ we need to take in the middle term $\ell = \bar{\ell}$ and here we can ignore other options but $\bar{\ell} = \nu\beta^{-1}$.

Then the summation of this term over subelements with $\rho \ge \max(\ell, \rho_*)$ results in $C\beta h^{-1}\min(\rho_*^{-2}, \ell^{-2})\bar{\ell}\ell^3$ and the summation over subelements with $\rho_* \le \rho \le \ell$ results in $C\beta h^{-1}\rho_*^{-2}\bar{\ell}(1 + |\log \rho_*\ell^{-1}|)\ell^3$ (and should be counted as $\ell \ge \rho_*$ only.

Finally, the contribution of subelements with $\rho \le \rho_*$ does not exceed $C\beta h^{-2}\rho_*^3\ell$ and $C\beta h^{-2}\rho_*\ell^3$ if $\rho_* \le \ell$ and $\rho_* \ge \ell$ respectively. So, in the former case the total contribution of all subelements does not exceed

$$C\beta h^{-1}\Bigl[\ell^{-1} + \ell^{-\frac{5}{3}}\nu^{\frac{2}{3}}h^{\frac{1}{3}} + \rho_*^{-2}\bar{\ell}(1 + |\log \rho_*\ell^{-1}|) + h^{-1}\rho_*^3\ell^{-2}\Bigr]\ell^3. \tag{28.3.91}$$

[16] Due to positivity quadratic form $\mathsf{D}(.,.)$ we need to consider only "pure" pairs. We will use this observation many times.

Minimizing this expression by ρ_* we get

(28.3.92)
$$C\beta h^{-1}\Big[\ell^{-1}+\nu^{\frac{2}{3}}h^{\frac{1}{3}}\ell^{-\frac{5}{3}}+\bar{\ell}^{\frac{3}{5}}h^{-\frac{2}{5}}(1+|\log \ell_*\ell^{-1}|)^{\frac{3}{5}}\ell^{-\frac{4}{5}}+h^{-1}\bar{\rho}^3\ell^{-2}\Big]\ell^3,$$

achieved for

$$\rho_*=\rho_*(\ell)\asymp \max((\bar{\ell}h\ell^2|\log h|)^{\frac{1}{5}},\bar{\rho}) \qquad \text{if } \ \ell\ge \ell_*=\max((\bar{\ell}h|\log h|)^{\frac{1}{3}},\ \bar{\rho}). \tag{28.3.93}$$

Then N-term does not exceed

(28.3.94)
$$C\beta h^{-1}\int_{\ell_x\ge\ell_*}\Big[\ell_x^{-1}+\nu^{\frac{2}{3}}h^{\frac{1}{3}}\ell_x^{-\frac{5}{3}}+\bar{\ell}^{\frac{3}{5}}h^{-\frac{2}{5}}(1+|\log \ell_*\ell_x^{-1}|)^{\frac{3}{5}}\ell_x^{-\frac{4}{5}}+h^{-1}\bar{\rho}^3\ell_x^{-2}\Big]\,dx+$$
$$C\beta h^{-1}\Big[\ell_*^{-1}+\nu^{\frac{2}{3}}h^{\frac{1}{3}}\ell_*^{-\frac{5}{3}}+\bar{\ell}^{\frac{3}{5}}h^{-\frac{2}{5}}\ell_*^{-\frac{4}{5}}+h^{-1}\bar{\rho}^3\ell_*^{-2}\Big]\,\mathsf{mes}(\{\ell_x\le\ell_*\})$$

where the first and second terms estimate contributions of elements with $\ell_x\ge\ell_*$ and $\ell_x\le\ell_*$ respectively.

Remark 28.3.29. Observe that

(i) Under non-degeneracy assumption (28.3.60) we get $C(R_0+R')$ as expected and under non-degeneracy assumption (28.3.63) we get $C(R_0+R'|\log h|)$ but this is only because we counted here the contribution of subelements with $\{x\colon \rho_x\le\ell_x\}$ in the less efficient way.

(ii) Under non-degeneracy assumption (28.3.65) we get $C(R_0+R'')$ and and in the general case we get $C(R_0+R''')$ where R_0, R', R'', R''' are defined in Propositions 28.3.24 and 28.3.26.

Similarly, the total contribution of the zone considered here (in *Part I*) to D-term does not exceed

$$C\beta^2h^{-2}\iint_{\ell_x\ge\ell_*,\ell_y\ge\ell_*,|x-y|\ge\max(\ell_x,\ell_y)} \tag{28.3.95}$$

$$\times \Big[\ell_x^{-1} + \nu^{\frac{2}{3}} h^{\frac{1}{3}} \ell_x^{-\frac{5}{3}} + \bar{\ell}^{\frac{3}{5}} h^{-\frac{2}{5}} (1 + |\log \ell_* \ell_x^{-1}|)^{\frac{3}{5}} \ell_x^{-\frac{4}{5}} + h^{-1} \bar{\rho}^3 \ell_x^{-2}\Big]$$
$$\times \Big[\ell_y^{-1} + \nu^{\frac{2}{3}} h^{\frac{1}{3}} \ell_y^{-\frac{5}{3}} + \bar{\ell}^{\frac{3}{5}} h^{-\frac{2}{5}} (1 + |\log \ell_* \ell_y^{-1}|)^{\frac{3}{5}} \ell_y^{-\frac{4}{5}} + h^{-1} \bar{\rho}^3 \ell_y^{-2}\Big]$$
$$\times |x-y|^{-1}\, dxdy$$
$$+C\beta^2 h^{-2}\Big[\ell_*^{-1}+\nu^{\frac{2}{3}} h^{\frac{1}{3}} \ell_*^{-\frac{5}{3}}+\bar{\ell}^{\frac{3}{5}} h^{-\frac{2}{5}} \ell_*^{-\frac{4}{5}}+h^{-1}\bar{\rho}^3 \ell_*^{-2}\Big]^2 \iint_{\ell_x \le \ell_*, \ell_y \le \ell_*} |x-y|^{-1}\, dxdy.$$

Then under non-degeneracy assumption (28.3.60) we get $C(R_0 + R')^2$ as expected while under weaker non-degeneracy assumption (28.3.63) we get $C(R_0 + R'|\log h|)^2$ but this is only because we counted here contribution of subelements with $\{x\colon \rho_x \le \ell_x\}$ in the less efficient way. Using the method employed in the proof of Proposition 28.3.24 we can recover estimate $C(R_0 + R')^2$ as well.

Further, under non-degeneracy assumption (28.3.63) we get $C(R_0 + R'')^2$ and under non-degeneracy assumption (28.3.65) we get $C(R_0 + R''')^2$.

Part 2. Consider the case of $\ell_x \ge Cr$ (and therefore $\ell_y \asymp \ell_x$). Then we apply the same arguments as before albeit with ℓ^2 replaced by ℓr. First, consider the pair of subelements with $\rho_x \ge \rho^*$, $\rho_y \ge \rho^*$. Their contribution to D-term does not exceed the product of expressions (28.3.83) with $\rho = \rho_x$, $\gamma = \gamma_x$ multiplied by $\rho_x^2(\beta h)^{-1}$ and (28.3.83) with $\rho = \rho_y$, $\gamma = \gamma_y$ multiplied by $\rho_x^2(\beta h)^{-1}$, and multiplied by $|x-y|^{-1}$. Then the double summation by ρ_x, ρ_y results in $Ch^{-4}(1 + \nu^{\frac{4}{3}} h^{\frac{2}{3}})\gamma_x^3 \gamma_y^3 |x-y|^{-1}$; and, finally, the double summation over x, y returns $Ch^{-4}(1 + \nu^{\frac{4}{3}} h^{\frac{2}{3}}) \iint |x-y|^{-1}\, dxdy \lesssim CR^2$.

Then we need to consider pairs with $\rho_x \le \rho^*$, $\rho_y \le \rho^*$ and also pairs with $|x-y| \le h \max(\rho_x^{-1}, \rho_y^{-1})$.

Next consider pairs of subelements with $\rho^* \ge \rho_x \ge (\ell r)^{\frac{1}{2}}$, $\rho^* \ge \rho_y \ge (\ell r)^{\frac{1}{2}}$. Their contributions to D-term does not exceed expression

$$C\beta^2 h^{-2}\big(\rho_x^{-1}\rho_y^{-1} + \bar{\ell}^2 \rho_x^{-2}\rho_y^{-2} + \rho_x^{-\frac{5}{3}} \rho_y^{-\frac{5}{3}} \nu^{\frac{4}{3}} h^{\frac{2}{3}}\big)\, \underbrace{\gamma_x^3 \gamma_y^3 |x-y|^{-1}}$$

and the double summation over x, y in $B(z, \ell)$ with $\ell_z = \ell$ results in the same expression with the selected factor replaced by ℓ^5 and then the double summation over ρ_x, ρ_y results in

$$C\beta^2 h^{-2}\Big[\ell^{-2} + \bar{\ell}^2 \ell^{-4} + \ell^{-\frac{10}{3}} \nu^{\frac{4}{3}} h^{\frac{2}{3}}\Big]\ell^5. \tag{28.3.96}$$

Meanwhile, considering pairs of subelements with $(\ell r)^{\frac12} \ge \rho_x \ge \rho_*$ and $(\ell r)^{\frac12} \ge \rho_y \ge \rho_*$ (we use $\rho_* = \rho_*(\ell)$ and ℓ_* introduced in (28.3.93)) we gain factor $\rho_x^2\rho_y^2/(\rho\ell)$ in the summation by subelements and we arrive to the same expression (28.3.96) but with a logarithmic factor at $\bar\ell^2$:

$$C\beta^2 h^{-2}\Big[\ell^{-2} + \bar\ell^2\ell^{-4}(1+|\log \rho_*\ell^{-1}|)^3 + \ell^{-\frac{10}{3}}\nu^{\frac43}h^{\frac23}\Big]\ell^5.$$

However we can get rid of logarithmic factors exactly as in the proof of Proposition 28.3.26 thus getting (28.3.96). Then we need to sum by balls $B(z,\ell_z)$ resulting in the same expression multiplied by ℓ^{-3} and integrated:

$$C\beta^2 h^{-2}\int_{\{\ell_x\ge\ell_*\}}\Big[\ell_x^{-2} + \bar\ell^2\ell_x^{-4} + \ell_x^{-\frac{10}{3}}\nu^{\frac43}h^{\frac23}\Big]\ell_x^2\,dx,$$

which we estimate by

$$C\beta^2 h^{-2}\int_{\ell\ge\ell_*}\Big[\ell^{-2} + \bar\ell^2\ell^{-4} + \ell^{-\frac{10}{3}}\nu^{\frac43}h^{\frac23}\Big]\ell^{2+m}\,d\ell \tag{28.3.97}$$

with $m = 2,1,0$ under non-degeneracy assumptions (28.3.63), (28.3.65) and in the general case respectively. Then we arrive to the terms of integrand multiplied by ℓ and calculated either for $\ell = 1$ or $\ell = \ell_*$. One can see easily that this does not exceed CR^2 with R defined in the corresponding statement of Proposition 28.3.24.

One also can derive easily the same estimate for contributions of the pairs of subelements with $\rho_x \le \rho_*(\ell)$, $\rho_y \le \rho_*(\ell)$, $\ell \ge \ell_*$, and for contributions of the pairs of subelements with $\rho_x \le \ell_*$, $\rho_y \le \ell_*$, $\ell \le \ell_*$, assuming in both cases that $\rho_x r \ge h$, $\rho_y r \ge h$.

Finally, like in the proof of Proposition 28.3.26 we estimate the contribution of zone $\{x,y\colon \rho_x r \le h,\ \rho_y r \le h\}$. We leave easy details to the reader. □

Remark 28.3.30. These arguments also work to estimate

$$\mathsf{D}\big(\Gamma_x(hD-A)_x\cdot\boldsymbol{\sigma}e(.,.,0),\,\Gamma_x\big(hD-A\big)_x\cdot\boldsymbol{\sigma}e(.,.,0)\big). \tag{28.3.98}$$

Indeed, Weyl expression for $\Gamma_x(hD-A)_x\cdot\boldsymbol{\sigma}e(.,.,0)$ is just 0. Therefore we arrive under either of non-degeneracy assumptions (28.3.60), (28.3.63), (28.3.65) and in the general case to estimate

$$\|\nabla A'\| \le C\kappa h^2 R, \tag{28.3.99}$$

which could be better or worse than estimate $\|\nabla A'\| \le C\kappa^{\frac12}$ which we have already. It is not clear if estimate $\|\nabla A'\| \le C\kappa$ holds.

28.4 Microlocal Analysis: $\beta h \gtrsim 1$

Now let us investigate the case of $\beta h \gtrsim 1$. In this case we assume not only that $\kappa \lesssim 1$ but also (28.2.27)*: $\kappa\beta h^2 |\log h|^K \le 1$. We can apply the same arguments as before and in the end of the day we will get the series of the statements; we leave most of the easy details to the reader.

28.4.1 Estimate to a Minimizer

Observe first that

$$\|\partial A'\|^2 \le C\beta h^{-2} \times \kappa h^2 = C\kappa\beta \le Ch^{-2}|\log h|^{-K} \tag{28.4.1}$$

and

$$|\Delta A'| \le C\beta h^{-2} \times \kappa h^2 = C\kappa\beta \le Ch^{-2}|\log h|^{-K},$$

and therefore

$$|\partial^2 A'| \le C\kappa\beta \le Ch^{-2}|\log h|^{-K}. \tag{28.4.2}$$

First of all, repeating arguments leading to Proposition 28.4.8, we arrive to estimate (28.3.46) modified

$$\begin{aligned}\|\partial^2 A'\|_{\mathscr{L}^\infty} \le C\kappa\, \underbrace{\beta h}\, \nu^{\frac12}|\log h|^2 \\ + C\kappa\beta h|\log h|\big(\underbrace{h^{-\frac35}\nu^{\frac{1}{10}}} + \underbrace{h^{-\frac47}\nu^{\frac17}} + h^{-\frac12}\nu^{\frac14}|\log h|^2\big) + C\kappa|\log h|\beta^{\frac12}\|\partial V\|_{\mathscr{L}^\infty} \\ + C\|\partial A'\|_{\mathscr{L}^\infty}.\end{aligned} \tag{28.4.3}$$

Note a new factor βh in the first line, which first becomes

$$C\kappa\beta h|\log h|\big(\nu^{\frac12} + (\mu+\nu h)|\log h|\big). \tag{28.4.4}$$

We prove it first for $\mu = 1$ and then rescale and in virtue of Remark 28.3.9(ii) we can always replace μ by $\nu^{\frac12} \ll h^{-1}$; then, using $\nu := \max\big(\|\partial^2 A'\|_{\mathscr{L}^\infty}, 1\big)$ and assumption (28.2.27)*, we reduce (28.4.4) to its final form in (28.4.3).

Further, under additional super-strong non-degeneracy assumption

$$\min_{x,j\ge 0} |V - 2j\beta h| \asymp 1 \tag{28.4.5}$$

we can skip two selected terms in the second line of (28.4.3), arriving to

$$\|\partial^2 A'\|_{\mathscr{L}^\infty} \le C\kappa\beta h\nu^{\frac12}|\log h|^2 + C\kappa\beta h^{-\frac12}\nu^{\frac14}|\log h|^3 + C\kappa|\log h|\beta^{\frac12}\|\partial V\|_{\mathscr{L}^\infty} + C\|\partial A'\|_{\mathscr{L}^\infty}. \tag{28.4.6}$$

Then we arrive to the following assertion:

Proposition 28.4.1 [17]**.** *Let $\beta h \gtrsim 1$, $\kappa \le \kappa^*$ and (28.2.27)* be fulfilled; let $V \in \mathscr{C}^2$; then*

(i) The following estimates hold:

$$\|\partial^2 A'\|_{\mathscr{L}^\infty} \le \nu \tag{28.4.7}$$

with

$$\nu := C\kappa\beta^{\frac12}|\log h| + C(\kappa\beta)^{\frac{10}{9}}h^{\frac49}|\log h|^K \qquad \text{for } \kappa\beta h \le 1 \tag{28.4.8}$$

and

$$\nu := C\kappa\beta^{\frac12}|\log h| + C(\kappa\beta)^{\frac43}h^{\frac23}|\log h|^K \qquad \text{for } \kappa\beta h \ge 1. \tag{28.4.9}$$

(ii) Moreover, under assumption (28.4.5) *estimate ν is given by* (28.4.9) *even for $\kappa\beta h \lesssim 1$.*

Remark 28.4.2. (i) While case $\beta h \asymp 1$ has been already explored, we missed an important case when non-degeneracy assumption (28.4.5) is fulfilled; so we reexamine this case.

(ii) While technically (28.4.3) and (28.4.6) hold even if assumption (28.2.27)* fails provided $\nu \le \epsilon\beta$, we cannot guarantee in this case that this inequality holds.

28.4.2 Trace Term Asymptotics

Further, continuing our analysis we arrive to the following assertion

Proposition 28.4.3 [18]**.** *Let $\beta h \gtrsim 1$, $\kappa \le \kappa^*$ and $\nu h^2 \le 1$* [19]*. Then*

[17] Cf. Proposition 28.3.10.

[18] Cf. Propositions 28.3.13, 28.3.15 and 28.3.16; only factor βh appears in the definition of Q_0.

[19] In the framework of Proposition 28.4.1 for a minimizer this assumption is due to (28.2.27)*.

(i) Under non-degeneracy assumption (28.3.60), *or* (28.3.63) *remainder estimate*

$$|\operatorname{Tr}(H^{-}_{A,V}\psi) + h^{-3}\int P_{Bh}(V)\psi\,dx| \le Q \tag{28.4.10}$$

holds with $Q = Q_0 + Q'$,

$$Q_0 \coloneqq C\beta + C\beta\nu^{\frac{4}{3}}h^{\frac{2}{3}}, \tag{28.4.11}$$

and Q' *defined by* (28.3.61).

(ii) Under non-degeneracy assumption (28.3.65) *remainder estimate* (28.4.10) *holds with* $Q = Q_0 + Q''$ *with* $Q'' = Q' + \nu|\log h$ *and* Q_0 *and* Q' *defined by* (28.4.10) *and* (28.3.61) *respectively.*

(iii) In the general case remainder estimate (28.4.10) *holds with* $Q = Q_0 + Q'''$ *with* Q_0 *and* Q''' *defined by* (28.4.10) *and* (28.3.66) *respectively.*

Applying Proposition 28.4.1 we arrive to

Corollary 28.4.4. *In the framework of Proposition 28.4.3 let* A' *be a minimizer. Then*

(i) Under non-degeneracy assumption (28.3.60), *or* (28.3.63), *or even* (28.3.65) *estimate* (28.4.10) *holds with*

$$Q = Q_0 = C\beta + C\kappa^{\frac{40}{27}}\beta^{\frac{67}{27}}h^{\frac{34}{27}}|\log h|^{K} \qquad \text{for } \kappa\beta h \le 1 \tag{28.4.12}$$

and

$$Q = Q_0 = C\beta + C\kappa^{\frac{16}{9}}\beta^{\frac{25}{9}}h^{\frac{14}{9}}|\log h|^{K} \qquad \text{for } \kappa\beta h \ge 1. \tag{28.4.13}$$

(ii) Furthermore, under assumption (28.4.5) Q_0 *is defined by* (28.4.13) *even for* $\kappa\beta h \le 1$.

(iii) In the general case estimate (28.4.10) *holds with*

$$Q = Q_0 + \beta h^{-\frac{1}{2}} + \kappa^{\frac{8}{5}}\beta^{\frac{13}{5}}h^{\frac{6}{5}}|\log h|^{K}. \tag{28.4.14}$$

Remark 28.4.5. Observe that

(i) If assumption (28.2.27)* holds, then $Q_0 \lesssim \kappa^{\frac{1}{3}}\beta^{\frac{4}{3}}h^{-\frac{4}{3}} \lesssim \beta h^{-2}$, where the middle expression appears in (28.2.25). On the other hand, if (28.2.27)* fails, then the reverse inequalities hold. In the general case we assume that $\beta h^2 \ll 1$ to get a remainder estimate smaller than the main term.

(ii) Also $\nu \lesssim \beta$ provided (28.2.27)* holds; if $\kappa = 1$ then $\nu \lesssim \beta$ if and only if (28.2.27)* holds.

28.4.3 Endgame

Similarly to Theorem 28.3.21 we arrive to

Theorem 28.4.6. *Let $\beta h \gtrsim 1$, $\kappa \le \kappa^*$ and (28.2.27)* be fulfilled. Then estimate* (28.3.78)

$$|\mathsf{E}^*_\kappa - \mathcal{E}^*_\kappa| \le CQ$$

holds where

(i) Under non-degeneracy assumption (28.3.65) *Q is defined by* (28.4.12) *and* (28.4.13).

(ii) In the general case Q is defined by (28.4.12)*; in particular, $Q = \beta h^{-\frac{1}{2}}$ as $\kappa\beta h \lesssim 1$.*

Problem 28.4.7[20]. In this new settings recover estimates for $\|\partial(A' - A'')\|$, $\|\partial(A' - A'')\|_{\mathscr{L}^\infty}$ and $\|\partial A'\|_{\mathscr{L}^\infty}$ where A'' is a minimizer for $\bar{\mathcal{E}}(A'')$.

28.4.4 N-Term Asymptotics and D-Term Estimates

Repeating arguments of the proofs of Propositions 28.3.24, 28.3.26 we arrive to

Proposition 28.4.8. *Let $\beta h \gtrsim 1$ and conditions* $(28.3.49)_{1,2}$ *be fulfilled. Then*

(i) Under non-degeneracy assumption (28.3.60) *or* (28.3.63) *estimate* (28.3.84) *holds with $R = R_0 + R'$,*

$$R_0 = \beta h^{-1} + \beta h^{-\frac{2}{3}}\nu^{\frac{2}{3}} \tag{28.4.15}$$

and R' defined by $(28.3.61)'$.

[20] Cf. Problem 28.3.22.

(ii) Under non-degeneracy assumption (28.3.63) *estimate* (28.3.84) *holds with* $R = R_0 + R''$, R_0 *and* R'' *defined by* (28.4.15) *and* (28.3.86).

(iii) In the general case estimate (28.3.84) *holds with* $R = R_0 + R'''$, R_0 *and* R''' *defined by* (28.4.15) *and* (28.3.88).

Repeating arguments of the proof of Propositions 28.3.27 and 28.3.27 we arrive to

Proposition 28.4.9. *Let* $\beta h \gtrsim 1$ *and conditions* $(28.3.49)_{1,2}$ *be fulfilled. Then*

(i) Under non-degeneracy assumptions (28.3.60) *or* (28.3.63) D*-term* (28.3.89) *does not exceed* CR^2 *with* $R = R_0 + R'$, R_0 *and* R' *defined by* (28.4.15) *and* $(28.3.61)'$ *respectively.*

(ii) Under non-degeneracy assumption (28.3.65) D*-term* (28.3.89) *does not exceed* CR^2 *with* $R = R_0 + R''$, R_0 *and* R' *defined by* (28.4.15) *and* (28.3.86).

(iii) In the general case D*-term* (28.3.89) *does not exceed* CR^2 *with* $R = R_0 + R'''$, R_0 *and* R' *defined by* (28.4.15) *and* (28.3.88).

Problem 28.4.10. In the general case (without any non-degeneracy assumptions) for $\beta h \lesssim 1$ and for $\beta h \gtrsim 1$ improve the remainder estimates for both the trace term and N-term and estimates for D-term (so, make R''' and Q''' smaller) under assumption $V \in \mathscr{C}^s$ with $s > 2$.

To do this use more advanced partition of unity as in Chapter 25. Most likely, however, it will affect only terms $C\beta h^{-\frac{1}{2}}$ and $C\beta h^{-\frac{3}{2}}$ in Q''' and R''' replacing them by $C\beta h^{(s-4)/(s+2)}$ and $C\beta h^{-1-2/(s+2)}$ respectively.

28.5 Global Trace aAsymptotics in the Case of Thomas-Fermi Potential: $B \le Z^{\frac{4}{3}}$

28.5.1 Introduction

In this Section we consider global trace asymptotics for Thomas-Fermi potential. First we consider the singularity zones where our results would follow from Section 27.3, then we consider their interaction with the regular zone which would lead to the deterioration of the remainder estimates for

$\beta \gg h^{-\frac{1}{2}}$ and finally the boundary zone where non-degeneration properties could be violated (especially for $M \geq 2$), which requires rather subtle analysis and usage of the specific properties of Thomas-Fermi potential.

Remark 28.5.1. Recall that according to Chapter 25 there are two cases:

(a) $B \leq Z^{\frac{4}{3}}$, when the most contributing to both the number of particles and the energy zone is $\{x\colon \ell(x) \asymp r^* = Z^{-\frac{1}{3}}\}$ (where $\ell(x)$ is the distance to the closest nucleus), and then rescaling $x \mapsto xr^{*-1}$, $\tau \mapsto \tau Z^{-\frac{4}{3}}$ we arrive in this zone to $\beta = BZ^{-1}$, $h = Z^{-\frac{1}{3}}$ with $\beta h \leq 1$.

(b) $Z^{\frac{4}{3}} \leq B \leq Z^3$, when the most contributing to both the number of particles and the energy zone is $\{x\colon \ell(x) \asymp r^* = B^{-\frac{2}{5}}Z^{\frac{1}{5}}\}$, and then rescaling $x \mapsto xr^{*-1}$, $\tau \mapsto \tau B^{-\frac{2}{5}}Z^{-\frac{4}{5}}$ we arrive in this zone to $\beta = B^{\frac{2}{5}}Z^{-\frac{1}{5}}$, $h = B^{\frac{1}{5}}Z^{-\frac{3}{5}}$ with $\beta h \geq 1$.

We also recall that in the free (movable) nuclei model the distances between nuclei were greater than ϵr^* (which would be the case in the current settings as well as we show later), so we will assume that it is the case deducting our main results.

28.5.2 Estimates to a Minimizer

Preliminary Analysis

Consider potential V with the Coulomb-like singularities, exactly as in Section 27.3 i.e. satisfying (27.3.1)–(27.3.3).

Proposition 28.5.2 [21]**.** *Let V satisfy* (27.3.1)–(27.3.2) *and*

$$|D^\alpha W| \leq C_\alpha \sum_{1\leq m\leq M} z_m\big(|x-\bar{y}_m|+1\big)^{-4}|x-\bar{y}_m|^{-|\alpha|} \qquad \forall \alpha : |\alpha| \leq 2. \tag{28.5.1}$$

Let $\kappa \leq \kappa^*$ and $\beta h \leq 1$. Then the near-minimizer A satisfies

$$|\operatorname{Tr}(H^-_{A,V}) + \int h^{-3}P_{\beta h}(V(x))\Big)\,dx| \leq Ch^{-2} \tag{28.5.2}$$

and

$$\|\partial A'\| \leq C\kappa^{\frac{1}{2}}. \tag{28.5.3}$$

[21] Cf. Proposition 27.3.1.

Proof. We follow the proof of Proposition 27.3.1. Observe that scaling $x \mapsto (x-\bar{y}_m)\ell^{-1}$, $\tau \mapsto \tau\zeta^{-2}$ leads us to

$$h \mapsto h_1 = h\ell^{-1}\zeta^{-1}, \qquad \beta \mapsto \beta_1 = \beta\ell\zeta^{-1}, \qquad \kappa \mapsto \kappa_1 = \kappa\zeta^2\ell. \tag{28.5.4}$$

Also observe that for $\zeta = \ell^{-\frac{1}{2}}$

$$\kappa_1\beta_1 h_1^2 \gtrsim 1 \implies \ell \gtrsim \ell^* = (\beta+1)^{-\frac{1}{2}}h^{-1} \tag{28.5.5}$$

and for $\kappa \asymp 1$ those are equivalent.

(i) First, we pick up $A' = 0$. Then

$$|\operatorname{Tr}\bigl(H^-_{A^0,V}(0)\bigr) + h^{-3}\int P_{\beta h}(V(x))\,dx| \le Ch^{-2}; \tag{28.5.6}$$

this estimate follows from the standard partition with ℓ-admissible partition elements, supported in $\{x\colon \ell(x) \lesssim \ell\}$ for $\ell = \ell_*$ and and in $\{x\colon \ell(x) \asymp \ell\}$ for $\ell \ge 2\ell_*$.

(ii) On the other hand, consider $A' \ne 0$. Let us prove first that

$$\mathsf{Tr}^-(\psi_\ell H\psi_\ell) \ge -C_\varepsilon h^{-2} - \varepsilon\kappa^{-1}h^{-2}\|\partial A'\|^2 \tag{28.5.7}$$

for $\ell = \ell_* = h^2$ where one can select constant ε arbitrarily small.

Rescaling $x \mapsto (x-\bar{y}_m)/\ell$ and $\tau \mapsto \tau/\ell$ and therefore $h \mapsto h\ell^{-\frac{1}{2}} \asymp 1$ and $A \mapsto A\ell^{\frac{1}{2}}$ (because singularity is Coulomb-like), we arrive to the same problem with the same κ and with $\ell = h = 1$ and with β replaced by βh^3. Then for $\beta h^3 \le 1$ we refer to Appendix 27.A.1 since $H_{A,V} \ge H_{A',V'}$ with $V' = V - \beta^2|x|^2$.

(iii) Consider now ψ_ℓ as in (i) with $\ell \ge \ell_*$. Then according to Theorems 28.3.21 and 28.4.6 for $\beta_1 h_1 \lesssim 1$ and $\kappa\zeta^2\ell \le \kappa^*$

$$\begin{aligned}\mathsf{Tr}^-\bigl(\psi_\ell H_{A,V}\psi_\ell\bigr) + h^{-3}\int P_{\beta h}(V(x))\psi_\ell^2(x)\,dx \\ \ge -C_\varepsilon\zeta^2(h_1^{-1}+\beta_1 h_1^{-1}) - \varepsilon\kappa^{-1}h^{-2}\|\partial A'\|^2.\end{aligned} \tag{28.5.8}$$

Remark 28.5.3. Observe that if ψ_ℓ is supported in $\{x\colon \frac{1}{2}r \le \ell(x) \le 2r\}$, then we can take a norm of $\partial A'$ over $\{x\colon \frac{1}{4}r \le \ell(x) \le 4r\}$. Indeed, we can just replace A' by $A'' = \phi_\ell(A'-\eta)$ with arbitrary constant η and with ϕ_ℓ supported in $\{x\colon \frac{1}{4}r \le \ell(x) \le 4r\}$ and equal 1 in $\{x\colon \frac{1}{3}r \le \ell \le 3r\}$ (and ε by $c\varepsilon$).

Then summation of these norms returns $-C_0\varepsilon\kappa^{-1}h^{-2}\|\partial A'\|^2$.

Furthermore, the first term in the right-hand expression of (28.5.8) is $-C_\varepsilon(\zeta^3\ell^{-1}h^{-1}+\zeta^2\ell^2\beta h^{-1})$ and summation over $\ell \ge h^2$ returns $-C_\varepsilon h^{-2}$ since $\zeta = \min(\ell^{\frac12},\, \ell^{-2})$.

(iv) Consider next zone where $\beta_1 h_1 \ge 1$ (and $\ell \ge 1$) but still $h_1 \le 1$. According to previous Section 28.5 inequality (28.5.8) should be replaced by

$$\mathsf{Tr}^-\bigl(\psi_\ell H_{A,V}\psi_\ell\bigr) + h^{-3}\int P_{\beta h}(V(x))\psi_\ell^2(x)\,dx \ge -C_\varepsilon\zeta^2\beta_1 h_1^{-1}\bigl(1+\nu_1^{\frac43}h_1^{\frac53}\bigr) - \varepsilon\kappa^{-1}h^{-2}\|\partial A'\|^2 \tag{28.5.9}$$

with $\nu_1 = (\kappa_1\beta_1)^{\frac{10}{9}}h_1^{\frac49}|\log h|^{K}$ [22] and $\kappa_1\beta_1 = \kappa\beta\zeta\ell^2 = \kappa\beta$ and thus with $\beta_1 h_1^{-1}\zeta^2 = \beta h^{-1}\zeta^2\ell^2$. Then summation of the first term in the right-hand expression results in its value when ℓ is the smallest i.e. $\beta_1 h_1 = 1$ and one can check easily[23] that this is less than Ch^{-2}.

Further, Remark 28.5.3 remains valid. Then adding this zone does not change inequality in question.

(v) The rest of the proof is obvious. Zone $\{x\colon \ell(x) \ge \ell^*\}$ is considered as a single element and just rough variational estimate is used there to prove that its contribution does not exceed Ch^{-2}. □

Remark 28.5.4. Later we will improve both upper and lower estimates using different tricks: imposing non-degeneracy assumptions, picking for an upper estimate semiclassical self-generated magnetic field, using Scott correction term (derived in Chapter 27). These improvements will lead not only to our final goal, but also to our intermediate one–getting better estimates for a minimizer.

Proposition 28.5.5 [24]**.** *In the framework of Proposition 28.5.2 there exists a minimizer A.*

Proof. After Proposition 28.5.2 has been proven we just repeat arguments of the proof of Proposition 27.2.2. □

---

[22] Because $\kappa_1\beta_1 h_1 = \kappa\beta h\ell \le \kappa(\beta h)^{\frac34} \le 1$.

[23] Sufficient to check for $\beta = h^{-1}$, $\ell = 1$ and $\kappa = 1$.

[24] Cf. Proposition 27.3.2.

Estimates to a Minimizer: Interior Zone

Recall equation (27.2.14) for a minimizer A:

$$\frac{2}{\kappa h^2}\Delta A_j(x) = \Phi_j := \\ -\operatorname{Re}\operatorname{tr}\sigma_j\Big(\big(hD-A\big)_x\cdot\boldsymbol{\sigma}e(x,y,\tau)+e(x,y,\tau)\,{}^t\big(hD-A\big)_y\cdot\boldsymbol{\sigma}\Big)\Big|_{y=x}. \tag{27.2.14}$$

After rescaling $x\mapsto x/\ell$, $\tau\mapsto\tau/\zeta^2$, $h\mapsto\hbar=h/(\zeta\ell)$, $A\mapsto A\zeta^{-1}\ell$, $\beta\mapsto\beta\zeta^{-1}\ell$ this equation becomes (27.3.13)

$$\Delta A_j = \\ -2\kappa\zeta^2\ell\hbar^2\operatorname{Re}\operatorname{tr}\sigma_j\Big(\big(\hbar D-\zeta^{-1}A\big)_x\cdot\boldsymbol{\sigma}e(x,y,\tau)+e(x,y,\tau)\,{}^t\big(\hbar D-\zeta^{-1}A\big)_y\cdot\boldsymbol{\sigma}\Big)\Big|_{y=x} \tag{27.3.13}$$

and since we can take $\zeta^2\ell=1$ we arrive to (27.3.14)

$$\Delta A_j = \\ -2\kappa\hbar^2\operatorname{Re}\operatorname{tr}\sigma_j\Big(\big(\hbar D-\zeta^{-1}A\big)_x\cdot\boldsymbol{\sigma}e(x,y,\tau)+e(x,y,\tau)\,{}^t\big(\hbar D-\zeta^{-1}A\big)_y\cdot\boldsymbol{\sigma}\Big)\Big|_{y=x}. \tag{27.3.14}$$

Let us modify arguments of Subsection 27.3.1. First observe that

$$|\partial A'|\le C\kappa^{\frac12}h^{-3},\quad |\partial^2A'|\le C\kappa^{\frac12}h^{-5}\qquad \text{for } \ell\le 2\ell_* \tag{28.5.10}$$

with $\ell_*=h^2$; this follows from above equations rescaled and from $\beta h^3\le\epsilon_0$. Let

$$\mu(r)=\sup_{\ell(x)\ge r}|\partial A'|\ell\zeta^{-1},\qquad \nu(r)=\sup_{\ell(x)\ge r}|\partial^2A'|\ell^2\zeta^{-1}; \tag{28.5.11}$$

then $\nu(r)$ should not exceed[25)]

$$F(\nu)=C\kappa_1\Big(1+\mu+\min\big(\beta_1^{\frac32}h_1^{\frac12},\,\beta_1^{\frac12}\big) \\ +\beta_1h_1\big(\nu^{\frac{1}{10}}h_1^{-\frac35}+\nu^{\frac17}h_1^{-\frac47}+\nu^{\frac14}h_1^{-\frac12}|\log h_1|^2\big)\Big)|\log h_1|+C\kappa^{\frac12}(\ell\zeta^2)^{-\frac12}, \tag{28.5.12}$$

where here $\nu=\nu(\frac12 r)$, $\mu=\mu(r)$, the last term is just an estimate for $\|\partial A'\|$ rescaled and $\ell\asymp r$ in that term. Indeed, (28.5.12) is derived exactly as (28.3.46), but here we cut a hole $\{x\colon \ell(x)\le\frac12 r\}$ in our domain.

[25)] As long as $\beta_1h_1\le 1$.

We also know that $\mu \le C\nu^{\frac{3}{5}}\kappa^{\frac{1}{5}}(\ell\zeta^2)^{-\frac{1}{5}}$. Using (28.5.12) and (28.5.10) one can prove easily that $\nu(r)$ does not exceed solution of the equation $\nu = F(\nu)$ multiplied by C [26], i.e.

$$\nu \le C\kappa_1\Big(1+\min\big(\beta_1^{\frac{3}{2}}h_1^{\frac{1}{2}},\, \beta_1^{\frac{1}{2}}\big)\Big)|\log h_1| + C\Big((\kappa_1\beta_1)^{\frac{10}{9}}h_1^{\frac{4}{9}} + (\kappa_1\beta_1)^{\frac{4}{3}}h_1^{\frac{2}{3}}\Big)|\log h_1|^K + C\kappa^{\frac{1}{2}}(\ell\zeta^2)^{-\frac{1}{2}}. \tag{28.5.13}$$

In particular, scaling back and setting $\zeta = \ell^{-\frac{1}{2}}$ we arrive to

$$|\partial^2 A'| \le C\kappa\Big(\ell^{-\frac{5}{2}} + \min\big(\beta^{\frac{3}{2}}h^{\frac{1}{2}}\ell^{-\frac{1}{2}},\, \beta^{\frac{1}{2}}\ell^{-\frac{7}{4}}\big)\Big)|\log \ell/\ell_*| + C\Big((\kappa\beta)^{\frac{10}{9}}h^{\frac{4}{9}}\ell^{-\frac{19}{18}} + (\kappa\beta)^{\frac{4}{3}}h^{\frac{2}{3}}\ell^{-\frac{5}{6}}\Big)|\log \ell/\ell_*|^K + C\kappa^{\frac{1}{2}}\ell^{-\frac{5}{2}}. \tag{28.5.14}$$

The same arguments work for $\beta_1 h_1 \ge 1$ but now we need to replace $|\log h_1|$ by $|\log \beta_1|$ which however is also $\asymp \ell/\ell_*$ as $\beta h \le 1$.

After this estimate is proven we can remove the last term in the right-hand expression and we arrive to

Proposition 28.5.6. *In the framework of Proposition 28.5.2*

$$|\partial^2 A'| \le C\kappa\Big(\ell^{-\frac{5}{2}} + \min\big(\beta^{\frac{3}{2}}h^{\frac{1}{2}}\ell^{-\frac{1}{2}},\, \beta^{\frac{1}{2}}\ell^{-\frac{7}{4}}\big)\Big)|\log \ell/\ell_*| + C\Big((\kappa\beta)^{\frac{10}{9}}h^{\frac{4}{9}}\ell^{-\frac{19}{18}} + (\kappa\beta)^{\frac{4}{3}}h^{\frac{2}{3}}\ell^{-\frac{5}{6}}\Big)|\log \ell/\ell_*|^K. \tag{28.5.15}$$

Estimates to a Minimizer: Exterior Zone

Let us estimate $|\partial^2 A'|$ as $\ell \ge \ell^*$. Observe that

$$A'_j(x) = -\frac{\kappa h^2}{4\pi}\int |x-y|^{-1}\Phi_j(y)\,dy, \tag{28.5.16}$$

where Φ_j is given by (27.2.14). Then $\partial^2 A'$ is expressed via Φ_j as an integral with a kernel $K(x,y)$, singular when $x = y$ and such that $|K(x,y)| \le c(|x|+|y|)^{-3}$ when $|x-y| \asymp |x|+|y|$. Further, applying representation like in Proposition 27.3.9, we can get an extra factor $|y|(|x|+|y|)^{-1}$ upgrading it to $|K(x,y)| \le c|y|(|x|+|y|)^{-4}$.

[26] As long as a resulting expression rescaled, see (28.5.14) is a decaying function of ℓ.

Then, starting from (28.5.15) and iterating (28.3.46) we arrive to estimate

$$|\partial^2 A'| \le C\kappa\ell^{-4}|\log h| + C(\kappa\beta)^{\frac{10}{9}} h^{\frac{4}{9}}\ell^{-\frac{32}{9}+\delta}|\log h|^K \qquad \text{for } \ell \ge 1$$

with arbitrarily small $\delta > 0$. Furthermore, using arguments of the proof of Proposition 28.5.6 we can make $\delta = 0$ thus arriving to

Proposition 28.5.7. *In the framework of Proposition 28.5.2*

$$|\partial^2 A'| \le C\kappa\ell^{-4}|\log h| + C(\kappa\beta)^{\frac{10}{9}} h^{\frac{4}{9}}\ell^{-\frac{32}{9}}|\log h|^K \qquad \textit{for } \ell \ge 1. \tag{28.5.17}$$

Remark 28.5.8. Sure, as $\ell \ge 1$, $\beta_1 h_1^{\frac{1}{2}}|\log h_1|^K \le 1$ this estimate could be improved but these improvements would not affect our crucial estimates.

28.5.3 Trace aAsymptotics

Before proving trace estimates observe

Remark 28.5.9. (i) All local asymptotics and estimates with mollification with respect to spatial variables [27] proven in Sections 28.3 and 28.4 with unspecified $\nu \le \epsilon\beta$ remain valid in the more general framework of the smooth non-degenerate external field $A^0(x)$: namely

$$\|\partial^4 A^0\| \le C_0\beta, \qquad B^0 = |\nabla \times A^0| \ge \epsilon_0\beta. \tag{28.5.18}_{1,2}$$

Indeed, we use only ε-approximations with $\varepsilon = h$ or $\varepsilon = h\rho^{-1}$ and we can always change coordinate system so magnetic lines are $(x_1, x_2) = \mathsf{const}$. We leave easy arguments to the reader.

(ii) However since we do not have estimates (28.3.47) or (28.4.7)–(28.4.9) in this more general framework[28], we also do not have (28.4.12), (28.4.13) then.

Now consider the trace term assuming that

$$d := \min_{1\le m<m'\le M} |\bar{y}_m - \bar{y}_{m'}| \gtrsim 1. \tag{28.5.19}$$

[27] Thus trace and N-term asymptotics and D-term estimates.

[28] Even if we believe that these estimates are true. So far we have no need in such generalization.

(a) Due to the proofs of Theorem 27.3.22 and Proposition 28.5.2 we can evaluate contribution of the zone $\{x\colon |x-\bar{y}_m|\le \epsilon\}$, provided $\beta\le 1$:

$$|\operatorname{Tr}(H^-_{A,V}\psi_m)-\operatorname{Tr}(H^-_{A,V_m}\psi_m) + h^{-3}\int P_{Bh}(V)\psi_m\,dx - h^{-3}\int P_0(V_m)\psi_m\,dx| \le C\big(h^{-1}+\kappa|\log\kappa|^{\frac13}h^{-\frac43}\big), \tag{28.5.20}$$

where $V_m = z_m|x-\bar{y}_m|^{-1}$ and ψ_m is supported in $\{x : |x-\bar{y}_m|\le\epsilon\}$ and equal 1 in $\{x : |x-\bar{y}_m|\le \frac12\epsilon\}$.

Further, we can replace in this estimate $\operatorname{Tr}(H^-_{A',V_m}\psi_m)+h^{-3}\int P_0(V_m)\psi_m$ by

$$\int\Big(\int_{-\infty}^0 e_{V_m,A'}(x,x,\tau)\,d\tau + h^{-3}P_0(V_m)\Big)\psi_m\,dx \tag{28.5.21}$$

and we can also replace in the latter expression ψ_m by 1.

(b) If $\beta\ge 1$, we can apply estimate (28.5.20) to the zone $\{x\colon |x-\bar{y}_m|\le \epsilon b\}$ with $b=\beta^{-\frac23}$ scaling $x\mapsto (x-\bar{y}_m)b^{-1}$ and $\tau\to\tau$ and $h\mapsto h_1 = hb^{-\frac12}$, $\beta\mapsto \beta b^{\frac32}=1$, $\kappa\mapsto\kappa$; now ψ_m is supported in $\{x : |x-\bar{y}_m|\le\epsilon b\}$ and equals 1 in $\{x : |x-\bar{y}_m|\le\frac12\epsilon b\}$ and the right-hand expression of (28.5.20) becomes

$$Cb^{-1}\big(h_1^{-1}+\kappa|\log\kappa|^{\frac13}h_1^{-\frac43}\big) = C\big(\beta^{\frac13}h^{-1}+\kappa|\log\kappa|^{\frac13}\beta^{\frac29}h^{-\frac43}\big). \tag{28.5.22}$$

If $\beta\ge 1$, let us consider contribution of the zone $\{x\colon \epsilon_0 b\le |x-\bar{y}_m|\le\epsilon_0\}$, where due to assumption (28.5.19) non-degeneracy condition (28.3.60) is automatically satisfied after rescaling; namely before rescaling it is

$$\min_j |V-2j\beta h| + |\nabla V|\ell \asymp \zeta^2. \tag{28.5.23}$$

A contribution of ℓ-element in this zone does not exceed

$$C\zeta^2\big(h_1^{-1}+h_1^{-\frac13}\nu^{\frac43}\big) \tag{28.5.24}$$

with

$$\nu = \sup_{|x-\bar{y}_m|\asymp\ell} |\partial^2 A'|\ell^2\zeta^{-1}, \tag{28.5.25}$$

and plugging (28.5.4) into (28.5.24) we get

$$C\big(\ell^{-\frac12}h^{-1}+(\kappa\beta)^{\frac{40}{27}}h^{\frac{7}{27}}\ell^{\frac{59}{54}}|\log(h\ell^{-\frac12})|^K\big),$$

which sums to

$$C\bigl(\beta^{\frac{1}{3}}h^{-1}+(\kappa\beta)^{\frac{40}{27}}h^{\frac{7}{27}}|\log h|^{K}\bigr), \tag{28.5.26}$$

which obviously does not exceed (28.5.22). Thus after scaling[29)] we arrive to

Proposition 28.5.10. *Let $V=W_B^{\mathsf{TF}}+\lambda$ be Thomas-Fermi potential with $N\le Z$, $N\asymp Z_1\asymp Z_2\asymp ...\asymp Z_M$, $B\lesssim Z^{\frac{4}{3}}$ and*

$$|\mathsf{y}_m-\mathsf{y}_{m'}|\ge d\gtrsim Z^{-\frac{1}{3}}\qquad \forall 1\le m<m'\le M. \tag{28.5.27}$$

Then if ψ_m is supported in ϵr^*-vicinity of y_m

$$\begin{aligned}|\operatorname{Tr}(H^-_{A,V}\psi_m)-\operatorname{Tr}(H^-_{A,V_m}\psi_m)&\\ +\int P_B(V)\psi_m\,dx-\int P_0(V_m)\psi_m\,dx|&\end{aligned} \tag{28.5.28}$$

does not exceed CQ_0 with

$$Q_0\coloneqq\begin{cases}\bigl(Z^{\frac{5}{3}}+\alpha|\log(\alpha Z)|^{\frac{1}{3}}Z^{\frac{25}{9}}\bigr) & \text{for } B\le Z,\\ \bigl(B^{\frac{1}{3}}Z^{\frac{4}{3}}+\alpha|\log(\alpha Z)|^{\frac{1}{3}}B^{\frac{2}{9}}Z^{\frac{23}{9}}\bigr) & \text{for } Z\le B\le Z^{\frac{4}{3}}.\end{cases} \tag{28.5.29}$$

Furthermore, if $B\le Z$, then expression (28.5.28) *does not exceed*

$$C\Bigl(Z^{\frac{5}{3}}[Z^{-\delta}+(BZ^{-1})^{\delta}+(dZ^{\frac{1}{3}})^{-\delta}]+\alpha|\log(\alpha Z)|^{\frac{1}{3}}Z^{\frac{25}{9}}\Bigr). \tag{28.5.30}$$

Here improved estimate (28.5.30) can be proven by our standard propagation arguments.

Further, let us consider the *regular exterior zone* $\{x\colon \epsilon_0 r^*\le |x-\mathsf{y}_m|\le \epsilon\bar{r}\}$ with $\bar{r}\coloneqq \min\bigl(B^{-\frac{1}{4}},(Z-N)_+^{-\frac{1}{3}}\bigr)$. Then due to Thomas-Fermi equation $W_B^{\mathsf{TF}}+\lambda$ satisfies here non-degeneracy condition (28.3.65) after rescaling and $\zeta=\ell^{-2}$, $h_1=\ell(x)$, $\beta_1=B\ell^3$.

Then the contribution of ℓ-element in this zone does not exceed (28.5.25) as long as $\beta_1 h_1\le 1$, $h_1\le 1$ i.e. $\ell(x)\le\min(\bar{r},1)$, and due to (28.5.24) this contribution does not exceed $C\zeta^2\bigl(h_1^{-1}+h_1^{-\frac{1}{3}}\nu^{\frac{4}{3}}\bigr)$, where ν_1 is estimate for $|\partial^2 A'|$ multiplied by $\zeta^{-1}\ell^2$:

$$\nu_1=\kappa|\log h|+(\kappa\beta)^{\frac{10}{9}}h^{\frac{4}{9}}\ell^{\frac{4}{9}}|\log h|^{K}. \tag{28.5.31}$$

[29)] $x\mapsto Z^{\frac{1}{3}}x$, $\tau\mapsto Z^{\frac{4}{3}}\tau$, $1\mapsto h=Z^{-\frac{1}{3}}$, $B\mapsto\beta=Z^{-1}$, $\alpha\mapsto\kappa=\alpha Z$; recall that $\beta h\lesssim 1\iff B\lesssim Z^{-\frac{4}{3}}$.

Then calculating ν_1 and plugging it and $h_1 = h\ell$ into $C\zeta^2\bigl(h_1^{-1} + h_1^{-\frac{1}{3}}\nu^{\frac{4}{3}}\bigr)$ one can see easily that here all terms contain ℓ in the negative powers.

Then summation by ℓ results in the same expression calculated for $\ell = r^*$ and one can observe easily that it does not exceed (28.5.29), (28.5.30) for $B \le Z$, $Z \le B \le Z^{\frac{4}{3}}$ respectively. One can see easily that dealing with terms $C\zeta^2 \times \mu^3\beta^{-2}h^{-2}$ due to (28.3.61) and $C\zeta^2\nu|\log h|$ (see Propositions 28.3.13 and 28.3.15) leads to smaller expressions.

Furthermore, using the standard propagation arguments one can upgrade (28.5.29) to (28.5.30). Therefore we conclude that

(28.5.32) Proposition 28.5.10 remains true for ψ_m supported in the zone $\{x\colon |x - y_m| \le \epsilon\,\mathsf{min}(\bar{r}, 1)\}$.

Consider now the contribution of the *boundary zone* $\{x\colon \ell(x) \ge \mathsf{min}(\bar{r}, 1)\}$.

(a) Let us start from more difficult and interesting case $B \ge 1$ assuming first that $Z = N$. Rescale this zone first $x \mapsto xB^{\frac{1}{4}}$, $\tau \mapsto \tau B^{-1}$, then we have $h_1 = B^{-\frac{1}{4}}$, $\beta_1 = B^{\frac{1}{4}}$. Observe that

(28.5.33) After this rescaling a rescaled magnetic field satisfies $|\partial^2 A'| \le \nu_1$ where ν_1 is given by (28.5.31) for $\ell = \bar{r}$.

As we know from Subsection 26.5.1, after the first scaling there exists the scaling function γ such that

$$|\partial^\alpha V| \le C\gamma^{4-|\alpha|} \qquad |\alpha| \le 4, \tag{28.5.34}$$

$$V \asymp \gamma^4, \qquad |\partial^2 V| \asymp \gamma^2 \tag{28.5.35}$$

and therefore we can use a γ-admissible partition. Then scaling again $x \mapsto x\gamma^{-1}$, $\tau \mapsto \tau\gamma^{-4}$, $h_1 \mapsto h_2 = h\gamma^{-3}$, $\beta_1 \mapsto \beta_2 = \beta_1\gamma^{-1}$ and $\nu_1 \mapsto \nu_2 = \nu_1$ we see that non-degeneracy assumption (28.3.65) is fulfilled and therefore according to Proposition 28.4.3(ii) the contribution of γ-element to the remainder does not exceed $CB\gamma^4\beta_2\bigl(1 + h_2^{\frac{2}{3}}\nu_2^{\frac{4}{3}}\bigr)$ because now $\beta_2 h_2 \ge 1$. Then the total contribution of such elements does not exceed

$$CB \int \beta_2\bigl(1 + h_2^{\frac{2}{3}}\nu_2^{\frac{4}{3}}\bigr)\gamma^{-3}\,dx \tag{28.5.36}$$

with integral taken over zone $\{x\colon \gamma(x) \ge \bar{\gamma} \coloneqq h_1^{\frac{1}{3}}\}$ where $h_2 \le 1$. Plugging β_2, h_2 and $\nu_2 = \nu_1$ we get in the second term γ^{-2} which is not good. Let us apply Remark 28.5.9.

Recall that $A'(x)$ is a solution of the Laplace equation and therefore $A'(x) = \int |x-y|^{-1} F(y)\,dy$; then $A'(x)$ with $x \in B(z, \gamma(z))$ can be decomposed into the sum of two terms; the first one is given by the integral over $\{y : |y-z| \ge \frac{3}{2}\gamma(z)\}$ and therefore is smooth and could be included in $A^0(x)$ while the second is given by integral over $\{y : |y-z| \le 2\gamma(z)\}$ and could be estimated by (28.3.46) with β, h, κ and ν replaced by β_2, h_2, $\kappa_2 = \kappa_1\gamma^5$ and ν_1 and then one can see easily that $\nu_2 \le \nu_1\gamma^{\frac{3}{2}+\delta}$. Therefore we conclude that

Remark 28.5.11. In the boundary zone calculating trace term, N- and D-terms one can take $\nu_2 = \nu_1\gamma^{\frac{3}{2}+\delta}$ with $\delta > 0$.

Plugging this improved ν_2 into (28.5.36) we get everywhere γ in the positive power and therefore expression (28.5.36) does not exceed the integrand for $\gamma = 1$, which is $CB\beta_1\bigl(1 + h_1^{\frac{2}{3}}\nu_1^{\frac{4}{3}}\bigr)$, which we already got when estimating the contribution of the regular zone.

(b) In the zone $\{x\colon \gamma(x) \le \bar{\gamma}\}$ we just reset $\gamma = \bar{\gamma}$ and since $h_2 \asymp 1$ we do not need any non-degeneracy condition here. Thus its contribution does not exceed $CB\beta_1$. Therefore we arrive to Proposition 28.5.12(i) with $Z = N$ and $B \ge 1$.

(c) In the case $B \le 1$ we need no non-degeneracy assumption in the zone $\{x\colon \ell(x) \gtrsim 1\}$ as $h_1 = 1$; Proposition 28.5.12(i) has been proven in this case as well.

(d) Explore now case $N < Z$. Then eventually we will need to take $V = W_B^{\mathsf{TF}} + \lambda$, where λ is a chemical potential. In this case the same arguments hold provided $B\gamma^4 \le |\lambda| \implies \gamma \le h_1^{\frac{1}{3}}$ which is equivalent to $(Z-N)_+ \le B^{\frac{5}{12}}$ since in this case $-\lambda \asymp (Z-N)_+\bar{r}^{-1} = (Z-N)_+B^{\frac{1}{4}}$.

(e) Further, for $M = 1$ we do not need assumption $N = Z$ since we can always refer to non-degeneracy condition (28.5.23), which is fulfilled, and we arrive to Proposition 28.5.12(ii). Indeed, as in Section 26.5 we do not partition further elements where this condition is fulfilled. We arrive to Proposition 28.5.12(i), (ii) below.

(f) Furthermore, consider case $M \ge 2$ and $B^{\frac{5}{12}} \le (Z-N)_+ \le B^{\frac{3}{4}}$. Then $B\bar\gamma^4 = (Z-N)_+ B^{\frac{1}{4}}$ and $\bar\gamma = (Z-N)_+^{\frac{1}{4}} B^{-\frac{3}{16}}$.

In this case the contribution of $\bar\gamma$-element (in the excess what was prescribed before) does not exceed term (28.3.66) multiplied by ζ^2. Note that two last terms in (28.3.66) are not new. Meanwhile, the first term there (i.e. $C\beta\nu^{\frac{6}{5}}h^{\frac{2}{5}}$) becomes $CB\bar\gamma^4 \times B^{\frac{1}{4}}\bar\gamma^{-1} \times \bar\nu^{\frac{6}{5}} \times (B^{-\frac{1}{4}}\bar\gamma^{-3})^{\frac{2}{5}}$ and after multiplication by $\bar\gamma^{-2}|\log\bar\gamma|$ it has $\bar\gamma$ in the negative degree, so it does not exceed the same value for $\bar\gamma = B^{-\frac{1}{12}}$. After easy but tedious calculations one can see that it is less than (28.5.22).

This leaves us with the second term in (28.3.66) (i.e. $C\beta h^{-\frac{1}{2}}$), which becomes $CB\bar\gamma^4 \times B^{\frac{1}{4}}\bar\gamma^{-1} \times B^{\frac{1}{8}}\bar\gamma^{\frac{3}{2}}$ and after multiplication by $\bar\gamma^{-2}|\log\bar\gamma|$ we get

$$CB^{\frac{11}{8}}\bar\gamma^{\frac{5}{2}}|\log\bar\gamma| \asymp CQ' := CB^{\frac{29}{32}}(Z-N)_+^{\frac{5}{8}}\bigl(1+|\log(Z-N)_+B^{-\frac{3}{4}}|\bigr). \tag{28.5.37}$$

(g) Finally, if $(Z-N)_+ \ge B^{\frac{3}{4}}$, we again end up with the term $C\zeta^2\beta h^{-\frac{1}{2}}$ this time with $\zeta^2 = (Z-N)_+^{\frac{4}{3}}$, $h = (Z-N)_+^{-\frac{1}{3}}$, $\beta = B(Z-N)_+^{-1}$ (now $\bar\gamma \asymp 1$); so we arrive to

$$CQ'' := CB(Z-N)_+^{\frac{1}{2}}. \tag{28.5.38}$$

Thus we arrive to Proposition 28.5.12(iii), (iv) below.

Proposition 28.5.12. *Let $V = W_B^{\mathsf{TF}} + \lambda$ be Thomas-Fermi potential with $N \le Z$, $N \asymp Z_1 \asymp Z_2 \asymp \dots \asymp Z_M$, $B \lesssim Z^{\frac{4}{3}}$ and chemical potential λ. Let assumption* (28.5.27) *be fulfilled. Then*

(i) For $Z = N$ ($\lambda = 0$) the trace remainder

$$|\mathsf{Tr}(H^-_{A,V}) + \int P_{Bh}(V)\,dx - \sum_{1\le m\le M}\Bigl(\mathsf{Tr}(H^-_{A,V_m}\psi_m) - \int P_0(V_m)\psi_m\,dx\Bigr)| \tag{28.5.39}$$

does not exceed CQ_0 with Q_0 defined by (28.5.29)*; the same is true for $(Z-N)_+ \le B^{\frac{5}{12}}$.*

(ii) For $M = 1$ *the trace remainder* (28.5.39) *also does not exceed* CQ_0.

(iii) For $M \ge 1$ *and* $B^{\frac{5}{12}} \le (Z-N)_+ \le B^{\frac{3}{4}}$ *the trace remainder* (28.5.39) *does not exceed* $C(Q_0 + Q')$ *with* Q' *defined by* (28.5.37).

(iv) For $M \ge 1$ *and* $(Z-N)_+^{\frac{4}{3}} \ge B$ *the trace remainder* (28.5.39) *does not exceed* $C(Q_0 + Q'')$ *with* Q'' *defined by* (28.5.38).

Remark 28.5.13. (i) For $B \le Z$ expression (28.5.29) could be upgraded to (28.5.30).

(ii) Terms (28.5.38) and (28.5.39) are rather superficial: they do not depend on α and they were not present in Chapter 25. Indeed, using more precise arguments of Chapter 25 one can get rid of them, at least for sufficiently small α.

However in the upper estimate we will need to deal with D-term as well and this would give us a far larger error.

28.5.4 Endgame

Main Theorem: $M = 1$

For $M = 1$ we almost immediately arrive to the following statement which we formulate in "rescaled" terms:

Theorem 28.5.14. *Let* $V = W_B^{\mathsf{TF}} + \lambda$ *be a Thomas-Fermi potential as* $B \le Z^{\frac{4}{3}}$, $N \asymp Z$ *and* $M = 1$. *Then*

$$\mathcal{E}_0^* + 2S(\alpha Z)Z^2 - CZ^{\frac{5}{3}}\big(1+\alpha B\big) \le \mathsf{E}_\alpha^* \le \mathcal{E}_\alpha^* + 2S(\alpha Z)Z^2 + C\big(Z^{\frac{5}{3}} + \alpha B^2 Z^{\frac{1}{3}}\big), \tag{28.5.40}$$

where $S(\alpha Z)Z^2$ *is a Scott correction term derived in Section 27.3.*

Proof: Estimate from above. We already know from (28.5.20) that after the standard rescaling for any magnetic field A' satisfying the same estimates as a minimizer of $\mathsf{E}_\kappa(A')$ the following estimate holds:

$$\mathsf{Tr}(H^-_{A,V}) + \kappa^{-1}h^{-2}\|\partial A'\|^2 \le -h^{-3}\int P_{Bh}(V)\,dx + \underbrace{(28.5.21) + \kappa^{-1}h^{-2}\|\partial A'\|^2}_{} + (28.5.22). \tag{28.5.41}$$

Here the left-hand expression is $\mathsf{E}_\kappa(A') \ge \mathsf{E}^*_\kappa$ and in expression (28.5.21) we take $\psi_1 = 1$.

Let us pick up A' which is a minimizer for the Coulomb potential $V_1(x) = z_1|x - y_1|^{-1}$ without any external magnetic field[30]. Then we can replace the selected sum of two terms by $2h^{-2}S(\kappa z)z^2$ (in virtue of Subsubsection 27.3.5.1 an error does not exceed (28.5.22)).

Unfortunately A' is not a minimizer for a local problem; however we can replace $P_{Bh}(V)$ by

$$P_{\beta h}(V) + \partial_\beta P_{\beta h}(V)\cdot \Phi, \qquad \Phi = \partial_1 A'_2 - \partial_2 A'_1 \tag{28.5.42}$$

and, if we apply partition, then on each partition element an error in (28.5.41) does not exceed $C\kappa_1\zeta^2\beta_1 h_1^{-\frac12} = C\kappa\beta h^{-\frac12}\zeta^{\frac52}\ell^{\frac52}$. Indeed, we know that for a minimizer $\|\partial A'\| \le C(\kappa + \kappa^{\frac12}h^{\frac12})$ (also see in the proof of the estimate from below).

Summation over partition results in $C\kappa\beta^2$ and we arrive to

$$-h^{-3}\int P_{\beta h}(V)\,dx - h^{-3}\int \partial_\beta P_{\beta h}(V)\cdot\Phi\,dx + C(h^{-1}+\kappa\beta^2) \tag{28.5.43}$$

in the right-hand expression where the first term is $\mathcal{E}^*_0$ [31].

The second term is rather unpleasant because we cannot estimate it by anything better than $C\beta h^{-1}$ (see in the estimate from below) but *here* we have a trick[32]: we replace A' by $-A'$ which is also a minimizer for the same Coulomb potential V_1 without external magnetic field. Then Φ and the second term change signs and since nothing else happens we can skip the second term which concludes the proof of the upper estimate.

Scaling back we arrive to the upper estimate in (28.5.40). □

Proof: Estimate from below. Again from (28.5.20) we already know that for a minimizer A' of $\mathsf{E}_\kappa(A')$ estimate (28.5.41) could be reversed

$$\begin{aligned}&\mathsf{Tr}(H^-_{A,V}) + \kappa^{-1}h^{-2}\|\partial A'\|^2\\ &\qquad \ge -h^{-3}\int P_{Bh}(V)\,dx + \underbrace{(28.5.21) + \kappa^{-1}h^{-2}\|\partial A'\|^2} - (28.5.22).\end{aligned} \tag{28.5.44}$$

---

[30] Actually since for the Coulomb potential the trace is infinite we take potential $V_1(x)+\tau$ with $\tau<0$, establish estimates and then tend $\tau\to -0$.

[31] I.e. Thomas-Fermi energy calculated for $A'=0$.

[32] Which unfortunately we cannot repeat in estimate from below.

Here the left-hand expression is $\mathsf{E}_\kappa(A') = \mathsf{E}^*_\kappa$ and the selected sum of two terms can be estimated from below by $2h^{-2}S(\kappa z)z^2$.

Again A' is not a minimizer for a local problem; however we can replace $P_{Bh}(V)$ by $P_{\beta h}(V)$ with an error not exceeding

$$Ch^{-3}\int |\partial_\beta P_{\beta h}(V)|\cdot|\partial A'|\,dx + Ch^{-3}\int |\partial^2_\beta P_{\beta h}(V)|\cdot|\partial A'|^2\,dx$$
$$\le Ch^{-3}\|\partial_\beta P_{\beta h}(V)\|\cdot\|\partial A'\| + Ch^{-3}\int |\partial^2_\beta P_{\beta h}(V)|\,dx\times\|\partial A'\|^2$$

with the right-hand expression not exceeding

$$C\beta h^{-1}|\partial A'\| + Ch^{-1}\|\partial A'\|^2. \tag{28.5.45}$$

However we already know that $\mathsf{E}^*_{2\kappa}\ge \mathcal{E}^*_0 - C(\kappa h^{-2}+h^{-1})$ and therefore since $\mathsf{E}_\kappa(A') = \mathsf{E}_{2\kappa}(A') + (2\kappa h^2)^{-1}\|\partial A'\|^2$ we conclude that

$$\|\partial A'\|\le C(\kappa+\kappa^{\frac12}h^{\frac12}); \tag{28.5.46}$$

then expression (28.5.45) does not exceed $C(\kappa\beta+1)h^{-1}$ which concludes the proof of the lower estimate.

Since A' is a minimizer in the presence of the external field, we cannot replace A' by $-A'$ and thus cannot repeat the trick used in the proof of the upper estimate. Thus in the estimate from below we are left with $C\kappa\beta h^{-1}$ rather than with $C\kappa\beta^2$.

Scaling back we arrive to the lower estimate in (28.5.40). □

Remark 28.5.15. (i) It is a very disheartening that our estimate deteriorated here. However it may be that indeed the better estimate does not hold due to the *entanglement* of the singularity and the regular zone via self-generated magnetic field. Still we did not loose Scott correction term as long as $\kappa\beta h\ll 1$.

(ii) Recall that in the Section 27.3 we already had an entanglement of different singularities which obviously remains with us for $M\ge 2$. Surely both of these entanglements matter only if we are looking for the remainder estimate better than $O(\kappa h^{-2})$. Otherwise we can just pick up $A'=0$ near singularities and the Scott correction term equal to $2h^{-2}S(0)z^2$;

(iii) The silver lining is that we do not need all these non-degeneracy conditions for such bad estimate and we expect that our arguments would work for $M \ge 2$. Still for $M \ge 2$ we will need to decouple singularities and to do this we will need to estimate $\|\partial A'\|_{\mathscr{L}^2(\{\ell(x)\asymp d\})}$ where d is the minimal distance between nuclei (see (28.5.19)).

For $\beta \ll 1$, $\kappa \ll h^{\frac{1}{3}}|\log h|^{-\frac{1}{3}}$ we can recover even Schwinger correction term:

Theorem 28.5.16. *Let V be a Thomas-Fermi potential $W_B^{\mathsf{TF}} + \lambda$ rescaled as $B \ll Z$, $N \asymp Z$ and $M = 1$. Let respectively $\beta = BZ^{-1}$, $h = Z^{-\frac{1}{3}}$, and $\kappa = \alpha Z \le \kappa^*$. Then*

$$|\mathsf{E}^*_\alpha - \bigl(\mathcal{E}^*_0 + 2S(\alpha Z)Z^2 + \mathsf{Schwinger}\bigr)| \le CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + B^\delta Z^{-\delta}\bigr) + C\alpha|\log \alpha Z|^{\frac{1}{3}} Z^{\frac{25}{9}} \tag{28.5.47}$$

where $\mathsf{Schwinger}$ *is a Schwinger correction term.*

Proof. The proof is standard like in Section 27.3: we invoke propagation arguments in the zone $\{x\colon (\beta + h)^\sigma \le \ell(x)Z^{\frac{1}{3}} \le (\beta + h)^{-\sigma}\}$. □

28.5.5 N-Term Asymptotics and D-Term Estimate

Consider now N-terms assuming that A' is a minimizer.

Case $M = 1$

Assume first that $M = 1$.

(a) Consider first singular and regular zones (but not the boundary zone). Then after rescaling the contribution of ℓ-element to the remainder does not exceed

$$C\bigl(h_1^{-2} + h_1^{-\frac{5}{3}}\nu_1^{\frac{2}{3}}\bigr) \tag{28.5.48}$$

and summation over zone $\{x\colon \ell(x) \le 1\}$ results in the value of this as $\ell = 1$ i.e.

$$C\bigl(h^{-2} + h^{-\frac{5}{3}}\nu^{*\frac{2}{3}}\bigr), \qquad \nu^* = (\kappa\beta)^{\frac{10}{9}} h^{\frac{4}{9}} |\log h|^K. \tag{28.5.49}$$

Recall that for $\ell \ge 1$ we have $h_1 = h\ell$, $\beta_1 = \beta\ell^3$ and ν_1 is defined by (28.5.31) which is sufficient even without invoking Remark 28.5.9 since all powers of ℓ in (28.5.48) become negative. Therefore the contribution of the regular exterior zone also does not exceed (28.5.49).

(b) Consider now the boundary zone. Let us repeat arguments used in the proof of Proposition 28.5.12: the contribution of γ-element does not exceed $C\beta_2\bigl(h_2^{-1} + h_2^{-\frac{2}{3}}\nu_2^{\frac{2}{3}}\bigr)$ and plugging $\beta_2 = \beta_1\gamma^{-1}$, $h_2 = h_1\gamma^{-3}$ and $\nu_2 = \nu_1\gamma^{\frac{3}{2}+\delta}$ we get $C\beta_1\bigl(h_1^{-1}\gamma^2 + h_1^{-\frac{2}{3}}\nu_1^{\frac{2}{3}}\gamma^{2+\delta}\bigr)$ and therefore the total contribution of the boundary zone to the remainder does not exceed

$$C\beta_1 \int \bigl(h_1^{-1}\gamma^{-1} + h_1^{-\frac{2}{3}}\nu_1^{\frac{2}{3}}\gamma^{-1+\delta}\bigr)\,dx \asymp C\bigl(h_1^{-2}|\log h| + h_1^{-\frac{5}{3}}\nu_1^{\frac{2}{3}}\bigr) \tag{28.5.50}$$

since $\beta_1 = h_1^{-1}$ and from Subsection 26.5.1 we also know that even in the general case

$$\mathsf{D}(\gamma^{-1+s}, \gamma^{-1+s}) \le Cs^{-2} \qquad \text{for } s > 0. \tag{26.5.14}$$

Here we integrate over $\gamma \ge \bar\gamma = h_1^{\frac{1}{3}}$ while the contribution of the zone $\{x\colon \gamma(x) \le \bar\gamma$ does not exceed Ch_1^{-2}.

If $\bar\gamma \ge h_1^{\frac{1}{3}}$ (i.e. $(Z-N)_+ \gtrsim B^{\frac{5}{12}}$) we invoke in the zone $\{x\colon \gamma(x) \le \bar\gamma\}$ the strong non-degeneracy assumption (28.3.60) fulfilled for $M = 1$ and estimate its contribution by the same expression (28.5.50) albeit without the logarithmic term. Similar arguments work also for $(Z-N)_+ \ge B^{\frac{3}{4}}$.

(c) In expression (28.5.50) the logarithmic factor is mildly annoying. However we can get rid of it using our standard propagation arguments like in Subsection 26.6.3; we leave easy details to the reader.

Note that so far in the estimate we also have $P'_{Bh}(V)$ rather than $P'_{\beta h}$; observe however that in the virtue of non-degeneracy assumption (28.3.60) fulfilledfor $M = 1$ the error when we replace $P'_{Bh}(V)$ by $P'_{\beta h}(V)$ does not exceed $C\beta_1 h_1^{-1}$ on the regular elements and Ch_2^{-2} on the boundary elements and summation in both cases results in $O(\beta h^{-1}\bar\ell^2) = O(\beta^{\frac{1}{2}}h^{-\frac{3}{2}})$. Therefore in contrast to the trace estimate there is no deterioration.

Scaling back, we arrive to estimate (28.5.51) below.

(d) In the framework of Theorem 28.5.16 we invoke our standard propagation arguments in the zone $\{x\colon (\beta+h)^{\sigma} \le \ell(x) \le (\beta+h)^{-\sigma}\}$; considering D-terms we invoke these arguments if both elements in the pair belong to this zone. Again, we leave easy details to the reader. Scaling back, we arrive to estimate (28.5.53) below.

(e) We deal with D-term in our usual manner considering double partition and different pairs of partition elements–disjoint when we just apply above arguments since the kernel $|x-y|^{-1}$ is smooth there and non-disjoint when we appeal to the local estimates of D-term. We we leave easy details to the reader.

Proposition 28.5.17. *Let $V = W_B^{\mathsf{TF}} + \lambda$ be a Thomas-Fermi potential for $B \le Z^{\frac{4}{3}}$, $N \asymp Z$ and $M = 1$. Then*

(i)

$$|\int \bigl(\operatorname{tr} e(x,x,0) - P'_B(V(x))\,dx| \le CR \tag{28.5.51}$$

and

$$\mathsf{D}\bigl(\operatorname{tr} e(x,x,0) - P'_B(V(x),\ \operatorname{tr} e(x,x,0) - P'_B(V(x)\bigr) \le CZ^{\frac{1}{3}}R^2 \tag{28.5.52}$$

with

$$R = R_0 \coloneqq DefZ^{\frac{2}{3}} + Z^{\frac{5}{9}}\nu^{*\frac{2}{3}}, \qquad \nu^* = (\alpha B)^{\frac{10}{9}} Z^{-\frac{4}{27}} |\log Z|^K. \tag{28.5.53}$$

(ii) In the framework of Theorem 28.5.16 estimates (28.5.51) *and* (28.5.52) *hold with*

$$R \coloneqq CZ^{\frac{2}{3}}\bigl(Z^{-\delta} + B^{\delta}Z^{-\delta} + (\alpha Z)^{\delta}\bigr). \tag{28.5.54}$$

Case $M \ge 2$

Consider now $M \ge 2$. In comparison with the case $M = 1$ we should get some extra terms because

(a) First, in the regular zone with $\ell(x) \ge \epsilon d$ the strong non-degeneracy assumption (28.3.60) is replaced by the strong assumption (28.3.65).

(b) In the boundary zone with $\gamma(x) \le \bar{\gamma}$ (and with $\bar{\gamma} \ge h_1^{\frac{1}{3}}$) there is no non-degeneracy assumption at all.

Consider a regular zone first. According to (28.3.86) we get an extra term

$$C\beta_1 h_1^{-1}\nu_1^{\frac12} \asymp C\beta h^{-1}(\kappa\beta)^{\frac59}\ell^{\frac{20}{9}}|\log h|^K \tag{28.5.55}$$

since other extra terms are smaller; summation over the regular zone results in the value with $\ell = \bar r$; since $\bar r = (\beta h)^{-\frac14}$ we get $C\kappa^{\frac59}\beta h^{-\frac{14}{9}}|\log h|^K$. Scaling back we arrive to

$$CR'' = C\alpha^{\frac59} BZ^{\frac{2}{27}}|\log Z|^K. \tag{28.5.56}$$

Using γ-partition in the boundary zone and plugging $h_2 = h_1\gamma^{-3}$, $\beta_2 = \beta_1\gamma^{-1}$, $\nu_2 = \nu_1\gamma^{\frac32+\delta}$ (see Remark 28.5.11) and using (28.5.52) we prove easily that if $\bar\gamma = h_1^{\frac13}$ (i.e. $(Z-N)_+ \le B^{\frac{5}{12}}$) the contribution of the boundary zone is smaller than CR''.

On the other hand, in the case $B^{\frac{5}{12}} \le (Z-N)_+ \le B^{\frac34}$ we need to add $C\beta_2 h_2^{-\frac32}\bar\gamma^{-2}(1+|\log\bar\gamma|)$. Plugging $h_2 = h_1\bar\gamma^{-3}$, $\beta_2 = \beta_1\bar\gamma^{-1}$, $\bar\gamma = (Z-N)_+^{\frac14}B^{-\frac{3}{16}}$ and scaling back we arrive to

$$CR''' = C(Z-N)_+^{\frac38}B^{\frac{11}{32}}\bigl(1+|\log(Z-N)_+B^{-\frac34}|\bigr). \tag{28.5.57}$$

Finally if $(Z-N)_+ \ge B^{\frac34}$ we get $C\beta_1 h_1^{-\frac32}$ with $\ell = (Z-N)_+^{-\frac13}Z^{\frac13}$ i.e.

$$CR''' = C(Z-N)_+^{-\frac12}B. \tag{28.5.58}$$

Thus we arrive to Proposition 28.5.18(i). The similar arguments work for D-term and we arrive to Proposition 28.5.18(ii)

Proposition 28.5.18. *Let $V = W_B^{\mathsf{TF}} + \lambda$ be a Thomas-Fermi potential with $B \le Z^{\frac43}$, $N \asymp Z$ and $M \ge 2$. Let $d \ge Z^{-\frac13}$. Then*

(i) Estimate (28.5.51) *holds with $R = R_0 + R''$ and R'' defined by* (28.5.56) *for $(Z-N)_+ \le B^{\frac{5}{12}}$, $R = R_0 + R'' + R'''$ and R''' defined by* (28.5.57) *for $B^{\frac{5}{12}} \le (Z-N)_+ \le B^{\frac34}$, $R = R_0 + R'''$ and R''' defined by* (28.5.58) *for $(Z-N)_+ \ge B^{\frac34}$.*

Furthermore, if $B \le Z$ estimate (28.5.51) *holds with*

$$R = Z^{\frac23}\bigl[Z^{-\delta} + B^\delta Z^{-\delta} + (dZ^{\frac13})^{-\delta} + (\alpha Z)^\delta\bigr]. \tag{28.5.59}$$

(ii) The left-hand expression of (28.5.57) *does not exceed* $CZ^{\frac{1}{3}}R_0^2 + CB^{\frac{1}{4}}R''^2$ *if* $(Z-N)_+ \le B^{\frac{5}{12}}$, $CZ^{\frac{1}{3}}R_0^2 + CB^{\frac{1}{4}}(R''+R''')^2$ *and* R''' *defined by* (28.5.57) *if* $B^{\frac{5}{12}} \le (Z-N)_+ \le B^{\frac{3}{4}}$, $CZ^{\frac{1}{3}}R_0^2 + (Z-N)_+^{\frac{1}{3}}R'''^2$ *and* R''' *defined by* (28.5.58) *if* $(Z-N)_+ \ge B^{\frac{3}{4}}$.

Furthermore, if $B \le Z$ *the left-hand expression of* (28.5.57) *does not exceed* $CZ^{\frac{1}{3}}R^2$ *with* R *defined by* (28.5.59).

28.5.6 More Estimates to a Minimizer

Now we want to provide different kinds of estimates to the minimizer for $\ell(x) \ge Z^{-\frac{1}{3}}$ in the original scale. More precisely, we are looking for

$$\alpha^{-1}\int \phi_r(x)|\partial A'|^2\,dx \tag{28.5.60}$$

with ϕ_r supported in $\{x\colon \ell(x) \asymp r\}$ because it will appear as an error when we decouple singularities for $M \ge 2$ (in this case we should take $r \asymp d$. Due to equation (27.2.14) it is D-type term as well: namely, with the integral taken over $\mathbb{R}^3$ it would be equal to $\alpha Z^{\frac{5}{3}}\mathsf{D}(\phi\Phi_j, \phi\Phi_j)$ calculated in the rescaled coordinates with Φ_j defined by (27.2.14); however with the cut-off the integral kernel $|x-y|^{-1}$ needs to be modified. Recall that the corresponding Weyl expression is 0.

First, using (28.5.16) and decomposition like in the proof of Proposition 27.3.9 we can rewrite (28.5.60) as

$$I \coloneqq \int K(z;x,y)\Phi(x)\Phi(y)\,dxdydz \tag{28.5.61}$$

multiplied by $\alpha Z^{\frac{5}{3}}$; here $K(z;x,y)$ is supported in $\{z\colon \ell(z) \asymp r\}$, singular at $x=z$ and $y=z$ and satisfies

$$|K(z;x,y)| \le |x-z|^{-2}|y-z|^{-2}|x|\cdot|y|(|x|+r)^{-1}(|y|+r)^{-1}. \tag{28.5.62}$$

Here we temporarily replaced r by $Z^{\frac{1}{3}}r$.

Let us make a double ℓ-admissible partition of unity and consider pairs of elements with $\ell(x) \asymp r_1$ and $\ell(y) \asymp r_2$. There are three cases: $r_1 \le \epsilon r$, $r_1 \asymp r$ and $r_1 \ge cr$, and so also for r_2, and we can consider only pure pairs.

Case $M = 1$

Assume first that $M = 1$. Then the contribution of each pair with $r_j \le \epsilon r$ (assuming that they belong to regular zone) does not exceed

$$C\zeta_1 r_1\bigl(h_1^{-2} + h_1^{-\frac{5}{3}}\nu_1^{\frac{2}{3}}\bigr) \times \zeta_2 r_2\bigl(h_2^{-2} + h_2^{-\frac{5}{3}}\nu_2^{\frac{2}{3}}\bigr) \times r^{-3}, \tag{28.5.63}$$

where $\zeta_j = r_j^{-2}$, $h_j = hr_j$, $\nu_j = (\kappa\beta)^{\frac{10}{9}} h^{\frac{4}{9}} r_j^{\frac{4}{9}}$ if $r_j \ge 1$ and $\zeta_j = r_j^{-\frac{1}{2}}$, $h_j = hr_j^{-\frac{1}{2}}$, $\nu_j = (\kappa\beta)^{\frac{10}{9}} h^{\frac{4}{9}}$ if $r_j \le 1$. Double summation returns its value if $r_1 = r_2 = 1$ i.e.

$$Ch^{-4}\bigl(1 + h^{\frac{2}{3}}{\nu^*}^{\frac{4}{3}}\bigr) r^{-3}. \tag{28.5.64}$$

Further, using Fefferman-de Llave decomposition one can prove easily that the contribution of pairs with $r_1 \asymp r_2 \asymp r$ (the only case when we have a singular kernel) does not exceed (28.5.63) calculated as $r_1 = r_2 = r$ which is decaying function of r and therefore does not exceed (28.5.64).

Furthermore, the contribution of each pair with $r_j \ge Cr$ (assuming that they belong to regular zone) does not exceed

$$C\zeta_1 r_1^{-2}\bigl(h_1^{-2} + h_1^{-\frac{5}{3}}\nu_1^{\frac{2}{3}}\bigr) \times \zeta_2 r_2^{-2}\bigl(h_2^{-2} + h_2^{-\frac{5}{3}}\nu_2^{\frac{2}{3}}\bigr) \times r^{3}, \tag{28.5.65}$$

and the double summation returns its value with $r_1 = r_2 = r$ which is the same as (28.5.63) calculated with $r_1 = r_2 = r$ and again does not exceed (28.5.64).

Finally, considering $r_1 \asymp r_2 \asymp \bar{r}$ we apply for $(Z - N)_+ \le B^{\frac{3}{4}}$ secondary partitions with respect to x and y and using our standard arguments we estimate the contribution of this zone by (28.5.65) calculated with $r_1 = r_2 = \bar{r}$.

Therefore we estimated expression (28.5.61) by (28.5.64). In particular, if $\kappa\beta \le h^{-\frac{17}{20}}|\log h|^{-K}$ i.e. $\alpha B \le Z^{\frac{17}{60}}|\log Z|^{-K}$), then $\nu^* \le h^{-\frac{1}{2}}$ and expression (28.5.61) does not exceed $Ch^{-4}r^{-3}$. Plugging $h = Z^{-\frac{1}{3}}$, multiplying by $\alpha Z^{\frac{5}{3}}$ and replacing r by $Z^{\frac{1}{3}}r$ we get $\alpha Z^2 r^{-3}$ thus proving Proposition 28.5.19(i).

On the other hand, for $\kappa\beta \ge h^{-\frac{17}{20}}|\log h|^{-K}$ estimate (28.5.61) by (28.5.64) could be improved. Indeed, let us apply all the above arguments only for $r_j \ge t$ with $1 \le t \le \epsilon r$. Then we get expression (28.5.63) with $r_1 = r_2 = t$ i.e.

$$Ch^{-4} \times {\nu^*}^{\frac{4}{3}} h^{\frac{2}{3}} t^{-\frac{128}{27}} r^{-3} \tag{28.5.66}$$

where we consider only term possibly exceeding $Ch^{-4}r^{-3}$.

To estimate the contribution of zone $\{x,y\colon \ell(x)\le t, \ell(y)\le t\}$ we replace Φ_j by $(\kappa h^{-2})\Delta A'_j$ and using the standard estimate for operator norm in $\mathscr{L}^2$ we conclude that the corresponding part of expression (28.5.61) does not exceed $C\kappa^{-2}h^{-4}\|\partial A'\|^2\times t^3r^{-3}\le Ch^{-4}t^3r^{-3}$ as long as $\|\partial A'\|\le C\kappa$.

Adding this to (28.5.66) and minimizing by $t\lesssim r$ we get $Ch^{-4}(\nu^{*2}h)^{\frac{54}{209}}r^{-3}$ provided $r\ge (\nu^{*2}h)^{\frac{18}{209}}$.

Plugging ν^* and h, multiplying by $\alpha Z^{\frac53}$ and replacing r by $Z^{\frac13}r$ we arrive to Proposition 28.5.19(ii).

Proposition 28.5.19. *Let $V=W_B^{\mathsf{TF}}+\lambda$ be a Thomas-Fermi potential with $B\le Z^{\frac43}$, $N\asymp Z$ and $M=1$. Then*

(i) A minimizer satisfies

$$\alpha^{-1}\int_{\{x\colon \ell(x)\ge r\}} |\partial A'|^2\,dx \le CT_0r^{-3}=C\alpha Z^2r^{-3} \tag{28.5.67}$$

for $r\ge r_*=Z^{-\frac13}$ holds provided

$$\alpha B\le Z^{\frac{17}{60}}|\log Z|^{-K}. \tag{28.5.68}$$

(ii) Otherwise a minimizer satisfies

$$\alpha^{-1}\int_{\{x\colon \ell(x)\ge r\}} |\partial A'|^2\,dx \le CT_0r^{-3}=C\alpha Z^3r_*^3r^{-3} \qquad \text{for } r\ge r_* \tag{28.5.69}$$

with

$$r_*:=(\alpha B)^{\frac{40}{209}}Z^{-\frac{81}{209}}|\log Z|^K\gtrsim Z^{-\frac13}. \tag{28.5.70}$$

Remark 28.5.20. (i) Assumption (28.5.68) means exactly that $r_*\le Z^{-\frac13}$.

(ii) Our usual approach implies that for $B\le Z$ the Tauberian error estimate could be slightly improved but it has no implications here because in contrast to $e(x,x,\tau)$ where the main term in the formal asymptotic decomposition is $h^{-3}P'_{Bh}$ and the next one is $\asymp\beta^2h^{-2}$, in Φ_j the main term is 0 and the next one is ηh^{-2} with the coefficient η depending on A' and trying to calculate it and plug the corresponding term into (28.5.61) instead of Φ_j will certainly result in the identity.

(iii) It may happen that $r_*\ge \bar r$; then it follows from the proof that r_* should be truncated to $\bar r$ in (28.5.69). Moreover, estimate (28.5.69) with $r_*=\bar r$ holds even for $M\ge 2$ if no non-degeneracy assumption is made.

Case $M \ge 2$

Assume now that $M \ge 2$ and that (28.5.19) is fulfilled. Then we need to take into account excess terms in our estimates. In the regular zone such excess term is

$$C\zeta_1 r_1 \beta_1 h_1^{-1} \nu_1^{\frac{1}{2}} \times \zeta_2 r_2 \beta_2 h_2^{-1} \nu_2^{\frac{1}{2}} \times r^{-3} \qquad \text{for } r_1 \le r, r_2 \le r \tag{28.5.71}$$

and

$$C\zeta_1 r_1^{-2} \beta_1 h_1^{-1} \nu_1^{\frac{1}{2}} \times \zeta_2 r_2^{-2} \beta_2 h_2^{-1} \nu_2^{\frac{1}{2}} \times r^{3} \qquad \text{for } r_1 \ge r, r_2 \ge r. \tag{28.5.72}$$

Plugging β_j, h_j and ν_j one observes easily that the former is a growing and the latter is a decaying function of r_j and these expressions coincide at $r_1 = r_2 = r$. To decouple singularities we need to consider $r \le \epsilon d$ where d is the minimal distance between singularities; so we will assume this. Observe that extra terms appear only if $r_j \ge \epsilon d$, so we need to consider only (28.5.72).

Therefore if $d \le \bar{r}$ the summation results in expression (28.5.72) calculated at $r_1 = r_2 = d$ which is

$$C\beta^2 h^{-\frac{14}{9}} (\kappa\beta)^{\frac{10}{9}} |\log h|^K d^{-\frac{32}{9}} r^3,$$

which results in the original settings in[33)]

$$CT' r^3 = C(\alpha B)^{\frac{19}{9}} B d^{-\frac{32}{9}} r^3; \tag{28.5.73}$$

recall that we plug β, h, κ, replace d and r by $Z^{\frac{1}{3}} d$ and $Z^{\frac{1}{3}} r$, and multiply by $\alpha Z^{\frac{5}{3}}$.

Meanwhile, using our standard arguments one can prove easily that the contribution of the boundary zone is less than this provided $(Z-N)_+ \le B^{\frac{5}{12}}$.

On the other hand, for $B^{\frac{5}{12}} \le (Z-N)_+ \le B^{\frac{3}{4}}$ an extra contribution of the boundary zone does not exceed

$$C\beta^2 h^{-3} \bar{\gamma}^{13} \bar{r}^{-5} r^3 (1 + |\log \bar{\gamma}|)^2,$$

which results in the original settings in[33)]

$$CT'' r^3 = C\alpha (Z-N)_+^{\frac{13}{4}} B^{\frac{13}{16}} \big(1 + |\log (Z-N)_+ B^{-\frac{3}{4}}|\big)^2 r^3. \tag{28.5.74}$$

[33)] I.e. after we plug κ, β, h, replace d and r by $Z^{\frac{1}{3}} d$ and $Z^{\frac{1}{3}} r$ and multiply by $\alpha Z^{\frac{5}{3}}$.

Finally, for $(Z-N)_+ \ge B^{\frac{3}{4}}$ an extra contribution of the boundary zone does not exceed

$$C\beta^2 h^{-3}\bar{r}^{-5}r^3,$$

which results in the original settings in[33)]

$$CT''r^3 = C\alpha(Z-N)_+^{\frac{5}{3}}B^2. \tag{28.5.75}$$

Thus we have proven

Proposition 28.5.21. *Let $V = W_B^{\mathsf{TF}} + \lambda$ be Thomas-Fermi potential with $B \le Z^{\frac{4}{3}}$, $N \asymp Z_1 \asymp Z_2 \asymp ... \asymp Z_M$ and $M \ge 2$. Let $r_* \ll r \ll d \le \epsilon\bar{r}$.*

Then expression

$$\alpha^{-1}\int_{\{x:\, \ell(x)\asymp r\}} |\partial A'|^2\,dx \tag{28.5.76}$$

does not exceed $C\big(T_0 r^{-3} + (T'+T'')r^3\big)$ with T_0 defined by (28.5.68) *or* (28.5.69) *and T' defined by* (28.5.73)*, and T'' either 0 (as $(Z-N)_+ \le B^{\frac{5}{12}}$) or defined by* (28.5.74)*, or* (28.5.75)*.*

Remark 28.5.22. (i) Recall that the decoupling error between the singularity and the regular part does not exceed $C\alpha BZ^{\frac{5}{3}}$.

(ii) Meanwhile in these settings $\mathsf{Scott} - \mathsf{Scott}_0 = O(\alpha Z^3)$ and if decoupling error is greater than this there is no point in decoupling.

(iii) Obviously we need to assume that $r_* \le \epsilon\bar{r}$ which implies that

$$(\alpha Z)^{40} B^{\frac{369}{4}} \le \epsilon Z^{121}, \tag{28.5.77}$$

which is just tiny bit stronger than $\alpha Z \lesssim 1$, $B \lesssim Z^{\frac{4}{3}}$. For $(Z-N)_+ \le B^{\frac{3}{4}}$ this condition is also sufficient.

(iv) Decoupling singularities we get an error (28.5.76) with integration over $\{x:\, \ell(x) \asymp r\}$; therefore if $r_* \ll d \le \bar{r}$ then minimizing $T_0 r^{-3} + T'r^3$ by $r : r_* \le r \le d$ we get

$$T_* := \big(T_0(T'+T'')\big)^{\frac{1}{2}} + (T'+T'')r_*^3 + T_0 d^{-3}. \tag{28.5.78}$$

28.5.7 Endgame: $M \ge 2$

For $M \ge 2$ we have two rather different results. In the first (28.5.39) we appeal to the sum of localized trace terms $\sum_{1\le m\le M} \mathsf{Tr}(\psi_m H^-_{A,V_m}\psi_m)$ where ψ_m is supported in $\{x\colon |x-y_m|\le \frac{1}{3}d\}$ (recall that d is the minimal distance between singularities).

In the second one we want to use $2h^{-2}\sum S(\alpha Z_m)Z_m^2$ instead. If $A'=0$ then transition would be immediate. However in our case we need to "decouple" singularities. Therefore in the estimate from below we need results from the previous subsubsection:

Theorem 28.5.23. *Let $V = W_B^{\mathsf{TF}} + \lambda$ be a Thomas-Fermi potential with $B \le Z^{\frac{4}{3}}$, $N \asymp Z$ and $M \ge 2$. Let $\kappa = \alpha Z \le \kappa^*$. Then if $r_* \le d \le \bar r$*

$$|\mathsf{E}^*_\alpha + \int P_B(V)\,dx - 2\sum S(\alpha Z_m)Z_m^2 - \mathsf{Schwinger}| \tag{28.5.79}$$

does not exceed $C(Q+T)$ where Q is the trace estimate obtained in Proposition 28.5.12(iii)–(iv) and T_* is an estimate for expression (28.5.76) *given by* (28.5.78).

Proof. (i) In the estimate from below we just replace A' in $\mathsf{E}_\alpha(A)$ by the sum $\sum_{1\le m\le M} A'\psi_m$ with ψ_m supported in $\{x\colon |x-y_m|\le \frac{1}{3}r\}$ and equal 1 in $\{x\colon |x-y_m|\le \frac{1}{4}r\}$ where r is the minimal distance between singularities, and observe that $\alpha^{-1}\|\partial A'\|^2$ increased by no more than CT.

(ii) In the estimate from above we just plug into $\mathsf{E}_\alpha(A)$ $A' = \sum_{1\le m\le M} A'_m\psi_m$ with A'_m minimizers for a single-singularity potential V_m. □

Remark 28.5.24. (i) Theorem 28.5.23 makes sense only if $r_* \ll d \le \bar r$ and $T_* \ll \alpha Z^3$; if any of these assumptions fails, we observe that $\mathsf{E}_\alpha(A')$ is greater than $\mathcal{E}_0 + \mathsf{Schwinger} - CQ - C\alpha Z^3$ and in this case we can replace $S(\alpha Z_m)$ by $S(0)$; in this case in the upper estimate we pick up $A'=0$.

(ii) In the estimate from above $T = \max_m T_m$ with T_m an estimate for a single-singularity potential V_m delivered by Proposition 28.5.19; thus $T = T_0 d^{-3}$ if $r_* \le d \le \bar r$. Still it is at least $C\alpha B^{\frac{3}{4}}Z^2$ while decoupling error of singularity and the regular zone is $C\alpha BZ^{\frac{5}{3}}$ which is smaller.

28.6 Global Trace Asymptotics in the Case of Thomas-Fermi Potential: $Z^{\frac{4}{3}} \le B \le Z^3$

28.6.1 Trace Estimates

In this Section we consider the case of $Z^{\frac{4}{3}} \le B \le Z^3$ (corresponding to $\beta h \ge 1$ after rescaling[34)]). We start with

Remark 28.6.1. (i) In contrast to the previous Section 28.5 in this case the remainder estimate will be at least $C\kappa h^{-2}$ and therefore there will be no difficulty to decouple between singularities or between singularities and a regular zone and the Scott correction term will be either $\sum 2S(0)Z_m^2$ or even absent.

Therefore in the estimate from above we just pick up $A' = 0$ both here and in the multiparticle problem and we will need only N-term and D-terms with $A' = 0$ referring to Chapter 25.

(ii) For $\beta h \ge 1$ we have a major dichotomy unrelated to the self-generated magnetic field:

(a) $\beta h^2 \le 1$ (i.e. $Z^{\frac{4}{3}} \le B \le Z^{\frac{7}{4}}$). In this case Scott correction term could be larger than the contribution of zone $\{x\colon \ell(x) \asymp 1\}$ to the remainder estimate which is no better than $O(\beta)$ and one probably needs to include Scott correction term in the final trace asymptotics.

(b) $\beta h^2 \ge 1$ (i.e. $Z^{\frac{7}{4}} \le B \le Z^3$). In this case the opposite is true; then one does not need to include Scott correction term for sure. Recall that condition $C \le Z^3$ is also unrelated to self-generated magnetic field.

(iii) Recall that we need to impose condition $\kappa\beta h^2 |\log \beta|^K \le 1$ which is equivalent to

$$\alpha B^{\frac{4}{5}} Z^{-\frac{2}{5}} |\log Z|^K \le 1. \tag{28.6.1}$$

[34)] Recall that as $Z^{\frac{4}{3}} \lesssim B \lesssim Z^3$ the scaling is $x \mapsto B^{\frac{2}{5}} Z^{-\frac{1}{5}} x$ (and the original distance between nuclei is at least $B^{-\frac{2}{5}} Z^{\frac{1}{5}}$), $\tau \mapsto B^{-\frac{2}{5}} Z^{\frac{4}{5}} \tau$, $\beta = B^{\frac{2}{5}} Z^{-\frac{1}{5}}$, $h = B^{\frac{1}{5}} Z^{-\frac{3}{5}}$ and $B \lesssim Z^3$.

[35)] Cf. Proposition 28.5.2.

Theorem 28.6.2 [35)]**.** *Let V be Thomas-Fermi potential $V \coloneqq W_B^{\mathsf{TF}} + \lambda$ with $Z^{\frac{4}{3}} \le B \le Z^3$, $N \asymp Z_1 \asymp Z_2 \asymp \dots \asymp Z_M$ and $N \le Z$. Let $\alpha Z \le \kappa^*$ and assumption* (28.6.1) *be fulfilled. Let A' be a minimizer. Then*

(i) If <u>either</u> $(Z-N)_+ \lesssim B^{\frac{4}{15}} Z^{\frac{1}{5}}$ <u>or</u> $M = 1$ and $\alpha B^{\frac{3}{5}} Z^{\frac{1}{5}} \gtrsim 1$, then expression

$$|\mathsf{E}_\kappa(A') - \mathsf{Scott}_0 + \int\int P_B(V(x))\,dx| \tag{28.6.2}$$

does not exceed

$$C\Big(B^{\frac{1}{3}} Z^{\frac{4}{3}} + B^{\frac{4}{5}} Z^{\frac{3}{5}} + \alpha Z^3 + \alpha^{\frac{16}{9}} B^{\frac{82}{45}} Z^{\frac{58}{45}} |\log Z|^K\Big). \tag{28.6.3}$$

(ii) If $M = 1$, $(Z-N)_+ \gtrsim B^{\frac{4}{15}} Z^{\frac{1}{5}}$ and $\alpha B^{\frac{3}{5}} Z^{\frac{1}{5}} \lesssim 1$, then expression (28.6.2) *does not exceed*

$$\begin{aligned} C\Big(B^{\frac{1}{3}} Z^{\frac{4}{3}} + B^{\frac{4}{5}} Z^{\frac{3}{5}} + \alpha Z^3 + \alpha^{\frac{16}{9}} B^{\frac{82}{45}} Z^{\frac{49}{45}} |\log Z|^K \\ + \alpha^{\frac{40}{27}} B^{\frac{74}{45}} Z^{\frac{131}{540}} (Z-N)_+^{\frac{85}{108}} |\log Z|^K\Big). \end{aligned} \tag{28.6.4}$$

(iii) If $M \ge 2$ and $(Z-N)_+ \gtrsim B^{\frac{4}{15}} Z^{\frac{1}{5}}$, then expression (28.6.2) *does not exceed*

$$\begin{aligned} C\Big(B^{\frac{1}{3}} Z^{\frac{4}{3}} + B^{\frac{4}{5}} Z^{\frac{3}{5}} + \alpha Z^3 + \alpha^{\frac{16}{9}} B^{\frac{82}{45}} Z^{\frac{49}{45}} |\log Z|^K \\ + B^{\frac{7}{10}} Z^{\frac{11}{40}} (Z-N)_+^{\frac{5}{8}} |\log (Z-N)_+ Z^{-1}|\Big). \end{aligned} \tag{28.6.5}$$

Proof. (a) Observe first that we need to prove only the estimate from below for expression (28.6.2) without absolute value since in the estimate from above we just pick $A' = 0$ and apply results of Chapter 25 producing estimate $CB^{\frac{4}{5}} Z^{\frac{3}{5}}$.

Proof of the estimate from below repeats the proof of Proposition 28.5.2. Namely, we apply an appropriate partition and on each element ψ_ι^2 estimate from below

$$\mathsf{Tr}^-(\psi_\iota H_{A,V} \psi_\iota) + (C_0\alpha)^{-1} \int |\partial A'|^2\,dx + \int\int P_B(V(x))\psi_\iota^2(x)\,dx \tag{28.6.6}$$

for $\iota \ge 1$ and

$$\mathsf{Tr}^-(\psi_0 H_{A,V}\psi_0) + (C_0\alpha)^{-1}\int |\partial A'|^2\,dx + \int\int P_B(V(x))\psi_0^2(x)\,dx - \mathsf{Scott}_0. \tag{28.6.7}$$

For $B \le Z^2$ we separate zone $\mathcal{X}_0 := \{x\colon \ell(x) \le r_* = B^{-\frac{2}{3}}Z^{\frac{1}{3}}\}$ in which after rescaling $x \mapsto r_*^{-1}x$, $\tau \mapsto r_* Z^{-1}\tau$, we have $\beta = 1$, $h = B^{\frac{1}{3}}Z^{-\frac{2}{3}}$ and $\kappa = \alpha Z$. Then for the corresponding partition element ψ_0^2 expression (28.6.7) in virtue of Chapter 26 does not exceed (by an absolute value)

$$C\bigl(h^{-1} + \kappa|\log\kappa|^{\frac{1}{3}}h^{-\frac{4}{3}}\bigr)\times Zr_*^{-1},$$

which does not exceed (28.6.3) without the last term.

For $B \ge Z^2$ we separate zone $\mathcal{X}_0 := \{x\colon \ell(x) \le r_* = Z^{-1}\}$ and after rescaling $x \mapsto r_*^{-1}x$, $\tau \mapsto Z^{-1}r_*\tau$ we have $h = 1$, $\beta = BZ^{-2}$ and apply variational estimates of Appendix 28.A.1 here. Then the contribution of $\mathcal{X}_0$ to the remainder does not exceed $C\beta \times Zr_*^{-1} = CB \le CB^{\frac{4}{5}}Z^{\frac{3}{5}}$.

(b) Further, a contribution of each regular element with $r_* \le \ell(x) \le \epsilon\bar{r}$ (recall that $\bar{r} = B^{-\frac{2}{5}}Z^{\frac{1}{5}}$) does not exceed

$$C\zeta^2 h_1^{-1}\Bigl(1 + (\kappa_1\beta_1)^{\frac{40}{27}}h_1^{\frac{34}{27}}|\log h_1|^K\Bigr) \qquad \text{for } \beta_1 h_1 \le C_0, \tag{28.6.8}$$

$$C\zeta^2\beta_1\Bigl(1 + (\kappa_1\beta_1)^{\frac{16}{9}}h_1^{\frac{14}{9}}|\log h_1|^K\Bigr) \qquad \text{for } \beta_1 h_1 \ge C_0 \tag{28.6.9}$$

with $\zeta = Z^{\frac{1}{2}}\ell^{-\frac{1}{2}}$, $\beta_1 = BZ^{-\frac{1}{2}}\ell^{\frac{3}{2}}$, $h_1 = Z^{-\frac{1}{2}}\ell^{-\frac{1}{2}}$, $\kappa_1 = \alpha Z$. Indeed, if $\beta_1 h_1 \ge C_0$ and $\ell(x) \le \epsilon\bar{r}$, then the super-strong non-degeneracy assumption (28.4.5) is fulfilled.

Observe that the first term in (28.6.8) has ℓ in the negative power and therefore sums to its value at $\ell = r_*$ while the second term has ℓ in the positive power and therefore sums to its value at $\beta_1 h_1 = 1$ (i.e. $\ell = B^{-1}Z$, $h_1 = B^{\frac{1}{2}}Z^{-1}$, $\beta_1 = B^{-\frac{1}{2}}Z$); one can see easily that it is less than αZ^3. Actually this zone appears only as $B \le Z^2$.

On the other hand, both terms in (28.6.9) have ℓ in the positive power and thus sum to their values at $\ell = \bar{r}$, $\beta_1 = B^{\frac{2}{5}}Z^{-\frac{1}{5}}$, $h_1 = B^{\frac{1}{5}}Z^{-\frac{3}{5}}$ and $\kappa_1 = \alpha Z$ which are exactly the second and the fourth terms in (28.6.2).

(c) *Boundary zone* $\{x\colon \epsilon \le \ell(x) \le c\}$ is treated in the same way albeit with $\zeta = B^{\frac{2}{5}} Z^{\frac{4}{5}} \gamma^2$, $\beta_1 = B^{\frac{2}{5}} Z^{-\frac{1}{5}} \gamma^{-1}$, $h_1 = B^{\frac{1}{5}} Z^{-\frac{3}{5}} \gamma^{-3}$ and $\kappa_1 = \alpha Z \gamma^5$ as long as $\gamma \ge C_0 \bar{\gamma}$ (with $\bar{\gamma} = (Z-N)_+^{\frac{1}{4}} Z^{-\frac{1}{4}}$ but reset to $B^{\frac{1}{15}} Z^{-\frac{1}{5}}$ if the latter is larger). Observe that plugging into (28.6.9) we get in both terms γ in the power greater than 2; therefore after summation with respect to partition elements we get expression (28.6.9) with $\gamma = 1$, $\beta_1 = B^{\frac{2}{5}} Z^{-\frac{1}{5}}$, $h_1 = B^{\frac{1}{5}} Z^{-\frac{3}{5}}$ and $\kappa_1 = \alpha Z$.

This proves the lower estimate (28.6.2) in the framework of the first clause of Statement (i) as contribution of the zone $\gamma \le B^{\frac{1}{15}} Z^{-\frac{1}{5}}$ is estimated easily; we leave it to the reader.

(d) Assume now that $(Z-N)_+ \ge B^{\frac{4}{15}} Z^{\frac{1}{5}}$. We do not partition zone $\{x\colon \gamma(x) \le C_0 \bar{\gamma}\}$ further. In this case we need to take

$$\nu_1 = \bigl((\kappa_1\beta_1)^{\frac{4}{3}} h_1^{\frac{2}{3}} + (\kappa_1\beta_1)^{\frac{10}{9}} h_1^{\frac{4}{9}}\bigr) |\log h_1|^K. \tag{28.6.10}$$

For $M = 1$ we should plug it into

$$C\zeta^2 \beta_1 \bigl(1 + h_1^{\frac{2}{3}} \nu_1^{\frac{4}{3}}\bigr) \gamma^{-2} \tag{28.6.11}$$

with $\zeta = B^{\frac{2}{5}} Z^{\frac{4}{5}} \gamma^2$ and $\gamma = \bar{\gamma}$.

For $\kappa\beta h \gtrsim 1$ we estimate it by the same expression with $\bar{\gamma}$ replaced by 1 but then in ν_1 dominates the first term and we arrive to the lower estimate (28.6.2) in the framework of the second clause of Statement (i).

(e) For $M = 1$ and $\kappa\beta h \lesssim 1$ we need to take into account term (28.6.11) with $\nu_1 = (\kappa_1\beta_1)^{\frac{10}{9}} h_1^{\frac{4}{9}} |\log h_1|^K$ which results in the last term in (28.6.4). Indeed, as $\gamma(x) \le C_0 \bar{\gamma}$ super-strong non-degeneracy condition is not fulfilled.

(f) For $M \ge 2$, we need to take into account term $C\zeta^2 \beta_1 h_1^{-\frac{1}{2}} \gamma^{-2} (1 + |\log \gamma|)$ with $\gamma = \bar{\gamma}$ which results in the last term in (28.6.5). This concludes estimate from below. □

Corollary 28.6.3. *In the framework of Theorem 28.6.2(i), (ii), (iii) expression* $\|\partial A'\|^2$ *does not exceed expressions* (28.6.3), (28.6.4) *and* (28.6.5) *respectively, multiplied by* α.

Proof. Indeed, the same estimates hold with α replaced by 2α. □

The same methods lead us to a similar result for $B \lesssim Z^{\frac{4}{3}}$ (we leave the oproof to the reader):

Theorem 28.6.4. *Let V be Thomas-Fermi potential $W_B^{\mathsf{TF}}+\lambda$ with $B \le Z^{\frac{4}{3}}$, $N \asymp Z_1 \asymp Z_2 \asymp ... \asymp Z_M$ and $N \le Z$. Let $\alpha Z \le \kappa^*$. Let A' be a minimizer. Then*

(i) If either $(Z-N)_+ \lesssim B^{\frac{5}{12}}$ or $M=1$, then expression

$$|\mathsf{E}_\kappa(A') - \mathsf{Scott}_0 + \int\int P_B(V(x))\,dx| \tag{28.6.12}$$

does not exceed

$$C\Big(B^{\frac{1}{3}}Z^{\frac{4}{3}} + Z^{\frac{5}{3}} + \alpha Z^3\Big);. \tag{28.6.13}$$

(ii) If $M \ge 2$ and $B^{\frac{5}{12}} \lesssim (Z-N)_+ \lesssim B^{\frac{3}{4}}$, then expression (28.6.12) *does not exceed*

$$C\Big(B^{\frac{1}{3}}Z^{\frac{4}{3}} + Z^{\frac{5}{3}} + \alpha Z^3 + B^{\frac{29}{32}}(Z-N)_+^{\frac{5}{8}}|\log(Z-N)_+B^{-\frac{3}{4}}|\Big). \tag{28.6.14}$$

(iii) If $M \ge 2$ and $(Z-N)_+ \gtrsim B^{\frac{3}{4}}$, then expression (28.6.12) *does not exceed*

$$C\Big(B^{\frac{1}{3}}Z^{\frac{4}{3}} + Z^{\frac{5}{3}} + \alpha Z^3 + B(Z-N)_+^{\frac{1}{2}}\Big). \tag{28.6.15}$$

28.6.2 Estimates to a Minimizer

Observe that only terms $B^{\frac{1}{3}}Z^{\frac{4}{3}}$ and αZ^3 are associated with the singularities and they are definitely smaller than $B^{\frac{4}{5}}Z^{\frac{3}{5}}$ if $B \gtrsim Z^{\frac{7}{4}}$. Therefore for $B \gtrsim Z^{\frac{7}{4}}$ we do not expect estimate for $\mathsf{D}(\rho_\Psi - \rho_B,\, \rho_\Psi - \rho_B)$ better than expressions (28.6.3)–(28.6.5).

However for $B \lesssim Z^{\frac{7}{4}}$ to improve such estimate we need to study a minimizer. We assume that the remainder in Theorem 28.6.4 does not exceed $C\big(B^{\frac{1}{3}}Z^{\frac{4}{3}} + \alpha Z^3\big)$ and therefore

$$\|\partial A'\| \le C\alpha^{\frac{1}{2}}B^{\frac{1}{6}}Z^{\frac{2}{3}} + C\alpha Z^{\frac{3}{2}} \tag{28.6.16}$$

or, after our usual scaling,

$$\|\partial A'\| \le \varsigma := C\big(\kappa + \kappa^{\frac{1}{2}}\beta^{\frac{1}{6}}h^{\frac{1}{2}}\big). \tag{28.6.17}$$

Observe that for $Z^{\frac{4}{3}} \le B \le Z^2$ we have all zones.

Proposition 28.6.5. *Let V be Thomas-Fermi potential $W_B^{\mathsf{TF}}+\lambda$ rescaled with $Z^{\frac43}\le B\le Z^3$, $N\asymp Z_1\asymp Z_2\asymp ...\asymp Z_M$ and $N\le Z$. Further, let $\alpha Z\lesssim 1$ and $\alpha B^{\frac25}Z^{-\frac25}|\log\beta|^K\lesssim 1$. Then under assumption* (28.6.17) *the minimizer A' satisfies*

(i) If $\ell\le r_*=h^2$ (i.e. $h_1\ge 1$) then

$$|\partial^2 A'|\le C\varsigma h^{-5}. \tag{28.6.18}$$

(ii) If $r_*\le\ell\le c(\beta h)^{-1}$ (i.e. $h_1\le 1$, $\beta_1 h_1\le c$), then

$$\begin{aligned}|\partial^2 A'|\le C\kappa\Big(\varsigma\ell^{-\frac52}+\min\big(\beta^{\frac32}h^{\frac12}\ell^{-1},\ \beta^{\frac12}\ell^{-\frac34}\big)\Big)|\log\ell/r_*|\\ +C(\kappa\beta)^{\frac{10}{9}}h^{\frac49}\ell^{-\frac{19}{9}}|\log\ell/r_*|^K.\end{aligned} \tag{28.6.19}$$

(iii) If $c(\beta h)^{-1}\le\ell\le c$, then

$$\begin{aligned}|\partial^2 A'|\le C\varsigma\ell^{-\frac52}+C\kappa\beta^{\frac12}\ell^{-\frac74}|\log\ell/r_*|\\ +C\Big((\kappa\beta)^{\frac{10}{9}}h^{\frac49}\ell^{-\frac{19}{9}}+(\kappa\beta)^{\frac43}h^{\frac23}\ell^{-\frac56}\Big)|\log\ell/r_*|^K.\end{aligned} \tag{28.6.20}$$

Proof. The proof of these two propositions repeats our standard arguments and is left to the reader. □

These propositions may not provide the best D-term estimate as $\kappa\beta h\le 1$ (i.e. $\alpha B^{\frac35}Z^{\frac15}\le 1$) and could be improved in virtue of the super-strong non-degeneracy assumption fulfilled at regular elements with $\ell\ge c(\beta h)^{-1}$ and at border elements with $\gamma\ge C_0\bar\gamma$. We want to improve term containing $(\kappa\beta)^{\frac{10}{9}}h^{\frac48}\ell^{-\frac{19}{9}}$ in (28.6.20). Assume now that $\beta h^2\le 1$ and $\kappa\beta h\le 1$ (case we need to cover). Let us consider zone $\{x:(\epsilon_0\beta h\ge V(x)\ge C_0|\eta|\}$ where in the corresponding scale super-strong non-degeneracy condition is fulfilled and $\eta=\lambda B^{-\frac25}Z^{\frac15}$.

Proposition 28.6.6. *Let conditions of Proposition 28.6.5 be fulfilled. Then*

(i) Estimate

$$|\partial^2 A'(x)|\le C\Big(\varsigma\ell^{-\frac52}+\kappa\beta^{\frac12}\ell(x)^{-\frac74}+(\kappa\beta)^{\frac43}h^{\frac23}\ell(x)^{-\frac56}\Big)|\log h|^K \tag{28.6.21}$$

holds provided

$$\beta h|\log h|^{-\delta}\ge V(x)\ge|\eta|\cdot|\log h|^{\delta} \tag{28.6.22}$$

with arbitrarily small exponent $\delta>0$.

(ii) Furthermore, if $|\eta| \le |\log h|^{-\delta}$*, then estimate*

$$|\partial^2 A'(x)| \le C\Big(\varsigma + \kappa\beta^{\frac12} + (\kappa\beta)^{\frac43} h^{\frac23} + (\kappa\beta)^{\frac{10}{9}} h^{\frac49} \bar\gamma^{\frac{28}{9}}\Big) |\log h|^K \tag{28.6.23}$$

holds provided $|V(x)| \lesssim 1$, $\bar\gamma = |\eta|^{\frac14}$.

Proof. (i) Let

$$\nu_n(t) = \sup_{\mathcal{X}_n(t)} |\partial^2 A'(x)| \ell(x)^{\frac52}, \qquad \mathcal{X}_n(t) = \{e^{-\epsilon n-1} t \le V(x) \le e^{\epsilon n+1} t\}.$$

Here $\epsilon > 0$ is arbitrarily small (but constants may depend on it). Assume that

$$e^{\epsilon n} t \le \epsilon_0, \qquad e^{-\epsilon n} t \ge C_0 |\eta|, \qquad e^{\epsilon n} \le |\log h|. \tag{28.6.24}$$

Here first two conditions assure that in $\mathcal{X}_n(t)$ the super-strong non-degeneracy assumption is fulfilled after rescaling and the last condition assures that $\ell(x)$ remains the same (modulo logarithmic factor) here. Then

$$\nu_n(t) \le C\Big(\varsigma + \kappa\beta_1^{\frac12} + C\kappa_1\beta_1 h_1^{\frac14} (\nu_{n+1}(t))^{\frac14}\Big) |\log h|^{K_1} \tag{28.6.25}$$

with $\kappa_1 = \kappa$, $\beta_1 = \beta r^{\frac32}$, $h_1 = h r^{-\frac12}$, $r = \min(t^{-1}, 1)$. Indeed, $|\Delta A'|$ in $\mathcal{X}_{n+1/2}(t)$ does not exceed the right-hand expression (without term ς and without logarithmic factor) multiplied by $r^{-\frac52}$ and $C\varsigma$ estimates $\mathscr{L}^2$-norm of $\partial A'$ (and we scale it properly). Recall that we scale $x \mapsto x/r$ if $r \le \epsilon_0$ and $x \mapsto x/\gamma$ if $r \asymp 1$ and in the latter case $\beta_1 = \beta\gamma^{-1}$, $h_1 = h\gamma^{-3}$ and $\kappa_1 = \kappa\gamma^5$; the uncertainty due to r or γ defined modulo logarithmic factor compensates by $|\log h|^{K_1}$ in the right-hand expression of (28.6.25).

Therefore

$$F_n(t) \le C\Big(\varsigma r^{-\frac53} + C\kappa\beta^{\frac12} r^{-\frac{11}{12}} + C\kappa\beta h^{\frac12} \times (F_{n+1}(t))^{\frac14}\Big) |\log h|^{K_1}$$

for $F_n(t) = \nu_n(t) r^{-\frac53}$. Iterating we see that

$$F_0(t) \le C\Big(\varsigma r^{-\frac53} + \kappa\beta^{\frac12} r^{-\frac{11}{12}}\Big) |\log h|^K + C(\kappa\beta h^{\frac12})^{\frac43} |\log h|^K \times \underbrace{(F_{n+1}(t))^{\frac{1}{4^n}}}.$$

Since $F_{n+1}(r) \le h^{-L}$ the last factor is bounded by a constant if $2^n \ge |\log h|$ and we can satisfy this and (28.6.24) as long as (28.6.22) holds. This proves Statement (i).

(ii) Consider the remaining zone $\mathcal{Y} = \{x\colon V(x) \le |\eta| \cdot |\log h|^{\delta}\}$ and let $\nu = \sup_{\mathcal{Y}} |\partial^2 A'|$. Observe that in $\mathcal{Y}$ $|\Delta A'|$ does not exceed

$$C\Big(\kappa\beta^{\frac12} + \kappa\beta h^{\frac12}|\nu|^{\frac14} + \kappa\beta h^{\frac25}\bar\gamma^{\frac{14}{5}}\nu^{\frac{1}{10}}\Big)|\log h|^{K}$$

and on its border (28.6.23) is fulfilled. It implies that (28.6.23) is fulfilled in $\mathcal{Y}$ as well. This proves Statement (ii). □

Remark 28.6.7. If $|\eta| \ge |\log h|^{-\delta}$ then Proposition 28.6.5 is sufficiently good in the remaining zone $\mathcal{Y}$.

28.6.3 N-Term Asymptotics and D-Term Estimates

We leave to the reader not complicated but rather tedious and error-prone task

Problem 28.6.8. Estimate remainder in N-term

$$|\int \big(e(x,x,\lambda') - P_B(V(x)+\lambda')\big)\,dx| \tag{28.6.26}$$

and D-term

$$\mathsf{D}\big(e(x,x,\lambda') - P_B(V(x)+\lambda'),\ e(x,x,\lambda') - P_B(V(x)+\lambda')\big). \tag{28.6.27}$$

After usual rescaling one needs to consider the following zones:

(a) Zone $\{x\colon \ell(x) \le (\beta h)^{-1}|\log h|^{\delta}\}$. In this zone one should use $\beta_1 = \beta\ell^{\frac32}$, $h_1 = h\ell^{-\frac12}$ and $\nu_1 = (\kappa\beta_1)^{\frac{10}{9}} h_1^{\frac49}|\log h_1|^{K}$ (other terms are not important here); then its contributions to expressions (28.6.26) and (28.6.27) do not exceed respectively $C\big(h_1^{-2} + h_1^{-\frac53}\nu_1^{\frac23}\big)$ and $C\big(h_1^{-2} + h_1^{-\frac53}\nu_1^{\frac23}\big)^2\ell^{-1}$ (for $\ell(x) \lesssim (\beta h)^{-1}$ but slight extension just adds some logarithmic factor). In the final tally $\ell = (\beta h)^{-1}|\log h|^{\delta}$.

(b) Zone $\{x\colon (\beta h)^{-1}|\log h|^{\delta} \le \ell(x) \le |\log h|^{-\delta}\}$. In this zone we have the same expressions for h_1 and β_1 and $\nu_1 = (\kappa\beta_1)^{\frac43} h_1^{\frac23}|\log h_1|^{K}$; then its contributions to expressions (28.6.26) and (28.6.27) do not exceed respectively $C\beta_1\big(h_1^{-1} + h_1^{-\frac23}\nu_1^{\frac23}\big)$ and $C\beta_1^2\big(h_1^{-1} + h_1^{-\frac23}\nu_1^{\frac23}\big)^2\ell^{-1}$. In the final tally $\ell = 1$.

(c) Zone $\{x\colon \ell(x) \ge |\log h|^{-\delta},\ \gamma(x) \ge \bar{\gamma}|\log h^{\delta}\}$. In this zone $h_1 = h\gamma^{-3}$ and $\beta_1 = \beta\gamma^{-1}$ and $\nu = (\kappa\beta)^{43} h^{\frac{2}{3}} |\log h|^{K}$ but we use according to Remark 28.5.9 instead $\nu_1 = \kappa_1\beta_1 h_1^{\frac{1}{4}}\nu^{\frac{1}{4}}$ with $\kappa_1 = \kappa\gamma^{5}$. Then

(c_1) For $M = 1$ contributions of γ-element to expressions (28.6.26) and (28.6.27) do not exceed $C\beta_1\bigl(h_1^{-1} + h_1^{-\frac{2}{3}}\nu_1^{\frac{2}{3}}\bigr)$ and $C\beta_1^2\bigl(h_1^{-1} + h_1^{-\frac{2}{3}}\nu_1^{\frac{2}{3}}\bigr)^2$ respectively.

(c_2) As $M \ge 2$ contributions of γ-element to expressions (28.6.26) and (28.6.27) do not exceed respectively $C\beta_1 h_1^{-1}\nu_1^{\frac{1}{2}}$ and $C\beta_1^2 h_1^{-2}\nu_1$.

In the final tally $\gamma = 1$ in both cases (c_1) and (c_2).

(d) Then for $M = 1$ contributions of $\bar{\gamma}$-element to expressions (28.6.26) and (28.6.27) do not exceed respectively (in comparison to what we have already) $C\beta_1 h_1^{-\frac{2}{3}}\nu_1^{\frac{2}{3}}$ and $C\beta_1^2 h_1^{-\frac{4}{3}}\nu_1^{\frac{4}{3}}$ with $\nu_1 = (\kappa\beta)^{\frac{10}{9}} h_1^{\frac{4}{9}}\bar{\gamma}^{\frac{58}{27}}|\log h|^{K}$.

On the other hand, for $M \ge 2$ contributions of $\bar{\gamma}$-element to expressions (28.6.26) and (28.6.27) do not exceed respectively (in comparison to what we have already) $C\beta_1 h_1^{-\frac{3}{2}}$ and $C\beta_1^2 h_1^{-3}$.

Let us partially summarize what we got. Let $\kappa\beta h \gtrsim 1$. Then for $M = 1$ the final results are $C\beta\bigl(h^{-1} + h^{-\frac{2}{9}}(\kappa\beta)^{\frac{8}{9}}|\log h|^{K}\bigr)$ and the same expression squared. On the other hand, for $M \ge 2$ the final results from all zones except $\{x\colon \gamma(x) \le C_0\bar{\gamma}\}$ are $C\beta h^{-\frac{1}{3}}(\kappa\beta)^{\frac{2}{3}}|\log h|^{K}$ and the same expression squared.

On the other hand, let $\kappa\beta h \lesssim 1$. Then for $M = 1$ the final results do not exceed $C\beta\bigl(h^{-1} + h^{-\frac{10}{27}}(\kappa\beta)^{\frac{20}{27}}|\log h|^{K}\bigr)$ and the same expression squared.

28.7 Applications to Ground State Energy

28.7.1 Preliminary Remarks

Recall that we are looking for

$$\langle \mathsf{H}\Psi, \Psi\rangle + \frac{1}{\alpha}\int |\partial A'|^2\, dx, \tag{28.7.1}$$

which should be minimized by $\Psi \in \mathfrak{H}$ and A'.

We know (see f.e. Subsection 25.2.1) that

$$\langle \mathsf{H}\Psi, \Psi\rangle \ge \mathsf{Tr}^-(H_{A,W+\lambda'}) + \lambda' N + \frac{1}{2}\mathsf{D}(\rho_\Psi - \rho,\ \rho_\Psi - \rho) - \frac{1}{2}\mathsf{D}(\rho,\ \rho) - C\int \rho_\Psi^{\frac{4}{3}}\,dx, \tag{28.7.2}$$

where $W = V - |x|^{-1} * \rho$, V is a Coulomb potential of nuclei, ρ and $\lambda \le 0$ are arbitrary.

Therefore to derive an estimate from below for expression (28.7.1) we just need to pick up ρ and λ' but we cannot pick up A'. Let us select ρ and λ equal to Thomas-Fermi density $= \rho_B^{\mathsf{TF}}$ and chemical potential λ respectively (but if $N \approx Z$ it is beneficial to pick up $\lambda' = 0$), add $\alpha^{-1}\int |\partial A'|^2\,dx$, and apply trace asymptotics without any need to consider N- or D-terms and we have an estimate from below which includes also "bonus term" $\frac{1}{2}\mathsf{D}(\rho_\Psi - \rho,\ \rho_\Psi - \rho)$ and is as good as a remainder estimate in the trace asymptotics rescaled–provided we estimate properly the last term in (28.7.2).

Thus here we are missing only estimate for $\int \rho_\Psi^{\frac{4}{3}}\,dx$ or more sophisticated estimate if we are interested in Dirac and Schwinger correction terms. We will prove in Appendix 28.A.2 that in the electrostatic inequality for near ground-state one can replace this term $-C\int \rho_\Psi^{\frac{4}{3}}\,dx$ by $-CZ^{\frac{5}{3}}$ for $B \le Z^{\frac{4}{3}}$ and $-CB^{\frac{4}{5}}Z^{\frac{3}{5}}$ for $Z^{\frac{4}{3}} \le B \le Z^3$; further, for $B \le Z$ one can replace it by $\mathsf{Dirac} - CZ^{\frac{5}{3}-\delta}$ thus proving Bach-Graf-Solovej estimate in our current settings.

Therefore due to these arguments estimates from below in Theorems 28.7.4 and 28.7.5 follow immediately from Theorems 28.5.14, 28.5.16 and 28.5.23 for $B \le Z^{\frac{4}{3}}$ and estimates from below in Theorem 28.7.11 follow immediately from Theorems 28.6.2 and 28.6.4 for $Z^{\frac{4}{3}} \le B \le Z^3$.

On the other hand, an estimate from above involves picking up ρ (which we select to be ρ_B^{TF} again) and picking A' as well–which we choose as in upper estimates of Section 28.5 (rescaled) and also picking up Ψ which we select $\phi_1(x_1,\varsigma_1)\cdots\phi_N(x_N,\varsigma_N)$ anti-symmetrized by $(x_1,\varsigma_1),\dots,(x_N,\varsigma_N)$ but we do not select λ' in the trace asymptotics which *must* be equal to λ_N, which is N-th eigenvalue of $H_{W,A}$ or to 0 if there are less than N negative eigenvalues of $H_{W,A}$.

In this case we need to estimate $|\lambda' - \lambda|$ and also

$$\mathsf{D}\bigl(\mathsf{tr}\, e(x,x,\lambda') - \rho_B^{\mathsf{TF}},\ \mathsf{tr}\, e(x,x,\lambda') - \rho_B^{\mathsf{TF}}\bigr), \tag{28.7.3}$$

which required some efforts in Chapters 25–27 but here we will do it rather easily because in Section 28.5 we took either A' equal to one for Coulomb potential and without external magnetic field (as $\beta h^2 \le 1$) or just 0 (as $\beta h^2 \ge 1$).

28.7.2 Estimate from above: $B \le Z^{\frac{4}{3}}$

Recall that now we can select ρ and A' but cannot select λ'.

If $B \le Z^{\frac{4}{3}}$ (or $\beta h \le 1$ after rescaling) we select A' as a minimizer for one-particle operator with Coulomb potential and without external magnetic field. Then after rescaling $x \mapsto Z^{\frac{1}{3}}x$, $\tau \mapsto Z^{-\frac{4}{3}}\tau$, $h = 1 \mapsto h = Z^{-\frac{1}{3}}$, $B \mapsto \beta = BZ^{-1}$, $\alpha \mapsto \kappa = \alpha Z$

$$|\partial A'| \le C\kappa\ell^{-\frac{3}{2}}, \qquad |\partial^2 A'| \le C\kappa\ell^{-\frac{5}{2}}|\log(\ell/h^2)|, \tag{28.7.4}$$

or before it

$$|\partial A'| \le C\alpha Z^{\frac{5}{3}}\ell^{-\frac{3}{2}}, \qquad |\partial^2 A'| \le C\alpha Z^{\frac{5}{3}}\ell^{-\frac{5}{2}}|\log(Z\ell)|. \tag{28.7.5}$$

Let us start from the easy case $M = 1$. We need the following

Proposition 28.7.1. *Let $M = 1$, $N \asymp Z$, $B \lesssim Z^{\frac{4}{3}}$ and $\alpha Z \le \kappa^*$. Assume that A' satisfies* (28.7.5)*. Then*

(i) The remainder in the trace asymptotics does not exceed

$$\begin{cases} C\bigl(Z^{\frac{5}{3}} + \alpha|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}}\bigr) & \text{for } B \le Z, \\ C\bigl(B^{\frac{1}{3}} Z^{\frac{4}{3}} + \alpha|\log(\alpha Z)|^{\frac{1}{3}} B^{\frac{2}{9}} Z^{\frac{23}{9}}\bigr) & \text{for } B \ge Z. \end{cases} \tag{28.7.6}$$

(ii) The remainder in N*-term asymptotics does not exceed $CZ^{\frac{2}{3}}$.*

(iii) D*-term does not exceed $CZ^{\frac{5}{3}}$.*

Proof. We cannot directly apply previous results because A' is now generated by much slower decaying Coulomb potential. The good news however is that A' is generated without presence of the external magnetic field. Let us scale as we mentioned above.

(i) Consider the remainder estimate in the trace asymptotics.

(ia) A contribution of the near singularity zone $\{x\colon \ell(x) \le \ell^* = \epsilon\,\mathsf{min}(\beta^{-\frac{2}{3}}, 1)\}$ does not exceed

$$\begin{cases} C(h^{-1} + \kappa|\log\kappa|^{\frac{1}{3}} h^{-\frac{4}{3}}) & \text{as } \beta \le 1,\\ C(\beta^{\frac{1}{3}} h^{-1} + \kappa|\log\kappa|^{\frac{1}{3}} \beta^{\frac{2}{9}} h^{-\frac{4}{3}}) & \text{as } \beta \ge 1. \end{cases} \tag{28.7.7}$$

(ib) A contribution of ℓ-element in the regular zone $\{x\colon \ell(x) \ge \ell^*\}$ does not exceed $C\zeta^2\big(h_1^{-1} + h_1^{-\frac{1}{3}}\nu_1^{\frac{2}{3}}\big)$. We plug $h_1 = h/(\zeta\ell)$, and in virtue of (28.7.4) $\nu_1 = \kappa\ell^{-\frac{5}{2}}\cdot \ell^3\zeta^{-1} = \kappa\ell^{\frac{1}{2}}\zeta^{-1}$. Taking a sum we arrive to the same expression at $\ell = \ell^*$ i.e. expression (28.7.7). Scaling back we arrive to (28.7.6).

(ic) We leave analysis of the boundary zone to the reader. It requires just repetition of the corresponding arguments of Section 28.5.

(ii) Next let us consider a remainder estimate in the N-term asymptotics.

(iia) Note that a contribution of ℓ-element in the regular zone does not exceed $C\big(h_1^{-2} + h_1^{-\frac{5}{3}}\nu_1^{\frac{1}{3}}\big)$. Then plugging h_1, ν_1 we arrive after summation to the same expression at $\ell = 1$ i.e. Ch^{-2}. One can prove easily that the contribution of the near singularity zone is $O(h^{-2+\delta})$.

Consider the contribution of the boundary zone. Note that this zone appears only if $B \ge (Z-N)_+^{\frac{4}{3}}$. Let us scale $x \mapsto x\bar\ell^{-1}$, $\tau \mapsto \bar\ell^{-4}\tau$, with $\bar\ell = (\beta h)^{-\frac{1}{4}}$. Then $h \mapsto h_1 = h^{\frac{3}{4}}\beta^{-\frac{1}{4}}$, $\beta \mapsto \beta_1 = h_1^{-1}$ and after scaling A' satisfies $|\partial^2 A'| \le \nu_1 = C\kappa\bar\ell^{\frac{3}{2}}|\log\kappa|$.

(iib) Consider a contribution of γ-element; scaling again $x \mapsto x\gamma^{-1}$, $\tau \mapsto \gamma^{-4}\tau$, $h_1 \mapsto h_2 = h_1\gamma^{-3}$, $\beta_1 \mapsto \beta\gamma^{-1}$, $\nu_1 \mapsto \nu_2 = \nu_1$ we see that it does not exceed $C\beta_2\big(h_2^{-1} + h_2^{-\frac{2}{3}}\nu_2^{\frac{2}{3}}\big) = C\beta_1\big(\gamma^2 h_1^{-1} + \gamma h_1^{-\frac{2}{3}}\nu_1^{\frac{2}{3}}\big)$. This expression must be divided by γ^2 and summed resulting in

$$C\big(h_1^{-2}|\log\bar\gamma| + \bar\gamma^{-1}h_1^{-\frac{5}{3}}\nu_1^{\frac{2}{3}}\big) \tag{28.7.8}$$

with $\bar\gamma \ge h_1^{\frac{1}{3}}$ (equality is achieved if $(Z-N)_+$ is small enough, otherwise partitioning may be cut-off by a chemical potential). One can get rid of the logarithmic factor by our standard propagation arguments; the second term in (28.7.8) does not exceed $Ch_1^{-2}\nu_1^{\frac{2}{3}}$ and plugging h_1, ν_1 we get $O(h^{-2}) = O(Z^{\frac{2}{3}})$.

(iii) D-term is analyzed in the same way. □

Proposition 28.7.2. *In the framework of Proposition 28.7.1 assume that $B \le Z$. Then*

(i) The remainder in the trace asymptotics (with the Schwinger term) does not exceed

$$CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + (BZ^{-1})^{\delta}\bigr) + \alpha|\log(\alpha Z)|^{\frac{1}{3}}Z^{\frac{25}{9}}. \tag{28.7.9}$$

(ii) The remainder in N-term asymptotics does not exceed $CZ^{\frac{2}{3}}\bigl(Z^{-\delta} + (BZ^{-1})^{\delta} + (\alpha Z)^{\delta}\bigr)$.

(iii) D-term does not exceed $CZ^{\frac{5}{3}}\bigl(Z^{-\delta} + (BZ^{-1})^{\delta} + (\alpha Z)^{\delta}\bigr)$.

Proof. Proof includes improved (due to the standard arguments of propagation of singularities) estimates of the contributions of *threshold zone* $\{x\colon h^{\delta'} \le \ell(x) \le h^{-\delta'}\}$ after rescaling. We leave details to the reader. □

Since we now have exactly the same N-term asymptotics and the same remainder term estimate as in Subsection 26.6.3 as if there was no self-generated magnetic field we immediately arrive to the same estimates of $|\lambda_N - \lambda|$ as there and therefore to the same estimates for $|\lambda_N - \lambda|\cdot N$ and not only for two D-terms

$$\mathsf{D}\bigl(\operatorname{tr} e(x,x,\tau) - P'_B(W+\tau),\ \operatorname{tr} e(x,x,\tau) - P'_B(W+\tau)\bigr)$$

with $\tau = \lambda$ and $\tau = \lambda_N$ but also for the third one

$$\mathsf{D}\bigl(P'_B(W+\lambda_N) - P'_B(W+\lambda),\ P'_B(W+\lambda_N) - P'_B(W+\lambda)\bigr).$$

The trace term however is different–with Scott correction term $2S(\alpha Z)Z^2$ instead of $2S(0)Z^2$ and the remainder estimate here includes an extra term related to α.

It concludes the proof of the estimate from above for E^*_N. Combined with estimate from below it concludes the proof of Theorem 28.7.4.

Consider now the case $M \ge 2$. Since we need to decouple singularities in this case we need sufficiently fast decaying magnetic field and thus potential generating it. So we will take $A' = \sum_m A'_m \phi_m$ with A'_m defined by $V = W^{\mathsf{TF}}_m$

(where $\mathsf{W}_m^{\mathsf{TF}}$ corresponds to a single nucleus) without any magnetic field and with $N = Z$ (i.e. $\lambda = 0$) and ϕ_m is supported in $\{x\colon |x - \mathsf{y}_m \le \frac{1}{3}d\}$ and equals 1 in $\{x\colon |x - \mathsf{y}_m \le \frac{1}{4}d\}$. However everywhere else we take $V = W_B^{\mathsf{TF}}$.

Assume first that $(Z - N)_+$ is sufficiently small and we take $Z = N$ even in the definition of W_B^{TF}. Then one can prove easily that

$$|\operatorname{Tr}^-(H_{A,V}) + \alpha^{-1}\int |\partial A'|^2\,dx + \int P_B(V)\,dx - \mathsf{Scott}| \le (28.7.6) + C\alpha Z^2 d^{-3}, \tag{28.7.10}$$

where the last term is due to decoupling; indeed, $|\partial A'|$ and $|\partial^2 A'|$ decay as ℓ^{-3} and ℓ^{-4} if $\ell \ge Z^{-\frac{1}{3}}$.

Moreover, for $B \le Z$ one can replace (28.7.6) by

$$CZ^{\frac{5}{3}}\big(Z^{-\delta} + (BZ^{-1})^{\delta} + (\alpha Z)^{\delta} + (dZ^{\frac{1}{3}})^{-\delta}\big) + C\alpha|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} \tag{28.7.11}$$

while including $\mathsf{Schwinger}$ into left-hand expression. This estimate is at least as good as what we got in the estimate from below but probably even better since magnetic field admits now better estimates.

Let us estimate $|\lambda_N|$ if $\lambda_N < 0$. To do this consider

$$\int \big[e(x,x,\lambda) - e(x,x,\lambda_N)\big]\,dx \tag{28.7.12}$$

with non-negative integrand. Then the contribution of ℓ-element into the main part of this expression, namely

$$\int \big[e(x,x,\lambda) - e(x,x,\lambda_N)\big]\psi_\iota^2\,dx \tag{28.7.13}$$

is

$$\int \big[P'(x,V(x)+\lambda) - P'(x,V(x)+\lambda_N)\big]\psi_\iota^2\,dx \tag{28.7.14}$$

and it does not depend on A'. On the other hand, since now $|\partial^2 A'|$ admits so good estimate, the contribution of this element to the remainder estimated as if there was no self-generated magnetic field.

The same is true for the boundary elements as well.

But then $|\lambda_N|$ is estimated exactly as if there was no self-generated magnetic field, i.e. exactly as in Section 26.6. But then all components of the estimate from above, with exception of the trace term, namely $|\lambda_N| \cdot N$

and all three D-terms are estimated as in Section 26.6. Under assumption small $(Z-N)_+$ all of them do not exceed $CZ^{\frac{5}{3}}$ which could be improved to

$$CZ^{\frac{5}{3}}\bigl(Z^{-\delta}+(BZ^{-1})^{\delta}+(\alpha Z)^{\delta}+(dZ^{\frac{1}{3}})^{-\delta}\bigr) \tag{28.7.15}$$

for $B\le Z$.

Similarly, if $(Z-N)_+$ is larger than the corresponding threshold, we need to consider two cases: $0>\lambda>\lambda_N$ and $0>\lambda_N>\lambda$ and estimate from below

$$\int \bigl(e(x,x,\lambda)-e(x,x,\lambda_N)\bigr)\psi_\iota^2\,dx \tag{28.7.16}$$

and

$$\int \bigl(e(x,x,\lambda_N)-e(x,x,\lambda)\bigr)\psi_\iota^2\,dx \tag{28.7.17}$$

respectively, leading to the estimate of $|\lambda_N-\lambda|$ and then $|\lambda_N-\lambda|\cdot N$ and all three D-terms and again here these terms are estimated as if there was no self-generating magnetic field.

This concludes the proof of Theorem 28.7.5.

Remark 28.7.3. For $M\ge 2$ one could be concerned about term coming from $C\beta h^{-\frac{1}{2}}$ in the trace term and $C\beta h^{-\frac{3}{2}}$ or its square in N- and D-terms but assuming that $d\lesssim \bar{r}$ we simply have $A'=0$ due to decoupling there and therefore apply theory of Chapter 25 without any modification.

28.7.3 Main Theorems: $B\le Z^{\frac{4}{3}}$

Ground State Energy Asymptotics

Theorem 28.7.4. *Let $M=1$, $N\asymp Z$, $B\le Z^{\frac{4}{3}}$ and $\alpha\le \kappa^* Z^{-1}$ with small constant κ^*. Then*

(i) If $B\le Z$, then

$$\mathsf{E}^*_N=\mathcal{E}^{\mathsf{TF}}_N+\mathsf{Scott}+O\Bigl(Z^{\frac{5}{3}}+\alpha|\log(\alpha Z)|^{\frac{1}{3}}Z^{\frac{25}{9}}\Bigr) \tag{28.7.18}$$

with $\mathsf{Scott}=2Z^2S(\alpha Z)$.

(ii) Moreover, if $B \ll Z$ *and* $\alpha|\log Z|^{\frac{1}{3}} \ll Z^{-\frac{10}{9}}$*, then this estimate could be improved to*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + 2Z^2 S(\alpha Z) + \mathsf{Schwinger} + \mathsf{Dirac} + O\Big(Z^{\frac{5}{3}}\big[Z^{-\delta} + B^{\delta} Z^{-\delta}\big] + \alpha|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}}\Big). \tag{28.7.19}$$

(iii) If $Z \le B \le Z^{\frac{4}{3}}$*, then*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + 2Z^2 S(\alpha Z) + O\Big(B^{\frac{1}{3}} Z^{\frac{4}{3}} + \alpha|\log(\alpha Z)|^{\frac{1}{3}} B^{\frac{2}{9}} Z^{\frac{23}{9}} + \alpha B Z^{\frac{5}{3}}\Big). \tag{28.7.20}$$

Theorem 28.7.5. *Let* $M \ge 2$*,* $N \asymp Z_1 \asymp Z_2 \asymp \dots \asymp Z_M$*,* $B \lesssim Z^{\frac{4}{3}}$*. Let* $\alpha \le \kappa^* Z^{-1}$*,* $d \ge Z^{-\frac{1}{3}}$ *be a minimal distance between nuclei capped by* $\bar{r} = \min\big(B^{-\frac{1}{4}}, (Z-N)_+^{-\frac{1}{3}}\big)$*. Then*

(i) If $B \le Z$*, then*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \mathsf{Scott} + O\Big(Z^{\frac{5}{3}} + \alpha\big[|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^2 d^{-3}\big]\Big) \tag{28.7.21}$$

with $\mathsf{Scott} = 2\sum_{1\le m\le M} Z_m^2 S(\alpha Z_m)$ *and, moreover,*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \mathsf{Scott} + \mathsf{Schwinger} + \mathsf{Dirac} + O\Big(Z^{\frac{5}{3}}\big[Z^{-\delta} + (BZ^{-1})^{\delta} + (dZ^{\frac{1}{3}})^{-\delta}\big] + \alpha\big[|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^2 d^{-3}\big]\Big). \tag{28.7.22}$$

(ii) If $B \ge Z$*,* $\alpha B \le Z^{\frac{17}{60}}|\log Z|^{-K}$ *and* $(Z-N)_+ \le B^{\frac{5}{12}}$*, then*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \mathsf{Scott} + O\Big(B^{\frac{1}{3}} Z^{\frac{4}{3}} + \alpha\big[|\log\alpha|^{\frac{1}{3}} B^{\frac{2}{9}} Z^{\frac{23}{9}} + BZ^{\frac{5}{3}} + Z^2 d^{-3}\big]\Big); \tag{28.7.23}$$

(iii) If $B \ge Z^{\frac{77}{60}}|\log Z|^{-K}$*,* $\alpha \ge B^{-1} Z^{\frac{17}{60}}|\log Z|^{-K}$*,* $(Z-N)_+ \le B^{\frac{5}{12}}$ *and* $d \ge \bar{d} = (\alpha B)^{\frac{40}{209}} Z^{-\frac{81}{209}}|\log Z|^{K}$*, then*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \mathsf{Scott} + O\Big(B^{\frac{1}{3}} Z^{\frac{4}{3}} + \alpha\big[|\log\alpha|^{\frac{1}{3}} B^{\frac{2}{9}} Z^{\frac{23}{9}} + BZ^{\frac{5}{3}} + (\alpha B)^{\frac{120}{209}} Z^{\frac{384}{209}} d^{-3}|\log Z|^{K}\big]\Big). \tag{28.7.24}$$

(iv) In any case

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \mathsf{Scott}_0 + O\big(B^{\frac{1}{3}}Z^{\frac{4}{3}} + \alpha Z^3\big) \tag{28.7.25}$$

with $\mathsf{Scott}_0 = 2\sum_{1\le m\le M} Z_m^2 S(0)$.

Recall that in the free nuclei model excess energy is $\asymp d^{-7}$ (as $d \le \epsilon B^{-\frac{1}{4}}$) and therefore an error must be greater than ϵd^{-7}. One can see easily that $d \ge \mathsf{min}(Z^{-\frac{5}{21}}, B^{-\frac{1}{4}})$ if $B \le Z$ and then in estimates (28.7.21) and (28.7.22) the last terms (with d^{-3}) could be skipped.

On the other hand, in (28.7.23)–(28.7.25) we can either skip the last terms (with d^{-3}) or assume that $d \asymp B^{-\frac{1}{4}}$ and these terms should be calculated under this assumption and we arrive to

Theorem 28.7.6. *Let $M \ge 2$, $N \asymp Z_1 \asymp Z_2 \asymp ... \asymp Z_M$, $B \lesssim Z^{\frac{4}{3}}$ and $(Z-N)_+ \lesssim B^{\frac{1}{2}}$. Consider a free nuclei model. Then*

(i) If $B \le Z$, then

$$\widehat{\mathsf{E}}^*_N = \widehat{\mathcal{E}}^{\mathsf{TF}}_N + \mathsf{Scott} + O\Big(Z^{\frac{5}{3}} + \alpha\big[|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}}\big]\Big) \tag{28.7.26}$$

and moreover

$$\widehat{\mathsf{E}}^*_N = \widehat{\mathcal{E}}^{\mathsf{TF}}_N + \mathsf{Scott} + \mathsf{Schwinger} + \mathsf{Dirac} + O\Big(Z^{\frac{5}{3}}\big[Z^{-\delta} + (BZ^{-1})^{\delta}\big] + \alpha\big[|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}}\big]\Big). \tag{28.7.27}$$

(ii) If $B \ge Z$, $\alpha \le B^{-1}Z^{\frac{17}{60}}|\log Z|^{-K}$, then

$$\widehat{\mathsf{E}}^*_N = \widehat{\mathcal{E}}^{\mathsf{TF}}_N + \mathsf{Scott} + O\Big(B^{\frac{1}{3}}Z^{\frac{4}{3}} + \alpha\big[|\log \alpha|^{\frac{1}{3}} B^{\frac{2}{9}} Z^{\frac{23}{9}} + Z^2 B^{\frac{3}{4}}\big]\Big). \tag{28.7.28}$$

(iii) If $B \ge Z^{\frac{77}{60}}|\log Z|^{-K}$, $B^{-1}Z^{\frac{17}{60}}|\log h|^{-K} \le \alpha \le B^{-\frac{369}{160}}Z^{\frac{81}{40}}|\log Z|^{-K}$, then

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \mathsf{Scott} \\ O\Big(B^{\frac{1}{3}}Z^{\frac{4}{3}} + \alpha\big[|\log \alpha|^{\frac{1}{3}} B^{\frac{2}{9}} Z^{\frac{23}{9}} + (\alpha B)^{\frac{120}{209}} Z^{\frac{384}{209}} B^{\frac{3}{4}} |\log Z|^{K}\big]\Big). \tag{28.7.29}$$

(iv) In any case

$$\widehat{\mathsf{E}}^*_N = \widehat{\mathcal{E}}^{\mathsf{TF}}_N + \mathsf{Scott}_0 + O\big(B^{\frac{1}{3}}Z^{\frac{4}{3}} + \alpha Z^3\big). \tag{28.7.30}$$

We leave to the reader the following

Problem 28.7.7. In the frameworks of fixed nuclei and free nuclei models consider the case $M \ge 2$, $B \ge Z$ and $(Z-N)_+ \ge B^{\frac{5}{12}}$. Use results of Sections 28.5 and 26.6. Recall that there are two cases: $B^{\frac{5}{12}} \le (Z-N)_+ \le B^{\frac{3}{4}}$ and $(Z-N)_+ \ge B^{\frac{3}{4}}$.

In particular find out for which B this assumption could be skipped without deterioration of the remainder estimates.

Ground State Density Asymptotics

Consider now asymptotics of ρ_Ψ. Apart of independent interest one needs them for estimate of excessive negative charge and estimate or asymptotics of the ionization energy.

Theorem 28.7.8. *Let $M=1$, $N \asymp Z$, $B \lesssim Z^{\frac{4}{3}}$ and $\alpha \le \kappa^* Z^{-1}$, with small constant κ^*. Then*

(i) If $B \le Z$, then

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}}) = O\big(Z^{\frac{5}{3}}\big) \tag{28.7.31}$$

and moreover this estimate could be improved to

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}}) = O\Big(Z^{\frac{5}{3}}\big[Z^{-\delta} + B^{\delta} Z^{-\delta} + (\alpha Z)^{\delta}\big]\Big); \tag{28.7.32}$$

(ii) If $Z \le B \le Z^{\frac{4}{3}}$, then

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}}) = O\Big(Z^{\frac{5}{3}} + (\alpha B)^{\frac{40}{27}} Z^{\frac{101}{81}} |\log Z|^{K}\Big). \tag{28.7.33}$$

Proof. We need to consider only the case when errors in the estimates for E^*_N exceed those announced in (28.7.31)–(28.7.33). Otherwise an estimate for $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}})$ follow from the estimates from above and below for E^*_N as estimates from below contain the "bonus term" $\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}})$.

Let in the estimate from below pick up $\lambda' = \lambda_N$ and in the estimate from above pick up A' as a minimizer for a potential $W_B^{\mathsf{TF}} + \lambda'$ with $\lambda' = \lambda_N$; we

do not calculate asymptotics of the trace terms since these terms in both estimates coincide[36]; then we arrive to estimate

$$\begin{aligned}(28.7.34)\quad &\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}})\\ &\qquad \le C\mathsf{D}(\operatorname{tr} e(x,x,\lambda_N) - \rho^{\mathsf{TF}},\, \operatorname{tr} e(x,x,\lambda_N) - \rho^{\mathsf{TF}}) + CZ^{\frac{5}{3}}\end{aligned}$$

and we need to estimate the first term in the right-hand expression.

Let us scale as usual. Then $\beta h \lesssim 1$ since $B \le Z^{\frac{4}{3}}$ and our standard arguments estimate this term by $C\bigl(h^{-2}+h^{-\frac{5}{3}}\nu^{\frac{2}{3}}\bigr)^2$ with $\nu = (\kappa\beta)^{\frac{10}{9}}h^{\frac{4}{9}}|\log h|^K$.

Plugging $\beta = BZ^{-1}$, $h = Z^{-\frac{1}{3}}$, $\kappa = \alpha Z$ and multiplying by $Z^{\frac{1}{3}}$ due to the spatial scaling we arrive exactly to (28.7.31) and (28.7.33).

Furthermore, as $\beta \ll 1$ let us consider contribution of the *main zone* $\{x\colon h^\delta \le \ell(x) \le h^{-\delta}+(\beta+\kappa)^\delta\}$ and use propagation arguments and improved electrostatic inequality; then we arrive to estimate $Ch^{-4}(h+\beta+\kappa)^\delta$ which after rescaling becomes (28.7.32).

We leave all easy details to the reader. □

Consider now case $M \ge 2$. Then no matter what is the distance between nuclei (as long as it is greater than $\epsilon Z^{-\frac{1}{3}}$) we need to add one or two more extra terms.

(a) The first one always appears and it is what becomes from $C\beta_1^2 h_1^{-2}\nu_1\ell^{-1}$ as we plug $\beta_1 = \beta\ell^3$, $h_1 = h\ell$, $\kappa_1 = \kappa\ell^{-3}$, $\nu_1 = (\kappa_1\beta_1)^{\frac{10}{9}}h_1^{\frac{4}{9}}|\log h_1|^K \asymp (\kappa\beta)^{\frac{10}{9}}h^{\frac{4}{9}}\ell^{\frac{4}{9}}|\log h|^K$, and multiply by ℓ^{-1} we get ℓ in the positive power and therefore we must plug the largest possible ℓ which in case $(Z-N)_+ \le B^{\frac{3}{4}}$ is $\ell = (\beta h)^{-\frac{1}{4}}$. Also plugging $\kappa = \alpha Z$, $\beta = BZ^{-1}$, $h = Z^{-\frac{1}{3}}$ and $\ell = (\beta h)^{-\frac{1}{4}} = B^{-\frac{1}{4}}Z^{\frac{1}{3}}$ and multiplying by $Z^{\frac{1}{3}}$ due to the scaling (with a possible improvement for $B \ll Z$) we arrive to $\alpha^{\frac{40}{27}}B^{\frac{9}{4}}|\log Z|^K$. One can see easily that this term is larger than the second term in (28.7.33).

For $(Z-N)_+ \ge B^{\frac{3}{4}}$ this term will be smaller than the second extra term.

(b) The second extra term appears only if $(Z-N)_+ \gtrsim B^{\frac{5}{12}}$.

(b)$_1$ For $B^{\frac{5}{12}} \le (Z-N)_+ \le B^{\frac{3}{4}}$ it is what becomes from $\beta_2^2 h_2^{-3}\bar\gamma^{-4}|\log\bar\gamma|^2$ with substitutions $\beta_2 = \beta_1\bar\gamma^{-1}$, $h_2 = h_1\bar\gamma^{-3}$, $\bar\gamma = (Z-N)_+^{\frac{1}{4}}B^{-\frac{3}{16}}$ and with β_1, h_1, ℓ defined above (we still need to multiply by $Z^{\frac{1}{3}}$).

[36] Due to the matching choices of A' and λ'.

(b)$_2$ For $(Z-N)_+ \ge B^{\frac{3}{4}}$ it is what becomes out $\beta_1^2 h_1^{-3}\ell^{-1}$ with $\ell = (Z-N)_+^{-\frac{1}{3}}$.

Thus we arrive to

Theorem 28.7.9. *Let $M \ge 2$, $N \asymp Z_1 \asymp ... \asymp Z_M$, $B \lesssim Z^{\frac{4}{3}}$. Further, let $\alpha \le \kappa^* Z^{-1}$, $d \gtrsim Z^{-\frac{1}{3}}$. Then*

(i) For $B \le Z$ estimate (28.7.31) *holds and, moreover, it could be improved to*

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) = O\Big(Z^{\frac{5}{3}}\big[Z^{-\delta} + B^\delta Z^{-\delta} + (\alpha Z)^\delta + (dZ^{\frac{1}{3}})^{-\delta}\big]\Big). \tag{28.7.35}$$

(ii) For $B \ge Z$ and $(Z-N)_+ \le B^{\frac{5}{12}}$

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) = O\Big(Z^{\frac{5}{3}} + \alpha^{\frac{10}{9}} B^{\frac{9}{4}} |\log Z|^K\Big). \tag{28.7.36}$$

(iii) For $B \ge Z$ and $B^{\frac{5}{12}} \le (Z-N)_+ \le B^{\frac{3}{4}}$

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) = O\Big(Z^{\frac{5}{3}} + \alpha^{\frac{10}{9}} B^{\frac{9}{4}} |\log Z|^K + B^{\frac{15}{16}}(Z-N)_+^{\frac{3}{4}}(1+|\log (Z-N)_+ B^{-\frac{1}{3}}|)^2\Big). \tag{28.7.37}$$

(iv) For $B \ge Z$ and $(Z-N)_+ \le B^{\frac{3}{4}}$

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) = O\Big(Z^{\frac{5}{3}} + B^2 (Z-N)_+^{-\frac{2}{3}}\Big). \tag{28.7.38}$$

Corollary 28.7.10. *Estimates* (28.7.31), (28.7.35)– (28.7.38) *hold for a free nuclei model.*

28.7.4 Main Theorems: $Z^{\frac{4}{3}} \le B \le Z^3$

Ground State Energy Asymptotics

For $Z^{\frac{4}{3}} \le B \le Z^3$ we select $A' = 0$ in the estimate from above and therefore just apply an upper estimate E_N^* from Subsection 26.6.3. Combined with estimate from below provided by Theorem 28.6.2 it implies the following

Theorem 28.7.11. *Let* $Z^{\frac{4}{3}} \lesssim B \lesssim Z^3$, $Z_1 \asymp ... \asymp Z_M \asymp N$, *and* $\alpha \le \kappa^* Z^{-1}$ *with small constant* κ^*, *and also* $\alpha \le B^{-\frac{4}{5}} Z^{\frac{2}{5}} |\log Z|^{-K}$. *Then*

(i) For $M = 1$ *and either* $(Z-N)_+ \lesssim B^{\frac{4}{15}} Z^{\frac{1}{5}}$ *or* $\alpha B^{\frac{3}{5}} Z^{\frac{1}{5}} \gtrsim 1$

$$|\mathsf{E}^*_N - \mathcal{E}^{\mathsf{TF}}_N - \mathsf{Scott}_0| \tag{28.7.39}$$

does not exceed

$$C\Big(B^{\frac{1}{3}} Z^{\frac{4}{3}} + B^{\frac{4}{5}} Z^{\frac{3}{5}} + \alpha Z^3 + \alpha^{\frac{16}{9}} B^{\frac{82}{45}} Z^{\frac{49}{45}} |\log Z|^K\Big). \tag{28.6.3}$$

(ii) For $M = 1$ *and* $(Z-N)_+ \gtrsim B^{\frac{4}{15}} Z^{\frac{1}{5}}$ *and* $\alpha B^{\frac{3}{5}} Z^{\frac{1}{5}} \lesssim 1$ *expression* (28.7.39) *does not exceed*

$$C\Big(B^{\frac{1}{3}} Z^{\frac{4}{3}} + B^{\frac{4}{5}} Z^{\frac{3}{5}} + \alpha Z^3 + \alpha^{\frac{16}{9}} B^{\frac{82}{45}} Z^{\frac{49}{45}} |\log Z|^K + \alpha^{\frac{40}{27}} B^{\frac{13}{15}} Z^{\frac{139}{135}} (Z-N)_+^{\frac{28}{27}} |\log Z|^K\Big). \tag{28.6.4}$$

(iii) For $M \ge 2$ *and* $(Z-N)_+ \lesssim B^{\frac{4}{15}} Z^{\frac{1}{5}}$ *expression* (28.7.39) *does not exceed*

$$C\Big(B^{\frac{1}{3}} Z^{\frac{4}{3}} + B^{\frac{4}{5}} Z^{\frac{3}{5}} (1 + |\log BZ^{-3}|)^2 + \alpha Z^3 + \alpha^{\frac{16}{9}} B^{\frac{82}{45}} Z^{\frac{49}{45}} |\log Z|^K\Big). \tag{28.7.40}$$

(iv) For $M \ge 2$ *and* $(Z-N)_+ \gtrsim B^{\frac{4}{15}} Z^{\frac{1}{5}}$ *expression* (28.7.39) *does not exceed*

$$C\Big(B^{\frac{1}{3}} Z^{\frac{4}{3}} + B^{\frac{4}{5}} Z^{\frac{3}{5}} (1 + |\log BZ^{-3}|)^2 + \alpha Z^3 + \alpha^{\frac{16}{9}} B^{\frac{82}{45}} Z^{\frac{49}{45}} |\log Z|^K + B^{\frac{2}{3}} (Z-N)_+ (1 + |\log (Z-N)_+ Z^{-1}|)^2\Big). \tag{28.7.41}$$

Ground State Density Asymptotics

Consider now asymptotics of ρ_Ψ. Apart of independent interest we need them for estimate of excessive negative charge and estimate or asymptotics of the ionization energy. We are interested as usual in $\mathsf{D}\big(\rho_\Psi - \rho^{\mathsf{TF}}_B, \rho_\Psi - \rho^{\mathsf{TF}}_B\big)$ and we know that

Corollary 28.7.12. *In the framework of Theorem 28.7.11(i), (ii), (iii), (iv)* $\mathsf{D}\big(\rho_\Psi - \rho^{\mathsf{TF}}_B, \rho_\Psi - \rho^{\mathsf{TF}}_B\big)$ *does not exceed the corresponding remainder estimate* (28.6.3), (28.6.4), (28.7.40), (28.7.41).

