- in Section 11.5 the domain is "very unbounded" and the spectrum is discrete only because the lower order terms are coercive. In particular, we treat the Schrödinger operator with potential V tending to $+\infty$ at infinity and with the spectral parameter τ tending to $+\infty$, usually like $|x|^{2\mu}$ with $\mu > 0$ and the growths of both $\mathsf{N}^{\mathsf{W}}_{\tau}$ and R_{τ} depend on μ.

Further, in Section 11.6 we treat asymptotics of the eigenvalues tending to the boundary of the essential spectrum. In particular, we treat the Schrödinger and Dirac operators with potentials tending to 0 at infinity, usually like $|x|^{2\mu}$ with $\mu \in (-1, 0)$ and the spectral parameter τ tending to -0 and $M - 0$ or $-M + 0$ respectively (where M is the mass in the case of the Dirac operator). Then the rates of the growth of both $\mathsf{N}^{\mathsf{W}}_{\tau}$ and R_{τ} depend on μ.

Section 11.7 is devoted to the multiparameter asymptotics; for example, there is the semiclassical parameter $h \to +0$ and the spectral parameter τ tending either to $+\infty$ or $-\infty$ (for the Schrödinger and Dirac operators in bounded domains or for the Schrödinger operator in unbounded domains), or to -0, $M - 0$ or $-M + 0$ (for the Schrödinger and Dirac operators in unbounded domains), or to $\inf V + 0$, $\inf V + M + 0$, $\sup V - M - 0$ (for the Schrödinger and Dirac operators) where for the Schrödinger operator $\inf V$ is not necessarily finite. Moreover, the case of a vector semiclassical parameter $\boldsymbol{h} = (h_1, \dots, h_d)$ is treated as well.

For semi-bounded operators, Riesz means are also treated.

Finally, in Section 11.8 we consider asymptotics of the spectrum of the negative order pseudodifferential operators tending to 0. While these operators are not exactly covered by the general theory and require special analysis, some special cases (like $\Delta^{-m} V$) are and the general results are the same.

For simplicity we assume the sufficient smoothness but the reader can generalize easily these results applying results for rough and irregular operators.

11.1 Semiclassical Eigenvalue Asymptotics

In this section the operator is fixed and only the semiclassical parameter $h \to +0$ varies.

11.1.1 General Analysis

Standard Remainder Estimates

Let us consider first operators which are semi-bounded from below and apply the results of Chapter 9 derived on the basis of the results of Parts II and III. This means that $\tau_1 = -\infty$ and without any loss of the generality one can assume that $\tau_2 = 0$.

Let us consider operator

$$A_h = \sum_{|\alpha|,|\beta|\le m} (hD)^\alpha a_{\alpha,\beta}(hD)^\beta \tag{11.1.1}$$

with coefficients satisfying

$$a_{\alpha,\beta} = a^\dagger_{\beta,\alpha}, \tag{11.1.2}$$

$$\|D^\sigma a_{\alpha,\beta}\| \le c\varrho\rho^{-|\alpha|-|\beta|}\gamma^{-|\sigma|} \qquad \forall \alpha,\beta : |\alpha| \le m, |\beta| \le m\ \forall \sigma : |\sigma| \le K \tag{11.1.3}$$

and

$$\sum_{|\alpha|=|\beta|=m} \langle a_{\alpha,\beta} v_\alpha, v_\beta\rangle \ge \epsilon_0 \varrho\rho^{-2m} \sum_{|\alpha|=m} \|v_\alpha\|^2 \qquad \forall v = (v_\alpha)_{|\alpha|=m} \quad \forall x : \rho\gamma \le h_0 \tag{11.1.4}$$

where scaling function γ satisfies $(9.1.6)_1$ on X and

$$\mathsf{mes}(\mathcal{X}_{\mathsf{sing}}) = 0 \qquad \text{where} \quad \mathcal{X}_{\mathsf{sing}} = \{x, \gamma(x) = 0\}, \tag{11.1.5}$$

functions ρ, ϱ satisfying $(9.1.6)_2$ and $(9.1.6)_3$ are defined in $\mathcal{X}_{\mathsf{reg}} = X \setminus \mathcal{X}_{\mathsf{sing}}$, and $h_0 = \mathsf{const} > 0$.

The sets $\mathcal{X}_{\mathsf{reg}}$ and $\mathcal{X}_{\mathsf{sing}}$ are called *regular* and *singular sets* respectively. These sets do not coincide with but are obviously related to the *regular* $X_{\mathsf{reg},h} = \{x, \rho\gamma \ge h\}$ and *singular zones* $X_{\mathsf{sing},h} = \{x, \rho\gamma \le 2h\}$ and respectively: $X_{\mathsf{reg},h} \subset \mathcal{X}_{\mathsf{reg}}$ and expands to it, $X_{\mathsf{sing},h} \supset \mathcal{X}_{\mathsf{sing}}$ and shrinks to it as $h \to +0$.

In particular, for the Schrödinger operator

$$A = \sum_{1\le j,k\le d} (hD_j - V_j) g^{jk} (hD_k - V_k) + V \tag{11.1.6}$$

with real-valued functions $g^{jk} = g^{kj}$, V_j and V we always take $\varrho = \rho^2$ and conditions (11.1.3)–(11.1.4) become

$$|D^\alpha g^{jk}| \le c\gamma^{-|\alpha|}, \quad |D^\alpha V_j| \le c\rho\gamma^{-|\alpha|}, \quad |D^\alpha V| \le c\rho^2\gamma^{-|\alpha|} \tag{11.1.7}$$

and

$$\epsilon_0|\xi|^2 \le \sum_{j,k} g^{jk}\xi_j\xi_k \le c|\xi|^2 \qquad \forall \xi \in \mathbb{R}^d. \tag{11.1.8}$$

Moreover, we assume that conditions (9.1.15) (the boundary regularity condition) are fulfilled in $\mathcal{X}_{\mathsf{reg}}$. For the sake of simplicity we assume that the Dirichlet boundary conditions are given in which case the ellipticity condition for the boundary value problem is fulfilled automatically. However later we discuss Neumann-like problems as well.

Then one can apply Theorem 9.1.7 with $X_{\mathsf{reg}} = X_{\mathsf{reg},h} = \{x \in X, \rho\gamma > h\}$ and $X_{\mathsf{sing}} = X_{\mathsf{sing},h} = \{x \in X, \rho\gamma \le 2h\}$ provided $h \le h_0$. Here conditions (11.1.2)–(11.1.4) yield the following estimate on X_{sing}:

$$(A_h u, u) \ge \epsilon_0 \int \varrho\Big(h^{2m}\rho^{-2m} \sum_{|\alpha|=m} |D^\alpha u|^2 - C_0 \sum_{|\alpha|\le m-1} h^{2|\alpha|}\rho^{-2|\alpha|}|D^\alpha u|^2\Big)\, dx \tag{11.1.9}$$

for all compactly supported functions $u \in \mathscr{C}^{2m}(\bar{X}_{\mathsf{sing}}, \mathbb{H})$ satisfying the Dirichlet boundary condition. Therefore Rozenblioum estimate (9.A.11) yields that the contribution of the zone X_{sing} to the upper estimate of N_h^- in Theorem 9.1.7 does not exceed CR_0h^{-d} with

$$R_0 = C\Big(\int_{X_{\mathsf{sing}}} \varrho^{-p}\rho^{2mp}\, dx\Big)^{\frac{d}{2mp}} \Big(\int_{X_{\mathsf{sing}}} \varrho^{q}\, dx\Big)^{\frac{d}{2mq}} \Big(\mathsf{mes}(X_{\mathsf{sing}})\Big)^{1-\frac{d}{2m}(\frac{1}{p}+\frac{1}{q})} \tag{11.1.10}$$

where p, q are arbitrarily chosen numbers such that

$$\frac{1}{p} + \frac{1}{q} \le \frac{2m}{d}, \qquad p \ge 1, q \ge 1 \tag{11.1.11}$$

and

$$\text{either} \quad \frac{1}{p}+\frac{1}{q}<\frac{2m}{d}, \tag{11.1.12}$$

$$\text{or} \quad \frac{1}{p}+\frac{1}{q}=\frac{2m}{d}, d\geq m \text{ and } d>m \implies q>1$$

$$\text{and } p>1 \implies 2m<\frac{d}{p}(p+1).$$

Recall that X_{sing} does not contribute to the lower estimate of N_h^-.

At the same time the contribution of the zone X_{reg} to both lower and upper estimates does not exceed $Ch^{1-d}R_1 + Ch^{s-d}R_2$ where

$$R_1 = \int_{X_{\mathsf{reg},h}\setminus X_{\mathsf{reg,ell},h}} \rho^{d-1}\gamma^{-1}\,dx, \tag{11.1.13}$$

$$R_2 = \int_{X_{\mathsf{reg},h}} \rho^{d-s}\gamma^{-s}\,dx \tag{11.1.14}$$

with arbitrarily chosen s and we assume that in every ball $\mathcal{B}\big(y,\gamma(y),X\big)$ with $y\in X_{\mathsf{reg}}$ one of the conditions of Parts II and III providing remainder estimate $O(h_{\mathsf{eff}}^{1-d})$ [1)] is fulfilled; here $h_{\mathsf{eff}}=h(\rho\gamma)^{-1}$.

Further, the principal term of the upper and lower estimates is $\mathsf{N}_h^{\mathsf{W}} = h^{-d}\mathsf{N}^{\mathsf{W}}$ with the *cut Weyl expression*

$$\mathsf{N}^{\mathsf{W}} = (2\pi)^{-d}\int_{T^*X_{\mathsf{reg},h}} \boldsymbol{n}(x,\xi,-\infty,0)\,dxd\xi \tag{11.1.15}$$

where $\boldsymbol{n}(x,\xi,.,.)$ is the eigenvalue counting function for the symbol

$$a(x,\xi)=\sum_{\alpha,\beta} a_{\alpha,\beta}\xi^{\alpha+\beta}; \tag{11.1.16}$$

recall that both X_{reg} and X_{sing} and thus N^{W} depend on h.

So the following statement is proven:

Theorem 11.1.1. *Let A be a self-adjoint operator (with the Dirichlet boundary conditions) of the form* (11.1.1) *in $\mathscr{L}^2(X,\mathbb{H})$ and let conditions* (11.1.2)–(11.1.5) *be fulfilled. Moreover, let us assume that, in every ball $\mathscr{B}\big(y,\gamma(y),X\big)$*

[1)] To be discussed in Remarks 11.1.3 and 11.1.4.

with $y \in \mathcal{X}_{\mathsf{reg}}$, one of the conditions of Parts II and III providing remainder estimate $O(h_{\mathsf{eff}}^{1-d})$ [1)] is fulfilled. Then the estimates

$$h^{-d}\mathsf{N}^{\mathsf{W}} - Ch^{1-d}R_1 \le \mathsf{N}^{-}(A_h) \le h^{-d}\mathsf{N}^{\mathsf{W}} + Ch^{1-d}R_1 + Ch^{s-d}R_2 + CR_0h^{-d} \tag{11.1.17}$$

hold with N^{W}, R_1, R_2 and R'' given by (11.1.15), (11.1.13), (11.1.14) *and* (11.1.10) *respectively.*

Corollary 11.1.2. *(i) For N^{W} in formula* (11.1.15) *let us replace the domain $X_{\mathsf{reg},h}$ by the domain $\mathcal{X}_{\mathsf{reg}}$ (or X); then the error does not exceed $C\int_{X_{\mathsf{sing},h}} \rho^d\,dx \le CR_0$ due to Hölder inequality. Therefore*

$$|\mathsf{N}^{-}(A_h) - \mathsf{N}^{\mathsf{W}}h^{-d}| \le Ch^{1-d}R_1 + Ch^{s-d}R_2 + Ch^{-d}R_0 \tag{11.1.18}$$

where N^{W} is now given by (uncut) Weyl expression and no longer depends on h.

(ii) This estimate yields that if

$$\rho^{d-s}\gamma^{-s} \in \mathscr{L}^1(\{X,\ \rho\gamma \ge h_0\}), \tag{11.1.19}$$

$$\rho^{d-1}\gamma^{-1} \in \mathscr{L}^1(X \setminus X_{\mathsf{reg},\mathsf{ell},h_0}) \tag{11.1.20}$$

and

$$R_0 = O(h) \qquad \text{as } h \to +0, \tag{11.1.21}$$

then

$$\mathsf{N}^{-}(A_h) = h^{-d}\mathsf{N}^{\mathsf{W}} + O(h^{1-d}). \tag{11.1.22}$$

These asymptotics will be improved and generalized below, where other asymptotics due to the results of Chapter 9 will be derived.

(iii) Let us assume that

$$\varrho \asymp \rho^k \quad \text{in } \mathcal{X}_{\mathsf{reg}} \tag{11.1.23}$$

and that one of the following conditions are fulfilled:

$$(11.1.24)_1 \qquad d > 2m, \qquad k \in [0, 2m];$$

$$(11.1.24)_2 \qquad m < d \le 2m, \qquad k \in [2m-d, d);$$

$$(11.1.24)_3 \qquad d = m, \qquad k = d.$$

Then one can choose p, q *satisfying condition* (11.1.11) *with equality and condition* (11.1.12) *and such that*

$$R_0 \asymp \int_{X_{\mathsf{sing},h}} \rho^d \, dx \le 2h \int_{X_{\mathsf{sing},h}} \rho^{d-1}\gamma^{-1} \, dx.$$

This inequality and (11.1.20) *yield that* $R_0 = o(h)$ *and therefore condition* (11.1.21) *is fulfilled. In particular, for* $d > 2m$ *one can take* $k = 2m$.

Remark 11.1.3. Let us list some cases when according to Parts II and III contribution of $\mathcal{B}(y, \gamma(y), X)$ to the remainder is $O(h^{1-d}\rho^{d-1}\gamma^{d-1})$; these conditions are uniform with respect to y (after rescaling):

(11.1.25) Assumptions (11.1.3), (11.1.4) and (9.1.15) are fulfilled with $K = K(d)$ and operator A is microhyperbolic on the energy level 0;

(11.1.26) A is Schrödinger operator, $d \ge 2$, assumptions (11.1.7), (11.1.8) and (9.1.15) are fulfilled with $K = K(d)$;

(11.1.27) A is "rough" operator described in Section 4.6 as $B(y, \gamma(y)) \subset X_{\mathsf{reg}}$ and in Section 7.5 otherwise.

Through bracketing $A^- \le A \le A^+$ between two rough operators such that contributions to N^{W} of $\mathcal{B}(y, \gamma(y), X)$ for A^- and A^+ differ by $O(h_{\mathsf{eff}}^{1-d})$ we cover also

(11.1.28) Assumptions (11.1.3), (11.1.4) are fulfilled with $K = 1$, $\nabla a_{\alpha,\beta}$ are continuous with continuity modulus $C\varrho\rho^{-|\alpha|-|\beta|}\gamma^{-1}|\log(|x-y|\gamma^{-1})|^{-1}$ and either $B(y, \gamma(y)) \subset X_{\mathsf{reg}}$ or extra conditions of Theorem 7.5.15 to the boundary are fulfilled, operator A is ξ-microhyperbolic on the energy level 0;

(11.1.29) A is Schrödinger operator, assumptions (11.1.7), (11.1.8) are fulfilled with $K = 1$, ∇g^{kl}, ∇V_k and ∇V are continuous with continuity moduli $C\rho^p\gamma^{-1}|\log(|x-y|\gamma^{-1})|^{-1}$, $p = 0, 1, 2$ respectively and either $B(y, \gamma(y)) \subset X_{\mathsf{reg}}$ or extra conditions of Theorem 7.5.15 to the boundary are fulfilled, $d \ge 3$ or $|V| + \gamma|\nabla V| \ge \epsilon\rho^2$;

(11.1.30) A is Schrödinger operator, $d = 2$, assumptions (11.1.7), (11.1.8) are fulfilled with $K = 2$, $\nabla^2 g^{kl}$, $\nabla^2 V_k$ and $\nabla^2 V$ are continuous with continuity moduli $C\rho^p\gamma^{-2}|\log(|x-y|\gamma^{-1})|^{-2}$, $p = 0, 1, 2$ respectively and either $B(y, \gamma(y)) \subset X_{\mathsf{reg}}$ or extra conditions of Theorem 7.5.15 to the boundary are fulfilled.

Remark 11.1.4. Actually we can weaken assumptions (11.1.28)–(11.1.30) because we can bracket symbol $a(x, \xi)$ between $a(x, \xi) \pm b_\varepsilon(x)$ where

$$b_\varepsilon(x) = C_0 \max_{\alpha,\beta} \operatorname{osc}(\nabla a_{\alpha,\beta}, x, \varepsilon) * \phi_\varepsilon \tag{11.1.31}$$

where

$$\operatorname{osc}(a, x, \varepsilon) = \max_{y:|x-y|\le\varepsilon} a - \min_{y:|x-y|\le\varepsilon} a \tag{11.1.32}$$

ϕ_ε is a standard mollification function. An easy proof is left to the reader.

Then for ξ-microhyperbolic operator contributions of $\mathcal{B}(y, \gamma(y), X)$ to N^{W} for A^- and A^+ differ by no more than

$$Ch_{\mathsf{eff}}^{-d} \max_{\alpha,\beta} \int \operatorname{osc}(\nabla a_{\alpha,\beta}, x, \varepsilon)\, dx \tag{11.1.33}$$

with an integral taken over $\mathcal{B}(y, \gamma(y), X)$ rescaled and in the end of the day results in an additional error

$$R_3 = Ch_{\mathsf{eff}}^{1-d} \max_{\alpha,\beta} \int_{X_{\mathsf{reg}} \setminus X_{\mathsf{reg,ell}}} \rho^d \operatorname{osc}\bigl(\nabla a_{\alpha,\beta}, x, \rho^{-1}\log(\rho\gamma)\bigr)\, dx. \tag{11.1.34}$$

So, to estimate (11.1.33) by $O(h_{\mathsf{eff}}^{1-d})$ we actually need to impose estimate $O(|\log\varepsilon|^{-1})$ to $\mathscr{L}^1$-norm rather than $\mathscr{L}^\infty$-norm of $\operatorname{osc}(\nabla a_{\alpha,\beta}, x, \varepsilon)$.

We leave to the reader the following easy problem:

Problem 11.1.5. Apply rescaling to modified expressions (11.1.33) and (11.1.34) for Schrödinger operator ($d \ge 3$) without condition $|V| \ge \epsilon\rho^2$.

Remark 11.1.6. Some of the conditions of Theorem 11.1.1 and Corollary 11.1.2 are too restrictive but we can weaken them.

(i) First of all, one can assume that $X = \mathcal{X}_{\mathsf{reg}} \cup \mathcal{X}_{\mathsf{sing}} \cup \mathcal{Y}$ where the domains $(\mathcal{X}_{\mathsf{reg}} \cup \mathcal{X}_{\mathsf{sing}})$ and $\mathcal{Y}$ are properly overlapping (with respect to the scaling

function γ), and that in $(\mathcal{X}_{\mathsf{reg}} \cup \mathcal{X}_{\mathsf{sing}})$ all the previous conditions are fulfilled and we assume that in $\mathcal{Y}$ the inequality

$$\sum_{\alpha,\beta} \langle a_{\alpha,\beta} v_\alpha, v_\beta \rangle \ge \epsilon_0 \sum_{|\alpha|=m} \varrho_1 \|v_\alpha\|^2 - C \sum_{|\alpha|\le m-1} \varrho_1 \rho_1^{2|\alpha|} \|v_\alpha\|^2 \tag{11.1.35}$$

holds with appropriate measurable functions ϱ_1 and ρ_1. Then one can take $X_{\mathsf{reg}} = \{x \in \mathcal{X}_{\mathsf{reg}}, \rho\gamma \ge h\}$ and $X_{\mathsf{sing}} = \{x \in \mathcal{X}_{\mathsf{reg}}, \rho\gamma \le 2h\} \cup X_{\mathsf{sing}} \cup \mathcal{Y}$ in which case R_0 is given by the formula

$$\begin{aligned} R_0 = C\Big(\int_{\mathcal{X}_{\mathsf{reg}} \cap \{\rho\gamma \le 2h\}} \rho^{-p} \rho^{2mp}\, dx + \int_{\mathcal{Y}} \varrho_1^{-p} dx\Big)^{\frac{d}{2mp}} \times \\ \Big(\int_{\mathcal{X}_{\mathsf{reg}} \cap \{\rho\gamma \le 2h\}} \varrho^q\, dx + \int_{\mathcal{Y}} \varrho_1^q \rho_1^{2mq}\, dx\Big)^{\frac{d}{2mq}} \times \\ \big(\mathsf{mes}(\mathcal{X}_{\mathsf{reg}} \cap \{\rho\gamma \le 2h\} \cup \mathcal{Y})\big)^{1-\frac{d}{2m}(\frac{1}{p}+\frac{1}{q})}. \end{aligned} \tag{11.1.36}$$

(ii) Further, one can assume that the Dirichlet boundary condition is given only on $\partial X \cap (\bar{\mathcal{X}}_{\mathsf{reg}} \cap \{\rho\gamma \le h_0\} \cup \bar{\mathcal{Y}})$; on other part of ∂X it could be different (but still appropriate boundary condition).

Furthermore, assume that even in $\partial X_{\mathsf{sing},h}$ Dirichlet boundary condition is assumed only on Y_{D} while on $Y_{\mathsf{N}} = \partial X_{\mathsf{sing},h} \setminus Y_{\mathsf{D}}$ another boundary condition is given, not necessary Neumann one but satisfying

$$\begin{aligned} (Au,u)_{X_{\mathsf{sing},h}} \ge \\ \epsilon \sum_{\alpha:|\alpha|=m} h^{2m} \|D^\alpha u\|^2 - C \sum_{\alpha:|\alpha|\le m-1} h^{2|\alpha|} \|\rho_1^{m-|\alpha|} D^\alpha u\|^2 \\ \forall u \in \mathfrak{D}(A):\ u = 0 \qquad \text{on}\ \ X \setminus X_{\mathsf{sing},h} \end{aligned} \tag{11.1.37}$$

Finally, let us assume that conditions (9.A.23)–(9.A.26) are fulfilled for X replaced by $X_{\mathsf{sing},h}$; recall that the inner boundary $\partial X_{\mathsf{sing},h} \cap \overset{\circ}{X}$ is considered as part of Y_{D}.

Then the previous estimate remain true with $\varrho_1 = 1$ and with ρ_1 replaced by

$$\rho_2 = \rho_1 + \sum_j h_j^{-1} \chi_j \tag{11.1.38}$$

in the estimates from above where χ_j is a characteristic function of X_j. In some examples specific arguments will improve even this estimate.

(iii) All these results remain true if we replace hD_j by $hD_j - V_j$ in the operator A where V_j are real-valued functions supported in $X_{\mathrm{reg},h}$ such that

$$|D^\alpha (D_j V_k - D_k V_j)| \le c\rho\gamma^{-|\alpha|-1} \qquad \forall \alpha : |\alpha| \le K. \tag{11.1.39}$$

In fact, after an appropriate gradient transform in every ball $\mathcal{B}(x, \epsilon\gamma(x), X)$ lying in $X_{\mathrm{reg},h}$ condition

$$|D^\alpha V_j| \le c\rho\gamma^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le K \tag{11.1.40}$$

is fulfilled.

(iv) If the operator $(A - \tau)$ satisfies all the conditions of Theorem 11.1.1 uniformly with respect to $\tau \in [\tau_1, 0]$ with $\tau_1 < 0$ then all the estimates and asymptotics of Theorem 11.1.1 and Corollary 11.1.2 remain true for this operator uniformly with respect to $\tau \in [\tau_1, 0]$. In particular, for the Schrödinger operator with $d \ge 2$ the condition of this statement is fulfilled automatically for $\tau_1 = -\infty$.

Remark 11.1.7. Let us consider the Riesz means

$$\mathsf{N}^-_{(\vartheta)}(A) = \int \tau_-^{\vartheta-1} \mathsf{N}^-(A - \tau)\, d\tau \tag{11.1.41}$$

of order $\vartheta > 0$ (i.e., we calculate them for the spectral parameter $\tau = 0$). Let us include in $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}$ (depending on h for $A = A_h$) a sufficient number of terms. So, in principle $\mathsf{N}^{\mathsf{W}}_{(0)}$ does not necessarily coincide with N^{W} (in more sharp asymptotics it may contain one extra term).

(i) Then the remainder estimates in the local semiclassical spectral asymptotics zone $X_{\mathrm{reg},h}$ yield that terms $h^{1-d}R_1$ and $h^s R_2$ should be replaced by $h^{1+\vartheta-d}R_{1(\vartheta)}$ and $h^s R_{2(\vartheta)}$ with

$$R_{1(\vartheta)} = \int_{X_{\mathrm{reg},h} \setminus X_{\mathrm{reg,ell},h}} \varrho^\vartheta \rho^{d-\vartheta-1} \gamma^{-\vartheta-1}\, dx, \tag{11.1.42}$$

$$R_{2(\vartheta)} = \int_{X_{\mathrm{reg}}} \varrho^\vartheta \rho^{d-s} \gamma^{-s}\, dx. \tag{11.1.43}$$

To do this we need $O(h^{1+\vartheta-d}_{\mathsf{eff}})$ remainder estimate which requires a stronger regularity: $K = 1 + \lfloor \vartheta \rfloor$ and the K-th derivatives should be continuous with the continuity modulus $O(|x-y|^{\vartheta - \lfloor\vartheta\rfloor} |\log |x-y||^{-1})$ and the boundary should be a bit smoother.

(ii) Further, in virtue of SubSection 9.2.4 and Appendix 9.A.2 term $h^{-d}R_0$ with R_0 defined by (11.1.10) should be replaced by $h^{-d}R_{0(\vartheta)}$ with $R_{0(\vartheta)}$ defined by the same formula but with the second factor in the right-hand expression should be given in the form

$$\int_0^\infty \tau^{\vartheta-1}\Big(\int_{X_{\mathsf{sing},h}} (\varrho_1-\tau)_+^q \, dx\Big)^{\frac{d}{2mq}} \, d\tau. \tag{11.1.44}$$

In particular, if one can take $q=\frac{d}{2m}$ and $p=\infty$ then

$$R_{0(\vartheta)} = C\int_{X_{\mathsf{sing},h}} \varrho^{\frac{d}{2m}+\vartheta}\, dx \times \sup_{X_{\mathsf{sing},h}} \big(\varrho^{-\frac{d}{2m}}\rho^d\big). \tag{11.1.45}$$

Furthermore, in virtue of Appendix 9.A.2 we can use this formula even if $d=2m$ but $\vartheta>0$ which is the case for the Schrödinger operator with $d=2$.

(iii) In particular, replacing conditions (11.1.19)–(11.1.21) by conditions

$$\varrho_1^\vartheta \rho^{d-s}\gamma^{-s} \in \mathscr{L}^1(\{x,\ \rho\gamma\ge h_0\}), \tag{11.1.46}$$

$$\varrho_1^\vartheta \rho^{d-1-\vartheta}\gamma^{-1-\vartheta} \in \mathscr{L}^1(X\setminus X_{\mathsf{reg},\mathsf{ell},h_0}) \tag{11.1.47}$$

and

$$R_{0(\vartheta)} = O(h^{1+\vartheta}) \qquad \text{as}\quad h\to +0, \tag{11.1.48}$$

we obtain t asymptotics

$$\mathsf{N}^-_{(\vartheta)}(A_h) = h^{-d}\mathsf{N}^{\mathsf{W}}_{(\vartheta)} + O(h^{1+\vartheta-d}). \tag{11.1.49}$$

In particular, in the framework of (11.1.23)–(11.1.24) (upgraded to $d\ge 2m, k\in[0,2m]$ as $\vartheta>0$) conditions (11.1.48) and (11.1.50) below follow from (11.1.47).

Non-Standard Remainder Estimates

So far we assumed that the remainder estimate in the local spectral asymptotics is $O(h_{\mathsf{eff}}^{1-d+\vartheta})$ as $\vartheta\ge 0$; $\vartheta=0$ refers to the most interesting case of the asymptotics without averaging.

Sharp and Sharper Asymptotics However the remainder estimate in the local spectral asymptotics could be better than this: it could be $o(h_{\mathsf{eff}}^{1+\vartheta-d})$ or even $O(h_{\mathsf{eff}}^{\kappa+\vartheta-d})$ with $\kappa > 1$. In the former case conditions (11.1.46)–(11.1.47) imply that the contribution of $X_{\mathsf{reg},h}$ to the remainder is $o(h^{1-d})$. Adding assumption

$$R_{0(\vartheta)} = o(h^{1+\vartheta}) \qquad \text{as} \quad h \to +0, \tag{11.1.50}$$

we arrive to asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(A) = h^{-d}\mathsf{N}^{\mathsf{W}}_{(\vartheta)} + o(h^{1+\vartheta-d}). \tag{11.1.51}$$

In the latter case conditions (11.1.47)–(11.1.48) should be upgraded to

$$\varrho_1^{\vartheta}\rho^{d-\kappa-\vartheta}\gamma^{-\kappa-\vartheta} \in \mathscr{L}^1(X \setminus X_{\mathsf{reg},\mathsf{ell},h_0}) \tag{11.1.52}$$

and

$$R_{0(\vartheta)} = O(h^{\kappa+\vartheta}) \qquad \text{as} \quad h \to +0 \tag{11.1.53}$$

respectively. Note that in the framework of (11.1.23)–(11.1.24) (upgraded to $d \ge 2m, k \in [0, 2m]$ as $\vartheta > 0$) condition (11.1.53) follows from (11.1.52).

Then we arrive to

$$\mathsf{N}^{-}_{(\vartheta)}(A) = h^{-d}\mathsf{N}^{\mathsf{W}}_{(\vartheta)} + O(h^{\kappa+\vartheta-d}). \tag{11.1.54}$$

Remark 11.1.8. (i) Let us recall that sharp local asymptotics are due to corresponding non-periodicity condition:

$$\mu_0\big((\Pi_+ \cup \Lambda_+) \cap (\Pi_- \cup \Lambda_-)\big) = 0 \tag{11.1.55}$$

where μ_0 is a measure introduced on Σ_0 and

$$\Pi_{\pm} = \{z : \exists t : \pm t > 0 : \Psi_t(z) \ni z\} \tag{11.1.56}$$

is the set of points "periodic" with respect to Hamiltonian flow Ψ_t with reflections, possibly branching and $\Lambda_{\pm}$ is the set of dead-end trajectories.

(ii) Recall, that we need also a bit more smoothness: for example, as $\vartheta = 0$ the first derivatives of the coefficients should be continuous with the continuity modulus $o(|\log|x-y||^{-1})$ rather than $O(|\log|x-y||^{-1})$ (after rescaling) and condition to the smoothness of the boundary should be also a bit stronger.

As $\vartheta > 0$ smoothness conditions grow stronger: $K = 1 + \lfloor \vartheta \rfloor$ and the K-th derivatives should be continuous with the continuity modulus $o(|x-y|^{\vartheta - \lfloor \vartheta \rfloor} |\log |x-y||^{-1})$.

We refer to these assumptions as *improved regularity conditions*.

(iii) Also a bit less degeneration is allowed: as we consider Schrödinger operator with $d = 2$ and $\vartheta = 0$ we need to assume that

$$\mathsf{mes}(\{x, V(x) = 0, F = |D_1 V_2 - D_2 V_1| \neq 0\}) = 0. \tag{11.1.57}$$

We refer to these assumptions as *improved non-degeneracy condition*

Remark 11.1.9. Recall that for sharper remainder estimates these improved conditions are required in the stronger form but since non-periodicity condition is so difficult to check we will consider only some special cases.

Less Sharp Asymptotics However, either due to irregularity (as in Theorem 4.6.21 and similar) or to degeneration or both the local asymptotics may have remainder estimate not as good as $O(h_{\mathsf{eff}}^{1-d+\vartheta})$; for example it could be $O(h_{\mathsf{eff}}^{\kappa-d+\vartheta})$ with $\kappa < 1$. Then again under assumptions (11.1.46), (11.1.52), (11.1.53) we arrive to asymptotics (11.1.54), this time with $\kappa < 1$.

While estimates from above relied upon taking $T \asymp 1$ in $X_{\mathsf{reg}} \cap X_{\mathsf{sing}}$ which is not necessary the case now, it does not matter as $\rho\gamma \asymp h$ in $X_{\mathsf{reg}} \cap X_{\mathsf{sing}}$.

11.1.2 Examples

Let us consider a series of examples.

Example 11.1.10. Let $d \geq 2$ and let X be a compact domain (or manifold) with the boundary. Let assumptions of Theorem 11.1.1 be fulfilled with $\rho \asymp 1$ and $\gamma \asymp 1$. Then asymptotics (11.1.22) holds.

Further, under appropriate smoothness condition (see Remark 11.1.8(i)) asymptotics (11.1.49) holds.

Furthermore, under non-periodicity condition (11.1.55)–(11.1.56), improved smoothness and non-degeneracy conditions of Remark 11.1.8 asymptotics (11.1.54) holds. Here $\Lambda_{\pm} = \emptyset$.

Finally, under corresponding stronger non-periodicity conditions sharper asymptotics hold.

The conditions of our theorems are local and all our analysis is local (until the end of the subsection). So we assume that outside of the singularities indicated below everything is well (in the sense of Example 11.1.10).

Example 11.1.11 (Conical vertex). Let $d \ge 2$ and in a neighborhood of 0 let the domain X coincide with the cone $X^0 = \{(r,\theta) \in \mathbb{R}^+ \times U\}$ where (r,θ) are spherical coordinates, U is a domain on the sphere $\mathbb{S}^{d-1}$ with the boundary ∂U.

Moreover, let the conditions of Theorem 11.1.1 be fulfilled with $\varrho = \rho^{2m}$, $\rho = r^{\mu}$, $\gamma = \epsilon r$ where here and below $\epsilon > 0$ is a small constant.

(i) Then ρ^d and (or) $\rho^{d-1}\gamma^{-1}$ belong to $\mathscr{L}^1(X)$ if and only if $\mu > -1$. Let us assume that

$$\mu > \max(-1, -\frac{d}{2m}). \tag{11.1.58}$$

Then asymptotics (11.1.22) holds.

(ii) Further, under non-periodicity condition and improved regularity and non-degeneracy condition asymptotics (11.1.54) holds. Here $\Lambda_{\pm}$ are sets of points such that $\Psi_t(z)$ "falls" to 0 in the finite time. For example, if problem is spherically symmetric then $\Lambda_{\pm}$ consists of points with $\xi \parallel x$ (i.e. with angular momentum equal 0).

(iii) On the other hand, $\varrho^{\vartheta}\rho^{d-1-\vartheta}\gamma^{-1-\vartheta} \in \mathscr{L}^1(X)$ if and only if

$$(\mu + 1 - 2\mu m)\vartheta < (d-1)(\mu+1) \tag{11.1.59}$$

and if this condition is fulfilled and if also $\mu > -\frac{d}{2m}$ then asymptotics (11.1.49) holds for given ϑ.

Moreover, under non-periodicity condition (11.1.55)–(11.1.56), improved smoothness and non-degeneracy conditions of Remark 11.1.8 asymptotics (11.1.54) holds.

(iv) Furthermore, in the case

$$(\mu + 1 - 2\mu m)\vartheta = (d-1)(\mu+1) \tag{11.1.60}$$

we obtain asymptotics

$$\mathsf{N}^-_{(\vartheta)}(A) = h^{-d}\mathsf{N}^{\mathsf{W}}_{(\vartheta)} + O(h^{1-d+\vartheta}\log h); \tag{11.1.61}$$

here we use Theorem 11.1.1 instead of Corollary 11.1.2 [2)].

(v) Finally, in the case

$$(\mu+1-2\mu m)\vartheta > (d-1)(\mu+1), \quad 2\mu m\vartheta + d(\mu+1) > 0 \tag{11.1.62}$$

we obtain asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(A) = h^{-d}\mathsf{N}^{\mathsf{W}}_{(\vartheta)} + O(h^{p}) \tag{11.1.63}$$

with

$$p = \frac{2\mu}{\mu+1} m\vartheta \in (-d,\ 1+\vartheta-d) \tag{11.1.64}$$

where only terms with the degree of h less than $p+d$ are included in $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}$.

Remark 11.1.12. (i) We assumed that $\mu > -d/2m$ only to guarantee that

$$a_{\alpha\beta} \in \mathscr{L}^{1}(X \cap \{|x| \le \epsilon\}) \tag{11.1.65}$$

and one can replace it by the latter, while also taking care that Rozenblioum estimate works; we leave details to the reader.

(ii) On the other hand, as $\mu \le -1$ it may happen that the corresponding quadratic form is not semi-bounded from below and thus operator A is not defined; even if we define it, its essential spectrum may occupy the whole $\mathbb{R}$.

Remark 11.1.13. (i) One can easily see that in the domain $X_{\mathsf{sing},h} = \{x \in X, r \le \epsilon h^{\frac{1}{\mu+1}}\}$ inequality

$$(A_h u, u) \ge \epsilon_0 \sum_{|\alpha|=m} h^{2m}\|D^{\alpha}u\|^2 \tag{11.1.66}$$

$$\forall u \in \mathscr{C}^{m}(\bar{X}) : \operatorname{supp} u \subset B(0, \epsilon h^{\frac{1}{\mu+1}})$$

[2)] Here and below $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}$ is given by the Weyl formula but in general we only integrate over the domain $X_{\mathsf{reg},h} = \{x \in X, |x| \ge \epsilon h^{1/(\mu+1)}\}$ so we have cut Weyl expression. Moreover, one can skip all the terms with $n-d > p$ in the local semiclassical spectral asymptotics and in the terms with $n-d < p$ integrate over X; $p = 1-d+\vartheta$ under condition (11.1.60).

holds. This inequality follows from the inequalities

$$h^k \sum_{|\alpha|=k} \|D^\alpha u\| \ge \epsilon_0 \varepsilon^{-\delta} \|r^{\mu k} u\| \qquad \forall k = 1, \dots, m \tag{11.1.67}$$

for the same u as in (11.1.66). Here $\delta > 0$ is a small enough exponent and ϵ_0 does not depend on ε.

In fact, for $h = \epsilon = 1$ estimate (11.1.67) follows easily from condition (11.1.58), and the estimate in the general case follows from the estimate in this special case by means of rescaling.

Therefore one can take $\rho = 0$, $\varrho = r^{2\mu m}$ in $X_{\mathsf{sing},h}$ and this simplifies the estimate of R_0. Further, we obtain that for

$$m\vartheta + d(\mu + 1) = 0 \tag{11.1.68}$$

asymptotics (11.1.63) holds with $p = -d$ and with $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}$ given only by the integration of the $n = 0$ term over the domain $X_{\mathsf{reg},h}$. Here $\mathsf{N}^{\mathsf{W}}_{(\vartheta)} = O(\log h)$; moreover, if

$$\inf_{v:\|v\|=1,\xi\in\mathbb{R}^d} \langle a(x,\xi)v, v\rangle \le -\epsilon_0 \rho^{2m} \qquad \forall x \in \Gamma \cap \{|x| \le \epsilon\} \tag{11.1.69}$$

for some non-empty cone $\Gamma \subset \mathbb{R}^+ \times U$ with vertex in 0 then $\mathsf{N}^{\mathsf{W}}_{(\vartheta)} \asymp \log h$.

(ii) Further, let us note that under condition (11.1.60) the main contribution to the remainder estimate in (11.1.63) is delivered by the zone

$$X_{h,\varepsilon} \coloneqq \{X, ch^{\frac{1}{\mu+1}} \le |x| \le \varepsilon_h\} \tag{11.1.70}$$

with $\varepsilon_h = o(1)$ for $h \to +0$ (the contribution of the other zones is "o" with respect to the contribution of this zone). In order to improve the remainder estimate let us assume that the operator A stabilizes at 0 to the quasihomogeneous operator A^0, i.e., that

$$D^\alpha(a_\beta - a^0_\beta) = o(|x|^{\mu|\beta|-|\alpha|}) \qquad \forall \beta : |\beta| \le 2m \quad \forall \alpha : |\alpha| \le K \tag{11.1.71}$$

for $|x| \to 0$ where a^0_β are positively homogeneous of degrees $\mu|\beta|$. Further, let us assume that the symbol

$$a^0(x,\xi) = \sum_\beta a^0_\beta(x)\xi^\beta \tag{11.1.72}$$

satisfies non-periodicity condition (11.1.55)–(11.1.56) to Hamiltonian flow. Here and below Σ^0_τ, μ^0_τ, $\Pi^0_\pm$, $\Lambda^0_\pm$ are constructed for a^0.

Then asymptotics

$$\mathsf{N}^-_{(\vartheta)}(A) = h^{-d}\mathsf{N}^{\mathsf{W}}_{(\vartheta)} + o(h^{1-d+\vartheta}\log h) \tag{11.1.73}$$

holds. Here in the term with $n = -d+1+\vartheta$ we integrate over the domain $X_{\mathsf{reg},h}$ and this term is $O(h^{1+\vartheta}\log h)$; in all the other terms we can integrate over X.

Example 11.1.14. We can treat the case when the singularity is more complicated. Namely, for the Schrödinger operator we can consider positively homogeneous g^{jk}, V_j, V and also ∂U which are not necessarily as regular as required by Theorem 11.1.1 on $\mathbb{S}^{d-1}$.

Let us assume that on $\mathbb{S}^{d-1}$ all the conditions are fulfilled with $\hat\rho$ and $\hat\gamma$ instead of ρ and γ. Then we can take $\rho = \hat\rho(\theta)r^\mu$ and $\gamma = \epsilon\hat\gamma(\theta)r$ with a small enough constant $\epsilon > 0$.

Let us note that $\rho^{2\vartheta+d} \in \mathscr{L}^1$ if and only if $\hat\rho^{2\vartheta+d} \in \mathscr{L}^1(U)$ and $(2\vartheta+d)\mu + d > 0$; moreover, let us note that $\rho^{\vartheta+d-1}\gamma^{-\vartheta-1} \in \mathscr{L}^1$ if and only if $\hat\rho^{\vartheta d-1}\hat\gamma^{-\vartheta-1} \in \mathscr{L}^1(U)$ and $(\mu-1)\vartheta + (\mu+1)(d-1) > 0$.

Therefore a more complicated structure is possible: one can treat a hierarchy of singularities: "vertices of singularities," "edges of singularities," "faces of singularities," etc.

We leave to the reader

Problem 11.1.15. Analyze the case in which

$$\gamma = \epsilon\min(|x_{(1)}|, \dots, |x_{(l)}|), \quad \rho = \prod_{S\subset\{1,\dots,l\}} \zeta_S^{\mu_S}, \quad \zeta_S = \sum_{j\in S}|x_{(j)}| \tag{11.1.74}$$

where $x = (x_{(1)}, \dots, x_{(l)}) \in \mathbb{R}^{d_1}\times\dots\times\mathbb{R}^{d_l}$ is an appropriate partition.

Example 11.1.16 (Conical edge). Let us consider a more general case. Let X be a bounded domain locally coinciding with $\mathbb{R}^{d'}\times\mathbb{R}^+\times U$ where spherical coordinates (r,θ) are introduced in $\mathbb{R}^{d''}$ ($d'' = d-d'$), and where $U \subset \mathbb{S}^{d''-1}$, $0 \le d' \le d-1$. Let conditions of Theorem 11.1.1 be fulfilled with $\varrho = \rho^{2m}$, $\rho = r^\mu$, $\gamma = \epsilon r$ and let

$$\mu > \max(-1, -\frac{d''}{2m}). \tag{11.1.75}$$

Then

(i) For

$$(\mu+1-2\mu m)\vartheta < (\mu+1)(d-1)-d' \tag{11.1.76}$$

asymptotics (11.1.49) holds. Further, under non-periodicity condition and improved regularity and non-degeneracy condition asymptotics (11.1.54) holds. Here $\Lambda_\pm$ are sets of points such that $\Psi_t(z)$ "falls" to $\mathbb{R}^{d'}\times 0$ in the finite time.

(ii) On the other hand, for

$$(\mu+1-2\mu m)\vartheta = (\mu+1)(d-1)-d' \tag{11.1.77}$$

asymptotics (11.1.61) holds and for

$$(\mu+1-2\mu m)\vartheta > (\mu+1)(d-1)-d',\quad 2\mu m\vartheta + d\mu + d'' \ge 0 \tag{11.1.78}$$

asymptotics (11.1.63) holds with

$$p=\frac{2\mu}{\mu+1}(m\vartheta - d') \tag{11.1.79}$$

where for

$$2\mu m\vartheta + d\mu + d'' = 0 \tag{11.1.80}$$

only one term in $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}$ remains and integration is taken over $X_{\mathsf{reg},h}$. In this case $\mathsf{N}^{\mathsf{W}}_{(\vartheta)} = O(\log h)$ and $\mathsf{N}^{\mathsf{W}}_{(\vartheta)} \asymp \log h$ under condition (11.1.69) fulfilled in $V\times\Gamma\cap\{x, |x''|\le\epsilon\}$ where V is a neighborhood of 0 in $\mathbb{R}^{d'}$ and Γ is a non-empty cone in $\mathbb{R}^+\times U$ with vertex at 0.

Let us note that in this example (in contrast to Example 11.1.11) the variants are possible even for $\vartheta = 0$.

(iii) Let $\vartheta = 0$. Then asymptotics (11.1.22) and (11.1.61) are replaced by asymptotics (11.1.63) with $p = -d+1-\delta$ with arbitrarily small exponent $\delta > 0$ while asymptotics (11.1.63) with $p < -d+1$ remains true.

Consider conical singularity with the critical exponents:

Example 11.1.17. Let $0 \in \bar{X}$ and all the conditions be fulfilled with $\gamma = \epsilon r$, $\rho = r^{\mu} |\log r|^{-\nu}$, $r = |x|$ where we assume that

$$\mu > -\frac{2m}{d},\ \mu \ge -1,\ \vartheta \ge 0,\ \nu > 0, \qquad 2m\mu\vartheta + (d - \vartheta - 1)(\mu + 1) = 0. \tag{11.1.81}$$

Then repeating the arguments of the previous examples with

$$X_{\mathsf{sing},h} = \{x \in X, |x| \le \epsilon h^{\frac{1}{\mu+1}} |\log h|^{\frac{\nu}{\mu+1}}\} \qquad \text{for } \mu > -1 \tag{11.1.82}$$

and

$$X_{\mathsf{sing},h} = \{x \in X, \log|x| \le -Ch^{-\frac{1}{\nu}}\} \qquad \text{for } \mu = -1 \tag{11.1.83}$$

and with corresponding $X_{\mathsf{reg},h}$ we conclude that

(i) Under condition

$$(2m\vartheta + d - \vartheta - 1)\nu > 1 \tag{11.1.84}$$

asymptotics (11.1.49) holds; moreover, under standard non-periodicity condition and improved regularity and non-degeneracy conditions asymptotics (11.1.51) holds.

(ii) On the other hand, under condition

$$(2m\vartheta + d - \vartheta - 1)\nu = 1 \tag{11.1.85}$$

asymptotics (11.1.61) holds.

(iii) Finally, if

$$(2m\vartheta + d - \vartheta - 1)\nu < 1 \tag{11.1.86}$$

and if either

$$\mu > -1 \tag{11.1.87}_1$$

or

$$\mu = -1 (\implies \vartheta = 0),\ \nu \ge \frac{1}{d} \tag{11.1.87}_2$$

then asymptotics (11.1.63) holds with

$$p = 2m\vartheta - \vartheta - \frac{1}{\nu}. \tag{11.1.88}$$

For $\mu = -1$, $\vartheta = 0$, $\nu = \frac{1}{d}$ we see that $\mathsf{N}^{\mathsf{W}} = O(\log h)$ and $\mathsf{N}^{\mathsf{W}} \asymp \log h$ provided condition (11.1.69) is fulfilled in some non-empty cone with vertex at 0 (for $|x| \le \epsilon$).

(iv) Moreover, in the first critical case (11.1.85) one can improve asymptotics (11.1.61). We do not do a careful analysis of the Hamiltonian trajectories here but refer to the arguments of the proofs of Example 11.5.21 (see below). Let us assume that the coefficients a_β of A stabilize to functions $a^0_\beta \big|\log|x|\big|^{-\nu|\beta|}$ in the sense that

$$D^\sigma\big(a_\beta \big|\log|x|\big|^{\nu|\beta|} - a^0_\beta\big) = o\big(|x|^{\mu|\beta|-|\sigma|}\big) \qquad \forall \beta : |\beta| \le 2m\ \forall \sigma : |\sigma| \le 1 \tag{11.1.89}$$

where a^0_β are positively homogeneous of degree $\mu|\beta|$. Moreover, let us assume that the quasihomogeneous symbol (11.1.72) satisfies the standard non-periodicity condition.

Then one can easily prove that asymptotics (11.1.73) holds with all the explanations made in Remark 11.1.13.

(v) For $\nu > 0$ satisfying the critical condition (11.1.85) one can treat the case in which $\rho = r^\mu |\log r|^{-\nu} \big|\log|\log r|\big|^{-\nu'}$ and analyze all the possible cases. In this case the conditions on ν are replaced by similar conditions on ν'. One can continue this process of complication.

(vi) On the other hand, one can treat the case in which $\rho = r^\mu |\log r|^{-\nu}$ even if equality in (11.1.81) is violated, i.e., μ is not the critical value. In this case for $2m\mu\vartheta + (d - \vartheta - 1)(\mu + 1) > 0$ asymptotics (11.1.49) (and even (11.1.51) under the standard non-periodicity condition to the Hamiltonian flow) holds and for $2m\mu\vartheta + (d - \vartheta - 1)(\mu + 1) < 0$ asymptotics (11.1.63) holds with the remainder estimate $O(h^p |\log h|^q)$ instead of $O(h^p)$. The calculation of q is left to the reader.

(vii) In all the above statements the condition $\nu > 0$ is not necessary if $\mu > -1$.

(viii) Statement (ii) of Example 11.1.16 remains true (with obvious modifications).

Different combinations of Statements (v) and (vi) are possible.

Example 11.1.18 (Quasiconical singularity). Let $0 \in \bar{X}$ and let us consider operator with coefficients $a_{\alpha\beta}$ which are L-*quasihomogeneous of degrees* $(2m - |\alpha| - |\beta|)\mu$ respectively, smooth away from 0. In a neighborhood of zero let X be an L-*quasiconical* domain and let ∂X be smooth away from 0. Here $L = (L_1, \dots, L_d)$ is an exponent vector with $L_j > 0$ $\forall j$ and $\max_j L_j = 1$.

Let us assume that either a Dirichlet or some other appropriate boundary condition is given and in the second case let us assume that the domain X satisfies the standard cone condition.

In this case $\gamma(x) = \epsilon[x]_L$, $\rho(x) = \gamma^{\mu}$, $\varrho(x) = \gamma^{2m\mu}$ with L-*quasihomogeneous norm* $[x]_L = \sum_j |x_j|^{\frac{1}{L_j}}$. Then repeating the arguments of Example 11.1.11 and assuming that

$$\mu > \max\bigl(-1, -\frac{L^*}{2m}\bigr), \qquad L^* = L_1 + \cdots + L_d \tag{11.1.90}$$

we conclude that

(i) For

$$(\mu + 1 - 2\mu m)\vartheta < (d-1)\mu + L^* \tag{11.1.91}$$

asymptotics (11.1.49) holds.

Moreover, under non-periodicity condition and improved regularity and non-degeneracy conditions asymptotics (11.1.51) holds.

On the other hand, for

$$(\mu + 1 - 2\mu m)\vartheta = (d-1)\mu + L^* \tag{11.1.92}$$

asymptotics (11.1.61) holds and for

$$(\mu + 1 - 2\mu m)\vartheta > (d-1)\mu + L^*, \quad 2m\mu\vartheta + d\mu + L^* > 0 \tag{11.1.93}$$

asymptotics (11.1.63) holds with $p = (2m\mu\vartheta + L^* - d)(\mu + 1)^{-1}$.

However the author have failed to solve

Problem 11.1.19. (i) Apply more advanced arguments of Remark 11.1.13.

(ii) Investigate the second critical case $2m\mu\vartheta + d\mu + L^* = 0$.

We leave to the reader to

Problem 11.1.20. Investigate the case $\rho = r^{\mu}$, $\gamma = \epsilon r^{1+\nu}$ with $\nu > 0$ arising in the analysis of the Schrödinger operator with potential $V = \rho^{2\mu} \sin r^{-\nu}$ and other examples of this type.

Let us treat exits to infinity. We assume that

(11.1.94) Either $X_{\mathsf{sing},h} = \emptyset$ or a Dirichlet boundary condition is given on $\partial X \cap \{|x| \ge c\}$.[3)]

Example 11.1.21 (Exit to infinity). (a) In a neighborhood of infinity let X coincide with $\{x, x_1 > 0, x' = F(x_1)\Omega\}$ where $\Omega \subset \mathbb{R}^{d-1}$ is a bounded domain satisfying assumptions of Theorem 11.1.1 with $\gamma(x') \asymp 1$, $x' = (x_2, \dots, x_d)$, $t\Omega = \{tx', x' \in \Omega\}$ and

$$F(x_1) \asymp x_1^{\beta}, \qquad \beta \le 1, \tag{11.1.95}$$

$$|D^{\alpha} F| \le c F^{1-|\alpha|} \qquad \forall \alpha : |\alpha| \le 2. \tag{11.1.96}$$

For $\beta = 1$ we have a conical exit, for $\beta \in (0,1)$ we have a slowly expanding quasiconical exit, for $\beta = 0$ we have a cylindrical exit and for $\beta < 0$ we have a constricting exit and these exits could be corrugated along the x_1 axis.

(b) Similarly, let us consider the case in which X coincides with $\{x, x' = F(|x''|)\Omega\}$ in a neighborhood of infinity where $x = (x'', x') \in \mathbb{R}^{d''} \times \mathbb{R}^{d'}$, $0 < d' < d = d' + d''$ and the function F satisfies conditions (11.1.95)–(11.1.96).

Then geometry yields that (at least for $|x''| \ge c$)

(11.1.97) X satisfies conditions of Theorem 11.1.1 with $\gamma \asymp F(|x''|)$.

Actually all we need is (11.1.96) with $K = 1$ and (11.1.97). Moreover, let us assume that the other conditions are fulfilled with $\gamma = \epsilon F(|x''|)$ and $\rho = |x''|^{\mu}$. Then

(i) If $\mu + \beta \ge 0$ one can take $X_{\mathsf{reg},h} = X$ and $X_{\mathsf{sing},h} = \emptyset$. Then under the condition

$$2m\mu\vartheta + d\mu + d'\beta + d'' < 0 \tag{11.1.98}$$

[3)] In the next sections we discuss how to weaken this assumption (albeit it is impossible to get rid of it).

(which provides that $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}$ converges) asymptotics (11.1.49) holds. Note that $\mu+\beta\ge 0$ and (11.1.98) imply that $\mu<0$, $\vartheta>0$.

Moreover, under the standard non-periodicity condition and improved regularity and non-degeneracy conditions asymptotics (11.1.51) holds.

(ii) Let $\mu+\beta<0$. Then one can take $X_{\mathsf{reg},h}=X\cap\{r\le Ch^{1/(\mu+\beta)}\}$ and $X_{\mathsf{sing},h}=X\cap\{r\ge \frac{1}{2}Ch^{1/(\mu+\beta)}\}$ where $r=|x''|$. Let us assume that a Dirichlet condition is given on $\partial X\cap\{|x''|\ge C\}$ [3]. Then inequality

$$h^m\sum_{\alpha:|\alpha|=m}\|D'^{\alpha}u\|_{(x'')}\ge \epsilon_0 F(r)^{-m}\|u\|_{(x'')} \tag{11.1.99}$$

(where $\|.\|_{(x'')}$ means the $\mathscr{L}^2$-norm over sections of X at points x'') yields that under condition

$$(2m\mu-\beta-\mu)\vartheta+(d-1)\mu-\beta+d'\beta+d''<0 \tag{11.1.100}$$

asymptotics (11.1.49) holds.

Moreover, under standard non-periodicity condition and improved regularity and non-degeneracy conditions asymptotics (11.1.51) holds.

(iii) On the other hand, for

$$(2m\mu-\beta-\mu)\vartheta+(d-1)\mu-\beta+d'\beta+d''=0 \tag{11.1.101}$$

asymptotics (11.1.61) holds and for

$$\begin{aligned}&(2m\mu-\beta-\mu)\vartheta+(d-1)\mu-\beta+d'\beta+d''>0,\\ &\qquad\qquad 2m\mu\vartheta+d\mu+d'\beta+d''\le 0\end{aligned} \tag{11.1.102}$$

asymptotics (11.1.63) holds with $p=(2m\mu\vartheta+d''-d''\beta)(\mu+\beta)^{-1}$; here in the case of equality in the last condition the integral in $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}$ is calculated over the domain $X_{\mathsf{reg},h}$ and $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}=O(\log h)$.

Moreover, let condition (11.1.69) be fulfilled for $|x''|\ge c, x''\in\Gamma$ and $x'\in F(|x''|)\Omega'$ where $\Gamma\subset\mathbb{R}^{d''}$ is a non-empty cone and $\Omega'\subset\Omega$ is a non-empty domain. Then $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}\asymp\log h$.

We leave to the reader to analyze the case of more general dependence of F on x''.

Example 11.1.22 (Conical exit to infinity). (i) In a neighborhood of infinity let the domain X coincide with the cone $X^0 = \{(r,\theta) \in \mathbb{R}^+ \times U\}$ and let the conditions be fulfilled with $\gamma = \epsilon r$, $\rho = r^\mu$. Then if

$$\mu \geq -1, \qquad 2m\mu\vartheta + (\mu+1)d < 0 \tag{11.1.103}$$

then asymptotics (11.1.49) holds.

Moreover, under standard non-periodicity condition and improved regularity and non-degeneracy conditions asymptotics (11.1.51) holds.

(ii) Let us treat the case

$$\mu < \min(-1, -\frac{2m}{d}); \tag{11.1.104}$$

then estimates (11.1.66) and (11.1.67) hold for functions u supported in $\mathbb{R}^d \setminus B(0, \epsilon^{-1}h^{1/(\mu+1)})$ and therefore under condition $(11.1.59)^\#$ asymptotics (11.1.49) holds.

Moreover, under standard non-periodicity condition and improved regularity and non-degeneracy conditions asymptotics (11.1.51) holds.

Here the superscript "#" means that the condition is replaced by its opposite (i.e., ">" by "<" and v.v., and "=" remains), $|x| \to 0$ is replaced by $|x| \to \infty$ and $|x| \leq \epsilon$ is replaced by $|x| \geq C$.

(iii) Further, under condition $(11.1.60)^\#$ we obtain asymptotics (11.1.61) and under condition $(11.1.62)^\#$ we obtain asymptotics (11.1.63) with p given by the same formula as before.

Finally, under condition $(11.1.68)^\#$ asymptotics (11.1.63) remains true with the same clarifications as before.

Moreover, under conditions $(11.1.60)^\#$, $(11.1.71)^\#$ and the standard non-periodicity condition and improved regularity and non-degeneracy conditions we obtain asymptotics (11.1.73).

Example 11.1.23 (Conical exit to infinity. II). Let $\gamma = \epsilon r$, $\rho = r^\mu \log^{-\nu} r$ where

$$\mu \leq -1. \qquad \mu < -\frac{2m}{d} \tag{11.1.105}$$

satisfies (11.1.59).

Then all the results of Example 11.1.17 remain true and the inequalities on ν do not change and in the stabilization conditions and in (11.1.69) $|x| \to 0$ is replaced by $|x| \to \infty$ and $|x| \le \epsilon$ is replaced by $|x| \ge C$. Again we need to change all inequalities to their opposites.

Example 11.1.24 (Quasiconical exit to infinity). In a neighborhood of infinity let X be an L-quasiconical domain and $\partial X \in \mathscr{C}^2$. Then in a neighborhood of infinity one can take $\gamma = \epsilon[x]^{\delta}_{\delta L}$ where we assume that $L = (L_1, \dots, L_d)$, $L_j \ge 1 \ \ \forall j$ and $\delta \le \min_j L_j^{-1}$. Let us assume that $\rho = \gamma^{\mu}$ and $\varrho = \gamma^{2\mu m}$.

In this case all the statements of Example 11.1.18 remain true with the inequalities on μ replaced by their opposites.

We leave to the reader the following rather easy problem:

Problem 11.1.25. Investigate the case in which $X = \mathbb{R}^{d'} \times \mathbb{T}^{d''}$ in a neighborhood of infinity and $\gamma = 1$.

11.1.3 Non-Semi-Bounded oOperators

Let us now consider operators which are non-semi-bounded. In this case we assume that $\vartheta = 0$ unless otherwise indicated. Since the order of operator is not necessarily even anymore, denote it by m rather than by $2m$.

Theorem 11.1.1 and Corollary 11.1.2, as well as Example 11.1.10, remain true in this case with obvious modifications. Moreover, one can treat the Dirac operator in $X = \mathbb{R}^d$ assuming that for $|x| \ge c$

$$V + M - \tau_2 \ge \epsilon_0 \rho^2, \qquad M - V + \tau_1 \ge \epsilon_0 \rho^2 \tag{11.1.106}$$

and

$$\rho\gamma \ge \epsilon_0, \tag{11.1.107}$$

$$\int \rho^{d-s}\gamma^{-s}\, dx < \infty \tag{11.1.108}$$

because these conditions ensure that $\{|x| \ge c\} \subset X_{\mathsf{reg,ell}}$. Recall that M is the mass.

We leave to the reader

Problem 11.1.26. (i) Include a neighborhood of infinity in $X_{\mathsf{sing},h}$ and skip condition (11.1.108);

(ii) Treat the case $X = \mathbb{R}^{d'} \times \mathbb{T}^{d''}$ with $d' > 0, d'' > 0$.

Furthermore, one can treat the *generalized Dirac* operator

$$A = \begin{pmatrix} V_1 & \mathcal{L} \\ \mathcal{L}^* & V_2 \end{pmatrix} \tag{11.1.109}$$

where V_k are matrix-valued functions, $\mathcal{L}$ is a uniformly elliptic operator of order m and for $|x| \ge c$

$$V_2 - \tau_2 \ge \epsilon_0 \rho^{2m}, \qquad V_1 - \tau_1 \le -\epsilon_0 (\rho+1)^{2m}, \qquad \rho\gamma \ge \epsilon_0. \tag{11.1.110}$$

Moreover, we assume that the coefficients of $\mathcal{L}$ satisfy conditions

$$\|D^\alpha b_\beta\| \le c\rho^{m-|\beta|}\gamma^{-|\alpha|} \qquad \forall \beta : |\beta| \le m \tag{11.1.111}$$

and

$$\|D^\alpha V_2\| \le c\rho^{2m}\gamma^{-|\alpha|}, \qquad \|D^\alpha V_1\| \le c(\rho+1)^{2m}\gamma^{-|\alpha|} \qquad \forall \alpha : 1 \le |\alpha| \le K \tag{11.1.112}$$

We can assume instead that the corresponding roughness conditions are fulfilled.

Then

(11.1.113) All examples with singularities at 0 [4] remain true for $X = \mathbb{R}^d$ if in the inequalities for exponents we replace $2m$ by m; however, we do not modify the inequalities (11.1.58) and (11.1.75) to reflect that m rather than $2m$ is an order of the operator.

Further,

(11.1.114) All examples with singularities at infinity [5] remain true without modification in the inequalities on exponents provided in a neighborhood of infinity

$$V_1 - \tau_1 \le -\epsilon_0, \qquad V_2 - \tau_2 \le -\epsilon_0 \rho^{2m}. \tag{11.1.115}$$

Recall that in these examples $\rho \le c$.

---

[4] I.e. Examples 11.1.10, 11.1.11 and 11.1.14–11.1.18.

[5] I.e. Examples 11.1.21–11.1.24.

Finally, let us note that under conditions (in X)

$$V_1 - \tau_1 \le -\epsilon_0, \qquad V_2 - \tau_1 \ge \epsilon_0, \qquad \rho \le c \tag{11.1.116}$$

one can treat

$$\mathsf{N}^-_{(\vartheta)}(A) = \int_{\tau_1}^{\tau_2} (\tau_2 - \tau)_+^{\vartheta-1} d\tau \tag{11.1.117}$$

with $\vartheta > 0$. Then Example 11.1.10 and all the examples with singularities at infinity[5)] remain true.

We leave to the reader

Problem 11.1.27. (i) Justify these claims (11.1.113) and (11.1.114) basing on the results of Chapter 10.

(ii) Based on Remark 10.2.23 pass from operators with rough coefficients to operators with irregular coefficients. In particular, using the fact that eigenvalues are monotone with respect to V_1, V_2 consider the case when only V_1 and V_2 are irregular and either τ_1 or τ_2 belong to spectral gap.

11.2 Large Eigenvalues for Operators with Weakly Singular Potentials

[Large Eigenvalues for Weakly Singular Potentials]Large Eigenvalues for Operators with Weakly Singular Potentials

This section is devoted to the General scheme and main theorems.

11.2.1 General Scheme

In this and the following two sections we consider the asymptotics of the eigenvalues of operator A, tending to $+\infty$. In fact, one can treat more general problem

$$(A - \lambda J)u = 0 \qquad u \in \mathfrak{D}(A) \tag{11.2.1}$$

where A and J are operators of orders $2m$ and $n < 2m$ respectively ($m \in \frac{1}{2}\mathbb{Z}$). Recall that in this problem one should assume that

(11.2.2) A is a self-adjoint operator, J is a symmetric operator and J is A-compact[6)] and at least one of operators A and J is positive definite.

Surely, the case $J = I$ is the most natural and interesting from the point of view of miscellaneous, in particular physical applications; in the next sections that case will be treated but in this section we consider the more general case (11.2.1) as well.

In this section we assume that A is semi-bounded from below; at the end of the section $J = I$ and A is not necessarily semi-bounded. Note that Birman-Schwinger principle yields that

(11.2.3) If the operator J is positive definite then the the number of eigenvalues of the problem (11.2.1) less than τ is equal to $\mathsf{N}^-(\tau)$ which is the number of negative eigenvalues of the operator $(A - \tau J)$

and

(11.2.4) If the operator A is positive definite then the number of eigenvalues $\lambda \in (0, \tau)$ of the problem (11.2.1) (with $\tau > 0$) is equal to $\mathsf{N}^-(\tau) - \mathsf{N}^-(+0)$ where $\mathsf{N}^-(\tau)$ is again the number of negative eigenvalues of the operator $(A - \tau J)$ and $\mathsf{N}^-(+0) = \mathsf{lim}_{\tau \to +0}\, \mathsf{N}^-(\tau)$.

There is no contradiction since as both A and J are positive definite problem (11.2.1) has only positive eigenvalues.

Therefore in the both cases we should consider the asymptotics of $\mathsf{N}^-(\tau)$ as $\tau \to +\infty$.

Let us assume that A is given by (11.1.1) with $h = 1$, $m \in \mathbb{Z}$, that conditions (11.1.2) and (11.1.3) are fulfilled and

$$J = \sum_{|\alpha|,|\beta| \le m, |\alpha|+|\beta| \le n} D^\alpha j_{\alpha,\beta} D^\beta, \tag{11.2.5}$$

with the coefficients satisfying

$$|D^\sigma a_{\alpha,\beta}| \le c\varrho\rho^{-|\alpha|-|\beta|}\gamma^{-|\sigma|}, \tag{11.2.6}$$

$$|D^\sigma j_{\alpha,\beta}| \le c\varrho_0\rho^{-|\alpha|-|\beta|}\gamma^{-|\sigma|} \qquad \forall \sigma : |\sigma| \le K \tag{11.2.7}$$

[6)] This condition will be fulfilled automatically in the frameworks of the theorems below.

or corresponding "rough" conditions.

Further, let us assume that the boundary ∂X is smooth enough after rescaling of $\mathcal{B}(y,\gamma(y),X)$ and that the coefficients of the boundary operator $B=(B_1,\dots,B_l)$ satisfy condition $(9.2.3)_2$. Furthermore, let us assume that the operator $\varrho^{-1}\rho^{2m}A$ is uniformly elliptic and that the boundary value problem $(\varrho^{-1}\rho^{2m}A, \varrho_{(1)}^{-1}B_1,\dots,\varrho_{(l)}^{-1}B_l)$ is uniformly elliptic as well.

One can easily see that in the zone $\{x\in X, \rho_\tau\gamma_\tau\ge 1\}$ operator $(A-\tau J)$ satisfies all the conditions of Section 9.1[7] with functions

$$\gamma_\tau=\gamma,\quad \rho_\tau=\rho\bigl(1+\frac{\tau\varrho_0}{\varrho}\bigr)^{\frac{1}{2m-n}},\quad \varrho_\tau=\varrho\bigl(1+\frac{\tau\varrho_0}{\varrho}\bigr)^{\frac{2m}{2m-n}},\quad \varrho_{\tau(j)}=\varrho_{(j)}\bigl(\frac{\tilde\rho}{\rho}\bigr)^{-m_j} \tag{11.2.8}$$

instead of γ, ρ, ϱ and $\varrho_{(j)}$ respectively[8].

Let us treat the microhyperbolicity or non-degeneracy condition in the zone

$$X'_{\mathsf{reg}}=\bigl\{x\in X, \tau\varrho_0\ge C\varrho\bigl(1+(\rho\gamma)^{n-2m}\bigr)\bigr\} \tag{11.2.9}$$

in which

$$\rho_\tau\gamma\ge C' \quad\text{and}\quad \rho_\tau\ge C'\rho \tag{11.2.10}$$

provided $C=C(C')$. We easily see that for large enough C' in this zone one can replace the complete symbols of the operators A, B and J by their senior symbols[9] in the verification of such condition and after rescaling with respect to x and ξ [10] we easily see that

(11.2.11) One needs to check this non-degeneracy condition with $\gamma\partial_x$ instead of ∂_x and with ∂_ξ preserved for the symbol $\bigl(\tilde a(x,\xi)-\tilde\jmath(x,\xi),\tilde b(x,\xi)\bigr)$

where tilde means that one needs to multiply a, j and b_k by ϱ^{-1}, ϱ_0^{-1} and $\varrho_{(k)}^{-1}$ respectively at point x; these factors are "well-differentiable" (in the corresponding scale) with respect to x.

---

[7] With the possible exception of the microhyperbolicity, or ξ-microhyperbolicity, or some other non-degeneracy condition.

[8] We use the notation $\varrho_{(k)}$ instead of the ϱ_k of Section 9.1 in order to avoid misunderstanding.

[9] I.e., the higher degree homogeneous symbols.

[10] I.e., rescaling with respect to x and multiplication of the operators by appropriate factors.

Let us first check the conditions which are not associated with the symbol $\tilde{b}$ of the boundary operator. Note that for $|\xi| \ge \epsilon$ with an arbitrarily small constant $\epsilon > 0$ the ellipticity of $\tilde{a}(x,\xi)$, the homogeneity of $\tilde{a}(x,\xi)$ and $\tilde{\jmath}(x,\xi)$ of degrees $2m$ and n with respect to ξ and the Euler identity yield that ξ-microhyperbolicity condition is fulfilled. Therefore *the remaining check should be done for $\xi = 0$ only*.

For general matrix operators one needs to check ξ-microhyperbolicity or microhyperbolicity condition and since $\tilde{a}$ with its first order derivatives vanishes at $\xi = 0$ this condition should be checked for $\tilde{\jmath}(x,\xi)$.

The three following cases are possible:

(i) $n = 0$; then microhyperbolicity condition means exactly that

(11.2.12) $n = 0$ and for every $x \in X_{\mathsf{reg}}$ there exists $\ell \in T_x X$ such that $|\ell| = 1$ and

$$\gamma\langle \ell j(x)v, v\rangle \ge \epsilon_0 \varrho_0 \|v\|^2 - c\varrho_0^{-1}\|j(x)v\|^2 \qquad \forall v \in \mathbb{H} \tag{11.2.13}$$

where $j(x) = J(x)$ and we returned to j from $\tilde{\jmath}$. In particular, this condition is fulfilled automatically if

(11.2.14) $n = 0$ and $\quad \|j(x)v\| \ge \epsilon\varrho_0\|v\| \qquad \forall x \in X' \quad \forall v \in \mathbb{H}$;

(ii) $n = 1$; in this case $\tilde{\jmath}(x,0) = 0$ and one should differentiate with respect to ξ only; then microhyperbolicity condition means exactly that

(11.2.15) $n = 1$ and for every $x \in X_{\mathsf{reg}}$ there exists $\xi \in T_x^* X$ such that $|\xi| = 1$ and

$$\langle j(x,\xi)v, v\rangle \ge \epsilon_0\varrho_0\rho^{-1}\|v\|^2 \qquad \forall v \in \mathbb{H}$$

where $j(x,\xi)$ is the senior symbol of $J(x,D_x)$.

(iii) $n \ge 2$; in this case $\tilde{\jmath}$ and its first order derivatives vanish at $\xi = 0$ and the microhyperbolicity condition is surely violated.

Note that ξ-microhyperbolicity condition is fulfilled in the cases (11.2.14) and (11.2.15) only; in this case remainder estimate $O(h_{\mathsf{eff}}^{1-d})$ is ensured under regularity conditions marginally stronger than $K = 1$ (see Sections 4.6 and 7.5); we refer to them as *minimal regularity assumptions*.

For scalar symbols a and j [11] the following additional possibilities arise:

(iv) $m = 1$, $d \ge 2$; then $(A - \lambda J)$ after all rescaling is the Schrödinger operator and no microhyperbolicity is needed; so we assume that

(11.2.16) $m = 1$, $n = 0, 1$, a and j are scalar symbols and $d \ge 2$; further, as either $d \ge 3$ or $d = 2$ or (11.2.12) holds we recover local remainder estimate $O(h_{\mathrm{eff}}^{1-d})$ under minimal regularity assumptions;

(v) $m = 1$, $d = 1$, $n = 0$; we recover local remainder estimate $O(h_{\mathrm{eff}}^{1-d})$ as $K = K(p)$ provided

(11.2.17) $m = 1$, $d = 1$, $n = 0$ and for every $x \in X_{\mathrm{reg}}$

$$\sum_{\alpha:|\alpha|\le p} \gamma^{|\alpha|} |D^\alpha j| \ge \epsilon_0 \varrho_0; \tag{11.2.18}$$

as $p = 1$ we recover local remainder estimate $O(\log(h_{\mathrm{eff}}))$ under minimal regularity assumptions[12];

(vi) $m = 1$, $d = 1$, $n = 1$; then

$$J = \frac{1}{2}(\langle D_x, j(x)\rangle + \langle j(x), D_x\rangle) + j'(x) \tag{11.2.19}$$

and different variants of non-degeneracy condition are possible:

(11.2.20) $m = 1$, $d = 1$, $n = 1$ and $|j(x)| \ge \epsilon_0 \varrho_0 \rho^{-1}$ for every $x \in X_{\mathrm{reg}}$ ensures local remainder estimate $O(\log(h_{\mathrm{eff}}))$ under under minimal regularity assumptions;

---

[11] It is sufficient to assume that either the eigenvalues of $a(x,\xi) - j(x,\xi)$ close to 0 are simple in a neighborhood of $\{\xi = 0\}$ or these eigenvalues are of constant multiplicity there and $\rho\gamma \le C$ in the latter case. For $n \ge 1$ that automatically yields that $(a - j)$ is a scalar symbol and the homogeneity of a and j yield that a and j are scalar symbols.

For $n = 0$ this conjecture is not necessary. In this case in the appropriate local coordinates $j = \begin{pmatrix} j'' & 0 \\ 0 & j'I \end{pmatrix}$, $a = \begin{pmatrix} * & * \\ * & a'I \end{pmatrix}$ where j'' is a non-degenerate matrix and j' and a' are scalar symbols and under the above condition all the following conditions should be checked for symbols a' and j'.

[12] As $p \ge 2$ we need to assume that A and J are scalar operators.

while

(11.2.21) $m = 1$, $d = 1$, $n = 1$ and (11.2.18) ensures local remainder estimate $O(1)$ as $K = K(p)$ [12].

(vii) If $m \ge 2$ then the first and the second order derivatives of a vanish at $\xi = 0$ and we obtain the following cases ensuring local remainder estimate $O(h_{\mathsf{eff}}^{1-d})$ under smoothness assumptions:

(11.2.22) $m \ge 2$, $d \ge 2$, $n = 0$ and for every $x \in X_{\mathsf{reg}}$ inequality

$$|j(x)| + \gamma |\nabla j(x)| \le \epsilon_0 \varrho_0 \tag{11.2.23}$$

yields that $\mathsf{Hess}\, j(x)$ has two eigenvalues with absolute values greater than $\epsilon_0 \varrho_0 \gamma^{-2}$;

(11.2.24) $m \ge 2$, $d \ge 2$, $n = 0$ and for every $x \in X_{\mathsf{reg}}$ (11.2.18) holds with $p = 1$ or $p = 2$ [12];

(11.2.25) $m \ge 2$, $n = 1$ and for every $x \in X_{\mathsf{reg}}$ inequality

$$|j(x)| + \gamma |(Dj)(x)| \ge \epsilon_0 \varrho_0 \rho^{-1} \tag{11.2.26}$$

holds where here J is defined by (11.2.19), $j = j(x)$ is a vector field and (Dj) is the matrix of its derivatives, $j' = j'(x)$.

(viii) Finally, as $m \ge 2$ we can consider $n = 2$ and arrive to

(11.2.27) $m \ge 2$, $d \ge 2$, $n = 2$ and

$$\sum_{\alpha : |\alpha| = 2} |j_\alpha| \ge \epsilon_0 \varrho_0 \rho^{-2} \tag{11.2.28}$$

for every $x \in X_{\mathsf{reg}}$ where j_α are the coefficients of the senior symbol of J.

Remark 11.2.1. (i) For $\vartheta > 0$ we recover a local remainder estimate $O(h_{\mathsf{eff}}^{1-d+\vartheta} \tau^{\vartheta})$ under corresponding regularity assumptions.

(ii) Let both A and J be scalar operators. Then in the smooth case we do not need any non-degeneracy assumptions to recover a local remainder estimate $O(h_{\mathsf{eff}}^{1-d+\vartheta}\tau^{\vartheta})$ as $\vartheta > 0$ and $O(h_{\mathsf{eff}}^{1-d-\delta})$ with arbitrarily small $\delta > 0$ as $\vartheta = 0$; "smooth" means "with $K = K(d, \vartheta)$ or $K = K(d, \delta)$ respectively".

Remark 11.2.2. To avoid $\mathsf{N}^{\mathsf{W}} = 0$ we need to assume that

(11.2.29) $j(x, \xi)$ (the principal symbol of J) is not a non-positive definite matrix (as long as we assume that $a(x, \xi)$ is a positive definite matrix).

We leave to the the following

Problem 11.2.3. Investigate the opposite case when according to Chapter 7 the local remainder estimate may be $O(h_{\mathsf{eff}}^{2-d})$ and $\mathsf{N}^{\mathsf{W}} \asymp h_{\mathsf{eff}}^{1-d}$.

Let us discuss conditions associated with the boundary value problem. Recall that this condition for 1-dimensional operator $f = \tilde{a} - \tilde{\jmath}$ is of the form

$$\mathsf{Re}\,\langle \ell f v, v\rangle_{+} + \mathsf{Re}\,\langle \ell \tilde{b} v, \beta v\rangle_{0} \ge \epsilon_0 \|v\|_{+}^2 \qquad \forall v \in \mathscr{S}'(\mathbb{R}^+, \mathbb{H}) : fv = 0 \text{ and } bv|_{x_1=0} = 0 \tag{11.2.30}$$

where we use the notation of Chapter 7 and make a rescaling; here $f = f(z, D_1)$, $b = b(z, D_1)$ and $\beta = \beta(z, D_1)$ is defined by equality

$$\langle fu, v\rangle_{+} + \langle \tilde{b} u, \beta v\rangle_{0} = \langle u, fv\rangle_{+} + \langle \beta u, \tilde{b} v\rangle_{0} \qquad \forall u, v \in \mathscr{S}(\mathbb{R}^+, \mathbb{H}) \tag{11.2.31}$$

where $z = (x', \xi')$.

Let us note that

(11.2.32) Condition (11.2.30) survives substitution $D_1 \mapsto \theta(z) D_1$ with $\theta \asymp 1$.

In fact, it is obvious for $\theta = \mathsf{const}$ and therefore we need check this statement only for θ equal to 1 at the point in question. In this case additional term

$$(\ell\theta)(z) \times \mathsf{Re}\big(\langle f' v, v\rangle_{+} + \langle \tilde{b}' v, \beta v\rangle_{0}\big) \tag{11.2.33}$$

in the left-hand expression of (11.2.30) appears where the prime means derivative with respect to θ. Let us introduce $v_\theta(x_1) = v(\theta^{-1} x_1)$; then

$f_\theta v_\theta = 0$ and $\tilde{b}_\theta v_\theta|_{x_1=0} = 0$. Therefore treating θ as an independent variable, differentiating and taking $\theta = 1$ we obtain that

$$f'v + fv' = 0, \qquad \tilde{b}'v + \tilde{b}v' = 0 \tag{11.2.34}$$

where the prime on v means derivative on θ also and therefore $v' = -x_1\partial_1 v$. Then (11.2.34), (11.2.31) and the equalities $fv = 0$, $\tilde{b}v|_{x_1=0} = 0$ obviously yield that the second factor in (11.2.30) vanishes; (11.2.32) has been proven.

Let us consider first $|\xi'| \ge \epsilon_0$ and let us introduce $\ell = \langle \xi', \partial_{x'}\rangle$, $\theta = |\xi'|$. Then 1-dimensional operators $\tilde{a}(x', \xi', \theta D_1)$ and $\tilde{\jmath}(x', \xi', \theta D_1)$ are positive homogeneous of degrees $2m$ and n on ξ' respectively. Moreover, operators $\tilde{b}_k(x', \xi', \theta D_1)$ are positive homogeneous of degrees m_k on ξ' and $b_k v = 0$. Therefore the Euler identity yields that the left-hand expression of (11.2.30) is equal to

$$2m\langle \tilde{a}v, v\rangle_+ - n\langle \tilde{\jmath}v, v\rangle_+.$$

Since $(\tilde{a} - \tilde{\jmath})v = 0$ we obtain that this expression is equal to

$$(2m - n)\langle \tilde{a}v, v\rangle_+ = (2m - n)\langle \tilde{\jmath}v, v\rangle_+.$$

Therefore we arrive to

Proposition 11.2.4. *As $|x'| \ge \epsilon_0$ condition* (11.2.30) *is fulfilled provided either*

$$\langle \tilde{a}v, v\rangle_+ \ge \epsilon_0 \|v\|_+^2 \qquad \forall v \in \mathscr{S}(\mathbb{R}^+, \mathbb{H}) : \ \tilde{b}v = 0 \ \textit{at} \ \ x_1 = 0 \tag{11.2.35}$$

or the same condition is fulfilled for $\tilde{\jmath}$:

$$\langle \tilde{\jmath}v, v\rangle_+ \ge \epsilon_0 \|v\|_+^2 \qquad \forall v \in \mathscr{S}(\mathbb{R}^+, \mathbb{H}) : \ \tilde{b}v = 0 \ \textit{at} \ \ x_1 = 0 \tag{11.2.36}$$

If A is a semi-bounded operator (under the boundary condition $Bv = 0$) then the ellipticity of the boundary value problem (A, B) yields that condition (11.2.35) is fulfilled. *In what follows when we consider non-semi-bounded operators A we assume that $J = I$* and then condition (11.2.36) is fulfilled automatically.

Let us consider the case $\xi' = 0$. Let us prove that

(11.2.37) As $|\xi'| = 0$ the kernel of the problem

$$fv = 0, \qquad \tilde{b}v = 0 \quad \text{at} \ \ x_1 = 0, \qquad v \in \mathscr{S}(\mathbb{R}^+, \mathbb{H}) \tag{11.2.38}$$

is trivial.

Then condition (11.2.30) will be automatically fulfilled.

Let us note that if $\xi' = 0$ then $\tilde{a} = a_0 D_1^{2m}$, $\tilde{j} = j_0 D_1^n$, $\tilde{b}_k = b_{0k} D_1^{m_k}$ where a_0, j_0, b_{0k} are matrices (depending on z). Let us replace D_1 by θD_1 and let us introduce $v_\theta(x_1) = v(\theta^{-1}x_1)$ with an arbitrary parameter θ. The above arguments yield the following equality

$$\langle f' v, v\rangle_+ + \langle \tilde{b}' v, \beta v\rangle_0 = 0$$

for any solution of the problem (11.2.38). Let us note that in our case $\tilde{b}' v = 0$ at $x_1 = 0$. Then equalities $fv = 0$, $f = \tilde{a} - \tilde{j}$ and $f' = 2m\tilde{a} - n\tilde{j}$ obviously yield that

$$\langle \tilde{a} v, v\rangle_+ = 0, \qquad \langle \tilde{j} v, v\rangle_+ = 0.$$

The first equality is impossible for $v \neq 0$ if A is a semi-bounded elliptic operator and the second equality is impossible for $v \neq 0$ if $J = I$. So, (11.2.37) and thus (11.2.30) are established.

Thus we arrive to the following

Proposition 11.2.5. *Let one of the following assumptions be fulfilled:*

(a) Either A and J are matrix matrix operators satisfying one of the conditions (11.2.12)–(11.2.15) *or A and J are operators with scalar senior symbols satisfying condition* (11.2.20)*;*

(b) $B\big(x,\gamma(x)\big)\cap\partial X = \emptyset$ and A and J are operators with scalar senior symbols satisfying one of the conditions (11.2.16), (11.2.17), (11.2.21)–(11.2.15)*;*

(c) $d \geq 2$ and A is the Schrödinger operator with a Dirichlet or Neumann boundary condition[13] *on $\partial X \cap B\big(x,\gamma(x)\big)$.*

Then the contribution of $\mathcal{B}\big(x,\gamma(x),X\big) \subset X'_{\mathrm{reg}}$ to the principal part of the asymptotics for $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau)$ is $O(h_{\mathrm{eff}}^{-d}\tau^\vartheta)$ [14] *and its contribution to the remainder is $O(h_{\mathrm{eff}}^{1-d+\vartheta}\tau^\vartheta)$ with*

$$h_{\mathrm{eff}} = \Big(\frac{\tau\varrho_0}{\varrho}\Big)^{-\frac{1}{2m-n}}\rho^{-1}\gamma^{-1} \tag{11.2.39}$$

[13] Or a Robin boundary condition with appropriate restrictions on lower order coefficients.

[14] Recall that under assumption (11.2.29) it is $\asymp h_{\mathrm{eff}}^{-d}\tau^\vartheta$.

and therefore the total contribution of X'_{reg} *defined by* (11.2.9) *to the remainder does not exceed*

$$R_{1(\vartheta)}(\tau) = \tau^{\frac{d-1-\vartheta}{2m-n}+\vartheta} \int_{X'_{\mathsf{reg}}} \Big(\frac{\varrho_0}{\varrho}\Big)^{\frac{d-1-\vartheta}{2m-n}} \rho^{d-1-\vartheta}\gamma^{-1-\vartheta}\, dx. \tag{11.2.40}$$

11.2.2 Weak Singularity

Now consider the contribution of

$$X''_{\mathsf{reg}} = X_{\mathsf{reg}} \setminus X'_{\mathsf{reg}} = \{\rho\gamma \ge 1,\ \tau\varrho_0 \le C_0\varrho\}; \tag{11.2.41}$$

we estimate the contribution of $\mathcal{B}\big(x, \gamma(x), X\big) \subset X''_{\mathsf{reg}}$ to both the main part and remainder estimate by $O(h_{\mathsf{eff}}^{-d}\varrho^{\vartheta}\varrho_0^{-\vartheta})$ with $h_{\mathsf{eff}} = \rho^{-1}\gamma^{-1}$ and the total contribution of X''_{reg} does not exceed

$$R_{2(\vartheta)}(\tau) = \int_{X''_{\mathsf{reg}}} \rho^d \varrho^{\vartheta}\varrho_0^{-\vartheta}\, dx \tag{11.2.42}$$

provided

$$\vartheta > 0 \implies J = I \quad \text{i.e.}\ \ n = 0,\ \varrho_0 = 1. \tag{11.2.43}$$

As A and J are scalar operators we can use Remark 11.2.1 and vastly improve the estimate of the contribution of X''_{reg} to the remainder.

As we use such crude estimate in X''_{reg} and hope to recover a reasonable result we will need to assume that singularity is weak.

Further, we need to estimate the contribution of X_{sing}. If we can apply Rozenblioum estimate we arrive to the following

Proposition 11.2.6. *(i) As* $\vartheta = 0$ *the contribution of* X_{sing} *to asymptotics does not exceed*

$$CR_0 + CR'_0 \tag{11.2.44}$$

where R_0 *is given by* (11.1.10) *with exponents satisfying* (11.1.11) *and* (11.1.12) *and*

$$\begin{aligned} R'_0 = \tau^{\frac{d}{2m-n}} &\Big(\int_{X_{\mathsf{sing}}} \varrho^{-p'}\rho^{2mp'}\, dx\Big)^{\frac{d}{(2m-n)p'}} \times \\ &\Big(\int_{X_{\mathsf{sing}}} \varrho_0^{q'}\rho^{-nq'}\, dx\Big)^{\frac{d}{(2m-n)q'}} \times \big(\mathsf{mes}(X_{\mathsf{sing}})\big)^{1-\frac{d}{2mq'}(\frac{1}{p'}+\frac{1}{q'})} \end{aligned} \tag{11.2.45}$$

with exponents p' *and* q' *satisfying conditions* (11.1.11)$^{\#}$ *and* (11.1.12)$^{\#}$ *where the* $^{\#}$ *means that we replace* $2m$, p *and* q *by* $2m-n$, p' *and* q' *respectively.*

We assume that a Dirichlet boundary condition is given on $\partial X \cap \bar{X}_{\mathsf{sing}}$. *Otherwise we should assume that a cone condition is fulfilled (with constant angle and height of the cone),* $\varrho \asymp \rho^{2m}$ *and* $\mathsf{mes}(X_{\mathsf{sing}}) < \infty$.

(ii) As $\vartheta > 0$ *and* $J = I$ *the contribution of the zone* X_{sing} *to the asymptotics does not exceed*

$$CR_{0(\vartheta)} + CR'_{0(\vartheta)} \tag{11.2.46}$$

where

$$R_{0(\vartheta)} = \int_0^\infty t^{\vartheta-1}\Big(\int_{X_{\mathsf{sing}}} (\varrho - t)_+^q \, dx\Big)^{\frac{d}{2mq}} dt \times \Big(\int_{X_sing} \varrho^{-p}\rho^{2mp}\, dx\Big)^{\frac{d}{2mp}} \times \big(\mathsf{mes}(X_{\mathsf{sing}})\big)^{1-\frac{d}{2m}(\frac{1}{p}+\frac{1}{q})}, \tag{11.2.47}$$

$$R'_{0(\vartheta)} = \tau^{\vartheta+\frac{d}{2m}}\Big(\int_{X_{\mathsf{sing}}} \varrho^{-p}\rho^{2mp}\, dx\Big)^{\frac{d}{2mp}} \times \big(\mathsf{mes}(X_{\mathsf{sing}})\big)^{1-\frac{d}{2mp}} \tag{11.2.48}$$

and exponents p *and* q *satisfy conditions* (11.1.11)–(11.1.12).

11.2.3 Main Theorems

Let us start from the standard asymptotics. Then we improve the remainder estimate under conditions on the Hamiltonian trajectories in X'_{reg}. Resulting from this analysis we obtain the following statements:

Theorem 11.2.7. *Let* $X = \mathcal{X}_{\mathsf{reg}} \cup \mathcal{X}_{\mathsf{sing}}$, $\mathsf{mes}(\mathcal{X}_{\mathsf{sing}}) = 0$. *Let us assume that in* $\mathcal{X}_{\mathsf{reg}}$ *all the conditions* (9.1.5)–(9.1.13), (9.1.15) *(excluding restriction* $\rho\gamma \ge 1$*) are fulfilled.*

Further, let us assume that $\varrho^{-1}\rho^{2m}a^0(x,\xi)$ *is uniformly classically elliptic and the corresponding boundary value problem for it is also uniformly classically elliptic at the boundary points.*

Furthermore, let us assume that in each ball $\mathcal{B}(x,\gamma(x),X) \subset \mathcal{X}_{\mathsf{reg}}$ *one of the assumptions (a), (b) or (c) of Proposition 11.2.5 is fulfilled. Then*

(i) The following lower estimate holds:

$$\mathsf{N}(0,\tau) \ge \mathsf{N}^{\mathsf{W}}(0,\tau) - CR_{1(0)}(\tau) \tag{11.2.49}$$

where $\mathsf{N}^{\mathsf{W}}(0,\tau)$ *is defined by cut Weyl formula (with integration over* X'_{reg}*):*

$$\mathsf{N}^{\mathsf{W}}(0,\tau) = \varkappa_0(\tau)\tau^{\frac{d}{2m-n}}, \tag{11.2.50}$$

$$\varkappa_0(\tau) = (2\pi)^{-d}\int_{X'_{\mathsf{reg}}(\tau)} \boldsymbol{n}(x,\xi;0,1)\,dxd\xi, \tag{11.2.51}$$

$\boldsymbol{n}(x,\xi;0,1)$ *is the eigenvalue counting function for the symbol* $j^{-1}(x,\xi)a(x,\xi)$ *on the interval* $(0,1)$*,* $R_{1(0)}(\tau)$ *is defined by* (11.2.40) *with* $\vartheta = 0$*;* $X'_{\mathsf{reg}}(\tau)$ *is defined by* (11.2.10)*.*

(ii) Further, let us assume that in

$$X_{\mathsf{sing}}(\tau) = X \setminus \bigl(X'_{\mathsf{reg}}(\tau) \cup X''_{\mathsf{reg}}(\tau)\bigr) \tag{11.2.52}$$

we can apply Rozenblioum estimate. Then the upper estimate holds

$$\mathsf{N}(0,\tau) \le \mathsf{N}^{\mathsf{W}}(0,\tau) + CR_{1(0)}(\tau) + CR_{2(0)}(\tau) + CR_0(\tau) + CR'_0(\tau) \tag{11.2.53}$$

where $R_{2(0)}(\tau)$*,* $R_0(\tau)$*,* $R'_0(\tau)$ *are defined by* (11.2.42)*,* (11.1.10)*,* (11.2.45) *respectively with* $X''_{\mathsf{reg}}(\tau)$ *and* $X_{\mathsf{sing}}(\tau)$ *defined by* (11.2.42) *and* (11.2.52)*.*

Similarly, as $\vartheta > 0$ we arrive to

Theorem 11.2.8. *Let assumptions of Theorem 11.2.7 be fulfilled. Moreover, let us assume that* $J = I$ *and* A *is semi-bounded from below. Then*

(i) The following lower estimate holds:

$$\mathsf{N}^{-}_{(\vartheta)}(\tau) \ge \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) - CR_{1(\vartheta)}(\tau) \tag{11.2.54}$$

where $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau)$ *is defined by cut Weyl formula (with integration over* X'_{reg}*),* $R_{1(\vartheta)}(\tau)$ *is defined by* (11.2.40)*.*

item Further, let us assume that in $X_{\mathsf{sing}}(\tau)$ *defined by* (11.2.52) *we can apply Rozenblioum estimate. Then the upper estimate holds*

$$\begin{aligned}\mathsf{N}^{-}_{(\vartheta)}(\tau) \ge \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau)+\\ CR_{1(\vartheta)}(\tau) + CR_{2(\vartheta)}(\tau) + CR_{0(\vartheta)}(\tau) + CR'_{0(\vartheta)}(\tau)\end{aligned} \tag{11.2.55}$$

where $R_{2(\vartheta)}(\tau)$*,* $R_{0(\vartheta)}(\tau)$*,* $R'_{0(\vartheta)}(\tau)$ *are defined by* (11.2.42)*,* (11.2.46)*,* (11.2.45) *respectively with* $X''_{\mathsf{reg}}(\tau)$ *defined by* (11.2.42)*.*

Obviously, if X is a compact domain with the smooth boundary and $J(x) = I$ we conclude that

$$\mathsf{N}^{-}_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{d-1-\vartheta}{2m}+\vartheta}\bigr) \qquad \text{as } \tau \to +\infty \tag{11.2.56}$$

with

$$\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) \asymp \tau^{\frac{d}{2m}+\vartheta}. \tag{11.2.57}$$

Our goal now is to consider the *weakly singular* case when this conclusion holds. Since X'_{reg} extends to $\mathcal{X}_{\mathsf{reg}}$ as $\tau \to +\infty$, we need to assume that

$$\bigl(\frac{\varrho_0}{\varrho}\rho^{2m-n}\bigr)^{\frac{d}{2m-n}} \in \mathscr{L}^1(X) \tag{11.2.58}$$

and

$$\bigl(\frac{\varrho_0}{\varrho}\rho^{2m-n}\bigr)^{\frac{d-1-\vartheta}{2m-n}} \gamma^{-1-\vartheta} \in \mathscr{L}^1(X). \tag{11.2.59}$$

Corollary 11.2.9. *Assume that conditions of Theorem 11.2.7 as $\vartheta = 0$ or Theorem 11.2.8 as $\vartheta > 0$ are fulfilled. Further, let conditions* (11.2.58)–(11.2.59) *be fulfilled. Then*

$$R_{2(\vartheta)}(\tau) = o\bigl(\tau^{\frac{d-1-\vartheta}{2m-n}+\vartheta}\bigr) \qquad \textit{as } \tau \to +\infty \tag{11.2.60}$$

and assuming that

$$R_{0(\vartheta)}(\tau) + R'_{0(\vartheta)}(\tau) = O\bigl(\tau^{\frac{d-1-\vartheta}{2m-n}+\vartheta}\bigr) \qquad \textit{as } \tau \to +\infty \tag{11.2.61}$$

we conclude that (11.2.56)–(11.2.57) *hold.*

Remark 11.2.10. (i) One can easily see that extending integration in $\mathsf{N}^{\mathsf{W}}(\tau)$ from X_{reg} to X causes an error not exceeding (11.2.44). So we can replace cut Weyl expression by the full Weyl expression.

(ii) Also skipping lower degree terms in N^{W} leads to an error not exceeding $CR_{1(0)}(\tau)$; this leads to (11.2.50)–(11.2.51).

(iii) Combining Statements (i) and (ii) we arrive to (11.2.51) with integration over X (then $\varkappa_0$ does not depend on τ).

(iv) Some of these conclusions remain true for $\vartheta > 0$, at least with some modifications: for example, (11.2.50)–(11.2.51) becomes

$$\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(0,\tau) = \sum_{0\le n<1+\vartheta} \varkappa_n(\tau)\tau^{\frac{d-n}{2m-n}+\vartheta} \tag{11.2.62}$$

but extension of integration in $\varkappa_n(\tau)$ terms is justified only under assumption (11.2.59) with ϑ replaced by n (and some other assumptions may be required as well).

(v) Theorems 11.2.7 and 11.2.8 and Corollary 11.2.9 remain true for compact $\mathscr{C}^K$ manifolds.

Remark 11.2.11. In the case $\varrho = \rho^{2m}$ and $2m-n<d$ one can set $q' = \frac{d}{2m-n}$ and then (11.2.59) yields (11.2.61).

We can slightly improve the results of above theorems under assumptions to Hamiltonian trajectories:

Theorem 11.2.12. *Assume that conditions of Theorem 11.2.7 as $\vartheta = 0$ or Theorem 11.2.8 as $\vartheta > 0$ are fulfilled.*

Further, let us assume that non-periodicity condition (11.1.55)–(11.1.56) *and improved smoothness and non-degeneracy conditions of Remark 11.1.8 hold for symbol $a^0(x,\xi) - j^0(x,\xi)$ on the energy level 0. Then sharp versions of asymptotics* (11.2.54), (11.2.55) *hold where "sharp version" means that $R_{1(\vartheta)}(\tau)$ is replaced by*

$$R'_{1(\vartheta)}(\tau) = o(1)R_{1(\vartheta)}(\tau) + R_{1(\vartheta-\delta)}(\tau) \tag{11.2.63}$$

where $\delta > 0$ is sufficiently small exponent and formula (11.1.39) *defining $R_{1(\vartheta)}$ is extended to $\vartheta < 0$ if needed; also in $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}$ one extra term should be included if needed.*

Sharper asymptotics under more restrictive conditions on the Hamiltonian flow will be treated later.

11.2.4 Examples

Consider some examples. Let us start with examples in which $J = I$, $\varrho = \rho = 1$. Then conditions (11.2.58), (11.2.59) mean respectively that

$$1 \in \mathscr{L}^1(X) \qquad \text{i.e.} \quad \mathsf{mes}(X) < \infty, \tag{11.2.64}$$

$$\gamma^{-1-\vartheta} \in \mathscr{L}^1(X). \tag{11.2.65}$$

In the first examples the coefficients of A are regular and γ is completely defined by the geometry of the domain X.

Example 11.2.13 (Quasipolygonal and quasipolyhedral domains). Let X be a bounded domain with ∂X contained in the union of a finite number of $\mathscr{C}^K$ hypersurfaces[15] $\tilde{S}_l$ (with $l = 1, \dots, L$).

Let $S_l = \tilde{S}_l \cap \partial X$ and δS_l be the relative boundary of S_l in $\tilde{S}_l$. Introduce the *singular set* of ∂X

$$\mathcal{K} = \bigcup_{l \neq k} (S_l \cap S_k) \cup \bigcup_{l} \delta S_k \tag{11.2.66}$$

Obviously, we can take

$$\gamma(x) \asymp \min\Big(\min_{l \neq k} \gamma_{lk}(x), \mathsf{dist}(x, \mathcal{K})\Big), \tag{11.2.67}$$

with

$$\gamma_{lk}(x) = \max\big(\gamma_l(x), \gamma_k(x)\big) \tag{11.2.68}$$

where $\gamma_l(x) = \mathsf{dist}(x, S_l)$.

Then condition (11.2.65) needs to be verified for γ_{lk} for all $l \neq k$ and for $\gamma'(x) = \mathsf{dist}(x, \mathcal{K})$ separately.

First of all,

(11.2.69) If the hypersurfaces $\tilde{S}_l$ and $\tilde{S}_k$ are transversal at $S_k \cap S_l$ then condition (11.2.65) is fulfilled for $\gamma = \gamma_{kl}$ and $\vartheta < \vartheta^*(= 1)$.

Moreover,

---

[15] Actually we need only regularity required to produce local remainder estimate $O(h_{\mathsf{eff}}^{1-d+\vartheta})$ or $o(h_{\mathsf{eff}}^{1-d+\vartheta})$ in case we are interested in the sharp asymptotics.

(11.2.70) If $\mathcal{K}$ is contained in the union of a finite number of $\mathscr{C}^K$ manifolds of codimension 2 then condition (11.2.65) is fulfilled for $\gamma = \gamma'$ for $\vartheta < \vartheta^* = 1$ as well.

One can see easily that the above assumptions yield the cone condition. Therefore

(i) For appropriate boundary conditions[16)] asymptotics (11.2.56) holds for $\vartheta < \vartheta^*$.

Moreover, under standard non-periodicity condition (11.1.55)–(11.1.56) to the Hamiltonian flow of the symbol $\mathsf{a}^0(x,\xi)$ on the energy level 1 asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + o\bigl(\tau^{\frac{d-1-\vartheta}{2m}+\vartheta}\bigr) \qquad \text{as } \tau \to +\infty \tag{11.2.56)*}$$

holds.

(ii) Further, our analysis yields that for $\vartheta = \vartheta^*$ asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{1}{2m}(d-\vartheta-1)+\vartheta}\log\tau\bigr) \tag{11.2.71}$$

holds as $\tau \to +\infty$ and for $\vartheta > \vartheta^*$ asymptotics

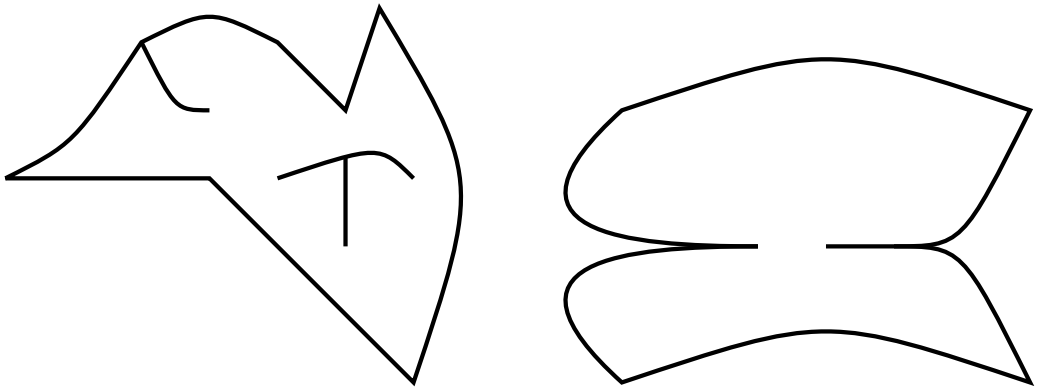
$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{1}{2m}(d-\vartheta^*-1)+\vartheta}\bigr) \tag{11.2.72}$$

holds as $\tau \to +\infty$.

Later we will show that under appropriate assumptions sharper asymptotics than (11.2.71)–(11.2.72) holds and in the latter case some extra non-Weyl term(s) associated with the singularities at $\mathcal{K}$ come into play.

Example 11.2.14 (Spikes and conjugations). Let us drop transversally condition (11.2.69) thus allowing *spikes*. Consider first spikes directed inward as on Figure 11.1(b).

[16)] Such as Dirichlet, Neumann and Robin boundary conditions, or boundary conditions which are smooth, elliptic, regular (see condition (7.1.14)) on $S_l \setminus \mathcal{K}$ and such that A is self-adjoint and $(Au,u) \ge \epsilon_0\|u\|^2_m - c\|u\|^2_0$.



(a) (b)

Figure 11.1: Conclusions of Example 11.2.13 holds despite on (b) transversally condition violated

(i) Assume first that locally only two surfaces S_k and S_l are involved and in appropriate coordinates

$$S_j = \{x_d = f_j(x'),\ x' \in X'\}, \qquad (f_j - f_i)|_{\partial X'} = 0 \tag{11.2.73}$$

where $X' \subset \mathbb{R}^{d-1}$, $x' = (x_1, \dots, x_{d-1})$, $|\nabla f_j| \le \epsilon$. Then assuming that locally $\mathsf{C}X$ is between surfaces

$$\mathsf{C}X = \{f_k(x') \le x_d \le f_l(x'),\ x' \in X'\} \cup \{f_l(x') \le x_d \le f_k(x'),\ x' \in X'\} \tag{11.2.74}$$

we conclude that $\gamma(x) \asymp \gamma(x') = \mathsf{dist}(x, \mathcal{K})$ with

$$\mathcal{K} = \{x : x' = \mathcal{K}', x_d = f_j(x')\}, \quad \mathcal{K}' = \partial X' \cup \{x', f_j(x') = f_k(x')\}. \tag{11.2.75}$$

Then condition (11.2.65) is fulfilled for $\vartheta < \vartheta^* = 1$ provided condition (11.2.70) is fulfilled. Moreover, cone condition is fulfilled as well and then all conclusions of Example 11.2.13 remain valid.

(ii) Further, the same conclusions obviously remain true as locally there is *conjugation* instead of spike

$$S_j = \{x_d = f_j(x'),\ x' \in X'_j\}, \qquad (f_j - f_k)|_{\partial X'_j \cap \partial X'_k} = 0 \quad \text{for} \quad k \ne j \tag{11.2.76}$$

as X'_j form locally a partition of the vicinity of 0 in $\mathbb{R}^{d-1}$.

(iii) Furthermore, we can consider inward spike or conjugation and add extra surfaces to ∂X assuming that each new surface is either transversal to existing surfaces or further limits $\complement X$. For example, we can consider multidimensional inward spike:

$$\complement X = \{x_1 > 0, x' \in f(x_1)X'\} \tag{11.2.77}$$

with $f > 0, f'_j > 0$ as $x_1 > 0$, $f(0) = f'(0) = 0$ and X' bounded convex quasipolygon of Example 11.2.14.

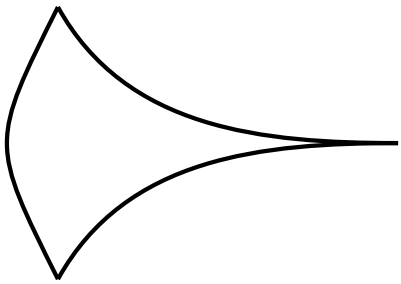


Figure 11.2: Outward spike

Example 11.2.15 (Spikes. II). Outward spike are completely different matter. Assume first that locally only two surfaces S_k and S_l are involved and in appropriate coordinates (11.2.73) and (11.2.74) are fulfilled with $\complement X$ replaced by X

$$X = \{f_k(x') < x_d < f_l(x'),\ x' \in X'\} \cup \{f_l(x') < x_d < f_k(x'),\ x' \in X'\} \tag{11.2.78}$$

as on Figure 11.2. Obviously, without any loss of the generality one can assume that $f_k = f$, $f_l = -f$ and then $\gamma_{kl} \asymp |f|$. Therefore condition (11.2.65) becomes

$$|f|^{-\vartheta} \in \mathscr{L}^1(X') \tag{11.2.79}$$

which obviously is fulfilled for $\vartheta = 0$, violated for $\vartheta \geq 1$ and may be fulfilled or not for any particular $\vartheta \in (0,1)$; f.e. as $f = f(x_1) \asymp x_1^r$ for $x_1 > 0$ ($r > 1$) this condition holds for $\vartheta < \vartheta^* = r^{-1}$ while for $f = O(x_1^\infty)$ at 0 this condition holds only for $\vartheta = 0$.

So, if (11.2.79) is fulfilled then asymptotics (11.2.56) holds for appropriate boundary conditions. Moreover, under the standard non-periodicity condition (11.1.55)–(11.1.56) to the Hamiltonian flow of the symbol $a^0(x,\xi)$ on the energy level 1 asymptotics (11.2.56)* holds.

Problem 11.2.16. (i) Derive asymptotics similar to (11.1.69) or (11.1.70) for particular functions f as condition (11.2.79) is violated.

(ii) Consider multidimensional outward spikes like one similar to (11.2.77):

$$X = \{x_1 > 0, x' \in f(x_1)X'\} \tag{11.2.80}$$

with $f > 0, f_j' > 0$ as $x_1 > 0$, $f(0) = f'(0) = 0$ and X' bounded convex quasipolygon of Example 11.2.14.

(iii) Consider the mixture of inward-outward spikes like (11.2.80) but without any convexity assumptions.

Remark 11.2.17. (i) n the case of "outward spike" the cone condition now is not ensured, so "appropriate boundary conditions" in 11.2.16(i), (ii) includes cone condition. In particular cone condition is fulfilled if at least on one side of the spike we have a Dirichlet boundary condition. There is not much known about more general conditions. Still for 2-dimensional Laplace operator with Neumann boundary condition Yu. Netrusov and Yu. Safarov [1, 2] in pretty special case derived variational estimate which allows to allow Neumann boundary condition on the whole boundary.

(ii) Later in Section 12.7 we will derive spectral asymptotics for multidimensional Neumann Laplacian and those methods could be applied in some of the examples discussed here to estimate the contribution of zone $\{x : \gamma(x) \le \tau^{-1/2}\}$ to the asymptotics thus extending corresponding results (see Subsection 12.7.8). However there will be also plenty of examples when conclusions valid for Dirichlet Laplacian are wrong for Neumann Laplacian.

In the series of examples below $\gamma(x) \asymp \mathsf{dist}(x, \mathcal{K})$ where $\mathcal{K}$ is the union of a finite number of $\mathscr{C}^K$ manifolds of codimension $\delta \ge 2$. Namely, we consider domains with conical singularities of the boundary, domains the boundaries of which contain components of codimension $\delta \in [2, 4m-1]$ [17]. Then under appropriate assumptions critical exponent is $\vartheta^* = \delta - 1$.

[17] For operators of order $2m$ a boundary operator of degree less than $2m - \frac{1}{2}\delta$ can be considered on a δ-codimensional submanifold.

Example 11.2.18 (Scheme). Let X' be a domain in $\mathbb{R}^{d'}$. Assume that

(11.2.81) X' satisfies condition (9.1.15) with γ replaced by $\gamma' = \gamma'(x')$ such that $\gamma' \le c$ and $\gamma'^{-1-\vartheta} \in \mathscr{L}^1(X')$

Let $X = \{x = (x', x''), x'' \in \mathbb{R}^{d''}, x' \in f(x'')X'\}$ [18] where the function f satisfies condition

$$|D^\alpha f| \le c f^{1-|\alpha|} \qquad \forall \alpha : |\alpha| \le K. \tag{11.2.82}$$

Then for the domain X the function

$$\gamma(x) = \epsilon \gamma'(x' f^{-1}(x'')) f(x'') \tag{11.2.83}$$

is admissible and in this case condition (11.2.65) is equivalent to

$$f^{d'-\vartheta-1} \in \mathscr{L}^1; \tag{11.2.84}$$

in particular, this condition as $\vartheta = 0$ is equivalent to the condition

(11.2.85) the $(d-1)$-dimensional measure of ∂X is finite.

Example 11.2.19 (Cusps). This scheme described in Example 11.2.18 includes cusps (exits to infinity): if $f \asymp |x''|^\nu$ with $\nu < 0$ for $|x''| \ge 1$ then the following cases are possible:

(a) Let $\vartheta < \vartheta^*$ with

$$\vartheta^* = d' - 1 - d''\nu^{-1} \iff (d' - 1 - \vartheta)\nu + d'' = 0. \tag{11.2.86}$$

Then asymptotics (11.2.56) holds.

Moreover, under standard non-periodicity condition (11.1.55)–(11.1.56) to the Hamiltonian flow of the symbol $a^0(x, \xi)$ on the energy level 1 asymptotics (11.2.56)* holds.

(b) For $\vartheta = \vartheta^*$ asymptotics with the remainder estimate $O\big(\tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta} \log \tau\big)$ holds.

[18] For $d'' = 1$ one can take only one semiaxis, i.e., replace $\mathbb{R}$ by $\mathbb{R}^\pm$.

(c) For $\vartheta > \vartheta^*$, $d'\nu + d'' < 0$, asymptotics with the remainder estimate $O\bigl(\tau^{\frac{1}{2m}(d-1-\vartheta^*)+\vartheta}\bigr)$ holds.

Moreover, if $\vartheta^* \in \mathbb{Z}^+$ then the last term of these asymptotics is of the form $\varkappa_{\vartheta,\vartheta^*+1}(\tau)\tau^{\frac{1}{2m}(d-1-\vartheta^*)+\vartheta}$ with $\varkappa_{\vartheta,\vartheta^*+1}(\tau) = O(\log\tau)$ while all other terms in this case and all terms in the other cases are of the form $\varkappa_{\vartheta,n}\tau^{\frac{1}{2m}(d-n)+\vartheta}$.

(d) If $d'\nu + d'' = 0$ then the previous statement remains true with only the term $\varkappa_{\vartheta,0}(\tau)\tau^{\frac{d}{2m}+\vartheta}$ in the principal part with $\varkappa_{\vartheta,0}(\tau) \asymp \log\tau$.

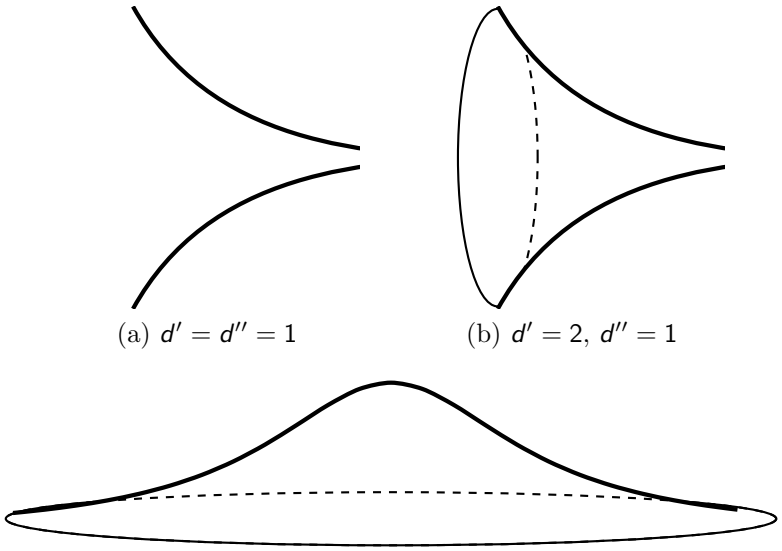

Figure 11.3: Cusps; in (c) X bounded by a drawn "infinitely wide hat" and horizontal plane

Remark 11.2.20. (i) As $d'' \geq 2$ we can consider more general cusp bases than $X'' = \mathbb{R}^{d''}$, most notably we can consider smooth consider a cone $X'' \subset \mathbb{R}^{d''}$ with a smooth boundary; rounding near $\partial X''$ here is obvious.

(ii) We treat Example 11.2.19 in Section 12.2 again and obtain non-Weyl asymptotics with a more precise remainder estimate in cases (b)–(d) and and also in the case $d'\nu + d'' > 0$. We will consider also a generalization mention above.

(iii) In Example 11.2.19 we need to assume that a Dirichlet boundary condition is given on a significant part of ∂X so the cone condition if fulfilled. For example, we can assume that the Dirichlet boundary condition is given as $x' \in Y_{\mathsf{D}} \subset \partial X'$ and the following infinite cone condition is fulfilled:

(11.2.87) there exist an infinite cone $\Gamma \subset \mathbb{R}^{d'}$ with a vertex at 0 such that for each $x' \in X'$ connected component of $(x' + \Gamma) \cap X'$ is disjoint from $\partial X' \setminus Y_{\mathsf{D}}$.

(iv) Without the assumption of (iii) (f.e. for Neumann Laplacian in domain with cusps we need to assume that the cusp is very thin: $|\log f| \asymp |x''|^{\kappa}$ with $\kappa > 0$. Otherwise massive essential spectrum appears. We treat the Neumann Laplacian in domain with "piggy-tail" cusps in Section 12.7 and derive possibly non-Weyl asymptotics.

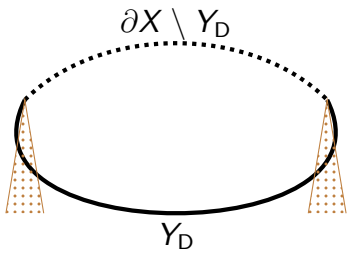

Figure 11.4: Infinite cone condition

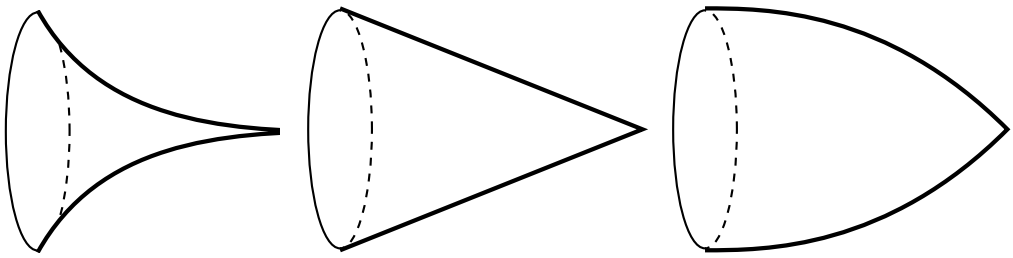
Example 11.2.21 (Conical and sharp quasiconical singularities). (i) The scheme described in Example 11.2.18 covers conical singularities as well as sharp quasiconical singularities directed outward. Namely let

$$X = \{x = (x', x''),\ x' \in |x''|^{\nu} \cdot X',\ |x''| \le 1\} \tag{11.2.88}$$

with $\nu \ge 1$; for $d'' = 1$ one can take only half of this singularity (lying in $\{x, x_1 > 0\}$ where here $x'' = (x_1)$ for $d'' = 1$)). Then we have conical and quasiconical singularities as $\nu = 1$ and $\nu > 1$ respectively. Here we use X', γ' and γ described in Example 11.2.19.

The classification coincides with that in Example 11.2.19 but in all the inequalities on the exponents "<" should be replaced by ">" and v.v., and case (d) is impossible.

(ii) If the domain X described in (i) is contained in the ball $B(0,R)$ then $\gamma(x) = \max\bigl(\gamma_{\mathsf{old}}(x)), \operatorname{dist}(x,\partial X)\bigr)$ works for the domain $\complement X$ where γ_{old} is defined as γ in (i). One can easily see that the classification given in (i) remains true. It allows us to cover sharp quasiconical singularities directed inward.



(a) acute (b) cone (c) blunt

Figure 11.5: Conical and quasiconical singularities, could be directed inward and outward

Example 11.2.22 (Blunt quasiconical singularity). (i) Let X' and γ' be as in Example 11.2.19 again, let $0 \in X'$ and let $X = \{x = (x', x''), x'' \in B(0,R), x' \in f(|x''|)X'\}$ where $f(0) = 0$ and f is a monotone decreasing function such that the inverse function f satisfies condition (11.2.82) in dimension 1. Then for $x'' \in B(0, \frac{1}{2}R)$ one can take $\gamma(x) = \epsilon|x|\gamma'(x'f^{-1}(|x''|))$. Then condition (11.2.65) fulfilled if and only if

$$f^{d'}(r)r^{-\vartheta-1+d''-1} \in \mathscr{L}^1([0,1]). \tag{11.2.89}$$

This example covers various blunt quasiconical singularities directed outward of the type $X = \{x = (x', x''), |x'| \le |x''|^\nu\}$ with $\nu \in (0,1]$.

(ii) One can replace X by $B(0,R) \setminus X$ with the γ defined above. Again condition (11.2.89) is crucial. This example covers various blunt quasiconical singularities directed inward.

Remark 11.2.23. In Examples 11.2.21 and 11.2.22 cone condition poses restrictions, especially as $\nu > 1$ in their parts (i). And again under certain assumptions we will be able to allow Neumann Laplacian (see Section 12.7).

Example 11.2.24 (Clews). We can consider domain containing "disk with an infinite cut" $r = r(\theta)$ with $\theta_0 \le \theta < \infty$ with $r(\theta) = \theta^{-\alpha}$ as $\theta \to \infty$ (we use polar coordinates here). As $\alpha \le 1$ the length of the cut is infinite.

On this cut Dirichlet boundary condition should be imposed. We leave details to the reader.

Example 11.2.25 (Combs). (i) Let

$$X = \{x = (x_1, x_2, x''), 0 < x_1 < 1,\ -1 < x_2 < f(x_1), |x''| < 1\} \tag{11.2.90}$$

where $f(x_1)$ is the jump function given by $f(x_1) = h_i = \mathsf{const} \ge 0$ for $x_1 \in I_i$ and $f(x_1) = 0$ for $x_1 \in I_\infty$ where $I_i \cap I_j = \emptyset$ for $i \ne j$, I_i with $i < \infty$ are open intervals of lengths l_i, $I_\infty = [0,1] \setminus \cup_{i<\infty} I_i$ and $\mathsf{mes}(I_\infty) = 0$.

Then the subdomain $X \cap \{x_2 > 0\}$ consists of separate "boxes" in each of which one should take γ according to scheme described in Example 11.2.18. Then for $\vartheta \in [0,1)$ the contribution of the i-th box to $\int \gamma^{-1-\vartheta} dx$ is of the order $h_i l_i^{-\vartheta} + l_i^{1-\vartheta}$.

On the other hand, on $X \cap \{x_2 \le 0\}$ one can take $\gamma(x) = \frac{1}{2}(-x_2 + \delta(x_1))$ where $\delta(x_1) = \mathsf{dist}(x_1, I_\infty)$. Then the contribution of this subdomain is of the order

$$\int |\log \delta(x_1)| dx_1 \asymp \sum_i -l_i \log l_i \qquad \text{for } \vartheta = 0,$$

$$\int \delta(x_1)^{-\vartheta} dx_1 \asymp \sum_i l_i^{1-\vartheta} \qquad \text{for } \vartheta > 0.$$

Therefore condition (11.2.65) with $\vartheta = 0$ means that

$$\sum_i h_i < \infty, \quad \sum_i -l_i \log l_i < \infty \tag{11.2.91}$$

and condition (11.2.65) with $\vartheta > 0$ means that

$$\sum_i h_i l_i^{-\vartheta} < \infty, \qquad \sum_i l_i^{1-\vartheta} < \infty. \tag{11.2.92}$$

(ii) Recall that under the cone condition, a Dirichlet boundary value problem can be replaced by an arbitrary regular boundary value problem. Recall that this condition does not mean that the cone Γ lies completely in X; we assume that the intersection of Γ with X is connected and a Dirichlet condition is given on $\Gamma \cap \partial X$.

Example 11.2.26 (Trees). One can consider example when X is a *tree*: for example it consists of cylindrical pipes $P_{i,j}$ of the lengths $l_{i,j}$ and radii r_i ($d''=1$, $d'=d-1$) where $i=1,\dots,\infty$, $j=1,\dots,J(i)$ and each pipe $P_{i,*}$ has no more than c pipes $P_{i+1,j}$ on its end. Let us assume that $l_i \ge r_i$ and $r_{i+1}\le r_i \le c r_{i+1}$ for all i.

Assume that the cross-section of pipes and conjugations are regular enough so we can select $\epsilon_0 r_i$ as γ around $P_{i,*}$. Then the total volume is finite if and only if

$$\sum_i r_i^{d-1} L_i < \infty, \tag{11.2.93}$$

and condition (11.2.65) holds if and only if

$$\sum_i r_i^{d-2-\vartheta} L_i < \infty, \tag{11.2.94}$$

where $L_i = \sum_{1\le j\le J(i)} l_{i,j}$.

These pipes are not necessarily cylindrical: we can take any bounded domain with $\mathscr{C}^K$ boundary and make $P_{i,j}$ by scaling it l_i times along $x''=(x_1)$ and r_i times along x'. These trees could be bounded as $\sum_i l_i^* < \infty$ or extended to infinity as $\sum_i l_i^* = \infty$, $l_i^* = \max_{1\le j\le J(i)} l_{i,j}$.

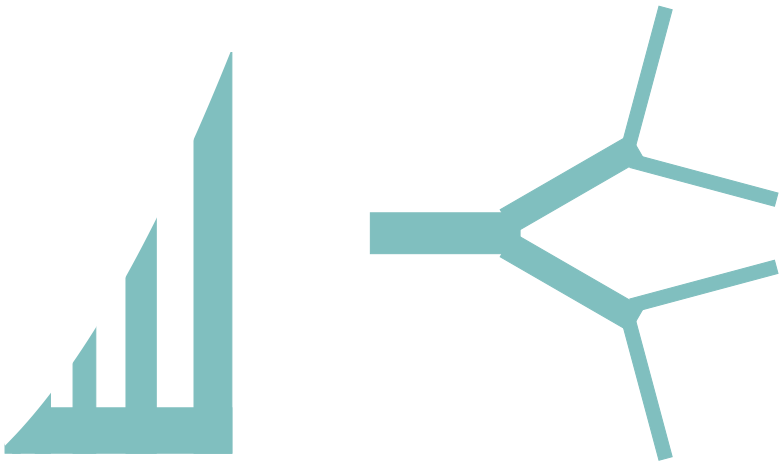
Let us discuss mixed boundary value problems assuming the cone condition is fulfilled in the indicated form.

Let the geometry of the domain (and the singularities of the coefficients of the operator A) are compatible with the scaling function $\gamma(x)=\gamma_0(x)$. Then in order to take into account the singularities of the boundary value problem we should replace $\gamma_0(x)$ by $\min(\gamma_0(x),\gamma_1(x))$ where scaling function $\gamma_1(x)$ corresponds to the singularities of the boundary value problem.

If $\gamma_0(y)\le 2\operatorname{dist}(y,\partial X)$ then one can take $\gamma(x)\asymp\gamma_0(x)$ in $\big(y,\frac{1}{3}\gamma(y)\big)$. Otherwise one can straighten ∂X in $\mathcal{B}\big(y,\frac{2}{3}\gamma(y),X\big)$ by means of a map which is uniformly smooth in the γ_0-scale with Jacobian disjoint from 0. Therefore without any loss of generality one can assume that

$$X\cap\mathcal{B}\big(y,\gamma(y),X\big) = \{x_1>0\}\cap B\big(y,\gamma(y)\big). \tag{11.2.95}$$

Then $\gamma_1(x)\asymp x_1+\gamma_1(x')$ in $X\cap\mathcal{B}\big(y,\frac{1}{2}\gamma(y),X\big)$ where here $\gamma_1(x)$ is defined only on ∂X in order to take into account the singularities of the boundary



(a) Comb (b) Tree

Figure 11.6: Comb (Example 11.2.25) and tree (Example 11.2.26) with infinite numbers of teeth and branches

value problem. Assuming that $\gamma_0^{-1-\vartheta} \in \mathscr{L}^1(X)$ we conclude that

$$\gamma_1^{-1-\vartheta} \in \mathscr{L}^1(X) \iff \begin{cases} \log \gamma_1 \in \mathscr{L}^1(\partial \mathcal{X}_{\mathsf{reg}}) & \text{for } \vartheta = 0, \\ \gamma_1^{-\vartheta} \in \mathscr{L}^1(\partial \mathcal{X}_{\mathsf{reg}}) & \text{for } \vartheta > 0 \end{cases} \tag{11.2.96}$$

where the standard surface measure is used on $\partial \mathcal{X}_{\mathsf{reg}}$. In particular, this condition is fulfilled for $\vartheta \in [0, \delta)$ as $\gamma_1(x) \geq \epsilon_0 \mathsf{dist}(x, \mathcal{K})$ where $\mathcal{K}$ is a subset of ∂X with the following property:

(11.2.97) For every $y \in \mathcal{X}_{\mathsf{reg}}$ $\mathcal{K} \cap B\big(y, \gamma_0(y), X\big)$ is contained in $\bigcup_{1 \leq l \leq L} \mathcal{K}_l$ where $\mathcal{K}_l$ (depending on y also) are uniformly $\mathscr{C}^K$ submanifolds (in the γ_0-scale) of $\partial \mathcal{X}_{\mathsf{reg}}$ of codimension δ.

This analysis provides us immediately with a series of examples for the Laplacian when on part of the boundary the Dirichlet condition is given and on the remaining part the Neumann boundary condition is given and $\vartheta < 1$.

Example 11.2.27. Let us consider a boundary value problem of variational origin with the functional

$$\mathbf{\Phi}(u) = \mathbf{\Phi}_{\mathsf{inn}}(u) + \mathbf{\Phi}_{\mathsf{bound}}(u) = \int_X \sum_{\alpha,\beta:|\alpha|\le m,|\beta|\le m} a_{\alpha,\beta}\langle a_{\alpha,\beta} D^\alpha u, D^\beta u\rangle \, dx + \int_{\partial X} \sum_{\alpha,\beta:|\alpha|\le m-1,|\beta|\le m-1} a_{\alpha,\beta}\langle b_{\alpha,\beta} D^\alpha u, D^\beta u\rangle \, dS \tag{11.2.98}$$

where dS is a standard measure at ∂X. Let us assume that the boundary terms of this functional are regular in the sense that after the rescaling $x \mapsto (x-\bar{x})\gamma(\bar{x})^{-1}$ and multiplication by $\gamma(\bar{x})^{2m-d}$ we obtain a functional the coefficients of which (and all their derivatives of order $\le K$) are bounded in $B(0,1)$. The same should be true for the boundary conditions which define $\mathfrak{D}(\mathbf{\Phi})$ but the l-th condition has its own weight $\varrho_{(l)}$ for multiplication and is given on the set $\Xi_l \subset \partial X$ $(l = 1, \dots, L)$.

Let us assume that the cone condition is fulfilled. Then $\mathcal{K}$ is the union of the relative (in ∂X) boundaries of Ξ_l. However, the possibly irregular structure of $\mathcal{K}$ prevents us from immediately applying the above arguments. Nevertheless, for $\vartheta = 0$ we avoid this difficulty by means of variational arguments. Namely, let us consider a covering of $\partial\Xi_l$ of finite multiplicity by balls $B\bigl(x^k, \epsilon\gamma(x^k)\bigr)$ lying in the $2\epsilon\gamma$-neighborhood of $\partial\Xi_l$; let $\omega_{l,\epsilon}$ be the union of these balls. Let us replace Ξ_l by $\Xi_l' = \Xi_l \cap \omega_{l,\epsilon}$ or by $\Xi_l'' = \Xi_l \setminus \omega_{l,\epsilon}$. We do the same with the set Ξ_0 where the Dirichlet boundary condition is given.

In the first case (when all the sets Ξ_l expand) the domain of $\mathbf{\Phi}$ shrinks and $\mathsf{N}^-(\tau)$ decreases, and in the second case (when all the sets Ξ_l shrink) the domain of $\mathbf{\Phi}$ expands and $\mathsf{N}^-(\tau)$ increases. Further, the cone condition remains true in both cases for small enough $\epsilon > 0$. Furthermore, in both cases the required regularity conditions are now fulfilled (because $\partial\Xi_l'$ and $\partial\Xi_l''$ intersected with ∂X_r lie in the union of spheres $S\bigl(x^k, \epsilon\gamma(x^k)\bigr)$ and every ball $B\bigl(\bar{x}, \gamma(\bar{x})\bigr)$ intersects no more than $C = C_\epsilon$ of these spheres. Therefore

$$\mathsf{N}'^-(\tau) \le \mathsf{N}^-(\tau) \le \mathsf{N}''^-(\tau) \tag{11.2.99}$$

and $\mathsf{N}'^-(\tau) = \varkappa_0 \tau^{\frac{d}{2m}} + O\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$ and the same is true for $\mathsf{N}''^-(\tau)$ with the same coefficient $\varkappa_0$ (because it does not depend on the boundary conditions).

Therefore *the same is true for the problem in question:*

$$\mathsf{N}^-(\tau) = \varkappa_0 \tau^{\frac{d}{2m}} + O\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr) \qquad \text{as } \tau \to +\infty. \tag{11.2.100}$$

Moreover, under the standard non-periodicity condition to Hamiltonian trajectories[19] asymptotics

$$\mathsf{N}'(\tau) = \varkappa_0 \tau^{\frac{d}{2m}} + \varkappa'_1 \tau^{\frac{1}{2m}(d-1)} + o\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$$

holds and the same is true for $\mathsf{N}''(\tau)$. Here $\varkappa'_1$ is a monotone non-increasing and $\varkappa''_1$ is a monotone non-decreasing function of $\epsilon \in (0, \epsilon_0)$ and $\varkappa'_1 \le \varkappa''_1$. Let us recall that the coefficient $\varkappa_1$ consists of two terms; one of them does not depend on boundary conditions and the other is an integral over ∂X_r of some function of the principal coefficients of the operator and the boundary operators. Therefore, assuming that

$$\mathsf{mes}_{\partial X}(\partial \Xi_l) = 0 \qquad \forall l = 0, \dots, L \tag{11.2.101}$$

we obtain that the limits of $\varkappa'_1$ and $\varkappa''_1$ as $\epsilon \to +\infty$ coincide and therefore the asymptotics

$$\mathsf{N}^-(\tau) = \varkappa_0 \tau^{\frac{d}{2m}} + \varkappa_1 \tau^{\frac{1}{2m}(d-1)} + o\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr) \qquad \text{as } \tau \to +\infty \tag{11.2.102}$$

holds.

Let us treat the case in which the boundary is very irregular.

Example 11.2.28. Let us assume that the operator A satisfies our conditions with $\gamma = \mathsf{const} > 0$. Then one can take $\gamma(x) = \mathsf{dist}(x, \partial X)$ in which case the remainder estimate in the asymptotics of $\mathsf{N}^-_{(\vartheta)}(\tau)$ is "O" of

$$\begin{aligned} \tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta} \int_{r \ge \tau^{\frac{1}{2m}}} r^{-1-\vartheta}\, d\mu(r) + \tau^{\frac{d}{2m}+\vartheta} \mu\bigl(\tau^{-\frac{1}{2m}}\bigr) \asymp \\ \tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta} \int_{r \ge \tau^{\frac{1}{2m}}} r^{-2-\vartheta} \mu(r)\, dr + \tau^{\frac{d}{2m}+\vartheta} \mu\bigl(\tau^{-\frac{1}{2m}}\bigr) \end{aligned} \tag{11.2.103}$$

with $\mu(r) = \mathsf{mes}(\{x \in X, \mathsf{dist}(x, \partial X) \le r\})$; we assume that $\mathsf{mes}(X) < \infty$. In particular, if $\mu(r) = O(r^\delta)$ as $r \to +0$ then for $\vartheta < \delta - 1$ [17] we obtain

[19] This condition is not associated with $\partial \Xi'_l$ or $\partial \Xi''_l$ because the $2d$-dimensional measures of points lying on trajectories issuing from these sets obviously vanish.

the remainder estimate $O\bigl(\tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta}\bigr)$; moreover, under standard non-periodicity condition to the Hamiltonian trajectories we obtain the remainder estimate $o\bigl(\tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta}\bigr)$.

On the other hand, we obtain the remainder estimate $O\bigl(\tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta}\log\tau\bigr)$ for $\vartheta = \delta - 1$ and we obtain the remainder estimate $O\bigl(\tau^{\frac{1}{2m}(d-\delta)+\vartheta}\bigr)$ for $\vartheta > \delta - 1$.

For $\vartheta = 0, \delta = 1$ and for $\vartheta = 0, \delta \in (0,1)$ we obtain the results of the papers J. Brüning [1] and J. Fleckinger, M. Lapidus [1] respectively. Finally, in these two cases under the condition $\mu(r) = o(r^\delta)$ as $r \to +0$ we obtain "o" in the remainder estimates.

Remark 11.2.29. Condition $\mu(r) = O(r^\delta)$ as $r \to +0$ means exactly that *inner Minkowski dimension of ∂X does not exceed $d - \delta$*. So called *Weyl-Berry conjecture* (in sanitized form: originally M. Berry thought about Hausdorff dimension) claims the second term $\kappa_\delta \tau^{(d-\delta)/2}$ and the remainder estimate $o(\tau^{(d-\delta)/2})$ for Dirichlet (Euclidean) Laplacian.

However, as J. Brossard and R. Carmona [1] had shown it is almost never the case as capacity enters the game (recall that Weyl conjecture is almost always true for sure for Euclidean domains and may be even always true).

11.3 Large Eigenvalues for Operators Wwith Weakly Singular Potentials (End)

11.3.1 Operators with Non-Periodic Flows

We start this subsection by discussing existence and some properties of the Hamiltonian billiard flow for second order operators.

Then we consider examples in which restrictive conditions on the Hamiltonian flow imply asymptotics with highly accurate remainder estimates (those we used to call *sharper*). $\vartheta = 0$. Here we do not treat smooth closed manifolds without boundary; the reader can find all those results in A. Volovoy [1, 2] and in the earlier papers P. Bérard [1], B. Randoll [1]. For the Laplace-Beltrami operator these statements yield the following

Example 11.3.1. (i) For the Laplace-Beltrami operator on a compact closed Riemannian $\mathscr{C}^K$ manifold of non-positive sectional curvature (for $d \ge 3$) or

without conjugate points (for $d = 2$) asymptotics of $\mathsf{N}^-(\tau)$ with remainder estimate $O\bigl(\tau^{\frac{1}{2}(d-1)}\log^{-1}\tau\bigr)$ holds.

(ii) For a certain class of surfaces of rotation and for a certain class of graded Lie algebras asymptotics of $\mathsf{N}^-(\tau)$ with the remainder estimate $O\bigl(\tau^{\frac{1}{2}(d-1-\delta)}\bigr)$ holds with $\delta > 0$.

Remark 11.3.2. In the context of our book the results on Hamiltonian flows obtained in these papers yield asymptotics for $\mathsf{N}^-_{(\vartheta)}(\tau)$ with remainder estimates $O\bigl(\tau^{\frac{1}{2}(d+\vartheta-1)}\log^{-\vartheta-1}\tau\bigr)$ and $O\bigl(\tau^{\frac{1}{2}(d+\vartheta-1-\delta)}\bigr)$ respectively.

Existence of the Billiard Flow

Let us consider the Laplace(-Beltrami) operator in compact domains or on compact manifolds with singularities. The following statement is necessary:

Theorem 11.3.3. *Let X be a bounded domain in $\mathbb{R}^d$ which is a Riemannian manifold with boundary with metric $g(x,\xi)$ satisfying conditions*

$$g^{jk} = g^{kj}, \qquad \epsilon_0|\xi|^2 \le g(x,\xi) = \sum_{jk} g^{jk}\xi_j\xi_k \le c|\xi|^2, \tag{11.3.1}$$

$$|D^\alpha g^{jk}| \le c\gamma^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le K \quad \forall j,k \tag{11.3.2}$$

and with scaling function $\gamma(x)$ such that $\gamma^{-1} \in \mathscr{L}^1(X)$.

Then there exist a set of measure 0 and also of the first Baire category $\Lambda \subset S^*\bar{X}$ and a continuous Hamiltonian flow Ψ_t on $S^*\bar{X}\setminus\Lambda$ with reflection at the boundary such that all its trajectories lie in $S^*\bar{X}_r$, $\bar{X}_{\mathsf{reg}} = \{x \in \bar{X}, \gamma(x) > 0\}$ and are transversal to ∂X; as usual $\bar{X} = X \cup \partial X$.

This flow conserves the natural measure $d\mu = dxd\xi : d\sqrt{g}$ on S^*X.

Proof. The proof coincides with the arguments of Chapter 6 in the book I. P. Cornfeld, S. V. Fomin and Y. G. Sinai, [1]. This proof follows the following scheme: first we establish that the flow where it is defined preserves measure μ.

Then we consider the set Λ_{t_1,t_2} of all points such that Ψ_t exists on time interval $[0,t_1]$ but breaks on $(t_1,t_2]$ (as $0 < t_1 < t_2$). Invariance of the measure μ implies that $\mu(\Lambda_{T,T+\varepsilon}) = \mu(\Lambda_{0,\varepsilon})$ and therefore

$$\mu(\Lambda_{0,T}) \le \mu(\Lambda_{0,\varepsilon})\lceil\frac{T}{\varepsilon}\rceil. \tag{11.3.3}$$

On the other hand, due to the bounded speed of propagation $\Lambda_{0,\varepsilon}$ is covered by $\{(x,\xi) : \gamma(x) \le C_1\varepsilon\}$ and by union of subsets

$$\big\{(x,\xi) :\ \gamma(x) \asymp \gamma \mathsf{dist}(x,\partial X) \le C_0\varepsilon\big\}$$

which trajectories have an angle less than δ with the boundary; here $\delta = \delta(\varepsilon\gamma^{-1}) = o(1)$ as $\varepsilon \to +0$, with $\gamma \ge C_1\varepsilon$.

Actually those points belong to $C_0\delta\varepsilon$-vicinity of ∂X. Obviously μ-measure of the first set does not exceed $C\,\mathsf{mes}(\{x, \gamma(x) \le C_0\varepsilon\})$ and μ-measure of the second set does not exceed $C\delta^2\varepsilon\gamma^{-1}\,\mathsf{mes}(\{x, \gamma(x) \asymp \gamma\})$.

Note that in virtue of $\gamma^{-1} \in \mathscr{L}^1$ we estimate the measure of the first set

$$\mathsf{mes}(\{x, \gamma(x) \le C_1\varepsilon\}) = o(\varepsilon) \tag{11.3.4}$$

and the measure of the second set by

$$C\int_{x:\gamma(x)\ge C_1\varepsilon} \delta^2\big(\frac{\varepsilon}{\gamma(x)}\big)\gamma^{-1}(x)\,dx = o(\varepsilon);$$

so $\mu(\Lambda_{0,\varepsilon}) = o(\varepsilon)$ as $\varepsilon \to +0$.

Combining with (11.3.3) we conclude that $\mu(\Lambda_{0,T}) = o(1)$ and thus $\mu(\Lambda_{0,T}) = 0$. Negative time direction is covered by the same way. □

Remark 11.3.4. Let us note that if we are interested only in trajectories of length not exceeding T then in the statement of this lemma one can replace Λ by a closed nowhere dense subset Λ_T. However, $S^*\bar{X} \setminus \Lambda_T$ is not invariant with respect to the flow Ψ_t.

Properties of Hamiltonian Billiard Flows and Asymptotics

Recall that to recover sharper remainder estimate we need to estimate the "divergence" of the billiard flow and its non-periodicity. The first notion is covered by the following

Definition 11.3.5. Let X be a compact γ-admissible Riemannian manifold with boundary where γ is an admissible scaling function such that $\gamma^{-1} \in \mathscr{L}^1(X)$.

We say that

(i) Ψ_t is *a power geodesic flow with reflections*is given on X if for every $T \geq 0$ there exists a closed set $\Xi_T \subset \Sigma$ with $\mu(\Xi_T) \leq CT^{-1}$ such that through every point $z \in \Sigma \backslash \Xi_T$ there passes a geodesic trajectory $\Psi_t(z) = \big(x(t), \xi(t)\big)$ with reflections from ∂X with $t \in [0, T]$ or $t \in [-T, 0]$, along which $\gamma(x(t)) \geq \varepsilon(T)$, the angle with ∂X is not less than $\varepsilon(T)$ at every point where the distance from the boundary is less than $\varepsilon(T)$, and also $|D\Psi_t| \leq \varepsilon(T)^{-1}$ where $\varepsilon(T) = T^{-L}$ with large enough C, L.

(ii) Similarly, we say that Ψ_t is *an exponential geodesic flow with reflections* if (i) holds with $\varepsilon(T) = e^{-CT}$ respectively.

We have a non-trivial *non-periodicity* condition. In order to take it into account we introduce

Definition 11.3.6. In the framework of Definition 11.3.5 we say that Ψ_t is a *non-periodic power (or exponential) geodesic flow* if in addition to the conditions of definition 11.3.5

$$\mu\big(\big\{z \in \Sigma \setminus \Xi_T, \exists t \in (0, T) : |t|^{-1}\mathsf{dist}(z, \Psi_t(z)) \leq \varepsilon(T)\big\}\big) = O(T^{-1}) \tag{11.3.5}$$

where we increase C and L in the definition of $\varepsilon(T)$ if necessary.

We conclude immediately that

Theorem 11.3.7. *(i) Let X be a domain with non-periodic power geodesic flow. Let γ_0 be scaling function describing singularities of domain and $\gamma \leq \gamma_0$ be scaling function describing singularities of operator and boundary conditions. Then as*

$$\gamma^{-1-\vartheta-\delta_1} \in \mathscr{L}^1(X) \tag{11.3.6}$$

with arbitrarily small exponent $\delta_1 > 0$, asymptotics

$$\mathsf{N}^-_{(\vartheta)} = \mathsf{N}^{\mathsf{W}}_{(\vartheta)} + O\big(\tau^{\frac{d-1-\vartheta}{2m}+\vartheta-\delta}\big) \tag{11.3.7}$$

holds with $\delta > 0$ as $\tau \to +\infty$.

(ii) Let X be a domain with non-periodic exponential geodesic flow. Let γ_0 be scaling function describing singularities of domain and $\gamma \leq \gamma_0$ be scaling

function describing singularities of operator and boundary conditions. Then as

$$\gamma^{-1-\vartheta}|\log\gamma|^{1+\vartheta}\in \mathscr{L}^1(X) \tag{11.3.8}$$

with arbitrarily small exponent $\delta_1>0$, asymptotics

$$\mathsf{N}^-_{(\vartheta)}=\mathsf{N}^{\mathsf{W}}_{(\vartheta)}+O\big(\tau^{\frac{d-1-\vartheta}{2m}+\vartheta}|\log\tau|^{-1-\vartheta}\big) \tag{11.3.9}$$

holds as $\tau\to+\infty$.

Examples

Polygons and Polyhedra Recall that according to Theorem 7.4.11 in a compact Euclidean polyhedral domain in $\mathbb{R}^d$ $|D\Psi_t(x,\xi)|\le C(|t|+1)$.

Theorem 11.3.8. *Let X be a polyhedral domain with cuts; assume that X is γ-admissible with $\gamma^{-1-\sigma}\in\mathscr{L}^1(X)$ with $\sigma>0$. Then there is a non-periodic power geodesic flow.*

Proof. Note first that

$$\mathsf{mes}\big(\big\{z=(x,\xi)\in\Sigma, \mathsf{dist}(x,\partial X)\le\varepsilon\big\}\big)\le C\varepsilon. \tag{11.3.10}$$

Let us cover set $\big\{z=(x,\xi)\in\Sigma, \mathsf{dist}(x,\partial X)\ge\varepsilon\big\}$ with no more than $C\varepsilon^{1-4d}$ balls of radius $O(\varepsilon^2)$ and let us divide the time interval $[0,T]$ into no more than $O(T\varepsilon^{-2})$ intervals of length $O(\varepsilon^2)$. Let $\varepsilon=O(T^{-L})$ with large enough exponent L.

Then if the distance between the Ψ_t-image of some ball and this ball is less than ε^2 for some t from the above subinterval then for all points (x,ξ) of this ball and for all t of this subinterval the geodesic flow is given by the formula

$$\Psi_t(x,\xi)=(y+\Pi x+t\Pi\xi,\Pi\xi)$$

with constant y and Π such that $\mathsf{dist}(\xi,\Pi\xi)\le\varepsilon$ for all ξ in question. Here $\Pi\in O(d)$ as in the proof of Theorem 7.4.11.

Taking into account that for every x the $\mathbb{S}^{d-1}$-measure of the set

$$\big\{\xi\in\mathbb{S}^{d-1}, |y+\Pi x-x+t\Pi\xi|\le\varepsilon^N \quad \text{for some } t \text{ with } |t|\ge\varepsilon\big\}$$

does not exceed $O(\varepsilon^N)$ we obtain after summation over all the balls and subintervals that (11.3.5) holds. □

Example 11.3.9. Obviously in Euclidean polyhedral domains (without cuts) $\gamma_0^{-1-\vartheta} \in \mathscr{L}^1(X)$ as $\vartheta < 1$. So the only condition to be checked is $\gamma^{-1-\vartheta} \in \mathscr{L}^1(X)$ where $\gamma = \mathsf{dist}(x, \mathcal{K})$ and $\mathcal{K}$ is the set of the cut ends and transition points. This condition is equivalent to $\gamma^{-\vartheta} \in \mathscr{L}^1(\partial X)$ as $\vartheta > 0$ and $|\log \gamma| \in \mathscr{L}^1(\partial X)$ as $\vartheta = 0$.

Elliptical Domains According to Theorem 7.4.12 in Euclidean elliptical domains (or domains between two confocal ellipses) Ψ_t is power growth geodesic flow with singularities (see (7.4.32)– (7.4.34) for more details).

Theorem 11.3.10. *Let X be a domain in $\mathbb{R}^2$ bounded by one or two confocal ellipses. Then there is a non-periodic power geodesic flow.*

Proof. Obviously (11.3.5) is equivalent to

$$\mathsf{mes}_{\Sigma'_2}\big(\big\{z' \in \Sigma'_2 : \exists k = 1, \dots, n : \mathsf{dist}(z', \Phi^k z') \le \varepsilon = n^{-M}\big\}\big) = O(n^{-\sigma}) \quad \text{as } n \to +\infty \tag{11.3.11}$$

for appropriate M and $\sigma > 0$. Recall that $\Sigma'_2 = \Sigma|_{Y_2} = B^* Y_2$ where Y_2 is an outer ellipse and we use other notations of the proof of Theorem 7.4.12.

(a) Let us first consider the zone $\{(x, \xi), \beta > 0\}$. Let us consider the lines $\{\eta = \mathsf{const}\}$. These lines are analytically parameterized by a cyclic parameter $u \in \mathbb{R}/2\pi\mathbb{Z}$ (see the proof of theorem-7.4.12)[20].

Let $w \in \mathbb{R}/\mathbb{Z}$ be a new cyclic coordinate: $w = w_\eta(u) = \nu_\eta((0, u))m_\eta^{-1}$ for $u \in [0, 2\pi]$ and then by periodicity. Here $m_\eta = \nu_\eta([0, 2\pi])$. One can easily see that $m_\eta \asymp \log|\beta|$ as $\beta \to +0$ for $a_2 > b_2$ and $m_\eta \asymp \beta^{-1}$ as $\beta \to +0$ for $a_2 = b_2$.

For every fixed η the map Φ_η of this line is analytic and preserves the measure $dw_\eta = m_\eta^{-1} d\nu_\eta$ and the orientation[21] and therefore Φ_η is a shift $\Phi_\eta : w_\eta \to w_\eta + f(\eta)$.

[20] More precisely, this line consists of two connected components. Billiard map Φ transforms every component into itself and the x-projection is an analytic diffeomorphism of this component to the ellipse Y_2. Every component is parameterized by u. Permutation of these components is equivalent to replacing Φ by Φ^{-1}.

[21] Moreover, it is well known (see I.P. Cornfeld, S. V. Fomin and Y. G. Sinai, [1]) that for generic η, Φ_η is an ergodic map.

Then in the proof of (11.3.11) for $\Sigma_2' \cap \{\beta > 0\}$ one needs to prove that

$$Cn\,\mathsf{mes}\big(\{\eta : \exists k, l = 1, \dots, n : |f(\eta) - \frac{k}{l}| \le \varepsilon = n^{-L}\}\big) = O(n^{-\sigma}) \quad \text{as } n \to +\infty \tag{11.3.12}$$

for admissible L and $\sigma > 0$; here mes means Lebesgue measure.

Obviously, $f(\eta)$ is a continuous function. One can easily prove that

$$\epsilon\beta^p \le |\frac{df}{d\eta}| \le c\beta^{-p} \qquad \text{for } |\eta| \le a_2 - \epsilon_0, \tag{11.3.13}$$

i.e., for $\beta \in (0, \beta_0)$ with small enough $\epsilon_0 > 0, \beta_0 > 0$. Recall that $\beta = b_2^2 - a_2^2 b_2^2 \eta^2$. Therefore (11.3.12) holds for the η indicated here.

On the other hand, Φ is an analytic map for $\beta \ne b_1^2$ (the case when rays are tangent to the inner ellipse Y_1). Therefore function $f(\eta)$ is analytic for $|\eta| < \eta_1 = a_2^{-1} b_2^{-1} (b_2^2 - b_1^2)^{\frac{1}{2}}$ and for $\eta_1 < |\eta| \le a_2^{-1}$. Obviously, $f(\eta)$ is not constant in each of these three intervals. One can easily see that $f_\pm(\zeta) = f(\bar\eta \pm \zeta^2)$ is an analytic function for $|\zeta| \le \epsilon_0$ and $\bar\eta = +\eta_1, -\eta_1$.

However one can easily see that

$$\mathsf{mes}(\{\zeta : |f(\zeta)| \le \varepsilon\}) = O(\varepsilon^\delta) \tag{11.3.14}$$

holds for every $\mathscr{C}^K$ function on the closed segment provided

$$\sum_{1 \le j \le K-1} |f^{(j)}| \ge \epsilon_0. \tag{11.3.15}$$

Therefore (11.3.12) holds.

(b) Let us treat the zone $\{(x, \xi) : 0 > \beta > b_2^2 - a_2^2\}$. In this case every line $\{\eta = \mathsf{const}\}$ consists of two connected components and every component is equivalent to $\mathbb{S}^1$ and the x-projection maps every component to one of two segments on the ellipse Y_2 describing by the inequality $x_2^2 \ge -\beta b_2^2 (a_2^2 - b_2^2)^{-1}$. The inverse map is two-valued.

Let us introduce on this connected component the cyclic coordinate u' which can be done in the following way: let us consider the confocal

hyperbola described by the equation $\frac{x_1^2}{a'^2} - \frac{x_2^2}{b'^2}$ with $a'^2 + b'^2 = a_2^2 - b_2^2$. This hyperbola intersects Y_2 in four points $(\bar{x}_1, \bar{x}_2)$ with

$$\bar{x}_1^2 = a_2^2(a_2^2 - b_2^2 + \beta)(a_2^2 - b_2^2)^{-1}, \quad \bar{x}_2^2 = -b_2^2\beta(a_2^2 - b_2^2)^{-1}.$$

Let us introduce parameter $u' \in \mathbb{S}^1$ on this hyperbola: $x_1 = a' \sec u'$, $x_2 = b' \tan u'$. Through every point of the hyperbola corresponding to this parameter there passes a tangent straight line hitting the corresponding segment of the ellipse. Then (x_1, x_2) is an intersection point and (ξ_1, ξ_2) is a unit vector along this tangent line, directed inside and outside for $\eta < 0$ and $\eta > 0$ respectively.

Let us introduce the parameter $w' \in \mathbb{R}/\mathbb{Z}$ in the same way as before. Again we take $dw' = m_\eta^{-1} d\nu_\eta$ with $m_\eta \asymp \log|\beta|$ as $\beta \to -0$ and $m_\eta \asymp 1$ as $\beta \to b_2^2 - a_2^2$. Moreover, in the latter case m_η is an analytic function of $\zeta' = (\beta + a_2^2 - b_2^2)^{\frac{1}{2}}$. One can easily see that if there is no inner ellipse Y_1 then Φ transforms one connected component of every line $\{\eta = \mathsf{const}\}$ to another and therefore for $\beta < -n^{-\sigma}$ the inequality $\mathsf{dist}(z', \Phi^k(z')) < \epsilon$ is impossible for odd k and the measure of the set $\{|\beta| \le n^{-\sigma}\}$ is $O(n^{-\delta})$.

On the other hand, if there is an inner ellipse Y_1 then the map Φ preserves both connected components of $\eta = \mathsf{const}$ but changes their orientations, i.e., the map is of the form $w_\eta \to \frac{1}{2}f(\eta) - w_\eta$ and therefore for odd k the $d\nu_\eta$-measure of points with $\mathsf{dist}(z', \Phi^k z') \le \varepsilon$ is $O(n^p\varepsilon)$. Therefore *in both cases only even k should be treated.*

Furthermore, on every connected component map Φ^2 is of the form $w_\eta \to w_\eta + f(\eta)$ where function f is again continuous and satisfies (11.3.13), this time for $|\eta| \ge a_2^{-1} + \epsilon_0$, i.e. $\beta \in (-\beta_0, 0)$ with small enough ϵ_0 and β_0.

This function is analytic for $a_2^{-1} < |\eta| < b_2^{-1}$, i.e., for $\beta \in (0, b_2^2 - a_2^2)$, and the functions $f(\pm(b_2^{-1} - \zeta^2))$ are analytic with respect to ζ with $|\zeta| \le \epsilon_0$. Therefore we obtain that (11.3.15) and thus (11.3.14) and (11.3.12) remain true in this case. □

Example 11.3.11. Let X be an elliptical domain or domain between two confocal ellipses. Then

(i) If the boundary problem is regular then asymptotics (11.3.7) holds for any $\vartheta \ge 0$.

(ii) We can allow singularities: transitions between different boundary value problems and cuts along some segments on semi-axis of the ellipses[22)]

Then the only condition to be checked is $\gamma^{-1-\vartheta} \in \mathscr{L}^1(X)$ where $\gamma = \mathsf{dist}(x, \mathcal{K})$ and $\mathcal{K}$ is the set of the cut ends and transition points. This condition again is equivalent to $\gamma^{-\vartheta} \in \mathscr{L}^1(\partial X)$ and $|\log \gamma| \in \mathscr{L}^1(\partial X)$ as $\vartheta = 0$.

Example 11.3.12. Let X be a ball or domain between two concentric spheres in $\mathbb{R}^d$.

Then

(i) If the boundary problem is regular then asymptotics (11.3.7) holds for any $\vartheta \geq 0$.

(ii) We can allow singularities: transitions between different boundary value problems. Then the only condition to be checked is $\gamma^{-1-\vartheta} \in \mathscr{L}^1(X)$ where $\gamma = \mathsf{dist}(x, \mathcal{K})$ and $\mathcal{K}$ is the set of the cut ends and transition points. Again, this condition is equivalent to $\gamma^{-\vartheta} \in \mathscr{L}^1(\partial X)$ for $\vartheta > 0$ and $|\log \gamma| \in \mathscr{L}^1(\partial X)$ as $\vartheta = 0$.

There are many open problems:

Problem 11.3.13. (i) Investigate domains bounded by one or two ellipses and one or two hyperbolas (all with the same foci).

(ii) Investigate domains whose boundary consists of segments of ellipses and hyperbolas (all with the same foci); investigate if one can add cuts along some segments on semi-axis.

(iii) Investigate ellipsoids of revolutions (i.e. with semi-axis $a_1 = a_2 = \dots = a_p = a > a_{p+1} = \dots = a_d = b$) or domains between two confocal ellipsoids of revolution (with the obvious meaning).

(iv) Investigate general ellipsoids.

Miscellaneous Remarks

Remark 11.3.14. Since the billiard trajectories of the principal symbol a^m coincide with those of a, all our discussion remains true for operators with the senior part Δ^m.

[22)] One can show easily that the reflection from cuts does not violate power non-periodicity.

Remark 11.3.15. (i) Billiard geodesic flow has power growth for certain Lie groups. One can easily see that in this case

$$\mu\big(\{z, \exists t \in [0, T] : \gamma(\Psi_t(z)) \le \varepsilon\}\big) \le C\varepsilon^\sigma T$$

and $\mu(\mathcal{Q}_{T,\varepsilon}) \le C\varepsilon T$ where $\mathcal{Q}_{T,\varepsilon} = \{z, \exists t \in [0, T]$ such that the distance from x to ∂X and the angle between $\frac{dx}{dt}$ and $T\partial X$ do not exceed $\epsilon\varepsilon$, and $\gamma(\Psi_t(z)) \ge \varepsilon\}$.

(ii) Billiard geodesic flow has power growth for manifolds with periodic geodesic flow (such manifolds can be either smooth or γ-admissible with $\gamma^{-1-\sigma} \in \mathscr{L}^1(X)$ for arbitrarily small $\sigma > 0$). We will analyze them in the next subsection.

(iii)

(iv) Recall that according to Theorem 7.4.10 in Euclidean strongly convex domains with $\mathscr{C}^3$-boundary geodesic billiard flow has (no more than) exponential growth. The same is true for compact Riemannian manifolds with geodesically strongly concave boundary and for compact closed Riemannian manifolds.

Remark 11.3.16. One can construct new manifolds of the corresponding type by the following methods:

(a) Taking a Cartesian product.

(b) Taking a factor manifold of X with respect to a finite group of its isometries.

(c) Considering reflections, i.e., metric preserving diffeomorphisms $S : \bar{X} \to \bar{X}$ such that $S^2 = Id$ and $S(x) = x \implies dS(x) \ne dx$ (X can have cuts so S does not necessarily preserve X) and removing from X some appropriate subset K of the set of fixed points of S. The condition on K is $\delta^{-1-\sigma} \in \mathscr{L}^1(X)$ for $\delta(x) = \mathsf{dist}(x, K)$.

Remark 11.3.17. (i) Let us note that $\mathsf{dist}(z, \Psi_t(z)) \asymp |t|$ for $|t| \le \epsilon\gamma(x)$, $z = (x, \xi)$. Therefore the non-periodicity condition should be checked only for $|t| \ge \epsilon\varepsilon(T)$.

(ii) Let us consider the Cartesian product X of two Riemannian manifolds X' and X'' with dimensions ≥ 1. Let us note that $\Psi_t(x', x'', \xi', \xi'') = (\Psi'_{t|\xi'|}(x', \xi'), \Psi''_{t|\xi''|}(x', \xi''))$ for $(x', x'', \xi', \xi'') \in S^*X$.

Then, if inequality $\mathsf{dist}(z', \Psi_t(z')) \geq \varepsilon|t|$ is fulfilled for all $t \in (0, T)$ for a point $z' = (x', \xi'_0) \in S^*X'$ then the same inequality with ε^2 instead of ε is fulfilled for a point $(x', x'', \xi', \xi'') \in S^*X$ with $\xi' = |\xi'|\xi'_0$ and $|\xi'| \geq \varepsilon$.

Note that $\mu\{(x, \xi) : |\xi'| \leq \varepsilon = O(\varepsilon)$. Therefore one should treat only points $(x', x'', \xi', \xi'') \in S^*X$ such that the non-periodicity condition is violated at both points $z' = (x', \xi'|\xi'|^{-1}) \in S^*X'$ and $z'' = (x'', \xi''|\xi''|^{-1}) \in S^*X''$. Let

$$T' = \mathsf{min}\big(t \geq \epsilon\varepsilon : \mathsf{dist}(z', \Psi'_t(z')) \leq \varepsilon\big)$$

and let define T'' in a similar way. Recall that we can assume that $|\xi'| \geq \varepsilon$ and $|\xi''| \geq \varepsilon$. Then taking into account condition on the Jacobi matrix we obtain that $\mathsf{dist}(\Psi'_t(z'), z') \geq \varepsilon^2$ provided $|\frac{t}{T'} - m| \geq \varepsilon\ \forall m \in \mathbb{Z}$ and $|t| \leq T$ (where $\varepsilon = \varepsilon(T)$. Therefore one needs to estimate the measure of the set

$$\mathcal{Q} = \big\{\phi \in \mathbb{S}^1 : \exists m', m'' \in \mathbb{Z} : \\ |m'| \leq \varepsilon^{-\sigma}, |m''| \leq \varepsilon^{-\sigma}, |m'T' \cos\phi + m''T'' \sin\phi| \leq \varepsilon\big\}$$

where ϕ is associated with ξ by the relations $|\xi'| = \cos\phi$, $|\xi''| = \sin\phi$ and one can take $\sigma > 0$ arbitrarily small. However, $\mathsf{mes}(\mathcal{Q}) = O(\varepsilon^\sigma)$ obviously.

Therefore for Cartesian products the non-periodicity condition always is fulfilled.

(iii) The above arguments also yield that $\mathsf{dist}(G^*z, \Psi_t(z)) \leq \varepsilon^2$ implies that $\mathsf{dist}(G^{*k}z, \Psi_{kt}(z)) \leq \varepsilon$ for constant k and the isometry $G^* : S^*\bar{X} \to S^*\bar{X}$ induced by the isometry $G : \bar{X} \to \bar{X}$. Therefore Definition 11.3.6 is stable under the above constructions of new manifolds in Remark 11.3.16(b) and (c) .

11.3.2 Operators with Periodic Flows

Regular Operators on Closed Manifolds

Let us now consider a closed manifold X and a scalar operator A on X with periodic Hamiltonian trajectories of the principal symbol. As before we assume that the manifold and operator are smooth enough; furthermore,

as before we divide the operator A by τ, introduce $h = \tau^{-\frac{1}{2m}}$ and obtain an h-pseudodifferential operator. Then if all the Hamiltonian trajectories on the energy level $\Sigma = \{a(x,\xi) = 1\}$ are periodic with period T_0 then every trajectory is T-periodic with $T(x,\xi) = T_0 a^{\frac{1}{2m}-1}(x,\xi)$ and then the Hamiltonian flow of the symbol $a^{\frac{1}{2m}}$ is $2mT_0$-periodic.

Without any loss of the generality we assume that $2mT_0 = 1$. According to Section 6.2 we must replace operator A by operator $\bar{A} = (\tau^{-1}A)^{\frac{1}{2m}}$ (one should use this formula only in a neighborhood of Σ).

Then conditions (6.2.2), (6.2.4) and (6.2.7) with $T_0 = 1$ are fulfilled with $\Omega_0 \supset \Sigma$. Calculating the action by formula (6.2.6) we obtain that $\alpha_1 = 0$ because symbol $\bar{a}$ is positively homogeneous of degree 1 on ξ. In what follows all the objects related to the operator $\bar{A}$ are denoted by the same letters as the corresponding objects related to A but equipped with a bar. Then according to (6.2.12)

$$b_0(x,\xi) = \frac{1}{2mT_0}\int_0^{T_0} (a^s \circ \Psi_t)(x,\xi)\,dt - \frac{\pi\alpha_0}{2} \qquad \text{on } \Sigma \tag{11.3.16}$$

and is positively homogeneous of degree 0 on ξ in a neighborhood of Σ. Here α_0 is the Maslov index.

Then results of Subsubsection *6.2.3.3 Spectral Gaps (the First Attempt)* and Subsection 6.4 yield

Theorem 11.3.18. *Let X be a closed compact $\mathscr{C}^K$ manifold and A an elliptic self-adjoint differential operator*[23)] *of order $2m$. Let the Hamiltonian flow of $a(x,\xi)$ be T_0-periodic on Σ.*

Let $\mathcal{L}$ be the image of the map $\Sigma \ni (x,\xi) \to b(x,\xi) \overset{\iota}{\to} \mathbb{R}/\mu\mathbb{Z}$ where $\mu = \pi(mT_0)^{-1}$ and $\iota : \mathbb{R} \to \mathbb{R}/\mu\mathbb{Z}$ is a natural map. Assume $\mathcal{L}$ does not coincide with $\mathbb{R}/\mu\mathbb{Z}$; then $\iota^{-1}\mathcal{L}$ is a union of intervals $\{I_n\}$ of length $O(1)$ such that $\omega \in I_n \implies |\omega| \asymp n$ for $|n| \ge 1$.

It follows that

$$\mathsf{Spec}(A^{\frac{1}{2m}}) \subset \bigcup_{n\ge 1} J_n \cup [-C, C] \tag{11.3.17}$$

where J_n are the $Cn^{\delta-1}$-neighborhoods of I_n, $\delta > 0$ is arbitrarily small and $C = C_\delta$; without loss of generality we assume that $A \ge I$.

Moreover, for $b_0 = \mathsf{const}$ one can take $\delta = 0$.

[23)] Or a classical pseudodifferential operator. In all cases we assume that $a \ge 0$.

Theorems 6.3.6 and 6.3.12 yield then

Theorem 11.3.19. *Let the conditions of Theorem 11.3.18 be fulfilled and let* $\omega_0 \in \mathcal{L}$,

$$(x,\xi) \in \Sigma,\ b_0(x,\xi) = \omega_0 \implies \text{either } \nabla_\Sigma b_0(x,\xi) \neq 0 \text{ or } \operatorname{rank} \operatorname{Hess}_\Sigma b_0(x,\xi) \geq r. \tag{11.3.18}$$

Further, let us assume that <u>*either*</u> *the Hamiltonian flow* Ψ_t *has no subperiodic trajectory on* Σ <u>*or*</u>

$$\operatorname{dist}\big(\Psi_t(x,\xi),(x,\xi)\big) \geq t(T_0 - t)\rho(x,\xi) \qquad \forall t \in (0, T_0)\ (x,\xi) \in \Sigma \tag{11.3.19}$$

where

$$|\nabla \rho| \leq c \quad \text{and} \quad \mu\big\{(x,\xi), \rho(x,\xi) \leq h\big\} = O(h^q) \quad \text{as } h \to +0. \tag{11.3.20}$$

Then for $\tau \to +\infty$ *such that* $|\iota \tau^{\frac{1}{2m}} - \omega_0| \leq \epsilon_0$ *(where* $\epsilon_0 > 0$ *is small enough) asymptotics*

$$\mathsf{N}^-(\tau) = \varkappa_0 \tau^{\frac{d}{2m}} + \big(\varkappa_1 + F(\tau^{\frac{1}{2m}})\big)\tau^{\frac{d-1}{2m}} + O\big(\tau^{\frac{d-1-p}{2m}}\big) \tag{11.3.21}$$

holds with

$$F(z) = (2mT_0)^{-1}(2\pi)^{-d} \int_\Sigma \Upsilon\Big(2mT_0\big(z - b(x,\xi)\big)\Big)\, dx d\xi : da, \tag{11.3.22}$$

$p = \min(1, \frac{r}{2} - \delta, \frac{q}{2} - \delta)$ *with an arbitrary small exponent* $\delta > 0$. *Here and below* $\Upsilon(z)$ *is a* 2π*-periodic function on* $\mathbb{R}$ *equal to* $\pi - z$ *on* $[0, 2\pi)$.

The following should be rather easy:

Problem 11.3.20. (i) Show that for generic differential and pseudodifferential symbols a^s condition (11.3.18) is fulfilled with $r = 2d - 2$ for all ω_0. In fact the function $b_0(x,\xi)$ is given *on* $\Sigma' = \Sigma/\Psi_t$ (the factor of Σ with respect to the Hamiltonian flow) which is a $2d-2$-dimensional manifold *rather than on* Σ.

(ii) Derive more precise asymptotics are possible as well and improved asymptotics of $\mathsf{N}^-_{(\vartheta)}(\tau)$ with remainder estimates which could be as good as $O(\tau^{(d-2-2\vartheta)/2m})$ (under an appropriate non-degeneracy condition).

Surely, Theorem 11.3.19 is applicable to a Laplace-Beltrami operator on a Riemannian manifold with periodic geodesic flow which is perturbed by a first-order operator. For a generic vector $(V_1, \dots, V_d)$ the field corresponding to the perturbation condition (11.3.18) is fulfilled with $r = 2d - 2$.

In particular, for the Laplace-Beltrami operator on the standard sphere $\mathbb{S}^d$ one can see easily that $\alpha_0 \equiv 2(d-1) \mod 4\mathbb{Z}$ and $T_0 = \pi$. Let us consider this operator with perturbation more carefully. Let $j : \mathbb{S}^d \to \mathbb{S}^d$ be the antipodal map $x \to -x$ and let $j^* : S^*\mathbb{S}^d \to S^*\mathbb{S}^d$ be the adjoint map $(x,\xi) \to (-x,-\xi)$. Then (11.3.16) yields that b_0 depends only on the even part of a^s: $a^s_{\mathsf{even}} = \frac{1}{2}(a^s + a^s \circ j^*)$. Let us now assume that a^s is skew-symmetric with respect to j^*:

$$a^s = -a^s \circ j^*. \tag{11.3.23}$$

Then $b_0 = 0$ and B is a (-1)-order operator (i.e., $\eta = h = \tau^{-\frac{1}{2}}$: see Section 6.2). Let us calculate then the principal symbol b_{-1} of the operator B. Given that the eigenvalues of unperturbed Laplace-Beltrami A_0 on $\mathbb{S}^d$ are $n(n+d-1)$ with $n \in \mathbb{Z}^+$ it will be more convenient for us to set

$$\bar{A} = h\Big(\big(A + \frac{1}{4}(d-1)^2\big)^{\frac{1}{2}} - \frac{1}{2}(d-1)\Big) \tag{11.3.24}$$

here instead of $\bar{A} = A^{\frac{1}{2}}$. Let

$$\bar{A}_0 = h\Big(\big(A_0 + \frac{1}{4}(d-1)^2\big)^{\frac{1}{2}} - \frac{1}{2}(d-1)\Big) \tag{11.3.25}$$

be the corresponding unperturbed operator.

Let $U(t) = \exp(ih^{-1}t\bar{A})$ and $U_0(t) = \exp(ih^{-1}t\bar{A}_0)$. Then

$$U_0(2\pi) = I, \qquad U_0(\pi) = J \quad \text{where} \quad Jv = v \circ j. \tag{11.3.26}$$

So *we want to calculate* $U(2\pi)$ *modulo operators of order* (-2) because near Σ the orders in the sense of standard pseudodifferential operators and in the sense of h-pseudodifferential operators coincide. Let us calculate $U(\pi)J$ modulo operators of order (-1) first. To do it we consider $V(t) = U(t)U_0(-t)$ which is a standard (h-)pseudodifferential operator. Then

$$\frac{d}{dt}V(t) = ih^{-1}U(t)(\bar{A} - \bar{A}_0)U_0(-t) = iV(t)U_0(t)QU_0(-t)$$

where $Q = h^{-1}(\bar{A} - \bar{A}_0)$ is an operator of order 0. Considering principal symbols we obtain that $\partial_t v = iv(b \circ \Psi_t)$. Since $v|_{t=0} = 1$ we obtain that

$$v(t) = \exp(-i \int_0^t I \circ \Psi_{t'}\, dt')$$

where $q = \frac{1}{2} a^s a^{-\frac{1}{2}}$ is the principal symbol of Q. Therefore (11.3.26) yields that

(11.3.27) $U(\pi)J$ is an h-pseudodifferential operator with the principal symbol $\exp(i\zeta \cdot \int_0^\pi q \circ \Psi_t\, dt)$

with $\zeta = 1$.

Let us consider operator $\bar{A}_\zeta = \bar{A}_0 + \zeta h Q$ and let us consider the corresponding unitary group $U_\zeta(t)$. Differentiating equalities

$$(hD_t - \bar{A}_\zeta)U_\zeta(t) = 0, \qquad U_\zeta(0) = I$$

with respect to ζ we obtain that

$$(hD_t - \bar{A}_\zeta)U'_\zeta(t) = hQU_\zeta, \qquad U'_\zeta(0) = 0$$

where the prime means the derivative with respect to ζ. Then

$$U'_\zeta(t) = i \int_0^t U_\zeta(t - t')QU_\zeta(t')\, dt'.$$

Let us set $t = 2\pi$ and divide interval $[0, 2\pi]$ of integration into subintervals $[0, \pi]$ and $[\pi, 2\pi]$ and replace t' by t in the first subinterval and by $t + \pi$ in the second one. We obtain that

$$U'_\zeta(2\pi) = iU_\zeta(2\pi) \int_0^\pi U_\zeta(-t)\tilde{Q}U_\zeta(t)\, dt \tag{11.3.28}$$

with $\tilde{Q} = Q + U_\zeta(-\pi)QU_\zeta(\pi)$. We know that $U_\zeta(\pi) = V_\zeta J$ and $U_\zeta(-\pi) = JV_\zeta^*$ where V_ζ is a unitary operator. Therefore

$$\tilde{Q} = Q + JQJ + JV_\zeta^*[Q, V_\zeta]J.$$

Then (11.3.23) yields that $\tilde{Q}$ is an operator of order (-1) with the principal symbol

$$\tilde{q} = 2q_{\mathrm{even}} + \zeta\{q, \int_0^\pi q \circ \Psi_{t'}\, dt'\}$$

where q_{even} is the even (with respect to j^*) part of q^s and the second term is also even. Therefore (11.3.28) yields that $-iU_\zeta(-2\pi)U'_\zeta(2\pi)$ is an operator of order (-1) with principal symbol

$$\int_0^\pi \tilde{q}\circ\Psi_{-t}\,dt = \int_0^{2\pi} q^s\circ\Psi_t\,dt + \zeta\int_0^\pi\int_0^\pi \{q\circ\Psi_t, q\circ\Psi_{t+t'}\}\,dtdt'$$

where we changed variables in the integration in the obvious way. Integrating over $\zeta\in[0,1]$ we obtain that

(11.3.29) $U(2\pi)-I$ is an operator of order (-1) with principal symbol $2\pi i b_{-1}$ where

$$b_{-1} = \frac{1}{2\pi}\Big(\int_0^{2\pi} q^s\Psi_t dt + \int_0^\pi\int_0^\pi \{q\circ\Psi_t, q\circ\Psi_{t+t'}\}\,dtdt'\Big). \tag{11.3.30}$$

Now theorems 6.3.6 and 6.3.12 yield

Theorem 11.3.21. *Let $A=\Delta+A'+A''$ where Δ is the (positive) Laplace-Beltrami operator on the standard sphere $\mathbb{S}^d$, $A'=A'(x,D)$ and $A''=A''(x,D)$ are symmetric operators of first and zero order respectively and A' anti-commutes with J (in which case a^s satisfies* (11.3.23)*). Let $b_{-1}(x,\xi)$ be defined by* (11.3.30) *with $q=\frac12 a' a^{-\frac12}$, $q^s=\frac12 a'' a^{-\frac12}-\frac18 a'^2 a^{-\frac32}$ where a' and a'' are the principal symbols of A' and A'' respectively.*

Let $\mathcal{L}'=[\lambda_1,\lambda_2]$ be the image of the map $\Sigma\ni(x,\xi)\to b_{-1}(x,\xi)\in\mathbb{R}$ and let $f(\tau)=\big(\tau+\frac14(d-1)^2\big)^{\frac12}-\frac12(d-1)$. Then

(i) $f(\operatorname{Spec} A)\subset\bigcup_{n\ge1} J'_n\cup[-C,C]$ where

$$J'_n=\big[n+\lambda_1 n^{-1}-Cn^{\delta-2}, n+\lambda_2 n^{-1}+Cn^{\delta-2}\big], \tag{11.3.31}$$

$C=C(\delta)$ is large enough, $\delta>0$ is arbitrarily small and for $\lambda_1=\lambda_2$ one can take $\delta=0$.

(ii) Let $\omega_1\in\mathcal{L}'$ and condition (11.3.18) *be fulfilled with ω_1 and b_{-1} instead of ω_0 and b_0. Then for $\tau\to+\infty$ such that*

$$f(\tau)\subset\bigcup_{n\ge1}[n+(\omega_1-\epsilon)\frac{1}{n}, n+(\omega_1+\epsilon)\frac{1}{n}]$$

with a sufficiently small constant $\epsilon > 0$ *asymptotics*

$$\mathsf{N}^-(\tau) = \varkappa_0 \tau^{\frac{d}{2}} + \varkappa_1 \tau^{\frac{d-1}{2}} + F\bigl(f(\tau), \tau\bigr)\tau^{\frac{d-1}{2}} + O\bigl(\tau^{\frac{d-1-p}{2}}\bigr) \tag{11.3.32}$$

holds with $p = \mathsf{min}(1, \frac{r}{2} - \delta)$ *with an arbitrarily small exponent* $\delta > 0$ *and with*

$$F(z,\tau) = 2(2\pi)^{-d-1} \int_{\Sigma} \Upsilon\Bigl(2\pi\bigl(z - \tau^{-\frac{1}{2}} b_{-1}(x,\xi)\bigr)\Bigr)\, dxd\xi : da. \tag{11.3.33}$$

The following seems to be easy:

Problem 11.3.22. (i) Prove that for an arbitrary fixed symbol a'' and for a generic differential symbol (i.e., vector field) as well as for a generic pseudodifferential symbol a' satisfying (11.3.23) the modified[24)] condition (11.3.18) is fulfilled with $r = 2d - 2$ for all $\omega_1 \in \mathbb{R}$.

(ii) Prove that the same is true for an arbitrary fixed a'' satisfying (11.3.23) and for a generic differential symbol (i.e., potential) as well as for a generic pseudodifferential symbol a''.

Let us now assume that

$$a' = 0, \quad a'' \circ j^* = -a''. \tag{11.3.34}$$

Then $b_{-1} = 0$ and the operator $U(2\pi) - I$ obviously is an operator of order ≤ -2 (we will prove that its order is actually (-3)) and our goal is to calculate its principal symbol. Now the calculations are simpler because the perturbation is weaker. Let $\bar{A}$ and $\bar{A}_0$ be defined as above. Then $\bar{A} = \bar{A}_0 + Q' + Q''$ [25)] where Q' is an operator of order (-1) with principal symbol $q' = -\frac{1}{2} a^{-\frac{1}{2}} a''$ anti-commuting with J and Q'' is an operator of order (-3) with principal symbol $q'' = -\frac{1}{8} a^{-\frac{3}{2}} a''^2$ [26)]. Then the equalities

$$(D_t - \bar{A}_0)U(t) = QU(t), \qquad U(0) = I$$

[24)] I.e., with ω_1, b_{-1} instead of ω_0, b_0.

[25)] For the sake of simplicity we do not write the factor $\tau^{-\frac{1}{2}}$ which in any case is reduced in the final formula.

[26)] In contrast with the above case we did not include a lower order operator commuting with J in A because we are mainly interested in differential operators. This generalization is left to the reader.

with $Q = Q' + Q''$ yield that

$$U(t) = U_0(t) + i \int_0^t U(t-t')QU(t')\,dt'$$

(this is similar to the calculation of V). After iteration we obtain $U(t)$ as an asymptotic series of operators with order decreasing by step 1. Let us set $t = 2\pi$. We then obtain that modulo operators of order (-4)

$$U(t) \equiv I + i\int_0^{2\pi} Q(t_1)\,dt_1 - \iint_{\Pi_2} Q(t_1)Q(t_2)\,dt_1dt_2 - i\iiint_{\Pi_3} Q(t_1)Q(t_2)Q(t_3)\,dt_1dt_2dt_3 \tag{11.3.35}$$

with $\Pi_k = \{t = (t_1, \dots, t_k) \in \mathbb{R}^k, 0 \le t_1 \le \dots \le t_k \le 2\pi\}$ and $Q(t) = U_0(-t)QU_0(t)$. Moreover, in the third and fourth terms we can replace Q by Q'.

Dividing the interval of integration in the second term into subintervals $[0,\pi]$ and $[\pi, 2\pi]$ and replacing t_1 by t and $t+\pi$ on these subintervals respectively we obtain that this term is a pseudodifferential operator with principal symbol $i\int_0^{2\pi} q'' \circ \Psi_t\,dt$.

The third term in the right-hand expression is equal to

$$-\frac{1}{2}\iint_{\Pi_2} \big(Q(t_1)Q(t_2) + Q(t_2)Q(t_1)\big)\,dt_1dt_2 - \frac{1}{2}\iint_{\Pi_2} [Q(t_1), Q(t_2)]\,dt_1dt_2.$$

The first term here equals half of $-Q(t_1)Q(t_2)$ integrated over the square $(t_1, t_2) \in [0, 2\pi]^2$; therefore it is equal to $-\frac{1}{2}(\int_0^{2\pi} Q(t)dt)^2$ and therefore is negligible as its principal symbol is 0.

The second term is an operator of order (-3) and after simple calculations we obtain that its principal symbol is

$$i\int_0^{\pi}\int_0^{\pi} \{q\circ\Psi_t, q\circ\Phi_{t+t'}\}\,dtdt'.$$

Finally, the third term in (11.3.35) is obviously an operator of order (-3). Making permutations of (t_1, t_2, t_3) and summing we obtain that modulo an operator of order (-4) this term is one-sixth of $Q(t_1)Q(t_2)Q(t_3)$ integrated over the cube $[0, 2\pi]^3$ and is therefore negligible.

Thus,

(11.3.36) $(U(2\pi)-I)$ is an operator of order (-3) with the principal symbol $2\pi i b_{-3}(x,\xi)$ where b_{-3} is given by (11.3.30) with $q' = \frac{1}{2}a''a^{-\frac{1}{2}}$ and $q'' = -\frac{1}{8}a''^2a^{-\frac{3}{2}}$ instead of q and q^s respectively.

Therefore Theorem 6.2.3 yields

Theorem 11.3.23. *Suppose that conditions of Theorem 11.3.21 and condition* (11.3.34) *are fulfilled. Let $\mathcal{L}'' = [\lambda_1, \lambda_2]$ be the image of the map $\Sigma \ni (x,\xi) \to b_{-3}(x,\xi) \in \mathbb{R}$. Then*

(i) $f(\operatorname{Spec} A) \subset \bigcup_{n\ge 1} J''_n \cup [-C, C]$ *where*

$$J''_n = \big[n + \lambda_1 n^{-3} - Cn^{\delta-4}, n + \lambda_2 n^{-3} + Cn^{\delta-4}\big], \tag{11.3.37}$$

$C = C(\delta)$ *is small enough,* $\delta > 0$ *is arbitrarily small and for* $\lambda_1 = \lambda_2$ *one can take* $\delta = 0$.

(ii) Let $\omega_2 \in \mathcal{L}''$ *and condition* (11.3.18) *be fulfilled with* ω_2 *and* b_{-3} *instead of* ω_0 *and* b_0. *Then for* $\tau \to +\infty$ *such that*

$$f(\tau) \subset \bigcup_{n\ge 1} [n + (\omega_2 - \epsilon)n^{-3}, n + (\omega_2 + \epsilon)n^{-3}]$$

with a sufficiently small constant $\epsilon > 0$ *asymptotics* (11.3.32) *holds with the same* p *as above and with*

$$F(z,\tau) = 2(2\pi)^{-d-1} \int_\Sigma \Upsilon\Big(2\pi\big(z - \tau^{-\frac{3}{4}} b_{-3}(x,\xi)\big)\Big)\, dxd\xi : da. \tag{11.3.38}$$

We leave to the reader

Problem 11.3.24. (i) Prove that for a generic differential symbol (i.e., potential) as well as for a generic pseudodifferential symbol a'' satisfying (11.3.34) the modified[27] condition (11.3.18) is fulfilled with $r = 2d-2$ for all $\omega_2 \in \mathbb{R}$.

(ii) Thus, in all the above cases for generic perturbations the remainder estimate is $O\big(\tau^{\frac{d-2}{2}}\big)$ for $d \ge 3$ and $O\big(\tau^{\frac{1}{2}(d-2+\delta)}\big)$ with an arbitrarily small exponent $\delta > 0$ for $d = 2$. Applying the more precise results of Section 6.2 we obtain that for $d = 2$ the remainder estimate is $O(1)$ if the principal symbol b has no saddle points at the corresponding level and $O(\log \tau)$ otherwise.

[27] I.e., with ω_2, b_{-3} instead of ω_0, b_0.

(iii) Derive the remainder estimate $O(1)$ in the latter case as well by including in the principal symbol the next symbol too (as we have seen it does not necessarily vanish even if the principal symbol vanishes identically).

(iv) Consider Riesz means asymptotics to the reader. Recall that the best possible remainder estimate is $O\bigl(\tau^{\frac{1}{2}(d-1-n\vartheta)}\bigr)$ where $n = 0, 1, 3$ is the order of B taken with the opposite sign.

11.3.3 Singular operators on Closed Manifolds

Let us now consider the singular case when not only an operator but also a manifold itself has singularities. Singularities are described by scaling function $\gamma(x)$:

Definition 11.3.25. (i) Let X be a Riemannian manifold (with or without boundary) such that $\bar{X}$ a closure of X in the Riemannian metrics is compact. Then we call X *singular compact Riemannian manifold*.

(ii) If the regular part of the boundary is empty, we call X *singular compact closed Riemannian manifold*.

(iii) Let γ be a scaling function on $\bar{X}$, such that $|\gamma(x,y) \le \frac{1}{2}\mathsf{dist}(x,y)$, $\partial X = \{x, \gamma(x) = 0\}$, $X = \{x, \gamma(x) > 0\}$ and let metrics on X be γ-admissible. Then we call X (singular) *γ-admissible compact Riemannian manifold*.

However we will need also a γ-admissible function $\zeta(x,\xi)$ describing how close trajectory $\Psi_t(x,\xi)$ can approach $\{\gamma = 0\}$ (see condition (11.3.39) below):

Theorem 11.3.26. *Let X be a γ-admissible compact closed Riemannian manifold, A a scalar elliptic γ-admissible operator of order $2m$ with the lower order terms satisfying the standard conditions of this section. Let us assume that $\gamma^{-1-\delta} \in \mathscr{L}^1(X)$ with $\delta > 0$.*

Further, let us assume that the Hamiltonian flow of $\mathsf{a}(x,\xi)$ is T_0-periodic on Σ. Furthermore, let us assume that a γ-admissible bounded function ζ is given on Σ such that

$$|D\Psi_t(z)| \le C\zeta^{-n}(z), \quad \gamma(\Psi_t(z)) \ge \epsilon\zeta^n(z) \qquad \forall z \in \Sigma \quad \forall t. \tag{11.3.39}$$

Finally, let us assume that conditions (11.3.18) *with* $r \ge 1$ *(for some fixed* ω_0*) and* (11.3.19)–(11.3.20) *(which is condition to subperiodic trajectories) with* $q > 0$ *are fulfilled.*

Then for $\tau \to +\infty$ *such that* $|\iota\tau^{\frac{1}{2m}} - \omega_0| \le \epsilon$ *asymptotics* (11.3.21) *holds with sufficiently small exponent* $p > 0$.

Proof. Dividing Σ into the zones $\{\zeta \ge \frac{1}{2}\tau^{-\delta}\}$ and $\{\zeta \le \tau^{-\delta}\}$ we can apply results of Section 6.2 in the former zone and the standard asymptotics in the latter one. □

Problem 11.3.27. We derived asymptotics which is marginally better than the standard one only as $\vartheta \le p$. The problem which is definitely rather difficult and very interesting is to derive asymptotics with the better remainder estimates; ideally one should derive asymptotics with the remainder estimates which are as good as in the regular case (surely one needs to impose more restricting conditions).

Example 11.3.28. (i) Consider *Zoll-Tannery manifold* with the rotational symmetry (see Example 8.3.9(iii). Recall that these manifolds are isometric (up to a factor) to a sphere $\mathbb{S}^d$ with the metrics $(r+h(\cos(s)))^2\, ds^2+\sin^2(s)\, d\theta^2$ with $s \in [0,\pi]$, $r = p/q$, $p, q \in \mathbb{N}$, $\gcd(p,q) = 1$ and odd function $h : (-1,1) \to (-r,r)$. Then the length of equator is 2π, the length of meridian $2\pi r$ and the length of general geodesics $2\pi p$. See A. Besse [1], Theorem 4.13.

Then $T_0 = 2\pi q$. Therefore one can take $A = \Delta^m$ (plus lower order terms) where Δ is the Laplace-Beltrami operator; these lower order terms must satisfy the standard assumptions of this section and also provide condition (11.3.12) with $p \ge 1$. Singularities (if there are any) are located at $s = 0, \pi$.

However these singularities do not prevent us from recovering remainder estimate $O(\tau^{(d-2)/2m})$ as long as non-degeneracy condition to the lower order terms is fulfilled. This asymptotics contains non-Weyl correction term.

(ii) Consider the same example replace rational r by irrational r; then we are basically in the framework of the Subsection 11.3.1 and can recover remainder estimate $O(\tau^{(d-1)/2m-\delta})$ without any condition to the lower order terms.

Repeating the arguments of Theorems 11.3.21 and 11.3.26 we can generalize them to operators with the singular perturbations on $\mathbb{S}^d$.

Remark 11.3.29. Let us consider the Laplace-Beltrami operator of Example 11.3.28 perturbed by a potential $V \in \mathscr{L}^s$ such that $\|V\|_{\mathscr{L}_s} < \epsilon$ with $s > d = 2$ or $s = d \geq 3$. Then the standard functional-analytic arguments yield that the cluster character of the spectrum remains true. The size of a cluster is $O(\epsilon\tau^{\frac{d}{2s}})$ and the distance between clusters is $\asymp \tau^{\frac{1}{2}}$; here $\epsilon = \|V\|_{\mathscr{L}^s}$ is assumed to be small only for $s = d$.

11.3.4 Manifolds with the Boundary

The possibility of singularities increases the possibilities even if the boundary is smooth.

Example 11.3.30. Consider manifolds of Example 8.3.9 which have boundaries (and these boundaries may also have singularities). Therefore one can take $A = \Delta^m$ (plus lower order terms) where Δ is the Laplace-Beltrami operator with the appropriate boundary conditions.

Then

(i) If r is rational the lower order terms and boundary conditions must satisfy the standard assumptions of this section and also provide condition (11.3.12) with $p \geq 1$. Then asymptotics with remainder estimate $O(\tau^{(d-1)/2m-\delta})$ holds; this asymptotics contains non-Weyl correction term.

(ii) If r is irrational we can recover remainder estimate $O(\tau^{(d-1)/2m-\delta})$ without any condition to the lower order terms and boundary conditions.

11.3.5 The Indefinite Case

In this subsection we discuss the case when the principal symbol is neither positive nor negative definite. We assume that the lower order terms are appropriate: conditions on these terms will be discussed in the next Subsection 11.3.6.

All the results of Sections 11.2 and 11.3 remain true for operators with elliptic principal symbols which are neither positive nor negative definite. In this case $\mathsf{N}^-(\tau)$ is the number of eigenvalues in the interval $(0, \tau)$ for $\tau > 0$ and $\mathsf{N}^+(\tau)$ is the number of eigenvalues in the interval $(\tau, 0)$ for $\tau < 0$ and we consider asymptotics of $\mathsf{N}^\mp(\tau)$ for $\tau \to \pm\infty$.

Surely, for $\tau \to +\infty$ and for $\tau \to -\infty$ we may obtain different asymptotics and the conditions on Hamiltonian trajectories may be different;

however in two most interesting examples – Dirac and Maxwell operators (see Example 8.4.4) results should be the same modulo remainder estimate and equal to $\frac{1}{2}\mathsf{N}^-(A^2-\tau^2)$; this would make those results look trivial.

However it is not the case, at least not for the Maxwell operator which should be considered on the subspace defined by under-defined system and as domain is irregular (for example, if it has edges directed inside, like in $(\mathbb{R}^d \setminus \mathbb{R}^{+2}\times\mathbb{R}^{d-2})$) one should be really careful ; in particular formally Maxwell system and system of hydrodynamics[28)] look the same but in such domains results are different. So, we suggest very difficult and interesting problem

Problem 11.3.31. Accurate analysis with the results of the same sharpness as in this Sections 11.2 and 11.3 for

(i) Maxwell system:

(a) isotropic (already difficult);

(b) anisotropic (much more difficult);

(ii) System of hydrodynamics[28)].

Further, all the results for $\vartheta>0$ remain true if we set

$$\mathsf{N}^{\mp}_{(\vartheta)}(\tau)=\pm\int_0^{\tau}|\tau'|^{\vartheta-1}N(\tau')d\tau' \tag{11.3.40}$$

for $\pm\tau>0$.

Furthermore, the results of Subsection 11.2.3 should remain true. In this case (instead of the assumption that $A(x,D)$ is a scalar operator) we assume that $a(x,\xi)$ has only one positive (or negative) eigenvalue $\lambda(x,\xi)$ which is simple provided we treat asymptotics as $\tau\to+\infty$ ($\tau\to-\infty$ respectively). In this case all the conditions of these subsections are assumed to be fulfilled for the Hamiltonian flow generated by $\lambda(x,\xi)$.

Moreover, to obtain conditions on lower order terms one should find pseudodifferential operator Q such that

$$Q^*Q\equiv QQ^*\equiv I \qquad \text{and} \qquad Q^*AQ\equiv\begin{pmatrix}A_1 & 0\\ 0 & A_2\end{pmatrix}$$

[28)] Without viscosity.

where A_1 is a scalar operator with principal symbol $\lambda(x,\xi)$ and A_2 an operator with principal symbol of the opposite sign. Then all the conditions should be imposed on the lower order terms of A_1.

Moreover, we can treat the Dirac operator; nevertheless the eigenvalues of its principal symbol are simple only for $D=2 \implies d=1,2,3$ (for $d=3$ one has a principally massless particle). However, one needs to check that all the symbols associated with A_1 and taken into account are scalar. Similar notes remain true for isotropic Maxwell and hydrodynamics systems and I suggest another very difficult and interesting problem

Problem 11.3.32. Accurate analysis with the results of the same sharpness as in this subsection 11.3.2 for

(i) Dirac operator;

(ii) Isotropic Maxwell system;

(iii) System of hydrodynamics[28)];

In order to prove the above statements one should apply the results of Parts II and III to the interval $(\frac12\tau,\tau)$ (we consider the case $\tau>0$ for the sake of simplicity). Then the routine remainder estimate $O(\tau^\nu)$ or $O(\tau^\nu \log^\sigma \tau)$ is obtained by standard methods. Let us replace τ by $2^{-j}\tau$ (with $j=0,\dots,n$ such that $\tau \asymp 2^n$) and sum all these asymptotics; then we obtain asymptotics for the number of eigenvalues lying in (τ_1,τ) with the same remainder estimate for $\nu>0$ and with the remainder estimate $O(\log^{\sigma+1}\tau)$ for $\nu=0, \sigma\ge 0$. On the other hand it is relatively easy to prove that $\mathsf{N}(0,\tau_1)<\infty$.

Moreover, in order to improve the final remainder estimate in the case when it grows slowly, one can apply the following arguments to obtain the remainder estimate $O(\tau^{-s})$ with arbitrarily chosen s for mollifications of $\mathsf{N}(\tau',\tau'')$ (the number of eigenvalues in the interval (τ',τ'')) with respect to τ' and τ'' with mollifying functions $\tau^{-1}\phi_1(\tau'\tau^{-1})$ and $\tau^{-1}\phi_2(\tau''\tau^{-1})$ where ϕ_1 and ϕ_2 are supported near $\frac12$ and 1 respectively. Replacing τ by $2^{-j}\tau$ and making a partition of unity one obtains the remainder estimate $O(1)$ for $\mathsf{N}(0,\tau')$ mollified near $\frac12\tau$. On the other hand, for $N(\tau',\tau)$ (even without mollification) we have the appropriate remainder estimate provided $\tau'\asymp\tau$.

So, semiclassical arguments look rather straightforward but there is also analysis in the singular zone and for indefinite operators it may become rather non-trivial. For $\vartheta>0$ one can apply analysis of the same type.

11.3.6 Conditions to Lower Order Terms

Let us discuss conditions to the lower order terms starting from a series of remarks:

Remark 11.3.33. All our results were proven for (ρ,γ)-admissible lower order terms provided

$$\rho^{d+2m\vartheta}\in \mathscr{L}^1(X), \tag{11.3.41}$$

$$\rho^{2m}\in \mathscr{L}^1(X), \tag{11.3.42}$$

$$\rho^{2m}\in \mathscr{L}^2(X), \tag{11.3.42*}$$

where (11.3.42) and (11.3.42)* are conditions in the semi-bounded and non-semibounded cases respectively. Here $2m$ is the order of the operator and $m\in \frac{1}{2}\mathbb{Z}$.

Recall that so far ρ was not mentioned at this section.

We can give a series of admissible lower order terms for all the types of operators treated above. However, it is very simple in the context of (ρ,γ)-admissibility. We leave this analysis to the reader and discuss how one can weaken these conditions which may be excessive (in contrast to Section 11.1 because now ρ does not enter in the assumptions on the principal part.

Example 11.3.34 (singularity at origin). (i) Let $\gamma=\epsilon|x|$ and $\rho=|x|^{\mu}$. Then conditions (11.3.42), (11.3.42) and (11.3.42)* mean respectively that

$$\mu>-d(d+2m\vartheta)^{-1},\qquad \mu>-\frac{d}{2m},\qquad \mu>-\frac{d}{4m}. \tag{11.3.43}$$

Let μ^* be the maximal forbidden value. Then for $\mu=\mu^*$ we can treat $\rho=|x|^{\mu}\bigl|\log|x|\bigr|^{\nu}$ with appropriate ν, etc.

However, arguments associated with estimates (11.1.66)–(11.1.67) imply that it is sufficient to assume that

$$\mu>\max(-1,-\frac{d}{2m}),\qquad \mu>\max(-1,-\frac{d}{4m}) \tag{11.3.44}$$

in the semi-bounded and non-semi-bounded cases respectively, i.e. that one should check (11.3.43) only with $\vartheta=0$.

Really, in such vicinity operator A_0 or A_0^2 (where A_0 contains no lower order terms) is larger in operator sense than $r^{-2m+\delta}$, $r^{-4m+\delta}$ with an arbitrarily small exponent $\delta > 0$ respectively.

Moreover, for $d > 2m$, $d > 4m$ respectively in these cases one can even take $\mu = -1$ assuming that in a neighborhood of 0

$$|a_{\alpha',\alpha''}| \le \epsilon \rho^{2m-|\alpha'|-|\alpha''|} \qquad \forall \alpha', \alpha'' : |\alpha'| \le m, |\alpha''| \le m, |\alpha'| + |\alpha''| \ge 1, \tag{11.3.45}$$

$$|a_\alpha| \le \epsilon \rho^{2m-|\alpha|} \qquad \forall \alpha : 1 \le |\alpha| \le 2m \tag{11.3.45}^*$$

respectively with small enough $\epsilon = \mathsf{const} > 0$.

(ii) Let us assume that in a neighborhood of 0 domain X coincides with the cone $\{(r,\theta) \in \mathbb{R}^+ \times U\}$ where $\partial U \in \mathscr{C}^K$. Further, let us assume that the Dirichlet boundary condition is given on a part of the boundary $\{(r,\theta) : r \le r_0, \theta \in U_1 \subset \partial U\}$ and that $r_0 > 0$ and $U_1 \ne \emptyset$ contains the ∂U-neighborhood of some point. Then one even does not need condition $\mu > -\frac{d}{2m}$ in the semi-bounded case.

Really, in such vicinity operator A_0 is larger in operator sense than ϵr^{-2m} with sufficiently small constant $\epsilon > 0$.

(iii) Moreover, for the Schrödinger operator with either $d \ge 3$ and with the Dirichlet boundary condition or with $d \ge 2$ and a domain and boundary conditions of the type described in (ii), variational arguments yield that one can assume that in a neighborhood of 0

$$V \ge -\epsilon\rho^2, \qquad |V_j| \le \epsilon\rho \tag{11.3.46}$$

with $\rho = |x|^{-1}$.

(iv) Let us treat the Schrödinger operator with $\mu = -1$, $d \ge 3$ assuming that either the Dirichlet boundary condition is given on ∂X or the domain and the boundary condition are of the type described in (ii). Then

$$(Au,u) \ge \sum_j \epsilon_0 \|(D_j - V_j)u\|^2 + (Vu,u). \tag{11.3.47}$$

Let us introduce spherical coordinates (r,θ) and remove the radial component of the magnetic potential by means of a gradient transform. We obtain that for functions supported in the vicinity of 0

$$(Au,u) \ge \epsilon_0 \|D_r u\|^2 + \epsilon_0 \sum_j \|r^{-1}\mathcal{L}_j u\|^2 + (Vu,u) - \varepsilon \|r^{-1}u\|^2 \tag{11.3.48}$$

where $\mathcal{L}_j$ are first-order operators with bounded coefficients on $\mathbb{S}^{d-1}$ and $\varepsilon > 0$ is arbitrarily small (the vicinity depends on ε). Let us consider

$$\|D_r u\|^2 = \int\int_0^{r_0} r^{d-1} |D_r u|^2 \, dr d\theta.$$

In order to do this we treat $\|r^\nu D_r u\|_1^2$ where $\|.\|_1$ and $(.,.)_1$ mean respectively $\mathscr{L}^2$-norm and inner product on $[0,r_0]$, $\nu = \frac{1}{2}(d-1)$. Substituting $u = r^{-\nu}v$ we obtain that

$$\begin{aligned}\|r^\nu \partial_r u\|_1^2 = \|(\partial_r - \nu r^{-1})v\|_1^2 = \|\partial_r v\|_1^2 + \nu^2 \|r^{-1}v\|_1^2 - \\ 2\nu \operatorname{Re}(\partial_r v, r^{-1}v)_1 = \|\partial_r v\|_1^2 + (\nu^2 - \nu)\|r^{-1}v\|_1^2.\end{aligned} \tag{11.3.49}$$

Let $d > 3$; then $\nu^2 > \nu$ and we conclude that in this case

$$\|r^\nu \partial_r u\|_1^2 \ge \epsilon_1 \|r^{\nu-1}u\|_1^2. \tag{11.3.50}$$

On the other hand, let $d = 3$. Then $\nu = 1$ in which case $\|r^\nu \partial_r u\|^2 = \|\partial_r v\|^2$ but then obviously (11.3.50) holds again. Therefore

(11.3.51) For $d \ge 3$ the second of conditions (11.3.46) is not necessary.

On the other hand, for $d = 2$, $\nu = \frac{1}{2}$ and $\nu^2 - \nu = -\frac{1}{4}$. In this case only one operator $\mathcal{L}_1 = D_\theta - w(r,\theta)$ is present and if for $\theta = \theta_1$ a Dirichlet boundary condition is given then $\|\mathcal{L}_1 u\|_2 \ge \epsilon_1 \|u\|_2$ where $\|.\|_2$ is $\mathscr{L}^2$-norm with respect to θ.

On the other hand, if $U = \{\theta, \theta_1 < \theta < \theta_2\}$ and if for both $\theta = \theta_1$ and $\theta = \theta_2$ the Neumann boundary condition is given then this estimate fails. However, if X is a complete neighborhood of 0 then this estimate remains true provided

$$\Big|\int_0^{2\pi} w(\theta,r)d\theta - 2\pi m\Big| \ge \epsilon_0 \qquad \forall m \in \mathbb{Z} \quad \forall r \in (0,r_0). \tag{11.3.52}$$

Conversely, if (11.3.52) fails for every $\epsilon_0 > 0$ then the previous inequality also fails. We conclude that

(11.3.53) Let $d = 2$ and either $U = \{\theta_1 < \theta < \theta_2\}$ and for θ_1 or for θ_2 a Dirichlet boundary condition is given, or X contains a complete neighborhood of 0 and (11.3.52) holds. Then the second of conditions (11.3.46) is not necessary.

(v) All these arguments remain true in the case $\gamma = \epsilon|x''|$, $\rho = |x''|^\mu$ with d replaced by d'' in the conditions.

Example 11.3.35. Using the arguments of Remark 11.1.13 we see that in the context of Example 11.2.19 one can assume that $\rho f(|x''|) \le \epsilon$ (with small enough constant $\epsilon > 0$) instead of assumption (11.3.42).

Remark 11.3.36. Certain generalizations can be obtained from functional-analytic arguments. For example, consider Schrödinger operator and asymptotics of $\mathsf{N}^-(\tau)$. Then

(i) Asymptotics with the remainder estimate $O\bigl(\tau^{\frac{1}{2}(d-1)}\bigr)$ remain true if one replaces potentials V and V_j by $V + V'$ and $V_j + V_j'$ with $V' \in \mathscr{L}^d(X)$, $V_j' \in \mathscr{L}^\infty(X)$.

(ii) Moreover, asymptotics with the remainder estimate $O\bigl(\tau^{\frac{1}{2}(d-1-\sigma)}\bigr)$ remain true provided $V_j' = 0$, $V' \in \mathscr{L}^{d(1-\sigma)^{-1}}(X)$.

(iii) Therefore approximating $V' \in \mathscr{L}^d(X)$ by the potentials $V_\varepsilon' \in \mathscr{L}^\infty(X)$ we obtain that asymptotics with the remainder estimate $o\bigl(\tau^{\frac{1}{2}(d-1)}\bigr)$ remain true for such perturbations.

(iv) Moreover, similar approximation arguments yield that asymptotics with the the remainder estimate $O\bigl(\tau^{\frac{1}{2}(d-1)} \log^{-\nu} \tau\bigr)$ remain true provided $V'|\log(|V'|+1)|^\nu \in \mathscr{L}^d(X)$.

(v) On the other hand, remainder estimates weaker than $O\bigl(\tau^{\frac{1}{2}(d-1)}\bigr)$ remain true under weaker conditions. However, our weakly singular potentials (i.e., the potentials which we considered in this section) do not necessarily belong to the indicated classes. Thus, a combination of the two methods is the most effective.

11.4 Large Eigenvalues for Operators in Essentially Unbounded Domains

11.4.1 Coercivity Condition and Standard Asymptotics

In this section, under the assumptions of the previous section concerning the domain X and the principal symbol, we consider operators with the lower order terms essential from the point of view of the domain of the operator and asymptotics[29]. These terms could be more singular than those studied before but they must satisfy *coercivity condition*.

We start with operators with positive principal symbol. In this case the coercivity condition is

$$\langle A(x,\xi)v, v\rangle \ge \epsilon_0(|\xi|+\rho)^{2m}\|v\|^2 \qquad \forall \xi \quad \forall v, \tag{11.4.1}$$

$$\sum_{\alpha,\beta:|\alpha|\le m,|\beta|\le m} \langle a_{\alpha,\beta}w_\alpha, w_\beta\rangle \ge \epsilon_0 \sum_{\alpha:|\alpha|\le m} \|w_\alpha\|^2\rho^{2m-2|\alpha|} \qquad \forall w=(w_\alpha)_{\{|\alpha|\le m\}} \tag{11.4.2}$$

where $\epsilon_0>0$,

$$A(x,\xi)=\sum_{\alpha,\beta:|\alpha|\le m,|\beta|\le m} a_{\alpha,\beta}\xi^{\alpha+\beta} \tag{11.4.3}$$

is the complete (symmetric) symbol of an operator A of the form (11.1.1) with $h=1$ and the first condition (11.4.1) is assumed to be fulfilled for all $x\in X$ while the second condition (11.4.2) (which is surely stronger) is assumed to be fulfilled only in $\{x\in X, \rho\gamma\ge\epsilon_0, \gamma\le\epsilon_0\}$. However, in the certain cases this condition is assumed to be fulfilled in a part of X which larger than this. Again we have assumed that

$$\varrho=\rho^{2m} \tag{11.4.4}$$

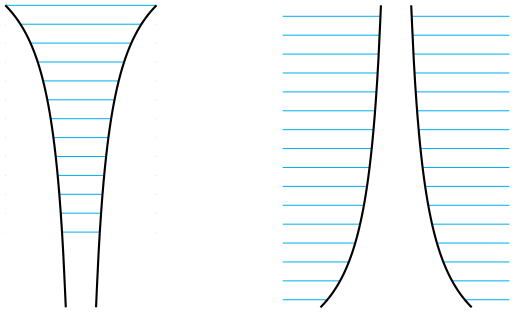
for the sake of simplicity. We leave to the reader to consider the more general case. In what follows we treat lower order terms which are sums of coercive

[29] Thus, it would be better to speak about senior symbols and junior terms.

and admissible indefinite (lower order) terms. For the Schrödinger operator (11.1.6) conditions (11.4.1) and (11.4.2) coincide with the condition

$$V \ge \epsilon_0 \rho^2 \qquad \forall x \tag{11.4.5}$$

provided condition (11.1.6) is fulfilled.



(a) (b)

Figure 11.7: Non-coercive weakly singular potential (a) and coercive singular potential (b); blue lines show symbolically energy levels of the corresponding Schrödinger operator. For weakly singular potential the lowest energy level on (a) exists.

As before we set $\gamma_\tau = \gamma$ and $\rho_\tau = \rho + \tau^{\frac12}$ and consider domain

$$X_{\mathsf{reg}} = \{x \in X,\ \tau^{\frac{1}{2m}}\gamma(x) \ge 1,\ \exists \xi\, \exists v \ne 0 :\ \ \langle A(x,\xi)v, v\rangle \le (1+\epsilon_1)\tau \|v\|^2\}$$

with an arbitrarily small constant $\epsilon_1 > 0$. Then condition (11.4.1) yields that $\rho \le C\tau^{\frac{1}{2m}}$.

As before we apply the results of Parts II and III in X_{reg} to obtain local semiclassical spectral asymptotics for $\mathsf{N}^-(\tau)$ (case $\vartheta > 0$ will be considered later) in the ball $\mathcal{B}\big(x, \gamma(x), X\big)$ with the remainder estimate $O\big(\tau^{\frac{1}{2m}(d-1)}\gamma^{d-1}\big)$ provided $\rho \le \epsilon_2 \tau^{\frac{1}{2m}}$, in which case operator is ξ-microhyperbolic.

Moreover, under condition to the Hamiltonian flow generated by the senior symbol this remainder estimate can be improved to $o\big(\tau^{\frac{1}{2m}(d-1)}\gamma^{d-1}\big)$ or sharper.

On the other hand, for balls with $\rho \ge \epsilon_2 \tau^{\frac{1}{2m}}$ the remainder estimate (as well as the principal part of the asymptotics) is $O\big(\tau^{\frac{d}{2m}}\gamma^d\big)$ in the general case; however it could be improved to $O\big(\tau^{\frac{1}{2m}(d-1+\delta)}\gamma^{d-1+\delta}\big)$ with an arbitrarily small exponent $\delta > 0$ for the scalar operators.

In order to obtain the remainder estimate $O\bigl(\tau^{\frac{1}{2m}(d-1)}\gamma^{d-1}\bigr)$ in the local spectral asymptotics in this zone one should check microhyperbolicity or another non-degeneracy condition there. In particular, for the Schrödinger operator with $d \ge 2$ we obtain this remainder estimate without any additional conditions. This improvement and condition will be important in the next sections but not now.

On the other hand, in the zone

$$X_+ = \bigl\{x \in X,\ \rho\gamma \ge \epsilon_1, \forall \xi\ \forall v\ \langle A(x,\xi)v, v\rangle \ge (1+\epsilon_1)\tau\|v\|^2\bigr\}$$

we obtain the remainder estimate[30] $O(\rho^{-s}\gamma^{-s})$ with arbitrarily chosen exponent s provided either $B\bigl(x,\gamma(x)\bigr)$ does not intersect ∂X, or m-th order Dirichlet boundary condition is given on ∂X.

Moreover, one can obtain the same answer provided[31]

$$(Au,u) \ge \sum_{\alpha,\beta:|\alpha|,|\beta|\le m} (a_{\alpha,\beta}D^\alpha u, D^\beta u) \quad \forall u \in \mathfrak{D}(A). \tag{11.4.6}$$

Let us note that $X_{\mathsf{reg}} \cup X_+ \supset \bigl\{x \in X, \tau^{\frac{1}{2m}}\gamma \ge C_0\bigr\}$. Thus we include X_+ either into semiclassical zone X_{reg} or into variational zone X_{sing}.

Let us assume that condition (11.4.2) is fulfilled in the domain

$$\mathcal{X} \supset \{x \in X,\ \rho\gamma \le \epsilon_1,\ \gamma \le \epsilon_1\}.$$

Then for u supported in $\mathcal{X}$ the following estimate

$$\bigl((A-\tau I)u,u\bigr) \ge -C\tau \int_{\mathcal{X}_-} \|u\|^2 dx$$

holds with $\mathcal{X}_- = \mathcal{X} \setminus \mathcal{X}_+$,

$$\mathcal{X}_+ = \bigl\{x \in \mathcal{X}, \sum_{\alpha,\beta:|\alpha|\le m,|\beta|\le m} \langle a_{\alpha,\beta}(x)w_\alpha, w_\beta\rangle \ge \tau \sum_{\alpha:|\alpha|\le m} \|w_\alpha\|^2 \quad \forall w_\alpha\bigr\}.$$

Surely $\mathcal{X}_+ \supset \bigl\{x \in X, \rho \ge C\tau^{\frac{1}{2m}}\bigr\}$. Therefore we conclude that

(11.4.7) Contribution of $\mathcal{X}$ to the remainder does not exceed $C\tau^{\frac{d}{2m}}\mathsf{mes}(\mathcal{X}_-)$ provided either the Dirichlet boundary condition or any other condition providing (11.4.6) on $\partial X \cap \bar{\mathcal{X}}$ is given; in the latter case we assume that the cone condition is fulfilled.

---

[30] The principal part vanishes here.

[31] This inequality is a restriction on the boundary conditions.

Let us note that

Remark 11.4.1. $\mathcal{X}$ and X_+ overlap and therefore we can subtract from X_+ and add to $\mathcal{X}$ zone

$$\tilde{\mathcal{X}} = \{x \in X, \mathsf{dist}(x, X \setminus \mathcal{X}) \ge \epsilon_1 \gamma\}.$$

So we arrive to the estimate

$$\bigl|\mathsf{N}^-(\tau) - \mathsf{N}^{\mathsf{W}}(\tau)\bigr| \le C\bigl(R_1(\tau) + R_2(\tau) + R_3(\tau)\bigr) \tag{11.4.8}$$

with

$$\mathsf{N}^{\mathsf{W}}(\tau) = (2\pi)^{-d} \iint_{X_{\mathsf{reg}} \times \mathbb{R}^d} \boldsymbol{n}(x,\xi;\tau)\, dx d\xi \tag{11.4.9}$$

where $\boldsymbol{n}(x,\xi;\tau)$ is now the eigenvalue counting function for the complete symbol $A(x,\xi)$,

$$R_1(\tau) = \int_{X_{\mathsf{reg}}} \tau^{\frac{d-1}{2m}} \gamma^{-1}\, dx, \tag{11.4.10}$$

$$R_2(\tau) = \tau^{\frac{d}{2m}}\, \mathsf{mes}(\mathcal{X}_- \cup \tilde{\mathcal{X}}), \tag{11.4.11}$$

$$R_3(\tau) = \int_{X_+ \setminus \tilde{\mathcal{X}}} \rho^{d-s} \gamma^{-s}\, dx, \tag{11.4.12}$$

$\tilde{\mathcal{X}} = \bigl\{x \in X_{\mathsf{reg}},\ \rho \ge \epsilon_2 \tau^{\frac{1}{2m}}\bigr\}$ in the general case. This zone can be reduced (or even voided) under microhyperbolicity or other non-degeneracy condition; in particular $\tilde{\mathcal{X}} = \emptyset$ for the Schrödinger operator with $d \ge 2$.

Similarly, for $\vartheta > 0$ estimate

$$\bigl|\mathsf{N}^-_{(\vartheta)}(\tau) - \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau)\bigr| \le C\bigl(R_{1(\vartheta)}(\tau) + R_{2(\vartheta)}(\tau) + R_{3(\vartheta)}(\tau)\bigr) \tag{11.4.13}$$

holds with $\mathsf{N}^-_{(\vartheta)}(\tau) = \tau_+^{\vartheta-1} * \mathsf{N}^-(\tau)$, $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) = \tau_+^{\vartheta-1} * \mathsf{N}^{\mathsf{W}}(\tau)$, $\mathsf{N}^{\mathsf{W}}(\tau)$ containing now lower order terms as well,

$$R_{1(\vartheta)}(\tau) = \int_{X_{\mathsf{reg}}} \tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta} \gamma^{-1-\vartheta}\, dx, \tag{11.4.14}$$

$$R_{2(\vartheta)}(\tau) = \tau^{\frac{d}{2m}+\vartheta}\, \mathsf{mes}(\mathcal{X}_- \cup \tilde{\mathcal{X}}), \tag{11.4.15}$$

$$R_{3(\vartheta)}(\tau) = \int_{X_+ \setminus \tilde{\mathcal{X}}} \rho^{2m\vartheta+d-s} \gamma^{-s}\, dx. \tag{11.4.16}$$

In particular, we have proven

Proposition 11.4.2. *Let*

$$\gamma^{-1-\vartheta} \in \mathscr{L}^1(X), \tag{11.4.17}$$

$$\rho^{2m\vartheta+d-s}\gamma^{-s} \in \mathscr{L}^1(X \setminus \tilde{\mathcal{X}}) \tag{11.4.18}$$

and

$$\mathsf{mes}(\mathcal{X}_- \cup \tilde{\mathcal{X}}) = O\bigl(\tau^{-\frac{1}{2m}(\vartheta+1)}\bigr); \tag{11.4.19}$$

then

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta}\bigr) \qquad \text{as } \tau \to +\infty. \tag{11.4.20}$$

For the Schrödinger operator with $d \geq 2$ and other scalar operators with $\vartheta > 0$ condition (11.4.19) is fulfilled automatically, but in the general case this condition is very unpleasant and it is best to check the microhyperbolicity condition for $(A - \tau)$ in $\tilde{\mathcal{X}}_-$ and then reduce this zone.

Remark 11.4.3. Let us discuss the principal differences between weakly and strongly singular potentials:

(i) For strongly singular potentials coercivity condition is required; without it operator may be even not essentially self-adjoint;

(ii) For weakly singular potentials small vicinity of the singular point is a singular zone; for strongly singular potential it belongs to a classically forbidden (due to coercivity) part of regular zone;

(iii) Finally, in the general case the principal parts of the asymptotics $\mathsf{N}^{\mathsf{W}}(\tau)$ and $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau)$ cannot be decomposed into a power series of $\tau^{\frac{1}{2m}}$ as in the previous section. Usually this decomposition leads to much worse remainder estimate than the original one.

11.4.2 Sharp Remainder Estimates

Let us discuss an improvement of the remainder estimate in the zone $X_{\mathsf{reg}} \cap \{\rho \leq C\tau^{\frac{1}{2m}}\}$; thus we consider the term $R_1(\tau)$ or $R_{1(\vartheta)}(\tau)$. Let us write our results as a series of remarks:

Remark 11.4.4. (i) Let the standard non-periodicity condition to the (billiard) Hamiltonian trajectories is fulfilled in X_{reg} for the symbol $a(x,\xi)$ on the energy level 1.

Then for any fixed $\bar\gamma > 0$ one can replace the contribution of zone $\{X, \gamma(x) \ge \bar\gamma\}$ to the remainder by $R^*_{1(\vartheta)}(\tau) = o\bigl(R_{1(\vartheta)}(\tau)\bigr)$.

(ii) Further, let condition (11.4.17) be fulfilled; then $R_{1(\vartheta)}(\tau) \asymp \tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta})$ and we can replace it by $R^*_{1(\vartheta)}(\tau) = o\bigl(\tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta}\bigr)$.

So, under condition (11.4.17) and improved assumption (11.4.19)

$$\mathsf{mes}(\mathcal{X}_- \cup \tilde{\mathcal{X}}) = o\bigl(\tau^{-\frac{1}{2m}(\vartheta+1)}\bigr) \tag{11.4.19*}$$

we can improve asymptotics (11.4.20) to

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + o\bigl(\tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta}\bigr) \qquad \text{as } \tau \to +\infty. \tag{11.4.20*}$$

In particular, for $\vartheta = 0$ the two-term asymptotics holds with the remainder estimate $o(\tau^{(d-1)/2m})$.

(iii) All the examples of Subsection 11.3.1 remain true. However, the principal part of these asymptotics should be given by the formulas of the present section.

Remark 11.4.5. (i) Let the enhanced non-periodicity condition to the (billiard) Hamiltonian trajectories is fulfilled in X_{reg} for the symbol $a(x,\xi)$ on the energy level 1. Namely, let us assume that this flow is of either exponential or power type and that the corresponding non-periodicity condition is fulfilled. Then one can replace $R_{1(\vartheta)}(\tau)$ by

$$R^{**}_{1(\vartheta)}(\tau) = \int_{X_{\mathsf{reg}}} \tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta} \gamma^{-1-\vartheta} \bigl(\log(\tau^{1/2m}\gamma)\bigr)^{-1-\vartheta}\, dx, \tag{11.4.14**}$$

or

$$R^{***}_{1(\vartheta)}(\tau) = \int_{X_{\mathsf{reg}}} \tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta} \gamma^{-1-\vartheta} (\tau^{1/2m}\gamma)^{-\delta}\, dx \tag{11.4.14***}$$

respectively.

(ii) So, under condition (11.4.17) and further improved assumption (11.4.19)

$$\mathsf{mes}(\mathcal{X}_- \cup \tilde{\mathcal{X}}) = O\bigl(\tau^{-\frac{1}{2m}(\vartheta+1)} |\log\tau|^{-1-\vartheta}\bigr) \tag{11.4.19**}$$

or

$$\mathsf{mes}(\mathcal{X}_- \cup \tilde{\mathcal{X}}) = O\bigl(\tau^{-\frac{1}{2m}(\vartheta+1)-\delta}\bigr) \tag{11.4.19***}$$

we can improve asymptotics (11.4.20) to

$$\mathsf{N}^{-}_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta}|\log\tau|^{-1-\vartheta}\bigr) \tag{11.4.20)**}$$

or

$$\mathsf{N}^{-}_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta-\delta}\bigr) \tag{11.4.20)***}$$

respectively.

In particular, for $\vartheta = 0$ the two-term asymptotics holds with the remainder estimate $O(\tau^{(d-1)/2m}(\log\tau)^{-1})$ or $O(\tau^{(d-1)/2m-\delta})$ respectively.

Remark 11.4.6. In the context of Subsection 11.3.2 (periodic billiard Hamiltonian flow) under condition (11.4.19)*** asymptotics

$$\mathsf{N}^{-}(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + \tau^{\frac{d-1}{2m}}\bigl(\varkappa_1 + F(\tau^{\frac{1}{2m}})\bigr) + O\bigl(\tau^{\frac{d-1}{2m}-\delta}\bigr) \tag{11.4.21}$$

holds as $\tau \to +\infty$.