If we want to get rid of $\alpha Z^3 + B^{\frac{1}{3}} Z^{\frac{4}{3}}$ terms (which may be dominant only for $B \le Z^{\frac{7}{4}}$ and $B \le Z^{\frac{11}{7}}$ respectively) we need not to find asymptotics of the trace term but to have trace term in the estimates from above and below more consistent. The only explored option is to take in the estimate from above the same A' as in the estimate from below, which is a minimizer for the corresponding one particle problem.

Theorem 28.7.13. *Let $Z^{\frac{4}{3}} \lesssim B \lesssim Z^3$, $Z_1 \asymp ... \asymp Z_M \asymp N$, and $\alpha \le \kappa^* Z^{-1}$ with small constant κ^*, and also $\alpha \le B^{-\frac{4}{5}} Z^{\frac{2}{5}} |\log Z|^{-K}$.*

(i) Let $M = 1$. Then $\mathsf{D}\big(\rho_\Psi - \rho_B^{\mathsf{TF}},\, \rho_\Psi - \rho_B^{\mathsf{TF}}\big)$ does not exceed

$$CB^{\frac{4}{5}} Z^{\frac{3}{5}} + C\Big(\alpha^{\frac{16}{9}} B^{\frac{82}{45}} Z^{\frac{49}{45}} + \alpha^{\frac{40}{27}} B^{-\frac{10}{9}} Z^{\frac{127}{27}} + \alpha^{\frac{40}{27}} B^{\frac{74}{45}} Z^{\frac{11}{90}} (Z-N)_+^{\frac{29}{54}}\Big) |\log Z|^K. \tag{28.7.42}$$

(ii) Let $M = 2$ and the minimal distance between nuclei $d \gtrsim B^{-\frac{2}{5}} Z^{\frac{1}{5}}$. Then $\mathsf{D}\big(\rho_\Psi - \rho_B^{\mathsf{TF}},\, \rho_\Psi - \rho_B^{\mathsf{TF}}\big)$ does not exceed

$$CB^{\frac{4}{5}} Z^{\frac{3}{5}} + C\Big(\alpha^{\frac{4}{3}} B^{\frac{22}{15}} Z^{\frac{19}{15}} + \alpha^{\frac{40}{27}} B^{-\frac{10}{9}} Z^{\frac{127}{27}} + B^{\frac{3}{5}} Z^{\frac{9}{20}} (Z-N)_+^{\frac{3}{4}}\Big) |\log Z|^K. \tag{28.7.43}$$

Proof. We will use Propositions 28.6.5 and 28.6.6 to estimate (28.6.27). Let us consider for each partition element

$$\Big| \int \big(e(x,x,\lambda') - P_B(V(x)+\lambda')\big)\psi(x)\, dx\Big|. \tag{28.7.44}$$

(a) Zone $\{x\colon \ell(x) \le B^{-1} Z |\log h|^\delta\}$. Here for each ℓ-element expression (28.7.44) does not exceed $R_a = C(h_1^{-2} + \beta_1 h_1^{-1})(1 + \nu_1^{\frac{2}{3}} h_1^{\frac{1}{3}})$ with $\beta_1 = \beta \ell^{\frac{3}{2}}$, $h_1 = h\ell^{-\frac{1}{2}}$ and ν_1 defined according to Proposition 28.6.5(ii). As usual $\beta = B^{\frac{2}{5}} Z^{-\frac{1}{5}}$ and $h = B^{\frac{1}{5}} Z^{-\frac{3}{5}}$.

Then one can prove easily that the total contribution of this zone to

$$\mathsf{D}\big(e(x,x,\lambda') - P_B(V(x)+\lambda'),\, e(x,x,\lambda') - P_B(V(x)+\lambda')\big) \tag{28.7.45}$$

does not exceed $CBZ^{-1}R_a^{2}$ [37] which is the second term in the parenthesis of (28.7.42) and (28.7.43) [38].

(b) Zone $\{x\colon B^{-1}Z|\log h|^{\delta} \le \ell(x) \le \epsilon B^{-\frac{2}{5}}Z^{\frac{1}{5}}\}$ (with the exception of the case $\bar\gamma \ge |\log h|^{-\delta}$ which we leave to the reader). Here for each ℓ-element expression (28.7.44) does not exceed $R_b = C\beta_1 h_1^{-1}(1+\nu_1^{\frac{2}{3}}h_1^{\frac{1}{3}})$ with $\beta_1 = \beta\ell^{\frac{3}{2}}$, $h_1 = h\ell^{-\frac{1}{2}}$ and ν_1 defined according to Proposition 28.6.6(i).

Then one can prove easily that the total contribution of this zone to (28.7.45) does not exceed $CB^{\frac{2}{5}}Z^{-\frac{1}{5}}R_b^{2}$ [37] which is the first term in the parenthesis of (28.7.42) [38].

(c) Zone $\{x\colon \bar\gamma|\log h|^{\delta} \le \gamma(x) \le C_0\}$. Here for each γ-element expression (28.7.44) does not exceed R_c where $R_c = C\beta_2 h_2^{-1}(1+\nu_2^{\frac{2}{3}}h_2^{\frac{1}{3}})$ (as $M=1$) and $R_c = C\beta_2 h_2^{-1}\nu_2^{\frac{1}{2}}$ (as $M \ge 2$) with $\beta_2 = \beta\gamma^{-1}$, $h_2 = h\gamma^{-3}$ and ν_2 defined by Proposition 28.6.6(i) and redefined by Remark 28.5.9.

Then one can prove easily that the total contribution of this zone to (28.7.45) does not exceed $CB^{\frac{2}{5}}Z^{-\frac{1}{5}}R_c^{2}$ [37] which is the first term in the parenthesis of (28.7.42) and (28.7.43) for $M=1$ and $M \ge 2$ respectively [38].

(d) Zone $\{x\colon \gamma(x) \le \bar\gamma|\log h|^{\delta}\}$. Here for each γ-element expression (28.7.44) does not exceed $R_d = C\beta_2 h_2^{-1}(1+\nu_2^{\frac{2}{3}}h_2^{\frac{1}{3}})$ (as $M=1$) and $R_d = C\beta_2 h_2^{-\frac{3}{2}}$ (as $M \ge 2$) with $\beta_2 = \beta\gamma^{-1}$, $h_2 = h\gamma^{-3}$ and ν_2 defined by Proposition 28.6.6(ii).

Then one can prove easily that the total contribution of this zone to (28.7.45) does not exceed $CB^{\frac{2}{5}}Z^{-\frac{1}{5}}R_d^{2}\bar\gamma^{-4}$ [37] which is the third term in the parenthesis of (28.7.42) and (28.7.43) for $M=1$ and $M \ge 2$ respectively [38]. □

28.A Appendices

28.A.1 Generalization of Lieb-Loss-Solovej Estimate

Proposition 28.A.1. *Consider operator H defined by* (27.1.1) *with* $A = A' + A''$, $A' = (A_1'(x'), A_2'(x'), 0)$, $x' = (x_1, x_2)$, *and* $A'' = (A_1''(x), A_2''(x), A_3''(x))$

[37] Calculated for ℓ or γ on its maximum.

[38] Modulo term not exceeding $CB^{\frac{4}{5}}Z^{\frac{3}{5}}$.

on Ω. *Assume that*

$$\int B'^{\,2}\,dx \ge \int B''^{\,2}\,dx \tag{28.A.1}$$

with $B = |\nabla \times A|$, $B' = |\nabla \times A'|$, $B'' = |\nabla \times A''|$. *Then*

$$-\mathsf{Tr}(H^-_{A,V}) \le \tag{28.A.2}$$
$$C\int V_+^{\frac{5}{2}}(x)\,dx + C\Big(\int B^2\,dx\Big)^{\frac{1}{2}}\Big(\int B''^{\,2}\,dx + \int V^2\,dx\Big)^{\frac{1}{4}}\Big(\int V^4\,dx\Big)^{\frac{1}{4}} +$$
$$C\Big(\int B^2\,dx\Big)^{\frac{3}{8}}\Big(\int V^2\,dx\Big)^{\frac{3}{8}}\Big(\int V^4\,dx\Big)^{\frac{1}{4}}.$$

Proof. Without any loss of the generality we can assume that $V \ge 0$. We apply the *moving frame technique* of Lieb-Loss-Solovej [1]. Obviously

$$-\mathsf{Tr}(H^-_{A,V}) = \int_0^\infty \mathsf{N}^-(H_{A,V}+\lambda)\,d\lambda = \tag{28.A.3}$$
$$\int_0^\infty \mathsf{N}^-(H_{A,0}+\lambda-V)\,d\lambda \le \int_0^\infty \mathsf{N}^-\big(H_{A,0}+(\lambda-V)\phi(\lambda)\big)\,d\lambda$$

with $\phi(\lambda) = \mathsf{max}(1, \lambda\mu^{-1})$ since $H_{A,0} \ge 0$. Since

$$H_{A,0} = \big(P\cdot\boldsymbol{\sigma}\big)^2 = \big(P'\cdot\boldsymbol{\sigma}'\big)^2 + P_3^2 + \sum_{j=1,2}[P_j,P_3]\,[\sigma_j,\sigma_3] \ge \tag{28.A.4}$$
$$H'_{A,0} + P_3^2 - B''$$

with

$$H'_{A,0} = \big(P'\cdot\boldsymbol{\sigma}'\big)^2 = \big(\sum_{j=1,2} P_j\cdot\sigma_j\big)^2, \tag{28.A.5}$$

$P_j = D_j - A_j$, we conclude that $-\mathsf{Tr}(H^-_{A,V})$ does not exceed

$$\int_0^\infty \mathsf{N}^-\big(H'_{A,0}+P_3^2-B''+(\lambda-V)\phi(\lambda)\big)\,d\lambda. \tag{28.A.6}$$

Consider this integral over (μ,∞); it is equal to

$$\int_\mu^\infty \mathsf{N}^-\big(H'_{A,0}+P_3^2-B''+(\lambda-V)\lambda\mu^{-1}\big)\,d\lambda \tag{28.A.7}$$

and since $H'_{A,0} \ge 0$ this integral does not exceed

$$\int_{\mu}^{\infty} \mathsf{N}^{-}\bigl(H'_{A,0} + a[P_3^2 - B'' + (\lambda - V)\lambda\mu^{-1}]\bigr)\, d\lambda \tag{28.A.8}$$

with $a \ge 1$; since $H'_{A,0} \ge P_1^2 + P_2^2 - |B|$ this integral (28.A.8) does not exceed

$$\int_{\mu}^{\infty} \mathsf{N}^{-}\bigl(P_1^2 + P_2^2 - B + a[P_3^2 - B'' + (\lambda - V)\lambda\mu^{-1}]\bigr)\, d\lambda \tag{28.A.9}$$

which can be estimated due to CLR inequality after rescaling $x_3 \mapsto a^{\frac12}x_3$, $P_3 \mapsto a^{-\frac12}P_3$ by

$$\begin{aligned} C\int\int_{\mu}^{\infty} a^{-\frac12}\bigl(B + a[B'' + (V-\lambda)\lambda\mu^{-1}]\bigr)_+^{\frac32}\, d\lambda dx \\ \le C\int\int_{\mu}^{\infty} a^{-\frac12}\bigl(B - \frac{1}{3}a\lambda^2\mu^{-1}\bigr)_+^{\frac32}\, d\lambda dx \\ + C\int\int_{\mu}^{\infty} a\bigl(B'' - \frac{1}{3}\lambda^2\mu^{-1}\bigr)_+^{\frac32}\, d\lambda dx \\ + C\int\int_{\mu}^{\infty} a(\lambda\mu^{-1})^{\frac32}\bigl(V - \frac{1}{3}\lambda\bigr)_+^{\frac32}\, d\lambda dx \\ \le Ca^{-1}\mu^{\frac12}\int B^2\, dx + Ca\mu^{\frac12}\int B''^2\, dx + Ca\mu^{-\frac32}\int V^4\, dx, \end{aligned}$$

where we integrated over $[0,\infty]$. Optimizing with respect to $a \ge 1$ we get

$$\begin{aligned} C\Bigl(\int B^2\, dx\Bigr)^{\frac12}\Bigl(\mu\int B''^2\, dx + \mu^{-1}\int V^4\, dx\Bigr)^{\frac12} \\ + C\mu^{\frac12}\int B''^2\, dx + C\mu^{-\frac32}\int V^4\, dx. \end{aligned} \tag{28.A.10}$$

Therefore integral (28.A.7) does not exceed (28.A.10).

Consider integral (28.A.6) over $[0,\mu]$; it is

$$\int_{0}^{\mu} \mathsf{N}^{-}\bigl(H'_{A,0} + P_3^2 - B'' + (\lambda - V)\bigr)\, d\lambda \tag{28.A.11}$$

and exactly as before it does not exceed

$$\begin{aligned} C\int\int_{0}^{\mu} a^{-\frac12}\bigl(B - \frac{1}{3}a\lambda\bigr)_+^{\frac32}\, d\lambda dx + C\int\int_{0}^{\mu} a\bigl(B'' - \frac{1}{3}\lambda\bigr)_+^{\frac32}\, d\lambda dx \\ + C\int\int_{0}^{\mu} a\bigl(V - \frac{1}{3}\lambda\bigr)_+^{\frac32}\, d\lambda dx \end{aligned}$$

with $a \ge 1$; in first two integrals we replace (in parenthesis) λ by $\lambda^2\mu^{-1}$ and expand integral to $[0,\infty]$, arriving to

$$Ca^{-1}\mu^{\frac12}\int B^2\,dx + Ca\mu^{\frac12}\int B''^2\,dx + C\int aV^{\frac32}\min(V,\mu)\,dx;$$

optimizing with respect to $a \ge 1$ we get

$$C\Big(\int B^2\,dx\Big)^{\frac12}\Big(\mu\int B''^2\,dx + \mu^{\frac12}\int V^{\frac32}\min(V,\mu)\,dx\Big)^{\frac12} + C\mu^{\frac12}\int B''^2\,dx + C\int V^{\frac32}\min(V,\mu)\,dx. \tag{28.A.12}$$

Therefore integral (28.A.11) does not exceed (28.A.12) and the whole expression does not exceed

$$C\Big(\int B^2\,dx\Big)^{\frac12}\Big(\mu\int B''^2\,dx + \mu^{-1}\int V^4\,dx + \mu^{\frac12}\int V^{\frac32}\min(V,\mu)\,dx\Big)^{\frac12} + C\mu^{\frac12}\int B''^2\,dx + C\mu^{-\frac32}\int V^4\,dx + C\int V^{\frac32}\min(V,\mu)\,dx;$$

replacing $\min(V,\mu)$ by $V^{\frac12}\mu^{\frac12}$ and V in the first and second lines respectively we get

$$C\Big(\int B^2\,dx\Big)^{\frac12}\Big(\mu\int B''^2\,dx + \mu^{-1}\int V^4\,dx + \underbrace{\mu\int V^2\,dx}\Big)^{\frac12} + C\mu^{\frac12}\int B''^2\,dx + C\mu^{-\frac32}\int V^4\,dx + C\int V^{\frac52}\,dx.$$

We skip the last term since it is already in (28.A.2); temporarily skip monotone increasing by μ selected term; optimizing the rest by $\mu > 0$ we get

$$C\Big(\int B^2\,dx\Big)^{\frac12}\Big(\int B''^2\,dx\Big)^{\frac14}\Big(\int V^4\,dx\Big)^{\frac14}.$$

Now we are left with

$$C\mu^{\frac12}\Big(\int B^2\,dx\Big)^{\frac12}\Big(\int V^2\,dx\Big)^{\frac12} + C\mu^{-\frac12}\Big(\int B^2\,dx\Big)^{\frac12}\Big(\int V^4\,dx\Big)^{\frac12} + C\mu^{-\frac32}\int V^4\,dx.$$

Optimizing by $\mu > 0$ we get

$$C\Big(\int B^2\,dx\Big)^{\frac12}\Big(\int V^2\,dx\Big)^{\frac14}\Big(\int V^4\,dx\Big)^{\frac14}+ \\ C\Big(\int B^2\,dx\Big)^{\frac38}\Big(\int V^2\,dx\Big)^{\frac38}\Big(\int V^4\,dx\Big)^{\frac14}$$

which concludes the proof. □

28.A.2 Electrostatic Inequality

Proposition 28.A.2. *(i) Let* $B \le Z^3$, $\alpha \le \kappa^* Z^{-1}$, $c^{-1}Z \le N \le cZ$. *Further, if* $B \ge Z^{\frac43}$ *then* $\alpha B^{\frac45} Z^{-\frac25} \le \epsilon$. *Then*

$$\sum_{1\le j<k\le M}\int |x_j - x_k|^{-1}|\Psi(x_1,\dots,x_N)|^2\,s dx_1\cdots dx_N \\ \ge \mathsf{D}(\rho_\Psi,\rho_\Psi) - C\big(Z^{\frac53} + B^{\frac25}Z^{\frac{17}{15}} + B\big); \tag{28.A.13}$$

(ii) Further, afor $B \le Z$ *one can replace the last term in* (28.A.13) *by* $\mathsf{Dirac} - CZ^{\frac53-\delta}$.

Remark 28.A.3. Without self-generated magnetic field the last term was $-C(Z^{\frac53} + B^{\frac25}Z^{\frac{17}{15}})$ and probably it holds here but does not give us any advantage; for $B \ge Z$ we need only $C\big(Z^{\frac53} + B^{\frac45}Z^{\frac35}\big)$ estimate.

Proof. Since we prove estimate from below we replace first

$$\langle \sum_{1\le j\le N} (H_{A,V})_{x_j}\Psi,\ \Psi\rangle$$

by

$$\langle \sum_{1\le j\le N} (H_{A,W})_{x_j}\Psi,\ \Psi\rangle + \int (W-V)\rho_\Psi\,dx$$

without changing anything else and then we estimate the first term here from below by $\mathsf{Tr}(H^-_{A,W})$; then in $\mathsf{Tr}(H^-_{A,W}) + \alpha^{-1}\|\partial A'\|^2$ we replace A' by a minimizer for this expression (rather than for the original problem) only decreasing this expression. So we can now consider A' a minimizer of Section 28.5.

Then we follow arguments of Appendix 26.A.1 but now we need to justify magnetic Lieb-Thirring estimate (26.A.12)

$$\mathsf{Tr}(H^-_{A,W}) \ge -C\int P_B(W)\,dx \tag{26.A.12}$$

in the current settings and with $W : CP'(W) = \rho_\Psi$ and then $W \asymp \min(B^{-2}\rho_\Psi^2; \rho_\Psi^{\frac{2}{3}})$.

Estimate (26.A.12) has been proven in L. Erdös [1] (Theorem 2.2) under assumption that intensity of the magnetic field $\vec{B}(x)$ has a constant direction which was the case in Chapter 25 but not here.

However we actually we do not need (26.A.12); we need this estimate but with an extra term $-CR$ in the right-hand expression where in (i) $R = (Z^{\frac{5}{3}} + B^{\frac{4}{5}}Z^{\frac{3}{5}})$ is the last term in (28.A.13) and in (ii) $R = CZ^{\frac{5}{3}-\delta}$.

Further, the same paper L. Erdös [1]) provides an alternative version of Theorem 2.2: as long as $|\partial A'| \le B$ it is sufficient to estimate $|\partial^2 A| \le cB^{\frac{3}{2}}$.

One can check easily that this pointwise estimate holds if either $B \le Z^2$ and $\ell(x) \ge r_* := B^{-\frac{3}{2}}Z^{\frac{1}{3}}$ or $Z^2 \le B \le Z^3$ and $\ell(x) \ge r_* = Z^{-1}$. Introducing partition into two zones $\{x\colon \ell(x) \ge r_*\}$ and $\{x\colon \ell(x) \le 2r_*\}$ adds $\ell^{-2}\phi(x)$ with $\phi(x) = \mathbf{1}_{\{x\colon r_* \le \ell(x) \le 2r_*\}}$, which adds $-CR$ to the right-hand expression of (26.A.12).

Therefore we need to deal with the zone $\{x\colon \ell(x) \le 2r_*\}$. In this zone however we can neglect an external field; indeed, as in Remark 27.4.1 we get the same estimate (27.4.25) but with B intensity of the combined field; however $\int B^2\,dx$ over this zone does not exceed CR. This concludes proof of Statement (i).

Statement (ii) is proven in the same manner as in Appendix 26.A.1. We leave details to the reader. □

28.A.3 Estimates for $(hD_{x_j} - \mu x_j)e(x,y,\tau)|_{x=y}$ for Toy-Model Operator

We will use here notations of Subsection 27.5.1.

Calculations

Let us calculate the required expressions as $X = \mathbb{R}^3$ and $A(x)$ and $V(x)$ are linear. To do this we can consider just Schrödinger operator (acting on

vector-functions) and then replace V by $V \pm \mu h$ where μ is the magnetic intensity; since $\sigma_j\sigma_k + \sigma_k\sigma_j = 2\delta_{jk}$ we have to consider scalar a Schrödinger operator. Let us apply calculations of Subsection 16.6.1 with operator

$$H = h^2 D_1^2 + (hD_2 - \mu x_1)^2 + hD_3^2 - 2\alpha x_1 - 2\beta x_3, \tag{28.A.14}$$

where without any loss of the generality we assume that $\alpha \ge 0$, $\beta \ge 0$.

After rescaling $x \mapsto \mu x$, $y \mapsto \mu y$, $t \mapsto \mu t$, $\mu \mapsto 1$ (but we will need to use old μ in calculations), $h \mapsto \hbar = \mu h$ we have $U(x,y,t) = U_{(1)}(x_3,y_3,t)U_{(2)}(x',y',t)$ where from (16.6.4)

$$U_{(1)}(x_3,y_3,t) = \frac{1}{2}\mu(2\pi\hbar|t|)^{-\frac{1}{2}} \exp\Big(i\hbar^{-1}\big(\mu^{-1}\beta t(x_3+y_3) + \frac{1}{8}t^{-1}(x_3-y_3)^2 + \frac{1}{3}\mu^{-2}\beta^2 t^3\big)\Big); \tag{28.A.15}$$

and repeating (16.2.9)–(28.A.16) we get

$$U_{(2)}(x,y,t) = i(4\pi\hbar)^{-1}\mu^2 \csc(t)\, e^{i\hbar^{-1}\bar{\phi}_{(2)}(x',y',t)} \tag{28.A.16}$$

with

$$\begin{aligned}\bar{\phi}_{(2)} \coloneqq & -\frac{1}{4}\cot(t)(x_1-y_1)^2 \\ & + \frac{1}{2}(x_1+y_1+2\alpha\mu^{-1})(x_2-y_2+2t\alpha\mu^{-1}) \\ & - \frac{1}{4}\cot(t)(x_2-y_2+2t\alpha\mu^{-1})^2 - t\alpha^2\mu^{-2}.\end{aligned} \tag{28.A.17}$$

Then

$$U(x,y,t) = i(2\pi h)^{-\frac{3}{2}}|t|^{-\frac{1}{2}}\mu^{\frac{3}{2}} \csc(t)\, e^{i\hbar^{-1}\bar{\phi}(x,y,t)} \tag{28.A.18}$$

with

$$\begin{aligned}\bar{\phi} \coloneqq & -\frac{1}{4}\cot(t)(x_1-y_1)^2 \\ & + \frac{1}{2}(x_1+y_1+2\alpha\mu^{-1})(x_2-y_2+2t\alpha\mu^{-1}) - \frac{1}{4}\cot(t)(x_2-y_2+2t\alpha\mu^{-1})^2 - t\alpha^2\mu^{-2} + \\ & \mu^{-1}\beta t(x_3+y_3) + \frac{1}{8}t^{-1}(x_3-y_3)^2 + \frac{1}{3}\mu^{-2}\beta^2 t^3\big).\end{aligned} \tag{28.A.19}$$

Therefore applying first $\hbar D_{x_1}$, $\hbar D_{x_2} - \mu x_1$, or $\hbar D_{x_3}$ and setting after this $x = y = 0$ we conclude that

$$(28.A.20)_1 \quad \bigl(\hbar D_{x_1} U\bigr)|_{x=y=0} = i\alpha\mu^{-1}t \times (2\pi h)^{-\frac{3}{2}}|t|^{-\frac{1}{2}}\mu^{\frac{3}{2}} e^{i\hbar^{-1}\varphi(t)},$$

$$(28.A.20)_2 \quad \bigl(\hbar D_{x_2} U\bigr)|_{x=y=0} = i\alpha\mu^{-1}(1 - t\cot(t)) \times (2\pi h)^{-\frac{3}{2}}|t|^{-\frac{1}{2}}\mu^{\frac{3}{2}} e^{i\hbar^{-1}\varphi(t)},$$

$$(28.A.20)_3 \quad \bigl(\hbar D_{x_3} U\bigr)|_{x=y=0} = i\beta\mu^{-1}t \times (2\pi h)^{-\frac{3}{2}}|t|^{-\frac{1}{2}}\mu^{\frac{3}{2}} e^{i\hbar^{-1}\varphi(t)}$$

with

$$\varphi(t) = \alpha^2\mu^{-2}t - \alpha^2\mu^{-2}t^2\cot(t) + \frac{1}{3}\mu^{-2}\beta^2 t^3. \tag{28.A.21}$$

In other words, in comparison with $U|_{x=y=0}$, calculated in Subsection 16.6.1, expressions $\bigl(\hbar D_{x_1} U\bigr)|_{x=y=0}$, $\bigl(\hbar D_{x_2} U\bigr)|_{x=y=0}$ and $\bigl(\hbar D_{x_3} U\bigr)|_{x=y=0}$ acquire factors $\mu^{-1}\alpha t$, $\mu^{-1}\alpha(1 - t\cot(t))$ and $\mu^{-1}\beta t$ respectively.

Recall that we had 2 cases: $\mu^2 h \le \alpha$ and $\mu^2 h \ge \alpha$.

Case $\alpha \ge \mu^2 h$

Then for each k, $1 \le |k| \le C_0\mu\alpha^{-1}$, the k-th tick contributed no more than

$$C\mu h^{-1} \underbrace{(\mu^2 h/\alpha|k|)^{\frac{1}{2}}} \times (\mu/h|k|)^{\frac{1}{2}} \tag{28.A.22}$$

to $F_{t\to\hbar^{-1}\tau} U|_{x=y=0}$ (see Subsection 16.6.2) and then it contributed no more than this multiplied by $|t_k|^{-1}$, i.e.

$$C\mu h^{-1}|k|^{-1} \underbrace{(\mu^2 h/\alpha|k|)^{\frac{1}{2}}} \times (\mu/h|k|)^{\frac{1}{2}} \tag{28.A.23}$$

to the corresponding Tauberian expression. Even when we multiply by $\mu^{-1}|k|$, we get (28.A.22) again proportional to $|k|^{-1}$; then summation with respect to k, $1 \le |k| \le k^* := C_0\mu(\alpha+\beta)^{-1}$ [39] returns its value at $k = 1$, i.e. $\mu^{\frac{3}{2}} h^{-1}\alpha^{-\frac{1}{2}}$ multiplied by logarithm $(1 + |\log k^*|)$ and therefore we arrive to Proposition 28.A.4 below for $j = 1, 3$.

Let $j = 2$. Since $t_k/\cot(t_k) \asymp \alpha^{-1}\mu$ we conclude that contribution of k-th tick does not exceed

$$C\mu h^{-1}|k|^{-1} \underbrace{(\mu^2 h/\alpha|k|)^{\frac{1}{2}}} \times (\mu/h|k|)^{\frac{1}{2}} \tag{28.A.24}$$

[39] As $|t| \ge k^*$ we have $\phi'(t) \ge c_1$ and then integrating by parts there we can recover factor $(t/k^*)^{-n}$ thus effectively confining us to integration over $\{t\colon |t| \le k^*\}$. This observation can also improve some results of Sections 16.6–16.10.

and summation by $|k| \ge 1$ returns its value as $|k| = 1$ i.e. $C\mu^{\frac{5}{2}}h^{-1}\alpha^{-\frac{1}{2}}$ and therefore we arrive to proposition 28.A.4 below for $j = 2$.

Proposition 28.A.4. *Let $\mu h \le \epsilon_0$, $\tau \asymp 1$, $\alpha \ge \mu^2 h$.*

Then

(i) Expression $(hD_{x_2} - \mu x_1)e(x, y, \tau)|_{x=y=0}$ does not exceed $C\mu^{\frac{5}{2}}h^{-1}\alpha^{-\frac{1}{2}}$.

(ii) Expression $hD_{x_j}e(x, y, \tau)|_{x=y=0}$ does not exceed $C\mu^{\frac{3}{2}}h^{-1}\alpha^{\frac{1}{2}}(1+|\log \mu(\alpha+\beta)^{-1}|)$, and $C\mu^{\frac{3}{2}}h^{-1}\beta\alpha^{-\frac{1}{2}}(1+|\log \mu(\alpha+\beta)^{-1}|)$ for $j = 1, 3$ respectively.

Case $\alpha \le \mu^2 h$

If $\mu^2 h \ge \alpha$, then the same arguments work only for $\bar{k} := \mu^2 h\alpha^{-1} \le |k| \le k^*$, resulting in contributions $C\mu^{\frac{3}{2}}h^{-1}\alpha^{\frac{1}{2}}(1 + |\log k^*\bar{k}^{-1}|)$, $C\mu^{\frac{1}{2}}h^{-2}\alpha^{\frac{1}{2}}$, and $C\mu^{\frac{3}{2}}h^{-1}\beta\alpha^{-\frac{1}{2}}(1 + |\log k^*\bar{k}^{-1}|)$ for $j = 1, 2, 3$ respectively if $\bar{k} \le k^*$ (i.e. $\mu h\beta \le \alpha$) or 0 otherwise.

Let $1 \le |k| \le \bar{k}$. We mainly consider the most difficult case $j = 2$ and (as $|t| \ge \epsilon_0$) only term arising from $-\alpha\mu^{-1}t\cot(t)$ factor, namely

$$\alpha\mu^{-1} \times \mu^{\frac{3}{2}}h^{-\frac{3}{2}} \int |t|^{-\frac{1}{2}} \cos(t)(\sin(t))^{-2} e^{ih^{-1}(\varphi(t)-t\tau)}\, dt, \tag{28.A.25}$$

where we took into account that we need to divide by t and skipped a constant factor.

Consider first (28.A.25) with integration over interval $\{t\colon |t - t_k| \le s_k\}$ near t_k. Observe that

$$\phi'(t) = (\sin(t))^{-2}\alpha^2\mu^{-2}t^2 - 2t(\sin(t))^{-1}\alpha^2\mu^{-2}t^2 + \beta^2t^2 \tag{28.A.26}$$

and transform (28.A.25) into

$$\begin{aligned}&\alpha^{-1}\mu^{\frac{7}{2}}h^{-\frac{1}{2}} \int_{t_k-s_k}^{t_k+s_k} |t|^{-\frac{5}{2}} \cos(t)\partial_t\big[e^{ih^{-1}(\varphi(t)-t\tau)}\big]\, dt \\ &+\alpha^{-1}\mu^{\frac{5}{2}}h^{-\frac{3}{2}} \int_{t_k-s_k}^{t_k+s_k} |t|^{-\frac{5}{2}} \cos(t)\big[2t(\sin(t))^{-1}\alpha^2\mu^{-2} - \beta^2t^2 + \tau\big]e^{ih^{-1}(\varphi(t)-t\tau)}.\end{aligned} \tag{28.A.27}$$

Integrating the first term by parts we get a non-integral term

$$\alpha^{-1}\mu^{\frac{7}{2}}h^{-\frac{1}{2}}|t|^{-\frac{5}{2}} \cos(t)e^{ih^{-1}(\varphi(t)-t\tau)}\big|_{t=t_k-s_k}^{t=t_k+s_k} \tag{28.A.28}$$

and we get an integral term

$$\begin{aligned}(28.A.29)\quad &\alpha^{-1}\mu^{\frac{5}{2}}h^{-\frac{3}{2}}\int_{t_k-s_k}^{t_k+s_k}\Big[\mu h\partial_t\big[|t|^{-\frac{5}{2}}\cos(t)\big]\\ &\qquad+|t|^{-\frac{5}{2}}\cos(t)\big[2t(\sin(t))^{-1}\alpha^2\mu^{-2}-\beta^2t^2+\tau\big]\Big]e^{i\hbar^{-1}(\varphi(t)-t\tau)}\,dt\\ &=2\alpha\mu^{\frac{1}{2}}h^{-\frac{3}{2}}\int_{t_k-s_k}^{t_k+s_k}|t|^{-\frac{3}{2}}\cot(t)e^{i\hbar^{-1}(\varphi(t)-t\tau)}\,dt+O\big(\alpha^{-1}\mu^{\frac{5}{2}}h^{-\frac{3}{2}}s_k|k|^{-\frac{5}{2}}\big).\end{aligned}$$

Repeating the same trick we can eliminate the first term in the right-most expression. Therefore we arrive to (28.A.28) with $O\big(\alpha^{-1}\mu^{\frac{5}{2}}h^{-\frac{3}{2}}s_k|k|^{-\frac{5}{2}}\big)$ error. When $s_k\asymp\alpha^2\mu^{-3}h^{-1}k^2$ we get

$$(28.A.30)\qquad C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}\times(\alpha/\mu^2h)|k|^{-\frac{1}{2}}$$

error.

On the other hand, consider integral over $[t_k+s_k,\,t_{k+1}-s_{k+1}]$, $k\neq0$. Decomposing $e^{i\mu^{-1}h^{-1}(\phi(t)-t\tau)}$ into Taylor series with respect to $\alpha^2h^{-1}\mu^{-3}\cot(t)$ one can prove easily that expression in question is

$$\alpha^{-1}\mu^{\frac{7}{2}}h^{-\frac{1}{2}}|t|^{-\frac{5}{2}}\cos(t)\big(e^{i\hbar^{-1}(\varphi(t)-t\tau)}-e^{i\hbar^{-1}(\varphi_{(1)}(t)-t\tau)}\big)\big|_{t=t_k+s_k}^{t=t_{k+1}-s_{k+1}}$$

with $\varphi_{(1)}(t)=\frac{1}{3}\mu^{-2}\beta^2t^3$ and with error not exceeding (28.A.30) multiplied by $(1+|\log s_k|)$:

$$(28.A.31)\qquad C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}\times(\alpha/\mu^2h)|k|^{-\frac{1}{2}}\times(1+|\log(\alpha^2\mu^{-3}h^{-1}k^2)|).$$

So non-integral terms with φ cancel one another because by the similar arguments we can also cover $[0,t_1-s_1]$ and $[t_{-1}+s_{-1}]$ and due to non-singularity of $t^{-1}(1-t\cot(t))\csc(t)$ at $t=0$ there will be no non-integral terms with $k=0$. So we are left with

$$-\alpha^{-1}\mu^{\frac{7}{2}}h^{-\frac{1}{2}}|t|^{-\frac{5}{2}}\cos(t)e^{i\hbar^{-1}(\varphi_{(1)}(t)-t\tau)}\big)\big|_{t=t_k-s_k}^{t=t_k+s_k}$$

and their absolute values do not exceed (28.A.30).

Finally, summation of (28.A.31) by $k:1\le|k|\le\min(\bar k,k^*)$ returns

$$\begin{aligned}(28.A.32)\quad &C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}(\alpha/\mu^2h)^{\frac{1}{2}}\\ &\qquad\times\begin{cases}(1+|\log(\mu h)|) & \beta\mu h\le\alpha,\\ (\alpha/\beta\mu h)^{\frac{1}{2}}(1+|\log(\mu h)|+|\log(\alpha/\beta\mu h)|) & \beta\mu h\ge\alpha.\end{cases}\end{aligned}$$

and we arrive to Proposition 28.A.5 below for $j=2$:

Proposition 28.A.5. *Let $\mu h \le \epsilon_0$, $\tau \asymp 1$, and $\alpha \le \mu^2 h$.*
Then

(i) Expression $(hD_{x_2} - \mu x_1)e(x,y,\tau)|_{x=y=0}$ does not exceed (28.A.32).

(ii) Expression $hD_{x_3}e(x,y,\tau)|_{x=y=0}$ does not exceed

$$C\begin{cases}\mu^{\frac{3}{2}}h^{-1}\beta\alpha^{-\frac{1}{2}}(1+|\log(\alpha/\beta\mu h)|) & \text{if } \beta\mu h \le \alpha,\\ \mu h^{-\frac{3}{2}}\beta^{\frac{1}{2}} & \text{if } \beta\mu h \ge \alpha.\end{cases} \tag{28.A.33}$$

(iii) Expression $hD_{x_1}e(x,y,\tau)|_{x=y=0}$ does not exceed

$$C\begin{cases}\mu^{\frac{3}{2}}h^{-1}\alpha^{\frac{1}{2}}(1+|\log(\alpha/\beta\mu h)|) & \text{if } \beta\mu h \le \alpha,\\ \mu h^{-\frac{3}{2}}\alpha^{\frac{1}{2}} & \text{if } \beta\mu h \ge \alpha.\end{cases} \tag{28.A.34}$$

Case $\mu h \ge \epsilon_0$

If $\mu h \ge \epsilon_0$ we consider a different representation: namely (16.2.15) for a spectral projector in dimension 2 (again after rescaling where we scale e_* as functions rather than Schwartz kernels):

$$e_{(2)}(x',y',\tau) = \tag{28.A.35}$$
$$(2\pi)^{-1}\mu h^{-1}\sum_{m\in\mathbb{Z}^+}\int \upsilon_m\bigl(\eta+\mu^{-\frac{1}{2}}h^{-\frac{1}{2}}(x_1-y_1)\bigr)\upsilon_m\bigl(\eta-\mu^{-\frac{1}{2}}h^{-\frac{1}{2}}(x_1-y_1)\bigr)$$
$$\times\theta\Bigl(\tau-\alpha\mu^{-1}(x_1+y_1)-2\alpha\mu^{-\frac{1}{2}}h^{\frac{1}{2}}\eta-\alpha^2\mu^{-2}-2m\mu h\Bigr)e^{i\mu^{-\frac{1}{2}}h^{-\frac{1}{2}}(x_2-y_2)\eta}\,d\eta,$$

where we also replaced $H_{(2)}$ by $H_{(2)}-\mu h$ and τ by $\mu h+\tau$. Since

$$e(x,y,\tau) = e_{(2)}(x',y',.)\ast_\tau e_{(1)}(x_3,y_3,.), \tag{28.A.36}$$

where $e_{(1)}(x_3,y_3,\tau)$ is a Schwartz kernel of the spectral projector of 1-dimensional operator

$$\mu^2h^2D_3^2 - 2\beta\mu^{-1}x_3, \tag{28.A.37}$$

we conclude that

$$e(x,y,\tau) \tag{28.A.38}$$
$$= (2\pi)^{-1}\mu h^{-1}\sum_{m\in\mathbb{Z}^+}\int \upsilon_m\bigl(\eta+\mu^{-\frac{1}{2}}h^{-\frac{1}{2}}(x_1-y_1)\bigr)\upsilon_m\bigl(\eta-\mu^{-\frac{1}{2}}h^{-\frac{1}{2}}(x_1-y_1)\bigr)$$
$$\times e_{(1)}\Bigl(x_3,y_3,\tau-\alpha\mu^{-1}(x_1+y_1)-2\alpha\mu^{-\frac{1}{2}}h^{\frac{1}{2}}\eta-\alpha^2\mu^{-2}-2m\mu h\Bigr)e^{i\mu^{-\frac{1}{2}}h^{-\frac{1}{2}}(x_2-y_2)\eta}\,d\eta.$$

Then

$$(28.A.39)\quad (\mu hD_{x_2} - x_1)e(x,y,\tau)\big|_{x=y=0} = (2\pi)^{-1}\mu^{\frac{3}{2}}h^{-\frac{1}{2}}\sum_{m\in\mathbb{Z}^+}\int \upsilon_m^2(\eta)\eta\times e_{(1)}\Big(0,0,\tau-2\alpha\mu^{-\frac{1}{2}}h^{\frac{1}{2}}\eta-\alpha^2\mu^{-2}-2m\mu h\Big)\,d\eta$$

and since $\upsilon_m(.)$ is an even (odd) function for even (odd) m we can replace $e_{(1)}(0,0,\tau' - 2\alpha\mu^{-\frac{1}{2}}h^{\frac{1}{2}}\eta)$ by

$$(28.A.40)\qquad e_{(1)}(0,0,\tau' - 2\alpha\mu^{-\frac{1}{2}}h^{\frac{1}{2}}\eta) - e_{(1)}(0,0,\tau' + 2\alpha\mu^{-\frac{1}{2}}h^{\frac{1}{2}}\eta).$$

In virtue of Subsubsection 5.2.1.3 *Asymptotics without Spatial Mollification* we know that an absolute value of this expression does not exceed $Ch^{-\frac{1}{2}}\alpha^{\frac{1}{2}}$ [40] we arrive to estimate[41]

$$(28.A.41)\qquad |(hD_{x_2} - \mu x_1)e(x,y,\tau)\big|_{x=y=0}| \le C\mu^{\frac{3}{2}}h^{-1}\alpha^{\frac{1}{2}}.$$

Further,

$$(28.A.42)\quad \mu hD_{x_1}e(x,y,\tau)\big|_{x=y=0} = i(2\pi)^{-1}\alpha\mu\sum_{m\in\mathbb{Z}^+}\int \upsilon_m^2(\eta)\times\partial_\tau e_{(1)}\big(0,0,\tau-2\alpha\mu^{-\frac{1}{2}}h^{\frac{1}{2}}\eta-\alpha^2\mu^{-2}-2m\mu h\big)\,d\eta$$
$$= i(2\pi)^{-1}\mu^{\frac{3}{2}}h^{-\frac{1}{2}}\sum_{m\in\mathbb{Z}^+}\int \upsilon_m(\eta)\upsilon_m'(\eta)\times e_{(1)}\big(0,0,\tau-2\alpha\mu^{-\frac{1}{2}}h^{\frac{1}{2}}\eta-\alpha^2\mu^{-2}-2m\mu h\big)\,d\eta$$

and using the same arguments we arrive to estimate[41]

$$(28.A.43)\qquad |hD_{x_1}e(x,y,\tau)\big|_{x=y=0}| \le C\mu^{\frac{3}{2}}h^{-1}\alpha^{\frac{1}{2}}.$$

Finally,

$$(28.A.44)\quad \mu hD_{x_3}e(x,y,\tau)\big|_{x=y=0} = (2\pi)^{-1}\mu h^{-1}\sum_{m\in\mathbb{Z}^+}\int \upsilon_m^2(\eta) \times \underbrace{\mu hD_{x_3}e_{(1)}\big(x_3,y_3,\tau-2\alpha\mu^{-\frac{1}{2}}h^{\frac{1}{2}}\eta-\alpha^2\mu^{-2}-2m\mu h\big)\big|_{x_3=y_3=0}}\,d\eta$$

[40] Only in the worst case when $|\tau - 2m\mu h|$ is not disjoint from 0.

[41] In the non-rescaled coordinates.

and again in virtue of Subsubsection 5.2.1.3 *Asymptotics without Spatial Mollification* we know that an absolute value of selected expression does not exceed $Ch^{-\frac{1}{2}}\beta^{\frac{1}{2}}$ [42] and we arrive to estimate[41]

$$|hD_{x_3}e(x,y,\tau)\big|_{x=y=0}| \le C\mu h^{-\frac{3}{2}}\beta^{\frac{1}{2}}. \tag{28.A.45}$$

Therefore we have proven

Proposition 28.A.6. *Let $\mu h \ge 1$, $\alpha \le 1$, $\beta \le 1$, $|\tau| \le c_0$. Then for operator $(H-\mu h)$ estimates* (28.A.41)*,* (28.A.43) *and* (28.A.45) *hold.*

Tauberian Estimates

Remark 28.A.7. Assume now that all assumptions are fulfilled only in $B(0,\ell)$ rather than in $\mathbb{R}^3$. Then there is also a Tauberian estimate which should be added to Weyl estimate. This Tauberian estimate (the same for all $j=1,2,3$) coincides with the Tauberian estimate was calculated in Chapter 16. Namely

(i) For $\mu h \le 1$, $\ell \ge C_0\mu^{-1}$ this Tauberian estimate was calculated in Proposition 16.6.2(ii)[41].

(ii) For $\mu h \ge 1$, $\ell \ge C_0 h$ this Tauberian estimate was calculated in Proposition 16.6.7(i) and corollary 16.6.8(i)[41] and it does not exceed $C\mu h^{-\frac{3}{2}}\ell^{-1}$.

Important Remarks

One can apply estimates of $\mathsf{D}(\rho_\Psi - \rho_B^{\mathsf{TF}},\ \rho_\Psi - \rho_B^{\mathsf{TF}})$ to the following problems we considered in the frameworks of chapters 25, 26 and 27:

1. Excessive negative charge (estimates).
2. Ionization energy (estimates and asymptotics: again we estimate only $(\mathsf{I}^* + \nu)_+$ rather than $|\mathsf{I}^* + \nu|$.
3. Excessive positive charge in the free nuclei model as $M \ge 2$.

We leave it to the reader.

[42] Without applying $(hD_j - \mu A_j(x))$ but it does not matter.

Spectral Asymptotics For The Semiclassical Dirichlet To Neumann Operator *,†

Andrew Hassell‡, Victor Ivrii§

Abstract

Let M be a compact Riemannian manifold with smooth boundary, and let $R(\lambda)$ be the Dirichlet-to-Neumann operator at frequency λ. The semiclassical Dirichlet-to-Neumann operator $R_{\mathsf{scl}}(\lambda)$ is defined to be $\lambda^{-1}R(\lambda)$. We obtain a leading asymptotic for the spectral counting function for $R_{\mathsf{scl}}(\lambda)$ in an interval $[a_1, a_2)$ as $\lambda \to \infty$, under the assumption that the measure of periodic billiards on T^*M is zero. The asymptotic takes the form

$$\mathsf{N}(\lambda; a_1, a_2) = \big(\kappa(a_2) - \kappa(a_1)\big)\,\mathsf{vol}'(\partial M)\lambda^{d-1} + o(\lambda^{d-1}),$$

where $\kappa(a)$ is given explicitly by

$$\kappa(a) = \frac{\omega_{d-1}}{(2\pi)^{d-1}}\bigg(-\frac{1}{2\pi}\int_{-1}^{1}(1-\eta^2)^{(d-1)/2}\frac{a}{a^2+\eta^2}\,d\eta \\ -\frac{1}{4} + H(a)(1+a^2)^{(d-1)/2}\bigg).$$

1 Introduction

Let M be a Riemannian manifold with boundary. The Dirichlet-to-Neumann operator is a family of operators defined on $L^2(\partial M)$ depending on the parameter $\lambda \geq 0$. It is defined as follows: given $f \in L^2(\partial M)$, we solve the equation (if possible)

$$(\Delta - \lambda^2)u = 0 \quad \text{on} \quad M, \qquad u|_{\partial M} = f. \tag{1.1}$$

Then the Dirichlet-to-Neumann operator at frequency λ is the map

$$R(\lambda) : f \mapsto -\partial_\nu u|_{\partial M}. \tag{1.2}$$

Here ∂_ν is the interior unit normal derivative, and Δ is the positive Laplacian on M.

It is well known that $R(\lambda)$ is a self-adjoint, semi-bounded from below pseudodifferential operator of order 1 on $L^2(\partial M)$, with domain $H^1(\partial M)$. It therefore has discrete spectrum accumulating only at $+\infty$. The Dirichlet-to-Neumann operator and closely related operators are important in a number of areas of mathematical analysis including inverse problems (such as Calderón's problem [Cal]), domain decomposition problems (such as the determinant gluing formula of Burghelea-Friedlander-Kappeler [BFK]), and spectral asymptotics (see e.g. [Fried]).

In this paper, we are interested in the spectral asymptotics of $R(\lambda)$ in the high-frequency limit, $\lambda \to \infty$. Let us recall standard spectral asymptotics for elliptic differential operators, for simplicity in the simplest case of a positive self-adjoint second order scalar operator. Suppose that Q is such an operator on a manifold M of dimension d, with principal symbol q. Then in the case that M is closed, we have an asymptotic for the number $\mathsf{N}(\lambda)$ of eigenvalues of Q (counted with multiplicity) less than λ^2:

$$\begin{aligned} \mathsf{N}(\lambda) &= (2\pi)^{-d}\,\mathsf{vol}\{(x,\xi) \in T^*M \mid q(x,\xi) \leq \lambda^2\} + O(\lambda^{d-1}) \\ &= \big(\frac{\lambda}{2\pi}\big)^d\,\mathsf{vol}\{(x,\xi) \in T^*M \mid q(x,\xi) \leq 1\} + O(\lambda^{d-1}), \end{aligned} \tag{1.3}$$

where the equality of the two expressions on the RHS is a simple consequence of the homogeneity of q. Moreover, if the set of periodic geodesics has measure zero, then there is a two-term expansion of the form

$$\big(\frac{\lambda}{2\pi}\big)^d\,\mathsf{vol}\{(x,\xi) \in T^*M \mid q(x,\xi) \leq 1\} + \frac{\lambda^{d-1}}{(2\pi)^d}\int_{\{q=1\}} \mathsf{sub}(Q) + o(\lambda^{d-1})$$

where $\mathsf{sub}(Q)$ is the subprincipal symbol of Q [DuGu]. This was generalised to the case of manifolds with boundary by the second author [Ivr1]. For simplicity we state the result in the case that $Q = \Delta$ is the (positive) metric Laplacian, which satisfies $\mathsf{sub}(\Delta) = 0$. Then Δ is a self-adjoint operator under either Dirichlet $(-)$ or Neumann $(+)$ boundary conditions, and if the set of periodic generalised bicharacteristics has measure zero, we get a two-term expansion for $\mathsf{N}_\Delta(\lambda)$ of the form

$$\Big(\frac{\lambda}{2\pi}\Big)^d \mathsf{vol}\, B^*M \pm \frac{1}{4}\Big(\frac{\lambda}{2\pi}\Big)^{d-1} \mathsf{vol}\, B^*\partial M + o(\lambda^{d-1}). \tag{1.4}$$

These statements can be generalized to the semiclassical setting. Consider a classical Schrödinger operator on M, $P = h^2\Delta + V(x) - 1$, where $h > 0$ is a small parameter ("Planck's constant") and V is a smooth real-valued function. We consider the asymptotic behaviour $\mathsf{N}_h^-(P)$ of the number of negative eigenvalues of P as $h \to 0$. This is equivalent to the problem above if $h = \lambda^{-1}$ and V is identically zero. Define $p(x,\xi)$ to be the semiclassical symbol of P, i.e. $p = |\xi|^2_{g(x)} + V(x) - 1$. Then, if M is closed, under the assumption that the measure of periodic bicharacteristics of P is zero in T^*M, and that 0 is a regular value for p, we have

$$\mathsf{N}_h^-(P) = (2\pi h)^{-d}\, \mathsf{vol}\{(x,\xi) \in T^*M \mid p(x,\xi) \le 0\} + O(h^{1-d}). \tag{1.5}$$

Moreover, for manifolds with boundary, we have an analogue of (1.4): under either Dirichlet $(-)$ or Neumann $(+)$ boundary conditions, if the set of periodic generalised bicharacteristics has measure zero, we get a two-term expansion for $\mathsf{N}_h^-(P)$ (where here we understand the self-adjoint realization of P with either Dirichlet or Neumann boundary condition) of the form

$$(2\pi h)^{-d}\, \mathsf{vol}\{(x,\xi) \in T^*M \mid p(x,\xi) \le 0\} \pm \frac{1}{4}(2\pi h)^{1-d}\, \mathsf{vol}\, \mathcal{H} + o(h^{1-d}), \tag{1.6}$$

where $\mathcal{H} \subset T^*(\partial M)$ is the hyperbolic region in the boundary, that is, the projection of the set $\{(x,\xi) \mid p(x,\xi) \le 0\} \cap T^*_{\partial M}M$ to $T^*\partial M$.

From the semiclassical point of view, since $R(\lambda)$ is a first order operator, it makes sense to consider $R_{\mathsf{scl}}(\lambda) := \lambda^{-1}R(\lambda)$ (for $\lambda > 0$), which we call the semiclassical Dirichlet-to-Neumann operator. Like $R(\lambda)$, it is a self-adjoint, semi-bounded from below operator on $L^2(\partial M)$, with discrete spectrum accumulating only at $+\infty$. The goal of this paper is to investigate the spectral asymptotics of $R_{\mathsf{scl}}(\lambda)$, that is, the asymptotics of

$$\mathsf{N}(\lambda; a_1, a_2) \coloneqq \#\{\beta :\ \beta \text{ is an eigenvalue of } \ R_{\mathsf{scl}}(\lambda),\ a_1 \le \beta < a_2\}, \tag{1.7}$$

the number of eigenvalues of $R_{\mathrm{scl}}(\lambda)$ in the interval $[a_1, a_2)$, as $\lambda \to \infty$.

Both $R(\lambda)$ and $R_{\mathrm{scl}}(\lambda)$ have the disadvantage that they are undefined whenever λ^2 is a Dirichlet eigenvalue, since then (1.1) is not solvable for arbitrary $f \in H^1(M)$. Indeed, when λ^2 is a Dirichlet eigenvalue, a necessary condition for solvability of (1.1) is that f is orthogonal to the normal derivatives of Dirichlet eigenfunctions at frequency λ. To overcome this issue, we introduce the *Cayley transform* of $R_{\mathrm{scl}}(\lambda)$: we define

$$C(\lambda) = (R_{\mathrm{scl}}(\lambda) - i)(R_{\mathrm{scl}}(\lambda) + i)^{-1}. \tag{1.8}$$

This family of operators is related to impedance boundary conditions: we have $C(\lambda)f = g$ if and only if there is a function u on M satisfying

$$(\Delta - \lambda^2)u = 0 \tag{1.9}$$

and

$$\frac{1}{2}(\lambda^{-1}\partial_\nu u - iu) = f, \qquad \frac{1}{2}(\lambda^{-1}\partial_\nu u + iu) = g. \tag{1.10}_{1,2}$$

As observed in [BH], $C(\lambda)$ is a well-defined analytic family of operators for λ in a neighbourhood of the positive real axis, which is unitary on the real axis. In particular, it is well-defined even when λ^2 is a Dirichlet eigenvalue of the Laplacian on M. As a unitary operator, $C(\lambda)$, $\lambda > 0$, has its spectrum on the unit circle, and as $R_{\mathrm{scl}}(\lambda)$ has discrete spectrum accumulating only at ∞, it follows that the spectrum of $C(\lambda)$ is discrete on the unit circle except at the point 1. Our question can be formulated in terms of $C(\lambda)$: given two angles θ_1, θ_2 satisfying $0 < \theta_1 < \theta_2 < 2\pi$, what is the leading asymptotic for

$$\tilde{\mathsf{N}}(\lambda; \theta_1, \theta_2) := \#\{e^{i\theta} : \ e^{i\theta} \text{ is an eigenvalue of } \ C(\lambda), \ \theta_1 \le \theta < \theta_2\} \tag{1.11}$$

the number of eigenvalues of $C(\lambda)$ in the interval $\{e^{i\theta} : \theta \in [\theta_1, \theta_2)\}$ of the unit circle, as $\lambda \to \infty$. Clearly, we have

$$\tilde{\mathsf{N}}(\lambda; \theta_1, \theta_2) = \mathsf{N}(\lambda; a_1, a_2), \text{ where } \ e^{i\theta_j} = \frac{a_j - i}{a_j + i}, \text{ i.e. } a_j = -\cot\Big(\frac{\theta_j}{2}\Big). \tag{1.12}$$

To answer this question we relate it to a standard semiclassical eigenvalue counting problem on M. To state the next result, we first define the self-adjoint operator $P_{a,h}$ on $L^2(M)$ by

$$\mathfrak{D}(P_{a,h}) = \{u \in H^2(M) : \ (h\partial_\nu + a)u = 0 \ \text{ at } \ \partial M\}, \tag{1.13}$$

$$P_{a,h}(u) = (h^2\Delta - 1)u, \quad u \in \mathfrak{D}(P_{a,h}). \tag{1.14}$$

It is the self-adjoint operator associated to the semi-bounded quadratic form

$$h^2\|\nabla u\|_M^2 - \|u\|_M^2 - ha\|u\|_{\partial M}^2. \tag{1.15}$$

The operator $P_{a,h}$ is linked with the semiclassical Dirichlet-to-Neumann operator as follows: if f is an eigenfunction of $R_{\mathsf{scl}}(\lambda)$ with eigenvalue a, then the corresponding Helmholtz function u defined by (1.1) is in the domain (1.13) of $P_{a,h}$, and $P_{a,h}u = 0$ (where $h = \lambda^{-1}$).

Then we have the following result, proved in Section 2.

Proposition 1.1. *Let $h = \lambda^{-1}$. Assume $0 < \theta_1 < \theta_2 < 2\pi$. Then the number of eigenvalues of $C(\lambda)$ in the interval $J_{\theta_1,\theta_2} := \{e^{i\theta} : \theta \in [\theta_1, \theta_2)\}$ is equal to*

$$\tilde{\mathsf{N}}(\lambda; \theta_1, \theta_2) = \mathsf{N}(\lambda; a_1, a_2) = \mathsf{N}_h^-(a_2) - \mathsf{N}_h^-(a_1), \tag{1.16}$$

where $a_j = -\cot(\theta_j/2)$ and

$$\mathsf{N}_h^-(a) \coloneqq \#\{\mu : \mu \text{ is an eigenvalue of } P_{a,h},\ \mu < 0\}. \tag{1.17}$$

Having thus reduced the problem to a standard question about semiclassical spectral asymptotics, we obtain (after some calculations in Section 3) our main result.

Theorem 1.2. *(i) The following estimate for the quantity (1.11) holds:*

$$\mathsf{N}(\lambda; a_1, a_2) = O(\lambda^{d-1}); \tag{1.18}$$

(ii) Further, if the set of periodic billiards on M has measure 0 then the following asymptotic holds as $\lambda \to +\infty$:

$$\mathsf{N}(\lambda; a_1, a_2) = \big(\kappa(a_2) - \kappa(a_1)\big)\,\mathsf{vol}'(\partial M)\lambda^{d-1} + o(\lambda^{d-1}), \tag{1.19}$$

where $\kappa(a)$ is given explicitly by

$$\kappa(a) = \frac{\omega_{d-1}}{(2\pi)^{d-1}}\bigg(-\frac{1}{2\pi}\int_{-1}^{1}(1-\eta^2)^{(d-1)/2}\frac{a}{a^2+\eta^2}\,d\eta \\ -\frac{1}{4} + H(a)(1+a^2)^{(d-1)/2}\bigg). \tag{1.20}$$

Here $H(\cdot)$ is the Heaviside function, ω_d is the volume of the unit ball in $\mathbb{R}^d$, and $\mathsf{vol}(M)$ and $\mathsf{vol}'(\partial M)$ are d-dimensional volume of M and $(d-1)$-dimensional volume of ∂M respectively.

(iii) In the case $d = 3$*, we can evaluate this integral exactly and we find that*

$$\kappa(a) = \frac{1}{4\pi}\Big(-\frac{1}{4} - \frac{1}{\pi}\operatorname{arccot}(a)(1+a^2) + (1+a^2) + \frac{1}{\pi}a\Big) \tag{1.21}$$

where arccot *has range* $(0,\pi)$*. This is simpler expressed in terms of* θ*. Defining* $\tilde\kappa(\theta) = \kappa(a)$ *where* $a = -\cot(\theta/2) = \cot(\pi - \theta/2)$*, we have (still under the zero-measure assumption on periodic billiards)*

$$\tilde{\mathsf{N}}(\lambda;\theta_1,\theta_2) = \big(\tilde\kappa(\theta_2) - \tilde\kappa(\theta_1)\big)\,\mathrm{vol}'(\partial M)\lambda^2 + o(\lambda^2), \tag{1.22}$$

$$\tilde\kappa(\theta) = \frac{1}{4\pi}\Big(-\frac{1}{4} + \frac{1}{2\pi}\big(\frac{\theta - \sin\theta}{\sin^2(\theta/2)}\big)\Big). \tag{1.23}$$

Remark 1.3. It looks disheartening that we only get an upper bound in case (i) and only a "o" remainder under a global geometric condition, but it is the nature of the beast.

In regards to case (i), consider M a hemisphere; then for $\lambda_n^2 = n(n+d-1)$ with $n \in \mathbb{Z}^+$ the operator $R(\lambda)$ has eigenvalue 0 of multiplicity $\asymp n^{d-1}$, hence $N(\lambda; a_1, a_2)$ jumps by at least $c\lambda^{d-1}$ as a_1 or a_2 crosses zero. Therefore, in this case, we do not have an asymptotic, but only an estimate.

In regards to case (ii), we believe that the "o" remainder is the best that can be achieved using current technology. To justify this, consider the problem of finding the spectral asymptotics of the semiclassical Dirichlet-to-Neumann operator for the operator $\Delta + \lambda^2$, instead of $\Delta - \lambda^2$ (for real λ). In this case, one can readily check that the semiclassical Dirichlet-to-Neumann operator is a semiclassically elliptic pseudodifferential operator on the boundary, with principal symbol $\sqrt{1 + h^2\Delta_{\partial M}}$. Then standard spectral asymptotics hold for this operator, and we would get a remainder term $O(\lambda^{d-2})$. However, for the operator $\Delta - \lambda^2$, the semiclassical Dirichlet-to-Neumann operator is only microlocally elliptic in the region $\{(y,\eta) \mid |\eta|_{g'} > 1\} \subset T^*\partial M$, where g' is the induced metric on the boundary. It is hyperbolic in the region where $|\eta|_{g'} < 1$, and that means there is (currently) no machinery for *directly* tackling its spectral asymptotics. Instead, we proceed by relating it to the spectral asymptotics for the interior problem with a family of boundary conditions depending on the spectral parameter a. This means that the problem is in some sense really d-dimensional, and our $o(\lambda^{d-1})$ remainder is the "ghost" of d-dimensional spectral asymptotics, in which the principal, Weyl term cancels under taking the difference (1.16),

and all we are left with is the second term — and only under the global geometric assumption of measure zero periodic billiard trajectories.

We note that under stronger assumptions on the billiard flow, the remainder could be improved, for example to $O(\lambda^{d-1-\delta})$ for some $\delta > 0$ in the case of a Euclidean ellipse or elliptical annulus — see Section 7.4 of [Ivr4].

Remark 1.4. One can consider eigenvalues of operator $\rho\lambda^{-1}R(\lambda)$ with $\rho > 0$ smooth on ∂M; then estimates (3.1), (1.18) and asymptotics (3.2), (1.19) hold in the frameworks of Statement (i) and (ii) of Theorem 1.2 respectively albeit with $\kappa(a)\,\mathsf{vol}'(\partial M)$ replaced by

$$\int_{\partial M} \kappa(\rho(x')a)\, d\sigma$$

where $d\sigma$ is a natural measure on ∂M; however without this condition $\rho > 0$ problem may be much more challenging; even self-adjointness is by no means guaranteed.

Remark 1.5. Operators of the form $P_{a,h}$ were considered by Frank and Geisinger [FG]. They showed that the trace of the negative part of $P_{a,h}$ has a two-term expansion as $h \to 0$ regardless of dynamical assumptions[1)], and the second term in their expansion (the $L_d^{(2)}$ term of [FG, Theorem 1.1]) is closely related to $\kappa(a)$ — see Remark 3.4.

Remark 1.6. We can rephrase Theorem 1.2 in terms of a limiting measure on the unit circle. For each $\lambda > 0$, let $\mu(h)$, $h = \lambda^{-1}$, denote the atomic measure determined by the spectrum of $C(\lambda)$:

$$\mu(h) = (2\pi h)^{d-1} \sum_{e^{i\theta_j} \in \mathsf{spec} C(h^{-1})} \delta(\theta - \theta_j), \tag{1.24}$$

where we include each eigenvalue according to its multiplicity as usual. Then Theorem 1.2 can be expressed in the following way: the measures $\mu(h)$ converge in the weak-$*$ topology as $h \to 0$ to the measure

$$\omega_{d-1}\,\mathsf{vol}'(\partial M)\frac{d}{d\theta}\tilde{\kappa}(\theta)d\theta \quad \text{on } (0, 2\pi), \text{ that is on } S^1 \setminus \{1\}. \tag{1.25}$$

[1)] The fact that Frank and Geisinger obtain a second term regardless of dynamical assumptions is simply due to the fact that they study $\mathsf{Tr}\, f(P_{a,h})$ with $f(\lambda) = -\lambda H(-\lambda)$ (H is the Heaviside function), which is one order smoother than $f(\lambda) = H(-\lambda)$.

In particular, this measure is absolutely continuous, and finite away from $e^{i\theta} = 1$ with an infinite accumulation of mass as $\theta \uparrow 2\pi$. In this form, we can compare our result with results on the semiclassical spectral asymptotics of scattering matrices. In [DGHH] and [GHZ], the scattering matrix $S_h(E)$ at energy E for the Schrödinger operator $h^2\Delta + V(x)$ on $\mathbb{R}^d$ was studied in the semiclassical limit $h \to 0$. Assuming that V is smooth and compactly supported, that E is a nontrapping energy level, and that the set of periodic trajectories of the classical scattering transformation on T^*S^{d-1} has measure zero, it was shown that the measure $\mu(h)$ defined by (1.24) converged weak-$*$ to a uniform measure on $S^1 \setminus \{1\}$, with an atom of infinite mass at the point 1. On the other hand, for polynomially decaying potentials, it was shown by Sobolev and Yafaev [H-SoYa] in the case of central potentials and by Gell-Redman and the first author more generally [GRH] that there is a limiting measure which is nonuniform, and is qualitatively similar to the measure for $C(h^{-1})$ above in that it is finite away from 1, with an infinite accumulation of mass at 1 from one side.

2 Reduction to Semiclassical Spectral Asymptotics

In this section we prove Proposition 1.1. This result actually follows directly from the Birman-Schwinger principle. As some readers may not be familiar with this, we give the details.

Proof of Proposition 1.1. We begin by recalling that the operator $P_{a,h}$ is the self-adjoint operator associated to the quadratic form (1.15), that is,

$$Q_{a,h}(u) := h^2\|\nabla u\|_M^2 - \|u\|_M^2 - ha\|u\|_{\partial M}^2.$$

We recall the min-max characterization of eigenvalues: the nth eigenvalue $\mu_n(a,h)$ of $P_{a,h}$ is equal to the infimum of

$$\sup_{v\in V, \|v\|=1} Q_{a,h}(v)$$

over all subspaces $V \in H^1(M)$ of dimension n. The monotonicity of $Q_{a,h}$ in a, for fixed h, shows that the eigenvalues are monotone nonincreasing with a. In fact, they are strictly decreasing, which follows from the fact

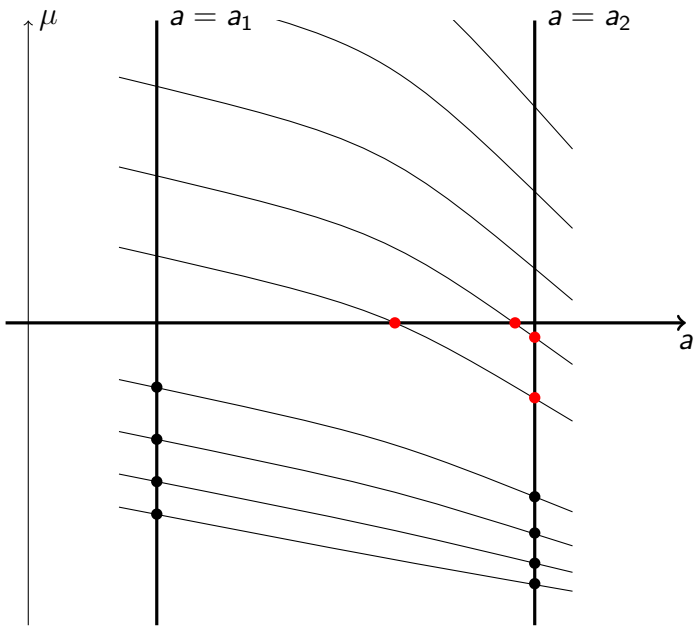

Figure 28.1: Diagram showing the variation of eigenvalues $\mu(a,h)$ of $P_{a,h}$ as a function of a for fixed h. The eigenvalues are strictly decreasing in a. Consequently, the number of negative eigenvalues of $P_{a_2,h}$ is equal to the number of negative eigenvalues of $P_{a_1,h}$ together with the number that cross the a-axis between $a = a_1$ and $a = a_2$.

that eigenfunctions of $P_{a,h}$ cannot vanish at the boundary. Indeed, the eigenfunctions satisfy the boundary condition $h\partial_\nu u = -au$, which shows that if u vanishes at the boundary, so does $\partial_\nu u$, which is impossible.

The eigenvalues $\mu_n(a,h)$ are thus continuous, strictly decreasing functions of a. Let $a_1 < a_2$ be real numbers. The Birman-Schwinger principle [Ivr3, Prop. 9.2.7] says that the number of negative eigenvalues of $P_{a_2,h}$ is equal to the number of negative eigenvalues of $P_{a_1,h}$, plus the number of eigenvalues $\mu_n(a,h)$ of $P_{a,h}$ that change from nonnegative to negative as a varies from a_1 to a_2. A diagram makes this clear: see Figure 28.1.

The strict monotonicity of $\mu(a,h)$ in a shows that the number of eigenvalues $\mu_n(a,h)$ of $P_{a,h}$ that change from nonnegative to negative as a varies from a_1 to a_2 is the same as the number of $\mu(a,h)$ (counted with multiplicity) equal to zero, for $a \in [a_1, a_2)$. Next, we observe that the space of eigenfunctions $u_n(a,h)$ of $P_{a,h}$ with zero eigenvalue, i.e. $\mu_n(a,h) = 0$ is in one-to-one

correspondence with the space of eigenfunctions of $C(\lambda)$, $\lambda = h^{-1}$, with eigenvalue $(a-i)(a+i)^{-1}$, or equivalently $e^{i\theta}$ where $a = -\cot(\theta/2)$. Indeed, whenever u_n is such an eigenfunction of $P_{a,h}$, then

$$f := \frac{1}{2}(h\partial_\nu u - iu)\big|_{\partial M} \tag{2.1}$$

is an eigenfunction of $C(\lambda)$, with eigenvalue $(a-i)(a+i)^{-1}$. Conversely, if f is an eigenfunction of $C(\lambda)$ with eigenvalue $(a-i)(a+i)^{-1}$, then by definition there exists a Helmholtz function u such that u is related to f according to (2.1), and we have $(h\partial_\nu + a)u = 0$ at ∂M. This completes the proof. □

Remark 2.1. We can apply similar arguments for $\lambda^{-\delta}\rho^{-1}R(\lambda)$ as $\rho > 0$ is a smooth function on ∂M and then plug corresponding parameters in the boundary conditions coming again to equality (1.16).

We next digress to prove that the eigenvalues of $C(\lambda)$ are monotonic (that is, they move monotonically around the unit circle) in λ. This plays no role in the remainder of our proof, but is (in the authors' opinion) of independent interest.

Proposition 2.2. *The eigenvalues of $C(\lambda)$ rotate clockwise around the unit circle as λ increases.*

Remark 2.3. This implies that the eigenvalues of $R_{\mathrm{scl}}(\lambda)$ are monotone decreasing in λ.

Proof. As discussed in the previous proof, $C(\lambda)$ has eigenvalue $e^{i\theta}$ if and only if $P_{a,h}$ has a zero eigenvalue, where $a = a(\theta) = -\cot(\theta/2)$. Thus, as a function of $h = \lambda^{-1}$, $\theta(h)$ is defined implicitly by the condition

$$\mu(a(\theta), h) = 0.$$

Since a is a strictly increasing function of θ, and we have just seen that μ is a strictly decreasing function of a, it suffices to show that when $\mu = 0$, μ is a strictly increasing function of h, hence a strictly decreasing function of λ.

We now compute the derivative of μ with respect to h, at a value of a and h where $\mu(a,h)=0$. We have

$$\begin{aligned}\frac{d}{dh}\mu(a,h) &= \frac{d}{dh}((h^2\Delta-1)u(h),u(h))_M \\ &= 2h(\Delta u,u)_M + ((h^2\Delta-1)u'(h),u(h))_M + ((h^2\Delta-1)u(h),u'(h))_M \\ &= 2h(\Delta u,u)_M + ((h^2\Delta-1)u',u)_M - (u',(h^2\Delta-1)u)_M.\end{aligned}$$

In the third line, we used the fact that $(h^2\Delta-1)u=0$ when $\mu(h)=0$. Note the second term is not zero, as u' is not in the domain of the operator due to the changing boundary condition, so we cannot move the operator to the right hand side of the inner product without incurring boundary terms. We use the Gauss-Green formula to express the last two terms as a boundary integral:

$$\begin{aligned}\mu'(h) &= 2h(\Delta u,u)_M + h(h\partial_\nu u',u)_{\partial M} - h(u',h\partial_\nu u)_{\partial M} \\ &= 2h(\Delta u,u)_M + h(h\partial_\nu u',u)_{\partial M} + ha(u',u)_{\partial M}.\end{aligned}$$

Differentiating the boundary condition we find that

$$(h\partial_\nu + a)u' = -h\partial_\nu u \text{ at } \partial M.$$

Substituting that in we get

$$\mu'(h) = 2h(\Delta u,u)_M - h(u,\partial_\nu u)_{\partial M}.$$

Applying Gauss-Green again, we get

$$\begin{aligned}\mu'(h) &= h(\Delta u,u)_M + h\|\nabla u\|^2_M \\ &= h^{-1}\Big(\|u\|^2_{L^2(M)} + \|h\nabla u\|^2_{L^2(M)}\Big) > 0.\end{aligned}$$

3 Semiclassical Spectral Asymptotics

In this section, we prove Theorem 1.2. Essentially, we have arrived at a rather standard semiclassical spectral asymptotics problem and results are due to [Ivr3], Chapter 5 or [Ivr4], Chapter 7. See the appendix to this paper for further discussion.

Proposition 3.1. *(i) Let* $\mathsf{N}_h^-(a)$ *be as in (1.17). The following asymptotic holds as* $h \to +0$*:*

$$\mathsf{N}_h^-(a) = (2\pi h)^{-d}\omega_d \operatorname{vol}(M) + O(h^{1-d}) \tag{3.1}$$

(ii) Further, if the set of periodic billiards on M *has measure* 0 *then as* $h \to +0$*:*

$$\mathsf{N}_h^-(a) = (2\pi h)^{-d}\omega_d \operatorname{vol}(M) + h^{1-d}\kappa(a)\operatorname{vol}'(\partial M) + o(h^{1-d}) \tag{3.2}$$

with $\kappa(a)$ *given by (1.20).*

Proof. One can check easily that the operator $P_{a,h}$ is microhyperbolic at energy level 0 at each point $(x,\xi) \in T^*M$ in the direction ξ; further, the boundary value problem is microhyperbolic at each point $(x';\xi') \in T^*\partial M$ at energy level 0 in the multidirection (ξ', ξ_1^-, ξ_1^+) with $\xi_1 = \xi_1^{\pm}$ roots of $\sum g^{jk}\xi_j\xi_k = 0$; finally, the boundary value problem is elliptic at each point of the elliptic zone ($\subset T^*\partial M$) if $a \le 0$, and either elliptic or microhyperbolic in the direction ξ' at each point of the elliptic zone ($\subset T^*\partial M$) if $a > 0$ — see definitions in Chapters 2, 3 of [Ivr4]. Then statements (1.18), (1.19) follow from Theorems 7.3.11 and 7.4.1 of [Ivr4].

We now assume that the set of periodic billiards on M has measure zero, and compute the second term in the spectral asymptotic explicitly. Similar calculations appear in [FG].

To do this, one can use method of freezing coefficients (see the appendix, or [Ivr4], 7.2) which results in

$$h^{1-d}\kappa(a) = \int_{\mathbb{R}^+} \bigl(e(0,x_1;0,x_1;1) - (2\pi h)^{-d}\omega_d\bigr)\,dx_1 \tag{3.3}$$

where $e(x',x_1;y',y_1;\tau)$ is the Schwartz kernel of the spectral projector $E(\tau)$ of the operator $H_a = h^2\Delta$ in half-space $\mathbb{R}^{d-1}\times\mathbb{R}^+ \ni (x',x_1)$ with domain $\mathfrak{D}(H_a) = \{u \in H^2 :\ (h\partial_{x_1} + a)u|_{x_1=0} = 0\}$.

We obtain this spectral projector by integrating the spectral measure. This in turn is obtained via Stone's formula

$$dE_L(\sigma) = \frac{1}{2\pi i}\Bigl(\bigl(L - (\sigma + i0)\bigr)^{-1} - \bigl(L - (\sigma - i0)^{-1}\Bigr)\,d\sigma. \tag{3.4}$$

Consider the resolvent for H_a, $(H_a - \sigma)^{-1}$, for $\sigma \in \mathbb{C} \setminus \mathbb{R}$. Using the Fourier transform in the x' variables, we can write the Schwartz kernel of this resolvent in the form

$$(2\pi h)^{1-d} \int e^{i(x'-y')\cdot\xi'} (T_a + |\xi'|^2 - \sigma)^{-1}(x_1, y_1)\, d\xi'. \tag{3.5}$$

Here T_a is the one-dimensional operator $T_a = -h^2\partial^2 + |\xi'|^2$ on $L^2(\mathbb{R}_+)$ under the boundary condition $(h\partial + a)u|_{x_1=0} = 0$. The spectral projector $E_{H_a}(1)$ is therefore given by

$$(2\pi h)^{1-d} \int_{-\infty}^{1} \int e^{i(x'-y')\cdot\xi'}\, dE_{T_a}(\sigma - |\xi'|^2)(x_1, y_1)\, d\xi'\, d\sigma. \tag{3.6}$$

Thus, we need to find the spectral measure for T_a. Write $\sigma - |\xi'|^2 = \eta^2$, where we take η to be in the first quadrant of $\mathbb{C}$ for $\operatorname{Im}\sigma > 0$, and in the fourth quadrant for $\operatorname{Im}\sigma < 0$.

Lemma 3.2. *Suppose that* $\operatorname{Im}\eta > 0$ *and* $\operatorname{Re}\eta \geq 0$. *Then the resolvent kernel* $(T_a - \eta^2)^{-1}$ *takes the form*

$$(T_a - \eta^2)(x,y) = \begin{cases} \frac{i}{2h\eta}\left(e^{i\eta(x-y)/h} + \frac{i\eta - a}{i\eta + a} e^{i\eta(x+y)/h}\right), & x > y \\ \frac{i}{2h\eta}\left(e^{i\eta(y-x)/h} + \frac{i\eta - a}{i\eta + a} e^{i\eta(x+y)/h}\right), & x < y. \end{cases} \tag{3.7}$$

If $\operatorname{Im}\eta < 0$ *and* $\operatorname{Re}\eta \geq 0$, *then the resolvent kernel* $(T_a - \eta^2)^{-1}$ *takes the form*

$$(T_a - \eta^2)(x,y) = \begin{cases} -\frac{i}{2h\eta}\left(e^{i\eta(y-x)/h} + \frac{i\eta + a}{i\eta - a} e^{-i\eta(x+y)/h}\right), & x > y \\ -\frac{i}{2h\eta}\left(e^{i\eta(x-y)/h} + \frac{i\eta + a}{i\eta - a} e^{-i\eta(x+y)/h}\right), & x < y. \end{cases} \tag{3.8}$$

Proof. In the regions $x < y$ and $x > y$, the resolvent kernel must be a linear combination of $e^{i\eta x/h}$ and $e^{-i\eta x/h}$. Moreover, for $\operatorname{Im}\eta > 0$, we can only have the $e^{+i\eta x/h}$ term, as $x \to \infty$, as the other would be exponentially increasing. So we can write the kernel in the form

$$\begin{cases} c_1 e^{+i\eta x/h}, & x > y \\ c_2 e^{+i\eta x/h} + c_3 e^{-i\eta x/h}, & x < y. \end{cases} \tag{3.9}$$

We apply the boundary condition, and the two connection conditions at $x = y$, namely continuity, and a jump in the derivative of $-1/h$, in order to

obtain the delta function $\delta(x-y)$ after applying T_a. These three conditions determine the c_i uniquely, and we find that, in the case $\operatorname{Im}\eta > 0$,

$$(3.10)_1 \qquad c_1 = \frac{i}{2h\eta}\big(e^{-i\eta y/h} + \frac{i\eta - a}{i\eta + a}e^{+i\eta y/h}\big),$$

$$(3.10)_{2,3} \qquad c_2 = \frac{i}{2h\eta}\frac{i\eta - a}{i\eta + a}e^{+i\eta y/h}, \qquad c_3 = \frac{i}{2h\eta}e^{+i\eta y/h},$$

yielding (3.7). A similar calculation yields (3.8). □

We now apply (3.4) to find the Schwartz kernel of the spectral measure for T_a.

Lemma 3.3. *The spectral measure $dE_{T_a}(\tau)$ is given by the following.*

(i) For $\tau \geq 0$, $\tau = \eta^2$

$$(3.11) \quad dE_{T_a}(\tau)$$
$$= \frac{1}{4\pi h\eta}\Big(e^{i\eta(x-y)/h} + e^{i\eta(y-x)/h} + \frac{i\eta - a}{i\eta + a}e^{i\eta(x+y)/h} + \frac{i\eta + a}{i\eta - a}e^{-i\eta(x+y)/h}\Big)\, 2\eta d\eta.$$

(ii) For $\tau < 0$, the spectral measure $dE(\tau)$ vanishes for $a \leq 0$, while for $a > 0$

$$(3.12) \qquad dE_{T_a}(\tau) = \frac{2a}{h}e^{-ax/h}e^{-ay/h}\delta(\tau + a^2)d\tau.$$

Proof. This follows directly from Lemma 3.2 and Stone's formula, (3.4). The extra term for $a > 0$ arises from the pole in the denominator, $i\eta + a$ for $\operatorname{Im}\eta > 0$ and $i\eta - a$ for $\operatorname{Im}\eta < 0$ in the expressions (3.7), (3.8), which only occurs for $a > 0$. For τ negative, we need to set $\eta = i\sqrt{-\tau} + 0$ in (3.7) and $\eta = -i\sqrt{-\tau} + 0$ in (3.8), and subtract. Then everything cancels except at the pole, where we obtain a delta function $-2\pi i\delta(\sqrt{-\tau} - a)$, which arises from $(\sqrt{-\tau} + i0 + a)^{-1} - (\sqrt{-\tau} - i0 + a)^{-1}$. This term arises from the negative eigenvalue $-a^2$ which occurs for $a > 0$, corresponding to the eigenfunction $\sqrt{2a/h}\, e^{-ax/h}$. □

Plugging this into (3.6), and making use of the fact that $d\sigma d\xi' = 2\eta d\eta d\xi'$, we find that the Schwartz kernel of $E_{H_a}(1)$ is given by

$$(3.13)\quad (2\pi h)^{-d}\int_0^1\int H(1-|\xi'|^2-\eta^2)e^{i(x'-y')\cdot\xi'} \times\left(e^{i\eta(x_1-y_1)/h}+e^{i\eta(y_1-x_1)/h}+\frac{i\eta-a}{i\eta+a}e^{i\eta(x_1+y_1)/h}+\frac{i\eta+a}{i\eta-a}e^{-i\eta(x_1+y_1)/h}\right)d\xi'\,d\eta$$

for $a\leq 0$ while for $a>0$, it is given by the sum of (3.13) and

$$(3.14)\quad (2\pi h)^{1-d}\frac{2a}{h}e^{-ax_1/h}e^{-ay_1/h}\int_{-\infty}^1\int e^{i(x'-y')\cdot\xi'}\delta(\sigma-|\xi'|^2+a^2)\,d\xi'\,d\sigma.$$

We are actually interested in the value on the diagonal. Setting $x=y$, and performing the trivial ξ' integral, we find that the Schwartz kernel of the spectral projector $E_{H_a}(1)(x,x)$ on the diagonal is given by

$$(3.15)\quad \frac{\omega_{d-1}}{(2\pi h)^d}\int_0^1(1-\eta^2)^{(d-1)/2}\left(2+\frac{i\eta-a}{i\eta+a}e^{2i\eta x_1/h}+\frac{i\eta+a}{i\eta-a}e^{-2i\eta x_1/h}\right)d\eta + H(a)\frac{(d-1)\omega_{d-1}}{(2\pi h)^{d-1}}\frac{a}{h}e^{-2ax_1/h}\int_{-a^2}^1(\sigma+a^2)^{(d-3)/2}\,d\sigma.$$

Since

$$\omega_{d-1}\int_0^1 2(1-\eta^2)^{(d-1)/2}\,d\eta=\omega_d,$$

we see by comparing with (3.3) that this term disappears in the expression for $\kappa(a)$ and we have, after performing the x_1 integral as in (3.3)

$$(3.16)\quad h^{1-d}\kappa(a)=\frac{\omega_{d-1}}{(2\pi h)^d}\int_0^1(1-\eta^2)^{(d-1)/2} \times\left(\frac{i\eta-a}{i\eta+a}\Big(\frac{ih}{2}(\eta+i0)^{-1}\Big)\;-\frac{i\eta+a}{i\eta-a}\Big(\frac{ih}{2}(\eta-i0)^{-1}\Big)\right)d\eta + H(a)\frac{(d-1)\omega_{d-1}}{2(2\pi h)^{d-1}}\int_{-a^2}^1(\sigma+a^2)^{(d-3)/2}\,d\sigma.$$

Simplifying a bit, and performing the σ integral, we have

$$\kappa(a) = -\frac{i\omega_{d-1}}{2(2\pi)^d}\int_{-1}^{1}(1-\eta^2)^{(d-1)/2}\frac{(i\eta-a)^2}{a^2+\eta^2}(\eta+i0)^{-1}\,d\eta + H(a)\frac{\omega_{d-1}}{(2\pi)^{d-1}}(1+a^2)^{(d-1)/2}. \tag{3.17}$$

We further simplify this expression by expanding $(i\eta-a)^2 = a^2 - 2ia\eta - \eta^2$, and noting that the contribution of the $-\eta^2$ term is zero, as this gives an odd integrand in the η integral. A similar statement can be made for the a^2 term, except that there is a contribution from the pole in this case. This leads to the expression

$$\kappa(a) = \frac{\omega_{d-1}}{(2\pi)^{d-1}}\Big(-\frac{1}{2\pi}\int_{-1}^{1}(1-\eta^2)^{(d-1)/2}\frac{a}{a^2+\eta^2}\,d\eta - \frac{1}{4} + H(a)(1+a^2)^{(d-1)/2}\Big). \tag{3.18}$$

Although not immediately apparent, this formula is continuous at $a=0$. In fact, the function $a(a^2+\eta^2)^{-1}$ has a distributional limit $(\operatorname{sgn} a)\pi\delta(\eta)$ as a tends to zero from above or below. The change of sign as a crosses 0 means that the integral in (3.18) has a jump of -1 as a crosses zero from negative to positive. That exactly compensates the jump in the final term.

In odd dimensions, we can compute this integral exactly. In particular, in dimension $d=3$, we find that

$$\kappa(a) = \frac{\omega_2}{(2\pi)^2}\Big(-\frac{1}{4}+\frac{a}{\pi}+(1+a^2)\big(1-\frac{\operatorname{arccot} a}{\pi}\big)\Big). \tag{3.19}$$

Proof of Theorem 1.2. This follows immediately from Proposition 3.1 and Proposition 1.1. □

Remark 3.4. The second term of the expansion in [FG, Theorem 1.1] is obtained by computing

$$(2\pi h)^{1-d}\int_{-\infty}^{1}(1-\sigma)\int e^{i(x'-y')\cdot\xi'}\,dE_{T_a}(\sigma-|\xi'|^2)(x_1,y_1)\,d\xi'\,d\sigma \tag{3.20}$$

instead of (3.6).

4 Relation to Dirichlet Boundary Condition

In this section we observe that the limit $a \to -\infty$ corresponds to the Dirichlet boundary condition. More precisely, we have

Proposition 4.1. *Let* $\mathsf{N}_h^-(-\infty)$ *denote the limit*

$$\mathsf{N}_h^-(-\infty) \coloneqq \lim_{a\to-\infty} \mathsf{N}_h^-(a),$$

where $\mathsf{N}_h^-(a)$ *is given by (1.17). Then we have*

$$\mathsf{N}_h^-(-\infty) = \#\{\lambda_j \le h^{-1} \mid \lambda_j^2 \text{ is a Dirichlet eigenvalue of } \Delta\}. \tag{4.1}$$

Remark 4.2. Because the quadratic form (1.15) is monotone in a, the counting function $\mathsf{N}_h^-(a)$ is monotone in a. Hence the limit above exists.

Proof. We use the min-max characterisation of eigenvalues. Let $\tilde{\mathsf{N}}_D(\lambda)$ denote the number of Dirichlet eigenvalues (counted with multiplicity) less than or equal to $\lambda = h^{-1}$. This is equal to the maximal dimension of a subspace of $H_0^1(M)$ on which the quadratic form Q_D, given by

$$Q_D(u,u) = h^2\|\nabla u\|_2^2 - \|u\|_2^2 \tag{4.2}$$

is negative semidefinite. On the other hand, $\tilde{\mathsf{N}}_h^-(a)$ is equal to the maximal dimension of a subspace of $H^1(M)$ on which the quadratic form Q_a given by (1.15) is (strictly) negative definite.

We first show that $\tilde{\mathsf{N}}_D(h^{-1}) \le \tilde{\mathsf{N}}_h^-(-\infty)$. Let V be the vector space spanned by Dirichlet eigenfunctions with eigenvalue $\le \lambda^2$. Clearly, the quadratic form Q_a is negative *semi*definite on V, and if λ^2 is not a Dirichlet eigenvalue, then it is negative definite, proving the assertion. In the case that λ^2 is a Dirichlet eigenvalue, we perturb V to V_ϵ, a vector space of $H^1(M)$ of the same dimension as V, so that, for for ϵ sufficiently small depending on a, Q_a is negative definite on V_ϵ. For simplicity we only do this in the case that the λ^2-eigenspace is one dimensional, leaving the general case to the reader. To do this, we choose an orthonormal basis of V (with respect to the L^2 inner product) of Dirichlet eigenfunctions $v_1, \dots, v_k$ with eigenvalues $\lambda_1^2 \dots \lambda_k^2$, where $\lambda_k = \lambda$. Then we perturb only v_k, leaving the others fixed. We choose $s \in H_0^1(M)^\perp$, the orthogonal complement of $H_0^1(M)$ in $H^1(M)$ (with respect to the inner product in $H^1(M)$), so that

$$Q_a(v_i, s) = 0, \quad i < k \text{ and } Q_a(v_k, s) > 0. \tag{4.3}$$

We check that this is possible. Notice that $s \in H_0^1(M)^\perp$ implies that $(\Delta + 1)s = 0$ in M. Then as v_i has zero boundary data, we have

$$(\lambda_i^2 + 1)(v_i, s)_M = (\Delta v_i, s)_M - (v_i, \Delta s)_M = \langle \partial_\nu v_i, s\rangle_{\partial M}. \tag{4.4}$$

We choose s so that $\langle \partial_\nu v_i, s\rangle_{\partial M}$ vanishes for $i < k$ and is positive for $i = k$. This is possible: in fact, due to the unique solvability of the boundary value problem

$$(\Delta + 1)s = 0, \quad s|_{\partial M} = f \in H^{1/2}(M), \tag{4.5}$$

for $s \in H^1(M)$, we see that s can have any boundary value in $H^{1/2}(\partial M)$ which is dense in $L^2(\partial M)$. Then using (4.4) we see that $\langle \partial_\nu v_k, s\rangle_{\partial M} > 0$ implies that $(v_k, s)_M > 0$.

We now define V_ϵ to be the span of $v_1, \dots, v_{k-1}$ and $v_k + \epsilon s$. Then we have

$$Q_a(v_i, v_k + \epsilon s) = 0, \ \ i < k \tag{4.6}$$

and

$$\begin{aligned} Q_a(v_k + \epsilon s, v_k + \epsilon s) &= Q_a(v_k, v_k) + 2\epsilon Q_a(v_k, s) + \epsilon^2 Q_a(s, s) \\ &= 2\epsilon Q_a(v_i, s_i) + \epsilon^2 Q_a(s_i, s_i) \\ &= -2\epsilon(h^2 + 1)(v_i, s_i)_M + O(\epsilon^2 a^2) \end{aligned} \tag{4.7}$$

which is strictly negative for ϵa^2 small enough. It follows that Q_a is negative definite on V_k when ϵa^2 is small enough. A similar construction can be made when λ^2 has multiplicity greater than 1.

We next show that $\tilde{\mathsf{N}}_D(h^{-1}) \geq \mathsf{N}_h^-(-\infty)$. We argue by contradiction: if not, then for any a, there is a vector space W of dimension $\geq k + 1$ on which Q_a is negative definite. Then there is a nonzero vector $w \in W$ orthogonal (in the $H^1(M)$ inner product) to V. We can write $w = w' + s$ where $w' \in H_0^1(M)$ and $s \in H_0^1(M)^\perp$. Then w' is a linear combination of Dirichlet eigenfunctions with eigenvalue $\geq \lambda' > \lambda$, where λ' is the smallest eigenvalue larger than λ. We then have

$$\begin{aligned} 0 > Q_a(w' + s, w' + s) &= Q_a(w', w') + 2Q_a(w', s) + Q_a(s, s) \\ &\geq (\lambda' - \lambda)\|w'\|_2^2 - 2(h^2 + 1)\|w'\|_2\|s\|_{L^2(M)} - ha\|s\|_{L^2(\partial M)}^2. \end{aligned} \tag{4.8}$$

However, some standard potential theory shows that $\|s\|_{L^2(M)}$ is bounded by a constant times $\|s\|_{L^2(\partial M)}$. To see this, extend M to a larger manifold $\tilde{M}$ of the same dimension, and let $G(x,y)$ be the Schwartz kernel of the inverse of $(\Delta_{\tilde{M}}+1)^{-1}$ on $L^2(\tilde{M})$, with Dirichlet boundary conditions at $\partial\tilde{M}$. We can write s as $\int_{\partial M} d_{\nu_y} G(x,y)h(y)\,dy$ where $(1/2+D)h = s|_{\partial M}$ and D is the double layer operator on ∂M determined by G. Standard arguments show that $(1/2+D)$ has a bounded inverse on $L^2(\partial M)$ and $d_{\nu_y}G(x,y)$ is a bounded integral operator from $L^2(\partial M)$ to $L^2(M)$. So we can write, for $a<0$,

$$\begin{aligned} 0 > Q_a(w'+s, w'+s) \\ \geq (\lambda'-\lambda)\|w'\|_2^2 - 2C(h^2+1)\|w'\|_2\|s\|_{L^2(\partial M)} + h|a|\|s\|^2_{L^2(\partial M)^2} \end{aligned}$$

and the RHS is clearly positive for $|a|$ large enough, giving us the desired contradiction. □

A Appendix

A.1 Standard Semiclassical Asymptotics

The proof of the standard semiclassical asymptotics (i.e. asymptotics of the number of negative eigenvalues of $H_a := h^2\Delta - 1$ with the boundary condition $(h\partial_{x_1}+a)u|_{\partial M}=0$) is in [Ivr4], Section 8.3 and also in [Ivr3], Section 5.3, but we describe a simplified albeit less general proof. Basically it is a simplified proof of [Ivr1], used also in [LH], Section 29.3.

A.2 Tauberian Theorem

We use the following 'semiclassical' version of the Tauberian theorem in [Ivr1].

Proposition A.1. *Let $e_h(\lambda)$ be an nondecreasing function of λ, depending on the parameter $h>0$, equal to zero for $\lambda \leq \Lambda_0$. Let $\beta \in C_c^\infty(\mathbb{R})$ be a cutoff function with $\beta(t)=1$, $|t|\leq 1/2$, $\beta(t)=0$, $|t|\geq 1$, and $\hat{\beta}(\lambda)>0$. Let $\beta_T(t)=\beta(t/T)$. Assume that for all λ, we have*

$$|e_h(\lambda)| \leq C'(1+|\lambda|)^M h^{-d} \tag{A.1}$$

and, for all $\lambda \in [\Lambda_0, \Lambda_1]$ *we have*

$$\frac{1}{h}\int_{-\infty}^{\infty} \hat{\beta}_T\big(\frac{\lambda-\mu}{h}\big)\, de_h(\mu) = A_0(\lambda)h^{-d} + A_1(\lambda)h^{1-d} + o(h^{1-d}), \quad h \to 0. \tag{A.2}$$

Then for all $\lambda \in [\Lambda_0, \Lambda_1 - \epsilon]$ *we have*

$$\Big| e_h(\lambda) - B_0(\lambda)h^{-d} - B_1(\lambda)h^{1-d} \Big| \leq \frac{C\|A_0\|_{L^\infty([\Lambda_0,\Lambda_1])}}{T} h^{1-d} + o(h^{1-d}), \tag{A.3}$$

where

$$B_i(\lambda) = \int_{-\Lambda_0}^{\lambda} A_i(\mu)\, d\mu$$

and C *depends only on* ϵ, Λ_1, C' *and* β.

This is proved by modifying the proof of the corresponding proposition in [Shub], pp 152-153.

A.3 Propagator

We now fix $a \in \mathbb{R}$ and let $e_h(\lambda)$ be the number of eigenvalues, counting multiplicity, of the operator $P_{a,h}$ that are less than λ, or equivalently, the trace of the spectral projection $E_{a,h}(\lambda)$ for $P_{a,h}$. According to Proposition A.1, it suffices to consider the smoothed spectral projector,

$$\mathrm{Tr}\Big(\frac{1}{h}\int_{-\infty}^{\infty} \hat{\beta}\big(\frac{\lambda-\mu}{h}\big)\, dE_{a,h}(\mu)\Big), \tag{A.4}$$

since it is straightforward to show that the estimate (A.1) holds with $M = d$. By the spectral theorem, this is precisely the trace of the operator

$$\mathrm{Tr}\Big(\hat{\beta}\big(\frac{\lambda - P_{a,h}}{h}\big)\Big). \tag{A.5}$$

If we are only interested in this for λ in some interval $[\Lambda, \Lambda_1]$, then, up to $O(h^\infty)$ errors we can compose with a smooth function $\phi(P_{a,h})$ where $\phi \in C_c^\infty(\mathbb{R})$, and $\phi = 1$ on $[\Lambda - \epsilon, \Lambda_1 + \epsilon]$. Then, using the Fourier transform we can express this operator in terms of the propagator $e^{itP_{a,h}/h}$:

$$\int_{-\infty}^{\infty} e^{-it\lambda/h}\beta(t)\phi(P_{a,h})e^{itP_{a,h}/h}\, dt. \tag{A.6}$$

Since $(hD_t - P_{a,h})e^{itP_{a,h}/h} = 0$, this is the same as

$$\int_{-\infty}^{\infty} e^{-it\lambda/h}\beta(t)\phi(hD_t)e^{itP_{a,h}/h}\,dt. \tag{A.7}$$

The advantage of the spectral cutoff $\phi(hD_t)$ is that the operator $\phi(hD_t)e^{itP_{a,h}/h}$ has finite speed of propagation.

A.4 Propagation of Singularities

Let $u_h(x, y, t)$ be the Schwartz kernel of $e^{ih^{-1}tP_{a,h}}$; then $u_h(x, y, t) = u_h^0(x, y, t)+ u_h^1(x, y, t)$ where $u_h^0(x, y, t)$ is a free space solution and $u_h^1(x, y, t)$ satisfies

$$(hD_t - P_{a,h})u^1 = 0, \quad u^1|_{t=0} = 0, \quad (hD_{x_1} + a)(u^0 + u^1)|_{\partial M} = 0. \tag{A.8}$$

We define

$$\sigma_h^i(t) \coloneqq \int_M \phi(hD_t)u^i(x, x, t)\,dx, \quad i = 0, 1. \tag{A.9}$$

We claim that, for suitable ϕ, $\sigma_h^i(t)$ has an isolated singularity (in the semiclassical sense of nontrivial behaviour as $h \to 0$) at $t = 0$. More precisely, we claim that if $\phi \in C^\infty$ and is supported in $(-\epsilon_0, \epsilon_0)$, then

$$\sigma_h^i(t) = O(h^\infty) \text{ for } \epsilon \le |t| \le \epsilon_0, \tag{A.10}$$

where ϵ_0 is a fixed, sufficiently small constant, and $0 < \epsilon < \epsilon_0$ is arbitrary.

This follows from propagation of singularities arguments. The bicharacteristic flow for $P_{a,h}$ is given by

$$\begin{cases} \dot t = 1, \\ \dot\tau = 0, \\ \dot x^i = 2g^{ij}(x)\xi_j, \\ \dot\xi_j = -2\dfrac{\partial g^{kl}}{\partial x^j}\xi_k\xi_l. \end{cases} \tag{A.11}$$

That is, with respect to the parameter t, (x, ξ) moves along a geodesic at speed $2|\xi|_g$, and τ is fixed. By standard propagation of singularities arguments, the (semiclassical) wavefront set of u^0 is contained in the conormal bundle of $\{t = 0, s = y\}$ together with the forward bicharacteristic

flow from this conormal bundle intersected with the characteristic variety of $hD_t - P_{a,h}$, namely $\{\tau = |\xi|_g^2 - 1\}$. Composing with $\phi(hD_t)$ restricts this wavefront set to be contained in $\{\tau \in (-\epsilon_0, \epsilon_0)\}$. That implies that $\big||\xi|_g - 1\big| \leq 2\epsilon_0$. So for small time, the wavefront set of u_0 is restricted to the set where $|d(x,y) - 2t| \leq 2\epsilon_0 t$. In particular, points with $x = y$ are not in the wavefront set for t in a deleted neighbourhood of 0. This proves (A.10) for $i = 0$.

A similar argument for u^1 shows that $\phi(hD_t)u^1(t,x,y)$ is $O(h^\infty)$ for $|t| \leq \epsilon_0$ unless we have

$$\mathsf{dist}(x, \partial M) + \mathsf{dist}(y, \partial M) \leq 2\epsilon_0(1 + 2\epsilon_0).$$

Thus, we can work in a collar neighbourhood of ∂M. We can choose coordinates $x = (x_1, x')$ so that the boundary is given by $x_1 = 0$, $x_1 \geq 0$ on M, and the metric takes the form $dx_1^2 + g'_{ij}(x_1, x')x'^i x'^j$, that is, Fermi coordinates near the boundary. Now we split the analysis of u^1 into two cases. We write the identity operator in the x' coordinates in the form $\mathsf{Id} = Q_{\mathsf{norm}} + Q_{\mathsf{tan}}$, where Q_* are pseudodifferential operators in the x' variables such that the symbol q_{norm} of Q_{norm} is supported in $\{|\xi'| \leq 2\epsilon_1\}$ and q_{tan} is supported in $\{|\xi'| \geq \epsilon_1\}$.

Correspondingly, write

$$\phi(hD_t)u^1 = \phi(hD_t)Q_{\mathsf{tan}}(x', hD_{x'})u^1 + \phi(hD_t)Q_{\mathsf{norm}}(x', hD_{x'})u^1.$$

For the first term, a standard positive commutator argument in the x' variables only shows that this term is $O(h^\infty)$ unless $\mathsf{dist}(x', y') \geq 2\epsilon_1 t - \epsilon'$ for arbitrary $\epsilon' > 0$; in particular, if $x' = y'$ then this is $O(h^\infty)$ for $t \geq \epsilon$, $\epsilon > 0$ arbitrary. On the other hand, for the Q_{norm} term, then we have $\xi_1^2 = 1 + O(\epsilon_0 + \epsilon_1)$. In particular, this means that $\dot{x}_1 = 1 + O(\epsilon_0 + \epsilon_1)$, so the propagation is transverse (in fact, nearly normal) to ∂M. A standard propagation of singularities argument shows that the wavefront set of $\phi(hD_t)Q_{\mathsf{norm}}u^1$ for $\epsilon \leq |t| \leq \epsilon_0$ is contained in

$$\begin{aligned}\mathsf{WF}_h(\phi(hD_t)Q_{\mathsf{norm}}u^1) \cap \{x = y,\ \epsilon \leq |t| \leq \epsilon_0\} \\ \subset \big\{(t,x,x;\tau,\xi,\eta) \mid \xi_1, \eta_1 = 1 + O(\epsilon_0 + \epsilon_1)\big\},\end{aligned}$$

since the only way to have $x = y$ is to bounce of the boundary, in which case ξ_1, the momentum in the normal direction, changes from being approximately opposite to η_1 to being approximately equal. This wavefront set is killed under restriction to $x = y$ and then integration in x, showing that $\phi(hD_t)Q_{\mathsf{norm}}u^1$ is also $O(h^\infty)$ for $\epsilon \leq |t| \leq \epsilon_0$. This establishes (A.10).

A.5 Method of Successive Approximations

We now observe that (A.10) self-improves to the statement that

$$\sigma_h^i(t) = O(h^\infty) \text{ for } h^{1-\delta} \le |t| \le \epsilon_0, \quad \delta > 0. \tag{A.12}$$

This follows from a simple scaling argument. Fix a base point $y \in \partial M$, and consider the scaled metric (following [Mel])

$$g_{T,y} = g_{ij}(TX + y)dX^i dX^j$$

where T is a small parameter. Let $u_{T,\hbar}(t, X)$ be given by

$$u_{T,\hbar}(t, X) = T^{d+1}\big(\phi(hD_t)u_{T\hbar}\big)(Tt, y + TX, y);$$

then, with $\hbar := h/T$ we have

$$\begin{aligned}\Big(\hbar D_t - \hbar^2 \Delta_{g_{T,y}}\Big) u_{T,\hbar}(t, X) = \\ T^{(d+1)}\Big(hD_t - h^2\Delta_g\Big)u_h(Tt, y + TX, y) = \phi(hD_t)\delta(t)\delta(X),\end{aligned} \tag{A.13}$$

$$(\hbar\partial_{X_1} + a)u_{T,\hbar}(t, X) = 0, \quad X_1 = 0. \tag{A.14}$$

Using (A.10) we see that we have

$$\int_M \phi(\hbar D_t)u_{T,\hbar}(X, X, t)\, dX = O(T^{-(d+1)}h^\infty) \text{ for } \epsilon \le |t| \le \epsilon_0, \tag{A.15}$$

In particular, (A.15) is $O(h^\infty)$ provided that $T \ge h^{1-\delta}$ for arbitrary $\delta > 0$. Unravelling the scaling demonstrates (A.12).

Therefore if we want to construct $\sigma(t)$ for $|t| \le \epsilon_0$ it suffices to construct it for $|t| \le t_* = h^{1-\delta}$. However on this short interval we can construct it by the method of successive approximations. For each $y \in M$ we let P_y be the constant coefficient differential operator $P_{a,h}$ with coefficients frozen at y. Then we regard $P_{h,a}$ as a perturbation of P_y for x close to y. So $K = P_{h,a} - P_y$ is a second order differential operator with coefficients that are $O(x-y)$. The perturbation K is $O(t_*)$ due to finite speed of propagation and each successive term in the approximation acquires a factor not exceeding $Ct_* \cdot t_*/h = Ct_*^2 h$ due to Duhamel's principle. So the construction works for $t_* \le h^{\frac{1}{2}+\delta}$.

If we apply this to the u^0 term then the calculation proceeds as follows. We let $\overline{u^0}$ denote the propagator for the constant coefficient operator P_y with coefficients frozen at $y \in M$ (and taking only the second order derivatives). Then, with E the forward fundamental solution for P_y, we obtain a formula

$$u^0 = \overline{u^0} + EKu^0,$$

leading to a formal series

$$u^0 = \sum_{k=0}^{m} (EK)^k \overline{u^0} + (EK)^{m+1} u^0. \tag{A.16}$$

Applying the Fourier transform in x, we find that the first term is

$$\phi(hD_t)\overline{u^0} = (2\pi h)^{-d} \int e^{i(x-y)\cdot\xi/h} e^{it(|\xi|^2-1)/h} \phi(|\xi|^2 - 1)\, d\xi.$$

If we then plug this term into (A.7) then we find that this term is h^{-d} times a smooth function of λ and a. The method of successive approximations then generates a series of the form $\sum_{n=1}^{\infty} \kappa'_n(a,\lambda) h^{-d+n}$, and the terms corresponding to odd n are given by the integral in ξ of an odd function of ξ, hence vanish.

Using this expansion of u^0, we compute a series for u^1. In this case, the leading term $\overline{u^1}$ is given as follows:

$$\phi(hD_t)\overline{u^1} = (2\pi h)^{-d} \int e^{-i(x_1+y_1)\xi_1/h} e^{i(x'-y')\cdot\xi'/h} e^{it(|\xi|^2-1)/h} \phi(|\xi|^2 - 1)\, \frac{i\xi_1 + a}{i\xi_1 - a} d\xi.$$

We can form a similar formal series for u^1, which converges when $t \leq h^{1/2+\delta}$. As with the case of u^0, we can check that the successive terms in the approximation for u^1, when plugged into (A.7), give a series with the contribution of $\phi(hD_t)\overline{u^1}$ at order h^{1-d} and with successive terms contributing at increasing integer powers of h.

Now, using this together with the Tauberian theorem, Proposition A.1, shows that we get a leading Weyl asymptotic with remainder term $O(h^{1-d})$, as in (1.18).

A.6 Two Term Expansion

If we assume that the measure of periodic generalized bicharacteristics is zero, then we can use the standard method to obtain a two-term expansion of the counting function. We briefly recall here the argument, following [Ivr1].

Let $\epsilon > 0$ be given. Then we decompose the identity operator on $L^2(M)$ as a sum of three terms. The first is multiplication by a cutoff function ζ identically 1 near ∂M and supported in a collar neighbourhood of ∂M, such that

$$\int_M \zeta^2 \leq \epsilon.$$

The second and third are pseudodifferential operators chosen as follows. With $T > 1$ a large constant to be chosen later, we let Λ_T denote the union of points in

$$\{(x, \xi) \in T^*M \mid |\xi|_g \in (1 - \epsilon_0, 1 + \epsilon_0)\}$$

which are either periodic with period $\leq T$ under generalized bicharacteristic flow (for $P_{a,h}$), or for which the generalized bicharacteristic of length T in both directions are not transverse to the boundary. This is a closed set of measure zero so one can find two open sets U_1, U_2 such that $T^*M = U_1 \cup U_2$, $\Lambda_T \subset U_1$, and the measure of U_1 is less than ϵ. Then we choose (semiclassical) pseudodifferential operators Q_1, Q_2 such that Q_i is microsupported in the conic set determined by U_i, and such that $\mathsf{Id} = \zeta^2 + Q_1^* Q_1 + Q_2^* Q_2$. We then define

$$\begin{aligned} e_h^0(\lambda) &= \mathsf{Tr}\, \zeta^2 E_{h,a}(\lambda) = \mathsf{Tr}\, \zeta E_{h,a} \zeta \\ e_h^i(\lambda) &= \mathsf{Tr}\, Q_i^* Q_i E_{h,a}(\lambda) = \mathsf{Tr}\, Q_i E_{h,a}(\lambda) Q_i^*, \quad i = 1, 2; \end{aligned}$$

notice that each of these is nondecreasing in λ, and the sum of the three terms is equal to the counting function for $P_{h,a}$. Correspondingly, we break (A.7) into a sum of three terms, with $i = 0, 1, 2$.

Using the series for u^0 and u^1 sketched above, we compute expansions for the three terms. Applying Proposition A.1 we find that

$$\left| e_h^0(\lambda) - A_0^0(\lambda) h^{-d} - A_1^0(\lambda) h^{1-d} \right| = O(\epsilon h^{1-d}),$$

since in this case $A_0^0(\lambda)$ is $O(\epsilon)$, as it is proportional to $\int_M \zeta^2$. For the term $i = 1$ we similarly find that

$$\left| e_h^1(\lambda) - A_0^1(\lambda) h^{-d} - A_1^1(\lambda) h^{1-d} \right| = O(\epsilon h^{1-d}),$$

since $A_0^1(\lambda)$ is proportional to the integral of $|\sigma(Q_1)|^2$ which is also $O(\epsilon)$. For the third term, we scale β to β_T, exploiting the condition that on the microsupport of Q_2, there are no periodic bicharacteristics up to time T, hence the trace of $\phi(hD_t) e^{itP_{a,h}/h}$ has no singularities for $t \in [-T, T]$ except

at $t = 0$. Hence this term also has an expansion in powers of h, and we find that

$$\left| e_h^2(\lambda) - A_0^2(\lambda) h^{-d} - A_1^2(\lambda) h^{1-d} \right| = O(\frac{h^{1-d}}{T}).$$

Choosing T sufficiently large, this is also $O(\epsilon h^{1-d})$, and we have shown the existence of a two-term expansion.

It only remains to identify the first two terms. But once we know that there *is* a two-term expansion, we can identify the coefficients from the first two terms in the expansion of $\mathsf{Tr}\, \phi(hD_t) e^{itP_{a,h}/h}$ at $t = 0$. From the method of successive approximations we see that these terms arise from the contribution of $\overline{u^0}$ and $\overline{u^1}$. We observe that $\overline{u^0} + \overline{u^1}$ gives precisely the propagator for the $h^2 \Delta_{\mathbb{R}^d_+}$, the flat Laplacian on the half-space $\mathbb{R}^d_+ = \{x_1 \geq 0\}$, with the boundary condition $(h\partial_{x_1} + a)\overline{u}(x, y, t) = 0$ at $x_1 = 0$. It follows that the local densities for each term of the two-term expansion is equal to the local density for the flat half-space model. This justifies the calculations in Section 3 based on this flat model.

Spectral Asymptotics for Fractional Laplacians*,†

Victor Ivrii‡

Abstract

In this article we consider fractional Laplacians which seem to be of interest to probability theory. This is a rather new class of operators for us but our methods works (with a twist, as usual). Our main goal is to derive a two-term asymptotics since one-term asymptotics is easily obtained by R. Seeley's method.

In this article we consider fractional Laplacians. This is a rather new class of operators for us but our methods works (with a twist, as usual). Our main goal is to derive a two-term asymptotics since one-term asymptotics is rather easily obtained by R. Seeley's method.

1 Problem Set-up

Let us consider a bounded domain $X \subset \mathbb{R}^d$ with the smooth boundary $\partial X \in \mathscr{C}^{\infty}$ [1)]. In this domain we consider a fractional Laplacian $\Lambda_m = (\Delta^{m/2})_{\mathfrak{D}}$ with $m > 0$ originally defined on functions $u \in \mathscr{C}^{\infty}(\mathbb{R}^d) : \theta_X u \in \mathscr{H}^{m/2}(\mathbb{R}^d)$ by

$$\Lambda_{m,X} \coloneqq (\Delta^{m/2})_{\mathfrak{D}} u = R_X \Delta^{m/2}(\theta_X u) \tag{1.1}$$

where θ_X is a characteristic function of X, R_X is an operator of restriction to X and $\Delta^{m/2}$ is a standard pseudodifferential operator in $\mathbb{R}^d$ with the Weyl symbol $g(x,\xi)^{m/2}$ where as usual $g(x,\xi)$ is non-degenerate Riemannian metrics.

[1)] Alternatively consider a bounded domain X on the Riemannian manifold $\mathscr{X}$.

Remark 1.1. (i) We consider $\Lambda_{m,X}$ as an unbounded operator in $\mathscr{L}^2(X)$ with domain $\mathfrak{D}(\Lambda_{m,X}) = \{u \in \mathscr{L}^2(\mathbb{R}^d) : \mathsf{supp}(u) \subset \bar{X}, R_X\Lambda_m \in \mathscr{L}^2(X)\} \subset \mathscr{H}^{m/2}_0(X)$.

(ii) This operator can also be introduced through positive quadratic form with domain $\{u \in \mathscr{H}^m(\mathbb{R}^d), \mathsf{supp}(u) \subset \bar{X}\}$ and is a positive self-adjoint operator which is Friedrichs extension of operator originally defined on $\mathscr{H}^m_0(X)$.

(iii) We can consider this operator as a bounded operator from $\mathscr{H}^{m/2}_0(X)$ to $\mathscr{H}^{-m/2}(X) \coloneqq \mathscr{H}^{m/2\,*}_0(X)$.

(iv) Let $0 < m \notin 2\mathbb{Z}$. Then $\mathfrak{D}(\Lambda_{m,X}) \subset \mathscr{H}^m(X)$ if and only if $m \in (0,1)$; otherwise even eigenfunctions of $\Lambda_{m,X}$ may not belong to $\mathscr{H}^m(X)$.

(v) Since Λ_m does not possess transmission property for $m \notin 2\mathbb{Z}$, we are not in the framework of the Boutet-de-Monvel algebra, but pretty close: Λ_m possess μ-transmission property introduced by L. Hörmander and systematically studied by G. Grubb in [5,6]. We provide definition in Subsection A.2.

We are interested in the asymptotics of the eigenvalue counting function $\mathsf{N}(\lambda)$ for $\Lambda_{m,X}$ as $\lambda \to +\infty$.

2 Preliminary aAnalysis

As usual we reduce problem to a semiclassical one. Let $A = A_h \coloneqq h^m\Lambda_{m,X} - 1$ with $h = \lambda^{-1/m}$, $e_h(x,y,\tau)$ the Schwartz kernel of $\theta(\tau - A_h)$ a spectral projector of A_h, and N^-_h the number of negative eigenvalues of A_h.

Proposition 2.1. *Let $\bar{x} \in X$, $B(\bar{x}, 2\gamma) \subset X$, $\gamma \ge h$. Then*

$$|e_h(x,x,0) - \mathsf{Weyl}(x)| \le Ch^{1-d}\gamma^{-1} \qquad \forall x \in B(\bar{x},\gamma) \tag{2.1}$$

and

$$\Big|\int \psi((x-\bar{x})/\gamma)\Big(e_h(x,x,0) - \mathsf{Weyl}(x)\Big)\,dx\Big| \le Ch^{1-d}\gamma^{d-1}\big(\gamma^{\delta} + h^{\delta}\gamma^{-\delta}\big) \tag{2.2}$$

as $\psi \in \mathscr{C}_0^\infty(B(0,1))$ *and* $\delta > 0$, *where*

$$\mathsf{Weyl}(x) = (2\pi h)^{-d}\,\mathsf{mes}(\{\xi\colon g(x,\xi) \le 1\})$$

is the standard pointwise Weyl expression.

Proof. Estimate (2.1) is easily proven by just rescaling as modulo $O(h^s\gamma^{-s})$ we get a $\hbar$-pseudodifferential operator with $\hbar = h\gamma^{-1}$.

Estimate (2.2) is easily proven by rescaling plus R. Seeley's method as described in Subsection 7.5.1 of [9]. We leave easy details to the reader. □

Then we immediately arrive to

Corollary 2.2. *(i) Contribution of the inner zone* $\{x : \mathsf{dist}(x,\partial X) \ge h\}$ *to the Weyl remainder does not exceed* Ch^{1-d}.

(ii) Contribution of the intermediate strip $\{x : \varepsilon \ge \mathsf{dist}(x,\partial X) \ge \varepsilon^{-1}h\}$ *to the Weyl remainder does not exceed* $\eta(\varepsilon)h^{1-d}$ *with* $\eta(\varepsilon) \to 0$ *as* $\varepsilon \to 0$.

Here and in what follows $\varepsilon > 0$ is an arbitrarily small constant.

Proposition 2.3. *The following estimate holds:*

$$|e_h(x,x,0)| \le Ch^{-d}. \tag{2.3}$$

Proof. The standard proof we leave to the reader. □

Theorem 2.4. *(i) For operator* A *the Weyl remainder in the asymptotics for* N_h^- *does not exceed* Ch^{1-d}.

(ii) For operator $\Lambda_{m,X}$ *the following asymptotics holds*

$$\mathsf{N}(\lambda) = \kappa_0\lambda^{\frac{d}{m}} + O(\lambda^{\frac{d-1}{m}}) \qquad \text{as} \quad \lambda \to +\infty, \tag{2.4}$$

where $\kappa_0 = (2\pi)^{-d}\varpi_d\,\mathsf{vol}(X)$, ϖ_d *is a volume of the unit ball in* $\mathbb{R}^d$ *and* $\mathsf{vol}(X)$ *means the Riemannian volume of* X.

Proof. Statement (i) follows immediately from Corollary 2.2(i) and Proposition 2.3. Statement (ii) follows immediately from (i) as $d \ge 2$. □

Remark 2.5. (i) Therefore, we extended the result, well-known for $m \in 2\mathbb{Z}^+$ to $m \in \mathbb{R}^+$.

(ii) This was easy but to recover the second term (which is also known for $m \in 2\mathbb{Z}^+$ under non-periodicity condition) is a much more daunting task requiring first to improve the contribution of the *near boundary strip* $\{x : \mathsf{dist}(x, \partial X) \le \varepsilon^{-1}h\}$ and also of the *inner zone* $\{x : \mathsf{dist}(x, \partial X) \ge \varepsilon\}$.

3 Propagation of Singularities near the Boundary

Without any loss of the generality one can assume that

$$X = \{x : x_1 > 0\}, \qquad g^{jk} = \delta_{1j} \quad \forall j = 1, \dots, d. \tag{3.1}$$

First let us study the propagation of singularities along the boundary:

Theorem 3.1. *On the energy level $\tau : |\tau| \le \epsilon_0$*

(i) Singularities (with respect to x') propagate with the speed not exceeding c with respect to (x, ξ').

(ii) For $|\xi'| \asymp \rho \ge Ch^{\frac{1}{2}-\delta}$, and $|t| \le T = \epsilon\rho$, singularities (with respect to x') move from $x' = y'$ with the speed $\asymp \rho$ with respect to x.

Proof. In the terminology of [9] both statements mean that $u = u_h(x, y, t)$, the Schwartz kernel of $e^{-ih^{-1}tA}$, satisfies

$$F_{t\to h^{-1}\tau}\chi_T(t) Q_{1,x}\, u\, {}^tQ_{2,y} = O(h^s), \tag{3.2}$$

where $F_{t\to h^{-1}\tau}$ is h-Fourier transform, $Q_1 = q_1(x, hD')$ and $Q_2 = q_2(x, hD')$ are h-pseudodifferential operators, ${}^tQ_{2,y}$ is a dual operator, acting with respect to y (and we write it to the right of the function, it is applied to), $\chi_T(t) = \chi(t/T)$, where

(a) in the Statement (i) $h^{\frac{1}{2}-\delta} \le T_0$, T_0 is the small constant, the distance between $\mathsf{supp}(q_1)$ and $\mathsf{supp}(q_2)$ is at least cT, and $\chi \in \mathscr{C}_0^\infty([-1, 1])$.

(b) in the Statement (ii) the diameter of $\mathsf{supp}(q_1) \cup \mathsf{supp}(q_2)$ is does not exceed $\epsilon\rho$, ϵ is the small constant, and $\chi \in \mathscr{C}_0^\infty([-1, -\frac{1}{2}] \cup [\frac{1}{2}, 1])$;

s is an arbitrarily large exponent, $\delta > 0$ is arbitrarily small,

The proof is standard, by means of the positive commutator method, like those proofs in the Chapters 2 and 3 of [9], since it involves only pseudodifferential operators $q_j(x, hD')$ and their commutators with A, but one can see easily that those commutators do not bring any troubles as the energy level is $\asymp 1$. We leave all easy details to the reader. □

Corollary 3.2. *(i) Let $\rho \ge Ch^{\frac{1}{2}-\delta}$, $h^{1-\delta} \le \gamma \le \epsilon$. Then the contribution of the zone $\{(x,\xi') : x_1 \le \gamma, |\xi'| \asymp \rho\}$ to the Tauberian remainder with $T \in (T_*(\rho), T^*(\rho))$, where $T_*(\rho) = h^{1-\delta}\rho^{-2}$, $T^*(\rho) = \epsilon\rho$ does not exceed*

$$C\rho^{d-1}h^{-d} \times \gamma \times h^{1-\delta}\rho^{-2} \times \rho^{-1}. \tag{3.3}$$

(ii) The total contribution of the zone $\{(x,\xi') : x_1 \le \gamma = h^{1-\delta}\}$ to the Tauberian error with $T = h^{1-3\delta}$ does not exceed $Ch^{-d+1+\delta}$.

Proof. In the terminology of [9] the *Tauberian error* is the difference between N_h^- and the *Tauberian expression*

$$\mathsf{N}_h^{\mathsf{T}} := h^{-1}\int_{-\infty}^{0}\Big(\int F_{t\to h^{-1}\tau}\bar\chi_T(t)u(x,x,t)\,dx\Big)\,d\tau, \tag{3.4}$$

where $\bar\chi \in \mathscr{C}_0^\infty([-1,1])$, $\bar\chi = 1$ on $[-\frac{1}{2},\frac{1}{2}]$.

The easy and standard proof of Statement (i) is left to the reader; it is like those proofs in Chapter 7 of [9].

Then the contribution of the zone $x_1 \le h^{1-\delta}$, $|\xi'| \ge Ch^\delta$ to the Tauberian error with $T = h^{1-3\delta}$ does not exceed $Ch^{-d+1+\delta}$. Since the contribution of the zone $\{(x,\xi') : x_1 \le \gamma = h^{1-\delta}, |\xi'| \le Ch^{2\delta}\}$ to the asymptotics does not exceed $C\rho^{d-1}h^{-d} \times \gamma \le Ch^{-d+1+\delta}$ we arrive to Statement (ii). □

Therefore in this zone $\{(x,\xi') : x_1 \le \gamma = h^{1-\delta}\}$ all we need is to pass from the Tauberian expression to the Weyl expression.

However the inner zone should be reexamined and we need to describe what happens with the propagation along Hamiltonian trajectory in the zone $\{(x,\xi) : x_1 \le h^{1-\delta}\}$. We can assume that $|\xi_1| \ge \varepsilon$ since the measure of the remaining trajectories is small, here $\varepsilon > 0$ is an arbitrarily small constant.

4 Reflection of Singularities from the Boundary

4.1 Toy-Model

We start from the pilot-model which will be used to prove the main case. Namely, let us consider 1-dimensional operator on half-line $\mathbb{R}^+$ with Euclidean metrics

$$B := B_{m,a,h} = ((h^2 D_x^2 + a^2)^{m/2})_{\mathfrak{D}} \tag{4.1}$$

with $a \geq 0$. We denote $e_{m,a,h}(x_1, y_1, \tau)$ the Schwartz kernel of its spectral projector.

Observe that scaling $x \mapsto x\gamma^{-1}$, $\tau \mapsto \tau\rho^{-m}$ transforms operator to one with $h \mapsto h/(\rho\gamma)$, $\tau \mapsto \tau\rho^{-m}$; because of this we can assume that $h = 1$ and the second scaling implies that we can assume that either $a = 1$ or $\tau = 1$.

Proposition 4.1. *(i) The spectrum of operator $\Lambda_{m,a}$ is absolutely continuos and it coincides with $[a^m, \infty)$.*

(ii) The following equalities hold:

$$e_{m,a,h}(x, y, \lambda) = e_{m,1,ha^{-1}}(ax, ay, \lambda a^{-m}) = \lambda^{1/m} e_{m,a\lambda^{-1/m},h}(\lambda^{1/m}x, \lambda^{1/m}y, 1) = a e_{m,1,h}(ax, ay, \lambda a^{-m}). \tag{4.2}$$

Proposition 4.2. *Let $\psi \in \mathscr{C}_0^\infty([-1,1])$, $\psi_\gamma(x) = \psi(x/\gamma)$ and $\phi \in \mathscr{C}_0^\infty([-1,1])$, $0 \leq a \leq 1 - \epsilon_0$. Then as $\gamma \geq h^{1-\delta}$, $T \geq C_0\gamma$, $h^\delta \geq \eta \geq h^{1-\delta}T^{-1}$*

$$\|\phi(\eta^{-1}(hD_t - 1))\psi_\gamma e^{i(mh)^{-1}tB}\psi_\gamma|_{t=T}\| \leq CT^{-1}\gamma + Ch^{\delta'}. \tag{4.3}$$

Proof. Observe first that if for u supported in $\mathbb{R}^+$ and $L = x_1 hD_1 - ih/2 = L^*$

$$\operatorname{Re} i(BLu, u) = \frac{1}{2}(i[B, L]u, u), \tag{4.4}$$

and then

$$\operatorname{Re}(Lu, u_t - ih^{-1}Bu) = \frac{1}{2}(ih^{-1}[B, L]u, u) + \frac{1}{2}\partial_t \operatorname{Re}(Lu, u) \tag{4.5}$$

and

$$\mathrm{Re}(ktu + Lu, u_t - ih^{-1}Bu) = \frac{1}{2}\partial_t\big(kt\|u\|^2 + (Lu,u)\big) + \frac{1}{2}\big((ih^{-1}[B,L]u,u) - k\|u\|^2\big). \tag{4.6}$$

Let us plug

$$u = \phi(\eta^{-1}(hD_t - 1))e^{ih^{-1}TB}\psi_\gamma v \tag{4.7}$$

with $\|v\| = 1$. Then the left hand expression in (4.6) is 0 and

$$\frac{1}{2}\partial_t\big(kt\|u\|^2 + (Lu,u)\big) \le \frac{1}{2}\big(-(ih^{-1}[B,L]u,u) + k\|u\|^2\big). \tag{4.8}$$

Let us estimate from above the right-hand expression; obviously

$$ih^{-1}[B_m, L] = m(B_m - a^2 B_{m-2}). \tag{4.9}$$

(a) Assume first that $m > 2$. Then since

$$(1 - C\eta)\|u\| \le \|B_m u\| \le (1 + C\eta)\|u\| \tag{4.10}$$

due to cutoff by ϕ and

$$B_{m-2} \le B_m^{(m-2)/m} \tag{4.11}$$

in virtue of Corollary A.2 we conclude that as $k = m(1-a^2)$ the right-hand expression does not exceed $C\eta$ and therefore

$$m(1-a^2)t\|u\|^2 + (Lu,u) \le C\gamma + C\eta T \tag{4.12}$$

since the value of the left-hand expression as $t = 0$ does not exceed $C\gamma$.

Further, observe that on the energy levels from $(1 - C_0\eta, 1 + C_0\eta)$ the singularities propagate with a speed (with respect to x_1) not exceeding $m(1-a^2)^{\frac{1}{2}}(1 + C_0\eta)$. Therefore we conclude that u is negligible as $|x_1| \ge m(1-a^2)^{\frac{1}{2}}(1 + C_0\eta)T + C\gamma$ and therefore since

$$\|D_1 u\| \le (B_2 u, u) \le ((1-a^2)^{\frac{1}{2}} + C_0\eta), \tag{4.13}$$

we conclude using (4.10) and (4.11) that

$$|(Lu,u)| \le m(1 - a^2 + C_0\eta)T + C\gamma - \epsilon_0 T\|\psi_\gamma(x_1)u\|^2 \tag{4.14}$$

and the left-hand expression of (4.12) is greater than $\epsilon_0 T\|\psi_\gamma u\|^2 - C(\eta T + \gamma)$ and we arrive to (4.3).

(b) Assume now that $0 < m < 2$. Then our above proof fails short in both estimating $\operatorname{Re} ih^{-1}([B, L]u, u)$ from below and $|(Lu, u)|$ from above and we need to remedy it.

Note first that away from $x_1 = 0$ only symbols are important and therefore the right-hand expression of (4.8) does not exceed $\frac{m}{2}(a^m - a^2)\|\psi_\sigma u\|^2 + Ch^2\sigma^{-2}$ since $\|B_{m-2}\| \le a^{m-2}$. Indeed, we need just to decompose $1 = \psi_\sigma^2 + \psi_\sigma'^2$ and use our standard arguments to rewrite the right-hand expression of (4.8) as the sum of the same expressions for $\psi_\sigma u$ and $\psi_\sigma' u$ plus $Ch^2\sigma^{-2}\|u\|^2\|$.

Similarly we deal $\operatorname{Re}(Lu, u) = \operatorname{Re}(L\psi_\sigma u, \psi_\sigma u) + \operatorname{Re}(L\psi_\sigma' u, \psi_\sigma' u)$ and the absolute value of the second term does not exceed $m(1 - a^2)^{\frac{1}{2}} T\|B_m^{1/m}\psi_\sigma'\|^2$.

We claim that

$$\operatorname{Re}(L\psi_\sigma u, \psi_\sigma u) \le C\sigma\|\psi_\sigma u\|^2 + C\sigma h^\delta; \tag{4.15}$$

we prove it later but now instead of (4.12) we arrive for $\sigma = \epsilon_0 t$ to

$$((1 - a^2) - \epsilon)P(T) \le Ch^{\delta'} + (a^m - a^2)T^{-1}\int_\gamma^T P(t)\,dt + C\gamma T^{-1}$$

with $P(t) = \|\psi_{\epsilon_0 t} u(., t)\|^2$. Then since $\nu = (a^m - a^2)/((1 - a^2) - \epsilon) < 0$ this inequality implies (4.3) again. □

Proof of (4.15). Indeed, as $h = 1$, $\|B_m^{1/m} u\| \le 1$ we from G. Grubb [5, 6] conclude that $|u(x_1)| \le Cx_1^{(m-1)/2}\|uB_m^{1/m}u\|$ and $|Lu(x_1)| \le Cx_1^{(m-1)/2}$ and therefore $|(Lu, u)| \le C\sigma^m\|B_m^{1/m}u\|^2$. Take $\sigma = 1$.

Scaling returns (4.15) as $\sigma = h$. □

Proposition 4.3. *Let $\Lambda = \Lambda_{m,X}$ be a d-dimensional operator* (1.1) *on the half-space $X = \{x \in \mathbb{R}^d, x_1 > 0\}$ with Euclidean metrics ($d \ge 2$) and $A = h\Lambda^{1/m} - 1$.*

Let $\psi \in \mathscr{C}_0^\infty([-1, 1])$, $\psi_\gamma(x) = \psi(x_1/\gamma)$, $\phi \in \mathscr{C}_0^\infty([-1, 1])$, $\varphi \in \mathscr{C}_0^\infty(\mathbb{R}^{d-1})$ supported in $\{|\xi'| \le 1 - \epsilon\}$ with $\epsilon > 0$. Finally, let $\gamma \ge h^{1-\delta}$, $T \ge Ch^{-\delta}\gamma$, $h^\delta \ge \eta \ge h^{1-\delta}T^{-1}$. Then

$$\|\phi(\eta^{-1}hD_t - 1)\varphi(hD')\psi_\gamma(x_1)e^{ih^{-1}tA}\psi_\gamma(x_1)|_{t=T}\| = O(h^s) \tag{4.16}$$

with arbitrarily large s.

Proof. By making Fourier transform $F_{x'\to h^{-1}\xi'}$ we reduce the general case to $d=1$ and operator B.

According to Proposition 4.2 $\|\phi(\eta^{-1}hD_t)\psi_\gamma e^{ih^{-1}TA}\psi\| \le h^\delta$. Thus for $s=\delta'$ (4.16) has been proven (we reduce δ' if necessary).

Without any loss of the generality we assume that $\psi(x_1)=1$ as $x_1\le 1$, $\psi(x_1)=0$ as $x_1\ge 2$. Observe that due to propagation as $t\le T$ and $x_1\ge\gamma$ we see that $\phi(\eta^{-1}hD_t)Q^+(hD_1)(1-\psi_\gamma)e^{ih^{-1}TA}\psi_\gamma$ is negligible where $Q^\pm\in\mathscr{C}^\infty(\mathbb{R})$ is supported in $\{\pm\xi_1>\epsilon\}$. Furthermore, from the standard ellipticity arguments we conclude that $\phi(\eta^{-1}hD_t)Q^0(hD_1)(1-\psi_\gamma)e^{ih^{-1}TA}\psi_\gamma$ is also negligible for $Q^0\in\mathscr{C}_0^\infty([-2\epsilon,2\epsilon])$.

Finally, due to propagation as $t\ge T$ and $x_1\ge\gamma$ we conclude that $\phi(\eta^{-1}hD_t)\psi_\gamma e^{ih^{-1}(t-T)A}Q^-(hD_1)(1-\psi_\gamma)e^{ih^{-1}TA}\psi_\gamma$ is negligible for $t\ge T$.

What is left is $\phi(\eta^{-1}hD_t)\psi_\gamma e^{ih^{-1}(t-T)A}Q^-(hD_1)\psi_\gamma e^{ih^{-1}TA}\psi_\gamma$ and since (4.16) holds for $s=\delta'$ we conclude that it holds for $s=2\delta'$ and T replaced by $2T$.

Continuing this process we see that (4.16) holds for $s=n\delta'$ and T replaced by nT. Therefore, as we redenote nT by T (and T by T/n respectively), we acquire factor $(\gamma n/T)^n$ in our estimate and it is $O(h^s)$ for any s as h is sufficiently small, $\gamma/T\le h^\delta$ and $n=s/\delta'$. □

4.2 General Case

Theorem 4.4. *Let $(\bar x,\bar\xi)$ be a point on the energy level 1. Consider a Hamiltonian trajectory $\Psi_t(\bar x,\bar\xi)$ with $\pm t\in[0,mT]$ (one sign only) with $T\ge\epsilon_0$ and assume that for each t indicated it meets ∂X transversally i.e.*

$$\mathsf{dist}(\pi_x\Psi_t(x,\xi),\partial X)\le\epsilon \implies |\frac{d}{dt}\mathsf{dist}(\pi_x\Psi_t(x,\xi),\partial X)|\ge\epsilon \qquad \forall t:\pm t\in[0,mT]. \tag{4.17}$$

Also assume that

$$\mathsf{dist}(\pi_x\Psi_t(x,\xi),\partial X)\ge\epsilon_0 \qquad \text{as}\quad t=0,\ \pm t=mT. \tag{4.18}$$

Let $\epsilon>0$ be a small enough constant, Q be supported in ϵ-vicinity of (x,ξ) and $Q_1\equiv 1$ in $C_0\epsilon$-vicinity of $\Psi_t(x,\xi)$ as $t=\pm mT$. Then operator $(I-Q_1)e^{-ih^{-1}tH}Q$ is negligible as $t=\pm mT$.

Proof. (a) Obviously without any loss of the generality one can assume that there is just one reflection from ∂X (and this reflection is transversal) and that (3.1) is fulfilled in its vicinity.

Further, without any loss of the generality one can assume that Q is supported in ε-vicinity of $(\bar{x},\bar{\xi})$, $Q_1 \equiv 1$ in ε-vicinity of $\Psi_{mT}(\bar{x},\bar{\xi})$ and $T \asymp \varepsilon$ with $\varepsilon = h^{\frac{1}{2}-\delta'}$. Then both $\bar{x}$ and $\pi_x \Psi_{mT}(\bar{x},\bar{\xi})$ belong to $C_0\varepsilon$-vicinity of ∂X.

Indeed, it follows from the propagation inside of domain.

(b) Then instead of isotropic vicinities we can consider anisotropic ones: ε with respect to (x',ξ'), $h^{1-3\delta'}$ with respect to x_1 and $h^{\delta'}$ with respect to ξ_1. Let now Q and Q_1 be corresponding operators.

In this framework from the propagation inside of domain it follows that without any loss of the generality one can assume that $T \asymp \gamma = h^{1-\delta''}$ and both $\bar{x}$ and $\pi_x \Psi_{mT}(\bar{x},\bar{\xi})$ belong to $C_0\gamma$-vicinity of ∂X.

(c) Then one can employ the method of the successive approximations freezing coefficients at point $\bar{x}$ and in this case the statement of the theorem follows from the construction of Section 7.2 of [9][2)] and Proposition 4.3. We leave easy details to the reader. □

Then we arrive immediately to

Corollary 4.5. *Under standard non-periodicity condition*[3)] N_h^- *is given with* $o(h^{1-d})$*-error by the Tauberian expression with* $T = h^{1-\delta}$.

Proof. Easy details are left to the reader. □

5 Main rResults

5.1 From Tauberian to Weyl Asymptotics

Now we can apply the method of successive approximations as described in Section 7.2 [2)] and prove that for operator A the Tauberian expression with

[2)] Insignificant and rather obvious modifications are required.

[3)] The set of all periodic billiards has measure zero.

$T = h^{1-\delta}$ (with sufficiently small $\delta > 0$) equals to Weyl expression $\mathsf{N}_h^{\mathsf{W}}$ with $O(h^{2-d-\delta''})$ error,

$$\mathsf{N}_h^{\mathsf{W}} = \kappa_0 h^{-d} + \kappa_{1,m} h^{1-d} + o(h^{1-m}) \tag{5.1}$$

with the standard coefficient $\kappa_0 = (2\pi)^{-d}\varpi_d \operatorname{vol}_d(X)$ and with

$$\kappa_{1,m} = (2\pi)^{1-d}\varpi_{d-1}\varkappa_m \operatorname{vol}_{d-1}(\partial X), \tag{5.2}$$

where

$$\varkappa_m = \tag{5.3}$$
$$= \frac{d-1}{m} \iint_1^\infty \lambda^{-(d-1)/m-1}\Big(\boldsymbol{e}_m(x_1, x_1, \lambda) - \pi^{-1}(\lambda-1)^{1/m}\Big)\, dx_1 d\lambda$$

with $\boldsymbol{e}_m(x_1, y_1, \tau) = \boldsymbol{e}_{m,1,1}(x_1, y_1, \tau)$ the Schwartz kernel of the spectral projector of operator $\boldsymbol{a}_m := B_{m,1,1}$ introduced by (4.1):

$$\boldsymbol{a}_m = ((D_x^2+1)^{m/2})_{\mathfrak{D}} \tag{5.4}$$

Recall that vol_d and vol_{d-1} are Riemannian volumes corresponding to metrics g and its restriction to ∂X respectively and $\pi^{-1}(\lambda-1)^{1/m}$ is a Weyl approximation to $\boldsymbol{e}_{m,1}(x_1, x_1, \lambda)$. Thus we arrive to

Theorem 5.1. *Under standard non-periodicity condition the following asymptotics holds:*

$$\mathsf{N}(\tau) = \kappa_0 \tau^{\frac{d}{m}} + \kappa_{1,m}\tau^{\frac{d-1}{m}} + o(\tau^{\frac{d-1}{m}}) \qquad \text{as} \quad \tau \to +\infty. \tag{5.5}$$

Proof. First we establish as described above asymptotics

$$\mathsf{N}_h^- = \kappa_0 h^{-d} + \kappa_{1,m} h^{1-d} + o(h^{1-d}) \qquad \text{as} \quad h \to +0, \tag{5.6}$$

which immediately implies (5.5). □

Remark 5.2. Based on our analysis one can prove easily also the asymptotics for the Riesz means:

$$\Big(\mathsf{N}(\tau) - \sum_{k<r+1} \kappa_{k,m}\tau^{\frac{d-k}{m}}\Big) * \tau_+^{r-1} = O(\tau^{\frac{d-1}{m}}) \qquad \text{as} \quad \tau \to +\infty, \tag{5.7}$$

and under standard non-periodicity condition

$$\Big(\mathsf{N}(\tau) - \sum_{k\le r+1} \kappa_{k,m}\tau^{\frac{d-k}{m}}\Big) * \tau_+^{r-1} = o(\tau^{\frac{d-1}{m}}) \qquad \text{as} \quad \tau \to +\infty, \tag{5.8}$$

with some coefficients $\kappa_{k,m}$.

5.2 Discussion

The following problems seem to be challenging

Problem 5.3. As $m_1 > 0$, $m_2 > 0$ consider

$$K = K_{m_1,m_2,X} \coloneqq \Lambda_{m,X} - \Lambda_{m_1,X}\Lambda_{m_2,X} \tag{5.9}$$

on $\mathfrak{D}(\Lambda_m)$ with $m = m_1 + m_2$. From Corollary A.2 we conclude that this is a non-negative operator. Furthermore, due to [12, 13] it is a positive operator. Obviously singularities of its Schwartz kernel $K(x, y)$ belong to $\partial X \times \partial X$.

(i) Provide an effective estimate for this operator from below.

(ii) Prove that as $X = \{x \in \mathbb{R}^d : x_1 > 0\}$ with Euclidean metrics its Schwartz kernel $K(x, y) = k(x_1, y_1, x' - y')$ which is positive homogeneous of degree $-m - d$ satisfies

$$|D_x^\alpha D_y^\beta K(x, y)| \leq C_{\alpha\beta} x_1^{-\frac{m}{2}-\alpha_1} y_1^{-\frac{m}{2}-\beta_1} (x_1 + y_1 + |z|)^{-d-|\alpha'|+|\beta'|}. \tag{5.10}$$

(iii) In the general case in the local coordinates in which $X = \{x : x_1 > 0\}$ and $x_1 = \mathsf{dist}(x, \partial X)$ not only (5.10) holds but also

$$|D_x^\alpha D_y^\beta \big(K(x, y) - K^0(x, y)\big)| \leq C_{\alpha\beta} (x_1 + y_1)^{-m-\alpha_1-\beta_1} (x_1 + y_1 + |z|)^{-d-|\alpha'|+|\beta'|+1} \tag{5.11}$$

where $K^0(x, y) = k(x_1, y_1, x' - y')$ and $g^{jk} = \delta_{jk}$ at point $(0, \frac{1}{2}(x' + y'))$.

Problem 5.4. For $m > 0$, $n > 0$ consider operator

$$K = K_{m,n,X} \coloneqq \Lambda_{m,X} - \Lambda_{n,X}^{m/n} \tag{5.12}$$

on $\mathfrak{D}(\Lambda_k)$ with $k = \mathsf{max}(m, n)$. Then this is a non-negative (non-positive) operator as $m > n$ ($m < n$ respectively. Furthermore, due to [12, 13] it is a positive (negative) operator respectively.

(i) Provide an effective estimate for this operator from below.

(ii) Prove that if $X = \{x \in \mathbb{R}^d : x_1 > 0\}$ with Euclidean metrics its Schwartz kernel $K(x,y) = k(x_1, y_1, x' - y')$ which is positive homogeneous of degree $-(m+d)$ and satisfies (5.10).

(iii) Prove that in the framework of Problem 5.3(iii) both (5.10) and (5.11) hold.

Problem 5.5. (i) Consider operators $(\Delta^{m/2})_{\mathfrak{D}}$ with $m < 0$ and the asymptotics of eigenvalues tending to $+0$.

(ii) Consider operators with degenerations like $A_{m,X} = h^m \Lambda_{m,X} + V(x)$.

(iii) Consider more general operators where instead of Δ general elliptic (matrix) operator is used.

Problem 5.6. (i) Consider Neumann boundary conditions: having smooth metrics g in the vicinity of $\bar{X}$ for each point $x \notin X$ in the vicinity of ∂X we can assign a mirror point $j(x) \in \bar{X}$ such that x and $j(x)$ are connected by a (short) geodesics orthogonal to Y at the point of intersection. Each u defined in X we can continue to the vicinity of $\bar{X}$ as $Ju(x) = \psi(x) u(j(x))$ with ψ supported in the vicinity of $\bar{X}$ and $\psi = 1$ in the smaller vicinity of $\bar{X}$. Then $\Lambda_m u = R_X \Delta^{m/2} Ju$.

- Establish eigenvalue asymptotics for this operator.
- Surely we need to prove that the choice neither of metrics outside of X nor ψ is important.

(ii) One can also try $Ju(x) = -\psi(x) u(j(x))$ and prove that eigenvalue asymptotics for this operator do not differ from what we got just for continuation by 0.

Problem 5.7. Consider manifolds with all geodesic billiards closed as in Section 8.3 of [9]. To do this we need to calculate the "phase shift" at the transversal reflection point itself seems to be an extremely challenging problem.

6 Global Theory

Let us discuss fractional Laplacians defined by (1.1) in domain $X \subset \mathbb{R}^d$. Then under additional condition

$$\mathsf{dist}(x,y) \le C_0 |x-y| \qquad \forall x, y \in X \tag{6.1}$$

(where $\mathsf{dist}(x,y)$ is a "connected" distance between x and y) everything seems to work. We leave to the reader:

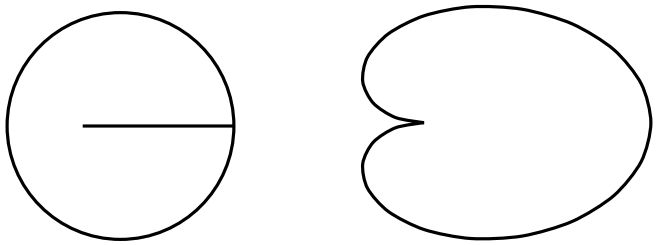
Problem 6.1. Under assumption (6.1)

(i) prove Lieb-Cwikel-Rozeblioum estimate (9.A.11) of [9].

(ii) Restore results of Chapter 9 of [9].

(iii) Reconsider examples of Sections 11.2 and 11.3 of [9].

Remark 6.2. Obviously domains with cuts and inner spikes (inner angles of 2π) do not fit (6.1). On the other hand, in the case of the domain with the cut due to non-locality of Δ^r with $r \in \mathbb{R}^+ \setminus \mathbb{Z}$ both sides of the cut "interact" and at least coefficient in the second term of two-term asymptotics may be wrong; in the case of the inner spike some milder effects are expected.



(a) (b)

Figure 28.1: Domain with a cut (a) and an inner spike (b).

The following problem seems to be very challenging:

Problem 6.3. (i) Investigate fractional Laplacians in domains with cuts and inner spikes and save whatever is possible.

(ii) Generalize these results to higher dimensions.

A Variational Estimates for Fractional Laplacian

A.1 Variational Estimates for Fractional Laplacian

We follow here R. Frank and L. Geisinger [4]. This is Lemma 19 and the next paragraph of their paper:

Lemma A.1. *(i) Let B be a non-negative operator with $\mathsf{Ker}\, B = \{0\}$ and let P be an orthogonal projection. Then for any operator monotone function $\phi : (0,\infty) \to \mathbb{R}$,*

$$P\phi(PBP)P \ge P\phi(B)P. \tag{A.1}$$

(ii) If, in addition, B is positive definite and ϕ is not affine linear, then $\phi(PBP) = P\phi(B)P$ implies that the range of P is a reducing subspace of B.

We recall that, by definition, the range of P is a reducing subspace of a non-negative (possibly unbounded) operator if $(B+\tau)^{-1}\,\mathsf{Ran}\, P \subset \mathsf{Ran}\, P$ for some $\tau > 0$. We note that this is equivalent to $(B+\tau)^{-1}$ commuting with P, and we see that the definition is independent of τ since

$$\begin{aligned}&(B+\tau')^{-1}P - P(B+\tau')^{-1}\\ &\quad = (B+\tau)(B+\tau')^{-1}\left((B+\tau)^{-1}P - P(B+\tau)^{-1}\right)(B+\tau)(B+\tau')^{-1}.\end{aligned}$$

We refer to the proof given there.

Corollary A.2. *The following inequality holds*

$$\Lambda_{m,X} \le \Lambda_{n,X}^{m/n} \qquad \text{as} \quad 0 < m < n. \tag{A.2}$$

Proof. Plugging into (A.1) $B = \Delta^{n/2}$ in $\mathbb{R}^d$, $P = \theta_X(x)$ and $\phi(\lambda) = \lambda^{m/n}$ we get (A.2). □

Repeating arguments of Proposition 20 and following it Subsection 6.4 of R. Frank and L. Geisinger [4] (powers of operators will be different but also negative) we conclude that

Proposition A.3. *Let $d \ge 2$. Then $-\varkappa_m$ is positive strictly monotone increasing function of $m > 0$.*

We leave details to the reader.

A.2 μ-Transmission Property

Proposition 1 of G. Grubb [6] claims that

Proposition A.4. *A necessary and sufficient condition in order that* $R_X P u \in \mathscr{C}^\infty(\bar{X})$ *for all* $u \in \mathscr{E}_\mu(\bar{X})$ *is that* P *satisfies the* μ-transmission condition *(in short: is of type* μ*), namely that*

$$\partial_x^\beta \partial_\xi^\alpha p_j(x,-N) = e^{\pi i(m-2\mu-j-|\alpha|)} \partial_x^\beta \partial_\xi^\alpha p_j(x,N) \qquad \forall x \in \partial\Omega, \tag{A.3}$$

for all j, α, β*, where* N *denotes the interior normal to* ∂X *at* x*,* m *is an order of classical pseudo-differential operator* P *and for* $\mu \in \mathbb{C}$ *with* $\operatorname{Re}\mu > -1$*.*

Here $\mathscr{E}_\mu(\bar{X})$ denotes the space of functions u such that $u = E_X d(x)^\mu v$ with $v \in \mathscr{C}^\infty(\bar{X})$ where E_X is an operator of extension by 0 to $\mathbb{R}^d \setminus X$ and $d(x) = \operatorname{dist}(x, \partial X)$.

Observe that for $\mu = 0$ we have an ordinary transmission property (see Definition 1.4.3) of [9].

Comments

This project started when I learned to my surprise that fractional Laplacians are of the interest to probability theory: which seem to be of interest to probability theory starting from R. M. Blumenthal, R. M. and R. K. Getoor [3] and then by R. Bañuelos and T. Kulczycki [1], R. Bañuelos, T. Kulczycki and B. Siudeja [2], M. Kwaśnicki [11]; some of these authors were interested in "Ivrii-type results" (i.e. generalizations from $m = 2$ to $m \in (0,2)$

Those operators were formulated in the framework of stochastic processes and thus were not accessible for me until I found paper R. Frank and L. Geisinger [4] provided definition we follow here. They showed that the trace has a two-term expansion regardless of dynamical assumptions[4)], and the second term in their expansion paper [4] defined by (3.2)–(3.3) is closely related to $\kappa_{1,m}$. It corresponds to $r = 1$ in Remark 5.2.

Furthermore, I learned that one-term asymptotics for more general operators (albeit without remainder estimate) was obtained by G. Grubb [7].

[4)] The fact that R. Frank and L. Geisinger obtain a second term regardless of dynamical assumptions is simply due to the fact that they study $\operatorname{Tr}(f(\Lambda_{m,X}))$ with $f(\lambda) = -\lambda\theta(-\lambda)$, which is one order smoother than $f(\lambda) = \theta(-\lambda)$.

Very recently I used the ideas of Section 4 to study sharp spectral asymptotics for Dirichlet-to-Neumann operator in [10].

I express my gratitudes to G. Grubb and R. Frank for pointing to rather nasty errors in the previous version of this article and very useful comments, and to R. Bañuelos for very useful comments. I also express my gratitudes to the referee of this paper for several useful remarks.

Spectral Asymptotics for Dirichlet to Neumann Operator in the Domains with Edges[*,†]

Victor Ivrii[‡]

Abstract

We consider eigenvalues of the Dirichlet-to-Neumann operator for Laplacian in the domain (or manifold) with edges and establish the asymptotics of the eigenvalue counting function

$$\mathsf{N}(\lambda) = \kappa_0 \lambda^d + O(\lambda^{d-1}) \qquad \text{as} \quad \lambda \to +\infty,$$

where d is dimension of the boundary. Further, in certain cases we establish two-term asymptotics

$$\mathsf{N}(\lambda) = \kappa_0 \lambda^d + \kappa_1 \lambda^{d-1} + o(\lambda^{d-1}) \qquad \text{as} \quad \lambda \to +\infty.$$

We also establish improved asymptotics for Riesz means.

1 Introduction

Let X be a compact connected $(d+1)$-dimensional Riemannian manifold with the boundary Y, regular enough to properly define operators J and Λ below[1)]. Consider *Steklov problem*

$$\Delta w = 0 \qquad \text{in} \quad X, \tag{1.1}$$

$$(\partial_\nu + \lambda) w|_Y = 0, \tag{1.2}$$

---

[1)] Manifolds with edges are of this type.

where Δ is the positive Laplace-Beltrami operator[2)], acting on functions on X, and ν is the unit inner normal to Y. In the other words, we consider eigenvalues of the Dirichlet-to-Neumann operator. For v, which is a restriction to Y of $\mathscr{C}^2$ function, we define $Jv = w$, where $\Delta w = 0$ in X, $w|_Y = v$, and $\Lambda v = -\partial_\nu Jv|_Y$.

Definition 1.1. Λ is called *Dirichlet-to-Neumann operator*.

The purpose of this paper is to consider manifold with the boundary which has edges: i.e. each point $y \in Y$ has a neighbourhood U in $\bar{X} := X \cap Y$, which is the diffeomorphic either to $\mathbb{R}^+ \times \mathbb{R}^d$ (then y is a *regular point*), or to $\mathbb{R}^{+2} \times \mathbb{R}^{d-1}$ (then y is an *inner edge point*) or to $(\mathbb{R}^2 \setminus \mathbb{R}^{-2}) \times \mathbb{R}^{d-1}$ (then y is an *outer edge point*). Let Z_{inn} and Z_{out} be sets of the inner and outer edge points respectively, and $Z = Z_{\mathsf{inn}} \cup Z_{\mathsf{out}}$.

One can prove easily the following proposition:

Proposition 1.2. *(i) Λ is a non-negative essentially self-adjoint operator in $\mathscr{L}^2(Y)$; $\mathsf{Ker}(\Lambda)$ consists of constant functions.*

(ii) Λ has a discrete accumulating to infinity spectrum with eigenvalues $0 = \lambda_0 < \lambda_1 \le \dots$ could be obtained recurrently from the following variational problem:

$$\int_X |\nabla w|^2 \, dx \mapsto \mathsf{min}(=\lambda_n) \quad as \quad \int_Y |w|^2 \, dx' = 1, \qquad \int_Y w w_k^\dagger \, dx' = 0 \quad for \quad k = 0, \dots, n-1. \tag{1.3}$$

Corollary 1.3. *The number of eigenvalues of Λ, which are less than λ, equals to the maximal dimension of the linear space of $\mathscr{C}^2$-functions, on which the quadratic form*

$$\int_X |\nabla w|^2 \, dx - \lambda \int_Y |w|^2 \, dx' \tag{1.4}$$

is negative definite.

Proposition 1.4. *Operator Λ has a domain $\mathscr{H}^1(Y)$ and*

$$\|\Lambda u\|_Y + \|u\|_Y \asymp \|u\|_{\mathscr{H}^1(Y)}, \tag{1.5}$$

where $(.,.)$ and $\|.\|$ denote $\mathscr{L}^2$ inner product and norm.

[2)] Defined via quadratic forms.

Proof. Let $L = \ell \cdot \nabla$, ℓ be a vector field which makes an acute angle with the inner normal (at Z–with both inner normals). Consider

$$0 = -(\Delta w, Lw)_X = (\nabla w, \nabla Lw)_X + (\partial_\nu w, Lw)_Y = \int Q(\nabla w)\, dy + O(\|w\|^2_{\mathscr{H}^1(X)}), \tag{1.6}$$

where

$$Q(\nabla w) = (\nu \cdot \nabla w)(\ell \cdot \nabla w) - \frac{1}{2}\nu \cdot \ell |\nabla w|^2. \tag{1.7}$$

This quadratic form has one positive and d negative eigenvalues. Further, on the subspace orthogonal to ℓ, all eigenvalues are negative. Then

$$\|\partial_\nu w\|^2 + C\|w\|^2_{\mathscr{H}^1(X)} \asymp \|w\|^2_{\mathscr{H}^(Y)}. \tag{1.8}$$

Combined with the estimate for $\|w\|^2_{\mathscr{H}^1(X)} \le C\|w\|^2_{\mathscr{H}^{\frac{1}{2}}(Y)}$ it implies the statement. □

Remark 1.5. (i) If Y is infinitely smooth, then Λ is the first-order pseudodifferential operator on Y with the principal symbol $(g_Y(x,\xi))^{1/2}$, where g_Y is the restriction of the metrics to Y. Then the standard results hold:

$$\mathsf{N}(\lambda) = \kappa_0 \lambda^d + O(\lambda^{d-1}) \qquad \text{as} \quad \lambda \to +\infty \tag{1.9}$$

with the standard coefficient $\kappa_0 = (2\pi)^{-d}\omega_d \,\mathsf{mes}(Y)$, where $\mathsf{mes}(Y)$ means d-dimensional volume of Y, ω_d is the volume of the unit ball in $\mathbb{R}^d$. We also can get two-term asymptotics with the same remainder estimate for $\mathsf{N}(\lambda) * \lambda_+^{r-1}$, $0 < r \le 1$.

(ii) Moreover, if the set of all periodic geodesics of Y has measure 0, then

$$\mathsf{N}(\lambda) = \kappa_0 \lambda^d + \kappa_1 \lambda^{d-1} + o(\lambda^{d-1}) \qquad \text{as} \quad \lambda \to \infty. \tag{1.10}$$

We also can get two-term asymptotics (three-term for $r = 1$) with the same remainder estimate for $\mathsf{N}(\lambda) * \lambda_+^{r-1}$, $0 < r \le 1$. The same asymptotics, albeit with a larger number of terms, hold for $r > 1$.

(iii) "Regular" singularities of the dimension $< (d-1)$ (like conical points in 3D) do not cause any problems for asymptotics of $\mathsf{N}(\lambda)$—we can use a rescaling technique to cover them; moreover, in the framework of this paper they would not matter even combined with edges (like vertices in 3D).

2 Dirichlet-to-Neumann Operator

2.1 Toy-Model: Dihedral Angle

Let $Z = \mathbb{R}^{d-1}$ with the Euclidean metrics, $X = \mathcal{X} \times Z$, $Y = \mathcal{Y} \times Z$, where $\mathcal{X}$ is a planar angle of solution α, $0 < \alpha \le 2\pi$, $\mathcal{Y} = \mathcal{Y}_1 \cup \mathcal{Y}_2$, $\mathcal{Y}_j$ are rays (see Figure .2).

Then one can identify Y with $\mathbb{R}^d$ with coordinates (s, z), where $z \in Z$ and

- $s = \mathsf{dist}(y, Z)$ for for a point $y \in Y_1 = \mathcal{Y}_1 \times Z$,
- $s = -\mathsf{dist}(y, Z)$ for for a point $y \in Y_2 = \mathcal{Y}_2 \times Z$.

Then we have a Euclidean metrics and a corresponding positive Laplacian Δ_Y on Y.

Remark 2.1. (i) We can consider any angle $\alpha > 0$, including $\alpha > 2\pi$ (in which case X could be defined in the polar coordinates, but then we need to address some issues with the domain of operator).

(ii) If $\alpha = \pi$, then $\Lambda = \Delta_Y^{1/2}$.

(iii) We say that X is a *proper angle* if $\alpha \in (0, \pi)$ and that X is a *improper angle* if $\alpha \in (\pi, 2\pi)$. We are not very concerned about $\alpha = \pi,\ 2\pi$ since these cases will be forbidden in the general case.

For this toy-model we can make a partial Fourier transform $F_{z\to\zeta}$ and then study equation in the planar angle:

$$\Delta_2 w + w = 0, \tag{2.1}$$

where Δ_2 is a positive 2D-Laplacian and we made also a change of variables $x'' \mapsto |\zeta| \cdot x''$, $x'' = (x_1, x_2)$. Denote by $\bar{J}$ and $\bar{\Lambda}$ operators J and Λ for (2.1). This problem is extensively studied in Appendix A.1.

Then we can use the separation of variables. Singularities at the vertex for solutions to (2.1) and $w|_Y = 0$, are the same as for $\Delta_2 w = 0$, $w|_Y = 0$ and they are combinations of $r^{\pi n/\alpha} \sin(\pi n\theta/\alpha)$ with $n = 1, 2, ...$, where $(r, \theta) \in \mathbb{R}^+ \times (0, \alpha)$ are polar coordinates.

This show the role of α: if $\alpha \in (0, \pi)$ those functions are in $\mathscr{H}^{\sigma}_{\mathsf{loc}}(\mathcal{X})$ with $\sigma < 1 + \pi n/\alpha$, and $\partial_\nu w|_Y$ belong to $\mathscr{H}^{\sigma-3/2}_{\mathsf{loc}}(\mathcal{Y})$.

One can prove easily the following Propositions 2.2 and 2.3 below:

Proposition 2.2. *The following are bounded operators*

$$\Delta_{\mathsf{D}}^{-1} : \mathscr{H}^{\sigma}(X) \to \mathscr{H}^{\sigma+2}(X), \tag{2.2}$$

$$J : \mathscr{H}^{\sigma+\frac{3}{2}}(Y) \to \mathscr{H}^{\sigma+2}(X), \tag{2.3}$$

$$\Lambda : \mathscr{H}^{\sigma+\frac{3}{2}}(Y) \to \mathscr{H}^{\sigma+\frac{1}{2}}(X), \tag{2.4}$$

where Δ_{D} *is an operator* Δ *with zero Dirichlet boundary conditions on* Y *and*

- $\sigma \in [-\frac{1}{2}, 0]$, *if* $\alpha \in (0, \pi)$, *and*
- $\sigma \in [-\frac{1}{2}, \bar{\sigma})$ *with* $\bar{\sigma} = \pi/\alpha - 1$ *otherwise.*

Proposition 2.3. *For equation* (2.1) *in* $\mathcal{X}$

$$\bar{\Lambda} - (D_s^2 + 1)^{1/2} = \sum_{j+k\le 1} D_s^j \bar{K}_{jk} D_s^k\,, \tag{2.5}$$

where operators $\bar{K}_{jk}$ *have Schwartz kernels* $\bar{K}_{jk}(s, s')$ *such that*

$$|D_s^p D_{s'}^q \bar{K}_{jk}(s, t')| \le C_{pqm} |s|^{-(\bar{\sigma}-p)_-} |s'|^{-(\bar{\sigma}-q)_-} (|s| + |s'|)^{-p-q+(\bar{\sigma}-p)_-+(\bar{\sigma}-q)_-} (|s| + |s'| + 1)^m \tag{2.6}$$

and $l_\pm := \max(\pm l, 0)$ *and* m *is arbitrarily large.*

Then

Corollary 2.4. *For the toy-model in* X

$$\Lambda - \Delta_Y^{1/2} = \sum_{j+k\le 1} D_s^j K_{jk} D_s^k\,, \tag{2.7}$$

where operators K_{jk} *have Schwartz kernels*

$$K_{j,k}(x', s; y', s') = (2\pi)^{1-d} \iint |\xi'|^{2-j-k} \bar{K}_{jk}(s|\xi'|,\, s'|\xi'|) e^{-i\langle x'-y', \xi'\rangle}\, d\xi'. \tag{2.8}$$

2.2 General Case

Consider now the general case. In this case we can again introduce coordinate s on Y and consider Y as a Riemannian manifold, but with the metrics which is only $\mathscr{C}^{0,1}$ (Lipschitz class); more precisely, it is $\mathscr{C}^{\infty}$ on both Y_1 and Y_2, but the first derivative with respect to s may have a jump on Z. It does not, however, prevent us from introduction of Δ_Y and therefore $\Delta_Y^{\frac{1}{2}}$, but the latter would not be necessarily the classical pseudodifferential operator.

We want to exclude the degenerate cases of the angles π and 2π. So, let us assume that

(2.9) $Z = \{x\colon x_1 = x_2 = 0\}$ and $X = Z \times \mathcal{X}$ with a planar angle $\mathcal{X} \ni (x_1, x_2)$, disjoint from half-plane and the plane with a cut.

Definition 2.5. For $z \in Z$ let $\alpha(z)$ be an internal angle between two leaves of Y at point z (calculated in the corresponding metrics). Due to our assumption either $\alpha(z) \in (0, \pi)$ or $\alpha(z) \in (\pi, 2\pi)$. Let Z_j be a connected component of Z.

(i) Z_j is a *inner edge* if $\alpha(z) \in (0, \pi)$ on Z_j, and

(ii) Z_j is an *outer edge* if $\alpha(z) \in (\pi, 2\pi)$ on Z_j.

One can prove easily

Proposition 2.6. *The following are bounded operators*

$$\Delta_{\mathsf{D}}^{-1} : \mathscr{H}^{\sigma}(X) \to \mathscr{H}^{\sigma+2}(X), \tag{2.10}$$

$$J : \mathscr{H}^{\sigma+\frac{3}{2}}(Y) \to \mathscr{H}^{\sigma+2}(X), \tag{2.11}$$

$$\Lambda : \mathscr{H}^{\sigma+\frac{3}{2}}(Y) \to \mathscr{H}^{\sigma+\frac{1}{2}}(X), \tag{2.12}$$

where Δ_{D} *is an operator* Δ *with zero Dirichlet boundary conditions on* Y *and*

(i) $\sigma \in [-\frac{1}{2}, 0]$, *if* $\alpha(z) \in (0, \pi)$ $\forall z \in Z$, *and*

(ii) $\sigma \in [-\frac{1}{2}, \bar{\sigma})$ *with* $\bar{\sigma} = \pi/\bar{\alpha} - 1$, $\bar{\alpha} = \max_{z\in Z} \alpha(z)$ *otherwise.*

One can also prove easily

Proposition 2.7. *In the general case, assuming that* $Z = \{x\colon x_1 = x_2 = 0\}$ *and* $X = Z \times \mathcal{X}$ *with a planar angle* $\mathcal{X} \ni (x_1, x_2)$ *of solution* $\in (0,\pi)\cup(\pi, 2\pi)$

$$\Lambda - \Delta_Y^{1/2} = b + \sum_{j+k\le 1} D_s^j K_{jk} D_s^k\,, \tag{2.13}$$

where b *is a bounded operator and operators* K_{jk} *have Schwartz kernels and*

$$K_{j,k}(x', s; y', s') = (2\pi)^{1-d} \iint |\xi'|^{2-j-k} \bar{K}_{jk}\bigl(\frac{1}{2}(x'+y'), s|\xi'|,\, s'|\xi'|\bigr)\, e^{-i\langle x'-y', \xi'\rangle}\, d\xi'. \tag{2.14}$$

Remark 2.8. On the distances $\gtrsim 1$ from Z, b is a classical 0-order pseudodifferential operator, on the distance $\gtrsim |\xi'|^{-1+\delta}$ it is a rough 0-order pseudodifferential operator[3)].

3 Microlocal Analysis

3.1 Propagation of Singularities near Edge

We are going to consider microlocal analysis near point $(\bar{x}, \bar{\xi}'') \in T^*Z$ under assumption (2.9). In our approach we use definition of operator Λ rather than its description of the previous Section 2. So, let $x = (x''; x') \in \mathbb{R}^2 \times \mathbb{R}^{d-1}$.

Proposition 3.1. *(i) Let* $q_j = q_j(\xi')$ *(*$j = 1, 2$*) be two symbols, constant as* $|\xi'| \ge C$*. Assume that the* $\mathsf{dist}(\mathsf{supp}(q_1), \mathsf{supp}(q_2)) \ge \epsilon$.

Consider h*-pseudodifferential operators* $Q_j = q_j^{\mathsf{w}}(h^{-1}D')$, $j = 1, 2$. *Then the operator norms of*

$$(3.1)_{1,2} \qquad Q_1\Delta_{\mathsf{D}}^{-1}Q_2 : \mathscr{L}^2(X) \to \mathscr{H}^2(X), \qquad Q_1 J Q_2 : \mathscr{H}^{\frac{1}{2}}(Y) \to \mathscr{H}^2(X),$$

$$(3.1)_3 \qquad Q_1 \Lambda Q_2 : \mathscr{H}^1(Y) \to \mathscr{L}^2(Y)$$

do not exceed $C'h^s$ *with arbitrarily large* s *where* Δ_{D} *is an operator* Δ *with zero Dirichlet boundary conditions on* Y.

(ii) Let $Q_j(x')$ *(*$j = 1, 2$*) be two functions. Then operators* $(3.1)_{1-3}$ *are infinitely smoothing by* x'.

[3)] I. e. with the symbols such that $|D_x^\alpha D_\xi^\beta| \le C_{\alpha\beta}\rho^{-|\beta|}\gamma^{-|\alpha}$ with $\rho\gamma \ge h^{1-\delta}$, $\rho\gamma \ge h^{1-\delta}$. Here $\rho = 1$, $\gamma = |x|$.

Proof. (i) Without any loss of the generality one can assume that q_j are constant also in the vicinity of 0. Then the operator norms of $[Q_j, \Delta]\Delta_{\mathsf{D}}^{-1}$ in $\mathscr{L}^2(X)$ do not exceed Ch; replacing Q_j by $Q_j^{(n)}$ with $Q_j^{(0)} = Q_j$ and $Q_j^{(n)} := [Q_j^{(n-1)}, \Delta]\Delta_{\mathsf{D}}^{-1}$ for $j = 1, 2, ...$, we prove by induction that the operator norms of $Q_j^{(n)}$ in in $\mathscr{L}^2(X)$ do not exceed Ch^n. Then one can prove by induction easily that the operator norm of $(3.1)_1$ does not exceed Ch^s.

Then one can prove easily that the operator norm of $(3.1)_{2,3}$ do not exceed Ch^s as well. It concludes the proof of Statement (i).

(ii) Statement (ii) is proven by the same way. □

Let $u(x, y, t)$ be Schwartz kernel of $e^{it\Lambda}$, $x, y \in Y$.

Proposition 3.2. *Consider h-pseudodifferential operator $Q = q^{\mathsf{w}}(x', h^{-1}D')$ where q vanishes $\{|\xi'| \le c_0\}$. Let $\chi \in \mathscr{C}_0^\infty(\mathbb{R})$, $T \ge h^{1-\delta}$. Then operator norms of $F_{t\to\tau}\chi_T(t)Q_x u$ and $F_{t\to\tau}\chi_T(t)u\,{}^tQ_y$ do not exceed $C_T' h^s$ for $\tau \le c$ for $c_0 = c_0(c)$.*

Proof. One need to consider $v = e^{it\Lambda}f$, $f \in \mathscr{H}^1(Y)$, $\|f\|_{\mathscr{L}^2(Y)} = 1$ and observe that it satisfies $(D_t - \Lambda)v = 0$. Using (1.5) we see that operator $(D_t - V)$ is elliptic in $\{|\xi'| \ge c_0, \tau \le c\}$ while Proposition 3.1 ensures its locality. □

Therefore, in what follows

Remark 3.3. Studying energy levels $\tau \le c$ we can always apply cut-out domain $\{|\xi'| \ge c_0\}$.

Now we can study the propagation of singularities. Let us prove that the propagation speed with respects to x and ξ' do not exceed C_0. For this and other our analysis we need the following Proposition 3.4:

Proposition 3.4. *For h-pseudodifferential operator $Q = q^{\mathsf{w}}(x, hD')$ the following formula connecting commutators $[\Delta, Q]$ and $[\Lambda + \partial_\nu, Q]$ holds:*

$$-\operatorname{Re} i([\Delta, Q]Jv, Jv)_X = \operatorname{Re} i(([\Lambda, Q] + [\partial_\nu, Q])v, v)_Y \tag{3.2}$$

Proof. First, consider real valued symbol $q = q(x, \xi')$ and $Q = q^{\mathrm{w}}(x, hD')$ its Weyl quantization. Let v denote just any function on Y and V its continuation as a harmonic function. Then for $w = Jv$

$$\begin{aligned} 0 = (Q\Delta w, w)_X = (\Delta Q w, w) - ([\Delta, Q]w, w)_X = \\ - ([\Delta, Q]w, w)_X + (Qw, \Delta w)_X - (\partial_\nu Qw, w)_Y + (Qw, \partial_\nu w)_Y = \\ - ([\Delta, Q]w, w)_X - (Q\partial_\nu w, w)_Y - ([\partial_\nu, Q]w, w)_Y + (Qw, \partial_\nu w)_Y = \\ - ([\Delta, Q]w, w)_X + (Q\Lambda v, v)_Y - ([\partial_\nu, Q]v, v)_Y - (v, Q\Lambda v)_Y = \\ - ([\Delta, Q]w, w)_X - (\Lambda Q v, v)_Y - ([\partial_\nu, Q]v, v)_Y, \end{aligned}$$

which implies (3.2). □

Now we can prove that at energy levels $\tau \le c$ the propagation speed with respects to x and ξ' do not exceed $C_0 = C_0(c)$.

Proposition 3.5 [4]**.** *Let $Q_j = q_j^{\mathrm{w}}(x, hD')$ and $\mathsf{dist}(\mathsf{supp}(q_1), \mathsf{supp}(q_2)) \ge C_0 T$ with fixed $T > 0$. Let $\chi \in \mathscr{C}_0^\infty([-1, 1])$. Then for $\tau \le c$*

$$|F_{t\to h^{-1}\tau}\big(\chi_T(t) Q_{1x} u\, {}^t Q_{2y}\big)| \le C h^m, \tag{3.3}$$

where here and below m is an arbitrarily large exponent and $C = C_m$.

Proof. (i) The proof is the standard one for propagation with respect to (x', ξ'): we consider $\phi(x', \xi', t)$ and prove that under the microhyperbolicity condition

$$\phi_t - \{|\xi'|, \phi\} \ge \epsilon_0, \tag{3.4}$$

which is equivalent to

$$2\phi_t - |\xi'|^{-1}\{|\xi'|^2, \phi\} \ge 2\epsilon_0 |\xi'|, \tag{3.5}$$

our standard propagation theorem (see Theorem 2.1.2 of [Ivr1]) holds, just repeating arguments of its proof, using equality (3.2) and the fact that $\|Jv\|_{\mathscr{H}^{1/2}(X)} \asymp \|v\|_{\mathscr{L}^2(Y)}$.

Then we plug $\phi(x', \xi', t) = \psi(x', \xi') - t$ with $|\nabla_{x', \xi'}\psi| \le \epsilon_0$, and prove that (3.3) for $q_j = q_j(x', \xi')$.

[4] Cf. Theorem 3.1(i) of [Ivr1].

(ii) We need also prove that the propagation speed with respect to (x_1, x_2) [5] does not exceed C_0, but it is easy since for $|s| \geq \epsilon$, Λ is a first-order pseudodifferential operator with the symbol $|\xi|$. □

Remark 3.6. In fact, it follows from the proof, that the propagation speed with respect to x' do not exceed C_0, and the propagation speed with respect to ξ' does not exceed $C_0|\xi'|$ with C_0, which does not depend on restriction $\tau \leq c$. Meanwhile, the propagation speed with respect (x_1, x_2) does not exceed 1.

Next we prove that at energy levels $\tau = 1$ the propagation speed with respects to x' in the vicinity of $(0, \bar{\xi}')$ with $|\bar{\xi}'| \geq \epsilon_0$ is at least $\epsilon_1 = \epsilon_1(\epsilon_0)$.

Proposition 3.7 [6]**.** *Let* $Q_j = q_j^{\mathsf{w}}(x, hD')$ *and*

$$\mathsf{dist}_{x'}(\mathsf{supp}(q_1), \mathsf{supp}(q_2)) \leq \epsilon_1 T$$

with fixed $T > 0$. *Let* $\chi \in \mathscr{C}_0^\infty([-1, -\frac{1}{2}] \cup [-\frac{1}{2}, -1])$. *Then for* $|\tau - 1| \leq \epsilon_0$ (3.3) *holds.*

Proof. After propagation theorem mentioned in the proof of Proposition 3.5 is proven we just plug $\phi(x', \xi'.t) = \psi(x', \xi') - \epsilon t$ with $\xi' \cdot \nabla_{x'}\psi \geq 1$. □

Corollary 3.8 [7]**.** *In the framework of Proposition 3.5 consider* $|\tau - 1| \leq \epsilon$. *Then*

$$|F_{t\to h^{-1}\tau}\Gamma_x\chi_T(t)u\,{}^tQ_y| \leq Ch^{1-d+m}T^{-m} \tag{3.6}$$

and

$$|F_{t\to h^{-1}\tau}\Gamma_x\big(\bar{\chi}_{T'}(t) - \bar{\chi}_T(t)\big)u\,{}^tQ_y| \leq Ch^{1-d+m}T^{-m}, \tag{3.7}$$

provided $\chi \in \mathscr{C}_0^\infty([-1, -\frac{1}{2}] \cup [\frac{1}{2}, 1])$, $\bar{\chi} \in \mathscr{C}_0^\infty([-1, 1])$, $\bar{\chi} = 1$ *on* $[-\frac{1}{2}, \frac{1}{2}]$, $h \leq T \leq T' \leq T_0$ *with small constant* T_0.

Proof. For small constant T (3.6) follows directly from Proposition 3.7, after one proves easily that we can insert $D_{x''}$, $D_{y''}$ to the corresponding estimate, which is easy.

For $h \leq T \leq T_0$ we use just rescaling like in the proof of Theorem 2.1.19 of [Ivr1]. Finally, (3.7) is obtained by the summation with respect to partition of unity with respect to t. □

[5] Or, equivalently, with respect to s.

[6] Cf. Theorem 3.1(ii) of [Ivr1].

[7] Cf. Corollary 2.2(ii) of [Ivr1].

This implies immediately

Corollary 3.9. $\mathsf{N}_h(\tau)$ *and* $\mathsf{N}_h(\tau)*\tau_+^{\sigma-1}$ *are approximated by the corresponding Tauberian expressions with* $T \asymp h^{1-\delta}$ *with errors* $O(h^{1-d})$ *and* $O(h^{1-d+\sigma})$ *respectively (as* $\tau = 1$ *and* $h \to +0$*).*

3.2 Reflection of Singularities from the Edge

The results of the previous subsubsection are sufficient to prove *sharp spectral asymptotics* (with the remainder estimate $O(\lambda^{d-1})$), which do not require conditions of the global nature, but insufficient to prove sharper spectral asymptotics (with the remainder estimate $o(\lambda^{d-1})$), which require conditions of the global nature.

For this more ambitious purpose we need to prove that the singularities propagate along geodesic billiards on the boundary Y, reflecting and refracting on the edge Z (so billiards will be branching), and the typical singularity (with $|\xi'| < \tau$) does not stick to Z.

To do this we will follow arguments of Subsubsection 4 of [Ivr1]. Assuming (2.9) consider operator $Q = x_1D_1 + x_2D_2 - i/2$, which acts along Y. As an operator in $\mathscr{L}^2(Y)$ it is self-adjoint, as an operator in $\mathscr{L}^2(X)$ it is not, but differs from a self-adjoint operator $Q = x_1D_1 + x_2D_2 - i$ by $i/2$, which does not affects commutators.

As a result, repeating the proof of Proposition 3.4 we arrive to

(3.8) Under assumption (2.9) equality (3.2) also holds for the operator $Q = x_1D_1 + x_2D_2 - i$.

To apply arguments of the proof of Propositions 4.2 and then 4.3 of [Ivr1], we need to check, if operator $i[\Lambda, Q]$ is positive definite, which in virtue of (3.2) is equivalent to the same property for the form in the left:

$$\mathsf{Re}(i[\Delta, Q]w, w) - \mathsf{Re}(i[\partial_\nu, Q]w, w)_Y \ge \epsilon\|\nabla w\|^2 \quad \text{for} \quad w\colon \Delta = 0. \tag{3.9}$$

For the toy-model $i[\Delta, Q] = 2(D_1^2 + D_2^2)$, $i[\partial_\nu, Q] = -\partial_\nu$, and the form on the left coincides with $\|\nabla w\|^2 - 2\|\nabla' w\|^2$ on w in question and therefore after Fourier transform $F_{x'\to\zeta}$ and change of variables $x_{1,2}$ it boils down to the inequality

$$\|\nabla w\|^2 - \|w\|^2 \ge \epsilon(\|\nabla w\|^2 + \|w\|^2) \qquad \text{for} \quad w\colon \Delta_2 w + w = 0 \tag{3.10}$$

for two-dimensional Δ_2, norms and scalar products.

This inequality is explored in Appendix A.1, and in virtue of Proposition A.11 (3.10) holds for $\alpha \in (\pi, 2\pi)$. Meanwhile due to Proposition A.16 (3.10) fails for $\alpha \in (0, \pi)$.

Therefore we arrive to

Proposition 3.10 [8]**.** *Consider two-dimensional toy-model (planar angle) with $\alpha \in (\pi, 2\pi)$.*

Let $\psi \in \mathscr{C}_0^\infty([-1,1])$, $\psi_\gamma(x) = \psi(x/\gamma)$ and $\phi \in \mathscr{C}_0^\infty([-1,1])$, $\tau \ge 1 + \epsilon_0$. Then as $\gamma \ge h^{1-\delta}$, $T \ge C_0\gamma$, $h^\delta \ge \eta \ge h^{1-\delta}T^{-1}$

$$\|\phi(\eta^{-1}(hD_t - \tau))\psi_\gamma e^{it\Lambda}\psi_\gamma|_{t=T}\| \le CT^{-1}\gamma + Ch^{\delta'}. \tag{3.11}$$

Proof. Proof follows the proof of Proposition 4.2 of [Ivr1] with $m = 1$, and uses equality (3.2) to reduce calculation of the commutator $[\Lambda, Q]$ to the calculation of the commutator $[\Delta, Q]$. □

Proposition 3.11 [9]**.** *Consider $(d+1)$-dimensional toy-model (dihedral angle) with $\alpha \in (\pi, 2\pi)$.*

Let $\psi \in \mathscr{C}_0^\infty([-1,1])$, $\psi_\gamma(x) = \psi(x_1/\gamma)$, $\phi \in \mathscr{C}_0^\infty([-1,1])$, $\varphi \in \mathscr{C}_0^\infty(\mathbb{R}^{d-1})$ supported in $\{|\xi'| \le 1 - \epsilon\}$ with $\epsilon > 0$. Finally, let $\gamma \ge h^{1-\delta}$, $T \ge Ch^{-\delta}\gamma$, $h^\delta \ge \eta \ge h^{1-\delta}T^{-1}$. Then

$$\|\phi(\eta^{-1}(hD_t - 1))\varphi(hD')\psi_\gamma(x_1)e^{it\Lambda}\psi_\gamma(x_1)|_{t=T}\| = O(h^m) \tag{3.12}$$

with arbitrarily large m.

Proof. Proof follows the proof of Proposition 4.3 of [Ivr1] with $m = 1$. □

Now we can consider the general case. Consider a point $\bar z = (\bar x, \bar\xi') \in T^*Z$, $|\bar x'| < 1$.

We can raise to points $\bar z^\pm = (\bar x, \bar\xi^\pm) \in T^*Y_{1,2}|_Z$ with $|\bar\xi^\pm| = 1$ and $\iota\bar z^\pm = \bar z$, where $\iota(x,\xi) = (x,\xi') \in T^*Z$ for $(x,\xi) \in T^*Y|_Z$.

Consider geodesic trajectories $\Psi_t(\bar z^\pm)$, going from $\bar z^\pm)$ into $T^*Y_{1,2}$ for $t < 0$, $|t| < \epsilon$; this distinguishes these two points.

We also can consider geodesic trajectories $\Psi_t(\bar z^\pm)$, going from $\bar z^\mp$ into $T^*Y_{1,2}$ for $t > 0$, $|t| < \epsilon$.

Let $\iota^{-1}\bar z = \{\bar z^+, \bar z^-\}$ and let $\Psi_t(\iota^{-1}\bar z)$ be obtained as a corresponding union as well[10]. So, for such point $\bar z$ $\Psi_t(\iota^{-1}z)$ with $t < 0$ consists of two

[8] Cf. Proposition 4.2 of [Ivr1].

[9] Cf. Proposition 4.3 of [Ivr1].

[10] So we actually restrict ι to $S^*Y|_Z$ and ι^{-1} to B^*Z.

incoming geodesic trajectories, $\Psi_t(\iota^{-1}z)$ with $t<0$ consists of two outgoing geodesic trajectories. Similarly, for $z\in (T^*(Y\setminus Z))$ we can introduce $\Psi_t(z)$: when trajectory hits Z it branches.

Theorem 3.12 [11]**.** *Consider a point $z=(x,\xi)\in T^*Y$, $|\xi|=1$. Consider a (branching) geodesic trajectory $\Psi_t(z)$ with $\pm t\in[0,T]$ (one sign only) with $T\ge\epsilon_0$ and assume that for each t indicated it meets ∂X transversally i.e.*

$$\mathsf{dist}(\pi_x\Psi_t(x,\xi),\partial X)\le\epsilon \implies |\frac{d}{dt}\mathsf{dist}(\pi_x\Psi_t(x,\xi),\partial X)|\ge\epsilon \qquad \forall t:\pm t\in[0,mT]. \tag{3.13}$$

Also assume that

$$\mathsf{dist}(\pi_x\Psi_t(x,\xi),\partial X)\ge\epsilon_0 \qquad \text{as}\ \ t=0,\ \pm t=T. \tag{3.14}$$

Let $\epsilon>0$ be a small enough constant, Q be supported in ϵ-vicinity of (x,ξ) and $Q_1\equiv 1$ in $C_0\epsilon$-vicinity of $\Psi_t(x,\xi)$ as $t=\pm T$. Then operator $(I-Q_1)e^{-it\mathsf{A}}Q$ is negligible as $t=\pm mT$.

Proof. Proof follows the proof of Theorem 4.4 of [Ivr1] with $m=1$. □

Adapting construction of the "dependence set" to our case, we arrive to the following

Definition 3.13. (i) The curve $z(t)$ in T^*Y is called a *generalized geodesic billiard* if a.e.

$$\frac{dz}{dt}\in K(z), \tag{3.15}$$

where

(a) $K(z)=\{H_g(z)\}$, $g(z)$ is a metric form, if $z\in T^*(Y\setminus Z)$,
(b) $K(z)=\{H_g(z')\colon z'\in\iota^{-1}\iota z\}$, if $z\in T^*Y|_Z$.

(ii) Let $\Psi_t(z)$ for $t\gtrless 0$ be a set of points $z'\in T^*Y$ such that there exists generalized geodesic billiard $z(t')$ with $0\lesseqgtr t'\lesseqgtr t$, such that $z(0)=z$ and $z(t)=z'$. Map $(z,t)\mapsto\Psi_t(z)$ is called a *generalized (branching) billiard flow*.

[11] Cf. Theorem 4.4 of [Ivr1].

(iii) Point $z \in T^*Y$ is *partially periodic* (with respect to Ψ) if for some $t \neq 0$ $z \in \Psi_t(z)$. Point $z \in T^*Y$ is *completely periodic* (with respect to Ψ) if for some $t \neq 0$ $\{z\} = \Psi_t(z)$

Then we arrive immediately to

Corollary 3.14. *Assume that Z consists only of only outer edges. Also assume that the set of all partially periodic points is zero.*

Then $\mathsf{N}_h(\tau)$ and $\mathsf{N}_h(\tau) * \tau_+^{r-1}$ are approximated by the corresponding Tauberian expressions with $T \asymp h^{1-\delta}$ with errors $o(h^{1-d})$ and $o(h^{1-d+r})$ respectively (as $\tau = 1$ and $h \to +0$).

Proof. Easy details are left to the reader. □

4 Main Results

4.1 From Tauberian to Weyl Asymptotics

Now we can apply the method of successive approximations as described in Section 7.2 of [Ivr1], considering an unperturbed operator

(a) As one in $\mathbb{R}^d$, with the metrics, frozen at point y, if $\mathsf{dist}(y, Z) \geq h^{1-\delta}$.

(b) As one in the dihedral edge, with the metrics, frozen at point $(y', 0)$, if $y = (y'; s)$ with $|s| = \mathsf{dist}(y, Z) \leq h^{1-\delta}$,

with the following modification: We calculate Λ also this way, applying successful approximations for both Δ, when we solve $\Delta w = 0$, $w|_Y = v$, and to ∂_ν, when we calculate $\partial_\nu w|_Y$.

Then we prove that for operator $h\Lambda$ the Tauberian expression $\mathsf{N}_h^{\mathsf{T}}(1)$ for $\mathsf{N}_h^-(1)$ with $T = h^{1-\delta}$ coincides modulo $O(h^m)$ with the (generalized) Weyl expression

$$\mathsf{N}_h^{\mathsf{W}} \sim \kappa_0 h^{-d} + \kappa_1 h^{1-d} + \dots, \tag{4.1}$$

with the standard coefficient κ_0 and with $\kappa_1 = \kappa_{1,Y\setminus Z} + \kappa_{1,Z}$, where $\kappa_{1,Y\setminus Z}$ is calculated in the standard way, for the smooth boundary, and

$$\kappa_{1,Z} = (2\pi)^{1-d}\omega_{d-1}\int_Z \varkappa(\alpha(y))\, dy\,, \tag{4.2}$$

$$\varkappa(\alpha) = \int_1^\infty \int_{-\infty}^\infty \lambda^{-d}\Big(e_\alpha(s,s,\lambda) - \pi^{-1}(\lambda-1)\Big)\, ds d\lambda\,, \tag{4.3}$$

$e_\alpha(s,s',\lambda)$ is a Schwartz kernel of the spectral projector of $\hat{\Lambda}$ in the planar angle of solution α and $\pi^{-1}(\lambda-1)$ is a corresponding Weyl approximation.

4.2 Main Theorems

Thus we arrive to the corresponding asymptotics for $N_h^-(1)$ and from them, obviously to asymptotics for $N(\tau)$:

Theorem 4.1. *Let Y be a compact manifold with edges. Then the following asymptotics hold as $\tau \to +\infty$:*

$$N(\tau) = \kappa_0 \tau^d + O(\tau^{d-1}) \tag{4.4}$$

and for $r > 0$

$$N(\tau) * \tau_+^{r-1} = \Big(\sum_{m<r} \kappa_m \tau^{d-r}\Big) * \tau_+^{r-1} + O(\tau^{d-1}). \tag{4.5}$$

Theorem 4.2. *Let Y be a compact manifold with edges. Assume that Z consists only of outer edges and that the set of all points, which are partially periodic with respect to the generalized billiard flow, has a measure 0. Then the following asymptotics hold as $\tau \to +\infty$:*

$$N(\tau) = \kappa_0 \tau^d + \kappa_1 \tau^{d-1} + o(\tau^{d-1}) \tag{4.6}$$

and for $r > 0$

$$N(\tau) * \tau_+^{r-1} = \Big(\sum_{m\le r} \kappa_m \tau^{d-r}\Big) * \tau_+^{r-1} + o(\tau^{d-1}). \tag{4.7}$$

4.3 Discussion

Remark 4.3. (i) Even for standard ordinary non-branching billiards, billiard flow Ψ_t could be multivalued. However, if through point $z \in T^*(Y \setminus Z)$ (where now Y is a manifold, and Z is its boundary) passes an infinitely long in the positive (or negative) time direction billiard trajectory, which always meets Z transversally, and each finite time interval contains a finite number of reflections, then $\Psi_t(z)$ for $\pm t > 0$ is single-valued. Points, which do not have such property, are called *dead-end points*. For ordinary billiards the set of dead-end points has measure zero.

(ii) For branching billiards (with velocities c_1, c_2) we can introduce the notion of the dead-end point as well: it is if at least one of the branches either meets Z non-transversally, or makes an infinite number of reflections on some finite time interval. As it was shown by Yu. Safarov and D. Vassiliev [SaVa], if c_1 and c_2 are not disjoint (our case!), the set of dead-end billiards could have positive measure.

Remark 4.4. (i) Checking non-periodicity assumption is difficult. But in some domains it will be doable. F.e. assume that $Y = Y_1 \cup Y_2$ globally is a domain of revolution, so Z is a $(d-1)$-dimensional sphere. Then the measure of the set of dead-end billiards is 0.

(ii) Assume that neither Y_1, nor Y_2 contains closed geodesics. Let $\varphi_j(\beta)$ be the length of the segment of geodesics in Y_j, with only ends on Z, where β is the reflection angle: Assume that $\varphi_j(\beta)$ are analytic and $\varphi_j(\beta) \to 0$ as

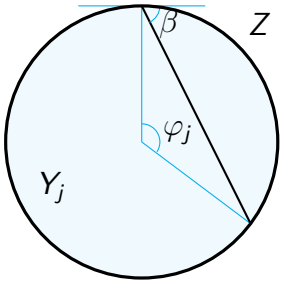

Figure 28.1: Trajectories on the manifold of revolution

$\beta \to +0$. Then the measure of the set of partially periodic billiards is 0.

Remark 4.5. Our arguments hold not only for compact X but also for $X \subset \mathbb{R}^{d+1}$ with the compact complement and with the metrics. stabilizing to Euclidean at infinity.

Remark 4.6. (i) In the next version of this paper we want to prove sharper asymptotics for domains with inner edges. To do this we need to understand, how singularities propagate near inner edges. One can prove that there are plenty of singularities, concentrated in $Z \times \mathbb{R} \ni (x,t)$ and $\{|\xi'| < \tau\}$. This is similar to the Rayleigh waves. And, we hope, exactly like Rayleigh waves, those singularities do not prevent us from the sharper asympotics.

What we need to prove is that the singularities in $\{|\xi'| < \tau\}$, coming from $Y \setminus Z$ transversally to Z, reflect and refract but leave Z instantly. In other words, that these two kinds of waves are completely separate. It is what I am trying to prove now.

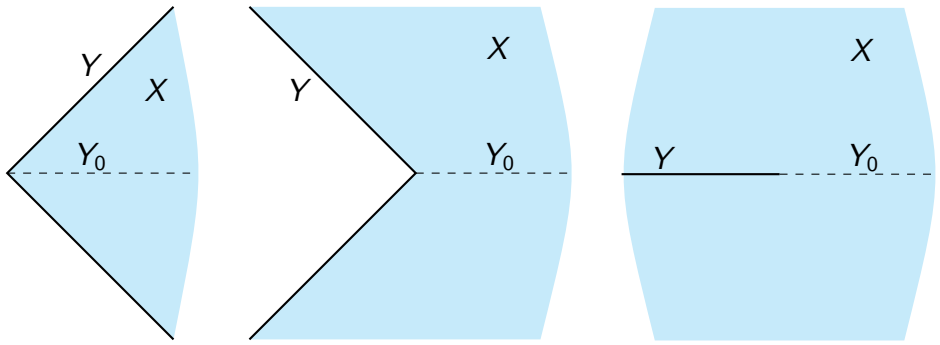
(ii) Let $\mathcal{K}$ be the linear span of the corresponding eigenfunctions. We need to prove that $\|\nabla w\| \geq \|w\|$ holds for $w = \hat{J}v$ with $v \in \mathcal{K}^{\perp}$. One can prove easily that $\|\nabla w\| = \|w\|$ for $w = \hat{J}v$ and eigenfunction v (Proposition A.16).

A Appendix

A.1 Planar Toy-Model

Preparatory Results

Here, in contrast to the whole article, $X = \{x \in \mathbb{R}^2, x_1 \geq |x_2| \operatorname{cot}(\alpha/2)\}$ is a planar angle of solution $\alpha \in (0, 2\pi]$ with a boundary $Y = Y_1 \cup Y_2$, $Y_{1,2} = \{x\colon x_1 = |x_2| \operatorname{cot}(\alpha/2),\ \pm x_2 < 0\}$ and a bisector $Y_0 = \{x\colon x_2 = 0, x_1 > 0\}$, and $\Delta = -\partial_1^2 - \partial_2^2$ is a positive Laplacian (so, for simplicity we do not write "hat").



(a) $\alpha \in (0, \pi)$ (b) $\alpha \in (\pi, 2\pi)$ (c) $\alpha = 2\pi$

Figure .2: Proper and improper angles

Remark A.1. (i) For $\alpha = \pi$ we have a regular half-plane $\{x\colon x_1 > 0\}$, and for $\alpha = 2\pi$ we have a plane with the cut $\{x\colon x_1 \leq 0,\ x_2 = 0\}$.

(ii) One can consider $\alpha > 2\pi$ on the covering of $\mathbb{R}^2$.

Consider real-valued[12] solutions of

$$Lw := (\Delta + 1)w = 0 \tag{A.1}$$

and operators J, Λ: $w = Jv$ solves (A.1) and $w|_Y = v$; $\Lambda v = -\partial_\nu w|_Y$ with $w = Jv$. Recall that ν is an inner normal to Y.

Observe that for any angle[13]

$$2\iint_X Lw \cdot w_{x_1}\, dx_1 dx_2 = \int_{\partial X} \Big((w_{x_1}^2 - w_{x_2}^2 - w^2)\nu_1 + 2w_{x_1}w_{x_2}\nu_2 \Big)\, dr, \tag{A.2}$$

where dr is a Euclidean measure on Y, and the then similar formula holds with x_1 and x_2 permuted. Then for solution of (A.1)

$$\int_{\partial X} \Big((w_{x_1}^2 - w_{x_2}^2)(\nu_1\ell_1 - \nu_2\ell_2) + 2w_{x_1}w_{x_2}(\nu_2\ell_1 + \nu_1\ell_2) - w^2(\nu_1\ell_1 + \nu_2\ell_2) \Big)\, dr = 0. \tag{A.3}$$

If on $\Gamma \subset \partial X$ $\ell_1 = \nu_1$, $\ell_2 = \nu_2$, then we can calculate invariantly as if $\ell_1 = \nu_1 = 0$, $\ell_2 = \nu_2 = 1$:

$$(w_{x_1}^2 - w_{x_2}^2)(\nu_1\ell_1 - \nu_2\ell_2) + 2w_{x_1}w_{x_2}(\nu_2\ell_1 + \nu_1\ell_2) - w^2(\nu_1\ell_1 + \nu_2\ell_2) = w_\nu^2 - w_r^2 - w^2, \tag{A.4}$$

where $w_r = \partial_r w$ and $w_\nu = \partial_\nu w$.

All these formulae hold not only for the original angle, but also for the smaller angle. Then let consider as X an upper half of the symmetric angle, $\partial X = Y_2 \cup Y_0$, on Y_0 the integrand is

$$\mathcal{I} := (w_{x_2}^2 - w_{x_1}^2 - w^2)\ell_2 + 2w_{x_1}w_{x_2}\ell_1 \tag{A.5}$$

with $\ell_1 = \sin(\alpha/2)$, $\ell_2 = -\cos(\alpha/2)$.

Consider different cases:

Antisymmetric case: $w|_{Y_0} = 0$, then $\mathcal{I} = -w_{x_2}^2 \cos(\alpha/2)$ and

$$\int_{Y_2} \big(w_\nu^2 - w_r^2 - w^2\big)\, dr - \cos(\alpha/2) \int_{Y_0} w_{x_2}^2\, dx = 0. \tag{A.6}$$

Symmetric case: $w_{x_2}|_{Y_0} = 0$, then $\mathcal{I} = (w_{x_1}^2 + w^2)\cos(\alpha/2)$ and

$$\int_{Y_2} \big(w_\nu^2 - w_r^2 - w^2\big)\, dr + \cos(\alpha/2) \int_{Y_0} (w_{x_1}^2 + w^2)\, dx_1 = 0. \tag{A.7}$$

[12] For complex-valued solutions then the main inequalities with w^2 replaced by $|w|^2$ follow automatically.

[13] Not necessary symmetric with respect to x_1-axis.

Proposition A.2. *Let w satisfy* (A.1). *Let either $\alpha \in (0, \pi]$ and w is antisymmetric, or $\alpha \in [\pi, 2\pi)$ and w is symmetric. Then*

$$\|\nabla w\|^2 \geq \|w\|^2. \tag{A.8}$$

Proof. In both cases $\int_{Y_2}(|\nabla w|^2 - w^2)\, dr \geq \int_{Y_2}(w_\nu^2 - w^2)\, ds \geq 0$. Applying this inequality to the angle, shifted by t along x_1, and integrating by $t \in (0, \infty)$, we obtain a double integral (divided by $\sin(\alpha/2)$).

Moreover, one can see easily, that this inequality is strict unless $w = 0$.

Similarly, if instead of multiplying by $(\nu_1 w_{x_1} + \nu_2 w_{x_2})$ we multiply by $(x_2 w_{x_1} - x_1 w_{x_2})$, then extra terms in the double integral will be $\pm w_{x_1} w_{x_2}$ and they cancel one another. However, on Y we get $x_2 = \nu_1 r$, $x_1 = -\nu_2 r$ and therefore contribution of Y_2 will be as in above with extra factor r:

$$\int_{Y_1} \left(w_\nu^2 - w_r^2 - w^2\right) r dr. \tag{A.9}$$

On Y_0 we get extra factor $x_1 = r$, but not $\nu_2 = -\cos(\alpha/2)$, and we arrive to

Antisymmetric case: $w|_{Y_0} = 0$, then $\mathcal{I} = w_{x_2}^2 x_1$ and

$$\int_{Y_2} \left(w_\nu^2 - w_r^2 - w^2\right) r dr + \int_{Y_0} w_{x_2}^2\, x_1 dx_1 = 0. \tag{A.10}$$

Symmetric case: $w_{x_2}|_{Y_0} = 0$, then $\mathcal{I} = (-w_{x_1}^2 - w^2)x_1$ and

$$\int_{Y_2} \left(w_\nu^2 - w_r^2 - w^2\right) r dr - \int_{Y_0} (w_{x_1}^2 + w^2)\, x_1 dx_1 = 0. \tag{A.11}$$

Let us explore dependence $\Lambda = \Lambda(\alpha)$ on α. Observe first that

$$\iint \left(\nabla w \cdot \nabla w' + w w'\right) dx d_1 dx_2 = \int Lw \cdot w' - \int_{\partial X} \partial_\nu w \cdot w'\, dr \tag{A.12}$$

where (r, θ) are polar coordinates and therefore dr is an Euclidean measure on Y. It implies

$$(\Lambda v, v')_Y = \iint \left(\nabla w \cdot \nabla w' + w w'\right) dx_1 dx_2, \tag{A.13}$$

for $w = Jv$, $w' = Jv'$. Therefore

(A.14) Λ is symmetric and nonnegative operator in $\mathscr{L}^2(Y)$.

Consider $X = X(\alpha)$, $Y = Y(\alpha)$, $\Lambda = \Lambda(\alpha)$ and keep w independent on α. Let us replace α by $\alpha + \delta\alpha$ etc. Then for a symmetric X we have $\delta v = -r(\partial_\nu w)\delta\alpha = \frac{1}{2} r(\Lambda v)\delta\alpha$ and it follows from (A.13) that

$$((\delta\Lambda)v, v)_Y + 2(\Lambda v, \delta v)_Y = \frac{1}{2}\int_Y \left(|\nabla w|^2 + |w|^2\right) r dr \times \delta\alpha$$

and therefore

$$((\delta\Lambda)v, v)_Y = -\frac{1}{2}\int_Y \left(w_\nu^2 - w_r^2 - |w|^2\right) r dr \times \delta\alpha. \tag{A.15}$$

Combining with (A.10) and (A.13) we arrive to

Proposition A.3. *(i) On symmetric functions $\Lambda(\alpha)$ is monotone increasing function of α.*

(ii) On antisymmetric functions $\Lambda(\alpha)$ is monotone inreasing function of α.

Let us identify Y with $\mathbb{R} \ni s$, $s = \mp r$ on $Y_{1,2}$ respectively.

Proposition A.4. *(i) On symmetric functions $\Lambda(\pi) = (D_s^2 + I)^{\frac{1}{2}}$.*

(ii) On antisymmetric functions $\Lambda(2\pi) \ge (D_s^2 + I)^{\frac{1}{2}}$.

Proof. Statement (i) is obvious. Statement (ii) follows from the fact that on antisymmetric function v $\Lambda(2\pi)v$ coincides with $\Lambda(\pi)v^0$, restricted to $\{x_1 < 0\}$, where v^0 is v, extended by 0 to $\{x_1 > 0\}$. □

Therefore, combining Propositions A.3 and A.4 we conclude that

Corollary A.5. *(i) On symmetric functions $\Lambda(\alpha) \ge (D_s^2 + I)^{\frac{1}{2}}$ for $\alpha \in [\pi, 2\pi]$.*

(ii) On antisymmetric functions $\Lambda(\alpha) \ge (D_s^2 + I)^{\frac{1}{2}}$ for $\alpha \in (0, 2\pi]$.

Remark A.6. One can prove easily, that inequalities are strict for $\alpha \in (\pi, 2\pi]$, $\alpha \in (0, 2\pi]$ respectively.

Now we want to finish general arguments and to prove inequality (A.8) for antisymmetric w and $\alpha \in (\pi, 2\pi]$. It will be more convenient to use polar coordinates (r, θ) and notations $\mathcal{Y}_\beta = \{(r, \theta) \colon : \theta = \beta\}$, $\mathcal{X}_{\beta_1,\beta_2} = \{(r, \theta) \colon : \beta_1 \le \theta \le \beta_2\}$. Here and below $\beta_* \in [-\alpha/2, \alpha/2]$.

Recall that

$$L = -\partial_r^2 - r^{-1}\partial_r - r^{-2}\partial_\theta^2 + 1. \tag{A.16}$$

Proposition A.7. *(i) Let w satisfy equation* (A.1) *in X. Then*

$$\mathcal{I}(\beta) := \int_{\mathcal{Y}_\beta} \Big[r^{-2} w_\theta^2 - w_r^2 - w^2 \Big] \, r dr \tag{A.17}$$

does not depend on β.

(ii) Therefore

$$\mathcal{J}(\beta_1, \beta_2) := \iint_{\mathcal{X}_{\beta_1,\beta_2}} \Big[r^{-2} w_\theta^2 - w_r^2 - w^2 \Big] \, r dr d\theta \tag{A.18}$$

depends only on $\beta_2 - \beta_1$ and therefore is proportional to it.

Proof. One proves (i) by analyzing $-\iint_{\mathcal{X}_{\beta_1,\beta_2}} Lw \cdot \partial_\theta w \, dxdy$ (which actually was done before, since $w_\theta = -x_2 w_{x_1} + x_1 w_{x_2}$.

To prove (ii) observe that $\partial_\beta \mathcal{J}(\beta_1, \beta) = \mathcal{I}(\beta)$. □

Proposition A.8. *(i) Function*

$$\mathcal{J}(\beta_1, \beta_2) := \int_{\mathcal{X}_{\beta_1,\beta_2}} w^2 r^{-1} \, dr d\theta \tag{A.19}$$

with fixed $\beta_{1,2} = \beta \mp \sigma$ is convex with respect to β (if $\sigma > 0$).

(ii) Further, if w is either symmetric or antisymmetric, then it reaches minimum as $\beta = 0$ (i.e. $\mathcal{X}_{\beta_1,\beta_2}$ is symmetric with respect to Y_0).

Proof. (i) Consider

$$0 = \iint_{\mathcal{X}_{\beta_1,\beta_2}} Lw \cdot w \, r dr d\theta = \iint_{\mathcal{X}_{\beta_1,\beta_2}} (w_r^2 + r^{-2} w_\theta^2 + w^2) \, r dr d\theta + \mathcal{I}'(\beta_1) - \mathcal{I}'(\beta_2) \tag{A.20}$$

with

$$\mathcal{I}'(\beta) = \int_{\mathcal{Y}_\beta} w w_\theta \, r^{-1} dr = \partial_\beta \mathcal{I}(\beta), \qquad \mathcal{I}(\beta) := \int_{\mathcal{Y}_\beta} w^2 \, r^{-1} dr. \tag{A.21}$$

Observe that the first term is positive. Then $\mathcal{I}'(\beta_2) - \mathcal{I}'(\beta_1) > 0$; on the other hand, it is the second derivative of $\mathcal{J}(\beta_1, \beta_2)$ with respect to β.

(ii) Moreover, for both symmetric and antisymmetric w $\mathcal{I}(\beta_2) - \mathcal{I}(\beta_1) = 0$. And the difference $\mathcal{I}(\beta_2) - \mathcal{I}(\beta_1) = 0$ for $\beta = 0$. □

Corollary A.9. *Since w_θ satisfies the same equation and is antisymmetric (symmetric) respectively, the same conclusions (i), (ii) hold for $\mathcal{J} := \int_{\mathcal{X}_{\beta_1,\beta_2}} w_\theta^2 r^{-1} \, r dr d\theta$.*

Then in virtue of Proposition A.7(ii) the same conclusions (i), (ii) hold for $\mathcal{J} := \iint_{\mathcal{X}_{\beta_1,\beta_2}} (w_r^2 + w^2) \, r dr d\theta$.

Next, observe that $Lr\partial_r w = 2\Delta w = -2w$ and if we use the same arguments, as in the proof of Proposition A.8(ii) for $r\partial_r w$, then instead of the first term in (A.20) we get

$$\iint_{\mathcal{X}_{\beta_1,\beta_2}} \big((r w_r)_r^2 + w_{r\theta}^2 + (r w_r)^2 - w^2\big) \, r dr d\theta, \tag{A.22}$$

where an additional last term appears as

$$\iint_{\mathcal{X}_{\beta_1\beta_2}} 2w\partial_r w \cdot r^2 dr d\theta = -\iint_{\mathcal{X}_{\beta_1\beta_2}} w^2 \, r dr d\theta.$$

Consider last two terms and skip integration by $d\theta$; plugging $w = r^{-3/2}u$ with $u(0) = 0$, we arrive to

$$\int \big(u_r - \frac{3}{2} r^{-1} u)^2 - r^{-2}u^2\big) \, dr = \int \big(u_r^2 - 3r^{-1}u_r u + \frac{5}{4} r^{-2}u^2\big) \, dr = \int \big(u_r^2 - \frac{1}{4} r^{-2}u^2\big) \, dr$$

which is again nonnegative term. Then we arrive to

Corollary A.10. *The same conclusions (i) and (ii) of Proposition A.8 hold for $\mathcal{J}(\beta_1, \beta_2)$ with w replaced by rw_r, i.e. $\mathcal{J}(\beta_1, \beta_2) := \iint_{\mathcal{X}_{\beta_1,\beta_2}} w_r^2 \, r dr d\theta$.*

Then in virtue of Proposition A.7(ii) the same conclusions (i), (ii) hold for

$$2\iint_{\mathcal{X}_{\beta_1,\beta_2}} |\partial_r w|^2\, r dr d\theta + \iint_{\mathcal{X}_{\beta_1,\beta_2}} (r^{-2}|\partial_\theta w|^2 - |\partial_r w|^2 - |w|^2|)\, r dr d\theta = \iint_{\mathcal{X}_{\beta_1,\beta_2}} (|\nabla w|^2 - |w|^2)\, dxdy. \tag{A.23}$$

Now we can prove

Proposition A.11. *Let $\alpha \in (\pi, 2\pi]$. Then for both symmetric and antisymmetric w* (A.8) *holds.*

Proof. Indeed, assume that it is not the case: $\iint_X (|\nabla w|^2 - w^2)\, dxdy < 0$ for some w. Then due to Corollary A.10 the same is true for X replaced by $\mathcal{X}_{\beta_1,\beta_2}$ with $\beta_{1,2} = \mp(2\pi - \alpha)/2$ and the same w. Then it is true for the sum of these to expressions (with $X == X_{-\alpha/2,\alpha/2}$ and $\mathcal{X}_{\beta_1,\beta_2}$), which is the sum of the same expressions for the half-planes $X_{\alpha/2-\pi,\alpha/2}$ and $X_{-\alpha/2,\pi-\alpha/2}$. However, for half-planes (A.8) holds. □

Let $P_\tau = \theta(\tau - \Lambda)$.

Proposition A.12. *(i) Let $\alpha \in [\pi, 2\pi]$. Then for any $\tau > 1$ for $w = Jv$, $v \in \mathsf{Ran}(I - P_\tau)$,*

$$\|\nabla w\|^2 \ge (1 + \delta)\|w\|^2 \tag{A.24}$$

with $\delta = \delta(\tau) > 0$.

(ii) Let $\alpha \in (0, \pi]$. Then for any $\tau > 1$ for antisymmetric $w = Jv$, $v \in \mathsf{Ran}(I - P_\tau)$, (A.24) *holds.*

Proof. Observe first that

$$\{v \in \mathsf{Ran}(I - P_\tau)\colon \|v\|_Y = 1,\ :\ \|\nabla Jv\|^2 \le (1+\delta')\|Jv\|^2\} \text{ is a compact set in } \mathscr{L}^2(Y) \text{ for } \delta' = \delta'(\tau) > 0. \tag{A.25}$$

Indeed, in the zone $\{x\colon |x| \ge R\}$ we can apply semiclassical arguments with $h := R^{-1}$ after scaling $x \mapsto R^{-1}x$.

Since in both cases (A.8) holds with a strict inequality for $w \ne 0$), we arrive to both Statements (i) and (ii). □

A.2 Spectrum

The above results are sufficient for our needs, for $\alpha \in (\pi, 2\pi]$. However we would like to explore the case of $\alpha \in (0, \pi)$ and even $\alpha \in (\pi, 2\pi]$ in more depth.

Corollary A.13. *(i) Let $\alpha \in [\pi, 2\pi]$. Then $\mathsf{Spec}(\Lambda) = [1, \infty)$ and it is continuous.*

(ii) Let $\alpha \in (0, \pi]$. Then $\mathsf{Spec}(\Lambda_{\mathsf{asym}}) = [1, \infty)$ and it is continuous, where Λ_{sym} and Λ_{asym} denote the restriction of Λ to the spaces of symmetric and antisymmetric functions, correspondingly.

Proof. We already know that the that essential spectrum of Λ is $[1, \infty)$. We also know that in the case (i) $\Lambda > I$ and in the case (ii) $\Lambda_{\mathsf{asym}} > I$. Therefore 1 is not an eigenvalue. Continuity of the spectrum follows from $(i[\Lambda, Q]v, v) \ge \delta\|v\|^2$ for $v \in \mathsf{Ran}(I - P_\tau)$, v is antisymmetric in the case (ii), which is due to Statements (i) and (ii) of Propostion A.12. □

Remark A.14. Paper [S-KP] is dealing mainly with the eigenvalues of Δ_2 in the planar sector under Robin boundary condition $(\partial_\nu + \gamma)w|_Y = 0$, $\gamma > 0$ [14]. Then eigenvalues τ of Λ and eigenvalues μ of that problem are related through Birman-Schwinger principle and scaling: $\mu_k = -\tau_k^{-2}\gamma^2$. Some of the results:

(i) Theorem 3.1 states that $(-\infty, -\gamma^2)$ contains only discrete spectrum of such operator and it is finite.

(ii) Theorem 2.3 states that for $\alpha \in (0, \pi)$ the bottom eigenvalue $-\gamma^2/\sin^2(\alpha/2)$ is simple and the corresponding eigenfunction is $\exp(-\gamma x_1/\sin(\alpha/2))$.

(iii) Theorem 3.6 states that for $\alpha \in [\frac{\pi}{3}, \pi)$ there is no other eigenvalues in $(0, 1)$, while Theorem 4.1 implies that the number of such eigenvalues is $\asymp \alpha^{-2}$ as $\alpha \to 0$ [15].

Then we conclude that

[14] In that paper α is a half-angle, and ν is a unit external normal. Below we refer to this paper using our notations.

[15] In fact, the compete asymptotic expansion of the eigenvalues is derived in Theorem 4.16 of [S-KP].

Corollary A.15. *(i) Interval* $(0,1)$ *contains only discrete spectrum of* Λ_{sym} *which is finite.*

(ii) For $\alpha \in (0,\pi)$ *the bottom eigenvalues is* $\sin(\alpha/2)$ *and the corresponding eigenfunction is* $\exp(-x_1)$.

The discrete spectrum would not prevent us from the extending our main results to $\alpha \in (0,\pi)$. Even (possible) eigenvalue 1 on the edge of the essential spectrum would not be an obstacle. However eigenvalues embedded into $(1,\infty)$ are an obstacle (see Proposition A.16).

Proposition A.16. *If* $w_p = Jv_p$ *where* v_p *are eigenfunctions of* Λ*, corresponding to eigenvalues* τ_p*, and* $\tau_j = \tau_k$*, then*

$$(\nabla w_j, \nabla w_k) - (w_j, w_k) = 0. \tag{A.26}$$

In particular,

$$\|\nabla w_j,\|^2 - \|w_j\|^2 = 0. \tag{A.27}$$

Proof. It follows from equality (3.2) for $Q = x_1D_1+x_2D_2+i/2$ and $([Q,\Lambda]v_j, v_k) = (\Lambda v_j, Qv_jk) - (Qv_j, \Lambda v_k) = 0$ for eigenfunction v_j v_k provided $\tau_j = \tau_k$. □

To extend the main sharp spectral asymptotics to operators in domains with inner edges one needs to prove the first following

Conjecture A.17. *For any* $\tau > 1$ *and for any* $w = Jv$ *with symmetric* $v \in \mathsf{Ran}(I - P_\tau)$ *estimate* (A.24) *holds.*

Remark A.18. (i) Recall that this is true for $\alpha \in [\pi, 2\pi]$ and, also, for $\alpha \in (0,\pi)$ and antisymmetric v. So, only the case of $\alpha \in (0,\pi)$ and symmetric v needs to be covered.

(ii) So far it is unknown, if in the the case of $\alpha \in (0,\pi)$ Λ_{sym} has eigenvalues embedded into continuous spectrum $(1,\infty)$ or on its edge.

(iii) Also it is unknown in any case, if the continuous spectrum is absolutely continuous (i.e. that the singular continuous spectrum is empty).

Asymptotics of the Ground State Energy in the Relativistic Settings*,†

Victor Ivrii‡

Abstract

The purpose of this paper is to derive sharp asymptotics of the ground state energy for the heavy atoms and molecules in the relativistic settings, and, in particular, to derive relativistic Scott correction term and also Dirac, Schwinger and relativistic correction terms. Also we will prove that Thomas-Fermi density approximates the actual density of the ground state, which opens the way to estimate the excessive negative and positive charges and the ionization energy.

1 Introduction

The purpose of this paper is to derive sharp asymptotics of the ground state energy for heavy atoms and molecules in the relativistic settings, and, in particular, to derive relativistic Scott correction term and also Dirac, Schwinger and relativistic correction terms. The relativistic Scott correction term was first derived in [SSS] which both inspired our paper and provided necessary functional analytic tools; our improvement is achieved due to more refined microlocal semiclassical technique.

Also we will prove that the Thomas-Fermi density approximates the actual density of the ground state, which opens the way to estimate the excessive negative and positive charges and the ionization energy.

*2010 *Mathematics Subject Classification*: 35P20, 81Q10.

†*Key words and phrases*: Relativistic Schrödinger operator, Heavy atoms and Molecules, Thomas-Fermi theory, Scott correction term, Microlocal Analysis, Sharp Spectral Asymptotics.

‡This research was supported in part by National Science and Engineering Research Council (Canada) Discovery Grant RGPIN 13827.

In the next paper [Ivr2] we will introduce a self-generated magnetic field and improve results of [EFS2].

Multielectron Hamiltonian is given by

$$\mathsf{H} = \mathsf{H}_N := \sum_{1\le j\le N} H_{V,x_j} + \sum_{1\le j<k\le N} \frac{\mathsf{e}^2}{|x_j - x_k|} \tag{1.1}$$

on

$$\mathfrak{H} = \bigwedge_{1\le n\le N} \mathscr{H}, \qquad \mathscr{H} = \mathscr{L}^2(\mathbb{R}^3, \mathbb{C}^q) \simeq \mathscr{L}^2(\mathbb{R}^3 \times \{1, \dots, q\}, \mathbb{C}) \tag{1.2}$$

with

$$H_V = T - \mathsf{e}V(x), \tag{1.3}$$

describing N same type particles in the external field with the scalar potential $-V$ and repulsing one another according to the Coulomb law; e is the charge of the electron, T is an *operator of the kinetic energy*.

In the non-relativistic framework this operator is defined as

$$T = \frac{1}{2\mu}(-i\hbar\nabla)^2. \tag{1.4}$$

In the relativistic framework this operator is defined as

$$T = \left(c^2(-i\hbar\nabla)^2 + \mu^2c^4\right)^{\frac{1}{2}} - \mu^2c^4. \tag{1.5}$$

Here

$$V(x) = \sum_{1\le m\le M} \frac{Z_m\mathsf{e}}{|x - \mathsf{y}_m|} \tag{1.6}$$

and

$$d = \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| > 0. \tag{1.7}$$

where $Z_m\mathsf{e} > 0$ and y_m are charges and locations of nuclei.

It is well-known that the non-relativistic operator is always semibounded from below. On the other hand, it is also well-known [Herb, LY] that

Remark 1.1. One particle relativistic operator is semibounded from below if and only if

$$Z_m\beta \le \frac{2}{\pi} \qquad \forall m = 1, \dots, M; \qquad \beta := \frac{\mathsf{e}^2}{\hbar c}. \tag{1.8}$$

We will assume (1.8), sometimes replacing it by a strict inequality:

$$Z_m\beta \le \frac{2}{\pi} - \epsilon \qquad \forall m = 1, \dots, M; \qquad \beta := \frac{\mathsf{e}^2}{\hbar c}. \tag{1.9}$$

We also assume that $d \ge CZ^{-1}$. Then we are interested in $\mathsf{E} := \inf \mathsf{Spec}(\mathsf{H})$.

Remark 1.2. (i) In the non-relativistic theory by scaling with respect to the spatial and energy variables we can make $\hbar = \mathsf{e} = \mu = 1$ while Z_m are preserved.

(ii) In the relativistic theory by scaling with respect to the spatial and energy variables we can make $\hbar = \mathsf{e} = \mu = 1$ while β and Z_m are preserved.

From now on we assume that such rescaling was already made and we are free to use letters $\hbar$, μ and c for other notations.

2 Functional Analytic Arguments

2.1 Estimate from below

In contrast to [SSS] we will start from the more traditional approach. We estimate $\sum_{1\le j<k\le N} \langle |x_j - x_k|^{-1}\Psi, \Psi\rangle$ from below, using Lieb's electrostatic inequality, by $\frac{1}{2}\mathsf{D}(\rho_\Psi, \Psi) - C\int \rho_\Psi^{4/3}\,dx$ where $\langle\cdot,\cdot\rangle$ means the inner product in $\mathfrak{H}$, $\rho_\Psi(x)$ is a one particle density,

$$\mathsf{D}(\rho, \rho') = \iint |x-y|^{-1}\rho(x)\rho'(y)\,dxdy,$$

and we use notations of Chapter 25 of [Ivr1].

The the standard lower estimate (25.2.2) from [Ivr1] holds:

$$\langle \mathsf{H}_N\Psi, \Psi\rangle \ge \sum_{1\le j\le N} \langle H_{V,x_j}\Psi, \Psi\rangle + \frac{1}{2}\mathsf{D}\big(\rho_\Psi, \rho_\Psi\big) - C\int \rho_\Psi^{\frac{4}{3}}(x)\,dx = \tag{2.1}$$

$$\sum_{1\le j\le N} \langle H_{W,x_j}\Psi, \Psi\rangle + \frac{1}{2}\mathsf{D}\big(\rho_\Psi - \rho, \rho_\Psi - \rho\big) - \frac{1}{2}\mathsf{D}\big(\rho, \rho\big) - C\int \rho_\Psi^{\frac{4}{3}}(x)\,dx,$$

where H_W is the one-particle Schrödinger operator (respectively, non-relativistic or relativistic) with the potential

$$W = V - |x|^{-1} * \rho, \tag{2.2}$$

and ρ is an arbitrary chosen real-valued non-negative function. Then again we get

$$\mathsf{E}_N \geq \mathsf{Tr}(H^-_{W+\lambda}) + \lambda N + \frac{1}{2}\mathsf{D}\big(\rho_\Psi - \rho, \rho_\Psi - \rho\big) - \frac{1}{2}\mathsf{D}\big(\rho,\rho\big) - C\int \rho_\Psi^{\frac{4}{3}}(x)\,dx \tag{2.3}$$

with arbitrary λ.

Remark 2.1. As usual, we will need to improve these estimates to recover a remainder estimate better than $O(Z^{\frac{5}{3}})$.

Now we need to prove estimate

$$\int \rho_\Psi^{\frac{4}{3}}(x)\,dx \leq CZ^{\frac{5}{3}} \tag{2.4}$$

for the ground state energy. It follows from

$$\int \rho_\Psi^{\frac{5}{3}}(x)\,dx \leq CZ^{\frac{7}{3}}, \tag{2.5}$$

equality $\int \rho_\Psi\,dx = N$ and assumption $N \lesssim Z$. To prove (2.5) we apply classical arguments of Lieb–Thirring, but replacing the Lieb–Thirring inequality by some relativistic inequalities (see Appendix A). Namely, let $\mathsf{b} := T - KU$ with $U = \rho_\Psi^{\frac{2}{3}}\varphi_< + \beta^{-1}\rho_\Psi^{\frac{1}{3}}\varphi_>$ where $\varphi_{\gtrless}$ is the characteristic function of $\{x\colon \rho_\Psi \gtrless \beta^{-3}\}$.

Consider the multiparticle operator $B = \sum \mathsf{b}_{x_j}$ and its lowest eigenvalue E_0. Obviously,

$$E_0 \leq \langle B\Psi,\Psi\rangle = \sum_j \langle T_{x_j}\Psi,\Psi\rangle - K\int (\rho_\Psi^{\frac{5}{3}}\varphi_< + \beta^{-1}\rho_\Psi^{\frac{4}{3}}\varphi_>)\,dx. \tag{2.6}$$

On the other hand, E_0 does not exceed the sum of negative eigenvalues of b, and due to Daubechies inequality (A.1), the absolute value of this sum does not exceed

$$C_0\int \max(U^{\frac{5}{2}}, \beta^3U^4)\,dx \leq C_0K^{\frac{5}{2}}\int \big(\rho_\Psi^{\frac{5}{3}}\varphi_< + \beta^{-1}\rho_\Psi^{\frac{4}{3}}\varphi_>\big)\,dx. \tag{2.7}$$

Therefore, assuming that $E_0 \leq 0$ we conclude that

$$\sum_j \langle T_{x_j}\Psi,\Psi\rangle - K\int \min(\rho_\Psi^{\frac{5}{3}},\ \beta^{-1}\rho_\Psi^{\frac{4}{3}}) + C_0K^{\frac{5}{2}}\int \big(\rho_\Psi^{\frac{5}{3}}\varphi_< + \beta^{-1}\rho_\Psi^{\frac{4}{3}}\varphi_>\big)\,dx \geq 0$$

and therefore, for small positive constant K, we conclude that

$$\sum_j \langle T_{x_j}\Psi,\Psi\rangle \ge 2\epsilon_0 \int (\rho_\Psi^{\frac53}\varphi_< + \beta^{-1}\rho_\Psi^{\frac43}\varphi_>)\,dx. \tag{2.8}$$

Thus, we proved that for any $\Psi\in\mathfrak{H}$ (2.8) holds. Then

$$\sum_j \langle H_{x_j}\Psi,\Psi\rangle = \sum_j \langle T_{x_j}\Psi,\Psi\rangle - \int V(x)\rho_\Psi(x)\,dx \ge \tag{2.9}$$
$$\int \big(2\epsilon_0\rho_\Psi^{\frac53} - V(x)\rho_\Psi\big)\varphi_<\,dx + \int \big(2\epsilon_0\beta^{-1}\rho_\Psi^{\frac43} - V(x)\rho_\Psi\big)\varphi_>\,dx.$$

We know, that the latter expression must be less than $-c_0Z^{\frac73}$ (it will follow, e. g., from the estimate from above). Observe that for $\ell(x)\ge aZ^{-\frac13}$ we have $V(x)<a^{-1}Z^{\frac43}$ and the integral over this zone of $-V\rho_\Psi$ is greater than $-C_0a^{-1}Z^{\frac43}N$. Here and below $\ell(x) :== \min_j|x-y_j|$. Let us fix a, a large enough constant.

Next,

$$\int_{\{x:\,\ell(x)\le aZ^{-1/3}\}} \big(\epsilon_0\rho_\Psi^{\frac53} - V(x)\rho_\Psi\big)\varphi_<\,dx \ge -C\int_{\{x:\,\ell(x)\le aZ^{-1/3}\}} V^{\frac52}\,dx \ge -C_1Z^{\frac73}$$

and $(\epsilon_0\beta^{-1}\rho_\Psi^{1/3}-V)\varphi_>$ is positive unless $\rho_\psi>\beta^{-3}$ and $V\ge\epsilon_1\beta^{-1}\rho_\Psi^{1/3}\ge\epsilon_1\beta^{-2}$ (and then $\ell(x)\le C_0\beta$).

Therefore, we estimate $\int(\rho_\Psi^{5/3}\varphi_< + \beta^{-1}\rho_\Psi^{4/3}\varphi_<)\,dx$ from above by $CZ^{7/3}$ plus $\int_{\{x:\ell(x)\le C\beta\}} V\rho_\Psi\,dx$, and to obtain (2.4), it is sufficient to estimate this term. Further, it is sufficient to replace V by V_m (since $V=V_m+O(\beta^2)$, provided distances between nuclei are $\ge C\beta$). Also we can replace V_m by $V_m+C\beta^{-2}$.

If $Z_m\beta\le\frac{2}{\pi}-\epsilon$, then we can decompose $H=\eta(H-V^1)+(1-\eta)(H-V^0)$, where $(1-\eta)V^0$ coincides with V in the β-vicinity of y_m and equals 0 outside of the 2β-vicinity of it and $V^1=\eta^{-1}(V-(1-\eta)V^0)$, and apply all above arguments for the operator with $V=V^1$ while simply observing that $H-V^0$ is a positive operator for η sufficiently small. So we have proven that

Proposition 2.2. *Under assumption* (1.9) *for the ground state,*

$$\int \min(\beta^{-1}\rho_\Psi^{\frac43},\rho_\Psi^{\frac53})\,dx \le CZ^{\frac73} \tag{2.10}$$

and (2.4) *holds.*

Then we immediately arrive to Statement (i) below, and Statement (ii) follows from the main theorems of either [Bach] (Theorem 1) or [GS] (Theorem 3):

Corollary 2.3. *Under assumption* (1.9)

(i) The following estimate holds

$$\mathsf{E}_N \ge \mathsf{Tr}(H^-_{W+\lambda}) - \frac{1}{2}\mathsf{D}(\rho,\rho) - C Z^{\frac{5}{3}} + \frac{1}{2}\mathsf{D}(\rho-\rho_\Psi,\, \rho-\rho_\Psi), \tag{2.11}$$

where ρ, λ are arbitrary and $W = V - |x|^{-1} * \rho$.

(ii) Further,

$$\begin{aligned}\mathsf{E}_N \ge \mathsf{Tr}(H^-_{W+\lambda}) - \frac{1}{2}\mathsf{D}(\rho,\rho) - {}& \\ \frac{1}{2}\int |x-y|^{-1}\, \mathsf{tr}\big(e_N^\dagger(x,y)\, e_N(x,y)\big)\, dxdy - C Z^{\frac{5}{3}-\delta} + {}& \\ \frac{1}{2}\mathsf{D}(\rho-\rho_\Psi,\, \rho-\rho_\Psi),&\end{aligned} \tag{2.12}$$

where $e_N(x,y)$ is the Schwartz kernel of the projector to N lower eigestates of H_W and tr *denotes the matrix trace.*

To cover[1)] the critical case[2)] we will use (2.21) from [SSS]

$$\sum_{1\le i<j\le N} |x_i - x_j|^{-1} \ge \sum_{j=1}^{N} (\rho * |x|^{-1} * \Phi_s)(x_j) - \frac{1}{2}\mathsf{D}(\rho,\rho) - CN\varepsilon^{-1}, \tag{2.13}$$

where, again, $\rho \ge 0$ is arbitrary, λ is arbitrary, $\Phi \ge 0$ is spherically symmetric with $\int \Phi\, dx = 1$, $\Phi_\varepsilon(x) = \varepsilon^{-3}\Phi(x/\varepsilon)$. Here the factor $\frac{1}{2}$ is due to the difference in notations and also now

$$W \coloneqq W_\varepsilon = V - |x|^{-1} * \rho * \Phi_\varepsilon \tag{2.14}$$

instead of (2.2) and the term $-CNs^{-1}$ replaces the last term in (2.3):

[1)] Unfortunately, only partially.

[2)] I.e. with the non-strict inequality (1.8) instead of (1.9).

Proposition 2.4. *Under assumption* (1.8)

$$\mathsf{E}_N \ge \mathsf{Tr}(H^-_{W+\lambda}) + \lambda N - \frac{1}{2}\mathsf{D}(\rho,\rho) - CN\varepsilon^{-1}. \tag{2.15}$$

Remark 2.5. (i) Later we set $\varepsilon = Z^{-\frac{2}{3}}$. This would lead to $O(Z^{\frac{5}{3}})$ remainder estimate.

(ii) Proposition 2.4 is weaker than Corollary 2.3 in two ways: there is no improved version of corollary 2.3(ii) and also there is no "bonus term" $\frac{1}{2}\mathsf{D}(\rho-\rho_\Psi,\rho-\rho_\Psi)$ in the right-hand expression.

2.2 Estimate from above

The estimate from above is straight-forward: we simply take Ψ as a Slater determinant of N lower eigenfunctions of H_W. If there are only $N' < N$ negative eigenvalues then we take only N' such eigenvalues, because $\mathsf{E}_N \le \mathsf{E}_{N'}$. Then we arrive to

Proposition 2.6.

$$\begin{aligned}\mathsf{E}_N \le \mathsf{Tr}(H^-_{W+\lambda}) - \frac{1}{2}\mathsf{D}(\rho,\rho)+ \\ |\lambda-\nu|\cdot|\mathsf{N}^-_{W+\nu}-N| + \mathsf{D}(\mathsf{tr}\, e_N(x,x)-\rho,\ \mathsf{tr}\, e_N(x,x,\nu)-\rho)- \\ \frac{1}{2}\int |x-y|^{-1}\,\mathsf{tr}\big(e_N^\dagger(x,y)e_N(x,y)\big)\,dxdy\end{aligned} \tag{2.16}$$

with an arbitrary ρ and any $\nu \le 0$, $W = V - |x|^{-1} * \rho$.

3 Semiclassical Methods

We will need the following semiclassical expressions:

$$P'(w) = (2\pi)^{-3} q \int_{\{\xi: b(\xi)\le w\}} d\xi, \tag{3.1}$$

and its integral

$$P(w) = (2\pi)^{-3} q \int_{\{\xi: b(\xi)\le w\}} b(\xi)\, d\xi, \tag{3.2}$$

where in the non-relativistic case $b(\xi) = \frac{\hbar^2}{2\mu}|\xi|^2$ and, correspondingly for $\mu = \hbar = 1$

$$P^{\mathsf{TF}\prime}(w) = \frac{q}{6\pi^2} w_+^{\frac{3}{2}}, \tag{3.3}$$

$$P^{\mathsf{TF}}(w) = \frac{q}{15\pi^2} w_+^{\frac{5}{2}}, \tag{3.4}$$

while in the relativistic case $b(\xi) = (c^2\hbar^2|\xi|^2 + \mu^2 c^4)^{\frac{1}{2}} - \mu c^2$ and, correspondingly for $\mu = \hbar = 1$

$$P^{\mathsf{RTF}\prime}(w) = \frac{q}{6\pi^2} w_+^{\frac{3}{2}}(1 + \beta^2 w_+)^{\frac{3}{2}}. \tag{3.5}$$

Note that $P^{\mathsf{RTF}}(w)$ is an elementary function as well, and a sadistic Calculus instructor can give it on the test. However it turns out that we really do not need any separate relativistic Thomas-Fermi theory.

After scalings we have a *semiclassical zone* $\mathcal{X}_{\mathsf{scl}} := \{x\colon \ell(x) \geq cZ^{-1}\}$, where the effective semiclassical parameter is $h = 1/\zeta\ell$. Then, from the semiclassical point of view, on the energy levels ≤ 0, the relativistic operator has the same properties as the non-relativistic one.

There is also a *singular zone* $\mathcal{X}_{\mathsf{sing}} := \{x\colon \ell(x) \leq cZ^{-1}\}$ and it covers the *relativistic zone* $\mathcal{X}_{\mathsf{rel}} := \{x\colon \ell(x) \leq c\beta\}$. The important properties are that

$$0 \leq V(x) - W(x) \leq C\zeta^2 := \min(Z^{\frac{4}{3}}, Z\ell^{-1}), \tag{3.6}$$

$$|\partial^\gamma (W - V)| \leq C\zeta^2 \ell(x)^{-|\gamma|} \qquad \forall \gamma : |\gamma| \leq 2. \tag{3.7}$$

3.1 Trace Term

Now the rescaling methods of [Ivr1] allow us to prove the following:

Proposition 3.1. *Let condition* (1.8) *be fulfilled and let* W *satisfy* (3.6) *and* (3.7).

(i) Let $\psi_0(x)$ *be* ℓ*-admissible function*[3)]*, being equal* 1 *in* $\{x\colon \ell(x) \geq 2a\}$ *and supported in* $\{x\colon \ell(x) \geq a\}$. *Then for* $W = W^{\mathsf{TF}}$

$$|\operatorname{Tr}(H^-_{W+\lambda}\psi_0) - \int P^{\mathsf{RTF}}(W+\lambda)\psi_0(x)\,dx| \leq \tag{3.8}$$

$$C\begin{cases} Z^{\frac{3}{2}} a^{-\frac{1}{2}} & a \leq Z^{-\frac{1}{3}}, \\ Z^{\frac{5}{3}}(aZ^{\frac{1}{3}})^{-\delta} & a \geq Z^{-\frac{1}{3}}. \end{cases}$$

[3)] I.e. $\partial^\alpha \psi_0| \leq C_\alpha \ell^{-\alpha}$.

(ii) Let $\psi_m(x)$ be ℓ-admissible, equal 1 in $\{x\colon |x-\mathsf{y}_m|\le a\}$ and supported in $\{x\colon |x-\mathsf{y}_m|\le 2a\}$. Then for $W=V_m=Z_m|x-\mathsf{y}_m|^{-1}$

$$|\int \bigl(\mathsf{tr}(e^1(x,x,0))-P^{\mathsf{RTF}}(V_m)\bigr)(1-\psi_m(x))\,dx|\le Z^{\frac{3}{2}}d^{-\frac{1}{2}}, \tag{3.9}$$

where $e^1(.,.,\tau)=\int_{-\infty}^{\tau} e(.,.,\tau')\,d\tau'$.

Proof. Indeed, the contribution of the ℓ-element of the partition[4)] to the remainder is $O(\zeta^3\ell)$, exactly as in the non-relativistic case. Summation by partition elements results in the right-hand expression. □

Next, we need to consider vicinities of the singularities. Then the methods of Chapter 25 of [Ivr1] allow us to prove the following:

Proposition 3.2. *In the framework of Proposition 3.1 let ϕ_m be equal 1 in $\{x\colon |x-\mathsf{y}_m|\le Z_m^{-1}\}$ and supported in $\{x\colon |x-\mathsf{y}_m|\le 2Z_m^{-1}\}$. Let $|\lambda|\le C_0Zd^{-1}$. Then*

$$\begin{aligned}|\,\mathsf{Tr}(H^-_{W+\lambda}\psi_m(1-\phi_m))-\mathsf{Tr}(H^-_{V_m}\psi_m(1-\phi_m))+\\ \int \bigl(P^{\mathsf{RTF}}(W+\lambda)-P^{\mathsf{RTF}}(V_m)\bigr)\psi_m(x)(1-\phi_m(x))\,dx|\le\\ C\begin{cases} Z^{\frac{3}{2}}d^{-\frac{1}{2}} & d\le Z^{-\frac{1}{3}},\\ Z^{\frac{5}{3}} & d\ge Z^{-\frac{1}{3}},\end{cases}\end{aligned} \tag{3.10}$$

where $d\ge cZ^{-1}$ is the minimal distance between nuclei.

Proof. Indeed, exactly as in the non-relativistic case, using methods of Sections 12.6 and 25.4 of [Ivr1] we estimate the contribution of an ℓ-element to the remainder by $O(\zeta\ell^3\bar\zeta^2\bar\ell^{-2})$ provided $Z^{-1+\delta}\lesssim\ell\lesssim d$, and by $O(\zeta^2\ell^2\bar\zeta^2)$ provided $Z^{-1}\lesssim\ell\lesssim Z^{-1+\delta}$. Here $\bar\ell=d$ and $\bar\zeta=Z^{\frac{1}{2}}d^{-\frac{1}{2}}$. This proves the required remainder estimate. For $d\le Z^{-1+\delta}$ we use a rescaling.

Summation by partition elements results in the right-hand expression.□

Remark 3.3. We need to include the cut-off $(1-\phi_m(x))$ because not only integrals of $P^{\mathsf{RTF}}(W+\lambda)$ and $P^{\mathsf{RTF}}(V_m)$ (of magnitude $\beta^3Z^4\ell^{-4}$) and $P^{\mathsf{RTF}\prime}(W+\lambda)$ are diverging at y_m, but even integral of their difference is logarithmically diverging.

[4)] I.e. ℓ-admissible function $\psi(x)$, supported in $\frac{1}{2}\ell(y)$ for some y; then $\ell(x)\asymp\ell(y)$ on $\mathsf{supp}(\psi)$.

Now we need to consider CZ^{-1} vicinities of y_m and we will use the following Proposition:

Proposition 3.4. *In the framework of Proposition 3.1*

(i) $H_W \ge -C_0Z^2$.

(ii) Further,

$$e(x,x,\lambda) \le CZ^{1-\delta}\ell(x)^{\delta-2} \qquad \text{for } |\lambda| \le c_0Z^2. \tag{3.11}$$

Proof. (a) Assume first that $Z \asymp \beta^{-1}$ (i. e. $Z \ge \epsilon_0\beta^{-1}$); then Statement (i) follows immediately from Lieb-Yau inequality (Theorem A.2): in the operator sense $H \ge \beta^{-1}\sqrt{\Delta} - \beta^{-2} - Z_m r^{-1} \ge -\beta^{-2}$, $r = |x - \mathsf{y}_m|$.

Then $e(x,x,\lambda) \le C\ell(x)^{-3}h^{-3}$ with the semiclassical parameter h, which is $\asymp 1$ for $\ell \lesssim Z^{-1}$, $\lambda \lesssim Z^2$. Therefore,

$$e(x,x,\lambda) \le C\ell(x)^{-3} \qquad \text{for } \lambda \le C_0Z^2,\ \ell(x) \lesssim Z^{-1}. \tag{3.12}$$

Unfortunately this estimate falls short for our needs. Let us shift $\mathsf{y}_m \mapsto 0$, and scale $x \mapsto Zx$, $\tau \mapsto Z^{-2}\tau$. Then we arrive to an operator which modulo $O(1)$ is $\sqrt{\Delta} - Zr^{-1}$. Due to

$$\sqrt{\Delta} - \frac{2}{\pi|x|} \ge A_s(\Delta)^s - B_s \tag{3.13}$$

for any $s \in [0,1/2)$ and $A_s, B_s > 0$ we can "trade" (due to Sobolev embedding theorem) $\ell^{-1+\delta}$ by 1 in the scaled inequality (3.12) and by $Z^{1-\delta}$ in the original one, thus arriving to (3.11).

(b) Let us consider $Z \le \epsilon_0\beta^{-1}$. Observe that in the operator sense

$$H \ge (\frac{1}{4}\beta^{-2}r^{-2} + \beta^{-4})^{1/2} - Zr^{-1} - C\beta^{-2} \ge CZ^{-2};$$

the latter inequality is proven separately for $r \lesssim \beta$ and for $r \gtrsim \beta$.

Moreover, we get $H \ge \epsilon_1 \min(r^{-2}, \beta^{-1}r^{-1})$ for $r \le \epsilon_1 Z^{-1}$ and then we can trade ℓ^{-3} to CZ^3 arriving even to the stronger version of (3.12): namely,

$$e(x,x,\lambda) \le CZ^3. \tag{3.14}$$

Actually estimate (3.14) holds as $Z_m\beta \le 2\pi^{-1} - \sigma$ for $\sigma > 0$ with $C = C(\sigma)$ which could be calculated explicitly. □

Then we immediately conclude that

Corollary 3.5. *In the framework of Proposition 3.1 for* $|\lambda| \le C_0 Z d^{-1}$

$$|\operatorname{Tr}(H^-_{W+\lambda}\phi_m) - \operatorname{Tr}(H^-_{V_m}\phi_m)| \le CZd^{-1}. \tag{3.15}$$

Now we can assemble all these results. However, before doing this we replace P^{RTF} by P^{TF}:

Proposition 3.6. *(i) Estimates* (3.8), (3.9) *and* (3.10) *hold with* P^{RTF} *replaced by* P^{TF}.

(ii) Estimate (3.10) *with* P^{RTF} *replaced by* P^{TF} *also holds with* $\phi_m = 0$.

Proof. Statement (i) follows immediately from

$$P^{\mathsf{RTF}}(w) - P^{\mathsf{TF}}(w) \asymp \beta^2 w^{\frac{7}{2}}, \qquad P^{\mathsf{RTF}\prime}(w) - P^{\mathsf{TF}\prime}(w) \asymp \beta^2 w^{\frac{5}{2}} \quad \text{for } \beta^2 w \lesssim 1 \tag{3.16}$$

due to (3.5). Statement (ii) follows immediately from $P^{\mathsf{TF}}(w) \asymp w^{\frac{5}{2}}$, $P^{\mathsf{TF}\prime}(w) \asymp w^{\frac{3}{2}}$. □

Remark 3.7. Meanwhile,

$$\int \bigl(P^{\mathsf{RTF}}(V+\lambda) - P^{\mathsf{TF}}(V+\lambda)\bigr)\psi(x)\,dx \asymp \beta^2 Z^4, \tag{3.17}$$

which could be as large as Z^2.

Due to the scaling properties of $e(x,x,0)$ for $H = H_V$ and $P^{\mathsf{TF}}(V)$ for $V = V_m$ we conclude that

$$\int \bigl(\operatorname{tr}(e^1(x,x,0)) - P^{\mathsf{RTF}}(V_m)\bigr)\,dx = qZ_m^2 S(Z_m\beta) \tag{3.18}$$

with an unknown function $S(Z_m\beta)$. Indeed, if $\mathsf{y}_m = 0$ then $x \mapsto x/k$ transforms the operator with parameters Z_m, β into the operator with parameters $Z_m k$, βk^{-1}, multiplied by k^{-2}.

Remark 3.8. Obviously, $S(Z_m\beta)$ monotonely decreases as $\beta \to 0+$ and tends to $S(0) = \frac{1}{2}$ for the Schrödinger operator.

Then due to (3.9) for $V = V_m$

$$|\int \bigl(\mathsf{tr}(e^1(x,x,0)) - P^{\mathsf{TF}}(V_m)\bigr)\psi_m(x)\,dx - qZ_m^2 S(Z_m\beta)| \le Z^{\frac{3}{2}} d^{-\frac{1}{2}} \tag{3.19}$$

and we arrive to

Proposition 3.9. *Let* (1.8) *be fulfilled. Then for* $W = W^{\mathsf{TF}}$

$$|\,\mathsf{Tr}(H^-_{W+\lambda}) + \int P^{\mathsf{TF}}(W+\lambda)\,dx - \sum_{1\le m\le M} qZ_m^2 S(Z_m\beta)| \le C\begin{cases} Z^{\frac{3}{2}} d^{-\frac{1}{2}} & d \le Z^{-\frac{1}{3}},\\ Z^{\frac{5}{3}} & d \ge Z^{-\frac{1}{3}}.\end{cases} \tag{3.20}$$

3.2 Trace tTerm. II

Let improve the above results for $d \gg Z^{-\frac{1}{3}}$. Observe first that the in this case the error in (3.8) can be made $O(Z^{\frac{5}{3}}(dZ^{\frac{1}{3}})^{-\delta} + Z^{\frac{5}{3}-\delta})$ provided we include the relativistic Schwinger correction term. Since this term has magnitude $Z^{\frac{5}{3}}$ and the contributions of the zones $\{x\colon \ell(x) \le Z^{-\frac{1}{3}-\delta_1}\}$ and $\{x\colon \ell(x) \ge Z^{-\frac{1}{3}+\delta_1}\}$ in this term are $O(Z^{\frac{5}{3}-\delta})$, the difference between the relativistic and the standard non-relativistic Schwinger terms is $O(Z^{\frac{5}{3}-\delta})$, and we can use the latter

$$\mathsf{Schwinger} = \bigl(\frac{q}{6\pi^2}\bigr)^{\frac{2}{3}} \int \rho^{\mathsf{TF}\,\frac{4}{3}}\,dx. \tag{3.21}$$

Next, consider the relativistic correction term

$$\int \Bigl(-P^{\mathsf{RTF}}(W+\lambda) + P^{\mathsf{RTF}}(V_m) + P^{\mathsf{TF}}(W+\lambda) - P^{\mathsf{TF}}(V_m)\Bigr)\psi_m(1-\phi_m)\,dx. \tag{3.22}$$

Again, one can see easily that we need to consider only the contribution of the *threshold zone* $\mathcal{Y} \coloneqq \{x\colon Z^{-\frac{1}{3}-\delta_1} \le \ell(x) \le Z^{-\frac{1}{3}+\delta_1}\}$ because the contributions of both zones $\{x\colon \ell(x) \le Z^{-\frac{1}{3}-\delta_1}\}$ and $\{x\colon \ell(x) \ge Z^{-\frac{1}{3}+\delta_1}\}$ in this term are $O(Z^{\frac{5}{3}-\delta})$.

One can see easily that in the threshold zone due to (3.5)

$$P^{\mathsf{RTF}}(w) - P^{\mathsf{TF}}(w) = \frac{q}{14\pi^2}\beta^2 w_+^{\frac{7}{2}} + O(Z^{\frac{8}{3}-\delta})$$

(for both $w = W^{\mathsf{TF}} + \lambda$ and $w = V_m$), and therefore modulo the same error expression (3.22) coincides with

$$\mathsf{RCT} \coloneqq \frac{q}{14\pi^2}\beta^2 \int \bigl(-(W^{\mathsf{TF}} + \lambda)_+^{\frac{7}{2}} + V^{\frac{7}{2}}\bigr)\, dx \tag{3.23}$$

with the integral taken over this zone or $\mathbb{R}^3$ (it does not matter). Then we arrive to

Proposition 3.10. *Let* (1.8) *be fulfilled and* $d \ge Z^{-\frac{1}{3}}$. *Then for* $W = W^{\mathsf{TF}}$

$$\begin{aligned} |\operatorname{Tr}(H^-_{W+\lambda}) + \int P^{\mathsf{TF}}(W+\lambda)\, dx - \sum_{1\le m\le M} qZ_m^2 S(Z_m\beta) - \\ \mathsf{Schwinger} - \mathsf{RCT}| \le C\bigl(Z^{\frac{5}{3}}(dZ^{\frac{1}{3}})^{-\delta} + Z^{\frac{5}{3}-\delta}\bigr). \end{aligned} \tag{3.24}$$

3.3 Trace Term. III

Obviously, all these results hold for $W = W_\varepsilon$ defined by (2.14) with $\rho = \rho^{\mathsf{TF}}$. However we need to estimate an error when we replace W_ε by W^{TF}. One can prove easily that

$$|W_\varepsilon - W^{\mathsf{TF}}| \le C_s(Z\ell^{-1})^{\frac{3}{2}}\varepsilon^2(\varepsilon\ell - 1)^s \tag{3.25}$$

with arbitrary s for $\ell \le \epsilon_0 Z^{-\frac{1}{3}}$ and with $s = \frac{1}{2}$ for $\ell \le \epsilon_0 Z^{-\frac{1}{3}}$, and therefore,

$$|\int \bigl(P^{\mathsf{TF}}(W_\varepsilon + \lambda) - P^{\mathsf{TF}}(W^{\mathsf{TF}} + \lambda)|\, dx| \le CZ^3\varepsilon^2; \tag{3.26}$$

adding error $CZ\varepsilon^{-1}$ in (2.15) we get $C(Z^3\varepsilon^2 + Z\varepsilon^{-1})$. It reaches minimum $CZ^{\frac{5}{3}}$ as $\varepsilon \asymp Z^{-\frac{2}{3}}$ and we arrive to

Proposition 3.11. *Let* (1.8) *be fulfilled. Then for* $W = W_\varepsilon$ *with* $\varepsilon = Z^{-\frac{2}{3}}$, (3.20) *holds and the left-hand expression of* (3.26) *is* $O(Z^{\frac{5}{3}})$.

3.4 N- and D-Terms

For these terms (needed for the estimate from above) arguments are simpler; let $\phi_0 = 1 - \phi_1 - \ldots - \phi_M$.

Proposition 3.12. *In the framework of Proposition 3.1*

(i) The following estimates hold

$$|\int \big(e(x,x,\lambda) - P^{\mathsf{RTF}\,\prime}(W+\lambda)\big)\phi_0(x)\,dx| \le CZ^{\frac{2}{3}} \tag{3.27}$$

and for $d \ge Z^{-\frac{1}{3}}$

$$|\int \big(e(x,x,\lambda) - P^{\mathsf{RTF}\,\prime}(W+\lambda)\big)\phi_0(x)\,dx| \le C\big(Z^{\frac{2}{3}}(dZ^{\frac{1}{3}})^{-\delta} + Z^{\frac{2}{3}-\delta}\big). \tag{3.28}$$

(ii) Further,

$$|\int e(x,x,\lambda)\phi_m(x)\,dx| \le C. \tag{3.29}$$

(iii) Finally,

$$|\int \big(P^{\mathsf{RTF}\,\prime}(W+\lambda) - P^{\mathsf{TF}\,\prime}(W+\lambda)\big)\phi_0(x)\,dx| \le CZ^{\frac{1}{3}}. \tag{3.30}$$

Proposition 3.13. *In the framework of Proposition 3.1*

(i) The following estimates hold

$$\mathsf{D}\big((e(x,x,\lambda) - P^{\mathsf{RTF}\,\prime}(W+\lambda))\phi_0,\ (e(x,x,\lambda) - P^{\mathsf{RTF}\,\prime}(W+\lambda))\phi_0\big) \le CZ^{\frac{5}{3}} \tag{3.31}$$

and for $d \ge Z^{-\frac{1}{3}}$

$$\mathsf{D}\big((e(x,x,\lambda) - P^{\mathsf{RTF}\,\prime}(W+\lambda))\phi_0,\ (e(x,x,\lambda) - P^{\mathsf{RTF}\,\prime}(W+\lambda))\phi_0\big) \le CZ^{\frac{5}{3}}(dZ^{\frac{1}{3}})^{-\delta} + CZ^{\frac{5}{3}-\delta}. \tag{3.32}$$

(ii) Further,

$$\mathsf{D}\big(e(x,x,\lambda)\phi_m(x),\ e(x,x,\lambda)\phi_m(x)\big) \le CZ. \tag{3.33}$$

(iii) Finally,

$$\mathsf{D}\big((P^{\mathsf{RTF}\,\prime}(W+\lambda) - P^{\mathsf{TF}\,\prime}(W+\lambda))\phi_0,\ (P^{\mathsf{RTF}\,\prime}(W+\lambda) - P^{\mathsf{TF}\,\prime}(W+\lambda))\phi_0\big) \le CZ. \tag{3.34}$$

Proof of Propositions 3.12 and 3.13. Proof is straightforward:

Statements (i) are proven by the semiclassical scaling technique exactly as in [Ivr1], Chapter 25.

Statements (ii) follow from Proposition 3.4. Statements (iii) follow from (3.5) and properties of W^{TF}. □

3.5 Dirac Term

Finally, consider the term $-\frac{1}{2}\iint \mathsf{tr}\big(e_N^{\dagger}(x,y)e_N(x,y)\big)\,dxdy$. The main contribution to it is delivered by the zone $\mathcal{Y}\times\mathcal{Y}$ where $\mathcal{Y}$ is the threshold zone, and in this zone the non-magnetic approximation delivers the correct expression

$$\mathsf{Dirac} = -\big(\frac{6}{\pi q}\big)^{\frac{1}{3}} q^{\frac{2}{3}} \int \rho^{\mathsf{TF}\,\frac{4}{3}}\,dx, \tag{3.35}$$

with an error $Z^{\frac{5}{3}-\delta}$.

4 Main Theorems

Now repeating arguments of Section 25.4 of [Ivr1] we arrive to our main results:

Theorem 4.1 [5]**.** *Let assumption* (1.8) *be fulfilled. Then*

(i) The following asymptotics holds

$$\mathsf{E}_N = \mathcal{E}_N^{\mathsf{TF}} + \mathsf{Scott} + O\big(Z^{\frac{5}{3}} + Z^{\frac{3}{2}}d^{-\frac{1}{2}}\big). \tag{4.1}$$

Recall that $\mathsf{Scott} = q\sum Z_m^2 S(Z_m\beta)$ *and* d *is the minimal distance between nuclei.*

(ii) Furthermore, let assumption (1.9) *be fulfilled. Then for* $d \ge Z^{-\frac{1}{3}}$

$$\mathsf{E}_N = \mathcal{E}_N^{\mathsf{TF}} + \mathsf{Scott} + \mathsf{Dirac} + \mathsf{Swinger} + \mathsf{RCT} + O\big(Z^{\frac{5}{3}}(dZ^{\frac{1}{3}})^{-\delta} + Z^{\frac{5}{3}-\delta}\big). \tag{4.2}$$

[5] Cf. Theorems 25.4.8 and 25.4.13 of [Ivr1].

Remark 4.2. (i) For the improved upper estimate in (4.2) we do not need assumption (1.9).

(ii) These theorems allow us to consider the free nuclei model and recover Theorem 25.4.14 of [Ivr1], albeit without assumption (1.9) we get only $\delta = 0$.

(iii) We also recover the estimate

$$|\lambda_N - \nu| \le C \begin{cases} Z^{\frac{8}{9}} & (Z-N)_+ \le Z^{\frac{2}{3}}, \\ (Z-N)_+^{\frac{1}{3}} & (Z-N)_+ \ge Z^{\frac{2}{3}}, \end{cases} \tag{4.3}$$

where ν is a chemical potential and λ_N is the N-th lowest eigenvalue of $H_{W^{\mathsf{TF}}}$ (reset to 0 if there are less than N negative eigenvalues). Furthermore, for $d \ge Z^{-\frac{1}{3}}$ one can include the factor $((dZ^{\frac{1}{3}})^{-\delta} + Z^{-\delta})$ into the right-hand expression.

Theorem 4.3 [6)]**.** *Let assumption* (1.9) *be fulfilled. Then*

(i) The following estimate holds:

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) \le CZ^{\frac{5}{3}}. \tag{4.4}$$

(ii) Furthermore, for $d \ge Z^{-\frac{1}{3}}$

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) \le C(Z^{\frac{5}{3}}(dZ^{\frac{1}{3}})^{-\delta} + Z^{\frac{5}{3}-\delta}). \tag{4.5}$$

Remark 4.4. (i) Estimates (4.4) and (4.5) allow us to consider the excessive negative charge and ionization energy and, repeating arguments of Section 25.5 of [Ivr1], to recover Theorems 25.5.3 and 25.5.4.

(ii) Further, these estimates allow us to consider the excessive positive charge in the free nuclei model and, repeating arguments of Section 25.6 of [Ivr1], to recover Theorems 25.6.1 and 25.6.3.

Remark 4.5. We can even make a poor man version of (4.2) in the critical case, when only assumption (1.8) is fulfilled.

[6)] Cf. Theorem 25.4.15 of [Ivr1].

(i) Consider how our terms depend on q. In the atomic case consider given Z, N and shift to $\mathsf{y}_1 = 0$. Then

$$\rho_q^{\mathsf{TF}}(x) = q^2\rho_1^{\mathsf{TF}}(q^{\frac{2}{3}}x), \qquad W_q^{\mathsf{TF}}(x) = q^{\frac{2}{3}}W_1^{\mathsf{TF}}(q^{\frac{2}{3}}x) \tag{4.6}$$

and $\mathcal{E}^{\mathsf{TF}} \asymp q^{\frac{2}{3}}Z^{\frac{7}{3}}$, $\mathsf{Scott} \asymp qZ^2$, $\mathsf{Dirac} \asymp q^{\frac{1}{3}}Z^{\frac{5}{3}}$, $\mathsf{Schwinger} \asymp q^{\frac{4}{3}}Z^{\frac{5}{3}}$ while $\mathsf{RCT} \asymp q^{\frac{4}{3}}\beta^2Z^{\frac{11}{3}}$.

(ii) Repeating the corresponding arguments in [SSS], one can prove that in the correlation inequality (2.13), the constant is $C(q) \le C_0q^{\frac{2}{3}}$. On the other hand, we use the estimate for $|W - W_\varepsilon| \asymp q\varepsilon^2Z^{\frac{3}{2}}\ell^{-\frac{3}{2}}$ and then the approximation error is $C_0Z^3q^2\varepsilon^2$. Optimizing $Z^3q^2\varepsilon^2 + Zq^{\frac{2}{3}}\varepsilon^{-1}$ by ε we get $Cq^{\frac{10}{9}}Z^{\frac{5}{3}}$ and for a large constant q it is less than $q^{\frac{4}{3}}$. In the "real life" $q = 2$.

A Some Inequalities

We follow [SSS] with some modifications:

The following two inequalities we recall are crucial in many of our estimates. They serve as replacements for the Lieb-Thirring inequality [LT] used in the non-relativistic case.

Theorem A.1 (Daubechies inequality). *(i) One-body case:*

$$\mathsf{Tr}\big[(\beta^{-2}\Delta + \beta^{-4})^{\frac{1}{2}} - \beta^{-2} - V(\mathsf{x})\big]^- \ge -C\int \Big(V_+^{(n+2)/2} + \beta^n V_+^{n+1}\Big)\,dx. \tag{A.1}$$

where $n \ge 3$ is a dimension.

(ii) Many-body case: Let $\Psi \in \bigwedge_{j=1}^N \mathscr{L}^2(\mathbb{R}^3;\mathbb{C}^q)$ and let ρ_Ψ be its one-particle density. Then for $n = 3$

$$\langle \sum_{j=1}^N \big[(\beta^{-2}\Delta_j + \beta^{-4})^{\frac{1}{2}} - \beta^{-2}\big]\Psi, \Psi\rangle \ge \int \min\big(\rho_\Psi^{\frac{5}{3}}, \beta^{-1}\rho_\Psi^{\frac{4}{3}}\big)\,dx. \tag{A.2}$$

This theorem also holds in the non-relativistic limit $\beta = 0$ and operator $(\beta^{-2}\Delta + \beta^{-4})^{\frac{1}{2}} - \beta^{-2}$ replaced by $\frac{1}{2}\Delta$.

Theorem A.2 (Lieb-Yau inequality). *Let $n = 3$. Let $C > 0$ and $R > 0$ and let*

$$H_{C,R} = \Delta^{\frac{1}{2}} - \frac{2}{\pi|x|} - C/R. \tag{A.3}$$

Then, for any density matrix γ and any function θ with support in $B_R = \{x \,|\, |x| \leq R\}$

$$\mathrm{Tr}\big[\bar{\theta}\gamma\theta H_{C,R}\big] \geq -4.4827\, C^4 R^{-1}\{3/(4\pi R^3) \int |\theta(x)|^2\, dx\}. \tag{A.4}$$

Note that when $\theta = 1$ on B_R then the term inside the brackets $\{\}$ equals 1.

Theorem A.3 (Critical Hydrogen inequality). *Let $n = 3$. For any $s \in [0, 1/2)$ there exists constants $A_s, B_s > 0$ such that*

$$\Delta^{\frac{1}{2}} - \frac{2}{\pi|x|} \geq A_s \Delta^s - B_s. \tag{A.5}$$

Theorem A.4 (Hardy-Littlewood-Sobolev inequality). *There exists a constant C such that*

$$D(f) := \iint |x-y|^{-1} f(x) f^\dagger(y)\, dxdy \leq C\, \|f\|^2_{\mathcal{L}^{6/5}}. \tag{A.6}$$

Asymptotics of the Ground State Energy in the Relativistic Settings and with Self-Generated Magnetic Field[*,†]

Victor Ivrii[‡]

Abstract

The purpose of this paper is to derive sharp asymptotics of the ground state energy for the heavy atoms and molecules in the relativistic settings, with the self-generated magnetic field, and, in particular, to derive relativistic Scott correction term and also Dirac, Schwinger and relativistic correction terms. Also we will prove that Thomas-Fermi density approximates the actual density of the ground state, which opens the way to estimate the excessive negative and positive charges and the ionization energy.

1 Introduction

Multielectron Hamiltonian is defined by

$$\mathsf{H} = \mathsf{H}_N := \sum_{1\le j\le N} H_{V,x_j} + \sum_{1\le j<k\le N} \frac{\mathsf{e}^2}{|x_j - x_k|} \tag{1.1}$$

on

$$\mathfrak{H} = \bigwedge_{1\le n\le N} \mathscr{H}, \qquad \mathscr{H} = \mathscr{L}^2(\mathbb{R}^3, \mathbb{C}^q) \simeq \mathscr{L}^2(\mathbb{R}^3 \times \{1, \dots, q\}, \mathbb{C}) \tag{1.2}$$

---

with

$$H_V = T - \mathsf{e}V(x), \tag{1.3}$$

describing N same type particles in the external field with the scalar potential $-V$ and repulsing one another according to the Coulomb law; e is a charge of the electron, T is an *operator of the kinetic energy*. Unless specifically mentioned, $q = 2$.

In the non-relativistic framework this operator is defined as

$$T = \frac{1}{2\mu}(-i\hbar\nabla - \mathsf{e}A)^2, \tag{1.4}_1$$

$$T = \frac{1}{2\mu}\big((i\nabla - \mathsf{e}A)\cdot\boldsymbol{\sigma}\big)^2 \tag{1.4}_2$$

in the magnetic (Schrödinger) and (Schrödinger-Pauli) settings respectively.

In the relativistic framework this operator is defined as

$$T = \Big(c^2(-i\hbar\nabla - \mathsf{e}A)^2 + \mu^2c^4\Big)^{\frac{1}{2}} - \mu^2c^4 \tag{1.5}_1$$

$$T = \Big(c^2\big((-i\hbar\nabla - \mathsf{e}A)\cdot\boldsymbol{\sigma}\big)^2 + \mu^2c^4\Big)^{\frac{1}{2}} - \mu^2c^4 \tag{1.5}_2$$

in the magnetic (Schrödinger) and (Schrödinger-Pauli) settings respectively.

Recall that in non-magnetic settings we have (1.4) and (1.5) of [Ivr2] in the non-relativistic and relativistic settings respectively. Here

$$V(x) = \sum_{1\le m\le M} \frac{Z_m\mathsf{e}}{|x - \mathsf{y}_m|} \tag{1.6}$$

and

$$d = \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| > 0. \tag{1.7}$$

where $Z_m\mathsf{e} > 0$ and y_m are charges and locations of nuclei.

It is well-known that the non-relativistic operator is always semibounded from below. On the other hand, it is also well-known [Herb, LY] that one particle relativistic non-magnetic operator is semibounded from below if and only if $Z_m\beta \le \frac{2}{\pi}$ for $m = 1, \dots, M$. In this paper we assume a strict condition:

$$Z_m\beta \le \frac{2}{\pi} - \epsilon \qquad \forall m = 1, \dots, M; \qquad \beta := \frac{\mathsf{e}^2}{\hbar c}. \tag{1.8}$$

In the non-magnetic case we were interested in $\mathsf{E} := \inf \mathsf{Spec}(\mathsf{H})$. In the magnetic case we consider only a self-generated magnetic field, that is we consider

$$\mathsf{E}^* = \inf_{A \in \mathscr{H}^1_0} \mathsf{E}(A), \tag{1.9}$$

where

$$\mathsf{E}(A) = \inf \mathsf{Spec}(\mathsf{H}_{A,V}) + \underbrace{\frac{\mathsf{e}^2}{\alpha\hbar^2} \int |\nabla \times A|^2 \, dx}, \tag{1.10}$$

$$\alpha Z_m \le \kappa^* (2\pi^{-1} - \beta Z_m)^{\frac{3}{2}} \qquad m = 1, \dots, M. \tag{1.11}$$

with a unspecified constant $\kappa^* > 0$. We also assume that $d \ge CZ^{-1}$.

Remark 1.1. (i) In the non-relativistic theory by scaling with respect to the spatial and energy variables we can make $\hbar = \mathsf{e} = \mu = 1$ while α and Z_m are preserved.

(ii) In the relativistic theory by scaling with respect to the spatial and energy variables we can make $\hbar = \mathsf{e} = \mu = 1$ while β, α and Z_m are preserved.

(iii) In the one particle case there are additional scalings with respect to the spatial and energy variables, preserving only $Z_m\alpha$ and $Z_m\beta$ (but not the Z_m, α, β).

From now on we assume that such rescaling was done and we are free to use letters $\hbar$, μ and c for other notations.

The sharp results in the non-relativistic frameworks, without magnetic field and with self-generated magnetic filed were obtained in Chapters 25 and 27 of [Ivr] respectively, and in the relativistic frameworks without magnetic field—in [Ivr2]. The transition from the non-relativistic framework to the relativistic one required mainly modifications of the function-analytic arguments in the *singular zone* $\bigcup_m \{x\colon |x - \mathsf{y}_m| \le cZ_m^{-1}\}$, and it was done in many articles, listed in the references, which we heavily use. On the other hand, transition from the non-magnetic case to the case of the self-generated magnetic field requires microlocal semiclassical arguments of Chapter 27 of [Ivr] in the *semiclassical zone* $\bigcap_m \{x\colon |x - \mathsf{y}_m| \ge cZ_m^{-1}\}$, which we also heavily rely upon. However relativistic settings require modifications of these arguments, and we are providing most of details when such modifications are needed, and are rather sketchy when no modifications are required.

2 Local Semiclassical Trace Asymptotics

2.1 Set-up

This section matches to Section 27.2 of [Ivr]. We consider potential W supported in $B(\mathsf{x}, r)$ (with $r = \ell(\mathsf{x})$ the half-distance to the nearest nucleus), and scale it to $B(0,1)$ with $W \asymp 1$.

Recall that the original non-relativistic operator is

$$\frac{1}{2}((D-A)\cdot\boldsymbol{\sigma})^2 - W, \tag{2.1}$$

which after rescaling $x \mapsto (x-\mathsf{x})/r$, $\tau \mapsto \tau/(Zr^{-1})$ becomes

$$\frac{1}{2}((hD-A')\cdot\boldsymbol{\sigma})^2 - W, \qquad h = Z^{-1/2}r^{-1/2}, \qquad A' = Z^{-1/2}r^{1/2}A, \tag{2.2}$$

while the "penalty" becomes

$$\frac{r}{\alpha}\int |\nabla\times A'|^2\,dx = \frac{1}{\kappa h^2}\int |\nabla\times A'|^2\,dx \tag{2.3}$$

with $\kappa = Z\alpha$ and we assume that $\kappa \le \kappa^*$.

What happens with our relativistic operator? The same scaling transforms $\bigl(\beta^{-2}((D-A)\cdot\boldsymbol{\sigma})^2 + \beta^{-4}\bigr)^{1/2} - \beta^{-2}$ into

$$rZ^{-1}\bigl(\beta^{-2}((r^{-1}D-A)\cdot\boldsymbol{\sigma})^2 + \beta^{-4}\bigr)^{1/2} - rZ^{-1}\beta^{-2} = \bigl(\gamma^{-2}((hD-A')\cdot\boldsymbol{\sigma})^2 + \gamma^{-4}\bigr)^{1/2} - \gamma^{-2} \tag{2.4}$$

with $\gamma = \beta h^{-1} \le 1$.

Exactly like in Subsubsection 27.2.1 of [Ivr] we need to start with the functional-analytic arguments.

2.2 Functional Analytic Arguments

Estimates

Proposition 2.1 [1]. *Let $V \in \mathscr{L}^{\frac{5}{2}} \cap \mathscr{L}^4$. Then*

$$\mathsf{E}^* \ge -Ch^{-3} \tag{2.5}$$

[1] Cf. Proposition 27.2.1 of [Ivr].

and either

$$\frac{1}{\kappa h^2}\int |\partial A|^2\,dx \le Ch^{-3} \tag{2.6}$$

or $\mathsf{E}(A) \ge ch^{-3}$.

Proof. Using Theorem A.1 (magnetic Daubechies inequality rather than magnetic Lieb-Thirring inequality) with $\gamma := \gamma h$, $V := h^{-2}V$, $A := h^{-1}A$ and with multiplication of the result by h^2, we have

$$\begin{aligned}\mathsf{Tr}(H^-_{A,V}) \ge \\ -Ch^{-3}\int \Big(V_+^{5/2} + \gamma^3 V_+^4\Big)\,dx - Ch^{-2}\Big(|\partial A|^2\,dx\Big)^{\frac14}\Big(V_+^4\,dx\Big)^{\frac34}\end{aligned} \tag{2.7}$$

(cf. (27.2.9) of [Ivr]; only the term $\gamma^3 V_+^4$ adds up); then (27.2.10) holds, which completes the proof. □

Proposition 2.2 [2]**.** *Let* $V_+ \in \mathscr{L}^{\frac52} \cap \mathscr{L}^4$, $\kappa \le ch^{-1}$ *and*

$$V \le -C^{-1}(1+|x|)^{\delta} + C. \tag{2.8}$$

Then there exists a minimizer A.

Proof. Let us consider a minimizing sequence A_j. Without any loss of the generality one can assume that $A_j \to A_\infty$ weakly in $\mathscr{H}^1$ and in $\mathscr{L}^6$ and then strongly in $\mathscr{L}^p_{\mathsf{loc}}$ with any $p < 6$ [3]. Then A_∞ is a minimizer.

Really, due to (2.6) and (2.8) negative spectra of $H_{A_j,V}$ are discrete and the number of negative eigenvalues is bounded by $N = N(h)$. Consider ordered eigenvalues $\lambda_{j,k}$ of $H_{A_j,V}$. Without any loss of the generality one can assume that $\lambda_{j,k}$ have limits $\lambda_{\infty,k} \le 0$ (we go to the subsequence if needed).

We claim that $\lambda_{\infty,k}$ are also eigenvalues and if $\lambda_{\infty,k} = ... = \lambda_{\infty,k+r-1}$ then it is eigenvalue of at least multiplicity r.

Indeed, let $u_{j,k}$ be corresponding eigenfunctions, orthonormal in $\mathscr{L}^2$. Then in virtue of A_j being bounded in $\mathscr{L}^6$ and $V \in \mathscr{L}^4$ we can estimate

$$\||D|^{1/2}u_{j,k}\| \le K\|u_{j,k}\|_6^{1-\delta}\cdot\|u_{j,k}\|^{\sigma} \le K\||D|^{1/2}u_{j,k}\|^{1-\delta}\cdot\|u_{j,k}\|^{\delta}$$

[2] Cf. Proposition 27.2.2 of [Ivr].

[3] Otherwise we select a converging subsequence.

with $\delta > 0$ which implies $\||D|^{1/2} u_{j,k}\| \le K$. Also assumption (2.8) implies that $\|(1+|x|)^{\delta/2} u_{j,k}\|$ are bounded and therefore without any loss of the generality one can assume that $u_{j,k}$ converge strongly.

Then

$$\lim_{j\to\infty} \mathsf{Tr}(H^-_{A_j,V}) \ge \mathsf{Tr}(H^-_{A_\infty,V}), \tag{2.9}$$

$$\liminf_{j\to\infty} \int |\partial A_j|^2 \, dx \ge \int |\partial A_\infty|^2 \, dx \tag{2.10}$$

and therefore $\mathsf{E}(A_\infty) \le \mathsf{E}^*$. Then A_∞ is a minimizer and there are equalities in (2.9)–(2.10) and, in particular, there no negative eigenvalues of $H_{A_\infty,V}$ other than $\lambda_{\infty,k}$. □

Properties of a Minimizer

Next, we need to study the minimizer[4)].

Proposition 2.3 [5)]**.** *Let A be a minimizer. Then*

$$\begin{aligned}\frac{2}{\kappa h^2}\Delta A_j(x) = \Phi_j \coloneqq \\ -\mathsf{Re}\,\mathsf{tr}\Big[\int_0^\infty \sigma_j((hD-A)_x\cdot\boldsymbol{\sigma})e^{-\lambda S}e(.,.,0)e^{-\lambda S}\,d\lambda\Big]\Big|_{x=y} \\ -\mathsf{Re}\,\mathsf{tr}\Big[\int_0^\infty \sigma_j e^{-\lambda S}e(.,.,0)e^{-\lambda S\,t}((hD-A)_y\cdot\boldsymbol{\sigma})\,d\lambda\Big]\Big|_{x=y}.\end{aligned} \tag{2.11}$$

where $A=(A_1,A_2,A_3)$, $\boldsymbol{\sigma}=(\sigma_1,\sigma_2,\sigma_3)$ and $e(x,y,\tau)$ is the Schwartz kernel of the spectral projector $\theta(-H)$ of $H=H_{A,V}$ and tr is a matrix trace;

$$S=\gamma^2(T+\gamma^{-2}) = \big((\gamma^2(hD-A)\cdot\boldsymbol{\sigma})^2+1\big)^{\frac12} \tag{2.12}$$

Proof. Consider variation δA of A and variation of $\mathsf{Tr}(H^-)$ where $H^- = H\theta(-H)$ is a negative part of H. Then, like in the proof of Proposition 27.2.4,

$$\delta\,\mathsf{Tr}(H^-) = \mathsf{Tr}\big((\delta H)\theta(-H)\big). \tag{2.13}$$

[4)] We do not know if it is unique, exactly like in the non-relativistic case; see Remark 27.2.3 of [Ivr].

[5)] Cf. Proposition 27.2.4 of [Ivr]. Observe that (2.11) is more complicated than (27.2.14) of [Ivr].

But we need to find $\delta H = \gamma^{-2}\delta S$, which is a bit more tricky than in the non-relativistic case. Observe that

$$\delta(S^2) = S(\delta S) + (\delta S)S; \tag{2.14}$$

then

$$\delta S = \int_0^\infty e^{-\lambda S}\delta(S^2)e^{-\lambda S}\, d\lambda \tag{2.15}$$

while

$$\gamma^{-2}S^2 = ((hD - A)\cdot\boldsymbol{\sigma})^2 + \gamma^{-2} \tag{2.16}$$

and therefore

$$\delta(\gamma^{-2}S^2) = -\sum_j \Big(\delta A_j\sigma_j((hD - A)\cdot\boldsymbol{\sigma}) - ((hD - A)\cdot\boldsymbol{\sigma})\delta A_j\sigma_j\Big), \tag{2.17}$$

exactly like in non-relativistic case.

Therefore $\mathsf{Tr}(\delta S\theta(-H))$ is equal to the sum of $\int_0^\infty d\lambda$ of

$$\begin{aligned}
&-\mathsf{Tr}\Big(e^{-\lambda S}\delta A_j\sigma_j((hD - A)\cdot\boldsymbol{\sigma})e^{-\lambda S}\theta(-H)\Big)\\
&-\mathsf{Tr}\Big(e^{-\lambda S}((hD - A)\cdot\boldsymbol{\sigma})\delta A_j\sigma_j e^{-\lambda S}\theta(-H)\Big) =\\
&-\mathsf{Tr}\Big(\delta A_j\sigma_j((hD - A)\cdot\boldsymbol{\sigma})e^{-tS}\theta(-H)e^{-\lambda S}\Big)\\
&-\mathsf{Tr}\Big(\delta A_j\sigma_j e^{-\lambda S}\theta(-H)e^{-\lambda S}((hD - A)\cdot\boldsymbol{\sigma})\Big).
\end{aligned}$$

Then $\mathsf{Tr}(\delta L\theta(-H)) = \int \sum_j \Phi_j(x)\delta A_j$, which implies equality (2.11). □

Proposition 2.4 [6]**.** *If for* $\kappa = \kappa^*$

$$\mathsf{E}^* \ge \mathsf{Weyl}_1 - CM \tag{2.18}$$

(2.19)

with $M \ge Ch^{-1}$*, then for* $\kappa \le \kappa^*(1 - \epsilon_0)$

$$\frac{1}{\kappa h^2}\int |\partial A|^2\, dx \le C_1 M. \tag{2.20}$$

[6] Cf. Proposition 27.2.5 of [Ivr].

Proof. Proof is obvious, also based on the upper estimate $\mathsf{E}^* \le \mathsf{E}(0) \le \mathsf{Weyl}_1 + Ch^{-1}$, which is due to [Ivr2]. □

Proposition 2.5 [7]**.** *Let estimate* (2.20) *be fulfilled and let*

$$\varsigma = \kappa M h \le c. \tag{2.21}$$

Then for $\tau \le c$

(i) Operator norm in $\mathscr{L}^2$ *of* $(hD)^k \theta(\tau - H)$ *does not exceed* C *for* $k = 0, 1$.

(ii) Operator norm in $\mathscr{L}^2$ *of* $(hD)^k \big((hD - A)\cdot\boldsymbol{\sigma}\big)\theta(\tau - H)$ *does not exceed* C *for* $k = 0$.

Proof. First, let us repeat of some arguments of the proof of Proposition 27.2.6 of [Ivr]. Let $u = \theta(\tau - H)f$. Then $\|u\| \le \|f\|$ and since

$$\|A\|_{\mathscr{L}^6} \le C\|\partial A\| \le C(\kappa M)^{\frac12} h, \tag{2.22}$$

we conclude that

$$\begin{aligned}\|hDu\| \le \|(hD - A)u\| + \|Au\| \le \|(hD - A)u\| + C\|A\|_{\mathscr{L}^6}\cdot\|u\|_{\mathscr{L}^3} \le \\ \|(hD - A)u\| + C(\kappa M)^{\frac12} h\|u\|^{1/2}\cdot\|u\|_{\mathscr{L}^6}^{1/2} \le \\ \|(hD - A)u\| + C(\kappa M h)^{\frac12}\|u\|^{1/2}\cdot\|hDu\|^{1/2} \le \\ \|(hD - A)u\| + \frac{1}{2}\|hDu\| + C\kappa M h\|u\|;\end{aligned}$$

therefore due to (2.21)

$$\|hDu\| \le 2\|(hD - A)u\| + C\kappa M h\|u\|. \tag{2.23}$$

Further, $\|Tu\| \le c_1\|u\|$ because $H \ge -c$, $|V| \le c$, $|\tau| \le c$; then $\|(T + \gamma^{-2})u \le (c_1 + \gamma^{-2})\|u\|$ and therefore

$$(((T + \gamma^{-2})^2 - \gamma^{-4})u, u) \le ((c_1 + \gamma^{-2})^2 - \gamma^{-4}) = (2c_1\gamma^{-2} + c_1^2)\|u\|^2,$$

and finally

$$(Lu, u) \le C\|u\|^2 \tag{2.24}$$

[7] Cf. Proposition 27.2.6 of [Ivr].

with

$$L := ((hD - A)\cdot\boldsymbol{\sigma})^2. \tag{2.25}$$

Then, again following the same proof, we conclude that

$$\|(hD - A)u\| \le C\|u\| \quad \text{and} \quad \|hDu\| \le C(1+\kappa Mh)\|u\|, \tag{2.26}$$

provided $\kappa M h^{1+\delta} \le c$ for sufficiently small $\delta > 0$. Therefore under assumption (2.21) for $j = 0, 1$ both Statements (i) and (ii) are proven. □

Thus, in contrast to Proposition 27.2.6 of [Ivr], we do not have $k = 2$ in Statement (i), and $k = 1$ in Statement (ii) so far and need some extra arguments.

Proposition 2.6. *Assume that* $\|V\|_{\mathscr{C}^2} \le c$. *Then*

$$\|[S, V]u\| \le Ch\gamma^2(\|L^{\frac12}u\| + \|u\|). \tag{2.27}$$

Proof. Recall that that $S^2 = \gamma^2 L + 1$. Therefore $\gamma^2[L, V] = [S, V]S + S[S, V]$ and then

$$[S, V] = \gamma^2 \int_0^\infty e^{-\lambda S}[L, V]e^{-\lambda S}\, d\lambda. \tag{2.28}$$

Also

$$\|[L, V]w\| \le Ch(\|L^{1/2}w\| + \|w\|) \tag{2.29}$$

and

$$\|e^{-\lambda S}\| \le e^{-\lambda}. \tag{2.30}$$

Proposition 2.7. *(i) Assume that* $\|V\|_{\mathscr{C}^2} \le c$ *and* $|\tau| \le c$. *Then the operator norm of* $(hD)^k\theta(\tau - H)$ *does not exceed* C *for* $k = 0, 1, 2$.

(ii) Assume that $\|V\|_{\mathscr{C}^3} \le c$ *and* $|\tau| \le c$. *Then the operator norm of operators* $(hD)^k((hD - A)_x\cdot\boldsymbol{\sigma})\theta(\tau - H)$ *and* $(hD)^k\hat{\Phi}_j\theta(\tau - H)$ *with*

$$\hat{\Phi}_j = \int_0^\infty \sigma_j((hD - A)_x\cdot\boldsymbol{\sigma})e^{-\lambda S}e(.,.,0)e^{-\lambda S}\, d\lambda \tag{2.31}$$

do not exceed C *for* $k = 0, 1, 2$.

Proof. (i) Let $u = \theta(\tau - H)f$ with $f \in \mathscr{L}^2$. Then u satisfies (2.2) and $\|Tu\| \le C\|u\|$. Also, which implies

$$\gamma^{-2}\|Lu\| = \|(T + 2\gamma^{-2})Tu\| \le C\gamma^{-2}\|u\| + C\gamma^{-1}\|[T, V]u\| \le C_1\gamma^{-2}\|u\|$$

due to (2.27) . Then, repeating arguments of the proof of Propositiob 27.2.6 of [Ivr], we conclude that $\|(hD)^2 u\| \le C\|u\|$, i.e. Statement (i).

(ii) Plugging $(T - V - \tau)u$ instead of u (with $\|(T - V - \tau)u\| \le C\|u\|$) we have $\|L(T - \tau - V)u\| \le C\|u\|$. Then

$$\|TLu\| \le C\|Lu\| + C\|[L, V]u\| \le C(\|Lu\| + \|u\|) \le C_1\|u\|.$$

Again plugging $(T - V - \tau)u$ instead of u we have

$$\gamma^{-2}\|L^2 u\| = \|(T + 2\gamma^{-2})TLu\| \le \\ \|T(T - V - \tau)Lu\| \le C\gamma^{-2}\|Lu\| + C\|T[L, V]u\|.$$

Further, the last term does not exceed $Ch\|TV'L^{\frac12}u\| + Ch^2\|TV''u\|$ where V' are miscellaneous first derivatives of V and $V'' = \Delta V$. Then, the former does not exceed $C\|Lu\|$, while the latter does not exceed $C\gamma^{-2}\|u\| + h\|\nabla(V''u)\|$, which does not exceed $C\gamma^{-2}\|u\|$.

Therefore $\|L^2 u\| \le C\|u\|$, which implies that $\|L((hD - A)\cdot\sigma)u\| \le C\|u\|$, which in turn implies that $\|(hD)^2((hD - A)\cdot\sigma)u\| \le C\|u\|$ and, finally, $\|(hD)^2\hat{\Phi}_j u\| \le C\|u\|$. □

Corollary 2.8. *(i) Assume that $\|V\|_{\mathscr{C}^2} \le c$ and $|\tau| \le c$. Then the operator norm of $\theta(\tau - H)$ from $\mathscr{L}^2$ to $\mathscr{C}^\delta$ does not exceed $Ch^{-3/2-\delta}$ for $0 \le \delta \le \frac12$.*

(ii) Assume that $\|V\|_{\mathscr{C}^3} \le c$ and $|\tau| \le c$. Then the operator norm of $\hat{\Phi}_j$ from $\mathscr{L}^2$ to $\mathscr{C}^\delta$ do not exceed $Ch^{-3/2-\delta}$ for $0 \le \delta \le \frac12$. Then $\|\Phi_j\|_{\mathscr{C}} \le Ch^{-3}$.

Corollary 2.9. *Under assumptions* (2.18)–(2.21) $\|A_j\|_{\mathscr{C}^{2-\delta}} \le C\kappa h^{-1}$ *for any $\delta > 0$.*

2.3 Microlocal Analysis and Local Theory

Microlocal Analysis Unleashed

Then we can apply all arguments of Subsection 27.2.2[8)] of [Ivr], even if expression for Φ_j differs. Indeed, observe first that we can restrict ourselves by $0 \le \lambda \le c|\log h|$. Then, using our standard arguments based on the analysis of the propagation of singularities, we can prove that the Tauberian expression with $T = h^{1-\delta}$ for Φ_j has an error $O(h^{-2})$ provided

$$V(x) \asymp 1. \tag{2.32}$$

Then our standard trick with the freezing coefficients works and with the same $O(h^{-2})$ error we can replace $\Phi_j(x)$ by its Weyl expression, i.e. expression we obtain if replace operators by their symbols, depending on x and ξ, integrating by $d\xi$ and multiplying by $(2\pi h)^{-3}$. However due to skew-symmetry with respect to $\xi - A(x)$, this Weyl expression is 0, and $\Phi_j(x) = O(h^{-2})$.

Finally, we can get rid of assumption (2.32) by the standard rescaling arguments. We leave all the details to the reader.

Local Theory and Rescaling

Then we can apply all arguments of Subsection 27.2.3 [9)] of [Ivr]. As a result we arrive under assumption (2.21) to the trace formula[10)] with the remainder estimate $O(h^{-1})$ and to estimate $\|\partial A\| = O(\kappa^{1/2}h^{1/2})$.

Moreover, under the standard assumption of the global nature we arrive to the trace formula with the remainder estimate $o(h^{-1})$ (but it will have the Schwinger-type correction term) and to estimate $\|\partial A\| = o(\kappa^{1/2}h^{1/2})$.

Finally, we an apply all arguments of Subsection 27.2.4 [11)] of [Ivr] and we weaken assumption (2.21), recovering the same estimates as before. Again, we leave all the details to the reader.

3 Global Trace Asymptotics in the Case of Coulomb-Like Singularities

3.1 Estimates to a Minimizer

Let us return to the original settings, with Coulomb-like singularities and parameters Z_m, α, β. At the moment we consider the one-particle Hamiltonian. Let us deal first with the vicinity of y_m.

Then we scale like in Section 27.3 of [Ivr]: $x \mapsto Z^{\frac{1}{3}}x$, $\tau \mapsto Z^{-\frac{4}{3}}\tau$, $A \mapsto Z^{-\frac{2}{3}}A$, $\beta \mapsto \beta Z^{\frac{3}{3}}$, arriving to the semiclassical problem with Coulomb singularities $z_m|x-\mathsf{y}_m|^{-1}$ ($z_m = Z_m Z^{-1}$), with $h = Z^{-\frac{1}{3}}$ and with $\kappa = \alpha Z^{\frac{2}{3}}$. In particular, E^* is a minimum with respect to A of

$$\mathsf{E}(A) \coloneqq \mathsf{Tr}(H^-_{A,W+\tau}) + \kappa^{-1}h^{-2}\|\partial A\|^2. \tag{3.1}$$

Let us follow arguments of Subsubsection *27.3.2.1 Preliminary Analysis*. Observe first that the estimate from above is

$$\mathsf{E}^* \le h^{-3}\int \mathsf{Weyl}_1(x)\,dx + Ch^{-2}; \tag{3.2}$$

we simply take $A = 0$ and refer to [Ivr2][12)].

Consider now estimate from below and apply ℓ-admissible partition exactly like in Subsection 27.3.2 of [Ivr]. Then, according to the previous section, for any element of partition with $\ell \ge ch^{-2}$ ($\ell \ge cZ_m^{-1}$ in the original settings) its contribution is estimated from below by the corresponding Weyl expression minus $Ch^{-1}\zeta^2 \times \zeta\ell = Ch^{-1}\zeta^3\ell^{-1}$ and summation with respect to these elements returns $\mathcal{E}^{\mathsf{TF}}$ minus $Ch^{-1}\zeta^3\ell|_{\ell=h^{-2}}$, i.e.

$$h^{-3}\int \mathsf{Weyl}_1(x)\,dx - Ch^{-2} \tag{3.3}$$

because the contribution of the zone $\mathcal{Z}_0 = \{x\colon \ell(x) \le ch^{-2}\}$ to the main term is $O(h^{-2})$.

On the other hand, the contribution of $\mathcal{Z}_0$ is $-Ch^{-2}$. Indeed, scale first $x \mapsto h^{-2}x$, $\tau \mapsto h^2\tau$, $h \mapsto 1$, $A \mapsto hA$, $\beta \mapsto \gamma = \beta h^{-1}$, and the Coulomb

[12)] In the original settings the remainder estimate would be $O(Z^2)$ exactly as in the non-relativistic case.

singularity remains the same while the magnetic energy becomes $\kappa^{-1}\|\partial A\|^2$. Observe that $\gamma = \beta_{\mathsf{orig}} Z_m$ [13], so (1.8), (1.11) become

$$\beta \le 2\pi^{-1} - \epsilon, \qquad \kappa \le \kappa^*\big(2\pi^{-1} - \beta\big). \tag{3.4}$$

Then we can apply a "singular magnetic Daubechies inequality" (A.3) and repeat all arguments of the regular case in a simple case of $h = 1$. There will be an extra terms $O(1)$ and $-C(1-\pi\gamma/2)^{-\frac{3}{2}}\|\partial A\|^2$ and that latter term requires (1.11).

Now we conclude that Proposition 27.3.1 of [Ivr] holds:

Proposition 3.1 [14]**.** *In our framework $\kappa \le \kappa^*$. Then the near-minimizer A satisfies*

$$\Big|\int \big(\operatorname{tr} e_{A,1}(x,x,0) - \mathsf{Weyl}_1(x)\big)\,dx\Big| \le Ch^{-2} \tag{3.5}$$

and

$$\|\partial A\| \le C\kappa^{\frac{1}{2}}. \tag{3.6}$$

It allows us to repeat arguments of the proof Proposition 2.2 and to prove

Proposition 3.2 [15]**.** *In our framework there exists a minimizer A* [4]*.*

Now we can repeat arguments of Subsubsection *27.3.2.2 Estimates to a Minimizer. I* of [Ivr], albeit with the right-hand expression of (27.3.14) given now by (2.11) and to prove the claim (27.3.28), which is marginally stronger than

$$\|\partial^2 A\|_{\mathscr{L}^\infty(B(0,1-\epsilon))} \le C\kappa^{\frac{1}{2}} h^{-\delta}. \tag{3.7}$$

Then we can repeat arguments of Subsubsection *27.3.2.3 Estimates to a Minimizer. II* of [Ivr] and recover Propositions 27.3.4, 27.3.6 and 27.3.7, estimating A and its derivatives as $\ell(x) \lesssim 1$:

---

[13] Considering vicinity of y_m it is more convenient to take the original rescaling with Z replaced by Z_m, and therefore $z_m = 1$.

[14] Cf. Proposition 27.3.1 of [Ivr].

[15] Cf. Proposition 27.3.2 of [Ivr].

Proposition 3.3 [16]**.** *In our framework if* $\ell(x) \ge \ell_* := h^2$*, then*

$$|A| \le C\kappa\ell^{-\frac{1}{2}}, \qquad |\partial A| \le C\kappa\ell^{-\frac{3}{2}} \tag{3.8}$$

and

$$|\partial A(x) - \partial A(y)| \le C_\theta \kappa \ell^{-\frac{3}{2}-\theta}|x-y|^\theta \qquad \text{as } \ |x-y| \le \frac{1}{2}\ell(x) \tag{3.9}$$

for any $\theta \in (0,1)$.

Consider now the non-semiclassical zone $\{x\colon \ell(x) \lesssim \ell_*\}$, which contains the relativistic zone $\{x\colon \ell(x) \lesssim \bar{\ell} := \gamma h\}$. Using arguments of the proof of Proposition 3.4 of [Ivr2], but additionally taking care of the magnetic field using arguments of the proofs of Propositions 2.5, 2.6 and 2.7 (we leave all details to the reader), we arrive to

Proposition 3.4. *In our framework* $H_{W,A} \ge C_0\ell_*^{-1}$ *and* $e(x,x,\lambda) \le C\ell_*^{-3}$ *for* $\ell(x) \le c\ell_*$ *and* $|\lambda| \le Ch^{-2}$.

Remark 3.5. (i) Then in the original settings $H_{W,A} \ge C_0 Z^{-2}$ and $e(x,x,\lambda) \le CZ^3$ for $\ell(x) \le cZ^{-1}$ and $|\lambda| \le C_0 Z^2$.

(ii) We have a better estimate than (3.11) of [Ivr2] due to assumptions (1.8) and (1.11).

Next, we follow arguments of Subsubsection *27.3.2.4 Estimates to a Minimizer. III* of [Ivr] and prove (again, leaving details to the reader)

Proposition 3.6 [17]**.** *In our framework*

$$|A| \le C\kappa\ell^{-2}, \qquad |\partial A| \le C\kappa\ell^{-3} \tag{3.10}$$

and

$$|\partial A(x) - \partial A(y)| \le C_\theta \kappa \ell^{-3-\theta}|x-y|^\theta \qquad \text{as } \ |x-y| \le \frac{1}{2}\ell(x) \tag{3.11}$$

if $\ell(x) \ge 1$ *(for all* $\theta \in (0,1)$*).*

[16] Cf. Proposition 27.3.7(i) of [Ivr].
[17] Cf. Proposition 27.3.9 of [Ivr].

3.2 Trace Estimates

Next we can go after trace asymptotics. Recall that we are dealing with the rescaled operator. Let a be the minimal distance between nuclei (after rescaling), capped by 1; recall that $a \ge \ell_*$.

After we estimated A for $\ell(x) \lesssim 1$ in Proposition 3.1 and $e(x,x,\lambda)$ for $\ell(x) \lesssim \ell_* = h^{-2}$, we can apply arguments of Subsection 27.3.3 of [Ivr] and arrive to

Proposition 3.7 [18]**.** *In our framework let ψ be a-admissible and supported in $\frac{1}{2}a$-vicinity of y_m, let φ be ℓ_*-admissible, supported in $2\ell_*$-vicinity and equal 1 in ℓ_*-vicinity of y_m, and let $V^0 = Z_m|x|^{-1}$. Then*

$$\mathsf{Tr}\big(\psi(H^-_{A,V} - H^-_{A,V^0})\psi\big) = \int \big(\mathsf{Weyl}_1(x) - \mathsf{Weyl}^0_1(x)\big)(1-\varphi(x))\,dx + O\big(a^{-\frac{1}{3}}h^{-\frac{4}{3}}\big). \tag{3.12}$$

Remark 3.8. Here and in Proposition 3.9 Weyl and Weyl_1 are defined for the relativistic operator (i.e. $\mathsf{Weyl} = P^{\mathsf{RTF}\prime}(V)$ and $\mathsf{Weyl} = -P^{\mathsf{RTF}}(V)$), but following arguments of 3.6 of [Ivr2], we can replace it by those for non-relativistic operator (i.e. $\mathsf{Weyl} = P^{\mathsf{TF}\prime}(V)$ and $\mathsf{Weyl} = -P^{\mathsf{TF}}(V)$) and then skip the factor $(1-\varphi(x))$.

Moreover, applying arguments of Subsection 27.3.4 of [Ivr] we arrive to

Proposition 3.9 [19]**.** *(i) In the framework of Proposition 3.7*

$$\mathsf{Tr}\big(\psi(H^-_{A,V} - H^-_{A,V^0})\psi\big) = \int \big(\mathsf{Weyl}_1(x) - \mathsf{Weyl}^0_1(x)\big)\,\psi^2(x)(1-\varphi(x))\,dx + O\big(h^{-\frac{4}{3}}a^{-\frac{1}{3}}\kappa|\log\kappa|^{\frac{1}{3}} + h^{-1}a^{-\frac{1}{2}}\big). \tag{3.13}$$

(ii) In particular, if

$$\kappa \le ca^{-\frac{1}{6}}h^{\frac{1}{3}}|\log ah^{-2}|^{-\frac{1}{3}}, \tag{3.14}$$

then the error in (3.13) *does not exceed $Ch^{-1}a^{-\frac{1}{2}}$ exactly as in the case without magnetic field.*

---

[18] Cf. Proposition 27.3.11 of [Ivr].

[19] Cf. Proposition 27.3.16 of [Ivr].

Next consider the case of exactly Coulomb potential $V = Z|x|^{-1}$ and $\nu = 0$. Then

Proposition 3.10 [20]**.** *Let $V = Z|x|^{-1}$, $h > 0$, $Z > 0$, and* (1.8) *and* (1.11) *be fulfilled. Then*

(i) The following limit exists [21]

$$\lim_{r\to\infty}\Biggl(\inf_{A}\Bigl(\mathsf{Tr}\bigl((\phi_r H_{A,V}\phi_r)^-\bigr)+\frac{1}{\kappa h^2}\int |\partial A|^2\,dx\Bigr) - \int \mathsf{Weyl}_1(x)\phi_r^2(x)\,dx\Biggr) =: 2Z^2h^{-2}S(Z\kappa, Z\beta). \tag{3.15}$$

(ii) And it coincides with (27.3.72) *and also with* (27.3.73) *of [Ivr].*

(iii) We also can replace in Statement (i) $\mathsf{Tr}\bigl((\phi_r H_{A,V}\phi_r)^-\bigr)$ *by* $\mathsf{Tr}\bigl(\phi_r H^-_{A,V}\phi_r\bigr)$.

Here $\phi \in \mathscr{C}_0^\infty(B(0,1))$, $\phi = 1$ in $B(0,\frac12)$, $\phi_r = \phi(x/r)$ and Weyl *and* Weyl_1 *are defined for non-relativistic operator.*

Then we also arrive to

Proposition 3.11 [22]**.** *In the framework of Proposition 3.10 for $0 < \kappa < \kappa'$, $\beta < \beta'$*

$$S(\kappa',\beta) \le S(\kappa,\beta) \le S(\kappa',\beta) + C\kappa'(\kappa^{-1}-\kappa'^{-1}), \tag{3.16}$$

$$S(\kappa,\beta) \le S(\kappa',\beta'). \tag{3.17}$$

Then, in the "atomic" case $M = 1$ we arrive instantly to the following theorem:

Theorem 3.12 [23]**.** *Let $M = 1$ and* (1.8) *and* (1.11) *be fulfilled. Then*

(i) The following asymptotics holds

$$\mathsf{E}^* = \int \mathsf{Weyl}_1(x)\,dx + 2z^2S(z\kappa, z\beta)h^{-2} + O(h^{-\frac43}\kappa|\log\kappa|^{\frac13} + h^{-1}). \tag{3.18}$$

[20] Cf. Proposition 27.3.18 of [Ivr].
[21] Cf. (27.3.71) of [Ivr] and (3.18) of [Ivr2].
[22] Cf. Proposition 27.3.20 of [Ivr] and Remark 3.8 of [Ivr2].
[23] Cf. Theorem 27.3.22 of [Ivr] and Propositions 3.9 and 3.10 of [Ivr2].

(ii) If $\kappa = o(h^{\frac{1}{3}}|\log h|^{-\frac{1}{3}})$, *then*

$$\mathsf{E}^* = \int \mathsf{Weyl}_1^*(x)\,dx + 2z^2 S(z\kappa, z\beta)h^{-2} + o(h^{-1}), \tag{3.19}$$

in which case Weyl_1^* *must in addition to* $-h^{-3}P^{\mathsf{TF}}(W+\nu)$ *contain the Schwinger correction, and also the relativistic correction.*

Next, using arguments Subsection 27.3.6 of [Ivr], in particular, decoupling of singularities (which is needed only in the case ofthe self-generated magnetic field), we arrive to

Theorem 3.13 [24]**.** *Let* $M \ge 2$, $\kappa \le \kappa^*$ *and* (1.8) *and* (1.11) *be fulfilled. Then*

(i) The following asymptotics holds

$$\mathsf{E}^* = \int \mathsf{Weyl}_1(x)\,dx + 2\sum_{1\le m\le M} z_m^2 S(z_m\kappa, z_m\beta)h^{-2} + O(R_1+R_2) \tag{3.20}$$

with

$$R_1 = \begin{cases} h^{-1} + \kappa|\log\kappa|^{\frac{1}{3}}h^{-\frac{4}{3}} & \text{if } \ a \ge 1, \\ a^{-\frac{1}{2}}h^{-1} + \kappa|\log\kappa|^{\frac{1}{3}}a^{-\frac{1}{3}}h^{-\frac{4}{3}} & \text{if } \ h^2 \le a \le 1 \end{cases} \tag{3.21}$$

(3.22)

and

$$R_2 = \kappa h^{-2}\begin{cases} a^{-3} & \text{if } \ a \ge |\log h|^{\frac{1}{3}}, \\ |\log h^2 a^{-1}|^{-1} & \text{if } \ h^2 \le a \le |\log h|^{\frac{1}{3}}. \end{cases} \tag{3.23}$$

(ii) If $\kappa = o(h^{\frac{1}{3}}|\log h|^{-\frac{1}{3}})$, $\kappa a^{-3} = o(h)$ *and* $a^{-1} = o(1)$, *then*

$$\mathsf{E}^* = \int \mathsf{Weyl}_1^*(x)\,dx + 2\sum_{1\le m\le M} z_m^2 S(z_m\kappa, z_m\beta)h^{-2} + o(h^{-1}). \tag{3.24}$$

[24] Cf. Theorem 27.3.24 of [Ivr].

4 Main Results

4.1 Asymptotics of the Ground State Energy

Now we can apply arguments of Section 27.4. In addition to (1.8) and (1.11) we assume that

$$d := \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge Z^{-1}, \tag{4.1}$$

$$N \asymp Z_1 \asymp ... \asymp Z_M. \tag{4.2}$$

Then the estimates from below follow immediately from the trace asymptotics, while for the estimate from above we need also estimate N and miscellaneous D-terems. We leave all the details to the reader.

Theorem 4.1 [25]**.** *(i) Under assumptions* (1.8), (1.11), (4.1) *and* (4.2) *the following asymptotics holds*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m, \beta Z_m) + O\big(Z^{\frac{4}{3}}(R_1+R_2)\big) \tag{4.3}$$

with R_1 and R_2 defined by (3.21) *and* (3.23) *respectively with $\kappa = \alpha Z$, $h = Z^{-\frac{1}{3}}$ and $a = Z^{\frac{1}{3}}d$, d is defined by* (4.1), *$d = \infty$ for $M = 1$.*

(ii) In particular, under assumption $d \gtrsim Z^{-\frac{1}{3}}$ the following asymptotics holds

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m, \beta Z_m) + O\big(\alpha|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^{\frac{5}{3}} + \alpha d^{-3}Z^2\big). \tag{4.4}$$

Theorem 4.2 [26]**.** *(i) Let assumptions* (1.8), (1.11), (4.1) *and* (4.2) *be fulfilled and let $\Psi = \Psi_{\boldsymbol{A}}$ be a ground state for a near optimizer $\boldsymbol{A}$ of the original multiparticle problem. Then*

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) \le CZ^{\frac{5}{3}}. \tag{4.5}$$

[25] Cf. Theorem 27.4.3 of [Ivr].

[26] Cf. Theorem 27.4.4 of [Ivr].

(ii) Furthermore, if $d \ge Z^{-\frac{1}{3}}$, *then*

$$\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}}) \le CZ^{\frac{5}{3}}\big(Z^{-\delta} + (dZ^{\frac{1}{3}})^{-\delta} + (\alpha Z)^{\delta}\big). \tag{4.6}$$

Theorem 4.3 [27]**.** *Let assumptions* (1.8), (1.11), (4.1) *and* (4.2) *be fulfilled, and let* $\alpha \le Z^{-\frac{10}{9}}|\log Z|^{-\frac{1}{3}}$. *Then*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m, \beta Z_m) + \mathsf{Dirac} + \mathsf{Schwinger} + \mathsf{RCT} + O\big(\alpha|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^{\frac{5}{3}-\delta} + \alpha d^{-3}Z^2\big) \tag{4.7}$$

where Dirac *and* Schwinger *are* Dirac *and* Schwinger correction terms *defined exactly as in non-magnetic non-relativistic case by* (25.1.29) *and* (25.1.30) *of [Ivr] respectively, and* RCT *is relativistic correction term, defined as in the non-magnetic case by* (3.23) *of [Ivr2].*

Theorem 4.4 [28]**.** *Let assumptions* (1.8), (1.11) *and* (4.2) *be fulfilled. Let us consider* $\mathsf{y}_m = \mathsf{y}^*_m$ *minimizing the full energy*

$$\widehat{\mathsf{E}}^*_N := \mathsf{E}^*_N + \sum_{1\le m<m'\le M} Z_m Z_{m'}|\mathsf{y}_m - \mathsf{y}_{m'}|^{-1}. \tag{4.8}$$

Then

$$d \ge \min\big(Z^{-\frac{5}{21}+\delta},\, Z^{-\frac{5}{21}}(\alpha Z)^{-\delta},\, \alpha^{-\frac{1}{4}}Z^{-\frac{1}{2}}\big) \tag{4.9}$$

and in the remainder estimates in (4.4) *and* (4.7) *one can skip* d*-connected terms; so we arrive to*

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m, \beta Z_m) + O\big(\alpha|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^{\frac{5}{3}}\big) \tag{4.10}$$

and

$$\mathsf{E}^*_N = \mathcal{E}^{\mathsf{TF}}_N + \sum_{1\le m\le M} 2Z_m^2 S(\alpha Z_m) + \mathsf{Dirac} + \mathsf{Schwinger} + \mathsf{RCT} + O\big(\alpha|\log(\alpha Z)|^{\frac{1}{3}} Z^{\frac{25}{9}} + Z^{\frac{5}{3}-\delta}\big) \tag{4.11}$$

respectively and also the same asymptotics with $\widehat{\mathsf{E}}^*_N$ *and* $\widehat{\mathcal{E}}^{\mathsf{TF}}_N$ *instead of* E^*_N *and* $\mathcal{E}^{\mathsf{TF}}_N$.

[27] Cf. Theorem 27.4.5 of [Ivr].
[28] Cf. Theorem 27.4.6 of [Ivr].

4.2 Related Problems

After Theorems 4.1–4.4 are proven, we can apply arguments of Sections 25.5 and 25.6 of [Ivr].

Theorem 4.5 [29]**.** *Let assumptions* (1.8), (1.11) *and* (4.2) *be fulfilled.*

(i) In the framework of the fixed nuclei model let us assume that $\mathsf{I}^*_N := \mathsf{E}^*_{N-1} - \mathsf{E}^*_N > 0$. *Then*

$$(N-Z)_+ \le CZ^{\frac{5}{7}} \begin{cases} 1 & \text{if } \ d \le Z^{-\frac{1}{3}}, \\ Z^{-\delta} + (dZ^{\frac{1}{3}})^{-\delta} + (\alpha Z)^{\delta} & \text{if } \ d \ge Z^{-\frac{1}{3}}. \end{cases} \tag{4.12}$$

(ii) In particular, for a single atom and for molecule with $d \ge Z^{-\frac{1}{3}+\delta}$

$$(N-Z)_+ \le Z^{\frac{5}{7}}\bigl(Z^{-\delta} + (\alpha Z)^{\delta}\bigr). \tag{4.13}$$

(iii) In the framework of the free nuclei model let us assume that $\widehat{\mathsf{I}}^*_N := \widehat{\mathsf{E}}^*_{N-1} - \widehat{\mathsf{E}}^*_N > 0$. *Then estimate* (4.13) *holds.*

Theorem 4.6 [30]**.** *Let assumptions* (1.8), (1.11) *and* (4.2) *be fulfilled and let* $N \ge Z - C_0 Z^{\frac{5}{7}}$. *Then*

(i) In the framework of the fixed nuclei model

$$\mathsf{I}^*_N \le CZ^{\frac{20}{21}}. \tag{4.14}$$

(ii) In the framework of the free nuclei model with $N \ge Z - C_0 Z^{\frac{5}{7}}\bigl(Z^{-\delta} + \alpha Z^{\delta}\bigr)$

$$\widehat{\mathsf{I}}^*_N := \widehat{\mathsf{E}}^*_{N-1} - \widehat{\mathsf{E}}^*_{N-1} \le Z^{\frac{20}{21}}\bigl(Z^{-\delta'} + (\alpha Z)^{\delta'}\bigr). \tag{4.15}$$

Theorem 4.7 [31]**.** *Let assumptions* (1.8), (1.11) *and* (4.2) *be fulfilled and let* $N \le Z - C_0 Z^{\frac{5}{7}}$. *Then in the framework of the fixed nuclei model under assumption* $b \ge C_1 (N-Z)^{-\frac{1}{3}}$

$$(\mathsf{I}^*_N + \nu)_+ \le C(Z-N)^{\frac{17}{18}} Z^{\frac{5}{18}} \begin{cases} 1 & \text{if } \ d \le Z^{-\frac{1}{3}}, \\ Z^{-\delta} + (dZ^{\frac{1}{3}})^{-\delta} & \text{if } \ d \ge Z^{-\frac{1}{3}}. \end{cases} \tag{4.16}$$

[29] Cf. Theorem 27.5.1 of [Ivr].
[30] Cf. Theorem 27.5.2 of [Ivr].
[31] Cf. Theorem 27.5.3 of [Ivr].

Theorem 4.8 [32]**.** *Let assumptions* (1.8), (1.11). *Then in the framework of free nuclei model with* $M \geq 2$ *the stable molecule does not exist unless*

$$Z - N \leq Z^{\frac{5}{7}}\big(Z^{-\delta} + (\alpha Z)^{\delta}\big). \tag{4.17}$$

A Some iInequalities

In this section we reproduce from [EFS2]: two new Lieb-Thirring type inequalities for the relativistic kinetic energy with a magnetic field.

Theorem A.1 [33]**.** *There exists a universal constant* $C > 0$ *such that for any positive number* $\gamma > 0$, *for any potential* V *with* $V_+ \in \mathscr{L}^{5/2} \cap \mathscr{L}^4(\mathbb{R}^3)$, *and magnetic field* $B = \nabla \times A \in \mathscr{L}^2(\mathbb{R}^3)$, *we have*

$$\begin{aligned}\mathsf{Tr}\Big(\big(\sqrt{\gamma^{-2}(D-A)\cdot\boldsymbol{\sigma})^2+\gamma^{-4}}-\gamma^{-2}-U(x)\big)^{-}\Big) \geq \\ -C\bigg\{\int U_+^{5/2}\,dx+\gamma^3\int U_+^4\,dx+\Big(\int|\nabla\times A|^2\,dx\Big)^{3/4}\Big(\int U_+^4\,dx\Big)^{1/4}\bigg\}.\end{aligned} \tag{A.1}$$

Notice that Theorem A.1 reduces to the well-known Daubechies inequality in the case $A = 0$ [Dau].

For the Schrödinger case, the Daubechies inequality was generalized (and improved to incorporate a critical Coulomb singularity) to non-zero A in [FLS] by using diamagnetic techniques. Theorem A.1 is the generalization of the Daubechies inequality for the Pauli operator, in which case there is no diamagnetic inequality. Moreover, in the $\gamma \to 0$ limit, (A.1) converges to the magnetic Lieb-Thirring inequality for the Pauli operator [LLS] since

$$\sqrt{\gamma^{-2}(D-A)\cdot\boldsymbol{\sigma})^2+\gamma^{-4}}-\gamma^{-2} \to \frac{1}{2}(D-A)\cdot\boldsymbol{\sigma})^2, \qquad \gamma\to 0. \tag{A.2}$$

Theorem A.1 does not cover the case of a Coulomb singularity. The next result shows that for γ smaller than the critical value $2/\pi$, the Coulomb singularity can be included.

---

[32] Cf. Theorem 27.5.6 of [Ivr].

[33] Theorem 2.2 of [EFS2].

[34] Theorem 2.3 of [EFS2].

Theorem A.2 [34]**.** *Let ϕ_r be a real function satisfying* $\operatorname{supp}\phi_r \subset \{|x| \le r\}$, $\|\phi_r\|_\infty \le 1$. *There exists a constant $C > 0$ such that if $\gamma \in (0, 2/\pi)$, then*

$$\begin{aligned}(\text{A.3}) \quad & \operatorname{Tr}\Big(\phi_r\big(\sqrt{\gamma^{-2}(D-A)\cdot\boldsymbol{\sigma})^2+\gamma^{-4}}-\gamma^{-2}-\frac{1}{|x|}-U\big)\phi_r\Big)^- \\ & \ge -C\Big\{\eta^{-3/2}\int|\nabla\times A|^2\,dx+\eta^{-3}r^3+\eta^{-3/2}\int U_+^{5/2}\,dx+\eta^{-3}\gamma^3\int U_+^4\,dx \\ & \qquad +\Big(\int|\nabla\times A|^2\,dx\Big)^{3/4}\Big(\int U_+^4\,dx\Big)^{1/4}\Big\},\end{aligned}$$

where $\eta := \frac{1}{10}(1-(\pi\gamma/2)^2)$.