Remark 11.4.7. Non-periodicity condition may be useful even with weakened assumptions (11.4.17)–(11.4.19).

11.4.3 Examples

Let us consider some examples. We start from the Schrödinger operator $\Delta + V(x)$ with potential $V(x) = \kappa|x|^{2\mu}$, $\kappa = \mathsf{const} \neq 0$, $\mu \leq -1$, singular at origin, gradually adding the complexity. Note that as $\mu < -1$ operator V is not Δ-bounded (see Definition 10.2.4) and as $\mu = -1$ it may be Δ-bounded[32)] but it's Δ-bound is not 0.

So, as $\mu < -1$, we *must* assume that $0 \notin X$ and $\kappa > 0$, defining operator $\Delta + V$ through quadratic form; as $\mu = -1$ we may[32)] allow $\kappa \geq \kappa_0$ with $\kappa_0 < 0$.

Then we can consider the case of singularity at origin when $\gamma(x) \asymp |x|$ and $\rho \asymp |x|^{\mu}$ with $\mu \leq -1$ and to generalize it to singularity at $\{x, x'' = 0\}$ of codimension d''.

Example 11.4.8 (Power singularities). (i) Let all the conditions be fulfilled with $\gamma \asymp |x''|$, $\rho \asymp |x''|^{\mu}$, $\mu \leq -1$. There one can take $\mathcal{X} = \emptyset$ for $\mu < -1$ and $\mathcal{X} = \{x \in X, |x''| \leq \epsilon_0\}$ for $\mu = -1$.

[32)] It is the case unless $d = 2$ and 0 is surrounded by X.

Then in the general case we should take the transitional zone $\tilde{\mathcal{X}} = \{\epsilon\tau \le |x''|^{2m\mu} \le C\tau\}$ arriving to

(a) For $d'' > \vartheta + 1$, $\mu \ge -d''(\vartheta+1)^{-1}$ asymptotics (11.4.20) holds.

Moreover, for $\mu > -d''(\vartheta+1)^{-1}$ under the standard non-periodicity condition to the Hamiltonian trajectories asymptotics (11.4.20)* holds.

Note that for $\vartheta = 0$ and $\mu > -d''$ one can replace full Weyl expression (including all terms of A) $\mathsf{N}^{\mathsf{W}}(\tau)$ by the standard two-term expression (one needs the second term only for sharp asymptotics) $\varkappa_0\tau^{\frac{d}{2m}} + \varkappa_1\tau^{\frac{d-1}{2m}}$ with the standard coefficients $\varkappa_0, \varkappa_1$ and with the same remainder estimate as above.

On the other hand, for $\mu = -d''$, $\mathsf{N}^{\mathsf{W}}(\tau) = \varkappa_0\tau^{\frac{d}{2m}} + O\bigl(\tau^{\frac{d-1}{2m}}\log\tau\bigr)$ in the general case and $\mathsf{N}^{\mathsf{W}}(\tau) = \varkappa_0\tau^{\frac{d}{2m}} + O\bigl(\tau^{\frac{d-1}{2m}}\bigr)$ in the case of a scalar principal symbol.

(b) For $d'' = \vartheta + 1$, $\mu = -1$ asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta}\log\tau\bigr) \tag{11.4.22}$$

holds and for $\vartheta = 0$, $d'' = 1$, $\mu = -1$ one can replace $\mathsf{N}^{\mathsf{W}}(\tau)$ by $\varkappa_0\tau^{\frac{d}{2m}}$.

(c) If $\mu < -d''(\vartheta+1)^{-1}$ then asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{d}{2m}+\frac{d''}{2m\mu}+\vartheta}\bigr) \tag{11.4.23}$$

holds.

Let us note that $\mu \ge -d''(\vartheta+1)^{-1}$, $\mu \le -1$ yield $d'' \le \vartheta + 1$ and therefore only the listed cases are possible.

(ii) One can slightly improve the above results in the number of cases. For the Schrödinger operator with $d \ge 2$ and general scalar operators with $\vartheta > 0$ one can extend X_{reg} and take $\tilde{\mathcal{X}} = \emptyset$. Moreover, one can easily see that if X is a conic with respect to the x'' domain in a neighborhood of $\{x'' = 0\}$ and

$$D^\alpha(a_{\beta',\beta''} - a^0_{\beta',\beta''}) = o(\rho^{2m-|\beta'|-|\beta''|}\gamma^{-|\alpha|}) \qquad \forall\beta', \beta'' \quad \forall\alpha : |\alpha| \le 1 \tag{11.4.24}$$

as $|x''| \to 0$ with functions $a^0_{\beta',\beta''}$ which are positively homogeneous of degrees $(2m - |\beta'| - |\beta''|)\mu$ then[33] checking the microhyperbolicity condition with

$$\ell = \langle\xi, \partial_\xi\rangle + \mu^{-1}\langle x'', \partial_{x''}\rangle$$

[33] We call conditions similar to (11.4.24) *stabilization conditions*.

we see that we can take $\tilde{X} = \emptyset$ as well.

In all these we obtain that

(a) For $d'' > \vartheta + 1$ asymptotics (11.4.20) holds. Moreover, under the standard non-periodicity condition to Hamiltonian trajectories asymptotics (11.4.20)* holds.

(b) For $d'' = \vartheta+1$ asymptotics (11.4.22) holds and for $d'' < \vartheta+1$ asymptotics (11.4.23) holds.

Let us note that in both cases for $\mu \le -d''$, even for the Schrödinger operator, it is possible that

$$\mathsf{N}^{\mathsf{W}}(\tau) - \varkappa_0 \tau^{\frac{d}{2m}} - \varkappa_1 \tau^{\frac{d-1}{2m}} \asymp \tau^{\frac{d}{2m}+\frac{d''}{2m\mu}}$$

and therefore for $\mu < -d''$ we cannot replace $\mathsf{N}^{\mathsf{W}}(\tau)$ by $\varkappa_0 \tau^{\frac{d}{2m}}$ and preserve the remainder estimate. Moreover, for $\mu = -d''$ we cannot replace $\mathsf{N}^{\mathsf{W}}(\tau)$ by $\varkappa_0 \tau^{\frac{d}{2m}} + \varkappa_1 \tau^{\frac{d-1}{2m}}$ and preserve the remainder estimate $o\bigl(\tau^{\frac{d-1}{2m}}\bigr)$.

Example 11.4.9 (Power singularities again). Let us consider Schrödinger operator with $d \ge 2$ [34] and let us assume that in a neighborhood of $\{x'' = 0\}$ domain X coincides with $X^0 = \{x = (x', r, \theta) \in \mathbb{R}^{d''} \times \mathbb{R}^+ \times U\}$ where $U \subset \mathbb{S}^{d''-1}$ is a $\tilde{\gamma}$-admissible domain with $\tilde{\gamma} = \tilde{\gamma}(x', \theta)$.

Let us assume that $g^{jk} = g^{jk}(x', \theta)$, $V_j = v_j(x', \theta)|x''|^\mu$, $V = v(x', \theta)|x''|^{2\mu}$ and $\mu \le -1$. Further, let us assume that $v \ge 0$ and the functions g^{jk}, v_j and v on $\mathbb{R}^{d'} \times \mathbb{S}^{d''-1}$ satisfy standard conditions (11.1.6)–(11.1.8) and (11.4.5) with $\tilde{\rho} = \sqrt{v}$ and with $\tilde{\gamma}$ instead of ρ and γ. Then

(i) Under additional assumption $|v_j| \le c\tilde{\rho}$ one can take $\rho = \tilde{\rho}|x''|^\mu$ and $\gamma = \epsilon_1 \tilde{\gamma}|x''|$ with small enough constant $\epsilon_1 > 0$.

(a) Then we obtain that under assumption

$$\tilde{\gamma}^{-1-\vartheta} \in \mathscr{L}^1(\mathbb{R}^{d'} \times U) \tag{11.4.25}$$

asymptotics (11.4.20) holds for $d'' > \vartheta + 1$.

(b) Moreover, under the standard non-periodicity condition to the Hamiltonian trajectories asymptotics (11.4.20)* holds.

[34] One can consider general scalar operators for $\vartheta > 0$.

(c) On the other hand, under condition (11.4.25) for $d'' = \vartheta + 1$ and $d'' < \vartheta + 1$ we obtain asymptotics (11.4.22) and (11.4.23) respectively.

(ii) Without condition $|v_j| \le c\tilde{\rho}$ we cannot use variational estimates. In this case we should assume that $\mu < -1$ and

$$\tilde{\rho}\tilde{\gamma} \ge \epsilon_0 > 0. \tag{11.4.26}$$

These conditions forbid the degeneration of v but permit certain singularities. Then all the statements of the previous assertion remain true.

(iii) Let $\mu < -1$, condition (11.4.26) be fulfilled and $V_j = v_j(x', \theta)|x''|^{\mu'}$ with $\mu' < \mu$ (the case $\mu' > \mu$ is trivial).

Then one can take $\rho = \tilde{\rho}|x'|^{\mu}$, $\gamma = \epsilon_1\tilde{\gamma}|x''|^{-\mu'+\mu+1}$. Then $\rho\gamma \ge \epsilon_2|x''|^{-\sigma}$ with $\sigma > 0$ provided $2\mu + 1 < \mu'$.

(a) Then, under assumption (11.4.25) we obtain asymptotics (11.4.20) for $d'' > (1 + \vartheta)(1 + \mu - \mu')^{-1}$.

(b) Moreover, under the standard non-periodicity condition to Hamiltonian trajectories we obtain asymptotics (11.4.20)*.

(c) On the other hand, for $d'' = (1+\vartheta)(1+\mu-\mu')^{-1}$ we obtain asymptotics (11.4.22) and for $d'' < (1 + \vartheta)(1 + \mu - \mu')^{-1}$ we obtain asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{d-\eta}{2}+\vartheta}\bigr) \tag{11.4.27}$$

with $\eta = \mu^{-1}\bigl((1 + \vartheta)(1 + 2\mu - \mu') - d''\bigr) \in (0, 1 + \vartheta)$.

Here we cannot consider the case $\mu' \le 2\mu + 1$ because the magnetic field is too strong near the origin. This case is left to the next part.

Let us note that every time assertions with large enough s are used, K (in the conditions on coefficients) depends on μ, μ', etc. (via s).

Example 11.4.10 (Exponential singularities). Let X, $g^{jk} = g^{jk}(x', \theta)$, $v_j = v_j(x', \theta)$ and $v = v(x', \theta)$ be as in statements (i) or (ii) of the previous Example 11.4.9. Let $V_j = v_j \exp(|x''|^{-\nu})$, $V = v \exp(2|x''|^{-\nu})$ with $\nu > 0$.

Then all the conditions will be fulfilled with $\rho = \tilde{\rho} \exp(|x''|^{-\nu})$ and $\gamma = \epsilon_1\tilde{\gamma}|x''|^{\nu+1}$. We obtain that

(a) For $(1+\nu)(1+\vartheta) < d''$ asymptotics (11.4.20) holds and under the standard non-periodicity condition to Hamiltonian trajectories asymptotics (11.4.20)* holds.

(b) Further, for $(1+\nu)(1+\vartheta) = d''$ asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{d-1+\vartheta}{2}} \log\log\tau\bigr) \tag{11.4.28}$$

holds and

(c) For $(1+\nu)(1+\vartheta) > d''$ asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{\frac{d-1+\vartheta}{2}} \log^{\sigma}\tau\bigr) \tag{11.4.29}$$

holds with $\sigma = \nu^{-1}\bigl((1+\nu)(1+\vartheta) - d''\bigr)$.

We leave it to the reader the following series of rather easy exercises:

Problem 11.4.11. (i) Consider examples in the spirit of Example 11.4.9(iii) with exponential singularities, i.e., with $V_j = v_j|x''|^{-l}\exp(|x''|^{-\nu})$ or with $V_j = v_j \exp(k|x''|^{-\nu})$, $k \in (1,2)$.

(ii) For different examples estimate $\bigl(\mathsf{N}^{\mathsf{W}}(\tau) - \varkappa_0\tau^{\frac{d}{2}}\bigr)$ from above and below.

(iii) Consider quasiconical domains and domains with cusps for potentials which grow at 0 or infinity.

(iv) Consider general scalar operators with $\vartheta > 0$.

11.4.4 Indefinite Perturbations

Now we consider the case when a strongly singular coercive potential is perturbed by a less singular indefinite potential. Let us assume that conditions (11.1.3)–(11.1.4) are fulfilled with $\rho+\rho'$ instead of ρ and with $\varrho = (\rho+\rho')^{2m}$ where ρ and ρ' are γ-admissible weight functions. We denote such conditions by (11.1.3)$'$–(11.1.4)$'$.

Meanwhile we replace conditions (11.4.1) and (11.4.2) by conditions

$$\langle A(x,\xi)v, v\rangle \ge \epsilon_0\bigl((|\xi|+\rho)^{2m} - C\rho'^{2m}\bigr)\|v\|^2 \qquad \forall\xi \quad \forall v \tag{11.4.1}'$$

and

$$(11.4.2)' \qquad \sum_{\alpha,\beta:|\alpha|\le m,|\beta|\le m} \langle a_{\alpha,\beta}(x)v_\alpha, v_\beta\rangle \ge \epsilon_0 \sum_{\alpha:|\alpha|\le m} \rho^{2m-2|\alpha|}\|v_\alpha\|^2 - C\sum_{\alpha:|\alpha|\le m-1} \rho'^{\,2m-2|\alpha|}\|v_\alpha\|^2 \qquad \forall v = (v_\alpha)_{\{|\alpha|\le m\}}$$

respectively.

Remark 11.4.12. Then the arguments of this and previous sections show that all the estimates of this section remain true with all domains defined by ρ if to their right-hand expressions we add

$$(11.4.30) \qquad R'(\tau) = C\Big(\int_{\mathcal{Z}} (\rho'^{\,2m})_+^q \, dx\Big)^{\frac{d}{2mq}} \times \big(\mathsf{mes}(\mathcal{Z})\big)^{1-\frac{d}{2mq}}$$

for $\vartheta = 0$, and

$$(11.4.31) \quad R'_{(\vartheta)}(\tau) = C\int_0^\infty t^{\vartheta-1}\Big(\int_{\mathcal{Z}} (\rho'^{\,2m} - t)_+^q \, dx\Big)^{\frac{d}{2mq}} dt \times \big(\mathsf{mes}(\mathcal{Z})\big)^{1-\frac{d}{2mq}}$$

for $\vartheta > 0$ where $q \ge \frac{d}{2m}$, $q \ge 1$ and one of these inequalities is strict, and

$$\mathcal{Z} = \{x \in X, \rho \le C\rho'\}.$$

Example 11.4.13. Consider a power singularity under the assumptions of Example 11.4.9(i) with potentials V, V_j replaced by $V + V'$, $V_j + V'_j$ respectively where $V' = w(x', \theta)|x''|^{2\nu}$, $V'_j = w_j(x', \theta)|x''|^\nu$, w and w_j are also functions on $\mathbb{S}^{d''-1} \times \mathbb{R}^{d'}$ satisfying conditions (11.1.6)–(11.1.8) with $\tilde\rho'$, $\tilde\gamma$.

Here $\tilde\rho'$ is a $\tilde\gamma$-admissible weight function on $\mathbb{S}^{d''-1} \times \mathbb{R}^{d'}$ and $\nu > \mu$, $\mu \le -1$, $\nu < 0$. Let us set $\gamma = \epsilon_1\tilde\gamma|x''|$, $\rho = \tilde\rho|x''|^\mu$, $\rho' = \tilde\rho'|x''|^\nu$ with $\tilde\rho = \sqrt{v}$. Then term (11.4.30) or (11.4.31) should be added to the right-hand expressions of our estimates, and one can see easily that this term does not exceed existing remainder estimate provided one of the following conditions is fulfilled:

$$(11.4.32)_1 \quad \iint_{\{\tilde\rho'^{\,2}\ge\epsilon v\}} \tilde\rho'^{\,-a} v^{\frac{b}{2}} \, d\theta dx' < \infty \qquad \text{if } \ b < 0,\ d \ge 3$$

with $a = (d'' + d\mu + 2\vartheta\mu)(\nu-\mu)^{-1}$, $b = (d'' + d\nu + 2\vartheta\nu)(\nu-\mu)^{-1}$,

$$(11.4.32)_2 \quad \iint_{\{\tilde\rho'^2 \ge \epsilon v\}} \tilde\rho'^{\,d+2\vartheta}\bigl(\log\frac{\tilde\rho'^2}{v}\bigr)_+ d\theta dx' < \infty \qquad \text{if } \ b=0,\ d\ge 3$$

$$(11.4.32)_3 \quad \iint_{\{\tilde\rho'^2 \ge \epsilon v\}} \tilde\rho'^{\,d+2\vartheta}\, d\theta dx' < \infty \qquad \text{if } \ b>0,\ d\ge 3,$$

$$(11.4.32)_4 \quad \iint_{\{\tilde\rho'^2 \ge \epsilon v\}} \tilde\rho'^{\,-a-\delta\bar a} v^{\frac{b}{2}+\delta}\, d\theta dx' < \infty \qquad \text{if } \ b\le 0,\ d=2,$$

$$(11.4.32)_5 \quad \iint_{\{\tilde\rho'^2 \ge \epsilon v\}} \tilde\rho'^{\,d+2\vartheta+\delta}\, d\theta dx' < \infty \qquad \text{if } \ b>0,\ d=2,$$

where $\delta > 0$ is arbitrarily small, $\bar a = \mu(\nu-\mu)^{-1}$, $\bar b = \nu(\nu-\mu)^{-1}$.

We leave to the reader

Problem 11.4.14. Modify and analyze the same way the other examples of this section.

11.4.5 Operators with Indefinite Principal Symbols

We leave to the reader

Problem 11.4.15. Analyze operators with indefinite principal symbols.

In this case one should replace conditions (11.4.1), (11.4.2) by

$$(11.4.1)^* \qquad \|A(x,\xi)v\| \ge \epsilon_0\bigl(|\xi|+\rho\bigr)^{2m}\|v\| \qquad \forall \xi \quad \forall v$$

and

$$(11.4.2)^* \qquad \Bigl\|\sum_{\alpha:|\alpha|\le 2m} a_\alpha(x) v_\alpha\Bigr\| \ge \epsilon_0 \sum_{\alpha:|\alpha|\le 2m} \rho^{2m-|\alpha|}\|v_\alpha\| \qquad \forall v = (v_\alpha)_{\{\alpha:|\alpha|\le 2m\}}$$

respectively. Moreover, one should replace conditions $(11.4.1)'$, $(11.4.2)'$ by

$$(11.4.1)^{*\prime} \qquad \|A(x,\xi)v\| \ge \epsilon_0\bigl(\bigl(|\xi|+\rho\bigr)^{2m} - C\rho'^{\,2m}\bigr)\|v\| \qquad \forall \xi \quad \forall v$$

and

$$(11.4.2)^{*\prime} \quad \| \sum_{\alpha:|\alpha|\le 2m} a_\alpha(x) v_\alpha \| \ge \epsilon_0 \sum_{\alpha:|\alpha|\le 2m} \rho^{2m-|\alpha|} \|v_\alpha\| - C \sum_{\alpha:|\alpha|\le 2m-1} \rho'^{2m} \|v_\alpha\| \quad \forall v = (v_\alpha)_{\{\alpha:|\alpha|\le 2m\}}$$

respectively.

Unfortunately we are not aware of any examples of this type which are interesting from the physical point of view. The reader can easily construct artificial examples (like generalized Dirac operator) and analyze them.

11.5 Large Eigenvalues for Operators in Essentially Unbounded Domains (End)

Now we consider *essentially unbounded domains* which are domains containing massive[35)] exits to infinity. In domains of this type the spectrum of the operator in question is discrete only because the operator contains lower degree terms which are coercive with the function ρ tending to ∞ at infinity (in almost all directions).

Therefore even the order of the asymptotics of $\mathsf{N}^{\mathsf{W}}(\tau)$ depends on the lower degree terms (which are not anymore "lower order terms" from our point of view).

We treat here only operators with positive definite senior symbols and leave the indefinite case to the reader.

11.5.1 Standard Results

We begin with potentials of the power growth at infinity. As the first example we use only the results of Parts II and III to obtain the following well known assertion:

Theorem 11.5.1. *Let X be an unbounded connected domain in $\mathbb{R}^d$ and let conditions* (11.1.1)–(11.1.3), (11.4.1) *and* (11.4.4) *be fulfilled with $\gamma = \epsilon_1\langle x\rangle$, $\rho = \langle x\rangle^\mu$, $\mu > 0$ where here and below $\langle x\rangle = (|x|^2+1)^{\frac{1}{2}}$.*

[35)] E.g., conical. Domains with cusps even having infinite volume do not qualify as essentially unbounded and will be treated in the next chapter.

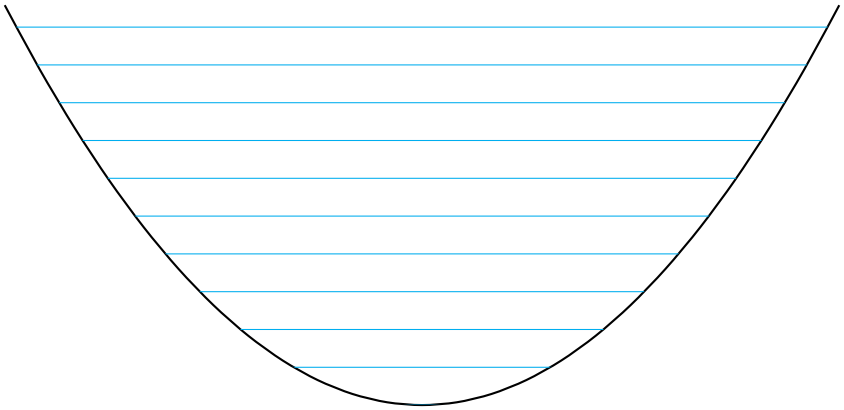


Figure 11.8: Coercive at infinity potential; blue lines show symbolically energy levels of the corresponding Schrödinger operator.

(i) Let us assume that for every $\tau > c$ one of the non-degeneracy conditions is fulfilled after rescaling for the symbol $A(x,\xi)\tau^{-1}$ on the energy level 1 uniformly with respect to τ, x, ξ (this assumption is only restrictive for $|x| \ge C_0$). Then asymptotics

$$N^-(\tau) = N^W(\tau) + O\big(\tau^{l(d-1)}\big) \tag{11.5.1}$$

holds as $\tau \to +\infty$ where $N^W(\tau)$ is given by (11.4.9) *and $N^W \asymp \tau^{ld}$, $l = \frac{1}{2m\mu}(\mu+1)$.*

(ii) Let us assume that for every $\tau > c$ one of the corresponding non-degeneracy conditions[36] *is fulfilled for the symbol $A(x,\xi)\tau^{-1}$ on the energy level 1 uniformly with respect to τ, x, ξ. Then for $\vartheta \ge 0$ asymptotics*

$$N^-_{(\vartheta)}(\tau) = N^W_{(\vartheta)}(\tau) + O\big(R_{(\vartheta)}(\tau)\big) \tag{11.5.2}$$

holds as $\tau \to +\infty$ with

$$R_{(\vartheta)}(\tau) = \begin{cases} \tau^{l(d-1)+\vartheta(1-l)} & \text{for } \vartheta < d-1, \\ \tau^{d-1}\log\tau & \text{for } \vartheta = d-1, \\ \tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta} & \text{for } \vartheta > d-1 \end{cases} \tag{11.5.3}$$

where $N^W_{(\vartheta)}(\tau) \asymp \tau^{ld+\vartheta}$.

[36] Recall that for operators with the scalar symbols some very weak non-degeneracy condition is needed only as $\vartheta = 0$.

Proof. Proof trivially follows from the corresponding results of Parts II and III (also see Introduction). □

Remark 11.5.2. (i) Obviously domain $\{|x| \asymp \tau^{1/(2m\mu)}\}$ provides the main contribution to the asymptotics. Further, as $\vartheta < \vartheta^* = (d-1)$ this domain also provides the main contribution to the remainder estimate.

(ii) However as $\vartheta > \vartheta^*$ inner domain $\{|x| \asymp 1\}$ provides the the main contribution to the remainder estimate while for $\vartheta = \vartheta^*$ intermediate domain $\{\epsilon^{-1} \le |x| \le \epsilon\tau^{1/(2m\mu)}\}$ provides the main contribution to the remainder estimate.

Therefore to improve remainder estimate one needs non-periodicity assumption for the corresponding Hamiltonian flow.

Theorem 11.5.3. *Let assumptions of Theorem 11.5.1 be fulfilled. Moreover, let $X \cap \{x \ge c_1\} = X^0 \cap \{x \ge c_1\}$ where X^0 is a conical (with respect to x) domain with $\partial X^0 \setminus 0 \in \mathscr{C}^K$ and let the stabilization conditions*

$$D^\alpha(a_\beta - a^0_\beta) = o\big(|x|^{(2m-|\beta|)\mu-|\alpha|}\big) \qquad \forall \beta : |\beta| \le 2m \quad \forall \alpha : |\alpha| \le 1 \tag{11.5.4}$$

be fulfilled as $|x| \to \infty$ with functions $a^0_\beta \in \mathscr{C}^K(\bar{X}^0 \setminus 0)$ which are positive homogeneous of degrees $(2m-|\beta|)\mu$ with respect to x.

(i) Further, let us assume that on the energy level $\tau = 1$ for the quasihomogeneous symbol

$$A^0(x,\xi) = \sum_{|\beta|\le 2m} a^0_\beta(x)\xi^\beta \tag{11.5.5}$$

the standard non-periodicity condition to the Hamiltonian trajectories in T^*X^0 is fulfilled and that these permitted trajectories[37] *never hit $0 \times \mathbb{R}^d$.*

Then for $\vartheta < \vartheta^* = (d-1)$ asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + o\big(R_{(\vartheta)}(\tau)\big) \tag{11.5.6}$$

holds $\tau \to +\infty$ with $R_{(\vartheta)}(\tau) = \tau^{l(d-1)+\vartheta(1-l)}$ according to (11.5.3).

[37] I.e. trajectories originated at $\{A^0(x,\xi) = 1\} \setminus \Lambda$ where Λ is an exceptional set.

(ii) On the other hand, let $\vartheta > \vartheta^*$, and the standard non-periodicity condition to Hamiltonian trajectories be fulfilled on the energy level $\tau = 1$ for the symbol

$$a(x,\xi) = \sum_{|\beta|=2m} a_\beta(x)\xi^\beta \tag{11.5.7}$$

in the domain X. Then asymptotics (11.5.6) *also holds as $\tau \to +\infty$ but this time with $R_{(\vartheta)}(\tau) = \tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta}$ according to* (11.5.3).

(iii) Finally, let $\vartheta = \vartheta^*$ and stabilization condition (11.5.4) *and the standard non-periodicity condition to Hamiltonian trajectories is fulfilled on the energy level $\tau = 1$ for the symbol*

$$a^0(x,\xi) = \sum_{|\beta|=2m} a^0_\beta(x)\xi^\beta \tag{11.5.8}$$

in the domain X^0 and these permitted[37] trajectories never hit $0 \times \mathbb{R}^d$. Then asymptotics (11.5.6) *holds as $\tau \to +\infty$ but this time with $R_{(\vartheta)}(\tau) = \tau^{d-1}\log\tau$ according to* (11.5.3).

Remark 11.5.4. (i) If only stabilization condition (11.5.4) is fulfilled then the microhyperbolicity condition is automatically fulfilled for the symbol $A(x,\xi)\tau^{-1}$ on the energy level 1 and

$$\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) = \varkappa_{0(\vartheta)}\tau^{ld}\big(1+o(1)\big) \tag{11.5.9}$$

as $\tau \to +\infty$.

(ii) As $\vartheta = 0$ asymptotics must include the second term $\varkappa_1\tau^{l(d-1)}$ where for the Schrödinger operator,

$$\varkappa_0 = (2\pi)^{-d}\omega_d \int_{X^0} \big(1-V^0\big)_+^{\frac{d}{2}} \sqrt{g^0}\,dx \tag{11.5.10}$$

and

$$\varkappa_1 = \mp\frac{1}{4}(2\pi)^{1-d}\omega_{d-1}\int_{\partial X^0} \big(1-V^0\big)_+^{\frac{d-1}{2}}\,dS^0 \tag{11.5.11}$$

for Dirichlet and Neumann boundary conditions respectively, dS^0 is the Riemannian density on ∂X^0 generated by the induced Riemannian metrics, $g^0 = \det(g^{jk0})^{-1}$.

Proof of Theorem 11.5.3. (i) One can see easily that as $\vartheta < \vartheta^*$ the contribution of zone $\{|x| \le \varepsilon\tau^{\frac{1}{2m\mu}}\}$ to the remainder does not exceed $\varepsilon^\delta R_{(\vartheta)}(\tau)$ and therefore only zone $\{\varepsilon\tau^{\frac{1}{2m\mu}} \le |x| \le C_0\tau^{\frac{1}{2m\mu}}\}$ should be considered: in all cases zone $\{|x| \ge C_0\tau^{\frac{1}{2m\mu}}\}$ is elliptic.

Let us apply the theorems of Parts II and III and we examine the behavior of the billiards generated by the symbol $A(x,\xi)$ on $\Sigma_\tau = \{(x,\xi), \tau \in \mathsf{Spec}\, A(x,\xi)\}$. We take

$$\Lambda_1 = \Lambda_{1,\tau,\epsilon,T} = \big\{(x,\xi) \in \Sigma_\tau, |x| \ge \varepsilon\tau^{\frac{1}{2m\mu}}, \quad |x\tau^{-\frac{1}{2m\mu}} - y| + |\xi\tau^{-\frac{1}{2m}} - \eta| \ge \epsilon \quad \forall (y,\eta) \in \Lambda^0_T\big\} \tag{11.5.12}$$

where $\Lambda^0_T = \Sigma^0 \setminus \Lambda^1_T$, $\Sigma^0 = \{(y,\eta), 1 \in \mathsf{Spec}\, A^0(y,\eta)\}$ and for every point of Λ^1_T the Hamiltonian frow of A^0 (with reflection from ∂X^0) for time T in an appropriate time direction does not enter ε-vicinity of $0 \times \mathbb{R}^d$ and periodicity is violated with at least divergence ε; we fix arbitrary small ε in advance.

By assumption $\mathsf{mes}(\Lambda^0_T) = 0$, on the other hand, Λ^0_T is a relatively closed subset of $\Sigma^0 \setminus \{x = 0\}$ for every T. The remaining arguments repeat those in the proof of Theorem 11.1.1: we check that the conditions on billiards generated by $A^0(x,\xi)$ and $A(x,\xi)$ coincide provided $\tau \ge C_{\varepsilon,T}$.

(ii) On the other hand, for $\vartheta > \vartheta^*$ the principal contribution to the remainder estimate is given by the zone $\{x \in X, |x| \le r\}$ (with arbitrarily large fixed r) in the sense that the contribution of the remaining part does not exceed $r^{-\delta}R_{(\vartheta)}(\tau)$.

Therefore, to prove Statement (ii) one should treat Hamiltonian billiards in this zone, in which one can replace $A(x,\xi)$ by $a(x,\xi)$ for large τ.

(iii) Finally, for $\vartheta = \vartheta^*$ the principal contribution to the remainder estimate is given by the zone $\{r \le |x| \le \varepsilon\tau^{\frac{1}{2m\mu}}\}$ for every fixed ε and r in the sense that the contribution of the remaining part does not exceed $(\varepsilon^\delta + r^{-\delta})R_{(\vartheta)}(\tau)$.

Therefore, to prove Statement (iii) one should treat Hamiltonian billiards in this zone, in which one can replace $A(x,\xi)$ by $a^0(x,\xi)$ for large τ, $|x|$. □

Let us consider scalar operators. Observing that the microhyperbolicity condition is automatically fulfilled for $|x| \le \epsilon\tau^{\frac{1}{2m\mu}}$ and recalling the results of Chapter 5 we arrive immediately to

Theorem 11.5.5. *Let X be an unbounded connected domain in $\mathbb{R}^d$ and let conditions* (11.1.1)–(11.1.3), (11.4.1), (11.4.4) *be fulfilled with $\gamma = \epsilon_1\langle x\rangle$, $\rho = \langle x\rangle^\mu$, $\mu > 0$.*

Moreover, let A be a scalar operator. Then

(i) Asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\bigl(\tau^{l(d-1)+\delta}\bigr) \tag{11.5.13}$$

holds as $\tau \to +\infty$ with an arbitrarily small exponent $\delta > 0$ and asymptotics (11.5.2) *holds for $\vartheta > 0$.*

(ii) Moreover, for $0 < \vartheta < \vartheta^* = (d-1)$, $\vartheta > \vartheta^*$, $\vartheta = \vartheta^*$ respectively Statements (i)–(iii) of Theorem 11.5.3 remain true.

11.5.2 Strongly Non-Periodic Hamiltonian Flow

In what follows we consider homogeneous coefficients with singularities and (what is more essential here) with degenerations. However, we now improve the remainder estimates under stronger conditions to Hamiltonian trajectories.

Theorem 11.5.6. *Let the conditions of Theorem 11.5.1 be fulfilled. Let A be a scalar operator. Assume that*

(11.5.14) *Either $X^0 = \mathbb{R}^d$ or A is the Schrödinger operator or its power.*

Further, let the strong stabilization condition

$$D^\alpha(a_\beta - a^0_\beta) = O\bigl(|x|^{2m-|\beta|)\mu-|\alpha|-\delta}\bigr) \qquad \forall \beta : |\beta| \le 2m \quad \forall \alpha : |\alpha| \le 1 \tag{11.5.4)*}$$

be fulfilled as $|x| \to \infty$ with some $\delta > 0$. Furthermore, let us assume that the Hamiltonian flow (with reflections at ∂X^0) is of non-periodic power type[38] *and that along trajectories $(x(t), \xi(t))$ with $(x(0), \xi(0)) \in \Lambda^0_{\varepsilon,T} \subset \Sigma_1$, $|x(0)| = 1$, $\varepsilon = T^{-M}$, condition $|x(t)| \ge T^{-M_1}$ is fulfilled.*

[38] We are aware of no example when the flow is of non-periodic exponential type but is not of non-periodic power type. We would appreciate construction of such example. We leave to the reader to formulate the statement in the case of non-periodic exponential type.

Then asymptotics

$$\mathsf{N}^{-}(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + \bigl(\varkappa_1 + O(\tau^{-\delta'})\bigr)\tau^{l(d-1)} \tag{11.5.15}$$

holds as $\tau \to +\infty$. *Moreover, for* $0 < \vartheta \le d-1-\delta$ *asymptotics*

$$\mathsf{N}^{-}_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{l(d-1)+\vartheta(1-l)-\delta'}\bigr) \tag{11.5.16}$$

holds as $\tau \to +\infty$ *with* $\delta' = \delta'(d, m, \delta, l) > 0$.

Example 11.5.7. (i) Growth and non-periodicity conditions of Theorem 11.5.6 to the Hamiltonian flow are fulfilled for the Schrödinger operator with $X^0 = \mathbb{R}^d$ and $A^0(x,\xi) = \bigl(|\xi|^2 + |x|^{2\mu}\bigr)$, $0 < \mu \ne 1$.

(ii) Therefore the statement of Theorem 11.5.6 is true for this operator (provided all the other conditions of this theorem, including (11.5.4)*, are fulfilled) and for the $2m$-order operator with $A^0(x,\xi) = (|\xi|^2 + |x|^{2\mu})^m$, and one can replace $X^0 = \mathbb{R}^d$ by the X^0 obtained after (a sequence of) the following transformations:

(a) We take the factor manifold of X^0 with respect to a finite rotation group (with center at the origin),

(b) We consider the reflection $S : \bar{X}^0 \to \bar{X}^0$ with respect to a hyperplane and remove from X^0 some subset $\mathcal{K}$ of this plane provided $\tilde{\gamma}^{-1-\vartheta} \in \mathscr{L}^1(\mathbb{S}^{d-1})$ with $\tilde{\gamma} = \mathsf{dist}(x, \mathcal{K})$.

Proof. Obviously it is sufficient to prove Statement (i). Moreover, the potential $V^0 = |x|^{2\mu}$ is spherically symmetric and therefore an angular momentum is constant along every Hamiltonian trajectory and therefore the x-projection of this trajectory lies in some 2-dimensional plane. Therefore it is sufficient to treat only the case $d = 2$. We introduce polar coordinates (r, θ) and use the fact that the *angular momentum* $M = \dot{\theta} r^2$ is constant where $\dot{\theta} = \frac{d\theta}{dt}$, etc.

Therefore the energy is equal to

$$E = \frac{1}{2}\dot{r}^2 + \frac{1}{2}M^2 r^{-2} + r^{2\mu} = \frac{1}{2}\dot{r}^2 + W(r, M) \tag{11.5.17}$$

and is also constant and therefore r obeys equation of oscillations

$$\ddot{r} = -W'(r, M) \tag{11.5.18}$$

with the *effective potential* $W(r) = \frac{1}{2}M^2r^{-2} + r^{2\mu}$.

Then a trajectory with $|M| \ge \varepsilon$ lies permanently in the zone $\{(\theta, r), r \ge M\sqrt{\frac{2}{E}}\}$. One can easily see that

$$|M| \le M_0(E) = (2\mu)^{\frac{1}{2}}\big(\frac{E}{\mu+1}\big)^{\frac{1}{2\mu}(\mu+1)} \tag{11.5.19}$$

and every trajectory oscillates between the largest and the smallest values $r = r_2(E, M)$ and $r = r_1(E, M)$ respectively where $r_1 < r_2$ [39)] are roots of the equation $W(r, M) = E$ (i.e. $\frac{1}{2}M^2r^{-2} + r^{2\mu} = E$) and the period of the oscillation is

$$T_\Pi = T_\Pi(E, M) = 2\int_{r_1(E,M)}^{r_2(E,M)} \big(2E - 2W(r, M)\big)^{-\frac{1}{2}}\, dr \tag{11.5.20}$$

while the increment of θ during a period is

$$\theta_\Pi = 2\int_{r_1(E,M)}^{r_2(E,M)} Mr^{-2}\big(2E - 2W(r, M)\big)^{-\frac{1}{2}}\, dr. \tag{11.5.21}$$

One can easily see that

(11.5.22) If $\varepsilon \le |M| \le M_0(E) - \varepsilon$ and $E \asymp 1$ then

$$|r_2(E, M) - r_1(E, M)| \ge \epsilon\varepsilon^p, \quad r_1(E, M) \ge \epsilon\varepsilon^p, \quad T_\Pi(E, M) \ge \epsilon\varepsilon^p, \quad \theta_\Pi \ge \epsilon\varepsilon^p$$

and the functions $f(E, M) = r_1(E, M), r_2(E, M), T_\Pi(E, M), \theta_\Pi(E, M)$ satisfy the inequalities

$$|D^\beta_{E,M} f| \le C_{|\beta|}\varepsilon^{-p|\beta|} \qquad \forall \beta$$

with appropriate constants $p, \epsilon > 0$ and $C_{|\beta|}$; $\varepsilon > 0$ is a small parameter here.

On the other hand,

(11.5.23) The $dxd\xi : dA^0$-measure of the set of points

$$\big\{(r, \theta) : E = 1, |M| \le \varepsilon \text{ or } E = 1, |M| \ge M_0(E) - \varepsilon\big\}$$

is less than $C\varepsilon^\delta$ with $\delta > 0$.

[39)] And $r_1(E, M) = r_2(E, M)$ if and only if $|M| = M_0(E)$.

These assertions (11.5.22) and (11.5.2) yield that the Hamiltonian flow is of power type. Let us prove that as $\mu \neq 1$ this flow is of non-periodic power type.

The arguments above yield that it is sufficient to prove that

(11.5.24) For $k, n \in \mathbb{Z}^+, m \le \varepsilon^{-1}, n \le \varepsilon^{-1}$ the measure of the set of points (x, ξ) with $E(x, \xi) = 1$ such that

$$|\theta_\Pi(1, M(x, \xi)) - 2\pi \frac{k}{n}| \le \varepsilon^L \tag{11.5.25}$$

does not exceed $O(\varepsilon^{\frac{L}{q}})$ where L is arbitrarily large.

Obviously, $\theta_\Pi(1, M)$ is an analytic function of $M \in (0, M_0(1))$; further, $\theta_\Pi(1, M_0(1) - \eta^2)$ is an analytic function of $\eta \in (-\epsilon_0, \epsilon_0)$.

Furthermore, it is well known (see, e.g., V. I. Arnold [2]) that

(11.5.26) For $\mu > 0, \mu \neq 1$ function $\theta_\Pi(1, M)$ is not constant.

Therefore the measure of points (x, ξ) with $E(x, \xi) = 1$ and $|M(x, \xi)| \ge \epsilon_1$, satisfying (11.5.25) is $O(\varepsilon^{\frac{L}{q}})$ as $\varepsilon \to +0$. Here $\epsilon_1 > 0$ is an arbitrary constant.

On the other hand, one can easily see that θ_Π is continuous at $[0, M_0(1)]$ and $\theta_\Pi(+0) = \pi$. Therefore in the zone $\{(x, \xi), 0 < M(x, \xi) \le \epsilon\epsilon_0\}$ inequality (11.5.25) can be fulfilled only with $k \asymp n$.

Further, one can easily see that for $M \in (0, \epsilon_0)$, $\theta_\Pi(1, M) = \mathcal{F}(M, M^{2\mu})$ where $\mathcal{F}$ is an analytic function of two variables in a neighborhood of $(0, 0)$. Furthermore, $\theta_\Pi(1, M) \neq \mathsf{const}$ and therefore $|\nabla_M \theta_\Pi(1, M)| \ge \epsilon_1 M^p$ for $M \in (0, \epsilon_1)$ with appropriate $\epsilon_1 > 0$ and p and therefore the measure of the set of points with $E(x, \xi) = 1$ and $M(x, \xi) \in (0, \epsilon_1)$ satisfying (11.5.25) is $O(\varepsilon^{\frac{L}{p}})$. □

Remark 11.5.8. (i) For $\vartheta > d - 1 + \delta$ one can easily improve the remainder estimate $O(\tau^{\frac{1}{2m}(d-1\vartheta)+\vartheta})$ to $O(\tau^{\frac{1}{2m}(d-1\vartheta)+\vartheta-\delta'})$ under a corresponding condition on the Hamiltonian flow of $a(x, \xi)$.

In order to reach uniformity one can assume that stabilization condition $(11.5.4)^*$ is fulfilled only for terms with $|\alpha| = 2m$. In this case only these terms should be scalar but if some junior terms are not scalar one should check that some non-degeneracy condition is fulfilled.

(ii) Moreover, one can consider the case $\vartheta = d-1$. It is easy to replace the factor $\log\tau$ by $\log^{1-\delta'}\tau$ but better improvements are possible only under much more complicated and restrictive conditions.

11.5.3 Periodic Hamiltonian Flow

Let A be a scalar operator and condition (11.5.14) be fulfilled. Further, let us assume that

(11.5.27) The Hamiltonian trajectories of $A^0(x,\xi)$ are periodic with period $T(A^0(x,\xi))$ and

$$A = A^{0\mathrm{w}}(x,D) + A'^{\mathrm{w}}(x,D), \tag{11.5.28}$$

where

$$D^\beta(a'_\alpha - a^1_\alpha) = O\big(|x|^{(2m-|\alpha|)\mu-\delta_1-\delta'-|\beta|}\big) \qquad \forall\alpha : |\alpha|\le 2m \quad \forall\beta : |\beta|\le K \qquad \text{as} \quad |x|\to\infty \tag{11.5.29}$$

where $a^1_\alpha(x)$ are positively homogeneous of degrees $(2m-|\alpha|)\mu-\delta_1$ with respect to x and are smooth away from 0, $0<\delta_1<2(\mu+1)$, $\delta'>0$.

Let us introduce function

$$b(x,\xi) = \frac{I}{T_0}\int_0^{T_0} A^1\circ\Psi_t dt \qquad \text{with} \quad A^1(x,\xi) = \sum_{|\alpha|\le 2m} a^1_\alpha(x)\xi^\alpha \tag{11.5.30}$$

on the surface $\Sigma^0 = \big\{(x,\xi), A^0(x,\xi)=1\big\}$; recall that $I = \frac{1}{2m\mu}(\mu+1)$ and $T_0 = T(1)$.

It follows from the quasihomogeneity of A^0 with respect to (x,ξ) that the action vanishes[40)].

Then the results of Sections 6.2, 8.3 immediately yield the following theorem:

[40)] In fact, the action is equal to

$$\frac{1}{T_0}\int_0^{T_0}\big(k\langle\xi, A^0_\xi\rangle + (1-k)\langle x, A^0_x\rangle - A\big)\circ\Psi_t dt$$

with an arbitrary constant k. Let us take $k=\mu(\mu+1)^{-1}$. Then the Euler identity yields that the integrand vanishes for $I=1$. On the other hand, we must assume that $I=1$: otherwise we should replace A by A^I in order to obtain $T=T_0$ for all (x,ξ).

Theorem 11.5.9. *Let conditions* (11.5.14) *and* (11.5.27)–(11.5.30) *be fulfilled. Further, let us assume that*

$$\mathsf{mes}_{\Sigma}\big(\{(x,\xi)\in\Sigma, |b(x,\xi)-\omega|\le\varepsilon\}\big) = O(\varepsilon^{\delta}) \qquad \text{as } \varepsilon\to+0 \tag{11.5.31}$$

with $\delta>0$ *and*

$$\mathsf{dist}(\Psi_t(x,\xi),(x,\xi)) \ge t(T_0-t)\gamma(x,\xi) \qquad \forall (x,\xi)\in\Sigma \quad \forall t\in(0,T_0) \tag{11.5.32}$$

with $\gamma\ge 0$ *such that* $\mathsf{mes}\big(\{(x,\xi),\gamma(x,\xi)\le\varepsilon\}\big)=O(\varepsilon^{\delta})$ *as* $\varepsilon\to+0$.

Then

(i) If $\delta_1<\mu+1$ *and condition* (11.5.31) *is fulfilled for every* $\omega\in\mathbb{R}$ *then asymptotics*

$$\mathsf{N}^{-}(\tau)=\mathsf{N}^{\mathsf{W}}(\tau)+\kappa_1\tau^{l(d-1)}+O\big(\tau^{l(d-1)-\delta''}\big) \tag{11.5.33}$$

holds as $\tau\to+\infty$ *with* $\delta''>0$.

(ii) If $\delta_1\in[\mu+1,2\mu+2)$ *then for* $\tau\to+\infty$ *such that* $\tau^l\in\bigcup_{n\in\mathbb{Z}^+}J_n$ *asymptotics*

$$\mathsf{N}^{-}(\tau)=\mathsf{N}^{\mathsf{W}}(\tau)+\big(\kappa_1+F(\tau)\big)\tau^{l(d-1)}+O\big(\tau^{l(d-1)-\delta''}\big) \tag{11.5.34}$$

holds with $\delta''>0$ *where*

$$J_n=\big[\nu(n+\frac{1}{4}\omega_0)+(\omega-\epsilon_1)(\nu n)^{l-\frac{\delta_1}{2m\mu}}, \nu(n+\frac{1}{4}\omega_0)+(\omega+\epsilon_1)(\nu n)^{l-\frac{\delta_1}{2m\mu}}\big],$$

ω_0 *is the Maslov index of the trajectory* $\Psi_t(x,\xi)$ *with* $t\in(0,T_0)$, $\nu=\frac{2\pi l}{T_0}$ *and* $\epsilon_1>0$ *is small enough,*

$$F(\tau)=(2\pi)^{-d}lT_0^{-1}\int_{\Sigma}\Upsilon\Big(T_0l^{-1}\big((\tau^l-\frac{1}{4}\pi\omega_0)-\tau^{l-\frac{\delta_1}{2m\mu}}b\big)\Big)\times dxd\xi : dA^0. \tag{11.5.35}$$

Let us consider the perturbed harmonic oscillator $A_0=\frac{1}{2}(|D|^2+|x|^2)$ in $\mathbb{R}^d$ more carefully. In this case $\mu=l=m=1$, $T_0=2\pi$, $\omega_0\equiv 2d \mod 4\mathbb{Z}$ and the x-projections of the Hamiltonian trajectories are ellipses centered at the origin.

Moreover,

(11.5.36) $\operatorname{Spec} A_0 = \{\tau_n = \frac{d}{2} + n, n \in \mathbb{Z}^+\}$. The multiplicity of τ_n is $P(n)$ where $P(.)$ is a polynomial of degree $d-1$.

Functional-analytic arguments yield that

(11.5.37) If the perturbing operator is a potential V with $\|V\|_{\mathscr{L}^\infty} \le \epsilon$ then the spectrum consists of clusters of length $\le \epsilon$.

We leave to the reader

Problem 11.5.10. Prove that for generic functions a^1_α ($|\alpha| \le k$) which are positively homogeneous of degree $(2-|\alpha|-\delta_1)$ condition (11.5.31) is fulfilled for every ω.

For such perturbations the theory of Section 6.2 yields that

(11.5.38) Asymptotics (11.5.33) holds for $0 < \delta_1 < 2$ and asymptotics (11.5.34)–(11.5.35) holds for $\delta_1 \ge 2$ where $\delta_k > 0$ ($k = 0, 1, 2$) are now arbitrary.

In particular, one can take $k = 0$ and a perturbing potential $V' = v_0 r^{2\mu-\delta_1}$ with arbitrary $v_0 \ne 0$ and $0 < \delta_1 \ne 2$.

Let us consider the case $b \equiv 0$. Then we have two possibilities.

The first (rather trivial) possibility is to assume that $A = A^{0\mathrm{w}} + A^{1\mathrm{w}} + A''^{\mathrm{w}}$ where A'' (instead of A') satisfies condition (11.5.29) with a^2_α, δ_2 instead of a^1_α, δ_1 respectively, $\delta_2 \in (\delta_1, 2\delta_1)$. Then one can construct the symbol $b(x,\xi)$ by formula (11.5.30) with A^2 instead of A^1, assume that condition (11.5.31) is fulfilled and obtain asymptotics (11.5.33) or (11.5.34)–(11.5.35) with δ_2 instead of δ_1.

However, for $\delta_2 = 2\delta_1$ the situation is more complicated because in this case b contains a term which is quadratic with respect to A^1.

So, let us assume that

$$A^1 \circ j^* = -A^1 \tag{11.5.39}$$

where j^* is the antipodal map $(x,\xi) \to (-x,-\xi)$. Repeating the arguments of the proof of Theorem 11.3.21 we again obtain formula (11.3.27):

$$b = \frac{1}{2\pi}\Big(\int_0^{2\pi} A^2 \circ \Psi_t \, dt + \int_0^\pi \int_0^\pi \{A^1 \circ \Psi_t, A^1 \circ \Psi_{t+t'}\} \, dt dt'\Big) \tag{11.5.40}$$

is a positive homogeneous symbol of degree $(2-2\delta_1)$ with respect to (x,ξ).

Therefore we have proven

Theorem 11.5.11. *Let* $X^0 = \mathbb{R}^d$, $A = A^{0\mathsf{w}} + A^{1\mathsf{w}} + A''^{\mathsf{w}}$ *where* A'' *satisfies* (11.5.29) *with* a^2_α *and* $\delta_2 > 0$ *instead of* a^1_α *and* δ_1. *Here* a^1_α *and* a^2_α *are functions smooth for* $x \neq 0$ *and positively homogeneous of degrees* $(2-|\alpha|-\delta_1)$, $(2-|\alpha|-\delta_2)$, *and* $\delta_2 = 2\delta_1$.

Further, let condition (11.5.39) *be fulfilled and let the symbol* b *be defined by* (11.5.40). *Then*

(i) If $\delta_2 < 2$ *and condition* (11.5.31) *is fulfilled for every* $\omega \in \mathbb{R}$ *then asymptotics* (11.5.33) *holds for* $\tau \to +\infty$.

(ii) If $\delta_2 \geq 2$ *and condition* (11.5.31) *is fulfilled for some* $\omega \in \mathbb{R}$ *then asymptotics* (11.5.34)–(11.5.35) *holds for* $\tau \to +\infty$ *and belonging to the intervals* J_n *indicated in Theorem 11.5.9(ii) with* $\omega_0 = 2(d-1)$, $\nu = 1$. *In these asymptotics as well as in the definition of the intervals* J_n *one should replace* δ_1 *with* δ_2.

We leave to the reader

Problem 11.5.12. (i) Prove that for generic positively homogeneous functions a^2_α ($|\alpha| \leq k$) with $k = 0, 1, 2$ condition (11.5.33) is fulfilled for all $\omega \in \mathbb{R}$.

(ii) Consider Riesz means with $\vartheta < \vartheta^* = (d-1)$.

Remark 11.5.13. It does not look right that in our results here $\delta'' > 0$ is unspecified small exponent. Later under certain conditions we will bring our results to be more sharp (up to being consistent with results of Section 6.2.

11.5.4 Singularities and Degenerations

Let us consider operators with homogeneous terms with singularities and (what is now more interesting) degenerations. In order to avoid non-degeneracy conditions we consider only the Schrödinger operator.

Theorem 11.5.14. *(i) Let* $d \geq 3$, $X = \{x = (r, \theta) \in \mathbb{R}^+ \times U\}$ *where* $U \subset \mathbb{S}^{d-1}$. *Let* $g^{jk} = g^{jk}(\theta)$, $V_j = v_j(\theta) r^\mu$, $V = v(\theta) r^{2\mu}$ *with* $\mu > 0$.

Further, let $v \geq 0$ *and let* U, g^{jk}, v_j, v *and* $\tilde{\rho} = \sqrt{v}$, $\tilde{\gamma} = \tilde{\gamma}(\theta)$ *satisfy conditions* (11.1.6)–(11.1.6) *and* (11.4.5).

Finally, let

$$v^{-\frac{d}{2\mu}}, v^{-\frac{d-1}{2\mu}}\tilde{\gamma}^{-1} \in \mathscr{L}^1(U). \tag{11.5.41}$$

Then asymptotics (11.5.1) *holds and one can substitute* $\mathsf{N}^{\mathsf{W}}(\tau)$ *by* $\varkappa_0\tau^{Id}$ *with* $I = \frac{1}{2\mu}(\mu+1)$ *and with the coefficient* $\varkappa_0$ *given by* (11.5.10).

Moreover, if $0 < \vartheta < \vartheta^* = (d-1)$ *and*

$$v^{-\frac{1}{2\mu}(d-1-\vartheta)}\tilde{\gamma}^{-1-\vartheta} \in \mathscr{L}^1(U) \tag{11.5.42}$$

then asymptotics (11.5.2)–(11.5.3) *holds.*

(ii) Let us assume that there exists a set $\Xi \subset \Sigma = \{(x,\xi), a(x,\xi) = 1\}$ *such that* $\mathsf{mes}_\Sigma(\Xi) = 0$ *and through every point of* $\Sigma \setminus \Xi$ *there passes an infinitely long non-periodic Hamiltonian billiard generated by the Hamiltonian*

$$H^0 = \tilde{\gamma}|x|\big(g^{jk}(\xi_j - V_j)(\xi_k - V_k) + V - 1\big). \tag{11.5.43}$$

Then asymptotics (11.5.6) *holds and one can substitute* $\mathsf{N}^{\mathsf{W}}(\tau)$ *by* $\varkappa_0\tau^{Id}$.

Moreover, if $0 < \vartheta < \vartheta^*$ *and*

$$v^{-\frac{1}{2\mu}(d-1-\vartheta)}\tilde{\gamma}^{-1-\vartheta} \in \mathscr{L}^1(U) \tag{11.5.44}$$

then asymptotics (11.5.6), (11.5.3) *holds.*

Proof. One can easily prove this theorem by the same method as Theorem 11.5.1 but also with analysis in the zone $X_{\mathsf{sing}} = \{\gamma \cdot (\tau^{\frac{1}{2}} + \rho) \le C_0\}$ with $\gamma = \tilde{\gamma}r$, $\rho = \tilde{\rho}r^\mu$.

In the calculation of $\mathsf{N}^{\mathsf{W}}(\tau)$ we use spherical coordinates and the change of variable $r = \tau^{\frac{1}{2\mu}}r'$. □

Remark 11.5.15. It should be noted that if in (11.5.43) we skip the regularizing factor $\tilde{\gamma}r$ in H^0 (i.e., replace H^0 by H^0_{st}) then the conditions of the Statement (ii) do not change because it follows from the assumptions of the Statement (i) that the set of the points through which pass Hamiltonian billiards generated by H^0_{st} and reaching $\{\tilde{\gamma}r = 0\}$ in a finite time is a set of measure 0.

We leave to the reader the following rather easy

Problem 11.5.16. Generalize Theorem 11.5.14 to operators different from the Schrödinger operator.

Example 11.5.17. Let $X = \mathbb{R}^d$, $d \ge 3$ and as $|x| \ge 1$ $V \asymp |x''|^{2\nu}|x|^{2\mu-2\nu}$ where $x = (x'; x'') = (x_1, \dots, x_{d'}; x_{d'+1} \dots, x_d)$, $d'' = d - d'$, $0 < d'' < d$ (in which case one should try $\rho(x) = |x''|^{\nu} \cdot |x|^{\mu-\nu}$, $\gamma(x) = \frac{1}{2}|x''|$).

Let us assume that the conditions to g^{jk}, V_j, V are fulfilled with the indicated γ and ρ. Then

(i) $v^{-\frac{d}{2\mu}} \in \mathscr{L}^1(\mathbb{S}^{d-1})$ and $v^{-\frac{1}{2\mu}(d-1-\vartheta)}\tilde{\gamma}^{-1-\vartheta} \in \mathscr{L}^1(\mathbb{S}^{d-1})$ if and only if

$$\nu < \nu_0^* = \mu\frac{d''}{d} \tag{11.5.45}$$

and

$$\nu < \nu_{1+\vartheta}^* = \mu(d'' - 1 - \vartheta)(d - 1 - \vartheta)^{-1} \tag{11.5.46}$$

respectively.

Therefore for $\nu < \mu(d''-1)(d-1)^{-1}$ asymptotics (11.5.1)[41] holds, and for $0 < \vartheta < d'' - 1$ under assumption (11.5.46) asymptotics (11.5.2)–(11.5.3) [42] holds.

(ii) Let $\vartheta = 0$. In order to treat the case $\nu \in [\nu_1^*, \nu_0^*]$ when condition (11.5.45) holds (or reaches the borderline value) and (11.5.46) fails, recall that the original remainder estimate was

$$R(\tau) = \int_{\{V \le C\tau, \sqrt{\tau}\gamma \ge 1\}} \tau^{\frac{d-1}{2}}\gamma^{-1}\,dx + \int_{\{V \le C\tau, \sqrt{\tau}\gamma \le 1\}} \tau^{\frac{d}{2}}\,dx.$$

Introducing spherical coordinates and integrating over r we obtain the remainder estimate

$$R(\tau) = \tau^{l(d-1)} \int_{\{v \le C\tau^{\mu+1}\tilde{\gamma}^{2\mu}\}} v^{-\frac{d-1}{2\mu}}\tilde{\gamma}^{-1}\,d\theta + \tau^{ld} \int_{\{v \ge C\tau^{\mu+1}\tilde{\gamma}^{2\mu}\}} v^{-\frac{d}{2\mu}}\,d\theta.$$

We can replace v by $|x''|^{2\nu} \cdot |x|^{2\mu-2\nu}$ here in which case we arrive to asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\bigl(\tau^{l(d-1)}\log\tau\bigr) \tag{11.5.47}$$

[41] As well as asymptotics (11.5.6) under the standard condition on Hamiltonian trajectories.

[42] As well as asymptotics (11.5.6), (11.5.3) under the standard condition on Hamiltonian trajectories. Both these footnotes remain true below.

as $\tau \to +\infty$ provided $\nu = \nu_1^*$ and the asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\bigl(\tau^{l(d-\eta)}\bigr) \tag{11.5.48}$$

as $\tau \to +\infty$ provided $\nu \in (\nu_1^*, \nu_0^*)$ and $\eta = (-\nu d + \mu d'')(\mu - \nu)^{-1} \in (0,1)$.

Here again one can replace $\mathsf{N}^{\mathsf{W}}(\tau)$ by $\varkappa_0 \tau^{ld}$ with $\varkappa_0$ given by (11.5.10).

(iii) Similarly, for $\nu = \nu_{\vartheta+1}^* = \mu(d'' - \vartheta - 1)(d - \vartheta - 1)^{-1}$ asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{l(d-1-\vartheta)+\vartheta} \log \tau\bigr) \tag{11.5.49}$$

holds as $\tau \to +\infty$ and for $\nu \in (\nu_{\vartheta+1}^*, \nu_0^*)$ asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{l(d-\eta)+\vartheta}\bigr) \tag{11.5.50}$$

holds as $\tau \to +\infty$ with $\eta = \bigl((d'' - \vartheta)\mu - (d - \vartheta)\nu\bigr)(\mu - \nu)^{-1} \in (0, \vartheta + 1)$.

(iv) Finally, for $\nu = \nu_0^*$ asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O(\tau^{ld}) \tag{11.5.51}$$

holds as $\tau \to +\infty$ where

$$\mathsf{N}^{\mathsf{W}}(\tau) = (2\pi)^{-d}\omega_d \int_{\gamma \ge \epsilon\tau^{-\frac{1}{2}}} (\tau - V)_+^{\frac{d}{2}} \sqrt{g}\, dx \tag{11.5.52}$$

and $\mathsf{N}^{\mathsf{W}}(\tau) \asymp \tau^{ld} \log \tau$ [43]. The results for $\vartheta > 0$ obviously follow from this statement.

In order to prove this statement one needs only note that in the domain $X_{\mathsf{sing}} = \{x, |x''| \le \epsilon\tau^{-\frac{1}{2}}\}$ one can take $\tilde\rho = 0$ in the inequality

$$\bigl((Au - \tau), u\bigr) \ge \epsilon \|u\|_m^2 - C\|\tilde\rho^m u\|^2 \tag{11.5.54}$$

for all $u \in \mathfrak{D}(A)$ supported in $\bar X_{\mathsf{sing}}$. Moreover, this estimate yields that

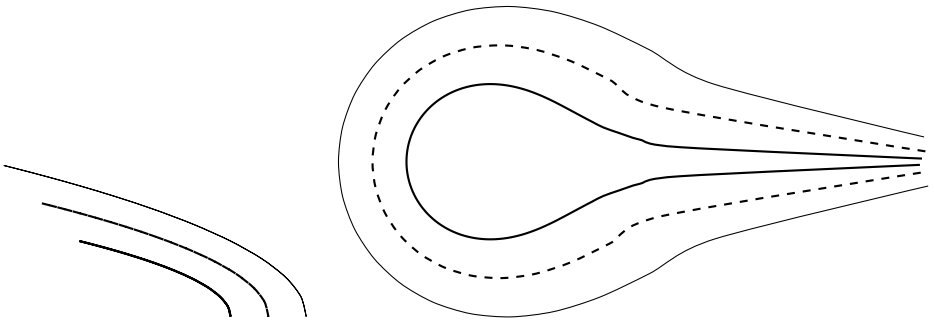
(v) All the results of Statements (i)–(iv) remain true for $d = 2$.

---

[43] Moreover, under stabilization condition (11.5.4)

$$\mathsf{N}^{\mathsf{W}}(\tau) = \bigl(\bar\varkappa + o(1)\bigr)\tau^{ld} \log \tau. \tag{11.5.53}$$

This statement remains true below.



(a) (b)

Figure 11.9: Level lines for non-degenerate (a) and degenerate in one direction (b) potential. In the latter case $V \le \tau$ forms a cusp but in contrast to cusps studied in Section 11.2 and 11.3 this cusp grows and fattens as $\tau \to +\infty$.

It is interesting to perturb the potentials treated above by potentials which have a lesser "average" growth at infinity bet does not have this degeneration. Namely, we can take perturbing potentials satisfying condition $(11.1.7)_3$ with the same γ as above and with $\rho' = (|x|+1)^{\mu'}$, $0 < \mu' < \mu$ instead of ρ:

$$|D^\alpha V'| \le c\rho'^2 \gamma^{-|\alpha|} \tag{11.5.55}$$

Then two different situations may arise:

(a) The perturbing potential is also coercive i.e., satisfies (11.4.5) with ρ replaced by ρ'

$$V' \ge \epsilon_0 \rho'^2 \qquad \forall x \tag{11.5.56}$$

in which case the perturbing potential "helps" to the unperturbed one. In this case the above analysis can be applied with no change.

(b) The perturbing potential is indefinite.

In the former case (a) we leave the detailed analysis to the reader and formulate the following statements:

Theorem 11.5.18 (Coercive perturbations). *(i) Let* $d \ge 3$ *and* X, g^{jk}, V_j^0 *and* V^0 *be as in Theorem 11.5.14. Let* $V_j = V_j^0 + V_j'$, $V = V^0 + V'$ *where* V_j' *and* V' *satisfy* (11.5.55) *and* (11.5.56) *with* $\rho' = \langle x\rangle^{\mu'}$, $0 < \mu' < \mu$. *Then asymptotics* (11.5.1) *holds with* $\mathsf{N}^{\mathsf{W}}(\tau) = \varkappa_0 \tau^{ld}\big(1 + o(1)\big)$ *as* $\tau \to +\infty$.

(ii) Moreover, if the Hamiltonian H^0 *given by* (11.5.43) *satisfies the conditions of the Statement (ii) of Theorem 11.5.14 then asymptotics* (11.5.6), (11.5.3) *holds as* $\vartheta = 0$.

(iii) Finally, if $0 < \vartheta < (d-1)$ *and* (11.5.42) *is fulfilled then in the frameworks of (i) and (ii) asymptotics* (11.5.2)–(11.5.3) *and* (11.5.6), (11.5.3) *hold respectively.*

Example 11.5.19. Let X, g^{jk}, V_j^0 and V^0 be as in Example 11.5.17. Let $V_j = V_j^0 + V_j'$, $V = V^0 + V'$ where V_j' and V' satisfy (11.5.55) and (11.5.56) with $\rho' = \langle x\rangle^{\mu'}$, $0 < \mu' < \mu$, and $\gamma = \epsilon|x''|$. Then

(i) If $\nu < \nu_{\vartheta+1}$ defined by (11.5.46), $0 \le \vartheta < (d''-1)$ then asymptotics (11.5.2)–(11.5.3) holds.

(ii) In the case of threshold value $\nu = \nu_{\vartheta+1}$, $0 \le \vartheta < (d''-1)$ asymptotics (11.5.47) holds.

(iii) In the case of above threshold value $\nu_{\vartheta+1} < \nu < \nu_0$, with ν_0 defined by (11.5.45), $0 \le \vartheta < (d''-1)$ asymptotics (11.5.50) holds with η given in Example 11.5.17(ii)$'$ provided $\mu' \le \mu'_* = (\mu-\nu)(\nu+1)^{-1}$.

(iv) On the other hand, for $\mu' > \mu'_*$ the remainder estimate is $O(\tau^q)$ with

$$q = \frac{1}{2}(d-\vartheta-1) + \frac{1}{2\mu'\nu}\big(d'\nu - (\mu-\nu+\mu')(d''-\vartheta-1)\big)$$

for $\vartheta < (d''-1)$ and with $q = \frac{d'}{2} + \frac{d'}{2\mu'} + \vartheta$ for $\vartheta > d''-1$.

For $\vartheta = (d''-1)$ the remainder estimate i $O(\tau^q \log\tau)$ with the same q.

(v) All these results remain true for $\nu = \nu_0$ and $\vartheta = 0$ with $\mathsf{N}^{\mathsf{W}}(\tau) \asymp \tau^{lq}\log\tau$.

(vi) Moreover, for $\nu > \nu_0$, $\vartheta = 0$ and $\mu' > \mu'_*$ these results remain true with $\mathsf{N}^{\mathsf{W}}(\tau) \asymp \tau^p$ with $p = \frac{1}{2}(d + \frac{d}{\mu'} - \frac{d''\mu}{\mu'\nu} + \frac{d''}{\nu})$. Then $p-q = \frac{1}{2\nu}\big(\nu+1-\frac{1}{\mu'}(\mu-\nu)\big) > 0$.

Let us now consider indefinite perturbations. In this case the perturbation cannot be too strong.

Theorem 11.5.20 (Indefinite perturbations). *(i) Let $d \ge 3$ and let X, g^{jk}, V_j^0 and V^0 be as in Theorem 11.5.14. Let $V_j = V_j^0 + V_j'$, $V = V^0 + V'$ where V_j' and V' satisfy* (11.5.55) *with $\rho' = \langle x\rangle^{\mu'}$, $0 < \mu' < \mu$ and $\gamma = \tilde\gamma|x|$. Then, if*

$$v^{-nd-\mu'\vartheta(\mu-\mu')^{-1}} \in \mathscr{L}^1(U) \tag{11.5.57}$$

and

$$v^{-n(d-\vartheta-1)-\mu'\vartheta(\mu-\mu')^{-1}}\tilde\gamma^{-\vartheta-1} \in \mathscr{L}^1(U) \tag{11.5.58}$$

with $n = \frac12(\mu'+1)(\mu-\mu')^{-1}$, $0 \le \vartheta < (d-1)$ then asymptotics (11.5.2)–(11.5.3) *holds and for $\vartheta = 0$ $\mathsf{N}^{\mathsf{W}}(\tau) = \varkappa_0\tau^{ld} + o(\tau^{l(d-1)})$.*

(ii) Moreover, if the Hamiltonian H^0 given by (11.5.43) *satisfies the conditions of Theorem 11.5.14(ii), then asymptotics* (11.5.6), (11.5.3) *holds.*

Proof. The proof is similar to the proof of Theorem 11.5.14 but the domain $\{V \le \tau\}$ consists of two overlapping zones $\{V^0 \le C\tau, \rho' \le C\tau^{\frac12}\}$ and $\{V^0 \le C\rho'^2, \tau \le C\rho'^2\}$.

Then $\tilde\rho(\tau) \asymp \tau^{\frac12}$ and $\tilde\rho(\tau) \asymp \rho'$ in the first and second zones respectively.□

Example 11.5.21. Let X, g^{jk}, V_j^0 and V^0 be as in Example 11.5.17. Let $V_j = V_j^0 + V_j'$, $V = V^0 + V'$ where V_j' and V' satisfy (11.5.55) with $\rho' = \langle x\rangle^{\mu'}$, $0 < \mu' < \mu$ and $\gamma = \epsilon|x''|$.

Let $\mu > \mu' + \nu$ (otherwise the potential V can be semi-bounded from above or even tend to $-\infty$ in the pipe $\{|x''| \le \epsilon\}$). Moreover, let us assume that

$$\nu < \frac{\mu-\mu'}{\mu'+1}. \tag{11.5.59}$$

Then considering the zone

$$X'' = \bigl\{x : |x''| \le z(x,\tau) = \epsilon\min\bigl(\tau^{-\frac12}, |x|^{-(\mu-\nu)(\nu+1)^{-1}}\bigr)\bigr\}$$

we see that we can take $\tilde\rho(\tau) = (\rho' - \epsilon_1 z^{-1})_+$ in condition (11.5.54) where $\epsilon_1 > 0$ does not depend on ϵ. Then (11.5.54) yields that we can take $\tilde\rho(\tau) = 0$ in X'' for $\tau \ge \epsilon^{-1}$ and small enough ϵ.

On the other hand, (11.5.59) yields that

$$(\tau^{\frac12}+\rho)\gamma \ge \epsilon_2 > 0, \quad \rho' \le C(\tau^{\frac12}+\rho)^{1-\delta}$$

outside of X'' where $\delta > 0$, $\rho = |x''|^{\nu}\cdot |x|^{\mu\mu-\nu}$, $\gamma = \epsilon_3|x''|$. Using these assertions one can easily prove that under condition (11.5.59) all the statements of Example 11.5.17 remain true.

We leave to the reader

Problem 11.5.22. (i) Consider the Schrödinger operator with coefficients satisfying conditions (11.1.6)–(11.1.8), (11.4.5) with $\rho = \langle x\rangle^{\mu}$, $\gamma = \epsilon\langle x\rangle^{1-\delta}$, $\mu > 0$, $\delta > 0$, $\mu + 1 > \delta$.

In this case the asymptotics $\mathsf{N}^{-}_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O(\tau^{q})$ appear with $\mathsf{N}^{\mathsf{W}}(\tau) \asymp \tau^{p}$ in domains conical at infinity.

(ii) Consider domains or Riemannian manifolds of type (11.5.69) (see below). Then asymptotics appear with other exponents p and q. In this example the magnetic field can grow strongly enough at infinity.

11.5.5 Quasihomogeneous Potentials

Let us now consider the quasihomogeneous case.

Example 11.5.23. (i) Let X be an L-quasiconical domain in $\mathbb{R}^d$ and let g^{jk}, V_j, V be L-quasihomogeneous on x of degrees 0, μ and 2μ respectively. Here $\mu > 0$ and $L = (L_1, \dots, L_d)$ with $L_j = 1$ for $1 \le j \le d'$ and $L_j > 1$ for $d'+1 \le j \le d$, $0 < d' < d$.

Let us assume that $\partial X \setminus 0 \in \mathscr{C}^{K}$ and $g^{jk}, V_j, V \in \mathscr{C}^{K}(\bar X \setminus 0)$ satisfy (11.1.8) and $V(x) > 0$ for $x \ne 0$.

Then all of the conditions (11.1.6)–(11.1.8) and (11.4.5) are fulfilled with

$$\rho = [x]_L^{\mu}, \qquad \gamma = \epsilon [x]_L \tag{11.5.60}$$

for

$$[x]_L \coloneqq \Big(\sum_j |x|^{\frac{\bar L}{L_j}}\Big)^{\frac{1}{\bar L}} \ge 1; \tag{11.5.61}$$

for $[x]_L < 1$ one should take $\gamma = [x]_L^{\bar L}$ with $\bar L = \max_j L_j$ here.

Then asymptotics

$$\mathsf{N}^-(\tau) = \varkappa_0 \tau^p + O(\tau^q) \tag{11.5.62}$$

holds with $p = \frac{d}{2} + \frac{L^*}{2\mu}$, $q = \frac{1}{2}(d-1) + \frac{1}{2\mu}(L^*-1)$, $L^* = \sum_j L_j$ and with the coefficient

$$\varkappa_0 = (2\pi)^{-d}\omega_d \int (1-V)_+^{\frac{d}{2}} \sqrt{g}\, dx. \tag{11.5.63}$$

We leave the analysis for $\vartheta > 0$ to the reader.

(ii) In order to improve these asymptotics let us consider the Hamiltonian billiards generated by the Hamiltonian

$$H = [x]_L^{1-\mu}\Big(\sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k) + V - \tau\Big). \tag{11.5.64}$$

Obviously, the contribution of the zones $\{x \in X, |x_i| \le \epsilon \tau^{\frac{L_j}{2\mu}}\}$ to the remainder estimate does not exceed $\epsilon_1 \tau^q$ with $\epsilon_1 \to 0$ as $\epsilon \to +0$ $(i = 1, \dots, d)$. So we consider billiards starting from complements to these zones.

One can easily see that along Hamiltonian trajectories

$$\frac{d\xi_i}{dt} = o\big(\tau^{\frac{1}{2}}\big), \qquad \frac{dx_i}{dt} = o\big(\tau^{\frac{L_i}{2\mu}}\big) \tag{11.5.65}$$

as $\tau \to +\infty$ for $i \ge d'+1$ provided $[x]_L \ge \epsilon \tau^{\frac{1}{2\mu}}$. Let us fix arbitrarily large T and arbitrarily small $\epsilon > 0$ and treat billiards of the length T.

Let us assume that $x' \ne 0$, $\nu' \ne 0$ on $\partial X \setminus 0$ where $x' = (x_1, \dots, x_{d'})$ and $\nu' = (\nu_1, \dots, \nu_{d'})$, $\nu = (\nu_1, \dots, \nu_d) = (\nu', \nu'')$ is a unit normal to ∂X. Then in the indicated zone $|\nu''| = o(1)$ and therefore the increment of ξ_i when a billiard reflects from ∂X is $o(\tau^{\frac{1}{2}})$ for $i \ge d'+1$.

Therefore $\tau^{-\frac{1}{2}}\xi_i$ and $\tau^{-\frac{L_i}{2\mu}} x_i$ with $i \ge (d'+1)$ are almost constant along billiards (if the length and the number of reflections are bounded).

Therefore if $(\bar{x}', \bar{\xi}')$ is a good starting point for a billiard generated by the Hamiltonian $H_{(\bar{x}'', \bar{\xi}'')} = H(x', \bar{x}'', \xi', \bar{\xi}'')$ in the cross-section domain $X_{(\bar{x}'')} = \{x' : (x', \bar{x}'') \in X\}$ then $(\bar{x}, \bar{\xi})$ is a good starting point for the original Hamiltonian.

Therefore the phase space measure of points which cannot be starting points does not exceed $\epsilon_2\tau^q$ with arbitrarily small $\epsilon_2 > 0$. Here $\tau \ge \tau_0(\epsilon_2)$.

Let us treat the non-periodicity. Let us assume that

$$g^{jk} = 0, \quad V_k = 0 \quad \text{for } j \le d',\ k \ge d'+1. \tag{11.5.66}$$

Then one can easily show that $|x''(0)-x''(t)| \ge \varepsilon|t|\tau^{\frac{1}{2\mu}}$ provided $t \in [-T, T]$, $|\xi''| \ge C_{\epsilon,T}\varepsilon\tau^{\frac{1}{2}}$, $\tau \ge \tau_0(\epsilon, \varepsilon, T)$ where ϵ is defined by the above conditions including the transversality condition. Therefore the non-periodicity condition is also fulfilled if we exclude a subset of measure $\epsilon_2\tau^q$ from the starting point set.

Therefore asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + \bigl(\varkappa_1 + o(1)\bigr)\tau^q \tag{11.5.67}$$

holds with the coefficient

$$\varkappa_1 = \mp\frac{1}{4}(2\pi)^{1-d}\omega_{d-1}\int_{\partial X}(1-V)_+^{\frac{d-1}{2}}\, dS'\sqrt{g''}\, dx'' \tag{11.5.68}$$

where dS' and $\sqrt{g''}dx''$ are Riemannian densities on the projections $(\partial X)_{x''} = \{x' : (x', x'') \in \partial X\}$ and $X_{x'} = \{x'' : (x', x'') \in X\}$ generated by the metrics $(g^{jk})_{j,k\le d'}$ and $(g^{jk})_{j,k\ge d'+1}$ respectively (these metrics and densities depend on x). Here the sign "$\mp$" corresponds to Dirichlet and Neumann boundary condition respectively.

Remark 11.5.24. Surely, these statements remain true in the case when the operator tends to an L-quasihomogeneous operator or if assumptions are fulfilled with ρ and γ defined by (11.5.60)–(11.5.61); in the latter case only Statement (i) remains true. In the former case $\mathsf{N}^{\mathsf{W}}(\tau) = \bigl(\varkappa_0 + o(1)\bigr)\tau^p$ without exact equality.

11.5.6 Quickly Growing Potentials

In this subsection we consider potentials with more than power growth at infinity. Then the volume of the domain $\{x : V(x) \le \tau\}$ grows slowly as $\tau \to +\infty$ and one should expect that

$$N^{\mathsf{W}}_{(\vartheta)} \asymp \mathsf{mes}(\{x : V(x) \le \tau\}) \cdot \tau^{\frac{d}{2}} \tag{11.5.69}$$

have slightly larger magnitude than in the case of the essentially bounded domain.

(a) (b)

Figure 11.10: Domains of the type (11.5.69)

Theorem 11.5.25. *(i) Let $d \ge 2$ and let X be a domain in $\mathbb{R}^d$ such that*

$$\mathsf{vol}(\{x \in X, |x| \asymp r\}) \asymp r^n \quad \text{as} \quad r \to +\infty, \tag{11.5.70}$$

$n \le d$.

Let conditions (11.1.6)–(11.1.8) *and* (11.4.5) *be fulfilled with $\gamma = \epsilon_1 \langle x\rangle^{1-\mu}$, $\rho = \exp\langle x\rangle^{\mu}$, $\mu > 0$.*

Then asymptotics (11.5.2) *holds with the principal part*

$$\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) \asymp \tau^{\frac{d}{2}+\vartheta}\sigma(\tau), \tag{11.5.71}$$

$$\sigma(\tau) = \begin{cases} \log^n \tau & \text{for } n > 0, \\ \log\log\tau & \text{for } n = 0, \\ 1 & \text{for } n < 0. \end{cases} \tag{11.5.72}$$

and remainder estimate

$$R_{(\vartheta)}(\tau) = \tau^{\frac{1}{2}(d+\vartheta-1)}\omega_{(\vartheta)}(\tau), \tag{11.5.73}$$

$$\omega_{(\vartheta)}(\tau) = \begin{cases} \log^q \tau & \text{for } q := (n-(1-\mu)(1+\vartheta))/\mu > 0, \\ \log\log\tau & \text{for } q = 0, \\ 1 & \text{for } q < 0. \end{cases} \tag{11.5.74}$$

(ii) Moreover, let $q \ge 0$ and for every fixed $k > 0$ let condition

$$\mathsf{vol}\big\{x \in X, |x| \le r,\ \mathsf{dist}(x, \partial X) \le k\gamma(x)\big\} = o(r^n) \tag{11.5.75}$$

as $r \to +\infty$

be fulfilled. Furthermore, let

$$|D^\alpha g^{jk}| = o(\gamma^{-1}) \qquad \text{as } |x| \to +\infty \quad \forall j,k,\alpha : |\alpha| = 1, \tag{11.5.76}$$

and

$$|D^\alpha V_j| \le C\rho\gamma^{-|\alpha|} \qquad \forall j,\alpha : |\alpha| \le 1. \tag{11.5.77}$$

Then asymptotics (11.5.6) *holds with* $R_{(\vartheta)}(\tau)$ *defined above and with* $\varkappa_1 = 0$ *for* $\vartheta = 0$.

Proof. One can easily prove Statement (i) in the standard way.

In order to prove Statement (ii) let us note that if $q > 0$ then for $\tau \ge \tau_0(\varepsilon)$ the contributions of the zones $\{x \in X, |x| \le \varepsilon \log^{\frac{1}{\mu}} \tau^{\frac{1}{2}}\}$ and $\{x \in X, |x| \ge (1-\varepsilon) \log^{\frac{1}{\mu}} \tau^{\frac{1}{2}}\}$ to the remainder do not exceed $\varepsilon_1 R_{(\vartheta)}(\tau)$ with $\varepsilon_1 \to 0$ as $\varepsilon \to 0$.

Moreover, condition (11.5.75) yields that the contribution of the zone $\{X, \operatorname{dist}(x, \partial X) \le k\gamma(x)\}$ to the remainder is $o(R_{(\vartheta)}(\tau))$ and therefore one need consider only billiards generated by the improved Hamiltonian and starting in the zones

$$X_{k,\varepsilon,\tau} = \big\{X \in X, \varepsilon \le |x| \log^{-\frac{1}{\mu}} \tau^{\frac{1}{2}} \le 1-\varepsilon, \operatorname{dist}(x, \partial X) \ge k(\log \tau^{\frac{1}{2}})^{\frac{1}{\mu}-1}\big\}.$$

Then for $t \in [-T, T]$ and $\tau \ge \tau_0(T, k, \varepsilon)$, $k \ge k_0(T, \varepsilon)$ these billiards lie in $X_{\frac{k}{2},\frac{\varepsilon}{2},\tau}$, they do not hit ∂X, and along them

$$\tau^{-\frac{1}{2}} V_j \equiv \tau^{-1} V \equiv 0, \quad g^{jk} \equiv \text{const}, \quad \gamma(\log \tau)^{1-\frac{1}{\mu}} \equiv \text{const},$$
$$\tau^{-\frac{1}{2}} \xi_j \equiv \text{const}, \quad \gamma^{-1} \frac{dx_j}{dt} \equiv 2\tau^{-\frac{1}{2}} \sum_k g^{jk}\xi_k, \quad \tau^{-1} \sum_{j,k} g^{jk}\xi_j\xi_k \equiv 1$$

modulo $o(1)$ as $\tau \to +\infty$.

The rest of the proof is similar to the proof of Theorems 11.2.7 and 11.2.8. The case $q = 0$ is treated in the same way with the removal of the zones $\{x \in X, |x| \le R\}$, $\{x \in X, |x| \ge \epsilon \log^{\frac{1}{\mu}} \tau\}$ and $\{x \in X, \operatorname{dist}(x, \partial X) \le k\gamma(x)\}$ with arbitrarily small $\epsilon > 0$ and arbitrarily large R. □

This theorem could be improved.

Theorem 11.5.26. *In the framework of the previous Theorem 11.5.25 assume that g^{jk} and the boundary satisfy smoothness assumptions with $\gamma(x) = \epsilon\langle x\rangle$ (then $n = d$). Then one can redefine* (11.5.74)

$$\omega_{(\vartheta)}(\tau) = \log^q \tau \qquad \text{for } q := (d - 1 - (1-\mu)\vartheta)/\mu. \tag{11.5.78}$$

Proof. One can see easily that we can then replace $\gamma(x) = \langle x\rangle^{1-\mu}$ by

$$\gamma_1(x) = \epsilon \min\big((\tau/\rho^2)^{\delta}\gamma(x),\ \langle x\rangle\big). \tag{11.5.79}$$

Indeed, one can check easily that it is scaling function ($|\nabla\gamma| \le \epsilon_1$) and that $|\nabla^\alpha V| \le C\tau\gamma_1^{-|\alpha|}$, $|\nabla^\alpha V_j| \le C\tau^{1/2}\gamma_1^{-|\alpha|}$ for $|\alpha| \le K$.

Then contribution of the zone $\{x : V(x) \le 2\tau\}$ to the remainder does not exceed $C\int \tau^{(d-1-\theta)/2}\gamma_1^{-1-\theta}\,dx$. Plugging $\gamma_1(x) = (\tau/\rho^2)^{\delta}\gamma(x)$ and $dx = r^{d-1}\,dr$ we get (11.5.74) with $q = d - 1 - (1-\mu)\vartheta$ and plugging $\gamma_1 = \langle x\rangle$ we get even better remainder estimate. □

In the same way the following theorem is proven:

Theorem 11.5.27. *Let $d \ge 2$, $X = \mathbb{R}^+ \times X'$ where X' is a bounded domain in $\mathbb{R}^{d-1} \ni x'$ with $\mathscr{C}^K$ boundary. Let all the conditions* (11.1.6)–(11.1.8) *and* (11.4.5) *be fulfilled with $\rho = \exp x_1$ and $\gamma = \epsilon_0 > 0$ and let*

$$g^{jk} - g^{jk0} = o(1), \qquad D_1 g^{jk} = o(1) \qquad \text{as } x_1 \to +\infty \tag{11.5.80}$$

where $g^{jk0} = g^{jk0}(x')$ and $g^{1k0} = 0$ for $k \ge 2$.

Further, let conditions (11.5.76)–(11.5.77) *be fulfilled. Then for every $\vartheta > 0$ asymptotics* (11.5.6) *holds with*

$$R_{(\vartheta)}(\tau) = \tau^{\frac{1}{2}(d+\vartheta-1)}\log\tau. \tag{11.5.81}$$

Further, for $\vartheta = 0$ the principal part is

$$\mathsf{N}^{\mathsf{W}}(\tau) + \varkappa_1 \tau^{\frac{1}{2}(d-1)}\log\tau \tag{11.5.82}$$

with coefficient

$$\varkappa_1 = \mp\frac{1}{8}(2\pi)^{1-d}\omega_{d-1}\int_{\partial X'} \frac{dS'}{\sqrt{g^{110}}} \tag{11.5.83}$$

where dS' is the Riemannian density on $\partial X'$ generated by the metric $(g^{jk0})_{j,k\ge 2}$.

Furthermore,

$$\mathsf{N}^{\mathsf{W}}(\tau) = \bigl(\bar{\varkappa}_0 + o(1)\bigr)\tau^{\frac{d}{2}}\log\tau \tag{11.5.84}$$

with the coefficient

$$\bar{\varkappa}_0 = \frac{1}{2}(2\pi)^{-d}\omega_d \int_{X'} \sqrt{g^{0\prime}}\frac{dx'}{\sqrt{g^{110}}} \tag{11.5.85}$$

where $\sqrt{g^{0\prime}}dx'$ *is a Riemannian density on* X' *generated by the same metric.*

The following problems look rather interesting but not very difficult:

Problem 11.5.28. (i) Consider more general operators than the Schrödinger operator.

(ii) Consider $X = \mathbb{R}^+ \times X'$, where X' is a bounded domain in $\mathbb{R}^{d-1}$ with $^{\prime}\mathscr{C}^{K}$-boundary, $\rho = \exp(x_1^{\mu})$, $\gamma \asymp x_1^{\sigma}$, $\sigma = \max(0, 1-\mu)$, $\mu > 0$.

(iii) Consider potentials with the degenerations and singularities (in the spirit of Section 11.5.4.

(iv) Consider other types of super-power growth.

11.5.7 Slowly Growing Potentials

Finally, let us consider potentials with slow growth at infinity. Here we should be very careful and specific since even formula (11.5.69) may be not valid anymore.

Namely, let $V = v(\theta)\log r$ in spherical coordinates (r,θ). We use $\rho_\tau = (\tau - V)_+^{\frac{1}{2}}$ and $\gamma_\tau = \epsilon_0 r \min(1, (\tau - V)_+ \log^{-1} r)$. Then we obtain

Theorem 11.5.29. *Let* $d \ge 3$ *and let* $g^{jk} = g^{jk}(\theta)$, $V_j = 0$, $V = v(\theta)\log r$, $X = \{\theta \in U\}$ *for* $r \ge c$ *where* (r,θ) *are spherical coordinates,* $g^{jk}, v, \partial U \in {}^{\prime}\mathscr{C}^{K}$ *and* (g^{jk}) *is a positive definite matrix. Let* $v_0 = \min_U v > 0$. *Then*

(i) Asymptotics (11.5.2) *holds with*

$$\mathsf{N}^{\mathsf{W}}_{(\vartheta)} \asymp \int_U \exp\Bigl(\frac{\tau d}{v}\Bigr)\,d\theta, \tag{11.5.86}$$

$$R_{(\vartheta)}(\tau) = \tau^{1+\vartheta}\int_{U'} \exp\Bigl(\frac{\tau(d-1-\vartheta)}{v}\Bigr)\,d\theta \qquad \text{for } \vartheta < d-1. \tag{11.5.87}$$

Moreover,

$$\mathsf{N}^{\mathsf{W}}(\tau) = a \int_{U'} v^{\frac{d}{2}} \exp\Big(\frac{\tau\ d}{v}\Big)\sqrt{g}\, d\theta \tag{11.5.88}$$

with $a = (2\pi)^{-d}\omega_d d^{-(1+\frac{d}{2})}\Gamma(1+\frac{d}{2}) = 2^{1-d}\pi^{-\frac{d}{2}} d^{-(1+\frac{d}{2})}$ *and* $U' = \{\theta \in U, v \le v_0 + \varepsilon\}$ *with arbitrarily small* $\varepsilon > 0$.

(ii) In particular, if $v = \mathsf{const} = v_0$ *then the principal part is* $\asymp \exp\big(\frac{\tau d}{v_0}\big)$ *and the remainder estimate is* $O\big(\tau^{1+\vartheta}\exp(\tau(d-\vartheta-1)v_0^{-1})\big)$ [44].

On the other hand, if $v(\theta) = v_0 \implies \theta \in \partial U, \nabla v(\theta) \ne 0$ *and* $\mathsf{rank}\,\mathsf{Hess}\, v|_{\partial U}(\theta) = d-2$ *then the principal part is* $\asymp \tau^{-\frac{d}{2}}\exp(\tau d v_0^{-1})$ *and the remainder estimate is* $O\big(\tau^{1+\vartheta-\frac{d}{2}}\exp(\tau(d-\vartheta-1)v_0^{-1}))\big)$.

In other cases the principal part of the asymptotics and the remainder estimate have intermediate orders.

We leave to the reader

Problem 11.5.30. (i) Investigate the case $\vartheta \ge (d-1)$. Note that one can take $\tilde\rho(\tau) = \tau^{\frac12} + (\log r)^{\frac12}$, $\tilde\gamma(\tau) = \epsilon_0 r$ and for $d \ge 2$ and smooth ∂X, g^{jk}, V_j and V we obtain the remainder estimate $R_{(\vartheta)}(\tau) = C\tau^d$ for $\vartheta = d-1$ and $R_{(\vartheta)}(\tau) = C\tau^{\frac12(d+\vartheta-1)}$ for $\vartheta > (d-1)$.

(ii) Consider potential $V = v(\theta)\log^\mu r$.

(iii) Consider potentials with degenerations and singularities. Obviously in this case the degeneration should be very weak, something like

$$(\log(|x|^2+2))^\mu \cdot (\log(|x''|^2+2))^{-\nu}.$$

11.5.8 Non-Dirichlet Boundary Conditions

All our results have been obtained for Dirichlet boundary conditions. Surely, they remain true for other boundary conditions provided these conditions are regular in the obvious sense and the domain satisfies the cone condition. In particular, for the Schrödinger operator Neumann conditions (and Robin

[44] One can take $\gamma_\tau = \epsilon_0 r\,\mathsf{min}(1, (\tau - V)_+)$ in this case and drop factor $\tau^{1+\vartheta}$ in the remainder estimate.

conditions provided the free term coefficient is regular in the obvious sense) are regular.

Then we obtain that if the domain satisfies the cone condition and if the asymptotics do not distinguish Dirichlet and Neumann boundary conditions then the asymptotics remain true for mixed boundary condition when Dirichlet and Neumann boundary conditions are given on $Y_0 \subset \partial X$ and $Y = \partial X \setminus Y_0$ respectively.

Let us consider more accurate asymptotics distinguishing Dirichlet and Neumann the boundary conditions. Then, repeating arguments of Subsection 11.2.3 we obtain that these asymptotics remain true for mixed boundary conditions with properly defined second coefficient provided either

(a) We are in the frameworks of Theorems 11.5.3, 11.5.14(ii)), 11.5.18(ii) and

$$\mathsf{mes}_{\partial X}\big((\bar{Y}_0 \cap \bar{Y}_1 \cap \{|x| \ge c\})_{\mathsf{cone}}\big) = 0 \tag{11.5.89}$$

or

(b) we are in the framework of Example 11.5.23(ii) and

$$\mathsf{mes}_{\Pi'\partial X}\big(\Pi'(\bar{Y}_0 \cap \bar{Y}_1 \cap \{|x| \ge c\})_{\mathsf{cone}}\big) = 0 \tag{11.5.90}$$

where Π' is the projection $\mathbb{R}^d \ni x \to x' \in \mathbb{R}^{d'}$ or

(c) We are in the framework of Theorem 11.5.27 and

$$\mathsf{mes}_{\partial X'}\big(\Pi'(\bar{Y}_0 \cap \bar{Y}_1 \cap \{|x| \ge c\})\big) = 0 \tag{11.5.91}$$

with the same Π'. Here M_{cone} is the conical hull of the set M.

Moreover, applying the arguments of Example 11.2.27 we obtain that asymptotics (11.5.16) remains true in the context of Example 11.5.7 provided

$$\mathsf{mes}_{\partial X}\{x \in \partial X, \mathsf{dist}(x, Y) \le \varepsilon\} = O(\varepsilon^{\delta}) \qquad \text{as } \varepsilon \to +0 \tag{11.5.92}$$

with $\delta > 0$ and $Y = (\bar{Y}_0 \cap \bar{Y}_1 \cap \{|x| \ge c\})_{\mathsf{cone}}$.

Finally, we would like to note that in almost all the above examples the remainder estimate is $O(\tau^{\frac{1}{2}(d+\vartheta-1)})$ for large enough ϑ (for the Schrödinger operator). In this case the principal contribution to the remainder estimate is provided by the zone $\{x \in X, |x| \le R\}$ with arbitrarily large R. In this

case the standard non-periodicity condition to the Hamiltonian $\sum_{j,k} g^{jk}\xi_j\xi_k$ on the energy level $\tau = 0$ provides the remainder estimate $o\bigl(\tau^{\frac{1}{2}(d+\vartheta-1)}\bigr)$ (see, e.g., Theorem 11.5.3).

The situation in which the principal contributions to the principal part of the asymptotics and to the remainder estimate are provided by different zones is not very exotic.

11.6 Asymptotics of Eigenvalues near -0

In this section we consider Schrödinger operators with potentials decaying at infinity. Under certain rather general assumptions its continuous spectrum is $[0,\infty)$ and the point -0 is the only possible limit point of the discrete spectrum. Moreover, there are no positive eigenvalues.

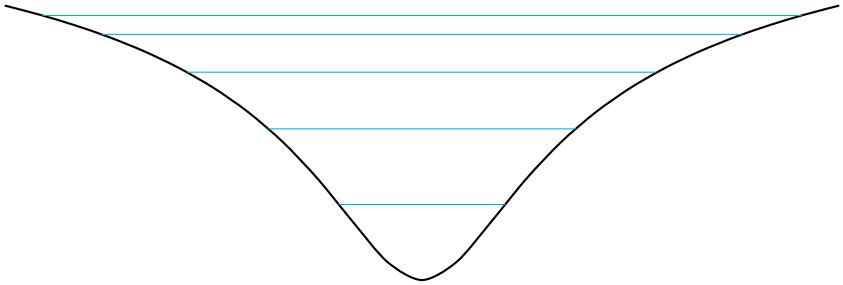


Figure 11.11: Slowly decaying at infinity potential; blue lines show symbolically energy levels of the corresponding Schrödinger operator.

Further, as potential is negative (at least in massive zones so that $\mathsf{mes}(\{x, V(x) < 0\}) = \infty$ and potential decays slowly ($|x|^{-2}$ is a threshold) -0 is a limit point of the discrete spectrum. In this case we obtain asymptotics of $\mathsf{N}^-(\tau)$ as $\tau \to -0$.

We treat more general higher-order operators and non-semi-bounded operators as well. In particular, we treat the Dirac operator with positive mass M where a spectral gap $(-M, M)$ appears in the case of $V = 0$ (while continuous spectrum occupies $(-\infty, -M] \cup [M, \infty)$ and in the general case of decaying potential there could be a discrete spectrum inside the spectral gap and if V decays slowly enough these eigenvalues accumulate to $-M + 0$ and/or $M - 0$. So we will treat *asymptotics of eigenvalues accumulating to the border of the essential spectrum*.

Later we consider much more subtle mechanism when the similar situation appears: Schrödinger and Dirac operators with magnetic field or operator with periodic coefficients. Essential spectrum may occupy spectral bands or separate points (separating spectral gaps). In both cases adding decaying potential one may create discrete spectrum inside the spectral gap and these eigenvalues may accumulate to its borders.

11.6.1 Standard Results

We start with semi-bounded operators. First of all the following statement holds:

Theorem 11.6.1 [45]**.** *Let X be an unbounded connected domain in $\mathbb{R}^d$ and let conditions* (11.1.1)–(11.1.3) *be fulfilled with $\gamma = \epsilon_1\langle x\rangle$, $\rho = \langle x\rangle^{\mu}$, $\mu \in (-1, 0)$.*

Let us assume that

$$\langle a(x,\xi)v, v\rangle \geq \epsilon_0|\xi|^{2m}\|v\|^2 \qquad \forall\xi\ \forall v \tag{11.6.1}$$

where $a(x,\xi)$ is the senior symbol of A.

Further, let us assume that for every $\tau \in (-\epsilon, 0]$ one of non-degeneracy conditions is fulfilled for the symbol $(A(x,\xi)\tau^{-1} - 1)$ uniformly with respect to (τ, x, ξ) (this condition is restrictive only for $|x| \geq C_0$). Then

(i) Asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\bigl(\tau^{l(d-1)}\bigr) \tag{11.6.2}$$

holds as $\tau \to -0$, where $\mathsf{N}^{\mathsf{W}}(\tau)$ is given by (11.4.9) *and $\mathsf{N}^{\mathsf{W}} = O(\tau^{ld})$ with $l = \frac{1}{2m\mu}(\mu + 1) < 0$.*

(ii) Moreover, for $0 < \vartheta \leq \vartheta_0^* = -ld$ asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(R_{(\vartheta)}(\tau)\bigr) \tag{11.6.3}$$

holds as $\tau \to -0$ with $\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) = \tau_+^{\vartheta-1} * \mathsf{N}^{\mathsf{W}}$ where in this case N^{W} should contain also lower order terms and

$$R_{(\vartheta)}(\tau) = \begin{cases} |\tau|^{l(d-1)+\vartheta(1-l)} & \text{for } \vartheta < \vartheta_1^*, \\ \log|\tau| & \text{for } \vartheta = \vartheta_1^*, \\ 1 & \text{for } \vartheta > \vartheta_1^* \end{cases} \tag{11.6.4}$$

[45] Cf. Theorem 11.5.1.

where $\vartheta_1^* = -l(d-1)(1-l)^{-1}$.

One can see easily that $0 < \vartheta_1^* < \vartheta_0^*$ *and that*

$$\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) = \begin{cases} O\big(|\tau|^{ld+\vartheta}\big) & \text{for } \vartheta < \vartheta_0^* \\ O\big(\log|\tau|\big) & \text{for } \vartheta = \vartheta_0^* \end{cases} \tag{11.6.5}$$

as $\tau \to -0$ *while for* $\vartheta > \vartheta_0^*$ *we have estimate* $\mathsf{N}^{\mathsf{W}}_{(\vartheta)} = O(1)$.

(iii) Furthermore, if

$$\begin{aligned} &\mathsf{mes}\big(\{x \in X : |x| \le r \quad \& \quad \exists \xi \in \mathbb{R}^d : \\ &\qquad \mathsf{Spec}\, A(x,\xi) \cap (-\infty, -\epsilon_1 \rho^{2m}] \ne \emptyset\}\big) \asymp r^d \qquad \text{as } r \to +\infty \end{aligned} \tag{11.6.6}$$

for some $\epsilon_1 > 0$ *then*

$$\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) \asymp \begin{cases} |\tau|^{ld+\vartheta} & \text{for } \vartheta < \vartheta_0^* \\ \log|\tau| & \text{for } \vartheta = \vartheta_0^* \end{cases} \tag{11.6.7}$$

as $\tau \to -0$.

For the Schrödinger operator condition (11.6.7) *is equivalent to*

$$\mathsf{mes}\big(\{x \in X : |x| \le r, V \le -\epsilon_1 \rho^2\}\big) \asymp r^d \qquad \text{as } r \to +\infty. \tag{11.6.8}$$

Theorem 11.6.2 [46]**.** *Let assumptions of Theorem 11.6.1 be fulfilled.*

Further, let us assume that $X \cap \{|x| \ge r_0\} = X^0 \cap \{|x| \ge r_0\}$ *where* X^0 *is a non-empty conical domain with* $\partial X^0 \backslash 0 \in \mathscr{C}^K$ *and that stabilization conditions* (11.5.4) *are fulfilled. Let us assume that as* $\tau = -1$ *the standard non-periodicity condition to Hamiltonian trajectories for the quasihomogeneous symbol*

$$A^0(x,\xi) = \sum_{|\beta| \le 2m} a^0_\beta(x)\xi^\beta \tag{11.6.9}$$

satisfies, and the permitted[37] *trajectories never hit* $0 \times \mathbb{R}^d$. *Then*

[46] Cf. Theorem 11.5.3.

(i) Asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + \bigl(\varkappa_1 + o(1)\bigr)|\tau|^{l(d-1)} \tag{11.6.10}$$

holds as $\tau \to -0$. *In particular, for the Schrödinger operator*

$$\varkappa_1 = \mp\frac{1}{4}(2\pi)^{1-d}\omega_{d-1}\int_{\partial X^0}\bigl(-1-V^0\bigr)_+^{\frac{d-1}{2}}\,dS^0 \tag{11.6.11}$$

for Dirichlet or Neumann boundary conditions respectively where the notation of (11.5.10)–(11.5.11) *is used.*

(ii) Moreover, for $0 < \vartheta < \vartheta_1^*$ *asymptotics*

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + o\bigl(R_{(\vartheta)}(\tau)\bigr) \qquad \text{as } \tau \to -0. \tag{11.6.12}$$

holds.

(iii) Finally, let $\vartheta = \vartheta_1^*$*; the condition on the domain and the stabilization condition remain true. Moreover, let the non-periodicity condition to Hamiltonian trajectories be fulfilled for the symbol* $A^0(x,\xi)$ *on the energy level* 0 *and let the permitted*[37] *trajectories never hit* $0 \times \mathbb{R}^d$.

Then asymptotics (11.5.6) *also holds (so the remainder estimate is* $o(\log|\tau|)$ *rather than* $O(\log|\tau|)$*).*

Proof of Theorems 11.6.1 and 11.6.2. The proof is similar to the proof of theorems 11.5.1 and 11.5.3 but now in the zone X'_{reg}, $\rho_\tau \asymp \rho$ (instead of $\rho_\tau \asymp |\tau|^{\frac{1}{2m}}$) and $X'_{\mathsf{reg}} \subset \{\rho \ge \epsilon_2|\tau|^{\frac{1}{2m}}\}$ with appropriate $\epsilon_2 > 0$.

Further, every bounded domain gives a finite contribution to the remainder estimate (and therefore in the contrast to 11.5.3 there is no assertion about improved asymptotics as $\vartheta > \vartheta_1^*$), Furthermore, the reduced Hamiltonian is now $|x|^{1-2m\mu+\mu}A^0(x,\xi)$.

We would like to emphasize that for $\vartheta > \vartheta_0^*$ we obtain the estimate $\mathsf{N}^-_{(\vartheta)}(-0) < \infty$ instead of asymptotics. This remark remains true in many examples below.

In the framework of Theorem 11.6.2 the remainder estimate is $o\bigl(|\tau|^{l(d-1)+\vartheta(1-l)}\bigr)$ and $o(\log|\tau|)$ in asymptotics (11.5.6) for $\vartheta < \vartheta_1^*$ and $\vartheta = \vartheta_1^*$ respectively.

Finally, the main contributions to the remainder estimate are made by the zones $\{x, |x| \ge \varepsilon|\tau|^{\frac{1}{2m}}\}$ and $\{x, R \le |x| \le \varepsilon|\tau|^{\frac{1}{2m}}\}$ for $\vartheta < \vartheta_1^*$ and $\vartheta = \vartheta_1^*$ respectively with arbitrarily small $\varepsilon > 0$ and arbitrarily large R. This difference leads to different non-periodicity conditions. □

Remark 11.6.3. If only stabilization conditions (11.5.4) (including the condition $X \cap \{|x| \ge r_0\} = X^0 \cap \{|x| \ge r_0\}$) are fulfilled then the non-degeneracy condition is automatically fulfilled and $\mathsf{N}^{\mathsf{W}}(\tau) = \varkappa_0 |\tau|^{ld}\big(1+o(1)\big)$ as $\tau \to -0$ where for the Schrödinger operator

$$\varkappa_0 = (2\pi)^{-d}\omega_d \int_{X^0} \big(-1 - V^0\big)_+^{\frac{d}{2}} \sqrt{g^0}\,dx \tag{11.6.13}$$

in the notation of (11.5.10)–(11.5.11).

For scalar operators we get the following

Theorem 11.6.4 [47]**.** *Let X be an unbounded connected domain in $\mathbb{R}^d$ and let conditions* (11.1.1)–(11.1.3) *be fulfilled with $\gamma = \epsilon_1\langle x\rangle$, $\rho = \langle x\rangle^{\mu}$, $\mu \in (-1, 0)$.*

Let condition (11.6.1) *be fulfilled and let A be a scalar operator. Then asymptotics*

$$\mathsf{N}(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\big(\tau^{l(d-1)-\delta}\big) \tag{11.6.14}$$

hold as $\tau \to -0$, and for $\vartheta > 0$ asymptotics (11.6.3) *holds.*

11.6.2 Strongly Non-Periodic Hamiltonian fFlow

In what follows we consider homogeneous potentials with singularities. Now we obtain a more precise remainder estimate under more restrictive conditions on the Hamiltonian flow. One can prove easily the following

Theorem 11.6.5 [48]**.** *Let the conditions of Theorem 11.6.1 be fulfilled and let A be a scalar operator. Moreover, let us assume* (11.5.14) *is fulfilled i.e. that* <u>*either*</u> *$X^0 = \mathbb{R}^d$* <u>*or*</u> *A is the Schrödinger operator or its power.*

Further, let stabilization condition $(11.5.4)^*$ *be fulfilled. Furthermore, let us assume that the Hamiltonian flow (with reflections at ∂X^0) is of non-periodic power type*[49] *at negative energy levels and that along the trajectories $(x(t), \xi(t))$ with $(x(0), \xi(0)) \in \Lambda^0_{\varepsilon, T} \subset \Sigma_{-1}$, $|x(0)| = 1$, $\varepsilon = T^{-M}$ condition $|x(t)| \ge T^{-M_1}$ is fulfilled.*

Then asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + \big(\varkappa_1 + O(|\tau|^{\delta'})\big)\tau^{l(d-1)} \tag{11.6.15}$$

[47] Cf. Theorem 11.5.5.

[48] Cf. Theorem 11.5.6.

[49] Footnote [38] of the previous section remains true.

holds as $\tau \to -0$ *with* $\delta' > 0$. *Moreover, for* $0 < \vartheta \le \vartheta_1^* - \delta$ *with* $\delta > 0$ *asymptotics*

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\big(|\tau|^{l(d-1)+\vartheta(1-l)+\delta'}\big) \tag{11.6.16}$$

holds as $\tau \to -0$ *with* $\delta' = \delta'(d, m, \delta, L) > 0$.

Let us consider the following

Example 11.6.6[50]. (i) The condition of Theorem 11.6.5 to the Hamiltonian flow is fulfilled for the Schrödinger operator with $X^0 = \mathbb{R}^d$ and $A^0(x,\xi) = |\xi|^2 - |x|^{2\mu}$ with $\mu \ne -\frac{1}{2}$. So we consider $\mu \in (-1, -\frac{1}{2}) \cup (-\frac{1}{2}, 0)$.

(ii) Therefore the statement of Theorem 11.6.5 is true for this operator (provided all the other conditions of this theorem, including (11.5.4)*, are fulfilled) and for any $2m$-order operator with $A^0(x,\xi) = (|\xi|^2 - |x|^{2\mu})^m$, and one can replace $X^0 = \mathbb{R}^d$ by the X^0 obtained after (a sequence of) the transformations (a),(b) of Example 11.5.7(ii).

11.6.3 Periodic Hamiltonian Flow

As in the previous section let us consider the case of periodic Hamiltonian flow:

Theorem 11.6.7[51]. *Let* $X^0 = \mathbb{R}^d$ *and conditions* (11.5.27)–(11.5.27), (11.5.32) *with* $\mu \in (-1, 0)$ *be fulfilled in the domain of negative energies. Let us introduce the symbol*

$$b(x,\xi) = -\frac{l}{T_0}\int_0^{T_0} A^1 \circ \Psi_t\, dt \tag{11.6.17}$$

where T_0 *is the period on the energy level* -1 *(compare with* (11.5.30)*; we have changed sign because* $A^0(x,\xi) = -1$ *now). Then*

(i) If $\delta_1 < (\mu + 1)$ *and condition* (11.5.31) *is fulfilled for all* ω *then asymptotics*

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\big(|\tau|^{l(d-1)+\delta''}\big) \tag{11.6.18}$$

holds as $\tau \to -0$ *with* $\delta'' > 0$.

---

[50] Cf. Example 11.5.7.

[51] Cf. Theorem 11.5.9.

(ii) If $\delta_1 \in [\mu+1, 2\mu+2]$ *then for* $\tau \to -0$ *such that* $|\tau|^l \in \bigcup_{n\in\mathbb{Z}^+} J_n$ *asymptotics*

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + F(\tau)|\tau|^{l(d-1)} + O\big(|\tau|^{l(d-1)+\delta''}\big) \tag{11.6.19}$$

holds with $\delta'' > 0$ *and*

$$F(\tau) = (2\pi)^{-d} l T_0^{-1} \int_{\Sigma_{-1}} \Upsilon\Big(T_0 l^{-1}\big((|\tau|^l - \frac{\pi}{4}\omega_0) - |\tau|^{l-\frac{\delta_1}{2m\mu}} b\big)\Big)\, dx d\xi : dA^0. \tag{11.6.20}$$

The intervals J_n *are defined in Theorem 11.5.9(ii) with* $\nu = -\frac{2\pi l}{T_0}$, ω_0 *replaced by* $-\omega_0$ *where* ω_0 *is the Maslov index of the trajectory* Ψ_t *with* $t \in (0, T_0)$.

Let us treat the perturbed Schrödinger operator with the Coulomb potential more carefully. In this case $A_0 = |D|^2 - |x|^{-1}$ and $\mu = -\frac{1}{2}$, $l = -\frac{1}{2}$, $T_0 = \frac{\pi}{2}$, $\nu = 2$ and the Hamiltonian trajectories are Keplerian ellipses (with one focus located at the origin). Moreover, $\omega_0 \equiv 2(d-1) \mod 4\mathbb{Z}$ and

$$\mathsf{Spec}(A_0) = \{\tau_n = -1(d+1+2n)^2,\ n \in \mathbb{Z}^+\} \tag{11.6.21}$$

and the multiplicity of τ_n is $P(n)$ where $P(n)$ is a polynomial of degree $(d-1)$ in n. Let us introduce the function $f(\tau) = \frac{1}{2}(-\tau)^{-\frac{1}{2}} - \frac{1}{2}$.

We leave to the reader

Problem 11.6.8. Prove that for generic positively homogeneous functions a^1_β (with $|\beta| \le k$) of degree $(-1+2|\beta|-\delta_1)$ condition (11.5.31) is fulfilled for all $\omega \in \mathbb{R}$ and therefore asymptotics (11.6.18) holds for $0 < \delta_1 < \frac{1}{2}$ while asymptotics (11.6.19)–(11.6.20) holds for $\delta_1 \ge \frac{1}{2}$, and now there is no restriction of the type "$\delta_1 \le 2\mu+2$" on δ_1 and $k = 0, 1, 2$ is arbitrary.

Moreover, prove that one can take $V' = v_0|x|^{-1-\delta}$ with an arbitrary exponent $\delta > 0$ and an arbitrary constant $v_0 \ne 0$.

Let us assume that $b = 0$. There are two possibilities in this case: the trivial possibility is to take $\delta_2 \in (\delta_1, 2\delta_1)$ and the non-trivial one is to take $\delta_2 = 2\delta_1$. In the first case all the previous statements remain true with δ_1 replaced by δ_2 etc.

In the second case we assume that condition (11.5.39) is fulfilled in which case the symbol $b(x,\xi)$ is given by formula (11.3.27) with b and b^s replaced

by $-\frac{1}{2}A^1(-A^0)^{-\frac{1}{2}}$ and $-\frac{1}{2}A^2(-A^0)^{-\frac{1}{2}}+\frac{3}{4}(A^1)^2(-A^0)^{-\frac{3}{2}}$ respectively and with integration from 0 to π, $\frac{\pi}{2}$ instead of 2π, π respectively.

Further, the numerical factor on every integral is $\frac{1}{\pi}$ instead of $\frac{1}{2\pi}$. Furthermore, one can move A^0 out of the Poisson brackets and then take $A^0=-1$. Therefore

$$b(x,\xi)=\frac{1}{2\pi}\int_0^{\pi}\bigl(A^2-\frac{3}{2}(A^1)^2\bigr)\circ\Psi_t\,dt+ \frac{1}{2\pi}\int_0^{\frac{\pi}{2}}\int_0^{\frac{\pi}{2}}\{A^1\circ\Psi_t, A^1\circ\Psi_{t+t'}\}\,dtdt'. \tag{11.6.22}$$

Therefore the following assertion has been proven:

Theorem 11.6.9. *Let $x^0=\mathbb{R}^d$, $A=A^{0\mathsf{w}}+A^{1\mathsf{w}}+A''^{\mathsf{w}}$ where A'' satisfies condition* (11.5.29) *with a^2_β, δ_2 instead of a^1_β, δ_1, $\delta_2=2\delta_1$ and a^j_β are functions which are positively homogeneous of degrees $(-1+2|\beta|-\delta_j)$ with respect to x, smooth for $x\ne 0$. Let condition* (11.5.39) *be fulfilled and let us define the symbol b by* (11.6.22). *Then*

(i) If $\delta_2<\frac{1}{2}$ and condition (11.5.31) *is fulfilled for every $\omega\in\mathbb{R}$ then asymptotics* (11.6.18) *hold as $\tau\to -0$.*

(ii) If $\delta_2\ge\frac{1}{2}$ and condition (11.5.31) *is fulfilled for some $\omega\in\mathbb{R}$ then asymptotics* (11.6.19)–(11.6.20) *holds as $\tau\to -0$ and $(-\tau)^{-\frac{1}{2}}\in\bigcup_{n\in\mathbb{Z}^+}$ where J_n are given in Theorem 11.5.9(ii) with $\omega_0=2(d-1), \mu=2$ and with δ_1 replaced by δ_2 everywhere.*

One can easily prove that for fixed a^1_β with $|\beta|\le 2$ satisfying (11.5.39) and for generic a^2_β with $|\beta|\le k$ condition (11.5.33) is fulfilled for all $\omega\in\mathbb{R}$; here $k=0,1,2$ is arbitrary.

11.6.4 Singularities

Let us consider homogeneous lower order terms with singularities (for the Schrödinger operator only):

Theorem 11.6.10 [52]**.** *Let $d\ge 2$, $X=\{(r,\theta)\in\mathbb{R}^+\times U\}$ where $U\subset\mathbb{S}^{d-1}$ and let $g^{jk}=g^{jk}(\theta)$, $V_j=v_j(\theta)r^\mu$, $V=v(\theta)r^{2\mu}$, $\mu\in(-1,0)$. Further, let*

[52] Cf. Theorem 11.5.14.

$\tilde\rho = \tilde\rho(\theta)$ and $\tilde\gamma = \tilde\gamma(\theta)$ be functions on U and let conditions (11.1.6)–(11.1.8) *be fulfilled.*

Furthermore, assume that <u>*either*</u> *$d \ge 3$* <u>*or*</u> *$\tilde\rho\tilde\gamma \ge \epsilon_0 > 0$. Finally, let*

$$\tilde\rho^{-\frac{d}{\mu}} \in \mathscr{L}^1(U), \tag{11.6.23}$$

$$\tilde\rho^{-\frac{1}{\mu}(d-1)}\tilde\gamma^{-1} \in \mathscr{L}^1(U). \tag{11.6.24}$$

Moreover, let $v(\bar\theta) < 0$ for some $\bar\theta \in U$.

Then asymptotics (11.6.2) *holds and $\mathsf{N}^{\mathsf{W}}(\tau) = \varkappa_0|\tau|^{Id}$ with the coefficient $\varkappa_0$ given by* (11.6.13).

Further, if $\vartheta \in (0, \vartheta_1^*)$, $\vartheta_1^* = -I(d-1)(1-I)^{-1} = (1+\mu)(d-1)(1-\mu)^{-1}$ and if

$$\tilde\rho^{-\frac{1}{\mu}(d-1-\vartheta)}\tilde\gamma^{-1-\vartheta} \in \mathscr{L}^1(U) \tag{11.6.25}$$

then asymptotics (11.6.3)–(11.6.4) *holds.*

Furthermore, let us assume that there exists a set $\Lambda \subset \Sigma = \Sigma_{-1}$ with $\mathsf{mes}_\Sigma(\Lambda) = 0$ such that through every point of $(\Sigma \setminus \Lambda)$ there passes an infinitely long non-periodic billiard generated by the Hamiltonian

$$H^0 = \tilde\gamma r^{1-\mu}\bigl(\tilde\rho + r^{-\mu}\bigr)^{-1}\Bigl(\sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k) + V + 1\Bigr) \tag{11.6.26}$$

which never hits $0 \times \mathbb{R}^d \cup \Lambda$. Then asymptotics (11.6.10) *holds with the coefficient $\varkappa_0$ given by* (11.6.11).

Moreover, let $\vartheta \in (0, \vartheta_1^*)$ and (11.6.25) *be fulfilled. Then asymptotics* (11.6.12) *holds.*

Example 11.6.11[53]. Let $x = \mathbb{R}^d$, $d \ge 2$ and $\rho = |x''|^\nu \cdot |x|^{\mu-\nu}$, $\gamma = \frac12|x''|$ with $\mu \in (-1, 0)$, $\nu \in (\mu, 0)$. Then

(i) Conditions (11.6.23) and (11.6.25) are fulfilled if and only if $\nu > \nu_0 = \mu d'' d^{-1}$ and $\nu > \nu_{\vartheta+1} = \mu(d'' - 1 - \vartheta)(d - 1 - \vartheta)^{-1}$ respectively.

Therefore for $\nu > \nu_1$ asymptotics (11.6.2) holds while for $\nu > \nu_{\vartheta+1}$, $\vartheta < \vartheta_1^*$ asymptotics (11.6.3) holds[54].

[53] Cf. Example 11.5.17.

[54] And under non-periodicity condition on the Hamiltonian flow asymptotics (11.6.10) holds. Further, asymptotics (11.6.12) (for $\nu > \nu_{\vartheta+1}$) holds.

(ii) The case $\nu \in [\nu_0, \nu_1)$ is treated in the same way as case (ii) of Example 11.5.17. We obtain that for $\nu = \nu_1$ asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\bigl(|\tau|^{l(d-1)} \log|\tau|\bigr) \tag{11.6.27}$$

holds as $\tau \to -0$ and for $\nu \in (\nu_0, \nu_1)$ asymptotics

$$\mathsf{N}(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\bigl(|\tau|^{q}\bigr) \tag{11.6.28}$$

holds as $\tau \to -0$ with $q = -\frac{1}{2}(\mu+1)d'(\nu-\mu)^{-1} = l(d-\eta)$, $\eta = (\mu d'' - \nu d)(\mu-\nu)^{-1} \in (0,1)$.

In these asymptotics $\mathsf{N}^{\mathsf{W}}(\tau) = \varkappa_0 |\tau|^{ld}$.

(iii) Similarly, for $\nu = \nu_{\vartheta+1}$, $\vartheta \in (0, \vartheta_1^*)$ asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(|\tau|^{l(d-1-\vartheta)+\vartheta} \log|\tau|\bigr) \tag{11.6.29}$$

holds as $\tau \to -0$ and for $\nu \in (\nu_0, \nu_{\vartheta+1})$ asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(|\tau|^{q+\vartheta}\bigr) \tag{11.6.30}$$

holds as $\tau \to -0$ with the same q as before.

(iv) Finally, for $\nu = \mu d'' d^{-1}$ asymptotics

$$\mathsf{N}(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\bigl(|\tau|^{ld}\bigr) \tag{11.6.31}$$

holds as $\tau \to -0$ with $\mathsf{N}^{\mathsf{W}}(\tau)$ given by (11.5.52) and moreover $\mathsf{N}^{\mathsf{W}}(\tau) \asymp |\tau|^{ld} \log|\tau|$. Moreover, footnotes [41], [42] section hold.

We now have no need of the coercivity condition and therefore Theorems 11.5.18 and 11.5.20 and Examples 11.5.19 and 11.5.21 are almost senseless. However, the following problems make sense:

Problem 11.6.12. (i) Examine potentials of the type $V^0 + V'$ where V^0 is a slowly decreasing and not very singular potential and V' decreases faster and is more singular, etc.

(ii) Let us note that for $d \ge 3$ in the zone $\{V \ge 0\}$ no condition excluding $|V_j| \le c\sqrt{V}$ is necessary. Consider examples with $\rho = \langle x\rangle^{\mu}$, $\gamma = \langle x\rangle^{1-\sigma}$ with $\mu < 0$, $\sigma \in (0, 1+\mu)$, where asymptotics with a worse remainder estimate may be obtained. In this case the magnetic field can decrease more slowly at infinity.

11.6.5 Quasihomogeneous Potentials

Let us consider non-homogeneous operators. Repeating the arguments of Example 11.5.23 with obvious modifications we obtain

Example 11.6.13. (i) Let X be an L-quasiconical domain in $\mathbb{R}^d$ and let g^{jk}, V_j, V be positively L-quasihomogeneous with respect to x of degrees 0, μ, 2μ respectively where $\mu \in (-1,0)$, $L = (L_1, \dots, L_d)$ with $L_j = 1$ for $1 \le j \le d'$ and $L_j > 1$ for $d'+1 \le j \le d$, $1 \le d' < d$.

Let us assume that $g^{jk}, V_j, V \in \mathscr{C}^K(\bar{X} \setminus 0)$ satisfy condition (11.1.8) and that $V(\bar{\theta}) < 0$ for some $\bar{\theta} \in X$. Then conditions (11.1.7) are fulfilled with $\rho = [x]_L^{\mu}$, $\gamma = \epsilon [x]_L$ for $[x]_L \ge 1$; for $[x]_L \le 1$ one should take $\gamma = \epsilon [x]_L^{\bar{L}}$ with $\bar{L} = \max_j L_j$. Then the asymptotics

$$\mathsf{N}^-(\tau) = \varkappa_0 |\tau|^p + O\big(|\tau|^q\big) \tag{11.6.32}$$

holds as $\tau \to -0$ with $p = \frac{d}{2} + \frac{L^*}{2\mu}$, $q = \frac{1}{2}(d-1) + \frac{1}{2\mu}(L^*-1)$, $L^* = \sum_j L_j$ and

$$\varkappa_0 = (2\pi)^{-d} \omega_d \int \big(-1 - V\big)_+^{\frac{d}{2}} \sqrt{g}\, dx. \tag{11.6.33}$$

(ii) Moreover, let us assume that $x' \ne 0$, $\nu' \ne 0$ on $\partial X \setminus 0$ where ν is a unit normal to ∂X and $x' = (x_1, \dots, x_{d'})$, $\nu' = (\nu_1, \dots, \nu_{d'})$. Let us assume that $g^{jk} = 0$, $V_k = 0$ for $j \le d'$, $k \ge d'+1$. Then asymptotics

$$\mathsf{N}^-(\tau) = \varkappa_0 |\tau|^p + \big(\varkappa_1 + o(1)\big)|\tau|^q \tag{11.6.34}$$

holds with

$$\varkappa_1 = \mp \frac{1}{4} (2\pi)^{1-d} \omega_{1-d} \int \big(-1 - V\big)_+^{\frac{d-1}{2}}\, dS' \sqrt{g''} dx'' \tag{11.6.35}$$

where dS' and $\sqrt{g''}dx''$ are the Riemannian densities introduced in Example 11.5.23.

11.6.6 Quickly Decreasing Potentials

Let us consider potentials which decrease rather quickly. We considered homogeneous potentials decreasing as $\langle x\rangle^{2\mu}$ with $\mu \in (-1,0)$ and $N^-(0) < \infty$ as either $\mu < -1$ or $\mu = -1$, $V \ge -\epsilon \langle x\rangle^{2\mu}$ with sufficiently small $\epsilon > 0$. So "rather quickly" should mean "a bit slower than $\langle x\rangle^{-2}$" .

Theorem 11.6.14. *Let X be an unbounded domain in $\mathbb{R}^d$ and let conditions* (11.1.1)–(11.1.3) *and* (11.6.1) *be fulfilled with*

$$\gamma = \epsilon\langle x\rangle, \qquad \rho = \langle x\rangle^{-1}\log^{\nu}\langle x\rangle \tag{11.6.36}$$

where we now take $\langle x\rangle = (|x|^2+4)^{\frac{1}{2}}$, $\nu > 0$.

Further, let us assume that for every $\tau \in (-\epsilon, 0]$ one of non-degeneracy conditions is fulfilled for the symbol $(A(x,\xi)\tau^{-1}-1)$ uniformly with respect to (τ, x, ξ) (this condition is restrictive only for $|x| \ge C_0$). Then

(i) Asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\big(\big|\log|\tau|\big|^{\nu(d-1)+1}\big) \tag{11.6.37}$$

holds as $\tau \to -0$ where $\mathsf{N}^{\mathsf{W}}(\tau) = O\big(\big|\log|\tau|\big|^{\nu d+1}\big)$ and under condition (11.6.8) $\mathsf{N}^{\mathsf{W}}(\tau) \asymp \big|\log|\tau|\big|^{\nu d+1}$.

(ii) Moreover, let $X \cap \{|x| \ge r_0\} = X^0 \cap \{|x| \ge r_0\}$ where X^0 is a conical domain with $\partial X^0 \setminus 0 \in \mathscr{C}^K$ and let stabilization conditions (11.5.4) *be fulfilled for functions $a_\beta \log^{-\nu(2m-|\beta|)}$ where the functions $a^0_\beta \in \mathscr{C}^K(\bar X^0 \setminus 0)$ are positively homogeneous of degrees $-(2m-|\beta|)$ on x.*

Then the microhyperbolicity condition is fulfilled automatically. Further, if the non-periodicity condition is fulfilled for the quasihomogeneous symbol

$$A^0(x,\xi) = |x|^{2m}\sum_{|\beta|\le 2m} a^0_\beta(x)\xi^\beta \tag{11.6.38}$$

on the energy level 0 then the asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + \big(\varkappa_1 + o(1)\big)\big|\log|\tau|\big|^{\nu(d-1)+1} \tag{11.6.39}$$

holds where, for the Schrödinger operator,

$$\varkappa_1 = \mp 2^{-\nu(d-1)-3}(2\pi)^{1-d}\omega_{d-1}\int_{\partial U}\big(V^0\big)_-^{\frac{d-1}{2}}\,dS, \tag{11.6.40}$$

$U = X^0 \cap \mathbb{S}^{d-1}$ is a domain on $\mathbb{S}^{d-1}$, $dS = dS^0 : dr$ is the natural density on ∂U, dS^0 is the Riemannian density on ∂X^0 generated by the metric g^{jk0} (compare with (11.6.12)*).*

(iii) On the other hand, if only the stabilization condition is fulfilled then $\mathsf{N}^{\mathsf{W}}(\tau) = \big(\varkappa_0 + o(1)\big)\big|\log|\tau|\big|^{\nu d+1}$ *where, for the Schrödinger operator,*

$$\varkappa_0 = 2^{-\nu d-1}(2\pi)^{-d}\omega_d \int_U \big(V^0\big)_-^{\frac{d}{2}} \sqrt{g^0}\, d\theta, \tag{11.6.41}$$

$d\theta = dx : dr$, $g^0 = \det(g^{jk0})^{-1}$ *(compare with (*11.6.11*)).*

Proof. Statement (i) follows immediately from our previous arguments; moreover, now $\rho\gamma = \log^{\nu}\langle x\rangle \to \infty$ as $|x| \to \infty$ and $X'' = \emptyset$.

In order to prove Statement (ii) let us note that the principal contribution to the remainder estimate is given by the zone $\{R \le |x| \le \epsilon\tau^{-\frac{1}{2m}}\}$ with arbitrary fixed R and $\epsilon > 0$. We need to examine the Hamiltonian trajectories starting in this zone and associated with the symbol

$$A_\tau(x,\xi) = \langle x\rangle^{2m}\log^{-\nu}\langle x\rangle\big(A(x,\xi)+\tau\big) \tag{11.6.42}$$

on $\Sigma_\tau = \{\det A_\tau(x,\xi) = 0\}$. Let $\Sigma^0 \supset \Lambda_T$ be a closed set of measure 0 such that through every point of $(\Sigma^0 \setminus \Lambda_T)$ there passes a non-periodic Hamiltonian trajectory (with reflections) of length $2T$ associated with the symbol A^0. Then one can take

$$\Lambda_{1,T,\epsilon,\varepsilon,\tau,R} = \big\{(x,\xi)\in\Sigma_\tau, R\le|x|\le\epsilon\tau^{-\frac{1}{2m}}, \\ \operatorname{dist}\big(\frac{x}{|x|},\partial X^0\big) > 0, \operatorname{dist}\big((\frac{x}{|x|},\xi|x|\log^{-\nu}|x|),\Lambda_T\big) > \varepsilon\big\}$$

with $R = R(\epsilon,\varepsilon,T)$. Moreover, one can see that $\log|x(t)|\log^{-1}|x(0)| = 1+o(1)$ as $|x(0)|\to\infty$ uniformly with respect to τ and $t\in[-2T,2T]$ with arbitrary fixed T. We leave the details to the reader. □

We leave to the reader the following set of rather easy problems:

Problem 11.6.15. (i) Prove a statement similar to Theorem 11.6.10 with

$$g^{jk} = g^{jk}(\theta), \qquad V_j = v_j(\theta)r^{-1}\log^{\nu} r, \qquad V = v(\theta)r^{-2}\log^{2\nu} r,$$

$X = (1,\infty)\times U$.

(ii) Consider the case when

$$\rho = \langle x\rangle^{\mu}\log^{\nu}\langle x\rangle, \tag{11.6.43}$$

$\vartheta \ge 0$ with either $\mu > -d(d+2m\vartheta)^{-1}$ or $\mu = -d(d+2m\vartheta)^{-1}$, $\nu \ge -1(d+2m\vartheta)^{-1}$.

Prove that under these conditions the principal part of the asymptotics is $\asymp I$ with either $I = |\tau|^p$ (with $p<0$) or $I = \bigl|\log|\tau|\bigr|^q$ (with $q>0$) or $I = \log\bigl|\log|\tau|\bigr|$ and the remainder estimate is either from the same list or $O(1)$.

(iii) Moreover, consider the case of potentials decreasing even more quickly when

$$\rho = \langle x\rangle^{-1}\bigl(\underbrace{\log\dots\log}_{r \text{ times}}\langle x\rangle\bigr)^{\nu} \tag{11.6.44}$$

when the principal part of the asymptotics and the remainder estimate are of the orders $\log|\tau| \times \zeta(\tau)^{\nu d}$ and $\log|\tau| \times \zeta(\tau)^{\nu(d-1)}$ respectively with $\zeta(\tau) = \underbrace{\log\dots\log}_{r \text{ times}}|\tau|$.

(iv) Prove that in the framework of Theorem 11.6.14 $\mathsf{N}^{-}_{(\vartheta)}(-0) < \infty$ for $\vartheta > 0$.

11.6.7 Slowly Decreasing Potentials

Let us consider the slowly decreasing potential $V = v(\theta)\log^{-1} r$ in the spherical coordinate system (r,θ). Using

$$\tilde\rho_\tau = (\tau - V)_+^{\frac12}, \qquad \tilde\gamma_\tau = \epsilon_0 r \min(1, (\tau-V)_+ \log r) \tag{11.6.45}$$

for $r \ge 2$ we easily prove

Theorem 11.6.16. *Let $d \ge 3$ and $X \cap \{r \ge r_0\} = \{r \ge r_0, \theta \in U\}$. For $|x| \ge r_0$ let*

$$g^{jk} = g^{jk}(\theta), \qquad V_j = 0, \qquad V = v(\theta)\log^{-1} r \tag{11.6.46}$$

where (r,θ) are spherical coordinates, $g^{jk}, v, \partial X \in \mathscr{C}^K$ and the matrix (g^{jk}) is positive definite. Let $v_0 = \min_U v < 0$. Then

(i) Asymptotics (11.6.3) *holds with*

$$\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) \asymp |\tau|^{d+2\vartheta}\int_U \exp\bigl(\frac{vd}{\tau}\bigr)\,d\theta, \tag{11.6.47}$$

$$R_{(\vartheta)}(\tau) = |\tau|^{d-2}\int_U \exp\bigl(\frac{v}{\tau}(d-\vartheta-1)\bigr)\,d\theta \tag{11.6.48}$$

for $\vartheta < d-1$. Moreover, one can take

$$\mathsf{N}^{\mathsf{W}}(\tau) = a\int_{U'} |\tau|^d v_-^{-\frac{d}{2}} F_d\bigl(-\frac{\tau}{v_-}\bigr)\exp\bigl(-\frac{vd}{\tau}\bigr)\sqrt{g}\,d\theta \tag{11.6.49}$$

where $U' = U\cap\{v < v_0+\varepsilon\}$ with arbitrarily small fixed $\varepsilon > 0$, $a = 2^{1-d}\pi^{-\frac{d}{2}}d^{-\frac{d}{2}+1}$,

$$F_d(s) = \frac{1}{\Gamma(\frac{d}{2}+1)}\int_0^{\frac{d}{s}-\varepsilon} t^{\frac{d}{2}}\bigl(1-\frac{st}{d}\bigr)^{-\frac{d}{2}}e^{-t}dt = 1+O(s) \tag{11.6.50}$$

as $s\to+0$.

(ii) In particular, for $v = v_0 = \mathsf{const}$ the principal part of the asymptotics is $\asymp |\tau|^{d+2\vartheta}\exp(\frac{v_0 d}{\tau})$ and the remainder estimate is $O(|\tau|^{d-2}\exp(\frac{v_0}{\tau}(d-1-\vartheta)))$.

Moreover, in this case one can take

$$\gamma_\tau = \epsilon_0 r\min\bigl(1,(\tau-V)_+\log^2 r\bigr)$$

and obtain a remainder estimate with the factor $|\tau|^{d+\vartheta-1}$ instead of $|\tau|^{d-2}$.

On the other hand, if $v = v(\theta) = v_0 \implies \theta\in\partial U, \nabla v(\theta)\ne 0$ and $\mathsf{rank}\,\mathsf{Hess}\, v|_{\partial U} = d-1$ then the principal part is $\asymp |\tau|^{\frac{3}{2}+2\vartheta}\exp(\frac{v_0 d}{\tau})$ and the remainder estimate is $O(|\tau|^{\frac{3}{2}d-3}\exp\bigl(\frac{v_0}{\tau}(d-1-\vartheta)\bigr))$. In other cases the principal part and the remainder estimate are of intermediate orders.

Problem 11.6.17. (i) Consider the case $\vartheta\ge(d-1)$. Then one can take $\rho_\tau = \log^{-\frac{1}{2}} r + |\tau|$ and $\gamma_\tau = \epsilon_0 r$ and for $d\ge 2$ one can derive the remainder estimates $O(|\tau|^d)$ for $\vartheta = (d-1)$ and $O(1)$ for $\vartheta > (d-1)$.

(ii) Consider potential $V = v(\theta)\log^{-\nu} r$ with arbitrary $\nu > 0$.

11.6.8 General Boundary cConditions

Remark 11.6.18. All the above results remain true for the Neumann boundary condition provided the domain satisfies the cone condition. Let us assume that this (cone) condition is fulfilled. Moreover, all the above results remain true for mixed boundary conditions (provided the asymptotics do not distinguish Dirichlet and Neumann boundary conditions) and also in the following cases:

(i) We are in the frameworks of Theorem 11.6.2 or 11.6.1011.6.10, and condition (11.5.89) is fulfilled.

(ii) We are in the frameworks of Example 11.6.13(ii), and condition (11.5.90) is fulfilled.

Moreover, in the context of Theorem 11.6.5 asymptotics (11.6.16) remain true if condition (11.5.91) is fulfilled.

11.6.9 Non-sSemi-Bounded Operators

Finally, let us consider non-semi-bounded operators. We consider the Dirac operator with mass $M > 0$ (otherwise in the context of this section the spectrum coincides with $\mathbb{R}$). Moreover, let $V \to 0$, $V_j \to 0$ as $|x| \to \infty$.

Then $\mathsf{Spec}_{\mathsf{ess}}(A) = (-\infty, M] \cup [M, \infty)$ and the spectral gap $(-M, M)$ contains either a finite or infinite number of eigenvalues. In the second case these eigenvalues tend to $-M + 0$ and (or) to $M - 0$ and we can consider the corresponding eigenvalue asymptotics. Let us consider $M - 0$. In order to replace it by -0 we replace the operator A by $A - M \cdot I$. Let us fix $\tau_1 \in (-2M, 0)$ and let us consider

$$\mathsf{N}^-(\tau) \coloneqq \mathsf{N}(\tau_1, \tau) \tag{11.6.51}$$

with $\tau \to -0$. Then

Remark 11.6.19. Under described modifications

(i) Theorems 11.6.1, 11.6.2, 11.6.14 and 11.6.5 and Examples 11.6.13, 11.6.6 remain true and one can check conditions on the Hamiltonian flow for the corresponding Schrödinger operator with the symbol

$$H = \sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k) + (V + M)^2 - M^2. \tag{11.6.52}$$

In this Hamiltonian one can skip the term V^2 which is negligible at infinity (as far as non-periodicity condition is concerned) in which case one can consider the Hamiltonian

$$H = \sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k) + 2MV. \tag{11.6.53}$$

Now, however, due to term V^2

$$\mathsf{N}^{\mathsf{W}}(\tau) = \varkappa_0 |\tau|^p \big(1 + O(|\tau|^{\delta})\big) \tag{11.6.54}$$

with $\delta > 0$ instead of $\mathsf{N}^{\mathsf{W}}(\tau) = \varkappa_0 |\tau|^p$.

(ii) Theorem 11.6.10 (and Example 11.6.11(i) for $d \ge 3$) remain true. In order to prove this let us note that only the analysis in the zone $\{\tilde\rho r^\mu \ge 1\}$ should be changed. In this zone instead of $\rho = \tilde\rho r^\mu$ one should set $\rho = \tilde\rho^2 r^{2\mu}$.

We include this zone in X_{sing}. In this zone $\rho^d \in \mathscr{L}^1$ due to assumption $\tilde\rho^{-\frac{d}{2\mu}} \in \mathscr{L}^1(U)$. Therefore the contribution of this zone to the asymptotics and to the remainder estimate is $O(1)$.

(iii) Theorem 11.6.16 also remains true. However, $\mathsf{N}^{\mathsf{W}}(\tau)$ should be calculated for the Dirac operator, i.e., for the Schrödinger operator with the symbol (11.6.52) and with the spectral parameter equal to 0.

In the proof one should replace $\rho_\tau = (\tau - V)_+^{\frac12}$ by

$$\rho_\tau = \big(\tau - V + C_1 r^{-1} \log^{-2} r\big)_+^{\frac12} \tag{11.6.55}$$

with large enough C_1 in the zone $X_{\mathsf{sing}} \cap \{\tau - V \le C|\tau|^{\frac23} r^{-\frac23}\}$. This does not increase the remainder estimate.

Let us consider Theorems 11.5.9 and 11.6.9. For simplicity we assume that

$$|v| \le 2M - \epsilon_0 \qquad \forall x. \tag{11.6.56}$$

We leave to the reader the following easy

Problem 11.6.20. Conduct analysis below without assumption (11.6.56).

Under assumption (11.6.56) for appropriate τ_1,

$$\mathsf{N}^-(\tau) = \tilde{\mathsf{N}}^-(\tau) - \tilde{\mathsf{N}}^-(\tau_1) \tag{11.6.57}$$

where $\tilde{\mathsf{N}}^-(\tau)$ is the number of the negative eigenvalues for the operator

$$A(\tau) = \mathcal{L}^*(2M - V + \tau)^{-1}\mathcal{L} + V - \tau \tag{11.6.58}$$

with

$$\mathcal{L} = \sum_j \Big(\sum_k \omega^{jk}(D_k - V_k) - \frac{i}{2}\omega^j\Big)\sigma'_j \tag{11.6.59}$$

where we assume that

$$\sigma_0 = \begin{pmatrix} I & 0 \\ 0 & -1 \end{pmatrix}, \qquad \sigma_j = \begin{pmatrix} 0 & \sigma_j'^{*} \\ \sigma'_j & 0 \end{pmatrix} \quad (j \ge 1)$$

and use the notation $\omega^j = \sum_k \partial_k \omega^{jk}$.

If we could take $\rho = \langle x\rangle^{-\frac{1}{2}}$, $\gamma = \epsilon_0\langle x\rangle$ for the original Dirac operator and if

$$D^\alpha(\omega^{jk} - \delta^{jk}) = O\big(|x|^{-\delta_0-|\alpha|}\big), \tag{11.6.60}$$

$$D^\alpha F_{jk} = O\big(|x|^{-\frac{3}{2}-\delta_3-|\alpha|}\big) \qquad \text{as } |x| \to \infty \quad \forall \alpha : |\alpha| \le K \tag{11.6.61}$$

(where $F_{jk} = i(\partial_j V_k - \partial_k V_j)$ is the tensor magnetic intensity) then the operator $A(\tau)$ is a scalar operator plus perturbation $\sum_j A'_j(D_j - V_j) + A'_0$ where

$$D^\alpha A'_j = O\big(|x|^{\max(-1-\delta_0,-2)-|\alpha|}\big), \tag{11.6.62}$$

$$D^\alpha A'_0 = O\big(|x|^{\max(-1-\delta_0,-2,-\frac{1}{2}-\delta_3)-|\alpha|-1}\big) \quad \text{as } |x| \to \infty \tag{11.6.63}$$

and in the context of the previous subsections this error does not matter provided that under the assumptions of Theorems 11.6.7 and 11.6.9

$$\delta_\iota < \frac{3}{2}, \quad \delta_\iota < \frac{1}{2} + \delta_0, \quad \delta_\iota < \frac{1}{2} + \delta_3 \tag{11.6.64}_{1,2,3}$$

respectively with $\iota = 1, 2$ (because the "order" of the operator $D_j - V_j$ is $-\frac{1}{2} + \delta'$ with arbitrarily small $\delta' > 0$ if we take the "order" of $|x|$ equal to 1). Then the operator $A(\tau)$ differs by negligible terms from the Schrödinger operator

$$B(\tau) = \sum_{j,k}(D_j - V_j)g^{jk}(2M - V + \tau)^{-1}(D_k - V_k) + V - \tau \tag{11.6.65}$$

and moreover, for

$$\delta_\iota < 1 \qquad (\iota = 1, 2) \tag{11.6.66}$$

one can replace this operator by the operator

$$B'(\tau) = (2M)^{-1} \sum_{j,k} (D_j - V_j) g^{jk} (D_k - V_k) + V - \tau. \tag{11.6.67}$$

So we arrive to

Theorem 11.6.21. *Let conditions* (11.6.60)–(11.6.63), $(11.6.64)_{1,2,3}$ *and* (11.6.66) *be fulfilled.*

Furthermore, let assumptions of some statement of Theorem 11.6.7 or Theorem 11.6.9 be fulfilled for the Schrödinger operator $B'(\tau)$ *defined by* (11.6.65) *(or equivalently by* (11.6.67)*); then* $\iota = 1, 2$ *respectively.*

Then the corresponding asymptotics holds for the Dirac operator. Namely, asymptotics (11.6.18)*) holds for* $\delta_\iota < \frac{1}{2}$ *(then condition* (11.6.64)*) is fulfilled automatically) and asymptotics* (11.6.19)*) holds for* $\delta_\iota \in (\frac{1}{2}, 1)$.

In these asymptotics $\mathsf{N}^{\mathsf{W}}(\tau)$ *is calculated for the Dirac operator and* $F(\tau)$ *is calculated for the Schrödinger operator and then it is multiplied by* $\frac{1}{2}\mathsf{D}$.

On the other hand, let condition (11.6.66) be violated but condition $(11.6.63)_{1,2,3}$ be (almost) fulfilled. Then one should replace $B(\tau)$ by

$$B''(\tau) = (2M)^{-1} \sum_{j,k} (D_j - V_j) g^{jk} (D_k - V_k) + V - \tau - (2M)^{-1} (V - \tau)^2 \tag{11.6.68}$$

and in the last term one can replace V by V^0 where V^0 is a smooth function equal to $-1(2M|x|)^{-1}$ for $|x| \ge c$. Changing variables $x \to \zeta x$ and multiplying by $2M\zeta^2$ with $\zeta = 1 - \tau M^{-1}$ we obtain, modulo negligible terms, operator

$$B'''(\tau') = \sum_{j,k} (D_j - V_j) g^{jk} (D_k - V_k) + W - \tau' \tag{11.6.69}$$

with the new potential

$$W = 2MV - (V^0)^2 \tag{11.6.70}$$

and with the modified spectral parameter

$$\tau' = \tau\big(1 - \frac{3\tau}{2M}\big) \tag{11.6.71}$$

This yields that

Theorem 11.6.22. *Let assumptions of some statement of either Theorem 11.6.7 or Theorem 11.6.9 be fulfilled for the Schrödinger operator* $B'''(0)$ *defined by* (11.6.69).

Let conditions (11.6.60)–(11.6.63), $(11.6.63)_{1,2,3}$ *be fulfilled but* $\delta_\iota \in [1, \frac{3}{2})$.

Then asymptotics (11.6.19) *remains true where* $\mathsf{N}^{\mathsf{W}}(\tau)$ *is calculated for the Dirac operator and* $F(\tau')$ *is calculated for the Schrödinger operator* $B'''(\tau')$ *and is then multiplied by* $\frac{1}{2}\mathsf{D}$, *and* τ' *is defined by* (11.6.71).

Let us weaken condition $(11.6.64)_{1,2,3}$.

Remark 11.6.23. For $d = 2$ one can assume without any loss of the generality that $\mathsf{D} = 2$. Then $A(\tau)$ is surely a scalar operator but we have not taken into account some terms. Taking them into account and applying the above analysis we can discard condition $(11.6.64)_{1,2,3}$ completely (in which case we have additional corrections for W and τ').

In the general case we assume that conditions (11.6.60)–(11.6.62) are fulfilled. If $\delta_1 \ge 1$ then the non-scalar terms in $A(\tau)$ are

$$\frac{1}{2}(2M)^{-3} r^{-3} \sum_{l \ne k} \sigma'^{*}_l \sigma'_k F_{lk} \tag{11.6.72}$$

modulo operators of the form $\sum_j b'_j D_j + b'_0$ where b'_j, b'_0 satisfy condition (11.6.60), (11.6.61) with "-2" replaced by "-3." Here we used the skew-symmetry of the matrices $\sigma'^{*}_l \sigma'_k$ with $l \ne k$; recall that $F_{lk} = (\partial_k A_l - = \partial_l A_k)$.

This statement remains true for $\delta_2 \ge 1$ (i.e., for $\delta_1 \ge \frac{1}{2}$) in the framework of Theorem 11.6.7. However, in this case the operator $A(\tau)$ also contains terms of type $b''_j D_j + b''_0$ with b''_j, b''_0 satisfying conditions (11.6.62)–(11.6.63) with "-2" replaced by "$-2-\delta_1$" and this operator skew-commutes with the antipodal map. In both cases these terms are negligible provided

$$\delta_\iota < 2, \quad \delta_\iota < \frac{1}{2} + \delta_3 \quad (\iota = 1, 2). \tag{11.6.73}_{1,2}$$

However, the second inequality is not necessary: for $\iota = 1$ it is fulfilled automatically and for $\iota = 2$ it is associated with terms of the type

$$-i\,\mathsf{const} \sum_{l \ne k} \sigma'^{*}_l \sigma'_l F_{lk}.$$

However, in this case $V_l \circ j^* = V_l$ and therefore $F_{lk} \circ j^* = -F_{lk}$ and the same is true for this extra term. Then one should check the condition $-2-\delta_1 < -1 < -2\delta_1$ which follows from the first inequality.

Let us consider Schrödinger operator with a (perturbed) Coulomb potential. Let us consider

$$\int_0^{T_0} r^{-3}(x_j\xi_k - x_k\xi_j)\circ \Psi_t \, dt$$

where Ψ_t is the Hamiltonian flow generated by $|\xi|^2 - |x|^{-1}$. One can easily see that this integral is equal to $\pi\mu_{jk}\mu^{-3}$ where μ_{jk} are components of the angular momentum tensor

$$\mu_{jk} = (x_j\xi_k - x_k\xi_j) \qquad \text{and} \qquad \mu = \Big(\sum_{j<k}\mu_{jk}^2\Big)^{\frac12}. \tag{11.6.74}$$

This calculation is easy for trajectories lying in the (x_1, x_2)-plane and then one can change coordinates.

Then we obtain that the contribution of the non-scalar terms to the operator $U(\pi,\tau)$ [55] is the multiplication by

$$I - i\pi\sum_{j,k}\sigma_j'^{*}\sigma_k'\mu_{jk}\mu^{-3} + O\big(|\tau|^{\frac32-\delta'}\big)$$

with arbitrarily small $\delta' > 0$. Applying corollary 5.A.7 and calculating the eigenvalues of μ_{jk} we obtain that in order to take into account non-scalar terms for $d \ge 3$ we can treat the family of operators

$$B'''(\tau') + k\nu|\tau|^{\frac32}M^{-2} \tag{11.6.75}$$

with an appropriate constant k and with $\nu \in \{-1, 0, 1\}$ of the corresponding multiplicities where M^s is an operator with the symbol μ^s with $\mu = \mu(x,\xi)$ defined by (11.6.74). One should check conditions for every such operator, calculate and sum $\mathsf{N}_\nu^-(\tau)$ with the corresponding multiplicities.

For $d = 2$ and $\mathsf{D} = 2$ we have $\nu = 0, 1$ and the operators

$$B'''(\tau') + 3\varsigma\nu|\tau'|^{\frac32}\mathcal{M}M^{-3} \tag{11.6.76}$$

with $\mathcal{M} = x_1D_2 - x_2D_1$, $\varsigma = i\sigma_0\sigma_1\sigma_2 = \pm 1$.

We leave the following rather easy problem to the reader:

Problem 11.6.24. Analyze the Schrödinger operator with a (perturbed) Coulomb potential in details.

---

[55] Here $U(\pi,\tau) = \exp\big(i\pi(-A(\tau)\big)^{-\frac12}\big)$ and π is the period of the corresponding Hamiltonian flow for $\tau = 0$.

11.7 Multiparameter Asymptotics

11.7.1 Problem Set-up

In this section we consider operators depending on more than one parameter. First of all, we consider semiclassical asymptotics in the case when the scalar semiclassical parameter h is replaced by a vector $\boldsymbol{h} = (h_1, \dots, h_d)$ with $h_j \to +0$.

Next we assume that there are two parameters: the semiclassical parameter $h \to +0$ and the spectral parameter τ. Let us recall that each of the semiclassical asymptotics of Section 11.1 was uniform with respect to the energy level τ lying in the interval in which conditions of the corresponding theorem were fulfilled[56] uniformly. Therefore there are two principally different situations in which non-trivial results are possible. We will explain them for the Schrödinger operator.

In the first situation τ increases and tends to a value τ^* such that the conditions of the corresponding theorem of Section 11.1 are violated for $\tau = \tau^*$ and therefore the asymptotics are no longer uniform. There are two cases:

(a) $\tau \to +\infty$ as in Sections 11.2–11.5 or

(b) $\tau \to \tau^* - 0$ with $\tau^* < \infty$ as in Section 11.6 where in the this case $\tau^* = \liminf_{|x|\to\infty} V$. In this case τ^* is the bottom of the essential spectrum and $\tau^* - 0$ is either a limit point of the discrete spectrum for every fixed $h > 0$ or there is only a finite discrete spectrum for every fixed $h > 0$ and in the second case the number of eigenvalues and (or) the remainder estimate near $\tau^* - 0$ are unusually large ($\gg \mathsf{const} \cdot h^{-d}$ and $\gg \mathsf{const} \cdot h^{1-d}$ respectively).

In all these cases we obtain estimates for the number of eigenvalues and for the remainder which are *worse* than for "normal" τ.

In the second situation τ decreases to the special value $\tau^* = \inf V$ and we obtain estimates for the number of eigenvalues and for the remainder which are *better* than for "normal" τ. Again there are two different cases:

(c) either $\inf V$ is finite in which case $\tau \to \tau^* + 0$ or

[56] In this subsection for the sake of simplicity we consider only the Schrödinger and Dirac operators and we no not need to check non-degeneracy conditions.

(d) $\inf V = -\infty$ but $-\infty$ is not a limit point of the spectrum for every fixed $h > 0$. Then for $h \to +0$ the bottom eigenvalues of the operator "fall" to $-\infty$ and we consider this process. Only the last case is impossible for the Dirac operator.

11.7.2 Semiclassical Asymptotics with a Vector Semiclassical Parameter

Let us consider the Schrödinger operator

$$A = A_{\boldsymbol{h}} = \sum_{j,k} P_j g^{jk} P_k + V, \qquad P_j = h_j - V_j \tag{11.7.1}$$

or the Dirac operator of the same type as before. Changing coordinates $x_{j\,\mathrm{new}} = x_{j\,\mathrm{old}} h_j^{-1}$ we obtain operator

$$A' = A'_{\boldsymbol{h}} = \sum_{j,k} (D_j - V_{j\boldsymbol{h}}) g^{jk}_{\boldsymbol{h}} (D_k - V_{k\boldsymbol{h}}) + V_{\boldsymbol{h}} \tag{11.7.2}$$

in the domain $X_{\boldsymbol{h}} = \{x, f_{\boldsymbol{h}}(x) \in X\}$ where X is the original domain and $v_{\boldsymbol{h}} = v \circ f_{\boldsymbol{h}}$ for every function v where $f_{\boldsymbol{h}}(x) = h \bullet x := (h_1 x_1, \dots, h_d x_d)$, $\boldsymbol{h} = (h_1, \dots, h_d)$. One can easily see that if (some of) the conditions (11.1.6)–(11.1.8), (11.4.5) were fulfilled for $X, \rho, \gamma, g^{jk}, V_j, V$ then the same conditions remain true for $X_{\boldsymbol{h}}, \rho_{\boldsymbol{h}}, h^{-1}\gamma_{\boldsymbol{h}}, V_{j\boldsymbol{h}}, V_{\boldsymbol{h}}$ where $h = \max_j h_j$. Moreover, if the cone condition was fulfilled for the domain X then it remains true for $X_{\boldsymbol{h}}$ provided $h \le 1$. This immediately yields

Theorem 11.7.1. *(i) Let $d \ge 3$ and let conditions* (11.1.6)–(11.1.8) *be fulfilled for $g^{jk}, V_j, V, \rho, \gamma$. Let $\gamma > 0$ a.e. and $V_-^{\frac{d}{2}}$, $\rho^{d-1}\gamma^{-1} \in \mathscr{L}^1(X)$. Then asymptotics*

$$\mathsf{N}^-(A_{\boldsymbol{h}}) = (h_1 \dots h_d)^{-1} \bigl(\mathsf{N}^{\mathsf{W}} + O(h)\bigr) \tag{11.7.3}$$

holds as $h = \max_j h_j \to +0$ where as usual

$$\mathsf{N}^{\mathsf{W}} = (2\pi)^{-d} \omega_d \int V_-^{\frac{d}{2}} \sqrt{g}\, dx. \tag{11.7.4}$$

(ii) Moreover, let us assume that

$$g^{jk} = V_j = 0 \qquad \text{for } \ j \ge d' + 1, k \le d', \tag{11.7.5}$$

$0 < d' < d$ *and that*

$$|\nu'| \ge \epsilon_0 > 0 \qquad \text{on } \partial X \cap \{V \le 0\} \tag{11.7.6}$$

where $\nu = (\nu_1, \dots, \nu_{d'}; \nu_{d'+1}, \dots, \nu_d) = (\nu'; \nu'')$ *is a unit normal to* ∂X. *Then asymptotics*

$$\mathsf{N}^-(A_{\boldsymbol{h}}) = (h_1 \dots h_d)^{-1}\big(\mathsf{N}^{\mathsf{W}} + \varkappa_1 h + o(h)\big) \tag{11.7.7}$$

holds as $h = \max_j h_j \to +0$, $h_j = o(h)$ $\forall j \ge d'+1$ *where*

$$\varkappa_1 = \mp\frac{1}{4}(2\pi)^{1-d}\omega_{d-1}\int_{\partial X} V_-^{\frac{d-1}{2}}\, dS'\sqrt{g''}dx'' \tag{11.7.8}$$

for Dirichlet and Neumann boundary conditions respectively and the Riemannian densities dS', $\sqrt{g''}dx''$ *were introduced in Example 11.5.23(ii) (see* (11.5.68)*).*

(iii) Furthermore, if $\vartheta > 0$, $V_-^{\frac{d}{2}+\vartheta}, \rho^{d-1+\vartheta} \in \mathscr{L}^1(X)$ *we have, in the frameworks of Statements (i) and (ii), asymptotics*

$$\mathsf{N}^-_{(\vartheta)}(A_{\boldsymbol{h}}) = (h_1 \dots h_d)^{-1}\big(\mathsf{N}^{\mathsf{W}}_{\vartheta,\boldsymbol{h}} + O(h^{1+\vartheta})\big) \tag{11.7.9}$$

and

$$\mathsf{N}^-_{(\vartheta)}(A_{\boldsymbol{h}}) = (h_1 \dots h_d)^{-1}\big(\mathsf{N}^{\mathsf{W}}_{\vartheta,\boldsymbol{h}} + o(h^{1+\vartheta})\big) \tag{11.7.10}$$

respectively.

(iv) The same results remain true for $d = 2$, $d' = d'' = 1$ *under additional restrictions* $\mathsf{mes}(Y) < \infty$ *where* $Y = \{X, \rho\gamma \le h_0\} < \infty$ *for some* $h_0 > 0$ *and* $V_-^{p+\vartheta} \in \mathscr{L}^1(X'')$ *for some* $p > 1$.

(v) Under the cone condition all these results remain true for Neumann boundary conditions and also for the Dirac operator (with the reasonable boundary conditions). In the case of Dirac operator we consider eigenvalues lying in the interval $[\tau_1, \tau_2]$ *with arbitrary fixed* τ_1, τ_2.

Proof. Statement (i) follows immediately from Theorem 9.1.7.

Statement (ii) follows from Theorem 9.1.7 with an improved remainder estimates under non-periodicity assumption. Analysis of the Hamiltonian billiards is based on the same arguments as in Example 11.5.23(ii); namely ξ_j

and $h_j x_j$ with $j \ge d'+1$ are "almost constant" (constant modulo $o(1)$) along these billiards (which is not true for $j \le d'$). But then $\frac{d}{dt} x_j \equiv \sum_{k \ge d'+1} g^{jk}\xi_k \mod o(1)$ as $j \ge d'+1$ and for generic ξ non-periodicity condition is fulfilled automatically.

The other Statements (iii)–(v) are proven by a similar method. □

11.7.3 Asymptotics of Eigenvalues near $+\infty$

Here and below we consider the Schrödinger operator A_h and consider the number of its eigenvalues lesser than τ. For the Dirac operator A_h (we use the same notation) we consider the number of eigenvalues lying in the interval $[\tau_1, \tau)$ with fixed τ_1.

Applying the arguments of Sections 11.2–11.5 with $\rho_{\tau,h} = h^{-1}(\rho + \sqrt{\tau})$ and $\gamma_{\tau,h} = \gamma$ we obtain modifications of the statements of these sections. However, we cannot anymore replace $\mathsf{N}^{\mathsf{W}}(\tau)$ by $\varkappa_0 \tau^{\frac{d}{2m}}$ in these assertions. In particular, we obtain the following statements:

Theorem 11.7.2. *(i) For the Schrödinger operator, let conditions* (11.1.6)–(11.1.8) *be fulfilled with auxiliary functions ρ, γ. Let $\vartheta \ge 0$ and*

$$\rho^{d+2\vartheta}, 1, \gamma^{-\vartheta-1} \in \mathscr{L}^1(X). \tag{11.7.11}$$

For $d = 2$ let us assume also that

$$\rho^{2p+2\vartheta} \in \mathscr{L}^1(X) \qquad \text{with some } \ p > 1. \tag{11.7.12}$$

Moreover, in the case of the Neumann condition let us in addition assume that the cone condition is also fulfilled[57]*. Then asymptotics*

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau, h) + O\bigl(\tau^{\frac{1}{2}(d+\vartheta-1)} h^{1-d+\vartheta}\bigr) \tag{11.7.13}$$

holds as $\tau \to +\infty, h \to +0$. In particular, for $\vartheta = 0$

$$\mathsf{N}^{\mathsf{W}}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d}. \tag{11.7.14}$$

(ii) Further, if the set of all points which are periodic with respect to the geodesic flow with reflections is of measure 0 then asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau, h) + o_\tau\bigl(\tau^{\frac{1}{2}(d+\vartheta-1)} h^{1-d+\vartheta}\bigr) \tag{11.7.15}$$

[57] We leave the analysis of mixed boundary conditions to the reader.

holds as $\tau \to +\infty, h \to +0$ *where* $M' = o_\zeta(M)$ *means that* $M'M^{-1} \le \varepsilon(\zeta)$ *with* $\varepsilon(\zeta) = o(1)$ *as* ζ *tends to the described limit.*

In particular, for $\vartheta = 0$ *asymptotics*

$$\mathsf{N}^-(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + \big(\varkappa_1 + o_\tau(1)\big)\tau^{\frac{1}{2}(d-1)}h^{1-d} \tag{11.7.16}$$

holds as $\tau \to +\infty, h \to +0$ *with the coefficient*

$$\varkappa_1 = \mp\frac{1}{4}(2\pi)^{1-d}\omega_{d-1}\,\mathsf{vol}'\big(\partial X \cap \{\gamma > 0\}\big) \tag{11.7.17}$$

for Dirichlet and Neumann boundary conditions respectively.

(iii) Furthermore, let us assume that $\gamma^{-1-\theta} \in \mathscr{L}^1(X)$ *with* $\theta > \vartheta$ *and that the geodesic flow is* <u>*either*</u> *of non-periodic power type* <u>*or*</u> *of non-periodic exponential type. Then these asymptotics hold the remainder estimates*

$$O\big(\tau^{\frac{1}{2}(d+\vartheta-1-\delta')}h^{1-d+\vartheta}\big) \tag{11.7.18}$$

or

$$O\big(\tau^{\frac{1}{2}(d+\vartheta-1)}h^{1-d+\vartheta}\,\mathsf{log}^{-1-\vartheta}\,\tau\big) \tag{11.7.19}$$

respectively.

(iv) All these asymptotics remain true if we drop condition $\rho^{d+2\vartheta} \in \mathscr{L}^1(X)$ *replacing it by the coercivity condition* (11.4.5).

(v) Statements (i)–(iii) remain true for $\vartheta = 0$ *for the Dirac operator*[58]*. In these assertions one should replace* $\mathsf{N}^-(\tau, h)$ *and* $\mathsf{N}^{\mathsf{W}}(\tau_2)$ *by* $\mathsf{N}(\tau_1, \tau_2, h)$ *and* $\mathsf{N}^{\mathsf{W}}(\tau_1, \tau_2)$ *respectively and take* $\tau = |\tau_1| + |\tau_2| \to \infty$*. One should assume that the boundary conditions are elliptic and the domain satisfies the cone condition.*

We leave to the reader the following easy set of problems

Problem 11.7.3. (i) Modify in the same way the complete set of Theorems 11.2.7, 11.2.8, 11.2.12 and Corollary 11.2.9.

(ii) Consider Examples 11.2.13, 11.2.14, 11.2.15, 11.2.17, 11.2.18, 11.2.19, 11.2.21, 11.2.22, 11.2.25, 11.2.26, 11.2.27, 11.3.34, 11.3.35, 11.4.8, 11.4.9, 11.4.10 and translate them into the framework of the present two-parameter theory (automatically or with minor modifications). The same for all other results of this type.

[58] For $\vartheta > 0$ one should modify $\mathsf{N}_{(\vartheta)}(\tau_1, \tau_2, h)$ in the obvious manner.

(iii) Modify Theorems 11.3.7, 11.3.18, 11.3.19, 11.3.21, 11.3.23, 11.3.26 etc.

Here one should assume that $h \ge \tau^{-n}$, and the principal part of the asymptotics is of the form $\mathsf{N}^{\mathsf{W}}(\tau)h^{-d}$ and the second term is of the form

$$\big(\varkappa_1 + F(\tau h^{-m})\big)h^{1-d}\tau^{\frac{1}{2m}(d-1)} \tag{11.7.20}$$

and there is additional factor h^{1-d} in the remainder estimate.

Let us consider the statements of Section 11.5. For the sake of simplicity let us consider only the Schrödinger operator. Then the following statements hold:

Theorem 11.7.4. *(i) In the framework of Theorem 11.5.1 (with the additional assumption that A is the Schrödinger operator) asymptotics*

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau, h) + O\big(R_{(\vartheta)}(\tau)h^{1-d+\vartheta}\big) \tag{11.7.21}$$

holds as $\tau \to +\infty, h \to +0$ where $R_{(\vartheta)}(\tau)$ is defined by (11.5.3).

(ii) Further, under the additional assumptions of Theorem 11.5.3(i) asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau, h) + o_{\tau}\big(R_{(\vartheta)}(\tau)h^{1-d+\vartheta}\big) \tag{11.7.22}$$

holds as $\tau \to +\infty, h \to +0$.

(iii) Furthermore, in the framework of Theorem 11.5.3(ii) asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau, h) + o_{\tau h^{-2}}\big(R_{(\vartheta)}(\tau)h^{1-d+\vartheta}\big) \tag{11.7.23}$$

holds as $\tau \to +\infty, h \to +0$. Moreover, the principal part in asymptotics (11.7.21) *with $\vartheta = 0$ is $\mathsf{N}^{\mathsf{W}}(\tau)h^{-d}$ and in* (11.7.22), (11.7.23) *the principal part is $\mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + \varkappa_1\tau^{l(d-1)}h^{1-d}$ with the coefficient $\varkappa_1$ given by* (11.5.11).

(iv) In the framework of Theorem 11.5.6 for $\vartheta \le d-1-\delta$ with $\delta > 0$ asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau, h) + O\big(\tau^{l(d-1)+\vartheta(1-l)-\delta'}h^{1-d}\big) \tag{11.7.24}$$

holds as $\tau \to +\infty, h \to +0$. Here for $\vartheta = 0$ the principal part is the same as in (11.7.22). *In particular, Example 11.5.7 applies.*

(v) In the frameworks of Theorems 11.5.14, 11.5.18 and 11.5.20 asymptotics (11.7.21) *remains true. Moreover, under the conditions of these theorems on the Hamiltonian trajectories with reflections asymptotics* (11.7.22) *remains true.*

(vi) In the frameworks of Example 11.5.23(i) and (ii) asymptotics

$$\mathsf{N}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d} + O(\tau^{q} h^{1-d}), \tag{11.7.25}$$

and

$$\mathsf{N}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d} + \bigl(\varkappa_1 + o_\tau(1)\bigr)\tau^{q} h^{1-d}, \tag{11.7.26}$$

hold respectively with the coefficient $\varkappa_1$ *given by* (11.5.68).

(vii) In the frameworks of Theorem 11.5.25(i) and (ii) the asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) h^{-d} + O\bigl(\tau^{\frac{1}{2}(d+\vartheta-1)} h^{1-d+\vartheta}\omega(\tau)\bigr), \tag{11.7.27}$$

and

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) h^{-d} + o\bigl(\tau^{\frac{1}{2}(d+\vartheta-1)} h^{1-d+\vartheta}\omega(\tau)\bigr) \tag{11.7.28}$$

hold respectively with

$$N^{\mathsf{W}}_{(\vartheta)}(\tau, h) \asymp \tau^{\frac{d}{2}+\vartheta} \log^{\frac{n}{\mu}} \tau h^{-d} \tag{11.7.29}$$

and $\omega(\tau)$ *defined by* (11.5.74). *For* $\vartheta = 0$ *we have* $\mathsf{N}^{\mathsf{W}}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d}$.

Moreover, asymptotics (11.7.28) *remains true in the framework of Theorem 11.5.27 and for* $\vartheta = 0$

$$\mathsf{N}^{\mathsf{W}}_{(0)}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d} + \varkappa_1 \tau^{\frac{1}{2}(d-1)} h^{1-d} \log \tau \tag{11.7.30}$$

where the coefficient $\varkappa_1$ *is defined by* (11.5.83).

(viii) In the framework of Theorem 11.5.29(i) asymptotics with the principal part

$$\mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau, h) \asymp \mathsf{N}^{\mathsf{W}}(\tau) h^{-d}, \qquad \mathsf{N}^{w}_{(0)}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d} \tag{11.7.31}$$

and with remainder estimate $h^{1-d+\vartheta} R_{(\vartheta)}(\tau)$ *holds where* $\mathsf{N}^{\mathsf{W}}(\tau)$ *and* $R_{(\vartheta)}(\tau)$ *are defined in the theorem.*

Moreover, the improvements made in Statement (ii) and in footnote [44] *remain true.*

We leave to the reader the following easy set of problems:

Problem 11.7.5. (i) Analyze Examples 11.5.17, 11.5.19 and 11.5.21.

(ii) Modify Theorems 11.5.5, 11.5.9 and 11.5.11.

Note that remark in Problem 11.7.3(iii) also remains true in this case.

11.7.4 Asymptotics of Eigenvalues near -0 and Related asymptotics

Applying the arguments of Section 11.6 with $\rho_{\tau,h} = h^{-1}(\rho + \sqrt{|\tau|})$ and $\gamma_{\tau,h} = \gamma$ we obtain

Theorem 11.7.6. *Again, we treat only the Schrödinger operator.*

(i) In the framework of Theorem 11.6.1 asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau, h) + O\big(h^{1-d+\vartheta} R_{(\vartheta)}(\tau)\big) \tag{11.7.32}$$

holds as $\tau \to -0$, $h \to +0$ with $R_{(\vartheta)}(\tau)$ defined by (11.6.4).

(ii) Moreover, in the framework of Theorem 11.6.2(i) asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau, h) + o_{\tau}\big(h^{1-d+\vartheta} R_{(\vartheta)}(\tau)\big) \tag{11.7.33}$$

holds as $\tau \to -0$, $h \to +0$.

For $\vartheta = 0$ the principal parts of these asymptotics are $\mathsf{N}^{\mathsf{W}}(\tau) h^{1-d}$ and

$$\mathsf{N}^{\mathsf{W}}(\tau) h^{1-d} + \varkappa_1 |\tau|^{l(d-1)} h^{1-d} \tag{11.7.34}$$

respectively with the coefficient $\varkappa_1$ given by (11.6.11).

(iii) In the framework of Theorem 11.6.5 with $\vartheta \le \vartheta_1 - \delta$, $\delta > 0$ asymptotics

$$\mathsf{N}^{-}_{(\vartheta)}(\tau, h) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau, h) + O(h^{1-d+\vartheta} |\tau|^{l(d-1)+\vartheta(1-l)+\delta'}) \tag{11.7.35}$$

holds with $\delta' > 0$. In these asymptotics the principal part for $\vartheta = 0$ is $\mathsf{N}^{\mathsf{W}}(\tau) h^{1-d} + \varkappa_1 |\tau|^{l(d-1)} h^{1-d}$. In particular, Example 11.6.6 applies.

(iv) In the framework of Theorem 11.6.10 asymptotics (11.7.32) *remains true and under a condition on Hamiltonian trajectories with reflection asymptotics* (11.7.33) *also remains true.*

(v) In the frameworks of Example 11.6.13(i) and (ii) asymptotics

$$\mathsf{N}^{-}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + O(|\tau|^{q}h^{1-d}), \tag{11.7.36}$$

and

$$\mathsf{N}^{-}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + \bigl(\varkappa_1 + o_\tau(1)\bigr)|\tau|^{q}h^{1-d} \tag{11.7.37}$$

hold with the coefficient $\varkappa_1$ *given by* (11.6.35).

(vi) In the frameworks of Theorems 11.6.14(i) and (ii) asymptotics

$$\mathsf{N}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + O\bigl(\bigl|\log|\tau|\bigr|^{\nu(d-1)+1}h^{1-d}\bigr), \tag{11.7.38}$$

and

$$\mathsf{N}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + \bigl(\varkappa_1 + o_\tau(1)\bigr)\bigl|\log|\tau|\bigr|^{\nu(d-1)+1}h^{1-d} \tag{11.7.39}$$

respectively hold with the coefficient $\varkappa_1$ *given by* (11.6.40).

(vii) Moreover, Statement (vi) remains true for $\nu = 0$ *with* $o_\tau(1)$ *replaced by* $o(1)$ *in asymptotics* (11.7.39).

Remark 11.7.7. Statement Statement (vii) dealing with potentials decaying as $|x|^{-2}$ has no analog in Section 11.6 because for $\nu = 0$ for every small enough fixed $h > 0$ the eigenvalues of A_h tend to -0 but in (11.7.38) both the principal part and the remainder estimate are of the same order $\log|\tau|$ and (11.7.38) is only an estimate (or a couple of estimates: from above and below), not asymptotics.

We leave to the reader

Problem 11.7.8. (i) Modify Example 11.6.11.

(ii) In the framework of Problem 11.6.15 derive asymptotics with the principal parts

$$N^{\mathsf{W}}_{(\vartheta)}(\tau, h) \asymp \mathsf{N}^{W}_{\vartheta,h}(\tau)h^{-d}, \qquad N^{\mathsf{W}}_{(0)}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d}$$

and remainder estimate $O\bigl(h^{1-d+\vartheta}R_{(\vartheta)}(\tau)\bigr)$ where $\mathsf{N}^{\mathsf{W}}(\tau)$, $R_{(\vartheta)}(\tau)$ are defined in that problem.

(iii) Modify Theorems 11.6.4, 11.6.7 and 11.6.9.

Note that remark in Problem 11.7.3(iii) also remains true in this case as $h \ge |\tau|^{n}$.

Let us consider the situation in which the conditions of Theorem 11.6.14 are fulfilled with $\nu < 0$ instead of $\nu > 0$.

In this case for every fixed $h > 0$ the discrete spectrum is finite. However, $V_-^{\frac{d}{2}} \notin \mathscr{L}^1(X)$ for $\nu \geq -d^{-1}$ provided condition (11.6.8) is fulfilled. In this case the above arguments lead us to the following

Theorem 11.7.9. *(i) Under the assumptions of Theorem 11.6.14(i) with* $\nu \in (-d^{-1}, 0)$ *asymptotics* (11.7.38) *holds for the Schrödinger operator for* $\tau \to -0$, $h \to +0$ *provided*

$$h = o\big(\big|\log|\tau|\big|^{\nu}\big). \tag{11.7.40}$$

In this asymptotics $\mathsf{N}^{\mathsf{W}}(\tau) = O\big(\big|\log|\tau|\big|^{\nu d+1}\big)$ *and under condition* (11.6.8) $\mathsf{N}^{\mathsf{W}}(\tau) \asymp \big|\log|\tau|\big|^{\nu d+1}$.

(ii) Under the assumptions of Theorem 11.6.14(i) with $\nu = -d^{-1}$ *asymptotics* (11.7.38) *holds for the Schrödinger operator for* $\tau \to -0$, $h \to +0$ *provided*

$$h = O\big(\big|\log|\tau|\big|^{\nu}\big). \tag{11.7.41}$$

In this asymptotics $\mathsf{N}^{\mathsf{W}}(\tau) = O\big(\log\big|\log|\tau|\big|\big)$ *and under condition* (11.6.8) $\mathsf{N}^{\mathsf{W}}(\tau) \asymp \log\big|\log|\tau|\big|$.

(iii) Under the assumptions of Theorem 11.6.14(ii) with $\nu \in [-d^{-1}, 0)$ *asymptotics* (11.7.39) *holds for the Schrödinger operator for* $\tau \to -0$, $h \to +0$ *satisfying* (11.7.40). *In this asymptotics coefficient* $\varkappa_1$ *is given by* (11.6.40).

Let us consider the case

$$h \geq \epsilon_0\big|\log|\tau|\big|^{\nu}. \tag{11.7.42}$$

Then the singular zone $X_{\mathsf{sing}} = \big\{(\rho + \sqrt{|\tau|})\gamma \leq \epsilon h\big\}$ is not necessarily empty. Considering only the lower estimate we obtain that under condition (11.6.8)

$$\mathsf{N}^-(\tau, h) \geq \epsilon_1 h^{\frac{1}{\nu}} \qquad \text{for } \nu \in (-\frac{1}{d}, 0), \tag{11.7.43}$$

and

$$\mathsf{N}^-(\tau, h) \geq \epsilon_1 h^{\frac{1}{\nu}} |\log h| \qquad \text{for } \nu = -\frac{1}{d} \tag{11.7.44}$$

with $\epsilon_1 > 0$.

On the other hand, for $d \ge 3$ one can apply a variational estimate in X_{sing} (with $\rho = 0$ for $\log^\nu r \le \epsilon_2 h$. Then we obtain estimate

$$\mathsf{N}^-(\tau, h) = O(h^{\frac{1}{\nu}}) \qquad \text{for } \ \nu \in (-\frac{1}{d}, 0), \tag{11.7.45}$$

and even asymptotics

$$\mathsf{N}^-(\tau, h) = \big(\mathsf{N}^{\mathsf{W}}_h(\tau) + O(1)\big) h^{-d} \qquad \text{for } \nu = -\frac{1}{d} \tag{11.7.46}$$

for $\tau \to -0$, $h \to +0$ with

$$\mathsf{N}^{\mathsf{W}}_h(\tau) = (2\pi)^{-d}\omega_d \int_{\{|\log|x|| \le Ch^{-\frac{1}{\nu}}\}} \big(-\tau - V\big)^{\frac{d}{2}}_+ \sqrt{g}\, dx \tag{11.7.47}$$

with an arbitrarily chosen constant C. Under condition (11.6.8) this expression is $\asymp \min\big(\log\big|\log|\tau|\big|, |\log h|\big)$ for $\nu = -d^{-1}$.

Let us recall that the asymptotics and estimates (11.7.43)–(11.7.46) were obtained under the restriction (11.7.42).

Thus we arrive to

Remark 11.7.10. (i) If $d \ge 3$, $\nu \in (-d^{-1}, 0)$ then under condition (11.6.8) $\mathsf{N}^-(\tau, h) \asymp h^{\frac{1}{\nu}}$ for $\tau \to -0$, $h \to +0$ satisfying (11.7.42). One can easily obtain this result by purely variational arguments.

(ii) For $d \ge 3$, $\nu = -d^{-1}$ we combine Statement (ii) of Theorem 11.7.9 and (11.7.46) to obtain

$$\mathsf{N}^-(\tau, h) = \mathsf{N}^{\mathsf{W}}_h(\tau) h^{-d} + O\Big(\min\big(h^{-d}, h^{1-d}\big|\log|\tau|\big|^{\frac{1}{d}}\big)\Big) \tag{11.7.48}$$

with $\mathsf{N}^{\mathsf{W}}_h(\tau)$ given by (11.7.47) and $\tau \to -0$, $h \to +0$.

We leave to the reader the following

Problem 11.7.11. (i) Treat the case $\nu \in [-(d-1)^{-1}, -d^{-1})$. In this case the principal part is standard and $\asymp h^{-d}$ but the remainder estimate is worse than usual. In this case we also obtain asymptotics for $\tau = 0$ in the context of Section 11.1.

(ii) rove that all the results of this subsection remain true for the Dirac operator with

$$\tau_1^0 = -M + \limsup_{|x|\to\infty} V < \tau_2^0 = M + \liminf_{|x|\to\infty} V. \tag{11.7.49}$$

One need only to replace $\mathsf{N}^-(\tau; h)$ by $\mathsf{N}(\tau_1, \tau; h)$ with fixed $\tau_1 \in (\tau_1^0, \tau_2^0)$ and respectively modify the formulas for N^{W}, $\mathsf{N}_h^{\mathsf{W}}$, $\varkappa_0$ and $\varkappa_1$; without any loss of the generality one can assume that $\tau_2^0 = 0$ and then $\tau \to -0$.

11.7.5 Asymptotics of Eigenvalues near $+0$

Arguments of the same type as above permit us also to treat the case $\tau \to +0$, $h \to +0$ and to obtain asymptotics of $\mathsf{N}^-(\tau, h)$ assuming that $\inf V = 0$ for the Schrödinger operator.

Similar results may be obtained for the Dirac operator for $\mathsf{N}(\tau_1, \tau; h)$ provided (11.7.49) holds, $\tau_1 \in (\tau_1^0, \tau_2^0)$ and

$$\tau_1^0 = -M + \sup V < \tau_1 \le \tau_2^0 = M + \inf V;$$

without any loss of the generality one can assume that $\tau_2^0 = 0$ and then $\tau \to +0$.

We formulate our statements only for the Schrödinger operator with Dirichlet boundary conditions. For the the Schrödinger operator with Neumann boundary conditions and for the Dirac operator with any self-adjoint boundary conditions these statements remain true as long as the domain X satisfies the cone condition.

It is easy to prove the following

Theorem 11.7.12. *(i) Let X be a bounded domain and let Y a $\mathscr{C}^1$ manifold of codimension d'' in $\mathbb{R}^d$, $2 \le d'' \le d$ such that $\bar{X} \cap Y \ne \emptyset$.*

Let conditions (11.1.6)–(11.1.8), (11.4.5) *be fulfilled with $\gamma = \epsilon r(x)$, $\rho(x) = r^\mu(x)$, $\epsilon > 0$, $\mu > 0$, $r(x) = \operatorname{dist}(x, Y)$. Then asymptotics*

$$\mathsf{N}^-(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d} + O\bigl(\tau^q h^{1-d}\bigr) \tag{11.7.50}$$

holds for $\tau \to +0$, $h \to +0$ with $\mathsf{N}^{\mathsf{W}}(\tau) = O(\tau^p)$, $p = \frac{1}{2}d + \frac{1}{2\mu}d''$ and $q = \frac{1}{2}(d-1) + \frac{1}{2\mu}(d''-1)$ [59),60)].

[59)] Surely we obtain asymptotics only for $h = o(\tau^l)$ with $l = \frac{1}{2\mu}(\mu+1)$, i.e., only if τ tends to $+0$ slowly enough. Otherwise we obtain only an upper estimate and for $h \ge \epsilon_0 \tau^l$ with a small enough constant ϵ_0 we obtain a lower estimate for $\mathsf{N}^-(\tau, h)$. This remark remains true for other asymptotics of this subsection.

[60)] We did not study the lowest eigenvalue but under rather general assumptions one can prove that it is $\tau_1 > 0 : \tau_1 \asymp h^{1/l}$.

Moreover, $\mathsf{N}^{\mathsf{W}}(\tau) \asymp \tau^{p}$ *provided*

$$\operatorname{vol}\bigl(X \cap \{r(x) < \bar{r}\}\bigr) \asymp r^{n} \quad \text{as } r \to 0 \tag{11.7.51}$$

with $n = d''$.

(ii) Further, let us assume that $Y = \{0\}$, $X \cap \{|x| \le r_0\} = X^0 \cap \{|x| \le r_0\}$ *where* $r_0 > 0$ *and* X^0 *is the non-empty open cone with* $\partial X^0 \setminus 0 \in \mathscr{C}^{K}$.

Let stabilization conditions (11.5.4) *be fulfilled for* $|x| \to 0$ *with functions* g^{jk0}, V_j^0 *and* V^0 *positively homogeneous of degrees* 0, μ *and* 2μ *respectively.*

Finally, let the standard non-periodicity condition be fulfilled for the domain X^0 *and the Hamiltonian*

$$H^0_{\mathsf{st}} = \sum_{j,k} g^{jk0}(\xi_j - V_j^0)(\xi_k - V_k^0) + V^0 - 1 \tag{11.7.52}$$

on the energy level 0. *Then the asymptotics*

$$\mathsf{N}^{-}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d} + \bigl(\varkappa_1 + o(1)\bigr)\tau^{l(d-1)} h^{1-d} \tag{11.7.53}$$

holds as $\tau \to +0$, $h = o(\tau^{l})$ *with the coefficient* $\varkappa_1$ *given by* (11.5.11).

Note that under the stabilization conditions alone, $\mathsf{N}^{\mathsf{W}} = \bigl(\varkappa_0 + o(1)\bigr)\tau^{ld}$ *with the coefficient* $\varkappa_0$ *given by* (11.5.10).

(iii) Finally, let the stabilization conditions

$$D^{\alpha}(a_\beta - a^0_\beta) = O\bigl(|x|^{(2m-|\beta|)\mu - |\alpha| + \delta}\bigr) \qquad \forall \beta : |\beta| \le 2m \quad \forall \alpha : |\alpha| \le 1 \tag{11.7.54}$$

be fulfilled as $|x| \to 0$ *with some* $\delta > 0$. *Let the Hamiltonian flow generated by* H^0_{st} *near* 0 *be of non-periodic power type. Then the asymptotics*

$$\mathsf{N}^{-}(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d} + \bigl(\varkappa_1 + O(h^{\delta'}\tau^{-l\delta'})\bigr) h^{1-d}\tau^{l(d-1)} \tag{11.7.55}$$

with $\delta' > 0$ *holds for* $\tau \to +0$, $h = o(\tau^{l})$.

We leave to the reader the following easy Problem 11.7.13 and the proofs of Theorems 11.7.14–11.7.16 below.

Problem 11.7.13. (i) Generalize Statement (ii) of Theorem 11.7.12 to the case $d'' < d$. The arguments of Example 11.5.23(ii) should be applied here.

(ii) Consider the case of periodic Hamiltonian flow.

(iii) Consider the case $d''=1$ when the logarithmic factor appears in the remainder estimate.

(iv) Consider the general operators and the case $\vartheta>0$.

Theorem 11.7.14. *Let X be a bounded domain, $0\in X$ and*

$$X\cap\{|x|\le r_0\}=X^0\cap\{|x|\le r_0\} \tag{11.7.56}$$

where X^0 is an L-quasiconical domain in $\mathbb{R}^d$. Let g^{jk}, V_j and V be L-quasihomogeneous with respect to x of degrees 0, μ, 2μ respectively with $\mu>0$, $L=(L_1,\dots,L_d)$, $L_j=1$ for $j\le d'$ and $L_j<1$ for $j\ge d'+1$, $0<d'<d$.

Let us assume that $\partial X\setminus 0\in \mathscr{C}^K$ and $g^{jk}, V_j, V\in \mathscr{C}^K(\bar X\setminus 0)$ satisfy condition (11.1.8)[61] *Finally, let us assume that*

$$V(x)>0\qquad \forall x\in \bar X\setminus 0. \tag{11.7.57}$$

Then

(i) Asymptotics

$$\mathsf{N}^-(\tau,h)=\varkappa_0\tau^p h^{-d}+O(\tau^q h^{1-d}) \tag{11.7.58}$$

holds for $\tau\to+0$, $h\to+0$ with $p=\frac12 d+\frac{1}{2\mu}L^*$, $q=\frac12(d-1)+\frac{1}{2\mu}(L^*-1)$, $L^*=L_1+\dots+L_d$ and with the coefficient $\varkappa_0$ given by (11.5.63) *with X replaced by X^0.*

(ii) Under the additional conditions of Example 11.5.23(ii) asymptotics

$$\mathsf{N}^-(\tau,h)=\varkappa_0\tau^p h^{-d}+\bigl(\varkappa_1+o(1)\bigr)\tau^q h^{1-d} \tag{11.7.59}$$

holds for $\tau\to-0$, $h=o(\tau^{\frac12+\frac{1}{2\mu}})$ with the coefficient $\varkappa_1$ given by (11.5.67).

Theorem 11.7.15. *Let X be a bounded domain and let Y be a $\mathscr{C}^1$ manifold of codimension d'' in $\mathbb{R}^d$, $2\le d''\le d$, $\bar X\cap Y\ne\emptyset$.*

Let conditions (11.1.6)–(11.1.8), (11.4.5) *be fulfilled with $\gamma=\epsilon r(x)$, $\rho=\exp\bigl(-r(x)^\nu\bigr)$ with $\nu<0$, $r(x)=\operatorname{dist}(x,Y)$.*

Let us assume that condition (11.7.51) *is fulfilled with an exponent n which is now not necessarily equal to d''. Then*

[61] Then one can take $\gamma=\epsilon[x]_L$, $\rho=\epsilon[x]_L^\mu$.

(i) Asymptotics

$$\mathsf{N}^-(\tau,h)=\mathsf{N}^{\mathsf{W}}(\tau)h^{-d}+O\bigl(\tau^{\frac{1}{2}(d-1)}|\log\tau|^{(\nu+n-1)\nu^{-1}}h^{1-d}\bigr) \tag{11.7.60}$$

holds for $\tau\to+0$, $h\to+0$ *and* $\mathsf{N}^{\mathsf{W}}(\tau)\asymp\tau^{\frac{1}{2}d}|\log\tau|^{n\nu^{-1}}$.

(ii) Moreover, let $Y=\{0\}$, $n=d$. *Let condition* (11.7.59) *be fulfilled for* $r\to+0$ *and every fixed* k *and let conditions* (11.5.76)–(11.5.77) *be fulfilled for* $|x|\to 0$. *Then asymptotics*

$$\mathsf{N}^-(\tau,h)=\mathsf{N}^{\mathsf{W}}(\tau)h^{-d}+o\bigl(\tau^{\frac{1}{2}(d-1)}|\log\tau|^{(\nu+n-1)\nu^{-1}}h^{1-d}\bigr) \tag{11.7.61}$$

holds for $\tau\to+0$, $h=o\bigl(\tau^{\frac{1}{2}}|\log\tau|^{(1-\nu)\nu^{-1}}\bigr)$.

Theorem 11.7.16. *Let* $d\ge 3$, $X=(0,\frac{1}{2})\times U$ *where* U *is a domain on* $\mathbb{S}^{d-1}$ *with* $\mathscr{C}^K$ *boundary,* $g^{jk}=g^{jk}(\theta)\in\mathscr{C}^K(\bar U)$ *satisfy* (11.4.5). *Let* $V_j=0$, $V=v(\theta)|\log r|^{-1}$ *with* $v\in\mathscr{C}^K(\bar U)$ *and* $\min_{\bar U}v=v_0>0$. *Then asymptotics*

$$\mathsf{N}^-(\tau,h)=\mathsf{N}^{\mathsf{W}}(\tau)h^{-d}+O\Bigl(h^{1-d}\tau^{d-2}\int_U\exp\bigl(-v(d-1)\tau^{-1}\bigr)\,d\theta\Bigr) \tag{11.7.62}$$

holds as $\tau\to+0$, $h\to+0$ *with*

$$\mathsf{N}^{\mathsf{W}}(\tau)=a\int_{U'}\tau^d v^{-\frac{d}{2}}F_d\bigl(\tfrac{\tau}{v}\bigr)\exp(-vd\tau^{-1})\sqrt{g}\,d\theta \tag{11.7.63}$$

where $U'=U\cap\{v<v_0+\varepsilon\}$, $\varepsilon>0$ *is arbitrarily small, and* a *and* F_d *are introduced in Theorem 11.6.14 in which the orders of* $\mathsf{N}^{\mathsf{W}}(\tau)$ *and the remainder estimate are also discussed.*

11.7.6 Asymptotics of Eigenvalues near $-\infty$

Let us consider asymptotics of $\mathsf{N}(\tau,h)$ for $\tau\to-\infty$, $h\to+0$. Recall that we consider the Schrödinger operator and now we assume that

$$\inf V=-\infty; \tag{11.7.64}$$

thus it is still the case"$\tau\searrow\inf V$". The results of this subsection surely do not make any sense for the Dirac operator. The same arguments as above give us the following

Theorem 11.7.17. *(i) Let X be a bounded domain in $\mathbb{R}^d$, $0 \in \bar{X}$ and let conditions* (11.1.6)–(11.1.8) *be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^\mu$, $\mu \in (-1, 0)$. Then asymptotics*[59),60)]

$$\mathsf{N}^-(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + O\big(|\tau|^{l(d-1)}h^{1-d}\big) \tag{11.7.65}$$

holds for $\tau \to -\infty$, $h \to +0$ and $\mathsf{N}^{\mathsf{W}}(\tau) = O(|\tau|^{ld})$.

Moreover, $\mathsf{N}^{\mathsf{W}}(\tau) \asymp |\tau|^{ld}$ provided

$$\mathsf{mes}\big(\{x \in X, |x| \le r, V \le -\epsilon_0\rho^2(x)\}\big) \asymp r^d \qquad \text{for } r \to +0. \tag{11.7.66}$$

(ii) Further, let $X \cap \{|x| \le r_0\} = X^0 \cap \{|x| \le r_0\}$ with some $r_0 > 0$ and an open non-empty cone X^0 such that $\partial X^0 \setminus 0 \in \mathscr{C}^K$. Let stabilization conditions (11.5.4) *be fulfilled for $|x| \to 0$ with functions $g^{jk0}, V_j^0, V^0 \in \mathscr{C}^K(\bar{X}^0 \setminus 0)$.*

Let the standard non-periodicity condition to the Hamiltonian flow be fulfilled on the energy level 0 for the Hamiltonian

$$H^0(x, \xi) = |x|^{1-\mu}\big(\sum_{j,k} g^{jk0}(\xi_j - V_j^0)(\xi_k - V_k^0) + V^0 + 1\big). \tag{11.7.67}$$

Then asymptotics

$$\mathsf{N}^-(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + \big(\varkappa_1 + o(1)\big)|\tau|^{l(d-1)}h^{1-d} \tag{11.7.68}$$

holds for $\tau \to -\infty$, $h = o\big(|\tau|^l\big)$ with the coefficient $\varkappa_1$ given by (11.6.11).

(iii) Furthermore, let stabilization conditions (11.7.54) *with $\delta > 0$ be fulfilled for $x \to 0$ and let the Hamiltonian flow corresponding to the Hamiltonian*

$$H^0_{\mathsf{st}}(x, \xi) = \sum_{j,k} g^{jk0}\big(\xi_j - V_j^0\big)(\xi_k - V_k^0) + V^0 + 1 \tag{11.7.69}$$

be of power non-periodic type near the energy level 0. Then asymptotics

$$\mathsf{N}^-(\tau, h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + \big(\varkappa_1 + O(h^{\delta'}|\tau|^{-l\delta'})\big)|\tau|^{l(d-1)}h^{1-d} \tag{11.7.70}$$

with $\delta' > 0$ holds for $\tau \to -\infty$, $h \to +0$.

We leave to the reader the following easy Problem 11.7.18 and Theorems 11.7.19, 11.7.20 and 11.7.22 below.

Problem 11.7.18. Treat the case of a singularity at a manifold of codimension less than d.

Theorem 11.7.19. *(i) Let conditions of Theorem 11.7.14 be fulfilled with $\mu \in (-1,0)$. Then asymptotics*

$$\mathsf{N}^-(\tau,h) = \varkappa_0 |\tau|^p h^{-d} + O\big(|\tau|^q h^{1-d}\big) \tag{11.7.71}$$

holds as $\tau \to -\infty$, $h \to +0$ with the same exponents p, q and coefficient $\varkappa_0$ as in Theorem 11.7.14 (i.e. given by (11.5.63) *with X replaced by X^0).*

(ii) Further, under the additional restrictions of Theorem 11.7.14(ii) asymptotics

$$\mathsf{N}^-(\tau,h) = \varkappa_0 |\tau|^p h^{-d} + \big(\varkappa_1 + o(1)\big)|\tau|^q h^{1-d} \tag{11.7.72}$$

holds for $\tau \to -\infty$, $h = o\big(|\tau|^{\frac{1}{2\mu}(\mu+1)}\big)$ with the coefficient $\varkappa_1$ given by (11.5.68).

Theorem 11.7.20. *Let X be a bounded domain in $\mathbb{R}^d$, $0 \in \bar{X}$ and let conditions* (11.1.6)–(11.1.8) *be fulfilled with $\gamma = \epsilon|x|$, $\rho = |x|^{-1}\big(\big|\log|x|\big|+1\big)^{\nu}$, $\nu \le -d^{-1}$. Then*

(i) For $\nu < -(d-1)^{-1}$ asymptotics

$$\mathsf{N}^-(\tau,h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d} + O\big((\log|\tau|)^{\nu(d-1)+1} h^{1-d}\big) \tag{11.7.73}$$

holds for $\tau \to -\infty$, $h \to +0$.

(ii) For $\nu = -(d-1)^{-1}$ the asymptotics

$$\mathsf{N}^-(\tau,h) = \mathsf{N}^{\mathsf{W}}(\tau) h^{-d} + O\big(\log(\log|\tau| \cdot h^{-\nu^{-1}}) h^{1-d}\big) \tag{11.7.74}$$

holds for $\tau \to -\infty$, $h = o(\log^{\nu}|\tau|)$.

(iii) Furthermore, let $X \cap \{|x| \le r_0\} = X^0 \cap \{|x| \le r_0\}$ with $r_0 > 0$ and a non-empty open cone X^0 with $\partial X^0 \setminus 0 \in \mathscr{C}^K$. Let the functions g^{jk}, $V_j\big|\log|x|\big|^{-\nu}$, $V\big|\log|x|\big|^{-2\nu}$ satisfy stabilization conditions (11.5.4) *for $|x| \to 0$ with $\mu = -1$ and with functions g^{jk0}, V_j^0, V^0 positively homogeneous of degrees 0, -1, -2 respectively.*

Moreover, let the standard non-periodicity condition be fulfilled with the Hamiltonian

$$H^0(x,\xi) = |x|^2\Big(\sum_{j,k} g^{jk0}(\xi_j - V^0_j)(\xi_k - V^0_k) + V^0\Big) \tag{11.7.75}$$

on the energy level 0. *Then in the framework of Statement (i) asymptotics*

$$\mathsf{N}^-(\tau,h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + \big(\varkappa_1 + o(1)\big)(\log|\tau|)^{\nu(d-1)+1}h^{1-d} \tag{11.7.76}$$

holds for $\tau\to-\infty$, $h = o(\log^\nu|\tau|)$ *and in the framework of Statement (ii) asymptotics*

$$\mathsf{N}^-(\tau,h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + \big(\varkappa_1 + o(1)\big)\log(\log|\tau|\cdot h^{-\nu^{-1}})h^{1-d} \tag{11.7.77}$$

holds for $\tau\to-\infty$, $h = o(\log^\nu|\tau|)$.

(iv) Furthermore, for $\nu\in(-(d-1)^{-1},-d^{-1})$ *asymptotics*

$$\mathsf{N}^-(\tau,h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + O\big(h^{\nu^{-1}}\big) \tag{11.7.78}$$

holds for $\tau\to-\infty$, $h = o(\log^\nu|\tau|)$.

In all these asymptotics $\mathsf{N}^{\mathsf{W}}(\tau) = O(\log^{\nu d+1}|\tau|)$ *and* $\mathsf{N}^{\mathsf{W}}(\tau)\asymp\log^{\nu d+1}|\tau|$ *under condition* (11.7.66).

(v) Let $\nu = -d^{-1}$. *Furthermore, suppose that* <u>*either*</u> $d\ge 3$ <u>*or*</u> $0\in\partial X$ *and a Dirichlet condition is given on* ∂X. *Then asymptotics*

$$\mathsf{N}^-(\tau,h) = \big(\mathsf{N}^{\mathsf{W}}(\tau,h) + O(1)\big)h^{-d} \tag{11.7.79}$$

holds for $\tau\to-\infty$, $h = o(\log^\nu|\tau|)$ *and* $\mathsf{N}^{\mathsf{W}}(\tau,h)$ *is give by* (11.7.47), $\mathsf{N}^{\mathsf{W}}(\tau,h) = O\big(\log(\log|\tau|\cdot h^{\nu^{-1}})\big)$.

Moreover, under condition (11.7.66) $\mathsf{N}^{\mathsf{W}}(\tau,h)\asymp\log(\log|\tau|\cdot h^{\nu^{-1}})$.

Remark 11.7.21. In the proof of the last statement of this theorem we also use the arguments of Remark 11.1.13(i).

Theorem 11.7.22. *Let* $d\ge 3$, X *be a conical domain with* $\partial X\setminus 0\in\mathscr{C}^K$, *and let* $g^{jk} = g^{jk}(\theta)\in\mathscr{C}^K(\mathbb{S}^{d-1})$ *satisfy condition* (11.4.5). *Let* $V_j = 0$, $V = v(\theta)|\log r|$ *with* $v\in\mathscr{C}^K(\mathbb{S}^{d-1})$ *and* $\min_{\bar X} v = v_0 < 0$. *Then asymptotics*

$$\mathsf{N}^-(\tau,h) = \mathsf{N}^{\mathsf{W}}(\tau)h^{-d} + O\Big(h^{1-d}\tau\int_U \exp\big(-\tau(d-1)v^{-1}\big)\,d\theta\Big) \tag{11.7.80}$$

holds as $\tau \to -\infty$, $h \to +0$ *with*

$$\mathsf{N}^{\mathsf{W}}(\tau) = a \int_U \exp(-\tau dv^{-1}) \sqrt{g}\, d\theta \tag{11.7.81}$$

where $U = X \cap \mathbb{S}^{d-1}$ *and the coefficient* a *is introduced in Theorem 11.5.29. The orders of* $\mathsf{N}^{\mathsf{W}}(\tau)$ *and the remainder estimate and more accurate results are discussed in Statement (ii) of that theorem.*

11.8 Distributions of Spectra for Negative Order Operators

Let $A = A^{\mathsf{w}}(x, D)$ be a classical pseudodifferential operator of order $m < 0$ on a compact closed manifold X. We are interested in the asymptotics of the eigenvalue counting function

$$\mathsf{N}^{\pm}(\tau) = \#\{\lambda > \tau,\ \pm\lambda \text{ is an eigenvalue of } A\} \tag{11.8.1}$$

and

$$\mathsf{N}^{\pm}_{(\vartheta)}(\tau) = \int (\lambda - \tau)^{\vartheta}_{+} d_{\lambda} \mathsf{N}^{\pm}(\lambda) \tag{11.8.2}$$

as $\tau \to +0$. First of all, the following theorem holds:

Theorem 11.8.1. *(i) Let* $a(x, \xi)$ *be a microhyperbolic symbol on the energy level* 0 *(in a direction depending on the point). Then asymptotics*

$$\mathsf{N}^{\pm}(\tau) = \varkappa^{\pm} \tau^{\frac{d}{m}} + O\bigl(\tau^{\frac{d-1}{m}}\bigr) \tag{11.8.3}$$

holds as $\tau \to +0$ *with*

$$\varkappa^{\pm} = (2\pi)^{-d} \int \boldsymbol{n}^{\pm}(x, \xi; 1)\, dx d\xi \tag{11.8.4}$$

where $\boldsymbol{n}^{\pm}(x, \xi; \tau)$ *is an eigenvalue counting function for* $a(x, \xi)$ *i.e. the number of eigenvalues of the symbol* $\pm a(x, \xi)$ *greater than* τ *and* a *is the principal symbol of* A.

(ii) Moreover, asymptotics

$$\mathsf{N}^{\pm}_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W},\pm}_{(\vartheta)}(\tau) + O\bigl(R_{(\vartheta)}(\tau)\bigr) \tag{11.8.5}$$

holds with

$$\mathsf{N}^{\mathsf{W},\pm}_{(\vartheta)}(\tau) = \sum_k \varkappa^{\pm}_{\vartheta k} \tau^{\frac{d-k}{m}} \tag{11.8.6}$$

and

$$R_{(\vartheta)}(\tau) = \begin{cases} \tau^{\frac{1}{m}(d-1-\vartheta)+\vartheta} & \text{for } \vartheta(1-m) < d-1, \\ |\log \tau| & \text{for } \vartheta(1-m) = d-1, \\ 1 & \text{for } \vartheta(1-m) > d-1. \end{cases} \tag{11.8.7}$$

(iii) Further, let $\vartheta(1-m) < d-1$ *and let the standard non-periodicity condition be fulfilled for the Hamiltonian trajectories of the symbol* $\pm a$ *on the energy level* 1*. Then asymptotics*

$$\mathsf{N}^{\pm}(\tau) = \varkappa^{\pm}\tau^{\frac{d}{m}} + \bigl(\varkappa_1 + o(1)\bigr)\tau^{\frac{d-1}{m}} \tag{11.8.8}$$

and asymptotics

$$\mathsf{N}^{\pm}_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W},\pm}_{(\vartheta)}(\tau) + o\bigl(R_{(\vartheta)}(\tau)\bigr) \tag{11.8.9}$$

hold as $\tau \to +0$*.*

(iv) Furthermore, let $\vartheta(1-m) = d-1$ *and the standard non-periodicity condition be fulfilled for the Hamiltonian trajectories of the symbol* $\pm a$ *on the energy level* 0*. Then asymptotics* (11.8.9) *holds.*

(v) On the other hand, if the symbol $\pm a(x,\xi)$ *is negative-definite for every* (x,ξ) *(which under the microhyperbolicity condition means precisely that* $\varkappa^{\pm} = 0$*) then*

$$\mathsf{N}^{\pm}(\tau) = O(1). \tag{11.8.10}$$

Proof. We leave all the details of the proof to the reader and indicate only the rescaling which should be applied in this proof: namely, we apply the rescaling $(\epsilon, \epsilon r)$ with respect to (x,ξ) where $r = |\xi|$ and $h_{\mathsf{eff}} = r + |\tau|^{\frac{1}{m}}$ afterwards. □

Remark 11.8.2. Asymptotics (11.8.3) and (11.8.5) are standard results under ellipticity condition

$$|a(x,\xi)v| \ge \epsilon_0 |v| \cdot |\xi|^m \qquad \forall (x,\xi) \quad \forall v \in \mathbb{H} \tag{11.8.11}$$

and asymptotics (11.8.8) and (11.8.9) for $\vartheta(1-m) < d-1$ under this condition and non-periodicity condition on the energy level 1.

Let us get rid of the microhyperbolicity condition. In the general case we can do nothing better than introduce the rescaling

$$(x_1, x', \xi_1, \xi') \mapsto (\zeta^{-2}x_1, \zeta^{-1}x', r^{-1}\xi_1, \zeta^{-1}r^{-1}\xi') \qquad \text{with} \quad r \asymp |\xi| \tag{11.8.12}$$

where the coordinate system is taken such that $\xi' = 0$ at some point of the element of the partition and

$$\zeta = \min_j(|\alpha_j| + \tau r^{-m} + r^{-\frac{1}{2}}) \qquad \text{for} \quad \tau \le Cr^m \tag{11.8.13}$$

and $\alpha_j = \alpha_j(x, \xi)$ are eigenvalues of $a(x, \xi|\xi|^{-1})$. Further

(11.8.14) Here and below we set $\zeta = 1$ for $\tau \ge r^m$.

Then $h_{\text{eff}} = r^{-1}\zeta^{-2}$ and the contribution of the zone $\{(x, \xi) : \ h_{\text{eff}} \ge 1\}$ to the asymptotics does not exceed $CR'_{(\vartheta)}$ with

$$R'_{(\vartheta)} = \begin{cases} \tau^{l+\vartheta} & \text{for } \vartheta < -l, \\ |\log \tau| & \text{for } \vartheta = -l, \\ 1 & \text{for } \vartheta > -l, \end{cases} \qquad l = -\frac{2d}{1-2m}. \tag{11.8.15}$$

Then one can easily obtain the following

Theorem 11.8.3. *(i) In the general case the following asymptotics holds:*

$$\mathsf{N}^{\pm}_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W},\pm}_{(\vartheta)}(\tau) + O\big(R_{(\vartheta)}(\tau) + R'_{(\vartheta)}(\tau)\big) \tag{11.8.16}$$

where $R_{(\vartheta)}$ and $R'_{(\vartheta)}$ are defined by (11.8.7) *and* (11.8.16) *respectively.*

(ii) Moreover, suppose that $\vartheta < \big(d(1-2m)^{-1} - 1\big)$ [62] *and let the standard non-periodicity condition be fulfilled for the Hamiltonian trajectories of the symbol $\pm a$ on the energy level 1. Then asymptotics* (11.8.8) *and* (11.8.9) *hold.*

(iii) On the other hand, if the symbol $\pm a(x, \xi)$ is non-positive definite for every $(x, \xi)(\Leftrightarrow \varkappa^{\pm} = 0)$ then estimate

$$\mathsf{N}^{\pm}(\tau) = O(\tau^l) \tag{11.8.17}$$

holds.

[62] Which implies that $d > 1 - 2m$ and $\vartheta(1-m) < (d-1)$ i.e. $R_{(\vartheta)} \gg R'_{(\vartheta)}$.

To improve results of Theorem 11.8.3 let us assume that

$$|D^{\alpha}_{(x,\xi)}a(x,\xi)| \le c\gamma^{\mu-|\alpha|} \qquad \forall \alpha : |\alpha| \le \mu \quad \forall (x,\xi) : |\xi| = 1, \tag{11.8.18}$$

$$|a(x,\xi)v| \ge \epsilon_0 \gamma^{\mu}|v| \quad \forall v \in \mathbb{H} \quad \forall (x,\xi) : |\xi| = 1, \tag{11.8.19}$$

where $\gamma(x,\xi) = \mathsf{dist}\big((x,\xi),\Lambda\big)$ and Λ is the union of a finite number of $\mathscr{C}^K$ manifolds of codimension $\ge p$. Then one can make rescalings

$$(x,\xi) \mapsto (\zeta^{-1}x, \zeta^{-1}r^{-1}\xi) \tag{11.8.20}$$

with

$$\zeta = \epsilon\big(\gamma + \tau^{\frac{1}{\mu}} r^{-\frac{m}{\mu}} + r^{-\frac{1}{2}}\big) \tag{11.8.21}$$

and obtain

Theorem 11.8.4. *Under assumptions* (11.8.18)–(11.8.19) *Statements (i)–(ii) of Theorem 11.8.3 hold with* $R'_{(\vartheta)}$ *defined by* (11.8.15) *but this time with* $l = -(2d-p)(\mu-2m)^{-1}$.

Let us now treat the scalar case. First of all, for $\vartheta > 0$ one can apply exactly the construction of the proof of Theorem 11.8.1 (no microhyperbolicity-type condition is necessary at all). On the other hand, for $\vartheta = 0$ one can apply rescaling (11.8.20) with

$$\zeta = \epsilon\Big(\sum_{|\alpha|<M} |D^{\alpha}a|^{\frac{M}{M-|\alpha|}} + |\tau r^{-m}|\Big)^{\frac{1}{M}} + \epsilon r^{-\frac{1}{2}} \tag{11.8.22}$$

with $M = 2$. Then microhyperbolicity is fulfilled for $h_{\mathsf{eff}} \le h_0$. After calculations one gets the remainder estimate $O\big(\tau^{\frac{d-1}{m}} + \tau^{l}\big)$ where this time $l = -d(1-m)^{-1}$ which is good for $m < (1-d)$.

On the other hand, taking arbitrarily large M one can refer to the weakest possible non-degeneracy condition (5.2.126) and after easy calculations get the remainder estimate $O\big(\tau^{\frac{1}{m}(d-1+\delta)}\big)$ with arbitrarily small $\delta > 0$. Therefore the following statement holds:

Theorem 11.8.5. *Let A be a scalar operator. Then*

(i) For $\vartheta = 0$ asymptotics (11.8.3) *hold if $m \le (1-d)$; further, asymptotics*

$$\mathsf{N}^{\pm}(\tau) = \varkappa^{\pm}\tau^{\frac{d}{m}} + O\big(\tau^{\frac{1}{m}(d-1+\delta)}\big) \tag{11.8.23}$$

holds with arbitrarily small exponent $\delta > 0$ if $m > (1-d)$.

(ii) For $\vartheta > 0$ *asymptotics* (11.8.5) *holds.*

(iii) Suppose that either $\vartheta > 0$ *or* $m \le (1-d)$ *and and that the standard non-periodicity condition is fulfilled for the Hamiltonian trajectories of the symbol* $\pm a$ *on the energy level* 1*. Then asymptotics* (11.8.8), (11.8.9) *hold.*

Comments

While some of the results in the simplest situations were established by different authors, all the results of Sections 11.1–11.7 were proven as the corollaries of the general theorems of Chapter 9 by the author during 1985–1986.

Results of Section 11.8 are brand new.

Chapter 12

Miscellaneous Asymptotics of Spectra

12.1 Introduction

In this chapter we apply the results and methods of the previous chapters in order to derive eigenvalue asymptotics for the miscellaneous problems, mostly to extend the results of the previous Chapter 11 to the cases when these results in their original forms are no longer valid.

In Section 12.2 we treat operators in the domains with the "thick" cusps. Let us recall that if the cusp is not thin enough then asymptotics

$$\mathsf{N}^{-}(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\bigl(\tau^{(d-1)l}\bigr) \tag{12.1.1}$$

(with $l = 1/(2m)$ where $2m$ is an order of operator) no longer follows from the results of Sections 11.2 and 11.3 and if the cusp is even thicker then even estimate

$$\mathsf{N}^{-}(\tau) = O\bigl(\tau^{dl}\bigr) \tag{12.1.2}$$

no more follows from these results. It occurs that these asymptotics and estimates are no longer valid and should be replaced by asymptotics either containing non-Weyl correction term or even having non-Weyl principal part.

Similarly, in Section 12.3 we consider operators in $\mathbb{R}^d$ with potentials growing at infinity as $|x|^{2m\mu}$ but degenerate in some directions (such as the Schrödinger operator with a positively homogeneous of degree 2μ potential

$V_\infty \ge 0$, which vanishes on some manifold Θ). We proved in Section 11.5 asymptotics (12.1.1) with $I = (\mu+1)/(2m\mu)$ assuming that the degeneration is "mild" i.e. neither it is too strong nor $\dim \Theta$ is too large or, in other words, that the *valley* $\{x : V(x) \le \tau\}$ has only thin cusps for any fixed $\tau > 0$. If the degeneration is stronger then this asymptotics no longer follows from the results of Section 11.5 and if the degeneration is even stronger then even estimate (12.1.2) no more follows from these results.

Again it occurs that these asymptotics are no longer valid and should be replaced by asymptotics either containing non-Weyl correction term or even having non-Weyl principal part.

Further, in Section 12.4 we consider operators in $\mathbb{R}^d$ with potentials decaying at infinity slowly enough (as $|x|^{2m\mu}$ with $\mu \in (-1, 0)$) and consider asymptotics of $\mathsf{N}^-(\tau)$ as $\tau \to -\infty$. However these potentials are falling to $-\infty$ along some manifold Θ. We proved in Section 11.6 asymptotics (12.1.1) with $I = (\mu + 1)/(2m\mu)$ assuming that the singularity is "mild" i.e. neither it is too strong nor $\dim \Theta$ is too large or, in other words, that the *gorge* $\{x : V(x) \le \tau\}$ has only thin cusps for any fixed $\tau < 0$. If the singularity is stronger then this asymptotics no longer follows from the results of Section 11.5 and if the singularity is even stronger then even estimate (12.1.2) no more follows from these results.

Again it occurs that these asymptotics are no longer valid and should be replaced by asymptotics either containing non-Weyl correction term or even having non-Weyl principal part.

Furthermore, Section 12.5 is devoted to maximally hypoelliptic operators with symplectic degeneration manifold Λ. In this case we derived no similar results in Chapter 11 but one can prove easily that if degeneration is mild then asymptotics (12.1.1) holds (with $I = 1/(2m)$) as if operator was elliptic; if degeneration is not that mild then this asymptotics holds with worse remainder estimate and if degeneration is even more severe then even estimate (12.1.2) is no longer valid. So, in Section 12.5 we derive correct asymptotics in the latter cases; again these asymptotics contain non-Weyl correction term or even non-Weyl principal part.

Moreover, Section 12.6 is devoted to asymptotics of Riesz means for operators with singularities at separate points: it may be conical singularities of the metrics and domain and weak singularities of lower order terms. Then while (12.1.1) with $I = 1/(2m)$ holds, asymptotics

$$\mathsf{N}^-_{(\vartheta)}(\tau) = \mathsf{N}^{\mathsf{W}}_{(\vartheta)}(\tau) + O\bigl(\tau^{(d-1-\vartheta)I+\vartheta}\bigr) \tag{12.1.3}$$

fails for $\theta \ge \bar{\vartheta}_1$ and for even larger ϑ even estimate $\mathsf{N}^-_{(\vartheta)}(\tau) = O\bigl(\tau^{d\ell+\vartheta}\bigr)$ is no longer valid and again our goal is to derive correct asymptotics.

Further, in Section 12.7 we consider Neumann Laplacian in domain with cusps (and its certain generalizations). Then we need to assume that the cusps are really very thin: with the width decaying as $\exp(-|x|^\nu)$ with $\nu > 1$; otherwise essential spectrum appears. Still, only as $\nu > \bar{\nu}_1$ we derive asymptotics (12.1.1) and only as $\nu > \bar{\nu}_0$ estimate (12.1.2) is valid; our goal here again is to derive correct asymptotics.

Finally, in Section 12.8 we consider operator $A_t = A - tW$ where A is a periodic operator, W is a potential decaying at infinity. It is known that the spectrum of A consists of *spectral bands* (of essential, usually continuous) spectrum separated by *spectral gaps* (containing no spectrum of A). As $t \ne 0$ the essential spectrum of A_t coincide with one of A but discrete eigenvalues may appear inside spectral gaps. We fix a point E either inside the spectral gap or on its boundary and consider $\mathsf{N}_E(\tau)$ the number of eigenvalues of A_t crossing E as t grows from 0 to τ [1)] and consider asymptotics of $\mathsf{N}_E(\tau)$ as $\tau \to +\infty$.

We consider also the "lite" version of this theory: when A is not a periodic but operator with the constant coefficients.

All these problems have certain common features:

(a) We do not apply the results of Chapters 9 and 10;

(b) The asymptotics either contain non-Weyl terms or are completely non-Weyl (otherwise they would follow from the results of Chapters 9 and 10); however it is not necessarily true for Sections 12.5, 12.7 and 12.8.

(c) Most of the problems in question differ from problems which can be treated by means of results of Chapters 9 and 10 by some parameters (exponents, dimensions, orders of singularity, of degeneration, of Riesz means, etc.).

(d) In some sections we apply the theory of Chapters 2 and 4 for operators with the operator-valued symbols: namely, in Section 12.2 let $x' \in Z$ be the base of the cusp and $x'' \in \sigma(x')Y$ be the shape of the cross-section of the cusp respectively and let $d' = \dim Z$, $d'' = \dim Y$. After a coordinate

[1)] With eigenvalues crossing while increasing counted with the sign "+" and with eigenvalues crossing while decreasing counted with the sign "−".

transform $x'' \mapsto x''\sigma(x')^{-1}$ we obtain a cylindrical cusp $Z \times Y$ and treat operator $\boldsymbol{A}(x', D') = \boldsymbol{A}(x', D'; x'', D'')$ given on the base of the cusp for which the auxiliary Hilbert space is $\mathscr{L}^2(Y)$.

Under appropriate assumptions this is a perturbed operator

$$a(x', D', x'', \sigma^{-1}(x')D'') = \sigma^{-2m}(x')a^0(x', \sigma(x')D', x'', D'') \tag{12.1.4}$$

and it satisfies non-degeneracy condition on the energy level τ; here a is the principal symbol of A. In particular, as $A = \Delta' + \Delta''$ this unperturbed operator is $\Delta' + \sigma^{-2}(x')\Delta''$ and if we deal with unperturbed operator we can decompose it into the direct sum of operators $A_k = \Delta' + \sigma^{-2}(x')\lambda_k$ where $\lambda_1 \le \lambda_2 \le \dots$ are eigenvalues of Δ'' (under inherited boundary conditions; we assume that those are Dirichlet conditions albeit one can consider more general boundary conditions as well).

As $\lambda_1 > 0$ all these operators are d'-dimensional Schrödinger operators and their asymptotics are given by Weyl formula with

$$\mathsf{N}^{\mathsf{W}}_k(\tau) = O\bigl(\tau^{d'l}\lambda_k^{-d'/(2m)}\bigr) \tag{12.1.5}$$

and with the remaining estimate

$$R^{\mathsf{W}}_k(\tau) = O\bigl(\tau^{(d'-1)l}\lambda_k^{-(d'-1)/(2m)}\bigr) \tag{12.1.6}$$

where $l = (\mu+1)/(2m\mu)$ as $\sigma(x') \asymp |x'|^{-\mu}$.

Now we need to sum all the main parts and we arrive to asymptotics with the principal part either $\asymp \tau^{d/(2m)}$ or $\asymp \tau^{d'l}$ whatever is greater but as degrees are equal we get principal part of magnitude $\asymp \tau^{d'l}|\log\tau|$.

Similarly, we need to sum all the remainder estimates and we arrive to $O(\tau^{(d-1)/(2m)})$ or $O(\tau^{d'l})$ whatever is greater but as degrees are equal we get the remainder $O(\tau^{(d'-1)l}|\log\tau|$.

Thus in Section 12.2 we extend this result to the case when operator in question does not decompose into direct sum and to the higher order operators. The main issue here is not only to express the principal part of the asymptotics (possibly containing more than one term) but also simplify it if possible invoking eigenvalue counting function $\boldsymbol{n}_\infty(\tau)$ of one axillary operator rather than the family $\boldsymbol{n}(x', \xi; \tau)$.

The similar approach works in Section 12.3 where in the case of the Schrödinger operator with potential $V(x)$, non-negative and positively homogeneous of degree $2\mu > 0$, x' are coordinates on $Z = \{x : V(x) = 0\}$

and x'' are coordinates in $Z^{\perp}$. Similarly in Section 12.4 in the case of the Schrödinger operator with potential $V(x)$, positively homogeneous of degree $2\mu \in (-2,0)$, x' are coordinates on $Z = \{x : V(x) = -\infty\}$ and x'' are coordinates in $Z^{\perp}$.

In Section 12.5 we consider pseudodifferential operators with the phase space Λ and with auxiliary Hilbert space $\mathscr{L}^2(\mathbb{R}^{d''})$ with $d'' = \frac{1}{2}\operatorname{codim}\Lambda$.

In Sections 12.2–12.5 there are zones where we apply the standard Weyl asymptotics of Part II, zones where we can obtain the same asymptotics with improved remainder estimates (these enhancements are due to results on the propagation of singularities for operators with the operator-valued symbols and zones where results of Chapter 4 are applicable; the second and third zones are overlapping, and one can combine the asymptotics obtained.

In Section 12.6, instead of operators with the operator-valued symbols we treat model operators with positively quasihomogeneous symbols; for these operators

$$\int \Big(e_{(\vartheta)}(x,x,0) - e^{\mathsf{W}}_{(\vartheta)}(x,x,0)\Big)\,dx = \varkappa h^{-\kappa} \tag{12.1.7}$$

converges as $\vartheta > \bar{\vartheta}$ and the equality is due to quasihomogeneity; here $e(.,.,\tau)$ is the Schwartz kernel of the spectral projector, $e^{\mathsf{W}}(.,.,\tau)$ is its Weyl approximation, and $_{(\vartheta)}$ means a Riesz mean of order ϑ with respect to τ; the right-hand expression is *Scott correction term*. We consider also similar expressions with homogeneous factor in the integral and basically result is the same albeit in some cases we need to include cut-off in the left-hand expression and the right-hand expression becomes $(\varkappa|\log h| + \varkappa_1)h^{-\kappa}$. We cannot represent the left-hand expression in (12.1.7) as the difference as both integrals diverge at infinity.

We apply then Weyl method to the difference of the spectral functions of the original and the model operators and derive sharp asymptotics for $\int e_{(\vartheta)}(x,x,0)\psi(x)\,dx$ with a fixed supported near 0 function $\psi \in \mathscr{C}_0^{\infty}$; this asymptotics contains Weyl part and one or more Scott correction terms (which could be actually larger than the Weyl part).