Complete Semiclassical Spectral Asymptotics for Periodic and Almost Periodic Perturbations of Constant Operators*,†

Victor Ivrii‡

Abstract

Under certain assumptions we derive a complete semiclassical asymptotics of the spectral function $e_{h,\varepsilon}(x,x,\lambda)$ for a scalar operator

$$A_\varepsilon(x,hD) = A^0(hD) + \varepsilon B(x,hD),$$

where A^0 is an elliptic operator and $B(x,hD)$ is a periodic or almost periodic perturbation.

In particular, a complete semiclassical asymptotics of the integrated density of states also holds. Further, we consider generalizations.

1 Introduction

1.1 Preliminary Remarks

This work is inspired by several remarkable papers of L. Parnovski and R. Shterenberg [PS1,PS2,PS3], S. Morozov, L. Parnovski and R. Shterenberg [MPS] and earlier papers by A. Sobolev [So1,So2]. I wanted to understand the approach of the authors and, combining their ideas with my own approach, generalize their results.

*2010 *Mathematics Subject Classification*: 35P20.

†*Key words and phrases*: Microlocal Analysis, sharp spectral asymptotics, integrated density of states, periodic and almost periodic operators, Diophantine conditions.

‡This research was supported in part by National Science and Engineering Research Council (Canada) Discovery Grant RGPIN 13827

In these papers the complete asymptotic expansion of the integrated density of states $\mathsf{N}(\lambda)$ for operators $\Delta+V$ was derived as $\lambda \to +\infty$; here Δ is a positive Laplacian and V is a periodic or almost periodic potential (satisfying certain conditions). In [MPS] more general operators were considered.

Further, in [PS3] the complete asymptotic expansion of $e(x,x,\lambda)$ was derived, where $e(x,y,\lambda)$ is the Schwartz kernel of the spectral projector.

I borrowed from these papers Conditions 1.2–1.6 and the *special gauge transformation* and added the *hyperbolic operator method* (actually non-stationary semiclassical Schrödinger operator method– [Ivr1]) and extremely long propagation of singularities. I believe that this is a simpler and more powerful approach. Also, in contrast to those papers I consider more general semiclassical asymptotics.

Consider a scalar self-adjoint h-pseudo-differential operator $A(x,hD)$ in $\mathbb{R}^d$ with the Weyl symbol $A(x,\xi)$, such that

$$|D_x^\alpha D_\xi^\beta A(x,\xi)| \le c_{\alpha\beta}(|\xi|+1)^m \qquad \forall \alpha,\beta\ \forall x,\xi \tag{1.1}$$

and

$$A(x,\xi) \ge c_0|\xi|^m - C_0 \qquad \forall x,\xi. \tag{1.2}$$

Then it is semibounded from below. Let $e_h(x,y,\lambda)$ be the Schwartz kernel of its spectral projector $E(\lambda)=\theta(\lambda-A)$. We are interested in the semiclassical asymptotics of $e_h(x,x,\lambda)$ and

$$\mathsf{N}_h(\lambda) = \mathsf{M}[e(x,x,\lambda)] \coloneqq \lim_{\ell\to\infty} (\mathsf{mes}(\ell X))^{-1} \int_{\ell X} e(x,x,\lambda)\,dx, \tag{1.3}$$

where $0\in X$ is an open domain in $\mathbb{R}^d$. The latter expression in the cases we are interested in does not depend on X and is called *Integrated Density of States*.

It is well-known that under *ξ-microhyperbolicity condition on the energy level λ*

$$|A(x,\xi,h)-\lambda| + |\nabla_\xi A(x,\xi,h)| \ge \epsilon_0 \tag{1.4}$$

the following asymptotics holds

$$e_h(x,x,\lambda) = \kappa_0(x,\lambda)h^{-d} + O(h^{1-d}) \qquad \text{as}\ \ h\to +0, \tag{1.5}$$

and therefore

$$\mathsf{N}_h(\lambda) = \bar\kappa_0(\lambda)h^{-d} + O(h^{1-d}), \tag{1.6}$$

where here and below

$$\bar{\kappa}_n(\lambda) = \mathsf{M}[\kappa_n(x,\lambda)]. \tag{1.7}$$

For generalization to matrix operators and degenerate scalar operators see Chapters 4 and 5 respectively. Also there one can find slightly sharper two-term asymptotics under non-periodicity conditions.

Also it is known (see Chapter 4) that under microhyperbolicity condition (1.4) for $|\tau-\lambda|<\epsilon$ the following complete asymptotics holds:

$$F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_T(t)\bigl(Q_{2x}u_h(x,y,t)\,{}^tQ_{1y}\bigr)|_{y=x}\bigr) \sim \sum_{n\ge 0}\kappa'_{n,Q_1,Q_2}(x,\tau)h^{1-d+n}, \tag{1.8}$$

where $u_h(x,y,t)$ is the Schwartz kernel of of the *propagator* $e^{ih^{-1}tA}$, $\bar{\chi}\in \mathscr{C}_0^\infty([-1,1])$, $\bar{\chi}(t)=1$ at $[-\frac12,\frac12]$, $T\in[h^{1-\delta},T^*]$, T^* is a small constant here and $Q_j=Q_j(x,hD)$ are h-pseudo-differential operator; we write operators, acting with respect to y on Schwartz kernels to the right of it.

Further, it is known that

$$\mathsf{supp}(Q_1)\cap\mathsf{supp}(Q_2)=\emptyset \implies \kappa'_{n,Q_1,Q_2}(x,\tau)=0, \tag{1.9}$$

where $\mathsf{supp}(Q_j)$ is a support of its symbol $Q_j(x,\xi)$ and

$$\tau\le\tau^*=\inf_{x,\xi}A(x,\xi) \implies \kappa'_{n,Q_1,Q_2}(x,\tau)=0. \tag{1.10}$$

Let

$$\kappa_{n,Q_1,Q_2}(x,\tau)=\int_{-\infty}^{\tau}\kappa'_{n,Q_1,Q_2}(x,\tau')\,d\tau. \tag{1.11}$$

In what follows we skip subscripts $Q_j=I$.

Remark 1.1. This equality (1.8) plus Hörmander's Tauberian theorem imply the remainder estimates $O(h^{1-d})$ for $Q_{2x}e_h(x,y,\tau)\,{}^tQ_{1y}|_{x=y}$. On the other hand, if we can improve (1.8) by increasing T^*, we can improve the remainder estimate to $O(T^{*-1}h^{1-d})$ [1),2)].

Observe that for $A=A(hD)$

$$e_h(x,x,\lambda)=\mathsf{N}_h(\lambda)=\kappa_0(\lambda)h^{-d}. \tag{1.12}$$

[1)] Provided $T^*=O(h^{-M})$ for some M.

[2)] This plus estimate for κ'_0 is a major method for obtaining sharp remainder estimates in [Ivr1].

In this paper we consider

$$A(x, hD) = A^0(hD) + \varepsilon B(x, hD), \tag{1.13}$$

where $A^0(\xi)$ satisfies (1.1), (1.2) and (1.4) and $B(x,\xi)$ satisfies (1.1) and $\varepsilon > 0$ is a small parameter. Later we assume that $B(x, hD)$ is almost periodic and impose other conditions.

First, we claim that for operator (1.13) with $\varepsilon \le \epsilon_0$ the equality (1.8) holds with $T^* = \epsilon_1 \varepsilon^{-1}$ where ϵ_j are small constants and we assume that $\varepsilon \ge h^M$ for some M. Then the remainder estimate is $O(\varepsilon h^{1-d})$ [3].

1.2 Main Theorem

Now we consider the main topic of this work where we will use ideas from [PS1, PS2, PS3, MPS]: the case of an almost periodic operator $B(x, hD)$,

$$B(x,\xi) = \sum_{\theta\in\Theta} b_\theta(\xi) e^{i\langle\theta,x\rangle} \tag{1.14}$$

with discrete (i.e. without any accumulation points) *frequency set* Θ.

Operator B is *quasiperiodic* if Θ is a finite set, *periodic* if Θ is a lattice and *almost periodic* in the general case.

Our goal is to derive (under certain assumptions) complete semiclassical asymptotics:

$$e_{h,\varepsilon}(x,x,\tau) \sim \sum_{n\ge 0} \kappa_{n,\varepsilon x}(x,\tau) h^{-d+n}. \tag{1.15}$$

First, in addition to microhyperbolicity condition (1.4) we assume that $\Sigma_\lambda = \{\xi\colon A^0(\xi) = \lambda\}$ is a *strongly convex surface* i.e.

$$\pm \sum_{j,k} A^0_{\xi_j\xi_k}(\xi)\eta_j\eta_k \ge \epsilon|\eta|^2 \qquad \forall \xi\colon A^0(\xi) = \lambda \ \ \forall \eta\colon \sum_j A^0_{\xi_j}(\xi)\eta_j = 0, \tag{1.16}$$

where the sign depends on the connected component of Σ_λ, containing ξ.

Without any loss of generality we assume that

(1.17) Θ spans $\mathbb{R}^d$, contains 0 and is symmetric about 0.

[3] See Theorem 2.4.

Condition 1.2. *For each $\theta_1, \dots, \theta_d \in \Theta$ either $\theta_1, \dots, \theta_d$ are linearly independent over $\mathbb{R}$ or they linearly dependent over $\mathbb{Z}$.*

Assume also that

Condition 1.3. *For any arbitrarily large L and for any sufficiently large real number ω there are a finite symmetric about 0 set $\Theta' := \Theta'_{(L,\omega)} \subset (\Theta \cap \mathsf{B}(0,\omega))$ (with $\mathsf{B}(\xi, r)$ the ball of the radius r and center ξ) and a "cut-off" coefficients $b'_\theta := b'_{\theta,(L,\omega)}$, such that*

$$B' := B'_{(L,\omega)}(x,\xi) := \sum_{\theta\in\Theta'} b'_\theta(\xi) e^{i\langle\theta,x\rangle} \tag{1.18}$$

satisfies

$$\|D_x^\alpha D_\xi^\beta (B - B')\|_{\mathscr{L}^\infty} \le \omega^{-L}(|\xi|+1)^m \qquad \forall \alpha,\beta\colon |\alpha|\le L, |\beta|\le L. \tag{1.19}$$

Remark 1.4. (i) Then

$$|D_\xi^\beta b_\theta| = O(|\theta|^{-\infty}(|\xi|+1)^m) \qquad \text{as } |\theta|\to\infty \tag{1.20}$$

and

$$|D_\xi^\beta (b_\theta - b'_\theta)| = O(\omega^{-\infty}(|\xi|+1)^m). \tag{1.21}$$

Indeed, one suffices to observe that $b_\theta(\xi) = \mathsf{M}(B(x,\xi)e^{-i\langle\theta,x\rangle})$ etc.

(ii) On the other hand, under additional assumption

$$\#\{\theta\in\Theta,\ |\theta|\le\omega\} = O(\omega^p) \qquad \text{as } \omega\to\infty \tag{1.22}$$

for some p, (1.20) implies Condition 1.3 with $\Theta'_{(L,\omega)} := \Theta\cap\mathsf{B}(0,\omega)$. However we will need $\Theta'_{(L,\omega)}$ in the next condition.

(iii) We need only to estimate the operator norm of the difference between $B(x,hD)$ and $B'(x,hD)$ (from $\mathscr{H}^m$ to $\mathscr{L}^2$); therefore for differential operators we can weaken (1.19): if

$$B = \sum_{\mu,\nu:|\alpha|\le m',|\beta|\le m'} D^\alpha b_{\alpha\beta}(x) D^\beta, \qquad b_{\alpha\beta} = b^\dagger_{\beta\alpha}, \tag{1.23}$$

where we assume that $b_{\alpha\nu}(x)$ and $b'_{\alpha\beta}(x)$ have similar decompositions (1.14) and (1.18) respectively, then (1.19) should be replaced by

$$\|D_x^\alpha (b_{\alpha\beta} - b'_{\alpha\beta})\|_{\mathscr{L}^\infty} \le \omega^{-L} \qquad \forall\alpha. \tag{1.24}$$

(iv) While Condition 1.3 is Condition B of [PS3], adopted to our case, Condition 1.2 and Conditions 1.5, 1.6 below are borrowed without any modifications (except changing notations).

The next condition we need to impose is a version of the Diophantine condition on the frequencies of B. First, we need some definitions. We fix a natural number K (the choice of K will be determined later by how many terms in the asymptotic decomposition of $e(x,x,\lambda)$ we want to obtain) and consider Θ'_K, which here and below denotes the algebraic sum of K copies of Θ':

$$\Theta'_K := \sum_{1\le i\le K} \Theta. \tag{1.25}$$

We say that $\mathfrak{V}$ is a *quasilattice subspace* of dimension q, if $\mathfrak{V}$ is a linear span of q linear independent vectors $\theta_1,\dots,\theta_q \in \Theta'_K \setminus 0$. Obviously, the zero space is a quasilattice subspace of dimension 0 and $\mathbb{R}^d$ is a quasilattice subspace of dimension d.

We denote by $\mathcal{V}_q$ the collection of all quasilattice subspaces of dimension q and also $\mathcal{V} := \bigcup_{q\ge 0} \mathcal{V}_q$.

Consider $\mathfrak{V},\mathfrak{U}\in\mathcal{V}$. We say that these subspaces are *strongly distinct*, if neither of them is a subspace of the other one. Next, let $\widehat{(\mathfrak{V},\mathfrak{U})}\in[0,\pi/2]$ be the angle between them, i.e. the angle between $\mathfrak{V}\ominus\mathfrak{W}$ and $\mathfrak{U}\ominus\mathfrak{W}$, $\mathfrak{W}=\mathfrak{U}\cap\mathfrak{V}$. This angle is positive iff $\mathfrak{V}$ and $\mathfrak{U}$ are strongly distinct.

Condition 1.5. *For each fixed L and K the sets $\Theta'_{(L,\omega)}$ satisfying (1.18) and (1.19) can be chosen in such a way that for sufficiently large ω we have*

$$s(\omega) = s(\Theta'_K) := \inf_{\mathfrak{V},\mathfrak{U}\in\mathcal{V}} \sin\bigl(\widehat{(\mathfrak{V},\mathfrak{U})}\bigr) \ge \omega^{-1} \tag{1.26}$$

and

$$r(\omega) := \inf_{\theta\in\Theta'_K\setminus 0} |\theta| \ge \omega^{-1}, \tag{1.27}$$

where the implied constant (i.e. how large should ω be) depends on L and K.

Let $\mathfrak{V}$ be the span of $\theta_1,\dots,\theta_q\in\Theta'_K\setminus 0$. Then due to Condition 1.2 each element of the set $\Theta'_K\cap\mathfrak{V}$ is a linear combination of $\theta_1,\dots,\theta_q$ with rational coefficients. Since the set $\Theta'_K\cap\mathfrak{V}$ is finite, this implies that the set $\Theta'_\infty\cap\mathfrak{V}$ is discrete and is, therefore, a lattice in $\mathfrak{V}$. We denote this lattice by $\Gamma(\omega;\mathfrak{V})$.

Our final condition states that this lattice cannot be too dense.

Condition 1.6. *We can choose $\Theta'_{(L;\omega)}$, satisfying Conditions 1.3 and 1.5 in such a way that for sufficiently large ω and for each $\mathfrak{V} \in \mathcal{V}$, $\mathfrak{V} \neq \mathbb{R}^d$, we have*

$$\mathsf{vol}(\mathfrak{V}/\Gamma(\omega;\mathfrak{V})) \geq \omega^{-1}. \tag{1.28}$$

Remark 1.7. See Section 2 of [PS3] for discussion of these conditions. In particular, if Θ is a lattice, then Conditions 1.2–1.6 are fulfilled. Further, if Θ is a finite set and Condition 1.2 is fulfilled, then $\Theta_\infty := \bigcup_{K\geq 1} \Theta_K$ is a lattice and Conditions 1.3–1.6 are fulfilled. Furthermore, the same is true, if Θ is an arithmetic sum of a finite set and a lattice.

The main theorem of this paper is

Theorem 1.8. *Let A be a self-adjoint operator* (1.13)*, where A^0 satisfies* (1.1)*,* (1.2)*,* (1.4) *and* (1.16) *and B satisfies* (1.1)*.*

Let Conditions 1.2–1.6 be fulfilled. Then for $|\tau - \lambda| < \epsilon$, $\varepsilon \leq h^\vartheta$, $\vartheta > 0$

$$e_{h,\varepsilon}(x,x,\tau) \sim \sum_{n\geq 0} \kappa_n(x,\tau;\varepsilon) h^{-d+n}. \tag{1.29}$$

Corollary 1.9. *In the framework of Theorem 1.8*

$$\mathsf{N}_{h,\varepsilon}(\tau) \sim \sum_{n\geq 0} \bar{\kappa}_n(\tau;\varepsilon) h^{-d+n}. \tag{1.30}$$

1.3 Plan of the Paper

Section 2 is devoted to the proof of Theorem 1.8. In Subsection 2.1 we make some general remarks, and, in particular, we prove more general albeit far less precise Theorem 2.4. Then, in Subsection 2.2 we describe a gauge transformation.

In Subsection 2.3 we consider a non-resonant zone and justify such transformation, which reduces operator microlocally to a constant symbol operator $A''(hD,h)$. This allows us to study a propagation of singularities with respect to ξ and prove that the singularities do not propagate with respect to ξ [4)]. In Subsection 2.5 we consider a resonant zone and justify such transformation, which reduces operator microlocally to an operator

[4)] For time $T^* = h^{-M}$ with arbitrarily large M.

$A''(x', hD, h)$, where $x' \in \mathfrak{V}$ the corresponding resonant subspace, and prove that the singularities propagate only with respect to ξ'. Then the convexity condition implies that the singularities actually do not propagate with respect to ξ [4)].

In Subsection 2.6 we consider propagation with respect to x and using the results of Subsections 2.3 and 2.5 we prove that the singularities "propagate away" and do not return[4)]. The we apply Tauberian theorem with $T = T^*$ and prove Theorem 1.8.

In Section 3 we generalize Theorem 1.8. First, in Subsection 3.1 we consider matrix operators with the simple eigenvalues of $A^0(\xi)$.

Then, in Subsection 3.2 we consider operators $A^0(hD) + \varepsilon V(x, hD)$ where symbol $V(x, \xi)$ decays as $|x| \to \infty$ and hybrid operators $A^0(hD) + \varepsilon(B(x, hD) + V(x, hD))$ with almost periodic B and decaying V and show that our methods work for them as well.

Finally, in Subsection 3.3 we discuss differentiability of our asymptotics with respect to τ.

2 Proof of the Main Theorem

2.1 Preliminary Analysis

Remark 2.1. (i) It follows from Section 4 that the contribution of the zone $\{\xi\colon |A^0(\xi) - \tau| \ge C_0\varepsilon + h^{1-\varsigma}\}$ to the remainder is negligible. Here and below $\varsigma > 0$ is an arbitrarily small exponent. Namely, let $Q_j = Q_j(hD)$ be operators with the symbols $Q_j(\xi)$, such that

$$\mathsf{supp}(Q_1) \cap \mathsf{supp}(Q_2) \cap \Omega_\tau = \emptyset \tag{2.1}$$

with

$$\Omega_\tau := \{\xi\colon |A^0(\xi) - \tau| \le C_0\varepsilon + h^{1-\varsigma}\} \tag{2.2}$$

and satisfying

$$|D^\alpha Q_j| \le C_\alpha h^{-(1-\varsigma)|\alpha|} \qquad \forall \alpha. \tag{2.3}$$

Then

$$(Q_{2x} e(x, y, \tau)\, {}^t Q_{1y})|_{y=x} = \kappa_{0,Q_1,Q_2} h^{-d} + O(h^\infty) \tag{2.4}$$

with

$$\kappa_{0,Q_1,Q_2} = (2\pi)^{-d} \int \theta(\tau - A^0(\xi)) Q_1(\xi) Q_2(\xi)\, d\xi \tag{2.5}$$

with $\theta(\tau - A^0(\xi))$ equal to either 0 or 1 on each connected component of $\Omega_\tau \cap \mathsf{supp}(Q_1) \cap \mathsf{supp}(Q_2))$.

Therefore we restrict ourself by the analysis in the zone Ω_τ.

(ii) To upgrade (1.8) with $T = T_*$ (a small constant) to (1.8) with $T = T^*$ it is sufficient to prove that

$$|F_{t\to h^{-1}\tau}\big(\chi_T(t)\big(Q_{2x}u_h(x,y,t)\,{}^tQ_{1y}\big)\big|_{y=x}\big)| \le C_s h^{-d+s}, \tag{2.6}$$

for $|\tau - \lambda| \le \epsilon,\ T \in [T_*,\ T^*]$ and $\chi \in \mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1])$, where s is an arbitrarily large exponent.

In the very general setting for $|t| \le h^{-M}$ the propagation speed with respect to ξ does not exceed $C\varepsilon$. More precisely

Proposition 2.2. *Let $A = A^0 + \varepsilon B$ where $A^0(hD)$ and $B(x,hD)$ are matrix operators satisfying* (1.1). *Let $Q_j(hD)$ be operators with symbols satisfying* (2.3). *Further, let $\mathsf{supp}(Q_j) \subset \{\xi\colon |\xi| \le c\}$ and*

$$\mathsf{dist}(\mathsf{supp}(Q_1),\ \mathsf{supp}(Q_2)) \ge \mathsf{max}(C_0\varepsilon T,\ h^{1-\varsigma}) \tag{2.7}$$

with $T \le h^{-M}$. Then for $|t| \le T$

$$\|Q_2 e^{ih^{-1}tA}Q_1\| \le C_{M,s}h^s. \tag{2.8}$$

Proof. One can prove easily by arguments of the proof of Theorem 2.1.2, applied to operator $\varepsilon^{-1}A = \varepsilon^{-1}A^0(hD_x) + B(x,hD)$ and $\phi(\xi,t)$, that the propagation speed with respect ξ does not exceed C_0; presence of the term $\varepsilon^{-1}A^0(hD_x)$ does not matter since it disappears in the commutator with $\phi(hD)$. Changing $t \mapsto \varepsilon t$ we conclude that for operator A the propagation speed with respect to ξ does not exceed $C_0\varepsilon$.

We do not need compactness of the domain in the phase space with respect to x since the propagation speed with respect to x does not exceed C_0 and we have such compactness implicitly. We leave easy details to the reader. □

Proposition 2.3. *In the framework of Proposition 2.2 assume that $A^0(hD)$ is microhyperbolic on the energy level λ* [5)].

Then for $T_* \le T \le T^* = \mathsf{min}(\epsilon_0\varepsilon^{-1}, h^{-M})$ (2.6) *holds.*

[5)] For definition for matrix operators see Definition 2.1.1.

Proof. It is sufficient to prove for $\mathsf{supp}(Q_1)$ contained in the small vicinity of some point $\bar\xi$. Then due to Proposition 2.2 $e^{ih^{-1}tA}Q_1 \equiv Q_2 e^{ih^{-1}tA}Q_1$ modulo operators with $O(h^\infty)$-norms [6] and with Q_2 also supported in the small vicinity of $\bar\xi$ and equal 1 in the vicinity of $\mathsf{supp}(Q_1)$.

Then on $\mathsf{supp}(Q_2)$ operator is microhyperbolic with respect to vector ℓ and we can employ the proof of Theorem 2.1.2 again, this time with $\phi(x,t) = \ell x - \epsilon_0 t$. For further details see Chapter 4. □

Then in virtue of (1.8) with $t = T_*$ (which is also due to the microhyperbolicity condition) (1.8) also holds with $T = T^*$ and applying Hörmander's Tauberian theorem we arrive to the remainder estimate $Ch^{1-d}T^{*-1} = C\varepsilon h^{1-d}$, thus proving the following theorem:

Theorem 2.4. *Let $A = A^0(hD) + \varepsilon B(x, hD)$ with A^0 satisfying conditions* (1.1), (1.2) *and* (1.4) *and B satisfying conditions* (1.1). *Then*

$$e_h(x,x,\tau) = \sum_{0\le n\le M} \kappa_n(x,\tau)h^{-d+n} + O(\varepsilon h^{1-d}) \tag{2.9}$$

provided $\varepsilon \ge h^M$, $|\tau - \lambda| \le \epsilon$.

From now on we discuss only Theorem 1.8.

Remark 2.5. (i) It suffices to prove asymptotics

$$e_h(x,x,\tau) = \sum_{0\le n\le M} \kappa_n(x,\tau)h^{-d+n} + O(h^{-d+M}) \tag{2.10}$$

with arbitrarily large fixed M. To do so we will use the *hyperbolic operator method* (which we implement as *semiclassical Schrödinger operator method*) with maximal time $T^* = h^{-M}$.

(ii) Then we can replace operator B by operator B', provided operator norm of $B - B'$ from $\mathscr{H}^m$ to $\mathscr{L}^2$ does not exceed Ch^{3M}.

Indeed, let $A' = A^0 + \varepsilon B'$. Due to Remark 2.1 we need to compare only $Q_1 e^{ih^{-1}tA'}Q_1$ and $Q_1 e^{ih^{-1}tA}Q_1$. Observe that due to (1.2)

$$\bigl\| e^{ih^{-1}tA}Q_1 - Q_2 e^{ih^{-1}tA}Q_1\bigr\|_k \le C_{k,s}h^s$$

[6] By default, operator norm is from $\mathscr{L}^2$ to $\mathscr{L}^2$.

with arbitrarily large k, s, where $\|\!|.|\!\|_k$ denotes an operator norms from $\mathscr{L}^2$ to $\mathscr{H}^k$ provided $\mathsf{supp}(Q_j) \subset \{\xi\colon A^0(\xi) \le 2jc\}$ and $Q_2 = 1$ in $\{\xi\colon A^0(\xi) < 3c\}$. The same is true for A' as well.

Then equality

$$e^{ih^{-1}tA'} - e^{ih^{-1}tA} = ih^{-1}\int_0^t e^{ih^{-1}(t-t')A}(A'-A)e^{ih^{-1}t'A'}\,dt'$$

and restriction $|t| \le T^*$ imply that $\|\!|\bigl(e^{ih^{-1}tA'} - e^{ih^{-1}tA}\bigr)Q|\!\|_k$ does not exceed $C_{k,s}h^s + Ch^{-1-M}\|\!|Q_2(B-B')Q_2|\!\|_k$.

Finally, observe that $\|\!|Q_2(B-B')Q_2|\!\|_k \le C_k h^{-k-m}\|\!|(B-B')|\!\|'_k$ where $\|\!|.|\!\|'_k$ denotes an operator norm from $\mathscr{H}^m$ to $\mathscr{L}^2$.

(iii) Since $\mathsf{N}_h(\tau)$ could be defined equivalently as

$$\mathsf{N}_h(\lambda) = \lim_{\ell\to\infty} (\mathsf{mes}(\ell X))^{-1}\mathsf{N}_h(\lambda, \ell X)e(x,x,\lambda)\,dx, \tag{2.11}$$

where $\mathsf{N}_h(\lambda, X)$ is an eigenvalue counting function for operator A in X with the Dirichlet (or Neumann–does not matter) boundary conditions on ∂X, for $\mathsf{N}_h(\tau)$ we can arrive to the same conclusion from the variational arguments.

(iv) First such replacement will be $B' := B'_{(L,\omega)}$ from Condition 1.3 with $\omega = h^{-\sigma}$, arbitrarily small $\sigma > 0$ and $L = 3M/\sigma$.

So, from now Θ and B are effectively replaced by $\Theta' := \Theta'_{(L,\omega)}$ and $B'_{(L,\omega)}$ correspondingly.

2.2 Gauge Transformation

Consider now the "gauge" transformation $A \mapsto e^{-i\varepsilon h^{-1}P}Ae^{i\varepsilon h^{-1}P}$ with h-pseudodifferential operator P. Observe that

$$\begin{aligned} e^{-i\varepsilon h^{-1}P}Ae^{i\varepsilon h^{-1}P} &= A - i\varepsilon h^{-1}[P,A] + \sum_{2\le n\le K-1}\frac{1}{n!}(-i\varepsilon h^{-1})^n\,\mathsf{Ad}_P^n(A)\\ &\quad + \int_0^1 \frac{1}{(K-1)!}(1-s)^{K-1}(-i\varepsilon h^{-1})^K e^{-i\varepsilon h^{-1}sP}\,\mathsf{Ad}_P^K(A)e^{i\varepsilon h^{-1}sP}\,ds, \end{aligned} \tag{2.12}$$

where $\mathsf{Ad}_P^0(A) = A$ and $\mathsf{Ad}_P^{n+1}(A) = [P, \mathsf{Ad}_P^n(A)]$ for $n = 0, 1, \ldots$.

Thus *formally* we can compensate εB, taking

$$P = \sum_{\theta} ih\big(A^0(\xi+\theta h/2) - A^0(\xi-\theta h/2)\big)^{-1} b_\theta(\xi) e^{i\langle\theta,x\rangle}, \tag{2.13}$$

so that

$$ih^{-1}[P,A^0] = B \implies ih^{-1}[P,A] = B + i\varepsilon h^{-1}[P,B]. \tag{2.14}$$

Then perturbation εB is replaced by $\varepsilon^2 B'$, which is the right hand expression in (2.12) minus A^0, i.e.

$$B' = -ih^{-1}[P,B] + \sum_{2\le n\le K-1} \frac{1}{n!}\varepsilon^{n-2}(-ih^{-1})^n \operatorname{Ad}_P^n(A), \tag{2.15}$$

where we ignored the remainder.

New perturbation, again formally, has a magnitude of ε^2. Repeating this process we will make a perturbation negligible.

Remark 2.6. However, we need to address the following issues issues:

(i) Denominator $h^{-1}\big(A^0(\xi+\theta h/2) - A^0(\xi-\theta h/2)\big) = \langle\nabla_\xi A^0,\theta\rangle + O(h^{1-\sigma})$ could be small.

(ii) In B' set Θ' increases: $\varepsilon^2 B' = \varepsilon^2 B'_2 + \varepsilon^3 B'_3 + ... + \varepsilon^M B'_M$, where for B'_j the frequency set is Θ'_j (the arithmetic sum of j copies of Θ').

(iii) We need to prove that the remainder is negligible.

(iv) This transformation was used in Section 9 of [PS3] (etc); in contrast to these papers we use Weyl quantization instead of pq-quantization, and have therefore $\big(A^0(\xi+\theta h/2) - A^0(\xi-\theta h/2)\big)$ instead of $\big(A^0(\xi+\theta h) - A^0(\xi)\big)$.

2.3 Non-Resonant Zone

2.4 Gauge Transformation

One can see easily that if inequality

$$|\langle\nabla_\xi A^0(\xi),\theta\rangle| \ge \gamma := \varepsilon^{\frac{1}{2}} h^{-\delta} \tag{2.16}$$

holds for all $\theta \in \Theta'_K \setminus 0$, then the terms could be estimated by $h^{\delta n}$ and our construction works with $K = 3M/\delta$. Here and below without any loss of the generality we assume that $\varepsilon \geq h$; so, in fact,

$$h^{\vartheta} \geq \varepsilon \geq h. \tag{2.17}$$

Indeed, if $P = P(x, hD)$ has the symbol, satisfying

$$|D_\xi^\alpha D_x^\beta P| \leq c_{\alpha\beta}\gamma^{-1-|\alpha|} \qquad \forall \alpha, \beta, \tag{2.18}$$

then $B' = \varepsilon h^{-1}[P, B]$ has a symbol, satisfying

$$|D_\xi^\alpha D_x^\beta B'| \leq c'_{\alpha\beta}\varepsilon\gamma^{-2-|\alpha|} \qquad \forall \alpha, \beta, \tag{2.19}$$

so indeed $\varepsilon' = \varepsilon\gamma^{-2}$.

Then we can eliminate a perturbation completely, save terms with the frequency 0, both old and new. The set of ξ satisfying (2.16) for all $\theta \in \Theta'_K$ we call *non-resonant zone* and denote by $\mathcal{Z}$. Thus, we arrive to

Proposition 2.7. *Let $Q = Q(hD)$ with the symbol supported in $\mathcal{Z} \cap \Omega$ and satisfying* (2.3)

Then there exists a pseudo-differential operator $P = P(x, hD)$ with the symbol, satisfying (2.18) *and such that*

$$\bigl(e^{-i\varepsilon h^{-1}P} A e^{i\varepsilon h^{-1}P} - A''\bigr) Q \equiv 0 \tag{2.20}$$

with

$$A'' = A^0(hD) + \varepsilon B''_0(hD) \tag{2.21}$$

modulo operator from $\mathscr{H}^m$ to $\mathscr{L}^2$ with the operator norm $O(h^{3M})$.

Remark 2.8. (i) This proposition is similar to Lemma 9.3 of [PS3]. However, in contrast to [PS1, PS2, PS3, MPS], after it is proven we do not write asymptotic decomposition there, but simply prove that singularities do not propagate with respect to ξ there.

(ii) It is our second replacement of operator A; recall that the first one was based on Condition 1.3, and now we ignore the remainder after transformation, which is justified by Remark 2.5(i).

Propagation.

Proposition 2.9. *Let $Q_j = Q_j(hD)$ with the symbols, satisfying* (2.3) *and let symbol of Q_1 be supported in $\mathcal{Z} \cap \Omega$.*

Let $\mathsf{dist}(\mathsf{supp}(Q_1), \mathsf{supp}(Q_2)) \geq c\gamma$. *Then*

$$\|Q_2 e^{ih^{-1}tA} Q_1\| = O(h^{2M}) \qquad \text{as} \quad |t| \leq T^* = h^{-M}. \tag{2.22}$$

Proof. One can prove easily that the operator norms of $Q_2 e^{ih^{-1}tA''} Q_1$ and $Q_2 e^{\pm i\varepsilon h^{-1}P} Q_1$ are $O(h^{2M})$. We leave all easy details to the reader. □

2.5 Resonant Zone

Consider now *resonant zone*

$$\Lambda := \bigcup_{\theta \in \Theta'_K \setminus 0} \Lambda(\theta), \tag{2.23}$$

where $\Lambda(\theta)$ is the set of ξ, violating (2.16) for given θ:

$$\Lambda(\theta) = \Lambda_\delta(\theta) := \{\xi \colon |\langle \nabla_\xi A^0(\xi), \theta\rangle| \geq \gamma = c\varepsilon^{\frac{1}{2}} h^{-\delta}\}. \tag{2.24}$$

Case $d = 2$. We start from the easiest case $d = 2$ (in the trivial case $d = 1$ there is no resonant zone). Observe that due to assumption (1.16) for each θ

$$\mathsf{mes}_1(\Lambda(\theta) \cap \Sigma_\lambda) \leq C\gamma. \tag{2.25}$$

Further, $\#\Theta'_K \leq Ch^{-\sigma}$ (as $h \leq h_0(K, \sigma)$) due to Condition 1.5. Thus $\mathsf{mes}_1(\Lambda \cap \Sigma_\lambda) \leq \gamma h^{-\sigma}$. Recall, that $\sigma > 0$ is arbitrarily small.

Since due to Proposition 2.9, the propagation which starts in the non-resonant zone $\mathcal{Z}$ remains there[7)] we conclude that the propagation which is started in some connected component of the resonant zone also remains there[7)].

Thus, $\nabla_\xi A^0(\xi)$ does not change by more than $\gamma h^{-\sigma}$ and since σ ais arbitrarily small we conclude that (2.22) also holds for Q_1, supported in the resonant zone. Therefore

[7)] May be, with different constant c in the definition of γ.

(2.26) Estimate (2.22) holds for all Q_1, Q_2 satisfying (2.3) and

$$\mathsf{dist}(\mathsf{supp}(Q_1), \mathsf{supp}(Q_2)) \ge \gamma. \tag{2.27}$$

Remark 2.10. (i) In the proof of Theorem 1.8 we need only to have estimate (2.22) holding for all Q_1, Q_2 satisfying (2.3) and (2.27) with arbitrarily small constant γ.

(ii) Then for $d = 2$ we can replace assumption (1.16) by

(2.28) $\varkappa(s)$ (a curvature of Σ_λ, naturally parametrized by s) has zeroes only of the finite order.

Indeed, then (2.25) will be replaced by $\mathsf{mes}_1(\Lambda(\theta)\cap\Sigma_\lambda) \le C\gamma^\nu$, $\nu = 1/(q+1)$ with q the maximal order of zeroes of $\varkappa(s)$.

General Case: Gauge Transformation. Consider now the general case $d \ge 2$. In this case due Conditions 1.2, 1.5 and 1.6 we can cover $\Lambda \cap \Omega_\tau$ by Λ^*,

$$\Lambda \cap \Omega_\tau \subset \Lambda^* = \bigcup_{1\le j\le d-1} \Lambda^*_j, \tag{2.29}$$

defined as:

(2.30) Let $\xi \in \Omega_\tau$; then $\xi \in \Lambda^*_j$ iff there exist $\theta_1, \dots, \theta_j \in \Theta'_K$ which are linearly independent and such that $\xi \in \Lambda_{\delta_j}(\theta_k)$ for all $k = 1, \dots, j$,

where $0 < \delta = \delta_1 < \delta_2 < \dots < \delta_{d-1}$ are arbitrarily fixed and we chose sufficiently small $\sigma > 0$ afterwards.

Further, due to Conditions 1.2, 1.5, 1.6 and (1.16) $\Lambda^*_{d-1} \cap \Omega_\tau$ could be covered by no more than γ_{d-1}-vicinities of some points ξ_ι, $\iota = 1, \dots, \omega^g$, $g = g(d)$. Recall that $\Omega_\tau := \{\xi\colon |A^0(\xi) - \tau| \le C_0\varepsilon + h^{1-\varsigma}\}$.

Consider some connected component Ξ of Λ^*_j. Let some point $\bar\xi$ of it belong to $\bigcap_{1\le k\le j} \Lambda_{\delta_j}(\theta_k) \cap \Omega_\tau$ with linearly independent $\theta_1, \dots, \theta_j$. Observe that $\mathsf{diam}(\bigcap_{1\le k\le j} \Lambda_{\delta_j}(\theta_k) \cap \Omega) \le c\gamma_j$ due to strong convexity assumption (1.16). Then this set either intersects or does not intersect with $\Lambda^*_{j+1} \cap \Omega$. In the former case we include it to Λ^*_{j+1} and exclude it from Λ^*_j.

After we redefined Λ^*_j we arrive to the following proposition:

Proposition 2.11. *Equation* (2.29) *still holds where now each connected component* Ξ *of* Λ_j^* *has the following properties:*

(i) $\operatorname{diam}\Xi \le c\gamma_j$.

(ii) There exist linearly independent $\theta_1, \dots, \theta_j \in \Theta'_K$, *such that for each* $\xi \in \Xi$ $|\langle \nabla_\xi A^0(\xi), \theta\rangle| \le c_j\gamma_j$ *for all* $\theta \in \mathfrak{V} \cap (\Theta'_K \setminus 0)$ *and* $|\langle \nabla_\xi A^0(\xi), \theta\rangle| \ge \epsilon_j\gamma_{j+1}$ *for all* $\theta \in \Theta'_K \setminus \mathfrak{V})$ *with* $\mathfrak{V} = \operatorname{Span}(\theta_1, \dots, \theta_j)$.

Now we generalize Proposition 2.7:

Proposition 2.12. *Let* $Q = Q(hD)$ *with the symbol supported in the connected component* Ξ *of* Λ_j^*, *corresponding to subspace* $\mathfrak{V}$, *and satisfying* (2.3). *Then there exists a pseudo-differential operator* $P = P(x, hD)$ *with the symbol, satisfying* (2.18) *and such that*

$$\left(e^{-i\varepsilon h^{-1}P} A e^{i\varepsilon h^{-1}P} - A''\right) Q \equiv 0 \tag{2.31}$$

modulo operator from $\mathscr{H}^m$ *to* $\mathscr{L}^2$ *with the operator norm* $O(h^{3M})$, *where* $A'' = A^0 + \varepsilon B''(x, hD)$, *where* B'' *is an operator with Weyl symbol*

$$B''(x,\xi) = \sum_{\theta \in \Theta'_K \cap \mathfrak{V}} b_{\mathfrak{V},\theta}(\xi) e^{i\langle \theta, x\rangle}. \tag{2.32}$$

Proof. The proof obviously generalizes the proof of Proposition 2.7. We eliminate all $\theta \notin \mathfrak{V}$ exactly in the same way as it was done there. □

General Case: Propagation.

Proposition 2.13. *Let* $Q_j = Q_j(hD)$ *with the symbols, satisfying* (2.3) *and let symbol of* Q_1 *be supported in* Λ_j^* .

Let $\operatorname{dist}(\operatorname{supp}(Q_1), \operatorname{supp}(Q_2)) \ge C_0\gamma_j$. *Then* $\|Q_2 e^{ih^{-1}tA} Q_1\| = O(h^{2M})$ *for* $|t| \le T_* = h^{-M}$.

Proof. In virtue of Proposition 2.9 it is sufficient to consider $\operatorname{supp}(Q_1)$ belonging to the connected component Ξ' of Λ_j^*. Indeed, the values of $\delta_1, \dots, \delta_{d-1}$ are arbitrarily small.

One can prove easily that the operator norm of $Q_2 e^{\pm i\varepsilon h^{-1}P} Q_1$ are $O(h^{2M})$. We need to prove that the operator norm of $Q_2 e^{\pm ih^{-1}tA''} Q_1$ is also $O(h^{2M})$. In the coordinates $(x'; x'') \in \mathfrak{V} \oplus (\mathbb{R}^d \ominus \mathfrak{V})$ we observe that the propagation

speed is only along $\mathfrak{V}$ as long as it remains in $\epsilon\gamma_j$ vicinity of $\mathsf{supp}(Q_1)$. The proof is similar to the proof of Proposition 2.2 and we leave it to the reader.

However propagation is confined to $\Omega'_\tau := \{\xi : |A^0(\xi) - \tau| \le C\varepsilon + 2h^{1-\varsigma}\})$ and due to (1.16) it remains in that vicinity as $\varsigma < \delta$. □

Now we arrive to the following proposition:

Proposition 2.14. *Let* Q_1, Q_2 *satisfy* (2.3) *and* $\mathsf{supp}(Q_1) \subset \Omega$. *Then for* $T_* \le T \le T^*$

$$F_{t\to h^{-1}\tau}\bigl(\chi_T(t) Q_{2x} u(x,y,t)\, {}^t Q_{1y}\bigr) = O(h^{2M}). \tag{2.33}$$

Proof. It is standard, due to Proposition 2.13, microhyperbolicity condition and the results of Chapter 2 of [Ivr1] we conclude that if $|\ell| = 1$ and

$$\langle \ell, \nabla_\xi A^0(\xi)\rangle \ge \epsilon_0 \qquad \forall \xi \in \mathsf{supp}(Q_1) \tag{2.34}$$

and

$$\langle \ell, x-y\rangle \le \epsilon_1 T \qquad \forall x \in \mathsf{supp}(\phi_1),\ y \in \mathsf{supp}(\phi_2), \tag{2.35}$$

then $\|\phi_2 e^{ih^{-1}tA} Q_1 \phi_2\| = O(h^{2M})$ for $T \le t \le 2T$.

This implies (2.33) provided $\mathsf{diam}(\mathsf{supp}(Q_1)) \le \epsilon$. But then for (2.33) we can drop this assumption. □

2.6 End of the Proof

Now we conclude that

$$F_{t\to h^{-1}\tau}\bigl([\bar\chi_T(t) - \bar\chi_{T_*}(t)] Q_{2x} u(x,y,t)\, {}^t Q_{1y}\bigr)\big|_{x=y} = O(h^{2M}) \tag{2.36}$$

and since

$$F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t) Q_{2x} u(x,y,t)\, {}^t Q_{1y}\bigr)\big|_{x=y} = \sum_{0\le n\le M} \kappa'_n(x,\varepsilon) h^{1-d+n} + O(h^{M+1}) \tag{2.37}$$

holds for $T = T_*$, it also holds for $T = T^*$.

Finally, Hörmander's Tauberian theorem implies Theorem 1.8.

3 Generalizations and Discussion

3.1 Matrix Operators

Consider now $n \times n$-matrix operators A^0 and B; then (1.2) should be understood in the matrix sense. Assume that

(3.1) Symbol $A^0(\xi)$ has only simple eigenvalues $a_1^0(\xi), \dots, a_n^0(\xi)$, which also satisfy (1.4) and (1.16).

Then there exists a unitary transformation $R^0 = R(\xi)$, such that $R^{0\,\dagger}(\xi)A^0(\xi)R^0(\xi) = \mathsf{diag}(a_1^0(\xi), \dots, a_n^0(\xi))$.

Then one can prove easily, that there exists a unitary operator $R(x, hD) = R^0(hD) + \varepsilon R'(x, D)$, such that $R^* A R = \mathsf{diag}(a_1, \dots, a_n)$, where $a_j = a_j(x, hD) = a_j^0(hD) + \varepsilon b_j(x, hD)$ (and we assume as before that (2.17) holds.

If Conditions 1.2–1.6 are fulfilled for $A(x, hD)$, then they are also fulfilled for $a_j(x, hD)$ and we can apply the same propagation arguments as before and Theorem 1.8 extends to such operators provided conditions (1.4) and (1.16) are fulfilled for $a_j(x, hD)$ with $j = 1, \dots, n$.

Let us replace (1.2) by more general ellipticity assumption

$$|A^0(\xi)v| \ge \epsilon |\xi|^m |v| \qquad \forall v \in \mathbb{C}^n \ \forall \xi \colon |\xi| \ge C_0. \tag{3.2}$$

Then we cannot restrict $e(x, y, \lambda)$ to $x = y$ but we can restrict $e(x, y, \lambda, \lambda')$, the Schwartz kernel of the difference of the corresponding projectors.

Theorem 1.8 trivially extends to such operators, if instead of $e(x, x, \lambda)$ we consider $e(x, x, \lambda, \lambda')$ provided conditions (1.4) and (1.16) are fulfilled for $a_j(x, hD)$ with $j = 1, \dots, n$ and for both λ and λ'. It also extends to

$$\int e(x, y, \lambda, \lambda')\phi(\lambda')\, d\lambda', \qquad \phi \in \mathscr{C}_0^\infty(\mathbb{R}), \tag{3.3}$$

provided conditions (1.4) and (1.16) are fulfilled for $a_j(x, hD)$ with $j = 1, \dots, n$ for λ.

Remark 3.1. Our reduction construction fails in the case of a scalar operator A^0 and a matrix operator B unless either $\varepsilon = h^{1+\delta}$ or the principal symbol of B satisfies some very restrictive condition. Therefore for a matrix operator A^0 with the eigenvalues of $A^0(\xi)$ of constant multiplicities our construction works only under similar assumptions.

3.2 Perturbations

Consider operators in question, perturbed by $\varepsilon V(x, hD)$ where $V(x,\xi)$ decays as $|x| \to \infty$. Such perturbations do not affect $\mathsf{N}_h(\lambda)$, but they do affect $e_h(x, x, \lambda)$.

Decaying Perturbations. We start from the easy case

$$A = A^0(hD) + \varepsilon V(x, hD), \tag{3.4}$$

where

$$|D_\xi^\alpha D_x^\beta V(x,\xi)| \le c_{\alpha\beta}(|\xi|+1)^m(|x|+1)^{-\delta-|\beta|} \qquad \forall \alpha,\beta\ \forall x,\xi. \tag{3.5}$$

First of all, we claim that

(3.6) Under assumption (3.7) below the propagation speed with respect to ξ does not exceed $c\varepsilon(|x|+1)^{-\delta}$.

Indeed, note first that due to Proposition 2.2 the propagation speed with respect to ξ does not exceed $c\varepsilon$. Next, consider domain $\{x\colon |x| \asymp r\}$ with $r \ge 1$. Scaling $x \mapsto x/r$, $t \mapsto t/r$ we get a domain $\{x\colon |x| \asymp 1\}$, $h \mapsto \hbar = h/r$ and we need to prove that after this scaling the propagation speed with respect to ξ does not exceed $\nu = c\varepsilon r^{-\delta}$, on the time interval $\{t\colon |t| \le 1\}$.

To prove this we can apply Proposition 2.2 but ewe need to have the microlocal uncertainty principle fulfilled: $\nu \ge \hbar^{1-\sigma}$ with $\sigma > 0$, where ν is a shift with respect to ξ. This inequality is equivalent to $\varepsilon r^{-\delta} \ge h^{1-\sigma} r^{-1+\sigma}$ i.e. $\varepsilon r^{1-\sigma-\delta} \ge h^{1-\sigma}$ and it suffice to have

$$\delta < 1, \qquad \varepsilon \ge h^{1-\sigma} \quad \text{with} \quad \sigma > 0. \tag{3.7}$$

To join different time intervals one can use the technique of Subsection 12.7.6.

Consider now ξ in the vicinity of $\bar\xi$ and x with $|x| \le c$. Then as long as $|\xi - \bar\xi| \le \epsilon$ with small enough constant $\epsilon > 0$, evolution goes away from 0 with the speed $\asymp 1$, so we are in the zone $\{x\colon |x| \asymp |t|\}$ and in this zone the propagation speed with respect to ξ does not exceed $c\varepsilon r^{-1-\delta}$, and therefore $|\xi - \bar\xi| \le c\varepsilon \int_1^\infty t^{-1-\delta}\,dt \le c\varepsilon$ and this is less that $\epsilon/2$ as $\varepsilon \le \epsilon_0$.

We can also consider evolution which starts from x with $|x| \ge 1$. Then the same arguments work albeit with $r \asymp |t - t^*|$ for some t^* with $|t^*| \le c|x|$.

Then we arrive to

Theorem 3.2. *Consider operator* (3.4) *with* V *satisfying* (3.5). *Let microhyperbolicity condition* (1.4) *on the energy level* λ *be fulfilled and* $\varepsilon \le \epsilon_0$. *Then the complete spectral asymptotics* (1.29) *holds.*

Hybrid Perturbations. Now we consider the hybrid operators, containing both εB and εV. However, trying to eliminate εB by the same approach as in Subsubsection 2.5.2, we get an another type of terms, and it is only natural to consider them being in the operator from the beginning:

$$A = A^0(hD) + \varepsilon\big(B(x, hD) + V(x, hD)\big), \tag{3.8}$$

where

$$V(x,\xi) = \sum_{\theta\in\Theta} e^{i\langle\theta,x\rangle} V_\theta(x,\xi), \tag{3.9}$$

$$|D_\xi^\alpha D_x^\beta V(x,\xi)| \le c_{\alpha\beta}(|\xi|+1)^m(|x|+1)^{-\delta} \quad \forall\alpha,\beta\ \forall x,\xi. \tag{3.10}$$

We impose condition

Condition 3.3. *For each* ω *and* L *for the same set* Θ' *as before there exists*

$$V'(x,\xi) = \sum_{\theta\in\Theta'} e^{i\langle\theta,x\rangle} V'_\theta(x,\xi), \tag{3.11}$$

such that

$$\|D_x^\alpha D_\xi^\beta\big(V - V'\big)\|_{\mathscr{L}^\infty} \le \omega^{-L}(|\xi|+1)^m \tag{3.12}$$

and

$$|D_x^\alpha D_\xi^\beta V'_\theta| \le c_{Ls\alpha\beta}(|x|+1)^{-1-\delta-|\alpha|}(|\theta|+1)^{-s} \tag{3.13}$$

$$\forall\alpha,\beta\colon |\alpha|\le L, |\beta|\le L\ \forall s.$$

Non-Resonant Zone. We deal with the purely exponential terms in our standard way and with the hybrid terms as if they were purely exponential (i.e. as if V'_θ were not depending on x), then a new kind of terms will be produced: they acquire factor $h(A^0(\xi+\theta h/2) - A^0(\xi-\theta h/2))^{-1}$ and the derivative with respect to x to V'_θ.

Eventually we end up with the operator of the same type (3.8) with $B(x,\xi)$ replaced by $B''(\xi)$ and with $V_\theta(x,\xi)$ replaced by $V''_\theta(x,\xi)$, such that

$$|D_\xi^\alpha D_x^\beta V''_\theta(x,\xi)| \le C_{n\alpha\beta}\varepsilon^{k+1}\gamma^{-2k-n-|\alpha|}(|x|+1)^{-n-\delta-|\beta|}$$

with $n+k \ge 3K$.

Then

$$|D_\xi^\alpha D_x^\beta \big[V''_\theta(x,\xi)e^{i\langle\theta,x\rangle}\big]| \le C_{s\alpha\beta}\varepsilon^{k+1}\gamma^{-2k-n-|\alpha|}(|x|+1)^{-n-\delta}(|\theta|+1)^{|\beta|};$$

recall that $|\theta| \le CKh^{-\sigma}$.

Let us pick up $\gamma = h^\delta$ with $\delta = \vartheta/6K$. Then, ignoring therms with $k \ge K$ which are negligible, and following the proof of (3.6), we can recover the same statement for the operator after transform, and, finally, to the analogue of Proposition 2.9.

Resonant Zone. If $d = 2$ we arrive to the analogue of Proposition 2.2 in the virtue of the we arguments as in Subsubsection 2.5.1.

If $d \ge 3$ we apply the reduction, similar to one, used in Subsubsection 2.5.3, and arrive again to operator of the type (3.8) with B replaced by $B''(x,\xi')$ and with $V_\theta(x,\xi)$ replaced by $V''_\theta(x,\xi)$.

Then we observe that the shift in direction $\mathbb{R}^d \ominus \mathfrak{V}$ does not exceed $c\varepsilon^{\delta/2}$ and if it is $\ll \gamma^2$ we arrive to the analogue of Proposition 2.13. It is doable by the choice of really small $\sigma_1 < ... < \sigma_{d-1}$. Then we arrive to the analogue of Proposition 2.14 and, finally, to

Theorem 3.4. *Let A be a self-adjoint operator* (3.8)*, where A^0 satisfies* (1.1), (1.2), (1.4) *and* (1.16) *and B satisfies* (1.1)*, V satisfies* (3.9) *and* (3.10).

Let Conditions 1.2–3.3 be fulfilled. Then for $|\tau-\lambda| < \epsilon$, $\varepsilon \le h^\vartheta$, $\vartheta > 0$ asymptotics (1.29) *holds.*

3.3 Differentiability

It also follows from Corollary 1.9 that

$$\frac{1}{\nu}\Big[\mathsf{N}_{h,\varepsilon}(\tau+\nu) - \mathsf{N}_{h,\varepsilon}(\tau)\Big] = \frac{1}{\nu}\Big[\mathcal{N}_{h,\varepsilon}(\tau+\nu) - \mathcal{N}_{h,\varepsilon}(\tau)\Big] + O(h^\infty) \tag{3.14}$$

provided $\nu \ge h^M$, where $\mathcal{N}_{h,\varepsilon}(\tau)$ is the right-hand expression of (1.30).

The question remains, if (3.14) holds for smaller ν, in particular, if it holds in $\nu \to 0$ limit? If the latter holds, then

$$\frac{\partial}{\partial\tau}\mathsf{N}_{h,\varepsilon}(\tau) = \frac{\partial}{\partial\tau}\mathcal{N}_{h,\varepsilon}(\tau) + O(h^\infty) \tag{3.15}$$

and we call the left-hand expression the *density of states*.

It definitely is not necessarily true, at least in dimension 1. From now on we consider only asymptotics with respect to $\tau \to +\infty$. Let $A = \Delta + V(x)$ with periodic V. It is well-known that for $d = 1$ and generic periodic V all spectral gaps are open which contradicts to

$$\frac{\partial}{\partial \tau}\mathsf{N}(\tau) = \frac{\partial}{\partial \tau}\mathcal{N}(\tau) + O(\tau^{-\infty}). \tag{3.16}$$

On the other hand, this objection does not work in case $d \geq 2$ since only several the lowest spectral gaps are open (Bethe-Sommerfeld conjecture, proven in [PS]).

Assume for simplicity, that $A = \Delta + V$ has no negative eigenvalues; then we can apply wave operator method[8]. We consider $u(x, y, t)$, the Schwartz kernel of $\cos(\sqrt{A}t)$,

$$u(x, y, t) = \int \cos(t\tau)\, d_\tau e(x, y, \tau^2). \tag{3.17}$$

Then, for compactly supported V [9]

$$u(x, y, t) = \begin{cases} O(e^{-\epsilon|t|}) & \text{for odd } \ d, \\ O(|t|^{-d}) & \text{for even } \ d \end{cases} \tag{3.18}$$

as $|x| + |y| \leq c$, $|t| \to +\infty$ and $\frac{\partial}{\partial \tau} e(x, x, \tau^2)$ could be completely restored by inverse $\cos$-Fourier transform, without any Tauberian theorem, and we arrive to asymptotics of $\frac{\partial}{\partial \tau} e(x, x, \tau^2)$. Moreover, we can differentiate complete asymptotics of the *Birman-Krein spectral shift function*

$$\xi(\tau) := \int \bigl(e(x, x, \tau^2) - e^0(x, x, \tau^2)\bigr)\, dx \sim \sum_{n \geq 0} \bar{\kappa}_n \tau^{-d+n}, \tag{3.19}$$

with

$$\bar{\kappa}_n := \int (\kappa_n(x) - \kappa_n^0)\, dx, \tag{3.20}$$

where $e^0(x, y, \tau)$ and κ_n^0 correspond to $A^0 = \Delta$. In the case of $A = \Delta$ in the exterior of smooth, compact and non-trapping obstacle and $A^0 = \Delta$ in $\mathbb{R}^d$ such asymptotics was derived in [PP].

---

[8] It could be applied without this assumption, but with tweaking.

[9] It, probably could be proven for V, decaying fast enough at infinity

Complete Differentiable Semiclassical Spectral Asymptotics*,†

Victor Ivrii‡

Abstract

For an operator $A \coloneqq A_h = A^0(hD) + V(x, hD)$ with a "potential" V decaying as $|x| \to \infty$ we establish under certain assumptions the complete and differentiable with respect to τ asymptotics of $e_h(x, x, \tau)$ where $e_h(x, y, \tau)$ is the Schwartz kernel of the spectral projector.

1 Introduction

Consider a self-adjoint matrix operator

$$A \coloneqq A_h = A^0(hD) + V(x, hD), \tag{1.1}$$

where

$$|D_\xi^\beta A^0(\xi)| \le c_{\alpha\beta}(|\xi| + 1)^m \qquad \forall \beta\ \forall \xi \tag{1.2}$$

and

$$A^0(\xi) \ge c_0|\xi|^m - C_0 \qquad \forall \xi. \tag{1.3}$$

We assume that $A^0(\xi)$ is ξ-*microhyperbolic at energy level* λ, i.e. for each ξ there exists a direction $\ell(\xi)$ such that $|\ell(\xi)| \le 1$ and

$$(\langle \ell(\xi), \nabla_\xi \rangle A^0(\xi)v, v) + |(A^0(\xi) - \lambda)v| \ge \epsilon_0|v|^2 \qquad \forall v. \tag{1.4}$$

*2010 *Mathematics Subject Classification*: 35P20.

†*Key words and phrases*: Microlocal Analysis, differentiable complete spectral asymptotics.

‡This research was supported in part by National Science and Engineering Research Council (Canada) Discovery Grant RGPIN 13827

Further, we assume that $V(x,\xi)$ is a real-valued function, satisfying

$$|D_\xi^\alpha D_x^\beta V(x,\xi)| \le c_{\alpha\beta}(|\xi|+1)^m(|x|+1)^{-\delta-|\beta|} \qquad \forall\alpha,\beta\ \forall x,\xi \tag{1.5}$$

and

$$|D_\xi^\alpha D_x^\beta V(x,\xi)| \le \varepsilon \qquad \forall\alpha,\beta\colon |\alpha|+|\beta|\le 1\ \forall x,\xi. \tag{1.6}$$

Our main theorem is

Theorem 1.1. *Let conditions* (1.2)– (1.4) *and* (1.6) *with sufficiently small constant* $\varepsilon > 0$ *be fulfilled. Then*

(i) The complete spectral asymptotics holds for $\tau\colon |\tau-\lambda|\le\epsilon$*:*

$$e_h(x,x,\tau) \sim \sum_{n\ge 0} \kappa_n(x,\tau) h^{-d+n} \tag{1.7}$$

where $e_h(x,y,\tau)$ *is the Schwartz kernel of the spectral projector* $\theta(\tau - A_h)$ *of* A_h*.*

(ii) This asymptotics is infinitely differentiable with respect to τ*.*

Remark 1.2. (i) Statement (i) was sketched under much more restrictive assumptions in Theorem 3.2 of [Ivr3]; however we provide here more detailed exposition.

(ii) In Theorem 2.8 we provide the dependence of the remainder on $|x|$.

(iii) This asymptotics is also infinitely differentiable with respect to x but it is really easy.

Differentiability and completeness of the spectral asymptotics are really different. F.e. for operators with almost periodic with respect to x perturbation $V(x,hD)$ the spectral asymptotics are complete (see [Ivr3] and references there) but in dimension 1 it is not necessarily differentiable even once due to spectral gaps. Furthermore, if we perturb an operator we study in this paper by an appropriate "negligible" operator (i. e. with $O(h^\infty)$ norm), the absolutely continuous spectrum on the segment $[\lambda_-,\lambda_+]$ with $\lambda_\mp = \lambda + O(h^\infty)$ will be replaced by an eigenvalue of the infinite multiplicity and then the spectral asymptotics will complete albeit non-differentiable even once.

To establish spectral asymptotics we apply the "hyperbolic operator method"; namely, let us consider the Schwartz kernel of the propagator $e^{ih^{-1}tA_h}$:

$$u := u_h(x,y,t) = \int e^{ih^{-1}t\tau}\, d_\tau e_h(x,y,\tau). \tag{1.8}$$

Then under ellipticity and microhyperbolicity conditions (1.3) and (1.4)

$$F_{t\to h^{-1}\tau}\bar\chi_T(t)u_h(x,x,t) \sim \sum_{n\ge 0} \kappa'_n(x,\tau)h^{1-d+n}, \tag{1.9}$$

where here and below $\chi \in \mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1])$, $\bar\chi \in \mathscr{C}_0^\infty([-1,1])$, $\bar\chi(t)=1$ on $[-\frac12,\frac12]$, $\chi_T(t)=\chi(t/T)$ etc, $\kappa'_n(x,\tau)=\partial_\tau\kappa_n(x,\tau)$, and $T=T_*>0$ is a small constant here.

Then, due to Tauberian theorem we arrive to the spectral asymptotics with the remainder estimate $O(h^{1-d})$. Next, under different assumptions one, using propagation of singularities technique, can prove that

$$|F_{t\to h^{-1}\tau}\chi_T(t)u_h(x,x,t)| = O(h^\infty) \tag{1.10}$$

for all $T\in[T_*,T^*]$. Then (1.9) holds with $T=T^*$ and again, due to Tauberian theorem, we arrive to the spectral asymptotics with the remainder estimate $O(T^{*\,-1}h^{1-d})$ (provided $T^*=O(h^{-K})$). In particular, if (1.10) holds provided $T^*=h^{-\infty}$, we arrive to complete spectral asymptotics. This happens f.e. in the framework of [Ivr3].

However we do not have Tauberian theorems for the derivatives (with respect to τ) and we need to use an inverse Fourier transform and its derivatives

$$\partial_\tau^n e_h(x,x,\tau) = (2\pi h)^{-1}\int_{\mathbb{R}} e^{-ih^{-1}\tau t}(-ih^{-1}t)^{n-1}u_h(x,x,t)\,dt \tag{1.11}$$

for $n\ge 1$. If we insert a factor $\bar\chi_T(t)$ into integral, we will get exactly n-th derivative of the right-hand expression of (1.7). However we need to estimate the remainder

$$(2\pi h)^{-1}\int_{\mathbb{R}} e^{-ih^{-1}\tau t}(-ih^{-1}t)^{n-1}(1-\bar\chi_T(t))u_h(x,x,t)\,dt \tag{1.12}$$

and to do this we need to properly estimate the left-hand expression of (1.10) for all $T\ge T_*$ (rather than for $T\in[T_*,T^*]$).

To achieve this we will use a more subtle propagation technique and prove that for $T\ge T_*(R)$ the left-hand expression of (1.10) is $O((h/T)^\infty)$, provided $|x|\le R$.

2 Proofs

2.1 Preliminary Remarks

Observe that, due to assumptions (1.6) and (1.5) a propagation speed with respect to ξ does not exceed $\min\bigl(\varepsilon,\ C(|x|+1)^{-1-\delta}\bigr)$ and one can prove easily, that for for a generalized Hamiltonian trajectory[1)] $(x(t),\xi(t))$ on energy level $\tau \le c$

$$\Sigma_\tau := \{(x,\xi)\colon\ \mathsf{Ker}(A(x,\xi)-\tau) \ne \{0\}\} \tag{2.1}$$

with $A(x,\xi) = A^0(\xi) + V(x,\xi)$ we have $|\xi(t)-\xi(0)| \le \varepsilon'$ for all t with $\varepsilon' = \varepsilon'(\varepsilon) \to 0$ as $\varepsilon \to 0$ and therefore

(2.2) Let conditions (1.2)–(1.4), (1.5) and (1.6) with $\varepsilon = \varepsilon(\varepsilon') > 0$ with arbitrarily small ε' be fulfilled. Then for a generalized Hamiltonian trajectory $(x(t),\xi(t))$ on Σ_τ

$$|\xi(t)-\xi(0)| \le \varepsilon' \quad \text{and} \quad |x(t)-x(0)| \ge \epsilon_2|t| \qquad \forall t \in \mathbb{R}. \tag{2.3}$$

Then we conclude immediately that inequality

$$|F_{t\to h^{-1}\tau}\chi_T(t)u_h(x,x,t)| \le C'_s(T)h^s \tag{2.4}$$

holds for arbitrarily constant $T > 0$.

Combining with (1.9) for small constant T we conclude that

(2.5) Let conditions (1.2)–(1.4), (1.5) and (1.6) with sufficiently small constant $\varepsilon > 0$ be fulfilled. Then asymptotic decomposition (1.9) holds with an arbitrarily large constant T.

2.2 Propagation and Local Energy Decay

First we have the finite speed with respect to x propagation:

Proposition 2.1. *For $\tau \le c$ the following estimate holds*

$$|F_{t\to h^{-1}\tau}\Bigl(\chi_T(t)u(x,y,t)\Bigr)| \le C'_s h^s R^{-s} \tag{2.6}$$
$$\forall x,y\colon |x-y| \ge C_0 T, |x|+|y| \asymp R.$$

[1)] For a definition of the generalized Hamiltonian trajectory see Definition 2.2.8 of [Ivr1].

Proof. In the zone $\{x\colon |x| \asymp R\}$ we can apply scaling $x \mapsto xR^{-1}$, $t \mapsto tR^{-1}$, $h \mapsto hR^{-1}$ and apply the standard theory of Chapter 2 of [Ivr1]. The rest is trivial. □

Next, we consider $R \le \epsilon_1 T$ and apply energy estimate method to prove the local energy decay. Observe that one can select smooth $\ell(\xi)$ in condition (1.4). Consider operator $L^0(x, hF)$ with Weyl symbol $-\langle x, \ell(\xi)\rangle$ and $L(x, hD; t) = L^0 + \varepsilon t$.

Then

$$
\begin{aligned}
(2.7)\quad 2h^{-1}\operatorname{Re} i((hD_t - A)v, Lv)_{\Omega_T} = \\
(Lv, v)\big|_{t=0}^{t=T} - \operatorname{Re} ih^{-1}([hD_t - A, L]v, v)_{\Omega_T} = \\
(Lv, v)\big|_{t=0}^{t=T} - \varepsilon\|v\|^2_{\Omega_T} + \operatorname{Re}(ih^{-1}[A, L]v, v)_{\Omega_T},
\end{aligned}
$$

where $\|.\|_\Omega$ and $(.,.)_\Omega$ are a norm and an inner product in $\mathscr{L}^2(\Omega)$ with $\Omega = \Omega_T = \mathbb{R}^d \times [0, T] \ni (x, t)$. Indeed, writing the left-hand expression as

$$
\begin{aligned}
ih^{-1}\big[((hD_t - A)v, Lv)_{\Omega_T} - (L, (hD_t - A)v)_{\Omega_T}\big] = \\
ih^{-1}\big[(L(hD_t - A)v, v)_{\Omega_T} - ((hD_t - A)L, v)_{\Omega_T}\big] + (Lv, v)\big|_{t=0}^{t=T}
\end{aligned}
$$

because $L^* = L$, we arrive to (2.7).

In virtue of (1.5) and (1.6) for sufficiently small constant ε and for $h \le h_0(\varepsilon_1)$ the operator norm of $h^{-1}[V, L]$ from $\mathscr{H}^m(\mathbb{R}^d)$ to $\mathscr{L}^2(\mathbb{R}^d)$ does not exceed ε_1 with $\varepsilon_1 = \varepsilon_1(\varepsilon) \to 0$ as $\varepsilon \to 0$, and then due to the microhyperbolicity assumption we conclude that

$$
(2.8)\qquad \operatorname{Re}(ih^{-1}[A, L]v, v) \ge (\epsilon_0 - 2\varepsilon_1)\|v\|^2 - C\|(A - \tau)v\|^2
$$

for both $\mathbb{R}^d$ and Ω_T.

Let us plug into (2.7) $v = \varphi_\varepsilon(A - \tau)e^{ihtA}w$ where $\varphi \in \mathscr{C}_0^\infty([-1, 1])$, $0 \le \varphi \le 1$; then for sufficiently small constant $\varepsilon > 0$ we arrive to

$$
(2.9)\qquad \epsilon\|v\|^2_{\Omega_T} + (Lv, v)\big|_{t=T} \le (Lv, v)\big|_{t=0}.
$$

On the other hand,

$$
(2.10)\qquad \operatorname{Re}(Lv, v)|_{t=T} \ge \varepsilon T\|v\|^2 - C\||x|^{\frac{1}{2}}v\|^2
$$

with

$$\||x|^{\frac12}v\|^2 = \||x|^{\frac12}v\|^2_{B(0,R)} + \||x|^{\frac12}v\|^2_{B(0,R')\setminus B(0,R)} + \||x|^{\frac12}v\|^2_{\mathbb{R}^d\setminus B(0,R')}$$

with $R' = C_0T$ and therefore for $R \le \varepsilon T$

$$\operatorname{Re}(Lv, v)|_{t=T} \ge \varepsilon T\|v\|^2 - CR'\|v\|^2_{B(0,R')\setminus B(0,R)} - \||x|^{\frac12}v\|^2_{\mathbb{R}^d\setminus B(0,R')}. \tag{2.11}$$

Observe that

$$|(Lv, v)|_{t=0} \le C\Big(\|v_0\|^2 + \||x|^{\frac12}v_0\|^2\Big)$$

and then (2.9) and (2.10) imply that if $R \le \varepsilon T$ then

$$\|v\|^2_{B(0,r)} \le \sigma\|v_0\|^2 + CT^{-1}\Big(\||x|^{\frac12}v\|^2_{\mathbb{R}^d\setminus B(0,R')} + \|v_0\|^2 + \||x|^{\frac12}v_0\|^2\Big) \tag{2.12}$$

with $\sigma < 1$ and $v|_0 = v|_{t=0}$; recall that $\|v\| = \|v_0\|$.

Recall that $v = e^{ih^{-1}tA}\varphi_\varepsilon(A-\tau)\psi_R(x)w$ where we plugged $\psi_R w$ instead of w, $\psi \in \mathscr{C}_0^\infty(B(0,1))$, $0 \le \psi \le 1$ and $\psi = 1$ in $B(0, \frac12)$.

One can prove easily that $Q = \varphi_\varepsilon(A-\tau)$ is an operator with Weyl symbol $Q(x,\xi)$, satisfying

$$|D_\xi^\alpha D_x^\beta Q| \le C_{\alpha\beta}\varepsilon^{-|\alpha|-|\beta|}(|x|+1)^{-|\beta|}.$$

Then $\|v_0\|_{\mathbb{R}^d\setminus B(0,2R)} \le C(h/R)^s\|w\|$ and therefore $\||x|^{\frac12}v_0\|^2 \le 2R\|w\|^2$. Further, then Proposition 2.1 implies that $\||x|^{\frac12}v\|^2_{\mathbb{R}^d\setminus B(0,R')} \le C(h/T)^s\|w\|$ provided or $R' \ge C_0T$ with sufficiently large C_0 and we arrive to

Proposition 2.2. *In the framework of Theorem 1.1*

$$\|\psi_R e^{ih^{-1}TA}\varphi_\varepsilon(A-\lambda)\psi_R\| < 1 \tag{2.13}$$

provided $\varepsilon T \ge R \ge 1$.

While this statement looks weak, it will lead to much stronger one:

Proposition 2.3. *In the framework of Theorem 1.1*

$$\|\psi_R e^{ih^{-1}TA}\varphi_\varepsilon(A-\lambda)\psi_R\| \le C_sR^sT^{-s} \tag{2.14}$$

provided $T \ge C_0R$, $R \ge 1$.

Proof. We want to prove by induction that

$$\|\psi_R e^{inh^{-1}TA}\varphi_\varepsilon(A-\lambda)\psi_R\| \le C\nu^N + C_s n R^s T^{-s} \tag{2.15}$$

with $\nu < 1$.

Assuming that for n we have (2.15), we apply the previous arguments on the interval $[nt,(n+1)T]$ to $v = e^{ih^{-1}tA}\varphi_\varepsilon(A-\lambda)\psi_{R/2}e^{ih^{-1}nTA}\psi_R w$ and derive an estimate

$$\begin{aligned}\|\psi_R e^{ih^{-1}tA}\varphi_\varepsilon(A-\lambda)\psi_{R/2}e^{ih^{-1}nTA}\psi_R w\| \le \\ \nu\|\varphi_\varepsilon(A-\lambda)\psi_R e^{ih^{-1}nTA}\psi_R w\| + C'_K(h/R)^K\|w\|\end{aligned} \tag{2.16}$$

with $\nu < 1$.

To make a step of induction we weed to estimate the norm of

$$\begin{aligned}\psi_R e^{ih^{-1}tA}\varphi_\varepsilon(A-\lambda)(1-\psi_{R/2})e^{ih^{-1}nTA}\psi_R w = \\ \psi_R e^{ih^{-1}tA}\varphi_\varepsilon(A-\lambda)(1-\psi_{R/2})Q^+ e^{ih^{-1}nTA}\psi_R + \\ \psi_R e^{ih^{-1}tA}\varphi_\varepsilon(A-\lambda)(1-\psi_{R/2})Q^- e^{ih^{-1}nTA}\psi_R,\end{aligned} \tag{2.17}$$

with $Q^\pm = Q^\pm(x,hD)$, $Q^+ + Q^- = I$ to be selected to ensure that

(2.18) Generalized Hamiltonian trajectories on Σ_τ, starting as $t=0$ from $\operatorname{supp}(Q^\pm)\cap\operatorname{supp}(1-\psi_{R/2})$ in the positive (negative) time direction, remain in the zone $\{|x|\ge \epsilon_1 R + \epsilon_2|t|\}$.

Then we show that

$$\|\psi_R e^{ih^{-1}tA}\varphi_\varepsilon(A-\lambda)(1-\psi_{R/2})Q^+\| \le C_s(h/R)^s \tag{2.19}$$

and

$$\|\varphi_\varepsilon(A-\lambda)(1-\psi_{R/2})Q^- e^{ih^{-1}nTA}\psi_R\| \le C_s(h/R)^s. \tag{2.20}$$

To achieve that consider $A^0(\xi)$ and for each ξ in the narrow vicinity $\mathcal{W}$ of Σ_τ let $K^+(\xi)\subset\mathbb{R}^d_x\times\bar{\mathbb{R}}^+$ be a forward propagation cone and $K^-(\xi) = -K^+(\xi)$ be a backward propagation cone. Let

$$\Omega^\pm = \{(x,\xi)\colon x\notin \pi_x K^\pm(\xi)\} \tag{2.21}$$

where π_x is x-projection.

Then $\Omega^{\pm}$ are open sets and since $\pi_x K^+(\xi) \cap \pi_x K^-(\xi) = \{0\}$ we conclude that $\Omega^+ \cup \Omega^- \supset \mathbb{S}^{d-1} \times \mathcal{W}$. We can then find smooth positively homogeneous of degree 0 with respect to x symbols $q^{\pm}(x,\xi)$ supported in $\Omega^{\pm}$ such that $q^+ + q^- = 1$ on $\mathbb{S}^{d-1} \times \mathcal{W}$. Let $q^0 = 1 - (q^+ + q^-)$; then $(A^0 - \tau)$ is elliptic on $\mathsf{supp}(q^0)$.

Finally, let $Q^{\pm}$ and Q^0 be operators with the symbols $q^{\pm}(x,\xi)\phi_R(x)$ and $q^0(x|,\xi)\phi_R(x)$ correspondingly, where $\phi \in \mathscr{C}_0^{\infty}(\mathbb{R}^d \setminus 0)$, equal 1 as $c^{-1} \le |x| \le c$ with large enough constant c. Then

$$Q^+ + Q^- + Q^0 = \phi_R(x), \tag{2.22}$$

where (2.18) holds and $(A - \tau)$ is elliptic on the support of the symbol of Q^0.

Then Proposition 2.4 below implies that for $R \le \varepsilon T$ with sufficiently small constant ε both (2.19) and (2.20) hold. On the other hand, ellipticity of $(A - \tau)$ on $\mathsf{supp}(Q^0)$ implies that

$$\|\varphi_\varepsilon(A - \lambda)(1 - \psi_{R/2})Q^0\| \le C_s(h/R)^s. \tag{2.23}$$

Then we can make an induction step by n and to prove (2.15). After this, let us replace in (2.15) R and T by r and t. Next, for given R, T such that $R \le \varepsilon^3 T$ let us plug into (2.15) $n = (T/R)^{\frac{1}{3}}$, $t = T^{\frac{2}{3}}R^{\frac{1}{3}} = T/n$ and $r = T^{\frac{1}{3}}R^{\frac{2}{3}} = nR$ (obviously $r \le \varepsilon t$). We arrive to (2.14) with a different but still arbitrarily large exponent s. □

As mentioned, we need the following proposition:

Proposition 2.4. *Let conditions of Theorem 1.1 be fulfilled. Let $\bar{x} \in \mathbb{R}^d \setminus 0$, $\bar{\xi} \in \mathcal{W}$ and assume that $0 \notin \bar{x} + \pi_x K^{\mp}(\xi)$. Let $\mathcal{K}^{\mp}$ be a conical η-vicinity of $K^{\mp}(\xi)$ and $\mathcal{V}$ be ηR-vicinity of $\bar{x}$, $R = |x|$. Then*

$$\|Q' e^{\pm ih^{-1}TA} Q\| \le C_s(h/R)^s \tag{2.24}$$

provided $Q = Q(x, hD)$ and $Q' = Q'(x, hD)$ are operators with the symbols satisfying

$$|D_\xi^\alpha D_x^\beta Q| \le c_{\alpha\beta} r^{-|\beta|} \tag{2.25}$$

with $r = T + R$ and $r = R$ respectively, $R \ge R(\eta)$ and support of symbol of Q does not intersect with $\mathcal{V} + \mathcal{K}^{\mp}|_{t=T}$, symbol of Q' is supported in the sufficiently small vicinity of $(\bar{x}, \bar{\xi})$.

Proof. Considering propagation in the zone $\{x\colon |x| \asymp r\}$, we see that the propagation speed with respect to ξ does not exceed $Cr^{-1-\delta}$. To prove this we scale $x \mapsto xr^{-1}$, $t \mapsto tr^{-1}$, $h \mapsto \hbar = hr^{-1}$ and apply the standard energy method (see Chapter 2 of [Ivr1]). We leave the easy details to the reader.

Therefore for time $t \asymp r$ variation of ξ does not exceed $Cr^{-\delta}$. Then, the propagation speed with respect to $\langle x, \ell(\bar{\xi})\rangle$ (which increases) is of magnitude 1 (as long as ξ remains in the small vicinity of $\bar{\xi}$). Again, to prove it we scale and apply the energy method (see Chapter 2 of [Ivr1]).

But then the contribution of the time interval $t \asymp r$ to the variation of ξ does not exceed $Cr^{-\delta}$ and therefore the variation of ξ for a time interval $[0, T]$ with $T \ge 0$ does not exceed $CR^{-\delta} \le \eta$ for $R \ge R(\eta)$. □

Proposition 2.5. *In the framework of Theorem 1.1*

$$\|\psi_R e^{ih^{-1}TA}\varphi_\varepsilon(A-\lambda)\psi_R\| \le C_s h^s, \tag{2.26}$$

provided $T \ge C_0 R$, $R \ge 1$.

Proof. It follows immediately from Proposition 2.4 with the semiclassical parameter hr^{-1} and with r set to its minimal value along the cone of propagation, which is 1. □

Combining Propositions 2.3 and 2.5 we arrive to

Corollary 2.6. *In the framework of Theorem 1.1*

$$\|\psi_R e^{ih^{-1}TA}\varphi_\varepsilon(A-\lambda)\psi_R\| \le C_s h^s R^s T^{-s} \tag{2.27}$$

provided $T \ge C_0 R$, $R \ge 1$.

2.3 Traces and the End of the Proof

Proposition 2.7. *In the framework of Theorem 1.1 the following estimates hold for* $T \ge 1$

$$|F_{t\to\tau}\chi_T(t)u(x,x,t)| \le C_s h^s (|x|+1)^{s+1}((|x|+1)+T)^{-s}, \tag{2.28}$$

$$|F_{t\to\tau}\chi_T(t)\int \psi_R(x)u(x,x,t)\,dx| \le C_s h^s T^{-s}, \tag{2.29}$$

provided $\psi \in \mathscr{C}_0^\infty(B(0,1))$. *Further,*

$$|F_{t\to\tau}\chi_T(t)\int \psi_R(x)u(x,x,t)\,dx| \le C_s h^s R^{-s} T^{-s}, \tag{2.30}$$

provided $\psi \in \mathscr{C}_0^\infty(B(0,1)\setminus B(0,\frac{1}{2}))$.

Proof. Estimate (2.28) follows immediately from (2.26). Estimate (2.30) follows from (2.26) and

$$|F_{t\to\tau}\chi_T(t)\int \psi_R(x)u(x,x,t)\,dx| \le C_s h^s R^{-s} T,$$

which holds because we can chose the time direction on the partition element (see Chapter 4 of [Ivr1]) and we chose the one in which $|x| \gtrsim R$ (which is possible; see the part of proof of Proposition 2.3 dealing with $Q^\pm$ and Q^0).

Finally, estimate (2.29) follows from (2.30). □

Then we immediately arrive to the following theorem, which in turn implies Theorem 1.1:

Theorem 2.8. *In the framework of Theorem 1.1 the following estimates hold*

$$|\partial_\tau^k\Big(e(x,x,\tau) - \sum_{n\le N-1}\kappa_n(x,\tau)h^{-d+n}\Big)| \le C_N h^{-d+N}(|x|+1)^{-N} + C_s h^s(|x|+1)^k \tag{2.31}$$

and for $\psi \in \mathscr{C}_0^\infty(B(0,1))$

$$|\partial_\tau^k\int\Big(e(x,x,\tau) - \sum_{n\le N-1}\kappa_n(x,\tau)h^{-d+n}\Big)\psi_R(x)\,dx| \le C_N h^{-d+N}. \tag{2.32}$$

2.4 Discussion

Corollary 2.9. *Let conditions of Theorem 1.1 be fulfilled. Assume that*

$$|D_x^\alpha V| \le c_\alpha(|\xi|+1)^m(|x|+1)^{-d-|\alpha|-\delta}. \tag{2.33}$$

Then the asymptotics of the Birman-Schwinger spectral shift function

$$\mathsf{N}_h(\tau) := \int\Big(e_h(x,x,\tau) - e_h^0(x,x,\tau)\Big)\,dx \sim \sum_{n\ge 0}\varkappa h^{-d+n} \tag{2.34}$$

is infinitely differentiable with respect to τ. *Here* $e_h^0(x,x,\tau) = \kappa_0^0 h^{-d}$ *and* $e_h^0(x,y,\tau)$ *is the Schwartz kernel of spectral projector for* $A^0(hD)$, *and*

$$\varkappa_n(\tau) = \int \bigl(\kappa_n(x,\tau) - \delta_{n0}\kappa^0\bigr)\,dx. \tag{2.35}$$

Indeed, condition (2.33) guarantees the absolute convergence of integrals in (2.35).

Remark 2.10. Our results could be easily generalized to non-semi-bounded elliptic A^0 (like in Subsection 3.1 of [Ivr3]). Then instead of $e(x,y,\lambda)$ one needs to consider $e(x,y,\lambda,\lambda')$ the Schwartz kernel of $\theta(\lambda - A) - \theta(\lambda' - A)$ and either impose conditions for both λ and λ', or only for λ and mollify with respect to λ'.

It looks strange that the last term in the remainder estimate (2.31) increases as $|x|$ increases, but so far I can neither improve it to the uniform with respect to x in the general case, nor show by the counter-example that such improvement is impossible. However I hope to prove

Conjecture 2.11. *Assume in addition that* A^0 *is a scalar operator and* $\Sigma_\lambda^0 = \{\xi\colon A^0(\xi) = \lambda\}$ *is a* strongly convex surface *i.e.*

$$\pm \sum_{j,k} A^0_{\xi_j\xi_k}(\xi)\eta_j\eta_k \ge \epsilon|\eta|^2 \qquad \forall \xi \in \Sigma_\lambda^0 \quad \forall \eta\colon \sum_j A^0_{\xi_j}(\xi)\eta_j = 0, \tag{2.36}$$

where the sign depends on the connected component of Σ_λ, *containing* ξ.

Then the last term in the right-hand expression of (2.31) *could be replaced by* $C_s h^s(|x|+1)^{k-d}$.

Rationale here is that only few Hamiltonian trajectories from x with $|x| = R \gg 1$ pass close to the origin and even they do not spend much time there.

Bethe-Sommerfeld Conjecture in Semiclassical Settings*,†

Victor Ivrii‡

Abstract

Under certain assumptions (including $d \geq 2$) we prove that the spectrum of a scalar operator in $\mathscr{L}^2(\mathbb{R}^d)$

$$A_\varepsilon(x, hD) = A^0(hD) + \varepsilon B(x, hD),$$

covers interval $(\tau - \epsilon, \tau + \epsilon)$, where A^0 is an elliptic operator and $B(x, hD)$ is a periodic perturbation, $\varepsilon = O(h^\varkappa)$, $\varkappa > 0$.

Further, we consider generalizations.

1 Introduction

1.1 Preliminary Remarks

This work is inspired by a paper [PS3] by L. Parnovski and A. Sobolev, in which a classical Bethe-Sommerfeld conjecture was proven for operators $(-\Delta)^m + B(x, D)$ with operator B of order $< 2m$. In this paper the crucial role was played by a (pseudodifferential) gauge transformation and thorough analysis of the resonant set, both introduced in the papers of L. Parnovski and R. Shterenberg [PSh1, PSh2, PSh3], S. Morozov, L. Parnovski and R. Shterenberg [MPS] and earlier papers by A. Sobolev [So2, So2], devoted to complete asymptotics of the integrated density of states.

* *2010 Mathematics Subject Classification*: 35P20.

† *Key words and phrases*: Microlocal Analysis, sharp spectral asymptotics, integrated density of states, periodic operators, Bethe-Sommerfeld conjecture.

‡This research was supported in part by National Science and Engineering Research Council (Canada) Discovery Grant RGPIN 13827

Later in [Ivr3] I used the gauge same transformation in the semiclassical settings, which allowed me to generalize the results and simplify the proofs of those papers[1)]. Now I would like to apply this gauge transform to Bethe-Sommerfeld conjecture in the semiclassical settings. The results obtained are more general (except the smoothness with respect to ξ assumptions in [PS3] are more general than here) and the proofs are simpler.

Consider a scalar self-adjoint h-pseudo-differential operator $A_h := A(x, hD)$ in $\mathbb{R}^d$ with the Weyl symbol $A(x,\xi)$, such that[2)]

$$|D_x^\alpha D_\xi^\beta A(x,\xi)| \le c_{\alpha\beta}(|\xi|+1)^m \qquad \forall \alpha,\beta \tag{1.1}$$

and

$$A(x,\xi) \ge c_0|\xi|^m - C_0 \qquad \forall (x,\xi)\in \mathbb{R}^{2d}. \tag{1.2}$$

Then A_h is semibounded from below. Also we assume that it is Γ-periodic with the *lattice of periods* Γ:

$$A(x+\mathsf{y},\xi) = A(x,\xi) \qquad \forall x\in\mathbb{R}^n \quad \forall \mathsf{y}\in\Gamma. \tag{1.3}$$

We assume that Γ is non-degenerate[3)] and denote by Γ^* the *dual lattice*:

$$\gamma\in\Gamma^* \iff \langle \gamma,\mathsf{y}\rangle \in 2\pi\mathbb{Z} \quad \forall \mathsf{y}\in\Gamma; \tag{1.4}$$

since we use Γ^* and it's elements in the paper much more often, than Γ and it's elements, it is more convenient for us to reserve notation γ for elements of Γ^*.

Also let $\mathcal{O} = \mathbb{R}^d/\Gamma$ and $\mathcal{O}^* = \mathbb{R}^d/\Gamma^*$ be *fundamental domains*; we identify them with domains in $\mathbb{R}^d$.

It is well-known that $\mathsf{Spec}(A)$ has a *band-structure*. Namely, consider in $\mathscr{L}^2(\mathcal{O})$ operator $A_h(\xi) = A(x, hD)$ with the *quasi-periodic boundary condition*:

$$u(x+\mathsf{y}) = e^{i\langle \mathsf{y},\xi\rangle}u(x) \qquad \forall x\in\mathcal{O} \quad \forall \mathsf{y}\in\Gamma \tag{1.5}$$

with $\xi\in\mathcal{O}^*$; it is called a *quasimomentum*. Then $\mathsf{Spec}(A_h(\xi))$ is discrete

$$\mathsf{Spec}(A_h(\xi)) = \bigcup_n \lambda_{n,h}(\xi) \tag{1.6}$$

[1)] The other components of the proof were not only completely different, but in the framework of the different paradigm.

[2)] In fact, we consider $A_h := A(x, hD, h)$.

[3)] I.e. with the $\Gamma = \{\mathsf{y} = n_1\mathsf{y}_1 + \ldots + n_d\mathsf{y}_d,\ (n_1,\ldots,n_d)\in\mathbb{Z}^d\}$ with linearly independent $\mathsf{y}_1,\ldots,\mathsf{y}_d\in\mathbb{R}^d$.

and depends on ξ continuously. Further,

$$\mathsf{Spec}(A_h) = \bigcup_{\xi\in\mathcal{O}^*} \mathsf{Spec}(A_h(\xi)) =: \bigcup_n \Lambda_{n,h}, \tag{1.7}$$

with the *spectral bands* $\Lambda_{n,h} := \bigcup_{\xi\in\mathcal{O}^*}\{\lambda_{n,h}(\xi)\}$.

One can prove that the with of the spectral band near energy level τ is $O(h)$. Spectral bands could overlap but they also could leave uncovered intervals, called *spectral gaps*. It follows from [Ivr3] that in our assumptions (see below) the width of the spectral gaps near energy level τ is $O(h^\infty)$. Bethe-Sommerfeld conjecture in the semiclassical settings claims that there are no spectral gaps near energy level τ (in the corresponding assumptions, which include $d \ge 2$).

1.2 Main Theorem (Statement)

We assume that

$$A_h := A(x, hD) = A^0(hD) + \varepsilon B(x, hD), \tag{1.8}$$

where $A^0(\xi)$ satisfies (1.1), (1.2) and $B(x,\xi)$ satisfies (1.1) and (1.3) and $\varepsilon > 0$ is a small parameter. For $A^0(\xi)$ instead of $\lambda_n(\xi)$ we have

$$\lambda^0_\gamma(\xi) := A^0(h(\gamma+\xi)) \qquad \text{with } \ \gamma\in\Gamma^*. \tag{1.9}$$

Recall that (as in [Ivr3])

$$B(x,\xi) = \sum_{\gamma\in\Gamma} b_\gamma(\xi) e^{i\langle\gamma,x\rangle} \tag{1.10}$$

with $\Theta = \Gamma^*$ where due to (1.1)

$$|D^\beta_\xi b_\gamma(\xi)| \le C_{L\beta}(|\gamma|+1)^{-L}(|\xi|+1)^m \qquad \forall\beta \quad \forall (x,\xi)\in\mathbb{R}^{2d} \tag{1.11}$$

with an arbitrarily large exponent L.

Theorem 1.1. *Let $d \ge 2$ and let operator A_h be given by* (1.8) *with $\varepsilon = O(h^\vartheta)$ with arbitrary $\varkappa > 0$ and with $A^0_h = A^0(hD)$ satisfying* (1.1), (1.2) *and $B(x,\xi)$ satisfying* (1.1) *and* (1.3).

Further, assume that the microhyperbolicity *and* strong convexity *conditions on the energy level τ are fulfilled:*

$$|A^0(\xi)-\tau|+|\nabla_\xi A^0(\xi)|\ge \epsilon_0 \tag{1.12}$$

and

$$\pm\sum_{j,k} A^0_{\xi_j\xi_k}(\xi)\eta_j\eta_k \ge \epsilon_0|\eta|^2 \qquad \forall \xi\colon A^0(\xi)=\tau \quad \forall \eta\colon \sum_j A^0_{\xi_j}(\xi)\eta_j=0. \tag{1.13}$$

Furthermore, assume that there exists $\xi\in\Sigma_\tau$ such that for every $\eta\in\Sigma_\tau$, $\eta\ne\xi$, such that $\nabla_\eta A^0(\eta)$ is parallel to $\nabla_\xi A^0(\xi)$ [4]

(1.14) *Σ_τ, intersected with some vicinity of η and shifted by $(\xi-\eta)$, coincides in the vicinity of ξ with $\{\zeta\colon \zeta_k=g(\zeta_{\hat k}\}$ and Σ_τ coincides in the vicinity of ξ with $\{\zeta\colon \zeta_k=f(\zeta_{\hat k}\}$* [5] *and $\nabla^\alpha(f-g)(0)\ne 0$ for some $\alpha\colon |\alpha|=2$* [6].

Then $\mathsf{Spec}(A_h)\supset[\tau-\epsilon,\tau+\epsilon]$ for sufficiently small $\epsilon>0$.

Remark 1.2. (i) If Σ_τ is strongly convex and connected then for every $\xi\in\Sigma_\tau$ there exists exactly one antipodal point $\eta\in\Sigma_\tau$; then $\nu<0$ and assumption (1.14) is fulfilled. In particular, if $A^0(\xi)=|\xi|^m$, then $\eta=-\xi$ and $\nu=-1$.

(ii) If Σ_τ is is strongly convex and consists of p connected components, then the set $\mathfrak{Z}(\xi)=\{\eta\in\Sigma_\tau,\eta\ne\xi\colon \nabla_\eta A^0(\eta)\parallel\nabla_\xi A^0(\xi)\}$ contains exactly $2p-1$ elements, and for p of them $\nu<0$ and assumption (1.14) is fulfilled for sure, while for $(p-1)$ of them $\nu>0$.

1.3 Idea of the Proof and the Plan of the Paper

One needs to understand, how gaps could appear, why they appear if $d=1$ and why it is not the case if $d\ge 2$. Observe that $\lambda_n(\xi)$ can be identified with some $\lambda^0_\gamma(\xi)$ only locally, if $\lambda^0_\gamma(\xi)$ is sufficiently different from $\lambda^0_{\gamma'}(\xi)$ for any $\gamma'\ne\gamma$.

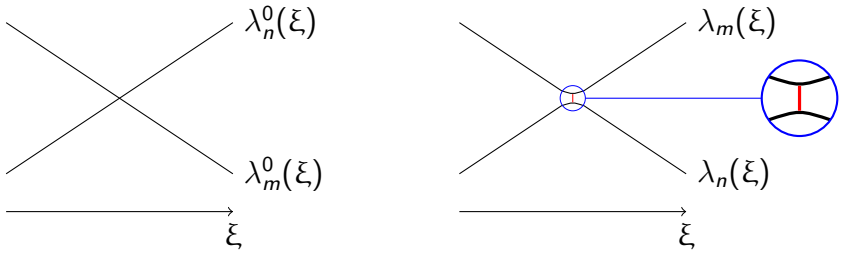
[4] I.e. $\eta A^0(\eta)=\nu\nabla_\xi A^0(\xi)$ with $\nu\ne 0$; we call η *antipodal point.*

[5] With $\zeta_{\hat k}$ meaning all coordinates except ζ_k.

[6] Obviously $\nabla(f-g)(0)=0$. One can prove easily, that if this condition holds at ξ with some $\alpha\colon|\alpha|>2$, then changing slightly ξ, we make it fulfilled with $|\alpha|=2$.

Indeed, in the basis of eigenfunctions of $A^0_\xi(hD)$ [7] perturbation $\varepsilon B(x,hD)$ can contain out-of-diagonal elements $\varepsilon b_{\gamma-\gamma'}(\xi)$ and such identification is possible only if $|\lambda^0_\gamma(\xi)-\lambda^0_{\gamma'}(\xi)|$ is larger than the size of such element.

If $d=1$, $A^0(\xi)=\xi^2$ and $\varepsilon\le\epsilon' h$ with sufficiently small $\epsilon'>0$ and $\tau\asymp 1$, it can happen only if γ' coincides with $-\gamma$ or with one of two adjacent points in Γ^* and $|\xi-\frac12(\gamma+\gamma')|=O(\varepsilon h^\infty)$. This exclude from possible values of either $\lambda^0_\gamma(\xi)$ or $\lambda^0_{\gamma'}(\xi)$ the interval of the width $O(\varepsilon h^\infty)$ and on such interval can happen (and really happens for a generic perturbation) the realignment:



(a) (b)

Figure 28.1: Spectral gap is a red interval

If $d\ge 2$ the picture becomes more complicated: there are much more opportunities for $\lambda^0_\gamma(\xi)$ and $\lambda^0_{\gamma'}(\xi)$ to become close, even if γ and γ' are not that far away; on the other hand, there is a much more opportunities for us to select $\xi=h(\gamma+\xi)\in\Sigma_\tau$ and then to adjust ξ so that $\xi=h(\gamma+\xi)$ remains on Σ_τ but $\eta=h(\gamma'+\xi)$ moves away from Σ_τ sufficiently far away[8] and then tune-up ξ once again so that $\tau\in\mathsf{Spec}(A_h(\xi))$.

In fact, we prove the following statement which together with Theorem 1.1 (which follows from it trivially) are semiclassical analogue of Theorem 2.1 of [PS3]:

Theorem 1.3. *In the framework of Theorem 1.1 there exist n and ξ^* such that $\lambda_n(\xi^*)=\tau$ and $\lambda_n(\xi)$ covers interval $[\tau-\upsilon h,\tau+\upsilon h]$ when ξ runs ball $\mathsf{B}(\xi^*,\upsilon)$ while $|\lambda_m(\xi)-\tau|\ge\epsilon\upsilon h$ for all $m\ne n$ and $\xi\in\mathsf{B}(\xi^*,\upsilon)$. Here*

$$\upsilon=\epsilon\begin{cases} h^{(d-1)^2}\min(1,\ \varepsilon^{-3(d-1)/2}h^{(d-1)+\sigma}) & d\ge 3,\\ h\min(|\log h|^{-1},\ \varepsilon^{-3/2}h^\sigma) & d=2\end{cases}\tag{1.15}$$

[7] Consisting of $\exp(i\langle x,\gamma+\xi\rangle)$.

[8] This will happen if either $\nabla_\eta A^0(\eta)$ differs from $\nu\nabla_\xi A^0(\xi)$, or if coincides with it but (1.14) is fulfilled.

with arbitrarily small exponent $\sigma > 0$.

Proof of Theorem 1.3 occupies two next sections. In Section 2 we reduce operator in the vicinity of Σ_τ to the block-diagonal form and study its structure. To do this we need to examine the structure of the resonant set of the operator. In Section 3 we prove Theorem 1.3 and thus Theorem 1.1.

Finally, in Section 4 we discuss our results and the possible improvements.

2 Reduction of Operator

2.1 Reduction

On this step we reduce A to the block-diagonal form in the vicinity of Σ_τ

$$\Omega_\tau := \{\xi\colon |A^0(\xi) - \tau| \le C\varepsilon h^{-\delta}\}. \tag{2.1}$$

In what follows, we assume that $\varepsilon \ge h$, i.e.

$$h \le \varepsilon \le h^\vartheta, \qquad \vartheta > 0. \tag{2.2}$$

To do this we need just to repeat with the obvious modifications definitions and arguments of Sections 1 and 2 of [Ivr3]. Namely, now $\Theta := \Gamma^*$ is a non-degenerate lattice rather than the pseudo-lattice, as it was in that paper, and all conditions 1.2, 1.3, 1.5, 1.6, and 3.3, are fulfilled with $\Theta' := \Theta \cap B(0,\omega)$ with $\omega = h^{-\varkappa}$ where we select sufficiently small $\varkappa > 0$ later and $\Theta'_K = \Theta \cap B(0, K\omega)$ be an arithmetic sum of K copies of Θ' with sufficiently large K to be chosen later.

We call point ξ *non-resonant* if

$$|\langle \nabla_\xi A^0(\xi), \theta\rangle| \ge \rho \qquad \forall \theta \in \Theta'_K \setminus 0 \tag{2.3}$$

with $\rho \in [\varepsilon^{1/2} h^{-\delta}, h^\delta]$ with arbitrarily small $\delta > 0$. Otherwise we call it *resonant*. More precisely

$$\Lambda := \bigcup_{\theta\in\Theta'_K\setminus 0} \Lambda(\theta), \tag{2.4}$$

where $\Lambda(\theta)$ is the set of ξ, violating (2.3) for given $\theta \in \Theta'_K \setminus 0$.

It obviously follows from the microhyperbolicity and strong convexity assumptions (1.12) and (1.13) that

(2.5) μ_τ-measure[9] of $\Lambda\cap\Sigma_\tau$, does not exceed $C_0 r^{d-1}\rho$ and Euclidean measure of $\Lambda \cap \{\xi\colon |A^0(\xi) - \tau| \le \varsigma\}$ does not exceed $C_0 r^{d-1}\rho\varsigma$, where $r = Kh^{-\varkappa}$.

Indeed, $(d-1)$-dimensional measure of $\{x\colon |x| = 1,\ |\langle x, \theta\rangle| \le \rho\}$ does not exceed $C_0|\theta|^{-1}\rho$ and and due to microhyperbolicity and strong convexity assumptions maps $\Sigma_\tau \to \nabla A^0(\xi)/|\nabla A^0(\xi)| \in \mathbb{S}^{d-1}$ and

$$\{\xi\colon |A^0(\xi) - \tau| \le \varsigma\} \to (\nabla A^0(\xi)/|\nabla A^0(\xi)|, A^0(\xi)) \in \mathbb{R}^d$$

are diffeomorphisms.

Furthermore, according to Proposition 2.7 of [Ivr3] that on the non-resonant set one can "almost" diagonalize $A(x, hD)$. More precisely

Proposition 2.1. *Let assumptions* (1.12) *and* (1.13) *be fulfilled.*

(i) Then there exists a periodic pseudodifferential operator $P = P(x, hD)$ such that

$$\bigl(e^{-i\varepsilon h^{-1}P} A e^{i\varepsilon h^{-1}P} - \mathcal{A}\bigr) Q \equiv 0 \tag{2.6}$$

with

$$\mathcal{A} = A^0(hD) + \varepsilon B'(hD) + \varepsilon B''(x, hD) \tag{2.7}$$

modulo operator from $\mathscr{H}^m$ to $\mathscr{L}^2$ with the operator norm $O(h^M)$ with M arbitrarily large and $K = K(M, d, \delta)$ in the definition of non-resonant point provided $Q = Q(hD)$ has a symbol, supported in $\{\xi\colon |A^0(\xi) - \tau| \le 2\varepsilon h^{-\delta}\}$.

Here $P(x, hD)$, $B'(hD)$ and $B''(x, hD)$ are operator with Weyl symbols of the same form (1.10) *albeit such that*

$$|D_\xi^\alpha D_x^\beta P| \le c_{\alpha\beta}\rho^{-1-|\alpha|} \qquad \forall \alpha, \beta, \tag{2.8}$$

$$|D_\xi^\alpha D_x^\beta B''| \le c'_{\alpha\beta}\rho^{-|\alpha|} \qquad \forall \alpha, \beta, \tag{2.9}$$

and symbol of B' also satisfies (2.9).

(ii) Further,

$$\xi \notin \Lambda(\theta) \implies b''_\theta(\xi) = 0. \tag{2.10}$$

and $B'(\xi)$ coincides with $b_0(\xi)$ modulo $O(\varepsilon\rho^{-2})$.

[9] $\mu_\tau = d\xi : dA^0(\xi)$ is a natural measure on Σ_τ.

In what follows

$$\mathcal{A}^0(hD) \coloneqq A^0(hD) + \varepsilon B'(hD) \qquad \text{and} \qquad \mathcal{B} \coloneqq B''(x, hD). \tag{2.11}$$

Remark 2.2. (i) Eigenvalues of $\mathcal{A}^0$ are

$$\lambda_\gamma(\xi) = \mathcal{A}^0(h(\gamma + \xi)). \tag{2.12}$$

(ii) If $\xi = h(\gamma + \xi)$ is non-resonant, then due to (2.10) in $\epsilon'\rho$-vicinity of ξ this $\lambda_\gamma(\xi)$ is also an eigenvalue of $\mathcal{A}$.

(iii) Without any loss of the generality one can assume that

$$|\theta| \ge \varepsilon h^{-\delta} \implies b''_\theta = 0. \tag{2.13}$$

We assume that this is the case.

(iv) Let us replace operator $\mathcal{A}$ defined by (2.7) by operator

$$\mathcal{A}' = \mathcal{A}^0(hD) + \varepsilon \mathcal{B}'(x, hD), \qquad \mathcal{B}'(x, hD) = T(hD)\mathcal{B}T(hD) \tag{2.14}$$

with $T(hD)$ operator with symbol $T(\xi)$ which is a characteristic function of Ω_τ defined by (2.1) with $C = 6$. Then (2.6) holds.

From now on $\mathcal{A} \coloneqq \mathcal{A}'$ and $\mathcal{B} \coloneqq \mathcal{B}'$.

It would be sufficient to prove Theorem 1.3 for operator $\mathcal{A}$. Indeed,

Proposition 2.3. *(i) For each point* $\lambda \in \mathsf{Spec}(A(\xi)) \cap \{|\lambda - \tau| \le \varepsilon h^{-\delta}\}$ $\mathsf{dist}(\lambda, \mathsf{Spec}(\mathcal{A}(\xi)) \le Ch^M$.

(ii) Conversely, for each point $\lambda \in \mathsf{Spec}(\mathcal{A}(\xi)) \cap \{|\lambda - \tau| \le \varepsilon h^{-\delta}\}$ $\mathsf{dist}(\lambda, \mathsf{Spec}(A(\xi)) \le Ch^M$.

(iii) Furthermore, if $\lambda \in \mathsf{Spec}(A(\xi)) \cap \{|\lambda - \tau| \le \varepsilon h^{-\delta}\}$ *is a simple eigenvalue separated from the rest of* $\mathsf{Spec}(A(\xi))$ *by a distance at least* $2h^{M-1}$, *then there exists* $\lambda' \in \mathsf{Spec}(\mathcal{A}(\xi)) \cap \{|\lambda' - \lambda| \le Ch^M\}$ *separated from the rest of* $\mathsf{Spec}(\mathcal{A}(\xi))$ *by a distance at least* h^{M-1}.

(iv) Conversely, if $\lambda' \in \mathsf{Spec}(\mathcal{A}(\xi)) \cap \{|\lambda - \tau| \le \varepsilon h^{-\delta}\}$ *is a simple eigenvalue separated from the rest of* $\mathsf{Spec}(\mathcal{A}(\xi))$ *by a distance at least* $2h^{M-1}$, *then there exists* $\lambda \in \mathsf{Spec}(A(\xi)) \cap \{|\lambda' - \lambda| \le Ch^M\}$ *separated from the rest of* $\mathsf{Spec}(A(\xi))$ *by a distance at least* h^{M-1}.

Proof. Trivial proof is left to the reader. □

Remark 2.4. One can generalize Statements (iii) and (iv) of Proposition 2.3 from simple eigenvalues to subsets of $\mathsf{Spec}(A(\xi))$ and $\mathsf{Spec}(\mathcal{A}(\xi))$ separated by the rest of the spectra; these subsets will contain the same number of elements.

2.2 Classification of Resonant Points

We start from the case $d = 2$. Then we have only one kind of resonant points $\Xi_1 = \Lambda$. If $d \ge 3$ then there are $(d-1)$ kinds of resonant points. First, following [PS3] consider *lattice spaces* $\mathfrak{V}$ spanned by n linearly independent elements $\theta_1, \dots, \theta_n \in \Gamma^* \cap \mathsf{B}(0, r)$, where we take $r = Kh^{-\varkappa}$. Let $\mathcal{V}_n$ be the set of all such spaces.

It is known [PS3] that

Proposition 2.5. *For $\mathfrak{V} \in \mathcal{V}_n$, $\mathfrak{W} \in \mathcal{V}_m$ either $\mathfrak{V} \subset \mathfrak{W}$, or $\mathfrak{W} \subset \mathfrak{V}$ or the angle*[10] *between $\mathfrak{V}$ and $\mathfrak{W}$ is at least ϵr^{-L} with $L = L(d)$ and $\epsilon = \epsilon(d, \Gamma)$.*

Fix $0 < \delta_1 < \dots < \delta_n$ arbitrarily small and for $\mathfrak{V} \in \mathcal{V}_n$ let us introduce

$$\Lambda(\mathfrak{V}, \rho_n) := \{\xi \in \Omega_\tau : |\langle \nabla_\xi A^0(\xi), \theta\rangle| \le \rho_n |\theta| \quad \forall \theta \in \mathfrak{V}\} \tag{2.15}$$

with $\rho_n = \varepsilon^{\frac{1}{2}} h^{-\delta_n}$.

We define Ξ_n by induction. First, $\Xi_d = \emptyset$. Assume that we defined $\Xi_d, \dots, \Xi_{n+1}$. Then we define

$$\Xi_n := \bigcup_{\mathfrak{V} \in \mathcal{V}_n,\ \xi \in \Lambda(\mathfrak{V}) \cap \Omega_\tau} (\xi + \mathfrak{V}) \cap \Omega_\tau. \tag{2.16}$$

It follows from Proposition 2.5 that

Proposition 2.6. *Let $\varkappa > 0$ in the definition of Θ' and $\delta > 0$ in the definition of Ω_τ be sufficiently small*[11]*. Then for sufficiently small h*

(i) $\Xi_n \subset \bigcup_{\mathfrak{V} \in \mathcal{V}} \Lambda(\mathfrak{V}, 2\rho_n)$.

[10] This angle $\widehat{(\mathfrak{V}, \mathfrak{W})}$ is defined as the smallest possible angle between two vectors $v \in \mathfrak{V} \ominus (\mathfrak{V} \cap \mathfrak{W})$ and $w \in \mathfrak{W} \ominus (\mathfrak{V} \cap \mathfrak{W})$.

[11] They depend on ϑ and $\delta_1, \dots, \delta_n$.

(ii) If $\xi \notin \Xi_{n+1}$ *and* $\xi \in \xi' + \mathfrak{V}$, $\xi \in \xi'' + \mathfrak{W}$ *for* $\xi' \in \Lambda(\mathfrak{V})$, $\xi'' \in \Lambda(\mathfrak{W})$ *with* $\mathfrak{V}, \mathfrak{W} \in \mathcal{V}_n$, *then* $\mathfrak{V} = \mathfrak{W}$.

Corollary 2.7. *Let* $\varkappa > 0$ *in the definition of* Θ' *and* $\delta > 0$ *in the definition of* Ω_τ *be sufficiently small*[11)]. *Let* h *be sufficiently small.*

Then for each $\xi \in \Xi_n \setminus \Xi_{n+1}$ *is defined just one* $\mathfrak{V} = \mathfrak{V}(\xi)$ *such that* $\xi \in \xi' + \mathfrak{V}$ *for some* $\xi' \in \Lambda(\mathfrak{V})$.

(2.17) We slightly change definition of Ξ_n: $\xi = h(\gamma + \xi) \in \Xi_{n,\mathsf{new}}$ iff $h\gamma \in \Xi_n$. From now on $\Xi_n := \Xi_{n,\mathsf{new}}$.

Consider $\xi', \xi'' \in \Xi_n \setminus \Xi_{n+1}$. We say that $\xi' \cong \xi''$ if there exists $\xi \in \mathfrak{V}$, $\mathfrak{V} \in \mathcal{V}$ such that $\xi', \xi'' \in \xi + \mathfrak{V}$ and if $\xi' - \xi'' \in \Gamma$. In virtue of above

(2.18) This relation is reflexive, symmetric and transitive.

For $\xi \in \Xi_n$ we define

$$\mathfrak{X}(\xi) = \{\xi' : \xi' \cong \xi\}. \tag{2.19}$$

Then

$$\mathsf{diam}(\mathfrak{X}(\xi)) \le C\rho_{d-1}. \tag{2.20}$$

2.3 Structure of Operator $\mathcal{A}$

For $\xi \in \Xi_n \setminus \Xi_{n+1}$ denote by $\mathfrak{H}(\xi)$ the subspace $\mathscr{L}^2(\mathcal{O})$ consisting of functions of the form

$$\sum_{\xi' \in \mathfrak{X}(\xi)} c_{\xi'} e^{i\langle x, \xi'\rangle}. \tag{2.21}$$

In virtue of the properties of $\mathcal{A}$ and $\mathcal{B}$ and of resonant sets we arrive to

Proposition 2.8. *Let* $\varkappa > 0$ *in the definition of* Θ' *and* $\delta > 0$ *in the definition of* Ω_τ *be sufficiently small*[11)]. *Let* h *be sufficiently small.*

Then for $\xi \in \Xi_n \setminus \Xi_{n+1}$ *operators* $\mathcal{B}$ *and* $\mathcal{A}$ *transform* $\mathfrak{H}(\xi)$ *into* $\mathfrak{H}(\xi)$.

Let us denote by $\mathcal{A}_\gamma(\xi)$ and $\mathcal{B}_\gamma(\xi)$ restrictions of $\mathcal{A}$ and $\mathcal{B}$ to $\mathfrak{H}(h(\gamma + \xi))$. Here for $n = 0$ we consider Ξ_0 to be the set of all non-resonant points and $\mathfrak{X}(\xi) = \{\xi\}$ for $\xi \in \Xi_0$.

Then due to Propositions 2.5 and 2.8 we arrive to

Proposition 2.9. *(i) For each point* $\lambda \in \mathsf{Spec}(A(\xi)) \cap \{|\lambda - \tau| \le \varepsilon h^{-\delta}\}$ *exists* $\gamma \in \Gamma^*$ *such that* $\xi = h(\gamma + \xi) \in \Omega_\tau$ *and* $\mathsf{dist}(\lambda, \mathsf{Spec}(\mathcal{A}_\gamma(\xi)) \le Ch^M$.

(ii) Conversely, for each point $\lambda \in \mathsf{Spec}(\mathcal{A}_\gamma(\xi)) \cap \{|\lambda - \tau| \le \varepsilon h^{-\delta}\}$ *and* $\xi = h(\xi + \gamma)$, $\mathsf{dist}(\lambda, \mathsf{Spec}(A(\xi)) \le Ch^M$.

(iii) Further, if $\lambda \in \mathsf{Spec}(A_\gamma(\xi)) \cap \{|\lambda - \tau| \le \varepsilon h^{-\delta}\}$ *is a simple eigenvalue separated from the rest of* $\mathsf{Spec}(A(\xi))$ *by a distance at least* $2h^{M-1}$, *then there exist* γ *and* λ', *such that for* $\xi = h(\gamma+\xi)$, $\lambda' \in \mathsf{Spec}(\mathcal{A}(\xi)) \cap \{|\lambda' - \lambda| \le Ch^M\}$, *separated from the rest of* $\mathsf{Spec}(\mathcal{A}_\gamma(\xi))$ *by a distance at least* h^{M-1} *and from* $\bigcup_{\gamma' \in \Gamma^*,\ \gamma' \ne \gamma} \mathsf{Spec}(\mathcal{A}_{\gamma'}(\xi)$ *by a distance at least* h^{M-1} *as well.*

(iv) Conversely, if $\lambda' \in \mathsf{Spec}(\mathcal{A}_\gamma(\xi)) \cap \{|\lambda - \tau| \le \varepsilon h^{-\delta}\}$ *is a simple eigenvalue separated from the rest of* $\mathsf{Spec}(\mathcal{A}_\gamma(\xi))$ *by a distance at least* $2h^{M-1}$, *and also separated from* $\bigcup_{\gamma' \in \Gamma^*,\ \gamma' \ne \gamma} \mathsf{Spec}(\mathcal{A}_{\gamma'}(\xi))$ *by a distance at least* $2h^{M-1}$, *then there exists* $\lambda \in \mathsf{Spec}(A(\xi)) \cap \{|\lambda' - \lambda| \le Ch^M\}$ *separated from the rest of* $\mathsf{Spec}(A(\xi))$ *by a distance at least* h^{M-1}.

Proof. Proof is trivial. □

3 Proof of Theorem 1.3

3.1 Choosing γ^*

The first approximation is $\xi^* \in \Sigma_\tau$ satisfying (1.14). Any $\xi \in \Sigma_\tau$ in ϵ'-vicinity of ξ^* also fits provided $\epsilon' > 0$ is sufficiently small.

(3.1) One can select $\xi^*_{\mathsf{new}} \in \Sigma_\tau$ such that $|\xi^*_{\mathsf{new}} - \xi^*| \le h^\delta$ and ξ^*_{new} satisfies (1.14) with $\rho = \gamma := h^\delta$. Here $\delta > 0$ is arbitrarily small and $\varkappa = \varkappa(\delta)$.

Indeed, it follows from (2.5). From now on $\xi^* := \xi^*_{\mathsf{new}}$.

Then, according to Proposition 2.1 we can diagonalize operator in γ-vicinity of ξ^* and there $\rho = \gamma$. Then there

$$|\nabla^\alpha(\mathcal{A}^0 - A^0)| \le C_\alpha(\varepsilon + \varepsilon^2 \rho^{-2-|\alpha|}) \tag{3.2}$$

and in particular

$$|\nabla^\alpha(\mathcal{A}^0 - A^0)| \le Ch^\delta \qquad \text{for } |\alpha| \le 2. \tag{3.3}$$

Let

$$\Sigma'_\tau = \{\xi\colon \mathcal{A}^0(\xi) = \tau\}. \tag{3.4}$$

Then in the non-resonant points we are interested in functions $\lambda_\gamma(\xi) = \mathcal{A}^0(h(\gamma+\xi))$ rather than in $\lambda^0_\gamma(\xi) = A^0(h(\gamma+\xi))$. One can prove easily the following statements:

Proposition 3.1. *(i) One can select $\xi^* := \xi^*_{\mathsf{new}} \in \Sigma'_\tau$ satisfying* (1.14) *and non-resonant with $\rho = \gamma$.*

(ii) Further, all antipodal to ξ^* points $\xi^*_1,\dots,\xi^*_{2p-1}$ have the same properties.

Let $\xi^* =: h(\gamma^* + \xi^*)$, $\gamma^* \in \Gamma^*$ and $\xi^* \in \mathcal{O}^*$. Then values in the nearby points are sufficiently separated:

$$|\lambda_\gamma(\xi) - \lambda_{\gamma^*}(\xi)| \ge \epsilon h^{1+\delta} \qquad \forall \gamma\colon |\gamma-\gamma^*| \le Kh^{-\varkappa}\ \ \forall \xi \in \mathcal{O}^*. \tag{3.5}$$

Indeed, $|\gamma-\gamma^*| \le Kh^{-\varkappa}$ implies that $(\gamma-\gamma^*) \in \Theta'_K$ and then

$$|\langle \nabla \mathcal{A}^0(\xi^*), \gamma-\gamma^*\rangle| \ge \gamma$$

while

$$|\lambda_\gamma(\xi) - \lambda_{\gamma^*}(\xi) - h\langle \nabla \mathcal{A}^0(\xi^*), \gamma-\gamma^*\rangle| \le Ch^{3-3\varkappa}.$$

3.2 Non-Resonant Points

Consider other non-resonant points (with $\rho = \varepsilon^{1/2}h^{-\delta}$). Let us determine how $\lambda_\gamma(\xi)$ changes when we change ξ. Due to (3.3)

$$\delta\lambda_\gamma := \lambda_\gamma(\xi+\delta\xi) - \lambda_\gamma(\xi) = h\langle \nabla A^0(\xi), \delta\xi\rangle + O(h^2|\delta\xi|^2). \tag{3.6}$$

To preserve $\lambda_{\gamma^*}(\xi) = \tau$ in the *linearized settings* we need to shift ξ by $\delta\xi$ which is orthogonal to $\nabla_\xi \mathcal{A}(\xi^*)$.

Let us take $\delta\xi = t\eta$

$$\ell\colon |\eta| = 1, \qquad \langle \nabla \mathcal{A}^0(\xi^*), \eta\rangle = 0. \tag{3.7}$$

Then in all non-resonant ξ the shift will be $\langle \nabla_\xi \mathcal{A}(\xi), \delta\xi\rangle$ with an absolute value $|\langle \nabla_\xi \mathcal{A}(\xi), \eta\rangle| \cdot |t|$.

Case $d = 2$. Let us start from the easiest case $d = 2$. Without any loss of the generality we assume that ξ^* is strictly inside $\mathcal{O}^*$ (at the distance at least $C\epsilon^*$ from the border). Then there is just one tangent direction η and

$$|\langle \nabla_\xi \mathcal{A}^0(\xi)|_{\xi=h\gamma}, \eta\rangle| \asymp |\sin \varphi(\gamma^*, \gamma)| \asymp h \min_{1\le k\le 2p} |\gamma - \gamma_k^*| \tag{3.8}$$

where $\varphi(\gamma^*, \gamma)$ is an angle between $\nabla_\xi \mathcal{A}^0(\xi)|_{\xi=h\gamma^*}$ and $\nabla_\xi \mathcal{A}^0(\xi)|_{\xi=h\gamma}$, and $\xi_1^*, \dots, \xi_{2p-1}^*$ are antipodal points, and $\xi_{2p}^* = \xi^*$.

As long as $\min_{1\le k\le 2p} |\gamma - \gamma_k^*| \gtrsim h^{1-\varkappa}$ we may replace here $\xi = h(\gamma + \xi)$ by $\xi = h\gamma$ and $\mathcal{A}^0$ by $\mathcal{A}$. In the nonlinear settings to ensure that

$$\lambda_{\gamma^*}(\xi^* + \delta\xi(t)) = \tau \tag{3.9}$$

we need to include in $\delta\xi(t)$ a correction: $\delta\xi(t) = t\eta + O(t^2)$ but still

$$\frac{d}{dt}\lambda_\gamma(\xi^* + \delta\xi(t)) \asymp h\langle \nabla_\xi \mathcal{A}(\xi)|_{\xi=h\gamma}, \eta\rangle^{-1}. \tag{3.10}$$

Then the set $\mathcal{T}(\xi) := \{t\colon |t| \le \epsilon_0,\ |\mathcal{A}^0(\xi(t)) - \tau| \le \upsilon h\}$ is an interval of the length $\asymp \upsilon$ and then the union of such sets over $\xi = h\gamma + \xi$ with indicated γ does not exceed $R\upsilon$ with

$$R := \sum_\gamma |\langle \nabla_\xi \mathcal{A}(\xi)|_{\xi=h\gamma}, \eta\rangle|^{-1}, \tag{3.11}$$

where we sum over set $\{\gamma\colon |\gamma - \gamma^*| \gtrsim h^{-\varkappa}\ \&\ |\lambda_\gamma(h\gamma) - \tau| \le 2Ch\}$. The last restriction is due to the fact that $\mathcal{T}(\xi) \ne \emptyset$ only for points with $|\lambda_\gamma(h\gamma) - \tau| \le 2Ch$.

One can see easily that $R \asymp h^{-1}|\log h|$. Then, as $R\upsilon \le \epsilon'$ the set $[-\epsilon_0, \epsilon_0] \setminus \bigcup_\gamma \mathcal{T}(h(\gamma + \xi))$ contains an interval of the length $\ell = \upsilon$ and for all t, belonging to this interval,

$$|\lambda_\gamma(h(\gamma + \xi + \delta\xi(t))) - \tau| \ge \epsilon\upsilon h. \tag{3.12}$$

Then we need to take $\upsilon = \epsilon R^{-1} = \epsilon h|\log h|^{-1}$ and for $d = 2$ as far as non-resonant are concerned, Theorem 1.3 is almost proven[12)].

[12)] We need to cover almost antipodal points and it will be done in the end of this subsection. We need to consider resonant points and as well, and it will be done in the next subsection.

Case $d \ge 3$. In this case we need to be more subtle and to make $(d-1)$ steps. We start from the point $\xi^* = h(\gamma^* + \xi^*)$; again without any loss of the generality we assume that ξ^* is strictly inside $\mathcal{O}^*$ (at the distance at least $C\epsilon^*$ from the border). Then after each step below it still will be the case (with decreasing constant).

Step I. On the first step we select $\eta = \eta_1$ and consider only γ such that (3.8) holds; more precisely, the left-hand expression needs to be greater than the right-hand expression, multiplied by ϵ [13]. Then $R \asymp h^{1-d}$ and therefore exists ξ^* such that $\lambda_{\gamma^*}(\xi^*) = \tau$ and $|\lambda_\gamma(\xi^*) - \tau| \ge \epsilon\upsilon_1 h$ with $\upsilon_1 = \epsilon h^{d-1}$ for all γ indicated above.

Step II. On the second step we select $\eta = \eta_2$ perpendicular to η_1. To preserve inequality (3.12) (with smaller constant ϵ) for γ, already covered by *Step I*, we need to take $|\delta\xi| \le \epsilon'\upsilon_1$ and consider $\delta\xi = t\eta_2 + O(t^2)$.

Then the same arguments as before results in inequality (3.12) with $\upsilon := \upsilon_2 = \epsilon R^{-1}\upsilon_1$ for a new bunch of points. Then for $d = 3$ as far as non-resonant are concerned, Theorem 1.3 is almost proven[13].

Next steps. Continuing this process, on k-th step we select η_k orthogonal to $\eta_1, \dots, \eta_{k-1}$. Then we get $\upsilon_k = \epsilon R^{-1}\upsilon_{k-1}$ and on the last $(d-1)$-th step we achieve a separation at least $\upsilon_{d-1} = \epsilon R^{1-d}$.

Remark 3.2. In Subsection 4.1 we discuss how to increase υ for $d \ge 3$.

Almost Antipodal Points. We need to cover points with $|\xi - \xi_k^*| \le h^{1-\kappa}$ for $k = 1, \dots, 2p-1$ and as we already know for each k (and fixed ξ) there exists no more than one such point $\xi = h(\gamma + \xi)$ with $|\lambda_\gamma(\xi) - \tau| \lesssim h^{1+\delta}$.

We take care of such points during *Step I*. Observe that during this step we automatically take care of any point with

$$|\nabla_\xi \mathcal{A}^0(\xi), \eta_1\rangle| \ge \epsilon h, \tag{3.13}$$

assuming that $|t| \le \epsilon_0$ with sufficiently small $\epsilon_0 = \epsilon_0(\epsilon)$.

Let us select η_1 so that on η_1 quadratic forms at points $\xi_1^*, \dots, \xi_{2p-1}^*$ in condition (1.14) are different from one at point ξ^* by at least ϵ_0. Then for each $j = 1, \dots, 2p-1$ the the measure of the set

$$\{t\colon |t| \le \epsilon_0,\ |\lambda_{\gamma_j}(\xi + \delta\xi(t))| \le \upsilon h\}$$

[13] One can see easily, that the opposite inequality holds.

does not exceed $Ch^{-1}(\upsilon h)^{\frac{1}{2}}$, and then the measure of the union of such sets (by j) also does not exceed it and therefore for $\upsilon_1 = \epsilon_1 h^{d-1}$ (for $d \ge 3$) and $\upsilon_1 = \epsilon_1 h|\log h|^{-1}$ (for $d = 2$) with sufficiently small ϵ_1 we can find $t\colon |t| \le \epsilon_0$ so that condition (3.8) is fulfilled for all non-resonant points.

3.3 Resonant Points

Next on this step we need to separate $\lambda_{\gamma^*}(\xi)$ from all $\lambda_n(\xi)$ (save one, coinciding with it) by the distance at least υh by choosing ξ. We can during the same steps as described in the previous section: let $\lambda_{\gamma j}(\xi)$ denote eigenvalues of $\mathcal{A}_\gamma(\xi)$ with $j = \#\mathfrak{X}(\gamma h)$.

Observe that both $\mathcal{A}_\gamma(\xi)$ and $\#\mathfrak{X}(\gamma h)$ depend on the equivalency class $[\gamma]$ of γ rather than on γ itself and that

$$\sum_{[\gamma]} \#\mathfrak{X}(\gamma h) = \sum_{1\le n\le d-1} \#(\Xi_n) = O(h^{1-d+\sigma'} + \varepsilon^{3/2} h^{-d-\sigma}), \tag{3.14}$$

where on the left $[\gamma]$ runs over all equivalency classes with $\gamma \in \bigcup_{1\le n\le d-1} \Xi_n$.

We also observe that for resonant points

$$|\sin \varphi(\xi, \xi^*)| \ge \epsilon h^{\delta} \tag{3.15}$$

and therefore for λ'_γ, which are eigenvalues of $\mathcal{A}^0(h(\gamma + \xi))$ [14] (3.10) holds and signs are the same for γ in the same block. On the other hand,

$$|\frac{d}{dt}\mathcal{B}(h(\gamma + \xi^* + \delta\xi(t))| \le C\varepsilon h \ll h^{1+\delta'} \tag{3.16}$$

and therefore for $\lambda_{\gamma,j}(t)$ which are eigenvalues of $\mathcal{A}_{[\gamma]}(\xi)$ (3.10) sill holds.

Therefore the arguments of each *Step I*, *Step II* etc extends to resonant points as well. However the number of *new points* to be taken into account on each step is given by the right-hand expression of (3.14) and therefore R needs to be redefined

$$R := h^{1-d} + \varepsilon^{3/2} h^{-d-\sigma}. \tag{3.17}$$

This leads to the final expression (1.15) for υ. Theorem 1.3 is proven.

[14] Recall, that $\mathcal{A}^0$ is diagonal matrix.

4 Discussion

4.1 Improving υ

Can we improve (increase) expression for υ given by (1.15)? I do not know if one can do anything with the restriction $\upsilon \le \epsilon\varepsilon^{-\frac{3}{2}(d-1)}h^{d(d-1)}$ which is due to resonant points, but restriction $\upsilon \le \epsilon h^{(d-1)^2}$ could be improved for $d \ge 3$, which makes sense only if

$$h \le h \le h^{\frac{2}{3}-\sigma}. \tag{4.1}$$

Indeed, on Step n, $n \ge 2$, we need to take into account only non-resonant points belonging to the set

$$\mathcal{J} := h(\Gamma^* + \xi) \cap \{\xi : |\mathcal{A}^0(\xi) - \tau| \le C\upsilon_{n-1}h\}. \tag{4.2}$$

Determination of upper estimate for such number falls into realm of the Number Theory. I am familiar only with the estimate

$$\#\mathcal{J} \le Ch^{1-d}\upsilon_{n-1} + Ch^{2-d-2/(d+1)}, \tag{4.3}$$

which follows from Theorem at page 224 of [Gui]. Probably it was improved, but those improvement have no value here.

The second term in the right-hand expression of (4.2) is larger, however, the second term in the right-hand expression of (3.17) is still larger and therefore on each Step $n \ge 2$ we have $R := \varepsilon^{3/2}h^{-d-\sigma}$, and this leads us to the following improvement of Theorem 1.3:

Theorem 4.1. *In the framework of Theorem 1.1, under additional assumptions $d \ge 3$ and* (4.1)*, the statement of Theorem 1.3 holds with*

$$\upsilon = \epsilon\varepsilon^{-3(d-2)/2}h^{d^2-d-1-\sigma} \tag{4.4}$$

with arbitrarily small exponent $\sigma > 0$. In particular, $\upsilon = \epsilon h^{d^2-5d/2+3-\sigma}$ for $\varepsilon = h$.

Remark 4.2. One can try to improve further (4.4) for $\varepsilon \le h$. In this case resonant points become the main obstacle. In the definition of resonant points we need to take $\rho = h^{1/2-\delta}$; however only resonant points ξ with

$$\mathfrak{X}(\xi) \cap \{\xi' : |\mathcal{A}^0(\xi') - \tau| \le C(\upsilon_{n-1}h + \varepsilon)\} \ne \emptyset$$

should be taken into account on n-th step.

4.2 Condition (1.14)

We know that for connected component Σ_τ this condition (1.14) is fulfilled automatically.

On the other hand, let $\Sigma_\tau = \bigcup_{1\le j\le p} \Sigma_\tau^{(j)}$ with connected $\Sigma_\tau^{(j)}$. Let $p = 2$ and condition (1.14) be violated at each point of Σ_τ. Does it mean that $\Sigma_\tau^{(2)} = \Sigma_\tau^{(1)} + \eta$ (i.e. $\Sigma_\tau^{(1)}$ shifted by η)?

Next, let $\Sigma_\tau^{(j)} = \Sigma_\tau^{(1)} + \eta_j$ for $j = 2, \dots, q$. Then for these components instead of condition (1.14) one can impose the similar condition involving level surfaces $\sigma_{\tau,\varepsilon}$ of $\mathcal{A}^0(\xi) + \varepsilon B_0(\xi)$. This would affect only *Step I* of our analysis, leading to $\upsilon_{1,\mathsf{new}} := \min(\varepsilon h, \upsilon_1)$ with υ_1 defined without taking into account of antipodal points. Since $\upsilon_1 \le h^{d-1}$ anyway, under assumption $\varepsilon \ge h$ we get the same formulae for υ for $d \ge 3$ as stated in Theorems 1.3 and 4.1, while for $d = 2$ we get

$$\upsilon = h \min(\varepsilon,\ \varepsilon^{-3/2} h^{\sigma}). \tag{4.5}$$

4.3 Differentiability

Definitely our result would follow from the asymptotics of the *density of states*

$$\mathsf{N}'_h(\tau) := \frac{d\mathsf{N}_h(\tau)}{d\tau} = (\kappa'_0(\tau) + o(1))h^{-d} \qquad \text{as} \quad h \to +0, \tag{4.6}$$

where

$$\mathsf{N}_h(\tau) = \int_{\mathcal{O}^*} \mathsf{N}_h(\xi, \tau)\, d\xi \tag{4.7}$$

is an *integrated density of states:*

$$\mathsf{N}_h(\xi, \tau) = \#\{\mu < \tau,\ \mu \ \text{ is an eigenvalue of } \ A_h(\xi)\}. \tag{4.8}$$

However, despite $\mathsf{N}_h(\xi, \tau)$ has a complete asymptotics (see f.e. [Ivr3]), we do not know anything about asymptotics of $\mathsf{N}'_h(\tau)$ (even $\mathsf{N}'_h(\tau) \asymp h^{-d}$ is unknown).

4.4 Bethe-Sommerfeld Conjecture for Almost Periodic Perturbations

While both the proof of Bethe-Sommerfeld conjecture and the statement of Theorem 1.3 rely upon periodicity, the conjecture itself (as stated in

Theorem 1.1) does not. It is only natural to try to prove it for almost periodic perturbations as in [Ivr3].

Scott and Thomas-Fermi approximations to electronic density *,†,‡

Victor Ivrii§

Abstract

In heavy atoms and molecules, on the distances $a \ll Z^{-1/2}$ from one of the nuclei (with a charge Z_m), we prove that the ground state electronic density $\rho_\Psi(x)$ is approximated in $\mathscr{L}^p$-norm by the ground state electronic density for a single atom in the model with no interactions between electrons.

Further, on the distances $a \gg Z^{-1}$ from all of the nuclei (with a charge $Z_1, \dots, Z_M$) we prove that $\rho_\Psi(x)$ is approximated in $\mathscr{L}^p$-norm, by the Thomas-Fermi density.

We cover both non-relativistic and relativistic cases.

1 Introduction

This paper is a result of my rethinking of one rather old but still remarkable article [IaLS], which I discovered recently and in which the asymptotic of the ground state electronic density on the distances $O(Z^{-1})$ from the nuclei is derived. While there are rather precise results about ground state energy, excessive charges and ionization energy asymptotics[1)] there are relatively few rigorous results about related electronic density.

1) See f.e. [Ivr1], (in particular, Chapter 25 of [Ivr1], Volume V), and [Ivr2] in non-relativistic and relativistic cases respectively.

The purpose of this paper is to provide a more refined asymptotics (with an error estimate in $\mathscr{L}^p$-norms) and on both small and large distances from the nuclei; we also cover relativistic case.

Multielectron Hamiltonian is given by

$$\mathsf{H} = \mathsf{H}_N := \sum_{1\le j\le N} H_{V,x_j} + \sum_{1\le j<k\le N} \frac{\mathsf{e}^2}{|x_j - x_k|} \tag{1.1}$$

on

$$\mathfrak{H} = \bigwedge_{1\le n\le N} \mathscr{H}, \qquad \mathscr{H} = \mathscr{L}^2(\mathbb{R}^3, \mathbb{C}^q) \simeq \mathscr{L}^2(\mathbb{R}^3 \times \{1, \dots, q\}, \mathbb{C}) \tag{1.2}$$

with

$$H_V = T - \mathsf{e}V(x), \tag{1.3}$$

describing N same type particles (electrons) in the external field with the scalar potential $-V$ and repulsing one another according to the Coulomb law; e is the charge of the electron, T is an *operator of the kinetic energy*.

In the non-relativistic framework this operator is defined as

$$T = \frac{1}{2\mu}(-i\hbar\nabla)^2. \tag{1.4}$$

In the relativistic framework this operator is defined as

$$T = \left(c^2(-i\hbar\nabla)^2 + \mu^2c^4\right)^{\frac{1}{2}} - \mu^2c^4. \tag{1.5}$$

Here

$$V(x) = \sum_{1\le m\le M} \frac{Z_m\mathsf{e}}{|x - \mathsf{y}_m|} \tag{1.6}$$

and

$$d = \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| > 0. \tag{1.7}$$

where $Z_m\mathsf{e} > 0$ and y_m are charges and locations of nuclei, μ is the mass of the electron.

It is well-known that the non-relativistic operator is always semibounded from below. On the other hand, it is also well-known [IH, LY] that it this is not necessarily true for the relativistic operator:

Remark 1.1. One particle relativistic operator is semibounded from below if and only if

$$Z_m\beta \le \frac{2}{\pi} \qquad \forall m = 1, \dots, M; \qquad \beta := \frac{\mathsf{e}^2}{\hbar c}. \tag{1.8}$$

We replace (1.8) it by a strict inequality:

$$Z_m\beta \le \frac{2}{\pi} - \epsilon \qquad \forall m = 1, \dots, M; \qquad \beta := \frac{\mathsf{e}^2}{\hbar c}. \tag{1.9}$$

Remark 1.2. (i) In the non-relativistic theory by scaling with respect to the spatial and energy variables we can make $\hbar = \mathsf{e} = 1$, $\mu = \frac{1}{2}$ while Z_m are preserved.

(ii) In the relativistic theory by scaling with respect to the spatial and energy variables we can make $\hbar = \mathsf{e} = 1$, $\mu = \frac{1}{2}$ while β and Z_m are preserved.

(iii) In the corresponding single nuclei theory without electron-to-electron interaction (which is used in the proof of Strong Scott conjecture) only βZ is preserved and we can assume that $Z = 1$.

From now on we assume that such rescaling was already made and we are free to use letters $\hbar$, μ and c for other notations.

We assume that

$$N \asymp Z = Z_1 + \dots + Z_M, \qquad Z_m \asymp Z \qquad \forall m \tag{1.10}$$

and

$$d = \min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge Z^{-1/3+\sigma} \tag{1.11}$$

with $\sigma \ge 0$.

Our purpose is to consider approximations to the *electronic density*

$$\rho_\Psi(x) = N \int |\Psi(x, x_2, \dots, x_N)|^2 \, dx_2 \cdots dx_N. \tag{1.12}$$

Consider first Scott approximation on the short distances from one of the nuclei.

Theorem 1.3. *Let conditions* (1.9), (1.10) *and* (1.11) *be fulfilled and let* $U \in \mathscr{L}^\infty$ *such that*

$$\mathsf{supp}(U) \subset B(\mathsf{y}_m, a), \qquad |U| \le 1 \tag{1.13}$$

where $a \le Z^{-1/2-\varkappa}$ *with arbitrarily small* $\varkappa > 0$.

Then the following estimate holds:

$$\Big| \int U\big(\rho_\Psi - \rho_{m,\beta}\big)\, dx\Big| \le CF^{1/2}\big((Za)^{3/2}\|\langle Z(x-\mathsf{y}_m)\rangle^{-3/2}U\|_{\mathscr{L}^1}\big)^{1/2} + CG \tag{1.14}$$

with

$$F = \big(Z^{13/6-\delta}a^{-1/2} + Z^4a^3\big)Z^\varkappa \tag{1.15}$$

and

$$G = \big(Z^{7/6-\delta}a^{3/2} + Z^2a^3\big)Z^\varkappa, \tag{1.16}$$

where

$$\rho_{m,\beta}(x) = qZ_m^3\bar\rho_{Z_m\beta}(Z_m(x-\mathsf{y}_m)), \tag{1.17}$$

$\delta = \delta(\sigma) > 0$ *for* $\sigma > 0$ *and* $\delta = 0$ *for* $\sigma = 0$, $\bar\rho_\beta(x) = \bar e_\beta(x,x,0)$, $\bar e_\beta(x,y,\tau)$ *is the Schwartz kernel of the spectral projector* $\theta(\tau - H_{V^0})$ *for toy-model operator* $H_{V^0} \coloneqq H_{\beta,V^0} = T_\beta - |x|^{-1}$ *in* $\mathscr{L}^2(\mathbb{R}^3,\mathbb{C})$ *with*

$$T_\beta = \begin{cases} \Big(-\beta^{-2}\Delta + \dfrac{1}{4}\beta^{-4}\Big)^{\frac12} - \dfrac{1}{2}\beta^{-2} & \beta > 0, \\ -\Delta & \beta = 0. \end{cases} \tag{1.18}$$

Here and below $\langle x\rangle = (|x|^2+1)^{1/2}$.

Corollary 1.4. *Let* <u>*either*</u> $a \asymp Z^{-1}$ *and* $X \subset B(\mathsf{y}_m, a)$ <u>*or*</u> $Z^{-1} \le a \le Z^{-1/2-\varkappa}$ *and* $X \subset B(\mathsf{y}_m, a) \setminus B(\mathsf{y}_m, a/2)$. *Then*

(i) The following estimate holds:

$$\|\rho_\Psi - \rho_{m,\beta}\|_{\mathscr{L}^1(X)} \le CF^{1/2}(\mathsf{mes}(X))^{1/2} + CG. \tag{1.19}$$

(ii) Assume that $|\rho_\Psi| \le \omega$ *in* X *with* $\omega \ge Z^{3/2}a^{-3/2}$ [2)]. *Then for* $p = 2, 3, \dots$ *the following estimate holds:*

$$\|\rho_\Psi - \rho_{m,\beta}\|_{\mathcal{L}^p(X)} \le C\omega^{1-2(1-2^{-p})/p}\Bigl(F^{(1-2^{-p})/p}(\mathsf{mes}(X))^{2^{-p}/p} + F^{(1-2^{1-p})/p}G^{1-2^{1-p}}\Bigr) + C\omega^{1-1/p}G^{1/p}. \tag{1.20}$$

Remark 1.5. (i) F is defined by its first term, as $a \le Z^{-11/21-2/\delta/7}$ and by its second term otherwise. G is defined by its first term as $a \le Z^{-5/9-2\delta/3}$ snd by its second term otherwise.

(ii) Scott approximation definitely is not right for $a \ge Z^{-1/3}$. On the other hand, resztriction $a \le Z^{-1/2-\varkappa}$ is due to requirement of Proposition 3.8. If we do not use this proposition, but all arguments of Section 4 prior to its use, we get estimate (1.14) with

$$F = \bigl(Z^{13/6-\delta} + a^{-1/2} + Z^{7/2}a^{3/2}\bigr)Z^{\varkappa} \tag{1.21}$$

and

$$G = \bigl(Z^{7/6-\delta}a^{3/2} + Z^{5/2}a^{7/2}\bigr)Z^{\varkappa} \tag{1.22}$$

which for $a \ge Z^{-1/2-\varkappa}$ are defined by their second terms.

(iii) On the other hand, while we believe that $\bar\rho_\beta$ is different from $\bar\rho_0$ (the same density in the non-relativistic case) we have no proof of this. We hope to do it later and to estimate the difference from below.

(iv) In [Ivr3] the upper pointwise estimates of ρ_Ψ has been derived in the non-relativistic case but except for Z^{-1}-vicinities of nuclei they are worse than $C\rho^{\mathsf{TF}}$.

Remark 1.6. Obviously

$$\bar\rho_\beta(x) = \frac{1}{4\pi}\sum_{n\ge 1}\sum_{0\le l\le n-1}(2l+1)R^2_{n,l}(|x|;\beta) \tag{1.23}$$

[2)] Such estimates in the non-relativistic case could be found in [Ivr3]: $\omega = Z^3$ for $a \le Z^{-8/9}$, $\omega = Z^{19/9}a^{-1}$ for $Z^{-8/9} \le a \le Z^{-7/9}$, $\omega = Z^{197/90}a^{-9/10}$ for $Z^{-7/9} \le a \le Z^{-1/3}$, $\omega = Z^{17/9}a^{-9/5}$ for $Z^{-1/3} \le a \le Z^{-5/18}$ and $\omega = Z^{19/9}a^{-1}$ for $a \ge Z^{-5/18}$.

with $R_{n,l}(r;\beta)$ defined by (B.5); in particular,

$$\bar\rho_0(0) = \frac{1}{4\pi}\sum_{n\ge 1}\frac{1}{n^3}. \tag{1.24}$$

Consider now Thomas-Fermi approximation on the larger distances from nuclei.

Theorem 1.7. *Let conditions* (1.9), (1.10) *and* (1.11) *be fulfilled and let* $U \in \mathscr{L}^\infty$ *such that*

$$\mathsf{supp}(U) \subset \{x\colon a \le \ell(x) \le 2a\}, \quad \epsilon Z^{-1} \le a \le \epsilon, \quad |U| \le 1\,, \tag{1.25}$$

where here and below

$$\ell(x) = \min_{1\le m\le M} |x - \mathsf{y}_m| \tag{1.26}$$

is the distance from x *to the nearest nucleus,*

$$\zeta = \begin{cases} Z^{1/2}\ell^{-1/2} & \ell \le Z^{-1/3}, \\ \ell^{-2} & \ell \ge Z^{-1/3}, \end{cases} \tag{1.27}$$

Then the following estimate holds:

$$\Big|\int U(x)\big(\rho_\Psi(x) - \rho^{\mathsf{TF}}(x)\big)\,dx\Big| \le C\Big(E\|U\|_{\mathscr{L}^1} + F^{1/3}\|U\|^{2/3}_{\mathscr{L}^1} + G\Big) \tag{1.28}$$

with

$$E = \zeta^2 a^{-1}, \qquad F = \zeta^{4/3}Z^{5/3-\delta}, \qquad G = \zeta^{-2}Z^{5/3-\delta} \tag{1.29}$$

and $\delta = \delta(\sigma)$, $\delta > 0$ *if* $\sigma > 0$ *and* $\delta = 0$ *if* $\sigma = 0$.

Corollary 1.8. *Let* <u>*either*</u> $a \asymp Z^{-1}$ *and* $X \subset B(\mathsf{y}_m, a)$ <u>*or*</u> $Z^{-1} \le a \le 1$ *and* $X \subset B(\mathsf{y}_m, a) \setminus B(\mathsf{y}_m, a/2)$. *Then*

(i) The following estimate holds:

$$\|\rho_\Psi - \rho^{\mathsf{TF}}\|_{\mathscr{L}^1(X)} \le C\Big(E\,\mathsf{mes}(X) + F^{1/3}(\mathsf{mes}(X))^{2/3} + G\Big). \tag{1.30}$$

(ii) Assume that $|\rho_\Psi| \le \omega$ *in* X *with* $\omega \ge Z^{3/2}a^{-3/2\,2)}$. *Then for* $p = 2, 3, ...$ *the following estimate holds:*

$$\|\rho_\Psi - \rho^{\mathsf{TF}}\|_{\mathscr{L}^p(X)} \le C\omega^{1-1/p} J_p^{1/p} \tag{1.31}$$

where J_p *with* $p = 1, 2, ...$ *is a solution to a recurrent relation*

$$J_p = \omega^{-1} E J_{p-1} + (\omega^{-2}F)^{1/3} J_{p-1}^{2/3} + G, \qquad J_0 = \omega\,\mathsf{mes}(X). \tag{1.32}$$

Remark 1.9. (i) As $\|U\|_{\mathscr{L}^(X)} \asymp a^3$ in Theorem 1.7 and $\mathsf{mes}(X) \asymp a^3$ in Corollary 1.8 the estimates of that paper are better than the corresponding estimates of this one, but for relatively small $\|U\|_{\mathscr{L}^1(X)}$ and $\mathsf{mes}(X)$ those of the present paper may be better.

However, as $\|U\|_{\mathscr{L}^1(X)}$ and $\mathsf{mes}(X)$ are too small the right-hand expressions of (1.28), (1.30) and (1.31) may be larger, than $\zeta^3 \int_X |U|\,dx$ or $\zeta^3\,\mathsf{mes}(X)$ respectively in which case those are no more remainder estimates.

(ii) The methods developed in this part paper also work without any modifications in the case of the self-generated magnetic field (see Chapter 27 of [Ivr1], Volume V).

Plan of the paper. In Sections 2 and 3 we consider a one-particle Hamiltonian (relativistic or not) with a potential $V = V^0 + \varsigma U$ where U is supported in $B(0, r)$ and satisfies $|U(x)| \le 1$, $0 < \varsigma r \le \epsilon$ and explore its eigenvalues and projectors, correspondingly.

In Section 4 we prove Proposition 4.1, using arguments of [IaLS], and then, using results of Section 2 and 3, we derive from it Theorem 1.3.

In Section 5 we prove Theorem 1.7. We start from the same estimate (4.1) but then we use microlocal analysis of a one-particle Hamiltonian with a potential $V = W^{\mathsf{TF}} + \varsigma U$ where U is supported in $\mathcal{X}$ and satisfies $|U(x)| \le W^{\mathsf{TF}}$. In Appendix A we estimate eigenfunctions of the non-relativistic hydrogen Hamiltonian and in Appendix B we generalize them to the relativistic hydrogen Hamiltonian.

2 Estimates of eigenvalues

Now we compare negative spectra of operators $H^0 := H_{V^0}$ and $H := H_V$ where $H_V = T - V$, $V^0 = |x|^{-1}$ and $V = V^0 + \varsigma U$ with

$$\mathsf{supp}(U) \subset B(0, r), \qquad r \ge 1, \qquad |U| \le 1 \tag{2.1}$$

and

$$0 < \varsigma r \le \epsilon_0 \tag{2.2}$$

with sufficiently small constant ϵ_0. Then both of these negative spectra are discrete.

According to Corollary B.7 the negative spectrum of H_V^0 consists of the clusters $\mathcal{C}_n^0 = \{\lambda_{n,k}^0(\beta)\}_{k=1,\dots,\nu_k}$ [3]. We denote by $u_{n,k} = u_{n,k}(r,\phi,\theta)$ corresponding eigenfunctios.

(2.3) Let us number eigenvalues of H_V correspondingly by $\lambda_{n,k}$ with with $n = 1, 2, \dots$ and $k = 1, 2, \dots, \nu_n$, so that $\lambda_{n,k} \le \mu_{n',k'}$ for all $n < n'$ and for all corresponding k and k' and $\lambda_{n,k}^0 \le \lambda_{n,k'}^0$ for all $k < k'$.

Proposition 2.1. *Let* (2.1) *and* (2.2) *be fulfilled and let us number eigenvalues of* H_V *and* H_{V^0} *according to* (2.3)*. Furthermore, assume that*

$$\varsigma r^{5/2} \le \epsilon n^3. \tag{2.4}$$

(i) Then the following estimate holds

$$|\lambda_{n,k} - \lambda_{n,k}^0| \le C \begin{cases} \varsigma r^{5/2} n^{-5} + n^{-3} & \text{for } \ r \le C_0 n^2, \\ \varsigma + n^{-3} & \text{for } \ r \ge C_0 n^2, \end{cases} \tag{2.5}$$

(ii) In particular, $-\lambda_{n,k} \asymp n^{-2}$.

Proof. Indeed, for U, which is smooth in r-scale, this estimate follows from the standard semiclassical asymptotics of the eigenvalue counting function:

$$\mathsf{N}(\tau) = \mathcal{N}^{\mathsf{W}}(\tau) + O(|\tau|^{-2}) \qquad \text{for } \ \tau < 0 \tag{2.6}$$

with

$$\mathcal{N}^{\mathsf{W}}(\tau) = \frac{1}{6\pi^2} \int (\tau - V)_+^{3/2} \, dx \asymp |\tau|^{-3} \tag{2.7}$$

[3] More precisely, in the non-relativistic case ($\beta = 0$) $\lambda_{n,k}^0 = \bar{\lambda}_n = -\frac{1}{4n^2}$ of multiplicity n^2, in the relativistic case for $0 < \beta \le \beta_1$ there are also clusters $\mathcal{C}_n^0$ of the width $O(\beta^2 n^{-3})$, containing n^2 eigenvalues and separated by the gaps of the width $\asymp n^{-3}$ and for $\beta_1 < \beta \le \frac{2}{\pi}$ separation into clusters is not unique but allows $O(1)$ number of elements moved to or from the neighbouring clusters, so each cluster contains $\nu_n = n^2 + O(1)$ eigenvalues (see Remark B.8(i)). All "O" are uniform with respect to n, k and β.

for both H_V and H_{V^0} and

$$|\mathcal{N}^{\mathsf{W}}(\tau; H_V) - \mathcal{N}^{\mathsf{W}}(\tau; H_{V^0})| \le C\varsigma r^{5/2} \tag{2.8}$$

for $r \le C_0|\tau|^{-1}$; otherwise in the right-hand expression we need to replace r by n^2.

Then using the standard variational arguments we can drop the smoothness condition. □

Proposition 2.2. *Let condition* (2.1) *be fulfilled and*

$$\varsigma r^{3/2} \le \epsilon_0 \tag{2.9}$$

with sufficiently small constant ϵ_0. *Then for* $n \ge C_0^{-1}\sqrt{r}$

(i) The spectrum of H_V *consists of the clusters* $\mathcal{C}_n = \{\lambda_{n,k}\}_{k=1,\dots,\nu_n}$ *of the width* $\le C_0(\beta^2+\varsigma)n^{-3}$ *separated by gaps of the width* $\asymp n^{-3}$. *Each cluster* $\mathcal{C}_n$ *contains exactly the same number of eigenvalues as* $\mathcal{C}_n^0$ *and they have common borders: both are contained in* $[\eta_n + \epsilon_1 n^{-3}, \eta_{n+1} - \epsilon_1 n^{-3}]$.

In particular, in the non-relativistic case and in the relativistic case with $\beta < \epsilon_1$ *with sufficiently small constant* ϵ_1 *(see Corollary B.7(i))*

$$\mathcal{C}_n \subset [\bar\lambda_n - C_0(\beta^2+\varsigma)n^{-3}, \bar\lambda_n - C_0(\beta^2+\varsigma)n^{-3}]. \tag{2.10}$$

(ii) Furthermore,

$$|\sum_k (\lambda_{n,k} - \lambda^0_{n,k})| \le C\varsigma r \|\langle x\rangle^{-3/2} U\|_{\mathscr{L}^1} n^{-3}. \tag{2.11}$$

Proof. We need to estimate $\lambda_{n,k}$ from above and below.

(a) We start from the easier upper estimate for $\lambda_{n,k}$. Let $\mathsf{N}(\tau)$ be the number of eigenvalues below $\tau \in [\lambda^0_{n,k}, \lambda^0_{n,k} + C_0 n^{-3}]$; we know from Proposition 2.1(ii) that under assumption (2.9) $\lambda_{n,k} \le \lambda^0_{n,k} + C_0 n^{-3}$ for sure. Recall that

$$\mathsf{N}(\tau) = \max \dim \mathcal{L}\,, \tag{2.12}$$

where maximum is taken over subspaces $\mathcal{L} \subset \mathscr{L}^2(\mathbb{R}^3)$ such that

$$(H_V u, u) - \tau\|u\|^2 < 0 \qquad \forall u \in \mathcal{L},\ u \ne 0. \tag{2.13}$$

Therefore we can replace the latter condition by

$$(H_{V^0}u,u)-\tau\|u\|^2+\varsigma(U_-u,u)\|^2<0 \qquad \forall u\in\mathcal{L},\ u\neq 0\,, \tag{2.14}$$

(where here and below $U_\pm \coloneqq \max(\pm U,0)$) but then instead of equality in (2.12) we get an inequality

$$\mathsf{N}(\tau)\ge \max\dim\mathcal{L}. \tag{2.12}_<$$

Let $\lambda=\lambda^0_{n,k}$; let us consider up $\mathcal{L}=\mathcal{L}_1\oplus\mathcal{L}_2$ with $\mathcal{L}_1=\oplus\sum_{n'<n_*}\mathscr{H}_{n',l'}$, $\mathcal{L}_2\subset\oplus\sum_{n_*\le n'\le n}\mathscr{H}_{n',l'}$, where $\mathscr{H}_{n',l'}$ is a linear span of basis functions[4)]

$$\Upsilon_{n',l',m}\coloneqq\Upsilon_{n',l',m}(r,\varphi,\theta;\beta)=R_{n',l'}(r;\beta)Y_{l',m}(x/|x|) \tag{2.15}$$

with $m=-l',\dots,l'$. Let $n_*=n-C_1$. Then (2.14) holds provided

$$\sum_{1\le i\le 2}\Big[(H_{V^0}u_i,u_i)-\tau\|u_i\|^2+2\varsigma(U_-u,u)\Big]<0 \tag{2.16}$$
$$\forall u_i\in\mathcal{L}_i,\ u=u_1+u_2\neq 0.$$

In virtue of Proposition 2.1(ii) under assumption (2.9) the left-hand expression of (2.16) is negative with any $\tau\ge\lambda^0_{n,k}$ for all $u=u_1\in\mathcal{L}_1$, $u\neq 0$. Then we need to consider only $u_2\in\mathcal{L}_2$. Decomposing $\mathcal{L}_2\ni v=\sum_{n',l'}R_{n',l'}(|x|)v_{n',l'}$, where $v_{n',l'}=v_{n',l'}(x/|x|)$ are eigenfunctions of the Laplacian on $\mathbb{S}^2$ corresponding to eigenvalue $-l'(l'+1)$, we estimate

$$\begin{aligned}(U_-u,u)&\le(\phi u,u)\\ &\le\sum_{n',n'';l'}\|v_{n',l'}\|\,\|v_{n'',l'}\|\int\phi(t)|R_{n',l'}(t)|\,|R_{n'',l'}(t)|\,t^2dt\\ &\le C\sum_{n',l'}\|v_{n',l'}\|^2\int\phi(t)|R_{n',l'}(t)|^2\,t^2dt\end{aligned} \tag{2.17}$$

with $\phi(x)\coloneqq\phi_r(x)$, characteristic function of $B(0,r)$; we used that $\phi(x)$ is spherically symmetric, that $w_{n',l'}$ and $w_{n'',l''}$ are orthogonal for $l'\neq l''$, and that n' and n'' are between $n^*=n-C_1$ and n. Here $\|v\|=\|v\|_{\mathscr{L}^2(\mathbb{S}^2)}$.

[4)] In the spherical coordinates (r,φ,θ). Here and below $R_{n,l}(r)$ are defined by (A.2), (B.5) in the non-relativistic and relativistic case respectively, $Y_{l',m}(\varphi,\theta)$ are spherical harmonics and a natural range is $m=-l',\dots,l'$.