Section 12.7 starts as Section 12.2, but $0 = \lambda_1 < \lambda_2$ (in more general situations $0 = \lambda_1 = ... = \lambda_k < \lambda_{k+1}$ and spectrum seems to become essential; however when we change variables $x'' \mapsto \sigma^{-1}(x')x''$ we get a weighted $\mathscr{L}^2$-space $\mathscr{L}^2(Z, \mathscr{L}^2(Y), \sigma^d(x')dx')$; considering quadratic form and substituting $u = \sigma^{-d/2}v$ we obtain operator in the standard $\mathscr{L}^2(Z, \mathscr{L}^2(Y))$-space and

this operator acquires an extra potential

$$V \sim \frac{d^2}{4} \sum_{j,k} g^{jk} (\partial_j \log \sigma)(\partial_k \log \sigma); \tag{12.1.8}$$

this potential grows at infinity as $|\nabla \log \sigma|^2 \asymp |x|^{2\mu}$ provided σ behaves like $\exp(-|x'|^\nu)$ with $\nu = \mu + 1$. Then the results similar to those of Section 12.2 are derived but since the Schrödinger operator corresponding to $\lambda_j = 0$ is so different from all others (which now have potentials with superexponential growth) logarithmic factor does not appear as two degrees collide.

In Section 12.8 we consider operator $A - tW$ where A is periodic operator and W is a decaying potential, and count eigenvalues crossing E which belongs either to spectral gap or its border. In this case we use Gelfand decomposition so A becomes $A(\xi)$ operator acting on $\mathscr{L}^2(\mathcal{Q})$ where $\mathcal{Q}$ is an elementary cell corresponding to periods lattice and $\xi \in \mathcal{Q}'$ is a quasimomentum where $\mathcal{Q}'$ is a dual cell. Meanwhile W becomes a negative order pseudodifferential operator with respect to ξ and we again apply the theory of operators with the operator-valued symbols. However in contrast to what we had before, dimension does not decrease.

12.2 Operators in Domains with Thick Cusps

12.2.1 Problem Set-up

Let us consider a uniformly elliptic operator of order $2m$

$$A = A^{\mathrm{w}}(x, D), \qquad A(x, \xi) = \sum_{|\alpha| \le 2m} a_\alpha(x) \xi^\alpha \tag{12.2.1}$$

where

(12.2.2) $a_\alpha(x)$ are Hermitian $\mathsf{D} \times \mathsf{D}-$matrix valued functions such that

$$|D^\beta a_\alpha| \le c \langle x \rangle^{-|\beta'| + \mu(2m - |\alpha|)} \tag{12.2.3}$$

$$\forall \alpha : |\alpha| \le 2m \, \forall \beta : |\beta| \le K, \beta'' = 0,$$

$$D^{\beta}a_{\alpha} = o\big(|x'|^{-|\beta'|+\mu(2m-|\alpha|+|\beta''|)}\big) \qquad \text{as} \quad |x'|\to\infty \tag{12.2.4}$$
$$\forall \alpha : |\alpha| \le 2m \ \forall \beta : |\beta| \le K, 2m-|\alpha|+|\beta''|>0,$$

$$\langle a(x,\xi)v, v\rangle \ge \epsilon |v|^2 \qquad \forall v \quad \forall (x,\xi) \tag{12.2.5}$$

where

$$a(x,\xi) = \sum_{|\alpha|=2m} a_{\alpha}(x)\xi^{\alpha} \tag{12.2.6}$$

is the principal symbol of A.

We consider this operator in the domain $X \subset \mathbb{R}^d$ such that

$$X = X_0 \cup X_{\mathsf{cusp}},\ \partial X \in \mathscr{C}^K,\ X_0 \Subset \mathbb{R}^d, \tag{12.2.7}$$
$$X_{\mathsf{cusp}} = \big\{x=(x',x'') : x'\in Z,\ x''\in \sigma(x')Y\big\}, \quad Y \Subset \mathbb{R}^{d''},\ \partial Y \in \mathscr{C}^K$$

with

$$\sigma(x') \asymp \langle x'\rangle^{-\mu}\ \mu>0, \tag{12.2.8}$$

$$|D^{\beta'}\sigma| \le c\langle x'\rangle^{-\mu-|\beta'|} \quad \forall \beta' : |\beta'|\le K \tag{12.2.9}$$

and

(12.2.10) Either $Z=\mathbb{R}^{d'}$ as $d'\ge 1$ or $Z=\mathbb{R}^{\pm}$ as $d'=1$ [2)].

Definition 12.2.1. We say that X_0 is the *compact part* of X, X_{cusp} is the *cusp*, Z and Y are the *cusp base and cusp cross-section* respectively and σ is the *cusp form defining function*.

Let us assume that

(12.2.11) A Dirichlet boundary condition (of order m) is given on ∂X.

One can prove easily that

(12.2.12) Under these conditions (12.2.1)–(12.2.11) A is a self-adjoint operator in $\mathscr{L}^2(X,\mathbb{H})$, $\mathbb{H}=\mathbb{C}^{\mathsf{D}}$ and has a compact resolvent.

[2)] Analysis of more general cusps will be formulated as Problem 12.2.23.

Moreover, the following statement follows from the results of Sections 11.2 and 11.3:

Theorem 12.2.2. *Let conditions* (12.2.1)–(12.2.11) *be fulfilled. Then*

(i) As $\sigma^{d''-1} \in \mathscr{L}^2(Z)$ *which is equivalent to*

$$\mu > \mu_1 := d'(d''-1)^{-1}, \qquad \mu_0 := d'd''^{-1} \tag{12.2.13}$$

then Weyl asymptotics

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O(\tau^{\frac{1}{2m}(d-1)}) \tag{12.2.14}$$

holds as $\tau \to \infty$ *with*

$$\mathsf{N}^{\mathsf{W}}(\tau) \asymp \tau^{\frac{d}{2m}}. \tag{12.2.15}$$

Here $\mathsf{N}^{\mathsf{W}}(\tau)$ *is given by the standard Weyl formula, and moreover, one can replace it here by* $\kappa_0\tau^{\frac{d}{2m}}$ *where* κ_0 *and* κ_1 *are standard coefficients which are finite for* $\mu > \mu_0$, $\mu > \mu_1$ *respectively.*

(ii) Moreover, under the standard non-periodicity condition to the generalized Hamiltonian flow of $\mathsf{a}(x,\xi)$ *with reflections at* ∂X *(and perhaps with branching at the points of reflection for* $m \ge 2$*) asymptotics*

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + \kappa_1\tau^{\frac{1}{2m}(d-1)} + o\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr) \tag{12.2.16}$$

holds as $\tau \to \infty$.

(iii) For $\mu = \mu_1$ *asymptotics*

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\bigl(\tau^{\frac{1}{2m}(d-1)}\log\tau\bigr) \tag{12.2.17}$$

holds as $\tau \to \infty$ *and for* $\mu \in [\mu_0, \mu_1)$ *asymptotics*

$$\mathsf{N}^-(\tau) = \mathsf{N}^{\mathsf{W}}(\tau) + O\bigl(\tau^{\frac{1}{2m}(d-q)}\bigr) \tag{12.2.18}$$

holds as $\tau \to \infty$ *with* $q = d'\mu^{-1} + d'' \in [0,1)$*; here* $q = 0 \iff \mu = \mu_0$, $q = 1 \iff \mu = \mu_1$, *and for* $\mu > \mu_0$ (12.2.15) *holds. Further, for* $\mu = \mu_0$

$$\mathsf{N}^{\mathsf{W}}(\tau) \asymp \tau^{\frac{d}{2m}}\log\tau \tag{12.2.19}$$

is given by cut Weyl formula and one can replace it by $\kappa_0^*\tau^{d/2m}\log\tau$.

Remark 12.2.3. (i) Surely, our conditions here are more restrictive than necessary but the case $\mu > \mu_1$ is not our goal here. Our goal is to treat the case $\mu \le \mu_1$ and to derive asymptotics with better remainder estimates. Namely, we obtain asymptotics with the remainder estimate $O\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$ and even $o\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$ under the standard non-periodicity condition for $d'=1$ and for $d'\ge 2$, $\mu > \mu^*$ with $\mu^* < \mu_1$; otherwise we obtain asymptotics with a worse remainder estimate.

Surely, one should replace $\mathsf{N}^{\mathsf{W}}(\tau)$ by another expression and some additional conditions appear.

(ii) For Riesz means the crucial values in the Weyl asymptotics are

$$\mu_{\vartheta+1} = d'(d''-\vartheta-1)^{-1} \tag{12.2.13$'$}$$

and μ_0 respectively: namely, for $\mu > \mu_{\vartheta+1}$ we get the remainder estimate $O\bigl(\tau^{\frac{1}{2m}(d-\vartheta-1)+\vartheta}\bigr)$ or even "o" instead of "O" under the standard non-periodicity condition. Further, for $\mu = \mu_{\vartheta+1}$ the remainder estimate is $O\bigl(\tau^{\frac{1}{2m}(d-\vartheta-1)+\vartheta}\log\tau\bigr)$ and for $\mu_0 < \mu < \mu_{\vartheta+1}$ it is $O\bigl(\tau^{\frac{d'(\mu+1)}{2m\mu}+\vartheta}\bigr)$.

One can easily see that this exponent lies in $\bigl(\frac{1}{2m}(d-\vartheta-1)+\vartheta, \frac{d}{2m}+\vartheta\bigr)$. At the same time the principal Weyl part is of order $\tau^{\frac{d}{2m}+\vartheta}$ and $\tau^{\frac{d}{2m}+\vartheta}\log\tau$ for $\mu > \mu_0$ and $\mu = \mu_0$ respectively.

12.2.2 Sharp Asymptotics

Standard Remainder Estimate

First of all let us divide $\mathsf{N}^-(\tau)$ into the sum

$$\mathsf{N}^-(\tau) = \mathsf{N}_0^-(\tau) + \mathsf{N}_{\mathsf{cusp}}^-(\tau) \tag{12.2.20}$$

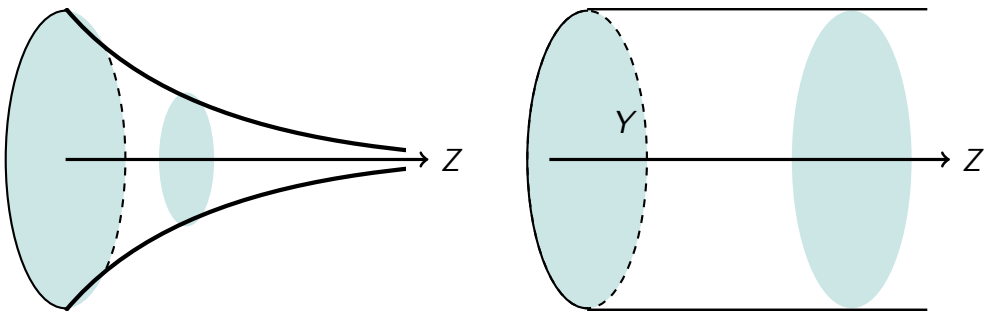
where

$$\mathsf{N}_\bullet^-(\tau) = \int \psi_\bullet(x')\,\mathsf{tr}\bigl(e(x,x,\tau)\bigr)\,dx, \tag{12.2.21}$$

$e(x,y,\tau)$ is the Schwartz kernel of the spectral projector of A and $\psi_0, \psi_{\mathsf{cusp}} \in \mathscr{C}^K$ are supported in $\{|x'|\le 3c\}$, $\{|x'|\ge 2c\}$ respectively, $\psi_0+\psi_{\mathsf{cusp}}=1$. We assume that $X_0 \subset \{|x'|\le \frac{3}{2}c\}$.

Then

(12.2.22) Weyl asymptotics holds for $\mathsf{N}_0^-(\tau)$ with the proper remainder estimate $O\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$ (and even $o\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$ under the standard non-periodicity condition to the Hamiltonian billiards).



(a) Cusp (b) Cylinder

Figure 12.1: Cusp transforms to a cylinder

So we need to derive asymptotics of $\mathsf{N}^-_{\mathsf{cusp}}(\tau)$. Let us introduce the coordinates (x', x'') with $x''_{\mathsf{new}} = \sigma(x')^{-1}x''$. In these coordinates cusp X_1 transforms to the cylinder $Z \times Y$ and the differential expression A transforms to a differential expression which is symmetric with weight $\sigma(x')^{d''}$ provided our test functions vanish for $|x'| \le \frac{1}{3}c$. In order to get rid of this weight we multiply the differential expression by $\sigma(x')^{\frac{1}{2}d''}$ and $\sigma(x')^{-\frac{1}{2}d''}$ on the left and right respectively, obtaining

$$\tilde{A} = \tilde{A}^{\mathsf{w}}(x, D), \quad \tilde{A}(x,\xi) = \sum_{|\alpha|\le 2m} a_\alpha (\xi' - b'\beta)^{\alpha'} \xi''^{\alpha''} \sigma(x')^{-|\alpha''|}, \tag{12.2.23}$$

$$b_k = \partial_k(\log\sigma) \quad k = 1, \dots, d', \qquad \beta = \langle x'', \xi''\rangle$$

in the coordinates $x = (x', x'')$. We treat this operator as an operator in $\mathscr{L}^2(Z, \mathbb{H})$ with $\mathbb{H} = \mathscr{L}^2(Y, \mathbb{H})$. Surely, we cannot discuss self-adjointness now because we cannot guarantee that our functions vanish for $|x'| \le \frac{5}{3}c$.

Recall that we are interested in the spectral projector $E(\tau)$ of A corresponding to the spectral parameter τ. Let us consider the $\gamma(\bar{x}')$-neighborhood of the point $\bar{x}'$ with $\gamma(x') = \frac{1}{2}|x'|$ where we always assume that $|\bar{x}'| \ge c_1$ with a large enough constant c_1. Let us rescale $x' \mapsto (x' - \bar{x}')\bar{\gamma}^{-1}$ and the make a corresponding multiplication.

Let us first treat case of $\bar{\sigma} \le \epsilon\tau^{-\frac{1}{2m}}$ (i.e., $|x'| \ge \epsilon_1^{-1}\tau^{\frac{1}{2\mu m}}$) where here and below $\epsilon_j > 0$ are sufficiently small and $\bar{f} = f(\bar{x}')$ for any function f. Multiplying operator A by $\bar{\sigma}^{2m}$ after rescaling we obtain an h-differential operator with $h = \bar{\sigma}\bar{\gamma}^{-1} < 1$; we are interested in the operator's spectral projector corresponding to the spectral parameter $\tau' = \tau\bar{\sigma}^{2m} < \epsilon_2$.

One can easily see that this operator $\boldsymbol{A}(x', D'; x'', D'')$ considered as operator with the operator-valued symbol $\boldsymbol{A}(x', \xi'; x'', D'')$ is of the type considered in Chapter 4 provided

(12.2.24) $B = (L_{(m)\mathsf{D}})$, $B_1 = (L_{(M)\mathsf{N}})^{mM^{-1}}$ where $L_M = (\Delta'' + I)^M$ and the subscripts "D" and "N" mean m-th order Dirichlet and Neumann boundary conditions respectively (of the proper order), Δ'' is the positive Laplacian in Y and M is taken large in order to obtain large $I = I(M)$ [3].

Then for $j \in [0, I]$ we see that $\mathbb{H}_j = \mathfrak{D}(B_1^j) = \mathscr{H}^{2mj}(Y)$ are Sobolev spaces and for $j \in [-I, 0]$ $\mathbb{H}_j = B_1^{-j}(\mathbb{H})$ are the spaces dual to $\mathscr{H}^{-2mj}(Y)$.

In particular, one can easily check that conditions (4.2.7), $(4.2.8)_I$, $(4.2.13)_{\frac{1}{2}}$ (i.e. $(4.2.13)_I$ with $I = \frac{1}{2}$), $(4.2.14)_+$, (4.2.15), (4.2.17) and (4.2.21) are fulfilled.

Further, we see that

(12.2.25) Operator $\boldsymbol{A}(x', D'; x'', D'')$ [4] is elliptic on the energy level s $\le \epsilon_2$.

---

[3] See Chapter 4 for B, B_1 and I.

[4] Considered as an operator with the operator-valued symbol.

One can check this easily by dropping lower order terms (with $|\alpha| < 2m$) in $\tilde{A}$ and assuming that D'' and a_α commute and the energy level is non-positive. This procedure is justified by condition (12.2.4) and the appropriate choice of $\epsilon_2 > 0$.

Furthermore, since A is a self-adjoint operator, $\|\exp(itA)\| = 1$ and $\|E(\tau)\| \le 1$. On the other hand, $\exp(itA)$ and $E(\tau)$ generate operator-valued operators in $B\bigl(\bar{x}', \gamma(\bar{x}')\bigr)$ via their Schwartz kernels and one can apply the theory of Chapter 4 (namely, Propositions 4.2.8–4.2.10). This trick permits us to avoid the discussion of the self-adjointness of $\tilde{A}$, etc.

Proposition 12.2.4. *Let conditions* (12.2.1)–(12.2.11) *be fulfilled and let* c_0 *be large enough. Then*

(i) Estimate

$$|e(x,y,\tau)| \le C'_s \langle x'\rangle^{-s}\langle y'\rangle^{-s} \qquad \forall \tau \ge 1 \quad \forall x, y \in X : |x'| + |y'| \ge c_0 \tau^{\frac{1}{2\mu m}} \tag{12.2.26}$$

holds.

(ii) Contribution of the far cusp zone $\{|x'| \ge c_0 \tau^{1/2m\mu}\}$ *to the asymptotics is* $O(\tau^{-s})$.

Proof. Then the results of Chapter 4 immediately yield that

$$\|B_1^j e(x,y,\tau) B_1^k\| \le C'_{jks} \langle x'\rangle^{-s}\langle y'\rangle^{-s} \qquad \forall j,k \le I \ \forall s \tag{12.2.27}$$

where the norm in the left-hand expression is the operator norm in $\mathbb{H}$ and therefore as $I = I(d)$ (and thus $K = K(d)$) we arrive to estimate (12.2.26) thus proving Statement (i).

Statement (ii) follows from Statement (i) immediately. □

Let us now treat the *main cusp zone*

$$\bigl\{c_0 \le |x'| \le \bar{\gamma}(\tau) := c_0 \tau^{\frac{1}{2m\mu}}\bigr\}. \tag{12.2.28}$$

Here we should multiply the operator by τ^{-1} and so we should consider the operator $\tau^{-1}A$ on the energy level 1. One can easily check that we are again in the framework of Chapter 4 with $h = \tau^{-\frac{1}{2m}}\bar{\gamma}^{-1}$ and

$$B = \tau^{-1}\bar{\sigma}^{-2m}\bigl(L_{(M)\mathsf{D}}\bigr)^{mM^{-1}} + I, \quad B_1 = \tau^{-1}\bar{\sigma}^{-2m}\bigl(L_{(M)\mathsf{N}}\bigr)^{mM^{-1}} + I \tag{12.2.29}$$

with the previous definition of $L_{(M)\mathsf{D}}$ and $L_{(M)\mathsf{N}}$.

One can easily check that this operator $\boldsymbol{A}(x', D'; x'', D'')$ [4)] is elliptic on the energy levels ≤ 1 for $|\xi'| \ge C_0$.

Moreover, one can easily check that this operator[4)] is microhyperbolic on the energy level 1 in the direction $\ell \in T_{(x',\xi')} T^*Z$ in each of the following cases[5)]:

(a) $m = 1$, $a_\alpha = o(1)$ for $|\alpha'| = |\alpha''| = 1$, $|\xi'| \ge \epsilon$, $\ell = \langle \xi', \partial_{\xi'} \rangle$;

(b) $m = 1$, $|\xi'| \le \varepsilon$ with a small enough constant $\varepsilon > 0$, $|\ell\sigma| \ge \epsilon\sigma |x'|^{-1}$, $\ell = \langle \ell', \partial_{x'} \rangle$ with an appropriate vector ℓ' such that $|\ell'| \le c$ and

$$\ell a_\alpha = o\bigl(|x'|^{-1+(2m-|\alpha|)}\bigr) \quad \text{as} \quad |x'| \to \infty \quad \forall \alpha : |\alpha| < 2m \tag{12.2.30}$$

(here this condition should be checked for $\alpha' = 0$ only);

(c) $m \ge 1$, $\ell\sigma = \sigma\bigl(1 + o(1)\bigr)|x'|^{-1}$ as $|x'| \to \infty$ with an appropriate vector ℓ, $|\ell| \le c$, (12.2.30) holds and $\ell = \langle \xi', \partial_{\xi'} \rangle + \langle \ell', \partial_{x'} \rangle$.

All these conditions are given in the original coordinates and in Conditions (a) and (c) one can take ℓ' depending on x'.

Then we arrive to

Proposition 12.2.5. *The microhyperbolicity condition is fulfilled for any ξ' provided*[5)] *one of the following conditions holds:*

(12.2.31) $m = 1$, $a_\alpha = o(1)$ *for* $|\alpha'| = |\alpha''| = 1$, $|\ell\sigma| \ge \epsilon\sigma |x|^{-1}$ *and* (12.2.30) *holds for* $\alpha' = 0$

(12.2.32) $a = \bar{a}^m + a'$ *where second-order symbol* $\bar{a}$ *satisfies* (12.2.31) *and all coefficients of* a' *satisfy*

$$a'_\alpha = o\bigl(|x'|^{\mu(2m-|\alpha|)}\bigr), \tag{12.2.33}$$

$$\ell a'_\alpha = o\bigl(|x'|^{-1+\mu(2m-|\alpha|)}\bigr) \tag{12.2.34}$$

(12.2.35) $m \ge 1$, $\ell\sigma = \sigma\bigl(1 + o(1)\bigr)|x'|^{-1}$ *and* (12.2.30) *holds.*

[5)] These conditions are sufficient but not necessary.

In what follows we assume that operator $\boldsymbol{A} = \tau^{-1}\tilde{A}$ is microhyperbolic on the energy level 1 [4) 6)].

Then, applying Theorem 4.4.8 as this operator is ξ'-microhyperbolic and Theorem 4.4.9 as this operator is (x', ξ')-microhyperbolic (i.e. in the general case) we obtain that if $\psi = \psi(x')$ is a γ-admissible function supported in $\{|x' - \bar{x}'| \le \frac{1}{2}\bar{\gamma}\}$ then

$$\|B_1^j \int \psi(x')\Big(e(x,y,\tau)_{x'=y'} - (2\pi)^{-d'}\int e(x',\xi',\tau)\,d\xi'\Big)\,dx' \cdot B_1^k\| \le C\tau^{\frac{1}{2m}(d'-1)}\gamma^{d'-1} \qquad \forall j,k \le l \tag{12.2.36}$$

where the norm in the left-hand expression is the operator norm in $\mathbb{H}$ and

(12.2.37) $\boldsymbol{e}(x',\xi',\tau)$ is the spectral projector of the operator $\boldsymbol{a}(x',\xi') := \boldsymbol{a}(x',\xi';x'',D'')$; the latter operator is an *operator-valued symbol* of $\tilde{A}(x,D)$ and we do not include factor τ^{-1} into operator or symbol.

Recall that $\tilde{A}$ is the operator $\sigma^{\frac{1}{2}d''}A\sigma^{-\frac{1}{2}d''}$ in the cylindrical coordinates (x', x'') (without division by τ)). Thus we obtain $\boldsymbol{a}(x',\xi';x'',D'')$ by replacing D' with ξ' in $\tilde{A}(x,D)$. So operator $\boldsymbol{a}(x',\xi')$ acts in $\mathbb{H} = \mathscr{L}^2(Y,\mathbb{H})$ and $\mathfrak{D}(\boldsymbol{a}) = \mathscr{H}^{2m}(Y,\mathbb{H}) \cap \mathscr{H}_0^m(Y,\mathbb{H})$.

Obviously, this operator is self-adjoint and therefore $\boldsymbol{e}(x',\xi',\tau)$ is well-defined.

Recalling the definition of B_1 one can easily see that

(12.2.38) As $l > \frac{1}{2m}d''$ B_1^{-l} is a trace operator in $\mathbb{H}$ with trace norm not exceeding $C\tau^{\frac{d''}{2m}}\sigma^{d''}$.

Therefore we immediately obtain the following estimate:

$$\Big|\int \psi(x')\,\mathsf{tr}\big(e(x,x,\tau)\big)\,dx - (2\pi)^{-d'}\iint \psi(x')\boldsymbol{n}(x',\xi',\tau)\,dx'd\xi'\Big| \le C\tau^{\frac{1}{2m}(d-1)}\gamma^{d'-1-\mu d''} \tag{12.2.39}$$

where

[6)] Which is the case provided[5)] one of conditions (12.2.31), (12.2.32) or (12.2.35) is fulfilled.

(12.2.40) $\boldsymbol{n}(x',\xi',\tau) = \mathsf{Tr}_{\mathbb{H}}\, \boldsymbol{e}(x',\xi',\tau)$ is an eigenvalue counting function of the operator $\boldsymbol{a}(x',\xi')$ in $\mathbb{H}$.

Really, due to (12.2.38) the trace norm (in $\mathbb{H}$) of the operator in the left-hand expression of (12.2.36) stripped of B_1^j and B_1^k does not exceed $C\tau^{\frac{1}{2m}(d'-1)}\gamma^{d'-1} \times \tau^{\frac{d''}{2m}}\sigma^{d''}$ which is exactly the right-hand expression of (12.2.39).

Summing over a partition of the unity in the main cusp zone (12.2.28) we obtain in the right-hand expression

$$C\tau^{\frac{1}{2m}(d-1)} \int_1^{\bar\gamma(\tau)} \gamma^{d'-1-\mu d''}\, d\gamma$$

which in turn is equal to

$$R^*(\tau) = \begin{cases} \tau^{\frac{1}{2m}(d-1)} & \text{for } \ d' < \mu d''+1, \\ \tau^{\frac{1}{2m}(d-1)}\log\tau & \text{for } \ d' = \mu d''+1, \\ \tau^{\frac{1}{2m\mu}(d'-1)(\mu+1)} & \text{for } \ d' > \mu d''+1. \end{cases} \tag{12.2.41}$$

Then, taking into account results in the zone $\{|x'|\le 2c_0\}$ (Weyl asymptotics) and far cusp zone $\bigl\{|x'|\ge \frac{1}{2}\bar\gamma(\tau)\bigr\}$ (Proposition 12.2.4) we obtain the following basic statement:

Theorem 12.2.6. *Let conditions* (12.2.1)–(12.2.11) *be fulfilled and let microhyperbolicity condition for* $\boldsymbol{a}(x',\xi')$ *be fulfilled*[6]*. Then asymptotics*

$$\mathsf{N}^-(\tau) = \mathcal{N}(\tau) + O\bigl(R^*(\tau)\bigr) \tag{12.2.42}$$

holds as $\tau\to+\infty$ *where* $R^*(\tau)$ *is given by* (12.2.41) *and*

$$\mathcal{N}(\tau) = (2\pi)^{-d}\iint \psi_0(x')n(x,\xi,\tau)\,dxd\xi + (2\pi)^{-d'}\iint \bigl(1-\psi_0(x')\bigr)\boldsymbol{n}(x',\xi',\tau)\,dx'd\xi', \tag{12.2.43}$$

$n(x,\xi,\tau)$ *is the eigenvalue counting function for symbol* $\boldsymbol{a}(x,\xi)$, $\psi_0\in \mathscr{C}^K$ *is supported in* $\{|x'|\le 2c_0\}$ *and* $\psi_0 = 1$ *for* $|x'|\le c_0$.

Moreover,

$$\mathcal{N}(\tau) \asymp \begin{cases} \tau^{\frac{d}{2m}} & \textit{for } \ d' < \mu d'', \\ \tau^{\frac{d}{2m}}\log\tau & \textit{for } \ d' = \mu d'', \\ \tau^{\frac{1}{2m\mu}d(\mu+1)} & \textit{for } \ d' > \mu d''. \end{cases} \tag{12.2.44}$$

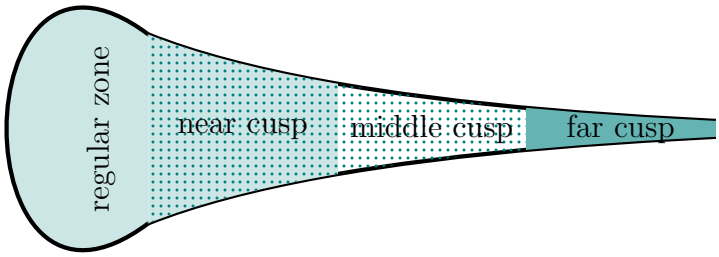


Figure 12.2: In both the *regular zone* and the *near cusp* we apply standard Weyl asymptotics (albeit in the near cusp we use propagation results for operators with the operator-valued symbols), in the *middle cusp* we use Weyl asymptotics for operators with the operator-valued symbols and *far cusp* is an elliptic zone for operator in question considered as operator with the operator-valued symbol; all zones overlap.

Improved Remainder Estimates

Assume first that $d' < 1+\mu d''$. Then the main contribution to the remainder estimate is given by the zone $\{|x'| \le t\}$ with an arbitrarily large constant t (the contribution of the complement does not exceed $\tau^{\frac{1}{2m}(d-1)}t^{-\delta}$ with $\delta > 0$); on the other hand, in this zone under the standard non-periodicity condition to the Hamiltonian billiards we have the remainder estimate $o\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$.

Therefore the following statement holds:

Theorem 12.2.7. *Let conditions* (12.2.1)–(12.2.11) *be fulfilled and let microhyperbolicity condition for* $a(x',\xi')$ *be fulfilled*[6)]*.*

Finally, let $d' < 1+\mu d''$ *and let the standard non-periodicity condition to the Hamiltonian billiards be fulfilled. Then asymptotics*

$$\mathsf{N}^-(\tau) = \mathcal{N}(\tau) + o\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr) \tag{12.2.45}$$

holds as $\tau \to +\infty$ *where* <u>now</u>

$$\begin{aligned}\mathcal{N}(\tau) = (2\pi)^{-d}\iint \psi_t(x')\bigl(n(x,\xi,\tau) + \kappa_1\tau^{\frac{d-1}{2m}}\bigr)\,dxd\xi + \\ (2\pi)^{1-d}\int \psi_t(x')\tilde{\kappa}_1\tau^{\frac{d-1}{2m}}\,dS + \\ (2\pi)^{-d'}\iint \bigl(1-\psi_t(x')\bigr)n(x',\xi',\tau)\,dx'd\xi',\end{aligned} \tag{12.2.46}$$

$$(12.2.47)_1 \qquad (2\pi)^{-d}\int \psi_t \kappa_1 \tau^{\frac{1}{2m}(d-1)}\, dx$$

and

$$(12.2.47)_2 \qquad (2\pi)^{1-d}\int_{\partial X} \psi_t \tilde{\kappa}_1 \tau^{\frac{1}{2m}(d-1)}\, dS$$

are the standard second terms in the Weyl asymptotics, $\psi_t(x') := \psi_0(\frac{x'}{t})$ *where* $t = t(\tau)$ *is an appropriate function such that* $t(\tau) \to +\infty$ *as* $\tau \to +\infty$ [7].

On the other hand, let $d' > 1 + d''\mu$. Then the main contribution to the remainder estimate in Theorem 12.2.6 is provided by the zone

$$(12.2.48) \qquad \{\varepsilon \le \tau^{-\frac{1}{2m\mu}}|x'| \le c_0\}$$

with arbitrarily small $\varepsilon > 0$; contribution of zone $\{|x'| \le 2\varepsilon\tau^{\frac{1}{2m\mu}}\}$ does not exceed $\varepsilon^\delta R^*(\tau)$.

However, in zone (12.2.48) $\boldsymbol{n}(x', \xi', \tau)$ does not exceed $\nu(\varepsilon) = \varepsilon^M$ and therefore we have effectively here matrix- rather than operator-valued operators.

Applying Theorems 4.4.11 and 4.4.12 and replacing $\boldsymbol{a}$ if necessary by another operator in $\mathbb{H}$ with eigenvalues asymptotically close to those of $\boldsymbol{a}$ we obtain the following statement:

Theorem 12.2.8. *Let conditions* (12.2.1)–(12.2.11) *be fulfilled and let microhyperbolicity condition for* $\boldsymbol{a}(x', \xi')$ *be fulfilled* [6].

Further, let $d' > 1 + \mu d''$ *and let the stabilization conditions*

$$(12.2.49)_1 \quad D^{\beta'}(a_\alpha - a_{\infty,\alpha}) = o\big(|x'|^{-|\beta'|}\big) \quad \forall \alpha : |\alpha| = 2m, \forall \beta' : |\beta'| \le K,$$

$$(12.2.49)_2 \quad D^{\beta'}(\sigma - \sigma_\infty) = o\big(|x'|^{-\mu-|\beta'|}\big) \qquad \forall \beta' : |\beta'| \le K$$

be fulfilled as $|x'| \to \infty$ *where* $a_{\infty,\alpha} = a_{\infty,\alpha}(x')$, $\sigma_\infty(x')$ *are positively homogeneous functions of* x' *of degrees* 0, $-\mu$ *respectively (surely,* $a_{\infty,\alpha}$ *can be matrix-valued).*

---

[7] If $t(\tau)$ works then every function $t'(\tau) \le t(\tau)$ such that $t'(\tau) \to +\infty$ as $\tau \to +\infty$ also works.

Let us consider operator-valued symbol

$$\boldsymbol{a}_\infty(x',\xi';D'') = \sum_{|\alpha|=2m} a_{\infty,\alpha}\sigma_\infty^{-|\alpha''|}\xi'^{\alpha'}D''^{\,\alpha''} \tag{12.2.50}$$

in $\mathbb{H}$*; let* $\zeta_j(x',\xi')$ *be its (non-decreasing) eigenvalues*[8]*.*

Finally, let us consider $\boldsymbol{a}_{\infty,j}(x',\xi') = \boldsymbol{a}_\infty(x',\xi')\boldsymbol{e}_\infty(x',\xi',\zeta_j(x',\xi'))$ *where* $\boldsymbol{e}_\infty(x',\xi',\tau)$ *is the spectral projector for* $\boldsymbol{a}_\infty(x',\xi')$ *and assume that*

(12.2.51) *For each* j *the standard non-periodicity condition is fulfilled for matrix-valued symbol* $\boldsymbol{a}_{\infty,j}$ *which means that with the exception of measure* 0 *on* $\Sigma_j = \{1 \in \operatorname{Spec} a_{\infty,j}(z)\}$ $\Psi_{j,t}(z) \not\ni z$ *and* $\Psi_{j,t}(z) \cap 0 \times \mathbb{R}^{d'} = \emptyset$ *for all* t *of the proper sign (depending on* $z = (x',\xi')$*) where* $\Psi_{j,t}$ *is a generalized Hamiltonian flow for* $\boldsymbol{a}_{\infty,j}$*.*

Then asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}(\tau) + \bigl(\kappa_1^* + o(1)\bigr)\tau^{\frac{1}{2m\mu}(d'-1)(\mu+1)} \tag{12.2.52}$$

hold as $\tau \to +\infty$ *with an appropriate coefficient* κ_1^* *(given in Remark 4.4.13).*

Condition (12.2.51) looks extremely cumbersome and impossible to check. However in the following rather special example this condition becomes much simpler:

Example 12.2.9. Let A satisfy (12.2.31) with $\bar{a} = |\xi|^2$; then eigenvalues of $\boldsymbol{a}_\infty$ are $\zeta_j(x',\xi') = \bigl(|\xi'|^2 + \sigma^{0\,-2}(x')\lambda_j\bigr)$ and they have constant multiplicities, λ_j are eigenvalues of $\Delta_{Y,\mathsf{D}}$.

Then one needs to check the standard non-periodicity condition for symbols $\zeta_j(x',\xi')$ and all of them are equivalent to the same standard non-periodicity condition for a scalar symbol

$$\zeta(x',\xi') = |\xi'|^2 + \sigma_\infty(x')^{-2} \tag{12.2.53}$$

(on the energy level 1).

In this case we need to check only check the standard non-periodicity condition for (12.2.53). Note that

(12.2.54) As $d' \ge 2$ the generic trajectory does not hit $0 \times \mathbb{R}^{d'}$.

[8] Then obviously $\zeta_j(tx', t^\mu\xi') = t^{2m\mu}\zeta_j(x',\xi')$.

Really, $\mu(\Sigma \cap \{|x'| \le 2\varepsilon\}) = O(\varepsilon^{d'})$ where $\mu = dx'd\xi' : d\zeta$ is the standard measure on $\Sigma = \{(x',\xi') : \zeta(x',\xi') = 1\}$ and trajectory intersecting $\{|x'| \le \varepsilon\}$ needs at least $\epsilon_0\varepsilon$-time to leave $\{|x'| \le 2\varepsilon\}$; therefore the μ-measure of points such that Ψ_t touches $\{|x'| \le \varepsilon\}$ for some $t : |t| \le T$ does not exceed $CT\varepsilon^{d'-1}$.

In particular, the standard non-periodicity condition for $\zeta(x',\xi')$ is fulfilled as $\sigma_\infty = |x'|^{-\mu}$, $\mu > 0$ and $\mu \ne 1$; recall that $d' \ge 2$.

Finally, let us consider the case $d' = 1 + d''\mu$. Considering diagonal operator with diagonal elements $\zeta_j^{\mathsf{w}}(x', D')$ one can prove easily the remainder estimate $o(\tau^{(d-1)/2m}\log\tau)$ (not subject to any non-periodicity condition). This leads us to conjecture which we were unable to prove

Conjecture 12.2.10. *As $d' = 1+d''\mu$ and stabilization conditions* $(12.2.49)_{1,2}$ *are fulfilled, remainder estimate is in fact $o(\tau^{(d-1)/2m}\log\tau)$.*

We leave to the reader the following easy

Problem 12.2.11. (i) Generalize Theorem 12.2.8 to the case when a_∞ depends on x''; then one should assume that $a_\infty(x', \sigma_\infty(x')x'')$ is positively homogeneous of degree 0 with respect to x'; then $\mathsf{a}_\infty = \mathsf{a}_\infty(x',\xi';x'',D'')$ and one should take Weyl quantization in the right-hand expression of (12.2.50).

(ii) Treat Riesz means and derive asymptotics with the remainder estimates

$$R^*_{(\vartheta)}(\tau) = \begin{cases} \tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta} & \text{for } d' < \mu d'' + 1 + \vartheta, \\ \tau^{\frac{1}{2m}(d-1-\vartheta)+\vartheta}\log\tau & \text{for } d' = \mu d'' + 1 + \vartheta, \\ \tau^{\frac{1}{2m\mu}(d'-1-\vartheta)(\mu+1)+\vartheta} & \text{for } d' > \mu d'' + 1 + \vartheta. \end{cases} \tag{12.2.55}$$

and in the analogs of Theorems 12.2.7 and 12.2.8 one should assume that $d' < \mu d'' + \vartheta + 1$, $d' > \mu d'' + \vartheta + 1$ respectively.

12.2.3 Effective Asymptotics

Scheme of Effective Asymptotics

The main defect of Theorems 12.2.6–12.2.8 is that the expression for $\mathcal{N}(\tau)$ is not effective and includes the eigenvalue counting function for the *family* of auxiliary operators $\mathsf{a}(x',\xi') = \mathsf{a}(x',\xi';x'',D'')$. We would like to derive a formula including the eigenvalue counting function for *one* auxiliary

operator or at least for a family of auxiliary operators with a smaller number of parameters (under certain conditions). We are aware that for a thick cusp (i.e., with $\sigma^{d''-1-\vartheta} \notin \mathscr{L}^1(Z)$) we cannot completely get rid of the auxiliary operators in the final answer.

Let us start with a more accurate Weyl analysis. Let $U(x,y,t)$ be the Schwartz kernel of the operator $\exp(it\tau^{-1}A)$. Then

$$\tau D_t U = A_x U, \qquad U|_{t=0} = \delta(x-y)I_{\mathbb{K}} \tag{12.2.56}$$

with $\mathbb{K} = \mathbb{C}^{\mathsf{D}}$.

Let us fix a point $\bar{x} \in X$ and consider its $\bar{\sigma}$-neighborhood. As usual, let us rescale $x_{\mathsf{new}} = (x_{\mathsf{old}} - \bar{x})\bar{\sigma}^{-1}$ and divide A by τ; then we transform A into an h_1-differential operator A_1 with $h_1 = \bar{\sigma}^{-1}\tau^{-\frac{1}{2m}}$. Introducing a new time scale $t_1 = th_1$ we obtain from (12.2.56) the scaled problem

$$h_1 D_{t_1} U = A_{1x} U, \qquad U|_{t_1=0} = \bar{\sigma}^{-d}\delta(x-y)I_{\mathbb{K}} \tag{12.2.56}_1$$

where we skip the subscript "new" at x and y. Then one can apply the results of Section 4.3; moreover, on the energy level 1 the microhyperbolicity condition is fulfilled provided h_1 is small enough.

Let $\bar{\chi} \in \mathscr{C}_0^K([-1,1])$, $\bar{\chi} = 1$ on $[-\frac{1}{2}, \frac{1}{2}]$ and let ψ' be $\bar{\sigma}$-admissible and be supported in the $\bar{\sigma}$-neighborhood of $\bar{x}$. Further, let $h_1 \le \varepsilon$ (i.e., $\bar{\sigma} \ge c_0\tau^{-\frac{1}{2m}}$), and let $T_1 = \varepsilon h_1^{-1}$ where here and below $\varepsilon > 0$ is a small enough constant. Then according to Section 4.3 we obtain the following estimate:

$$\begin{aligned} \Big| \int \Big(F_{t\to\lambda}\bar{\chi}_{T_1}(t)\Gamma_x U - \sum_{0\le j\le J-1} \kappa'_j(x,\lambda\tau)^{\frac{1}{2m}(d-j)-1}\tau \Big)\psi'\,dx - \\ \int_{\partial X} \sum_{1\le j\le J-1} \tilde{\kappa}'_j(x,\lambda\tau)^{\frac{1}{2m}(d-j)-1}\tau\psi'\,dS \Big| \le C\tau^{\frac{1}{2m}(d-J)}\bar{\sigma}^{d-J} \end{aligned} \tag{12.2.57}$$

where $\lambda \in [\epsilon_0, c]$ here and below, dS is the standard Riemannian density on ∂X, κ'_j, $\tilde{\kappa}'_j$ are the standard Weyl coefficients and

$$|\kappa'_j| \le C\bar{\sigma}^{-j}, \qquad |\tilde{\kappa}'_j| \le C\bar{\sigma}^{1-j}. \tag{12.2.58}$$

Recall that one can obtain these coefficients in the following way:

$$\mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}\,\psi'(\tau - A)^{-1}\big) \sim \int \sum_j \psi'\kappa'_j\tau^{\frac{1}{2m}(d-j)-1}\,dx \tag{12.2.59}$$

and

$$\mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}\, \psi'\big((\tau - A)_D^{-1} - (\tau - A)^{-1}\big)\big) \sim \sum_j \int_{\partial X} \psi' \tilde{\kappa}'_j \tau^{\frac{1}{2m}(d-j)-1}\, dS \tag{12.2.60}$$

where $(\tau - A)^{-1}$ and $(\tau - A)_{\mathsf{D}}^{-1}$ are parametrices of the pseudodifferential operator $(\tau - A)$ in terms of the formal calculus of pseudodifferential operators and the Dirichlet problem for the same operator in terms of the formal calculus of pseudodifferential operators (with the transmission property) and Green operators (see, e.g., Section 1.4), and for the sake of simplicity the ordinary matrix trace tr is included in the operation Γ_x in (12.2.57).

Therefore under the same conditions for the $\bar{\gamma}$-admissible function $\psi = \psi(x')$ supported in the $\bar{\gamma}$-neighborhood of $\bar{x}'$ estimate

$$\begin{aligned} \Big| \int \Big(F_{t\to\lambda} \bar{\chi}_{T_1}(t) \Gamma_x U - \sum_{0\le j\le J-1} \kappa'_j(x, \lambda\tau)^{\frac{1}{2m}(d-j)-1} \tau \Big) \psi\, dx - \\ \int_{\partial X} \sum_{1\le j\le J-1} \tilde{\kappa}'_j(x, \lambda\tau)^{\frac{1}{2m}(d-j)-1} \tau \psi'\, dS \Big| \le C \tau^{\frac{1}{2m}(d-J)} \bar{\sigma}^{d''-J} \bar{\gamma}^{d'} \end{aligned} \tag{12.2.61}$$

holds where the right-hand expression acquired factor $\bar{\gamma}^{d'} \bar{\sigma}^{-d'}$.

So far there is nothing beyond analysis of Sections 11.2 and 11.3. However, let us take another point of view. Namely, let us treat the $\bar{\gamma}$-neighborhood of $\bar{x}'$, rescale $x'_{\mathsf{new}} = (x'_{\mathsf{old}} - \bar{x}')\bar{\gamma}^{-1}$ and divide A by τ; earlier we transformed X_{cusp} to a cylinder in the routine way.

Then A is transformed to a h_2-differential operator (with respect to x') A_2 with the operator-valued symbol; surely $h_2 = \bar{\gamma}^{-1}\tau^{-\frac{1}{2m}} \ll 1$ here. Introducing the new time scale $t_2 = t h_2 \tau^{-1}$ we obtain from (12.2.56) another scaled problem

$$\tau D_{t_2} U = A_{2x} U, \qquad U|_{t_2=0} = \bar{\gamma}^{-d'} \delta(x' - y') I_{\mathbb{H}}. \tag{12.2.56)$_2$}$$

Assume that A_2 is a microhyperbolic operator with the operator-valued symbol[6]. Let us apply the strongest version of Theorem 2.1.19 to estimate

$$\Big| \int F_{t\to\lambda} \chi_T(t) \Gamma_x U \psi'\, dx \Big| \tag{12.2.62}$$

with $\chi \in \mathscr{C}_0^K([-1,1])$ vanishing on $[-\frac{1}{2}, \frac{1}{2}]$.

Namely, formula (4.3.52) yields that in the right-hand expressions in (2.1.58) and (2.1.59) one can add the factor $h = h_2$, i.e., one can take the right-hand expressions to be $h^{1-d-|\alpha|}\bigl(\frac{h}{T}\bigr)^s$.

Therefore scaling we obtain that

Proposition 12.2.12. *Let A_2 be a microhyperbolic operator with the operator-valued symbol, $\chi \in \mathscr{C}_0^K([-1,1])$ vanishing on $[-\frac12,\frac12]$ and ψ $\bar\gamma$-admissible and supported in the $\bar\gamma$-neighborhood of $\bar x'$.*

Then estimate

$$\|F_{t\to\lambda}B_1^j\chi'_T\Gamma'\psi UB_1^k\| \le Ch_2^{-d'}T^{-s} \tag{12.2.63}$$

holds for any $T \in [\epsilon_0, T_2]$, $T_2 = \epsilon h_2^{-1}$; here Γ' means that we take $x' = y'$ and integrate over x', and we take the operator norm in $\mathbb{H}$ in the left-hand expression.

Applying Sobolev embedding theorem we take the trace norm in the left-hand expression with the price of additional factor $h_1^{-d''}$ in the right-hand expression and shedding of some factors B_1^j and B_1^k; we still assume that $\bar\sigma \ge c_0\tau^{-\frac{1}{2m}}$.

Therefore we conclude that

(12.2.64) Expression (12.2.62) does not exceed $Ch_2^{-d'}T^{-s}h_1^{-d''}$.

Taking an appropriate partition of unity in the interval $[T_1', T_2']$ we obtain estimate

$$\bigl|F_{t\to\lambda}\bigl(\bar\chi_{T_2'}(t)-\bar\chi_{T_1'}(t)\bigr)\Gamma\psi U\bigr| \le Ch_2^{-d'}h_1^{-d''}T_1'^{-s} \tag{12.2.65}$$

for $\epsilon \le T_1' < T_2' \le T_2$.

Let us set $T_j' = T_j$ $(= \varepsilon h_j^{-1})$. Then estimates (12.2.65) and (12.2.61) yield that

(12.2.66) If A_2 is a microhyperbolic operator with the operator-valued symbol then estimate (12.2.61) remains true with T_1 replaced by T_2.

Applying the routine Tauberian technique we then obtain then the following estimate

$$\Big|\Big(\int \psi\big(\mathsf{tr}(e(x,x,\tau)) - \sum_{0\le j\le J-1} \kappa_j(x)\tau^{\frac{1}{2m}(d-j)}\big)\,dx - \int_{\partial X}\psi \sum_{1\le j\le J-1} \tilde{\kappa}_j(x)\tau^{\frac{1}{2m}(d-j)}\,dS\Big)\Big|_{\tau=\tau'}^{\tau=\tau}\Big| \le C\bar{\sigma}^{d''}\bar{\gamma}^{d'-1}\tau^{\frac{1}{2m}(d-1)} + C\bar{\sigma}^{d''-J}\bar{\gamma}^{d'}\tau^{\frac{1}{2m}(d-J)} \tag{12.2.67}$$

provided $\tau \ge \epsilon\bar{\sigma}^{-2m}$, $\tau' \asymp \tau$ and $J \le d$.

For $J > d$ one should replace in the left-hand expression the terms with $j = d$ by $\kappa_d \log\tau$ and $\tilde{\kappa}_d \log\tau$. Here and below the Weyl coefficients κ_j and $\tilde{\kappa}_j$ satisfy (12.2.58) [9].

Thus, *using propagation of singularities for operators with the operator-valued symbols we have improved the Weyl asymptotics in the cusp zone* $\{x : \sigma(x') \ge \tau^{-\frac{1}{2m}}\}$.

However now we need to take into account many terms in the decomposition which undermines our intention to get an effective asymptotics. To remedy this we consider A as a perturbation of some other operator A^0. So let A^0 be another operator in the domain X^0 with the same cusp part X_{cusp} also satisfying all the conditions above with the same exponents. Moreover, let us assume that the operators A and A^0 are close at infinity in the sense that

$$\big|D^\beta(a_\alpha - a^0_\alpha)\big| \le C\eta\langle x'\rangle^{-|\beta'|+\mu(2m-|\alpha|+|\beta''|)} \qquad \forall\alpha : |\alpha| \le 2m \quad \forall\beta : |\beta| < K \tag{12.2.68}$$

with

$$\eta = \eta(x') \asymp \langle x'\rangle^{-\nu}, \quad \nu > 0. \tag{12.2.69}$$

Remark 12.2.13. In most of the arguments below one need only assume that η is a γ-admissible weight function and $\eta = o(1)$ as $|x'| \to \infty$.

All the objects associated with A^0 have an additional superscript "0".

Let us introduce the formal differential expression $A^\theta = A^0 + \theta(A - A^0)$ with $\theta \in [0,1]$; then $A^1 = A$. We also assign Dirichlet boundary conditions to

[9] A similar estimate also holds for Riesz means. Namely, the first term in the right-hand expression of (12.2.67) should be multiplied by $\tau^\vartheta\bar{\sigma}^\vartheta\bar{\gamma}^{-\vartheta}$ and the second term should be multiplied by τ^ϑ.

A^θ. Below all the objects associated with A^θ have the additional superscript "θ". Then applying estimate (12.2.67) to both operators we obtain estimate

$$\begin{aligned}(12.2.70)\quad \Big|\Big(\int \psi\Big(e(x,x,\tau)-e^0(x,x,\tau)-\\ \sum_{0\le j\le J-1}\big(\kappa_j(x)-\kappa_j^0(x)\big)\tau^{\frac{1}{2m}(d-j)}\Big)\,dx-\\ \int_{\partial X}\psi\sum_{1\le j\le J-1}\big(\tilde\kappa_j(x)-\tilde\kappa_j^0(x)\big)\tau^{\frac{1}{2m}(d-j)}\,dS\Big)\Big|_{\tau=\tau'}^{\tau=\tau}\Big|\le\\ C\bar\sigma^{d''}\bar\gamma^{d'-1}\tau^{\frac{1}{2m}(d-1)}+C\bar\sigma^{d''-J}\bar\gamma^{d'}\tau^{\frac{1}{2m}(d-J)}.\end{aligned}$$

provided $J\le d$; otherwise terms with $j=d$ contain the additional factor $\log\tau$.

Moreover, differentiating representations (12.2.59), (12.2.60) with respect to θ one can easily see that

$$(12.2.71)\qquad |\partial_\theta\kappa_j^\theta(x)|\le c_1\bar\eta\bar\sigma^{-j},\qquad |\partial_\theta\tilde\kappa_j^\theta(x)|\le c_1\bar\eta\bar\sigma^{1-j}$$

in the same notations as before; we first obtain these estimates for the coefficients $\kappa_j'^\theta$, $\tilde\kappa_j'^\theta$.

Integrating on θ from 0 to 1 and passing from ψ' to ψ we obtain that

$$(12.2.72)\qquad |\kappa_j(x)-\kappa_j^0(x)|\le c_1\bar\eta\bar\sigma^{1-j},\qquad |\tilde\kappa_j(x)-\tilde\kappa_j^0(x)|\le c_1\bar\eta\bar\sigma^{1-j}$$

These estimates and (12.2.70) yield that

$$\begin{aligned}(12.2.73)\quad \Big|\Big(\int \psi\Big(e(x,x,\tau)-e^0(x,x,\tau)-\\ \sum_{0\le j\le J-1}\big(\kappa_j(x)-\kappa_j^0(x)\big)\tau^{\frac{1}{2m}(d-j)}\Big)\,dx-\\ \int_{\partial X}\psi\Big(\sum_{1\le j\le J-1}\big(\tilde\kappa_j(x)-\tilde\kappa_j^0(x)\big)\tau^{\frac{1}{2m}(d-j)}\,dS\Big)\Big|_{\tau=\tau'}^{\tau=\tau}\Big|\le\\ C\bar\sigma^{d''}\bar\gamma^{d'-1}\tau^{\frac{1}{2m}(d-1)}+C\bar\sigma^{d''-s}\bar\gamma^{d'}\tau^{\frac{1}{2m}(d-s)}+C\bar\eta\bar\sigma^{d''-J}\bar\gamma^{d'}\tau^{\frac{1}{2m}(d-J)}.\end{aligned}$$

with arbitrarily large exponent s where K surely depends on s.

This estimate is accurate enough to obtain the final theorems under certain restrictions on ν from below (we leave this easy task to the reader).

However, in order to prove these theorems under weaker conditions one needs a more refined analysis. Namely, *we want to shed of the second term in the right-hand expression of* (12.2.73) which is not nice for h_1 close to 1 (i.e., for $\bar\gamma$ close to $\tau^{\frac{1}{2m\mu}}$).

Remark 12.2.14. Without any loss of the generality we can assume that $X = X^0$. Really, one can arrange this by replacing both X and X^0 with $X^1 := X_{\mathsf{cusp}} \cap \{|x'| \ge c_0\}$ (or possibly $X_{\mathsf{cusp}} \cap \{x_1 \ge c_0\}$ in the case $d' = 1$) and taking Dirichlet boundary conditions on ∂X; surely the operators remain self-adjoint; moreover as $\mathfrak{D}(A^0) = \mathfrak{D}(A^1)$.

Surely, as we do this function $e^\theta(x, y, \tau)$ changes because we changed the geometrical domains. However the routine Tauberian arguments yield that in the frameworks of Theorems 12.2.6–12.2.8 the errors appearing in $\int \psi e^\theta(x, x, \tau)\, dx$ (with ψ supported in $\{|x'| \ge 2c_0\}$) do not exceed the remainder estimates in the asymptotics of these terms in the corresponding theorems and since we are not going to improve these remainder estimates but to provide a better principal part everything is fine.

Then operators $A^\theta = A^0 + \theta(A - A^0)$ with $\mathfrak{D}(A^\theta) = \mathfrak{D}(A^0)$ are self-adjoint and all the functions $e^\theta(x, y, \tau)$ and $U^\theta(x, y, t)$ do not lose their meanings as Schwartz kernels of $E^\theta(\tau)$ and $\exp(i\tau^{-1}tA^\theta)$ respectively as $\theta \in [0, 1]$; $E^\theta(.)$ is the spectral projector of A^θ.

Then

$$\partial_\theta \exp\bigl(it\tau^{-1}A^\theta\bigr) = i\tau^{-1}\int_0^t \exp\bigl(it'\tau^{-1}A^\theta\bigr)\cdot\bigl(A^1 - A\bigr)\cdot\exp\bigl(i\tau^{-1}(t-t')A^\theta\bigr)\,dt' \tag{12.2.74}$$

and one can easily prove that for $\lambda \in [\epsilon, c]$

$$\bigl|F_{t\to\lambda}\bar\chi_T(t)\partial_\theta U^\theta(x, y, t)\bigr| \le C\bar\eta h_1^{-p}T \tag{12.2.75}$$

for any $T > 0$ with large enough p. One can improve this estimate and calculate p but this improvement provides no advantage for arguments below.

We want to calculate (12.2.74) after we multiply it by $\bar\chi_T(t)\psi(x)$ and calculate the trace. Let us do it first as T is small enough: applying routine arguments associated with the successive approximation method

and increasing T_1 from $h_1^{\frac12+\delta}$ (*only here,* the subscript 1 at T means that we use the t_1-scale) to ϵ in Sections 4.3 and 7.2 we conclude that

$$\begin{aligned}(12.2.76)\quad \Big|\partial_\theta\Big(\int\Big(F_{t\to\lambda}\bar\chi_T(t)\Gamma_x U^\theta - \sum_{0\le j\le J-1}\kappa_j'^\theta(\lambda\tau)^{\frac{1}{2m}(d-j)-1}\tau\Big)\psi'\,dx-\\ \int_{\partial X}\sum_{1\le j\le J-1}\tilde\kappa_j'^\theta(\lambda\tau)^{\frac{1}{2m}(d-j)-1}\psi'\,dS\Big)\Big|\le C\bar\eta\tau^{\frac{1}{2m}(p-J)}\bar\sigma^{p-J}\end{aligned}$$

where $T=T_1=\epsilon h_1^{-1}$ and p is large enough[10)].

Therefore estimate (12.2.76) holds with $\psi(x')$ (which is γ-admissible) instead of ψ' (which was σ-admissible) and with the additional factor $h_2^{-d'}h_1^{d'}$ in the right-hand expression.

Moreover, applying arguments associated with operators the with operator-valued symbols one can easily obtain from (12.2.75) that

$$(12.2.77)\qquad \big|F_{t\to\lambda}\chi_T(t)\Gamma\big(\psi\partial_\theta U^\theta\big)\big|\le \bar\eta h_2^{-d'}h_1^{-p}T^{-s}$$

for $T\in[T_1,T_2]$ and therefore

$$(12.2.78)\qquad \big|F_{t\to\lambda}\big(\bar\chi_{T_2'}-\bar\chi_{T_1'}\big)\Gamma\big(\psi\partial_\theta U^\theta\big)\big|\le C\bar\eta h_2^{-d'}h_1^{-p}T_1'^{-s}$$

with the same T_1, T_2, T_1', T_2', χ and $\bar\chi$ as in (12.2.65) and (12.2.65).

Therefore estimate (12.2.76) holds with $T=T_2$ instead of $T=T_1$. Integrating over θ from 0 to 1 we see that

(12.2.79) Estimate (12.2.76) holds with $T=T_2$ and with the derivative on θ replaced by the difference operator; so $\partial_\theta f^\theta$ is replaced by (f^1-f^0).

Let us apply the Tauberian technique. Surely, $\Gamma\big(\psi\big(e(.,.,\tau)-e^0(.,.,\tau)\big)\big)$ is not necessarily a monotone function of τ and one should apply the estimate

$$(12.2.80)\quad \Big|\Gamma\Big(\psi\big(e^\theta(.,.,\tau)-e^\theta(.,.,\tau')\big)\Big)\Big|\le \bar\gamma^{d'}\bar\sigma^{d''}\tau^{\frac{d}{2m}}h_2=\bar\gamma^{d'-1}\bar\sigma^{d''}\tau^{\frac{1}{2m}(d-1)}$$

for $|\tau'-\tau|\le h_2$. This estimate was obtained by the Tauberian method (see Sections 4.2 and 4.4) for functions $\Gamma\big(\psi e^\theta(.,.,\tau)\big)$ which are monotone of τ.

[10)] However, considering this estimate with large $J'=J+p$ instead of J and applying estimates (12.2.58) one can reach $p=d$.

This gives the improved estimate (12.2.73):

$$\begin{aligned}(12.2.81)\quad \Big|\Big(\int\Big(\big(e(x,x,\tau)-e^0(x,x,\tau)\big)\\ -\sum_{0\le j\le J-1}\big(\kappa_j(x)-\kappa_j^0(x)\big)\tau^{\frac{1}{2m}(d-j)}\Big)\psi\,dx-\\ \int_{\partial X}\sum_{1\le j\le J-1}\big(\tilde\kappa_j(x)-\tilde\kappa_j^0(x)\big)\tau^{\frac{1}{2m}(d-j)}\psi\,dS\Big)\Big|_{\tau=\tau'}^{\tau=\tau}\Big|\le\\ C\bar\sigma^{d''}\bar\gamma^{d'-1}\tau^{\frac{1}{2m}(d-1)}+C\bar\eta\bar\sigma^{d''-J}\bar\gamma^{d'}\tau^{\frac{1}{2m}(d-J)}.\end{aligned}$$

Recall that $\tau'\in[\epsilon\tau,\tau]$, $\tau\bar\sigma^{2m}\ge\epsilon$ here and terms with $j=d$ contain the factor $\log\tau$ [11)].

Therefore, the following statement has been proven:

Proposition 12.2.15. *(i) In the framework of Theorem 12.2.6 estimate* (12.2.67) *holds.*

(ii) Moreover, let both operators A and A^0 satisfy assumptions of Theorem 12.2.6 and let (12.2.68) *be fulfilled (in $X_{\mathsf{cusp}}\cap|x'-\bar x'|\le\bar\gamma$). Then estimate* (12.2.81) *holds.*

Recall that ψ is γ-admissible and supported in the $\bar\gamma$-neighborhood of $\bar x'$. Let us replace τ and τ' by $2^{-n}\tau$ and $2^{-n-1}\tau$ and sum over $n=0,\dots,n_0=c_0\lfloor\log(\tau\bar\sigma^{2m})\rfloor+c_1$. Applying Proposition 12.2.4 we obtain

Corollary 12.2.16. *(i) In the framework of Theorem 12.2.6 estimate*

$$\begin{aligned}(12.2.82)\quad \mathsf{R}_1:=\Big|\int\Big(\mathsf{tr}(e(x,x,\tau))-\sum_{0\le j\le J-1}\kappa_j(x)\tau^{\frac{1}{2m}(d-j)}\Big)\psi\,dx-\\ \int_{\partial X}\sum_{1\le j\le J-1}\tilde\kappa_j(x)\tau^{\frac{1}{2m}(d-j)})\psi\,dS\Big|\le\\ C\bar\sigma^{d''}\bar\gamma^{d'-1}\tau^{\frac{1}{2m}(d-1)}+C\bar\sigma^{d''-J}\bar\gamma^{d'}\tau^{\frac{1}{2m}(d-J)}\end{aligned}$$

holds for $J<d$; for $J=d$ estimate

$$(12.2.83)\qquad \mathsf{R}_1\le C\bar\sigma^{d''}\bar\gamma^{d'-1}\tau^{\frac{1}{2m}(d-1)}+C\bar\sigma^{-d'}\bar\gamma^{d'}\log(\tau\bar\sigma^{2m})$$

[11)] One can see easily that for Riesz means both terms in the right-hand expression should be modified in the way indicated in [9)].

holds and for $J = d+1$ *the estimate*

$$\mathsf{R}_1 \le C\bar\sigma^{d''}\bar\gamma^{d'-1}\tau^{\frac{1}{2m}(d-1)} + C\bar\sigma^{-d'}\bar\gamma^{d'} \tag{12.2.84}$$

holds, and in the latter case the terms with $j = d$ *are* $\kappa_d \log(\tau\bar\sigma^{2m})$ *and* $\tilde\kappa_d \log(\tau\bar\sigma^{2m})$.

(ii) In the framework of Proposition 12.2.15(ii) estimates

$$\begin{aligned}\mathsf{R}_2 \coloneqq \Big|\Big(\int\Big(\mathsf{tr}(e^\theta(x,x,\tau) - \sum_{0\le j\le J-1}\kappa_j^\theta(x)\tau^{\frac{1}{2m}(d-j)}\Big)\psi\,dx - \\ \int_{\partial X}\sum_{1\le j\le J-1}\tilde\kappa_j^\theta(x)\tau^{\frac{1}{2m}(d-j)}\psi\,dS\Big)\Big|_{\theta=0}^{\theta=1}\Big| \le \\ C\bar\sigma^{d''}\bar\gamma^{d'-1}\tau^{\frac{1}{2m}(d-1)} + C\bar\eta\bar\sigma^{d''-J}\bar\gamma^{d'}\tau^{\frac{1}{2m}(d-J)},\end{aligned} \tag{12.2.85}$$

$$\mathsf{R}_2 \le C\bar\sigma^{d''}\bar\gamma^{d'-1}\tau^{\frac{1}{2m}(d-1)} + C\bar\eta\bar\sigma^{-d'}\bar\gamma^{d'}\log(\tau\bar\sigma^{2m}) \tag{12.2.86}$$

and

$$\mathsf{R}_2 \le C\bar\sigma^{d''}\bar\gamma^{d'-1}\tau^{\frac{1}{2m}(d-1)} + C\bar\eta\bar\sigma^{-d'}\bar\gamma^{d'} \tag{12.2.87}$$

hold for $J < d$, $J = d$, $J = d+1$ *respectively (we remind the reader that terms with* $j = d$ *contain a logarithmic factor).*

Then after summation over a γ-admissible partition of unity in Z we can obtain miscellaneous formulas (later under certain conditions we will calculate the terms associated with the operator A^0):

(i) Let us sum the estimates for R_2 in the domain $\{t_1 \le |x'| \le c_0\tau^{\frac{1}{2m\mu}}\}$ and apply Theorem 12.2.2 in the domain $\{|x'| \le 2t_1\}$. Then we derive the following formula

$$\begin{aligned}\mathsf{N}^-(\tau) = \\ \sum_{j=0,1}\int\phi\big(\frac{x'}{t_1}\big)\kappa_j(x)\tau^{\frac{1}{2m}(d-j)}\,dx + \int\phi\big(\frac{x'}{t_1}\big)\tilde\kappa_1(x)\tau^{\frac{1}{2m}(d-1)}\,dS +\end{aligned} \tag{12.2.88}$$

$$\sum_{j=0,1}\int \bigl(1-\phi(\frac{x'}{t_1})\bigr)\bigl(\kappa_j(x)-\kappa_j^0(x)\bigr)\tau^{\frac{1}{2m}(d-j)}\,dx+$$
$$\int \phi(\frac{x'}{t_1})\bigl(\tilde\kappa_1(x)-\tilde\kappa_1^0(x)\bigr)\tau^{\frac{1}{2m}(d-1)}\,dS+$$
$$\int \bigl(1-\phi(\frac{x'}{t_1})\bigr)\,\mathsf{tr}\bigl(e^0(x,x,\tau)\bigr)\,dx+$$
$$O\bigl(\mathsf{R}^*(\tau)+\tau^{\frac{1}{2m\mu}(d'(\mu+1)-\nu)}\bigr)$$

where $R^*(\tau)$ was introduced by (12.2.41) and here and below $\phi\in \mathscr{C}_0^K(\mathbb{R}^{d'})$, $\phi=1$ in a neighborhood of the origin.

Remark 12.2.17. In formula (12.2.88) we have taken $J=2$ because we gain nothing by increasing J and so we have dropped all the terms with $j\ge 2$.

Further, in (12.2.88) t_1 is either a large enough constant or a slowly increasing function of τ. Moreover, one can skip terms with $j=1$ in the third and fourth items in the right-hand expression in all cases excluding $d'=(d''-1)\mu+\nu$, $\nu<\mu+1$ when the remainder estimate is $O(\tau^{\frac{1}{2m}(d-1)})$, and the contribution of this term is $O\bigl(\tau^{\frac{1}{2m}(d-1)}\log\tau\bigr)$ (and this estimate is the best possible).

Furthermore, for $t_1=\mathsf{const}$ one can skip terms with $j=1$ in the first and second items in the right hand expression. In any case, one can effectively calculate all terms with $j=0,1$.

(ii) Consider the case $d'<1+\mu d''$, $\nu>\mu(1-d'')+d'$. In this case the remainder estimate in (12.2.88) is $O\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$.

Moreover, the contribution of the zone $\{t_1\le |x'|\}$ to the remainder estimate is $o\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$ for $t_1=t_1(\tau)\to+\infty$ as $\tau\to+\infty$. Then, applying the improved Weyl estimate in the zone $\{|x'|\le t_1\}$ under the standard non-periodicity condition to the Hamiltonian billiards we obtain asymptotics

(12.2.89) $\mathsf{N}^-(\tau)=$
$$\sum_{j=0,1}\int \phi(\frac{x'}{t_1})\kappa_j(x)\tau^{\frac{1}{2m}(d-j)}\,dx+\int \phi(\frac{x'}{t_1})\tilde\kappa_1(x)\tau^{\frac{1}{2m}(d-1)}\,dS+$$
$$\int \bigl(1-\phi(\frac{x'}{t_1})\bigr)\bigl(\kappa_0(x)-\kappa_0^0(x)\bigr)\tau^{\frac{d}{2m}}\,dx+$$
$$\int \bigl(1-\phi(\frac{x'}{t_1})\bigr)\,\mathsf{tr}\bigl(e^0(x,x,\tau)\bigr)\,dx+o\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$$

where we have dropped terms with $j = 1$ in the third and fourth items in the right-hand expression of (12.2.89).

(iii) Consider now an opposite case $d' > 1 + \mu d''$, $\nu > \mu + 1$; then the remainder estimate in (12.2.88) is $O\big(\tau^{\frac{1}{2m\mu}(d'-1)(\mu+1)}\big)$. Moreover, in this case one can drop all terms with $j = 1$.

Furthermore, the contribution of the zone $\{|x'| \le t_2\}$, $t_2 = \varepsilon\tau^{\frac{1}{2m\mu}}$ to the remainder estimate is $\varepsilon'\tau^{\frac{1}{2m\mu}(d'-1)(\mu+1)}$ with $\varepsilon' = \varepsilon'(\varepsilon) \to 0$ as $\varepsilon \to 0$.

On the other hand, for every fixed $\varepsilon > 0$ in the zone $t_2(\tau) \le |x'| \le c_0\tau^{\frac{1}{2m\mu}}$ in the context of Theorem 12.2.7 one can improve the remainder estimate. Namely, taking a standard partition of unity in (x', ξ')-space and applying the standard Tauberian arguments we obtain that the contributions of both elements of this partition do not exceed $\varepsilon''\tau^{\frac{1}{2m\mu}(d'-1)(\mu+1)}$ with arbitrarily small $\varepsilon'' > 0$ because the support of the first element is small enough and in the second element one can take $T_2 = (h_2\varepsilon''')^{-1}$ with arbitrarily small $\varepsilon''' > 0$ in the Tauberian arguments.

Remark 12.2.18. The only element of these arguments which is not completely standard is that we apply the propagation results derived from the theory of operators with the operator-valued symbols to Weyl asymptotics.

This approach will be heavily used in forthcoming sections and chapters.

Then we obtain the following asymptotics

$$\begin{aligned}(12.2.90)\quad \mathsf{N}^-(\tau) = \int \phi\big(\frac{x'}{t_1}\big)\kappa_j(x)\tau^{\frac{d}{2m}}\,dx + \\ \int \big(1-\phi\big(\frac{x'}{t_1}\big)\big)\big(\kappa_0(x)-\kappa_0^0(x)\big)\tau^{\frac{d}{2m}}\,dx + \\ \int \big(1-\phi\big(\frac{x'}{t_1}\big)\big)\,\mathsf{tr}\big(e^0(x,x,\tau)\big)\,dx + o\big(\tau^{\frac{1}{2m\mu}(d'-1)(\mu+1)}\big);\end{aligned}$$

here we have dropped all terms with $j = 1$ in (12.2.88). Here as above t_1 is either a large enough constant or a slowly increasing function of τ.

(iv) If one replaces t_1 by $t_1' \ge t_1$ in (12.2.88)–(12.2.90) then the left-hand expression does not change, and in order to estimate the increment of the right-hand expression one can apply one of estimates (12.2.82)–(12.2.84) for

R_1. Then one can easily see that for $t_1' \le \tau^\delta$ with a small enough exponent $\delta > 0$ this increment does not exceed the remainder estimate and therefore in (i)–(iii) one can formulate the condition of slow growth of t_1 more exactly: $t_1 \le \tau^\delta$. We leave the details and the calculation of this exponent $\delta > 0$ to the reader.

(v) One could apply formula (12.2.82) for $|x'| \le 2t_2$ and formula (12.2.85) for $t_2 \le |x'| \le c_0\tau^{\frac{1}{2m\mu}}$ where t_2 is now less than $c_0\tau^{\frac{1}{2m\mu}}$. Therefore the following formula holds:

$$\mathsf{N}^-(\tau) = \sum_{0\le j\le J} \int \phi\bigl(\frac{x'}{t_2}\bigr)\kappa_j(x)\tau^{\frac{1}{2m}(d-j)}\,dx + \sum_{1\le j\le J}\int_{\partial X} \phi\bigl(\frac{x'}{t_2}\bigr)\tilde{\kappa}_j(x)\tau^{\frac{1}{2m}(d-j)}\,dS + \int \bigl(1-\phi\bigl(\frac{x'}{t_2}\bigr)\bigr)e^0(x,x,\tau)\,dx + O(R^* + R_2) \tag{12.2.91}$$

with some remainder estimate expression $R_2 = R_{2,J}(\tau, t_2)$. Taking $t_2 = t_{2,J}(\tau)$ as providing the best possible estimate one can obtain certain asymptotics, maybe with worse remainder estimates. Improvements in the spirit of (ii) and (iii) are possible.

(vi) Let us pick two cases in which the formulas based on (12.2.85)–(12.2.87) and (12.2.82)–(12.2.84) well match and in (12.2.91) we can take $J = 2$ and $t_2 = c_0\tau^{\frac{1}{2m\mu}}$ and the same remainder estimate as in formulas (12.2.88)–(12.2.90). This is the case when $\kappa_j^0 = \kappa_j$ $(j = 0, 1)$, $\tilde{\kappa}_1^0 = \tilde{\kappa}_1$. And these equalities surely hold in the following cases:

(a) A and A^0 differ only in lower order terms. The only coefficient in the Weyl formula depending on lower order terms is κ_1 but even this coefficient surely does not depend on lower order terms because A is a differential operator of even order; moreover, this coefficient vanishes provided the principal symbol a is not only Hermitian but also real-valued (in which case it is symmetric).

(b) The principal symbol of A can be obtained from the principal symbol of A^0 by the transformation $\xi' \to \xi' - T(x, \xi'')$ with scalar function $T(x, \xi'')$ linear in ξ''. In fact, under the completely Weyl procedure this transform surely preserves κ_0, κ_1 and some part of κ_1 which does not depend on the lower order terms; however, the other part surely vanishes.

Simplifying the Answer

Now let us consider the term

$$\int \bigl(1-\phi(\frac{x'}{t})\bigr)\,\mathsf{tr}\bigl(e^0(x,x,\tau)\bigr)\,dx \tag{12.2.92}$$

with $t \ge c_0$ and apply Theorems 12.2.6–12.2.8. Then the remainder estimate is preserved.

Moreover, applying Theorem 12.2.7 one can replace the non-periodicity condition to billiards (which is now unnatural because it is associated with the operator A^0 in the truncated domain X^1) with the condition "$t \to +\infty$ as $\tau \to +\infty$". Let us investigate when the formulae for (12.2.92) associated with A^0 are simpler than in the general case.

(i) Let the principal operator-valued symbol of A^0 [12)] be of the form

$$a^0(x',\xi') = \sigma(x')^{-2m} a_\infty(x'', \sigma(x')\xi'; D'') \tag{12.2.93}$$

in which case the answer is

$$(2\pi)^{-d'} \iint \bigl(1-\phi(\frac{x'}{t})\bigr)\, n_\infty(\xi', \tau\sigma(x')^{2m})\sigma(x')^{d'}\, dx'd\xi' \tag{12.2.94}$$

where $n_\infty(\xi',\tau)$ is the eigenvalue counting function for the operator $a(\xi'; x'', D'')$ in $\mathbb{H} = \mathscr{L}^2(Y,\mathbb{K})$. In this case the final answer uses the eigenvalue counting function for the operator family depending only on ξ'.

Moreover, one can consider the case when a_∞ depends on $x'|x'|^{-1}$.

(ii) On the other hand, let the principal operator-valued symbol of A^0 [12)]

$$a^0(x',\xi') = \sigma(x')^{-2m} F(x', \sigma(x')\xi'; \Lambda(x')) \tag{12.2.95}$$

where $\Lambda = \Lambda(x'; x'', D'')$ is a self-adjoint operator in $\mathbb{H}$ (an elliptic differential operator of order $2m$ with Dirichlet boundary conditions) and $F(x',\xi',\lambda)$ is a monotone increasing function of λ.

Then the answer is

$$(2\pi)^{-d'} \iint \nu\bigl(x', f(x',\xi',\tau\sigma(x')^{2m})\bigr)\sigma(x')^{-d'}\, dx'd\xi' \tag{12.2.96}$$

where $\nu(x',\lambda)$ is the eigenvalue counting function for $\Lambda(x')$ and $\lambda = f(x',\xi',\tau)$ is solution of the equation $F(x',\xi',\lambda) = \tau$.

[12)] After mapping the cusp to the cylinder.

(iii) In particular, let $m = 1$ and let the principal operator-valued symbol of $A^{0\,12)}$ be

$$a^0(x', \xi') = b(x', \xi') + \sigma(x')^{-2}\Lambda(x'; x'', D'') \tag{12.2.97}$$

where $b(x', \xi') = \sum_{jk} b_{jk}(x')\xi'_j\xi'_k$ is a positive scalar quadratic form in ξ'. Then the final answer is

(12.2.98)
$$\frac{1}{2}(2\pi)^{-d'} d'\omega_{d'} \iint \nu(x', \lambda)\sigma(x')^{-d'}\beta(x')^{-\frac{1}{2}}\big(\tau\sigma(x')^2 - \lambda\big)_+^{\frac{1}{2}(d'-2)}\, d\lambda dx'$$

where $\beta(x')$ is the determinant of the matrix of the quadratic form $b(x', .)$.

Main Results

Let us formulate the principal theorems proved in this section. They are due to the results above. Moreover, we need to assume only that A^0 is a symmetric operator given in the cusp and we should not assume that A^0 is self-adjoint. Indeed, otherwise it could be replaced by $\frac{1}{2}(\mathcal{A} + \mathcal{A}^*)$ with

$$\mathcal{A} = \phi\big(\frac{x'}{t_0}\big)A + \big(1 - \phi\big(\frac{x'}{t_0}\big)\big)A^0.$$

Then we obtain the following statements:

Theorem 12.2.19. *(i) Let conditions* (12.2.1)–(12.2.11) *and stabilization conditions* (12.2.68), (12.2.69) *be fulfilled. Further, let microhyperbolicity condition for* $a(x', \xi')$ *be fulfilled*[6)]*.*

Then asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}_1(\tau) + O\big(R^*(\tau) + \tau^{\frac{1}{2m\mu}(d'(\mu+1)-\nu)}\big) \tag{12.2.99}$$

holds where $R^*(\tau)$ *is given by* (12.2.41) *and*

(12.2.100) $\mathcal{N}_1(\tau) =$

$$\sum_{j=0,1}\int \phi\big(\frac{x'}{t_1}\big)\kappa_j(x)\tau^{\frac{1}{2m}(d-j)}\, dx + \int_{\partial X}\phi\big(\frac{x'}{t_1}\big)\tilde{\kappa}_1(x)\tau^{\frac{1}{2m}(d-1)}\, dS +$$

$$\sum_{j=0,1}\int \big(1 - \phi\big(\frac{x'}{t_1}\big)\big)\big(\kappa_j(x) - \kappa_j^0(x)\big)\tau^{\frac{1}{2m}(d-j)}\, dx +$$

$$\int_{\partial X}\phi\big(\frac{x'}{t_1}\big)\big(\tilde{\kappa}_1(x) - \tilde{\kappa}_1^0(x)\big)\tau^{\frac{1}{2m}(d-1)}\, dS +$$

$$(2\pi)^{-d'}\iint \big(1 - \phi\big(\frac{x'}{t_1}\big)\big)\boldsymbol{n}^0(x', \xi', \tau)\, dx' d\xi'$$

where n^0 *is the eigenvalue counting function for* $\mathsf{a}^0(x',\xi';x'',D'')$ *in* $\mathbb{H}$, ϕ *is introduced above,* $c_0 \le t_1 \le \tau^\delta$ *with a small enough exponent* $\delta > 0$.

Moreover, (12.2.44) *remains true for* $\mathcal{N}_1(\tau)$.

(ii) Further, let $d' < 1 + \mu d''$, $\nu > d' - \mu(d''-1)$ [13]. *Moreover, let the standard non-periodicity condition be fulfilled for the Hamiltonian billiards of* $\mathsf{a}(x',\xi')$.

Then asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}_1(\tau) + o\bigl(\tau^{\frac{d-1}{2m}}\bigr) \tag{12.2.101}$$

holds as $\tau \to +\infty$ *provided* $t_1 = t_1(\tau) \to +\infty$ *(we still assume that* $t_1 \le \tau^\delta$*).*

(iii) On the other hand, let $d' > 1 + \mu d''$, $\nu > \mu + 1$ [14] *Moreover, let stabilization conditions* $(12.2.49)_{1,2}$ *and condition* (12.2.51) *be fulfilled* [15].

Then the asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}_1(\tau) + \varkappa_1^*\tau^{\frac{1}{2m\mu}(d'-1)(\mu+1)} + o\bigl(\tau^{\frac{1}{2m\mu}(d'-1)(\mu+1)}\bigr) \tag{12.2.102}$$

holds with the coefficient $\varkappa_1^*$ *given in Remark 4.4.13.*

We leave to the reader the following series of rather easy problems:

Problem 12.2.20. Derive miscellaneous results in the spirit of (12.2.91) (it would be better to take $J = 2$ because we do not know nice formulas for κ_j, $\tilde\kappa_j$ with $j \ge 2$):

(i) Consider cases when σ and η are not purely power functions (for example, if these functions contain logarithmic factors), which is significant for the orders of the principal part of asymptotics and remainder estimate only for $d' \ge \mu d''$, $d' \ge 1 + \mu d''$ respectively.

(ii) Consider slowly shrinking cusps with f.e. with $\sigma \asymp \log^{-\nu}|x'|$.

---

[13] Then the remainder estimate in (12.2.99) is $O\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$.

[14] Then the remainder estimate in (12.2.99) is $O\bigl(\tau^{\frac{1}{2m\mu}(d'-1)(\mu+1)}\bigr)$.

[15] In these conditions $a_{\infty,\alpha}$ should not necessarily coincide with the coefficients in (12.2.68) and in the definition of $\mathcal{N}_1$ as here we need only "$o(.)$" in the right-hand expression.

(iii) Formulate and prove all results of this section for a domain with more than one cusp (with different characteristics)

$$X = X_0 \cup X_{\mathsf{cusp}(1)} \cup ... \cup X_{\mathsf{cusp}(N)}, \qquad X_{\mathsf{cusp}(j)} \cap X_{\mathsf{cusp}(k)} = \emptyset \text{ as } \ 0 < j < k.$$

This problem is trivial even if the dimensions of these cusps (d'_j) and the exponents of shrinking (μ_j) differ. We only note that in some situations the bounded part of the domain and even some cusps can be ignored in the final answer).

(iv) Derive asymptotics for the Riesz means. We mention only that $R^*_{(\vartheta)}(\tau)$ in this case is defined by (12.2.55) and the additional error due to perturbation is $O\big(R^*_{(\vartheta)}(\tau) + \tau^{\frac{1}{2m\mu}(d'(\mu+1)-\nu)+\vartheta}\big)$ and so the remainder estimate is $O(R^*_{(\vartheta)})$ provided $\nu \ge \min\big((\mu+1)(1+\vartheta), d' - d''\mu + (1+\vartheta)\mu\big)$.

Further, we leave to the reader the following series of problems:

Problem 12.2.21. (i) Generalize to the cases of mixed boundary conditions which are Dirichlet for $|x'| \ge c$, or Dirichlet on the upper boundary of the cusp and Neumann on the lower boundary of the cusp for $|x'| \ge c$ and $d'' = 1$.

Further, consider generalizations for $d'' \ge 2$. Domain must satisfy cone condition which does not contradict shrinking as cone is truncated by the part of the boundary on which Dirichlet condition is imposed.

(ii) Consider more general boundary conditions under assumptions that all the eigenvalues of $\boldsymbol{a}(x', \xi')$ including the lowest ones have the same power growth at infinity. This is rather difficult and interesting modification as we cannot apply results of Chapter 2 directly because $\mathfrak{D}(\boldsymbol{a}(x', \xi')$ depends on (x', ξ').

Probably, the easiest way to overcome this obstacle would be to introduce an unitary operator $Q(x', \xi')$ in $\mathbb{H}$ such that $Q(x', \xi')\, \mathfrak{D}(\boldsymbol{a}(x', \xi')$ does not depend on (x', ξ').

(iii) Derive more precise remainder estimates in the framework of Theorem 12.2.7 as Hamiltonian flow associated with $a(x, \xi)$ is of power or exponential non-periodic type.

(iv) Derive more precise remainder estimate in the frameworks of Theorem 12.2.8 and Example 12.2.9 assuming that the Hamiltonian flow associated with $\zeta(x',\xi')$ is of power or exponential non-periodic type; in particular, consider Schrödinger operator in Euclidean metrics in domains of with $\sigma(x') = |x|^{-\mu}$, $\mu > 0$, $\mu \neq 1$ (with appropriate d' and d'').

(v) In the frameworks of Theorem 12.2.8 and Example 12.2.9 investigate the case when the Hamiltonian flow associated with $\zeta(x',\xi')$ is periodic; in particular, consider Schrödinger operator in Euclidean metrics in domains of with $\sigma(x') = |x|^{-1}$ (with appropriate d' and d'').

(vi) Consider combs and trees as in Examples 11.2.25 and 11.2.26 respectively, but thicker than there.

Remark 12.2.22. If we wish to improve the remainder estimate in the final theorem in the case when the stabilization exponent ν is not large enough then the following algorithm is suggested. In the domain $|x'| \le t$ we apply the previous analysis. So we need to treat

$$\int \psi(x')\,\mathsf{tr}(e^{\theta}(x',\xi',\tau))\,dx'd\xi'$$

with $\theta = 1$ and a γ-admissible function ψ supported in $B(\bar{x}',\bar{\gamma})$ (and later sum on a partition of unity in the zone $|x| \ge t_2$). This expression is smooth with respect to θ because of the microhyperbolicity property.

Then one can apply Taylor's formula with N terms. The remainder estimate is $O\big(\bar{\gamma}^{d'}\bar{\sigma}^{d''}\bar{\eta}^{N}\tau^{d'}\big)$ (for $|\bar{x}''| \le \tau^{\frac{1}{2m\mu}}$) and after summation on the partition of unity we obtain $O\big(R^*(\tau) + R_3(t_2,\tau)\big)$ with R_3 depending on N and ν.

So, the total remainder estimate is $O\big(R^*(\tau) + R_2(\tau,t_2) + R_3(\tau,t_2)\big)$ where R_2 is an upper estimate for R_2. Picking $t_2 = t_2(\tau)$ as providing the best possible remainder estimate we obtain the final formula. However, this formula is rather complicated even in the Case (iii) of the previous Subsubsection 12.2.3.2. Namely, the additional term with $n = 1$ in the Taylor expansion is

$$\mathsf{const}\iint \big(\tau\sigma(x')^{2m} - \lambda\big)^{\frac{d-2}{2}}\, d_\lambda\big(\mathsf{tr}(a'E(\lambda))\big)_+\, dx' \tag{12.2.103}$$

provided $a(x,D) - a^0(x,D) = a'(x,D'')$ where $E(\lambda)$ is the spectral projector for Λ in $\mathbb{H}$, and this term is slightly more complicated for more general perturbations.

However, the next terms (with $n \ge 2$) are very complicated. Still if we know that a_α and σ can be decomposed into cut-off series of positive homogeneous terms (modulo terms decaying fast enough) we can find that these complicated terms in $\mathcal{N}(\tau)$ are of the power (may be multiplied by a logarithm) type.

We leave this task to the reader as well as the generalization to the Riesz means.

It would be very interesting and under certain assumptions not very difficult to

Problem 12.2.23. Consider cusps with Z of more general type than here:

(i) for example, let Z be an open cone in $\mathbb{R}^{d'}$, $Z_0 = Z \times \{0\} \subset \mathbb{R}^d$ with the smooth boundary and

$$\sigma(x') \le \langle x' \rangle^{-\mu} \ \mu > 0, \tag{12.2.104}$$

$$|D^{\beta'}\sigma| \le c\sigma\gamma^{-|\beta'|} \quad \forall \beta' : |\beta'| \le K \tag{12.2.105}$$

with

$$\gamma = \operatorname{dist}(x', \partial Z) \tag{12.2.106}$$

Then provided

$$\int \sigma^{d''}\gamma^{-1}\,dx' \le C|x'|^{-\mu d''+d'-1}. \tag{12.2.107}$$

we can recover the same remainder estimate as for $Z = \mathbb{R}^{d''}$.

(ii) Alternatively $\sigma \asymp \langle x' \rangle^{-\mu}$ but near ∂Z a rounding up of the radius $\asymp \sigma$ is added. Then (12.2.107) holds with the logarithmic factor in the right-hand expression and we can recover almost the same remainder estimate as in (i)–with $R^*_{(\vartheta)}(\tau)$ replaced by $R^*_{(\vartheta)}(\tau)\log\tau$.

(iii) In (i) and (ii) consider quasiconical base Z.

12.3 Operators with Degenerate Potentials Growing at Infinity

12.3.1 Problem Set-up

Let us start from

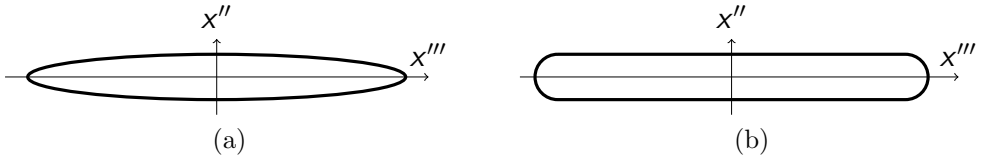

Figure 12.3: As $x' = (x_1, x'')$ we show cross-section with $x_1 = \mathsf{const}$ of the cusp from (i) on (a) and from (ii) on (b)

Example 12.3.1. Consider self-adjoint (matrix) operator on $\mathbb{R}^d$

$$A = \sum_{\alpha:|\alpha|\le 2m} a_\alpha(x) D^\alpha \tag{12.3.1}$$

(possibly in the divergent form) with coefficients such that

$$|D^\beta a_\alpha| \le c\langle x\rangle^{(2m-|\alpha|)\mu-|\beta|} \qquad \forall \beta : |\beta| \le K \tag{12.3.2}$$

with $\mu > 0$.

As usual we assume that operator is elliptic and positive

$$a^0(x,\xi) = \sum_{\alpha:|\alpha|=2m} a_\alpha(x)\xi^\alpha \ge \epsilon_0 |\xi|^{2m} \tag{12.3.3}$$

and that A is a perturbation of operator $A_{(0)}$ with the coefficients $a_{\alpha(0)}(x)$ such that for $j = 0$

$$D^\beta a_{\alpha(j)}|_\Lambda = 0 \qquad \mathsf{as} \qquad |\beta| < (2m - |\alpha|)\nu - j \tag{12.3.4}$$

with $0 < \nu < \mu$ where $\nu \in \mathbb{Z}$ and

(12.3.5) Λ is a conic $\mathscr{C}^K$-manifold of codimension d'', $\zeta(x) = \mathsf{dist}(x, \Lambda)$

and

$$\sum_{\alpha:|\alpha|\le 2m} a_{\alpha,0}(x)\xi^\alpha \ge \epsilon_0 \big(|\xi|^2 + |x|^{2\mu-2\nu}\cdot \zeta(x)^{2\nu}\big)^m. \tag{12.3.6}$$

We will show that "admissible perturbations" are

$$a_\alpha(x) = \sum_{j\le (2m-|\alpha|)\nu} a_{\alpha(j)}(x) \tag{12.3.7}$$

where $a_{\alpha(j)}(x)$ satisfy (12.3.4) and also

$$|D^\beta a_{\alpha(j)}| \le c\langle x\rangle^{(2m-|\alpha|)\mu-|\beta|-(\mu+1)(\nu+1)^{-1}j} \tag{12.3.8}$$

and also condition (12.3.19) below.

Without any loss of the generality we can assume that (at least locally) $\Lambda = \{x : x'' = 0\}$. Then we need to introduce

$$\zeta(x) = \frac{1}{2}|x''|, \qquad \gamma(x) = \frac{1}{2}|x'|, \qquad \rho(x) = \zeta(x)^\nu \cdot |x'|^{\mu-\nu} \tag{12.3.9}$$

scales with respect to x'', x' and ξ respectively.

One can consider more general operators. Assume that $\nu \in (0,\mu)$ is not necessary integer anymore, ζ, γ and ρ are defined by (12.3.9), but ρ, ζ are then redefined by

$$\rho^*(x) = \max\bigl(\rho(x), \sigma_0(x')^{-1}\bigr), \qquad \zeta^*(x) = \max\bigl(\frac{1}{2}|x''|, \sigma_0(x')\bigr) \tag{12.3.10}$$

with

$$\sigma_0(x') \coloneqq c_0\langle x'\rangle^{-(\mu-\nu)/(\nu+1)}. \tag{12.3.11}$$

Assume that

$$|D^\beta a_\alpha| \le C{\rho^*}^{2m-|\alpha|}\gamma^{-|\beta'|}{\zeta^*}^{-|\beta''|}. \tag{12.3.12}$$

Potential surfaces are shown on figure 12.4.

Consider this operator first in the framework of the theory of Section 11.5; after scaling $x_{\mathsf{new}} = x/\sigma$, $\xi_{\mathsf{new}} = \tau^{-1/(2m)}\xi$ we conclude that operator $\tau^{-1}A$ is elliptic on the energy levels 1 and below provided

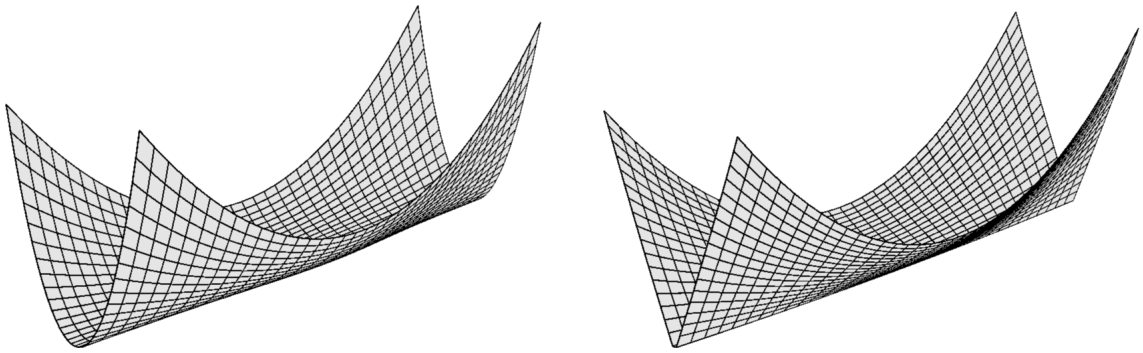
$$|x''| \ge \sigma(x',\tau) \coloneqq c_0|x'|^{-(\mu-\nu)/\nu}\tau^{1/(2m\nu)}, \tag{12.3.13}$$

(we assume that $\tau \gg 1$, $|x'| \gg |x''|$ and $|x'| \gg 1$) and the uncertainty principle $\rho(x)\zeta(x) \ge 1$ is fulfilled provided

$$|x''| \ge \sigma_0(x') \coloneqq c_0\langle x'\rangle^{-(\mu-\nu)/(\nu+1)} \tag{12.3.14}$$

as in (12.3.11).

Then we arrive immediately to the following



(a) Valley with smooth bottom (b) Valley with non-smooth bottom

Figure 12.4: Potential graphs

Proposition 12.3.2. *Let conditions* (12.3.1), (12.3.3), (12.3.6) *and* (12.3.9)–(12.3.12) *be fulfilled at the point* $\bar{x} \in \mathbb{R}^d$.

(i) Then

$$|e(x,y,\tau)| \le C\langle x\rangle^{(\mu-\nu)d/(\nu+1)}\zeta(x)^{-s}\sigma^s(x',\tau) \qquad \forall x,y \in B\bigl(\bar{x}, \frac{1}{2}\zeta(\bar{x})\bigr) \tag{12.3.15}$$

with an arbitrarily large exponent s.

(ii) Moreover, if $U(x,y,t)$ *is the Schwartz kernel of the operator* $\tau^{-1}A$ *then*

$$\bigl|F_{t\to\lambda}\bar{\chi}_{T,T'}(t)U(x,y,t)\bigr| \le C\langle x\rangle^{(\mu-\nu)d/(\nu+1)}\zeta(x)^{-s}\sigma(x',\tau)^s \qquad \forall x,y \in B\bigl(\bar{x}, \frac{1}{2}\zeta(\bar{x})\bigr) \quad \forall T' \in \mathbb{R},\ T = \sigma(\bar{x}) \quad \forall \lambda \le 1+\epsilon \tag{12.3.16}$$

with a small enough constant $\epsilon > 0$.

Remark 12.3.3. Consider "valley" $\mathcal{X}(\tau) = \{x, |x''| \le \sigma(x',\tau)\}$. It consists of the *regular part* where $|x| \le c\tau^{1/(2m\mu)}$ and the *cusp* where $|x| \ge c\tau^{1/(2m\mu)}$; this cusp stretches along $Z = \{x, x'' = 0\}$ and shrinks at infinity (on $|x|$) for any $\tau > 0$.

Let us apply now the theory of operators with the operator-valued symbols (in rather limited manner at this time); to do this we need to analyze operator $\mathsf{a}(x',\xi') = A(x',\xi';x'',D'')$:

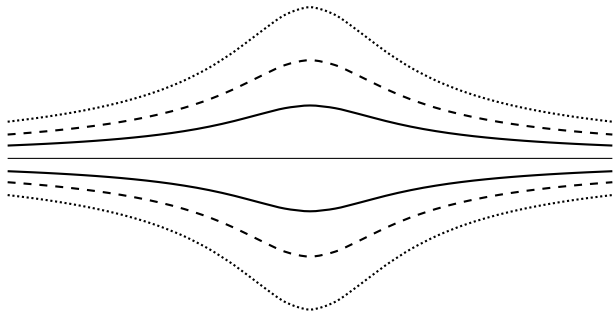


Figure 12.5: Cusps defined for different τ

Proposition 12.3.4. *Let conditions* (12.3.1), (12.3.3), (12.3.6) *and* (12.3.9)–(12.3.12) *be fulfilled. Let* $\lambda_k(x',\xi')$ *be eigenvalues of* $\mathsf{a}(x',\xi')$ *in* $\mathbb{H}=\mathscr{L}^2(\mathbb{R}^{d''})$. *Then*

$$|\lambda_k(x',\xi)| \le c_k\Big(|\xi'|+\frac{1}{\sigma_0(x')}\Big)^{2m} \tag{12.3.17}$$

and

$$\lambda_k(x',\xi') \ge \epsilon_0\Big(|\xi'|+\frac{1}{\sigma_0(x')}\Big)^{2m} \qquad \text{as} \quad k\ge \bar{k}. \tag{12.3.18}$$

where $\sigma_0(x')$ *is defined by* (12.3.11).

Proof. Scaling $x''\mapsto \sigma_0(x')^{-1}x''$, $D''\mapsto \sigma_0(x')D''$ we arrive to elliptic operator with a parameter in $\mathbb{R}^{d''}$ and both statements (12.3.17) and (12.3.18) are well-known. □

Finally we assume that

(12.3.19) Inequality (12.3.18) is fulfilled for all k.

Due to our assumptions $A(x',D';x'',D'')$ is elliptic as an operator with operator valued symbol on the energy level τ and below unless $|\xi'|\le c\tau^{\frac{1}{2m}}$ and $|x'|\le r^*(\tau)$ with

$$r^*(\tau) := c_0|\tau|^{(\nu+1)/2m(\mu-\nu)}. \tag{12.3.20}$$

Proposition 12.3.5. *Let conditions* (11.1.6), (11.1.8) *and* (12.3.1), (12.3.3), (12.3.6), (12.3.9)–(12.3.12) *and* (12.3.19) *be fulfilled. Then estimate*

$$|e(x,y,\tau)| \le C\langle x\rangle^{-s}\langle y\rangle^{-s}\tau^{-s} \qquad \forall x,y : |x| \ge r^*(\tau), |y| \ge r_*(\tau) \tag{12.3.21}$$

holds.

Proof. Our statement is due to Proposition 4.2.8 as we take

$$B_1 = \bigl(\Delta + |x''|^{2\nu}|x''|^{2(\mu-\nu)}\bigr)^m \tag{12.3.22}$$

where

$$\bigl(\Delta + |x''|^{2\nu}|x''|^{2(\mu-\nu)}\bigr) \ge \epsilon_0 |x'|^{2(\mu-\nu)/(\nu+1)} \tag{12.3.23}$$

in the operator sense. Recall that $\mathbb{H} = \mathscr{L}^2(\mathbb{R}^{d''}, \mathbb{K})$, $\mathbb{K} = \mathbb{C}^{\mathsf{D}}$. □

Remark 12.3.6. (i) $\sigma_0(x') \lesssim \sigma(x',\tau)$ if and only if $|x'| \lesssim r^*(\tau)$.

(ii) Note that $\mathsf{mes}\bigl(\mathcal{X}(\tau)\bigr) = O(\tau^{d/(2m\mu)})$ if and only if $\mu d'' > \nu d$. Under this condition the principal part of the Weyl formula is $\asymp \tau^{\frac{1}{2m\mu}d(\mu+1)}$.

(iii) Let us drop condition $\mu d'' > \nu d'$ and let us restrict integration to domain $\{x, |x| \le r^*(\tau)\}$ in the Weyl formula due Proposition 12.3.5. Then the principal part of the Weyl asymptotics (modified in this way) is

$$\asymp \begin{cases} |\tau|^{d(\mu+1)/(2m\mu)} & \text{for } d\dfrac{\nu}{\mu} < d'', \\ |\tau|^{d(\mu+1)/(2m\mu)}|\log|\tau|| & \text{for } d\dfrac{\nu}{\mu} = d'', \\ |\tau|^{d'(\mu+1)/2m(\mu-\nu)} & \text{for } d\dfrac{\nu}{\mu} > d''. \end{cases} \tag{12.3.24}$$

where in this section we can replace $|\tau|$ by τ and $|\log\tau|$ by $\log\tau$.

(iv) Let us consider the remainder estimate in the Weyl formula. We can integrate only over domain $\{x, |x| \le r^*(\tau)\}$ because of Proposition 12.3.5. Then the remainder estimate in the modified Weyl asymptotics is $O\bigl(R(\tau)\bigr)$ with

(12.3.25) $R(\tau) =$

$$\begin{cases} |\tau|^{(d-1)(\mu+1)/(2m\mu)} & \text{for } (d-1)\dfrac{\nu}{\mu} < (d''-1), \\ |\tau|^{(d-1)(\mu+1)/(2m\mu)}|\log|\tau|| & \text{for } (d-1)\dfrac{\nu}{\mu} = (d''-1), \\ |\tau|^{d'(\mu+1)/2m(\mu-\nu)} & \text{for } (d-1)\dfrac{\nu}{\mu} > (d''-1). \end{cases}$$

(v) Let $\mu(d''-1) > \nu(d-1)$. Then under standard stabilization conditions of a_α as $|x| \to \infty$ to positively homogeneous $a_{\infty,\alpha}$ and standard restrictions to the Hamiltonian flow generated by the corresponding Hamiltonian $a_\infty(x,\xi)$ one can obtain the remainder estimate $o(\tau^{\frac{1}{2m\mu}(d-1)(\mu+1)})$.

In this remark the role of the "operator-valued theory" is very limited: it only provides a nice cut-off in the Weyl formulas.

We leave to the reader the following easy

Problem 12.3.7. Calculate the principal part of the asymptotics and remainder estimate for Riesz means in Remark 12.3.6.

12.3.2 Sharp Asymptotics

So, as we are interested in the asymptotics of $\mathsf{N}^-(\tau)$ and remainder estimate (12.3.25) is sharp as $(d-1)\nu/\mu < (d''-1)$, our analysis should be done as

$$\mu(d''-1) \le \nu(d-1). \tag{12.3.26}$$

Here we should treat only the cusp zone

$$\mathcal{X}_{\mathsf{cusp}}(\tau) = \bigl\{c_1\tau^{\frac{1}{2m}} := r_*(\tau) \le |x'| \le r^*(\tau),\ |x''| \le c_2\sigma(x',\tau)\tau^{\delta}\bigr\} \tag{12.3.27}$$

with $r^*(\tau)$ and $\sigma(x',\tau)$ defined by (12.3.20) and (12.3.13) and an arbitrarily small exponent $\delta > 0$.

In fact, estimate (12.3.15) and Proposition 12.3.5 yield that for $|x'| \ge c_1\tau^{\frac{1}{2m\mu}}$ outside of $\mathcal{X}(\tau)$ function $e(x,x,\tau)$ is negligible; on the other hand, we have

Proposition 12.3.8. *(i) Contribution of the regular zone*

$$\mathcal{X}_{\mathsf{reg}}(\tau) = \{x,\ |x'| \le cr_*(\tau)\} \tag{12.3.28}$$

(with arbitrarily large constant c) to the principal part of the Weyl asymptotics and to the remainder estimate are $O\bigl(\tau^{\frac{d(\mu+1)}{2m\mu}}\bigr)$ and $O\bigl(\tau^{\frac{(d-1)(\mu+1)}{2m\mu}}\bigr)$ respectively[16].

(ii) Moreover, under standard stabilization condition (11.5.4) *to quasihomogeneous symbol $a_\infty(x,\xi)$ and the standard non-periodicity condition to the Hamiltonian flow generated by symbol $a_\infty(x,\xi)$ the contribution of the zone $\mathcal{X}_{\mathsf{reg}}(\tau)$ to the remainder estimate is $o\bigl(\tau^{\frac{1}{2m\mu}(d-1)(\mu+1)}\bigr)$.*

Proof. The proof is absolutely standard in the framework of Section 11.5.

To deal with the possible irregularity near $\{x''=0\}$ note that in the zone $\bigl\{x:\ |x'|\le cr_*(\tau),\ |x''|\le \epsilon r_*(\tau)\bigr\}$ with sufficiently small constant $\varepsilon>0$ operator $\tau^{-1}A$ after rescaling is ξ-microhyperbolic on the energy level 1 and $h_{\mathsf{eff}}=\tau^{-1/(2m)}\zeta^{*-1}\le \tau^{-\delta''}$ with $\delta''>0$; so propagation theory of Chapter 2 works. □

Furthermore, the same arguments yield that treating zone $\bigl\{|x'|\le c_0 r^*(\tau)\tau^{-\delta'}\bigr\}$ with an arbitrarily small exponent $\delta'>0$ one can set $\delta=0$ in the definition of $\mathcal{X}(\tau)$; in this case constant c_2 should be large enough.

To treat the cusp zone (12.3.27) let us apply theory of Section 4.4. For this we need to check if operator in question is (x',ξ') microhyperbolic on the energy level τ in (γ,ρ_τ)-scale with $\gamma(x')=\frac12|x'|$ and $\rho_\tau=\tau^{1/2m}$.

Consider first the pilot-model operator with the coefficients

$$a_{\alpha(j)}(x)=\sum_{\beta:|\beta|=(2m-|\alpha|)\nu-j} b_{\alpha,\beta}(x')x''^{\beta} \tag{12.3.29}$$

where

(12.3.30) Coefficients $b_{\alpha,\beta}(x')$ in the decompositions (12.3.29) are positively homogeneous of degrees $(\mu-\nu)\bigl(2m-|\alpha|-j(\nu+1)^{-1}\bigr)$

which is fulfilled as we take terms with $|\beta|=(2m-|\alpha|)\nu-j$ of Taylor decomposition of $a_{\alpha(j)}(x)$ provided

(12.3.31) Coefficients $a_{\alpha(j)}(x)$ are positively homogeneous of degrees $(2m-|\alpha|)-(\mu+1)(\nu+1)^{-1}j$.

[16] Subject to conditions of Section 11.5. For example, as either operator is the Schrödinger operator or its perturbed power or stabilization condition (11.5.4) is fulfilled.

Then rescaling $x'' \mapsto x''\sigma_0(x')$, $D'' \mapsto D''\sigma_0^{-1}(x')$ we arrive to operator

$$\mathsf{a}(x', D') = \sum_{\alpha':|\alpha'|\le 2m} \mathsf{a}_{\alpha'}(x') D'^{\alpha'} \tag{12.3.32}$$

where operator coefficients $\mathsf{a}_{\alpha'}(x') = \mathsf{a}_{\alpha'}(x'; x'', D'')$ are positively homogeneous of degrees $(2m - |\alpha|)(\mu - \nu)(\nu + 1)^{-1}$.

Therefore under assumption (12.3.29)–(12.3.30) microhyperbolicity condition is fulfilled. Then this condition is fulfilled under assumption (12.3.31) as well and therefore we arrive to the Statement (i) of Proposition 12.3.9 below; Statement (ii) follows from the similar arguments.

Proposition 12.3.9. *(i) In the framework of Example 12.3.1 operator* $\mathsf{a}(x', D')$ *is* (x', ξ')*-microhyperbolic under stabilization condition*

$$D^{\beta}\big(\mathsf{a}_{\alpha(j)} - \mathsf{a}^{\infty}_{\alpha(j)}\big) = o\big(|x'|^{(2m-|\alpha|)\mu - |\beta| - (\mu+1)(\nu+1)^{-1}j}\big) \tag{12.3.33}$$
$$\text{as } \ |x'| \to \infty, x'' = 0, |\beta| \le (2m - |\alpha|)\nu + 1$$

(ii) In the general case operator $\mathsf{a}(x', D')$ *is* (x', ξ')*-microhyperbolic under stabilization condition*

$$D^{\beta}_{x'}\big(\mathsf{a}_{\alpha} - \mathsf{a}^{\infty}_{\alpha}\big)(x', \sigma_0(x')y'') = o\big(|x'|^{(2m-|\alpha|)(\mu-\nu)/(\nu+1) - |\beta|}\big) \tag{12.3.34}$$
$$\text{as } \ |x'| \to \infty, |y''| \le c_3, |\beta| \le 1.$$

We leave to the reader the following easy

Problem 12.3.10. Establish other conditions providing (x', ξ')-microhyperbolicity of $\mathsf{a}(x', D')$.

So, assume that microhyperbolicity condition is fulfilled. Then (after all rescalings) one can take

$$B = B_1 = \theta\big(\Delta + \langle x''\rangle^{2\nu}\big)^m, \qquad \theta = \tau^{-1}\gamma^{2m(\mu-\nu)/(\nu+1)} \tag{12.3.35}$$

in $\mathscr{L}^2(\mathbb{R}^{d''})$.

We will need to take the trace norm; one can easily see that

(12.3.36) For $k > d''(\nu + 1)/(2m\nu)$ and $r_*(\tau) \le |x'| \le r^*(\tau)$ the trace norm of B^{-k} does not exceed $\theta^{-d''(\nu+1)/2m\nu}$ which in turn is equal to $\big(\gamma/r^*(\tau)\big)^{-d''(\mu-\nu)/\nu}$.

Then, applying Theorem 4.4.8 as this operator is ξ'-microhyperbolic and Theorem 4.4.9 as this operator is (x',ξ')-microhyperbolic (i.e. in the general case) we obtain that if $\psi=\psi(x')$ is a γ-admissible function supported in $\{|x'-\bar{x}'|\le \frac{1}{2}\bar{\gamma}\}$ with $\bar{\gamma}=\gamma(\bar{x})$ then

$$\Big|\int \psi(x')e(x,x,\tau)\,dx - (2\pi)^{-d'}\iint \psi(x')\boldsymbol{n}(x',\xi',\tau)\,dx'd\xi'\Big|\le \tag{12.3.37}$$
$$C\hbar^{1-d'}\big(\bar{\gamma}/r^*(\tau)\big)^{-d''(\mu-\nu)/\nu} = C\big(\tau^{1/(2m)}\bar{\gamma}\big)^{(d'-1)}\big(\bar{\gamma}/r^*(\tau)\big)^{-d''(\mu-\nu)/\nu}$$

where $\boldsymbol{n}(x',\xi',\tau)$ is the eigenvalue counting function for operator $\boldsymbol{a}(x',\xi')=\boldsymbol{a}(x',\xi';x'',D'')$ which is the operator-valued symbol of A (after a coordinate transform), $\hbar=\tau^{-1/(2m)}\bar{\gamma}^{-1}$.

Let us sum over a γ-admissible partition of unity in the zone

$$\big\{t_1 r_*(\tau)\le |x'|\le r^*(\tau)\big\}; \tag{12.3.38}$$

the right-hand expression then sums to

$$R^*(\tau)=\begin{cases} |\tau|^{(d-1)(\mu+1)/(2m\mu)} & \text{for } (d-1)\dfrac{\nu}{\mu}<d'',\\ |\tau|^{(d-1)(\mu+1)/(2m\mu)}|\log|\tau|| & \text{for } (d-1)\dfrac{\nu}{\mu}=d'',\\ |\tau|^{(d'-1)(\mu+1)/2m(\mu-\nu)} & \text{for } (d-1)\dfrac{\nu}{\mu}>d''.\end{cases} \tag{12.3.39}$$

Let us apply Weyl asymptotics in the regular zone $\{|x'|\le t_1\tau^{1/(2m\mu)}\}$. To ensure (x,ξ)-microhyperbolicity there we assume that the standard stabilization condition (11.5.4) is fulfilled[17].

Then we arrive to the following assertion

Theorem 12.3.11[18]**.** *Let conditions* (12.3.1), (12.3.3), (12.3.6), (12.3.9)–(12.3.12) *and stabilization conditions* (11.5.4)[16),17)], (12.3.34) *be fulfilled.*

Let $\psi\in \mathscr{C}_0^K(\mathbb{R}^{d'})$, $\psi(x')=1$ *as* $|x'|\le c_0$. *Then*

(i) Asymptotics

$$\mathsf{N}^-(\tau)=\mathcal{N}(\tau)+O\big(R^*(\tau)\big) \tag{12.3.40}$$

[17] But for some operators this condition may be weakened or skipped completely. Also the total contribution of the regular zone to the asymptotics may be smaller than the contribution of the cusp to the remainder estimate.

[18] Cf. Theorem 12.2.6.

holds with $\mathcal{N}(\tau)$ *defined by* (12.2.43) *with* $\psi_t(x') = \psi(x'/t)$ *where* $t \asymp r_*(\tau)$ [19] *and with* $R^*(\tau)$ *defined by* (12.3.39).

(ii) Moreover, $\mathcal{N}(\tau)$ *has a magnitude described in* (12.3.24).

Let us note that for $(d-1)\nu < d''\mu$ the main contribution to the remainder estimate is provided by the zone

$$\{x : \ |x'| \le t\tau^{\frac{1}{2m}}\} \tag{12.3.41}$$

with arbitrarily large t (the contribution of the complement does not exceed $\tau^{(d-1)(\mu+1)/(2m\mu)}t^{-\delta}$ with $\delta > 0$); on the other hand, in this zone under the standard non-periodicity condition to the Hamiltonian billiards we have the remainder estimate $o\bigl(\tau^{\frac{1}{2m}(d-1)}\bigr)$. Then applying improved Weyl asymptotics we arrive to the following assertion:

Theorem 12.3.12 [20]**.** *Let the conditions of Theorem 12.3.11 be fulfilled with* $(d-1)\nu < d''\mu$.

Moreover, let the standard stabilization condition to quasihomogeneous symbol $a_\infty(x,\xi)$ *and the standard non-periodicity condition to the Hamiltonian trajectories generated by* $a_\infty(x,\xi)$ *be fulfilled. Then asymptotics*

$$\mathsf{N}^-(\tau) = \mathcal{N}(\tau) + o\bigl(\tau^{\frac{1}{2m}(d-1)(m+1)}\bigr) \tag{12.3.42}$$

holds as $\tau \to +\infty$ *where* $\mathcal{N}(\tau)$ *is defined by* (12.2.46),

$$(2\pi)^{-d}\int \psi\kappa_1\tau^{\frac{1}{2m}(d-1)}\,dx \quad \text{and} \qquad (2\pi)^{1-d}\int_{\partial X} \psi\tilde{\kappa}_1\tau^{\frac{1}{2m}(d-1)}\,dS \tag{12.3.43}$$

are the standard second terms[21] *in the Weyl asymptotics,* $\psi_t(x') = \psi_0(x'/t)$ *where* $t = t(\tau)$ *is an appropriate function such that* $t(\tau)/r_*(\tau) \to +\infty$ *as* $\tau \to +\infty$ [22].

---

[19] One can assume that $t = t(\tau)$ and $t(\tau)/r_*(\tau)$ is either bounded or tends slowly to $+\infty$. Recall that $r_*(\tau) = \tau^{1/(2m\mu)}$.

[20] Cf. Theorem 12.2.7.

[21] We will discuss domains with the boundaries later.

[22] If $t(\tau)$ works then every function $t'(\tau) \le t(\tau)$ such that $t'(\tau)/r_*(\tau) \to +\infty$ as $\tau \to +\infty$ also works.

On the other hand, as $d' > 1 + d''\mu$, the main contribution to the remainder estimate in Theorem 12.3.11 is provided by the zone

$$\{\varepsilon r^*(\tau) \le |x'| \le c_0 r^*(\tau)\} \tag{12.3.44}$$

with arbitrarily small $\varepsilon > 0$; contribution of zone $\{|x'| \le 2\varepsilon r^*(\tau)\}$ does not exceed $\varepsilon^\delta R^*(\tau)$.

However, in zone (12.3.44) $\boldsymbol{n}(x', \xi', \tau)$ does not exceed $\nu(\varepsilon) = \varepsilon^M$ and therefore we have effectively here matrix- rather than operator-valued operators.

Applying Theorems 4.4.11 and 4.4.12 and replacing $\boldsymbol{a}$ if necessary by another operator $\boldsymbol{a}_\infty$ in $\mathbb{H}$ with eigenvalues asymptotically close to those of $\boldsymbol{a}$ we obtain the following statement:

Theorem 12.3.13 [23]**.** *Let the conditions of Theorem 12.3.11 be fulfilled with* $(d-1)\nu < d''\mu$.

Let us consider operator-valued symbol $\boldsymbol{a}_\infty(x', \xi'; D'')$ *in* $\mathbb{H}$*; let* $\lambda_j(x', \xi')$ *be its (non-decreasing) eigenvalues*[24]*. Let us consider*

$$\boldsymbol{a}_{\infty,j}(x', \xi') = \boldsymbol{a}_\infty(x', \xi')\boldsymbol{e}_\infty(x', \xi', \zeta_j(x', \xi')) \tag{12.3.45}$$

where $\boldsymbol{e}_\infty(x', \xi', \tau)$ *is the spectral projector for* $\boldsymbol{a}_\infty(x', \xi')$ *and let assume that non-periodicity condition* (12.2.51) *is fulfilled.*

Then asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}(\tau) + \bigl(\kappa_1^* + o(1)\bigr)\tau^{(d'-1)(\mu+1)/2m(\mu-\nu)} \tag{12.3.46}$$

holds as $\tau \to +\infty$ *with an appropriate coefficient* κ_1^* *(given in Remark 4.4.13).*

Condition (12.2.51) looks extremely cumbersome and impossible to check. However in the following rather special example this condition becomes much simpler:

Example 12.3.14 [25]. Let $d'' = 1$ and A be a Schrödinger operator stabilizing at infinity to $|\xi^2| + |x_d|^2 \cdot \omega(x')^2$ with ω, positively homogeneous of degree $2(\mu - \nu)$.

---

[23] Cf. Theorem 12.2.8.

[24] Then obviously $\lambda_j(tx', t^k\xi') = t^{2mk}\omega_j(x', \xi')$ with $k = (\mu - \nu)/(\nu + 1)$.

[25] Cf. Example 12.2.9.

Then one needs to check the standard non-periodicity condition for symbols $\lambda_j(x',\xi') = |\xi'|^2 + (2j-1)\omega(x')$ and all of them are equivalent to the same standard non-periodicity condition for a scalar symbol

$$\lambda(x,\xi) = |\xi|^2 + \omega(x')^{2/(\nu+1)} \tag{12.3.47}$$

(on the energy level 1). This conclusion holds as A is a Schrödinger operator stabilizing at infinity to $|\xi^2| + |x_d|^{2\nu}\cdot\omega(x')^2$.

In this case we need to check only check the standard non-periodicity condition for (12.3.47). Note that

(12.3.48) As $d' \ge 2$ the generic trajectory does not hit $0\times\mathbb{R}^{d'}$.

Really, $\mu(\Sigma\cap\{|x'|\le 2\varepsilon\}) = O(\varepsilon^{d'})$ where $\mu = dx'd\xi' : d\lambda$ is the standard measure on the surface $\Sigma = \{(x',\xi') : \lambda(x',\xi') = 1\}$ and any trajectory intersecting $\{|x'|\le\varepsilon\}$ needs at least $\epsilon_0\varepsilon$-time to leave $\{|x'|\le 2\varepsilon\}$; therefore the μ-measure of points such that Ψ_t touches $\{|x'|\le\varepsilon\}$ for some $t : |t|\le T$ does not exceed $CT\varepsilon^{d'-1}$.

In particular, the standard non-periodicity condition for $\lambda(x',\xi')$ is fulfilled as $\sigma\sim|x'|^{-\eta}$, $\eta>0$ and $\eta\ne 1$; recall that $d'\ge 2$.

Finally, let us consider the case $d' = 1 + d''\mu$. Considering diagonal operator with diagonal elements $\lambda_j^{\mathsf{w}}(x',D')$ one can prove easily the remainder estimate $o(\tau^{(d-1)/2m}\log\tau)$ (not subject to any non-periodicity condition). This leads us to conjecture which we were unable to prove

Conjecture 12.3.15 [26]**.** *As $(d-1)\nu = d''\mu$ remainder estimate is in fact $o(\tau^{(d-1)/(2m\mu)}\log\tau)$.*

We leave to the reader the following easy

Problem 12.3.16 [27]*.* Treat Riesz means and derive asymptotics with

$$R^*_{(\vartheta)}(\tau) = \begin{cases} |\tau|^{(d-1-\vartheta)(\mu+1)/(2m\mu)+\vartheta} & \text{for } (d-1-\vartheta)\dfrac{\nu}{\mu} < d'' \\ |\tau|^{(d-1-\vartheta)(\mu+1)/(2m\mu)+\vartheta}|\log|\tau|| & \text{for } (d-1-\vartheta)\dfrac{\nu}{\mu} = d'' \\ |\tau|^{(d'-1-\vartheta)(\mu+1)/2m(\mu-\nu)+\vartheta} & \text{for } (d-1-\vartheta)\dfrac{\nu}{\mu} > d'' \end{cases} \tag{12.3.49}$$

[26] Cf. Conjecture 12.2.10.

[27] Cf. Problem 12.2.11.

and in the analogs of Theorems 12.3.12 and 12.3.13 one should assume that $d' < \mu d'' + \vartheta + 1$, $d' > \mu d'' + \vartheta + 1$ respectively.

12.3.3 Effective Asymptotics

Simplifying the Answer

The main defect of Theorems 12.3.11–12.3.13 again is that the expression for $\mathcal{N}(\tau)$ is not effective and includes the eigenvalue counting function for the *family* of auxiliary operators $A(x', \xi')$. Exactly like in the previous Section 12.2 we would like to derive a formula including the eigenvalue counting function for *one* auxiliary operator or at least for a family of auxiliary operators with a smaller number of parameters; however in contrast to the previous section we want also to simplify these axillary operators.

Again, let us start with a more accurate Weyl analysis. Repeating arguments of the Subsection 12.2.3 one can easily prove in the framework of Example 12.3.1 the following estimate similar to (12.2.67):

$$\Big|\int \psi(x')\big(\mathsf{tr}(e(x,x,\tau)) - \sum_{0\le j\le J-1} \kappa_j(x,\tau)\big)\Big|_{\tau=\tau'}^{\tau=\tau}\, dx\Big| \le C\bar\gamma^{d'-1-\frac{\mu d''}{\nu}}\tau^{\frac{d-1}{2m}+\frac{d''}{2m\nu}} + C\tau^{\frac{d-J}{2m}}\bar\sigma^{d''-J}\bar\gamma^{d'} \tag{12.3.50}$$

where $\psi = \psi(x')$ is γ-admissible and supported in $B\big(\bar x', \frac12\bar\gamma\big)$, $r_*(\tau) \le \bar\gamma = |\bar x'| \le r^*(\tau)$, $\tau' \in [\epsilon\tau, \tau)$, $\bar\sigma = \bar\gamma^{-(\mu-\nu)/\nu}\tau^{1/(2m\nu)}$ and the Weyl coefficients κ_j (which now include also powers of effective semiclassical parameter) satisfy the inequalities

$$\Big|\int \psi(x')\kappa_j(x,\tau)\, dx\Big| \le C\tau^{\frac{d-j}{2m}}\bar\sigma^{d''-j}\bar\gamma^{d'} \tag{12.3.51}$$

and

$$\kappa_0 = (2\pi)^{-d}\int n(x,\xi,\tau)\, d\xi \tag{12.3.52}$$

where as before $n(x,\xi,\tau)$ is an eigenvalue counting function for symbol $A(x,\xi)$.

However in the general case one should add to the right-hand expressions of (12.3.50) and (12.3.51) terms reflecting irregularity as $x'' = 0$; one can

think about last terms in (12.3.50) and (12.3.51) with $\bar\sigma$ replaced by $\bar\sigma_0 = \bar\gamma^{-(\mu-\nu)/(\nu+1)}$ as $J > d''$ or $j > d''$ and with extra factor $\log(\bar\sigma/\bar\sigma_0)$ as $J = d''$ or $j = d''$ but in fact these terms are better.

Thus, as in the previous section, using propagation of singularities for operators with operator-valued symbols we have improved the Weyl asymptotics in the cusp zone. However again we need to take into account many terms in the decomposition and in contrast to the previous section singularity as $x'' = 0$ may prevent us from doing this. To remedy this we consider A as a perturbation of some other operator A^0. So let A^0 be another operator also satisfying all the conditions above with the same exponents.

Let us take $J = 1$ and assume that

$$|D^\beta\big(a_\alpha - a^0_\alpha\big)| \le \sum_{q\in Q} \varepsilon_q(x')|x''|^{q-|\beta|}\rho^{*\,2m-|\alpha|} \qquad \forall \beta : |\beta| \le 1 \tag{12.3.53}$$

with the finite set $Q \subset \mathbb{R}^+ \cup 0$. Note that effectively $(A - A^0)$ contains a factor $|x''|^q$ which due to Proposition 12.3.2 in the estimates translates into factor $\sigma(\gamma,\tau)^q$. Then the following estimate similar to (12.2.82) can be proven in the same way:

$$\mathsf{R}_1 \coloneqq \Big|\int \Big(\big(e(x,x,\tau) - e^0(x,x,\tau)\big) - \psi(x')\big(\kappa_0 - \kappa^0_0\big)\Big)\Big|_{\tau=\tau'}^{\tau=\tau} dx\Big| \le \\ C\bar\gamma^{d'-1-\frac{\mu d''}{\nu}}\tau^{\frac{d-1}{2m}+\frac{d''}{2m\nu}} + C\tau^{\frac{d-1}{2m}}\bar\sigma^{d''-1}\bar\gamma^{d'}\bar\eta \tag{12.3.54}$$

with

$$\Big|\int \psi(x')\big(\kappa_0(x,\tau) - \kappa^0_0(x,\tau)\big)\,dx\Big| \le C\tau^{\frac{d}{2m}}\bar\sigma^{d''}\bar\gamma^{d'}\bar\eta \tag{12.3.55}$$

where A^0 satisfy the same conditions as A, all the objects associated with A^0 have an additional superscript "0" and in comparison with (12.3.50)–(12.3.51) we gain factor

$$\bar\eta = \sum_{q\in Q} \sigma(\bar\gamma,\tau)^q \varepsilon_q(\bar\gamma). \tag{12.3.56}$$

We leave to the reader to prove easily that the logarithmic factor does not appear in the last term (12.3.54) even if $d'' = 1$, $q = 0$; this proof is based on representation of κ_1 and assumption $\nu > 0$.

So we have proved the following assertion:

Proposition 12.3.17. *Let both operators A and A^0 satisfy assumptions of Theorem 12.3.11. Moreover, let condition* (12.3.53) *be fulfilled. Then estimates* (12.3.54)–(12.3.56) *hold.*

Now our arguments basically repeat those of Subsection 12.2.3.

Let us replace τ and τ' by $2^{-n}\tau$ and $2^{-n-1}\tau$ respectively and sum over $n = 0, \dots, n_0 = c_0\lfloor \log(\tau\bar{\sigma}^{2m})\rfloor + c_1$. Applying Proposition 12.3.2 we can get rid of τ' in all these estimates arriving to the statement similar to Corollary 12.2.16. We leave easy details to the reader.

Assume that

(12.3.57) ε_q are γ-admissible with no more than a polynomial growth and $\eta = O(\gamma^{-\varkappa})$ as $\gamma \to \infty$.

Recall that ψ is γ-admissible and supported in the $\bar{\gamma}$-neighborhood of $\bar{x}'$. Then after summation over a γ-admissible partition of unity in Z we can obtain miscellaneous formulae (later under certain conditions we will calculate the terms associated with the operator A^0):

First, we obtain formula (12.2.88); then immediately we arrive to

Proposition 12.3.18. *(i) Let both operators A and A^0 satisfy assumptions of Theorem 12.3.11. Moreover, let condition* (12.3.53) *be fulfilled with $Q = \{0, 1\}$, $\varepsilon_1 = \gamma^{-1}$, $\varepsilon_0 = \sigma_0\gamma^{-1}$. Then estimate* (12.3.54) *holds with the right hand expression $O\bigl(R^*(\tau)\bigr)$.*

(ii) Further, in the framework of Theorem 12.3.12 we obtain formula (12.2.89) *with the remainder estimate $o\bigl(\tau^{(d-1)(\mu+1)/(2m\mu)}\bigr)$ rather than $o\bigl(\tau^{(d-1)/(2m)}\bigr)$.*

(iii) Furthermore, in framework of Theorem 12.3.13 we obtain formula (12.2.90) *with the remainder estimate $o\bigl(\tau^{(d'-1)(\mu+1)/2m(\mu-\nu)}\bigr)$ as $\varepsilon_1 = o(\gamma^{-1})$, $\varepsilon_0 = o(\sigma_0\gamma^{-1})$.*

(iv) In particular, in the framework of Example 12.3.1 in Statements (i)–(ii) one can take

$$a^0_{\alpha(j)}(x) = \sum_{\beta'':|\beta''|=\mu(2m-|\alpha|)-j} \bigl(\partial^{\beta''}_{x''} a_{\alpha(j)}(x)\bigr)_{x''=0} \frac{x''^{\beta''}}{\beta''!} \tag{12.3.58}$$

while in Statement (iii) one should add a correction term $\varkappa'_1\tau^{(d'-1)(\mu+1)/2m(\mu-\nu)}$.

Main Theorems

Let us formulate the principal theorems proved in this section. They are due to the results above. Then we obtain the following statements:

Theorem 12.3.19 [28]**.** *Let conditions* (12.3.1), (12.3.3), (12.3.6), (12.3.9)–(12.3.12), (12.3.19) *and stabilization conditions* (11.5.4), (12.3.34) *and* (12.3.56)–(12.3.57) *be fulfilled.*

(i) Then asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}_1(\tau) + O\big(R^*(\tau) + \tau^b\big), \qquad b = \frac{(\mu+1)}{2m(\mu-\nu)}\big(d-1-\frac{(\nu+1)}{\nu}(d''-1)-\varkappa\big) \tag{12.3.59}$$

holds where $R^*(\tau)$ *is given by* (12.3.39) *and* $\mathcal{N}_1(\tau)$ *is defined by* (12.2.100), $\boldsymbol{n}^0(x',\xi',\tau)$ *is the eigenvalue counting function for operator* $\boldsymbol{a}^0(x',\xi';x'',D'')$ *in* $\mathbb{H}$ *and* $c_0 \le t_1\tau^{-1/(2m\mu)} \le \tau^\delta$ *with a small enough exponent* $\delta > 0$.

Moreover, (12.3.24) *remains true for* $\mathcal{N}_1$.

(ii) Further, let $(d-1)\nu < \mu d''$, $\kappa > \nu^{-1}\big(d-1-(\nu+1)(d''-1)\big)$ [29]*. Moreover, let the standard non-periodicity condition be fulfilled for the Hamiltonian flow of* $a(x',\xi')$.

Then asymptotics

$$\mathsf{N}^-(\tau) = \mathcal{N}_1(\tau) + o\big(\tau^{\frac{(d-1)(\mu+1)}{2m\mu}}\big) \tag{12.3.60}$$

holds as $\tau \to +\infty$ *provided* $t_1 \to +\infty$ *(we assume that* $t_1 \le \tau^\delta$*).*

(iii) Furthermore, let $(d-1)\nu < \mu d''$, $\kappa > (d'-1)\mu(\mu+1)^{-1} - (d''-1)\nu^{-1}$ [30]*.*

Moreover, let non-periodicity condition (12.2.51) *be fulfilled. Then the asymptotics*

$$\mathsf{N}^-(\tau) = \mathcal{N}_1(\tau) + \varkappa_1^*\tau^{\frac{1}{2m\mu}(d'-1)(\mu+1)} + o\big(\tau^{\frac{1}{2m(\mu-\nu)}(d'-1)}\big) \tag{12.3.61}$$

holds with the coefficient $\varkappa_1^*$ *given in Remark 4.4.13.*

---

[28] Cf. Theorem 12.2.19.

[29] Then the remainder estimate in (12.3.59) is $O\big(\tau^{\frac{1}{2m\mu}(d-1)}\big)$.

[30] Then the remainder estimate in (12.3.59) is $O\big(\tau^{\frac{1}{2m(\mu-\nu)}(d'-1)}\big)$.

Discussion

We leave to the reader the following series of problems:

Problem 12.3.20. (i) Formulate and prove all results of this section for a domain where Λ (the manifold of the degeneration) consists of more than one connected components (with different characteristics) $\Lambda = \Lambda_1 \cup \dots \cup \Lambda_N$, $\Lambda_j \cap \Lambda_k = \emptyset$ as $0 \neq j \neq k \neq 0$. This problem is trivial even if the dimensions of these cusps (d'_k) and the exponents of degenerations (μ_k) differ.

(ii) Consider the case when $X \neq \mathbb{R}^d$ but as $|x| \geq c$ it coincides with the conic domain assuming that

(12.3.62) each connected component of degeneration manifold Λ either does not intersect ∂X or is contained there.

Then coefficients $\tilde{\kappa}_j$ will appear here as well.

(iii) Investigate different boundary conditions.

(iv) In the framework of (ii) get rid of assumption (12.3.62).

(v) Write explicit expressions as $m = 2$, $\nu = 1$.

In this case operator $a_\infty(x', x'; x'', D'')$ is a quadratic Hamiltonian and due to ellipticity it is after metaplectic transformation (see Subsection 1.2.5) it becomes a direct sum of harmonic oscillators $\sum \omega_j(D_j^2 + x_j^2)$ with very well known spectrum and eigenvalue counting function

$$n_\infty(\tau) = \#\{\alpha \in \mathbb{Z}^{+k}, \sum_k \omega_k(2\alpha_k + 1) < \tau\}. \tag{12.3.63}$$

(vi) Conduct analysis similar to one in the cases (iv), (v) of Subsubsection *12.2.3.1 Scheme of Effective Asymptotics*.

(vii) Repeat with trivial modifications arguments of Subsubsection 12.2.3.

(viii) Derive more precise remainder estimates in the framework of Theorem 12.3.12 as Hamiltonian flow associated with $a(x, \xi)$ is of power or exponential non-periodic type.

(ix) Derive more precise remainder estimate in the framework of Theorem 12.3.13 and Example 12.3.14 assuming that the Hamiltonian flow associated with $\zeta(x',\xi')$ is of power or exponential non-periodic type.

(x) Investigate the case in the framework of Theorem 12.3.13 and Example 12.3.14 assuming that the Hamiltonian flow associated with $\zeta(x',\xi')$ is periodic.

(xi) Derive asymptotics for Riesz means.

Obviously Remark 12.2.22 stays.

12.4 Operators with Singular Potentials Decaying at Infinity

12.4.1 Problem Set-up

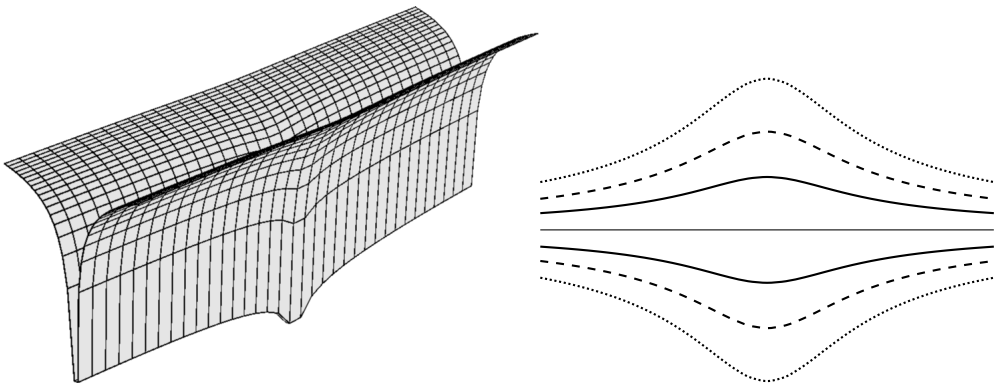
Let us start from the following example:

Example 12.4.1. Consider self-adjoint (matrix) operator on $\mathbb{R}^d$ (12.3.1) (possibly in the divergent form) with the positively homogeneous of degrees $(2m-|\alpha|)\mu$ (as $|x|\ge c$) coefficients a_α. In Section 11.6 we investigated the case when (12.3.2), (12.3.3) hold, $0>\mu>-1$ and established asymptotics for $\mathsf{N}^-(\tau)$ as $\tau\to -0$.

Now we want to consider the case when coefficients are singular at Λ, behaving basically as $\rho^{2m-|\alpha|}$ with $\rho(x)=\zeta(x)^\nu |x|^{\mu-\nu}$, $\zeta(x)=\mathsf{dist}(x,\Lambda)$ where Λ satisfies (12.3.5) and $0>\nu>\mu>-1$.

Without any loss of the generality we can assume that (at least locally) $\Lambda=\{x : x''=0\}$. Then we need to introduce $\zeta(x)$, $\gamma(x)$ and $\rho(x)$ by (12.3.9). However we do not want to have true singularities as $x''=0$: one can manage to investigate them too but it will be a pain with no gain - extra analysis without new effects; so instead we assume that (12.3.12) holds with ρ, ζ redefined as ρ^*, ζ^* by (12.3.10)–(12.3.11).

Remark 12.4.2. (i) We need condition $\nu>\mu$ for the cusp to shrink at infinity. As $0>\nu>-1$ the gorge would be too narrow to generate eigenvalues tending to $-\infty$ even if we did not "regularized" coefficients, departing from Example 12.4.1.



(a) Gorge (b) Cusp

Figure 12.6: Potential graph and level lines

(ii) Our results here are very similar to those of the previous Section 12.3 and could be formally obtained from them by replacing "$\tau \to +\infty$" by "$\tau \to -0$" and assumption $\mu > \nu > 0$ by $0 > \nu > \mu > -1$.

Consider operator first in the framework of the theory of Section 11.6; after scaling $x_{\mathsf{new}} = x\bar{\sigma}$, $\xi_{\mathsf{new}} = |\tau|^{-1/(2m)}\xi$ we conclude that operator $|\tau|^{-1}A$ is elliptic on the energy levels (-1) and below provided

$$|x''| \ge \sigma(x', \tau) \coloneqq c_0 |x'|^{-(\mu-\nu)/\nu} \tau^{\frac{1}{2m\nu}}, \tag{12.4.1}$$

(we assume that $|x'| \gg |x''|$ and $|x'| \gg 1$) and the uncertainty principle $\rho(x)\zeta(x) \ge 1$ is fulfilled provided

$$|x''| \ge \sigma_1(\tau) \coloneqq |\tau|^{-\frac{1}{2m}}. \tag{12.4.2}$$

Then we arrive immediately to the following assertion:

Proposition 12.4.3 [31]**.** *Let conditions* (12.3.1), (12.3.3) *and* (12.3.9)–(12.3.12) *be fulfilled at the point* $\bar{x} \in \mathbb{R}^d$.

(i) Then

$$|e(x, y, \tau)| \le C|\tau|^{\frac{d}{2m}} \zeta(x)^{-s} \sigma_1(\tau)^s \qquad \forall x, y \in B\Big(\bar{x}, \frac{1}{2}\zeta(\bar{x})\Big) \tag{12.4.3}$$

with an arbitrarily large exponent s.

[31] Cf. Proposition 12.3.2.

(ii) Moreover, if $U(x,y,t)$ *is the Schwartz kernel of the operator* $\tau^{-1}A$ *then*

$$\bigl|F_{t\to\lambda}\bar{\chi}_{T,T'}(t)U(x,y,t)\bigr| \le C|\tau|^{d/(2m)}\zeta(x)^{-s}\sigma_1(\tau)^s \tag{12.4.4}$$
$$\forall x,y\in B\bigl(\bar{x},\frac{1}{2}\zeta(\bar{x})\bigr)\quad \forall T'\in\mathbb{R},\ T=\sigma(\bar{x})\quad \forall \lambda\le 1+\epsilon$$

with a small enough constant $\epsilon>0$.

Remark 12.4.4[32]. Consider the "gorge"

$$\mathcal{X}(\tau)=\bigl\{x,|x''|\le\sigma(x',\tau)\bigr\}. \tag{12.4.5}$$

It consists of the *regular part* where $|x|\le c|\tau|^{1/(2m\mu)}$ and the *cusp* where $|x|\ge c|\tau|^{1/(2m\mu)}$; this cusp stretches along $X'=\{x,x''=0\}$ and shrinks at infinity (on $|x|$) for any $\tau>0$.

Let us apply now the theory of the operators with the operator-valued symbols (in rather limited manner at this time); to do this we need to analyze operator $\mathsf{a}(x',\xi')=A(x',\xi';x'',D'')$:

Proposition 12.4.5[33]**.** *Let conditions* (12.3.1), (12.3.3) *and* (12.3.9)–(12.3.12) *be fulfilled. Let* $\lambda_k(x',\xi')$ *be eigenvalues of* $\mathsf{a}(x',\xi')$ *in* $\mathbb{H}=\mathscr{L}^2(\mathbb{R}^{d''})$. *Then*

$$\lambda_k(x',\xi)\ge\epsilon_0|\xi'|^{2m}-\varepsilon_k\sigma_0(x')^{-2m} \tag{12.4.6}$$

where $\sigma_0(x')$ *is defined by* (12.4.2).

Proof. Coincides with the proof of Proposition 12.3.4. □

Due to our assumptions $|\tau|^{-1}\mathsf{a}(x',\xi')$ is elliptic as an operator with an operator-valued symbol on the energy level (-1) unless $|\xi'|\le c\tau^{1/(2m)}$ and $|x'|\le r^*(\tau)$ with $r^*(\tau)$ defined by (12.3.20).

Proposition 12.4.6[34]**.** *Let conditions* (11.1.6), (11.1.8) *and* (12.3.1), (12.3.3) *and* (12.3.9)–(12.3.12) *be fulfilled. Then estimate* (12.3.21) *holds.*

Proof. Coincides with the proof of Proposition 12.3.5. □

[32] Cf. Remark 12.3.3.
[33] Cf. Proposition 12.3.4.
[34] Cf. Proposition 12.3.5.

Remark 12.4.7[35]. (i) Note that $|\tau|^{1/(2m)} \lesssim \sigma(x',\tau)$ if and only if $|x'| \lesssim r^*(\tau)$.

(ii) Note that $\mathsf{mes}\big(\mathcal{X}(\tau)\big) = O(|\tau|^{d/(2m\mu)})$ if and only if $\mu d'' < \nu d$. Under this condition the principal part of the Weyl formula is $\asymp |\tau|^{d(\mu+1)/(2m\mu)}$.

(iii) Let us drop condition $\mu d'' < \nu d'$ and let us restrict integration to the domain $\{x, |x| \le r^*(\tau)\}$ in the Weyl formula due Proposition 12.4.6. Then the principal part of the Weyl asymptotics (modified in this way) has the magnitude of (12.3.24).

(iv) Let us consider the remainder estimate in the Weyl formula. We can integrate only over domain $\{x, |x| \le r^*(\tau)\}$ due to Proposition 12.4.6. Then the remainder estimate in the modified Weyl asymptotics is (12.3.25)

(v) Let $\mu(d''-1) < \nu(d-1)$. Then under standard stabilization conditions of a_α as $|x| \to \infty$ to positively homogeneous $a_{\infty,\alpha}$ and standard restrictions to the Hamiltonian flow generated by the corresponding Hamiltonian $a_\infty(x,\xi)$ one can obtain the remainder estimate $o\big(|\tau|^{(d-1)(\mu+1)/(2m\mu)}\big)$.

Again, in this remark the role of the "operator-valued theory" is very limited: it only provides a nice cut-off in the Weyl formulas.

We leave to the reader the following easy problem:

Problem 12.4.8[36]. Calculate the principal part of the asymptotics and remainder estimate for Riesz means in the Remark 12.4.7.

12.4.2 Sharp Asymptotics

So, as we are interested in the asymptotics of $\mathsf{N}^-(\tau)$, our analysis should be done as

$$\mu(d''-1) \le \nu(d-1). \tag{12.4.7}$$

Here we should treat only the cusp zone

$$\mathcal{X}_{\mathsf{cusp}}(\tau) = \big\{c_1\tau^{\frac{1}{2m}} \coloneqq r_*(\tau) \le |x'| \le r^*(\tau),\ |x''| \le c_2\sigma(x',\tau)|\tau|^{-\delta}\big\} \tag{12.4.8}$$

[35] Cf. Remark 12.3.6.

[36] Cf. Problem 12.3.7.

with $r^*(\tau)$ and $\sigma(x',\tau)$ defined by (12.3.20) and (12.4.1) and an arbitrarily small exponent $\delta > 0$.

Really, estimate (12.4.3) and Proposition 12.4.6 yield that for $|x'| \ge c_1\tau^{1/(2m\mu)}$ outside of $\mathcal{X}$ function $e(x,x,\tau)$ is negligible; on the other hand, we have

Proposition 12.4.9 [37]**.** *(i) Contribution of the regular zone* (12.3.28) *(with arbitrarily large constant c) to the principal part of the Weyl asymptotics and to the remainder estimate are $O\bigl(|\tau|^{d(\mu+1)/(2m\mu)}\bigr)$ and $O\bigl(|\tau|^{(d-1)(\mu+1)/(2m\mu)}\bigr)$ respectively* [38]*.*

(ii) Moreover, under standard stabilization conditions and the standard non-periodicity condition to the Hamiltonian flow the contribution of the zone $\mathcal{X}_{\mathsf{reg}}(\tau)$ to the remainder estimate is $o\bigl(|\tau|^{(d-1)(\mu+1)/(2m\mu)}\bigr)$.

Proof. Coincides with the proof of Proposition 12.3.8. □

Furthermore, the same arguments yield that treating zone $\bigl\{|x'| \le c_0 r^*(\tau)|\tau|^{\delta'}\bigr\}$ with an arbitrarily small exponent $\delta' > 0$ one can set $\delta = 0$ in the definition of $\mathcal{X}(\tau)$; in this case constant c_2 should be large enough.

To treat the cusp zone (12.4.8) let us apply theory of Section 4.4. For this we need to check if operator in question is (x',ξ') microhyperbolic on the energy level τ in (γ,ρ_τ)-scale with $\gamma(x') = \frac{1}{2}|x'|$ and $\rho(x') = \sigma_0(x')^{-1}$.

Proposition 12.4.10 [39]**.** *Operator $a(x',D')$ is (x',ξ')-microhyperbolic under stabilization condition* (12.3.34).

Proof. Coincides with the proof of Proposition 12.3.9. □

We leave to the reader the following easy problem:

Problem 12.4.11 [40]*.* Establish other conditions providing (x',ξ')-microhyperbolicity of $a(x',D')$.

---

[37] Cf. Proposition 12.3.8.

[38] Subject to conditions of Section 11.5. For example, as either operator is the Schrödinger operator or its perturbed power or stabilization condition (11.5.4) is fulfilled.

[39] Cf. Proposition 12.3.9.

[40] Cf. Problem 12.3.10.

So, assume that microhyperbolicity condition is fulfilled. Then we can apply Theorem 4.4.8 as this operator is ξ'-microhyperbolic and Theorem 4.4.9 as this operator is (x', ξ')-microhyperbolic (i.e. in the general case) but there is a problem: operators B_1^{-k} is not of the trace norm. So we need to modify our arguments.

First of consider trace only with respect to x' and consider $\mathbb{H} \to \mathbb{H}$ operator norm; then the contribution of γ-element to the remainder does not exceed

$$C\hbar^{1-d'} = C\rho^{d'-1}\gamma^{d'-1} \tag{12.4.9}$$

as $\hbar = \rho^{-1}\gamma^1$. Then due to embedding theorem if we consider just pointwise norm (on (x'', y'')), the the contribution of γ-element to the remainder does not exceed expression (12.4.9) multiplied by $\rho^{d''/(2m)}$, i.e. $C\rho^{d-1}\gamma^{d'-1}$. Then after cut-off as $\zeta(x) \le \sigma(x', \tau)$ leads to the the remainder estimate

$$\int_{\sigma_0}^{\sigma} (\zeta^{\nu}\gamma^{\mu-\nu})^{d-1}\gamma^{d'-1}\zeta^{d''-1}\, d\zeta \tag{12.4.10}$$

on the other hand as $|x''| \ge \sigma(x', \tau)$ the pointwise norm does not exceed

$$C|\tau|^{\frac{d}{2m}}\gamma^{d'-1} \times |x''|^{-s}\sigma(x', \tau)^s$$

where we used the standard ellipticity of our operator here and the contribution of this zone to the remainder estimate does not exceed (12.4.10).

So, the total remainder estimate is

$$\int_{r_*(\tau)}^{r^*(\tau)} \int_{\sigma_0}^{\sigma} (\zeta^{\nu}\gamma^{\mu-\nu})^{d-1}\gamma^{d'-2}\zeta^{d''-1}\, d\zeta\, d\gamma \tag{12.4.11}$$

and one can prove easily that it is $\asymp R^*(\tau)$ defined by (12.3.39).

Let us apply Weyl asymptotics in the zone $\{|x'| \le t_1|\tau|^{1/(2m\mu)}\}$. To ensure (x, ξ)-microhyperbolicity there we assume that the standard stabilization condition (11.5.4) is fulfilled[17].

Then we obtain the following theorem:

Theorem 12.4.12 [41]**.** *Let conditions* (12.3.1), (12.3.3), (12.3.9)–(12.3.12) *and stabilization conditions* (11.5.4) [38),17)], (12.3.34) *be fulfilled.*

Let $\psi \in \mathscr{C}_0^K(\mathbb{R}^{d'})$, $\psi(x') = 1$ *as* $|x'| \le c_0$. *Then*

[41] Cf. Theorems 12.2.6 and 12.3.11.

(i) Asymptotics (12.3.40) *holds as* $\tau \to -0$ *with* $\mathcal{N}(\tau)$ *defined by* (12.2.43) *with* $\psi_t(x') = \psi(x'/t)$ *where* $t \asymp r_*(\tau)$ [19] *and with* $R^*(\tau)$ *defined by* (12.3.39).

(ii) Moreover, $\mathcal{N}(\tau)$ *has a magnitude described in* (12.3.24).

Repeating corresponding arguments of Section 12.3 we arrive to the following theorem:

Theorem 12.4.13 [42]**.** *Let the conditions of Theorem 12.4.12 be fulfilled with* $(d-1)\nu > d''\mu$.

Moreover, let the standard non-periodicity condition to the Hamiltonian trajectories generated by $a_\infty(x,\xi)$ *be fulfilled. Then asymptotics* (12.3.42) *holds as* $\tau \to -0$ *where* $\mathcal{N}(\tau)$ *is defined by* (12.2.46),

$$(12.4.12)\quad (2\pi)^{-d}\int \psi\kappa_1\tau^{\frac{1}{2m}(d-1)}\,dx \quad \text{and} \quad (2\pi)^{1-d}\int_{\partial X}\psi\tilde{\kappa}_1\tau^{\frac{1}{2m}(d-1)}\,dS$$

are the standard second terms [29] *in the Weyl asymptotics,* $\psi_t(x') = \psi_0(x'/t)$ *where* $t = t(\tau)$ *is an appropriate function such that* $t(\tau)/r_*(\tau) \to +\infty$ *as* $\tau \to -0$ [30]

Theorem 12.4.14 [43]**.** *Let the conditions of Theorem 12.4.12 be fulfilled with* $(d-1)\nu < d''\mu$.

Let us consider operator-valued symbol $a_\infty(x',\xi')$ *in* $\mathbb{H}$*; let* $\lambda_j(x',\xi')$ *be its (non-decreasing) eigenvalues*[24]*. Let us consider*

$$(12.4.13)\qquad a_{\infty,j}(x',\xi') = a_\infty(x',\xi')e_\infty(x',\xi',\zeta_j(x',\xi'))$$

where $e_\infty(x',\xi',\tau)$ *is the spectral projector for* $a_\infty(x',\xi')$ *and assume that non-periodicity condition* (12.2.51) *is fulfilled.*

Then asymptotics (12.3.46) *holds as* $\tau \to -0$ *with an appropriate coefficient* κ_1^* *(given in Remark 4.4.13).*

Condition (12.2.51) looks extremely cumbersome and impossible to check. However in the following rather special example this condition becomes much simpler:

---

[42] Cf. Theorems 12.2.7 and 12.3.12.

[43] Cf. Theorems 12.2.8 and 12.3.13.

Example 12.4.15[44]. Let $d''=1$ and A be a Schrödinger operator stabilizing at infinity to $|\xi^2|+|x_d|^{2\nu}\cdot\omega(x')^2$ with ω, positively homogeneous of degree $2(\mu-\nu)$.

Then one needs to check the standard non-periodicity condition for symbol In particular, the standard non-periodicity condition for $\lambda(x',\xi')$ is fulfilled as $\sigma^0=|x'|^{-\eta}$, $\eta<0$ and $\eta\neq\frac12$; recall that $d'\geq 2$.

Finally, let us consider the case $d'=1+d''\mu$. Considering diagonal operator with diagonal elements $\lambda_j^{\mathsf{w}}(x',D')$ one can prove easily the remainder estimate $o(\tau^{(d-1)/2m}|\log|\tau||)$ (not subject to any non-periodicity condition). This leads us to conjecture which we were unable to prove

Conjecture 12.4.16[45]**.** *As $(d-1)\nu<d''\mu$ remainder estimate is in fact $o(|\tau|^{(d-1)/(2m\mu)}|\log|\tau||)$.*

We leave to the reader the following easy albeit interesting problem:

Problem 12.4.17[46]. (i) Treat Riesz means and derive asymptotics with $R^*_{(\vartheta)}(\tau)$ defined by (12.3.49).

(ii) Here one needs also to improve results of Section 11.6. To do it one can consider propagation and extend time from $T\asymp|x|^{1-\mu}$ to $T\asymp|\tau|^{(1-\mu)/(m\mu)}$.

12.4.3 Effective Asymptotics

Simplifying the Answer

Again, the main defect of Theorems 12.4.12–12.4.14 again is that the expression for $\mathcal{N}(\tau)$ is not effective and includes the eigenvalue counting function for the *family* of auxiliary operators $a(x',\xi')$. Exactly like in the previous Section 12.3 we would like to derive a formula including the eigenvalue counting function for *one* auxiliary operator or at least for a family of auxiliary operators with a smaller number of parameters; however in contrast to the previous section we want also to simplify these axillary operators.

Let us assume that (12.3.53) holds with the finite set $Q\subset\mathbb{R}^+\cup 0$. Note that effectively $(A-A^0)$ contains a factor $|x''|^q$ which due to Proposition 12.4.3

[44] Cf. Examples 12.2.9 and 12.3.14.
[45] Cf. Conjectures 12.2.10 and 12.3.15.
[46] Cf. Problems 12.2.11 and 12.3.16.

in the estimates translates into factor $\sigma(\gamma,\tau)^q$. Then arguments leading to (12.2.82) (or (12.3.54) imply that

$$\mathsf{R}_1 \le R + \varepsilon_q(\gamma)\int_{\sigma_0}^{\sigma} (\zeta^\nu \gamma^{\mu-\nu})^{d-1}\gamma^{d'}\zeta^{d''-2+q}\,d\zeta \tag{12.4.14}$$

where R_1 is defined by (12.3.54) and the right-hand expression is (12.4.10) modified in the obvious way. Further, one can estimate the left-hand expression of (12.3.55) in the same way.

Recall that A^0 satisfy the same conditions as A, all the objects associated with A^0 have an additional superscript "0".

Then after summation with the respect to partition we conclude that redefined R_1 does not exceed

$$\int_{r_*(\tau)}^{r^*(\tau)}\int_{\sigma_0}^{\sigma} (\zeta^\nu \gamma^{\mu-\nu})^{d-1}\gamma^{d'-1+(\mu-\nu)q/(\nu+1)}\zeta^{d''+q-2}\,d\zeta d\gamma \tag{12.4.15}$$

as $\varepsilon_q(\gamma) = \gamma^{-p+(\mu-\nu)q/(\nu+1)}$. One can see easily that this expression does not exceed $CR^* + C|\tau|^b$ because $(\zeta^\nu\gamma^{\mu-\nu})^{d-1}\gamma^{d'+(\mu-\nu)q/(\nu+1)}\zeta^{d''+q-1}$ calculated as $\gamma = r^*(\tau)$, $\zeta = \sigma_0(r^*(\tau))$ is exactly the second term here.

Now our arguments basically repeat those of Subsections 12.2.3 and 12.3.3. First, we obtain formula (12.2.88); then immediately we arrive to asymptotics similar to (12.3.54)–(12.3.56). Further, in the framework of Theorem 12.4.13 we obtain formula (12.2.89) with the remainder estimate $o(R^*) + O(|\tau|^b)$. Furthermore, in the framework of Theorem 12.4.13 we obtain formula (12.2.90) with the remainder estimate $o(R^*) + O(|\tau|^b)$.

Problem 12.4.18[47]. (i) Consider domains with the boundary (with appropriate boundary conditions), assuming that (12.3.62) holds. Then coefficients $\tilde\kappa_j$ will appear here as well.

(ii) Conduct analysis similar to one in the Cases (iv) and (v) of Subsubsection *12.2.3.1 Scheme of Effective Asymptotics*.

(iii) Repeat with trivial modifications arguments of Subsubsection *12.2.3.2 Scheme of Effective Asymptotics*.

[47] Cf. Problem 12.3.20.

Main tTheorems

Let us formulate the principal theorems proved in this section. They are due to the results above.

Then we obtain the following statements:

Theorem 12.4.19 [48]**.** *Let conditions* (12.3.1), (12.3.3), (12.3.9)–(12.3.12) *and stabilization conditions* (11.5.4), (12.3.34) *and* (12.3.56)–(12.3.57) *be fulfilled.*

(a) Then asymptotics (12.3.59) *holds where* $R^*(\tau)$ *is given by* (12.3.39), $\mathcal{N}_1(\tau)$ *is defined by* (12.2.100), $n^0(x',\xi',\tau)$ *is the eigenvalue counting function for operator* $a^0(x',\xi';x'',D'')$ *in* $\mathbb{H}$ *and* $c_0 \le t_1|\tau|^{-1/(2m\mu)} \le |\tau|^{-\delta}$ *with a small enough exponent* $\delta > 0$.

Moreover, (12.3.24) *remains true for* $\mathcal{N}_1$.

(b) Further, let $(d-1)\nu < \mu d''$ *and* $b > (d-1)\nu$. *Moreover, let the standard non-periodicity condition be fulfilled for the Hamiltonian flow of* $a(x',\xi')$.

Then asymptotics (12.3.60) *holds as* $\tau \to -0$ *provided* $t_1 \to +\infty$ *(we assume that* $t_1 \le |\tau|^{-\delta}$*).*

(c) Furthermore, let $(d-1)\nu < \mu d''$ *and* $R_1^* = o(R^*)$. *Moreover, let non-periodicity condition* (12.2.51) *be fulfilled.*

Then the asymptotics (12.3.61) *holds with the coefficient* $\varkappa_1^*$ *given in Remark 4.4.13.*

We leave to the reader the following easy series of problems:

Problem 12.4.20 [49]. (i) Formulate and prove all results of this section for a domain where Λ (the manifold of the degeneration) consists of more than one connected components (with different characteristics) $\Lambda = \Lambda_1 \cup ... \cup \Lambda_N$, $\Lambda_j \cap \Lambda_k = \emptyset$ as $0 \ne j \ne k \ne 0$. This problem is trivial even if the dimensions of these cusps (d_k') and the exponents of degenerations (μ_k) differ.

(ii) Consider the case when $X \ne \mathbb{R}^d$ but as $|x| \ge c$ it coincides with the conic domain assuming that each component of Λ either does not intersect ∂X or is contained in ∂X. Investigate different boundary conditions.

---

[48] Cf. Theorems 12.2.19 and 12.3.19.

[49] Cf. Problem 12.4.20.

(iii) Derive more precise remainder estimates in the framework of Theorem 12.4.13 as Hamiltonian flow associated with $a(x,\xi)$ is of power or exponential non-periodic type.

(iv) Derive more precise remainder estimate in the framework of Theorem 12.4.14 assuming that the Hamiltonian flow associated with $\zeta(x',\xi')$ is of power or exponential non-periodic type.

(v) Derive asymptotics for Riesz means.

Obviously Remark 12.2.22 stays.

12.5 Spectral Asymptotics for Maximally Hypoelliptic Operators

12.5.1 Maximally Hypoelliptic Operators

In this section we consider a class of pseudodifferential operators on a compact closed $\mathscr{C}^{K'}$ manifold X degenerating on a symplectic manifold $\Lambda \subset T^*X \setminus 0$ conical in ξ. The same results hold with no change for operators acting in Hermitian bundles. Moreover, similar results hold after an obvious modification for differential operators on manifolds with boundary provided $\Lambda|_{\partial X} = \emptyset$. We leave these modification to the reader. So, let us assume that

(12.5.1) X is a compact $\mathscr{C}^{K'}$ manifold, $\Lambda \subset T^*X \setminus 0$ is a symplectic manifold conic in ξ, $d = \dim X$, $2d' = \dim \Lambda$, $1 \le d' < d$, $d'' = d - d'$.

Definition 12.5.1. Let $\boldsymbol{\Psi}^{m,\mu}(X,\Lambda,\mathbb{K})$ with $m \in \mathbb{R}$, $\mu \in \mathbb{Z}^+$ denote the class of pseudodifferential operators from $\mathscr{H}^s(X,\mathbb{K})$ to $\mathscr{H}^{s-m}(X,\mathbb{K})$ [50] with symbols in every local chart of the form

$$a = \sum_{0\le n\le K-1} a_{\frac{n}{2}} + a'_{\frac{K}{2}} \tag{12.5.2}$$

[50] With $s \in (-\bar{s},\bar{s})$ and with $\bar{s} = \bar{s}(K',d,m) \to +\infty$ as $K' \to +\infty$ and d,m are fixed. This footnote holds until the end of this section.

where $a_{\frac{n}{2}}$ are $\mathscr{C}^{K'-n}$ symbols positively homogeneous of degrees $(m-\frac{n}{2})$ in ξ and such that

$$a^{(\alpha)}_{\frac{n}{2}(\beta)}(z)=0 \qquad \forall z\in\Lambda \quad \forall \alpha,\beta : |\alpha|+|\beta|+n<\mu \tag{12.5.3}$$

and the remainder $a'_{\frac{K}{2}}$ is assumed to be smooth enough and decrease quickly enough as $|\xi|\to\infty$. Here and below $K'>2K$ and K are large enough.

It is well known (see also Section 1.2) that these classes are microlocally invariant. In an appropriate microlocal symplectic coordinate system on $T^*X\setminus 0$ we have

$$\Lambda=\bigl\{(x,\xi)\in T^*X:\ x''=\xi''=0\bigr\} \tag{12.5.4}$$

where $x=(x';x'')=(x_1,\dots,x_{d'};x_{d'+1},\dots,x_d)$ and similar notation is applied to ξ. Then for the operator $A\in\boldsymbol{\Psi}^{m,\mu}(X,\Lambda,\mathbb{K})$ and for $z\in\Lambda$ let us introduce the operator

$$A_z(x'',D'')\coloneqq \sum_{|\alpha|+|\beta|+n=\mu} \frac{1}{\alpha!\beta!}a^{(\alpha)}_{\frac{n}{2}(\beta)}(z)x''^{\beta}D''^{\alpha} \tag{12.5.5}$$

acting in the space $\mathscr{L}^2(\mathbb{R}^{d''},\mathbb{K})$ [51]. Recall that $f^{(\alpha)}_{\beta}=\partial^{\alpha}_{\xi}\partial^{\beta}_{x}f$.

Definition 12.5.2. This operator $A_z(x'',D'')$ is called the *microlocalization* (of order μ) of the operator A at the point $z\in\Lambda$.

It is well known (see Subsection 1.2.5) that in another microlocal coordinate system with the same form of Λ we obtain the microlocalization $A'_z=Q_z^*A_zQ_z$ where Q_z is a unitary metaplectic (see Definition 1.2.39) operator in $\mathscr{L}^2(\mathbb{R}^{d''})$ also acting in $\mathscr{L}^2(\mathbb{R}^{d''},\mathbb{K})=\mathscr{L}^2(\mathbb{R}^{d''})\otimes\mathbb{K}$.

Definition 12.5.3. One says that the operator $A\in\boldsymbol{\Psi}^{m,\mu}(X,\Lambda,\mathbb{K})$ is *maximally hypoelliptic* if and only if the following two conditions are fulfilled: the inequality

$$\|a_0(x,\xi)v\|\ge\epsilon_0\sigma^{\mu}(x,\xi)|\xi|^m\|v\| \qquad \forall (x,\xi)\in T^*X \quad \forall v\in\mathbb{K} \tag{12.5.6}$$

holds with a constant $\epsilon_0>0$ and with

$$\sigma(x,\xi)=\operatorname{dist}\bigl((x,\xi|\xi|^{-1}),\Lambda\bigr)\asymp |x''|+|\xi''|\cdot|\xi'|^{-1} \tag{12.5.7}$$

where the last relation holds as Λ is given by (12.5.4) and only in the conical vicinity of Λ and

[51] A Hermitian bundle $\mathbb{K}$ should be replaced by its fiber $\mathbb{K}_z$ over z in this definition.

(12.5.8) Operator A_z is injective in $\mathbb{H} = \mathscr{L}^2(\mathbb{R}^{d''}, \mathbb{K})$ at every point $z \in \Lambda$. In this case

$$\|A_z v\|_{\mathbb{H}} \geq \epsilon_0 \|v\|_{\mathbb{H}} \qquad \forall v \in \mathbb{H} \quad \forall z \in \Lambda \cap \{|\xi'| = 1\} \tag{12.5.9}$$

with an appropriate constant $\epsilon_0 > 0$.

Here and below $\|.\|_{\mathbb{K}}$, $\|.\|_{\mathbb{H}}$ and $\|.\|$ are the norms in $\mathbb{K}$, $\mathbb{H}$ and $\mathscr{L}^2(X, \mathbb{K})$ respectively and $\langle ., . \rangle_{\mathbb{K}}$, $\langle ., . \rangle_{\mathbb{H}}$ and $(., .)$ are the corresponding inner products.

It is well known L. Boutet de Monvel [2] that

Theorem 12.5.4. *(i) Every maximally hypoelliptic operator is microlocally hypoelliptic; more precisely, operator $A \in \boldsymbol{\Psi}^{m,\mu}(X, \Lambda, \mathbb{K})$ satisfies*

$$\mathsf{WF}^{s+l}(u) \subset \mathsf{WF}^{s}(Au) \qquad \forall u \in \mathscr{D}'(X, \mathbb{K}) \tag{12.5.10}$$

with $l = m - \frac{\mu}{2}$ if and only if it is maximally hypoelliptic.

(ii) Moreover, in this case (and only in this case) the resolvent of A is a bounded operator from $\mathscr{H}^s(X, \mathbb{K})$ to $\mathscr{H}^{s+l}(X, \mathbb{K})$.

In this section we treat a maximally hypoelliptic operator A with

$$l = m - \frac{\mu}{2} > 0. \tag{12.5.11}$$

Corollary 12.5.5. *If $A \in \boldsymbol{\Psi}^{m,\mu}(X, \Lambda, \mathbb{K})$ and (12.5.11) holds then the resolvent of A is a compact operator in $\mathscr{L}^2(X, \mathbb{K})$ and the spectrum of A is discrete with no accumulation point (provided A is self-adjoint).*

Remark 12.5.6. One can easily prove that this is wrong for $l \leq 0$; moreover, for $l < 0, m > 0$ the continuous spectrum fills either the semiaxis or axis, while for $l = 0, m > 0$ and $l < 0, m = 0$ the spectrum is more complicated: there is an infinite number of accumulation points or points of the infinite multiplicity point spectrum (provided the operator is self-adjoint); for $m < 0$ the structure of the spectrum is transparent.

We leave to the reader the following easy problem

Problem 12.5.7. Prove that

(i) If Weyl symbol of A is Hermitian at every point $z \in T^*X$ then the Weyl symbol of A_z is Hermitian at every point $z'' \in T^*(\mathbb{R}^{d''})$ and therefore A_z is obviously symmetric in $\mathbb{H}$.

(ii) Moreover, under condition (12.5.8) A_z is an elliptic global operator (see Section 1.1.4) and is therefore self-adjoint.

(iii) A symmetric maximally hypoelliptic operator satisfying (12.5.11) is self-adjoint. Moreover, a self-adjoint maximally hypoelliptic operator satisfying (12.5.11) is semibounded from above if and only if both of the following two conditions are fulfilled:

(12.5.12) $a_0(z)$ is a negative definite matrix in $\mathbb{K}$ at every point $z \in (T^*X \setminus 0) \setminus \Lambda$

and

(12.5.13) A_z is a negative definite operator in $\mathbb{H}$ at every point $z \in \Lambda$.

12.5.2 Getting sStarted

So, let $A \in \boldsymbol{\Psi}^{m,\mu}(X, \Lambda, \mathbb{K})$ be a maximally hypoelliptic and self-adjoint operator and let (12.5.11) be fulfilled. Let $\mathsf{N}^{\pm}(\tau)$ be the number of eigenvalues of A lying in the intervals $[0, \tau)$ and $(-\tau, 0]$ respectively. We are interested in the asymptotics of $\mathsf{N}^{+}(\tau)$ as $\tau \to +\infty$. One can obtain the asymptotics of $\mathsf{N}^{-}(\tau)$ by replacing A by $-A$.

First of all, let us rewrite $\mathsf{N}^{\pm}(\tau)$ in the form

$$\mathsf{N}^{\pm}(\tau) = \mathsf{N}_0^{\pm}(\tau) + \mathsf{N}_1^{\pm}(\tau), \qquad \mathsf{N}_j^{\pm}(\tau) = \int \psi_j(x)\, \mathsf{tr}(e(x,x,))\, dx \tag{12.5.14}$$

where $e(x, y, \tau)$ is the Schwartz kernel of the spectral projector of A and ψ_j are classical pseudodifferential operators of order 0,

$$\mathsf{supp}(\psi_0) \cap \Lambda = \emptyset, \qquad \mathsf{supp}(\psi_1) \subset \mathcal{Z} = \big\{(x,\xi) : \ \sigma(x,\xi) < \epsilon\big\} \tag{12.5.15}$$

where $\epsilon > 0$ is an arbitrarily small constant. Recall that $\sigma(x, \xi)$ is defined by (12.5.7). Then

Proposition 12.5.8. *Let A be a self-adjoint operator. Then for $\mathsf{N}_0^{\pm}(\tau)$ the standard Weyl asymptotics holds with principal part*

$$\kappa_0\tau^{\frac{1}{m}(d-1)} + \kappa_{\frac{1}{2}}\tau^{\frac{1}{m}(d-\frac{1}{2})} + \kappa_1\tau^{\frac{1}{m}(d-1)} \tag{12.5.16}$$

and with remainder estimate $O\bigl(\tau^{\frac{1}{m}(d-1)}\bigr)$ and even $o\bigl(\tau^{\frac{1}{m}(d-1)}\bigr)$ under the standard condition non-periodicity condition to the Hamiltonian trajectories of a_0 on the energy level $\tau = 1$. Here $\kappa_{\frac{1}{2}} = 0$ provided $a_{\frac{1}{2}} = 0$.

Therefore we should treat $\mathsf{N}_1^{\pm}(\tau)$ in the same way we treated $\mathsf{N}_{\mathsf{cusp}}^{\pm}(\tau)$ before. First of all we need the following assertion

Proposition 12.5.9. *Let $A \in \boldsymbol{\Psi}^{m,\mu}(X,\Lambda,\mathbb{K})$ be a self-adjoint operator and $\psi_1 \in \boldsymbol{\Psi}^0(X)$ satisfy* (12.5.15).

(i) Let $\phi \in \mathscr{C}_0^{K'}(\mathbb{R}^{d''})$ be supported in $B(0,\epsilon)$ with a small enough constant $\epsilon > 0$. Then estimate

$$\bigl|\bigl(\phi(\tau^{-\frac{1}{m}}D')\psi_1 e\bigr)(x,y,\tau',\tau)\bigr| \le C\tau^{-s} \tag{12.5.17}$$

holds with arbitrarily large s for $\tau > 0$, $\tau' \in [\epsilon_0\tau, \tau]$.

(ii) Let A be maximally hypoelliptic and let $(1-\phi) \in \mathscr{C}_0^{K'}(\mathbb{R}^{d'})$ and ϕ be supported in $\{|\xi'| \ge C_0\}$ with a large enough constant C_0. Then estimate

$$\bigl|\bigl(\phi(\tau^{-\frac{1}{l}}D')\psi_1 e\bigr)(x,y,\tau',\tau)\bigr| \le C\tau^{-s} \tag{12.5.18}$$

holds with arbitrarily large s for $\tau > 0$, $\tau' \in [\epsilon_0\tau, \tau]$.

(iii) Let $\phi \in \mathscr{C}_0^{K'}(\mathbb{R}^{d'})$, $0 \notin \mathsf{supp}(\phi)$ and $\varphi \in \mathscr{C}_0^{K'}(\mathbb{R}^{d''})$. Let $r \ge \tau^{\delta}$, $\epsilon \ge \sigma \ge r^{-\frac{1}{2}}$ and $\rho^{\mu} r^{m} \le \varepsilon\tau$ with an arbitrarily small exponent $\delta > 0$ and with a small enough constant $\varepsilon > 0$. Then estimate

$$\bigl|\bigl(\varphi(\rho^{-1}x'', \rho^{-1}r^{-1}D'')\phi(r^{-1}D')\psi_1 e\bigr)(x,y,\tau',\tau)\bigr| \le C\tau^{-s} \tag{12.5.19}$$

holds with arbitrarily large s for $\tau > 0$, $\tau' \in [\epsilon_0\tau, \tau]$.

Proof. Statement (i) follows from the ellipticity of operator $(\tau - A)$ in the zone $\bigl\{|\xi| \le \varepsilon\tau^{\frac{1}{m}}\bigr\}$ with a small enough constant $\varepsilon > 0$.

Further, Statement (iii) follows from the ellipticity of operator $(\tau - A)$ in the zone $\bigl\{\epsilon r \le |\xi'| \le cr, |x''| + |\xi''|r^{-1} \le c\rho\bigr\}$ with the indicated r and ρ.

On the other hand, Statement (ii) follows from the maximal hypoellipticity of operator $(\tau - A)$ in the zone $\{|\xi'| \ge C_0\tau^{\frac{1}{l}}, \sigma(x,\xi) \le \epsilon\}$. More precisely, estimate

$$\|Au\|_s + \|u\|_s \ge \epsilon_0 \|A'u\|_s \tag{12.5.20}$$

holds where as usual $\|.\|$ means the norm in the Sobolev space $\mathscr{H}^s(X,\mathbb{K})$ and A' means any operator belonging to $\mathbf{\Psi}^{m,\mu}(X,\Lambda,\mathbb{K})$ (Boutet de Monvel [2]). In particular,

$$\|Au\|_s + \|u\|_s \ge \epsilon_0 \|u\|_{s+l} \tag{12.5.21}$$

and estimate (12.5.20) yields Statement (ii). □

Therefore, in what follows we need to treat zone

$$\begin{aligned}\mathcal{U} = \{\sigma(x,\xi) \le \epsilon, \epsilon_0\tau^{\frac{1}{m}} \coloneqq r_*(\tau) \le |\xi'| \le r^*(\tau) \coloneqq C_0\tau^{\frac{1}{l}},\\ \epsilon_0 \le \sigma(x,\xi)|\xi'|^{-\frac{m}{\mu}}\tau^{\frac{1}{\mu}}\}.\end{aligned} \tag{12.5.22}$$

In this zone let us make a $(\epsilon_1, \epsilon_1|\xi'|; \epsilon_1\sigma(x,\xi), \epsilon_1\sigma(x,\xi)|\xi'|)$-admissible partition of unity on $(x',\xi';x'',\xi'')$ with a small enough constant $\epsilon_1 > 0$ and let us treat some element $\bar{q}$ of this partition; let $\bar{r}$ and $\bar{\sigma}$ be the values of $|\xi'|$ and σ calculated at $\bar{z} \in \bar{q}$; then

$$\epsilon_0\tau \le \bar{r}^m\bar{\sigma}\mu \le c_0\tau, \qquad r_*(\tau) \le \bar{r} \le r^*(\tau). \tag{12.5.23}$$

12.5.3 Weyl Asymptotics

Let us start with the completely Weyl theory. For this let us consider an $(\epsilon_1, \epsilon_1\sigma^2 r; \epsilon_1\sigma r, \epsilon_1\sigma)$-admissible partition of unity on $(x',\xi';x'',\xi'')$. Then rescaling $x''_{\mathsf{new}} = x''\bar{\sigma}^{-1}$ we transform A to an h-pseudodifferential operator $\bar{r}^m\bar{\sigma}^\mu\tilde{A}_h$ provided

$$h \coloneqq \bar{r}^{-1}\bar{\sigma}^{-2} \le h_0 \tag{12.5.24}$$

with a small constant h_0.

Then the contribution of this element to the principal part of the asymptotics is 0 and its contribution to the remainder estimate is $O(h^s)$ with an arbitrarily large exponent s provided one of the following two conditions is fulfilled:

(a) a_0 is negative definite on $T^*X \setminus 0$;

(b) $\bar{r}^m \bar{\sigma}^\mu \ge C_0 \tau$.

Then after summation over such elements we conclude that

(12.5.25) The total contribution of all such elements of the partition lying in $\mathcal{U}$ to the principal part of the Weyl asymptotics is 0 and to the remainder estimate is $O\bigl(\tau^{d'l-1}\bigr)$.

Really, it does not exceed

$$\iint_{\mathcal{U}} \sigma^{-2d'-1} r^{-1}\, d\sigma\, dr \asymp \int_{r\le \tau^{l-1}} r^{d'-1}\, dr \asymp \tau^{d'l-1}.$$

In particular, applying Proposition 12.5.9 we arrive to the following two statements

(12.5.26) If A is maximally hypoelliptic and a_0 is negative definite then the contribution of $\complement\mathcal{V}$ to the asymptotics is $O\bigl(\tau^{d'l-1}\bigr)$ where

$$\mathcal{V} = \bigl\{|\xi| \ge c_0, \sigma(x,\xi) \le \epsilon, \sigma^2(x,\xi)|\xi'| \le c_0\bigr\}.$$

and

(12.5.27) In the general case the contribution of zone

$$\mathcal{W} = \bigl\{|\xi| \ge c_0, |\xi'|^m \sigma(x,\xi)^\mu \ge C_0\tau\bigr\}$$

to the asymptotics is $O\bigl(\tau^{d'l-1}\bigr)$ as well.

On the other hand, let us consider zone $\mathcal{V}$. Again due to Proposition 12.5.9 we should consider only elements with $r_*(\tau) \le |\xi'| \le r^*(\tau)$. Applying the previous arguments with σ replaced by $\rho(\xi') = |\xi'|^{-\frac{1}{2}}$ and $h = 1$ we see that

(12.5.28) The total contribution of $\mathcal{V}$ to the asymptotics is $O\bigl(\tau^{d'l-1}\bigr)$ as well.

So we obtain as a corollary the following rather well known estimate

$$\mathsf{N}^+(\tau) = O\bigl(\tau^{\frac{1}{l}d'}\bigr) \qquad \text{as} \quad \tau \to +\infty \tag{12.5.29}$$

for maximally hypoelliptic operators with negative definite symbols.

Let us consider the general case and let us treat the elements of the above partition with $r\sigma^2 \ge C_0$, $r \ge c_0$, $r^m\sigma^\mu \asymp \tau$. Let us note that

(12.5.30) After the coordinate transform $x''_{\mathsf{new}} = x''\bar\sigma^{-1}$ and multiplication by τ^{-1} operator A is microhyperbolic in the direction $\langle x, \partial_\xi\rangle$ provided C_0 is large enough.

Then the contribution of each element to the principal part is given by Weyl expression

$$(2\pi)^{-d}\iint \bar q_1^{\mathsf{w}}(x,\xi) n^+(x,\xi,\tau)\,dxd\xi$$

where $n^+(x,\xi,\tau)$ is the number of eigenvalues of the symbol $a_0(x,\xi)+a_{\frac12}(x,\xi)$ in the interval $[0,\tau)$; one can introduce $n^-(x,\xi,\tau)$ and $n(x,\xi,\tau)$ in the same way.

On the other hand, the contribution of this element to the remainder is $O(h^{1-d}) = O\bigl(\bar r^{d-1}\bar\sigma^{2(d-1)}\bigr)$. Then the contribution of the element of a $(\epsilon_1,\epsilon_1|\xi'|;\epsilon_1\sigma,\epsilon_1\sigma|\xi'|)$-admissible partition to the remainder is

$$O\bigl(\bar r^{d-1}\bar\sigma^{2(d''-1)}\bigr) = O\bigl(\bar r^{d-1-2(d''-1)\frac{m}{\mu}}\tau^{\frac{2}{\mu}(d''-1)}\bigr)$$

and after summation on this partition of unity we obtain the remainder estimate

$$R^{\mathsf{W}}(\tau) = \begin{cases} O\bigl(\epsilon'\tau^{\frac{1}{m}(d-1)}\bigr) & \text{for} \quad (d-1)l > d'm\\ O\bigl(\tau^{\frac{1}{m}(d-1)}\log\tau\bigr) & \text{for} \quad (d-1)l = d'm\\ O\bigl(\tau^{\frac{1}{l}d'}\bigr) & \text{for} \quad (d-1)l < d'm \end{cases} \tag{12.5.31}$$

where $\epsilon' = \epsilon'(\epsilon) \to +0$ as $\epsilon \to +0$.

So (also taking into account estimates for other zones) we arrive to the following theorem

Theorem 12.5.10. *Let $A \in \boldsymbol{\Psi}^{m,\mu}(X,\Lambda,\mathbb{K})$ be a maximally hypoelliptic (self-adjoint) operator, $l > 0$ and suppose a_0 is not a negative definite symbol. Then*

(i) For $(d-1)l > d'm$ *asymptotics*

$$\mathsf{N}^{+}(\tau) = \mathsf{N}^{\mathsf{W}+}(\tau) + O\bigl(\tau^{\frac{d-1}{m}}\bigr) \tag{12.5.32}$$

holds with

$$\mathsf{N}^{\mathsf{W}+}(\tau) = (2\pi)^{-d} \iint n^{+}(x,\xi,\tau)\, dxd\xi. \tag{12.5.33}$$

(ii) Moreover, if $(d-1)l > d'm$ *and if the symbol* a_0 *satisfies the standard non-periodicity condition on the energy level* $\tau = 1$ *then asymptotics*

$$\mathsf{N}^{+}(\tau) = \mathsf{N}^{\mathsf{W}+}(\tau) + \kappa_1' \tau^{\frac{d-1}{m}} + o\bigl(\tau^{\frac{d-1}{m}}\bigr) \tag{12.5.34}$$

hold with the standard coefficient κ_1'.

(iii) Further, for $(d-1)l = d'm$ *asymptotics*

$$\mathsf{N}^{+}(\tau) = \mathsf{N}^{\mathsf{W}+}(\tau) + O\bigl(\tau^{\frac{d-1}{m}} \log \tau\bigr) \tag{12.5.35}$$

holds.

(iv) Furthermore, for $(d-1)l < d'm \le dl$ *asymptotics*

$$\mathsf{N}^{+}(\tau) = \mathsf{N}^{\mathsf{W}+}(\tau) + O\bigl(\tau^{\frac{d'}{l}}\bigr) \tag{12.5.36}$$

holds where for $d'm = dl$ $\mathsf{N}^{\mathsf{W}+}(\tau)$ *is given by cut-off Weyl formula* (12.5.33) *with integration only in the domain* $\bigl\{|\xi'| \ge \tau^{\frac{1}{l}}, \sigma(x,\xi) \ge |\xi'|^{-\frac{1}{2}}\bigr\}$ *and* $\mathsf{N}^{\mathsf{W}+}(\tau) \asymp \tau^{\frac{d'}{l}} \log \tau$.

(v) Finally, for $dl < d'm$ *estimate*

$$\mathsf{N}^{+}(\tau) = O\bigl(\tau^{\frac{d'}{l}}\bigr) \tag{12.5.37}$$

holds. Moreover, the same estimate holds if $a_0(x,\xi)$ *is negative definite.*

(vi) Moreover, in all these asymptotics one can replace $\mathsf{N}^{\mathsf{W}+}(\tau)$ *by*

(12.5.38) $\mathsf{N}_1^{\mathsf{W}+}(\tau) =$

$$\begin{cases} \kappa_0 \tau^{\frac{1}{m}d} + \kappa_{\frac12} \tau^{\frac{1}{m}(d-\frac12)} + \kappa_1'' \tau^{\frac{1}{m}(d-1)} & \text{for } (d-1)l > d'm, \\ \kappa_0 \tau^{\frac{1}{m}d} + \kappa_{\frac12} \tau^{\frac{1}{m}(d-\frac12)} & \text{for } (d-\frac12)l > d'm \ge (d-1)m, \\ \kappa_0 \tau^{\frac{1}{m}d} + \kappa'_{\frac12} \tau^{\frac{1}{m}(d-\frac12)} \log \tau & \text{for } (d-\frac12)l = d'm, \\ \kappa_0 \tau^{\frac{1}{m}d} & \text{for } (d-\frac12)l < d'm < (d-1)m < dl, \\ \kappa'_0 \tau^{\frac{1}{m}d} \log \tau & \text{for } d'm < (d-1)m = dl \end{cases}$$

with positive constants κ_0 *and* κ'_0.

Moreover, $\kappa_{\frac12} = \kappa'_{\frac12} = 0$ *provided* $a_{\frac12} \equiv 0$.

We leave to the reader the following easy problem

Problem 12.5.11. (i) Similarly prove that for Riesz means the remainder estimate is

$$(12.5.39) \quad R^{\mathsf{W}}_{(\vartheta)}(\tau) = \begin{cases} O\bigl(\epsilon' \tau^{\frac{1}{m}(d-1-\vartheta)+\vartheta}\bigr) & \text{for } (d-1-\vartheta)l > d'm, \\ O\bigl(\tau^{\frac{1}{m}(d-1-\vartheta)+\vartheta} \log \tau\bigr) & \text{for } (d-1-\vartheta)l = d'm, \\ O\bigl(\tau^{\frac{1}{l}d'+\vartheta}\bigr) & \text{for } (d-1-\vartheta)l < d'm \end{cases}$$

while the principal part contains terms $\kappa_j \tau^{\frac{1}{m}(d-j)+\vartheta}$ with $j \in \frac12 \mathbb{Z}$; for $(d-j)l = d'm$ one should replace this term by $\kappa'_j \tau^{\frac{1}{m}(d-j)+\vartheta} \log \tau$ while the remainder estimate is $O\bigl(\tau^{\frac{1}{m}(d-j)+\vartheta}\bigr)$ (if $j < 1+\vartheta$).

(ii) Moreover, let $k \notin \mathbb{Z}$ and $a_j \equiv 0$ for all $j \notin \mathbb{Z} : j \le k$. Prove that then $\kappa_k = 0$.

So, if a_0 is not negatively definite in what follows we need only to treat the case $(d-1)l \le d'm$ (or $(d-1-\vartheta)l \le d'm$ if we are interested in Riesz means).

12.5.4 Sharp Asymptotics

Let us treat x'' as an additional variable; however, we do not now introduce the special Hilbert space $\mathbb{H}$. First of all, let us note that standard ellipticity arguments yield the following

Proposition 12.5.12. *Let $q' \in \mathscr{C}_0^{K'}(\mathbb{R}^{2d'})$ and $q'' \in \mathscr{C}_0^{K'}(\mathbb{R}^{2d''})$ be fixed functions vanishing in neighborhoods of $\{\xi' = 0\}$ and $\{x'' = \xi'' = 0\}$ respectively. Moreover, let $\sigma > 0$ be a small enough constant and let $\bar{r} \ge c_\sigma \tau^{\frac{1}{m}}$ where σ and c_σ depend on q', q'' and c_σ is large enough.*

Then for the operators $Q' = q'(x', \bar{r}^{-1}D')$ and $Q'' = q''(\sigma^{-1}x'', \sigma^{-1}\bar{r}^{-1}D'')$ estimate

$$\begin{aligned}(12.5.40)\quad &\bigl|F_{t\to\lambda}\chi_T(t)Q'_x\psi_1 Q''_x U\bigr| \le C\hbar^s\\ &\qquad \forall x, y \in X \quad \forall \lambda : |\lambda - \tau| \le \epsilon\tau \quad \forall T \in [\bar{r}^\delta\tau^{-1}, T_0\bar{r}\tau^{-1}]\end{aligned}$$

holds with an arbitrarily small exponent $\delta > 0$, an arbitrarily large exponent s and with small enough constants $T_0 > 0$ and $\epsilon > 0$; here and below $U(x, y, t)$ is the Schwartz kernel of the operator $\exp(itA)$ and $\hbar = \bar{r}^{-1}$.

This proposition permits us to include x''-mollifying operator $q(x'', \bar{r}^{-1}D'')$ with compactly supported q in our expressions whenever necessary.

Let us note that if $\phi = \phi(x', \hbar D')$ then in the ϵ-neighborhood of the point $(\bar{x}', \bar{\xi}')$ with $|\bar{\xi}'| \asymp \bar{r}$ operator $\bar{r}[A, \phi]$ belongs to $\boldsymbol{\Psi}^{m,\mu}(X, \Lambda, \mathbb{K})$ uniformly in $(\bar{x}', \bar{\xi}')$.

Proposition 12.5.13. *Let $q'_1, q'_2 \in \mathscr{C}_0^{K'}(\mathbb{R}^{2d'})$ be fixed functions and let q' vanish in a neighborhood of $\{\xi' = 0\}$, $q'_2 = 1$ in a neighborhood of $\operatorname{supp}(q'_1)$. Then for the operators $Q'_j = q'_j(x', \bar{r}^{-1}D')$ estimate*

$$\begin{aligned}(12.5.41)\quad &\bigl|F_{t\to\lambda}\psi_1\chi_T(t)Q'_{1x}(I - Q'_{2x})U\bigr| \le C\hbar^s\\ &\qquad \forall x, y \in X \quad \forall \lambda : |\lambda - \tau| \le \epsilon\tau \quad \forall T \in [\bar{r}^\delta\tau^{-1}, T_0\bar{r}\tau^{-1}]\end{aligned}$$

holds with an arbitrarily small exponent $\delta > 0$, an arbitrarily large exponent s and with small enough constants $T_0 > 0$ and $\epsilon > 0$.

Proof. Proof uses the standard energy estimate technique of Chapter 2 (see proof of Theorem 2.1.2 and takes into account estimate (12.5.20) and Proposition 12.5.12.

Easy details are left to the reader. □

This proposition shows us that singularities with respect to (x', ξ') of U propagate with the speed not exceeding $(\bar{r}^{-1}\tau, \tau)$ along (x', ξ') (without rescaling on ξ') while in the zone which is semiclassical with respect to

all the variables singularities propagate along (x'', ξ'') with the speed not exceeding $\bar{\sigma}^{-1}(\bar{r}^{-1}\tau, \tau)$.

Let us consider the $(\epsilon, \epsilon\bar{r})$-neighborhood of $(\bar{x}', \bar{\xi}')$ with $|\bar{\xi}'| = \bar{r}$. Let $\boldsymbol{a}(x', \xi') = A(x', x'', \xi', D'')$ be an operator acting on x'' only. We claim that

Proposition 12.5.14. *For the operator $\boldsymbol{a}(x', \xi)$ the microhyperbolicity estimate*

$$\operatorname{Re} \langle (\langle \bar{\xi}', \partial_{\xi'} \rangle \boldsymbol{a}) v, v \rangle \geq \epsilon_0 |\tau| \cdot \|v\|^2 - c_2 |\tau|^{-1} \|(\tau - \boldsymbol{a}) v\|^2 - C \bar{r}^{-s} \|w\|^2 \tag{12.5.42}$$

holds for $v = \psi_1 w$ where norms and inner products are here considered only on x'', (x', ξ') belongs to this neighborhood, and $\tau > 0$ is such that $r_*(\tau) \leq \bar{r} \leq r^*(\tau)$; here $\epsilon_0 > 0$ is a small enough constant and c_2 and C are large enough constants; none of the constants depends on $(\bar{x}', \bar{\xi}')$ and τ; s is an arbitrarily large exponent.

Proof. It is sufficient to prove this estimate for $\xi' = \bar{\xi}'$. Let us apply Taylor's formula to A; we obtain that

$$\boldsymbol{a}(x', \xi'; x'', D'') \equiv \sum_{|\alpha|+|\beta|+n=\mu} a^{(\alpha)}_{\frac{n}{2}(\beta)}(x', \xi') \frac{1}{\alpha! \beta!} x''^{\beta} D''^{\alpha} \qquad \operatorname{mod} \boldsymbol{\Psi}^{m, \mu+1}$$

where here and below we take $x'' = \xi'' = 0$ in $a^{(\alpha)}_{\frac{n}{2}(\beta)}$. Then for $\xi' = \bar{\xi}'$ we obtain the equality

$$\langle \xi', \partial_{\xi'} \rangle \boldsymbol{a}(x', \xi'; x'', D'') \equiv \sum_{|\alpha|+|\beta|+n=\mu} (m - n - |\alpha|) a^{(\alpha)}_{\frac{n}{2}(\beta)}(x', \xi') \frac{1}{\alpha! \beta!} x''^{\beta} D''\alpha \equiv l\boldsymbol{a} - i[L, \boldsymbol{a}] \qquad \operatorname{mod} \boldsymbol{\Psi}^{m, \mu+1}$$

with $L = \frac{1}{2}\langle x'', D'' \rangle - \frac{1}{4} i d''$. Then estimates (12.5.40)–(12.5.41) together with the assumption that $l > 0$ yield estimate (12.5.42). □

Again applying the analysis of Chapter 2 (see proof of Proposition 2.1.16 and Corollary 2.1.17) we conclude that

Proposition 12.5.15. *In the framework of Proposition 12.5.12 estimate*

$$\bigl|F_{t\to\lambda}\Gamma'_x\psi_1\chi_T(t)Q'_{1x}U\bigr| \le C\bar r^{-s} \tag{12.5.43}$$

holds for x', y', τ and T indicated in this proposition provided χ vanishes in a neighborhood of 0; Γ' means that we set $y'=x'$ and then integrate over x'.

Then we want to apply the successive approximation method but we lack auxiliary spaces $\mathbb{H}$ and $\mathbb{H}_j$. In order to overcome this difficulty we treat two cases:

(a) $\bar r \le r^*(\tau)\tau^{-\delta}$,

(b) $\bar r \ge r_*(\tau)\tau^{\delta}$

with $\delta>0$; these cases overlap and together cover the case $\bar r\in[r_*(\tau), r^*(\tau)]$.

In the former Case (a) we can apply our standard technique with an unperturbed operator $\bar A = a(y,D_x)$ and we obtain estimate

$$\bigl|F_{t\to\lambda}\bar\chi_T(t)\operatorname{tr}(\Gamma Q_x U) - \sum_{0\le j\le J-1} \varkappa'_{\frac{j}{2}}(\tau)\bigr| \le C\tau^{-s} \qquad \forall\lambda : |\lambda-\tau|\le\epsilon\tau \tag{12.5.44}$$

with arbitrary $T\in[\tau^{-1}h^{-\delta'}, T_0\tau^{-1}h^{-1}]$ where $T_0>0$ is a small enough constant, $\delta'>0$ and s are arbitrary and $h=\bar r^{-1}\bar\sigma^{-2}$; in contrast to the previous $\bar\sigma$ is not a small constant but a parameter such that $h\le 1$.

Here $J=J(d,m,\mu,s,\delta,\delta')$ is sufficiently large and $\varkappa'_{\frac{j}{2}}$ are Weyl terms (rather than coefficients) depending on Q and satisfying estimate

$$|\varkappa'_{\frac{j}{2}}| \le C\bigl(\bar r\bar\sigma^2\bigr)^{d-\frac{j}{2}}\tau^{-1} \tag{12.5.45}$$

provided the symbol of Q is supported in the $\epsilon(1,\bar\sigma^2\bar r,\bar\sigma,\bar\sigma\bar r)$-neighborhood of $(\bar x',\bar\xi',\bar x'',\bar\xi'')$, $|\bar\xi'|\asymp\bar r$; here and below we refer to the standard 1-symbol of Q instead of the $\hbar$-symbol.

These estimates (12.5.44) and (12.5.45) are due to the standard micro-hyperbolicity of a_0 in the direction $\langle\xi,\partial_\xi\rangle$ after the coordinate transform $x'_{\text{new}}=x'_{\text{old}}$, $\xi'_{\text{new}}=\xi'_{\text{old}}\bar\sigma^{-2}$, $x''_{\text{new}}=x''_{\text{old}}\bar\sigma^{-1}$, $\xi''_{\text{new}}=\xi''_{\text{old}}\bar\sigma^{-1}$.

It should be noted that in Case (a) in virtue of standard ellipticity arguments we automatically obtain that only points with $h\le\tau^{-\delta''}$ with

sufficiently small exponent $\delta'' > 0$ should be treated. Then for operator Q with symbol supported in the $\epsilon(1, \bar{r}, \bar{\sigma}, \bar{\sigma}\bar{r})$-neighborhood of $(\bar{x}', \bar{\xi}', \bar{x}'', \bar{\xi}'')$ we obtain the same result with another estimate of these terms:

$$\bigl|\varkappa'_{\frac{j}{2}}\bigr| \le C\bar{r}^{d-\frac{j}{2}}\bar{\sigma}^{2(d''-\frac{j}{2})}\tau^{-1}. \tag{12.5.46}$$

Moreover, (12.5.40) yields that the same estimates hold with Q replaced by $\psi_1 Q'$ where $Q' = q'(x', \bar{r}^{-1}D')$ and q' is supported in the ϵ-neighborhood of $(\bar{x}', \bar{\xi}'\bar{r}^{-1})$. Furthermore, estimate (12.5.43) then yields that estimate (12.5.44) holds for arbitrary $T \in [\tau^{-1}h^{-\delta'}, T_0\tau^{-1}\hbar^{-1}]$.

Applying the standard Tauberian technique we obtain that

$$\Bigl|\Bigl(\int \mathsf{tr}(Q'_x\psi_1 e)(x, x, \tau)\,dx - \sum_{0\le j\le J-1} \varkappa_{\frac{j}{2}}(\tau)\Bigr)_{\tau=\tau'}^{\tau=\tau}\Bigr| \le C\bar{r}^{d-1}\bar{\sigma}^{2d''} \asymp C\bar{r}^{d-1-2d''\frac{m}{\mu}}\tau^{\frac{2d''}{\mu}} \tag{12.5.47}$$

with $\tau' \in [\epsilon_0\tau, \tau]$, $\tau > 0$ where $\varkappa_{\frac{j}{2}}(\tau)$ are standard Weyl terms equal to the integrals of $\varkappa'_{j/2}(\tau)$ with respect to τ and therefore

$$\bigl|\varkappa_{\frac{j}{2}}(\tau)\bigr| \le C\bar{r}^{d-\frac{j}{2}}\bar{\sigma}^{2(d''-\frac{j}{2})}. \tag{12.5.48}$$

Let us discuss the terms $\varkappa_{\frac{j}{2}}(\tau)$. Recall that

$$\sum_{0\le j\le J-1} \varkappa'_{\frac{j}{2}} \sim (2\pi)^{-d-1}i^{-1}\,\mathsf{Res}_{\mathbb{R}} \int \bigl((\tau - A)^{-1}Q'\psi_1\bigr)_{\mathsf{w}}(x, \xi)\,dxd\xi \tag{12.5.49}$$

where the subscript "$_{\mathsf{w}}$" means that we take the Weyl symbol of the corresponding operator and $(\tau - A)^{-1}$ is a parametrix of $(\tau - A)$ in the framework of the formal calculus of pseudodifferential operators; we cut this symbol after we have taken a large enough number of $(m, 1)$-quasihomogeneous terms (on (τ, ξ)) of the symbol of $(\tau - A)^{-1}$ and derivatives of these terms on (x, ξ) and therefore derivatives of the symbol of $Q'\psi_1$ on (ξ, x).

Let us note that any differentiation of ψ_1 gives us a term which does not exceed the right-hand expression in (12.5.47); the same is true for any differentiation with respect to x' and therefore with respect to ξ' (and *vice versa*) made in the calculation of $(\tau - A)^{-1}$ and of its product with Q'.

Therefore estimate (12.5.47) remains true if, in the definition of terms coefficients, we replace the right-hand expression of (12.5.49) by

$$(12.5.50) \qquad (2\pi)^{-d-1} i^{-1} \operatorname{Res}_{\mathbb{R}} \int \big((\tau - a)^{-1} \big)_{\mathsf{w}} (x,\xi) Q'(x',\xi') \psi_1(x,\xi)\, dx d\xi$$

where $(\tau - a)^{-1}$ is the parametrix of $(\tau - a)$ in the framework of the formal calculus of pseudodifferential operators with respect to x' and the subscript "w" means the Weyl symbol of the corresponding operator; here $a(x',\xi') = A(x',\xi'; x'', D'')$ but later we will change this definition.

Recall that $\big((\tau - a)^{-1}\big)_{\mathsf{w}}$ is a distribution. However, if we use spherical coordinates $\xi = (r,\varphi)$ with $\varphi \in \mathbb{S}^{d-1}$ and integrate on r (multiplying by a $\mathscr{C}_0^\infty$ function beforehand) we obtain a regular function of (τ, x, φ) provided $(x'', \varphi'') \neq 0$.

Let us introduce the spherical coordinate system $(\zeta, z) \in \mathbb{R}^+ \times \mathbb{S}^{2d''-1}$ in $\mathbb{R}^{2d''} \ni (x'', \varphi'')$; then one can rewrite the term of $\big((\tau - a)^{-1}\big)_{\mathsf{w}}$ which is $(m,1)$-quasihomogeneous of order $(-m - \frac{j}{2})$ in the form

$$\sum_{0 \le k \le J-1} \tau^{-1} b_{jk}(\tau, r, z) \zeta^{k-j} + b'_j(\tau, r, z, \zeta)$$

where b'_j are regular functions. Then a similar representation holds for $\operatorname{Res}_{\mathbb{R}} \big((\tau - a)^{-1}\big)_{\mathsf{w}}$. Let us integrate it with respect to the measure $dx' dz d\varphi' \times \zeta^{2d''-1} d\zeta \times r^{d-1} dr$. Then after integration over τ from τ' to τ and summation over a partition of unity in the zone $\{r_*(\tau) \le r \le \eta\}$ we obtain the following

Proposition 12.5.16. *Let conditions* (12.5.1)–(12.5.3), (12.5.6)–(12.5.9) *and* (12.5.11) *be fulfilled and let*

$$(12.5.51) \qquad Q' = q_2(x', \varepsilon \tau^{-\frac{1}{m}} D') - q_1(x', \eta^{-1} D')$$

with fixed smooth functions q_j supported in $\{|\xi'| \le c\}$ and equal to 1 for $|\xi'| \le \epsilon_0$. Then estimate

$$(12.5.52) \qquad \big| \big(\int \operatorname{tr}(Q'_x \psi_1 e)(x,x,\tau) dx - \mathcal{N}(\tau,\eta) \big)_{\tau=\tau'}^{\tau=\tau} \big| \le C R_1^*(\tau)$$

holds with

$$(12.5.53) \qquad \mathcal{N}(\tau,\eta) = \mathcal{N}_0(\tau) + \mathcal{N}_1(\tau,\eta),$$

$$\mathcal{N}_0(\tau) = \sum_{j=0,1,2} \kappa_{\frac{j}{2}} \tau^{\frac{1}{m}(d-\frac{j}{2})} + \sum_{j,k=0,1,2:(d-\frac{j}{2})l=(d'-\frac{k}{2})m} \kappa'_{\frac{j}{2}} \tau^{\frac{1}{m}(d-\frac{j}{2})} \log \tau, \tag{12.5.54}$$

$$\mathcal{N}_1(\tau,\eta) = \sum_{j,k\le J:(d-\frac{j}{2})l\ne(d'-\frac{k}{2})m} \kappa_{jk} \tau^{\frac{1}{\mu}(2d''+k-j)} \eta^{\frac{2}{\mu}((d'-\frac{k}{2})m-(d-\frac{j}{2})l)} - \sum_{j,k=0,1,2:(d-\frac{j}{2})l=(d'-\frac{k}{2})m} \kappa'_{\frac{j}{2}} m \tau^{\frac{1}{m}(d-\frac{j}{2})} \log \eta, \tag{12.5.55}$$

$$R_1^*(\tau) = \begin{cases} \varepsilon' \tau^{\frac{1}{m}(d-1)} & \text{for } (d-1)l > (d'-1)m \\ C\tau^{\frac{1}{m}(d-1)} \log \tau & \text{for } (d-1)l = (d'-1)m \\ C\tau^{\frac{1}{l}(d'-1)-\delta''} & \text{for } (d-1)l < (d'-1)m \end{cases} \tag{12.5.56}$$

where the coefficients κ_j, κ'_j and κ_{jk} do not depend on τ and η, $J = J(d,m,\delta)$ is large enough, $\delta'' > 0$ and $\varepsilon' \to +0$ as $\varepsilon \to +0$.

Let us now treat Case (b) $\bar r \ge r_*(\tau)\tau^\delta$. In this case in order to obtain the unperturbed operator $\bar A$ we freeze $x' = y'$ in the operator $A_{(x',D')}(x'',D'')$ where $A_{(x',\xi')}(x'',D'')$ is the microlocalization (12.5.4) of $A(x,D)$ at the point (x',ξ') and we take Weyl quantization on x'.

We now treat this operator $\bar A$, and A itself, as pseudodifferential operators on x' with operator-valued symbols in $\mathbb{H} = \mathscr{L}^2(\mathbb{R}^{d''},\mathbb{K})$. Then all the constructions of the propagation of singularities of Chapter 2 are applicable including the proof of microhyperbolicity (we explained this proof above) as well as the successive approximation method.

Moreover, no sandwich procedure is necessary now because we apply a pseudodifferential operator ψ_1 mollifying on x''. So, we obtain that if $Q' = q'(x',\bar r^{-1}D')$ with q' supported in the ϵ-neighborhood of $(\bar x',\bar\xi'\bar r^{-1})$ with $\bar r \asymp |\bar\xi'|$ and $r^*(\tau) \ge \bar r \ge r_*(\tau)\tau^\delta$ then for $T \in [\tau^{-1}\bar r^{\delta'}, T_0\tau^{-1}\bar r]$ with a sufficiently small constant $T_0 > 0$ asymptotics

$$\bigl|F_{t\to\lambda}\chi_T(t)\Gamma\psi_1 Q'_x\bigl(U - \sum_{0\le n\le M} U_n\bigr)\bigr| \le C\tau^{-s} \qquad \forall\lambda : |\lambda-\tau| \le \epsilon\tau \tag{12.5.57}$$

holds where U_n are the terms of the successive approximation method, the number $M = M(d,m,\mu,\delta,s)$ is large enough and

$$\bigl|F_{t\to\lambda}\chi_T(t)\Gamma\psi_1 Q'_x U_n\bigr| \le C\bar r^{d-2d''m\mu^{-1}-\nu(n)}\tau^{2d''\mu^{-1}-1} \tag{12.5.58}$$

for the same values of T, τ with $\nu(n) \to +\infty$ as $n \to +\infty$. Therefore

$$\bigl|F_{t\to\lambda}\chi_T(t)\Gamma\psi_1 Q'_x U\bigr| \le C\bar r^{d-2d''m\mu^{-1}}\tau^{2d''\mu^{-1}-1} \tag{12.5.59}$$

for the same values of T, τ. We leave all the easy details to the reader.

Then applying the standard Tauberian technique we obtain estimate

$$\Bigl|\int \mathsf{tr}(Q'_x\psi_1 e)(x,x,\tau',\tau)\,dx - \sum_{0\le n\le M}\int_{\tau'}^{\tau}\bigl(F_{t\to\lambda}\bar\chi_T(t)\Gamma\psi_1 Q'_x U_{n(q)}\bigr)\,d\lambda\Bigr| \le C\bar r^{d-1-2d''m\mu^{-1}}\tau^{2d'\mu^{-1}} \tag{12.5.60}$$

for $\tau' \in [\epsilon_0\tau, \tau]$ where the conditions on $\bar r$ and T were given above, the subscript "(q)" has no meaning at this time and $\bar\chi \in \mathscr{C}_0^K([-1,1])$ is equal to 1 on $[-\frac12, \frac12]$.

Let us note that if we sum the right-hand expression of estimate (12.5.60) on a partition of unity on the interval for the $\bar r$ indicated above we obtain that the remainder does not exceed $CR_2^*(\tau)$ with

$$R_2^*(\tau) = \begin{cases} \tau^{\frac1m(d-1)-\delta''} & \text{for } (d-1)l > (d'-1)m,\\ \tau^{\frac1m(d-1)-\delta''}\log\tau & \text{for } (d-1)l = (d'-1)m,\\ \varepsilon'\tau^{\frac1l(d'-1)} & \text{for } (d-1)l < (d'-1)m \end{cases} \tag{12.5.61}$$

where $\varepsilon' = 1$ at this moment.

Further, let $(d-1)l < (d'-1)m$ and let us sum only over the partition in the zone $\{\varepsilon r^*(\tau) \ge \bar r \ge r_*\tau^\delta\}$ then $\varepsilon' = \varepsilon'(\varepsilon) \to +0$ as $\varepsilon \to +0$ and C does not depend on ε.

On the other hand, for $\bar r \in [\varepsilon r^*, r^*(\tau)]$ operator $\boldsymbol{a}(x',\xi') = A_{(x',\xi')}(x'', D'')$ has no more than $L(\varepsilon)$ eigenvalues in $[-2\tau, 2\tau]$ and operator $A(x',\xi'; x'', D'')$ is close to this operator in the natural sense.

Therefore for $\bar r$ from this interval and under the standard non-periodicity condition for the generalized Hamiltonian flow generated by operator-valued symbol $\boldsymbol{a}(x',\xi')$ on the energy level $\tau = 1$ (see (12.2.51)) one can replace the right-hand expression in estimate (12.5.60) by $o\bigl(\tau^{\frac1l(d'-1)}\bigr)$; this and the arbitrary choice of $\varepsilon' > 0$ yield that

(12.5.62) For $(d-1)l < (d'-1)m$ under the standard non-periodicity condition for $\boldsymbol{a}(x',\xi')$ on the energy level $\tau = 1$ the remainder estimate is $o\bigl(\tau^{\frac1l(d'-1)}\bigr)$ even for the sum over the partition of unity in the zone $\{r^*(\tau) \ge \bar r \ge r_*\tau^\delta\}$.

12.5.5 Calculations

Let us consider the terms $F_{t\to\lambda}\bar\chi_T(t)\Gamma\psi_1 Q'_x U_{n(q)}$ with $\lambda\in[\epsilon_0\tau,\tau]$ in (12.5.60). Then the standard arguments of Section 4.4 associated with the microhyperbolicity yield that one can replace $\bar\chi_T$ with 1 in these terms; the error caused by this operation is $O(\tau^{-s})$. Moreover, explicit calculation yields that one can replace ψ_1 by 1 in these terms.

On the other hand, one can easily see that for $Q'=q(x',r^*(\tau)^{-1}D')$ with $q'(x',\xi')$ supported in $\{|\xi'|\ge\frac12\}$ and equal to 1 for $|\xi'|\ge 1$ we obtain from Proposition 12.5.9(ii) that the first term in the left-hand expression of (12.5.60) is $O(\tau^{-s})$ and all the other terms modified above (i.e., with $\psi_1=I,\bar\chi=1$) simply vanish (we can write them explicitly and note that the operator $A(x',\xi')$ has no eigenvalue in $[-2\tau,2\tau]$. So for this operator Q' the modified formula (12.5.60) also holds. Therefore we obtain the following

Proposition 12.5.17. *(i) Consider $Q'=q'(x',\eta^{-1}D')$ with q' supported in $\{|\xi'|\ge\frac12\}$ and equal to 1 for $|\xi'|\ge 1$.*

Then for $\eta\in[r_*(\tau)\tau^\delta, r^*(\tau)]$, $\tau'\in[\epsilon_0\tau,\tau]$ asymptotics

$$\int \mathsf{tr}\big(Q'_x\psi_1 e\big)(x,x,\tau',\tau)\,dx = \sum_{0\le n\le M}\int_{\tau'}^{\tau}\big(F_{t\to\lambda}\Gamma Q'_x U_{n(q)}\big)\,d\lambda + O\big(R_2^*(\tau)\big) \tag{12.5.63}$$

holds.

(ii) Moreover, let $(d-1)l<(d'-1)m$ and let the standard non-periodicity condition (12.2.51) *for the generalized Hamiltonian flow generated by operator-valued symbol $A(x',\xi)$ on the energy level $\tau=1$ be fulfilled.*

Then asymptotics (12.5.61) *holds with "$O\big(R_2^*(\tau)\big)$" replaced by "$o\big(R_2^*(\tau)\big)$."*

This proposition is not our final goal. Let us consider all the terms in the expansion in the right-hand expression of (12.5.61). Let us first note that any differentiation on x' (which is accompanied by differentiation on ξ' and *vice versa*) decreases the magnitude of the term in (12.5.60) by an additional factor $\bar r^{-1}$ and therefore

(12.5.64) Asymptotics (12.5.60) remain true even if we skip all the terms containing differentiation on (x',ξ').

Moreover,

(12.5.65) The sharper asymptotics with remainder estimate "$o\big(R_2^*(\tau)\big)$" remains true if we preserve terms with only one differentiation on x' (and one on ξ'). Furthermore, even in this case one can skip all terms with differentiation of the symbol of Q' provided $\eta = o\big(r^*(\tau)\big)$.

In fact, such a term is supported in the zone $\bar{r} \asymp \eta$ and its order coincides with the order of the right-hand expression of (12.5.60), i.e., it is "$o\big(R_2^*(\tau)\big)$" provided $(d-1)l < (d'-1)m$ and $\eta = o\big(r^*(\tau)\big)$.

Therefore one should consider only terms of the form

$$U_{n(q)} = F^{-1}_{\lambda\to t}\, \mathsf{Res}_{\mathbb{R}}\, F_n(x', \xi', \lambda) Q(x', \xi') \tag{12.5.66}$$

where as $\lambda \in \mathbb{C}\setminus\mathbb{R}$ $F_n(x', \xi', \lambda)$ is a product of $(k+1)$ copies of the operator $\big(\lambda - A_{(x',\xi')}(x'', D'')\big)^{-1}$ separated by k operators $B_j(x', \xi', x'', D'')$ of the form

$$B_j = \sum_{\alpha,\beta:|\alpha|+|\beta|\le\mu+q} b_{j\alpha\beta}(x', \xi') x''^{\alpha} D''^{\beta}$$

and $b_{j\alpha\beta}$ are positively homogeneous of degrees $m + \frac{1}{2}(|\alpha| - |\beta| - \mu - q)$ on ξ' and $k \ge n$, $q = 1, 2, \dots$.

Therefore, assigning the index q to the operator B_j we also assign the index q to F_n as the sum of all the indices of factors of this type in the product. Then (12.5.58) holds with $\nu(n) = \delta'' q$.

Further, let us introduce spherical coordinates $\xi' = (r, \varphi)$. Then after the coordinate transform $x''_{\mathsf{new}} = x'' r^{\frac{1}{2}}$, $D''_{\mathsf{new}} = D'' r^{-\frac{1}{2}}$ we rewrite the corresponding term in the decomposition of $F_{t\to\lambda} U_{n(q)}$ in the form

$$\int_0^\infty \mathsf{Res}_{\mathbb{R}}\, F_n(\lambda r^{-l}) Q(r) r^{d'-1-l-\frac{q}{2}}\, dr \tag{12.5.67}$$

where here and below F_n is now calculated for operator $A_{(x',\varphi)}(x'', D'')$ with $\varphi \in \mathbb{S}^{d'-1}$ and we do not indicate the dependence on (x', φ) and integration on these variables. Moreover, one can assume that $Q(r) = \phi(r^{-l}\eta^l)$ where $\phi \in \mathscr{C}_0^K([-1, 1])$ is a fixed function equal to 1 in a neighborhood of 0. Then after substituting $\lambda = z r^l$ we rewrite (12.5.67) in the form

$$\frac{1}{l} \lambda^{\frac{1}{l}(d'-\frac{q}{2})-1} \int_0^\infty \mathsf{Res}_{\mathbb{R}}\, F_n(z) \phi(z\eta^l \lambda^{-1}) z^{-\frac{1}{l}(d'-\frac{q}{2})}\, dz. \tag{12.5.68}$$

For $\omega = \lambda\eta^{-l}$ let us consider expression

$$\Phi_{n(q)}(\omega) = \int_0^\infty \mathsf{Res}_{\mathbb{R}}\, F_n(z)\phi\big(\frac{z}{\omega}\big) z^{\frac{1}{l}(\frac{q}{2}-d')}\, dz. \tag{12.5.69}$$

Proposition 12.5.18. *For $\omega \to +\infty$ asymptotics*

$$\mathsf{Tr}\,\Phi_{n(q)} = \kappa_q + \kappa'_q \log\omega + \sum_{p:\, \frac{1}{l}(d'-\frac{q}{2})\neq \frac{2}{p}(d''-\frac{p}{2})} \kappa'_{qp}\omega^{\frac{2}{\mu}(d''-\frac{p}{2})-\frac{1}{l}(d'-\frac{q}{2})} + O(\omega^{-s}) \tag{12.5.70}$$

holds with arbitrarily large s. Here we sum over $p \in \mathbb{Z}^+$ such that $p \le J(d, m, \mu, s)$ and the term $\kappa'_q \log\omega$ arises if and only if there exists $p \in \mathbb{Z}^+$ with $\frac{1}{l}\big(d' - \frac{q}{2}\big) = \frac{2}{\mu}\big(d'' - \frac{p}{2}\big)$; here we do not indicate the dependence on n.

Proof. Let us differentiate $\Phi_{(q)}(\omega)$:

$$\mathsf{Tr}\,\Phi'_{(q)} = \omega^{-\frac{1}{l}(d'-\frac{q}{2})} \int \mathsf{Tr}\,\mathsf{Res}_{\mathbb{R}}\, F(z)\psi\big(\frac{z}{\omega}\big)\,\frac{dz}{\omega}$$

where $\psi = z_+^{1-\frac{1}{l}(d'-\frac{q}{2})}\phi'(z)$ obviously belongs to $\mathscr{C}_0^K([\epsilon_0, c_0])$; the prime here means the derivative.

One can easily see that modulo $O(\omega^{-s})$ the integral in the right-hand expression is equal to

$$\mathsf{tr}\big(\psi(\omega^{-1}D_t)\bar\chi_T(t)\Gamma' V_k\big)|_{t=0} \tag{12.5.71}$$

with arbitrary $T \ge \omega^{-\delta-1}$ and an arbitrarily small exponent $\delta > 0$; here $\Gamma' v = \int v(x'', x'', .)dx''$ and one defines the functions V_k from the recurrence relations

$$(D_t - a)V_0 = 0, \qquad V_0|_{t=0} = \delta(x'' - y'')I, \tag{12.5.72}_0$$

$$(D_t - a)V_k = B_k V_{k-1}, \qquad V_k|_{t=0} = 0 \quad (k \ge 1), \tag{12.5.72}_1$$

$a(x', \xi)$ here and below means microlocalization, $(k+1)$ is the number of factors $(\omega - a)^{-1}$ in the definition of F and B_j are the other factors in this definition; further, operators $a = a(x'', D'')$ and $B_j = B_j(x'', D'')$ are calculated at (x', ξ').

However, one can apply the standard Weyl successive approximation method of Chapter 4 on x'' with the semiclassical parameter $\omega^{-\mu^{-1}}$; therefore the reader can easily prove (there are no Tauberian arguments!) that expression (12.5.71) is equal to

$$\sum_{p\le J} \kappa''_{qp}\omega^{\frac{1}{\mu}(2d'-p)-1}$$

modulo $O(\omega^{-s})$. Finally, multiplying by $\omega^{-\frac{1}{\mu}(d'-\frac{q}{2})}$ and integrating we obtain (12.5.70). □

Let us set $\eta \le \tau^{\frac{1}{l}(1-\delta)}$ (in which case $\omega \ge \tau^{\delta}$). Then (12.5.71) yields that modulo $O(\lambda^{-s})$ the trace of (12.5.68) is equal to

$$\begin{aligned}(12.5.73)\quad &\bigl(\kappa_q + \kappa'_q \log\lambda - \kappa'_q l\log\eta\bigr)\lambda^{\frac{1}{l}(d'-\frac{q}{2})-1}+\\ &\sum_{p:\frac{1}{l}(d'-\frac{q}{2})\ne\frac{2}{\mu}(d''-\frac{p}{2})} \kappa'_{qp}\lambda^{\frac{1}{\mu}(2d''-p)-1}\eta^{-(2d''-p)\frac{l}{\mu}+(d'-\frac{q}{2})}.\end{aligned}$$

After integration over λ from τ' to τ we obtain terms of expansion (12.5.60). Therefore we have proven the following

Proposition 12.5.19. *(i) For $\eta \in [\tau^{\frac{1}{m}+\delta}, \tau^{\frac{1}{l}-\delta}]$ asymptotics*

$$(12.5.74)\qquad \int \mathsf{tr}\bigl(Q'_x\psi_1 e\bigr)(x,x,\tau',\tau)\,dx = \bar{\mathcal{N}}(\tau,\eta)\bigr|_{\tau=\tau'}^{\tau=\tau} + O\bigl(R_2^*(\tau)\bigr)$$

holds with

$$(12.5.75)\qquad \bar{\mathcal{N}}(\tau,\eta) = \bar{\mathcal{N}}_0(\tau) + \bar{\mathcal{N}}_1(\tau,\eta),$$

$$(12.5.76)\qquad \bar{\mathcal{N}}_0(\tau) = \sum_q \bar{\kappa}_q \tau^{(d'-\frac{q}{2})} + \bar{\kappa}_0 \log\tau,$$

and

$$\begin{aligned}(12.5.77)\quad \bar{\mathcal{N}}_1(\tau,\eta) = \bar{\kappa}'_0\bigl(\log^2\tau - 2l\log\tau\log\eta\bigr)+\\ \sum_{q,p:\frac{1}{l}(d'-\frac{q}{2})=\frac{1}{m}(2d''-p)} \bar{\kappa}''_q\tau^{\frac{1}{l}(d'-\frac{q}{2})}\bigl(\log\tau - l\log\eta\bigr) + \sum_{q\ne 2d'} \bar{\kappa}'''_q\eta^{(d'-\frac{q}{2})}\log\tau+\\ \sum_{q,p:\frac{1}{l}(d'-\frac{q}{2})\ne\frac{1}{\mu}(2d''-p)} \bar{\kappa}'_{qp}\tau^{\frac{1}{\mu}(2d''-p)}\eta^{(d'-\frac{q}{2})-(2d''-p)\frac{l}{\mu}}\end{aligned}$$

and $R_2^*(\tau)$ *given by* (12.5.61). *Here all the coefficients* $\bar{\kappa}^*_{**}$ *do not depend on* τ, τ', η *and we sum over* $p, q \le J = J(d, m, \mu, \delta)$.

(ii) Moreover, for $(d-1)l < (d'-1)m$ *and the standard non-periodicity condition (see* (12.2.51)*) on the Hamiltonian flow for operator-valued symbol* $a(x', \xi')$ *on the energy level* $\tau = 1$ *the sharper asymptotics*

$$\int \mathsf{tr}(Q'_x \psi_1 e)(x, x, \tau', \tau)\, dx = \bar{\mathcal{N}}(\tau, \eta)\big|_{\tau=\tau'}^{\tau=\tau} + o\big(\tau^{\frac{1}{l}(d'-1)}\big) \tag{12.5.78}$$

holds.

Let us combine propositions 12.5.16 and 12.5.19 and note that the final answer *should not* depend on the choice of η (lying in the given interval). Moreover, we know the Weyl asymptotics for $\mathsf{N}_0^+(\tau)$ in (12.5.14). Then we obtain the following statement for $\mathsf{N}(\tau', \tau)$ with $\tau' \in [\epsilon_0 \tau, \tau]$ instead of $\mathsf{N}^+(\tau)$ and with $\mathcal{N}(\tau', \tau) = \mathcal{N}^+(\tau)\big|_{\tau=\tau'}^{\tau=\tau}$ instead of $\mathcal{N}^+(\tau)$:

Theorem 12.5.20. *Let* $A \in \boldsymbol{\Psi}^{m,\mu}(X, \Lambda, \mathbb{K})$ *be a self-adjoint operator satisfying conditions* (12.5.1)–(12.5.9) *and* (12.5.11). *Then*

(i) Asymptotics

$$\mathsf{N}^+(\tau) = \mathcal{N}^+(\tau) + O\big(R^*(\tau)\big) \tag{12.5.79}$$

holds with

$$R^*(\tau) = \begin{cases} \tau^{\frac{1}{m}(d-1)} & \text{for } (d-1)l > (d'-1)m \\ \tau^{\frac{1}{m}(d-1)} \log \tau & \text{for } (d-1)l = (d'-1)m \\ \tau^{\frac{1}{l}(d'-1)} & \text{for } (d-1)l > (d'-1)m \end{cases} \tag{12.5.80}$$

where

$$\mathsf{N}^+(\tau) = \sum_{p=0,1,2} \kappa_{\frac{p}{2}} \tau^{\frac{1}{m}(d-\frac{p}{2})} + \sum_{q=0,1,2} \bar{\kappa}_{\frac{q}{2}} \tau^{\frac{1}{l}(d'-\frac{q}{2})} \tag{12.5.81}$$

provided $(d - \frac{p}{2})l \ne (d' - \frac{q}{2})m$ *for all* p, q *indicated above.*

On the other hand, if $(d - \frac{p}{2})l = (d' - \frac{q}{2})m$ *for some* p, q *then one should replace term* $\kappa_{\frac{p}{2}} \tau^{\frac{1}{m}(d-\frac{p}{2})}$ *by* $\kappa_{\frac{p}{2}} \tau^{\frac{1}{l}(d-\frac{p}{2})} \log \tau$.[52)]

[52)] One can easily see that there is usually at most one logarithmic term; there are two logarithmic terms if $m = 2l$, $d = 2d'$.

(ii) Moreover, let $(d-1)l > (d'-1)m$ *and let the standard non-periodicity condition on the Hamiltonian flow for* $a_0(x,\xi)$ *be fulfilled on the energy level* $\tau = 1$*. Then asymptotics*

$$\mathsf{N}^+(\tau) = \mathcal{N}^+(\tau) + o\bigl(\tau^{\frac{1}{m}(d-1)}\bigr) \tag{12.5.82}$$

holds.

(iii) On the other hand, let $(d-1)l < (d'-1)m$ *and let non-periodicity condition (see* (12.2.51)*) to the Hamiltonian flow for operator-valued symbol* $\mathsf{a}(x',\xi')$ *on the energy level* $\tau = 1$ *be fulfilled. Then asymptotics*

$$\mathsf{N}^+(\tau) = \mathcal{N}^+(\tau) + o\bigl(\tau^{\frac{1}{l}(d'-1)}\bigr) \tag{12.5.83}$$

holds.

Finally, let us replace τ and τ' by $2^{-n}\tau$ and $2^{-n-1}\tau$ and sum over $n = 1, \dots, n_0 \le [\log \tau] + 1$. Then we obtain this theorem in the final form (i.e., with $\tau' = 0$).

Remark 12.5.21. (i) Moreover, one obtains similar statements for Riesz means with

(12.5.84)
$$R^*_{(\vartheta)}(\tau) = \begin{cases} \tau^{\frac{1}{m}(d-1-\vartheta)+\vartheta} & \text{for } (d-1-\vartheta)l > (d'-1-\vartheta)m \\ \tau^{\frac{1}{m}(d-1-\vartheta)+\vartheta}\log\tau & \text{for } (d-1-\vartheta)l = (d'-1-\vartheta)m \\ \tau^{\frac{1}{l}(d'-1-\vartheta)+\vartheta} & \text{for } (d-1-\vartheta)l > (d'-1-\vartheta)m \end{cases}$$

and with principal part

$$\mathcal{N}^+_{(\vartheta)}(\tau) = \sum_{p\le 2+2\vartheta} \kappa_{\frac{p}{2}}\tau^{\frac{1}{m}(d-\frac{p}{2})+\vartheta} + \sum_{q\le 2+2\vartheta} \bar{\kappa}_{\frac{q}{2}}\tau^{\frac{1}{l}(d'-\frac{q}{2})+\vartheta} \tag{12.5.85}$$

provided $(d-\frac{p}{2})l \ne (d'-\frac{q}{2})m$ for all p, q indicated above.

On the other hand, if $(d-\frac{p}{2})l = (d'-\frac{q}{2})m$ for some p, q then one should replace the term $\kappa_{\frac{p}{2}}\tau^{\frac{1}{m}(d-\frac{p}{2})}$ by $\kappa_{\frac{p}{2}}\tau^{\frac{1}{m}(d-\frac{p}{2})}\log\tau$ [53]. Coefficients κ_*, $\bar{\kappa}_*$ depend on $\vartheta \ge 0$.

Surely, some terms are smaller than the remainder estimate and should be removed. One can see that for $\vartheta > \frac{2}{\mu}(ld - md') - 1$ we obtain a Weyl remainder estimate (but the asymptotics contain non-Weyl terms).

[53] So as two terms have equal powers of τ one of them has an extra logarithmic factor.

(ii) Moreover, let $p \notin \mathbb{Z}$ and $a_j \equiv 0$ for all $j \notin \mathbb{Z} : j \le k$. Then $\kappa_p = 0$ which is also true in the case $(d-p)l = (d-q)m$ for some $q \in \frac{1}{2}\mathbb{Z}$: so the logarithmic term does not arise.

12.5.6 Operators with Negative Principal Symbols

Let us consider the case when $a_0(x,\xi)$ is a negative definite symbol. However, we assume that $\boldsymbol{a}(x',\xi') = A_{(x',\xi')}(x'',D'')$ is not a negative definite operator (otherwise A is semibounded from above). However in this case $\boldsymbol{a}(x',\xi')$ has only finite number of positive eigenvalues and thus its positive part is essentially a matrix.

Our goal is to prove the following

Theorem 12.5.22. *Let the conditions of Theorem 12.5.20 be fulfilled and let the condition*

(12.5.86) $a_0(x,\xi)$ *is a negative definite symbol on* $T^*X \setminus 0 \setminus \Lambda$

also be fulfilled.

Then

(i) Asymptotics

$$\mathsf{N}^+(\tau) = \mathcal{N}^+(\tau) + O\bigl(\tau^{\frac{1}{l}(d'-1)}\bigr) \tag{12.5.87}$$

holds with

$$\mathcal{N}^+(\tau) = \bar{\kappa}_0 \tau^{\frac{1}{m}d'} + \bar{\kappa}_{\frac{1}{2}} \tau^{\frac{1}{l}(d'-\frac{1}{2})} + \bar{\kappa}_1 \tau^{\frac{1}{l}(d'-1)}. \tag{12.5.88}$$

(ii) Moreover, let the non-periodicity condition (see (12.2.51)*) for Hamiltonian flow for operator-valued symbol* $\boldsymbol{a}(x',\xi')$ *on the energy level* $\tau = 1$ *be fulfilled. Then asymptotics*

$$\mathsf{N}^+(\tau) = \mathcal{N}^+(\tau) + o\bigl(\tau^{\frac{1}{l}(d'-1)}\bigr) \tag{12.5.89}$$

holds.

Proof. First of all, (12.5.57) and the explicit formula for U_n yield that for $\chi \in \mathscr{C}_0^K(\mathbb{R})$ vanishing in a neighborhood of 0 one can replace (12.5.59) by estimate

$$\bigl|F_{t\to\lambda}\chi_T(t)\Gamma\psi_1 Q'_x U\bigr| \le C\bar{r}^{d-\frac{2}{\mu}d''m}T^{\frac{2}{\mu}d''-1-s}T^{-sl} \tag{12.5.90}$$

for $T\in[T_0\tau^{-1}, T_0\tau^{-1}\bar{r}]$, $\lambda\in[\epsilon_0\tau, c\tau]$. Therefore the same estimate holds for

$$\bigl|F_{t\to\lambda}\bigl(\bar{\chi}_{T'}(t)-\bar{\chi}_T(t)\bigr)\Gamma\psi_1 Q'_x U\bigr|$$

for $T, T'\in[T_0\tau^{-1}, T_0\tau^{-1}\bar{r}]$, $T<T'$ and $\bar{\chi}\in\mathscr{C}_0^K(\mathbb{R})$ equal to 1 in a neighborhood of 0.

On the other hand, for $T\in[T_0, \tau^{-1}h^{-\delta}, T_0\tau^{-1}h^{-1}]$ with $h=\bar{r}^{-\frac{2}{\mu}}T^{\frac{2}{\mu}}$, the standard Weyl formula (which is derived by setting $\bar{A}=a_0(y,D)$) holds modulo terms which do not exceed the right-hand expression in (12.5.90).

Condition (12.5.74) also yields that all the coefficients in this formula vanish. Taking $T=T_0\tau^{-1}\bar{h}'^{-1}$ we replace (12.5.59) by the estimate

$$\bigl|F_{t\to\lambda}\bar{\chi}_T(t)\Gamma\psi_1 Q'_x U\bigr| \le C\bar{r}^{d-\frac{2}{\mu}d''m+s}T^{\frac{2}{\mu}d''-1-s}T^{-sl} \tag{12.5.91}$$

with $T\in[T_0, \tau^{-1}\tau^{-1}\bar{h}'^{-\delta}, T_0\tau^{-1}\bar{r}]$, $\lambda\in[\epsilon_0\tau, c\tau]$ and with another still arbitrarily large s. Here we have omitted the prime on T.

Therefore one can replace $\bar{\chi}$ with a Hörmander function χ and apply the routine Tauberian technique to obtain that the left hand expression in (12.5.60) now does not exceed

$$C\bar{r}^{d-1-\frac{2}{\mu}d''m+sl}T^{\frac{2}{\mu}d''-s}.$$

Then after summation over a partition of unity in the zone $\bigl\{r_*(\tau)\le|\xi'|\le\varepsilon r^*(\tau)\bigr\}$ we obtain remainder estimate $\varepsilon'\tau^{\frac{1}{l}(d'-1)}$ with $\varepsilon'=\varepsilon'(\varepsilon)\to+0$ as $\varepsilon\to+0$. Therefore under condition (12.5.86) Proposition 12.5.17 holds with the remainder estimate $O\bigl(\tau^{\frac{1}{l}(d'-1)}\bigr)$; moreover it holds with the remainder estimate $o\bigl(\tau^{\frac{1}{l}(d'-1)}\bigr)$ under standard non-periodicity condition to the Hamiltonian flow for matrix-valued symbol $a(x',\xi')$ on the energy level $\tau=1$.

On the other hand, Proposition 12.5.9 yields that the remainder estimate in Proposition 12.5.16 is now $O(\tau^{-s})$. Therefore for $\mathsf{N}(\tau',\tau)$ with $\tau'\in[\epsilon_0,\tau]$ the remainder estimate is $O\bigl(\tau^{\frac{1}{l}(d'-1)}\bigr)$ [54]. This estimate yields the same remainder estimate for $\mathsf{N}^+(\tau)$ for $d'\ge 2$.

For $d'=1$ standard arguments with τ, τ' replaced by $2^{-n}\tau$, $2^{-n-1}\tau$, etc., yield the remainder estimate $O\bigl(\log\tau\bigr)$ but one can also easily obtain the

[54] And even $o\bigl(\tau^{\frac{1}{l}(d'-1)}\bigr)$ under the standard non-periodicity condition.

remainder estimate $O(1)$. In fact, one has the remainder estimate $O(1)$ for $\mathsf{N}(\tau',\tau)$ and the remainder estimate $O(\tau^{-s})$ for

$$\int \phi\bigl(\frac{\lambda}{\tau}\bigr)\, d_\lambda \mathsf{N}^+(\lambda) d\lambda$$

with $\phi \in \mathscr{C}_0^K([\epsilon_0, c])$ (this estimate is the routine estimate with mollification, the deduction of which requires neither the Tauberian technique nor condition (12.5.86)). Replacing $\phi(\lambda)$ by $\bigl(\bar\phi(\tau) - \bar\phi(2\tau)\bigr)$ with $\bar\phi \in \mathscr{C}^K(\mathbb{R})$ supported in $[-\infty, 1]$ and equal to 1 on $[-\infty, \frac{1}{2}]$ and replacing τ by $2^{-n}\tau$, etc., we obtain the remainder estimate $O(1)$ for

$$\int \bar\phi\bigl(\frac{\lambda}{\tau}\bigr)\, d_\lambda \mathsf{N}^+(\lambda) d\lambda,$$

and this remainder estimate and the remainder estimate for $\mathsf{N}(\tau',\tau)$ obviously yield the remainder estimate $O(1)$ for $\mathsf{N}^+(\tau)$. So, both remainder estimates in Theorem 12.5.22 have been proven.

Moreover, in Proposition 12.5.16 we obtain $\mathcal{N}(\tau,\eta) = 0$ because of condition (12.5.86) (recall that standard Weyl asymptotics were applied here) and in Proposition 12.5.18 one should replace (12.5.70) by the asymptotics

$$\mathsf{Tr}\, \Phi_{n(q)}(\omega) = \kappa_q + O(\omega^{-s}). \tag{12.5.92}$$

Therefore expression (12.5.73) is reduced to

$$\kappa_q \tau^{\frac{1}{l}(d'-\frac{q}{2})-1}$$

and $\bar{\mathcal{N}}(\tau,\eta) = 0$.

Thus for $d' \ge 2$ we obtain expression (12.5.88) exactly for $\mathcal{N}^+(\tau)$, but for $d' = 1$ an additional term $\bar\kappa_1' \log \tau$ arises (this term is less than the remainder estimate for $d' \ge 2$). Then we apply the Remark 12.5.23 below. □

Remark 12.5.23. By explicit calculation prove that $\bar\kappa_1' = 0$ for $d' = 1$. Note that the same calculation was done in the analysis of non-semibounded boundary value problems for operators with positive principal symbols in Subsection 7.3.3 (one can apply these arguments without any modification).

Remark 12.5.24. The remainder estimate for Riesz means is $O\bigl(\tau^{\frac{1}{l}(d-1-\vartheta)+\vartheta}\bigr)$ and even $o\bigl(\tau^{\frac{1}{l}(d-1-\vartheta)+\vartheta}\bigr)$ under the standard condition to the Hamiltonian flow.

12.5.7 Coefficients in Spectral Asymptotics

Let us discuss the coefficients κ_p and $\bar{\kappa}_q$ in the asymptotics of Theorems 12.5.20, 12.5.22 and Remarks 12.5.21, 12.5.24. First of all the following obvious remark holds (we discuss coefficients for $\vartheta = 0$; the coefficients of $\tau^{k+\vartheta}$ for $\vartheta > 0$ have the extra factor $k(k+\vartheta)^{-1}$ compared with the coefficient of τ^k for $\vartheta = 0$).

Remark 12.5.25. (i) If $p\,(= 0, \frac{1}{2}, 1, \dots)$ is such that $l(d-p) > d'm$ then for κ_p the standard Weyl formula holds, the integral in which surely converges; in particular,

$$\kappa_0 = (2\pi)^{-d} \int n_0^+(x,\xi,1)\, dxd\xi \tag{12.5.93}$$

where $n_0^+(x,\xi,1)$ is the number of eigenvalues of $a_0(x,\xi)$ lying in $[0,1]$. Therefore $\kappa_0 > 0$ provided $a_0(x,\xi)$ is not negative definite.

(ii) On the other hand, for $p\,(= 0, \frac{1}{2}, 1, \dots)$ let equality $(d-p)l = d'm$ hold. Then the integral providing the standard Weyl coefficient of $\tau^{\frac{1}{m}(d-p)}$ diverges logarithmically; namely, modulo convergent integrals we have

$$\int \omega(x',\xi';\varphi)\, dx'd\xi'd\varphi \frac{d\zeta}{\zeta}$$

with $\varphi = \varrho^{-1}\cdot(x'', \xi''|\xi'|^{-1}) \in \mathbb{S}^{2d''-1}$, $\varrho = \bigl(|x''|^2 + |\xi''|^2|\xi'|^{-2}\bigr)^{\frac{1}{2}}$; then the coefficient $\bar{\kappa}_p$ at $\tau^{(\frac{1}{m}d-p)}\log\tau$ is given by formula

$$\bar{\kappa}_p = \frac{1}{2l}\int \omega(x',\xi',\varphi)\, dx'd\xi'd\varphi.$$

In particular, for $dl = d'm$ the coefficient $\bar{\kappa}_0$ at $\tau^{\frac{d}{m}}\log\tau$ is

$$\bar{\kappa}_0 = \frac{1}{2l(2\pi)^d}\int_{\Lambda\times\mathbb{S}^{2d''-1}} \tilde{n}^+(x',\xi',\varphi,1)\, dx'd\xi'd\varphi \tag{12.5.94}$$

where $\tilde{n}^+(x',\xi',\varphi,1)$ is the number of eigenvalues of the symbol

$$\tilde{a}_0(x',\xi',\varphi) = \sum_{|\alpha|+|\beta|=\mu} \frac{1}{\alpha!\beta!} a_{0(\beta)}^{(\alpha)}(x',\xi') x''^{\beta}\xi''^{\alpha} \tag{12.5.95}$$

again with $\varphi = \varrho^{-1}\cdot(x'', \xi''|\xi''|^{-1})(x,\xi) \in \mathbb{S}^{2d''-1}$.

(iii) Either let $q = (0, \frac{1}{2}, 1, \dots)$ be such that $(d' - q)m > dl$ or let $a_0(x, \xi)$ be a negative definite symbol. Then the coefficient $\bar{\kappa}_q$ is given by a convergent integral

$$\frac{1}{2d' - q} \int_0^\infty \operatorname{Tr} \operatorname{Res}_{\mathbb{R}} F_{(q)}(z) z^{-\frac{1}{l}(d'-q)} dz$$

where $F_{(q)}$ is the sum of all the symbols with the given index q. In particular, if either $d'm > dl$ or $a_0(x, \xi)$ is a negative definite symbol then

$$\bar{\kappa}_0 = (2\pi)^{-d'} \int_\Lambda \boldsymbol{n}^+(x', \xi', 1)\, dx' d\xi' = \frac{1}{(2\pi)^d d} \int_{\Lambda \cap S^* X} \omega(z)\, dz \tag{12.5.96}$$

where $\omega(z) = \sum_j \eta_j^{-\frac{d}{l}}$, η_j are all the positive eigenvalues of $A_{(x', \xi')}$ and dz is the natural density on $\Lambda \cap S^* X$ provided a Riemannian metric is introduced on X.

(iv) $a_{\frac{1}{2}} = 0$ yields that $\kappa_{\frac{1}{2}} = 0$. See also problem 12.5.11(ii).

(v) Moreover, let μ be even. Let us again treat the zone $\{|\xi'| \le r^*(\tau)\tau^{-\delta}\}$. Let us consider a term in the expansion of $\varkappa_{\frac{j}{2}}(x, \xi)$ in terms which are homogeneous with respect to $(x'', \xi''|\xi'|^{-1})$. Obviously, if this term is odd with respect to $(x'', \xi''|\xi'|^{-1})$ then its integral vanishes. Therefore a term with a logarithmic factor appears only if the equality $\left(d - \frac{j}{2}\right)l = \left(d' - \frac{k}{2}\right)m$ holds with $j \equiv k \mod 2$. So, if μ is even then a term $\kappa_{\frac{j}{2}} \tau^{\frac{1}{m}(d - \frac{j}{2})} \log \tau$ appears only if $\left(d - \frac{j}{2}\right)l = \left(d' - \frac{k}{2}\right)m$ and $j \equiv k \,(\mod 2)$.

(vi) Let $a_{\frac{1}{2}} \equiv 0$. Then in the previous analysis one should only treat even j (and therefore only even k). On the other hand, analysis in the zone $\{|\xi'| \ge r_*(\tau)\tau^{\delta}\}$ proves that $\bar{\kappa}_{\frac{q}{2}} = 0$ for odd q. So, if $a_{\frac{1}{2}} \equiv 0$ and μ is even then in (12.5.81), (12.5.88) one should treat only $p = 0, 2$ and $q = 0, 2$ in the calculation of powers and in the criterion for terms with a logarithmic factor. Similarly, for $\vartheta > 0$ in this case ($a_{\frac{n}{2}} \equiv 0$ for odd n and μ is even) one should consider only even p, q in the criterion for terms with a logarithmic factor.

(vii) On the other hand, one can easily see that for an operator with the symbol $\begin{pmatrix} \lambda & \mathcal{L} \\ \mathcal{L}^* & \lambda \end{pmatrix}$ with $\mathcal{L} \in \boldsymbol{\Psi}^{1,1}$ and $\lambda \in \mathbb{C}$ the previous statement for $\bar{\kappa}_q$ is wrong.

(viii) Finally, if $a_{\frac{1}{2}} \equiv 0$, μ and m are even and a_0 and a_1 are homogeneous (not only positive homogeneous) of degrees m and $(m-1)$ in ξ respectively then in (12.5.81) one should treat only $p=0$ in the calculation of powers and in the criterion for terms with a logarithmic factor.

We leave to the reader the following set of problems

Problem 12.5.26. (i) Consider the asymptotics of Riesz means.

(ii) Consider manifolds with boundary. In this case one should assume that every connected component of Λ either does not intersect $T^*X|_{\partial X}$ or is contained in this manifold. In the second case one should consider $A_{(x',\xi')}(x'', D'')$ as an operator in the half-space of $\mathbb{R}^{d''}$ and the problem of boundary conditions arises.

Moreover, there are more variants for the leading term of the asymptotics because we know that the condition that the operator is semi-bounded on a manifold with boundary consists of two conditions, and if the first condition is fulfilled and the second condition is violated then the first term on the asymptotics vanishes in the non-degenerate case.

(iii) The other problem left to the reader is to return to Sections 12.2–12.4 and obtain (under appropriate conditions) the non-Weyl term in the asymptotics in a simpler form (as we did here, and in the form used here).

12.6 Riesz Means Asymptotics for Operators Singular at a Point

12.6.1 Problem Set-up

In this section we consider h-differential operator $A = A_h$ with Weyl symbol

$$A(x,\xi) = \sum_{|\alpha|\le m} a_\alpha(x)\xi^\alpha, \tag{12.6.1}$$

Hermitian and such that in $B(0,1)$

$$|D^\beta a_\alpha| \le c|x|^{\mu(m-|\alpha|)-|\beta|} \qquad \forall \alpha : |\alpha| \le m \quad \forall \beta : |\beta| \le K \tag{12.6.2}$$

with

$$\mu > \max\bigl(-1, -\frac{d}{m}\bigr). \tag{12.6.3}$$

Moreover, we assume that

$$\langle a(x,\xi)v, v\rangle \ge \epsilon_0|\xi|^m\|v\|^2 \qquad \forall (x,\xi) \in T^*B(0,1) \quad \forall v \in \mathbb{K} \tag{12.6.4}$$

where $a(x,\xi) = \sum_{|\alpha|=m} a_\alpha(x)\xi^\alpha$ is the senior symbol of A.

Let us consider the operator A in the domain $X \subset \mathbb{R}^d$ assuming that

$$B(0,1) \subset X, \quad d \ge 2 \tag{12.6.5}$$

and

(12.6.6) A is a self-adjoint operator with $\mathfrak{D}(A) \supset \mathscr{C}_0^m\bigl(B(0,1), \mathbb{K}\bigr)$.

We are interested in semiclassical asymptotics of the Riesz mean

$$\int \psi(x)\,\mathsf{tr}\bigl(e_{(\vartheta)}(x,x,0)\bigr)\,dx \tag{12.6.7}$$

where $\psi \in \mathscr{C}_0^K\bigl(B(0,\frac{1}{2})\bigr)$ and $e_{(\vartheta)}(.,.,\tau)$ is the Riesz mean of order ϑ of the Schwartz kernel $e(.,.,\tau)$ of the spectral projector A, $\vartheta > 0$:

$$e_{(\vartheta)}(.,.,\tau) = \frac{1}{\Gamma(\vartheta+1)}\int_0^\tau (\tau-\lambda)^\vartheta\, d_\lambda e(.,.,\lambda) \tag{12.6.8}$$

where $\Gamma(.)$ is an Euler' Γ-function.

In Section 11.1 we proved that under an appropriate condition associated with microhyperbolicity (namely, condition (12.6.34) below) asymptotics

$$\int \psi(x)\,\mathsf{tr}\bigl(e_{(\vartheta)}(x,x,0)\bigr)\,dx = \sum_{0\le j\le J} h^{-d+j}\int \psi(x)\kappa_{(\vartheta)j}(x)\,dx + O\bigl(R_{(\vartheta)}(\tau)\bigr) \tag{12.6.9}$$

holds with

$$R_{(\vartheta)}(\tau) = \begin{cases} h^{-d+\vartheta+1} & \text{for } \vartheta < \bar\vartheta_p,\\ h^{-d+\vartheta+1}\log h & \text{for } \vartheta = \bar\vartheta_p,\\ h^l & \text{for } \vartheta > \bar\vartheta_p \end{cases} \tag{12.6.10}$$

where here and below

$$\bar\vartheta_p = \begin{cases} \big((d-1)(\mu+1)+p\big)(-m\mu+\mu+1)^{-1} & \text{for } m\mu<\mu+1,\\ +\infty & \text{for } m\mu\ge\mu+1,\end{cases} \tag{12.6.11}$$

and

$$l = l_0 = m\mu\vartheta(\mu+1)^{-1}, \qquad l_p = (m\mu\vartheta+p)(\mu+1)^{-1}, \tag{12.6.12}$$

$\kappa_{(\vartheta)j}$ are standard Weyl coefficients and

$$J = \begin{cases} \lfloor\vartheta\rfloor+1 & \text{for } \vartheta\le\bar\vartheta_p,\\ d+\lfloor l\rfloor & \text{for } \vartheta\ge\bar\vartheta_p\end{cases} \tag{12.6.13}$$

excluding the special case

$$J=\vartheta \qquad \text{for } \vartheta=\bar\vartheta_p\in\mathbb{N}. \tag{12.6.13}'$$

Further, for $\vartheta>\bar\vartheta_p$ and $l\in\mathbb{N}$ one should cut the corresponding term near the origin, i.e., replace $\psi(x)$ by $\psi(x)\phi(xr_*(h)^{-1})$ in the term with $j=d+l$ of the right-hand expression of (12.6.9) where here and below

$$r_*(h) = h^{1/(\mu+1)}, \tag{12.6.14}$$

$(1-\phi)\in \mathscr{C}_0^K(\mathbb{R}^d)$ and ϕ vanishes in a neighborhood of 0.

Furthermore, we proved that if $\vartheta<\bar\vartheta_p$ and the standard non-periodicity condition is fulfilled on the energy level $\tau=0$ then one can replace $O(h^{-d+\vartheta+1})$ by $o(h^{-d+\vartheta+1})$ in asymptotics (12.6.9).

The principal part of the asymptotics is $O(h^{-d})$ for $m\mu\vartheta>-d(\mu+1)$ and $O(h^{-d}\log h)$ for $m\mu\vartheta+p=-d(\mu+1)$ and $O(h^l)$ for $m\mu\vartheta+p<-d(\mu+1)$ [55]; so in the last case we have only an estimate instead of an asymptotics.

Remark 12.6.1. All these statements hold for $p=0$ but also remain true with $l=l_p$ for $p\ge 0$ provided

$$\operatorname{supp}(\psi)\subset B(0,\frac{1}{2}), \tag{12.6.15}$$

$$|D^\alpha\psi|\le c|x|^{p-|\alpha|} \qquad \forall\alpha:|\alpha|\le K \tag{12.6.16}$$

instead of the previous assumptions. One can see easily that $\vartheta_p>p$.

[55] There are equivalence relations under obvious conditions.

We leave to the reader the following easy problem:

Problem 12.6.2. Consider case $-d < p < 0$, $m\mu < \mu+1$; consider separately $m\mu < \mu+1$ and $m\mu \ge \mu+1$.

12.6.2 The Scott Correction Term

Our goal is to treat the case $\vartheta \ge \bar{\vartheta}_p$ and to improve this remainder estimate. This better estimate, obtained under appropriate conditions, requires an additional non-Weyl term ωh^l in the asymptotics. Physicists call this term the *Scott correction term*. Later we will obtain more than one such term for large ϑ. In this analysis, without any loss of the generality we can treat

$$\int x^\alpha \psi(x)\, \mathsf{tr}\big(e_{(\vartheta)}(x,x,0)\big)\, dx$$

with $|\alpha| = p$ and $\psi \in \mathscr{C}_0^K(\mathbb{R}^d)$ as

$$\bar{\vartheta}_p < +\infty \qquad (\iff m\mu < \mu+1). \tag{12.6.17}$$

Instead we consider more general case

(12.6.18) $\psi \in \mathscr{C}^K\big(\mathbb{R}^d \setminus 0\big)$ is positively homogeneous of degree p in $B(0,\frac{1}{2})$ and $\mathsf{supp}(\psi) \subset B(0,1)$.

First of all we should treat the positive homogeneous case:

Proposition 12.6.3. *Let conditions* (12.6.2)–(12.6.5) *be fulfilled. Moreover, let $X = \mathbb{R}^d$, A be a self-adjoint operator with $\mathfrak{D}(A) \supset \mathscr{C}_0^m(\mathbb{R}^d, \mathbb{K})$ and let us assume that*

(12.6.19) *The coefficients a_α are positively homogeneous of degrees $(m-|\alpha|)\mu$ in x.*

Finally, let us assume that

(12.6.20) *$A(x,\xi)$ is microhyperbolic in (x,ξ) on the energy level $\tau = 0$ for $x \ne 0$* [56].

[56] Surely, the constants in the microhyperbolicity condition depend on $|x|$.

Then for any $\beta \in \mathbb{N}^d$ *and for* $W \in \mathscr{C}^K\big(\mathbb{R}^d \setminus 0, \mathsf{Hom}(\mathbb{K},\mathbb{K})\big)$ *positively homogeneous of degree* $(p-\mu|\beta|)$ *in* x *equality*

$$\int W(x)\Big(\big((hD_x)^\beta e_{(\vartheta)}\big)(x,x,0) - \phi\big(\frac{x}{r_*}\big)\sum_{0\le j\le J}\varkappa_{(\vartheta)\beta,j}(x)h^{-d+j}\Big)\,dx = \omega h^l \tag{12.6.21}$$

holds with the coefficients $\kappa_{(\vartheta)\beta,j}(x)$ [57] *and a certain constant coefficient* $\omega \in \mathsf{Hom}(\mathbb{K},\mathbb{K})$ *which depends on* W,β,ϕ [58] *and* $J \ge [l]+d$ *and the integral in the left-hand expression converges at infinity* [59].

Moreover, in terms with $j < l+d$ *one can replace* ϕ *by* 1 [60]*; in particular, if either* $l \notin \mathbb{N}$ *or* $l \in \mathbb{N}$ *but* $\kappa_{(\vartheta)\beta,l+d} \equiv 0$ *then one can set* $J = \lfloor l \rfloor + d$ *and replace* ϕ *by* 1 *in all the terms.*

Proof. Let us first note that in the context of the proposition

(12.6.22) Coefficients $\kappa_{(\vartheta)\beta,j}(x)$ are positively homogeneous in x of degrees $\big(d\mu + m\mu\vartheta - j(\mu+1) - |\beta|\big)$.

Moreover, let us note that after rescaling $x_{\mathsf{new}} = x_{\mathsf{old}}/r_*(h)$ with $r_*(h) = h^{-1/(\mu+1)}$ operator $A^{\mathsf{w}}(x,hD)$ is transformed into operator $h^{m\mu(\mu+1)^{-1}}A^{\mathsf{w}}(x,D)$ and therefore

$$e_{(\vartheta)}(x,y,0;h) = h^{(m\mu\vartheta+d)/(\mu+1)}e_{(\vartheta)}(xh^{-1/(\mu+1)}, yh^{-1/(\mu+1)},0;1) \tag{12.6.23}$$

due to the definition of $e_{(\vartheta)}(.,.,.,.)$; here the fourth variable is the semiclassical parameter h.

This equality and (12.6.22) yield that the left-hand expression in (12.6.21) is positively homogeneous of degree l on h provided it converges; therefore we should prove only that the integral in (12.6.21) converges at infinity.

However, Theorem 4.4.6 yields that if $\psi' \in \mathscr{C}_0^K\big(\mathbb{R}^d, \mathsf{Hom}(\mathbb{K},\mathbb{K})\big)$ vanishes in a neighborhood of 0 then the estimate

---

[57] Here we do not take the trace and therefore the coefficients κ_* and ω are matrix-valued in this statement.

[58] Recall that ϕ is a fixed function such that $(1-\phi) \in \mathscr{C}_0^K(\mathbb{R}^d)$, $\phi = 1$ near 0.

[59] It surely converges at 0 due to the cutting function ϕ.

[60] Surely, the constant ω changes.

$$\Big|\int \psi'\big(\frac{x}{r}\big)\Big(\big((hD_x)^{\beta} e_{(\vartheta)}\big)(x,x,0) - \phi\big(\frac{x}{r_*}\big)\sum_{0\le j\le J} \kappa_{(\vartheta)\beta,j}(x) h^{-d+j}\Big)\,dx\Big| \le Ch^{-d+J+1} r^{l(\mu+1)(l-J-1)}$$

holds uniformly on $r \ge r_* = h^{(\mu+1)^{-1}}$; this estimate immediately yields that the integral in the left-hand expression of (12.6.21) converges for $J \ge \lfloor l \rfloor + d$. □

12.6.3 Improved Asymptotics: the First Attempt

Our first goal is to improve the remainder estimate $O(h^l)$ for $\vartheta > \bar{\vartheta}_p$ in the general situation. To do this we will pass from one operator to another to reduce the problem.

Proposition 12.6.4. *Let the operators A and A' satisfy conditions* (12.6.2)–(12.6.6) *and coincide in $B(0,1)$. Let $\psi \in \mathscr{C}_0^K\big(B(0,\frac{1}{2})\big)$, $\psi \ge 0$. Moreover, let estimate*

$$\Big|\int \psi(x) e(x,x,\tau+h,\tau)\,dx\Big| \le Ch^{1-d} \qquad \forall \tau : |\tau| \le \epsilon_0 \tag{12.6.24}$$

hold. Then the same estimate holds for A' as well and, moreover, estimate

$$\Big|\int \psi(x)\big(e_{(\vartheta)}(x,x,0) - e'_{(\vartheta)}(x,x,0)\big)\,dx\Big| \le Ch^{1-d+\vartheta} \tag{12.6.25}$$

holds where here and below $e(.,.,.)$ with a superscript is associated with the operator A with the same superscript.

Proof. Proof follows from the same analysis as in Chapter 9. We leave the easy details to the reader. □

Therefore the remainder estimate which will not be better than $O\big(h^{1-d+\vartheta}\big)$ is preserved if we change the operator A outside of $B(0,\epsilon_0)$ with some fixed $\epsilon_0 > 0$.

(12.6.26) Let us pick an operator A' coinciding with A in $B(0,\epsilon_0)$ and such that the negative spectrum of A' is discrete for every $h \in (0,h_0]$ (we can even pick an operator with negative spectrum, finite for every $h \in (0,h_0]$).

Let us now assume that $\vartheta \ge 1$. In fact the arguments below are really only good for $\vartheta = 1$ but we will later modify them to work in the case $\vartheta < 1$ and to provide a really good estimate for $\vartheta > 1$.

Proposition 12.6.5. *For $\theta \in [0,1]$ let the operator $A^\theta = A^0 + \theta B$ satisfy conditions* (12.6.2)–(12.6.6)*, let the negative spectrum of A be discrete and let B be supported in $B(0, \frac{1}{2})$. Then equality*

$$\int \mathsf{tr}\big(e^1_{(\vartheta)}(x,x,\tau) - e^0_{(\vartheta)}(x,x,\tau)\big)\,dx = - \int_0^1 d\theta \int \mathsf{tr}\big(B_x e^\theta_{(\vartheta-1)}\big)(x,x,\tau)\,dx \tag{12.6.27}$$

holds for $\tau \le 0$ and $\vartheta \ge 1$.

Proof. Let $E^\theta(\tau)$ be the spectral projector of A^θ. Let us differentiate the equality

$$\partial_\tau \mathsf{Tr}\big(E^\theta(\tau)\big) = \mathsf{Tr}\big(\mathsf{Res}_{\mathbb{R}}\big(\tau - A^\theta\big)^{-1}\big), \tag{12.6.28}$$

which holds for $\tau < 0$ in the distribution sense, with respect to θ. We obtain

$$\partial_\tau \partial_\theta \mathsf{Tr}\big(E^\theta(\tau)\big) = -\partial_\tau^2 \mathsf{Tr}\big(BE^\theta(\tau)\big).$$

This equality and the semiboundedness of A^θ from below yield that

$$\partial_\eta \mathsf{Tr}\big(E^\theta(\tau)\big) = -\partial_\tau \mathsf{Tr}\big(BE^\theta(\tau)\big). \tag{12.6.29}$$

Integrating over θ from 0 to 1 and convolving with $\tau_+^{(\vartheta-1)}/\Gamma(\theta)$ we obtain after integration by part (12.6.27) for $\tau < 0$. Semi-continuity from the left also yields (12.6.27) for $\tau = 0$. □

Let us assume that the coefficients b_α of the operator $B = A - A^0$ satisfy estimates

$$|D^\beta b_\alpha| \le c|x|^{\mu(m-|\alpha|)+\nu-|\beta|} \qquad \forall \alpha : |\alpha| \le m \quad \forall \beta : |\beta| \le K \tag{12.6.30}$$

with $\nu > 0$ and

$$\mathsf{supp}(b_\alpha) \subset B(0,r), \qquad 1 \ge r \ge r_*(h) = h^{1/(\mu+1)} \tag{12.6.31}$$

where r is a parameter as well as h.

Let us apply the Weyl approximation to the right-hand expression in (12.6.27); this means that we should replace the integrand by the convolution of

$$(2\pi)^{-d}\int \operatorname{Res}_{\mathbb{R}} \operatorname{tr}\bigl(B(\tau - A)^{-1}\bigr)_{\mathsf{w}}(x,\xi)\,d\xi \tag{12.6.32}$$

with $\tau_+^{\vartheta-1}/\Gamma(\vartheta)$; recall that the subscript w means the Weyl symbol and all calculations are done in the context of the formal calculus of pseudodifferential operators.

In this situation let us reverse the deduction of (12.6.27). We then obtain the routine answer

$$\sum_{0\le j\le \lfloor\vartheta\rfloor} h^{-d+j}\int \bigl(\kappa^1_{(\vartheta)j}(x) - \kappa^0_{(\vartheta)j}(x)\bigr)\,dx \tag{12.6.33}$$

where $\kappa^\theta_{(\vartheta)j}$ are the Weyl coefficients for the operator A^θ. However, we gain a remainder estimate: calculating the remainder estimate in our Weyl approximation we obtain

Proposition 12.6.6. *Let the operator $A^\theta = A + \theta B$ satisfy conditions* (12.6.2)–(12.6.6), (12.6.30), (12.6.31) *uniformly on $\theta \in [0,1]$.*

In addition, let the negative spectrum of A^θ be discrete and let us assume that

(12.6.34) *Symbol $A(xr, \xi r^\mu) r^{-m\mu}$ is microhyperbolic in (x,ξ) on the energy level 0 uniformly with respect to $x \in \mathbb{S}^{d-1}$, $\xi \in \mathbb{R}^d$, $r \in (0,1)$.*

Then estimate

$$\Bigl|\int \operatorname{tr}\bigl(e^1_{(\vartheta)}(x,x,0) - e^0_{(\vartheta)}(x,x,0)\bigr) - \sum_{0\le j\le\lfloor\vartheta\rfloor+1} \bigl(\varkappa^1_{(\vartheta)j}(x) - \varkappa^0_{(\vartheta)j}(x)\bigr)\phi\bigl(\frac{x}{r_*}\bigr) h^{-d+j}\,dx\Bigr| \le C R_1^*(r,h) \tag{12.6.35}$$

holds with

$$R_1^*(r,h) = \begin{cases} h^{-d+\vartheta} r^{m\mu\vartheta + (d-\vartheta)(\mu+1)+\nu} & \text{for } \vartheta < \bar\vartheta_\nu,\\ h^{-d+\vartheta}\,|\log r| & \text{for } \vartheta = \bar\vartheta_\nu,\\ h^{l'} & \text{for } \vartheta > \bar\vartheta_\nu \end{cases} \tag{12.6.36}$$

where according to (12.6.11) *and* (12.6.12)

$$\bar{\vartheta}_\nu = \big(d(\mu+1)+\nu\big)(\mu+1-m\mu)^{-1} > \bar{\vartheta}_0, \tag{12.6.37}$$

and

$$l' = l_\nu = (m\mu\vartheta+\nu)(\mu+1)^{-1} > l. \tag{12.6.38}$$

Recall that $r_*(h) = h^{1/(\mu+1)}$, ϕ *is a fixed function with* $(1-\phi) \in \mathscr{C}_0^K(\mathbb{R}^d)$, *and* ϕ *vanishes in a neighborhood of* 0.

Moreover, for $\vartheta < \bar{\vartheta}_\nu$ *one can replace* ϕ *by* 1 *in all the terms; one can also do this for* $\vartheta = \bar{\vartheta}_\nu$, *skipping terms with* $j = \vartheta$; *furthermore, for* $\vartheta > \bar{\vartheta}_\nu$ *one can skip terms with* $j > l' + d$ *and one can replace* ϕ *by* 1 *in terms with* $j < l' + d$.

Proof. Proof follows the scheme we indicated but with the following details:

We apply the Weyl approximation only in the semiclassical zone, i.e., for $r \ge r_*$. In the ball $B(0, r_*)$ we apply a routine estimate of Chapter 9 and obtain that the contribution of this ball to the asymptotics does not exceed $h^{l'}$ with l' given by (12.6.38).

Surely we only treated the case of a bounded function B in Chapter 9. However, it follows from (12.6.3) that on $\mathscr{C}_0^m\big(B(0,2r_*),\mathbb{K}\big)$ operator A satisfies inequalities

$$A \ge -C_0 h^l, \qquad A + C_0 h^l \ge h^{l-2mq/(m+1)} L^* L \tag{12.6.39}$$

for any operator L of the same type as A but with m replaced by $\frac{q}{2}$, $q \le m$; then the routine estimates of Chapter 9 yield the estimate

$$\mathsf{Tr}\big(ME(-\infty,0)\big) \le h^{mq/(m+1)} \tag{12.6.40}$$

for $M = L^*L$ with M supported in $B(0, \frac{3}{2}r_*)$ and therefore the same estimate (12.6.40) holds for every operator M supported in $B(0, r_*)$ of the same type as A but with m replaced by q. □

Furthermore, let $X = \mathbb{R}^d$ and let conditions (12.6.2), (12.6.4) be fulfilled in $\mathbb{R}^d$ instead of $B(0,1)$. Applying the arguments of Chapter 9 one can easily prove estimate

$$\Big|\int \big(1-\psi\big(\frac{x}{r_*}\big)\big)\big(e^1_{(\vartheta)}(x,x,0) - e^0_{(\vartheta)}(x,x,0)\big)\,dx\Big| \le Ch^{-d+\vartheta+1} \tag{12.6.41}$$

provided $\psi = 1$ in $B(0, \frac{1}{3})$ [61] and $r \le \epsilon r^*$ where $r^* > 0$ is an arbitrarily small constant and $\epsilon > 0$ is sufficiently small.

Moreover, the local spectral asymptotics of Chapter 4 applied in the zone $\{1 \ge |x| \ge \frac{1}{4} r\}$ yield that

Proposition 12.6.7. *Let microhyperbolicity condition* (12.6.34) *be fulfilled for operator* $A = A^0$ [62]. *Then estimate*

$$\Big|\int \mathsf{tr}\big(\psi\big(\frac{x}{r^*}\big) - \psi\big(\frac{x}{r}\big)\big)\big(e^{\theta}_{(\vartheta)}(x,x,0) - \sum_{0\le j\le \lfloor \vartheta\rfloor +1} \kappa^{\theta}_{(\vartheta)j} h^{-d+j}\big)\, dx\Big| \le C R^*_2(r,h) \tag{12.6.42}$$

holds with

$$R^*_2(r,h) = \begin{cases} h^{-d+\vartheta+1} r^{m\mu\vartheta + (d-\vartheta-1)(\mu+1)} & \text{for } \vartheta > \bar{\vartheta}_\nu, \\ h^{-d+\vartheta+1} \log r & \text{for } \vartheta = \bar{\vartheta}_\nu. \end{cases} \tag{12.6.43}$$

Then (12.6.35)–(12.6.36), (12.6.41) and (12.6.42)–(12.6.43) yield estimate

$$\Big|\int \psi\big(\frac{x}{r^*}\big)\, \mathsf{tr}\Big(e^1_{(\vartheta)}(x,x,0) - e^0_{(\vartheta)}(x,x,0) - \sum_{0\le j\le \lfloor \vartheta\rfloor +1} \big(\kappa^1_{(\vartheta)j}(x) - \kappa^0_{(\vartheta)j}(x)\big)\phi\big(\frac{x}{r_*}\big) h^{-d+j}\Big)\, dx\Big| \le C R^*_1(r,h) + C R^*_2(r,h) \tag{12.6.44}$$

with R^*_1, R^*_2 given by (12.6.36) and (12.6.43).

Further, Proposition 12.6.4 yields that one can skip the assumptions that $X = \mathbb{R}^d$, that condition (12.6.2) is fulfilled in X instead of $B(0,1)$ and that the negative spectrum of A is discrete. In fact, it is easy to construct an appropriate extension of A to $\mathbb{R}^d$.

Furthermore, let $\bar{A}^0$ coincide with A^0 in $B(0, \frac{1}{2} r)$ and be self-adjoint. Then the arguments of Chapter 9 easily yield that

$$\Big|\int \psi\big(\frac{x}{r}\big)\, \mathsf{tr}\big(e^0_{(\vartheta)}(x,x,0) - \bar{e}^0_{(\vartheta)}(x,x,0)\big)\, dx\Big| \le C R^*_1. \tag{12.6.45}$$

---

[61] This condition is also assumed to be fulfilled below.

[62] Then it is also fulfilled for $A = A^\eta$ for $r \le r^*$.

Finally, in this case $\kappa^0_{(\vartheta)j}(x) = \bar\kappa^0_{(\vartheta)j}(x)$ in a neighborhood of $\mathsf{supp}(\psi(x/r))$. Therefore, one can skip condition (12.6.31) on the support of B in the deduction of estimate (12.6.44).

Therefore we conclude that

(12.6.46) Estimate (12.6.44) remains true under the following weakened assumptions: A^0 is an operator in $\mathbb{R}^d$ satisfying conditions of Proposition 12.6.3, A^1 is an operator in the domain $X \supset B(0,1)$ satisfying conditions (12.6.6) and $b_\alpha = a_\alpha - a^0_\alpha$ satisfying (12.6.30).

Here and below we skip the superscript "1".

Again applying estimates (12.6.42)–(12.6.43) we obtain that

(12.6.47) Estimate (12.6.44) remains true under weakened assumptions if we replace r by r_* in its left-hand expression. Moreover, dividing the left-hand expression into two parts (associated with A, $\kappa_{(\vartheta)j}$ and with A^0, $\kappa^0_{(\vartheta)j}$) we see that in the second part one can replace r by arbitrary $r' > r$; moreover, one can even pick $r' = +\infty$, i.e., replace ψ by 1 here.

Minimizing the right-hand expression by $r \in [r_*, \epsilon r^*]$ (the left-hand expression surely does not depend on r and the optimal value is $r \asymp \bar r = h^{1/(\mu+\nu+1)}$) we obtain estimate

$$
\begin{aligned}
(12.6.48)\quad & \Big|\int \psi\big(\frac{x}{r^*}\big)\,\mathsf{tr}\Big(e_{(\vartheta)}(x,x,0) - \sum_{0\le j\le \lfloor\vartheta\rfloor+1} \kappa_{(\vartheta)j}\phi\big(\frac{x}{r_*}\big)h^{-d+j}\Big)\,dx - \\
& \int \psi\big(\frac{x}{r_2}\big)\,\mathsf{tr}\Big(e^0_{(\vartheta)}(x,x,0) - \sum_{0\le j\le \lfloor\vartheta\rfloor+1} \kappa^0_{(\vartheta)j}\phi\big(\frac{x}{r_*}\big)h^{-d+j}\Big)\,dx\Big| \le CR^*
\end{aligned}
$$

with

$$
(12.6.49)\qquad R^* = R^*(h) = \begin{cases} h^{-d+\vartheta+1}|\log h| & \text{for } \vartheta = \bar\vartheta_0,\\ h^{l''} & \text{for } \bar\vartheta_0 < \vartheta < \bar\vartheta_\nu,\\ h^{l'}|\log h| & \text{for } \vartheta = \bar\vartheta_\nu,\\ h^{l'} & \text{for } \vartheta > \bar\vartheta_\nu \end{cases}
$$

where

$$
(12.6.50)\qquad l'' = \big(m\mu\vartheta - (d-\vartheta-1)\nu\big)(\mu+\nu+1)^{-1}.
$$

One can easily see that $l < l'' < l'$ for $\bar{\vartheta}_0 < \vartheta \le \bar{\vartheta}_\nu$, $l'' = l = -d + \vartheta + 1$ for $\vartheta = \bar{\vartheta}_0$, $l'' = l'$ for $\vartheta = \bar{\vartheta}_\nu$.

In virtue of Proposition 12.6.3 with $J = \lfloor \vartheta \rfloor + 1$ the second line in the left-hand expression of (12.6.48) is equal to $\omega h^{l''}$; picking up $r_2 = +\infty$ we arrive to asymptotics

$$\int \psi(x)\,\mathsf{tr}\big(e_{(\vartheta)}(x,x,0)\big)\,dx = \sum_{0\le j\le \lfloor \vartheta\rfloor+1} h^{-d+j}\int \psi(x)\kappa_{(\vartheta)j}(x)\phi\big(\frac{x}{r_*}\big)\,dx + \omega h^{l''} + R^* \tag{12.6.51}$$

with R^* given by (12.6.49) and $\psi \in \mathscr{C}_0^\infty$, $\psi = 1$ in the vicinity of 0.

Therefore, we have proven the following

Theorem 12.6.8. *Let the operator A satisfy conditions* (12.6.2)–(12.6.6). *Furthermore, let $b_\alpha = a_\alpha - a_\alpha^0$ satisfy* (12.6.30) *with (matrix-valued) coefficients a_α^0 which are positively homogeneous of degrees $(m - |\alpha|)\mu$. Let $\vartheta \ge \max(\bar{\vartheta}_0, 1)$.*

Then asymptotics (12.6.51) *holds with Weyl coefficients $\kappa_{(\vartheta)j}(x)$ and some (non-Weyl) coefficient ω and with the remainder estimate given by* (12.6.49).

Recall that $r_* = h^{(\mu+1)^{-1}}$ and that in the terms with $j < \vartheta + 1$ one can replace ϕ by 1 (changing ω).

Let us note that here we gained nothing for $\vartheta = \bar{\vartheta}_0$.

12.6.4 Adjustment for $\vartheta < 1$

Let us consider the case $\vartheta < 1$ when one should modify the above arguments. Let us pick $\tau = 0$. Moreover, let us consider a partition unity on $\mathbb{R}$ corresponding to the scaling function $\frac{1}{2}(|\tau| + L)$ where we choose parameter L later. Then $\psi(x)e_\vartheta(x,x,0)$ is equal to a sum of terms of the form

$$\vartheta \iint \lambda_-^{\vartheta-1}\varphi\big(\frac{\lambda}{\ell}\big)\psi(x)e(x,x,\lambda)\,d\lambda dx \tag{12.6.52}$$

with <u>either</u> $\varphi = \varphi_0 \in \mathscr{C}_0^K([-1,1])$ and $\ell = L$ <u>or</u> $\varphi = \varphi_1 \in \mathscr{C}_0^K([\frac{1}{2},1])$ and $\ell \ge L$.

We apply this decomposition (12.3.54) *only* with $\psi(x/r)$ instead of ψ where we will choose $r \in [r_*, 1]$ later. Let us apply the arguments of the

previous subsection which are not associated with Proposition 12.6.5 (and therefore do not require the assumption $\vartheta \ge 1$). In particular, let us apply estimates (12.6.41) and (12.6.42) [63]. We then obtain that one needs to evaluate

$$\frac{1}{\Gamma(\vartheta)} \iint \lambda_-^{\vartheta-1} \varphi_0(\frac{\lambda}{\ell}) \psi(\frac{x}{r}) \operatorname{tr}\bigl(e^{\theta}(x,x,\lambda)\bigr)\, d\lambda dx \tag{12.6.53}$$

and

$$\frac{1}{\Gamma(\vartheta)} \iint \lambda_-^{\vartheta-1} \varphi_1\bigl(\frac{\lambda}{\ell}\bigr) \operatorname{tr}\bigl(e(x,x,\lambda) - e^{0}(x,x,\lambda)\bigr)\, d\lambda dx \tag{12.6.54}$$

where $\theta = 0, 1$, the error $O(R_2^*)$ (which is $= O\bigl(h^{-d+1+\vartheta} r^{m\mu\vartheta+(d-\vartheta-1)(\mu+1)}\bigr)$ in this case) is already accounted for, R_2^* is given by (12.6.43) and without any loss of the generality one can assume that conditions (12.6.2), (12.6.4) are fulfilled in $\mathbb{R}^d$.

Applying standard Weyl asymptotics to (12.6.53) one gets the remainder estimate $O\bigl(L^{\vartheta} h_{\mathrm{eff}}^{1-d}\bigr)$. On the other hand, one can apply the arguments of the proof of Proposition 12.6.5 to (12.6.54) and represent it in the form

$$\int_0^1 dt \iint \bigl(\partial_\tau^2 \lambda_-^{\vartheta} \varphi_1\bigl(\frac{\lambda}{\ell}\bigr)\bigr) \operatorname{tr}\bigl(B_x e^{\eta}\bigr)(x,x,\lambda)\, d\lambda dx. \tag{12.6.55}$$

Let us apply Weyl asymptotics to this expression. We obtain then the remainder estimate $O\bigl(r^{m\mu+\nu} \ell^{\vartheta-1} h_{\mathrm{eff}}^{1-d}\bigr)$ provided

$$m\mu + \nu + (d-1)(\mu+1) > 0. \tag{12.6.56}$$

After summation on the partition of unity we obtain that the total contribution of the terms of (12.6.54) type to the remainder is $O\bigl(r^{m\mu+\nu} L^{\vartheta-1} h_{\mathrm{eff}}^{1-d}\bigr)$ while the contribution of (12.6.53) is $O\bigl(L^{\vartheta} h_{\mathrm{eff}}^{1-d}\bigr)$. Minimizing the sum with respect to L (the optimal value is $L \asymp r^{m\mu+\nu}$) we obtain

$$O\bigl(h^{1-d} r^{(m\mu+1)\vartheta+(\mu+1)(d-1)}\bigr). \tag{12.6.57}$$

Recall that there is also an error $O\bigl(h^{-d+1+\vartheta} r^{m\mu\vartheta+(d-\vartheta-1)(\mu+1)}\bigr)$. Minimizing their sum over r (the optimal value is again $\asymp \bar{r} = h^{1/(\mu+\nu+1)}$) we obtain the final remainder estimate $O\bigl(h^{l''}\bigr)$ where l'' is given by (12.6.50).

So, the following statement has been proven:

---

[63] In order to get these with the convolutions, including the cut-off function φ, one should apply Theorem 4.4.1.

Theorem 12.6.9. *Let all the conditions of Theorem 12.6.8 be fulfilled excluding $\vartheta \geq 1$. Let $\bar{\vartheta}_0 < \vartheta < 1$ and condition* (12.6.56) *be fulfilled (which means exactly that $\bar{\vartheta}_\nu > 1$).*

Then asymptotics (12.6.51) *remains true with the Weyl coefficients $\kappa_{\vartheta j}(x)$ and some (non-Weyl) coefficient ω and with the remainder estimate given by* (12.6.49).

Remark 12.6.10. Surely, even if condition (12.6.56) is violated one can get semiclassical asymptotics for (12.6.55) but the remainder estimate will be worse and the final remainder estimate will be also worse. However, this condition is only technical, and we are going to get rid of it without deterioration of the remainder estimate in the general approach.

12.6.5 The General Case

Let us pick up $\bar{r} = h^{(1+\mu+\nu)^{-1}}$ and then apply the same arguments as before in the zone $\{\bar{r} \leq |x| \leq 1\}$.

Then

(12.6.58) The contribution of this zone $\{\bar{r} \leq |x| \leq 1\}$ to the remainder is $O\bigl(R_2^*(\bar{r})\bigr)$ as before.

Let us consider $B(0, \bar{r})$ and apply the same partition of unity here. Thus one should consider the same expression

$$\frac{1}{\Gamma(\vartheta+1)} \int \tau_-^{\vartheta} \mathsf{Tr}\bigl(\psi\, d_\tau E(\tau)\bigr) \tag{12.6.59}$$

as before. We skip all the subscripts at ψ. Let us define $r = \frac{1}{2}(|x| + r_*)$ at some point of $\mathsf{supp}(\psi)$ and let us pick up

$$L = L(r) = hr^{m\mu+\nu-\mu-1} \tag{12.6.60}$$

for this element. Let us consider the same partition on $\mathbb{R}$ as before and let us replace $\mathsf{Tr}\,\psi\, d_\tau E(\tau)$ with its Weyl expression (with cut-off for $|x| \leq r_*$). Then the contribution of the element with $\ell \leq 2L$ to the remainder does not exceed $CR(r,h)$ with

$$R(r,h) = h^{-d+1} r^{(d-1)(\mu+1)} L^{\vartheta} = h^{-d+1+\vartheta} r^{(m\mu+\nu)\vartheta+(d-1-\vartheta)(\mu+1)}. \tag{12.6.61}$$

Summation (12.6.61) over the partition of unity on x results in the same expression with $r = r_*$ or $r = \bar{r}$ as $(m\mu+\nu)\vartheta + (d-1-\vartheta)(\mu+1) \lessgtr 0$ with an extra factor $\log(\bar{r}/r_*)$ in the case of equality; so we get

$$R^*(h) = \begin{cases} h^{l''} & \text{for } (m\mu+\nu)\vartheta + (d-1)(\mu+1) > 0 \\ h^{l'} \log h & \text{for } (m\mu+\nu)\vartheta + (d-1)(\mu+1) = 0 \\ h^{l'} & \text{for } (m\mu+\nu)\vartheta + (d-1)(\mu+1) < 0 \end{cases} \tag{12.6.62}$$

where

$$l'' = \big((m\mu+\nu)\vartheta - (d-1)\nu\big)(\mu+\nu+1)^{-1}, \tag{12.6.63}$$

$$l' = (m\mu+\nu)\vartheta(\mu+1)^{-1}. \tag{12.6.64}$$

Moreover, the contribution of $B(0,3r_*)$ to the remainder does not exceed $Ch^{l''}$.

Let us consider elements with $\ell \geq L$. Then one can apply the same arguments as before with k differentiations instead of 1 and easily get the following generalization of (12.6.27):

$$\begin{aligned} &\int \varphi(\tau)\tau_-^{\vartheta}\, d_\tau E^1(\tau) = \\ &\sum_{0\leq j\leq k-1} \int \varphi_{\vartheta,j}(\lambda_1,\dots,\lambda_{j+1}) E^0(\lambda_1) B E^0(\lambda_2)\cdots B E^0(\lambda_{j+1})\, d\lambda_1\cdots d\lambda_{j+1} + \\ &\int_0^1 (k+1)(1-\theta)^k\, d\theta \times \\ &\qquad \int \varphi_{\vartheta,k+1}(\lambda_1,\dots,\lambda_{k+1}) E^\theta(\lambda_1) B E^\theta(\lambda_2)\cdots B E^\theta(\lambda_{k+1})\, d\lambda_1\cdots d\lambda_{k+1} \end{aligned} \tag{12.6.65}$$

where $E^\theta(\lambda)$ is the spectral projector of A^θ and

$$\varphi_{\vartheta,j} = (-1)^{j+1} \int \delta(\tau-\lambda_1)\cdots\delta(\tau-\lambda_j)\Big(\partial_\tau^{j+1}\big(\tau_-^{\vartheta}\varphi(\tau)\big)\Big)\, d\tau, \tag{12.6.66}$$

understood as a distribution on $(\lambda_1,\dots,\lambda_j)$, is in fact a smooth function such that

$$\operatorname{supp}(\varphi_{j,\vartheta}) \subset [\frac{1}{2}\ell, 2\ell]^j, \qquad |D_\lambda^\beta \varphi_{\vartheta,j}| \leq c\ell^{\vartheta+1-2j-|\beta|}. \tag{12.6.67}$$

Let us multiply by ψ and take the trace. Our goal is to evaluate the result.

First of all we are going to evaluate the elements with $r \geq 2r_*$. For this purpose let us return to Chapters 4 and 7. Under the standard assumptions of those chapters let us consider the following problems:

$$(12.6.68)_0 \qquad \big(hD_t - A\big)U_0(t) = 0, \qquad U_0(0) = I$$

$$(12.6.68)_j \qquad \big(hD_t - A\big)U_j(t) = B_j U_{j-1}(t), \qquad U_j(0) = 0, \qquad j \geq 1$$

where the operators B_j are also regular h-pseudodifferential operators of order 0. Then the results of Chapters 2 and 3 concerning the oscillatory front set of $U = U_0$ obviously remain true for U_j as well.

In particular, we get[64)]

(12.6.69) Under the microhyperbolicity condition for the operator A on the energy level 0 (with the boundary conditions, if there is a boundary), $\varphi(hD_t)\chi_T(t)\big(\Gamma\psi U_j\big)$ is negligible for $\varphi \in \mathscr{C}_0^K$ supported in a small neighborhood of 0, $\chi \in \mathscr{C}_0^K\big([-1, -\frac{1}{2}] \cup [\frac{1}{2}, 1]\big)$ and a sufficiently small constant $T > 0$.

Applying rescaling-decomposition arguments one can prove easily that[65)]

(12.6.70) Estimate (2.1.58) remains true for $U = U_j$ as well

On the other hand, one can apply the successive approximation method in the interval $|t| \leq h^{\frac{1}{2}+\delta}$. Let us note that for $B_1 = B_2 = \cdots = B_j = B$,

$$\varphi(hD_t)\Gamma\,\mathsf{tr}\big(\psi U_j(.,t)\big)\big|_{t=0}$$

is exactly the term to be evaluated (for $j = k+1$ one should integrate over the parameter θ, and A depends on this parameter.

Thus for $r \asymp 1$ the remainder estimate (after we replace the whole thing by its Weyl expression) is $Ch^{1-d}\ell^{\vartheta}\big(1 + \ell/h\big)^{-s}$ where we have taken into account condition (12.6.67) on φ.

Remark 12.6.11. The procedure to get the Weyl approximation is obvious: one replaces $d_\tau E(\tau)$ by the formal parametrix $(\tau - A)^{-1}$ of the operator A (with the corresponding boundary conditions), then takes $A = A^\theta = A_0 + \theta B$ and calculates the j-th derivative with respect to θ. Afterward one applies $\mathsf{Res}_{\mathbb{R}}$ and formally calculates the trace of this operator.

---

64) Cf. Corollary 2.1.17 and Theorem 3.3.5.

65) Cf. Theorems 2.1.19 and 3.3.6.

Rescaling, we obtain that for $r \ge r_*$ the contribution to the remainder estimate is

$$C\ell^{\vartheta-j}r^{(m\mu+\nu)j}\bigl(\frac{h}{r^{\mu+1}}\bigr)^{1-d+\vartheta-j}\bigl(1+\frac{\ell r^{\mu+1-m\mu}}{h}\bigr)^{-s}. \tag{12.6.71}$$

For $j > \vartheta$ we obtain that the sum with respect to $\ell \ge L(r)$ does not exceed this expression with $\ell = L(r)$ which is equal to $CR(r,h)$ with $R(r,h)$ given by (12.6.61) and after summation over the partition on r we get $CR^*(h)$ with $R^*(h)$ given by (12.6.62). *Let us pick* $k > \vartheta$.

In order to treat $j \le \vartheta$ let us replace $\sum_{r\le \bar r}\sum_{\ell\ge L(r)}$ by $\sum_{\ell\ge L^*}\sum_{r\le r(L)}$ where $L^* = L(r_*) = h^{m\mu(\mu+1)^{-1}}$ and

$$r(\ell) = \bigl(\ell/h\bigr)^{1/(m\mu+\nu-\mu-1)} \tag{12.6.72}$$

inverse function to $L(r)$ defined by (12.6.60). Let us now consider the sum on r only.

(i) For

$$f(j) := m\mu\vartheta + (\mu+1)(d-1-\vartheta) + (\mu+\nu+1)j > 0 \tag{12.6.73}$$

we replace the corresponding term in the partition of the right-hand expressions of (12.6.65) by its Weyl approximations. Then the error will not exceed $CR'(\ell)$ with $R'(\ell) = R\bigl(r(\ell)\bigr)$. After summation on $\ell \ge L^*$ one again obtains $CR^*(h)$.

(ii) Observe that for $f(j) = 0$ one gets the same answer with the additional factor $|\log h|$ in the right-hand expression. Thus, we need to replace $R^*(h)$ by

$$R^{**}(h) = \begin{cases} h^{l'''} & \text{for } (m\mu+\nu)\vartheta + (d-1)(\mu+1) > 0,\\ & \qquad \vartheta - (\mu+1)(d-1)(\mu+\nu+1)^{-1} \notin \mathbb{Z}^+,\\ h^{l'''}\,|\log h| & \text{for } (m\mu+\nu)\vartheta + (d-1)(\mu+1) > 0,\\ & \qquad \vartheta - (\mu+1)(d-1)(\mu+\nu+1)^{-1} \in \mathbb{Z}^+,\\ h^{l'}\,|\log h| & \text{for } (m\mu+\nu)\vartheta + (d-1)(\mu+1) = 0,\\ h^{l'} & \text{for } (m\mu+\nu)\vartheta + (d-1)(\mu+1) < 0. \end{cases} \tag{12.6.74}$$

(iii) Let us consider the terms with $f(j) < 0$. We replace them by their Weyl expressions as well but treat these terms in a different way. First, we consider the difference between the terms and their Weyl approximations on each element of the partition of unity, but we *do not estimate it by* (12.6.71).

Instead we sum this difference with respect to $r \le r(\ell)$, then we replace $\sum_{r\le r(\ell)}$ by $\sum_{r<\infty} - \sum_{r>r(\ell)}$ and only then for $r > r(\ell)$ let us apply the above remainder estimate (12.6.71) and get the same answer as before. However we also get $\sum_{r<\infty}$.

One can easily see that the contribution of $B(0, r_*) \times [0, 3L^*]$ to the original expression does not exceed $Ch^{l''}$.

Later we will prove that

(12.6.75) The contribution of $B(0, 2r_*)$ to terms with $f(j) > 0$ does not exceed $Ch^{l''}$ as well.

Then modulo $O\big(R^{**}(h)\big)$ our original expression is equal to

$$\mathsf{Weyl} + \sum_{j:f(j)<0} c_j \iint \tau_-^{\vartheta-1} \operatorname{tr}\big(\mathcal{K}_{(B(\tau-A^0)^{-1})^j}(x,x) - \mathsf{Weyl}_j(x,\tau)\big)\, dxd\tau \tag{12.6.76}$$

where the first Weyl is some combination of the Weyl expressions and Weyl_j is the Weyl approximation for $\mathcal{K}_{(B(\tau-A^0)^{-1})^j}(x,x)$ where $\mathcal{K}_S$ denotes the Schwartz kernel of operator S and c_j are some numerical coefficients; these terms are coming from $\sum_{r<\infty}$.

Recall that all these Weyl expressions contain the factor $\big(1-\phi(x/r_*)\big)$ cutting them in $B(0, r_*)$.

Now, let us assume for the sake of simplicity that

(12.6.77) Operator B is quasihomogeneous; i.e., $B(\zeta x, \zeta^\mu \xi) = \zeta^{m\mu+\nu} B(x,\xi)$ $\forall x, \xi, \zeta > 0$.

Later we will get rid of this condition with the possible deterioration of the remainder estimate, and it is not necessary from the very beginning if $f(1) \ge 0$.

Under this condition (12.6.77) let us consider terms with $f(j) < 0$ and with integration on $x \in \mathbb{R}^d$. Then same homogeneity arguments as in Proposition 12.6.3 imply that

(12.6.78) The terms with $f(j) < 0$ in (12.6.76) are equal to $\omega_{(\vartheta)j} h^{(m\mu\vartheta+\nu j)(\mu+1)^{-1}}$ with unknown numerical coefficients $\omega_{(\vartheta)j}$.

We will call them *Scott correction terms*. Note that

$$f(j) < 0 \iff (m\mu\vartheta + \nu j)(\mu+1)^{-1} < \min(l', l''). \tag{12.6.79}$$

Further, one can easily see that modulo $O\big(R^{**}(h)\big)$ the first Weyl is equal to

$$\begin{aligned} &\sum_{p<d+\min(l',l'')} \kappa_{(\vartheta)p} h^{-d+p} + \\ &\sum_{p<d+\min(l',l''),j:-d+p=(m\mu\vartheta+\nu j)/(\mu+1)} \kappa'_{(\vartheta)p} h^{-d+p} |\log h| \end{aligned} \tag{12.6.80}$$

plus the sum of the "superficial" terms $c_{(\vartheta)p,j} h^{-d+p+\nu j} \bar{r}^{\alpha_{p,j}}$ with exponents $\alpha_{p,j} := (\mu+1)(d-p-\nu j) \neq 0$ and $c_{(\vartheta)p,j} h^{-d+p+\nu j} \log \bar{r}$ with $\alpha_{p,j} = 0$.

Here $\kappa_{(\vartheta)p}$ are standard Weyl coefficients (one can easily see that the integrals defining them converge (at 0) for $p < d + m\mu\vartheta 1/(\mu+1)$. Taking into account the fact that one can pick any $\bar{r} \asymp h^{(\mu+\nu+1)^{-1}}$ and the final answer should not depend on $\bar{r}$ we see that all these coefficients $c_{(\vartheta)p,j}$ should vanish and only (12.6.80) survives.

Therefore (12.6.76) modulo $O\big(R^{**}(h)\big)$ is equal to (12.6.80) plus sum of the terms from (12.6.78):

$$\begin{aligned} &\sum_{p<d+\min(l',l'')} \kappa_{(\vartheta)p} h^{-d+p} + \\ &\sum_{p<d+\min(l',l''),j:-d+p=(m\mu\vartheta+\nu j)/(\mu+1)} \kappa'_{(\vartheta)p} h^{-d+p} |\log h| + \\ &\sum_{j:(m\mu\vartheta+\nu j)/(\mu+1)<\min(l',l'')} \omega_{(\vartheta)j} h^{(m\mu\vartheta+\nu j)/(\mu+1)} \end{aligned} \tag{12.6.81}$$

where $\omega_j h^{(m\mu\vartheta+\nu j)/(\mu+1)}$ are (multiple) Scott correction terms. More precisely, defining

$$\bar{\vartheta}_J := \max\Big(\big((\mu+1)(d-1) + (\mu+\nu+1)J\big)(\mu+1-m\mu)^{-1}, J\Big) \tag{12.6.82}$$

we see that

(12.6.83) For $\bar\vartheta_{J-1} < \vartheta \le \bar\vartheta_J$ there are exactly J Scott correction terms ($j = 1, \dots$)

To prove pending claim (12.6.75) let us now consider an element of the partition supported in $B(0, 2r_*)$. Let us replace every factor B by $B_1 = \bar\psi B$ where the cut-off function $\bar\psi$ is supported in $B(0, 4r_*)$ and equal to 1 in $B(0, r_*)$. We will explain how to get rid of this cut-off function later.

Let us note that

(12.6.84) For $\tau \le 0$ the operator norm of $\bar\psi B E^\theta(\tau)$ does not exceed $r_*^{m\mu+\nu}$ while the trace norm of $\bar\psi E^\theta(\tau)$ does not exceed C [66)].

One can prove this easily for $h = r_* = 1$ and then extend to the general case by rescaling (recall that $r_*^{\mu+1} = h$).

Then the trace norm of the operator

$$\int \varphi_{\vartheta,k+1}(\lambda_1, \dots, \lambda_j)\psi E^\theta(\lambda_1) B_1 E^\theta(\lambda_2) \cdots B_1 E^\theta(\lambda_{k+1})\, d\lambda_1 \cdots d\lambda_{k+1}$$

does not exceed $\ell^{\vartheta-k} r_*^{(m\mu+\nu)k}$ and after summation on the partition we get the same expression with $\ell = L = r_*^{m\mu+\nu}$ provided $k > \vartheta$. Namely, we get $r_*^{(m\mu+\nu)\vartheta} = h^{(m\mu+\nu)\vartheta/(\mu+1)}$.

Finally, we should consider similar expressions with some copies of B replaced by $\bar B$ and other copies replaced by $\psi' B$ where ψ' is supported outside of $B(0, 3r_*)$. Taking partitions one can replace the i-th copy of ψ' by ψ_i supported in $\{\frac{1}{2} r_i \le |x| \le 2r_i\}$. Combining the above arguments one can estimate this term through $r_*^{(m\mu+\nu)\vartheta} \prod_i \big(r_*/r_i\big)^s$ and the total contribution will not exceed $r_*^{(m\mu+\nu)\vartheta}$ again.

Thus, all the estimates are done. Therefore the first statement of the following theorem has been proven:

Theorem 12.6.12. *Let the conditions of Theorem 12.6.8 be fulfilled.*

[66)] One can add the factor $\big(|\tau| r_*^{-m\mu} + 1\big)^{-s}$ with arbitrarily large s to the right side of these estimates but it is not important here.

(i) Moreover, let condition (12.6.77) *be fulfilled. Then asymptotics*

$$\int \psi(x) e_{(\vartheta)}(x,x,\tau)\,dx = \sum_{p:p<d+\min(l',l'')} \kappa_{(\vartheta)p} h^{-d+p} + \sum_{p<d+\min(l',l''),j:-d+p=(m\mu\vartheta+\nu j)/(\mu+1)} \kappa'_{(\vartheta)p} h^{-d+p}|\log h| + \sum_{j:(m\mu\vartheta+\nu j)/(\mu+1)<\min(l',l'')} \omega_{(\vartheta)j} h^{(m\mu\vartheta+\nu j)/(\mu+1)} + O\big(R^{**}(h)\big) \tag{12.6.85}$$

holds with $R^{**}(h)$ *given by* (12.6.74).

(ii) Moreover, for $\vartheta \le \bar{\vartheta}_1$ *one can drop condition* (12.6.77).

(iii) Let us assume that

$$\big|D^\beta\big(a_\alpha - a^0_\alpha - b^0_\alpha\big)\big| \le c|x|^{(m-|\alpha|)\mu+\nu'-|\beta|} \tag{12.6.86}$$

where a^0_α, b^0_α *are positively homogeneous of degrees* $(m-|\alpha|)\mu$, $(m-|\alpha|)\mu+\nu$ *respectively,* $\nu' > \nu$.

Then asymptotics (12.6.85) *holds with* $R^{**}(h)$ *replaced by* $R^{**}(h)+R^{*\prime}(h)$ *where* $R^{*\prime}(h)$ *is given by* ((12.6.49) *with* ν' *instead of* ν.

The proof of Statement (iii) is simple: we first make the transition from A to A^0+B^0 (then the remainder estimate $O\big(R^*(h)\big)$ arises) and then apply Statement (i).

We believe that it would not be difficult to

Problem 12.6.13. Generalize this theorem to the case when

$$D^\beta\big(b_\alpha - b^1_\alpha - ... - b^s_\alpha\big) = O\big(|x|^{(m-\alpha)\mu+\nu_{s+1}-|\beta|}\big)$$

and b^k_α are positively homogeneous of degrees $(m-|\alpha|)\mu+\nu_k$.

12.6.6 Propagation of Singularities

Now our goal is to improve the remainder estimate, which requires some condition of a global nature on the symbol $A^0(x,\xi)$. To formulate the

condition the reader must recall the definitions of generalized bicharacteristics and generalized δ-bicharacteristics (see Definition 2.2.8 or similar notion in Chapter 3); otherwise we should assume that the eigenvalues of $A^0(x,\xi)$ which are close to 0 have constant multiplicities. Moreover, the reader should remember quasiconical sets and the quasiconical hull of a set; these notions are associated with the rescaling family $\Phi_\zeta : (x,\xi) \to (\zeta x, \zeta^\mu \xi)$ with $\zeta > 0$.

Definition 12.6.14. We say that the *escape condition* is fulfilled if there exist quasiconical sets Λ^+ and Λ^- closed in $(\mathbb{R}^d \setminus 0) \times \mathbb{R}^d$ and numbers $T_0 > 0$, $\epsilon_1 > 0$ such that

$$\Lambda^+ \cup \Lambda^- = \Sigma^0 = \bigl\{(x,\xi) \in (\mathbb{R}^d \setminus 0) \times \mathbb{R}^d : \det A^0(x,\xi) = 0\bigr\} \tag{12.6.87}$$

and for every point $(\bar x, \bar\xi)$ belonging to the ϵ_1-neighborhood of $\Lambda^\pm$ intersected with $\bigl\{(x,\xi) : |x| = 1\bigr\} \cap \Sigma^0$ all the generalized bicharacteristics of the symbol $-A^0(x,\xi)$ passing through $(\bar x, \bar\xi)$ in the direction of $\pm t > 0$ are infinitely long with respect to t, and along them

$$(x(t),\xi(t)) \in \Lambda^\pm, \quad |x(t)| \ge 2|\bar x| \qquad \forall t : \pm t \ge T_0; \tag{12.6.88}$$

these conditions should be fulfilled for each sign "+" and "−" separately.

We discuss this condition below; here we make certain corollaries and remarks concerning it.

Remark 12.6.15. (i) Condition (12.6.4) yields that $\Sigma^0 \cap \{|x| = 1\}$ is compact.

(ii) Under condition (12.6.88) for each generalized bicharacteristics $(x(t),\xi(t))$ with $(x(0),\xi(0)) \in \Lambda^\pm_{\epsilon_1}$ for $\pm t > 0$ inequalities

$$\epsilon_0 \le |x(t)| \cdot \bigl(|x(0)| + |t|^\sigma\bigr)^{-1} \le C_0 \tag{12.6.89}$$

hold with

$$\sigma^{-1} := \sigma' := 1 + \mu - m\mu > 0 \tag{12.6.90}$$

(otherwise $\bar\vartheta_0 = +\infty$) and with appropriate constants ϵ_0, C_0 which do not depend on t and $(x(0),\xi(0))$; here and below $\Lambda^\pm_\varepsilon$ denotes the intersection of the quasiconical hull of ε-neighborhood of $\Lambda^\pm \cap \{|x| + 1\}$ with Σ^0.

In fact, let us pick t_n: $t_0 = 0$, $t_{n+1} = t_n + T_0 r_n^{\sigma'}$ with $r_n = |x(t_n)|$. Then condition (12.6.88) and the quasihomogeneity of A^0 and the quasiconic nature of Λ^+ yield that $2r_n \le r_{n+1} \le c_0 r_n$ (we have taken $(x(0),\xi(0)) \in \Lambda^+$ for notational simplicity).

Therefore $r_n \to +\infty$ as $n \to +\infty$. Then these inequalities and the definition of t_{n+1} obviously yield the inequality $r_{n+1} \le c_1 t_{n+1}^{\sigma}$ (and hence $t_n \to +\infty$ as $n \to +\infty$) and the inequality $t_{n+1} r_{n+1}^{-\sigma'} \le c_2 + (1-\epsilon) t_n r_n^{\sigma'}$ with $\epsilon > 0$. This inequality yields by induction that $t_n r_n^{-\sigma'} \le c_3$ with a sufficiently large constant c_3. So, both inequalities (12.6.89) are fulfilled for $t = t_n$ with $n = 0, 1, ...$ and therefore these inequalities are fulfilled for $t \in (t_n, t_{n+1}]$ as well.

(iii) Let us replace the symbol $A^0(x,\xi)$ with another symbol $A^1(x,\xi)$ also of the form (12.6.1) such that

$$\bigl|D^{\beta}(a^1_{\alpha} - a^0_{\alpha})\bigr| \le \varepsilon |x|^{\mu(m-|\alpha|)-|\beta|} \qquad \forall \alpha : |\alpha| \le m \quad \forall \beta : |\beta| \le K \tag{12.6.91}$$

with a small enough constant $\varepsilon > 0$. We *do not* assume that $A^1(x,\xi)$ is a quasihomogeneous symbol. Then

$$|\xi| \le c_3 |x|^{\mu} \qquad \text{on} \quad \Sigma^j \qquad j = 0, 1 \tag{12.6.92}$$

and the microhyperbolicity of A^0 on the energy level 0 yields that

$$\forall (x,\xi) \in \Sigma^0 \quad \exists (x',\xi') \in \Sigma^1 : \quad |x - x'| \le c_3 \varepsilon |x| \ \text{ and } \ |\xi - \xi'| \le c_4 \varepsilon |x|^{\mu} \tag{12.6.93}$$

and *vice versa* (one can permute Σ^0 and Σ^1 in this assertion), and c_4 does not depend on ε.

Let us introduce the sets

$$\Lambda_1^{\pm} = \bigl\{(x,\xi) \in \Sigma^1 : \exists (x',\xi') \in \Lambda^{\pm} : |x - x'| \le \epsilon |x| \ \text{ and } \ |\xi - \xi'| \le \epsilon |x|^{\mu}\bigr\} \tag{12.6.94}$$

with sufficiently small $\epsilon > 0$. Moreover, let us introduce the sets $\Lambda_2^{\pm}$ in the same way but with ϵ replaced 2ϵ.

Then the properties of the generalized bicharacteristics (see Lemma 2.2.9) and condition (12.6.88) yield that if $\epsilon > 0$ is a small enough constant and if $\varepsilon = \varepsilon(\epsilon) > 0$ is also small enough then every generalized bicharacteristics $(x(t), (\xi(t))$ of the symbol $A^1(x,\xi)$ passing through the point $(\bar{x}, \bar{\xi}) \in \Lambda_2^{\pm}$ in the direction of positive $\pm t$ can be extended to the time interval $\pm t \in [0,\, T_1 |\bar{x}|^{\sigma'}]$, and for $\pm t \in [2T_0 |\bar{x}|^{\sigma'},\, T_1 |\bar{x}|^{\sigma'}]$ along this bicharacteristics

$$(x(t), \xi(t)) \in \Lambda_1^{\pm}, \qquad |x(t)| \ge \frac{3}{2} |\bar{x}|; \tag{12.6.88}'$$

$T_1 > 2T_0$ is arbitrarily large and ϵ and ε depend on T_1.

Then the same arguments as in Statement (i) yield that along these trajectories inequalities (12.6.91) are fulfilled with constants c_0, ϵ_0 which do not depend on T_1. Then the arbitrary choice of T_1 yields that this statement remains true even for $T_1 = +\infty$.

(iv) The same analysis remains true if we assume that (12.6.91) is fulfilled in $B(0,r)$ instead of $\mathbb{R}^d$; surely, we should treat the trajectory only as long as it remains in $B(0,r)$. In this case (12.6.91) yields that all the statements remain true in the time interval $\pm t \in [0, \epsilon_2 r^{\sigma'}]$ with a small enough constant $\epsilon_2 > 0$ and $|\bar{x}| \le \frac{1}{2}r$.

(v) Therefore in the analysis of the trajectories on the energy level τ instead of $\tau = 0$ all the Statements (i)–(iii) remain true with the following modifications:

(a) For $\mu < 0$ one should replace r with $\min\bigl(r, \epsilon_2|\tau|^{(m\mu)^{-1}}\bigr)$, i.e., one should treat the starting points $(\bar{x}, \bar{\xi})$ with $|\bar{x}| \le \min\bigl(r, \epsilon_2|\tau|^{(m\mu)^{-1}}\bigr)$ and the time interval $\pm t \in \bigl[0, \epsilon_2 \min(r^{\sigma'}, |\tau|^{(m\mu\sigma)^{-1}})\bigr]$.

(b) For $\mu > 0$ one should leave both r and the time interval $\pm t \in [0, \epsilon_2 r^{\sigma'}]$ unchanged and one should treat the starting points $(\bar{x}, \bar{\xi})$ with $c_2|\tau|^{(m\mu)^{-1}} \le |\bar{x}| \le r$.

(c) rem-12-5-15-vc For $\mu = 0$ one should leave r and the time interval $\pm t \in [0, \epsilon_2 r^{\sigma'}]$ and the condition $|\bar{x}| \le r$ unchanged and one should only assume that $|\tau| \le \epsilon_2$ where $\epsilon_2 > 0$ is a small enough constant.

Remark 12.6.16. Further, let us consider a more complicated flow. Namely, let us assume that at the moments $\pm t_n = T_1^n |\bar{x}|^{\sigma'}$ with $n = 1, 2, \ldots$ the point $(x(t), \xi(t))$ makes random "jumps"; namely it jumps to an arbitrary point in its εr_n-neighborhood intersected with the set Ω; $\Omega = \Pi_{\tau_0}$ for $\mu \le 0$ and $\Omega = \Pi_{\tau_n}$ with $\tau_n = (r_n/r_*)^{m\mu}\tau_0$ for $\mu > 0$ where $\Pi_\zeta = \cup_{\tau:|\tau|\le\zeta} \Sigma_\tau^1$ and we assume that $\tau_0 > 0$.

So, we assume that the "jump" and the flow itself preserve the energy levels only approximately. This exotic flow will be useful later. We claim that for sufficiently small $\varepsilon > 0$ and for sufficiently large $T_1 > 0$, Statements (i)–(v) of Remark 12.6.15 remain true.

In fact, let $r_n = |x(\pm t_n \pm 0)|$. Then Remark 12.6.15 and the conditions on the jump at the end of a segment of the trajectory yield that if

$$0 < \epsilon_0 \le r_n t_n^{-\sigma} \le c_0 \tag{12.6.95}_n$$

then for sufficiently large $T_1 > 0$ depending on c_0, ϵ_0 estimates

$$r_n + \epsilon_1 t_{n+1}^{\sigma} \le r_{n+1} \le r_n + c_1 t_{n+1}^{\sigma}$$

hold with c_1, ϵ_1 which do not depend on c_0, ϵ_0. Then under an appropriate choice of the constants c_0, $\epsilon_0 > 0$ condition $(12.6.95)_n$ yields $(12.6.95)_{n+1}$ with the same constants c_0, ϵ_0; then induction on n yields (12.6.91).

Moreover, the energy level after a jump remains admissible.

Let us prove some assertions concerning the long-time propagation of singularities:

Proposition 12.6.17. *Let the operator A satisfy* (12.6.2)–(12.6.6). *Let $b_\alpha = a_\alpha - a_\alpha^0$ satisfy* (12.6.30) *and let a_α^0 be positively homogeneous functions of degrees $(m - |\alpha|)\mu$. Let symbol A^0 satisfy conditions* (12.6.20) *and escape condition* (12.6.87)–(12.6.88).

Further, let $r \in [r_* h^{-\delta}, \varepsilon_0]$ with $r_* = h^{(\mu+1)^{-1}}$, an arbitrarily small exponent $\delta > 0$ and a sufficiently small constant $\varepsilon_0 > 0$. Let $h' = hr^{-\mu-1}$, $\gamma = h'^{\rho}$ with an exponent $\rho \in (0, \frac{1}{2})$. Let $\tau_0 = \epsilon_3 r^{m\mu}\gamma$ for $\mu < 0$ and $\tau_0 = \epsilon_3 r^{m\mu}$ for $\mu \ge 0$.

Furthermore, let $Q \in \boldsymbol{\Psi}_{h,\gamma r^\mu,\gamma r}$ be an operator with the symbol supported in the intersection of the $\varepsilon(r, r^\mu)$-neighborhood (in (x,ξ)) of the set $\Lambda^{\pm} \cap \{\epsilon_0 r \le |x| \le c_0 r\}$ and Π_{τ_0}.

Finally, let

$$T'' = \begin{cases} \epsilon_3 \min(1, r^{\sigma'}\gamma^{(m\mu\sigma)^{-1}}) & \text{for } \mu < 0, \\ \epsilon_3 & \text{for } 0 \le \mu < (m-1)^{-1} \end{cases} \tag{12.6.96}$$

and $T' = c_3 r^{\sigma'}$ with small enough constants $\epsilon_3 > 0$ and $\varepsilon > 0$ and a large enough constant c_3. Let $\bar{T} \in [T', T'']$.

Then there exists an operator $\bar{Q} = \bar{Q}_{\bar{T}} \in \boldsymbol{\Psi}_{h,\bar{\gamma}\bar{r}^\mu,\bar{\gamma}\bar{r}}$ with the symbol supported in the $\varepsilon(\bar{r}, \bar{r}^\mu)$-neighborhood (in (x,ξ)) of the set $\Lambda^{\pm} \cap \{\bar{\epsilon}_0 r \le |x| \le \bar{c}_0 r\}$ with $\bar{r} = \bar{T}^{\sigma'}$, $\bar{h}' = h\bar{r}^{-\mu-1}$, $\bar{\gamma} = \bar{h}'^{\bar{\rho}}$ such that the equality

$$U(\pm\bar{T})Q \equiv \bar{Q}U(\pm\bar{T})Q \tag{12.6.97}$$

holds for the operator $U(t) = \exp(ih^{-1}tA)$ *modulo operators with operator norm less than* Ch^s *with arbitrarily large* s.

Moreover, constants $\bar\epsilon_0$, $\bar c_0$ *do not depend on* $\varepsilon > 0$ *(but the constant* c_3 *does) and one can choose the exponent* $\bar\rho > \rho$ *arbitrarily close to* ρ, *and the statement that the operator belongs to the operator class is uniform with respect to the parameters* $h, r, \bar T$.

Proof. Let us consider the sign "+" for definiteness. Let us pick $Q_0 = Q$ and define moments t_n according to Remark 12.6.16 with T_1 depending on ε. Let $r_n = t_n^\sigma$. Let us introduce γ_n, h'_n with r replaced by r_n and with ρ replaced by $\bar\rho$ as was done above. We want to construct operators $Q_n \in \mathbf{\Psi}_{h,\gamma_n r_n^\mu,\gamma_n r_n}$ with symbols supported in the $\varepsilon(r_n, r_n^\mu)$-neighborhoods of the sets $\Lambda \cap \{\bar\epsilon_0 r_n \le |x| \le \bar c_0 r_n\}$ intersected with Π_{τ_n} (where we define τ_n later) such that for all n with $t_n \le T''$ equalities

$$U(t_{n+1} - t_n)Q_n \equiv Q_{n+1}U(t_{n+1} - t_n)Q_n \tag{12.6.98}$$

are fulfilled, and all statements that operators belong to operator classes and all equivalence relations are uniform in h, r, n; here $t_0 = 0$.

Let us rescale $x_{\mathsf{new}} = x_{\mathsf{old}} r_n^{-1}$, $\xi_{\mathsf{new}} = \xi_{\mathsf{old}} r_n^{-\mu}$, $t_{\mathsf{new}} = t_{\mathsf{old}} r_n^{-\sigma'}$ and set $h_n = h r_n^{-\mu-1}$. Then we get a routine problem of propagation of singularities in bounded time in the domain $\{\epsilon \le |x_{\mathsf{new}}| \le c, |\xi_{\mathsf{new}}| \le c\}$.

This problem was treated in Sections 2.1, 2.2 and therefore Theorem 2.2.10 and the Remark 12.6.16 yield the following procedure to construct Q_n: let Q_n be constructed and let M_n be the support of its symbol. Let us consider all the generalized bicharacteristics passing through M_n at the moment $t = 0$; let M'_{n+1} be the set of all the ends of these trajectories at the moment $t = (t_{n+1} - t_n)$.

Then we can choose Q_n from the class indicated above, with symbol equal to 1 in the $\frac12\varepsilon(r_{n+1}, r_{n+1}^\mu)$-neighborhood of M'_{n+1} intersected with $\Pi_{\tau_{n+\frac12}}$ and supported in the $\varepsilon(r_{n+1}, r_{n+1}^\mu)$-neighborhood of M'_{n+1} intersected with $\Pi_{\tau_{n+1}}$ where $\tau_k = \tau_0(1 + kh^{\delta'})$ with a small enough exponent $\delta' > 0$ for $\mu \le 0$ and $\tau_k = \epsilon' r_k^{m\mu}$ with a small enough constant $\epsilon' > 0$ for $\mu > 0$ [67]. Obviously, $t_k \le T''$ yields $k \le C_0|\log h|$ and therefore $\tau_k \le 2\tau_0$ for $\mu \le 0$.

Then (12.6.98) yields that for n with $t_{n+1} \le T''$

$$U(t_{n+1})Q_0 \equiv Q_{n+1}U(t_{n+1} - t_n)Q_n(t_n - t_{n-1})Q_{n-1} \cdots Q_1 U(t_1)Q_0$$

[67] A neighborhood of $\Pi_{\tau_{n+\frac12}}$ may be cut out by standard elliptic arguments.

and we immediately obtain (12.6.97) for $\bar{T} = t_{n+1}$. However, if $t_n < \bar{T} < t_{n+1}$ then one can always redefine t_n and take $t_{n+1} = \bar{T}$ in our analysis. □

So, in our analysis for $\mu \ge 0$ we can take small enough constants $\tau_0 > 0$ and $T'' > 0$. For $\mu < 0$ the situation is more subtle: we took the smallest $\tau_0 = r^{m\mu}\gamma$ admissible by the uncertainty principle (for coordinates and momenta) and the condition $T'' \le \epsilon_3 r^{\sigma'}\gamma^{(m\mu\sigma)^{-1}}$ means that $\tau_0 \le |x|^{m\mu}$ along the trajectory. In order to avoid this restriction we must use some subtle arguments.

Now we want to extend the time interval:

Proposition 12.6.18. *Let the conditions of Proposition 12.5.17 be fulfilled and let* $\varphi \in \mathscr{C}_0^K(\mathbb{R}^d)$ *be supported in* $\{1 \le |x| \le 2\}$, $\chi \in \mathscr{C}_0^K([\frac14, 1])$ [68]. *Then for the Schwartz kernel* $u(x,y,t)$ *of the operator* $U(t) = \exp(ith^{-1}A)$ *estimate*

$$\bigl|F_{t\to h^{-1}\tau}\operatorname{tr}\Bigl(\chi_T(t)\int \varphi\bigl(\frac{x}{r}\bigr)u(x,x,t)\,dx\Bigr)\bigr| \le Ch^s \qquad \forall \tau : |\tau| \le \frac{1}{2}\tau_0 \quad \forall T \in [3T', T^*] \tag{12.6.99}$$

holds where $\tau^* = \min(\frac12\tau_0, \epsilon')$, $T^* > 0$ *and* $\epsilon' > 0$ *are small enough constants,* $T' = c_1 r^{\sigma'}$, c_1 *is a large enough constant and* $\chi \in \mathscr{C}_0^K([-1,1])$ *is arbitrary. Recall that* $r \in (r^*, \varepsilon_0)$.

Remark 12.6.19. (i) Therefore one can pick $\tau^* = \epsilon'$ for $\mu \le 0$ and $\tau^* = \epsilon' r^{m\mu}$ for $\mu > 0$.

(ii) This proposition and Corollary 12.6.20 (see below) remain true if one replaces $u(x,y,t)$ by $B_{j+1}u_j(x,y,t)$ where u_j is a solution of the recurrence problem $(12.6.68)_0$–$(12.6.68)_j$.

Proof of Proposition 12.6.18. Let us make a partition of unity in a neighborhood of $\operatorname{supp}(\varphi_r)$ where $\varphi_r(x) = \varphi(x/r)$: $\varphi_r = Q^+ + Q^- + Q'$ where $Q^+, Q^-, Q' \in \boldsymbol{\Psi}_{h,\gamma r^\mu,\gamma r}$ with symbols of $Q^\pm$ supported in the $\varepsilon(r, r^\mu)$-neighborhoods of $\Lambda^\pm \cap \{\epsilon_0 r \le |x| \le c_0 r\}$ intersected with Π_{τ_0} and with symbol of Q' supported in $\{\epsilon_0 r \le |x| \le c_0 r\} \setminus \Pi_{\frac23\tau_0}$. Then

$$U(t)\varphi_r = U(t)Q^+ + U(t)Q^- + U(t)Q' \tag{12.6.100}$$

[68] Then this proposition remains true for $\chi \in \mathscr{C}_0^K([-1,-\frac14]\cup[\frac14,1])$.

and standard elliptic arguments yield that for $V(t) = U(t)Q'$ estimate

$$\|F_{t\to h^{-1}\tau}\chi_T(t)V(t)\| \le Ch^s \quad \forall T \in [3T', T^*] \quad \tau : \forall \tau : |\tau| \le \tau^* \tag{12.6.101}$$

holds where the norm in the left-hand expression is the operator norm and we use the definition of Q', τ_0, T' and the inequalities $r \ge h^{(\mu+1)^{-1}-\delta}$ and $\tau_0 T \ge h^{1-\delta'}$ due to $\mu < (m-1)^{-1}$.

We denote equivalence modulo operator-valued functions satisfying (12.6.101) by "$\cong$." So,

$$U(\pm t)\varphi_r \cong U(\pm t)Q^+ + U(\pm t)Q^-. \tag{12.6.102}$$

Then applying $F_{t\to h^{-1}\tau}\chi_T(t)\,\mathsf{Tr}$ we obtain that for $T \in [3T', T'']$, both terms in the right-hand expression of (12.6.102) will result in $O(h^s)$ in the final answer; this follows from Proposition 12.6.17, and for the second term one should pass to the adjoint operator and then permute Q^{-*} and $U(-t)$ because of the presence of "Tr".

Thus, for $\mu \ge 0$ the proposition is proven and for $\mu < 0$ it is proven only under the additional restriction $T < T''$.

Let $\mu < 0$ and $T > T''$; then $T'' < T^*$. Let us take $T_1 = \epsilon T''$ with sufficiently small $\epsilon > 0$ and let us construct the operators $\bar{Q}^+$ and $\bar{Q}^-$ associated with $Q = Q_0^+ = Q^+$ and with $Q = Q_0^- = Q^-$ respectively according to Proposition 12.6.17; $\bar{T} = T_1$. Then (12.6.97) yields that

$$U\big(\pm t\big)Q_0^{\pm} \cong U\big(\pm(t-T_1)\big)\bar{Q}^{\pm}U\big(\pm T_1\big)Q_0^{\pm}. \tag{12.6.103)$_1$}$$

Let us represent $\bar{Q}^{\pm}$ in the form $\bar{Q}^{\pm} = Q_1^{\pm} + Q_1^{\pm\prime}$ where $Q_\bullet \in \boldsymbol{\Psi}_{h,\gamma_1 r^{*\mu},\gamma_1 r^*}$ and the symbols of $Q_1^{\pm}$ and $Q_1^{\pm\prime}$ are supported in the $\varepsilon(r^*, r^{*\mu})$-neighborhoods of $\Lambda^{\pm}\cap\{\bar{\epsilon}_1 r^* \le |x| \le \bar{c}_1 r^*\}$ intersected with Π_{τ_1} and in $\{\bar{\epsilon}_1 r^* \le |x| \le \bar{c}_1 r^*\}\setminus\Pi_{\frac{2}{3}\tau_1}$ respectively where $r_n = T_n^\sigma$, $\hbar_n = hr_n^{-\mu-1}$, $\gamma_n = \hbar_n^{\rho_n}$, $\rho < \rho_1 < \ldots < \rho_n$ now and one can choose ρ_n arbitrarily close to ρ; now the subscript "1" replaces the "bar."

Elliptic arguments again yield that $U(t-T_1)Q^{\pm\prime} \cong 0$ and the presence of the factor $U(T_1)Q^{\pm}$ is not essential because here we do not apply "Tr". Therefore (12.6.96)$_1$ remains true with $\bar{Q}_1^{\pm}$ replaced by $Q_1^{\pm}$ where we replace τ_0 by τ_1 in the definition of "$\cong$." Repeating this process we obtain that

$$\begin{aligned}(12.6.103)_n \quad & U\big(\pm t\big)Q_0^{\pm} \cong \\ & U\big(\pm(t-T_n)\big)Q_n^{\pm}U\big(\pm(T_n-T_{n-1})\big)Q_{n-1}^{\pm}\cdots Q_1^{\pm}U\big(\pm T_1\big)Q_0^{\pm}\end{aligned}$$

where we replace τ_0 by τ_n in the definition of "$\cong$."

Therefore again applying Proposition 12.6.17 we obtain that

$$U(\pm t)Q_0^{\pm} \cong \bar{\varphi}_{r_n} U(\pm t) Q_0^{\pm}$$

provided $T \in [\bar{\epsilon}_n, T_{n+1}]$, $\bar{\varphi} = 1$ in $\{|x| \ge \epsilon_4\}$ with a sufficiently small constant $\epsilon_4 > 0$ and χ is supported in $[\frac{1}{4}, 1]$. Hence, applying the operator $F_{t\to h^{-1}\tau}\chi_T(t)\,\mathsf{Tr}$ we obtain relations

$$F_{t\to h^{-1}\tau}\chi_T(t)\,\mathsf{Tr}\, U(t)Q^{\pm} = O(h^s)$$

where in the "$-$" case one should pass to the adjoint operator and move Q_0^{-*} to the right (and replace Q_0^{-*} by Q_0^{-} in the analysis).

Therefore, it remains to prove that in the case $\mu < 0$ we can pass from $r_* \ge h^{1/(\mu+1)-\delta}$ to $r_n > \varepsilon_0$ with a small enough constant ε_0 in a finite number of steps depending only on the exponents. But this assertion obviously follows from the equality

$$hr_n^{-\mu-1} = \mathsf{const}_n \bigl(hr_{n-1}^{-\mu-1}\bigr)^{1-\rho_{n-1}/(m\mu)}$$

which is due to (12.6.96) for $r_n < \epsilon$; here $1 - \rho_{n-1}(m\mu)^{-1} > 1 - \rho(m\mu)^{-1} > 1$ and $hr_*^{-\mu-1} \le h^{\delta''}$ with $\delta'' > 0$ and therefore for appropriate n the inequality $hr_n^{-\mu-1} \le Ch$ holds. □

12.6.7 Improved Remainder Estimates

Applying Proposition 12.6.18 we obtain Statement (i) of the following assertion:

Corollary 12.6.20. *(i) In the framework of Proposition 12.6.18 estimate*

$$\bigl|F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_{T_2}(t) - \bar{\chi}_{T_1}(t)\bigr)\int \varphi\bigl(\tfrac{x}{r}\bigr)\Gamma u(x,x,)\,dx\bigr| \le Ch^s \qquad \forall \tau : |\tau| \le \tau^* \tag{12.6.104}$$

holds with a sufficiently small constant $T_2 > 0$ and $T_1 = C_0 r^{\theta'}$. Recall that $\bar{\chi} \in \mathscr{C}_0^K([-1,1])$ and $\bar{\chi} = 1$ on $[-\frac{1}{2}, \frac{1}{2}]$.

(ii) Moreover, $T_1 = \varepsilon r^{\sigma'}$ works with an arbitrarily small constant $\varepsilon > 0$.

Proof. To prove Statement (ii) note that in the time interval $|t| \le T_1$ Theorem 2.2.10 is applicable with no modification and escape condition (12.6.87)–(12.6.88) obviously forbids periodic generalized trajectories for the symbol A^0 on the energy level 0. So these trajectories are also forbidden for A under the restrictions $|x| = r$, $T \le Lr^{\sigma'}$, $r \le r_*$ with arbitrarily large L and sufficiently small $r_* = r_*(L) > 0$; moreover, one can consider energy levels τ with $|\tau| \le \tau^*$. □

Now we can get very precise remainder estimates:

Theorem 12.6.21. *Let conditions of Theorem 12.6.8 and escape condition* (12.6.87)–(12.6.88) *be fulfilled.*

(i) Moreover, let condition (12.6.77) *be fulfilled. Then asymptotics*

$$\mathsf{R} := \Big| \int \psi(x) e_{(\vartheta)}(x,x,\tau)\,dx - \sum_{p} \kappa_{(\vartheta)p} h^{-d+p} - \sum_{p,j:\,-d+p=(m\mu\vartheta+\nu j)/(\mu+1)} \kappa'_{(\vartheta)p} h^{-d+p} |\log h| - \sum_{j} \omega_{(\vartheta)j} h^{(m\mu\vartheta+\nu j)/(\mu+1)} \Big| = O\big(R^{\#}(h)\big) \tag{12.6.105}$$

holds with

$$R^{\#}(h) = h^{\min(-d+1+\vartheta,\, l')}; \tag{12.6.106}$$

recall that $l' = (m\mu+\nu)\vartheta(\mu+1)^{-1}$.

Moreover, for $\vartheta \le 1$ *one can skip condition* (12.6.77) *unless* $\vartheta = 1$ *and* $(m\mu+\nu) = (-d+p)(\mu+1)$ *with* $p = 0, 1$.

(ii) Furthermore, let conditions of Statement (i) be fulfilled and

$$\vartheta(m\mu+\nu-\mu-1) + (d-1)(\mu+1) > 0 \tag{12.6.107}$$

(then $l' > -d+1+\vartheta$ *and Statement 12.6.21 yields the remainder estimate* $O(h^{-d+1+\vartheta})$*) and let the standard non-periodicity condition for the operator* A *be fulfilled.*

Then one can replace the remainder estimate $O\big(h^{-d+\vartheta+1}\big)$ *with* $o\big(h^{-d+\vartheta+1}\big)$.

(iii) Replacing condition (12.6.77) *with* (12.6.86) *one should replace* $R^{\#}(h)$ *by* $R^{\#}(h)+R^{*\prime}(h)$ *with* $R^{*\prime}(h)$ *defined by* (12.6.62) *with* ν' *instead of* ν.

Proof. Let us first consider the zone $\{|x|\ge r'_*=r_*h^{-\delta}\}$. Let us change the coordinate system $x'=xr^{-1}$ and set $h'=hr^{-\mu-1}$, $t'=tr^{-\sigma}$. Then

$$F_{t\to h^{-1}\tau}\chi_T(t)\int \varphi\bigl(\frac{x}{r}\bigr)u(x,x,t)\,dx \tag{12.6.108}$$

transforms to

$$r^{\sigma}F_{t'\to h'^{-1}\tau'}\chi_{T'}(t)\int \varphi(x')u'(x',x',t')\,dx'$$

where $T'=Tr^{-\sigma}$, $\tau'=\tau r^{-m\mu}$ (then $|\tau|\le\tau_0 \implies |\tau'|\le\epsilon'$), $u'(.,.,t')$ is the Schwartz kernel of the operator $\exp(ith'^{-1}A')$, $A'=r^{-m\mu}A$ in the new coordinate system and then for $T=T_1=\epsilon_0 r^{\sigma'}$ with small enough constants ϵ_0, ϵ_1 the results of Chapter 4 yield the standard Weyl formula for expression (12.6.108) with $T=T_1$ modulo $O(h^s)$. Therefore this formula also holds for expression (12.6.108) with $T=T_2$.

Recall that in Proposition 12.6.17 $\gamma=h'^{\rho}$ with an exponent $\rho\in(0,\frac12)$ and τ_0 is defined there. Then, for sufficiently small $\rho>0$ we obtain that $\tau^*\ge h^{1-\delta''}$ with $\delta''=(\mu+1-m\mu)(\mu+1)^{-1}>0$ and therefore taking $T=T_2$ and applying standard Tauberian arguments we obtain estimate

$$\Bigl|\int \varphi\bigl(\frac{x}{r}\bigr)\bigl(e_{(\vartheta)}(x,x,0)-\sum_{0\le p\le\bar p}\kappa_{(\vartheta)p}(x)h^{-d+p}\bigr)\,dx\Bigr|\le \tag{12.6.109}$$
$$Ch^{-d+\vartheta+1}r^{m\mu\vartheta+(d-\vartheta-1)(\mu+1)}\bigl(\frac{T_1}{T_2}\bigr)^{\vartheta+1}=Ch^{-d+\vartheta+1}r^{d(\mu+1)-m\mu}.$$

Here the right-hand expression has an additional factor

$$\bigl(\frac{T_1}{T_2}\bigr)^{\vartheta+1}\asymp r^{(\vartheta+1)\theta'}=r^{(\vartheta+1)(\mu+1-m\mu)}$$

if we compare it with the right-hand expression obtained in Subsection 12.6.1, $\bar p=\bar p(d,m,\mu,\vartheta,s,\delta)$ is large enough.

Since $d(\mu+1)-m\mu>0$ we immediately obtain that

(12.6.110) The contribution of the zone $\{r_3\le|x|\le\varepsilon\}$ to the remainder does not exceed $\varepsilon' h^{1-d+\vartheta}$ with $\varepsilon'\to0$ as $\varepsilon\to0$.

Let us apply the arguments of Subsection 12.6.3 with $r'_* = h^{(\mu+1)^{-1}-\delta}$, $L = L(r^*) = h^{(m\mu+\nu)(\mu+1)^{-1}}$ and sufficiently small $\delta > 0$ depending on $d, m, \mu, \vartheta < \bar{\vartheta}_1, \nu$.

(a) Let us first assume that condition (12.6.107) is fulfilled. Then the terms with $m\mu\vartheta+\nu j > (-d+1+\vartheta)(\mu+1)$ are not essential (their total contribution is less than $\varepsilon' h^{-d+1+\vartheta}$).

So, we only need to consider terms with

$$m\mu\vartheta + \nu j \le (-d+1+\vartheta)(\mu+1) \implies j < \vartheta.$$

In order to handle these terms by the same method as before we should estimate

$$\iint \tau_-^{\vartheta-1} \operatorname{tr}\bigl(\mathcal{K}_{(B(\tau-A^0)^{-1})^j} - \mathsf{Weyl}_j\bigr)\, dxd\tau. \tag{12.6.111}$$

We do this exactly as before but due to escape condition (12.6.87)–(12.6.88) an extra factor $T^{-1-\vartheta+j}$ appears in the right-hand expression where one can take $T(x) \asymp h_{\mathsf{eff}}^{-s}$ with arbitrarily large s; recall that $h_{\mathsf{eff}} = hr^{-\mu-1}$. One can easily see that for an appropriate s the corresponding integrals converge and are negligible.

Thus, under condition (12.6.107) Statement (i) has been proven. Then Statement (ii) follows by standard arguments (recall that we have also proven that the contribution of $B(0,\varepsilon)$ to the remainder estimate does not exceed $\varepsilon' h^{1-d+\vartheta}$). The proof of Statement (iii) is obvious.

(b) Let us now assume that condition (12.6.107) is violated. Then applying the same arguments as before we obtain the required estimates for the contributions of $B(0,2r_*)$ and $B(0,1)\setminus B(0,r'_*)$. Further, in $B(0,2r'_*)\setminus B(0,r_*)$ the only source of trouble is the presence of Weyl approximation errors of the form $h^{l'}\bigl(r/r_*\bigr)^{\zeta}$ with exponents $\zeta \ge 0$.

To handle them let us apply the above propagation results. In order to do this let us rescale $x' = \gamma^{-1}x$, then one obtains $r' = \gamma^{-1}$ and $h' = h\gamma^{-1-\mu}$ instead of r and h. To fulfill conditions $1 \ge r' \ge h'^{1/(\mu+1)-\delta'}$ let us pick $\gamma = r\bigl(r/r_*\bigr)^{s}$ with large s. Then for arbitrarily large s and sufficiently small δ and δ' depending on s one can set $T = \bigl(r/r_*\bigr)^{s}$ which means that we should multiply the right-hand expression of the remainder estimate by T^{-1} and obtain $h^{l'}\bigl(r/r_*\bigr)^{\zeta}$ with $\zeta < 0$. Then the contribution of such terms does not exceed $Ch^{l'}$. □

12.6.8 Final Remarks

Let us discuss escape condition (12.6.87)–(12.6.88) and some generalizations of our results.

Remark 12.6.22. (i) Escape condition (12.6.87)–(12.6.88) is fulfilled for $A^0 = \big(|\xi|^2 - V(x)\big)^{\frac{m}{2}}$ with $V(x)$ positively homogeneous of degree 2μ, $\mu > -1$ and $V(x) \asymp |x|^{2\mu}$. Really, one needs to consider only $m = 2$. Then for $\varphi = \langle x, \xi\rangle$, on the energy level 0

$$\{A^0, \varphi\} = 2\big(|\xi|^2 + \mu V(x)\big) = 2(\mu+1)|\xi|^2 \asymp |x|^{2\mu}$$

due to positive homogeneity of $V(x)$ and therefore one can apply Theorem 12.6.21.

(ii) For $\mu = -\frac{1}{2}$, $d = 3$, $m = 2$, $V(x) = |x|^{-\frac{1}{2}}$ and $\vartheta = 1$ the numerical value of the coefficient ω_0 is well known (see V. Ivrii and I. M. Sigal [1], for example).

Remark 12.6.23. (i) One can easily generalize Theorems 12.6.8, 12.6.9 and 12.6.12 to the case when X is a conical domain (in a neighborhood of 0) and Dirichlet boundary condition are given on ∂X.

(ii) In particular, consider domain X with conical points, operator with smooth coefficients in the vicinity of $\bar{X}$, $h = 1$ and asymptotics of $\mathsf{N}^-_{(\vartheta)}(\tau)$ as $\tau \to +\infty$. Then if the domain was smooth the remainder estimate would be $O\big(\tau^{\vartheta + (d-1-\vartheta)/m}\big)$.

Applying the generalization we mentioned (with $\mu = 0$, $\nu = 1$ and with h replaced by $\tau^{-1/m}$) we arrive to the same remainder estimate and with Scott correction terms $\omega_{(\vartheta)j}\tau^{\vartheta - j/m}$ and the main (with $j = 0$) is above remainder estimate as $\vartheta > (d-1)$; as $\vartheta = (d-1)$ singularity manifests itself through cut Weyl term $\kappa'_{(\vartheta)\vartheta}\tau^{\vartheta}|\log\tau|$ and if the remainder estimate is "o" rather than "O" through Scott correction term as well.

Remark 12.6.24. (i) Moreover, one could extend Theorem 12.6.21 under nice propagation of singularities results. Namely, escape condition has the following important corollaries:

(12.6.112) For $t = T_0$ and $(x,\xi) \in \Lambda^{\pm}_{\epsilon_1} \cap \{|x| = 1\}$ we conclude that $K^{\pm}_t(x,\xi) \subset \Lambda^{\pm} \cap \{|x| \ge 2\}$ where $K^{\pm}_t$ mean propagation of singularities

"cones" on the energy level 0 for A^0 (see Sections 2.2 and 3.3). Moreover, this property is stable with respect to small perturbations of A^0

and

(12.6.113) $(x,\xi) \notin K_t^{\pm}(x,\xi)$ for $t > 0$. Moreover, this property is also stable.

Exactly these conditions along with a stability condition apply to boundary-value problems. By the geometric interpretation of Section 3.3 one can replace $K_t(x,\xi)$ by a union of generalized bicharacteristics (in which case stability is achieved automatically).

(ii) Let us consider $\mu = 0$ and $A^0(x,\xi)$ which is $(1,0)$-homogeneous of degree m in (x,ξ), and the energy level $\tau = 1$ instead of $\tau = 0$. We obtain this problem when we treat the asymptotics of Riesz means when the spectral parameter τ tends to $+\infty$.

In order to prove escape condition note that one can take the function $\phi = \langle x,\xi\rangle$ in the analysis of propagation of singularities in Section 3.1. For $x \in \partial X$ this function is constant on the layers $\{(x,\xi + n\lambda), \lambda \in \mathbb{R}\}$ where n is a normal to ∂X at x and we assume that X is a conical set; moreover, the microhyperbolicity conditions are fulfilled with $\ell = H_\phi$. Therefore, for $(x,\xi) \in \Sigma_{1,f}$, $(y,\eta) \in K^{\pm}(x,\xi)$ (see definitions of $\Sigma_{\tau,b}$, $\Sigma_{\tau,f}$ in Chapter 3) the inequality $\pm\langle y,\eta\rangle \ge \pm\langle x,\xi\rangle + \epsilon_0 t$ holds.

Therefore condition (12.6.113) is fulfilled. Moreover, ellipticity yields that ξ is bounded on Σ_1 and $\langle x,\xi\rangle |x|^{-1}$ is bounded on $\Sigma_{1,b}$. Therefore picking $\Lambda^{\pm} = \{\pm\langle x,\xi\rangle \ge -\epsilon_1|x|\}$ with sufficiently small ϵ_1 we obtain $K_t^{\pm}(x,\xi) \subset \{(y,\eta), |y| \ge \epsilon(|x| + t)\}$ for $t \ge 0$ and therefore condition (12.6.112) is also fulfilled.

Note that condition (12.6.107) is now "$(\nu - 1)\vartheta > 1 - d$". Moreover, the non-Weyl terms are $\omega_{(\vartheta)j}\tau^{\vartheta - \frac{1}{m}\nu j}$ while the Weyl terms are $\kappa_{(\vartheta)p}\tau^{\vartheta + \frac{1}{m}(d-p)}$ and a logarithmic factor appears as soon as these exponents coincide or one of them vanishes. For $\nu = 1$ condition (12.6.107) is fulfilled for all ϑ and there are many terms with logarithms.

(iii) All the arguments in Statements (i) and (ii) apply to other boundary conditions provided that for fixed h the problem is elliptic in the classical sense and the operator is semibounded from below.

Remark 12.6.25. Let us assume that $X = \mathbb{R}^d$ (or X is a cone). Further, let stabilization condition (12.6.30) be fulfilled as $|x| \to \infty$ as well but with the operator A^∞ and exponents $\mu' \in (-1, 0), \nu' < 0$ instead of A^0 and μ, ν. Furthermore, let us assume that escape condition is fulfilled for this operator A^∞ as well with the sets $\Lambda^\pm_\infty$ instead of $\Lambda^\pm$.

Let us define the sets $\Lambda^\pm_1$ according to (12.6.94); we define these sets for $|x| \le \epsilon$ and $|x| \ge R$ with $\epsilon > 0$ very small and R very large. Finally, let us assume that there exists t_0 such that if $(x(0), \xi(0))$ lies in the (small) set $\Lambda^\pm_1 \cap \{|x| \le \epsilon\}$ then $(x(\pm t_0), \xi(\pm t_0)) \in \Lambda^\pm_1 \cap \{|x| \ge R\}$.

Under these assumptions we control the propagation of singularities for very large T ($\asymp h^{-s}_{\mathsf{eff}}$ with an arbitrarily large s) and therefore

(12.6.114) In the framework of Theorem 12.6.21 and the assumptions of this remark the remainder estimate is $O\bigl(h^{l'}\bigr)$ with $l' = (m\mu + \nu)\vartheta(\mu+1)^{-1}$ even if $l' > -d + 1 + \vartheta$. Moreover, for $(\mu+1)d + m\mu\vartheta < 0$ one can take $\psi = 1$.

As an example one can consider $X = \mathbb{R}^d$ and the Schrödinger operator with potential $W(|x|)$ where $W(r)$ is positively homogeneous of degrees 2μ and $2\mu'$ for $|x| \le \epsilon$ and $|x| \ge R$ respectively, $-1 < \mu' \le \mu < 0$, and $W(r) < 0$, $\frac{d}{dr} r^2 W(r) < 0$ $\forall r$. Moreover, one can perturb this Schrödinger operator slightly and get rid of its spherical symmetry and homogeneity.

The following problem seems to be very interesting and challenging:

Problem 12.6.26. (i) Construct the similar theory as singularity is on manifolds Z of dimension d' rather than 0.

One may suspect that Scott correction terms should be in the form

$$\omega_{(\vartheta)d',j,k} h^{-d'+k+(m\mu\vartheta+\nu j)(\mu+1)^{-1}} \qquad j, k \in \mathbb{Z}^+. \tag{12.6.115}$$

(ii) In particular, consider the case of the regular operator in domain with $(d-2)$-dimensional edges (i.e. when ∂X consists of smooth manifolds which intersect only pairwise along submanifolds of dimension $(d-2)$).

(iii) Allow edges of any codimension. Then as $h = 1$ and we consider $\mathsf{N}^-_{(\vartheta)}(\tau)$ as $\tau \to +\infty$, in accordance to (12.6.115) we should expect Scott terms associated with edges of dimension d' to be $\omega'_{(\vartheta),d',k} \tau^{\vartheta+(d'-k)/m}$ and the final answer should contain their sum with respect to d', k.

In Part (i) propagation along Z seems to be a difficult obstacle and in Part (iii) additional difficulties appear from "collision" of different manifolds Z_k.

12.7 Sharp Spectral Asymptotics for Neumann Laplacian in Thin Cusps

12.7.1 Problem Set-up

In this section we consider the Neumann Laplacian and similar operators in domains with ultrathin cusps (with $\exp(-|x|^{\mu+1})$-like width ($\mu > 0$)) and recover eigenvalue asymptotics with accurate remainder estimate.

It is known that in some classes of domains the spectral theories of the Neumann and Dirichlet Laplacians could be very different. In particular, in domains with cusps the spectrum of Dirichlet Laplacian is always discrete and, moreover, Weyl formula holds as cusp is not very thick while for Neumann Laplacian the spectrum is essential unless cusp is very thin and the Weyl formula holds even for thinner cusps.

As in Section 12.2 we considered this operator in the domain $X \subset \mathbb{R}^d$ such of (12.2.7)-type i.e.

$$X = X_0 \cup X_{\mathsf{cusp}},\ \partial X \in \mathscr{C}^K,\ X_0 \Subset \mathbb{R}^d, \tag{12.7.1}$$
$$X_{\mathsf{cusp}} = \bigl\{x = (x', x'') : x' \in Z,\ x'' \in \sigma(x')Y\bigr\}, \quad Y \Subset \mathbb{R}^{d''},\ \partial Y \in \mathscr{C}^K$$

We consider here only second-order $\mathsf{D} \times \mathsf{D}$-matrix operators

$$A \coloneqq \sum_{j,k} D_j a_{jk} D_k + \sum_j (a_j D_j + D_j a_j^\dagger) + a_0 \tag{12.7.2}$$

which are defined by a quadratic form

$$Q(u) = \int \Bigl(\sum_{j,k} \langle a_{jk} D_k u, D_j u\rangle + 2\,\mathsf{Re}\langle a_k D_k u, u\rangle + \langle a_0 u, u\rangle\Bigr)\,dx \tag{12.7.3}$$

where we assume that this operator is self-adjoint

$$a_{kj} = a_{jk}^\dagger, \qquad a_0 = a_0^\dagger, \qquad a_b = a_b^\dagger \tag{12.7.4}$$

in $\mathscr{L}^2(X, \mathbb{C}^{\mathsf{D}})$ and (uniformly) elliptic

$$C_0|\xi|^2 \ge a(x,\xi) := \sum a_{jk}\xi_j\xi_k \ge \epsilon_0|\xi|^2 \qquad \forall x,\xi. \tag{12.7.5}$$

We supply quadratic form with no boundary conditions which leads to the *Neumann boundary conditions*

$$Bu := \Big(\sum_j n_j\big(\sum_k a_{jk}D_k + a_j^\dagger\big) + ia_b\Big)u\big|_{\partial X} = 0 \tag{12.7.6}$$

with $a_b = 0$ where (n_j) is an interior unit normal to ∂X.

More generally we consider quadratic form

$$Q(u) = \int_X \Big(\sum_{j,k}\langle a_{jk}D_k u, D_j u\rangle + 2\,\mathsf{Re}\langle a_k D_k u, u\rangle + \langle a_0 u, u\rangle\Big)\,dx + \int_{\partial X}\langle a_b u, u\rangle\,dS \tag{12.7.7}$$

where dS is a Lebesgue measure on ∂X. Then a_b in (12.7.6) does not necessary vanish.

Let us recall analysis of Section 12.3.1. Let us introduce new variables $x''_{\mathsf{new}} = x''_{\mathsf{old}}\sigma(x')^{-1}$ transforming a cusp X_{cusp} into a cylinder $Z \times Y$ as on Figure 12.1; then $dx_{\mathsf{old}} = \sigma(x')^d dx''_{\mathsf{new}}$ and to preserve $\mathscr{L}^2(X, \mathbb{C}^{\mathsf{D}})$ we also plug $u_{\mathsf{old}} = \sigma(x')^{-\frac{d''}{2}}u_{\mathsf{new}}$ resulting in the quadratic form

$$Q_{\mathsf{new}}(u) := \int_{Z\times Y}\Big(\sum_{j,k}\langle a_{jk}P_k u, P_j u\rangle + 2\,\mathsf{Re}\sum_k\langle a_k P_k u, u\rangle + \langle a_0 u, u\rangle\Big)\,dx'dx'' + \int_{Z\times\partial Y}\sigma^{-1}(x')\langle a_b u, u\rangle\,dx'dS'' \tag{12.7.8}$$

where

$$P_j = \begin{cases} D_j - b_j(x')L & \text{as } j = 1,\dots,d',\\ \sigma^{-1}(x')D_j & \text{as } j = d'+1,\dots,d\end{cases} \tag{12.7.9}$$

with

$$b_j(x') = \partial_{x_j}\log\sigma(x') \tag{12.7.10}$$

and

$$L = \langle x'', D''\rangle - \frac{1}{2}d''i = \frac{1}{2}\big(\langle x'', D''\rangle + \langle D'', Dx''\rangle\big). \tag{12.7.11}$$

This is another version of (12.2.23). Sure, we changed coordinates in all coefficients.

Our first question is *if all the spectrum of operator discrete?* The problem now is that condition (12.3.14) fails for D lowest eigenvalues of $\boldsymbol{a}$ corresponding to constant $w(x'')$. Therefore, at least heuristically, to answer this question we need to restrict our quadratic form to the space of such functions (which coincides with $\mathcal{L}^2(Z, \mathbb{C}^{\mathsf{D}})$)

$$Q'(v) \coloneqq \int_Z \Big(\sum_{j,k}\langle a'_{jk}P'_k v, P'_j v\rangle + 2\,\mathrm{Re}\sum_k \langle a'_k P'_k v, v\rangle + \langle a'_0 v, v\rangle\Big)\,dx' \tag{12.7.12}$$

where summation is taken over $j, k = 1, \dots, d'$,

$$a'_{jk}(x') = \int_Y a_{jk}\,dx'', \qquad a'_k(x') = \int_Y a_k\,dx'', \tag{12.7.13$_{1-3}$}$$

$$a'_0(x') = \int_Y a_0\,dx'' + \int_{\partial Y} a_b(x)\,dS'',$$

$$P'_j = D_j + \frac{i}{2}d''b_j, \qquad P'^{*}_j = D_j - \frac{i}{2}d''b_j \tag{12.7.14}$$

and corresponding operator is

$$A' = \sum_{j,k} P'^{*}_j a'_{jk} P'_k + \sum_k \big(P'^{*}_k a'^{\dagger}_k + a'_k P'_k\big) + a'_0 = \tag{12.7.15}$$

$$\sum_{j,k} D_j a'_{jk} D_k + \sum_k \big(D_k a''^{\dagger}_k + a''_k D_k\big) + a''_0$$

with

$$a''_0 = a'_0 + \frac{1}{4}d''^2\sum_{jk} a_{jk}b_j b_k + \frac{i}{2}d''\sum_k b_k\big(a'_j - a'^{\dagger}_j\big), \tag{12.7.16}$$

$$a''_k = a'_k - \frac{i}{2}d''\sum_j b_j a_{jk}. \tag{12.7.17}$$

Assuming that the lower order coefficients a_j, a_0 and a_b are not important (we will ensure this imposing conditions) we conclude that in order to ensure that the spectrum of A' and thus of A is discrete we should assume that a_0'' grows at infinity i.e.

$$|\nabla \log \sigma| \to \infty \qquad \text{as} \quad |x'| \to \infty. \tag{12.7.18}$$

This is definitely not the case for cusps described in Section 12.7.1.

The spectral asymptotics for operator A' may play an important role in this section. To fall into conditions of Section 11.5 let us assume that

$$-\log \sigma \asymp |x'|^{\mu+1}, \tag{12.7.19}$$

$$|\nabla \log \sigma| \asymp |x'|^{\mu} \tag{12.7.20}$$

and

$$|\nabla^\alpha \log \sigma| \le c|x|^{\mu+1-|\alpha|} \qquad \forall \alpha : |\alpha| \le K \tag{12.7.21}$$

with $\mu > 0$. Further, let us assume that

$$|\nabla^\alpha a_{jk}''| \le c|x'|^{-|\alpha'|}, \qquad |\nabla^\alpha a_j''| \le c|x'|^{-|\alpha'|-1}, \qquad |\nabla^\alpha a_0''| \le c|x'|^{-|\alpha'|-2} \tag{12.7.22}_{1-3}$$

and

$$a_0(x', \xi') \ge \epsilon(|\xi'|^2 + |x'|^{2\mu}) \qquad \text{as} \quad |x'| \ge c \tag{12.7.23}$$

with

$$a_0(x', \xi') = \sum_{j,k} a_{jk}'' \xi_j' \xi_k' + \sum_j (a_j'' + a''^{\dagger}) \xi_j' + a_0''. \tag{12.7.24}$$

Let us also assume that

$$|\nabla^\alpha a_{jk}| \le c\gamma^{-|\alpha'|}\sigma^{-|\alpha''|}, \qquad |\nabla^\alpha a_j| \le c\gamma^{-|\alpha'|-1}\sigma^{-|\alpha''|}, \tag{12.7.25}_{1-2}$$

$$|\nabla^\alpha a_0| \le c\gamma^{-|\alpha'|-2}\sigma^{-|\alpha''|} \qquad |\nabla^\alpha a_b| \le c\gamma^{-|\alpha'|-1}\sigma^{-|\alpha''|} \tag{12.7.25}_{3-4}$$

with $\gamma(x') = |x'|^{-\mu}$; these and all the other inequalities are supposed to hold as $|\alpha| \le K = K(d, m)$, $|x'| \ge c$.

12.7.2 Weyl Part of Asymptotics

Let us consider the "core domain" and the "near cusp". Let us introduce the scaling function $\epsilon\sigma(x')$. Let $\psi(x)$ be a ($\sigma(x')$-admissible) function supported in

$$\mathcal{X}(\tau) = \{x : \ \sigma(x) \ge \epsilon\tau^{-\frac{1}{2}}\} \tag{12.7.26}$$

and equal 1 in $\mathcal{X}(\tau/2)$. Then the theory of Section 11.2 and and 11.3 implies that

$$|\int \psi(x)\big(e(x,x,\lambda) - \mathsf{Weyl}(x)\big)\,dx| \le C\tau^{\frac{d-1}{2}} \int_{\mathcal{X}(\tau)} \sigma^{-1}\,dx \tag{12.7.27}$$

where $\mathsf{Weyl}(x)$ is the standard Weyl expression for $A(x,D)$ and we should assume that a_j, a_0 and a_b do not grow very fast as $|x'| \to \infty$.

In particular, if

$$\int_X \sigma(x')^{-1}\,dx \asymp \int_Y \sigma(x')^{d''-1}\,dx' \tag{12.7.28}$$

converges which is the case as $d'' \ge 2$ due to superfast decay of $\sigma(x')$, the right-hand expression of (12.7.27) is $O\big(\tau^{\frac{1}{2}(d-1)}\big)$.

Furthermore, the same arguments imply that then one can replace $\int \psi(x)\mathsf{Weyl}(x)\,dx$ by $\int \mathsf{Weyl}(x)\,dx$ and by $\varkappa_0\tau^{\frac{d}{2}}$ in the very end.

Moreover, in this case under standard non-periodicity assumption to Hamiltonian billiard trajectories generated by $a(x,\xi)$ the remainder estimate is $o\big(\tau^{\frac{1}{2}(d-1)}\big)$ but one should include in the left-hand expression lower order and boundary terms so the final expression is $\varkappa_0\tau^{\frac{1}{2}d} + \varkappa_1\tau^{\frac{1}{2}(d-1)}$.

On the other hand, as $d'' = 1$ no matter how fast $\sigma(x')$ decays, integral (12.7.28) does not converge and the right-hand expression of (12.7.27) is of magnitude $\tau^{\frac{1}{2}(d-1)}r_*^{d'}(\tau)$ where

$$r_*(\tau) \asymp (\log\tau)^{1/(\mu+1)} \tag{12.7.29}$$

is defined from $|x'| \le r_*(\tau) \implies \sigma(x') \le \tau^{-\frac{1}{2}}$.

In Subsection 12.7.4 we will improve it by the long-range propagation arguments. So far we proved

Proposition 12.7.1. *Let operator A satisfy assumptions of Theorem 11.2.7 with $m = 2$ and σ satisfy* (12.7.19), (12.7.21).

Then[69)]

(i) Asymptotics

$$\int \psi_\tau(x')e(x,x,\tau)\,dx = \varkappa_0\tau^{\frac{1}{2}d} + O\big(R(\tau)\big) \tag{12.7.30}$$

holds where

$$R(\tau) = \begin{cases} \tau^{\frac{1}{2}(d-1)} & \text{as } \ d''\ge 2,\\ \tau^{\frac{1}{2}(d-1)}\,|\log\tau|^{(d-1)/(\mu+1)} & \text{as } \ d''=1, \end{cases} \tag{12.7.31}$$

coefficients $\varkappa_0$ and $\varkappa_1$ are standard Weyl coefficients.

(ii) Let $d''\ge 2$ and the standard non-periodicity condition be fulfilled to Hamiltonian billiard trajectories generated by $a(x,\xi)$. Then

$$\int \psi_\tau(x')e(x,x,\tau)\,dx = \varkappa_0\tau^{\frac{1}{2}d} + \varkappa_1\tau^{\frac{1}{2}(d-1)} + o\big(\tau^{\frac{1}{2}(d-1)}\big). \tag{12.7.32}$$

12.7.3 Cusp pPart of Asymptotics

Now we need to calculate the contribution of the remaining part of the cusp

$$\mathcal{X}'(\tau) := \big\{x, \sigma(x') \le 2\epsilon\tau^{-\frac{1}{2}}\big\}. \tag{12.7.33}$$

We would like to transform our cusp to a cylinder and apply the theory of operators with the operator-valued symbols. According to Subsection 12.7.1 after change of coordinates $x'_{\text{new}} = x'_{\text{old}}$, $x''_{\text{new}} = \sigma(x')^{-1}x''_{\text{old}}$ we arrive to operator A_{new} corresponding to quadratic form Q_{new} defined by (12.7.8)

$$A_{\text{new}}(x,D) = \sum_{j,k} P_j^* a_{jk} P_k + \sum_k \big(a_k P_k + P_k^* a_k^\dagger\big) + a_0 \tag{12.7.34}$$

with P_j defined by (12.7.9). Then "no boundary condition" to quadratic form translates to boundary condition

$$B_{\text{new}}u := \Big(\sum_j \nu_j\big(\sum_k a_{jk}P_k + a_j^\dagger\big) + i\sigma^{-1}a_b\Big)u\big|_{\partial X} = 0 \tag{12.7.35}$$

with

[69)] No matter if we consider Dirichlet or Neumann boundary conditions.

(12.7.36) $\nu_j = n_j$ for $j = d'+1, \dots, d$, $\nu_j = -(\partial_{x_j}\sigma_j)\langle x'', n''\rangle$ for $j = 1, \dots, d'$ as $n'' = (n_{d'+1}, \dots, n_d)$ is a unit normal to ∂Y.

However in contrast to the Dirichlet boundary problem now the boundary operator contains differentiation with respect to x' and we cannot apply directly theory of Chapter 4. Instead we decompose $\mathbb{H} = \mathscr{L}^2(Y, \mathbb{C}^{\mathsf{D}})$ into $\mathbb{H}_0 \oplus \mathbb{H}_1$ where $\mathbb{H}_0$ consists of constants and $\mathbb{H}_1 = \mathbb{H}_0^{\perp}$. Then

$$(12.7.37)\quad \boldsymbol{a}(x', \xi') = \begin{pmatrix} \boldsymbol{a}_{00}(x', \xi') & \boldsymbol{a}_{01}(x', \xi') \\ \boldsymbol{a}_{10}(x', \xi') & \boldsymbol{a}_{11}(x', \xi') \end{pmatrix}, \qquad \boldsymbol{b}(x', \xi') = \begin{pmatrix} \boldsymbol{b}_0(x', \xi') \\ \boldsymbol{a}_1(x', \xi') \end{pmatrix}$$

and the problem $(hD_t - A)U = 0$, $BU = 0$ (we skip subscript "new") becomes a system

$$(12.7.38)_1 \qquad \big(hD_t - \boldsymbol{a}_{00}\big) U_{0j} - \boldsymbol{a}_{01} U_{1j} = 0,$$

$$(12.7.38)_2 \qquad -\boldsymbol{a}_{10} U_{0j} + \big(hD_t - \boldsymbol{a}_{11}\big) U_{1j} = 0,$$

$$(12.7.39) \qquad \big(\boldsymbol{b}_0 u_0 + \boldsymbol{b}_1 u_1\big)\big|_{\partial Y} = 0.$$

We will use $(12.7.38)_2$–(12.7.39) to express U_{1j} through U_{0j} and to plug it into $(12.7.38)_1$.

One can see easily that the first step is possible in the zone in question provided

$$(12.7.40)\quad \langle \boldsymbol{a}(x', \xi'; x'', D'')v, v\rangle \ge \epsilon_0\big(|\xi'|^2 + \sigma(x')^{-2}\big)\|v\|^2 + \|D''v\|^2 \qquad \forall v \in \mathbb{H}_1$$

which is ensured by

$$(12.7.41)_{2-4}\quad |a_j(x)| \le c\rho(x'), \qquad |a_0(x)| \le c\rho(x')^2, \qquad |a_b(x)| \le c\sigma(x')\rho(x')^2$$

with $\rho(x') = |x'|^{\mu}$ and we get that $\boldsymbol{a}_{01}U_{1j} = \boldsymbol{r}(x', hD_t, hD')U_{0j}$ with h-pseudodifferential operator $\boldsymbol{r}(x', hD_t, hD')$ with $h = \tau^{-\frac{1}{2}}$.

Further, one can see easily that $\boldsymbol{r}(x', hD_t, hD')$ decays as $\tau \to +\infty$ provided

$$(12.7.41)_1 \qquad |(a_{jk}(x) - \bar{a}_{jk}(x')| \le c\sigma(x'),$$

Then one arrives to the following proposition:

Proposition 12.7.2. *Assume that* (12.7.41)$_{1-4}$, (12.7.19), (12.7.21) *and*

$$c^{-1}\bigl(|\xi'|^2+\rho(x')^2\bigr)\le \boldsymbol{a}_0(x',\xi')\le c\bigl(|\xi'|^2+\rho(x')^2\bigr) \tag{12.7.42}$$

are fulfilled where $\boldsymbol{a}_0=A'$ *is defined by* (12.7.15).

Then contribution of zone (12.7.33) *to the asymptotics is given by the Weyl approximation for* d'*-dimensional operator* $\boldsymbol{a}_0^{\mathsf{w}}(x',D')$

$$\mathsf{N}_{\mathsf{cusp}}(\lambda)=(2\pi)^{-d'}\int \boldsymbol{n}(x',\xi')\,dx'd\xi', \tag{12.7.43}$$

$\boldsymbol{n}(x',\xi')$ *is an eigenvalue counting function for symbol* $\boldsymbol{a}_0(x',\xi)$ *and the contribution of this zone to the remainder estimate is* $O\bigl(R'(\tau)+\tau^{d'/2}\bigr)$ *where* $R'(\tau)$ *is the corresponding remainder estimate*

(i) $R'(\tau)=O\bigl(\tau^{d'(\mu+1)/2\mu}\bigr)$ *in the general case.*

(ii) $R'(\tau)=O\bigl(\tau^{(d'-1)(\mu+1)/2\mu}\bigr)$ *provided* <u>*either*</u> $\boldsymbol{a}_0$ *is* (x',ξ')*-microhyperbolic on the energy level* τ <u>*or*</u> $\mathsf{D}=1$ *and* $d'\ge 2$.

(iii) $R'(\tau)=O\bigl(\tau^{\delta}\bigr)$ *provided* $\mathsf{D}=1$ *and* $d'=1$.

Proof. One needs to prove only that extra term $\boldsymbol{r}$ does not contribute much to the principal part of the asymptotics. One can see easily that its norm does not exceed $C\tau\sigma$ and then one can see easily that its contribution to the principal part is $O(\tau^{d'/2})$. □

Further, we arrive to

Proposition 12.7.3. *Let assumptions of Proposition 12.7.2(ii) be fulfilled. Furthermore, assume that* $d'\ge 2$ *and* $\boldsymbol{a}_0(x',\mathsf{x}')$ *stabilizes to quasihomogeneous symbol* $\boldsymbol{a}_{0,\infty}(x',\xi')$ *and the standard non-periodicity condition is fulfilled for the Hamiltonian flow generated by* $\boldsymbol{a}_{0,\infty}(x',\xi)$.

Then the contribution of zone (12.7.33) *to the asymptotics is given by improved two-term Weyl approximation* $\mathsf{N}^*_{\mathsf{cusp}}(\tau)$ *for* $\boldsymbol{a}_0$ *and the contribution of this zone to the remainder estimate is* $o\bigl(R'(\tau)\bigr)+O\bigl(\tau^{d'/2}\bigr)$.

12.7.4 Main Results. I

Combining Propositions 12.7.1–12.7.3 we arrive to the following theorem:

Theorem 12.7.4. *Let conditions* (12.7.1)–(12.7.5) *be fulfilled and let* σ *satisfy* (12.7.19), (12.7.21).

Further, let conditions $(12.7.41)_{1-4}$ *and* (12.7.42) *be fulfilled where* $\mathsf{a}_0 = A'$ *is defined by* (12.7.15).

Then

(i) For $d'' \ge 2$ *asymptotics*

$$\mathsf{N}(\tau) = \varkappa_0 \tau^{\frac{d}{2}} + \mathsf{N}_{\mathsf{cusp}}(\tau) + O\bigl(\tau^{\frac{d-1}{2}}\bigr) + O\bigl(R'(\tau)\bigr) \tag{12.7.44}$$

holds where $\varkappa_0$ *and* $\varkappa_1$ *(see below) are standard Weyl coefficients for operator* A *and* $\mathsf{N}_{\mathsf{cusp}}(\tau)$ *is the Weyl approximation for* d'*-dimensional operator* $\mathsf{a}_0^{\mathsf{w}}(x', D')$ *given by* (12.7.43) *and* $R'(\tau)$ *is defined in Proposition 12.7.2.*

(ii) For $d'' = 1$ *the following estimate holds*

$$\mathsf{N}(\tau) = \varkappa_0 \tau^{\frac{d}{2}} + \mathsf{N}_{\mathsf{cusp}}(\tau) + O\bigl(\tau^{\frac{d-1}{2}} (\log \tau)^{\frac{d-1}{\mu+1}}\bigr) + O\bigl(R'(\tau)\bigr). \tag{12.7.45}$$

(iii) Moreover, if $d'' \ge 2$ *and the Hamiltonian billiard flow generated by* $\mathsf{a}(x,\xi)$ *on* T^*X *satisfies the standard non-periodicity condition then one can replace* $O(\tau^{(d-1)/2})$ *by* $\bigl(\varkappa_1 + o(1)\bigr)\tau^{\frac{1}{2}(d-1)}$.

(iv) On the other hand, if $d' \ge 2$ *if* $\mathsf{a}_0(x', \xi')$ *stabilizes to quasihomogeneous symbol* $\mathsf{a}_{0,\infty}(x', \xi')$ *and the Hamiltonian flow generated by* $\mathsf{a}_{0,\infty}(x', \xi')$ *on* T^*Z *satisfies the standard non-periodicity condition then one can replace* $\mathsf{N}_{\mathsf{cusp}}(\tau)$ *by improved two-term Weyl approximation* $\mathsf{N}^*_{\mathsf{cusp}}(\tau)$ *and* $O(\tau^{(d-1)(\mu+1)/2\mu})$ *by* $o(\tau^{(d-1)(\mu+1)/2\mu})$.

(v) Skipping conditions ensuring that the Weyl zone contribution to the remainder estimate is $O(\tau^{(d-1)/2})$ *we should replace* $\mathsf{N}^{\mathsf{W}}(\tau)$ *by* $O(\tau^{d/2})$.

12.7.5 Improved Estimate as $d'' = 1$

In this case $d'' = 1$ the semiclassical part of the cusp (also called *near cusp*, cf. (12.7.26) where we use the same notation)

$$\mathcal{X}(\tau) = \{x : |x'| \ge R, \sigma(x') \ge \epsilon \tau^{-\frac{1}{2}}\} \tag{12.7.46}$$

contributes a bit more (by the logarithmic factor) then usual to the remainder estimate as it contributes $\mathsf{N}^{\mathsf{W}}(\tau)$ to the main part. This is important only as $(d-1)/2 \ge (d-2)(\mu+1)/(2\mu)$ i.e.

$$\mu \ge d-2. \tag{12.7.47}$$

So we need to consider

$$\int \mathsf{tr}(e(x,x,\tau))\psi_1(x')\,dx \tag{12.7.48}$$

where $\psi_1(x')$ is supported in $\{x' : |x'| \ge R, \sigma(x') \ge \epsilon\tau^{-\frac{1}{2}}\}$ and equals 1 in $\{x' : |x'| \ge 2R, \sigma(x') \ge 2\epsilon\tau^{-\frac{1}{2}}\}$ with constant R.

To improve this remainder estimate we need (x',ξ')-microhyperbolicity for operator $\boldsymbol{a}(x',\xi') = A(x',\xi';x'',D_{x''})$ under boundary condition $\boldsymbol{b}(x',\xi)v=0$ with $\boldsymbol{b} = B(x',\xi';x'',D_{x''})$. This condition is obviously defined provided "mixed" coefficients a_{jk} (i.e. with $j=1,\dots,d'$, $k=d'+1,\dots,d$) decay as $|x'|\to\infty$ because according to $(12.7.41)_{2-4}$ lower order terms are not large enough to influence it. In the general case we do not have the notion of (x',ξ')-microhyperbolicity in Chapter 2 but we essentially have it in Chapter 3 (see Definition 3.1.4.

Let us assume that condition (12.7.20) is fulfilled.

Then the error does not exceed

$$C\tau^{(d-1)/2}\int_{\mathcal{X}(\tau)} \gamma(x')^{-1}\,dx \asymp C\tau^{(d-1)/2}\int_{\mathcal{X}(\tau)} \gamma(x')^{-1}\sigma(x')\,dx' \tag{12.7.49}$$

where $\gamma(x') \asymp |x'|^{-\mu}$ is the scale with respect to x'. This integral does not exceed $\varepsilon(R)$ (with $\varepsilon(R)=o(1)$ as $r\to\infty$) if taken over $\{|x'|\ge R\}$.

Further, if we consider

$$\tau^{(d-j)/2}\int_{\mathcal{X}(\tau)} \sigma(x')^{-j}\,dx \asymp \tau^{(d-j)/2}\int_{\mathcal{X}(\tau)} \sigma(x')^{1-j}\,dx' \tag{12.7.50}$$

we conclude that it is $o(\tau^{(d-1)/2})$ as $\mu > d-2$ and is $O(\tau^{(d-1)/2})$ as $\mu = d-2$. Therefore we need to consider only terms with $j=0,1$ unless $\mu = d-2$ and we are interested in the remainder estimate $o(\tau^{(d-1)/2})$ in which case we need to consider also $j\ge 2$.

Furthermore,

$$\int_{\mathcal{X}'(\tau)} \tau^{d/2}\,dx \asymp \int_{\mathcal{X}'(\tau)} \tau^{d/2}\sigma(x')^1\,dx' \tag{12.7.51}$$

is $o(\tau^{(d-1)/2})$ as $\mu > d-2$ and $O(\tau^{(d-2)/2})$ as $\mu = d-2$; here and below $\mathcal{X}'(\tau) = \{x : \sigma(x') \le \epsilon\tau^{-\frac{1}{2}}$ is a *far cusp*.

To provide (x', ξ')-microhyperbolicity we need the following proposition:

Proposition 12.7.5. *Let conditions of Theorem 12.7.4 be fulfilled. Further, let condition* (12.7.20) *be fulfilled and*

$$|\nabla^{\alpha}\big(a_{jk}(x) - a_{jk,\infty}(x')\big)| \le c|x'|^{-\varsigma-|\alpha'|}\sigma(x')^{-|\alpha''|} \tag{12.7.52}$$

with $\varsigma > 0$, $ajk, \infty(x')$ *positively homogeneous of degree* 0. *Then operator* $A(x', \xi'; x'', D_{x''})$ *with* $B(x', \xi'; x'', D_{x''})v = 0$ *is uniformly* (x', ξ')*-microhyperbolic.*

Proof. Proof is trivial as one needs to consider operator with variables (ξ', σ) where σ is now independent variable and to prove that it is (ξ', σ)-microhyperbolic. □

Now we arrive to Statements (i) and (ii) of the following theorem:

Theorem 12.7.6. *Let* $d'' = 1$ *and conditions* (12.7.47), (12.7.1)–(12.7.5) *be fulfilled and let* σ *satisfy* (12.7.19)–(12.7.21)*; let* (12.7.52) *be fulfilled.*

Further, let conditions $(12.7.41)_{1-4}$ *and* (12.7.42) *be fulfilled where* $a_0 = A'$ *is defined by* (12.7.15).

Then

(i) Asymptotics

$$\mathsf{N}(\tau) = \varkappa_0\tau^{\frac{d}{2}} + \nu(\tau) + \mathsf{N}^{\mathsf{W}}_{\mathsf{cusp}}(\tau) + O\big(\tau^{\frac{d-1}{2}}\big) \tag{12.7.53}$$

holds with

$$\nu(\tau) = \tau^{(d-1)/2}\int \big(1 - \psi'_{\tau}(x)\big)\kappa_1(x)\,dx \tag{12.7.54}$$

with $\mathsf{supp}(\psi'_{\tau}) \subset \mathcal{X}'(\tau)$.

(ii) Moreover, if $\mu > d-2$ *and the standard non-periodicity condition is fulfilled for Hamiltonian billiard flow generated by symbol* $a(x, \xi)$ *one can replace* $O\big(\tau^{\frac{d-1}{2}}\big)$ *by* $o(\tau^{\frac{d-1}{2}})$.

(iii) Let $\mu = d-2$ and the standard non-periodicity condition be fulfilled. Further, let $d \ge 3$, $a_0(x',\xi')$ stabilize to quasihomogeneous symbol $a_{0,\infty}(x',\xi')$ and the Hamiltonian flow generated by $a_{0,\infty}(x',\xi')$ on T^*Z satisfy the standard non-periodicity condition.

Then asymptotics

$$\mathsf{N}(\tau) = \varkappa_0 \tau^{\frac{d}{2}} + \nu_1(\tau) + \mathsf{N}^{\mathsf{W}}_{\mathsf{cusp}}(\tau) + \varkappa_1 \tau^{\frac{d-1}{2}} + o\bigl(\tau^{\frac{d-1}{2}}\bigr) \tag{12.7.55}$$

holds with

$$\nu_1(\tau) = \nu(\tau) - \tau^{\frac{d}{2}} \int \kappa_0(x)\psi'_\tau(x)\,dx. \tag{12.7.56}$$

(iv) Under stabilization condition alone one can replace $\nu(\tau)$ and $\nu_1(\tau)$ by

$$\varkappa'_1 \tau^{\frac{d-1}{2}} |\log \tau|^{(d-\mu-2)/(\mu+1)} \tag{12.7.57}$$

and

$$\tau^{\frac{d-1}{2}} \bigl(\varkappa'_1 |\log \tau|^{(d-\mu-2)/(\mu+1)} + \varkappa''_1\bigr) \tag{12.7.58}$$

respectively.

Proof. To prove Statement (iii) one needs just to notice that $|\kappa_j| \ll c\sigma^{-j}$ as $j \ge 2$ because only terms which do not satisfy this inequality could come from the analysis of 1-dimensional operator $A(x',\xi';D'')$ with boundary condition $B(x',\xi';x'',D_{x''})v = 0$ on each side of the segment Y and one can prove easily by formal calculations that in this case $\kappa_j = 0$ as $j \ge 2$.

Proof of Statement (iv) is trivial. □

Remark 12.7.7. All the above results hold for manifolds with the compact boundary and with cusps, like $Z \times Y$ with the metrics $dx'^2 + \sigma(x')^2 dx''^2$ where now Y is a compact closed manifold. In particular we can consider surfaces of revolutions.

Remark 12.7.8. Let $\mathsf{D} = 1$. Then we can get rid of derivatives with respect to x' in the boundary conditions. One can see easily that one can introduce variables $x'_{\mathsf{new}} = x'_{\mathsf{old}} - F(x)$ with

$$|\nabla^\alpha F| \le c|x'| \cdot \sigma(x')\gamma(x')^{-1-|\alpha'|} \tag{12.7.59}$$

such that in the new coordinates the quadratic form is of the same type with the same inequalities and $\tilde{a}_{jk} = 0$ as $j \le d', k \ge d''+1$ and $x'' \in \partial Y$ and we replaced $\sigma(x')$ by $\sigma(x'_{\mathsf{new}})$ which leads to the negligible perturbations.

12.7.6 Maxwell System

Reminder

We are interested in eigenvalue asymptotics for Maxwell operator A in $X \subset \mathbb{R}^d$. Namely, let $\mathfrak{H} = \mathscr{L}^2(X, \Lambda^k) \oplus \mathscr{L}^2(X, \Lambda^{k+1})$ where Λ^k is a space of exterior forms of a degree $k = 0, \dots, d$ [70], and let for

$$\phi = \sum_I \phi_I dx_I, \quad dx_I = dx_{i_1} \wedge \dots dx_{i_k} : \tag{12.7.60}$$

$$I = (i_1, \dots, i_k), 1 \le i_1 < \dots < i_k \le d$$

we define

$$\|\phi\|^2 = \sum_I \|\phi_I\|^2_{\mathscr{L}^2(X)} \qquad \text{and} \qquad \|\begin{pmatrix}\phi\\ \psi\end{pmatrix}\|^2 = \|\phi\|^2 + \|\psi\|^2. \tag{12.7.61}$$

Let us consider an operator

$$A = \begin{pmatrix} 0 & \beta^\dagger \mathsf{d}^* \alpha^\dagger \\ \alpha \mathsf{d} \beta & 0 \end{pmatrix} \tag{12.7.62}$$

with domain

$$\mathfrak{D}(A) = \{\begin{pmatrix}\phi\\ \psi\end{pmatrix} \in \mathfrak{H}, Au \in \mathfrak{H}, \iota_{\partial X}\phi = 0\} \tag{12.7.63}$$

where $\mathsf{d} = i\langle dx, D\rangle\wedge : \mathscr{C}^\infty(X, \Lambda^k) \to \mathscr{C}^\infty(X, \Lambda^{k+1})$ is the operator of the exterior differentiation and $\mathsf{d}^* : \mathscr{C}^\infty(X, \Lambda^{k+1}) \to \mathscr{C}^\infty(X, \Lambda^k)$ is the formally adjoint operator[71]; for ϕ in form (12.7.60) we have

$$\mathsf{d}\phi = \sum_j (iD_j\phi_I) dx_j \wedge dx_I, \qquad \mathsf{d}^*\phi = \sum_{1\le p\le k} (iD_{i_p}\phi_I)(-1)^p dx_{I\setminus i_p}, \tag{12.7.64}$$

(12.7.65) $\alpha(x) \in \mathcal{L}(\Lambda^{k+1}, \Lambda^{k+1})$; and $\beta(x) \in \mathcal{L}(\Lambda^k, \Lambda^k)$ are nondegenerate matrices smoothly depending on x and constant close to infinity (or quickly stabilizing to constant),

---

[70] At a given point, $\dim \Lambda^k = \frac{d!}{k!(d-k)!}$ and we consider complex rather than real spaces.

[71] We can define action of $\mathcal{D}$, $\mathcal{D}^*$ and $\mathcal{A}$ at distributions as well.

$\iota_Y : \mathscr{C}^\infty(X, \Lambda^k(X)) \to \mathscr{C}^\infty(X, \Lambda^k(Y))$ is the restriction of the exterior form to submanifold Y [72].

There is no problem with self-adjoint expansion of such an operator defined on functions with compact support first provided ∂X, α and β are smooth enough. Furthermore, we assume that

(12.7.66) α and β are Hermitian positive matrices

(otherwise one can reach it by means of the unitary transformation $\begin{pmatrix} T_1 & 0 \\ 0 & T_2 \end{pmatrix}$ with unitary matrices $T_1(x)$ and $T_2(x)$).

Remark 12.7.9. (i) Let $\begin{pmatrix} \phi \\ \psi \end{pmatrix}$ be an eigenfunction with eigenvalue $\lambda \neq 0$. Then automatically

$$\mathsf{d}\alpha^{-1}\psi = \mathsf{d}^*\beta^{-1}\phi = 0 \tag{12.7.67}$$

and further,

$$\iota_{\partial X}\alpha^{-1}\psi = 0. \tag{12.7.68}$$

(ii) Further, $\begin{pmatrix} \phi \\ -\psi \end{pmatrix}$ is an eigenfunction with an eigenvalue $(-\tau)$.

Then we conclude that

Remark 12.7.10. (i) The number of eigenvalues of operator A belonging to $(0, \tau)$ is

$$\mathsf{N}_k(\tau) = \mathsf{N}^-_{\Delta_{k,0}}(\tau^2) - \mathsf{N}^-_{\Delta_{k,0}}(0+0) \tag{12.7.69}$$

where $\mathsf{N}^-_{\Delta_{k,0}}(\lambda)$ is the number of the eigenvalues of operator $\Delta_{k,0}$ generated by a quadratic form

$$Q(\phi) = \|\alpha\mathsf{d}\beta\phi\|^2 + \|\alpha_1^{-1}\mathsf{d}^*\beta^{-1}\phi\|^2 \tag{12.7.70}$$

on the space

$$\mathbb{H}_{k,0} = \{\phi \in \mathscr{L}^2(X, \Lambda^k), \mathsf{d}^*\beta^{-1}\phi = 0\} \tag{12.7.71}$$

[72] One can see easily that if Y is smooth of codimension 1 and $\phi \in \mathscr{L}^2(X, \Lambda^K)$, $\mathsf{d}\phi \in \mathscr{L}^2$ then $\iota_Y\phi$ is well-defined; if $Y = \{x_1 = 0\}$ in appropriate coordinates and ϕ is of the form (12.7.60) then $\iota_Y\phi = \sum_{I \not\ni 1} \phi_I|_Y dx_I$.

with domain

$$\mathfrak{D}(Q) = \{\phi \in \mathbb{H}_{k,0},\, Q(\phi) < \infty, \iota_{\partial X}\beta\phi = 0\} \tag{12.7.72}$$

which are less than λ; later in our conditions it will be a finite number; $\alpha_1 \in \mathcal{L}(\Lambda^{k-1}, \Lambda^{k-1})$ is a nondegenerate matrix (usually constant close to infinity).

(ii) Furthermore, considering the same form $Q(u)$ on the space

$$\mathbb{H}_k = \{\phi \in \mathscr{L}^2(X, \Lambda^k)\} \tag{12.7.73}$$

with domain

$$\mathfrak{D}(Q) = \{\phi \in \mathbb{H}_k \colon Q(\phi) < \infty,\ \iota_{\partial X}\beta\phi = 0\} \tag{12.7.74}$$

we get an operator Δ_k; one can check easily that for $\tau > 0$ eigenspaces $\mathbb{H}_k(\tau)$ and $\mathbb{H}_{k,0}(\tau)$ of $\Delta_{k,0}$ and Δ_k satisfy

$$\mathbb{H}_k(\tau) \subset \mathbb{H}_{k,0}(\tau), \tag{12.7.75}$$

$$\mathbb{H}_k(\tau) \ominus \mathbb{H}_{k,0}(\tau) = \beta^{-1}\mathsf{d}\alpha_1^{-1}\big(\alpha_1^{-1}\mathsf{d}^*\beta^{-1}\mathbb{H}_k(\tau)\big) \tag{12.7.76}$$

and that $\alpha_1^{-1}\mathsf{d}^*\beta^{-1}\mathbb{H}_k(\tau)$ is an eigenspace of the operator $\Delta_{k-1,0}$ generated by a quadratic form $\|\beta^{-1}\mathsf{d}\alpha_1^{-1}\phi'\|^2 + \dots$ on the space

$$\mathbb{H}_{k-1,0} = \{\phi \in \mathscr{L}^2(X, \Lambda^{k-1}), \mathsf{d}^*\alpha_1\phi = 0, \iota_{\partial X}\alpha_1^{-1}\phi = 0\}. \tag{12.7.77}$$

(iii) Therefore

$$\mathsf{N}(\tau) = \mathsf{N}^-_{\Delta_k}(\tau^2) - \mathsf{N}^-_{\Delta_k}(0+0) - \mathsf{N}^-_{\Delta_{k-1,0}}(\tau^2) + \mathsf{N}^-_{\Delta_{k-1,0}}(0+0) \tag{12.7.78}$$

(iv) This reduction is not necessarily correct for non-smooth problems unless we are able to prove that $\mathfrak{D}(\Delta_k) \subset \mathscr{H}^2_{\mathsf{loc}}(X)$ which is not true even for $\alpha = \beta = I$ and $X = W \oplus \mathbb{R}^{d-2}$ with a sector W with an angle between π and 2π.

(v) Note that for $k = d-1$, $\alpha = I$, $\beta = I$ and $\psi = u dx_1 \wedge \dots \wedge dx_d$ we obtain exactly eigenvalue problem for the Neumann Laplacian.

Remark 12.7.11. (i) These formulae lead us to standard (known) asymptotics for compact domains with smooth boundaries:

$$\mathsf{N}(\tau^2) = \kappa_0 \tau^d + O(\tau^{d-1}) \tag{12.7.79}$$

(here and below we omit indices k and may be 0) and even

$$\mathsf{N}(\tau^2) = \kappa_0 \tau^d + \kappa_1 \tau^{d-1} + o(\tau^{d-1}) \tag{12.7.80}$$

provided

$$\det\Big(\tau^2 - \beta \mathsf{d}(\xi)^\dagger \alpha^2 \mathsf{d}(\xi)\beta\Big) = \tau^r \big(\tau^2 - g(x,\xi)\big)^s \tag{12.7.81}$$

where $\mathsf{d}(\xi) = i\langle dx, \xi\rangle\wedge$ is a principal symbol of d, g is a metrics on X and standard billiard condition holds.

(ii) The same results hold for other types of compact domains: as long as formula (12.7.78) holds, the irregularity of the boundary should be of the type described in Sections 11.2 and 11.3 and inner cone condition should be fulfilled.

Thin Cusps. Heuristics

Let us consider domains with cusps; we consider one cusp for simplicity. So we consider domains of the type described in Section 12.2.

Look first for operators Δ_k. As we already know, boundary conditions are very important for the Laplace operator: if we have the Dirichlet boundary condition then the spectrum of operator is discrete (provided cusp shrinks at infinity).

On the other hand for operator with a Neumann boundary condition spectrum is discrete only if cusp is very thin ($\log \sigma \asymp |x'|^{\mu+1}$ with $\mu > 0$) and for such operators asymptotics with sharp remainder estimate are derived in Subsections 12.7.1–12.7.5.

So basically we should determine first if for operator Δ_k condition is "Dirichlet"-like or "Neumann"-like at infinity; then for "Neumann"-like cusp assume that it is ultra-thin and write the cusp contribution; for "Dirichlet"-like cusp we need to describe non-Weyl contribution.

Let us consider the space

$$\Phi_k = \big\{\phi \in \mathscr{C}^\infty(Y, \Lambda^k(X)), \quad \mathsf{d}''\beta\phi = \mathsf{d}''^*\beta^{-1}\phi = 0, \iota_{Z\times\partial Y}\beta\phi = 0\big\} \tag{12.7.82}$$

(so we consider full forms with coefficients depending on x'' only); one can see easily that $\mathsf{dim}\,\Phi_k$ does not depend on the choice of matrix β and

$$\mathsf{dim}\,\Phi_k = \sum_j \frac{d'!}{j!(d'-j)!}\,\mathsf{dim}\,\Phi''_{k-j} \tag{12.7.83}$$

where

$$\Phi''_j = \bigl\{\phi \in \mathscr{C}^\infty(Y, \Lambda(Y)^j), \mathsf{d}''\phi = \mathsf{d}''^*\phi = 0, \iota_{\partial Y}\phi = 0\bigr\}. \tag{12.7.84}$$

From the point of view of operator Δ_k the cusp is "Dirichlet"-like iff $\mathsf{dim}\,\Phi_k = 0$; we will discuss this case later and assume that $\mathsf{dim}\,\Phi_k \geq 1$. Let us consider operator

$$\ell_k(x', D') = \boldsymbol{P}_k\beta M_k(x', D')^*\alpha^2 M_k(x', D')\beta + \beta^{-1}M_{k-1}(x', D')\alpha_1^{-2}M_{k-1}(x', D')^*\beta^{-1}\phi \tag{12.7.85}$$

acting from $\mathscr{C}^\infty(Z, \Phi_k)$ to $\mathscr{C}^\infty(Z, \Phi_k)$ with

$$M(x', D') = \mathsf{d}' + \frac{d''}{2}(D'\log\sigma)\wedge \tag{12.7.86}$$

acting from : $\mathscr{C}^\infty(Z, \Phi_k)$ to $\mathscr{C}^\infty(Z, \Lambda(Y)^{k+1})$, $M(x', D')^*$ a formally adjoint operator and $\boldsymbol{P}_k$ orthogonal projector from $\mathscr{L}^2(Y, \Lambda^k)$ to Φ_k.

Then the cusp term for operator Δ_k will be

$$\mathsf{N}_{k,\mathsf{cusp}}(\tau) = (2\pi)^{-d'}\iint \boldsymbol{n}_k(x', \xi', \tau^2)\,dx'd\xi' \tag{12.7.87}$$

where $\boldsymbol{n}_k(x', \xi', \tau)$ is the eigenvalue counting function for finite-dimensional[73] symbol $\ell_k(x', \xi')$ of an operator $\ell_k(x', D')$.

Applying then formula (12.7.78) we conclude that the cusp contribution for operator $\Delta_{k,0}$ is given by the formula (12.7.87) with $\boldsymbol{n}_k(x', \xi', \tau^2)$ replaced by $\boldsymbol{n}_{k,0}(x', \xi', \tau^2)$ which is the eigenvalue counting function for $\mathcal{L}(\Phi_{k,0}, \Phi_{k,0})$-valued symbol $\ell_{k,0}(x', \xi') = \boldsymbol{P}_{k,0}(x', \xi')\ell_{k,0}(x', \xi')$; here

$$\Phi_{k,0}(x', \xi') = \bigl\{\phi \in \Phi_k, M_{k-1}(x', \xi')^*\beta^{-1}\phi = 0\bigr\} \tag{12.7.88}$$

and $\boldsymbol{P}_{k,0}(x', \xi')$ is the orthogonal projection onto $\Phi_{k,0}(x', \xi')$.

[73] $\mathcal{L}(\Phi_k, \Phi_k)$-valued.

One can see easily that

$$\dim \Phi_{k,0} = \dim \Phi_k - \dim \Phi_{k-1,0}, \qquad \dim \Phi_{0,0} = 0 \tag{12.7.89}$$

and (12.7.83), (12.7.89) yield that

$$\dim \Phi_{k,0} = \sum_j \frac{(d'-1)!}{j!(d'-1-j)!} \dim \Phi''_{k-j}. \tag{12.7.90}$$

Furthermore, for $\alpha = I$, $\beta = I$ near infinity

$$\mathsf{N}_{k,\mathsf{cusp}}(\tau^2) = (\dim \Phi_k) N_{\mathsf{cusp}}(\tau^2), \tag{12.7.91}$$

$$\mathsf{N}_{k,0,\mathsf{cusp}}(\tau^2) = (\dim \Phi_{k,0}) N_{\mathsf{cusp}}(\tau^2) \tag{12.7.92}$$

where $\mathsf{N}_{\mathsf{cusp}}(\tau^2)$ is a cusp contribution to the asymptotics for Neumann Laplacian on $\mathscr{L}^2(X, \mathbb{C})$.

One can expect that Δ_k or $\Delta_{k,0}$ are "Neumann-like" iff $\dim \Phi_k \neq 0$ or $\dim \Phi_{k,0} \neq 0$ respectively.

Thin cusps. Results

Theorem 12.7.12 [74]**.** *Let* <u>*either*</u> $\Delta := \Delta_k$ *and* $\dim \Phi_k \geq 1$ <u>*or*</u> $\Delta = \Delta_{k,0}$ *and* $\dim \Phi_{k,0} \geq 1$. *Let*

$$\alpha = I, \ \beta = I \qquad \text{as} \ \ |x| \geq C \tag{12.7.93}$$

and let conditions (12.7.19)–(12.7.21) *be fulfilled with* $\mu > 0$. *Then*

(i) For $d'' \geq 2$ *the following asymptotics holds*

$$\mathsf{N}(\tau) = \varkappa_0 \tau^d + \mathsf{N}_{\mathsf{cusp}}(\tau^2) + O\bigl(\tau^{d-1}\bigr) + O\bigl(\tau^q\bigr) \tag{12.7.94}$$

where $\varkappa_0$ *and* $\varkappa_1$ *(see below) are standard Weyl coefficients,* $\mathsf{N}_{\mathsf{cusp}}(\tau) \asymp \tau^q$ *is defined by* (12.7.87) *for Neumann Laplacian,* $p = d'(\mu+1)/\mu$, $q = (d'-1)(\mu+1)/\mu$ *and we skip operator-related indices* k *and may be* 0.

(ii) For $d'' = 1$ *the following asymptotics holds*

$$\mathsf{N}(\tau) = \varkappa_0 \tau^d + \mathsf{N}_{\mathsf{cusp}}(\tau^2) + O\bigl(\tau^{d-1}(\log \tau)^{(d-1)/(\mu+1)}\bigr) + O(\tau^q). \tag{12.7.95}$$

[74] Cf. Theorem 12.7.4.

(iii) Moreover, if $d'' \ge 2$, (12.7.81) *holds,* $\Delta = \Delta_{k,0}$ *(and similar condition for* $\Delta = \Delta_k$*) and standard Hamiltonian condition is fulfilled, then one can replace* $O(\tau^{d-1})$ *in asymptotics* (12.7.94) *by* $(\varkappa_1 + o(1))\tau^{d-1}$.

(iv) Moreover, as $d'' \ge 2$ *and stabilization and non-periodicity condition of Theorem 12.7.4(iv) are fulfilled then one can replace* $O(\tau^q)$ *by* $\big(\varkappa_1^* + o(1)\big)\tau^q$.

Theorem 12.7.13 [75]**.** *Let* $d'' = 1$, $\mu \ge d-2$ *and conditions* (12.7.93) *and* (12.7.19)–(12.7.21) *be fulfilled and let* $\log \sigma$ *be positively homogeneous of degree* $(\mu+1)$. *Then*

(i) Asymptotics

$$\mathsf{N}(\tau) = c_0\tau^d + \nu(\tau^2) + N_{\mathsf{cusp}}(\tau^2) + O\big(\lambda^{fracd-12}\big) \tag{12.7.96}$$

holds with

$$\nu(\tau^2) = \varkappa_1'\tau^{d-1}(\log\tau)^{(d-1)/(\mu+1)} + O(\tau^{d-1}) \tag{12.7.97}$$

the Weyl expression for second order term in domain $\{\sigma(x')\tau \le 1\}$.

(ii) Moreover, if $\mu > d-2$, (12.7.81) *holds,* $\Delta = \Delta_{k,0}$ *(and similar condition for* $\Delta = \Delta_k$*) and standard Hamiltonian condition is fulfilled, then one can replace* $O(\tau^{d-1})$ *in asymptotics* (12.7.96) *by* $\big(\kappa_1 + o(1)\big)\tau^{d-1}$.

(iii) Further, as $d'' = 1$, $\mu = d-2$ *and stabilization and non-periodicity condition of Theorem 12.7.6(iii) are fulfilled then one can replace* $\nu(\tau) + O(\tau^q)$ *by* $\nu_1(\tau) + o(\tau^q)$.

Remark 12.7.14. One can weaken condition (12.7.93). Moreover, same asymptotics holds for manifolds and for manifolds with compact boundary one can skip condition (12.7.93).

Thick Cusps. Sketch

In the case of the "Dirichlet"-like' cusp condition of being ultra-thin is no longer necessary and in this case we leave to the reader rather interesting and challenging

Problem 12.7.15. Derive asymptotics with the sharp remainder estimates exactly in the same type as in Section 12.2.

[75] Cf. Theorem 12.7.6.

The only one real difficulty is in the case of operator $\Delta_{k,0}$ as $\dim \Phi_{k,0} = 0$ and $\dim \Phi_k \ge 1$ but one can overcome it by taking α_1 fast growing rather than constant at infinity.

Another difficulty is that we need to study operators with the operator-valued symbols with domain depending on (x', ξ') but it already was discussed in Problem 12.2.21.

12.7.7 Generalizations

Higher Order Operators–Discussion

Remark 12.7.16. As we mentioned in Problem 12.2.21 results of Section 12.2 should hold for appropriate boundary value problem such that all eigenvalues $\lambda_k(x', \xi')$ of $\mathsf{a}(x', \xi')$ satisfy (12.3.14) (actually this is condition only for few lowest eigenvalues).

Let us recall that $\mathsf{a}(x', \xi')$ is an operator obtained by replacing in $A(x, D)$ $D' \mapsto (x', \xi')$ and $(x'', D'') \mapsto (\sigma(x')x'', \sigma(x')^{-1}D'')$ and considered on Y where Y is a fixed domain in $\mathbb{R}^{d''}$ defining the shape of the cusp cross-section.

Now we want to consider the case when condition (12.3.14) fails for few lowest eigenvalues. This failure can be of very different nature: it may fail just for some x' or fail mildly in the sense that $\lambda_1(x', \xi') \ge (|\xi'| + \sigma(x')^{-\theta})^{2m}$; and the failure is basically very unstable.

Consider operator

$$\sum_{\alpha,\beta:|\alpha|=m,|\beta|=m} D^\alpha a_{\alpha,\beta}(x) D^\beta \tag{12.7.98}$$

defined by the corresponding quadratic form

$$\int \sum_{\alpha,\beta:|\alpha=m,|\beta|=m} \langle a_{\alpha\beta}(x) D^\beta u, D^\alpha u\rangle \, dx \tag{12.7.99}$$

with the boundary condition

$$D^\alpha u|_{\partial X} = 0 \qquad \forall \alpha : |\alpha| \le n-1. \tag{12.7.100}$$

Remark 12.7.17. Note that different quadratic forms may lead to the same differential expression but to different boundary conditions f.e. consider

$$Q_1(u) = \|D_1^2 u\|^2 + \|D_2^2 u\|^2 + 2\|D_1 D_2 u\|^2 \tag{12.7.101}$$

and

$$Q_2(u) = \|D_1^2 u\|^2 + \|D_2^2 u\|^2 + 2\,\mathsf{Re}(D_1^2 u, D_2^2 u) \tag{12.7.102}$$

leading to operator Δ^2 but with the different boundary conditions (as $n = 0$ in (12.7.100)) and only (12.7.101) leads to elliptic problem. However as $n = 1$ these forms coincide and lead to elliptic problem.

Assume that quadratic form

$$q(x)(\mathbf{v}) = \sum_{\alpha,\beta:|\alpha=m,|\beta|=m} \langle a_{\alpha\beta} v_\beta, v_\alpha\rangle \tag{12.7.103}$$

satisfies

(12.7.104) $q(x)(\mathbf{v}) \asymp \|\mathbf{v}\|^2$ uniformly with respect to x' and $\mathbf{v} = (v_\alpha)_{|\alpha|=m}$.

Only form (12.7.101) satisfies this condition.

Then we need to consider $u(x'; x'')$ which are polynomial of degree $(m-1)$ with respect to x'' and check if such polynomials satisfying (12.7.100) must be identically 0. The existence of non-zero such polynomials is rather unstable. So if originally Y depended mildly on x' and we arrive to constant Y by a change of variables x'' then the resulting operator will not be of form (12.7.98) (lower order term come into play) and violation of assumption (12.3.14) for the lowest λ_k could be mild.

Let us consider quadratic forms after rescaling (which means that originally these forms contained lower order terms)

$$Q_1(u) = \|D_1^2 u\|^2 + \|\sigma^{-2} D_2^2 u\|^2 + 2\|\sigma^{-1} D_1 D_2 u\|^2 + (Wu, u) \tag{12.7.105}$$

and

$$Q_2(u) = \|D_1^2 u\|^2 + \|\sigma^{-2} D_2^2 u\|^2 + (Wu, u) \tag{12.7.106}$$

with $\sigma = \sigma(x_1)$ rapidly decaying at infinity and $W = W(x_1)$ polynomially growing at infinity.

Obviously only form (12.7.105) satisfies (12.7.104) after rescaling back; however it does not prevent problem associated with (12.7.106) from being uniformly elliptic.

Consider quadratic forms with D_1 replaced by ξ_1 and integration over x_2 only. Both forms behave the same way on $v = \mathsf{const}$; so for both forms $\lambda_1(x_1, \xi_1) = \xi_1^4 + W(x_1)$. However on $v = \mathsf{const} x_2$ we get $\lambda_2(x_1, \xi_1) = \xi_1^4 + c^2\xi_1^2\sigma^{-2} + W(x_1)$ and $\lambda_2(x_1, \xi_1) = \lambda_1(x_1, \xi_1) = \xi_1^4 + W(x_1)$ for forms (12.7.105) and (12.7.106) respectively.

We leave to the reader the following series of the problems

Problem 12.7.18. (i) Develop theory covering (12.7.105); in particular explore if $\lambda_2(x', \xi')$ produces any noticeable contribution to $\mathsf{N}_{\mathsf{cusp}}(\tau)$.

For this purpose one needs to construct the theory similar to one of Section 11.5 but for matrix operators with eigenvalues of the symbol having different growth as (x', ξ') escaping to infinity.

(ii) Develop theory covering (12.7.106). This theory seems to be rather straightforward and easy.

More General cCusps

One can consider more general cusps. We believe that the first problem is rather challenging:

Problem 12.7.19. Consider cusps as in Problem 12.2.23(i) and (ii) albeit with "superexponential" as in this section rather than power decay as in Section 12.2 and with the Neumann-like rather than the Dirichlet-like boundary conditions.

The next problem seems to be rather easy:

Problem 12.7.20. Analyze the case when a_0 is a Schrödinger operator with a potential having valleys as in Section 12.3.

It will be the case as $|\nabla \log \sigma| \asymp |x'|^\nu |x'''|^\varsigma$ where $x''' = (x_{d'''+1}, \dots, x_{d'})$ and $1 \le d''' \le d'$, $\nu > 0$, $\varsigma > 0$; then $|\log \sigma| \asymp |x'|^\nu |x'''|^{\varsigma+1}$ and thus $\sigma \cong \exp\bigl(-|x'|^\nu |x'''|^{\varsigma+1}\bigr)$.

Domains with Spikes

We consider domains with the *spikes* which are "cusps of the finite length" (see Figure 11.2). Now Z is a compact domain with a smooth boundary and

we can assume locally that $Z = \{x_1 > 0\}$ and $X = \{x : x' \in Z, x'' \in \sigma(x')Y\}$ with compact domain Y with the smooth boundary ∂Y and $\sigma(x_1) \le cx_1$,

$$|D^\alpha \nu(x')| \le c\sigma(x')|x_1|^{-|\nu|}. \tag{12.7.107}$$

We also assume that

$$|D^\nu a_{\alpha\beta}(x')| \le c|x_1|^{-|\nu'|+\mu(2m-|\alpha|-|\beta|)}\sigma(x')^{-|\nu''|} \tag{12.7.108}$$

with $\mu > \max(-1, -d/2m)$.

We consider quadratic form with the boundary terms satisfying conditions

$$|D^\alpha a'_{\alpha\beta}(x')| \le c|x_1|^{-|\nu'|+\mu(2m-2-|\alpha|-|\beta|)}\sigma(x')^{-|\nu''|}. \tag{12.7.109}$$

The following problem seems to be rather easy:

Problem 12.7.21. Using arguments of this section prove that for such domains under Neumann (or reduced order Dirichlet leading to mixed boundary conditions) standard asymptotics as in the domains with the smooth boundaries hold (despite cone condition does not necessarily hold).

More precisely, after coordinates $x''_{\mathsf{new}} = x''_{\mathsf{old}}/\sigma(x')$ transforming spike into finite cylinder $Z \times Y$ singular at $x_1 = 0$ but with singularities not violating positivity. Moreover the possible degeneration of the lowest eigenvalues of $A(x'', \xi''; x'', D'')$ is compensated by lower order term $W(x')u$ with $W \ge \epsilon|x_1|^{-2m}$.

12.7.8 Operators with Degenerate Potentials

While not covered by this section, the following topic is related:

Example 12.7.22. Consider Schrödinger operator

$$A = D_1^2 + |D''|^2 + V(x), \qquad V(x) = e^{2|x_1|^{\mu+1}}|x''|^2 - e^{|x_1|^{\mu+1}}k \tag{12.7.110}$$

with $k = d''$. Without degeneration such operators were considered in Section 11.5; one can see easily that even with this degeneration but with $k < d''$ such operators would be still covered by the general theory of that section.

However now the lower eigenvalue of $|D''|^2 + V(x)$ is 0. Then changing variables $x''_{\mathsf{new}} = x''_{\mathsf{old}} \exp(|x_1|^{\mu+1})$ we arrive to the operator not much different from

$$A = D_1^2 + cx_1^{2\mu} + e^{x_1^{\mu+1}}B, \qquad \text{with } \ B = |D''|^2 + |x''|^2 - d''. \tag{12.7.111}$$

Problem 12.7.23. Develop the theory, covering Example 12.7.22.

12.8 Periodic Operators

In this section we consider number $\mathsf{N}(\tau)$ of eigenvalues of operator $A_t(x,D) = A(x,D) - tW(x,x)$ crossing level E as t runs from 0 to τ, $\tau \to \infty$. Here A is periodic matrix operator, matrix W is positive, periodic with respect to the first copy of x and decaying as second copy of x goes to infinity, E either belongs to a spectral gap of A or is one its ends.

12.8.1 Periodic Operators

Let us consider in $\mathbb{R}^d$ $\mathsf{D}\times\mathsf{D}$-matrix operator $A(x,x,D) = A^{\mathsf{w}}(x,x,D)$ with the Weyl symbol

$$A(z,y,\xi) = \sum_{|\sigma|\le m} a_\sigma(z,y)\xi^\sigma \tag{12.8.1}$$

where

(12.8.2) Operator $A(z,y,D)$ is z-periodic with period lattice

$$\Gamma = \mathbb{Z}e_1 \oplus \mathbb{Z}e_2 \oplus \dots \mathbb{Z}e_d \tag{12.8.3}$$

and transformation matrices $\{T_1,\dots,T_d\}$, which means that

$$A(z+e_j,y,D) = T_j^\dagger A(z,y,D)\,T_j \qquad \forall j = 1,\dots,d \tag{12.8.4}$$

with unitary commuting matrices T_j.

Let $T^n = T_1^{n_1}\cdots T_d^{n_d}$ for $n = n_1e_1 + \cdots + n_de_d \in \Gamma$.

Further, let us assume that

$$|\nabla_z^\alpha \nabla_y^\beta \bigl(a_\sigma(z,y) - a_\sigma^\infty(z)\bigr)| \le C\langle y\rangle^{-\delta-|\beta|} \qquad \forall \alpha : |\alpha| \le K\ \forall |\beta| : |\beta| \le K \tag{12.8.5}$$

$$|\nabla_z^\alpha a_\sigma^\infty(z)| \le C \qquad \forall \alpha : |\alpha| \le K \tag{12.8.6}$$

with $\delta > 0$ and large enough $K = K(m,d,\mu)$ where

(12.8.7) Operator $A^\infty(z, D_z)$ is z-periodic with period lattice (12.8.3) and transformation matrices $\{T_1, \dots, T_d\}$.

Furthermore, as usual we assume that A is elliptic:

$$|A(x,\xi)v| \ge \epsilon_0\big(|\xi|^m - C\big)|v| \qquad \forall x, \xi \in \mathbb{R}^d \ \forall v \in \mathbb{C}^D \tag{12.8.8}$$

and that

$$A(x,\xi)^\dagger = A(x,\xi) \qquad \forall (x,\xi). \tag{12.8.9}$$

To describe the spectrum of operator A^∞ (and the essential spectrum of A) we need the following definition:

Definition 12.8.1. Function $v(x)$ is *quasiperiodic with quasimomentum* ξ *and transformation matrices* $\{T\} = \{T_1, \dots, T_d\}$ if

$$u(x+n) = T^{-n}u(x)e^{i\langle n,\xi\rangle} \qquad \forall n \in \Gamma. \tag{12.8.10}$$

We denote by $\mathbb{H}_{\xi,\{T\}}$ the space of such functions with an inner product as in $\mathscr{L}^2(\mathcal{Q}, \mathbb{C}^d)$ but multiplied by $(2\pi)^{-d}\operatorname{vol}(\mathcal{Q}')$ where $\mathcal{Q} = [0,1]e_1 \oplus \dots [0,1]e_d$ is an *elementary cell*, $\mathcal{Q}' = [0,1]e_1' \oplus \dots \oplus [0,1]e_d'$ is a *dual elementary cell* and $\langle e_j', e_k\rangle = 2\pi\delta_{jk} \ \ \forall j,k$.

Then we arrive to the following proposition:

Proposition 12.8.2. *Both operators A and A^∞ are self-adjoint in $\mathscr{L}^2(\mathbb{R}^d, \mathbb{C}^{\mathsf{D}})$ and both essential spectra of A and A^∞ and spectrum of A^∞ coincide with*

$$\mathcal{E} := \bigcup_k \mathcal{E}_k, \qquad \mathcal{E}_k := \bigcup_{\xi\in\mathcal{Q}'} \lambda_k(\xi) \tag{12.8.11}$$

where $\lambda_k(\xi)$ are eigenvalues of operator A^∞ restricted to $\mathbb{H}_{\xi,\{T\}}$.

Remark 12.8.3. (i) Proposition 12.8.2 as well as Statements (i)–(iv) below are well-known and their proofs are easy.

(ii) k runs $\mathcal{K}$ where $\mathcal{K} = \{1,2,3,\dots\}$ if and only if A^∞ is semi-bounded from below, $\mathcal{K} = \{0,-1,-2,\dots\}$ if and only if A^∞ is semi-bounded from above and $\mathcal{K} = \mathbb{Z}$ otherwise.

(iii) Spectrum of A^∞ restricted to $\mathbb{H}_{\xi,\{T\}}$ is discrete and consists of eigenvalues $\lambda_k(\xi)$.

(iv) Functions $\lambda_k(\xi)$ are periodic with respect to the *dual lattice* $\Gamma' = \mathbb{Z}e'_1 \oplus \mathbb{Z}e_2 \oplus ... \mathbb{Z}e'_d$ and thus we can consider them as defined on $\mathcal{Q}'$.

(v) Without any loss of the generality we assume that

$$\lambda_k(\xi) \ge \lambda_{k-1}(\xi) \qquad \forall k. \tag{12.8.12}$$

So, $\mathsf{Spec}(A^\infty)$ has is *zone spectrum* with possible overlapping of *spectral zones* (*spectral bands*)

$$\mathcal{E}_k = [\min_\xi \lambda_k(\xi), \max_\xi \lambda_k(\xi)] \tag{12.8.13}$$

separated by *spectral gaps*

$$\mathcal{G}_k := (\max_\xi \lambda_k(\xi), \min_\xi \lambda_{k+1}(\xi)) \tag{12.8.14}$$
$$\text{provided} \quad \max_\xi \lambda_k(\xi) < \min_\xi \lambda_{k+1}(\xi).$$

If operator A^∞ is semibounded from below (above) we introduce also the spectral gap $\mathcal{G}_0 := (-\infty, \mathsf{min}_\xi\, \lambda_1(\xi))$ or $\mathcal{G}_0 := (\mathsf{max}_\xi\, \lambda_0(\xi), \infty)$ respectively.

It follows from Proposition 12.8.2 that

Corollary 12.8.4. $\mathsf{Spec}(A)$ *intersected with the spectra gap* $\mathcal{G}_k$ *is discrete and may be accumulating to one or both ends of it.*

12.8.2 Statement of the Problem

Let us pick some energy level which is in the spectral gap: $E \in \mathcal{G}_k$.

Later we consider also cases when E is either lower end or upper end of the spectral gap: $[E, E+\epsilon) \cap \mathsf{Spec}(A^\infty) = \{E\}$ or $(E-\epsilon, E] \cap \mathsf{Spec}(A^\infty) = \{E\}$.

Let $W(x) = W(x, x)$ where

(12.8.15) Matrices $W(z, y)$ and $W^\infty(z, y)$ are Hermitian and z-periodic with the period lattice Γ and transformation matrices $\{T\} = \{T_1, ..., T_d\}$ with respect to x,

and

$$|\nabla_z^\alpha \nabla_y^\beta W(z, y)| \le C\langle y\rangle^{-m\mu-|\beta|} \tag{12.8.16}$$
$$\forall \alpha : |\alpha| \le K \ \forall |\beta| : |\beta| \le K, \qquad \mu > 0$$

$$|\nabla_z^\alpha \nabla_y^\beta \big(W(z,y) - W^\infty(z,y)\big)| = o(|y|^{-m\mu-|\beta|}) \quad \text{as } |y| \to \infty \quad \forall \beta : |\beta| = 1 \tag{12.8.17}$$

$$\langle W(z,y)v, v\rangle \ge C|v|^2\langle y\rangle^{-m\mu} \qquad \forall x, y \in \mathbb{R}^d \ \forall v \in \mathbb{C}^d \tag{12.8.18}$$

where

(12.8.19) $W^\infty(z,y)$ is positive homogeneous with respect to y of degree $-m\mu$ and satisfies condition (12.8.18) as well.

In the the framework of the previous assumptions let us consider operator $A_t = A - tW$ with $t > 0$. Then

Remark 12.8.5. (i) Let E reside within spectral gap; then for each t only finite number of eigenvalues of A_t belong to $(E-\epsilon, E+\epsilon)$;

(ii) Further, if E is the lower end of the spectral gap then under appropriate conditions for each t only finite number of eigenvalues of A_t belong to $(E, E+\epsilon)$;

(iii) Similarly, if E is the upper end of the spectral gap then under appropriate conditions for each t only finite number of eigenvalues of A_t belong to $(E-\epsilon, E)$;

(iv) All the eigenvalues are monotone decreasing functions of t.

Let $\mathsf{N}_E(\tau)$ be a number of the eigenvalues of $A - tW$ (counting multiplicities) passing through the *observation point* E in in the framework of (i) (reaching E from above, leaving E to below respectively in the frameworks of (ii) and (iii)) as t changes from $0+$ to $\tau-$.

We are interested in asymptotics of $\mathsf{N}_E(\tau)$ as $\tau \to +\infty$. There is also a lite version of the problem when there is no periodic variable at all; then formally $\mathcal{Q} = \{0\}$ and $\mathcal{Q}' = \mathbb{R}^d$.

12.8.3 Reformulation of the Problem

We start from the following proposition:

Proposition 12.8.6. *In the framework of our assumptions*

(i) Equality

$$\mathsf{N}_E(t) = \mathsf{N}(L_E; [0,t)) \tag{12.8.20}$$

holds where $\mathsf{N}(L; [0,t))$ *is a number of eigenvalues of the operator*

$$L = L_E = W^{-\frac{1}{2}}(A-E)W^{-\frac{1}{2}} \tag{12.8.21}$$

belonging to $[0,t)$.

(ii) L_E *is a self-adjoint operator in* $\mathscr{L}^2(\mathbb{R}^d, \mathbb{C}^{\mathsf{D}})$.

Proof. Both statement are obvious for $A = A^\infty$ and

$$L_E^\infty = W^{-\frac{1}{2}}(A^\infty - E)W^{-\frac{1}{2}}$$

because $(A^\infty - E)$ is invertible if $E \notin \mathsf{Spec}(A^\infty)$ and this is true for perturbed operator L_E since L_E^∞-bound of the operator

$$L'_E = W^{-\frac{1}{2}}(A - A^\infty)W^{-\frac{1}{2}}$$

is 0 which means that

$$\|L'_E u\| \le \epsilon \|L_E^\infty u\| + C_\epsilon \|u\| \qquad \forall u\ \forall \epsilon > 0.$$

Furthermore,

$$\mathsf{Spec}_{\mathsf{ess}}(L_E) = \emptyset. \tag{12.8.22}$$

Remark 12.8.7. Moreover, even if E is the extreme of a spectral gap, conditions of our theorems will assure that L_E^∞ is self-adjoint unbounded operator with compact inverse and therefore all above statements (save that $(A^\infty - E)$ is invertible) remain true.

12.8.4 Reduction to Operators with Operator-Valued Symbols

One can try to apply arguments of Chapters 9 and 10 directly but they lead to sharp remainder estimates only if $\rho^{d-1} \in \mathscr{L}^1$ even in the framework of more relaxed Theorem 12.8.12 below. We need to involve operator-valued theory of Chapter 4) and we introduce Gelfand' transformation:

Definition 12.8.8. Let Γ and $\{T\}$ be introduced above. Then

$$\mathcal{F}u(\xi,x) = (2\pi)^{\frac{d}{2}}(\mathsf{vol}(\mathcal{Q}'))^{-1}\sum_{n\in\Gamma} T^n e^{-i\langle x-n,\xi\rangle}u(x-n). \tag{12.8.23}$$

is a *Gelfand' transformation* of u.

Proposition 12.8.9. *(i) As defined for x in $\mathbb{R}^d$ $\mathcal{F}(\xi,x)$ is x-quasiperiodic with quasimomentum ξ and transformation matrices $\{T\}$.*

(ii) $\mathcal{F}$ is an unitary operator from $\mathscr{L}^2(\mathbb{R}^d,\mathbb{C}^{\mathsf{D}})$ to $\mathscr{L}^2(\mathcal{Q}',\mathbb{H}_{\xi,\{T\}})$.

(iii) Inverse Gelfand's transform is defined by

$$u(x) = (2\pi)^{-\frac{d}{2}}\int_{\mathcal{Q}'} e^{i\langle x,\xi\rangle}(\mathcal{F}u)(\xi,x)\,d\xi. \tag{12.8.24}$$

Proof. Statement (i) is obvious.

Plugging (12.8.23) into the right-hand expression of (12.8.24) and using the first of equalities

$$\int_{\mathcal{Q}'} e^{i\langle n,\xi\rangle}\,d\xi = c\delta_{n0}, \qquad \sum_{n\in\Gamma} e^{i\langle n,\xi\rangle} = c\sum_{k\in\Gamma'}\delta(\xi-k), \qquad \text{with } \ c=\mathsf{vol}(\mathcal{Q}') \tag{12.8.25}_{1,2}$$

we get $u(x)$; similarly, plugging (12.8.24) into the right-hand expression of (12.8.23) with $\mathcal{F}u(\xi,x)$ replaced by $v(\xi,x)$ which is x-quasiperiodic with quasimomentum ξ and transformation matrices $\{T\}$ and using the $(12.8.25)_2$ we get $v(\xi,x)$. This proves Statement (iii).

Finally, calculating $\int_{\mathcal{Q}'}\|\mathcal{F}(\xi,x)\|^2_{\mathbb{H}_{\xi,\{T\}}}\,d\xi$ and using $(12.8.25)_1$ again we get $\sum_{n\in\Gamma}\int_{\mathcal{Q}}\|u(x+n)\|^2\,dx = \|u\|^2_{\mathscr{L}^2(\mathbb{R}^d,\mathbb{C}^{\mathsf{D}})}$ which proves Statement (ii). □

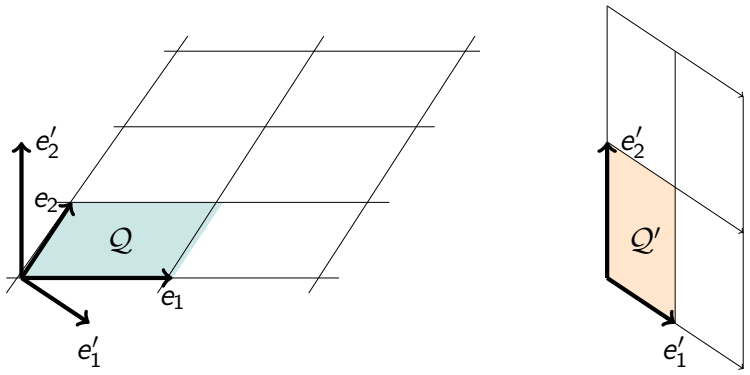
Remark 12.8.10. (i) Operator

$$u\to \mathcal{F}'u(x,\xi) \coloneqq (2\pi)^{\frac{d}{2}}(\mathsf{vol}(\mathcal{Q}'))^{-1}\sum_{n\in\Gamma} T^n e^{i\langle n,\xi\rangle}u(x-n) \tag{12.8.26}$$

with

$$u(x) = (2\pi)^{-\frac{d}{2}}\int_{\mathcal{Q}'}(\mathcal{F}'u)(\xi,x)\,d\xi \tag{12.8.27}$$

has the similar properties albeit transforms $\mathscr{L}^2(\mathbb{R}^d,\mathbb{C}^{\mathsf{D}})$ into $\mathscr{L}^2(\mathcal{Q}',\mathbb{H}_{0,\{T\}})$.



(a) Lattice (b) Dual lattice

Figure 12.7: Lattice, elementary cell $\mathcal{Q}$, dual lattice and dual elementary cell $\mathcal{Q}'$.

(ii) Consider $T = I$, replace Γ by $\varepsilon\Gamma$ and calculate limits as $\varepsilon \to +0$. Then $\mathcal{F}(\xi, x) \to (2\pi)^{d/2} F_{x\to\xi} u$.

Proposition 12.8.11. *Operator $\mathcal{F}$ transforms our operators in the following way:*

$$\mathcal{F} A^{\mathsf{w}} \mathcal{F}^* = A^{\mathsf{w}}(x - D_\xi, x, \xi + D_x), \tag{12.8.28}$$

$$\mathcal{F} A^{\infty\,\mathsf{w}} \mathcal{F}^* = A^{\infty\,\mathsf{w}}(x, \xi + D_x), \tag{12.8.29}$$

$$\mathcal{F} W \mathcal{F}^* = W^{\mathsf{w}}(x - D_\xi, x). \tag{12.8.30}$$

Proof. Proof is easy by direct calculations from (12.8.24). The only thing to notice is that we can treat the fast copy of x in $\mathbb{R}^d$ in different ways than the slow one using periodicity with respect to fast x. □

12.8.5 Main Theorem: E inside Spectral Gap

Theorem 12.8.12. *Let conditions* (12.8.2), (12.8.15), (12.8.5)–(12.8.9) *and* (12.8.16)–(12.8.18) *be fulfilled and let*

$$E \notin \mathsf{Spec}(A^\infty). \tag{12.8.31}$$

(i) Further, let us assume that there is an infinite number of $\lambda_k(\xi)$ exceeding E (or equivalently A is not semibounded from above). Then the following

asymptotics holds as $\tau \to +\infty$*:*

$$|\mathsf{N}(\tau) - \mathcal{N}(\tau)| \le R(\tau) = \begin{cases} \tau^{(d-1)/m} & \text{for } \mu > 1, \\ \tau^{(d-1)/m} \log \tau & \text{for } \mu = 1, \\ \tau^{(d-1)/(m\mu)} & \text{for } \mu < 1, \end{cases} \tag{12.8.32}$$

with

$$\mathcal{N}(\tau) = \int_{\mathbb{R}^d} \int_{\mathcal{Q}'} \boldsymbol{n}(y, \xi, \tau)\, d\xi dy \tag{12.8.33}$$

where $\boldsymbol{n}(y, \xi, \tau)$ *is the number of eigenvalues of operator* $A(x, y, D_x) - tW(x, y)$ *crossing* E *as* t *runs from* $0+$ *to* $\tau - 0$*; this operator depends on* y *and is restricted to* $\mathbb{H}_{\xi,\{T\}}$*.*

Moreover,

$$\mathcal{N}(\tau) \asymp \begin{cases} \tau^{d/m} & \text{for } \mu > 1, \\ \tau^{d/m} \log \tau & \text{for } \mu = 1, \\ \tau^{d/(m\mu)}, & \text{for } \mu < 1. \end{cases} \tag{12.8.34}$$

(ii) Further, if $\mu > 1$ *and the standard non-periodicity condition for symbol*

$$L_m(x, \xi) = A_m W^{-1}(x), \qquad A_m(x, \xi) = \sum_{\sigma : |\sigma| = m} a_\sigma(x) \xi^\sigma \tag{12.8.35}$$

is fulfilled then asymptotics

$$\mathsf{N}(\tau) = \mathcal{N}(\tau) + \big(\kappa_1 + o(1)\big)\tau^{(d-1)/m} \tag{12.8.36}$$

holds.

(iii) Finally, let us assume that there is finite number of λ_k *exceeding* E *(or equivalently* A *is semibounded from above). Then*

$$|\mathsf{N}(\tau) - \mathcal{N}(\tau)| \le C\tau^{(d-1)/(m\mu)} \tag{12.8.37}$$

and

$$\mathsf{N}(\tau) \asymp \tau^{d(m\mu)}. \tag{12.8.38}$$

To prove Theorem 12.8.12 let us consider operator $L = L_E(x, D)$ defined by (12.8.21) and the Schwartz kernel $e_L(x, x, \tau)$ of its spectral projector. Then Theorem 12.8.12 follows from Proposition 12.8.13 below as we pick up $\rho(y) = \langle y \rangle^{-\mu}$ and $\gamma_*(\tau) = \tau^{1/(m\mu)}$ and consider γ-admissible partition of unity with $\gamma = \frac{1}{2}\langle x \rangle$.

Proposition 12.8.13. *Let conditions* (12.8.2), (12.8.15), (12.8.4)–(12.8.9) *and* (12.8.16)–(12.8.18) *be fulfilled.*

(i) Let ψ be γ-admissible function supported in $B(\bar{x}, \frac{1}{2}\gamma)$ with $\gamma \le C\gamma_*(\tau)$. Then

$$\mathsf{R}_1 := \Big| \int \psi(x)\Big(e_L(x,x,\tau) - e_L(x,x,\frac{1}{2}\tau) - (2\pi)^{-d}\int \big(\nu_{L_m}(x,\xi,\tau) - \nu_{L_m}(x,\xi,\frac{1}{2}\tau)\big)\,d\xi\Big)\,dx\Big| \le C\tau^{(d-1)/m}\rho^{d-1}\gamma^d \tag{12.8.39}$$

where $\nu_{L_m}(x,\xi,\tau)$ is the eigenvalue counting function for symbol $L_m(x,\xi)$ defined by (12.8.35).

(ii) Further, for fixed r under non-periodicity condition for symbol $L_m(x,\xi)$

$$\mathsf{R}_1 := \Big| \int \psi(x)\Big(e_L(x,x,\tau) - e_L(x,x,\frac{1}{2}\tau) - (2\pi)^{-d}\int \big(\nu_{L_m}(x,\xi,\tau) - \nu_{L_m}(x,\xi,\frac{1}{2}\tau)\big)\,d\xi - \kappa_1(x)\tau^{(d-1)/m}\Big)\,dx\Big| = o\big(\tau^{(d-1)/m}\rho^{d-1}\gamma^d\big). \tag{12.8.40}$$

(iii) Furthermore, for $2 < \gamma \le C\gamma_*(\tau)$

$$\Big| \int \psi(x)\Big(e_L(x,x,\tau) - e_L(x,x,\frac{1}{2}\tau) - (2\pi)^{-d}\int \big(\boldsymbol{n}_M(x,\xi,\tau) - \boldsymbol{n}_M(x,\xi,\frac{1}{2}\tau)\big)\,d\xi\Big)\,dx\Big| \le C\tau^{(d-1)m}\mathsf{r}^{(1-\mu)(d-1)}\rho^{d-1}\gamma^{d-1} \tag{12.8.41}$$

where

$\boldsymbol{n}_M(y,\xi,\tau)$ is the number of eigenvalues between 0 and τ of operator (12.8.42)

$$M(y,\xi;z,D_z) = W^{-\frac{1}{2}}(z,y)\big(A(z,y,\xi+D_z) - E\big)W^{-\frac{1}{2}}(z,y) \tag{12.8.43}$$

restricted to the space $\mathbb{K}_{\xi,\{T\}}$ for fixed "slow" argument y.

(iv) Let $E \notin \mathsf{Spec}(A^{\infty})$. *Then for* $\gamma \ge C_0\gamma_*(\tau)$ *with large enough constant* C_0

$$|\int \psi(x)\big(e_L(x,x,\tau) - e_L(x,x,\frac{1}{2}\tau)\big)\,dx| \le C\tau^{-s}\gamma^{-s} \tag{12.8.44}$$

with arbitrarily large s.

(v) Finally, let A *be semibounded from above. Then estimate* (12.8.44) *also holds for* $\gamma \le \epsilon_0\gamma_*(\tau)$ *with small enough constant* ϵ_0.

Proof. (a) Statements (i) and (ii) follow from the standard local spectral asymptotics.

(b) Statement (iii) follows from the spectral asymptotics for operator $M(D_\xi, \xi; x, D_x)$ with the operator-valued symbol $M(y, \xi; z, D_z)$.

Let us apply Theorems 4.4.5, 4.4.6, 4.4.8 and 4.4.9) with $B = (I + \Delta_z)^{m/2}$ in $\mathbb{H}$; due to Remark 12.8.10(i) we can pass from $\mathbb{H}_\xi$ to $\mathbb{H}_0$.

Remark 12.8.14. Here and during all remaining part of the section ξ plays the role of the spatial variable, $z \in \mathcal{Q}$ is an "inner variable" defining $\mathcal{K} = \mathscr{L}^2(\mathcal{Q}, \mathbb{C}^{\mathsf{D}})$ and $y \to D_\xi$ is a dual to ξ variable, so $(y, \xi) \in T^*\mathcal{Q}'$.

To prove Statement (iii) we need to establish that

(12.8.45) $M(y, \xi; z, D_z)$ is (y, ξ)-microhyperbolic on the energy level $\tau \gg 1$

which is due to (12.8.5) and (12.8.17).

(c) Finally, Statements (iv) and (v) and follow from the fact that zones in question are classically forbidden for operators with operator-valued symbols introduced in Part (b) of this proof and uses Theorem 4.4.2. □

Corollary 12.8.15. *(i) In the framework of Theorem 12.8.12(i) with* $\mu > d(d-1)^{-1}$ *the standard Weyl asymptotics holds with the remainder estimate* $O(\tau^{(d-1)/m})$ *and even* $o(\tau^{(d-1)/m})$ *under standard non-periodicity condition as in Theorem 12.8.12(ii).*

(ii) In the framework of Theorem 12.8.12(i) with $\mu > 1$ *and*

$$|\nabla_y^\beta \big(W(z,y) - W^\infty(z,y)\big)| = o(|y|^{-\delta-m\mu-|\beta|}) \quad \text{as } |y| \to \infty \ \forall \beta : |\beta| = 1 \tag{12.8.46}$$

with $\delta > \delta_0 = 1 - (d-1)(\mu-1)$ *asymptotics* (12.8.32) *holds with*

$$\mathcal{N}(\tau) = \int_{\mathbb{R}^d}\int_{\mathcal{Q}'} \boldsymbol{n}^\infty(y,\xi,\tau)\,d\xi dy + (2\pi)^{-d}\int_{\mathbb{R}^{2d}} \Big(\nu(x,\xi,\tau) - \nu(x,\xi,0) - \nu^\infty(x,\xi,\tau) + \nu^\infty(x,\xi,0)\Big)\,dxd\xi \tag{12.8.47}$$

where $\nu^\infty(x,\xi,\tau)$ *is defined in the same way as* $\nu(x,\xi,\tau)$ *but for* $A^\infty(x,\xi)$ *and* $W^\infty(x,x)$ *and* $\boldsymbol{n}^\infty(y,\xi,\lambda)$ *is defined in the same way as* $\boldsymbol{n}(y,\xi,\tau)$ *but for operators* A^∞ *and* W^∞.

(iii) In the framework of Theorem 12.8.12(i) with $\mu < (d-1)d^{-1}$ *and* (12.8.46), (12.8.17) *with* $\delta > (1-\mu)(d-1)(d-d\mu-1)^{-1}$ *asymptotics* (12.8.32) *holds with*

$$\mathcal{N}(\tau) = \int_{\mathbb{R}^d}\int_{\mathcal{Q}'} \boldsymbol{n}^\infty(y,\xi,\tau)\,d\xi dy. \tag{12.8.48}$$

(iv) In the framework of Theorem 12.8.12(ii) and (12.8.46), (12.8.17) *with* $\delta > 1$ *asymptotics* (12.8.32) *holds with* $\mathcal{N}$ *defined by* (12.8.48).

Proof. Statement (iii) is due to Proposition 12.8.13(i) and (ii).

Note that if $\gamma^{-\delta} < h = \tau^{-1/m}\gamma^{\mu-1}$ then one can replace in Proposition 12.8.13(iii) $\boldsymbol{n}$ by $\boldsymbol{n}^\infty$. Combining with second part of Proposition 12.8.13(iv) we get Statement (iv) and with Proposition 12.8.13(i) we get Statement (iii).

To prove Statement (ii) note that if $\tau^{d/m}\gamma^{-\delta+d(1-\mu)} < \tau^{(d-1)/m}$ then one can replace in Proposition 12.8.13(iii) $\boldsymbol{n}$ by $\boldsymbol{n}^\infty$. On the hand, one can employ the theory of operators with operator-valued symbols for propagation of singularities only. This yields standard Weyl asymptotics as in Proposition 12.8.13(i) but with the remainder estimate

$$C\big(\tau^{(d-2)/m}\gamma^{(1-\mu)(d-2)+2} + \tau^{(d-1)/m}\gamma^{(1-\mu)(d-1)}\big)$$

where the first part comes from the third term in complete Weyl asymptotics. One can find γ satisfying first condition and making last expression less than $O(\tau^{(d-1)/m})$ iff $\delta > \delta_0$. □

Now let us assume that either $\mu < 1$ or A is semi-bounded from above. Then the main contribution to the remainder is delivered by zone

$$\{\epsilon\gamma_*(\tau) \le |x| \le C_0\gamma_*(\tau)\}. \tag{12.8.49}$$

To improve remainder estimate $O\big(\tau^{(d-1)/(m\mu)}\big)$ we need to consider Hamiltonian flow generated by operator-valued symbol

$$M^\infty(D_\xi, \xi; z, D_z) := W^{\infty-\frac12}(-D_\xi, z)\big(A^{\infty,\mathsf{w}}(x, \xi + D_z) - E\big)W^{\infty-\frac12}(-D_\xi, z) \tag{12.8.50}$$

which leads immediately to the following theorem:

Theorem 12.8.16. *Let in the framework of Theorem 12.8.12 either $\mu < 1$ or A be semi-bounded from above. Further let the standard non-periodicity condition be fulfilled for operator-valued symbol* (12.8.50).

Then asymptotics

$$\mathsf{N}(\tau) = \mathcal{N}(\tau) + \big(\varkappa_1^* + o(1)\big)\tau^{(d-1)/(m\mu)} \tag{12.8.51}$$

holds with an appropriate coefficient $\varkappa_1^*$.

Now let us consider the case $\bar\mu = 1$ but W contains extra-logarithmic factor.

Theorem 12.8.17 [76]**.** *(i) Let all the conditions of Theorem 12.8.12 be fulfilled excluding* (12.8.16)–(12.8.18) *which are replaced by*

$$|\nabla_z^\alpha\nabla_y^\beta W(z,y)| \le C\rho(y)^m\langle y\rangle^{-|\beta|} \qquad \forall\alpha : |\alpha| \le K\ \forall\beta : |\beta| \le K, \tag{12.8.16}'$$

$$|\nabla_y^\beta\big(W(z,y) - W^\infty(z,y)\big)| = o\big(\rho(y)^m\langle y\rangle^{-|\beta|}\big) \quad \text{as } |y| \to \infty \quad \forall\beta : |\beta| = 1, \tag{12.8.17}'$$

$$\langle W(z,y)v, v\rangle \ge C\rho(y)^m|v|^2 \qquad \forall x, y \in \mathbb{R}^d\ \forall v \in \mathbb{C}^d \tag{12.8.18}'$$

[76] Cf. Theorem 12.8.12.

with

$$\rho(y) = |y|^{-\mu}(\log|y|)^{-\mu_1}(\log\log|y|)^{-\mu_2}\cdots(\underbrace{\log\dots\log}_{l\ \text{times}}|y|)^{-\mu_l} \qquad (|y|>C) \tag{12.8.52}$$

with

$$\mu > 0. \tag{12.8.53}$$

Then Statements (i) and (ii) of Theorem 12.8.12 remain true as soon as

$$\int \rho^{d-1}\gamma^{d-2}\,d\gamma < \infty. \tag{12.8.54}$$

On the other hand, if this assumption is violated, Statement (i) of Theorem 12.8.12 modified in the obvious way remains true (modification affects remainder estimate which is now

$$R(\tau) = \tau^{(d-1)/m}\int_{\gamma<\gamma_*(\tau)} \rho^{d-1}\gamma^{d-2}\,d\gamma \tag{12.8.55}$$

with $\gamma_*(\tau)$ *defined from*

$$\tau^{\frac{1}{m}}\rho(\gamma_*(\tau)) = 1. \tag{12.8.56}$$

Moreover, as soon as

$$\int \rho^{d}\gamma^{d-1}\,d\gamma < \infty \tag{12.8.57}$$

magnitude of the principal part does not change; if this assumption is violated, the principal part will be

$$\mathcal{N}(\tau) \asymp \int_{\gamma<\gamma_*(\tau)} \rho^{d}\gamma^{d-1}\,d\gamma. \tag{12.8.58}$$

(ii) Further, Statement (iii) of Theorem 12.8.12 remains true after modification of the remainder estimate and the the principal part (which are now

$$R_0(\tau) = \gamma_*(\tau)^{d-1} \tag{12.8.59}$$

and

$$\mathcal{N}(\tau) \asymp \gamma_*(\tau)^{d} \tag{12.8.60}$$

respectively).

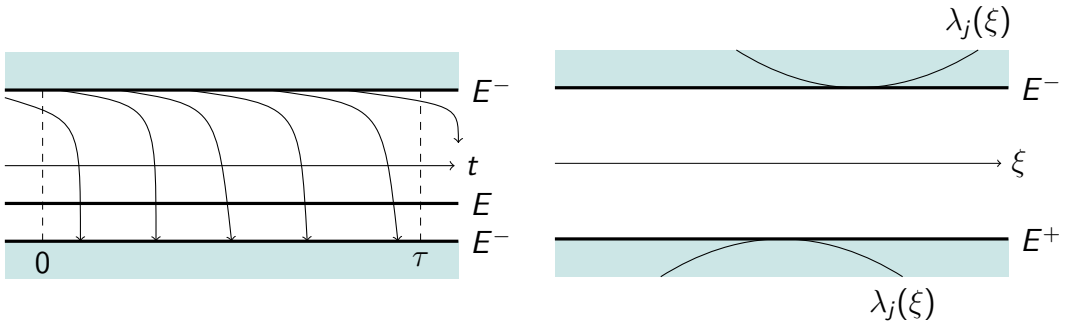
12.8.6 E on the Bottom of Spectral Gap

Now let us consider the case when E is a boundary of the spectral gap: either that either

$$[E, E+\epsilon) \cap \mathsf{Spec}(A^\infty) = \{E\} \tag{12.8.61}^+$$

or

$$(E-\epsilon, E] \cap \mathsf{Spec}(A^\infty) = \{E\}. \tag{12.8.61}^-$$



(a) Observation points (E inside spectral gap, E^+ on the bottom and E^- on the top) and eigenvalues of $A - tW$;

(b) Illustration to $(12.8.62)^\pm$

Figure 12.8: Spectral gap, observation points and behavior of $\lambda_j(\xi)$.

In the former case

$$\exists j : \lambda_k(\xi) \le E \quad \forall k \le j, \qquad \lambda_k(\xi) \ge E+\epsilon \quad \forall k > j \qquad \forall \xi, \tag{12.8.62}^+$$

while in the latter

$$\exists j : \lambda_k(\xi) \le E \quad \forall k \le j, \qquad \lambda_k(\xi) \ge E+\epsilon \quad \forall k > j \qquad \forall \xi \tag{12.8.62}^-$$

In virtue of Proposition 12.8.13 we need to consider only an *external zone*

$$X_{\mathsf{ext}} := \{x : \ |x| \ge \gamma_*(\tau)\} \tag{12.8.63}$$

as an *inner zone* $X_{\mathsf{inn}} := \{x : \ |x| \ge \gamma_*(\tau)\}$ is already covered.

However situation is really different under assumptions $(12.8.61)^+$ and $(12.8.61)^-$. In this subsection we consider only the much easier former case.

Theorem 12.8.18. *Let assumptions of one of Theorems 12.8.12, 12.8.16 or 12.8.17 be fulfilled, except assumption* (12.8.31) $E \notin \mathsf{Spec}(A^\infty)$, *which is replaced by* $(12.8.61)^+$. *Also let us assume that* $A = A^\infty$.

Then all assertions of the corresponding theorem remain true.

Proof. The Gelfand's transform transforms A^∞ into $A^\infty(\xi)$ which in turn due to $(12.8.62)^+$ one transforms by unitary operator $V(\xi)$ in $\mathbb{H}_{\xi,\{T\}}$ into the block-diagonal form

$$V(\xi)\big(A^\infty(\xi) - E\big)V^*(\xi) = \begin{pmatrix} \Lambda^-(\xi) & 0 \\ 0 & \Lambda^+(\xi) \end{pmatrix}, \tag{12.8.64}$$

$$V(\xi)WV^*(\xi) = \begin{pmatrix} W^{--} & W^{-+} \\ W^{+-} & W^{++} \end{pmatrix} \tag{12.8.65}$$

with

$$\Lambda^-(\xi) \le 0, \qquad \Lambda^+(\xi) \ge \epsilon. \tag{12.8.66}$$

and $W^{\cdots}$ ξ-pseudodifferential operators.

As $|y| \ge \gamma_*(\tau)$ [77] we can invert $\big(\Lambda^+(\xi) - E - tW^{++}\big)$ which is elliptic operator as $t \ge 0$, plug into the second equation and derive that the system is elliptic and negative.

Then under condition $(12.8.61)^+$ contribution of external zone to the remainder is negligible. We do not need the uncertainty principle assumption here because we have a define sign. □

12.8.7 E on the Top of Spectral Gap

Now let us consider the most complicated case when condition $(12.8.61)^-$ is fulfilled.

Let us assume that

(12.8.67) $\lambda_k(\xi) = E$ implies that $\lambda_k(\xi)$ is the simple eigenvalue of $A^\infty(x, D_x)$ on $\mathbb{H}_{\xi,\{T\}}$ [78]

---

[77] With a large enough constant in its definition, so $\rho^m\tau \le \epsilon$ there.

[78] Then in virtue of $(12.8.62)^+$ there exists j such that only for $k = j$

$$\Sigma_k := \{\xi :\ \lambda_k(\xi) = E\} \ne \emptyset. \tag{12.8.68}$$

In what follows $\Sigma := \Sigma_j$.

and

(12.8.69) $\lambda_j(\xi) = E$ implies that $\mathsf{Hess}\, \lambda_j(\xi)$ is non-degenerate.

Then

(12.8.70) $\Lambda = \{\xi :\ \lambda_j(\xi) = E\} = \{\bar{\xi}_0^{(i)}, i = 1, \dots \bar{i}\}$ with $\bar{i} < \infty$ and

$$\epsilon\omega(\xi) \le \mp\big(\lambda_j(\xi) - E\big) \le C\omega^2(\xi) \tag{12.8.71}$$

with $\omega(\xi) \coloneqq \mathsf{min}_i\, |\xi - \bar{\xi}^{(i)}|$.

Considering operator $A-E-tW$ near $\bar{\xi}^{(i)} \in \Sigma$ and assuming for simplicity that $\bar{\xi}^{(i)} = 0$ we observe that it is similar to $\Delta - tW(y)$ "projected" to the null-space of operator $(A - E)$ and unless W decays faster than $|y|^{-2}$ it may happen that this operator has a sequence of eigenvalues accumulating to -0. To avoid this we assume that

(12.8.72) Either $\mu' \coloneqq m\mu/2 > 1$, or $\mu' = 1$ and $\mu_1 = \dots = \mu_{l-1} = 0$ and $\mu_l > 0$ $(k = 1, \dots, n-1)$.

So, we need to consider X_{ext} defined by (12.8.63) and only as $\omega(\xi) \le \epsilon$. In this zone we can make reduction similar to (12.8.64)–(12.8.66)

$$V(\xi)\big(A^{\infty}(\xi) - E\big)V^*(\xi) = \begin{pmatrix} \lambda(\xi) & 0 \\ 0 & \Lambda'(\xi) \end{pmatrix}, \tag{12.8.73}$$

$$V(\xi)WV^*(\xi) = \begin{pmatrix} W^{00} & W^{0\prime} \\ W^{\prime 0} & W^{\prime\prime} \end{pmatrix} \tag{12.8.74}$$

with

$$|\lambda(\xi)| \le \epsilon, \qquad |\big(\Lambda'(\xi) - E\big)^{-1}| \le c_0 \tag{12.8.75}$$

where $\lambda(\xi) = \lambda_j(\xi) - E$.

Due to our methods we can consider in the zone X_{ext} a different operator, namely,

$$\lambda(D) - \tau V \tag{12.8.76}$$

with

$$V = W^{00} - \tau W^{0\prime}\big(\Lambda'(D) - \tau - W^{\prime\prime}\big)^{-1} W^{0\prime} \tag{12.8.77}$$

and problem is to find the number of negative eigenvalues of operator (12.8.76); this is basically the very special case of our original problem (one we mentioned as the "lite" problem: when A is not a periodic but a constant coefficients operator.

Due to (12.8.68) this is a semiclassical problem with an effective semiclassical parameter

$$\hbar = (\tau\rho^m)^{\frac{1}{2}}\gamma \tag{12.8.78}$$

and then $\hbar \ll 1 \iff |x| \le \gamma^*(\tau)$ with $\gamma^*\tau$ defined from equation

$$\tau\rho^m\gamma^2 = 1. \tag{12.8.79}$$

In the normal Weyl theory contribution of the zone

$$X'_{\mathsf{ext}} := \{x : \gamma_*(\tau) \le |x| \le \gamma^*(\tau)\} \tag{12.8.80}$$

to the principal part of asymptotics is

$$\mathcal{N}'_{\mathsf{ext}} := (2\pi)^{-d} \iint_{\{y\in X'_{\mathsf{ext}}, \lambda(y,\xi)-\tau V(y,\xi,\tau)<0\}} \psi_{\mathsf{ext}}(y)\, dyd\xi \tag{12.8.81}$$

and has a magnitude

$$\tau^{\frac{d}{2}} \int_{\{\gamma_*(\tau)\le|x|\le\gamma^*(\tau)\}} (\rho^m\gamma^2)^{d/2}\, \gamma^{-d}\, dx \tag{12.8.82}$$

while contribution to the remainder does not exceed

$$R'_{\mathsf{ext}} = C\tau^{\frac{1}{2}(d-1)} \int_{\{\gamma_*(\tau)\le|x|\le\gamma^*(\tau)\}} (\rho^m\gamma^2)^{(d-1)/2}\, \gamma^{-d}\, dx. \tag{12.8.83}$$

In this subsection we assume that $\mu' > 1$ i.e. $\mu > m/2$. Then contribution of the zone in question to the remainder does not exceed $C(\tau\rho^m\gamma^2)^{(d-1)/2}$ calculated as $\gamma = \gamma_*(\tau)$ and in turn it is equal to $C\gamma_*(\tau)^{d-1}$ which is no more than the contribution of X_{inn}.

It clears remainder estimate "O" obtained before and even "o" as $\mu \ge 1$; however as $\mu < 1$ we get here "o" as well due to increasing old $\gamma_*(\tau)$ to $C_0(\tau)\gamma_*(\tau)$ with slowly growing $C_0(\tau)$.

Further, to estimate contribution of the zone $X''_{\mathsf{ext}} := \{x : |x| \ge a = \gamma^*(\tau)\}$ to the remainder one needs to consider the quadratic form $\|Du\|^2 - \tau(Vu, u)$

under the Dirichlet boundary condition on $\partial X''_{\mathsf{ext}}$ and estimate properly the dimension of its negative subspace $\mathsf{N}''_{\mathsf{ext}}(\tau)$, applying then arguments of Chapter 9.

As $d \geq 3$

$$\mathsf{N}''_{\mathsf{ext}}(\tau) \leq \tau^{\frac{d}{2}} \int_{X''_{\mathsf{ext}}} \rho^d \, dx \tag{12.8.84}$$

due to Rozenblioum estimate (9.A.11). Note that the right hand expression does not exceed C as $\mu' > 1$.

As $d = 2$ however we should be a bit more subtle and refer to Rozenblioum–Solomyak estimate (see Theorem 12.A.1) which says that in our assumptions Rozenblioum' estimate (9.A.11) with $q = 1$ still is applicable. Then we arrive to the following assertion:

(12.8.85) As $\mu' > 1$ a contribution of the zone

$$X''_{\mathsf{ext}} = \{x : |x| \geq \gamma^*(\tau)\} \tag{12.8.86}$$

to both main part of the asymptotics and the remainder does not exceed C.

Therefore as $\mu' = \mu m/2 > 1$ we arrive to the same remainder estimate as before but we need also include into asymptotics term (12.8.81) of magnitude $O(\tau^{-d/m\mu})$ [79] Obviously as the result here is given by Weyl formula the final answer is also given by Weyl formula and we arrive to the following theorem:

Theorem 12.8.19 [80]**.** *Let assumptions of one of Theorems 12.8.12, 12.8.16 or 12.8.17 be fulfilled, except assumption* (12.8.31) $E \notin \mathsf{Spec}(A^\infty)$*, which is replaced by assumption* $(12.8.61)^-$ *and conditions* (12.8.67)–(12.8.79)*. Also let us assume that* $A = A^\infty$ *and* $m\mu > 2$*.*

Then all assertions of the corresponding theorem remain true.

Situation may drastically change as $m\mu = 2$. In this case to ensure that $\rho^{dm/2}$ and $\rho^{(d-1)m/2}\gamma^{-1}$ belong to $\mathscr{L}^1$ we need to assume that either $\mu'_1 = m\mu_1/2 > 1$ or $\mu'_1 = 1$ and then the same condition recurrently goes to $\mu'_2 = m\mu_2/2$.

This implies the following theorem:

---

[79] As $\rho = \gamma^{-\mu}$; otherwise extra logarithmic factors come into game.

[80] Cf. Theorem 12.8.18.

Theorem 12.8.20. *Let assumptions of one of Theorems 12.8.12, 12.8.16 or 12.8.17, except assumption* (12.8.31) $E \notin \mathsf{Spec}(A^\infty)$ *which is replaced by assumption* $(12.8.61)^-$, *and conditions* (12.8.67)–(12.8.79). *Also let us assume that* $A = A^\infty$ *and* $m\mu = 2$.

(i) Let

$$m\mu_1(d-1) = 2,\ \dots,\ m\mu_{l-1}(d-1) = 2,\ m\mu_l(d-1) > 2. \tag{12.8.87}$$

Then all assertions of the corresponding theorem in question.