Recall that due to Propositions A.8(iii) and B.5 in the non-relativistic and relativistic cases respectively,

$$|R_{n',l}| \le C \begin{cases} \langle x\rangle^{-3/4} n'^{-3/2} & \text{for } \ l \le C_0\langle x\rangle^{1/2}, \\ l^{-s} n'^{-3/2} & \text{for } \ l \ge C_0\langle x\rangle^{1/2}. \end{cases} \tag{2.18}$$

Then

$$(U_- u, u) \le C r^{3/2} n^{-3} \sum_{n',l'} \|v_{n',l'}\|^2 = C r^{3/2} n^{-3} \|u\|^2 \qquad \text{for } \ u \in \mathcal{L}_2\,. \tag{2.19}$$

Therefore we can take $n_* = n$:

$$\lambda_{n',k'} \le \lambda^0_{n,k} \qquad \text{for } \ n' < n,\ k,\ k'. \tag{2.20}_<$$

Further, we conclude that

$$\lambda_{n,k} \le \mu_{n,k} \tag{2.21}_<$$

which are eigenvalues of $\pi^0_n H_{V^0+2\varsigma U_-}\pi^0_n$ where π^0_n is a projector to $\mathcal{L}_2 = \oplus \sum_l \mathscr{H}_{n,l}$. Therefore

$$\sum_k \lambda_{n,k} \le \mathsf{Tr}\big[\pi^0_n H_{V^0-2\varsigma U_-}\pi^0_n\big] = \mathsf{Tr}\big[\pi^0_n H_{V^0}\pi^0_n\big] + 2\varsigma\, \mathsf{Tr}\big[\pi^0_n U_-\pi^0_n\big] \tag{2.22}_<$$

where the first term equals $\sum_k \lambda^0_{n,k}$ and

$$\begin{aligned} \mathsf{Tr}\big[\pi^0_n U_-\pi^0_n\big] &= \sum_{l,m} \int U_-(x) |R_{n,l}(|x|)|^2 |Y_{l,m}(x/|x|)|^2\, dx \\ &= \frac{1}{4\pi} \sum_{l,m} (2l+1) \int U_-(x) |R_{n,l}(|x|)|^2\, dx \le C r \|\langle x\rangle U_-\|_{\mathscr{L}^1} n^{-3} \end{aligned} \tag{2.23}_<$$

due to equality

$$\sum_m |Y_{l,m}|^2 = \frac{1}{4\pi}(2l+1) \tag{2.24}$$

and (2.18). We arrive to

$$\sum_k (\lambda_{n,k} - \lambda^0_{n,k}) \le C\varsigma r \|\langle x\rangle^{-3/2} U_-\|_{\mathscr{L}^1}. \tag{2.11}_<$$

(b) To estimate $\lambda_{n,k}$ from below we need to estimate $\mathsf{N}(\tau)$ from above. To do this we replace (2.16) by

$$\sum_{1\le i\le 2}\Big[(H_{V^0}u_i,u_i)-\tau\|u_i\|^2-2\varsigma(U_+u_i,u_i)\Big]<0 \qquad \forall u_i\in\mathcal{H}_i,\ u=u_1+u_2\neq 0. \tag{2.25}$$

Then $\mathcal{H}_1$ and $\mathscr{H}_2$ become "detached". Let us take $\mathcal{H}_1=\oplus\sum_{n'\le n^*,l'}\mathscr{H}_{n',l'}$ with $n^*=n+C_1$, and $\mathcal{H}_2=\mathscr{L}^2(\mathbb{R}^3)\ominus\mathcal{H}_1$. Then in virtue of Proposition 2.1 for $u=u_2\in\mathcal{H}_2$ expression (2.25) is non-negative and therefore (2.12) holds with maximum taken over $\mathcal{L}\subset\mathcal{H}_1$.

Note that

$$\mathsf{N}(\tau)=N-\tilde{\mathsf{N}}(\tau)\qquad \text{with}\quad \tilde{\mathsf{N}}(\tau)=\max\dim\tilde{\mathcal{L}}\,, \tag{2.26}$$

where maximum is taken over subspaces on which quadratic form

$$(H_{V^0}u,u)-\tau\|u\|^2+2\varsigma(U_+u,u)\ge 0 \tag{2.27}$$

and $N=\dim\mathcal{H}_1$. Now we need to estimate $\tilde{N}(\tau)$ from below can pick-up test functions delivering this inequality. We consider $\tilde{\mathcal{L}}\subset\oplus\sum_{n\le n'\le n^*,l'}\mathscr{H}_{n',l'}$.

Then, repeating arguments of Part (a) we arrive to

$$\lambda_{n',k'}>\lambda^0_{n,k}\qquad \text{for}\quad n'>n,\ k,\ k'. \tag{2.20)$_>$}$$

Further, we conclude that

$$\lambda_{n,k}\ge\mu'_{n,k} \tag{2.21)$_>$}$$

which are eigenvalues of $\pi^0_n H_{V^0-2\varsigma U_+}\pi^0_n$ and

$$\sum_k\lambda_{n,k}\le\mathsf{Tr}\big[\pi^0_nH_{V^0-2\varsigma U_+}\pi^0_n\big]=\mathsf{Tr}\big[\pi^0_nH_{V^0}\pi^0_n\big]-2\varsigma\,\mathsf{Tr}\big[\pi^0_nU_+\pi^0_n\big] \tag{2.22)$_>$}$$

where the first term equals $\sum_k\lambda^0_{n,k}$ and

$$\mathsf{Tr}\big[\pi^0_nU_+\pi^0_n\big]\le Cr\|\langle x\rangle U_+\|_{\mathscr{L}^1}n^{-3} \tag{2.23)$_>$}$$

due to equality (2.24) and (2.18). We arrive to

$$-\sum_k(\lambda_{n,k}-\lambda^0_n)\le C\varsigma r\|\langle x\rangle^{-3/2+\nu}U_+\|_{\mathscr{L}^1}n^{-3}. \tag{2.11)$_>$}$$

We leave details to the reader.

Combining $(2.20)_<$ and $(2.20)_>$ we arrive to Statement (i) and combining $(2.11)_<$ and $(2.11)_>$ we arrive to Statement (ii). □

Proposition 2.3. *Let conditions* (2.1) *and* (2.9) *be fulfilled. Then for* $n \le C_0^{-1}\sqrt{r}$ *the following estimates hold:*

$$|\lambda_{n,k} - \lambda^0_{n,k}| \le C\varsigma\big(\|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1(B(0,C_0n^2))} + \|\langle x\rangle^{-s}U\|_{\mathscr{L}^1(B(0,r)\setminus B(0,C_0n^2))}\big), \tag{2.28}$$

and

$$\sum_k |\lambda_{n,k} - \lambda^0_{n,k}| \le C\varsigma\big(\|\langle x\rangle^{-1/2}U\|_{\mathscr{L}^1(B(0,C_0n^2))} + \|\langle x\rangle^{-s}U\|_{\mathscr{L}^1(B(0,r)\setminus B(0,C_0n^2))}\big) \tag{2.29}$$

with arbitrarily large exponent s.

Proof. Proof follows the proof of Proposition 2.2 and takes in account that

$$|R_{n,l}(r)| \le Cr^{-s} \qquad \text{for } \ n \le C_0^{-1}\sqrt{r}. \tag{2.30}$$

We leave easy details to the reader. □

3 Estimates of projectors

In this subsection we first consider projectors associated with operators H_{V^0} and H_V and provide some estimate for them; then we combine these results with the results of Section 2. We assume that condition (2.9) is fulfilled. Then due to Proposition 2.2(i) there is a cluster of eigenvalues $\mathcal{C}^0_n = \{\lambda^0_{n,k}\}_{k=1,\dots,\nu_n}$ and $\mathcal{C}_n = \{\lambda_{n,k}\}_{k=1,\dots,\nu_n}$ of operators $H^0 := H_{V^0}$ and $H := H_V$ respectively. Let us denote by π^0_n and π_n the projectors to the corresponding spectral subspaces.

Proposition 3.1. *(i) In the framework of Proposition 2.2 assume that*[5)]

$$\varsigma\big(r^{3/2}(1 + |\log(rn^{-2})|) + n^2\big) \le \epsilon. \tag{3.1}$$

[5)] Obviously this is a stronger assumption than (2.9).

Then the following estimate holds:

$$\|\pi_n - \pi_n^0\| \le C\varsigma\big(r^{3/2}(1+|\log(rn^{-2})|)+n^{1/2}r^{3/4}\big) \times\Big[1+\big(\varsigma\big(r^{3/2}(1+|\log(rn^{-2})|)+n^2\big)\big)^{K-1}\varsigma n^3\Big] \tag{3.2}$$

with arbitrarily large exponent K.

(ii) On the other hand, in the framework of Proposition 2.3 assume that $\mathsf{supp}(U)\subset B(0,r)\setminus B(0,r/2)$. *Then the following estimate holds*

$$\|\pi_n - \pi_n^0\| \le C\varsigma r^{-s} \tag{3.3}$$

with arbitrarily large exponent s.

Proof. Due to Lemma 3.2 below it is sufficient to prove estimates (3.2) and (3.3) for operator $(\pi_n-\pi_n^0)\pi_n^0$.

(i) Note that

$$\pi_n = \frac{1}{2\pi i}\oint_{\gamma_n}(z-H)^{-1}\,dz\,, \tag{3.4}$$

where γ_n is the circle of radius $\asymp n^{-3}$ with counter-clockwise orientation, contains inside cluster of the eigenvalues $\mathcal{C}_n$ and outside all other clusters and $\mathsf{dist}(\gamma_n,\mathsf{Spec}(H))\asymp n^{-3}$. Similar formula holds for π_n^t, corresponding to operator $H^t=H_{V^0+t\varsigma U}$, and we can select a circle which serves to all $|t|\le 1$.

Then

$$\begin{aligned}\pi_n-\pi_n^0 &= \frac{1}{2\pi i}\oint_{\gamma_n}\big[(z-H)^{-1}-(z-H^0)^{-1}\big]\,dz = \\ &\sum_{1\le k\le K} -\frac{\varsigma^k}{2\pi i}\oint_{\gamma_n}(z-H^0)^{-1}U\cdots U(z-H^0)^{-1}\,dz \\ &\quad -\frac{\varsigma^{K+1}}{2\pi i}\oint_{\gamma_n}(z-H)^{-1}U(z-H^0)^{-1}U\cdots U(z-H^0)^{-1}\,dz\,,\end{aligned} \tag{3.5}$$

where each *regular term* (with $k\le K$) contains $(k+1)$ factors $(z-H^0)^{-1}$ and k factors U, while the *remainder term* contains $(K+1)$ factors $(z-H^0)^{-1}$, one factor $(z-H)^{-1}$ (not on the last position) and $(K+1)$ factors U. "Out

of the box" the each factor $(z-H^0)^{-1}$ or $(z-H)^{-1}$ has an operator norm not exceeding Cn^3, so the operator norm of the whole term does not exceed $C(\varsigma n^3)^k$. To improve it, multiply by π^0_n from the right:

$$(\pi_n-\pi^0_n)\pi^0_n = \sum_{1\le k\le K} -\frac{\varsigma^k}{2\pi i}\oint_{\gamma_n}(z-H^0)^{-1}U\cdots U(z-H^0)^{-1}\pi^0_n\,dz \\ -\frac{\varsigma^{K+1}}{2\pi i}\oint_{\gamma_n}(z-H)^{-1}U(z-H^0)^{-1}U\cdots U(z-H^0)^{-1}\pi^0_n\,dz\,. \tag{3.6}$$

Observe that $\|U\pi^0_n\|\le Cr^{3/4}n^{-3/2}$ in virtue of (2.18), so the operator norm of k-th term does not exceed $C(\varsigma n^3)^k r^{3/4}n^{-3/2}$.

To improve this estimate, let us replace j-th copy of $(z-H^0)^{-1}$ (with $j=1,\dots,k$) by

$$\pi^0_{p_j}(z-H^0)^{-1} = \pi^0_{p_j}(z-H^0)^{-1}\pi^0_{p_j}$$

with $p_j\asymp n$. Then each factor U will be sandwiched between $\pi^0_{p_j}$ and $\pi^0_{p_{j+1}}$ and $\|\pi^0_q U\pi^0_p\|\le Cr^{3/2}$ again in virtue of (2.18). Therefore the operator norm of this new k-th term (with $k\le K$) does not exceed

$$C(\varsigma r^{3/2})^k \prod_{1\le j\le k}(|p_j-n|+1)^{-1}$$

because

$$\|\pi^0_p(z-H^0)^{-1}\|\le Cn^3(|p-n|+1)^{-1}.$$

If we take a sum of this expression over $p_j\colon |p_j-n|\le P$ we get

$$C(\varsigma r^{3/2})^k(1+\log(P))^k \tag{3.7}$$

(with $1\le P\le n/2$) and therefore if we insert instead of π_{p_j} their sums

$$\Pi_{n,P} = \sum_{p\colon |p-n|\le P}\pi^0_p \tag{3.8}$$

we get that the operator norm would not exceed (3.7) (for $P\ge 1$).

On the other hand, if instead of $\Pi_{n,P}$ we insert $(I-\Pi_{n,P})$, then the corresponding factor $\varsigma r^{3/2}(1+\log(P)))$ in the estimate should be replaced by ςn^3P^{-1} because $\|(I-\Pi_{n,P})(z-H^0)^{-1}\|\le Cn^3P^{-1}$.

(3.9) For the left-most copy, however of $(z - H^0)^{-1}$, since it serves just one U (on the right of it), we actually get $\varsigma(n^{3/2}r^{3/4}(1 + \log(P)) + n^3P^{-1})$.

Therefore the operator norm of the regular term with $k = 1$ in (3.6) does not exceed $C\varsigma\bigl(r^{3/2}\log(P) + n^{3/2}r^{3/4}P^{-1}\bigr)$ and optimizing this expression by P: $P \le n/2$ we get the first factor in the right-hand expression of (3.2), achieved as $P \asymp \min(n^{3/2}r^{-3/4},\, n)$.

Further, the operator norm of the regular term with $k \ge 2$ in (3.6) does not exceed $C\varsigma^k\bigl(r^{3/2}\log(P) + n^{3/2}r^{3/4}P^{-1}\bigr)\bigl(r^{3/2}\log(Q) + n^3Q^{-1}\bigr)^{k-1}$ because we can take $\Pi_{n,P}$ for the left-most factor $(z - H^0)^{-1}$ and $\Pi_{n,Q}$ for all other factors $(z - H^0)^{-1}$ and we take P the same as above and $Q \asymp \min(n^3r^{-3/2},\, n)$. Then we get the first factor in the right-hand expression of (3.2), multiplied by

$$\bigl(\varsigma\bigl(r^{3/2}(1 + |\log(rn^{-2})|) + n^2\bigr)\bigr)^{k-1}, \tag{3.10}$$

which due to condition (3.1) is less than 1.

The same procedure, applied to the remainder term, results in the expression for $k = K$ multiplied by ςn^3, which means the first factor in (3.2), multiplies by expression (3.10) with $k = K$, and multiplied by ςn^3. It completes the proof of Statement (i).

(ii) Proof of Statement (ii) is trivial due to (properties of $R_{n,l}$)2.18) and assumption $\mathsf{supp}(U) \subset B(0, r) \setminus B(0, r/2)$ with $n \le C_0^{-1}\sqrt{r}$. □

Lemma 3.2. *Let π and π^0 be two orthogonal projectors such that*

$$\|(I - \pi)\pi^0\| \le \varepsilon < \frac{1}{2} \tag{3.11}$$

and

$$\dim \mathsf{Ran}(\pi) = \dim \mathsf{Ran}(\pi^0) < \infty. \tag{3.12}$$

Then for all p: $1 \le p \le \infty$

$$\|\pi - \pi^0\|_p \le 2(1 - \varepsilon)^{-1}\|(I - \pi)\pi^0\|_p. \tag{3.13}$$

Proof. Due to assumption (3.11) operator $\pi : \mathsf{Ran}(\pi^0) \to \mathsf{Ran}(\pi)$ is injective and therefore due to (3.12) it is invertible, and the norm of an inverse operator $\varphi : \mathsf{Ran}(\pi) \to \mathsf{Ran}(\pi^0)$ does not exceed $(1-\varepsilon)^{-1}$ and also

$$\|(I-\varphi)\pi\|_p \le (1-\epsilon)^{-1}\|\pi-\pi^0\|_p.$$

Then the same estimate holds for the corresponding norm of

$$\pi^0(I-\varphi)\pi = \pi^0\pi - \pi^0\varphi\pi = \pi^0\pi - \pi$$

and for adjoint to it: $\|\pi\pi^0-\pi\|_p \le (1-\epsilon)^{-1}\|\pi-\pi^0\|_p$. Since

$$\|\pi^0-\pi\|_p \le \|\pi\pi^0-\pi\|_p + \|\pi\pi^0-\pi^0\|_p$$

we arrive to (3.18). □

Proposition 3.3. *(i) In the framework of Proposition 2.2 the following estimates hold*

$$|\mathsf{Tr}[U\pi_n^0]| \le Cr\|\langle x\rangle^{-3/2}\|_{\mathscr{L}^1} n^{-3} \tag{3.14}$$

and under assumption (3.1) *also*

$$\begin{aligned} |\mathsf{Tr}[U(\pi_n-\pi_n^0)]| &\le C\varsigma r\|\langle x\rangle^{-3/2}\|_{\mathscr{L}^1}\bigl(r^{3/2}n^{-3}(1+|\log(rn^{-2})|)+n^{-1}\bigr) \\ &\quad + C\varsigma r^{5/2}\Bigl(\varsigma\bigl(r^{3/2}(1+|\log(rn^{-2})|)+n^2\bigr)\Bigr)^{K-1}\varsigma n^3\Bigr]. \end{aligned} \tag{3.15}$$

(ii) In the framework of Proposition 3.1(ii) the following estimate holds

$$|\mathsf{Tr}[U\pi_n^0]| + |\mathsf{Tr}[U\pi_n]| \le Cr^{-s}. \tag{3.16}$$

Proof. We actually proved (3.14) (see $(2.23)_<$ and $(2.23)_>$).

To prove (3.15) we apply the same approach as in the proof of (3.2) but we insert factors $\pi^0_{m_j}$ or $(I-\Pi_{n,Q})$ after the last copy of $(z-H_0)^{-1}$ and, due to the trace, the same factor appears in front of the first copy of U. So again, each factor U is sandwiched between two factors of of the type π^0_m or $(I-\Pi_{n,Q})$.

Observe that in the regular terms one of the factors must be π^0_n; otherwise the integrand is holomorphic inside of the contour of integration γ_n and

an integral is 0. And since there is one factor π_n^0, the second appears automatically (on both sides of the same copy of $(z-H^0)^{-1}$.

Therefore two estimate this term for two copies of $U\pi_n^0$ and $\pi_n^0 U$ we can use Hilbert-Schmidt norms. But

$$\|U\pi_n^0\|_2^2 = \|\pi_n^0 U\pi_n^0\|_2^2 = \mathsf{Tr}[\pi_n^0|U|^2\pi_n^0] \le C\|\langle x\rangle^{-3/2}U^2\|_{\mathscr{L}^1} \tag{3.17}$$

and due to assumption $|U| \le 1$ we can replace there U^2 by U. So in comparison with the norm estimate each rregular term acquires two factors $\|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1}^{1/2}$ (thus, just one factor $\|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1}$). Then the absolute value of the first term does not exceed

$$C_\varsigma r\|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1}^{\|}\big(r^3n^{-3}(1+\log(P)) + r^{3/2}P^{-1}\big)\,,$$

and optimizing by $P\colon P\le n$ we arrive to the first term in (3.15).

The k-th regular term is estimated in the same way albeit with an extra factor (3.10), which is less than 1.

While the remainder term could be estimated a bit better than in (3.15), we do not care, since under proper assumption it will be negligible anyway. The same applies to estimate (3.16) as well. □

Proposition 3.4. *The following formula holds*

$$\mathsf{Tr}\big[H_V^- - H_{V^0}^-\big] = -\int_0^\varsigma \mathsf{Tr}\big[U\theta(-H_{V^t})\big]\,dt. \tag{3.18}$$

with $V^t = V^0 + tU$.

Proof. The proof is trivial.

Remark 3.5. (i) One can rewrite the right-hand expression of (3.18) as

$$-\varsigma\,\mathsf{Tr}\big[U\theta(-H_{V^0})\big] - \int_0^\varsigma \mathsf{Tr}\big[U\big(\theta(-H_{V^t}) - \theta(-H_{V^0})\big)\big]\,dt \tag{3.19}$$

with the last term equal

$$\sum_{n\ge 1} -\int_0^\varsigma \mathsf{Tr}\big[U(\pi_n^t - \pi_n^0)\big]\,dt \tag{3.20}$$

with π_n^t associated with H_{V^t}.

(ii) Further, each term in this sum could be rewritten as

$$\sum_{1\le k\le \nu_n} (\lambda_{n,k} - \lambda^0_{n,k}). \tag{3.21}$$

Indeed, Statement (i) is trivial, and to prove Statement (ii) observe that expression (3.21) is equal to

$$\begin{aligned}\frac{1}{2\pi i}\,\mathsf{Tr}\Big[\oint_{\gamma_n} H_{V^t}(z-H_{V^t})^{-1}\,dz\Big]_{t=0}^{t=\varsigma} &= \frac{1}{2\pi i}\,\mathsf{Tr}\Big[\int_0^{\varsigma}\Big(\frac{\partial}{\partial t}\oint_{\gamma_n} H_{V^t}(z-H_{V^t})^{-1}\,dz\Big)\,dt\Big]\\ &= \frac{1}{2\pi i}\,\mathsf{Tr}\Big[\int_0^{\varsigma}\Big(-\oint_{\gamma_n} U(z-H_{V^t})^{-1}\,dz\\ &\quad + \oint_{\gamma_n} \underbrace{H_{V^t}(z-H_{V^t})^{-1}U(z-H_{V^t})^{-1}}\,dz\Big)\,dt\Big].\end{aligned}$$

Observe that because of the trace we can rewrite the selected expression as $H_{V^t}(z-H_{V^t})^{-2}U$ and that $\oint_{\gamma_n}(z-H_{V^t})^{-2}\,dz = 0$. What remains is obviously equal to the term in (3.20).

Proposition 3.6. *In the framework of Proposition 3.1 assume that*

$$r \le \varsigma^{-2/3+\varkappa} \tag{3.22}$$

with arbitrarily small exponent $\varkappa > 0$. Then

$$|\,\mathsf{Tr}\big[H_V^- - H_{V^0}^-\big] + \varsigma\,\mathsf{Tr}\big[U\theta(-H_{V^0})\big]| \le C\varsigma^{2-\varkappa} r \|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1}. \tag{3.23}$$

Proof. The left-hand expression in (3.22) does not exceed

$$\begin{aligned}&\sum_{n\le N} |\sum_{k\le \nu_n}\big(\lambda_{n,k}-\lambda^0_{n,k}\big) + \varsigma\,\mathsf{Tr}[U\pi^0_n]\,| +\\ &\qquad \sum_{n>N}\Big(\sum_{k\le\nu_n}\underbrace{|\lambda_{n,k}-\lambda^0_{n,k}|} + |\varsigma\,\mathsf{Tr}[U\pi^0_n]|\Big),\end{aligned} \tag{3.24}$$

where N satisfying (3.1) (if we substitute it instead of n) we will chose later.

Then the terms in the first sum due to Proposition 3.3 and Remark 3.5 do not exceed the right-hand expression of (3.15), multiplied by ς, and their sum does not exceed the first term in the expression below (we sum for n: $C_0^{-1}\sqrt{r} \le n \le N$ assuming that $N \ge C_0^{-1}\sqrt{r}$).

Meanwhile, due to Proposition 2.2 the terms in the second sum do not exceed $C\varsigma r\|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1}n^{-3}$ and their sum does not exceed the second term in the same expression below:

$$C\varsigma r\|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1}\Big(\varsigma(1+|\log(rN^{-2})|)+N^{-2}\Big). \tag{3.25}$$

We skipped the remainder term which is justified under assumption

$$\varsigma^{1-\varkappa}(r^{3/2}+N^2)\le 1 \tag{3.26}$$

with arbitrarily small exponent $\varkappa>0$; then the remainder term does not exceed ς^s. Condition (3.26) is slightly more restrictive than (3.1) and is fulfilled due to (3.22) and the choice $N=\varsigma^{-(1-\varkappa)/2}$, which almost minimizes (3.25) but also satisfies (3.26).

While Proposition 3.6 will be completely sufficient for our purpose in Section 4 for small distances from the nuclei, for larger distances we will need a bit more complicated setup. Namely, instead of V^0 unperturbed potential will be $V^0+\varepsilon\Phi$, where Φ satisfies the same restriction (2.1) as U.

First, however, we need to modify Proposition 3.3:

Proposition 3.7. *In the framework of Proposition 2.2 assume that*

$$\operatorname{supp}(\Phi)\subset B(0,r),\qquad |\Phi|\le 1. \tag{3.27}$$

and

$$(\varepsilon+\varsigma)^{1-\varkappa}(r^{3/2}+n^2)\le 1 \tag{3.28}$$

wirh arbitrarily small exponent $\varkappa>0$. Then the following estimate holds:

$$\begin{aligned}&|\operatorname{Tr}\big[U(\pi_n(\varepsilon,\varsigma)-\pi_n^0)\big]|+|\operatorname{Tr}\big[\Phi(\pi_n(\varepsilon,\varsigma)-\pi_n^0)\big]|\\ &\qquad\le Cr\big(\varsigma\|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1}+\varepsilon r^{3/2}\big)\big(r^{3/2}n^{-3}(1+|\log(rn^{-2})|)+n^{-2}\big)\,,\end{aligned} \tag{3.29}$$

where $\pi_n(\varepsilon,\varsigma)$ are projectors corresponding operator to $H_{V^0+\varsigma U+\varepsilon\Phi}$.

Proof. Proof repeats the proof of Proposition 3.3. We leave easy details to the reader. □

Now we can modify Proposition 3.6:

Proposition 3.8. *In the framework of Proposition 2.2 assume that*

$$\varepsilon r^{3/2} \le \epsilon_0 \tag{3.30}$$

and (3.27) *is fulfilled. Then the following estimate holds:*

$$|\operatorname{Tr}\big[H^-_{V^0+\varepsilon\Phi} - H^-_{V^0} - H^-_{V^0+\varsigma U+\varepsilon\Phi} + H^-_{V^0+\varsigma U}\big]| \le C(\varsigma+\varepsilon)^{1-\varkappa} r\big(\varsigma\|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1} + \varepsilon r^{3/2}\big). \tag{3.31}$$

Proof. Observe that the left-hand expression of (3.31) equals (without traces or absolute value)

$$\begin{aligned} U\int_0^{\varsigma}\Big(\theta(H_{V^0+\varepsilon\Phi+t\varsigma U}) - \theta(H_{V^0+tU})\Big)\,dt \\ = U\int_0^{\varsigma}\Big(\theta(H_{V^0+\varepsilon\Phi+t\varsigma U}) - \theta(H_{V^0})\Big)\,dt \\ - U\int_0^{\varsigma}\Big(\theta(H_{V^0+\varepsilon\Phi}) - \theta(H_{V^0})\Big)\,dt\,, \end{aligned} \tag{3.32}$$

and under assumption (3.28) we can break the last expressions into sums of terms with $\theta(...)$ replaced by the corresponding projectors. We also can combine the first with the second and the third with the fourth terms, rather than the first with the third and the second with the fourth terms.

Then using the corresponding estimates in Proposition 3.7 we can estimate the sum over n: $n \le N$ by the right-hand expression of (3.29), multiplied by ς or by ε (of our choice). Since we take $N = (\varepsilon+\varsigma)^{-\frac{1}{2}-\varkappa}$ as dictated by (3.28), it does not exceed the right-hand expression of (3.31).

Unfortunately, we are not that lucky with $n \ge N$: we have only estimates

$$|\sum_k \big(\lambda_{n,k}(\varepsilon,\varsigma) - \lambda_{n,k}(\varepsilon,0)\big)| \le Cr\big(\varsigma\|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1} + \varepsilon r^{3/2}\big)n^{-3}, \tag{3.33}$$

and

$$|\sum_k \big(\lambda_{n,k}(\varepsilon,\varsigma) - \lambda_{n,k}(0,\varsigma)\big)| \le Cr\big(\varsigma\|\langle x\rangle^{-3/2}U\|_{\mathscr{L}^1} + \varepsilon r^{3/2}\big)n^{-3} \tag{3.34}$$

which follow from estimate (2.11): namely, we have the same estimate for

$$|\sum_k \big(\lambda_{n,k}(\varepsilon,\varsigma) - \lambda^0_{n,k}\big)|.$$

Then the sum over n: $n \ge N = (\varepsilon+\varsigma)^{-\frac{1}{2}-\varkappa}$ does not exceed the right-hand expression of (3.31). □

4 Electronic Density: Scott approximation

Proposition 4.1. *Under assumption* (1.11) *the following estimate holds:*

$$\varsigma \int U\rho_\Psi \, dx \le \mathsf{Tr}\big[H^-_{W+\nu}\big] - \mathsf{Tr}\big[H^-_{W+\varsigma U+\nu}\big] + CZ^{5/3-\delta} \tag{4.1}$$

with $\delta = \delta(\sigma) > 0$ *as* $\sigma > 0$ *and* $\delta = 0$ *as* $\sigma = 0$ *in* (1.7).

Proof. We know the following upper estimate[6)]

$$\langle \mathsf{H}_{N,Z}\Psi, \Psi\rangle \le \mathsf{Tr}\big[H^-_{W+\nu}\big] + \nu N - \frac{1}{2}\mathsf{D}(\rho^{\mathsf{TF}}, \rho^{\mathsf{TF}}) + \mathsf{Dirac} + CZ^{5/3-\delta}, \tag{4.2}$$

where $\coloneqq W^{\mathsf{TF}}$ and ρ^{TF} are *Thomas-Fermi potential* and *Thomas-Fermi density*[7)], ν is a chemical potential[8)] and $\mathsf{D}(f,g) = \iint |x-y|^{-1} f(x)g(y)\,dxdy$.

On the other hand, similarly to the deduction of the lower estimate in Subsubsection 25.2.1 of [Ivr1], Volume V, for *any potential* $W' = W + U$

$$\begin{aligned}
&\langle \mathsf{H}_{N,Z}\Psi, \Psi\rangle \\
&\ge \sum_n (H_{V,n}\Psi, \Psi) + \frac{1}{2}\mathsf{D}(\rho_\Psi, \rho_\Psi) - CZ^{5/3-\delta} \\
&= \sum_n (H_{W+U,n}\Psi, \Psi) + \int (W + U - V)\rho_\Psi \, dx + \frac{1}{2}\mathsf{D}(\rho_\Psi, \rho_\Psi) - CZ^{5/3-\delta} \\
&= \sum_n (H_{W+U,n}\Psi, \Psi) + \int U\rho_\Psi \, dx + \frac{1}{2}\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) \\
&\qquad\qquad - \frac{1}{2}\mathsf{D}(\rho^{\mathsf{TF}}, \rho^{\mathsf{TF}}) - CZ^{5/3-\delta} \\
&\ge \mathsf{Tr}\big[H^-_{W+U+\nu}\big] + \nu N + \int U\rho_\Psi \, dx + \frac{1}{2}\mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}}, \rho_\Psi - \rho^{\mathsf{TF}}) \\
&\qquad\qquad - \frac{1}{2}\mathsf{D}(\rho^{\mathsf{TF}}, \rho^{\mathsf{TF}}) - CZ^{5/3-\delta}.
\end{aligned} \tag{4.3}$$

Therefore combining (4.2), (4.2) we arrive to (4.1). □

[6)] See f.e. Section 25.4 of [Ivr1], Volume V, and [Ivr2] in non-relativistic and relativistic settings respectively.

[7)] See f.e. Subsubsection 25.1.3 of [Ivr1], Volume V.

[8)] See f.e. Subsubsection 25.2.3 of [Ivr1], Volume V.

Remark 4.2. Replacing in (4.1) U by $-U$ and then multiplying by -1, we estimate the left-hand expression of (4.1) from below

$$\varsigma \int U\rho_\Psi \, dx \ge \mathsf{Tr}\big[(H^-_{W-\varsigma U+\nu}\big] - \mathsf{Tr}\big[H^-_{W+\nu}\big] - CZ^{5/3-\delta}. \tag{4.4}$$

In this section we consider ρ_Ψ on rather short distance from the nucleus y_m and want to replace W^{TF} by $V^0_m = Z_m|x-\mathsf{y}_m|^{-1}$ [9].

Let U be supported in $B(\mathsf{y}_m, a)$ with some fixed m and satisfy there $|U| \le Z^2$. Further, let ϕ be a smooth a-admissible function[10], $\phi(x) = 1$ for $|x-\mathsf{y}_m| \le b$ and $\phi(x) = 0$ for $|x-\mathsf{y}_m| \ge 2b$, $b \ge \mathsf{min}(Z^{-1+\delta'}, 2a)$ with small $\delta' > 0$.

Rescaling $x \mapsto (x-\mathsf{y}_m)Z_m$, $\tau \mapsto \tau Z_m^{-2}$ we find ourselves in the framework of Sections 2 and 3. On the other hand, due to Sections 25.4 of citeSS-monsterbook and 12.6 of [Ivr1] (Volumes V and II respectively).

$$|\,\mathsf{Tr}\big[[(1-\phi)H^-_{W+\nu}\big] - \mathsf{Tr}\big[(1-\phi)H^-_{W+\varsigma U+\nu}\big]| \le CZ^{5/3-\delta} \tag{4.5}$$

(with $\delta = \delta(\sigma)$) and we can insert ϕ into right-hand expression of (4.1):

$$\varsigma \int U\rho_\Psi \, dx \le \mathsf{Tr}\big[(\phi H^-_{W+\nu}\big] - \mathsf{Tr}\big[\phi H^-_{W+\varsigma U+\nu}\big] + CZ^{5/3-\delta}. \tag{4.6}$$

Indeed, $W + \varsigma U = W'$ is smooth b-admissible function in the zone $\{x\colon b \le |x-\mathsf{y}_m| \le 9b\}$.

Then since $|V^0_m - W| \le CZ^{4/3}$ in $2b$-vicinity of y_m and $|\nu| \le CZ^{4/3}$ we can replace $W+\nu$ by V^0_m with an error not exceeding $CZ^{4/3} \times r^{3/2}$, where we prefer to use a scaled distance $r = Z_m a$ rather than a:

$$\varsigma \int U\rho_\Psi \, dx \le \mathsf{Tr}\big[(\phi H^-_{V^0_m}\big] - \mathsf{Tr}\big[\phi H^-_{V^0_m+\varsigma U}\big] + CZ^{5/3-\delta} + CZ^{4/3}r^{3/2}. \tag{4.7}$$

Indeed, using arguments of Sections 25.4 and 12.6 of [Ivr1] (volumes V and II respectively), we can first replace W by W_m, coinciding with V^0_m on $B(\mathsf{y}_m, 3b)$ and with W outside of $B(\mathsf{y}_m, 4b)$ [11] and then replace W_m by V^0_m using the same arguments and that $\mathsf{supp}(\phi)$ is "smaller".

---

[9] In Section 5 we use microlocal approach to study ρ_Ψ on the larger distances from all nuclei and do not do such replacement.

[10] I.e. $|D^\alpha \phi| \le C_\alpha b^{-|\alpha|}$ for all α.

[11] This replacement brings an extra error–the last term in the right-hand expression of (4.7). There should be b rather than a but $b \asymp a$ unless $b \asymp Z^{-1+\delta''}$ in which case the previous term is larger.

Note that the last term in the right-hand expression of (4.7) is smaller than the previous one, and we can drop it, as $r \le Z^{2/9-2\delta/3}$, or

$$a \le Z^{-7/9-2\delta/3}. \tag{4.8}$$

Next, using rescaling $x \mapsto (x - \mathsf{y}_m)Z_m$, $U \mapsto \bar{U} = Z_m^{-2}U$ we find ourselves in the framework of Sections 2 and 3 with $r = Z_m a$. Therefore, using decomposition of Remark 3.5(i) and Proposition 3.6, and Remark 4.2, we arrive to

$$|\int \bar{U}(\rho_\Psi - \rho_m)\,dx| \le C\varsigma^{1-\varkappa} r \|\langle x\rangle^{-3/2}\bar{U}\|^*_{\mathscr{L}^1} + C\varsigma^{-1}Z^{-1/3-\delta} \tag{4.9}$$

with an arbitrarily small exponent $\varkappa > 0$ and $\bar{U} = Z^{-2}U$, satisfies (1.13). Here and below $\|.\|^*_{\mathscr{L}^1}$ is calculated *after rescaling*; in comparison with $\|.\|_{\mathscr{L}^1}$, calculated *before rescaling*, it has an extra factor Z^3.

However we can do better than this. Namely, observe that $W'_m := W^{\mathsf{TF}} - V^0_m$ satisfies

$$|W'_m(x) - W'_m(\mathsf{y}_m)| \le CZ_m^{3/2}|x - \mathsf{y}_m|^{1/2} \tag{4.10}$$

before rescaling[12)] and therefore, if we replace V^0_m by $V^0_m + W'_m(0) - \nu$ in (4.7), the last term in the right-hand expression is replaced by CZr^2:

$$\varsigma \int U\rho_\Psi\,dx \le \mathsf{Tr}\big[(\phi H^-_{V^0_m+W'_m(0)-\nu}\big] - \mathsf{Tr}\big[\phi H^-_{V^0_m+W'_m(0)-\nu+\varsigma U}\big] + CZ^{5/3-\delta} + CZr^2. \tag{4.11}$$

The last term in the right-hand expression of (4.11) is smaller than the previous one, and we can drop it as $r \le Z^{1/3-\delta/2}$, or

$$a \le Z^{-2/3-\delta/2}. \tag{4.12}$$

Remark 4.3. Therefore, (4.9) remains true under this assumption. Indeed, adding a constant to V^0 we just shift all eigenvalues of V^0 and $V^0 + \varsigma U$ and preserve all projectors π^0_n.

[12)] It follows from $|\Delta W'| \le CZ_m^{3/2}|x - \mathsf{y}_m|^{-3/2}$ due to Thomas-Fermi equation.

To improve our results on the distances $a \ge Z^{-2/3-\delta/2}$ we will use Proposition 3.8. Due to (4.10) $\varepsilon = Z^{-1/2}a^{1/2}$ and to satisfy $\varepsilon r^{3/2} \le Z^{-\varkappa}$ we assume that

$$a \le Z^{-1/2-\varkappa}. \tag{4.13}$$

Then due to Proposition 3.8 the right-hand expression of (4.9) should be replaced by

$$\begin{aligned} &C\varsigma^{-1}(\varsigma+\varepsilon)\big(\varsigma r\|\langle x\rangle^{-3/2}\bar U\|^*_{\mathscr{L}^1} + \varepsilon r^{5/2}\big)Z^{\varkappa} + C\varsigma^{-1}Z^{-1/3-\delta} \\ &\qquad \asymp C\varsigma r\|\langle x\rangle^{-3/2}\bar U\|^*_{\mathscr{L}^1}Z^{\varkappa} + C\varepsilon r^{5/2}Z^{\varkappa} + C\varsigma^{-1}\big(\varepsilon^2 r^{5/2}Z^{\varkappa} + Z^{-1/3-\delta}\big); \end{aligned}$$

as we will see $\varsigma \ge Z^{-s}$ with sufficiently large exponent s. We rewrite the last expression as

$$\begin{aligned} C\Big(&\varsigma Z^4 a\|\langle Z(x-\mathsf{y}_m)\rangle^{-3/2}\bar U\|_{\mathscr{L}^1} \\ &+ Z^2a^3 + \varsigma^{-1}\big(Z^{3/2}a^{7/2} + Z^{-1/3-\delta}\big)\Big)Z^{\varkappa}, \end{aligned} \tag{4.14}$$

which would lead to the same final estimate (1.14)–(1.16).

Minimizing (4.14) by $\varsigma\colon \varsigma \le Z^{-\varkappa}r^{-3/2} = Z^{-3/2-\varkappa}a^{-3/2}$, we arrive to

$$\begin{aligned} C\Big(&\big(Z^4 a\|\langle Z(x-\mathsf{y}_m)\rangle^{-3/2}\bar U\|_{\mathscr{L}^1}\big)^{1/2}\big(Z^{3/2}a^{7/2} + Z^{-1/3-\delta}\big)^{1/2} \\ &+ Z^2a^3 + Z^{3/2}a^{3/2}\big(Z^{3/2}a^{7/2} + Z^{-1/3-\delta}\big)\Big)Z^{\varkappa}. \end{aligned} \tag{4.15}$$

Therefore writing U instead of $\bar U$, we have

$$\begin{aligned} &\Big|\int U\big(\rho_\Psi - \rho_m\big)\,dx\Big| \le \\ &\quad C\Big(\big(Z^{3/2}a^{3/2}\|\langle Z(x-\mathsf{y}_m)\rangle^{-3/2}U\|_{\mathscr{L}^1}\big)^{1/2}\big(Z^4a^3 + Z^{13/6-\delta}a^{-1/2}\big)^{1/2} \\ &\qquad + Z^2a^3 + Z^3a^5 + Z^{7/6-\delta}a^{3/2}\big)\Big)Z^{\varkappa}. \end{aligned} \tag{4.16}$$

Since $Z^3a^5 \le Z^2a^3$ we arrive to estimate (1.14)–(1.16), which concludes the proof of Theorem 1.3.

Observe that $\mathsf{supp}(U) \subset B(\mathsf{y}_m, a) \setminus B(\mathsf{y}_m, a/2)$ implies

$$Z^{3/2}a^{3/2}\|\langle Z(x-\mathsf{y}_m)\rangle^{-3/2}U\|_{\mathscr{L}^1} \asymp \|U\|_{\mathscr{L}^1}.$$

To prove Corollary 1.4(i) we plug

$$U(x) = \chi_X(x)\,\mathsf{sign}\big(\rho_\Psi(x) - \rho_m(x)\big) \tag{4.17}$$

with characteristic function χ_X of X; then the left-hand expression becomes $\|\rho_\Psi - \rho_m\|_{\mathscr{L}^1(X)}$ and $\|U\|_{\mathscr{L}^1} = \mathsf{mes}(X)$.

To prove Corollary 1.4(ii) we plug

$$U(x) = \epsilon_0 \omega^{1-p} \chi_X(x)\,\mathsf{sign}\big(\rho_\Psi(x) - \rho_m(x)\big)|\rho_\Psi(x) - \rho_m(x)|^{p-1}\,, \tag{4.18}$$

which satisfies (1.13) due to assumptions $\rho_\Psi \le \omega$ in X and estimate $\rho_m \le CZ^{3/2}a^{-3/2} \le C\omega$ and since $\|U\|_{\mathscr{L}^1} = \omega^{-1} J_{p-2}$, we get that

$$J_p \le C\big((\omega^{-1}F)^{1/2} J_{p-1}^{1/2} + G\big) \tag{4.19}$$

with $J_p := \omega^{1-p}\int_X |\rho_\Psi - \rho_m|^p\,dx$ and $J_0 = \omega\,\mathsf{mes}(X)$, and therefore

$$J_p \le C\Big((\omega^{-1}F)^{1-2^{-p}} J_0^{2^{-p}} + (\omega^{-1}F)^{1-2^{1-p}} G^{2^{1-p}} + G\Big),$$

which implies (1.20).

5 Proof of main Theorem 1.7

We consider only non-relativistic case, in the relativistic case proof is the same and we use the same W^{TF} and ρ^{TF} (without any relativistic corrections) and also

$$P'_\beta(W^{\mathsf{TF}}) = P'(W^{\mathsf{TF}}) + O(\beta\ell^{-1}\zeta^3) = \rho^{\mathsf{TF}} + O(\zeta^2\ell^{-1}) \tag{5.1}$$

because $\zeta\beta \le 1$ in the framework of Theorem 1.7.

We assume that

$$\mathsf{supp}(U) \subset \{x\colon a \le \ell(x) \le 2a\}, \qquad \epsilon Z^{-1} \le a \le \epsilon, \qquad |U| \le \zeta^2\,, \tag{5.2}$$

where ℓ and ζ are defined by (1.25) and (1.26) and

$$0 < \varsigma \le \epsilon. \tag{5.3}$$

We rewrite the right-hand expression as

$$-\int_0^\varsigma \mathsf{Tr}\big(U\theta(-H_{W\pm sU+\nu})\big)\,ds. \tag{5.4}$$

After rescaling $x \mapsto xa^{-1}$, $\tau \mapsto \tau\zeta^{-2}$ we are in the semiclassical settings with $h = 1/(\zeta a)$. Condition to a ensures that $h \le 1$.

Due to Tauberian method we can rewrite the integrand as

$$h^{-1} \int_{-\infty}^{0} F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma(U(x)u_s)\bigr)\, d\tau \tag{5.5}$$

with an error, essentially not exceeding

$$C_\varsigma T^{-1} \sup_{|\tau|\le\epsilon_1} |F_{t\to\tau}\bigl(\bar\chi_T(t)\Gamma(|U(x)|u_s)\bigr)| \tag{5.6}$$

(we will write an exact statement later) where $\bar\chi_T(t) = \bar\chi(t/T)$, $\bar\chi \in \mathscr{C}_0^\infty([-1,1])$, equal 1 on $[-\frac12, \frac12]$, $h \le T \le \epsilon$, and

(5.7) $u_s(x,y,t)$ is a Schwartz kernel of $\exp(-ih^{-1}tH_{W+sU+\nu})$,

$\Gamma v = \int (\Gamma_x v)\, dx$ and $\Gamma_x v = v(x,x,\cdot)$.

Under assumptions (5.2)–(5.4), using two-terms successive approximation method with unperturbed operator $H_{W+\nu}$ and perturbation sU, we can evaluate

$$F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma(U(x)u_s)\bigr) \tag{5.8}$$

as

$$F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma(U(x)u_0)\bigr) \tag{5.9}$$

with an error, not exceeding

$$C\|U\|_{\mathscr{L}^1} a^{-3} h^{-1} T^2 \varsigma \times h^{-3}. \tag{5.10}$$

Indeed, one can see easily that the absolute value of n-th term is estimated by

$$Ch^{1-n} T^n \varsigma^{n-1} \times \|U\|_{\mathscr{L}^1} a^{-3} h^{-3} \tag{5.11}$$

for $n \ge 1$ and (5.10) is (5.11) with $n = 1$.

However, we can do better than this:

Proposition 5.1. *Under assumptions* (5.2)–(5.3) *and* $T \le \epsilon$ *the following estimate holds:*

$$|F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma(U(x)u_0)\bigr)| \le C\|U\|_{\mathscr{L}^1} a^{-3} h^{-2}\,. \tag{5.12}$$

Proof. Estimate (5.12) is due to semiclassical microlocal arguments applied to $\Gamma_x u$, in which case non-smoothness of U plays no role.

Indeed, for $\ell(x) \le \epsilon Z^{-1/3}$ we have $W := W^{\mathsf{TF}} \asymp Z\ell^{-1}$, and $0 \le -\nu \le CZ^{4/3}$, so in this case operator $H_{W+\nu}$ is x-microhyperbolic on the energy level 0.

Furthermore, this operator is also x-microhyperbolic on the energy level 0 for $\ell(x) \le \epsilon_0|\nu|^{1/4} \asymp \epsilon_0(Z-N)_+^{-1/3}$ [13] and elliptic for $\ell(x) \ge C_0|\nu|^{1/4}$.

Finally, as $\epsilon_0|\nu|^{-1/4} \le \ell(x) \le C_0|\nu|^{-1/4}$ x-microhyperbolicity fails but estimate (5.12) follows from the partition-rescaling technique of Subsubsection 5.1.1 of [Ivr1], Volume I, (since dimension is 3). We leave easy details to the reader. □

Thus, in the framework of Proposition 5.1 we can estimate expression (5.8):

$$|F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma\bigl(U(x)u_s\bigr)\bigr)| \le C\|U\|_{\mathscr{L}^1}a^{-3}\bigl(h^{-2}+\varsigma T^2h^{-4}\bigr)\,, \tag{5.13}$$

where the first term in the right-hand expression is due to (5.12) and the second one is (5.10).

Using this estimate and standard Tauberian arguments we can estimate

$$\begin{aligned}|\,\mathsf{Tr}\bigl[U\theta(-H_{W+sU+\nu})\bigr] &\\ - h^{-1}\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma U(x)u_s(.,.,t)\bigr)\,d\tau|&\\ \le C\|U\|_{\mathscr{L}^1}a^{-3}\bigl(T^{-1}h^{-2}+\varsigma Th^{-4}\bigr)\,,&\end{aligned} \tag{5.14}$$

where the right-hand expression is the right-hand expression of (5.13), multiplied by T^{-1}.

On the other hand, without these microlocal arguments and for $\varphi \in \mathscr{C}_0^\infty([-1,-\frac12])$, $LT \ge h$ the following estimate holds:

$$\begin{aligned}|\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\varphi_L(\tau)\bigl(\bar\chi_T(t)\Gamma\bigl(U(x)(u_0-u_s)\bigr)\,d\tau| \le&\\ C_kL\|U\|_{\mathscr{L}^1}a^{-3}h^{-1}T^2\varsigma h^{-3}\times(h/TL)^kL&\end{aligned} \tag{5.15}$$

with arbitrarily large exponent k.

[13] Recall that $|\nu| \asymp (Z-N)_+^{1/4}$.

Therefore, if we replace in the left-hand expression $\varphi_L(\tau)$ by 1, the result would not exceed the same right-hand expression with $L = h/T$, i.e. $C_k\|U\|_{\mathscr{L}^1}a^{-3}T\varsigma h^{-3}$, and therefore

$$h^{-1}\Big|\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t)\Gamma(U(x)(u_s-u_0))\big)\,d\tau\Big| \le C\|U\|_{\mathscr{L}^1}a^{-3}\varsigma T h^{-4}. \tag{5.16}$$

Therefore

(5.17) Estimate (5.14) remains true, if we replace there u_s by u_0.

However, then we can replace Tauberian expression by the corresponding Weyl expression

$$\frac{q}{6\pi^2}\int U(W+\nu)_+^{3/2}\,dx = \int U(x)\rho^{\mathsf{TF}}(x)\,dx \tag{5.18}$$

because $W = W^{\mathsf{TF}}$.

Plugging it into (5.14) and minimizing by $T \in [h,1]$ we get

$$\big|\mathsf{Tr}\big[U\big(\theta(-H_{W+sU+\nu})\big]-\int U(x)\rho^{\mathsf{TF}}(x)\,dx\big| \le C\|U\|_{\mathscr{L}^1}a^{-3}\big(\varsigma^{1/2}h^{-3}+h^{-2}\big) \tag{5.19}$$

for $T \asymp \min\big(h\varsigma^{-1/2},\,1\big)$.

Since

$$\mathsf{Tr}\big[H^-_{W+\nu}\big]-\mathsf{Tr}\big[H^-_{W\pm\varsigma U+\nu}\big] = \int_0^{\varsigma}\mathsf{Tr}\big[U\big(\theta(-H_{W+sU+\nu})\big]\,ds \tag{5.20}$$

inequality (4.1) implies, after we divide by $\varsigma\zeta^2$,

$$\Big|\int \bar{U}(x)\big(\rho_\Psi(x)-\rho^{\mathsf{TF}}(x)\big)\,dx\Big| \le C\|\bar{U}\|_{\mathscr{L}^1}a^{-3}\big(\varsigma^{1/2}\zeta^3a^3+\zeta^2a^2\big)+\varsigma^{-1}\zeta^{-2}Z^{5/3-\delta}. \tag{5.21}$$

with $\bar{U} = \zeta^{-2}U$, satisfying (1.25). *From now on we redefine* $U \coloneqq \bar{U}$.

Minimizing the right-hand expression by $\varsigma \le \epsilon$ we arrive to estimate (1.28)–(1.29). Theorem 1.7 has been proven.

Next, picking up

$$U(x) = \mathsf{sign}(\rho_\Psi(x) - \rho^{\mathsf{TF}}(x))\chi_X(x)$$

with χ_X characteristic function of X we arrive to (1.28) with the left-hand expression replaced by $\|\rho_\Psi - \rho^{\mathsf{TF}}\|_{\mathscr{L}^1(X)}$ and the right-hand expression with $\|U\|_{\mathscr{L}^1} = \mathsf{mes}(X)$, which proves Corollary 1.8(i).

Furthermore, in the framework of Corollary 1.8(ii) we pick up

$$U(x) = \omega^{1-p}\,\mathsf{sign}(\rho_\Psi(x) - \rho^{\mathsf{TF}}(x))|(\rho_\Psi(x) - \rho^{\mathsf{TF}}(x))|^{p-1}\chi_X(x)$$

and we conclude that $J_p^* \coloneqq \omega^{1-p}\|\rho_\Psi - \rho^{\mathsf{TF}}\|^p_{\mathscr{L}^p(X)}$ satisfies

$$J_p^* \le C\big(\omega^{-1}EJ_{p-1}^* + (\omega^{-2}F)^{1/3}J_{p-1}^{*\,2/3} + G\big), \qquad J_0^* \le \omega\,\mathsf{mes}(X) \tag{5.22}$$

with E, F and G defined by (1.29) and therefore $J_p^* \le C_p J_p$ with J_p defined as solutions of (1.32). This conclude the proof of Corollary 1.8(ii).

A Properties of eigenfunctions of Coulomb-Schrödinger operator

A.1 General

Consider operator $H^0 = -\Delta - r^{-1}$; $r = |x|^{-1}$. It is known that its eigenfunctions, corresponding to eigenvalues $-\frac{1}{4n^2}$, with norm 1, are (in the spherical coordinates)

$$u_{n,l,m}(r,\varphi,\theta) = R_{n,l}(r)Y_{l,m}(\varphi,\theta) \tag{A.1}$$

where $Y_{l,m}(\varphi,\theta)$ are spherical functions with $m = -l, -l+1, \dots, l-1, l$, $l = 0, 1, \dots, n$ and

$$R_{n,l}(r) = \sqrt{\frac{(n-l-1)!}{2n^4(n+l)!}}\big(\frac{r}{n}\big)^l e^{-r/2n} L^{(2l+1)}_{n-l-1}\big(\frac{r}{n}\big) \tag{A.2}$$

with associated Laguerre polynomials

$$L_n^{(k)}(z) = \frac{1}{n!}z^{-k}e^z\frac{d^n}{dz^n}\big(e^{-z}z^{n+k}\big) = \sum_{0\le j\le n}\frac{(n+k)!}{(n-j)!(k+j)!j!}(-z)^j. \tag{A.3}$$

Then

$$L^{(2l+1)}_{n-l-1}(z) = \sum_{0\le j\le n-l-1} \frac{(n+l)!}{(n-l-1-j)!(2l+1+j)!j!}(-z)^j. \tag{A.4}$$

Then $v := v_{n,l} = R_{n,l}(r)r$ satisfies

$$-v'' + \frac{l(l+1)}{r^2}v - \frac{1}{r}v = \lambda_n v \tag{A.5}$$

and is $(n-l)$-th eigenfunction and λ_n is $(n-l)$-th eigenvalue of such operator na $\mathscr{L}^2(\mathbb{R}^+)$ and the associated variational form is

$$\int \big(v^2 + \frac{l(l+1)}{r^2}v^2 - \frac{1}{r}v^2\big)\, dr. \tag{A.6}$$

A.2 Zeroes

Proposition A.1. *$v_{n,l}$ has exactly $(n-l-1)$ zeroes*

$$l(l+1) < r_* < r_1 < \ldots < r_{n-l-1} < r^* < 4n^2, \tag{A.7}$$

where $r_* < r^*$ are two roots of

$$W(r) := \frac{1}{r} - \frac{l(l+1)}{r^2} = -\lambda_n \tag{A.8}$$

and

$$r_k \asymp (l+k+1)^2. \tag{A.9}$$

Proof. Standard variational methods imply that $v_{n,l}(r)$ has exactly $(n-l-1)$ zeroes.

Further, equation (A.5) and $v(0) = v(\infty) = 0$ imply that all zeroes are simple and satisfy $W(r) > -\lambda_n$, which implies (A.7).

Consider two points $r_* < r' < r'' < r^*$ and observe that $W(r) \ge \min(W(r'), W(r''))$ on (r', r''). Then v must have a zero on (r', r'') as long as $r'' - r' > \pi/\sqrt{\min(W(r'), W(r'')) + \lambda_n}$.

Therefore, if $cl(l+1) \le r \le c^{-1}n^2$, then in $2\pi r^{1/2}$-vicinity of r must be zero of v. Thus the distance between two consecutive zeroes r_k and $r_{k\pm1}$ with $cl(l+1) \le r_k \le c^{-1}n^2$ is $O(r_k^{1/2})$. From this one can prove easily that then

$$|r_k - r_{k\pm1}| = \pi r_k^{1/2}\Big(1 + O\big(\frac{l(l+1)}{r_k} + \frac{r_k}{n^2}\big)\Big)$$

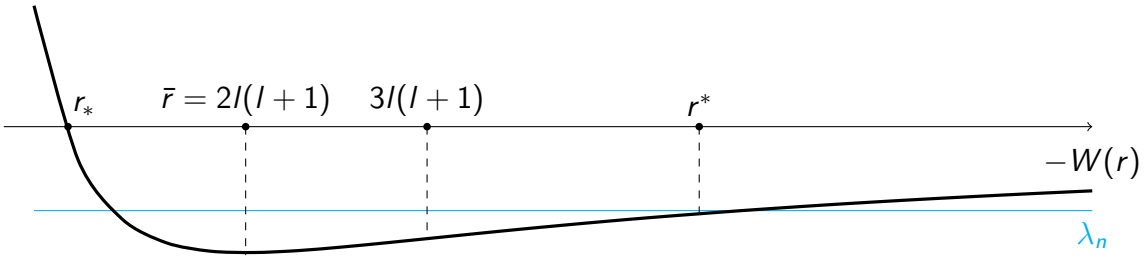

Figure .2: Marked points: left-bound for λ_{l+1}, minimum point, inflection point, right bound for λ_n.

and therefore

$$|r_k^{1/2} - r_{k\pm1}^{1/2}| = \frac{\pi}{2}\Big(1 + O\big(\frac{l(l+1)}{r_k} + \frac{r_k}{n^2}\big)\Big).$$

Further, there must be zeroes to the left of $cl(l+1)$ and to the right of $c^{-1}n^2$.

Finally, observe that $W(r) \ge 1/4l(l+1)$ and therefor e $(r_{k+1} - r_k) \ge 2\pi\sqrt{l(l+1)}$ and therefore $(r_{k+1}^{1/2} - r_k^{1/2}) \ge c^{-1}\pi$ for all k with $r_k \le cl(l+1)$. This implies (A.9). □

Remark A.2. Since $-\partial^2 \ge \frac{1}{4r^2}$ in fact $r_k \ge (l+1/2)^2$; in particular, $r_k \ge \frac{1}{4}$ as $l = 0$.

Let us analyze r_k more carefully. Due to monotonicity of $W(r)$ on $(0, \bar r)$ and $(\bar r, \infty)$ we conclude that

$$\text{(A.10)}\quad r_k \ge \bar r \implies s_{k+1} \ge s_k, \quad \frac{\pi}{\sqrt{W(r_k) + \lambda_n}} \le s_k \le \frac{\pi}{\sqrt{W(r_{k+1}) + \lambda_n}}$$

and

$$\text{(A.11)}\quad r_k \le \bar r \implies s_{k-1} \ge s_k, \quad \frac{\pi}{\sqrt{W(r_k) + \lambda_n}} \le s_k \le \frac{\pi}{\sqrt{W(r_{k-1}) + \lambda_n}}.$$

Consider r_k close to r^*. In this case $W(r) \asymp (r^* - r)/r^{*2}$ and $s_k \asymp r^*/\sqrt{(r^* - r_k)}$ provided $W(r_{k+1}) \asymp W(r_k)$; then $(r^* - r_k) \ge Cs_k$ as $(r^* - r_k) \ge r^*2/3$ and we arrive to Statement (i) below; Statement (ii) is proven the same way[14]. From the same arguments follows Statement (iii).

[14] Assumption $n - l \ge 3$ is needed to have at least 2 zeroes.

Proposition A.3. *Let* $n - l \geq 3$, $n \geq c$. *Then*

(i) As $r_k \asymp r^*$ *and* $(r^* - r_k) \geq Cn^{4/3}$

$$s_k \asymp r^*/\sqrt{(r^* - r_k)} \qquad \text{and} \qquad r^* - r_k \asymp r^{*2/3}(n - l - k)^{2/3}. \tag{A.12}$$

(ii) As $r_k \asymp r_*$ *and* $(r_k - r_*) \geq Cl^{4/3}$

$$s_k \asymp r_*/\sqrt{(r_k - r_*)} \qquad \text{and} \qquad r_k - r_* \asymp r^{*2/3}k^{2/3}. \tag{A.13}$$

(iii) There are no more than C' *zeroes in the zones* $\{r\colon r \leq r_* + Cr_*^{2/3}\}$ *and* $\{r\colon r \geq r^* - Cr^{*2/3}\}$.

A.3 Estimates

From(A.5) it follows that

$$\int_{r_k}^{r_{k+1}} (-2v''v' + \frac{2l(l+1)}{r^2}vv' - \frac{2}{r}vv' - 2\lambda_n vv')\, dr = 0$$

and then

$$-v'^2(r_{k+1}) + v'^2(r_k) = \int_{r_k}^{r_{k+1}} (-\frac{2l(l+1)}{r^3} + \frac{1}{r^2})\, v^2\, dr, \tag{A.14}$$

where $k = 0, \dots, n - l - 1$, and $r_0 := 0$, $r_{n-l} := \infty$.

Then we conclude that

$$|v'(r_k)| > |v'(r_{k+1})| \qquad \text{for} \quad r_k \geq 2l(l+1) \tag{A.15}$$

and

$$|v'(r_k)| < |v'(r_{k+1})| \qquad \text{for} \quad r_{k+1} \leq 2l(l+1). \tag{A.16}$$

Consider first $r_k\colon (1+\epsilon)r_* \leq r_k \leq (1-\epsilon)r^*$ [15].

Then one can see easily that

$$v(r) = v_k'(r_k)\frac{s_k}{\pi}\sin\big(\frac{\pi(r - r_k)}{s_k}\big)\big(1 + O(r_k^{-1/2})\big) \tag{A.17}$$

$$\text{for} \quad r_k \leq r \leq r_{k+1}$$

[15] Which is possible if and only if $l \leq (1 - \epsilon')n$.

and we calculate the right-hand expression of (A.14) arriving to

$$v'^2(r_{k+1}) = v'^2(r_k)\Big[1 - \frac{1}{2}r_k^{-2}\frac{s_k^3}{\pi^2}\Big(1 - \frac{2l(l+1)}{r_k} + O(r_k^{-1/2})\Big)\Big]. \tag{A.18}$$

Then in virtue of (A.11)

$$v'^2(r_{k+1}) = \tag{A.19}$$
$$v'^2(r_k)\Big[1 - \frac{1}{2}r_k^{-1}s_k\Big(1 - \frac{2l(l+1)}{r_k})\Big)\Big(1 - \frac{l(l+1)}{r_k} + \lambda_n\Big)^{-1} + O(r_k^{-1})\Big].$$

Then

$$v'^2(r_{k+1})r_{k+1}^{1/2} = \tag{A.20}$$
$$v'^2(r_k)r_k^{1/2}\Big[1 + \frac{1}{2}r_k^{-1}s_k\Big(\frac{l(l+1)}{r_k} + \lambda_n)\Big)\Big(1 - \frac{l(l+1)}{r_k} + \lambda_n\Big)^{-1} + O(r_k^{-1})\Big] =$$
$$v'^2(r_k)r_k^{1/2}(1+\varepsilon_k)$$

with $\varepsilon_k = O(\frac{l(l+1)}{r_k^{3/2}} + \frac{1}{r_k})$. In virtue of (A.9) $\sum \varepsilon_k \le C$ and therefore we arrive to

$$v'^2(r_k)r_k^{1/2} \asymp v'^2(r_m)r_m^{1/2}. \tag{A.21}$$

Since

$$\max_{r_k \le r \le r_{k+1}} |v(r)| \asymp |v'(r_k)(r_{k+1} - r_k) \tag{A.22}$$

we arrive to

$$r_k^{-1/4} \max_{r_k \le r \le r_{k+1}} |v(r)| \asymp r_m^{-1/4} \max_{r_m \le r \le r_{m+1}} |v(r)|. \tag{A.23}$$

Then taking $m \asymp n$ and using (A.9) we conclude that $p_k \asymp p_m k^{1/2} n^{-1/2}$ with p_k the left-hand expression of (A.21). Since

$$\int_{r_k}^{r_{k+1}} v^2(r)\,dr \asymp \max_{r_k \le r \le r_{k+1}} v^2(r)(r_{k+1} - r_k) \tag{A.24}$$

we conclude that it is $\asymp p_n^2 k^2 n^{-1}$ and therefore their sum is $\asymp p_m^2 n^2$; since it should not exceed 1, we conclude that $p_m \le Cn^{-1}$; applying $p_k \asymp p_m k^{1/2} n^{-1/2}$ again we arrive to

Proposition A.4. *Assume that*

$$l \le (1-\epsilon')n. \tag{A.25}$$

Then for $(1+\epsilon)r_* \le r_k \le (1-\epsilon)r^*$

$$\max_{r_k \le r \le r_{k+1}} |v(r)| \le C' r^{1/4} n^{-3/2}. \tag{A.26}$$

Remark A.5. It follows from the arguments below that actually in (A.26) there is "$\asymp$" sign.

Consider now zone $\{r\colon \max((1-\epsilon)r^* \le r \le r^* - Cr^{*2/3}\}$, again, under assumption (A.26).

Recall, that in this zone A.12) holds and also

$$W(r) = (r^* - r)r^{*-2}\Big(1 + O\big(\frac{r^*}{(r^*-r_k)^{3/2}}\big)\Big) \tag{A.27}$$

and

$$s_k = \frac{\pi r^*}{\sqrt{r^* - r_k}}\Big(1 + O\big(\frac{r^*}{(r^*-r_k)^{3/2}}\big)\Big). \tag{A.28}$$

Then for $r_k \le r \le r_{k+1}$

$$v(r) = v'(r_k)\frac{s_k}{\pi}\sin\big(\frac{\pi(r-r_k)}{s_k}\big)\Big(1 + O\big(\frac{r^*}{(r^*-r_k)^{3/2}}\big)\Big). \tag{A.29}$$

Then (A.14) implies that

$$v'^2(r_{k+1}) - v'^2(r_k) = -\frac{1}{2}v'^2(r_k)\frac{s_k^3}{\pi^2 r^{*2}}\Big(1 - \frac{2l(l+1)}{r^*}\Big)\Big(1 + O\big(\frac{r^*}{(r^*-r_k)^{3/2}}\big)\Big),$$

where (A.25) ensures that the first large parentheses are disjoint 0. Then plugging (A.28) we conclude that

$$v'^2(r_{k+1}) = v'^2(r_k)\Big[1 - \frac{1}{2}\frac{s_k}{(r^*-r_k)}\Big(1 - \frac{2l(l+1)}{r^*}\Big)\Big(1 + O\big(\frac{r^*}{(r^*-r_k)^{3/2}}\big)\Big)\Big]. \tag{A.30}$$

Then

$$v'^2(r_{k+1})(r^* - r_{k+1})^{-1/2} = v'^2(r_k)(r^* - r_{k+1})^{-1/2}\Big[1 + \frac{(r_{k+1}-r_k)}{(r^*-r_k)}\frac{l(l+1)}{r^*} + \varepsilon_k\Big] \tag{A.31}$$

with $\sum_k \varepsilon_k < \infty$.

Therefore

$$v'^2(r_k)(r^* - r_k)^{-1/2+\sigma} \asymp v'^2(r_m)(r^* - r_m)^{-1/2+\sigma},$$

and

$$|v'(r_k)| \asymp |v'(r_m)|(r^* - r_k)^{1/4-\sigma/}(r^* - r_m)^{-1/4+\sigma/2},$$

and finally

$$\max_{r_k<r<r_{k+1}} |v(r)| \asymp \max_{r_m<r<r_{m+1}} |v(r)|(r^* - r_k)^{-1/4-\sigma/2}(r^* - r_m)^{1/4+\sigma/2}.$$

Taking $m \asymp n$ such that $r_m \le (1-\epsilon)r^*$ we arrive in virtue of Proposition A.4 to

Proposition A.6. *Under assumption* (A.25) *for* $(1-\epsilon)r^* \le r < r^* - Cr^{*2/3}$

$$|v(r)| \le C'(r^* - r)^{-1/4-\sigma/2} n^{-1/2+\sigma}, \qquad \sigma = \frac{l(l+1)}{r^*}. \tag{A.32}$$

Consider now zone $\{r\colon r_* + Cr_*^{2/3} \le r \le (1+\epsilon)r_*\}$ provided (A.25). The same arguments lead us to

$$\max_{r_k\le r\le r_{k+1}} |v(r)| \asymp (r_k - r_*)^{-3/4+\sigma'/2}(r_m - r_*)^{3/4-\sigma'/2} \max_{r_m\le r\le r_{m+1}} |v(r)|.$$

and taking $m \asymp l$ such that $r_m \le (1+\epsilon)r_*$ and therefore $r_m \lesssim n^{-3/2}l^{1/2}$, we arrive to

Proposition A.7. *Under assumption* (A.25) *for* $r_* + Cr_*^{2/3} \le r \le (1+\epsilon)r_*$

$$|v(r)| \le C'(r - r_*)^{-3/4+\sigma'/2} n^{-3/2} l^{2-\sigma'}, \qquad \sigma' = \frac{l(l+1)}{r_*}. \tag{A.33}$$

Proposition A.8. *Let assumption* (A.25) *be fulfilled. Then*

(i) The following estimates hold

$$|v(r)| \le C' n^{-5/6-\sigma/3} \qquad \textit{for} \quad r \ge r^* - Cr^{*2/3} \tag{A.34}$$

and

$$|v(r)| \le C' n^{-3/2} l^{1-2\sigma'/3} \qquad \textit{for} \quad r \le r_* + Cr_*2/3. \tag{A.35}$$

(ii) Furthermore, let $b := C_s r^{*2/3}$. *Then*

$$|v(r)| \le C' n^{-5/6-\sigma/3} \Big(\frac{b}{r - r^*}\Big)^s \qquad \text{for } r \ge r^* + b. \tag{A.36}$$

(iii) On the other hand, let $b := C_s r_*^{2/3}$. *Then*

$$|v(r)| \le C' n^{-3/2} \bar{l}^{1-\sigma'/3} \Big(\frac{b}{r_* - r}\Big)^s \qquad \text{for } r \le r_* - b. \tag{A.37}$$

Proof. (i) Estimates (A.34) and (A.35) for $r^* - Cr^{*2/3} \le r \le r^* + Cr^{*2/3}$ and $r_* - Cr_*^{2/3} \le r \le r_* + Cr_*^{*2/3}$ follow from estimates (A.32) and (A.33) and equation (A.5).

(ii) Consider $\phi \in \mathscr{C}^\infty$, $\phi = 0$ on $(-\infty, \frac{1}{2})$ and $\phi = 1$ on $(1, \infty)$ and $\varphi(r) = \phi((r - r^*)/a)$. Then multiplying (A.5) by φv and integrating by parts we get

$$\int \varphi(r) v'^2(r)\, dr + \int \big(W(r) - \lambda_n\big)\varphi(r) v^2(r)\, dr = \frac{1}{2} \int \varphi''(r) v^2(r)\, dr$$

and therefore

$$\int_{r^*+a}^{\infty} r^{-2} v^2(r)\, dr \le Ca^{-3} \int_{r^*+a/2}^{r^*+a} v^2(r)\, dr$$

which implies after iterations estimate

$$\int_{r^*+a}^{\infty} v^2(r)\, dr \le C' a M^2 \Big(\frac{b}{a}\Big)^s, \tag{A.38}$$

for integral from $r^* + a$ to $r^* + 2a$, where M is the right-hand expression of (A.34), which, in turn, implies (A.38) in full measure.

Then the same proof implies that

$$\int_{r^*+a}^{\infty} v'^2(r)\, dr \le C' a^{-1} M^2 \Big(\frac{b}{a}\Big)^s$$

which combined with (A.38) implies (A.36).

(iii) Statement (iii) is proven in the same way. □

Consider now the case $l \geq (1-\epsilon n$. In this case both $r_* \approx r^* \approx 4n^2 \approx r_*/4n^2$ and, $(r^* - r_*) \approx 4n^{3/2}\sqrt{2(n-l)}$, $W(r) \approx (r-r_*)(r^*-r)r^{*-2}$, where $\approx$ means that the ration is close to 1.

Further $Cr^{*,2/3}$ should be replaced by $Cr^*/(r^*-r_*)^{1/3}$ and we want $Cr^*/(r^*-r_*)^{1/3} \leq (r^*-r_*)$ i.e. $(r^*-r_*) \geq Cr^{*\,3/4}$ which is equivalent

$$C_0 \leq (n-l) \leq \epsilon n. \tag{A.39}$$

Proposition A.9. *(i) Let condition* (A.39) *be fulfilled. Then*

$$|v(r)| \leq C' \begin{cases} L^{-1/4+\sigma/2}(r^*-r)^{-1/4-\sigma/2} & r^* - \epsilon L \leq r \leq r^* - Cr^* L^{-1/3}, \\ L^{-1/2} & r_* + \epsilon L \leq r \leq r^* - \epsilon L, \\ L^{1/4-\sigma'/2}(r-r_*)^{-3/4+\sigma'/2} & r_* + Cr_* L^{-1/3} \leq r \leq r_* + \epsilon L \end{cases} \tag{A.40}$$

with $L = r^* - r_*$.

(ii) Further,

$$|v(r)| \leq C' L^{-1/3+2\sigma/3} r^{*\,-1/4-\sigma/2} \begin{cases} 1 & r \geq r^* - Cb, \\ \left(\dfrac{b}{r-r^*}\right)^s & r \geq r^* + Cb \end{cases} \tag{A.41}$$

with $b = r^* L^{-1/3}$.

(iii) Furthermore,

$$|v(r)| \leq C' L^{1/2-2\sigma'/3} r_*^{-3/4+\sigma'} \begin{cases} 1 & r \leq r^* + Cb, \\ \left(\dfrac{b}{r_*-r}\right)^s & r \leq r_* - Cb \end{cases} \tag{A.42}$$

with $b = r_* L^{-1/3}$.

Proof. Statement (i) is proven in the same way as Propositions A.4, A.6 and A.7. Statements (ii) and (iii) are proven in the same way as Proposition A.8. □

Finally, consider the remaining case $1 \leq n - l \leq C$. In the same way

Proposition A.10. *Let* $1 \le n - l \le C$. *Then*

$$|v(r)| \le C' n^{-1/2} \begin{cases} \big(\frac{n^2}{r}\big)^s & r \ge Cn^2, \\ 1 & C^{-1}n^2 \le r \le Cn^2, \\ \big(\frac{\langle r\rangle}{n^2}\big)^s & r \le C^{-1}n^2. \end{cases} \tag{A.43}$$

We would need the following

Corollary A.11. *As* $r \le 2r^*$

$$|v(r)| \le C' r^{1/4} n^{-3/2}. \tag{A.44}$$

Proof. It follows from Propositions A.4–A.10. □

B Properties of eigenvalues and eigenfunctions of Coulomb-Schrödinger operator in relativistic settings

Consider first the negative spectra of operators

$$H^0_\beta := H_{\beta,V^0} = T_\beta - \frac{1}{r} \tag{B.1}$$

in $\mathscr{L}^2(\mathbb{R}^3, \mathbb{C})$ where T_β is defined by (1.18) and $r = |x|$. We assume that

$$0 < \beta \le \frac{2}{\pi} \tag{B.2}$$

and compare it with non-relativistic operator operator $H^0 := -\Delta - \frac{1}{r}$, the eigenvalues of which $\lambda^0_n = -\frac{1}{4n^2}$ (of multiplicity n^2) is well-known.

Note that

(B.3) Negative spectrum of operator H^0_β consists of eigenvalues $\mu^0_{n,l} := \mu^0_{n,l}(\beta)$ $(l = 0, 1, \dots, n-1)$ of multiplicities $(2l+1)$ (some of those could coincide) which are eigenvalues of operator

$$K_l(\beta) = \sqrt{\beta^{-2}\big(-\partial_r^2 + \frac{l(l+1)}{r^2}\big) + \frac{1}{4}\beta^{-4}} - \frac{1}{2}\beta^{-2} - \frac{1}{r} \tag{B.4}$$

in $\mathscr{L}^2(\mathbb{R}^+, \mathbb{C})$ and eigenfunctions of H^0_β are $R_{n,l}(r;\beta)Y_{l,m}(\phi,\theta)$ where

$$R_{n,l}(r;\beta) = r^{-1}w_{n,l}(r;\beta), \tag{B.5}$$

$w_{n,l}(r;\beta)$ are corresponding orthonormal eigenfunctions of $K_l(\beta)$ and $n = l+1, l+2, ...$

Recall that $Y_{l,m}(\phi,\theta)$ are spherical harmonics.

Proposition B.1. *Under assumption* (B.2) *the following hold:*

$$\mu_{n,l}(\beta) < \mu_{n,l}(\beta') \le \lambda^0_n = -\frac{1}{4n^2} \qquad \textit{for} \quad \beta' < \beta, \tag{B.6}$$

$$\mu^0_{n,l}(\beta) < \mu^0_{n+1,l+1}(\beta). \tag{B.7}$$

Proof. Observe that

$$T_l(\beta) \coloneqq \sqrt{\beta^{-2}\Lambda + \frac{1}{4}\beta^{-4}} - \frac{1}{2}\beta^{-2} \tag{B.8}$$
$$= \left(\sqrt{4\beta^2\Lambda + 1} + 1\right)^{-\frac{1}{2}} 2\Lambda \left(\sqrt{4\beta^2\Lambda + 1} + 1\right)^{-\frac{1}{2}}$$

with $\Lambda \coloneqq \Lambda_{n,l} = -\partial_r^2 - \frac{l(l+1)}{r^2}$. Then $T_l(\beta') < T_l(\beta) \le \Lambda$ (B.6) follows from the variational principle, since λ^0_n are eigenvalues of operator

$$K_l(0) \coloneqq \Lambda - \frac{1}{r}. \tag{B.9}$$

Since $T_{l+1} > T_l$, and $(n-l)$ numbers eigenvalues, starting from the first, we have (B.7). □

Proposition B.2. *Let* $l \le \epsilon n$ [16]. *Then the following estimate holds:*

$$\mu^0_{n,l} \ge \lambda^0_n - Cn^{-3}. \tag{B.10}$$

Proof. Consider eigenvalue counting functions $N_{l,\beta}(\lambda)$ and $\mathsf{N}_l(\lambda)$ for 1-dimensional operators $K_l(\beta)$ and $K_l(0)$ respectively, $\lambda < 0$. Under assumption

$$l \le \epsilon|\lambda|^{-1/2} \tag{B.11}$$

[16] We cover case $l \ge \epsilon n$ separately.

the standard semiclassical methods show that

$$\mathsf{N}_{l,\beta}(\lambda) = \mathcal{N}^{\mathsf{W}}_{l,\beta}(\lambda) + O(1), \qquad \mathsf{N}_{l}(\lambda) = \mathcal{N}^{\mathsf{W}}_{l}(\lambda) + O(1), \tag{B.12}$$

where $\mathcal{N}^{\mathsf{W}}_{l,\beta}(\lambda)$ and $\mathcal{N}^{\mathsf{W}}_{l}(\lambda)$ are corresponding Weyl expressions.

Indeed, under assumption (B.11) these operators are microhyperbolic (with effective semiclassical parameter $h \asymp r^{-1/2}$) and the remainder estimate is $C\int_{r_*}^{r^*} r^{-1}\,dr = O(\log(r^*/r_*))$ with $r^* \asymp |\lambda|^{-1}$, $r_* \asymp (l+1)^{-2}$ and it is $O(1)$ as $l \asymp |\lambda|^{-1/2}$.

Further, considering propagation of singularities in the direction of increasing r, one can update the remainder estimate to

$$C\int_{r_*}^{r^*} \bigl(r^{-1+\delta} r^{*\,-\delta} + r^{-s}\bigr)\,dr = O(1)$$

with $\delta > 0$.

Finally, one can see easily that the contribution of the zone $\{r\colon r \le C_0\}$ to both $\mathsf{N}_{l,\beta}(\lambda)$ and $\mathcal{N}^{\mathsf{W}}_{l,\beta}(\lambda)$ does not exceed C.

On the other hand, one can see easily that $\mathcal{N}^{\mathsf{W}}_{l,\beta}(\lambda) = \mathcal{N}^{\mathsf{W}}_{l}(\lambda) + O(1)$ and since $\mathcal{N}^{\mathsf{W}}_{l}(\lambda) \asymp |\lambda|^{-1/2}$ for $r_* \le \epsilon r^*$ we arrive to (B.10) in this case. Here we calculate r^* exactly as in Appendix A for non-relativistic operator $K_l(0)$. One can see easily that assumption (B.11) is equivalent to $l \le \epsilon n$ (with different but still small constant $\epsilon > 0$). We leave easy details to the reader. □

Recall that $w_{n,l} \coloneqq w_{n,l}(r;\beta)$ are eigenfunctions of K_l, $\|w_{n,l}\| = 1$ where $\|.\|$ and $\langle .,.\rangle$ are norm and an inner product in $\mathscr{L}^2(\mathbb{R}^+,\mathbb{C})$.

Proposition B.3. *Under assumption* (B.2) *the following estimates hold with arbitrarily large exponent* s*:*

$$|w_{n,l}(r)| \le Cr^{-s} \qquad \textit{for}\ \ r \ge C_0 n^2 \tag{B.13}$$

and

$$|w_{n,l}(r)| \le C\|\!|w_{n,l}|\!\|_{l;s} \coloneqq C\sum_{k\ge 0} t_k^{-s}\|\phi_{t_k} w_{n,l}\| \qquad \textit{for}\ \ r \le C_0^{-1} l^2\,, \tag{B.14}$$

where $\phi_t(r) = \phi(r/t)$ *and* $\phi \in \mathscr{C}_0^\infty([-1,1])$, $\phi(r) = 1$ *on* $(-\frac12,\frac12)$, $t_k = 2^k l$.

Proof. (a) Proof is standard: observe that for $w := w_{n,l}$

$$|\langle((K_l(\beta)-\mu^0_{n,l})\psi_t w,\ \psi_t w\rangle| \le C|\langle[[K_l(\beta),\psi_t]v,\psi_t]w,\ w\rangle| \le C_0 t^{-2}\|\psi_{t'}v\|^2 + Ct^{-2s}\|w\|^2\,, \tag{B.15}$$

where $1-\psi \in \mathscr{C}_0^\infty([-1,1])$, $\psi(r)=0$ on $(-1-\varepsilon, 1+\varepsilon)$, $t'=(1+2\varepsilon)^{-1}t$.

On the other hand, for $t \ge C_0 n^{-2}$

$$\langle((K_l(\beta)-\mu^0_{n,l})\psi_t w,\ \psi_t w\rangle \ge Cn^{-2}\|\psi_t w\|^2 - Cn{-}2s\|w\|^2\,. \tag{B.16}$$

Combining (B.15) and (B.16) and iterating we arrive to $\|\psi_t w\| \le Ct^{-s}$. Then

$$\|(\beta^{-2}\Lambda+\beta^{-4})^{1/2}\psi_t w\| \le \beta^{-2}\|\phi_t w\| + Ct^{-2s} \implies \langle(\beta^{-2}\Lambda+\beta^{-4})\psi_t w,\ \psi_t w\rangle \le \beta^{-2}\|\psi_t w\|^2 + 2C\beta^{-2}l^{-2s} \implies \langle\Lambda\psi_t w,\ \psi_t w\rangle \le Ct^{-2s}\,.$$

Then

$$\|\partial\psi_t w\| + l\|r^{-1}\psi_t w\| \le Ct^{-s}\,, \tag{B.17}$$

which implies (B.13).

(b) The proof of (B.3) follows the same scheme albeit now $\psi \in \mathscr{C}_0^\infty([-1,1])$, $\psi(r)=0$ on $(-1+\varepsilon, 1-\varepsilon)$, $t'=(1-2\varepsilon)^{-1}t$ and we select $t=C_0^{-1}l^2$. Then (B.15) is replaced by

$$|\langle((K_l(\beta)-\mu^0_{n,l})\psi_t w,\ \psi_t w\rangle| \le C_0 t^{-2}\|\psi_{t'}v\|^2 + C\|\!|w_{n,l}|\!\|_{l;s}\,. \tag{B.18}$$

Then (B.16) is replaced by

$$\langle((K_l(\beta)-\mu^0_{n,l})\psi_t w,\ \psi_t w\rangle \ge Cl^2t^{-1}\|\psi_t w\|^2 - C\|\!|w_{n,l}|\!\|_{l;s}\,, \tag{B.19}$$

and combining (B.18) and (B.19) we arrive to $\|\psi_t w\| \le C\|\!|w_{n,l}|\!\|_{l;s}$. Next two inequalities are preserved, but t^{-2s} is replaced by $\|\!|w_{n,l}|\!\|_{l;s}$ there. □

Proposition B.4. *Under assumption* (B.2) *the following estimate hold swith arbitrarily large exponent* s*:*

$$\|P_{l,s}w_{n,l}\| \le C\|\!|w_{n,l}|\!\|_{l;s}\,, \tag{B.20}$$

with

$$P_{l,s} := -\partial_r^2 + V_s(r,\lambda_n,l,\mu^0_{n,l}) + W_s(r,\lambda_n,l,\mu^0_{n,l})\partial_r\,, \tag{B.21}$$

and

$$V_s(r,\lambda_n,l,\mu) := \frac{l(l+1)}{r^2} - \frac{1}{r} - \mu + \sum_{j,k:\ 2\le j+k\le s} V_{j,k}(r/r_*,\beta)r^{-j}\mu^k\,, \tag{B.22}$$

and

$$W_s(r,\lambda_n,l,\mu) := \sum_{j,k:\ 2\le j+k\le s} W_{j,k}(r/r_*,\beta)r^{-j}\mu^k \tag{B.23}$$

with coefficients which could be decomposed asymptotically in positive powers of β *and non-positive of* r/r_**.*

Proof. Due to Proposition B.3 we need to consider only $r \le C_0 n^2$. Then semiclassical microlocal methods imply that

$$\|(1-\varphi_\tau(D_r))\psi_t(r)w_{n,l}\| \le C\|\!|w_{n,l}|\!\|_{s,l} \tag{B.24}$$

provided $\psi \in \mathscr{C}_0^\infty([\frac12,1))$, $\varphi \in \mathscr{C}_0^\infty([-1,1])$, $\varphi = 1$ on $(-\frac12,\frac12)$ and $\tau = t^{-1/2+\delta}$ with arbitrarily small exponent $\delta > 0$, $t \le C_0 n^2$.

Then $T_l w_{n,l}$ could be approximated in this zone by the (asymptotic) $\sum_{k\ge0} c_k\beta^k\Lambda^{k+1}w_{n,l}$ with $c_0 = 1$, and it equals to

$$\sum_{k\ge0} c_k\beta^k\Lambda^k(\frac{1}{r}+\mu_{n,l})w_{n,l}$$
$$= \sum_{k\ge0} c_k\beta^k(\frac{1}{r}+\mu_{n,l})\Lambda^k w_{n,l} + \sum_{k\ge0} c_k\beta^k[\Lambda^k,(\frac{1}{r}+\mu_{n,l})]w_{n,l}$$

Giving weights $-\frac12$ to ∂_r, -1 to Λ and r^{-1}, and 0 to $l(l+1)/r$, we see that $[\Lambda, r^{-1}]$ has weight of $-\frac52$ and both $[\Lambda,\partial_r]$ and $[r^{-1},\partial_r]$ have weight of -2.

In this process we replace $-\partial_r^2$ by $\Lambda - \frac{l(l+1)}{r^2}$, and when Λ reaches $w_{n,l}$ we replace it by $-(\frac1r+\mu_{n,l})$.

As a result we have

$$\big(K_l - \mu^0_{n,l}\big)w_{n,l} \equiv \big(I+Q\big)P_{l,s} \tag{B.25}$$

with

$$Q = \beta^2 \sum_{j,k:\ 1\le j+k\le s} d_{j,k}(\beta) r^{-j}\mu^k + \beta^2 \sum_{j,k:\ 1\le j+k\le s} d'_{j,k}(\beta) r^{-j}\mu^k \partial_r\,. \tag{B.26}$$

It implies the statement of the proposition. □

Proposition B.5. *Under assumption* (B.2) *the following estimate hold swith arbitrarily large exponent* s*:*

$$|v_{n,l}(x)| \le C r^{1/4} n^{-3/2} \qquad \textit{for}\ \ r_* \le r \le r^* \tag{B.27}$$

with $r_* = \epsilon_0 (l+1)^2$ *and* $r^* = C_0 n^2$.

Proof. We can get rid of the last term in expression (B.21) by the substitution $w_{n,l} = e^{\Phi}\tilde w_{n,l}$ with bounded Φ, because this term is $O(r^{-2}+\mu^2) = O(r^{-2})$ for $r \le r^*$ provided $|\mu| \le c_0 n^{-2}$, which is guaranteed by (B.10) (and it is the only place where we need (B.2). Then we can apply arguments of Appendix A and derive (B.27), uniform by $\beta \le c_0$.

Namely, let us repeat with the minor modifications arguments of Appendix A. Then

(a) Note that we do not claim that $w_{n,l}(r)$ has exactly $(n-l-1)$ zeroes as $v_{n,l}(r)$ has[17] .

(b) On the other hand, as $r \ge C$ (large enough constant) the distance between consecutive zeroes is at least $\epsilon' r^{1/2}$ while for

$$C(l+1)^2 \le r \le (1-\epsilon)^{-1}\mu_{n,l}^{0\,-1}$$

this distance does not exceed $Cr^{1/2}$. More precisely, (A.10) and (A.11) hold[18] and also Proposition A.3, Statements (i) and (ii)[18] hold.

(c) Also Proposition A.4 and Remark A.5 hold[19].

(d) Also Propositions A.6, A.7, A.8 and hold A.9 [20].

(e) Also Propositions A.10 holds. □

[17] See Proposition A.1.
[18] The latter, only as $l \ge C$.
[19] Under extra assumption $r_k \ge C$.
[20] With all statements, referring to r_* only as $r \ge C$.

Remark. We need to remember that equation is fulfilled modulo $O(r^{-s})$ but it would matter only if $|w| + |w'| = O(r^{-s'})$ but then in the process we can prove that it is not the case.

Proposition B.6. *Under assumption* (B.2) *the following estimate hold swith arbitrarily large exponent* s*:*

$$|\mu^0_{n,l}(\beta) - \mu^0_{n,l}(\beta)| \le C|\beta^2 - \beta'^2| n^{-3}(l+1)^{-1}; \tag{B.28}$$

in particular

$$\mu^0_{n,l}(\beta) \le \bar\lambda_n - C\beta^2 n^{-3}(l+1)^{-1}; \tag{B.29}$$

recall that $K_l(\beta) < K_l(\beta') < K_l(0)$ *for* $0 < \beta' < \beta$ *and therefore*

$$\mu^0_{n,l}(\beta) < \mu^0_{n,l}(\beta') < \bar\lambda_n \tag{B.30}$$

Proof.

$$\mu^0_{n,l}(\beta) - \lambda^0_n = \int_{\beta'}^{\beta} \langle (\partial_{\gamma^2} K_{n,l}(\gamma) w_{n,l},\ w_{n,l}\rangle \, d\gamma^2. \tag{B.31}$$

and we use (B.27). □

Corollary B.7. *Consider* $\mu^0_{n,l}$ *as eigenvalues of the corresponding* $3D$*-operator. Then only two cases are possible:*

(i) If $\beta \le \epsilon_1$ *with sufficiently small constant* ϵ_1*, then all these eigenvalues* $\mu^0_{n,l}$ *are in the clusters* $\mathcal{C}^0_n$ *of the width* $\le C_0\beta^2 n^{-3}$*, separated by gaps of the width* $\asymp n^{-3}$*.*

Each cluster contains exactly n^2 *eigenvalues.*

(ii) Otherwise, if $\beta > \epsilon_1$*, we can break* $\mu^0_{n,l}$ *into clusters* $\mathcal{C}^0_n$ *of the width* $\asymp n^{-3}$*, separated by gaps of the width* $\asymp n^{-3}$*. In this case* $\mu^0_{n,l} \in \mathcal{C}_n$ *for* $l \ge C_0$ *but for* $l < C_0$ *it could belong to* $\mathcal{C}^0_m$ *with* $n - C_0 \le m \le n$*.*

Each cluster $\mathcal{C}^0_n$ *contains* $\nu_n \in [n^2 - C_1,\ n^2 + C_1]$ *eigenvalues.*

Remark B.8. (i) We do not know what is the case as (B.2) ever occurs under assumption (B.2) and it would be intersting to learn. However it does not matter for our purposes: we simply change numeration of $\mu^0_{n,l}$ so that $\mu^0_{n,l}$ with $n = l+1, \dots, l+\nu_n$ belongs to $\mathcal{C}^0_n$.

(ii) Probably, in addition to (B.28) the opposite inequality also holds

$$|\mu^0_{n,l}(\beta) - \mu^0_{n,l}(\beta)| \geq \epsilon_0 |\beta^2 - \beta'^2| n^{-3}(l+1)^{-1}. \tag{B.32}$$

(iii) It would be interesting to derive an estimate for $\|w_{n,l}(\beta) - w_{n,l}(\beta')\|$ and a poinwise estimate for $|w_{n,l}(\beta) - w_{n,l}(\beta')|$.

Upper Estimates for the Electronic Density in Heavy Atoms and Molecules[*,†]

[‡]

Victor Ivrii[§]

Abstract

We derive an upper estimate for the electronic density $\rho_\Psi(x)$ in heavy atoms and molecules. While not sharp, on the distances $\gtrsim Z^{-1}$ from the nuclei it is still better than the known estimate CZ^3 (Z is the total charge of the nuclei, $Z \asymp N$ the total number of electrons.

1 Introduction

This paper is a result of my rethinking of three rather old but still remarkable papers [HHT, ILS, S1], which I discovered recently. The first of them derives the estimate electronic density $\rho_\Psi(x)$ from above via some integral also containing ρ_Ψ, the second one provides an estimate $\rho_\Psi(x) = O(Z^3)$ where Z is the total charge of nuclei and the third one derives the asymptotic of the averaged electronic density on the distances $O(Z^{-1})$ from the nuclei but its method works also on the larger distances.

The purpose of this paper is to provide a better upper estimate for $\rho_\Psi(x)$ on distances larger than Z^{-1} from the nuclei.

Let us consider the following operator (quantum Hamiltonian)

$$\mathsf{H} = \mathsf{H}_N := \sum_{1\le j\le N} H_{V,x_j} + \sum_{1\le j<k\le N} |x_j - x_k|^{-1} \tag{1.1}$$

on

$$\mathfrak{H} = \bigwedge_{1\le n\le N} \mathscr{H}, \qquad \mathscr{H} = \mathscr{L}^2(\mathbb{R}^3, \mathbb{C}^q) \tag{1.2}$$

with

$$H_V = -\Delta - V(x) \tag{1.3}$$

describing N identical particles (electrons) in the external field with the scalar potential $-V$ and repelling each other according to the Coulomb law.

Here $x_j \in \mathbb{R}^3$ and $(x_1, \dots, x_N) \in \mathbb{R}^{3N}$. A potential $V(x)$ is assumed to be real-valued. Except when specifically mentioned we otherwise assume that

$$V(x) = \sum_{1\le m\le M} \frac{Z_m}{|x - \mathsf{y}_m|} \tag{1.4}$$

where $Z_m > 0$ and y_m are charges and locations of nuclei.

The mass is equal to $\frac{1}{2}$ and the Plank constant and the charge are equal to 1 here. We assume that $N \asymp Z = Z_1 + \dots + Z_M$.

Our purpose is to derive a pointwise upper estimate for the *electronic density*

$$\rho_\Psi(x) = N \int |\Psi(x, x_2, \dots, x_N)|^2 \, dx_2 \cdots dx_N. \tag{1.5}$$

Let

$$\ell(x) = \min_{1\le m\le M} |x - \mathsf{y}_m| \tag{1.6}$$

is the distance to the nearest nucleus. Our goal is to prove the following theorem:

Theorem 1.1. *Let*

$$\min_{1\le m<m'\le M} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge Z^{-1/3+\sigma} \tag{1.7}$$

with $\sigma > 0$. Then:

(i) For $\ell(x) \le Z^{-1/3}$ the following estimate holds:

$$\rho_\Psi(x) \le C \begin{cases} Z^3 & \text{for } \ell(x) \le Z^{-8/9}, \\ Z^{19/9}\ell^{-1} & \text{for } Z^{-8/9} \le \ell(x) \le Z^{-7/9}, \\ Z^{197/90}\ell^{-9/10} & \text{for } Z^{-7/9} \le \ell \le Z^{-1/3}. \end{cases} \tag{1.8}$$

(ii) For $\ell(x) \ge Z^{-1/3}$ the following estimate holds:

$$\rho_\Psi(x) \le C \begin{cases} Z^{17/9}\ell^{-9/5} & \text{for } \ Z^{-1/3} \le \ell \le Z^{-5/18}, \\ Z^{19/9}\ell^{-1} & \text{for } \ \ell \ge Z^{-5/18}. \end{cases} \tag{1.9}$$

(iii) Furthermore, if $(Z - N) \ge C_0 Z^{5/6}$ then

$$\rho_\Psi(x) \le Z^{19/9}\ell^{-1} \qquad \text{for } \ \ell(x) \ge C_0 (Z-N)_+^{-1/3}. \tag{1.10}$$

Remark 1.2. We would like to prove an estimate $\rho_\Psi(x) \le C\zeta^3$, or to discover that it does not necessarily hold.

Plan of the paper. In Section 2 we prove a more subtle version of the main estimate of [HHT]. In Section 3 we provide upper estimates and asymptotics of ρ_Ψ integrated over small balls. In Section 4 we study the energy of electron-to-electron interaction (it involves a two-point correlation function) and in Section 5 we prove upper estimates for $\rho_\Psi(x)$.

2 Main intermediate inequality

We start from the main intermediate equality.

Proposition 2.1. *Let Ψ be an eigenfunction of H_N with an eigenvalue λ. Let $\phi(|x|)$ be a real-valued spherically symmetric function. Then*

$$\begin{aligned} \rho_\Psi(0) = {} & \\ (2\pi)^{-1} N \iint (\partial_r K(x)) \Psi(x, x_2, \dots, x_N) \Psi^*(x, x_2, \dots, x_N) \phi(|x|)\, dx dx_2 \cdots dx_N & \\ - (8\pi)^{-1} \int \rho_\Psi(x) \phi'''(|x|)\, dx, & \end{aligned} \tag{2.1}$$

where

$$K(x) \coloneqq -\mathsf{H}_N - (\partial_r^2 + 2r^{-1}\partial_r) \tag{2.2}$$

is an operator in the auxiliary space $\mathcal{H} \coloneqq \bigotimes_{n=2,\dots,N} \mathscr{L}^2(\mathbb{R}^3, \mathbb{C}^q) \otimes \mathbb{C}^q$ with an inner product $\langle .,. \rangle$, $\phi'''(r) = \partial_r^3 \phi(r)$ and $x = (r, \theta) \in \mathbb{R}^+ \times \mathbb{S}^2$.

Proof. Let us consider Ψ as a function of $x \in \mathbb{R}^3$ with values in the auxiliary space $\mathcal{H}$, and and let $u = r\Psi$ where (r, θ) are spherical coordinates in $\mathbb{R}^3$. Then similar to (9) of [HHT]

$$\langle \Psi(0), \Psi(0)\rangle = -(2\pi)^{-1} \int \langle \partial_r u, \partial_r^2 u\rangle \phi(r) r^{-2}\, dx - (4\pi)^{-1} \int \langle \partial_r u, \partial_r u\rangle \phi'(r) r^{-2}\, dx \tag{2.3}$$

and since $r^{-1}\partial_r^2 u = r\Delta_r \Psi := r(\partial_r^2 + 2r^{-1}\partial_r)\Psi$, the first term on the right is equal to

$$\begin{aligned} &-(2\pi)^{-1} \iint \langle \partial_r u, r\Delta_r \Psi\rangle \phi(r)\, dr d\theta \\ &\qquad = \pi^{-1} \iint \langle \partial_r u, (K+\lambda)u\rangle \phi(r) dr d\theta = \\ &= -(2\pi)^{-1} \int \langle \Psi, K'\Psi\rangle \phi(r)\, dx - (2\pi)^{-1} \iint \langle \Psi, (K+\lambda)\Psi\rangle \phi'(r)\, dx \end{aligned} \tag{2.4}$$

because $\Delta_r \Psi = -2(K+\lambda)\Psi$, where $-K$ is the rest of the multiparticle Hamiltonian (including $-r^{-2}\Delta_\theta$) and we integrated by parts.

The first term in the latter formula is a corresponding term in [HHT], albeit truncated with ϕ, and we have two new terms

$$-(4\pi)^{-1} \iint \langle \partial_r(r\Psi), \partial_r(r\Psi)\rangle \phi'(r)\, dr d\theta - (2\pi)^{-1} \int \langle \Psi, (W+\lambda)\Psi\rangle \phi'(r)\, dx\,.$$

Integrating the first term by parts we get

$$(4\pi)^{-1} \iint \langle r\Psi, \partial_r^2(r\Psi)\rangle \phi'(r)\, dr d\theta + (4\pi)^{-1} \iint \langle r\Psi, \partial_r(r\Psi)\rangle \phi''(r)\, dr d\theta,$$

where the first term cancels the second term in (2.4), while the second term integrates by parts one more time resulting in the last term in (2.1). □

Applying (2.1) to our problem, and using skew-symmetry of Ψ, we get

$$\rho_\Psi(0) = (2\pi)^{-1} \int \sum_m Z_m \frac{x\cdot(x-\mathsf{y}_m)}{|x|\cdot|x-\mathsf{y}_m|^3}\rho_\Psi(x)\phi(|x|)\,dx \tag{2.5}$$
$$+ (2\pi)^{-1} N(N-1) \int \underbrace{\frac{x_1\cdot(x_2-x_1)}{|x_1|\cdot|x_2-x_1|^3}}\, |\Psi(x_1,x_2,\dots,x_N)|^2 \underbrace{\phi(|x_1|)}\, dx_1\cdots dx_N$$
$$- (2\pi)^{-1} N \int |x|^{-3}|\nabla_\theta \Psi(x,x_2,\dots,x_N)|^2\phi(|x|)\,dx dx_2\cdots dx_N$$
$$- (8\pi)^{-1}\int \rho_\Psi(x)\phi'''(|x|)\,dx.$$

Symmetrizing the second term with respect to x_1 and x_2 e instead of the product of two indicated factors we will get

$$\frac{1}{4}\big(\phi(|x_1|)+\phi(|x_2|)\big)\Big(\frac{x_1\cdot(x_2-x_1)}{|x_1|\cdot|x_2-x_1|^3} - \frac{x_2\cdot(x_2-x_1)}{|x_2|\cdot|x_2-x_1|^3}\Big)$$
$$+\frac{1}{4}\big(\phi(|x_1|)-\phi(|x_2|)\big)\Big(\frac{x_1\cdot(x_2-x_1)}{|x_1|\cdot|x_2-x_1|^3} + \frac{x_2\cdot(x_2-x_1)}{|x_2|\cdot|x_2-x_1|^3}\Big)$$

with the big parenthesis on the first line equal to

$$-\frac{|x_1|+|x_2|}{|x_1-x_2|^3}\Big(1-\frac{x_1\cdot x_2}{|x_1|\cdot|x_2|}\Big) \tag{2.6}$$

and the big parenthesis on the second line equal to

$$-\frac{|x_1|-|x_2|}{|x_1-x_2|^3}\Big(1+\frac{x_1\cdot x_2}{|x_1|\cdot|x_2|}\Big)\,. \tag{2.7}$$

One can see that the former is negative, and the latter, multiplied by $\big(\phi(|x_1|)-\phi(|x_2|)\big)$, is non-negative if ϕ is a non-decreasing function. Let us shift the origin to point x and observe that the first term in (2.5) is equal to

$$(2\pi)^{-1}\int \sum_m Z_m \frac{(x-\mathsf{x})\cdot(x-\mathsf{y}_m)}{|x-\mathsf{x}|\cdot|x-\mathsf{y}_m|^3}\rho_\Psi(x)\phi(|x-\mathsf{x}|)\,dx\,. \tag{2.8}$$

Consider first case $\phi = 1$. Then we get

$$\rho_\Psi(\mathsf{x}) \le (2\pi)^{-1}\int \sum_m Z_m|x-\mathsf{y}_m|^{-2}\rho_\Psi(x)\,dx. \tag{2.9}$$

Indeed, the second term in the right-hand expression of (2.5) is non-positive due to above analysis analysis, so is the third term, and the fourth term vanishes while the first term does not exceed the right-hand expression

Applying Proposition 3.1 below we arrive to the following estimate

$$\rho_\Psi(x) \le CZ^3. \tag{2.10}$$

In the general case we arrive to

Proposition 2.2. *In the framework of Proposition 2.1*

$$\begin{aligned}\rho_\Psi(\mathsf{x}) \le (2\pi)^{-1} \int \sum_m Z_m \frac{(x-\mathsf{x})\cdot(x-\mathsf{y}_m)}{|x-\mathsf{x}|\cdot|x-\mathsf{y}_m|^3}\rho_\Psi(x)\phi(|x-\mathsf{x}|)\,dx \\ + Ct^{-1}\iint_{B(\mathsf{x},t)\times B(\mathsf{x},t)} |x-y|^{-1}\rho^{(2)}_\Psi(x,y)\,dxdy \\ + C\iint_{B(\mathsf{x},t)\times(\mathbb{R}^3\setminus B(\mathsf{x},t))} |y-\mathsf{x}|^{-2}\rho^{(2)}_\Psi(x,y)\,dxdy\,,\end{aligned} \tag{2.11}$$

where

$$\rho^{(2)}_\Psi(x,y) \coloneqq N(N-1)\int |\Psi(x,y,x_3,\dots,x_N)|^2\,dx_3\cdots dx_N \tag{2.12}$$

is a two-point correlation function.

Recall that

$$\int \rho^{(2)}_\Psi(x,y)dy = (N-1)\rho_\Psi(x). \tag{2.13}$$

Remark 2.3. (i) Inequality (2.9) for $M=1$ and $\mathsf{x}=\mathsf{y}_1$ is the main result of [HHT]. Our main achievement so far is an introduction of the truncation ϕ. However it brings three new terms in the right-hand expression of the estimate.

(ii) Estimate (2.10) (with a specified albeit not sharp constant) was proven in [S1] for $x=\mathsf{y}_m$.

(iii) This estimate definitely has the correct magnitude as $|x-\mathsf{y}_m| \lesssim Z^{-1}$ and $Z_m \asymp Z$.

3 Estimates of the averaged electronic density

We will need the following estimate (3.3) from [Ivr2]:

$$\int U\rho_\Psi \, dx \le \mathsf{Tr}(H^-_{W+\nu}) - \mathsf{Tr}(H^-_{W+U+\nu}) + CZ^{5/3-\delta} \tag{3.1}$$

with $\delta = \delta(\sigma)$, $\delta > 0$ for $\sigma > 0$ and $\delta = 0$ for $\sigma = 0$.

First, we use this estimate in the very rough form:

Proposition 3.1. *The following estimate holds:*

$$\int |x - y_m|^{-2} \rho_\Psi(x)\, dx \le CZ^2. \tag{3.2}$$

Proof. Let $\psi(x)$, $\psi_0(x)$ be cut-off functions, $\psi(x) = 0$ in $\{x\colon \ell(x) \le b\}$, $\psi_0(x) = 0$ in $\{x\colon \ell(x) \ge 2b\}$, $\psi + \psi_0 = 1$, $b = Z^{-1}$. Then

$$\mathsf{Tr}(H^-_{W+U+\nu}) = \mathsf{Tr}(H^-_{W+U+\nu}\psi_0) + \mathsf{Tr}(H^-_{W+U+\nu}\psi) \tag{3.3}$$

Using the semiclassical methods of [Ivr1], Section 25.4 in the simplest form, we conclude that for $U = \epsilon|x - y_m|^{-2}$ the second term on the right (with an opposite sign) could be replaced by its Weyl approximation

$$-\frac{2}{5}\kappa \int (W + U + \nu)_+^{5/2}\psi(x)\, dx \tag{3.4}$$

with an error not exceeding CZ^2 where here and below $\kappa = q/(6\pi^2)$. The same is true for $U = 0$. One can see easily that the difference between expression (3.4) and the same expression for $U = 0$ does not exceed

$$C\int \left[(W + \nu)_+^{3/2} U + U^{5/2}\right] dx, \tag{3.5}$$

which does not exceed CZ^2.

Consider the first term in the right-hand expression of (3.3). Using variational methods of [Ivr1], Section 9.1, we can reduce it to the analysis of the same operator in $\mathcal{X}^0 := \{x\colon \ell(x) \le 4b\}$ with the Dirichlet boundary conditions on ∂X. Observing that eigenvalue counting function for such operator is $O(1+\lambda^{3/2}Z^{-3})$ (for ϵ sufficiently small), we conclude that the first term in (3.3) also does not exceed CZ^2. Estimate (3.2) has been proven. □

Let us return to (3.1) and consider $U = \zeta^2\phi_t(x;\mathsf{x})$ where x is a fixed point with

$$\ell(x) \coloneqq \min_m |x - \mathsf{y}_m| \ge Z^{-1}, \tag{3.6}$$

$$\zeta(x) \coloneqq \max\bigl(Z^{1/2}\ell(x)^{-1/2},\, \ell(x)^{-2}\bigr) \tag{3.7}$$

and $\phi_t(x;\mathsf{x}) = \phi_0(t^{-1}|x-\mathsf{x}|)$, $\phi \in \mathscr{C}_0^\infty([-1,1])$, $0 \le \phi \le 1$. We assume that

$$\zeta^{-1} \le t \le \frac{\ell}{2} \tag{3.8}$$

with $\ell = \ell(\mathsf{x})$, $\zeta = \zeta(\mathsf{x})$, where the last inequality allows us to apply semiclassical methods. Consider with $0 \le \varsigma \le 1$

(3.9)
$$\mathsf{Tr}(H^-_{W+\nu}) - \mathsf{Tr}(H^-_{W+\varsigma U+\nu}) = \int_0^\varsigma \mathsf{Tr}\Bigl(U\bigl[\theta(-H_{W+sU+\nu}) - \theta(-H_{W+\nu})\bigr]\Bigr)\,ds$$

and apply semi-classical methods to the right-hand expression. Then we get

$$\begin{aligned}(3.10)\quad &\mathsf{Tr}(H^-_{W+\nu}) - \mathsf{Tr}(H^-_{W+\varsigma U+\nu})\\ &\quad= \kappa\int\int_0^\varsigma \Bigl(U\bigl[(W+sU+\nu)_+^{3/2} - (W+\nu)_+^{3/2}\bigr]\Bigr)\,dxds + O(\varsigma\zeta^4t^2)\\ &\quad= \frac{2}{5}\kappa\int\Bigl((W+\varsigma U+\nu)_+^{5/2} - (W+\nu)_+^{5/2}\Bigr)\,dx + O(\varsigma\zeta^4t^2).\end{aligned}$$

Indeed, factor U is $O(\zeta^2)$ and therefore the semiclassical error is $O(\zeta^4t^2)$ since the effective semiclassical parameter is $h = (\zeta t)^{-1}$. Observe that the principal part in the right-hand expression does is $O(\varsigma\zeta^5t^3)$.

Then after division by $\varsigma\zeta^2$ (3.1) becomes

$$\begin{aligned}(3.11)\quad \int \phi_t(x;\mathsf{x})\rho_\Psi(x)\,dx \le \int \phi_t(x;\mathsf{x})\rho(x)\,dx\\ + C\Bigl(\zeta^2t^2 + \varsigma\zeta^3t^3 + \varsigma^{-1}Z^{5/3-\delta}\Bigr).\end{aligned}$$

Replacing $\phi_t(x;\mathsf{x})$ by $-\phi_t(x;\mathsf{x})$ in this inequality and minimizing by $\varsigma \in (0,1]$ we arrive to the first statement of the following proposition:

Proposition 3.2. *(i) Under assumptions* (3.6)–(3.8)

(3.12)
$$|\int (\rho_\Psi(x)-\rho(x))\phi_t(x;\mathsf{x})\,dx| \le C\Big(\zeta^2 t^2+\zeta^{1/2}t^{3/2}Z^{5/6-\delta/2}+\zeta^{-2}Z^{5/3-\delta}\Big).$$

(ii) Further,

$$|\int \rho_\Psi(x)\phi_t(x;\mathsf{x})\,dx| \le C\Big(\zeta^3 t^3 + t^{6/5}Z^{1-3\delta/5}\Big). \tag{3.13}$$

(iii) Furthermore, if $N < Z$ then

$$|\int \rho_\Psi(x)\phi_t(x;\mathsf{x})\,dx| \le Ct^{6/5}Z^{1-3\delta/5} \qquad \textit{for } \ell(\mathsf{x}) \ge C_0(Z-N)_+^{-1/3}. \tag{3.14}$$

To prove the second statement, we consider $\varsigma > 0$ (without restriction $\varsigma \le 1$); then instead of (3.11) we have

$$\int \phi_t(x;\mathsf{x})\rho_\Psi(x)\,dx \le C\Big(\zeta^3 t^3 + \varsigma^{3/2}\zeta^3 t^3 + \varsigma^{-1}\zeta^{-2}Z^{5/3-\delta}\Big) \tag{3.15}$$

and we optimize it by $\varsigma > 0$.

The third statement follows from the same arguments and the fact that that $\rho^{\mathsf{TF}}(x) = 0$ for $\ell(x) \ge C_0(Z-N)_+^{-1/3}$ and therefore (3.15) holds without the first term in the right-hand expression.

4 Estimates of the correlation function

We will need the following Proposition 25.5.1 from [Ivr1] (first proven in [RS]):

Proposition 4.1. *Let $\theta \in \mathscr{C}^\infty(\mathbb{R}^3)$, such that*

$$0 \le \theta \le 1. \tag{4.1}$$

Let $\chi \in \mathscr{C}^\infty(\mathbb{R}^6)$ and

$$\mathcal{J} = |\int \Big(\rho_\Psi^{(2)}(x,y)-\rho(y)\rho_\Psi(x)\Big)\theta(x)\chi(x,y)\,dxdy| \le \tag{4.2}$$
$$C\sup_x \|\nabla_y\chi\|_{\mathscr{L}^2(\mathbb{R}^3_y)}\Big((Q+\varepsilon^{-1}N+T)^{\frac12}\Theta + P^{\frac12}\Theta^{\frac12}\Big) + C\varepsilon N\|\nabla_y\chi\|_{\mathscr{L}^\infty}\Theta$$

with

$$Q = \mathsf{D}(\rho_\Psi - \rho^{\mathsf{TF}},\, \rho_\Psi - \rho^{\mathsf{TF}}), \tag{4.3}$$

$$\Theta = \Theta_\Psi \coloneqq \int \theta(x)\rho_\Psi(x)dx, \tag{4.4}$$

$$T = \sup_{\mathsf{supp}(\theta)} W, \tag{4.5}$$

$$P = \int |\nabla \theta^{\frac{1}{2}}|^2 \rho_\Psi \, dx. \tag{4.6}$$

respectively and arbitrary $\varepsilon \le Z^{-\frac{2}{3}}$.

We cannot apply it directly to estimate the second to the last term in (2.11) because of singularities. Let us consider

$$\iint_{\mathbb{R}^3\times\mathbb{R}^3} |x-y|^{-1}\rho^{(2)}_\Psi(x,y)\, dxdy. \tag{4.7}$$

Let us make an ℓ-admissible partition of unity ϕ_ι in with ℓ-admissible $\phi_\iota^{1/2}$. We set $\ell(x) = Z^{-1}$ if $|x - \mathsf{y}_m| \le Z^{-1}$. Let us consider first

$$\int |x-y|^{-1}\rho^{(2)}_\Psi(x,y)\phi_\iota(x)\phi_\varkappa(y)\, dxdy \tag{4.8}$$

in the case of ϕ_ι and ϕ_κ having disjoint supports. Without any loss of the generality we can consider $\ell_x \le \ell_y$, where subscripts x, y are referring to supports of ϕ_ι, ϕ_κ respectively.

Let $\theta(x) = \phi_\iota(x)$ and

$$\chi(x,y) = \bar\chi(x,y) \coloneqq |x-y|^{-1}\bar\phi_\iota(x)\phi_\kappa(y) \tag{4.9}$$

where $\bar\phi_\iota$ which are ℓ-admissible and equal 1 in the ℓ-vicinity of $\mathsf{supp}(\phi_\iota)$. Then $T = \zeta_x$ and for $\ell_x \le Z^{-5/21}$ in virtue of Proposition 3.2 [1)]

$$\Theta_\Psi \asymp \zeta_x^3\ell_x^3, \qquad P \asymp \zeta_x^3\ell_x \tag{4.10}$$

and

$$\|\nabla_y\chi\|_{\mathscr{L}^2(\mathbb{R}^3_y))} \asymp d_{x,y}^{-1}\ell_y^{1/2}, \qquad \|\nabla\chi\|_{\mathscr{L}^\infty} \asymp d_{x,y}^{-1}\ell_y^{-1} \tag{4.11}$$

[1)] Indeed, $\zeta^3\ell^3 \ge Z^{5/3-\delta}\zeta^{-2} \iff \ell \le Z^{-5/21+\delta/7}$.

where $d_{x,y} \ge \ell_y$ is the distance between supports of ϕ_ι and $\phi_\varkappa$. Then the right-hand expression of (4.2) is

$$C\zeta_x^3\ell_x^3\Big(\ell_y^{-1/2}(Z^{5/6}+\zeta_x)+\varepsilon^{-1/2}\ell_y^{-1/2}Z^{1/2}+\varepsilon Z\ell_y^{-2}+\ell_y^{-1/2}\ell_x^{-1}\Big)$$

and minimizing by $\varepsilon \le Z^{-2/3}$ we get

$$C\zeta_x^3\ell_x^3\Big(\ell_y^{-1/2}(Z^{5/6-\delta}+\zeta_x)+Z^{2/3}\ell_y^{-1}+\ell_y^{-1/2}Z^{5/6}+\ell_y^{-1/2}\ell_x^{-1}\Big).$$

Observe that all powers of ℓ_y are negative. Therefore summation over all elements of the y-partition results in the same expression albeit with ℓ_y replaced by $\ell_x = \ell$:

$$C\zeta^3\ell^2\Big(\ell^{1/2}(Z^{5/6}+\zeta)+Z^{2/3}+\ell^{-1/2}+\ell^{1/2}Z^{5/6}\Big).$$

For $\ell \le Z^{-1/3}$ we have $\zeta = Z^{1/2}\ell^{-1/2}$ and all powers are positive with the exception of one term, where the power is 0, and for $\ell \ge Z^{-1/3}$ we have $\zeta = \ell^{-2}$ and all powers are negative. Therefore summation over all elements of x-partition results in the same expression albeit with $\ell = Z^{-1/3}$, $\zeta = Z^{2/3}$, with the exception of one term which gains a logarithmic factor. We get CZ^2. Then

$$|\sum_{\iota,\varkappa}\iint\Big(\rho_\Psi^{(2)}(x,y)-\rho(y)\rho_\Psi(x)\Big)\phi_\iota(x)\phi_\kappa(y),dxdy| \le CZ^2 \tag{4.12}$$

with summation over indicated pairs of elements of the partition (disjoint, with $\ell_x \le \min(Z^{-5/21+\delta/7},\ \ell_y)$).

Let us prove that

(4.13) Estimate (4.12) also holds with $\rho_\Psi(x)$ replaced by $\rho(x)$ and therefore it holds for a sum over pairs of elements with $\min(\ell_x,\ \ell_y) \le \ell^* = Z^{-5/21+\delta/7}$.

Indeed, in virtue of the proof of Proposition 3.2 (before minimizing by ς) the error

$$|\iint\big(\rho_\Psi(x)-\rho(x)\big)\rho(y)\phi_\iota(x)\phi_\kappa(y)\,dxdy| \tag{4.14}$$

on each pair of elements does not exceed $C\zeta_y^3\ell_y^2$ with all powers of ℓ_y positive for $\ell_y \le Z^{-1/3}$ and negative for $\ell_y \ge Z^{-1/3}$. Then summation with respect to y-partition (recall, that $\ell_y \ge \ell_x$) results in

$$C\big(\zeta_x^2\ell_x^2 + \varsigma\zeta_x^3\ell_x^3 + \varsigma^{-1}\zeta_x^{-2}Z^{5/3-\delta}\big) \times \begin{cases} Z^{4/3} & \text{for } \ell_x \le Z^{-1/3}, \\ \zeta_x^3\ell_x^2 & \text{for } \ell_x \ge Z^{-1/3}, \end{cases}$$

with the first line corresponding to $\ell_y = Z^{-1/3}$, $\zeta_y = Z^{2/3}$ and the second line corresponding to $\ell_y = \ell_x$, $\zeta_y = \zeta_x$.

Powers of ℓ_x are positive for $\ell_x \le Z^{-1/3}$ and negative for $\ell_x \ge Z^{-1/3}$, and summation with respect to x-partition results in the value as $\ell_x = Z^{-1/3}$, $\zeta_x = Z^{2/3}$, which is

$$CZ^2 + C\varsigma Z^{7/3} + C\varsigma^{-1}Z^{5/3-\delta}.$$

Minimizing by $\varsigma = Z^{-1/3}$ we conclude that the sum of expressions (4.14) over required pairs does not exceed CZ^2, which in turn implies (4.12).

Consider now the case when the supports of elements are not disjoint. Then we take

$$\chi(x,y) = \bar{\chi}(x,y)\eta(|x-y|/s) = |x-y|^{-1}\bar{\phi}_\iota(x)\phi_\kappa(y)\eta(|x-y|/s) \tag{4.15}$$

with $\eta(t)$ smooth function, equal 0 at $(0, \frac{1}{2})$ and 1 at $(1,\infty)$; $s \le Z^{-1/3}$ will be selected later[2)]. Then while (4.10) is preserved, (4.11) should be replaced by

$$\|\nabla_y\chi\|_{\mathscr{L}^2(\mathbb{R}^3_y))} \asymp s^{-1/2}, \qquad \|\nabla_y\chi\|_{\mathscr{L}^\infty} \asymp s^{-2}. \tag{4.16}$$

Then the right-hand expression (4.2) is

$$Cs^{-1/2}\zeta^3\ell^3\Big((Z^{5/6}+\zeta) + \varepsilon^{-1/2}Z^{1/2} + \varepsilon s^{-3/2}Z + \ell^{-1}\Big),$$

and minimizing by $\varepsilon \le Z^{-2/3}$ we get

$$\begin{aligned} |\int \phi_\iota(x)\chi(x,y)\big(\rho^{(2)}_\Psi(x,y) - \rho_\Psi(x)\rho(y)\big)\,dxdy| \\ \le Cs^{-1/2}\zeta^3\ell^3\Big(Z^{5/6} + \zeta + s^{-1/2}Z^{2/3} + \ell^{-1}\Big). \end{aligned} \tag{4.17}$$

[2)] Since in this case $\ell_x = \ell_y$ and $\zeta_x = \zeta_y$ we skip subscripts.

Note that summation of (4.17) over partition returns its value as $\ell = Z^{-1/3}$, namely, $Cs^{-1}Z^{5/3}$.

Consider for $t\colon s \le t \le \ell$ zone $\{(x,y)\colon |x-y| \asymp y\}$ and make there a t-admissible subpartition with respect to x, y (this means that the radii of the supports of subelements ϕ_* do not exceed t, and $|D^\alpha \phi_*| \le c_\alpha t^{-|\alpha|}$). Then contribution of each pair of subelements to

$$|\int \phi_\iota(x)\chi(x,y)\bigl(\rho_\Psi(x)-\rho(x)\bigr)\rho(y)\,dxdy|$$

does not exceed

$$C\bigl(\zeta^2 t^2 + \varsigma\zeta^3 t^3 + \varsigma^{-1}\zeta^{-2}Z^{5/3-\delta}\bigr)\zeta^3 t^2$$

and since there are $\asymp \ell^3 t^{-3}$ of such pairs, we get

$$C\bigl(\zeta^2 t^2 + \varsigma\zeta^3 t^3 + \varsigma^{-1}\zeta^{-2}Z^{5/3-\delta}\bigr)\zeta^3 \ell^3 t^{-1}.$$

Then summation over $t\colon s \le t \le \ell$ returns

$$C\bigl(\zeta^2 \ell + \varsigma\zeta^3 \ell^2 + \varsigma^{-1}s^{-1}\zeta^{-2}Z^{5/3-\delta}\bigr)\zeta^3 \ell^3$$

and summation over over the partition returns its value as $\ell = Z^{-1/3}$, namely

$$C\bigl(Z^2 + \varsigma Z^{7/3} + \varsigma^{-1}s^{-1}Z^{4/3-\delta}\bigr).$$

Minimizing by $\varsigma = (sZ)^{-1/2}$ we get $C\bigl(Z^2 + s^{-1/2}Z^{11/6-\delta}\bigr)$.

On the other hand,

$$\iint \phi_\iota(x)\bigl(\bar\chi(x,y)-\chi(x,y)\bigr)\rho(x)\rho(y)\,dxdy \asymp s^2\zeta^6\ell^3\,,$$

and summation over $\ell \ge Z^{-1/3}$ returns its value at $Z^{-1/3}$, which is Cs^2Z^3, but summation over $\ell \le Z^{-1/3}$ returns $s^2Z^3 \log Z$. To remedy this we replace for $\ell \le Z^{-1/3}$ constant s by $s_x = s(\ell_x Z^{1/3})^{\delta'}$ with small $\delta' > 0$. It will not affect our previous estimates.

Consider the sum of these three right-hand expressions

$$C\bigl(Z^2 + s^{-1}Z^{5/3} + s^{-1/2}Z^{11/6-\delta} + s^2Z^3\bigr)$$

and minimize it by s; we get $CZ^{19/9}$ achieved as $s = Z^{-4/9}$.

Since we want $s \le \ell$ we finally set

$$s_x = \begin{cases} Z^{-4/9} & \text{for } \ell_x \ge Z^{-1/3}, \\ \min(Z^{-4/9}(\ell_x Z^{1/3})^{\delta'},\ \ell_x) & \text{for } \ell_x \le Z^{-1/3}. \end{cases} \tag{4.18}$$

Observe that

$$\iint_{\{x:\ \ell_x \ge Z^{-5/21}\}} |x-y|^{-1}\rho(x)\rho(y) \asymp Z^{41/21}$$

and we arrive to

$$\iint_{\Omega} |x-y|^{-1}\big(\rho^{(2)}_\Psi(x,y) - \rho(x)\rho(y)\big)\,dxdy \le CZ^{19/9} \tag{4.19}$$

and

$$\iint_{\mathbb{R}^3_x\times\mathbb{R}^3_y\setminus\Omega} |x-y|^{-1}\rho(x)\rho(y)\,dxdy \le CZ^{19/9} \tag{4.20}$$

with

$$\Omega = \{(x,y)\colon \ell_x \le Z^{-5/21},\ |x-y| \ge s_y\}. \tag{4.21}$$

Therefore

$$\int_{\Omega} |x-y|^{-1}\rho^{(2)}_\Psi(x,y)\,dxdy \ge \int_{\mathbb{R}^6} |x-y|^{-1}\rho(x)\rho(y)\,dxdy - CZ^{19/9}. \tag{4.22}$$

However we know that (see, f.e. Section 25.2 of [Ivr1])

$$E_N \ge \mathsf{Tr}\big((H_W-\nu)^-\big) - \mathsf{D}(\rho_\Psi,\rho) + \frac{1}{2}\int |x-y|^{-1}\rho^{(2)}_\Psi(x,y)\,dxdy \tag{4.23}$$

and

$$E_N \le \mathsf{Tr}\big((H_W-\nu)^-\big) - \frac{1}{2}\mathsf{D}(\rho,\rho) + CZ^{5/3} \tag{4.24}$$

with $\rho = \rho^{\mathsf{TF}}$, $W = W^{\mathsf{TF}}$, $\mathsf{D}(f,g)\colon \iint |x-y|^{-1}f(x)g(x)\,dx$. Then

$$\int |x-y|^{-1}\rho^{(2)}_\Psi(x,y)\,dxdy \le 2\mathsf{D}(\rho_\Psi-\rho,\rho) + \mathsf{D}(\rho,\rho) + CZ^{5/3}$$

and from

$$|\mathsf{D}(\rho_\Psi-\rho,\rho)| \le \mathsf{D}(\rho_\Psi-\rho,\rho_\Psi-\rho)^{1/2}\mathsf{D}(\rho,\rho)^{1/2} \le CZ^{5/6}\times Z^{7/6} = CZ^2$$

we conclude that

$$\int |x-y|^{-1}\rho^{(2)}_\Psi(x,y)\,dxdy \le \mathsf{D}(\rho,\rho) + CZ^2. \tag{4.25}$$

Combining with (4.22) we conclude that

$$\int_{\mathcal{Z}} |x-y|^{-1}\rho^{(2)}_\Psi(x,y)\,dxdy \le CZ^{19/9} \tag{4.26}$$

for $\mathcal{Z} = \mathbb{R}^3_x \times \mathbb{R}^3_y \setminus \Omega$.

5 Proof of Theorem 1.1

Now in the last two terms

$$\begin{aligned} &Ct^{-1}\iint_{B(\mathsf{x},t)\times B(\mathsf{x},t)} |x-y|^{-1}\rho^{(2)}_\Psi(x,y)\,dxdy\\ +&C\iint_{B(\mathsf{x},t)\times (\mathbb{R}^3\setminus B(\mathsf{x},t))} |y-\mathsf{x}|^{-2}\rho^{(2)}_\Psi(x,y)\,dxdy, \end{aligned}$$

in (2.11) we replace $\rho^{(2)}_\Psi(x,y)$ by $\rho(x)\rho(y)$ and get

$$\begin{aligned} &Ct^{-1}\iint_{B(\mathsf{x},t)\times B(\mathsf{x},t)} |x-y|^{-1}\rho(x)\rho(y)\,dxdy\\ +&C\iint_{B(\mathsf{x},t)\times (\mathbb{R}^3\setminus B(\mathsf{x},t))} |\mathsf{x}-y|^{-2}\rho(x)\rho(y)\,dxdy \end{aligned} \tag{5.1}$$

and the first term does not exceed $C\zeta^6 t^4$, while the second term does not exceed

$$C\zeta^3 t^3 \int_{\mathbb{R}^3\setminus B(\mathsf{x},t)} |\mathsf{x}-y|^{-2}\rho(y)\,dy. \tag{5.2}$$

The largest error comes from the first term when integral is taken over $B(\mathsf{x},t)\times B(\mathsf{x},t)\cap\mathcal{Z}$ and in virtue of of (4.26) it does not exceed $Ct^{-1}Z^{19/9}$, all other errors are lesser (to prove it we need just to repeat arguments of the previous subsection).

Observe that for $\ell := \ell_{\mathsf{x}} \le Z^{-1/3}$ the largest contribution to the integral in (5.2) comes from the layer $\{y\colon \ell_y \asymp \ell_{\mathsf{x}}\}$ and it is of magnitude $\zeta^3\ell_x$. On

the other hand, for $\ell_{\mathsf{x}} \ge Z^{-1/3}$ the largest contribution to the integral in (5.1) comes from the layer $\{y\colon \ell_y \asymp Z^{-1/3}\}$ and it is of magnitude $Z\ell^{-2}$; the first term in (5.1) is smaller.

Therefore we estimate two last terms in (2.11) by

$$Ct^{-1}Z^{19/9} + C\begin{cases} Z^3\ell^{-2}t^3 & \text{for } \ell \le Z^{-1/3},\\ Z\ell^{-8}t^3 & \text{for } \ell \ge Z^{-1/3}.\end{cases} \tag{5.3}$$

Consider the second term in (2.11):

$$(2\pi)^{-1}\int \sum_m Z_m \frac{(x-\mathsf{x})\cdot(x-\mathsf{y}_m)}{|x-\mathsf{x}|\cdot|x-\mathsf{y}_m|^3}\rho_\Psi(x)\phi(|x-\mathsf{x}|)\,dx.$$

We replace in the integral in the right-hand expression $\rho_\Psi(x)$ by $\rho(x)$ and get

$$(2\pi)^{-1}\sum_m Z_m \int \frac{(x-\mathsf{x})\cdot(x-\mathsf{y}_m)}{|x-\mathsf{x}|\cdot|x-\mathsf{y}_m|^3}\rho(x)\phi(|x-\mathsf{x}|)\,dx \tag{5.4}$$

with an error

$$(2\pi)^{-1}\sum_m Z_m \int \frac{(x-\mathsf{x})\cdot(x-\mathsf{y}_m)}{|x-\mathsf{x}|\cdot|x-\mathsf{y}_m|^3}(\rho_\Psi(x)-\rho(x))\phi(|x-\mathsf{x}|)\,dx \tag{5.5}$$

and one can see easily that (5.4) does not exceed $CZ\zeta^3\ell^{-3}t^4$ [3)].

To estimate (5.5) we make a partition in $B(\mathsf{x},t)$ with subelements supported in the layers $\{x\colon |x-\mathsf{x}| \asymp t'\}$ with $p < t' \le t$ and in $B(\mathsf{x},p)$ with $\zeta^{-1} \le p \le t$. According to (3.12) the contribution of each layer does not exceed $CZ\ell^{-2}\bigl(\zeta^2 t'^2 + \zeta^{-2}Z^{5/3-\delta}\bigr)$ and summation over layers returns its value as $t' = t$, with $\zeta^{-2}Z^{5/3-\delta}$ acquiring logarithmic factor with we compensate by decreasing δ:

$$CZ\ell^{-2}\bigl(\zeta^2 t^2 + \zeta^{-2}Z^{5/3-\delta}\bigr). \tag{5.6}$$

Meanwhile, contribution of the ball $B(\mathsf{x},p)$ into (5.5) does not exceed $CZ\ell^{-2}\|\rho_\Psi - \rho\|_{\mathscr{L}^1(B(\mathsf{x},p))}$ and to estimate it we use Theorem 1.1 of [Ivr3] with

[3)] Indeed, it suffices to take a half-sum of the integrand in (5.4) with its value at symmetric about x point, because both $|x-\mathsf{y}_m|$ and $\rho(x)$ satisfy $|\nabla f| \le Cf\ell^{-1}$.

$a = \ell$ and $\mu = p^3\ell^{-3}$:

$$(5.7)\quad \|\rho_\Psi - \rho^{\mathsf{TF}}\|_{\mathscr{L}^1(B(x,s))}$$
$$\le C \begin{cases} p^2\ell^{-2/3}Z^{11/9-\delta/3} + p^3 Z\ell^{-2} & \text{as } \ p \ge Z^{-5/18-\delta}\ell^{5/6}, \quad Z^{-1} \le \ell \le Z^{-1/3}, \\ p^2\ell^{-8/3}Z^{5/9-\delta/3} & \text{as } \ p \ge Z^{5/9-\delta}\ell^{10/3}, \quad Z^{-1/3} \le \ell \le Z^{-5/21}. \end{cases}$$

Therefore (2.11) implies

$$(5.8)\quad \rho_\Psi(x) \le C\Big(Z\zeta^3\ell^{-3}t^4 + Z^{19/9}t^{-1} + Z\zeta^2\ell^{-2}t^2\Big) + C\Big(\zeta^3 + Z^{8/3-\delta}\zeta^{-2}\ell^{-2} + Z\ell^{-2}\|\rho_\Psi - \rho\|_{\mathscr{L}^1(B(x,p))}\Big),$$

where only first line depends on t. One can see easily that the third term in the first line does not exceed the sum of two first terms. Further, the second term there is larger than $Z^{19/9}\ell^{-1}$ which is larger than CZ^3 as $\ell \le Z^{-8/9}$ and since we already have the estimate (2.10), we should consider only $\ell \ge Z^{-8/9}$. Furthermore, $Z^{19/9}\ell^{-1} \ge \zeta^3$.

Finally, optimizing remaining two terms in the first line of (5.8) by t: $\zeta^{-1} \le t \le \ell$, we get

$$(5.9)\quad \rho_\Psi(x) \le C\Big(Z^{17/9}\zeta^{3/5}\ell^{-3/5} + Z\zeta^{-1}\ell^{-3} + Z^{19/9}\ell^{-1}\Big) + C\Big(Z^{8/3-\delta}\zeta^{-2}\ell^{-2} + Z\ell^{-2}\|\rho_\Psi - \rho\|_{\mathscr{L}^1(B(x,p))}\Big).$$

Let us compare terms there.

(i) Let $Z^{-8/9} \le \ell \le Z^{-1/3}$. Then one can see easily that the first line is defined by the third term $Z^{19/9}\ell^{-1}$ for $Z^{-8/9} \le \ell \le Z^{-7/9}$ and by the first term, which is $Z^{197/90}\ell^{-9/10}$, for $Z^{-7/9} \le \ell \le Z^{-1/3}$.

One can see easily that the first term in the second line of (5.9) is smaller than $Z\ell^{-1}$. Using the first case in (5.7) with $p = \max(\zeta^{-1}, \ell^{5/6}Z^{-5/18})$ and $\delta = 0$, we see that the second term in the second line is smaller than the first line as well. Thus we arrive to Theorem 1.1, Statement (i).

(ii) Let $\ell \ge Z^{-1/3}$. Then one can see easily that the first line of (5.9) is defined by the first term, which is $Z^{17/9}\ell^{-9/5}$ for $Z^{-1/3} \le \ell \le Z^{-5/18}$ and by $Z\ell^{-1}$ for $\ell \ge Z^{-5/18}$.

Consider the second line and impose condition $\ell \le Z^{-2/9}$. Then the first line dominates the first term here. Using the second case in (5.7) with $p = \max(\zeta^{-1}, \ell^{10/3} Z^{5/9})$ and $\delta = 0$, we see that the first line dominates the last term in the second line as well.

Further, let $\ell \ge Z^{-2/9}$. Recall that the second line (except $C\zeta^3$) was a result of the estimate of the second term in (2.11), which, however, could be estimated by

$$CZ\ell^{-2} \int_{B(x,\ell(x))} \rho_\Psi(x)\, dx. \tag{5.10}$$

It is well known that $\int \rho_\Psi \le CZ$ and therefore (5.10) does not exceed $CZ^2\ell^{-2}$ which covers $\ell \ge Z^{-1/9}$.

Furthermore, in the remaining range $Z^{-2/9} \le \ell \le Z^{-1/9}$ we can use Proposition 3.2(ii) to show, that the first term in the second line does not exceed $Z^{19/9}\ell^{-1}$ while the second term there is estimated again by the second case in (5.7). Thus we arrive to Theorem 1.1, Statement (ii).

(iii) Finally, using Proposition 3.2(iii) we prove Theorem 1.1, Statement (iii).

Victor Ivrii[‡]

Abstract

We establish (with respect to x, y) semiclassical asymptotics and estimates for the Schwartz kernel $e_h(x,y,\tau)$ of spectral projector for a second order elliptic operator on the manifold with a boundary. While such asymptotics for its restriction to the diagonal $e_h(x,x,\tau)$ and, especially, for its trace $\mathsf{N}_h(\tau) = \int e_h(x,x,\tau)\,dx$ are well-known, the out-of-diagonal asymptotics are much less explored, especially uniform ones.

Our main tools: microlocal methods, improved successive approximations and geometric optics methods.

Our results would also lead to *classical* asymptotics of $e_h(x,y,\tau)$ for fixed h (say, $h=1$) and $\tau \to \infty$.

1 Introduction

Asymptotics away from the boundary. Let us start from the case of asymptotics when points x and y are disjoint from the boundary. While sharp classical asymptotics of $e(x,x,\tau)$ for elliptic operators are known from L. Hörmander [Hö], and could be traced to B. M. Levitan [Lev1, Lev2] and V. G. Avakumovič [Av1], I could not find asymptotics of $e(x,y,\tau)$, despite it could be easily derived by the method of Fourier integral operators combined with Tauberian theorem.

Theorem 1.1. *Let $A = A^{\mathsf{w}}(x, hD, h)$ be a self-adjoint scalar pseudo-differential operator with $\mathscr{C}^K$-symbol ($K = K(d)$) which is ξ-microhyperbolic in $B(0,1) \subset X$ on the energy level τ* [1)]*. Further, let $\{\xi\colon a(x,\xi) = \tau\}$ be strongly convex. Then*

$$e_h(x,y,\tau) = e_h^{\mathsf{W}}(x,y,\tau) + O(h^{1-d}) \qquad \forall x, y \in B(0,\epsilon) \tag{1.2}$$

where

$$e_h^{\mathsf{W}}(x,y,\tau) = (2\pi h)^{-d} \int_{\{a(\frac{1}{2}(x+y),\xi)<\tau\}} e^{ih^{-1}\langle x-y,\xi\rangle}\, d\xi \tag{1.3}$$

is corresponding Weyl expression.

We will prove this theorem and discuss its generalizations and also more precise results in Section 2.

Asymptotics near the boundary. Classical asymptotics of $e(x,x,\tau)$ for second order elliptic operators are known from R. Seeley [Se1, 2], and sharp ones from V. Ivrii. The semiclassical version would carry remainder estimate $O(h^{1-d}\nu(x)^{-\frac{1}{2}})$ and $O(h^{1-d})$ respectively while the trivial remainder estimate would be $O(h^{1-d}\nu(x)^{-1})$ where $\nu(x) = \mathsf{dist}(x, \partial X)$.

Let

$$\ell^0(x,y) \coloneqq |x-y|,$$
$$\ell\,(x,y) \coloneqq |x-y| + \nu(x) + \nu(y).$$

Theorem 1.2. *Let*

$$A = \sum_{j,k} \big(hD_j - V_j(x)\big) g^{jk}(x) \big(hD_k - V_k(x)\big) + V(x), \qquad g^{jk} = g^{kj}, \tag{1.4}$$

be a self-adjoint scalar operator which is elliptic second order differential operator with $\mathscr{C}^K$-coefficients ($K = K(d,\delta)$), and it is ξ-microhyperbolic in $B(0,1)$ on the energy level τ, with either Dirichlet or Neumann boundary condition on $\partial X \cap B(0,1)$, and $\partial X \in \mathscr{C}^K$ [2)]*. Then*

[1)] Which means that

$$|a(x,\xi) - \tau| + |\nabla_\xi a(x,\xi)| \ge \epsilon_0 \tag{1.1}$$

where $a(x,\xi) \coloneqq A(x,\xi,0)$.

[2)] More general boundary conditions could be also considered.

(i) For $d \geq 3$ asymptotics (1.2) *holds where now for Dirichlet or Neumann boundary condition*

$$e_h^{\mathsf{W}}(x,y,\tau) = e_h^{0,\mathsf{W}}(x,y,\tau)\ [\mp]\ e_h^{0,\mathsf{W}}(x,\tilde{y},\tau) \tag{1.5}$$

respectively, $e_h^{0,\mathsf{W}}(x,y,\tau)$ defined by (1.3) *and $\tilde{y}$ is a reflected point.*

(ii) For $d = 2$ under one of the following assumptions

(a) $\ell(x,y) \leq h^{\frac{1}{3}+\delta}$,

(b) $\ell(x,y) \geq h^{\frac{1}{3}-\delta}$,

(c) $\nu(x)+\nu(y) \geq C_0(\ell^2 + h^{\frac{2}{3}-2\delta})$

where here and below $\delta > 0$ is an arbitrarily small exponent, asymptotics

$$e_h(x,y,\tau) = e_h^{\mathsf{W}}(x,y,\tau) + e_{h,\mathsf{corr}}(x,y,\tau) + O(h^{1-d}) \quad \forall x,y \in B(0,\epsilon) \tag{1.6}$$

holds with correction term $e_{h,\mathsf{corr}}(x,y,\tau)$ to be defined by (5.53) *later.*

(iii) Finally, for $d = 2$ if neither of condition (a)–(c) is fulfilled

$$e_h(x,y,\tau) = O(h^{-1-\delta}). \tag{1.7}$$

Remark 1.3. (i) According to [Ivr2], Theorem 8.1.6 asymptotics (1.2) holds for $x = y$ in the coordinate system such that x_1 is the distance from x to ∂X in the metrics $g^{jk}(\tau - V)^{-1}$. Such precision is needed for $d = 2$ only.

(ii) The leading term $e_h^{\mathsf{W}}(x,y,\tau)$ is $\asymp h^{-\frac{d-1}{2}}\ell^{-\frac{d+1}{2}}$. In particular it is $O(h^{1-d})$ as $\ell \gtrsim h^{\frac{d-1}{d+1}}$.

(iii) The correction term (as $d = 2$) is $O(h^{-\frac{3}{2}}\ell^{\frac{1}{2}})$ if $\ell \leq h^{\frac{1}{2}}$ and $O(h^{-\frac{1}{2}}\ell^{-\frac{3}{2}})$ if $h^{\frac{1}{2}} \leq \ell \leq \epsilon$.

(iv) The trivial estimate (in much more general settings) is

$$|e_h(x,y,\tau) - e_h^{\mathsf{W}}(x,y,\tau)| \leq Ch^{1-d}(1+\ell^{-1}(x,y)). \tag{1.8}$$

Ideas of proofs. I. Consider $x, y \in B(0, \frac{1}{2})$. We already know that under pretty general assumptions (which will be discussed later), in particular, in the frameworks of Theorems 1.1 and 1.2, the following estimate holds:

$$e(x, x, \tau' + h) - e(x, x, \tau') \le Ch^{1-d} \qquad \text{for } |\tau' - \tau| \le \epsilon_0. \tag{1.9}$$

Then

$$|e(x, y, \tau) - e(x, y, \tau')| \le Ch^{-d}|\tau - \tau'| + h^{1-d} \tag{1.10}$$

and therefore due to Tauberian methods

$$|e_h(x, y, \tau) - e^{\mathsf{T}}_{T,h}(x, y, \tau)| \le CT^{-1}h^{1-d} \tag{1.11}$$

where

$$e^{\mathsf{T}}_{T,h}(x, y, \tau) = h^{-1} \int_{-\infty}^{\tau} F_{t \to h^{-1}\tau'}\big(\bar\chi_T(t) u_h(x, y, t)\big)\, d\tau' \tag{1.12}$$

is the *Tauberian expression*, $u_h(x, y, t)$ is the Schwartz kernel of the propagator $e^{ih^{-1}At}$, $h \le T \le \epsilon_1$, ϵ_1 is a small constant and $\bar\chi_T(t) = \bar\chi(t/T)$ and $\bar\chi \in \mathscr{C}_0^\infty([-1, 1])$, $\bar\chi(t) = 1$ on $(-\frac{1}{2}, \frac{1}{2})$.

Assume first that $B(0, 1) \subset X$. Then for a small constant T we can construct $u_h(x, y, t)$ as an oscillatory integral and we can construct $e^{\mathsf{T}}_h(x, y, \tau)$ even as $d = 2$ or without strong convexity assumption. However the result could be simplified to $e^{\mathsf{W}}_h(x, y, \tau)$ in the framework of Theorem 1.1 (for scalar operators under strong convexity assumption). This is done in Section 2.

Ideas of proofs. II. Construction of the propagator is much more complicated close to the boundary, because there could be many generalized billiard rays with at least one reflection from ∂X, from x to y on the energy level τ. If

$$\ell(x, y) \coloneqq |x - y| + \nu(x) + \nu(y) \le \epsilon_1 \tag{1.13}$$

the length of all such rays is $\asymp \ell(x, y)$. Further, if

$$\nu(x) + \nu(y) \ge \sigma \ell(x, y) \tag{1.14}$$

with $\sigma \ge C_0\ell(x, y)$ there is exactly one such ray and it has exactly one reflection, and the reflection angle $\ge \epsilon_1(\nu(x) + \nu(y))/\ell(x, y)$. It allows us in the framework of Theorem 1.2 under assumption (1.14) with $\sigma =$

$h^{\frac12-\delta}\ell(x,y)^{-\frac12}+C_0\ell(x,y)$ to construct a reflected wave as an oscillatory integral and simplify it. It will be done in Section 5.

So, we should consider a case when (1.14) is violated and we will do it in Section 4. As $|x-y|\le Ch^{\frac12-\delta}$ the propagator could be constructed by the standard method of successive approximations with unperturbed constant coefficients operator.

Furthermore, in the framework of Theorem 1.2 under certain assumptions, which are complementary to (1.14) as $\ell\le h^{\frac13+\delta}$, the reflected wave could be constructed also by the method of the successive approximations, but with unperturbed the operator

$$\bar{A}(z,hD_z)=h^2D_1^2+A(0,w',hD'_z), \tag{1.15}$$

where $x=(x_1;x')=(x_1;x_2,\dots,x_d)$ and $X\cap B(0,1)=\{x\colon x_1>0\}\cap B(0,1)$ and we make a change of variables $w'=\frac12(x'+y')$ and $z'=\frac12(x'-y')$, leaving x_1 and y_1 unchaned.

Ideas of proofs. III. Finally, to estimate the Tauberian expression rather than to find its asymptotics we apply in Section 3 only methods of propagations. Let us illustrate this away from the boundary. Let $Q_{1,2}$ be pseudodifferential operators with the symbols equal 1 in ρ-vicinity of $\{\xi\in\Sigma(w,\tau)\colon \nabla_\xi a(w,\xi)\parallel \bar{x}-\bar{y}\}$; this set consists of just two points. Then

$$e_h^{\mathsf{T}}(\bar{x},\bar{y},\tau)=Q_{2x}e_h^{\mathsf{T}}(x,y,\tau)\,{}^tQ_{1y}|_{x=\bar{x},y=\bar{y}}+O(h^s) \tag{1.16}$$

provided microlocal uncertainty principle $\rho\times\rho\ell\ge h^{1-\delta}$ is fulfilled. It allows us to upgrade $|e_h^{\mathsf{T}}(x,y,\tau)|\le Ch^{1-d}\ell^{-1}(x,y)$ to

$$|e_h^{\mathsf{T}}(x,y,\tau)|\le C\rho^{d-1}h^{1-d}\ell^{-1}(x,y). \tag{1.17}$$

We need also $\rho\ge C_0\ell$. We need also $\rho\ge C_0\ell$.

2 Asymptotics inside domain

2.1 Tauberian asymptotics

As we already mentioned, asymptotics

$$e_h(x,x,\tau)=\kappa_0(x,\tau)h^{-d}+O(h^{1-d}) \tag{2.1}$$

is known under much more general assumptions. It holds for matrix operators under ξ-microhyperbolicity condition at point x on the energy level τ and for Schrödinger operator without any condition in dimension $d \geq 3$ (see [Ivr2], Sections 5.4 and 5.3 correspondingly).

Asymptotics (2.1) implies (1.9) and then (1.10). Then the standard Tauberian arguments (see f.e. [Ivr2], Section 5.2) imply (1.11)–(1.12) with small constant T.

2.2 Weyl asymptotics

While asymptotics (2.1) holds in much more general assumptions, to construct $u_h(x,y,t)$ we need to impose some restrictions. Let A be a scalar operator[3)]. While construction of propagator as an oscillatory integral is possible even if ξ-microhyperbolicity condition is violated, we assume that it is fulfilled from the beginning, as we need it anyway.

Without any loss of the generality one can assume that

$$a(y,0) < 0. \tag{2.2}$$

Indeed, otherwise we can achieve it by a corresponding gauge transformation. Then the strong convexity of $\Sigma(y,\tau) = \{\theta\colon a(y,\theta) = \tau\}$ implies that

$$\langle \nabla_\theta a(y,\theta), \theta\rangle \geq \epsilon_0 \qquad \forall \theta \in \Sigma(y,\tau). \tag{2.3}$$

Proposition 2.1. *Let A be a scalar operator, ξ-microhyperbolic in $B(\bar{x},2\epsilon) \subset X$ on energy level τ and let $x,y \in B(\bar{x},\epsilon)$. Let* (2.3) *be fulfilled. Then*

$$u_h(x,y,t) \equiv \int e^{ih^{-1}\Phi(x,y,t,\theta)} B(x,y,t,\theta,h)\, d\theta \tag{2.4}$$

modulo functions such that

$$F_{t\to h^{-1}\tau'}\bar{\chi}_T(t) v_h(x,y,t) = O(h^s) \qquad \forall x,y \in B(0,\epsilon) \tag{2.5}$$

as $T \leq \epsilon_1$, $|\tau'-\tau| \leq \epsilon_1$ where

$$\Phi(x,y,t,\theta) = \varphi(x,y,\theta) + ta(y,\theta), \tag{2.6}$$

[3)] Construction also works for matrix operators with characteristic roots of constant multiplicity.

$\varphi(x,y,\theta)$ *satisfies stationary eikonal equation*

$$a(x,\nabla_x\varphi)=a(y,\theta) \tag{2.7}$$

and

$$\varphi(x,y,\theta)|_{\langle x-y,\theta\rangle=0}=0, \tag{2.8}$$

$$\nabla_x\varphi(x,y,\theta)|_{x=y}=\theta \tag{2.9}$$

and

$$B(x,y,t,\theta,h)\sim\sum_{n\ge 0}B_n(x,y,t,\theta)h^n, \tag{2.10}$$

and amplitudes B_{jn} are defined from the Cauchy problems for transport equations; all functions are uniformly smooth; here and below s is an arbitrarily large exponent.

Proof. The proof is original L. Hörmander's construction (see M. Shubin [Shu], Theorem 20.1). □

While in [Hö, 3] this decomposition was used to calculate $e_h^{\mathsf{T}}(x,y,\tau)$ as $x=y$ (actually, it's classical variant), we will use it without this restriction. Due to ξ-microhyperbolicity

$$\begin{aligned} &F_{t\to h^{-1}\tau'}\bigl(\bar\chi_T(t)u_h(x,y,t)\bigr)\\ &\qquad\sim(2\pi h)^{-d}h\int_{\Sigma(y,\tau')}e^{ih^{-1}\varphi(x,y,\theta)}B'(x,y,\theta)\,d\theta : da(y,\theta)\end{aligned} \tag{2.11}$$

with $\Sigma(y,\tau)=\{\theta\colon a(y,\theta)=0\}$, $d\theta : da(y,\theta)$ a natural density on $\Sigma(y,\tau')$ and $B'(x,y,\theta)$ also allowing (2.10) decomposition with uniformly smooth B'_n.

Proposition 2.2. *Let in $B(\bar x,2\epsilon_1)$ both ξ-microhyperbolicity and strong convexity conditions are fulfilled on energy level τ. Then for $|\tau'-\tau|\le\epsilon_1$ and $x\ne y$ $\varphi(x,y,\theta)$ has exactly two stationary points $\theta^*_\pm(x,y,\tau')$ on $\Sigma(y,\tau')$, defined from*

$$\nabla_\theta\varphi(x,y,\theta)=-t_\pm\nabla_\theta a(y,\theta),\qquad a(y,\theta)=\tau',\qquad \pm t_\pm>0. \tag{2.12}$$

These points are non-degenerate and $t_\pm\asymp|x-y|$ in (2.12).

Furthermore,

$$\theta^*_\pm(x,y,\tau') = \bar\theta_\pm(x,y,\tau') + O(|x-y|), \tag{2.13}$$

where $\bar\theta_\pm(x,y,\tau')$ *are defined from*

$$x-y = -t'_\pm \nabla_\theta a(y,\theta), \qquad a(y,\theta)=\tau', \quad \pm t'_\pm > 0 \tag{2.14}$$

and also $t'_\pm = t_\pm + O(|x-y|^2)$.

Proof. Proof follows trivially from

$$\varphi(x,y,\theta) = \langle x-y,\theta\rangle + O(|x-y|^2), \tag{2.15}$$

which follows from (2.8), (2.9). □

Proposition 2.3. *In the framework of Proposition 2.2 the following asymptotics hold*

$$F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)u_h(x,y,t)\bigr) \sim (2\pi)^{-d}h^{\frac{1-d}{2}}\sum_{\varsigma=\pm} e^{ih^{-1}S_\varsigma(x,y,\tau)}B'_\varsigma(x,y,\tau) \tag{2.16}$$

and with $c\ell \le T \le \epsilon$

$$e^{\mathsf{T}}_{T,h}(x,y,\tau) \sim (2\pi)^{-d}h^{\frac{1-d}{2}}\sum_{\varsigma=\pm} e^{ih^{-1}S_\varsigma(x,y,\tau)}B''_\varsigma(x,y,\tau) \tag{2.17}$$

with

$$S_\varsigma(x,y,\tau) = \varphi(x,y,\theta^*_\varsigma(x,y,\tau)) \tag{2.18}$$

and B'_ς, B''_ς *also decomposed into asymptotic series albeit with* $B'_{\varsigma n}\ell^{n+\frac{d-1}{2}}$ *and* $B''_{\varsigma n}\ell^{n+\frac{d+1}{2}}$ *uniformly smooth.*

Proof. Asymptotics (2.17) follows from Proposition 2.2 and stationary phase principle with effective semiclassical parameter $\hbar = h\ell^{-1}$, $\ell = |x-y|+h$.

To prove (2.18) we first rewrite (1.12) as the sum of two integrals with cut-off functions $\phi_1(\tau')$ and $\phi_2)(\tau')$; $\phi_j \in \mathscr{C}_0^\infty$, $\mathsf{supp}(\phi_1) \subset (\tau-\epsilon,\tau+\epsilon)$, $\mathsf{supp}(\phi_2) \subset (-\infty,\tau-\epsilon/2)$. In the integral with ϕ_1 we plug (2.4), observe that there are no stationary points in $\{\theta\colon \tau-\epsilon < a(y,\theta) < \tau\}$ and use Proposition 2.2 and stationary phase principle with effective semiclassical parameter $\hbar = h\ell^{-1}$. In the integral with ϕ_2 we simply observe that it has a complete asymptotics because it contains a mollification by τ' (see, f.e. Proposition 3.5 below). □

Proposition 2.4. *In the framework of Proposition 2.2*

(i) The following estimates hold:

$$|F_{t\to h^{-1}\tau}\Big(\bar{\chi}_T(t)u_h(x,y,t)\Big)| \le Ch^{\frac{1-d}{2}}\ell^{\frac{1-d}{2}} \tag{2.19}$$

and as $c\ell \le T \le \epsilon$

$$|e^{\mathsf{T}}_{T,h}(x,y,\tau)| \le Ch^{\frac{1-d}{2}}\ell^{\frac{-1-d}{2}}. \tag{2.20}$$

(ii) The following estimate holds as $\max(c\ell,\ h^{1-\delta}) \le T \le \epsilon$*:*

$$|e^{\mathsf{T}}_{T,h}(x,y,\tau) - e^{\mathsf{W}}_{h}(x,y,\tau)| \le Ch^{1-d}. \tag{2.21}$$

Proof. (a) Estimates (2.19)–(2.20) follow from (2.16)–(2.17).

(b) To prove Statement (ii) for $d \ge 3$ one can observe that both $|e^{\mathsf{T}}_{T,h}(x,y,\tau|$ and $|e^{W}(x,y,\tau)|$ do not exceed Ch^{1-d} as $h^{\frac12} \le \ell \le \epsilon$, while for $\ell \le h^{\frac12}$, due to (2.15), replacing $\Phi(x,y,t,\theta)$ by

$$\bar{\Phi}(x,y,\theta) = \langle x-y,\theta\rangle + ta(\frac{1}{2}(x+y),\theta) \tag{2.22}$$

brings an error not exceeding the right-hand expression of (2.20) multiplied by $C\ell^2h^{-1}$, that is $Ch^{-\frac{1+d}{2}}\ell^{\frac{3-d}{2}} \le Ch^{1-d}$.

Moreover, if we also replace $B(x,y,t,\theta,h)$ by 1 then the error will not exceed the right-hand expression of (2.20) multiplied by $C\ell$, that is $Ch^{\frac{1-d}{2}}\ell^{\frac{1-d}{2}} \le Ch^{1-d}$.

Finally, with this choice of the phase function $\bar{\Phi}(x,y,t,\theta)$ and amplitude $B=1$, we get $e^{\mathsf{T}}_{T,h}(x,y,\tau) = e^{\mathsf{W}}(x,y,\tau) + O(h^{\infty})$.

(c) As $d=2$ we need more subtle arguments (which would also work for $d\ge 3$). Indeed, estimate (2.20) implies that $|e^{\mathsf{T}}_{T,h}(x,y,\tau)| \le Ch^{-1}$ as $h^{\frac13} \le \ell \le \epsilon_1$ and estimate (2.21) leads to $O(h^{-1})$ error only as $\ell \asymp h$.

We refer to Proposition 5.13(i). □

Finally, Theorem 1.1 follows from estimate (1.11) and Proposition 2.4.

2.3 Improvements and generalizations

Two-term asymptotics. We know that if A is a scalar operator on the closed manifold, ξ-microhyperbolic at point x and if *non-looping condition*

$$\mu_{x,\tau}\{\xi \in \Sigma(x,\tau)\colon \exists t \neq 0, \pi_x e^{tH_a(x,\xi)} = x\} = 0 \tag{2.23}$$

is fulfilled at point x then two-term asymptotics

$$e_h(x,x,\tau) = \kappa_0(x,\tau)h^{-d} + \kappa_1(x,\tau)h^{1-d} + o(h^{1-d}) \tag{2.24}$$

holds; here $\Sigma(x,\tau) = \{\xi\colon a(x,\xi) = \tau\}$, $\mu_{x,\tau}$ is a natural measure on $\Sigma(x,\tau)$, corresponding to a density $dxd\xi : d_\xi a(x,\xi)$, H_a is a Hamiltonian field generated by a and e^{tH_a} is a Hamiltonian flow (see, f.e. [Ivr2], Section 5.3). Can we get a two-term asymptotics for $e_h(x,y,\tau)$?