(ii) Let

$$m\mu_1(d-1) = 2,\ \dots,\ m\mu_{k-1}(d-1) = 2,\ m\mu_k(d-1) \le 2. \tag{12.8.88}$$

Then all assertions of the corresponding theorem remain true with the remainder estimate

$$R(\tau) = C\tau^{1/m\mu_1} \times \begin{cases} 1 & \text{as } \ k=1, m\mu_1(d-1) < 2, \\ |\log \tau| & \text{as } \ k=1, m\mu_1(d-1) = 2, \\ |\log_{k-1} \tau|^{1-m\mu_k(d-1)/2} & \text{as } \ k>1, m\mu_k(d-1) < 2, \\ |\log_k \tau| & \text{as } \ k>1, m\mu_k(d-1) = 2, \end{cases} \tag{12.8.89}$$

where $\log_l \tau = \underbrace{\log \dots \log}_{l \text{ times}} \tau$.

(iii) Meanwhile the main part of asymptotics has the magnitude as in the theorem in question provided $m\mu_1 d > 2$.

Proof. Observe that as $m\mu = -2$ we have $\rho^{m(d-1)/2}\gamma^{-1} \in \mathscr{L}^1$ if and only if (12.8.87) holds; otherwise $\tau^{(d-1)/2}\int_{X'_{\mathsf{ext}}} \rho^{m(d-1)/2}\gamma^{-1}\,dx$ is given by (12.8.89) and is larger than that what we got before. So, Statements (i) and (ii) are proven.

Note that $\rho^{md/2} \in \mathscr{L}^1$ as $m\mu_1 d > 2$. It implies Statement (iii). □

12.8.8 E on the Top of Spectral Gap. II. Improved Asymptotics

Now we want to consider case of $\rho^{m(d-1)/2}|x|^{-1} \notin \mathscr{L}^1$ and improve the remainder estimate (12.8.89) adding some correction; this correction will be even larger than the previous type of asymptotics as $\rho^{md/2} \notin \mathscr{L}^1$.

Let us consider first

$$A = \Delta - tW(x), \qquad W(x) = |x|^{-2} V(\log|x|) \tag{12.8.90}$$

where

$$|D^\alpha V(z)| \le C\varrho(z)^2 |z|^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le K, \tag{12.8.91}$$

$$|\partial_z| V(z) \asymp \varrho^2(z)|z|^{-1} \qquad \text{as} \quad |z| \ge C \tag{12.8.92}$$

$$\varrho(z) = |z|^{-\nu_\pm} \qquad \text{as} \quad \pm z \ge C, \nu_\pm > 0. \tag{12.8.93}$$

As $V(z)$ decays fast enough as $z \to \pm\infty$ non-degeneracy condition (12.8.92) will not be needed.

Then introducing spherical coordinates $(r, \theta) \in \mathbb{R}^+ \times \mathbb{S}^{d-1}$, separating variables and then substituting $z = \log r$ we arrive to the equivalent problem for the operator

$$A' = D_z^2 + \lambda + \frac{1}{4}(d-2)^2 - tV(z) \tag{12.8.94}$$

where

$$\lambda \in \mathsf{Spec}(\Lambda) \text{ and } \Lambda \text{ is Laplace-Beltrami operator on } \mathbb{S}^{d-1}. \tag{12.8.95}$$

To this operator we can apply Weyl asymptotics:

$$\mathsf{N}_\lambda^-(\tau) = \mathsf{N}_\lambda^{\mathsf{W}}(\tau) + O(1) \tag{12.8.96}$$

with

$$\mathsf{N}_\lambda^{\mathsf{W}}(\tau) = \frac{1}{\pi} \int \Big(\tau V(z) - \lambda - \frac{1}{4}(d-2)^2\Big)_+^{\frac{1}{2}}\, dz, \tag{12.8.97}$$

as $\lambda + \frac{1}{4}(d-2)^2 \ge \epsilon_0 > 0$ and after summation over eigenvalues of Λ we arrive to the asymptotics with the principal part

$$\mathcal{N}(\tau) := \frac{1}{\pi} \sum_{\lambda \in \mathsf{Spec}(\Lambda)} \int \big(\tau V(z) - \lambda - \frac{1}{4}(d-1)^2\big)_+^{\frac{1}{2}}\, dz = \tag{12.8.98}$$

$$\frac{1}{\pi} \sum_n P(n,d) \int \big(\tau V(z) - (n + \frac{1}{2}d - 1)^2\big)_+^{\frac{1}{2}}\, dz$$

where $P(n,d)$ is the multiplicity of the eigenvalue $n(n+d-2)$ of Λ and with the remainder estimate

$$\sum_{\lambda\in \mathsf{Spec}(\Lambda)\le \tau} 1 \asymp \tau^{(d-1)/2}.$$

Obviously

$$\mathcal{N}(\tau) \asymp \begin{cases} \tau^{d/2} & \text{as } -d\nu > 1,\\ \tau^{d/2}|\log\tau| & \text{as } -d\nu = 1,\\ \tau^{1/2\nu} & \text{as } -d\nu < 1, \end{cases} \tag{12.8.99}$$

where $\nu = \min(\nu_+,\nu_-)$.

Formula (12.8.99) holds as either $d\ge 3$ or $\lambda\in\mathsf{Spec}(\Lambda)$ is not 0.

So, as $d=2$ we need to investigate $\lambda=0$ separately. In this case we arrive to the operator $D_z^2 - \tau V(z)$ and to avoid the infinite negative spectrum we must assume that $V(z) = o(|z|^{-2})$ as $|z|\to\infty$.

Recall that as $d=2$ the critical value of the previous subsection is exactly $\alpha=1$. Thus we now are interested in $V(z) = |z|^{-2}V_1(\log z)$ with $V_1(z_1)$ decaying at infinity as $|z_1|^{-2}$ or slower. We consider only $z\ge 0$; the second semi-axis is treated in the same way.

Then plugging into quadratic form $u = e^{-z_1/2}u_1$, $z = e^{z_1}$ we arrive to quadratic form

$$\|D_z u\|^2 - t(z^{-2}V_1(\log z)u,u) = \|D_{z_1}u_1\|^2 + \frac{1}{4}\|u_1\|^2 - t(V_1(z_1)u_1,u_1) \tag{12.8.100}$$

and a $V_1(z_1)\to 0$ as $|z_1|\to\infty$ we guarantee that there is only finite number negative eigenvalues. Moreover, as $V(z_1)\asymp |z_1|^{-2\beta_1}$ with $\beta_1\le 1$ the remainder estimate is $O(\log\tau)$ and the main part is given by the Weyl formula

$$\mathsf{N}_0^{\mathsf{W}}(\tau) = \frac{2}{\pi}\int \Big(\tau V_1(z_1) - \frac{1}{4}\Big)^{\frac{1}{2}}\, dz_1 \tag{12.8.101}$$

While remainder estimate is below one we received earlier, the main part is of magnitude $\tau^{(\beta_1+1)/(2\beta_1)}$ and it is above of what we got earlier.

So, we have proven the following theorem:

Theorem 12.8.21. *(i) Let* $d \ge 3$, $W(x) = |x|^{-2}V(\log|x|)$ *where* $V(z)$ *is a function of the type described above.*

Then asymptotics

$$\mathsf{N}(\tau) = \mathcal{N}(\tau) + O(\tau^{\frac{1}{2}(d-1)}) \qquad \text{as } \tau \to \infty \tag{12.8.102}$$

holds with the principal part (12.8.98) *of magnitude* (12.8.99).

(ii) Let $d = 2$, $W(x) = |x|^{-2}|\log|x||^{-2}V_1(\log|\log|x||, \pm)$ *where* $V(z)$ *is a function of the type described above and* $\pm$ *is responsible for different behavior as* $|x| \to \infty$ *and* $|x| \to 0$.

Then asymptotics

$$\mathsf{N}(\tau) = \mathcal{N}^{\#}(\tau) + O(\tau^{\frac{1}{2}(d-1)}) \qquad \text{as } \tau \to \infty \tag{12.8.103}$$

holds where superscript $^{\#}$ *means that the term with* $\lambda = 0$ *is replaced by* (12.8.101) *of magnitude* $\tau^{(\beta+1)/(2\beta)}$.

We leave to the reader the following series of interesting problems and probably not very difficult problems:

Problem 12.8.22. (i) Prove that the similar results hold as $W(x) = W(|x|)$ is replaced by $W(x) = W_r(|x|)w(\theta)$ with smooth disjoint from 0 function $w(\theta)$.

Investigate if we need condition $w(\theta) \ne 0$ or one can replace it by a condition $|w(\theta)| + |\nabla_\theta w(\theta)| \asymp 1$ or drop it completely (depending on dimension)?

(ii) Prove that the similar results hold as $W(x)$ fast enough stabilizes to $W^\infty(x) = W_r(|x|)w(\theta)$ described above; then there will be a mixture of Weyl terms associated with $(W - W^\infty)$ and non-Weyl (with respect to θ) terms depending only on W^∞.

(iii) Extend Part (ii) to the case when Δ is replaced by $\lambda^{\mathsf{w}}(x, D)$ with $\lambda(x, \xi) = g(x, \xi)$ where $g(x, \xi)$ is non-degenerate quadratic form with respect to ξ stabilizing to $g^\infty(\theta, \xi)$ as $|x| \to \infty$.

(iv) As $W(x)$ has no singularity at 0 extend Part (iii) to the case when $\lambda^{\mathsf{w}}(x, D)$ is a pseudodifferential operator with the symbol $\lambda(x, \xi) = g(x, \xi) + O(|\xi|^3)$ uniformly with respect to x with $g(x, \xi)$ described in Part (iii).

Problem 12.8.23. Using Problem 12.8.22 improve results of the previous Subsection 12.8.7 by using non-Weyl asymptotics of the type (12.8.102), (12.8.103) in the external zone.

12.8.9 Case of Positive $(A-E)$

Let us consider case when operator $(A-E)$ is positive definite albeit not necessarily disjoint from 0 but W is indefinite. So, E is either inside the spectral gap $\mathcal{G}_0$ or on its top.

Note that eigenvalues of $(A-tW)$ can cross E only in the negative direction. Let $\mathsf{N}_E([0,\tau])$ be a number of eigenvalues crossing 0 as t changes from 0 to τ. Then

$$\mathsf{N}_E([0,\tau]) = \mathsf{N}^-(A-E-\tau W). \tag{12.8.104}$$

Problem 12.8.24. (i) Prove that the corresponding results of the previous subsections remain true in these settings as well.

(ii) Generalize these results to the case when $W=W(x,D)$ is an operator of lower order than A.

12.8.10 Generalizations and Modifications

Let us consider the operators treated in M.S. Birman, A. Laptev and T. Suslina [1] and in M.S. Birman and T. Suslina [1–3] but without remainder estimates:

Problem 12.8.25. (i) Prove that the same asymptotics hold for operators not in $\mathbb{R}^d$ but in a domain X^∞ and with the boundary condition $Bu|_{\partial X}=0$ satisfying the following periodicity conditions:

$$X^\infty + \Gamma = X^\infty \tag{12.8.105}$$

with the lattice Γ (see Figure 12.9(a)),

(12.8.106) There exist functions ϕ_j $(j=1,\dots,d')$ such that

$$\phi_j(x+e_k)-\phi_j(x)=\delta_{jk} \qquad \forall j,k=1,\dots,d' \tag{12.8.107}$$

and

$$B^\infty e^{i\langle\phi(x),\xi\rangle}u|_{\partial X^\infty} = B^\infty u|_{\partial X^\infty} \qquad \forall \xi \tag{12.8.108}$$

where $\langle \phi(x), \xi\rangle = \sum_j \phi_j(x)\xi_j$.

In this case $\mathcal{Q}$ should be replaced by $\mathcal{Q}\cap X$ with the previous definition of the elementary cell $\mathcal{Q}$ and $\mathcal{Q}'$ remains intact. In this case the auxiliary space $\mathbb{H}_{\xi,\{T\}}$ is subspace of $\mathscr{L}^2_{\mathsf{loc}}(\pi^{-1}X^\infty, \mathbb{C}^{\mathsf{D}})$ satisfying condition of quasiperiodicity with the quasimomentum ξ and transformation matrices $\{T\}$; $\mathbb{H}_{\xi,\{T\}}$ is identified with $\mathscr{L}^2(\pi^{-1}\mathcal{Q}\cap X^\infty, \mathbb{C}^{\mathsf{D}})$. Here $d' = d$ and $\pi = I$.

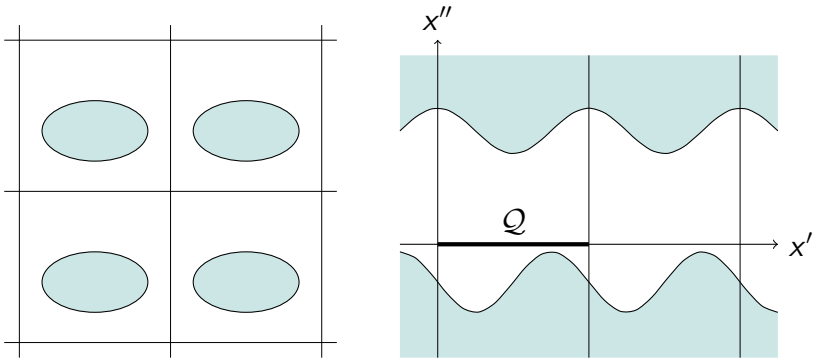
(ii) Generalize these results to the case when X and B coincide with X^∞ and B^∞ as $|x| \ge c$.

Problem 12.8.26. Prove that the similar asymptotics hold for operators in waveguides i.e. domains bounded in $x'' = (x_{d'+1}, \dots, x_d)$ and satisfying above conditions with $\Gamma \subset Z = \mathbb{R}^{d'} \ni x' = (x_1, \dots, x_{d'})$ (see Figure 12.9(b)) and matrices $T_1, \dots, T_{d'}$; here $d' < d$.

Now $\mathcal{Q} \subset Z$ is an elementary cell, $\pi : X \ni (x', x'') \to x' \in Z$ is a projection. Then one should expect $\mathsf{N}(\tau) \asymp \mathsf{max}\big(\tau^{d'/(m\mu)}, \tau^{d/m}\big)$ and $R(\tau) \asymp \mathsf{max}\big(\tau^{(d'-1)/(m\mu)}, \tau^{(d-1)/m}\big)$ as E is inside the spectral gap or on its bottom, whatever power is larger and the logarithmic factor appears as powers coincide; similar results hold as E is on the top of the spectral gap.

In this case $d' = 1$ should be also treated.

Note that in the previous two Problems 12.8.25 and 12.8.26 X is not necessarily a connected domain.



(a) Periodic domain (b) Waveguide

Figure 12.9: Periodic domain in full dimension ($d' = d$) and "waveguide" i.e. periodic domain in reduced dimension ($d' < d$)

Problem 12.8.27. Prove that the same asymptotics hold for operators with Weyl symbol $a(x, \xi - \alpha x)$ where α is a constant matrix such that

$$\alpha n \in \Gamma' \qquad \forall n \in \Gamma. \tag{12.8.109}$$

In this case $\mathbb{H}_{\xi,\{T\}}$ is the space of functions such that

$$u(x+n) = T^{-n} u(x) e^{i\langle n, \xi + \alpha x\rangle} u(x) \qquad \forall n \in \Gamma; \tag{12.8.110}$$

without condition (12.8.109) this is impossible equality.

Condition (12.8.109) needs to be satisfied only for skew-symmetric part of α as we can get rid of symmetric part by the gauge transformation. So, condition is

$$\frac{1}{2\pi} \int_{\mathcal{Q}_{jk}} d\omega \in \mathbb{Z} \qquad \forall j \neq k \tag{12.8.111}$$

where $\omega = \sum_j (\alpha x)_j dx_j$ and d denotes an exterior differential.

Therefore the problem is admissible as αx is replaced by non-linear vector-potential $V(x)$ both in operator and in condition (12.8.111): now $\omega = \sum_j V_j(x) dx_j$.

As an example one can consider Schrödinger operators with periodic magnetic field with "admissible" but not necessary vanishing flows over elementary cell.

Remark 12.8.28. As condition (12.8.111) is violated and some of the left-hand expressions are irrational operator seems to be beyond reach of the modern methods.

12.A Appendices

12.A.1 Variational Estimates as $m = 1$, $d = 1, 2$

In the $m = 1, d = 2$ case Rozenblioum estimate (9.A.11) is not often good enough as it contains $q > 1$ which often does not work (f.e. if potential is $|x|^{-2} |\log |x||^{-2\alpha}$). However there are other estimates albeit not of the same level of the generality and elegance, which work better.

First of all as $d = 1, 2$ replacing Δ by $\Delta + \epsilon |x|^{-2}$ with arbitrarily small constant ϵ saves the day restoring Rozenblioum estimate (9.A.11) with $q = 1$ (A. Laptev [2]). However consider unmodified Δ.

Let us start from $d = 1$ and half-line $\mathbb{R}^+ = \{x > 0\}$,

$$Q(u) = \int_0^\infty \bigl(|\nabla u|^2 - V(x)|u|^2\bigr)\,dx \tag{12.A.1}$$

with $V(x) \ge 0$.

In this case G. Rozenblioum-M.Z. Solomyak [2] paper provides estimate

$$\mathsf{N}^-(Q) \le C \int_1^\infty \Bigl(t^{-1} \int_t^{2t} V(x)\,dx\Bigr)^{\frac{1}{2}}\,dt \tag{12.A.2}$$

which is the estimate following (5.3) in the mentioned paper modified in the obviously equivalent way. Then for potentials V such that

$$|x| \asymp |y| \implies V(x) \asymp V(y) \tag{12.A.3}$$

the right-hand expression of (12.A.2) is equivalent to the right-hand expression of

$$\mathsf{N}^-(Q) \le C \int_{\mathbb{R}^+} V(x)^{\frac{1}{2}}\,dx \tag{12.A.4}$$

which is Rozenblioum estimate with formal $q = \frac{1}{2}$.

Consider now $d = 2$ and a potential satisfying (12.A.3). This is the same as considering radial potential $V(r)$ with $r = |x|$. Then we can go to polar coordinates (θ, r) and split u into two parts: one is radial $u_0(r)$ and another orthogonal $u_1(r,\theta) = \sum n \ne 0 u_n(r)e^{in\theta}$.

Then $\mathsf{N}^-(Q) = N_0^-(Q) + \mathsf{N}_2^-(Q)$ and due to A. Laptev [2] for $\mathsf{N}_1^-(Q)$ Rozenblioum estimate holds:

$$\mathsf{N}_1^-(Q) \le C \int_{\mathbb{R}^2} V(x)\,dx \asymp C \int_0^\infty V(r) r\,dr. \tag{12.A.5}$$

So, we need to consider only radial component. Then we arrive to quadratic form

$$\int_0^\infty r\bigl(|D_r|^2 - V(r)|u|^2\bigr)\,dr = \int_{-\infty}^\infty \bigl(|u|^2 - V(e^z)e^{2z}\bigr)\,dz \tag{12.A.6}$$

where we changed variables $r = e^z$ and skipped index "0". So we arrive to one-dimensional problem with "effective potential" $F(z) = e^{2z}V(e^z)$. This effective potential does not necessary satisfies condition (12.A.3) even if original potential V satisfied it. However assume that $F(z)$ satisfies this condition, or equivalently, that

(12.A.7) $V(r) = r^{-2}F(\log r)$ where $F(z)$ satisfies (12.A.3).

Then in virtue of (9.A.4)

$$\mathsf{N}_0^-(Q) \le C\int_{-\infty}^{\infty} e^{2z}V(e^z)\,dz = C\int_0^{\infty} rV(r)\,dr. \tag{12.A.8}$$

Thus we arrive to

Theorem 12.A.1. *(i) As $m = 1$, $d = 1$ and V satisfies* (12.A.3) *Rozenblioum' estimate* (9.A.11) *holds with $p = \infty$, $q = \frac{1}{2}$.*

(ii) As $m = 1$, $d = 2$ and V satisfies (12.A.7) *Rozenblioum' estimate* (9.A.11) *holds with $p = \infty$, $q = 1$.*

Comments

There are few papers devoted to the non-classical asymptotics in the domains with thick cusps (we are aware only about the existence of these papers); however, there are either no accurate remainder estimates or even no remainder estimate at all. The principal part of asymptotics in these papers, naturally, coincides with the one derived in Section 12.2.

The theory of operators with the strong degeneration of the potential at infinity also is not very well developed. I am aware of the paper M. Z. Solomyak [1] in which there is also no remainder estimate and again the principal part coincides with the one derived in Section 12.3.

There seem to be no papers[81)] at all related to Section 12.4.

The list of papers devoted to the operators with the degenerations is much larger. We cannot list them all. The following papers are devoted to operators of the type we consider in Section 12.5: A. Menikoff and J. Sjöstrand [1–3], C. Iwasaki and N. Iwasaki [1], A. Mohamed [1, 2] etc. Remainder estimates were not obtained in them. A special case was treated in R. Melrose [5] and the remainder estimate was accurate in the case when it was Weyl and was not accurate otherwise.

There are many papers[81)] dealing with the Scott correction term in mathematical physics. The reader can find a survey in V. Ivrii, V. and I.M. Sigal [1]. However, the method was completely different from the one

[81)] Prior to our analysis.

we employ in Section 12.6 and only the spherically symmetric case was treated.

In V. Jakšić, S. Molčanov and B. Simon [1] the eigenvalue asymptotics for Neumann operators in domains with ultra-thin cusps was derived without remainder estimate. This paper inspired our research in Section 12.7. As cusp decay rate is exponential rather than superexponential the spectrum is continuous and the scattering theory was developed by many authors.

Finally, problems for periodic operators as in Section 12.8 were treated in papers of M. Sh. Birman [5, 8–10], M. Sh. Birman and -A. Laptev [2, 3], M.S. Birman, A. Laptev and T. Suslina [1], and M.S. Birman and T. Suslina [1–3]. These papers inspired our research.

Remark. We understand that these commentaries are completely inadequate and we are completely open and will be extremely grateful for suggestions.

Smooth Theory in Dimensions 2 and 3

Chapter 13

Schrödinger Operator. Standard Theory in Dimensions 2 and 3

13.1 Introduction

In this chapter we analyze 2- and 3-dimensional Schrödinger operators with the strong magnetic field; now we have not only a small parameter h but a large parameter μ (a coupling constant with the magnetic field or simply a magnetic parameter); moreover, a natural condition $\mu \le h^{-1}$ arises.

In Section 13.2, which has a preliminary character, we obtain a formula for $e(x,x,\tau)$ for operators in $\mathbb{R}^d$ with constant g^{jk}, V and F_{jk} (which is the tensor intensity of the magnetic field) and we also prove some preliminary assertions.

In Section 13.3 we obtain microlocal canonical forms for $d = 2, 3$ which are the basis for the advanced analysis.

In Section 13.4 we derive (quasi)Weyl and related asymptotics for $d = 2, 3$ in the case of a weak magnetic field ($\mu \le h^{\delta-1}$ with arbitrarily small exponent $\delta > 0$).

Further, in Section 13.5 we derive non-Weyl asymptotics in the case of a noderate magnetic field ($\mu \ge h^{-\delta}$); these formulae permit us to justify the (quasi)Weyl asymptotics under weaker restrictions than those of Section 13.4.

All these results are essentially different in the cases $d = 2$ and $d = 3$. For example, in $\mathbb{R}^d$ for constant g^{jk}, V and $(F_{jk}) \ne 0$ the spectrum of

the Schrödinger operator for $d = 2$ is pure point of infinite multiplicity while it is absolutely continuous for $d = 3$. The remainder estimate in Sections 13.4 and 13.5 in the case $d = 2$ under appropriate non-degeneracy assumptions is $O(\mu^{-1}h^{-1})$ or even better (the best possible is $O(1)$); so it is better than in the standard case (without magnetic field); however, without such assumptions the remainder estimate is as bad as $O(\mu h^{-1})$ which can be derived from the results in the standard case.

On the other hand, for $d = 3$ the remainder estimate is $O\big(h^{-2} + \mu h^{-1-\delta}\big)$ without any assumptions and $O(h^{-2})$ under very weak non-degeneracy assumption. Thus, as either $\mu \le h^{-1+\delta}$ or mentioned non-degeneracy condition is fulfilled we obtain the same estimate $O(h^{-2})$ as in the non-magnetic case. So in the case $d = 2$ the remainder estimate is way more more sensitive to additional restrictions.

In Section 13.6 we consider strong magnetic field $\mu \ge \epsilon h^{-1}$ and slightly modify our results; we also consider magnetic Schrödinger-Pauli operators which provide us with non-trivial results even as $\mu \ge Ch^{-1}$. Then the principal part of asymptotics is of magnitude μh^{1-d} rather than h^{-d} and remainder estimate is $O(\mu h^{-1})$ (or a bit worse, depending on non-degeneracy assumptions) as $d = 3$ and $O(1)$ (or worse, depending on non-degeneracy assumptions) as $d = 2$. Further, in the same section for $d = 2$ t we treat spectral gaps not containing the semiclassical approximation of the spectrum and we obtain complete spectral asymptotics (i.e., $O(h^s)$ with arbitrary s). Under appropriate assumptions these gaps may appear even if $\mu \ge h^{-\delta}$.

Furthermore, in Section 13.7 under additional restrictions of a global nature we treat the long-term propagation of singularities and justify the classical mechanics answer: in the 3-dimensional case singularities propagate along magnetic lines while in the 2-dimension case they propagate along magnetic drift lines (with average velocities $\asymp 1$ and $\asymp \nu\mu^{-1}$ where parameter $\nu \in (0, 1]$ appears in assumptions). This provides us with slightly improved remainder estimates under conditions on these lines including conditions on the growth of the Jacobi matrix elements, avoidance of the boundary and irrevocability of the movement.

Also in this section we consider the case of 3-dimensional Schrödinger operator when classical movement along magnetic lines is trapped by potential and then we can trace very long-time movement (up to $T \asymp \mu$) and under appropriate non-degeneracy assumptions including assumption that the total drift is present (magnetic lines may drift in 3-dimensional case with the speed $\nu\mu^{-1}$) we recover supersharp remainder estimate $O(\mu^{-1}h^{-2})$.

Finally, in Section 13.8 we apply the method of partition of unity and rescaling plus some additional arguments and we weaken the conditions on the assertions proven earlier: while condition $V \asymp 1$ is removed for $d = 2.3$, conditions $F \asymp 1$ and $B(0,1) \subset X$ are removed for $d = 3$ only because for $d = 2$ much more subtle arguments allow to derive much sharper asymptotics and we will do it in two next chapters.

13.2 Preliminary Analysis

13.2.1 Settings

In this chapter we treat the Schrödinger operator

$$A = \sum_{j,k} P_j g^{jk} P_k + V, \qquad \text{with } P_j = hD_j - \mu V_j \tag{13.2.1}$$

where

(13.2.2) $g^{jk} = g^{kj}$, V_j and V are real-valued functions, $h \in (0,1]$, $\mu \in [1,\infty)$.

and in $B(0,1) \subset X$ the following conditions are fulfilled:

$$|D^\alpha g^{jk}| \le c, \quad |D^\alpha V_j| \le c, \quad |D^\alpha V| \le c \qquad \forall \alpha : |\alpha| \le K, \tag{13.2.3}_{1-3}$$

$$\epsilon_0 \le \sum_{j,k} g^{jk}\eta_j\eta_k \cdot |\eta|^{-2} \le c \quad \forall \eta \in \mathbb{R}^d \setminus 0 \quad \forall x \in B(0,1) \tag{13.2.4}$$

and unless opposite is specified, we always assume that

$$X \supset B(0,1). \tag{13.2.5}$$

Let us note that

(13.2.6) $e(x,x,\tau)$ does not change if we replace A by the unitarily equivalent operator $e^{-i\mu h^{-1}\phi} A e^{i\mu h^{-1}\phi}$ with an arbitrary real-valued function $\phi(x)$ which means precisely that we replace V_j by $V_j + \partial_{x_j}\phi$ and $e(x,y,\tau)$ by $e(x,y,\tau)e^{-i\mu h^{-1}(\phi(y)-\phi(x))}$ (*gauge transformation*).

Therefore one can replace condition $(13.2.3)_2$ by

$$|D^\alpha F_{jk}| \le c \quad \forall \alpha : |\alpha| \le K-1 \tag{13.2.3}'_2$$

where

$$F_{jk} = \partial_k V_j - \partial_j V_k \tag{13.2.7}$$

is the *tensor intensity* of the magnetic field.

13.2.2 Toy-Model Case

Calculations

Let us start with the toy-model case in which $X = \mathbb{R}^d$, g^{jk}, V and F_{jk} are constant:

Theorem 13.2.1. *Let $X = \mathbb{R}^d$, g^{jk}, V and F_{jk} be real constants and let condition* (13.2.4) *be fulfilled.*

(i) Then

$$e(x,x,\tau) = h^{-d}\mathcal{N}_x^{\mathsf{MW}}(\tau,\mu h) \tag{13.2.8}$$

where

$$\mathcal{N}^{\mathsf{MW}}(\tau,\mu h) \coloneqq (2\pi)^{r-d}\varpi_{d-2r}\sqrt{g}\times \sum_{\alpha\in\mathbb{Z}^{+r}} \Big(\tau - \sum_{1\le j\le r}(2\alpha_j+1)\mu h f_j - V\Big)_+^{\frac{d-2r}{2}} f_1\cdots f_r(\mu h)^r, \tag{13.2.9}$$

(13.2.10) $2r = \mathsf{rank}(F_{jk})$, $f_j > 0$ *and* $\pm i f_j$ $(j = 1,\dots,r)$ *are all the eigenvalues (counting multiplicities) of the matrix* $(F_j^l) = (g^{lj})(F_{jk})$, $g = \det(g^{jk})^{-1}$.

(ii) In particular, for $2r = d$ the spectrum of the operator A is pure point of infinite multiplicity and is given by the formula

$$\mathsf{Spec}(A) = \Big\{ \sum_{1\le j\le r}(2\alpha_j+1)\mu h f_j + V, \quad \alpha\in\mathbb{Z}^{+r}\Big\} \tag{13.2.11}$$

and in order to have equality (13.2.8) *at every point $\tau\in\mathbb{R}$ we take function τ_+^0 semicontinuous from the left in* (13.2.9).

(iii) On the other hand, if $2r < d$ then the spectrum of A is absolutely continuous and is given by the formula

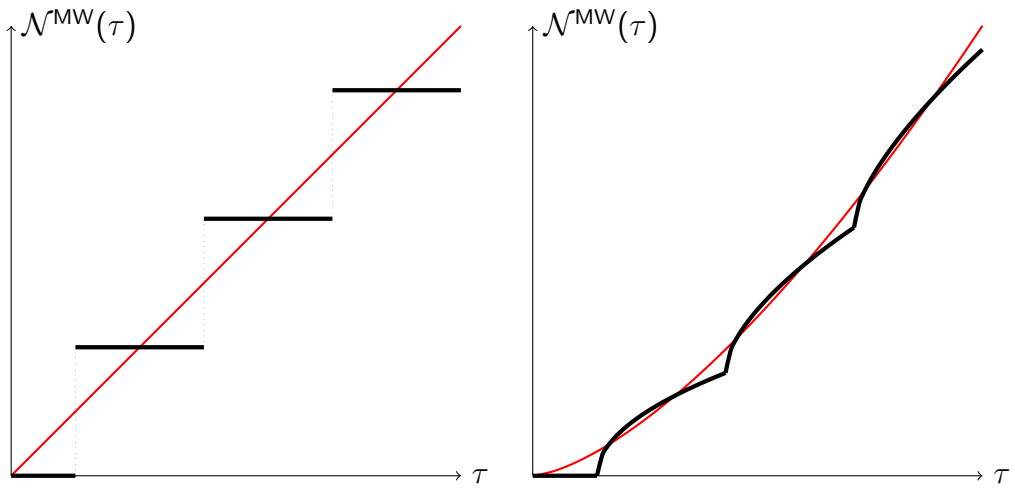
$$(13.2.11)' \qquad \mathsf{Spec}(A) = [\mu h(f_1 + ... + f_r) + V, \infty)\,.$$

Definition 13.2.2. (i) $h^{-d}\mathcal{N}^{\mathsf{MW}}(\tau, \mu h)$ is called *Magnetic Weyl expression.*

(ii) The numbers

$$(13.2.12) \qquad \lambda(\alpha) := \sum_{1\le j\le r} (2\alpha_j + 1)\mu h f_j + V$$

with $\alpha \in \mathbb{Z}^{+r}$ are called *Landau levels.*



(a) $d = 2$ (b) $d = 3$

Figure 13.1: Graph of $\mathcal{N}^{\mathsf{MW}}(\tau)$; red line shows graph of $\mathcal{N}^{\mathsf{W}}(\tau)$

Corollary 13.2.3. *In the framework of Theorem 13.2.1*

(i) Let $d = 2$ and $F_{12} \ne 0$. Then the spectrum of A is pure point of infinite multiplicity, is equal to $\{(2j + 1)\mu hF,\ j \in \mathbb{Z}^+\}$ and

$$(13.2.9)_{(2)} \quad \mathcal{N}^{\mathsf{MW}}(\tau, \mu h) = \#\{j \in \mathbb{Z}^+ : (2j + 1)\mu hF + V \le \tau\} \cdot (2\pi)^{-1}\sqrt{g}(\mu h)F,$$

where

$$F = \frac{1}{\sqrt{g}}|F_{21}| \tag{13.2.13)$_{(2)}}$$

is the scalar intensity of the magnetic field.

(ii) Let $d = 3$ and $(F_{jk}) \neq 0$. Then the spectrum of A is absolutely continuous, is equal to $[\mu hF, \infty]$ and

$$\mathcal{N}^{\mathsf{MW}}(\tau, \mu h) = \sum_{0\le j<\infty} \big(\tau - (2j+1)\mu hF - V\big)_+^{\frac{1}{2}} \mu hF \cdot (2\pi)^{-2}\sqrt{g} \tag{13.2.9)$_{(3)}}$$

where

$$F = \big(\sum_{j,k} g_{jk}F^jF^k\big)^{\frac{1}{2}} = \frac{1}{2}\big(\sum_{j,k,l,m} g^{jk}g^{lm}F_{jl}F_{km}\big)^{\frac{1}{2}} \tag{13.2.13)$_{(3)}}$$

is the scalar intensity of the magnetic field,

$$F^j = \sum_{k,l} \frac{1}{2}\varepsilon^{jkl}F_{kl} \tag{13.2.14}$$

is the vector intensity of the magnetic field;

(13.2.15) *(ε^{jkl}) is the absolutely skew-symmetric tensor with $\varepsilon^{123} = 1/\sqrt{g}$, $(g_{jk}) = (g^{jk})^{-1}$.*

Proof of Theorem 13.2.1. One can see easily that under a coordinate change $\mathcal{N}^{\mathsf{MW}}$ changes as a density; we know that $e(x, x, \tau)$ also changes as a density and therefore we can make a linear coordinate change by which we can arrange $g^{jk} = \delta_{jk}$; then by an orthogonal coordinate change we can reduce (F_{jk}) to the canonical form for skew-symmetric matrices: $F_{2l-1,2l} = f_l$, $F_{2l,2l-1} = -f_l$ for $l = 1, \dots, r$ and all the other elements of F_{jk} vanish.

Further, without any loss of the generality one can assume that V_j are linear functions, $V_{2l} = -f_l x_{2l-1}$, $l = 1, \dots, r$ and all the other components of the vector potential vanish; we can obtain this by a gauge transform.

Furthermore, without any loss of the generality we can assume that $V = 0$ (otherwise we replace V by 0 and τ by $(\tau - V)$), that $h = 1$ (otherwise we

divide A and τ by h^2, i.e., we replace h, μ, τ, V by 1, μh^{-1}, τh^{-2} and Vh^{-2} respectively) and that $\mu = 1$ (otherwise we include μ in V_j); the statements of our theorem is invariant with respect to all these transformations.

So we need to consider a toy-model operator

$$A = \sum_{1\le j\le r} \Bigl(D_{2j-1}^2 + (D_{2j} + x_{2j-1}f_j)^2\Bigr) + \sum_{2r+1\le j\le d} D_j^2. \tag{13.2.16}$$

Let $x' = (x_1, x_3, \dots, x_{2r-1})$, $x'' = (x_2, x_4, \dots, x_{2r})$ and $x''' = (x_{2r+1}, \dots, x_d)$. Let us make Fourier transformation $x'' \to \xi'', x''' \to \xi'''$; then A will be transformed into operator

$$A_I = \sum_{1\le j\le r} \Bigl(D_{2j-1}^2 + (x_{2j-1}f_j + \xi_{2j})^2\Bigr) + |\xi'''|^2. \tag{13.2.17}$$

Further, let us change coordinates $\tilde{x}_{2j-1} = \frac{1}{\sqrt{f_j}}(x_{2j-1}f_j + \xi_{2j})$; then we obtain operator

$$A_{II} = \sum_{1\le j\le r} f_j(D_{2j-1}^2 + x_{2j-1}^2) + |\xi'''|^2. \tag{13.2.18}$$

The operators $(D_{2j-1}^2 + x_{2j-1}^2)$ are harmonic oscillators with eigenvalues $(2k+1)$, $k \in \mathbb{Z}^+$ and with the corresponding eigenfunctions υ_k which are Hermite functions[1)]. Then the Schwartz kernel of the spectral projector of A_{II} is

$$e_{II}(x', \xi'', \xi'''; y', \eta'', \eta'''; \tau) = \sum_{\alpha} \upsilon_\alpha(x')\upsilon_\alpha(y')\delta(\xi'' - \eta'')\delta(\xi''' - \eta''') \tag{13.2.19}$$

where

$$\upsilon_\alpha(x') := \prod_{1\le j\le r} \upsilon_{\alpha_j}(x_{2j-1}) \tag{13.2.20}$$

and we sum in (13.2.19) with respect to $\alpha \in \mathbb{Z}^{+r}$ such that

$$\sum_{1\le j\le r} (2\alpha_j + 1)f_j + |\xi'''|^2 < \tau. \tag{13.2.21}$$

[1)] We take orthonormal and real-valued Hermite functions.

Then the Schwartz kernel of the spectral projector of A_l is

$$e_l(x',\xi'',\xi''';y',\eta'',\eta''';\tau) = \sum_{\alpha} \upsilon_\alpha(\tilde{x}')\upsilon_\alpha(\tilde{y}')(f_1\cdots f_r)^{\frac{1}{2}}\delta(\xi''-\eta'')\delta(\xi'''-\eta''') \tag{13.2.22}$$

with

$$\tilde{x}_{2j-1} = \frac{1}{\sqrt{f_j}}(x_{2j-1}f_j + \xi_{2j}) \tag{13.2.23}$$

and therefore

$$e(x,y,\tau) = (2\pi)^{r-d}\sum_{\alpha}\iint \upsilon_\alpha(\tilde{x}')\upsilon_\alpha(\tilde{y}')(f_1\cdots f_r)^{\frac{1}{2}}\times e^{i\langle x''-y'',\xi''\rangle+\langle x'''-y''',\xi'''\rangle}\,dx''d\xi''' \tag{13.2.24}$$

where we sum with respect to $\alpha\in\mathbb{Z}^{+r}$ and integrate with respect to $\xi''\in\mathbb{R}^r$ and $\xi'''\in\mathbb{R}^{d-2r}$ such that (13.2.21) holds. Let us set $x=y$; going from integration with respect to ξ'' to integration with respect to $\tilde{x}'$ (see (13.2.23) we obtain that

$$\int \upsilon_\alpha(\tilde{x}')^2\,d\xi'' = (f_1\cdots f_r)^{\frac{1}{2}}$$

and therefore

$$e(x,x,\tau) = (2\pi)^{r-d}\sum_{\alpha\in(\mathbb{Z}^+)^r}\int d\xi'''\cdot f_1\cdots f_r$$

where we sum with respect to $\alpha\in(\mathbb{Z}^+)^r$ and integrate with respect to $\xi''\in\mathbb{R}^r$ and $\xi'''\in\mathbb{R}^{d-2r}$ such that (13.2.21) holds; this formula implies (13.2.9).

Statement (i) is proven; Statements (ii) and (iii) follow immediately from it. □

Magnetic Weyl Expression vs (Standard) Weyl Expression

Let us compare magnetic Weyl expression $\mathcal{N}^{\mathsf{MW}}(\tau,\hbar)$ defined by (13.2.9) and the standard Weyl expression

$$\mathcal{N}^{\mathsf{W}}(\tau) \coloneqq (2\pi)^{-d}\varpi_d\sqrt{g}\big(\tau-V\big)_+^{\frac{d}{2}} \tag{13.2.25}$$

(which is also formula (13.2.9) with $r = 0$).

Without any loss of the generality one can assume that $V = 0$. Let us notice that the right-hand expression in (13.2.9) can be treated as a Riemann integral sum for the r-dimensional integral of the function

$$\varphi(z) = (2\pi)^{r-d}2^{-r}\varpi_{d-2r}\sqrt{g}\big(\tau - f_1z_1 - ... - f_rz_r\big)_+^{\frac{d-2r}{2}} f_1\cdots f_r \tag{13.2.26}$$

with respect to $z \in \mathbb{R}^{+r}$ with step $2\hbar$ on each variable z_j, $\hbar = \mu h$. Therefore as $\hbar \to 0$, $\mathcal{N}^{\mathsf{MW}}(\tau, \hbar)$ tends to the corresponding integral which is equal to (13.2.25).

The corresponding integral formula is accurate to the second order but the deduction that $\mathcal{N}^{\mathsf{MW}}(\tau, \hbar) = \mathcal{N}^{\mathsf{W}}(\tau) + O(\hbar^2)$ is not necessarily true because the function φ is not necessarily smooth enough.

So we must treat this formula with more care if needed and with better precision if possible. First of all note[2)] that for one-dimensional smooth function φ

$$\Phi_1 := 2\hbar \sum_{0\le\alpha\le N-1} \varphi\big((2\alpha+1)\hbar\big) \sim \sum_{n\ge 0} c_n\hbar^{2n}\int_0^a \varphi^{(2n)}(z)\,dz \sim \int_0^a \varphi(z)\,dz + \sum_{n\ge 1} c_n\hbar^{2n}\varphi^{(2n-1)}(z)\Big|_{z=0}^{z=a} \tag{13.2.27}$$

with absolute constants c_k, $c_0 = 1$ and $c_1 = -\frac{1}{6}$, $a = 2N\hbar$.

Then after easy calculations we arrive to the *formal decomposition*

$$\mathcal{N}^{\mathsf{MW}}(\tau, \hbar) \sim \sum_{n\ge 0} \kappa_n\hbar^{2n}\tau^{\frac{d}{2}-2n} \tag{13.2.28}$$

with

$$\kappa_0 = \mathcal{N}^{\mathsf{W}}(1), \qquad \kappa_1 = -\frac{1}{6}\big(f_1^2 + ... + f_r^2\big)\big(\partial_\tau^2\mathcal{N}^{\mathsf{W}}(\tau)\big)\big|_{\tau=1}. \tag{13.2.29}$$

Let us find out an actual error in (13.2.28).

Proposition 13.2.4. *Formula* (13.2.28) *holds with an error* $O(\tau^{d/2-l}\hbar^l)$, $l = \frac{1}{2}(d-2r)+1$ *and one should take summation* $n \le N-1$ *with* $N = \lceil \frac{1}{4}(d-2r+2)\rceil$.

[2)] This well-known formula of numerical integration is an easy first year Calculus exercise.

Proof. Without any loss of the generality one can assume that $\tau \asymp 1$ (and even $\tau = 1$). Note that if

$$\rho(z) := \tau - \bigl(f_1 z_1 + ... + f_r z_r\bigr) > \hbar \tag{13.2.30}$$

for $z = (z_1, ..., z_r)$, $z_j = (2\alpha_j + 1)\hbar$ then both inequalities $\epsilon_0 \rho(z) \le \rho(z') \le c\rho(z)$ hold for all points z, z' belonging to the box

$$\Omega_\alpha := \bigl\{z : (2\alpha_j - 1)\hbar \le z_j \le (2\alpha_j)\hbar \quad \forall j\bigr\}$$

and hence the error of our integral formula in this box does not exceed

$$C\hbar^{2N} \int_{\Omega_\alpha} \rho(z)^{\frac{1}{2}(d-2r)-2N}\, dz.$$

After summation over all such boxes we arrive to the same expression with an integral over zone described by (13.2.30) which is $O(\hbar^{2N})$ and $O(\hbar^l)$ as $\frac{1}{2}(d-2r) - 2N > -1$ and $\frac{1}{2}(d-2r) - 2N < -1$ respectively.

As $\frac{1}{2}(d-2r) - 2N = -1$ we get $O(\hbar^{2N}|\log\hbar|)$. However we simply increase N and notice that the newly acquired term simply vanishes. So, due to the choice of N we get $O(\hbar^l)$.

On the other hand, in zone where (13.2.30) is violated $|\varphi(z)| \le C\hbar^{\frac{1}{2}(d-2r)}$ and the total volume of this zone is $O(\hbar)$; then contribution of this zone to asymptotics is $O(\hbar^l)$ as well. □

One can ask if an error is actually less than $O(\hbar^l)$.

Remark 13.2.5. (i) As $d = 2$, $r = 1$ $\mathcal{N}^{\mathsf{MW}}(\tau, \hbar)$ is a jump function and an uniform with respect to τ error cannot be better than $O(\hbar)$. The same is true as $d = 2r$, $r \ge 2$ and $f_1, ..., f_r$ are commensurable and may be not true otherwise.

(ii) As $d = 3$, $r = 1$ one cannot improve error estimate $O(\hbar^{\frac{3}{2}})$ either. Really, formula $(13.2.9)_{(3)}$ yields that as $\tau = (2m+1)\hbar f \asymp 1$, $m \in \mathbb{Z}^+$, $\delta > 0$

$$\mathcal{N}^{\mathsf{MW}}(\tau + \delta\hbar) \ge \mathcal{N}^{\mathsf{MW}}(\tau, \hbar) + c_1\sqrt{\tau}\delta\hbar + c_2\hbar^{\frac{3}{2}}\sqrt{\delta} + O(\hbar^{\frac{3}{2}}\delta)$$

with positive constants c_1 and c_2; on the other hand

$$\mathcal{N}^{\mathsf{W}}(\tau + \delta\hbar) = \mathcal{N}^{\mathsf{W}}(\tau) + c_1\sqrt{\tau}\delta\hbar + O(\hbar^2\delta^2)$$

and therefore the error estimate $O(\hbar^{\frac{3}{2}})$ is the best possible in either τ or $\tau + \delta\hbar$.

We leave to the reader

Problem 13.2.6. (i) Examine the general case $d > 2r$ as *either* $r = 1$ *or* $r \ge 2$ and $f_1, \dots, f_r$ are commensurable.

(ii) Examine the Riesz means.

(iii) Prove the similar results[3)] for *modified Magnetic Weyl expression* which will appear later for magnetic Schrödinger-Pauli and magnetic Dirac operators:

$$(13.2.9)' \quad \mathcal{N}^{\mathsf{MW}}(\tau, \mu h) := (2\pi)^{r-d}\varpi_{d-2r}\sqrt{g}\times \sum_{\alpha\in\mathbb{Z}^{+r}} 2^{-\#\{j:\alpha_j=0\}}\Big(\tau - \sum_{1\le j\le r} 2\alpha_j\mu h f_j - V\Big)_+^{\frac{d-2r}{2}} f_1\cdots f_r(\mu h)^r.$$

Dynamics

Consider classical dynamics for the toy-model operator; without any loss of the generality one can assume that it is in the form (13.2.16) with f_j replaced by μf_j and we assume only that $fj \ne 0$.

(i) As $d = 2$, $r = 1$ we get $\pi f^{-1}\mu^{-1}$-periodic movements[4)]

$$(13.2.31) \qquad x_1 = \bar{x}_1 + \mu^{-1}a\cos(2\mu ft), \qquad x_2 = \bar{x}_2 + \mu^{-1}a\sin(2\mu ft),$$

$$(13.2.32) \qquad \xi_1 = -af\sin(2\mu ft), \qquad \xi_2 = -\mu f\bar{x}_1$$

where (13.2.31) is gauge invariant and describes circular movement, $\bar{x}$ is the center of the circle, $\mu^{-1}a$ its radius. Note that (13.2.32) are not gauge invariant and as one transforms terms $\xi_1^2 + (\xi_2 + \mu f x_1)^2$ to more symmetric form

$$(13.2.33) \qquad \big(\xi_1 - \frac{1}{2}\mu f x_2\big)^2 + \big(\xi_2 + \frac{1}{2}\mu f x_1\big)^2$$

we arrive to

$$(13.2.32)' \quad \xi_1 = \frac{1}{2}\mu f\bar{x}_2 - \frac{1}{2}af\sin(2\mu ft), \qquad \xi_2 = -\frac{1}{2}\mu f\bar{x}_1 + \frac{1}{2}af\cos(2\mu ft).$$

[3)] With $-\frac{1}{6}$ replaced by $\frac{1}{3}$.

[4)] Meanwhile quantum dynamics is only $2\pi f^{-1}\mu^{-1}$-periodic.

Note that

$$p_1 := \xi_1 - \frac{1}{2}\mu f x_2, \qquad p_2 := \xi_2 + \frac{1}{2}\mu f x_1 \tag{13.2.34}$$

then evolve as

$$p_1 = -af\sin(2\mu f t), \qquad p_2 = af\cos(2\mu f t) \tag{13.2.35}$$

independently from gauge transform and energy is $\tau = a^2 f^2$.

Meanwhile *angular momentum with respect to* $\bar{x}$ is

$$M := (x_1 - \bar{x}_1)p_2 - (x_2 - \bar{x}_2)p_1 = \mu^{-1}a^2 f. \tag{13.2.36}$$

(ii) As $d = 2r$, $r \ge 2$ we have the same equations for x_{2j-1}, x_{2j}, ξ_{2j-1}, ξ_{2j}, p_{2j-1}, p_{2j} with a and f replaced by f_j and p_j respectively, $j = 1, \dots, r$. Then we conclude that the dynamics is periodic if and only if $f_1, \dots, f_r$ are commensurable[5)] and quasiperiodic otherwise. While it does not affect the nature of the spectrum, it affects its distribution. In this case energy is $\tau = \sum_j a_j^2 f_j^2$.

(iii) As $d > 2r$ in addition to *magnetic coordinates* $x_1, \dots, x_{2r}$ *free coordinates* $x_{2r+1}, \dots, x_d$ appear with evolution

$$\xi_k = \bar{\xi}_k, \qquad x_k = \bar{x}_k + \bar{\xi}_k t \qquad k = 2r+1, \dots, d. \tag{13.2.37}$$

So dynamics is no more periodic at all (with the possible exception as $\bar{\xi}_{2r+1} = \dots \bar{\xi}_d = 0$). In this case energy is

$$\tau = \sum_{1 \le j \le r} a_j^2 f_j^2 + \sum_{2r+1 \le k \le d} \xi_k^2 \tag{13.2.38}$$

Lines described by (13.2.37) (with $x_k = \mathsf{const}$ as $k = 1, \dots, 2r$) are called *magnetic lines*. Their directions form $\mathsf{Ker}\, F$ where $F = (F_{jk})$ is a matrix intensity of the magnetic field. In particular, as $d = 3$, $r = 1$ magnetic lines are integral curves of the vector intensity of the magnetic field (which is constant in our case).

[5)] If $f_j \in \mathbb{Z}f$ for all $j = 1, \dots, r$ then the classical dynamics is $\pi\mu^{-1}f^{-1}$-periodic while quantum dynamics $\pi\mu^{-1}f^{-1}$-periodic as r is even and only $2\pi\mu^{-1}f^{-1}$-periodic as r is odd.

(iv) Let us perturb the toy-model operator by a constant electric field i.e. by the linear potential $V(x) = -\langle \boldsymbol{e}, x\rangle$. As each pair of magnetic variables and each free variable are affected separately, we consider only case $d = 2$, $r = 1$.

Then we have

$$\frac{d}{dt}x_1 = 2p_1, \qquad \frac{d}{dt}x_2 = 2p_2 \tag{13.2.39}$$

$$\frac{d}{dt}p_1 = -2\mu f p_2 + e_1, \qquad \frac{d}{dt}p_2 = 2\mu f p_1 + e_2 \tag{13.2.40}$$

and the second pair of equations implies

$$p_1 = -\frac{1}{2}\mu^{-1}f^{-1}e_2 - af\sin(2\mu ft), \qquad p_2 = \frac{1}{2}\mu^{-1}f^{-1}e_1 + af\cos(2\mu ft) \tag{13.2.35)*}$$

while the first pair of equations then implies

$$x_1 = \bar{x}_1 + \mu^{-1}a\cos(2\mu ft) - \mu^{-1}f^{-1}e_2 t, \qquad x_2 = \bar{x}_2 + \mu^{-1}a\sin(2\mu ft) + \mu^{-1}f^{-1}e_1 t. \tag{13.2.31)*}$$

Therefore we have an additional *drift* with the velocity $\mu^{-1}f^{-1}\boldsymbol{e}^{\perp} = \mu^{-1}F^{-1}\boldsymbol{e}$ with $\boldsymbol{e}^{\perp} = (-e_2, e_1)$ and F^{-1} inverse matrix to F.

Therefore, as $d = 2r$ magnetic drift has velocity $-\mu^{-1}F^{-1}\nabla V$. As $d > 2r$ there is a magnetic drift in magnetic variables and a movement with Hamiltonian $(|\xi_k|^2 - e_k x_k)$ in each of the free variables.

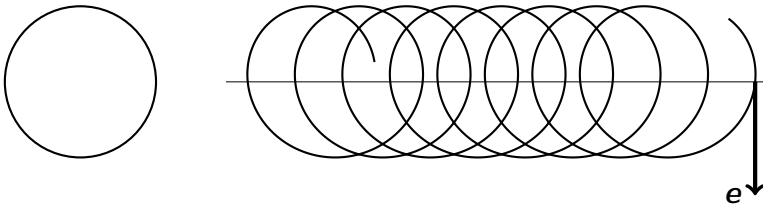
13.2.3 Rough Estimates

Functional Analytic Arguments

Let us now turn to functional analytic arguments.

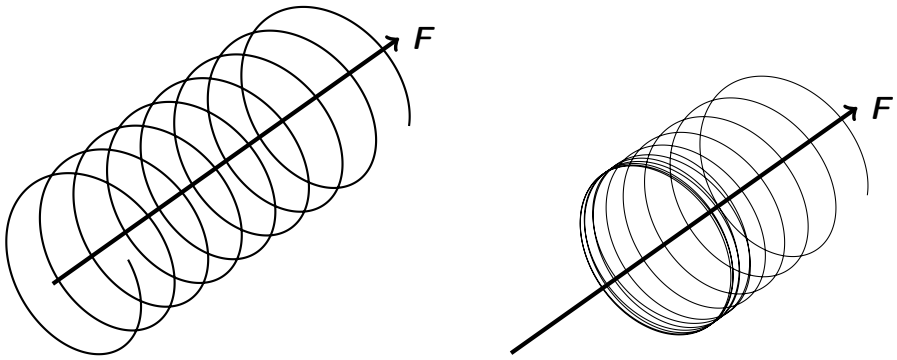
Theorem 13.2.7. *Let conditions* (13.2.1)–(13.2.4) *be fulfilled with* $K > \frac{d}{2}$. *Let* $h \in (0, 1]$, $\mu \geq 1$. *Assume that operator* A *is self-adjoint and that* $u \in \mathscr{C}_0^2(B(0,1))$ *belongs to* $\mathfrak{D}(A)$ *if and only if* $u|_{\partial X} = 0$ [6]. *Then* $U(x, y, t)$,

[6] In this theorem we do not assume that condition (13.2.5) is fulfilled.



(a) Periodic (b) Drift

Figure 13.2: Trajectories for 2-dimensional model operator:
(a) Unperturbed (b) Perturbed by a constant electric field



(a) Helix (b) Deformed helix

Figure 13.3: Trajectories for 3-dimensional model operator:
(a) Unperturbed (b) Perturbed by a constant electric field parallel to magnetic lines: non-uniform movement along magnetic lines; drift is negligible in comparison

the Schwartz kernel of $\exp(ith^{-1}A)$*, satisfies*

$$(13.2.41)\quad |F_{t\to h^{-1}\tau}\chi_{T,T'}(t)U(x,y,t)| \le C'Th^s\mu^{-s}(|\tau|+1)^{-s}$$
$$\forall x,y\in X\cap B(0,1-\epsilon)\quad \forall \tau \le \inf_{X\cap B(0,1)}(V+\mu h\,\mathrm{Tr}^+(gF))-\epsilon(1+\mu h)$$

where

$$(13.2.42)\quad \mathrm{Tr}^+(gF) := \textstyle\sum_{1\le j\le r} f_j \text{ and } \pm if_j \text{ are all the eigenvalues of } ((gF)^k_j),$$
$f_j > 0$ [7)]

[7)] Note that $(gF)\sim g^{\frac12}Fg^{\frac12}$ which is skew-symmetric matrix.

and s, $\epsilon > 0$, $T > \epsilon_0 h^{1-\delta}$, $\delta > 0$, T' *are arbitrary and* $C' = C'(d, c, \delta, \epsilon, s)$.

Proof. Let us note that the proof of Proposition 4.2.6 obviously yields estimate

$$\|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)U\| \le C' T \mu^L h^{-L}(|\tau|+1)^L \qquad \forall x \in X \cap B(0, 1-\epsilon) \quad \forall \tau \in \mathbb{R} \tag{13.2.43}$$

where $L = d/2$ and in the left-hand expression the $\mathscr{L}^2$-norm with respect to y is calculated, also the same estimate with permuted x and y and also estimate

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)U(x,y,t)| \le C' T \mu^L h^{-L}(|\tau|+1)^L \qquad \forall x, y \in X \cap B(0, 1-\epsilon) \quad \forall \tau \in \mathbb{R} \tag{13.2.44}$$

with $L = d$; moreover, this proof yields similar estimates with $F_{t\to h^{-1}\tau}\chi_{T,T'}(t)U$ replaced by $e(x, y, -\infty, \tau)$.

The key in the forthcoming arguments is

Lemma 13.2.8. *If the conditions of Theorem 13.2.7 are fulfilled with* $K = 2$ *then*

$$\epsilon \sum_j \|P_j w\|^2 + \epsilon(\mu h + |\tau| + 1)\|w\|^2 \le C'\|(\tau - A)w\| \cdot \|w\| + C' h \|w\|^2 \tag{13.2.45}$$

$$\forall \tau \le \inf_{X\cap B(0,1)} (V + \mu h \,\mathsf{Tr}^+(gF)) - \epsilon(\mu h + 1)$$

$$\forall w \in \mathscr{C}^2(X \cap B(0,1)) : \ \mathsf{supp}(w) \subset B(0, 1-\epsilon),\ w|_{\partial X} = 0.$$

This lemma will be proven later; now let us finish the proof of Theorem 13.2.7. Let

$$v \in \mathfrak{D}(A), \qquad u = \exp(ith^{-1}A)v \tag{13.2.46}$$

Then equation and boundary condition

$$(hD_t - A)u = 0 \tag{13.2.47}$$

$$u|_{\partial X \cap B(0,1)} = 0, \tag{13.2.48}$$

Lemma 13.2.8 and the standard elliptic arguments with induction with respect to s yield estimate

$$\sum_j \|P_j \hat{w}\| + \|\hat{w}\| \le C' T \mu^{-s} h^s (|\tau|+1)^{-s} \|v\|$$

for $\hat{w} = F_{t\to h^{-1}\tau}\big(\chi_{T,T'}(t)\psi u\big)$ where $\psi \in \mathscr{C}_0^\infty(B(0,1-\epsilon))$ is arbitrary fixed function and constant C' also depends on ψ; at every step the support of ψ is decreased but remains arbitrary.

Then treating our equation and boundary condition (13.2.47)–(13.2.48) again we conclude by induction with respect to $m = 1, \dots, K$ that

$$\sum_{|\alpha|\le m} \|D^\alpha \psi \hat{w}\| \le C' T \mu^{-s} h^s (|\tau|+1)^{-s} \|v\| \tag{13.2.49}$$

where s decreases at every step but remains arbitrarily large. Then the embedding inequalities yield that the same estimate holds for $|\hat{w}(x,\tau)|$ with arbitrary $x \in X \cap B(0,1-\epsilon)$; recalling definition of $\hat{w}$ and that in (13.2.46) v is arbitrary we conclude that

$$\|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)U(x,.,t)\| \le C' T \mu^{-s} h^s (|\tau|+1)^{-s}$$

for every $x \in X \cap B(0,1-\epsilon)$ and for the indicated τ where in the left-hand expression the $\mathscr{L}^2$-norm with respect to y is calculated. The previous arguments with y instead of x and with $u(y,t) = U(x,y,t)$ with fixed x, the dual to (13.2.47) equation and estimate (13.2.44) prove theorem.

Proof of Lemma 13.2.8. Note that it is sufficient to prove that if all the assumptions of the lemma excluding the conditions on V are fulfilled and if

$$\inf(V + \mu h \operatorname{Tr}^+(gF)) \ge \epsilon(\mu h + 1) \tag{13.2.50}$$

then

$$(Aw, w) \ge C^{-1}\epsilon\Big(\sum_j \|P_j w\|^2 + (\mu h+1)\|w\|^2\Big) - Ch\|w\|^2. \tag{13.2.51}$$

Also note that it is sufficient to prove this inequality under the additional assumption that w is supported in $B(\bar{x},\varepsilon)$ with an arbitrarily small constant $\varepsilon > 0$. In fact, let ψ_ν^2 be an ε-admissible partition of unity; then

$$|(Aw,w) - \sum_\nu (A\psi_\nu w, \psi_\nu w)|$$

and

$$|\|P_j w\|^2 - \sum_\nu \|P_j \psi_\nu w\|^2|$$

do not exceed $Ch\varepsilon^{-1}\|w\|^2$ and therefore estimate (13.2.51) for w follows from the same estimate for $\psi_\nu w$.

Without any loss of the generality one can assume that $g^{jk} = \delta_{jk}$ at $\bar{x}$. Let $G = (G^{jk})$ be a real skew-symmetric matrix with operator norm (in $\mathcal{L}(\mathbb{R}^d, \mathbb{R}^d)$) equal to 1. Then

$$\sum_j \|P_j w\|^2 \geq |\sum_{j,k} (G^{jk} P_j w, P_k w)| = \frac{1}{2}|\sum_{j,k} (G^{jk}[P_k, P_j]w, w)| = \frac{1}{2}\mu h|\sum_{j,k} (G^{jk} F_{kj} w, w)|.$$

Note that one can choose G of the indicated type such $\sum_{j,k} G^{jk} F_{jk} = 2\,\mathsf{Tr}^+(gF)$; this is easy to do in the coordinate system in which (F_{kj}) is in the canonical form for skew-symmetric matrices, in which case $G^{jk} = -\operatorname{sgn}(F_{jk})$ is an appropriate matrix. Then the previous inequality implies that

$$\sum_j \|P_j w\|^2 \geq \mu h(\mathsf{Tr}^+(gF)w, w) - C\varepsilon\mu h\|w\|^2;$$

since $g^{jk} = \delta_{jk}$ we conclude that

$$(Aw, w) \geq \big((\mu h\, \mathsf{Tr}^+(gF) + V)w, w\big) - C\varepsilon\mu h\|w\|^2.$$

This inequality and (13.2.50) yield (13.2.51). □

Theorem 13.2.7 and the standard Tauberian arguments (see the proof of Proposition 4.2.6 again) yield

Theorem 13.2.9. *Let assumptions of Theorem 13.2.7 be fulfilled. Then*

$$|e(x, y, \tau)| \leq C'\mu^{-s} h^s (|\tau| + 1)^{-s} \quad \forall x, y \in X \cap B(0, 1-\epsilon) \quad \forall \tau \leq \inf_{(X \cap B(0,1))} (V + \mu h F) - \epsilon(\mu h + 1) \tag{13.2.52}$$

with the same s, ϵ and C' as in Theorem 13.2.7.

Remark 13.2.10. (i) Condition on τ in (13.2.41), (13.2.52) can be weakened for $d = 2, 3$ (see Sections 13.5, 13.6).

(ii) Now assumption

$$\mathsf{Tr}^+(gF) \geq \epsilon_0 \tag{13.2.53}$$

and the condition $\tau \leq c$ on the energy level yield that one can assume that $\mu h \leq C_0$. Hence without any loss of the generality one can assume that

$$\mu h \leq c_0. \tag{13.2.54}$$

(iii) However it would not be the case for Schrödinger-Pauli and Dirac operators. Moreover, as we will see in Subsection 13.8.2 and Chapter 14 that for degenerating magnetic field condition (13.2.54) is too restrictive and needs to be replaced by a weaker one.

Propagation of sSingularities

Let us now prove that singularities propagate with finite speed with respect to x at energy levels $\tau \leq c$.

Theorem 13.2.11. *Let assumptions of Theorem 13.2.7 be fulfilled. Then*

$$|F_{t\to h^{-1}\tau}\chi_T(t)U(x,y,t)| \leq C'h^s \tag{13.2.55}$$
$$\forall T \geq h^{1-\delta} \quad \forall x,y \in X \cap B(0, 1 - C_0T) : |x-y| \geq C_0T \quad \forall \tau \leq c$$

where $C_0 = C_0(c, \epsilon_0)$, $C' = C'(d, c, \epsilon_0, \delta, s)$, s *and* $\delta > 0$ *are arbitrary.*

Proof. Let us note that it is sufficient to prove this estimate only for $T \geq \epsilon$ with an arbitrarily small constant $\epsilon > 0$ and with C' also depending on ϵ. The generalization is made by the rescaling method (see the proof of Theorem 2.1.19).

Moreover, elliptic arguments (see the proof of Theorem 13.2.7) yield that it is sufficient to prove that if $\bar{x}, \bar{y} \in B(0, 1 - C_0T)$, $|\bar{x} - \bar{y}| \geq C_0T$, $\zeta \in \mathscr{L}^2(X \cap B(\bar{y}, \epsilon_1))$ with a small enough constant $\epsilon_1 > 0$ and $u = U(t)\zeta$ then

$$\|F_{t\to h^{-1}\tau}\chi_T(t)u\|_{X\cap B(\bar{x},\epsilon_1)} \leq C'h^s\|\zeta\| \qquad \forall T \in [\epsilon, T_0] \quad \forall \tau \leq c. \tag{13.2.56}$$

In order to prove this estimate we apply the method of the proof of Theorem 2.1.2.

Let $u^{\pm} = \theta(\pm t)u$, $v^{\pm} = \Phi(hD_t)\bar{\chi}(t)u^{\pm}$ where $\Phi \in \mathscr{C}^{\infty}(\mathbb{R})$ is fixed and supported in $[-\infty, 2c]$, $\Phi(\tau) = 1$ for $\tau \le \frac{3}{2}c$, $\bar{\chi} \in \mathscr{C}_0^{\infty}([-2T, 2T])$ and $\bar{\chi} = 1$ at $[-\frac{3}{2}T, \frac{3}{2}T]$. Then

$$(hD_t - A)v^{\pm} = \mp ih\Phi(hD_t)\delta(t)\zeta(x) \quad \text{for} \quad |t| \le T \tag{13.2.57}$$

modulo terms with $\mathscr{L}^2$-norm not exceeding $C'h^s$ where here and in what follows C' depends on all the auxiliary functions and constants.

Let $\phi \in \mathscr{C}^{\infty}(B(0,1))$ be real-valued and satisfy

$$|\nabla_x \phi| \le \varepsilon, \tag{13.2.58}$$

and

$$\phi < 0 \quad \text{provided either} \quad |x| \ge 1 - 2\epsilon_1 \text{ or } |x - y| \le 2\epsilon_1 \tag{13.2.59}$$

where $\varepsilon > 0$ will be chosen later.

Let $\chi_0 \in \mathscr{C}^{\infty}(\mathbb{R})$ be supported in $[-\infty, 1]$, $\chi_0(t) = 1$ for $t \le 0$ and $\chi_0 = \chi_1^2$, $\chi' = d\chi_0/dt = -\chi_2^2$ with real-valued functions $\chi_1, \chi_2 \in \mathscr{C}^{\infty}(\mathbb{R})$. Then for $\alpha = \alpha(c, \epsilon_0, \epsilon_1)$ function $\psi(x,t) = \chi_0(\alpha(t - \phi(x))$ belongs to $\mathscr{C}^{\infty}(B(0,1) \times \mathbb{R})$ and

$$\operatorname{supp}(\psi) \cap \{t \ge 0\} \subset \{|x| \le 1 - \epsilon_1, |x - y| \ge \epsilon_1\}.$$

Finally, let $\chi(t) = \chi_0(\gamma t)$ and $\chi_3(t) = \chi_0(-\gamma_1 t - 1)$. Then modulo terms with absolute value not exceeding $C'h^{2s}\|\zeta\|^2$

$$\begin{aligned} 0 \equiv 2\operatorname{Re}\big(i\Phi(hD_t)\delta(t)\zeta(x), e^{-2t}\chi\chi_3\psi v^+\big) \equiv \\ -h^{-1}\operatorname{Re} i([hD_t - A, e^{-2t}\chi\chi_3\psi]v^+, v^+) \equiv \\ \operatorname{Re}(2\chi\chi_3\psi e^{-2t}v^+, v^+) - \operatorname{Re}(\chi'\chi_3\psi e^{-2t}v^+, v^+) - \\ \operatorname{Re} i(h^{-1}[hD_t - A, \psi]e^{-2t}\chi\chi_3 v^+, v^+) \ge \\ 2\|(\chi\chi_3\psi)^{\frac{1}{2}}e^{-t}v^+\|^2 - \operatorname{Re} i(h^{-1}[hD_t - A, \psi]e^{-2t}\chi\chi_3 v^+, v^+) \end{aligned} \tag{13.2.60}$$

where $(.,.)$ and $\|.\|$ denote the inner product and the norm in $\mathscr{L}^2(X \times \mathbb{R})$.

Let us consider the second term in the right-hand expression; it is equal to

$$\alpha \operatorname{Re}\big((I + B)w^+, w^+\big) + h(\Psi v^+, v^+)$$

where $B = -2\sum_{j,k} g^{jk}(D_j\phi)P_k$, $w^+ = e^{-t}\psi_2(\chi\chi_3)^{\frac12}v^+$, $\psi_2 = \chi_2(\alpha(t-\phi))$ and $\Psi_{\dots}$ here and in what follows denotes a $\mathscr{C}^\infty$-function supported in $\mathsf{supp}(\chi\chi_3\psi)$.

Then assumption (13.2.58) yields that

$$
\begin{aligned}
(13.2.61)\quad |(Bw^+, w^+)| &\le C_0\varepsilon\bigl(\|w^+\|^2 + (g^{jk}P_jw^+, P_kw^+)\bigr) \le \\
&C_0\varepsilon\bigl(\|w^+\|^2 + (Aw^+, w^+)\bigr) \le \\
&C_0\varepsilon\bigl(\|w^+\|^2 + (Av^+, e^{-2t}\chi\chi_3\psi_2^2v^+)\bigr) + h(\Psi'v^+, v^+)
\end{aligned}
$$

where we change C_0 if necessary.

On the other hand, (13.2.57), the definition of ψ_2 and (13.2.59) yield that

$$
\begin{aligned}
(13.2.62)\quad (Av^+, e^{-2t}\chi\chi_3\psi_2^2v^+) &\equiv (hD_tv^+, e^{-2t}\chi\chi_3\psi_2^2v^+) \equiv \\
&\bigl(hD_t\Phi(hD_t)(\chi\chi_3)^{\frac12}\psi_2u^+, \Phi(hD_t)(\chi\chi_3)^{\frac12}\psi_2u^+\bigr) + \\
&\sum_{n\ge1} h^n(\Phi_n(hD_t)\Psi_nu^+, u^+)
\end{aligned}
$$

where $\Phi_n \in \mathscr{C}_0^\infty([c, 2c])$ and $\Psi_n \in \mathscr{C}^\infty$ are supported in $\mathsf{supp}(\chi\chi_3\psi)$. The first term in the right-hand expression of (13.2.62) does not exceed

$$
\|\Phi(hD_t)(\chi\chi_3)^{1/2}\psi_2u^+\| \equiv 2c\|w^+\|^2 + \sum_{n\ge1} h^n(\Phi_n(hD_t)\Psi_nu^+, u^+)
$$

where we change Φ_n and Ψ_n if necessary. Then (13.2.61) and (13.2.62) yield that

$$
|(Bw^+, w^+)| \le \frac14 C_0\varepsilon\|w^+\|^2 + \sum_{n\ge1} h^n(\Phi_n(hD_t)\Psi_nu^+, u^+)
$$

and then (13.2.60) yields that for $\varepsilon \le 1/(3C_0)$

$$
\|(\chi\chi_3\psi)^{\frac12}e^{-t}v^+\|^2 \le \sum_{n\ge1} h^n(\Phi_n(hD_t)\Psi_nu^+, u^+) + C'h^{2s}\|\zeta\|^2.
$$

Moreover, one can allow Φ and Ψ to be smooth functions here (nevertheless these functions were not smooth when they appeared the first time).

Using this inequality and applying induction with respect to s (where the supports of χ_0 and Φ are decreased at each step) we can easily prove that if ϕ satisfies (13.2.58) and (13.2.59) with $\varepsilon = 1/(3C_0)$ then for $T \in [\epsilon, T_0]$

$$
\|\Phi(hD_t)\chi_T(t)\chi_1(\alpha(t-\phi))u^+\| \le C'h^s\|\zeta\|.
$$

Since we can arbitrarily choose ϕ satisfying (13.2.58) and (13.2.59) with $\varepsilon = 1/(3C_0)$ we obtain (13.2.56). □

Remark 13.2.12. (i) In this chapter for $d = 2, 3$ using microlocal canonical form we will essentially improve Theorems 13.2.7 and 13.2.11 (assuming that the coefficients are smooth enough).

(ii) Later we will improve these theorems in the higher dimensions.

Let us conclude this section with the following assertion on the support of singularities:

Theorem 13.2.13. *Let conditions* (13.2.1)–(13.2.5) *be fulfilled with* $K = K(d, s)$. *Let* $q \in \mathsf{S}^0_{h,\rho,1,K}$, $\mu h \le 1$, $\rho \ge 1$,

$$\rho \ge \mu^{\frac{1}{2}} h^{\frac{1}{2}-\delta} \tag{13.2.63}$$

with $\delta > 0$ *and let* q *be supported in* $\{|\xi| \ge C_0\rho\}$. *Let*

$$Q = q(x, hD_1 - \mu V_1, \dots, hD_d - \mu V_d)$$

be an operator with symbol $Q(x,\xi) = q(x, h\xi_1 - \mu V_1(x), \dots, h\xi_d - \mu V_d(x))$.

Further, let $\psi \in \mathscr{C}_0^K(B(0, 1-\epsilon))$. *Then*

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q\psi U| \le C'MTh^s(|\tau|+1)^{-s} \qquad \forall x, y \in X \cap B(0, 1-\epsilon) \quad \forall \tau \le c \tag{13.2.64}$$

where $T \ge h^{1-\delta}$, T', $\epsilon > 0$, $\delta > 0$ *and* s *are arbitrary,* $C_0 = C_0(c, \epsilon_0)$, $K = K(d, \delta, s)$, $C' = C'(d, c, \epsilon_0, \epsilon, \delta, s)$ *and* $M = \|\psi\| \cdot \|\!|q|\!\|$.

Proof. The proof is standard elliptic, based on the equation (13.2.47), estimates (13.2.41), (13.2.43) and the ellipticity of the operator $(hD_t - A)$ as $\tau \le c$ and $\sum_j |\xi_j - \mu V_j|^2 \ge C_0^2$.

It should be mentioned that the condition (13.2.63) is necessary to obtain $Q(x,\xi) \in \mathsf{S}^0_{h,\rho_1,\rho_2,K}$ with $\rho_1 \ge 1$, $\rho_2 \in (0, 1]$, $\rho_1\rho_2 \ge h^{-\delta'}$ with $\delta' > 0$; this condition is essential only for $\mu \in [h^{\delta-1}, h^{-1}]$. □

13.3 Microlocal Canonical Form

In this section for $d = 2, 3$ we construct the microlocal canonical form for operator (13.2.1) satisfying conditions (13.2.2)–(13.2.4) and

$$F \geq \epsilon_0 \tag{13.3.1}$$

in the ball $B(0,1) \subset X$ where F is the scalar intensity of the magnetic field.

13.3.1 Symplectic Canonical Form

Let us multiply operator (13.2.1) by μ^{-2} and then note that $\mu^{-2}A$ is a $\mu^{-1}h$-differential operator

$$\mu^{-2}A = \sum_{j,k} (\mu^{-1}hD_j - V_j) g^{jk} (\mu^{-1}hD_k - V_k) + \mu^{-2}V) \tag{13.3.2}$$

with principal symbol

$$a_\varepsilon(x,\xi) = a(x,\xi) + \varepsilon V, \qquad \varepsilon = \mu^{-2}, \tag{13.3.3}$$

with

$$a(x,\xi) = \sum_{j,k} g^{jk} (\xi_j - V_j)(\xi_k - V_k). \tag{13.3.4}$$

Symplectic Canonical Form: $\varepsilon = 0$

Let us first treat the symbol $a(x,\xi)$; conditions (13.2.1)–(13.2.4) yield that $a \geq 0$ and the stationary set of a is

$$\Lambda = \{(x,\xi) : \ da(x,\xi) = 0\} = \{(x,\xi) : \ a(x,\xi) = 0\} = \{(x,\xi) : \ \xi_j = V_j(x) \quad \forall j = 1, \dots, d\} \tag{13.3.5}$$

which is a d-dimensional $\mathscr{C}^K$ manifold. Moreover, (13.3.1) yields that

(13.3.6) For $d = 2$, Λ is a symplectic manifold

and

(13.3.7) For $d = 3$ the restriction to Λ of the symplectic form has constant rank 2 and therefore there exists a unique (modulo a scalar factor) vector field on Λ which is tangent and symplectically orthogonal to Λ at the same time.

This field is the Hamiltonian field generated by

$$F(x,\xi) := \sum_j F^j(\xi_j - V_j) \tag{13.3.8}$$

where F^j are the components of the vector intensity of the magnetic field.

For $d \geq 4$ conditions (13.2.1)–(13.2.4) and (13.3.1) do not completely fix the structure of Λ.

Proposition 13.3.1. *Let conditions* (13.2.1)–(13.2.4) *and* (13.3.1) *be fulfilled. Then*

(i) For $d = 2$ there exists a symplectomorphism Ψ^{-1} of a neighborhood $\mathcal{W}$ of every point $z \in \Lambda$ to a neighborhood $\mathcal{U}$ of

$$\Lambda^0 = \{(x,\xi) : \ x_2 = \xi_2 = 0, (x_1,\xi_1) \in \bar{\Omega}\} \tag{13.3.9}$$

where Ω is a domain in $\mathbb{R}^2$ such that the inverse symplectomorphism Ψ has the following properties:

$$\Psi(\Lambda^0) = \Lambda \cap \mathcal{U}, \tag{13.3.10}$$

$$a \circ \Psi \equiv \sum_{1 \leq n \leq N-1} b_n(x_1,\xi_1)(x_2^2 + \xi_2^2)^n \qquad \mathrm{mod}\ O_{2N-1}(\Lambda^0) \tag{13.3.11}$$

where $O_M(\Lambda)$ is the set of functions vanishing together with all their derivatives up to order $(M-1)$ on Λ; moreover,

$$b_1 = F \circ \bar{\Psi}, \tag{13.3.12}$$

and

$$\bar{\Psi}^{-1*}(dx' \wedge d\xi_1) = F\sqrt{g}\,dx \tag{13.3.13}$$

where $\bar{\Psi} : \Lambda^0 \to \Lambda$ is the restriction of Ψ to Λ^0 and $\bar{\Psi}^*$ is the induced map of densities, and $x' = x_1$, $dx' = dx_1$ for $d = 2$.

(ii) For $d = 3$ there exists a symplectomorphism Ψ^{-1} of a neighborhood $\mathcal{W}$ of every non-closed Hamiltonian trajectory Γ of the finite length generated by the Hamiltonian $F(x,\xi)$ and lying on Λ to a neighborhood of

$$\Lambda^0 = \{(x,\xi) : \ x_3 = \xi_3 = 0, (x_1, x_2, \xi_1) \in \bar{\Omega}\} \tag{13.3.14}$$

where Ω is a domain in $\mathbb{R}^3$ such that the inverse symplectomorphism Ψ satisfies (13.3.10),

$$a \circ \Psi \equiv \xi_2^2 + \sum_{1\le n\le N-1} b_n(x', \xi_1)(x_3^2 + \xi_3^2)^n \qquad \mathsf{mod}\ O_{2N-1}(\Lambda^0), \tag{13.3.15}$$

and also both (13.3.12) *and* (13.3.13) *where $x' = (x_1, x_2)$, $dx' = dx_1 \wedge dx_2$ for $d = 3$.*

(iii) In (i) for $F = \mathsf{const}$

$$b_2 = \frac{1}{8} F \kappa \circ \bar{\Psi} \tag{13.3.16}$$

where κ is the scalar curvature corresponding to the metrics $g^{jk}F^{-1}$.

Remark 13.3.2. (i) In this proposition N is arbitrary and $K = K(N)$ in condition (13.2.3); moreover, $b_n \in \mathscr{C}^N$. Therefore (13.3.11) and (13.3.15) hold with O_{2N} instead of O_{2N-1}.

(ii) It follows from the proof that for $d = 3$ one can also take another canonical form

$$(\xi_2^2 + x_3^2 + \xi_3^2) \sum_{1\le n\le N-1} b_n(x', \xi_1)(x_3^2 + \xi_3^2)^{n-1} \qquad \mathsf{mod}\ O_{2N-1}(\Lambda^0). \tag{13.3.15}'$$

This remark will be essential in the case of the strong magnetic field (see Section 13.6).

Proof of Proposition 13.3.1. (i) Let us first treat the simpler case $d = 2$. Since Λ is a 2-dimensional symplectic manifold, $a \ge 0$ and a has a zero on

Λ of precisely the second order then there exist functions $w_j(x,\xi)$ $(j=1,2)$ such that

$$w_j = 0 \quad \text{at} \quad \Lambda\cap\mathcal{W} \qquad (\forall j = 1,\dots,d), \tag{13.3.17}$$

$$\{w_1, w_2\} = 1 \qquad \text{at} \quad \Lambda\cap\mathcal{W}, \tag{13.3.18}$$

$$a \equiv b_1(w_1^2 + w_2^2) \qquad \operatorname{mod} O_3(\Lambda\cap\mathcal{W}). \tag{13.3.19}$$

Moreover, it is easy to see that here one can take $\mathcal{W} = B(0,1)\times\mathbb{R}^2$.

Further, one can replace (13.3.18) by

$$\{w_1, w_2\} \equiv 1 \qquad \operatorname{mod} O_M(\Lambda\cap\mathcal{W}) \tag{13.3.18}'_M$$

with arbitrary M (in which case $K = K(M)$).

In fact, if $(13.3.18)'_M$ holds then replacing w_2 by $w_2' = w_2 + \mathcal{P}(w;x,\xi)$ where $\mathcal{P}$ is a homogeneous polynomial of order $(M+1)$ with respect to $w = (w_1, w_2)$ and noting that

$$\{w_1, \mathcal{P}\} \equiv \partial_{w_2}\mathcal{P} \qquad \operatorname{mod} O_{M+1}(\Lambda\cap\mathcal{W}) \tag{13.3.20}$$

we obtain that for appropriate $\mathcal{P}$ condition $(13.3.18)'_{M+1}$ will be fulfilled.

Furthermore, one can replace $(13.3.18)'_M$ by

$$\{w_1, w_2\} = 1 \qquad \text{in} \quad \mathcal{W}. \tag{13.3.18}''$$

In fact, one can reach this equality by replacing w_2 with $w_2' \equiv w_2 \mod O_M(\Lambda)$ because $\nabla^{\#}w_1 = \{w_1, .\}$ is a non-vanishing tangent to Λ vector field in $\mathcal{W}$.

But if (13.3.17) and $(13.3.18)''$ are fulfilled then there exists a symplectomorphism $\Psi_{\frac{3}{2}}$ of a neighborhood of Λ^0 onto $\mathcal{W}$ (where $\mathcal{W}$ is decreased if necessary) such that $w_1\circ\Psi_{\frac{3}{2}} = \xi_2$ and $w_2\circ\Psi_{\frac{3}{2}} = x_2$. This yields (13.3.11) with $\Psi = \Psi_{\frac{3}{2}}$ and $N = 2$.

Let us calculate the non-zero eigenvalues of skew-Hessians of $a(x,\xi)$ and $x_2^2+\xi_2^2$ at points of Λ and Λ^0 respectively; we obtain $\pm 2iF$ and $\pm 2i$ respectively; this yields (13.3.12) and (13.3.13) [8)].

Let us now prove that

[8)] We recall that symplectomorphisms preserve the spectra of skew-Hessians at stationary points and the canonical density $dx\wedge d\xi$.

(13.3.21) If (13.3.11) is fulfilled with some $N \geq 2$ then there exists a symplectomorphism Ψ_N of a neighborhood of Λ^0 onto a neighborhood of Λ^0 such that $\Psi_N \equiv I \mod O_{2N-2}(\Lambda^0)$ and (13.3.11) holds for Ψ replaced by $\Psi \circ \Psi_N$ with N replaced by $(N + \frac{1}{2})$.

Then for $\Psi = \Psi_{\frac{3}{2}} \circ \Psi_2 \circ \cdots \circ \Psi_{N-\frac{1}{2}}$ we have equality (13.3.11) with arbitrarily chosen N.

To prove (13.3.21) let us construct this symplectomorphism Ψ_N as an exponential map $\Psi_N = \exp(\nabla^\# S)$ where $\nabla^\# S$ is the Hamiltonian field generated by $S \in O_{2N-1}(\Lambda^0)$. Then for any smooth enough function $f(x, \xi)$

$$f \circ \Psi_N \sim f + \{S, f\} + \frac{1}{2}\{S, \{S, f\}\} + ... \tag{13.3.22}$$

where the order of the zero at Λ^0 increases when the number of the term increases. In particular,

$$x_2 \circ \Psi_N \equiv x_2 + \{S, x_2\}, \quad \xi_2 \circ \Psi_N \equiv \xi_2 + \{S, \xi_2\}, \quad x_1 \circ \Psi_N \equiv x_1, \quad \xi_1 \equiv \xi_1 \mod O_{2N-1}(\Lambda^0) \tag{13.3.23}$$

and

$$a \circ \Psi \circ \Psi_N \equiv a \circ \Psi_N + b_1\{S, x_2^2 + \xi_2^2\} \mod O_{2N}(\Lambda^0). \tag{13.3.24}$$

Therefore the existence of the appropriate generating function S follows from

Lemma 13.3.3. *Let $d = 2$. Then for every $M \in \mathbb{Z}^+ \setminus 0$ and for every function $Q \in O_M(\Lambda^0)$ there exist functions $S \in O_M(\Lambda^0)$ and ω such that*

$$Q \equiv \{S, x_2^2 + \xi_2^2\} + \omega(x_2^2 + \xi_2^2)^{\frac{M}{2}} \mod O_{M+1}(\Lambda^0).$$

Moreover, for odd M, $\omega = 0$ and S $(\mod O_{M+1}(\Lambda^0))$ is defined uniquely, while for even M, S $(\mod O_{M+1}(\Lambda^0))$ is defined uniquely modulo the term $\omega'(x_2^2 + \xi_2^2)^{\frac{M}{2}}$ and ω $(\mod O_1(\Lambda^0))$ is defined uniquely.

Proof. The proof of this lemma is obvious. □

(ii) Let us now treat the case $d = 3$. Then the symplectic structure of Λ and the properties of a yield that there exist functions $w_j(x, \xi)$ $(j = 1, 2, 3)$ such that (13.3.1) holds and

(13.3.25) dw_j $(j = 1, 2, 3)$ are linearly independent on $\Lambda \cap \mathcal{W}$,

(13.3.26) $$\{w_1, w_2\} = 1, \quad \{w_1, w_3\} = \{w_2, w_3\} = 0 \quad \text{at} \quad \Lambda \cap \mathcal{W},$$

and

(13.3.27) $$a \equiv w_3^2 + b_1(w_1^2 + w_2^2) \qquad \mathsf{mod}\ O_3(\Lambda^0 \cap \mathcal{W});$$

then on $\Lambda \cap \mathcal{W}$, $\sum_j F^j d(\xi_j - V_j)$ and dw_3 differ by a scalar factor. Here one can take $\mathcal{W} = B(0, 1) \times \mathbb{R}^3$.

We assert that one can replace (13.3.26) by

(13.3.26)′ $$\{w_1, w_2\} \equiv 1, \quad \{w_1, w_3\} \equiv \{w_2, w_3\} \equiv 0 \qquad \mathsf{mod}\ O_2(\Lambda \cap \mathcal{W}).$$

In fact, (13.3.26) means precisely that

$$\{w_j, w_k\} \equiv \varepsilon_{jk} + \sum_l \alpha_{jkl} w_l \qquad \mathsf{mod}\ O_2(\Lambda \cap \mathcal{W})$$

with $\varepsilon_{12} = 1$, $\varepsilon_{13} = \varepsilon_{23} = 0$; the Jacobi identity yields that $\alpha_{132} = -\alpha_{231}$ on $\Lambda \cap \mathcal{W}$. It is easy to reach (13.3.26)′ by replacing w_j by $w_j + \mathcal{P}_j(w; x, \xi)$ with appropriate homogeneous second degree polynomials $\mathcal{P}$ of $w = (w_1, w_2, w_3)$; here we use the equalities

$$\{w_1, \mathcal{P}\} \equiv \partial_{w_2}\mathcal{P}, \quad \{w_2, \mathcal{P}\} \equiv -\partial_{w_1}\mathcal{P}, \{w_3, \mathcal{P}\} \equiv 0 \qquad \mathsf{mod}\ O_2(\Lambda \cap \mathcal{W})$$

and the equality $\alpha_{132} = -\alpha_{231}$ on $\Lambda \cap \mathcal{W}$.

Moreover, one can replace (13.3.26)′ by

(13.3.26)″ $$\{w_1, w_2\} = 1, \quad \{w_1, w_3\} = \{w_2, w_3\} = 0 \qquad \text{in} \quad \mathcal{W}.$$

In fact, since $\nabla^{\#} w_3$ is a non-vanishing vector field in $\mathcal{W}$ tangent to Λ, Γ is the non-closed trajectory of $\nabla^{\#} w_3$ and $\mathcal{W}$ is a narrow neighborhood of Γ then the second of these equalities will be fulfilled if we replace w_1 by an appropriate function $w_1' \equiv w_1 \ \mathsf{mod}\ O_2(\Lambda)$.

Further, the first equality in (13.3.26)′ remains true and the third equality remains true automatically. Then the vector fields $\nabla^{\#} w_1$ and $\nabla^{\#} w_3$ commute and are linearly independent and it is easy to reach the first and third equalities in (13.3.26)′ by replacing w_2 with an appropriate function $w_2' \equiv w_2$ $\mathsf{mod}\ O_2(\Lambda)$.

Furthermore, the same arguments with vector fields yield that there exist smooth functions w_4, w_5, w_6 in $\mathcal{W}$ such that

(13.3.28) $\{w_j, w_k\} = 1$ for $j = k-1$ and even k; otherwise $\{w_j, w_k\} = 0$ as $j \le k$.

and therefore there exists a symplectomorphism $\Psi_{\frac{3}{2}}$ such that

$$w_1 \circ \Psi_{\frac{3}{2}} = \xi_3, \quad w_2 \circ \Psi_{\frac{3}{2}} = x_3, \quad w_3 \circ \Psi_{\frac{3}{2}} = \xi_2; \tag{13.3.29}$$

these equalities yield (13.3.15) with $\Psi = \Psi_{\frac{3}{2}}$ and $N = 2$.

Calculating the non-vanishing eigenvalues of the skew-Hessians of a and $x_3^2 + \xi_3^2$ on Λ and Λ^0 respectively we obtain $\pm 2iF$ and $\pm 2i$ respectively and this yields (13.3.12) and (13.3.13).

Let us prove that

(13.3.30) If (13.3.15) is fulfilled with $N \ge 2$ then there exists a symplectomorphism Ψ_N of a neighborhood of Λ^0 onto a neighborhood of Λ^0 such that $\Psi_N \equiv I \mod O_{2N-2(\Lambda^0)}$ and (13.3.15) holds with Ψ replaced by $\Psi \circ \Psi_N$ and N replaced by $(N + \frac{1}{2})$ in the sum in the right-hand expression and in $R'_n \in O_{2N-2n-1}(\Lambda^0)$.

(a) Let us first treat the most delicate case $N = 2$. Let

$$\Psi' = \exp(\nabla^{\#} S'), \qquad S' = \alpha(x', \xi_1)\xi_2^2 + \beta(x', \xi_1)(x_3^2 + \xi_3^2).$$

Then formula (13.3.22) is wrong but one can see easily that

$$(x_3^2+\xi_3^2)\circ\Psi' = (\xi_3^2+\xi_3^2), \quad x_1\circ\Psi' \equiv x_1, \quad \xi_1\circ\Psi' \equiv \xi_1, \quad x_2\circ\Psi' \equiv x_2+\partial_{\xi_2}S' \mod O_2(\Lambda^0)$$

and $\xi_2 \equiv \xi_2 - \partial_{x_2} S' \mod O_3(\Lambda^0)$; then

$$\xi_3 \circ \Psi' \equiv \xi_2 \cos(2\beta) - x_3 \sin(2\beta), \quad x_3 \circ \Psi' \equiv x_3 \cos(2\beta) + \xi_3 \sin(2\beta) \mod O_2(\Lambda^0).$$

Therefore

$$a \circ \Psi_{\frac{3}{2}} \circ \Psi' \equiv a \circ \Psi_{\frac{3}{2}} + \{S', a^0\}_2 + \sum_{1 \le k \le 3} T_k(x', \xi_1; x_3, \xi_3)\xi_2^{3-k} \mod O_4(\Lambda^0) \tag{13.3.31}$$

where

$$a^0 = \xi_2^2 + b_1(x_3^2 + \xi_3^2), \tag{13.3.32}$$

$$\{f, g\}_2 := \partial_{\xi_2} f \cdot \partial_{x_2} g - \partial_{x_2} f \cdot \partial_{\xi_2} g \tag{13.3.33}$$

and T_k are homogeneous k-th order polynomials of (x_3, ξ_3) with coefficients smoothly depending on (x', ξ_1); moreover,

(13.3.34) The trace of the matrix of the quadratic form T_2 vanishes.

Then (13.3.31)–(13.3.33) yield that for appropriate functions α and β

$$a \circ \Psi_{\frac{3}{2}} \circ \Psi' \equiv a^0 + \sum_{1 \le k \le 3} T'_k(x', \xi_1; x_3, \xi_3)\xi_2^{3-k} \qquad \mod O_4(\Lambda^0)$$

where T'_k are homogeneous k-th order polynomials of (x_3, ξ_3) with coefficients smoothly depending on (x', ξ_1); moreover, (13.3.33) holds.

Let $S'' \in O_3(\Lambda^0)$ and $\Psi'' = \nabla^\# S''$. Then (13.3.22) yields that

$$a \circ \Psi_{\frac{3}{2}} \circ \Psi' \circ \Psi'' \equiv a^0 + b_1\{S'', x_3^2 + \xi_3^2\} + \sum_{1 \le k \le 3} T'_k(x', \xi_1; x_3, \xi_3)\xi_2^{3-k} \qquad \mod O_4(\Lambda^0)$$

and one can see easily that for appropriate S''

$$a \circ \Psi_{\frac{3}{2}} \circ \Psi' \circ \Psi'' \equiv a^0 \qquad \mod O_4(\Lambda^0).$$

This completes the proof of (13.3.30) with $N = 2$.

(b) Let us consider the case $N \ge \frac{5}{2}$. Let us look for Ψ_N in the form $\Psi_N = \exp(\nabla^\# S)$, $S = S' + S''$ where

$$S' = \sum_{0 \le k \le \lfloor N \rfloor} \alpha_k(x', \xi_1)(x_3^2 + \xi_3^2)^k \xi_2^{2N-2k-2} \tag{13.3.35}$$

belongs to $O_{2N-2}(\Lambda^0)$ and $S'' \in O_{2N-1}(\Lambda^0)$. Then (13.3.19) yields that

$$a \circ \Psi \circ \Psi_N \equiv a \circ \Psi + \{S', a^0\}_2 + b_1\{S'', x_3^2 + \xi_3^2\} \qquad \mod O_{2N}(\Lambda^0)$$

and the existence of the appropriate generating function S follows from the following

Lemma 13.3.4. *Let $d = 3$, $a^0 = \xi_2^2 + b_1(x_3^2 + \xi_3^2)$, $b_1 = b_1(x', \xi_1) > 0$. Then for every $M \in \mathbb{Z}^+$ and for every function $Q \in O_M(\Lambda^0)$ there exists S' of the form $(13.3.35)_N$ with $N = \frac{1}{2}(M+1)$, $S'' \in O_M(\Lambda^0)$ and b ($b = 0$ for odd M) such that*

$$Q \equiv \{S', a^0\}_2 + b_1\{S'', x_3^2 + \xi_3^2\} + b(x_3^2 + \xi_3^2)^{\frac{M}{2}} \qquad \mathrm{mod}\ O_{M+1}(\Lambda^0).$$

Proof. The proof of this lemma is obvious. □

Thus (13.3.30) is proven in the full scope and it implies Statement (ii).

(iii) Without any loss of the generality one can assume that $F = 1$; then $b_1 = 1$. Let us introduce a local conformal coordinate system[9)].

Then $g^{11} = g^{22} = \rho^2$, $g^{12} = 0$ and $a(x, \xi) = s^2 + t^2$, $\{s, t\} = \pm 1$ at Λ where $s = \rho(\xi_1 - V_1)$, $t = \rho(\xi_2 - V_2)$. Permuting x_1 and x_2, s and t if necessary we obtain that $\{s, t\} = 1$ at Λ. Then

$$\{s, t\} = 1 + \beta s - \alpha t, \quad \alpha = -\partial_1\rho, \quad \beta = -\partial_2\rho. \tag{13.3.36}$$

Therefore $w_1 = s$, $w_2 = t$ fulfill the initial relations (13.3.17)–(13.3.19).

Let us take $w_1' = s + ut$, $w_2' = t - us$ with $u \in O_1(\Lambda)$; then

$$a \equiv w_1'^2 + w_2'^2 \qquad \mathrm{mod}\ O_4(\Lambda)$$

and

$$\{w_1', w_2'\} \equiv \{s, t\} - s\{s, u\} - t\{t, u\} \qquad \mathrm{mod}\ O_2(\Lambda).$$

Then (13.3.12) yields that $\{w_1', w_2'\} \equiv 1 \mod O_2(\Lambda)$ for $u = \alpha s + \beta t$. More detailed calculation then gives that

$$\begin{aligned}\{w_1', w_2'\} \equiv 1 + s^2\big(2\alpha^2 - \beta^2 - \{s, \alpha\}\big) + \\ st\big(6\alpha\beta - \{t, \alpha\} - \{s, \beta\}\big) + t^2\big(2\beta^2 - \alpha^2 - \{t, \beta\}\big) \\ \mathrm{mod}\ O_3(\Lambda).\end{aligned} \tag{13.3.37}$$

Let us construct functions w_1'' and w_2'' coinciding modulo $O_3(\Lambda)$ with w_1' and w_2' and such that

$$\{w_1'', w_2''\} \equiv 1 \qquad \mathrm{mod}\ O_3(\Lambda), \tag{13.3.38}$$

[9)] See f.e. B. A. Dubrovin, A. T. Fomenko and S. P. Novikov [1].

and

$$a \equiv w_1''^2 + w_2''^2 + \omega\big(w_1''^2 + w_2''^2\big)^2 \qquad \mathrm{mod}\ O_5(\Lambda), \tag{13.3.39}$$

and let us calculate the coefficient ω. In order to fulfill (13.3.39) let us note that

$$a = \big(w_1'^2 + w_2'^2\big)\big(1+u^2\big)^{-1} \equiv \big(w_1'^2 + w_2'^2\big)\big(1-u^2\big) \qquad \mathrm{mod}\ O_5(\Lambda)$$

and let us set

$$w_1'' = s + ut - \frac{1}{2}(\omega(s^2+t^2) + u^2) + vt,$$
$$w_2'' = t - us - \frac{1}{2}(\omega(s^2+t^2) + u^2) - vs$$

with $v \in O_2(\Lambda)$. Then (13.3.13) yields that

$$\{w_1'', w_2''\} \equiv 1 + s^2\big(-\beta^2 - \{s,\alpha\} - 2\omega\big) + st\big(2\alpha\beta - \{t,\alpha\} - \{s,\beta\}\big) + t^2\big(-\alpha^2 - \{t,\beta\} - 2\omega\big) - s\{s,v\} - t\{t,v\} \qquad \mathrm{mod}\ O_3(\Lambda). \tag{13.3.40}$$

Then Lemma 13.3.3 yields that (13.3.38) holds for appropriate $v \in O_2(\Lambda)$ if and only if the sum of coefficients at s^2 and t^2 in (13.3.40) vanishes, i.e.,

$$\omega = \frac{1}{4}\big(-\{s,\alpha\} - \{t,\beta\} - \alpha^2 - \beta^2\big).$$

Equalities (13.3.36) and the definitions of s and t then yield that

$$\omega = \frac{1}{4}(\rho\Delta\rho - (\nabla\rho)^2) = \frac{1}{4}\rho^2\Delta\log\rho \tag{13.3.41}$$

where Δ is the two-dimensional Laplace operator and therefore the formula for the scalar curvature in a conformal coordinate system[9)] yields that $\omega = \frac{1}{8}\kappa$.

This equality yields (13.3.16) if we take a symplectomorphism Ψ such that $w_1'' \circ \Psi = \xi_2$, $w_2'' \circ \Psi \equiv x_2 \ \mathrm{mod}\ O_4(\Lambda^0)$); moreover, (13.3.11) is fulfilled with $N = 3$. Taking this symplectomorphism as the initial point of the construction used in Part (i) we obtain (13.3.11) for arbitrary N; moreover, (13.3.16) is also fulfilled.

On the other hand, if Φ is an arbitrary symplectomorphism of a neighborhood of Λ_1^0 onto a neighborhood of Λ_2^0 where in the definition of Λ_j^0 domains Ω_j are taken instead of Ω ($j = 1, 2$) and if Φ preserves the decomposition (13.3.11) then $\Phi = \Phi' \circ \Phi''$ where $\Phi'(x_1, \xi_1, x_2, \xi_2) = (\bar{\Phi}'(x_1, \xi_1), x_2, \xi_2)$, $\bar{\Phi}' : \Lambda_1^0 \to \Lambda_2^0$ is a symplectomorphism and Φ'' is also a symplectomorphism and $\Phi''|_{\Lambda_1^0} = I$.

Then $\Phi'' = \exp(\nabla^{\#} S)$ with $S \in O_2(\Lambda_1^0)$. Since Φ' obviously preserves the decomposition (13.3.11) the same also is true for Φ''; then the arguments of Part (i) yield that

$$S \equiv \sum_{1 \le n \le N-1} \phi_n(x_1, \xi_1)(x_2^2 + \xi_2^2)^n \qquad \mathsf{mod}\ O_{2N-1}(\Lambda_1^0).$$

One can see easily that all the coefficients b_n are invariant with respect to Φ' (i.e., $b_n \to b_n \circ \bar{\Phi}'$) and that Φ'' transforms coefficient b_2 to $b_2 + \{\phi_1, b_1\}$ (so it is also invariant provided b_1 is constant, i.e., provided F is constant).

Therefore (13.3.16) holds for every symplectomorphism Ψ reducing $a(x, \xi)$ to its canonical form. Statement (iii) of Proposition 13.3.1 is proven. □

Problem 13.3.5. Generalize Proposition 13.3.1 to higher dimensions. First of all one needs to assume that

(13.3.42) F has constant rank $2r$, or equivalently restriction of symplectic form to Λ has constant rank $2r$.

Then

(13.3.43) Λ stratifies into $(d - 2r)$ dimensional leafs and restriction of symplectic form to each leaf is 0.

(i) Assumption (13.3.42) with $r = 1$ is sufficient for reduction. On the other hand, as $r \ge 2$ for reduction modulo $O_{M+1}(\Lambda)$ one needs *non-resonance condition*

$$(13.3.44)_M \qquad |\sum_j f_j(x)\alpha_j| \ge \epsilon_M \qquad \forall \alpha \in \mathbb{Z}^r : \sum_j |\alpha_j| < M + 1.$$

In particular, as $M = 2$ this condition is equivalent to $|f_j - f_k| \ge \epsilon\ \forall j \ne k$ and for $r = 2$ we have $(13.3.44)_\infty$ equivalent to f_1/f_2 is irrational.

(ii) Explore more complicated case when A has eigenvalues $\pm if_j$ of constant multiplicities r_j, $j = 1, \dots, m$. Even as modified (in an obvious) non-resonance conditions are fulfilled canonical form becomes more complicated and includes polynomials of all "basic" quadratic forms commuting with a.

Form: $\varepsilon \neq 0$

Let us now treat the case $\varepsilon \neq 0$.

Theorem 13.3.6. *Let conditions* (13.2.1)–(13.2.4) *and* (13.3.1) *be fulfilled. Then*

(i) Let $d = 2$. Then for every $\varepsilon \in [-\epsilon_0, \epsilon_0]$ [10] *there exists a symplectomorphism Ψ_ε^{-1} of a neighborhood $\mathcal{W}$ of every point $z \in \Lambda$ to a neighborhood of Λ^0 (defined by* (13.3.9)*), depending smoothly on ε, coinciding with Ψ^{-1} (defined in Proposition 13.3.1(i)) as $\varepsilon = 0$* [11] *and such that the inverse symplectomorphism Ψ has the following properties:*

$$a_\varepsilon \circ \Psi_\varepsilon = \sum_{m+n\le N-1} b_{mn}(x_1, \xi_1)\varepsilon^m (x_2^2 + \xi_2^2)^n + \sum_{0\le n\le N} \varepsilon^n R_n(x, \xi, \varepsilon) \tag{13.3.45}$$

where the coefficients b_{mn} and R_n are smooth functions of all their arguments; moreover

$$b_{00} = 0, \qquad b_{01} = F \circ \bar{\Psi}_0, q \qquad b_{10} = V \circ \bar{\Psi}_0 \tag{13.3.46}_{1-3}$$

and $R_n \in O_{2N-2n}(\Lambda^0)$.

(ii) Let $d = 3$. Then for every $\varepsilon \in [-\epsilon_0, \epsilon_0]$ [10] *there exists a symplectomorphism Ψ_ε^{-1} of a neighborhood $\mathcal{W}$ of every non-closed Hamiltonian trajectory Γ of finite length generated by the Hamiltonian $F(x, \xi) = \sum_j F^j(\xi_j - V_j)$ and lying on Λ to a neighborhood of Λ^0 = (defined by* (13.3.14)*), depending smoothly on ε, coinciding with Ψ^{-1} (defined in Proposition 13.3.1(ii)) as $\varepsilon = 0$* [10] *and such that the inverse symplectomorphism Ψ_ε has the following properties:*

$$a_\varepsilon \circ \Psi_\varepsilon \equiv \xi_2^2 + \sum_{1\le m+n\le N-1} b_{mn}(x', \xi_1)\varepsilon^m (x_3^2 + \xi_3^2)^n + \sum_{0\le n\le N} \varepsilon^n R_n(x, \xi, \varepsilon) \tag{13.3.47}$$

[10] Where $\epsilon_0 > 0$ is a small enough constant.

[11] Therefore we will denote Ψ, etc as Ψ_0 etc.

where the coefficients b_{mn} *and* R_n *are smooth functions. Moreover,* $(13.3.46)_{1-3}$ *hold and* $R_n \in O_{2N-2n}(\Lambda^0)$.

(iii) If $d = 2$ *and* $F = \mathrm{const}$ *then*

$$b_{02} = \frac{1}{8} F\kappa \circ \bar{\Psi}_0 \tag{13.3.48}_1$$

$$b_{11} = \big(\frac{1}{4}\sum_{j,k} g^{jk} F^{-1} \partial_j \partial_k V + \sum_j k^j \partial_j V\big) \circ \bar{\Psi}_0, \tag{13.3.48}_2$$

and

$$b_{20} = \big(\sum_j l^j \partial_j V\big) \circ \bar{\Psi}_0 \tag{13.3.48}_3$$

where the coefficients k^j *and* l^j *depend on the method of reduction and can be chosen arbitrarily at every point separately.*

Proof. If we take the symplectomorphism Ψ constructed in Proposition 13.3.1 instead of Ψ_ε then (13.3.45) or (13.3.47) will be fulfilled modulo $\varepsilon O_1(\Lambda^0)$ and the coefficients in these decompositions will satisfy $(13.3.46)_{1-3}$.

Therefore it is sufficient to prove that

(13.3.49) If (13.3.45) or (13.3.47) are fulfilled modulo $\varepsilon^L O_1(\Lambda^0)$ with $L \geq 1$ then there also exists a symplectomorphism $\Psi_{\varepsilon,L}$ of a neighborhood of Λ^0 onto a neighborhood of Λ^0, depending smoothly on ε and such that

$$\Psi_\varepsilon \equiv I \mod O(\varepsilon^L) \tag{13.3.50}$$

and (13.3.45) or (13.3.47) is fulfilled modulo $\varepsilon^{L+1} O_1(\Lambda^0)$ for $\Psi\varepsilon$ replaced by $\Psi_\varepsilon \circ \Psi_{\varepsilon,L}$.

Note that equalities $(13.3.48)_{1-3}$ automatically remain true at each step.

To prove (13.3.49) we assert first that

(13.3.51) In the framework of (13.3.49) there exists a symplectomorphism also satisfying (13.3.50) and such that $a_\varepsilon \circ \Psi_\varepsilon \circ \Psi_{\varepsilon,L,0}$ is equal to the right-hand expression of (13.3.45) or (13.3.47) modulo $\varepsilon^L O_2(\Lambda^0) + O(\varepsilon^{L+1})$.

In fact, for $d = 2$ the term preventing us from having the last equality is $\varepsilon^L(\alpha\xi_2 + \beta x_2)$ with $\alpha = \alpha(x_1, \xi_1)$ and $\beta = \beta(x_1, \xi_1)$. Let us set

$$w_1 = \xi_2 + \alpha_1 \varepsilon^L,\ w_2 = x_2 + \beta_1 \varepsilon^L,\ w_3 = \xi_1,\ w_4 = x_1$$

with $\alpha_1 = \alpha/(2b_1)$, $\beta_1 = \beta/(2b_1)$. Then the necessary commutation relations are fulfilled modulo $O(\varepsilon^L)$. Furthermore, perturbing w_j with $j = 1, 2$ by functions of the class $\varepsilon^L O_1(\Lambda^0)$ we obtain a commutation relation between w_1 and w_2 fulfilled modulo $\varepsilon^L O_1(\Lambda^0) + O(\varepsilon^{L+1})$.

Then there exist functions w'_j fulfilling the same commutation relations exactly and such that $w'_j \equiv w_j \mod (\varepsilon^L O_1(\Lambda^0) + O(\varepsilon^{L+1}))$ for $j = 1, 2$ and $w'_j \equiv w_j \mod O(\varepsilon^L)$ for $j = 3, 4$. Then symplectomorphism $\Psi_{\varepsilon,L,0}$ transforming (w'_1, w'_2, w'_3, w'_4) into (ξ_2, x_2, ξ_1, x_1) is obviously the required symplectomorphism.

Similarly, for $d = 3$ the term preventing us from having the equality claimed in (13.3.51) is $\varepsilon^L(\alpha\xi_3 + \beta x_3 + \gamma\xi_2)$ with $\alpha = \alpha(x', \xi_1)$, $\beta = \beta(x', \xi_1)$ and $\gamma = \gamma(x', \xi_1)$. Let us set

$$w_1 = \xi_3 + \alpha_1\varepsilon^L,\ w_2 = x_3 + \beta_1\varepsilon^L,\ w_3 = \xi_2 + \gamma_1\varepsilon^L$$

with $\alpha_1 = \alpha/(2b_1)$, $\beta_1 = \beta/(2b_1)$, $\gamma_1 = \gamma/(2b_1)$ and, moreover, let us set $w_4 = x_2$, $w_5 = \xi_1$, $w_6 = x_1$. Then all the remaining arguments used for $d = 2$ remain true with the obvious modifications.

So, (13.3.51) has been proven. Therefore to prove (13.3.49) it is sufficient to prove that

(13.3.52) If (13.3.45) or (13.3.47) is fulfilled modulo $\varepsilon^L O_M(\Lambda^0) + O(\varepsilon^{L+1})$ with $2 \le M \le 2(N - L) - 1$ then there exists a symplectomorphism

$$\Psi_{\varepsilon,L,M} \equiv I \mod (\varepsilon^L O_{M-1}(\Lambda^0) + O(\varepsilon^{L+1}))$$

such that for Ψ_ε replaced by $\Psi_\varepsilon \circ \Psi_{\varepsilon,L,M}$ the same equality is fulfilled modulo $\varepsilon^L O_{M+1}(\Lambda^0) + O(\varepsilon^{L+1})$.

Repeating the arguments used in the Parts (i) or (i) of the proof of Proposition 13.3.1 as $d = 2, 3$ respectively one can construct easily this symplectomorphism in the form $\Psi_{\varepsilon,L,M} = \exp(\varepsilon^L \nabla^\# S)$ where

(i) $S \in O_M(\Lambda^0)$ for $d = 2$ and

(ii) $S = S' + S''$ where S' is of the form $(13.3.35)_N$ with $\frac{1}{2}(M + 1)$ instead of N and $S'' \in O_M(\Lambda^0)$ for $d = 3$.

We only note that (13.3.22) is replaced by formula

$$f \circ \Psi_{\varepsilon,L,M} \sim f + \varepsilon^L\{S, f\} + \frac{1}{2}\varepsilon^{2L}\{S, \{S, f\}\} + \dots$$

which is always applicable. So Statements (i) and (ii) of Theorem 13.3.6 are proven.

Let us prove Statement (iii). Note first that $(13.3.48)_1$ follows from (13.3.16). Without any loss of generality one can assume in the proof of $(13.3.48)_{2,3}$ that $F = 1$. Let us again consider a conformal coordinate system. Let Ψ be the symplectomorphism constructed in Proposition 13.3.1(iii); let us consider the decomposition of $W = V \circ \Psi$ in powers of x_2, ξ_2:

$$W \sim \sum_{\gamma \in \mathbb{Z}^{+2}} v_\gamma(x_1, \xi_1) x_2^{\gamma_1} \xi_2^{\gamma_2}.$$

Let us return to the very beginning of the proof of Statement (i). Recall that we took $w_1 = \xi_2 + \alpha_1\varepsilon$, $w_2 = x_2 + \beta_1\varepsilon$, $w_3 = \xi_1$ and $w_4 = x_1$ and noted that the commutation relations were fulfilled modulo $O(\varepsilon)$. It is easy to see that one can change $w_1, \dots, w_4$ by functions of the class $\varepsilon O_1(\Lambda^0)$ such that for new $w_1, \dots, w_4$ all the commutation relations (not only between w_1 and w_2) will be fulfilled modulo $\varepsilon O_1(\Lambda^0) + O(\varepsilon^2)$ and therefore $w_j' \equiv w_j$ $\mathsf{mod}\ \varepsilon O_1(\Lambda^0) + O(\varepsilon^2)$ for the appropriate method of reduction. Therefore for the symplectomorphism constructed at this step

$$a_\varepsilon \circ \Psi_\varepsilon \equiv a \circ \Psi + \varepsilon Q(x_1, \xi_1; x_2, \xi_2) - \varepsilon^2(\alpha_1^2 + \alpha_2^2) \quad \mathsf{mod}\ \big(\varepsilon O_2(\Lambda^0) + \varepsilon^2 O_1(\Lambda^0) + O(\varepsilon^3)\big)$$

with

$$Q(x_1, \xi_1; x_2, \xi_2) = v_{(20)} x_2^2 + 2v_{(21)} x_2\xi_2 + v_{(02)}\xi_2^2;$$

symplectomorphisms of the remaining part of the proof of Statement (i) kill the traceless part of the quadratic form Q and preserve its trace part. Since $\alpha_1 = \frac{1}{2}v_{(01)}^2$, $\beta_1 = \frac{1}{2}v_{(10)}$ we conclude that

$$(13.3.53)_{1,2} \qquad b_{11} = \frac{1}{2}(v_{(20)} + v_{(02)}), \quad b_{20} = -\frac{1}{4}(v_{(10)}^2 + v_{(01)}^2)$$

and we only need to calculate $v_{(10)}$, $v_{(01)}$, $v_{(20)}$, $v_{(02)}$. But

$$v_{(10)} = -\{W, \xi_2\} \circ \pi = -\{V, w_1\} \circ \Psi \circ \pi$$

where here and below $w_1 = \xi_2 \circ \Psi^{-1}$, $w_2 = x_2 \circ \Psi^{-1}$, $\pi(x, \xi) = (x_1, \xi_1, 0, 0)$; since $w_1 \equiv s$, $w_2 \equiv t$ $\mathsf{mod}\ O_2(\Lambda^0)$ (see the Part (iii) of the proof of Proposition 13.3.1) then

$$v_{(10)} = \{s, V\} \circ \bar\Psi = \rho\partial_1 V \circ \bar\Psi$$

and similarly $v_{(01)} = -\rho\partial_2 V \circ \bar{\Psi}$; these equalities yield $(13.3.48)_3$ with $l^j = -\frac{1}{4}\rho^2\partial_j V$.

Moreover,

$$v_{(20)} = \frac{1}{2}\{\{W, \xi_2\}, \xi_2\} \circ \pi = \frac{1}{2}\{\{V, w_1\}, w_1\} \circ \Psi \circ \pi$$

and a similar equality is true for $v_{(02)}$. Let us recall that $w_1 \equiv s + ut$, $w_2 \equiv t - us \mod O_3(\Lambda)$ with $u = \alpha s + \beta t$; then (13.3.36) and (13.3.53) yield that

$$b_{11} = \frac{1}{4}(\rho^2 \Delta V) \circ \bar{\Psi};$$

this equality yields $(13.3.48)_2$ with $k^j = 0$.

Finally, if Φ_ε is an arbitrary symplectomorphism of a neighborhood of Λ_1^0 onto a neighborhood of Λ_2^0, smoothly depending on ε, mapping Λ_1^0 onto Λ_2^0 and preserving decomposition (13.3.25), then repeating the corresponding arguments of the proof of Proposition 13.3.1(i) with obvious modifications we obtain that

$$\Phi_\varepsilon \equiv \Phi' \circ \Phi''_\varepsilon \qquad \mod \sum_n \varepsilon^n O_{2N-2n-2}(\Lambda_1^0)$$

where Φ' is a symplectomorphism preserving (x_2, ξ_2) (as in the end of the proof of Proposition 13.3.1(iii)) and $\Phi''_\varepsilon = \exp(\nabla^\# S_\varepsilon)$,

$$S_\varepsilon = \sum_{1 \le m+n \le N-1} \phi_{mn}(x_1, \xi_1)\varepsilon^m (x_2^2 + \xi_2^2)^n$$

with arbitrary functions ϕ_{mn}; all the coefficients b_{mn} are invariant with respect to Φ'; on the other hand, Φ''_ε transforms b_{20} and b_{11} to $b_{20} + \{\phi_{10}, b_{10}\}$ and $b_{11} + \{\phi_{01}, b_{10}\}$ respectively. This and $(13.3.46)_3$ yield $(13.3.48)_{2,3}$ and the possibility of choosing k^j and l^j arbitrarily at every fixed point. □

At the end of this subsection let us get rid of the condition that F is constant in Statement (iii):

Proposition 13.3.7. *Let $d = 2$ and Ψ_ε be the symplectomorphism constructed in Theorem 13.3.6(i). Then*

$$a_\varepsilon \circ \Psi_\varepsilon = \sum_{m+n \le N-1} b'_{mn}(x_1, \xi_1)\varepsilon^m \bar{a}_\varepsilon^n + \sum_{0 \le n \le N} \varepsilon^n R'_n(x, \xi, \varepsilon) \tag{13.3.54}$$

where b'_{mn}, R'_n are smooth functions and $R'_n \in O_{2N-2n-1}(\Lambda^0)$,

$$\bar{a}_\varepsilon := x_2^2 + \xi_2^2 + \varepsilon b(x_1, \xi_1), \tag{13.3.55}$$

$$b = v \circ \bar{\Psi}_0, \quad v = \frac{V}{F}, \tag{13.3.56}$$

$$b'_{00} = b'_{10} = 0, \quad b'_{01} = F \circ \bar{\Psi}_0 \tag{13.3.57}$$

and

$$b'_{20} = (\frac{1}{8} F \kappa v^2 - \frac{1}{4} \sum_{j,k} g^{jk} v \partial_j \partial_k v + \sum_j m^j \partial_j v) \circ \bar{\Psi}_0, \tag{13.3.58}$$

and m^j depend on the method of reduction and can be chosen arbitrarily at every fixed point.

Proof. Formulae (13.3.54)–(13.3.57) obviously follow from Theorem 13.3.6(i); formula (13.3.58) for constant F follows from Statement (iii) of the same theorem and $m^j = l^j - k^j v$ here.

Let us prove (13.3.58) in the general case; the proof of assertion (i) of Theorem 13.3.6(i) yields that it is sufficient to do the reduction with $N = 3$. Let Ψ'_ε be a symplectomorphism, reducing $F^{-1} a_\varepsilon$; then modulo terms negligible for $N = 3$

$$(F^{-1} a_\varepsilon) \circ \Psi'_\varepsilon \equiv \bar{a}_\varepsilon + \gamma(x_1, \xi_1)\varepsilon^2 + f(x_1, \xi_1)\bar{a}_\varepsilon$$

with $\gamma = b_{20} - b_{11} b + b_{02} b^2$ and $f \in O_2(\Lambda^0) + O(\varepsilon)$. Theorem 13.3.6(iii) yields that γ coincides with the right-hand expression of (13.3.58) multiplied by $F^{-1} \circ \bar{\Psi}_0$. Then

$$a_\varepsilon \circ \Psi'_\varepsilon = (F \circ \Psi'_\varepsilon) \cdot (\bar{a}_\varepsilon + \gamma\varepsilon^2 + f \bar{a}_\varepsilon) \equiv (b'_{01} + f')\bar{a}_\varepsilon + b'_{20}\varepsilon^2$$

where b'_{10} and b'_{20} are given by (13.3.56) and (13.3.57) and $f' \in O_1(\Lambda^0) + O(\varepsilon)$.

One can easily construct a symplectomorphism $\Psi''_\varepsilon = \exp(\nabla^\# S_\varepsilon)$ with $S_\varepsilon = (\varepsilon S' + S'')\bar{a}_\varepsilon$, where $S' \in O_1(\Lambda^0)$ and $S'' \in O_2(\Lambda^0)$ are chosen consequently, such that

$$a_\varepsilon \circ \Psi''_\varepsilon \equiv (b'_{01} + f'')\bar{a}_\varepsilon + b'_{20}\varepsilon^2$$

with $f'' = \phi_1(x_1, \xi_1)\varepsilon + \phi_2(x_1, \xi_1)\bar{a}_\varepsilon$; the proposition is proven. □

13.3.2 Operator Reduction

Let us proceed from symplectomorphisms to Fourier integral operators. First of all let us consider the $\hbar$-differential operator

$$A'_{\hbar,\varepsilon} = \sum_{j,k} (\hbar D_j - V_j) g^{jk} (\hbar D_k - V_k) + \varepsilon V, \tag{13.3.59}$$

depending on a small parameter ε. In what follows[12)]

$$\hbar = \mu^{-1} h \qquad \text{and} \qquad \varepsilon = \mu^{-2}. \tag{13.3.60}$$

Theorem 13.3.8. *Let conditions* (13.2.1)–(13.2.5) *and* (13.3.1) *be fulfilled. Then for* $d = 2, 3$ *and small enough* ε *there exists an* $\hbar$*-Fourier integral operator* $\mathcal{F}_{\hbar,\varepsilon}$*, depending smoothly on* ε *and corresponding to the symplectomorphism* Ψ_ε *constructed in Theorem 13.3.6, such that modulo* $\hbar$*-pseudodifferential operators depending smoothly on* ε *with symbols vanishing in a neighborhood*[13)] *of* Λ^0

$$\mathcal{F}^*_{\hbar,\varepsilon} \mathcal{F}_{\hbar,\varepsilon} \equiv I, \tag{13.3.61}$$

$$\mathcal{F}^*_{\hbar,\varepsilon} A'_{\hbar,\varepsilon} \mathcal{F}_{\hbar,\varepsilon} \equiv \mathcal{A}'_{\hbar,\varepsilon} \tag{13.3.62}$$

and modulo $\hbar$*-pseudodifferential operators depending smoothly on* ε *with symbols vanishing in a neighborhood* $\mathcal{W}$ *of any point*[14)] $z \in \Lambda$ *(for* $d = 2$*) or any non-closed Hamiltonian trajectory*[14)] Γ *of finite length generated by* $F(x, \xi)$ *(for* $d = 3$*)*

$$\mathcal{F}_{\hbar,\varepsilon} \mathcal{F}^*_{\hbar,\varepsilon} \equiv I, \tag{13.3.63}$$

$$\mathcal{F}_{\hbar,\varepsilon} \mathcal{A}'_{\hbar,\varepsilon} \mathcal{F}^*_{\hbar,\varepsilon} \equiv A'_{\hbar,\varepsilon} \tag{13.3.64}$$

where for $d = 2$

$$\mathcal{A}'_{\hbar,\varepsilon} = \sum_{0 \le n \le N-1} B^{\mathrm{w}}_n (x_1, \hbar D_1, \varepsilon, \hbar) \mathcal{L}_0^n + R \tag{13.3.65}$$

and for $d = 3$

$$\mathcal{A}'_{\hbar,\varepsilon} = \hbar^2 D_2^2 + \sum_{0 \le n \le N-1} B^{\mathrm{w}}_n (x', \hbar D_1, \varepsilon, \hbar) \mathcal{L}_0^n + R \tag{13.3.66}$$

[12)] One needs to distinguish between $\hbar = \mu h$ and $\hbar = \mu^{-1} h$.

[13)] All neighborhoods mentioned in this theorem do not depend on $(\varepsilon, \hbar)$.

[14)] Fixed beforehand.

with

$$\mathcal{L}_0 = x_d^2 + \hbar^2 D_d^2, \tag{13.3.67}$$

and

$$R = \sum_{m+n\le N} R_{mn}(x, \hbar D, \varepsilon, \hbar)\varepsilon^m \hbar^n \mathcal{L}_0^{N-m-n}, \tag{13.3.68}$$

B_n^{w} *and* R_{mn} *are* $\hbar$*-pseudodifferential operators depending smoothly on* ε*, the Weyl symbols of* B_n *are real-valued and*

$$B_0(.,.,\varepsilon,\hbar) = \varepsilon V \circ \bar{\Psi}_0 + O(\varepsilon^2 + \hbar^2), \tag{13.3.69}_1$$

and

$$B_1(.,.,0,0) = F \circ \bar{\Psi}_0. \tag{13.3.69}_2$$

Definition 13.3.9. We call (13.3.65) and (13.3.66) with $\mathcal{L}_0$ defined by (13.3.67)–(13.3.68) *microlocal canonical form* for two- and three-dimensional Schrödinger operators with magnetic field.

We call (13.3.45) and (13.3.47) *symplectic canonical form* and we refer to any of (13.3.45), (13.3.47), (13.3.65) and (13.3.66) as *Birkhoff normal form*.

Proof of Theorem 13.3.8. Let $\mathcal{F}'_{\hbar,\varepsilon}$ be a compactly supported $\hbar$-Fourier integral operator corresponding to the symplectomorphism Ψ_ε, depending smoothly on ε and satisfying (13.3.61); then (13.3.63) is fulfilled automatically.

Theorem 13.3.6 yields that operator $\mathcal{B}'_{\hbar,\varepsilon} = {\mathcal{F}'_{\hbar,\varepsilon}}^* A'_{\hbar,\varepsilon}\mathcal{F}'_{\hbar,\varepsilon}$ differs from operator $\mathcal{A}'_{\hbar,\varepsilon}$ of the form (13.3.65) or (13.3.66) by a term $\hbar r(x, \hbar D, \varepsilon, \hbar)$ where r is an $\hbar$-pseudodifferential operator; all operators here and in what follows depend smoothly on ε.

Since $A'_{\hbar,\varepsilon}$ is formally self-adjoint the same is true for $\mathcal{B}'_{\hbar,\varepsilon}$, i.e., its Weyl symbol is real-valued.

Further, one can see easily that the subprincipal symbol of $A'_{\hbar,\varepsilon}$ is equal to 0; therefore the subprincipal symbol of $B'_{\hbar,\varepsilon}$ is a linear combination of the first-order derivatives of its principal symbol. Hence r is an $\hbar$-pseudodifferential operator and $r(.,.,0,0) = 0$ at Λ^0. This yields $(13.3.69)_2$ automatically in what follows.

It is sufficient to prove that there exists an $\hbar$-pseudodifferential operator $Q_{\hbar,\varepsilon}$ such that

$$Q^*_{\hbar,\varepsilon} Q_{\hbar,\varepsilon} \equiv I, \qquad Q_{\hbar,\varepsilon} Q^*_{\hbar,\varepsilon} \equiv I, \tag{13.3.70}$$

and

$$Q^*_{\hbar,\varepsilon}\mathcal{B}'_{\hbar,\varepsilon}Q_{\hbar,\varepsilon} \equiv \mathcal{A}'_{\hbar,\varepsilon}, \qquad Q_{\hbar,\varepsilon}\mathcal{A}'_{\hbar,\varepsilon}Q^*_{\hbar,\varepsilon} \equiv \mathcal{B}'_{\hbar,\varepsilon}, \tag{13.3.71}$$

modulo $\hbar$-pseudodifferential operators with symbols vanishing in a neighborhood of Λ^0 where $\mathcal{A}'_{\hbar,\varepsilon}$ is an operator of the form (13.3.65) or (13.3.66).

Then $\mathcal{F}_{\hbar,\varepsilon} = \mathcal{F}'_{\hbar,\varepsilon}Q_{\hbar,\varepsilon}$ satisfies (13.3.61)–(13.3.64). Obviously, we need to fulfill only first equalities in (13.3.70) and (13.3.71); the second equalities follow from them automatically.

In order to construct this operator $Q_{\hbar,\varepsilon}$ it is sufficient to prove that

(13.3.72) Let operator $\mathcal{B}'_{\hbar,\varepsilon}$ differ from an operator of the form (13.3.65) or (13.3.66) by a term $\hbar^J\varepsilon^L r^{\mathrm{w}}(x,\hbar D,\varepsilon,\hbar)$ where r is an $\hbar$-pseudodifferential operator with real-valued symbol such that $r(.,.,0,0) \in O_M(\Lambda^0)$ and $J \ge 1$, $M \ge 1$, $L \ge 0$.

Then there exists an $\hbar$-pseudodifferential operator $q_{\hbar,\varepsilon}$ satisfying (13.3.70) such that $q^*_{\hbar,\varepsilon}\mathcal{B}'_{\hbar,\varepsilon}q_{\hbar,\varepsilon}$ differs from an operator of the form (13.3.65) or (13.3.66) by a term $\hbar^J\varepsilon^L r'^{\mathrm{w}}(x,\hbar D,\varepsilon,\hbar)$ where r' is an $\hbar$-pseudodifferential operator (automatically with real-valued symbol) such that $r'(.,.,0,0) \in O_{M+1}(\Lambda^0)$.

We start with $M = 1$ because the term $\hbar^J\varepsilon^L r^{\mathrm{w}}(x',\hbar D_1,\varepsilon,\hbar)$ can be included in decomposition (13.3.65) or (13.3.66).

It is easy to construct $q_{\hbar,\varepsilon}$ by means of simplifications of the arguments of the proof of Proposition 13.3.1: we search for $q_{\hbar,\varepsilon}$ of the form $\exp(i\hbar^{J-1}\varepsilon^L S^{\mathrm{w}}(x,\hbar D))$ with a real-valued function S; here

(i) $S \in O_M(\Lambda^0)$ for $d = 2$ and

(ii) $S = S' + S''$ where $S' \in O_{M-1}(\Lambda^0)$ is of the form $(13.3.35)_N$ with $N = \frac{1}{2}(M+1)$ and $S'' \in O_M(\Lambda^0)$ for $d = 3$.

Then for $J = 1$, $q_{\hbar,\varepsilon}$ is an operator with principal symbol $\exp(i\varepsilon^L S(x,\xi))$ and for $J \ge 2$ $q_{\hbar,\varepsilon}$ differs from I by an operator with principal symbol $i\hbar^{J-1}\varepsilon^L S(x,\xi)$. □

For $d = 2$ one can slightly improve this theorem:

Proposition 13.3.10. *Let conditions* (13.2.1)–(13.2.5) *and* (13.3.1) *be fulfilled and let* $\mathcal{A}'_{\hbar,\varepsilon}$ *be a reduced operator of the form* (13.3.65). *Then one can rewrite it in the form*

$$\mathcal{A}'_{\hbar,\varepsilon} \equiv \sum_{1\le n\le N-1} b_n(x_1,\hbar D_1,\varepsilon,\hbar)\mathcal{L}^n + R' \tag{13.3.73}$$

where R' is an operator of the form (13.3.68)*, b_n are now not necessarily real-valued but still $b_1(.,.,0,0) = F \circ \bar{\Psi}_0$ as in* $(13.3.69)_2$*,*

$$\mathcal{L} = x_2^2 + \hbar^2 D_2^2 + \varepsilon B^{\mathrm{w}}(x_1, \hbar D_1, \varepsilon, \hbar), \tag{13.3.74}$$

$$B(.,.,\varepsilon,\hbar) = v \circ \bar{\Psi}_0 + \varepsilon\omega_1 + \hbar\omega_2 + O(\varepsilon^2) + O(\hbar^2\varepsilon^{-1}) + O(\varepsilon\hbar), \tag{13.3.75}$$

$$\omega_1 = \big(\frac{1}{8}\kappa v^2 - \frac{1}{4}\sum_{j,k} g^{jk}F^{-1}v\partial_j\partial_k v + \sum_j m^j\partial_j v\big) \circ \bar{\Psi}_0, \tag{13.3.76}_1$$

and

$$\omega_2 = \big(\sum_j r^j\partial_j v\big) \circ \bar{\Psi}_0. \tag{13.3.76}_2$$

Let us recall that $v = VF^{-1}$ and κ is the scalar curvature corresponding to the metrics $F^{-1}g^{jk}$; here r^j and m^j can be chosen arbitrarily at every fixed point.

Proof. All of the proposition excluding formulas $(13.3.76)_{1,2}$ follows immediately from Theorem 13.3.8; $(13.3.76)_1$ follows from Proposition 13.3.7 and $(13.3.76)_2$ follows from the fact that the subprincipal symbol of $\mathcal{A}'_{\hbar,\varepsilon}$ is a linear combination of the first-order derivatives of its principal symbol.

The possibility of choosing m^j arbitrarily was proven and the possibility of choosing r^j arbitrarily then follows if we multiply $\mathcal{A}'_{\hbar,\varepsilon}$ by q^* and $q = \exp(iS(x_1, \hbar D_1))$ on the left and right respectively. □

Remark 13.3.11. (i) No part of the reduction process (from Proposition 13.3.1 to Proposition 13.3.10) is uniquely determined; however, it can be taken stable in the natural sense; surely there are natural limitations on $k^j, \dots, r^j$: $|k^j| \le c$, etc.

(ii) One can see easily that (as in, e.g., the construction of Theorem 13.2.1) if g^{jk}, F_{jk} and V are constant then (13.3.65) and (13.3.66) are replaced respectively by

$$\mathcal{A}'_{\hbar,\varepsilon} \equiv F(x_2^2 + \hbar^2 D_2^2) + \varepsilon V, \tag{13.3.65}'$$

and

$$\mathcal{A}'_{\hbar,\varepsilon} \equiv \hbar^2 D_2^2 + F(x_3^2 + \hbar^2 D_3^2) + \varepsilon V. \tag{13.3.66}'$$

(iii) This fact and stability yields that if

$$(13.3.77)_{1-3} \quad |D^\alpha(g^{jk}-\bar g^{jk})|\le c\bar\nu, \quad |D^\alpha(F_{jk}-\bar F_{jk})|\le c\bar\nu, \quad |D^\alpha(V-\bar V)|\le c\bar\nu \qquad \forall \alpha : |\alpha|\le K \quad \forall x\in B(0,1)$$

with constant $\bar g^{jk}$, $\bar F_{jk}$, $\bar V$ then in (13.3.65), (13.3.66) and (13.3.67) operators $\bar\nu^{-1}(B_0-\bar V)$, $\bar\nu^{-1}(B_1-\bar F)$ and $\bar\nu^{-1}B_n$ with $n\ge 2$ are $\hbar$-pseudodifferential operators uniformly with respect to $\bar\nu\in(0,1]$.

Further, in (13.3.73), (13.3.74) the same conclusion is true for operators $\bar\nu^{-1}(b_1-\bar F)$, $\bar\nu^{-1}(B-\bar V\bar F^{-1})$ and $\bar\nu^{-1}b_n$ with $n\ge 2$.

Furthermore, in (13.3.75) one can replace $O(\varepsilon^2)$, etc., by $O(\varepsilon^2\bar\nu)$, etc.

Remark 13.3.12. In what follows we assume without any loss of the generality and without special mention that the symbol of the $\hbar$-pseudodifferential operator $\mathcal{F}^*_{\hbar,\varepsilon}\mathcal{F}_{\hbar,\varepsilon}$ is supported in a small enough neighborhood of Λ^0.

13.3.3 Reduced Problems

Let us consider what we have obtained in the investigation of U, etc. Let $\mu\ge 1$, $h\in(0,1]$, $\mu h\le 1$ and $\hbar=\mu^{-1}h$, $\varepsilon=\mu^{-2}$. Let operator $\mathcal{F}=\mathcal{F}_{\hbar,\varepsilon}$ be the operator constructed in Theorem 13.3.8 and let

$$(13.3.78) \qquad \mathsf{U}=\mathcal{F}^*_x U\, {}^t\mathcal{F}^*_y.$$

Then

$$(13.3.79) \qquad (hD_t-\mathcal{A})\mathsf{U}\equiv 0,$$

and

$$(13.3.80) \qquad \mathsf{U}|_{t=0}\equiv \delta(x-y)$$

modulo functions f and f' respectively such that if Q is a $\mu^{-1}h$-pseudodifferential operator with symbol q supported in a small enough neighborhood of Λ^0 such that

$$(13.3.81) \qquad \|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_x f\|\le C'Th^s$$

and

$$(13.3.82) \qquad \|Q_x f'\|\le C'h^s$$

for arbitrary s [15)], $T \ge h^{1-\delta}$, T' and $\delta > 0$ are arbitrary, C' depends on $c, \epsilon_0, N, s, \delta$ and contains factors $\|\!|q|\!\|_{\mathsf{S}_{\mu^{-1}h}}$ and $\|\chi\|_{\mathscr{C}^K}$ (only in (13.3.81)).

Further,

$$\mathcal{A} = \mathcal{A}_{\mu,h} \equiv \mu^2 \mathcal{A}'_{\mu,h} \tag{13.3.83}$$

where $\mathcal{A}'_{\mu,h}$ is given by (13.3.65) or (13.3.73) as $d = 2$, and $\mathcal{A}'_{\mu,h}$ is given by (13.3.66) as $d = 3$, $\hbar = \mu^{-1}h$, $\varepsilon = \mu^{-2}$.

Moreover, U satisfies the dual equation and the properties of U yield similar properties of U:

$$\mathsf{U}(x, y, t) = \mathsf{U}^\dagger(y, x, -t), \tag{13.3.84}$$

and

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)\mathsf{U}| \le C'\mu T h^{-d} \tag{13.3.85}$$

provided $T \ge h^{1-\delta}$ where C' is the same constant as above and one can assume without loss of generality that

$$\mathsf{supp}(\mathsf{U}) \subset B(0, c_1) \times B(0, c_1) \times \mathbb{R}. \tag{13.3.86}$$

Finally, the definition of U, (13.3.61), (13.3.62) and Theorem 13.2.13 yield that

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)\big(U - \mathcal{F}_x \mathsf{U}^t \mathcal{F}_y\big)| \le C' T h^s \qquad \forall x, y \in \mathcal{W}_x \quad \forall \tau \le 4c \tag{13.3.87}$$

where $\mathcal{W}_x$ is the x-projection of $\mathcal{W}$.

13.4 Weak Magnetic Field

In this section we obtain spectral asymptotics under the initial assumption that the magnetic field is not very strong, i.e.,

$$\mu \in [\mu_0, h^{\delta-1}] \tag{13.4.1}$$

where here and in what follows μ_0 is a large enough constant and the exponent $\delta > 0$ is arbitrarily small. Under this condition the rescaled

[15)] Provided $K = K(N, s, \delta)$ in condition (13.2.3).

operator (as $x \mapsto \mu^{-1}x$, $hD \mapsto \mu hD$) is $\hbar$-pseudodifferential operator with semi-classical parameter $\hbar \le h^{\delta}$. Recall that $\hbar = \mu h$ appeared in section 13.2 twice: in the calculations for the model case in Subsection 13.2.2 and as the result of rescaling in Subsubsection 13.2.3.

Other restriction to μ will depend on properties of the coefficients[16] and appear later. The results obtained here make it possible to assume in the next sections that $\mu \ge h^{-\delta}$; in this case the remainder R in decompositions (13.3.65), (13.3.66) as well as all the terms containing large negative degrees of μ will be negligible.

In this section the microlocal canonical form is applied only to obtain a more refined results on the propagation of singularities; the calculations are taken from Subsection 4.3.3 and are made for the original (non-reduced to the canonical form) operator; a more accurate analysis of the propagation of singularities permits us to increase $T \asymp \mu^{-1}$ [17] in the Tauberian arguments. In the following sections the microlocal canonical form will also be used for calculations. We always assume that all the assumptions used in Section 13.3 are fulfilled.

13.4.1 Analysis of Singularities

Let us start with the analysis of singularities. First of all let us analyze their location, starting from rather crude "elliptical" result:

Proposition 13.4.1. *Let* $d = 2, 3$ *and let conditions* (13.3.1), (13.4.1) *be fulfilled. Consider symbol* $q \in \mathsf{S}_{\mu^{-1}h,\mu^{-1},\mu^{-1},K}(T^*\mathbb{R}^d)$ *and operator* $Q = \mathsf{Op}(q) = q(x, \mu^{-1}hD, \mu^{-1}h)$*; let us assume that*

$$(13.4.2)_{(2)} \quad \mathsf{supp}(q) \cap \{\tau_1 \le \bar{B}(x_1,\xi_1) + \bar{B}_1(x_1,\xi_1)(x_2^2+\xi_2^2)\mu^2 \le \tau_2\} = \emptyset,$$

$$(13.4.2)_{(3)} \quad \mathsf{supp}(q) \cap \{\tau_1 \le \bar{B}_0(x',\xi_1) + \bar{B}_1(x',\xi_1)(x_3^2+\xi_3^2)\mu^2 + \mu^2\xi_2^2 \le \tau_2\} = \emptyset$$

for $d = 2, 3$ *respectively where the bar means that the corresponding symbol is calculated for* $\hbar = \varepsilon = 0$ *and where* $-\infty \le \tau_1 < \tau_2 \le \infty$.

[16] Mainly $(V-\tau)F^{-1}$ where τ is an energy level in question; under assumption $|\nabla((V-\tau)F^{-1})| \asymp 1$ condition (13.4.1) would suffice.

[17] Usually to $T \asymp \mu$ or $T \asymp 1$ as $d = 2, 3$ respectively.

Then

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_x\mathsf{U}| \le C'Th^s\big(1+\min(\tau-\tau_1,\tau_2-\tau)\big)^{-s} \quad \forall x,y\in\mathbb{R}^d \quad \forall \tau\in[\tau_1+\epsilon,\tau_2-\epsilon] \tag{13.4.3}$$

where $s,\epsilon>0,\delta>0, T\ge h^{1-\delta}$ *and* T' *are arbitrary,* $K=K(\delta,s)$, $N=N(\delta,s)$ *in* (13.3.65), (13.3.66), $\mu_0=\mu_0(c,\epsilon)$ *in* (13.4.1) *and* $C'=C'(c,\epsilon,\delta,s)$ *also includes factors* $\|\!|q|\!\|$ *and* $\|\chi\|$.

This estimate remains true for Q_x *replaced by* ${}^tQ_y$ *(written as usual to the right from* $\boldsymbol{U}$*.*

Proof. Let us consider equation (13.3.79). The principal symbol of the $\hbar$-pseudodifferential operator $\mathcal{A}$ is

$$\bar{B}_0+\bar{B}_1(x_2^2+\xi_2^2)\mu^2+O\big((x_2^2+\xi_2^2)^2\mu^2+\mu^{-2}\big) \tag{13.4.4$_{(2)}$}$$

for $d=2$ and

$$\bar{B}_0+\bar{B}_1(x_3^2+\xi_3^2)\mu^2+\mu^2\xi_2^2+O\big((x_3^2+\xi_3^2)^2\mu^2+\mu^{-2}\big) \tag{13.4.4$_{(3)}$}$$

for $d=3$. Therefore operator $(hD_t-\mathcal{A})$ is elliptic under condition (13.4.2)$_{(2)}$ or (13.4.2)$_{(3)}$ in the zone

$$\{(x,\xi):\ \lambda(x,\xi)\le\epsilon', \tau_1+\epsilon\le\tau\le\tau_2-\epsilon\}$$

where $\epsilon'>0$ is a small enough constant and $x'=x_1$, $\lambda(x,\xi)=x_2^2+\xi_2^2$ for $d=2$ and $x'=(x_1,x_2)$, $\lambda(x,\xi)=x_3^2+\xi_3^2+\xi_2^2$ for $d=3$.

On the other hand, for any $\epsilon'>0$ and $\mu\ge\mu_0(c,\delta,\epsilon,\epsilon')$ this operator is automatically elliptic in the zone

$$\{(x,\xi):\ \lambda(x,\xi)\ge\epsilon', \tau_1+\epsilon\le\tau\le\tau_2-\epsilon\}$$

(recall that $\bar{B}_1\ge\epsilon_0$ in virtue of (13.3.12) and condition (13.3.1)).

Therefore, the standard elliptic arguments, estimate (13.3.85) and Remark 13.3.12 conclude the proof of this proposition. □

Remark 13.4.2. (i) Let us note that for $\tau_1=-\infty$, $\tau_2\le c$ and q supported in $\{(x,\xi):\ \lambda(x,\xi)\ge C_0\mu^{-2}\}$ with $C_0=C_0(c)$ condition (13.4.2) is fulfilled automatically; therefore Proposition 13.4.1 asserts in particular that

(13.4.5) U is negligible outside of the zone $\{(x,\xi):\ \lambda(x,\xi)\le C_0\mu^{-2}\}$

and hence in decompositions (13.3.65), (13.3.66) and (13.3.73) $R=O(\mu^{2-2N})$ in the heuristic sense.

Replacing U by $Q_x\mathsf{U}\equiv\mathsf{U}$ with $q=1$ for $\lambda(x,\xi)\le C_0\mu^{-2}$ and supported in $\{(x,\xi):\ \lambda(x,\xi)\le 2C_0\mu^{-2}\}$ we reach $R=O(\mu^{2-2N})$ in the sense that $R\mathsf{U}\equiv R'\mathsf{U}$ with $\mu^{2N-2}R'\in \boldsymbol{\Psi}_{\mu^{-1}h,\mu^{-1},\mu^{-1},K}$.

(ii) Moreover, Remark 13.3.11(ii) yields that $\bar\nu^{-1}\mu^{2N-2}R'\in \boldsymbol{\Psi}_{\mu^{-1}h,\mu^{-1},\mu^{-1},K}$ under conditions $(13.3.77)_{1-3}$.

Let us proceed to an analysis of propagation of singularities; here we obtain the principal difference between $d=2$ and $d=3$:

Theorem 13.4.3. *Let* $d=2,3$ *and conditions* (13.3.1), (13.4.1) *be fulfilled with* $\mu_0=\mu_0(c,\delta)$.

Let $Q'=\mathsf{Op}(q')$, $Q''=\mathsf{Op}(q'')$, $q',q''\in \mathsf{S}_{\boldsymbol{h},\rho,\gamma,K}(T^*\mathbb{R}^d)$ *where*

(13.4.6) $\boldsymbol{h}=(h_1,\dots,h_d)$, $\boldsymbol{\gamma}=(\gamma_1,\dots,\gamma_d)$, $\boldsymbol{\rho}=(\rho_1,\dots,\rho_d)$,
$h_1=\mu^{-1}h$, $h_2=h_3=h$, $\rho_j,\gamma_j\in(0,1]$, $\rho_j\gamma_j\ge h_jh^{-\delta}\quad\forall j$, $\gamma_d\le\mu^{-1}$

and quantization is taken with the vector semiclassical parameter $\boldsymbol{h}$.

(i) Let $d=3$ *and one of the following conditions*

$(13.4.7)_1$ $|x_1-y_1|\ge C_0\mu^{-1}T+\gamma_1$,

$(13.4.7)_2$ $|\xi_1-\eta_1|\ge C_0\mu^{-1}T+\rho_1$,

$(13.4.7)_3$ $|x_2-y_2|\ge C_0T+\gamma_2$,

$(13.4.7)_4$ $|\xi_2-\eta_2|\ge C_0T+\rho_2$

be fulfilled for all $(x,\xi)\in\mathsf{supp}(q')$ *and for all* $(y,\eta)\in\mathsf{supp}(q'')$ *where*

$(13.4.8)_{(3)}$ $T\in[h^{1-\delta},T_0]$,

$C_0=C_0(c)$, $T_0=T_0(c,\delta)>0$. *Then*

(13.4.9) $|F_{t\to h^{-1}\tau}\chi_T(t)Q'_x\mathsf{U}\,{}^tQ''_y|\le C'h^s\qquad\forall x,y\in\mathbb{R}^d\quad\forall\tau\le c.$

(ii) Let $d = 2$ *and one of conditions* $(13.4.7)_{1,2}$ *be fulfilled with*

$$T \in [h^{1-\delta}, \mu T_0]. \tag{13.4.8}_{(2)}$$

Then with C_0, T_0 *the same as before, estimate* (13.4.9) *remains true.*

(iii) Furthermore, if $\rho_d = \mu^{\frac{1}{2}} h^{\frac{1}{2}(1-\delta)}$, $\gamma_d = \mu^{-\frac{1}{2}} h^{\frac{1}{2}(1-\delta)}$ *and if condition*

$$|\mu^2 x_d^2 + \xi_d^2 - \mu^2 y_d^2 - \eta_d^2| \ge C\mu^{-l} + \rho_d \tag{13.4.10}$$

is fulfilled for all $(x, \xi) \in \mathsf{supp}(q')$ *and for all* $(y, \eta) \in \mathsf{supp}(q'')$ *with* $C = C(c, \delta, l)$ *then for* T *satisfying* $(13.4.8)_{(d)}$ *estimate* (13.4.9) *holds.*

We will prove this theorem together with Theorem 13.4.4 below. Statements (i) and (ii) mean that the velocity of propagation of singularities with respect to (x_1, ξ_1) does not exceed $C_0\mu^{-1}$ and for $d = 3$ the velocity with respect to (x_2, ξ_2) does not exceed C_0 and Statement (iii) means that expression $(\mu^2 x_d^2 + \xi_d^2)$ is almost constant for large μ (all these assertions hold for energy levels not exceeding c and for quantization corresponding to the vector $\boldsymbol{h}$) indicated in (13.4.6).

Let us emphasize that for $d = 2$ and $d = 3$ the restrictions on T from above are different, which will be essential for the Tauberian arguments.

For $d = 2, 3$ a more accurate theorem will be proven in Section 6.5. For $d = 2$ we have the more accurate

Theorem 13.4.4. *Let* $d = 2$ *and* $q', \dots, Q''$ *be as in Theorem 13.4.3. Let us assume that conditions* $(13.3.77)_{1-3}$ *are fulfilled and that*

$$\nu^{-1}(B - \beta) \in \boldsymbol{\Psi}_{\mu^{-1}h,K}(T^*\mathbb{R}^d) \tag{13.4.11}$$

where B *is the operator introduced in* (13.3.74) *and* $\beta = \mathsf{const}$.

Furthermore, let us assume that

$$1 \ge \bar\nu \ge \mu^{-l'}, \qquad \bar\nu \ge \nu \ge \mu^{-l}\bar\nu \tag{13.4.12}_{1,2}$$

and in what follows N, K, μ_0, C_0 *and* C *also depend on* l *and* K' *and* C' *also depend on* l, l'. *Then*

(i) Let one of the following conditions

$$|x_1 - y_1| \ge C_0\nu\mu^{-1}T + \gamma_1, \tag{13.4.7}'_1$$

$$|\xi_1 - \eta_1| \ge C_0\nu\mu^{-1}T + \rho_1 \tag{13.4.7}'_2$$

be fulfilled for all $(x,\xi)\in \mathsf{supp}(q')$ *and for all* $(y,\eta)\in \mathsf{supp}(q'')$ *with*

$$T\in [\bar\nu\nu^{-1}h^{1-\delta}, \mu\nu^{-1}T_0], \tag{13.4.8$'_{(2)}$}$$

and with $T_0 = T_0(c,\delta,l) > 0$. *Then estimate* (13.4.9) *remains true for* $|\tau|\le c\nu\bar\nu^{-1}$.

(ii) Moreover, if $\rho_2 = \mu^{\frac12}h^{\frac12(1-\delta)}$, $\gamma_2 = \mu^{-\frac12}h^{\frac12(1-\delta)}$ *and if the condition*

$$|\mu^2x_2^2+\xi_2^2-\mu^2y_2^2-\eta_2^2|\ge C\mu^{-l}\bar\nu+\rho_2 \tag{13.4.10$'$}$$

is fulfilled for all $(x,\xi)\in \mathsf{supp}(q')$ *and for all* $(y,\eta)\in \mathsf{supp}(q'')$ *then for the* T *and* τ *indicated in (i) estimate* (13.4.9) *holds.*

Let us note that for $\bar\nu=\nu$ condition (13.4.11) is fulfilled automatically by Remark 13.3.11(ii).

Proof of Theorems 13.4.3 and 13.4.4. The proof is similar to that of Theorem 2.1.2.

(i) Theorem 13.4.3(i) obviously follows from Theorem 13.4.4; let us prove the latter theorem. Dividing equation (13.3.79) by ν and introducing $t'=\mu\nu^{-1}t$ in place of t we obtain the following equation

$$\bigl(h_1D_{t'}-M(x_1,h_1D_1,h_1,\mu^{-2})\mathcal{B}-R'\bigr)\boldsymbol{U}\equiv 0 \tag{13.4.13}$$

with

$$\mathcal{B}=\nu^{-1}\mu^2\mathcal{L}=\nu^{-1}(\mu^2x_2^2+h^2D_2^2)+\nu^{-1}B^{\mathsf{w}} \tag{13.4.14}$$

and with

$$M=\sum_{0\le n\le N-2} b_{n+1}(x_1,h_1D_1,h_1,\mu^{-2})\mathcal{L}^n. \tag{13.4.15}$$

Moreover, Remark 13.4.2 yields that we can assume without any loss of the generality that $\mu^NR'\in \boldsymbol{\Psi}_{\boldsymbol{h},\rho,\gamma,K}$; condition (13.4.12) justifies all these transformations.

Let us note that the operator M is elliptic in the indicated zone and therefore equation (13.4.13) yields that

$$\mathcal{B}\mathsf{U}\equiv M'\bigl(h_1D_{t'}-R'\bigr)\mathsf{U}, \tag{13.4.16}$$

where M' is a parametrix of M.

Further, let us note that if function $\omega(x', \xi', \lambda)$ satisfies inequalities

$$|D^{\alpha}_{x'} D^{\beta}_{\xi'} D^{\sigma}_{\lambda} \omega| \le c_1 \boldsymbol{\rho}'^{-\beta} \boldsymbol{\gamma}'^{-\alpha} \bar{\rho}^{-\sigma} \qquad \forall \alpha, \beta, \sigma : |\alpha| + |\beta| + \sigma \le K_0 + K \tag{13.4.17}$$

with $\boldsymbol{\rho}' = (\rho_1)$, $\boldsymbol{\gamma}' = (\gamma_1)$ for $d = 2$ [18] and with $\bar{\rho} = \mu^{\frac{1}{2}} h^{\frac{1}{2}(1-\delta)}$ and if condition (13.4.6) is fulfilled then the symbol $\psi(x, \xi) = \omega(x_1, \xi_1, \mu^2 x_2^2 + \xi_2^2)$ belongs to $\mathsf{S}_{\boldsymbol{h}, \boldsymbol{\rho}, \boldsymbol{\gamma}, K}$ in the zone $\{\mu^2 x_2^2 + \xi_2^2 \le C_0\}$ where $\boldsymbol{\rho} = (\rho_1, \rho_2)$, $\boldsymbol{\gamma} = (\gamma_1, \gamma_2)$, ρ_1 and γ_1 were introduced earlier and $\rho_2 = \bar{\rho}$, $\gamma_2 = \mu^{-1}\bar{\rho}$ for $d = 2$.

Moreover, the absolute values of the Poisson brackets $\{\psi, \mathcal{B}\}$ and $\{\psi, M\}$ do not exceed $C_0 |\nabla_{x_1, \xi_1} \omega|$ and the absolute value of the Poisson bracket $\{\psi, R'\}$ does not exceed $C_0 \mu^{-l} |\nabla_{x_1, \xi_1, \lambda} \omega|$ with arbitrarily large l [19].

Taking into account these observations we can apply the arguments used in the proof of Theorem 2.1.2 to

$$\phi(x, \xi, t') = \psi(x, \xi) + t' = \omega(x_1, \xi_1, \mu^2 x_2^2 + \xi_2^2) + t' \tag{13.4.18}_{(2)}$$

provided conditions (13.4.17) and (13.4.6) with $j = 1$ are fulfilled and

$$|\nabla_{x_1, \xi_1} \omega| \le C_0^{-1}, \qquad |\partial_{\lambda} \omega| \le C^{-1} \mu^{l}. \tag{13.4.19}_{(2)}$$

(ii) Theorem 13.4.3(ii) is proven in the same way but now we neither divide by ν, nor introduce the variable t' and apply a parametrix M' of M; we need only apply the arguments used in the proof of Theorem 2.1.2 to symbol

$$\phi(x, \xi, t) = \omega(x', \xi', \mu^2 x_3^2 + \xi_3^2) + t \tag{13.4.18}_{(3)}$$

where ω satisfies (13.4.17) with $\boldsymbol{\rho}' = (\rho_1, \rho_2)$, $\boldsymbol{\gamma}' = (\gamma_1, \gamma_2)$ and

$$|\nabla_{x_1, \xi_1} \omega| \le C_0^{-1} \mu, \quad |\nabla_{x_2, \xi_2} \omega| \le C_0^{-1}, \quad |\partial_{\lambda} \omega| \le C^{-1} \mu^{l}, \tag{13.4.19}_{(3)}$$

and condition (13.4.6) with $j = 1, 2$ is fulfilled. □

Theorems 13.4.3, 13.4.4 and 13.2.13 and formula (13.3.87) immediately imply the following

[18] And with $\boldsymbol{\rho}' = (\rho_1, \rho_2)$, $\boldsymbol{\gamma}' = (\gamma_1, \rho_2)$ for $d = 3$ below.

[19] After the calculation of the gradients one should substitute $\lambda = \mu^2 x_2^2 + \xi_2^2$.

Theorem 13.4.5. *Let conditions* (13.2.1)–(13.2.5), (13.3.1) *and* (13.4.1) *be fulfilled.*

(i) Further, let $d = 2$ *and condition* $(13.4.8)_{(2)}$ *be fulfilled. Then*

$$|F_{t\to h^{-1}\tau}\chi_T(t)U(x,y,t)| \le C'h^s \quad \forall x,y \in B(0,\frac{3}{4}) : |x-y| \ge C_0\mu^{-1}(T+1) \quad \forall \tau \le c. \tag{13.4.20}$$

(ii) Let $d = 2$ *and conditions* $(13.3.77)_{1-3}$, (13.4.11), (13.4.12), $(13.4.8)'_{(2)}$ *be fulfilled. Then the same estimate* (13.4.20) *holds for all* $x, y \in B(0, \frac{3}{4})$ *and* τ *such that*

$$|x-y| \ge C_0\mu^{-1}(\nu T+1) \qquad \text{and} \qquad |\tau| \le c\nu. \tag{13.4.21}$$

(iii) On the other hand, let $d = 3$ *and condition* $(13.4.8)_{(3)}$ *be fulfilled. Then estimate* (13.4.20) *holds for all* $x, y \in B(0, \frac{3}{4}), \tau \le c$ *such that*

$$\operatorname{dist}(x, \Gamma(y)) \ge C_0\mu^{-1} \tag{13.4.22}$$

where $\Gamma(y)$ *is a magnetic line passing through* y *(more precisely, its segment lying in* $B(0,1)$*).*

Remark 13.4.6. (i) Thus for $d = 2$ the average (in time intervals greater than ϵ_0) spatial velocity of propagation of singularities does not exceed $C_0\mu^{-1}$ which permits us to control U on a time interval of length $T_0\mu$ (under the assumptions of Statement 13.4.5(ii) this length increases to $\mu\nu^{-1}T_0$).

(ii) On the other hand, for $d = 3$ singularities propagate almost along magnetic lines. Moreover, let us recall that the average (on time intervals greater than $h^{1-\delta}$) spatial velocity of propagation of singularities does not exceed C_0 (see Theorem 13.2.11); this is important for $d = 3$ and for $d = 2$ for short time intervals.

13.4.2 Refined Estimates

Let us proceed with a more refined analysis. It will be convenient for us to use symbols of the form

(13.4.23) $q = q_1 q_2 \in \mathsf{S}_{\boldsymbol{h},\boldsymbol{\rho},\boldsymbol{\gamma},K}(T^*\mathbb{R}^d)$ with factors $q_1 \in \mathsf{S}_{\boldsymbol{h}',\boldsymbol{\gamma},\boldsymbol{\gamma},K}(T^*\mathbb{R}^{d-1})$ and $q_2 = \varphi(\mu^2 x_d^2 + \xi_d^2) \in \mathsf{S}_{h,\bar\rho,\mu^{-1}\bar\rho,K}(T^*\mathbb{R})$ where $\boldsymbol{\rho} = (\gamma,\gamma,\mu\bar\rho)$, $\boldsymbol{\gamma} = (\gamma,\gamma,\bar\rho)$, $\bar\rho \ge \mu^{\frac12} h^{\frac12(1-\delta)}$, φ satisfies (13.4.17), i.e.,

$$|D_\lambda^\sigma \varphi(\lambda)| \le C\bar\rho^{-\sigma} \qquad \text{for } \ \sigma : |\sigma| \le K$$

and $\mathsf{diam}(\mathsf{supp}(\varphi)) \le c\bar\rho$, $\mathsf{diam}(\mathsf{supp}(q_1)) \le c\gamma$.

Restrictions on γ depending on d will be given later; let us recall that $\boldsymbol{h}$ and $\boldsymbol{h}'$ are defined in (13.4.6).

Elliptic Estimates

Standard elliptic methods combined with the rough estimate (13.3.85) easily imply

Proposition 13.4.7. *Let conditions* (13.2.1)–(13.2.5), (13.3.1) *and* (13.4.1) *be fulfilled.*

(i) Let $d = 2$ *and conditions* $(13.3.77)_{1-3}$, (13.4.11) *and* (13.4.12) *be fulfilled and* $Q = \mathsf{Op}(q)$, q *of the form* (13.4.23). *Further, assume that*

$$\gamma \ge \mu^{-\frac12} h^{\frac12(1-\delta)} + C\mu^{-l}, \tag{13.4.24}$$

$$|\lambda + B(x_1,\xi_1,\mu^{-2},0)| \ge \zeta \ge \epsilon_0(\bar\rho + \nu\gamma^2), \tag{13.4.25}$$

and

$$|\nabla B(x_1,\xi_1,\mu^{-2},0)| \le c\nu\gamma \quad \forall (x_1,\xi_1) \in \mathsf{supp}(q_1)\ \forall \lambda \in \mathsf{supp}(\varphi). \tag{13.4.26}$$

Then

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t) Q_x \mathsf{U}| \le C' T h^s \qquad \forall \tau : |\tau| \le \epsilon\zeta \quad \forall x,y \in \mathbb{R}^d \tag{13.4.27}$$

where $T \ge h^{1-\delta}\zeta^{-1}$, T' *and* s *are arbitrary, and here and in what follows* $\epsilon = \epsilon(c, l, \epsilon_0, \delta) > 0$ *is a small enough constant.*

(ii) Let $d = 3$, $Q = \mathsf{Op}(q)$ *where* q *of the form* (13.4.23). *Further, assume that*

$$\gamma \ge h^{\frac12(1-\delta)} + C\mu^{-l}, \tag{13.4.24}$$

$$|\xi_2^2 + \mathcal{B}(x',\xi_1,\lambda,\mu^{-2},0)| \ge \zeta \ge \epsilon_0(\bar\rho + \gamma^2) \tag{13.4.25}$$

and

$$(13.4.26)_{(3)} \quad |\xi_2| + |\nabla\mathcal{B}(x',\xi_1,\lambda,\mu^{-2},0)| \le c\gamma \qquad \forall (x',\xi') \in \mathsf{supp}(q_1) \quad \forall \lambda \in \mathsf{supp}(\varphi)$$

where here and below

$$\mathcal{B} = \sum_{0\le n\le N-1} B_n(x',\xi_1,.,.)\lambda^n \tag{13.4.28}$$

and B_n are taken from decomposition (13.3.66)*.*

Then estimate (13.4.27) *holds.*

Propagation of Singularities

Let us now treat propagation of singularities. Our final goal is to prove that if we cut propagator $U(x,y,t)$, then take a trace, the result will be negligible as $T_* \le |t| \le T^*$; later *in this section* we request $T_* \le \epsilon\mu^{-1}$ as on interval $|t| \le \epsilon\mu^{-1}$ the standard theory works (f.e. in virtue of rescaling).

Proposition 13.4.8. *Let conditions* (13.2.1)–(13.2.5)*,* (13.3.1) *and* (13.4.1) *be fulfilled.*

(i) Further, let $d = 2$, conditions $(13.3.77)_{1-3}$*,* (13.4.11) *and* (13.4.12) *be fulfilled*[20]*, $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$, q' and q'' of the form* (13.4.23) *and γ satisfy* $(13.4.24)_{(2)}$*.*

Moreover, let us assume that $(13.4.26)_{(2)}$ *is fulfilled on* $\mathsf{supp}(q')$ *and that*

$$(13.4.29)_{(2)} \quad |x_1 - y_1| + |\xi_1 - \eta_1| \ge C_0\nu\mu^{-1}\gamma T + \gamma \qquad \forall (x_1,\xi_1) \in \mathsf{supp}\, q' \quad \forall (y_1,\eta_1) \in \mathsf{supp}(q'').$$

Then estimate (13.4.9) *holds for all $x, y \in \mathbb{R}^2$ and all τ : $|\tau| \le c\nu\gamma$ provided*

$$(13.4.30)_{(2)} \qquad T \in [h^{1-\delta}\frac{1}{\gamma\nu}, \mu\frac{T_0}{\nu}]$$

with a small constant $T_0 > 0$.

[20] Recall that these conditions are always fulfilled with $\bar\nu = \nu = 1$.

(ii) On the other hand, let $d = 3$, $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$, q' *and* q'' *of the form* (13.4.23) *and* γ *satisfy* $(13.4.24)_{(3)}$.

Moreover, let us assume that $(13.4.26)_{(3)}$ *is fulfilled on* $\mathsf{supp}(q')$ *and that*

$$(13.4.29)_{(3)} \quad \mu(|x_1 - y_1| + |\xi_1 - \eta_1|) + |x_2 - y_2| + |\xi_2 - \eta_2| \geq C_0\gamma T + \gamma \qquad \forall (x', \xi') \in \mathsf{supp}(q') \quad \forall (y', \eta') \in \mathsf{supp}(q'').$$

Then estimate (13.4.9) *holds for all* $x, y \in \mathbb{R}^3$ *and all* $\tau : \ |\tau| \leq c\gamma$ *provided*

$$(13.4.30)_{(3)} \qquad T \in [h^{1-\delta}\gamma^{-1}, T_0].$$

with a small constant $T_0 > 0$.

Proof. The proof is very similar to that of Propositions 2.1.12 and 2.1.13; moreover, we take into account the remarks to the proofs of Theorems 13.4.3 and 13.4.4. The easy details are left to the readers. □

Moreover, the same arguments and arguments used in the proofs of Corollaries 2.1.14 and 2.1.17 and Proposition 2.1.16 and and the same remarks yield the following assertion similar to Corollary 2.1.17:

Proposition 13.4.9. *Let conditions* (13.2.1)–(13.2.5), (13.3.1) *and* (13.4.1) *be fulfilled.*

(i) Further, let $d = 2$, *conditions* $(13.3.77)_{1-3}$, (13.4.11) *and* (13.4.12) *be fulfilled*[20], $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$, q' *and* q'' *of the form* (13.4.23) *and* γ *satisfy* $(13.4.24)_{(2)}$.

Moreover, let us assume that on $\mathsf{supp}(q')$ *condition* $(13.4.26)_{(2)}$ *is fulfilled and*

$$(13.4.31)_{(2)} \qquad |\nabla B| \geq \epsilon_0\nu\gamma \quad \textit{on} \quad \mathsf{supp}(q').$$

Finally, let $\chi, \bar{\chi} \in \mathscr{C}_0^K([-1,1])$, $\bar{\chi} = 1$ *on* $[-\frac{1}{2}, \frac{1}{2}]$ *and let* T', T *satisfy* $(13.4.30)_{(2)}$ *and*

$$(13.4.32) \qquad T_* := \frac{h^{1-\delta}}{\nu\gamma^2} \leq T' \leq T.$$

Then

$$(13.4.33) \quad |F_{t\to h^{-1}\tau}\chi_T(t)\bigl(1 - \bar{\chi}_{T'}\bigr)\Gamma Q'_x U\, {}^tQ''_y| \leq C'h^s \qquad \forall \tau : |\tau| \leq \epsilon\frac{\nu\gamma^2}{\bar{\nu}}.$$

(ii) On the other hand, let $d = 3$, $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$, q' *and* q'' *of the form* (13.4.23) *and* γ *satisfy* $(13.4.24)_{(3)}$.

Moreover, let us assume that on $\mathsf{supp}(q')$ *condition* $(13.4.26)_{(3)}$ *is fulfilled and*

$$(13.4.31)_{(3)} \qquad |\xi_2| + |\nabla \mathcal{B}| \ge \epsilon_0 \gamma \quad \textit{on} \quad \mathsf{supp}(q').$$

Finally, let $\chi, \bar{\chi} \in \mathscr{C}_0^K([-1,1])$, $\bar{\chi} = 1$ *on* $[-\frac{1}{2}, \frac{1}{2}]$ *and let* T', T *satisfy conditions* $(13.4.30)_{(3)}$ *and* (13.4.32) *where*

(13.4.34) $\bar{\nu} = \nu = 1$ *automatically for* $d = 3$ *in this section.*

Then estimate (13.4.33) *holds.*

Remark 13.4.10 (Remark to the proof). (i) For $d = 3$ we treat four cases, namely when one of the following conditions holds on $\mathsf{supp}(q')$:

$$(13.4.35)_1 \qquad |\partial_{x_1} \mathcal{B}| \ge \epsilon_0 \nu \gamma,$$

$$(13.4.35)_2 \qquad |\partial_{\xi_1} \mathcal{B}| \ge \epsilon_0 \nu \gamma,$$

$$(13.4.35)_3 \qquad |\partial_{x_2} \mathcal{B}| \ge \epsilon_0 \gamma,$$

$$(13.4.35)_4 \qquad |\xi_2| \ge \epsilon_0 \gamma$$

with $\nu = 1$.

Moreover, our arguments repeat those of the proof of Proposition 2.1.16 with no change if one of conditions $(13.4.35)_{3,4}$ is fulfilled; the same is true if one of conditions $(13.4.35)_{1,2}$ is fulfilled but in the latter case we also need to change coordinates: $x_{1\mathsf{new}} = \mu x_1$.

Moreover, in the auxiliary partition of unity (see proof of Proposition 2.1.16) we use standard h- (but not $\boldsymbol{h}$-) pseudodifferential operators.

(ii) For $d = 2$ we treat only two cases $(13.4.35)_{1,2}$ and our arguments repeat those of the proof of Proposition 2.1.16.

Remark 13.4.11. (i) Proposition 13.4.7 yields that in estimates (13.4.9) and (13.4.33) in Propositions 13.4.8 and 13.4.9 we can replace Q', Q'' by Q_1', Q_1'' respectively where $Q_1' = \mathsf{Op}(q_1')$, $Q_1'' = \mathsf{Op}(q_1'')$, q_1' and q_1'' are taken from decomposition (13.4.23).

In this case we need to check conditions $(13.4.26)_{(3)}$ and $(13.4.31)_{(3)}$ with λ violating condition $(13.4.25)_{(3)}$ with $\zeta = \epsilon(\bar{\rho}+\gamma)$; the concrete choice of λ is not essential.

(ii) For $d = 2$ the corresponding conditions do not include λ at all.

Estimates. I

On the other hand, propagation with respect to $(\mu x_d, \xi_d)$ has a speed $\asymp 1$ provided $(\mu^2 x_d^2 + \xi_d^2) \asymp 1$ and the corresponding trajectories are not periodic as $|t| \le \epsilon\mu^{-1}$. Then we immediately arrive to

Proposition 13.4.12. *Let* $d = 2, 3$, $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$, q' *and* q'' *of the form* (13.4.23),

$$\gamma \ge (\mu h)^{\frac{1}{2}-\delta} \tag{13.4.36}$$

and

$$(\mu^2 x_d^2 + \xi_d^2) \ge \epsilon_0 \qquad \textit{on} \quad \mathsf{supp}(q). \tag{13.4.37}$$

Then

$$|F_{t\to h^{-1}\tau}\bar{\chi}_{T'}(t)\Gamma Q'_x \mathsf{U}\, {}^t Q''_y| \le Ch^{1-d}\gamma^{2(d-1)} \qquad \forall \tau : |\tau| \le c, \tag{13.4.38}$$

as

$$h\gamma^{-2} \le T' \le \epsilon\mu^{-1}. \tag{13.4.39}$$

Proof. Proof is the standard one: as usual in virtue of propagation we establish that

(13.4.40) The left-hand expression of (13.4.38) with $\bar{\chi}$ replaced by χ does not exceed $Ch^{1-d}\gamma^{2(d-1)}h^s T'^{-s}$ with arbitrarily large exponent s under assumptions (13.4.37), (13.4.39)

and also establish crude

(13.4.41) The left-hand expression of (13.4.38) does not exceed $Ch^{-d}\gamma^{2d}T'$.

Summation over partition of unity with respect to t concludes the proof. □

Now, combining results of Propositions 13.4.9 and 13.4.12 we arrive to

Corollary 13.4.13. *Let assumptions of Proposition 13.4.12 and either of Proposition 13.4.9(i) or of Proposition 13.4.9(ii) be fulfilled.*

Then estimate (13.4.38) *holds for all* τ *satisfying* (13.4.33) *and* $h\gamma^{-2} \le T' \le T^*$ *with* T^* *defined by* $(13.4.30)_{(2)}$ *or* $(13.4.30)_{(3)}$ *respectively.*

Recall that $e(x,y,\tau)$ is the Schwartz kernel of the spectral projector. Consider $\mathcal{E}(x,y,\tau) = \mathcal{F}^*_x e'(.,.,\tau)\, {}^t\mathcal{F}_y$ its transformation by $\mathcal{F} = \mathcal{F}_{\mu^{-2},\mu^{-1}h}$ introduced in Theorem 13.3.8.

Consider its Tauberian approximation

$$\mathcal{E}^{\mathsf{T}}(x,y,\tau) \coloneqq h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau'}\bigl(\bar{\chi}_{T'}(t)U\bigr)\,d\tau' \tag{13.4.42}$$

with

$$h^{1-\delta}\gamma^{-2} \le T' \le \epsilon\mu^{-1} \tag{13.4.43}$$

where the second inequality in (13.4.43) will be needed only in the next subsection.

Then applying Tauberian arguments we arrive to

Proposition 13.4.14. *Let assumptions of Proposition 13.4.12 and either of Proposition 13.4.9(i) or of Proposition 13.4.9(ii) be fulfilled.*

Then the following estimate holds:

$$|\Gamma Q'_x\Bigl(\mathcal{F}^*_x e(.,.,\tau)\,{}^t\mathcal{F}_y - \mathcal{E}^{\mathsf{T}}(x,y,\tau)\Bigr)\,{}^tQ''_y| \le CT^{*-1}h^{1-d}\gamma^{2(d-1)} \tag{13.4.44}$$

and, moreover, the following Riesz means estimate holds:

$$|\tau_+^{\vartheta-1} * \Gamma Q'_x\Bigl(\mathcal{F}^*_x e'(.,.,\tau)\,{}^t\,\mathcal{F}_y - \mathcal{E}^{\mathsf{T}}(x,y,\tau)\Bigr)\,{}^tQ''_y| \le CT^{*-1-\vartheta}h^{1-d+\vartheta}\gamma^{2(d-1)} \tag{13.4.44}$$

where $\tau = 0$ *(or satisfies* (13.4.33)*) and* T^* *is defined by* $(13.4.30)_{(2)}$ *or* $(13.4.30)_{(3)}$ *respectively.*

On the other hand, applying Tauberian arguments we arrive to

Proposition 13.4.15. *Let assumptions of Proposition 13.4.12 be fulfilled.*

Then estimates (13.4.44) *and* $(13.4.44)_\vartheta$ *hold with* T^* *replaced by* $T_* = \epsilon\mu^{-1}$.

Remark 13.4.16. (i) In propositions above we do not need cut-off with respect to $(\mu^2 x_d^2 + \xi_d^2)$ which automatically is selected to break ellipticity on level 0 of operator $\mathcal{B}$. However we need it to fulfill (13.4.37) to cover interval $|t| \le \epsilon\mu$; however as $d = 3$ the same effect will be achieved by $|\xi_2| \ge \epsilon$ so we can replace (13.4.37) by

$$(\mu^2 x_3^2 + \xi_3^2 + \xi_2^2) \ge \epsilon_0 \qquad \text{on} \quad \mathsf{supp}(q). \tag{13.4.37}_{(3)}$$

(ii) Note that condition (13.4.37) or $(13.4.37)_{(3)}$ is fulfilled as ellipticity assumption $(13.4.25)_{(2)}$ or $(13.4.25)_{(3)}$ respectively as $d = 2, 3$ is broken if and only if

$$V \le -\epsilon_0 \qquad \forall x \in B(0,1). \tag{13.4.45}$$

(iii) Furthermore to cover interval $|t| \le \epsilon\mu^{-1}$ we may assume that

$$|V| + |\nabla V| \ge \epsilon_0 \qquad \forall x \in B(0,1). \tag{13.4.46}$$

Then using γ-admissible partition of unity we immediately arrive to

Proposition 13.4.17. *Let condition* (13.4.46) *be fulfilled. Further, let* <u>*either*</u> $d = 2$ *and conditions* $(13.3.77)_{1-3}$ *and* (13.4.11) *be fulfilled with*

$$\nu \ge \mu h^{1-\delta} \tag{13.4.47}$$

<u>*or*</u> *let* $d = 3$.

Furthermore, let $\gamma = \gamma(x', \xi')$ *be a scaling function such that*

(13.4.48) *As* $\gamma \ge \bar{\gamma} := (\mu h \nu^{-1})^{\frac{1}{2}} h^{-\delta}$ *and* $\lambda \in \mathbb{R}$ *either ellipticity condition* $|\mathcal{B}| \ge \epsilon\nu\gamma^2$ *or nondegeneracy condition* $(13.4.31)_{(d)}$ *be fulfilled.*

Let $Q', Q'' \in \boldsymbol{\Psi}_h$ *be fixed operators. Then*

(i) As $d = 2$ *the left-hand expression of* $(13.4.44)_\vartheta$ *does not exceed*

$$C\mu^{-1-\vartheta} h^{-1+\vartheta} \nu^{-1-\vartheta} + C\mu^{1+\vartheta} h^{-1+\vartheta}\, \mathsf{mes}_2(\Omega_2) \tag{13.4.49}_\vartheta$$

with

$$\Omega_{2d-2} := \{(x', \xi') \in \mathsf{supp}(q) \colon \gamma(x', \xi') \le C_0 \bar{\gamma}\} \tag{13.4.50}$$

(ii) As $d = 3$ the left-hand expression of $(13.4.44)_\vartheta$ *does not exceed*

$$Ch^{-2+\vartheta} + C\mu^{1+\vartheta}h^{-2+\vartheta}\,\mathsf{mes}_4(\Omega_4). \tag{13.4.51}_\vartheta$$

Finally, we can get rid of transformation to canonical form in the expression we estimate (albeit not yet in the non-degeneracy conditions):

Remark 13.4.18. Consider Tauberian approximation to $e(x,y,\tau)$

$$e^{\mathsf{T}}(x,y,\tau) \coloneqq h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau'}\bigl(\bar{\chi}_{T'}(t)U\bigr)\,d\tau' \tag{13.4.52}$$

with T' satisfying (13.4.43).

Then estimates $(13.4.49)_\vartheta$ (as $d = 2$) and $(13.4.51)_\vartheta$ (as $d = 3$) hold for

$$\mathsf{R}^{\mathsf{T}} \coloneqq |\Gamma\psi(x)\bigl(e(.,.,\tau) - e^{\mathsf{T}}(x,y,\tau)\bigr)| \tag{13.4.53}$$

(as $\vartheta = 0$) and

$$\mathsf{R}^{\mathsf{T}}_{(\vartheta)} \coloneqq |\tau_+^{\vartheta-1} * \Gamma\psi(x)\bigl(e(.,.,\tau) - e^{\mathsf{T}}(x,y,\tau)\bigr)| \tag{13.4.53}_\vartheta$$

(as $\vartheta > 0$) where $\tau = 0$; now all conditions should be checked in the vicinity of $\bar{\Psi}_0(\mathsf{supp}(\psi))$.

Estimates. II

Let us discuss the right-hand expression of our estimates. So far "remainder" means R^{T} as $\vartheta = 0$ and $\mathsf{R}^{\mathsf{T}}_{(\vartheta)}$ as $\vartheta > 0$; we will deal with the left-hand expression in the next subsection.

Remark 13.4.19. Let $Q' = Q'' = I$.

(i) Note that $\Omega_d = \emptyset$ provided

$$|\nabla \frac{V}{F}| \ge \epsilon_0 \tag{13.4.54}$$

and therefore for $\vartheta \ge 0$ remainder is $O\bigl(\mu^{-1-\vartheta}h^{-1+\vartheta}\bigr)$ (as $d = 2$) and $O\bigl(h^{-2+\vartheta}\bigr)$ (as $d = 3$)

Furthermore, in this case[21)] no partition is needed and condition (13.4.46) is fulfilled automatically, and one does not need condition (13.4.45).

[21)] And so far only in this case; in Subsection 13.8.1 we get rid of condition (13.4.45) in general.

(ii) On the other hand, let $d = 2$ and conditions $(13.3.77)_{1-3}$ are fulfilled and

$$(13.3.77)^*_3 \qquad |D^\alpha(\frac{V}{F})| \le c\nu \qquad \forall \alpha : 1 \le |\alpha| \le K$$

then $\Omega_2 = \emptyset$ as

$$(13.4.54)'_3 \qquad |\nabla \frac{V}{F}| \ge \epsilon_0 \nu$$

and

$$(13.4.55) \qquad \nu \ge \max\bigl(\mu h^{1-\delta}, C(\epsilon_0)\mu^{-2}\bar{\nu}\bigr).$$

Therefore for $\vartheta \ge 0$ remainder is $O\bigl(\mu^{-1-\vartheta} h^{-1+\vartheta} \nu^{1+\vartheta}\bigr)$.

(iii) As $d = 3$ automatically $\mathsf{mes}_4(\Omega_4) \le C(\mu h)^{\frac{1}{2}} h^{-\delta}$. Therefore estimate $O(h^{-2+\vartheta})$ is achieved as $\mu \le h^{-1/(3+2\vartheta)+\delta}$. In particular, as $\vartheta = 0$ remainder estimate $O(h^{-2})$ is achieved as $\mu \le h^{-\frac{1}{3}+\delta}$.

(iv) On the contrary, as $d = 2$ one always needs some nondegeneracy condition. Otherwise remainder estimate $O(\mu^{1+\vartheta} h^{-1+\vartheta})$ could not be improved.

(v) In particular, under non-degeneracy condition

$(13.4.56)_r$ $|\nabla(V/F)| \le \epsilon\nu$ implies that $\mathsf{Hess}(V/F)$ has r eigenvalues by absolute value larger than ϵ

$\mathsf{mes}_2(\Omega_2) \le C(\mu h/\nu)^{r/2} h^{-\delta}$. In particular, as $\vartheta = 0$, $\nu = 1$ we derive remainder estimate $O(\mu^{-1}h^{-1})$ as $\mu \le h^{-r/(r+4)+\delta}$.

(vi) Under non-degeneracy condition

$$(13.4.57)_m \qquad \sum_{1\le|\alpha|\le m} |D^\alpha(\frac{V}{F})| \ge \epsilon\nu$$

$\mathsf{mes}_2(\Omega_2) \le (\mu h/\nu)^\sigma h^{-\delta}$ with $\sigma = \sigma(m)$. Therefore, under these conditions we arrive to remainder estimate $O(\mu^{-1-\vartheta} h^{-1+\vartheta} \nu^{1+\vartheta})$ as $\mu \le h^{-\sigma'}$, $\nu \ge h^{\sigma'}$ with $\sigma' = \sigma'(m, \vartheta)$.

13.4.3 Calculations

Let us proceed from estimates to calculations. In this subsection $d \ge 2$ is arbitrary and the crucial statement is the following:

Proposition 13.4.20. *Let conditions* (13.2.1)–(13.2.5) *and* (13.4.1) *be fulfilled and let* $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$, $q', q'' \in \mathsf{S}_{h,\gamma,\gamma,K}$,

$$\gamma \ge (\mu h)^{\frac{1}{2}-\delta} \tag{13.4.58}$$

and $\psi', \psi'' \in \mathscr{C}_0^K(B(0,\frac{3}{4}))$, $\chi \in \mathscr{C}_0^\infty([-1,1])$. *Then*

(i) For $T \in [h^{1-\delta}, (\mu^{-1}h)^{\frac{1}{2}+\delta}]$ *the following estimate holds:*

$$\begin{aligned} &|F_{t\to h^{-1}\tau}\chi_T(t)\big(Q'_x\psi'(x)U\psi''(y)\,{}^tQ''_y\big)(x,x,t)- \\ &\sum_{m+n\le M} Th^{-1}\int \hat\chi\big(\frac{(\tau-\tau')T}{h}\big)\varkappa'_{mn}(x,\tau')\mu^m h^{1-d+m+n}\,d\tau'| \le \\ &\qquad C'h^{1-d}(\mu h)^s \qquad\qquad \forall x\in\mathbb{R}^d \quad \forall \tau : |\tau|\le c \end{aligned} \tag{13.4.59}$$

where κ_{mn} *depend also on* Q', Q''.

Further, for $L \in [(\mu h)^{1-\delta}, 1]$, $T' \ge h^{1-\delta}L^{-1}$ *the following estimate holds:*

$$\begin{aligned} &\Big|\int \phi\big(\frac{\tau}{L}\big)\big(F_{t\to h^{-1}\tau}\bar\chi_T(t)(Q'_x\psi'(x)U)(x,x,t)- \\ &\sum_{m+n\le M} \varkappa'_{mn}(x,\tau)\mu^m h^{1-d+m+n}\big)\,d\tau\Big| \le C'h^{1-d}(\mu h)^s \qquad \forall x\in\mathbb{R}^d \end{aligned} \tag{13.4.60}$$

where $\varkappa_{mn} \in \mathscr{C}^s(B(0,1), \mathscr{S}'(\mathbb{R}))$ *are supported in* $\{\tau \ge V(x)\}$, $\varkappa'_{mn} = \partial_\tau \varkappa_{mn}$ *and we assume that* $\chi, \bar\chi \in \mathscr{C}_0^K([-1,1])$ *are fixed,* $\bar\chi = 1$ *in* $[-\frac{1}{2}, \frac{1}{2}]$ *and* $\phi \in \mathscr{C}_0^K([-c,c])$ *is also fixed,* $\delta > 0$ *and* s *are arbitrary and* $K = K(d,\delta,s)$, $M = M(d,\delta,s)$.

Furthermore, terms in both decompositions become smaller as $(m+n)$ *increases; in particular, for* $\gamma = L = 1$ *in* (13.4.60) *one can take* $s = (M+1)$.

(ii) Moreover, if condition (13.4.45) *is fulfilled then for* $|\tau| \le \frac{1}{2}\epsilon_0$ *estimate* (13.4.59) *holds with every* $T \in [h^{1-\delta}, \mu^{-1}T_0]$ *where* $T_0 = T_0(d,c,\epsilon_0,\delta) > 0$ *is a small enough constant.*

In particular, if $\mathsf{diam}(\mathsf{supp}(q')) \le c\gamma$ *then under condition* (13.4.45) *the following estimate holds:*

$$|F_{t\to h^{-1}\tau}\chi_T(t)(Q'_x\psi'(x)U\psi''(y)\,{}^tQ''_y)(x,x,t)| \le C'h^{1-d}\gamma^{d-2} \qquad \forall x\in\mathbb{R}^d \quad \forall \tau : |\tau| \le \frac{1}{2}\epsilon_0 \tag{13.4.61}$$

where T *is as before.*

(iii) On the other hand, if condition (13.4.46) *is fulfilled then for* $\gamma = 1$ *estimate*

$$\Big|\int F_{t\to h^{-1}\tau}\chi_T(t)\big((Q'_x\psi'(x)U\psi''(y)\,{}^tQ''_y)(x,x,t) - \sum_{m+n\le M} Th^{-1}\int \hat\chi(\frac{(\tau-\tau')T}{h})\varkappa'_{mn}(x,\tau')\mu^m h^{1-d+m+n}d\tau'\big)\,dx\Big| \le C'h^{1-d}(\mu h)^s \qquad \forall \tau : |\tau|\le\epsilon \tag{13.4.62}$$

(which is due to (13.4.59)*) holds for* $\epsilon = \epsilon(d,c,\epsilon_0) > 0$ *with the same* T *as in Statement (ii).*

(iv) Furthermore,

$$\varkappa_{00} = (2\pi)^{-d}\int_{\{a(x,\xi)<\tau\}} Q'_0(x,\xi)q''_0(x,\xi)\psi'(x)\psi''(x)\,d\xi \tag{13.4.63}$$

where

$$a(x,\xi) = \sum_{j,k} g^{jk}(x)\big(\xi_j - \mu V_j(x)\big)\big(\xi_k - \mu V_k(x)\big) + V \tag{13.4.64}$$

and Q'_0, Q''_0 *denote the principal symbols of* Q', Q'' *in* (13.4.63).

(v) Finally, for $Q' = Q'' = I$

$$\varkappa_{00} = (2\pi)^{-d}\varpi_d(\tau - V)_+^{d/2}\sqrt{g}\psi'\psi'' \tag{13.4.65}$$

and

(13.4.66) $\varkappa_{mn} = 0$ *unless both* m *are* n *is even.*

Proof. (i) Let us rescale $x_{\mathsf{new}} = \mu(x - \bar{x})$; we then obtain the case in which h and μ are replaced by $h_{\mathsf{new}} = \mu h$ and $\mu_{\mathsf{new}} = 1$ respectively. In this case Statement (i) is due to Proposition 4.3.7; we obtain series with respect to powers of μh and h also (because the basic operator, cutting operators and functions depend on μ^{-1} (which is a coefficient of some copies of x). One can obtain the same results simply repeating constructions of Section 4.3 (the method of successive approximations) in which case no rescaling is necessary.

(ii) Moreover, an analysis based on Appendix 4.A.1 yields that under condition (13.4.45) and $\gamma = 1$ the coefficients $\varkappa'_{mn}$ are bounded functions, even regular with respect to $\tau \in [-\epsilon, \epsilon]$; this yields Statement (ii).

Similarly, the same arguments imply that under condition (13.4.46) and $\gamma = 1$ the coefficients $\varkappa'_{mn}$ integrated with respect to $x \in B(0,1)$ are bounded functions, even regular with respect to $\tau \in [-\epsilon, \epsilon]$; this yields Statement (iii).

(iii) Formulae (13.4.63) and (13.4.65) for $\varkappa_{00}$ are well known (see Chapter 4).

(iv) Let us note that replacing h and μ by $-h$ and $-\mu$ respectively we preserve the basic operator and therefore we also preserve $e(x,x,\tau)$; on the other hand, the functions

$$\int \phi(\frac{\tau}{L})(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)U(x,x,t))\,d\tau \tag{13.4.67}$$

and

$$h\int \phi(\frac{\tau}{L})\,d_\tau e(x,x,\tau) \tag{13.4.68}$$

coincide modulo $O(h^s)$ and hence for $Q' = Q'' = I$ all the terms in our decompositions with odd $(m-n)$ vanish. Really, the term with $m = n = 0$ does not vanish; obviously the factor h^{1-d} arises as $|h|^{1-d}$ through the Jacobian) [22)].

[22)] Alternatively, one can notice that in the method of successive approximation each factor h unaccompanied by μ comes from factor $(x_j - y_j)$ and leads to differentiation with respect to ξ_j which changes the parity of the term with respect to ξ. Meanwhile each factor μh comes from factor factor $(x_j - y_j)\xi_k$ and leads to differentiation with respect to ξ_j and multiplication by ξ_k and does not change the parity of the term. After integration with respect to ξ all odd terms disappear as $q' = q'' = 1$ (or are even with respect to ξ).

(v) Moreover, let us note that replacing μ by $-\mu$ we replace the basic operator by its complex conjugate and therefore we also preserve $e(x,x,\tau)$ in this case; since $e(x,x,\tau)$ is real-valued, all terms with odd n in our decompositions vanish for $Q'=Q''=I$. Statement (v) is also proven. □

Let us treat the terms with $n=0$ for $Q'=Q''=I$. The standard calculations of the method of successive approximations yield that for $x=\bar{x}$ these coefficients depend only on $g^{jk}(\bar{x})$, $\partial_k V_j(\bar{x})$ and $V(\bar{x})$ and therefore calculating these coefficients one can assume without any loss of the generality that g^{jk} and V are constants and V_j are linear functions.

Moreover, the same calculations yield that if g^{jk} and V are constants and V_j are linear functions then as $Q'=''=I$, $\psi'=\psi''=1$ only terms with $n=0$ will appear in our decompositions and since (13.4.67) and (13.4.68) coincide modulo $O(h^s)$ we obtain from Theorem 13.2.1 that

Proposition 13.4.21. *(i) In the framework of Proposition 13.4.20*

$$\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h) \sim \sum_{m\in\mathbb{Z}^+} \varkappa_{m0}(x)(\mu h)^m \tag{13.4.69}$$

in the weak sense[23] *where* $\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)$ *defined by* (13.2.8) *with* $g^{jk}=g^{jk}(x)$, $V=V(x)$ *and* $F_{jk}=F_{jk}(x)$.

(ii) Thus in all statements and estimates of Proposition 13.4.20 one can replace sum of terms with $m\le M$, $n=0$ *by* $h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)$.

We noted earlier that $\mathcal{N}^{\mathsf{MW}}(\tau,\mu h)$ can be treated as a Riemann sum for the function $\varphi(z)$ defined by (13.2.26):

$$\varphi(z)=(2\pi)^{r-d}2^{-r}\varpi_{d-2r}\bigl(\tau-f_1z_1-\cdots-f_rz_r\bigr)_+^{\frac{d-2r}{2}}f_1\cdots f_r\sqrt{g}$$

but this function was not smooth; however after multiplication by $\phi(\tau)$ and integration on $\mathbb{R}_\tau$ the resulting function will be smooth and hence we can obtain a complete decomposition with respect to powers of μh. Therefore we obtain

[23] I.e. this asymptotic decomposition will be true if we multiply it by $\phi\in\mathscr{C}_0^\infty(\mathbb{R})$ and integrate over $\mathbb{R}$; surely we proved this only for equality (13.4.69) differentiated with respect to τ but (13.4.69) is also true without differentiation because the supports of both sides are semi-bounded from below with respect to τ).

Proposition 13.4.22. *For* $Q' = Q'' = I$ *and* $\psi' = \psi'' = 1$

$$\varkappa_{m0} = \partial_\tau (\tau - V)_+^{\frac{d}{2}} \mathcal{P}_m(f_1^2, \dots, f_r^2)\sqrt{g} \tag{13.4.70}$$

where $\mathcal{P}_m$ *are homogeneous symmetric polynomials of degrees* $\frac{m}{2}$ *also depending on* d *and* r*. In particular,*

$$\varkappa_{20} = -c\partial_\tau^2 (\tau - V)_+^{\frac{d}{2}} F^2 \sqrt{g} \tag{13.4.71}$$

where $c = \frac{1}{3}(2\pi)^{r-d} 2^{-r-1} \varpi_{d-2r}$ *and*

$$F = \bigl(f_1^2 + \dots + f_r^2\bigr)^{\frac{1}{2}} = \frac{1}{2}\Bigl(\sum_{j,k,l,m} g^{jk} g^{lm} F_{jl} F_{km}\Bigr)^{\frac{1}{2}} \tag{13.4.72}$$

is the scalar intensity of the magnetic field.

Remark 13.4.23. Let us note that if Q' is an operator with Weyl symbol $q'(x,\xi)$ even with respect to ξ and h then Q is preserved if we replace h by $-h$ and for Q complex and Hermitian conjugation coincide. Therefore for this operator Q' and for $Q'' = I$, $\psi' = \psi'' = 1$ in a neighborhood of $\mathsf{supp}(q')$, $\varkappa_{mn}$ vanish unless m and n are even. Se also footnote [22)].

13.4.4 Synthesis

Let us plug the results of the previous subsection into Propositions 13.4.9, 13.4.12, 13.4.14, 13.4.15, 13.4.17 and Corollary 13.4.13 and take into account Remark 13.4.19.

Then we obtain the following

Proposition 13.4.24. *Let conditions* (13.2.1)–(13.2.5)*,* (13.3.1) *and* (13.4.1) *be fulfilled. Then*

(i) Under the condition (13.4.54) *estimate* (13.4.62) *holds with* $T = \mu T_0$ *for* $d = 2$ *and with* $T = T_0$ *for* $d = 3$*.*

(ii) Further, let $d = 2$*, conditions* $(13.3.77)_{1-3}$*,* (13.4.11)*,* (13.4.12) *and* (13.4.45) *be fulfilled.*

Let $\tilde{Q}' = \mathsf{Op}(\tilde{q}')$*,* $\tilde{Q}'' = \mathsf{Op}(\tilde{q}'')$*,* $\tilde{q}', \tilde{q}'' \in \mathsf{S}_{h_1,\gamma,\gamma,K}(T^*\mathbb{R})$*,*

$$1 \ge \gamma \ge \bar{\gamma} := \bigl(\frac{\mu h}{\nu}\bigr)^{\frac{1}{2}} h^{-\delta}, \tag{13.4.73}$$

condition $(13.4.31)_{(2)}$ *be fulfilled on* $\mathsf{supp}(\tilde{q}'\tilde{q}'')$ *and* $Q' = \mathcal{F}\tilde{Q}'\mathcal{F}^*$, $Q'' = \mathcal{F}\tilde{Q}''\mathcal{F}^*$.

Then estimate (13.4.62) *holds for* $\tau : |\tau| \le \epsilon\nu\gamma^2$ *with* $T = \mu T_0/\nu$ [24)]

(iii) On the other hand, let $d = 3$, $\tilde{Q}' = \mathsf{Op}(\tilde{q}')$, $\tilde{Q}'' = \mathsf{Op}(\tilde{q}'')$, $\tilde{q}', \tilde{q}'' \in \mathsf{S}_{\boldsymbol{h}',\gamma,\gamma,K}(T^*\mathbb{R}^2)$, *let conditions* (13.4.45) *and* (13.4.73) *be fulfilled with* $\nu = 1$ *and let condition* $(13.4.31)_{(3)}$ *be fulfilled on* $\mathsf{supp}(\tilde{q}'\tilde{q}'')$ *and* $Q' = \mathcal{F}\tilde{Q}'\mathcal{F}^*$, $Q'' = \mathcal{F}\tilde{Q}''\mathcal{F}^*$.

Then estimate (13.4.62) *holds with* $T = T_0$.

Combining this proposition with the standard Tauberian arguments we immediately arrive to the following two statements:

Theorem 13.4.25. *Let conditions* (13.2.1)–(13.2.5), (13.3.1), (13.4.1) *and* (13.4.54) *be fulfilled. Then*

(i) For $d = 2$ *estimates*

$$(13.4.74)_{(2)} \quad \mathsf{R}^{\mathsf{W}\prime} := \Big| \int \psi(x)\Big(e(x,x,-\infty,\tau) - h^{-d}\sum_{m\le M} \varkappa_{m0}(x,\tau)(\mu h)^m\Big)\,dx\Big| \le C\mu^{-1}h^{-1} + C'h$$

and

$$(13.4.75)_{(2)} \quad \mathsf{R}^{\mathsf{W}\prime}_{(\vartheta)} = \Big| \int \tau_+^{\vartheta-1} * \psi(x)\Big(e(x,x,-\infty,\tau) - h^{-d}\sum_{m\le M,n\le N} \varkappa_{mn}(x,\tau)(\mu h)^m h^n\Big)\,dx\Big| \le C(\mu h)^{-1+\vartheta} + C'h^s$$

hold for $|\tau| \le \epsilon$, $\vartheta > 0$ *where* M *and* N *depend on* ϑ *and restriction to* μ *here and below.*

(ii) for $d = 3$ *estimates*

$$(13.4.74)_{(3)} \qquad \mathsf{R}^{\mathsf{W}\prime} \le Ch^{-2} + C',$$

[24)] Thus T does not depend on γ satisfying (13.4.73), $(13.4.31)_{(2)}$.

and

$$(13.4.75)_{(3)} \qquad \mathsf{R}^{\mathsf{W}\prime}_{(\vartheta)} \le Ch^{-2+\vartheta} + C'h^{s},$$

hold for $|\tau| \le \epsilon$, $\vartheta > 0$.

Remark 13.4.26. (i) We dropped terms with $n \ge 1$ for $\vartheta = 0$ because they do not exceed the remainder estimate due to Proposition 13.4.20(v). Similarly we can drop some terms as $\vartheta > 0$.

(ii) On the other hand, all the derivatives of ψ could be moved to other factors and in virtue of conditions (13.4.45) integration the coefficients $\varkappa_{mn}$ by ξ makes these terms smooth.

Proposition 13.4.27. *Suppose conditions* (13.2.1)–(13.2.5), (13.3.1), (13.4.1) *and* (13.4.45) *are fulfilled.*

Let $\tilde{Q}' = \mathsf{Op}(\tilde{q}')$, $\tilde{q}' \in \mathsf{S}_{\boldsymbol{h}',\gamma,\gamma,K}(T^*\mathbb{R}^{d-1})$ *where* γ *satisfies* (13.4.73), $\mathsf{diam}(\mathsf{supp}(\tilde{q}')) \le c\gamma$ *and* $Q' = \mathcal{F}\tilde{Q}'\mathcal{F}^*$. *Then*

(i) Let $d = 2$ *and conditions* $(13.3.77)_{1-3}$, (13.4.11) *and* (13.4.12) *be fulfilled.*

Moreover, let condition $(13.4.31)_{(2)}$ *be fulfilled on* $\mathsf{supp}(\tilde{q}')$. *Then the estimates*

$$(13.4.76)_{(2)} \quad \mathsf{R}^{\mathsf{W}\prime\prime} := \Big| \int \Big((Q'_x\psi(x)e)(x,x,-\infty,0) - h^{-d} \sum_{m\le M, n\le N} \varkappa_{mn}(x,0)(\mu h)^m h^n \Big)\, dx \Big| \le C\nu\gamma^2\mu^{-1}h^{-1} + C'h^{s},$$

and

$$(13.4.77)_{(2)} \quad \mathsf{R}^{\mathsf{W}\prime\prime}_{(\vartheta)} := \Big| \int \tau_+^{\vartheta-1} * \Big((Q'_x\psi(x)e)(x,x,-\infty,\tau) - h^{-d} \sum_{m\le M, n\le N} \varkappa_{Q'\psi,mn}(x,\tau)(\mu h)^m h^n \Big) dx \Big| \le C\nu^{1+\vartheta}\gamma^2(\mu h)^{-1+\vartheta} + C'h^{s}$$

hold for $\tau = 0$.

(ii) Let $d = 3$, $\nu = 1$ *and condition* $(13.4.31)_{(3)}$ *be fulfilled on* $\mathsf{supp}(\tilde{q}'\tilde{q}'')$. *Then the estimates*

$$(13.4.76)_{(3)} \qquad \mathsf{R}^{\mathsf{W}\prime\prime} \le C\gamma^4 h^{-2} + C'h^{s},$$

and

$$\mathsf{R}^{\mathsf{W}\prime\prime}_{(\vartheta)} \le C\gamma^4 h^{-2+\vartheta} + C'h^s, \tag{13.4.77}_{(3)}$$

hold for $\tau = 0$.

Taking in account zone where $(13.4.31)_{(2)}$ or $(13.4.31)_{(3)}$ is violated we again arrive to the following

Proposition 13.4.28. *Suppose conditions* (13.2.1)–(13.2.5), (13.3.1), (13.4.1) *and* (13.4.45) *be fulfilled. Then*

(i) Let $d = 2$ *and let conditions* $(13.3.77)_{1-3}$, (13.4.11) *and* (13.4.12) *be fulfilled. Then estimate*

$$\mathsf{R}^{\mathsf{W}\prime}_{(\vartheta)} \le C\nu^{1+\vartheta}(\mu h)^{-1+\vartheta} + C\mu^{1+\vartheta}h^{-1+\vartheta}\,\mathsf{mes}_2(\Omega_2) + C'h^s \tag{13.4.78}_{(2)}$$

holds for $\tau = 0$, $\vartheta \ge 0$*; recall that* Ω_2 *was defined as a set violating* $(13.4.31)_{(2)}$.

(ii) For $d = 3$ *the estimate*

$$\mathsf{R}^{\mathsf{W}\prime}_{(\vartheta)} \le Ch^{-2+\vartheta} + C\mu^{1+\vartheta}h^{-2}(\mu h)^{\frac{1}{2}-\delta}\,\mathsf{mes}_3(\Omega_3) + C'h^s \tag{13.4.78}_{(3)}$$

holds for $\tau = 0$, $\vartheta \ge 0$ *where* Ω_3 *is* (x', ξ_1)*-projection of* Ω_4. *Recall that* Ω_4 *was defined as a set violating both* $(13.4.31)_{(3)}$ *and ellipticity.*

We leave it to the reader the following

Problem 13.4.29. Treat the remainder estimates after convolution with the function $\varphi(\tau L^{-1})$ where φ is either a smooth function or satisfies (4.2.75). In this case an additional factor $\big(h(LT)^{-1}\big)^{\vartheta}$ arises in the right-hand expression in $(13.4.74)_{(d)}$, $(13.4.76)_{(d)}$ with corresponding T while the right-hand expression in estimates $(13.4.78)_{(d)}$ will be $h^{1-d}\gamma^{2d-2}\min\big(\mu h/L)^{\vartheta}, 1\big)$ and we assume that $L \ge hT^{-1}$. This yields the obvious modifications of the further estimates.

13.4.5 Miscellaneous Modifications of $\mathsf{R}^{\mathsf{W}\prime}$

At the end of this section let us consider various modifications of $\mathsf{R}^{\mathsf{W}\prime}$. So $\vartheta = 0$ here. The case $\vartheta > 0$ is left to the reader, except that we want to note that for $\mu \le h^{-\sigma}$ with $\sigma = \sigma(\vartheta) > 0$ all the arguments below remain true.

First of all, for $d = 3$, $\mu \le h^{-\frac{1}{2}}$ and for $d = 2$, $\mu \le h^{-\frac{1}{3}}$ in estimate $(13.4.74)_{(d)}$ one can obviously take $M = 0$ and therefore replace $\mathsf{R}^{\mathsf{W}\prime}$ by genuine Weyl expression

$$\mathsf{R}^{\mathsf{W}} = |\int \psi(x)\Big(e(x,x,-\infty,0) - (2\pi)^{-d}\varpi_d h^{-d} V_-^{\frac{d}{2}}\sqrt{g}\Big)\,dx|. \tag{13.4.79}$$

Moreover,

(13.4.80) For $d = 2$ and condition (13.4.45) formula (13.4.70) yields that $\varkappa_{m0} = 0$ for $m \ge 1$ in which case $\mathsf{R}^{\mathsf{W}\prime}$ and R^{W} coincide.

Let us discuss the possibility of replacing $\mathsf{R}^{\mathsf{W}\prime}$ by

$$\mathsf{R}^{\mathsf{MW}} = |\int \psi(x)\Big(e(x,x,-\infty,0) - h^{-d}\mathcal{N}^{\mathsf{MW}}(x,0,\mu h)\Big)\,dx|. \tag{13.4.81}$$

Let us recall that equality (13.4.69) holds only in the weak sense. However, if condition (13.4.54) is fulfilled then after multiplication by $\psi'(x)$ and integration over $\mathbb{R}^d_x$ the function F given by (13.4.72) in the proof of Proposition 13.4.22 will be smooth with respect to (τ, z) and therefore the equality

$$\int \psi'(x)\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)\,dx \equiv \sum_{0\le m\le M}\int \psi'(x)\varkappa_{m0}(x,\tau)(\mu h)^m\,dx \qquad \mathsf{mod}\ O(h^s) \tag{13.4.82}$$

holds in the strong sense for $|\tau| \le \epsilon$ and $M = M(d,s)$. Therefore

(13.4.83) Theorem 13.4.25 remains true for $\mathsf{R}^{\mathsf{W}\prime}$ replaced by R^{MW}.

Moreover, one can see easily that if $\psi' \in \mathscr{C}_0^K(B(0,1))$ with $\mathsf{diam}(\mathsf{supp}\,\psi') \le c\gamma$,

$$|D^\alpha \psi'| \le c\gamma^{-|\alpha|} \qquad \forall \alpha : |\alpha| \le K, \tag{13.4.84}$$

and if conditions (13.4.45),

$$|D^\alpha\big(\frac{V}{F}\big)| \le c\nu \qquad \forall \alpha : 1 \le |\alpha| \le K, \tag{13.4.85}$$

and

$$c\nu\gamma \ge |\nabla \frac{V}{F}| \ge \epsilon_0 \nu\gamma \qquad \text{on} \quad \operatorname{supp}\psi' \tag{13.4.86}$$

are fulfilled then

$$|D_z^\alpha \int \psi' \varphi(x,z,\tau)dx| \le C'\gamma^{d-2|\alpha|}\nu^{-|\alpha|} \tag{13.4.87}$$
$$\forall \alpha : |\alpha| \le K' \quad \forall \tau : |\tau| \le \epsilon\nu\gamma$$

for arbitrary K' (K depends on K') and therefore (13.4.84) holds.

On the other hand, if condition (13.4.86) is violated then the difference between the left-hand and right-hand expressions in (13.4.84) does not exceed $C\gamma^d\mu h$. Summing with respect to a partition of unity we then obtain that the estimate

$$|\mathsf{R}^{\mathsf{MW}} - \mathsf{R}^{\mathsf{W}\prime}| \le C\mu h^{-1} \operatorname{mes}\bigl(\{x\colon |\nabla \frac{V}{F}| \le \bar\gamma\}\bigr) + C'h \tag{13.4.88}_{(2)}$$

holds with $\bar\gamma = (\mu h\nu)^{\frac12-\delta}$.

The same (with the factor h^{-2} instead of h^{-1}) is true for $d = 3$, but we could rewriting the function $\varphi(x,z,\tau)$ in the form

$$\varphi(x,z,\tau) = \operatorname{const} \int \theta(\tau - V - Fz - \eta^2)\, d\eta\sqrt{g} \tag{13.4.89}$$

with $\eta \in \mathbb{R}$, $z \in \mathbb{R}$ and making an appropriate partition of unity with respect to (x,η) with condition (13.4.86) replaced by the condition

$$c\gamma \ge |\eta| + |\nabla \frac{V}{F}| \ge c^{-1}\gamma \qquad \text{at} \quad \operatorname{supp}\psi' \tag{13.4.86}'$$

we obtain the estimates

$$|\mathsf{R}^{\mathsf{MW}} - \mathsf{R}^{\mathsf{W}\prime}| \le \tag{13.4.88}_{(3)}$$
$$C\mu h^{-2} \operatorname{mes}_4\bigl(\{(x,\eta) : |\eta| + |\nabla \frac{V}{F}| \le \bar\gamma\}\bigr) + C'h \le$$
$$C'\mu^{\frac32} h^{-\frac32-\delta} \operatorname{mes}_3\bigl(\{x, |\nabla \frac{V}{F}| \le \bar\gamma\}\bigr) + C'h$$

with $\bar\gamma = (\mu h)^{\frac12-\delta}$.

Therefore Theorem 13.4.25, Propositions 13.4.22, 13.4.24, 13.4.27 and 13.4.28, Remarks 13.4.23 and 13.4.26 and formulae $(13.4.88)_{(2)}$ and $(13.4.88)_{(3)}$ yield the following

Theorem 13.4.30. *(i) In the framework of Theorem 13.4.25 estimates* $(13.4.74)_{(2)}$ *and* $(13.4.74)_{(3)}$ *hold for* R^{MW} *as well.*

(ii) In the framework of Proposition 13.4.28(i) with the additional assumption (13.4.85) *estimate*

$$(13.4.90)_{(2)} \quad \mathsf{R}^{\mathsf{MW}}_{(\vartheta)} \le C\nu^{1+\vartheta}\mu^{-1-\vartheta}h^{-1+\vartheta}+ C\mu^{1+\vartheta}h^{-1+\vartheta}\Big(\mathsf{mes}\big(\{x : |\nabla\frac{V}{F}| \le \bar\gamma\}\big) + \mathsf{mes}_2(\Omega_2)\Big) + C'h^s$$

holds with $\bar\gamma = (\mu h/\nu)^{\frac12-\delta}$ *but now we need to include in* $\mathsf{R}^{\mathsf{MW}}_{(\vartheta)}$ *also terms with* $n \ge 1$.

(iii) Then under non-degeneracy condition $(13.4.57)_m$

$$(13.4.91)_{(2)} \qquad \mathsf{R}^{\mathsf{MW}}_{(\vartheta)} \le C\nu^{1+\vartheta}\mu^{-1-\vartheta}h^{-1+\vartheta}$$

as $d = 2$, $\mu \le h^{-\delta}$.

(iv) Without any non-degeneracy condition

$$(13.4.91)_{(3)} \qquad \mathsf{R}^{\mathsf{MW}}_{(\vartheta)} \le Ch^{-2+\vartheta}$$

as $d = 3$, $\mu \le h^{-1/(2\theta+3)+\delta}$.

(v) In the frameworks of Propositions 13.4.27(i) and (ii) estimates $(13.4.74)_{(2)}$, $(13.4.74)_{(3)}$, *etc respectively hold for* R^{MW} *also.*

Remark 13.4.31. (i) We will prove that in many cases we can choose $\bar\gamma = (\mu h)^{\frac12}$ or $\bar\gamma = (\mu h/\nu)^{\frac12}$ and improve both estimates and restrictions to μ.

(ii) Our latest estimates invoke measures of two sets: one in x related to V/F and another in (x', ξ_1) related to $\mathcal{B}$. Under assumption $\nu\gamma \ge C\bar\nu\mu^{-2}$ they are the same.

Remark 13.4.32. One could apply successive approximations method with unperturbed operator

$$\bar A = \sum_{j,k} \bar P_j g^{jk}(y)\bar P_k + V(\bar y) \tag{13.4.92}$$

with

$$\bar P_j = hD_{x_j} - \mu A_j(y) - \mu\sum_k (\partial_k A_j)(y)\cdot(x_k - y_k). \tag{13.4.93}$$

We will follow this route in forthcoming chapters.

13.5 Moderate Magnetic Field

13.5.1 Decomposition of the Fundamental Solution and Propagation of Singularities

In this section we will always assume that $d = 2, 3$ and

$$h^{-\delta} \le \mu \le h^{-1} \qquad (\delta > 0). \tag{13.5.1}$$

Then the remainder term R in decomposition (13.3.65), (13.3.66) or (13.3.68) is negligible by Theorem 13.2.13 and Remark 13.4.2, and we skip it.

But then x_d and D_d are included in the operator $\mathcal{A}$ only through the harmonic oscillator $\mathcal{L}_0 = x_d^2 + \mu^{-2}h^2D_d^2$. Decomposing all functions of x_d into series with respect to eigenfunctions of $\mathcal{L}_0$ we decompose $\mathcal{A}$ into a direct sum of $\boldsymbol{h}'$-pseudodifferential operators with respect to x' which we treat by the methods of Chapter 4.

In particular, all of the analysis of Section 13.4 can be repeated with the weakened restrictions on γ and ζ.

Let us recall that

(13.5.2) Operator $\mathcal{L}_0$ has simple eigenvalues $(2j+1)\mu^{-1}h$ with eigenfunctions

$$\Upsilon_j(x_d) = (\frac{\mu}{h})^{\frac{1}{4}} \upsilon_j(\sqrt{\frac{\mu}{h}}x_d) \tag{13.5.3}$$

which are orthonormal in $\mathscr{L}^2(\mathbb{R})$ where υ_j are real-valued orthonormal Hermite functions and here and in what follows $j \in \mathbb{Z}^+$.

Theorem 13.5.1. *Let condition* (13.5.1) *be fulfilled.*

(i) For some $j \in \mathbb{Z}^+$ let

$$(2j+1)\mu h\bar{B}_1 + \bar{B}_0' \ge \bar{\tau} + \epsilon_0 \qquad \forall (x', \xi_1) \in \Omega \tag{13.5.4}$$

with $\epsilon_0 > 0$, $\bar{\tau} \le c$ where

$$\bar{B}_1 := B_1|_{\varepsilon=h_1=0}, \qquad \bar{B}_0' := (\varepsilon^{-1}B_1)|_{\varepsilon=h_1=0}, \tag{13.5.5}$$

Then estimate

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t) \int Q_x'U(x,y,t)\Upsilon_j(x_d)\,dx_d| \le C'Th^s(1+j\mu h)^{-s}(1+\bar{\tau}-\tau)^{-s} \tag{13.5.6}$$

$$\forall x' \in \mathbb{R}^{d-1} \quad \forall y \in \mathbb{R}^d \quad \forall \tau \le \bar{\tau} \quad \forall T \ge h^{1-\delta}$$

holds with $Q' = I$ *where here and in what follows* $C' = C'(c, \epsilon_0, \delta, s)$, $N = N(\delta, s)$, $K = K(\delta, s)$ *and* $\delta > 0$ *and* s *are arbitrary.*

(ii) On the other hand, let $d = 3$, $Q' = \mathsf{Op}(q')$ *with* $q' \in \mathsf{S}_{\boldsymbol{h}',K}(T^*\mathbb{R}^2)$, $\mathsf{supp}(1 - q') \subset \{|\xi_2| \le c\}$ *and for some* $j \in \mathbb{Z}^+$ *let*

$$\xi_2^2 + (2j+1)\mu h\bar{B}_1 + \bar{B}_0' \ge \bar{\tau} + \epsilon_0 \qquad \forall (x', \xi') \in \mathsf{supp}\, q' \tag{13.5.7}$$

with the same constants ϵ_0 *and* $\bar{\tau}$*; then estimate* (13.5.6) *remains true.*

(iii) The following decomposition holds

$$\mathsf{U} \equiv \sum_{j,k \le J} \mathsf{U}_{j,k}(x', y', t)\Upsilon_j(x_d)\Upsilon_k(y_d) \tag{13.5.8}$$

modulo functions f *satisfying* (13.3.81) *with arbitrary* $q \in \mathsf{S}_{\boldsymbol{h}',K}(T^*\mathbb{R}^{d-1})$ *supported in* Ω *and* $Q = \mathsf{Op}(q)$*; here* $\bar{\tau} \le c$ *is arbitrary and*

$$J = J(\bar{\tau}) := \mathsf{min}\{j \in \mathbb{Z}^+ : (2j+1)\mu h\bar{B}_1 + \bar{B}_0' \ge \bar{\tau} + \epsilon_0 \quad \forall (x', \xi_1) \in \Omega\}. \tag{13.5.9}$$

(iv) Furthermore,

$$\mathsf{U}_{j,k}(x', y', t) = \mathsf{U}_{k,j}^{\dagger}(y', x', -t), \tag{13.5.10}$$

estimate

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)\mathsf{U}_{j,k}| \le CT\mu h^{1-d}(1 + |\tau|)^{d-1} \quad \forall x', y' \in \mathbb{R}^{d-1} \quad \forall j, k \quad \forall \tau \quad \forall T \ge h^{1-\delta} \tag{13.5.11}$$

holds and $\mathsf{U}_{j,k}$ *satisfy Cauchy problems*

$$\big(hD_t - \mathcal{A}_{jx}\big)\mathsf{U}_{j,k} \equiv 0, \tag{13.5.12}$$

$$\mathsf{U}_{j,k}|_{t=0} \equiv \delta_{jk}\delta(x' - y') \tag{13.5.13}$$

modulo functions f *and* f' *respectively satisfying* (13.3.81) *and* (13.3.82) *with arbitrary* $q \in \mathsf{S}_{\boldsymbol{h}',K}$ *supported in* Ω *(*$d = 2$*) and in* $\Omega \times \{|\xi_2| \le c\}$ *(*$d = 3$*) where* δ_{jk} *is the Kronecker symbol and*

$$\mathcal{A}_j = \sum_{0 \le n \le N-1} B_n(x_1, h_1D_1, \mu^{-2}, h_1)\mu^{2-2n}\big((2j+1)\mu h\big)^n \tag{13.5.14}$$

for $d = 2$

and

$$\mathcal{A}_j = h^2 D_2^2 + \sum_{0\le n\le N-1} B_n(x', h_1 D_1, \mu^{-2}, h_1)\mu^{2-2n}\big((2j+1)\mu h\big)^n \quad \text{for } d=3; \tag{13.5.15}$$

let us recall that $h_1 = \hbar = \mu^{-1}h$.

(v) $\mathsf{U}_{j,k}$ *also satisfy dual problems*

$$\mathsf{U}_{j,k}\big(hD_t - {}^t\mathcal{A}_{ky}\big) \equiv 0, \tag{13.5.12}$$

and (13.5.13) *modulo functions* f *and* f' *respectively satisfying* (13.3.81)† *and* (13.3.82)† *dual*[25] *to* (13.3.81) *and* (13.3.82).

Proof. First of all (13.5.10) and (13.5.11) follow from (13.3.84) and (13.3.85) respectively if we set

$$\mathsf{U}_{j,k} = \iint \mathsf{U}(x,y,t)\Upsilon_j(x_d)\Upsilon_k(y_d)\,dx_d dy_d. \tag{13.5.16}$$

Consider $q' \in \mathsf{S}_{\boldsymbol{h},\rho,\gamma,K}(T^*\mathbb{R}^d)$ with $\rho_j, \gamma_j \in (0,1]$, $\rho_j\gamma_j \ge h_j h^{-\delta}$ $\forall j \le d-1$, $\rho_d = \mu^{\frac12} h^{\frac12-\delta'}$, $\gamma_d = \mu^{-\frac12} h^{\frac12-\delta'}$, $\delta' > 0$. One can prove easily by standard elliptic arguments that if

$$\operatorname{supp} q' \cap \{\mu^2 x_2^2 + \xi_2^2 \le h^{-\delta''}\} = \emptyset \quad \text{for } d=2, \tag{13.5.17}_{(2)}$$

$$\operatorname{supp} q' \cap \{\mu^2 x_3^2 + \xi_3^2 \le h^{-\delta''},\ \xi_2^2 \le C_0\} = \emptyset \quad \text{for } d=3 \tag{13.5.17}_{(3)}$$

with $\delta'' > 0$ then for $f = \mathsf{U}$, $q = Q'$ estimate (13.3.81) holds; in this deduction we also cut U (see Remark 13.3.12).

This yields that for $j \ge J' = \mu^{-1}h^{-1-\delta''}$ estimate (13.5.6) holds and therefore decomposition (13.5.8) with J' instead of J holds.

Then formulae (13.3.79), (13.3.80) and (13.3.65), (13.3.66) yield (13.5.12), (13.5.13) and (13.5.14), (13.5.15) respectively.

Furthermore, (13.5.12), (13.5.11) and the standard elliptic arguments yield the implications (13.5.4) $\implies$ (13.5.6) and (13.5.7) $\implies$ (13.5.6); therefore in decomposition (13.5.8) one can replace J' by J given by formula (13.5.9).

Finally, (13.5.10) and Statement (iii) imply Statement (v) and that one can skip $k \ge J$ in summation as well. □

[25] Where here and below "dual" means that $Q_x f$ is replaced by $f\,{}^tQ_y$ and j and k are permuted everywhere save $\boldsymbol{U}_{j,k}$.

We can now apply all the methods of Section 2.1, Chapter 4 and Section 13.4 to the analysis of $\mathsf{U}_{j,k}$; moreover, when we apply the methods of Section 13.4 we can weaken restrictions on γ and ζ associated with the uncertainty principle for $\boldsymbol{h}$-pseudodifferential operators because we now have only $\boldsymbol{h}'$-pseudodifferential operators and therefore condition (13.4.6) should be replaced by

$$\boldsymbol{h}' = (h_1, \dots, h_{d-1}),\ \boldsymbol{\gamma}' = (\gamma_1, \dots, \gamma_{d-1}),\ \boldsymbol{\rho}' = (\rho_1, \dots, \rho_{d-1}), \quad h_1 = \mu^{-1}h,\ h_2 = h,\ \rho_j, \gamma_j \in (0,1],\ \rho_j\gamma_j \ge h_j h^{-\delta} \quad \forall j = 1, \dots, d-1. \tag{13.5.18}$$

Proposition 13.5.2. *Let $d = 2$, $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$ with $q', q'' \in \mathsf{S}_{h_1,\rho_1,\gamma_1,K}(T^*\mathbb{R})$ and let condition* (13.5.18) *be fulfilled. Then*

(i) If

$$\operatorname{supp} q' \cap \bigl\{\tau_1 \le (2j+1)\mu h + \bar{B}(x_1,\xi_1) \le \tau_2\bigr\} = \emptyset \tag{13.5.19}$$

with $-\infty \le \tau_1 < \tau_2 \le \infty$ [26] *then estimate*

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q'_x\mathsf{U}_{j,k}| \le C'Th^s\bigl(1+\min(\tau-\tau_1,\tau_2-\tau)\bigr)^{-s} \quad \forall x', y' \in \mathbb{R}^{d-1} \quad \forall \tau \in [\tau_1+\epsilon, \tau_2-\epsilon] \quad \forall T \ge h^{1-\delta} \tag{13.5.20}$$

and the holds (and due to (13.5.10) *dual estimate holds).*

(ii) For $h^{1-\delta} \le T \le \mu T_0$ estimate

$$|F_{t\to h^{-1}\tau}\chi_T(t)\mathsf{U}_{j,k}| \le C'h^s \qquad \forall x', y' \in \mathbb{R}^{d-1} \quad \forall \tau \le c \quad \forall j \ne k \tag{13.5.21}$$

holds.

(iii) If $h^{1-\delta} \le T \le \mu T_0$ and one of the conditions $(13.4.7)_{1,2}$ *is fulfilled then estimate*

$$|F_{t\to h^{-1}\tau}\chi_T(t)Q'_x\mathsf{U}_{j,k}{}^tQ''_y| \le C'h^s \qquad \forall x', y' \in \mathbb{R}^{d-1} \quad \forall \tau \le c \tag{13.5.22}$$

holds.

[26] Here and in what follows B is taken from (13.3.74) and as in (13.5.5) $\bar{B} = B|_{\varepsilon=h_1=0}$.

(iv) Moreover, if conditions $(13.3.77)_{1-3}$, (13.4.11) *and* (13.4.12) *are fulfilled then in Statement (i) we can replace* ϵ *by* $\epsilon\nu$ *and in Statements (ii) and (iii) we can take* $T \in [h^{1-\delta}\nu^{-1}, \mu T_0\nu^{-1}]$, $|\tau| \le c\nu$ *and replace conditions* $(13.4.7)_{1,2}$ *by* $(13.4.7)'_2$.

Proposition 13.5.3. *Let* $d = 3$, $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$ *with* $q', q'' \in \mathsf{S}_{\boldsymbol{h}',\boldsymbol{\rho}',\gamma',K}(T^*\mathbb{R}^2)$ *and let condition* (13.5.18) *be fulfilled. Then*

(i) If

$$\text{(13.5.23)}\quad \operatorname{supp} q' \cap \bigl\{\tau_1 \le \xi_2^2 + (2j+1)\mu h\bar{B})_1(x',\xi_1) + \bar{B}'_0(x',\xi_1) \le \tau_2\bigr\} = \emptyset$$

with $-\infty \le \tau_1 < \tau_2 \le \infty$ *then estimate* (13.5.20) *holds.*

(ii) For $h^{1-\delta} \le T \le T_0$ *estimate* (13.5.21) *holds.*

(iii) If $h^{1-\delta} \le T \le T_0$ *and one of conditions* $(13.4.7)_{1-4}$ *is fulfilled then estimate* (13.5.22) *holds.*

Proof of Propositions 13.5.2 and 13.5.3. The proof of both Statements (i) is based on the standard elliptic arguments, and Statements (ii) and (iii) follow from the theory of propagation of singularities (see Section 2.1 and proof of Theorem 13.4.3) □

13.5.2 Calculations

Let us proceed from estimates to calculations[27)]. First, we need to replace U by its transformation $\boldsymbol{U}$ (and in the end, by $\boldsymbol{U}_{j,k}$ and we want to get the expression of the same type as before.

Proposition 13.5.4. *Let* $d = 2$ *and* $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$ *with* $q', q'' \in \mathsf{S}_{h_1,\rho_1,\gamma_1,K}(T^*\mathbb{R})$. *Let condition* (13.5.18) *be fulfilled and let* $\tilde{Q}' = \mathcal{F}Q'\mathcal{F}^*$, $\tilde{Q}'' = \mathcal{F}Q''\mathcal{F}^*$. *Further, let* $\psi', \psi'' \in \mathscr{C}_0^K(B(0, \frac{1}{2}))$ *be fixed functions. Then*

[27)] More refined calculations will be made in the next subsection.

(i) The following equality holds modulo $O(h^s)$

$$(13.5.24)_{(2)}\quad F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(\tilde{Q}'_x\psi'(x)U\psi''(y)\,{}^t\tilde{Q}''_y\big)\equiv$$
$$\sum_{j\le J}\sum_{r+m+p\le N} F_{t\to h^{-1}\tau}\chi_T(t)\Gamma'\big(Q'_x\mathsf{M}_{rmp}(x_1,y_1,h_1D_{x_1},h_1D_{y_1})\mathsf{U}_{j,j}\,{}^tQ''_y\big)\times$$
$$((2j+1)\mu h)^r\,\mu^{-2(m+r)-p}h^p$$

for $\tau\le\epsilon_1$, $T\in[h^{1-\delta},\mu T_0]$ *where* J *is defined by* (13.5.9) *with* $\bar\tau=0$ *and* $\epsilon=2\epsilon_1$, Γ' *is the operator of restriction to the diagonal and integration acting with respect to the variables* x' *and* y', M_{rmp} *are operators with symbols*

$$(13.5.25)_{(2)}\quad \mathsf{M}_{rmp}(x_1,y_1,\xi_1,\eta_1)=\sum_{|\alpha|+|\beta|\le 2p+2r+m}\mathsf{m}_{rmp\alpha\beta}(x_1,y_1,\xi_1,\eta_1)\times$$
$$(D^\alpha\psi')\circ\bar\Psi_0(x_1,\xi_1)\times(D^\beta\psi'')\circ\bar\Psi_0(y_1,\eta_1),$$

$\mathsf{m}_{rmp\alpha\beta}$ *are smooth symbols independent of* ψ',ψ'', $\mathsf{m}_{rmp\alpha\beta}=1$ *for* $m=p=r=\alpha=\beta=0$ *and* $\mathsf{m}_{rmp\alpha\beta}=0$ *for* $m+p+r>0$, $\alpha=\beta=0$.

(ii) Moreover, if conditions $(13.3.77)_{1-3}$, (13.4.11) *and* (13.4.12) *are fulfilled then equality* $(13.5.24)_{(2)}$ *holds for* $|\tau|\le\epsilon_1\nu$, $T\in[h^{1-\delta}\nu^{-1},\mu T_0\nu^{-1}]$.

(iii) Further, if $\psi''=1$ *in a neighborhood of* $\operatorname{supp}\psi'$ *then one can take* M_{rmp} *depending only on* (x_1,ξ_1) *and* $\mathsf{m}_{\dots}=0$ *for* $\beta\ne 0$.

(iv) In particular, if $F=\mathsf{const}$ *and we apply the reduction method described in Proposition 13.3.1(iii) then in the conformal coordinate system*

$$(13.5.26)_1\qquad \mathsf{M}_{010}=-\frac{1}{2}(\rho^2\nabla\psi'\cdot\nabla v)\circ\bar\Psi_0,$$

and

$$(13.5.26)_2\qquad \mathsf{M}_{100}=\frac{1}{4}(\rho^2\Delta\psi')\circ\bar\Psi_0.$$

(v) Furthermore, if conditions $(13.3.77)_{1-3}$ *are fulfilled then*

$$(13.5.27)\qquad |D^\sigma\mathsf{m}_{rmp\alpha\beta}|\le C\bar\nu$$

for all r,m,p,α,β *indicated above and for all* $\sigma:1\le\sigma\le K_1$ *with arbitrary* K_1 *(*K *depends on* K_1*).*

Proposition 13.5.5. *Let $d = 3$ and $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$ with $q', q'' \in \mathsf{S}_{\boldsymbol{h}',\rho',\gamma',K}(T^*\mathbb{R}^2)$. Let condition* (13.5.18) *be fulfilled and let $\tilde{Q}' = \mathcal{F}Q'\mathcal{F}^*$, $\tilde{Q}'' = \mathcal{F}Q''\mathcal{F}^*$ and $\psi', \psi'' \in \mathscr{C}_0^K(B(0, \frac{1}{2}))$ be fixed functions. Then*

(i) The following equality holds modulo $O(h^s)$:

$$(13.5.24)_{(3)} \quad F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(\tilde{Q}'_x\psi'(x)U\psi''(y)\,{}^t\tilde{Q}''_y\big) \equiv$$
$$\sum_{j\le J}\ \sum_{r+m+p+k'+k''\le N} F_{t\to h^{-1}\tau}\chi_T(t)\Gamma'\big(Q'_x\mathsf{M}_{rmpk'k''}(x', y', \boldsymbol{h}'D_{x'}, \boldsymbol{h}'D_{y'})\times$$
$$(hD_{x_2})^{k'}(hD_{y_2})^{k''}\mathsf{U}_{j,j}\,{}^tQ''_y\big)\cdot((2j+1)\mu h)^r\,\mu^{-2(m+r)-p-k'-k''}h^p$$

for $\tau \le \epsilon_1$, $T \in [h^{1-\delta}, T_0]$ with the same J and Γ' as before, $\mathsf{M}_{rmpk'k''}$ operators with symbols

$$(13.5.25)_{(3)} \quad \mathsf{M}_{rmpk'k''}(x', y', \xi', \xi'') =$$
$$\sum_{|\alpha|+|\beta|\le 2p+2r+m+k'+k''} \mathsf{m}_{rmpk'k''\alpha\beta}(x', y', \xi_1, \eta_1)\times$$
$$(D^\alpha\psi')\circ\bar{\Psi}_0(x', \xi_1)\times(D^\beta\psi'')\circ\bar{\Psi}_0(y', \eta_1),$$

where $\mathsf{m}_{rmpk'k''\alpha\beta}$ are smooth symbols independent of ψ', ψ'' and $\mathsf{m}_{rmpk'k''\alpha\beta} = 1$ for $m = p = r = k' = k'' = \alpha = \beta = 0$ and $\mathsf{m}_{rmpk'k''\alpha\beta} = 0$ for $m + p + r + k' + k'' > 0$, $\alpha = \beta = 0$.

(ii) Further, if $\psi'' = 1$ in a neighborhood of $\operatorname{supp}\psi'$ then one can take M_{rmp} depending only on (x_1, ξ_1) and $\mathsf{m}_{rmpk'k''\alpha\beta} = 0$ for $(\beta, k') \ne 0$.

(iii) Statement (v) of Proposition 13.5.4 remains true. moreover, it is true for $k' + k'' > 0$ and $\sigma = 0$.

Proof of Propositions 13.5.4 and 13.5.5. Let us first consider the operators $\mathcal{Q}'(x, \mu^{-1}hD, \mu^{-2}, \mu^{-1}h) = \mathcal{F}^*\psi'\mathcal{F}$ and $\mathcal{Q}''$ (which is defined in a similar way and has similar properties).

We know that

$$(13.5.28) \qquad \mathcal{Q}' \sim \sum_p \mathcal{Q}'_p(x, \mu^{-1}hD, \mu^{-2})(\mu^{-1}h)^p,$$

where $\mathcal{Q}'_0 = \psi'\circ\Psi_{\mu^{-2}}$ and $\mathcal{Q}'_p$ is a linear combination of $D^\alpha\psi'\circ\Psi_{\mu^{-2}}$ with $1 \le |\alpha| \le 2p$ for $p \ge 1$.

Let us decompose $\mathcal{Q}'_p$ with respect to powers of μ^{-2}. Moreover, let us decompose $\mathcal{Q}'_p$ with respect to powers of x_d and $\mu^{-1}hD_d$; for $d = 3$ let us also decompose $\mathcal{Q}'_p$ with respect to powers of $\mu^{-1}hD_2$. Then Remark 13.4.2 and condition (13.5.1) yield that we need to take only a finite number of terms provided we apply the operator $\mathcal{Q}'_x$ or ${}^t\mathcal{Q}''_y$ to U and then we apply operator $F_{t\to h^{-1}\tau}\chi_T(t)$ with $\tau \le c$.

Therefore for $d = 3$

$$\mathcal{Q}' \sim \sum_{m,\sigma,k,p} \mathcal{Q}'_{mp\sigma k}(x', \mu^{-1}hD_1)\mu^{-2m-p-k}h^p x_3^{\sigma_1}(\mu^{-1}hD_3)^{\sigma_2}(hD_2)^k \tag{13.5.29}$$

where $\mathcal{Q}'_{0000} = \psi \circ \bar{\Psi}_0$ and $\mathcal{Q}'_{mp\sigma k}$ is a linear combination of $D^\alpha\psi' \circ \bar{\Psi}_0$ with $1 \le |\alpha| \le m + 2p + |\sigma| + k$ for $m + 2p + |\sigma| + k \ge 1$.

It will be convenient for us to pass from this formula to the formula

$$\mathcal{Q}' \sim \sum_{m,\sigma,k,p} \mathcal{Q}'_{mp\sigma k}(x', \mu^{-1}hD_1)\mu^{-2m-p-k}h^p(\mu^{-1}h)^{\frac{1}{2}|\sigma|}Z_+^{\sigma_1}Z_-^{\sigma_2}(hD_2)^k \tag{13.5.30}$$

with operators[28)]

$$Z_\pm = \sqrt{\frac{\mu}{h}}\bigl(x_d \pm i\mu^{-1}hD_d\bigr) \tag{13.5.31}$$

and with coefficients $\mathcal{Q}'_{mp\sigma k}$ of the same nature as before; then $[Z_+, Z_-] = 2$. A similar but simpler formula holds for $d = 2$.

Let us apply operators $F_{t\to h^{-1}\tau}\mathcal{Q}'_x$ and ${}^t\mathcal{Q}''_y$ to U and let us take decomposition (13.5.8) for U; let us take into account that Proposition 13.5.2 yields that only terms with $j = k \le J$ are not necessarily negligible in this decomposition with the T and τ indicated in Proposition 13.5.4(i),(ii) for $d = 2$ and in Proposition 13.5.5(i) for $d = 3$.

Furthermore, let us apply equalities

$$(z + \partial_z)v_j = \sqrt{2j}v_{j-1}, \qquad (z - \partial_z)v_j = \sqrt{2(j+1)}v_{j+1}, \tag{13.5.32}_{1-2}$$

for our Hermite functions.

We obtain that in the resulting formula for the left-hand expression in $(13.5.24)_{(d)}$ terms with multiindices σ' and σ'' from the decompositions of

[28)] Often called annihilation and creation operators in quantum mechanics.

$\mathcal{Q}'$ and $\mathcal{Q}''$ are negligible unless $\sigma'_1 - \sigma'_2 = \sigma''_1 - \sigma''_2$; therefore $|\sigma'| + |\sigma''|$ is even.

Moreover, the inner product in $\mathscr{L}^2(\mathbb{R})$ of functions $Z_+^{\sigma'_1} Z_-^{\sigma'_2} \Upsilon_j$ and $Z_+^{\sigma''_1} Z_-^{\sigma''_2} \Upsilon_j$ is a $\frac{1}{2}(|\sigma'| + |\sigma''|)$-degree polynomial of $(2j+1)$; this yields $(13.5.24)_{(d)}$ for the indicated T and τ. The same calculations also yield $(13.5.25)_{(d)}$.

Therefore Proposition 13.5.4(i),(ii) and Proposition 13.5.5(i) are proven. Further, the same arguments yield Propositions 13.5.4(ii) and 13.5.5(ii).

Furthermore, the same arguments yield Propositions 13.5.4(v) and 13.5.5(iii). In fact, if $d = 3$, $g^{jk} = \delta_{jk}$, $F^1 = F^3 = 0$ and $F^2 = \mathsf{const}$, $V = \mathsf{const}$ then in the framework of the proof of Theorem 13.2.1

$$\mathcal{Q}' = \psi'(x_1 - \mu^{-1} h\ell D_3, x_2, x_3 - \mu^{-1} h\ell D_1)$$

with constant ℓ; a similar equality holds for $d = 2$, $g^{jk} = \delta_{jk}$ and $F = \mathsf{const}$, $V = \mathsf{const}$. Therefore in these cases $\mathsf{m}_{\dots} = \mathsf{const}$; moreover, $\mathsf{m}_{\dots} = 0$ for $d = 3$ and $k' + k'' \ge 1$. Then the stability of all the procedures yields Propositions 13.5.4(v) and 13.5.5(iii).

Finally, in order to prove Proposition 13.5.4(iv) it is sufficient to note that under indicated method of reduction

$$\mathsf{M}_{100} = \frac{1}{2}\Big(\{x_2, \{x_2, \mathcal{Q}'\}\} + \{\xi_2, \{\xi_2, \mathcal{Q}'\}\}\Big)|_{\Lambda^0, \varepsilon=0} = \frac{1}{2}\Big(\{w''_2, \{w''_2, \psi'\}\} + \{w''_1, \{w''_1, \psi'\}\}\Big)\Big|_{\Lambda, \varepsilon=0} \circ \bar{\Psi}_0, \tag{13.5.33}$$

and

$$\mathsf{M}_{010} = \partial_\varepsilon \psi'|_{\Lambda, \varepsilon=0} \circ \bar{\Psi}_0 \tag{13.5.34}$$

where w''_1, w''_2 are defined in the proof of Proposition 13.3.1(iii); the remaining arguments are the same as in the proof of Theorem 13.3.6(iii). □

13.5.3 Estimates

Now we are able to apply the results of Chapters 4 and 5 in their complete power.

Estimates in the Zone $\{\gamma \ge \bar{\gamma}\}$

Let us recall that in the weak magnetic field theory there was a zone where gradient of the principal symbol exceeded $\bar{\gamma} = (\mu h)^{\frac{1}{2}} h^{-\delta}$ or $\nu\bar{\gamma}$ with

$\bar\gamma = (\mu h/\nu)^{\frac12} h^{-\delta}$ as $d = 2$ and some conditions are fulfilled. Our next step is to recover similar results albeit with $\delta = 0$.

Proposition 13.5.6. *Let either* $d = 2$ *or* $d = 3$ *and let* $q', q'', Q', Q'', \tilde Q', \tilde Q''$ *be the same symbols and operators as in Proposition 13.5.4 or Proposition 13.5.5 respectively with* $\rho_j = \gamma_j = \gamma \ge \bar\gamma$ *and*

$$\bar\gamma = \bigl(\mu h \nu^{-1}\bigr)^{\frac12}. \tag{13.5.35}$$

Let $\operatorname{diam}(\operatorname{supp} q') \le c\gamma$, $\operatorname{diam}(\operatorname{supp} q'') \le c\gamma$ *and suppose that on* $\operatorname{supp}(q')$ *conditions* $(13.4.26)_{(d)}$ *and* $(13.4.31)_{(d)}$ [29] *be fulfilled where* $\nu = 1$ *for* $d = 3$.

Furthermore, let conditions $(13.3.77)_{1-3}$, (13.4.11) *and* (13.4.12) *be fulfilled as* $d = 2$ *and* $\nu < 1$. *Then the estimate*

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma \tilde Q'_x \psi'(x) U \psi''(y)\, {}^t\tilde Q''_y| \le Ch^{1-d}\gamma^{2d-2} + C'h^s \qquad \forall \tau : |\tau| \le \epsilon\nu\gamma \tag{13.5.36}$$

holds with arbitrary $T \in [h^{1-\delta}\nu^{-1}\gamma^{-2}, \mu T_0 \nu^{-1}]$ *for* $d = 2$, $T \in [h^{1-\delta}\gamma^{-2}, T_0]$ *for* $d = 3$*; recall that* $T_0 > 0$ *is a small constant.*

Proof. The arguments of Subsections 5.2.1 and s 5.2.2 yield that

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma' Q'_x \mathsf{U}_{j,j}\, {}^t Q''_y| \le C\mu h^{2-d}\gamma^{2d-4}\nu^{-1} + C'h^s \tag{13.5.37}$$

for the T and τ indicated above and for all $j \in \mathbb{Z}^+$. In fact, we should replace d by $(d-1)$ in all the corresponding estimates and remember that the semiclassical parameter with respect to (x_1, ξ_1) is $h_1 = \mu^{-1}h$; however the semiclassical parameter for t is h or even $h\nu^{-1}$ so we need to rescale $t : t_{\mathsf{new}} = \mu^{-1}\nu t_{\mathsf{old}}$ which brings a factor $\mu\nu^{-1}$ to the right-hand expressions.

Further, for $d = 3$ we should add another factor μ in the right-hand expressions because of the additional $\mu^{-1}\gamma$-admissible partition of unity with respect to ξ_1 or x_1 (which is necessary in order to be in the context of this subsection when its arguments are applied).

Furthermore, if condition

$$|-\bar\tau + (2j+1)\mu h + B(x_1, \xi_1, \mu^{-2})| \ge \epsilon_0 \nu\gamma^2, \tag{13.5.38}_{(2)}$$

[29] Let us recall that in these conditions for $d = 3$ we take λ violating condition $(13.4.25)_{(3)}$ with ζ replaced by $\epsilon\gamma^2$.

or

$$|-\bar\tau+\xi_2^2+\mathcal{B}(x',\xi_1,(2j+1)\mu h,\mu^{-2},0)|\ge\epsilon_0\gamma^2, \tag{13.5.38}_{(3)}$$

is fulfilled on $\mathsf{supp}(q')$ for $d=2,3$ respectively (compare these conditions with $(13.4.25)_{(2,3)}$) then for $|\bar\tau-\tau|\le\epsilon\nu\gamma^2$ and for indicated T the left-hand expression in (13.5.37) does not exceed $C'h^s$.

Finally, for every τ from the indicated interval the quantity of numbers j violating condition $(13.5.38)_{(d)}$ does not exceed $C_0\nu\gamma^2(\mu h)^{-1}$ because $C_0\nu\gamma^2(\mu h)^{-1}\gtrsim 1$ iff $\gamma\gtrsim\bar\gamma$ as $\bar\gamma$ is defined by (13.5.36).

This fact, estimate (13.5.37) and Propositions 13.5.4 and 13.5.6 yield that the left-hand expression of (13.5.36) does not exceed

$$C(\mu^{-1}h)^{d-2}\gamma^{2d-4}\times\mu\nu^{-1}\times\mu^{d-2}\times\nu\gamma^2(\mu h)^{-1} \tag{13.5.39}$$

which is exactly the right-hand expression of it. □

Now applying the standard Tauberian arguments of Chapter 4 we immediately obtain that under the assumptions of Proposition 13.5.6 estimates

$$\begin{aligned}\mathsf{R}^{\mathsf{T}} := |\Gamma\big(\tilde Q_x'\psi'(x)e\psi''(y)\,{}^t\tilde Q_y''\big)(-\infty,\tau)-\\ h^{-1}\int_{-\infty}^{\tau}\big(F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma\big(\tilde Q_x'\psi'(x)U\psi''(y)\,{}^t\tilde Q_y''\big)\big)\,d\tau|\le R_{1(0)}\end{aligned} \tag{13.5.40}$$

and

$$\mathsf{R}^{\mathsf{T}}_{(\vartheta)}\le R_{1(\vartheta)} \tag{13.5.40}_{(\vartheta)}$$

hold for $\vartheta>0$, $|\tau|\le\epsilon\nu\gamma$ where for $\vartheta>0$ $\mathsf{R}^{\mathsf{T}}_{(\vartheta)}$ is the convolution of "R^{T} without absolute value" with $\tau_+^{\vartheta-1}$ and

$$R_{1(\vartheta)}=\begin{cases}Ch^{\vartheta-1}\gamma^2\big(\dfrac{\nu}{\mu}\big)^{\vartheta+1}+C'h^s & \text{for } d=2,\\ Ch^{-2+\vartheta}\gamma^4+C'h^s & \text{for } d=3,\end{cases} \tag{13.5.41}$$

for $\vartheta\ge 0$, $T=\mu\nu^{-1}T_0$ for $d=2$, $T=T_0$ for $d=3$ and $\bar\chi=1$ on $[-\frac12,\frac12]$. While we can do better than this, it would have no implication for the final result.

We can apply Proposition 13.5.4 or 13.5.5 to reduce the calculation of the second term in the middle expression in (13.5.40) to the calculation of $F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma' Q'_x \mathsf{M}\mathsf{U}_{j,j}\,{}^t Q''_y$ where actually we have the sum of such expressions with different Q', Q'' and M.

Further, we can calculate these expressions by means of the methods of Section 4.3. The fact that $\mathsf{M} = \mathsf{M}(x', y', \boldsymbol{h}' D_{x'}, \boldsymbol{h}' D_{y'})$ is an an obstacle. We conclude that

$$h^{-1}\int_{-\infty}^{\tau} \bigl(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(\tilde{Q}'_x\psi'(x)U\psi''(y)\,{}^t\tilde{Q}''_y)\bigr)\,d\tau \equiv \sum_{j\le J}\sum_{m,p,l\le N} \mu^{1-2m-2p-l}h^{1+l-d}\bigl((2j+1)\mu h\bigr)^m \Theta_{j,mpl}(\tau) \tag{13.5.42}$$

with $\Theta_{j,mpl}$ defined below and thus arrive to

Proposition 13.5.7. *(i) Under the assumptions of Proposition 13.5.6 the following estimates hold:*

$$\mathsf{R}^{\mathsf{MW}}_{\infty} := |\Gamma(\tilde{Q}'_x\psi'(x)e)(-\infty,\tau) - \sum_{j\le J}\sum_{k,p,l\le N} \mu^{1-2m-2p-l}h^{1+l-d}\bigl((2j+1)\mu h\bigr)^m \Theta_{j,kpl}(\tau)| \le R_{1(0)}, \tag{13.5.43}$$

$$\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} \le R_{1(\vartheta)} \tag{13.5.43$_{(\vartheta)}$}$$

where for $\vartheta > 0$ $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)}$ *is the convolution of "*$\mathsf{R}^{\mathsf{MW}}_{\infty}$ *without absolute value" with* $\tau_+^{\vartheta-1}$ *and*

$$\Theta_{j,kpl}(\tau) := \int \theta\bigl(\tau - \mathcal{A}_j(x',\xi',\mu^{-2},\mu^{-1}h,h^2)\bigr) f_{kpl}(x',\xi')\,dx'd\xi' \tag{13.5.44}$$

with symbols f_{kpl} *such that*

$$\operatorname{supp} f_{kpl} \subset \operatorname{supp} q', \tag{13.5.45}$$

$$|D^{\alpha}_{x',\xi'} f_{kpl}| \le C\gamma^{-|\alpha|-2l} \qquad \forall \alpha : |\alpha| \le K', \tag{13.5.46}$$

where K' *is arbitrary and*

$$f_{000} = (2\pi)^{1-d} q'(x',\xi')(\psi'\circ\bar{\Psi}_0)(x',\xi_1). \tag{13.5.47}$$

(ii) In particular, for $d = 2$ *and* $\tau = 0$ *we can replace in* (13.5.44) *symbol* $\mathcal{A}_j$ *by*

$$\bar{\mathcal{A}}_j := \bigl((2j+1)\mu h + B(x_1, \xi_1, \mu^{-2}, \mu^{-1}h, h^2)\bigr) \tag{13.5.48}$$

Using map $\bar{\Psi}$ one can rewrite integral defining $\Theta_{...}$ as integral with respect to x as $d = 2$ and as integral with respect to (x, η) with $\eta = \langle \boldsymbol{F}^0, \xi\rangle$ as $d = 3$. In comparison wit $\bar{\Theta}_{...}$ introduced in the similar way arguments of θ contain many terms we consider as perturbation which explains subscript "∞" in our notations.

Our next goal is to estimate $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)}$ with $Q' = I$. In this case for $d = 3$, $\mu \ge h^{-1+\delta}$, $\vartheta = 0$ the desired estimate will be more precise under conditions $(13.3.77)_{1-3}$, (13.4.85), and (13.4.86).

In order to use this condition let us prove

Proposition 13.5.8. *Let* $d = 3$ *and conditions* (13.4.85), (13.4.85) *and* (13.4.86) *be fulfilled with* $\nu \ge \mathsf{max}(\mu h, \mu^{-2})$.

Let $Q' = \mathsf{Op}(q')$, $q' \in \mathsf{S}_{\boldsymbol{h}',\boldsymbol{\rho}',\boldsymbol{\gamma}',K}(T^*\mathbb{R}^2)$ *with* $\rho_1 = \gamma_1 = \gamma_2 = \bigl(\mu h/\nu\bigr)^{\frac{1}{2}}$, $\rho_2 = (\mu h)^{\frac{1}{2}}$. *Let* $\mathsf{diam}(\mathsf{supp}\, q') \le c\gamma_1$ *and let the following conditions be fulfilled on* $\mathsf{supp}(q')$*:*

$$|\xi_2| \le c\rho_2, \tag{13.5.49}$$

$$|\mathcal{A}_j| \le \epsilon_0 \mu h \implies \epsilon_0 \bigl(\mu h \nu\bigr)^{\frac{1}{2}} \le |\nabla_{x',\xi_1} \mathcal{A}_j| \le c\bigl(\mu h \nu\bigr)^{\frac{1}{2}}. \tag{13.5.50}$$

Then

$$\mathsf{R}^{\mathsf{MW}}_{\infty} \le C\mu h^{-1}\gamma_1^4 + C' h^s \qquad \forall \tau : |\tau| \le \epsilon \mu h. \tag{13.5.51}$$

Proof. First of all, let us apply an $\epsilon(\boldsymbol{\rho}', \boldsymbol{\gamma}')$-admissible partition of unity on $\mathsf{supp}(q')$; we conclude that without any loss of the generality one can assume that condition $|\mathcal{A}_j| \ge \epsilon\mu h$ can be violated on $\mathsf{supp}(q')$ for only one number $j = \bar{\jmath}$. But then the standard elliptic arguments yield estimates

$$|F_{t\to h^{-1}\tau}\chi_T(t) Q'_x \mathsf{U}_{j,k}| \le C' h^s \qquad \forall j \ne \bar{\jmath},$$

and

$$|F_{t\to h^{-1}\tau}\chi_T(t) \mathsf{U}_{j,k}\, {}^{t}Q'_y| \le C' h^s \qquad \forall k \ne \bar{\jmath}$$

with arbitrary $T \in [\mu^{-1}h^{-\delta}, h^{-l}]$, $\tau : |\tau| \le \epsilon\mu h$ and therefore for these T and τ estimate $(13.5.24)_{(3)}$ holds.

Let us multiply the operator $\mathcal{A}_j$ with $j = \bar{j}$ by a parametrix of $\bar{B}_1$ and by ν^{-1}; we then obtain a $(\mu^{-1}h, h\nu^{-\frac{1}{2}})$-pseudodifferential operator with respect to x' and we can apply the arguments of Chapter 5; in the estimates we obtain an additional factor $\mu\nu^{-\frac{1}{2}}$ in the right-hand expressions because we need an additional $\gamma_1\mu^{-1}\nu^{\frac{1}{2}}$-partition of unity with respect to ξ_1 or x_1. □

Let us note that under the assumptions of Proposition 13.5.8 (excluding condition (13.5.50)) we can replace ν by an arbitrary $\nu' \in [\nu, 1]$ and therefore we can make an appropriate partition of unity in the zone

$$\{(x', \xi_1) : \ \max\big(\mu h, \ (\mu h\nu)^{\frac{1}{2}}\big) \le |\nabla_{x',\xi_1}\mathcal{A}_j| \le (\mu h)^{\frac{1}{2}}\} \tag{13.5.52}$$

where $j \in \mathbb{Z}^+$ is defined in order to satisfy condition $|\mathcal{A}_j| \le \epsilon\mu h$ (in which case the choice of j is unique).

Let us note that for $d = 2$ Proposition 13.4.7 leaves only zone

$$\{(x_1, \xi_1) : \ |\nabla B| \le \epsilon_0(\mu h\nu)^{\frac{1}{2}}\} \tag{13.5.53}$$

uncovered, and for $d = 3$ Proposition 13.4.8 leaves only zone

$$\{(x', \xi') : \ |\xi_2| \le \epsilon_0(\mu h)^{\frac{1}{2}}, |\nabla_{x',\xi_1}\mathcal{A}_j| \le \epsilon_0(\mu h\nu)^{\frac{1}{2}}\}$$

uncovered where $j \in \mathbb{Z}^+$ is always taken by the indicated method.

Moreover, for $d = 3$, $\nu < 1$, both these propositions together leave only zone

$$\{(x', \xi') : \ |\xi_2| \le \epsilon_0(\mu h)^{\frac{1}{2}}, |\nabla_{x',\xi_1}\mathcal{A}_j| \le \epsilon_0(\mu h\nu)^{\frac{1}{2}}\} \tag{13.5.54}$$

uncovered.

Let us sum with respect to a partition of unity the remainder estimates obtained in Propositions 13.5.7 and 13.5.8. We arrive to

$$\int R_{1(\vartheta)}\gamma^{-d-1}\, d\gamma \tag{13.5.55}$$

with $R_{1(\vartheta)} = R_{1(\vartheta)}(\gamma)$ defined by (13.5.41).

As $d = 3$ essential term in $R_{1(\vartheta)}(\gamma)$ is $Ch^{-2+\vartheta}\gamma^4$ and (13.5.55) is $Ch^{-2+\vartheta}$ (modulo negligible). Therefore we arrive to

Proposition 13.5.9. *Let $d = 3$.*

(i) Suppose conditions (13.4.85), (13.5.47) *with $\bar{\nu} = 1$ and $\nu \ge \mu h$ are fulfilled and let $Q'' = \mathsf{Op}(q'')$ where $q'' \in \mathsf{S}_{\boldsymbol{h}',\boldsymbol{\rho}',\bar{\gamma},K}(T^*\mathbb{R}^2)$ with $\rho_1 = \bar{\gamma}$ with $\bar{\gamma}$ defined by* 13.5.35) *$\rho_2 = (\mu h)^{\frac{1}{2}}$ and*

$$
\begin{aligned}
(13.5.56)\quad & \operatorname{supp} q'' \subset \bigl\{(x',\xi') : \ |\xi_2| \le c(\mu h)^{\frac{1}{2}}, |\nabla_{x',\xi_1}\mathcal{A}_j| \le c(\mu h)^{\frac{1}{2}}\bigr\},\\
& \qquad q'' = 1 \quad \text{at} \quad \bigl\{(x',\xi') : \ |\xi_2| \le \epsilon_0(\mu h)^{\frac{1}{2}}, |\nabla_{x',\xi_1}\mathcal{A}_j| \le \epsilon_0(\mu h\nu)^{\frac{1}{2}}\bigr\}
\end{aligned}
$$

where j is defined for given (x',ξ') by the method indicated above. Then for $Q' = I - Q''$, $\vartheta = 0$ estimate

$$
(13.5.57)_0 \qquad \mathsf{R}^{\mathsf{MW}}_{\infty} \le Ch^{-2} + C'h^{s}
$$

holds.

(ii) Furthermore, for $\nu = \mu h$ we obtain $\bar{\gamma} = 1$ and condition (13.5.56) *means exactly that*

$$
\begin{aligned}
(13.5.56)' \quad & \operatorname{supp} q'' \subset \bigl\{(x',\xi') : \ |\xi_2| \le c(\mu h)^{\frac{1}{2}}\bigr\},\\
& \qquad q'' = 1 \quad \text{at} \quad \bigl\{(x',\xi') : \ |\xi_2| \le \epsilon_0(\mu h)^{\frac{1}{2}}\bigr\}.
\end{aligned}
$$

(iii) Finally, let $Q'' = \mathsf{Op}(q'')$ where $q'' \in \mathsf{S}_{\boldsymbol{h}',\boldsymbol{\rho}',\bar{\gamma},K}(T^*\mathbb{R}^2)$ with $\rho_1 = \rho_2 = \bar{\gamma} = (\mu h)^{\frac{1}{2}}$. Let condition (13.5.56) *with $\nu = 1$ be fulfilled, $Q' = I - Q''$. Then estimate*

$$
(13.5.57)_{(\vartheta)} \qquad \mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} \le Ch^{-2+\vartheta} + C'h^{s}
$$

holds for $\vartheta > 0$.

As $d = 2$ situation is more subtle as essential term in $R_{1(\vartheta)}(\gamma)$ is $Ch^{\vartheta-1}\nu^{\vartheta+1}\mu^{-\vartheta-1}\gamma^2$ and (13.5.55) is $Ch^{\vartheta-1}\nu^{\vartheta+1}\mu^{-\vartheta-1}(|\log\bar{\gamma}| + 1)$ (modulo negligible). However we will need some non-degeneracy condition anyway and one easily can get rid of logarithmic factor under weak non-degeneracy condition

$$
(13.5.58)_m \qquad \sum_{1\le|\alpha|\le m} |D^{\alpha}B| \ge \epsilon_0\nu \qquad \forall (x_1,\xi_1).
$$

Proposition 13.5.10. *Let $d = 2$.*

(i) Let conditions $(13.3.77)_{1-3}$, (13.5.12), (13.5.13) [30] *and* (13.4.85) *be fulfilled.*

Let $Q'' = \mathsf{Op}(q'')$ where $q'' \in \mathsf{S}_{h_1,\bar\gamma,\bar\gamma,K}(T^*\mathbb{R})$ with $\bar\gamma$ defined by (13.5.47). *Moreover, let us assume that*

$$\mathsf{supp}\, q'' \subset \bigl\{(x_1,\xi_1):\ |\nabla B| \le c(\mu h\nu)^{\frac12}\bigr\}, \qquad q''=1 \quad \text{at}\ \ \bigl\{(x_1,\xi_1):\ |\nabla B| \le \epsilon_0(\mu h\nu)^{\frac12}\bigr\}. \tag{13.5.59}$$

Then for $Q' = I - Q''$, $\vartheta \ge 0$ estimate

$$\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} \le C\nu^{1+\vartheta}\mu^{-\vartheta-1}h^{-1+\vartheta}\bigl(|\log(\mu h/\nu)|+1\bigr) + C'h^s \tag{13.5.60}$$

holds.

(ii) Under non-degeneracy condition $(13.5.58)_m$ *estimate*

$$\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} \le C\nu^{1+\vartheta}\mu^{-\vartheta-1}h^{-1+\vartheta} + C'h^s \tag{13.5.61}$$

holds.

Now, after summation with respect to partitions we conclude that

Corollary 13.5.11. *Let all the above conditions be fulfilled and let $\mu h \le \nu \le 1$, $\vartheta \ge 0$.*

(i) Let $d = 2$. Then contributions of zone, complimentary to (13.5.59), *to $\mathsf{R}^{\mathsf{T}}_{(\vartheta)}$ and $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)}$ do not exceed $C\mu^{-1-\vartheta}h^{-1+\vartheta}\nu^{1+\vartheta}(|\log(\mu h/\nu)|+1)$ and under non-degeneracy condition* $(13.5.58)_m$ *these contributions do not exceed $C\mu^{-1-\vartheta}h^{-1+\vartheta}\nu^{1+\vartheta}$.*

(ii) Let $d = 3$. Then contributions of zone, complimentary to (13.5.56), *to $\mathsf{R}^{\mathsf{T}}_{(\vartheta)}$ and $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)}$ do not exceed $Ch^{-2+\vartheta}$.*

Estimates in the Zone $\{\gamma \le \bar\gamma\}$

Now we need to consider contributions of zones (13.5.59) as $d = 2$ and (13.5.56) as $d = 3$ to $\mathsf{R}^{\mathsf{T}}_{(\vartheta)}$ and thus to $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)}$.

[30] For $\nu \le \mu h$ this statement is empty.

Remark 13.5.12. We can apply the same arguments as before with the exception that the number of indices affected does not exceed C (or even 1) now instead of $C\nu\gamma^2(\mu h)^{-1}$ and therefore estimate (13.5.39) of the contribution of one partition element to the remainder loses the last factor and becomes

$$C(\mu^{-1}h)^{d-2}\gamma^{2d-4}\times \mu\nu^{-1}\times \mu^{d-2}. \tag{13.5.39$'$}$$

However it makes a difference as now power of γ is $(2d-4)$ and $(d-4)$ after division by γ^d it becomes negative. Therefore we need to apply more subtle arguments.

Let us consider $d=2$ first. Note that if q'' is $\bar\gamma$-admissible symbol with $\mathsf{diam}(\mathsf{supp}\, q'')\le \epsilon\bar\gamma$ then all operators $\mathcal{A}_j$ with $j\ne \bar\jmath$ are elliptic and thus contributions of all indices $j\ne\bar\jmath$ to R^{T} and $\mathsf{R}^{\mathsf{MW}}_{\infty}$ are negligible.

Then we can apply arguments of Section 5.2. We arrive to

Proposition 13.5.13. *Let $d=2$ and let all above conditions be fulfilled. Then*

(i) Let $\vartheta=0$ and a weak non-degeneracy condition $(13.5.58)_m$ *be fulfilled.*

Then contributions of zone (13.5.59) *to* R^{T} *and* $\mathsf{R}^{\mathsf{MW}}_{\infty}$ *do not exceed $Ch^{-\delta}+C'h^s$ with arbitrarily small exponent $\delta>0$.*

(ii) Let $\vartheta=0$ and a strong non-degeneracy condition

$$|\nabla B|\le \epsilon_0\nu \implies |\det \mathsf{Hess}\, B|\ge \epsilon_0\nu^2. \tag{13.5.62}$$

be fulfilled. Then contributions of zone (13.5.59) *to* R^{T} *and* $\mathsf{R}^{\mathsf{MW}}_{\infty}$ *do not exceed $C+C'h^s$.*

(iii) Let $\vartheta>0$. Then contributions of zone (13.5.59) *to* $\mathsf{R}^{\mathsf{T}}_{(\vartheta)}$ *and* $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)}$ *do not exceed $C\nu^{\vartheta}\mu^{-\vartheta}h^{\vartheta}$.*

Proof. As we mentioned, proof follows up arguments of Section 5.2: Statements 13.5.13 and (ii) follow them up to Subsection 5.2.4 and Statement (iii) follows them up to Subsection 5.2.1 or Subsection 5.2.2 as $\det \mathsf{Hess}\, B \gtrless 0$ respectively.

We leave details to the reader. □

Remark 13.5.14. The same arguments allow us to get rid of logarithmic factor and derive estimate (13.5.61) for contribution of zone complimentary to (13.5.59) as $\vartheta > 0$ even without $(13.5.58)_m$.

Consider $d = 3$ now. Note that if q'' is $\bar{\gamma}$-admissible symbol with $\mathsf{diam}(\mathsf{supp}\, q'') \le \epsilon\bar{\gamma}$ and $\mathsf{supp}\, q'' \subset \{|\xi_2| \le \epsilon(\mu h)^{\frac{1}{2}}\}$ then all operators $\mathcal{A}_j$ with $j \ne \bar{\jmath}$ are elliptic and thus contributions of all indices $j \ne \bar{\jmath}$ to R^{T} and $\mathsf{R}^{\mathsf{MW}}_{\infty}$ are negligible.

Again following arguments of Section 5.2 we arrive to

Proposition 13.5.15. *Let $d = 3$ and all above conditions be fulfilled. Then*

(i) Let $\vartheta = 0$. Then contributions of zone (13.5.56) *to R^{T} and $\mathsf{R}^{\mathsf{MW}}_{\infty}$ do not exceed $C\mu h^{-1-\delta} + C'h^s$ with arbitrarily small exponent $\delta > 0$.*

(ii) Let $\vartheta = 0$ and weak non-degeneracy condition

$$(13.5.63)_m \qquad \sum_{|\alpha|\le m} |D^{\alpha}\mathcal{B}_j| \ge \epsilon_0\nu \qquad \forall(x', \xi_1)$$

be fulfilled. Then contributions of zone (13.5.56) *to R^{T} and $\mathsf{R}^{\mathsf{MW}}_{\infty}$ do not exceed $C\mu h^{-1} + C'h^s$.*

(iii) Let $\vartheta > 0$. Then contribution of zone (13.5.56) *to $\mathsf{R}^{\mathsf{T}}_{(\vartheta)}$ and $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)}$ do not exceed $Ch^{-2+\vartheta} + C'h^s$.*

Proof. As we mentioned, proof follows up arguments of Section 5.2 up to Subsection 5.2.3.

Factor μh^{-1} appears as $\hbar^{-1}$. Again we leave all easy details to the reader. □

Synthesis

Combining Corollary 13.5.11(i) with Remark 13.5.14 and Proposition 13.5.13 we arrive to the following

Theorem 13.5.16. *Let $d = 2$, $Q' = I$, $\tau = 0$. Let conditions* $(13.3.77)_{1-3}$, (13.4.11) *and* (13.4.12) *be fulfilled. Let $\nu \ge C'\bar{\nu}\mu^{-2}$. Then*

(i) Under weak non-degeneracy condition $(13.4.57)_m$ *estimate*

$$\mathsf{R}^{\mathsf{MW}}_{\infty} \le C\frac{\nu}{\mu h} + Ch^{-\delta} + C'h^s \tag{13.5.64}$$

holds.

(ii) Under strong non-degeneracy condition

$$|\nabla \frac{V}{F}| \le \epsilon_0\nu \implies |\det \mathsf{Hess}\, \frac{V}{F}| \ge \epsilon_0\nu^2 \tag{13.5.65}$$

estimate

$$\mathsf{R}^{\mathsf{MW}}_{\infty} \le C\frac{\nu}{\mu h} + C + C'h^s \tag{13.5.66}$$

holds.

(iii) As $\vartheta > 0$ *estimate*

$$\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} \le C\nu^{1+\vartheta}\mu^{-1-\vartheta}h^{-1+\vartheta} + C\nu^{\vartheta}\mu^{-\vartheta}h^{\vartheta} + C'h^s \tag{13.5.67}$$

holds.

Combining Corollary 13.5.11(ii) and Proposition 13.5.15 we arrive to the following

Theorem 13.5.17. *Let* $d = 2$, $Q' = I$, $\tau = 0$. *Then*

(i) Under non-degeneracy condition $(13.4.57)_m$ *estimate*

$$\mathsf{R}^{\mathsf{MW}}_{\infty} \le Ch^{-2} + C'h^s \tag{13.5.68}$$

holds.

(ii) In the general case estimate

$$\mathsf{R}^{\mathsf{MW}}_{\infty} \le Ch^{-2} + C\mu h^{-1-\delta} + C'h^s \tag{13.5.69}$$

holds with arbitrarily small exponent $\delta > 0$*; in particular, as* $\mu \le h^{-1+\delta}$ *estimate* (13.5.68) *holds.*

(iii) As $\vartheta > 0$ *estimate*

$$\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} \le Ch^{-2+\vartheta} + C'h^s \tag{13.5.70}$$

holds.

Synthesis: Estimates with Mollifications

Finally, Propositions 13.5.4 and 13.5.5 and the same arguments of Section 5.2 yield the following

Proposition 13.5.18. *Let φ satisfy condition* (4.2.73)–(4.2.75) *with $\vartheta(z)$ replaced by z_+^ϑ with $\vartheta > 0$.*

(i) In the framework of Theorem 13.5.16 estimate

$$\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)L} := \Big| \int \phi\big(\frac{\tau-\tau'}{L}\big) d_{\tau'}\big((\Gamma\psi(x)e)(-\infty,\tau') - \sum_{j\le J} \sum_{m,p,l,n\le N, n\le 2l} \mu^{1-2(m+p)-l} h^{l-1} ((2j+1)\mu h)^m \Theta^{(n)}_{j,mpln}(\tau')\big)\Big| \le CR_1\big(\frac{h\nu}{\mu L}\big)^\vartheta \qquad \forall \tau : |\tau| \le c\nu \quad \forall L \in [\nu h\mu^{-1}, c] \tag{13.5.71}$$

holds where $\Theta_{j,mpln}(\tau)$ are given by (13.5.43) *with f_{mpln} instead of f_{mpl} with $f_{mpln} \in \mathscr{C}^{K'}$ and $f_{mpl0} = f_{mpl}$, the superscript (n) means the n-th order derivative with respect to the spectral parameter, and here and below R_1 is the right-hand expression in the corresponding estimate for $\mathsf{R}^{\mathsf{MW}}_\infty$ (in the general case or under some additional condition).*

(ii) In the framework of Theorem 13.5.17 estimate

$$\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)L} \le C' R_1\big(\frac{h}{L}\big)^\vartheta \qquad \forall \tau \le c \quad \forall L \in [h, c] \tag{13.5.72}$$

holds.

(iii) In particular, for $\phi \in \mathscr{C}_0^K(\mathbb{R})$ and $L \ge h^{1-\delta}\nu\mu^{-1}$, $L \ge h^{1-\delta}$ estimate $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)L} = O(h^s)$ holds without any additional conditions.

Remark 13.5.19. (i) For odd integers ϑ one should also include in $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)}$ an extra term possibly regularized.

(ii) For $d = 3$ the extra term appears only if the condition

$$|\frac{V}{F} + (2j+1)\mu h| + |\nabla \frac{V}{F}| \le \epsilon_0 \implies \mathsf{Hess}\,\frac{V}{F} \text{ has an eigenvalue } f \ge \epsilon_0 \tag{13.5.73}_+$$

is violated in which case it does not exceed $C\mu h^{-1+\vartheta}|\log h|$ (so it is negligible for $\mu \le h|\log h|^{-1}$ anyway).

(iii) For $d=2$ the extra term appears only if the condition

$$(13.5.74)_+ \qquad |\frac{V}{F}+(2j+1)\mu h|+|\nabla\frac{V}{F}|\le \epsilon_0\nu \implies \det \mathsf{Hess}\,\frac{V}{F}\ge \epsilon_0\nu^2$$

is violated in which case it does not exceed $C\nu\vartheta\mu^{-\vartheta}h^{\vartheta}|\log \mu^{-1}h|$ (so it is negligible for $\nu \ge \mu h|\log \mu^{-1}h|$ anyway).

(iv) The reader can easily prove that one can replace the eigenvalues of the skew-Hessian of the reduced symbol by $\pm\sqrt{-\zeta_k}$ where ζ_k are the eigenvalues of the matrix (V^j_l) with $V^j_l=\sum_k g^{jk}\partial_{kl}(V/F)$.

13.5.4 Effective Asymptotics

General Scheme

The asymptotics obtained in Theorems 13.5.16 and 13.5.17 are optimal in a reasonable sense, but the answer is given by ansatz in the right hand expression of (13.5.42)

$$(13.5.75) \qquad \sum_{j\le J}\sum_{m,p,l\le N}\mu^{1-2m-2p-l}h^{1+l-d}\big((2j+1)\mu h\big)^m\Theta_{j,mpl}(\tau)$$

with

$$(13.5.44) \quad \Theta_{j,mpl}(\tau):=\int \theta\big(\tau-\mathcal{A}_j(x',\xi',\mu^{-2},\mu^{-1}h,h^2)\big)f_{mpl}(x',\xi')\,dx'd\xi'$$

and we cannot effectively calculate all the terms of the decompositions of $\mathcal{A}_j$ and amplitudes $f_{\dots}$. Therefore our purpose through the end of this section is to obtain simpler (though more special and maybe not so optimal) asymptotics and estimates.

The good candidate is the standard Magnetic Weyl expression and our main goal is to estimate

$$(13.5.76) \qquad \mathsf{R}^{\mathsf{MW}}=|\int \psi(x)\Big(e(x,x,-\infty,\tau)-h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)\Big)\,dx|$$

and

$$(13.5.77) \quad \mathsf{R}^{\mathsf{MW}}_{(\vartheta)}= |\iint (\tau-\tau')^{\vartheta}_+\psi(x)\,d_{\tau'}\Big(e(x,x,-\infty,\tau')-h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau',\mu h)\Big)\,dx|$$

where $\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)$ is given by $(13.2.9)_{(2)}$ and $(13.2.9)_{(3)}$ for $d=2,3$ respectively.

We deduce them from Theorems 13.5.16 and 13.5.17, Proposition 13.5.18 and the results of Section 13.4 by means of a certain universal approach which will be described right now.

Let us skip all the terms with $m+p+l\ge 1$ in formula (13.5.75) and replace $\mathcal{A}_j(x',\xi',\mu^{-2},\mu^{-1}h,h^2)$ by $\bar{\mathcal{A}}_j(x',\xi')=\mathcal{A}_j(x',\xi',0,0)$ in (13.5.44).

Furthermore, let us integrate with respect to ξ_2 for $d=3$. So we obtain an integral over Λ^0 in both cases $d=2,3$.

Then going from an integral with respect to $(x',\xi_1)\in\Lambda^0$ to an integral with respect to $x\in\Lambda$ (by means of the symplectomorphism $\bar\Psi_0$) and taking into account formulas (13.5.47) with $\psi'=\psi$, $Q'=I$ and

$$\bar{\mathcal{A}}_j=\bigl((2j+1)\mu hF+V\bigr)\circ\bar\Psi_0 \tag{13.5.78}$$

(which follows from Proposition 13.3.1 and the definition of $\mathcal{A}_j$) we obtain that expression (13.5.75) becomes precisely

$$h^{-d}\int \psi(x)\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)\,dx. \tag{13.5.79}$$

Therefore we need to consider an error (13.5.75)–(13.5.79)

$$\mathcal{J}:=\sum_{j\le J}\mu h^{1-d}\Bigl(-\bar\Theta_{j,000}(\tau)+\sum_{r+m+p+l\le N} h^{l+r}\mu^{-2(m+p)-l}\bigl((2j+1)\mu h\bigr)^m\Theta_{j,mplr}(\tau)\Bigr) \tag{13.5.80}$$

where here and in what follows the functions $\bar\Theta_{j,\dots}(\tau)$ are given by (13.5.44) with $\bar{\mathcal{A}}_j$ instead of $\mathcal{A}_j$.

Let us note that if we introduce $z=(2j+1)\mu h$ and formally apply formula $(13.A.3)_1$ (replacing the sum with respect to j by an integral with respect to z divided by $2\mu h$) then under condition (13.4.46) we obtain for $|\tau|\le\epsilon$ that

$$\mathcal{J}=h^{-d}G_0(\tau,\mu^{-1})+h^{1-d}G_1(\tau,\mu^{-1})+O(h^{2-d}) \tag{13.5.81}$$

with functions $G_k(\tau,\zeta)$ smooth in the neighborhood of $(0,0)$; here we have integrated with respect to $z\in(0,C_0)$ and for $z\in(\frac13 C_0,3C_0)$ the integrand

vanishes. Here condition (13.4.46) provides the smoothness in a neighborhood of $(0,0)$ of the functions $\Theta_{\dots}(z,\tau)$ and $\bar\Theta_{\dots}(z,\tau)$ obtained from $\Theta_{j,\dots}(\tau)$ and $\bar\Theta_{j,\dots}(\tau)$ respectively by the substitution $z=(2j+1)\mu h$.

Therefore the following estimate holds:

$$|\int \psi(x)\Big(e(x,x,-\infty,\tau)-h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)\Big)\,dx- h^{-d}G_0(\tau,\mu^{-1})-h^{1-d}G_1(\tau,\mu^{-1})|\le \mathsf{R}^{\mathsf{MW}}_{\infty}+\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}+C'h^{2-d} \tag{13.5.82}$$

where

(13.5.83) $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ is an error obtained when we replaced the sum with respect to j by the integral with respect to z (divided by $2\mu h$) in the definition of $\mathcal{J}$.

A similar estimate holds for $\vartheta>0$.

Moreover, if we perform the same procedure but with preliminary mollification with respect to τ with $L=1$ then Proposition 13.5.18 yields estimate

$$|\int \phi(\tau)\Big(\int \psi(x)\Big(e(x,x,-\infty,\tau)-h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)\Big)\,dx- h^{-d}G_0(\tau,\mu^{-1})-h^{1-d}G_1(\tau,\mu^{-1})\Big)\,d\tau|\le C'h^{2-d} \tag{13.5.84}$$

with the same functions G_0 and G_1; here application of formula $(13.\mathrm{A}.3)_1$ is justified rather than merely formal because

$$|D_z^k\int \phi(\tau)\Theta_{\dots}(z,\tau)\,d\tau|\le C,$$

$$|D_z^k\int \phi(\tau)\big(\Theta_{\dots}(z,\tau)-\bar\Theta_{\dots}(z,\tau)\big)\,d\tau|\le C\mu^{-2}$$

for all $k\le K'$ and $z\in[0,C_0]$ provided ϕ is smooth enough.

On the other hand, Proposition 13.4.20 and formula (13.4.69) (in the weak sense) yield that estimate

$$|\mathsf{R}^{\mathsf{MW}}_{L}|:=|\iint \phi(\tau)\Big(e(x,x,-\infty,\tau)-h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)\Big)\,dxd\tau|\le C'h^{2-d} \tag{13.5.85}$$

holds for $1 \le \mu \le h^{\delta-1}$.

Comparing (13.5.84) and (13.5.85) for $h^{-\delta} \le \mu \le h^{\delta-1}$ we obtain that the functions

$$\int \phi(\tau) G_j(\tau, \zeta) d\tau$$

with $j = 1, 2$ have a zero of arbitrarily high order at $\zeta = 0$; since mollifying function ϕ is arbitrary and $G_j(\tau, \zeta)$ are smooth near $(0, 0)$ we obtain that the functions $G_j(z, \tau)$ have a zero of arbitrarily high order at $\zeta = 0$ provided $|\tau| \le \epsilon$.

Then (13.5.82) and (13.5.84) yield respectively

Proposition 13.5.20. *Let condition* (13.4.46) *be fulfilled. Then for* $h^{-\delta} \le \mu \le h^{-1}$ *estimates* (13.5.85) *and*

$$|\mathsf{R}^{\mathsf{MW}}| \le |\mathsf{R}^{\mathsf{MW}}_{\infty}| + |\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}| + C' h^{2-d} \qquad \forall \tau : |\tau| \le \epsilon \tag{13.5.86}$$

hold.

Remark 13.5.21. A similar estimates hold for $\vartheta > 0$ but for $\vartheta > 1$ one should add the correction terms

$$-\kappa_2(\tau, \mu h) h^{2-d} - \kappa_4(\tau, \mu h) h^{4-d} - \dots, \tag{13.5.87}$$

and for odd integers ϑ the extra term described in Remark 13.5.19 should be included as well.

So in order to estimate R^{MW} we should estimate $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$.

Implementation: Strongest Non-Degeneracy Condition

First of all let us note that under strongest non-degeneracy condition (13.4.54) the following inequalities hold:

$$|D_z^k \Theta(z, \tau)| \le C', \qquad |D_z^k (\Theta(z, \tau) - \bar{\Theta}(z, \tau))| \le C' \mu^{-2} \qquad \forall \tau : |\tau| \le \epsilon \quad \forall z \in [0, C_0] \quad \forall k \le K'. \tag{13.5.88}$$

Therefore $|\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}| \le C' h^{2-d}$ in this case; so we obtain

Theorem 13.5.22. *Let conditions* (13.2.1)–(13.2.5), (13.3.1), (13.4.46) *and* (13.4.54) *be fulfilled. Let* $\vartheta > 0$. *Then for* $d = 2, 3$ *respectively the following estimates hold:*

$$|\mathsf{R}^{\mathsf{MW}}_{(\vartheta)}| \le C\mu^{-1-\vartheta}h^{\vartheta-1} + C + C'h^s, \tag{13.5.89}_{(2)}$$

$$|\mathsf{R}^{\mathsf{MW}}_{(\vartheta)}| \le Ch^{-2+\vartheta} + Ch^{-1} + C' \tag{13.5.89}_{(3)}$$

Proof. Case $\mu \ge h^{-\delta}$ is covered by above arguments and Theorem 13.4.25 permitted us to get rid of condition (13.5.1). □

Implementation: $d = 3$

In what follows we assume that condition (13.4.45) is fulfilled; we will get rid of this restriction in Section 13.8. Let us first treat the case $d = 3$ which is simpler as the target remainder estimate is relatively larger and there is additional integration over ξ_2. We will return to this case later when studying supersharp asymptotics.

Theorem 13.5.23. *Let* $d = 3$, $\vartheta = 0$, $\tau = 0$ *and let conditions* (13.2.1)–(13.2.5), (13.4.45) *and* (13.3.1) *be fulfilled. Then*

(i) Estimate (13.5.68) *holds for* R^{MW} *under under weak non-degeneracy condition* $(13.4.57)_m$.

(ii) Estimate (13.5.69) *holds for* R^{MW} *in the general case.*

Proof. Recall equality

$$\mathcal{B}_j = \Big(V + (2j+1)\mu hF\Big) \circ \bar{\Psi}_0 + O(\mu^{-2}). \tag{13.5.90}$$

We want to estimate $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ and $\mathsf{R}^{\mathsf{MW}}_{(\vartheta)}\mathsf{corr}$; for this purpose let us introduce scaling function

$$\gamma_1 = \gamma_1(x', \xi') = \min_j(|\bar{\mathcal{A}}_j| + |\nabla\bar{\mathcal{A}}_j|^2)^{\frac{1}{2}} \tag{13.5.91}$$

and let us introduce scaling function γ_2 in the same way with $\mathcal{A}_j$ instead of $\bar{\mathcal{A}}_j$. Let us treat various zones and various γ_1- and γ_2-admissible partitions of unity in those zones:

(a) Zone $\{(x',\xi') : \gamma_1 \ge \max(C_0\mu^{-1}, \sqrt{\mu h})\}$; in this zone $\gamma_1 \asymp \gamma_2$. One can easily see that if $\Theta(z)$ and $\bar\Theta(z)$ are functions associated with the same element of the partition of unity ($\tau = 0$ and m, p, l are omitted here for the sake of simplicity) then

$$|D_z^k \bar\Theta(z)| \le C_k \gamma_1^{2d-2-2k} + C' h^s \qquad \forall k \le K' \tag{13.5.92)$_1$}$$

and the same estimate with γ_1 replaced by γ_2 (and this replacement is not essential in this zone) holds for $\Theta(z)$.

Further, let us apply formula

$$\Theta(z) - \bar\Theta(z) = \int_0^1 \partial_t \Theta(z,t)\,dt$$

with $\Theta(t,z)$ defined by (13.5.44) with $\tau = 0$ and with $\mathcal{A}_j t + \bar{\mathcal{A}}_j(1-t)$ instead of $\mathcal{A}_j$; we then easily obtain estimate

$$|D_z^k(\Theta(z) - \bar\Theta(z))| \le C_k \mu^{-2} \gamma_1^{2d-4-2k} + C' h^s \qquad \forall k \le K'. \tag{13.5.92)$_2$}$$

Furthermore, let us note that outside of an interval of length $C_0\gamma_1^2$ the functions $\Theta(z)$ and $\bar\Theta(z)$ are constant and that for $\vartheta = 0$ the integrands are polynomial with respect to z; since the integral formula (13.A.3)$_1$ is exact on polynomials of arbitrary fixed degree we obtain in the error estimate an additional factor $C_0\gamma_1^2$.

So the contribution to $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ of this element of the partition does not exceed

$$C_k h^{-d} \mu^{-2} \gamma_1^{2d-4-2k} (\mu h)^k \gamma_1^2 + C' h^s. \tag{13.5.93}$$

On the other hand, in the zone $\{(x',\xi') : 2C_0\mu^{-1} \ge \gamma_1\}$ a similar inequality[31)] holds for γ_2; in this zone we treat $\bar\Theta$ and Θ separately; we do not apply (13.5.92)$_2$ in this case and so we take γ_1- and γ_2-admissible partitions of unity for $\bar\Theta$ and Θ respectively. We consider the contribution of $\bar\Theta$; the contribution of Θ is treated similarly:

[31)] I.e. $C_1\mu^{-1} \ge \gamma$.

(b) Let us treat subzone $\{(x_1,\xi_1) : 2C_0\mu^{-1} \ge \gamma_1 \ge \sqrt{\mu h}\}$. In this case we apply $(13.5.92)_1$ and obtain that the contribution to $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ of such an element of the partition does not exceed

$$C_k h^{-d}\gamma_1^{2d-2-2k}(\mu h)^k\gamma_1^2 + C'h^s \tag{13.5.94}$$

if we treat $\bar{\Theta}$ only; a similar estimate with γ_2 instead of γ_1 (for the corresponding element) holds if we treat Θ only.

(c) Let us treat subzone $\{(x_1,\xi_1) : 2C_0\mu^{-1} \le \gamma_1 \le \sqrt{\mu h}\}$. In this case we treat the integrals and Riemann sums separately; however since the integral formulas are exact on polynomials we must integrate over an interval of length not exceeding $C_0\mu h$ and we must take less than C_0 terms in the Riemann sum. This remark and estimates $(13.5.92)_{1,2}$ yield that the contribution of this element of the partition does not exceed

$$Ch^{-d}\mu^{-2}\gamma_1^{2d-4}\mu h + C'h^s; \tag{13.5.95}$$

let us recall that in this case $\gamma_1 \asymp \gamma_2$ and we take the same partition for $\bar{\Theta}$ and Θ.

(d) Let us consider subzone $\{(x_1,\xi_1) : 2\min(\sqrt{\mu h}, C_0\mu^{-1}) \ge \gamma_1\}$; then a similar inequality holds for γ_2. In this zone we apply the same arguments as in (c) but we do not use $(13.5.92)_2$ and consider $\bar{\Theta}$ and Θ separately. Then the contribution to R^{MW} of this element does not exceed

$$Ch^{-d}\gamma_1^{2d-2}\mu h + C'h^s \tag{13.5.96}$$

if we treat $\bar{\Theta}$ only; a similar estimate (for the corresponding element) holds if we treat Θ only.

Summing with respect to partitions, using (13.5.93)–(13.5.96) and observing that the estimates of the contribution of the common element of two (sub)zones calculated by different recipes are equivalent we obtain that

$$\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}} \le \sum_{\iota=1,2} Ch^{-d}\int \min\Big(\mu^{-2}\big(\frac{\mu h}{\gamma_\iota^2}\big)^k, \mu h\big(\frac{\mu h}{\gamma_\iota^2}\big)^k, \mu^{-1}h\gamma_\iota^{-2}, \mu h\Big)\,dx'd\xi' + C'h^{-1}. \tag{13.5.97}$$

The right-hand expression in this estimate can only increase if we replace γ_ι by functions which are smaller. Then for $d = 3$ we can replace both γ_1

and γ_2 by $|\xi_2|$ and then separately treating the cases $\mu \le h^{-\frac{1}{3}}$ and $\mu \ge h^{-\frac{1}{3}}$ we obtain that in both cases $|\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}| \le Ch^{-2} + C'h^s$; we will get more precise estimates below.

So our theorem is proven under condition (13.5.1) (but Theorem 13.4.30(iv) yields that we can skip this condition). □

Obviously, the same arguments hold for $\vartheta > 0$ but we obtain estimate (13.5.70) with the additional term Ch^{-2} in the right-hand expression which is obviously bad. In order to get rid of this term let us consider mollification with the function $\phi(\tau/L)$ with a smooth function ϕ. Obviously in this case all the arguments of the proof remain true with γ_ι replaced by $\gamma_\iota + L^{\frac{1}{2}}$.

Then, summing over a partition of non-smooth φ via $\phi(\tau/L)$, with smooth ϕ for $L \ge \mu h$ and with non-smooth ϕ for $L = \mu h$ (as we did in Section 4.4), we obtain estimates

$$\mathsf{R}^{\mathsf{MW}}_{(\vartheta)\mathsf{corr}} \le C\mu h^{1-d} \int_{\{\gamma \ge \sqrt{\mu h}\}} (\mu h)^{\vartheta} \big(\frac{\mu h}{\gamma^2}\big)^s \, dx' d\xi' + C\mu h^{1-d} \int_{\{\gamma \le \sqrt{\mu h}\}} (\mu h)^{\vartheta} \, dx' d\xi' \tag{13.5.98}$$

provided $\mu^3 h \le 1$, $\vartheta \le 1$ and

$$\mathsf{R}^{\mathsf{MW}}_{(\vartheta)\mathsf{corr}} \le C\mu^{-2} h^{-d} \int_{\{\gamma \ge \sqrt{\mu h}\}} (\mu h)^{\vartheta} \big(\frac{\mu h}{\gamma^2}\big)^s \, dx' d\xi' + C\mu^{-2} h^{-d} \int_{\{\mu^{-1} \le \gamma \le \sqrt{\mu h}\}} \gamma^{-2} (\mu h)^{\vartheta} \, dx' d\xi' + C\mu h^{1-d} \int_{\{\gamma \le \mu^{-1}\}} (\mu h)^{\vartheta} \, dx' d\xi' \tag{13.5.99}$$

provided $\mu^3 h \ge 1$, $\vartheta \le 1$.

These estimates yield the estimate

$$\mathsf{R}^{\mathsf{MW}}_{(\vartheta)\mathsf{corr}} \le R_{2(\vartheta)} \coloneqq \begin{cases} C\mu^{\vartheta+\frac{3}{2}} h^{\vartheta-\frac{3}{2}} & \text{for } \ \mu \le h^{-\frac{1}{3}}, \\ C\mu^{-\frac{3}{2}+\vartheta} h^{-\frac{5}{2}+\vartheta} & \text{for } \ \mu \ge h^{-\frac{1}{3}} \end{cases} \tag{13.5.100}$$

in the general case and the estimate

$$\mathsf{R}^{\mathsf{MW}}_{(\vartheta)\mathsf{corr}} \le Ch^{-2+\vartheta} \tag{13.5.101}$$

under intermediate non-degeneracy condition

$$|\frac{V}{F} + (2j+1)\mu h| + |\nabla \frac{V}{F}| + |\operatorname{Hess} \frac{V}{F}| \ge \epsilon_0. \tag{13.5.102}$$

Normally to achieve such estimate we need to consider many terms but the largest extra term does not exceed Ch^{-1}. Therefore, the following statement is proven:

Theorem 13.5.24. *Let $d = 3$, $\vartheta > 0$, $\tau = 0$. Then*

(i) Estimate

$$\mathsf{R}^{\mathsf{MW}}_{(\vartheta)} \le Ch^{-2+\vartheta} + Ch^{-1} \tag{13.5.103}$$

holds provided either $\mu \ge h^{-1/(3-2\vartheta)}$ or $\mu \le h^{-1/(3+2\vartheta)}$ or condition (13.5.102) *is fulfilled.*

(ii) In the general case for $h^{-1/(3+2\vartheta)} \le \mu \le h^{-1/(3-2\vartheta)}$ estimate

$$|\mathsf{R}^{\mathsf{MW}}_{(\vartheta)}| \le Ch^{-2+\vartheta} + Ch^{-1} + R_{3(\vartheta)} \tag{13.5.104}$$

holds where $R_{3(\vartheta)}$ is the right-hand expression of (13.5.98), (13.5.99) *for $\mu \le h^{-\frac{1}{3}}$ and $\mu \ge h^{-\frac{1}{3}}$ respectively.*

Moreover, $R_{3(\vartheta)} \le R_{2(\vartheta)}$ defined by (13.5.100).

Recall that for $\vartheta = 1$, $\mathsf{R}^{\mathsf{MW}}_{(\vartheta)}$ contains an additional regularized term by Remark 13.5.19.

We leave to the reader the following rather easy problem:

Problem 13.5.25. (i) Improve estimates for $\mathsf{R}^{\mathsf{MW}}_{(\vartheta)\mathsf{corr}}$ under more restrictive conditions (taking into account the term $\kappa_2 h^{-1}$ with $\kappa_2 = \kappa_2(\tau, \mu h)$).

(ii) Consider the case $\vartheta > 1$ when this term should always be taken into account.

(iii) Improve estimates for $\mathsf{R}^{\mathsf{MW}}_{(\vartheta)\mathsf{corr}}$ as $\bar{\nu} < 1$.

(iv) Improve estimates for $\mathsf{R}^{\mathsf{MW}}_{(\vartheta)\mathsf{corr}}$ from $O(h^{-2+\vartheta})$ to $o(h^{-2+\vartheta})$ calculating $\mathcal{A}_j$ modulo $O\big(\mu^{-4} + \mu^{-2}\gamma^2\big)$ instead of $O(\mu^{-2})$ as we did. In this case in $\mathsf{R}^{\mathsf{MW}}_{(\vartheta)}$ an integrand $\mathcal{N}^{\mathsf{MW}}(x, \tau', \mu h)$ should be replaced by $\mathcal{N}^{\mathsf{MW}}((x, \tau' - \rho(x)\mu^{-2}, \mu h)$ and additional terms of the type $\mathsf{m}_j(x)\mu^{-2j}h^{-3}$ appear.

Implementation: $d = 2$

Obviously, our arguments apply to the case $d = 2$ as well. In particular, estimate (13.5.97) remains true for $d = 2$, $\nu = 1$, $\vartheta = 0$ as well but we want to improve it for $\mu \ge C_0 h^{-\frac{1}{3}}$. Namely, we want to estimate the contribution of the (sub)zone

$$\{x : \ \epsilon_0(\mu h)^{\frac{1}{2}} \ge \gamma_1 \ge C_1\mu^{-1}\} \tag{13.5.105}$$

more accurately where C_1 depends on $\epsilon > 0$.

More precisely, if $|v + (2j+1)\mu h| \ge \epsilon\gamma_1^2$ on the element of the partition of unity (with $j \in \mathbb{Z}^+$ for which this absolute value is minimal) then Θ_j and $\bar\Theta_j$ coincide for all $j \le J$ and therefore the contributions to the error of Riemann sums vanish for $m = p = l = 0$ and since $\Theta(z)$ and $\bar\Theta(z)$ coincide outside of intervals of the length $C_0\mu^{-2}$, the contribution of $\big(\Theta(z) - \bar\Theta(z)\big)$ to the error does not exceed

$$Ch^{1-d}\gamma_1^{2d-4}\mu^{-1} + C'h^s. \tag{13.5.106}$$

The contributions of all the other terms do not exceed the previous estimate in zone (c) in the proof of Theorem 13.5.24 with the additional factor μ^{-2} and so they are less than this estimate.

Now applying estimate (13.5.97) with this improvement and Theorem 13.5.16 we immediately obtain that under condition (13.5.1) (which could be skipped by Remark 13.4.19) the following theorem holds:

Theorem 13.5.26. *Let $d = 2$, $\vartheta = 0$, $\tau = 0$ and let conditions* (13.2.1)–(13.2.5)*,* (13.3.1)*,* (13.4.45) *and* (13.5.1) *be fulfilled. Then*

(i) For $\mu^3 h \le C_0$ the following estimate holds:

$$\mathsf{R}^{\mathsf{MW}} \le \frac{C}{\mu h} + \frac{C'}{\mu h}\int_{\{\gamma \ge C_0\mu^{-1}\}} \big(\frac{\mu h}{\gamma}\big)^s \frac{dx}{\gamma^2} + C\frac{\mu}{h}\int_{\{\gamma \le C_0\mu^{-1}\}} dx + C'. \tag{13.5.107}$$

Moreover, under condition (13.5.73) *estimate*

$$\mathsf{R}^{\mathsf{MW}} \le \frac{C}{\mu h} + C\mu^{\frac{3}{2}}h^{-\frac{1}{2}} \tag{13.5.108}$$

holds and under condition

$$|\frac{V}{F} + (2j+1)\mu h| + |\nabla\frac{V}{F}| + |\det \mathsf{Hess}\, \frac{V}{F}| \ge \epsilon_0 \tag{13.5.109}$$

estimate $(13.5.89)_{(2)}$ *holds.*

(ii) For $\mu^3 h \ge C_0$ the following estimate holds:

$$\mathsf{R}^{\mathsf{MW}} \le \frac{C}{\mu h} + \frac{C'}{\mu h}\int_{\{\gamma\ge\sqrt{\mu h}\}} \big(\frac{\mu h}{\gamma^2}\big)^s \frac{dx}{\gamma^2} + \frac{C}{\mu h}\int_{\{\sqrt{\mu h}\ge\gamma\ge C_1\mu^{-1}, |v+(2j+1)\mu h|\le\epsilon\mu h\}} \frac{dx}{\gamma^2} + C\frac{\mu}{h}\int_{\{\gamma\le C_0\mu^{-1}\}} dx + C'. \tag{13.5.110}$$

Moreover, under condition (13.5.73) *estimate*

$$|\mathsf{R}^{\mathsf{MW}}| \le Ch^{-1} + C' \tag{13.5.111}$$

holds and under the condition

$$|\frac{V}{F} + (2j+1)\mu h| + |\nabla\frac{V}{F}| \le \epsilon_0 \implies \det \mathsf{Hess}\, \frac{V}{F} \ge \epsilon_0 \tag{13.5.109}_+$$

estimate $(13.5.89)_{(2)}$ *holds; furthermore, under condition* (13.5.109) *the estimates*

$$\mathsf{R}^{\mathsf{MW}} \le \frac{C}{\mu h}\big(1 + |\log\frac{\hat\tau}{\mu h}|\big) + C' \le \frac{C}{\mu h}(1+\log\mu^3 h) + C' \tag{13.5.112}$$

hold where $\hat\tau = (\min_x \gamma^2(x) + \mu^{-2})$.

Remark 13.5.27. (i) Theorem 13.4.30 yields that in the general case and under conditions (13.5.73) and (13.5.109) the corresponding estimates have a place even if condition (13.5.1) is violated.

(ii) We leave the case $\vartheta > 0$ to the reader: in this case even condition $(13.5.109)_+$ does not provide estimate $(13.5.89)_{(2)}$ for $\mathsf{R}^{\mathsf{MW}}_{(\vartheta)}$ for μ close to $h^{\frac{1}{3}}$.

Implementation: $d = 2$, II

In order to improve estimate (13.5.112) we need more sophisticated arguments which are applicable in other situations as well. So let us assume that $\mu^3 h \ge C_0$ and condition (13.5.109) holds but $(13.5.109)_+$ does not. Without any loss of the generality one can assume that $v = V/F$ has only one stationary point $\bar x$ in $B(0,1)$ (in which case this point is a saddle point) and that $\tau = 0$.

Let us replace $\mathcal{A}_j(x_1,\xi_1,\dots)$ in the argument of the Heaviside function by $(2j+1)\mu h + B(x,\xi,\dots)$. In our previous arguments we dropped $O(\mu^{-2})$ here;

let us now preserve this term but drop $O(\mu^{-4})$, $O(h^2)$ and $O(\mu^{-2}\gamma)$; equalities $(13.3.76)_{1,2}$ yield that this is equivalent to replacing B by $v\circ\bar\Psi_0+\bar\omega_1\mu^{-2}$ where $\bar\omega_1$ is the value of the coefficient ω_1 at $\bar x$,

$$\bar\omega_1=\bigl(\frac{1}{8}\kappa v^2-\frac{1}{4}\sum_{j,k}g^{jk}F^{-1}\partial_j\partial_k v\bigr)(\bar x). \tag{13.5.113}$$

Moreover, we skip all terms with $m+p+l\ge 1$ as before. If in the difference (between original and final expressions) we replace the sum with respect to j by the corresponding integral then the previous arguments yield that the error is $O\bigl(\mu^{-1}h^{-1}\mu h|\log(\hat\tau\mu^{-1}h^{-1})|\bigr)$ and therefore Theorem 13.5.16(ii) yields estimate

$$|\int \psi(x)\Bigl(e(x,x,-\infty,0)-h^{-2}\mathcal{N}^{\mathsf{MW}}(x,-\bar\rho\mu^{-2},\mu h)\Bigr)\,dx- h^{-2}G(\mu^{-2})|\le \frac{C}{\mu h}+C\mu h|\log\frac{\hat\tau}{\mu h}|+C' \tag{13.5.114}$$

with $\bar\rho=\bar\omega_1 F(\bar x)$; this estimate holds for $h^{-\delta}\le\mu\le h^{-1}$ and moreover, for $\mu\le h^{-\frac{1}{3}}$ this estimate holds without the second term in the right-hand expression.

However, we know that under condition (13.4.45) and for $\mu\le h^{\delta-\frac{1}{3}}$, $|\tau|\le\epsilon$

$$\int \psi(x)\Bigl(\mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)-\frac{1}{4}(\tau-V)\sqrt{g}\Bigr)\,dx=O(h^s)$$

and, moreover, we know that in this case Weyl asymptotics holds with remainder estimate $O(\mu^{-1}h^{-1})$ (see Theorem 13.4.30(iii)). Then comparing (13.5.114) and the Weyl asymptotics we deduce that the function $G(\zeta)-\mathsf{m}\zeta$ has at $\zeta=0$ a zero of arbitrarily high order with coefficient $\mathsf{m}=\frac{1}{4}\int\psi\sqrt{g}\,dx$. Therefore the following estimate holds:

$$\mathsf{R}_1^{\mathsf{MW}}:= |\int \psi(x)\Bigl(e(x,x,-\infty,0)-h^{-2}\mathcal{N}^{\mathsf{MW}}(x,-\bar\rho\mu^{-2},\mu h)-\bar\rho\sqrt{g}\mu^{-2}h^{-2}\Bigr)\,dx|\le \frac{C}{\mu h}+C\mu h|\log\frac{\hat\tau}{\mu h}|+C' \tag{13.5.115}$$

where $\bar\rho = \bar\omega_1 F(\bar x)$ and $\bar\omega_1$ is given by (13.5.113). This estimate is effective. Further, it is worse than corresponding estimate for $\mathsf{R}^{\mathsf{MW}}_\infty$ only if

$$(\mu h)^2 |\log \frac{\hat\tau}{\mu h}| \ge 1 \implies \mu \ge h^{-1} |\log h|^{-\frac12}$$

i.e. in the case of intermediate magnetic field; however, we will transform this estimate slightly.

Here subscript "1" in our notations indicates that only one perturbation term is present in the arguments of θ.

The same arguments with the Riemann sum replaced by an integral and with the same error estimate as in the proof of Theorem 13.5.22 yield that if $\psi_1 \in \mathscr{C}^K$ coincides with ψ for $|x-\bar x| \ge \frac12\gamma$, vanishes in $B(\bar x, \frac12\gamma)$ and satisfies the inequalities $|D^\alpha \psi_1| \le c\gamma^{-|\alpha|}$ and if $\gamma = \sqrt{\mu h}$, $\mu^3 h \ge 1$ then

$$\Big|\int \psi_1(x)\Big(\mathcal{N}^{\mathsf{MW}}(x, -\bar\rho\mu^{-2}, \mu h) - \mathcal{N}^{\mathsf{MW}}(x,0,\mu h) + \frac{1}{4\pi}\bar\rho\mu^{-2}\sqrt{g}\Big)\,dx\Big| \le C\mu^{-1}h + C'h^2.$$

Let us consider a similar expression for ψ_1 supported in $B(\bar x, \gamma)$, $\psi_1 = \psi$ in $B(\bar x, \frac12\gamma)$; it is easy to prove that in this case

$$\Big|\int \psi_1(x)\Big(\mathcal{N}^{\mathsf{MW}}(x, -\bar\rho\mu^{-2}, \mu h) - \mathcal{N}^{\mathsf{MW}}(x,0,\mu h) + \frac{1}{4\pi}\bar\rho\mu^{-2}\sqrt{g}\Big)\,dx - \sigma(\bar x)\mu^{-1}h\Big| \le C\mu^{-1}h + C'h^2$$

where

$$\sigma(\bar x) = \frac{\mu^2}{\pi}\big(f(\bar\tau') - f(\bar\tau)\big) F\sqrt{g}\,|\det \mathsf{Hess}\, v|^{-\frac12}\psi\big|_{x=\bar x}, \tag{13.5.116}$$

$$f(\tau) = \tau \log\big(\frac{|\tau|}{\mu h}\big), \tag{13.5.117}$$

$$\bar\tau = v(\bar x) + (2\bar\jmath + 1)\mu h, \quad \bar\tau' = \bar\tau + \bar\rho\mu^{-2}, \quad \bar\rho = \bar\omega_1 F(\bar x) \tag{13.5.118}$$

and for $j = \bar\jmath$ the quantity $|v(\bar x + (2j+1)\mu h|$ is minimal on $\mathbb{Z}^+$.

We leave this proof to the reader; let us note only that it is convenient to use the coordinate system in which $\bar x = 0$, $v = x_1x_2|\det \mathsf{Hess}\, v(\bar x)|^{-\frac12}$ in this proof.

Passing from the case with one critical point to general one we obtain the following

Theorem 13.5.28. *Let $d = 2$ and let conditions* (13.2.1)–(13.2.5), (13.3.1), (13.4.45) *and* (13.5.73) *be fulfilled.*

Then for $\mu^3 h \ge 1$ the following estimate holds:

$$\mathsf{R}^{\mathsf{MW}\prime} = \Big| \int \psi(x)\Big(e(x,x,-\infty,0) - h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0,\mu h)\Big)\,dx - \sum_{x_k\in\mathfrak{M}} \frac{1}{\mu h}\sigma(x_k)\Big| \le \frac{C}{\mu h} + C\mu h|\log\frac{\hat\tau}{\mu h}| + C' \tag{13.5.119}$$

where $\mathfrak{M}$ is the set of saddle points of $v = V/F$ and at every point $x_k \in \mathfrak{M}$, $\sigma(x_k)$ is given by formulae (13.5.116)–(13.5.118), (13.5.113) *with x_k instead of $\bar x$.*

Remark 13.5.29. (i) Here and in estimates (13.5.112) and (13.5.115) we can redefine $\hat\tau = \min_{x_k\in\mathfrak{M}} |\tau(x_k)| + \mu^{-2}$.

(ii) Similarly one can treat the case of $\vartheta \in [0,1]$. In this case we replace $\mathcal{A}_j$ by $\bar{\mathcal{A}}'_j = \mathcal{A}_j + O\big(\mu^{-4}\mu^{-2}\gamma^2\big)$ and note that by a shift one can get rid of the term which is linear with respect to x in $\bar{\mathcal{A}}'_j$ (which is $O(\mu^{-2}\gamma)$). One can easily prove the required estimate for $\mathsf{R}^{\mathsf{MW}}_{1(\vartheta)}$.

However, we have failed to derive an estimate for something similar to $\mathsf{R}^{\mathsf{MW}\prime}_{(\vartheta)}$ (with $\vartheta > 0$).

(iii) Moreover, the same approach works when condition (13.5.73) is fulfilled; the Morse theorem yields that without any loss of the generality one can assume that

$$v(x) = \bar v(x_1) \pm x_2^2. \tag{13.5.120}_{\pm}$$

We leave to the reader the detailed proofs of the following two statements (using the same arguments as we did before):

Theorem 13.5.30. *Under the assumptions of Theorem 13.5.28 estimate* (13.5.60) *holds for $\mathsf{R}^{\mathsf{MW}}_{1(\vartheta)}$ with $\vartheta \in [0,1]$.*

Theorem 13.5.31. *Let $d = 2$, $\vartheta = 0$ and let conditions* (13.2.1)–(13.2.5), (13.3.1) *and* $(13.5.120)_{\pm}$ *be fulfilled. Then*

(i) For $h^{-\frac15} \le \mu \le h^{-\frac13}$ the following estimate holds:

$$\mathsf{R}_1^{\mathsf{MW}} \le C\mu^{-1}h^{-1} + C' \tag{13.5.121}$$

where $\mathsf{R}_1^{\mathsf{MW}}$ is given by (13.5.114)*, ω_1 is given by* (13.5.113) *and in this theorem the bar means that the corresponding function is calculated at $x_2 = 0$.*

(ii) For $\mu \ge h^{-\frac13}$ the following estimate holds:

$$\mathsf{R}_1^{\mathsf{MW}} \le C\mu^{-1}h^{-1} + C\mu^{\frac12}h^{-\frac12} + C' \tag{13.5.122}$$

and moreover the following estimate holds as well:

$$\mathsf{R}_1^{\mathsf{MW}} \le \frac{C}{\mu h} + C\int_{\{\sqrt{\mu^{-1}h}\le\gamma_1\le\sqrt{\mu h}\}} \frac{dx_1}{\gamma_1} + C\mu^{\frac12}h^{-\frac12}\int_{\{\gamma_1\le\sqrt{\mu^{-1}h}\}} dx_1 + C' \tag{13.5.123}$$

where

$$\gamma_1 = \gamma_1(x_1) = \min_{j\in\mathbb{Z}^+}\bigl(|\partial_1\bar{w}|^2 + |\bar{w} + (2j+1)\mu h|\bigr)^{\frac12}$$

and $\bar{w} = \bar{v} + \mu^{-2}\bar{\omega}_1$.

Implementation: $d = 2$, III

Let us now treat the case $d = 2$ and $\nu < 1$. In this case the optimal estimate (13.5.60) for R^{T} and $\mathsf{R}_\infty^{\mathsf{MW}}$ is better than in the case $\nu = 1$ but the transition to estimates for R^{MW} and similar effective estimates can make it essentially worse.

In this case it is important whether $\nu \ge \mu h$ or $\nu \le \mu h$; in the second case the transition from summation to integration is completely useless in the analysis of the term with $m = p = l = 0$ but in this case the replacement of $\mathcal{A}_j$ by $\bar{\mathcal{A}}_J$ changes only terms with less than C_0 numbers j. Taking into account this observation we prove the following two theorems (the second theorem improves the first one):

Theorem 13.5.32. *Let $d = 2$, $\vartheta = 0$ and let conditions* (13.2.1)–(13.2.5)*,* (13.3.1)*,* $(13.3.77)_{1-3}$*,* $(13.4.12)_{1,2}$*,* (13.3.58)*,* (13.5.1)*,* (13.4.45) *and*

$$|\nabla\frac{V}{F}| \ge \epsilon_0\nu \ge C_0\bar{\nu}\mu^{-2} + Ch^{1-\delta} \tag{13.5.124}$$

be fulfilled. Then

(i) For $\nu \ge \mu h$ the following estimate holds:

$$\mathsf{R}^{\mathsf{MW}} \le C\frac{\nu}{\mu h} + C'\bar\nu\nu^{-2}\big(\frac{\mu h}{\nu}\big)^s + C' \qquad \forall \tau : |\tau| \le \epsilon\nu \tag{13.5.125}$$

with arbitrary s and with $\epsilon = \epsilon(c, \epsilon_0) > 0$.

(ii) For $\nu \le \mu h$ the following estimate holds:

$$\mathsf{R}^{\mathsf{MW}} \le C\frac{\bar\nu}{\mu h\nu} + C' \qquad \forall \tau : |\tau| \le \epsilon\nu \tag{13.5.126}$$

with $\epsilon = \epsilon(c, \epsilon_0) > 0$.

Theorem 13.5.33. *Let $d = 2$, $\vartheta = 0$ and let conditions* (13.2.1)–(13.2.5), (13.3.1), $(13.3.77)_{1-3}$, (13.5.1) *and* (13.4.45) *be fulfilled. Let us assume that*

$$|D^\alpha\big(\frac{V}{F} + \omega_1\mu^{-2}\big)| \le c\nu \qquad \textit{in} \quad B(0,1) \quad \forall \alpha : 1 \le |\alpha| \le K, \tag{13.5.127}$$

with

$$\nu \ge C_0\bar\nu(\mu^{-4} + h^2), \tag{13.5.128}$$

and

$$\min_j |\frac{V}{F} + (2j+1)\mu h + \omega_1\mu^{-2}| + |\nabla\big(\frac{V}{F}v + \omega_1\mu^{-2}\big)| \ge \epsilon_0\nu \qquad \textit{in} \quad B(0,1) \tag{13.5.129}$$

where

$$\omega_1 = \frac{1}{8}\kappa v^2 - \frac{1}{4}v\mathcal{L}v - \sum_{j,k}\frac{1}{4}g^{jk}\partial_j v\cdot\partial_k v, \qquad v = \frac{V}{F}, \tag{13.5.130}$$

and

$$\mathcal{L}v = \frac{1}{F\sqrt{g}}\sum_{j,k}\partial_j(g^{jk}\sqrt{g}\partial_k v), \tag{13.5.131}$$

(i.e., $\mathcal{L}$ is the Laplace-Beltrami operator in the metric $F^{-1}g^{jk}$). Then

(i) For $\mu h \le \nu$ and $\tau = 0$ the following estimate holds

$$\mathsf{R}_1^{\mathsf{MW}} := |\int\Big(\psi(x)e(x,x,-\infty,\tau) - h^{-2}\mathcal{N}_\psi^{\mathsf{MW}\prime}(x,\mu h,\mu^{-2})\Big)\,dx| \le C\frac{\nu}{\mu h} + C'\bar\nu\mu^{-2}\nu^{-2}(\frac{\mu h}{\nu})^s + C' \tag{13.5.132}$$

where

$$\mathcal{N}_{\psi}^{\mathsf{MW}\prime} = \frac{1}{2\pi}\Big(\sum_{j\in\mathbb{Z}^+} \theta\big(-v-(2j+1)\mu h-\omega_1\mu^{-2}\big)(\psi+\psi'\mu^{-2})\mu h + \frac{1}{4}\mu^{-2}(\omega_1\psi+v\psi') + \frac{1}{4}\mu^{-4}\omega_1\psi'\Big)F\sqrt{g}, \tag{13.5.133}$$

$$\psi' = -\frac{1}{4}v\mathcal{L}\psi - \frac{1}{2}\sum_{j,k} vg^{jk}F^{-2}\partial_j F\cdot\partial_k\psi. \tag{13.5.134}$$

(ii) For $\mu h \ge \nu$ and $\tau = 0$ the following estimate holds:

$$\mathsf{R}_1^{\mathsf{MW}} \le C'\big(1+\bar\nu\mu^{-3}h^{-1}\nu^{-1}+\bar\nu\mu h\nu^{-1}\big). \tag{13.5.135}$$

Proof. We will prove Theorem 13.5.33; the proof of Theorem 13.5.32 is similar but simpler.

In the argument of the Heaviside function in the terms with $m+p\le 1$, $l=0$ let us skip terms which are $O(\mu^{-4}\bar\nu)$, $O(h^2\bar\nu)$ and $O(\mu^{-1}h\nu)$; then repeating the previous arguments we obtain that modulo a term with an absolute value not exceeding the right-hand expression of estimate (13.5.132) for $\mu h\le\nu$ (or the right-hand expression of estimate (13.5.135) for $\mu h\ge\nu$) the correction is of the form $h^{-2}G_0(\mu^{-2})+\mu^{-1}h^{-1}G_1(\mu^{-2})$.

The same arguments give the same answer if we drop all terms with $m+p+2l\ge 2$. Let us treat terms with $m+p=1$, $l=0$; they are of the form

$$\frac{1}{2\pi h^2}\int\sum_j \theta\big(-v-(2j+1)\mu h-\omega_1\mu^{-2}\big)\times \big(\psi'+(v+(2j+1)\mu h+\omega_1\mu^{-2})\psi''\big)\mu^{-2}F\sqrt{g}\,dx.$$

Here we have replaced the integration with respect to (x_1,ξ_1) with the integration with respect to x by means of the symplectomorphism $\bar\Psi_0$. Then similar arguments show that if we skip terms which are $O(\nu)$ in ψ' and if we skip ψ'' completely then the correction has the same form with the same error estimate; in the second case we used the fact that the function $f(z)$ (which is integrated with respect to z) satisfies the estimate

$$|D_z^k f|\le C\nu^{1-k}\qquad \forall k\le K'$$

on the "bad" interval of length $C_0\nu$ (if $\nu \ge \mu h$); moreover, on the "bad" interval of length $C_0\mu h$ the estimate $|f| \le C\nu$ holds for $\nu \le \mu h$. Thus the expression

$$\mathsf{R}_1^{\mathsf{MW}\prime} := \Big| \int \psi(x)\Big(e(x,x,-\infty,0) - \frac{1}{2\pi h^2}\sum_{j\in\mathbb{Z}^+} \theta\big(-v-(2j+1)\mu h - \omega_1\mu^{-2}\big)(\psi+\psi'\mu^{-2})\mu h\Big)\,dx - h^{-2}G_0(\mu^{-2}) - \mu^{-1}h^{-1}G_1(\mu^{-2})\Big|$$

does not exceed the right-hand expression of (13.5.132) or (13.5.135) for $\mu h \ge \nu$ and $\mu h \le \nu$ respectively.

Furthermore, the same estimate remains true if we replace $\tau = 0$ by $\tau \in [-\epsilon\nu, \epsilon\nu]$ (with a small constant $\epsilon > 0$) and if we simultaneously replace V by $(V-\tau)$ in the argument of the Heaviside function and in the definition of ω_1 and ψ'; moreover, in this case the functions G_0 and G_1 depend smoothly on τ.

Finally, if we have mollified (inside the absolute value) with respect to τ with a small constant $L > 0$ and with ϕ supported in $[-1,1]$ we would obtain the remainder estimate C'.

But then Proposition 13.4.20 and formula (13.4.69) yield that for $1 \le \mu \le h^{\delta-1}$ the same estimate (with mollification) remains true with

$$\bar{G}_0(\zeta) = \frac{1}{4}\zeta(\omega_1 + v\psi') + \frac{1}{4}\zeta^2\omega_1\psi', \quad \bar{G}_1(\zeta) = 0 \tag{13.5.136}$$

instead of G_0 and G_1 respectively; here $\tau \in [-\epsilon, \epsilon]$ enters into the definition of these functions through v, ω_1 and ψ'.

Comparing these two estimates for $h^{-\delta} \le \mu \le h^{\delta-1}$ we conclude that the functions $\big(G_0 - \bar{G}_0\big)$ and G_1 have zeros of arbitrarily high order at $\zeta = 0$, $\tau \in [-\epsilon, \epsilon]$; we first make this conclusion for functions mollified with respect to τ and then we use the arbitrary choice of mollifying function and the smoothness of the functions G_0, $\bar{G}_0$, G_1 (see proof of Theorem 13.5.22).

But then we can replace G_0 and G_1 by $\bar{G}_0$ and $\bar{G}_1 = 0$ in the definition of $\mathsf{R}_1^{\mathsf{MW}\prime}$ (without mollification); so the theorem is almost proven: we only need to calculate ω_1 and ψ'.

In order to calculate ω_1 and ψ' let us note that in the conformal coordinate system for $F = 1$ and for the method of reduction used in Proposi-

tion 13.3.1(iii)

$$\omega_1 = \frac{1}{8}\kappa v^2 - \frac{1}{4}v\rho^2\Delta v - \frac{1}{4}\rho^2(\nabla v)^2,$$

i.e., ω_1 is given by (13.5.130); moreover, in this case

$$\psi' \equiv -\frac{1}{4}v\rho^2\Delta\psi \qquad \mathsf{mod}\ |\nabla v|,$$

i.e., ψ' is given by (13.5.134).

Furthermore, let us note that in the transition from $F = 1$ to arbitrary F (see the procedure used in Theorem 13.3.6) the arguments in the Heaviside functions do not change and the trace of the matrix of quadratic form

$$(S_1 w_1 + S_2 w_2)\big\{(\{\psi, w_2\}w_1 - \{\psi, w_1\}w_2), w_1^2 + w_2^2\big\} \qquad \mathsf{mod}\ O(\nu)$$

is added to ψ'; here S_1 and S_2 are chosen from the equation

$$F\{S_1 w_1 + S_2 w_2, w_1^2 + w_2^2\} + \{F, w_2\}w_1 - \{F, w_1\}w_2 = 0 \qquad \text{at } \Lambda.$$

Then explicit calculation gives that this quantity is equal to $-\frac{1}{2}v\rho^2\nabla F \cdot \nabla\psi$ and therefore ψ' is again given by (13.5.134).

Since formulae (13.5.130) and (13.5.134) are invariant with respect to coordinate transformations we conclude that ω_1 and ψ' are given by these formulas in an arbitrary coordinate system. □

Remark 13.5.34. (i) In a method of reduction different from the method used in Proposition 13.3.1(iii) and Theorem 13.3.6 the term $O(\nu)$ is added to ω_1 and the term $O(1)$ is added to ψ'.

We have not managed to work with these additional terms and to preserve estimate (13.5.132) (or (13.5.135)); namely in this estimate the term $C'\nu^{-1}(\mu h\nu^{-1})^s$ (or $C'\mu^{-1}h^{-1}$ respectively) should be added to the right-hand expression.

(ii) On the other hand, item $O(\nu^2)$ in ω_1 could be skipped; therefore term $-\frac{1}{4}\sum_{j,k} g^{jk}\partial_j v \cdot \partial_k v$ could also be skipped.

Problem 13.5.35. Investigate the case when

$$|\nabla(v + \omega_1\mu^{-2})| + \min_j |(2j+1)\mu h + v + \omega_1\mu^{-2}| \le \epsilon_0\nu \implies \det \mathsf{Hess}(v + \omega_1\mu^{-2}) \ge \epsilon_0\nu^2 \qquad \text{in } B(0,1) \tag{13.5.137}$$

or when this condition is fulfilled for the absolute value of the Hessian determinant.

Let us formulate without proof only a simpler statement:

Theorem 13.5.36. *Let $d = 2$, $\vartheta = 0$ and let conditions* (13.2.1)–(13.2.5), (13.3.1), $(13.3.77)_{1-3}$, (13.5.1), $(13.4.12)_{1,2}$, (13.5.47) *and* (13.4.45) *be fulfilled.*

Let us assume that

$$|\frac{V}{F} + (2j+1)\mu h| + |\nabla \frac{V}{F}| \le \epsilon_0 \nu \implies |\det \mathsf{Hess}\, \frac{V}{F}| \ge \epsilon_0 \nu^2 \tag{13.5.138}$$

Then

(i) For $\nu \ge \mu h$, $\bar\nu \ge \mu^3 h$ the following estimate holds:

$$|\mathsf{R}^{\mathsf{MW}}| \le C\big(\frac{\nu}{\mu h} + \frac{\bar\nu \mu^2}{\nu}\big) + C'. \tag{13.5.139}$$

(ii) For $\nu \ge \mu h$, $\bar\nu \le \mu^3 h$ the following estimate holds:

$$|\mathsf{R}^{\mathsf{MW}}| \le C' \frac{\bar\nu}{\mu h \nu}\big(1 + \log \frac{\mu^3 h}{\bar\nu}\big) + C'. \tag{13.5.140}$$

Moreover, under condition $(13.5.135)_+$ *estimate* (13.5.126) *remains true in this case.*

(iii) For $\nu \le \mu h$ (and then $\bar\nu \le \mu^3 h$ automatically) the following estimate holds:

$$|\mathsf{R}^{\mathsf{MW}}| \le C \frac{\bar\nu}{\mu h \nu}\big(1 + \log \frac{\nu \mu^2}{\bar\nu} + 1\big) + C'. \tag{13.5.141}$$

Moreover, under condition $(13.5.74)_+$ *estimate* (13.5.126) *holds.*

13.6 Strong Magnetic Field

In this section we consider the case of *strong magnetic field*

$$\mu \ge \epsilon h^{-1} \tag{13.6.1}$$

covering also the case of *intermediate magnetic field*

$$\epsilon h^{-1} \le \mu \le C h^{-1} \tag{13.6.2}$$

and strong magnetic field proper $\mu \ge Ch^{-1}$. In the latter case to avoid trivial results as the lower Landau level becomes $\asymp \mu h$ we either consider *Magnetic Schrödinger-Pauli operator*

$$A = \sum_{j,k} P_j g^{jk} P_k + V - \mu h F, \qquad \text{with } P_j = hD_j - \mu V_j \tag{13.6.3}$$

where F is a scalar intensity of magnetic field[32] thus subtracting μhF from V or subtract $\mu h\mathfrak{z}F$ from V (alternatively setting $\tau = \mu h\mathfrak{z}F$ rather than $\tau = 0$ if $F = \mathsf{const}$). Here and below with $\mathfrak{z} = \mathsf{const}$.

In all these cases we can divide by μh thus reducing everything to the case $\mu h \asymp 1$ but $\nu \le 1$.

The behavior is very different for $d = 2$ and $d = 3$: as $d = 2$ we get spectral gaps; this also happens in the case $\nu \le \mu h$ even as $\mu h \le 1$; so basically we can say even in this case that magnetic field is strong.

We will prove that as $d = 2$, $\mu h \ge 1$ and $\tau \le c\mu h$ then the main part of asymptotics is $\asymp \mu h^{-1}$ and the remainder estimate could be as good as $O(\mu^{-s})$ (with arbitrarily large exponent s) as τ belongs to the spectral gap and $O(1)$ otherwise.

For $d = 3$ we get no new spectral gaps in addition to one from $-\infty$ to $\mathsf{inf}(V + \mu hF)$ but it may happen that one-dimensional Schrödinger operator will have effective potential $V_* \asymp \nu \le 1$ or, in other words, it will have semiclassical parameter $h_* = h\nu^{-\frac{1}{2}}$ instead of h.

We will prove that as $d = 3$, $\mu h \ge 1$ and $\tau \le c$ then for Magnetic Schrödinger-Pauli operator (13.6.3) the main part of asymptotics is $\asymp \mu h^{-2}$ and the remainder estimate could be as good as $O(\mu^{-s})$ (with arbitrarily large exponent s) as τ belongs to the (lower) spectral gap and $O(\mu h^{-1})$ otherwise.

In what follows we discuss also alternative forms of our main results.

13.6.1 Existence of Spectral Gaps

First of all, using by the standard elliptic methods (for the reduced operator) one can prove easily the following two propositions:

---

[32] We consider genuine Magnetic Schrödinger-Pauli operator in Chapter 17; now we consider just "half" of it.

Proposition 13.6.1. *Let $d = 2$ and let conditions* (13.2.1)–(13.2.5), (13.3.1), $(13.3.77)_{1-3}$,

$$\mu \ge h^{-\delta} \tag{13.6.4}$$

and $(13.4.12)_1$ *be fulfilled.*

Moreover, let us assume that for some $j \in \mathbb{Z}^+$ and $\varsigma = \pm 1$

$$\varsigma\big((2j+1)\mu h + B(x_1, \xi_1, \mu^{-2}, \mu^{-1}h, h^2)\big) \ge \zeta^2 \ge C_0\bar{\nu}\mu^{-2}h^2 \qquad \forall (x_1, \xi_1) \in \Omega. \tag{13.6.5}$$

(i) Then

$$|F_{t\to h^{-1}\tau}\chi_T(t)Q_x\mathsf{U}_{jk}| \le C'T\mu h^{-1}\big(\frac{\mu^{-1}h\sqrt{\bar{\nu}}}{\zeta}\big)^s(1+|\tau|)^{-s} \qquad \forall x, y, \in \mathbb{R}^d \quad \forall T \ge h\zeta^{-2} \quad \forall \tau : \varsigma\tau \le \epsilon\zeta^2. \tag{13.6.6}$$

(ii) In particular, if condition (13.6.5) *holds for $j = 0$ and $\varsigma = 1$ (in which case it holds for $\varsigma = 1$ for all $j \in \mathbb{Z}^+$) then*

$$|F_{t\to h^{-1}\tau}\chi_T(t)U| \le C'T\mu h^{-1}\big(\frac{\mu^{-1}h\sqrt{\bar{\nu}}}{\zeta}\big)^s(1+|\tau|)^{-s} \qquad \forall x, y, \in B(0, \frac{1}{2}) \quad \forall T \ge h\zeta^{-2} \ge h \quad \forall \tau : \varsigma\tau \le \epsilon\zeta^2. \tag{13.6.7}$$

Proposition 13.6.2. *Let $d = 3$ and let conditions* (13.2.1)–(13.2.5), (13.3.1), $(13.3.77)_{1-3}$, (13.6.4) *and* $(13.4.12)_1$ *be fulfilled.*

Moreover, let us assume that

$$\mathcal{B}_0(x', \xi_1, \mu^{-2}, \mu^{-1}h, h^2) \ge \zeta^2 \ge C_0\bar{\nu}\mu^{-2}h^2 \qquad \forall (x', \xi_1) \in \Omega. \tag{13.6.8}$$

Then

$$|F_{t\to h^{-1}\tau}\chi_T(t)U| \le C'T\mu h^{-2}\big(\frac{\mu^{-1}h\sqrt{\bar{\nu}}}{\zeta}\big)^s \qquad \forall x, y, \in B(0, \frac{1}{2}) \quad \forall T \ge h\zeta^{-2} \quad \forall \tau : \tau \le \epsilon\zeta^2. \tag{13.6.9}$$

Proof. In Proposition 13.6.2 taking in account that hD_2 enters into equation in a very special way making ellipticity "stronger" we conclude that effective semiclassical parameter is still $\mu^{-1}h$. □

By the standard Tauberian methods, Propositions 13.6.1 and 13.6.2 imply the following two statements:

Proposition 13.6.3. *Let* $d = 2$ *and let conditions* (13.2.1)–(13.2.5), (13.3.1), $(13.3.77)_{1-3}$, (13.6.1), $(13.4.12)_1$ *and* (13.6.5) *be fulfilled. Then as* $\zeta \ge \mu^{-1}h^{1-\delta}$

(i) For $j = k$ *the following estimate holds:*

$$|\mathsf{e}_{Q,jk}(\tau_2) - \mathsf{e}_{Q,jk}(\tau_1)| \le C'\mu h^s \big(1 + \min(|\tau_1|, |\tau_2|)\big)^{-s} \qquad \forall \tau_1, \tau_2 : \varsigma\tau_1 \le \epsilon\zeta^2, \varsigma\tau_2 \le \epsilon\zeta^2 \quad \forall x_1, y_1 \in \mathbb{R} \tag{13.6.10}$$

where

$$\mathsf{e}_{Q,jk}(x_1, y_1, \tau) \coloneqq \iint Q_x \mathcal{F}^*_x e(x, y, -\infty, \tau)\, {}^t\mathcal{F}^*_y \Upsilon_j(x_2)\Upsilon_k(y_2)\, dx_2 dy_2 \tag{13.6.11}$$

and the functions Υ_j *are introduced by* (13.5.3).

(ii) Therefore estimate (13.6.10) *holds for* $j \ne k$ *as well.*

(iii) Therefore making a γ*-admissible partition of unity in* Ω *with* $\gamma = \mu^{-\frac{1}{2}} h^{\frac{1}{2}-\delta}$ *and applying a similar theorem with* x *and* y *permuted we obtain that estimate* (13.6.10) *holds for* $j \ne k$ *even if condition* (13.6.5) *is violated but* $\mu^{\frac{3}{2}} h^{\frac{1}{2}+\delta} \ge \bar{\nu}$.

In particular, this estimate holds for $\mu \ge h^{-\frac{1}{3}-\delta}$.

(iv) Therefore if condition (13.6.5) *with* $\varsigma = 1$ *is fulfilled then*

$$|\mathsf{e}_{Q,jk}(x_1, y_1, \tau)| \le C''\mu h^s (1 + |\tau|)^{-s} \quad \forall \tau \le \epsilon\zeta^2 \quad \forall x_1, y_1 \in \mathbb{R} \quad \forall k. \tag{13.6.12}$$

(v) On the other hand, if condition (13.6.5) *with* $\varsigma = -1$ *is fulfilled then estimate*

$$|\mathsf{e}_{Q,jk}(x_1, y_1, 0) - \int \phi(\tau)\, d_\tau \mathsf{e}_{Q,jk}(\tau)| \le C'\mu h^s \qquad \forall x_1, y_1 \in \mathbb{R} \quad \forall k \tag{13.6.13}$$

holds where ϕ is an arbitrary fixed function, equal to 0 for $\tau \le 0$ and equal to 1 for $\tau \ge 2c$.

(vi) Therefore if

$$|(2j+1)\mu h + B(x_1, \xi_1, \mu^{-2}, \mu^{-1}h, h^2)| \ge \zeta^2 \ge \bar{\nu}\mu^{-2}h^{2-\delta} \quad \forall (x_1, \xi_1) \in \Omega \quad \forall j \in \mathbb{Z}^+ \tag{13.6.14}$$

then estimate

$$|\int \psi(x)\Big(e(x,x,-\infty,0) - \int_{-\infty}^{\infty} h^{-1}\phi(\tau)\big(F_{t\to h^{-1}\tau}\chi_T(t)U^J(x,y,t)\big)\,d\tau\Big)\,dx| \le C'\mu h^s \tag{13.6.15}$$

holds for $T \in [h^{1-\delta}, 1]$ where

$$U^J = \mathcal{F}_x \sum_{j,k \le J-1} \mathsf{U}_{jk}(x_1, y_1, t)\Upsilon_j(x_2)\Upsilon_k(y_2)\,{}^t\mathcal{F}_y \tag{13.6.16}$$

with

$$J = \max\{j \in \mathbb{Z}^+ : (2j-1)\mu h + B < 0 \qquad \forall (x_1, \xi_1)\}. \tag{13.6.17}$$

In particular, $J = 0$ if and only if condition (13.6.5) *with $\varsigma = 1$ and $j = 0$ is fulfilled.*

(vii) Therefore if (13.6.5) *holds with $\varsigma = 1$, $j = 0$ and $\zeta \ge C\mu^{-1}h^{1-\delta}$ then*

$$|e(x,y,-\infty,\tau)| \le C'\mu h^s(1+|\tau|)^{-s} \quad \forall x, y \in B(0, \frac{1}{2}) \quad \forall \tau \le \epsilon\zeta^2. \tag{13.6.18}$$

Proposition 13.6.4. *In the framework of Proposition 13.6.2 (i.e. $d = 3$) with $\zeta \ge \mu^{-1}h^{1-\delta}$ estimate* (13.6.18) *holds.*

Remark 13.6.5. (i) One can prove that Statement (iii) of Proposition 13.6.3 remains true for $d = 3$ as well provided $\zeta \ge h^{1-\delta}$.

(ii) The construction of Section 13.3 yields that the conditions of Proposition 13.6.2 are fulfilled provided $d = 3$ and

$$V + \mu hF \ge \zeta^2 \ge C_0(\mu^{-1}h + h^2) \qquad \text{in} \quad B(0,1). \tag{13.6.19}$$

In this way one can prove that the assertion of Proposition 13.6.3(ii) remains true provided

$$V + \mu hF \ge \zeta^2 \ge C_0 h^2. \tag{13.6.20}$$

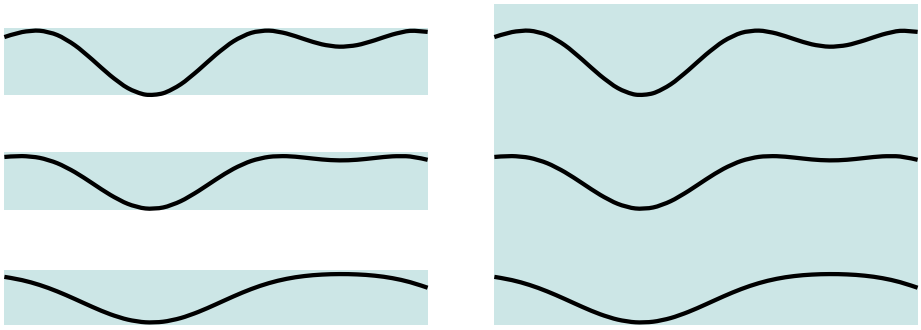
Moreover, one can weaken this condition. However, we will use another method which is simpler (see Remark 13.6.10refrem-13-5-10-ii below).

(iii) Moreover, the same construction yields that if $d = 2$ and conditions $(13.3.77)_{1-3}$, $(13.4.12)_1$ are fulfilled then conditions of Proposition 13.6.3(i) are fulfilled provided

$$V+\mu hF+\frac{1}{4}\sum_{j,k} g^{jk}\partial_j\partial_k\big(\frac{V}{F}\big)\mu^{-1}h \ge \zeta^2 \ge C_0\bar{\nu}h^2 \qquad \forall x \in B(0,1). \tag{13.6.21}$$

(iv) As $\zeta \ge C\mu^{\delta-1}h$ [33)] one can replace in all the estimates above and below h^s by μ^{-s}.

In particular, it is always the case in Proposition 13.6.3(ii) and (iii).



(a) 2D (b) 3D

Figure 13.4: Landau levels (depending on x), spectral bands (filled) and spectral gaps (white); there also is a spectral gap $(-\infty, \min_x(V + \mu hF))$

[33)] Which is different from $\zeta \ge C\mu^{-1}h^{1-\delta}$ in the case of $\mu \gg h^{-s}$ for any s.

13.6.2 Calculations in Spectral Gaps as $d = 2$

Let us pass from the analysis of the lower ("under-bottom") spectral gap to the other gaps. So, let $d = 2$ and let us assume that conditions (13.5.1) and (13.6.14) are fulfilled and $J \ge 1$. In this case Proposition 13.5.2(ii) yields that in decomposition (13.6.16) all the terms with $j \ne k$ are negligible.

Thus, repeating the decomposition of Section 13.5 in a very rough form one can replace estimate (13.5.71) by

$$\Big|\int e(x,x,-\infty,0)\psi(x)\,dx- \int \phi(\tau)\sum_{j<J}\sum_{m,p,l,n\le N}\mu^{1-2(m+p)-l}h^{l-1}\big((2j+1)\mu h\big)^m\Theta^{(n)}_{j,mpln}(\tau)\,d\tau\Big| \le C'h^s$$

provided $\phi \in \mathscr{C}_0^\infty(\mathbb{R}^+)$ and $\int_0^\infty \phi d\tau = 1$.

Recall that the functions $\Theta_{\dots}$ are given by (13.5.44). Let us note that in this decomposition one can replace $\theta(\dots)$ by 1 in which case all terms with $n \ge 1$ disappear and we obtain

$$\Big|\int e(x,x,-\infty,0)\psi(x)\,dx- \sum_{j<J}\sum_{m,p,l,\le N}\mu^{1-2(m+p)-l}h^{l-1}\big((2j+1)\mu h\big)^m\int f_{mpl}\,dx_1 d\xi_1\Big| \le C'h^s.$$

Further, let us note that in this case the only source of terms with $l+m+p \ge 1$ is the transformation of ψ: we introduce the $\mu^{-1}h$-pseudodifferential operator $\mathcal{F}^*\psi\mathcal{F} = q(x,\mu^{-1}hD,\mu^{-2},\mu^{-1}h)$ which we then decompose in powers of x_2, $\mu^{-1}hD_2$ and μ^{-2}, $\mu^{-1}h$.

Therefore, f_{mpl} with $m+p+l \ge 1$ are linear combinations of $D^\alpha\psi\circ\bar\Psi$ with $1 \le |\alpha| \le \frac12(p+l)+m$ and only terms with $p+l \in 2\mathbb{Z}^+$ arise.

Therefore we obtain the following estimate

$$\Big|\int \Big(e(x,x,-\infty,0)\psi(x)- (2\pi)^{-1}\sum_{k+m+p\le N} J^{k+1}\mu^{1-2m-k-p}h^{k+p-1}(\mathcal{L}_{kmp}\psi)F\sqrt{g}\Big)\,dx\Big| \le C'h^s \tag{13.6.22}$$

where $N = N(s,\delta)$, J is defined by (13.6.17), $\mathcal{L}_{kmp}$ are $2(k+m+p)$-th order linear partial differential operators with the coefficients depending

on $D^\alpha g_{..}$, $D^\alpha F$, $D^\alpha V$ with $|\alpha| \le 2(k+m+p)$ and $\mathcal{L}_{000} = I$, $\mathcal{L}_{kmp}1 = 0$ for $k+m+p > 0$. In this deduction we have also used Proposition 13.5.4 and formula (13.3.13). Moreover, Proposition 13.5.4(v) yields that

$$|\mathcal{L}_{kmp}(F\sqrt{g})| \le C'\bar{\nu} \qquad \forall k, m, p : 1 \le k+m+p \le K. \tag{13.6.23}$$

Therefore we have proven

Theorem 13.6.6. *Let $d = 2$. Let us assume that conditions* (13.2.1)–(13.2.5), $(13.3.77)_{1-3}$, $(13.4.12)_1$, (13.5.1) *and* (13.6.14) *are fulfilled.*

Then estimates (13.6.22) *and*

$$|e(x, y, \tau_1, \tau_2)| \le C'h^s \qquad \forall x, y \in B(0, \frac{1}{2}) \quad \forall \tau_1, \tau_2 \in [-\epsilon\zeta^2, \epsilon\zeta^2] \tag{13.6.24}$$

hold.

Theorem 13.6.7. *Let $d = 2$. Let us assume that conditions* (13.2.1)–(13.2.5), $(13.3.77)_{1-3}$, $(13.4.12)_1$, (13.5.1) *are fulfilled.*

Furthermore, let

$$|\frac{V}{F} + (2j+1)\mu h| \ge \zeta^2 \ge C_0\mu^{-2}\bar{\nu} \qquad \forall x \in B(0,1). \tag{13.6.25}$$

Then estimates (13.6.22) *and* (13.6.24) *hold with*

$$J = \max\{j \in \mathbb{Z}^+ : V + (2j-1)\mu hF \le 0 \quad \forall x \in B(0,1)\} \tag{13.6.26}$$

and $J = 0$ if the right-hand set is empty.

Remark 13.6.8. Under condition (13.6.25) one can apply the method of successive approximations to the operator which is reduced to canonical form modulo $O(\nu(|x_2| + |\xi_2|) + \mu^{-1}h)$ provided

$$\zeta^2 \ge \nu\mu^{-1}h^{-\delta'} \tag{13.6.27}$$

with arbitrarily small δ'. Then one can take $\mathcal{F}$ and q which do not depend on μ^{-2} explicitly. Then calculations easily show that all the terms with $m \ge 1$ vanish in (13.6.22).

We leave the details to the reader (see also the proof of Proposition 17.6.9 below. However, one can easily see that condition (13.6.25) with $j \ge 1$ yields condition (13.4.85) with $\nu = (\mu h)^{1-\delta'}$ with arbitrarily small $\delta' > 0$, and this ν fulfils the above inequality.

Let us note that if $|D^\alpha f| \le c\bar\nu \quad \forall \alpha : |\alpha| \le 2$ and $f \ge \zeta^2$ in $B(0,1)$ then $|\nabla f| \le c_1(\bar\nu f)^{\frac12}$ and

$$f + t\sum_k m^k \partial_k f \ge \zeta^2(1-\epsilon) - C_2 t^2 \bar\nu$$

where $C_2 = C_2(c,\epsilon)$, $\epsilon > 0$ is arbitrary and we assume that $|\boldsymbol{m}| \le c$, $\boldsymbol{m} = (m^1, m^2)$; therefore the term $\sum_k m^k \partial_k (\frac{V}{F}) \circ \bar\Psi_0$ in the expression for ω_1 is not essential and therefore Theorem 13.6.6 yields the following theorem

Theorem 13.6.9. *Let $d = 2$ and suppose conditions* (13.2.1)–(13.2.5), $(13.3.77)_{1-3}$, $(13.4.12)_1$ *and* (13.5.1) *are fulfilled.*

Furthermore, let

$$|\frac{V}{F} + (2j+1)\mu h + \mu^{-2}\omega_1| \ge \zeta^2 \ge C_0\bar\nu(\mu^{-4} + h^2) \qquad \forall x \in B(0,1) \quad \forall j \in \mathbb{Z}^+ \tag{13.6.28}$$

where now

$$\omega_1 = \frac18 \kappa v^2 - \frac14 v\mathcal{L}v, \qquad v = \frac{V}{F}; \tag{13.6.29}$$

let us recall that κ and $\mathcal{L}$ are the scalar curvature and the Laplace-Beltrami operator in the metric $\frac{1}{F} g^{jk}$.

Then estimates (13.6.22) *and* (13.6.24) *hold with*

$$J = \max\{j \in \mathbb{Z}^+ : v + (2j-1)\mu h + \mu^{-2}\omega_1 \le 0 \quad \forall x \in B(0,1)\} \tag{13.6.30}$$

and $J = 0$ if the right-hand set is empty.

13.6.3 Final Remarks as $d = 2$

Let us make a few final remarks for $d = 2$.

Remark 13.6.10. (i) If there is a spectral gap described by (13.6.28) with $J \ge 1$ and $\bar\nu \ge \mu h$ then the following inequality holds:

$$|D^\alpha v| \le C\bar\nu\mu^{-2} + C'\bar\nu\big(\frac{\mu h}{\bar\nu}\big)^{1-\delta} \qquad \forall \alpha : |\alpha| \le K_0 \quad \forall x \in B(0, \frac{9}{10}) \tag{13.6.31}$$

where $C' = C'(c, \delta)$ and $\delta > 0$ is arbitrary and C depends only on K_0 and on a constant c for which the basic inequalities hold with K replaced by $K_0 + 2$.

Therefore for

$$\zeta^2 \geq C_0\bar{\nu}\mu^{-4} + C'\mu^{-1}h\big(\frac{\bar{\nu}}{\mu h}\big)^{\delta} \tag{13.6.32}$$

in the definition of the spectral gap (13.6.28) one can set $\omega_1 = \frac{1}{8}\kappa v^2$. Conversely if condition (13.6.28) holds with $\omega_1 = \frac{1}{8}\kappa v^2$ then this condition also holds with ω_1 given by (13.6.29).

(ii) On the other hand, for

$$\zeta^2 \geq C_0\bar{\nu}\big(\mu^{-4} + \mu^{-1}h\big) \tag{13.6.33}$$

the last term in the left-hand expression of (13.6.21) can be dropped.

Therefore for the restrictions on ζ indicated in (i) one can always set $\omega_1 = \frac{1}{8}\kappa v^2$.

Remark 13.6.11. Direct calculation shows that $\int(\mathcal{L}_{kmp}\psi)F\sqrt{g}\,dx$ with $p = 0$ and $k + m = 1$ does not necessarily vanish.

Remark 13.6.12. (i) If

$$\zeta \geq (\mu^{-1}h)^{\frac{4}{5}}\bar{\nu}^{-\frac{1}{2}} \tag{13.6.34}$$

then in the proof of Proposition 13.6.1 we can replace the Gårding inequality with the Gårding-Melin inequality (1.1.131); this leads us to the condition

$$\begin{aligned}(13.6.5)'\quad & \varsigma\big((2j+1)\mu h + B(x_1, \xi_1, \mu^{-2}, \mu^{-1}h, h^2)\big) + \\ & \frac{1}{2}\,\mathsf{Tr}^+(\mathsf{Hess}^{\#}\, B(x_1, \xi_1, \mu^{-2}, 0, 0)) \geq \zeta^2 \geq C_0\bar{\nu}(\mu^{-2}h^{2-\delta} + \mu^{-\frac{8}{5}}h^{\frac{8}{5}})\end{aligned}$$

instead of (13.6.5) where $\mathsf{Hess}^{\#}$ is the skew-Hessian of B and $\mathsf{Tr}^+ M$ is the semi-sum of absolute values of the purely imaginary eigenvalues of the matrix M.

Since for $d = 2$, $\mathsf{Hess}^{\#} B$ has only two eigenvalues η and $-\eta$ then

$$\mathsf{Tr}^+(\mathsf{Hess}^{\#} B) = (-\frac{1}{2}\,\mathsf{Tr}(\mathsf{Hess}^{\#} B)^2)_+^{\frac{1}{2}} = \frac{1}{\sqrt{2}}(\det(\mathsf{Hess}\, B))_+^{\frac{1}{2}}. \tag{13.6.35}$$

Formula (13.3.13) yields that the latter expression is equal to $2\omega_3 \circ \bar{\Psi}_0 + O(\mu^{-2}\bar{\nu})$ where

$$\omega_3 = \frac{1}{F\sqrt{8g}}(\det \mathsf{Hess}\, v)_+^{\frac{1}{2}} \tag{13.6.36}$$

and therefore (13.6.28) should here be replaced by

(13.6.37) For every $j \in \mathbb{Z}^+$ one of the following two conditions holds:

$$\pm\big(v + (2j+1)\mu h + \mu^{-2}\omega_1\big) + \mu^{-1}h\omega_3 \geq \zeta^2 \geq C_0\big(\mu^{-4} + h^2\big)$$

(in which case $\zeta^2 \geq C(\mu^{-2}h^{2-\delta} + \mu^{-\frac{8}{5}}h^{\frac{8}{5}})$ automatically) and condition (13.6.21) should be replaced here by

$$v + \mu h + \mu^{-1}h\omega_4 \geq \zeta^2 \geq C_0\bar{\nu}\big(h^2 + \mu^{-\frac{8}{5}}h^{\frac{8}{5}}\big) \tag{13.6.38}$$

where

$$\omega_4 = \frac{1}{4}\sum_{j,k} g^{jk}F^{-1}\partial_j\partial_k v + \frac{1}{F\sqrt{8g}}(\det \mathsf{Hess}\, v)_+^{\frac{1}{2}}. \tag{13.6.39}$$

(ii) One can see easily that for $d = 2, 3$ and conditions (13.2.1)–(13.2.4) and (13.3.1) operator A can be written in the form

$$A = \mathcal{M}_1^*\mathcal{M}_1 + V + \mu hF + h^2V' \tag{13.6.40}$$

and

$$A = \mathcal{M}_2^*\mathcal{M}_2 + \mathcal{M}_1^*\mathcal{M}_1 + V + \mu hF + h^2V' \tag{13.6.41}$$

respectively with $\mathcal{M}_k = \sum_j \rho_{jk}P_j$ with complex-valued (real-valued for $k = 2$) coefficients ρ_{kj} and with

$$|D^\alpha V'| \leq C' \qquad \forall \alpha : |\alpha| \leq K' - 2. \tag{13.6.42}$$

(iii) This easily yields that the assertion of Proposition 13.6.3(ii) holds for $d = 2, 3$ provided conditions (13.2.1)–(13.2.4), (13.3.1) and (13.6.20) are fulfilled in $B(0,1) \cap \bar{X}$ even if $B(0,1) \cap \partial X \neq \emptyset$ but all the conditions of Theorem 13.2.9 (excluding the restriction on τ in (13.2.52)) are fulfilled and the Dirichlet boundary condition is fulfilled on $B(0,1) \cap \partial X$.

(iv) However, this is not true for the Neumann boundary condition.

Remark 13.6.13. (i) Assume that $g^{jk} = \mathsf{const}$, $F = \mathsf{const}$ or conditions $(13.3.77)_{1,2}$ are fulfilled with really small $\bar{\nu}$; we leave details to the reader). Then the term largest uncontrolled term h^2 in the canonical form either disappears or is tamed by factor $\bar{\nu}$.

In this case we do not even need to assume that h is small parameter; it can be even large parameter as long as $\hbar = \mu^{-1}h$ remains a small parameter.

(ii) As $\mu h \ge 1$ the worst perturbation in the canonical form is $\asymp h^2$ and it comes from the "kinetic part" (not from V/F). In this case we need either to consider $\mathsf{R}^{\mathsf{MW}}_1$ instead of R^{MW} where in comparison with R^{MW} arguments of θ contain an extra term $\omega'_1 h^2$ or to assume that $\mu \le h^{-2}$ or to impose conditions $(13.3.77)_{1-2}$ with $\bar{\nu} \le C\mu^{-1}h^{-2}$.

Conclusion: As $d = 2$ and one Landau level is separated from other levels by spectral gaps (one spectral gap if we are discussing the lowest Landau level) its contribution to asymptotics is $\asymp \mu h^{-1}$. The remainder estimate as $\mu h \ge 1$ could be as good as $O(\mu^{-s})$ if τ belongs to the spectral gap and as good as $O(1)$ otherwise (as τ is close to Landau level).

13.6.4 Case $d = 3$

As $d = 3$ we really need to consider only case $\mu h \asymp 1$, $\nu < 1$.

Theorem 13.6.14. *Let* $d = 3$, $\mu h \le 1$ *and suppose conditions* (13.2.1)–(13.2.5) *and*

$$|D^{\alpha}\bigl(\frac{V}{F} + \mu h\bigr)| \le c\nu \qquad \forall \alpha : |\alpha| \le K \tag{13.6.43}$$

be fulfilled with $\nu \ge h^2$ *and* $K = K(m, \delta)$. *Then*

(i) Under non-degeneracy condition

$$\sum_{\alpha:|\alpha|\le m} |D^{\alpha}\bigl(\frac{V}{F} + (2j+1)\mu h\bigr)| \ge \epsilon\nu \qquad \forall j \in \mathbb{Z}^+ \tag{13.6.44}_m$$

estimate

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{-2}\nu + C\mu h^{-1} \tag{13.6.45}$$

holds.

(ii) In the general case estimate

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{-2}\nu + C'\mu h^{-1-\delta}\nu^{\frac{1}{2}\delta} \tag{13.6.46}$$

holds.

(iii) Meanwhile $\mathsf{N}^-(0) = O\big(\mu h^{-2}\nu^{\frac{1}{2}} + h^{-3}\nu^{\frac{3}{2}}\big)$ *and as* $(V + \mu hF) < -\epsilon\nu$ *at least in one point* $\mathsf{N}^-(0) \asymp \big(\mu h^{-2}\nu^{\frac{1}{2}} + h^{-3}\nu^{\frac{3}{2}}\big)$.

Proof. We proved it albeit with summation with respect to $\alpha > 0$ in non-degeneracy condition $(13.6.44)_m$ as $\nu = 1$. However we actually need non-degeneracy condition $(13.6.44)_m$ and we dropped $\alpha = 0$ as it used to be $\mu h \le \epsilon$.

As $\mu h \lesssim \nu$ we can reduce it to the case $\nu = 1$ dividing operator by ν; then $\mu_{\mathsf{new}} = \mu\nu^{-\frac{1}{2}}$, $h_{\mathsf{new}} = h\nu^{-\frac{1}{2}}$ and $\nu_{\mathsf{new}} = 1$.

As $\nu \le \epsilon\mu h$ we need to consider in the canonical form only $j = 0$ and then dividing canonical form by ν leads us to the same theory as before albeit while $h_1 = \mu^{-1}h$ as it used to be, $h_2 = h\nu^{-\frac{1}{2}}$. □

Alternatively we can reformulate it as

Theorem 13.6.15. *Let* $d = 3$, $\mu h \ge 1$ *and suppose conditions* (13.2.1)–(13.2.5) *and* (13.6.43) *be fulfilled with* $\nu \ge h^2$ *and* $K = K(m, \delta)$.

Then for Magnetic Schrödinger-Pauli operator (13.6.3) *all statements of Theorem 13.6.14 remain true albeit one should replace* $(V + \mu hF)$ *by* V *everywhere. In particular*

$$\mathcal{N}^{\mathsf{MW}}(\tau, \mu h) = \sum_{0\le j<\infty} \big(\tau - 2j\mu hF\big)_+^{\frac{1}{2}} \mu hF \cdot (2\pi)^{-2}\sqrt{g}. \tag{13.2.9}'_{(3)}$$

Proof. As $\mu h \ge 1$ we divide operator by μh thus getting $h_{\mathsf{new}} = (\mu^{-1}h)^{\frac{1}{2}}$, $\mu_{\mathsf{new}} = h_{\mathsf{new}}^{-1}$, $\nu_{\mathsf{new}} = \nu(\mu h)^{-1}$ with $h_{\mathsf{new}}\nu_{\mathsf{new}}^{-\frac{1}{2}} = h\nu^{-\frac{1}{2}}$, $\mu_{\mathsf{new}}h_{\mathsf{new}}^{-1} = \mu h^{-1}$. □

Conclusion: As $d = 3$ and $\mu h \ge 1$ for the Magnetic Schrödinger-Pauli operator (13.6.3) main part of the asymptotics is of magnitude μh^{-2} (or $\mu h^{-2}\nu^{\frac{1}{2}}$ as $\nu < 1$) and the remainder estimate is $O(\mu h^{-1})$ or slightly worse.

13.7 Propagation of Singularities and Sharper aAsymptotics

In this section we consider the two- and three-dimensional cases and under some assumptions of a global nature we obtain slightly more precise estimates than in the previous sections; with the except of the last subsection this improvement will be by no more than an additional factor $\varsigma \in [\mu^{-\delta'}, 1]$ with a small enough exponent $\delta' > 0$ in the right-hand expression of the estimates.

These results are not very important from the point of view of applications but they seem to be interesting enough by themselves. Here we need to revise all the arguments of Sections 13.3–13.6.

We start with the two-dimensional case when singularities propagate along magnetic drift lines and then proceed to the three-dimensional case when singularities propagate along magnetic lines which could however have "side-drift".

In the last Subsection 13.7.3 we consider supersharp asymptotics as $d = 3$ with the remainder estimate $O(\mu^{-1}h^{-2})$ as $\mu h \le 1$ and $O(h^{-1})$ as $\mu h \ge 1$.

13.7.1 Case $d = 2$

Classical Dynamics and Heuristics

Let us start from the classical dynamics. We assume that potential is truly generic i.e. no special conditions with ν are assumed. To make things simpler we assume at the moment that $g^{jk} = \delta_{jk}$ and $F = \mathsf{const}$.

Looking at the canonical form we conclude that there is fast circular movement in $(\mu x_2, \xi_2)$ and there is a slow drift movement in $(x_1, \mu^{-1}\xi_1)$. More precisely, consider first two terms of the canonical form:

$$\omega_0(x_1, \mu^{-1}\xi_1) + \omega_1(x_1, \mu^{-1}\xi_1)(\mu^2 x_2^2 + \xi_2) + O(\mu^{-2}) \tag{13.7.1}$$

and we understand that along $(\mu x_2, \xi_2)$ there is a circular movement with period $T(\mu) = \pi\mu^{-1}\omega_1^{-1} + O(\mu^{-3})$ and along $(x_1, \mu^{-1}\xi_1)$ there is a drift with the velocity $\mu^{-1}\nabla^{\#}(\omega_0 + \omega_1 k)$ with Hamiltonian calculated with respect to (x_1, ξ_1) only and with $k = (\tau - \omega_0)\omega_1$ plugged after (as we are interested at energy level 0).

Going back with symplectomorphism $\bar{\Psi}$ we conclude that modulo $O(\mu^{-3})$

$$T(\mu) = \pi\mu^{-1}F^{-1} \tag{13.7.2}$$

and the drift speed is

$$v_{\mathsf{drift}} = \mu^{-1}\bigl(\nabla\bigl(\frac{V-\tau}{F}\bigr)\bigr)^{\perp} \tag{13.7.3}$$

which defines *magnetic drift lines* which are level lines of $(V-\tau)F^{-1}$ [34].

Remark 13.7.1. Note that in an invariant form

$$F = \frac{1}{\sqrt{g}}|F_{12}|, \quad F_{12} = \partial_1 V_2 - \partial_2 V_1, \quad g = (g^{11}g^{22} - g^{12}g^{21})^{-1} \tag{13.7.4}$$

and magnetic drift is described by

$$\frac{dx_1}{dt} = \frac{1}{\sqrt{g}}\partial_2\frac{V}{f}, \qquad \frac{dx_2}{dt} = -\frac{1}{\sqrt{g}}\frac{V}{f}. \tag{13.7.5}$$

where

$$f = \frac{1}{\sqrt{g}}F_{12} \tag{13.7.6}$$

is a *pseudo-scalar*[35].

Remark 13.7.2. Magnetic drift lines are terminated in the critical points of $(V-\tau)F^{-1}$ [36].

If we are interested in the time $T \gg \mu$ we need to follow magnetic drift line either close to termination point, or to large distance, or assume that it is closed smooth line. However we need to remember that Hamiltonian trajectories follow drift lines albeit do not coincide with them!

Example 13.7.3. Let $g^{jk} = \delta_{jk}$, $F = 1$.

(i) As $V = x_2$ magnetic drift lines are just straight lines $x_2 = \mathsf{const}$ with no termination points and Hamiltonian trajectories are cycloids of Figure 13.2(b).

---

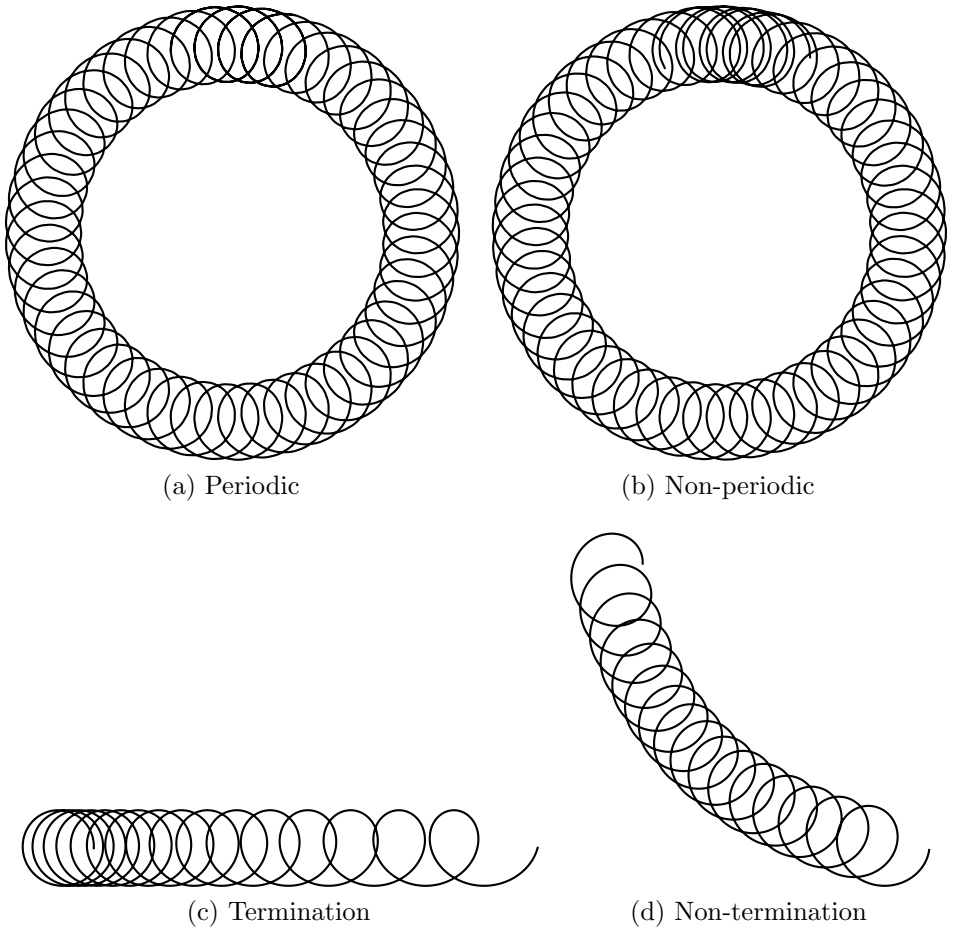
[34] In the special case $F = \mathsf{const}$ magnetic drift lines are level lines of V.

[35] I.e. it changes sign as we change orientation of the coordinate system.

[36] In the special case $F = \mathsf{const}$ those are critical points of V.

(ii) Consider $V = \pm(x_1^2 + x_2^2)$. Then magnetic drift lines are circles $x_1^2 + x_2^2 = \mathsf{const}$. On the other hand, Hamiltonian trajectories are cycloids with frequencies $2\mu(1 + O(\mu^{-2}))$ and $2\mu^{-1} + (1 + O(\mu^{-2}))$ and they are periodic only as $\mu = \mu_k = k^{\frac{1}{2}}(1 + O(k^{-1}))$ with $k \in \mathbb{Q}^+$. See Figure 13.5(a),(b).

(iii) Consider $V = x_1x_2$. Then magnetic drift lines are hyperbolas $x_1x_2 = \mathsf{const}$. On the other hand, Hamiltonian trajectories are shown on Figure 13.5(c),(d), one which terminates in $x = 0$ and another which bypasses it.



(a) Periodic (b) Non-periodic

(c) Termination (d) Non-termination

Figure 13.5: Trajectories for 2-dimensional model operator to Examples 13.7.3(ii) (in (a),(b)) and 13.7.3(iii) (in (c),(d))

Our conjecture is that we can derive remainder estimate $o\bigl(\mu^{-1}h^{-1}+1\bigr)$ in all the cases when drift lines are not closed; if drift lines are closed we can derive this remainder estimate for μ except belonging to rather thin exceptional set.

One should notice that magnetic drift lines escaping to infinity are rather dangerous as then V does not grow which may indicate presence of the essential spectrum.

Propagation of Singularities

Theorem 13.7.4. *Let $d=2$ and ψ_1,ψ_2 satisfy* (13.4.84) *with $\gamma=\mu^{-1}$.*

Let us assume that along trajectories of (13.7.5) *starting in the intersection of the $C_0\gamma$-vicinity of $\operatorname{supp}\psi_1$ with $\{-V/(\mu hF)\in\mathbb{Z}^+\}$ (where here and below C_0 is a large enough constant, $L=L(I)$ is large enough and $\delta=\delta(I)>0$ is small enough) the following conditions are fulfilled*

$$(13.7.7)_{1-3}\quad |D^\alpha g^{jk}|\le c\zeta^{-I},\quad |D^\alpha f|\le c\zeta^{-I},\quad |D^\alpha V|\le c\zeta^{-I}\qquad \forall \alpha:|\alpha|\le K,$$

$$F\ge \epsilon_0\zeta^I, \tag{13.7.8}$$

$$\sum_{j,k} g^{jk}\eta_j\eta_k\ge \epsilon_0\zeta^I|\eta|^2\qquad \forall \eta\in\mathbb{R}^3, \tag{13.7.9}$$

$$\operatorname{dist}(\phi_t(x),\partial X)\ge \epsilon_0\zeta^I, \tag{13.7.10}$$

$$\operatorname{dist}(\phi_t(x),x)\ge \epsilon_0\zeta^I\min(|t|,1), \tag{13.7.11}$$

$$|D_x\phi_t(x)|\le c\zeta^{-I} \tag{13.7.12}$$

where ϕ_t is a magnetic drift flow defined by system (13.7.5), *$D_x\phi_t(x)$ denotes the Jacobi matrix of $\phi_t(x)$ and $\zeta\ge h^\delta$, $0\le\pm t\le\pm T'$,*

$$|T'|\le T\le \zeta^{-1}\nu^{-1} \tag{13.7.13}$$

$\delta>0$ is a sufficiently small exponent and $\nu=1$ in (i).

Moreover, let us assume that for $t=T$ the distance between these trajectories and $\operatorname{supp}\psi_2$ is larger than $C_0\mu^{-1}\zeta^{-L}$.

Then

(i) The following estimate holds:

$$|D_x^\alpha D_y^\beta F_{t\to h^{-1}\tau}\chi_{\mu T,\mu T'}(t)\psi_1(x)U\psi_2(y)| \le Ch^s \quad \forall \tau : \mu T|\tau| \le h^{1-\delta} \quad \forall \alpha,\beta : |\alpha| \le s, |\beta| \le s. \tag{13.7.14}$$

(ii) Moreover, if conditions

$$|D^\alpha g^{jk}| \le c\nu\mu\zeta^{-l}, \quad |D^\alpha F| \le c\nu\mu\zeta^{-l}, \quad |D^\alpha \frac{V}{F}| \le c\nu\zeta^{-l} \quad \forall \alpha : 1 \le |\alpha| \le K, \tag{13.7.7}'_{1-3}$$

hold along this trajectory then one can replace $T = \zeta^{-1}$ by $T = \nu^{-1}\zeta^{-1}$.

(iii) As $\mu h \ge 1$ both Statements (i) and (ii) remain true for operator with V replaced by $(V - k\mu hF)$ with $k = \mathsf{const}$.

Proof. We leave the details proof to the reader. The main and actually only obstacle is the absence of the global reduction. However, reduction can be done locally and then one can break interval $[-\mu T, \mu T]$ on the subintervals of the lengths $\asymp \mu\zeta^l$. □

Remark 13.7.5. Recall that as $\mu h \ge \nu$ the spectral gaps may appear and in this case we need to apply our results only outside of those gaps.

We will need however a more delicate theorem to tackle periodic trajectories of the magnetic drift flow. Recall that these lines are level lines of VF^{-1} and therefore if some such line is closed and non-degenerate, all lines close to it have the same property and therefore such lines lines are always coming "en masse".

Theorem 13.7.6. *Assume that the level lines*

$$\ell(\lambda) = \{x \in X : VF^{-1} = \lambda\} \tag{13.7.15}$$

are closed and non-degenerate (i.e. $|\nabla(VF^{-1})| \ge \epsilon$). Let $T(\lambda)$ be a corresponding period

$$T(\lambda) = \frac{1}{2}\int_{\ell(\lambda)} \frac{|dx|_g}{|\nabla(VF^{-1})|_{g^{-1}}} \tag{13.7.16}$$

where both lengths are measured according in the corresponding metrics:

$$|dx|_g = \Big(\sum_{j,k} g_{jk}\,dx_j\,dx_k\Big)^{\frac12}, \qquad |\nabla v|_{g^{-1}} = \Big(\sum_{j,k} g^{jk}\partial_j v\partial_k v\Big)^{\frac12}. \tag{13.7.17}$$

Let T' be an arbitrarily large constant. Let ψ_1, ψ_2 be supported in ε-vicinity of $\bar{x}$ with $\bar{\lambda} = (VF^{-1})(\bar{x})$ and $\varepsilon = \varepsilon(T')$. Then

(i) Let $|T' - nT(\bar{\lambda})| \ge C_0 T$ for all $n \in \mathbb{Z}$ and $T = C_0\varepsilon$. Then (13.7.14) *holds. Here C_0 does not depend on T' and ε.*

(ii) Let $|T' - nT(\bar{\lambda})| \le C_0 T'$ for some $n = \bar{n} =\in \mathbb{Z}$. Let now ψ_1, ψ_2 be supported in γ-vicinity of $\bar{x}$ with $\gamma = \mu^{-\frac12} h^{\frac12-\delta}$ and $\mu \ge Ch^{1-2\delta}$. Then

$$|\Gamma F_{t\to h^{-1}\tau}\chi_{\mu T,\mu T'}(t)\psi_1(x)U\psi_2(y)| \le Ch^s \qquad \forall \tau : \mu T|\tau| \le h^{1-\delta} \tag{13.7.18}$$

unless

$$|T' - nT(\bar{\lambda})| \le C_0\gamma, \qquad |n\rho(\bar{\lambda}, \mu^{-1})\mu^2 - m| \le C\mu\gamma \tag{13.7.19}$$

with some $m \in \mathbb{Z}$ where

$$\rho(\lambda, \mu^{-1}) \sim \sum_{j\ge 0} \rho_j(\lambda)\mu^{-j}, \tag{13.7.20}$$

$$\rho_0(\lambda) = \frac{1}{\pi}\int_{\ell(\lambda)} \frac{F|dx|_g}{|\nabla(VF^{-1})|_{g^{-1}}} \tag{13.7.21}$$

Proof. Details we leave to the reader as well, just note that during one period $\mu T(\lambda)$ fast movement makes $\mu^2\rho(\lambda, \mu^{-1})$ rotations and for it minimal distance in uncertainty principle is $\mu\gamma$ (could be improved). □

Spectral Asymptotics

Applying standard Tauberian arguments one can easily prove the following

Theorem 13.7.7. *Let $d = 2$ and let conditions* (13.2.1)–(13.2.5), (13.3.1) *and* (13.4.3) *be fulfilled.*

Further, let conditions (13.4.85), $(13.3.77)_{1-3}$ *and* $(13.4.12)_{1,2}$ *be fulfilled and*

$$\min_j |V + (2j+1)\mu hF| + |\nabla\big(V + (2j+1)\mu hF\big)| \ge \epsilon_0\nu. \tag{13.7.22}$$

Furthermore, let either $\mu \ge h^{-\delta}$ or $\nu \ge \mu h^{1-\delta}$ *and condition* (13.4.46) *be fulfilled.*

Finally, let $\Xi_1, \dots, \Xi_n$ *be closed subsets in* $B(0,1)$ *and let* $1 \le T_1 \le \dots \le T_n \le \mu^{\delta'}$ *with a small enough exponent* $\delta' = \delta'(\delta, l) > 0$. *Let us assume that through every point* x *belonging to the* γ_i*-neighborhood of* Ξ_i *(with* $\gamma_i = \mu^{-1}\zeta_i^{-L}$, $\zeta_i = T_i^{-1}$ *where* $L = L(\delta, l)$ *is large enough) there passes a trajectory of the flow* $\phi_t(x)$ *given by the system* (13.7.5) *with* $\phi_0(x) = x$, $\pm t \in [0, \nu^{-1}T_i]$ *along which conditions* $(13.7.7)'_{1-3}$, (13.7.8)–(13.7.9),

$$(13.7.10)' \qquad \operatorname{dist}(\phi_t(x), \partial X) \ge \gamma_i,$$

$$(13.7.11)' \qquad \operatorname{dist}(\phi_t(x), x) \ge \gamma_i \min(|t|, 1),$$

(13.7.12) *and* (13.7.12) *are fulfilled.*

(i) Then estimate

$$(13.7.23) \quad \mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} \le C\Big(\frac{\mu h}{\nu} + 1\Big) \sum_{0 \le i \le n} \sum_j \frac{h^{-1+\vartheta}\nu^{1+\vartheta}\mu^{-1-\vartheta}}{T_i^{1+\vartheta}} \int_{\Xi_i \cap \{V_j = 0\}} dx : dV_j + C' h^s$$

holds where $V_j = V + (2j+1)\mu h$ *and* $\Xi_0 = B(0,1) \setminus (\Xi_1 \cup \dots \cup \Xi_n)$.

(ii) Moreover, for $\nu = 1$, $\vartheta = 0$, *the same estimate holds for* R^{MW} *if* either $\mu h \ll 1$ *or one includes the term* $-\kappa_2$ *into* R^{MW}.

(iii) As $\mu h \ge 1$ *Statements (i) and remain (ii) true for operator with* V *replaced by* $(V - k\mu h F)$ *with* $k = \mathsf{const}$ [37].

Corollary 13.7.8. *Let* $d = 2$ *and let conditions* (13.2.1)–(13.2.5), (13.3.1) *and* (13.4.3) *be fulfilled. Further, let condition* (13.7.22) *be fulfilled with* $\nu = 1$.

Finally, let Λ *be closed subset of measure* 0 *in* $B(0,1)$ *and let us assume that through every point* x *belonging to the* $B(0,1)\setminus\Lambda$ *there passes a trajectory of the flow* $\phi_t(x)$ *given by the system* (13.7.5) *with* $\phi_0(x) = x$, $\pm t \in [0, \infty)$ *along which conditions* (13.7.7)–(13.7.12) *holds with* $\zeta = \zeta(x,t)$.

(i) Then $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} = o(h^{-1+\vartheta}\mu^{-1-\vartheta})$ *as* $h \to +0$, $\mu \to +\infty$.

[37] Sure, we need to plug this into $\mathcal{N}^{\mathsf{MW}}$ as well.

(ii) Moreover, for $\vartheta = 0$, the same estimate holds for R^{MW} if either $\mu h \ll 1$ or one includes the term $-\kappa_2$ in R^{MW}.

(iii) As $\mu h \ge 1$ Statements (i) and (ii) remain true for operator with V replaced by $(V - k\mu hF)$ with $k = \mathsf{const}$ [37].

Assume now that 0 is (an only) non-degenerate critical point of VF^{-1} in $B(0,1)$. Then introducing $\gamma(x) = \frac{1}{2}|x|$ we conclude that in $B(\bar{x}, \gamma(\bar{x})) \mapsto B(0,1)$ after rescaling $x \mapsto (x - \bar{x})\gamma(\bar{x})^{-1}$ conditions of theorem are fulfilled with $\mu_{\mathsf{new}} = \mu\gamma$, $h_{\mathsf{new}} = h\gamma^{-1}$, $\nu_{\mathsf{new}} = \gamma$, and therefore, as $\gamma \ge \bar{\gamma} := (\mu^{-1}h)^{\frac{1}{2}}$ its contribution to R^{T} does not exceed

$$C\Big(\frac{\nu_{\mathsf{new}}}{\mu_{\mathsf{new}} h_{\mathsf{new}}} + 1\Big) = C\Big(\frac{\gamma}{\mu h} + 1\Big)$$

and therefore the contribution of all such elements with $C\mu^{-1} \le |x| \le \varepsilon$ does not exceed

$$C \int \Big(\frac{\gamma}{\mu h} + 1\Big) \frac{\gamma \, d\gamma}{\gamma^2} \asymp C\Big(\frac{\varepsilon}{\mu h} + |\log \mu|\Big). \tag{13.7.24}$$

One can prove easily that contribution of $B(0, \bar{\gamma})$ is less than this.

Further, if 0 is a saddle point we can play with escape and replace $|\log \mu|$ by 1 and if 0 is an extremum there is no escape in points close to 0.

Thus we arrive to

Corollary 13.7.9. *In the framework of Corollary 13.7.8 let us allow non-degenerate critical points of VF^{-1} and escape condition is fulfilled in all other points.*

(i) Then as $h \to 0$, $\mu \to \infty$, $\mu h \to 0$ $\mathsf{R}^{\mathsf{MW}}_{\infty} = o(\mu^{-1}h^{-1})$.

(ii) Further, as either $\mu \le h^{-\frac{1}{3}+\delta}$ or $\mu \ge h^{-\frac{1}{3}-\delta}$ the same is true for R^{MW}. Otherwise one needs to replace R^{MW} by $\mathsf{R}^{\mathsf{MW}}_1$.

More delicate but also due to standard Tauberian estimates and Theorem 13.7.6 is the following theorem:

Theorem 13.7.10. *Let conditions of Theorem 13.7.6 be fulfilled as original points of flow ϕ_t belongs to $B(0,1)$. Then*

(i) Assume that

$$\mathsf{mes}\{x : \rho_0(\lambda(x)) = k\} = 0 \qquad \forall k \in \mathbb{R}^+. \tag{13.7.25}$$

Then Statements (i) and (ii) of Corollary 13.7.8 hold as $h \to 0$, $\mu \to \infty$, $\mu \le h^{\delta-1}$.

(ii) Assume that

$$\rho(\lambda, \mu^{-1}) = \rho(\mu^{-1}). \tag{13.7.26}$$

Then Statements (i) and (ii) of Corollary 13.7.8 hold as $h \to 0$, $\mu \to \infty$, $\mu \le h^{2\delta-1}$ *provided* μ *satisfies also*

$$\mathsf{dist}\big(\mu^2\rho(\mu^{-1})n, \mathbb{Z}\big) \ge \epsilon_n \mu^{\frac{1}{2}} h^{\frac{1}{2}-\delta} \qquad \forall n \in \mathbb{Z}. \tag{13.7.27}$$

Example 13.7.11. In the framework of Example 13.7.3(ii) we have a quadratic Hamiltonian

$$\mathsf{a}(x, \xi) = (\xi_1 - \frac{1}{2}\mu x_2)^2 + (\xi_2 + \frac{1}{2}\mu x_1)^2 + \varsigma(x_1^2 + x_2^2) \tag{13.7.28}$$

and eigenvalues of $\frac{1}{2}\,\mathsf{Hess}^{\#}\,\mathsf{a}$ are purely imaginary $\pm i\omega_1$, $\pm i\omega_2$ with

$$\omega_{1,2}^2 = \frac{1}{2}(\mu^2 + 2\varsigma) \pm \Big(\frac{1}{2}(\mu^2 + 2\varsigma)^2 - \varsigma^2\Big)^{\frac{1}{2}}. \tag{13.7.29}$$

Note that

$$\omega_1^2 = \mu^2 + 2\varsigma - \varsigma^2\mu^{-2} + O(\mu^{-4}), \qquad \omega_2^2 = \varsigma^2\mu^{-2} + O(\mu^{-4}). \tag{13.7.30}$$

Then (13.7.30) implies classical dynamics as on Figure 13.5(a) and (b) with $\rho = \mu^{-2}\omega_1/\omega_2 = |\varsigma|^{-1} + O(\mu^{-2})$ but also that the eigenvalues are

$$\tau_{m,n} = (2m+1)\omega_1 h + (2n+1)\omega_2 h \qquad m, n \in \mathbb{Z}^+. \tag{13.7.31}$$

Therefore we get two imposed lattices with steps $2\omega_1 h$ and $2\omega_2 h$.

13.7.2 Case $d = 3$

Now we consider 3-dimensional case.

Preliminaries and Improved Reduction

It is well known from physics that the classical three-dimensional particles in a strong magnetic field move almost along magnetic lines. So it is not surprising that in our analysis magnetic lines are also important. Let us recall that a magnetic line of the magnetic field $\boldsymbol{F} = (F^1, F^2, F^3)$ is an integral curve $x = x(t)$ of the field $F^{-1}\boldsymbol{F}$. Thus, $x(t)$ is given by the system

$$\frac{dx_j}{dt} = \frac{2}{F}F^j \qquad (j = 1, 2, 3) \tag{13.7.32}$$

where

$$F = \big(\sum_{j,k} g_{jk}F^jF^k\big)^{\frac{1}{2}} = \frac{1}{2}\big(\sum_{j,k,l,m} g^{jk}g^{lm}F_{jl}F_{km}\big)^{\frac{1}{2}} \tag{13.7.33}$$

is the scalar intensity; let us introduce the corresponding flow Φ_t on X.

It follows from the definition of $\boldsymbol{F}$ that this field is solenoidal, i.e.,

$$\sum_j \partial_j(F^j\sqrt{g}) = 0 \tag{13.7.34}$$

and therefore

(13.7.35) *Magnetic flow* Φ_t preserves the density $\sqrt{g}dx$ on X.

Moreover,

(13.7.36) Magnetic flow ϕ_t can be lifted to the Hamiltonian flow $\tilde{\Phi}_t$ on Λ which is given by the Hamiltonian

$$\frac{1}{F}\sum_j F^j\big(\xi_j - \mu V_j(x)\big). \tag{13.7.37}$$

Remark 13.7.12. We could define the flow Φ_t by the system

$$\frac{dx_j}{dt} = \frac{2}{F}\omega F^j \quad (j = 1, 2, 3) \tag{13.7.32$'$}$$

with functions ω and ω^{-1} regular along the trajectory; then $\tilde{\Phi}_t$ would be given by the Hamiltonian

$$\frac{\omega}{F}\sum_j F^j\big(\xi_j - \mu V_j(x)\big) \tag{13.7.37$'$}$$

and the invariant density would be $\omega^{-1}F\sqrt{g}dx$.

The proof of Proposition 13.3.1 and the analysis which follows in Section 13.3 easily yield the following statement (the detailed proof of which we leave to the reader):

Theorem 13.7.13. *Let conditions* (13.2.1)–(13.2.5) *and* (13.3.1) *be fulfilled.*

Let $\hat{x} \in B(0, \frac{1}{2})$ *and for all* $x \in B(0, \zeta^l)$ *let the flow* Φ_t *be defined by system* (13.7.32) *with* $t \in [-T_1, T_2]$ *where* $\zeta \in [\mu^{-\delta'}, 1]$, $\delta' > 0$ *is small enough,* $0 \le T_i \le \zeta^{-1}$ *and* $T_1 T_2 = 0$.

Moreover, let us assume that the following conditions are fulfilled along this flow:

$$(13.7.38)_{1-3} \quad |D^\alpha g^{jk}| \le c\zeta^{-l}, \quad |D^\alpha F^j| \le c\zeta^{-l}, \quad |D^\alpha V| \le c\zeta^{-l} \qquad \forall \alpha : |\alpha| \le K,$$

$$F \ge \epsilon_0 \zeta^l, \tag{13.7.39}$$

$$\sum_{j,k} g^{jk}\eta_j\eta_k \ge \epsilon_0 \zeta^l |\eta|^2 \qquad \forall \eta \in \mathbb{R}^3, \tag{13.7.40}$$

$$\operatorname{dist}(\Phi_t(x), \partial X) \ge \epsilon_0 \zeta^l, \tag{13.7.41}$$

$$\operatorname{dist}(\Phi_t(x), x) \ge \epsilon_0 \zeta^l \min(|t|, 1), \tag{13.7.42}$$

$$|D_x \Phi_t(x)| \le c\zeta^{-l} \tag{13.7.43}$$

where $D_x\Phi_t(x)$ *denotes the Jacobi matrix of* $\Phi_t(x)$. *Then*

(i) All the reductions of Section 13.3 can be done in the subdomain

$$\bigcup_{t \in [-T_1, T_2]} \Phi_t\big(B(\hat{x}, \epsilon\zeta^l)\big) \tag{13.7.44}$$

of X *where* $\epsilon = \epsilon(l, c, \epsilon_0) > 0$ *is a small enough constant, and then all the symplectomorphisms and symbols satisfy the estimates*

$$(13.7.45)_{1-2} \quad |D^\alpha \Psi_{\dots}(x, \xi)| \le C'\zeta^{-L}, \quad |D^\alpha b_{\dots}(x, \xi)| \le C'\zeta^{-L} \qquad \forall \alpha : |\alpha| \le K'$$

with arbitrary N *and* K' *(and then* K, L, δ' *depend on* N, K', l*); moreover, for* $x \in \Phi_t(B(\hat{x}, \epsilon\zeta^l))$ *with* $|t| \le \epsilon$ *both these inequalities hold with* $L = 0$.

(ii) Moreover, the same statement remains true for the flow Φ_t *defined by* $(13.7.32)'$ *provided that on domain* (13.7.44)

$$|D^\alpha \omega| \le c_1 \zeta^{-l} \qquad \forall \alpha : |\alpha| \le K, \tag{13.7.45}_3$$

and

$$\omega \ge \epsilon_1^{-1} \zeta^l. \tag{13.7.46}$$

(iii) Finally, this statement remains true without condition (13.7.42) *if we introduce coordinates* (x_2, x') *in the pipe* (13.7.44) *transforming it into a cylinder (thus removing self-intersections).*

Remark 13.7.14. Even from the heuristic point of view there is an essential difference:

(i) Magnetic lines depend only on F while magnetic drift lines depend on V as well. In order to the get magnetic drift lines on the energy level τ one should replace V by $V - \tau$. Then, for $F \ne \mathsf{const}$ the magnetic drift lines depend on the energy level as well.

(ii) As soon as magnetic lines are defined, the movement along them is defined by the quantum number j and the energy level τ. Moreover, the direction of the movement depends on (13.7.37). In contrast, in the two-dimensional case the choice of j is automatic and the movement is defined only by the energy level which should be fixed. System (13.7.5) is a dynamical system while (13.7.32) only describes geometrical shape.

(iii) The movement along magnetic drift lines is given in scaled time; the real time is μt. According to the theory of Sections 2.2 and 2.4, t should not be too large. Moreover, under condition (13.4.85) it is sufficient to assume that νt is not too large (because we can divide operator by ν and then the scaled time will be νt).

(iv) Vf^{-1} is constant along magnetic drift lines and for big enough μ (e.g., $\mu \ge h^{-\frac{1}{2}}$) one need only consider lines with $-V/(\mu hF) \in 2\mathbb{Z}^+ + 1$.

Weak Magnetic Field

In this subsection we assuming that (13.4.1) holds improve certain statements of Section 6.4. For this goal let us first assume that the reduction of the

Section 13.3 is done and let us take $(\bar{x}', \bar{\xi}_1) \in \Omega$ [38]. Let us introduce sets

$$\Lambda^0_{(\bar{x}_1,\bar{\xi}_1)} = \{(x', \xi') \in \Omega \times \mathbb{R}, x_1 = \bar{x}_1, \xi_1 = \bar{\xi}_1\}, \tag{13.7.47}$$

1-dimensional Hamiltonians

$$H_{(\bar{x}_1,\bar{\xi}_1)r}(x_2, \xi_2) = \xi_2^2 + \bar{B}'_0(\bar{x}_1, x_2, \bar{\xi}_1) + \bar{B}_1(\bar{x}_1, x_2, \bar{\xi}_1)r \tag{13.7.48}$$

and the corresponding Hamiltonian flows $\Psi_{t,r}$ on $\Lambda^0_{(\bar{x}_1,\bar{\xi}_1)}$. Here $(\bar{x}_1, \bar{\xi}_1, r)$ is considered constant when we define the Hamiltonian field.

Theorem 13.7.15. *Let $q', q'' \in S_{\boldsymbol{h},\rho,\gamma,K}(T^*\mathbb{R}^3)$ and $\boldsymbol{h}, \boldsymbol{\rho}, \boldsymbol{\gamma}$ satisfy* (13.4.6)*, $\rho_1 = \rho_2 = \gamma_1 = \gamma_2 = \gamma$ and $\rho_3 = \mu^{\frac{1}{2}} h^{\frac{1}{2}(1-\delta)}$, $\gamma_3 = \mu^{-\frac{1}{2}} h^{\frac{1}{2}(1-\delta)}$.*

Further, let $\epsilon_0 \le T^* \le \zeta^{-1}$ and let $\delta' = \delta'(\delta, s, l)$ in the condition $\zeta \ge \mu^{-\delta'}$ to ζ.

Furthermore, let us assume that

$(13.7.49)_\pm$ *If the point (x, ξ) belongs to the $(\boldsymbol{\rho}, \boldsymbol{\gamma})$-neighborhood of $\operatorname{supp}(q')$ and if $|r - (\mu^2 x_3^2 + \xi_3^2)| \le C\mu^{-l} + \rho_3$ then for all t: $\pm t \in [0, 2T^*]$*

$$\Psi_{t,r}(x', \xi') \in \Omega \times \mathbb{R}$$

and along $\Psi_{t,r}(x', \xi')$ conditions (13.7.38)–(13.7.43) *and the following conditions are fulfilled:*

$$(13.7.50)_{1,2} \quad |D^\alpha B_n| \le c\zeta^{-l}, \quad |D^\alpha R| \le c\mu^{-N}\zeta^{-l} \qquad \forall \alpha : |\alpha| \le K \quad \forall n \le N$$

where B_n and R are taken from (13.3.66)*, $N = N(\delta, s, l)$, $K = K(\delta, s, l)$ and*

$$|D_{(x',\xi')}\Psi_{t,r}(x', \xi')| \le c\zeta^{-l} \tag{13.7.51}$$

where $D_Z\Psi$ means the Jacobi matrix of Ψ at the point Z. Then

(i) Let one of the following conditions be fulfilled:

$$(13.7.52)_1 \qquad |x_1 - y_1| \ge C_0 T^* \mu^{-1}\zeta^{-L} + \gamma,$$

$$(13.7.52)_2 \qquad |\xi_1 - \eta_1| \ge C_0 T^* \mu^{-1}\zeta^{-L} + \gamma,$$

$$(13.7.52)_3 \qquad |x_2 - y_2| \ge C_0 T^* \zeta^{-L},$$

$$(13.7.52)_4 \qquad |\xi_2 - \eta_2| \ge C_0 T^* \zeta^{-L},$$

[38] Recall that $\Lambda^0 = \{(x, \xi),\ (x', \xi_1) \in \Omega, \xi_2 = \xi_3 = x_3 = 0\}$.

for all $(x,\xi) \in \operatorname{supp} q'$ *and for all* $(y,\eta) \in \operatorname{supp} q''$ *or let condition* (13.4.10) *be fulfilled where* $L = L(\delta, s, l)$ *is large enough here.*

Then for all $x, y \in \mathbb{R}^3$, $\tau \le c$ *estimate* (13.4.9) *with* $\chi_T(t)$ *replaced by* $\chi_{T^*,\pm T^*}(t)$ *holds; recall that* χ *is supported in* $[-\frac{1}{2}, \frac{1}{2}]$, $Q' = \operatorname{Op}(q')$, $Q'' = \operatorname{Op}(q'')$.

(ii) Let $\gamma \ge \mu^{\frac{1}{2}} h^{\frac{1}{2}(1-\delta)}$. *Moreover, let us assume that if* $(x,\xi) \in \operatorname{supp} q'$ *and* $|r - (\mu^2 x_3^2 + \xi_3^2)| \le C_0 \mu^{-l} + \rho_3$ *and*

$$|-\bar\tau + \xi_2^2 + \bar B_0'(x',\xi_1) + \bar B_1(x',\xi_1) r| \le C\rho_3 + C\zeta^{-L}\mu^{-2} = C\bar\gamma \tag{13.7.53}$$

then

$$\begin{aligned} &\operatorname{dist}(\Phi_{t,r}(x',\xi'),(y',\eta')) \ge C\bar\gamma \\ &\qquad \forall (y,\eta) \in \operatorname{supp} q'' : |\mu^2 y_3^2 + \eta_3^2 - r| \le C_0\mu^{-l} + \rho_3 \quad \forall t : \pm t \in [T', T''] \end{aligned} \tag{13.7.54}$$

where $0 \le T' < T'' \le 2T^*$. *Then estimate* (13.4.9) *with* $\chi_T(t)$ *replaced by* $\chi_{T,\pm T'''}(t)$ *with* $T = \frac{1}{2}(T'' - T')$, $T''' = \frac{1}{2}(T'' + T')$ *holds for all* $x, y \in \mathbb{R}^3$, $\tau \in [\bar\tau - \epsilon\bar\gamma, \bar\tau + \epsilon\bar\gamma]$ *where* $\epsilon > 0$ *is a small enough constant.*

Proof. Let us apply Theorem 2.4.12. In order to do this we need to compare the Hamiltonian flow generated by the three-dimensional Hamiltonian $\mathcal{A}(x,\xi)$ with the flow $\Psi_{t,r}$. Let us introduce variables

$$Z = (x_1, \mu^{-1}\xi_1, x_2, \xi_2, r, \mu^{-2}x_3, \mu^{-2}\xi_3)$$

with $r = \mu^2 x_3^2 + \xi_3^2$, which will be treated as an "independent" variable in what follows.

In these variables the flow $\Psi_{t,r}$ is described by the system $dZ/dt = f(Z)$ and the Hamiltonian flow generated by $\mathcal{A}(x,\xi)$ is described by the system $dZ/dt = \tilde f(Z)$, and the first, second, sixth and seventh components of f vanish, and for $(x',\xi_1) \in \Omega$ with $\xi_2^2 + \xi_3^2 + \mu^2 x_3^2 \le C_0\zeta^{-l}$ estimate

$$|D^\alpha(f(Z) - \tilde f(Z))| \le C\mu^{-1}\zeta^{-L} \qquad \forall \alpha : |\alpha| \le K \tag{13.7.55}$$

holds with appropriate L.

Let $Z(t)$ and $\tilde Z(t)$ be trajectories corresponding to these two systems originating from the same point. We assert that

$$|Z(t) - \tilde Z(t)| < C\mu^{-1}\zeta^{-L'} \qquad \forall t : \pm t \in [0, 2T^*] \tag{13.7.56}$$

with appropriate $L' = L'(\delta, s, l)$.

In fact, if this statement is wrong then (13.7.56) holds for $\pm t \in [0, T)$ with $T < 2T^*$ and for $\pm t = T$ there is equality in (13.7.56). But in this case (13.7.55) yields that for $\pm t \in [0, T]$

$$|\frac{d}{dt}(Z - \tilde{Z})(t) - (D_{Z(t)}f)(Z - \tilde{Z})(t)| \le C\mu^{-1}\zeta^{-L}$$

where $(D_Z f)(Z')$ means the differential of f at the point Z applied to Z'. Therefore (13.7.51) yields that

$$|\frac{d}{dt}\mathcal{J}^{-1}(Z - \tilde{Z})(t)| \le C\mu^{-1}\zeta^{-2L}$$

where $\mathcal{J}$ is the 7×7 Jacobi matrix corresponding to the system $dZ/dt = f(Z)$; its elements are equal to δ_{jk} for $j \ne 3, 4$, to 0 for $j = 3, 4$ and $k = 6, 7$ and the upper left 4×5-submatrix of $\mathcal{J}$ is equal to $D_{(x',\xi',r)}\Phi_{t,r}(x', \xi')$; the determinant of $\mathcal{J}$ is equal to 1.

Therefore (13.7.51) yields that the norms of $\mathcal{J}$ and $\mathcal{J}^{-1}$ do not exceed $C\zeta^{-2L}$. Since $\mathcal{J}(0) = I$, $Z(0) = \tilde{Z}(0)$ and $T \le \zeta^{-1}$ it follows that

$$|\mathcal{J}^{-1}(Z - \tilde{Z})(t)| \le C\mu^{-1}\zeta^{-3L}$$

and therefore $|(Z - \tilde{Z})(t)| \le C\mu^{-1}\zeta^{-5L}$. But then for $\zeta \le \zeta_0 = \mathsf{const}$ condition (13.7.56) with $L' = 9L$ cannot be violated and for $\zeta \in [\zeta_0, 1]$ this condition is provided by the appropriate choice of C_0. So condition (13.7.56) is fulfilled and for the sake of simplicity one can assume that $L' = L$.

Let us now verify conditions of Theorem 2.4.12 on Jacobi matrix. Let us vary the initial data in which case we obtain the system

$$\frac{d}{dt}\mathfrak{d}\tilde{Z} = (D_{\tilde{Z}}\tilde{f})\mathfrak{d}\tilde{Z}$$

where $\mathfrak{d}$ denotes variation; this equation and (13.7.56) yield that

$$\frac{d}{dt}\mathfrak{d}\tilde{Z} = (D_Z\tilde{f})\mathfrak{d}\tilde{Z} + O(\mu^{-1}\zeta^{-2L}|\mathfrak{d}\tilde{Z}|)$$

and therefore

$$|\frac{d}{dt}\mathcal{J}(t)^{-1}\mathfrak{d}\tilde{Z}| \le C\mu^{-1}\zeta^{-3L}|\mathcal{J}(t)^{-1}\mathfrak{d}\tilde{Z}|.$$

This inequality yields that $|\mathcal{J}(t)^{-1}\mathfrak{d}\tilde{Z}| \le C|\mathfrak{d}\tilde{Z}(0)|$ provided $\delta' > 0$ is small enough in the condition on ζ. Then

$$|\frac{d}{dt}\mathcal{J}(t)^{-1}\mathfrak{d}\tilde{Z}| \le C\mu^{-1}\zeta^{-3L}|\mathfrak{d}\tilde{Z}(0)|$$

and therefore

$$|\mathfrak{d}\tilde{Z}(t) - \mathcal{J}(t)\mathfrak{d}\tilde{Z}(0)| \le C\mu^{-1}\zeta^{-5L}|\mathfrak{d}\tilde{Z}(0)|.$$

This latter inequality obviously yields that

$$|D_{(x(0),\xi(0))}(x'(t),\xi(t))| \le C\zeta^{-5L}$$

and

$$|D_{(x(0),\xi(0))}(x_3(t),\xi_3(t))| \le C\mu\zeta^{-5L}.$$

Therefore for $\mu \in [\mu_0, h^{-\delta'}]$ with a small enough exponent $\delta' > 0$ our theorem follows from Theorem 2.4.12.

On the other hand, for $\mu \in [h^{-\delta}, h^{\delta-1}]$ this theorem is due to Proposition 13.7.21 which will be proven independently below and which is also due to Theorem 2.4.12; excluding (x_3,ξ_3) from the analysis we will be able to check conditions only for part of the Jacobi matrix. □

Remark 13.7.16. One can replace condition (13.7.51) in Theorem 13.7.15 by condition

$$|\xi_2| \ge \epsilon\zeta^{l} \qquad \text{along } \Psi_{t,r}(x',\xi'). \tag{13.7.57}$$

In order to prove this let us first of all note that the definition of $\Psi_{t,r}$ yields that in $\Psi_{t,r}(x',\xi')$ only (x_2,ξ_2)-components need to be checked. Moreover, the fact that $H_{(\bar{x}_1,\bar{\xi}_1)r}(x_2,\xi_2)$ is constant along trajectories, $(13.7.50)_{1,2}$ and (13.7.57) yield that one need check only x_2-component (we change l if necessary).

Let $z = (x_1,\xi_1,r)$ and $W(z,x_2) = \bar{B}_0'(z,x_2) + \bar{B}_1(z,x_2)r$. Then

$$\pm 2t = \int_{x_2(0)}^{x_2(t)} (E - W(z,s))^{-\frac{1}{2}}\,ds \tag{13.7.58}$$

with $E = \xi_2^2(0) + W(z,x_2(0))$. Moreover, (13.7.57) yields that

$$E - W(z,s) = \xi_2^2 \ge \epsilon_0\zeta^{2l}.$$

Let us treat $x_2(t)$ as an implicit function of $E, z, x_2(0)$ and t (where E is a function of $\xi_2(0)$, $x_2(0)$ and r but the derivatives of E with respect to these variables are easily estimated). Then (13.7.58) and (13.7.57) yield that the absolute values of the first order partial derivatives of t with respect to E and z do not exceed $C\zeta^{-2l}|t|$ and that the absolute values of the first order partial derivatives of t with respect to $x_2(t)$ and $x_2(0)$ do not exceed $C\zeta^{-l}$ and are greater than $\epsilon\zeta^l$ (we have again used (13.7.50)).

This yields that the absolute values of the first order partial derivatives of $x_2(t)$ with respect to $x_2(0), z, \xi_2(0)$ do not exceed $C\zeta^{-5l}$.

Remark 13.7.17. (i) Condition (13.7.57) provides that the movement is irrevocable:

$$\mathsf{dist}(\Phi_{t,r}(x',\xi'),(x',\xi')) \ge \epsilon\zeta^l \min(|t|,1) \qquad \forall t : \pm t \in [0, 2T^*]. \tag{13.7.59}$$

(ii) One can rewrite condition (13.7.57) in the form

$$|\sum_j F^j(\xi_j - \mu V_j)| \ge \epsilon\zeta^l \tag{13.7.60}$$

or

$$|\tau - V - rF| \ge \epsilon\zeta^l \tag{13.7.61}$$

along the trajectory in the original coordinates.

(iii) Moreover, returning to the original coordinates one can write the trajectory equation in the form

$$\frac{dx_j}{dt} = \frac{2}{F}(\tau - V - rF)^{\frac{1}{2}}F^j \qquad (j = 1,2,3) \tag{13.7.32}''$$

where we reverse the time if necessary.

(iv) Finally, returning to $U(t)$ one can pick $Q' = \psi'$, $Q'' = Q'''\psi''$ where $Q''' = \mathcal{F}\tilde{Q}'''\mathcal{F}^*$ and r runs through all the possible values of $x_3^2 + \mu^2\xi_3^2$ on $\mathsf{supp}(\tilde{q}'''\psi'')$ where small and capital letters denote symbols and corresponding operators.

Alternatively, r runs through all the possible values of

$$F^{-1}\big(\tau - V - F^{-2}\big(\sum_j F^j(\xi_j - \mu V_j)\big)^2\big) \tag{13.7.62}$$

on $\mathsf{supp}\, q'''$.

Therefore Theorem 13.7.15 yields that if its conditions and condition (13.7.57) are fulfilled then estimate (13.4.33) holds with $T = T^*$ and with $T' \in [h^{1-\delta}, T^*]$ for all $\tau \in [-\epsilon'\zeta^l, \epsilon'\zeta^l]$. Therefore we can apply Tauberian arguments with $T = T^*$ instead of $T = T_0$.

Let us now assume that condition (13.4.46) is fulfilled. Then the analysis of Section 13.4 yields that for $\mu \le h^{\delta-\frac{1}{3}}$ the main contribution to R is given by the zone $\{(x,\xi) : |\xi_2| \ge c\zeta\}$.

More precisely, if we calculate R' for the operator $Q' = \mathcal{F}\tilde{Q}'\mathcal{F}^*$ with $\tilde{Q}' = \mathsf{Op}(\tilde{q}')$, $\tilde{q}' \in \mathsf{S}_{\boldsymbol{h}',\zeta,\zeta,K}(T^*\mathbb{R}^2)$ supported in $\{|\xi_2| \le 2c\zeta\}$ and for the function ψ_1 supported in $B(0, \frac{1}{2})$ and satisfying (13.4.84) then the estimate

$$\mathsf{R}' \le C\zeta\gamma^3 h^{-2} + C'h^s \tag{13.7.63}$$

holds provided $\mathsf{diam}(\mathsf{supp}\,\psi_1) \le c\gamma$.

Let us estimate the contribution of the zone $\{(x,\xi), |\xi_2| \ge c\zeta\}$ to R by means of Tauberian arguments. Namely, let us estimate R' for operator $Q' = \mathcal{F}\tilde{Q}'\mathcal{F}^*$ with $\tilde{Q}' = \mathsf{Op}(\tilde{q}')$, $\tilde{q}' \in \mathsf{S}_{\boldsymbol{h}',\zeta,\zeta,K}(T^*\mathbb{R}^2)$ supported in $\{|\xi_2| \ge c\zeta\}$ and for the function ψ_1 supported in $B(0, \frac{1}{2})$ and satisfying (13.4.84) with $\gamma \ge \mu^{-1}$ and $\mathsf{diam}(\mathsf{supp}\,\psi_1) \le c\gamma$.

Then under conditions on the flows $\Phi_{\bar{t}}$ and $\Psi_{t,r}$ estimate (13.7.63) holds; here $\Phi_{\bar{t}}$ is given by (13.7.32)$''$ with $(\pm)\bar{t} \in [0, \bar{T}]$ and $\bar{T} \le \zeta^{-l}$, conditions $(13.7.45)_{1,2}$, $(13.7.49)_{\pm}$ are assumed to be fulfilled and the signs $(\pm)$ of $\bar{t}$ and $\pm$ of t are independent; moreover, one should take $r \in [0, r^*]$ where r^* is the minimal value of $r \in \mathbb{R}$ for which the inequality

$$V + Fr + c^2\zeta^2 \ge 0 \quad \text{at} \quad B(\hat{x}, \zeta^l) \tag{13.7.64}$$

is fulfilled (we now pick $\tau = 0$).

One can easily see that all the conditions excluding irrevocability should be checked for $r = 0$ only. Thus, let us consider the flow defined by (13.7.32)$''$ with $r = 0$, $\tau = 0$:

$$\frac{dx_j}{dt} = \frac{2}{F}\sqrt{-V}F^j \qquad (j = 1,2,3). \tag{13.7.32}'''$$

Let Φ_t be the corresponding flow.

Then the irrevocability for $r \in [r^*, r]$ is due to the following condition

$$v(\Phi_t(x)) \le v(x) + c^2\zeta^2 \qquad \forall t : \pm t \in [0, T] \tag{13.7.65}$$

with $v = VF^{-1}$.

Then our arguments yield estimate (13.7.63) in this case also; thus it is true for $Q = I$ as well. Summing with respect to a partition of unity in $B(0, \frac{2}{3})$ we obtain the principal statement of this step:

Theorem 13.7.18. *Let conditions* (13.2.1)–(13.2.5), (13.3.1), (13.4.1) *and* (13.4.46) *be fulfilled.*

Let $\Xi_1, \dots, \Xi_n$ be closed subsets of $B(0,1)$ and let $1 \le T_1 \le \dots \le T_n \le \mu^{\delta'}$ with a small enough exponent $\delta' = \delta'(\delta, I) > 0$.

Let us assume that through every point x belonging to the γ_i-neighborhood of Ξ_i (with

$$\gamma_i = (\mu^{\frac{1}{2}} h^{\frac{1}{2}(1-\delta)} + C_0\mu^{-1})\zeta_i^{-L},$$

$\zeta_i = T_i^{-1}$ where $L = L(\delta, I)$ is large enough) there passes a trajectory of the flow $\Phi_t(x)$ given by the system (13.7.32)‴ *with $\Phi_0(x) = x$, $\pm t \in [0, T_i]$ and along this trajectory conditions* (13.7.38)–(13.7.40), (13.7.43), (13.7.65),

$$V \le -\epsilon\zeta^2, \tag{13.7.66}$$

(13.7.38)$_{1-3}$, (13.7.43) *and*

$$\operatorname{dist}(\Phi_t(x), \partial X) \ge \gamma_i, \tag{13.7.41}'$$

$$\operatorname{dist}(\Phi_t(x), x) \ge \gamma_i \min(|t|, 1), \tag{13.7.42}'$$

are fulfilled with $\zeta = \zeta_i$. Then

(i) For $\mu \le h^{\delta - \frac{1}{3}}$ estimate

$$\mathsf{R}^{\mathsf{MW}} \le \sum_{0 \le i \le n} C T_i^{-1} h^{-2} \operatorname{mes}(\Xi)_i + C' \tag{13.7.67}$$

holds with $T_0 = 1$, $\Xi_0 = B(0,1) \cap \{V \le 0\} \setminus (\Xi_1 \cup \dots \cup \Xi_n)$.

(ii) Under condition (13.4.54) *this estimate holds for $\mu \le h^{\delta - 1}$.*

Remark 13.7.19. (i) In the theorem we have replaced $\gamma_i = \zeta_i^l$ which follows from the previous analysis by $\gamma_i = \mu^{-1}\zeta_i^{-L}$.

One can do this for the following reasons. Let us note that despite the absence of condition (13.7.42) which prevents the global[39] reduction of our

[39] I.e., in $\bigcup_t \Phi_t(B(\hat{x}, \zeta^{\frac{1}{2}})$.

operator to canonical form, we may still reduce the operator to canonical form locally[40] provided $|T_2 - T_1| \le \zeta^{L'}$ with appropriate exponent L').

Moreover, the absence of condition (13.7.42) does not prevent us from making the global reduction in the canonical coordinates described in Theorem 13.7.13(iii). But then the singularities of $U\psi''(y)\,{}^tQ''_y$ (intersected with $\{|\tau| \le \epsilon\gamma\}$) lie in the pipe consisting of the lines described below starting in the γ-vicinity of $\operatorname{supp}\psi''$.

Moreover, for $t \in [T_1, T_2]$ with $|T_2 - T_1| \le \zeta^{L'}$ these singularities lie in the part of the pipe where reduction is possible. This permits us to skip condition (13.7.42) and prove estimate

$$|F_{t\to h^{-1}\tau}\chi_{T,\pm T'}(t)Q'_x\psi'(x)U\psi''_y\,{}^tQ''_y| \le C'h^s \qquad \forall \tau \in [-\epsilon\gamma\zeta^L, \epsilon\gamma\zeta^L]$$

provided $Q' = \operatorname{Op}(q')$, $Q'' = \operatorname{Op}(q'')$, $q', q'' \in \mathscr{S}_{h,\gamma,\gamma,K}(T^*\mathbb{R}^3)$, ψ', ψ'' satisfy (13.4.84), $\operatorname{diam}(\operatorname{supp}\psi') \le c\gamma$, $\operatorname{dist}(\operatorname{supp}\psi', \partial X) \ge \epsilon_0\gamma$ (and the same is true for ψ''),

$$\operatorname{supp} q' \subset \iota\{|\omega| \ge c\zeta^l\} \tag{13.7.68}$$

where $\iota : T^*X \to X \times \mathbb{R}$ is the natural projection $\iota(x,\xi) = (x,\omega)$ with $\omega = \frac{1}{F}\sum_j F^j(\xi_j - \mu V_j)$, and the following condition is fulfilled:

(13.7.69) If we consider trajectories of the system

$$\frac{dx_j}{dt} = 2\omega\frac{1}{F}F^j \quad (j = 1,2,3), \tag{13.7.70}_1$$

$$F\frac{d\omega}{dt} = -(\omega^2 F^j\partial_j F + F^j\partial_j\frac{V}{F}) \tag{13.7.70}_2$$

passing through $\iota(\operatorname{supp} q')$, then along these trajectories $\pm\omega \ge \zeta^l$ and for $t \in [T' - T, T' + T]$

$$\operatorname{dist}((x(t),\omega(t),\iota(y,\eta)) \ge \gamma \qquad \forall (y,\eta) \in \operatorname{supp} q'',$$

or if similar conditions with x, y, q', q'', t replaced by $y, x, q'', q', -t$ respectively are fulfilled. System $(13.7.70)_{1,2}$ is an alternative form of $(13.7.32)''$.

Results of this type permit us to apply Tauberian arguments.

[40] I.e., in $\bigcup_t \Phi_{t\in[T_1,T_2]}(B(\hat{x}, \zeta^{\frac{1}{2}L'})$.

(ii) Let us replace condition (13.7.41) by (13.7.41)$'$.

In order to do this let us apply the previous arguments but in each "small" time interval let us add the following idea: let us "move" the boundary ∂X by the distance ζ^l and let us treat the new fundamental solution U^0; our previous arguments yield that $Q'_x\psi'(x)U^0$ is negligible provided $y \in X$ and $\mathsf{dist}(y, \partial X) \ge \mu^{-1}\zeta^{-L'}$ where X means the "old" X; it is then easy to obtain that $Q'_x\psi'(x)U \equiv Q'_x\psi'(x)U^0$, i.e., the analysis of propagation of singularities along trajectories satisfying (13.7.41)$'$ can be reduced to the analysis of propagation of singularities of U^0 (along trajectories satisfying (13.7.41) in X_{new}).

(iii) The connections between $\mathsf{R}^{\mathsf{W}\prime}$ and R^{W} (see Section 13.4) and between R and R^{MW} (see Section 13.5) yield that in Theorem 13.7.18 estimate (13.7.67) remains true for both R^{W} and R^{MW} as $\mu \le h^{\delta-\frac{1}{3}}$; moreover, under condition (13.4.54) this estimate holds for R^{MW} as $\mu \le h^{\delta-1}$.

We leave to the reader the following easy problem

Problem 13.7.20. (i) Formulate the statement similar to Corollary 13.7.8.

(ii) Consider the case $\vartheta > 0$. Recall that in this case the contribution of the zone $\{(x,\xi) : |\xi_2| \le c\zeta\}$ is negligible without a condition on VF^{-1} only if $\mu \le h^{-\delta''}$ with $\delta' = \delta''(\vartheta)$.

Moderate Magnetic Field

Let us assume now that condition (13.5.1) is fulfilled; we want to improve the arguments of Section 13.5. In order to do this let us introduce the one-dimensional Hamiltonian (13.7.48) with $r = (2j+1)\mu h$; let us denote it by $H_{(x_1,\xi_1)j}(x_2,\xi_2)$ and let us denote the corresponding Hamiltonian flow by $\Phi_{t,j}(x_2,\xi_2)$. Let us improve Proposition 13.5.3 (in what follows we will improve it again):

Proposition 13.7.21. *Let* $j \in \mathbb{Z}^+$, $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$ *where* $q', q'' \in \mathsf{S}_{\boldsymbol{h}',\gamma,\gamma,K}(T^*\mathbb{R}^2)$ *with* $\gamma \ge h^{\frac{1}{2}(1-\delta)}$ *and* $\boldsymbol{h}'$ *defined in* (13.5.18). *Let us assume*

$(13.7.71)_{\pm}$ [41] *If* (x',ξ') *belongs to* γ*-neighborhood of* $\mathsf{supp}(q')$ *then for all* $t : \pm t \in [0, 2T^*]$ $\Phi_{t,j}(x',\xi')$ *belongs to* $\Omega \times \mathbb{R}$

[41] Compare with $(13.7.49)_{\pm}$.

and also that along $\Phi_{t,j}(x',\xi')$ *conditions* (13.7.38)–(13.7.40), (13.7.43), (13.7.50)–(13.7.51) *are fulfilled.*

Further, let $\zeta \in [\mu^{-\delta'},1]$ *with* $\delta'=\delta'(\delta,l,s)>0$. *Then*

(i) Let <u>*either*</u> *one of conditions* $(13.7.52)_{1-4}$ *be fulfilled* <u>*or*</u> *let* $j\neq k$. *Then estimate* (13.5.22) *holds with* $\chi_T(t)$ *replaced by* $\chi_{T^*,\pm T^*}$.

(ii) Furthermore, assume that for all $(x',\xi')\in \operatorname{supp} q'$, $(y',\eta')\in \operatorname{supp} q''$

$$(13.7.72)_{\pm} \qquad \operatorname{dist}\bigl(\Phi_{t,j}(x',\xi'),(y',\eta')\bigr)\geq C\bar\gamma \qquad \forall t:\pm t\in[T',T''],$$

with

$$(13.7.73) \qquad \bar\gamma = h^{\frac12(1-\delta)}+C_0\zeta^{-L}\mu^{-2},\quad 0\leq T'<T''\leq 2T^*.$$

Then estimate (13.5.22) *holds with* $\chi_T(t)$ *replaced by* $\chi_{T,\pm T'''}(t)$ *where* $x,y\in\mathbb{R}^3$, $\tau\in[\bar\tau-\epsilon\bar\gamma,\bar\tau+\epsilon\bar\gamma]$, $T=\frac12(T''-T')$, $T'''=\frac12(T''+T')$.

Proof. This proof repeats the proof of Theorem 13.7.15 but now the variables (x_3,ξ_3,r) are absent and the proof is simplified. Moreover, for $h^{-\delta}\leq\mu\leq h^{\delta-1}$ Theorem 13.7.15 obviously follows from this proposition. □

Remark 13.7.22. (i) Obviously, one need only check conditions $(13.7.71)_{\pm}$ and $(13.7.72)_{\pm}$ for (x',ξ') such that

$$(13.7.74) \qquad |H_{(x_1,\xi_1),j}(x_2,\xi_2)-\bar\tau|\leq C\bar\gamma$$

and for (y',η') satisfying the same restriction.

(ii) One should remember the relationship $r=(2j+1)\mu h$ between $r\in\mathbb{R}^+$ from the previous subsection and $j\in\mathbb{Z}^+$ used here.

Proposition 13.7.23. *Let the conditions of Proposition 13.5.5 be fulfilled and let* $\rho_1=\rho_2=\gamma_1=\gamma_2\geq h^{\frac12(1-\delta)}$.

Let us assume that for every $j\leq J$ *conditions* $(13.7.71)_{\pm}$ *are fulfilled and along the trajectory conditions* (13.7.38)–(13.7.40), (13.7.43), (13.7.50), (13.7.51) *are fulfilled*[42)].

Then formula $(13.5.24)_{(3)}$ *remains true for* $\tau\in[\bar\tau-\epsilon\bar\gamma,\bar\tau+\epsilon\bar\gamma]$ *and* $T\in[1,2T^*]$.

[42)] We take into account remark 13.7.22).

Proof. Let us recall that in Proposition 13.5.5 the restriction $T \le T_0$ appeared only in order to get rid of terms with $j \ne k$. But now Theorem 13.7.18(i) permits us to do this for $T \le 2T^*$. In fact, applying an admissible partition of unity we see that we should prove $(13.5.24)_{(3)}$ under additional condition $\mathsf{diam}(\mathsf{supp}\, q' \cup \mathsf{supp}\, q'') \le c\gamma$. □

Let us assume that the magnetic field is not very strong, i.e., that condition (13.4.1) is fulfilled. Then by Section 13.5 the contribution to R_1 of the zone $\{|\xi_2| \le \zeta^L\}$ with $\zeta \le \mu^{-\delta'}$ does not exceed $Ch^{-2}\zeta$ where $\delta > 0$ is arbitrarily small, L is large enough and $\delta' = \delta'(\delta, L) > 0$ is small enough.

So, only the zone $\{|\xi_2| \ge \zeta^L\}$ should be treated and in this zone all the arguments of the previous subsection remain true. Then we obtain the following proposition:

Proposition 13.7.24. *Let the conditions of Theorem 13.7.18 be fulfilled as well as condition* (13.5.1)*. Then estimate* (13.7.67) *holds for* $\mathsf{R}^{\mathsf{MW}}_{\infty}$ *and* $\mathsf{R}^{\mathsf{MW}}_{1}$ *without any additional assumptions.*

However, the transition from $\mathsf{R}^{\mathsf{MW}}_{1}$ to R^{MW} is not very smooth: one can easily prove that $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ (defined by (13.5.83)) does not exceed

$$R' := Ch^{-2} \int_{\{\gamma \ge \mu^{-1}\}} \Big(\frac{\mu h}{\gamma^2}\Big)^s \, dx + Ch^{-2}(\mu^3 h)^s \, \mathsf{mes}(\{\gamma \le \mu^{-1}\}) \tag{13.7.75}$$

for $\mu^3 h \le 1$ and does not exceed

$$\begin{aligned} R' := C\mu^{-\frac{3}{2}} h^{-\frac{5}{2}} \int_{\{\gamma \ge \sqrt{\mu h}\}} \Big(\frac{\mu h}{\gamma^2}\Big)^s \, dx + \\ C\mu^{-1}h^{-2} \int_{\{\mu^{-1} \le \gamma \le \sqrt{\mu h}\}} \gamma^{-1} \, dx + Ch^{-2} \, \mathsf{mes}(\{\gamma \le \mu^{-1}\}) \end{aligned} \tag{13.7.76}$$

for $\mu^3 h \ge 1$; recall that

$$\gamma = |\nabla \frac{V}{F}| + \min_j |\frac{V}{F} + (2j+1)\mu h|^{\frac{1}{2}}. \tag{13.7.77}$$

Therefore we obtain the following proposition:

Proposition 13.7.25. *Let the conditions of Theorem 13.7.18 be fulfilled as well as condition* (13.5.1).

(i) Then estimate

$$\mathsf{R}^{\mathsf{MW}} \le \sum_{0\le i\le n} CT_i^{-1}h^{-2}\,\mathsf{mes}(\Xi_i) + R' + C' \tag{13.7.78}$$

holds with R' given by (13.7.75) *and* (13.7.76) *for $\mu^3 h \le 1$ and $\mu^3 h \ge 1$ respectively.*

(ii) In particular, one can skip the second term under non-degeneracy condition $(13.5.58)_m$ *with $\nu = 1$.*

Corollary 13.7.26 [43]**.** *Let conditions* (13.2.1)–(13.2.5), (13.3.1), (13.4.1) *and* (13.4.46) *be fulfilled.*

Finally, let Λ be closed subset of measure 0 in $B(0,1)$ and let us assume that through every point x belonging to the $B(0,1)\setminus\Lambda$ there passes an infinitely long in one direction trajectory of the flow $\Psi_{r,t}(x)$ along which conditions of Theorem 13.7.18 are fulfilled with $\zeta = \zeta(x,t)$ [44]

(i) As $h \to 0$, $\mu \to \infty$ and <u>either</u> $\mu^3 h = o(1)$ <u>or</u>

$$\mathsf{mes}(\{x : \nabla \frac{V}{F} = 0\}) = 0 \tag{13.7.80}$$

asymptotics

$$\mathsf{R}^{\mathsf{MW}} = o(h^{-2}) \tag{13.7.81}$$

holds.

(ii) Without additional assumptions of (i) this us true for R^{MW} modified in the following way: magnetic Weyl expression is written for $V(x) + \kappa(x)\mu^{-2}$ and $-\kappa_1 h^{-3}\mu^{-2}$ is subtracted.

Problem 13.7.27. We again leave the case $\vartheta > 0$ to the reader.

---

[43] Cf. Corollary 13.7.8.

[44] Note that then

$$\frac{V}{F}(\Phi_t(x)) \le \frac{V}{F}(x) \qquad \forall t : \pm t > 0 \tag{13.7.79}$$

Now let us assume that the magnetic field is transitional, i.e.,

$$h^{1-\delta} \le \mu \le h^{-1} \tag{13.7.82}$$

with an arbitrarily small exponent $\delta > 0$.

Recall that both R^{T} and R^{MW} do not exceed $C(h^{-2} + \mu h^{-1}(h/\sqrt{\nu})^{-\delta}$ and in order the second (uncontrollable) term did not exceed $Ch^{-2}\zeta$ (where ζ is the measure of the smallness) one should assume that condition (13.4.85) with

$$\nu \le ch^2(\zeta/\mu h)^L \tag{13.7.83}$$

with arbitrarily large exponent L is fulfilled.

Alternatively both R^{T} and R^{MW} do not exceed Ch^{-2} under <u>either</u> non-degeneracy condition $(13.5.58)_m$ with $\nu = 1$ <u>or</u> (13.4.85) and non-degeneracy condition $(13.5.58)_m$ with $\nu < 1$. Then the "matching" part of the remainder which corresponds to a single number j in the definition of Landau levels is $C\mu h^{-1}$ and we assume that

$$\zeta \ge c\mu h. \tag{13.7.84}$$

Then in both cases (general with (13.7.83) and non-degenerate with (13.7.84)) results of Section 13.5 yield that the contributions of the zone $\{(x', \xi') : |\xi_2| \le 2c\zeta\}$ to R^{T} and $\mathsf{R}^{\mathsf{MW}}_{\infty}$ do not exceed $C\zeta h^{-2}$.

Then all the above arguments remain true and we easily get the following proposition:

Proposition 13.7.28. *Let all the conditions of Proposition 13.7.25 excluding condition* (13.4.1) *be fulfilled. Further, let condition* (13.7.84) *be fulfilled*[45)].

Furthermore, let condition (13.4.85) *be fulfilled where <u>either</u> ν satisfies* (13.4.82) *or non-degeneracy condition* $(13.5.58)_m$ *is fulfilled.*

(i) Then estimate (13.7.78) *remains true for* $\mathsf{R}^{\mathsf{MW}}_1$.

(ii) Moreover if non-degeneracy condition is fulfilled with $\nu = 1$ then estimate (13.7.78) *remains true for* R^{MW}.

Proof. Easy details are left to the reader. We just note that without non-degeneracy condition error resulting from dropping term $O(\mu^{-2})$ while going from $\mathsf{R}^{\mathsf{MW}}_1$ to R^{MW} could be as bad as $O(\mu^{-1} \times \mu h^{-2}) = O(h^{-2})$.

We leave to the reader to weaken assumption $\nu = 1$ in Statement (ii).□

[45)] All conditions of this proposition should be fulfilled for all $\zeta = T_i^{-1}$, $i = 1, \dots, n$.

Strong Magnetic Field

Now we are going to consider case

$$\mu h = 1. \tag{13.7.85}$$

We recall that the case of $\mu h \ge \nu$ and the case of the Schrödinger-Pauli operator with $\mu h \ge 1$ can be reduced to this one.

Then in our decompositions $j \le \bar{\jmath}$. Without any loss of the generality one can assume that

$$V + (2\bar{\jmath} + 3)\mu h \ge \epsilon_0 \tag{13.7.86}_1$$

and

$$V + (2\bar{\jmath} - 1)\mu h \le -\epsilon_0 \tag{13.7.86}_2$$

in $B(0,1)$ (otherwise we can arrange this by an ϵ-partition of unity).

If $\bar{\jmath} \ge 2$ then the contribution of terms with $j = 0, \dots, \bar{\jmath} - 1$ can be estimated according to the above results. One can easily see that only trajectories with $j = \bar{\jmath} - 1$ need to be treated.

Let us consider the contribution of $j = \bar{\jmath}$ and for the sake of simplicity in the following statements let us assume that $\bar{\jmath} = 1$. Moreover, let us assume that

$$|D^\alpha V_{\bar{\jmath}}| \le c\nu \qquad \forall \alpha : |\alpha| \le K \tag{13.7.87}$$

and

$$|V_{\bar{\jmath}}| + |\nabla V_{\bar{\jmath}}| \ge \epsilon_0 \nu \tag{13.7.88}$$

with $\nu \ge h^2$, $V_j = V + (2j+1)\mu h F$. Then in order to improve the results of Section 13.5 one should treat the trajectories of the system

$$\frac{dx_i}{dt} = \frac{1}{F\sqrt{\nu}}(-V_{\bar{\jmath}})^{\frac{1}{2}} F^i \qquad (i = 1,2,3). \tag{13.7.32}^{IV}$$

One should assume that $\zeta_i^{-1} = T_i \le {h'}^{-\delta'}$ with $h' = \left(h/\sqrt{\nu}\right)$ and that along these trajectories all the conditions (13.7.38), (13.7.43), $(13.7.41)'$, $(13.7.42)'$,

$$|D^\alpha V_{\bar{\jmath}}| \le c\nu\zeta^{-l}, \tag{13.7.38}'_3$$

and

$$V_{\bar{\jmath}} \ge \epsilon_0 \zeta^l \tag{13.7.65}'$$

are fulfilled.

Proposition 13.7.29. *(i) Under all these assumptions estimate*

$$\mathsf{R}^{\mathsf{MW}} \le \sum_{0\le i\le n} Ch^{-2}T_i^{-1}\,\mathsf{mes}(\Xi_i) + C'h^{-2}h'^{s} \tag{13.7.78}'$$

holds.

(ii) Under all these assumptions with $\nu = 1$, $\mu h \ge 1$ for Schrödinger-Pauli operator (with properly modified main part) estimate

$$\mathsf{R}^{\mathsf{MW}} \le \sum_{0\le i\le n} C\mu h^{-1}T_i^{-1}\,\mathsf{mes}(\Xi_i) + C'\mu h^{s} \tag{13.7.78}''$$

holds.

Proof. We leave details of the proof and the possible corollaries and generalizations to the reader. □

13.7.3 Supersharp Estimates as $d = 3$

Framework

Now instead of escape conditions we assume that all trajectories of $\Psi_{r,t}$ are trapped either because all magnetic lines are periodic or by the growing potential. We discuss only the latter case but the former could be analyzed in the same way. Idea is that magnetic lines drift with a speed $O(\mu^{-1})$ and because of this drift we can increase T^* from $\asymp 1$ to $\asymp \mu$.

So, let us consider coordinate system in which $F^1 = F^2 = 0$, $F^3 \ne 0$ and

$$\frac{V}{F} > 0 \qquad \text{as } |x'| < 1,\ |x_3| \ge C_0 \tag{13.7.89}$$

where $x' = (x_1, x_2)$.

Then V/F reaches its minimum $z^0(x')$ with respect to x_3 at $[-C_0, C_0]$; we assume that this minimum is unique and non-degenerate we also assume that it is unique and moreover

$$\epsilon_0 \le \big(x_3 - z^0(x')\big)^{-1}\partial_{x_3}\frac{V}{F} \le C_0. \tag{13.7.90}$$

We also assume first that $|\nabla(V/F)| \ge \epsilon$. Then we can extend time $T_* = h^{1-\delta}$ to $T^* = \epsilon$ but now we will try to go beyond using canonical form. First, we

have a fast magnetron movement in (x_3, ξ_3), then an oscillatory movement in (x_2, ξ_2) and finally a slow magnetic drift movement in (x_1, ξ_1).

Let us denote by $T(x, r)$ the oscillation time with respect to (x_2, ξ_2) on energy level 0. Then the drift velocity is $\mu^{-1}\nabla_1^{\#}(b_0 + b_1 r)$ with $b_0 = V \circ \bar{\Psi}$, $b_1 = F \circ \bar{\Psi}$ where $\nabla_1^{\#}$ means that we consider Hamiltonian field only with respect to (x_1, ξ_1).

Therefore (x_1, ξ_1)-shift will be

$$\mu^{-1} \int_0^{T(x_1,\xi_1,r)} \nabla_1^{\#}(b_0 + b_1 r)\, dt = \mu^{-1} \int_{z^-}^{z^+} \frac{\nabla_1^{\#}(b_0 + b_1 r)}{\sqrt{-b_0 - b_1 r}}\, dx_2 \tag{13.7.91}$$

which in turn is equal to $-2\mu^{-1}\nabla_1^{\#}\eta + O(\mu^{-2})$ with

$$\eta(x_1, \xi_1, r) = \int_{z^-}^{z^+} \bigl(-b_0 - b_1 r\bigr)^{\frac{1}{2}}\, dx_2 \tag{13.7.92}$$

where $z^{\pm} = z^{\pm}(x_1, \xi_1, r)$ are roots of

$$b_0(x_1, \xi_1, z) + b_1(x_1, \xi_1, z) r = 0, \tag{13.7.93}$$

$z^- < z^0 < z^+$, and

(13.7.94) We use the same notation for functions of (x_1, ξ_1) and for functions of $x' = (x_1, x_2)$ as $(x_1, x_2) = \bar{\Psi}(x_1, \xi_1)$;

$$r \le \bar{r}(x_1, \xi_1) = -\frac{b_0}{b_1}(x_1, \xi_1, z^0(x_1, \xi_1)) \tag{13.7.95}$$

and

$$T(x_1, \xi_1, r) = \int_{z^-}^{z^+} \frac{dx_2}{\sqrt{-b_0 - b_1 r}} \tag{13.7.96}$$

is a period of oscillations. Note that due to (13.7.90)

(13.7.97) $|\nabla_1^{\#}\eta| \asymp 1$ as $z^{\pm}$ are close to $z^0(x_1, \xi_1)$

and therefore shift is observable: $\mu^{-1} \gg \mu^{-1}h$. The same is true for any r provided $|\nabla\eta| \asymp 1$ for all $r \le \bar{r}(x_1, \xi_1)$.

Note that we can rewrite this condition

$$|\nabla_{x'}\eta(x', r)| \ge \epsilon_0 \qquad \forall x', r \le \bar{r}(x') \tag{13.7.98}$$

with

$$\eta(x',r)=\int_{\ell(x')}\bigl(-V-Fr\bigr)^{\frac12}\,ds \tag{13.7.99}$$

where x' coordinates on the surface transversal to magnetic lines and ds is an element of length along such lines where $\ell(x',r)$ indicates the segment of the magnetic line $\Phi_t(x')$ where $V+rF<0$. Our "new" η is connected with "old" η in the obvious way.

Therefore $T^*\asymp 1$ is upgraded to $T^*\asymp \mu$.

Case $\mu h\le 1$

The fact that the standard under condition (13.7.101) below $T^*\asymp 1$ can be replaced by $T^*\asymp\mu$ without adding new singularities implies that the standard remainder estimate $\mathsf{R}^{\mathsf{T}}\le Ch^{-2}$ and $\mathsf{R}^{\mathsf{MW}}_{\infty}\le Ch^{-2}$ could be upgraded to $\mathsf{R}^{\mathsf{T}}\le C\mu^{-1}h^{-2}$ and $\mathsf{R}^{\mathsf{MW}}_{\infty}\le C\mu^{-1}h^{-2}$ respectively as $\mu h\le 1$. So we arrive to

Theorem 13.7.30. *Let conditions* (13.2.1)–(13.2.5), (13.3.1), (13.4.46) *and* (13.4.54) *be fulfilled.*

Further, let conditions (13.7.89), (13.7.90) *and* (13.7.98) *be fulfilled. Finally let non-degeneracy condition*

$$|\nabla\bigl(\frac{V}{F}\bigr)|\le\epsilon \implies |\det \mathsf{Hess}\bigl(\frac{V}{F}\bigr)|\ge\epsilon \tag{13.7.100}$$

be fulfilled. Then as $\mu h\le 1$ estimate

$$\mathsf{R}^{\mathsf{MW}}\le C\mu^{-1}h^{-2} \tag{13.7.101}$$

holds.

Proof. We leave to the reader an easy exercise to prove that all extra terms in $\mathsf{R}^{\mathsf{MW}}_{\infty}$ could be dropped so $\mathsf{R}^{\mathsf{MW}}_{\infty}$ becomes R^{MW}. □

This theorem is illustrated by Example 13.7.34(i) below. On the other hand, assume that η has a critical point. Let us introduce γ-admissible partition of unity with respect to (x_1,ξ_1) with

$$\gamma=\gamma(x_1,\xi_1,r)\coloneqq \mathsf{max}\bigl(\epsilon|\nabla\eta|, C\bar\gamma\bigr). \tag{13.7.102}$$

Then the shift during period is of magnitude $\mu^{-1}\gamma$ and uncertainty principle requires $\mu^{-1}\gamma\times\gamma\asymp\mu^{-1}h$ or $\gamma\asymp h^{\frac12}$. Therefore selecting $\bar\gamma = h^{\frac12-\delta}$ we conclude that the contribution of the zone $\{\gamma\ge\bar\gamma\}$ to R^{MW} does not exceed $C\mu^{-1}h^{-2}$. Meanwhile contribution of the zone $\{\gamma\le\bar\gamma\}$ does not exceed $Ch^{-2}\,\mathsf{mes}(\{x:\ |\nabla\eta(x)|\le\bar\gamma\})$ which is $Ch^{-2}\bar\gamma^2$ under assumption (13.7.107) below. Then we arrive to the remainder estimate

$$\mathsf{R}^{\mathsf{MW}}\le C\mu^{-1}h^{-2}+Ch^{\delta-1} \tag{13.7.103}$$

with an arbitrarily small exponent $\delta>0$.

One can improve it by using logarithmic uncertainty principle; then we can select $\bar\gamma = C(h|\log h|)^{\frac12}$ leading us to the remainder estimate

$$\mathsf{R}^{\mathsf{MW}}\le C\mu^{-1}h^{-2}+Ch^{-1}|\log h| \tag{13.7.104}$$

However we can do better than this. Let us select $\bar\gamma = Ch^{\frac12}$. The following problem is easily accessible by our methods and we leave it to the reader:

Problem 13.7.31. (i) Prove that as $Q'=Q'(x_1,\mu^{-1}hD_1,j)$, $Q''=Q''(x_1,\mu^{-1}hD_1,j)$ are γ-admissible elements with $\gamma\ge C_0\bar\gamma$ then

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma Q'_{x'}\mathsf{U}_{j,j}\,{}^tQ''_y|\le C\mu h^{-1}\gamma^2\,T\big(\frac{\bar\gamma}{T\gamma}\big)^s\Big) \tag{13.7.105}$$

(ii) Then prove that the contribution of γ-element to R^{T} with $T=\epsilon$ does not exceed

$$Ch^{-2}\gamma^2\Big(\mu^{-1}+\big(\frac{\bar\gamma}{\gamma}\big)^s\Big). \tag{13.7.106}$$

Then we arrive to the following

Theorem 13.7.32. *Let all conditions of Theorem 13.7.30 except* (13.7.98) *be fulfilled. Then under condition*

$$|\nabla_{x'}\eta(x',r)|\le\epsilon\implies|\det\mathsf{Hess}_{x'}\,\eta(x',r)|\ge\epsilon\qquad\forall x',r\le\bar r(x') \tag{13.7.107}$$

as $\mu h\le 1$ *estimate* (13.7.101) *holds.*

Remark 13.7.33. (i) As $\epsilon_0h^{-1}\le\mu\le h^{-1}$ we need to check conditions (13.7.98), (13.7.107) only $r=(2j+1)\mu h$; also condition (13.7.100) should be checked only as $|V-(2j+1)\mu hF|\le\epsilon$.

(ii) Estimate $o(h^{-2})$ holds for $\mu h \le 1$ under weak non-degeneracy condition

$$\mathsf{mes}(\{x' : \nabla\eta(x', r) = 0\}) = 0 \qquad \text{as} \quad r = (2j+1)\mu h \quad \forall j. \tag{13.7.108}$$

(iii) Estimate $O\big(\mu^{-1}h^{-2} + h^{-\frac{3}{2}}\big)$ holds for $\mu h \le 1$ under intermediate non-degeneracy condition

$$|\nabla_{x'}\eta(x', r)| \le \epsilon \implies |\mathsf{Hess}_{x'}\,\eta(x', r)| \ge \epsilon \qquad \forall x', r = (2j+1)\mu h, j \in \mathbb{Z}^+. \tag{13.7.109}$$

Example 13.7.34. Consider

$$a = (\xi_1 - \frac{1}{2}\mu x_2)^2 + (\xi_2 + \frac{1}{2}\mu x_1)^2 + V(x). \tag{13.7.110}$$

(i) As

$$V = k^2x_3^2 + lx_1 - \tau \qquad (\tau > 0) \tag{13.7.111}$$

$k > 0$ ensures trapping and $l \ne 0$ ensures condition (13.7.98).

(ii) As

$$V = k^2x_3^2 + m_1x_1^2 + m_2x_2^2 - \tau \qquad (\tau > 0) \tag{13.7.112}$$

$k > 0$ ensures trapping and $l_1 \ne 0$, $l_2 \ne 0$ ensures condition (13.7.107).

(iii) In (ii) assume that $m_1 = m_2 = l^2 > 0$; then we have at least two oscillatory movements (with respect to (x_2, ξ_2) and slow oscillatory drift movement with respect to (x_1, ξ_1)). Then we can increase T^* to $T^* \gg \mu$ and under appropriate non-commensurability condition we can get remainder estimate $o(\mu^{-1}h^{-2})$ instead of $O(\mu^{-1}h^{-2})$.

As $\mu h \to 0$ the third periodic movement (with respect to (x_3, ξ_3) in the canonical form) plays role and non-commensurability means that at least one of two commensurability conditions should be violated. This is fulfilled automatically for non-commensurable k and l while for commensurable k and l we get one non-commensurability condition to μ. Then we get remainder estimate $o(\mu^{-1}h^{-2})$ instead of $O(\mu^{-1}h^{-2})$.

(iv) Let

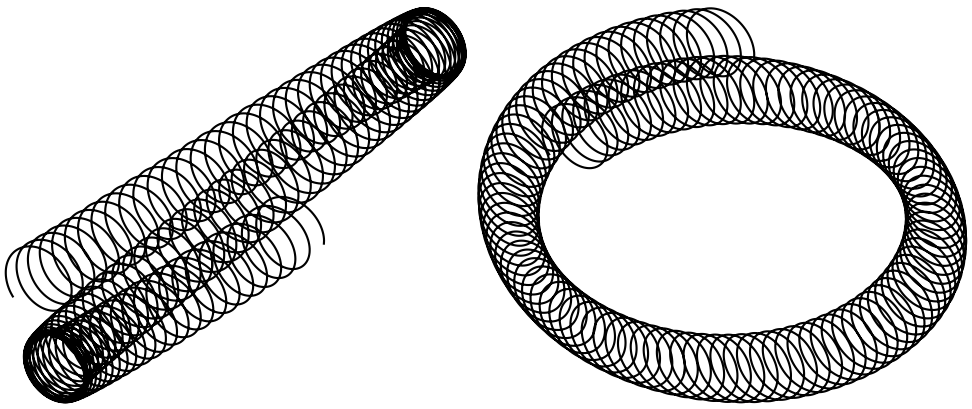
$$V = k^2 x_3^2 - \tau \qquad (\tau > 0). \tag{13.7.113}$$

Then there is no drift but while fast rotations have frequency 2μ, normal oscillation have frequency $2k$ and unless they are commensurable we get non-periodic movement and as $\mu h \to 0$ we get remainder estimate $o(h^{-2})$ under appropriate assumption to μ as $\mu h \to +0$.

Problem 13.7.35. (i) Investigate case when potential traps only trajectories with $r \ge \bar{r}$ and other trajectories escape. One should expect remainder estimate $\mathsf{R}^{\mathsf{MW}} = o(h^{-2})$.

(ii) Investigate the case when all magnetic lines are periodic and V/F is constant along them.

(iii) Investigate the case when all magnetic lines are periodic and V/F is not constant along them (then trajectories of $\Psi_{r,t}$ with $r \ge \bar{r}$ are trapped and other trajectories are periodic).



(a) Oscillation and drift (b) Periodic and drift

Figure 13.6: Trajectories for 3-dimensional model operator:
(a) Operator (13.7.110)–(13.7.111) (b) Operator (13.7.114)

Example 13.7.36.

$$a = \xi_1^2 + \xi_2^2 + (\xi_3 - \mu\alpha(|x'|))^2 + w(|x'|) - \tau \tag{13.7.114}$$

Then $\boldsymbol{F} = (-x_2, x_1, 0) f(|x'|)|x'|^{-1}$, $F = f(|x'|)$, $f(\rho) = \partial_\rho \alpha > 0$ and and all magnetic lines are circles.

(i) Then drift speed is $\partial_\rho \eta(\rho)$ with $\eta = (-w(\rho) - r|f(\rho)|)$ and it is directed along x_3. Then under appropriate assumptions ensuring (13.7.98) or (13.7.100) one can derive corresponding asymptotics.

(ii) As $w(\rho) = -\tau$ and $f(\rho) = \mathsf{const}$ there is no drift and again one can derive asymptotics $o(h^{-2})$ under non-commensurability condition as $\mu h \to 0$.

Schrödinger-Pauli Operator as $\mu h \ge 1$

Consider now Schrödinger-Pauli operator (13.6.3) as $\mu h \ge 1$. We assume that modified condition (13.7.100)

$$\min_j |\frac{V}{F} - 2j\mu h| + |\nabla(\frac{V}{F})| \le \epsilon \implies |\det \mathsf{Hess}(\frac{V}{F})| \ge \epsilon \tag{13.7.100)$'}$$

is fulfilled. Then exactly the same arguments as in the proofs of Theorems 13.7.30 and 13.7.32 lead us to the following theorem:

Theorem 13.7.37. *Consider Schrödinger-Pauli operator* (13.6.3) *with* $\mu h \ge 1$. *Let conditions* (13.2.1)–(13.2.5), (13.3.1), (13.4.46) *and* (13.4.54) *be fulfilled.*

Further, let conditions (13.7.89), (13.7.90) *and* (13.7.100)$'$ *be fulfilled. Then*

(i) Under assumption

$$|\nabla_{x'} \eta(x', r)| \ge \epsilon_0 \qquad \forall x', r \le \bar{r}(x') \qquad \forall x', r = 2j\mu h,\ j \in \mathbb{Z}^+ \tag{13.7.98)$'}$$

estimate

$$\mathsf{R}_1^{\mathsf{MW}} \le Ch^{-1} + C'_s \mu h^s \tag{13.7.115}$$

where $\mathsf{R}_1^{\mathsf{MW}}$ *is due to the perturbation term* $\asymp h^2$ *in the canonical form*[46)].

[46)] See Remark 13.6.13(ii). We should not care about this before as the sharpest remainder estimate was $O(\mu h^{-1+\delta})$.

(ii) Estimate

$$\mathsf{R}^{\mathsf{MW}} \le C\mu \tag{13.7.116}$$

holds under condition

$$|\nabla_{x'}\eta(x',r)| \le \epsilon \implies |\det \mathsf{Hess}_{x'}\,\eta(x',r)| \ge \epsilon \qquad \forall x', r = 2j\mu h,\ j \in \mathbb{Z}^+ \tag{13.7.107}'$$

Proof. We leave easy details to the reader. □

Remark 13.7.38. (i) Estimate $\mathsf{R}^{\mathsf{MW}} = o(\mu h^{-1})$ holds under weak non-degeneracy condition

$$\mathsf{mes}(\{x' : \nabla\eta(x',r) = 0\}) = 0 \qquad \text{as} \quad r = 2j\mu h \ \ \forall j. \tag{13.7.108}'$$

(ii) Estimate $\mathsf{R}^{\mathsf{MW}} = O(\mu h^{-\frac{1}{2}})$ holds under intermediate non-degeneracy condition

$$|\nabla_{x'}\eta(x',r)| \le \epsilon \implies |\mathsf{Hess}_{x'}\,\eta(x',r)| \ge \epsilon \qquad \forall x', r = 2j\mu h, j \in \mathbb{Z}^+. \tag{13.7.109}'$$

Schrödinger-Pauli Operator as $\mu h \ge 1$ reloaded

While most likely one can improve (13.7.115) to

$$\mathsf{R}^{\mathsf{MW}}_1 \le Ch^{-1} + C'\mu \exp(\epsilon h^{-1}) \tag{13.7.117}$$

we still want to improve it and (13.7.116) further. To do this we consider operator in the reduced form; as $\mu h \ge C$ we need to consider only operator $\mathcal{A}_0(x_1, \hbar D_1; x_2, hD_2)$ with $\hbar = \mu^{-1}h$ and we consider it as $\hbar$-pseudodifferential operator with an operator-valued symbol $\boldsymbol{a}(x_1, \xi_1; x_2, hD_2)$ acting in the axillary space $\mathbb{H} = \mathscr{L}(\mathbb{R}_{x_2})$. Then under condition (13.7.98) it is microhyperbolic which leads us to Statements (i) and (ii) of the following theorem:

Theorem 13.7.39. *(i) Let conditions of Theorem 13.7.37(i) be fulfilled. Then as $h \in (\mu^{-1}, h_0)$ where h_0 is small enough constant*

$$\mathsf{R}^{\mathsf{MW}}_2 := \Bigl|\int \Bigl(e(x,x,0) - (2\pi)^{-1}\mu h^{-1}\boldsymbol{e}(x_1,x_2;x_3,x_3;0)\Bigr)\psi(x)\,dx\Bigr| \le Ch^{-1} \tag{13.7.118}$$

where $\mathbf{e}(x';x_3,y_3;\tau)$ *is the Schwartz kernel of the spectral projector* $\mathbf{e}(x';\tau)$ *of operator* $\mathbf{a}(x')=\mathbf{a}(x_1,x_2;x_3,hD_3)$ *and as usual we identify objects depending on* x *and on* (x_1,ξ_1,x_2) *through* $\bar{\Psi}$.