First of all, we need to improve Tauberian estimate (1.11). Asymptotics (2.24) at point x implies

$$|e(x,x,\tau + T^{-1}h) - e(x,x,\tau')| \le CT^{-1}h^{1-d} + o_T(h^{1-d}) \tag{2.25}$$

and then

$$\begin{aligned}|e(x,y,\tau) - e(x,y,\tau')| \\ \le C|\tau-\tau'|h^{-d} + C|\tau-\tau'|^{\frac12}h^{\frac12-d} + CT^{-\frac12}h^{1-d} + o_T(h^{1-d})\end{aligned}$$

with arbitrarily large T. Here condition (2.23) is fulfilled at one of points x, y. Then the standard Tauberian arguments imply

$$|e_h(x,y,\tau) - e^{\mathsf{T}}_{T,h}(x,y,\tau)| \le CT^{-\frac12}h^{1-d} + o_T(h^{1-d})$$

and propagation results combined with non-looping condition at one of points x, y imply that in the left hand expression one can replace T by $T' = T(x,y)$ while still having arbitrary T in the right hand-expression, and then we arrive to

$$e_h(x,y,\tau) = e^{\mathsf{T}}_{T,h}(x,y,\tau) + o(h^{1-d}) \qquad \text{with} \quad T = T(x,y). \tag{2.26}$$

Further, if we add another condition

$$\mu_{x,\tau}\{\xi \in \Sigma(x,\tau)\colon \exists t \neq 0, \pi_x e^{tH_a(x,\xi)} = y\} = 0 \tag{2.27}$$

or a similar condition, obtained by permutation of x and y (let's call it (2.26)′), then from (2.26) and propagation results we obtain that

(a) If $\ell(x,y) \ge \epsilon$ then $e_h(x,y,\tau) = o(h^{1-d})$,

(b) If $\ell(x,y) \le \epsilon$, then we can take $T(x,y) = c\ell(x,y)$ in (2.26).

Weyl asymptotics. In particular, in the framework of Theorem 1.1, under extra assumptions (2.23) and either (2.26) or (2.26)′, we can apply the machinery developed in Subsection 2.2 (with the only exception $d = 2$ and neither $\ell \gg h^{\frac{1}{3}}$ nor $\ell \ll h^{\frac{1}{3}}$). One can prove easily that then

$$\big(e(x,y,\tau) = e^{\mathsf{W}}(x,y,\tau)\big) + o(h^{1-d}) \qquad \forall x,y \in B(0,\epsilon) \tag{2.28}$$

where $e^{\mathsf{W}}_h(x,y,\tau)$ is defined by (1.3) with a replaced by $a + ha_1$ where a_1 is the subprincipal symbol of A, that is with the main term defined by (1.3) and with the second term

$$-(2\pi h)^{1-d} \int_{\Sigma(z,\tau)} a_1(z,\theta) e^{i\langle x-y,\theta\rangle}\, d\theta : d_\theta a(z,\theta), \qquad z = \frac{1}{2}(x+y). \tag{2.29}$$

Generalizations.

(i) We can consider the case when $a(x,\xi)$ has characteristic roots $\lambda_j(x,\xi)$ of constant multiplicity; and we need only to assume that it happens as $|\lambda_j(x,\xi) - \tau| \le \epsilon$.

(ii) If we consider only $y\colon y - x \in \Gamma$ where Γ is a cone in $\mathbb{R}^d$ with a vertex at 0, then in virtue of propagation results (see [Ivr2], Section 2.2) we need the previous assumption only for ξ such that

$$\Gamma \cap \big(K(x,\xi) \cup -K(x,\xi)\big) \neq \emptyset \tag{2.30}$$

where $K(x,\xi)$ is a cone dual to $K'(x,\xi)$ which is a connected component of

$$\{\eta\colon ((\eta \cdot \partial_\xi a(x,\xi))v, v) \ge 0\ ; \forall v\colon \|(a-\tau)v\| \le \epsilon\|v\|\}.$$

(iii) Also, instead of strong convexity we need to assume only that at points ξ satisfying (2.30), the matrix of the curvatures of the surface $\{\xi\colon \lambda(x,\xi) = \tau\}$ has at least two eigenvalues, disjoint from 0. Then it would be similar to the case $d \ge 3$ in Proposition 2.4. Probably, it would suffice to have just one eigenvalue, to recover more delicate arguments of the case $d = 2$ in Proposition 2.4.

3 Microlocal methods

3.1 Propagation

Recall that we consider Schrödinger operator (1.4) and for such operator under ξ-microhyperbolicity near boundary condition on the energy level τ instead of on-diagonal asymptotics (2.1) asymptotics with a boundary-layer type term and remainder estimate $O(h^{1-d})$ holds; see [Ivr2], Section 8.1. In particular, under Dirichlet or Neumann boundary conditions (and we consider only those for simplicity) asymptotics (1.5) holds as $x = y$ and also (1.9) holds. Then (1.10)–(1.12) hold and all we need is to rewrite Tauberian expression (1.12) in more explicit terms.

Let us decompose

$$u_h(x,y,t) = u_h^0(x,y,t) + u_h^1(x,y,t) \tag{3.1}$$

where $u_h^0(x,y,t)$ is the solution for the "free space" and $u_h^1(x,y,t)$ is a reflected wave, satisfying

$$hD_t u_h^1 = A(x,hD,h)u_h^1, \tag{3.2}$$

$$B(x,hD,h)u_h^1|_{\partial X} = -B(x,hD,h)u_h^0|_{\partial X}, \tag{3.3}$$

where $B(x,hD,h)$ is a boundary operator. Then

$$e_h^{\mathsf{T}}(x,y,\tau) = e_h^{0,\mathsf{T}}(x,y,\tau) + e_h^{1,\mathsf{T}}(x,y,\tau), \tag{3.4}$$

where $e_h^{0,\mathsf{T}}(x,y,\tau)$ and $e_h^{1,\mathsf{T}}(x,y,\tau)$ are derived by Tauberian expression (1.12) from $u_h^0(x,y,t)$ and $u^1(x,y,t)$ correspondingly with $T = \epsilon_1$.

While $u_h^0(x,y,t)$ can be constructed as an oscillatory integral, our purpose is to construct $u_h^1(x,y,t)$ in some way. To do this, in this section we apply the improved method of successive approximations near boundary, in the same way as the standard method was applied in [Ivr2], Section 7.2 while in the next Section 5 we use the geometric optics method.

Recall that now A is a second order elliptic operator and $X \cap B(0,1) = \{x\colon \nu(x) > 0\} \cap B(0,1)$ with $|\nabla\nu| \ge \epsilon_0$. Without any loss of the generality one can assume that

$$X \cap B(0,1) = \{x\colon x_1 > 0\} \cap B(0,1) \text{ with } V_1(x) = 0,\ g^{1k} = \delta_{1k} \tag{3.5}$$

and therefore

$$\nu(x) = x_1, \qquad \ell(x,y) = |x' - y'| + x_1 + y_1 \tag{3.6}$$

and A is ξ-microhyperbolic on the energy level τ at x as long as

$$|V(x) - \tau| \ge \epsilon_0, \tag{3.7}$$

and in this case $\{\xi\colon a(x,\xi) = \tau\}$ is strongly convex.

Proposition 3.1. *(i) As $T \le \epsilon\ell(x,y)$ the following estimate holds:*

$$|F_{t\to h^{-1}\tau}\Big(\bar\chi_T(t)u^1_h(x,y,t)\Big)| \le Ch^{-d}\Big(\frac{h}{T}\Big)^s. \tag{3.8}$$

(ii) Let condition (3.1) *be fulfilled. Then for $\mathsf{max}(C\ell(x,y),\, h^{1-\delta}) \le T \le T' \le \epsilon_1$ the following estimate holds:*

$$|F_{t\to h^{-1}\tau}\Big(\big(\bar\chi_{T'}(t) - \bar\chi_T(t)\big)u^1_h(x,y,t)\Big)| \le Ch^{-d}\Big(\frac{h}{T}\Big)^s. \tag{3.9}$$

Proof. Statement (i) follows from the finite speed of propagation and Statement (ii) follows from the fact that the speed of propagation with respect to x is disjoint from 0 (either along ∂X, if $|\xi'|$ is disjoint from 0 or in direction of x_1 if ξ_1 is disjoint from 0)–see [Ivr2], Chapter 3. □

Corollary 3.2. *Let $e^{1,\mathsf{T}}_h(x,y,\tau)$ be defined by* (1.12) *with $u^1_h(x,y,t)$ instead of $u_h(x,y,t)$.*

(i) Then in $e^{1,\mathsf{T}}_h(x,y,\tau)$ one can replace $T = \epsilon_1$ by $T = C\,\mathsf{max}(\ell(x,y),\, h^{1-\delta})$.

(ii) Further, in the framework of Proposition 3.1(ii) and $\ell(x,y) \ge h^{1-\delta}$ one can replace $\bar\chi_T(t)$ with $T = \epsilon_1$ by $\big(\bar\chi_T(t) - \bar\chi_{T'}(t)\big)$ with $T = C_0\ell(x,y)$ and $T' = C_0^{-1}\ell(x,y)$.

We need to be more precise about propagation especially with respect to x_1 and ξ_1 as $\ell^0 \asymp \ell$. Let us $\bar x$, $\bar y$ and $\bar w$ be fixed final values of x, y and w respectively and we need to consider case $\ell := \ell(\bar x, \bar y) \ge h^{1-\delta}$.

Proposition 3.3. *Let* $h^{1-\delta} \le T \le \epsilon_1$, $T = C_0\ell$ *and*

$$\rho T \ge h^{1-\delta}, \qquad \rho \ge T^2. \tag{3.10}_{1,2}$$

Let $b(\bar{y}', \bar{\xi}') = \tau$ *and*

$$|\nabla_{y'} b(y', \bar{\xi})_{y'=\bar{y}'}| \le \rho T^{-1} \tag{3.11}$$

where here and below

$$b(x', \xi') := a(x, \xi)|_{x_1=\xi_1=0}; \tag{3.12}$$

and let $Q_1(y, \eta')$ *have a symbol supported in* (T, ρ)*-vicinity of* $(\bar{y}, \bar{\xi}')$.

(i) Let $Q_2(x, \xi')$ *have a symbol, equal* 0 *in* $\{(x, \xi')\colon |\xi' - \bar{\xi}'| \le C_1\rho\}$. *Then*

$$F_{t\to h^{-1}\tau}\Bigl(\bar{\chi}_T(t) Q_{2x} u_h^1(x, y, t)\, {}^t Q_{1y}\Bigr) = O(h^s). \tag{3.13}$$

(ii) Assume instead that $Q_2(x, hD')$ *has a symbol, equal* 0 *as* $x_1 \le C_1\sigma T$ *where here and below*

$$\sigma = (\rho^{\frac{1}{2}} + T). \tag{3.14}$$

Then (3.13) *holds.*

(iii) Assume instead that $Q_2(x, hD')$ *has a symbol, equal* 0 *in*

$$\{(x', \xi')\colon |x' - \bar{y}' + t\nabla_{\xi'} b(\bar{y}', \xi')|_{\xi=\bar{\xi}'}| \le C_1\rho T\} \qquad \forall t\colon \epsilon T \le \pm t \le C_0 T. \tag{3.15}$$

Assume also that

$$\rho^2 T \ge h^{1-\delta}, \qquad \rho \ge C_0 T. \tag{3.16}$$

Then

$$F_{t\to h^{-1}\tau}\Bigl(\chi_T^{\pm}(t) Q_{2x} u_h^1(x, y, t)\, {}^t Q_{1y}\Bigr) = O(h^s). \tag{3.17}$$

where $\chi^{\pm} \in \mathscr{C}_0^{\infty}(\mathbb{R})$ *is supported in* $\{t\colon \epsilon \le \pm t \le 1\}$.

Proof. (i) Observe that under assumptions $(3.10)_2$ and (3.11) the propagation speed with respect to ξ' does not exceed $C_1(\rho+T)$ in

$$\{(x,\xi')\colon |x'-\bar{y}'|+|x_1|+|y_1|\le C_1T,\ |\xi'-\bar{\xi}'|\le C_1\rho\}.$$

This implies Statement (i) by the standard methods of propagation; see Subsection 5.1.2 of [Ivr2]. Here $(3.10)_1$ is the microlocal uncertainty principle).

(ii) Due to Statement (i) the propagation is confined to $\{(x,\xi')\colon |b(x',\xi')-\tau|\le C_0\sigma^2\}$ and thus to $|\xi_1|\le C\sigma$ and then to $x_1\le C_1\sigma\ell$. The microlocal uncertainty principle with respect to (x_1,ξ_1), that is $\sigma\times\sigma\ell\ge h^{1-\delta}$ is fulfilled due to $(3.10)_1$ and therefore we can consider propagation with respect to (x_1,ξ_1) as $x_1\ge\sigma T$.

(iii) Due to Statement (i) the propagation in the time direction $\pm t>0$ is confined to the domain (3.15) and here (3.16) is a microlocal uncertainty principle. □

Remark 3.4. (i) We can achieve (3.11) by gauge transformation, not affecting x_1,ξ_1. Further, if

$$\rho\ge T \tag{3.18}$$

then (3.11) is fulfilled automatically.

(ii) Obviously, condition (3.11) is important only as $\rho\le T$, which is not the case as $T\le h^{\frac12}$. Therefore we can cover also $\ell\le h^{1-\delta}$ with $T=h^{1-\delta}$.

(iii) Both statements of Proposition 3.3 hold for $\tau'\colon |\tau-\tau'|\le\sigma^2=(\rho+\ell^2)$.

3.2 Spectral estimates

The following proposition will be useful in the proof of Theorem 1.2:

Proposition 3.5. *(i) Let $L\ell^0(x,y)\ge h^{1-\delta}$. Let $\phi\in\mathscr{C}_0^\infty(\mathbb{R})$. Then*

$$\int \phi((\tau-\tau')/L)F_{t\to h^{-1}\tau'}\Big((\bar{\chi}_T(t)u_h(x,y,t)\Big)\,d\tau'=O(h^s). \tag{3.19}$$

(ii) Let $L\ell(x,y)\ge h^{1-\delta}$. Let $\phi\in\mathscr{C}_0^\infty(\mathbb{R})$. Then

$$\int \phi((\tau-\tau')/L)F_{t\to h^{-1}\tau'}\Big((\bar{\chi}_T(t)u_h^1(x,y,t)\Big)\,d\tau'=O(h^s). \tag{3.20}$$

Proof. The left-hand expressions are just $\phi((hD_t-\tau)/L)u_h(x,y,t)\big|_{t=0}$ and $\phi((hD_t-\tau)/L)u_h^1(x,y,t)\big|_{t=0}$ correspondingly and we apply finite speed of propagation. □

Proposition 3.6. *Under ξ-microhyperbolicity condition on the energy level τ estimates* (1.8) *and*

$$|e_h(x,y,\tau)| \le Ch^{1-d}\bigl(1+\ell^{0\,-1}(x,y)\bigr) \tag{3.21}$$

hold.

Proof. In virtue of Subsection 2.1 for $h \le \mathsf{T} \le \epsilon$

$$\begin{aligned} e_h(x,y,\tau) &= e_h^{\mathsf{T}}(x,y,\tau) + O(\mathsf{T}^{-1}h^{1-d}) \\ &= e_h^{0,\mathsf{T}}(x,y,\tau) + e_h^{1,\mathsf{T}}(x,y,\tau) + O(\mathsf{T}^{-1}h^{1-d}) \end{aligned}$$

and for $T = \epsilon_1\ell(x,y)$

$$e_h^{0,\mathsf{T}}(x,y,\tau) = e^{0,\mathsf{W}}(x,y,\tau) + O(h^{-d}(h\ell^{-1})^s)$$

and

$$e_h^{1,\mathsf{T}}(x,y,\tau) = O(h^s)$$

due to the finite speed of propagation, which implies (1.8). Estimate (3.21) is proven in the same way. □

As $h^{1-\delta} \le \ell(\bar{x},\bar{(}y)) \le \epsilon_1$ let us introduce $\bar{\xi}'^{\pm}$:

$$\nabla_{\xi'} b(\bar{w}',\xi')|_{\xi'=\bar{\xi}'^{\pm}} = t(\bar{y}-\bar{x}), \qquad b(\bar{w}',\bar{\xi}'^{\pm}) = \tau, \qquad \pm t > 0 \tag{3.22}$$

with $w' = \frac{1}{2}(\bar{x}'+\bar{y}')$. Due to strong convexity $\bar{\xi}'^{\pm}$ are defined uniquely and $t \asymp \ell(\bar{x},\bar{(}y))$.

Proposition 3.7. *Let $h^{1-\delta} \le T \le \epsilon_1$, $T = C_0\ell$,* (3.18) *and* (3.16) *be fulfilled. Then*

$$e_h^{1,\mathsf{T}}(\bar{x},\bar{y},\tau) = Q_{2x}e_h^{1,\mathsf{T}}(x,y,\tau)\,{}^tQ_{1y}|_{x=\bar{x},y=\bar{y}} + O(h^s) \tag{3.23}$$

where Q_1, Q_2 are operators with symbols equal 1 *in $(C_1\ell, C_1\rho)$ vicinities of $(\bar{w}',\bar{\xi}'^{\pm})$.*

Proof. Due to Proposition 3.5

$$e_h^{1,\mathsf{T}}(x,y,\tau) = h^{-1}\int_{-\infty}^{\tau} \bar\phi((\tau-\tau')L^{-1})F_{t\to h^{-1}\tau'}\bigl(\bar\chi_{\mathsf{T}}(t)u_h^1(x,y,t)\bigr)\,d\tau' + O(h^s) \tag{3.24}$$

where $\bar\phi \in \mathscr{C}^\infty(\mathbb{R})$, $\bar\phi(\tau)=1$ as $\tau\le 1$ and $\bar\phi(\tau)=0$ as $\tau\ge 2$, $L\ell \ge h^{1-\delta}$.

Due to Proposition 3.1(ii) we can replace $\bar\chi_{\mathsf{T}}(t)$ by $\chi_{\mathsf{T}}(t)=\bar\chi_{\mathsf{T}}(t)-\bar\chi_{\epsilon\mathsf{T}}(t)$. Then Proposition 3.3(iii) implies that if $\psi_1,\psi_2\in\mathscr{C}_0^\infty$ are supported in $\epsilon\ell$-vicinities of $\bar y$ and $\bar x$ respectively and $Q'=Q'(hD')$ is 0 in $C\rho$-vicinities of $\bar\xi'^{\pm}$ then as $|\tau'-\tau|\le L = h^{1-\delta}L^{-1}$

$$F_{t\to h^{-1}\tau'}\Bigl(\chi_{\mathsf{T}}(t)Q'_x\psi_2(x)u_h^1(x,y,t)\psi_1(y)\Bigr) = O(h^s),$$
$$F_{t\to h^{-1}\tau'}\Bigl(\chi_{\mathsf{T}}(t)\psi_2(x)u_h^1(x,y,t)\psi_1(y)\,{}^tQ'_y\Bigr) = O(h^s)$$

Indeed condition now are stronger than those of Proposition 3.3(iii).

Then these equalities and (3.24) imply (3.23). □

Proposition 3.8. *In the framework of Proposition 3.7*

$$|e_{T,h}^{1,\mathsf{T}}(x,y,\tau)| \le Ch^{1-d}\ell^{-1}\sigma\rho^{d-2} \tag{3.25}$$

with $\sigma = h^{\frac12-\delta'}\ell^{-\frac12}+\ell$.

Proof. Due to Propositions 3.1(ii) and 3.7 we need to estimate the right-hand expression of (3.24) with symbols of Q_1 and Q_2 supported in Ω, the union of $(C_1\ell, C_1\rho)$-vicinities of $(\bar w', \bar\xi'^{+})$ and $(\bar w', \bar\xi'^{-})$ intersected with

$$\{\xi\colon |b(x',\xi')-\tau|\le C\sigma^2\},$$

and with $\bar\chi_{\mathsf{T}}(t)$ replaced by $\chi_{\mathsf{T}}(t)=\bar\chi_{\mathsf{T}}(t)-\bar\chi_{\epsilon\mathsf{T}}(t)$. Observe that modulo $O(h^s)$

$$e_h^{1,\mathsf{T}}(x,y,\tau) \equiv h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau'}\Bigl(\chi_{\mathsf{T}}(t)u_h^1(x,y,t)\Bigr)\,d\tau' = T^{-1}F_{t\to h^{-1}\tau}\Bigl(\beta_{\mathsf{T}}(t)u_h^1(x,y,t)\Bigr)$$

with $\beta(t)=t^{-1}\chi(t)$.

Since $\ell \asymp \ell^0$ it sufficient to prove it for $e^{\mathsf{T}}_{T,h}(x,y,\tau)$. Expressing $u_h(x,y,t) = \int e^{ih^{-1}t\tau}\, d_\tau e_h(x,y,\tau)$ we see that expression in question equals

$$\int \hat{\beta}\big(\frac{(\tau-\tau')\,T}{h}\big)\, d_{\tau'} Q_{2x} e_h(x,y,\tau')\, {}^t Q_{1y}$$

which does not exceed

$$C \sup_{\tau' :\, |\tau'-\tau|\le L} |Q_{2x} e_h(x,y,\tau' + hT^{-1},\tau')\, {}^t Q_{1y}| + C' h^s.$$

Since $e_h(x,y,\tau)$ is the Schwartz kernel of the orthogonal projector this does not exceed

$$C \sup_{\tau' :\, |\tau'-\tau|\le L} |Q_{2x} e_h(x,z,\tau' + hT^{-1},\tau')\, {}^t Q_{2z}|_{z=x}|^{\frac{1}{2}} \times |Q_{1z} e_h(z,y,\tau' + hT^{-1},\tau')\, {}^t Q_{1y}|_{z=y}|^{\frac{1}{2}} + C' h^s.$$

Applying Tauberian estimate for $x = y$ we see that the right-hand expression does not exceed

$$Ch^{1-d}\ell^{-1} \sup_{\tau' :\, |\tau'-\tau|\le L} \int_{\Sigma(x,\tau')\cap(\Omega\times\mathbb{R}_{\xi_1})} d\xi : d_\xi a.$$

The integral in the right-hand expression does not exceed $C\sigma\rho^{d-2}$. Finally, recall that $T \asymp \ell$. □

Taking $\rho = \max((h^{1-\delta'}\ell^{-1})^{\frac{1}{2}},\, \ell)$ to satisfy (3.16) and (3.18), and thus $\sigma = \rho$ we get

Corollary 3.9. *The following estimates hold as* $|x_1| + |y_1| \le C\sigma\ell$

$$e^{1,\mathsf{T}}_h(x,y,\tau) = O(h^{1-d}) \quad \textit{for} \quad \begin{cases} \ell \ge h^{\frac{1}{2}+\delta} & d \ge 4, \\ \ell \ge h^{\frac{1}{2}-\delta} & d = 3, \\ \ell \ge h^{\frac{1}{3}-\delta} & d = 2. \end{cases} \tag{3.26}$$

Remark 3.10. (i) Then $\sigma \ge h^{\frac{1}{3}-\delta'}$.

(ii) The similar arguments work under assumption $|x'-y'| \ge \epsilon|x_1| + |y_1|$ instead of $|x_1| + |y_1| \le C\sigma\ell$.

(iii) The similar but simpler arguments work for $e^{0,\mathsf{T}}_h(x,y,\tau)$ as $\rho^2\ell^0 \ge h^{1-\delta}$.

4 Successive approximations

4.1 Successive approximations inside domain

Standard successive approximations

In this Section we are going to apply method of successive approximations to derive asymptotics of $e_h(x,y,\tau)$ near boundary. However we start from the partial proof of Theorem 1.1 by this method away from the boundary. According to [Ivr2], Section 5.3 (which is our standard reference here), we consider problem for propagator $u_h(x,y,t)$

$$(hD_t - A)u_h = 0, \qquad u|_{t=0} = \delta(x-y)$$

with $A = A(x, hD_x, h)$ and rewrite for $u_h^{\pm}(x,y,t) := u_h(x,y,t)\theta(\pm t)$. We have equation

$$(hD_t - A)u_h^{\pm} = \mp ih\delta(x-y)\delta(t) \tag{4.1}$$

which we are going to solve by the successive approximations with unperturbed operator $\bar{A} = a(y, hD_x)$. Then (4.1) yields the equality

$$(hD_t - \bar{A})u_h^{\pm} = \mp ih\delta(x-y)\delta(t) + Ru_h^{\pm} \tag{4.2}$$

and hence

$$u_h^{\pm} = \mp ih\bar{G}^{\pm}\delta(x-y)\delta(t) + \bar{G}^{\pm}Ru_h^{\pm}, \tag{4.3}$$

where $\bar{G}^{\pm}$ and $G^{\pm}$ are parametrices of the problems

$$(hD_t - \bar{A})v = f, \qquad \operatorname{supp}(v) \subset \{\pm(t-t_0) \ge 0\} \tag{4.4}$$

and

$$(hD_t - A)v = f, \qquad \operatorname{supp}(v) \subset \{\pm(t-t_0) \ge 0\} \tag{4.5}$$

respectively with $\operatorname{supp}(f) \subset \{\pm(t-t_0) \ge 0\}$ for some $t_0 \in \mathbb{R}$; $R = A - \bar{A}$.

Moreover, equation (4.1) yields that

$$u_h^{\pm} = \mp ihG^{\pm}\delta(x-y)\delta(t). \tag{4.6}$$

Iterating (4.3) N times and then substituting (4.6) we obtain the equality

$$u_h^{\pm} = \mp ih \sum_{0\le n\le N-1} (\bar{G}^{\pm}R)^n\bar{G}^{\pm}\delta(x-y)\delta(t) \mp ih(\bar{G}^{\pm}R)^nG^{\pm}\delta(x-y)\delta(t). \tag{4.7}$$

Finally, we apply ${}^tQ_y = {}^tQ(y, hD_y)$ to the right of (4.7), where Q is an operator with compactly supported symbol, equal 1 as $a(y,\xi) \le \tau + \epsilon$. After this cut-off, according to [Ivr2], Section 5.3, norms of the terms in (4.7) in the strip $\{(x,t)\colon |t| \le T\}$ do not exceed $Ch^{-M-n}T^{2n}$ and as $T \le h^{\frac12+\delta}$ we can ignore the remainder term. Since we need to consider $T \le c\ell(x,y)$ in the end we arrive to

$$\max(c\ell,\ h^{1-\delta}) \le T \le h^{\frac12+\delta}. \tag{4.8}$$

Then as it was shown (see [Ivr2], simplified (4.3.33))

$$\begin{aligned} &F_{t\to h^{-1}\tau}\Big(\bar\chi_T u_h^{\pm}(x,y,t)\,{}^tQ_y\Big) \\ &\equiv \mp i \sum_{0\le n\le N} (2\pi)^{-d-1} h^{-d+n} \int e^{ih^{-1}\langle x-y,\xi\rangle} F_n(y,\xi,\tau)[q_2(y,\xi,h)]\,d\xi, \quad \pm \operatorname{Im}\tau < 0, \end{aligned} \tag{4.9}$$

where $F_n = \sum_{\beta\colon |\beta|\le n} F_{n,\beta}\partial_\xi^\beta$ are differential operators applied to q_2, with coefficients $F_{n\beta}$ holomorphic with respect to ξ,τ as $\operatorname{Im}\tau \ne 0$, and have poles as $\tau \in \mathbb{R}$; denominators are $(\tau - a(y,\xi))^{2n+1+|\beta|}$. Then

$$\begin{aligned} &F_{t\to h^{-1}\tau}\Big(\bar\chi_T u_h(x,y,t)\Big) \\ &\qquad \equiv \sum_{0\le n\le N} (2\pi)^{-d-1} h^{-d+n} \int e^{ih^{-1}\langle x-y,\xi\rangle} \mathcal{F}_n(y,\xi,\tau)\,d\xi, \qquad \tau\in\mathbb{R} \end{aligned} \tag{4.10}$$

where $\mathcal{F}_n(y,\xi,\tau) = i\big(F_{n0}(y,\xi,\tau - i0) - F_{n0}(y,\xi,\tau+i0)\big)$. Then the principal term in $e^{\mathsf{T}}_{T,h}(x,y,\tau)$ can be rewritten as $e^{\mathsf{W}}_h(x,y,\tau)$ while all other terms as

$$h^{-d+n-|\alpha|} \sum_{\alpha\colon |\alpha|\le 2n-1} (x-y)^\alpha \int_{\Sigma(y,\tau)} W_{n,\alpha}(y,\xi) e^{ih^{-1}\langle x-y,\xi\rangle}\,d\xi \tag{4.11}$$

with $n \ge 1$ and smooth $W_{n,\alpha}$.

Indeed, taking ξ-partition and using ξ-microhyperbolicity, we can rewrite on each element $\mathcal{F}_n$ as a sum of $W'_{n,\alpha}(y,\xi)\partial_\xi^\alpha \delta'(\tau - a(y,\xi))$. Then, integrating by parts we will get (4.11) for terms in $e^{\mathsf{T}}_{T,h}(x,y,\tau)$.

Now due to strong convexity and stationary phase principle these terms do not exceed

$$Ch^{-d+n-|\alpha|}(h/\ell)^{\frac{d-1}{2}}\ell^{|\alpha|} \le Ch^{-\frac{d+1}{2}+n-|\alpha|}\ell^{-\frac{d-1}{2}+|\alpha|}, \tag{4.12}$$

which is $O(h^{1-d})$ as $d \ge 3$ and $O(h^{-\frac32}\ell^{\frac12})$ as $d = 2$. Recall that $\ell \le h^{\frac12+\delta}$.

Improved successive approximations

To improve this approach we need to freeze symbol at point $w = \frac{1}{2}(x+y)$ and to do this let us observe that

$$\begin{aligned}&\bigl(hD_t - A(x, hD_x, h)\bigr)u_h(x,y,t) = 0,\\ &\bigl(hD_t - A(y, -hD_y, h)\bigr)u_h(x,y,t) = 0, \qquad u_h|_{t=0} = \delta(x-y)\end{aligned}$$

and therefore denoting $v_h(w,z,t) = u_h(w+\frac{1}{2}z, w-\frac{1}{2}z, t)$ we have

$$\bigl(hD_t - \mathfrak{A}(w,z,hD_z,hD_w,h)\bigr)v_h(w,z,t) = 0, \qquad v_h|_{t=0} = \delta(z) \tag{4.13}$$

with

$$\mathfrak{A} = \frac{1}{2}\bigl(A(w+\frac{1}{2}z, hD_z + \frac{1}{2}hD_w, h) + A(w-\frac{1}{2}z, hD_z - \frac{1}{2}hD_w, h)\bigr). \tag{4.14}$$

Taking as unperturbed operator

$$\bar{\mathfrak{A}} = A(w, hD_z, h) \tag{4.15}$$

we get $R = \mathfrak{A} - \bar{\mathfrak{A}}$ a a sum of $z^\alpha(h\partial_w)^\beta$ with $|\alpha| + |\beta| \ge 2$.

With this modification we can write formula, similar to (4.7). Due to the propagation results we can add to R factor $\bar{\chi}_{cT}(h\partial_w)$ and then each new term in this formula adds an extra factor $C(T^2+h)Th^{-1}$ instead of CT^2h^{-1} and we can replace (4.8) by a weaker condition

$$\max(c\ell,\ h^{1-\delta}) \le T \le h^{\frac{1}{3}+\delta}. \tag{4.16}$$

Calculations, similar to those in the standard method lead us to the main term $e^{\mathsf{W}}(x,y,\tau)$ and to (4.11) replaced by

$$h^{-d+n-|\alpha|}\sum_{\alpha:\ 2|\alpha|\le 3n-1}(x-y)^\alpha \int_{\Sigma(w,\tau)} W_{n,\alpha}(w,\xi)e^{ih^{-1}\langle z,\xi\rangle}\,d\xi. \tag{4.17}$$

and to the same estimate (4.12) albeit with a restrictions $|\alpha| \le (3n-1)/2$, $\ell \le h^{\frac{1}{3}}$, and we get $O(h^{1-d})$ as $d \ge 1$.

4.2 Successive approximations near boundary

Standard successive approximations

We know (see [Ivr2], Section 7.2) that $u_h^0(x,y,t)$ and then $u_h^1(x,y,t)$ for $|t| \le T = h^{\frac{1}{2}+\delta}$, $x_1 + y_1 \le C_0 T$ could be constructed by the method of

successive approximations with unperturbed operator $\bar{A} = a(0, y'; hD_x)$ (so the principal part of A is frozen at point $(0, y')$): it leads us to the expression for $e_h^{\mathsf{T}}(x, y, \tau)$.

In this case unperturbed term would be as for $\bar{A}$ in the half-space and it will not exceed $Ch^{-d}(h/\ell)^{d+1/2}$ and and one can prove that the perturbed term would acquire factor T^2/h with $T \asymp \ell$ and it does not exceed (4.12) (with redefined $\ell(x, y)$ now) and it is $O(h^{1-d})$ as $d \geq 3$ and $Ch^{-\frac{3}{2}}\ell^{\frac{1}{2}}$ as $d = 2$.

Since we assumed that the boundary conditions are either Dirichlet or Neumann, we arrive to the expression (1.3) for $e_h^{1,\mathsf{T}}(x, y, \tau)$ as described in Theorem 1.2.

Improved successive approximations

Let us improve this construction in the same manner as we did inside domain. Consider problem for u_h^1:

$$(hD_t - A)u_h^1 = 0, \qquad u_h^1|_{t=0} = 0, \tag{4.18}$$

$$\eth B u_h^1 = -\eth B u_h^0|_{x\in\partial X}, \tag{4.19}$$

where $u_h^0(x, y, t)$ satisfies the same equation in the "whole space" and $\eth$ is an operator restriction to $\partial X \ni x$. Then

$$(hD_t - A)u_h^{1,\pm} = 0, \tag{4.20}$$

$$\eth B u_h^{1\pm} = -\eth B u_h^{0\pm} \tag{4.21}$$

where again $u^{j\pm} = \theta(\pm t)u_h^j(x, y, t)$ and

$$(hD_t - \bar{A})u_h^{1\pm} = Ru^{1\pm}, \tag{4.22}$$

$$\eth B u_h^{1\pm} = -Bu_h^{0\pm}, \tag{4.23}$$

where $u_h^{0,\pm}$ satisfies (4.2); recall that $B = I$ or $B = D_1$ for Dirichlet and Neumann boundary conditions correspondingly[4] Then like in [Ivr2], Section 7.2

$$u_h^{1\pm} = -\bar{G}'^{\pm}\eth B u_h^{0\pm} + \bar{G}^{\pm}Ru_h^{1\pm}, \tag{4.24}$$

where $\bar{G}^{\pm}$ are parametrices for the problems

$$(hD_t - \bar{A})v = f, \qquad \eth Bv = 0, \qquad \mathsf{supp}(v) \subset \{\pm(t - t_0) \geq 0\} \tag{4.25}$$

[4] For more general boundary conditions we would need to replace B by $\bar{B} + R_1$.

and $\bar{G}'^{\pm}$ are parametrices for the problems

$$(hD_t - \bar{A})v = 0, \qquad \eth Bv = f, \qquad \operatorname{supp}(v) \subset \{\pm(t - t_0) \geq 0\} \tag{4.26}$$

respectively with $\operatorname{supp}(f) \subset \{\pm(t - t_0) \geq 0\}$ for some $t_0 \in \mathbb{R}$; $R = A - \bar{A}$. Moreover,

$$u_h^{1\pm} = -G'^{\pm}\eth Bu_h^{0\pm} \tag{4.27}$$

where $G^{\pm}$ and $G'^{\pm}$ are parametrices for the problems (4.25) and (4.26) but for operator A. Iterating (4.24) N times and then substituting (4.27) we arrive to formula similar to (4.7)

$$u_h^{1\pm} = -\sum_{0\leq n\leq N-1} (\bar{G}^{\pm}R)^n \bar{G}'^{\pm}\eth Bu_h^{0\pm} - (\bar{G}^{\pm}R)^N G'^{\pm}\eth Bu_h^{0\pm}. \tag{4.28}$$

What is more, we plug $u_h^{0\pm}$ given by (4.7) with $\bar{G}^{\pm}$ and $G^{\pm}$ replaced by $\bar{G}^{0\pm}$ and $G^{0\pm}$ which are parametrices for (4.4) and (4.5) in the "whole space".

Finally, we apply ${}^tQ_1 = {}^tQ(y_1, z', hD'_z)$ to the right of (4.27) and (4.7), where Q_1 is an operator with the symbol, supported in

$$\Omega_{T,\rho,\sigma} := \{(x_1, z', \zeta) \colon |z'| \leq T,\ |\zeta - \bar{\xi}'| \leq \rho,\ |x_1| \leq \sigma T\} \tag{4.29}$$

where $|a(0, \bar{x}', 0, \bar{\xi}') - \tau)| \leq c\rho^2$. Then due to Proposition 3.3, under assumptions (3.11) and $(3.10)_{1,2}$ we can insert $Q_2(x_1, hD'_z)$ to the right of each copy of R with symbol supported in $\Omega_{3T,3\rho,3\sigma}$ and equal 1 in $\Omega_{2T,2\rho,2\sigma}$.

So far we we followed exactly [Ivr2], Section 7.2, except there we had $\rho = c$. However now instead of $\bar{A} = a(0, y'; hD_x)$ we take

$$\bar{A} = a(w, hD_x), \qquad w = (0, w'), \qquad w' = \frac{1}{2}(x' + y'). \tag{4.30}$$

Then, the norm of $\bar{G}^{\pm}RQ_2$ does not exceed $C(T^2 + \sigma T + h)Th^{-1}$ and we can replace (4.8) by a weaker condition $(T^2 + \sigma T + h)T \leq h^{1+\delta}$, which is equivalent to (4.16) plus

$$\sigma\ell^2 \leq h^{1+\delta}. \tag{4.31}$$

Remark 4.1. Recall that σ is defined by (3.14) and with $\rho = h^{1-\delta}\ell^{-1}$ condition (4.31) is also equivalent to (4.16). However, for us it is more important which value of the reflection angle is allowed in this method.

Thus we arrive to the following statement:

Proposition 4.2. *Let $Q = Q(x_1, z', hD'_z)$ be an operator with the symbol $q(x_1, z', \zeta')$ supported in $\Omega_{T,\rho,\sigma}$ where condition* (3.11) *is fulfilled and let conditions* (4.16) *and* (4.31) *be also fulfilled.*

Then we can skip remainder terms in both (4.27) *and modified* (4.7)*, which are $O(h^s)$, leaving us only with $\bar{G}^{\pm}$, $\bar{G}'^{\pm}$ and $\bar{G}^{0\pm}$.*

Thus (4.28) without the last term becomes an asymptotic series. Now let us calculate $e_h^{1,\mathsf{T}}(x, y, \tau)$ under these assumptions.

Proposition 4.3. *In the framework of Proposition 4.2*

$$
\begin{aligned}
(4.32)\quad & F_{t\to h^{-1}\tau}\Big(\bar{\chi}_T(t)u_h^{1\pm\,{}^t}Q_1\Big)\\
&\sim \sum_{n\ge 0} h^{-d+n}\int T\hat{\bar{\chi}}\big(\frac{(\tau-\tau')T}{h}\big)\,d\tau'\int d\xi'\int_{\gamma_+} d\xi_1\int_{\gamma_-} d\eta_1\\
&\qquad\qquad \times e^{ih^{-1}(x_1\xi_1-y_1\eta_1+\langle x'-y',\xi'\rangle)}F_n(w,\xi',\xi_1,\eta_1,\tau')[q(w,\xi')]
\end{aligned}
$$

for $\tau\in\mathbb{C}_{\mp}$, where $\gamma_{\pm}$ are closed contours in $\mathbb{C}_{\pm}$ passing once around the poles of $\big(\tau-a(z,\xi_1)\big)^{-1}$ lying in $\mathbb{C}_{\pm}$ and not passing around the poles lying in $\mathbb{C}_{\mp}$; for real z and $\operatorname{Im}\tau\neq 0$ there is no real pole, and F_n are sums of the terms

$$
\begin{aligned}
(4.33)\quad & \xi_1^j\eta_1^k W_{n,l,m,p,j,k}(w,\xi',\tau)\\
&\qquad\times\big(\tau-a(w,\xi_1,\xi')\big)^{-l}\big(\tau-a(w,\eta_1,\xi')\big)^{-m}\big(\tau-b(w,\xi')\big)^{-p}
\end{aligned}
$$

with

$$
b(w,\xi') = a(w,0,\xi'), \tag{4.34}
$$

$$
l\ge 1,\ m\ge 1,\ 2(l+m+p)\le 3n+j+k+3,\ j\le l,\ k\le m \tag{4.35}
$$

and uniformly smooth $W_{n,l,m,p,j,k}$.

Proof. Proof follows the proof of Theorem 7.2.13 of [Ivr2] with the some modifications, mainly introduced in Subsection 4.1. We rewrote A as $\mathfrak{A}$ by (4.14) and defined $\bar{\mathfrak{A}}$ by (4.15) with the exception that w' and z' are now $(d-1)$-dimensional variables (see (4.30)) and we preserve x_1 and y_1.

The main part of the perturbation R is quadratic with respect to z', hD'_w and linear with respect to x_1. In comparison with (7.2.60) of [Ivr2] formula (4.33) is simpler, because we have scalar factors here and products collapse into powers. On the other hand, instead of claiming that W of that proof are holomorphic satisfying (7.2.38) of [Ivr2] here we do it in much explicit way since now we need to follow very carefully what are relations between j, l, l, m, p and n.

We have operators $a(w, hD_1, hD'_z, hD'_w)$ with symbols which do not depend on x. Let us make h-Fourier transform by x' and t.

Consider first $u^0_h(x, y, t)$. We claim that

$$\begin{aligned}(4.36)\quad & F_{t\to h^{-1}\tau}\Big(\bar\chi_T(t)\eth(hD_{x_1})^r u^{0\pm}_h {}^tQ_1\Big)\\ &\sim \sum_{n\ge 0} h^{1-d+n}\int T\hat{\bar\chi}\big(\frac{(\tau-\tau')T}{h}\big)\,d\tau'\int d\xi'\int_{\gamma_-} d\eta_1\\ &\qquad\qquad \times e^{ih^{-1}(-y_1\eta_1+\langle x'-y',\xi'\rangle)}F^0_n(w,\xi',\eta_1,\tau')[q(w,\xi')]\end{aligned}$$

for $\tau\in\mathbb{C}_\mp$, $r=1$ and F^0_n are sums of the terms

$$(4.37)\qquad \eta_1^k W^0_{n,m,j,k}(w,\xi',\tau)\big(\tau-a(w,\xi_1,\xi')\big)^{-l}\big(\tau-a(w,\eta_1,\xi')\big)^{-m}$$

with $2m\le 3n+k+2-r$ and $k<m$ with the only exception $n=0$, $m=1$, $k=r=1$.

(a) Like in that proof of [Ivr2], each factor z_r and hD_{w_r} with $r=2,\dots,d$ is moved to the right towards $\delta(z')$, using commutator relations

$$(4.38)\qquad z_r\bar G^{0\pm}=\bar G^{0\pm}z_r-\bar G^{0\pm}[\bar{\mathfrak{A}},z_r]\bar G^{0\pm}$$

which also hold for hD_{w_r}. So, each such commuting adds factor h and increases either m or p by 1. However, each pair of those factors are accompanied by $\bar G^{0\pm}$, and therefore in this process increment of the power of h by 1 is "paid" by increment of m with the factor $3/2$ [5)]. On the other hand, commuting with ${}^tQ_1$, each increment power of h by 1 is "paid" by increment of $(m+p)$ with the factor 1.

[5)] Compare with the standard method, when the factor was 2.

(b) Also recall that each factor x_1 is moved to the left, towards $\eth B$, also using (4.38) but for x_1. In this commutator factor $h\eta_1$ is also gained and m is increased by 1 and also $\bar{G}^{0\pm}$ is applied so in the end m is increased by 2. When x_1 reaches $\eth B$ the term disappears for Dirichlet boundary condition, or this factor cancels with $B = h\partial_{x_1}$ for Neumann boundary condition (and factor h is gained). process each increment power of $h\eta_1$ by 1 is "paid" by increment of m with the factor 2. Therefore (4.36)–(4.37) has been proven.

(c) Then for

$$F_{t\to h^{-1}\tau}\Bigl(\bar{\chi}_T(t)\bar{G}'^{\pm}\eth B u_h^{0\pm\,t}Q_1\Bigr) \tag{4.39}$$

formula (4.33) holds with $l = 1$, $p = 0$ and $j = 1, 0$ for Dirichlet and Neumann boundary conditions respectively.

(d) Again each factor z_r and hD_{w_r} with $r = 2, \dots, d$ is moved to the right towards $\delta(z')$, using commutator relations (4.38) for $\bar{G}^{\pm}$ rather than for $\bar{G}^{0\pm}$ and also

$$z_r\bar{G}'^{\pm} = \bar{G}'^{\pm}z_r - \bar{G}^{\pm}[\bar{\mathfrak{A}}, z_r]\bar{G}'^{\pm} \tag{4.40}$$

which holds also for hD_{w_r}. Observe that that p can increase but again as in (a) increment of the power of h by 1 is "paid" by increment of $m + p$ with the factor $3/2$ [6].

(e) Also recall that each factor x_1 which is to the left from $\bar{G}'^{\pm}\eth B$ is moved to the right, towards $\bar{G}'^{\pm}\eth B$ but instead of (4.38) we use

$$x_1\bar{G}_*^{\pm} = \bar{G}_{\mathsf{D}}^{\pm}x_1 - \bar{G}_{\mathsf{D}}^{\pm}[\bar{\mathfrak{A}}, x_1]\bar{G}_*^{\pm}, \tag{4.41}$$

$$x_1\bar{G}_*'^{\pm} = -\bar{G}_{\mathsf{D}}^{\pm}[\bar{\mathfrak{A}}, x_1]\bar{G}_*'^{\pm} \tag{4.42}$$

with $* = \mathsf{D}, \mathsf{N}$ (in particular, for $\bar{G}_{\mathsf{D}}$ (4.38) holds).

Again, similarly to (c) either $l+p$ is increased by 2 and j does not change, or j is decreased by 1 and $l + p$ is increased by 1.

[6] Indeed, it is sufficient to consider boundary value problem for ODE $(\tau - D^2)v = f$ with $f(x) = \int_{\gamma_+}\xi^j(\tau-\xi^2)^{-l}e^{ix\xi}\,d\xi$. One can see easily that

$$v(x) = \int_{\gamma_+}\Bigl(\xi^j(\tau-\xi^2)^{-l-1} - \kappa\xi^{j'}\tau^{(j-j')/2-l}(\tau-\xi^2)^{-1}\Bigr)e^{ix\xi}\,d\xi$$

satisfies this equation and $v(0) = 0$ for some constant $\kappa = \kappa_{\mathsf{D}jl}$ and $j' \equiv j \mod 2$ and $j' = 0, 1$. Also $v'(0) = 0$ with some other constant $\kappa = \kappa_{\mathsf{N}jl}$.

(f) Then we have $n = n' + j + k$ with $l + p = l' + 2j$, $m = m' + 2k$ and $l' + m' \le \frac{3}{2}n' + 2$. Those are "the worst case scenarios" when we consider the main part of perturbation R, quadratic by $(x' - y')$ and linear by x_1. For the rest of perturbation increments of $l + p, m$ are relatively smaller. In the end we arrive to (4.35).

(g) One can see easily that for the main term we have $l = m = 1$, $p = 0$ and $j + k = 1$ with $j = 0, 1$ for Dirichlet and Neumann problems respectively and $W_* = \mathsf{const}$. □

Proposition 4.4. *In the framework of Proposition 4.2*

$$\begin{aligned}(4.43)\quad & F_{t\to h^{-1}\tau}\Bigl(\bar\chi_T(t)u_h^{1\pm\, t}Q_1\Bigr)\\ &\sim \sum_{n\ge 0, j\ge 0, k\ge 0} h^{-d+n}\int T\hat{\bar\chi}\bigl(\frac{(\tau-\tau')T}{h}\bigr)\,d\tau'\int d\xi'\int_{\gamma_+} d\xi_1\\ &\qquad\qquad \times e^{ih^{-1}((x_1+y_1)\xi_1+\langle x'-y',\xi'\rangle)}F_{n,j,k}(w,\xi',\xi_1,\tau')[q(w,\xi')]\end{aligned}$$

for $\tau \in \mathbb{C}_\mp$ where $F_{n,j,k}$ are sums of the terms

$$(4.44)\qquad \xi_1^j\eta_1^k W_{n,l,j,k}(w,\xi',\tau)\bigl(\tau - a(y',\xi_1,\xi')\bigr)^{-l}$$

with $1 \le l \le \frac{3}{2}n + j + k + 1$ and uniformly smooth $W_{n,l,j,k}$ and also

$$\begin{aligned}(4.45)\quad & F_{t\to h^{-1}\tau}\Bigl(\bar\chi_T(t)u_h^{1\, t}Q_1\Bigr)\\ &\sim \sum_{n\ge 0, j\ge 0, k\ge 0} h^{-d+n}\int T\hat{\bar\chi}\bigl(\frac{(\tau-\tau')T}{h}\bigr)\,d\tau'\int d\xi\\ &\qquad\qquad \times e^{ih^{-1}((x_1+y_1)\xi_1+\langle x'-y',\xi'\rangle)}\mathcal{F}_{n,j,k}(w,\xi',\xi_1,\tau')[q(w,\xi')],\end{aligned}$$

where $\mathcal{F}_{n,j,k}(w,\xi',\xi_1,\tau') = F_{n,j,k}(w,\xi',\xi_1,\tau' - i0) - F_{n,j,k}(w,\xi',\xi_1,\tau' + i0)$.

Proof. (4.43)–(4.44) follows from Proposition 4.3 by calculating residues at zeroes of $(\tau - a(x,\xi_1,\xi'))$ and $(\tau - a(x,\eta_1,\xi'))$ in (4.33) and (4.43).

Next we observe that in (4.43) we can replace integral along γ_+ by integral along $\mathbb{R}$. Then (4.45) follows trivially. □

Proposition 4.5. *Let ξ-microhyperbolicity condition be fulfilled at energy level τ and let*

$$\nu(x)+\nu(y)\le \sigma\ell \tag{4.46}$$

with

$$\ell(x,y)\le h^{\frac{1}{3}+\delta},\quad \sigma = h^{\frac{1}{2}+\delta}\ell^{-\frac{1}{2}}. \tag{4.47}$$

Let $T = T^*\ge C_0\ell(x,y)$. Then for any T: $T^*\le T\le \epsilon$

(i) As $d\ge 3$ estimate

$$|e^{1,\mathsf{T}}_{T,h}(x,y,\tau) - [\mp]e^{0,\mathsf{W}}_h(x,\tilde y,\tau)|\le Ch^{1-d} \tag{4.48}$$

with sign $[\mp]$ for Dirichlet and Neumann boundary conditions respectively.

(ii) As $d=2$ estimate

$$|e^{1,\mathsf{T}}_{T,h}(x,y,\tau) - [\mp]e^{0,\mathsf{W}}_h(x,\tilde y,\tau) - e_{h,\mathsf{corr}}(x,y,\tau)|\le Ch^{-1} \tag{4.49}$$

with $e_{h,\mathsf{corr}}(x,y,\tau)$ given by (4.54) *below.*

Proof. (a) Consider first $\ell\le h^{\frac{1}{2}-\delta}$. Let us take $\rho = \min((h/\ell)^{\frac{1}{2}}h^{-\delta}, C_2)$. Then $\rho\ge C_0\ell$, $\sigma=\rho^{\frac{1}{2}}$ and

$$\sigma\ell^2\le h^{1+\delta}\qquad \text{as}\quad \ell\le h^{\frac{3}{7}+\delta} \tag{4.50}$$

and the method of successive approximations works. Let us take take ρ-admissible partition of unity by ζ' in ρ-vicinity of $\Sigma(w,\tau)$. In this case $\rho\ge\ell$ and $\sigma=\rho^{\frac{1}{2}}$. Moreover, as $\rho = C_2$ it covers the whole domain $\{\zeta'\colon b(w,\zeta')< 2\tau\}$ and as $\rho<C_2$ and therefore $\ell\ge h^{1-2\delta}$ and also $\rho^2\ell\ge h^{1-2\delta}$ we can use the fact that

(4.51) If $\rho\ell\ge h^{1-\delta}$, $\rho\ge C_0\ell^2$, (3.11) is fulfilled and Q_1 is an operator with the symbol equal 0 in ρ-vicinity of $\Sigma(w,\tau)$ and $\ell\ge h^{1-\delta}$ then

$$e^{1,\mathsf{T}}_h(x,y,\tau)\,{}^tQ_{1,z} = O(h^s)$$

which follows from Section 3. Therefore we can take cut-off operator $Q_1 = I$.

Then the main term of the final expression equals to $e_h^{0,\mathsf{W}}(x,\tilde{y},\tau)$ and is $\asymp h^{-d}(h\ell^{-1})^{(d+1)/2}$ and n-th term does not exceed

$$Ch^{-d-\delta'}\bigl(\frac{h}{\ell}\bigr)^{(d+1)/2}\times\bigl(\rho^{\frac{1}{2}}\ell^2h^{-1}\bigr)^{n-1} \tag{4.52}$$

due to the same microlocal arguments as above. One can see easily that expression (4.52) is $O(h^{1-d+\delta''})$ as $d\ge 2$ and $n\ge 3$ and $\ell\le h^{\frac{1}{3}+\delta}$. Furthermore, if we consider terms $O(\ell^2)$ in R then the corresponding second term does not exceed

$$Ch^{-d-\delta'}\bigl(\frac{h}{\ell}\bigr)^{(d+1)/2}\times\ell^3h^{-1})^{n-1} = O(h^{1-d+\delta''}). \tag{4.53}$$

Therefore we need to consider only the second term in the successive approximations. It is equal to

$$\begin{aligned}&[\mp]e_{h,\mathsf{corr}}(x,y,\tau)\\ &\qquad := -\frac{1}{2}(2\pi h)^{-d}\int_{\Sigma(w,\tau)}\lambda(w',\xi')(x_1+y_1)e^{ih^{-1}\langle x-\tilde{y},\xi\rangle}\,d\xi : d_\xi a(w,\xi)\end{aligned} \tag{4.54}$$

with

$$\lambda(w',\xi') = a_{x_1}(x_1,w',\xi)|_{x_1=\xi_1=0}. \tag{4.55}$$

Indeed, one can see easily that the second term in the successive approximation for $[\mp]F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_T(t)u_h^{1\pm}(x,y,t)\bigr)$ is equal to

$$\begin{aligned}&\pm 2h^3(2\pi h)^{-1-d}\int_{\gamma_+\times\mathbb{R}}\lambda(w',\xi')\xi_1(\tau-a(x,\xi))^{-3}e^{i\langle x-\tilde{y},\xi\rangle}\,d\xi\\ &=\mp\frac{i}{2}h^2(2\pi h)^{-1-d}\int_{\gamma_+\times\mathbb{R}}\lambda(w',\xi')(x_1+y_1)(\tau-a(x,\xi))^{-2}e^{i\langle x-\tilde{y},\xi\rangle}\qquad \mp\mathsf{Im}\,\tau<0;\end{aligned}$$

then the second term in decomposition for $[\mp]F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_T(t)u_h^1(x,y,t)\bigr)$ is equal to

$$-\frac{1}{2}h(2\pi h)^{-d}\int\lambda(w',\xi')(x_1+y_1)e^{ih^{-1}\langle x-\tilde{y},\xi\rangle}\delta'(\tau-a(w,\xi))\,d\xi$$

which implies (4.55).

(b) Due to stationary phase integral in 4.54) does not exceed $Ch^{-d}\bigl(\frac{h}{\ell}\bigr)^{(d-1)/2}$, and expression (4.54) is $O(h^{1-d})$ as $d \ge 3$, $x_1 + y_1 \le \sigma\ell$.

Due to Corollary 3.9 as $d \ge 3$ we need to consider only this case $\ell \le h^{\frac{1}{2}-\delta}$. Therefore Statement (i) has been proven.

(c) Let $d = 2$. Then we need to consider also $h^{\frac{1}{2}-\delta} \le \ell \le h^{\frac{1}{3}+\delta}$ and with selected $\rho = (h/\ell)^{\frac{1}{2}}h^{-\delta}$ condition $\sigma\ell^2 \le h^{1+\delta}$ may fail. We need to consider lesser ρ. Let us pick up $\rho = h^{1-\delta}\ell^{-1}$. Then $\rho \ge C_0\ell^2$ and $\sigma\ell^2 \le h^{1+\delta}$ as $\ell \le h^{\frac{1}{3}-\delta}$.

However condition $\rho \ge C_0\ell$ may fail and then we need to take care of (3.11) at each point of $\Sigma(w,\tau) \cap \{\xi_1 = 0\}$.

The good news is that this set consists of two points $\bar{\xi}'^{\pm}$ and we do not need $\rho^2\ell \ge h^{1-\delta}$ because we can deal with each of these two points separately. Therefore we can replace ρ-admissible operator Q_1 with the symbol, equal 1 in ρ-vicinity of $\bar{\xi}'^{\pm}$ by operator with the symbol equal 1 in ϵ-vicinity of this point. Observing that the required gauge transformations are $\xi_2 \mapsto \xi_2 - h^{-1}\alpha_{\pm}z_2$, that are multiplications by $e^{ih^{-1}\alpha_{\pm}z_2^2/2}$ which do not affect $e(x,y,\tau)$ as $z_2 = \frac{1}{2}(x_2 - y_2)$. Therefore again we can take $Q_2 = I$.

Then n-th term does not exceed (4.52) which is $O(h^{-1+\delta''})$ as $n \ge 3$ in current settings. Again, if we consider $O(\ell^2)$ terms in R then the corresponding second term does not exceed (4.53). Thus again we are left with expression (4.54) but this time we cannot claim that it is $O(h^{-1})$ even for $\ell \le h^{\frac{1}{2}+\delta}$ and $\rho = h^{1-\delta'}\ell^{-1}$. Therefore Statement (ii) has been proven. □

5 Geometric optics method

5.1 Constructing solution

Proposition 5.1. *Let*

$$\nu(x) + \nu(y) \ge C_0\ell^2(x,y) \tag{5.1}$$

and $\ell(x,y) \le \epsilon$. TThen on the energy level τ there exists a single generalized Hamiltonian billiard of the length $\le c\epsilon$ with at least one reflection from ∂X, from y to x and one from x to y, and each has exactly one reflection and the incidence angles are $\asymp \bigl(\nu(x) + \nu(y)\bigr)\ell^{-1}(x,y)$ (so, they are standard Hamiltonian billiards*).*

Proof. The proof is obvious. □

Remark 5.2. Assumption (5.1) is essential. Indeed, if ∂X is strongly concave[7)] then for $\nu(x)+\nu(y)\le C_0\ell^2(x,y)$ there could be multiple reflections and if ∂X is strongly convex[7)] then the incidence angle may be 0. In the former case there could be also multiple reflections and multiple billiard rays from x to y on the same energy level τ while in the latter case there could be no rays at all.

Proposition 5.3. *(i) Let A be ξ-microhyperbolic on the energy level $\tau = a(y,\theta)$ and*

$$a(x,0) < \tau - \epsilon.$$

Let $\varphi^0(x,y,\theta)$ be a solution of the stationary eikonal equation (2.7) *satisfying* (2.8) *and* (2.9)*. Then*

$$|\partial_x^\alpha\partial_y^\beta\partial_\theta^\gamma\varphi^0(x,y,\theta)| \le C_{\alpha\beta\gamma}\begin{cases} T & \alpha=\beta=0,\\ 1 & |\alpha|+|\beta|\ge 1\end{cases} \qquad \forall x,y\colon |x-y|\le T \tag{5.2}$$

provided $T\le\epsilon$ with sufficiently small constant $\epsilon>0$.

(ii) Let $\varphi(x,y)$ be another solution of the same equation satisfying

$$\varphi|_{x_1=0} = \varphi^0|_{x_1=0}, \qquad \partial_{x_1}\varphi|_{x_1=0} = -\partial_{x_1}\varphi^0|_{x_1=0}. \tag{5.3}$$

Assume that

$$\sigma = |\partial_{x_1}\varphi|_{x_1=0}| \ge C_0 T. \tag{5.4}$$

Then as $|x-y|\le T$ the following inequalities hold:

$$|\partial_x^\alpha\partial_y^\beta\partial_\theta^\gamma\varphi| \le C_{\alpha\beta\gamma}\begin{cases} T & \alpha=\beta=0,\\ 1 & \alpha_1\le 1,\\ \sigma^{3-\alpha_1-|\alpha|-|\beta|-|\gamma|} & \alpha_1\ge 2.\end{cases} \tag{5.5}$$

(iii) Furthermore,

$$|\partial_x^\alpha\partial_y^\beta\partial_\theta^\gamma\varphi| \le C_{\alpha\beta\gamma}\sigma^{4-\alpha_1-|\alpha|-|\beta|-|\gamma|} \qquad \alpha_1\ge 2,\ |\gamma'|\ge 1. \tag{5.6}$$

[7)] With respect to Hamiltonian trajectories.

Proof. (a) Consider first $\varphi = \varphi^0$. Then the left-hand expression of (5.2) does not exceed $C_{\alpha\beta\gamma}$ and we need to consider only $\alpha = \beta = 0$. Applying ∂_θ^γ to eikonal equation we see that $\frac{d}{dt}\partial_\theta^\gamma\varphi$ is bounded where here and below

$$\frac{d}{dt} \coloneqq \bigl(\partial_t - \sum_k a^{(k)}(x, \nabla_x\varphi)\bigr). \tag{5.7}$$

Since $|\partial_\theta^\gamma\varphi^0(x,y,t,\theta)| \le C_\gamma T$ as $t = 0$ and $|x-y| \le T$ we conclude that the same is true for $|t| \le T$.

(b) First, we provide this estimate as $x_1 = 0$; from (5.2) and (5.3) we conclude that (5.5) holds as $\alpha_1 = 0, 1$. Consider

$$\varphi_{x_1}^2 = a(y,\theta) + b(x, \nabla_{x'}\varphi), \tag{5.8}$$
$$b(x, \nabla_{x'}\varphi) \coloneqq -V - \sum_{j\ge 2} g^{jk}(\varphi_{x_j} - V_j)(\varphi_{x_k} - V_k).$$

Differentiating once by x_1 we get

$$2\varphi_{x_1}\varphi_{x_1x_1} = b_{x_1}(x, \nabla_{x'}\varphi) + \sum_{k\ge 2} b^{(k)}(x, \nabla_{x'})\varphi_{x_kx_1} \tag{5.9}$$

which in virtue of (5.5) with $\alpha_1 \le 1$ does not exceed C and therefore

$$|\varphi_{x_1x_1}| \le C\sigma^{-1}. \tag{5.10}$$

Further, applying to (5.8) $\partial_x^{\alpha-\varepsilon}\partial_y^\beta\partial_\theta^\gamma$ with $\varepsilon = (1,0,\dots,0)$ and $\alpha_1 = 2$ and plugging $x_1 = 0$ we see that $2\varphi_{x_1}\varphi_{\alpha\beta\gamma}$ [8] is a linear combination with bounded coefficients of $\varphi_{\alpha^1\beta^1\gamma^1}$ with $|\alpha^1| + |\beta^1| + |\gamma^1| < |\alpha| + |\beta| + |\gamma|$ plus bounded terms, and then by induction by $|\alpha| + |\beta| + |\gamma|$ we arrive to (5.5) for $\alpha_1 = 2$.

Consider induction by α_1. Assume that (5.5) is proven for lesser α_1 and for arbitrary α', β, γ.

Applying to (5.8) $\partial_{x,t}^{\alpha-\varepsilon}\partial_y^\beta\partial_\theta^\gamma$ and plugging $x_1 = 0$ we get linear combinations with bounded coefficients of products

$$\prod_{1\le j\le m} \varphi_{\alpha^j\beta^j\gamma^j} \tag{5.11}$$

where $\sum_j |\alpha^j| \le |\alpha| + m - 1$, $\sum_j \beta^j \le \beta$, $\sum_j \gamma^j \le \gamma$. These terms appear when

[8] Here and below we use notation $\varphi_{\alpha\beta\gamma} = \partial_{x,t}^\alpha\partial_y^\beta\partial_\theta^\gamma\varphi$.

(A) We differentiate $b(x, \nabla_{x'}\varphi)$, in this case $\sum_j \alpha_1^j < \alpha_1$, $\sum_j |\alpha^j| \le |\alpha|$ and these terms due to induction assumption are $O(\sigma^{4-\alpha_1-|\alpha|-|\beta|-|\gamma}$).

(B) We differentiate $\varphi_{x_1}^2$ and $m = 2$, $|\alpha^1| + |\alpha^2| = |\alpha| + 1$, $\alpha_1^1 + \alpha_1^2 = \alpha_1 + 1$, $\alpha_1^j < \alpha$ and these terms due to induction also are $O(\sigma^{4-\alpha_1-|\alpha|-|\beta|-|\gamma|})$.

(C) We differentiate $\varphi_{x_1}^2$ and $m = 1$, $\alpha_1^1 = \alpha_1$, $\alpha_1^1 < \alpha_1$. Then we apply induction by $|\alpha|+|\beta|+|\gamma|$, and these terms due to induction assumption are $O(\sigma^{4-\alpha_1-|\alpha|-|\beta|-|\gamma|})$ as well.

Then dividing by φ_{x_1} and we get $O(\sigma^{4-\alpha_1-|\alpha|-|\beta|-|\gamma|})$. We need base of the induction in (C). However as $|\alpha| = \alpha_1$, $\beta = \gamma = 0$ terms of type (C) do not appear.

(c) We need to expand these estimates to $x_1 > 0$. Applying to equation (5.8) $\partial_{x,t}^{\alpha}\partial_y^{\beta}\partial_\theta^{\gamma}$ with $|\alpha| + |\beta| + |\gamma| = 1$ we see that $\dfrac{d}{dt}\varphi_{\alpha\beta\gamma}$ is bounded and therefore in this case we extend (5.5) from $x_1 = 0$ to $x_1 > 0$.

Next, for $|\alpha|+|\beta|+|\gamma| = 2$ we get that $\dfrac{d}{dt}\varphi_{\alpha\beta\gamma}$ does not exceed $C(S+1)$ with

$$S = \sum_{\alpha,\beta,\gamma:=|\alpha|+|\beta|+|\gamma|=2} |\varphi_{\alpha\beta\gamma}|^2 \tag{5.12}$$

and therefore $|\dfrac{dS^{\frac12}}{dt}| \le C(S+1)$; since $S|_{x_1=0} = O(\sigma^{-1})$ due to (5.10) we conclude that for $T \le \epsilon\sigma$ estimate $S^{\frac12} \le C\sigma^{-1}$ holds. Then

$$|\varphi_{\alpha\beta\gamma}| \le C\sigma^{-1} \qquad \text{for } \ |\alpha| + |\beta| + |\gamma| = 2. \tag{5.13}$$

But then, taking $\alpha_1 \le 1$ we get that $\dfrac{d}{dt}\varphi_{\alpha\beta\gamma}$ does not exceed $C\sigma^{-1}(S^{\frac12}+1)$ with S defined by (5.12) with summation restricted to $\alpha_1 \le 1$ and then due to (5.5) for $x_1 = 0$ we conclude that

$$|\varphi_{\alpha\beta\gamma}| \le C \qquad \text{for } \ |\alpha| + |\beta| + |\gamma| = 2, \ \alpha_1 \le 1. \tag{5.14}$$

And then, taking $\alpha_1 = 0$ we get that $\dfrac{d}{dt}\varphi_{\alpha\beta\gamma}$ does not exceed C and then due to (5.5) for $x_1 = 0$ we conclude that

$$|\varphi_{\alpha\beta\gamma}| \le CT \qquad \text{for } \ \alpha = \beta = 0, \ |\gamma| = 2. \tag{5.15}$$

So, (5.5) holds as $|\alpha| + |\beta| + |\gamma| \le 2$, $x_1 > 0$.

(d) Assume that for $|\alpha|+|\beta|+|\gamma|<p$ estimate (5.5) has been proven. Applying to equation (5.8) $\partial_{x,t}^{\alpha}\partial_y^{\beta}\partial_\theta^{\gamma}$ with $|\alpha|+|\beta|+|\gamma|=p\ge 3$ we again get a linear combination with bounded coefficients of (5.11) products (plus bounded terms) where this time $\sum_j|\alpha^j|\le|\alpha|+m$. Then, as $\alpha_1=q$, $|\alpha|+|\beta|+|\gamma|=p$ we see from the same analysis as in (ii) that

$$|\frac{d}{dt}\varphi_{\alpha\beta\gamma}|\le C\sigma^{-1}S^{\frac12}+C\sigma^{3-p-q}+C$$

and then (5.5) is extended from $x_1=0$ to $x_1>0$, but for $\alpha=\beta=0$, when we proved so far that $\partial_\theta^{\gamma}=O(1)$. But then $|\frac{d}{dt}\varphi_\gamma|\le C$ and (5.5) is again extended from $x_1=0$ to $x_1>0$.

(e) To prove Statement (iii) we again start from estimates at $x_1=0$. Then, exactly like in (b) we prove see that

$$\varphi_{x_1}\varphi_{x_1x_1\theta_j}+\varphi_{x_1\theta_j}\varphi_{x_1x_1}=O(1)$$

and since $\varphi_{x_1\theta_j}=-\varphi^0_{x_1\theta_j}=O(\sigma)$ as $j\ge 2$, and we know that $\varphi_{x_1x_1}=O(\sigma^{-1})$, we conclude that $\varphi_{x_1x_1\theta_j}=O(\sigma^{-1})$. Again, like in (b), using double induction by $|\alpha|+|\beta|+|\gamma|$ and α_1 we prove (5.6) as $x_1=0$.

Finally, like in (c) and (d) we expand this estimate to $x_1>0$. We leave easy details to the reader. □

Proposition 5.4. *Let $\varphi^0(x,y,\theta)$ and $\varphi(x,y,\theta)$ be defined in Proposition 5.3(i) and (ii) respectively. Consider asymptotic solution*

$$u_h^0(x,y,t)\sim(2\pi h)^{-d}\int e^{i\Phi^0(x,y,t,\theta)}\sum_{n\ge0}B_n^0(x,y,t,\theta)h^n\,d\theta \tag{5.16}$$

where $\Phi^0(x,y,t,\theta)=\varphi^0(x,y,\theta)+ta(y,\theta)$ and

$$\Phi(x,y,t,\theta)=\varphi(x,y,\theta)+ta(y,\theta), \tag{5.17}$$

and B_n^0 are uniformly smooth and satisfying corresponding transport equations with initial conditions such that $u_h^0(x,y,0)=\delta(x-y)$:

$$|\partial_{x,t}^{\alpha}\partial_y^{\beta}\partial_\theta^{\gamma}B_n^0(x,y,t,\theta)|\le C_{\alpha\beta\gamma}\quad\forall x,y,t\colon|x-y|+|t|\le T\ \forall\alpha,\beta,\gamma. \tag{5.18}$$

Consider formal asymptotic solution

$$U_h^1(x,y,t) = (2\pi h)^{-d} \int e^{i\varphi(x,y,t,\theta)} \sum_{n\ge 0} B_n(x,y,t,\theta) h^n \, d\theta \tag{5.19}$$

where B_n satisfy corresponding transport equations and one of the boundary conditions

$$B_n = -B_n^0 \qquad \text{as} \quad x_1 = 0, \tag{5.20}$$

$$\varphi_{x_1} B_n - i\partial_{x_1} B_{n-1} = \varphi_{x_1} B_n^0 + i\partial_{x_1} B_{n-1}^0 = 0 \qquad \text{as} \quad x_1 = 0, \tag{5.21}$$

corresponding to $u_h^1 = -u_h^0$ as $x_1 = 0$ and $\partial_{x_1} u_h^1 = -\partial_{x_1} u_h^0$ as $x_1 = 0$ respectively. Then the following inequalities hold:

$$|\partial_{x,t}^\alpha \partial_y^\beta \partial_\theta^\gamma B_n| \le C_{n\alpha\beta\gamma} \begin{cases} 1 + T\sigma^{-1-|\alpha|-|\beta|-|\gamma|} & \alpha_1 = n = 0, \\ \sigma^{-3n-\alpha_1-|\alpha|-|\beta|-|\gamma|} & \alpha_1 + n \ge 1, \end{cases} \tag{5.22}$$

and if $|\gamma| \ge 1$

$$|\partial_{x,t}^\alpha \partial_y^\beta \partial_\theta^\gamma B_n| \le C_{n\alpha\beta\gamma} \begin{cases} 1 + T\sigma^{-|\alpha|-|\beta|-|\gamma|} & \alpha_1 = n = 0, \\ \sigma^{1-3n-\alpha_1-|\alpha|-|\beta|-|\gamma|} & \alpha_1 + n \ge 1. \end{cases} \tag{5.23}$$

Proof. (a) Observe that the transport equation is

$$\Big(\frac{d}{dt} + f\Big) B_n = \mathcal{L} B_{n-1}, \tag{5.24}$$

where f is a linear combination with the smooth coefficients of second derivatives of Φ, $\mathcal{L} = \mathcal{L}(x, D_x)$ is a second order differential operator with the smooth coefficients, and with the coefficient 1 at $D_{x_1}^2$, and $B_{-1} = 0$. In virtue of (5.5)

$$|D_{x,t}^\alpha D_y^\beta D_\theta^\gamma f| \le \sigma^{-1-\alpha_1-|\alpha|-|\beta|-|\gamma|}. \tag{5.25}$$

Consider first $n = 0$. Then equation (5.24) has a right-hand expression 0 and boundary condition (5.21) becomes $B_0 = \mp B_0^0$ as $x_1 = 0$. Let us establish first (5.22) as $x_1 = 0$. As $\alpha_1 = 0$ these estimates follow from the above boundary condition and (5.18). Consider transport equation (5.24):

$$\varphi_{x_1} B_{0,x_1} + \sum_{k\ge 2} b^{(k)}(x, \nabla_{x'}\varphi) B_{0,x_k} - \frac{1}{2} B_{0,t} + \frac{1}{2} f B_0 = 0 \tag{5.26}$$

and set $x_1 = 0$. Then all terms in (5.26) are smooth, except the first and the last one, and the latter satisfies

$$|\partial_{x,t}^{\alpha-\varepsilon}\partial_y^\beta\partial_\theta^\gamma(f\,B_0)| \le C\sigma^{-|\alpha|-|\beta|-|\gamma|} \qquad \alpha_1 = 1$$

due to (5.21) and smoothness of B_0 at $x_1 = 0$. Sinnce $\partial_{x,t}^{\alpha}\partial_y^\beta\partial_\theta^\gamma\varphi$ is obtained by division by φ_{x_1} we arrive to (5.22) as $n = 0$, $\alpha_1 = 0$.

Next we apply a double induction by α_1 and $|\alpha| + |\beta| + |\gamma|$ exactly as in the proof of Proposition 5.3, Part (b) with the following modifications:

(A) We use transport equation (5.24) rather than eikonal equation.

(B) We observe that $\partial_{x,t}^{\alpha-\varepsilon}\partial_y^\beta\partial_\theta^\gamma$, applied to the first term in (5.26) equals to $\varphi_{x_1}\varphi_{\alpha\beta\gamma}$ plus a linear combination of

$$\prod_{1\le j\le m} \varphi_{\alpha^j\beta^j\gamma^j}\partial_{x,t}^{\alpha^0}\partial_y^{\beta^0}\partial_\theta^{\gamma^0}B_0 \tag{5.27}$$

with $m = 1$ and $\sum_j \alpha^j = \alpha + \varepsilon$, $\sum_j \beta^j = \beta$, $\sum_j \gamma^j = \gamma$ [9] and $|\alpha^0| + |\beta^0| + |\gamma^0| < |\alpha| + |\beta| + |\gamma|$.

(C) We observe that $\partial_{x,t}^{\alpha-\varepsilon}\partial_y^\beta\partial_\theta^\gamma$, applied to the second term in (5.26) also is a linear combination with bounded coefficients of (5.27) with $\sum_j \beta^j = \beta$, $\sum_j \gamma^j = \gamma$, $\sum_j |\alpha^j| \le |\alpha| + m$, $\sum_j \alpha_1^j < \alpha_1$ [9] and $|\alpha^j| + |\beta^j| + |\gamma^j| \ge 2$ for $j \ge 1$; it is possible that $m = 0$ here.

We leave simple but tedious arguments to the reader.

(b) Then we extend these estimates to $x_1 > 0$, $T \le \sigma$. We apply arguments of Parts (c), (d) of the proof of Proposition 5.3. First, transport equation (5.24) and boundary condition $B_0 = B_0^0$ as $x_1 = 0$ imply that $|B_0| \le C$ for $T \le C_0^{-1}\sigma$.

Then applying $\partial_{x,t}^{\alpha}\partial_y^\beta\partial_\theta^\gamma$ with $|\alpha| + |\beta| + |\gamma| = 1$ to transport equation (5.24) we get

$$|\frac{d}{dt}B_{0,\alpha\beta\gamma}| \le C\sigma^{-1}S^{\frac12} + C\sigma^{-3}, \qquad S := \Big(\sum_{\alpha,\beta,\gamma}|B_{0,\alpha\beta\gamma}|^2\Big)^{\frac12} \tag{5.28}$$

[9] With summation over $0 \le j \le m$

due to estimates $|\partial^2_{x,y,\theta}\varphi| \le C\sigma^{-1}$ and $|\partial_{x,t,y,\theta}f| \le C\sigma^{-3}$ ($B_{n,\alpha\beta} := \partial^\alpha_{x,t}\partial^\beta_y\partial^\gamma_\theta B_n$) and then for $T \le C_0^{-1}\sigma$ we get from this estimate and estimate $|B_{0,\alpha\beta\gamma}| \le C\sigma^{-2}$ at $x_1 = 0$ to estimate $|B_{0,\alpha\beta\gamma}| \le C\sigma^{-2}$. So far the only restriction is $|\alpha| + |\beta| + |\gamma| = 1$–here and in summation in the definition of S.

However, if we add an extra restriction $\alpha_1 = 0$, then due to this estimate (without restriction) and estimates $|\partial^2_{x,y,\theta}\varphi| \le C$ and $|\partial_{x,y,t,\theta}f| \le C\sigma^{-2}$ if there is only one derivative with respect to x_1, we arrive to

$$|\frac{d}{dt}B_{0,\alpha\beta\gamma}| \le C\sigma^{-1}S^{\frac12} + C\sigma^{-2}$$

where S is defined by (5.28) with summation under the same restriction. Then due to this estimate and estimate $|B_{0,\alpha\beta\gamma}| \le C$ as $x_1 = 0$ and $\alpha_1 = 0$ we arrive to the estimate $|B_{0,\alpha\beta\gamma}| \le C + CT\sigma^{-2}$.

We apply induction by $q := |\alpha| + |\beta| + |\gamma|$. Assuming that for lesser values it is proven, we due to this induction assumption and estimates (5.5) and (5.25) arrive to

$$|\frac{d}{dt}B_{0,\alpha\beta\gamma}| \le C\sigma^{-1}S^{\frac12} + C\sigma^{p-1-2|\alpha|+|\beta|+|\gamma|}, \quad S := \Big(\sum_{\alpha,\beta,\gamma} |B_{0,\alpha\beta\gamma}|^2\Big)^{\frac12} \tag{5.29}$$

under restrictions

$$|\alpha| + |\beta| + |\gamma| = q, \quad \alpha_1 \le |\alpha| - p \tag{5.30}$$

with $p = 0$ and then we recover estimate

$$|B_{0,\alpha\beta\gamma}| \le C\sigma^{p-2|\alpha|-|\beta|-|\gamma|} \tag{5.31}$$

under these restrictions. Based on it we arrive to (5.29) then to (5.31) now under restriction (5.30) with $p = 1$; again due to (5.31) at $x_1 = 0$, and so on for $p = 2, ...$ until we reach $p = |\alpha|$ but in the latter case we use $|B_{0,\alpha\beta\gamma}| \le C_{\alpha\beta\gamma}$ at $x_1 = 0$ as $\alpha_1 = 0$ and thus we achieve some improvement over (5.31): namely we get (5.22) as $n = \alpha_1 = 0$. We leave easy but tedious details to the reader.

(c) Next we apply induction by $n \ge 1$ to estimate $B_{n,\alpha\beta\gamma}$ at $x_1 = 0$. However, first we consider $n = 1$ to establish the pattern. Observe first that under condition (5.20) $B_n = -B_n^0$ and therefore

$$|B_{n,\alpha\beta\gamma}| \le C_{\alpha\beta\gamma} \qquad \text{at } \ x_1 = 0 \ \text{ as } \ \alpha_1 = 0, \tag{5.32}$$

but under condition (5.21)

$$B_n = -B_n^0 + i\varphi_{x_1}^{-1}\big(B_{n-1,x_1} + B_{n-1,x_1}^0\big) \qquad \text{at } \ x_1 = 0$$

and therefore estimate (5.22) holds as $n = 1$, $\alpha_1 = 0$, $x_1 = 0$. It follows from estimates for $|\partial_{x_1} B_{0,\alpha\beta\gamma}| \le C_{\alpha\beta\gamma}\sigma^{-2-|\alpha|-|\beta|-|\gamma|}$ as $\alpha_1 = 0$, $x_1 = 0$ (but we divide by φ_{x_1} which brings an extra factor σ^{-1}).

Recall that the transport equation is

$$(\frac{d}{dt} + f)B_n = G_n, \qquad G_n \coloneqq \mathcal{L}B_{n-1}, \tag{5.33}$$

and due to results of Part (b)

$$|G_{n,(\alpha-\varepsilon)\beta\gamma}| \le C\sigma^{1-3n-\alpha_1-|\alpha|-|\beta|-|\gamma|} \tag{5.34}$$

and therefore in both cases estimate (5.22) holds (as $n = 1$, $\alpha_1 = 1$ and $x_1 = 0$).

Applying the same argument as in Part (b) we can extend (5.34) and (5.22) to arbitrary α_1 as $n = 1$, and using induction by n to arbitrary n as well. Again, we leave easy but tedious details to the reader.

(d) Using the same arguments as in Part (e) of the proof of Proposition 5.3, we can improve these estimates to (5.23) as $|\gamma| \ge 1$. □

Remark 5.5. Under assumption (5.20) we can further improve estimates (5.22) and (5.23) for $n \ge 1$. However it would not improve our final result.

Remark 5.6. One can wonder how sharp are our estimates.

(i) Due to (5.2) and (5.3) $\varphi_{x_1x_1} \asymp \sigma^{-1}$ as $b_{x_1}(x, \nabla_{x'}\varphi) \asymp 1$. Indeed

$$2\varphi^0_{x_1}\varphi^0_{x_1x_1} + \sum_{k\ge 2} b^{(k)}(x, \nabla_{x'}\varphi^0)\varphi^0_{x_kx_1} - \varphi^0_{x_1t} + b_{x_1}(x, \nabla_{x'}\varphi^0) = 0,$$
$$2\varphi_{x_1}\varphi_{x_1x_1} + \sum_{k\ge 2} b^{(k)}(x, \nabla_{x'}\varphi)\varphi_{x_kx_1} - \varphi_{x_1t} + b_{x_1}(x, \nabla_{x'}\varphi) = 0,$$

and since φ^0 is smooth function, we conclude that

$$\sum_{k\ge 2} b^{(k)}(x, \nabla_{x'}\varphi^0)\varphi^0_{x_kx_1} - \varphi^0_{x_1t} + b_{x_1}(x, \nabla_{x'}\varphi^0) = O(\sigma)$$

and then due to (5.3) that

$$\varphi_{x_1}\varphi_{x_1x_1} + b_{x_1}(x, \nabla_{x'}\varphi) = O(\sigma) \qquad \text{as} \quad x_1 = 0.$$

Therefore estimates (5.5) cannot be improved, at least for derivatives only with respect to x_1.

(ii) Repeating construction of Proposition 5.3, we conclude that under the same assumption $b_{x_1}(x, \nabla_{x'}\varphi) \asymp 1$, $\partial_{x_1}^k \varphi \asymp \sigma^{3-2k}$ for all $k \ge 2$. Then from transport equation (5.24) we we conclude that $B_{0,x_1} \asymp \sigma^{-2}$ and repeating construction of Proposition 5.4 we conclude that $\partial_{x_1}^k B_0 \asymp \sigma^{-2k}$ for all $k \ge 1$ and finally $\partial_{x_1}^k B_n \asymp \sigma^{-3n-2k}$ for all $n \ge 0$, $k \ge 1$.

Proposition 5.7. *(i) In the framework of Proposition 5.3(i) as* $|\alpha| \le 1$

$$|\partial_{x,t}^{\alpha}\partial_{\theta}^{\gamma}\bigl(\Phi^0 - \bar{\Phi}^0\bigr)| \le C_\gamma T^{2-|\alpha|} \quad \text{with} \quad \bar{\Phi}^0 := \langle x-y, \theta\rangle + ta(y,\theta). \tag{5.35}$$

(ii) In the framework of Proposition 5.3(ii) as $|\alpha| \le 1$, $\alpha_1 = 0$

$$|\partial_{x,t}^{\alpha}\partial_{\theta}^{\gamma}\bigl(\Phi \ - \bar{\Phi}\ \bigr)| \le C_\gamma\bigl(\sigma^{1-|\alpha|-|\gamma|}T^2 + T^{2-|\alpha|}\bigr) \quad \text{with} \quad \bar{\Phi} := \langle x-\tilde{y}, \theta\rangle + ta(0,y',\theta), \tag{5.36}$$

where $\tilde{y} = (-y_1, y')$ *as* $y = (y_1, y')$.

Proof. Proof of both statements follows from decomposition of $\partial_{x,t}^{\alpha}\partial_{\theta}^{\gamma}\Phi^0$ into Taylor series with quadratic error. First we prove (i) using estimates (5.2) and then (ii) using estimates (5.5).

For $d = 2$ we will need a better approximation; it will be proven later.□

Then we have immediately

Corollary 5.8. *(i) In the framework of Proposition 5.3(i) for* $Ch \le \ell^0(x,y) + |t| \le \epsilon$

$$a(x, \nabla_x\varphi^0) = \tau, \quad \nabla_\theta\Phi^0(x,y,t,\theta) = 0 \tag{5.37}$$

has no more than a single solution θ *and if it has, then* $|t| \asymp \ell^0$ *and* $\nabla_\theta^2\Phi^0$ *is a positive definite matrix. This solution* $\theta = \bar{\theta} + O(T)$ *where* $\bar{\theta}$ *is a solution to* $t\nabla_\theta a(x,\theta) = y - x$.

(ii) In the framework of Proposition 5.3(ii) for $Ch \le \ell(x,y)+|t| \le \epsilon$

$$a(x,\nabla_x\varphi)=\tau, \quad \nabla_\theta\Phi(x,y,t,\theta)=0 \tag{5.38}$$

has has no more than a single solution θ *and if it has then* $|t| \asymp \ell$ *and* $\nabla^2_\theta\Phi$ *is a positive definite matrix. This solution* $\theta=\bar\theta+O(T)$ *where* $\bar\theta$ *is a solution to* $t\nabla_\theta a(x,\theta)=\tilde y-x$.

Proposition 5.9. *In the framework of Proposition 5.3(ii) under extra assumption*

$$\sigma^2\ell \ge h^{1-\delta} \tag{5.39}$$

the following estimate holds

$$|F_{t\to h^{-1}\tau}\Big(\bar\chi_{T'}(t)u^1_h(x,y,t)-\bar\chi_T(t)U^1_h(x,y,t)\Big)| \le Ch^s \tag{5.40}$$

with $U^1_h(x,y,t)$ *defined by* (5.19) *with* $B_n(x,y,t,\theta)$ *described above and multiplied by* $\phi(\theta)$ *supported in* $2\epsilon_3\rho$*-vicinity and equal* 1 *in* $\epsilon_3\rho$*-vicinity of* θ *described in Corollary 5.8(ii) and with* $Ch \le T \le T' \le \epsilon$, $T=c\ell$, $\rho=\sigma^2$.

Proof. Let us fix $x=\bar x$ and $y=\bar y$ in (5.40) and use x as a variable. Due to Proposition 5.1 there is a single generalized billiard of the length $\le \epsilon$ with reflections at ∂X from $\bar x$ to $\bar y$. It has the length $\asymp \ell$, exactly one reflection and a reflection angle $\asymp \rho=(\nu(\bar x)+\nu(\bar y))\ell^{-1} \gtrsim h^{\frac13-\delta}$.

Further, Proposition 5.4(ii) implies that for $\sigma \ge h^{\frac13-\delta}$ (which is due to (5.39) and $\sigma \ge C_0\ell$) (5.19) is a proper asymptotic series as $|t| \le T$ and we define $U^1_h(x,y,t)$ through it (with cut-off).

Furthermore, Corollary 5.8 implies that then $U^1_h(x,y,t)$ is negligible outside $\Omega_{2T,3\rho,3\sigma}$ (by (x_1,x',ξ')) of this billiard while the standard propagation results imply that $u^1_h(x,y,t)\,{}^tQ_y$ is also negligible outside of this vicinity provided symbol of Q is supported in the similar vicinity of $(\bar y,\bar\theta')$, $\bar\theta'$ corresponds to this billiard. Let symbol of Q be 1 in the similar vicinity of $(\bar y,\bar\xi')$. Then $u^1_h(x,y,t)\,{}^tQ_y \equiv U^1_h(x,y,t)$ for $-T \le t \le T$ with $0<T=C_0\ell$.

On the other hand, in this case $u^1_h(x,y,t)(I-{}^tQ_y)\equiv 0$ in $(\epsilon\rho\ell,\epsilon\ell)$-vicinity of $\bar x$ as $-T \le t \le \epsilon T$. Case of $-\epsilon T \le t \le T$ is considered in the same way, albeit with the billiard from $\bar x$ to $\bar y$. Then we arrive to (5.40) with $T'=T$.

Finally, the standard propagation results imply that

$$|F_{t\to h^{-1}\tau}\Big(\big(\bar\chi_{T'}(t)-\bar\chi_T(t)\big)u^1_h(x,y,t)\Big)| \le Ch^s \tag{5.41}$$

as $T \le T' \le \epsilon$. Then (5.40) expands to T': $T \le T' \le \epsilon$. □

5.2 Spectral asymptotics

Proposition 5.10. *In the framework of Proposition 5.3(ii) under extra assumption*

$$\sigma^2\ell \ge h^{1-\delta}, \qquad \ell \ge h^{\frac{3}{5}} \tag{5.42}$$

the following asymptotics holds

$$e_h^{1,\mathsf{T}}(x,y,\tau) = (2\pi h)^{-d}\int_{a(y,\theta)<\tau} e^{ih^{-1}\varphi(x,y,\theta)}\,d\theta + O(h^{1-d}). \tag{5.43}$$

Proof. Let us plug U_h^1 instead of u_h^1 into Tauberian expression $e_h^{1,\mathsf{T}}(x,y,\tau)$ with $\mathsf{T}=\epsilon$. Let us decompose $B_n(x,y,t,\theta)$ into asymptotic series by t^k.

(a) Then terms with $k=0$ become

$$(2\pi h)^{-d}\int_{a(y,\theta)<\tau}\sum_{n\ge 0} e^{ih^{-1}\varphi(x,y,\theta)}B_n(x,y,0,\theta)h^n\,d\theta \tag{5.44}$$

and we claim that these terms do not exceed $C\sigma^{-3n}h^{-d+n}(h\ell^{-1})^{(d+1)/2}$. Indeed, we know from Proposition 5.3(ii) that φ is uniformly infinitely smooth by θ and from Corollary 5.8 that there are no stationary points by θ and restriction of $\varphi(x,y,\theta)$ to $\Sigma(y,\tau)$ has two non-degenerate critical points. The leading terms would be of this magnitude, while all other terms would have extra factors not exceeding $h/\sigma^2\ell$ due to (5.22).

We want to estimate all extra terms by Ch^{1-d}. One can see easily, that $d=2$ is the worst case but even then therms with $n\ge 1$ are $O(h^{1-d})$ and terms with $h/\sigma^2\ell$ appear when we differentiate $B_0(x,y,0,\theta)$ by θ. Then due to (5.23) these terms do not exceed

$$Ch^{-d}(h\ell^{-1})^{\frac{d+3}{2}}(1+\ell\sigma^{-2})$$

and this does not exceed Ch^{1-d} under assumption (5.32).

Finally, since $B_0(x,y,0,\theta)=1+O(\ell\sigma^{-1})$ we can replace $B_0(x,y,0,\theta)$ by 1 resulting in the main part of asymptotics (5.43).

(b) Consider now terms with $k\ge 1$ in the decomposition of $B_n(x,y,t,\theta)$. We can rewrite these terms as

$$(2\pi h)^{1-d}\partial_\tau^{k-1}\int_{\Sigma(y,\tau)} B'_{n,k}(x,y,\theta)h^{n+k-1}\,d\theta : d_\theta a(y,\theta)$$

and using ξ-microhyperbolicity rewrite it as

$$(2\pi h)^{1-d}\int_{\Sigma(y,\tau)} B''_{n,k}(x,y,\theta)h^n(h\ell^{-1})^k\,d\theta : d_\theta a(y,\theta). \tag{5.45}$$

with $B''_{n,k}$ coming from B_n with k derivatives by t and no more than $(k-1)$ by θ. Then using (5.22)–(5.23) we can estimate these terms by $Ch^{-\frac{d-1}{2}}\ell^{-\frac{d-1}{2}} \le Ch^{1-d}$. □

Remark 5.11. The similar asymptotics

$$e_h^{0,\mathsf{T}}(x,y,\tau) = (2\pi h)^{-d}\int_{a(y,\theta)<\tau} e^{ih^{-1}\varphi^0(x,y,\theta)}\,d\theta + O(h^{1-d}) \tag{5.46}$$

is well-known.

Remark 5.12. Consider in the framework of Proposition 5.3(i), (ii) integrals $I_h(\varphi)$ and $I_h(\varphi^0)$ in the right-hand expressions of (5.46) and (5.43) correspondingly:

$$I_h(\varphi) := (2\pi h)^{-d}\int_{a(y,\theta)<\tau} e^{ih^{-1}\varphi(x,y,\theta)}\,d\theta. \tag{5.47}$$

(i) Let $d \ge 3$. Then $I_h(\varphi^0) = I_h(\bar\varphi^0) + O(h^{1-d})$ and $I_h(\varphi) = I_h(\bar\varphi) + O(h^{1-d})$ with $\bar\varphi^0(x,y,\theta) = \langle x-y,\theta\rangle$, $\bar\varphi^0(x,y,\theta) = \langle x-\tilde y,\theta\rangle$.

(ii) Let $d = 2$. Then $I_h(\varphi^0) \equiv I_h(\bar\varphi^0)$ with an error $O(h^{-1})$ as $\ell^0 \ge h^{\frac13}$, $O(h^{-1})$ as $\ell^0(x,y) \ge h^{\frac13}$, $O(h^{-\frac12}\ell^{-\frac32})$ as $h^{\frac12} \le \ell^0(x,y) \le h^{\frac13}$ and $O(h^{-\frac32}\ell^{\frac12})$ as $h \le \ell^0(x,y) \le h^{\frac12}$.

Also $I_h(\varphi) \equiv I_h(\bar\varphi)$ with an error $O(h^{-1})$ as $\ell^0 \ge h^{\frac13}$, $O(h^{-1})$ as $\ell^0(x,y) \ge h^{\frac13}$, $O(h^{-\frac12}\ell^{-\frac32})$ as $h^{\frac12} \le \ell(x,y) \le h^{\frac13}$ and $O(h^{-\frac32}\ell^{\frac12})$ as $h \le \ell(x,y) \le h^{\frac12}$.

Proof. Observe first that due to the stationary phase principle $I_h(\varphi) = Ch^{-d}(h\ell^{-1})^{(d+1)/2}$ and the same is true for $I_h(\bar\varphi)$. Therefore for $\ell \ge h^{\frac12}$ we have simply estimates rather than the error estimates.

On the other hand due to proposition 5.7 $\varphi(x,y,\theta) = \langle x-\tilde y,\theta\rangle + O(\ell^2)$, for $\ell \le h^{\frac12}$ the error does not exceed $Ch^{-d}(h\ell^{-1})^{(d+1)/2} \times \ell^2 h^{-1}$ which is $O(h^{1-d})$.

The same is true for $I_h(\varphi^0)$ and $I_h(\bar\varphi^0)$ albeith with ℓ^0 rather than ℓ. □

Now we need to deal with $d = 2$ and $\ell^0 \le h^{\frac{1}{3}}$ or $\ell \le h^{\frac{1}{3}}$.

Proposition 5.13. *Let $d = 2$. Then*

(i) In the framework of Proposition 5.3(i) for $h^{1-\delta} \le \ell^0(x,y) \le h^{\frac{1}{3}}$

$$\int_{a(y,\theta)<\tau} e^{ih^{-1}\varphi^0(x,y,\theta)}\,d\theta = \int_{a(w,\xi)<\tau} e^{ih^{-1}\langle x-y,\xi\rangle}\,d\xi + O(h) \tag{5.48}$$

with $w = \frac{1}{2}(x+y)$.

(ii) In the framework of Proposition 5.3(ii) for $h^{1-\delta} \le \ell(x,y) \le h^{\frac{1}{3}}$

$$\int_{a(y,\theta)<\tau} e^{ih^{-1}\varphi(x,y,\theta)}\,d\theta = \int_{a(w,\xi)<\tau} e^{ih^{-1}(\langle x-\tilde{y},\xi\rangle + \frac{1}{2}\varkappa(w',\xi',\tau)(x_1^2+y_1^2))}\,d\xi + O(h) \tag{5.49}$$

with $w = (0, \frac{1}{2}(x'+y'))$ and with

$$\varkappa(x',\xi',\tau) = (\tau - b(x_2,\xi_2))^{-\frac{1}{2}} a_{x_1}(x,\xi)|_{x_1=\xi_1=0}; \tag{5.50}$$

recall that $b(w_2,\xi_2) = a(x,\xi)|_{x_1=\xi_1=0}$.

Proof. (i) Consider $(z,\bar{\xi})$: $a(\bar{w},\bar{\xi}) = \tau$ and Hamiltonian trajectory $\Psi_t(\bar{w},\bar{\xi})$ of $a(x,\xi)$, $\Psi_0(\bar{w},\bar{\xi}) = (\bar{w},\bar{\xi})$. Then as $(y(t),\theta(t)) = \Psi_t(\bar{w},\bar{\xi})$ and $(x(t),.) = \Psi_{-t}(\bar{w},\bar{\xi})$, $|t| \le C_0\ell$ we have

$$\varphi^0(x(t),y(t),\theta(t)) = \langle x(t)-y(t),\bar{\xi}\rangle + O(\ell^3) \tag{5.51}$$

where in this part of the proof for simplicity we write ℓ rather than ℓ^0.

Observe that as $\ell \ge h^{1-\delta}$ we can reduce integrals in (5.48) to $\Sigma(y,\tau)$ and $\Sigma(\bar{w},\tau)$ respectively, gaining factor $h\ell^{-1}$. Consider first those reduced integrals over ϵ-vicinities of $\theta(t)$ and $\bar{\xi}$. We see that there is a diffeomorphism of these vicinities and

$$\varphi^0(x(t),y(t),\theta(\bar{w},\xi(s),t)) = \langle x(t)-y(t),\xi\rangle + O(\ell^3 + s^2\ell)$$

provided $a_\theta \parallel \theta$ at $(\bar{w},\bar{\xi})$ (we can assume it without any loss of the generality), s is an angle parameter on $\Sigma(\bar{w},\tau)$, $\xi(0) = \bar{\xi}$. Making change of variables

we estimate an error by $C(h\ell^{-1})^{\frac{3}{2}} \times (\ell^3 h^{-1} + \varepsilon^2 \ell h^{-1} + \ell)$ when we integrate over $|s| \le \varepsilon$, and when we integrate over $|s| \ge \varepsilon$, we can multiply it by an arbitrary large power of $h/\varepsilon^2\ell$. Taking $\varepsilon = (h\ell^{-1})^{\frac{1}{2}}$ we make both errors $O(h)$.

On the other hand, fix $\bar{x}$ and $\bar{y}$ and find corresponding $\bar{w}$, $\bar{\xi}$ and t. One can see easily that $\bar{w} = w + O(\ell^2)$ and the error in the integral in the right hand expression of (5.48) when we redefine w does not exceed $C(h\ell)^{\frac{1}{2}}\ell^2 = O(h)$.

(ii) Making change of variables $\mathsf{x}_1 = x_1 + \frac{1}{2}\varkappa(w_2, \xi', \tau)x_1^2$ and therefore $\mathsf{y}_1 = y_1 + \frac{1}{2}\varkappa(w_2, \xi', \tau)y_1^2$ we would arrive to operator with the symbol which, after division by $(a - \tau)$, modulo $O(\ell^2)$ does not depend on x_1 and therefore with the corresponding phase function

$$\varphi = (\mathsf{x}_1 + \mathsf{y}_1)\xi_1 + (x_2 - y_2)\xi_2 + O(\ell^3).$$

Then we can use the the method of reflection and after this, Statement (i). So we get

$$\int_{a(w,\xi)<\tau} e^{ih^{-1}((\mathsf{x}_1+\mathsf{y}_1)\xi_1+(x_2-y_2)\xi_2}\, d\xi + O(h) \tag{5.52}$$

with $w = (0, \frac{1}{2}(x_2 + y_2))$; which is exactly the right-hand expression of (5.49). □

Remark 5.14. (i) Therefore in Theorem 1.2

$$\begin{aligned} &e_{h,\mathsf{corr}}(x, y, \tau) \\ &\quad = [\mp](2\pi h)^{-1} \int_{\{a(\frac{1}{2}(x+y),\xi)<\tau\}} e^{ih^{-1}\langle x-\tilde{y},\xi\rangle} \left(e^{ih^{-1}\frac{1}{2}\varkappa(\frac{1}{2}(x_2+y_2),\xi_2,\tau)} - 1\right) d\xi \end{aligned} \tag{5.53}$$

with $\varkappa(x_2, \xi_2, \tau)$ defined by (5.50).

(ii) One can see easily that in the framework of Proposition 4.5 expressions (5.53) and (4.49) coincide modulo $O(h^{-1})$.

6 Synthesis and final remarks

Proof of Theorems 1.1 and 1.2. We know that for $\ell(x,y) \le \epsilon$ in the frameworks of Theorems 1.1 and1.2 estimate (1.8) holds.

$$e_h(x,y,\tau) = e^{\mathsf{T}}_{T,h}(x,y,\tau) + O(h^{1-d}).$$

(i) We also know from Section 2 that in the framework of Theorem 1.1 $e^{\mathsf{T}}_{T,h}(x,y,\tau)$ can be defined as an oscillatory integral and Proposition 5.13(i) implies that modulo $O(h^{1-d})$ this oscillatory integral can be rewritten as $e^{\mathsf{W}}_h(x,y,\tau)$ defined by (1.3). This proves Theorem 1.1.

(ii) In the framework of Theorem 1.2 we established in Section 3

$$e^{1,\mathsf{T}}_{T,h}(x,y,\tau) = O(h^{1-d})$$

as $d \ge 3$ and $\ell(x,y) \ge h^{\frac12-\delta}$ and as $d=2$ and $\ell(x,y) \ge h^{\frac13-\delta}$. Further, we proved there that $e^{1,\mathsf{T}}_{T,h}(x,y,\tau) = O(h^{1-d-\delta})$ as $d=2$ and $\ell(x,y) \ge h^{\frac13+\delta}$. In both cases we also assume there that $|x'-y'| \ge \epsilon\ell(x,y)$. However it follows from Section 5 that this latter condition is not necessary. Combined with Remark 1.3(ii) it proves Theorem 1.2 in this case.

Let $d \ge 3$. In Section 4 we proved asymptotics

$$e^{1,\mathsf{T}}_{T,h}(x,y) = [\mp] e^{0,\mathsf{W}}_h(x,\tilde{y},\tau) + O(h^{1-d}) \tag{6.1}$$

if either $\ell(x,y) \le h^{\frac12+\delta}$ or $h^{\frac12+\delta} \le \ell(x,y) \le h^{\frac12-\delta}$ and

$$\nu(x)+\nu(y) \le \sigma\ell(x,y) \tag{6.2}$$

with $\sigma = h^{2\delta}$. In Section 5 we proved the same asymptotics as

$$\nu(x)+\nu(y) \ge \sigma\ell(x,y) \tag{6.3}$$

with $\sigma = h^{\frac12-\delta}\ell^{-\frac12} + C_0\ell$. These domains overlap and cover all values of $\ell \le h^{\frac12-\delta}$ and σ.

(iii) Let $d=2$. Then instead of asymptotics (6.1) we have

$$e^{1,\mathsf{T}}_{T,h}(x,y) = [\mp] e^{0,\mathsf{W}}_h(x,\tilde{y},\tau) + e_{h,\mathsf{corr}}(x,y,\tau) + O(h^{1-d}) \tag{6.4}$$

and Sections 4 and 5 cover cases (6.2) with $\sigma = h^{1+\delta}\ell^{-2}$ and (6.3) with $\sigma = h^{\frac13-\delta}$, $\ell(x,y) \le h^{\frac13+\delta}$. These domains overlap and cover all values $\ell \le h^{\frac13+\delta}$ and σ. Here we are left with domain $h^{\frac13+\delta} \le \ell \le h^{\frac13-\delta}$, $\sigma = h^{\frac13-\delta}$ where we have less precise estimate $e^{1,\mathsf{T}}_{T,h}(x,y,\tau) = O(h^{1-d-\delta})$. □

Remark 6.1. (i) We would like to derive remainder estimate $O(h^{-1})$ as $d = 2$ and $\ell(x,y) \le \epsilon$, thus removing the gap $h^{\frac{1}{3}+\delta} \le \ell \le h^{\frac{1}{3}-\delta}$, $\nu(x)+\nu(y) \le h^{\frac{1}{3}-\delta}$.

(ii) For Schrödinger operator (1.4) can get rid of ξ-microhyperbolicity assumption by rescaling method using scaling function

$$\gamma_x = (\epsilon |V(x) - \tau| + h^{\frac{2}{3}}). \tag{6.5}$$

Then using arguments of Proposition 3.2 and Remark 4.1 of [Ivr3] we have a remainder estimate $O(h^{1-d}\gamma_x^{(d-3)/2}\gamma_y^{(d-3)/2})$ which as $d \ge 3$ is $O(h^{1-d})$; however as $d = 2$ it is as bad as $O(h^{-\frac{4}{3}})$.

(iii) As $d = 2$ away from ∂X remainder estimate $O(h^{-1})$ in the regular zone and $O(h^{-\frac{16}{15}})$ or better in the singular zone has been derived in [Ivr3]. However it required the analysis of the Hamiltonian trajectories and introduction of the correction term. This does not look feasible near the boundary especially because both the boundary and degeneration define correction term.

Pointwise Spectral Asymptotics out of the Diagonal near Degeneration*,†

Victor Ivrii‡

Abstract

We establish uniform (with respect to x, y) semiclassical asymptotics and estimates for the Schwartz kernel $e_h(x,y;\tau)$ of spectral projector for a second order elliptic operator inside domain under microhyperbolicity (but not ξ-microhyperbolicity) assumption. While such asymptotics for its restriction to the diagonal $e_h(x,x,\tau)$ and, especially, for its trace $\mathsf{N}_h(\tau)=\int e_h(x,x,\tau)\,dx$ are well-known, the out-of-diagonal asymptotics are much less explored, especially uniform ones.

Our main tools: microlocal methods, improved successive approximations and geometric optics methods.

1 Introduction

In this paper we consider a self-adjoint scalar operator which is elliptic second order differential operator with $\mathscr{C}^K$-coefficients ($K=K(d,\delta)$)

$$A=\sum_{j,k}\bigl(hD_j-V_j(x)\bigr)g^{jk}(x)\bigl(hD_k-V_k(x)\bigr)+V(x),\qquad g^{jk}=g^{kj}, \tag{1.1}$$

and under microhyperbolicity condition

$$|V(x)-\tau|+|\nabla V(x)|\ge\epsilon_0\qquad \forall x\in B(0,1)\subset\mathbb{R}^d,\ d\ge 2, \tag{1.2}$$

*2010 Mathematics Subject Classification: 35P20.

†Key words and phrases: Microlocal Analysis, sharp spectral asymptotics

‡This research was supported in part by National Science and Engineering Research Council (Canada) Discovery Grant RGPIN 13827

we establish sharp (with $O(h^{1-d})$ remainder) asymptotics of the Schwartz kernel of the spectral projector $e_h(x,y,\tau)$ as $h \to +0$.

Under ξ-microhyperbolicity assumption

$$|V(x)-\tau| \ge \epsilon_0 \qquad \forall x \in B(0,1) \subset \mathbb{R}^d \tag{1.3}$$

such asymptotics of $e_h(x,x,\tau)$ is well-known for much more general operators including matrix ones (with a proper definition of ξ-microhyperbolicity). However out-of-diagonal asymptotics, especially uniform with respect to x,y, are much less explored and for simple main part and sharp remainder estimate in addition to ξ-microhyperbolicity

$$|a(x,\xi)-\tau| + |\nabla_\xi a(x,\xi)| \ge \epsilon_0 \tag{1.4}$$

where $a(x,\xi)$ is the principal symbol one needs a strong convexity of the energy surface $\{\xi\colon a(x,\xi)=\tau\}$; see [Ivr3], Theorem 1.1.

On the other hand, under only microhyperbolicity condition

$$|a(x,\xi)-\tau| + \nabla_{x,\xi} a(x,\xi)| \ge \epsilon_0 \tag{1.5}$$

(which could be generalized for matrix operators) sharp asymptotics of

$$\mathsf{N}_h(\tau) = \int e_h(x,x,\tau)\,dx \tag{1.6}$$

are well-known (see [Ivr2], Chapter 4) [1]. However in this case even uniform asymptotics of $e_h(x,x,\tau)$ are much less explored and only for operator (1.1) (see Subsection 5.3.1, Subsubsection "Asymptotics without Spatial Mollification") because while microhyperbolicity conditions does not allow *short periodic trajectories*, it allows *short loops*[2].

Theorem 1.1. *Consider elliptic self-adjoint operator* (1.1) *with smooth coefficients. Assume that microhyperbolicity condition* (1.2) *is fulfilled. Then asymptotics*

$$e_h(x,y,\tau) = e_h^{\mathsf{W}}(x,y,\tau) + \begin{cases} O(h^{1-d}) & d \ge 3,\\ O(h^{-\frac{4}{3}}) & d=2 \end{cases} \tag{1.7}$$

[1] And even near the boundary (see [Ivr2], Chapter 7).

[2] But ξ-microhyperbolicity does not allow short loops.

holds for all $x, y \in B(0,\epsilon)$ *with*

$$e_h^{\mathsf{W}}(x,y;\tau) = (2\pi h)^{-d} \int_{\{a(\frac{1}{2}(x+y),\xi)<\tau\}} e^{ih^{-1}\langle x-y,\xi\rangle}\, d\xi, \tag{1.8}$$

$$a(x,\xi) = \sum_{j,k} g^{jk}(x)\xi_j\xi_k + V(x). \tag{1.9}$$

Theorem 1.2. *Consider elliptic self-adjoint operator* (1.1) *with smooth coefficients. Assume that microhyperbolicity condition* (1.2) *is fulfilled. Let* $d = 2$ *and* $x, y \in B(0, \frac{1}{2})$. *Then*

(i) Asymptotics

$$e_h(x,y,\tau) = e_h^{\mathsf{W}}(x,y,\tau) + O(h^{-1}) \tag{1.10}$$

holds if <u>*either*</u> *condition* (1.3) *is fulfilled,* <u>*or*</u> $\ell(x,y) \ge h^{\frac{1}{3}}$, <u>*or*</u> $\ell(x,y) \ge h^{\frac{2}{5}}$ *and*

$$\bigl|4V(x-\tau)V(y-\tau) - |x-y|^2_{(g_{jk})}|\nabla V|^2_{(g^{jk})} + \langle x-y, \nabla V\rangle^2\bigr| \ge \epsilon\ell(x,y)^2 \tag{1.11}$$

where

$$\ell(x,y) = \max(|x-y|,\, |V(x)-\tau|,\, |V(y)-\tau|,\, h^{\frac{2}{3}}), \tag{1.12}$$

$(g_{jk}) = (g_{jk})^{-1}$ *and* ∇V *is calculated at* $\frac{1}{2}(x+y)$.

(ii) Without condition (1.11) *for* $h^{\frac{1}{3}} \ge \ell(x,y) \ge h^{\frac{2}{5}}$ *the following estimate holds:*

$$e_h(x,y,\tau) = O(h^{-\frac{2}{3}}\ell(x,y)^{-1}). \tag{1.13}$$

(iii) Further, for $\ell(x,y) \le h^{\frac{2}{5}}$ *asymptotics*

$$e_h(x,y,\tau) = e_h^{\mathsf{W}}(x,y,\tau) + e_{\mathsf{corr},k,h}(x,y,\tau) + O(h^{-1}) \tag{1.14}$$

holds with correction term $e_{\mathsf{corr},k,h}(x,y,\tau)$ *to be defined by* (2.46) *later if* <u>*either*</u> *condition* (1.11) *is fulfilled* <u>*or*</u> $\ell(x,y) \le h^{\frac{4}{9}}$.

(iv) Without condition (1.11) *for* $h^{\frac{2}{5}} \ge \ell(x,y) \ge h^{\frac{4}{9}}$ *the following estimate holds:*

$$e_h(x,y,\tau) = e_{\mathsf{corr},k,h}(x,y,\tau) + O(h^{-\frac{5}{3}}\ell(x,y)^{\frac{3}{2}}). \tag{1.15}$$

(v) Finally, as $x = y$ *one can replace* k *by* 0 *while preserving remainder estimate and define* $e_{\mathsf{corr},0,h}(x,y,\tau)$ *as*

$$2h^{-\frac{8}{3}} \int_{-\infty}^{\tau} (\tau - \tau')\, \mathsf{Ai}(-2h^{-\frac{2}{3}}(\tau' - V(x))\, d\tau' - \frac{1}{2\pi h^2}(\tau - V(x))_+ \tag{1.16}$$

provided $|\nabla V|_{g^{jk}} = 1$ *where* $\mathsf{Ai}(\cdot)$ *denotes Airy function.*

Remark 1.3. As $d = 1, 2$ and $x = y$ asymptotics are already known: see [Ivr2], Subsection 5.3.1, Subsubsection Asymptotics without Spatial Mollification and Short Loops.

Plan of the paper. *General idea.* Our main method is to prove (as $d \ge 2$) *Tauberian asymptotics*

$$e_h(x,y,\tau) = e^{\mathsf{T}}_{T,h}(x,y,\tau) + O(h^{1-d}) \tag{1.17}$$

with the *Tauberian expression*

$$e^{\mathsf{T}}_{T,h}(x,y,\tau) = \frac{1}{h}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau}\Big(\bar\chi_T(t) u_h(x,y,t)\Big)\, d\tau \tag{1.18}$$

where $u_h(x,y,t)$ is the *propagator* (the Schwartz kernel of $e^{ih^{-1}tA_h}$), and $\bar\chi_T(t) = \bar\chi(T^{-1}t)$ is the appropriate cut-off. Then from Tauberian expression we pass to Weyl expression and a correction term if needed. So far our arguments are similar to those of [Ivr3] where we considered points near boundary but assumed ξ-microhyperbolicity.

To prove Tauberian asymptotics we need to prove that Fourier transform in (1.18) with $T \asymp 1$ is $O(h^{1-d})$.

Section 2. We start from the toy-model (2.1), study Hamiltonian trajectories and then do all calculations explicitly. We arrive to the oscillatory integral with the phase function which has four stationary points, corresponding to two trajectories from x to y and two trajectories from y to x on the energy level τ, provided we are in the *regular zone* where the

left-hand expression in (1.11) without absolute value is positive: two are short trajectories and two are long ones. If the same expression is negative (*shadow zone*) there are neither any trajectories nor stationary points, and if (1.11) fails (*singular zone*) these points almost coincide.

Then we repeat these steps for the generalized toy-model (2.31).

Section 3. We follow the same path, but we get semi-explicit expression: using special coordinates and x_1-microhyperbolicity we construct in the standard way $F_{x_1\to h^{-1}\xi_1, y_1\to -h^{-1}\eta_1} u_h(x,y,t)$ as an oscillatory integral and then make inverse Fourier transform. Then we prove (1.17) and either pass from Tauberian expression to Weyl expression (as $\ell(x,y)\ge h^{\frac{2}{5}}$) and estimate the error, or use the perturbation method (as $\ell(x,y)\le h^{\frac{2}{5}}$) and estimate

$$\bigl(e^{\mathsf{T}}_{T,h}(x,y,\tau)-\bar{e}^{\mathsf{T}}_{T,k,h}(x,y,\tau)\bigr)-\bigl(e^{\mathsf{W}}_{h}(x,y,\tau)-\bar{e}^{\mathsf{W}}_{k,h}(x,y,\tau)\bigr)$$

where $\bar{e}^{\mathsf{T}}_{T,k,h}(x,y,\tau)$ and $\bar{e}^{\mathsf{W}}_{k,h}(x,y,\tau)$ correspond to an appropriate generalized toy-model. Then we define correction term as

$$e_{\mathsf{corr},k,h}=\bigl(\bar{e}^{\mathsf{T}}_{T,k,h}(x,y,\tau)-\bar{e}^{\mathsf{W}}_{k,h}(x,y,\tau)\bigr).$$

Section 4. Here we show how simple rescaling arguments allows to get rid off assumption (1.3). We also discuss easier case $d=1$.

2 Toy-model

Let us consider a toy-model operator with $d\ge 2$, $g^{jk}=\delta_{jk}$, $V_j(x)=0$ and $V(x)=-x_1$:

$$\bar{A}_h := \frac{1}{2}h^2D^2-x_1=\frac{1}{2}h^2D_1^2+\frac{1}{2}h^2D'^2-x_1 \tag{2.1}$$

By shift $x_1\mapsto x_1+\tau$ we can reduce $\tau\in\mathbb{R}$ to $\tau=0$. After this by rescaling $x\mapsto h^{\frac{2}{3}}$, $\tau\mapsto h^{\frac{2}{3}}$ we can reduce $h>0$ to $h=1$.

2.1 Hamiltonian trajectories

Proposition 2.1. *Consider toy-model operator* (2.1)*. Then*

(i) Hamiltonian trajectories from $(\bar{x},\bar{\xi})=(\bar{x},\bar{\xi}_1,\bar{\xi}')$, $\bar{x}_1>0$ *on the energy level* 0 *(so,* $\bar{\xi}_1=\mp\sqrt{2\bar{x}_1-|\bar{\xi}'|^2}$*) are*

$$\xi'=\bar{\xi}',\ x_1=\bar{x}_1+\frac{t^2}{2}\mp t\sqrt{2\bar{x}_1-|\bar{\xi}'|^2},\ x'=\bar{x}'+\bar{\xi}'t,\ \xi_1=t\mp\sqrt{2\bar{x}_1-|\bar{\xi}'|^2}.$$

(ii) If $d = 2$ *and* $\pm\bar\xi_1 < 0$ *their projections to* x*-space are parabolas*

$$x_1 = \frac{1}{2\bar\xi_2^2}\Big(x_2 - \bar x_2 \mp \bar\xi_2\sqrt{2\bar x_1 - \bar\xi_2^2}\Big)^2 + \frac{\bar\xi_2^2}{2}$$

which at $t = \pm\frac{2\bar x_1}{\sqrt{2\bar x_1 - \bar\xi_2^2}}$ *are tangent to the parabola* $\Gamma = \{x_1 = \frac{1}{4\bar x_1}|x' - \bar x_2|^2\}$.

(iii) Any point x *above* Γ *(that is with* $x_1 > \frac{1}{4\bar x_1}(x_2 - \bar x_2^2)$*) is covered by two such rays, one of them touches* Γ *between* $\bar x$ *and* x*, and another outside of this segment. Any point* x *below* Γ *(that is with* $x_1 < \frac{1}{4\bar x_1}(x_2 - \bar x_2)^2$*) is not reachable from* $\bar x$ *by rays on the energy level* 0*, and any point on* Γ *is reachable by just one ray (when point above* Γ *tends to* Γ *both rays tend to the same limit).*

(iv) The vertices of these parabolas are on the ellipse $L = \{(2x_1 - \bar x_1)^2 + (x_2 - \bar x_2)^2 = \bar x_1^2\}$*; between* Γ *and* L *along both rays* ξ_1 *have the same sign (opposite to one of* $\bar x_1$*) while inside* L *(brown on Figure 28.3) this is true only for a long ray, while for a short ray sign of* ξ_1 *coincides with the sign of* $\bar\xi_1$.

Proof. Easy proof by direct calculations is left to the reader. □

Remark 2.2. Observe that for a trajectory between points x and y

(i) For a long trajectory $\ell(x,y) \asymp |x'-y'|+\nu(x)+\nu(y)$ with $\nu(x) = |V(x)-\tau|$ and $T(x,y) \asymp \ell^{\frac12}(x,y)$ is a time to reach.

(ii) Either $\ell(x,y) \asymp \ell^0(x,y) := |x-y|$ and $T^0(x,y) \asymp T(x,y)$ where $T^0(x,y)$ is time to reach along short trajectory, or $|\xi_{\mathsf{long}} - \xi_{\mathsf{short}}| \asymp \nu(x)^{\frac12}$ and $|\eta_{\mathsf{long}} - \eta_{\mathsf{short}}| \asymp \nu(y)^{\frac12}$, where ξ_* and η_* correspond to these trajectories at x and y for $|t| \asymp T(x,y)$ or $T^0(x,y)$.

(iii) Further, since $\xi'_{\mathsf{short}}\ell^0 = \xi'_{\mathsf{long}}\ell$, we conclude that

$$\ell^0 < \epsilon\ell \implies |\xi'_{\mathsf{short}}| > \epsilon^{-1}|\xi'_{\mathsf{long}}|. \tag{2.2}$$

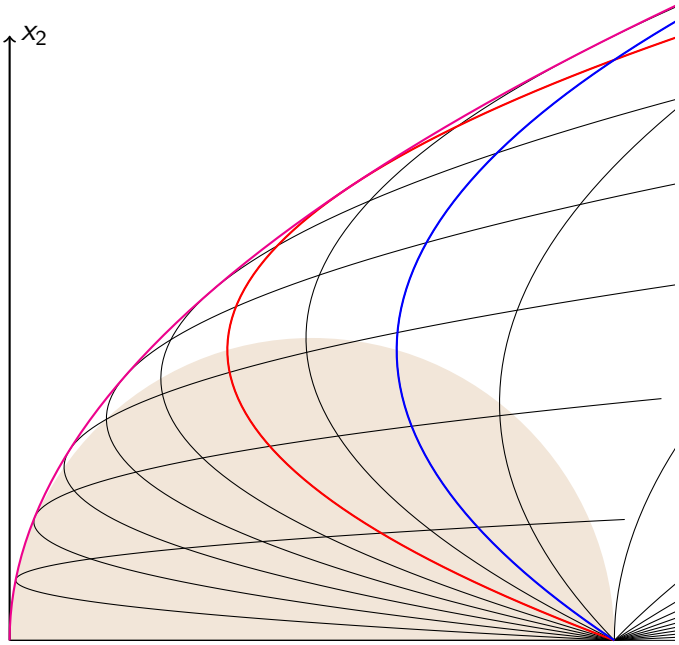

Figure 28.3: $d = 2$. Hamiltonian rays from $\bar{x}$ as $\bar{\xi}_2 > 0$, $t > 0$, scaled.

2.2 Calculations

As usual, consider $u_h^{\pm}(x, y, t) = u_h(x, y, t)\theta(\pm t)$ with Heaviside function θ; then

$$\Big(hD_t - \frac{1}{2}h^2 D_1^2 - \frac{1}{2}h^2|D'|^2 + x_1\Big)u_h^{\pm} = \mp ih\delta(t)\delta(x-y); \tag{2.3}$$

making h-Fourier transform

$$\widehat{u_h^{\pm}}(\xi, y, \tau) := F_{t\to h^{-1}\tau, x\to h^{-1}\xi} u_h^{\pm} = \iint e^{-ih^{-1}(t\tau+\langle x,\xi\rangle)} u_h^{\pm}(x, y, t)\, dxdt$$

we get as $\mp \operatorname{Im}\tau > 0$

$$\Big(\tau - \frac{1}{2}\xi_1^2 - \frac{1}{2}|\xi'|^2 + ih\partial_{\xi_1}\Big)\widehat{u_h^{\pm}} = \mp ie^{ih^{-1}(-y_1\xi_1 - \langle y',\xi'\rangle)}; \tag{2.4}$$

rewriting it as

$$\partial_{\xi_1}\Big(e^{-ih^{-1}((\tau-|\xi'|^2/2)\xi_1 - \xi_1^3/6)}\widehat{u_h^{\pm}}\Big) = \mp e^{ih^{-1}(-y_1\xi_1 - \langle y',\xi'\rangle - (\tau-|\xi'|^2/2)\xi_1 + \xi_1^3/6)},$$

we arrive to

$$\widehat{u_h^{\pm}}(\xi, y, \tau) = \mp e^{ih^{-1}((\tau-|\xi'|^2/2)\xi_1-\xi_1^3/6)} \int_{\mp\infty}^{\xi_1} e^{ih^{-1}(-y_1\eta_1-\langle y',\xi'\rangle-(\tau-|\xi'|^2/2)\eta_1+\eta_1^3/6)}\, d\eta_1 \tag{2.5}$$

and making partial inverse h-Fourier transform

$$F_{t\to h^{-1}\tau} u_h^{\pm} = \mp(2\pi h)^{-d} \iint \Big(\int_{\mp\infty}^{\xi_1} e^{ih^{-1}(x_1\xi_1-y_1\eta_1+\langle x'-y',\xi'\rangle+(\tau-|\xi'|^2/2)(\xi_1-\eta_1)-(\xi_1^3-\eta_1^3)/6))}\, d\eta_1\Big)\, d\xi_1 d\xi'. \tag{2.6}$$

Then as $\tau \in \mathbb{R}$

$$F_{t\to h^{-1}\tau} u_h = (2\pi h)^{-d}\times \iint \Big(\int_{-\infty}^{\infty} e^{ih^{-1}(x_1\xi_1-y_1\eta_1+\langle x'-y',\xi'\rangle+(\tau-|\xi'|^2/2)(\xi_1-\eta_1)-(\xi_1^3-\eta_1^3)/6))}\, d\eta_1\Big)\, d\xi_1 d\xi' = h^{(1-2d)/3} J\big(h^{-\frac{2}{3}}\tau, h^{-\frac{2}{3}}x_1, h^{-\frac{2}{3}}y_1, h^{-\frac{2}{3}}(x'-y')\big), \tag{2.7}$$

with

$$J(\tau, x_1, y_1, z') := (2\pi)^{-d}\times \iiint e^{i(x_1\xi_1-y_1\eta_1+\langle z',\xi'\rangle+(\tau-|\xi'|^2/2)(\xi_1-\eta_1)-(\xi_1^3-\eta_1^3)/6))}\, d\xi_1 d\eta_1 d\xi'. \tag{2.8}$$

We can see easily that the phase function

$$\Phi(x_1, y_1, z'; \xi_1, \eta_1, \xi'; \tau) = x_1\xi_1 - y_1\eta_1 + \langle z', \xi'\rangle + (\tau - \frac{1}{2}|\xi'|^2)(\xi_1-\eta_1) - \frac{1}{6}(\xi_1^3-\eta_1^3) \tag{2.9}$$

has four stationary points (with respect to (ξ_1, η_1, ξ')): on all of them

$$2x_1 = -2\tau + \xi_1^2 + |\xi'|^2, \quad 2y_1 = -2\tau + \eta_1^2 + |\xi'|^2, \quad z' = \xi'(\xi_1-\eta_1), \tag{2.10}$$

and for corresponding trajectories on the energy τ

$$T(x, y) = |\xi_1 - \eta_1| \tag{2.11}$$

but

(a) on two of them $|\xi_1 - \eta_1|$ is the smallest (short rays) and $\ell^0(x,y) \asymp |x_1 - y_1| \asymp |x - y|$ with $x_1 \ge 0$, $y_1 \ge 0$;

(b) on the other two $|\xi_1 - \eta_1|$ are largest (long rays) ξ_1 and η_1 have opposite signs and $\ell(x,y) \asymp x_1 + y_1 \asymp |x - y| + x_1 + y_1$ with $x_1 \ge 0$, $y_1 \ge 0$.

Then we arrive easily to the following proposition:

Proposition 2.3. *For a toy-model operator* (2.1) *with* $d \ge 1$ *the following estimate holds:*

$$|e^{\mathsf{T}}_{\epsilon_1,h}(x,y,\tau) - e^{\mathsf{T}}_{T,h}(x,y,\tau)| \le Ch^{\frac{1-2d}{3}} \tag{2.12}$$

with $T = \max(\epsilon_2\sqrt{\ell(x,y)},\, h^{\frac{1}{3}-\delta})$.

In particular, the right-hand expression is $O(h^{1-d})$ *for* $d \ge 3$, $O(h^{-\frac{4}{3}})$ *for* $d = 2$ *and* $O(h^{-\frac{2}{3}})$ *for* $d = 1$.

It shows that case $d = 2$ requires special consideration. In this case

$$\partial_\tau J(\tau, x_1, y_1, z_2) = \frac{i}{4\pi^2}\iiint (\xi_1 - \eta_1) e^{i(x_1\xi_1 - y_1\eta_1 + z_2\xi_2 + (\tau - \xi_2^2/2)(\xi_1 - \eta_1) - (\xi_1^3 - \eta_1^3)/6)}\, d\xi_1 d\eta_1 d\xi_2$$

which after substitution $\xi_1 = \alpha + \beta$, $\eta_1 = \alpha - \beta$ becomes

$$\frac{i}{\pi^2}\iiint \beta e^{i\beta((x_1+y_1+2\tau) - \xi_2^2 - \alpha^2 - \beta^2/3) + iz_2\xi_2 + i(x_1 - y_1)\alpha}\, d\alpha d\beta d\xi_2$$

and calculating integrals with respect α and ξ_2 we arrive to

$$\partial_\tau J(\tau, x_1, y_1, z_2) = \frac{1}{\pi}\int_{-\infty}^{\infty} e^{i(\beta(x_1+y_1+2\tau) + \frac{1}{4\beta}((x_1-y_1)^2 + z_2^2) - \frac{1}{3}\beta^3)}\, d\beta. \tag{2.13}$$

One can see easily that

(2.14) Stationary points

$$\beta^2 = \frac{1}{2}\Big(x_1 + y_1 + 2\tau) \pm \sqrt{4x_1y_1 - z_2^2}\Big)$$

are non-degenerate as $4(x_1 + \tau)(y_1 + \tau) > z_2^2$ and there are no real stationary points as $4(x_1 + \tau)(y_1 + \tau) < z_2^2$.

Proposition 2.4. *Consider toy-model operator* (2.1) *with* $d = 2$. *Let* $x_1 \ge 0$, $y_1 \ge 0$, $\ell(x,y) \coloneqq \max(|x-y|,\, x_1,\, y_1) \ge C_0 h^{\frac{2}{3}}$.

(i) If $\ell^0(x,y) \coloneqq |x-y| \le \epsilon' \ell(x,y)$ *with* $\epsilon' = \epsilon'(\epsilon) > 0$ *then the following estimate holds:*

$$|e^{\mathsf{T}}_{\epsilon_1,h}(x,y,0) - e^{\mathsf{T}}_{T,h}(x,y,0)| \le Ch^{-\frac{1}{2}} \ell(x,y)^{-\frac{5}{4}} \tag{2.15}$$

with $T = C_0 \sqrt{\ell^0(x,y)}$.

(ii) Further, if $\ell^0(x,y) \ge \epsilon \ell(x,y)$ *then the following estimates holds:*

$$|e^{\mathsf{T}}_{\epsilon_1,h}(x,y,0)| \le Ch^{-\frac{2}{3}} \ell(x,y)^{-1}. \tag{2.16}$$

(iii) More precisely, if $\ell^0(x,y) \ge \epsilon \ell(x,y)$ *and*

$$(x_2-y_2)^2 \le 4x_1y_1 - \epsilon \ell(x,y)^2 \tag{2.17}$$

then

$$|e^{\mathsf{T}}_{\epsilon_1,h}(x,y,0)| \le Ch^{-\frac{1}{2}} \ell(x,y)^{-\frac{5}{4}}. \tag{2.18}$$

(iv) On the other hand, if

$$(x_2-y_2)^2 \ge 4x_1y_1 + \epsilon \ell(x,y)^2 \tag{2.19}$$

then this estimate and all similar estimates below acquire factor $(\ell(x,y)h^{-\frac{2}{3}})^{-s}$*:*

$$|e^{\mathsf{T}}_{\epsilon_1,h}(x,y,0)| \le Ch^{(2s-4)/3} \ell(x,y)^{-s}. \tag{2.20}$$

Proof. Integration by τ and multiplication by h^{-1} results in the formal expression

$$\frac{1}{8\pi^2 h^2 i} \iiint (\xi_1-\eta_1)^{-1} e^{ih^{-1}\Phi(x_1,y_1,z';\xi_1,\eta_1,\xi';0)}\, d\xi_1 d\eta_1 d\xi' \tag{2.21}$$

and we need to apply the stationary phase principle counting only points (in $\mathbb{C}^3$) corresponding to $|\xi_1-\eta_1| \gtrsim \sqrt{\ell}$. Then

(a) Due to above analysis in the *regular zone* described in Statements (i) and (iii) all three eigenvalues of $\mathsf{Hess}_{\xi_1,\eta_1,\xi_2}\Phi$ are real and $\asymp \sqrt{\ell}$ and therefore the left-hand expressions in (2.15) and (2.18) do not exceed $Ch^{-2}\ell^{-\frac{1}{2}}(h\ell^{-\frac{1}{2}})^{\frac{3}{2}}$.

(b) On the other hand, in the *singular zone* where

$$|4x_1y_1 - (x_2 - y_2)^2| \le \epsilon\ell(x,y)^2 \tag{2.22}$$

this is true only for two eigenvalues and therefore the left-hand expression in (2.16) does not exceed $Ch^{-2}\ell^{-\frac12}(h\ell^{-\frac12})^{\frac22} \times h^{\frac13}$.

(c) In the *shadow zone* described in Statement (iv) again all eigenvalues of Hessian are $\asymp \sqrt{\ell}$ but only two are real and the third has imaginary part $\asymp \sqrt{\ell}$ and therefore the left-hand expression in (2.18) does not exceed $Ch^{-2}(h\ell^{-\frac12})^s$. □

Remark 2.5. (i) We can be more precise in the analysis in the singular zone.

(ii) Statements (ii)–(iv) remain true as $|x_1| \le h^{\frac23}$ or $|y_1| \le h^{\frac23}$.

(iii) Further, if either $x_1 < -h^{\frac23}$, or $y_1 < -h^{\frac23}$, or both $x_1 < -h^{\frac23}$ and $y_1 < -h^{\frac23}$ then stationary points move to imaginary axis and estimates in Statements (ii) and (iii) and all similar estimates below acquire correspondingly either factor $h^{\frac{2s}{3}}|x_1|^s$, or $h^{\frac{2s}{3}}|y_1|^s$, or both.

(iv) The right-hand expression of (2.15) is $O(h^{-1})$ as $\ell(x,y) \ge h^{\frac25}$ and the right-hand expression of (2.16) is $O(h^{-1})$ as $\ell(x,y) \ge h^{\frac13}$.

(v) Improvements similar to Proposition 2.4(i)–(iv) are possible for $d \ge 3$ as well.

Now we want to replace $e^{\mathsf{T}}_{T,h}(x,y,0)$ in the left-hand expression of (2.15) by $e^{\mathsf{W}}_h(x,y,0)$ described by (1.8).

Proposition 2.6. *(i) For a toy-model operator* (2.1) *with* $d \ge 3$ *and* $\ell(x,y) \le 1$

$$e^{\mathsf{T}}_{\epsilon_1,h}(x,y,0) = e^{\mathsf{W}}_h(x,y,0) + O(h^{1-d}). \tag{2.23}$$

(ii) For a toy-model operator (2.1) *with* $d = 2$

$$e^{\mathsf{T}}_{\epsilon_1,h}(x,y,0) = e^{\mathsf{W}}_h(x,y,0) + e_{\mathsf{corr},h}(x,y,0) + O(h^{-1}) \tag{2.24}$$

with the correction term

$$e_{\mathsf{corr},h}(x,y,0) = \frac{1}{h^2}\int_{-\infty}^{0} J\big(h^{-\frac{2}{3}}\tau, h^{-\frac{2}{3}}x_1, h^{-\frac{2}{3}}y_1, h^{-\frac{2}{3}}(x_2-y_2)\big)\,d\tau - e_h^{\mathsf{W}}(x,y,0). \tag{2.25}$$

Proof. (a) As $\ell(x,y) \le h^{\frac{2}{3}}$ we have both $e^{\mathsf{T}}_{\epsilon_1,h}(x,y,0) = O(h^{-\frac{2d}{3}})$ and $e_h^{\mathsf{W}}(x,y,0) = O(h^{-\frac{2d}{3}})$. Those are $O(h^{-\frac{4}{3}})$ for $d=2$ and $O(h^{1-d})$ for $d \ge 3$.

(b) As $\ell(x,y) \ge h^{\frac{2}{3}}$ due to rescaling $x \mapsto \ell^{-1}x$, $y \mapsto \ell^{-1}y$, $\tau \mapsto \ell^{-1}\tau$ and $h \mapsto \hbar = \ell^{-\frac{3}{2}}h$ we have

$$e^{\mathsf{T}}_{\epsilon_1,h}(x,y,0) - e_h^{\mathsf{W}}(x,y,0) = O\big(\hbar^{1-d}\times \ell^{-d}\big) = O\big(h^{1-d}\ell^{\frac{d-3}{2}}\big) \tag{2.26}$$

which is $O(h^{-\frac{4}{3}})$ for $d=2$, $O(h^{-2})$ for $d=3$ and $O(h^{1-d})$ for $d \ge 4$, $\ell \le 1$. Statement (i) has been proven.

(c) As $d=2$ for a toy-model operator we can replace with $O(h^s)$ error $e^{\mathsf{T}}_{\epsilon_1,h}(x,y,0)$ by $e^{\mathsf{T}}_{\infty,h}(x,y,0)$ which due to (2.7) is exactly the first term in the right-hand expression in (2.25); so Statement (ii) is just a definition. □

Remark 2.7. (i) Due to (2.13) the first term in the right-hand expression of (2.25) can be rewritten as

$$-\frac{2}{\pi}\int_{-\infty}^{0}\int_{0}^{\infty} \tau\cos\Big(\beta(x_1+y_1+2\tau) + \frac{1}{4\beta}\big((x_1-y_1)^2+z_2^2\big) - \frac{1}{3}\beta^3\Big)\,d\beta d\tau. \tag{2.27}$$

As $x=y$ it becomes

$$-\frac{2}{\pi}\int_{-\infty}^{0}\int_{0}^{\infty} \tau\cos\big(2\beta(x_1+\tau) + \frac{1}{3}\beta^3\big)\,d\beta d\tau = -2\int_{-\infty}^{0}\tau\,\mathsf{Ai}(-2(x_1+\tau))\,d\tau \tag{2.28}$$

with Airy function $\mathsf{Ai}(\cdot)$.

(ii) One can prove easily that

$$e^{\mathsf{W}}(x,y,\tau) = \frac{1}{4\pi^2 r^2}\int_0^{2\pi}\int_0^{h^{-1}r\rho} \cos(\sigma\cos(\theta))\,\sigma\,d\sigma\,d\theta \tag{2.29}$$
$$\text{with}\quad \rho = \sqrt{2(\tau V((x+y)/2))},\quad r=|x-y|$$

and in the framework of Proposition 2.4(ii)

$$|e^{\mathsf{W}}_h(x,y,0)| \le Ch^{-\frac{1}{2}}\ell(x,y)^{-\frac{5}{4}}. \tag{2.30}$$

(iii) In Proposition 3.6 in much more general settings will be proven that in the framework of Proposition 2.4(i) $e^{\mathsf{W}}(x,y,0)$ provides a good approximation for $e^{\mathsf{T}}_{T,h}(x,y,0)$ with $T=\epsilon'\sqrt{\ell(x,y)}$.

2.3 Generalized toy-model

Let us consider now a generalized toy-model operator with $d=2$, $g^{jk}=\delta_{jk}$, $V_2(x)=0$, $V_1=-kx_1$ and $V(x)=-x_1-\frac{1}{2}k^2x_1^2$:

$$\bar{A}_{k,h} := \frac{1}{2}h^2D_1^2+\frac{1}{2}h^2(D_2-kx_1)^2+V(x) \tag{2.31}$$
$$= \frac{1}{2}h^2D_1^2+\frac{1}{2}h^2D_2-(1+khD_2)x_1$$

As in Subsection 2.2 considering equation to propagator and making h-Fourier transform we get equation similar to (2.4):

$$\Bigl(\tau-\frac{1}{2}\xi_1^2-\frac{1}{2}\xi_2^2+ih(1+k\xi_2)\partial_{\xi_1}\Bigr)\widehat{u^{\pm}_h} = \mp ie^{ih^{-1}(-y_1\xi_1-y_2,\xi_2)} \tag{2.32}$$

as $\mp\mathsf{Im}\,\tau>0$; rewriting it as

$$\partial_{\xi_1}\Bigl(e^{-ih^{-1}(1+k\xi_2)^{-1}((\tau-\xi_2^2/2)\xi_1-\xi_1^3/6)}\widehat{u^{\pm}_h}\Bigr) =$$
$$\mp(1+k\xi_2)^{-1}e^{-ih^{-1}(1+k\xi_2)^{-1}((\tau-\xi_2^2/2)\xi_1-\xi_1^3/6)-ih^{-1}(y_1\xi_1+y_2\xi_2)},$$

we arrive to expression similar to (2.5)

$$\widehat{u^{\pm}_h}(\xi,y,\tau) = \mp(1+k\xi_2)^{-1}e^{ih^{-1}((\tau-x_2^2/2)\xi_1-\xi_1^3/6)} \tag{2.33}$$
$$\times\int_{\mp\infty}^{\xi_1} e^{-ih^{-1}(1+k\xi_2)^{-1}((\tau-\xi_2^2/2)\eta_1-\eta_1^3/6)-ih^{-1}(y_1\eta_1+y_2\xi_2)}\,d\eta_1$$

and making partial inverse h-Fourier transform we arrive to the final answer similar to (2.6):

$$(2.34)\quad F_{t\to h^{-1}\tau}u_h^{\pm} = \mp(2\pi h)^{-2}\iint(1+k\xi_2)^{-1}$$
$$\times\int_{\mp\infty}^{\xi_1} e^{ih^{-1}(1+k\xi_2)^{-1}((\tau-\xi_2^2/2)(\xi_1-\eta_1)-(\xi_1^3-\eta_1^3)/6)+ih^{-1}(x_1\xi_1-y_1\eta_1+(x_2-y_2)\xi_2)}\,d\eta_1 d\xi_1 d\xi_2.$$

Then as $\tau\in\mathbb{R}$ we get (cf. (2.7))

$$(2.35)\quad F_{t\to h^{-1}\tau}u_h = (2\pi h)^{-2}\iiint(1+k\xi_2)^{-1}$$
$$e^{ih^{-1}(1+k\xi_2)^{-1}((\tau-\xi_2^2/2)(\xi_1-\eta_1)-(\xi_1^3-\eta_1^3)/6)+ih^{-1}(x_1\xi_1-y_1\eta_1+(x_2-y_2)\xi_2)}\,d\eta_1 d\xi_1 d\xi_2.$$

We can see easily that for $|k|\le C$ and $\min(|x_1|,|y_1|)\le\epsilon$ the phase function

$$(2.36)\quad \Phi_k(x_1,y_1,z_2;\xi_1,\eta_1,\xi_2;\tau)$$
$$= x_1\xi_1 - y_1\eta_1 + z_2\xi_2 + (1+k\xi_2)^{-1}[(\tau-\frac{1}{2}\xi_2^2)(\xi_1-\eta_1)-\frac{1}{6}(\xi_1^3-\eta_1^3)]$$

has four stationary points (with respect to $(\xi_1,\eta_1,\xi_2)\in\mathbb{C}^3$): on all of them $|\xi_2|\le C_0\sqrt{\epsilon}$,

$$(2.37)\qquad 2x_1 = (1+k\xi_2)^{-1}[-2\tau+\xi_1^2+\xi_2^2],$$
$$(2.38)\qquad 2y_1 = (1+k\xi_2)^{-1}[-2\tau+\eta_1^2+\xi_2^2],$$

and

$$(2.39)\quad z_2 = \xi_2(1+k\xi_2)^{-1}(\xi_1-\eta_1)$$
$$+k(1+k\xi_2)^{-2}\big[(\tau-\frac{1}{2}\xi_2^2)(\xi_1-\eta_1)-\frac{1}{6}(\xi_1^3-\eta_1^3)\big]$$

and for corresponding trajectories on the energy level τ

$$(2.40)\qquad T(x,y) = (1+k\xi_2)^{-1}|\xi_1-\eta_1|.$$

Then the same conclusion as for $k=0$ holds:

(a) Proposition 2.3 remains true;

(b) All statements of Proposition 2.4 remain true with regular, singular and shadow zones defined exactly by (2.17), (2.22) and (2.19).

(c) All statements of Remark 2.5 remain true.

Again consider $\partial_\tau J_k(\tau, x_1, y_1, z_2)$ this time based on (2.35):

$$\frac{i}{4\pi^2 i}\iiint (1+\kappa\xi_2)^{-2}(\xi_1-\eta_1) \times e^{i(1+\kappa\xi_2)^{-1}(\tau-\xi_2^2/2)(\xi_1-\eta_1)-(\xi_1^3-\eta_1^3)/6)+ih^{-1}(x_1\xi_1-y_1\eta_1+z_2\xi_2)}\, d\eta_1 d\xi_1 d\xi_2.$$

Plugging $\xi_1 = \alpha+\beta$, $\eta_1 = \alpha-\beta$ and then substituting $\beta := (1+\kappa\xi_2)\beta$ we arrive to

$$\frac{i}{\pi^2}\iiint d\alpha d\beta d\xi_2 \times \tag{2.41}$$
$$\beta \exp\Big[i\Big((2\tau-\xi_2^2-\alpha^2)\beta-\frac{1}{3}(1+\kappa\xi_2)\beta^3+(1+\kappa\xi_2)(x_1+y_1)\beta+z_2\xi_2+(x_1-y_1)\alpha\Big)\Big].$$

Then we can calculate integrals with respect to α and ξ_2, arriving to formula similar to (2.27):

$$-\frac{1}{\pi}\int_{-\infty}^{\infty} d\beta \times \tag{2.42}$$
$$\exp\Big[i\Big((2\tau+x_1+y_1)\beta-\frac{1}{3}\beta^3+\frac{1}{4\beta}(x_1-y_1)^2+\frac{1}{4\beta}\big(z_2-\underbrace{\frac{1}{3}\kappa\beta^3-\kappa(x_1+y_1)\beta}\big)^2\Big)\Big].$$

(a) Consider first $\beta \asymp \sqrt{\ell}$. Observe that selected terms in the phase in (2.43) are $O(\ell^{\frac{3}{2}})$ and squared and divided by β they are $O(\ell^{\frac{5}{2}})$ and therefore assuming that $\ell \le h^{\frac{2}{5}}$ we arrive to the following conclusion: if we neglect their square the error will not exceed

$$\begin{cases} Ch^{-\frac{1}{2}}\ell^{-\frac{5}{4}} \times \ell^{\frac{5}{2}}h^{-1} = O(h^{-1}) & \text{in the regular zone,}\\ Ch^{-\frac{2}{3}}\ell^{-1} \times \ell^{\frac{5}{2}}h^{-1} = O(h^{-\frac{5}{3}}\ell^{\frac{3}{2}}) & \text{in the singular zone,}\\ Ch^{(2s-2)/3}\ell^{-s} & \text{in the shadow zone.}\end{cases} \tag{2.43}$$

(b) On the other hand, consider $\beta \le \epsilon\sqrt{\ell}$ and therefore $\ell^0 := |z_2|+|x_1-y_1| \le \ell$, and then one can estimate the error in the cases $\ell^0\sqrt{\ell} \ge h$ and $\ell^0\sqrt{\ell} \le h$ and in both cases the error will be smaller than given by the first line of (2.43).

But then (2.42) becomes

(2.44)
$$\partial_\tau J_\kappa(\tau,x_1,y_1,z_2) \equiv -\frac{2}{\pi}\int_0^\infty \cos\Big((2\tau+x_1+y_1)\beta-\frac{1}{3}\beta^3+\frac{1}{4\beta}[(x_1-y_1)^2+z_2^2]\Big) \times \exp\Big[i\Big(-\frac{1}{6}\kappa z_2\beta^2-\frac{1}{2}\kappa z_2(x_1+y_1)\Big)\Big]\,d\beta$$

and and scaling back we arrive to

Proposition 2.8. *Consider generalized toy-model operator* (2.31) *in dimension* $d=2$. *Then as* $h^{\frac{2}{3}}\le \ell \le h^{\frac{2}{5}}$ *with an error* (2.42)

$$e^{\mathsf{T}}_{\epsilon_1,h}(x,y,0) \equiv e^{\mathsf{W}}_h(x,y,0)+e_{\mathsf{corr},k,h}(x,y,0) \tag{2.45}$$

with the correction term

(2.46)
$$e_{\mathsf{corr},k,h}(x,y,0) = \frac{1}{h^2}\int_{-\infty}^0 J_{h^{\frac{1}{3}}k}\big(h^{-\frac{2}{3}}\tau, h^{-\frac{2}{3}}x_1, h^{-\frac{2}{3}}y_1, h^{-\frac{2}{3}}(x_2-y_2)\big)\,d\tau - e^{\mathsf{W}}_h(x,y,0)$$

where $\partial_\tau J_\kappa(\tau,x_1,y_1,z_2)$ *defined by* (2.44) *and* $e^{\mathsf{W}}_h(x,y,0)$ *by* (2.29).

Remark 2.9. Obviously $J_\kappa(\tau,x_1,y_1,0)=J_0(\tau,x_1,y_1,0)$.

3 General case

In the framework of Theorems 1.1 and 1.2 without any loss of the generality one can assume that

$(3.1)_{1,2}$ $V(x)=x_1W(x)$, $W(0)=1$,

$(3.2)_{1-3}$ $\bar{x}=(\bar{x}_1,0)$ $\bar{y}=(\bar{y}_1,\bar{y}')$, $\bar{y}_1\le\bar{x}_1$,

$(3.3)_{1-4}$ $g^{j1}=\delta_{j1}$, $g^{jk}(0)=\delta_{jk}$, $V_1=0$, $V_j(0)=0$,

where $\bar{x}$ and $\bar{y}$ are two "target" points. Indeed, we can reach this by a change of variables. We will assume that these assumptions are fulfilled until the end of this section. Then according to (1.12)

$$\ell(x,y)\asymp \max(|x_1|,\,|y_1|,\,|x'-y'|,\,h^{\frac{2}{3}}). \tag{3.4}$$

3.1 Preliminary remarks

Proposition 3.1. *(i) The following estimate holds*

$$|F_{t\to h^{-1}\tau}\Big(\chi_T(t)u_h(x,y,t)\Big)| \le Ch^{1-d}\ell^{(d-2)/3}\hbar^s \tag{3.5}$$

with $|\tau| \le \epsilon T^2$, $T = \max(C_0\ell^{\frac12},\, h^{\frac13})$ *and* $\hbar = T^{-3}h$.

(ii) Furthermore, if $\ell^0 = \ell^0(x,y) := |x-y| \ge \epsilon_0\ell$ *and* $\ell \ge h^{\frac23}$, *then in the same framework*

$$|F_{t\to h^{-1}\tau}\Big(\bar\chi_T(t)u_h(x,y,t)\Big)| \le Ch^{1-d}\ell^{(d-2)/3}\hbar^s. \tag{3.6}$$

Here and below $\ell = \ell(x,y)$, $\chi \in \mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1])$, $\bar\chi \in \mathscr{C}_0^\infty([-1,1])$ *equal* 1 *on* $[-\frac12,\frac12]$, s *is an arbitrarily large exponent and* $\delta > 0$ *is an arbitrarily small exponent.*

Proof. (a) Consider first T which is a small constant: $T = \epsilon_3$ (which we can assume is 1; otherwise we achieve it by scaling) and assume only that $T \ge C_0\sqrt{\ell}$. Then Statement (i) follows from the fact that the propagation speed with respect to ξ_1 is disjoint from 0 plus ellipticity arguments.

Statement (ii) follows from the fact that he propagation speeds with respect to x and ξ are bounded.

(b) Then we scale $x \mapsto T^{-2}x$, $y \mapsto T^{-2}y$, $\ell \mapsto T^{-2}\ell$, $\tau \mapsto T^{-2}\tau$ and $h \mapsto \hbar = T^{-3}h$. □

Proposition 3.2. *The following estimates hold for* $\tau\colon |\tau| \le \epsilon$, $T\colon h^{\frac23} \le T \le \epsilon_1$*:*

$$|F_{t\to h^{-1}\tau}\Big(\bar\chi_T(t)u_h(x,y,t)\Big)| \le Ch^{1-d}, \tag{3.7}$$

$$|e_h(x,y,\tau+h) - e_h(x,y,\tau) \le Ch^{1-d}, \tag{3.8}$$

and for $T \ge T^* := C_0\max(\sqrt{\ell},\, h^{\frac13})$

$$|e_h(x,y,0) - e^{\mathsf{T}}_{T,h}(x,y,0)| \le Ch^{-2d/3}\hbar^s + Ch^{1-d} \tag{3.9}$$

again with $\hbar = T^{-3}h$.

Proof. (a) It is sufficiently to prove for $\tau = 0$ since shift of V by $\tau\colon |\tau| \le \epsilon_2$ preserves conditions[3)]. Simple scaling shows that if $\ell^0(x,y) \le \epsilon\ell(x,y)$ then with $T = T^*$ the left-hand expression of (3.7) with $T = T^*$ does not exceed $Ch^{1-d}T^{*\,2(d-2)/3}$.

On the other hand, considering partition by $T\colon T^* \le T \le \epsilon_1$ we see from Proposition 3.1(i) that the same left-hand expression but with $\bar\chi_T(t)$ replaced by $\bar\chi_T(t) - \bar\chi_{T^*}(t)$ also does not exceed this. So, with indicated T the same left-hand expression does not exceed this, which is $O(h^{1-d})$.

Finally, for $\ell^0(x,y) \ge \epsilon\ell(x,y)$ the same estimate (3.7) holds again due to (3.5).

(b) In particular, taking $x = y$ and $T = \epsilon_1$ and applying standard Tauberian arguments, Part I, we conclude that (3.8) holds with $x = y$. And then it holds for $x \ne y$ due to

$$|e_h(x,y,\tau+h) - e_h(x,y,\tau)| \le |e_h(x,x,\tau+h) - e_h(x,x,\tau)|^{\frac12}|e_h(y,y,\tau+h) - e_h(y,y,\tau)|^{\frac12}.$$

(c) Then (3.9) holds with $T = \epsilon_1$ due to standard Tauberian arguments, Part II. Then due to Proposition 3.1(i)

$$|e^{\mathsf T}_{2T,h}(x,y,0) - e^{\mathsf T}_{T,h}(x,y,0)| \le CT'^{\,d-3}\hbar^s$$

and summation by partition over $[T,\epsilon_1]$ results in the same answer which implies (3.9). □

Therefore

(3.10) To evaluate $e_h(x,y,\tau)$ modulo $O(h^{1-d})$ it is enough to consider only $T \le C_0 \max(\sqrt{\ell(x,y)},\ h^{\frac13-\delta})$.

3.2 Propagator as an oscillatory integral

Proposition 3.3. *Let $x, y \in B(0,\epsilon)$, $C_0\sqrt{\ell} \le T \le C_0\epsilon$) and $|\tau| \le \epsilon$. Then*

$$(3.11)\quad F_{t\to h^{-1}\tau}\Big(\bar\chi_T(t)u_h(x,y,t)\Big) = (2\pi h)^{-d}\iint e^{ih^{-1}\varphi(x,y,\xi_1,\eta_1,\xi',\tau)}b(x,y,\xi_1,\eta_1,\xi',\tau,h)\,d\xi_1 d\eta_1 + O(h^s)$$

[3)] Albeit changes x_1 and $\ell(x,y)$.

where phase function $\varphi(x,y,\xi_1,\eta_1,\xi',\tau)$ *differs from the phase function* $\bar\varphi(x,y,\xi_1,\eta_1,\xi',\tau)$ *in* (2.7) *by* $O(T^4)$ *and amplitude* $b(x,y,\xi_1,\eta_1,\xi',\tau,h)$ *differs from the amplitude* $\bar b_k(x,y,\xi_1,\eta_1,\xi',\tau,h)$ *there by* $O(T)$.

Proof. (a) Let us start from the formal construction. Let us apply h-Fourier transform with respect to x_1, y_1: $\hat u_h(\xi_1,x',\eta_1,y',t) = F_{x_1\to h^{-1}\xi_1,y_1\to -h^{-1}\eta_1}u_h$. Then the problem

$$(hD_t - A(x,hD_x))u_h(x,y,t) = 0, \tag{3.12}$$

$$u_h(x,y,0) = \delta(x-y) \tag{3.13}$$

becomes

$$(hD_t - A(-hD_{\xi_1},x',\xi_1,hD_{x'}))\hat u_h(\xi_1,x',\eta_1,y',t) = 0, \tag{3.14}$$

$$\hat u_h(\xi_1,x',\eta_1,y',t) = 2\pi h\delta(\xi_1-\eta_1)\delta(x'-y')\,. \tag{3.15}$$

This operator is x_1-microhyperbolic where x_1 is a variable dual to ξ_1. Then using the standard arguments[4] we can construct $\hat u_h(\xi_1,x',\eta_1,y',t)$ near energy level 0 for $x,y\in B(0,\epsilon_1)$ as a "simple" oscillatory integral

$$\begin{aligned}&\hat U_h(\xi_1,x',\eta_1,y',t)\\ &\quad = (2\pi h)^{1-d}\int e^{ih^{-1}(\psi(\xi_1,x',\eta_1,y',\theta,t)+a(-\theta_1,y',\theta')t)}b(\xi_1,x',\eta_1,y',\theta,h)\,d\theta,\end{aligned} \tag{3.16}$$

with the phase satisfying

$$a(-\partial_{\xi_1}\psi,x',\partial_{x'}\psi) = a(-\theta_1,y',\theta'), \tag{3.17}$$

$$\psi|_{\xi_1=\eta_1} = \langle x'-y',\theta'\rangle, \tag{3.18}$$

$$\nabla_{\xi_1,x'}\psi|_{\xi_1=\eta_1,x'=y'} = \theta \tag{3.19}$$

and with amplitude $b(\xi_1,x',\eta_1,y',\theta,h)$ decomposing into asymptotic series

$$b(\xi_1,x',\eta_1,y',\theta,h)\sim\sum_{n\ge 0}b_n(\xi_1,x',\eta_1,y',\theta)h^n. \tag{3.20}$$

Then for $|\tau|\le\epsilon$

$$\begin{aligned}&F_{t\to h^{-1}\tau}\hat U_h(x,y,t)\\ &\quad = (2\pi h)^{2-d}\int_{\Sigma(\xi_1,y',\tau)} e^{ih^{-1}(\psi(\xi_1,x',\eta_1,y',\theta,\tau))}b(\xi_1,x',\eta_1,y',\theta,h)\,d\theta : d_\theta a\end{aligned} \tag{3.21}$$

[4] See f.e. [Shu], Theorem 20.1 or [Ivr3], Section 2.

where $\Sigma(\xi_1, y', \tau) = \{\theta\colon a(-\theta_1, y', y', \theta') = \tau\}$. Due to x_1-microhyperbolicity we can express θ_1 as function of $\xi_1, \eta_1, x', y', \tau$ and rewrite the right-hand expression as an integral over $\theta' \in \mathbb{R}^{d-1}$.

Finally, making inverse h-Fourier transform by ξ_1, η_1 and plugging $\theta' = \xi'$ we arrive to (3.11) for u_h with

$$\varphi(x, y, \xi_1, \eta_1, \xi', \tau) = \psi(\xi_1, x', \eta_1, y', \theta_1(\xi_1, x', \eta_1, y', \xi'\tau), \xi', \tau) + x_1\xi_1 - y_1\eta_1.$$

(b) To justify (3.11) for u_h we observe that for given $x, y \in B(0, \epsilon)$ and $T \le C_0\epsilon$ behaviour of$a(x, \xi)$ for $|x| \ge c\epsilon$ does not matter.

(c) Finally, since $\varphi = O(T^3)$ and relative error of A_h in comparison to generalized toy-model operator $\bar{A}_h$ is $O(T)$ we conclude that the relative errors in φ and B_h are also $O(T)$ and therefore absolute errors are $O(T^4)$ and $O(T^2)$ correspondingly. □

Therefore we arrive immediately to the following statements:

Proposition 3.4. *Let operator A_h satisfy* $(3.1)_{1,2}$, $(3.2)_{1-3}$ *and* $(3.3)_{1-4}$. *Then*

(i) In the framework of Proposition 2.3 estimate (2.12) *holds.*

(ii) In the framework of Proposition 2.4(i) estimate (2.15) *holds.*

(iii) In the framework of Proposition 2.4(ii) estimate (2.16) *holds.*

(iv) In the framework of Proposition 2.4(iii) estimate (2.18) *holds.*

(v) In the framework of Proposition 2.4(iv) estimate (2.20) *holds.*

Also observe that all statements of Remark 2.5 remain valid.

Corollary 3.5. *Let $d \ge 3$. Then $e_h(x, y, \tau) = e_h^{\mathsf{W}}(x, y, \tau) + O(h^{1-d})$. Furthermore $e_h(x, y, 0) = O(h^{1-d})$ unless $\nu(x) \asymp \nu(y) \ge h^{\frac{2}{3}}$ and $\ell^0(x, y) \le \epsilon\nu(x)$.*

Proof. If $\ell^0(x, y) \le \epsilon\ell(x, y)$, $\ell(x, y) \ge h^{\frac{2}{3}}$ we prove estimate (1.7) by simple rescaling. Otherwise the simple rescaling shows that $|e_{T,h}^{\mathsf{T}}(x, y, 0)| \le Ch^{1-d}$ and therefore $|e_h(x, y, 0)| \le Ch^{1-d}$ and one can see easily that in this case also $|e_h^{\mathsf{W}}(x, y, 0)| \le Ch^{1-d}$ due to stationary phase principle. □

So, Theorem 1.1 has been proven. From now we consider only $d = 2$.

Proposition 3.6. *Let $d = 2$, $\ell(x,y) \le \epsilon_1$ and $\ell^0(x,y) \le \epsilon\ell(x,y)$. Then*

$$|e^{\mathsf{T}}_{T_*,h}(x,y,0) - e^{\mathsf{W}}_h(x,y,0)| \le Ch^{-1} + C\ell^{-2}. \tag{3.22}$$

Proof. Following arguments of [Ivr3], Section 2 one can prove easily that after rescaling the left-hand expression does not exceed

$$C\hbar^{-\frac12}\ell^{0\,-\frac32}\min\Big(1, \frac{\ell^{0\,3}\ell}{\hbar}\Big) + C\hbar^{-1}\ell + C \tag{3.23}$$

where the first term is the difference between

$$(2\pi\hbar)^{-2}\iint e^{i\hbar^{-1}(it\tau-\varphi^0(x,y,\theta))}B_0(x,y,\theta,t)\chi_{T_*/\tau}(t)\,d\theta dt$$

and $e^{\mathsf{W}}_h(x,y,0)$. Further, the second term comes from the amplitude $B_1\hbar$ in the same expression (and acquires factor ℓ due to scaling of V_j) and the third term comes from the amplitude $B_2\hbar^2$ in the same expression, which are in $e^{\mathsf{T}}_{T_*,h}(x,y,0)$ but are skipped in $e^{\mathsf{W}}_h(x,y,0)$ [5] .

The first term in (3.23) does not exceed $C\hbar^{-1}\ell^{\frac12}$, so the left-hand expression of (3.22) does not exceed $C\hbar^{-1}\ell^{\frac12} + C$. Scaling back (that is multiplying by ℓ^{-2} and plugging $\hbar = \ell^{-\frac32}h$) we get $Ch^{-1} + C\ell^{-2}$. □

Combining Propositions 3.6 and 3.4(ii) we arrive to

Corollary 3.7. *In the framework of Proposition 3.6*

$$|e_h(x,y,0) - e^{\mathsf{W}}_h(x,y,0)| \le Ch^{-\frac12}\ell^{-\frac54} + C\ell^{-2} + Ch^{-1}. \tag{3.24}$$

In particular, for $\ell \ge h^{\frac25}$ the right-hand expression does not exceed Ch^{-1}.

3.3 Perturbation methods

Now we compare $e^{\mathsf{T}}_{T,h}(x,y,0)$ with the same function for generalized toy-model operator (2.31) assuming that

$$V_{x_1}(0) = -1, \qquad V_1 = 0, \qquad V_{2\,x_1}(0) = k \tag{3.25}_{1-3}$$

because we can achieve $(3.25)_1$ by scaling and $(3.25)_3$ as a definition. Then

[5] These amplitudes $B_n(x,y,\theta,t)$ should not be confused with the amplitudes b_n in the proof of Proposition 3.3.

(3.26) The phase function $\varphi(x,y,\xi_1,\eta_1,\xi',\tau)$ in expression (3.11) differs from the phase function $\bar\varphi(x,y,\xi_1,\eta_1,\xi',\tau)$ in (2.35) by $O(T^5)$ and amplitude $b(x,y,\xi_1,\eta_1,\xi',\tau,h)$ differs from the amplitude $\bar b_k(x,y,\xi_1,\eta_1,\xi',\tau,h)$ there by $O(T^2)$.

Indeed, in comparison to the Part (c) of the proof of Proposition 3.4 now the relative error in A_h in comparison to generalized toy-model operator $\bar A_{k,h}$ is $O(T^2)$ we conclude that the relative errors in φ and B_h are also $O(T^2)$.

Let us assume that

$$\ell(x,y)\le h^{\frac25}. \tag{3.27}$$

Proposition 3.8. *Let* (3.25) *and* (3.27) *be fulfilled. Then*

(a) Asymptotics

$$\bigl(e^{\mathsf T}_{T^*,h}(x,y,0)-e^{\mathsf W}_h(x,y,0)\bigr)-\bigl(\bar e^{\mathsf T}_{k,h}(x,y,0)-\bar e^{\mathsf W}_{k,h}(x,y,0)\bigr)=O(h^{-1}) \tag{3.28}$$

holds for all $x,y\in B(0,\epsilon)$: $|x-y|\le \epsilon\ell(x,y)$.

(b) Estimates

$$|e^{\mathsf T}_{T^*,h}(x,y,0)-\bar e^{\mathsf T}_{k,T^*,h}(x,y,0)| \tag{3.29}$$
$$\le\begin{cases} Ch^{-\frac12}\ell^{-\frac54}\times\ell^{\frac52}h^{-1}=O(h^{-1}) & \text{in the regular zone,}\\ Ch^{-\frac23}\ell^{-1}\times\ell^{\frac52}h^{-1}=O(h^{-\frac53}\ell^{\frac32}) & \text{in the singular zone,}\\ Ch^{(2s-2)/3}\ell^{-s} & \text{in the shadow zone}\end{cases}$$

and

$$e^{\mathsf W}_h(x,y,0)-\bar e^{\mathsf W}_{k,h}(x,y,0)=O(h^{-1}) \tag{3.30}$$

hold for all $x,y\in B(0,\epsilon)$: $|x-y|\ge\epsilon\ell(x,y)$ *where* $\bar e_{k,h}(x,y,\tau)$, $\bar e^{\mathsf W}_{k,h}(x,y,\tau)$ *and* $\bar e^{\mathsf T}_{k,T,h}(x,y,\tau)$ *are defined for a generalized toy-model operator* (2.31).

Proof. (a) Observe that $A_h-\bar A_{k,h}=O(\ell^2)$. Indeed, when we replace V by x_1 the error is $O(\ell^2)$ due to $(3.25)_1$ and when we replace V_1 by kx_1 the error is $O(\ell^{\frac52})$ due to $(3.25)_{2-3}$ where extra factor $\ell^{\frac12}$ comes from factor ξ_2.

Therefore as $|x-y| \le \epsilon\ell(x,y)$ the following estimate holds

$$|\big(e^{\mathsf{T}}_{T^*,h}(x,y,0) - e^{\mathsf{T}}_{T_*,h}(x,y,0)\big) - \big(\bar{e}^{\mathsf{T}}_{k,T^*,h}(x,y,0) - \bar{e}^{\mathsf{T}}_{k,T_*,h}(x,y,0)\big)| \le Ch^{-1} \tag{3.31}$$

and as $|x-y| \ge \epsilon\ell(x,y)$ estimate (3.30) holds, where we recall that $T^* = C_0\sqrt{\ell}$ and $T_* = \epsilon'\sqrt{\ell}$ with arbitrarily small constant ϵ'. The proof is similar to the proof of Proposition 2.8 and the right-hand expression in (3.29) is exactly expression (2.43).

(b) Further, if $|x-y| \le \epsilon_1\ell(x,y)$ then combining (3.31) and (3.22) we conclude that the left-hand expression of (3.27) does not exceed $Ch^{-1} + C\ell^{-2}$ which implies (3.27) for $\ell \ge h^{\frac{1}{2}}$.

However, for $\ell(x,y) \le h^{\frac{1}{2}}$ we need more subtle arguments. Namely, recall that $C\ell^{-2}$ comes from $\hbar^0 \times \ell^{-2}$ which in turn comes from the decomposition (3.16) with $B_n = O(\ell^{-\frac{3n}{2}})$. However since operators A_h and $\bar{A}_{k,h}$ after rescaling differ by $O(\ell^2)$ rather than $O(\ell)$ we can estimate $B_n - \bar{B}_{k,n} = O(\ell^{1-\frac{3n}{2}})$ and therefore

$$|\big(e^{\mathsf{T}}_{T_*,h}(x,y,0) - e^{\mathsf{W}}_{h}(x,y,0)\big) - \big(\bar{e}^{\mathsf{T}}_{T_*,k,h}(x,y,0) - \bar{e}^{\mathsf{W}}_{k,h}(x,y,0)\big)| \le Ch^{-1} + C\ell^{-\frac{3}{2}} \le Ch^{-1}. \tag{3.32}$$

(c) On the other hand, if $\ell^0(x,y) \ge \epsilon_1\ell(x,y)$ then one can prove easily

$$|e^{\mathsf{W}}_{h}(x,y,0) - \bar{e}^{\mathsf{W}}_{k,h}(x,y,0)| \le Ch^{-1} + C\ell^{-\frac{3}{2}} \le Ch^{-1}. \tag{3.33}$$

□

Remark 3.9. (i) One can prove easily that

$$e^{\mathsf{W}}_{h}(x,y,0) - \bar{e}^{\mathsf{W}}_{k,h}(x,y,0) = O(h^{-2}\ell^2) \tag{3.34}$$

even as $|x-y| \ge \epsilon\ell(x,y)$. Therefore

$$e_h(x,y,0) = \bar{e}_{k,h}(x,y,0) + O(h^{-1}) \qquad \text{as } \ell(x,y) \le h^{\frac{1}{2}}. \tag{3.35}$$

However, one can easily note that it may fail as $\ell(x,y) \gg h^{\frac{1}{2}}$. Thus, as $h^{\frac{1}{2}} \le \ell(x,y) \le h^{\frac{2}{5}}$ we need to use both terms $e^{\mathsf{W}}_{h}(x,y,0)$ and $e_{\mathsf{corr},k,h}(x,y,0)$ in the asymptotics.

(ii) We can replace k by $k=0$ and preserve remainder estimate $O(h^{-1})$ if and only if $|k||x_2-y_2| \lesssim \ell^{\frac14} h^{\frac12}$. In particular, we can do it as $x_2=y_2$.

(iii) We know that in any dimension $d \ge 2$ $e_h(x,y,0)$ is $O(h^s)$ if either $x_1 < -h^{\frac23-\delta}$ or $y_1 < -h^{\frac23-\delta}$ or $4x_1y_1 \le (1-\epsilon)|x'-y'|^2 - h^{\frac43-\delta}$ but it is not the case for $e_h^{\mathsf{W}}(x,y,0)$!

3.4 Proof of Theorem 1.2

Proof of Theorem 1.2. Without any loss of the generality one can assume that $\tau=0$, and assumptions $(3.1)_{1,2}$, $(3.2)_{1-3}$, $(3.3)_{1-4}$ and $(3.25)_{1-3}$ are fulfilled. Then the left-hand expression in (1.11) is $(x_1-x_2)^2-4x_1y_1$ modulo $O(\ell^3)$.

As $\ell(x,y) \ge h^{\frac23-\delta}$ we can replace in the Tauberian expressions $T=C_0\sqrt{\ell}$ by $T=\epsilon_1$ with $O(h^s)$ error. Then

(a) Statements (i) and (ii) of Theorem 1.2 follow immediately from Proposition 3.4.

(b) Statements (iii) and (iv) of Theorem 1.2 follow immediately from Proposition 3.8.

(c) Further, as $\ell(x,y) \le h^{\frac23-\delta}$ we can take $T^*=h^{\frac13-\delta}$ and apply the same arguments.

(d) Finally, Statement (v) of Theorem 1.2 follows from (2.44) and (2.28). □

4 Generalizations and final remarks

Remark 4.1. (i) In any dimension $d \ge 1$ without assumption (1.3) the simple rescaling with the scaling function

$$\gamma_x = (\epsilon|V(x)-\tau| + h^{\frac23}) \tag{4.1}$$

results in the estimate

$$|e_h(x,y,\tau) - e_h^{\mathsf{W}}(x,y,\tau)| \le Ch^{1-d}\gamma_x^{(d-3)/2} \tag{4.2}$$

as long as $\ell(x,y) \le \gamma_x$ (and then $\gamma_y \asymp \gamma_x$) [6].

(ii) To explore the case $\ell(x,y) \ge \gamma_x$ observe that the standard Tauberian method, Part I, implies

$$e_h(x,x,\tau + h\gamma_x^{-\frac12}) - e_h(x,x,\tau) \le Ch^{1-d}\gamma_x^{(d-3)/2} \tag{4.3}$$

Then

$$|e_h(x,y,\tau + h\gamma_*^{-\frac12}) - e_h(x,y,\tau)| \le Ch^{1-d}\gamma^{*(d-1)/4}\gamma_*^{(d-5)/4} \tag{4.4}$$

with $\gamma^* = \max(\gamma_x,\, \gamma_y)$ and $\gamma_* = \min(\gamma_x,\, \gamma_y)$.

Applying standard Tauberian methods, Part II, we arrive to the estimate

$$\begin{aligned} |e_h(x,y,\tau)| &\le CT_{x,y}^{-1}\gamma_*^{\frac12} \times h^{1-d}\gamma^{*(d-1)/4}\gamma_*^{(d-5)/4} \\ &\le Ch^{1-d}\gamma^{*(d-3)/4}\gamma_*^{(d-3)/4} = Ch^{1-d}\gamma_x^{(d-3)/4}\gamma_y^{(d-3)/4} \end{aligned} \tag{4.5}$$

where $T_{x,y} \gtrsim |x-y|^{\frac12} \ge \gamma^{*\frac12}$ is the minimal propagation time between x and y on the energy level τ.

Therefore, in the worst case remainder estimate is $O(h^{-\frac23})$ for $d=1$, $O(h^{-\frac43})$ for $d=2$ and $O(h^{1-d})$ for $d \ge 3$.

Remark 4.2. (i) Under assumption (1.3) following arguments of Proposition 3.2 we upgrade (4.3) to

$$e_h(x,x,\tau + h) - e_h(x,x,\tau) \le Ch^{1-d}\gamma_x^{(d-2)/2} \tag{4.6}$$

and then

$$|e_h(x,y,\tau) - e^{\mathsf{T}}_{\epsilon_1,h}(x,y,\tau)| \le Ch^{1-d}\gamma_x^{(d-2)/4}\gamma_y^{(d-2)/4}. \tag{4.7}$$

Therefore, in the worst case remainder estimate is $O(h^{-\frac13})$ for $d=1$, $O(h^{-1})$ for $d=2$ and $O(h^{1-d})$ for $d \ge 3$.

(ii) However to replace $e^{\mathsf{T}}_{\epsilon_1,h}(x,y,\tau)$ by $e^{\mathsf{W}}_h(x,y,\tau)$ and preserve this remainder estimate we may need to add a correction term (in any dimension!)

[6] As $d=1$ Weyl expression should be modified so it contains a true eikonal rather than $\langle x-y,\theta\rangle - a(\frac12(x+y),\theta)$ approximation.

which in the regular zone is of magnitude $h^{(1-d)/2}\ell(x,y)^{-(d+3)/4}$ and in the singular zone is $O\big(h^{(2-3d)/6}\ell(x,y)^{-(d+2)/4}\big)$ [7]. For toy-model (2.1) it is

$$e_{\mathrm{corr},h}(x,y,\tau)=\frac{2}{(2\pi)^{\frac{d}{2}}\Gamma(\frac{d}{2}+1)h^{d+1}}\int_{-\infty}^{\tau}\int_{0}^{\infty}(\tau-\tau')^{\frac{d}{2}} \tag{4.8}$$
$$\times\cos\Big[h^{-1}\Big(\beta(x_1+y_1+2\tau)+\frac{1}{4\beta}\big((x_1-y_1)^2+|z'|^2\big)-\frac{1}{3}\beta^3\big)\Big)-\frac{\pi}{4}(d+2)\Big]\,d\beta d\tau$$
$$-e_h^{\mathsf{W}}(x,y,\tau)$$

with $z'=x'-y'$. Then $e_{\mathrm{corr},h}(x,x,\tau)$ can be expressed through Airy function.

Remark 4.3. To get rid off condition (1.3) we can use the simple rescaling with the scaling function

$$\gamma_{2x}=(\epsilon|V(x)-\tau|+|\nabla V|^2+h)^{\frac{1}{2}}; \tag{4.9}$$

then $\hbar=\gamma_{2x}^{-2}h$ and the remainder estimates are not spoiled in dimensions $d\ge 2$, but in dimension $d=1$ it becomes $O(\hbar^{-\frac{1}{3}}\gamma_{2x}^{-1})=O(h^{-\frac{1}{3}}\gamma_{2x}^{-\frac{1}{3}})$ which is $O(h^{-\frac{1}{2}})$ in the worst case.

Pointwise Spectral Asymptotics near Singularity *,†

Victor Ivrii‡

Abstract

We establish semiclassical asymptotics and estimates for the $e_h(x,x,\tau)$ where $e_h(x,y,\tau)$ is the Schwartz kernel of the spectral projector for a second order elliptic operator inside domain with power singularity in the origin. While such asymptotics for its trace $\mathsf{N}_h(\tau) = \int e_h(x,x,\tau)\,dx$ are well-known, the poinwise asymptotics are much less explored.

Our main tools: microlocal methods, improved successive approximations and geometric optics methods.

Chapter 29

Introduction

In this paper we consider semiclassical diagonal poinwise asymptotics of $e_h(x,x,\tau)$ where $e_h(x,y,\tau)$ is the Schartz kernel of the spectral projector for a *toy-model operator*

$$A_h^0 = -\frac{1}{2}h^2\Delta - |x|^{-2\alpha} \qquad \text{with } \ 0<\alpha<1 \tag{0.1}$$

or a *perturbed toy-model operator*

$$A_h = \sum_{j,k} g^{jk}(hD_j - V_j)(hD_k - V_k) + V, \tag{0.2}$$

assuming that

$$D^\sigma(g^{jk} - \delta_{jk}) = O(|x|^{\beta-|\sigma|}), \tag{0.3}$$

$$D^\sigma V_j(x) = O(|x|^{-\alpha+\beta-|\sigma|}) \tag{0.4}$$

and

$$D^\sigma(V(x) + |x|^{-2\alpha}) = O(|x|^{-2\alpha+\beta-|\sigma|}) \qquad \forall \sigma\colon |\sigma|\le K \tag{0.5}$$

with $\beta>0$ and sufficiently large K.

1 Toy-model operator

Let $A_h := A_h^0$ be toy-model operator (0.1) in $\mathbb{R}^d$. It is self-adjoint in $\mathscr{L}^2(\mathbb{R}^d))$. Let $E_h^0(\tau)$ be its spectral projector and $e_h^0(x,y,\tau)$ be a Schwartz kernel of $E_h^0(\tau)$.

Theorem 1.1. *Consider toy-model operator A_h^0. Then*

(i) For $h \in (0,1]$, $|x| \le 1$, $|y| \le 1$, $T \ge C_0$ the following estimate holds

$$|e_h(x,y,0) - e_{T,h}^{\mathsf{T}}(x,y,0)| \le Ch^s T^{-s} \tag{1.1}$$

with the Tauberian expression

$$e_{T,h}^{\mathsf{T}}(x,y,\tau) = h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau'}\Big(\bar\chi_T u_h(x,y,t)\Big)\,d\tau' \tag{1.2}$$

where here and below $u_h(x,y,t)$ is the Schwartz kernel of $e^{ith^{-1}A_h}$, $\bar\chi \in \mathscr{C}_0^{(}[-1,1])$, $\chi^- \in \mathscr{C}_0([-1,-\frac12])$, $\chi^+ \in \mathscr{C}_0([\frac12,1])$, $\chi = \chi^+ + \chi^-$, $\chi_T(t) = \chi(t/T)$ etc.

(ii) For x: $|x| = 1$

$$|e_{T,h}^{\mathsf{T}}(x,x,0) - e_{T',h}^{\mathsf{T}}(x,x,0)| \le Ch^{\frac32-d} + C\bar\rho^{d-1}h^{1-d} \tag{1.3}$$

with

$$\bar\rho = \begin{cases} h^{\frac12-\delta} & \text{as } (1-\alpha)^{-1} \notin 2\mathbb{Z},\\ h^{\frac13-\delta} & \text{as } (1-\alpha)^{-1} \in 2\mathbb{Z}. \end{cases} \tag{1.4}$$

with an arbitrary small exponent $\delta > 0$ and an arbitrarily small constant $T' > 0$.

(iii) Furthermore, as $0 < \alpha \le \frac12$ one can skip the first term in the right-hand expression of (1.3).

Remark 1.2. We know that for small enough constant $T_* > 0$

$$e_{T_*,h}^{\mathsf{T}}(x,x,\tau) = e_h^{\mathsf{W}}(x,x,\tau) + O(h^{2-d}) \tag{1.5}$$

with the Weyl expression

$$e_h^{\mathsf{W}}(x,x,\tau) = (2\pi h)^{-d}\varpi_d(2(\tau - V(x)))^{\frac{d}{2}} \tag{1.6}$$

with ϖ_d a volume of $B(0,1) \subset \mathbb{R}^d$.

2 General case

Consider general operator (0.2) in $\mathscr{L}^2(X)$ with $0 \in X \subset \mathbb{R}^d$. If $\partial X \neq \emptyset$, assume that there are boundary conditions on ∂X.

Theorem 2.1. *Consider general operator* (0.2) *in* $\mathscr{L}^2(X)$ *with* $0 \in X \subset \mathbb{R}^d$. *Assume that conditions* (0.3)–(0.5) *are fulfilled in* $B(0,2)$ *and that*

(2.1) A_h *is a self-adjoint operator.*

Then

(i) For $h \in (0,1]$, $\epsilon_0 r \le |x| \le r$, $\epsilon_0 r \le |y| \le r$, $\bar{r} \le r \le r_0$, $T \ge C_0 r_0^{1+\alpha}$ *where* r_0 *is a small constant and* $\bar{r} = h^{1/(1-\alpha)}$, *the following estimates hold*

$$|e_h(x,y,0) - e^{\mathsf{T}}_{T,h}(x,y,0)| \le C h^{1-d} r^{2\alpha-\alpha d} \tag{2.2}$$

and

$$|e_h(x,y,0) - e^0_h(x,x,0) - e^{\mathsf{T}}_{T,h}(x,y,0) + e^{0\,\mathsf{T}}_{T,h}(x,y,0)| \le C h^{1-d} r^{2\alpha-\alpha d+\beta} \tag{2.3}$$

with the Tauberian expression $e^{\mathsf{T}}_{T,h}(x,y,\tau)$ *defined by* (1.2).

(ii) For x: $r_* = h^{1/(1-\alpha)-\delta} \le r = |x| \le r_0$

$$\begin{aligned} &|e^{\mathsf{T}}_{T,h}(x,x,0) - e^{\mathsf{T}}_{T',h}(x,x,0)| \\ &\quad \le C h^{\frac{3}{2}-d} r^{-\frac{3}{2}(1-\alpha)-\alpha d} + C\bar{\rho}^{d-1} h^{1-d} r^{-1+\alpha-\alpha d} + C h^{1-d} r^{-1+\alpha-\alpha d+\beta d-\beta} \end{aligned} \tag{2.4}$$

with

$$\bar{\rho} = \begin{cases} \hbar^{\frac{1}{2}-\delta} & \text{as } (1-\alpha)^{-1} \notin 2\mathbb{Z}, \\ \hbar^{\frac{1}{3}-\delta} & \text{as } (1-\alpha)^{-1} \in 2\mathbb{Z}, \end{cases} \qquad \hbar = h r^{-1+\alpha} \tag{2.5}$$

with an arbitrary small exponent $\delta > 0$, $K = K(s,\delta)$ *in* (0.3)–(0.5) *and* $T' = \epsilon' r^{1+\alpha}$ *with an arbitrarily small constant* $\epsilon' > 0$.

(iii) Further, for $r_* \le r \le r^* = h^{1/(1-\alpha+\beta)}$

$$\begin{aligned} &|e^{\mathsf{T}}_{T,h}(x,x,0) - e^{\mathsf{T}}_{T',h}(x,x,0) - e^{0\,\mathsf{T}}_{T,h}(x,x,0) + e^{0\,\mathsf{T}}_{T',h}(x,x,0)| \\ &\qquad \le C h^{\frac{1}{2}-d} r^{-\frac{1}{2}(1-\alpha)-\alpha d+\beta} + C\bar{\rho}^{d-1} h^{-d} r^{\beta-\alpha d} + C h^{-d} r^{-\alpha d+\beta d} \end{aligned} \tag{2.6}$$

(iv) Furthermore, as $0 < \alpha \le \frac{1}{2}$ *one can skip the first terms in the right-hand expressions of* (2.4) *and* (2.6).

Remark 2.2. (i) We know that in the framework of Theorem 2.1(ii)

$$|e^{\mathsf{T}}_{T',h}(x,x,0) - e^{\mathsf{W}}_{h}(x,x,0))| \le Ch^{2-d}r^{-2+2\alpha-\alpha d} + Ch^{1-d}r^{-\alpha d+\alpha-1+\beta}. \tag{2.7}$$

and in the framework of Theorem 2.1(ii)

$$|e^{\mathsf{T}}_{T',h}(x,x,0) - e^{\mathsf{W}}_{h}(x,x,0) - e^{0\,\mathsf{T}}_{T',h}(x,x,0) + e^{0\,\mathsf{W}}_{h}(x,x,0)| \le Ch^{2-d}r^{-2+2\alpha+\beta-\alpha d}. \tag{2.8}$$

(ii) Estimate (2.4) without the last term is estimate (1.3) scaled.

(iii) Combining estimates (2.2), (2.4) and (2.7) we can estimate

$$e_h(x,x,0) - e^{\mathsf{W}}_{h}(x,x,0)$$

and combining estimates (2.2), (2.6) and (2.8) we can estimate

$$e_h(x,x,0) - e^{\mathsf{W}}_{h}(x,x,0) - e^{0}_{h}(x,x,0) + e^{0\,\mathsf{W}}_{h}(x,x,0).$$

3 Plan of the paper.

In Section 30 we study a toy-model operator A^0_h. First, in Subsection 1 we study corresponding Hamiltonian trajectories. In Subsection 2 we study propagation of singularities, especially long-range propagation and propagation near $\{(x,\xi)\colon |x\times\xi| = 0\}$, and derive microlocal and local pointwise spectral asymptotics with the improved remainder estimates. Finally, in Subsection 3 we scale the previous results.

In Section 31 we study operator A_h which is perturbed a toy-model operator A^0_h. In Subsection 1 we study propagation of singularities, especially long-range propagation and propagation near $\{(x,\xi)\colon |x\times\xi| = 0\}$, and derive microlocal and local pointwise spectral asymptotics with the improved remainder estimates. In Subsection 2 by the metod of successive approximations the difference $e_h(x,x,\tau) - e^0_h(x,x,\tau)$. Finally, in Subsection 3 we consider cases $|x| \le \bar{r} = h^{1/(1-\alpha)}$ and $\bar{r} \le |x| \le r_* = h^{1/(1-\alpha)-\delta}$.

In the next paper (or the next variant of this paper) we consider out of diagonal asymptotics for such operators.

Chapter 30

Toy-model operator

1 Hamiltonian trajectories

Geometry: $\mathbf{d = 2}$. As $d = 2$ trajectories on the energy level 0 are defined in the polar coordinates by

$$\frac{dr}{dt} = \pm\sqrt{2r^{-2\alpha} - M^2r^{-2}}, \tag{1.1}$$

$$\frac{d\theta}{dt} = Mr^{-2} \tag{1.2}$$

with *angular momentum* M. Then

$$d\theta = \pm\frac{Mr^{-2}\,dr}{\sqrt{2r^{-2\alpha} - M^2r^{-2}}} = \pm\frac{M\rho^{-2}\,d\rho}{\omega\sqrt{2\rho^{-1} - M^2\rho^{-2}}}, \tag{1.3}$$

with $\rho = r^\omega$ with $\omega = 2 - 2\alpha$, $0 < \omega < 2$. The latter describes Kepler's parabolas as $M \neq 0$ in (θ, ρ) coordinates and therefore we need to perform a conformal transform $\rho \mapsto r = \rho^{1/\omega}$, $\theta \mapsto \omega^{-1}\theta$. Since increment of θ along parabola is $\pm 2\pi$, increment of θ along original Hamiltonian trajectory is $2\pi\omega^{-1}$ and therefore

(1.4) Every Hamiltonian trajectory with $M \neq 0$ has $n := -1 - \lceil -\omega^{-1}\rceil = -1 - \lceil -(2-2\alpha)^{-1}\rceil$ self intersections. In particular, the number of self-intersections is 0 for $0 < \alpha \le \frac{1}{2}$, 1 for $\frac{1}{2} < \alpha \le \frac{3}{4}$, etc.

All these trajectories are similar and obtained from one with $M = 1$ by scaling and rotation. Because of this

(1.5) Let $\frac{1}{2} < \alpha < 1$. Then through every point $x \neq 0$ there pass exactly n Hamiltonian trajectories with $M = M_k^+(x) = \mu_k |x|^{2-2\alpha}$, $0 < \mu_1 < ... < \mu_n$, returning to x once after k winding around 0 in the counter-clockwise direction, and also n Hamiltonian trajectories with $M = M_k^-(x) = -\mu_k |x|^{1-\alpha}$, returning to x once after k winding around 0 in the clockwise direction.

(1.6) Let $\frac{1}{2} < \alpha < 1$. Consider trajectory with $M = 1$. Denote by γ_k, $k = n, n-1, ..., 1$ the radius of $(n-k+1)$-th intersection counting from ininity; then $\gamma_n > \gamma_{n-1} > ... > \gamma_1$ and therefore $\mu_k = \gamma_k^{\alpha-1}$ satisfy $\mu_1 > ... > \mu_n$.

Let $\mu_0 = 0$.

(1.7) Let $x, y \in \mathbb{R}^2 \setminus 0$. There are n trajectories from x to y, winding around 0 in the counter-clockwise direction either $1, 2, ..., n$ or $0, 1, ..., n-1$ times correspondingly, and n trajectories from x to y windingaround 0 in the clockwise direction either $0, 1, ..., n-1$ or $1, 2, ..., n$ times correspondingly.

Indeed, consider two trajectories, issued from x in the corresponding direction, with the angular momenta M_1 and M_2, parametrized by θ. Then $|r_1(\theta) - |x|| > |r_2(\theta) - |x||$ provided $\theta \gtrless 0$ and $|M_1| < |M_2|$.

The trajectory is (rotated)

$$r^\omega = \frac{M^2}{(1 - \cos(\omega\theta))}. \tag{1.8}$$

Indeed, it follows from the fact that as $\omega = 1$ the trajectory is a parabola $r = \frac{A}{1-\cos(\theta)}$ and therefore in the general case $r^\omega = \frac{A}{(1-\cos(\omega\theta))}$. Applying dynamic equations

$$\frac{dr}{dt} = \pm\sqrt{2r^{\omega-2} - M^2 r^{-2}}, \tag{1.9}$$

$$\frac{d\theta}{dt} = Mr^{-2} \tag{1.10}$$

we conclude that $A^\omega = M^2$. Then self-intersections are achieved as

$$2\theta_k + 2\pi k = 2\pi\omega^{-1} \implies \theta_k = \pi\omega^{-1} - \pi k, \tag{1.11}$$

$$\gamma_k^\omega = \frac{1}{(1 - \cos(\omega\pi k))}, \qquad \mu_k = \gamma_k^{-\omega/2} = (1 - \cos(\omega\pi k))^{\frac{1}{2}}. \tag{1.12}$$

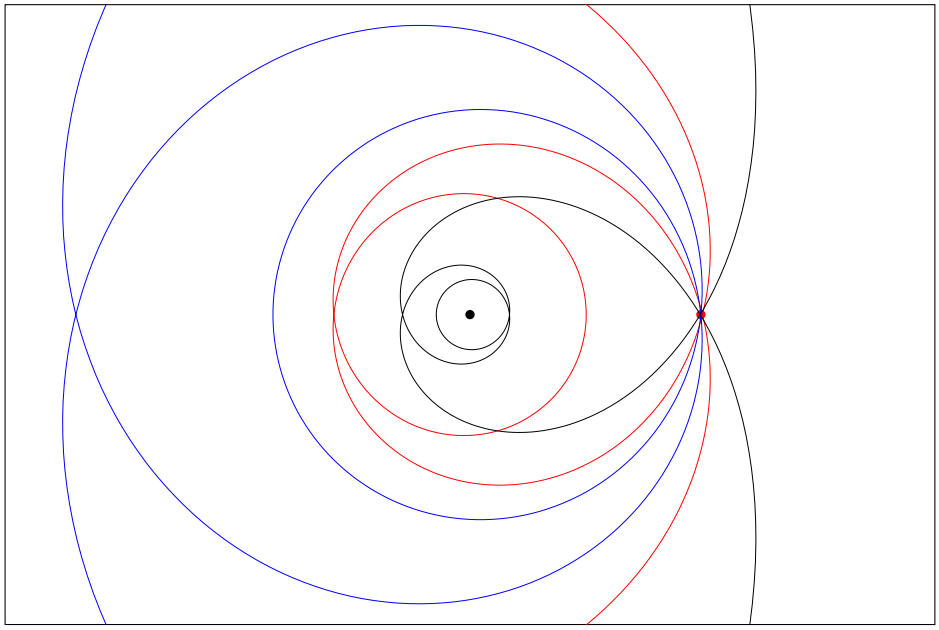

Figure 30.1: This figure shows several loops in the same (red) point, around origin (black point).

Dynamics: $\mathbf{d}=\mathbf{2}$. Consider trajectory passing through x with x being k-th points of self-intersection. Then $T_k(x) = t_k|x|^{1+\alpha}$. Meanwhile

$$
\begin{aligned}
(1.13)\quad dt = r^2 d\theta = M^{4/\omega}(1-\cos(\beta\theta))^{-2/\omega}\, d\theta& \\
\implies t_k =& 2\mu_k^{4/\omega}\int_{\theta_k}^{\pi}(1-\cos(\omega\theta))^{-2/\omega}\, d\theta \\
=& 2(1-\cos(\omega\theta_k))^{2/\omega}\int_{\theta_k}^{\pi}(1-\cos(\omega\theta))^{-2/\omega}\, d\theta.
\end{aligned}
$$

Remark 1.1. (i) We do not know how t_k are ordered and even if they are ordered at all.

(ii) There is however the purely radial movement with $M=0$ which is the limit of trajectories as $M\to 0$. We denote its time by

$$
(1.14)\qquad t_0 = 2\int_0^1 r^{\alpha}\, dr = \frac{2}{1+\alpha}.
$$

$d \geq 3$.

(1.15) As $x = ky \neq 0$, due to rotational symmetry (along straight line passing through 0 and x) instead of n separate curves we get n $(d-2)$-parameter families.

(1.16) On the other hand, if $x \neq ky$ since the trajectory from x to y belongs to a single 2-dimensional plane, passing through $x, y, 0$ the number of trajectories is as for $d = 2$.

2 Estimates

Proposition 2.1. *Consider toy-model operator* (0.1). *Then*

(i) For $T \geq \epsilon$, $|y| \leq C_0 T^{1/(1+\alpha)}$ *and* $|x| \geq 2C_0 T^{1/(1+\alpha)}$

$$|F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t) u_h(x,y,t)\big)| \leq Ch^s T^{-s} \qquad \forall \tau\colon |\tau| \leq \epsilon_1 T^{-2\alpha/(1+\alpha)}. \tag{2.1}$$

(ii) For $T \geq C_0$, $|x| \leq \epsilon T^{1/(1+\alpha)}$ *and* $|y| \leq \epsilon T^{1/(1+\alpha)}$

$$|F_{t\to h^{-1}\tau}\big(\chi_T(t) u_h(x,y,t)\big)| \leq Ch^s T^{-s} \qquad \forall \tau\colon |\tau| \leq \epsilon_1 T^{-2\alpha/(1+\alpha)}. \tag{2.2}$$

Proof. Let $\zeta \in \mathscr{C}^\infty(\mathbb{R})$, $\zeta(t) = 0$ as $t \geq 1$ and $\zeta(t) = 1$ as $t \leq 0$, $\zeta(t) < 1$ as $0 < t < 1$.

(i) Assume first that $|y| \leq 1$, $|x| \geq 2$ and $T = \epsilon$. Then the proof is standard, based for $\pm t > 0$ on $\phi(x,\xi,t) := \zeta(C_0 t - |x| + c)$ with an appropriate constant c; then

$$|\{\tfrac{1}{2}|\xi|^2 - |x|^{-2\alpha},\, |x|\}| \leq C_0 \qquad \text{for} \quad |\xi| \leq 1. \tag{2.3}$$

One can see easily that in the commutator of $hD_t - A$ with ϕ all next terms acquire factors h but not any negative powers of x.

After (2.1) is proven in this special case we prove it in the general case by scaling $x \mapsto xR^{-1}$, $\xi \mapsto \xi R^{\alpha}$, $t \mapsto tR^{-1+\alpha}$, $h \mapsto hR^{-1+\alpha}$.

(ii) Again consider first $T \asymp 1$, $|y| \le 1$. Let us use our standard method with $\phi(x,t,\xi) \coloneqq \zeta(-\epsilon_0 t + \langle x,\xi\rangle + c)$. Observe that

$$\{\tfrac12|\xi|^2 - |x|^{-2\alpha},\ \langle x,\xi\rangle\} = |\xi|^2 - 2\alpha|x|^{-2\alpha} \tag{2.4}$$

which on the energy level 0 equals $2(1-\alpha)|x|^{-2\alpha}$. We select c such that $\phi = 0$ as $|x| \le 1$, $|\xi|^2 - 2|x|^{-2\alpha} = 0$. Then according to (i) we conclude that

$$|F_{t\to h^{-1}\tau}\bigl(\chi_T^+(t)(I-Q^+)u_h(x,y,t)\bigr)| \le Ch^s \qquad \forall \tau\colon |\tau| \le \epsilon_2 \tag{2.5}$$

where $Q^+ = q^{+\mathsf{w}}$, $\mathsf{supp}(q^+) \subset \{(x,\xi)\colon \langle x,\xi\rangle \ge \epsilon \ge \epsilon_2 T^{(1-\alpha)/(1+\alpha)}\}$, which implies

$$|F_{t\to h^{-1}\tau}\bigl(\chi_T^+(t)u_h(x,y,t)\bigr)| \le Ch^s \quad \forall x\colon |x| \le \epsilon_3 T^{1/(1+\alpha)}\ \forall \tau\colon |\tau| \le \epsilon_3.$$

Like in Part (i) one can see easily that in the commutator of $hD_t - A$ with ϕ all next terms acquire factors h but not any negative powers of x.

Also, after (2.2) is proven in this special case we prove it in the general case by the same scaling as in Part (i). □

Proof of Theorem 1.1(i). It follows by standard Tauberian method from

$$|F_{t\to h^{-1}\tau}\bigl(\bar\chi_T u_h(x,y,\tau)\bigr)| \le Ch^{1-d} \qquad \forall \tau\colon |\tau| \le \epsilon \tag{2.6}$$

with $x = y$ and small constant T that

$$|e(x,x,\tau) - e(x,x,\tau')| \le Ch^{-d}|\tau-\tau'| + Ch^{1-d} \qquad \forall \tau,\tau'\colon |\tau| \le \epsilon_1, |\tau'| \le \epsilon_1 \tag{2.7}$$

which in turn implies (2.6) with arbitrarily large T and $C = C_T$; then we take $T = T_0$ and applying it we conclude that (2.6) holds for arbitrarily large T with C independent on T and with arbitrary $x\colon |x| \le 1$, $y\colon |y| \le 1$, which in turn implies (1.1). □

Now we need to consider $x,y\colon |x| \le 1$, $|y| \le 1$ and $T \le T_0$.

Proposition 2.2. *Consider toy-model operator* (0.1). *Let* $Q_l = q_l^{\mathsf{w}}(x, hD)$ *be operators such that*

$$\mathsf{supp}(q_1) \subset \{(x,\xi)\colon |x| \le 1,\ |x\times\xi| \ge (1+\epsilon)\rho\} \tag{2.8}$$

and

$$\mathsf{supp}(q_2) \subset \{(x,\xi)\colon |x| \le 1, \quad |x\times\xi| \le (1-\epsilon)\rho\} \tag{2.9}$$

where here and until further notice $\rho > 0$ *is an arbitrarily small constant. Then for* $T \ge \epsilon_0$

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)Q_{2x}u_h(x,y,t)\,{}^tQ_{1y}| \le C_T h^s \qquad \forall \tau\colon |\tau| \le \epsilon'. \tag{2.10}$$

Proof. Easy proof by standard microlocal methods based on that operators $(x_kD_j - x_jD_k)$ commute with A, is left to the reader. □

(2.11) Note that in the framework of (2.8) Hamiltonian trajectories passing through $\mathsf{supp}(q_1)$ are contained in $\{(x,\xi)\colon |x| \ge \epsilon''\}$ and one can describe $u_h(x,y,t)\,{}^tQ_{1y}$ as semiclassical Fourier integral distribution corresponding to the Lagrangian manifold $\Lambda = \{(x,\xi,t;y,-\eta,\tau)\colon (y,\eta) = \Phi_t(x,\xi),\ \tau = a(x,\xi)\}$ where $\Phi_t = \Phi_t(x,y)$ denotes a Hamiltonian flow generated by $a(x,\xi)$.

Proposition 2.3. *Consider toy-model operator* (0.1) *with* $d \ge 2$. *Let* $Q_1 = q_1^{\mathsf{w}}(x,hD)$ *be operator with the symbol satisfying* (2.8).

(i) Then for $T\colon \epsilon_0 \le T \le T^*$

$$|F_{t\to h^{-1}\tau}\chi_T(t)u_h(x,y,t)\,{}^tQ_{1y}| \le Ch^{\frac{3}{2}-d} \qquad \forall \tau\colon |\tau| \le \epsilon'. \tag{2.12}$$

(ii) Furthermore, if $|x\times y| \ge \rho$ *then*

$$|F_{t\to h^{-1}\tau}\chi_T(t)u_h(x,y,t)\,{}^tQ_{1y}| \le Ch^{\frac{1}{2}(1-d)} \qquad \forall \tau\colon |\tau| \le \epsilon'. \tag{2.13}$$

Proof. Let us fix $(\bar{x},\bar{\xi})$ and assume that $\Phi_t(\bar{x},\bar{\xi}) = (\bar{y},\bar{\eta})$ for $t = \bar{t} \ne 0$. Consider in the vicinity of $(\bar{\xi},\bar{t})$ the set $\{\xi\colon \Phi_t(\bar{x},\xi) = \bar{y}\}$. We claim that

(2.14) If $\bar{x}\times\bar{y} = 0$ then $\mathsf{rank}(d_{\xi,t}\pi_x\Phi_t(\bar{x},\xi))|_{\xi=\bar{\xi},t=\bar{t}} = 2$

and

(2.15) If $\bar{x}\times\bar{y} \ne 0$ then $\mathsf{rank}(d_{\xi,t}\pi_x\Phi_t(\bar{x},\xi))|_{\xi=\bar{\xi},t=\bar{t}} = d$.

The easy proof of these claims we leave to the reader.

Then combined (2.11) with (2.14) and (2.15) imply Statements (i) and (ii) respectively. □

Remark 2.4. (i) Let $0 < \alpha \le \frac{1}{2}$. Then the lack of self-intersections as $|x \times \xi| > 0$ implies that if $Q_1 = q_1^{\mathsf{w}}(x, hD)$ satisfies (2.8) then for $T\colon \epsilon_0 \le T \le T^*$

$$|F_{t\to h^{-1}\tau}\chi_T(t)u_h(x,y,t)\,{}^tQ_{1y}\big|_{x=y}| \le C_T h^s \qquad \forall \tau\colon |\tau| \le \epsilon'. \tag{2.16}$$

(ii) Let $\frac{1}{2} < \alpha < 1$. Then the lack self-intersections as $0 < |x \times \xi| < (1+\epsilon)\rho$ with small enough constant $\rho > 0$ implies that if $Q_1 = q_1^{\mathsf{w}}(x, hD)$ satisfies

$$\mathsf{supp}(q_1) \subset \{(x,\xi)\colon |x| \le 1,\ (1-\epsilon)\rho' < |x \times \xi| < (1+\epsilon)\rho\} \tag{2.17}$$

with sufficiently small constant $\rho > 0$ and arbitrarily small constant $\rho'\colon 0 < \rho' < \rho$ then (2.16) holds.

(iii) Let $h^{\delta'} < \rho' < \rho \le \epsilon'$ with sufficiently small exponent $\delta' > 0$. Then we still can apply standard microlocal methods and prove Proposition 2.2. Furthermore, we can use long-range propagation[1),2)] and conclude that singularities propagate along Hamiltonian trajectories. Then Statements (i) and (ii) of this Remark hold.

Now we need to consider the same expressions albeit with q_1 satisfying (2.17) with $h^{1-\delta} < \rho' < \rho < h^{\delta'}$. We want to to prove first that the propagation is confined to the strip

$$\{(x,\xi)\colon (1-\epsilon)\rho < |x \times \xi| < (1+\epsilon)\rho\}$$

and that there it happens along Hamiltonian trajectories. The most precise results (with the least restrictions on ρ) can be achieved in spherical coordinates $x = (\theta, r) \in \mathbb{S}^{d-1} \times \mathbb{R}^+$. Let $\xi = (\vartheta, \varrho) \in T^*_\theta \mathbb{S}^{d-1} \times \mathbb{R}$ be dual coordinates in the phase space. Then in $\mathscr{L}^2(\mathbb{S}^{d-1} \times \mathbb{R}^+)$ operator is transformed to

$$A = h^2\Big(D_r^2 + \frac{1}{4}(d-1)(d-3)r^{-2} + r^{-2}\Delta_\theta\Big) + V(r) \tag{2.18}$$

where Δ_θ is a positive Laplacian on $\mathbb{S}^{d-1}$. Then instead of Proposition 2.2 we have

---

[1)] See Subsection 2.4.2, [Ivr2].

[2)] Because $D\Phi_t$ has a polynomial growth.

Proposition 2.5. *Consider toy-model operator* (0.1). *Let* $Q_l = q_l^{\mathsf{w}}(\theta, hD_\theta)$ *be operators such that*

$$\mathsf{supp}(q_1) \subset \{(x,\xi)\colon\ |\vartheta| \ge (1+\epsilon)\rho\} \tag{2.19}$$

and

$$\mathsf{supp}(q_2) \subset \{(x,\xi)\colon |x| \le 1,\quad |\vartheta| \le (1-\epsilon)\rho\} \tag{2.20}$$

where $h^{1-\delta} \le \rho \le h^{\delta'}$. *Then for* $x = (\theta, r)$, $y = (\theta', r')$ *and* $T \ge \epsilon_0$

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)Q_{2x}u_h(x,y,t)\,{}^tQ_{1y}| \le C_T h^s \qquad \forall \tau\colon |\tau| \le \epsilon'. \tag{2.21}$$

Proof. Proof is by the standard elliptic microlocal arguments. □

Next we want to prove that propragation is along the Hamiltonian trajectories. Since along such trajectory the minimum of $|x$ is $\asymp r(\rho) \coloneqq \rho^{1/(1-\alpha)}$ we need to assume that $r(\rho) \gtrsim r_* = h^{1/(1-\alpha)-\delta}$ that is $\rho \ge h^{1-\delta}$ with an arbitrarily small exponent $\delta > 0$. This assumption we already made.

As $r \asymp r(\rho)$ standard scaling and long-range propagation results[1)] imply this if we take (after scaling) $\mathcal{W}$ which is $\hbar^{\frac12-\delta'}$-vicinity by (y,η) singularities there for time $t\colon\ :|t| \le T = \hbar^{-\delta''}$ propagate to $\Phi_t(\mathcal{W})$. Here $\hbar = h\rho^{-1}$ [3)].

Therefore we need to explore propagation from (y,η) to (x,ξ) and from (x,ξ) to (y,η) assuming that $|y| \asymp 1$, $|\eta| \asymp 1$, $|x| \asymp r(\rho)\hbar^{-\delta'}$ and $|\xi| \asymp |x|^{-\alpha}$.

Consider first corresponding Hamiltonian flow in the spherical coordinates. For fixed $\rho = |\vartheta|$ we have

$$\frac{dr}{dt} = \varrho = \bigl(r^{-2\alpha} + 2\tau - r^{-2}\rho^2\bigr)^{\frac12} = r^{-\alpha}\bigl(1 + 2r^{2\alpha}\tau - r^{2\alpha-2}\rho^2\bigr)^{\frac12} \tag{2.22}$$
$$\implies t = (1+\alpha)^{-1}r^{1+\alpha} + O\bigl(r^{3\alpha+1}|\tau| + r^{3\alpha-1}\rho^2\bigr)$$

as long as

$$C_0 r(\rho) \le r \le \epsilon_0 \tau_-^{-1/2\alpha}; \tag{2.23}$$

we count t from the point with the minimal $|x|$. On the other hand, we see that in the framework of (2.23)

$$\Phi_t(x,\xi) = (r(t), \varrho(t); \Psi_s(\theta, \vartheta/\rho)) \tag{2.24}$$

[3)] Since scaling translates $x \to x^{-1}r^{-1}(\rho)$, $\xi \to \xi r^{\alpha}(\rho)$ and $h \to \hbar = hr^{-1+\alpha}(\rho) = h\rho^{-1}$.

where Ψ_s is the geodesic flow on the $\mathbb{S}^*(\mathbb{S}^{d-1})$ and $s = s(t)$

$$ds = \rho r^{-2} dt = \rho r^{-2+\alpha}\bigl(1 + 2r^{2\alpha}\tau - r^{2\alpha-2}\rho^2\bigr)^{-\frac{1}{2}} dr \tag{2.25}$$
$$\implies s = s_0 - (1-\alpha)^{-1}\rho r^{-1+\alpha} + O\bigl(r^{3\alpha-1}\rho|\tau| + r^{3\alpha-3}\rho^3\bigr).$$

Remark 2.6. According to the proof of long-term propagation theorem [2)]

$$e^{ih^{-1}tA_h} Q = Q(t) e^{ih^{-1}tA_h} \tag{2.26}$$

provided $Q = q^{\mathsf{w}}(x, hD)$ with the symbol satisfying

$$\mathsf{supp}(q) \subset \{(x,\xi)\colon 1 \le |x| \le 2,\ 1 \le |\xi| \le 2,\ \langle x,\xi\rangle > 0\}, \tag{2.27}$$

$$|\partial_x^\mu \partial_\xi^\nu q| \le C_{\mu\nu} h^{-\frac{1}{2}(1-\delta')(|\mu|+\nu|)}, \tag{2.28}$$

$$|D\Phi_t| \le h^{-\delta''} \quad \text{and} \quad T \le h^{-\delta''} \tag{2.29}$$

with arbitrarily small exponent $\delta' > 0$ ($\langle x,\xi\rangle > 0$ means that the propagation goes in the direction away from the origin). Here $Q(t) = q^{\mathsf{w}}(x, hD_x; t)$ is the solution of

$$Q_t(t) - ih^{-1}[A_h, Q(t)] = 0 \tag{2.30}$$

and its symbol $q(t)$ satisfies

$$|\partial_x^\mu \partial_\xi^\nu q_2| \le C_{\mu\nu} h^{-\frac{1}{2}(1-\delta''')(|\mu|+\nu|)} \tag{2.31}$$

with $\delta'' = \delta''(\delta') > 0$, $\delta''' = \delta'''(\delta') > 0$ and

$$\mathsf{supp}\, q(t) = \Phi_t(\mathsf{supp}(q)). \tag{2.32}$$

Applying the standard scaling we conclude that for symbol q_n supported in $\{(x,\xi)\colon |x| \asymp r_n, |\xi| \asymp r_n^{-\alpha}\}$ with $r_n \ge r_*$ we can take $T_n = r_n^{(1+\alpha)} h_n^{-\delta''}$ with $h_n = h r_n^{-1+\alpha}$ and thus we arrive to a symbol $q'_{n+1} = q'(t_{n+1} - t_n)$ supported in $\{(x,\xi)\colon |x| \asymp r_{n+1},\ |\xi| \asymp r_{n+1}^{-\alpha}\}$ with $r_{n+1} = r_n h_n^{-\delta_4}$, so $h_{n+1} = h_n^{1+\delta_5}$.

Based on (2.22)–(2.25) we see that if q satisfies in the spherical coordinates after corresponding rescaling (2.28) then $q(t)$ satisfies in the corresponding scaling (2.28) again, with the same exponent δ'. Therefore with $N = N(\delta, \delta_5)$ jumps we can go from $r_1 \asymp r(\rho)$ to $r_N \asymp 1$.

We want to do it in order to have

$$\begin{aligned}(2.33)\quad & e^{ih^{-1}tA_h}Q_1 \equiv e^{ih^{-1}tA_h}Q_1'Q_1 \equiv e^{ih^{-1}(t-T_1)A_h}Q_2e^{ih^{-1}T_1}Q_1\\ & \equiv e^{ih^{-1}(t-T_1)A_h}Q_2'Q_2e^{ih^{-1}T_1}Q_1 \equiv e^{ih^{-1}(t-T_1-T_2)A_h}Q_3e^{ih^{-1}T_2A_h}Q_2e^{ih^{-1}T_1}Q_1\\ & \equiv Q_{N+2}'(t)e^{ih^{-1}(t-T_1-T_2-\dots-T_N)A_h}Q_{N+1}e^{ih^{-1}T_NA_h}\cdots Q_3e^{ih^{-1}T_3A_h}Q_2e^{ih^{-1}T_1}Q_1\end{aligned}$$

with $Q_n = q_n^{\mathsf{w}}(x, hD)$, $Q_n' = q_n'^{\mathsf{w}}(x, hD)$ with symbols satisfying after rescalings (2.27) and (2.31) respectively and $(I - Q_n')Q_n \equiv 0$.

Finally, $|t - T_1 - \dots - T_N| \le T_{N+1}$. This equality (2.33) will imply the required propagation result, but we need to look at $\mathsf{supp}(q_n)$ and $\mathsf{supp}(q_n')$.

Remark 2.7. As mentioned, we do it in the spherical coordinates (r, θ). This will lead to the condition

$$\rho \ge h^{\frac12-\delta} \tag{2.34}$$

which is stronger than the original assumption

$$\rho \ge h^{1-\delta}. \tag{2.35}$$

Proposition 2.8. *Consider toy-model operator* (0.1). *Let* $(\bar x, \bar\xi) = \Psi_t(\bar y, \bar\eta)$ *and*

$$(1-\epsilon)\rho \le |\bar x \times \bar\xi| = |\bar y \times \bar\eta| = (1+\epsilon)\rho \tag{2.36}$$

with $\rho \ge h^{\frac12-\delta}$. *Let* $Q_1 = q_1^{\mathsf{w}}(x, hD)$ *be operator with the symbol* q_1 *supported in* $\hbar^{\frac12-\delta'}(r_y, r_y^{-\alpha})$*–vicinity of* $(\bar y, \bar\eta)$ *and* $Q_2 = q_2^{\mathsf{w}}(x, hD)$ *be an operator with the symbol* q_2 *equal* 1 *in* $C_0\hbar^{\frac12-\delta'}(r_x, r_x^{-\alpha})$*–vicinity of* $(\bar x, \bar\xi)$, *where* $r_x = |\bar x|$ *and* $r_y = |\bar y|$.

Then

$$e^{ih^{-1}tA_h}Q_1 \equiv Q_2e^{ih^{-1}tA_h}Q_1. \tag{2.37}$$

Proof. (i) Assume first that $|\pi_x\Psi_{t'}|$ only increases as t' changes from 0 to t. Consider in the scaled spherical coordinates $\hbar^{\frac12-\delta'}$-vicinity $\mathcal{U}$ of $(\bar y, \bar\eta)$. Then $\Psi_t(\mathcal{U}) \subset \mathcal{V}$ which is $C_0\hbar^{\frac12-\delta'}$-vicinity of $\Phi_t(\bar x, \bar\xi)$ again in the scaled spherical coordinates. Combined with (2.33) implies (2.37). Here we can take any $\hbar \ge h^{1-\delta}r_y^{\alpha-1}$.

(ii) Similarly we can consider a case when $|\pi_x\Psi_{t'}|$ only decreases as t' changes from 0 to t. Here we can take any $\hbar \ge h^{1\delta}r_x^{\alpha-1}$.

(iii) Therefore such statement remains true if $|\pi_x \Psi_{t'}|$ first decreases and then increases as t' changes from 0 to t. Here we must take $\hbar \ge h^{1-\delta}\rho^{-1}$. □

Proposition 2.9. *Consider toy-model operator* (0.1). *Let*

$$|\bar{x}| = 1, \qquad a(\bar{x}, \bar{\xi}) = 0, \qquad 0 < \rho = |\bar{x} \times \bar{\xi}| \le \epsilon, \tag{2.38}$$

with sufficiently small constant $\epsilon = \epsilon(\epsilon_0) > 0$. *Then*

(i) If $(1-\alpha)^{-1} \notin 2\mathbb{Z}$ *then*

$$\min_{t:\ |t|\ge\epsilon_0} |\pi_x \Psi_t(\bar{x}, \bar{\xi}) - \bar{x}| \asymp 1. \tag{2.39}$$

(ii) If $(1-\alpha)^{-1} \in 2\mathbb{Z}$ *then*

$$\min_{t:\ |t|\ge\epsilon_0} |\pi_x \Psi_t(\bar{x}, \bar{\xi}) - \bar{x}| \asymp \rho. \tag{2.40}$$

Proof. (i) If $(1-\alpha)^{-1} \notin 2\mathbb{Z}$ then the rotation angle when $\rho \to 0$ tends to $\pi(1-\alpha)^{-1} \notin 2\pi\mathbb{Z}$, which implies (2.39).

(ii) If $(1-\alpha)^{-1} = 2n$, $n \in \mathbb{Z}$ then the rotation angle when $\rho \to 0$ tends to $2\pi n$. Further, if $n = 1$ then the trajectory is a parabola with the curvature radius $\asymp r_\rho = \rho^2$ near 0 and then on the distance $\asymp 1$ from 0 the distance between branches is $\asymp \rho$. For $n \ge 2$ instead of this parabola we get its image under transformation $r \mapsto r^n$, $\theta = n\theta$ (if $d = 2$) and then the distance between branches $\asymp r_\rho^{1/2n} = \rho$ again.

Thus we arrive to (2.40). □

Proposition 2.10. *Consider toy-model operator* (0.1). *Let* $Q = q^{\mathrm{w}}(x, hD)$ *be an operator with the symbol* q *supported in* $\epsilon''\rho$*-vicinity of* $(\bar{x}, \bar{\xi})$ *satisfying* (2.38) *with sufficiently small constant* $\epsilon > 0$. *Then*

(i) If $(1-\alpha)^{-1} \notin 2\mathbb{Z}$ *and* $\rho \ge h^{\frac{1}{2}-\delta}$ *then*

$$F_{t\to h^{-1}\tau}\Big(\chi_T(t) u_h(x, y, t)\, {}^t Q_{1y}\Big)\Big|_{y=x} = O(h^s) \qquad \forall T \in [\epsilon_1, T_1]\ \forall \tau\colon |\tau| < \epsilon_2. \tag{2.41}$$

with an arbitrarily small constant $\epsilon_1 > 0$, *arbitrarily large constant* T_1 *and* $\epsilon_2 = \epsilon_2(T_1)$.

(ii) If $(1-\alpha)^{-1} \in 2\mathbb{Z}$ *and*

$$\rho \ge h^{\frac{1}{3}-\delta} \tag{2.42}$$

then (2.41) *holds.*

Proof. In virtue of Proposition 2.8 we need to check that the left-side expression of (2.39) is larger than $C\hbar^{\frac{1}{2}-\delta'}$. Recall that $\hbar = h/\rho$.

(i) $(1-\alpha)^{-1} \notin 2\mathbb{Z}$ we need to check $\hbar^{\frac{1}{2}-\delta'} \le \epsilon_3$ which follows from $\rho \ge h^{\frac{1}{2}-\delta}$ which we need for Proposition 2.8.

(ii) $(1-\alpha)^{-1} \in 2\mathbb{Z}$ we need to check $\hbar^{\frac{1}{2}-\delta'} \le \epsilon_3\rho$ which is equivalent to (2.42). □

Now we need to check the contribution of zone $\{(x,\xi)\colon |x\times\xi| < \rho\}$ with $\rho = h^{\frac{1}{2}-\delta}$ in the framework of Proposition 2.10(i) and $\rho = h^{\frac{1}{3}-\delta}$ in the framework of Proposition 2.10(ii).

Proposition 2.11. *Consider toy-model operator* (0.1). *Let* $Q = q^{\mathrm{w}}(x, hD)$ *be an operator with the symbol* q *supported in* $\epsilon''\rho$*-vicinity of* $(\bar{x},\bar{\xi})$ *satisfying*

$$|\bar{x}| = 1, \qquad a(\bar{x},\bar{\xi}) = 0, \qquad |\bar{x}\times\bar{\xi}| \le \rho, \tag{2.43}$$

Then

$$|F_{t\to h^{-1}\tau}\Big(\chi_T(t)u_h(x,y,t)\,{}^tQ_{1y}\Big)\Big|_{y=x}| \le C\rho^{d-1}h^{1-d} \qquad \forall T\in[\epsilon_1, T_1]\ \forall \tau\colon |\tau| < \epsilon_2 \tag{2.44}$$

with an arbitrarily small constant $\epsilon_1 > 0$, *arbitrarily large constant* T_1 *and* $\epsilon_2 = \epsilon_2(T_1)$.

Proof. Proof follows from standard arguments and the standard estimate (2.44) with $\chi_T(t)$ replaced by $\bar{\chi}_{T'}(t)$ with small enough constant T'. □

Taking the sum with respect to partition of unity we arrive to

Proposition 2.12. *Consider toy-model operator* (0.1). *Then*

(i) For $|x|=1$

$$|F_{t\to h^{-1}\tau}\Big(\chi_T(t)u_h(x,x,t)\Big)| \le Ch^{\frac{3}{2}-d} + C\bar\rho^{d-1}h^{1-d} \qquad \forall T\ge \epsilon_0\ \forall \tau\colon |\tau|<\epsilon_2 T^{-2\alpha/(1+\alpha)} \tag{2.45}$$

(ii) Furthermore, as $0<\alpha\le \frac12$ *one can skip the first term in the right-hand expression of* (2.45).

Proof. Indeed, the first term in the right-hand expression of (2.45) is due to loops (which are absent as $0<\alpha\le\frac12$ while the second term is a contribution of zone $\{\xi\colon |x\times\xi|\le\bar\rho\}$ with $\bar\rho$ defined by (1.4).. □

Remark 2.13. If we want to get rid off the first term in the right-hand expression of (2.45) as $\frac12<\alpha<1$, we need to calculate contribution of loops (in the zone $\{(x,\xi)\colon |x\times\xi|>\epsilon\}$. One can do it, arriving to the estimate

$$|F_{t\to h^{-1}\tau}\Big((\bar\chi_T(t)-\bar\chi_{T'}(t))u_h(x,x,t)\Big) - \sum_{1\le k\le n}\sum_{\pm}\sum_{m\ge 0} \varkappa^{\pm}_{k,m}(x,\tau)\exp(\pm ih^{-1}\phi_k(x,\tau))h^{\frac{3}{2}-d+m}| \le C\bar\rho^{d-1}h^{1-d} \tag{2.46}$$

for all $T\ge C_0$, $T'=\epsilon_0$ and $\tau\colon |\tau|<\epsilon_2 T^{-2\alpha/(1+\alpha)}$.

Proof of Theorem 1.1. Statements (ii) and (iii) of Theorem 1.1 follow from Statements (i) and (ii) of Proposition 2.12. □

3 Scaling

Now we assume that

(3.1) Operator A_h in question coincides with toy-model (0.1) as $|x|\le R$, $R\ge 2$.

Then, assuming (1.12) (that is, A_h is a self-adjoint operator) we estimate for $|x|\asymp|y|\asymp 1$

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)u_h(x,y,t)|\le Ch^{1-d} \qquad \text{as}\quad T\le \epsilon R^{1+\alpha},\ |\tau|\le \epsilon R^{-2\alpha}.$$

Taking $x = y$ we apply standard Tauberian arguments (Part I)[4] to get estimate

$$|e_h(x,x,\tau) - e_h(x,x,\tau')| \le C\big(h^{1-d}R^{-1-\alpha} + h^{-d}|\tau-\tau'|\big) \quad \text{as } |\tau|+|\tau'| \le \epsilon R^{-2\alpha}.$$

Now take $|x| = r \le 1$. Then scaling $x \mapsto r^{-1}|x|$, $\tau \mapsto \tau r^{2\alpha}$, $R \mapsto r^{-1}R$ and $h \mapsto \hbar := hr^{\alpha-1}$ we arrive to

$$|e_h(x,x,\tau) - e_h(x,x,\tau')| \le Cr^{-(d-2)\alpha}\big(h^{1-d}R^{-1-\alpha} + h^{-d}|\tau-\tau'|\big) \quad \text{as } |\tau|+|\tau'| \le \epsilon R^{-2\alpha}$$

which for $R = 2$ becomes

$$|e_h(x,x,\tau) - e_h(x,x,\tau')| \le Cr^{-(d-2)\alpha}\big(h^{1-d} + h^{-d}|\tau-\tau'|\big) \quad \text{as } |\tau|+|\tau'| \le \epsilon \tag{3.2}$$

provided

$$\bar{h} := h^{1/(1-\alpha)} \le r \le 1 \tag{3.3}$$

where the last assumption means exactly that $\hbar \le 1$. Then (3.2) implies

$$\begin{aligned} |e_h(x,y,\tau) - e_h(x,y,\tau')| &\le Cr_x^{-(d-2)\alpha/2} r_y^{-(d-2)\alpha/2}\big(h^{1-d} + h^{-d}|\tau-\tau'|\big) \\ &\text{as } |\tau|+|\tau'| \le \epsilon,\ \ \bar{r} \le r_x = |x| \le 1,\ \ \bar{r} \le r_y = |y| \le 1 \end{aligned} \tag{3.4}$$

Apply standard Tauberian arguments (Part II)[4] we arrive to

Proposition 3.1. *Consider self-adjoint operator coinciding with the toy-model operator* (0.1) *as* $|x| \le 2$. *Then*

$$|e_h(x,y,\tau) - e^{\mathsf{T}}_{T,h}(x,y,\tau)| \le Cr_x^{-(d-2)\alpha/2} r_y^{-(d-2)\alpha/2} h^{1-d} \tag{3.5}$$

as $|\tau| \le \epsilon,\ \ \bar{r} \le r_x = |x| \le 1,\ \ \bar{r} \le r_y = |y| \le 1,\ \ T = C_0(r_x + r_y)^{1+\alpha}$

with the Tauberian expression

$$e^{\mathsf{T}}_{T,h}(x,y,\tau) = h^{-1}\int_{-\infty}^{\tau} \Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)u_h(x,y,t)\Big)\,d\tau. \tag{3.6}$$

[4] See [Ivr2], Chapter 4.

From now $x = y$. Then scaling results of Theorem 1.1 and Remark 1.2 and combining with (3.5) we arrive to

Proposition 3.2. *Consider self-adjoint operator coinciding with the toy-model operator* (0.1) *as* $|x| \le 2$. *Then for* $\bar{r} \le r = |x| \le 1$

(i) Estimate holds

$$|e_h(x,x,0) - e^{\mathsf{T}}_{T_*,h}(x,x,0)| \le Cr^{-(d-2)\alpha}h^{1-d} + Cr^{-\frac{3}{2}-\alpha(d-\frac{3}{2})}h^{\frac{3}{2}-d} + C\bar{\rho}^{d-1}r^{-1-\alpha(d-1)}h^{1-d} \tag{3.7}$$

with

$$\bar{\rho} = \begin{cases} \hbar^{\frac{1}{2}-\delta} & \text{as } (1-\alpha)^{-1} \notin 2\mathbb{Z}, \\ \hbar^{\frac{1}{3}-\delta} & \text{as } (1-\alpha)^{-1} \in 2\mathbb{Z} \end{cases} \tag{3.8}$$

with $\hbar = hr^{\alpha-1}$ *and with* $T_* = \epsilon r^{1+\alpha}$.

(ii) Further, as $0 < \alpha \le \frac{1}{2}$ *one can skip the second term in the right-hand expression of* (3.7).

(iii) Furthermore,

$$e^{\mathsf{T}}_{T_*,h}(x,x,\tau) = e^{\mathsf{W}}_h(x,x,\tau) + O(r^{-2-(d-2)\alpha}h^{2-d}) \tag{3.9}$$

with Weyl expression $e^{\mathsf{W}}_h(x,x,0)$ *defined by* (1.6).

Remark 3.3. Scaling, rotational symmetry and Remark 2.13 imply that for $\bar{r} \le r = |x|$ and $T_* = \epsilon_0 r^{1+\alpha}$

$$e^{\mathsf{T}}_{T_*,h} \sim \sum_{j=1}^{\infty} \kappa^0_j(\tau|x|^{2\alpha})h^{-d+2j}|x|^{-\alpha d-2j(1-\alpha)}. \tag{3.10}$$

and for $T^* = C_0 r^{1+\alpha}$

$$e^{\mathsf{T}}_{T,h} - e^{\mathsf{T}}_{T_*,h} \sim \sum_{1\le k\le n}\sum_{\pm}\sum_{j\ge 0} \kappa^{0\pm}_{k,j}(\tau|x|^{2\alpha})h^{\frac{3}{2}-d+j}|x|^{-\alpha d-(\frac{3}{2}+j)(1-\alpha)} \exp\bigl(\pm ih^{-1}|x|^{1-\alpha}\phi^0_k(\tau|x|^{2\alpha})\bigr). \tag{3.11}$$

Chapter 31

General case

1 Standard results for perturbed operator

Consider now operator A_h defined by (0.2) and satisfying (0.3)–(0.5) in $B(0,R) \subset X$. Then in $B(0,R)$

$$|D^\sigma (g^{jk} - \delta_{jk})| \le c_\sigma \varepsilon |x|^{-|\sigma|}, \tag{1.1}$$

$$|D^\sigma V_j(x)| \le c_\sigma \varepsilon |x|^{-\alpha-|\sigma|}, \tag{1.2}$$

$$|D^\sigma (V(x) + |x|^{-2\alpha})| \le c_\sigma \varepsilon |x|^{-2\alpha-|\sigma|} \qquad \forall \sigma : |\sigma| \le K \tag{1.3}$$

with $\varepsilon = R^\beta$. We assume that

$$r_* := h^{1/(1-\alpha)-\delta} \le r \le R \tag{1.4}$$

with an arbitrarily small exponent $\delta > 0$.

Remark 1.1. Usual scaling $x \mapsto xR^{-1}$, $\xi \mapsto \mathsf{x} R^\alpha$, $\tau \mapsto \tau R^{2\alpha}$ and $h \mapsto \hbar = hR^{-1+\alpha}$ produces operator (0.2) satisfying (1.1)–1.3) with $\varepsilon = R^\beta$ in $B(0,R)$. In contrast to Subsection 3 here $R \le \epsilon$.

However below we consider operator (0.2) under assumptions (1.1)–(1.4) for $R \ge r_*$ and then scale as necessary. This leads to different ε in different applications.

Repeating proof of Proposition 2.1 we arrive to

Proposition 1.2. *For operator* (0.2) *under assumptions* (1.1)–(1.3) *in* $B(0,R)$ *both Statements (i) and (ii) of Propositions 2.1 remain true as* $r_*^{1+\alpha} \le T \le \epsilon_2 R^{1+\alpha}$, $\varepsilon \le \epsilon_0$ *where* $\epsilon_0 > 0$, ϵ_2 *are small enough constants.*

Then similarly to Theorem 1.1(i) and Proposition 3.1 we arrive to

Corollary 1.3. *Consider operator* (0.2) *under assumptions* (1.1)–(1.3) *in* $B(0,2)$. *Then* (3.5) *remains true.*

Proof of Theorem 2.1(i). We take $R = 2r_0$ so that $\varepsilon \le \epsilon_0$. □

Similarly to Proposition 2.2 we have

Proposition 1.4. *Consider operator* (0.2) *under assumptions* (1.1)–(1.3) *in* $B(0,2)$. *Let assumptions* (2.8)–(2.9) *be fulfilled with*

$$\rho \ge C\varepsilon \tag{1.5}$$

where here ρ *is a small constant and* $C = C(\epsilon)$ *with* ϵ *from* (2.8)–(2.9). *Then* (2.10) *remains true for* $|x| \le 1$, $|y| \le 1$, $\epsilon_1 \le T \le c_0$.

Proof. In contrast to the toy-model operator when $\{a(x,\xi), x_j\xi_k - x_k\xi_j\} = 0$ we have now that on the energy level τ: $|\tau| \le \epsilon_0 |x|^{-2\alpha}$

$$|\{a(x,\xi), x_j\xi_k - x_k\xi_j\}| \le C_0\varepsilon |x|^{-2\alpha}. \tag{1.6}$$

Then we can apply standard propagation results. More sophisticated arguments will be required when both ρ and ε are small parameters. □

Repeating proof of Proposition 2.3 we arrive to

Proposition 1.5. *Consider operator* (0.2) *under assumptions* (1.1)–(1.3) *in* $B(0,R)$. *Let* $Q_1 = q_1^{\mathrm{w}}(x, hD)$ *be operator with the symbol satisfying* (2.8) *with an arbitrarily small constant* ρ.

Then both Statements (i) and (ii) of Proposition 2.3 remain true for $T \ge \epsilon_1$ *provided* ε *satisfies* (1.5).

Remark 1.6. (i) Under assumption (1.5) Statements (i)–(ii) of Remark 2.4 remain true. Furthermore, Statement (iii) remains true due to long-range propagation of singularities [1)] and Proposition 1.7 below.

(ii) For operator (0.2) instead of (2.14) and (2.15) we have respectively

(1.7) If $|\bar{x} \times \bar{y}| \le C_0\varepsilon$ then $\mathsf{rank}(d_{\xi,t}\pi_x \Phi_t(\bar{x},\xi))|_{\xi=\bar{\xi},t=\bar{t}} \ge 2$

and

(1.8) If $|\bar{x}\times\bar{y}|\ge C_0\varepsilon$ then $\mathsf{rank}\big(d_{\xi,t}\pi_x\Phi_t(\bar{x},\xi)\big)|_{\xi=\bar{\xi},t=\bar{t}}=d$.

(iii) I believe that for generic perturbations $\mathsf{rank}\big(d_{\xi,t}\pi_x\Phi_t(\bar{x},\xi)\big)|_{\xi=\bar{\xi},t=\bar{t}}=d$ even as $|\bar{x}\times\bar{y}|\le C_0\varepsilon$; morover, the largest absolute value of $d\times d$–minors of $d_{\xi,t}\pi_x\Phi_t(\bar{x},\xi)\big)$ is $\asymp\varepsilon^{d-2}$.

Proposition 1.7. *Consider operator* (0.2) *under assumptions* (1.1)–(1.3) *in* $B(0,2)$. *Then in the zone* $\{(x,\xi)\colon |x\times\xi|\ge\rho\}$ *with* $\rho\ge C\varepsilon$ *Hamiltonian flow* Φ_t *satisfies*

$$|D_{x,\xi}\Phi_t(x,\xi)|\le C\Big(1+\frac{|t|}{r_x^{1+\alpha}}\Big)^N. \tag{1.9}$$

Proof. It follows easily from

$$\frac{d}{dt}x|x|^{-1}=\sqrt{2}|x|^{-1-\alpha}\Big(1+O(\rho+\varepsilon)\Big). \tag{1.10}$$

Combining with long-term propagation of singularities[1)] we arrive to

Proposition 1.8. *Consider operator* (0.2) *under assumptions* (1.1)–(1.3) *in* $B(0,2)$. *Then*

(i) Statement of Proposition 2.5 remains true in the zone $\{(x,\xi)\colon |x\times\xi|\ge\rho\}$ *with*

$$\rho\ge h^{1-\delta}+C\varepsilon. \tag{1.11}$$

(ii) Statement of Remark 2.6 remains true in the zone $\{(x,\xi)\colon |x\times\xi|\ge\rho\}$ *with*

$$\rho\ge h^{\frac{1}{2}-\delta}+C\varepsilon. \tag{1.12}$$

Continuing, we arrive to

Proposition 1.9. *Consider operator* (0.2) *under assumptions* (1.1)–(1.3) *in* $B(0,2)$. *Let condition* (1.11) *be fulfilled. Then*

(i) Statements of Remark 2.7 and Proposition 2.8 remain true.

(ii) Both Statements (i) and (ii) of Proposition 2.9 remain true.

(iii) Both Statements (i) and (ii) of Proposition 2.10 remain true.

(iv) Statement of Proposition 2.11 remains true.

Taking the sum with respect to partition of unity (like in Proposition 2.12) we see that estimate (2.45) holds with $\bar{\rho}$ replaced by $\bar{\rho}_\varepsilon := \bar{\rho} + C\varepsilon$:

Proposition 1.10. *Consider operator* (0.2). *Assume that* (1.1)–(1.3) *with small parameter* ε *are fulfilled in* $B(0,2)$. *Also assume that the same assumptions albeit with* ε *replaced by* ϵ_2 *which is a small constant are fulfilled in* $B(0,R)$ *with* $R \ge 2$. *Then for* $|x| = 1$,

$$|F_{t\to h^{-1}\tau}\Big(\chi_T(t)u_h(x,x,t)\Big)| \le Ch^{\frac{3}{2}-d} + C\bar{\rho}^{d-1}h^{1-d} + C\varepsilon^{d-1}h^{1-d} \qquad \forall T \ge \epsilon_0\ \forall \tau\colon |\tau| < \epsilon_2 T^{-2\alpha/(1+\alpha)} \tag{1.13}$$

for $\epsilon_1 \le T \le T^* := \epsilon_1 R^{1/(1+\alpha)}$ *with* $\bar{\rho}$ *defined by* (1.4).

Furthermore, as $0 < \alpha \le \frac{1}{2}$ *one can skip the first term in the right-hand expression of* (1.13).

Remark 1.11. Here we need assumptions (1.1)–(1.3) twice:

(i) In $B(0,2)$ with small parameter ε to estimate the contribution to the left-hand expression of (2.44) with χ_T replaced by $\chi_T^{\pm}$ of zone

$$\{\xi\colon |x\times\xi| \le \bar{\rho},\ \pm\langle x,\xi\rangle < 0\}$$

where singularities propagate first towards 0,

(ii) In $B(0,R)$ with the small constant ϵ_2 and $R \gg 1$ to ensure that the singularities propagating away from 0 will continue this until time T^*.

(iii) If the my conjecture (see Remark 1.6(iii)) is correct, then for generic perturbations with $\varepsilon \ge h$ one can replace the first term in the right-hand expression of (1.13) by $Ch^{(1-d)/2}\varepsilon^{1-d/2}$. This improvement will be carried out to estimates (1.14) and (2.4).

Standard Tauberian arguments imply

Corollary 1.12. *Consider operator* (0.2). *Let assumptions of Proposition 1.10 be fulfilled. Then for* x: $|x| = 1$

$$|e_h(x,x,0) - e^{\mathsf{T}}_{T_*,h}(x,x,0)| \le CT^{*-1}h^{1-d} + Ch^{\frac{3}{2}-d} + C\bar\rho^{d-1}h^{1-d} + C\varepsilon^{d-1}h^{1-d} \tag{1.14}$$

with the Tauberian expression (3.4), $T^* = \epsilon_1 R^{1/(1+\alpha)}$ *and arbitrarily small constant* $T_* > 0$.

Furthermore, as $0 < \alpha \le \frac{1}{2}$ *one can skip the second term in the right-hand expression of* (1.14).

Proof of Theorem 2.1(ii), (iv). Now standard scaling and setting $\varepsilon = C_0 r^\beta$ imply estimate (2.4) (that is Theorem 2.1(ii)).

Furthermore, we see that as $0 < \alpha \le \frac{1}{2}$ one can skip the first term in the right-hand expression of this estimate (that is, part of Theorem 2.1(iv)). □

Remark 1.13. We know that for $|x| \asymp 1$ and small enough constant $T_* > 0$ and $|x| = 1$

$$e^{\mathsf{T}}_{T_*,h}(x,x,\tau) = e^{\mathsf{W}}_h(x,x,\tau) + O(h^{2-d} + \varepsilon h^{1-d}) \tag{1.15}$$

with the Weyl expression

$$e^{\mathsf{W}}_h(x,x,0) = (2\pi h)^{-d}\varpi_d g(x)^{-\frac{1}{2}}(2(\tau - V(x))^{\frac{d}{2}}, \qquad g = \det(g^{jk}). \tag{1.16}$$

Now standard scaling and setting $\varepsilon = C_0 r^\beta$ imply estimate (2.7) (that is Remark 2.2(i)).

2 Perturbations of $e_h(x,y,0)$

Let us denote unperturbed operator as A^0_h and corresponding spectral function and propagator as $e^0_h(x,y,\tau)$ and $u^0_h(x,y,t)$.

Consider in the framework of Proposition 1.10 for $|x| \asymp |y| \asymp 1$

$$F_{t\to h^{-1}\tau}\bigl(\bar\chi_T(t)u_h(x,y,t)\bigr) = F_{t\to h^{-1}\tau}\bigl(\bar\chi_{T'}(t)u_h(x,y,t)\bigr) + F_{t\to h^{-1}\tau}\bigl((\bar\chi_T(t) - \bar\chi_{T'}(t))u_h(x,y,t)\bigr) \tag{2.1}$$

with $T = T^* = C_0$ and $T' = T_* = \epsilon_0$ and corresponding formula for A^0_h and $u^0_h(x,y,t)$.

Let us integrate both by τ and multiply by h^{-1}. Then taking the difference we arrive to

$$e^{\mathsf{T}}_{T,h}(x,y,\tau) - e^{0,\mathsf{T}}_{T,h}(x,y,\tau) = e^{\mathsf{T}}_{T',h}(x,y,\tau) - e^{0,\mathsf{T}}_{T',h}(x,y,\tau) + h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau'}\Big(\big(\bar{\chi}_T(t)-\bar{\chi}_{T'}(t)\big)\big(u_h(x,y,t)-u^0_h(x,y,t)\big)\Big)\,d\tau'. \tag{2.2}$$

Proposition 2.1. *Consider operator* (0.2). *Assume that* (1.1)–(1.3) *are fulfilled in* $B(0,2)$. *Then for* $|x|=1$ *and arbitrarily small constant* T'

$$|e^{\mathsf{T}}_{T',h}(x,y,\tau) - e^{0,\mathsf{T}}_{T',h}(x,y,\tau) - e^{\mathsf{W}}_{h}(x,y,\tau) + e^{0,\mathsf{W}}_{h}(x,y,\tau)| \le C\varepsilon h^{2-d} + C'h^{s} \qquad \forall \tau\colon |\tau|\le \epsilon. \tag{2.3}$$

Proof. Let $A'_h = \varepsilon^{-1}(A_h - A^0_h)$. Then $A_h \coloneqq A_{\varepsilon,h} = A^0_h + \varepsilon A'_h$ and ecomposition

$$e^{\mathsf{T}}_{T',h}(x,y,\tau) \sim \sum_{m\ge 0} \varkappa_m(x,\varepsilon,\tau) h^{-d+2m} \tag{2.4}$$

and similar decomposition for $e^{0\mathsf{T}}_{T',h}(x,y,\tau)$ together with

$$\varkappa_m(x,\varepsilon,\tau) \sim \sum_{j\ge 0} \kappa_{m,j}(x,\tau)\varepsilon^{j} \tag{2.5}$$

imply (2.3). □

Proposition 2.2. *Consider operator* (0.2). *Assume that* (1.1)–(1.3) *with small parameter* $\varepsilon \le h$ *are fulfilled in* $B(0,2)$. *Also assume that the same assumptions albeit with* ε *replaced by* ϵ_2 *which is a small constant are fulfilled in* $B(0,R)$ *with* R. *Then for* $|x|=1$,

$$|h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau'}\Big(\big(\bar{\chi}_T(t)-\bar{\chi}_{T'}(t)\big)\big(u_h(x,y,t)-u^0_h(x,y,t)\big)\big|_{y=x}\Big)\,d\tau'| \le C\varepsilon h^{\frac12-d} + C\varepsilon\bar{\rho}^{d-1}h^{-d} + C'h^{s} \tag{2.6}$$

for $\epsilon_1 \le T \le T^* \coloneqq \epsilon_1 R^{1/(1+\alpha)}$ *with* $\bar{\rho}$ *defined by* (1.4).

Furthermore, as $0<\alpha\le \frac12$ *one can skip the first term in the right-hand expression of* (2.6).

Proof. (i) Let $Q = q^{\mathrm{w}}(x, hD)$ be an operator with the symbol supported in $\{x\colon 1-\epsilon_3 \le |x| \le 1+\epsilon_3,\ |x\times\xi| \ge \epsilon_3\}$. Then

$$h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau'}\Big((\bar\chi_T(t)-\bar\chi_{T'}(t))u_h(x,y,t)\,{}^tQ_y\big|_{y=x}\Big)\,d\tau' \sim \sum_k\sum_{m\ge 0} e^{ih^{-1}\varphi_k(x,\varepsilon,\tau)}\varkappa_{k,m}(x,\varepsilon,\tau)h^{\frac{3}{2}-d+m} \tag{2.7}$$

and the same is true for $u_h^0(x,y,t)$. Moreover

$$\varphi_k(x,\varepsilon,\tau)\sim\sum_{j\ge 0}\phi_{k,j}(x,\tau)\varepsilon^j,\qquad \varkappa_{k,m}(x,\varepsilon,\tau)\sim\sum_{j\ge 0}\kappa_{k,m,j}(x,\tau)\varepsilon^j \tag{2.8}$$

and therefore the difference between expression (2.7) and (2.7) with $\varepsilon = 0$ does not exceed $C\varepsilon h^{\frac12-d}+C'h^s$.

(ii) Let $Q = q^{\mathrm{w}}(x, hD)$ be an operator with the symbol supported in $\{x\colon 1-\epsilon_3 \le |x| \le 1+\epsilon_3,\ \bar\rho \le |x\times\xi| \le \epsilon_3\}$. Then the same expressions are $O(h^s)$.

(iii) Finally, let $Q = q^{\mathrm{w}}(x, hD)$ be an operator with the symbol supported in $\{x\colon 1-\epsilon_3 \le |x| \le 1+\epsilon_3,\ |x\times\xi| \le \bar\rho\}$. Then from the standard perturbation method[1)] follows that

$$|h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau'}\Big((\bar\chi_T(t)-\bar\chi_{T'}(t))\big(u_h(x,y,t)-u_h^0(x,y,t)\big)\,{}^tQ_y\big|_{y=x}\Big)\,d\tau'|$$

does not exceed $C\varepsilon h^{-1}\times\bar\rho^{d-1}h^{1-d}$ which is the second term in the right-hand expression of (2.6). □

Corollary 2.3. *Let $\varepsilon \le h$. Then*

$$|h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau'}\Big((\bar\chi_T(t)-\bar\chi_{T'}(t))\big(u_h(x,y,t)-u_h^0(x,y,t)\big)\big|_{y=x}\Big)\,d\tau'| \le C\varepsilon h^{2-d}+C\varepsilon h^{\frac12-d}+C\varepsilon\bar\rho^{d-1}h^{-d}+C'h^s. \tag{2.9}$$

Furthermore, as $0<\alpha\le\frac12$ one can skip the second term in the right-hand expression of (2.9).

[1)] See [Ivr2].

Conjecture 2.4. *Estimate (2.3) and (2.6) hold without $C'h^s$ in their right-hand expression.*

Proof of Theorem 2.1(iii), (iv). Now standard scaling and setting $\varepsilon = C_0 r^\beta$ imply estimate (2.6) (that is Theorem 2.1(iii)).

Furthermore, we see that as $0 < \alpha \le \frac{1}{2}$ one can skip the first term in the right-hand expression of this estimate (that is, remaining part of Theorem 2.1(iv)). □

3 Near singularity

Now we need to investigate zone $\{x\colon |x| \le r_* = h^{1/(1-\alpha)-\delta}\}$ which we divide into non-semiclassical subzone $\{x\colon |x| \le \bar r = h^{1/(1-\alpha)}\}$ and intermediate subzone $\{x\colon \bar r \le |x| \le r_*\}$.

3.1 Non-semiclassical subzone

Proposition 3.1. *As $|x| \le \bar r$, $|y| \le \bar r$ and $\tau \le C_0 \bar r^{-2}$*

$$|e_h(x,y,0)| \le C\bar r^{-d} \tag{3.1}$$

and

$$|e_h(x,y,0) - e_h^0(x,y,0)| \le C\bar r^{\beta-d} \tag{3.2}$$

Proof. (i) Let $E_h(\tau)$ be a spectral projector of A_h. Then $\|E_h(\tau)f\|_{\mathcal{L}^2} \le \|f\|_{\mathcal{L}^2}$. Then $\|A_h E_h(\tau)\| \le |\tau|$ implies that for $\tau \le c\bar r^{-2}$, $\hbar \asymp 1$ and $\|f\|_{\mathscr{L}^2} = 1$

$$\|DE_h(\tau)f\|_{\mathscr{L}^2} \le C\bar r^{-1} \tag{3.3}$$

which in virtue Sobolev inequality implies that

(a) $d = 1 \implies \|E_h(\tau)f\|_{\mathscr{C}} \le C\bar r^{-\frac{1}{2}}$,

(b) $d \ge 2 \implies \|E_h(\tau)f\|_{\mathscr{L}^p} \le C\bar r^{-1}$ with any $p < \infty$ for $d = 2$ and $p = 2d/(d-2)$ for $d \ge 3$.

In the latter case using inequalities $\|Vv\|_{\mathscr{L}^q} \le C\|V\|_{\mathscr{L}^s}\|v\|_{\mathscr{L}^p}$ as $q^{-1} = s^{-1} + p^{-1}$ and $\|V\|_{\mathscr{L}^s(B(0,r))} \le Cr^{d/s-2\alpha}$ as $d/s > 2\alpha$ we upgrade (3.3) to

$$\|D^2 E_h(\tau)f\|_{\mathscr{L}^q} \le C\bar r^{-2} \tag{3.4}$$

which in virtue Sobolev inequality implies that

(c) $\|E_h(\tau)f\|_{\mathscr{C}} \le C\bar r^{-d/2}$ as either $d=2$ or $d\ge 3$ and $1/p<0$,

(d) $\|E_h(\tau)f\|_{\mathscr{L}^{p'}} \le C\bar r^{-d/2+d/p'}$ as $d\ge 3$ and $1/p'>0$

with $1/p'=1/p-\delta>0$ with δ which does not depend on p. Repeating these arguments we decrease $1/p$ until it becomes negative and arrive to $\|E_h(\tau)f\|_{\mathscr{C}} \le C\bar r^{-d/2}$ for all f with $\|f\|_{\mathscr{L}^2}=1$ which is equivalent to

$$\|e_h(x,y,\tau)\|_{\mathscr{L}^2_y} \le C\bar r^{-d/2} \qquad \forall x\in B(0,\bar r) \tag{3.5}$$

which implies (3.2).

(ii) Further, standard perturbation methods imply that

$$\|(E_h(\tau)-E_h^0(\tau))f\|_{\mathcal{L}^2(B(0,2\bar r))} \le C\varepsilon\|f\|_{\mathcal{L}^2} \quad \text{as} \quad \operatorname{supp}(f)\subset B(0,2\bar r)$$

with $\varepsilon=\bar r^{\beta}$.

Then applying standard perturbation arguments[1)] and combining with arguments of Part (i) of the proof one can prove that

(e) $\|\big(E_h(\tau)-E_h^0(\tau)\big)f\|_{\mathscr{C}} \le C\bar r^{\beta-\frac12}$as either $d=1$,

(f) $\|\big(E_h(\tau)-E_h^0(\tau)\big)f\|_{\mathscr{C}} \le C\varepsilon\bar r^{\beta-d/2}$ as either $d=2$ or $d\ge 3$ and $1/p<0$,

(g) $\|\big(E_h(\tau)-E_h^0(\tau)\big)f\|_{\mathscr{L}^{p'}} \le C\varepsilon\bar r^{\beta-d/2+d/p'}$ as $d\ge 3$ and $1/p'>0$

with $\varepsilon=C\bar r^{\beta}$.

Repeating these arguments we decrease $1/p$ until it becomes negative and arrive to $\|\big(E_h(\tau)-E_h^0(\tau)\big)f\|_{\mathscr{C}} \le C\bar r^{-d/2}$ for all f with $\|f\|_{\mathscr{L}^2}=1$ which is equivalent to

$$\|\big(e_h(x,y,\tau)-e_h^0(x,y,\tau)\big)\|_{\mathscr{L}^2_y} \le C\bar r^{\beta-d/2} \qquad \forall x\in B(0,\bar r) \tag{3.6}$$

which together with 3.5) for both $e_h(x,y,\tau)$ and $e_h^0(x,y,\tau)$ implies (3.3).

We leave details to the reader. □

3.2 Intermediate subzone

Remark 3.2. In the framework of Theorem 2.1 in the intermediate zone $\{x\colon \bar{r} \le |x| \le r_*\}$

(i) Estimates (2.2) and (2.3) with $r_*^{1+\alpha} \le T \le \epsilon_0$ remain true.

(ii) Estimates

$$|e^{\mathsf{T}}_{T,h}(x,x,0) - e^{\mathsf{T}}_{T'',h}(x,x,0)| \le Ch^{-d+s} r^{-\alpha d-(1-\alpha)s} \tag{3.7}$$

and

$$|e^{\mathsf{T}}_{T,h}(x,x,0) - e^{0\mathsf{T}}_{T,h}(x,x,0) - e^{\mathsf{T}}_{T',h}(x,x,0) + e^{0\mathsf{T}}_{T',h}(x,x,0)| \le Ch^{-d+s} r^{-\alpha d-(1-\alpha)s+\beta} \tag{3.8}$$

with $T' = C_0 r^{1+\alpha}$ follow from the similar estimates by rescaling.

(iii) Estimates (2.4) and (2.6) with $T' = \epsilon_0 r^{1+\alpha}$ follow from the same estimates by rescaling.

(iv) Furthermore, as $0 < \alpha \le \frac{1}{2}$ corresponding terms in the right-hand expressions could be skipped.

(v) Estimates (2.7) and (2.8) with $T' = \epsilon_0 r^{1+\alpha}$ follow from the same estimates by rescaling.

100 years of Weyl's Law

Victor Ivrii

July 9, 2023

Abstract

We discuss the asymptotics of the eigenvalue counting function for partial differential operators and related expressions paying the most attention to the sharp asymptotics. We consider Weyl asymptotics, asymptotics with Weyl principal parts and correction terms and asymptotics with non-Weyl principal parts. Semiclassical microlocal analysis, propagation of singularities and related dynamics play crucial role.

We start from the general theory, then consider Schrödinger and Dirac operators with the strong magnetic field and, finally, applications to the asymptotics of the ground state energy of heavy atoms and molecules with or without a magnetic field.

1 Introduction

A Bit of History

In 1911, Hermann Weyl, who at that time was a young German mathematician specializing in partial differential and integral equations, proved the following remarkable asymptotic formula describing distribution of (large) eigenvalues of the Dirichlet Laplacian in a bounded domain $X \subset \mathbb{R}^d$:

$$\mathsf{N}(\lambda) = (2\pi)^{-d}\omega_d \,\mathsf{vol}(X)\lambda^{d/2}(1+o(1)) \qquad \text{as} \quad \lambda \to +\infty, \tag{1.1}$$

where $\mathsf{N}(\lambda)$ is the number of eigenvalues of the (positive) Laplacian, which are less than λ [1)], ω_d is a volume of the unit ball in $\mathbb{R}^d$, $\mathsf{vol}(X)$ is the

[1)] $\mathsf{N}(\lambda)$ is called the *eigenvalue counting function*.

volume of X. This formula was actually conjectured independently by Arnold Sommerfeld [Som] and Hendrik Lorentz [Lor] in 1910 who stated the *Weyl's Law* as a conjecture based on the book of Lord Rayleigh "The Theory of Sound" (1887) (for details, see [ANPS]).

H. Weyl published several papers [2–5, W1](1911–1915) devoted to the eigenvalue asymptotics for the Laplace operator (and also the elasticity operator) in a bounded domain with regular boundary. In [W4], he published what is now known as *Weyl's conjecture*

$$\mathsf{N}(\lambda) = (2\pi)^{-d}\omega_d \,\mathsf{vol}(X)\lambda^{d/2} \mp \frac{1}{4}(2\pi)^{1-d}\omega_{d-1}\,\mathsf{vol}'(\partial X)\lambda^{(d-1)/2} \quad \text{as} \quad \lambda \to +\infty \tag{1.2}$$

for Dirichlet and Neumann boundary conditions respectively where $\mathsf{vol}'(\partial X)$ is the $(d-1)$-dimensional volume of $\partial X \in \mathscr{C}^\infty$. Both these formulae appear in the toy-model of a rectangular box $X = \{0 < x_1 < a_1, \dots, 0 < x_d < a_d\}$ and then $\mathsf{N}(\lambda)$ is the number of integer lattice points in the part of ellipsoid $\{z_1^2/a_1^2 + \dots + z_d^2/a_d^2 < \pi^2\lambda\}$ with $z_j > 0$ and $z_j \ge 0$ for Dirichlet and Neumann boundary conditions respectively[2)].

After his pioneering work, a huge number of papers devoted to spectral asymptotics were published. Among the authors were numerous prominent mathematicians.

After H. Weyl, the next big step was made by Richard Courant [Cour](1920), who further developed the variational method and recovered the remainder estimate $O(\lambda^{(d-1)/2}\log\lambda)$. The variational method was developed further by many mathematicians, but it lead to generalizations rather than to getting sharp remainder estimates and we postpone its discussion until Section 3. Here we mention only Mikhail Birman, Elliott Lieb and Barry Simon and their schools.

The next development was due to Torsten Carleman [C1, C2](1934, 1936) who invented the *Tauberian method* and was probably the first to consider an arbitrary spacial dimension (H. Weyl and R. Courant considered only dimensions 2 and 3) followed by Boris Levitan [Lev1](1952) and V. G. Avakumovič [Av](1956) who, applied *hyperbolic operator method* (see Section 1) to recover the remainder estimate $O(\lambda^{(d-1)/2})$, but only for closed manifolds and also for $e(x, x, \lambda)$ away from the boundary[3)].

[2)] Finding sharp asymptotics of the number of the lattice points in the inflated domain is an important problem of the number theory.

[3)] Where here and below $e(x, y, \lambda)$ is the Schwartz kernel of the spectral projector.

After this, Lars Hörmander [Hör1, Hör2](1968, 1969) applied Fourier integral operators in the framework of this method. Hans Duistermaat and Victor Guillemin [DG](1975) recovered the remainder estimate $o(\lambda^{(d-1)/2})$ under the assumption that

(1.3) The set of all periodic geodesics has measure 0

observing that for the sphere neither this assumption nor (1.2) hold. Here, we consider the phase space T^*X equipped with the standard measure $dxd\xi$ where X is a manifold[4]. This was a very important step since it connected the sharp spectral asymptotics with classical dynamics.

The main obstacle was the impossibility to construct the parametrix of the hyperbolic problem near the boundary[5]. This obstacle was partially circumvented by Robert Seeley [See1, See2](1978, 1980) who recovered remainder estimate $O(\lambda^{(d-1)/2})$; his approach we will consider in Subsection 4. Finally the Author [Ivr1](1980), using very different approach, proved (1.2) under assumption that

(1.4) The set of all periodic geodesic billiards has measure 0,

which obviously generalizes (1.3). Using this approach, the Author in [Ivr2] (1982) proved (1.1) and (1.2) for elliptic systems on manifolds without boundary; (1.2) was proven under certain assumption similar to (1.3).

The new approaches were further developed during the 35 years to follow and many new ideas were implemented. The purpose of this article is to provide a brief and rather incomplete survey of the results and techniques. Beforehand, let us mention that the field was drastically transformed.

First, at that time, in addition to the problem that we described above, there were similar but distinct problems which we describe by examples:

(b) Find the asymptotics as $\lambda \to +\infty$ of $\mathsf{N}(\lambda)$ for the Schrödinger operator $\Delta + V(x)$ in $\mathbb{R}^d$ with potential $V(x) \to +\infty$ at infinity;

(c) Find the asymptotics as $\lambda \to -0$ of $\mathsf{N}(\lambda)$ for the Schrödinger operator in $\mathbb{R}^d$ with potential $V(x) \to -0$ at infinity (decaying more slowly than $|x|^{-2}$);

[4] In fact the general scalar pseudodifferential operator and Hamiltonian trajectories of its principal symbol were considered.

[5] Or even inside for elliptic systems with the eigenvalues of the principal symbol having the variable multiplicity.

(d) Find the asymptotics as $h \to +0$ of $\mathsf{N}^-(h)$ the number of the negative eigenvalues for the Schrödinger operator $h^2\Delta + V(x)$.

These four problems were being studied separately albeit by rather similar methods. However, it turned out that the latter problem (d) is more fundamental than the others which could be reduced to it by the variational *Birman-Schwinger principle*.

Second, we should study the *local semiclassical spectral asymptotics*, i.e. the asymptotics of $\int e(x,x,0)\psi(x)\,dx$ where $\psi \in \mathscr{C}_0^\infty$ supported in the ball of radius 1 in which[6] V is of magnitude 1[7]. By means of scaling we generalize these results for ψ supported in the ball of radius γ in which[6] V is of magnitude ρ with $\rho\gamma \ge h$ because in scaling $h \mapsto h/\rho\gamma$. Then in the general case we apply partition of unity with *scaling functions* $\gamma(x)$ and $\rho(x)$.

Third, in the *singular zone* $\{x : \rho(x)\gamma(x) \le h\}$b we can apply variational estimates and combine them with the semiclassical estimates in the *regular zone* $\{x : \rho(x)\gamma(x) \ge h\}$. It allows us to consider domains and operators with singularities.

Some further developments will be either discussed or mentioned in the next sections. Currently, I am working on the Monster book [Ivr4] which summarizes this development. It is almost ready and is available online and we will often refer to it for details, exact statements and proofs.

Finally, I should mention that in addition to the variational methods and method of hyperbolic operator, other methods were developed: other Tauberian methods (like the method of the heat equation or the method of resolvent) and the almost-spectral projector method [ST]. However, we will neither use nor even discuss them; for survey of different methods, see [RSS].

Method of the Hyperbolic Operator

The method of the hyperbolic operator is one of the Tauberian methods proposed by T. Carleman. Applied to the Laplace operator, it was designed as follows: let $e(x,y,\lambda)$ be the Schwartz kernel of a spectral projector and

[6] Actually, in the proportionally larger ball.

[7] Sometimes, however, we consider *pointwise semiclassical spectral asymptotics*, i.e. asymptotics of $e(x,x,0)$.

let

$$u(x,y,t)=\int_0^\infty \cos(\lambda t)\, d_\lambda e(x,y,\lambda^2); \tag{1.5}$$

observe, that now λ^2 is the spectral parameter. Then, $u(x,y,t)$ is a *propagator* of the corresponding wave equation and satisfies

$$u_{tt}+\Delta u=0, \tag{1.6}$$

$$u|_{t=0}=\delta(x-y),\quad u|_{t=0}=0 \tag{1.7}$$

(recall that Δ is a positive Laplacian).

Now we need to construct the solution of (1.6)–(1.7) and recover $e(x,y,t)$ from (1.5). However, excluding some special cases, we can construct the solution $u(x,y,t)$ only modulo smooth functions and only for $t: |t|\le T$, where usually T is a small constant. It leads to

$$F_{t\to\tau}\big(\bar\chi_T(t)u(x,x,t)\big)=T\int \widehat{\bar\chi}((\lambda-\tau)T)\, d_\lambda e(x,x,\lambda^2)= c_0(x)\lambda^{d-1}+c_1(x)\lambda^{d-2}+O(\lambda^{d-3}) \tag{1.8}$$

where F denotes the Fourier transform, $\bar\chi\in \mathscr{C}_0^\infty(-1,1)$, $\bar\chi(0)=1$, $\bar\chi'(0)=0$ and $\bar\chi_T(t)=\bar\chi(t/T)$ [8].

Then using Hörmander's Tauberian theorem[9], we can recover

$$e(x,x,\lambda^2)=c_0(x)d^{-1}\lambda^d+O(\lambda^{d-1}T^{-1}). \tag{1.9}$$

To get the remainder estimate $o(\lambda^{d-1})$ instead, we need some extra arguments. First, the asymptotics (1.8) holds with a cut-off:

$$F_{t\to\tau}\big(\bar\chi_T(t)(Q_x u)(x,x,t)\big)=T\int \widehat{\bar\chi}((\lambda-\tau)T)\, d_\lambda (Q_x e)(x,x,\lambda^2)= c_{0Q}(x)\lambda^{d-1}+c_{1Q}(x)\lambda^{d-2}+O_T(\lambda^{d-3}) \tag{1.10}$$

where $Q_x=Q(x,D_x)$ is a 0-order pseudo-differewntial operator (acting with respect to x only, before we set $x=y$; and $T=T_0$ is a small enough constant. Then the Tauberian theory implies that

$$(Q_x e)(x,x,\lambda^2)=c_{0Q}(x)d^{-1}\lambda^d+c_{1Q}(x)(d-1)^{-1}\lambda^{d-1}+ O\big(\lambda^{d-1}T^{-1}\mu(\operatorname{supp}(Q))\big)+o_{Q,T}\big(\lambda^{d-1}\big) \tag{1.11}$$

[8] In fact, there is a complete decomposition.

[9] Which was already known to Boris Levitan.

where $\mu = \frac{dxd\xi}{dg}$ is a natural measure on the *energy level surface* $\Sigma = \{(x,\xi) : g(x,\xi) = 1\}$ and we denote by $\mathsf{supp}(Q)$ the support of the symbol $Q(x,\xi)$.

On the other hand, propagation of singularities (which we discuss in more details later) implies that if for any point $(x,\xi) \in \mathsf{supp}(Q)$ geodesics starting there are not periodic with periods $\le T$ then asymptotics (1.10) and (1.11) hold with T.

Now, under the assumption (1.4), for any $T \ge T_0$ and $\varepsilon > 0$, we can select Q_1 and Q_2, such that $Q_1 + Q_2 = I$, $\mu(\mathsf{supp}(Q_1)) \le \varepsilon$ and for $(x,\xi) \in \mathsf{supp}(Q_2)$ geodesics starting from it are not periodic with periods $\le T$. Then, combining (1.11) with Q_1, T_0 and with Q_2, T, we arrive to

$$e(x,x,\lambda^2) = c_0(x)d^{-1}\lambda^d + c_1(x)(d-1)^{-1}\lambda^{d-1} + O\big(\lambda^{d-1}(T^{-1}+\varepsilon)\big) + o_{\varepsilon,T}(\lambda^{d-1}) \tag{1.12}$$

with arbitrarily large T and arbitrarily small $\varepsilon > 0$ and therefore

$$e(x,x,\lambda^2) = c_0(x)d^{-1}\lambda^d + c_1(d-1)^{-1}\lambda^{d-1} + O(\lambda^{d-1}T^{-1}). \tag{1.13}$$

holds. In these settings, $c_1 = 0$.

More delicate analysis of the propagation of singularities allows under certain very restrictive assumptions to the geodesic flow to boost the remainder estimate to $O(\lambda^{d-1}/\log\lambda)$ and even to $O(\lambda^{d-1-\delta})$ with a sufficiently small exponent $\delta > 0$.

2 Local Semiclassical Spectral Asymptotics

Asymptotics Inside the Domain

As we mentioned, the approach described above was based on the representation of the solution $u(x,y,t)$ by an oscillatory integral and does not fare well in (i) domains with boundaries because of the trajectories tangent to the boundary and (ii) for matrix operators whose principal symbols have eigenvalues of variable multiplicity. Let us describe our main method. We start by discussing matrix operators on closed manifolds.

So, let us consider a self-adjoint elliptic matrix operator $A(x,D)$ of order m. For simplicity, let us assume that this operator is semibounded from below and we are interested in $N(\lambda)$, the number of eigenvalues not exceeding λ, as $\lambda \to +\infty$. In other words, we are looking for the number $\mathsf{N}^-(h)$ of

negative eigenvalues of the operator $\lambda^{-1}A(x,D) - I = H(x,hD,h)$ with $h = \lambda^{-1/m}$ [10].

Propagation of Singularities

Thus, we are now dealing with the semiclassical asymptotics. Therefore, instead of individual functions, we should consider families of functions depending on the *semiclassical parameter* h [11] and we need a *semiclassical microlocal analysis*. We call such family *temperate* if $\|u_h\| \le Ch^{-M}$ where $\|\cdot\|$ denotes usual $\mathscr{L}^2$-norm.

We say that $u := u_h$ is *s-negligible* at $(\bar{x},\bar{\xi}) \in T^*\mathbb{R}^d$ if there exists a symbol $\phi(x,\xi)$, $\phi(\bar{x},\bar{\xi}) = 1$ such that $\|\phi(x,hD)u_h\| = O(h^s)$. We call the *wave front set of* u_h the set of points at which u_h is not negligible and denote by $\mathsf{WF}^s(u_h)$; this is a closed set. Here, $-\infty < s \le \infty$.

Our first result is rather trivial: if $P = P(x,hD,h)$,

$$WF^s(u) \subset WF^s(Pu) \cup \mathsf{Char}(P) \tag{2.1}$$

where $\mathsf{Char}(P) = \{(x,\xi), \det P^0(x,\xi) = 0\}$; we call $P^0(x,\xi) := P(x,\xi,0)$ the *principal symbol* of P and $\mathsf{Char}(P)$ the *characteristic set* of L.

We need to study the propagation of singularities (wave front sets). To do this, we need the following definition:

Definition 2.1. Let P^0 be a Hermitian matrix. Then P is *microhyperbolic at* (x,ξ) *in the direction* $\ell \in T(T^*\mathbb{R}^d)$, $|\ell| \asymp 1$ if

$$\langle (\ell P^0)(x,\xi)v, v\rangle \ge \epsilon|v|^2 - C|P^0(x,\xi)v|^2 \qquad \forall v \tag{2.2}$$

with constants $\epsilon, C > 0$ [12].

Then we have the following statement which can be proven by the *method of the positive commutator*:

Theorem 2.2. *Let $P = P(x,hD,h)$ be an h-pseudodifferential operator with a Hermitian principal symbol. Let $\Omega \Subset T^*\mathbb{R}^d$ and let $\phi_j \in \mathscr{C}^\infty$ be real-valued functions such that P is microhyperbolic in Ω in the directions $\nabla^{\#}\phi_j$,*

[10] If operator is not semi-bounded we consider the number of eigenvalues in the interval $(0,\lambda)$ (or $(-\lambda,0)$) which could be reduced to the asymptotics of the number of eigenvalues in the interval $(-1,0)$ (or $(0,1)$) of $H(x,hD,h)$.

[11] Which in quantum mechanics is called Planck constant and usually is denoted by $\hbar$.

[12] Here and below ℓP^0 in is the action of the vector field ℓ upon P^0.

$j = 1, \dots, J$ *where* $\nabla^{\#}\phi = \langle(\nabla_\xi\phi), \nabla_x\rangle - \langle(\nabla_x\phi), \nabla_\xi\rangle$ *is the Hamiltonian field generated by* ϕ.

Let u *be tempered and suppose that*

$$\mathrm{WF}^{s+1}(Pu) \cap \Omega \cap \{\phi_1 \le 0\} \cap \dots \cap \{\phi_J \le 0\} = \emptyset, \tag{2.3}$$

$$\mathrm{WF}^{s}(u) \cap \partial\Omega \cap \{\phi_1 \le 0\} \cap \dots \cap \{\phi_J \le 0\} = \emptyset. \tag{2.4}$$

Then,

$$\mathrm{WF}^{s}(u) \cap \Omega \cap \{\phi_1 \le 0\} \cap \dots \cap \{\phi_J \le 0\} = \emptyset. \tag{2.5}$$

Proof. This is Theorem 2.1.2 from [Ivr4]. See the proof and discussion there. □

The above theorem immediately implies:

Corollary 2.3. *Let* $H = H(x, hD, h)$ *be an* h*-pseudodifferential operator with a Hermitian principal symbol and let* $P = hD_t - H$. *Let us assume that*

$$|\partial_{x,\xi} H^0 v| \le C_0|v| + C|(H^0 - \bar\tau)v| \qquad \forall v. \tag{2.6}$$

Let $u(x, y, t)$ *be the Schwartz kernel of* $e^{ih^{-1}tH}$.

(i) For a small constant $T^* > 0$,

$$WF(u) \cap \{|t| \le T^*,\ \tau = \bar\tau\} \subset \{|x-y|^2 + |\xi+\eta|^2 \le (C_0 t)^2\}. \tag{2.7}$$

(ii) Assume that H *is microhyperbolic in some direction* $\ell = \ell(x, \xi)$ *at the point* (x, ξ) *at the energy level* $\bar\tau$ [13]. *Then for a small constant* $T^* > 0$,

$$WF(u) \cap \{0 \le \pm t \le T^*,\ \tau = \bar\tau\} \subset \{\pm(\langle \ell_x, x-y\rangle + \langle \ell_\xi, \xi+\eta\rangle) \ge \pm\epsilon_0 t\}. \tag{2.8}$$

Proof. It is sufficient to prove the above statements for $t \ge 0$. We apply Theorem 2.2 with

(i) $\phi_1 = t$ and $\phi_2 = t - C_0^{-1}(|x - \bar x|^2 + \epsilon^2)^{\frac12} + \varepsilon$,

(ii) $\phi_1 = t$ and $\phi_2 = \big(\langle \ell_x, x-y\rangle + \langle \ell_\xi, \xi+\eta\rangle\big) - \epsilon_0 t + \varepsilon$,

[13] Which means that $H - \bar\tau$ is microhyperbolic in the sense of Definition 2.1.

where $\varepsilon > 0$ is arbitrarily small. □

Corollary 2.4. *(i) In the framework of Corollary 2.3(ii) with $\ell = (\ell_x, 0)$, the inequality*

$$|F_{t\to h^{-1}\tau}\chi_T(t)(Q_{1x}u\,{}^tQ_{2y})(x,x,t)| \le C_s h^{-d}(h/|t|)^s \tag{2.9}$$

holds for all s, $\tau : |\tau - \bar\tau| \le \epsilon$, $h \le |t| \lesssim T \le T^*$ where $Q_{1x} = Q_1(x, hD_x)$, $Q_{2y} = Q_2(y, hD_y)$ are operators with compact supports, ${}^tQ_2$ is the dual rather than the adjoint operator and we write it to the right of the function, $\chi \in \mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1])$, $\chi_T(t) = \chi(t/T)$, and ϵ, T^* are small positive constants.

(ii) In particular, we get the estimate $O(h^s)$ as $T_* := h^{1-\delta} \le |t| \le T \le T^*$.

(iii) More generally, when $\ell = (\ell_x, \ell_\xi)$, the same estimates hold for the distribution $\sigma_{Q_1,Q_2}(t) = \int (Q_{1x}u\,{}^tQ_{2y})(x,x,t)\,dx$.

Proof. (i) If $t \asymp 1$, (2.9) immediately follows from Corollary 2.3(ii). Consider $t \asymp T$ with $h \le T \le T^*$ and make the rescaling $t \mapsto t/T$, $x \mapsto (x-y)/T$, $h \mapsto h/T$. We arrive to the same estimate (with $T^{-d}(h/T)^s$ in the right-hand expression where the factor T^{-d} is due to the fact that $u(x,y,t)$ is a density with respect to y). The transition from $|t| \asymp T$ to $|t| \lesssim T$ is trivial.

(ii) Statement (ii) follows immediately from Statement (i).

(iii) Statement (iii) follows immediately from Statements (i) and (ii) if we apply the metaplectic transformation $(x,\xi) \mapsto (x - B\xi, \xi)$ with a symmetric real matrix B. □

Therefore under the corresponding microhyperbolicity condition, we can construct $(Q_{1x}u\,{}^tQ_{2y})(x,x,t)$ or $\sigma_{Q_1,Q_2}(t)$ for $|t| \le T_*$ and then we automatically get it for $|t| \le T^*$. Since the time interval $|t| \le T_*$ is very short, we are able to apply the successive approximation method.

Successive Approximation Method

Let us consider the propagator $u(x,y,t)$. Recall that it satisfies the equations

$$(hD_t - H)u = 0, \tag{2.10}$$

$$u|_{t=0} = \delta(x-y)I \tag{2.11}$$

and therefore,

$$(hD_t - H)u^{\pm}\,{}^tQ_{2y} = \mp ih\delta(t)\delta(x-y)\,{}^tQ_{2y}, \tag{2.12}$$

where $u^{\pm} = u\theta(\pm t)$, θ is the Heaviside function, I is the unit matrix, $Q_{1x} = Q_1(x, hD_x)$, $Q_{2y} = Q_2(y, hD_y)$ have compact supports, ${}^tQ$ is the *dual operator*[14] and we write operators with respect to y on the right from u in accordance with the notations of matrix theory.

Then,

$$(hD_t - \bar{H})u^{\pm}\,{}^tQ_{2y} = H'u \mp ih\delta(t)\delta(x-y)\,{}^tQ_{2y}I \tag{2.13}$$

with $\bar{H} = H(y, hD_x, 0)$ obtained from H by freezing $x = y$ and skipping lower order terms and $H' = H'(x, y, hD_x, h) = H - \bar{H}$. Therefore,

$$u^{\pm}\,{}^tQ_{2y} = \bar{G}^{\pm}ihH'u^{\pm}\,{}^tQ_{2y} \pm ih\bar{G}^{\mp}\delta(t)\delta(x-y)\,{}^tQ_{2y}I. \tag{2.14}$$

Iterating, we conclude that

$$u^{\pm}\,{}^tQ_{2y} = \sum_{0\le n\le N-1} (\bar{G}^{\pm}ihH')^n \bar{u}^{\pm}\,{}^tQ_{2y} + (\bar{G}^{\pm}ihH')^N u^{\pm}\,{}^tQ_{2y}, \tag{2.15}$$

$$\bar{u}^{\pm} = \mp ih\bar{G}^{\pm}\delta(t)\delta(x-y)\,{}^tQ_{2y}I \tag{2.16}$$

where $\bar{G}^{\pm}$ is a parametrix of the problem

$$(ihD_t - \bar{H})v = f, \qquad \operatorname{supp}(v) \subset \{\pm t \ge 0\} \tag{2.17}$$

and $G^{\pm}$ is a parametrix of the same problem problem albeit for H.

Observe that

$$H' = \sum_{1\le|\alpha|+m\le N-1} (x-y)^{\alpha}h^m R_{\alpha,m}(y, hD_x) + \sum_{|\alpha|+m=N} (x-y)^{\alpha}h^m R_{\alpha,m}(x, y, hD_x); \tag{2.18}$$

therefore due to the finite speed of propagation, its norm does not exceed CT as long as we only consider strips $\Pi_T^{\pm} := \{0 \le \pm t \le T\}$. Meanwhile, due to the Duhamel's integral, the operator norms of $G^{\pm}$ and $\bar{G}^{\pm}$ from $\mathscr{L}^2(\Pi_T^{\pm})$ to $\mathscr{L}^2(\Pi_T^{\pm})$ do not exceed $Ch^{-1}T$ and therefore each next term in the successive

[14] I.e. ${}^tQv = (Q^*v^{\dagger})^{\dagger}$ where $v^{\dagger}$ is the complex conjugate to v.

approximations (2.15) acquires an extra factor $Ch^{-1}T^2 = O(h^\delta)$ as long as $T \le h^{\frac12(1+\delta)}$ and the remainder term is $O(h^s)$ if N is large enough.

To calculate the terms of the successive approximations, let us apply h-Fourier transform $F_{(x,t)\to h^{-1}(\xi,\tau)}$ with $\xi \in \mathbb{R}^d$, $\tau \in \mathbb{C}_\mp := \{\tau : \mp \operatorname{Im}\tau > 0\}$ and observe that $\delta(t)\delta(x-y) \mapsto (2\pi)^{-d-1}e^{-ih^{-1}\langle y,\eta\rangle}$, ${}^tQ_{2y}$ and $R_{\alpha,m}$ become multiplication by $Q_2(y,\eta)$ and $R_{\alpha,m}(y,\xi)$ respectively, and $\bar G^\pm$ becomes multiplication by $(\tau - H^0(y,\xi))^{-1}$. Meanwhile, $(x_j - y_j)$ becomes $-ih\partial_{\xi_j}$.

Therefore the right-hand expression of (2.15) without the remainder term becomes a sum of terms $\mp i\mathcal{F}_m(y,\xi,\tau)h^{m+1}e^{-ih^{-1}\langle y,\eta\rangle}$ with $m \ge 0$ and $\mathcal{F}_m(y,\xi,\tau)$ the sum of terms of the type

$$(\tau - H^0(y,\xi))^{-1}b_*(y,\xi)(\tau - H^0(y,\xi))^{-1}b_*(y,\xi)\cdots b_*(y,\xi)\times (\tau - H^0(y,\xi))^{-1}Q_2(y,\eta) \tag{2.19}$$

with no more than $2m+1$ factors $(\tau - H^0(y,\xi))^{-1}$. Here, the b_* are regular symbols. In particular,

$$\mathcal{F}_0(y,\xi,\tau) = (2\pi)^{-d-1}(\tau - H^0(y,\xi))^{-1}Q_2(y,\eta). \tag{2.20}$$

If we add the expressions for u^+ and u^- instead of $\mathcal{F}_m(y,\xi,\tau)$ with $\tau \in \mathbb{C}_\mp$, we get the distributions $\bigl(\mathcal{F}_m(y,\xi,\tau+i0) - \mathcal{F}_m(y,\xi,\tau-i0)\bigr)$ with $\tau \in \mathbb{R}$.

Applying the inverse h-Fourier transform with respect to x, operator Q_{1x}, and setting $x = y$, we cancel the factor $e^{-ih^{-1}\langle y,\eta\rangle}$ and gain a factor of h^{-d}. Thus we arrive to the Proposition 2.5(i) below; applying Corollary 2.4(ii) and (iii), we arrive to its Statements (ii) and (iii). We also need to use

$$u(x,y,t) = \int e^{ih^{-1}t\tau}\, d_\tau e(x,y,\tau). \tag{2.21}$$

Proposition 2.5. *(i) As* $T_* = h^{1-\delta} \le T \le h^{\frac12+\delta}$ *and* $\bar\chi \in \mathscr{C}_0^\infty([-1,1])$

$$T\int \widehat{\bar\chi}\bigl((\lambda-\tau)Th^{-1}\bigr)\, d_\tau(Q_{1x}e\,{}^tQ_{2y})(y,y,\tau) \sim \sum_{m\ge 0} h^{-d+m}T\int \widehat{\bar\chi}\bigl((\lambda-\tau)Th^{-1}\bigr)\kappa'_m(y,\tau)d\tau, \tag{2.22}$$

where $\widehat{\bar\chi}$ *is the Fourier transform of* $\bar\chi$ *and*

$$\kappa'_m(y) = \int \bigl(\mathcal{F}_m(y,\xi,\tau+i0) - \mathcal{F}_m(y,\xi,\tau-i0)\bigr)\, d\eta. \tag{2.23}$$

(ii) If H is microhyperbolic on the energy level $\bar\tau$ on $\mathsf{supp}(Q_2)$ in some direction ℓ with $\ell_x = 0$ then (2.21) *holds with $T_* \le T \le T^*$, $|\lambda - \bar\tau| \le \epsilon$, where T^* is a small constant.*

(iii) On the other hand, if $\ell_x \ne 0$, then (2.21) *still holds with $T \le T^*$, albeit only after integration with respect to y:*

$$T\int \widehat{\bar\chi}\big((\lambda-\tau)Th^{-1}\big)\,d_\tau\Big(\int (Q_{1x}e^{\,t}Q_{2y})(y,y,\tau)\,dy\Big) \sim \sum_{m\ge 0} h^{-d+m}T\int \widehat{\bar\chi}\big((\lambda-\tau)Th^{-1}\big)\varkappa'_m(\tau)\,d\tau \tag{2.24}$$

with

$$\varkappa'_m(\tau) = \iint \big(\mathcal{F}_m(y,\xi,\tau+i0) - \mathcal{F}_m(y,\xi,\tau-i0)\big)\,dyd\eta. \tag{2.25}$$

For details, proofs and generalizations, see Section 4.3 of [Ivr4].

Recovering Spectral Asymptotics

Let $\alpha(\tau)$ denote $(Q_{1x}e^{\,t}Q_{2y})(y,y,\tau)$ (which may be integrated with respect to y) and $\beta(\tau)$ denote the convolution of its derivative $\alpha'(\tau)$ with $T\widehat{\bar\chi}(\tau T/h)$. To recover $\alpha(\tau)$ from $\beta(\tau)$, we apply *Tauberian methods*. First of all, we observe that under the corresponding microhyperbolicity condition the distribution $\kappa'_m(y,\tau)$ or $\varkappa'_m(\tau)$ is smooth and the right-hand side expression of (2.22) or (2.24) does not exceed Ch^{-d+1}.

Let us take $Q_1 = Q_2$; then $\alpha(y,\tau)$ or $\alpha(\tau)$ is a monotone non-decreasing matrix function of τ. We choose a Hörmander function[15] $\bar\chi(t)$ and estimate the left-hand expressions of (2.22) or (2.24) from below by

$$\epsilon_0 T\big(\alpha(\lambda+hT^{-1}) - \alpha(\lambda-hT^{-1})\big),$$

which implies that $\big(\alpha(\lambda+hT^{-1})-\alpha(\lambda-hT^{-1})\big) \le CT^{-1}h^{-d+1}$ and therefore

$$|\alpha(\lambda)-\alpha(\mu)| \le Ch^{-d+1}|\lambda-\mu| + CT^{-1}h^{-d+1} \tag{2.26}$$

as $\lambda,\mu \in (\bar\tau-\epsilon, \bar\tau+\epsilon)$. Then (2.26) automatically holds, even if Q_1 and Q_2 are not necessarily equal.

[15] I.e. a compactly supported function with positive Fourier transform.

Further, (2.26) implies that

$$|\alpha(\lambda)-\alpha(\mu)-h^{-1}\int_{\mu}^{\lambda}\beta(\tau)\,d\tau|\le CT^{-1}h^{-d+1} \tag{2.27}$$

and therefore

$$|\int\Big(\alpha(\lambda)-\alpha(\mu)-h^{-1}\int_{\mu}^{\lambda}\beta(\tau)\,d\tau\Big)\phi(\mu)\,d\mu|\le CT^{-1}h^{-d+1} \tag{2.28}$$

if $\bar\chi=1$ on $[-\frac12,\frac12]$, $\lambda,\mu\in(\bar\tau-\epsilon,\bar\tau+\epsilon)$ and $\phi\in\mathscr{C}_0^\infty((\bar\tau-\epsilon,\bar\tau+\epsilon))$ with $\int\phi(\tau)\,d\tau=1$.

On the other hand, even without the microhyperbolicity condition, our successive approximation construction is not entirely useless. Let us apply $\varphi_L(hD_t-\lambda)$ with $\varphi\in\mathscr{C}_0^\infty([-1,1])$ and $L\ge h^{\frac12-\delta}$, and then set $t=0$. We arrive to

$$\int\varphi((\tau-\lambda)L^{-1})\big(\alpha'(\tau)-\beta(\tau)\big)\,d\tau=O(h^\infty). \tag{2.29}$$

This allows us to extend (2.28) to $\phi\in\mathscr{C}_0^\infty(bR))$ with $\int\phi(\tau)\,d\tau=1$. For full details and generalizations, see Section 4.4 of [Ivr4].

Thus, we have proved:

Theorem 2.6. *Let $H=H(x,hD,h)$ be a self-adjoint operator. Then,*

(i) The following asymptotics holds for $L\ge h^{\frac12-\delta}$:

$$\int\phi((\tau-\lambda)L^{-1})\Big(d_\tau(Q_{1x}e^{\,t}Q_{2y})(y,y,\tau)-\sum_{m\ge0}h^{-d+m}\kappa'(y,\tau)\,d\tau\Big)=O(h^\infty). \tag{2.30}$$

(ii) Let H be microhyperbolic on the energy level $\bar\tau$ in some direction ℓ with $\ell_x=0$. Then for $|\lambda-\bar\tau|\le\epsilon$,

$$(Q_{1x}e^{\,t}Q_{2y})(y,y,\lambda)=h^{-d}\kappa_0(y,\lambda)+O(h^{-d+1}) \tag{2.31}$$

with $\kappa_m(y,\lambda):=\int_{-\infty}^{\lambda}\kappa_m'(y,\tau)\,d\tau$.

(iii) Let H be microhyperbolic on the energy level $\bar\tau$ in some direction ℓ. Then for $|\lambda-\bar\tau|\le\epsilon$,

$$\int (Q_{1x}e\,{}^tQ_{2y})(y,y,\lambda)\,dy = h^{-d}\varkappa_0(\lambda)+O(h^{-d+1}) \tag{2.32}$$

with $\varkappa_m(y) \coloneqq \int_{-\infty}^{\lambda}\varkappa_m'(\tau)\,d\tau$.

(iv) In particular, it follows from (2.20) *that*

$$\kappa_0(\lambda,x) = (2\pi)^{-d}\int q_1^0(x,\xi)\theta(\lambda-H^0(x,\xi))q_2^0(x,\xi)\,d\xi \tag{2.33}$$

and

$$\varkappa_0(\lambda) = (2\pi)^{-d}\int q_1^0(x,\xi)\theta(\lambda-H^0(x,\xi))q_2^0(x,\xi)\,dxd\xi \tag{2.34}$$

Remark 2.7. (i) So far we have assumed that Q_1, Q_2 had compactly supported symbols in (x,ξ). Assuming that these symbols are compactly supported with respect to x only, in particular when $Q_1=\psi(x)$, $Q_2=1$, with $\psi\in\mathscr{C}_0^\infty(X)$, we need to assume that

(2.35) $\{\xi : \exists x\in X : \operatorname{Spec} H^0(x,\xi)\cap(-\infty,\lambda+\epsilon_0]\ne\emptyset\}$ is a compact set.

(ii) If we assume only that

(2.36) $\{\xi : \exists x\in X : \operatorname{Spec} H^0(x,\xi)\cap(\mu-\epsilon_0,\lambda+\epsilon_0]\ne\emptyset\}$ is a compact set,

instead of (2.31) and (2.32), we get

$$|(Q_{1x}e\,{}^tQ_{2y})(y,y,\lambda,\mu)-h^{-1}\kappa_0(y,\lambda,\mu)|\le Ch^{-d+1} \tag{2.37}$$

and

$$\Big|\iint (Q_{1x}e\,{}^tQ_{2y})(y,y,\lambda,\mu)\,dy - h^{-1}\varkappa_0(\lambda,\mu)\Big|\le Ch^{-d+1}, \tag{2.38}$$

where $\mu\le\lambda$, $e(x,y,\lambda,\mu)\coloneqq e(x,y,\lambda)-e(x,y,\mu)$, $\kappa_m(y,\lambda)\coloneqq\int_\mu^\lambda\kappa_m'(y,\tau)\,d\tau$, $\varkappa_m(y,\lambda)\coloneqq\int_\mu^\lambda\varkappa_m'(y,\tau)\,d\tau$ and we assume that the corresponding microhyperbolicity assumption is fulfilled on both energy levels μ and λ.

(iii) If $H^0(x,\xi)$ is an elliptic symbol which is positively homogeneous of degree $m > 0$ with respect to ξ, then the microhyperbolicity condition is fulfilled with $\ell = (0, \pm\xi)$ on energy levels $\tau \neq 0$. Furthermore, the compactness condition of (ii) is fulfilled, and if $H^0(x,\xi)$ is also positive-definite, then the compactness condition of (i) is also fulfilled.

Second Term and Dynamics

Propagation of Singularities To derive two-term asymptotics, one can use the scheme described in Section 1, albeit one needs to describe the propagation of singularities. For matrix operators, this may be slightly tricky.

Let us introduce the *characteristic symbol* $g(\mathsf{x},\xi) := \det(\tau - H^0(\mathsf{x},\xi))$ where $\mathsf{x} = (x_0, x)$, $\xi = (\xi_0,\xi)$ etc; then $\mathsf{Char}(\xi_0 - H(x,\xi)) = \{(x,\xi) : g(x,\xi) = 0\}$. Let ξ_0 be a root of multiplicity r of $g(x,\xi_0,\xi)$; then $g^{(\alpha)}_{(\beta)}(x,\xi) = 0$ for all $\alpha,\beta : |\alpha| + |\beta| < r$. Let us consider the r-jet of g at such a point:

$$g_{(x,\xi)}(y,\eta) := \sum_{\alpha,\beta:|\alpha|+|\beta|<r} \frac{1}{\alpha!\beta!} g^{(\alpha)}_{(\beta)}(x,\xi) y^\beta \eta^\alpha; \tag{2.39}$$

it is a hyperbolic polynomial with respect to η_0. Consider its *hyperbolicity cone* $K(x,\xi)$, which is the connected component of $\{(\mathsf{y};\eta) \in \mathbb{R}^{2d+2} : g_{(x,\xi)}(\mathsf{y},\eta) \neq 0\}$ containing $\{(y,\eta) : \eta_0 = 1, y = \eta = 0\}$ and the *dual hyperbolicity cone*

$$K^\#(x,\xi) = \{(\mathsf{y}',\eta') : \langle \mathsf{y}',\eta\rangle - \langle \mathsf{y},\eta'\rangle > 0\} \subset \{y_0 = 0\}. \tag{2.40}$$

Definition 2.8. (i) An absolutely continuous curve $(\mathsf{x}(t), \xi(t))$ (with $x_0 = t$) is called a *generalized Hamiltonian trajectory* if a.e.

$$(1, \frac{dx}{dt}; \frac{d\xi}{dt}) \in K^\#(x,\xi_0,\xi). \tag{2.41}$$

Note that $\xi_0 = \tau$ remains constant along the trajectory.

(ii) Let $\mathcal{K}^\pm(x,\xi)$ denote the union of all generalized Hamiltonian trajectories issued from (x,ξ) in the direction of increasing/decreasing t.

If $g = \alpha g_1^r$ where $\alpha \neq 0$ and $g_1 = 0 \implies \nabla g_1 \neq 0$, the generalized Hamiltonian trajectories are just (ordinary) Hamiltonian trajectories of g_1 and $\mathcal{K}^{\pm}(x,\xi)$ are just half-trajectories[16].

The following theorem follows from Theorem 2.2:

Theorem 2.9. *If $u(x,y,t)$ is the Schwartz kernel of $e^{ih^{-1}tH}$, then*

$$\mathsf{WF}(u) \subset \{(x,\xi;y,-\eta;t,\tau) : \pm t > 0, (t,x;\tau,\xi) \in K^{\pm}(0,y;\tau,\eta)\}. \tag{2.42}$$

Then, we obtain:

Corollary 2.10. *In the framework of Theorem 2.9,*

$$\mathsf{WF}(\sigma_{Q_1,Q_2}(t)) \subset \{(t,\tau) : \exists (x,\xi) : (t,x;\tau,\xi) \in \mathcal{K}^{\pm}(0,x;\tau,\xi)\}, \tag{2.43}$$

and for any x,

$$\mathsf{WF}(Q_{1x} u\, {}^tQ_{2y}) \subset \{(t,\tau) : \exists \xi,\eta : (t,x;\tau,\xi) \in \mathcal{K}^{\pm}(0,x;\tau,\eta)\}. \tag{2.44}$$

Definition 2.11. (i) A *periodic point* is a point (x,ξ) which satisfies $(t,x;\tau,\xi) \in \mathcal{K}^{\pm}(0,x;\tau,\xi)$ for some $t \neq 0$.

(ii) A *loop point* is a point x which satisfies $(t,x;\tau,\xi) \in \mathcal{K}^{\pm}(0,x;\tau,\eta)$ for some $t \neq 0$, ξ,η; we call η a *loop direction*.

Application to Spectral Asymptotics Combining Corollary 2.10 with the arguments of Section 1, we arrive to

Theorem 2.12. *(i) In the framework of Theorem 2.6(ii) let for some x the set of all loop directions at point x on energy level λ have measure 0*[17]*. Then,*

$$(Q_{1x} e\, {}^tQ_{2y})(y,y,\lambda) = h^{-d}\kappa_0(y,\lambda) + h^{1-d}\kappa_1(y,\lambda) + o(h^{-d+1}). \tag{2.45}$$

(ii) In the framework of Theorem 2.6(iii), suppose that the set of all periodic points on energy level λ has measure 0[18]*. Then,*

$$\int (Q_{1x} e\, {}^tQ_{2y})(y,y,\lambda)\, dy = h^{-d}\varkappa_0(\lambda) + h^{1-d}\varkappa_1(\lambda) + o(h^{-d+1}). \tag{2.46}$$

[16] Since $e^{ih^{-1}tH}$ describes evolution with revert time, time is also reverted along (generalized) Hamiltonian trajectories.

[17] There exists a natural measure $\mu_{\lambda,x}$ on $\{\xi : \det(\lambda - H^0(x,\xi)) = 0\}$.

[18] There exists a natural measure μ_λ on $\{(x,\xi) : \det(\lambda - H^0(x,\xi)) = 0\}$.

Remark 2.13. (i) When studying propagation, we can allow H to also depend on $x_0 = t$; for all details and proofs, see Sections 2.1 and 2.2 of [Ivr4].

(ii) Recall that $e(x, y, \lambda)$ is the Schwartz kernel of $\theta(\lambda - H)$. We can also consider $e_\nu(x, y, \tau)$ which is the Schwartz kernel of $(\lambda - H)^\nu_+ := (\lambda - H)^\nu \theta(\lambda - H)$ with $\nu \ge 0$. Then in the Tauberian arguments, $h^{-d} \times (h/T)$ is replaced by $h^{-d} \times (h/T)^{1+\nu}$ and then in the framework of Theorem 2.6(ii) and (iii) remainder estimates are $O(h^{-d+1+\nu})$ and in the framework of Theorem 2.6(i) and (ii), the remainder estimates are $o(h^{-d+1+\nu})$; sure, in the asymptotics one should include all the necessary terms $\kappa_m h^{-d+m}$ or $\varkappa_m h^{-d+m}$ [19].

(iii) Under more restrictive conditions on Hamiltonian trajectories instead of T an arbitrarily large constant, we can take T depending on h [20]; see Section 2.4 of [Ivr4]. Usually, we can take $T = \epsilon |\log h|$ or even $T = h^{-\delta}$.

Then in the remainder estimate, the main term is

$$C\big(\mu(\Pi_{T,\gamma}) h^{-d+1} + h^{-d+1+\nu} T^{-1-\nu}\big),$$

where $\Pi_{T,\gamma}$ is the set of all points $z = (x, \xi)$ (on the given energy level) such that $\operatorname{dist}(\Psi_t(z), z) \le \gamma$ for some $t \in (\epsilon, T)$ and $\gamma = h^{1/2-\delta'}$. Here, however, we assume that either H^0 is scalar or its eigenvalues have constant multiplicities and apply the Heisenberg approach to the long-term evolution.

Then the remainder estimates could be improved to $O(h^{-d+1+\nu} |\log h|^{-1-\nu})$ or even to $O(h^{-d+1+\nu+\delta})$ respectively. As examples, we can consider the geodesic flow on a Riemannian manifold with negative sectional curvature (log case) and the completely integrable non-periodic Hamiltonian flow (power case). For all details and proofs, see Section 4.5 of [Ivr4].

Rescaling Technique

The results we proved are very uniform: as long as we know that operator in question is self-adjoint and that the smoothness and non-degeneracy conditions are fulfilled uniformly in $B(\bar{x}, 1)$, then all asymptotics are also uniform (as $x \in B(\bar{x}, \frac{1}{2})$ or $\operatorname{supp}(\psi) \subset B(\bar{x}, \frac{1}{2})$). Then these results could self-improve.

---

[19] Here, we need to assume that H is semi-bounded from below; otherwise some modifications are required.

[20] Usually these restrictions are $T \le h^{-\delta}$ and $|D\Psi_t(z)| \le h^{-\delta}$ with sufficiently small $\delta > 0$.

Here we consider only the Schrödinger operator away from the boundary; but the approach could be generalized for a wider class of operators. For generalizations, details and proofs, see Chapter 5 of [Ivr4].

Proposition 2.14. *Consider the Schrödinger operator. Assume that* $\rho\gamma \ge h$ *and in* $B(\bar{x},\gamma)\subset X$,

$$|\partial^\alpha g^{jk}| \le c_\alpha \gamma^{-|\alpha|}, \qquad |\partial^\alpha V| \le c_\alpha \rho^2 \gamma^{-|\alpha|}. \tag{2.47}_{1,2}$$

Then,

(i) In $B(\bar{x},\frac{1}{2}\gamma)$,

$$e(x,x,0) \le C\rho^d h^{-d}. \tag{2.48}$$

(ii) If in addition $|V| + |\nabla V|\gamma \ge \epsilon\rho^2$, *then for* $\mathsf{supp}(\psi)\subset B(\bar{x},\frac{1}{2}\gamma)$ *such that* $|\partial^\alpha\psi| \le c_\alpha\gamma^{-|\alpha|}$,

$$\left|\int \bigl(e(x,x,0) - \kappa_0 V_-^{d/2}\bigr)\,dx\right| \le C\rho^{d-1}\gamma^{d-1}h^{1-d}; \tag{2.49}$$

(iii) If in addition $|V| \ge \epsilon\rho^2$ *in* $B(\bar{x},\gamma)$ *then*

$$|e(x,x,0) - \kappa_0 V_-^{d/2}| \le C\rho^{d-1}\gamma^{-1}h^{1-d}; \tag{2.50}$$

(iv) If in addition $V \ge \epsilon\rho^2$ *in* $B(\bar{x},\gamma)$, *then for any* s,

$$|e(x,x,0)| \le C\rho^{d-s}\gamma^{-s}h^{s-d}. \tag{2.51}$$

Proof. Indeed, we have already proved this in the special case $\rho=\gamma=1$, $h\le 1$. In the general case, we can reduce the problem to the special case by rescaling $x\mapsto x\gamma^{-1}$, $\tau\mapsto\tau\rho^{-2}$ (so we multiply operator by ρ^{-2}) and then automatically $h\mapsto \hbar = h\rho^{-1}\gamma^{-1}$. Recall that $e(x,y,\tau)$ is a function with respect to x but a density with respect to y so an extra factor γ^{-d} appears in the right-hand expressions. □

Let us assume that the conditions $(2.47)_{1,2}$ are fulfilled with $\rho=\gamma=1$. We want to get rid of the non-degeneracy assumption $|V|\asymp 1$ in the pointwise asymptotics. Let us introduce the *scaling function* $\gamma(x)$ and also $\rho(x)$

$$\gamma(x) = \epsilon|V(x)| + \bar{\gamma} \quad \text{with} \quad \bar{\gamma} = h^{\frac{2}{3}}, \qquad \rho(x) = \gamma(x)^{\frac{1}{2}}. \tag{2.52}$$

One can easily see that

$$|\nabla\gamma| \le \frac{1}{2}, \qquad \rho\gamma \ge h, \tag{2.53}$$

$(2.47)_{1,2}$ are fulfilled and either $|V| \ge \epsilon\rho^2$ or $\rho\gamma \asymp h$ and therefore (2.50) holds ($\hbar \asymp 1$ as $\rho\gamma \asymp h$ and no non-degeneracy condition is needed). Note that for $d \ge 3$, the right-hand expression of (2.50) is $O(h^{1-d})$ and for $d = 1, 2$, it is $O(h^{-\frac{2}{3}d})$. So, we got rid of the non-degeneracy assumption $|V| \asymp 1$, and the remainder estimate deteriorated only for $d = 1, 2$.

Remark 2.15. (i) We can improve the estimates for $d = 1, 2$ to $O(h^{\frac{1}{3}-\frac{2}{3}d})$, but then we will need to add some correction terms first under the assumption $|V| + |\nabla V| \asymp 1$ and then get rid of it by rescaling; these correction terms are of boundary-layer type (near $V = 0$) and are $O(h^{-\frac{2}{3}d})$ and are due to short loops. For details, see Theorems 5.3.11 and 5.3.16 of [Ivr4].

(ii) If $d = 2$, then under the assumption $|V| + |\nabla V| \asymp 1$, the weight $\rho^{-1}\gamma^{-1}$ is integrable, and we arrive to the local asymptotics with the remainder estimate $O(h^{1-d})$.

(iii) We want to get rid of the non-degeneracy assumption $|V| + |\nabla V| \asymp 1$ in the local asymptotics. We can do it with the scaling function

$$\gamma(x) = \epsilon\big(|V(x)| + |\nabla V|^2\big)^{\frac{1}{2}} + \bar\gamma \quad \text{with} \quad \bar\gamma = h^{\frac{1}{2}}, \qquad \rho(x) = \gamma(x). \tag{2.54}$$

Then for $d = 2$, we recover remainder the estimate $O(h^{-1})$; while for $d = 1$, the remainder estimate $O(h^{-\frac{1}{2}})$ which could be improved further up to $O(1)$ under some extremely weak non-degeneracy assumption or to $O(h^{-\delta})$ with an arbitrarily small exponent $\delta > 0$ without it.

(iv) If $d \ge 2$, then in the framework of Theorem 2.12(i), we can get rid of the non-degeneracy assumption as well. This is true for the magnetic Schrödinger operator as well if $d \ge 2$; when $d = 2$, some modification of the statement is required; see Remark 5.3.4 of [Ivr4].

(v) Furthermore, if we consider asymptotics for $\mathsf{Tr}\big((\lambda - H)^{\nu}_{+}\psi\big)$ (see Remark 2.13(ii)) with $\nu > 0$ then in the local asymptotics, we get the remainder estimate $O(h^{1-d+s})$ without any non-degeneracy assumptions. For details, see Theorem 5.3.5 of [Ivr4].

Operators with Periodic Trajectories

Preliminary Analysis Consider a scalar operator H. For simplicity, assume that X is a compact closed manifold. Assume that all the Hamiltonian trajectories are periodic (with periods not exceeding $C(\mu)$ on the energy levels $\lambda \le \mu$). Then the period depends only on the energy level and let $T(\lambda)$ be the minimal period such that all trajectories on the energy level λ are $T(\lambda)$ periodic[21].

Without any loss of the generality, one can assume that $T(\lambda) = 1$. Indeed, we can replace H by $f(H)$ with $f'(\lambda) = 1/T(\lambda)$. Then,

$$e^{\nabla^{\#} H^0} = I \tag{2.55}$$

and therefore,

$$e^{ih^{-1}H} = e^{i\varepsilon h^{-1}B}, \tag{2.56}$$

where $B = B(x, hD, h)$ is an h-pseudo-differential operator which could be selected to commute with H, at this point, $\varepsilon = h$. Then, $H_0 = H - \varepsilon B$ satisfies

$$e^{ih^{-1}H_0} = I \implies \mathsf{Spec}(H_0) \subset 2\pi h\mathbb{Z}; \tag{2.57}$$

we call this *quantum periodicity* in contrast to the *classical periodicity* (2.55).

We can calculate the multiplicity $\mathsf{N}_{k,h} = O(h^{1-d})$ of the eigenvalue $2\pi hk$ with $k \in \mathbb{Z}$ modulo $O(h^{\infty})$. The formula is rather complicated especially since subperiodic trajectories[21] cause the redistribution of multiplicities between eigenvalues (however, this causes no more than $O(h^{1-d+r})$ error).

We consider $H := H_\varepsilon = H_0 + \varepsilon B$ as a perturbation of H_0 and we assume only that $\varepsilon \ll 1$. If $\varepsilon \le \epsilon_0 h$, the spectrum of H consists of *eigenvalue clusters* of the width $C_0\varepsilon$ separated by *spectral gaps* of the width $\asymp h$, but if $\varepsilon \ge \epsilon_0 h$, these clusters may overlap.

Long Range Evolution Consider

$$e^{ih^{-1}tH} = e^{ih^{-1}tH_0} e^{-ih^{-1}t\varepsilon B} = e^{ih^{-1}t'H_0} e^{ih^{-1}t''B} \tag{2.58}$$

[21] However, there could be *subperiodic trajectories*, i.e. trajectories periodic with period $T(\lambda)/p$ with $p = 2, 3, \dots$. It is known that the set Λ_p of subperiodic trajectories with subperiod $T(\lambda)/p$ is a union of symplectic submanifolds $\Lambda_{p,r}$ of codimension $2r$.

with $t'' = \varepsilon t$, $t' = t - \lfloor t \rfloor$. We now have a *fast evolution* $e^{ih^{-1}t'H_0}$ and a *slow evolution* $e^{ih^{-1}t''B}$ and both t', t'' are bounded as $|t| \le T^* := \varepsilon^{-1}$. Therefore, we can trace the evolution up to time T^*.

Let the following non-degeneracy assumption be fulfilled:

$$|\nabla_{\Sigma(\lambda)} b| \ge \epsilon_0, \tag{2.59}$$

where b is the principal symbol of B, $\Sigma(\lambda) := \{(x,\xi) : H^0(x,\xi) = \lambda\}$ and $\nabla_{\Sigma(\lambda)}$ is the gradient along $\Sigma(\lambda)$. Then using our methods, we can prove that

$$|F_{t\to h^{-1}\tau}\chi_T(t) \int u(x,x,t)\psi(x)\,dx| \le CTh^{1-d}(h/\varepsilon T)^s, \tag{2.60}$$

and therefore

$$F_{t\to h^{-1}\tau}\bar\chi_T(t) \int u(x,x,t)\psi(x)\,dx| \le Ch^{1-d}(\varepsilon^{-1}h+1) \tag{2.61}$$

for $\epsilon_0(\varepsilon^{-1}h+1) \le T \le \epsilon_0\varepsilon^{-1}$; recall that $\chi \in \mathscr{C}_0^\infty([-1,-\frac12]\cup[\frac12,1]$ and $\bar\chi \in \mathscr{C}_0^\infty([-1,1]$, $\bar\chi = 1$ on $[-\frac12,\frac12]$.

Then the Tauberian error does not exceed the right-hand expression of (2.61) multiplied by $T^{*-1} \asymp \varepsilon$, i.e. $Ch^{1-d}(\varepsilon + h)$. In the Tauberian expression, we need to take $T = \epsilon_0(\varepsilon^{-1}h^{1-\delta}+1)$.

Calculations We can pass from Tauberian expression to a more explicit one. Observe that the contribution to the former are produced only by time intervals $t \in [n-h^{1-\delta}, n+h^{1-\delta}]$ with $|n| \le T_*$; contribution of the remaining interval will be either negligible (if there are no subperiodic trajectories) or $O(h^{2-d})$ (if such trajectories exist). Such an interval with $n=0$ produces the standard Weyl expression.

Consider $n \ne 0$. Then the contribution of such intervals lead to a correction term

$$\mathsf{N}_{\mathsf{corr},Q_1,Q_2}(\lambda) := (2\pi)^{-d}h^{1-d}\int_{\Sigma_\tau} q_1^0\Upsilon_1\bigl(h^{-1}(H^0-\varepsilon b)\bigr)\,d\mu_\tau q_2^0, \tag{2.62}$$

where $\Upsilon_1(t) = 2\pi\lceil\frac{t}{2\pi}\rceil - t + \frac12$.

Theorem 2.16. *Under assumptions* (2.55), (2.56), (2.59) *and* $\varepsilon \ge h^M$,

$$\begin{aligned}\int (Q_{1x}e^{\,t}Q_{2y})(y,y,\lambda)\,dy &= h^{-d}\varkappa_{0,Q_1,Q_2}(\lambda)\\ &\quad + h^{1-d}\varkappa_{1,Q_1,Q_2}(\lambda) + \mathsf{N}_{\mathsf{corr},Q_1,Q_2}(\lambda) + O\bigl(h^{1-d}(\varepsilon+h)\bigr).\end{aligned} \tag{2.63}$$

For a more general statement with (2.59) replaced by a weaker non-degeneration assumption, see Theorem 6.2.24 of [Ivr4]. Further, we can skip a correction term (2.62) if $\varepsilon \ge h^{1-\delta}$; while if $h^M \le \varepsilon \le h^{1-\delta}$, this term is $O(h^{1-d}(h/\varepsilon)^s)$ for $\varepsilon \ge h$ and of magnitude h^{1-d} for $h^M \le \varepsilon \le h$.

For further generalizations, details and proofs, see Sections 6.2 and 6.3 of [Ivr4]. For related spectral asymptotics for a family of commuting operators, see Section 6.1 of [Ivr4].

One can also consider the case when there is a massive set of periodic trajectories, yet non-periodic trajectories exist. For details, see [SV1] and Subsection 6.3.7 of [Ivr4].

Boundary Value Problems

Preliminary Analysis

Let X be a domain in $\mathbb{R}^d$ with boundary ∂X and H an h-differential matrix operator which is self-adjoint in $\mathscr{L}^2(X)$ under the h-differential boundary conditions. Again, we are interested in the local and pointwise spectral asymptotics, i.e. those of $\int e(x,x,0)\psi(x)\,dx$ with $\psi \in \mathscr{C}_0^\infty(B(0,\frac12))$ and of $e(x,x,0)$ with $x \in B(0,\frac12)$.

Assume that in $B(0,1)$, everything is good: ∂X and coefficients of H are smooth, H is ξ-microhyperbolic on the energy levels $\lambda_{1,2}$ ($\lambda_1 < \lambda_2$) and also H is elliptic as a differential operator, i.e.

$$\|H(x,\xi)v\| \ge (\epsilon_0|\xi|^m - C_0)\|v\| \qquad \forall v \quad \forall x \in B(0,1)\ \forall \xi. \tag{2.64}$$

Then,

$$e(x,x,\lambda_1,\lambda_2) = \kappa_0(x,\lambda_1,\lambda_2)h^{-d} + O(h^{1-d}\gamma(x)^{-1}) \tag{2.65}$$

for $x \in B(0,\frac12)$ and $\gamma(x) \ge h$,

$$\kappa_0(x,\lambda_1,\lambda_2) = (2\pi)^{-d}\int \bigl(\theta(\lambda_2 - H^0(x,\xi)) - \theta(\lambda_1 - H^0(x,\xi))\bigr)\,d\xi \tag{2.66}$$

and $\gamma(x) = \frac12 \mathsf{dist}(x,\partial X)$.

Indeed, the scaling $x \mapsto (x-y)/\gamma$ and $h \mapsto \hbar/\gamma$ brings us into the framework of Theorem 2.6(ii) because ξ-microhyperbolicity (in contrast to

the (x,ξ)-microhyperbolicity) survives such rescaling. Then,

$$\int_{\{x:\,\gamma(x)\ge h\}} \bigl(e(x,x,\lambda_1,\lambda_2) - h^{-d}\kappa_0(x,\lambda_1,\lambda_2)\bigr)\psi(x)\,dx = O(h^{1-d}\log h), \tag{2.67}$$

since $\int_{\{x:\,\gamma(x)\ge h\}} \gamma(x)^{-1}\,dx \asymp |\log h|$.

One can easily show that if the boundary value problem for H is elliptic then

$$e(x,x,\lambda_1,\lambda_2) = O(h^{-d}) \tag{2.68}$$

and therefore,

$$\int \bigl(e(x,x,\lambda_1,\lambda_2) - h^{-d}\kappa_0(x,\lambda_1,\lambda_2)\bigr)\psi(x)\,dx = O(h^{1-d}\log h). \tag{2.69}$$

To improve this remainder estimate, one needs to improve (2.67) rather than (2.65) but to get sharper asymptotics, we need to improve both. We will implement the same scheme as inside the domain.

Propagation of Singularities

Toy-Model: Schrödinger Operator Let us consider the Schrödinger operator

$$H := h^2\Delta + V(x) \tag{2.70}$$

with the boundary condition

$$\bigl(\alpha(x)h\partial_\nu + \beta(x)\bigr)v|_{\partial X} = 0, \tag{2.71}$$

where

$$\Delta = \sum_{j,k} D_j g^{jk} D_k, \qquad \partial_\nu = \sum_j g^{j1}\partial_j \tag{2.72}$$

is derivative in the direction of the inner normal ν (we assume that $X = \{x : x_1 > 0\}$ locally[22)]), α and β are real-valued and do not vanish simultaneously. Without any loss of the generality, we can assume that locally

$$g^{j1} = \delta_{j1}. \tag{2.73}$$

[22)] I.e. in intersection with $B(0,1)$.

First of all, near the boundary, we can study the propagation of singularities using the same scheme as in Subsection 2 as long as $\phi_j(x,\xi) = \phi_j(x,\xi')$ do not depend on the component of ξ which is "normal to the boundary". The intuitive way to explain why one needs this is that at reflections, ξ_1 changes by a jump.

For the Schrödinger operator, it is sufficient for our needs: near *glancing points* (x,ξ') (which are points such that $x_1 = 0$ and the set $\{\xi_1 : H^0(x',\xi',\xi_1) = \tau\}$ consists of exactly one point), we can apply this method. On the other hand, near other points, we can construct the solution by traditional methods of oscillatory integrals.

It is convenient to decompose $u(x,y,t)$ into the sum

$$u = u^0(x,y,t) + u^1(x,y,t), \tag{2.74}$$

where $u^0(x,y,t)$ is a *free space solution* (without boundary) which we studied in Subsection 2 and $u^1 := u - u^0$ is a *reflected wave*.

Observe that even for the Schrödinger operator, we cannot claim that the singularity of $u(x,x,t)$ at $t = 0$ is isolated. The reason are *short loops* made by trajectories which reflect from the boundary in the normal direction and follow the same path in the opposite direction. However, these short loops affect neither $u(x,x,t)$ at the points of the boundary nor $u(x,x,t)$ integrated in any direction transversal to the boundary (and thus do not affect $\sigma_\psi(t)$ defined below).

Furthermore, they do not affect $(Q_{1x}u\,{}^tQ_{2y})(x,x,t)$ as long as at least one of operators $Q_j = Q_j(x,hD',hD_t)$ cuts them of. Then we get the estimate (2.9). Consider $Q_1 = Q_2 = 1$. Then, if $V(x) - \lambda > 0$, we get the same estimate at the point $x \in \partial X$. On the other hand, if either $V(x) - \lambda < 0$ or $V(x) = \lambda,\ \nabla_{\partial X} V(x) \neq 0$ (where $\nabla_{\partial X}$ means "along ∂X") at each point of $\mathsf{supp}(\psi)$, we get the same estimate for $\sigma_\psi(x) = \int u(x,x,t)\,dx$. As usual, λ is an energy level.

Moreover, $\sigma^1_\psi(t) = \int u^1(x,x,t)\psi(x)\,dx$ satisfies

$$|F_{t\to h^{-1}\tau}\chi_T(t)\sigma^1_\psi(t)| \le C_s h^{1-d}(h/|t|)^s. \tag{2.75}$$

In contrast to the Dirichlet ($\alpha = 0$, $\beta = 1$) or Neumann ($\alpha = 1$, $\beta = 0$) conditions, under the more general boundary condition (2.71), the classically forbidden level λ (i.e. with $\lambda < \inf_{B(0,1)} V$) may be not forbidden after all. Namely, in this zone, the operator $hD_t - H$ is elliptic and we can construct

the *Dirichlet-to-Neumann operator* $L : v|_{\partial X} \to h\partial_1 v|_{\partial X}$ as $(hD_t - H)v \equiv 0$. This is an h-pseudo-differential operator on ∂X with principal symbol

$$L^0(x', \xi', \tau) = -\big(V + \sum_{j,k\ge 2} g^{jk}\xi_j\xi_k - \tau\big)^{\frac{1}{2}}. \tag{2.76}$$

Then the boundary condition (2.71) becomes

$$Mw := (\alpha L + \beta)w \equiv 0, \qquad w = v|_{\partial X}. \tag{2.77}$$

The energy level $\lambda < V(x)$ is indeed forbidden if the operator M is elliptic as $\tau = \lambda$, i.e. if $M^0(x', \xi', \lambda) = \alpha L^0(x', \xi', \lambda) + \beta \ne 0$ for all ξ'; it happens as either $\alpha^{-1}\beta < 0$ or $W := V - \alpha^{-2}\beta^2 > \lambda$. Otherwise, to recover (2.75)[23], we assume that M is either ξ'-microhyperbolic or (x', ξ')-microhyperbolic ($W > \lambda$ and $W = \lambda \implies \nabla_{\partial X} W \ne 0$ respectively).