(ii) In particular, for $\psi=\psi(x')$

$$\mathsf{R}_2^{\mathsf{MW}}=|\int\Big(\int e(x,x,0)\,dx_3-(2\pi)^{-1}\mu h^{-1}\mathbf{n}(x_1,x_2;0)\Big)\psi(x')\,dx'| \tag{13.7.119}$$

where $\mathbf{n}(x';\tau)=\mathsf{Tr}_{x_3}\,\mathbf{e}(x';\tau)$ *is an eigenvalue counting function of operator* $\mathbf{a}(x')$.

Proof. Proof is standard: as the propagation speed with respect to (x_1,ξ_1) is $\asymp\mu^{-1}$ we can take $T^*\asymp\mu$ and $T_*\asymp\mu^{\delta}h$ with an arbitrarily small exponent $\delta>0$ and then we can launch successive approximations with unperturbed operator frozen as $x_1=y_1$; then $(x_1-y_1)=O(\mu^{-1}T_*)$.

We leave easy details to the reader. Note only that we need $h\in(\mu^{-1},h_0)$ because actually $\eta=\eta(x_1,\xi_1,h)$ and to have $|\nabla\eta|\asymp 1$ we need the above assumption. □

Assume now that condition (13.7.107) is fulfilled instead.

Theorem 13.7.40. *Let conditions of Theorem 13.7.37(ii) be fulfilled. Let* $h\in(\mu^{-1},h_0)$. *Then estimate*

$$\mathsf{R}_2^{\mathsf{MW}}\le Ch^{-1}|\log\mu| \tag{13.7.120}$$

with an arbitrarily small exponent holds.

Proof. Proof is standard. Consider $\eta=\eta(x_1,\xi_1,h)$ which as $h\in(\mu^{-1},h_0)$ has non-degenerate critical point.

Then propagation speed with respect to (x_1,ξ_1) speed is $\asymp\mu^{-1}\gamma$ we can take $T^*\asymp\mu$ and $T_*\asymp|\log\mu|h/\gamma^2$ and then we can launch successive approximations with unperturbed operator frozen as $x_1=y_1$; then $(x_1-y_1)=O(\mu^{-1}\gamma T_*)$. Here we must assume that $\gamma\ge\bar{\gamma}=\mu^{-\frac{1}{2}}|\log\mu|$ and contribution to the remainder of the zone $\{\gamma\le\bar{\gamma}\}$ does not exceed $C\mu h^{-1}\bar{\gamma}^2$.

We leave easy details to the reader. □

Example 13.7.41. (i) Example 13.7.34(i) and (ii) illustrates Theorems 13.7.39 and 13.7.40.

(ii) In particular, consider Example 13.7.34(ii). Then (as $\psi = 1$) the number of eigenvalues below 0 equals to the number of the lattice points $\{(2i+1)l\mu^{-1}h, (2j+1)kh\}$ in the triangle $\{z_1 \ge 0, z_2 \ge 0, z+1+z_2 < \tau\}$. Transition to "Weyl" expression with respect to (x_1, ξ_1) means that we replace summation with respect to i by integration thus making an error $O(1)$ for each j and the total error $O(h^{-1})$, resulting in the expression $\mathsf{const} \cdot \mu h^{-1} \sum_j \big(\tau - (2j+1)h\big)_+$.

13.8 Certain gGeneralizations

In this section we discuss what happens to the results of the previous sections (Sections 13.4–13.7) in the case in which condition "$V \le -\epsilon$" is violated.

We also consider the case when one of the conditions "$F \ge \epsilon_0$" and "$B(0,1) \subset X$" is violated but, at least as $d = 2$ our results here are far from optimal and are preliminary. Much more delicate analysis of the next Chapters 14 and 15 will lead to much more sharp results.

We also discuss the Weyl asymptotics following from the non-Weyl asymptotics of Sections 13.5 and 13.7.

13.8.1 Getting Rid of the Condition "$v \le -\epsilon$"

Let us treat the case in which condition "$v \le -\epsilon$" is violated. Recall that $v = V/F$.

Formal Rescaling

Until further notice we assume that

$$\nu = 1. \tag{13.8.1}$$

Remark 13.8.1. (i) Recall that in the case of a weak magnetic field we need this condition (13.4.45) only to calculate $F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t)\psi U\big)$ as $T \in [h^{1-\delta}, \epsilon\mu^{-1}]$. However the same result could be achieved under assumption

$$|v| + |\nabla v| \ge \epsilon_0. \tag{13.8.2}$$

(ii) In the case of the moderate magnetic field this condition was needed only to reference to the case of weak magnetic field.

(iii) In the case of the strong magnetic field such comparison was not needed and thus even assumption (13.8.2) was not needed.

Consider *formal rescaling technique* applied to estimate $\mu^{-\sigma}h^{1-d+\vartheta}$. As we rescale $x \mapsto x/\gamma$ and divide by ρ^2 i.e. $\xi \mapsto \xi/\rho$ we have $h \mapsto h/(\rho\gamma)$ and $\mu \mapsto \mu\gamma/\rho$ and therefore we estimate contribution of $B(x,\gamma(x))$ to the remainder by

$$C\Big(\frac{\mu\gamma}{\rho}\Big)^{-\sigma}\Big(\frac{h}{\gamma\rho}\Big)^{1-d+\vartheta} = C\mu^{-\sigma}h^{1-d+\vartheta}\gamma^{d}\times\gamma^{-1-\vartheta-\sigma}\rho^{\sigma-1+d+\vartheta} \tag{13.8.3}$$

and as $\rho=\gamma$ the second factor in the right-hand expression is $\gamma^{d-2}\le 1$.

This means that taking

$$\gamma=\rho=\max\big(\epsilon(|v|+|\nabla v|^2)^{\frac12}\bar\gamma\big), \tag{13.8.4}$$

which instantly allows us to drop condition (13.8.2). Here we take

$$\bar\gamma=(\mu h)^{\frac12} \tag{13.8.5}$$

as $\mu h\mapsto \mu h/\gamma^2$ and as $\gamma=\bar\gamma$ we get $\mu h\mapsto 1$.

We could even start rescaling from

$$\gamma=\rho^2=\max\big(\epsilon|v|,\bar\gamma\big), \tag{13.8.6}$$

with $\bar\gamma$ defined by (13.8.5) but then the second factor in the right-hand expression of (13.8.3) would be $\gamma^{\frac12(d-3-\sigma-\vartheta)}$ and after integration with respect to x under condition (13.8.2) we would get $O(1)$ as $d>1+\sigma+\vartheta$; so as $d=3$, $\vartheta=0$, $\sigma\le 1$ everything would be fine. Then rescaling again with γ defined by (13.8.4) we would drop condition (13.8.3).

Justification: $d=3$

Consider $d=3$. Then

(13.8.7) We need no justification for the results of Sections 13.4 and 13.5 with $\mu\le h^{\delta-1}$ as $\vartheta=0$ and with $\mu\le h^{-1}$ as $\vartheta>0$.

Really, in this cases estimate $O(h^{-2+\vartheta})$ was proven under no non-degeneracy conditions.

(13.8.8) We need no justification for the results of Section 13.5 with $\mu \in [h^{\delta-1}, 1]$ as $\vartheta = 0$.

Really, in this case we do not need to compare with weak magnetic field at all: removing $O(\mu^{-2})$ terms in the argument of $\mathcal{N}^{\mathsf{MW}}$ leads to the error not exceeding

$$C\big(\mu^{-2}h^{-3} + \mu^{-1} \times \mu h^{-2}\big) \tag{13.8.9}$$

which does not exceed Ch^{-2} as $\mu \ge h^{-\frac{1}{2}}$; this error estimate does not require any additional assumption. So, for $\vartheta = 0$ condition "$|v| \asymp 1$" was needed only for $\mu \le h^{-\frac{1}{2}}$.

Furthermore, as contribution of zone $\{x, \gamma < \varepsilon\}$ to the remainder according to formal scaling does not exceed $C\varepsilon = o(1)$ we conclude that

(13.8.10) Remainder estimate $o(h^{-2})$ remains true for R^{T} or $\mathsf{R}^{\mathsf{MW}}_1$. Further, under non-degeneracy condition $(13.4.57)_m$ remainder estimate $o(h^{-2})$ remains true for R^{T} or $\mathsf{R}^{\mathsf{MW}}_1$.

Finally, consider supersharp results of Subsection 13.7.3. As $\gamma \ge C\bar{\gamma}$ with

$$\bar{\gamma} := (\mu h)^{\frac{1}{2}-\delta'} \tag{13.8.11}$$

now, consider two cases

(a) $|\nabla v| \gtrsim \gamma$ on element in question. Then after rescaling $|\nabla v| \asymp 1$ and we can apply weak magnetic field approach as $\mu_{\mathsf{new}} =\le h_{\mathsf{new}}^{\delta''-1}$. Recall that $\mu_{\mathsf{new}} = \mu$ and $h_{\mathsf{new}} = h\gamma^{-2}$ we rewrite this condition as $\gamma \ge \bar{\gamma}$ with $\bar{\gamma}$ defined by (13.8.11) and $\mu \le h^{1-\delta}$.

(b) $|v| \gtrsim \gamma^2$ and $|\nabla v| \le \epsilon\gamma$ on element in question. Then after rescaling $|v| \asymp 1$, $\nabla v| \le C_0\epsilon$ and elements of $\mathsf{Hess}\, v$ are preserved. So condition (13.7.100) survives. Applying weak magnetic field approach we conclude that contribution of this particular element to the remainder does not exceed

$$C\mu_{\mathsf{new}}^{-1}h_{\mathsf{new}}^{-2} + C\mu_{\mathsf{new}}(\mu_{\mathsf{new}}h_{\mathsf{new}})^2 h_{\mathsf{new}}^{-2-\delta} = C\mu^{-1}h^{-2}\gamma^4 + C\mu^3 h^{-\delta}\gamma^{2\delta}.$$

dividing by γ^3 and integrating and using (13.7.100) again we conclude that the total error does not exceed $C\mu^{-1}h^{-2} + C\mu^3 h^{-\delta}$ and the second term

does not exceed the first one provided $\mu \le h^{\delta-\frac{1}{2}}$. So, in this case our dream estimate is proven.

Let us apply a moderate magnetic field approach as $\mu \ge h^{\delta-\frac{1}{2}}$. Note that removing $O(\mu^{-4}+h^2)$ terms in the argument of $\mathcal{N}^{\mathsf{MW}}$ leads to the error not exceeding $C(\mu^{-4}+h^2)h^{-3}$ due to (13.7.100) again and this does not exceed $C\mu^{-1}h^{-2}$ as $\mu \ge h^{-\frac{1}{3}}$. So the only term $O(\mu^{-2})$ in the argument of $\mathcal{N}^{\mathsf{MW}}$ should be treated separately.

But the same condition (13.7.100) implies that removing this term in the argument of $\mathcal{N}^{\mathsf{MW}}$ and in ψ (transformed, the latter error never exceeded the former one) and replacing the sum by an integral leads to correction term $C\kappa\mu^{-2}h^{-3}$ plus the same error as before plus $O(\mu^{-1}h^{-2})$ error. As zones $\mu \ge h^{-\frac{1}{3}}$ and $\mu \le h^{\delta-\frac{1}{2}}$ overlap we conclude that κ must be equal to 0 which implies that we can use unmodified $\mathcal{N}^{\mathsf{MW}}$ with $O(\mu^{-1}h^{-2})$ error.

We used the fact that extra analysis of Subsection 13.7.3 was needed to extend $|t| \le \epsilon$ to $|t| \le \epsilon\mu$ and did not use assumption (13.8.2) at all.

So, we arrive to

Theorem 13.8.2. *Let* $d = 3$ *(and not necessary* $\nu = 1$*). Then estimates for* R^{MW} *and* $\mathsf{R}^{\mathsf{MW}}_1$ *derived in Sections 13.4–13.7 remain true without condition "*$|v| \asymp 1$*"*[47]*.*

Justification: $d = 2$, $\nu = 1$

Consider case $d = 2$.

Theorem 13.8.3. *Let* $d = 2$*. Theorem 13.5.26 remains true without condition "*$|v| \asymp 1$*"*[47]*.*

Proof. (i) Let us introduce a function ρ by means of (13.8.4) with $\bar{\rho} = \epsilon_0\sqrt{\mu h}$ and let us make a ρ-admissible partition of unity, division and rescaling. We leave "γ" to denote function used in Theorem 13.5.26.

Let us treat various elements of this partition as in the previous subsubsection. Then

(a) Let $\rho \ge C\bar{\rho}$ and $|\nabla v| \ge \epsilon\rho$. Then after rescaling we get into the situation of "$|\nabla v| \asymp 1$" and the contribution to R^{MW} of this element does not exceed

[47] Or even condition (13.8.2).

$C\mu_{\mathsf{new}}^{-1}h_{\mathsf{new}}^{-1} = C\rho^2\mu^{-1}h^{-1}$ and the total contribution to R^{MW} of such elements does not exceed $C\mu^{-1}h^{-1}$.

(b) Let $\rho \ge C\bar{\rho}$ and $-v \ge \epsilon\rho^2$. Then after rescaling we get into the situation of Theorem 13.5.26. Let us treat various subvariants:

(b)$_1$ Let $\mu^{\frac{3}{2}}h^{\frac{1}{2}} \le C_0\gamma$. Then we get into the situation of Theorem 13.5.26(i). Substituting $\mu_{\mathsf{new}} = \mu$, $h_{\mathsf{new}} = h\rho^{-2}$ and $\gamma_{\mathsf{new}} = \gamma\rho^{-1}$ in place of μ, h, γ in (13.5.107) we obtain that the contribution to R^{MW} of this element does not exceed

$$C\rho^2\mu^{-1}h^{-1} + C'\mu^{-1}h^{-1}\int_{\{\gamma\ge C_0\mu^{-1}\rho\}}\bigl(\frac{\mu h}{\gamma^2}\bigr)^s\gamma^{-2}\,dx+ C\mu h^{-1}\int_{\{\gamma\le C_0\mu^{-1}\rho\}} dx \tag{13.8.12}$$

where we have taken into account that $dx_{\mathsf{new}} = \rho^{-2}dx$ and where here and in what follows we integrate only over one element of the covering if we discuss a separate element of the partition (we do not indicate this in what follows).

Obviously this expression (13.8.12) does not decrease if the domains in the second and third terms are replaced by $\{\gamma \ge C_0\mu^{-1}\}$ and $\{\gamma \le C_0\mu^{-1}\}$ respectively. Then the total contribution of such elements of the partition does not exceed the right-hand expression of (13.5.107).

(b)$_2$ Let $\mu^{\frac{3}{2}}h^{\frac{1}{2}} \ge C_0\rho$. Then we get into the situation of Theorem 13.5.23(ii). According to (13.5.110) the contribution to R^{MW} of such an element does not exceed

$$C\rho^2\mu^{-1}h^{-1} + C'\mu^{-1}h^{-1}\int_{\{\gamma\ge\sqrt{\mu h}\}}\bigl(\frac{\mu h}{\gamma^2}\bigr)^s\gamma^{-2}\,dx+ C\mu^{-1}h^{-1}\int_{\{\sqrt{\mu h}\ge\gamma\ge C_1\mu^{-1}\rho, |v+(2j+1)\mu h|\le\epsilon_2\mu h\}}\gamma^{-2}\,dx+ C\mu h^{-1}\int_{\{\gamma\le C_1\mu^{-1}\rho\}} dx. \tag{13.8.13}$$

If $\mu^{\frac{3}{2}}h^{\frac{1}{2}} \ge C_0$ here then expression (13.8.13) does not decrease if in the restrictions on γ from below in the third term and in the restrictions on γ from above in the fourth term we replace ρ by 1; then summing with respect to the partition of unity we obtain that the total contribution of all such terms does not exceed the right-hand expression of (13.5.110).

On the other hand, if $\mu^{\frac{3}{2}}h^{\frac{1}{2}} \le C_0$ then expression (13.8.13) does not decrease if we replace the domain of integration in the second term by $\{\gamma \ge C_0\mu^{-1}\}$ and we replace the integral over the remaining part of the original domain and two other integrals (in the third and fourth terms) by

$$C\mu h^{-1}\int_{\{\gamma\le C_0\mu^{-1}\}} dx.$$

Then the total contribution of all such terms does not exceed the right-hand expression of (13.5.107).

(c) Finally, Theorem 13.2.9 yields that the contribution of the zone $\{\rho \le 2\bar\rho\}$ does not exceed $C'h'^s\bar\rho^{-2}$. Therefore Statement (i) of Theorem 13.5.26 has been proven (without condition (13.4.45)) [47].

(ii) Let us now assume that condition (13.5.73) is fulfilled. Then without any loss of the generality we can assume that $v = \pm x_1^2 + w(x_2)$. Let us introduce function $\rho'(x_2)$ by formula (13.8.4) with v replaced by w.

Then applying a $\frac{1}{2}|x_1|$-admissible partition of unity and referring to the case "$|\nabla v| \asymp 1$" we obtain that

(13.8.14) The contribution to R^{MW} of the zone $\{|x_1| \ge \frac{1}{2}C_0\rho'\}$ does not exceed $C\mu^{-1}h^{-1} + C'$.

Let us consider zone $\{|x_1| \le C_0\rho'\}$ and ρ'-admissible partition of unity there. Then repeating the previous arguments and referring to Theorem 13.5.26 we obtain that the contribution to R^{MW} of the separate element does not exceed

$$(13.8.15)_{1,2} \qquad C\rho'^2\mu^{-1}h^{-1} + C\mu^{\frac{3}{2}}h^{-\frac{1}{2}}\rho' \qquad \text{or} \qquad C'\rho'^2h^{-1}$$

respectively for $\rho' \ge \mu^{\frac{3}{2}}h^{\frac{1}{2}}$ or $\rho' \le \mu^{\frac{3}{2}}h^{\frac{1}{2}}$.

Note that if $\mu^{\frac{3}{2}}h^{\frac{1}{2}} \le 1$ then elements of both types can occur and one can easily see that the total contribution does not exceed the right-hand expression of (13.5.108).

On the other hand, if $\mu^{\frac{3}{2}}h^{\frac{1}{2}} \ge 1$ then only elements of the second type can occur and one can easily see that the total contribution does not exceed the right-hand expression of (13.5.111).

Therefore Statement (ii) of Theorem 13.5.26 has been proven without condition (13.4.45) [47].

(iii) Let us now assume that condition (13.5.109) is fulfilled. Without any loss of the generality one can assume that $x = 0$ is the unique critical point of v. Let us set

$$r = \begin{cases} (-v(0))^{\frac{1}{2}} & \text{as} \quad v(0) \le -\epsilon_0 \mu h, \\ (\epsilon_0 \mu h)^{\frac{1}{2}} & \text{as} \quad v(0) \ge -\epsilon_0 \mu h. \end{cases} \tag{13.8.16}$$

Then the previous arguments which refer to the case "$|\nabla v| \asymp 1$" give that the contribution to R^{MW} of the zone $\{|x| \ge \epsilon_0 r\}$ does not exceed $C\mu^{-1}h^{-1} + C'$.

Moreover, referring to Theorem 13.5.24 we conclude that

(13.8.17) If $v(0) \le -\epsilon_0 \mu h$ then contribution to R^{MW} of the zone $\{|x| \le 2\epsilon_0 r\}$ does not exceed $C\mu^{-1}h^{-1}$ provided either condition $(13.5.109)_+$ is fulfilled or $\mu^3 h \le r^2$.

Really, in the second case $\mu^3_{\mathsf{new}} h_{\mathsf{new}} \le 1$.

On the other hand, if condition $(13.5.109)_+$ is violated and $\mu^3 h \ge r^2$ then this contribution does not exceed $Cr^2\mu^{-1}h^{-1}(|\log \mu^3 h r^{-2}| + 1)$ again due to Theorem 13.5.26; this expression only increases if we replace r by $C_0 \min(\mu^{\frac{3}{2}} h^{\frac{1}{2}}, 1)$.

We then obtain that the contribution in question does not exceed $C\mu^{-1}h^{-1}$ for $\mu^3 h \le 1$ and $C\mu^{-1}h^{-1}(|\log \mu^3 h| + 1)$ for $\mu^3 h \ge 1$. Moreover, if condition $(13.5.109)_+$ is violated, $\mu^3 h \ge 1$ and

$$\hat{\lambda} = \min_j (|v(0) + (2j+1)\mu h| \ge \mu^{-2}$$

then estimate (13.5.112) yields that the indicated contribution does not exceed $Cr^2\mu^{-1}h^{-1}(|\log \hat{\lambda}\mu^{-1}h^{-1}| + 1)$ and the last expression is maximal for $r = 1$.

Finally for $v(0) \ge -\epsilon_0 \mu h$ we can apply Theorem 13.2.9. In this case we obtain estimate $(13.5.89)_{(2)}$ provided either $\mu^3 h \le 1$ or condition $(13.5.109)_+$ is fulfilled and estimate (13.5.112) otherwise. □

Theorem 13.8.4. *Theorem 13.5.28 remains true without condition* (13.4.45) [47].

Proof. The arguments used in the proof of the previous proposition provide the estimate

$$\mathsf{R}^{\mathsf{MW}\prime} \le C\mu^{-1}h^{-1} + C|\log \frac{\hat\lambda}{\mu h}|$$

which does not coincide with estimate (13.5.119) only if $\mu h \ge |\log \frac{\hat\lambda}{\mu h}|^{-1}$ ($\ge |\log h|^{-1}$). So for $\mu \le h^{\delta-1}$ this proposition is proven.

In order to prove it for $\mu \in [h^{\delta-1}, h^{-1}]$ let us recall that we had the estimate

$$\mathsf{R}^{\mathsf{MW}}_{\infty} \le C\mu^{-1}h^{-1}$$

without condition (13.4.45) which appeared only when we replaced Riemann sums with integrals because we wanted to obtain a regular function as an integrand. However, if we apply the integral formula $(13.A.3)_1$ of the first order of accuracy we have no need of this condition. On the other hand, for $\mu \ge h^{-\frac12}$ we need only an integral formula of the first order of accuracy and therefore for $\mu \le h^{-\frac12}$ we obtained (13.5.119) without condition (13.4.45) from the beginning. □

We leave to the reader the proof of the following theorem:

Theorem 13.8.5. *Theorem 13.5.30 remains true without condition* (13.4.45) [47].

Summing all the achieved results we obtain

Theorem 13.8.6. *As* $d = 2$ *and* $\nu = 1$ *results of Sections 13.4–13.7 remain true without condition "*$|v| \asymp 1$*"* [47].

Justification: $d = 2$, $\nu < 1$

Let us note that one can assume that $\nu = 1$. As this is important only for $d = 2$ we consider $d = 2$ only. In fact, if $\nu < 1$ then one of the following conditions is fulfilled:

(a) $v \ge \epsilon\nu$ in $B(0,1)$;

(b) $v \le -\epsilon\nu$ in $B(0,1)$;

(c) $|v| \le c\nu$ in $B(0,1)$.

In cases (a) and (b) dividing the operator A by $\varrho = |v(0)|$ and introducing

$$h' = h\varrho^{-\frac12}, \qquad \mu' = \mu\varrho^{-\frac12}, \qquad \nu' = \nu\varrho^{-1} \tag{13.8.18}$$

we get into the situation of conditions

(a)′ $v' \geq \epsilon$,

(b)′ $v' \leq -\epsilon$

respectively. Moreover, Theorem 13.2.9 yields estimate (13.2.52) for $\tau \leq 0$ in case (a) unconditionally and in cases (b) and (c) as $\mu h \geq C_0 r$. Thus we can assume that $\mu h \leq C_0 \varrho$ and we should discuss the results of Sections 13.4, 13.5 and 13.7. One can see easily that

$$\frac{\nu}{\mu h} = \frac{\nu'}{\mu' h'}, \quad \frac{\nu'}{\mu'} = \frac{\nu \varrho^{\frac{1}{2}}}{\mu}$$

and that the conditions $\mu \geq h^{-\delta}$, $\nu \geq C_0 \mu^{-2} \bar{\nu}$ are also fulfilled for h', μ', ν' and $\bar{\nu}' = \bar{\nu}$.

Moreover, one can see easily that the conditions of all our statements remain true after this reduction and that the estimates become stronger as h, μ, ν are replaced by h', μ', ν' respectively. Therefore in cases (a) and (b) the condition $v \leq -\epsilon$ in the statements indicated above is not necessary.

Let us treat case (c). Dividing the operator A by $\varrho = \nu$ and introducing h', μ' and ν by (13.8.18) we get into the situation of the case $\nu' = 1$; recall that $\nu \geq C_0^{-1} \mu h$ and therefore $\mu' h' \leq C_0$. One can check easily that after this reduction all the conditions and estimates are also preserved.

So we can assume in our previous statements that $\nu = 1$. Let us note that a similar reduction is applicable to Theorem 13.4.30 provided either $\nu \geq \mu h^{1-\delta'}$ or $|v(0)| \geq \mu h^{1-\delta'}$ with arbitrarily small $\delta' > 0$.

13.8.2 Getting Rid of the Condition "$F \geq \epsilon$"

Let us now treat the case when condition (13.3.1) is violated. Then the restriction $\mu h \leq 1$ is no longer natural and assumed; however, cases $\mu h \leq 1$ and $\mu h \geq 1$ differ in the order of the principal part of the asymptotics.

Case $d = 3$

Let us start with the case $d = 3$.

Theorem 13.8.7. *Let* $d = 3$ *and let conditions* (13.2.3)–(13.2.5) *be fulfilled. Then*

(i) Let $\vartheta = 0$, $\mu \le h^{-1+\delta}$ and let

$$\sum_{1\le j\le 3}\sum_{\alpha:|\alpha|\le m} |D^\alpha F^j| \ge \epsilon_0 \tag{13.8.19}_m$$

with a constant $\epsilon_0 > 0$. Then estimate

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{-2} + C' \tag{13.8.20}$$

holds.

(ii) For $0 < \vartheta \le 1$, $\mu \le h^{-2}$ estimates

$$\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} \le Ch^{-2+\vartheta}\mu^{\frac{\vartheta}{2}} \tag{13.8.21}$$

and

$$\mathsf{R}^{\mathsf{MW}}_{(\vartheta)} \le Ch^{-2+\vartheta}\mu^{\frac{\vartheta}{2}} + C\min\bigl(\mu^{\frac{3}{2}+\vartheta}h^{-\frac{3}{2}+\vartheta}, \mu^{\frac{2}{5}\vartheta}h^{-2+\frac{4}{5}\vartheta}\bigr) \tag{13.8.22}$$

hold.

(iii) In the general case for $\vartheta = 0$, $\mu \le h^{-L}$ estimate

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{-2}\mu^{\delta} \tag{13.8.23}$$

holds with arbitrarily small $\delta > 0$.

Proof, Part I. Let us assume that under condition $(13.8.19)_{m-1}$ this theorem is proven. Let us introduce the scaling function

$$\gamma(x) = \epsilon\sum_j \Bigl(\sum_{|\alpha|\le m-1} |D^\alpha F_j|^{\frac{m}{m-|\alpha|}}\Bigr)^{\frac{1}{m}} + \bar\gamma, \qquad \bar\gamma = \mu^{-\frac{1}{m+1}} + h. \tag{13.8.24}_m$$

Then $|\nabla\gamma| \le \frac{1}{2}$ for sufficiently small constant ϵ. Let us introduce a γ-admissible partition and consider its separate element. After the standard rescaling we obtain that conditions (13.2.3)–(13.2.5) are fulfilled with $h' = h\gamma^{-1}$ and $\mu' = \mu\gamma^{m+1}$ instead of h and μ respectively.

(a) Moreover, for $\gamma \ge 2\bar\gamma$ condition $(13.8.19)_{m-1}$ is fulfilled as well and so we can apply an induction assumption. Thus, if $0 < \vartheta \le 1$ the contribution of this element to $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)}$ does not exceed $Ch^{-2+\vartheta}\gamma^{2-\vartheta}$, $Ch^{-2+\vartheta}\mu^{\frac{\vartheta}{2}}\gamma^{2+\frac{\vartheta}{2}(m-1)}$

for $m=1$, $m\ge 2$ respectively. Here case $m=1$ is different as we appeal to the case $m=0$ and then the remainder estimate is $Ch^{-2+\vartheta}$.

Moreover, the contribution of this element to $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}(\vartheta)}$ does not exceed

$$C\min\bigl(\mu^{\frac{3}{2}+\vartheta}h^{-\frac{3}{2}+\vartheta}\gamma^{(\frac{3}{2}+\vartheta)(m+1)+(-\frac{3}{2}+\vartheta)}, \mu^{-\frac{3}{2}+\vartheta}h^{-\frac{5}{2}+\vartheta}\gamma^{(-\frac{3}{2}+\vartheta)(m+1)+(-\frac{5}{2}+\vartheta)}\bigr),$$

$$C\min\bigl(\mu^{\frac{3}{2}+\vartheta}h^{-\frac{3}{2}+\vartheta}\gamma^{(\frac{3}{2}+\vartheta)(m+1)+(-\frac{3}{2}+\vartheta)}, \mu^{\frac{2}{5}\vartheta}h^{-2+\frac{4}{5}\vartheta}\gamma^{\frac{2}{5}\vartheta(m+1)+(2-\frac{4}{5}\vartheta)}\bigr)$$

for $m=1$, $m\ge 2$ respectively. Therefore, the total contribution of such elements of the partition does not exceed these expressions multiplied by γ^{-3} and integrated over x.

Due to condition $(13.8.19)_m$ in an appropriate coordinate system $\gamma\ge \epsilon|x_1|$ and therefore the total contribution of such elements to $\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)}$ does not exceed $Ch^{-2+\vartheta}\gamma^{-\vartheta}$ calculated as $\gamma=\bar\gamma$ if $m=1$ and $Ch^{-2+\vartheta}\mu^{\frac{\vartheta}{2}}\gamma^{\frac{\vartheta}{2}(m-1)}$ calculated as $\gamma=1$ and in both cases we get $Ch^{-2+\vartheta}\mu^{\frac{\vartheta}{2}}$.

The same arguments imply that the total contribution to $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}(\vartheta)}$ does not exceed

$$C\min\bigl(\mu^{\frac{3}{2}+\vartheta}h^{-\frac{3}{2}+\vartheta}, \mu^{\frac{2}{5}\vartheta}h^{-2+\frac{4}{5}\vartheta}\bigr).$$

The same arguments apply to $\vartheta=0$ as well provided $\mu\le h^{-1+\delta}$. However, at each step of the induction there appears an additional factor $\log\mu$ in the total contribution to R^{MW}.

Moreover, the same arguments are applicable for $h^{-1+\delta}\le\mu\le h^{-1}$ but in this case the remainder estimate is $O(h^{-2}\mu^{\delta})$ and this estimate does not change under the induction transition.

(b) Let us consider elements with $\gamma\le 2\bar\gamma$. On these elements $\mu'=1$ and their contributions do not exceed $Ch^{-2+\vartheta}\bar\gamma^{2-\vartheta}$. Due to condition $(13.8.19)_m$ their number does not exceed $C\bar\gamma^{-2}$ and their total contribution to the remainder estimate does not exceed $Ch^{-2+\vartheta}\mu^{\frac{\vartheta}{2}}$ for $0\le\vartheta\le 1$.

Thus Statement (i) is proven albeit with an additional factor $\log^m\mu$ and Statement (ii) is proven under the additional condition (13.8.19). In order to get rid of this condition one can apply the same arguments with large m without reference to condition $(13.8.19)_m$. Then keeping in mind that $\gamma\ge\mu^{\delta}$ with $\delta=\frac{1}{m+1}$ we obtain Statements (ii) and (ii). □

Proof, Part II. To get rid of logarithmic factor in Statement (i) we apply more subtle arguments.

First of all, applying the same arguments as in Theorem 5.2.10 one can see that the total contribution of the complement of the set

$$\mathcal{X} = \{x, \exists \boldsymbol{e}, \boldsymbol{f}, \bar{x} : \mu\gamma^{m+1} \ge 1, |D^{\alpha}(\boldsymbol{F} - \boldsymbol{f}\ell(x)^m)| \le \gamma^{m-|\alpha|+\delta'} \\ \forall \alpha : |\alpha| \le m, -V \ge \gamma^{\delta_1}\}$$

to R^{MW} does not exceed Ch^{-2} where $\ell(x) = \langle \boldsymbol{e}, x - \bar{x}\rangle$, $\gamma(x) = |\ell(x)|$, $\delta' > 0$ is sufficiently small and $\delta_1 > 0$ is arbitrarily small.

Let us consider $\gamma^{1-\delta''}$-vicinity of the point $\bar{x}$. Without any loss of the generality one can assume that $g^{jk} = \delta_{jk}$ in $\bar{x}$ and therefore $|g^{jk} - \delta_{jk}| \le \gamma^{\delta}$ in this vicinity. Then condition $\langle \nabla, \boldsymbol{F}\sqrt{g}\rangle = 0$ yields that without any loss of the generality one can assume that $\langle \boldsymbol{e}, \boldsymbol{f}\rangle = 0$ and therefore in an appropriate coordinate system this "approximate" field is $(x_2^m, 0, 0)$.

Considering magnetic lines of length $\gamma^{1-\delta'''}$ with sufficiently small $\delta''' > 0$ one can easily see that they are non-closed and that all the assumptions of Theorem 13.7.18 are fulfilled with $T = \min\bigl(\gamma^{-\delta'''}, (\mu\gamma^{m+1})^{\delta'''}\bigr)$. Then the contribution of the γ-vicinity of $x \in \mathcal{X}$ to the remainder estimate does not exceed

$$Ch^{-2}\gamma^2(\gamma^{\delta'''} + (\mu\gamma^{m+1})^{-\delta'''})$$

and therefore the total contribution of $\mathcal{X}$ is $O(h^{-2})$ as well.

We leave all the details to the reader. □

Remark 13.8.8. (i) Assume that $\mu h \gg 1$. Then the principal part of the asymptotics does not exceed $Ch^{-d}\,\mathsf{mes}(\{x, \mu hF + V \le t\})$ with $t = \epsilon$ and is larger than the same expression with $t = -\epsilon$. More precisely, under condition $(13.8.19)_1$ the principal part of asymptotics is $\asymp (\mu h)^{-1}h^{-d}$ and under condition $(13.8.19)_m$ the principal part of asymptotics is $O\bigl((\mu h)^{-\delta}h^{-d}\bigr)$ with $\delta = \delta_m > 0$.

(ii) Surely, one can improve the remainder estimate for (13.8.20) for $\vartheta = 0$, $\mu \ge h^{-1+\delta}$ under an appropriate condition non-degeneracy condition (as will be done for $d = 2$; see condition $(13.8.25)_m$). However, for $d = 3$ and degenerate $\boldsymbol{F}$ the function F is not necessarily smooth.

(iii) Consider Schrödinger-Pauli operator with $\mu h \ge 1$. Then contribution of zone $\mu' h' \le 1$ to the remainder is estimated exactly as before.

However as $\mu' h' \ge 1$ i.e. $\gamma \ge (\mu h)^{1/m}$ contribution of $B(x, \gamma(x))$ to the remainder does not exceed $C\mu' h'^{-1-\delta} = C\mu h^{-1-\delta}\gamma^{m+2+\delta}$; dividing by γ^3 and integrating we arrive to $C\mu h^{-1-\delta}$. Surely condition $\mu \le h^{-L}$ is not natural anymore.

Case $d = 2$

As $d = 2$ the function F is smooth and we can write non-degeneracy condition assuming that $V \asymp 1$:

$$\sum_{1\le|\alpha|\le m} |D^\alpha \frac{F}{V}| \ge \epsilon_0. \tag{13.8.25}_m$$

However we postpone analysis until Chapter 14 when we prove remainder estimate $O(\mu^{-\frac{1}{2}} h^{-1})$ as $(13.8.25)_1$ holds (instead of $O(h^{-1})$ which one can easily prove using current technique).

13.8.3 Getting Rid of the cCondition "$B(0,1) \subset X$"

Finally, let us treat the case in which $B(0,1)$ is not contained in X but $\partial X \cap B(0,1)$ is not very singular. We assume that $F \asymp 1$, $V \asymp 1$.

Case $d = 3$

Consider point $\bar{x} \in X$, $\ell(\bar{x}) \ge C\mu^{-1}$ with

$$\ell(x) = \epsilon \mathsf{dist}(x, \partial X). \tag{13.8.26}$$

Then for time $T(x) = \ell(x)$ classical and quantum movement started at $B(\bar{x}, \ell(\bar{x}))$ are not affected (modulo negligible) by the boundary and contribution of $B(\bar{x}, \ell(\bar{x}))$ to the remainder does not exceed $CT(\bar{x})^{-1}\ell(\bar{x})^3 h^{-2} = C\ell(\bar{x})^2 h^{-2}$ as long as $\mu \le h^{\delta-1}$. The same result could be achieved by rescaling $x \mapsto x\ell^{-1}$, $h \mapsto h\ell^{-1}$, $\mu \mapsto \mu\ell$.

Then the total contribution of zone

$$X_{\mathsf{inn}} := \{x : \mathsf{dist}(x, \partial X) \ge C\mu^{-1}\} \tag{13.8.27}$$

to the remainder does not exceed

$$Ch^{-2} \int_{\mathsf{dist}(x,\partial X)\ge C\mu^{-1}} T(x)^{-1}\, dx \tag{13.8.28}$$

and the contribution of zone

$$X_{\mathsf{bound}} := \{x : \mathsf{dist}(x, \partial X) \le C\mu^{-1}\} \tag{13.8.29}$$

does not exceed $C\mu h^{-2}\,\mathsf{mes}(X_{\mathsf{bound}})$. So the total remainder estimate is

$$Ch^{-2}\int_{X_{\mathsf{inn}}} T(x)^{-1}\,dx + C\mu h^{-2}\,\mathsf{mes}(X_{\mathsf{bound}}). \tag{13.8.30}$$

As ∂X is regular enough the first term is $O(h^{-2}\log h)$ while the second term is $O(h^{-2})$.

So, we need to reconsider contribution of zone X_{bound} and for this purpose we have a Seeley' method but we need to modify it first to tackle degenerations.

Let

$$T_{\pm}(x) = \mathsf{max}\{t :\ \mathsf{dist}(\Phi_{t'}(x), \partial X) \ge \frac{1}{2}C\mu \ \ \forall t' \in (0, \pm t)\}, \tag{13.8.31}$$

$$T^*(x) = \mathsf{max}\big(T_+(x), T_-(x)\big), \qquad T(x) = \mathsf{min}\big(T^*(x), \ell(x)^{1-\delta}\big) \tag{13.8.32}$$

where Φ_t is magnetic flow.

Theorem 13.8.9. *Let $d = 3$, $\vartheta = 0$. Then under Dirichlet boundary condition*[48)]

(i) As $\mu \le h^{\delta'-1}$ estimate

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{-2}\int_{X_{\mathsf{inn}}} T(x)^{-1}\,dx + C\mu h^{-2}\,\mathsf{mes}(X_{\mathsf{bound}}). \tag{13.8.34}$$

holds.

(ii) Further, let in the framework of (i)

$$\int_{X\cap B(0,1)} T(x)^{-1}dx < \infty \tag{13.8.35}$$

which is true under rather minimal regularity conditions to ∂X. Then $\mathsf{R}^{\mathsf{MW}} \le Ch^{-2}$.

[48)] Or Neumann boundary condition i.e.

$$\sum n_j g^{jk} P_k u|_{\partial X} = 0 \tag{13.8.33}$$

where $\boldsymbol{n} = (n_1, \dots, n_d)$ is a normal to ∂X, as domain satisfies cone condition.

(iii) Finally, estimate $\mathsf{R}^{\mathsf{MW}} \le Ch^{-2} + C\mu h^{-1-\delta}$ *holds.*

Proof. Obviously, we need to consider only X_{bound}.

First, both $T_{\pm}(x) \gtrsim \ell(x)$ and then Statement (i) is proven with $T(x) = \ell(x)$ which however leads to logarithmical divergence of integral.

Proof is almost trivial but one needs to take in account that for some r magnetic dynamics $\Psi_{t,r}$ moving in the chosen direction may be almost instantly turned back by potential v. However as $|\langle \boldsymbol{F}(x), \xi\rangle| \ge \ell(x)^{1-\delta}$ this dynamics would move in the chosen direction for time greater than $\ell(x)^{1-\delta}$. Then contribution of this zone to the remainder does not exceed the first term in (13.8.30).

On the other hand, one can see easily that as $\mu \le h^{-\delta'}$ the contribution of the alternative zone to the remainder does not exceed the first term in (13.8.30) with $T(x) = \ell(x)^{1-\delta}$. So, as $\mu \le h^{-\delta'}$ theorem is proven.

As $\mu \ge h^{-\delta'}$ we can consider different magnetic numbers j and notice that dynamics moves in the chosen direction at least time $(\mu h|j - \bar{\jmath}(x)|)^{\frac{1}{2}}$ as $j \ne \bar{\jmath}(x)$. Then repeating arguments of Section 13.5 one can prove easily that contribution of $j \ne \bar{\jmath}(x)$ to the remainder does not exceed the first term in (13.8.30) and the contribution of $j = \bar{\jmath}(x)$ does not exceed $C\mu h^{-1-\delta''}$. Therefore as $\mu \le h^{\delta'-1}$ estimate we arrive to the announced estimate. Also as $\mu \ge h^{\delta'-1}$ we arrive to estimate $O(h^{-2-\delta})$. So, Statements (ii) and (iii) are proven. □

We leave to the reader rather challenging

Problem 13.8.10. (i) Prove that under non-degeneracy conditions $(13.4.57)_m$ with $\nu = 1$ and may be

$$\sum_{1\le|\alpha|\le m} |\nabla^{\alpha}_{\partial X}\bigl(\frac{V}{F}\bigr)| \ge \epsilon \tag{13.8.36}_m$$

where $\nabla_{\partial X}$ mean gradient along the boundary estimate (13.8.34) holds even as $\mu \in [h^{\delta'-1}, h^{-1}]$.

(ii) Investigate Schrödinger-Pauli operator as $\mu h \ge 1$.

However, as $\vartheta > 0$ situation deteriorates and the same arguments imply

Theorem 13.8.11. *Let* $d = 3$, $\vartheta > 0$. *Then under Dirichlet boundary condition*[48)]

(i) Then

$$\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} \le Ch^{\vartheta-2}\int_{X_{\mathsf{inn}}} T(x)^{-1-\vartheta}\,dx + C\mu^{1+\vartheta}h^{-2}\,\mathsf{mes}(X_{\mathsf{bound}}). \tag{13.8.37}$$

(ii) As

$$\mathsf{mes}\big(\{x\in X\,\mathsf{dist}(x,\partial X)<\rho\}\cap B(0,1)\big) = O(\rho) \tag{13.8.38}$$

estimate

$$\mathsf{R}^{\mathsf{MW}}_{\infty(\vartheta)} \le C\mu^{\vartheta}h^{-2} \tag{13.8.39}$$

holds.

Proof. Proof is trivial with $T(x)=\ell(x)$. □

Proof. The simple rescaling technique works for estimate of X_{inn}. To estimate contribution of X_{bound} we just make $\mu^{-\frac{1}{2}}$-partition and rescale; the contribution of each such element to the remainder does not exceed C. □

Case $d=3$, Improved Remainder Estimates

Magnetic billiards must follow magnetic lines; but magnetic lines are not billiards and all of them bounce back from the boundary going the same path in the opposite direction. So escape condition in the bounded domain fails for sure but these magnetic lines drift.

Consider what happens as Hamiltonian trajectory reflects from the boundary. We need to analyze only the following

Example 13.8.12. Let

$$a(x,\xi) = \frac{1}{2}\big(x_1^2+(\xi_2-\mu x_1)^2+\xi_3^2\big) \tag{13.8.40}$$

and $X=\{x : x_3 > kx_1\}$ i.e. we assume that magnetic lines are transversal to ∂X.

Then before reflection movement is described by

$$\begin{aligned} x_1=\mu^{-1}\rho\sin(\mu t)+\bar{x}_1,\quad x_2=\mu^{-1}\rho\cos(\mu t)+\bar{x}_2,\quad x_3=\sigma t+\bar{x}_3,\\ \xi_1=\rho\cos(\mu t),\quad \xi_2=\mu\bar{x}_1,\quad \xi_3=\sigma \end{aligned} \tag{13.8.41}$$

with constant $\bar{x}$, $\rho \geq 0$, σ and after reflection movement is described by (13.8.41)$'$ with parameters $\bar{x}$, ρ', σ' and with t replaced by t'.

One can prove easily that

$$\rho^2 + \sigma^2 = \rho'^2 + \sigma'^2 \tag{13.8.42}$$

and

$$\bar{x}_1' = \bar{x}_1, \quad , \bar{x}_2' = \bar{x}_2 - 2\mu^{-1} l k, \quad \sigma' = \sigma - 2l \tag{13.8.43}$$

with $l \in [\sigma - \rho|k|, \sigma + \rho|k|]$ the cosine of the incidence angle.

So, if $k = 0$ i.e. $\boldsymbol{F}$ is orthogonal to ∂X nothing really happens: $\bar{x}' = \bar{x}$, $\rho' = \rho$ and $\sigma' = -\sigma$.

However if $k \neq 0$ i.e. $\boldsymbol{F}$ is not orthogonal to ∂X, $\bar{x}$ jumps by $-2\mu^{-1} l k$ in the direction $\boldsymbol{F}^{\perp} \cap T\partial X$ and also energy between movement along magnetic line and winding redistributes thus magnetic number j which has sense only away from the boundary, jumps by $O((\mu h)^{-1} k)$.

Therefore even calculation of the total jump seems to be a difficult problem; most likely there is no consistent movement but just a wobbling.

Microlocal implications especially as μ is close to h^{-1} seem to be really unclear. This leads to an interesting and very challenging

Problem 13.8.13. Repeat analysis of Subsection 13.7.3 and recover remainder estimate $O(\mu^{-1} h^{-2})$ as $\mu h \leq 1$ under appropriate assumptions:

(i) Either magnetic drift of trajectories is larger than the possible effect of shifting

(ii) Or movement along magnetic line is bounded by ∂X only on one side and by a growing potential on the other; then jumps are going only in one direction and drift direction is disjoint from it.

(iii) Consider Schrödinger-Pauli operator as $\mu h \geq 1$ and recover remainder estimate $O(\mu h^{-1})$ under similar assumptions.

Another challenging problem is

Problem 13.8.14. In the generic case as $\mu h \to 0$ prove the remainder estimate $o(h^{-2})$.

Case $d = 2$

One can prove that under usual non-degeneration assumptions the contribution of inner zone to the remainder estimate does not exceed

$$C\mu^{-1}h^{-1}\int_{X_{\mathsf{inn}}} T(x)^{-1}\,dx \tag{13.8.44}$$

as $\mu \le h^{-\frac{1}{2}}$ with X_{inn} defined by (13.8.27) and $T(x)$ defined by (13.8.31)–(13.8.32) with Φ_t replaced by drift flow ϕ_t. Under assumption (13.8.33) it would be $O(\mu^{-1}h^{-1})$.

However contribution of X_{bound} is estimated by $C\mu h^{-1}\,\mathsf{mes}(X_{\mathsf{bound}})$ and it is $\asymp h^{-1}$. It could be improved to $O(\mu^{-1}h^{-1})$ under certain assumptions; we will do it in the dedicated Chapter 15.

13.A Appendices

13.A.1 Two Integral Formulae

Let us define numbers A_k and B_k with $k \in \mathbb{Z}^+$ such that

$$\sum_{0\le k\le m-1} A_k \frac{(2m+1)!}{(2m-2k-1)!} = 1, \tag{13.A.1}_1$$

$$\sum_{0\le k\le m-1} B_k \frac{(2m+1)!}{(2m-2k-1)!} = -2m; \tag{13.A.1}_2$$

in particular, $A_0 = \frac{1}{6}$, $B_0 = -\frac{1}{3}$.

Then for $m \in \mathbb{Z}^+$ the formulas

$$I(c-h, c+h) \sim 2hf(c) + \sum_{0\le k\le m-1} A_k h^{2k+2} f^{(2k+1)}(x)\big|_{x=c-h}^{x=c+h}, \tag{13.A.2}_1$$

$$I(c-h, c+h) \sim h(f(c-h)+f(c+h)) + \sum_{0\le k\le m-1} B_k h^{2k+2} f^{(2k+1)}(x)\big|_{x=c-h}^{x=c+h} \tag{13.A.2}_2$$

with $I(a,b) = \int_a^b f(x)dx$ are exact provided $f(x)$ is a polynomial of degree not exceeding $2m+1$. This is easy to prove for $c = 0$ by first observing that these formulas are exact for all odd functions; then we translate. Applying the Taylor formula we therefore obtain that the error $\mathcal{R}'_m$ of formula $(13.A.2)_j$ (i.e., the absolute value of the difference between its left- and right-hand expressions) does not exceed

$$C_m h^{2m+1+i} \max_{c-h\le x\le c+h} |f^{(2m+i)}(x)|$$

with $i = 0, 1, 2$.

Let us treat the segment $[a,b]$ of length $L = b-a$; let us divide it into N subsegments of length $2h = \frac{L}{N}$. Let us consider the integral formulas

$$(13.A.3)_1 \quad I(c-h, c+h) \sim \sum_{0\le j\le N-1} f(a+(2j+1)h)\cdot 2h + \sum_{0\le k\le m-1} A_k h^{2k+2} f^{(2k+1)}(x)|_{x=a}^{x=b},$$

$$(13.A.3)_2 \quad I(c-h, c+h) \sim (f(a)+f(b))h + \sum_{1\le j\le N-1} f(a+2jh)\cdot 2h + \sum_{0\le k\le m-1} B_k h^{2k+2} f^{(2k+1)}(x)|_{x=a}^{x=b}$$

which follow from $(13.A.2)_{1,2}$ by the substitution $c = a+(2j+1)h$ and summation with respect to $j = 0, \dots, N-1$.

Then the previous statements imply that these formulas are exact on all polynomials of degree not exceeding $2m+1$ and their errors satisfy the estimates

$$(13.A.4) \quad \mathcal{R}_m \le C_m L h^{2m+i+1} \sum_{0\le j\le N-1} \max_{a+2jh\le x\le a+2(j+1)h} |f^{(2m+i)}(x)| \le C_m L h^{2m+i} \max_{a\le x\le b} |f^{(2m+i)}(x)|$$

with $i = 0, 1, 2$.

In particular, for $m = 0$ we have formulas of second order accuracy.

13.A.2 Trajectories of the Classical Particles in a Magnetic Field

Let us treat the movement of a classical particle of mass $m = \frac{1}{2}$ and energy τ in various situations. We assume that $g^{jk} = \delta_{jk}$.

Case $V = 0, \boldsymbol{F} = \text{const}$

Let there be no electric field (i.e., $V = 0$) and let the magnetic field be constant: $F_{12} = \mu$ (and $F_{13} = F_{23} = 0$ in the three-dimensional case). Then the equations

$$\frac{dp_1}{dt} = -2\mu p_2 - \partial_{x_1} V, \quad \frac{dp_2}{dt} = 2\mu p_1 - \partial_{x_2} V, \quad \frac{dp_3}{dt} = -\partial_{x_3} V, \qquad \frac{dx_j}{dt} = 2p_j \qquad (j = 1, 2, 3) \tag{13.A.5}$$

yield that a two-dimensional particle moves along the circle

$$x_1 = \bar{x}_1 + \frac{a}{\mu}\cos 2\mu t, \quad x_2 = \bar{x}_2 + \frac{a}{\mu}\sin 2\mu t \tag{13.A.6}$$

with $a^2 = \tau$ where here and in what follows we replace t by $t - t_0$ if necessary. The corresponding drift line degenerates into a point.

A three-dimensional particle moves along the spiral

$$x_1 = \bar{x}_1 + \frac{a}{\mu}\cos 2\mu t, \quad x_2 = \bar{x}_2 + \frac{a}{\mu}\sin 2\mu t, \quad x_3 = \bar{x}_3 + 2bt \tag{13.A.7}$$

with $a^2 + b^2 = \tau$. The magnetic lines are parallel to the x_3-axis.

Case $\nabla V = \text{const}, \boldsymbol{F} = \text{const}$

Let us assume that electric field is constant (and the magnetic field as the same as before until otherwise indicated). Then for $d = 2$ one can assume without any loss of the generality that $V = Ex_2$ where E is the scalar intensity of the electric field; then the particle moves along the (epi-, hypo-) cycloid

$$x_1 = \bar{x}_1 + \frac{a}{\mu}\cos 2\mu t + \frac{E}{\mu}t, \quad x_2 = \bar{x}_2 + \frac{a}{\mu}\sin 2\mu t \tag{13.A.8}$$

with

$$a^2 + \frac{1}{4\mu^2}E^2 + E\bar{x}_2 = \tau. \tag{13.A.9}$$

So the average speed of the particle is equal to $\mu^{-1}E$ and is orthogonal to electric field. The corresponding drift lines are parallel to the x_1-axis.

For $d = 3$ one can assume without loss of generality that $V = E_1x_1 + E_3x_3$ in which case

$$x_1 = \bar{x}_1 + \frac{a}{\mu}\cos 2\mu t, \quad x_2 = \bar{x}_2 + \frac{a}{\mu}\sin 2\mu t - \frac{E_1}{\mu}t, \quad x_3 = \bar{x}_3 + 2bt - E_3t^2 \tag{13.A.10}$$

with $a^2 + \frac{1}{4\mu^2}E_1^2 + E_1\bar{x}_1 + E_3\bar{x}_3 + \frac{1}{4}b^2 = \tau$. The corresponding magnetic lines are parabolas (for $E_3 \neq 0$) or straight lines (for $E_3 = 0$).

Case $V = \frac{1}{4}k^2|x|^2$, $\boldsymbol{F} = \mathrm{const}$

Let $V = \frac{1}{4}k^2|x|^2$ with $k > 0$. Then the two-dimensional particle moves along the cycloidal curve

$$\begin{cases} x_1 = \dfrac{A_1}{\omega_1}\cos\omega_1 t + \dfrac{A_2}{\omega_2}\cos(\omega_2 t + \varphi), \\ x_2 = \dfrac{A_1}{\omega_1}\sin\omega_1 t + \dfrac{A_2}{\omega_2}\sin(\omega_2 t + \varphi) \end{cases} \tag{13.A.11}$$

with

$$\omega_{1,2} = (k^2 + \mu^2)^{\frac{1}{2}} \mp \mu \tag{13.A.12}$$

and

$$A_1^2(1 + \frac{k^2}{\omega_1^2}) + A_2^2(1 + \frac{k^2}{\omega_2^2}) = 4\tau. \tag{13.A.13}$$

It is obvious that for $k \in (0, 1]$ and $\mu \gg 1$ we obtain $\omega_1 \asymp k^2/\mu$ and $\omega_2 \asymp \mu$. The corresponding drift lines are circles.

In the three-dimensional case one should to add the third equation

$$x_3 = A_3\cos(kt + \psi) \tag{13.A.14}$$

and the energy equation is now

$$A_1^2(1+\frac{k^2}{\omega_1^2})+A_2^2(1+\frac{k^2}{\omega_2^2})+k^2A_3^2=4\tau. \tag{13.A.15}$$

The corresponding magnetic lines are parallel to the x_3-axis.

Let us note that in the case 13.A.2.2 *Case* $\nabla V = \mathsf{const}, \boldsymbol{F} = \mathsf{const}$ Hamiltonian trajectories are non-periodic and in the case 13.A.2.3 *Case* $V=\frac{1}{4}k^2|x|^2, \boldsymbol{F}=\mathsf{const}$ generic Hamiltonian trajectories are non-periodic; less generic trajectories (with commensurable ω_1 and ω_2 for $d=2$ and with commensurable ω_1, ω_2 and k for $d=3$) are long-periodic (with period $\ge \epsilon\mu/k^2$). On the other hand, in the case 13.A.2.1 *Case* $V=0, \boldsymbol{F}=\mathsf{const}$ Hamiltonian trajectories are short-periodic (with period $2\tau/\mu$).

Case $V=\frac{1}{4}k^2x_3^2, \boldsymbol{F}=\mathsf{const}$

One can easily prove that in this case generic trajectories are non-periodic and less generic trajectories (with commensurable k and μ) are periodic (with period $\ge \epsilon\,\mathsf{max}(1/k, 1/\mu)$).

Comments

The spectral theory of the Schrödinger operator with magnetic field became rather popular lately but majority of the authors are concentrating on other problems.

Relevant papers, especially those of Y. Colin de Verdiere, H. Tamura, G. Raikov, G. Rozenblum and A. Sobolev will be mentioned in the forthcoming chapters.

The same normal forms as we use here can also be used in the analysis of Schrödinger magnetic operators at the bottom; see f.e. N. Raymond and S. Vu-Ngoc [1], B. Helffer, Y. Kordyukov, N. Raymond and S. Vu-Ngoc [1] and few earlier papers.

Chapter 14

2D-Schrödinger Operator with the Strong Degenerating Magnetic Field

In this chapter we consider 2D-Schrödinger operator (13.2.1) with the strong magnetic field like in the previous chapter albeit now magnetic intensity F degenerates along smooth line and the degeneration is precisely of order $\nu - 1$ with $\nu \geq 2$. Surely, we are most interested in the generic case $\nu = 2$.

We start from very short Section 14.1 where we apply results of the previous Chapter rescaled to understand shortcomings of this approach.

Then in Section 14.2 we consider classical dynamics which is useful both for understanding and proofs of our main results. We will notice the obvious difference between cases of odd and even ν.

In Section 14.3 we consider corresponding quantum (semiclassical) dynamics and the Tauberian remainder estimates. It appears that there will be several zones: a *classically forbidden zone* $\{|x_1| \geq \bar{\gamma}_1 = C(\mu h)^{1/(\nu-1)}\}$ [1) 2)], a *regular zone* $\mathcal{X}_{\mathsf{reg}} = \{\bar{\gamma}_0 = C\mu^{-1/\nu} \leq |x_1| \leq \bar{\gamma}_1\}$ and a *degeneration zone* $\mathcal{X}_{\mathsf{deg}} = \{|x_1| \leq \bar{\gamma}_0\}$ divided into a *non-periodic zone* and a rather thin *periodic zone* with the analysis in the latter one the most difficult and interesting. The width (in the phase space) of the periodic zone is defined by the uncertainty principle and it increases as μ grows.

In Section 14.4 we instead of implicit main part of asymptotics derived in Section 14.3 provide much more explicit answer $h^{-2}\mathcal{N}^{\mathsf{MW}} + h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ where $h^{-2}\mathcal{N}^{\mathsf{MW}}$ is the standard Magnetic Weyl expression of the previous chapter and $h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ is a *correction term*. All the analysis in Sections 14.3 and 14.4

[1)] Only as $Ch^{-1} \leq \mu \leq Ch^{-\nu}$; otherwise $\bar{\gamma}_1$ is artificially set to ϵ.

[2)] Here and below coordinate x_1 is defined so that $\Sigma = \{x_1 = 0\}$.

is under assumption $\mu \le h^{-\nu+\delta}$.

Section 14.5 is devoted to the similar analysis in the case of a *very trong magnetic field* $h^{-\nu+\delta} \le \mu \le \epsilon h^{-\nu}$ which is in some sense easier and in some sense more difficult than the previous one because $\hbar = \mu^{1/\nu} h$ is not very small anymore.

Let us recall that in the previous Chapter 13 we called the case $\mu \gtrsim h^{-1}$ *strong magnetic field* and the difference between this case and the case of $\mu \lesssim h^{-1}$ remains crucial. However now due to degeneration our focus shifts to larger μ.

Then in Section 14.6 we summarize our results as main theorems and generalize them for vanishing V and discuss some other generalizations.

In Section 14.7 we modify potential V replacing it by $V - \mu h_3 F$ and establish our results in this case as well.

With this new V we consider in Section 14.8 a case of *superstrong magnetic field* $\mu h^{\nu} \ge C$ which is not trivial anymore.

Finally, Appendix 14.A is devoted to the analysis of eigenvalues of some auxiliary 1D-operator.

14.1 Preliminary Analysis

14.1.1 Set-up

So, consider operator (13.2.1) ($d = 2$) satisfying conditions (13.2.2)–(13.2.5) and (13.4.45) ($V \le -\epsilon_0$) [3] but we do not assume that F is disjoint from 0; however we are mainly interested in the case of the generic degeneration

$$|F_{12}| + |\nabla F_{12}| \ge \epsilon_0. \tag{14.1.1}$$

Remark 14.1.1. It is well-known (see f.e. V. Arnold [2]) that the generic 2-form in dimension 2 may degenerate in a very special way: locally it can be reduced to form

$$\omega = x_1 dx_1 \wedge dx_2 \tag{14.1.2}$$

matching to 14.1.1).

[3] Condition (13.4.45) will be dropped in the very end by rescaling arguments.

Then $\Sigma = \{x : F_{12}(x) = 0\}$ is a smooth curve. We call Σ *degeneration line*. One can introduce a coordinate x_1 as a Riemannian distance from x to Σ; then $g^{11} = 1$. One can always change x_2 to keep $g^{12} = 0$ and then

$$A = P_1^2 + P_2 g^{-1} P_2 + V, \qquad P_j = D_j - \mu V_j. \tag{14.1.3}$$

Furthermore, without any loss of the generality one can assume locally that

$$V_1 = 0, \qquad V_2 \asymp |x_1|^\nu \tag{14.1.4}$$

with $\nu = 2$; one can achieve this by the gauge transformation. Actually instead we consider operator (14.1.3) with positive integer $\nu \ge 2$ and in the classical dynamics we even take any real $\nu \ge 2$.

As usual we are interested in an asymptotics as $h \to +0$, $\mu \to +\infty$ of

$$\int e(x,x,0)\psi(x)\,dx$$

where $e(x,y,\tau)$ is the Schwartz kernel of the spectral projector $E(\tau)$ of operator A. We will prove later that $e(x,x,\tau)$ will be $O(\mu^{-s})$ as $\mu \ge C_0 h^{-\nu}$ and therefore we will assume that

$$\mu \le C_0 h^{-\nu}. \tag{14.1.5}$$

The natural answer coming from the non-degenerate case is $\int h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0)\psi(x)\,dx$ where $\mathcal{N}^{\mathsf{MW}}$ is defined by $(13.2.9)_{(2)}$ i.e.

$$\mathcal{N}^{\mathsf{MW}} = \frac{1}{2\pi}\sum_{n\ge 0} \theta\big(\tau - V - (2n+1)\mu hF\big)\mu hF\sqrt{g}$$

which implies that there are actually two different cases:

Remark 14.1.2. There are two cases: the case of the strong magnetic field in the sense of the previous chapter

$$1 \le \mu\epsilon \le h^{-1} \implies \mathcal{N}^{\mathsf{MW}} = O(1), \tag{14.1.6}$$

and the case of the superstrong magnetic field in the sense of the previous chapter

$$\epsilon h^{-1} \le \mu \le C_0 h^{-\nu} \implies \mathcal{N}^{\mathsf{MW}} = O\big((\mu h)^{-1/(\nu-1)}\big); \tag{14.1.7}$$

in the latter case the contribution to the answer will be given by the strip

$$\big\{x,\ |x_1| \le \bar{\gamma}_1 = C_0(\mu h)^{-1/(\nu-1)}\big\}. \tag{14.1.8}$$

The standard rescaling procedure applied to results of Chapter 13 implies

$$\mathsf{R}^{\mathsf{MW}} := \Big| \int \Big(e(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0)\Big)\psi(x)\,dx\Big| \le Ch^{-1} \tag{14.1.9}$$

(see Subsection 14.1.2) but an aim of this chapter is much better estimate, up to $O(\mu^{-1/\nu}h^{-1})$. So we are going to improve remainder estimate (14.1.9).

14.1.2 Zones and Rescaling: the First Blood

Let us consider case (14.1.6) $B(x,\gamma(x))$ with $\gamma(x) = \frac{1}{2}\mathsf{dist}(x,\Sigma)$ and rescale $x \mapsto x/\gamma$, $h \mapsto h_{\mathsf{new}} = h\gamma^{-1}$, $\mu \mapsto \mu_{\mathsf{new}} = \mu\gamma^{\nu}$ where we select

$$\bar{\gamma} := \mu^{1/\nu} \tag{14.1.10}$$

to keep $\mu_{\mathsf{new}} \ge 1$. As $\gamma \le \epsilon$ non-degeneracy condition $|\nabla V/F| \ge \epsilon$ is obviously fulfilled[4)] and therefore due to the results of the previous chapter contribution of $B(x,\gamma(x))$ to the remainder does not exceed

$$C\mu_{\mathsf{new}}^{-1}h_{\mathsf{new}}^{-1} = C\mu^{-1}h^{-1}\gamma^{1-\nu} \tag{14.1.11}$$

and then the contribution of *regular zone*

$$\mathcal{X}_{\mathsf{reg}} := \{x,\ \gamma(x) \ge \bar{\gamma}\} \tag{14.1.12}$$

to the remainder does not exceed

$$C\int_{\mathcal{X}_{\mathsf{reg}}} \mu^{-1}h^{-1}\gamma^{1-\nu} \times \gamma^{-2}\,dx \asymp C\mu^{-1}h^{-1}\bar{\gamma}^{-\nu} \asymp Ch^{-1} \tag{14.1.13}$$

exactly as we promised. Meanwhile as $\gamma(x) \le \bar{\gamma}$ we reset $\gamma = \bar{\gamma}$ and then $\mu_{\mathsf{new}} = 1$ and the contribution of $B(x,\bar{\gamma})$ to the remainder does not exceed (14.1.11) with $h_{\mathsf{new}} = h\bar{\gamma}^{-1}$ and $\mu_{\mathsf{new}} = 1$ (which is $Ch^{-1}\bar{\gamma}$) and then contribution of *degeneration zone*

$$\mathcal{X}_{\mathsf{deg}} := \{x,\ \gamma(x) \le \bar{\gamma}\} \tag{14.1.14}$$

to the remainder does not exceed Ch^{-1}.

Therefore we need to improve estimates of contributions of both zones: $\mathcal{X}_{\mathsf{reg}}$ and $\mathcal{X}_{\mathsf{deg}}$.

[4)] As we replace F by $\gamma^{1-\nu}F$.

14.2 Classical Dynamics

In this section we consider classical dynamics on energy level 0 described by Hamiltonian

$$a = \sum_{j,k} g^{jk}(x) p_j p_k - V, \qquad p_j = \xi_j - \mu V_j \tag{14.2.1}$$

where all conditions of Subsection 14.1.1 are assumed to be fulfilled.

14.2.1 Toy-mModel

Let us consider first a model

$$a = \xi_1^2 + \bigl(\eta - \frac{1}{\nu}|x_1|^{\nu}\bigr)^2 - 1 \tag{14.2.2}$$

with $\nu \geq 2$, corresponding to $\mu = 1$, $V = -1$, $\eta = \xi_2$.

Proposition 14.2.1. *For symbol* (14.2.2)

(i) Along trajectories $\eta = \mathsf{const}$, *and*

(a) If $\eta > 1$ *then on the energy level* 0 *these trajectories oscillate* <u>*either*</u> *between* $x_1 = b_1(\eta)$ *and* $x_1 = b_2(\eta)$ <u>*or*</u> *between* $x_1 = -b_1(\eta)$ *and* $x_1 = -b_2(\eta)$ *with*

$$b_1(\eta) = \bigl((\eta - 1)\nu\bigr)^{1/\nu}, \quad b_2(\eta) = \bigl((\eta + 1)\nu\bigr)^{1/\nu}. \tag{14.2.3}$$

(b) If $\eta = 1$ *then these trajectories oscillate between* $b_1(1) = 0$ *and* $b_2(1) = 1$ *or between* -1 *and* 0*; there is also an exceptional trajectory* $x_1 = \xi_1 = 0$, $x_2 = 2t + \mathsf{const}$.

(c) If $-1 < \eta < 1$ *then these trajectories oscillate between* $x_1 = b_1(\eta) := -b_2(\eta)$ *and* $x_1 = b_2(\eta)$ *with* $b_2(\eta)$ *defined by* (14.2.3).

(d) If $\eta = -1$ *then the energy level* 0 *degenerates into* $\{x_1 = \xi_1 = 0\}$ *and this trajectory is* $x_1 = \xi_1 = 0$, $x_2 = -2t + \mathsf{const}$.

(e) energy level 0 is empty as $\eta < -1$.

(ii) Along each of these trajectories phase coordinates (x_1, ξ_1) *are periodic with period*

$$T(\eta) = \int_{b_1\eta)}^{b_2\eta)} \frac{1}{\sqrt{1-(\eta-|y|^\nu/\nu)^2}}\, dy \tag{14.2.4}$$

and $x_2(t) = v(\eta)t + \tilde{x}_2(t)$ *where* $v(\eta) = I(\eta)/T(\eta)$,

$$I(\eta) = 2\int_{b_1\eta)}^{b_2\eta)} \frac{\eta-|y|^\nu/\nu}{\sqrt{1-(\eta-|y|^\nu/\nu)^2}}\, dy, \tag{14.2.5}$$

where $b_2(\eta)$ *defined by* (14.2.3) *and* $b_1(\eta) := -b_2(\eta)$ *is redefined as* $\eta < 1$ *and* $\tilde{x}_2(t)$ *is* $T(\eta)$*-periodic function.*

Proof. Proof is obvious consequence of the fact that evolution in (x_1, ξ_1) is described by 1-dimensional Hamiltonian (14.2.2) while $\xi_2 = \eta = \mathsf{const}$. Potential

$$U = U(x, \eta) = \bigl(\eta - \frac{1}{\nu}|x|_1^\nu\bigr)^2 - 1 \tag{14.2.6}$$

has two wells as $\eta > 0$ and one well as $\eta \le 0$; as $k = 0$ it has a flat bottom. Note that the bottoms of the potential are in $\pm b(\eta)$, $b(\eta) = (\eta\nu)^{1/\nu}$.

Further, as $\eta > 1$ we have $U(0;\eta) > 0$ and thus the dynamics lives in one well oscillating either between $b_1(\eta)$ and $b_2(\eta)$ or between $-b_2(\eta)$ and $-b_1(\eta)$. As $\eta < 1$ we have either one-well potential or $U(0;\eta) < 0$ so dynamics oscillates between $b_1(\eta) = -b_2(\eta)$ and $b_2(\eta)$. As $\eta = 1$ dynamics moves between $b_1(1) = 0$ (as $t \to \pm\infty$) and $\pm b_2(1)$ (as long as $\nu \ge 2$). □

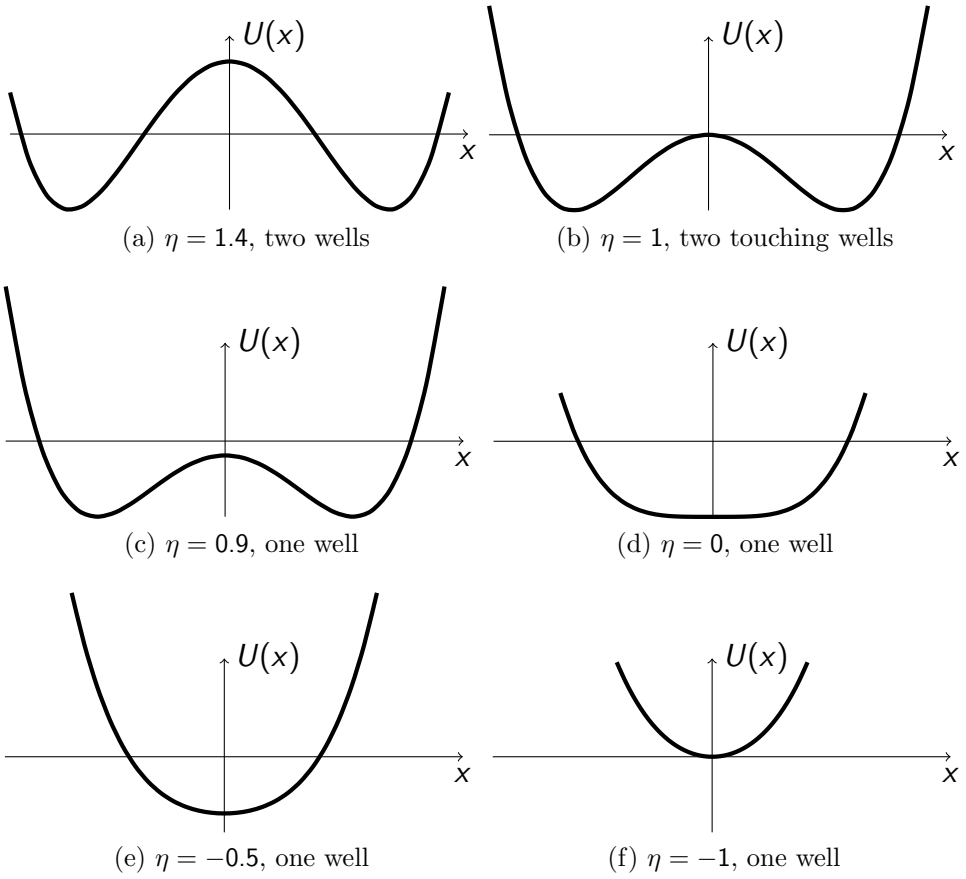
Proposition 14.2.2. *(i)* $v(\eta) > 0$ *and both* $T(\eta)$ *and* $v(\eta)$ *are decreasing functions of* $\eta > 1$.

(ii) The width of the wells is $\sim 2b(\eta)^{(1-\nu)/\nu}$ *and* $T(\eta) \sim \pi b(\eta)^{1-\nu}$, $v(\eta) \sim (\nu-1)b(\eta)^{-\nu}$ *as* $\eta \to +\infty$, $b(\eta) = (\eta\nu)^{1/\nu}$.

(iii) $T(\eta) \sim 2\bigl|\log|\eta-1|\bigr|$ *(for* $\nu = 2$*),* $T(\eta) \sim \mathsf{const}|\eta-1|^{(2-\nu)/2\nu}$ *(for* $\nu > 2$*) and* $v(\eta) \sim 1$ *as* $\eta \to 1+0$.

Proof. Consider $\eta > 1$. Changing $z = y^\nu/\nu - \eta$ we arrive to

$$T(\eta) = \int_{-1}^{1} \bigl((\eta+z)\nu\bigr)^{\frac{1}{\nu}-1}(1-z^2)^{-\frac{1}{2}}\, dz, \tag{14.2.7}$$



(a) $\eta = 1.4$, two wells (b) $\eta = 1$, two touching wells

(c) $\eta = 0.9$, one well (d) $\eta = 0$, one well

(e) $\eta = -0.5$, one well (f) $\eta = -1$, one well

Figure 14.1: Graphs of $U(x;\eta)$, 1-st toy-model (14.2.2) with $\nu = 2$

and

$$I(\eta) = 2\int_{-1}^{1} z\big((\eta+z)\nu\big)^{\frac{1}{\nu}-1}(1-z^2)^{-\frac{1}{2}}\,dz = \int_{-1}^{1} z\Big(\big((\eta-z)\nu\big)^{\frac{1}{\nu}-1} - \big((\eta+z)\nu\big)^{\frac{1}{\nu}-1}\Big)(1-z^2)^{-\frac{1}{2}}\,dz, \tag{14.2.8}$$

which implies that $I(\eta) > 0$ as $\eta > 1$.

Asymptotics $T(\eta) \sim \pi(\eta\nu)^{(1-\nu)/\nu}$, $I(\eta) \sim \pi(\nu-1)(\eta\nu)^{(2\nu-1)/2}$ as $\eta \to +\infty$ follow from (14.2.7) and (14.2.8) as well.

Also (14.2.7) and (14.2.8) imply that

$$\frac{\partial T}{\partial \eta} = -(\nu-1)\int_{-1}^{1} \big((\eta+z)\nu\big)^{\frac{1}{\nu}-2}(1-z^2)^{-\frac{1}{2}}\,dz, \tag{14.2.9}$$

$$\frac{\partial I}{\partial \eta} = -2(\nu-1)\int_{-1}^{1} z\big((\eta+z)\nu\big)^{\frac{1}{\nu}-2}(1-z^2)^{-\frac{1}{2}}\,dz, \tag{14.2.10}$$

$$\frac{\partial v}{\partial \eta} = -\nu(\nu-1)T^{-2}\times \int_{-1}^{1}\int_{-1}^{1}(z-z')^2\big((\eta+z)\nu\big)^{\frac{1}{\nu}-2}\big((\eta+z')\nu\big)^{\frac{1}{\nu}-2}(1-z^2)^{-\frac{1}{2}}\,dzdz' \tag{14.2.11}$$

implying monotonicity properties.

Asymptotics as $\eta \to 1+0$ follow directly from (14.2.4),(14.2.5). □

Remark 14.2.3. In the strong magnetic field the magnetic drift is described by

$$\frac{dx}{dt} = -\mathcal{L}VF^{-1} = (\partial_{x_2}F, -\partial_{x_1}F) = (0, (\nu-1)x_1^{-\nu}) \tag{14.2.12}$$

as $V=-1$ and this matches to asymptotics of v as $\xi_2 \to +\infty$.

As $-1<\eta<1$ one can rewrite

$$T(\eta) = 2\int_0^{b_2}\Big(1-(\eta-y^\nu/\nu)^2\Big)^{-\frac{1}{2}}\,dy = 2(\eta+1)^{\frac{1}{\nu}-\frac{1}{2}}\nu^{\frac{1}{\nu}}\int_0^1 (1-y^\nu)^{-\frac{1}{2}}\Big(2-(\eta+1)(1-y^\nu)\Big)^{-\frac{1}{2}}\,dy = 2(\eta+1)^{\frac{1}{\nu}-1}\nu^{\frac{1}{\nu}}\int_0^1 (1-y^\nu)^{-\frac{1}{2}}\varphi(u,y^\nu)\,dy \tag{14.2.13}$$

and

$$I(\eta) = 4\int_0^{b_2}(\eta-y^\nu/\nu)\Big(1-(\eta-y^\nu/\nu)^2\Big)^{-\frac{1}{2}}\,dy = 4\big((\eta+1)\nu\big)^{\frac{1}{\nu}}\int_0^1 (1-y^\nu)^{-\frac{1}{2}}\varphi_1(u,y^\nu)\,dy \tag{14.2.14}$$

with $u = \eta/(\eta+1) \in (-\infty, \frac{1}{2})$,

$$\varphi(u,z) = (1-2u+z)^{-\frac{1}{2}}, \qquad \varphi_1(u,z) = (u-z)(1-2u+z)^{-\frac{1}{2}}.$$

Let $T_1(u)$, $I_1(u)$ denote integrals in the right-hand expressions of (14.2.13) and (14.2.14) respectively. Then

$$\frac{\partial T_1}{\partial u} > 0, \qquad \frac{\partial I_1}{\partial u} = (1-u)\frac{\partial T_1}{\partial u} > 0$$

because $\frac{\partial \varphi}{\partial u} = (1-2u+z)^{-\frac{3}{2}}$, $\frac{\partial \varphi_1}{\partial u} = (1-u)(1-2u+z)^{-\frac{3}{2}}$.

Then

$$\frac{\partial}{\partial u}\frac{I_1}{T_1} = T_1^{-2}\frac{\partial T_1}{\partial u}\big((1-u)T_1 - I_1\big) = T_1^{-2}\frac{\partial T_1}{\partial u} \times \int_0^1 (1-y^\nu)^{-\frac{1}{2}}\big(1-2u+y^\nu\big)^{\frac{1}{2}}\,dy > 1$$

due to Cauchy inequality.

Since $\frac{1}{2}v(\eta) = (\eta+1)I_1(u)/T_1(u)$ and $(\eta+1)\frac{du}{d\eta} = (1-u)$

$$\frac{1}{2}\frac{\partial v}{\partial \eta} = (1-u)\frac{\partial}{\partial u}\frac{I_1}{T_1} + \frac{I_1}{T_1} > \frac{1}{T_1}\big((1-u)T_1 + I_1\big) = \frac{1}{T_1}\int_0^1 (1-y^\nu)^{\frac{1}{2}}\big(1-2u+y^\nu\big)^{-\frac{1}{2}}\,dy > 0.$$

Proposition 14.2.4. *(i) There exists $\eta^* = \eta^*_\nu \in (0,1)$ such that*

$$v(\eta)(\eta-\eta^*)^{-1} > 0 \tag{14.2.15}$$

and it is both bounded and disjoint from 0 as $\eta \in (-1+\epsilon, 1)$.

(ii) $v(\eta)$ is monotone increasing at $(-1,1)$.

(iii) $T(\eta) \sim \mathsf{const}(\eta+1)^{1/\nu}$ and $v(\eta) \sim -1$ as $\eta \to -1+0$.

(iv) $T(\eta) \sim 4\big|\log|\eta-1|\big|$ (for $\nu = 2$), $T(\eta) \sim 2\mathsf{const}|\eta-1|^{(2-\nu)/2\nu}$ (for $\nu > 2$) and $v(\eta) \sim 1$ as $\eta \to 1+0$.

Proof. Statement (ii) is already proven. Statements (iii) and (iv) are easy and Statement (i) follows from Statements (ii)–(iii) and from $v(0) < 0$. □

Remark 14.2.5. (i) Calculating derivative one can prove easily that $T(\eta)$ is monotone decreasing function of η for $\nu = 2$; we are not sure if this is the case for larger ν.

(ii) $dx_2/dt > 0$ iff $|x_1| < (\eta\nu)^{1/\nu}$; in particular $dx_2/dt < 0$ on the whole trajectory iff $-1 < \eta < 0$.

(iii) One can prove easily that

$$\frac{\partial v}{\partial \eta} \sim \mp \mathsf{const} |\eta - 1|^{-\frac{1}{\nu}-\frac{1}{2}} |\log |\eta - 1||^{-2\delta_{\nu 2}} \qquad \text{as} \quad \eta \to 1 \pm 0. \tag{14.2.16}$$

(iv) In particular, $x_2(t)$ is periodic iff $\eta = \eta^*$.

(v) Since

$$\frac{\partial I_1}{\partial \nu} = \int_0^1 (u-1)^2 (1-y^\nu)^{-\frac{3}{2}} (1-2u+y^\nu)^{-\frac{3}{2}} y^\nu (-\log y)\, dy > 0$$

we conclude that η^*_ν monotonically decreases; one can see easily that $\eta^*_\nu \to +0$ as $\nu \to +\infty$.

(vi) Maple (see Subappendix 14.A.5) experiments show that $\eta^*_2 \approx 0.65$ (but not $2/3$).

The following series of Figures 14.2(a)–(l) show (x_1, x_2)-trajectories at level 0 for different values of η as $\nu = 2$. In particular, Figure 14.2(g) shows periodic curve.

Proposition 14.2.6. *There exist functions $Z = Z(x_1, \xi_1)$, $\alpha = \alpha(x_1, \xi_1, \eta)$ and $\beta = \beta(x_1, \eta)$, such that*

$$\{a, x_2 - Z\} = \eta - \{a, Z\} = \alpha(\eta - \eta^*) + \beta a(x_1, \xi_1, \eta). \tag{14.2.17}$$

Further, Z is odd and α, β are even with respect to each of variables x_1, ξ_1.

Proof. Consider now periodic curve as $\eta_=\eta^*$ with the "center" at 0. It is described by equations in (x, ξ)-phase space

$$\eta = \eta^*, \quad a(x_1, \xi_1, \eta) = 0, \quad x_2 = Z(x_1, \xi_1) \tag{14.2.18}$$

with smooth odd with respect to each x_1, ξ_1 function Z. We cannot express it via x_1 or ξ_1 alone. Then

$$\{a, x_2 - Z\} = \eta - \{a, Z\} = 0 \qquad \text{as} \quad \eta = \eta^*, \ a(x_1, \xi_1, \eta) = 0.$$

Note that da and $d\eta$ are linearly independent unless $\xi_1 = 0$ and $(\eta - |x_1|^\nu/\nu)x_1 = 0$ which for $a = 0$ means that $\xi_2 = \pm 1$. Therefore we arrive to (14.2.17). □

Remark 14.2.7. For even integer ν all these functions are analytic.

14.2.2 Another Toy-Model

Consider now another model

$$a = \xi_1^2 + \bigl(\eta - \frac{1}{\nu}|x_1|^\nu \operatorname{sgn}(x)\bigr)^2 - 1 \tag{14.2.19}$$

with $\nu \geq 2$, corresponding to $\mu = 1$, $V = -1$. Again we are looking at energy level 0. Consider again the graph of potential.

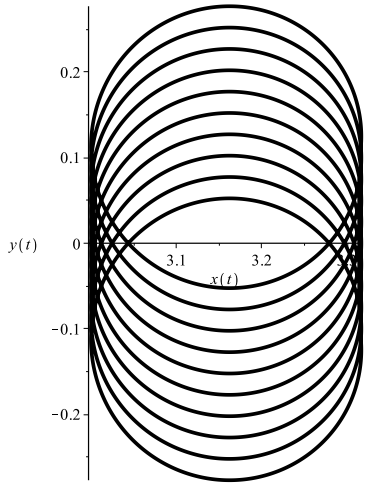
In the similar way movement in (x_1, ξ_1) is described by Hamiltonian with one-well potential and if $\eta \geq 1$ this particle moves only in $\{x_1 \geq 0\}$ and the evolution coincides with given in Figures 14.2(a)–(d) (where we considered only one component anyway) but for $-1 < \eta < 1$ picture changes; it is not central symmetric as on Figures 14.2(e)–(f) and oscillates between $b_1(\eta)$ and $b_2(\eta)$ where $b_2(\eta)$ is still defined by (14.2.3) and $b_1(\eta) := -b_2(-\eta)$ is redefined again.

As $\eta = 0$ movement is periodic, as $\eta < 0$ dynamics is central reflected to one with $-\eta$ (so we arrive to Figures 14.4(g)–(e) and then to Figures 14.2(d)–(a) rotated by π).

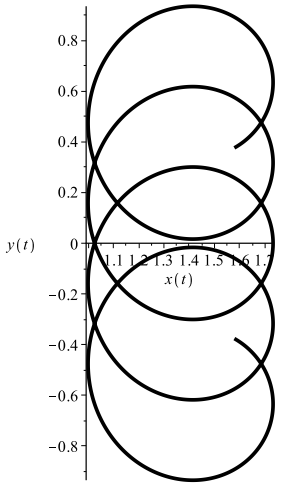
Then

$$T(\eta) = \frac{1}{2}\bigl(T_+(\eta) + T_+(-\eta)\bigr), \qquad I(\eta) = \frac{1}{2}\bigl(I_+(\eta) - I_+(-\eta)\bigr) \tag{14.2.20}$$

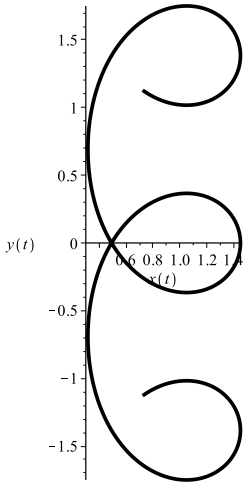
where $T_+(\eta)$, $I_+(\eta)$ are exactly what we introduced as $T(\eta)$ and $I(\eta)$ for Hamiltonian (14.2.2) by (14.2.13) and (14.2.14) respectively. However due to monotonicity of $|y|^\nu \operatorname{sgn}(y)$ we can apply idea of Proposition 14.2.2:



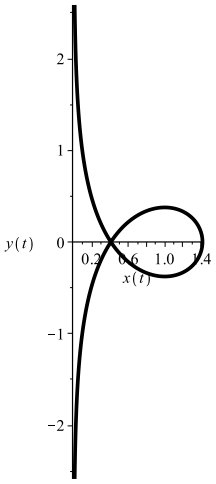
(a) $\eta = 10$, $w \approx 0.34$



(b) $\eta = 2$, $w \approx 0.73$

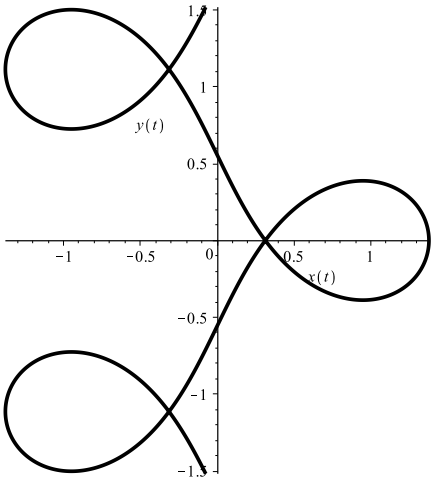


(c) $\eta = 1.1$, $w \approx 1.13$

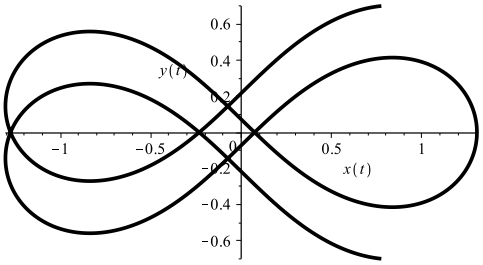


(d) $\eta = 1$, $w \approx 1.13$, first critical case

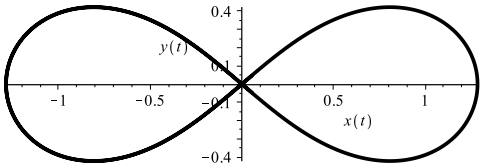
Figure 14.2: Drift up; and rotation clockwise, each figure has its mirror with respect to x_2-axis with drift up and rotation counter-clockwise as F changes sign; $w = \sqrt{\eta + 1} - \sqrt{\eta - 1}$ is the width. Aspect ratio is preserved albeit scaling differs.



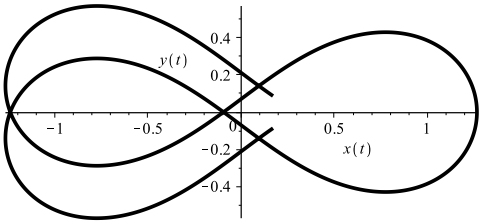
(e) $\eta = 0.9$, $w \approx 4.32$



(f) $\eta = 0.7$, $w \approx 3.78$

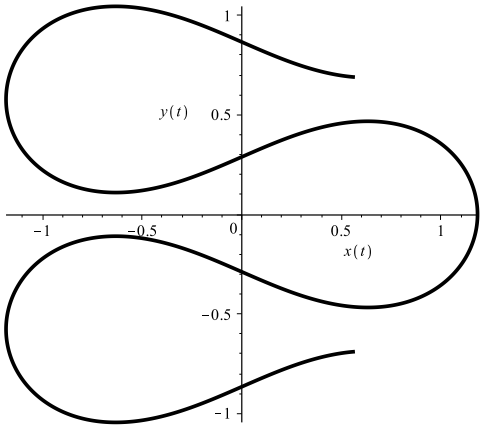


(g) $\eta \approx 0.65$, $w \approx 3.65$, second critical case

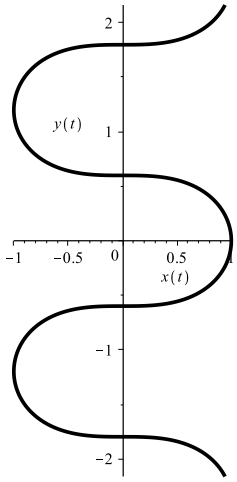


(h) $\eta = 0.6$, $w \approx 3.52$

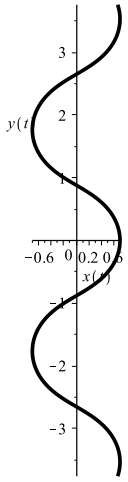
Figure 14.2: (continued) As η decreases drift slows down, (g) movement is periodic ($v(\eta^*) = 0$) and on (h) drift is down; $w = 2\sqrt{\eta + 1}$ is the width.



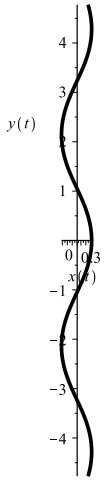
(i) $\eta = 0.4$, $w \approx 2.28$



(j) $\eta = 0$, $w = 2$

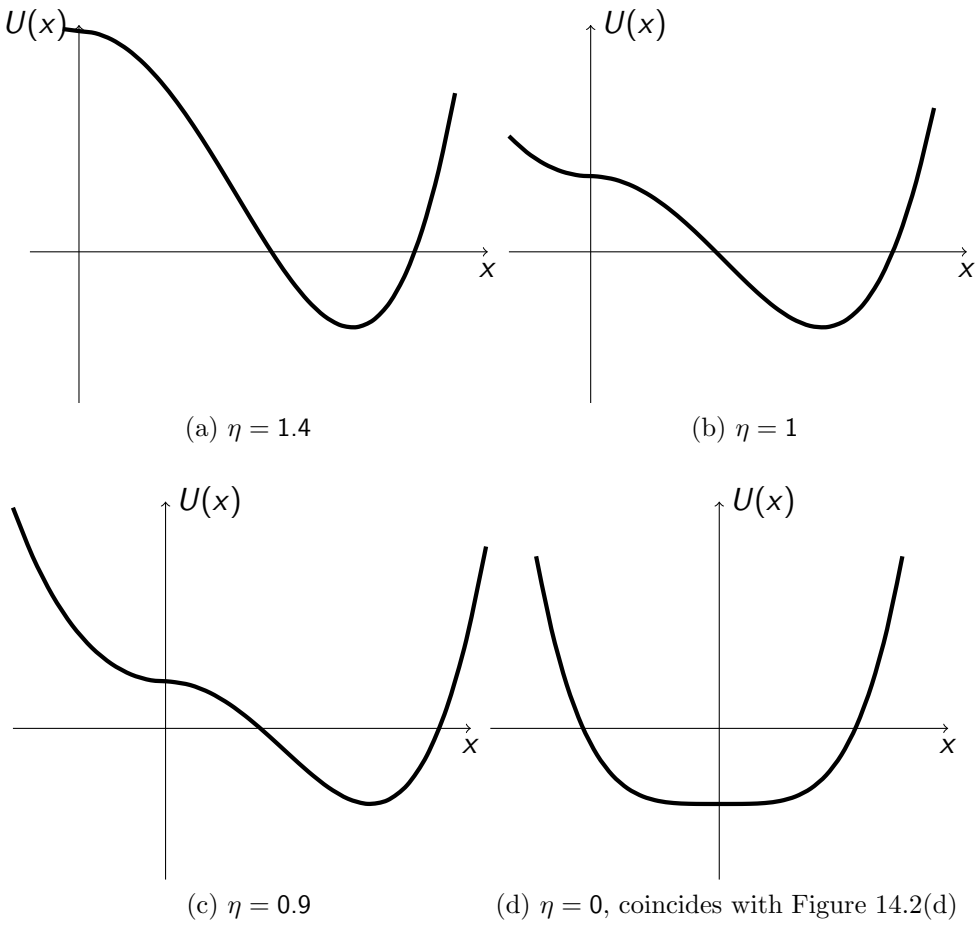


(k) $\eta = -0.5$, $w \approx 1.41$



(l) $\eta = -0.9$, $w \approx 0.63$

Figure 14.2: (continued) As η decays further drift down accelerates and width decays.



(a) $\eta = 1.4$ (b) $\eta = 1$

(c) $\eta = 0.9$ (d) $\eta = 0$, coincides with Figure 14.2(d)

Figure 14.3: Graphs of $U(x;\eta)$, 2-nd toy-model (14.2.19) with $\nu = 2$. As $\eta < 0$ graph coincides with mirror image of $U(x;-\eta)$

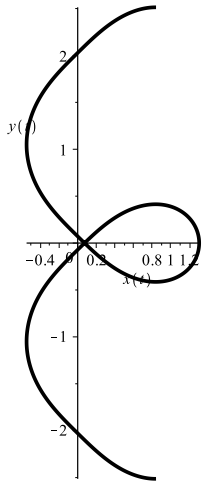
introducing $z = |y|^\nu \operatorname{sgn}(y) - \eta$ we arrive to

$$T(\eta) = \int_{-1}^{1} |(\eta+z)\nu|^{\frac{1}{\nu}-1}(1-z^2)^{-\frac{1}{2}}\,dz, \tag{14.2.21}$$

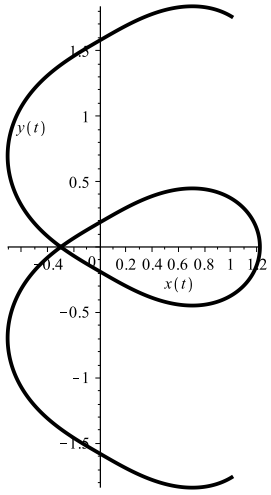
$$I(\eta) = -2\int_{-1}^{1} z|(\eta+z)\nu|^{\frac{1}{\nu}-1}(1-z^2)^{-\frac{1}{2}}\,dz = 2\int_{0}^{1} z\Big(|(\eta-z)\nu|^{\frac{1}{\nu}-1} - |(\eta+z)\nu|^{\frac{1}{\nu}-1}\Big)(1-z^2)^{-\frac{1}{2}}\,dz \tag{14.2.22}$$

and obviously $\epsilon_0 I(\eta)/\eta \le c_0$ as $\eta \ne 0$.

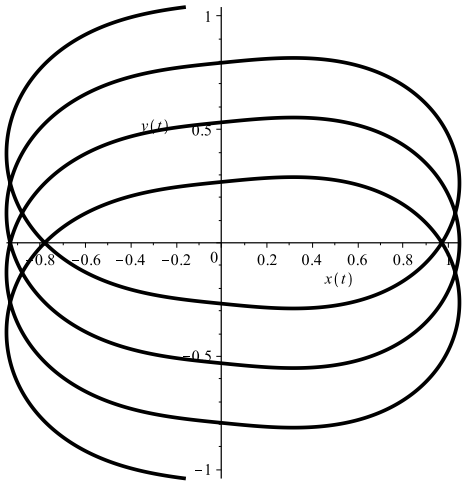
Thus we arrive to



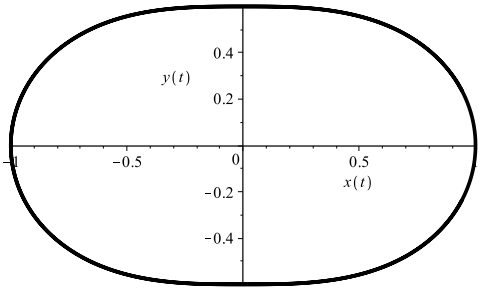
(e) $\eta = 0.9$, $w \approx 2.4$



(f) $\eta = 0.5$, $w \approx 2.73$



(g) $\eta = 0.1$, $w \approx 2.82$



(h) $\eta = 0$, $w \approx 2.83$, second critical case

Figure 14.4: Drift is up and movement clockwise. As η decays from 1 to 0 drift up slows down; (h) corresponds to periodic case; we skip $\eta \geq 1$ which repeat those at Figures 14.2(a)–(d), $\eta \leq -1$ which will be mirror-symmetric to them with drift down and also clockwise and $-1 < \eta < 0$ as central-symmetric to given there with drift down and also clockwise.

Proposition 14.2.8. *Consider on level* 0 *trajectories of Hamiltonian* (14.2.19) *with* $\eta \in (-1,1)$. *Along them*

(i) Phase coordinates (x_1,ξ_1) *are* $T(\eta)$*-periodic and* x_1 *oscillates between* $b_1 = -((1-\eta)\nu)^{1/\nu}$ *and* $b_2 = ((1+\eta)\nu)^{1/\nu}$.

(ii) $x_2(t) = \tilde{x}_2(t) + v(\eta)t$ *with* $T(\eta)$*-periodic* $\tilde{x}_2(t)$ *and* $v(\eta) = I(\eta)/T(\eta)$.

(iii) $\epsilon_0 I(\eta)/\eta \le c_0$ *as* $\eta \ne 0$.

(iv) Therefore the only periodic trajectory is with $\eta = 0$.

(v) Proposition 14.2.6 holds with $\eta^* = 0$ *but* Z *is even and* α, β *are odd with respect to* ξ_1.

(vi) For odd integer $\nu \ge 3$, Z, α, β *are analytic.*

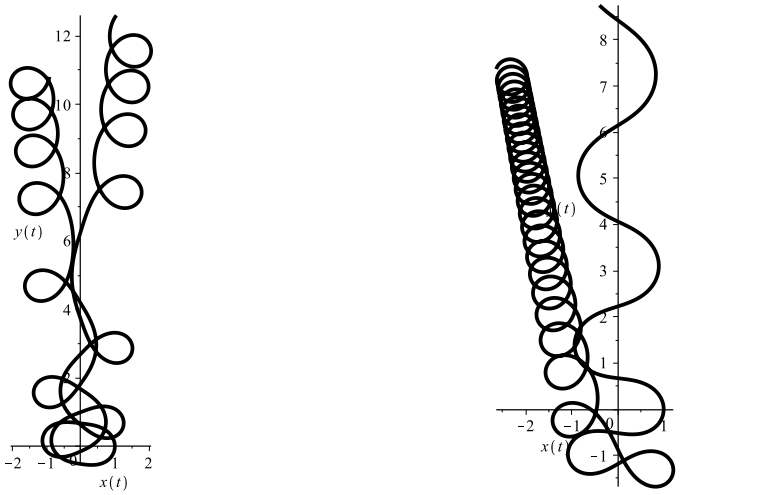
14.2.3 Toy-Models Perturbed

The periodic trajectories of our toy-models are very fragile and one can destroy them easily. Consider *heuristically* the same Hamiltonians albeit with $V = -\alpha x_1$ with $\alpha > 0$ instead of $V = -1$. Then $d\xi_2/dt = -\partial_{x_2} V = \alpha$ and thus $\xi_2 = c_0 + \alpha t$. Then the averaged movement along $y = x_2$ is described by

$$\frac{d}{dt}y = (-V)^{\frac{1}{2}} v\big(\xi_2(t)(-V)^{-\frac{1}{2}}\big) \sim (\alpha y)^{\frac{1}{2}} v\big(\alpha t(\alpha y)^{-\frac{1}{2}}\big)$$
$$\Longleftrightarrow \quad \frac{d}{dt}z \sim 2v\big(tz^{-1}\big)$$

with $z = 2\sqrt{y/\alpha}$. This "equation" has a solution $z = \beta_\pm^{-1} t$ as $\pm t > 0$ as $\beta_\pm v(\beta_\pm) = 2$ and $\pm\beta_\pm > 0$.

In the second toy-model this equation has two solutions $\beta_\pm$ with $-\beta_- = \beta_+ > 2$ and therefore on them "in average" $x_1 \sim (\nu\xi_2 V^{-1/2})^{1/\nu} V^{1/2\nu} \sim \rho y^{1/\nu}$. In the first toy-model there is just one solution $\beta_- = -2$. These observations explain the evolutions in vertical direction on Figures 14.5(a)–(b).



(a) First toy-model perturbed (b) Second toy-model perturbed

Figure 14.5: Both toy-models are perturbed by a weak electric field directed up ($V = \alpha x_2$)

14.2.4 General Case

Remarks

We are going to consider

$$a = \xi_1^2 + \sigma(x)^2\bigl(\xi_2 - \mu\phi(x)\varrho_\nu(x_1)/\nu\bigr)^2 + V(x) \tag{14.2.23}$$

with coefficients

$$\sigma \ge \epsilon_0, \quad \phi \ge \epsilon_0, \quad -V \ge \epsilon_0 \tag{14.2.24}$$

and all of them are smooth and with $\varrho_\nu = |x_1|^\nu$ or $\varrho_\nu = |x_1|^\nu \operatorname{sgn} x_1$, $\nu \ge 2$.

Let

$$p_1 = \xi_1, \quad p_2 = \xi_2 - \mu\phi(x)\varrho_\nu(x_1)/\nu; \tag{14.2.25}$$

then

$$\{p_1, p_2\} = -\mu\partial_{x_1}\bigl(\phi(x)\varrho_\nu(x_1)/\nu\bigr) = \\ -\mu\phi(x)\varrho_{\nu-2}(x_1)x_1\bigl(1 + O(x_1)\bigr). \tag{14.2.26}$$

We want to consider trajectories on level $\{a = 0\}$ (and thus on any level $\{a = \tau\}$) and thus we can multiply a by any smooth factor disjoint from 0; then we can assume that

$$\sigma|_\Sigma = \phi|_\Sigma = 1. \tag{14.2.27}$$

Really, starting from (14.2.23) we can multiply a by smooth function ω^2 and redefine x_1 according to the new metrics; then we redefine x_2 to get rid of the mixed term. Then (14.2.23) will still hold but with $V \mapsto \omega^2 V$, $\sigma|_\Sigma \mapsto (\sigma\omega^2)|_\Sigma$, $\phi|_\Sigma \mapsto (\phi\omega^\nu)|_\Sigma$ and picking up $\omega = (\sigma\phi)^{-1/(\nu+1)}$ we arrive to the case $(\sigma\phi)|_\Sigma = 1$ with

$$V \mapsto V^* = (\sigma\phi)^{-2/(\nu+1)} V. \tag{14.2.28}$$

Finally, replacing x_2 by $\rho(x_2)$ we can achieve $\sigma|_\Sigma = 1$ and thus (14.2.27).

From now on

$$W(x_2) \coloneqq -V^*(0, x_2) = \big((\sigma\phi)^{-2/(\nu+1)} V\big)(0, x_2) \tag{14.2.29}$$

(i. e. $W(x_2) = -V(0, x_2)$ under assumption (14.2.27)).

Regular Zone

Proposition 14.2.9. *For a general Hamiltonian* (14.2.23) *in* $B(0, 1)$ *satisfying* (14.2.24)

(i) There exists $b = b(x, p_1, p_2)$*, such that as* $|a| \le \epsilon_0$ *and* $|f| \ge \bar\gamma = C\mu^{-1/\nu}$

$$C_0^{-1} \le \frac{b}{f} \le C_0, \tag{14.2.30}$$

$$|\{a, b\}| \le C_0 \mu^{-1} |f|^{-1}; \tag{14.2.31}$$

here and below $f \in \mathscr{C}^\infty$*,* $f = 0$*,* $\nabla f \ne 0$ *on* Σ*.*

(ii) Trajectories starting at $t = 0$ *from* $(\bar x, \bar\xi) \in B(0, \frac12) \cap \{x, \pm f(x) = \gamma\}$ *with* $\gamma \ge \bar\gamma$ *for time* $|t| \le T^* = \epsilon_0 \mu f(\bar x)^2$ *remain in* $B(0, 1)$ *and along them* $\epsilon \le \pm f(x(t))/\gamma \le C$*.*

(iii) Trajectories starting at $t = 0$ *from* $(\bar x, \bar\xi) \in B(0, \frac12) \cap \{x, |f(x)| \le \gamma = \bar\gamma\}$ *for time* $|t| \le T^* = \epsilon$ *remain in* $B(0, 1)$ *and along them* $|f(x(t))| \le C_1\bar\gamma$*.*

Proof. Let us consider a trajectory starting at $(\bar{x},\bar{\xi})$ with $\bar{x}\in B(0,\frac{1}{2})$, $a\le c$, $\gamma=|\bar{x}_1|\ge\bar{\gamma}=C_0\mu^{-1/\nu}$. Consider this trajectory as long as it is contained in $B(0,1)$ but not further than $T^*=\epsilon\mu\gamma^{\nu}$ [5)].

Along this trajectory

$$\frac{1}{2}\frac{d\xi_2}{dt}=\frac{1}{2}\{a,\xi_2\}=\sigma^2(x)p_2\phi_{x_2}(x)\times\mu\varrho_\nu(x_1)/\nu+O(1). \tag{14.2.32}$$

Then for $X:=\xi_2-\beta(x)p_1$

$$\frac{1}{2}\frac{dX}{dt}=\frac{1}{2}\{a,X\}=\sigma^2p_2\mu\varrho_\nu(x_1)\big(\frac{1}{\nu}\phi_{x_2}(x)-\phi(x)\beta x_1^{-1}\big)+O(1) \tag{14.2.33}$$

(as $a=0$) and therefore $\frac{d}{dt}X=O(1)$ for

$$X=\xi_2-\beta(x)p_1,\qquad \beta=\frac{1}{\nu}x_1\phi_{x_2}\phi^{-1}=\frac{1}{\nu}x_1\partial_{x_2}\log|\phi(x)|. \tag{14.2.34}$$

Therefore $|X(x)-X(\bar{x})|\le CT\le C\epsilon\mu\gamma^{\nu}$, which together with inequality $|p_2|\le c$ imply that $|\xi_2-\bar{\xi}_2|\le C\epsilon\mu\gamma^{\nu}$; for small enough constant $\epsilon>0$ we also get $\epsilon_1\mu\gamma^{\nu}\le|\xi_2|\le c_1\mu\gamma^{\nu}$ (recall that $\mu\gamma^{\nu}\ge C$) and thus $\epsilon_1^{-1}\gamma\le|x_1|\le c_1\gamma$.

Thus this trajectory remains in the strip described above and since the drift speed according to Chapter 13 does not exceed $C_0(\mu\gamma^{\nu})^{-1}$ there we are insured that this trajectory remains in $B(0,1)$ for time T. This proves Statement (ii).

On the other hand, if a trajectory starts in $(\bar{x},\bar{\xi})$ with $|\bar{x}_1|\le\bar{\gamma}$, it remains in $B(0,1)$ for time $T=\epsilon$ since the speed does not exceed C_0 and due to above arguments it cannot get into zone $\{x_1\ge C\bar{\gamma}\}$. This proves Statement (iii).

To prove Statement (i) consider $b=(\mu^{-1}X)^{1/\nu}$; then as $|x_1|\ge\bar{\gamma}$ obviously $b\asymp|x_1|$ and furthermore $|\{a,b\}|\le C(\mu^{-1}|\xi_2|)^{1/\nu}|\xi_2|^{-1}\le c\mu^{-1}|x_1|^{1-\nu}$ which is exactly (14.2.31). □

Obviously $\frac{d}{dt}x_2=2\sigma^2p_2$ and for $Y=x_2-\mu^{-1}\varrho_{-\nu}(x_1)x_1\beta'p_1$ we have

$$\frac{dY}{dt}=2\sigma^2\big(1-\beta'\phi\big)p_2+2(\nu-1)\beta'\mu^{-1}\varrho_{-\nu}(x_1)p_1^2+O(\mu^{-1}|x_1|^{1-\nu}).$$

So, let $\beta'=\phi^{-1}$; then the first term vanishes and

$$\frac{dY}{dt}=(\nu-1)\beta'\mu^{-1}\varrho_{-\nu}(x_1)(a-V)+(\nu-1)\beta'\mu^{-1}\varrho_{-\nu}(x_1)(p_1^2-\sigma^2p_2^2)+O(\mu^{-1}|x_1|^{1-\nu})$$

[5)] Then $T^*\asymp 1$ as $|\bar{x}_1|\asymp\bar{\gamma}$ and $T^*\asymp\mu$ as $|\bar{x}_1|\asymp 1$.

as $a - V = p_1^2 + \sigma^2 p_2^2$ and redefining

$$Y = x_2 - \mu^{-1}\varrho_{-\nu}(x_1)x_1\beta' p_1 - \mu^{-2}\varrho_{-2\nu}(x_1)x_1 p_1 p_2 \tag{14.2.35}$$

we arrive to

$$\frac{dY}{dt} = -(\nu-1)\beta'\mu^{-1}\varrho_{-\nu}(x_1) + O\big(\mu^{-2}|x_1|^{-2\nu} + \mu^{-1}|x_1|^{1-\nu}\big), \tag{14.2.36}$$

and finally we arrive to

Proposition 14.2.10. *Along trajectories in the* regular zone $\{\epsilon \ge |x_1| \ge \bar\gamma\}$

$$\epsilon_0(\mu\gamma^\nu)^{-1}|t| \le \pm\varrho_0(\bar x)\big(Y(t) - Y(0)\big) \le C(\mu\gamma^\nu)^{-1}|t| \tag{14.2.37}$$

as $0 \le \pm t \le \epsilon\mu\gamma^\nu$.

Degeneration Zone

Now we need to consider trajectories lying in the degeneration zone $\mathcal{X}_{\mathsf{deg}} = \{x : |x_1| \le C\bar\gamma\}$. Here function X is still defined but Y is not and from the analysis of the toy-models one can guess that the important role is played by function $X(x,p)|V(0,x_2)|^{-\frac12}$.

Proposition 14.2.11. *Let conditions* (14.2.24) *and* (14.2.27) *be fulfilled. Further let conditions* $|\xi_2(0)| \le C$ *and*

$$\varsigma\big(\xi_2 - \eta^*|V|^{\frac12}\big) \ge \epsilon_1, \qquad \varsigma = \pm 1 \tag{14.2.38}$$

be satisfied as $t = 0$. *Then*

(i) For $|t| \le T = \epsilon$ *this latter condition is satisfied (with* ϵ_1 *replaced by* $\frac12\epsilon_1$*).*

(ii) Moreover

$$\epsilon_2|t| \le \pm\varsigma\big(x_2(t) - x_2(0)\big) \le c_2|t| \qquad \text{as} \qquad c\bar\gamma \le \pm t \le T \tag{14.2.39}$$

and

$$\epsilon_2|t| \le |x(t) - x(0)| + |p(t) - p(0)| \le c_2|t| \qquad \text{as} \qquad |t| \le c\bar\gamma. \tag{14.2.40}$$

Proof. Proof of Statement (i) is obvious; (14.2.39) and (14.2.40) then follow from comparison of the general and toy-model system. □

So there are no T-periodic trajectories with $0 < T \le \epsilon$ unless

$$\rho = |\xi_2 - \eta^* W^{\frac{1}{2}}| \le \epsilon_1. \tag{14.2.41}$$

Note that now

$$\frac{d\xi_2}{dt} = W_{x_2} + O(\bar\gamma) \tag{14.2.42}$$

which immediately yields the following proposition:

Proposition 14.2.12. *Let conditions* (14.2.24), (14.2.27), (14.2.41) *be fulfilled and*

$$\varsigma \partial_{x_2} W \ge \epsilon_0 \qquad \textit{with} \quad \varsigma = \pm 1. \tag{14.2.43}$$

Then trajectories on level 0 *satisfy*

$$\pm\varsigma\big(\xi_2(t) - \xi_2(0)\big) \ge \epsilon|t| \qquad \textit{as} \quad 0 \le \pm T \le \epsilon. \tag{14.2.44}$$

In what follows we will consider more precisely trajectories satisfying (14.2.41) and also $|W_{x_2}| \le \epsilon_0$.

We still want to consider such trajectories as long as they are in a certain vicinity of the original point $x(0)$. For the toy-models this vicinity is $B(0,1)$ and $T^* = \epsilon\rho^{-1}$ as $|\xi_2 - \eta^*| = \rho$ but for other Hamiltonians both vicinity and time may be smaller.

Proposition 14.2.13. *For any of two toy-models with coupling constant* $\mu \ge 1$ *and potential* $V = -1 \mp \zeta x_2$, $0 \le \zeta \le \epsilon$

(i) Trajectory starting at $(\bar x, \bar\xi)$ *satisfying* (14.2.41) *remains in* $B(0,1)$ *and satisfies* (14.2.41) *with* $2\epsilon_1$ *as long* $|t| \le T^* = \epsilon \min\big(\zeta^{-\frac{1}{2}}, \rho^{-1}\big)$.

(ii) Along it

$$|x_2(t) - x_2(0)| \le C(\zeta|t|^2 + \rho|t|) + C\bar\gamma, \qquad \xi_2(t) - \xi_2(0) = \pm\frac{1}{2}\zeta t \tag{14.2.45}$$

and in at least one time direction

$$|x_2(t) - x_2(0)| \ge \epsilon(\zeta|t|^2 + \rho|t|) - C\bar\gamma. \tag{14.2.46}$$

Proposition 14.2.14. *For a general Hamiltonian* (14.2.23), *satisfying conditions* (14.2.24), (14.2.27) *and*

$$|\partial_{x_2} W| \le \zeta \tag{14.2.47}$$

(i) Statement (i) of Proposition 14.2.13 holds as

$$\rho \ge \bar\gamma, \qquad \zeta \ge \bar\gamma \tag{14.2.48}$$

and $|\xi_2 - \eta^* W^{\frac12}| \le \rho$.

(ii) Assuming (14.2.48)*, if*

$$\left|\partial_{x_2} W\right| \ge \epsilon_1 \zeta \tag{14.2.49}$$

then

$$|\xi_2(t) - \xi_2(0)| \ge \epsilon\zeta|t|. \tag{14.2.50}$$

(iii) Assuming (14.2.48)*, if*

$$\left|\xi_2(0) - \eta^* W(x(0))^{\frac12}\right| \ge \epsilon_1\rho \tag{14.2.51}$$

then in at least one time direction

$$|x_2(t) - x_2(0)| \ge \epsilon\rho|t|. \tag{14.2.52}$$

Proofs of Propositions 14.2.13 and 14.2.14. Easy proofs are left to the reader.□

Hamiltonian mMaps

Now we need to analyze more precisely what happens in the periodic zone $\mathcal{X}_{\mathsf{per}} = \{x,\ |x_1| \le c\bar\gamma, |\xi_2 - \eta^* W^{\frac12}| \le \rho\}$ where ρ will be specified in the next section. Let us consider toy-models first.

If on each energy level τ, $|\tau| \le \epsilon$ all the trajectories were periodic with period $T = T(\tau)$ then replacing Hamiltonian a by $g(a)$ with

$$g(\tau) = \frac{1}{\bar T}\int^{\tau} T(\tau)\, d\tau \tag{14.2.53}$$

we would get $\bar T$-periodic Hamiltonian flow.

However it is not the case:

(14.2.54) For both toy-model Hamiltonians on each energy level τ the only periodic trajectory is one with

$$\xi_2 = \xi_2(\tau) = \eta^*(1+\tau)^{\frac12} \tag{14.2.55}$$

and a period is

$$T(\tau) = \bar T(1+\tau)^{-\frac{1}{2\nu}(\nu-1)} \tag{14.2.56}$$

Still defining $g(\tau)$ accordingly let us consider the Hamiltonian $g(a)$.

Proposition 14.2.15. *For a toy-model symbol a given by* (14.2.2) *or* (14.2.19)

$$e^{\bar{T}H_{g(a)}} = e^{H_b}, \tag{14.2.57}$$

$$g(\tau) = \kappa^{-1}(1+\tau)^{\kappa} - \kappa^{-1}, \qquad \kappa = \frac{\nu+1}{2\nu}, \tag{14.2.58}$$

$$b = \bar{b}(\xi_2, a) = (1+a)^{\kappa}\Big(\frac{\xi_2}{(1+a)^{\frac{1}{2}}} - \eta^*\Big)^2 \omega\Big(\frac{\xi_2}{(1+a)^{\frac{1}{2}}}\Big) \tag{14.2.59}$$

where $\bar{T}$ is an elementary period and

$$\omega(\eta^*) = \frac{1}{2}\partial_\eta I(\eta)\big|_{\eta=\eta^*}. \tag{14.2.60}$$

Proof. As a is a toy-model Hamiltonian then taking $\xi_2 = \eta^*$, $a = 0$ we would conclude that the Hamiltonian trajectories are periodic with period $\bar{T}$. As $a = \tau$ disjoint from -1 we have both $\xi_2^*(\tau)$ and $T(\tau)$ defined by (14.2.55)–(14.2.56).

To get period which is independent on energy level one must replace a by $g(a)$ with $g(\tau)$ defined by (14.2.53); then $e^{\bar{T}H_{g(a)}} = I$ as $\xi_2 = \xi_2^*(a)$; period is $\bar{T}$ rather than 1 since we define $g(a)$ without factor $\bar{T}$.

As $\xi_2 \neq \xi_2^*(a)$ periodicity is broken. Since H_a and H_{ξ_2} near $\{a = 0\}$ are linearly independent we conclude that $e^{\bar{T}H_{g(a)}} = I + 2(\xi_2 - \xi_2^*(a))\omega_1(x_1, \xi_1, \xi_2)$. However since it is a symplectic map it must be of the form e^{H_b} with

$$b = (\xi_2 - \xi_2^*(a))^2\omega_2(x_1, \xi_1, \xi_2) + \lambda(x_1, \xi_1).$$

We know that as $\xi_2 = \xi_2^*(a)$ we have $e^{H_b} = e^{H_\lambda} = I$ and since λ is "small" we conclude that $\lambda = \mathsf{const}$ (and thus we can take it 0).

Since e^{H_b} commutes with e^{H_a} we conclude that $\omega = \omega(\xi_2, a)$ and due to homogeneity properties $\omega_2 = \omega\big(\xi_2(1+a)^{-\frac{1}{2}}\big)(1+a)^{\kappa-1}$. Then x_2-shift as $a = 0$ and $\xi_2 \approx \eta^*$ is $2\omega(k^*)(\xi_2 - \eta^*) + O\big((\xi_2 - \eta^*)^2\big)$ which implies (14.2.60). □

If we consider a toy-model but with $\mu \neq 1$ one needs to replace (14.2.57) by

$$e^{\bar{\gamma}\bar{T}g(a)} = e^{\bar{\gamma}H_b}. \tag{14.2.61}$$

Consider now trajectories residing in $B(0, C_0\bar\gamma)$ and corresponding to these Hamiltonians but with potential $V = -1 - \zeta x_2$. One can see easily that (14.2.61) will remain true with $b = \bar b - \frac{1}{2}\bar T W + b'$, $W := -V(0, x_2)$ and b' satisfying (14.2.63) below. Then for the general Hamiltonians one can prove easily the following proposition:

Proposition 14.2.16. *For a general Hamiltonian* a *defined by* (14.2.23) *with* σ, ϕ *satisfying* (14.2.27) *and with* W, $W(0) = 1$, *satisfying in* $C_0\bar\gamma$*-vicinity of* 0

$$|\partial_{x_2} W| \le \zeta \tag{14.2.62}$$

with $\zeta \ge C\bar\gamma$, *equality* (14.2.61) *holds with symbol* $b = \bar b - \frac{1}{2}\bar T W(x_2) + b'$ *where* $\bar b = \bar b(\xi_2, a)$ *is defined by* (14.2.59), *and*

$$|\partial_x^\alpha b'| \le C\big(\zeta(\zeta+\rho) + \bar\gamma\big)\bar\gamma^{1-|\alpha|}, \qquad |\alpha| \le 1. \tag{14.2.63}$$

14.3 Quantum Dynamics

14.3.1 Preliminary Notes. Forbidden Zone

Starting from this section $\nu \ge 2$ is an integer and magnetic potentials

$$V_1 = 0, \quad V_2 = \phi(x)\nu^{-1}\varrho_\nu(x_1), \qquad \varrho_\nu(x_1) := x_1^\nu. \tag{14.3.1}$$

Thus we have different toy-models for even and odd ν.

In this subsection we consider $\mu \ge h^{-1}$ and *forbidden zone* is defined by (14.3.2) below. Also we consider ξ_2-localization which is useful when μ is close to $h^{-\nu}$.

Proposition 14.3.1. *Let* $\mu \ge h^{-1}$ *and*

$$\mu h F + V \ge \epsilon \tag{14.3.2}$$

in $B(\bar x, \gamma)$ *with*

$$\gamma \ge \max\big(h, \bar\gamma\big), \qquad \bar\gamma := C\mu^{-\frac{1}{\nu}}. \tag{14.3.3}$$

Then

$$|e(x, x, 0)| \le C\gamma^{-2}\big(\mu^{-1}h\gamma^{-\nu-1}\big)^s \qquad \text{in } \ B(\bar x, \gamma). \tag{14.3.4}$$

Proof. Proof follows from results of the previous Chapter 13 just by rescaling. □

Corollary 14.3.2. *In particular, as*

$$h^{-1} \le \mu \le C_0 h^{-\nu} \tag{14.3.5}$$

the total contribution to $\int e(x,x,0)\psi(x)\,dx$ *of the* classically forbidden zone *defined by* (14.3.2) *does not exceed* $C\bar{\gamma}_1^{-1}(\mu h^{\nu})^s$. *Thus we need to consider only* classically allowed zone $\{x,\ \mu hF + V \le \epsilon\}$ *and there*

$$\gamma \le \bar{\gamma}_1 := C_0(\mu h)^{-1/\nu-1)}. \tag{14.3.6}$$

This result is not very useful as $\mu \ge h^{-\nu+\delta}$. However using logarithmic uncertainty principles and related arguments one can prove easily

Proposition 14.3.3. *Let conditions* (14.3.2), (14.3.5) *be fulfilled and*

$$\gamma \ge \max\bigl(Ch|\log h|, \bar{\gamma}\bigr). \tag{14.3.7}$$

with $C = C_s$. *Then*

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\psi u| \le CTh^s \qquad \forall \tau \le \epsilon \quad \forall T \ge Ch|\log h| \tag{14.3.8}$$

and therefore $e(x,x,0) \le Ch^s$ *in* $B(\bar{x},\gamma)$.

In particular, (14.3.7) is fulfilled automatically as $|x_1| \ge \bar{\gamma}_1$ provided

$$\mu \le \epsilon(h|\log h|)^{-\nu} \tag{14.3.9}$$

while the *superstrong magnetic field* case when (14.3.9) is violated requires some special consideration based on the analysis operators with operator-valued symbols. We need the following axillary proposition:

Proposition 14.3.4. *Let* $\lambda = \lambda_n(\eta)$ *be eigenvalues of* 1*-dimensional Schrödinger operator*

$$L(\eta) := D_1^2 + \bigl(\eta - \mu\nu^{-1}\varrho_\nu(x_1)\bigr)^2 \tag{14.3.10}$$

in $\mathscr{L}^2(\mathbb{R})$*; here we assume only that* $2 \le \nu \in \mathbb{R}$ *and either* $\varrho_\nu(x_1) = |x_1|^\nu$ *or* $\varrho_\nu(x_1) = |x_1|^\nu \cdot \operatorname{sgn}(x_1)$. *Then*

(i) $\lambda_n(\eta) > 0$.

(ii) Assume that either $\eta \ge 0$ *or* $\varrho_\nu = |x_1|^\nu \operatorname{sgn}(x_1)$. *Then for* $n \le \epsilon|\eta|^{(\nu+1)/\nu}$

$$\lambda_n(\eta) \asymp |\eta|^{(nu-1)/\nu} n, \tag{14.3.11}$$

$$0 < \partial_\eta \lambda_n(\eta) \cdot \operatorname{sgn}(\eta) \asymp |\eta|^{-1/\nu} n. \tag{14.3.12}$$

(iii) Assume that $\eta < 0$ *and* $\varrho_\nu = |x_1|^\nu$. *Then*

$$\lambda_n(\eta) \asymp \eta^2 + n^{2\nu/(\nu+1)}. \tag{14.3.13}$$

Proof. Proof of Statement (i) is obvious; Statements (ii) and (iii) easily follow from the semiclassical character of the spectrum as $|\eta| + n \gg 1$, $n \gg 1$ respectively. Easy details are left to the reader. More detailed analysis is left for Appendix 14.A. □

Furthermore, using operators with operator-valued symbols one can prove easily the following proposition:

Proposition 14.3.5. *Let* $\mu \ge Ch^{-\nu}$. *Then*

$$|e(x,x,\tau)| \le C\mu^{-s} \qquad \text{for } \tau \le \epsilon\big(\mu h^\nu\big)^{2/(\nu+1)}. \tag{14.3.14}$$

So, in what follows can assume that $\mu \le Ch^{-\nu}$. It will not be a case starting from Section 14.7 when we modify potential. As usual in what follows $u = u(x,y,t)$ is the propagator, i.e. the Schwartz kernel of operator $e^{ih^{-1}tA}$.

Proposition 14.3.6. *Let* $\mu \le Ch^{-\nu}$ *and let* $\varphi \in \mathscr{C}^\infty(\mathbb{R})$, $\varphi(t) = 1$ *as* $t \ge 2$, $\varphi(t) = 0$ *as* $t \le 1$. *Then*

(i) The following inequality holds

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\varphi\big(\pm\epsilon(\mu h^\nu)^{1/(\nu-1)}hD_{x_2}\big)\psi u| \le C(T+1)h^s \qquad \forall \tau \le \epsilon \quad \forall T \ge Ch|\log h| \tag{14.3.15}$$

and therefore

$$|\varphi\big(\pm\epsilon(\mu h^\nu)^{1/(\nu-1)}hD_2\big)e(x,y,0)| \le Ch^s; \tag{14.3.16}$$

here and below $x, y \in B(0, 1-\epsilon)$.

(ii) Furthermore, for even ν

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\varphi\big(-\epsilon hD_2\big)\psi u| \le C(T+1)h^s \qquad \forall \tau \le \epsilon \quad \forall T \ge Ch|\log h| \tag{14.3.17}$$

and therefore

$$|\varphi\big(-\epsilon hD_2\big)e(x,y,0)| \le Ch^s. \tag{14.3.18}$$

Proofs of Propositions 14.3.5 and 14.3.6. Easy proofs are left to the reader. Inequalities (14.3.15) and (14.3.17) are easily proven by the standard elliptic methods. Then inequalities (14.3.16) and (14.3.18) are proven by the standard Tauberian methods. □

Thus in what follows we localized u with respect to hD_{x_2} (and thus with respect to hD_{y_2} as well due to symmetry). This localization is more precise than x_1, y_1 localization as $\epsilon(h|\log h|)^{-\nu} \le \mu \le Ch^{-\nu}$; as $\mu \le \epsilon(h|\log h|)^{-\nu}$ both localizations are equivalent.

14.3.2 Regular Zone

In this subsection we consider *regular zone* $\mathcal{X}_{\mathsf{reg}} = \{C_0\bar{\gamma} \le |x_1| \le \bar{\gamma}_1\}$ with

$$\bar{\gamma} := \mu^{-1/\nu} \le \bar{\gamma}_1 := \min\big(\epsilon, C(\mu h)^{-1/(\nu-1)}\big) \tag{14.3.19}$$

which mathes to

$$\mathcal{X}_{\mathsf{reg}} = \{C_0 \le |\xi_2| \le \min\big(\epsilon\mu, (\mu h^\nu)^{-1/(\nu-1)}\big)\}. \tag{14.3.19}'$$

This definition works fine under assumption (14.3.9) but under assumption

$$\epsilon(h|\log h|)^{-\nu} \le \mu \le C_0 h^{-\nu} \tag{14.3.20}$$

it should be modified to

$$\mathcal{X}_{\mathsf{reg}} = \{C_0 \le |\xi_2| \le C(\mu h^\nu)^{-1/(\nu-1)}\} \tag{14.3.21}$$

while restriction to x_1 becomes

$$|x_1| \le Ch|\log h| \tag{14.3.21}'$$

with an extra logarithm due to logarithmical uncertainty principle.

Remark 14.3.7. For even ν we need to add restriction to sign: $\xi_2 > 0$, i.e. $\xi_2 \ge C_0$.

Our first statement is that in the quantum dynamic in this zone the magnitude of x_1 (and ξ_2) persists.

Proposition 14.3.8. *(i) Let* $\bar{x} \in B(0, \frac{1}{2}) \cap \{x, \pm x_1 \ge C\bar{\gamma}\}$, $\gamma = \epsilon|\bar{x}_1|$ *satisfy* (14.3.7) *and* $\psi \in \mathscr{C}_0^\infty(B(\bar{x}, \gamma))$ *be a rescaling of the standard function. Let* ψ_1 *be* γ*-admissible and supported in* $\{1/(2C_0) \le x_1/\bar{x}_1 \le 2C_0\}$ *and equal* 1 *in* $\{1/C_0 \le x_1/\bar{x}_1 \le C_0\gamma\}$. *Let* $T^* = \epsilon\mu\gamma^\nu$. *Then for* $T = T^*$

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)(1-\psi_{1x})u\psi_y| \le Ch^s. \tag{14.3.22}$$

(ii) Let $\bar{\xi}_2 = \pm\rho$, $\rho \ge C$ *and* $\varphi \in \mathscr{C}_0^\infty([\frac{3}{4}, \frac{3}{4}])$ *and* $\varphi_1 \in \mathscr{C}_0^\infty$, $\varphi_1 = 1$ *on* $[\frac{1}{2}, \frac{3}{2}]$ *be the standard functions. Let* $T^* = \epsilon\rho$. *Then for* $T = T^*$

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Big(1-\varphi_1\big(\frac{1}{\bar{\xi}_2}hD_x\big)\Big)u\,{}^t\varphi\big(\frac{1}{\bar{\xi}_2}hD_y\big)| \le Ch^s. \tag{14.3.23}$$

Proof. Note that both statements are equivalent as $\rho \asymp \mu\gamma^\nu$; so we will prove Statement (ii). As $|x_1| \ge \bar{\gamma}$ we constructed by (14.2.34) symbol which after rescaling becomes $X = \xi_2 - \mu^{-1}x_1^{1-\nu}\beta(x)p_1$ such that

$$|\{a, X\} - \alpha a| \le C_0 \tag{14.3.24}$$

Then using arguments of the proof of Theorem 2.3.2 with symbol

$$\chi(\varsigma Ct \pm X) \tag{14.3.25}$$

with the same standard function χ as in this proof and $\varsigma = \pm 1$, one can easily prove Statement (ii) as long as symbol (14.3.25) is quantizable; this latter condition is equivalent to (14.3.7).

Surely one needs to check that in time T^* we stay in $B(0,1)$ but it will be done in the next Proposition 14.3.9.

If (14.3.7) is violated (and thus (14.3.9) is violated as well) we can quantize with respect to (x_2, ξ_2) but not with respect to (x_1, ξ_1) unless $x_1 \ge Ch|\log h|$ and instead we note that

$$\{a, \xi_2\} = \alpha a + \sigma^2\big(\xi_2 - \phi\varrho_\nu/\nu\big) + O(1)$$

and then $X = \omega\xi_2$ with $\omega = \phi(0, x_2)^{-1}$ satisfies (14.3.24) and therefore the same arguments of the proof of Theorem 2.3.2 remain valid but we consider h-pseudodifferential operators with operator-valued symbols (in the axillary space $\mathbb{K} = \mathscr{L}^2(\mathbb{R}^1)$). □

The following proposition estimates by $C_0\mu^{-1}\gamma^{-\nu}$ and by $C\rho^{-1}$ x_2-speed of the propagation from above; the similar result will hold for degeneration zone as well.

Proposition 14.3.9. *(i) In the framework of Proposition 14.3.8(i) let ψ be supported in ℓ-vicinity of $\bar{y}$ and $\psi_2 = \psi_2(x_2)$ satisfy*

$$\psi_2 = 1 \qquad \text{in} \quad \{|y_2 - \bar{y}_2| \le C_0(\mu\gamma^{\nu})^{-1}T + C_0\ell\} \tag{14.3.26}$$

with $\ell = C_0\mu^{-1}\gamma^{1-\nu}$.

Then for $T_* C_0 h|\log h| \le T \le T^*$

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)(1-\psi_{2x})u\psi_y| \le Ch^s \qquad \forall \tau \in (-\epsilon,\epsilon); \tag{14.3.27}$$

(ii) In the framework of Proposition 14.3.8(ii) let $\psi = \psi(x_2)$ be supported in ℓ-vicinity of $\bar{y}_2$, $\varphi = \varphi(\xi_2)$ in $\epsilon\rho$-vicinity of $\bar{\xi}_2$ and ψ_2 satisfy (14.3.25)*. Let*

$$\ell\rho \ge Ch|\log h|. \tag{14.3.28}$$

Then for $T_* \le T \le T^*$

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)(1-\psi_{2x})u\psi_y\, {}^t\varphi(hD_{y_2})| \le Ch^s \qquad \forall \tau \in (-\epsilon,\epsilon). \tag{14.3.29}$$

Proof. Both statements are equivalent under condition (14.3.7).

(i) Assume first that (14.3.7) holds. Then symbol

$$Y = x_2 - \phi^{-1}\mu^{-1}x_1^{1-\nu}\xi_1 \tag{14.3.30}$$

satisfies

$$|\{a, Y\}| \le C_0\rho^{-1} \tag{14.3.31}$$

with $\rho = \mu\gamma^{\nu}$ and symbols

$$\chi\big(C_0\varsigma\frac{t}{T} \pm \frac{Y}{\rho^{-1}T}\big) \tag{14.3.32}$$

($\varsigma = \pm 1$) are quantizable as long as

$$T \ge T_0 = C\big(\gamma h|\log h|\big)^{\frac{1}{2}} \tag{14.3.33}$$

and then the standard energy estimates method (see proof of Theorem 2.3.2) implies (14.3.28) with ψ and ψ_2 replaced by h-pseudodifferential operators Q and Q_2 with symbol of Q supported in the first domain and symbol of Q_2 equals 1 in the second domain:

$$\{(y,\eta) : |y_1 - \bar{y}_1| \le \epsilon\gamma, |Y(y,\eta_1) - Y(\bar{y},\bar{\xi}_1)| \le \ell\},$$
$$\{(x,\xi) : |x_1 - \bar{y}_1| \le 2\epsilon\gamma, |Y(x,\xi_1) - Y(\bar{y},\bar{\xi}_1)| \le \ell + C\mu^{-1}\gamma^{-\nu}T\},$$

as $T_0 \le T \le T^* = C\mu\gamma^\nu$ and

$$\ell_0 = C\big(\gamma h|\log h|\big)^{\frac{1}{2}}\rho^{-1} \le \ell \le \epsilon. \tag{14.3.34}$$

Original estimate (14.3.27) follows from this because $|Y(x,\xi_1) - x_2| \le C_0\ell$.

As (14.3.27) is proven for $T = T_0$ it is valid also for $T \in [T_*, T_0]$.

(ii) Assume now that condition (14.3.7) is violated. Then x_1 is localized only in $Ch|\log h|$-vicinity of 0 rather than in γ-vicinity of it and x_1 is not separated from 0. However a naive idea that $\mu\phi x_1^\nu/\nu$ should be replaced by ξ_2 and thus we should define

$$Y = x_2 - \nu^{-1}x_1\xi_1\xi_2^{-1} \tag{14.3.35}$$

instead of (14.3.30) works; (14.3.31) and (14.3.32) are preserved, also (14.3.33) becomes $T^* = Ch|\log h|$ and (14.3.34) becomes (14.3.28). □

The following proposition estimates by $\epsilon_0\mu^{-1}\gamma^{-\nu}$ (and almost equivalently) by $\epsilon_0\rho^{-1}$ x_2-speed of the propagation from below; this result would fail in the degeneration zone unless far from periodic trajectories.

Proposition 14.3.10. *(i) In the framework of Proposition 14.3.8(i) let ψ be supported in γ-vicinity of $\bar{y}$ and $\psi_2 = \psi_2(x_2)$ satisfy*

$$\psi_2 = 1 \qquad \text{in } \ \{|y_2 - \bar{y}_2| \ge \epsilon_0(\mu\gamma^\nu)^{-1}T - C_0\ell\} \tag{14.3.36}$$

with $\ell = \mu^{-1}\gamma^{1-\nu}$.

Then for $T_0' = C_0\gamma \le T \le T^*$ inequality (14.3.28) *holds.*

(ii) In the framework of Proposition 14.3.8(ii) let $\psi = \psi(x_2)$ be supported in ℓ-vicinity of $\bar{y}_2$, $\varphi = \varphi(\xi_2)$ in $\epsilon\rho$-vicinity of $\bar{\xi}_2$ and ψ_2 satisfy (14.3.35). *Let ℓ satisfy* (14.3.29).

Then for $T_* = C_0h|\log h| \le T \le T^*$ inequality (14.3.30) *holds.*

Proof. One needs to apply the standard arguments with

$$\chi\big(C_0\varsigma\frac{Y}{\rho^{-1}T}\pm\frac{t}{T}\big) \tag{14.3.37}$$

assuming that inequality (14.3.32) is reversed to

$$|\{a, Y\}| \ge \epsilon_0\rho^{-1}. \tag{14.3.38}$$

In the framework of (14.3.7) one needs to modify Y in the spirit of (14.2.35) which would be equivalent to the following modification in the framework of Statement (ii). Namely, note that as $\gamma \ll 1$, $\rho \gg 1$

$$\{a, Y\} = \xi_2^{-1}\big(-\nu^{-1}p_1^2 + p_2^2\big) + o(\rho^{-1}) = \\ \frac{1}{2}(1+\nu^{-1})\xi_2^{-1}(p_2^2 - p_1^2) + \frac{1}{2}(1-\nu^{-1})\xi_2^{-1}(p_2^2 + p_1^2) + o(\rho^{-1})$$

and if we redefine Y as

$$Y = x_2 - \nu^{-1}x_1\xi_1\xi_2^{-1} + \frac{1}{2}\nu^{-1}(1+\nu^{-1})x_1\xi_1 p_2\xi_2^{-2} \tag{14.3.39}$$

we arrive to

$$\{a, Y\} = \frac{1}{2}(1-\nu^{-1})\xi_2^{-1}(p_2^2 + p_1^2) + o(\rho^{-1}) = \\ \frac{1}{2}(1-\nu^{-1})\xi_2^{-1}(a - V) + o(\rho^{-1}) \tag{14.3.40}$$

which implies (14.3.39) and also symbols (14.3.38) are quantizable. □

From the proof of Proposition 14.3.10 immediately follows that (14.3.29) holds with $\psi(x_2)$, $\psi_2(x_2)$ replaced by $\psi(Y(x,\xi))^{\mathsf{w}}$, $\psi_2(Y(x,\xi))^{\mathsf{w}}$ with assumption $\ell = C_0\mu^{-1}\gamma^{1-\nu}$ replaced by (14.3.28) i.e.

$$\ell = C_0\mu^{-1}\gamma^{-\nu}h|\log h|. \tag{14.3.28)$'}$$

Then we immediately get the following corollary:

Corollary 14.3.11. *(i) In the framework of Proposition 14.3.8(i)*

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(u\psi\big)| \le Ch^s \qquad \forall\tau\in(-\epsilon,\epsilon); \tag{14.3.41}$$

as $T_* = Ch|\log h| \le T \le T^*$ *and thus*

$$|F_{t\to h^{-1}\tau}\big(\bar\chi_{T^*}(t) - \bar\chi_{T_*}(t)\big)\Gamma\big(u\psi\big)| \le Ch^s \tag{14.3.42}$$

where we recall that $\bar\chi$ *is supported in* $[-1,1]$ *and equal* 1 *in* $[-\frac12,\frac12]$.

(ii) In the framework of Proposition 14.3.8(ii) (14.3.41) *and* (14.3.42) *hold with* $\psi(x_1, x_2)$ *replaced by* $\psi(x_2)\varphi(hD_2)$ *with* φ *supported in* $\{|\xi_2| \ge C\}$.

Assume now that condition (14.3.7) is fulfilled. Then we arrive to

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(u\psi)| \le C\gamma h^{-1} \qquad \forall T \in [T_*, T^*] \tag{14.3.43}$$

as $\psi = \psi'(x_1)\psi'(x_2)$ is an element of γ-admissible partition with respect to x_1; really this estimate holds with $T \le T_0 = \gamma T^*$ due to the results of Chapter 13 in non-degenerate case rescaled: $x \mapsto x/\gamma$, $h \mapsto h' = h/\gamma$, $t \mapsto t/\gamma$ and $\mu \mapsto \mu' = \mu\gamma^\nu$ with $\mu' h' \le 1$ and contribution of interval $[T_0, T^*]$ is negligible.

Then contribution of each element of γ-admissible (sub)partition with respect to x contributes $C(h/\gamma)^{-1} \times \gamma$ with extra-factor γ coming from dt in Fourier transform $F_{t\to h^{-1}\tau}$. After summation with respect to all such subelements with fixed magnitude of γ we get (14.3.43),

After (14.3.43) is established we can apply Tauberian arguments and conclude immediately that the contribution of ψ to the Tauberian remainder does not exceed

$$CT^{*-1} \times h^{-1}\gamma = C(\mu\gamma^\nu)^{-1}h^{-1}\gamma = C\mu^{-1}\gamma^{1-\nu} \tag{14.3.44}$$

while the principal part is given by the standard Tauberian expression

$$h^{-1}\int_{-\infty}^{0} \Bigl(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\bigl(u\psi\bigr)\Bigr)\,d\tau \tag{14.3.45}$$

with arbitrary $T \in\in [T_*, T^*]$.

Then summation of (14.3.44) over zone $\{|x_1| \ge \gamma\}$ results in $C\mu^{-1}h^{-1}\gamma^{1-\nu}$ coinciding with $C\bar{\gamma}h^{-1}$ as $\gamma = \bar{\gamma}$ and we arrive to

Proposition 14.3.12. *Under condition* (14.3.9) *contribution of the whole regular zone* $\mathcal{X}_{\mathsf{reg}} = \{x,\ |x_1| \ge C_0\bar{\gamma}\}$ *to the Tauberian remainder*

$$\mathsf{R}^{\mathsf{T}} = |\Gamma(e\psi) - h^{-1}\int_{-\infty}^{0} \Bigl(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(u\psi)\Bigr)\,d\tau| \tag{14.3.46}$$

does not exceed $C\bar{\gamma}h^{-1}$ *where* $\psi = 1 - \phi\bigl(x_1/(C_0\bar{\gamma})\bigr)\psi'(x_1)\psi''(x_2)$ *with all functions regular.*

The similar results as condition (14.3.9) violated will be derived later in Sections 14.5 and 14.6. We will replace (14.3.45) by more explicit expression in Section 14.4. Basically it will be the answer prescribed by the non-vanishing magnetic field theory but for μ large enough some correction will be needed.

14.3.3 Degeneration Zone

General Analysis

Recall that the degeneration zone is $\mathcal{X}_{\mathsf{deg}} = \{|\xi_2| \le C_0\}$ or under condition (14.3.9) equivalently (around energy level 0) $\mathcal{X}_{\mathsf{deg}} = \{|x_1| \le C_0\bar\gamma\}$; under condition (14.3.20) we would have $\{|x_1| \le C_0 h|\log h|\}$ in the microlocal sense in this zone.

Let us start from the confinement of the propagation in the degeneration zone and a finite speed of propagation; proofs repeating those of the corresponding propositions of the previous subsection are left to the reader. Just to remark that in this zone we study ξ_2 and x_2 directly without going to X and Y.

Proposition 14.3.13. *(cf. Proposition 14.3.8)*

(i) Let condition (14.3.9) *be fulfilled. Let* $\bar x \in B(0,\frac12) \cap \{x, |x_1| \le \bar\gamma\}$ *and* $\psi \in \mathscr{C}_0^\infty(B(\bar x, \bar\gamma))$ *be a rescaling of the standard function. Let* ψ_1 *be* $\bar\gamma$*-admissible, supported in* $\{|x_1| \le 3C_0\bar\gamma\}$ *and equal* 1 *in* $\{|x_1| \le 2C_0\bar\gamma\}$*. Let* $T^* = \epsilon$*. Then estimate* (14.3.22) *holds with* $T = T^*$*.*

(ii) Without condition (14.3.9) *let* $\psi \in \mathscr{C}_0^\infty\big((\frac12,\frac12)\big)$*,* $\varphi \in \mathscr{C}_0^\infty\big((-C_0, C_0)\big)$*,* $\varphi_1 \in \mathscr{C}_0^\infty\big((-3C_0, 3C_0)\big)$ *and equal* 1 *in* $(-2C_0, 2C_0)$*. Then estimate* (14.3.23) *holds with* $\bar\xi_2 = 1$ *and* $T = T^*$*.*

Proposition 14.3.14. *(cf. Proposition 14.3.9)*

(i) In the framework of Proposition 14.3.13(i) let $\psi_1 = \psi(x_2)$*,*

$$\psi_1 = 1 \qquad \text{in} \quad \{|y_2 - \bar y_2| \le C_0 T\}.$$

Then for $T_0 = C_0\bar\gamma \le T \le T_1$ *inequality*

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)(1-\psi_{1x})uQ_y| \le Ch^s \qquad \forall \tau \in (-\epsilon,\epsilon); \tag{14.3.47}$$

holds with $Q_y = \psi_y$*.*

(ii) Without condition (14.3.9) *this estimate holds with* $Q_y = \psi(y_2)\varphi(-hD_{y_2})$ *where* $\varphi \in \mathscr{C}_0^\infty\big((-C_0, C_0)\big)$.

Now we are studying the finite speed with respect to ξ_2 and the proof repeats those of Proposition 14.3.9:

Proposition 14.3.15. *Let* $\psi = \psi(x_2) \in \mathscr{C}_0^\infty\big((-\frac{1}{2}, \frac{1}{2})\big)$, $\varphi \in \mathscr{C}_0^\infty\big(B(\bar\xi_2, \rho)\big)$ *and* $\varphi_1 \in \mathscr{C}_0^\infty\big(B(\bar\xi_2, 3\rho)\big)$ *be equal to* 1 *in* $B(\bar\xi_2, 3\rho)$ *be standard functions rescaled. Let*

$$\rho \ge C_1 h|\log h| + C_1\bar\gamma \tag{14.3.48}$$

Then for $T_0 = C_2\bar\gamma \le T \le T^*(\rho) = \epsilon\rho$ *inequality*

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\big(1-\varphi_1(hD_{x_2})\big)u\psi_y\varphi(-hD_{y_2})| \le Ch^s \quad \forall \tau \in (-\epsilon, \epsilon); \tag{14.3.49}$$

holds.

We will prove more specific statements later. Let us prove that as ξ_2 is disjoint from $\eta^* W^{\frac{1}{2}}$ there is a drift with the velocity $\asymp (\xi_2 - \eta^* W^{\frac{1}{2}})$ (with the correct sign). Let $\varphi = \varphi(\xi_2) \in \mathscr{C}_0^\infty\big(B(\bar\xi_2, \rho)\big)$ and $\psi = \psi(x_2) \in \mathscr{C}_0^\infty(B(\bar y_2, \ell)$, $\ell = \epsilon_1\rho$ be standard functions rescaled. Assuming that

$$\rho \ge C(h|\log h|)^{\frac{1}{2}} + C_0\bar\gamma \tag{14.3.50}$$

we conclude from Propositions 14.3.14 and 14.3.15 that

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\big(1-\varphi_1(hD_{x_2})\psi_2(x_2)\big)u\psi(y_2)\varphi(-hD_{y_2})| \le Ch^s \qquad \forall \tau \in (-\epsilon, \epsilon)$$

as long as $T \le \epsilon\rho$.

Proposition 14.3.16. *Let conditions* (14.3.9) *and* (14.2.27) *be fulfilled. Let* $\psi = \psi(x_2) \in \mathscr{C}_0^\infty\big(B(\bar y_2, \ell)\big)$ *and* $\varphi \in \mathscr{C}_0^\infty\big(B(\bar\xi_2, \rho)\big)$ *be also standard function rescaled, with* $\rho \le C_0$,

$$\bar\xi_2 - \eta^* W(\bar y_2)^{\frac{1}{2}} = \pm\rho. \tag{14.3.51}$$

Further, let $\psi_1 = \psi_1(x_2)$ *be also a standard function rescaled and equal* 1 *in* $\{|x_2 - \bar y_2| \ge \epsilon_0\rho T - C_0\ell\}$.

Then estimate (14.3.47) *holds with* $Q_y = \psi(y_2)\varphi(-hD_{y_2})$ *as* $|\tau| \le \epsilon\rho$, $\ell \ge \bar\gamma$,

$$\rho\ell \ge Ch|\log h|, \tag{14.3.52}$$

$$T \ge C_0\frac{\ell}{\rho}. \tag{14.3.53}$$

Proof. Without any loss of the generality we can assume that $W(\bar{y}_2) = 1$. Let us consider

$$Y = x_2 - \bar{\gamma} Z\big(\frac{x_1}{\bar{\gamma}}, \xi_1\big) \tag{14.3.54}$$

where Z is a function introduced in Proposition 14.2.6 and pick up $\bar{\gamma} = \mu^{-1/\nu}$ exactly. Then

$$|\{a, Y\} - \beta(\xi_2 - \eta^*) - \alpha a| \le \epsilon' \rho$$

with a constant ϵ' which one can make arbitrarily small.

Then we can apply standard arguments with

$$\chi\Big(C_0 \varsigma \frac{1}{\ell}\big(Y(x,\xi) - Y(y,\eta)\big) \pm \frac{t}{T}\Big) \tag{14.3.55}$$

as long as $T\rho \ge C\ell$; symbol (14.3.55) is obviously quantizable. □

Further, it follows from this proof that estimate (14.3.47) holds with $Q_y = \psi(Y)^{\mathsf{w}} \phi(-hD_2)$ and ψ_1 replaced by $\psi_1(Y)^{\mathsf{w}}$ without assumption $\ell \ge \bar{\gamma}$; this estimate immediately implies

Corollary 14.3.17. *In the framework of Proposition 14.3.16 estimate* (14.3.59) *(see below) holds with the standard function ψ and $|\tau| \le \epsilon\rho$ as long as*

$$\rho \ge C_0 (h|\log h|)^{\frac{1}{2}}, \tag{14.3.56}$$

$$T_* = T_*(\rho) := \frac{C_0 h|\log h|}{\rho^2} \le T \le T^*(\rho) = \epsilon\rho. \tag{14.3.57}$$

Note that $T_*(\rho) \le \epsilon\bar{\gamma}$ as long as

$$\rho \ge \bar{\rho}_1 := C\big(\frac{h}{\bar{\gamma}}\big)^{\frac{1}{2}} \tag{14.3.58}$$

and we arrive to

Proposition 14.3.18. *Let conditions* (14.3.9), (14.2.27) *and* (14.3.58) *be fulfilled. Then*

(i) Estimates

$$|F_{t\to h^{-1}\tau} \chi_T(t) \Gamma\big(\varphi(hD_2)\psi u\big)| \le Ch^s \tag{14.3.59}$$

and

$$|F_{t\to h^{-1}\tau} \big(\bar{\chi}_{T_1}(t) - \bar{\chi}_{\bar{T}_0}(t)\big) \Gamma\big(\varphi(hD_2)\psi u\big)| \le Ch^s \tag{14.3.60}$$

hold with $|\tau| \le \epsilon\rho$ and $T_* = Ch|\log h| \le T \le T^*(\rho) = \epsilon\rho$.

(ii) Furthermore

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(\varphi(hD_2)\psi u)| \le Ch^{-1}\bar{\gamma}\rho \tag{14.3.61}$$

as $T \le T_*(\rho)$.

Proof. We need to cover $T \le \epsilon\bar{\gamma}$ only. After rescaling $x \mapsto x/\bar{\gamma}$, $t \mapsto t/\bar{\gamma}$, $h \mapsto \hbar = h/\bar{\gamma}$ we find ourselves in the framework of the standard propagation and therefore estimate (14.3.41) with h replaced by $\hbar$ would hold as long as $C_0\hbar|\log\hbar| \le T/\bar{\gamma} \le \epsilon$.

Then if $\hbar \le h^{\delta}$ or equivalently $\mu \le h^{\delta-\nu}$ with arbitrarily small exponent $\delta > 0$ we arrive to original (14.3.41) with indicated T, τ.

Further, these arguments imply estimate (14.3.61) with no such restriction.

For $h^{\delta-\nu} \le \mu \le \epsilon(h|\log h|)^{-\nu}$ we instead can make a fine $(\epsilon'\bar{\gamma}, \epsilon')$-subpartition with respect to (x_1, ξ_1) and then depending on subelement apply standard arguments with one of

$$\chi\Big(C_0\varsigma\frac{1}{T}(x_1-y_1)\pm\frac{t}{T}\Big), \qquad \chi\Big(C_0\varsigma\frac{1}{T}(\xi_1-\eta_1)\pm\frac{t}{T}\Big) \tag{14.3.62}$$

which are quantizable. Easy details are left to the reader. □

Then applying the standard Tauberian arguments we conclude that

(14.3.63) Contribution of this element to the Tauberian remainder does not exceed $Ch^{-1}\bar{\gamma}\rho/T^*(\rho) \asymp Ch^{-1}\bar{\gamma}$.

Then after summation over partition in $\rho \ge \epsilon_1$ we get Tauberian remainder estimate $Ch^{-1}\bar{\gamma}$; we will cover smaller values of ρ in the next subsubsection. Thus we arrive to

Proposition 14.3.19. *Under conditions* (14.3.9) *and* (14.2.27) *contribution of zone*

$$\big\{|x_1| \le \bar{\gamma}, |\xi_2 - \eta^* W(x_2)^{\frac{1}{2}}| \ge \epsilon_0\big\}$$

to the Tauberian remainder does not exceed $C_\epsilon\mu^{-1/\nu}h^{-1}$.

Near Periodic Sub-Zone

Now we need to consider *near-periodic* zone

$$\bigl\{|x_1| \le \bar{\gamma}, |\xi_2 - \eta^* W(x_2)^{\frac{1}{2}}| \le \epsilon_0\bigr\}.$$

Let us investigate this case under condition (14.2.27), assuming first that W_{x_2} is disjoint from 0. We consider a bit more general case: namely $W_{x_2} \asymp \zeta$ with a large enough parameter ζ. We consider first propagation assuming that $|W_{x_2}| \le \zeta$.

Proposition 14.3.20. *Let conditions* (14.3.9) *and* (14.2.27) *be fulfilled and*

$$|\partial_{x_2} W| \le \zeta \tag{14.3.64}$$

with

$$\zeta \ge C_0 \bar{\gamma}. \tag{14.3.65}$$

Let $\psi = \psi(x_2) \in \mathscr{C}_0^\infty(B(0, \frac{1}{2}))$ be a standard function and $\varphi = \varphi(\xi_2)$ be a standard function rescaled supported in $\{|\xi_2 - \eta^* W^{\frac{1}{2}}(0)| \le \rho\}$ [6] *with*

$$\rho \ge C_0 \zeta. \tag{14.3.66}$$

Further, let $\varphi_1 = \varphi_1(\xi_2)$ be also a standard function rescaled, equal 1 as $|\xi_2 - \eta^* W^{\frac{1}{2}}(x_2)| \le 3\rho$. Then

(i) Estimate (14.3.49) *holds as $|\tau| \le \epsilon\zeta$ and $Ch\zeta^{-1}|\log h| \le T \le \epsilon$.*

(ii) In addition, if

$$\rho \ge \bar{\rho}_1 := (C\bar{\gamma}^{-1} h |\log h|)^{\frac{1}{2}} + C\bar{\gamma}. \tag{14.3.67}$$

estimate (14.3.49) *holds as $|\tau| \le \epsilon\zeta$ and*

$$T_* := Ch\zeta^{-1}|\log h| \le T \le \mathsf{T}^* := \epsilon \min\bigl(\frac{1}{\rho}, \frac{\rho}{\zeta}\bigr). \tag{14.3.68}$$

Proof. We leave to the reader a standard proof based on the axillary symbol

$$\chi\Bigl(C_0\varsigma \frac{t}{T} \pm \frac{1}{\rho}(\xi_2 - \eta_2)\Bigr).$$

[6] Then under condition (14.3.66) $|\xi_2 - \eta^* W^{\frac{1}{2}}(x_2)| \le 2\rho$ for all x_2.

(which under our assumptions is quantizable) that the speed of propagation with respect to ξ_2 does not exceed $C\zeta$. This implies Statement (i).

To prove Statement (ii) one needs to show in addition that the "averaged" speed of propagation with respect to x_2 does not exceed ρ; under condition (14.3.68) one can easily do it for $t = \bar{T}W(0)^{\frac{1}{2}}$ by means of the standard microlocal analysis. Recall that $\bar{T} = T(\eta^*)$ is a period.

We leave details to the reader. More delicate analysis of Section 14.3.4 will also imply results of this subsection. □

Proposition 14.3.20 immediately implies

Corollary 14.3.21. *Under conditions* (14.3.20), (14.2.27),(14.3.64)–(14.3.67) *propagation remains confined to*

$$\bigl\{|x_2| \le \frac{3}{4}, |\xi_2 - \eta^* W(0)^{\frac{1}{2}}| \le \rho + \zeta + \zeta T\bigr\}$$

as $T \le T^* := \epsilon \min\bigl(\rho^{-1}, \zeta^{-\frac{1}{2}}\bigr)$.

Now let us estimate from below the propagation speed with respect to ξ_2.

Proposition 14.3.22. *Let conditions* (14.3.9), (14.2.27), (14.3.67) *be fulfilled and*

$$\epsilon_0\zeta \le |\partial_{x_2} W| \le \zeta \tag{14.3.69}$$

with $\zeta \ge C_0\bar{\gamma}$. *Let* $\varphi = \varphi(\xi_2)$ *be a standard function rescaled supported in* ρ*-vicinity of* $\bar{\eta}_2 = \eta^* W(0)^{\frac{1}{2}}$. *Then estimate* (14.3.49) *holds as* $|\tau| \le \epsilon\zeta$,

$$T_* := C\rho\zeta^{-1} \le T \le T^* := \epsilon \min\bigl(\rho^{-1}, \zeta^{-\frac{1}{2}}\bigr), \tag{14.3.70}$$

$\varphi_1 = 1 - \varphi$.

Proof. We leave to the reader a standard proof based on the axillary symbol

$$\chi\Bigl(C_0\varsigma\frac{1}{\rho}(\xi_2 - \eta_2) \pm \frac{t}{T}\Bigr)$$

which under our assumptions is quantizable. □

Then in the framework of this proposition estimate (14.3.59) holds. Note that $T_* \le \epsilon\bar{\gamma}$ as

$$\zeta \ge C\bar{\gamma}^{-1}h|\log h| \tag{14.3.71}$$

and due to the same arguments as in Proposition 14.3.18 we arrive to

Proposition 14.3.23. *Let conditions of Proposition 14.3.22 and condition* (14.3.71) *be fulfilled. Then estimates* (14.3.59), (14.3.60) *and* (14.3.61) *hold as* $T_* = Ch|\log h| \le T \le T^*$ *with* T^* *defined by* (14.3.70).

Then due to the standard Tauberian arguments we arrive immediately to

Proposition 14.3.24. *Under conditions* (14.3.9), (14.2.27) *and* (14.3.71) *the contribution of the degeneration zone to the Tauberian remainder* R^{T} *does not exceed* $C\mu^{-1/\nu}h^{-1}$.

In particular $\zeta \asymp 1$ satisfies (14.3.71) under condition (14.3.9). Case of smaller $\zeta \le Ch\bar{\gamma}^{-1}|\log h|$ will be considered in Subsection 14.3.4.

Near Periodic Sub-Zone. End

Let us finish analysis in the *near-periodic* but not the *periodic* zone. To do this we are going to analyze elements of (x_2, ξ_2) partitions on which $|\xi_2 - \eta^* W^{1/2}| \le C\bar{\rho}_1$ but $|\partial_{x_2} W| \gtrsim \zeta\ell^{-1}$ branding the rest as a *periodic zone*.

The following results would be the results of the previous subsection rescaled but some conditions are more relaxed because after rescaling $x \mapsto x/\ell$, $\bar{\gamma} \mapsto \bar{\gamma}/\ell$, $\zeta \mapsto \zeta\ell$ our new symbols have smaller derivatives (with a factor ℓ) with respect to x_1 than it was assumed there.

Proposition 14.3.25. *(cf. Proposition 14.3.20 and Corollary 14.3.21) Let conditions* (14.3.9), (14.2.27) *and* (14.3.67) *be fulfilled. Consider point* $(\bar{y}_2, \bar{\eta}_2)$ *and assume that*

$$|\bar{\eta}_2 - \eta^* W^{\frac{1}{2}}(0, \bar{y}_2)| \le \rho, \tag{14.3.72}$$

$$|\partial^\alpha_{x_2} W| \le C_\alpha \zeta \ell^{1-|\alpha|} \qquad \text{as} \quad |x_2 - \bar{y}_2| \le \ell \qquad \forall \alpha : |\alpha| \le K, \tag{14.3.73}$$

$$\ell\rho \ge Ch|\log h|, \tag{14.3.74}$$

$$\ell\zeta \le \epsilon\rho, \tag{14.3.75}$$

$$\ell \ge C_0\bar{\gamma}, \quad \rho \ge C_0\bar{\gamma}, \quad \zeta \ge C_0\bar{\gamma} + C_0 h^{1-\delta}. \tag{14.3.76}$$

Then for $|\tau| \le \rho$,

$$|t| \le T^* := \epsilon \min\big(\frac{\ell}{\rho}, \frac{\rho}{\zeta}\big) \tag{14.3.77}$$

quantum evolution starting from $\{|y_2 - \bar{y}_2| \le \frac{1}{3}\ell, |\eta_2 - \bar{\eta}_2| \le \frac{1}{3}\rho\}$ *is confined to* $\{|y_2 - \bar{y}_2| \le \ell, |\eta_2 - \bar{\eta}_2| \le \frac{1}{2}\rho\}$.

Proposition 14.3.26 [7]**.** *Let conditions of Proposition 14.3.25 be fulfilled.*

(i) If

$$|\bar{\eta}_2 - \eta^* W^{\frac{1}{2}}(0, \bar{y}_2)| \le \rho, \tag{14.3.78}$$

then estimate (14.3.59) *holds for* $|\tau| \le \rho$,

$$T_0 := C\frac{h|\log h|}{\rho^2} \le T \le T_1; \tag{14.3.79}$$

(ii) If condition (14.3.69) *is fulfilled as* $|x_2 - \bar{y}_2| \le \ell$ *then estimate* (14.3.59) *holds for* $|\tau| \le \rho$,

$$T_* := C\frac{h|\log h|}{\zeta\ell} \le T \le T^*. \tag{14.3.80}$$

Proofs of Propositions 14.3.25 and 14.3.26. Easy proofs are left to the reader.□

Now, given point $(\bar{y}_2, \bar{\eta}_2)$ let us define

$$\ell = \rho = \zeta = \varrho(\bar{y}_2, \bar{\eta}_2) \qquad \text{with} \tag{14.3.81}$$

$$\varrho(x_2, \xi_2) := \epsilon\Big(|\xi_2 - \eta^* W(x_2)^{\frac{1}{2}}| + |\partial_{x_2} W(x_2)|\Big).$$

Note that (14.3.74), (14.3.76) become equivalent to (14.3.67) and thus Propositions 14.3.25 and 14.3.26 hold with $T^* = \epsilon$ under condition (14.3.67). Also note that $T_* \le \epsilon\bar{\gamma}$ is equivalent to condition (14.3.67).

Then using the same arguments as above we arrive to (14.3.59) with $T_* = Ch|\log h| \le T \le T^*$ and also to estimate

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\big(\varphi(hD_2)\psi u\big)| \le Ch^{-1}\rho\bar{\gamma}\ell \qquad \forall \tau : |\tau| \le \epsilon\rho \tag{14.3.82}$$

and $T_* \le T \le T^*$.

Therefore due to the standard Tauberian arguments

[7] Cf. Proposition 14.3.22.

(14.3.83) Contribution of (ℓ,ρ)-vicinity of $(\bar{y}_2,\bar{\eta}_2)$ to the Tauberian remainder does not exceed the right-hand expression of (14.3.82) multiplied by $CT^{*\,-1}$, i.e. $Ch^{-1}\bar{\gamma}\rho\ell$;

recall that $\ell=\rho$ here.

Then for given ρ the contribution of zone $\{(x_2,\xi_2),\frac{1}{2}\rho\le\varrho(x_2,\xi_2)\le\rho\}$ to the Tauberian remainder does not exceed $Ch^{-1}\rho\bar{\gamma}$. Finally, summation over ϱ results in $Ch^{-1}\bar{\gamma}$. This yields Statement (i) of the following proposition:

Proposition 14.3.27. *Under conditions* (14.3.9), (14.2.27)

(i) Contribution of zone $\{(x_2,\xi_2):\varrho(x_2,\xi_2)\ge\bar{\rho}_1\}$ *to the Tauberian remainder* (14.3.46) *with any* $T\in[T_*,\epsilon]$ *does not exceed* $C\mu^{-1/\nu}h^{-1}$.

(ii) The total Tauberian remainder (14.3.46) *does not exceed*

$$C\mu^{-\frac{1}{\nu}}h^{-1}+C\bar{\rho}_1h^{-1}; \tag{14.3.84}$$

(iii) In particular, as $\bar{\rho}_1\le\bar{\gamma}$ *which is equivalent to*

$$\mu\le C(h|\log h|)^{-\frac{\nu}{3}} \tag{14.3.85}$$

the total Tauberian remainder (14.3.46) *does not exceed* $C\mu^{-1/\nu}h^{-1}$.

Proof. To prove Statement (ii) one needs to estimate the contribution of *periodic zone* $\{\varrho\le C\bar{\rho}_1\}$. One can take $T^*=\epsilon\bar{\gamma}$ there and thus its contribution does not exceed $Ch^{-1}\bar{\rho}_1\bar{\gamma}\times\bar{\gamma}^{-1}=Ch^{-1}\bar{\rho}_1$.

Statement (iii) follows trivially. □

14.3.4 Periodic Zone

Toy-Model

Therefore one needs to consider contribution of the *periodic zone*

$$\mathcal{X}_{\mathsf{per}}=\{(x_2,\xi_2),\varrho(x_2,\xi_2)\le\bar{\rho}_1=C(\bar{\gamma}^{-1}h|\log h|)^{\frac{1}{2}}\} \tag{14.3.86}$$

as (14.3.85) is violated i.e. as

$$C(h|\log h|)^{-\frac{\nu}{3}}\le\mu\le\epsilon(h|\log h|)^{-\nu}. \tag{14.3.87}$$

Assume that the statements of Proposition 14.3.26 remain valid[8] as

$$\bar{\rho}_0 = C(h|\log h|)^{\frac{1}{2}} + C\bar{\gamma} \le \varrho \le \bar{\rho}_1. \tag{14.3.88}$$

Then for particular partition element inequality

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\big(\varphi(hD_2)\psi(x_2)u\big)| \le Ch^{-2}\varrho^2\bar{\gamma} \times \frac{h|\log h|}{\varrho^2} = Ch^{-1}\bar{\gamma}|\log h| \tag{14.3.89}$$

holds as $|\tau| \le \epsilon\rho^2$, $T_* = Ch\rho^{-2}|\log h| \le T \le T_* = \epsilon$ where the second factor in the middle expression of (14.3.89) is just T_*.

Inequality (14.3.89) leads to the estimate of the contribution of the given element to the Tauberian remainder, equal to the right-hand expression of (14.3.89) (since $T^* \asymp 1$). Then the total contribution of the zone $\{(x_2,\xi_2) : \frac{1}{2}\rho \le \varrho(x_2,\xi_2) \le \rho\}$ is equal to $Ch^{-1}\bar{\gamma}\rho^{-1}|\log h|$. This estimate is not only is not good enough for the sharp remainder estimate but is much worse than estimates we had before[9].

To improve the estimates above let us start from the toy-model operator. However let us consider first 1-dimensional Schrödinger operator

$$A(\eta) = \hbar^2 D_1^2 + \big(\eta - x_1^\nu/\nu\big)^2 - 1 \tag{14.3.90}$$

with $\hbar = h/\bar{\gamma}$.

Proposition 14.3.28. *As $\hbar \ll 1$*

$$\operatorname{Spec}\big(A(\eta)\big) \cap [-\epsilon,\epsilon] = \check{g}\Big(\frac{\pi}{T(\eta)}(2n+1)\hbar;\eta,\hbar\Big) + O(\hbar^2), \quad n \in \mathbb{Z}^+ \tag{14.3.91}$$

and consists of simple eigenvalues where $\check{g}(\tau;\eta,\hbar)$ is an analytic function of all its arguments as $|\tau| < \epsilon, \hbar < \epsilon, |\eta - \eta^*| < \epsilon$, inverse (with respect to τ) to

$$g(\tau;\eta,\hbar) := \int T\big(\eta(1+\tau)^{-\frac{1}{2}}\big)(1+\tau)^{(1-\nu)/2\nu}\,d\tau - \hbar + O(\hbar^2) \tag{14.3.92}$$

and $T(\eta)$ is an elementary period of Section 14.2 calculated as $\mu = 1$, $\tau = 0$.

In particular,

$$e^{i\hbar^{-1}T(\eta)g(A(\eta);\eta,\hbar)}\bar{\chi}_\epsilon(A(\eta)) = \bar{\chi}_\epsilon(A(\eta)). \tag{14.3.93}$$

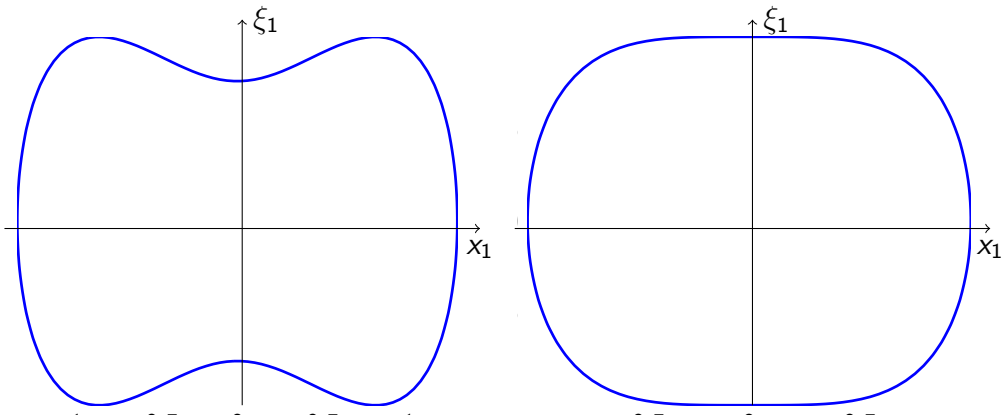
[8] Actually they do but with a twist.

[9] One can increase T^* and decrease $\bar{\rho}_0$ in the toy-model cases improving this estimate but (14.3.89) should be improved as well.

Proof. Note that for $\mathbf{a}(\eta)$ Hamiltonian flow on the energy level τ is periodic with period

$$T(\tau,\eta) = T\bigl(\eta(1+\tau)^{-1/2}\bigr)(1+\tau)^{(1-\nu)/2\nu}. \tag{14.3.94}$$

Proof now follows from Bohr-Sommerfeld formula. To derive asymptotics with $O(\hbar^2)$ error one should note that subprincipal symbol of $\mathbf{a}(\eta)$ is 0 and Maslov' index ι_M of the trajectory in (x_1,ξ_1) space is 2.



(a) First toy-model, $\nu=2$, $\eta=\eta^*=0.65$ (b) Second toy-model, $\nu=2$, $\eta=\eta^*=0$

Figure 14.6: Lagrangian manifolds for toy-model operators

Easy details are left to the reader.

Proposition 14.3.29. *Let condition* (14.3.9) *be fulfilled and let* $Q=\varphi(hD_2)$ *be a partition element supported in* $B(\eta^*,\rho)$. *Let us assume for simplicity that* $W(0)=1$. *Let* A *be the toy-model operator:*

$$A=\bar{A}:=\hbar^2D_1^2+(hD_2-\mu x_1^\nu/\nu)^2-1 \tag{14.3.95}$$

Assume that $\bar\gamma\ge Ch|\log h|$. *Then modulo negligible operator*

$$e^{ih^{-1}\bar\gamma T^*\mathcal{A}}Q\bar\chi_\epsilon(\mathcal{A})\equiv e^{ih^{-1}\bar\gamma B}Q\bar\chi_\epsilon(\mathcal{A}) \tag{14.3.96}$$

as

$$\mathcal{A}=g(A,\eta^*,\hbar),\qquad T^*=T(\eta^*), \tag{14.3.97}$$

$B = \beta(hD_2, A, \hbar)$ *such that*

$$\beta(\xi_2, \tau, \hbar) = \kappa(\xi_2, \hbar)\big(\xi_2 - \eta^*_\hbar\big)^2 + \kappa_1(\hbar) + O(|\tau|) \tag{14.3.98}$$

and function $\beta(\xi_2, \tau, 0)$ *coincides with* b *defined by* (14.2.59). *Further,* $\eta^*_\hbar = \eta^* + O(\hbar)$, $\kappa_1 = O(\hbar)$ *are analytic functions as* $\hbar \ll 1$.

Proof. Proof immediately follows from Propositions 14.2.15and 14.3.28. □

Remark 14.3.30. From now in the analysis of periodic zone we set $\eta^* = \eta^*_\hbar$ and respectively $\rho = |\xi_2 - \eta^*_\hbar|$ or $\rho = |\xi_2 - \eta^*_\hbar W^{1/2}|$

Now formula (14.3.96) implies that

$$e^{ih^{-1}t\mathcal{A}} Q\bar{\chi}_{\epsilon\rho}(A) \equiv e^{ih^{-1}t''\mathcal{A}} e^{ih^{-1}t'B} Q\bar{\chi}_{\epsilon\rho}(A), \tag{14.3.99}$$
$$\text{with} \quad t' = \bar{\gamma}\lfloor \frac{t}{\bar{\gamma}} \rfloor, \quad t'' = t - t' \qquad \text{as} \quad |t| \le T^* = \epsilon\rho^{-1}.$$

Here important thing is that on the partition element in question operator $e^{ih^{-1}t'B}$ is a proper Fourier integral operator as long as

$$|t'| \le T^{*\prime} := \frac{\bar{\gamma}}{\rho^2} \tag{14.3.100}$$

which is greater than $T'_* = C\rho^{-2}h|\log h|$. Then repeating corresponding analysis of Subsubsections 14.3.3 and 14.3.3 one can prove easily the following proposition:

Proposition 14.3.31. *Let* ρ *be defined as in Remark 14.3.30. Then statements of Proposition 14.3.20(ii), Corollary 14.3.21 and Proposition 14.3.26 remains valid with condition* (14.3.67) *replaced by condition* (14.3.88).

These extended statements allow us to prove the following proposition:

Proposition 14.3.32. *In the framework of Proposition 14.3.29 assume that* $\operatorname{supp}(\varphi) \cap B(\eta^*_\hbar, \frac{1}{2}\rho) = \emptyset$ *and that* ψ *is a fixed admissible function. Then*

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\big(\varphi(hD_2)\psi(x_2)u\big)| \le C\rho^{-1}|\log h|^2. \tag{14.3.101}$$

Proof. Due to Proposition 14.3.26 extended by Proposition 14.3.31 it is sufficient to consider $T = T_*$ only.

Consider the left-hand expression of (14.3.101) with $\bar\chi_T(t)$ replaced by $\chi_n(t) = \bar\chi_{\bar\gamma}(t - n\bar T\bar\gamma)$, $|n| \le T_0/\bar T\bar\gamma$ with $\bar T = T(\eta^*)$. Note that then $e^{ih^{-1}\bar\gamma nB}$ is h-pseudodifferential operator with the symbol which will be regular after rescaling $x_1 \mapsto x_1/(\bar\gamma|\log h|)$, $\xi_1 \mapsto \xi_1/|\log h|$, $\xi_2 \mapsto \xi_2/|\log h|$. Therefore

$$|F_{t\to h^{-1}\tau}\chi_n(t)\Gamma\big(\varphi(hD_2)\psi(x_2)u\big)| = |F_{t\to h^{-1}\tau}\chi_0(t)\Gamma\big(Q_n u\big)| \tag{14.3.102}$$

with $Q_n = e^{ih^{-1}\bar\gamma nB}\varphi(hD_2)\psi(x_2)$ and therefore expression (14.3.102) does not exceed $C\rho\bar\gamma h^{-2} \times h|\log h| = C\rho\bar\gamma h^{-1}|\log h|$ due to the standard theory.

After summation by $n : |n| \le CT_0/\bar\gamma$ we get $C\rho\bar\gamma h^{-1}|\log h| \times h\rho^{-2}\bar\gamma^{-1}|\log h|$ which is exactly the right-hand expression of (14.3.101). □

We believe that factor $|\log h|^2$ is superficial and one can easily get rid of it: one factor $|\log h|$ is due to an inaccuracy in the estimate of (14.3.101) modified and another due to the lost factor $\big(1 + n\bar\gamma/T'_*\big)^{-s}$ in the same estimate (with $T'_* = C\rho^{-2}h$). However even such weakened estimate is sufficient for our needs unless μ is really close to $h^{-\nu}$ and the latter special case will be considered separately.

Really, after (14.3.101) is proven, Tauberian theorem implies that the contribution of this partition element to the Tauberian remainder does not exceed $C\rho^{-1}|\log h|^2 \times T^{*-1} = C|\log h|^2$ and thus the total contribution of zone $\{|\xi_2 - \eta^*_\hbar| \ge C\bar\gamma\}$ to the Tauberian remainder does not exceed this expression integrated over $\rho^{-1}\,d\rho$ resulting in $C|\log h|^3$ while contribution of zone $\{|\xi_2 - \eta^*_\hbar| \le C\bar\gamma\}$ does not exceed $C\bar\gamma h^{-1}$ as we already know. Thus we arrive to

Proposition 14.3.33. *For operator coinciding with the toy-model* (14.3.95) *in* $B(0,1)$ *the Tauberian remainder*[10)] *does not exceed* $C\bar\gamma h^{-1}$ *as* $\mu \le Ch^{-\nu}|\log h|^{-2\nu}$.

Another Example

Consider now the toy-model (14.3.95) perturbed by potential $W(x_2)$ satisfying

$$\epsilon_0\zeta \le |\partial_{x_2}W| \le \zeta \qquad \forall x. \tag{14.3.103}$$

[10)] Which still means R^{T} given by (14.3.46).

Then we can apply the same arguments as above for partition elements with $\rho^2 \ge \zeta$ thus covering completely case $\zeta \le C\bar{\gamma}^2$. On the other hand, as $\zeta \ge \bar{\gamma}^2$ we replace ρ by $\varrho = \mathsf{max}(\zeta^{\frac{1}{2}}, \rho)$ and on partition elements with $\varrho = \zeta^{\frac{1}{2}}$ we again can apply the same arguments with $T^* = \epsilon\zeta^{-\frac{1}{2}}$, $T'_* = \epsilon h\zeta^{-1}|\log h|$.

So, we arrive to

Proposition 14.3.34. *For operator coinciding in $B(0,1)$ with the toy-model perturbed by potential $W(x_2)$ satisfying* (14.3.96) *Tauberian remainder does not exceed $O(\bar{\gamma}h^{-1})$ as long as $\zeta^{\frac{1}{2}} + \bar{\gamma} \ge Ch|\log h|^3$ i.e. either $\mu \le Ch^{-\nu}|\log h|^{-3\nu}$ or $\zeta \ge Ch^2|\log h|^6$.*

General Case

Consider now the general case. Let $\varphi(\xi_2)$ and $\psi(x_2)$ are two ρ- and ℓ-admissible functions supported in $\frac{1}{3}\rho$- and $\frac{1}{3}\ell$-vicinities of $\bar{\xi}_2$ and $\bar{x}_2$ respectively. Let us assume that conditions (14.3.72)–(14.3.76) are fulfilled.

Then due to Proposition 14.3.26 extended by Proposition 14.3.31 as

$$|t| \le T^* := \epsilon\,\mathsf{min}\big(\frac{\ell}{\rho}, \frac{\rho}{\zeta}\big) \asymp \epsilon\rho\ell\big(\rho^2 + \ell\zeta\big)^{-1} \tag{14.3.104}$$

propagation started from $\mathsf{supp}\,\varphi \times \mathsf{supp}\,\psi$ is confined to $(\frac{1}{3}\rho, \frac{1}{3}\ell)$-vicinity of it.

Now we can easily generalize Proposition 14.3.29:

Proposition 14.3.35. *Let conditions* (14.3.9), (14.2.27) *and* (14.3.72)–(14.3.76) *be fulfilled. Assume for simplicity that $W(0) = 1$, Then*

(i) Equality (14.3.96) *holds as $\mathcal{A}$ is defined by* (14.3.97).

(ii) Therefore equality (14.3.99) *holds.*

Proof. Proof repeats one of Proposition 14.3.29. We leave easy details to the reader.

Proposition 14.3.36. *Let conditions* (14.3.9), (14.2.27) *and* (14.3.72)–(14.3.76) *be fulfilled. Assume for simplicity that $W(0) = 1$. Then estimate*

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\big(\varphi(hD_2)\psi(x_2)u\big)| \le CT\rho\ell h^{-1}|\log h| \tag{14.3.105}$$

holds as

$$\bar{\gamma} \le T \le T'_* := C_1 h|\log h|(\rho^2 + \zeta\ell)^{-1}. \tag{14.3.106}$$

Proof. Let us note that for $|t'| \le T'_*$ operator $e^{ih^{-1}t'B}$ remains legitimate h-pseudodifferential operator and therefore contribution to the left-hand expression of (14.3.105) of the time interval $[t_1, t_2]$ with $|t_j| \le T'_*$, $|t_2 - t_1| = \epsilon\bar{\gamma}$ does not exceed $C\rho\ell\bar{\gamma}h^{-1}|\log h|$ and therefore the contribution of $\asymp T/\bar{\gamma}$ of such intervals does not exceed the right-hand expression of (14.3.105). □

It immediately implies

Corollary 14.3.37. *Let in the framework of the previous propositions either*

$$|\xi_2 - \eta^*_\hbar W(x_2)^{\frac{1}{2}}| \ge \rho, \tag{14.3.107}$$

or

$$|\partial_{x_2} W| \ge \epsilon_0\zeta \tag{14.3.108}$$

in ℓ-vicinity of $\bar{x}_2$. Then

(i) The left-hand expression of (14.3.105) *with $T \le T_1$ does not exceed $CT'_0\rho\ell h^{-1}|\log h|^2$.*

(ii) Contribution of the partition element $\varphi(hD_2)\psi(x_2)$ to the Tauberian remainder does not exceed $C|\log h|^2$.

Proof. Statement (i) immediately follows from Proposition 14.3.26 extended and Proposition 14.3.36.

Statement (ii) then follows from the Tauberian arguments: contribution of this element to the Tauberian remainder does not exceed $Ch^{-1}\rho\ell|\log h| \times T'_*/T^* = C|\log h|^2$ since $T'_*/T^* = Ch|\log h|/(\rho\ell)$. □

Assume now that

$$|\partial_{x_2} W| + |\partial^2_{x_2} W| \ge \epsilon_0. \tag{14.3.109}$$

Let us introduce function ϱ by (14.3.81) and let us consider ϱ-admissible partition in (x_2, ξ_2) and apply the same arguments with $\rho = \zeta = \ell = \varrho$; then on each partition element either $|\xi_2 - \eta^*_\hbar W(x_2)^{\frac{1}{2}}| \ge \epsilon_0\varrho$ or $|\partial_{x_2} W(x_2)| \ge \epsilon\varrho$ and previous propositions work as long as

$$\varrho \ge C\bar{\gamma}, \qquad \varrho \ge C(h|\log h|)^{\frac{1}{2}} \tag{14.3.110}$$

where the second inequality is equivalent to logarithmic uncertainty principle $C\ell\rho \ge Ch|\log h|$.

We know that the contribution of each such element to the Tauberian remainder does not exceed $C|\log h|^2$ and therefore the total contribution of all such elements does not exceed $C\log h|^2 I$ with $I = \int \varrho^{-2}\,dx_2 d\xi_2 \asymp C|\log h|$ due to condition (14.3.109).

On the other hand, as $\varrho \le \bar{\varrho} = C\bar{\gamma} + C(h|\log h|)^{\frac{1}{2}}$ let us redefine ϱ as $\bar{\varrho}$. Then contribution of each such partition element to the Tauberian remainder does not exceed $C\bar{\varrho}^2 h^{-1} = C\bar{\gamma}^2 h^{-1} + C|\log h|^2$ and again due to condition (14.3.109) there is no more than C of such elements. Thus we arrive to

Proposition 14.3.38. *For magnetic Schrödinger operator satisfying in* $B(0,1)$ *conditions* (14.2.27) *and* (14.3.109) *the Tauberian remainder is* $O(\bar{\gamma}h^{-1})$ *as long as* $\mu \le Ch^{-\nu}|\log h|^{-3\nu}$.

On the other hand, exactly the same approach but without any non-degeneracy condition (14.3.109) results in the remainder estimate

$$C\bar{\varrho}^{-1}|\log h|^2 + C\bar{\varrho}h^{-1}$$

where the first term is an upper estimate of $C|\log h|^2 I$ with integral over $\{\varrho \ge \bar{\varrho}\}$ and the second term is the contribution of elements with $\varrho \asymp \bar{\varrho}$. Picking up $\bar{\varrho} = C\max(\bar{\gamma}, h^{\frac{1}{2}}|\log h|)$ we arrive to the remainder estimate

$$C\bar{\gamma}h^{-1} + Ch^{-\frac{1}{2}}|\log h|$$

which is our target $C\bar{\gamma}h^{-1}$ as long as $\bar{\gamma} \ge h^{\frac{1}{2}}|\log h|$ i.e. $\mu \le Ch^{-\nu/2}|\log h|^{-\nu}$. Thus we arrive to

Proposition 14.3.39. *For magnetic Schrödinger operator satisfying in* $B(0,1)$ *condition* (14.2.27)

(i) The Tauberian remainder is $O(\bar{\gamma}h^{-1})$ *as long as* $\mu \le h^{-\nu/2}|\log h|^{-\nu}$.

(ii) The Tauberian remainder is $O(h^{-\frac{1}{2}}|\log h|)$ *as long as* $h^{-\nu/2}|\log h|^{-\nu} \le \mu \le Ch^{-\nu}|\log h|^{-\nu}$.

General Case. II

Finally we are going to prove the most general proposition:

Proposition 14.3.40. *(i) Under conditions* (14.3.9), (14.2.27) *and*

$$\sum_{1\le k\le m} |\partial_{x_2}^k W| \ge \epsilon_0. \tag{14.3.111}_m$$

the Tauberian remainder does not exceed $C\bigl(|\log h|^{m+1} + \bar\gamma h^{-1}\bigr)$ *and thus the remainder estimate* $O(\bar\gamma h^{-1}) = O\bigl(\mu^{-1/\nu} h^{-1}\bigr)$ *holds as long as* $\mu \le Ch^{-\nu}|\log h|^{-(m+1)\nu}$.

(ii) In the general case[11] *the Tauberian remainder does not exceed* $C\bigl(\bar\gamma^{-\delta} + \bar\gamma h^{-1}\bigr)$ *and thus the remainder estimate* $O\bigl(\bigl(\bar\gamma h^{-1}\bigr)$ *holds as long as* $\mu \le Ch^{-\nu+\delta_1}$ *with arbitrarily small exponents* $\delta, \delta_1 > 0$.

Proof. Let us consider the scaling function

$$\ell(x_2) \coloneqq \epsilon_1\Bigl(\sum_{1\le k\le m-1} |\partial_{x_2}^k W(x_2)|^{\frac{m}{m-k}}\Bigr)^{\frac{1}{m}} + \bar\ell \tag{14.3.112}_m$$

with small enough constant $\epsilon_1 > 0$ such that $|\partial_{x_2}\ell| \le \frac{1}{2}$. Let us consider ℓ-admissible covering of $(-1, 1)$.

Then

$$|\partial_{x_2}^k W| \le C_0 \ell(x_2)^{m-k} \qquad \forall k : k = 1, \dots, m-1; \tag{14.3.113}_m$$

further, on each element with $\ell \ge 2\bar\ell$ one of these inequalities could be reversed with C_0 replaced by ϵ_0:

$$|\partial_{x_2}^k W| \ge \epsilon_0 \ell(x_2)^{m-k} \qquad k = 1, \dots, m-1. \tag{14.3.114}_k$$

Furthermore,

(14.3.116) Under condition $(14.3.111)_m$ there is no more than C_0 of ℓ-elements with $\ell \in (l, 2l)$ for each l and thus no more than $C|\log \bar\ell|$ elements in total

while

(14.3.117) In the general case there is no more than $C_0 l^{-1}$ of ℓ-elements with $\ell \in (l, 2l)$ for each l and thus no more than $C\bar\ell^{-1}$ elements in total.

[11] I.e. without non-degeneracy condition $(14.3.111)_m$.

On each ℓ-element oscillation of $W(x_2)$ does not exceed $C\ell^m$ and thus we can ponder condition

$$|\xi_2 - \eta^*_\hbar W(\bar{y})^{\frac{1}{2}}| \asymp \rho$$

with $\rho \ge C\ell^m$ and $\bar{y}$ the center of this element. As this condition is fulfilled and also $\rho\ell \ge Ch|\log h|$, $\rho \ge h^{1-\delta}$ we can apply Corollary 14.3.37(ii) and conclude that the contribution of this element to the remainder estimate does not exceed $C|\log h|^2$.

Now we need to sum contributions of all such elements. To do it in the most efficient way we redefine

$$(14.3.118)_m \quad \ell(x_2,\xi_2) := \epsilon_1\Big(|\xi_2 - \eta^*_\hbar W^{\frac{1}{2}}(x_2)| + \sum_{1\le k\le m-1} |\partial^k_{x_2} W(x_2)|^{\frac{m}{m-k}}\Big)^{\frac{1}{m}} + \bar{\ell}.$$

Then for each given ρ the total contribution of all elements of this type would not exceed $C|\log h|^2$ and $C\rho^{-1/m}|\log h|^2$ under condition $(14.3.111)_m$ and without it respectively; after integration with respect to $\rho^{-1}d\rho$ we get $C|\log h|^3$ and $C\bar{\ell}^{-1}|\log h|^2$ respectively and both these expressions do not exceed claimed in Statements 14.3.40 and (ii) remainder estimates[12] as we pick up

$$\bar{\ell} = C_1\bar{\gamma}^{1/(m-1)} + C_1(h|\log h|)^{1/(m+1)}. \tag{14.3.119}$$

On the other hand, the contribution of each element with $\ell \asymp \bar{\ell}$ does not exceed $C\bar{\ell}^{m+1}h^{-1}|\log h|^2$ and the total contribution of such elements does not exceed $C\bar{\ell}^{m+1}|\log h|^2h^{-1}$ and $C\bar{\ell}^m|\log h|^2h^{-1}$ under condition $(14.3.111)_m$ and without it respectively and these expressions do not exceed remainder estimates announced in Statements 14.3.40 and (ii) respectively.

Thus we need to consider only elements with $\rho \le C\ell^m$ and $\ell \ge 2\bar{\ell}$ with ℓ given by $(14.3.112)_m$ rather than $(14.3.118)_m$. Let us consider one such element $(\bar{y} - \frac{1}{2}\ell, \bar{y} + \frac{1}{2}\ell)$; after rescaling

$$x \mapsto (x-\bar{y})/\ell,\ W(x_2) - W(\bar{y}) \mapsto \big(W(x_2) - W(\bar{y})\big)/\ell^m,\ \rho \mapsto \rho\ell^{-m}$$

we find ourselves in the framework of condition $(14.3.111)_{m-1}$.

[12] Provided m is large enough in (ii) which we assume.

So in the rescaled coordinates let us define scaling function ℓ_1' by $(14.3.118)_{m-1}$ and redefine W as $\ell^{-m}W$. However, as we return to the original scale this new rescaling function $\ell_1 = \ell_1'\ell$ will be defined by $(14.3.118)_{m-1}$ with original W.

Now we can repeat the same arguments as before with $\bar{\ell}_1$ defined by $(14.3.119)_{m-1}$. However now in the total partition there is no more than C_1 of ℓ_1 elements with $\ell_1 \in (l, 2l)$ if original condition $(14.3.111)_m$ was fulfilled and no more than $C_1 l^{-1}$ of them otherwise because as we mentioned after rescaling of the elements in question $(14.3.111)_{m-1}$ always is fulfilled.

Then we eliminate elements of ℓ_1 partition with $\ell_1 \le 2\bar{\ell}_1$ and with $\rho \ge C_1\ell_1^{m-1}$ estimating their total contribution by $C|\log h|^{m+1} + C\bar{\gamma}h^{-1}$ and $C|\log h|^{m+1} + C\bar{\ell}_1^{m+1}\bar{\ell}^{-1}h^{-1}$ in the frameworks of Statements 14.3.40 and (ii) respectively which do not exceed remainder estimates announced there.

We will continue this process as long as our scaling function ℓ_k is defined just by $(14.3.118)_{m-k}$ i.e. until $k = m-2$. Then all elements remaining are eliminated by Corollary 14.3.37(ii) under condition $|\partial_{x_2} W| \asymp \zeta$. □

Thus we have covered the case

$$\mu \le h^{-\nu}|\log h|^{-\nu N} \tag{14.3.120}$$

leaving the case of the strong magnetic field $h^{-\nu}|\log h|^{-\nu N} \le \mu \le Ch^{-\nu}$ for Section 14.5.

14.4 Calculations

So far we recovered good remainder estimates but the Tauberian expression (14.3.45) we derived was implicit. In this section we am going to rewrite it in more explicit form as either

$$h^{-2}\int \mathcal{N}^{\mathsf{MW}}(x,0)\psi(x)\,dx \tag{14.4.1}$$

which is of magnitude $h^{-2}\big(1+\mu h\big)^{-1/(\nu-1)}$ or the same expression but with a smaller correction term. Again we consider only the case (14.3.120) leaving the case of the strong magnetic field for Section 14.5.

Remark 14.4.1. Without any loss of the generality one can assume that $\psi = \psi_2(x_2)\psi_1(x_1)$ with fixed admissible functions ψ_j; moreover, one can take

$\psi_1 = 1$ as $\mu \ge Ch^{-1}$. Really, it follows from the analysis of Subsection 14.1 that for fixed ψ vanishing as $x_1 = 0$ the Magnetic Weyl remainder (with the principal part is given by (14.4.1)) does not exceed

$$C \int_{\{\gamma \ge \bar\gamma\}} \mu^{-1} h^{-1} \gamma^{1-\nu} \times \gamma^{-1}\, dx + Ch^{-1}\bar\gamma = Ch^{-1}\bar\gamma = C\mu^{-1/\nu} h^{-1}$$

where the first and second terms are contribution of the regular and degeneration zones respectively and in comparison with (14.1.13) and Ch^{-1} they have an extra factor γ if $\psi = 0$ as $x_1 = 0$.

14.4.1 Regular Zone

Recall that the regular zone is $\mathcal{X}_{\mathsf{reg}} = \{C\bar\gamma \le |x_1| \le \bar\gamma_1\}$ and in this subsection γ ranges from $\bar\gamma$ to $\bar\gamma_1$ as well. Let us also recall that according to Subsection 14.3.2 we can take here $T = Ch|\log h|$ in (14.4.1).

Proposition 14.4.2. *Let condition* (14.3.9) *be fulfilled. Then*

$$|h^{-1} \int_{-\infty}^{0} \Big(F_{t\to h^{-1}\tau} \bar\chi_T(t) \Gamma\big(\psi(1-\psi_1)u\big)\Big)\, d\tau - h^{-2} \int \mathcal{N}^{\mathsf{MW}}(x,0)\big(\psi(1-\psi_1)\big)\, dx| \le C(\mu h + 1)^{1/(\nu-1)} \tag{14.4.2}$$

for $T = Ch|\log h|$, *fixed function* ψ *and* $\psi_1(x_1) = \bar\psi_1(x_1/\bar\gamma)$ *with a fixed admissible function* $\bar\psi$, *supported in* $(-2,2)$ *and equal* 1 *in* $(-1,1)$.

In particular we get $C\bar\gamma h^{-1}$*-estimate as* $\mu \le Ch^{-\nu^2/(2\nu-1)}$.

Proof. It follows from argument of Section 13.4 that for 2-dimensional Schrödinger operator with non-degenerate magnetic field, binding parameter μ and semiclassical parameter h under non-degeneracy condition $|\nabla V/F| \ge \epsilon_0$ the following asymptotic expansion holds

$$h^{-1} \int_{-\infty}^{0} \Big(F_{t\to h^{-1}\tau} \bar\chi_T(t) \Gamma\big(\psi u\big)\Big)\, d\tau \sim \sum_{m,n\ge 0} \kappa_{mn} h^{-2+2n+2m} \mu^{2m} \tag{14.4.3}$$

as $\mu \le h^{\delta-1}$ where

$$\sum_{m\ge 0} \kappa_{m0} h^{-2} (\mu h)^{2m} \sim h^{-2} \int \mathcal{N}^{\mathsf{MW}}(x,0)\psi(x)\, dx \tag{14.4.4}$$

and therefore one can replace (14.4.3) by (14.4.4) with an error $\kappa_{10}+O((\mu h)^2)$.

It also follows that in the same settings but with $h^{\delta-1} \le \mu \le Ch^{-1}$ another asymptotic expansion holds

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\big(\psi u\big)\Big)\,d\tau \sim \sum_{m,n\ge 0}\kappa'_{m,n}h^{-2+2n+2m}+\sum_{m,n\ge 0}\kappa''_{m,n}\mu^{-2-2m}h^{-2+2n} \tag{14.4.5}$$

and comparison of this expression with (14.4.3) where they overlap implies that $\kappa''_{**}=0$ and an error in question is given again by $\kappa_{10}+O((\mu h)^2)$.

Therefore in our setting the contribution (to this error) of any element of γ-partition in the regular zone will be of magnitude 1. To calculate the total contribution of the regular zone one must integrate the latter expression over $\gamma^{-2}d\gamma$ resulting in $O(\bar{\gamma}^{-1})$ which however is not as good as $O(\bar{\gamma}_1^{-1})$ with $\bar{\gamma}_1=\min\big(1,(\mu h)^{-1/(\nu-1)}\big)$ which we claimed.

On the other hand, substitution $\mu\mapsto\mu\gamma^{\nu}$, $h\mapsto h/\gamma$ into $O((\mu h)^2)$ and integration produces $O(\bar{\gamma}_1^{-1})$ which is exactly what we claimed and one needs just to calculate explicitly the correction appearing from κ_{10}-term.

In the non-degenerate settings this latter correction does not depend on μ and therefore one can calculate it as $\mu=0$. But this is non-magnetic case and then due to the standard theory and condition $|V|\ge\epsilon_0$

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t)u\big)\Big)\,d\tau\sim\sum_{n\ge 0}\varkappa_n(x)h^{-2+2n}$$

(without integration with respect to dx) with $\varkappa_0(x)=\mathcal{N}^{\mathsf{W}}(x,0)$ and therefore the total contribution of this correction term is $O(1)$. □

Now we am going to derive a bit sharper remainder estimate; to do this we must appeal to the spectral projector of the corresponding 1-dimensional Schrödinger operator:

Proposition 14.4.3. *Let condition* (14.2.27) *be fulfilled and let* ψ_1 *be an even function,* $\psi=\psi(x_2)$. *Then as* $h^{-\nu^2/(2\nu-1)}\le\mu\le\epsilon(h|\log h|)^{-\nu}$, $T=\epsilon\bar{\gamma}$ *the following estimate holds:*

$$|h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\big(\psi(1-\psi_1)u\big)\Big)\,d\tau- \tag{14.4.6}$$

$$h^{-2}\int \Big(\mathcal{N}^{\mathsf{MW}}(x,0)-\mathcal{N}_0^{\mathsf{MW}}(x,0)\Big)\psi(x_2)(1-\psi_1(x_1))\,dx-$$
$$(2\pi h)^{-1}\int e_0(x_1,x_1;x_2,\xi_2,0,\hbar)\psi(x_2)\big(1-\bar\psi_1(x_1)\big)\,dxd\xi_2|\le$$
$$Ch^{-1}\bar\gamma + C|\log h|^K$$

where $e_0(x_1,y_1;x_2,\xi_2,\tau,\hbar)$ *is the Schwartz kernel of the spectral projector* $e_0(x_2,\xi_2,\tau,\hbar)$ *for 1-dimensional Schrödinger operator*

$$a_0(x_2,\xi_2,\hbar)=\hbar^2D_1^2+(\xi_2-x_1^\nu/\nu)^2-W(x_2) \tag{14.4.7}$$

with $\hbar=h/\bar\gamma$, *while*

$$\mathcal{N}_0^{\mathsf{MW}}(x,0)=\frac{1}{2\pi}\sum_{n\ge 0}\theta\Big(\tau+W(x_2)-(2n+1)\mu h x_1^{\nu-1}\Big)\mu h x_1^{\nu-1} \tag{14.4.8}$$

is Magnetic Weyl approximation (without factor h^{-2}*) for corresponding toy-model operator.*

Proof. (a) To calculate $u(x,y,t)$ let us apply first the method of successive approximations with unperturbed operator $\bar A$ obtained from A by freezing $x_2=y_2$ in V, σ, ϕ:

$$\bar A=h^2D_1^2+\bar\sigma(x_1)^2\big(\xi_2-\mu\bar\phi(x_1)x_1^\nu)/\nu\big)^2+\bar V(x_1) \tag{14.4.9}$$

with $\bar\sigma=\sigma(x_1,y_2)$, $\bar\phi=\phi(x_1,y_2)$, $\bar V=V(x_1,y_2)$.

Then the first term of the Tauberian expression

$$h^{-1}\int_{-\infty}^0\Big(F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma\big(\psi(1-\psi_1)u\big)\Big)\,d\tau \tag{14.4.10}$$

is also given by formula (14.4.10) but for operator $\bar A$ instead of A and it is $O\big(h^{-3}\bar\gamma_1T_*\big)=O\big(h^{-2}\bar\gamma_1|\log h|\big)$ [13].

The estimate for the second term gains the factor $CT_*^2/h\asymp Ch|\log h|^2$ provided $\phi=1$ identically or factor

$$CT_*^2\big(1+\mu\bar\gamma_1^{\nu+1}h\big)/h\asymp C\big(h+\bar\gamma_1^2\big)|\log h|^2$$

[13] Actually factor $|\log h|$ is superficial and the first term is of magnitude $h^{-2}\bar\gamma_1$; further, all logarithmic factors below are superficial as effectively one can take in estimates $T_*=h$ rather than $T_*=Ch|\log h|$.

in the general case (recall that then $\phi = 1$ as $x_1 = 0$); therefore the second term does not exceed $Ch^{-2}\bar{\gamma}_1\big(h + \bar{\gamma}_1^2\big)|\log h|^3$.

Finally, in this two-term approximation the remainder gains one more such factor and thus does not exceed $Ch^{-2}\bar{\gamma}_1(h^2+\bar{\gamma}_1^4)|\log h|^5$. One can check easily that this is less than $Ch^{-1}\bar{\gamma}$ unless $\nu = 2$ and $\mu \le h^{-\nu^2/(2\nu-1)}|\log h|^K$ in which *special case* there will be an extra $|\log h|^K$ factor (rather superficial); then we consider three-term approximation and one can see easily that the remainder estimate will be $Ch^{-1}\bar{\gamma}$.

So we are left only with expression (14.4.10) for

$$u \mapsto \bar{u} = -ih\sum_{\varsigma=\pm} \bar{G}^{\varsigma}\delta(t)\delta(x_2-y_2)\delta(x_1-y_1) \tag{14.4.11}$$

where here and below "$\mapsto$" means "replaced by" and two extra terms given by (14.4.10) again for

$$u \mapsto \bar{u}_1 = -ih\sum_{\varsigma=\pm} \bar{G}^{\varsigma}A_1\bar{G}^{\varsigma}\delta(t)\delta(x_2-y_2)\delta(x_1-y_1) \tag{14.4.12}$$

and

$$u \mapsto \bar{u}_2 = -ih\sum_{\varsigma=\pm} \bar{G}^{\varsigma}A_1\bar{G}^{\varsigma}A_1\bar{G}^{\varsigma}\delta(t)\delta(x_2-y_2)\delta(x_1-y_1) \tag{14.4.13}$$

where $\bar{G}^{\pm}$ are corresponding parametrices and $A_1 = A - \bar{A}$.

Also, note that replacing in (14.4.12) A_1 by $\bar{A}_1 = (x_2-y_2)\cdot B_1$ with $B_1 = (\partial_{x_2}A)|_{x_2=y_2}$ one gets a proper remainder estimate with the exception of the special case in which in addition to terms due to (14.4.11)–(14.4.13) one must consider also an extra term given by (14.4.10) for

$$u \mapsto \bar{u}_2' = -ih\sum_{\varsigma=\pm} \bar{G}^{\varsigma}A_2\bar{G}^{\varsigma}\delta(t)\delta(x_2-y_2)\delta(x_1-y_1) \tag{14.4.14}$$

with $\bar{A}_2 = \frac{1}{2}(x_2-y_2)^2\cdot(\partial_{x_2}^2A)|_{x_2=y_2}$.

(b) We will tackle terms due to (14.4.12)–(14.4.14) later; now let us concentrate on the main term due to (14.4.11). After this term is derived with $T = Ch|\log h|$ one can increase T to T_1 where $T^* = \epsilon\mu\gamma^{\nu}$; however arguments of Subsection 14.3.2 applied to $\bar{A}$ (whose coefficients do not depend on x_2) imply that now one can take even $T = +\infty$.

With $T = +\infty$ one can rewrite this term (before integration by ψ and integration over x_2) as

$$(2\pi h)^{-1} \int \boldsymbol{e}(x_1, x_1; x_2, \xi_2, 0, \hbar)\bigl(1 - \bar{\psi}_1(x_1)\bigr)\, dx_1 d\xi_2 \tag{14.4.15}$$

where $\boldsymbol{e}(x_1, y_1; x_2, \xi_2, 0, \hbar)$ is the Schwartz kernel of 1-dimensional Schrödinger operator $\boldsymbol{a}(x_2, \xi_2, \hbar)$ obtained from $\bar{A}$ by change of variables $x_1 \mapsto \bar{\gamma} x_1$ (and thus $\mu \mapsto 1$) and $hD_2 \mapsto \xi_2$ while $\boldsymbol{e}^{\mathsf{W}}(x_1; x_2, \xi_2, \hbar)$ would be Weyl approximation for its restriction to diagonal.

However we would like to refer to a canonical operator $\boldsymbol{a}_0$ rather than to more general operator $\boldsymbol{a}$ and thus few extra steps are needed. We will delay them slightly.

(c) Consider now the second term corresponding to (14.4.12); recall that it does not exceed $Ch\gamma|\log h|^2$ with the superficial logarithmic factor factor. We claim that

(14.4.16) The total contribution of the second term is 0 modulo $C\mu^{-1/\nu}h^{-1} + |\log h|^K$.

Really, note first that one can assume that $\mu \le h^{-\nu}|\log h|^{-K}$, otherwise the total contribution $Ch^{-1}\bar{\gamma}_1|\log h|^2$ is less than announced. Let us rewrite the term in question as

$$\begin{aligned} u \mapsto \bar{u}_1 = &- ih \sum_{\varsigma=\pm} \bar{G}^{\varsigma} B_1 \bar{G}^{\varsigma} [\bar{A}, x_2 - y_2] \bar{G}^{\varsigma} \delta(t)\delta(x_2 - y_2)\delta(x_1 - y_1) \\ &- ih \sum_{\varsigma=\pm} \bar{G}^{\varsigma} [x_2 - y_2, B_1] \bar{G}^{\varsigma} \delta(t)\delta(x_2 - y_2)\delta(x_1 - y_1). \end{aligned} \tag{14.4.17}$$

Let us apply to (14.4.17) the method of successive approximations with an unperturbed operator frozen as $x_1 = y_1$; then each next term will acquire factor $C\mu\gamma^{\nu-1}h|\log h| \asymp (\gamma/\bar{\gamma}_1)^{\nu-1}|\log h|$ and therefore the second term in the successive approximation decomposition does not exceed $Ch^{-1}\bar{\gamma}|\log h|^{-K_1}$ as long as $\gamma \le \bar{\gamma}|\log h|^{K_2}$.

Meanwhile, the leading term in the successive approximation decomposition is just a standard Weyl expression without any axillary operators; this expression is odd with respect to $(\xi_2 - \mu x_1^{\nu}/\nu)$ and thus it produces 0 after integration with respect to ξ_2.

On the other hand, as $\gamma \ge C\bar{\gamma}|\log h|^{K_2}$ one can apply successive approximation method with unperturbed operator $\hat{A}$ which is obtained from $\bar{A}$ by transformation $\mu x_1^\nu/\nu \mapsto \xi_2 + \mu z_1^{\nu-1}(x_1 - z_1)$ with $z_1 = (\mu^{-1}\nu\xi_2)^{1/\nu}$ and the same is true for commutators $[\bar{A}, x_2 - y_2]$ and $[B_1, x_2 - y_2]$.

Then since both x_1 and y_1 are confined to an interval of the length $\beta = (\mu\gamma^{\nu-1})^{-1}$, each next term acquires factor $\beta\gamma^{-1}|\log h| \asymp \mu^{-1}h|\log h|\gamma^{-\nu}$ and therefore the second term does not exceed $C\mu^{-1}h^{-1}|\log h|^2\gamma^{1-\nu}$ and its total contribution does not exceed what is announced as $\gamma \ge \bar{\gamma}|\log h|^{K_2}$.

Meanwhile the leading term corresponds to the harmonic oscillator and obviously sums to 0 as $x_1 = y_1$ runs through $\mathbb{R}$.

So we will keep $T = Ch|\log h|$ for a while. In the analysis below we are going to consider expression (14.4.10) with Γ replaced by Γ' which contains integration with respect to x_1 but not x_2; then one can assume without any loss of the generality that

(14.4.18) V, σ, ϕ do not depend on x_2.

It is convenient to have $\phi = 1$; one can always reach it now changing $x_1 \mapsto x_1 + O(x_1^2)$ and paying the price: now

$$\bar{A} = \sigma_1(x_1)^2(hD_1)^2 + \sigma(x_1)^2\bigl(hD_2 - \mu x_1^\nu/\nu\bigr)^2 + V(x_1) \tag{14.4.19}$$

with $\sigma = \sigma_1 = 1$ as $x_1 = 0$.

Let us apply the method of successive approximations again this time using as unperturbed operator $\bar{A}_0$ obtained from $\bar{A}$ by freezing $x_1 = 0$ in V, σ and σ_1:

$$\bar{A}_0 = (hD_1)^2 + \bigl(hD_2 - \mu x_1^\nu/\nu\bigr)^2 + V(0). \tag{14.4.20}$$

In these successive approximations the first term is still $O\bigl(h^{-2}\bar{\gamma}_1|\log h|\bigr)$ and an estimate for each subsequent term is gaining an extra factor $CT_*\bar{\gamma}_1/h \asymp \bar{\gamma}_1|\log h|$; therefore $(n{+}1)$-th term does not exceed $Ch^{-2}\bar{\gamma}_1^n|\log h|^n$ which is small for large n since $\bar{\gamma}_1 \le h^{(\nu-1)/(2\nu-1)}$ due to our assumption $\mu \ge h^{-\nu^2/(2\nu-1)}$. Note that we can write

$$A \sim \sum_{k=0}^{K} x_1^k \bar{A}_k \qquad \text{with} \quad \bar{A}_k = \bar{A}_k(x_1, x_2, hD_1, hD_2; h, \mu) \quad \text{as} \quad k \ge 1,$$

$\bar{A}_0$ is already defined by (14.4.20). Plugging it into successive approximation formula we get many terms but the first term results in

$$(2\pi h)^{-1}\int e_0(x_1,x_1;x_2,\xi_2,0,\hbar)\bigl(1-\bar{\psi}_1(x_1)\bigr)\,dx_1d\xi_2 \tag{14.4.21}$$

(after finally one takes $T=+\infty$ instead of $T=Ch|\log h|$) and the second term will be one for the approximation $A=\bar{A}_0+x_1\bar{A}_1$.

But then the contribution to (14.4.15) of this refined second term would be 0 because (before integration over $\psi\,dx_2$) it is equal to

$$\int \mathsf{Tr}_1\bigl(b(\xi_2)\bar{\psi}_1\bigr)\,d\xi_2 \tag{14.4.22}$$

where $b(\xi_2)$ is an operator in $\mathbb{H}=\mathscr{L}^2(\mathbb{R})$, Tr_1 is the trace in this auxiliary space and $\mathcal{T}b(\xi_2)\mathcal{T}=-b(\xi_2')$ with $\xi_2'=(-1)^\nu\xi_2$, $(\mathcal{T}v)(x_1)=v(-x_1)$.

(d) Now let us consider terms in this successive approximation with $n\ge 3$; they will be still too large just to be skipped. Let us apply to them the successive approximations method taking as unperturbed operator $\hat{A}_0$ with x_1^ν/ν replaced by $y_1^\nu/\nu+y_1^{\nu-1}(x-x_1)$:

$$\hat{A}_0=(hD_1)^2+\bigl(hD_2-\mu\bigl(y_1^\nu/\nu+y_1^{\nu-1}(x-x_1)\bigr)\bigr)^2+V(0). \tag{14.4.23}$$

One can see easily that each successive term of this approximation is gaining factor $\mu\gamma^{\nu-2}T^3/h\asymp\mu\gamma^{\nu-2}h^2|\log h|^3$. Further, contributions of the second terms to (14.4.15) will be equal 0 again after easy calculations. Finally, the remainder will be then less than

$$Ch^{-2}\bar{\gamma}_1^3\times(\mu h^2\bar{\gamma}_1^{\nu-2})^2|\log h|^K\asymp C\bar{\gamma}_1|\log h|^K\le 1$$

where the first factor is the estimate of the 3-rd term in the previous approximations and the second factor is what we gained now. So we can leave only the first terms in these last approximations.

Now when we sum all these terms with $n\ge 3$, we get $h^{-2}\bigl(\mathcal{N}^{\mathsf{MW}}-\mathcal{N}_0^{\mathsf{MW}}\bigr)$ (multiplied by $\psi(1-\psi_1)$ and integrated in the end of the day) where $h^{-2}\mathcal{N}_0^{\mathsf{MW}}$ is what we would get for the first term if we ran last round of successive approximations for it; and this is exactly $h^{-2}\mathcal{N}_0^{\mathsf{MW}}(x_1,x_2,\tau,\mu,h)$.

However since we did not do it we have the same expression but with a correction term

$$(2\pi h)^{-1}\int e_0(x_1/\bar{\gamma};\xi_2,\tau,\hbar)\,d\xi_2-h^{-2}\mathcal{N}_0^{\mathsf{MW}}(x_1,x_2,\tau,\mu,h). \tag{14.4.24}$$

(e) Consider now the second term given by (14.4.10) with u replaced by $\bar{u}_1$ defined by (14.4.12). This term does not exceed $Ch^{-1}\gamma|\log h|^2$ (with a superficial logarithmic factor). Again applying the successive approximations of (ii) one can see that replacing $\bar{G}^\varsigma$ by $\bar{G}_0^\varsigma$ brings an extra factor $\gamma|\log h|^K$ and therefore all the terms but the first one do not exceed $Ch^{-1}\bar{\gamma}_1^2|\log h|^K$ which is less than the right-hand expression of of (14.4.6) (unless in the framework of the special case). Similarly one can replace A_1 by

$$\bar{A}_1 = -2\mu(x_2-y_2)\beta(y_2)x_1^{\nu+1}\bigl(hD_2 - \mu x_1^\nu/\nu\bigr) - (x_2-y_2)w(y_2).$$

One can even consider the original second term; recall that it does not exceed $Ch^{-1}\gamma|\log h|$.

(f) Now there is a special case when one needs to consider extra terms due to (14.4.13), (14.4.14) and the second term in approximation of (iv); all these terms do not exceed $Ch^{-1}\bar{\gamma}_1^2|\log h|^K$ and one needs only to get rid of this logarithmic factor.

Replacing $\bar{G}^\zeta$, $\bar{G}_0^\zeta$ by $\hat{G}_0^\zeta$ linked to $\hat{A}_0$ defined by (14.4.23) we will get errors less than the right-hand expression of (14.4.6). On the other hand, calculations after this substitution show that these terms do not exceed $Ch^{-1}\bar{\gamma}_1^2$ (so there is no logarithmic factor) which even in the special case does not exceed $Ch^{-1}\bar{\gamma}$. Easy but tedious calculations we leave to the reader. □

Proposition 14.4.4. *(i) Let condition* (14.2.27) *be fulfilled and let* ψ_1 *be an even function,* $\psi = \psi(x_2)$. *Then as* $Ch^{-1} \le \mu \le h^{-\nu^2/(2\nu-1)}$

$$(14.4.25)\quad |(2\pi h)^{-1}\int e_0(x_1,x_1;x_2,\xi_2,0,\hbar)\bigl(1-\bar{\psi}_1(x_1)\bigr)\,dx_1d\xi_2 - h^{-2}\int \mathcal{N}_0^{\mathsf{MW}}(x_1,x_2,\xi_2,0,\hbar)\bigl(1-\psi_1(x_1)\bigr)\,dx_1| \le C\bar{\gamma}h^{-1}.$$

(ii) Therefore estimate (14.4.6) *holds for* $Ch^{-1} \le \mu \le h^{-\nu^2/(2\nu-1)}$ *as well.*

Proof. Statement (i) instantly follows from Proposition 14.4.2 for $A = \bar{A}_0$ and Statement (ii) follows from Propositions 14.4.2 and (i).

14.4.2 Degeneration Zone

Singularity at $t = 0$

Now we need to consider an degeneration zone $\mathcal{X}_{\mathsf{deg}} = \{|x_1| \le \bar\gamma\}$. In this subsubsection we consider Tauberian expression

$$h^{-1}\int_{-\infty}^{0} \Bigl(F_{t\to h^{-1}\tau}\bar\chi_T \Gamma\bigl(\psi\psi_1 u\bigr)\Bigr)\,d\tau \tag{14.4.26}$$

with $T = Ch|\log h|$ even if this formula does not necessarily represent $\Gamma(\psi\psi_1 e)|_{\tau=0}$ with a desired precision, leaving the necessary correction for the rest of the section. In the end of this subsection we will list cases (due to Section 14.3) when provides the desired precision.

Running an absolutely standard method of successive approximations (i.e. taking as unperturbed operator with $x = y$) one can easily recover Weyl asymptotics with $C\bar\gamma h^{-2}\times \hbar^2 = C\bar\gamma^{-1}$ error with $\hbar = h\bar\gamma^{-1}$ while the contribution of the whole degeneration zone to the asymptotics is of magnitude $h^{-2}\bar\gamma$ [14].

This $C\bar\gamma^{-1}$ error does not exceed $Ch^{-1}\bar\gamma$ as long as $\bar\gamma \ge \epsilon h^{\frac12}$ which means exactly that

$$\mu \le Ch^{-\nu/2}. \tag{14.4.27}$$

This is not extremely restrictive condition, much weaker than condition $\mu \le (h|\log h|)^{-\nu/3}$ (i. e. $\bar\gamma \ge (h|\log h|)^{\frac13}$) arising as $h^{-1}(\hbar|\log h|)^{\frac12} \le h^{-1}\bar\gamma$ to provide remainder estimate $Ch^{-1}\bar\gamma$ for the spectral asymptotics in the general case. Moreover, (14.4.27) is even weaker a bit than condition $\mu \le (h|\log h|)^{-\nu/2}$ (i.e. $\bar\gamma \ge (h|\log h|)^{\frac12}$) arising as $h^{-1}(\hbar|\log h|) \le h^{-1}\bar\gamma$ to provide remainder estimate $Ch^{-1}\bar\gamma$ for the spectral asymptotics under condition (14.3.109).

And in the degeneration zone we can write a standard Weyl approximation or magnetic Weyl approximation to our sole discretion[15].

Observe that

(14.4.28) Both Weyl and magnetic Weyl expressions are actually more precise in the degeneration zone than we have written before, giving an error not exceeding $Ch^{-2}\bar\gamma\times\hbar^4$.

---

[14] It is easy to get rid of superficial logarithmic factors in this case.

[15] Which would not be the case in the outer zone where we must use magnetic Weyl at least as $\mu \ge h^{-1}$.

Really, when we write the complete decomposition in powers of μ and h fixing $\bar\gamma \asymp \bar\mu^{-1/\nu}$ but considering $\mu \le \bar\mu$ as variable, we realize that terms with $\mu^{2k}h^{-2+2k}$ all are in the magnetic Weyl approximation, terms without μ are produced by Weyl expression for non-singular operator and thus are estimated by $Ch^{-2+2k}\bar\gamma$ rather than by $Ch^{-2}\hbar^{2k}\bar\gamma$ and unaccounted terms contain factor $\mu^{2k}h^{2l}$ with $l \ge k \ge 1$ and thus an error term does not exceed $Ch^{-2}\hbar^4\bar\gamma = Ch^2\bar\gamma^{-3}$.

Note that $Ch^2\bar\gamma^{-3} \le Ch^{-1}\bar\gamma$ as $\bar\gamma \ge h^{3/4}$ or equivalently $\mu \le Ch^{-3\nu/4}$. Further, in virtue of the above arguments one can rewrite expression (14.4.26) as

$$\int \frac{T}{h}\hat{\bar\chi}\bigl(-\frac{T}{h}\tau\bigr)\int h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0)\psi_1(x)\psi(x)\,dxd\tau$$

which can be rewritten as expression (14.4.29) below with $O(1)$ error. Therefore we arrive to

Proposition 14.4.5 [16]**.** *With an error $Ch^2\bar\gamma^{-3}$ one can rewrite Tauberian expression* (14.4.26) *with $T = Ch|\log h|$ as*

$$h^{-2}\int \mathcal{N}^{\mathsf{MW}}(x,0)\psi_1(x)\psi(x)\,dx. \tag{14.4.29}$$

Therefore due to Subsection 14.3 we arrive to

Corollary 14.4.6. *(i) In the general case the contribution of the degeneration zone $\mathcal{X}_{\mathsf{deg}}$ to the remainder with the principal part* (14.4.29) *does not exceed*

$$Ch^{-1}\bar\gamma + Ch^{-1}(h|\log h|/\bar\gamma)^{\frac12}; \tag{14.4.30}$$

in particular as $\mu \le (h|\log h|)^{-\nu/3}$ the remainder estimate is $O(h^{-1}\bar\gamma)$.

(ii) Under conditions (14.2.27) *and* (14.3.109) *the contribution of the degeneration zone to the remainder with the principal part* (14.4.29) *does not exceed*

$$Ch^{-1}\bar\gamma + C|\log h|\bar\gamma^{-1}; \tag{14.4.31}$$

in particular as $\mu \le (h|\log h|)^{-\nu/2}$ this remainder estimate is $O(h^{-1}\bar\gamma)$.

[16] Cf. Proposition 14.4.2.

(iii) Under conditions (14.2.27) *and* (14.3.103) *with*

$$\zeta \ge Ch|\log h|/\bar\gamma + C\bar\gamma \tag{14.4.32}$$

the contribution of the degeneration zone to the remainder with the principal part (14.4.29) *does not exceed*

$$Ch^{-1}\bar\gamma + Ch^{2}\bar\gamma^{-3}; \tag{14.4.33}$$

in particular as $\mu \le h^{-3/4\nu}$ *this remainder estimate is* $Ch^{-1}\bar\gamma$.

Then combining with the result of the regular zone analysis we arrive to the following theorem:

Theorem 14.4.7. *Let condition* (14.3.9) *be fulfilled. Then*

(i) In the general case R^{MW} *defined by* (14.1.9) *does not exceed* (14.4.30)*; in particular,* $\mathsf{R}^{\mathsf{MW}} = O(Ch^{-1}\bar\gamma)$ *as* $\mu \le C(h|\log h|)^{-\nu/3}$.

(ii) Under conditions (14.2.27) *and* (14.3.109) R^{MW} *does not exceed* (14.4.31)*; in particular,* $\mathsf{R}^{\mathsf{MW}} = O(Ch^{-1}\bar\gamma)$ *as* $\mu \le C(h|\log h|)^{-\nu/2}$.

(iii) Under conditions (14.2.27) *and* (14.3.103) *with* ζ *satisfying* (14.4.32) R^{MW} *does not exceed* (14.4.33)*; in particular,* $\mathsf{R}^{\mathsf{MW}} = O(Ch^{-1}\bar\gamma)$ *as* $\mu \le Ch^{-\nu^2/(2\nu-1)}$.