General Operators For more general operators and boundary value problems, we use similar arguments albeit not relying upon the representation of $u(x, y, t)$ via oscillatory integrals. It follows from (2.74) that

$$(hD_t - H)u^{1\pm} = 0, \tag{2.78}$$

$$Bu^{1\pm}|_{x_1=0} = -Bu^{0\pm}|_{x_1=0}, \tag{2.79}$$

where as before, $u^{k\pm} = u^k\theta(\pm t)$, $k = 0, 1$. Assuming that H satisfies (2.64), we reduce (2.78)–(2.79) to the problem

$$\mathcal{A}U^{1\pm} := (\mathcal{A}_0 hD_1 + \mathcal{A}_1)U^{1\pm} \equiv 0, \tag{2.80}$$

$$\mathcal{B}U^{1\pm}|_{x_1=0} = -\mathcal{B}U^{0\pm} \tag{2.81}$$

with $\mathcal{A}_k = \mathcal{A}_k(x, hD', hD_t)$, $\mathcal{B} = \mathcal{B}(x, hD', hD_t)$ and $U = S_x u\, {}^tS_y$ with $S = S(x, hD_x, hD_t)$ etc[24].

In a neighbourhood of any point $(\bar{x}', \bar{\xi}', \lambda)$, the operator $\mathcal{A}$ could be reduced to the block-diagonal form with blocks $\mathcal{A}_{kj}$ ($k = 0, 1$, $j = 1, \dots, N$) such that

(a) For each $j = 1, \dots, N-1$, the equation $\det(\mathcal{A}^0_{0j}\eta + \mathcal{A}^0_{1j}) = 0$ has a single real root η_j (at the point $(\bar{x}', \bar{\xi}', \lambda)$ only), η_j are distinct, and

[23] With d replaced by $d - 1$.

[24] If H is a $\mathsf{D} \times \mathsf{D}$ matrix operator of order m then $\mathcal{A}$ and S are $m\mathsf{D} \times m\mathsf{D}$ and $m\mathsf{D} \times \mathsf{D}$ matrix operators, B and $\mathcal{B}$ are $\frac{1}{2}m\mathsf{D} \times \mathsf{D}$ and $\frac{1}{2}m\mathsf{D} \times m\mathsf{D}$ matrix operators respectively.

(b) $\mathcal{A}_{kN} = \begin{pmatrix} 0 & \mathcal{A}'_{kN} \\ \mathcal{A}''_{kN} & 0 \end{pmatrix}$ with $\det(\mathcal{A}'^0_{0N}\eta + \mathcal{A}'^0_{1N}) = 0$ and $\det(\mathcal{A}''^0_{0N}\eta + \mathcal{A}''^0_{1N}) = 0$ has only roots with $\operatorname{Im}\eta < 0$ and with $\operatorname{Im}\eta > 0$ respectively.

We can prove a statement similar to Theorem 2.2, but instead of functions $\phi_*(x,\xi)$, we now have arrays of functions $\phi_{*j}(x,t,\xi',\tau)$ $(j = 1,\dots,N-1)$ coinciding with $\phi_{*N}(x',t,\xi',\tau)$ as $x_1 = 0$. Respectively, instead of microhyperbolicity of the operator in the direction $\ell \in T(T^*(X\times\mathbb{R}))$, we now have the *microhyperbolicty of the boundary value problem in the multidirection* $(\ell',\nu_1,\dots,\nu_{N-1}) \in T(T^*(\partial X\times\mathbb{R}))\times\mathbb{R}^{N-1}$; see Definition 3.1.4 of [Ivr4]. It includes the microhyperbolicity of $\mathcal{A}_j$ in the direction $(\ell',0,\nu_j)$ for $j = 1,\dots,N-1$ and a condition invoking $\mathcal{A}_N$ and $\mathcal{B}$ and generalizing the microhyperbolicity of operator M for the Schrödinger operator. Respectively, instead of the microhyperbolicity of an operator in the direction $\nabla^{\#}\phi_*$, we want the microhyperbolicity in the multidirection $(\nabla'^{\#}\phi_*, \partial_1\phi_{*1},\dots,\partial_1\phi_{*(N-1)})$.

As a corollary, under the microhyperbolicity assumption on the energy level λ, we prove estimates (2.9) for $\sigma^0_\psi(t)$, $\sigma_\psi(t)$ and (2.75) for $\sigma^1_\psi(t)$ as τ is close to λ. Furthermore, if the operator H is elliptic on this energy level then $\sigma^0_\psi(t)$ is negligible and (2.75) holds for $\sigma^1_\psi(t)$ and $\sigma_\psi(t)$.

For details, proofs and generalizations, see Chapter 3 of [Ivr4].

Successive Approximations Method

After the (2.9) and (2.75)-type estimates are established, we can apply the successive approximations method like in Subsection 2 but with some modifications: to construct $Bu^{0\pm}|_{x_1=0}$ and from it to construct $u^{1\pm}$, we freeze coefficients in $(y',0)$ rather than in y. As a result, we can calculate all terms in the asymptotics and under microhyperbolicity in the multidirection condition, we arrive to the formulae (2.24) for $e^0(.,.,\tau)$, $e^1(.,.,\tau)$ and $e(.,.,\tau)$ [25] with $m \ge 1$ for $e^1(.,.,\tau)$.

The formulae for $\varkappa^1_m(\tau)$ (and thus for $\varkappa_m(\tau) = \varkappa^0_m(\tau)+\varkappa^1_m(\tau)$ are however rather complicated and we do not write them here. For the Schrödinger operator with $V = 0$ and boundary condition (2.71), the calculation of $\varkappa^1_1(\tau)$ is done in [HA].

Similar formulae also hold if we take $x_1 = y_1 = 0$ and integrate over ∂X (but in this case $m \ge 0$ even for $e^1(.,.,\tau)$).

Furthermore, if $\ell'_x = 0$ and $\nu_1 = \dots = \nu_{N-1}$ in the condition of microhyperbolicity, we are able to get formulae for $e^0(x,x,\tau)$, $e^1(x,x,\tau)$ and

[25] With the obvious definitions of $e^0(.,.,\tau)$ and $e^1(.,.,\tau)$.

$e(x,x,\tau)$ without setting $x_1=0$ and without integrating but $e^1(x,x,\tau)$ is a boundary-layer type term.

For details and proofs, see Section 7.2 of [Ivr4].

Recovering Spectral Asymptotics

Repeating the arguments of Subsection 2, we can recover the local spectral asymptotics:

Theorem 2.17. *(i) Let an operator H be microhyperbolic on $\mathsf{supp}(\psi)$ on the energy levels λ_1 and λ_2 ($\lambda_1<\lambda_2$) and the boundary value (H,B) problem be microhyperbolic on $\mathsf{supp}(\psi)\cap\partial X$ on these energy levels. Then,*

$$\int_X e(y,y,\lambda_1,\lambda_2)\psi(y)\,dy = h^{-d}\int_X \kappa_0(y,\lambda_1,\lambda_2)\psi(y)\,dy + O(h^{-d+1}). \tag{2.82}$$

(ii) Suppose that an operator H is elliptic on $\mathsf{supp}(\psi)$ on the energy levels λ_1 and λ_2 ($\lambda_1<\lambda_2$)[26] *and the boundary value (H,B) problem is microhyperbolic on $\mathsf{supp}(\psi)\cap\partial X$ on these energy levels. Then,*

$$\int_X e(y,y,\lambda_1,\lambda_2)\psi(y)\,dy = h^{1-d}\int_X \kappa_1(y,\lambda_1,\lambda_2)\psi(y)\,dy + O(h^{-d+2}). \tag{2.83}$$

On the other hand, for the Schrödinger operator, we can calculate the contributions of near normal trajectories explicitly and then we arrive to:

Theorem 2.18. *Let (H,B) be the Schrödinger operator* (2.70)–(2.71) *and let $|V|\neq\lambda$ on $\mathsf{supp}(\psi)$. Then,*

$$e(y,y,\lambda) = h^{-d}\bigl(\kappa_0(x,\lambda)+\mathcal{Q}(x',\lambda;h^{-1}x_1)\bigr)+O(h^{-d+1}) \tag{2.84}$$

where $\mathcal{Q}$ depends on the "normal variables" (x',λ) and a "fast variable" $s=h^{-1}x_1$ and decays as $O(s^{-d+1/2})$ as $s\to+\infty$. Here, $x_1=\mathsf{dist}(x,\partial X)$.

For details, exact statement and proofs, see Section 8.1 of [Ivr4].

[26] Then, it is elliptic on all energy levels $\tau\in[\lambda_1,\lambda_2]$.

Second Term and Dynamics

As in Subsection 2, we can improve our asymptotics under certain conditions to the dynamics of propagation of singularities. However, in the case that the manifold has a non-empty boundary, propagation becomes really complicated. For Schrödinger operators, we can prove that singularities propagate along Hamiltonian billiards unless they "behave badly" that is become tangent to ∂X at some point or make an infinite number of reflections in finite time. However, the measure of *dead-end points*[27] is 0.

Thus, applying the arguments of Section 1 we arrive to

Theorem 2.19. *Let $d \geq 2$, $|V-\lambda| + |\nabla V| \neq 0$ on $\mathsf{supp}(\psi)$ and $|V-\lambda| + |\nabla_{\partial X} V| \neq 0$ on $\mathsf{supp}(\psi) \cap \partial X$. Further, assume that the measure of periodic Hamiltonian billiards passing through points of $\{H^0(x,\xi)=0\} \cap \mathsf{supp}(\psi)$ is 0*[28]*. Then,*

$$\int e(y,y,\lambda)\psi(y)\,dy = h^{-d}\int \kappa_0(y,\lambda)\psi(y)\,dy + o(h^{-d+1}). \tag{2.85}$$

Remark 2.20. If we are interested in the propagation of singularities without applications to spectral asymptotics, the answer is "singularities propagate along the generalized Hamiltonian billiards" (see Definition 3.2.2 in [Ivr4]).

One can easily show:

Theorem 2.21. *Let $d \geq 3$. Assume that we are in the framework of Theorem 2.17(ii). Further assume that the set of periodic trajectories of the Schrödinger operator on ∂X with potential W introduced after* (2.77) *has measure 0. Then,*

$$\int e(y,y,\lambda)\psi(y)\,dy = h^{1-d}\varkappa_{1,\psi}(\lambda) + h^{2-d}\varkappa_{2,\psi}(\lambda) + o(h^{-d+2}). \tag{2.86}$$

Remark 2.22. Analysis becomes much more complicated for more general operators even if we assume that the inner propagation is simple. For example, if the operator in question is essentially a collection of m Schrödinger operators intertwined through boundary conditions then every incidence ray after reflection generates up to m reflected rays and we have *branching*

[27] I.e. points $z \in \Sigma(\lambda)$ the billiard passing through which behaves badly.

[28] There is a natural measure $dxd\xi : dH^0$.

Hamiltonian billiards. Here, a *dead-end point* is a point $z \in \Sigma(\lambda)$ such that *some of the branches* behave badly and a *periodic point* is a point $z \in \Sigma(\lambda)$ such that *some of the branches* return to it.

Assume that the sets of all periodic points and all dead-end points on the energy level $\Sigma(\lambda)$ have measure 0 (as shown in [SV2], the set of all dead-end points may have positive measure). Then, the two-term asymptotics could be recovered. However, the investigation of branching Hamiltonian billiards is a rather daunting task.

Rescaling Technique

The rescaling technique could be applied near ∂X as well. Assume that $\lambda = 0$. Then to get rid of the non-degeneracy assumption $V(x) \le -\epsilon$, we use scaling functions $\gamma(x)$ and $\rho(x)$ as in Subsection 2. It may happen that $B(x, \gamma(x)) \subset X$ or it may happen that $B(x, \gamma(x))$ intersects ∂X. In the former case, we are obviously done and in the latter case we are done as well because in the condition (2.71) we scale $\alpha \mapsto \alpha\rho\nu$, $\beta \mapsto \beta\nu$ where $\nu > 0$ is a parameter of our choice. Thus, in the pointwise asymptotics, we can get rid of this assumption for $d \ge 3$, and in the local asymptotics for $d \ge 2$ assuming that $|V| + |\nabla V| \asymp 1$ because the total measure of the balls of radii $\le \gamma$ which intersect ∂X is $O(\gamma)$. For details, exact statements and proofs, see Section 8.2 of [Ivr4].

Operators with Periodic Billiards

Simple Billiards Consider an operator on a manifold with boundary. Assume first that all the billiard trajectories (on energy levels close to λ) are *simple* (i.e. without branching) and periodic with a period bounded from above; then the period depends only on the energy level. Example: the Laplace-Beltrami operator on the semisphere. Under some non-degeneracy assumptions similar to (2.59), we can derive asymptotics similar to (2.63) but with two major differences:

(i) We assume that $\varepsilon \asymp h$ and recover remainder estimate only $O(h^{1-d+\delta})$; it is still good enough to have the second term of the non-standard type.

(ii) We can consider $b(x, \xi)$ (which is invariant with respect to the Hamiltonian billard flow) as a phase shift for one period. Now, however, it could

be a result not only of the quantum drift as in Subsection 2, but also of an instant change of phase at the moment of the reflection.

For exact statements, details and proofs, see Subsection 8.3.2 of [Ivr4].

Branching Billiards with "Scattering" We now assume that the billiard branches but only one ("main") branch is typically periodic. For example, consider two Laplace-Beltrami operators intertwined through boundary conditions: one of them is an operator on the semisphere X_1 and another on the disk X_2 with ∂X_1 and ∂X_2 glued together. Then all billiards on X_1 are periodic but there exist nowhere dense sets $\Lambda_j(\lambda)$ of measure 0, such that the billiards passing through $\Sigma_j(\lambda) \setminus \Lambda_j(\lambda)$ and containing at least one segment in X_2 are not periodic. Assume also that the boundary conditions guarantee that at reflection, the "observable" part of energy escapes into X_2. Then to recover the sharp remainder estimates, we do not need a phase shift because for time $T \gg 1$, we have

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\, d_\tau e(y,y,\tau)\, dy| \le C_0 h^{1-d} \sum_{|n|\le T} q^n + o_T(h^{1-d}), \tag{2.87}$$

where $q \le 1$ estimates from above the "portion of energy" which goes back to X_1 at each reflection; if $q < 1$, as we have assumed the right-hand expression does not exceed $C_1 h^{1-d} + o_T(h^{1-d})$ and we recover asymptotics similar to (2.63) with the remainder estimate $o(h^{1-d})$.

For exact statements, details and proofs, see Subsection 8.3.3 of [Ivr4].

Two Periodic Billiards We can also consider the case when the billiards flows in X_1 and X_2 are both periodic but "magic" happens at reflections. For exact statements, details and proofs, see Subsection 8.3.4 of [Ivr4].

3 Global Asymptotics

In this section, we consider global spectral asymptotics. Here we are mainly interested in the asymptotics with respect to the spectral parameter λ. We consider mainly examples.

Weyl Asymptotics

Regular Theory

We start from examples in which we apply only the results of the previous Chapter 2 which may be combined with *Birman-Schwinger principle* and the rescaling technique.

Simple Results

Example 3.1. Consider a self-adjoint operator A with domain $\mathfrak{D}(A) = \{u : Bu|_{\partial X} = 0\}$. We assume that A is elliptic and the boundary value problem (A, B) is elliptic as well.

(i) We are interested in $\mathsf{N}(0, \lambda)$, the number of eigenvalues of A in $[0, \lambda)$. Instead we consider $\mathsf{N}(\lambda/2, \lambda)$, which is obviously equal to $\mathsf{N}_h(\frac{1}{2}, 1)$, the number of eigenvalues of $A_h = \lambda^{-1}A$ that lie in $[\frac{1}{2}, 1)$, with $h = \lambda^{-1/m}$ where m is the order of A. In fact, more is true: the principal symbols of semiclassical operators A_h and B_h coincide with the senior symbols of A and B. Then the microhyperbolicity conditions are satisfied and the semiclassical asymptotics with the remainder estimate $O(h^{1-d})$ hold which could be improved to two-term asymptotics under our standard non-periodicity condition. As a result, we obtain

$$\mathsf{N}(0, \lambda) = \varkappa_0 \lambda^{\frac{d}{m}} + O(\lambda^{\frac{d-1}{m}}) \tag{3.1}$$

and

$$\mathsf{N}(0, \lambda) = \varkappa_0 \lambda^{\frac{d}{m}} + \varkappa_1 \lambda^{\frac{d-1}{m}} + o(\lambda^{\frac{d-1}{m}}), \tag{3.2}$$

as $\lambda \to +\infty$ in the general case and under the standard non-periodicity condition respectively. Here,

$$\varkappa_0 = (2\pi)^{-d} \iint \boldsymbol{n}(x, \xi)\, dx d\xi \tag{3.3}$$

where $\boldsymbol{n}(x, \xi)$ is the number of eigenvalues of $A^0(x, \xi)$ in $(0, 1)$ and $m = m_A$ is the order of A.

(ii) Suppose that A_B is positive definite (then $m_A \geq 2$) and V is an operator of the order $m_B < m_A$, symmetric under the same boundary conditions. We are interested in $\mathsf{N}(0, \lambda)$, the number of eigenvalues of VA_B^{-1} in (λ^{-1}, ∞).

Using the Birman-Schwinger principle, we can again reduce the problem to the semiclassical one with $H = h^{m_A}A - h^{m_V}V$, $h = \lambda^{-1/m}$, $m = m_A - m_V$. The microhyperbolicity condition is fulfilled automatically unless $\xi = 0$ and $V^0(x,\xi)$ is degenerate. Still under certain appropriate assumptions about V^0, we can ensure microhyperbolicity (for $m_B = 0, 1$ only). Then (3.1) and (3.2) (the latter under standard non-periodicity condition) hold with $\boldsymbol{n}(x,\xi)$ the number of eigenvalues of $V^0(x,\xi)(A^0(x,\xi)^{-1})$ in $(1,\infty)$.

(iii) Alternatively, we can consider the case when V is positively defined (and A_B may be not).

(iv) For scalar operators, one can replace microhyperbolicity by a weaker non-degeneracy assumption. Furthermore, without any non-degeneracy assumption we arrive to one-term asymptotics with the remainder estimate $O(\lambda^{(d-1+\delta)/m})$.

(v) Also one can consider operators whose all Hamiltonian trajectories are periodic; in this case the oscillatory correction term appears.

(vi) Suppose the operator A_B has negative definite principal symbol but A_B is not semi-bounded from above and V is positive definite. Then instead of (3.1) or (3.2), we arrive to

$$\mathsf{N}(0,\lambda) = \varkappa_1\lambda^{\frac{d-1}{m}} + O(\lambda^{\frac{d-2}{m}}) \tag{3.4}$$

and

$$\mathsf{N}(0,\lambda) = \varkappa_1\lambda^{\frac{d-1}{m}} + \varkappa_2\lambda^{\frac{d-2}{m}} + o(\lambda^{\frac{d-2}{m}}), \tag{3.5}$$

(the latter under an appropriate non-periodicity assumption).

Fractional Laplacians The fractional Laplacian $\Lambda_{m,X}$ appears in the theory of stochastic processes. For $m > 0$, it is defined first on $\mathbb{R}^d$ as $\Delta^{m/2}$, and in a domain $X \subset \mathbb{R}^d$, it is defined as $\Lambda_{m,X}u = R_X\Delta^{m/2}(\theta_X u)$ where R_X is the restriction to X and θ_X is the characteristic function of X. It differs from the $m/2$-th power of the Dirichlet Laplacian in X and for $m \notin 2\mathbb{Z}$, it does not belong to the Boutet de Monvel's algebra. In particular, even if X is a bounded domain with $\partial X \in \mathscr{C}^\infty$ and $u \in \mathscr{C}^\infty(\bar{X})$, $\Lambda_{m,X}u$ does not necessarily belong to $\mathscr{C}^\infty(\bar{X})$ (smoothness is violated in the direction normal to ∂X).

Then the standard Weyl asymptotics (3.1) and (3.2) hold (the latter under standard non-periodicity condition) with the standard coefficient $\varkappa_0 = (2\pi)^{-d}\omega_{d-1}\,\mathsf{vol}_d(X)$ and with

$$\varkappa_{1,m} = (2\pi)^{1-d}\omega_{d-1}\sigma_m\,\mathsf{vol}_{d-1}(\partial X), \tag{3.6}$$

$$\sigma_m = \frac{d-1}{m}\iint_1^\infty \tau^{-(d-1)/m-1}\Big(e_m(x_1,x_1,\tau) - \pi^{-1}(\tau-1)^{1/m}\Big)\,dx_1\,d\tau \tag{3.7}$$

where $e_m(x_1,y_1,\tau)$ is the Schwartz kernel of the spectral projector of operator

$$a_m = ((D_x^2+1)^{m/2})_{\mathsf{D}} \tag{3.8}$$

on $\mathbb{R}^+$. To prove this, we need to redo some analysis of Chapter 2. While tangent rays are treated exactly as for the ordinary Laplacian, normal rays require some extra work. However, we can show that the singularities coming along transversal rays do not stall at the boundary but reflect according the standard law. For exact statements, details and proofs, see [Ivr5].

Semiclassical Dirichlet-to-Neumann Operator Consider the Laplacian Δ in X. Assuming that λ is not an eigenvalue of Δ_{D}, we can introduce the Dirichlet-to-Neumann operator $L_\lambda : v \mapsto \lambda^{-\frac{1}{2}}\partial_\nu u|_{\partial X}$ where u is defined as $(\Delta-\lambda)u = 0$, $u|_{\partial X} = v$ and ν is the inner unit normal. Here, L_λ is a self-adjoint operator and we are interested in $\mathsf{N}_\lambda(a_1,a_2)$, the number of its eigenvalues in the interval $[a_1,a_2)$. Due to the Birman-Schwinger principle, it is equal to $N_h^-(a_1) - N_h^-(a_2)$ where $N_h^-(a)$ is the number of the negative eigenvalues of $h^2\Delta - 1$ under the boundary condition $(h\partial_\nu - a)u|_{\partial X} = 0$ and then we arrive to

$$\mathsf{N}_\lambda(a_1,a_2) = O(\lambda^{\frac{d-1}{m}}) \tag{3.9}$$

and

$$\mathsf{N}_\lambda(a_1,a_2) = \varkappa_1(a_1,a_2)\lambda^{\frac{d-1}{2}} + o(\lambda^{\frac{d-1}{2}}) \tag{3.10}$$

(the latter under a standard non-periodicity condition). For exact statements, details and proofs, see [HA].

Rescaling Technique We are interested in the asymptotics of either

$$\mathsf{N}^-(\lambda) = \int e(x,x,\lambda)\,dx \tag{3.11}$$

or

$$\mathsf{N}(\lambda_1,\lambda_2) = \int e(x,x,\lambda_1,\lambda_2)\,dx \qquad \text{with} \quad \lambda_1 < \lambda_2 : \tag{3.12}$$

with respect to either the spectral parameter(s), or semiclassical parameter(s), or some other parameter(s). We assume that there exist *scaling functions* $\gamma(x)$ and $\rho(x)$ satisfying

$$|\nabla\gamma| \le \frac{1}{2}, \qquad |x-y| \le \gamma(y) \implies c^{-1} \le \rho(x)/\rho(y) \le c, \tag{3.1.13)$_{1,2}}$$

such that after rescaling $x \mapsto x/\gamma(y)$ and $\xi \mapsto \xi/\rho(y)$ in $B(y,\gamma(y))$, we find ourselves in the framework of the previous chapter with an *effective semiclassical parameter* $\hbar \le 1$ [29].

To avoid non-degeneracy assumptions, we consider only the Schrödinger operator (2.70) in $\mathbb{R}^d$, assuming that $g^{jk} = g^{kj}$,

$$|\nabla^\alpha g^{jk}| \le c_\alpha \gamma^{-|\alpha|}, \qquad |\nabla^\alpha V| \le c_\alpha \rho^2 \gamma^{-|\alpha|} \tag{3.14}$$

and

$$\sum_{j,k} g^{jk}\xi_j\xi_k \ge \epsilon_0 |\xi|^2 \qquad \forall x,\xi. \tag{3.15}$$

In the examples below, $h \asymp 1$.

Example 3.2. (i) Suppose the conditions (3.14), (3.15) are fulfilled with $\gamma(x) = \frac{1}{2}(|x|+1)$ and $\rho(x) = |x|^m$, $m > 0$. Further, assume that the *coercivity condition*

$$V(x) \ge \epsilon_0 \rho^2 \tag{3.16}$$

holds for $|x| \ge c_0$. Then if $|x| \le C\lambda^{1/2m}$, for the operator $H - \lambda$, we can use $\rho_\lambda(x) = \lambda^{1/2}$ and then the contribution of the ball $B(x,\gamma(x))$ to the remainder does not exceed $C\lambda^{(d-1)/2}\gamma^{d-1}(x)$; summation over these balls results in $O\big(\lambda^{(d-1)(m+1)/2m}\big)$.

[29] In purely semiclassical settings, $\hbar = h/\rho\gamma$ and we assume $\rho\gamma \ge h$.

On the other hand, if $|x| \le C\lambda^{\frac{1}{2m}}$, for the operator $H-\lambda$ we can use $\rho(x)=\gamma^m(x)$ but there the ellipticity condition is fulfilled and then the contribution of the ball $B(x,\gamma(x))$ to the remainder does not exceed $C\gamma^{-s}$; summation over these balls results in $o\big(\lambda^{(d-1)(m+1)/2m}\big)$. Then we arrive to

$$\mathsf{N}(\lambda) = c_0 h^{-d}\int (\lambda - V(x))_+^{\frac{d}{2}} + O\big(\lambda^{(d-1)(m+1)/2m}\big) \tag{3.17}$$

as $\lambda \to +\infty$. Obviously the main part of the asymptotics is $\asymp \lambda^{d(m+1)/2m}$.

(ii) Suppose instead $0 > m > -1$. We are interested in its eigenvalues tending to the bottom of the continuous spectrum (which is 0) from below. We no longer require the assumption (3.16).

We use the same $\gamma(x)$ but now $\rho_\lambda(x)=\gamma(x)^m$ for $|x| \le C|\lambda|^{1/2m}$. Then the contribution of the ball $B(x,\gamma(x))$ to the remainder does not exceed $C\gamma(x)^{(d-1)(m+1)}$; summation over these balls results in $O\big(|\lambda|^{(d-1)(m+1)/2m}\big)$.

On the other hand, if $|x| \ge C|\lambda|^{1/2m}$, for the operator $H-\lambda$ we can use $\rho_\lambda(x)=|\lambda|^{\frac{1}{2}}$, but there the ellipticity condition is fulfilled and then the contribution of the ball $B(x,\gamma(x))$ to the remainder does not exceed $C|\lambda|^{-s}\gamma^{d-s}$; summation over these balls results in $o\big(|\lambda|^{(d-1)(m+1)/2m}\big)$. Then we arrive to asymptotics (3.17) again as $\lambda \to -0$.

Obviously the main part of the asymptotics is $O\big(|\lambda|^{d(m+1)/2m}\big)$ and under the assumption $V(x) \le -\epsilon\rho(x)^2$, in some cone it is $\asymp |\lambda|^{d(m+1)/2m}$.

(iii) In both cases (i) and (ii), the main contribution to the remainder is delivered by the zone $\{\varepsilon < |x||\lambda|^{-1/2m} < \varepsilon^{-1}\}$ and assuming that $g^{jk}(x)$ and $V(x)$ stabilize as $|x| \to +\infty$ to $g^{jk0}(x)$ and $V^0(x)$, positively homogeneous functions of degrees 0 and $2m$ respectively, and that the set of periodic trajectories of the Hamiltonian $\sum_{j,k} g^{jk}(x)\xi_j\xi_k + V^0(x)$ on energy level 1 in (i) or -1 in (ii) has measure 0, we can improve the remainder estimates to $o\big(|\lambda|^{(d-1)(m+1)/2m}\big)$.

Example 3.3. Consider the Dirac operator

$$H = \sum_{1\le j\le d} \sigma_j D_j + M\sigma_0 + V(x), \tag{3.18}$$

where σ_j ($j=0,\dots,d$) are Pauli matrices in the corresponding dimension and $M>0$. Let $V(x)\to 0$ as $|x|\to\infty$. Then the essential spectrum of H

is $(-\infty,-M]\cup[M,\infty)$ and for V as in Example 3.2(ii), we can get similar results for the asymptotics of eigenvalues tending to $M-0$ or $-M+0$: so instead of $\mathsf{N}(\lambda)$, we consider $\mathsf{N}(0,M-\eta)$ or $\mathsf{N}(M+\eta,0)$ with $\eta\to+0$.

Example 3.4. Consider the Schrödinger operator, either in a bounded domain $X\ni 0$ or in $\mathbb{R}^d$ like in Example 3.2(i) and assume that $g^{jk}(x)$ and $V(x)$ have a singularity at 0 satisfying there (3.14)–(3.16) with $\gamma(x)=|x|$ and $\rho(x)=|x|^m$ with $m<-1$.

Consider the asymptotics of eigenvalues tending to $+\infty$. As in Example 3.2(i), we take $\gamma(x)=\frac{1}{2}|x|$ and $\rho_\lambda(x)=\lambda^{1/2}$ for $|x|\ge\epsilon_0\lambda^{1/2m}$ (then the contribution of $B(x,\gamma(x))$ to the remainder does not exceed $\lambda^{(d-1)/2}|x|^{d-1}$) and $\rho_\lambda(x)=|x|^m$ as $|x|\le\epsilon_0\lambda^{1/2m}$ (then due to the ellipticity the contribution of $B(x,\gamma(x))$ to the remainder does not exceed $\rho^{-s}\gamma^{-s-d}$). We conclude that the contribution of $B(0,\epsilon)$ to the remainder does not exceed $C\lambda^{(d-1)/2}\epsilon^{d-1}$ which means that this singularity does not prevent remainder estimate as good as $o(\lambda^{(d-1)/2})$. However, this singularity affects the principal part which should be defined as in (3.17).

Example 3.5. (i) When analyzing the asymptotics of the large eigenvalues, we can consider a potential that is either rapidly increasing (with $\rho=\exp(|x|^m)$, $\gamma(x)=|x|^{1-m}$, $m>0$), or slowly increasing (with $\rho=(|\log x|)^m$, $\gamma(x)=|x|$, $m>0$) which affects both the magnitude of the main part and the remainder estimate.

(ii) When analyzing the asymptotics of the eigenvalues tending to the bottom of the essential spectrum, we can consider a potential that is either rapidly decreasing (with $\rho=|x|^{-1}(\log|x|)^m$ with $m>0$, $\gamma(x)=|x|$, $m>0$) or slowly decreasing (with $\rho=(|\log x|)^m$, $\gamma(x)=|x|$, $m<0$) which affects both the magnitude of the main part as well as the remainder estimate.

Remark 3.6. We can consider the same examples albeit assuming only that $h\in(0,1)$; then the remainder estimate acquires the factor h^{-d+1}.

Singularities

Let us consider other types of singularities when there is *a singular zone* where after rescaling $\hbar\le 1$ [29]. Still, it does not prevent us from using the approach described above to get an estimate from below for (3.11) or (3.12): we only need to decrease these expressions by inserting ψ ($0\le\psi\le 1$) that

is supported in *the regular zone* (aka *the semiclassical zone*) defined by $\hbar \le 2\hbar_0$ after rescaling and equal to 1 for $\hbar \le \hbar_0$ and applying the rescaling technique there.

Let us discuss an estimate from above. If there was no regular zone at all, we would have no estimate from below at all but there could be some estimate from above of variational nature. The best known is the LCR (Lieb-Cwikel-Rosenblum) estimate

$$\mathsf{N}^-(0) \le Ch^{-d} \int V_-^{\frac{d}{2}}\, dx \tag{3.19}$$

for the Schrödinger operator with Dirichlet boundary conditions as $d \ge 3$. For $d = 2$, the estimate is marginally worse (see [Roz1] for the most general statement for arbitrary orders of operators and dimensions and [Shar] for the most general results for the Schrödinger operator in dimension 2).

It occurs that we can split our domain into an overlapping *regular zone* $\{x :\ \rho(x)\gamma(x) \ge h\}$ and a *singular zone* $\{x :\ \rho(x)\gamma(x) \le 3h\}$, then evaluate the contribution of the regular zone using the rescaling technique and the contribution of the singular zone by the variational estimate as if on the inner boundary of this zone (i.e. a part of its boundary which is not contained in ∂X) the Dirichlet boundary condition was imposed, and we add these two estimates:

$$\begin{aligned} -Ch^{1-d} \int_{\{\rho\gamma\ge h, V\le\epsilon\rho^2\}} \rho^{d-1}\gamma^{-1}\sqrt{g}\, dx& \\ \le \mathsf{N}^-(0) - (2\pi)^{-d}\omega_d h^{-d} \int_{\{\rho\gamma\ge h\}} V_-^{d/2}\, dx& \\ \le Ch^{1-d} \int_{\{\rho\gamma\ge h, V\le\epsilon\rho^2\}} \rho^{d-1}\gamma^{-1}\, dx + Ch^{-d} \int_{\{\rho\gamma\le h, V\le\epsilon\rho^2\}} \rho^d\, dx.& \end{aligned} \tag{3.20}$$

See Theorems 9.1.7 and 9.1.13 of [Ivr4] for more general statements. Further, similar statements could be proven for operators which are not semi-bounded (see Theorems 10.1.7 and 10.1.8 of [Ivr4]).

In particular, we have:

Example 3.7. (i) Let

$$\int \rho^{d-1}\gamma^{-1}\, dx < \infty. \tag{3.21}$$

Then,

$$\mathsf{N}^-(0) = (2\pi)^{-d}\omega_d h^{-d}\int V_-^{d/2}\sqrt{g}\,dx + O(h^{1-d}). \tag{3.22}$$

(ii) If in addition the standard non-periodicity condition is satisfied then

$$\mathsf{N}^-(0) = (2\pi)^{-d}\omega_d h^{-d}\int V_-^{d/2}\sqrt{g}\,dx - \frac{1}{4}(2\pi)^{1-d}\omega_{d-1}h^{1-d}\int V_-^{(d-1)/2}\,dS + o(h^{1-d}), \tag{3.23}$$

where dS is a corresponding density on ∂X.

Example 3.8. Consider the Dirichlet Laplacian in a domain X assuming that there exists scaling function $\gamma(x)$ such that (3.14) holds and

(3.24) For each $y \in X$, the connected component of $B(y,\gamma(x))\cap X$ containing y coincides with $\{x \in B(0,1), x_1 \le f(x')\}$, where $x' = (x_2,\dots,x_d)$ and

$$|\nabla^\alpha f| \le C_\alpha \gamma^{1-|\alpha|} \qquad \forall \alpha, \tag{3.25}$$

where we rotate the coordinate system if necessary[30)].

(i) Then the principal part of asymptotics is

$$c_0 \lambda^{\frac{d}{2}} h^{-d}\int_{\{x:\gamma(x)\ge\lambda^{-\frac12}\}} dx \tag{3.26}$$

and the remainder does not exceed

$$C\lambda^{\frac{d-1}{2}}h^{1-d}\int_{\{x:\gamma(x)\ge\lambda^{-\frac12}\}}\gamma(x)^{-1}\,dx + C\lambda^{\frac{d}{2}}h^{-d}\int_{\{x:\gamma(x)\le\lambda^{-\frac12}\}} dx. \tag{3.27}$$

(ii) In particular, if

$$\int_X \gamma(x)^{-1}\,dx < \infty, \tag{3.28}$$

[30)] It is precisely the condition that we need to impose on the boundary for the rescaling technique to work.

then the standard asymptotics with the remainder estimate $O(\lambda^{(d-1)/2}h^{1-d})$ hold. Moreover, under the standard condition (1.3), we arrive to the two-term asymptotics (1.2).

These conditions are satisfied for domains with vertices, edges and conical points. In fact, we may allow other singularities including outer and inner spikes and cuts.

Furthermore, these conditions are satisfied for unbounded domains with cusps (exits to infinity) provided these cusps are thin enough (basically having finite volume and area of the boundary).

(iii) These results hold under the Neumann or mixed Dirichlet-Neumann boundary condition, but then we need to assume that the domain satisfies the cone condition; for the two-term asymptotics, we also need to assume that the border between the parts of ∂X with the Dirichlet and Neumann boundary conditions has $(d-1)$-dimensional measure 0.

Example 3.9. (i) Suppose that the potential is singular at $0 \in X$ like $|x|^{2m}$ with $m \in (-1, 0)$. Then this singularity does not affect the asymptotics of large eigenvalues.

(ii) Let us consider Example 3.2(i) albeit allow $V \ge 0$ to vanish along certain directions. Then we have *canyons* and $\{x : V(x) \le \lambda\}$ are cusps. If the canyons are narrow and steep enough then the same asymptotics (3.17) hold. Moreover, under the non-periodicity condition, the remainder estimate is "o".

(iii) Let us consider Example 3.2(ii) albeit allow $V \ge 0$ to be singular along certain directions. Then we have *gorges* and $\{X : V(x) \le \lambda\}$ are cusps. If the gorges are narrow and shallow enough then the same asymptotic (3.17) hold. Moreover, under the non-periodicity condition, the remainder estimate is "o".

Example 3.10. We can consider also multiparameter asymptotics, for example with respect to $h \to +0$ and λ. In addition to what we considered above, the following interesting possibility appears: $\lambda \searrow \lambda_* := \inf V(x)$ which is either finite or $-\infty$. Then if λ tends to λ_* slowly enough so that $\mathsf{N}_h^-(\lambda) \to +\infty$, we get interesting asymptotics.

In particular, as either $V(x) \asymp |x|^{2m}$ with $m > 0$ and $\lambda \to +0$ or $V(x) \asymp |x|^{2m}$ with $0 > m > -1$ and $\lambda \to -\infty$, then this condition is $h = o(|\lambda|^{(m+1)/2m})$.

Remark 3.11. We can also consider $\mathsf{Tr}((-H)^{\nu}\theta(-H))$ with $\nu > 0$. Then in the estimates above, $\rho^d \mapsto \rho^{d+2\nu}$ and $\rho^{d-1} \mapsto \rho^{d+\nu-1}\gamma^{-\nu-1}$.

For full details, proofs and generalizations, see Chapter 11 of [Ivr4] which covers also non-semibounded operators.

Non-Weyl Asymptotics

Partially Weyl Theory

Analyzing the examples of the previous section, one can observe that for some values of the exponents, the condition (3.21) (or it special case (3.28)) fails but the main term of the asymptotics is still finite and has the same rate of the growth as it had before, while for other values of the exponent, it is infinite. In the former case, we get Weyl asymptotics but with a worse remainder estimate, in the latter case, all we can get is an estimate rather than the asymptotics. Can one save the day?

In many cases, the answer is positive and we can derive either the Weyl asymptotics but with a non-Weyl correction term or completely non-Weyl asymptotics. The main but not the only tool is the spectral asymptotics for operators with operator-valued symbols. Namely, in some zone of the phase space, we separate the variables[31] $x = (x'; x'')$ and $(\xi'; \xi'')$ respectively and consider the variables (x', ξ') as *semiclassical variables* (or *Weyl variables*), similar to (x, ξ) in the previous scheme. So we get an operator $\mathsf{H}(x', D')$ with an operator-valued symbol which we can study in the same way as the operator H before.

One can say that we have a matrix operator but with a twist: first, instead of finite-dimensional matrices, we have unbounded self-adjoint operators in the auxilary infinite-dimensional Hilbert space $\mathbb{H}$ (usually $\mathscr{L}^2$ in the variables x''); second, we are interested in the asymptotics

$$\int \mathsf{tr}_{\mathbb{H}}\bigl(\hat{e}(x', x', \lambda)\bigr)\, dx', \tag{3.29}$$

[31] After some transformation, the transformations and separations in the different zones are not necessarily the same.

rather than in the asymptotics without trace where $\hat{e}(x', y'; \lambda)$ is an operator in $\mathbb{H}$ (with Schwartz kernel $e(x', y'; x'', y''; \lambda)$); and, finally, the main term in asymptotics is

$$\int \mathsf{tr}_{\mathbb{H}}\big(\mathsf{e}(x', \xi'; \lambda)\big)\, d\xi' dx', \tag{3.30}$$

where $\mathsf{e}(x', \xi', \lambda)$ is a spectral projector (in $\mathbb{H}$) of $\mathsf{H}(x', \xi')$. Here, we need to assume that $\mathsf{H}(x', \xi')$ is microhyperbolic with respect to (x', ξ'). Since the operator $\mathsf{tr}_{\mathbb{H}}$ is now unbounded, both the main term of the asymptotics of (3.29) and the remainder estimate *may* have magnitudes different from what they would be without $\mathsf{tr}_{\mathbb{H}}$.

Since the operator $\mathsf{H}(x', \xi')$ is rather complicated, we want to replace it by some simpler operator and add some easy to calculate correction terms.

We consider multiple examples below. Magnetic Schrödinger, Schrödinger-Pauli and Dirac operators studied in Sections 2 and 3 are also of this type.

Domains with Thick Cusps

This was done in Section 12.2 of [Ivr4] for operators in domains with thick cusps of the form $\{x : x'' \in f(x')\Omega\}$ where Ω is a bounded domain in $\mathbb{R}^{d''}$ with smooth boundary, defining the cusp crossection. Here again we consider for simplicity the Dirichlet Laplacian. Assume first that the metric is Euclidean and the domain $X = \{x = (x', x'') : x' \in X' := \mathbb{R}^{d'}, x'' \in f(x')\Omega\}$. Then, the change of variables $x'' \mapsto x''/f(x')$ transforms Δ to the operator

$$P = \sum_{1\le j\le d'} \Big(D_j + g_{x_j} L + \frac{id''}{2} g_{x_j}\Big)\Big(D_j + g_{x_j} L - \frac{id''}{2} g_{x_j}\Big) + \frac{1}{f^2}\Delta'' \tag{3.31}$$

in $\mathscr{L}^2(X' \times \Omega) = \mathscr{L}^2(\mathbb{R}^{d'}, \mathbb{H})$ where $L = \langle x'', D''\rangle$, $g = -\log f$, $\mathbb{H} = \mathscr{L}^2(\Omega)$, Δ' is a Laplacian in X', and $\Delta'' = \Delta''_{\mathsf{D}}$ is a Dirichlet Laplacians in Ω, and we simultaneously multiply u by $f^{-d''/2}$ to have the standard Euclidean measure rather than the weighted one $f^{d''} dx$. We consider the operator (3.31) as a perturbation of the operator

$$\bar{P} := \Delta' + \frac{1}{f^2}\Delta'', \tag{3.32}$$

which is a direct sum of d'-dimensional Schrödinger operators $P_n = \Delta' + \mu_n f^{-2}$ in X' where $\mu_n > 0$ are the eigenvalues of Δ''_{D}. Assuming that

$$f \asymp |x|^{-m}, \qquad |\nabla f| \asymp |x|^{-m-1} \qquad \text{for } |x'| \ge c, \tag{3.33}$$

we can ensure that the microhyperbolicity condition (with respect to $(x';\xi')$) is fulfilled for P_n, $\bar{P}$, as well as for P.

Then according to the previous section, for P_n the eigenvalue counting function is

$$\mathsf{N}_n(\lambda) = c_{d'} \int \big(\lambda - \mu_n f^{-2}(x')\big)_+^{\frac{d'}{2}}\, dx' + O\big(\lambda^{(d'-1)(m+1)/2m}\mu_n^{-(d'-1)/2m}\big), \tag{3.34}$$

where the remainder estimate is uniform with respect to n. Observe that for $\bar{P}$ the eigenvalue counting function is $\bar{\mathsf{N}}(\lambda) = \sum_n \mathsf{N}_n(\lambda)$. Using $\mu_n \asymp n^{2/d''}$, we arrive to

$$\mathsf{N}_n(\lambda) = c_{d'} \iint (\lambda - \mu f^{-2}(x'))_+^{\frac{d'}{2}}\, dx' d_\mu \boldsymbol{n}(\mu) + O(R(\lambda)) \tag{3.35}$$

with

$$R(\lambda) = \lambda^{\frac{1}{2}(d-1)} + \lambda^{\frac{m+1}{2m}(d'-1)} + \delta_{(d'-1),md''}\lambda^{\frac{1}{2}(d-1)}\log\lambda, \tag{3.36}$$

where $\boldsymbol{n}(\mu)$ is the eigenvalue counting function for Δ''_{D}.

We show, moreover, that the same asymptotics holds for our original operator (3.31). Furthermore, if the first term in (3.35) is dominant, then under the standard non-periodicity assumption we can replace $O(\lambda^{(d-1)/2})$ by $o(\lambda^{(d-1)/2})$; we need to add the standard boundary term to the right-hand expression in (3.35).

On the other hand, if the second term in (3.35) dominates, then assuming that f stabilizes as $|x'| \to \infty$ to a positively homogeneous function f_0, under the corresponding non-periodicity assumption (now in $T^*\mathbb{R}^{d'}$) for $|\xi'|^2 + f_0^{-2}(x')$, we can replace $O(\lambda^{(m+1)(d'-1)/2m})$ by $o(\lambda^{(m+1)(d'-1)/2m})$. Finally, if both powers coincide then under the stabilization condition, the remainder estimate is $o(\lambda^{(d-1)/2}\log\lambda)$ but we need to add the modified boundary term to the right-hand expression in (3.35).

Obviously, the principal part in (3.35) is of the magnitude

$$S(\lambda) = \lambda^{\frac{1}{2}d} + \lambda^{\frac{m+1}{2m}d'} + \delta_{d',md''}\lambda^{\frac{1}{2}d}\log\lambda. \tag{3.37}$$

If X is not exactly of the same form and the metric only stabilizes (fast enough) at infinity to $g^{jk0} := \delta_{jk}$, then we can recover the same remainder estimate and reduce the principal part to

$$\begin{aligned} c_{d'} \iint (\lambda - \mu f^{-2}(x'))_+^{\frac{d'}{2}} \phi(x')\, dx' d_\mu \boldsymbol{n}(\mu) \\ + c_d \lambda^{d/2} \int_X (\sqrt{g} - \sqrt{g^0}\phi(x'))\, dx, \end{aligned} \tag{3.38}$$

where $\mathsf{supp}(\phi) \subset \{|x'| \ge c\}$, $\phi = 1$ in $\{|x'| \ge c\}$. Here, the first part is exactly as above and the second term is actually the sum of two terms; one of them $c_d\lambda^{d/2}\int \sqrt{g}(1-\phi(x'))\,dx$ is the contribution of the "finite part of the domain" (without the cusp) and the second $c_d\lambda^{d/2}\int(\sqrt{g}-\sqrt{g^0})\phi(x')\,dx$ is a contribution of the cusp in the correction.

Note that now to get the remainder estimate $o(\lambda^{(d-1)/2})$, one needs to include the standard boundary term in the second part of (3.38).

The crucial part of our arguments is a *multiscale analysis*. As long as $r \le c\lambda^{1/2m-\delta}$, we can scale $x \mapsto xr^m$ and consider $\sigma_0(t) = \mathsf{Tr}\big(e^{ih^{-1}tH}\phi(x'/r)\big)$; here $H = \lambda^{-1}P$, $h = \lambda^{-1/2}r^m$. From the propagation with respect to (x,ξ), we know that on energy level 1, the time interval $(h^{1-\delta},\epsilon)$ contains no singularities of $\sigma_0(t)$.

On the other hand, for $r \ge c$, we can scale $x \mapsto x/r$ and consider $\sigma_1(t) = \mathsf{Tr}\big(e^{i\hbar^{-1}tH}\phi(x'/r)\big)$; here $\hbar = \lambda^{-1/2}r^{-1}$. From the propagation with respect to (x',ξ'), we know that on energy level 1, the time interval $(\hbar^{1-\delta},\epsilon)$ contains no singularities of $\sigma_1(t)$.

Observe first that $\sigma_1(t) = \sigma_0(r^{-1-m}t)$ and therefore the time interval $(h^{1-\delta},\epsilon r^{m+1})$ contains no singularities of $\sigma_0(t)$. This allows us to improve the remainder estimate in the full Weyl asymptotics but we need to include many terms which are difficult to calculate.

On the other hand, for $\lambda^\delta \le r \le c\lambda^{1/2m}$, we can consider H as a perturbation of $\bar{H} = \lambda^{-1}\bar{P}$. We do it first in the framework of the theory of operators with operator-valued symbols. Then we consider all perturbation terms and apply to them "full Weyl theory" and due to the stabilization assumption, the error is less than (3.36). This gives us another asymptotics, also with many terms which are difficult to calculate.

Comparing these two asymptotics in their common domain $\lambda^\delta \le r \le \lambda^{1/2m-\delta}$, we conclude that all terms but those present in both must be 0; it allows us to eliminate almost all the terms and sew these asymptotics resulting in (3.38).

Using the same approach, we can consider higher order operators, the case when X' is a conical set and there are several cusps X_k which may have different dimensions d_k' and rates of decay (then both the principal part and the remainder estimate should be modified accordingly).

Neumann Laplacian in Domains with Ultra-Thin Cusps

Consider the Neumann Laplacian in domains with cusps. Recall that since these domains do not satisfy the cone condition, we so far have no results even if the cusp is thin. Applying the same arguments as before, we hit two obstacles. The first (minor) obstacle is that the Neumann boundary condition for the operator (3.31) coincides with the same condition for Δ'' only asymptotically. The second (major) obstacle is that $\mu_1 = 0$ and $P_1 = \Delta'$ has a continuous spectrum. In fact, we should not reduce P to $\bar{P}$; from (3.31) we conclude that

$$P_1 = \sum_{1\le j\le d'} \Big(D_j + \frac{id''}{2} g_{x_j}\Big)\Big(D_j - \frac{id''}{2} g_{x_j}\Big) = \Delta' + W \tag{3.39}$$

with

$$W = \frac{d''^2}{4}|\nabla g|^2 + \frac{d''}{2}\Delta' g. \tag{3.40}$$

Still this operator may have a continuous spectrum unless $|\nabla g| \to \infty$ as $|x| \to \infty$. We need to assume that f has superexponential decay: $f = e^{-g}$ with

$$|\nabla^\alpha g| \le c_\alpha |x|^{1+m-|\alpha|} \qquad \forall \alpha, \tag{3.41}$$

$$g \asymp |x'|^{m+1}, \quad |\nabla g| \asymp |x'|^m \qquad \text{for } |x'| \ge c, \tag{3.42}$$

$$|\nabla |\nabla g|^2| \asymp |x|^{2m-1} \qquad \text{for } |x'| \ge c, \tag{3.43}$$

where $m > 0$ and (3.43) is a microhyperbolicity condition for P_1. Then one can prove easily that when $d'' \ge 2$,

$$\mathsf{N}(\lambda) = c_d \lambda^{d/2} \int_X \sqrt{g}\, dx + c_{d'} \int (\lambda - W)_+^{d'/2}\, dx' + O(R(\lambda)) \tag{3.44}$$

with

$$R(\lambda) = \lambda^{\frac{1}{2}(d-1)} + \lambda^{\frac{m+1}{2m}(d'-1)}. \tag{3.45}$$

Moreover, if the first term in (3.35) dominates, then under the standard non-periodicity assumption, we can replace $O(\lambda^{(d-1)/2})$ by $o(\lambda^{(d-1)/2})$ (simultaneously including the standard boundary term); if the second term dominates, then assuming that W stabilizes as $|x'| \to \infty$ to a positively homogeneous function W_0, under the corresponding assumption for $|\xi'|^2 + W_0(x')$ we can replace $O(\lambda^{(m+1)(d'-1)/2m})$ by $o(\lambda^{(m+1)(d'-1)/2m})$.

One can see easily that $\mathsf{N}(\lambda) \asymp S(\lambda) = \lambda^{\frac{1}{2}d} + \lambda^{\frac{m+1}{2m}d'}$. Observe that in contrast to (3.36) and (3.37), even if the exponents coincide, a logarithmic factor does not appear.

The case $d'' = 1$ is special since even an ultra-thin cusp is also thick (according to the classification of the previous Subsection 3) and the corresponding formulae should include a modified boundary term containing the double logarithm of λ. For this and other generalizations, see Section 12.7 of [Ivr4]. Also one can consider *spikes* with $\mathsf{supp}(f) = \{|x'| \le L\}$, in which case the standard Weyl asymptotics holds.

Operators in $\mathbb{R}^d$

The scheme of Subsection 3 is repeated in many similar cases.

First, consider eigenvalues tending to $+\infty$ for the Schrödinger operator with potential V which generically is $\asymp |x|^{2m}$ but vanishes along some directions.

For example, consider the toy-model $V = |x|^{2m-2m'}|x''|^{2m'}$ with $m > m' > 0$. Let $X' = \mathbb{R}^{d'} \ni x'$ and $X'' = \mathbb{R}^{d''} \ni x''$. Consider only the conical vicinity of X' and here we instead consider the potential $V = |x'|^{2m-2m'}|x''|^{2m'}$. Consider only the part of operator which is related to x'': $\Delta'' + |x'|^{2m-2m'}|x''|^{2m'}$ and after the change of variables $x'' \mapsto x''|x'|^k$ with $k = (m-m')/(m'+1)$, it becomes $|x'|^{2k}L$ with $L = \Delta'' + U(x'')$, $U = |x''|^{2m''}$. The condition $m'' > 0$ ensures that the spectrum of L is discrete and accummulates to $+\infty$.

So basically we have a mixture of the Schrödinger operator on $\mathbb{R}^d$ with a potential growing as $|x|^{2m}$ and the Schrödinger operator with the operator-valued symbol on $\mathbb{R}^{d''}$ with a potential growing as $|x|^{2k}$ and we recover the asymptotics with the remainder estimate $O(R(\lambda))$, where

$$R(\lambda) = \lambda^{\frac{m(d-1)}{(m+1)}} + \lambda^{\frac{k(d'-1)}{(k+1)}} + \delta_{\frac{m(d-1)}{(m+1)},\frac{k(d'-1)}{(k+1)}}\lambda^{\frac{m(d-1)}{(m+1)}}\log\lambda \tag{3.46}$$

and the principal part is $\asymp S(\lambda)$, where

$$S(\lambda) = \lambda^{\frac{md}{(m+1)}} + \lambda^{\frac{kd'}{(k+1)}} + \delta_{\frac{md/(m+1)}{,}\frac{kd'}{(k+1)}}\lambda^{\frac{md}{(m+1)}}\log\lambda. \tag{3.47}$$

In a rather general situation, this principal part is similar to the one in (3.38) where $\boldsymbol{n}(\mu)$ is the eigenvalue counting function for L. Further, under similar

non-periodicity assumptions, we can replace "O" by "o". For generalizations, details and proofs, see Section 12.3 of [Ivr4].

Second, consider eigenvalues tending to -0 for the Schrödinger operator with a potential V which generically is $\asymp |x|^{2m}$ with $m \in (-1, 0)$ but is singular in some directions. Again, consider a toy-model $V = -|x|^{2m-2m'}|x''|^{2m'}$ with $-1 < m < m' < 0$. Again, $L = \Delta'' + U(x'')$, $U = -|x''|^{2m''}$ and its negative spectrum is discrete and accummulates to -0. The formulae (3.46) and (3.47) remain valid (albeit $\lambda \to -0$). For generalizations, details and proofs, see Section 12.4 of [Ivr4].

Maximally Hypoelliptic Operators

Third, consider the eigenvalues tending to $+\infty$ for *maximally hypoelliptic operators with a symplectic manifold of degeneration*. Consider the toy-model $P = \Delta'' + |x''|^{2m}\Delta'$. In this case, after the partial Fourier transform, we get $\Delta'' + |x''|^{2m}|\xi'|^2$ and after the change of variables $x'' \mapsto |\xi'|^k x''$, we get $|\xi'|^{2k} L$, $L = \Delta'' + |x''|^{2m}$ and $k = 1/(m+1)$.

This toy-model is maximally hypoelliptic as the spectrum of L is discrete and accummulates to $+\infty$. So basically we have a blend of operator of order 2 on $\mathbb{R}^d$ and of order $2k$ on $\mathbb{R}^{d'}$ and we recover the asymptotics with remainder estimate $O(R(\lambda))$ with

$$R(\lambda) = \lambda^{\frac{(d-1)}{2}} + \lambda^{\frac{(d'-1)}{2k}} + \delta_{d-1,(d'-1)/k}\lambda^{\frac{(d-1)}{2}} \log \lambda \tag{3.48}$$

and principal part $\asymp S(\lambda)$ with

$$S(\lambda) = \lambda^{\frac{d}{2}} + \lambda^{\frac{d'}{2k}} + \delta_{d,d'/k}\lambda^{\frac{d}{2}} \log \lambda. \tag{3.49}$$

Further, under similar non-periodicity assumptions, we can replace "O" by "o". For generalizations, details and proofs, see Section 12.5 of [Ivr4].

Trace Asymptotics for Operators with Singularities

Here, we also consider only one example (albeit the most interesting one) of a Schrödinger operator $H := h^2\Delta - V(x)$ in $\mathbb{R}^3$ with potential $V(x)$ at 0 stabilizing to a positive homogeneous function V_0 of degree -1:

$$|\nabla^\alpha (V - V_0)| \le c_\alpha |x|^{-|\alpha|} \qquad \forall \alpha. \tag{3.50}$$

We assume that $V(x)$ decays fast enough at infinity and we are interested in the asymptotics of $\mathsf{Tr}(H_-)$, which is the sum of the negative eigenvalues of H. While generalizations are considered in Section 12.6 of [Ivr4], exactly this problem with $V_0 = |x|^{-1}$ arises in the asymptotics of the ground state energy of heavy atoms and molecules.

It follows from Section 3 that N_h^- has purely Weyl asymptotics with the remainder estimate $O(h^{-2})$ and[32] it could be improved to $o(h^{-2})$ but we have a different object and if the potential had no singularities, the remainder estimate would be $O(h^{-1})$ or even $o(h^{-1})$ [32),33)].

Therefore considering the contribution of the ball $B(x, \gamma(x))$ with $\gamma(x) = \frac{1}{2}|x|$, we have a contribution to the Weyl expression

$$-ch^{-3} \int V_+^{\frac{5}{2}}\, dx \tag{3.51}$$

of magnitude $C\rho^2(h/\rho\gamma)^{-3} = Ch^{-3}\rho^5\gamma^3$, while the contribution to the remainder does not exceed $C\rho^2(h/\rho\gamma)^{-1} = Ch^{-1}\rho\gamma$ with $\rho = |x|^{-\frac{1}{2}}$. We see that the former converges at 0 and the latter diverges. This analysis could be done for $\rho\gamma \ge h$ i.e. if $|x| \ge h^2$. Then we conclude that the contribution of the zone $\{x : |x| \ge a\}$ to the remainder does not exceed $Ch^{-1}a^{-\frac{1}{2}}$ which as $a = h^2$ is $O(h^{-2})$. On the other hand, one can easily prove that the contribution of $B(0, h^2)$ to the asymptotics is also $O(h^{-2})$.

To improve this estimate, we analyze $B(0, a)$ in more detail. In virtue of (3.50), we can easily prove that the contribution of $B(x, \gamma)$ to $\mathsf{Tr}(H_- - H_{0-})$ (with $H_0 = h^2\Delta - V_0$) does not exceed $C(h/\rho\gamma)^{-2} = Ch^{-2}\rho^2\gamma^2$ and therefore the contribution of $B(0, a)$ to the remainder is $O(h^{-2}a)$. Minimizing the total error $h^{-2}a + h^{-1}a^{-\frac{1}{2}}$ in a, we get $a = h^{\frac{2}{3}}$ and the remainder $O(h^{-\frac{4}{3}})$, which is better than $O(h^{-2})$ but not as good as $O(h^{-1})$.

But then we need to include in the asymptotics the extra term

$$\int \bigl(e_0^1(x, x, 0) - cV_+^{\frac{5}{2}}(x)\bigr)\psi(a^{-1}x)\, dx, \tag{3.52}$$

where $e(\cdot, \cdot, \lambda)$ is the Schwartz kernel of the spectral projectors for H, $e^1(\cdot, \cdot, 0) = \int_{-\infty}^0 \lambda\, d_\lambda e(\cdot, \cdot, \lambda)$ and the subscript 0 means that it is for H_0 and $\psi \in \mathscr{C}_0^\infty(B(0, 2))$ and equals 1 in $B(0, 1)$.

[32] Under the standard non-periodicity condition.

[33] But then the principal part of asymptotics should include the third term ch^{-1} while the second term vanishes.

Basically, all that we achieved so far was to replace H by H_0 in (3.52). The same arguments allow us to replace ψ by 1 in this expression with the same error $O(h^{-1}a^{-\frac{1}{2}})$. This time, we cannot decompose it as the difference of two integrals because each of them is diverging at infinity (since V_0 decays there not fast enough). Further, due to the homogeneity of V_0, one can prove that this remodelled expression (3.52) is homogeneous of degree -2 with respect to h and thus is equal to κh^{-2}. Here, κ is some unknown constant, but for $V_0 = |x|^{-1}$, it could be calculated explicitly.

Therefore, we conclude that with the remainder estimate $O(h^{-\frac{4}{3}})$, $\mathsf{Tr}(H_-)$ is given by the Weyl expression plus the *Scott corretion term* κh^{-2}.

To improve this remainder estimate, we should carefully study the propagation of singularities. We can prove that if $h^{2-\delta} \le \gamma \le 1$, then the singularities do not come back "in real time" $\asymp 1$, which is a vast improvement over $\asymp \gamma\rho^{-1} \asymp \gamma^{\frac{3}{2}}$. Then the contribution of $B(x,\gamma)$ to the "trace remainder" does not exceed $Ch^{-1}\rho^2\gamma^3$ but then the principal part of asymptotics should have a lot of terms; the n-th term is of the magnitude $h^{-3+2n}\rho^{2-2n}\gamma^{3-2n}$; however, using (3.50) we conclude that the difference between such terms for H and H_0 is $O(h^{-3+2n}\rho^{-2n}\gamma^{3-2n})$ which leads to the estimate

$$\left|\int \bigl(e^1(x,x,0) - e_0^1(x,x,0) - cV_+^{\frac{5}{2}}(x) + cV_{0+}^{\frac{5}{2}}(x)\bigr)\,dx\right| \le Ch^{-1}. \tag{3.53}$$

This estimate implies that with the remainder estimate $O(h^{-1})$, $\mathsf{Tr}(H_-)$ is given by the Weyl expression plus κh^{-2}. Moreover, this estimate could be further improved to $o(h^{-1})$ [32),33)].

Similar results hold for other singularities (including singularities of the boundary), dimensions and $\mathsf{Tr}(H_-^\nu)$ with $\nu > 0$. However, note that there could be more than one such correction term.

Periodic Operators

Finally, consider an operator $H_0 = H_0(x,D)$ with periodic coefficients (with the lattice of periods Γ). Then its spectrum is usually absolutely continuous and consists of *spectral bands* $\{\lambda_k(\xi) : \xi \in \mathcal{Q}'\}$ separated by *spectral gaps*. Here, λ_k are the eigenvalues of operator H_0 with *quasiperiodic boundary conditions*

$$u(x+n) = T^n e^{i\langle n,\xi\rangle}(x) \qquad \forall n \in \Gamma, \tag{3.54}$$

Γ^* is the dual lattice[34], $\mathcal{Q}$ and $\mathcal{Q}'$ are corresponding *elementary cells*[35]; ξ is called the *quasimomentum*. Here, $T = (T_1, \dots, T_d)$ is a family of commuting unitary matrices.

Let us consider an operator $H_t = H_0 - tW(x)$ with $W(x) > 0$ decaying at infinity. Then, while the essential spectra of H and H_t are the same, H_t can have discrete eigenvalues in the spectral gaps and these eigenvalues decrease as t increases.

Let us fix an *observation point* E belonging to either the spectral gap or its boundary and introduce $\mathsf{N}_E(\tau)$, the number of eigenvalues of H_t crossing E as t changes between 0 and τ. We are interested in the asymptotics of $\mathsf{N}_E(\tau)$ as $t \to \infty$.

Then using Gelfand's transform,

$$\mathcal{F}u(\xi, x) = (2\pi)^{\frac{d}{2}}(\mathsf{vol}(\mathcal{Q}'))^{-1} \sum_{n\in\Gamma} T^n e^{-i\langle n-x,\xi\rangle} u(x-n) \tag{3.55}$$

with $(x, \xi) \in \mathcal{Q} \times \mathcal{Q}'$, this problem is reduced to the problem for operators with operator-valued symbols on $\mathscr{L}^2(\mathcal{Q}', \mathbb{H}_{\xi,\{T\}})$ where $\mathbb{H}_{\xi,\{T\}}$ is the space of functions satisfying (3.54).

After that, different results are obtained in three essentially different cases: when E belongs to the spectral gap, E belongs to the bottom of the spectral gap, and E belongs to the top of the spectral gap. For exact results, proofs and generalizations, see Section 12.8 of [Ivr4].

4 Non-Smooth Theory

So far we have considered operators with smooth symbols in domains with smooth boundaries. Singularities were possible but only on "lean" sets. However, it turns out that many results remain true under very modest smoothness assumptions.

Non-Smooth Symbols and Rough Microlocal Analysis

To deal with non-smooth symbols, we approximate them by *rough* symbols $p \sim \sum_m p_m$, depending on a small *mollification parameter* ε and satisfying

$$|\nabla_\xi^\alpha \nabla_x^\beta p_m(x,\xi)| \le C_{m\alpha\beta} \boldsymbol{\rho}^{-\alpha} \boldsymbol{\gamma}^{-\beta} \varepsilon^{-m} \tag{1.1}$$

[34] I.e. if $\Gamma = \mathbb{Z}e_1 \oplus \mathbb{Z}e_2 \oplus \dots \oplus \mathbb{Z}e_d$ then $\Gamma^* = \mathbb{Z}e'_1 \oplus \mathbb{Z}e'_2 \oplus \dots \oplus \mathbb{Z}e'_d$ with $\langle e_j, e'_k\rangle = \delta_{jk}$.

[35] I.e. $\mathcal{Q} = \{x_1e_1 + \dots + x_de_d : \ x \in [0,1]^d\}$ and $\mathcal{Q}'* = \{\xi_1e'_1 + \dots + \xi_de'_d : \ \xi \in [0,1]^d\}$.

with

$$\min_j \rho_j\gamma_j \ge \varepsilon \ge Ch^{1-\delta} \tag{1.2}$$

(*microlocal uncertainty principle*), which could be weakened to

$$|\nabla_\xi^\alpha\nabla_x^\beta p_m(x,\xi)| \le C^{|\alpha|+|\beta|+m+1}\alpha!\beta!m!\boldsymbol{\rho}^{-\alpha}\boldsymbol{\gamma}^{-\beta}\varepsilon^{-m} \tag{1.3}$$
$$\forall \alpha,\beta,m : |\alpha|+|\beta|+2m \le N = C|\log h|^{-1}$$

with

$$\min_j \rho_j\gamma_j \ge \varepsilon \ge Ch|\log h| \tag{1.4}$$

(*logarithmic uncertainty principle*). At this point, microlocal analysis ends: the assumptions cannot be weakened any further.

Assuming that

$$|\nabla_\xi^\alpha\nabla_x^\beta\nabla p_0(x,\xi)| \le C^{|\alpha|+|\beta|+1}\alpha!\beta!\boldsymbol{\rho}^{-\alpha}\boldsymbol{\gamma}^{-\beta} \tag{1.5}$$

and

$$|\nabla_\xi^\alpha\nabla_x^\beta\nabla p_m(x,\xi)| \le C^{|\alpha|+|\beta|+m+1}\alpha!\beta!m!\boldsymbol{\rho}^{-\alpha}\boldsymbol{\gamma}^{-\beta}\varepsilon^{1-m} \quad (m\ge 1), \tag{1.6}$$

we can restore Theorem 2.2 (see Theorem 2.3.2 of [Ivr4]) and therefore also the Corollaries 2.3 and 2.4, assuming ξ-microhyperbolicity instead of the usual microhyperbolicity. For proofs and details, see Section 2.3 of [Ivr4].

After this, we can than use the successive approximation method like in Subsection 2 (definitely some extra twisting required) and then recover the spectral asymptotics – originally only for operators which are ξ-microhyperbolic.

To consider non-smooth symbols, we can bracket them between rough symbols: for example, for the Schrödinger operator $p^-(x,\xi,h) \le p(x,\xi,h) \le p^+(x,\xi,h)$ where $p^\pm = p_\varepsilon \pm C\nu(\varepsilon)$ and p_ε is the symbol p, ε-mollified and $\nu(\varepsilon)$ is the modulus of continuity of the metric and potential; $\varepsilon = Ch|\log h|$.

Then for $\nu(\varepsilon) = O(\varepsilon|\log\varepsilon|^{-1})$ [36], we can recover the remainder estimate $O(h^{1-d})$; under even weaker regularity conditions by rescaling, we can recover weaker remainder estimates. On the other hand, if $\nu(\varepsilon) = o(\varepsilon|\log\varepsilon|^{-1})$,

[36] Which means that the first partial derivatives are continuous with modulus of continuity $\nu_1(\varepsilon) = \nu(\varepsilon)\varepsilon^{-1}$.

we can recover the remainder estimate $o(h^{1-d})$ under the standard non-periodicity condition[37]. For proofs and details, see Section 4.6 of [Ivr4]. There is an alternative to the bracketing construction based on perturbation theory, which works better for the trace asymptotics and also covers the pointwise asymptotics. For an exposition, see Section 4.6 of [Ivr4].

Further, for scalar and similar operators, the rescaling technique allows us to replace ξ-microhyperbolicity by microhyperbolicity under really weak smoothness assumptions; here we also use ε depending on the point so that we can consider scalar symbols under weaker and weaker non-degeneracy assumptions albeit stronger and stronger smoothness assumptions. See Section 5.4 of [Ivr4].

Non-Smooth Boundaries

Let us consider a domain with non-smooth boundary (with the Dirichlet boundary condition). Here, the standard trick to flatten out the boundary by the change of variables $x_1 \mapsto x_1 - \phi(x')$ works very poorly: the operator principal symbol contains the first partial derivatives ϕ and therefore we need to require $\phi \in \mathscr{C}^2$. Fortunately, the method of R. Seelley [See1] can help us. This method was originally developed for the Laplacian with a smooth metric and a smooth boundary.

Here, we consider only the Schrödinger operator; assume first that the metric and potential are smooth. Consider a point $\bar{x} \in X$ and assume that the metric is Euclidean at $\bar{x}$ and nearby, X looks like $\{x : x_1 \ge \phi(x')\}$ with $\nabla'\phi(\bar{x}') = 0$. Observe that these assumptions do not require any smoothness beyond $\mathscr{C}^1$.

Consider a trajectory starting from $(\bar{x}, \xi)$. If $|\xi_1| < \rho := Ch|\log h|/\gamma$, the trajectory starts parallel to ∂X and ∂X can "catch up" only at time at least $T = \sigma(\gamma)$ where $\gamma = \frac{1}{2}\mathsf{dist}(x, \partial X)$ and σ is the inverse function to ν, which is a modulus of continuity for ϕ[36].

If $\xi_1 > \rho$ then this trajectory "runs away from ∂X" and ∂X can "catch up" only at time at least $T = \sigma(\gamma) + \sigma_1(\xi_1)$ where σ_1 is the inverse function to ν_1[36]. On the other hand, if $\xi_1 < -\rho$, then we can revert the trajectory (which works only for local but not pointwise spectral asymptotics).

[37] However, even for the Schrödinger operator without boundary, the dynamic equations do not satisfy the Lipschitz condition and thus the flow could be multivalued.

These arguments allow us to estimate the contribution of $B(x,\gamma(x))$ to the remainder by $Ch^{1-d}\gamma^d h|\log h|\sigma(\gamma)^{-1}$ and then the total remainder by $Ch^{1-d}\int \sigma(\gamma)^{-1}\,dx$. The latter integral converges for $\nu(t) = t|\log t|^{-1-\delta}$.

Sure, this works only when $\gamma \ge \bar\gamma = Ch|\log h|$. However, if we smoothen the boundary with a smoothing parameter $C\bar\gamma$, for $\gamma \le \bar\gamma$, we will be in the framework of the smooth theory after rescaling and we can take $T = \bar\gamma$. The contribution of this strip to the remainder does not exceed $Ch^{1-d}\bar\gamma T^{-1}$ as its measure does not exceed $C\bar\gamma$. One can easily check that the variation of $\mathsf{vol}(X)$ due to the smoothing of the boundary is Ch^{1-d} and we can use the bracketing of X as well.

We can even improve the remainder estimate to $o(h^{1-d})$ under the standard non-periodicity condition.

Furthermore, if the metric and potential are not smooth, we need to mollify them, taking the mollification parameter ε larger near ∂X and taking $\rho = Ch|\log h|/\varepsilon$, but it works. For systems, we can exploit the fact that most of the cones of dependence are actually trajectories. For exact statements, proofs and details, see Section 7.5 of [Ivr4].

Aftermath

After the non-smooth local theory is developed, we can use all the arguments of Section 3 and consider "stronger but more concentrated" singularities added on the top of the weaker ones.

2 Magnetic Schrödinger Operator

Introduction

This Section is entirely devoted to the study of the *magnetic Schrödinger operator*

$$H = (-ih\nabla - \mu A(x))^2 + V(x) \tag{2.1}$$

and of the Schrödinger-Pauli operator

$$H = ((-ih\nabla - \mu A(x))\cdot \boldsymbol{\sigma})^2 + V(x) \tag{2.2}$$

with a small semiclassical parameter h and large *magnetic intensity parameter* (coupling constant) responsible for the interaction of a particle with the

magnetic field μ. Here, $\boldsymbol{\sigma} = (\sigma_1, \dots, \sigma_d)$ where $\sigma_1, \dots, \sigma_d$ are Pauli $\mathsf{D} \times \mathsf{D}$-matrices and A is *magnetic vector potential*. We are interested in the two-parameter asymptotics (with respect to h and μ) as well as related asymptotics.

Standard Theory

Preliminaries

For a detailed exposition, generalizations and proofs, see Chapter 13 of [Ivr4].

Consider the most interesting cases $d = 2, 3$ with smooth $V(x)$ and $A(x)$. If $d = 2$, the magnetic field could be described by a single (pseudo)scalar $F_{12} = \partial_1 A_2 - \partial_2 A_1$ and by a scalar $F = |F_{12}|$. If $d = 3$, the magnetic field could be described by a (pseudo)vector $\boldsymbol{F} = \nabla \times A$ (*vector magnetic intensity*) and by a scalar $F = |\boldsymbol{F}|$ (*scalar magnetic intensity*). As a toy-model, we consider an operator in $\mathbb{R}^d$ with constant V and $\boldsymbol{F}$. Then canonical form of the operator (2.1) is

$$H = h^2 D_1^2 + (hD_2 - \mu F x_1)^2 + \underbrace{h^2 D_3^2} + V, \tag{2.3}$$

with the third term omitted when $d = 3$. Then we can calculate

$$e(x, x, \tau) = h^{-d} \mathcal{N}_d^{\mathsf{MW}}(\tau - V, \mu h F) \tag{2.4}$$

with

$$\mathcal{N}_d^{\mathsf{MW}}(\tau, F) = \kappa_d \sum_{n \ge 0} \big(\tau - (2n+1)F\big)_+^{\frac{1}{2}(d-2)} F, \tag{2.5}$$

where $\kappa_2 = 1/(2\pi)$, $\kappa_3 = 1/(2\pi^2)$. In particular, if $d = 2$, $F \neq 0$ this operator has a pure point spectrum of infinite multiplicity. Eigenvalues $(2m+1)\mu h F$ are called *Landau levels*. If $d = 3$, this operator has an absolutely continuous spectrum.

In these cases, the operator (2.2) is a direct sum of $\mathsf{D}/2$ operators H_- and $\mathsf{D}/2$ operators H_+ where $H_\mp = H_0 \mp \mu h F$, H_0 is the operator (2.1); then

$$\mathcal{N}_d^{\mathsf{MW}}(\tau - V, \mu h F) := \kappa_d D \Big(\frac{1}{2} \tau_+^{\frac{1}{2}(d-2)} + \sum_{n \ge 1} \big(\tau - 2nF\big)_+^{\frac{1}{2}(d-2)} \Big) F \tag{2.6}$$

Classical dynamics are different as well: when $d = 2$, the trajectories are *magnetrons*–circles of radii $(\mu F)^{-1}$, while if $d = 3$, there is also free movement along *magnetic lines*–integral curves of $\boldsymbol{F}$, so the trajectories are solenoids.

Canonical Form

Using the $\hbar$-Fourier transform, we can reduce the magnetic Schrödinger operator to its microlocal canonical form

$$\mu^2 \sum_{n\ge 0} B_n(x_1, \hbar D_1, \mu^{-2}, \hbar)\mathcal{L}_0^n \qquad \text{for } d = 2, \tag{2.7}$$

$$h^2 D_2^2 + \mu^2 \sum_{n\ge 0} B_n(x', \hbar D_1, \mu^{-2}, \hbar)\mathcal{L}_0^n \qquad \text{for } d = 3, \tag{2.8}$$

with $\hbar = \mu^{-1}h$, $\mathcal{L}_0 = x_d^2 + \hbar^2 D_d^2$, $x' = x_1$ and $x' = (x_1, x_2)$ when $d = 2, 3$ respectively. Further, the principal symbols of the operators B_0 and B_1 are $\mu^{-2}V \circ \Psi$ and $F \circ \Psi$ respectively, where Ψ is a diffeomorphism $(x', \xi_1) \to x$.

This canonical form allows us to study both the classical trajectories and the propagation of singularities in the general case. When $d = 2$, there is still movement along the magnetrons but magnetrons are drifting with the velocity $v = \mu^{-1}(\nabla((V - \tau)/F_{12}))^{\perp}$ where $^{\perp}$ denotes the counter-clockwise rotation by $\pi/2$. If $d = 3$, trajectories are solenoids winding around magnetic lines and the movement along magnetic lines is described by an 1-dimensional Hamiltonian but there there is also side-drift as in $d = 2$.

We can replace then $\mathcal{L}_0$ by its eigenvalues which are $(2j + 1)\hbar$, thus arriving to a family of $\hbar$-pseudodifferential operators with respect to x_1 if $d = 2$ and to a family of $\hbar$-pseudodifferential operators with respect to x_1 which is also a Schrödinger operator with respect to x_2.

Asymptotics: Moderate Magnetic Field

We can always recover the estimate $O(\mu h^{1-d})$ with the standard Weyl principal part simply by using the scaling $x \to \mu x$, $h \mapsto \mu h$, $\mu \mapsto 1$. On the other hand, for $d = 2$, we cannot in general improve it as follows from the example with constant F and V.

However, under a(THE?) non-degeneracy assumption, the remainder estimate is much better:

Theorem 2.1. *Let $d = 2$, $F \asymp 1$, $\mu h \lesssim 1$ and*

$$|\nabla VF^{-1}| + |\det \operatorname{Hess} VF^{-1}| \ge \epsilon. \tag{2.9}$$

Then

$$\int \Big(e(x, x, 0) - h^{-2}\mathcal{N}_2^{\mathsf{MW}}(x, -V, \mu hF)\Big)\psi(x)\, dx = O(\mu^{-1}h^{-1}). \tag{2.10}$$

The explanation is simple: each of the non-degenerate 1-dimensional $\hbar$-pseudodifferential operators contributes $O(1)$ to the remainder estimate and there is $\asymp (\mu h)^{-1}$ of them which should be taken into account. Another explanation is that under the non-degeneracy assumption, the drift of the magnetrons destroys the periodicity but we can follow the evolution for time $T^* = \epsilon\mu$, so the remainder estimate is $O(T^{*-1}h^{-1})$.

If $d = 3$, we cannot get the local remainder estimate better than $O(h^{-2})$ without global non-periodicity conditions due to the evolution along magnetic lines. On the other hand, we do not need strong non-degeneracy assumptions:

Theorem 2.2. *Let $d = 3$, $F \asymp 1$ and $\mu h \lesssim 1$. Then,*

$$\int \Big(e(x,x,0) - h^{-3}\mathcal{N}_3^{\mathsf{MW}}(x,-V,\mu hF)\Big)\psi(x)\,dx = O(h^{-2} + \mu h^{-1-\delta}) \tag{2.11}$$

in the general case and

$$\int \Big(e(x,x,0) - h^{-3}\mathcal{N}_3^{\mathsf{MW}}(x,-V,\mu hF)\Big)\psi(x)\,dx = O(h^{-2}), \tag{2.12}$$

provided

$$\sum_{\alpha:\, 1\le|\alpha|\le K} |\nabla^\alpha V F^{-1}| \ge \epsilon. \tag{2.13}$$

Further, in the general case, as(FOR?) $\mu \le h^{-\frac{1}{3}}$, we can replace the magnetic Weyl expression $\mathcal{N}_3^{\mathsf{MW}}$ by the standard Weyl expression $\mathcal{N}_3$.

Asymptotics: Strong Magnetic Field

Let us now consider the strong magnetic field case $\mu h \gtrsim 1$. Then the remainder estimates (2.10), (2.11) and (2.12) acquire a factor of μh^{-1}:

Theorem 2.3. *Let $d = 2$, $F \asymp 1$ and $\mu h \gtrsim 1$. Then for the operator* (2.3),

(i) Under the assumption

$$|\tau V - (2j+1)\mu hF| \ge \epsilon_0 \qquad \forall j \in \mathbb{Z}^+, \tag{2.14}$$

the following asymptotics holds:

$$e(x,x,\tau) - h^{-2}\mathcal{N}_2^{\mathsf{MW}}(x,\tau - V,F) = O(\mu^{-s}h^s). \tag{2.15}$$

(ii) Under the assumption

$$|\tau V - (2j+1)\mu hF| + |\nabla((V-\tau)F^{-1})| + |\det \mathsf{Hess}((V-\tau)F^{-1})| \ge \epsilon_0 \qquad \forall j \in \mathbb{Z}^+, \tag{2.16}$$

the following asymptotics holds:

$$\int \Big(e(x,x,\tau) - h^{-2}\mathcal{N}_2^{\mathsf{MW}}(x,\tau - V, F)\Big)\psi(x)\,dx = O(1). \tag{2.17}$$

Remark 2.4. If $d = 2$, we only need that $\mu^{-1}h \ll 1$ rather than $h \ll 1$.

Theorem 2.5. *Let $d = 3$, $F \asymp 1$ and $\mu h \gtrsim 1$. Then for the operator* (2.3),

$$\int \Big(e(x,x,0) - h^{-3}\mathcal{N}_3^{\mathsf{MW}}(x,-V,\mu hF)\Big)\psi(x)\,dx = O(\mu h^{-1-\delta}) \tag{2.18}$$

in the general case and

$$\int \Big(e(x,x,0) - h^{-3}\mathcal{N}_3^{\mathsf{MW}}(x,-V,\mu hF)\Big)\psi(x)\,dx = O(\mu h^{-1}) \tag{2.19}$$

under the assumption

$$|V + (2j+1)\mu hF| + \sum_{\alpha:\, 1\le|\alpha|\le K} |\nabla^\alpha V F^{-1}| \ge \epsilon \qquad \forall j \in \mathbb{Z}^+. \tag{2.20}$$

Remark 2.6. (i) $\mathcal{N}_d^{\mathsf{MW}} = O(\mu h)$ for $\mu h \gtrsim 1$.

(ii) For the Schrödinger-Pauli operator (2.4), one only needs to replace "$(2j+1)$" by "$2j$" in the assumptions above.

2D case, Degenerating Magnetic Field

Preliminaries

Since μF plays such a prominent role when $d = 2$, one may ask what happens if F vanishes somewhere? Obviously, one needs to make certain assumptions; it turns out that in the generic case

$$|F| + |\nabla F| \asymp 1, \tag{2.21}$$

the *degeneration manifold* $\Sigma := \{x : F(x) = 0\}$ is a smooth manifold and the operator is modelled by

$$h^2 D_1^2 + (hD_2 - \mu x_1^2/2)^2 + V(x_2), \tag{2.22}$$

which we are going to study. We consider the local spectral asymptotics for ψ supported in a small enough vicinity of Σ. Under the assumption (2.21) (or, rather more a general one), the complete analysis was done in Chapter 14 of [Ivr4].

Moderate and Strong Magnetic Field

We start from the case $\mu h \lesssim 1$. Without any loss of the generality, one can assume that $\Sigma = \{x : x_1 = 0\}$. Then, the scaling $x \mapsto x/\gamma(\bar{x})$ (with $\gamma(x) = \frac{1}{2}\mathsf{dist}(x, \Sigma)$), brings us to the case of the non-degenerate magnetic field with $h \mapsto h_1 = h/\gamma$ and $\mu \mapsto \mu_1 = \mu\gamma^2$ as long as $\gamma \ge \mu^{-\frac{1}{2}}$. Then the contribution of $B(x, \gamma(x))$ to the remainder does not exceed $C\mu_1^{-1}h_1^{-1} = C\mu^{-1}h^{-1}\gamma^{-1}$ and the total contribution of the *regular zone* $\mathcal{Z} = \{\gamma(x) \ge C_0\mu^{-\frac{1}{2}}\}$ does not exceed $C\int \mu^{-1}h^{-1}\gamma^{-3}\,dx = Ch^{-1}$.

On the other hand, in the *degeneration zone* $\mathcal{Z}_0 = \{\gamma(x) \le C_0\mu^{-\frac{1}{2}}\}$, we use $\gamma = \mu^{-\frac{1}{2}}$ and the contribution of $B(x, \gamma(x))$ does not exceed $Ch_1^{-1} = Ch^{-1}\mu^{-\frac{1}{2}}$ and the total contribution of this zone also does not exceed Ch^{-1}.

Thus we conclude that the left-hand expression of (2.10) is now $O(h^{-1})$. Can we do any better than this?

Analysis of the evolution and propagation in the zone $\mathcal{Z}$ shows that there is a drift of magnetic lines along Σ with speed $C\mu^{-1}\gamma^{-1}$ which allows us to improve $T^* \asymp \mu\gamma^2$ to $T^* \asymp \mu\gamma$ (both before rescaling) and improve the estimate of the contribution of $B(x, \gamma(x))$ to $C\mu^{-1}h^{-1}$ and the total contribution of this zone to $C\int \mu^{-1}h^{-1}\gamma^{-2}\,dx = C\mu^{-\frac{1}{2}}h^{-1}$.

Analysis of evolution and propagation in the zone $\mathcal{Z}_0$ is more tricky. It turns out that there are *short periodic trajectories* with period $\asymp \mu^{-\frac{1}{2}}$, but there are not many of them which allows us to improve the remainder estimate in this zone as well.

Theorem 2.7. *Let $d = 2$ and suppose the condition* (2.21) *is fulfilled. Let $\Sigma := \{F = 0\} = \{x_1 = 0\}$ and $-V \asymp 1$. Let $\mu \le h^{-1}$. Then,*

(i) The left-hand expression of (2.17) *is $O(\mu^{-\frac{1}{2}}h^{-1} + h^{-1}(\mu^{\frac{1}{2}}h|\log h|)^{\frac{1}{2}})$. In particular, for $\mu \lesssim (h|\log h|)^{-\frac{2}{3}}$, it is $O(\mu^{-\frac{1}{2}}h^{-1})$.*

(ii) Further,

$$\int \Big(e(x,x,0) - h^{-2}\mathcal{N}_2^{\mathsf{MW}}(x,-V,\mu hF)\Big)\psi(x)\,dx - h^{-1}\int \mathcal{N}_{\mathsf{corr}}^{\mathsf{MW}}(x_2,0)\psi(x_2,0) = O(\mu^{-\frac12}h^{-1}+h^{-\delta}) \tag{2.23}$$

with

$$h^{-1}\mathcal{N}_{\mathsf{corr}}^{\mathsf{MW}} := (2\pi h)^{-1}\int \boldsymbol{n}_0(\xi_2,-W(x_2),\hbar)\,d\xi_2 - h^{-2}\int \mathcal{N}^{\mathsf{MW}}(-W(x_2),\mu hF(x_1))\,dx_1 \tag{2.24}$$

where $\boldsymbol{n}_0(\xi_2,\tau,\hbar)$ *is an eigenvalue counting function for the operator* $\boldsymbol{a}_0(\xi_2,\hbar) = \hbar^2 D_1^2 + (\xi_2 - x_1^2/2)^2$ *on* $\mathbb{R}^1 \ni x_1$, $\hbar = \mu^{\frac12}h$ *and* $W(x_2) = V(0,x_2)$.

(iii) Furthermore, under the non-degeneracy assumption

$$\sum_{1\le k\le m} |\partial_{x_2}^k W| \asymp 1 \tag{2.25}$$

(in the framework of assumption (2.22)*), one can take* $\delta = 0$ *in* (2.23).

Remark 2.8. (i) Under some non-degeneracy assumptions, Theorem 2.7(i) could also be improved.

(ii) Theorem 2.7 remains valid for $h^{-1} \le \mu \lesssim h^{-2}$ as well but then the zone $\{x : \gamma(x) \ge C(\mu h)^{-1}\}$ is forbidden, contribution to the principal part is delivered by the zone $\{x : \gamma(x) \lesssim (\mu h)^{-1}\}$ and it is $\lesssim \mu^{-1}h^{-3}$.

(iii) As $\mu \ge Ch^2$, the principal part is 0 and the remainder is $O(\mu^{-s})$.

For further details, generalizations and proofs, see Section 14.6 of [Ivr4].

Strong and Superstrong Magnetic Field

Assume now that $\mu \gtrsim h^{-1}$ and replace V by $V - (2j+1)\mu hF_{12}$ with $j \in \mathbb{Z}^+$. Then the zone $\{x : \gamma(x) \ge C(\mu h)^{-1}\}$ is no longer forbidden, the principal part of asymptotics is of the magnitude μh^{-1} (cf. Remark 2.8(ii) and the remainder estimate becomes $O(\mu^{-\frac12}h^{-1}+h^{-\delta})$ (and under the non-degeneracy assumption one can take $\delta = 0$).

Furthermore, the case $\mu \ge Ch^{-2}$ is no longer trivial. First, one needs to change the correction term by replacing $\boldsymbol{a}_0$ with $\boldsymbol{a}_{2j+1} \coloneqq \boldsymbol{a}_0 - (2j+1)\hbar x_1$. Second, the non-degeneracy condition should be relaxed by requiring (2.25) only if

$$|\hbar^{2/3}\lambda_{j,n}(\eta) + W(x_2)| + |\partial_\eta \lambda_{j,n}(\eta) \ge \epsilon \qquad \forall \eta, \tag{2.26}$$

fails, where $\lambda_{j,n}$ are the eigenvalues of $\boldsymbol{a}_{2j+1}$ with $\hbar = 1$.

Furthermore, if

$$|\hbar^{2/3}\lambda_{j,n}(\eta) + W(x_2)| \ge \epsilon \qquad \forall \eta, \tag{2.27}$$

then 0 belongs to the spectral gap and the remainder estimate is $O(\mu^{-s})$.

For further details, exact statements, generalizations and proofs, see Sections 14.7 and 14.8 of [Ivr4].

2D Case, near the Boundary

Moderate Magnetic Field

We now consider the magnetic Schrödinger operator with $d = 2$, $F \asymp 1$ in a compact domain X with $\mathscr{C}^\infty$-boundary. While the dynamics inside the domain do not change, the dynamics in the boundary layer of the width $\asymp \mu^{-1}$ are completely different. When the magnetron hits ∂X, it reflects according to the standard "incidence angle equals reflection angle" law and thus the "particle" propagates along ∂X with speed $O(1)$ rather than $O(\mu^{-1})$. Therefore, physicists distinguish between *bulk* and *edge particles*. Note however that in general, this distinction is not as simple as in the case of constant F and V. Indeed, a drifting inner trajectory can hit ∂X and become a *hop trajectory*, while the latter could leave the boundary and become an inner trajectory.

It follows from Section 2 that the contribution of $B(x, \gamma(x))$ with $\gamma(x) = \frac{1}{2}\mathsf{dist}(x, \partial X) \ge \bar\gamma = C\mu^{-1}$ to the remainder is $O(\mu^{-1}h^{-1}\gamma^2 T(x)^{-1})$, where $T(x)$ is the length of the drift trajectory inside the *bulk zone* $\{x \in X : \gamma(x) \ge \bar\gamma\}$. Then the total contribution of this zone to the remainder does not exceed $C\mu^{-1}h^{-1}\int T(x)^{-1}\,dx = O(\mu^{-1}h^{-1})$ since $T(x) \gtrsim \gamma(x)^{\frac{1}{2}}$ (in the proper direction).

On the other hand, due to the rescaling $x \mapsto x/\bar\gamma$, the contribution of $B(x, \bar\gamma)$ with $\gamma(x) \le \bar\gamma$ to the remainder does not exceed $C\mu h^{-1}\bar\gamma^2$ and the

total contribution of the *edge zone* $\{x \in X : \gamma(x) \le \bar\gamma\}$ does not exceed $C\mu h^{-1}\bar\gamma = Ch^{-1}$ and the total remainder is $O(h^{-1})$. Thus, if we want a better estimate, we need to study propagation along ∂X.

Theorem 2.9. *Under the non-degeneracy assumption* $|\nabla_{\partial X}(VF^{-1})| \asymp 1$ *on* $\mathsf{supp}(\psi)$ *(contained in the small vicinity of* ∂X*) for* $\mu h \lesssim 1$

$$
\begin{aligned}
(2.28)\quad \int_X \Big(e(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0,\mu h)\Big)\psi(x)\,dx - \\
h^{-1}\int_{\partial X} \mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}(x,0,\mu h)\psi(x)\,ds_g = O(\mu^{-1}h^{-1}),
\end{aligned}
$$

where $\mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}$ *is introduced in* $(5.4.2)_{\mathsf{D}}$ *or* $(5.4.2)_{\mathsf{N}}$ *below for the Dirichlet or Neumann boundary conditions respectively with* $\hbar = \mu h F(x)$ *and* τ *replaced by* $-V(x)$.

Here,

$$
\begin{aligned}
&(5.4.2)_{\mathsf{D}} \quad \mathcal{N}^{\mathsf{MW}}_{\mathsf{D},\mathsf{bound}}(\tau,\hbar) := \\
&(2\pi)^{-1}\int_0^\infty \sum_{j\ge 0}\Big(\int \theta\big(\tau - \hbar\lambda_{\mathsf{D},j}(\eta)\big)\upsilon^2_{\mathsf{D},j}(x_1,\eta)\,d\eta - \theta\big(\tau-(2j+1)\hbar\big)\Big)\hbar^{\frac12}\,dx_1
\end{aligned}
$$

and

$$
\begin{aligned}
&(5.4.2)_{\mathsf{N}} \quad \mathcal{N}^{\mathsf{MW}}_{\mathsf{N},\mathsf{bound}}(\tau,\hbar) := \\
&(2\pi)^{-1}\int_0^\infty \sum_{j\ge 0}\Big(\int \theta\big(\tau-\hbar\lambda_{\mathsf{N},j}(\eta)\big)\upsilon^2_{\mathsf{N},j}(x_1,\eta)\,d\eta-\theta\big(\tau-(2j+1)\hbar+\big)\Big)\hbar^{\frac12}\,dx_1,
\end{aligned}
$$

where $\lambda_{\mathsf{D},j}(\eta)$ *and* $\lambda_{\mathsf{N},j}(\eta)$ *are eigenvalues and* $\upsilon_{\mathsf{D},j}$ *and* $\upsilon_{\mathsf{N},j}$ *are eigenfunctions of operator*

$$
(2.30)\qquad \mathsf{a}(\eta,x_1,D_1) = D_1^2 + x_1^2 \qquad as \quad x_1 < \eta
$$

with the Dirichlet or Neumann boundary conditions respectively at $x_1 = \eta$.

Remark 2.10. Under weaker non-degeneracy assumptions $|\nabla VF^{-1}| \asymp 1$ and $\nabla_{\partial X} VF^{-1} = 0 \implies \pm\nabla^2_{\partial X} VF^{-1} \ge \epsilon$, less sharp remainder estimates are derived. The sign in the latter inequality matters since it affects the dynamics. It also matters whether Dirichlet or Neumann boundary conditions are considered: for the Dirichlet boundary condition we get a better remainder estimate.

For exact statements, generalizations and proofs, see Sections 15.2 and 15.2 of [Ivr4].

Strong Magnetic Field

We now consider the strong magnetic field $\mu h \gtrsim 1$ and for simplicity assume that $F = 1$. In this case, we need to study an auxillary operator $D_1^2+(x_1-\eta)^2$ as $x_1 < 0$ with either the Dirichlet or Neumann boundary conditions at $x_1 = 0$ or equivalently the operator (2.30) and our operator is basically reduced to a perturbed operator

$$a(\hbar D_2, x_1, D_1) - (2j+1) - (\mu h)^{-1} W(x_2) \qquad \hbar = \mu^{-1} h, \tag{2.31}$$

with $W(x_2) = V(0, x_2)$. Then we need to analyze either $\lambda_{\mathsf{D},j}(\eta)$ or $\lambda_{\mathsf{N},j}(\eta)$ more carefully. It turns out that:

Proposition 2.11. *$\lambda_{\mathsf{D},n}(\eta)$ and $\lambda_{\mathsf{N},n}(\eta)$, $n = 0, 1, 2, \dots$ are real analytic functions with the following properties:*

(i) $\lambda_{\mathsf{D},k}(\eta)$ are monotone decreasing for $\eta \in \mathbb{R}$; $\lambda_{\mathsf{D},k}(\eta) \nearrow +\infty$ as $\eta \to -\infty$; $\lambda_{\mathsf{D},k}(\eta) \searrow (2k+1)$ as $\eta \to +\infty$; $\lambda_{\mathsf{D},k}(0) = (4k+3)$.

(ii) $\lambda_{\mathsf{N},k}(\eta)$ are monotone decreasing for $\eta \in \mathbb{R}^-$; $\lambda_{\mathsf{N},k}(\eta) \nearrow +\infty$ as $\eta \to -\infty$; $\lambda_{\mathsf{N},k}(\eta) < (2n+1)$ as $\eta \ge (2n+1)^{\frac{1}{2}}$; $\lambda_{\mathsf{N},k}(0) = (4n+1)$.

(iii) $\lambda_{\mathsf{N},k}(\eta) < \lambda_{\mathsf{D},k}(\eta) < \lambda_{\mathsf{N},(k+1)}(\eta)$; $\lambda_{\mathsf{D},k}(\eta) > (2k+1)$, $\lambda_{\mathsf{N},n}(\eta) > (2k-1)_+$.

Proposition 2.12. *(i) $\partial_\eta \lambda_{\mathsf{D},k}(\eta) < 0$.*

(ii) $\partial_\eta \lambda_{\mathsf{N},n}(\eta) \gtreqless 0$ if and only if

$$\lambda_{\mathsf{N},k}(\eta) \lesseqgtr \eta^2. \tag{2.32}$$

(iii) $\lambda_{\mathsf{N},k}(\eta)$ has a single stationary point[38] *η_k, it is a non-degenerate minimum, and at this point* (2.32) *holds.*

(iv) In particular, $(\lambda_{\mathsf{N},k}(\eta) - \eta^2)$ has the same sign as $(\eta_k - \eta)$.

[38] And it must have one due to Proposition 2.11.

We see the difference between the Dirichlet and Neumann cases because we need non-degeneracy for $\lambda_{*,k}(\hbar D_2) - (2j+1) + W(x_2)$. It also means the difference in the propagation of singularities along ∂X: in the Dirichlet case, all singularities move in one direction (constant sign of $\lambda'_{\mathsf{D},k}$), while in the Neumann case, some move in the opposite direction (variable sign of $\lambda'_{\mathsf{N},k}$); this effect plays a role also in the case when $\mu h \lesssim 1$.

Assume here that τ is in an "inner" spectral gap:

$$|(2j+1)\mu h + V - \tau| \geq \epsilon_0 \mu h \qquad \forall x\ \forall j \in \mathbb{Z}^+. \tag{2.33}$$

Theorem 2.13. *Suppose that $\mu h \gtrsim 1$ and the condition* (2.33) *is fulfilled. Then,*

(i) In case of the Dirichlet boundary condition, the left-hand expression in (2.28) *is $O(1)$.*

(ii) In case of the Neumann boundary condition, assume additionally that

$$\begin{aligned}(5.4.7)_{\pm}\quad & |\bigl(\lambda_{\mathsf{N},j}(\eta)\mu h + V - \tau| \leq \epsilon_0 \mu h, \\ & |\lambda'_{\mathsf{N},j}(\eta)| + |\partial_{x_2} V| \leq \epsilon_0 \implies \pm \partial^2_{x_2} V \geq \epsilon_0 \qquad \forall j = 0,1,2,...\end{aligned}$$

Then, the left-hand expression in (2.28) *is $O(1)$ under the assumption $(2.34)_+$ and $O(\log h)$ under the assumption $(2.34)_-$.*

Remark 2.14. (i) If (2.33) is fulfilled for all $\tau \in [\tau_1, \tau_2]$, then the asymptotics is "concentrated" in the boundary layer.

(ii) For a more general statement when (2.33) fails (i.e. when τ is no longer in the "inner" spectral gap) and is replaced with the condition

$$|V + (2j+1)\mu h - \tau| + |\nabla V| \asymp 1 \tag{2.35}$$

on $\mathsf{supp}(\psi)$, see Theorem 15.4.18 of [Ivr4].

Pointwise Asymptotics and Short Loops

We are now interested in the pointwise asymptotics inside the domain. Surprisingly, it turns out that the standard Weyl formula for this purpose is better than the Magnetic Weyl formula.

Case $d = 2$

We start from the case $d = 2$, $F = 1$, $|\nabla V| \asymp 1$. One can easily see that in classical dynamics, short loops of the lengths $\asymp \mu^{-1} n$ with $n = 1, \dots, N$, $N \asymp \mu$ appear. We would like to understand how these loops affect the asymptotics in question.

Theorem 2.15. *For the magnetic Schrödinger operator which satisfies the above assumptions in a domain $X \subset \mathbb{R}^2$, with $B(0,1) \subset X$, the following estimates hold at a point $x \in B(0, \frac{1}{2})$*

(i) For $1 \le \mu \le h^{-\frac{1}{2}}$,

$$|e(x,x,\tau) - h^{-2}\mathcal{N}^{\mathsf{W}}_x(\tau)| \le C\mu^{-1}h^{-1} + C\mu^{\frac{1}{2}}h^{-\frac{1}{2}} + C\mu^2 h^{-\frac{1}{2}} \tag{2.36}$$

and

$$\begin{aligned} \mathsf{R}^{\mathsf{W}}_{x(r)} := |e(x,x,0) - h^{-2}\big(\mathcal{N}^{\mathsf{W}}_x(0) + \mathcal{N}^{\mathsf{W}}_{x,\mathsf{corr}(r)}(0)\big)| \le \\ C\mu^{-1}h^{-1} + C\mu^{\frac{1}{2}}h^{-\frac{1}{2}} + C\mu h^{-1}\big(\mu^2 h\big)^{r+\frac{1}{2}} + \\ C \begin{cases} \Big(h^{-1}\big(h\mu^{\frac{5}{2}}\big)^{r+\frac{1}{2}} + \mu^{\frac{1}{3}}h^{-\frac{2}{3}}\Big) & \text{as} \quad \mu \le h^{-\frac{2}{5}}, \\ \mu^{\frac{5}{3}}h^{-\frac{1}{3}} & \text{as} \quad \mu \ge h^{-\frac{2}{5}} \end{cases} \end{aligned} \tag{2.37}$$

where $\mathcal{N}^{\mathsf{W}}_{x,\mathsf{corr}(r)}$ is the r-term stationary phase approximation to some explicit oscillatory integral (see Section 16.3 of [Ivr4]).

(ii) For $h^{-\frac{1}{3}} \le \mu \le h^{-1}$,

$$\begin{aligned} \mathsf{R}^{\mathsf{W}\prime\prime}_{x(r)} := \\ |\Big(e(x,x,\tau) - h^{-2}\mathcal{N}_{x,\mathsf{corr}(r)} - \bar{e}_x(x,x,\tau) + h^{-2}\bar{\mathcal{N}}_{x,\mathsf{corr}(r)}\Big)| \le \\ C\mu^{\frac{1}{2}}h^{-\frac{1}{2}} + C \begin{cases} \mu^{-2}h^{-2}(\mu^2 h)^{r+\frac{1}{2}} & \text{for} \ \ \mu \le h^{-\frac{1}{2}} \\ h^{-1} & \text{for} \ \ \mu \ge h^{-\frac{1}{2}} \end{cases} \\ + C \begin{cases} h^{-1}\big(\mu^{\frac{5}{2}}h\big)^{r+\frac{1}{2}} + \mu^{\frac{1}{3}}h^{-\frac{2}{3}} & \text{for} \ \ \mu \le h^{-\frac{2}{5}} \\ \mu^{\frac{5}{3}}h^{-\frac{1}{3}} & \text{for} \ \ h^{-\frac{2}{5}} \le \mu \le h^{-\frac{1}{2}} \\ \mu^{-\frac{1}{3}}h^{-\frac{4}{3}} & \text{as} \ \ \mu \ge h^{-\frac{1}{2}} \end{cases} \end{aligned} \tag{2.38}$$

while for $r = 0$,

$$\mathsf{R}^{\mathsf{W}\prime\prime}_{x(0)} := |e(x,x,\tau) - \bar{e}_x(x,x,\tau)| \le C\mu^{\frac12}h^{-\frac12} + C\begin{cases} h^{-1}\mu^{\frac12} & \text{for } \mu \le h^{-\frac12},\\ \mu^{-\frac12}h^{-\frac32} & \text{for } \mu \ge h^{-\frac12}\end{cases} \tag{2.39}$$

where here and in (iii), $\bar{e}_y$ *is constructed for the toy-model in* y *(with* $F = F(y)$ *and* $V(x) = V(y) + \langle \nabla V(y), x-y\rangle$*).*

(iii) For $\mu \ge h^{-1}$, $\tau \le c\mu h$,

$$|e(x,x,\tau) - \bar{e}_x(x,x,\tau)| \le C\mu^{\frac12}h^{-\frac12}. \tag{2.40}$$

Case $d = 3$

For $d = 3$, we cannot expect a remainder estimate better than $O(h^{-1})$. On the other hand, the purely Weyl approximation has a better chance to succeed as the loop condition now includes returning free movement along the magnetic line in addition to the returning circular movement. We formulate only one theorem out of many from Section 16.7 of [Ivr4]:

Theorem 2.16. *Let* $d = 3$. *Then,*

(i) In the general case,

$$|e(x,x,\tau) - h^{-3}\mathcal{N}^{\mathsf{W}}_x(x,x,\tau)| \le Ch^{-2} + C\mu^{\frac32}h^{-\frac32}. \tag{2.41}$$

(ii) Under non-degeneracy condition

$$|\nabla_{\perp \boldsymbol{F}}(V-\tau)/F| \asymp 1, \tag{2.42}$$

where $\nabla_\perp$ *is the component of the gradient perpendicular to* $\boldsymbol{F}$, *for* $\mu \le h^{-\frac12}$, *we have the estimates*

$$|e(x,x,\tau) - h^{-3}\mathcal{N}^{\mathsf{W}}_x(x,x,\tau)| \le Ch^{-2} + C\mu^{\frac52}h^{-1} \tag{2.43}$$

and

$$|e(x,x,\tau) - h^{-3}\mathcal{N}^{\mathsf{W}}_x(x,x,\tau) - h^{-3}\mathcal{N}_{x,\mathsf{corr}(r)}| \le Ch^{-2} + C\mu^{\frac32}h^{-\frac32}(\mu^2h)^{r+\frac12}. \tag{2.44}$$

Here we use stationary phase approximations again.

Remark 2.17. One can also consider the cases $h^{-\frac12} \lesssim \mu \lesssim h^{-1}$ and $\mu \gtrsim h^{-1}$. But then one needs to include the toy-model expression (with constant $\boldsymbol{F}$ and ∇V) into the approximation.

Related Asymptotics

Apart from the pointwise asymptotics, one can consider the related asymptotics of

$$\int \omega(\frac{1}{2}(x+y), x-y) e(x,y,\tau) e(y,x,\tau)\, dxdy \tag{2.45}$$

and estimates of

$$\int \omega(\frac{1}{2}(x+y), x-y)\big(e(x,x,\tau) - e^{\mathsf{W}}(x,x,\tau)\big)\times \big(e(y,y,\tau) - e^{\mathsf{W}}(y,y,\tau)\big)\, dxdy. \tag{2.46}$$

For all the details, see Chapter 16 of [Ivr4]. These expressions play important role in Section 4.

Magnetic Dirac oOperators

We discuss the magnetic Dirac operators

$$H = ((-ih\nabla - \mu A(x)) \cdot \boldsymbol{\sigma}) + \sigma_0 M + V(x) \tag{2.47}$$

and

$$H = ((-ih\nabla - \mu A(x)) \cdot \boldsymbol{\sigma}) + V(x). \tag{2.48}$$

If $d = 3$, for the second operator, we can consider 2×2 matrices rather than 4×4 matrices.

If $V = 0$ then H^2 equals to the Schrödinger-Pauli operator (plus M^2) and therefore the theory of magnetic Dirac and Schrödinger operators are closely connected. If $V = 0$ and $0 \neq \boldsymbol{F}$ is constant then the operator for $d = 2$ has a pure point spectrum of infinite multiplicity consisting of $\pm\sqrt{M^2 + 2j\mu h F}$ with $j \in \mathbb{Z}^+$ [39] and for $d = 3$, this operator has absolutely continuous spectrum $(-\infty, -M] \cup [M, \infty)$. Thus we get corresponding *Landau levels*.

The results similar to those of Section 2 hold (for details, exact statements and proofs, see Chapter 17 of [Ivr4]. Further, the results of Sections 2 and 2 probably are not difficult to generalize, and maybe the results of Section 2 as well under correctly posed boundary conditions.

[39] However, one of the points $\pm M$ is missing depending on whether $F_{12} \gtrless 0$ and $\sigma_1\sigma_2\sigma_3 = \pm i$.

3 Magnetic Schrödinger Operator. II

Higher Dimensions

General Theory

We can consider a magnetic Schrödinger (and also Schrödinger-Pauli and Dirac) operators in higher dimensions. In this case, the magnetic intensity is characterized by the skew-symmetric matrix $F_{jk} = \partial_j A_k - \partial_k A_j$ rather than by a pseudo-scaler F_{12} or a pseudo-vector $\boldsymbol{F}$. As a result, the magnetic Weyl expression becomes more complicated; as before, it is exactly $e(x,x,\tau)$ for the operator in $\mathbb{R}^d$ if F_{jk} and V constant:

$$h^{-d}\mathcal{N}_d^{\mathsf{MW}}(\tau) \coloneqq (2\pi)^{-r}\mu^r h^{-r} \sum_{\alpha\in\mathbb{Z}^{+r}} \Big(\tau - \sum_j (2\alpha_j+1) f_j \mu h - V\Big)_+^{\frac{1}{2}(d-2r)} f_1\cdots f_r\sqrt{g}, \tag{3.1}$$

where $2r = \mathsf{rank}(F_{jk})$ and $\pm i f_j$ (with $j = 1,\dots,r$, $f_j > 0$) are its eigenvalues[40] which are not 0; recall that $z_+^0 = \theta(z)$.

One can see that H has pure point of infinite multiplicity spectrum when $d = 2r$ and H has an absolutely continuous spectrum when $d > 2r$. In any case, the bottom of the spectrum is $\mu h(f_1 + \dots + f_r)$.

We are interested in the asymptotics with the sharpest possible remainder estimate like the one for $d = 2$ or $d = 3$ in the cases $d = 2r$ and $d > 2r$ respectively[41]. Asymptotics without a remainder estimate were derived in [Rai1, Rai2].

As we try to reduce the operator to the canonical form, we immediately run into problem of *resonances* when $f_1 m_1 + \dots + f_r m_r = 0$ at some point with $m \in \mathbb{Z}^d$; $|m_1| + \dots + |m_r|$ is *an order of resonance*. If the lowest order of resonances is k, then we can reduce the operator to its canonical form modulo $O(\mu^{-k})$ for $\mu h \le 1$ (when $\mu h \ge 1$, this problem is less acute).

It turns out, however, that we can deal with an incomplete canonical form (with a sufficiently small remainder term).

Another problem is that we cannot in general assume that the f_j are constant (for $d = 2, 3$, we could achieve this by multiplying the operator by $f_1^{-1/2}$) and the microhyperbolicity condition becomes really complicated.

---

[40] In the general case, the eigenvalues of $(F_k^j) = (g^{jl})(F_{lk})$ where (g^{jk}) is a metric.

[41] We assume that $(F_{jk}(x))$ has constant rank.

Case $2r = d$ In this case, only the resonances of orders $2, 3$ matter as we are looking for an error $O(\mu^{-1}h^{1-d})$ when $\mu h \le 1$. If the magnetic field is weak enough, we use the incomplete canonical form only to study propagation of the singularities and if the magnetic field is sufficiently strong, the omitted terms $O(\mu^{-4})$ in the canonical form are small enough to be neglected.

As a result, the indices $j = 1, \dots, r$ are broken into several groups (indices j and k belong to the same group if they "participate" in the resonance of order 2 or 3 after all the reductions). Then under a certain non-degeneracy assumption called $\mathfrak{N}$-microhyperbolicity (see Definition 19.2.5 of [Ivr4]) in which this group partition plays a role, we can recover the remainder estimate $O(\mu^{-1}h^{1-d})$ for $\mu h \lesssim 1$ (in which case, the principal part has magnitude h^{-d}) and $O(\mu^{r-1}h^{1-d+r})$ for $\mu h \gtrsim 1$ (in which case, the principal part has magnitude $\mu^r h^{r-d}$). If we ignore the resonances of order 3, we get a partition into smaller groups and we need a weaker non-degeneration assumption called microhyperbolicity (see Definition 19.2.4 of [Ivr4]) but the remainder estimate would be less sharp.

In an important special case of constant $f_1, \dots, f_r$, both these conditions are equivalent to $|\nabla V|$ disjoint from 0 (on $\mathsf{supp}(\psi)$) but it could be weakened to V having only non-degenerate critical points (if there are saddles, we need to add a logarithmic factor to the remainder estimate).

On the other hand, without any non-degeneracy assumptions, the remainder estimate can be as bad as $O(\mu h^{1-d})$ for $\mu h \lesssim 1$ and as bad as the principal part itself for $\mu h \gtrsim 1$.

For exact statements, details, proofs and generalizations, see Chapter 19 of [Ivr4].

Case $2r < d$ In this case, only the resonances of order 2 matter since we are expecting a larger error than in the previous case. As a result, the indices $j = 1, \dots, r$ are broken into several groups (indices j and k belong to the same group if $f_j = f_k$).

Then under a certain non-degeneracy assumption called microhyperbolicity (see Definition 20.1.2 of [Ivr4]) in which this group partition plays a role, we can recover the remainder estimate $O(h^{1-d})$ for $\mu h \lesssim 1$ (then the principal part is of the magnitude h^{-d}) and $O(\mu^r h^{1-d+r})$ for $\mu h \gtrsim 1$ (then the principal part is of the magnitude $\mu^r h^{r-d}$).

In an important special case of constant $f_1, \dots, f_r$, this condition is equiv-

alent to $|\nabla V|$ being disjoint from 0 (on $\mathsf{supp}(\psi)$) but it could be weakened to "$\nabla V = 0 \implies \mathsf{Hess}\, V$ has a positive eigenvalue"; if we assume only that "$\nabla V = 0 \implies \mathsf{Hess}\, V$ has a non-zero eigenvalue", but we need to add a logarithmic factor to the remainder estimate.

As expected, for $2r = d-1$, we can recover less sharp remainder estimates even without any non-degeneracy assumptions and for $2r \le d-2$, we do not need any non-degeneracy conditions at all. For exact statements, details, proofs and generalizations, see Chapter 20 of [Ivr4].

Case $d = 4$: More Results

This case is simpler than the general one since we have only f_1 and f_2 and resonance happens if either $f_1 = f_2$ or $f_1 = 2f_2$ (or $f_2 = 2f_1$).

If we assume that the magnetic intensity matrix (F_{jk}) has constant rank 4, this case is simpler than the general one ($d = 2r$) and we can recover sharp remainder estimates under less restrictive conditions. For exact statements, details, proofs and generalizations, see Chapter 22 of [Ivr4].

On the other hand, if we consider (F_{jk}) of variable rank, then in the generic case, it has the eigenvalues $\pm if_1$ and $\pm if_2$ and $\Sigma = \{x : f_1(x) = 0\}$ is a $\mathscr{C}^\infty$ manifold of dimension 3, $\nabla f_1 \ne 0$ on Σ, while f_2 is disjoint from 0. It is similar to a 2-dimensional operator which we considered in Section 2, although with a twist: the symplectic form restricted to Σ has rank 2 everywhere except on a 1-dimensional submanifold Λ where it has rank 0.

Our results are also similar to those of Section 2 with rather obvious modifications but the proofs are more complicated.

For exact statements, details, proofs and generalizations, see Chapter 21 of [Ivr4].

Non-Smooth Theory

As in Chapter 4, we do not need to assume that the coefficients are very smooth. As before, we bracket the operator in question between two "rough" operators with the same asymptotics and with sharp remainder estimates. However, the lack of sufficient smoothness affects the reduction to the canonical form: it will be incomplete even if there are no resonances. Because of this, to get as sharp asymptotics as in the smooth case, we need to request more smoothness than in Chapter 4.

Case $d = 2$ For $d = 2$, we require smoothness of F_{12}, g^{jk} and V marginally larger than $\mathscr{C}^2$ to recover the same remainder estimate as in the smooth case, but there is a twist: unless the smoothness is $\mathscr{C}^3$, a correction term needs to be included. This is due to the fact that $V(x)$ and $W(x)$ differ and a more precise formula should use $W(x)$ rather than $V(x)$. Here, W is V averaged along a magnetron with center x. In fact, it is possible to consider V of the lesser smoothness than $\mathscr{C}^2$ (but marginally better than $\mathscr{C}^1$), but one gets a worse remainder estimate. For exact statements, details and proofs, see Chapter 18 of [Ivr4] and especially Section 18.5.

Case $d = 3$ Results are similar to those in the smooth case. However, in this case, if we assume no non-degeneracy conditions then the exponent δ in the estimates (2.11) and (2.18) depends on the smoothness and if we assume a non-degeneracy condition (2.13) or (2.20) then obviously K depends on the smoothness. Under the non-degeneracy assumption with $K = 1$, we need smoothness marginally better than $\mathscr{C}^1$ but again unless the smoothness is $\mathscr{C}^2$, we need to use the averaged potential $W(x)$ rather than $V(x)$.

For exact statements, details and proofs, see Chapter 18 of [Ivr4] and especially Section 18.9.

Case $d \geq 4$ Basically, the results are similar to those for $d = 2$ (if $\mathsf{rank}(F_{jk}) = d$) or for $d = 3$ (if $\mathsf{rank}(F_{jk}) < d$), but we cannot recover the sharp remainder estimate if the smoothness of V is less than $\mathscr{C}^3$ or $\mathscr{C}^2$ respectively because we cannot replace $V(x)$ by its average $W(x)$ in the canonical form.

For exact statements, details and proofs, see Chapters 19 (if $\mathsf{rank}(F_{jk}) = d$) and Chapters 20 (if $\mathsf{rank}(F_{jk}) < d$) of [Ivr4].

Global Asymptotics

For magnetic Schrödinger and Dirac operators, one can derive results similar to those of Sections 3 and 3. We describe here only some results which are very different from those already mentioned and only for the Schrödinger operator.

Case $d = 2r$

Assume that $F_{jk} = \mathsf{const}$, $\mathsf{rank}(F_{jk}) = 2r = d$, $\mu = h = 1$ and V decays at infinity. Then instead of an eigenvalue of infinite multiplicity $\lambda_{j,\infty} = (2j_1+1)f_1 + ... + (2j_r+1)f_r$ (with $j \in \mathbb{Z}^{+r}$), we have a sequence of eigenvalues $\lambda_{j,n}$ tending to $\lambda_{j,\infty}$ as $n \to \infty$ and we want to consider the asymptotics of $\mathsf{N}_j^-(\eta)$ which is the number of eigenvalues in $(\lambda_{j,\infty} - \epsilon, \lambda_{j,\infty} - \eta)$ and $\mathsf{N}_j^+(\eta)$ which is the number of eigenvalues in $(\lambda_{j,\infty} + \eta, \lambda_{j,\infty} + \epsilon)$, as $\eta \to +0$.

It turns out that in contrast to the Schrödinger operator without a magnetic field, there are meaningful results no matter how fast V decays.

Theorem 3.1. *Let us consider a Schrödinger operator in $\mathbb{R}^2$ satisfying the above conditions, $\mu = h = 1$ and*

$$|\nabla^\alpha V| \le c_\alpha \rho^2 \gamma^{-|\alpha|}, \tag{3.2}$$

with $\rho = \langle x\rangle^m$, $\gamma = \langle x\rangle$, $m < 0$. Let

$$\mp V \ge -\epsilon\rho^2 \implies |\nabla V| \ge \epsilon\rho^2\gamma^{-1} \qquad \text{for } |x| \ge c. \tag{6.3.2}_\mp$$

Then,

(i) The asymptotics

$$\mathsf{N}_j^\mp(\eta) = \mathcal{N}^\mp(\eta) + O(\log \eta) \tag{6.3.3}_\pm$$

hold with

$$\mathcal{N}^\mp(\eta) = \frac{1}{2\pi} \int_{\{\mp V > \eta\}} F\, dx \tag{6.3.4}_\pm$$

and in our conditions $\mathcal{N}^\mp(\eta) = O(\eta^{1/m})$. Moreover, $\mathcal{N}^\mp(\eta) \asymp \eta^{1/m}$ provided that $\mp V \ge \epsilon\rho^2$ for $x \in \Gamma$, where Γ is a non-empty open sector (cone) in $\mathbb{R}^2$.

(ii) Furthermore, if

$$\mp V \ge \epsilon\rho^2 \qquad \text{for } |x| \ge c, \tag{6.3.5}_\pm$$

then the remainder estimate is $O(1)$. In this case, the points $(2j+1)F \pm 0$ are not limit points of the discrete spectrum.

This theorem is proved by rescaling the results of Subsection 2 which do not require $h \ll 1$, but only $\mu h \gtrsim 1$ and $\mu^{-1}h \ll 1$ (see Remark 2.4); in our case, after rescaling $\mu = 1/\rho\gamma$ and $\mu = \gamma/\rho$, so that $\mu h = 1/\rho^2$ and $\mu^{-1}h = \gamma^{-2}$. Therefore, the remainder does not exceed $\int \gamma^{-2}\, dx$, where we integrate over $\{x : |V(x)| \ge (1-\epsilon)\eta\}$ in the general case and over $\{x : (1+\epsilon)\eta \ge |V(x)| \ge (1-\epsilon)\eta\}$ under the assumption $(6.3.5)_\pm$.

Remark 3.2. (i) Similar results hold in the d-dimensional case ($d \ge 4$) when $(F) = \mathsf{const}$ and $d = \mathsf{rank}(F)$: the remainder is $O(\eta^{(d-2)/2m})$ and the principal part is $O(\eta^{d/2m})$.

(ii) One can consider the case $\rho = \exp(-\langle x\rangle^m)$, $\gamma = \langle x\rangle^{1-m}$, $0 < m < 1$, and recover remainder estimate $O(|\log\eta|^{(d-2)/m+2})$ in the general case and $O(|\log\eta|^{(d-2)/m+1})$ under the assumption $(6.3.5)_{\pm}$ with $\mathcal{N}^{\mp}(\eta) = O(|\log\eta|^{d/m})$.

(iii) On the other hand, the cases when V decays like $\exp(-2\langle x\rangle)$ or faster, or is compactly supported, are out of reach of our methods but the asymptotics (without a remainder estimate) were obtained in [MR, RT, RW].

For exact statements, details, proofs and generalizations for arbitrary $\mathsf{rank}(F_{jk}) = d = 2r$, see Subsection 23.4.1 of [Ivr4].

Case $d > 2r$. I

This case is less "strange" than case $d = 2$. Here, we can discuss only the eigenvalue counting function $\mathsf{N}_0^-(\eta)$.

Theorem 3.3. *Let us consider a Schrödinger operator in $\mathbb{R}^3$ satisfying $F = \mathsf{const}$ and (3.2) with $\rho = \langle x\rangle^m$, $\gamma = \langle x\rangle$, $m \in (-1, 0)$. Then,*

(i) The asymptotics

$$\mathsf{N}_0^-(\eta) = \mathcal{N}^-(\eta) + O(\eta^{\frac{1}{m}-\delta}) \tag{6.3.6}_-$$

hold with

$$\mathcal{N}^-(\eta) = \frac{1}{2\pi^2}\int F(-V-\eta)_+^{\frac{1}{2}}\,dx \tag{3.8}$$

and arbitrarily small $\delta > 0$, and furthermore, $\mathcal{N}^-(\eta) = O(\eta^{\frac{3}{2m}+\frac{1}{2}})$. Moreover, $\mathcal{N}^-(\eta) \asymp \eta^{\frac{3}{2m}+\frac{1}{2}}$, provided $-V \ge \epsilon\rho^2$ for $x \in \Gamma$ where Γ is a non-empty open cone in $\mathbb{R}^3$.

(ii) Further, under the assumption

$$\sum_{|\alpha|\le K} |\nabla^\alpha V|\cdot\gamma^{|\alpha|} \ge \epsilon\rho^2 \qquad \text{for } |x| \ge c, \tag{3.9}$$

the asymptotics (3.8) hold with $\delta = 0$.

Remark 3.4. (i) Similar results hold in the d-dimensional case when $(F_{jk}) = \mathsf{const}$ and $d > 2r = \mathsf{rank}(F_{jk})$: the remainder estimate is $O(\eta^{(d-2r-1)/2+(d-1)/2m-\delta})$ [42] and $\mathcal{N}^-(\eta) = O(\eta^{(d-2r)/2+d/2m})$.

(ii) Observe that for $m = -1$, both the principal part and the remainder estimate have magnitude η^{-r}.

(iii) One can also consider $\rho = \langle x\rangle^{-1}|\log\langle x\rangle|^{\alpha}$ with $\alpha > 0$.

For exact statements, details, proofs and generalizations, see Subsection 24.4.1 of [Ivr4].

Case $d > 2r$. II

We now discuss faster decaying potentials. Assume that $d = 2r+1$ (otherwise there will be no interesting results). Assume for simplicity that $g^{jk} = \delta_{jk}$ and $F_{dk} = 0$. Further, one can assume that $A_d(x) = 0$; otherwise one can achieve it by a gauge transformation. Then, $A_j = A_j(x')$ with $x' = (x_1, \dots, x_{2r})$ and the operator is of the form

$$D_d^2 + V(x) + H_0', \qquad \text{with} \quad H_0' \coloneqq \sum_{1\le j\le d-1} (D_j - A_j(x'))^2. \tag{3.10}$$

For any fixed $x' : |x'| \ge c$, consider the one-dimensional operator

$$L \coloneqq D_t^2 + V(x'; t) \tag{3.11}$$

on $\mathbb{R} \ni t$. It turns out that under the assumption

$$|V(x'; t)| \le \varepsilon t^{-2}, \tag{3.12}$$

with $\varepsilon \le (\frac{1}{4} - \epsilon)$, this operator has no more than one negative eigenvalue $\lambda(x')$; moreover, it has exactly one negative eigenvalue

$$\lambda(x') = -\frac{1}{4} W(x')^2 + O(\varepsilon^3), \tag{3.13}$$

provided

$$W(x') \coloneqq \int_{\mathbb{R}} V(x'; t) < 0 \qquad \text{and} \quad -W(x') \asymp \varepsilon. \tag{3.14}$$

[42] Where $\delta = 0$ if either $d \ge 2r + 2$ or the assumption (3.9) is fulfilled.

Furthermore, in this case $\lambda(x')$ nicely depends on x'.

Let

$$|\nabla^{\alpha} V| \le c_{\alpha}\rho^{2}\gamma_{1}^{-|\alpha'|}\gamma^{-\alpha_{d}}, \tag{3.15}$$

with $\rho = \langle x\rangle^{l}\langle x'\rangle^{k}$, $\gamma = \langle x\rangle$, $\gamma_1 = \langle x'\rangle$ and $l \le -2$, $m \coloneqq 2l + 2k + 1 < 0$ and if

$$W(x') < 0, \qquad W(x') \asymp \rho', \qquad \rho' \coloneqq \langle x'\rangle^{m}, \tag{3.16}$$

then we are essentially in the $(d-1)$-dimensional case of an operator $H' \coloneqq H'_0 + \lambda(x')$, and for $\mathsf{N}^{-}(\eta)$, we have the corresponding asymptotics of Subsubsection 3.

For exact statements, details, proofs and generalizations, see Subsections 24.4.2 of [Ivr4]. For improvements for slower decaying potentials, see Subsections 24.4.3 of [Ivr4].

4 Applications to Multiparticle Quantum Theory

Problem Set-up

In this Chapter, we discuss an application to Thomas-Fermi Theory. Consider a large (heavy) atom or molecule; it is described by a *Multiparticle Quantum Hamiltonian*

$$\mathsf{H}_N = \sum_{1\le n\le N} H_V(x_n) + \sum_{1\le n<k\le N} \frac{1}{|x_n - x_k|} \tag{4.1}$$

where H is a *one-particle quantum Hamiltonian*, Planck constant $\hbar = 1$, electron mass $= \frac{1}{2}$, electron charge $= -1$. This operator acts on the space $\mathfrak{H} \coloneqq \wedge_{1\le j\le N}\mathscr{L}^2(\mathbb{R}^3, \mathbb{C}^2)$ of totally antisymmetric functions $\Psi(x_1, \varsigma_1; \dots; x_N, \varsigma_N)$ because the electrons are fermions, $x_n = (x_n^1, x_n^2, x_n^3)$ is a coordinate and $\varsigma_n \in \{-\frac{1}{2}, \frac{1}{2}\}$ is the *spin* of n-th particle. We identify the $\mathbb{C}^2$-valued function $\psi(x)$ on $\mathbb{R}^3$ with a scalar-valued function $\psi(x, \varsigma)$.

If the electrons did not interact between themselves, but the field potential was $-W(x)$, then they would occupy the lowest eigenvalues and the ground state wave functions would be the anti-symmetrized product

$\phi_1(x_1,\varsigma_1)\phi_2(x_2,\varsigma_2)\dots\phi_N(x_N,\varsigma_N)$, where ϕ_n and λ_n are the eigenfunctions and eigenvalues of H_W respectively.

Then the local electron density would be $\rho_\Psi = \sum_{1\le n\le N}|\phi_n(x)|^2$ and according to the pointwise Weyl law (if there is no magnetic field)

$$\rho_\Psi(x) \approx \frac{1}{3\pi^2}(W+\nu)_+^{\frac{3}{2}}, \tag{4.2}$$

where $\nu = \lambda_N$. We first assume that there is no magnetic field and therefore, $H_V = -\Delta - V(x)$.

This density would generate the potential $-|x|^{-1}*\rho_\Psi$ and we would have $W \approx V - |x|^{-1}*\rho_\Psi$.

Replacing all approximate equalities by strict ones, we arrive to the *Thomas-Fermi equations*:

$$V - W^{\mathsf{TF}} = |x|^{-1}*\rho^{\mathsf{TF}}, \tag{4.3}$$

$$\rho^{\mathsf{TF}} = \frac{1}{3\pi^2}(W^{\mathsf{TF}}+\nu)_+^{\frac{3}{2}}, \tag{4.4}$$

$$\int \rho^{\mathsf{TF}}\,dx = N, \tag{4.5}$$

where $\nu \le 0$ is called the *chemical potential* and in fact approximates λ_N.

Considering atoms and molecules, we assume that

$$V(x) = \sum_{1\le m\le M}\frac{Z_m}{|x-\mathsf{y}_m|}, \tag{4.6}$$

where y_m is the *position* and Z_m is the *charge* of the m-th nuclei, M is fixed and $Z_1 \asymp Z_2 \asymp \dots \asymp Z_M \asymp N \to \infty$.

Thomas-Fermi theory has been rigorously justified (with pretty good error estimates) and we want to explain how.

Reduction to One-Particle Problem

Estimate from below

We start from the estimate from below. The *ground state energy* $\mathsf{E}_N := \inf\langle \mathsf{H}_N\Psi,\Psi\rangle$, taken over all $\Psi\in\mathfrak{H}$ with $\|\Psi\|=1$, where $\langle\cdot,\cdot\rangle$ denotes the inner product in $\mathfrak{H}$. Classical mathematical physics provides a wealth of results. One of them is the *electrostatic inequality* due to

E. H. Lieb [L]:

$$(4.7)\quad \sum_{1\le j<k\le N}\int |x_j-x_k|^{-1}|\Psi(x_1,\dots,x_N)|^2\,dx_1\cdots dx_N \ge \frac{1}{2}\mathsf{D}(\rho_\Psi,\rho_\Psi)-C\int \rho_\Psi^{\frac{4}{3}}(x)\,dx,$$

with ρ_Ψ defined by (4.2). This inequality holds for all (not necessarily antisymmetric) functions Ψ with $\|\Psi\|_{\mathscr{L}^2(\mathbb{R}^{3N})}=1$. Therefore,

$$(4.8)\quad \langle \mathsf{H}_N\Psi,\Psi\rangle \ge \sum_{1\le j\le N}\langle H_{V,x_j}\Psi,\Psi\rangle+\frac{1}{2}\mathsf{D}\big(\rho_\Psi,\rho_\Psi\big)-C\int\rho_\Psi^{\frac{4}{3}}(x)\,dx = \sum_{1\le j\le N}\langle H_{W,x_j}\Psi,\Psi\rangle+\frac{1}{2}\mathsf{D}\big(\rho_\Psi-\rho,\rho_\Psi-\rho\big)-\frac{1}{2}\mathsf{D}\big(\rho,\rho\big)-C\int\rho_\Psi^{\frac{4}{3}}(x)\,dx$$

and H_W is a one-particle Schrödinger operator with potential

$$(4.9)\qquad W=V-|x|^{-1}*\rho,$$

where ρ is an arbitrarily chosen real-valued non-negative function and therefore,

$$(4.10)\qquad (V-W,\rho_\Psi)=-\mathsf{D}(\rho,\rho_\Psi).$$

The physical sense of the second term in W is transparent: it is a potential created by the charge $-\rho$. Skipping the positive second term in the right-hand expression of (4.8) and believing that the last term is not very important for the ground state function Ψ [43)], we see that we need to estimate from below the first term. Since the first term is simply the sum of operators acting with respect to different variables, we can estimate it from below by

$$(4.11)\qquad \langle (H_{W,x_j}-\nu)\Psi,\Psi\rangle+\lambda N$$

with arbitrary ν; therefore, it is bounded from below by $\mathsf{Tr}((H_W-\nu)_-)$, where $(H_W-\nu)_-$ denotes the negative part of the operator $(H_W-\nu)$, and hence its trace is the sum of the negative eigenvalues.

[43)] When we derive the upper estimate for E, we will get an upper estimate for this term as a bonus.

Here, the assumption that Ψ is antisymmetric is crucial. Namely, for general (or symmetric–does not matter) Ψ, the best possible estimate is $\lambda_1 N$ where λ_1 is the lowest eigenvalue of H_W (we always assume that there are sufficiently many eigenvalues below the bottom of the essential spectrum of H_W) and we cannot apply semiclassical theory.

Thus we arrive to

$$\mathsf{E}_N \ge \mathsf{Tr}((H_W-\nu)_-) + \nu N - \frac{1}{2}\mathsf{D}\big(\rho,\rho\big) - CN^{\frac{5}{3}}, \tag{4.12}$$

where we used another result of E. H. Lieb [L]: $\int \rho_\Psi^{\frac{4}{3}}(x)\,dx \le CN^{\frac{5}{3}}$ for the ground state Ψ.

Estimate from above

Here, we simply plug in a test function Ψ which is an (anti-symmetrized) product $\phi_1(x_1,\varsigma_1)\phi_2(x_2,\varsigma_2)\dots\phi_N(x_N,\varsigma_N)$ where ϕ_n and λ_n are eigenfunctions and eigenvalues of H_W respectively, and we pick W later. It may happen, however, that H_W does not have N negative eigenvalues, then we can reduce N and use the inequality $\mathsf{E}_N \le E_{N'}$ as $N' \le N$.

Then, E_N is estimated from above by

$$\begin{aligned}\langle \mathsf{H}_N\Psi,\Psi\rangle = {}& \sum_n (H_{W,x_j}-\lambda)\Psi,\Psi\rangle + \lambda N - (V-W,\rho_\Psi) + \frac{1}{2}\mathsf{D}(\rho_\Psi,\rho_\Psi)\\ & - \frac{1}{2}\sum_n \iint |x-y|^{-1}|\psi_n(x)|^2|\psi_n(y)|^2\,dxdy\end{aligned} \tag{4.13}$$

and therefore recalling (4.10), we obtain

$$\mathsf{E}_N \le \mathsf{Tr}((H_W-\lambda)_-) + \lambda N + \frac{1}{2}\mathsf{D}(\rho_\Psi-\rho,\rho_\Psi-\rho) - \frac{1}{2}\mathsf{D}(\rho,\rho) \tag{4.14}$$

and $\rho_\Psi = \mathsf{tr}\, e_N(x,x)$ where $e_N(x,y)$ and $e(x,y,\lambda)$ are the Schwartz kernels of the projector to the N lowest eigenvalues of H_W and of the operator $\theta(\lambda - H_W)$ respectively; here tr denotes the matrix trace, and $\lambda = \lambda_N$ if $\lambda_N < 0$ and $\lambda = 0$ otherwise. Finally, we conclude that

$$\begin{aligned}\mathsf{E}_N \le {}& \mathsf{Tr}((H_W-\nu)_-) + \nu N + |\lambda-\nu|\cdot|\mathsf{N}^-(H_W-\nu) - N|\\ & + \frac{1}{2}\mathsf{D}(\mathsf{tr}\, e_N(x,x)-\rho, \mathsf{tr}\, e_N(x,x)-\rho) - \frac{1}{2}\mathsf{D}(\rho,\rho)\end{aligned} \tag{4.15}$$

with arbitrary $\nu \le 0$.

Semiclassical Approximation

Estimate from below

In the estimate from below (4.12), we replace $\mathsf{Tr}((H_W-\nu)_-)$ by its semiclassical approximation

$$\mathsf{Tr}((H_W-\nu)_-) \approx -\int P(W+\nu)\,dx \tag{4.16}$$

with

$$P(W+\nu) := \frac{2}{5\pi^2}(W+\nu)_+^{\frac{5}{2}}, \tag{4.17}$$

and also plug in $\rho = \frac{1}{4\pi}\Delta(W-V)$; then we obtain the functional

$$\Phi_*(W,\nu) = -\int P(W+\nu)\,dx - \frac{1}{8\pi}\|\nabla(W-V)\|^2 + \nu N; \tag{4.18}$$

maximizing it, we arrive to the Thomas-Fermi equations and its maximal value is $\mathcal{E}_N^{\mathsf{TF}}$, delivered by Thomas-Fermi theory. Then, we need to understand the semiclassical error. To do this, we use the properties of the Thomas-Fermi potential and rescale $x \mapsto xN^{\frac{1}{3}}$ and $\tau \mapsto N^{-\frac{4}{3}}\tau$ (so, $\nu \mapsto N^{-\frac{4}{3}}\nu$) with

$$H_W = -h^2\nabla^2 - W, \tag{4.19}$$

where near y_m, the rescaled potential is Coulomb-like: $W \sim z_m|x-y|^{-1}$ with $z_m = Z_m N^{-1}$.

Then, we can apply results Subsection 3 (see (3.53)): for the operator (4.19),

$$\mathsf{Tr}((H_W-\nu)_-) = -h^{-3}\int P(W+\nu)\,dx + \kappa h^{-2} + O(h^{-1}), \tag{4.20}$$

where in this case, the numerical value of $\kappa = 2\sum_m z_m^2$ is well-known. Scaling back, we obtain $\mathcal{E}_N^{\mathsf{TF}} + \mathsf{Scott} + O(N^{\frac{5}{3}})$ where the leading term is of magnitude $N^{\frac{7}{3}}$ and the Scott correction term $\mathsf{Scott} = 2\sum_m Z_m^2$. Here, we need to assume that $|\mathsf{y}_m - \mathsf{y}_{m'}| \gtrsim 1$ after rescaling (and $|\mathsf{y}_m - \mathsf{y}_{m'}| \gtrsim N^{-\frac{1}{3}}$ before it).

Indeed, after rescaling, we get an operator which is uniformly in the framework of Subsection 3 due to the following properties of the Thomas-Fermi potential:

(4.21) Before rescaling, $W^{\mathsf{TF}} = Z_m|x-\mathsf{y}_m|^{-1} + O(N)$ for $|x-\mathsf{y}_m| \lesssim N^{-\frac{1}{3}}$ and $W^{\mathsf{TF}} \asymp \sum_m \big(|x-\mathsf{y}_m|^{-4} + (Z-N)_+|x-\mathsf{y}_m|^{-1}\big)$ for $|x-\mathsf{y}_m| \gtrsim 1$ for all $m = 1, \dots, M$.

In fact, the analysis of Subsection 3 was mainly motivated by this problem.

Estimate from above

Again, using the semiclassical approximation (4.16) for $\mathsf{Tr}((H_W-\nu)^-)$ and also $e_N(x,x) \approx P'(W+\nu)$ with $P' = \frac{1}{3\pi^2}(W+\nu)^{\frac{3}{2}}$ the derivative of $P(W+\nu)$, we arrive to the functional

$$\Phi^*(W,\nu) = -\int P(W+\nu)\,dx - \frac{1}{8\pi}\|\nabla(W-V)\|^2 + \nu N + \mathsf{D}(P'(W+\nu) - \frac{1}{4\pi}\Delta(W-V),\ P'(W+\nu) - \frac{1}{4\pi}\Delta(W-V)); \tag{4.22}$$

minimizing it, we again arrive to the Thomas-Fermi equations and the minimal value is $\mathcal{E}_N^{\mathsf{TF}}$, again delivered by Thomas-Fermi theory.

However, in addition to the semiclassical error for the trace, we have other errors from (4.15):

$$|\lambda-\nu|\cdot|\mathsf{N}^-(H_W-\nu) - N|, \tag{4.23}$$

$$\mathsf{D}(\mathsf{tr}\, e(x,x,\nu) - P'(W+\nu),\ \mathsf{tr}\, e(x,x,\nu) - P'(W+\nu)) \tag{4.24}$$

and

$$\mathsf{D}(\mathsf{tr}\, e_N(x,x) - \mathsf{tr}\, e(x,x,\nu),\ \mathsf{tr}\, e_N(x,x) - \mathsf{tr}\, e(x,x,\nu)). \tag{4.25}$$

The expression (4.24) is the semiclassical error and after rescaling it, we can estimate it by $O(h^{-4})$ (due to the pointwise spectral asymptotics). When scaling back, we gain the factor $N^{\frac{1}{3}}$, resulting in $O(N^{\frac{5}{3}})$.

Expressions (4.23) and (4.25) can be also estimated by $O(N^{\frac{5}{3}})$ based on another semiclassical error

$$\mathsf{N}^-(H_W-\sigma) - \int P'(W+\sigma)\,dx = O(h^{-2}), \tag{4.26}$$

(for $\sigma \le 0$) after rescaling and thus, $O(N^{\frac{2}{3}})$ in the original scale, due to the definitions of λ and ν. One needs to consider four cases depending on whether $\lambda < 0$ (i.e. $N^-(H_W) \ge N$) or $\lambda = 0$ (i.e. $N^-(H_W) < N$) and whether $\nu < 0$ (i.e. $N < Z$) or $\nu = 0$ (i.e. $N \ge Z$), where $Z = Z_1 + \dots + Z_M$ is the total charge of the nuclei.

More Precise Estimates

If we want to improve the remainder estimate $O(N^{\frac{5}{3}})$, then we need to improve the semiclassical remainder estimates and also deal with $O(N^{\frac{5}{3}})$ in Lieb's electrostatic inequality (4.7).

The first task could be done under the assumption

$$a := \min_{m\neq m'} |\mathsf{y}_m - \mathsf{y}_{m'}| \gg \bar{a} := N^{-\frac{1}{3}}, \tag{4.27}$$

which is completely reasonable (see Section 4). In this case, in each zone $\mathcal{Y}_m := \{x : |x-\mathsf{y}_m| \le a^{1-\eta}\bar{a}^{\eta}\}$, with $\eta > 0$, both ρ^{TF} and W^{TF} are close to those of a single atom which are spherically symmetric. Then one can prove easily that the standard conditions to the trajectories are fulfilled and we may use the improved remainder estimates. On the other hand, contributions of the "outer" zone $\mathcal{Y}_0 := \{x : |x-\mathsf{y}_m| \ge a^{1-\eta}\bar{a}^{\eta}\ \forall m = 1,\dots,M\}$ to these remainders is smaller.

Therefore all remainder estimates acquire the factor $(h^{\delta} + b^{-\delta})$ with $b = a\bar{a}^{-1}$ before scaling back, i.e. $(N^{\frac{1}{3}\delta} + (aN^{\frac{1}{3}})^{-\delta})$ after it. However, the trace asymptotics should also include the term $-\kappa_1 h^{-1}$ before scaling back or $-\kappa_1 N^{\frac{5}{3}}$ after it; for the potential W^{TF}, it is numerically equal to $\mathsf{Schwinger} = -c_1 \int \rho^{\mathsf{TF}\,\frac{4}{3}}\,dx$ which is called the *Schwinger correction term*.

The second task requires an improvement in Lieb's electrostatic inequality due to [GS] and [Ba]: one can replace the last term in (4.8) for the ground state energy Ψ by

$$-\frac{1}{2}\iint |x-y|^{-1}\,\mathsf{tr}\big(e_N^{\dagger}(x,y)e_N(x,y)\big)\,dxdy - O(N^{\frac{5}{3}-\delta}), \tag{4.28}$$

where the first term coincides with the last term in (4.13) (the estimates from above) and again modulo $O(N^{\frac{5}{3}-\delta})$ can be rewritten as

$$-\frac{1}{2}\iint |x-y|^{-1}\,\mathsf{tr}\big(e^{\dagger}(x,y,\nu)e(x,y,\nu)\big)\,dxdy. \tag{4.29}$$

So far, we have not explored such expressions but we can handle them.

For this expression, after rescaling, we can derive the asymptotics with principal term $-\kappa_2 h^{-4}$ and with remainder estimate as good as $O(h^{-3})$, which after scaling back becomes $O(N^{\frac{4}{3}})$ (which is an overkill). Here, we use the representation of $e(x,y,\nu)$ by an oscillatory integral modulo a term whose $\mathscr{L}^2(\mathbb{R}^6)$ norm does not exceed Ch^{-2}.

To calculate κ_2, we can consider the operator with constant potential W, and for this operator, we calculate $-\frac{1}{2}\int |x-y|^{-1}\,\mathsf{tr}\big(e^{\dagger}(x,y,\nu)e(x,y,\nu)\big)\,dy$ obtaining $-\mathsf{const}(W+\nu)^2h^{-4}$, then plug in $W=W(x)$ and integrate over x. For $W=W^{\mathsf{TF}}$, after scaling back, we arrive to $\mathsf{Dirac}=-c_2\int \rho^{\mathsf{TF}\,\frac{4}{3}}\,dx$ which is called the *Dirac correction term*.

Despite having completely different origins, these correction terms differ only by numerical constants.

We arrive to the theorem:

Theorem 4.1. *As* $Z=Z_1+\ldots+Z_M\asymp N\to\infty$, M *remains bounded,* $a=\min_{m\neq m'}|\mathsf{y}_m-\mathsf{y}_{m'}|\gtrsim N^{-\frac{1}{3}}$ *and*

$$\mathsf{E}_N=\mathcal{E}_N^{\mathsf{TF}}+\mathsf{Scott}+\mathsf{Schwinger}+\mathsf{Dirac}+O(R) \qquad (4.30)$$
$$\text{with}\quad R=N^{\frac{5}{3}}\big(N^{-\delta}+(aN^{\frac{1}{3}})^{-\delta}\big)$$

where $\delta>0$ *is unspecified.*

As a byproduct of the proof, we obtain

$$\mathsf{D}(\rho_\Psi-\rho^{\mathsf{TF}},\,\rho_\Psi-\rho^{\mathsf{TF}})=O(R). \qquad (4.31)$$

For details and proofs, see Sections 25.1–25.4 of [Ivr4].

Ramifications

First, instead of the *fixed nuclei model*, we can consider the *free nuclei model* where we add to both E_N and $\mathcal{E}_N^{\mathsf{TF}}$ the energy of nuclei-to-nuclei interaction

$$\sum_{m<m'} Z_mZ_{m'}|\mathsf{y}_m-\mathsf{y}_{m'}|^{-1} \qquad (4.32)$$

and minimize the results by the position of nuclei $(\mathsf{y}_1,\ldots,\mathsf{y}_m)$; denote the results by $\widehat{\mathsf{E}}_N$ and $\widehat{\mathcal{E}}_N^{\mathsf{TF}}$ respectively.

Combining (4.30) with the non-binding theorem in Thomas-Fermi theory[44], we obtain that in the free nuclei model (with $Z_1\asymp\ldots\asymp Z_M\asymp Z\asymp N$),

$$a=\min_{m\neq m'}|\mathsf{y}_m-\mathsf{y}_{m'}|\gtrsim N^{-\frac{5}{3}+\delta} \qquad (4.33)$$

[44] In the Thomas-Fermi theory, molecules do not exist.

and then (4.30) and (4.31) hold with $R = N^{\frac{5}{3}-\delta}$.

Next, using methods already developed by mathematical physicists before asymptotics (4.30) and (4.31) were derived, we can answer several questions with far better precision than before; for simplicity, we assume that $a \ge N^{-\frac{1}{3}+\delta}$.

(i) How many extra electrons can the system bind? In other words, if $\mathsf{E}_N < \mathsf{E}_{N-1}$, what we can say about $N - Z$? According to a classical theorem due to G. Zhislin, the system can bind at least Z electrons. Our answer: $(N-Z)_+ = O(N^{\frac{5}{7}-\delta})$, based on the fact that in the Thomas-Fermi theory, negative ions do not exist.

(ii) What we can say about the *ionization energy* $\mathsf{I}_N = \mathsf{E}_{N-1} - \mathsf{E}_N$? Our answer: $\mathsf{I}_N = O(N^{\frac{20}{21}-\delta})$ if $N-Z \ge -CN^{\frac{5}{7}-\delta}$ and $\mathsf{I}_N = -\nu + O((Z-N)^{\frac{17}{18}} Z^{\frac{5}{18}-\delta}$ if $N - Z \le -CN^{\frac{5}{7}-\delta}$; if $N \le Z$ $\nu \asymp (Z-N)^{\frac{4}{3}}$.

(iii) In the free nuclei model (with $M \ge 2$), what can we say about $N-Z > 0$ if a stable configuration exists? Our answer: $Z - N \le CN^{\frac{5}{7}-\delta}$ (again based on the non-binding theorem).

For details and proofs, see Sections 25.5 and 25.6 of [Ivr4].

Adding Magnetic Field

Adding External Magnetic Field

Consider the Schrödinger-Pauli operator with magnetic field

$$H_{A,V} = ((-ih\nabla - \mu A(x)) \cdot \boldsymbol{\sigma})^2 - V(x). \tag{4.34}$$

Then instead of $P(w)$ defined by (4.17), we need to define it according to (2.5) by

$$P(w) = \frac{2}{\pi^2}\Big(\frac{1}{2} w_+^{\frac{3}{2}} B + \sum_{j=1}^{\infty} (w - 2jB)_+^{\frac{3}{2}} B\Big), \tag{4.35}$$

where B is the scalar intensity of the magnetic field. This changes both the Thomas-Fermi theory and properties of the Thomas-Fermi potential W^{TF} and Thomas-Fermi density ρ^{TF}.

Case $B \lesssim Z^{4/3}$ For $B \lesssim Z^{4/3}$, the main contributions to the (approximate) electronic charge $\int \rho^{\mathsf{TF}}\,dx$ and the energy $\mathcal{E}^{\mathsf{TF}}$ come from the zone $\{x : d(x) \asymp Z^{-1/3}\}$ ($d(x) = \min_m |x - \mathsf{y}_m|$), exactly as for $B = 0$.

Furthermore, $W^{\mathsf{TF}} \asymp Z_m d(x)^{-1}$ if $d(x) \lesssim Z^{-1/3}$ and (for $Z = N$) $W^{\mathsf{TF}} \asymp d(x)^{-4}$ if $Z^{-1/3} \le d(x) \lesssim B^{-1/4}$ but $\rho^{\mathsf{TF}} = 0$ if $d(x) \ge C_0 B^{-1/4}$ [45)].

Finally, as we using scaling to bring our problem to the standard one, we get that in the zone $\{x : d(x) \asymp Z^{-1/3}\}$, the effective semiclassical parameter is $h_{\mathsf{eff}} = Z^{-1/3}$ which leads to $\mathcal{E}^{\mathsf{TF}} \asymp Z^{7/3}$ again exactly as for $B = 0$.

As a result, assuming that $M = 1$, we can recover asymptotics for the ground state energy E with the Scott correction term but with the remainder estimate $O(Z^{5/3} + Z^{4/3}B^{1/3})$. For $M \ge 2$ and $N \ge Z$, our estimates are almost as good (provided $a = \min_{m \ne m'} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge Z^{-1/3}$), but deteriorate when both $(Z - N)_+$ and B are large.

Moreover, for $B \ll Z$ assuming (4.27), we can marginally improve these results and include the Schwinger and Dirac correction terms.

The main obstacles we need to overcome are that now W^{TF} is not infinitely smooth but only belongs to the class $\mathscr{C}^{5/2}$ and that for $M \ge 2$, the nondegeneracy assumption ($|\nabla W| \asymp 1$ after rescaling) fails.

Case $B \gtrsim Z^{4/3}$ On the other hand, for $B \gtrsim Z^{4/3}$, the the main contributions to the (approximate) electronic charge and the energy $\mathcal{E}^{\mathsf{TF}}$ come from the zone $\{x : d(x) \asymp B^{-1/4}\}$ and (for $Z = N$) $W^{\mathsf{TF}} \asymp Z d(x)^{-1}$ if $d(x) \lesssim B^{-1/4}$ but $W^{\mathsf{TF}} = 0$ if $d(x) \ge C_0 B^{-1/4}$. In this case, $\mathsf{E}^{\mathsf{TF}} \asymp B^{2/5} Z^{9/5}$.

Further, as we using scaling to bring our problem to the standard one, we see that in the zone $\{x : d(x) \asymp B^{-1/4}\}$, the effective semiclassical parameter is $h_{\mathsf{eff}} = B^{1/5} Z^{-3/5}$ and therefore unless $B \ll Z^3$, the semiclassical approximation fails and the correct answer should be expressed in completely different terms [LSY1].

As a result, assuming that $M = 1$ if $Z^{4/3} \le B \le Z^3$, we can recover the asymptotics for E with the Scott correction term but with the remainder estimate $O(B^{4/5} Z^{3/5} + Z^{4/3} B^{1/3})$.

For $M \ge 2$ and $N \ge Z$, our estimates are almost as good (provided $a = \min_{m \ne m'} |\mathsf{y}_m - \mathsf{y}_{m'}| \ge B^{-1/4}$), but deteriorate when $(Z - N)_+$ is large.

Again the main obstacles we need to overcome are that now W^{TF} is not infinitely smooth but only belongs to $\mathscr{C}^{5/2}$ and that for $M \ge 2$, the nondegeneracy assumption ($|\nabla W| \asymp 1$ after rescaling) fails.

[45)] So, the radii of atoms in Thomas-Fermi theory are $\asymp \min(B^{-1/4}, (Z - N)_+^{-1/3})$.

For details, exact statement and proofs, see Sections 26.1 and 26.6 of [Ivr4]. We also estimate the left-hand expression of (4.20) and are able to obtain results similar to those mentioned in Section 4. For details and proofs, see Sections 26.7–26.8 of [Ivr4].

Adding Self-Generated Magnetic Field

Let

$$\mathsf{E}(A) = \inf \mathsf{Spec}(\mathsf{H}_{A,V}) + \underline{\alpha^{-1} \int |\nabla \times A|^2 \, dx} \tag{4.36}$$

and

$$\mathsf{E}^* = \inf_{A \in \mathscr{H}^1_0} \mathsf{E}(A), \tag{4.37}$$

where A is an unknown magnetic field and the underlined term is its energy. One can prove that an "optimal" magnetic field exists (for given parameters $Z_1, \dots, Z_M, \mathsf{y}_1, \dots, \mathsf{y}_M, N$) but we do not know if it is unique[46].

Using the same arguments as before, we can reduce this problem to the one-particle problem with $\inf \mathsf{Spec}(\mathsf{H}_{A,V})$ replaced by $\mathsf{Tr}((H_{A,W} + \nu)_-)$ plus some other terms. However, in the estimate from below, most of the terms do not depend on A and in the estimate from above, we pick up A.

Then after the usual rescalings, the problem is reduced to the problem of minimizing

$$\mathsf{Tr}((H_{A,W} + \nu)_-) + \underline{\frac{1}{\kappa h^2} \int |\nabla \times A|^2 \, dx} \tag{4.38}$$

and then the optimal magnetic potential A must satisfy

$$\begin{aligned} &\frac{2}{\kappa h^2} \Delta A_j(x) = \Phi_j := \\ &\quad - \operatorname{Re} \mathsf{tr} \Big(\sigma_j \Big((hD - A)_x \cdot \boldsymbol{\sigma} e(x,y,\tau) + e(x,y,\tau)\, {}^t(hD - A)_y \cdot \boldsymbol{\sigma} \Big) \Big|_{y=x} \Big), \end{aligned} \tag{4.39}$$

where $e(x,y,\tau)$ is the Schwartz kernel of the spectral projector $\theta(-H)$ of $H = H_{A,W}$ and tr is the matrix trace. As usual, we are mainly interested in $h = Z^{-1/3}$ (and then $\kappa = \alpha Z$).

[46] If it was unique, then for $M = 1$, the spherical symmetry would imply that $A = 0$.

First, (4.39) allows us to claim a certain smoothness of A. Second, the right-hand expression is something we studied in pointwise spectral asymptotics, and the Weyl expression here is 0, so the right-hand expression of (4.39) is something that we could estimate. Surely, it is not that simple but improving our methods in the case of smooth W, we are able to prove that A is so small that the ordinary asymptotics with remainder estimates $O(h^{-2})$ and $O(h^{-1})$ would hold in both the pointwise asymptotics and the trace asymptotics. Moreover, under standard conditions, we would be able to get the remainder estimates $o(h^{-2})$ and $o(h^{-1})$ in the eigenvalue counting and the trace asymptotics respectively.

However, in reality, the above is not exactly true since W has Coulomb-like singularities $W \sim z_m|x-\mathsf{y}_m|^{-1}$ with $z_m \asymp 1$. If $M=1$, $z_m=1$, a singularity leads us to the Scott correction term $S(\kappa)h^{-2}$ derived in the same way as without a self-generated magnetic field. However, we do not have an explicit formula for $S(\kappa)$; we even do not know its properties except that it is non-increasing function of $\kappa \in [0,\kappa^*)$; we even do not know if we can take $\kappa^*=\infty$. If the optimal magnetic potential A was unique, then $A=0$ and $S(\kappa)=S(0)$, which corresponds to this term without a magnetic field.

Then as $M \ge 2$, the Scott correction term is $\sum_{1\le m\le M} S(\kappa z_m) z_m^2 h^{-2}$ in the general case. However, as $M \ge 2$ we need to decouple singularities as all of them are served by the same A and it leads to decoupling errors depending on the internuclei distance.

For details, exact statements and proofs, see Sections 27.2–27.3 of [Ivr4].

As a result, we derive the ground state asymptotics with the Scott correction term $\sum_{1\le m\le M} S(\alpha Z_m) Z_m^2$. We also estimate the left-hand expression of (4.20) and are able to obtain results similar to those mentioned in Section 4. For details, exact statements and proofs, see Sections 27.3–27.4 of [Ivr4].

Combining External and Self-Generated Magnetic Fields

We can also combine a constant strong external magnetic field and a self-generated magnetic field. Results are very similar to those of Subsection 4, but this time, the Scott correction term and the decoupling errors are like in Subsection 4. For details, exact statements and proofs, see Chapter 28 of [Ivr4].