On the other hand, repeating (almost all) arguments of the proof of Proposition 14.4.3 one can prove easily

Proposition 14.4.8. *In the framework of Proposition 14.4.3*

$$\begin{aligned} |h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar\chi_\tau(t)\Gamma\big(\psi\psi_1 u\big)\Big)\,d\tau - \\ h^{-2}\int\Big(\mathcal{N}^{\mathsf{MW}}(x,0)-\mathcal{N}_0^{\mathsf{MW}}(x,0)\Big)\psi(x_2)\psi_1(x_1)\,dx - \\ (2\pi h)^{-1}\int \frac{T}{h}\hat{\bar\chi}\big(-\frac{T}{h}\tau\big)\big)\int e_0(x_1,x_1;x_2,\xi_2,\tau,\hbar)\psi(x_2)\bar\psi(x_1)\,dx d\xi_2\tau| \le \\ Ch^{-1}\bar\gamma + C|\log h|^{K} \end{aligned} \tag{14.4.34}$$

Combining with the results of the previous subsection we arrive to

Theorem 14.4.9. *Let conditions* (14.2.27) *and* (14.3.103) *be fulfilled with* ζ *satisfying* (14.4.32) *and let* $\psi = \psi(x_2)$.

Then for $h^{-\nu^2/(2\nu-1)} \le \mu \le h^{-\nu}|\log h|^{-K}$

$$|\int \Big(e(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0)\Big)\psi(x)\,dx - h^{-1}\int \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x_2,0)\psi(x_2)\,dx_2| \le Ch^{-1}\bar\gamma + C|\log h|^K \tag{14.4.35}$$

with correction term

$$h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} := (2\pi h)^{-1}\int e_0(x_1,x_1;x_2,\xi_2,\tau,\hbar)\,dx_1 d\xi_2 - h^{-2}\int \mathcal{N}^{\mathsf{MW}}_0(x,\tau)\,dx_1. \tag{14.4.36}$$

Extending Time Interval

In Section 14.3 we derived asymptotics with the principal part which is the sum of

$$\sum_m h^{-1}\int_{-\infty}^0 \Big(F_{t\to h^{-1}\tau}\bar\chi_{T_m}(t)\Gamma(\psi_1\psi Q_m u)\Big)\,d\tau \tag{14.4.37}$$

where Q_m are elements of partition (in hD_2 and may be x_2) and $T_m = Ch|\log h|/\varrho_m^2$. We can rewrite (14.4.37) as the sum of (14.4.26) with $T = \bar T = \epsilon\bar\gamma$ and

$$\sum_m h^{-1}\int_{-\infty}^0 \Big(F_{t\to h^{-1}\tau}\big(\bar\chi_{T_m}(t) - \bar\chi_{\bar T}(t)\big)\Gamma(\psi_1\psi Q_m u)\Big)\,d\tau. \tag{14.4.38}$$

Consider now expression (14.4.26) with $T = \epsilon\bar\gamma$. Also due to propagation results of Section 14.3 one can replace there $T = \epsilon\bar\gamma$ by $T = Ch|\log h|$; then all the results of the previous subsection are applicable. It includes (14.4.34) as well where one can replace back $T = Ch|\log h|$ by $T = \epsilon\bar\gamma$ in the first and/or the last term of the left-hand expression.

Moreover, again due to propagation results of Section 14.3, all terms in (14.4.38) with $\varrho_m \ge C\bar\rho_1$ are negligible and therefore one can rewrite (modulo negligible) expression (14.4.37) as the sum of expressions (14.4.26) with $T = Ch|\log h|$ and (14.4.38) with $\bar T = \epsilon\bar\gamma$ with summation with respect to m such that $\varrho_m \le C\bar\rho_1$. Therefore we arrive to the following proposition:

Proposition 14.4.10. *(i) With an error not exceeding* $Ch^{-1}\bar{\gamma} + C\bar{\gamma}_1^{-1}$ *one can rewrite expression* (14.4.37) *as the sum of expressions* (14.4.29) *and* (14.4.38) *with* $\bar{T} = \epsilon\bar{\gamma}$ *and* Q_m *partition of unity in the periodic zone only.*

(ii) In particular, as $\mu \le Ch^{-\nu^2/(2\nu-1)}$ *this error does not exceed* $Ch^{-1}\bar{\gamma}$.

As $\mu \ge Ch^{-\nu^2/(2\nu-1)}$ we need a bit more subtle analysis:

Proposition 14.4.11. *(i) With an error not exceeding* $C\bar{\gamma}h^{-1} + C|\log h|^K$ *one can rewrite expression* (14.4.37) *as the sum of the following three expressions:*

$$(14.4.39)\quad h^{-2}\int \Big(\mathcal{N}^{\mathsf{MW}}(x,0) - \mathcal{N}_0^{\mathsf{MW}}(x,0)\Big)\psi(x_2)\psi_1(x_1)\,dx + (2\pi h)^{-1}\int e_0(x_1,x_1;x_2,\xi_2,0,\hbar)\psi(x_2)\bar{\psi}(x_1)\,dxd\xi_2$$

where the first term is actually less than the remainder estimate,

$$(14.4.40)\quad (2\pi h)^{-1}\int \Big(\frac{T}{h}\hat{\bar{\chi}}(-\frac{T}{h}\tau)) - \delta(\tau)\Big)\times \int e_0(x_1,x_1;x_2,\xi_2,\tau,\hbar)\psi(x_2)\bar{\psi}(x_1)\,dxd\xi_2\,d\tau$$

with $T = \bar{T} = \epsilon\bar{\gamma}$, *Dirac* δ*-function* <u>*and*</u> *the third expression is* (14.4.38) *where now* $\{Q_m\}$ *is a partition of unity in the periodic zone only.*

(ii) Further, one can rewrite (14.4.40) *as the sum*

$$(14.4.41)\quad \sum_m (2\pi h)^{-1}\int \Big(\frac{T}{h}\hat{\bar{\chi}}(-\frac{T}{h}\tau)) - \delta(\tau)\Big)\times \int e_0(x_1,x_1;x_2,\xi_2,\tau,\hbar)\psi(x_2)\bar{\psi}(x_1)Q_m(x_2,\xi_2)\,dxd\xi_2\,d\tau$$

where now $\{Q_m\}$ *is a partition of unity in the periodic zone only.*

Proof. Proposition immediately follows from Proposition 14.4.8 and propagation results of Section 14.3 with the only exception that in (14.4.41)

summation is taken over all m, and one needs to prove that the corresponding terms are negligible in the non-periodic zone where condition

$$\bigl(|\xi_2 - W^{\frac{1}{2}}\eta^*_\hbar| + |\partial_{x_2} W|\bigr) \asymp \rho \le C\bar{\rho}_1 \tag{14.4.42}$$

is violated.

Note that the expression in question is the sum of

$$(2\pi T)^{-1}\hat{\chi}\bigl(-\frac{h}{T}\tau\bigr)\int e_0(x_1,x_1;x_2,\xi_2,\tau,\hbar)\times \psi(x_2)\bar{\psi}(x_1)Q_m(x_2,\xi_2)\,dxd\xi_2\,d\tau = \int h^{-1}\int_{-\infty}^{0}\Bigl(F_{t\to h^{-1}\tau}\chi_T(t)\bigl(\Gamma'\psi_1(x_1)Q_m(y_2,hD_2)\bar{u}_0\bigr)\Bigr)\psi(y_2)\,dy_2d\tau \tag{14.4.43}$$

with T running from $\epsilon\bar{\gamma}$ to $+\infty$ and $\bar{u}_0$ defined for operator $\bar{A}_0$.

If $|\xi_2 - W^{\frac{1}{2}}\eta^*_\hbar| \ge \rho$ on partition element Q_m then expression (14.4.43) does not exceed $Ch^s(T+1)^{-s}$ as $T \ge C_0 h|\log h|/\rho^2$ just due to propagation results of Section 14.3 applied to $\bar{u}_0$ and $\bar{A}_0$ and since for $C_0h|\log h|/\rho^2 \le \epsilon\bar{\gamma}$ as $\rho \ge \bar{\rho}_1$, these elements are covered.

On the other hand, if $|W_{x_2}| \asymp \rho$ on the partition element in question, one can notice that $\bar{A}_0$ depends on y_2 via $-W(y_2)$ only and introducing new variable $y_2' = -W(y_2)$ we get mollification with respect to the spectral parameter and thus expression (14.4.43) does not exceed $Ch^s(T+1)^{-s}$ as well.

We leave easy details to the reader. □

14.4.3 Periodic and Near-Periodic Orbits

Toy-Model

Thus we need to analyze periodic zone $\mathcal{X}_{\mathsf{per}}$ more accurately defining it by (14.4.42) rather than by

$$\rho := |\xi_2 - W^{\frac{1}{2}}\eta^*_\hbar| \le C\bar{\rho}_1 \tag{14.4.44}$$

and only in the case when magnetic field is strong enough to prevent Corollary 14.4.6 from delivering a sharp remainder estimate.

Namely, we need to consider term

$$h^{-1}\int_{-\infty}^{0}\Bigl(F_{t\to h^{-1}\tau}\bigl(\bar{\chi}_T(t) - \bar{\chi}_{\bar{T}_*}(t)\bigr)\Gamma(\psi_1\psi Qu)\Bigr)\,d\tau \tag{14.4.45}$$

with partition element $Q = Q(x_2, hD_2)$, $T = T^*$ where T_* and T^* are defined in two last subsubsections of Section 14.3.4 and $\bar{T}_* = C_0 h|\log h|$. Here due to propagation results of these subsections we can take any $T \in [T_*, T^*]$ to our discretion, in particular $T = T_*$.

Let consider a toy-model first; more precisely, let us assume that operator under consideration coincides with a toy-model in $B(0,1)$. Then $T_* = C\rho^{-2}h|\log h|$ and $T^* = \epsilon\rho$ with $|\xi_2 - \eta^*_\hbar| \asymp \rho$ on $\operatorname{supp} Q$.

Then expression for correction (14.4.45) will be the same (modulo negligible) if one replaces u by $\bar{u}$ constructed for operator coinciding with toy-model in $\mathbb{R}^2$. But then one can replace $T = \epsilon\rho^{-1}$ by $T = \infty$. Also one can remove restriction from below on $\rho : \rho \ge \bar{\gamma}$.

Also in this case one can replace $\bar{\psi}_1$ by 1 since contribution to (14.4.45) of the regular zone is negligible due to propagation results there and contribution of the forbidden zone is negligible as well. Further, one does not need to integrate over $\psi(x_2)dx_2$ in (14.4.45) anymore.

After all these modifications there is no need to consider a partition and then correction (14.4.45) is transformed into

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\big(1-\bar{\chi}_{\bar{T}_*}(t)\big)\Gamma'\bar{u}\Big)\,d\tau \tag{14.4.46}$$

where we recall that $\Gamma' v = \int v(x_1,x_2;x_1,x_2)\,dx_1$; in our case $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ does not depend on x_2.

Obviously

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\Gamma'\bar{u}\Big)\,d\tau = (2\pi h)^{-1}\int \boldsymbol{n}_0(\xi_2,\hbar)\,d\xi_2 \tag{14.4.47}$$

where

(14.4.48) $\boldsymbol{n}_0(\xi_2,\hbar)$ is the number of negative eigenvalues of operator $\boldsymbol{a}_0(\xi_2,\hbar)$ with $W = 1$.

On the other hand, we know that modulo remainder estimate under weak magnetic field approach, i.e. $O\big(\bar{\gamma}h^{-1} + h^{-1}\hbar^{\frac{1}{2}}\big)$

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar{\chi}_{\bar{T}_*}(t)\Gamma'\bar{u}\Big)\,d\tau \equiv h^{-2}\int \mathcal{N}_0^{\mathsf{MW}}(x,0)\,dx_1. \tag{14.4.49}$$

Really, it follows from our earlier arguments that contribution of zone $\gamma \le \bar{\gamma}$ and therefore $\mu_{\mathsf{eff}} h_{\mathsf{eff}} \le 1$, contribution of γ-admissible element to the error does not exceed $C\gamma^{-1} \times (\gamma/\bar{\gamma})^s$. Therefore

$$h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} \equiv (2\pi h)^{-1} \int \boldsymbol{n}_0(\xi_2, \hbar)\, d\xi_2 - h^{-2} \int \mathcal{N}^{\mathsf{MW}}_0(x, 0)\, dx_1 \tag{14.4.50}$$

also modulo $O(\bar{\gamma}_1^1)$.

The error in (14.4.50) does not exceed $Ch^{-1}\bar{\gamma}$ even if $\bar{\gamma}^{-1} \ge \bar{\gamma} h^{-1}$ because in this case we already made an error replacing the left-hand expression of (14.4.49) by its right-hand-expression in the analysis of Subsection 14.4.1 and now we just compensated it by adding the skipped term. One can consider (14.4.50) as a definition of the correction term for the model operator. Thus we arrive to the following proposition:

Proposition 14.4.12. *For an operator, coinciding with the toy-toy-model in* $(-1, 1) \times \mathbb{R}$*,*

$$\int e(x, x, 0)\, dx_1 \equiv h^{-2} \int \mathcal{N}^{\mathsf{MW}}_0\, dx_1 + h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} \mod O\bigl(\bar{\gamma}h^{-1} + h^{-\delta}\bigr) \tag{14.4.51}$$

where $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *is defined by* (14.4.50).

Expression (14.4.50), multiplied by $\psi(x_2)dx_2$ and integrated will be used in two next subsubsections in the general case as well. However to get more explicit even if less precise expression one can replace (14.4.46) by

$$h^{-1} \int_{-\infty}^{0} \Bigl(F_{t\to h^{-1}\tau}\bigl(1 - \bar{\chi}_{\bar{T}_*}(t)\bigr)\Gamma'\phi(hD_2)\bar{u}\Bigr)\, d\tau \tag{14.4.52}$$

with ϕ supported in $[-2C_0, 2C_0]$ and equal 1 in $[-C_0, C_0]$, making the same error as in (14.4.51).

Using equalities

$$h^{-1} \int_{-\infty}^{0} \Bigl(F_{t\to h^{-1}\tau}\Gamma'\phi(hD_2)\bar{u}\Bigr)\, d\tau = (2\pi h)^{-1} \int \boldsymbol{n}_0(\xi_2, \hbar)\phi(\xi_2)\, d\xi_2 \tag{14.4.53}$$

and

$$h^{-1} \int_{-\infty}^{0} \Bigl(F_{t\to h^{-1}\tau}\bar{\chi}_{\bar{T}_*}\Gamma'\phi(hD_2)\bar{u}\Bigr)\, d\tau \equiv (2\pi h)^{-1} \int n_0^{\mathsf{W}}(\xi_2, \hbar)\phi(\xi_2)\, d\xi_2 \tag{14.4.54}$$

with the second equality modulo $O(h^{-1}\hbar^2) = O(h\bar{\gamma}^{-2})$ with

$$n_0^{\mathsf{W}}(\xi_2,\hbar) = (\pi\hbar)^{-1}\int \Big(1 - \big(\xi_2 - x_1^{\nu}/\nu\big)^2\Big)_+^{\frac{1}{2}}\, dx_1 \tag{14.4.55}$$

the Weyl approximation of $\boldsymbol{n}_0(\xi_2,\hbar)$, we arrive to

Proposition 14.4.13. *For an operator, coinciding with toy-model in* $(-1,1)\times\mathbb{R}$

$$h^{-2}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} \equiv (2\pi h)^{-1}\int \Big(\boldsymbol{n}_0(\xi_2,\hbar) - n_0^{\mathsf{W}}(\xi_2,\hbar)\Big)\phi(\xi_2)\, d\xi_2 \qquad \mathsf{mod}\ O\big(h\bar{\gamma}^{-2}\big). \tag{14.4.56}$$

To calculate expression (14.4.56) more explicitly we need to calculate eigenvalues $\lambda_n(\xi_2,\hbar)$ of operator $\boldsymbol{a}_0(\xi_2,\hbar)$ and we are interested in those eigenvalues which are close to 0 as ξ_2 is close to $\eta^*_\hbar$.

These eigenvalues are defined modulo $O(\hbar^2)$ from *Bohr-Sommerfeld condition*

$$\frac{1}{2\pi\hbar}S(\xi_2,\tau) + \frac{1}{4}\iota_M\big(\mathcal{L}(\xi_2,\tau)\big) \in \mathbb{Z} \qquad \text{as}\ \ \tau = \lambda_n \tag{14.4.57}$$

where

$$S(\xi_2,\tau) = \oint_{\mathcal{L}(\xi_2,\tau)} \xi_1\, dx_1 \tag{14.4.58}$$

and $\iota_M\big(\mathcal{L}(\xi_2,\tau)\big)$ is Maslov' index of the closed trajectory $\mathcal{L}(\xi_2,\tau)$ (on 2-dimensional phase plane) on the energy level τ; $\iota_M\big(\mathcal{L}(\xi_2,\tau)\big) = 2$ as $\tau \approx 0$.

Since $\partial_\tau S(\xi_2,\tau) = T(\xi_2,\tau)$ due to Hamiltonian mechanics, the spacing between two consecutive eigenvalues is $2\pi\hbar/T(\xi_2,\tau) + O(\hbar^2)$. Further, all these eigenvalues $\lambda_n(\xi_2,\hbar)$ are uniformly analytic functions of ξ_2, $|\xi_2| \ll 1$, $\hbar \ll 1$ as $|\lambda_n| \ll 1$ and also $\partial^2_{\xi_2}\lambda_n \ge \epsilon_0$. This yields immediately

Proposition 14.4.14. *As* $\mu \le \epsilon(h|\log h|)^{-\nu}$

(i) $|\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}| \le C\hbar^{\frac{1}{2}}$*; in particular,* $|\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}| \le C\bar{\gamma}$ *as* $\mu \le Ch^{-\nu/3}$.

(ii) One can calculate $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *with an error not exceeding* $C\hbar^{(k+1)/2}$ *replacing* $\lambda_n(\xi_2,\hbar)$ *by its approximation modulo* $O\big(\rho^{2k+2}+\hbar^{k+1}\big)$ *with* $k = 1,2,\dots$ *where here and below* $\rho = \xi_2 - \eta^*_\hbar$.

(iii) In particular, one can calculate $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *with an error not exceeding* $C\hbar$ *(which does not exceed* $C\bar{\gamma}$ *as* $\mu \le Ch^{-\nu/2}$*) replacing* $\lambda_n(\xi_2,\hbar)$ *by its approximation modulo* $O\big(\rho^4+\hbar^2\big)$.

(iv) And one can calculate $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *with an error not exceeding* $C\hbar^{3/2}$ *(which does not exceed* $C\big(\bar{\gamma}+h\bar{\gamma}_1^{-1}\big)$ *as* $\nu\ge 3$*) replacing* $\lambda_n(\xi_2,\hbar)$ *by its approximation modulo* $O\big(\rho^6+\hbar^3\big)$.

(v) And as $\nu=2$ *one can calculate* $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *with an error not exceeding* $C\hbar^2$ *(which does not exceed* $Ch\bar{\gamma}_1^{-1}$*)) replacing* $\lambda_n(\xi_2,\hbar)$ *by its approximation modulo* $O\big(\rho^8+\hbar^8\big)$.

To exploit Proposition 14.4.14(iii)one can replace $\lambda_n(\xi_2,\hbar)$ by its approximate value

$$\lambda_n(\xi_2,\hbar)\equiv \bar{\lambda}(\xi_2)+\frac{(2n+1)\pi\hbar}{T(\xi_2)}. \tag{14.4.59}$$

Here $\bar{\lambda}(\xi_2)$ is a "classical eigenvalue" corresponding to $n=0$ and Maslov index 0 (instead of 2) and one can find it from (14.4.57) as $\tau=0$; then

$$\bar{\lambda}(\xi_2)=-S(\xi_2,\tau)/\big(\partial_\tau S(\xi_2,\tau)\big)\big|_{\tau=0}. \tag{14.4.60}$$

Recall that

$$\big(\partial_\tau S\big)\big|_{\tau=0}=T(\xi_2),\qquad \partial_{\xi_2}S|_{\tau=0}=I(\xi_2) \tag{14.4.61}$$

with $I(\xi_2)$ defined by (14.2.5) for even ν and similar formula for odd ν; further,

$$I(\eta^*)=0,\qquad \partial_{\xi_2}I(\eta^*)=\kappa>0. \tag{14.4.62}$$

Then

$$\begin{aligned}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}\equiv (2\pi)^{-1}\int\Big(\frac{1}{2\pi\hbar}S(\xi_2)-\Big\lfloor\frac{1}{2\pi\hbar}S(\xi_2)+\frac{1}{2}\Big\rfloor\Big)\,d\xi_2\equiv\\ (2\pi)^{-1}\int\Big(\frac{1}{2\pi\hbar}\big(S_0+\frac{1}{2}\kappa\eta^2\big)-\Big\lfloor\frac{1}{2\pi\hbar}\big(S_0+\frac{1}{2}\kappa\eta^2\big)+\frac{1}{2}\Big\rfloor\Big)\,d\eta=\\ (2\pi)^{-\frac{3}{2}}\hbar^{\frac{1}{2}}\kappa^{-\frac{1}{2}}G\big(\frac{S_0}{2\pi\hbar}\big)\qquad \mathsf{mod}\ O(\hbar)\end{aligned} \tag{14.4.63}$$

with function $G(t)$ defined by

$$G(t) \coloneqq \int_{\mathbb{R}} \Big(t + \frac{1}{2}\eta^2 - \big\lfloor t + \frac{1}{2}\eta^2 + \frac{1}{2}\big\rfloor\Big)\, d\eta \tag{14.4.64}$$

with the converging integral in the right-hand expression.

One can prove easily that

$$G \not\equiv 0, \quad G(t+1) = G(t), \qquad \int_0^1 G(t)\, dt = 0, \qquad G \in \mathscr{C}^{\frac{1}{2}}. \tag{14.4.65}$$

To exploit Proposition 14.4.14(ii) with $k \ge 2$ one can use more precise version of (14.4.59)

$$\lambda_n(\xi_2, \hbar) \equiv \bar{\lambda}(\xi_2) + \frac{(2n+1)\pi\hbar}{T(\xi_2)} + \sum_{1\le j\le k} \varkappa_j(\xi_2)\hbar^{j+1}. \tag{14.4.66}$$

Then modulo $O(\hbar(k+1)/2)$ (14.4.63) holds albeit with $S_0 + \frac{1}{2}\kappa\eta^2$ corrected by $\sum_{j,l} S_{j,l}\hbar^j\eta^l$ with $2j + l \ge 3$. Changing η we arrive to the middle line of (14.4.63) modified:

$$(2\pi)^{-1} \int \Big(\frac{1}{2\pi\hbar}\big(S(\hbar) + \frac{1}{2}\kappa\eta^2\big) - \Big\lfloor \frac{1}{2\pi\hbar}\big(S(\hbar) + \frac{1}{2}\kappa\eta^2\big) + \frac{1}{2}\Big\rfloor\Big)\times \Big(1 + \sum_{j,l} \kappa'_{jl}\,\hbar^j\eta^l\Big)\, d\eta \tag{14.4.67}$$

with

$$S(\hbar) \equiv S_0 + S_1\hbar + S_2\hbar^2 + \dots \tag{14.4.68}$$

and with some constants S_j, κ'_{jm} (and κ_{jm} below); obviously odd powers of η in (14.4.67) result in 0; plugging $l = 2m$ and integrating by parts m times we arrive to

$$\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}} \sim (2\pi)^{-\frac{3}{2}}\hbar^{\frac{1}{2}}\kappa^{-\frac{1}{2}}\Big(G\big(S(\hbar)\big) + \sum_{j,m} \kappa_{jm}\,\hbar^{j+m} G_m\big(S(\hbar)\big)\Big) \tag{14.4.63)*}$$

where

(14.4.69) $G_m \in \mathscr{C}^{m+\frac{1}{2}}$ satisfy (14.4.65), $\partial_t G_m(t) = G_{m-1}(t)$, $G_0(t) = G(t)$ and therefore

$$G_m(t) = \int_0^t G_{m-1}(t')\, dt' - \int_0^1 (1-t')G_{m-1}(t')\, dt'. \tag{14.4.70}$$

Thus we arrive to

Proposition 14.4.15. *For operator coinciding in $B(0,1)$ with the toy-model with potential $W=1$ and fixed ψ, ψ_1 ($\psi_1=1$ as $|x_1|\le\epsilon$) in asymptotics* (14.4.55)

(i) Modulo $O\big(h^{-1}\hbar^{1/2}\big)$ one can skip correction term $h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$.

(ii) In particular, uncorrected asymptotics has sharp remainder estimate $O(\bar\gamma h^{-1})$ if and only if $\hbar^{\frac12}\le C\bar\gamma$ i.e. $\mu\le Ch^{-\nu/3}$.

(iii) Further, one can define $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ by (14.4.63)–(14.4.64) *without spoiling remainder estimate $O(\bar\gamma h^{-1})$ as $Ch^{-\nu/3}\le\mu\le Ch^{-\nu/2}$*

(iv) Furthermore, one can define $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ by (14.4.63)*, (14.4.68)–(14.4.70) *without spoiling remainder estimate $O(\bar\gamma h^{-1})$ as $Ch^{-\nu/3}\le\mu\le Ch^{\delta-\nu}$ with an arbitrarily small exponent $\delta>0$ (with the number of terms in* (14.4.63)* *and* (14.4.68) *defined by δ).*

Remark 14.4.16. (i) One can then generalize Proposition 14.4.15 immediately to a toy-model with potential $W=\mathsf{const}$ instead of $W=1$ by replacing $h\mapsto hW^{-1/2}$, $\mu\mapsto\mu W^{-1/2}$ and therefore $\hbar\mapsto\hbar W^{-(\nu+1)/2\nu}$ just modifying (14.4.63) to

$$\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}\equiv(2\pi)^{-\frac32}\hbar^{\frac12}\kappa^{-\frac12}W^{(\nu-1)/(4\nu)}G\Big(\frac{S_0W^{(\nu+1)/(2\nu)}}{2\pi\hbar}\Big) \tag{14.4.71}$$

and similarly modifying (14.4.63)*.

(ii) One should expect the similar correction for the general operators as well but one can see easily that under condition $|\partial_{x_2}W|\ge\epsilon$ integrated correction term

$$h^{-1}\int\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x)\psi\,dx_2 \tag{14.4.72}$$

is negligible, and under condition (14.3.109) it should not exceed $Ch^{-1}\hbar$ (and be of this magnitude if there are critical points of W) with integrated versions of (14.4.63) valid modulo $O(h^{-1}\hbar^{\frac32})$.

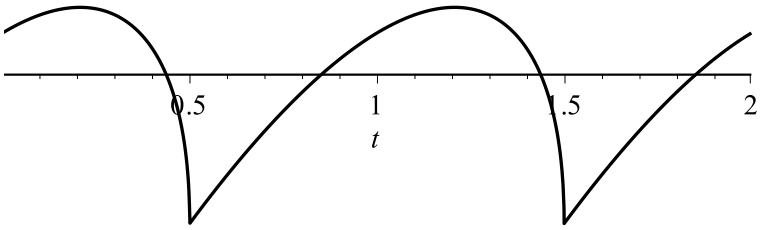


Figure 14.7: Plot of $G(t)$.

Generic Settings

Now let us consider degeneration zone in the framework of two last subsubsections of Subsection 14.3.4 when we managed to prove sharp remainder estimate $O(\bar{\gamma}h^{-1})$ as $\mu \le h^{\delta-\nu}$ producing the final result as the sum of expressions (14.4.37) taken over partitions $\psi = \psi_m(x_2)$ and $Q = Q_m(hD_2)$ of unity. Recall that ψ_m is ℓ-admissible and Q_m is ρ-admissible with ℓ, ρ satisfying some conditions the most important of which are (14.3.74)–(14.3.76); here ℓ denotes the scaling function associated with the finest of subpartitions and we assume that on this element

$$|\partial_{x_2} W| \le C_0\zeta, \qquad |\xi_2 - \eta^*_\hbar W^{\frac{1}{2}}| \le C_0\rho \tag{14.4.73}$$

with one of these inequalities being reversible (with ϵ_0 instead of C_0); then one can take in (14.4.37) any T ranging from

$$T_* = Ch|\log h| \min\bigl(\frac{1}{\rho^2}, \frac{1}{\ell\zeta}\bigr) = C\epsilon^{-1}h|\log h| \times T_1 \tag{14.4.74}$$

to T^*.

There are also exceptional elements with $T = \bar{T}_* = Ch|\log h|$ but they will be treated easily in the same manner.

Therefore we need to consider a main part–expression (14.4.37) with $T = \bar{T}_* = Ch|\log h|$ and also correction terms (14.4.45) with arbitrarily $T \in [T_*, T^*]$ depending on the partition element; index m indicating partition element we are skipping.

One can replace then $\bigl(\bar{\chi}_T(t) - \bar{\chi}_{\bar{T}}(t)\bigr)$ by the sum of $\chi_T(t)$ with T running from $\bar{T}_*$ to T_* and with χ supported in $(-1, -\frac{1}{2}) \cup (\frac{1}{2}, 1)$ thus

replacing expression (14.4.45) with the sum of terms

$$h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(\psi_1\psi Qu)\Big)\,d\tau = \tag{14.4.75}$$
$$iT^{-1}F_{t\to h^{-1}\tau}\check{\chi}_T(t)\Gamma(\psi_1\psi Qu)$$

with $\check{\chi}(t)=t^{-1}\chi(t)$ and $T\in[\bar{T},T_0]$.

Further, one needs to consider only T ranging from $\bar{T}'=\epsilon\bar{\gamma}$ to T_* because terms (14.4.75) with T ranging from $\bar{T}$ to $\bar{T}'$ are negligible; therefore partition elements with $T_*\le\bar{T}'$ [17] will be eliminated.

Remark 14.4.17. (i) Obviously expression (14.4.75) does not exceed $Ch^{-2}\bar{\gamma}\rho\ell$ and thus expression (14.4.45) does not exceed $Ch^{-2}\bar{\gamma}\rho\ell|\log h|$.

(ii) Further, one can decompose expression (14.4.75) in the same way as in the proof of Proposition 14.3.32. Therefore this expression does not exceed $Ch^{-2}\bar{\gamma}\rho\ell\times h|\log h|/\bar{\gamma}=Ch^{-1}\rho\ell\times|\log h|$ and thus expression (14.4.45) does not exceed $Ch^{-1}\rho\ell|\log h|^2$.

Even if this is the remainder estimate obtained by taking $T=\epsilon\bar{\gamma}$ in the Tauberian arguments (with a superficial logarithmic factor), it provides a solid ground for the further estimates.

Let us consider regular elements and apply successive approximation method freezing in unperturbed operator $x_2=y_2$ as usual. However to estimate approximation terms we will not commute (x_2-y_2) with $G^{\pm},\bar{G}^{\pm}$ but simply remember that $|x_2-y_2|\le C\rho T_*+C\bar{\gamma}$ on the partition element in question in propagation as $T\le T_*$; this is due to Proposition 14.3.26 extended according to Proposition 14.3.35.

In this subsection we consider the case when condition (14.3.109) is fulfilled leaving the most general case for the next one.

Then $\rho=\zeta=\ell$ and $T_*=C\rho^{-2}h|\log h|$ and hence $|x_2-y_2|\le C\rho T_*+\bar{\gamma}$. Therefore the norm of perturbation $R_1=(x_2-y_2)\partial_{x_2}A+O\big(|x_2-y_2|^2\big)$ does not exceed

$$C\zeta(\rho T_*+\bar{\gamma})+C(\rho T_*+\bar{\gamma})^2\asymp r:=\big(h|\log h|+\rho\bar{\gamma}+\rho^{-2}h^2|\log h|^2+\bar{\gamma}^2\big).$$

[17] Or equivalently with $(\zeta\ell+\rho^2)\bar{\gamma}\ge Ch|\log h|$.

Therefore while the first term of what is obtained when one plugs approximations into (14.4.75) does not exceed $Ch^{-1}\rho\ell|\log h| = Ch^{-1}\rho^2|\log h|$, each next term acquires a factor

$$r \times Th^{-1} \asymp \bigl(h|\log h| + \rho\bar{\gamma} + \rho^{-2}h^2|\log h|^2 + \bar{\gamma}^2\bigr) \times \rho^{-2}|\log h|; \tag{14.4.76}$$

to keep this factor less than 1 one needs to consider

$$\rho \ge \rho_0^* := Ch^{\frac{1}{2}}|\log h|. \tag{14.4.77}$$

Without any loss of the generality one can assume that $\rho_0^* \ge C\bar{\gamma}$ i.e.

$$\mu \ge h^{-\nu/2}|\log h|^{-\nu} \tag{14.4.78}$$

because under condition (14.3.109) and $\mu \le h^{-\nu/2}|\log h|^{-\nu}$ remainder estimate $O\bigl(h^{-1}\bar{\gamma}\bigr)$ is already proven without any correction terms.

Under conditions (14.4.77) and (14.4.78) expression (14.4.76) is of magnitude of $\bigl(\rho^{-2}h|\log h|^2 + \rho^{-1}\bar{\gamma}|\log h|\bigr)$.

Now the second term of approximations does not exceed

$$Ch^{-1}\rho^2|\log h| \times \bigl(\rho^{-2}h|\log h|^2 + \rho^{-1}\bar{\gamma}|\log h|\bigr) \asymp |\log h|^3 + Ch^{-1}\rho\bar{\gamma}|\log h|.$$

Finally, summation with respect to all partition results in $C|\log h|^K + Ch^{-1}\bar{\gamma}\bar{\rho}_1|\log h|$ which does not exceed $Ch^{-1}\bar{\gamma}$ under condition (14.3.120).

On the other hand, contribution of the *periodic core* $\{\rho \le \rho_0^*\}$ to the Tauberian remainder due to the Tauberian arguments with $T = \epsilon\bar{\gamma}$ does not exceed $Ch^{-1}\rho_0^{*\,2} \le C|\log h|^K$.

So, one needs to consider only the first term of the approximation:

(14.4.79) Under conditions (14.3.109), (14.4.78) and $\mu \le h^{-\nu}|\log h|^{-K}$ remainder estimate $Ch^{-1}\bar{\gamma}$ still holds with u replaced in the principal part (14.4.37) by the first term of this successive approximation procedure.

Thus we can take $T_* = \infty$ thus arriving to

$$\begin{aligned} h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr},Q} = \int \Bigl(& \bigl((2\pi h)^{-1} e(x_1, x_1, 0; x_2, \xi_2, \hbar, \mu) - \\ & h^{-1}\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\bar{\chi}\bar{\tau}(t)\Gamma_x(u)\,d\tau\Bigr)\psi(x_2)\bar{\psi}_1(x)\varphi(\xi_2)\,dx_1dx_2d\xi_2 \end{aligned} \tag{14.4.80}$$

where $\boldsymbol{e} = \boldsymbol{e}(x_1, y_1, \tau; x_2, \xi_2, \hbar, \mu)$ is a Schwartz kernel of the spectral projector, associated with one-dimensional Schrödinger operator $\boldsymbol{a} = \boldsymbol{a}(x_2, \xi_2, \hbar, \mu)$ which is obtained from A by replacement $hD_2 \mapsto \xi_2$ and subsequent change of variables $x_1 \mapsto x_1/\bar{\gamma}$ but not setting $\sigma = \phi = 1$, $V = -W$; finally $\boldsymbol{u} = \boldsymbol{u}(x_1, y_1, t; x_2, \xi_2, \hbar, \mu)$ is a corresponding propagator, i.e. Schwartz kernel of $e^{i\hbar^{-1}t\boldsymbol{a}}$. Here and below $Q = \psi(x_2)\varphi(\xi_2)$ denotes partition element.

However after summation over x_1-partition remembering that as $|x_1| \asymp C$ on $\mathsf{supp}\,\bar{\psi}_1$ we get negligible terms, we can replace $\bar{\psi}_1$ by 1 thus arriving to

$$h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr},Q} = \int \Big((2\pi h)^{-1}\boldsymbol{n}(0; x_2, \xi_2, \hbar, \mu) - h^{-1}\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\bar{\chi}_{\bar{T}}(t)\Gamma'(\boldsymbol{u})\,d\tau\Big)\psi(x_2)\varphi(\xi_2)\,dx_2 d\xi_2 \tag{14.4.81}$$

with $\boldsymbol{n}$ eigenvalue counting function associated with the same operator $\boldsymbol{a}$; recall that Γ' includes integration with respect to x_1.

Without the last term formula (14.4.80) delivers the correct principal part of asymptotics which after summation over all partitions (including non-periodic and outer zones) is

$$(2\pi h)^{-1}\int \boldsymbol{e}(x_1, x_1, 0; x_2, \xi_2, \hbar, \mu)\psi(x_2)\psi_1(x_1)\,dx_1 dx_2 d\xi_2 \tag{14.4.82}$$

which as we show in the next subsubsection is a correct answer without condition (14.3.109) as well.

However, we would like to replace the reference to operator $\boldsymbol{a}$ by the reference to operator $\boldsymbol{a}_0$.

Recall that

$$h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr},Q} = h^{-1}\int \Big(\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T}(t) - \bar{\chi}_{\bar{T}}(t)\big)\Gamma'(\bar{U})\,d\tau\Big)\varphi(\xi_2)\psi(x_2)\,dx_2 d\xi_2 \tag{14.4.83}$$

and one can rewrite it as the sum of partition with respect to t:

$$T^{-1}\int \Big(\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\check{\chi}(t)\Gamma'(\bar{U})\,d\tau\Big)\varphi(\xi_2)\psi(x_2)\,dx_2 d\xi_2. \tag{14.4.84}$$

Consider operator $\boldsymbol{a}$ as a perturbation of $\boldsymbol{a}_0$ and applying method of successive approximations; recall that contribution of ρ-element to the correction

term is of magnitude $h^{-1}\rho^2$ under condition (14.3.109) and we need to consider only elements with $\rho \le \hbar^{\frac12}|\log h|^{\frac12}$ and we want a remainder $O(\bar\gamma h^{-1})$ so we need to consider $\bar\gamma^{1/2} \le \rho \le \hbar^{\frac12}|\log h|^{\frac12}$ and only as $\bar\gamma \le h^{\frac12}|\log h|^{\frac12}$.

Then each successive approximation term acquires factor $CT_* h^{-1}\sigma = C\sigma\rho^{-2}$ where σ is the bound of $(\boldsymbol{a}-\boldsymbol{a}_0)$ and so the next term does not exceed $Ch^{-1}\rho^2 \times \sigma\rho^{-2} = Ch^{-1}\sigma$ and summation over partition results in estimate $O(h^{-1}\sigma|\log h|)$. To achieve $O(h^{-1}\bar\gamma)$ we need to have $\sigma \le C\bar\gamma|\log h|^{-1}$.

While it is not generally the case we obviously can get rid of all the terms except containing just one extra factor x_1 and now we need to think about the latter. Further, next terms of successive approximations acquire factor $\bar\gamma\rho^{-2}$ again and the third term does not exceed $Ch^{-1}\bar\gamma^2\rho^{-2}$ and summation over partition as $\{\rho \ge \bar\gamma^{\frac12}$ results in $O(\bar\gamma h^{-1})$ so only the second term needs to be calculated.

It will contain however $\mathsf{Res}_{\mathbb{R}}\, \mathsf{Tr}\big((\boldsymbol{a}_0-\tau)^{-1}x_1(\boldsymbol{a}_0-\tau)^{-1}\big)$ and as operator inside is odd with respect to $x_1 \mapsto -x_1$ as ν is even this trace will be 0. On the other hand, as ν is odd the operator inside is odd with respect to $(x_1,\xi_2) \mapsto (-x_1,-\xi_2)$ transformations so trace will be odd with respect to ξ_2 and if symbol of $Q = Q(x_2, hD_2)$ is even with respect to ξ_2 the integral also will be 0.

Thus the second term in successive approximations is simply 0. Therefore we have proven the following proposition:

Proposition 14.4.18. *Let condition* (14.3.109) *be fulfilled. Then as* $h^{-\nu/2} \le \mu \le h^{-\nu}|\log h|^{-K}$

(i) With an error not exceeding $C\rho\bar\gamma h^{-1}$ *one can replace in the right-hand expressions of* (14.4.83) $\bar U$ *by* $\bar U_0$ *associated with operator* $\boldsymbol{a}_0(x_2,\xi_2,\hbar)$*; therefore in* (14.4.81) *one can replace* $\boldsymbol{n}$ *by* $\boldsymbol{n}_0$ *and simultaneously* $\bar U$ *by* $\bar U_0$*.*

(ii) $|h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}| \le C\bar\gamma^{-1}$ *and this estimate cannot be improved unless* $W(x_2)$ *has no critical points at all. In particular, as* $\mu \le Ch^{-\nu/2}$ *and only then one can skip* $h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *without deteriorating remainder estimate* $C\bar\gamma h^{-1}$*.*

Therefore we under non-degeneracy condition we arrive to

Proposition 14.4.19. *Let non-degeneracy condition* (14.3.109) *be fulfilled. Then as* $h^{-\nu/2} \le \mu \le h^{-\nu}|\log h|^{-K}$

(i) Asymptotics

$$\int e(x,x,0)\psi(x)\,dx \equiv h^{-2}\int \mathcal{N}^{\mathsf{MW}}(x)\psi(x)\,dx + h^{-1}\int \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x_2)\psi(x_2)\,dx_2 \quad \mathsf{mod}\ O\bigl(h^{-1}\bar{\gamma}\bigr) \tag{14.4.85}$$

holds with $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *defined by* (14.4.50).

(ii) Moreover, with $O\bigl(h^{-1}\hbar^{3/2}\bigr)$*-error one can replace* $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *by expression* (14.4.71) *and with* $O\bigl(h^{-1}\hbar^{K}\bigr)$*-error one can replace* $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ *by expressions* $(14.4.63)^*$ *modified in the same way.*

General Settings. II

Let us skip non-degeneracy condition (14.3.109). Then we need to consider $\rho \ge \bar{\gamma}$ as contribution of zone $\{\rho \le \bar{\gamma}\}$ to the Tauberian remainder and correction is $O(\bar{\gamma}h^{-1})$.

Next let us note that contribution of ρ-element to the correction does not exceed $C\rho h^{-1}$ and an error when substituting $\boldsymbol{a}$ by $\boldsymbol{a}_0$ does not exceed $C\rho h^{-1}\times T_*\sigma h^{-1} = C\rho^{-1}h^{-1}\sigma$ and the total error does not exceed $C\bar{\gamma}^{-1}\sigma h^{-1} = O(\bar{\gamma}h^{-1})$ as $\sigma = O(\bar{\gamma}^2)$.

Therefore we can shed of all terms $O(x_1^2)$ in metrics and in $V(x)$ anytime we want and we need to consider operator

$$\boldsymbol{a}(\eta,\bar{\gamma}) = (1+\alpha_1)\hbar^2 D_1^2 + (1+\alpha_2\bar{\gamma}x_1)(\eta - x_1^{\nu}/\nu)^2 - W + \alpha_3\bar{\gamma}x_1 \tag{14.4.86}$$

with $\alpha_j = \alpha_j(x_2)$. Without any loss of the generality we can rescale and make $W = 1$ (while $\hbar \mapsto \hbar W^{-1/(2\nu+2)}$).

Let us consider $T(\eta)$ as a period of Hamiltonian flow associated with $\boldsymbol{a}_0(\eta)$ and operator $\exp(i\hbar^{-1}T(\eta)\boldsymbol{a}(\eta,\bar{\gamma}))$ as a perturbation for $\exp(i\hbar^{-1}T(\eta)\boldsymbol{a}_0(\eta))$. Recall that $\bar{\gamma}\le \hbar^{\frac{1}{2}}$. Unless $\hbar$ is close to 1, semiclassical approach works the best. Let $T = T(\eta,\bar{\gamma})$ be a period associated with a perturbed operator.

Then we can apply Bohr-Sommerfeld formula and arrive to formulae (14.4.71) and rescalings (to $W\mapsto 1$) of $(14.4.63)^*$ albeit with $S_0(\bar{\gamma})$ instead of S_0 and with coefficients also depending on $\bar{\gamma}$. The dependence coefficients of $\bar{\gamma}$ is not essential as replacing there $\bar{\gamma}$ by 0 leads to an error $O\bigl(h^{-1}\hbar^{\frac{1}{2}}\bar{\gamma}\bigr)$.

What about argument of G and related functions? Let us note that

$S_0(\bar{\gamma})$ is an even function of $\bar{\gamma}$. (14.4.87)

Really, potential well is always symmetric for even ν and potential well is symmetric as $\eta = \eta^* = 0$ for odd ν.

Therefore replacing $\bar\gamma$ by 0 leads to an error $O(\bar\gamma^2\hbar^{-1})$ in an argument (recall that $\bar\gamma^2\hbar^{-1} \le \epsilon$ as otherwise correction term is $O(\bar\gamma h^{-1})$) and since $G \in \mathscr{C}^{\frac12}$ the total error is $O\big(h^{-1}\hbar^{\frac12} \times (\bar\gamma^2\hbar^{-1})^{\frac12}\big) = O(\bar\gamma h^{-1})$.

Therefore we conclude that

(14.4.88) As $\hbar \le h^\delta$ (i.e. $\mu \le h^{-\nu+\delta_1}$)) one can replace in the correction term $\boldsymbol{a}$ by $\boldsymbol{a}_0$ with an error $O(\bar\gamma h^{-1})$.

Assume now that $\hbar \ge h^\delta$ (i.e. $\mu \ge h^{-\nu+\delta_1}$)). To cover this case we need the following proposition:

Proposition 14.4.20. *(i) There exists $\eta^*_\hbar$ smoothly depending on $\hbar \in (0,\epsilon)$ such that as $\rho = |\eta - \eta^*_\hbar| \le \epsilon$, $\bar\gamma \le \epsilon$ the spacing between neighboring eigenvalues $\lambda_n(\eta,\bar\gamma)$ of $\boldsymbol{a}(\eta,\bar\gamma)$ is of magnitude $\hbar$ and therefore interval $[-c\rho^2, c\rho^2]$ contains no more than $C\rho^2\hbar^{-1}+1]$ of them.*

(ii) Moreover as $\rho \ge C\bar\gamma$ these eigenvalues satisfy

$$|\nabla_\eta \lambda_n| \asymp \rho. \tag{14.4.89}$$

(iii) As ν is even

$$|\lambda_n(\eta,\bar\gamma) - \lambda^0_n(\eta)| \le C\bar\gamma^2\hbar^{-1} \tag{14.4.90}$$

where λ^0_n are corresponding eigenvalues of $\boldsymbol{a}_0$.

(iv) As ν is odd

$$|\lambda_n(\eta,\bar\gamma) - \lambda^0_n(\eta) - \beta(\eta,\bar\gamma)\eta\bar\gamma| \le C\bar\gamma^2\hbar^{-1} \tag{14.4.91}$$

where

$$|\beta(\eta,\bar\gamma)| \le C \tag{14.4.92}$$

and $\eta^*_\hbar = 0$.

Proof. Statements (i) and (ii) obviously follow from the semi-classical theory of 1-dimensional operators.

Observe that $\boldsymbol{a}(\eta) = \boldsymbol{a}_0(\eta) + \bar\gamma\boldsymbol{a}'(\eta)$ with $\boldsymbol{a}'(\eta)$ bounded by $C\bar\gamma\big(\boldsymbol{a}(\eta) + C_0\big)$. Therefore due to the Rellich decomposition to prove Statements (iii) and (iv) one needs just to find $(\partial_{\bar\gamma}\lambda_n)(\eta,0)$.

As ν is even eigenfunctions Υ_n of $\boldsymbol{a}_0$ are even or odd functions alternatively and therefore $\langle \boldsymbol{a}'\Upsilon_n, \Upsilon_n\rangle = 0$; recall that

$$\boldsymbol{a}' = \alpha_1 x_1 D_1^2 + \alpha_2 x_1(\eta - x_1^\nu/\nu)^2 + \alpha_3 x_1. \tag{14.4.93}$$

So, (14.4.90) holds.

Consider odd ν. Then $\eta^*_\hbar = 0$ just due to symmetry and the above arguments are applicable for $\eta = 0$ which implies (14.4.91). □

Recall that according to (14.4.48) the correction term is expressed through eigenvalue counting function

$$\boldsymbol{n}(x_2, \eta, \tau, \bar\gamma, \hbar) = \sum_n \theta\big(\tau - \lambda_n(\eta, \bar\gamma)\big) \tag{14.4.94}$$

and setting here $\bar\gamma = 0$ leads for even ν to an error not exceeding

$$Ch^{-1}\int_{\{\rho\ge\bar\gamma\hbar^{-1/2}\}} \big(\frac{\rho^2}{\hbar}+1\big)\cdot\frac{\bar\gamma^2}{\hbar}\cdot\frac{1}{\rho^2}\,d\rho + Ch^{-1}\int_{\{\rho\ge\bar\gamma\hbar^{-1/2}\}} d\rho \asymp Ch^{-1}\bar\gamma\hbar^{-\frac12} \tag{14.4.95}$$

which is $O(h^{-1-\delta})$ in our settings (as $\hbar \ge h^\delta$); for odd ν we get instead

$$Ch^{-1}\int_{\{\rho\ge\bar\gamma\hbar^{-1/2}\}} \big(\frac{\rho^2}{\hbar}+1\big)\cdot\big(\frac{\bar\gamma^2}{\hbar}+\bar\gamma\rho\big)\cdot\frac{1}{\rho^2}\,d\rho + Ch^{-1}\int_{\{\rho\ge\bar\gamma\hbar^{-1/2}\}} d\rho \asymp Ch^{-1}\bar\gamma|\log h|\hbar^{-\frac12} \tag{14.4.96}$$

which is $O(h^{-\delta})$ in our settings. So we arrive to

(14.4.97) As $\hbar \ge h^\delta$ (i.e. $\mu \ge h^{-\nu+\delta_1}$)) one can replace in the correction term $\boldsymbol{a}$ by $\boldsymbol{a}_0$ with an error $O(h^{-\delta})$.

This is exactly the Tauberian remainder estimate we derived in the general settings without non-degeneracy conditions.

Assume now that non-degeneracy condition $(14.3.111)_m$ is fulfilled. Then the Tauberian remainder estimate is $O(\bar\gamma h^{-1})$ and therefore we need to

improve our arguments. Consider (ρ,ℓ) partition as we did in the previous section while deriving Tauberian estimates.

In virtue of our above arguments contribution of zone $\{x:\ell\le \bar\ell\}$ to an error does not exceed $Ch^{-1}\bar\gamma\hbar^{-\frac12}|\log h|\times \mathsf{mes}(\{x:\ell\le\bar\ell\})$ where factor $|\log h|$ appears for odd ν only. However under assumption $(14.3.111)_m$ $\mathsf{mes}(\{x:\ell\le\bar\ell\})=O(\bar\ell^\sigma$ with $\sigma=\sigma(m)$ and selecting $\bar\ell=h^{\delta_2}$ with arbitrarily small $\delta_2>0$ and then selecting $\delta=\delta(\delta_2)>0$ we get $O(1)$.

Consider now elements with $\ell\ge\bar\ell$. If we know that on such element $|W_{x_2}|\ge\zeta$ the same is true for $|\partial_{x_2}\lambda_n|$ and we can replace in the left-hand expressions of (14.4.94) and (14.4.95) factor ρ^{-2} by $(\rho^2+\zeta)^{-1}$. Then summation with respect to ρ would result in $Ch^{-1}\bar\gamma^2\zeta^{-1}$.

The similar arguments work for odd ν with the only exception of the term linear with respect to $\bar\gamma$. However this term is just 0 as $\lambda_n(\eta)$ are even with respect to η and this copy of $\bar\gamma$ comes with cofactor η.

Now summation with respect to partition of unity would result in the proper estimate as well and we can run induction with respect to m exactly in the standard manner of rescaling technique. We leave details to the reader.

Thus we arrive to

(14.4.98) As $\hbar\ge h^\delta$ (i.e. $\mu\ge h^{-\nu+\delta_1}$)) one can replace in the correction term $a(\eta)$ by $a_0(\eta)$ with an error $O(\bar\gamma h^{-1})$ under non-degeneracy condition $(14.3.111)_m$.

Combining with (14.4.88) and (14.4.97) we arrive to

Proposition 14.4.21. *Let $\mu\le Ch^{-\nu}|\log h|^{-K}$. Then*

(i) Under non-degeneracy condition $(14.3.111)_m$ *asymptotics* (14.4.85) *holds with the correction term defined by* (14.4.50) *and the remainder estimate* $O\big(\bar\gamma h^{-1}\big)$.

(ii) In the general case asymptotics (14.4.85) *holds with the correction term defined by* (14.4.50) *and the remainder estimate* $O\big(\bar\gamma h^{-1}+h^{-\delta}\big)$.

Thus all our main results are established as $\mu\le h^{-\nu}|\log h|^{-K}$ albeit in the case $\mu\ge h^{\delta-\nu}$ we rely upon expression (14.4.82) as main answer which has not been established yet.

14.5 Very Strong Magnetic Field

In this section we assume that μ is close to $h^{-\nu}$; more precisely we assume that

$$h^{\delta-\nu} \le \mu \le \epsilon h^{-\nu} \tag{14.5.1}$$

with a very small exponent $\delta > 0$ and constant ϵ and we leave the case $\mu \ge \epsilon h^{-\nu}$ for the Section 14.8. Under assumption (14.5.1) parameter $\hbar = h/\bar\gamma$ is small but not very small: $h^\delta \le \hbar \ll 1$. Moreover, as $\hbar \ge \epsilon |\log h|^{-1}$ variable x_1 is no more microlocal.

We are going to consider operator in the framework of pseudodifferential operators theory with operator valued symbols in the axillary space $\mathbb{H} = \mathscr{L}^2(\mathbb{R})$ with inner product $\langle .,. \rangle$ and norm $\|.\|$.

14.5.1 Regular Zone

Propagation theory in the regular zone is basically done: as $\mu \le \epsilon h^{-\nu} |\log h|^{-\nu}$ we already proved that the propagation trace $F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(\psi Qu)$ is negligible as $T \in [T_*, T^*]$ with $T_* = Ch|\log h|$ and $T^* = \epsilon'\rho$, where $\psi = \psi(x_2)$ and $Q = Q(hD_2)$ with $\rho \le |\eta| \le 2\rho$ on the support of Q and $C \le \rho \le C\bigl(\mu h^\nu\bigr)^{-1/(\nu-1)}$.

Further, as $\rho \ge C\bigl(\mu h^\nu\bigr)^{-1/(\nu-1)}$ the standard ellipticity arguments imply that the propagation trace is negligible even as $\chi_T(t)$ is replaced by $\bar\chi_T(t)$.

Also we proved that as $\epsilon h^{-\nu}|\log h|^{-\nu} \le \mu \le Ch^{-\nu}$ propagation trace $F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(\psi Qu)$ is negligible as $T \in [T_*, T^*]$ with the same T_*, T^* and $C \le \rho \le C|\log h|^\nu$ while ellipticity arguments work as $\rho \ge C\mu h^\nu |\log h|^\nu$.

But then one can prove estimate

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma(\psi Qu)| \le Ch^{-1}\bar\gamma\rho^{1/\nu}|\log h| \tag{14.5.2}$$

which is "almost perfect": the problem here lies only with the logarithmic factor.

To improve estimate (14.5.2) let us launch the successive approximation method, fixing in the coefficients of unperturbed operator $x_2 = y_2$ as usual and also fixing $x_1 = 0$ there but not in $\mu x_1^\nu/\nu$. Then one can estimate easily the final contribution of the first term by the same $Ch^{-1}\bar\gamma\rho^{1/\nu}|\log h|$ as before and also estimate by C contribution of all other terms. Therefore

in the estimate part only the first term should be reconsidered. But then one needs to calculate

$$h^{-1}\int \Big(F_{t\to h^{-1}\tau}\big(\Gamma' U(t;\eta)\big)\Big)\, Q(\eta)\, dx_2 d\eta \tag{14.5.3}$$

where

$$U = U(x_1, y_1, t; x_2, \eta) = \sum_n e^{ih^{-1}\lambda_n(x_2,\eta,\hbar)t}\Upsilon_n(x_1; x_2, \eta, \hbar)\Upsilon_n(y_1; x_2, \eta, \hbar) \tag{14.5.4}$$

is a propagator for 1-dimensional operator which after change of variable $x_1 \mapsto x_1/\bar{\gamma}$ is just $\boldsymbol{a}_0 = \boldsymbol{a}_0(x_2, \eta, \hbar)$.

In the arguments below let us skip integration over x_2 and also x_2 in the notations. So, $\lambda_n(\eta, \hbar)$ are just eigenvalues of $\boldsymbol{a}_0(\eta, \hbar)$ and $\Upsilon_n(x_1; \eta, \hbar)$ are orthonormalized eigenfunctions. Plugging (14.5.4) into (14.5.3) we arrive to expression

$$\sum_n h^{-1} T \int \widehat{\chi}\Big(\frac{T}{h}\big(\tau - \lambda_n(\eta, \hbar)\big)\Big)\, Q(\eta)\, d\eta \tag{14.5.5}$$

and in the case of even ν let us consider separately sums with respect to eigenvalues corresponding to eigenfunctions which are odd and even with respect to x_1.

Proposition 14.5.1. *As $\hbar \ll 1$ eigenvalues $\lambda_n(\eta, \hbar)$ of $\boldsymbol{a}_0(\eta, \hbar)$ have the following properties as $|\eta| \ge C_0$:*

(i) $\lambda_n(\eta, \hbar) \ge \Delta(\eta, \hbar) := \epsilon_0 \hbar |\eta|^{(\nu-1)/\nu} - C_1$.

(ii) For even ν and $\eta \le -\epsilon$ all eigenvalues are larger than $C_0\epsilon^2$.

(iii) Spacing between two consecutive eigenvalues[18] *$\lambda_n(\eta, \hbar)$ and $\lambda_{n+1}(\eta, \hbar)$ belonging to interval $(-\epsilon_0, \epsilon_0)$ is not less than $\Delta(\eta, \hbar)$.*

(iv) Also for these eigenvalues of Statement (iii)

$$\epsilon_0 \le \eta \partial_\eta \lambda_n(\eta, \hbar) \le C_1. \tag{14.5.6}$$

[18] As ν is even we consider two series of eigenvalues separately: those with even with respect to x_1 eigenfunctions and those with odd eigenfunctions.

Proof. Proofs of Statements (i)–(iii) follow from the Bohr-Sommerfeld theory with the semiclassical parameter $h' = \hbar\rho^{(\nu-1)/\nu}$ when it is small enough. Note that zone $\{|x_1| \le \epsilon\bar{\gamma}\rho^{1/\nu}\}$ is classically forbidden with the small parameter $h'' = \hbar/\rho$.

The easiest way to prove (14.5.6) is to observe that the propagation results of Subsection 14.3.2 basically are equivalent to these inequalities as $\mu \le \epsilon h^{-\nu}|\log h|^{-\nu}$; however this condition could be replaced just by $\hbar \le \epsilon'$ because $e_0(x_1, y_1, ., .)$ depends on $\hbar$ and η rather than μ and h separately.□

Let us consider expression (14.5.5). Since $\widehat{\bar{\chi}}$ is fast-decaying at infinity, each term in (14.5.5) does not exceed

$$h^{-1}T\int \bigl(1+T|\tau-\lambda_n(\eta)|h^{-1}\bigr)^{-s}\,d\eta \asymp \rho$$

due to (14.5.6); on the other hand, the number of terms in (14.5.5) does not exceed $C\Delta^{-1} \asymp \hbar^{-1}\rho^{(1-\nu)/\nu}$. Therefore we arrive to

Proposition 14.5.2. *As $\hbar \ll 1$ and $\rho \ge C$ expression* (14.5.5) *does not exceed $C\hbar^{-1}\rho^{1/\nu}$.*

Thus, we got rid of the logarithmic factor in (14.5.2). Then dividing by $T^* = \epsilon\rho$ we conclude that the contribution of this partition element Q to the remainder estimate does not exceed $C\hbar^{-1}\rho^{(1-\nu)/\nu}$. After integration over $d\rho/\rho$ we conclude that the contribution of the whole regular zone to the Tauberian remainder does not exceed $C\hbar^{-1} = Ch^{-1}\bar{\gamma}$. Thus we arrive to the following proposition:

Proposition 14.5.3. *Under condition* (14.5.1) *contribution of the regular zone $\mathcal{X}_{\mathsf{reg}} = \{|\eta| \ge C\}$ to the Tauberian remainder does not exceed $Ch^{-1}\bar{\gamma}$.*

14.5.2 Degeneration Zone

Non-Periodic Zone

So far we have no results in this zone $\mathcal{X}_{\mathsf{deg}} = \{|\eta| \le C_0\}$ as $\mu \ge \epsilon h^{-\nu}|\log h|^{-\nu}$. Thus we cannot even refer to operator $a_0(\eta, \hbar)$ directly. However let us start from the properties of this operator $a_0 = a_0(\eta, \hbar)$ with potential $V = -1$. Let us first to move through $\eta = 1$ or $\eta = \pm 1$ for even and odd ν respectively.

Proposition 14.5.4. *Let* $\hbar \le \epsilon$ *and*

$$1-\epsilon \le |\eta| \le C_0 \tag{14.5.7}$$

with small enough constant $\epsilon > 0$*. Then operator* $\boldsymbol{a}_0(\eta,\hbar)$ *is microhyperbolic with respect to* η *on energy level* 0*; more precisely*

$$\eta\langle \partial_\eta \boldsymbol{a}_0(\eta,\hbar)v, v\rangle \ge \epsilon\|v\|^2 - C\hbar^{-r}\|\boldsymbol{a}_0(\eta,\hbar)v\|^2 \qquad \forall v \in \mathfrak{D}(\boldsymbol{a}_0(\eta,\hbar)) \tag{14.5.8}$$

with large enough exponent r*.*

Proof. Let us consider $\eta \ge 1-\epsilon$ in the both cases; case $\eta \le -1+\epsilon$ and odd ν is treated then due to the symmetry. It is sufficient to prove (14.5.8) for $v \in \big(\boldsymbol{e}(\eta,\hbar;\epsilon\hbar^r) - \boldsymbol{e}(\eta,\hbar;-\epsilon\hbar^r)\big)\mathbb{H}$ where $\boldsymbol{e}(\eta,\hbar;\lambda,\hbar)$ is the spectral projector of $\boldsymbol{a}_0(\eta,\hbar)$.

Then the standard WKB approach implies that for any v described above with $\|v\| = 1$ and $\varepsilon > 0$ one can approximate v by WKB solution as $x_1 > \varepsilon$. Namely, $\|v-w\|_{\{x_1\ge\epsilon_1\}} \le C\hbar^{r-2}$ where w is a WKB solution constructed for $\lambda = 0$, $C = C(\epsilon_1)$, and $\|w\|_{\{x_1\ge\epsilon_1\}} \le 2$. Then

$$|w|^2 = \varkappa\Big(\frac{1}{\sqrt{1-(\eta - x_1^\nu/\nu)^2}} - o(1)\Big) \tag{14.5.9}$$

with $0 \le \varkappa \le c$.

Then, from explicit the WKB calculations it follows that

$$\langle \partial_\eta \boldsymbol{a}_0(\eta,\hbar)w, w\rangle_{\{x_1\ge\varepsilon\}} = \operatorname{const}\Big(\int_\varepsilon^{b(\xi_2)} \frac{(\eta - x_1^\nu/\nu)\,dx_1}{\sqrt{1-(\eta - x_1^\nu/\nu)^2}} - o(1)\Big) \ge 3\epsilon\|w\|^2_{\{x_1\ge\varepsilon\}}$$

and therefore

$$\langle \partial_\eta \boldsymbol{a}_0(\eta,\hbar)v, v\rangle_{\{x_1\ge\varepsilon\}} \ge 2\epsilon\|v\|^2_{\{x_1\ge\varepsilon\}} - C\hbar^{r-2}. \tag{14.5.10}$$

The last inequality holds for domain $\{x_1 \le -\varepsilon\}$ as well because it is either classically forbidden (for odd ν) or just due to symmetry (for even ν). Furthermore (14.5.10) obviously holds for domain $\{|x_1| \le \varepsilon\}$.

After summation we arrive to (14.5.10) with integration over $\mathbb{R} \ni x_1$. Easy details linked to WKB calculations we leave to the reader. □

Proposition 14.5.5. *Let $\hbar \le \hbar_0(\epsilon_0)$. Consider eigenvalues $\lambda_n(\eta,\hbar)$ of $\mathsf{a}_0(\eta,\hbar)$. Further, let ν be even. Then*

(i) As $1+\epsilon_0 \le \eta \le \mathsf{C}_0$ the spacing between consecutive eigenvalues[19] *$\lambda_n(\eta,\hbar)$ and $\lambda_{n+1}(\eta,\hbar)$ (since ν is even we separate two series of eigenvalues; see footnote* [18]*.) is at least $\epsilon\hbar$ where here and below ϵ is a small positive constant.*

(ii) As $\epsilon_0 \le \eta \le 1-\epsilon_0$ spacing between consecutive eigenvalues $\lambda_n(\eta,\hbar)$ and $\lambda_{n+1}(\eta,\hbar)$ (here we do not separate two series of eigenvalues anymore) is at least $\epsilon\hbar$.

(iii) As $|\eta| \le \epsilon_0$ spacing between consecutive eigenvalues $\lambda_n(\eta,\hbar)$ and $\lambda_{n+1}(\eta,\hbar)$ is at least $\epsilon\hbar^{2\nu/(\nu+1)}$.

Proposition 14.5.6. *Let $\hbar \le \hbar_0(\epsilon_0)$. Consider eigenvalues $\lambda_n(\eta,\hbar)$ of $\mathsf{a}_0(\eta,\hbar)$. Further, let ν be odd. Then*

(i) As $1+\epsilon_0 \le |\eta| \le \mathsf{C}_0$ spacing between consecutive eigenvalues $\lambda_n(\eta,\hbar)$ and $\lambda_{n+1}(\eta,\hbar)$ is at least $\epsilon\hbar$.

(ii) As $|\eta| \le 1-\epsilon_0$ spacing between consecutive eigenvalues $\lambda_n(\eta,\hbar)$ and $\lambda_{n+1}(\eta,\hbar)$ is at least $\epsilon\hbar$.

Proof of Propositions 14.5.5 and 14.5.6. All Statements except (iii) follow easily from the standard WKB method.

Moreover, Statement (iii) follows from the standard WKB method and rescaling. Easy details are left to the reader. □

Here we do not mention case $1-\epsilon_0 \le \eta \le 1+\epsilon_0$ as ν is odd and $1-\epsilon_0 \le |\eta| \le 1+\epsilon_0$ as ν is even but we do not need them because they are covered by Proposition 14.5.4.

Therefore, the spacing between consecutive eigenvalues is rather large– larger than $\epsilon\hbar^2$ (as $\hbar^2 \ge h^{-\delta}$) and therefore their derivatives of order α could be estimated by $\mathsf{C}_\alpha\hbar^{-2\alpha}$. Further, the first order derivative is bounded:

$$|\partial_{\eta,\hbar}\lambda_n(\eta_2)| \le \mathsf{C}_0. \tag{14.5.11}$$

[19] In this proposition we consider only eigenvalues belonging to $[-\epsilon,\epsilon]$.

Then decomposing $u(x,y,t)$ into $\Upsilon_n(x_1/\bar\gamma; hD_2, \hbar)$ [20] which are functions of x_1 but also h-pseudodifferential operators with respect to x_2

$$u(x,y,t) \equiv \sum_{n,l} \bar\gamma^{-1}\Upsilon_n\big(\frac{x_1}{\bar\gamma}; hD_{x_2}, \hbar\big)\, u_{nl}(x_2,y_2,t)\, {}^t\Upsilon_l\big(\frac{y_1}{\bar\gamma}; hD_{y_2}, \hbar\big) \tag{14.5.12}$$

one can rewrite the basic equation $(hD_t - A)u = 0$ as a system

$$\Big(hD_t - \Lambda_n(x_2, hD_2, \hbar)\Big)u_{nl} \equiv \sum_k \mathcal{B}_{kl}u_{kl}, \tag{14.5.13}$$

with

$$\Lambda_n(x_2, hD_2, \hbar) = \lambda_n(hD_2, \hbar) - W(x_2) \tag{14.5.14}$$

and with operators $\mathcal{B}_{kl}$ estimated by $Ch\hbar^{-K}$ where we increase K if needed.

Let us consider $\epsilon\hbar^2$-sized intervals with respect to x_2 and τ. Note that on each such interval at most one of operators $hD_t - \Lambda_n(x_2, hD_2, \hbar)$ fails to be elliptic there (with the ellipticity constant $\epsilon\hbar^2$).

There is one exception though: if ν is even and $\eta \ge 1-\epsilon$ "odd" and "even" eigenvalues[21] could be pretty close to one another and then there are at most two such operators with numbers n and $(n+1)$ (we cannot separate eigenvalues anymore; n corresponds to even eigenfunctions and $(n+1)$ to odd ones).

Let n be such exceptional number. Then one can rewrite system (14.5.13) either as a single equation

$$\Big(hD_t - \Lambda_n(x_2, hD_2, \hbar) - \mathcal{B}'_n\Big)u_{nl} \equiv 0 \tag{14.5.15}$$

where u_{kn} with $k \ne n$ are expressed via u_{nl} and $\mathcal{B}'_n \equiv \mathcal{B}_{nn}$ modulo operators not exceeding $h^2\hbar^{-K}$, or as a 2×2-system with Λ_n replaced by $\begin{pmatrix}\Lambda_n & 0\\ 0 & \Lambda_{n+1}\end{pmatrix}$ and with 2×2 matrix operator $\mathcal{B}'_n$.

Proposition 14.5.7. *In the framework of Proposition 14.5.5 or 14.5.6*

$$\pm\partial_\eta\lambda_n(\eta,\hbar) \ge \epsilon_1 \tag{14.5.16}$$

as long as $\pm(\eta-\eta^*) \ge \epsilon_0$, $\hbar \le \epsilon_1$ *and* $|\lambda_n(\eta,\hbar)| \le \epsilon_1$.

---

[20] Where $\Upsilon_n(x_1,\eta,\hbar)$ are eigenfunctions of $\mathbf{a}_0(\xi_2,\hbar)$.

[21] I.e. eigenvalues corresponding to eigenfunctions even or odd with respect to x_1.

Proof. Proof immediately follows from Bohr-Sommerfeld approximation for $\lambda_n(\eta,\hbar)$. Again we leave easy details for the reader. □

Remark 14.5.8. So far Propositions 14.5.5–14.5.7 were proven for $W=1$ but they obviously hold for any $W\ge\epsilon$ with the critical values $\pm 1, \eta^*$ replaced by $\pm W^{1/2}$, $\eta^* W^{1/2}$ respectively.

Then one can easily recover all the results similar to those of Subsection 14.3.3 and thus one can set $T_1=\epsilon$, $T_0=C\hbar^{-r}h|\log h|$ in the degeneration but not periodic zone

$$\mathcal{X}_{\mathsf{deg}}\setminus\mathcal{X}_{\mathsf{per}}=\{\epsilon_0\le|\eta-\eta^* W^{\frac12}|\le C_0\}. \tag{14.5.17}$$

These propagation results imply immediately estimate

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma(Q\psi u)|\le C\hbar^{-r}h^{-1-\delta K}\bar\gamma|\log h|\le C\bar\gamma h^{-1-\delta_1}.$$

However one can engage the successive approximation method as in Subsection 14.5.1 (with $\rho=1$ now); then one needs to consider only the first term of it and following arguments of Subsection 14.5.1 one can see easily that in fact

$$|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma(Q\psi u)|\le C\bar\gamma h^{-1-\delta_1}. \tag{14.5.18}$$

We leave easy details to the reader. Thus estimate immediately leads to

Proposition 14.5.9. *For fixed ϵ_0 contribution of zone $\mathcal{X}_{\mathsf{deg}}\setminus\mathcal{X}_{\mathsf{per}}$ defined by* (14.5.17) *to the Tauberian remainder does not exceed $C\bar\gamma h^{-1}$ as $\mu\le\epsilon h^{-\nu}$ with a small enough constant $\epsilon=\epsilon(\epsilon_0)$.*

Periodic Zone

Now we need to treat periodic zone $\mathcal{X}_{\mathsf{per}}:=\{|\eta-\eta^* W^{\frac12}|\le\epsilon_0\}$. However now we have just one equation rather than 2×2-system due to Proposition 14.5.5 and the construction after it.

We need the following

Proposition 14.5.10. *Let $\mathsf{a}_0(\eta,\hbar)$ be a toy-model operator with the potential $V=-1$ and $\hbar\le\epsilon=\epsilon(\epsilon_0)$. Then*

$$\partial_\eta^2\lambda_n(\eta,\hbar)\ge\epsilon_1\qquad\forall\eta:|\eta-\eta^*|\le\epsilon_0\quad\forall n:|\lambda_n(\xi_2,\hbar)|\le\epsilon. \tag{14.5.19}$$

Proof. Proof follows from Bohr-Sommerfeld approximation and Propositions 14.2.4 and 14.2.8 for even and odd ν respectively. □

Now one can apply our standard rescaling technique as in Section 14.4 (but in a marginally simpler form) with unperturbed operator $\lambda_n(hD_2,\hbar) - W(x_2)$ leading to

Proposition 14.5.11. *Contribution of zone* $\mathcal{X}_{\mathsf{per}} = \{|\eta - \eta^* W^{1/2}| \le \epsilon_0\}$ *to the Tauberian remainder does not exceed* $C\bar{\gamma}h^{-1}$ *as non-degeneracy condition* $(14.3.111)_m$ *is fulfilled and* $C\bar{\gamma}h^{-1-\delta}$ *otherwise with an arbitrarily small exponent* $\delta > 0$.

14.5.3 Calculations

Now let us apply our standard successive approximation technique as in Section 14.4 with an unperturbed operator $a_0(hD_2,\hbar) - W(y_2)$ in the regular and degenerate non-periodic zones and with an unperturbed operator $\lambda_n(hD_2,\hbar) - W(y_2)$ in the periodic zone leading exactly to

Proposition 14.5.12. *Under condition* (14.5.1) *with the Tauberian remainder equal to* $C\bar{\gamma}h^{-1}$ *as non-degeneracy condition* $(14.3.111)_m$ *is fulfilled and* $C\bar{\gamma}h^{-1-\delta'}$ *otherwise with arbitrarily small exponent* $\delta' > 0$ *the following asymptotics holds*

$$\int e(x,x,0)\psi(x_2)\,dx \equiv (2\pi h)^{-1}\int n_0(x_2,\xi_2,0)\psi(x_2)\,dx_2 d\xi_2. \tag{14.5.20}$$

One can see easily that $h^{-2}\mathcal{N}^{\mathsf{MW}} \equiv h^{-2}\mathcal{N}_0^{\mathsf{MW}} \mod O(1)$ under condition (14.5.1); thus this proposition finalizes the proof of Theorem 14.6.1 below under condition (14.5.1).

14.6 Main Theorem and Generalizations

14.6.1 Main Theorem

Thus we arrive to the main theorem of this part of the Chapter:

Theorem 14.6.1. *As* $d = 2$ *consider magnetic Schrödinger operator* (14.1.1) *with sufficiently smooth coefficients. Let conditions* (14.1.4) *and* (13.4.45) *be*

fulfilled and let ψ be supported in the small enough neighborhood of $\{x_1 = 0\}$. Then

(i) As $1 \le \mu \le \mu_1^* := C_0 h^{-\nu/3}$ estimate

$$\mathsf{R}^{\mathsf{MW}} := \Big| \int \Big(e(x,x,0) - h^{-2} \mathcal{N}^{\mathsf{MW}}(x,0) \Big) \psi(x)\, dx \Big| \le C \mu^{-1/\nu} h^{-1} \tag{14.6.1}$$

holds.

(ii) As $\mu_1^* \le \mu \le \mu_2^* := \epsilon h^{-\nu}$ estimate

$$\mathsf{R}^{\mathsf{MW}}_* := \Big| \int \Big(e(x,x,0) - h^{-2} \mathcal{N}^{\mathsf{MW}}(x,0) \Big) \psi(x)\, dx - h^{-1} \int \mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x_2,0) \psi(0,x_2)\, dx_2 \Big| \le C \mu^{-1/\nu} h^{-1} + C h^{-\delta} \tag{14.6.2}$$

holds with arbitrarily small exponent $\delta > 0$ and with the correction term $h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ defined by (14.4.50) *in the terms of the eigenvalue counting function $\boldsymbol{n}_0$ of the axillary 1-dimensional Schrödinger operator* (14.4.7) *with semiclassical parameter $\hbar = \mu^{1/\nu} h$.*

(iii) Under non-degeneracy condition $(14.3.111)_m$ *for $W(x_2)$ defined by* (14.2.28)–(14.2.29) *as $\mu \le \epsilon h^{-\nu}$ with small enough constant $\epsilon = \epsilon(\epsilon_0, m)$ (where ϵ_0 is a constant in* $(14.3.111)_m$*)one can skip the last term in the right-hand expression of* (14.6.2)*.*

Remark 14.6.2. In the framework of Theorem 14.6.1 (may be without condition (13.4.45)) the main part of asymptotics is $O(h^{-2})$ as $\mu \le h^{-1}$ and $O(h^{-2}(\mu h)^{1/(\nu-1)})$ as $h^{-1} \le \mu \le \epsilon h^{-\nu}$.

Moreover, under condition (13.4.45) as $\mu \le \epsilon h^{-\nu}$ it has exactly indicated magnitudes: it is $\asymp h^{-2}$ as $\mu \le h^{-1}$ and $\asymp h^{-2}(\mu h)^{1/(\nu-1)}$ as $h^{-1} \le \mu \le \epsilon h^{-\nu}$.

Remark 14.6.3. (i) Generally correction term (integrated) is $O(h^{-1}\hbar^{\frac{1}{2}})$ and in the general case this estimate cannot be made smaller; however under some nondegeneracy assumptions one can improve this estimate and thus push μ_1^* up: if W has no critical points integrated corrected term is $O(h^{-1}\hbar^K)$ with arbitrarily large K; if W has no degenerate critical points integrated corrected term is $O(h^{-1}\hbar)$.

(ii) One can replace $\boldsymbol{n}_0$ by Bohr-Sommerfeld approximation for it, providing formula $(14.4.63)^*$ modulo $O(h^{-1}\hbar^K)$.

14.6.2 Generalization: Vanishing V

We can also generalize all our results to the case of V vanishing. However we need some strong non-degeneracy condition to VF^{-1} as x_1 is small but fixed. Before it was automatic, but now we need to impose it directly, so we assume non-degeneracy condition (14.6.3).

Theorem 14.6.4. *Theorem 14.6.1 remains true if condition* (13.4.45) *is replaced by non-degeneracy condition*

$$|V| + |\partial_{x_2} V| \ge \epsilon_0. \tag{14.6.3}$$

Proof. Consider ℓ-admissible partition with $\ell = \epsilon|V|$.

(a) First, consider elements on which $\ell \le \epsilon_1 |x_1|$. Then rescaling $x \mapsto x/\ell$ and diving by ℓ we arrive to the situation of non-vanishing magnetic field $\mu_{\mathsf{eff}} = \mu\gamma^{\nu-1}\ell^{1/2}$ with $F_{\mathsf{eff}} = F\gamma^{-\nu}$ and $V_{\mathsf{eff}} = V\ell^{-1}$ with a parameter $\gamma \asymp |x_1|$.

One can see easily that after rescaling $V_{\mathsf{eff}}/F_{\mathsf{eff}} = (V/F)\cdot(\gamma^\nu/\ell) \asymp 1$ and also $\ell|\nabla V_{\mathsf{eff}}/F_{\mathsf{eff}}| \asymp 1$.

To apply "non-vanishing" theory with $h_{\mathsf{eff}} = h\ell^{-3/2}$ and μ_{eff} one must assume that $h_{\mathsf{eff}} \le 1$, $\mu_{\mathsf{eff}} \ge 1$ or equivalently

$$\ell \ge \bar{\ell} := C_0 \max\bigl(h^{\frac{2}{3}}, (\mu\gamma^{\nu-1})^{-2}\bigr). \tag{14.6.4}$$

Then the contribution of such element to the remainder does not exceed $C\mu_{\mathsf{eff}}^{-1}h_{\mathsf{eff}}^{-1} = C\mu^{-1}h^{-1}\ell\gamma^{1-\nu}$.

After summation over partition with fixed γ one gets due to condition (14.6.3) the same expression but with $\ell = \gamma$ i.e. $C\mu^{-1}h^{-1}\gamma^{2-\nu}$. One must assume that condition (14.6.4) is fulfilled for this top ℓ, which is equivalent to

$$\gamma \ge L := C_0 \max\bigl(h^{\frac{2}{3}}, \mu^{-2/(2\nu-1)}\bigr). \tag{14.6.5}$$

Then summation over x_1-partition satisfying this condition results in $\mu^{-1}h^{-1}L^{2-\nu}$ as $\nu > 2$ and $\mu^{-1}h^{-1}|\log L|$ as $\nu = 2$ which in both cases as one can check easily does not exceed $C\mu^{-1/\nu}h^{-1}$.

(b)

(c) One needs also to consider elements satisfying (14.6.5) but not (14.6.4). Let us unify such elements, so in fact we redefine ℓ setting it $\ell = \epsilon|V| + \bar{\ell}$. Then on elements with $\ell \asymp \bar{\ell}$ either $\mu_{\mathsf{eff}} \asymp 1$ or $h_{\mathsf{eff}} \asymp 1$. In the former case the condition of a potential being disjoint from 0 is not needed due to the theory of non-magnetic Schrödinger operator while in the latter case element in question is forbidden as $\mu_{\mathsf{eff}} \ge C_1$ and the condition of a potential being disjoint from 0 is not needed again.

The contribution to the remainder of of each of these elements is either Ch_{eff}^{-1} (as $\mu_{\mathsf{eff}} \asymp 1$) or $C\mu_{\mathsf{eff}}^{-s}$ (as $h_{\mathsf{eff}} \asymp 1$) and in any case it does not exceed $C\mu_{\mathsf{eff}}^{-1}h_{\mathsf{eff}}$ again. Repeating summation procedure of Part (a) of the proof one can see that the total contribution of such elements does not exceed $C\mu^{-1/\nu}h^{-1}$.

So one needs to consider two other types of elements.

(d) Consider first elements on which

$$|x_1| \le C\ell, \qquad \ell = \epsilon|W|. \tag{14.6.6}$$

Then rescaling $x \mapsto x/\ell$ and dividing by ℓ brings us to the frames of our main theory with $\mu_{\mathsf{eff}} = \mu\ell^{\nu-1/2}$, $h_{\mathsf{eff}} = h\ell^{-3/2}$ and one must assume that

$$\ell \ge C_0 \max\bigl(h^{\frac{2}{3}}, \mu^{-2/(2\nu-1)}\bigr). \tag{14.6.7}$$

Then the contribution of each element to the remainder does not exceed $C\mu_{\mathsf{eff}}^{-1/\nu}h_{\mathsf{eff}}^{-1} = C\mu^{-1/\nu}h^{-1}\ell^{(\nu+1)/2}$ and the sum over partition results in $C\mu^{-1/\nu}h^{-1}$. The exceptional elements will be covered in the Part (e) of the proof.

(e) So, we are left with the analysis of the zone $\{|x_1| + |W| \le L\}$ with L defined by (14.6.5). Due to condition (14.6.3) without any loss of the generality this zone could be replaced by $\{|x| \le L\}$. Rescaling $x \mapsto x/L$ and dividing by L we arrive to the same situation as we started but with $h_{\mathsf{eff}} = hL^{-3/2}$, $\mu_{\mathsf{eff}} = \mu L^{\nu-\frac{1}{2}}$ instead of h, μ i.e. with either $h_{\mathsf{eff}} \le 1$, $\mu_{\mathsf{eff}} \asymp 1$ or with $h_{\mathsf{eff}} \asymp 1$, $\mu_{\mathsf{eff}} \ge 1$.

In the former case we just refer to the classical theory: contribution of this zone to the remainder does not exceed $Ch_{\mathsf{eff}}^{-1} = Ch^{-1}L^{3/2} \le Ch^{-1}\mu^{-1/\nu}$. In the latter case contribution of this zone to the whole asymptotics does not exceed $C\mu_{\mathsf{eff}}^{-s}$ as this zone is "forbidden"; one can prove it easily going to the axillary space $\mathscr{L}^2(\mathbb{R}_{x_1})$. □

14.7 Strong Magnetic Field Reloaded

14.7.1 Statement of the Problem

Let us recall that for the non-degenerate magnetic field as $\mu \ge h^{-1}$ we also considered operator "(14.1.3)$-\mu h\mathfrak{z}F$":

$$A = \sum_{j,k} P_j g^{jk}(x) P_k - V - \mu h\mathfrak{z}F \tag{14.7.1}$$

with $\mathbb{R} \ni \mathfrak{z} > 0$ and F scalar intensity of the magnetic field.

Remark 14.7.1. (i) In Section 13.6 we assumed that $\mathfrak{z} \ge 1$ as for $\mathfrak{z} < 1$ and $\mu h \ge C_{\mathfrak{z}}$ we still would get negligible $e(x,x,0)$ but it not a case anymore.

(ii) For even ν we need to modify definition of F because usual definition $F = |F_{12}|g^{-\frac{1}{2}}$ would lead to non-smooth F. So let us redefine

$$F \coloneqq F_{12}g^{-\frac{1}{2}}, \qquad F_{12} = \partial_{x_1}V_2 - \partial_{x_2}V_1 \tag{14.7.2}$$

$g = \det(g^{jk})^{-1}$. So for odd ν we still have $F \ge 0$ while for even ν now F has the same sign as x_1; our old F is just $|F|$.

Then as $\mathfrak{z} \in (2\mathbb{Z}^+ + 1)$ zone

$$\mathcal{X}'' \coloneqq \{|x_1| \ge \bar{\gamma}_1 \coloneqq C(\mu h)^{1/(\nu-1)},\ F > 0\} \tag{14.7.3}$$

is not forbidden anymore[22)] at least as $\mu \le h^{-\nu}|\log h|^{-\nu}$ (even stronger magnetic field we consider in the next sections).

On the other hand, as $\mathfrak{z} \ge 1$ but $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ this zone will be forbidden and lacunar but not the lowest lacunar zone. In both cases the contribution of this zone (with possible exception of case $\mathfrak{z} = 1$ when the sign of V is crucial) contribution of this formerly forbidden zone to the main part of asymptotics is $\asymp \mu h^{-1}$.

To make a meaningful statement about remainder we need either to assume that either $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ or some non-degeneracy condition is fulfilled and we adopt generic condition (14.6.3) where as before we are interested in the asymptotics of $\int e(x,x,0)\psi(x)\,dx$ where and $\psi \in \mathscr{C}_0^\infty(B(0,\frac{1}{2}))$ is supported in the small but fixed vicinity of $\{x_1 = 0\}$.

[22)] For even ν zone $\{x_1 \le -C(\mu h)^{1/(\nu-1)}\}$ is still forbidden.

Actually instead of (14.6.3) we assume that on $\mathsf{supp}\,\psi$ one of the following three conditions is fulfilled

$$\pm W \ge \epsilon_0, \tag{14.7.4}_{\pm}$$

$$|\partial_{x_2} W| \ge \epsilon_0. \tag{14.7.5}$$

In this section we analyze the case $\mu \le \epsilon h^{-\nu}$. Analysis in the zone $\mathcal{X}' := \{|x_1| \le 2\bar{\gamma}_1\}$ remains basically the same and the main attention is paid here to the formally forbidden zone (14.7.3).

As $\mu \ge \epsilon h^{-\nu}$ this separation to zones is no more reasonable and will be modified.

Further, in Section 14.8 we analyze the case of $\mu \ge \epsilon h^{-\nu}$.

14.7.2 Simple Rescaling

As in Subsection 14.1.1 the simple rescaling arguments help us to get the easy but not sharp results.

As we mentioned, in this section we assume that $\mu \le Ch^{-\nu}$ [23]. Rescaling arguments in $\mathcal{X}' = \{|x_1| \le 2\bar{\gamma}_1\}$ work exactly in the same manner as in Subsection 14.1.1 leading to the asymptotics of $\int e(x,x,0)\psi'(x)\,dx$ with the principal part $h^{-2}\int \mathcal{N}^{\mathsf{MW}}(x,0)\psi'(x)\,dx$ and the remainder estimate $O(h^{-1})$ where $\psi'(x)$ and $\psi''(x)$ are cut-off functions supported in zones $\mathcal{X}'$ and $\mathcal{X}''$ (defined as above) respectively; one can take $\psi'(x) = \psi(x)\psi_0(x_1/\bar{\gamma}_1)$ and $\psi'' = \psi - \psi'$ where $\psi_0 \in \mathscr{C}_0^\infty$ is supported in $(-1,1)$ and equals 1 in $[-\frac{1}{2},\frac{1}{2}]$.

Consider previously forbidden zone $\mathcal{X}''$.

(14.7.6) If $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ then contribution of $\mathcal{X}''$ to the remainder does not exceed $C\mu(\mu h^\nu)^s$ with arbitrarily large exponent s while contribution to the principal part is

$$h^{-2}\int \mathcal{N}^{\mathsf{MW}}(x)\psi''(x)\,dx = \frac{1}{4\pi}\mu h^{-1} I \int \psi''|F|\sqrt{g}\,dx \tag{14.7.7}$$

with $I = \lfloor(\mathfrak{z}-1)/2\rfloor$; recall that ψ'' is supported in $\mathcal{X}''$ defined by (14.7.3) and for even ν we discard forbidden zone mentioned in footnote [22].

[23] We weaken our assumption temporarily.

Really, contribution of element $B(x,\gamma)\subset \mathcal{X}''$ to the remainder does not exceed then $C\mu_{\text{eff}}^{-s-1}= C(\mu\gamma^{\nu})^{-s-1}$ and the total contribution does not exceed

$$C\int_{\{\gamma\ge\bar\gamma_1\}} (\mu\gamma^{\nu})^{-s-1}\gamma^{-2}\,d\gamma \asymp C(\mu\gamma_1^{\nu})^{-s-1}\gamma_1^{-1}.$$

Let $\mathfrak{z}\in (2\mathbb{Z}^+ +1)$. Then

(14.7.8) Under condition (14.6.3) the contribution of the previously forbidden zone $\mathcal{X}''$ to the remainder does not exceed Ch^{-1}.

Really, contribution of element $B(x,\gamma)\subset \mathcal{X}''$ to the remainder does not exceed then C and the total contribution does not exceed

$$C\int_{\{\bar\gamma_1\le\gamma\le 1\}} \gamma^{-2}\,d\gamma \asymp C\bar\gamma_1^{-1}$$

which is $O(h^{-1})$ due to assumption $\mu\le Ch^{-\nu}$.

Meanwhile

(14.7.9) Under condition $(14.7.4)_{\pm}$ contribution of $\mathcal{X}''$ to the principal part is given by (14.7.7) where under assumption $(14.7.4)_{-}$ one should replace I by $(I-1)$.

Actually then one can improve the remainder estimate.

Without assumption $(14.7.4)_{\pm}$ the above formula remains true for the contribution of the subzone $\mathcal{X}''\cap\{|W|\ge C\gamma\}$; for the contribution of the subzone $\mathcal{X}''\cap\{|W|\le C\gamma\}$ one needs to use the left-hand expression of (14.7.7) but also to take into account correction term (see Section 13.6) $\sum_m \kappa_m\mu_{\text{eff}}h_{\text{eff}}^{1+2m}$ for the case $\mu_{\text{eff}}h_{\text{eff}}\ge 1$, $h_{\text{eff}}\le 1$ where in the rescaling and division arguments $\mu_{\text{eff}}=\mu\gamma^{\nu-\frac{1}{2}}$, $h_{\text{eff}}=h\gamma^{-\frac{3}{2}}$ and the number of balls is $O(1)$ for each γ. Then the total contribution of this correction terms is $O\big(\mu h\big)$ as $\nu\ge 3$ and $O\big(\mu h|\log h|\big)$ as $\nu=2$.

Replacing ψ by $x_1\psi$ in the above arguments one gains factor γ in each integrand; then the total contribution of the zone $\mathcal{X}'$ to the remainder does not exceed

$$C\int \mu^{-1}h^{-1}\gamma^{1-\nu}\times\gamma\times\gamma^{-2}\,d\gamma \asymp C\mu^{-1/\nu}h^{-1}$$

which is exactly what we want. On the other hand, the contribution of zone $\mathcal{X}''$ to the remainder becomes $O(\int\gamma^{-1}\,d\gamma)=O(|\log h|)$ which is what we

want as $\mu \le C(h|\log h|)^{-\nu}$ only. To fix it under condition $(14.7.4)_{\pm}$ one can notice that zone $\mathcal{X}''$ is the spectral gap and therefore the contribution of the individual ball to the remainder estimate is $O(\gamma h_{\mathsf{eff}}^{s})$ with $h_{\mathsf{eff}} = h\gamma^{-1}$ rather than $O(1)$ and therefore the total contribution of zone $\mathcal{X}''$ to the remainder estimate is $O(1)$.

As before, under condition (14.6.3) only these arguments are applicable in the subzone $\mathcal{X}'' \cap \{|W| \ge C\gamma\}$ with $h_{\mathsf{eff}} = h/(\gamma|W|^{1/2})$ as long as $h_{\mathsf{eff}} \le 1$. This leads to $O(1)$ estimate of the contribution of the subzone

$$\mathcal{X}'' \cap \{|W| \ge C\gamma, |W|^{1/2}\gamma \ge h\}$$

into the remainder. One can see easily that the integral of γ^{-1} taken over subzones $\mathcal{X}'' \cap \{|W| \ge C\gamma, |W|^{1/2}\gamma \le h\}$ and $\mathcal{X}'' \cap \{|W| \le C\gamma\}$ is $O(1)$ as well. Thus rescaling arguments provide remainder estimate $O\big(\mu^{-1/\nu}+1\big)$ if ψ contains an extra factor x_1 and under condition (14.6.3) alone correction terms are taken into account.

Therefore

(14.7.10) As $\mu \le Ch^{-\nu}$ in what follows one can assume without any loss of the generality that $\psi(x) = \psi_1(x_1)\psi_2(x_2)$.

Remark 14.7.2. As $\mu \ge Ch^{\nu}$ simple rescaling arguments work as $\{|x_1| \ge Ch\}$ providing $O(h^{-1})$ contribution of this zone to the remainder while the contribution of zone $\{|x_1| \le Ch\}$ will be $O(\mu h^{\nu-1})$. The main part of the asymptotics will be the same as above.

Moreover, these arguments work as $\{|x_1| \ge Ch\}$ providing $O(1)$ contribution of this zone to the remainder estimate as ψ is replaced by $x_1\psi$ while the contribution of zone $\{|x_1| \le Ch\}$ will be $O(\mu h^{\nu})$.

In the next section we will improve these latter results.

14.7.3 Estimates

Regular Zone

In Section 14.3 and subsections 14.5.1–14.5.2 various properties of operator A were proven in the regular and degeneration zones $\mathcal{X}_{\mathsf{reg}} = \{\bar\gamma \le |x_1| \le 2\bar\gamma_1\}$ and $\mathcal{X}_{\mathsf{deg}} = \{|x_1| \le 2\bar\gamma\}$ with $\bar\gamma := C\mu^{-1/\nu}$ as long as $\bar\gamma \le \bar\gamma_1$ i.e. $\mu \le \epsilon h^{-\nu}$.

These properties were proven first in Section 14.3 under assumption

$$C \le \mu \le \epsilon(h|\log h|)^{-\nu} \tag{14.7.11}$$

using standard microlocal analysis with logarithmic uncertainty principle and then in Subsections 14.5.1–14.5.1 under assumption

$$\epsilon(h|\log h|)^{-\nu} \le \mu \le \epsilon h^{-\nu} \tag{14.7.12}$$

they were proven by applying microlocal analysis for h-pseudodifferential operators with respect to x_2 with operator-valued symbols which are operators in the auxiliary space $\mathbb{H} = \mathscr{L}^2(\mathbb{R}_{x_1})$. Recall that in te case (14.7.12) localization was done with respect to ξ_2 rather x_1.

Therefore in both cases (14.7.11) and (14.7.12) in the *redefined regular zone*

$$\mathcal{X}_{\mathsf{reg}} = \{\bar\gamma \le |x_1| \le \bar\gamma_1' = \epsilon\bar\gamma_1\} \tag{14.7.13}$$

(with the small constant $\epsilon > 0$) all these arguments remain true leading us eventually to three following statements; we leave the proofs of Propositions 14.7.3 and 14.7.5 and Corollary 14.7.4 to the reader.

Proposition 14.7.3. *Let conditions* (14.1.4) *and* $((14.7.4)_+$ *be fulfilled. Let* $\psi = \psi(x_2)$ *be supported in* $B(0, \frac12)$ *and let* $\varphi = \varphi(\xi_2)$ *be supported in the strip*

$$\mathcal{Y}_\gamma := \{\mu\gamma^\nu \le |\xi_2| \le 2\mu\gamma^\nu\} \tag{14.7.14}$$

with $C_1\bar\gamma \le \gamma \le \epsilon_1\bar\gamma_1$. *Then*

(i) As $\mu \le \epsilon h^{-\nu}$ *estimates*

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(Qe)| \le Ch^s \tag{14.7.15}$$

and

$$\mathsf{R}^{\mathsf{T}} := |\Gamma\big(Qe\big) - h^{-1}\int_{-\infty}^{0}\Big(F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma(Qe)\Big)\,d\tau| \le C\mu^{-1}\gamma^{1-\nu}h^{-1} \tag{14.7.16}$$

hold with $Qe = \varphi(hD_2)\big(e\psi\big)$, $e = e(x,y,\tau)$, $|\tau| \le \epsilon$, $T \in [T_0, T_1]$, $T_0 = Ch|\log h|$, $T_1 = \epsilon\mu^{-1}\gamma^{-\nu}$.

(ii) Moreover, under condition (14.7.11) *Statement (i) holds with* $Q = \psi_1\psi$, $\psi_1 = \psi_1(x_1)$ *supported in* $\mathcal{X}_{\mathsf{reg},\gamma} \coloneqq \{\gamma \le |x_1| \le 2\gamma\}$.

Corollary 14.7.4. *Let conditions* (14.1.4) *and* $(14.7.4)_+$ *be fulfilled. Let* $\psi = \psi(x_2)$ *be supported in* $B(0, \frac{1}{2})$ *and* $\varphi = \varphi(\xi_2)$ *be supported in the regular zone defined in the terms of* ξ_2

$$\mathcal{Y}_{\mathsf{reg}} = \bigl\{C_0 \le |\xi_2| \le \epsilon\bigl(\mu h^\nu\bigr)^{-1/(\nu-1)}\bigr\}. \tag{14.7.17}$$

Then

(i) As $\mu \le \epsilon h^{-\nu}$ *estimate*

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{-1/\nu}h^{-1} \tag{14.7.18}$$

holds.

(ii) Moreover, under condition (14.7.11) *Statement (i) holds with* $Q = \psi_1\psi$, $\psi_1 = \psi_1(x_1)$ *supported in* $\mathcal{X}_{\mathsf{reg}}$.

On the other hand, under condition $(14.7.4)_-$ the whole zone $\mathcal{X}' \coloneqq \mathcal{X}_{\mathsf{deg}} \cup \mathcal{X}_{\mathsf{reg}}$ will be forbidden leading us to the following statement not having analogues in Sections 14.1–14.6:

Proposition 14.7.5. *Let conditions* (14.1.4) *and* $(14.7.4)_-$ *be fulfilled. Let* $\psi = \psi(x)$, $\psi_1 = \psi_1(x_1)$ *be supported in* $B(0, \frac{1}{2})$ *and* $\mathcal{X}'$ *respectively and let* $\varphi = \varphi(\xi_2)$ *be supported in the zone*

$$\mathcal{Y}' = \bigl\{|\xi_2| \le \epsilon\bigl(\mu h^\nu\bigr)^{-1/(\nu-1)}\bigr\}. \tag{14.7.19}$$

Then

(i) $|Qe| \le Ch^s$ *with* $Qe = \varphi(hD_2)\bigl(e\psi\bigr)$, $e = e(x, y, \tau)$, $|\tau| \le \epsilon$ *as* $\mu \le \epsilon h^{-\nu}$.

(ii) Moreover, under condition (14.7.11) *Statement (i) holds with* $Q = \psi_1\psi$, $\psi_1 = \psi_1(x_1)$ *supported in* $\mathcal{X}'$.

Therefore as $\mu \le \epsilon h^{-\nu}$ and condition $(14.7.4)_-$ is fulfilled one needs to discuss the contribution of the degeneration zone $\mathcal{X}_{\mathsf{deg}} = \{|x_1| \le \bar\gamma\}$ or equivalently $\mathcal{Y}_{\mathsf{deg}} = \{|\xi_2| \le C_0\}$ [24] to the remainder.

[24] These two definitions are essentially equivalent under condition (14.7.11) but in the case (14.7.12) one needs always use definition in the framework of ξ_2.

Furthermore one needs to consider the contribution of the previously forbidden zone $\mathcal{X}'' = \{|x_1| \ge \bar{\gamma}_1'\}$ or equivalently $\mathcal{Y}'' = \{|\xi_2| \ge \epsilon\big(\mu h^\nu\big)^{-1/(\nu-1)}\}$ [24] to the remainder.

Degeneration Zone

The degeneration zone is analyzed exactly as in Section 14.3 and Subsections 14.5.1–14.5.2 leading us eventually to the following proposition:

Proposition 14.7.6. *Let conditions* (14.1.4) *and* $(14.7.4)_+$ *be fulfilled. Let* $\psi = \psi(x_2)$ *and* $\psi_1 = \psi_1(x_1)$ *be supported in* $B(0, \frac{1}{2})$ *and* $\mathcal{X}_{\mathsf{deg}}$ *respectively and let* $\varphi = \varphi(\xi_2)$ *be supported in* $\mathcal{Y}_{\mathsf{deg}} = \{|\xi_2| \le C_0\}$. *Then all the results of Section 14.3 and Subsections 14.5.1–14.5.2 remain true; in particular*

(i) As $\mu \le Ch^{\delta-\nu}$

$$\mathsf{R}^{\mathsf{T}\prime} := |\Gamma\big(Qe\big) - h^{-1}\sum_j \int_{-\infty}^{0} \Big(F_{t\to h^{-1}\tau}\bar{\chi}_{T_j}(t)\Gamma\big(Q_j e\big)\Big)\, d\tau| \le C\mu^{-1/\nu}h^{-1} \tag{14.7.20}$$

with $Qe = \varphi(hD_2)\big(e\psi\big)$, $e = e(x, y, \tau)$, $Q = \sum_j Q_j$ *and* $|\tau| \le \epsilon$ *where partition* Q_j *and* $Ch|\log h| \le T_j$ *are defined immediately after formula* (14.4.37).

(ii) Moreover, under nondegeneracy condition $(14.3.111)_m$ $\mathsf{R}^{\mathsf{T}\prime}$ *does not exceed* $C\mu^{-1/\nu}h^{-1}$ *as* $\mu \le \epsilon h^{-\nu}$.

(iii) On the other hand, in the general case $\mathsf{R}^{\mathsf{T}\prime}$ *does not exceed* $C\mu^{-1/\nu}h^{-1} + Ch^{-\delta}$ *as* $\mu \le \epsilon h^{-\nu}$.

(iv) Furthermore, under condition (14.7.11) *all Statements (i)–(iii) hold with* $Q = \psi_1\psi$.

Proof. We leave the easy proof to the reader. □

Remark 14.7.7. In the framework of Proposition 14.7.6 estimate (14.7.15) holds for $Q = Q_m$ and $T \in [T_m, T_m']$ with T_m' defined by (14.3.104) (it was denoted by T_1 then).

Extended Formerly Forbidden Zone

Now we need to consider the extended formerly forbidden zone

$$\mathcal{Y}'' = \{|\xi_2| \ge \epsilon\mu\bar{\gamma}_1^{\nu}\}$$

consisting of the *transitional zone*

$$\mathcal{X}_{\mathsf{trans}} := \{\epsilon\bar{\gamma}_1 \le |x_1| \le 2C\bar{\gamma}_1\} \tag{14.7.21}$$

and the *formerly forbidden zone*

$$\mathcal{X}_{\mathsf{ff}} := \{|x_1| \ge C\bar{\gamma}_1\}. \tag{14.7.22}$$

Let us apply the theory of operators with operator-valued symbols. However, as $\mu \le \epsilon(h|\log h|)^{-\nu}$ one can apply a usual microlocal analysis with logarithmic uncertainty principle.

So, let us consider A as h-pseudodifferential operator $\mathcal{A}(x_2, hD_2)$ with operator-valued symbol $\mathcal{A}(x_2,\xi_2)$. However, before doing this one can assume without any loss of the generality that $g^{11}=1$, $g^{12}=0$ and therefore

$$\boldsymbol{a}(x_2,\xi_2) = h^2D_1^2 + \sigma^2(x)\big(\xi_2 - \mu V_2(x)\big)^2 - \mathfrak{z}\mu hF + V(x), \qquad V_2 = \phi(x)\frac{1}{\nu}x_1^{\nu} \tag{14.7.23}$$

with $\phi(x)=1$ as $x_1=0$; then $f=\sigma\phi$.

Further, for given x_2 by change of variable x_1 one can transform $\boldsymbol{a}(x_2,\xi_2)$ unitarily to the similar operator with $\phi=1$ and with

$$\sigma = 1 \qquad \text{as } x_1 = 0; \tag{14.7.24}$$

but this new operator is multiplied from the left and the right by $\alpha(x)$. So operator $\boldsymbol{a}(x_2,\xi_2)$ is unitary equivalent to

$$\boldsymbol{a}'(x_2,\xi_2) = \alpha(x)\Big(h^2D_1^2 + \sigma^2(x)\big(\xi_2 - \mu\frac{1}{\nu}x_1^{\nu}\big)^2 - \mathfrak{z})\mu h\sigma(x)x_1^{\nu-1} - W'(x)\Big)\alpha(x). \tag{14.7.25}$$

Proposition 14.7.8. *Let condition* (14.1.4) *be fulfilled and* $\mu \le \epsilon h^{-\nu}$. *Then*

(i) As $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ $\mathcal{X}_{\mathsf{ff}}$ *is a lacunar zone and its contribution to the Tauberian remainder* R^{T} *is* $O(\mu^{-s})$.

(ii) On the other hand, as $\mathfrak{z} \in (2\mathbb{Z}^+ + 1)$ *and condition* $(14.7.4)_\pm$ *is fulfilled* $\mathcal{X}_{\mathsf{ff}}$ *also is a lacunar zone and its contribution to the Tauberian remainder* R^{T} *also is* $O(\mu^{-s})$.

In both cases R^{T} *is defined by* (14.7.16) *with* $Qe = \varphi(hD_2)(e\psi)$, φ *supported in the zone* $\mathcal{Y}_{\mathsf{ff}}$, $T \ge T_0 = Ch|\log h|$.

Proof. Really, Proposition 14.A.5(i) implies that under condition $(14.7.4)_\pm$ zone $\mathcal{Y}_{\mathsf{ff}}$ is forbidden on energy levels $|\tau| \le \epsilon$ as long as $\mu \le \epsilon h^{-\nu}$; namely

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)(Qu)(x,y,t)| \le CTh^s \qquad \forall \tau : |\tau| \le \epsilon \tag{14.7.26}$$

as $Q\psi = \varphi(hD_2)(u\psi)$ with φ supported in the zone $\mathcal{Y}_{\mathsf{ff}}$ and therefore its contribution to the remainder R^{T} defined by (14.7.16) is negligible as well.□

Consider now transitional zone $\mathcal{Y}_{\mathsf{trans}}$. Proposition 14.A.5(ii) implies that under condition $(14.7.4)_\pm$ in this zone operator $\boldsymbol{a}(\xi_2)$ is microhyperbolic with respect to ξ_2 and we immediately arrive to the following proposition:

Proposition 14.7.9. *Let conditions* (14.1.4) *and* $(14.7.4)_\pm$ *be fulfilled and* $\mu \le \epsilon h^{-\nu}$.

Then estimate $\mathsf{R}^{\mathsf{T}} \le C$ *holds as* R^{T} *is defined by* (14.7.16) *with* $Qe = \varphi(hD_2)(e\psi)$, φ *supported in the zone* $\mathcal{Y}_{\mathsf{trans}}$, $T \in [T_0, T_1]$, $T_0 = Ch|\log h|$, $T_1 = \epsilon(\mu h^\nu)^{-1/(\nu-1)}$.

We can be completely happy with this result unless condition $(14.7.4)_-$ is fulfilled as in this case all other zones are lacunar and we wonder if the same is true for $\mathcal{Y}_{\mathsf{trans}}$. Theory of Section 13.6 tells us that this is the case provided

$$|(2n+1-\mathfrak{z})\mu hF + V| \ge \epsilon \qquad \forall n \in \mathbb{Z}^+ \tag{14.7.27}$$

which is obviously impossible as $n = 1$ save trivial under condition $(14.7.4)_-$ case $\mathfrak{z} \le 1$.

Synthesis

So, we arrive to

Proposition 14.7.10. *Under assumptions* (14.1.4) *and* $(14.7.4)_\pm$ *consider Tauberian remainder* R^{T} *with* $\varphi = 1$ *as* $\mu \le \epsilon h^{-\nu}$.

Then under condition $(14.7.4)_+$ *the main contribution to* R^{T} *is delivered by* $\mathcal{X}_{\mathsf{reg}} \cup \mathcal{X}_{\mathsf{deg}}$ *and it is* $O(\mu^{-1/\nu}h^{-1} + h^{-\delta})$ *in the general case and* $O(\mu^{-1/\nu}h^{-1})$ *under non-degeneracy condition* $(14.3.111)_m$.

Remark 14.7.11. The analysis of all zones under condition (14.7.5) will be done in Subsection 14.7.5.

14.7.4 Calculations

Calculations. I

After estimates were derived in the previous subsection under assumption $Ch^{-1} \le \mu \le \epsilon h^{-\nu}$ and condition $(14.7.4)_{\pm}$ calculations in zone $\mathcal{Y}_{\mathsf{deg}} \cup \mathcal{Y}_{\mathsf{reg}} \cup \mathcal{Y}_{\mathsf{trans}}$ are done exactly as in Section 14.4.

On the other hand, calculations in zone $\mathcal{Y}_{\mathsf{ff}}$ as $\mu \le \epsilon h^{-\nu}$ are rather obvious under assumptions $Ch^{-1} \le \mu \le \epsilon h^{-\nu}$ and $(14.7.4)_{\pm}$. Therefore we arrive to the following intermediate estimate

$$|\int \Big(\big(\varphi(hD_2)e\big)(x,x,0) - (2\pi h)^{-1} \int e(x_1,x_1;x_2,\xi_2,0)\varphi(\xi_2)\,d\xi_2\Big)\psi_2(x_2)\,dx| \le R \tag{14.7.28}$$

where R is an estimate already derived in the corresponding conditions (also see below) and $\varphi \in \mathscr{C}_0^\infty(-\epsilon',\epsilon')$ with sufficiently small constant ϵ'.

Then the same estimate holds with $\psi(x_2)$ replaced by $\psi(x)$ such that $\psi(x) = \psi_2(x_2)$ as $|x_1| \le C_1\epsilon'$ because this transition leads to a negligible error. We take ψ also satisfying $\psi(x) = 0$ as $|x_1| \ge 2C_1\epsilon'$. Then in the latter estimate we can replace φ by 1. Really, then the error would be

$$|\int \Big(\big((1-\varphi(hD_2))e\big)(x,x,0) - (2\pi h)^{-1} \int e(x_1,x_1;x_2,\xi_2,0)(1-\varphi(\xi_2))\,d\xi_2\Big)\psi(x)\,dx| \tag{14.7.29}$$

and replacing ψ by ψ' equal to ψ as $|x_1| \ge 2C_2^{-1}\epsilon'$ and equal to 0 as $|x_1| \le C_2^{-1}\epsilon'$ leads to a negligible error. However, to expression (14.7.29) modified this way one can apply the theory of operators with non-degenerating magnetic field and then to estimate expression (14.7.29) by C.

Thus we derived estimate (14.7.28) with φ replaced by 1 and $\psi_2(x_2)$ replaced by some "special" function $\psi(x)$. Then due to rescaling arguments like before (14.7.10 the same estimate holds for a general function $\psi(x)$ supported in $\{|x_1| \le 2C_1\epsilon'\}$. Thus we arrive to

Proposition 14.7.12. *Let conditions* (14.1.4) *and* $(14.7.4)_+$ *be fulfilled. Then*

(i) As <u>*either*</u> $\mu \le h^{\delta-\nu}$ <u>*or*</u> *condition* $(14.3.111)_m$ *is fulfilled and* $\mu \le \epsilon h^{-\nu}$ *the following estimate holds*

$$\mathsf{R}_I := \Big| \int \Big(e(x,x,0) - (2\pi h)^{-1} \int \mathbf{e}(x_1,x_1;x_2,\xi_2,0)\, d\xi_2 \Big) \psi(x)\, dx \Big| \le C\mu^{-\frac{1}{\nu}} h^{-1} \tag{14.7.30}$$

where here and below $\mathbf{e}(x_1,y_1;x_2,\xi_2,\tau)$ *is the Schwartz kernel of the spectral projector* $\mathbf{e}(x_2,\xi_2,\tau)$ *of operator* $\mathbf{a}(x_2,\xi_2)$ *defined by* (14.7.23) *and* $\delta > 0$ *is an arbitrarily small exponent.*

(ii) In the general case with $\mu \le \epsilon h^{-\nu}$ *estimate*

$$\mathsf{R}_I \le C\mu^{-\frac{1}{\nu}} h^{-1} + Ch^{-\delta} \tag{14.7.31}$$

holds.

Recall remind that in both statements of Proposition 14.7.12 the principal part of asymptotics has magnitude $\asymp \mu h^{-1}$ (as $\mu \ge h^{-1}$). Therefore if due to condition $(14.7.4)_-$ we remove $\mathcal{Y}_{\mathsf{deg}} \cup \mathcal{Y}_{\mathsf{reg}}$ from the analysis we arrive to the better remainder estimate:

Proposition 14.7.13. *Let conditions* (14.1.4) *and* $(14.7.4)_-$ *be fulfilled. Further, let* $\mathfrak{z} > 1$ [25]*.*

Then for $Ch^{-1} \le \mu \le \epsilon h^{-\nu}$ *estimate* $\mathsf{R}_I \le C$ *holds while the principal part of asymptotics has magnitude* $\asymp \mu h^{-1}$*.*

Calculations. II

Transition to the auxiliary operator $\mathbf{a}_0$ without increasing error estimates could be done easily in zone $\mathcal{Y}_{\mathsf{reg}}$ exactly as it was done in the proof of Propositions 14.4.3 and 14.4.4 while arguments of the proof of Proposition 14.4.8 etc work in zone $\mathcal{Y}_{\mathsf{deg}}$.

[25] Otherwise the principal part of asymptotics would be 0 and remainder estimate would be $O(\mu^{-s})$.

On the other hand, this transition in zone $\mathcal{Y}_{\mathsf{ff}}$ is obvious under condition $(14.7.4)_{\pm}$, and we arrive to two theorems below as $\mu \le h^{-\nu}|\log h|^{-K}$ and function ψ is "special" in the sense of the previous subsection. Then the same arguments as there extend theorem to the general function ψ.

Furthermore, under condition $(14.7.4)_{\pm}$ the case $h^{-\nu}|\log h|^{-K} \le \mu \le \epsilon h^{-\nu}$ is analyzed exactly as in Section 14.5 leading to the extension of these theorems to $\mu \le \epsilon h^{-\nu}$:

Theorem 14.7.14. *Let conditions* (14.1.4) *and* $(14.7.4)_{+}$ *be fulfilled. Then*

(i) As <u>*either*</u> $\mu \le h^{\delta-\nu}$ <u>*or*</u> *condition* $(14.3.111)_m$ *is fulfilled and* $\mu \le \epsilon h^{-\nu}$

$$\mathsf{R}^* := \Big| \int \Big(e(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0)\Big)\psi(x)\,dx - \int h^{-2}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x_2,0)\psi(0,x_2)\,dx_2\Big| \tag{14.7.32}$$

does not exceed $C\mu^{-1/\nu}h^{-1}$ *where*

$$h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}(x,\tau) := (2\pi h)^{-1}\int e_0(x_1,x_1;x_2,\xi_2,\tau,\hbar)\,dx_1\,d\xi_2 - \int \tilde{\mathcal{N}}^{\mathsf{MW}}_0(x,\tau)\,dx_1, \tag{14.7.33}$$

and here and below $e_0(x_1,y_1;x_2,\xi_2,\tau)$ *is the Schwartz kernel of the spectral projector* $e_0(x_2,\xi_2,\tau)$ *of operator* $a_0(x_2,\xi_2)$ *defined by* (14.7.23) *and with* α,ϕ,σ,W *restricted to* $\{x_1=0\}$ *and* $h^{-2}\mathcal{N}^{\mathsf{MW}}_0$ *is Magnetic Weyl approximation for this operator.*

(ii) In the general case with $\mu \le \epsilon h^{-\nu}$ *estimate* $\mathsf{R}^* \le C\mu^{-1/\nu}h^{-1} + Ch^{-\delta}$ *holds.*

Similarly, Proposition 14.7.13 is upgraded to the following theorem:

Theorem 14.7.15. *Let conditions* (14.1.4) *and* $(14.7.4)_{-}$ *be fulfilled. Further, let* $\mathfrak{z} > 1$ [25]*.*

Then as $Ch^{-1} \le \mu \le \epsilon h^{-\nu}$ *estimate* $\mathsf{R}^* \le C$ *holds while the principal part of asymptotics has magnitude* $\asymp \mu h^{-1}$*.*

Remark 14.7.16. Obviously the same approximate expressions (14.4.63), $(14.4.63)^*$, hold for the part of $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ "associated" with $\mathcal{Y}_{\mathsf{deg}}$.

14.7.5 Analysis under Condition (14.7.5)

Estimates

We start from the remainder estimate in zone $\mathcal{X}_{\mathsf{deg}} \cup \mathcal{X}_{\mathsf{reg}} \cup \mathcal{X}_{\mathsf{trans}}$ which is trivial:

Proposition 14.7.17. *Let conditions* (14.1.4), (14.7.24) *and* (14.7.5) *be fulfilled. Then*

(i) Estimate (14.7.16) *holds with* $Qe = \varphi(hD_2)(e\psi)$, φ *supported in the strip* $\mathcal{Y}_\gamma$ *with the same restrictions to* γ *and the same* T_0, T_1 *as in Proposition 14.7.3(i).*

(ii) Furthermore, the same estimate holds as φ *is supported in zone* $\mathcal{Y}_{\mathsf{deg}}$ *and* $\gamma = \bar\gamma_0 = \mu^{-1/\nu}$.

(iii) Therefore R^{T} *defined by* (14.7.16) *does not exceed* $C\mu^{-1/\nu}h^{-1}$ *as* φ *is supported in zone* $\mathcal{X}_{\mathsf{deg}} \cup \mathcal{X}_{\mathsf{reg}} \cup \mathcal{X}_{\mathsf{trans}}$ *and* $T = T_0$.

Now let us analyze zone $\mathcal{Y}_{\mathsf{ff}}$ under condition (14.7.5):

Proposition 14.7.18. *Let conditions* (14.1.4), (14.7.24) *and* (14.7.5) *be fulfilled. Then as* $\mathfrak{z} \in (2\mathbb{Z}^+ + 1)$ [26] *estimate* $\mathsf{R}^{\mathsf{T}} \le C$ *holds as* R^{T} *is defined by* (14.7.16) *with* $Qe = \varphi(hD_2)(e\psi)$, φ *supported in the zone* $\mathcal{Y}_{\mathsf{ff}}$.

Proof. (a) Let us note first that estimate

$$|F_{t\to h^{-1}\tau}\bigl(\bar\chi_{T^*}(t) - \bar\chi_{\bar T_*}(t)\bigr)(Qu)(x,y,t)| \le Ch^s \qquad \forall \tau : |\tau| \le \epsilon \tag{14.7.34}$$

holds with $T^* = \epsilon\mu^{-1}\gamma^{-\nu}$, $\bar T_* = Ch|\log h|$ as $Qu = \varphi(hD_2)(u\psi)$, φ supported in the strip $\mathcal{Y}_{(\gamma)} = \{\mu\gamma^\nu \le |\xi_2| \le 2\gamma^\nu\}$ with $\gamma \ge C\bar\gamma_1$.

Really, us consider a partial trace $\Gamma'(Qu)$ (with respect to x_1). Due to Proposition 14.A.5 the propagation speed with respect to x_2 does not exceed $C|\xi_2|^{-1} \asymp C(\mu\gamma^\nu)^{-1}$ and the propagation speed with respect to ξ_2 does not exceed C [27]; moreover, under condition (14.7.5) this propagation speed with respect to ξ_2 is greater than ϵ.

[26] Recall that for $\mathfrak{z} \in (2\mathbb{Z}^+ + 1)$ contribution of $\mathcal{Y}_{\mathsf{ff}}$ to the remainder would be negligible.

[27] Under some assumptions this would be equivalent to the estimate of the the average propagation speed with respect to x_1 of Qu by $C\gamma(\mu\gamma^\nu)^{-1}$; further one can estimate average propagation speed with respect to x_2 of Qu by $C(\mu\gamma^\nu)^{-1}$ as well.

On the other hand, an obvious estimate

$$|F_{t\to h^{-1}\tau}\bar{\chi}_{T_*}(t)\Gamma(Qu)(t)| \le C\mu\gamma^\nu h^{-1}\times T_* = C\mu\gamma^\nu|\log h| \tag{14.7.35}$$

holds where the first factor is $\mu_{\mathsf{eff}}h_{\mathsf{eff}}^{-1}\gamma^{-1}$; furthermore, due to (14.7.34) this estimate holds for the left-hand expression with T_* replaced by T^*.

Therefore the contribution of the strip $\mathcal{Y}_\gamma$ to the Tauberian remainder does not exceed

$$C\mu\gamma^\nu|\log h|\times T^{*\,-1} = C|\log h| \tag{14.7.36}$$

and therefore the total contribution of $\mathcal{Y}_{\mathsf{ff}}$ to the Tauberian remainder does not exceed $C|\log h|\int \gamma^{-1}\,d\gamma \asymp C|\log h|^2$.

This estimate is as good as we need for $\mu \le Ch^{-\nu}|\log h|^{-2\nu}$. However for $Ch^{-\nu}|\log h|^{-2\nu} \le \mu \le \epsilon h^{-\nu}$ we would like to improve it getting rid of two logarithmic factors.

(b) Getting rid of one of these two factors is easy: rescaling $t\mapsto t/T$, $(x_j-y_j)\mapsto (x_j-y_j)/T$, $\mu\mapsto \mu T$, $h\mapsto h/T$ estimates for Schrödinger operator with strong non-degenerate magnetic field of Chapter 13 (with arbitrary parameters μ and h such that $\mu h\ge C$) we arrive to two following inequalities

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(Qu)| \le C\mu\big(\frac{h}{T}\big)^s \tag{14.7.37}$$

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(Qu)| \le C\mu \tag{14.7.38}$$

as $h\le T\le 1$, $|\tau|\le\epsilon$ under condition $|W|+|\nabla W|\ge\epsilon_0$.

Then using our standard scaling $x_1\mapsto x_1/\gamma$, $x_2\mapsto (x_2-y_2)/\gamma$, $\mu\mapsto\mu_{\mathsf{eff}}=\mu\gamma^\nu$, $h\mapsto h_{\mathsf{eff}}=h/\gamma$ and $T\mapsto T/\gamma$ we arrive to estimate (14.7.35) without logarithmic factor

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(Qu)(t)| \le C\mu\gamma^\nu \tag{14.7.35}^*$$

as $|\tau|\le\epsilon$, $T/\gamma\le\epsilon\mu\gamma^\nu \iff T\le T_1^*=\epsilon\mu\gamma^{\nu+1}$. Further, in virtue of (14.7.34) this estimate holds as $h\le T\le T^*=\epsilon\mu\gamma^\nu$ provided $T_1^*\ge Ch$ i.e. $\gamma\ge\bar{\gamma}_1$.

Then the contribution of the strip $\mathcal{Y}_\gamma$ to the remainder R^{T} is C and therefore the total estimate is $C|\log h|$.

(c) To get rid of the second logarithmic factor we need to further increase T^* in the previous arguments and for this purpose we need for each γ to make x_2-partition of $\mathcal{Y}_\gamma$ of the size

$$\ell = \epsilon|W(0,x_2)| + \bar{\ell}, \qquad \bar{\ell} \ge C\gamma. \tag{14.7.39}$$

Consider first elements $\mathcal{U}_{\gamma,\ell}$ with $\ell \ge C\bar{\ell}$. For every such element on levels τ with $|\tau| \le \epsilon\ell$ after rescaling

$$x_2 \mapsto x_2\ell^{-1}, \quad h \mapsto h' = h\ell^{-\frac{3}{2}}, \quad t \mapsto t\ell^{-1}, \quad \mu \mapsto \mu' = \mu\ell^{\frac{1}{2}} \tag{14.7.40}$$

we are in the elliptic situation.

Therefore contribution of each such element to the Tauberian remainder R^{T} does not exceed $C\mu'(h')^s$ and therefore the total contribution of such elements is negligible as $\bar{\ell} = h^\delta$.

So we need to consider only elements $\mathcal{U}'_\gamma = \mathcal{U}_{\gamma,\ell}$ with $\ell \asymp \bar{\ell} = h^\delta$. For such elements after rescaling (14.7.40) we can apply estimate (14.7.35)*; then scaling back we get the same estimate (14.7.35)* again but with $Q = \psi'(x_2)\varphi(hD_2)$ supported in $\mathcal{U}'_\gamma$, $|\tau| \le \epsilon\ell$ and $Ch|\log h|\ell^{-1} \le T \le T^* = \epsilon\mu\gamma^{\nu+1}$ [28]. Furthermore, applying (14.7.34) we can increase T^* to $\epsilon\mu\gamma^\nu$.

So far we gained nothing: the estimate we proved alone would bring us the same final remainder estimate $C|\log h|$ as before but now we can further increase T^* and thus reduce the remainder estimate.

Namely, let us consider propagation in the time direction in which $|\xi_2|$ increases. If only propagation with respect to ξ_2 was considered, until time $\epsilon_3\mu$ it would be confined to the zone

$$\bigl\{\epsilon_0 \le |\xi_2|\bigl(\mu\gamma^\nu + |t|\bigr)^{-1} \le C\bigr\} \subset \bigl\{\frac{1}{2}\mu\gamma^\nu \le |\xi_2| \le \epsilon_1\mu\bigr\}$$

and thus to $\{|x_1| \le \epsilon_3\}$.

However let us note that the propagation speed with respect to x_2 does not exceed $C\ell/|\xi_2|$ as $\ell \ge C|W| + \bar{\ell}$. Therefore one can prove easily that propagation, which started in the zone $\{|x_2| \le \frac{1}{2}, |V| \le h^\delta\}$ as we

[28] It is consistent with the fact that support of ψ' is of the length ℓ but now $\bar{T}_* = Ch|\log h|/\ell$.

have assumed, until time $T_2^* = \mu\gamma^\nu h^{-\delta_1}$ is confined to a bit larger zone $\{|x_2| \le \frac{3}{4}, |W| \le h^{\delta/2}\}$ of the same type.

Therefore estimate (14.7.35)* holds with $Ch^{1-2\delta} \le T \le T_2^*$. Then due to the Tauberian approach contribution of each partition element $\mathcal{U}'_\gamma$ to the Tauberian remainder R^{T} does not exceed $C\mu\gamma^\nu T_2^{*\,-1} = Ch^{\delta_1}$ and the contribution of the whole strip $\mathcal{Y}_\gamma$ does not exceed Ch^{δ_1} as well and of the whole zone $\mathcal{Y}_{\mathsf{ff}}$ does not exceed Ch^{δ_2}.

Clearly, at some moment we increased slightly T_* but after summation over partition was done we can (using negligibility of the trace on $[Ch|\log h|, h^{1-\delta}]$ time interval on energy levels $|\tau| \le \epsilon$) return to original $\bar{T}_*$.

(d) If $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ then $\mathcal{Y}_{\mathsf{ff}}$ remains a forbidden zone and estimate (14.7.34) holds also for $\bar{\chi}_T(t)$ with $T = \bar{T}_*$, $T = T^*$ rather than their difference and the contribution of $\mathcal{Y}_{\mathsf{ff}}$ to the Tauberian remainder is negligible. □

Calculations

Calculations in zone $\mathcal{Y}_{\mathsf{deg}} \cup \mathcal{Y}_{\mathsf{reg}} \cup \mathcal{Y}_{\mathsf{trans}}$ are exactly as in Section 14.4. However one should be more careful with calculations in zone $\mathcal{Y}_{\mathsf{ff}}$ as $\mathfrak{z} \in (2\mathbb{Z}^+ + 1)$.

Let us recall that according to sections 13.3, 13.6 in the nondegenerate case with $\mu h \ge C$ the operator in question is reduced to one-dimensional $\mu^{-1}h$-pseudodifferential operator $B(x_2, \mu^{-1}hD_2, h^2)$ [29] with the "main symbol" $B(x_2, \xi_2, 0) = -W \circ \Psi$ and therefore the contribution of the partition element to the final answer will be given as in Section 13.6 by magnetic Weyl expression $\int h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0)\psi(x)\,dx$ plus correction terms $\mu h^{1+2m}\int \varkappa_{l,m}(x)\psi(x)\,dx$ with $m = 0, 1, ...$

After rescaling $\mu \mapsto \mu\gamma^\nu$, $h \mapsto h/\gamma$, $dx \mapsto \gamma^{-2}dx$ these terms are transformed into

$$\mu h^{1+2m} \int \varkappa_{l,m}(x,\gamma)\psi(x)\gamma^{\nu-2m-3}\,dx \tag{14.7.41}$$

integrated over zone $\{x\colon \bar{\gamma}_1 \le \gamma(x) \le \epsilon\}$.

One can see easily that if there was an extra factor γ one would be able to rewrite this expression (14.7.41) modulo $O(1)$ as the similar expression

[29] Where x_2 is not our original x_2.

with integration over $\{x, \gamma(x) \le \epsilon\}$ as $2m+2 < \nu$ [30)] or to simply skip it as $2m+2 > \nu$ or to get a term which is $O\big(\mu h^{\nu} |\log h|\big)$ as $2m+2 = \nu$.

To gain this extra factor one needs to consider the difference of expressions $\int e(x,x,0)\psi(x)\,dx$ for two operators with coefficients $g^{jk}(x)$, $f(x)$, $V(x)$ coinciding as $x_1 = 0$. As this second operator it is natural to pick up the simplest one i.e.

$$A_0 = h^2 D_1^2 + \big(hD_2 - \mu x_1^{\nu}/\nu\big)^2 - (2l+1)\mu h x_1^{\nu-1} - W(x_2) \tag{14.7.42}$$

Therefore we arrive to the following proposition:

Proposition 14.7.19. *Under condition* (14.7.5) *estimate*

$$\Big|\int \Big(e(x,x,0) - e_0(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0) + h^{-2}\mathcal{N}_0^{\mathsf{MW}}(x,0)\Big)\psi(x)\,dx - \sum \kappa'_{l,m}\mu h^{1+2m}\Big| \le C\mu^{-1/\nu}h^{-1} \tag{14.7.43}$$

holds as $\mu \le h^{-\nu}|\log h|^{-K}$ *where* e_0 *and* $\mathcal{N}_0^{\mathsf{MW}}$ *are defined for operator* A_0.

(14.7.44) Now in what follows we can consider operator A_0 instead of A.

Then we can apply the standard method of successive approximations with unperturbed operator $a(y_2, hD_2)$ and plug the results of successive approximations into expression

$$h^{-1}\int_{-\epsilon}^{0} \Big(F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(Qu)\Big)\,d\tau \tag{14.7.45}$$

which calculates exactly contribution of the "problematic" eigenvalue λ_l as $\mathfrak{z} = (2l+1)$ of the corresponding one-dimensional Schrödinger operator; recall that $T = \bar{T} = Ch|\log h|$.

Thus while the main part of asymptotics is estimated by $C\mu h^{-2}\gamma^{\nu}T = C\mu h^{-1}\gamma^{\nu}|\log h|$, each next term seemingly acquires factor

$$Ch^{-1}\big(\mu h\gamma^{\nu-1}\big)^{1/2}T^2 \asymp Ch\big(\mu h\gamma^{\nu-1}\big)^{1/2}|\log h|^2; \tag{14.7.46}$$

since the propagation speed with respect to x_2 is estimated by $C_0(\mu h\gamma^{\nu-1})^{1/2}$ such factor could be larger than 1.

[30)] Thus resulting in exactly expression $\kappa_{l,m}\mu h^{1+2m}$ as in non-degenerate case.

In fact however, $C_0(\mu h\gamma^{\nu-1})^{1/2}$ is the estimate for the instant propagation speed only. Using instead the mentioned reduction to a one-dimensional $\mu^{-1}h$-pseudodifferential operator one can find that the propagation speed with respect to x_2 is estimated by $C_0\mu^{-1}$ if magnetic field is non-degenerate and then in the canonical coordinates for time $T = \bar{T}_*$ the shift of (x_2', ξ_2') will be estimated by $C_0\bigl(\mu^{-}h|\log h|\bigr)^{1/2}$ which is the smallest distance allowed by the logarithmic uncertainty principle[31)] and this would persist if one returns back to the original $(x_2, \mu^{-1}\xi_2)$; so one would be able to estimate $(x_2 - y_2)$ on the time interval in question by $C_0\bigl(\mu^{-1}h|\log h|\bigr)^{1/2}$.

In the degenerate case described here one must replace μ, h by $\mu\gamma^{\nu}$, h/γ respectively and then multiply by γ thus producing final estimate for $|x_2 - y_2|$

$$\varrho := C\bigl(\mu^{-1}h\gamma^{1-\nu}|\log h|\bigr)^{1/2} \asymp Ch\bar{\gamma}_1^{\frac{1}{2}(\nu-1)}\gamma^{-\frac{1}{2}(\nu-1)}|\log h|^{\frac{1}{2}} \tag{14.7.47}$$

and therefore each next term acquires factor $\varrho|\log h|$. Then m-th term of the final answer is estimated by

$$C\mu h^{-1}\varrho^{m-1}|\log h|^{K} \asymp C\mu h^{m-2}\gamma^{\nu-\frac{1}{2}(\nu-1)(m-1)}\bar{\gamma}_1^{\frac{1}{2}(\nu-1)(m-1)}|\log h|^{K}. \tag{14.7.48}$$

After integration over $\gamma^{-1}\,d\gamma$ with $\bar{\gamma}_1 \le \gamma \le \epsilon$ expression (14.7.48) results in $C\mu h^{m-2}\bar{\gamma}_1^{\nu}|\log h|^{K}$ as $\nu - \frac{1}{2}(\nu-1)(m-1) \le 0$ or in $C(\mu^{-1}h)^{(m-3)/2}|\log h|^{K}$ otherwise. One can check easily that in either case the answer is $O(|\log h|^{K})$ as $m \ge 3$ and only terms with $m = 1, 2$ should be considered more carefully under condition (14.7.11).

On the other hand, the main term appears as (14.7.45) with u replaced by $\bar{u}$ and modulo negligible one can rewrite it with any $T \ge \bar{T}_*$, in particular with $T = \infty$ which leads to

$$(2\pi h)^{-1}\int e_0(x_1, x_1, 0; x_2, \xi_2)\psi(x_1)\varphi(\xi_2)\,dx_2\,d\xi_2 \tag{14.7.49}$$

where we recall that $e_0(x_1, y_1, 0; x_2, \xi_2)$ is the Schwartz kernel of the spectral projector of one-dimensional Schrödinger operator $a_0(x_2, \xi_2)$.

Let us consider terms with $m = 2$ i.e. expression (14.7.45) with u replaced by $\bar{u}_1$; similarly to the above analysis one can estimate contribution

[31)] Since $\mu^{-1}h$-Fourier integral operators are involved later one needs the same distance in each (x, ξ) direction.

of $O\big((x_2-y_2)^2\big)$ terms in the perturbation $\boldsymbol{a}(x_2, hD_2)-\boldsymbol{a}(y_2, hD_2)$ by $C|\log h|^K$. Therefore one should consider only $\boldsymbol{a}(x_2, hD_2) - \boldsymbol{a}(y_2, hD_2) = (x_2 - y_2)B_1(y_2)$ in which case $\bar{u}_1$ is defined by (14.4.12) without the last term since B_1 commutes with $(x_2 - y_2)$:

$$u \mapsto \bar{u}_1 = -ih\sum_{\varsigma=\pm} \varsigma \bar{G}^{\varsigma} B_1 \bar{G}^{\varsigma}[\bar{A}, x_2 - y_2]\bar{G}^{\varsigma}\delta(t)\delta(x_2 - y_2)\delta(x_1 - y_1). \tag{14.7.50}$$

One needs to multiply this by $h^{-1}\psi$, integrate with respect to τ and apply Γ to it. Obviously since for odd ν operators $\bar{G}^{\varsigma}$ and $[\bar{A}, x_2 - y_2]$ are even and odd respectively as $x_1 \mapsto -x_1$, $\xi_2 \mapsto -\xi_2$ the answer would be 0 if ψ is even with respect to x_1.

To cover the case of even ν and general ψ let us note that B_1 commutes with $\bar{G}^{\varsigma}$ considered as operators in the auxiliary space $\mathscr{L}^2(\mathbb{R}^1_{x_1})$. Then if $\bar{G}^{\varsigma}$ commuted with ψ, taking trace and integrating with respect to τ would result in

$$\mathsf{const}\cdot \partial_{\xi_2} B_1 \sum_{\varsigma=\pm} \varsigma\, \mathsf{Tr}\big(\bar{G}^{\varsigma}\psi\big)$$

which after integration over ξ_2 results in 0.

However $\bar{G}^{\varsigma}$ does not commute with ψ, so instead of 0 one gets

$$\mathsf{const}\cdot B_1 \sum_{\varsigma=\pm} \mathsf{Tr}\,\varsigma\Big(\bar{G}^{\varsigma}\big(\partial_{\xi_2}\bar{G}^{\varsigma}\big)\bar{G}^{\varsigma}[\bar{A}, \psi]\Big)$$

and to this expression one can apply the same type of transformations and calculations as in the proof of Proposition 14.7.19 resulting in the expression $\sum_m \kappa_{l,m}\mu h^{1+2m}$ where coefficients $\kappa_{l,m}$ are changed as needed.

Therefore combining with the results for zone $\mathcal{Y}_{\mathsf{deg}} \cup \mathcal{Y}_{\mathsf{reg}} \cup \mathcal{Y}_{\mathsf{trans}}$ we arrive to

Proposition 14.7.20. *For a toy-model operator*

$$|\int \Big(e_0(x, x, 0) - (2\pi h)^{-1}\int \boldsymbol{e}_0(x_1, x_1, 0; x_2, \xi_2)\, d\xi_2\Big)\psi(x)\, dx - \sum \kappa_m \mu h^{1+2m}| \le C\mu^{-1/\nu}h^{-1} \tag{14.7.51}$$

as $\mu \le Ch^{-\nu}|\log h|^{-K}$.

Further, combining this with Proposition 14.7.18 we get estimate (14.7.52) as $\mu \le h^{-\nu}|\log h|^{-K}$:

Theorem 14.7.21. *Under condition* (14.7.5) *estimate*

$$(14.7.52)\quad \Big|\int \Big(e(x,x,0) - (2\pi h)^{-1}\int \mathsf{e}_0(x_1,x_1,0;x_2,\xi_2)\,d\xi_2 - h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0) + h^{-2}\mathcal{N}_0^{\mathsf{MW}}(x,0)\Big)\psi(x)\,dx - \sum \kappa_{l,m}\mu h^{1+2m}\Big| \le C\mu^{-1/\nu}h^{-1}$$

holds as $\mu \le \epsilon h^{-\nu}$.

Proof. To finish the proof of this theorem one needs to cover the case $h^{-\nu}|\log h|^{-K} \le \mu \le \epsilon h^{-\nu}$, getting rid of the term $|\log h|^K$ in the error estimates.

The first problematic error comes from the correction terms in Proposition 14.7.19, namely from the terms of the type $\mu h^{1+2m}\int \varkappa_{l,m}(x_2)\gamma^{\nu-2m-3+k}\,dx$ with $k \ge 1$, $\nu - 2m - 3 + k = -1$ and this error term is $O(1)$ unless $k = 1$, $\nu = 2m+1$ in which case it it is $\kappa'_l\mu h^\nu|\log h|$.

This is possible only for odd ν in which case operator a_0 is even with respect to $x_1 \mapsto -x_1$, $\xi_2 \mapsto -\xi_2$ but perturbation contains exactly one factor x_1 and therefore it is odd and after integration with respect to x_1, ξ_2 this correction term results in 0 if ψ is even with respect to x_1.

Further, one needs to consider terms corresponding to $m = 3$ in the successive approximations leading to Proposition 14.7.20 and there one can replace $\mathsf{a}_0(x_2,\xi_2) - \mathsf{a}_0(y_2,\xi_2)$ by $B_1(x_2-y_2)$, and also terms corresponding to $m = 2$ in the same successive approximations and there one can replace $\mathsf{a}_0(x_2,\xi_2) - \mathsf{a}_0(y_2,\xi_2)$ by $B_2(x_2-y_2)^2$.

To calculate the contribution of such terms one can apply the same approach as in the proof of Proposition 14.7.19 and the contribution of γ-admissible partition element with respect to x_1 will be

$$\sum_m \mu h^{1+2m}\int \varkappa_{l,m,k}(x_2)\psi(x)\gamma^{\nu-2m-3+k}\,dx$$

with $k \ge 0$; however since this expression should be $O(|\log h|^K)$ all the terms but those with $\nu \le 2m+1$, $k \ge 1$ should vanish; further, the total contribution of all remaining terms save those with $\nu = 2m+1$ and $k = 1$ is $O(1)$, which leaves us with no "bad" terms for even ν and with one "bad" term $\kappa'_l\mu h^\nu \log h$ for odd ν, $m = (\nu-1)/2$. However, parity considerations with respect to x_1 show that this term should vanish as well. □

Remark 14.7.22. (i) All the coefficients $\varkappa_{I,*}$ and $\kappa_{I,*}$ vanish for $I = 0$.

(ii) Obviously the same approximate expressions (14.4.63), (14.4.63)* hold for part $\mathcal{N}^{\mathsf{MW}}_{\mathsf{corr}}$ "associated" with $\mathcal{Y}_{\mathsf{deg}}$.

14.8 Superstrong Magnetic Field

14.8.1 Preliminary Analysis

In this section we consider the case of *superstrong magnetic field*

$$\mu \geq \epsilon_0 h^{-\nu} \tag{14.8.1}$$

which in turn consists of two subcases: transitional superstrong magnetic field

$$\epsilon_0 h^{-\nu} \leq \mu \leq C_0 h^{-\nu} \tag{14.8.2}$$

and genuine superstrong magnetic field

$$\mu \geq C_0 h^{-\nu}. \tag{14.8.3}$$

In the latter case the previous definition of distances does not make sense anymore and we need to consider 1D-pseudodifferential operator with operator valued symbol, which is a perturbed operator

$$h^2 D_1^2 + \bigl(hD_2 - \mu x_1^\nu/\nu\bigr)^2 - \mu h x_1^{\nu-1}\mathfrak{z} - W(x); \tag{14.8.4}$$

rescaling $x_1 \mapsto x_1/\hbar$ with

$$\hbar = (\mu^{-1}h)^{1/(\nu+1)} \tag{14.8.5}$$

we arrive to a perturbed operator

$$(\mu h^\nu)^{2/\nu+1}\Bigl(D_1^2 + \bigl(\hbar D_2 - x_1^\nu/\nu\bigr)^2 - \mu h x_1^{\nu-1}\mathfrak{z}\Bigr) - W(\hbar x_1, x_2). \tag{14.8.6}$$

In virtue of Appendix 14.A this latter operator could be diagonalized to a perturbed operator

$$(\mu h^\nu)^{2/\nu+1}\lambda_n(\hbar D_2) - W(\hbar x_1, x_2) \tag{14.8.7}$$

where

(14.8.8) $\lambda_n(\eta) = \lambda_n(\eta;\mathfrak{z})$ ($n = 0, 1, ...$) are eigenvalues of operator

$$L(\eta;\mathfrak{z}) = D_1^2 + \bigl(\eta - x_1^\nu/\nu\bigr)^2 - \mu h x_1^{\nu-1}\mathfrak{z} \tag{14.8.9}$$

and all of these operators save C are elliptic; in the case of (14.8.3) only operators with $n = 0, ..., \lfloor \frac{1}{2}(\mathfrak{z}-1)\rfloor$ may be not elliptic. In particular, we conclude that

Proposition 14.8.1. *(i) For* $\mathfrak{z} \in [0,1)$ *case* (14.8.3) *is trivial with the main part of asymptotics equal* 0 *and the remainder estimate* $O(\mu^{-s})$.

(ii) For $\mathfrak{z} \in [0,1]$ *under assumption* $(14.7.4)_-$ *case* (14.8.1) *is trivial.*

14.8.2 Transitional Superstrong Magnetic Field

Let us consider case (14.8.2) when factor $(\mu h^\nu)^{2/(\nu+1)}$ in front of λ_n is of magnitude 1. Note that $\lambda_n(\eta)$ stabilize as $\eta \to \pm\infty$ either to $\pm\infty$ or to 0. In the former case we are in the framework of elliptic theory; in the latter case we are in the framework of elliptic theory under conditions $(14.7.4)_\pm$ and in both cases contribution of zones $\pm\eta \ge C$ to the remainder are negligible:

(14.8.10) Let condition (14.8.2) be fulfilled. Further, let either $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ or condition $(14.7.4)_\pm$ be fulfilled. Then all operators (14.8.7) and thus operator $\mathsf{a}(x_2,\eta)$ are elliptic in the zone $\mathcal{Y}_{\mathsf{ff}}$ and the contribution of $\mathcal{Y}_{\mathsf{ff}}$ to the Tauberian remainder estimate is negligible.

On the other hand, if $\mathfrak{z} = (2l+1)$ with $l \in \mathbb{Z}^+$ then all operators (14.8.7) with $n \ne l$ (and even with $n = l$ but with $-\eta \gg 1$ as ν is even) are elliptic but operator with $n = l$ is not. However under condition (14.7.5) we are in the framework of microhyperbolic theory everywhere:

Proposition 14.8.2. *Similarly, let* $\mathfrak{z} \in (2\mathbb{Z}^+ + 1)$. *Then under conditions* (14.8.2) *and* (14.7.5) *operator* $\mathsf{a}(x,\eta)$ *is* x_2*-microhyperbolic everywhere and the total remainder estimate is* $O(1)$.

Proof. Really, contributions of zones $\{|\eta| \le C\}$ and $\{\eta \asymp \rho\}$ are obviously $O(1)$ due to microhyperbolicity and remainder estimate $O(|\log\mu|)$ is trivial. To recover remainder estimate $O(1)$ let us notice that in propagation in the direction of increasing $|\eta|$ in zone $\{|\eta| \ge C\}$ one can take $T^*(\eta) \asymp |\eta|^{1+\delta}$ rather than $T^*(\eta) \asymp |\eta|$ and then $\int T^{*-1}(\eta)\,d\eta \le C$. We leave easy details to the reader. □

In the absence of condition (14.7.5) consider zone $\{|\eta| \le C\}$. We have a real problem as we do not know how for η with $|\eta| \le C$ $\lambda_n(\eta)$ depends on η (albeit we know for $|\eta| \gg 1$). It contrasts to the case of $\nu = 1$ but operator on half-line when this behavior is well established (see Appendix 15.A). In our present case we may only have some conjectures.

However we do know that $\lambda_n(\eta, \mathfrak{z})$ are analytic and non-constant except of the case of odd ν, $\mathfrak{z} = 1$ and $n = 0$ and therefore with this singular exception we conclude that condition

$$\sum_{1\le k\le m} |\partial_\eta^k \lambda_n(\eta)| \ge \epsilon_0 \qquad n \le C, |\eta| \le C \tag{14.8.11}_r$$

for some $r = r(\nu, C)$.

Then in virtue of results of Subsection 5.2.3 we arrive to the remainder estimate $O(1)$ under assumption

$$|(\mu h^\nu)^{2/(\nu+1)}\lambda_n(\eta, \mathfrak{z}) - W(x_2)| + |\partial_{x_2} W(x_2)| + |\partial_{x_2}^2 W(x_2)| \ge \epsilon_1 \qquad \forall n \quad \forall \eta, x_2. \tag{14.8.12}$$

Symmetrically, the remainder estimate is also $O(1)$ under assumptions $(14.8.11)_2$ and $(14.3.111)_m$ for some m.

On the other hand in virtue of results of Subsection 5.2.4 without this assumption the remainder is $O(h^{-\delta})$ with arbitrarily small exponent $\delta > 0$.

Note, that under condition

$$|(\mu h^\nu)^{2/(\nu+1)}\lambda_n(\eta, \mathfrak{z}) - W(x_2)| \ge \epsilon_1 \qquad \forall n \quad \forall \eta, x_2 \tag{14.8.13}$$

we are in the framework of elliptic theory; in particular, we are in the framework of elliptic theory in the case of odd ν, $\mathfrak{z} = 1$ and $n = 0$ provided $(14.7.4)_+$ is fulfilled (while this case is trivial under condition $(14.7.4)_-$) .

Meanwhile the principal part of asymptotics is expected to be of magnitude $O(\mu^{-1}h)$ but it would be less, only $O(\mu^{-1/(\nu+1)}h^{1/\nu+1})$ if only zone $\{|\eta| \le C\}$ contributes there.

So, we arrive to two propositions below:

Proposition 14.8.3. *Let condition* (14.8.2) *be fulfilled. Then under condition* (14.8.13) *Tauberian remainder is* $O(\mu^{-s})$.

Proposition 14.8.4. *Let condition* (14.8.2) *be fulfilled. Assume that* <u>*either*</u> $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ <u>*or*</u> $\mathfrak{z} \in (2\mathbb{Z}^+ + 1)$ *and one of conditions* $(14.7.4)_\pm$ *is fulfilled. Then*

(i) Tauberian remainder is $O(\mu^{\delta})$.

(ii) Under assumption (14.8.12) *Tauberian remainder is* $O(1)$.

(iii) Under assumptions $(14.8.11)_2$ *and* $(14.3.111)_m$ *for some* m *Tauberian remainder is* $O(1)$ *as well.*

Calculations in this case also do not differ from those in Section 14.5 except that in zone $\{|\eta| \le C\}$ in absence of strong non-degeneracy condition one needs to have $\lambda_n(x_2,\eta)$ the full Weyl symbols of diagonalized operators. So we arrive to the following theorem:

Theorem 14.8.5. *Let condition* (14.8.2) *be fulfilled. Further, let* <u>*either*</u> $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ <u>*or*</u> $\mathfrak{z} \in (2\mathbb{Z}^+ + 1)$ *and one of condition* $(14.7.4)_{\pm}$, (14.7.5) *be fulfilled. Then for* R_I *defined by* (14.7.30) *for complete symbol* $a(x_2,\xi_2)$ *of the reduced operator estimates of Propositions 14.8.3 and 14.8.4 hold under additional assumptions of these propositions.*

According to Chapter 5 we can ignore $O(\hbar)$ perturbations without deteriorating (much) remainder estimate if either (14.7.5) is fulfilled, or both (14.8.12) and $(14.8.11)_2$ are fulfilled and in the latter case remainder is $O(1)$ if $\lambda_{k,\eta\eta}$ and $-W_{x_2x_2}$ have the same signs in the critical points; otherwise remainder is $O(|\log\hbar|)$. Finally, under either condition (14.8.12), $(14.8.11)_2$ remainder is $O(\hbar^{-1})$. So we arrive to another theorem:

Theorem 14.8.6. *Let condition* (14.8.2) *be fulfilled. Further, let* <u>*either*</u> $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ <u>*or*</u> $\mathfrak{z} \in (2\mathbb{Z}^+ + 1)$ *and one of conditions* $(14.7.4)_{\pm}$, (14.7.5) *be fulfilled. Then for* R^* *defined by* (14.7.32) *the following estimates hold:*

(i) $O(\mu^{-s})$ *under condition* (14.8.13).

(ii) $O(1)$ *as* <u>*either*</u> *condition* (14.7.5) <u>*or*</u> *both conditions* (14.8.12) *and* $(14.8.11)_2$ *are fulfilled and in such points* $\lambda_{k,\eta\eta}$ *and* $-W_{x_2x_2}$ *have the same signs.*

(iii) $O(\log\mu)$ *as both conditions* (14.8.12) *and* $(14.8.11)_2$ *are fulfilled.*

(iv) $O(\hbar^{-\frac{1}{2}}) = O(\mu^{1/(2(\nu+1))}h^{-1/(2(\nu+1))})$ *as one of conditions* (14.8.12) *and* $(14.8.11)_2$ *is fulfilled.*

14.8.3 Genuine Superstrong Magnetic Field

Now we consider the previously forbidden case (14.8.3) with sufficiently large constant C_0. In this case all zones should be redefined as mentioned in Subsection 14.8.1.

Recall that now λ_n acquire a large factor $(\mu h^\nu)^{2/(\nu+1)}$ or, alternatively that W acquires a small factor $(\mu h^\nu)^{-2/(\nu+1)}$.

Degeneration Zone

Degeneration zone $\{|\eta| \le C\}$ can be treated approximately as in the case of condition (14.8.2). We refer here to methods of Section 15.4 [32] which could be applied without any modifications.

Then we arrive to the following proposition:

Proposition 14.8.7. *Let* (14.8.3) *be fulfilled. Then contribution of zone* $\{|\eta| \le C\}$ *to the Tauberian remainder and* R_I *are*

(i) $O(\mu^{-s})$ *provided*

$$|\lambda_n(\eta)| \ge \epsilon_0 \qquad \forall n, |\eta| \le C. \tag{14.8.14}$$

(ii) $O(1)$ *provided one of conditions* $(14.8.11)_1$, (14.7.5) *is fulfilled.*

(iii) $O(|\log \mu|)$ *if both* $(14.3.111)_2$ *and* $(14.8.11)_2$ *are fulfilled; further, if both* $\lambda_{n,\eta\eta}(\eta)$ *and* $-W_{x_2x_2}(x_2)$ *have the same signs as*

$$|\lambda_n(\eta)| + |\lambda_{n,\eta}(\eta)| + |W_{x_2}(x_2)| \le \epsilon.$$

this estimate is actually $O(1)$.

Recall that as ν is odd, $\mathfrak{z} = 1$ then λ_0 is identically 0 and as $n = 0$ no other above assumption but (14.7.5) could be fulfilled. However then assumption $(14.7.4)_\pm$ provides ellipticity as $n = 0$; meanwhile then $\lambda_n \ge \epsilon$ for all $n \ge 1$ and we arrive to the following proposition:

Proposition 14.8.8. *Let conditions* (14.8.3) *and* $(14.7.4)_\pm$ *be fulfilled,* ν *be odd and* $\mathfrak{z} = 1$. *Then Tauberian remainder and* R_I *are* $O(\mu^{-s})$*; meanwhile the principal part of asymptotics is* 0 *under condition* $(14.7.4)_-$.

[32] Chapter 15 was written before this chapter and is independent from it with the singular exception of Subsection 15.5.3.

Corollary 14.8.9. *(i) As* $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ *all statements of Proposition 14.8.7 hold for total* R^*.

(ii) As $\mathfrak{z} = (2l+1)$, $l \in \mathbb{Z}^+$ *in what follows we need to investigate only* $n = l$.

(iii) As $\mathfrak{z} = 1$ *and* ν *is odd we need in what follows to investigate only* $n = 0$ *and only if* $(14.7.4)_\pm$ *are violated.*

Regular Zone: Case $\mathfrak{z} \neq 1$

As $|\eta| \geq C$ let us consider first eigenvalues $\lambda_n(x_2, \xi_2, \mu, h)$ of operator $a_0(x_2, \xi_2, \mu, h)$. Then in virtue of Proposition 14.A.3

(14.8.15) As $\mathfrak{z} \neq 2n+1$ and $|\eta| \geq C_0$,

$$\lambda_n(x_2, \eta, \mu, h) \asymp (2n+1-\mathfrak{z})|\eta|^{(\nu-1)/\nu}; \tag{14.8.16}$$

and signs of the left and right-hand expressions coincide[33)]

and in virtue of Proposition 14.A.5

(14.8.17) As $\mathfrak{z} = 2n+1$

$$\lambda_n(x_2, \xi_2, \mu, h) \sim \alpha_n \eta^{-2/\nu} \qquad \text{with} \quad \alpha_n > 0. \tag{14.8.18}$$

Therefore we conclude that

(14.8.19) As $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ zone $\{|\eta| \geq C_0\}$ is elliptic and its contribution to the Tauberian remainder is $O(\mu^{-s})$

and

(14.8.20) As $\mathfrak{z} = 2n+1$ with $n \geq 1$ zone $\{C_0 \leq |\eta| \leq \epsilon(\mu h^\nu)^{\nu/(\nu+1)}\}$ is elliptic and its contribution to the Tauberian remainder is $O(\mu^{-s})$.

On the other hand,

[33)] Recall that for even ν zone $\{\eta \leq -C_0\}$ is always elliptic and only zone $\{\eta \geq C_0\}$ needs to be considered now.

(14.8.21) Let $\mathfrak{z} = 2n+1$, $n \ge 0$ and condition $(14.7.4)_\pm$ be fulfilled. Then zone $\{|\eta| \ge C(\mu h^\nu)^{\nu/(\nu+1)}\}$ is elliptic as well and its contribution to the Tauberian remainder estimate is $O(\mu^{-s})$.

Therefore as $\mathfrak{z} = 2n+1$ with $n \ge 1$ and condition $(14.7.4)_\pm$ is fulfilled, one needs to analyze only zone

$$\mathcal{Y}_{\mathsf{trans}} := \{\epsilon\rho_1 \le |\eta| \le C\rho_1\}, \qquad \rho_1 = (\mu h^\nu)^{\nu/(\nu+1)} \tag{14.8.22}$$

and for even ν we need to consider here only $\eta > 0$.

In the zone $\mathcal{Y}_{\mathsf{trans}}$ propagation speed with respect to x_2 is exactly of magnitude[34)]

$$\lambda_{n,\eta} \asymp (\mu h^\nu)^{2/(\nu+1)}\rho^{-2/\nu-2} \asymp \rho^{-1}$$

(with $\rho = \rho_1$) due to Proposition 14.A.5 again[35)] and the propagation speed with respect to η is $O(1)$ and therefore one can take

$$T_* = C\hbar|\log\hbar|, \qquad T^* = \epsilon_1\rho_1 \tag{14.8.23}$$

and for $T \in [T_*, T^*]$ propagation on the energy levels $\tau \in [-\epsilon, \epsilon]$ which started in $B(0, \frac{1}{2})$ does not leave $B(0,1)$ but the shift with respect to x_2 is $\asymp \rho^{-1}T$ and it satisfies logarithmic uncertainty principle and thus the spectral trace is negligible.

Remark 14.8.10. These arguments are easily extended to the case when $\boldsymbol{a}$ does not coincide with $\boldsymbol{a}_0$ since perturbation will change speed by $O(\hbar)$ and original zone $\{|x_1| \le \epsilon\}$ becomes $\{|\eta| \le \epsilon\hbar^{-1}\}$.

Therefore[34)] expression

$$|F_{t\to\hbar^{-1}\tau}\bar{\chi}_T(t)(Qu)| \tag{14.8.24}$$

does not exceed $C\hbar^{-1}\rho T_* = C\rho|\log\mu|$ where Q is a partition element corresponding to $\mathcal{Y}_{\mathsf{trans}}$, $|\tau| \le \epsilon$.

Then due to the Tauberian arguments the contribution of this zone to the remainder is $O(\hbar^{-1}T_*/T^*) = O(\log\mu)$. One can get rid of this superficial logarithmic factor both in the estimate of (14.8.24) and in the remainder estimate; standard details we leave to the reader. Thus we arrive to the following proposition:

[34)] After rescaling $t_{\mathsf{new}} = \hbar h^{-1}t_{\mathsf{old}} = (\mu h^\nu)^{-1/(\nu+1)}t_{\mathsf{old}}$. Recall that $\hbar = (\mu^{-1}h)^{1/(\nu+1)}$.

[35)] At least if either $\boldsymbol{a} = \boldsymbol{a}_0$.

Proposition 14.8.11. *Let* $\mathfrak{z} = 2n+1$ *with* $n \ge 1$ *and conditions* $(14.7.4)_\pm$ *and* (14.8.3) *be fulfilled. Then as* Q *is supported in the zone* $\mathcal{Y}_{\mathsf{trans}}$ *expression* (14.8.24) *does not exceed* $C\rho_1$ *and the contribution of* $\mathcal{Y}_{\mathsf{trans}}$ *to the Tauberian remainder is* $O(1)$.

On the other hand we would like to note that eigenvalue $\lambda_l(\eta)$ tends to $+0$ as $|\eta| \to +\infty$ and therefore we conclude that

Proposition 14.8.12. *Let condition* (14.8.3) *be fulfilled. Let* $1 \ne \mathfrak{z} \in (2\mathbb{Z}^+ + 1)1$ *and condition* $(14.7.4)_-$ *be fulfilled. Then zone* $\mathcal{Y}_{\mathsf{trans}}$ *is elliptic and its contribution to the remainder is* $O(\mu^{-s})$,

Regular Zone: Case $\mathfrak{z} = 1$

Let us consider the special case $\mathfrak{z} = 1$; recall that then only eigenvalue $\lambda_0(\eta)$ should be considered and that condition $(14.7.4)_-$ leads then to the asymptotics with the principal part 0 and remainder estimate $O(h^s)$ and therefore is excluded from the further consideration.

Further, as ν is odd $\lambda_0 = 0$ identically, condition $(14.7.4)_+$ provides ellipticity everywhere. Thus we arrive to

Proposition 14.8.13. *Let* $\mathfrak{z} = 1$, ν *be odd and conditions* $(14.7.4)_-$ *and* (14.8.3) *be fulfilled. Then the remainder estimate is* $O(\mu^{-s})$ *while the principal part is given by* (14.7.45).

On the other hand, if $\mathfrak{z} = 1$, ν is even and condition $(14.7.4)_-$ is fulfilled then due to Proposition 14.A.6 $\lambda_0(\eta)$ decays exponentially and ellipticity is violated only in the strip

$$\mathcal{Y}_{\mathsf{trans}} = \{\epsilon_1\Delta \le |\eta - \sigma\rho_0| \le C\Delta\}, \quad \text{with } \sigma \asymp |\log\rho_0|^{\nu/(\nu+1)} \text{ and } \Delta = \rho_0 |\log\rho_0|^{-1/(\nu+1)} \tag{14.8.25}$$

where as before $\rho_0 = (\mu h^\nu)^{1/(\nu+1)}$. In this strip propagation speed with respect to x_2 is $\asymp \Delta^{-1}$ and again

$$T_* = C\hbar\Delta|\log\hbar|, \qquad T^* = \epsilon\Delta \tag{14.8.26}$$

and expression (14.8.24) does not exceed $C\hbar^{-1}\Delta T_* = C\Delta|\log h|$ and therefore the Tauberian remainder is $O(|\log h|)$. Further, by the standard arguments one can get rid of the superficial logarithmic factors. Thus we arrive to

Proposition 14.8.14. *Let* $\mathfrak{z} = 1$, ν *be even and conditions* $(14.7.4)_+$ *and* (14.8.3) *be fulfilled. Then the contribution of* $\mathcal{Y}_{\mathsf{trans}}$ *to the remainder is* $O(1)$ *while the principal part is given by* (14.7.45) *with* T_0, T_1 *defined by* (14.8.26).

We leave details to the reader who can also look to Section 15.4 [32] for more detailed analysis as there all eigenvalues tend to their limits exponentially.

Regular Zone: Case of Condition (14.7.5)

Now we want to derive estimates under condition (14.7.5) instead of conditions $(14.7.4)_\pm$. Without condition $(14.7.4)_\pm$ some zones cease to be elliptic and should be reexamined:

(14.8.27) As $\mathfrak{z} = 2l+1$, $l \ge 1$ these zones are $\mathcal{Y} = \{\eta \ge \rho_1\}$ with ρ_1 defined by (14.8.22);

(14.8.28) As $\mathfrak{z} = 1$, ν even this zone is $\{|\eta| \ge C\rho_0 |\log \rho_0|^{\nu/(\nu+1)}\}$ with ρ_0 defined by (14.8.25);

(14.8.29) As $\mathfrak{z} = 1$, ν odd this zone is $\{|\eta| \le \epsilon\hbar^{-1}\}$.

Since condition (14.7.5) provides $T_* = C\hbar|\log\hbar|$ anyway the standard partition-rescaling arguments in all these zones imply that their total contribution to the remainder are $O(\log\mu)$; however additional arguments of the proof of Proposition 14.7.18 allow us to reduce it to $O(1)$. Therefore we arrive to

Proposition 14.8.15. *Let conditions* (14.8.3) *and* (14.7.5) *be fulfilled. Then the remainder estimate is* $O(1)$ *while the principal part of the asymptotics is given by* (14.7.45) *for different zones with any* $T \in [T_*, T^*]$, $T_* = C\hbar|\log\hbar|$ *and* T^* *defined as in Propositions 14.8.11–14.8.14.*

14.8.4 Calculations and Main Results

In this subsection we derive in more explicit form the principal parts of asymptotics.

Degeneration Zone and Case $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$

Consider degeneration zone $\{|\eta| \le C_0\}$. Then the standard method of successive approximations allows us to replace Tauberian expression with

$$(2\pi\hbar)^{-1} \int \mathsf{e}(x_2, \eta, 0)\psi(x_2)\varphi(\eta)\, dx_2 d\eta \tag{14.8.30}$$

with the same error as in Proposition 14.8.7. In similar way we can shed from operator $\boldsymbol{a}$ all terms which are $O(\hbar)$. We leave details to the reader; they are no different from those in Subsubsection 15.4.4.2 *Boundary Zone*[32].

This covers completely degenerate cases when ellipticity condition is fulfilled as $\{|\eta| \ge C_0\}$ and we arrive to the following statement except the case of condition $(14.7.4)_+$:

Theorem 14.8.16. *Let condition* (14.8.3) *be fulfilled. Assume also that* <u>*either*</u> $\mathfrak{z} \notin (2\mathbb{Z}^+ + 1)$ <u>*or*</u> $\mathfrak{z} \in (2\mathbb{Z}^+ + 1)$ *and one of condition* $(14.7.4)_\pm$ *is fulfilled. Then* R^* *defined by* (14.7.32) *is*

(i) $O(\mu^{-s})$ *under condition* (14.8.14).

(ii) $O(1)$ *provided one of conditions* $(14.8.11)_1$, (14.7.5) *is fulfilled.*

(iii) $O(|\log \mu|)$ *if both* $(14.3.111)_2$ *and* $(14.8.11)_2$ *are fulfilled; further, if both* $\lambda_{n,\eta\eta}(\eta)$ *and* $-W_{x_2x_2}(x_2)$ *have the same signs as*

$$|\lambda_n(\eta)| + |\lambda_{n,\eta}(\eta)| + |W_{x_2}(x_2)| \le \epsilon.$$

this estimate is actually $O(1)$.

We also arrive to

Theorem 14.8.17. *Let conditions* (14.8.3) *and* $(14.7.4)_\pm$ *be fulfilled,* ν *be odd and* $\mathfrak{z} = 1$. *Then Tauberian remainder and* R_I *are* $O(\mu^{-s})$*; meanwhile the principal part of asymptotics is* 0 *under condition* $(14.7.4)_-$.

Calculations under Conditions $(14.7.4)_\pm$

Consider now case not covered by the previous subsubsection, however we assume that $(14.7.4)_+$ is fulfilled. Then for $\mathfrak{z} = (2n+1)$ we need to consider only zone $\mathcal{Y}_{\mathsf{trans}}$ defined by (14.8.22) or (14.8.25) respectively as $n \ge 1$ and $n = 0$. Details are similar to those in Subsubsection 15.4.4.3 *Transitional Zone*[32] but simpler; we leave them to the reader. This finishes justification of Theorem 14.8.16.

Calculations under Condition (14.7.5)

In this case we need to reconsider only zones $\{|\eta| \ge C\rho_1\}$ and $\{|\eta| \ge C\rho_0\}$ with ρ_1 or ρ_0 defined by (14.8.22) or (14.8.25) respectively as $n \ge 1$ and $n = 0$. Details are similar to those in Subsubsection 15.4.4.1 *Inner Zone*[32)] but simpler; we leave them to the reader. Then we arrive to

Theorem 14.8.18. *Let conditions* (14.8.3) *and* (14.7.5) *be fulfilled. Then* R^* *defined by* (14.7.32) *is* $O(1)$.

14.A Eigenvalues of 1D-Operators

General Observations

In this Appendix $\lambda_n(\eta, \mathfrak{z})$ ($n = 0, 1, \dots$) denote eigenvalues of one-dimensional toy-model Schrödinger operators with $\mu = h = 1$

$$L(\eta, \mathfrak{z}) \coloneqq a_0(\eta, \mathfrak{z}, 1, 1) = D^2 + (\eta - x^\nu/\nu)^2 - \mathfrak{z}x^{\nu-1} \tag{14.A.1}$$

with $\nu = 2, 3, \dots$.

If there were parameters μ, h

$$a_0(\eta, \mathfrak{z}, \mu, h) = h^2D^2 + (\eta - \mu x^\nu/\nu)^2 - \mathfrak{z}\mu h x^{\nu-1} \tag{14.A.2}$$

then scaling $x \mapsto x\gamma$, $D \mapsto \gamma^{-1}D$ with $\gamma = (\mu^{-1}h)^{-1/(\nu+1)}$ we get operator $(\mu h^\nu)^{2(\nu+1)}L(\eta', \mathfrak{z})$ with $\eta' = (\mu h^\nu)^{-1/(\nu+1)}$.

We are interested in operator (14.A.1) with fixed $\mathfrak{z} \in \mathbb{R}$ and variable η. One can prove easily the following statement:

Proposition 14.A.1. *Let* $\mathfrak{z} \in \mathbb{R}$. *Then*

(i) As $|\eta| \le C_0$ *the spacing between two consecutive eigenvalues* $\lambda_n(\eta, \mathfrak{z})$ *and* $\lambda_{n+1}(\eta, \mathfrak{z})$ *with* $n \le c_0$ *is* $\asymp 1$.

(ii) For operator $L(\eta, \mathfrak{z})$ *with odd* ν $\lambda_n(-\eta, \mathfrak{z}) = \lambda_n(\eta, \mathfrak{z})$.

(iii) For operator $L(\eta, \mathfrak{z})$ *with even* ν *and* $\eta \le 0$ $\lambda_n(\eta, \mathfrak{z}) \ge (1 - \epsilon)\eta^2 - C_1$ $\forall n = 0, 1, \dots$.

However, the case of even ν and $\eta \to -\infty$ is rather exceptional.

14.A.1 Asymptotics as $\eta \to +\infty$

Remark 14.A.2. Observe that

(i) As ν is odd operators in question have for large η one potential well with the bottom near $x = \ell = (\nu\eta)^{1/\nu}$; in the case of $\mathfrak{z} = 0$ bottom is exactly in $x = \ell$.

(ii) As ν is even and $\eta \ge C_0$ there will be two distant potential wells with the bottoms near $x = \pm\ell = \pm(\nu\eta)^{1/\nu}$; in the case of $\mathfrak{z} = 0$ these wells are symmetric and bottoms are exactly at $\eta = \pm\ell$.

To derive asymptotics of $\lambda_n(\eta, \mathfrak{z})$ as $\eta \to +\infty$ (and thus in the case of odd ν also as $\eta \to -\infty$) let us consider these wells (separately as ν is even).

Let us plug $\eta = \ell^\nu/\nu$ with $\ell \gg 1$ where in the case even ν this is the only scenario and in the case of odd ν analysis of scenario $\xi_2 = -\ell^\nu/\nu$ is done by the symmetry. Then after shift $x \mapsto x + \ell$ operator $L(\eta, \mathfrak{z})$ is transformed into operator

$$D^2 + x^2\Big(\ell^{\nu-1} + \frac{1}{2}(\nu-1)x\ell^{\nu-2} + \frac{1}{6}(\nu-1)(\nu-2)x^2\ell^{\nu-3} + \dots\Big)^2 - \mathfrak{z}\Big(\ell^{\nu-1} + (\nu-1)x\ell^{\nu-2} + \frac{1}{2}(\nu-1)(\nu-2)x^2\ell^{\nu-3} + \dots\Big)$$

and after rescaling $x \mapsto x\ell^{(1-\nu)/2}$ this operator is transformed into $\ell^{\nu-1}\boldsymbol{b}_\varepsilon$ where

$$\boldsymbol{b}_\varepsilon = D^2 + x^2\Big(1 + \frac{1}{2}(\nu-1)x\varepsilon + \frac{1}{6}(\nu-1)(\nu-2)x^2\varepsilon^2 + \dots\Big)^2 - \mathfrak{z}\Big(1 + (\nu-1)x\varepsilon + \frac{1}{2}(\nu-1)(\nu-2)x^2\varepsilon^2 + \dots\Big)$$

with $\varepsilon = \ell^{-(\nu+1)/2}$. Then

$$\boldsymbol{b}_\varepsilon = \underbrace{D^2 + x^2 - \mathfrak{z}}_{\boldsymbol{h}_0} + \varepsilon \underbrace{(\nu-1)\Big(x^3 - \mathfrak{z}x\Big)}_{\boldsymbol{h}_1} + \varepsilon^2 \underbrace{(\nu-1)\Big((\frac{7}{12}\nu - \frac{11}{12})x^4 - \frac{1}{2}\mathfrak{z}(\nu-2)x^2\Big)}_{\boldsymbol{h}_2} + O(\varepsilon^3) \tag{14.A.3}$$

which immediately implies

Proposition 14.A.3. *(i) As ν is odd for $n \le c_0$, $|\eta| \gg 1$*

$$\lambda_n(\eta, \mathfrak{z}) = (2n+1-\mathfrak{z})(\eta\nu)^{(\nu-1)/\nu} + O(\eta^{-2/\nu}); \tag{14.A.4}$$

(ii) As ν is even then for $|\eta| \gg 1$, $\eta > 0$ there are two series of eigenvalues

$$\lambda_{\pm,n}(\eta, \mathfrak{z}) = (2n+1\mp\mathfrak{z})(\eta\nu)^{(\nu-1)/\nu} + O(\eta^{-2/\nu}). \tag{14.A.5}$$

Proof. Indeed, the standard theory just gives

$$\lambda_n(\eta, \mathfrak{z}) = \big(2n+1-\mathfrak{z}+O(\varepsilon^2)\big)\ell^{\nu-1}$$

in both Statements (i) and (ii) as we plug $x \mapsto x+\ell$ and also

$$\lambda_n(\eta, \mathfrak{z}) = \big(2n+1+\mathfrak{z}+O(\varepsilon^2)\big)\ell^{\nu-1}$$

in Statement (ii) only as we plug $x \mapsto x-\ell$. We eliminate linear terms by $O(\varepsilon)$ shift with respect to x. □

This leaves us with

Corollary 14.A.4. *(i) As ν is odd and $\eta \ge C_0$ the spacing between eigenvalues with $n \le c_0$ is $\asymp (1+|\eta|)^{(\nu-1)/\nu}$; further, eigenvalues with $2n+1 \lessgtr \mathfrak{z}$ are $\asymp \eta^{(\nu-1)/\nu}$ and negative (positive respectively).*

(ii) As ν is even the spacing between eigenvalues in the same series with $n \le c_0$ is $\asymp (1+|\eta|)^{(\nu-1)/\nu}$; further, eigenvalues $\lambda_{\pm,n}(\eta, \mathfrak{z})$ with $2n+1 \lessgtr \pm\mathfrak{z}$ are $\asymp \eta^{(\nu-1)/\nu}$ and negative (positive respectively).

This completely describes eigenvalue $\lambda_n(\eta, \mathfrak{z})$ as $\mathfrak{z} \ge 0$ and $\mathfrak{z} \ne 2n+1$.

To describe case $2n+1 = \mathfrak{z}$ let us denote by Ω_ε and U_ε its eigenvalue close to 0 and the corresponding eigenfunction. Then

$$\Omega_\varepsilon = \omega_1\varepsilon + \omega_2\varepsilon^2 + ... \qquad \text{and} \qquad U_\varepsilon = u_0 + u_1\varepsilon + u_2\varepsilon^2 + ... \tag{14.A.6}$$

where obviously $u_0 = v_l$ is a Hermite function, $\omega_1 = \omega_3 = ... = 0$ and

$$\boldsymbol{h}_0 u_1 + \boldsymbol{h}_1 u_0 = 0 \qquad \boldsymbol{h}_0 u_2 + \boldsymbol{h}_1 u + \boldsymbol{h}_2 u_0 = \omega_2 u_0. \tag{14.A.7}$$

Therefore

$$\omega_2 = \langle \boldsymbol{h}_1 u + \boldsymbol{h}_2 u_0, u_0\rangle = -\langle u, \boldsymbol{h}_0 u\rangle + \langle \boldsymbol{h}_2 u_0, u_0\rangle. \tag{14.A.8}$$

It is known that $(x-iD)\upsilon_k = (2k+2)^{1/2}\upsilon_{k+1}$, $(x+iD)\upsilon_k = (2k)^{1/2}\upsilon_{k-1}$ and therefore

$$x\upsilon_n = \tfrac{1}{2}\Big((2n+2)^{1/2}\upsilon_{n+1} + (2n)^{1/2}\upsilon_{n-1}\Big),$$

$$x^2\upsilon_n = \tfrac{1}{4}\Big((2n+2)^{1/2}(2n+4)^{1/2}\upsilon_{n+2} + (4n+2)\upsilon_n + (2n)^{1/2}(2n-2)^{1/2}\upsilon_{n-2}\Big),$$

$$\big(x^2-2n-1\big)\upsilon_n = \tfrac{1}{4}\Big((2n+2)^{1/2}(2n+4)^{1/2}\upsilon_{n+2} - 2(2n+1)\upsilon_n + (2n)^{1/2}(2n-2)^{1/2}\upsilon_{n-2}\Big),$$

$$x\big(x^2-2n-1\big)\upsilon_n = \tfrac{1}{8}\Big((2n+2)^{1/2}(2n+4)^{1/2}(2n+6)^{1/2}\upsilon_{n+3} - (2n+2)^{1/2}(2n-2)\upsilon_{n+1} - (2n)^{1/2}(2n+4)\upsilon_{n-1} + (2n)^{1/2}(2n-2)^{1/2}(2n-4)^{1/2}\upsilon_{n-3}\Big),$$

which imply

$$\langle \boldsymbol{h}_0 u, u\rangle = \frac{1}{64}(\nu-1)^2\Big(\frac{1}{6}(2n+2)(2n+4)(2n+6) + \frac{1}{2}(2n+2)(2n-2)^2 - \frac{1}{2}(2n)(2n+4)^2 - \frac{1}{6}(2n)(2n-2)(2n-4)\Big) = \frac{1}{16}(\nu-1)^2\big(-2n^2-2n+3\big).$$

On the other hand

$$\langle \boldsymbol{h}_2 u_0, u_0\rangle = (\nu-1)\Big((\frac{7}{12}\nu - \frac{11}{12})\|x^2u_0\|^2 - \frac{1}{2}(\nu-2)(2n+1)\|xu_0\|^2\Big) = (\nu-1)(\frac{7}{12}\nu-\frac{11}{12})\cdot\frac{1}{16}\Big((2n+2)(2n+4) + (4n+2)^2 + (2n)(2ln-2)\Big) - \frac{1}{4}(\nu-1)(\nu-2)\cdot(2n+1)^2 = (\nu-1)(7\nu-11)\cdot\frac{1}{16}\Big(2n^2+2n+1\Big) - \frac{1}{4}(\nu-1)(\nu-2)(2n+1)^2$$

and

$$\omega_2 = \frac{1}{16}(\nu-1)\Big((7\nu-11)\big(2n^2+2n+1\big) - 4(\nu-2)\big(4n^2+4n+1\big) - (\nu-1)\big(-2n^2-2n+3\big)\Big) = \frac{1}{2}(\nu-1)n(n+1),$$

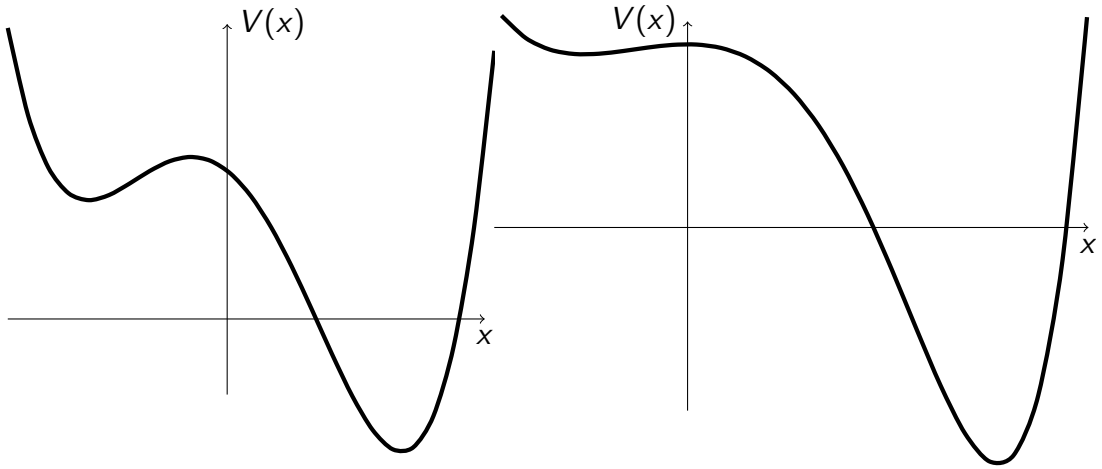
Therefore $\Omega_\varepsilon = \omega_2\varepsilon^2 + O(\varepsilon^4)$ as $\varepsilon \to 0$ (because $\omega_3 = 0$ as well) which implies the following statement with $\kappa = \omega_2\nu^{-2/\nu}$:

Proposition 14.A.5. *(i) Let* ν *be odd,* $\mathfrak{z} = 2n+1$, $n \geq 1$. *Then as* $|\eta| \to +\infty$

$$\lambda_n(\eta, \mathfrak{z}) = \kappa \eta^{-2/\nu} + O\big(\eta^{-(\nu+3)/\nu}\big) \tag{14.A.9}$$

with $\kappa > 0$.

(ii) Let ν *be even,* $\mathfrak{z} = 2n+1$, $n \geq 1$. *Then as* $\eta \to +\infty$ (14.A.9) *holds for* $\lambda_{+,n}(\eta, 2n+1)$.



(a) ν even (b) ν odd

Figure 14.8: Graphs of $V(x) = V(x; \eta, \mathfrak{z})$, with $\mathfrak{z} > 0$; one see two wells but the right one is much deeper.

14.A.2 Case of $\mathfrak{z} = 1$

Here cases of odd and even ν differ drastically. Note first that

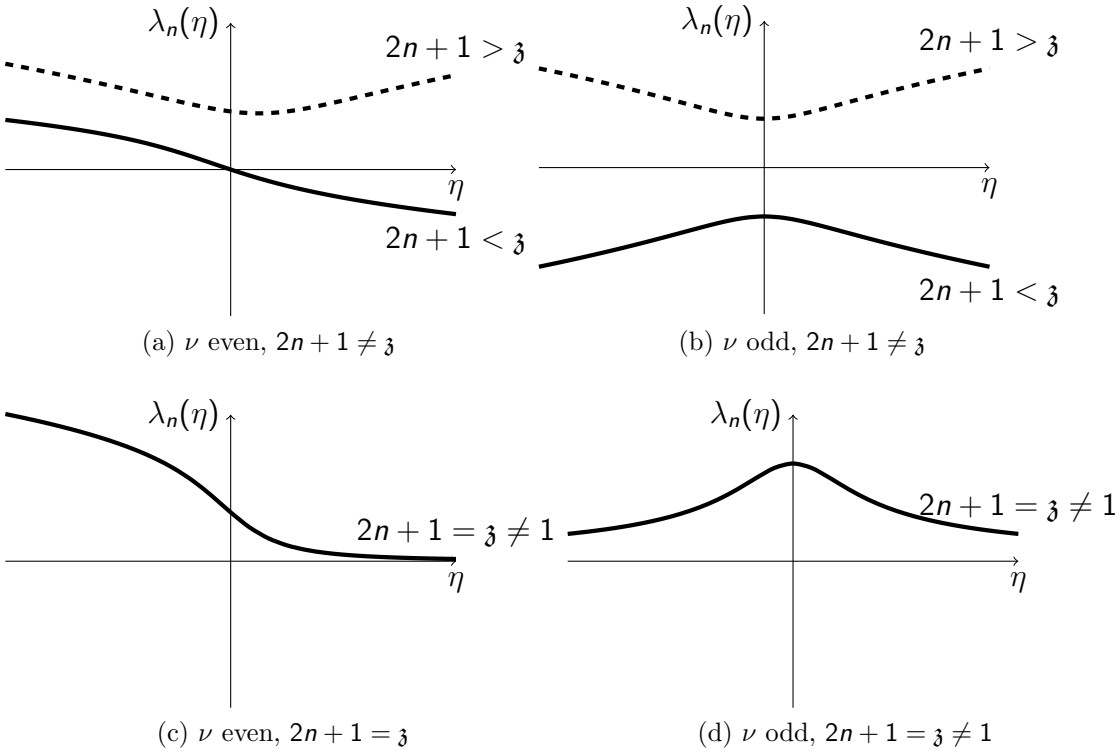
$$L(\eta, 1) = \big(iD + \eta - x^\nu/\nu\big)\big(-iD + \eta - x^\nu/\nu\big) = \boldsymbol{b}(\eta)^* \boldsymbol{b}(\eta) \tag{14.A.10}$$

with

$$\boldsymbol{b} = -\partial + \eta + x^\nu/\nu \tag{14.A.11}$$

and as ν is odd operator $L(\eta, 1)$ has the bottom eigenvalue $\lambda_0(\eta, 1)$ with eigenfunction defined from equation $\boldsymbol{b}v = \big(-\partial + \xi_2 - x^\nu/\nu\big)v = 0$ i.e.

$$v(x, \eta) = \exp(\eta x - x^{\nu+1}/\nu(\nu+1)) \tag{14.A.12}$$



(a) ν even, $2n+1 \neq \mathfrak{z}$ (b) ν odd, $2n+1 \neq \mathfrak{z}$

(c) ν even, $2n+1 = \mathfrak{z}$ (d) ν odd, $2n+1 = \mathfrak{z} \neq 1$

Figure 14.9: Sketches of graphs of $\lambda_n(\eta, \mathfrak{z})$: not the actual calculations.

and therefore $\lambda_0(\eta, 1)$ is identically 0.

Thus we arrive to Statement (i) of the following proposition:

Proposition 14.A.6. *(i) For odd ν the bottom eigenvalue of $L(\eta, 1)$ is identically 0.*

(ii) For even ν the bottom eigenvalue of $L(\eta, 1)$ is $\lambda_0(\eta, 1)$ such that

$$\lambda_0(\eta, 1) \sim 2(\nu\eta)^{(\nu-1)/\nu} \exp(-\kappa\eta^{(\nu+1)/\nu}), \qquad \kappa = 4\nu(\nu+1)/\nu/(\nu+1), \tag{14.A.13}$$

$$\partial_\eta^k \lambda_0(\eta, 1) \sim 2(-\kappa(\nu+1)/\nu)^k \eta^{k/\nu} \lambda_0(\eta, 1) \qquad k = 1, 2, ... \tag{14.A.14}$$

Proof. We need to consider the case of even ν only. While one can prove this statement based on construction of quazimodes (see B. Helffer–M. Klein–F. Nier [1] or A. Bovier–M. Eckhoff–V. Gayrard–M. Klein [1].

We, using basically the same idea will give a simplified "in-house" proof because we are interested in a single bottom eigenvalue $\lambda_0(\eta,1)$. While the same decomposition (14.A.10)–(14.A.11) holds for even ν but then operator $\boldsymbol{b}(\eta)$ has no null-space as $v(x,\eta)$ grows as $x\to-\infty$ and we conclude that $\lambda_0(\eta,1)>0$.

Here we skip in notations $\mathfrak{z}=1$. Let us modify operator and decomposition and define $M(\eta)$ by (14.A.10) but with

$$\boldsymbol{b}(\eta)=-\partial+(\eta-x^{\nu}/\nu)\,\mathsf{sgn}(x+\ell),\qquad \ell=(\nu\eta)^{1/\nu}; \tag{14.A.15}$$

then

$$M(\eta)=L(\eta)+2x^{\nu-1}\theta(-x-\ell) \tag{14.A.16}$$

and

$$V(x,\eta)=\begin{cases}\exp\bigl(\eta x-x^{\nu+1}/\nu(\nu+1)\bigr) & x>-\ell,\\ \exp\bigl(-\eta x+x^{\nu+1}/\nu(\nu+1)\bigr) & x<-\ell\end{cases} \tag{14.A.17}$$

annuls $\boldsymbol{b}(\eta)$. Note that $V(x,\eta)$ reaches its single maximum $\exp(\ell^{\nu+1}/(\nu+1))$ as $x=\ell$ and then as we define

$$v(x,\eta)=\pi^{-\frac14}\ell^{(\nu-1)/4}\exp\bigl(-s(x)\bigr) \tag{14.A.18}$$

with

$$s(x)=\begin{cases} S(x) & \text{as } x>-\ell,\\ -S(x)+2S(-\ell) & \text{as } x\le -\ell\end{cases}, \tag{14.A.19}$$

$$S(x)=-(x-\ell)\eta+(x^{\nu+1}-\ell^{\nu+1})/\nu(\nu+1), \tag{14.A.20}$$

we get $\|v\|\sim 1$. Here we took an extra factor $\sqrt{S''(\ell)/\pi}$ to ensure this as $S(\ell)=S'(\ell)=0$, $S''(\ell)=\ell^{\nu-1}$.

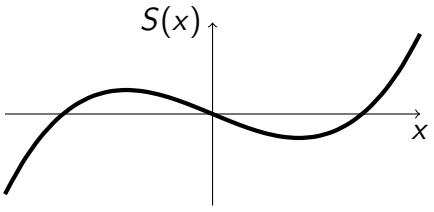


Figure 14.10: $S(x)$

Meanwhile

$$(L(\eta)v,v)=2\int_{-\infty}^{-\ell}|x|^{\nu-1}|v|^2\,dx\sim \ell^{\nu-1}\exp\bigl(-2S(-\ell)\bigr)= \tag{14.A.21}$$

$$\ell^{\nu-1}\exp\bigl(-4\ell^{\nu+1}/(\nu+1)\bigr)=:\varepsilon(\ell)$$

and

$$\|L(\eta_0)v\|^2 \sim 2\ell^{2(\nu-1)}\exp\bigl(-4\ell^{\nu+1}/(\nu+1)\bigr) = 2\ell^{\nu-1}\varepsilon(\ell) \tag{14.A.22}$$

as $S(-\ell) = 2\ell^{\nu+1}/(\nu+1)$, $S'(-\ell) = 0$, $S''(-\ell) = -S''(\ell)$.

Therefore

$$\lambda_0(\eta) \le \varepsilon(\ell)\bigl(1+o(1)\bigr). \tag{14.A.23}$$

So, upper estimate for $\lambda_0(\eta)$ has been proven.

Let u_n be all orthonormal eigenfunctions. As $\lambda_n \gtrsim \ell^{\nu-1}$ for $n \ge 1$ we conclude from

$$\lambda_n(\eta)(v,u_n) = (L(\eta)v,u_n) \le \|L(\eta)v\| \le c\ell^{(\nu-1)/2}\varepsilon^{1/2}$$

that

$$|(v,u_n)| \le c\ell^{(1-\nu)/2}\varepsilon^{1/2} \qquad \forall n \ge 1, \qquad (v,u_0) = 1 + O(\ell^{1-\nu}\varepsilon) \tag{14.A.24}$$

as $\|v\| = 1 + O(\ell^{1-\nu}\varepsilon)$, $\|u_0\| = 1$.

On the other hand

$$\lambda_0(eta) = \|(-\partial+\eta-x^\nu/\nu)u_0\|^2 \ge \|(-\partial+\eta-x^\nu/\nu)u_0\|^2_{x<y} = \|\partial u_0\|^2_{x<y} + \int_{-\infty}^{y}\bigl((\eta-x^\nu/\nu)^2 - x^{\nu-1}\bigr)|u_0|^2\,dx - (\eta-y^\nu/\nu)|u(y)|^2 \tag{14.A.25}$$

and picking $y = \ell - z$, $0 < z \asymp \gamma \ll \ell$ we conclude that

$$|u(-\ell-z)|^2 \le c\ell^{1-\nu}\gamma^{-1}\lambda_0 \asymp \lambda_0 \tag{14.A.26}$$

as $\gamma \asymp \ell^{1-\nu}$. Then scaling $x \mapsto (x+\ell)/\gamma$ with we find that in the new scale in equation (multiplied by γ^2) all large parameters disappear and then as this estimate (14.A.26) holds for $\partial_z u$ (after rescaling) as well and therefore

(14.A.27) Estimate (14.A.26) with c replaced by $C(t)$ holds for all $z : |z| \le t\gamma$.

Then $\|u\|_{x<-\ell+t\gamma} \le C(t)\lambda_0^{1/2}$ and taking into account (14.A.24) we conclude that $\|v\|_{x<-\ell+t\gamma} \le C(t)\lambda_0^{1/2} + C_0\varepsilon^{1/2}$. However the left-hand expression is $C_1(t)\varepsilon^{1/2}$ with $C_1(t) \ge 2C_0$ large for large enough $t > 0$. Then $\varepsilon \le C\lambda_0$ and lower estimate for λ_0 has been proven.

Now, we need to prove exact asymptotics. Obviously

$$0 = (L(\eta)v, u)_{x>-\ell} = (v, M(\eta)u)_{x>-\ell} + (uv_x - vu_x)|_{x=-\ell} = \lambda_0(\eta)(u, v)_{x>-\ell} - v(-\ell)\partial u(-\ell)$$

because $v_x(-\ell) = 0$ and therefore

$$\lambda_0(\ell) = v(-\ell, \ell)u_x(-\ell, \ell) + O\big(\lambda_0 \varepsilon^{1-\delta}\big) \tag{14.A.28}$$

where we consider ℓ rather than η as a main variable.

Let $v_1 = \pi^{-\frac{1}{4}} \ell^{(\nu-1)/4} \exp\big(-S(x)\big)$ and v_2 another element of null-space of $L(\eta)$ satisfying $v_2' v_1 - v_2 v_1' = 1$ and decaying as $x \to -\infty$:

$$v_2 = v_1 \int_{-\infty}^{x} v_1^{-2}(y)\, dy. \tag{14.A.29}$$

Then $L(\eta)u_0 = \lambda_0 u_0$ implies that

$$u_0 = \alpha v_2 - \lambda v_1 \int_{-\infty}^{x} v_2 u\, dy + \lambda v_2 \int_{-\infty}^{x} v_1 u\, dy$$

and by method of successive approximations we conclude that modulo much smaller terms it is just αv_2 and in order to be consistent with u_0 as $x > -\ell$

$$\alpha v_2(-\ell) \equiv v_1(-\ell), \qquad \alpha v_2'(-\ell) = u'(-\ell) \equiv \lambda_0 / v_1(-\ell)$$

as $v_1'(-\ell) = 0$, $v_2'(-\ell) = 1/v_1(-\ell)$ we conclude that

$$\lambda_0(\eta) \equiv v_1(-\ell)/v_2(-\ell) = \Big(\int_{-\infty}^{-\ell} v_1(x)^{-2}\, dx\Big)^{-1} = \operatorname{const}\big(\ell^{(1-\nu)/2} \int_{-\infty}^{-\ell} e^{2S(x)}\, dx\big)^{-1} \sim \ell^{1-\nu} e^{-2S(-\ell)}. \tag{14.A.30}$$

exactly as we claimed. □

Remark 14.A.7. In B. Helffer–M. Klein–F. Nier [1] full asymptotics was derived in much more general settings. In our setting our arguments lead also to full asymptotics.

14.A.3 Generalizations

Consider more general operator

$$L(\eta,\Lambda)=(1+\alpha_1 x+\beta_1^2x^2)D^2+(1+\alpha_2x+\beta_2^2x^2)(\eta-x^\nu/\nu)^2-\mathfrak{z}(1+\alpha_3x)x^{\nu-1} \tag{14.A.31}$$

with $\nu=2,3,...$ and $\beta_j>\alpha_j^2/4$ and also

$$a(\eta,\Lambda,\mu,h)=(1+\alpha_1x+\beta_1^2x^2)h^2D^2+(1+\alpha_2x+\beta_2^2x^2)(\eta-\mu x^\nu/\nu)^2-\mathfrak{z}\mu h(1+\alpha_3x)x^{\nu-1}; \tag{14.A.32}$$

then the same scaling as Subsection 14.A reduces latter to the former.

Proposition 14.A.8. *(i) For operator* (14.A.31) *statements of Propositions 14.A.1, 14.A.3, 14.A.5, 14.A.6 and Corollary 14.A.4 remain true.*

(ii) For operator (14.A.31) *with* $(2\mathbb{Z}^+ +1)\ni\mathfrak{z}\neq 1$ *as* $\eta\to+\infty$ *(and thus as* $\eta\to-\infty$ *and* ν *is odd)*

$$\partial_{\alpha_j}\lambda_l(\eta)\big|_{\alpha=\beta=0}=\kappa_j\eta+O(\eta^{-1/\nu}) \tag{14.A.33}$$

with $\kappa_1=\kappa_2=-\kappa_3/2$, $\alpha=(\alpha_1,\alpha_2,\alpha_3)$, $\beta=(\beta_1,\beta_2,\beta_3)$ *and furthermore*

$$\sum_{1\le j\le 3}\partial_{\alpha_j}\lambda_l(\eta)\big|_{\alpha=\beta=0}=\kappa_4\eta^{1/\nu}\lambda_l+O(\eta^{-2/\nu}). \tag{14.A.34}$$

Proof. (i) Proofs are rather easy and we leave them to the reader.

(ii) After obvious transformations

$$\partial_{\alpha_j}\lambda_l(\eta)\big|_{\alpha=\beta=0}=\gamma^{\nu-1}\langle \boldsymbol{k}_jU_\varepsilon,U_\varepsilon\rangle$$

with

$$\begin{aligned}
&\boldsymbol{k}_1=(\gamma+\varepsilon x)D^2,\\
&\boldsymbol{k}_2=x^2\Big(1+\frac{1}{2}(\nu-1)x\varepsilon+\frac{1}{6}(\nu-1)(\nu-2)x^2\varepsilon^2+...\Big)^2\\
&\boldsymbol{k}_3=-\Lambda\Big(1+(\nu-1)x\varepsilon+\frac{1}{2}(\nu-1)(\nu-2)x^2\varepsilon^2+...\Big)
\end{aligned}$$

and therefore

$$\langle \mathbf{k}_j U_\varepsilon, U_\varepsilon\rangle = \gamma\langle \mathbf{k}'_j u_0, u_0\rangle + O\big(\varepsilon^2\gamma\big)$$

with $\mathbf{k}'_1 = D^2$, $\mathbf{k}'_2 = x^2$, $\mathbf{k}'_3 = -\Lambda$ which implies (14.A.33).

Known equalities $\langle x^2 v_l, v_l\rangle = \langle D^2 v_l, v_l\rangle = \Lambda/2$ imply that $\kappa_1 = \kappa_2 = -\kappa_3/2$. Further, $\sum_{1\le j\le 3}\langle \mathbf{k}_j U_\varepsilon, U_\varepsilon\rangle = \gamma\lambda_l + O(\varepsilon^2)$ which implies (14.A.34). □

Now we consider operator

$$L(y,\eta) \coloneqq \beta\Big(\alpha h^2 D^2\alpha + \alpha^{-2}(\eta - \mu x^\nu/\nu)^2 - \Lambda\mu h x^{\nu-1}\Big)\beta \tag{14.A.35}$$

with

$$\alpha = \alpha(x,y),\quad \beta = \beta(x,y),\quad \alpha(0,y) = 1,\quad c_0^{-1} \le \beta \le c_0. \tag{14.A.36}$$

Again we can reduce the general case to one with $\mu = h = 1$ to the former and to prove

Proposition 14.A.9. *For operator* (14.A.35) *statements of Propositions 14.A.1, 14.A.3, 14.A.5, 14.A.6 and Corollary 14.A.4 remain true.*

Remark 14.A.10. Instead of operator (14.A.1) with integer ν we consider operators

$$L(\eta, \mathfrak{z}) = D^2 + (\eta - |x|^\nu/\nu)^2 - \mathfrak{z} x^{\nu-1}\operatorname{sgn}(x) \tag{14.A.37}$$

and

$$L(\eta, \mathfrak{z}) = D^2 + (\eta - |x|^\nu \operatorname{sgn}(x)/\nu)^2 - \mathfrak{z} x^{\nu-1} \tag{14.A.38}$$

with $1 \le \nu \in \mathbb{R}$; these operators are similar to those with even and odd integer ν respectively.

14.A.4 Open Problems

The following problem seems to be really challenging:

Problem 14.A.11. Figure 14.9 shows plots of $\lambda_n(\eta;\mathfrak{z})$ schematically. Prove that these graphs are correct; in particular, prove the impossibility of

$$\lambda_n(\eta;\mathfrak{z}) = \lambda_{n,\eta}(\eta;\mathfrak{z}) = 0, \tag{14.A.39}$$

and

$$\lambda_{n,\eta}(\eta;\mathfrak{z}) = \lambda_{n,\eta\eta}(\eta;\mathfrak{z}) = 0. \tag{14.A.40}$$

Problem 14.A.12. Using Matlab make real calculations and construct plots of $\lambda_n(\eta; \mathfrak{z})$ for some values of $\mathfrak{z}$, n.

14.A.5 Maple for Trajectories

Chapter 15

2D-Schrödinger Operator with the Strong Magnetic Field near the Boundary

Our goal is to derive spectral asymptotics of 2-dimensional Schrödinger operator near the boundary. So we basically want to generalize results of Chapter 13 as $d = 2$ to the case of $\operatorname{supp}\psi \cap \partial X \neq \emptyset$. We assume that condition (13.3.1) is fulfilled: $F \asymp 1$.

However it is not a simple generalization as propagation near the boundary is completely different from one inside the domain. While classical dynamics inside is a normal speed cyclotron movement combined with a slow (with the speed $O(\mu^{-1})$) magnetic drift, it is not the case near boundary: when cyclotron hits the boundary it reflects from it and we arrive to a normal speed (with the speed $O(1)$) hop movement along the boundary.

The really difficult part is that hop movement is not separated from cyclotron plus magnetic drift movement: first, as we move away from the boundary the former is replaced by the latter; second, during some hop the hop movement can be torn away from the boundary and become cyclotron plus magnetic drift movement and v.v.: cyclotron plus magnetic drift movement can collide with the boundary and become hop movement.

The main goal is to investigate the generic case as $\nabla VF^{-1} \neq 0$ and $\nabla_{\partial X} VF^{-1} = 0 \implies \nabla^2_{\partial X} VF^{-1} \neq 0$ on ∂X.

Plan of the Chapter

Section 15.1 is preliminary: first, we consider a classical dynamics, described above, in details. Then we consider a toy-model operator in the half-plane and derive precise formula for it.

In Section 15.2 we consider a weak magnetic field case $\mu h \ll 1$ when classical dynamics defines everything. Then hop movement breaks periodic cyclotron movement which allows us to prove that the contribution of this zone to the remainder is $O(\mu^{-1}h^{-1})$ where factor μ^{-1} is the width of the boundary zone and 1 is the time for which we typically follow classical dynamics. Recall that the contribution of inner zone to the remainder (under appropriate non-degeneracy conditions) also is $O(\mu^{-1}h^{-1})$ albeit there factor μ^{-1} comes from time $\asymp \mu$ for which we typically follow a classical dynamics. Sure, there is a transitional zone between boundary and inner zones but as magnetic field is not strong, it is very thin.

In Section 15.3 we study a moderate magnetic field case. In Subsections 15.3.1–15.3.3 we establish Tauberian remainder estimates under different non-degeneracy assumptions.

In Subsection 15.3.4 we study propagation of singularities in the transitional zone and find that under Dirichlet boundary condition we are able to prove better results than under Neumann boundary condition. This difference is not technical as it is the first manifestation of the fact that as magnetic field grows stronger the classical dynamics loses its value as predictor of the propagation and in the case of Neumann boundary condition some singularities propagate along the boundary in the direction opposite to hops; this is not related to a magnetic drift but rather to a different behavior of the eigenvalues of the toy-model operator.

In Subsection 15.3.5 in the case of the intermediate magnetic field we pass from estimates to calculations and derive our final results.

In Section 15.4 we consider the cases of the strong magnetic field ($\mu h \asymp 1$ and $\mu h \gg 1$ respectively; in the latter case we need to take potential $-\mu h \mathfrak{z} F + V$ rather than V to prevent pushing bottom of the spectrum to high. Here $\mathfrak{z} \ge 1$ under Dirichlet boundary condition but could be smaller under Neumann boundary condition; then spectral asymptotics are concentrated near boundary). As we know from Chapter 13 cyclotrons are no more observable due to uncertainty principle but magnetic drift preserves its sense. The same remains true near boundary: we do not see hops but we observe propagation along the boundary and it can be torn away from

the boundary and became magnetic drift and v.v.

Finally, in Section 15.5 we consider generalizations: first, we get rid of condition $V \asymp 1$ and then we get rid of condition $F \asymp 1$. In the latter case as we know from Chapter 14 our remainder estimate *must* deteriorate to $O(\mu^{-\frac{1}{2}}h^{-1})$.

Appendix 15.A is devoted to auxiliary 1-dimensional harmonic oscillator $-\partial_x^2 + x^2$ considered on $(-\infty, \eta]$ with Dirichlet or Neumann boundary condition as $x = \eta$. We study its eigenvalues $\lambda_{\mathsf{D},n}(\eta)$ and $\lambda_{\mathsf{N},n}(\eta)$ reproducing results of B. Helffer, C. Bolley and M. Dauge. These properties are crucial for our formulae and for analysis of Section 15.4.

15.1 Preliminary Discussion

15.1.1 Inner and Boundary Zones

Let us consider 2-dimensional Magnetic Schrödinger operator near the boundary. Let as usual $\gamma(x) = \frac{1}{2}\mathsf{dist}(x, \partial X)$ and consider disk (i.e. 2-dimensional ball) $B(y, \gamma(y))$. Scaling it $x \mapsto (x-y)\gamma^{-1}$ to the unit disk we get

$$h \mapsto h_{\mathsf{new}} = h\gamma^{-1}, \quad \mu \mapsto \mu_{\mathsf{new}} = \mu\gamma, \quad \nu \mapsto \nu_{\mathsf{new}} = \nu\gamma, \quad \bar{\nu} \mapsto \bar{\nu}_{\mathsf{new}} = \bar{\nu}\gamma \tag{15.1.1}$$

where recall ν and $\bar{\nu}$ are introduced in (13.4.11) and $(13.3.77)_{1-3}$. We assume that originally $\nu = \bar{\nu} = 1$. Then according to Chapter 13 under reasonable conditions contribution of $B(y, \gamma(y))$ to the remainder $\mathsf{R}^{\mathsf{MW}}_{\infty}$ does not exceed

$$C\nu_{\mathsf{new}}\mu_{\mathsf{new}}^{-1}h_{\mathsf{new}}^{-1} = C\mu^{-1}h^{-1}\gamma \tag{15.1.2}$$

as $\gamma \ge \mu h$ and dividing by γ^2 and integrating we conclude that the contribution of the *inner zone*

$$X_{\mathsf{inn}} := \{x, \gamma(x) \ge \bar{\gamma} := C_0\mu^{-1}\} \tag{15.1.3}$$

to $\mathsf{R}^{\mathsf{MW}}_{\infty}$ does not exceed

$$C\mu^{-1}h^{-1}\int \gamma^{-1}\,dx \asymp C\mu^{-1}h^{-1}\log\mu \tag{15.1.4}$$

as $\mu \le h^{-\frac{1}{2}}$.

Remark 15.1.1. We *must* take C_0 large enough in (15.1.2) to ensure that $\mu_{\text{new}} \ge \mu_0$ where μ_0 is large enough constant.

One can get rid of logarithmic factor in (15.1.4) using Seeley' approach. One also should consider case $\mu \ge h^{-\frac{1}{2}}$ but then zone $\{\mu h \ge \gamma \ge C_0\mu^{-1}\}$ appears and its contribution to remainder is estimated differently, as

$$C\int \gamma(x)^{-1}\, T(x)^{-1}\, dx. \tag{15.1.5}$$

We will postpone this until real proofs.

In the *boundary zone*

$$X_{\text{bound}} := \{x, \gamma(x) \le 2\bar{\gamma}\} \tag{15.1.6}$$

one can apply standard Weyl remainder estimate after rescaling. Then contribution of $B(y, \bar{\gamma})$ to R^{W} does not exceed $Ch_{\text{new}}^{-1} = Ch^{-1}\bar{\gamma}$ and the total contribution of X_{bound} to the remainder does not exceed $Ch^{-1}\bar{\gamma} \times \bar{\gamma}^{-1} = Ch^{-1}$. This is much worse than the contribution of the inner zone we derived and needs to be fixed. To do it we need to extend dynamics from time $T \asymp \bar{\gamma} \asymp \mu^{-1}$ ($T \asymp 1$ after rescaling) to $T \asymp 1$ ($T \asymp \mu$ after rescaling) or even more in the moderate, intermediate and strong magnetic field cases.

15.1.2 Classical Dynamics near the Boundary

To understand the role of the boundary, consider classical dynamics. Let us consider first a half-plane $X = \mathbb{R}^2_+ = \{x,\ x_1 > 0\}$, $g^{jk} = \delta_{jk}$, $F = 1$ and $V = 0$. Let us write the toy-model operator in the form

$$\bar{A} := h^2 D_1^2 + (hD_2 - \mu x_1)^2, \tag{15.1.7}$$

as $F_{12} := \partial_2 V_1 - \partial_1 V_2 = -1$ according to (13.2.7).

Then we have a Hamiltonian circular trajectory

$$\begin{aligned} x_1 = \mu^{-1}\bar{\xi}_2 + a\mu^{-1}\cos(2\mu t), \qquad & x_2 = \bar{x}_2 - a\mu^{-1}\sin(2\mu t), \\ & \xi_1 = -a\sin(2\mu t), \qquad \xi_2 = \bar{\xi}_2 \end{aligned} \tag{15.1.8}$$

where $a = \tau^{\frac{1}{2}}$ and τ is an energy level. So we got circular counter-clock-wise trajectories of the radius $\tau^{\frac{1}{2}}$ centered at $\bar{x}$ with $\bar{x}_1 = \mu^{-1}\bar{\xi}_2$ and depending on $\bar{\xi}_2$ these trajectories behave differently:

(a) As $\bar{\xi}_2 \geq \tau^{\frac{1}{2}}$ trajectory does not intersect ∂X or just touches it and remains circular.

(b) As $\bar{\xi}_2 < \tau^{\frac{1}{2}}$ trajectory reflects from ∂X and we get a "hop"-movement:

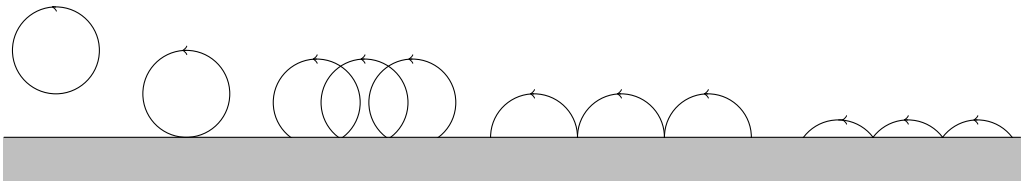

Figure 15.1: Different classical trajectories in half-plane for a toy-model operator

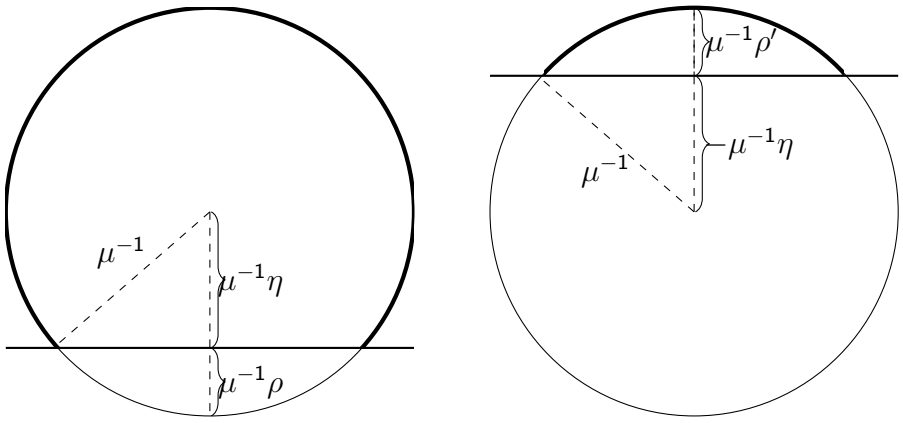
(c) As $\bar{\xi}_2 \searrow -\tau^{\frac{1}{2}}$ trajectory stays closer and closer to ∂X and becomes a kind of gliding ray in the limit. And we are interested only at zone $\{\xi_2 \geq -\tau^{\frac{1}{2}}\}$.

So, trajectories described in (b) are not periodic even for the toy-model operator.



(a) $\xi_2 > 0$ (b) $\xi_2 < 0$

Figure 15.2: Calculating the length of the hop; $\rho = 1 - \eta$, $\rho' = 1 + \eta$

One can calculate easily that

(15.1.9) The *length of the hop* (i.e. the distance between hop's start and end points) is $2a\mu^{-1}(1-\eta^2)^{\frac12}$ with $\eta = \xi_2/a$ while the length of the arc is $2a\mu^{-1}(\pi - \arccos\eta)$ and thus the time of the hop is $\mu^{-1}(\pi - \arccos\eta)$.

Therefore

(15.1.10) As $|\eta|<1$ *the average hop-speed* along x_2 is $\frac{\delta x_2}{\delta t} = -2av(\eta)$ with

$$v(\eta) \coloneqq \frac{(1-\eta^2)^{\frac12}}{\pi - \arccos(\eta)} \tag{15.1.11}$$

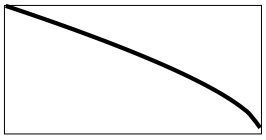


Figure 15.3: $v(\eta)$

This is a plot of $v(\eta)$. One can see easily that $v(\eta)$ is defined on $(-1,1)$ where it decays from 0 to 1; $\eta = 1$ is a threshold between circular and hop-movement and $\eta = -1$ corresponds to gliding rays.

As we cannot get remainder estimate better than $O(\mu h^{-1})$ for a toy-model operator we need to consider a perturbation by a potential:

$$A \coloneqq h^2D_1^2 + (hD_2 - \mu x_1)^2 + V(x); \tag{15.1.12}$$

a classical dynamics for a general operator (13.2.1) in dimension $d=2$ will be not different in our assumptions.

Then one should use the same classification as before with

$$\eta \coloneqq \frac{\xi_2}{W_0(x)^{\frac12}}, \qquad W = (\tau - V(x))F(x)^{-1},\ W_0 = W|_{\partial X} \tag{15.1.13}$$

where *so far* $F(x)=1$.

Actually the last statement is not completely true in the *transitional zone* (where now we consider zones in (x,ξ)-space)

$$\mathcal{X}_{\mathsf{trans}} = \bigl\{(x,\xi):\ |\xi_2 - W_0(x)^{\frac12}| \le 2\bar\rho\bigr\} \tag{15.1.14}$$

or equivalently $\{|\eta - 1| \le C_0\bar\rho\}$ where *so far*

$$\bar\rho = C_0\mu^{-1} \tag{15.1.15}$$

but later it may be increased due to uncertainty principle.

So, let us introduce an *inner zone*

$$\mathcal{X}_{\mathsf{inn}} = \{(x,\xi):\ \xi_2 - W_0(x)^{\frac12} \ge \bar\rho\} \tag{15.1.16}$$

and a *boundary zone*

$$\mathcal{X}_{\mathsf{bound}} = \{(x,\xi):\ \xi_2 - W_0(x)^{\frac12} \le -\bar\rho\}. \tag{15.1.17}$$

There is no need to consider *gliding zone*

$$\mathcal{X}_{\mathsf{glid}} = \{(x,\xi):\ \xi_2 + W_0(x)^{\frac12} \le \bar\rho\} \tag{15.1.18}$$

separately from $\mathcal{X}_{\mathsf{bound}}$.

Recall that inside the domain potential causes magnetic drift

$$\frac{d}{dt}x_1 = \mu^{-1}\partial_{x_2}W, \qquad \frac{d}{dt}x_2 = -\mu^{-1}\partial_{x_1}W. \tag{15.1.19}_{1,2}$$

Let us analyze what happens near the boundary. Note first that

(15.1.20) Billiards do not branch as $\mu \ge \mu_0$ where μ_0 is large enough.

Really, one can prove easily that

(15.1.21) With respect to Hamiltonian trajectories ∂X is strongly concave in the gliding zone and strongly convex in the transitional zone (and domain X has opposite property) as $\mu \ge \mu_0$.

Recall that (according to Figure 15.2) $\rho = 1-\eta$, $\rho' = 1+\eta$, $\eta = \xi_2 W_0^{-1}$. Then along Hamiltonian trajectories

$$\frac{d\rho'}{dt} = \frac{d}{dt}\big(\xi_2 W_0^{-\frac12}\big) = W_{x_2}W_0^{-\frac12} - \frac12\xi_2 W_0^{-\frac32}W_{0x_2}\frac{dx_2}{dt} \equiv$$
$$W_{0x_2}W_0^{-\frac12}\Big(1-\frac12\xi_2 W_0^{-1}\frac{dx_2}{dt}\Big) \qquad \mathsf{mod}\ O\big(\mu^{-1}\rho'\big)$$

as $x_1 = O(\mu^{-1}\rho')$ and therefore for one hop

$$\frac{\delta\rho'}{\delta x_2} \equiv W_{0x_2}W_0^{-\frac12}\Big(1-\frac12\xi_2 W_0^{-1}\frac{\delta x_2}{\delta t}\Big)$$

with W_0, W_{0x_2}, ξ_2 calculated in the middle of it

$$\equiv W_{0x_2}W_0^{-\frac12}\Big(1+\eta v(\eta)\Big)v(\eta)^{-1} \equiv \frac23\rho' W_{0x_2}W_0^{-\frac12} \qquad \mathsf{mod}\ O\big(\rho'(\mu^{-1}+\rho')\big)$$

as $\eta = \rho'-1$ and $v(\eta) = 1-\frac13\rho'\ \ \mathsf{mod}\ \rho'^2$.

Therefore

(15.1.22) Along trajectories of the length ≤ 1 $\rho' \exp(-\frac{4}{3} W_0^{\frac{1}{2}})$ remains constant modulo $O\big(\rho'(\mu^{-1}+\rho')\big)$.

Remark 15.1.2. The similar statement would be completely wrong for ρ because as $\rho \approx 0$ $\frac{\delta \rho}{\delta t} \approx -W_{0x_2} W_0^{-\frac{1}{2}}$ and therefore as $W_{0x_2} < 0$ hop-trajectories[1)] will be torn out of the boundary and begin magnetic drift movement. Meanwhile as $W_{0x_2} > 0$ trajectories drifting in the inner zone may collide with the boundary and begin hop-movement[1)].

In other words hops move away from the boundary (to the boundary) in the direction along the boundary, in which W_0 decreases (increases).

Example 15.1.3. Meanwhile W_{x_1} has more subtle effect. As hop-speed is larger than $C_0 \mu^{-1}$ (i.e. in $\mathcal{X}_{\mathsf{bound}}$) magnetic drift with respect to x_2 has no qualitative effect. However there are no hops in $\mathcal{X}_{\mathsf{inn}}$. Therefore as $W_{x_1} \asymp 1$ we have two rather different cases:

(i) $W_{x_1} > 0$. Then according to $(15.1.19)_2$ magnetic drift is to the left, in the same direction as hops. Then all dynamics is to the left[1)]. In particular as $W_{x_2} > 0$ hop-trajectories are torn from the boundary and begin drift movement (see Figure 15.4(a)) while as $W_{x_2} < 0$ drift-trajectories collide with the boundary and begin hop-movement (see Figure 15.4(b)).

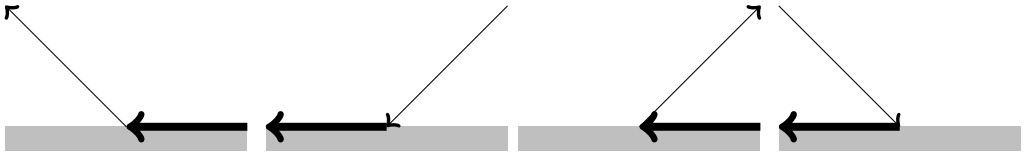
(ii) $W_{x_1} < 0$. Then according to $(15.1.19)_2$ magnetic drift is to the right, in the opposite direction to the hops. So direction of dynamics (with respect to x_2) in $\mathcal{X}_{\mathsf{inn}}$ is opposite to the hop-movement. In particular as $W_{x_2} \le -\epsilon_0$ hop-trajectories are torn from the boundary and begin drift movement (see Figure 15.4(c)) while as $W_{x_2} \ge \epsilon_0$ drift-trajectories collide with the boundary and begin hop-movement (see Figure 15.4(d)).

This is consistent with the fact that drift trajectories are level curves of W.

Example 15.1.4. Assume now that W_{x_2} vanishes at some point but $W_{x_2x_2} \ne 0$. Then repeating analysis of the previous example we arrive to the following four pictures:

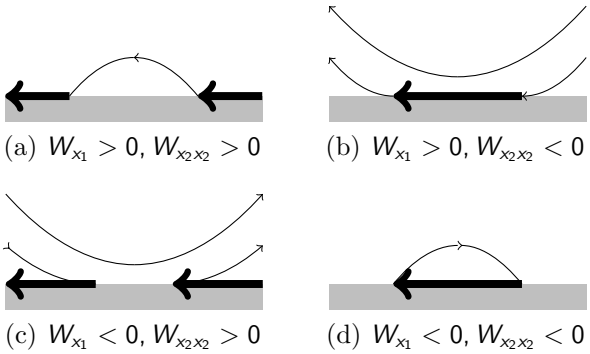
Again this is consistent with the fact that drift trajectories are level curves of W: in cases shown at Figures (a), (d) and (b)–(c) point $\bar{x}$ is a local minimum, maximum and minimax respectively.

[1)] In the positive time direction (and negative x_2-direction).



(a) $W_{x_1} > 0, W_{x_2} > 0$ (b) $W_{x_1} > 0, W_{x_2} < 0$ (c) $W_{x_1} < 0, W_{x_2} > 0$ (d) $W_{x_1} < 0, W_{x_2} < 0$

Figure 15.4: To Example 15.1.3. Bold lines show hop movement and thin lines show drift movement which is along level lines of W.



(a) $W_{x_1} > 0, W_{x_2x_2} > 0$ (b) $W_{x_1} > 0, W_{x_2x_2} < 0$

(c) $W_{x_1} < 0, W_{x_2x_2} > 0$ (d) $W_{x_1} < 0, W_{x_2x_2} < 0$

Figure 15.5: To Example 15.1.4. Bold lines show hop movement and thin lines show drift movement which is along level lines of W.

However the following observation basically remains true:

(15.1.23) The speed of magnetic drift is $O(\mu^{-1})$ (the typical speed is $\asymp \mu^{-1}$) while the speed of hop-movement is $O(1)$ (and the typical speed is $\asymp 1$).

15.1.3 Spectrum of the Toy-Model Operator

Consider toy-model operator (15.1.7) as $x_1 > 0$ with the Dirichlet or Neumann boundary condition $u|_{x_1=0}$ or $D_1 u|_{x_1=0}$. Making h-Fourier transform we arrive to 1-dimensional operator

$$h^2 D_1^2 + (\xi_2 - \mu x_1)^2 \tag{15.1.24}$$

which after transformations $x_1 \mapsto \mu x_1$ or $x_1 \mapsto \hbar^{-\frac{1}{2}} x_1$ with $\hbar := \mu^{-1} h$ becomes

$$\hbar^2 D_1^2 + (\xi_2 - x_1)^2 \qquad \text{with} \quad \hbar = \mu h \tag{15.1.25}$$

or

$$L(\eta) \coloneqq \hbar\big(D_1^2 + (\eta - x_1)^2\big) \qquad \text{with } \eta = \hbar^{-\frac{1}{2}}\xi_2 \tag{15.1.26}$$

at $\mathbb{R}^+ \ni x_1$ respectively, again with the Dirichlet or Neumann boundary condition at $x_1 = 0$. As in the previous chapters one needs to distinguish between $\hbar = \mu h$ and $\hbar = \mu^{-1} h$.

Obviously

(15.1.27) Each of these operators has a simple discrete spectrum, let $0 \le \lambda_{*,0}(\eta) < \lambda_{*,1}(\eta) < \lambda_{*,2}(\eta) < \dots$ be eigenvalues of operator $L_*(\eta)$ defined by (15.1.26) as $\hbar = 1$ where $*$ means either D or N and as usual D and N denote Dirichlet and Neumann respectively.

Further

(15.1.28) Let $\upsilon_{*,j}(x_1, \eta)$ be real-valued orthonormal eigenfunctions of operator $L_*(\eta)$ (as $\hbar = 1$) corresponding to eigenvalues $\lambda_{*,j}(\eta)$.

We will analyze them in details later (see Appendix 15.A), so far let us notice only that $\lambda_{*,j}(\eta) \to +\infty$ as $\eta \to -\infty$ and as $\lambda_{*,j}(\eta)$ are analytic we conclude that

Proposition 15.1.5. *(i) Spectrum of the toy-model operator* (15.1.7) *in* $\{x_1 > 0\}$ *with Dirichlet or Neumann boundary conditions is absolutely continuous and occupies* $[\hbar \cdot \inf_\eta \lambda_{*,0}(\eta), +\infty)$.

(ii) Schwartz kernel of its spectral projector is

$$e(x, y, \tau, \mu, h) = \tag{15.1.29}$$

$$(2\pi)^{-1}\hbar^{-1} \sum_{j \ge 0} \int e^{i\hbar^{-\frac{1}{2}}(x_2 - y_2)\eta} \theta\big(\tau - \hbar\lambda_{*,j}(\eta)\big) \upsilon_{*,j}(\hbar^{-\frac{1}{2}} x_1, \eta) \upsilon_{*,j}(\hbar^{-\frac{1}{2}} y_1, \eta)\, d\eta.$$

Setting $x = y$, subtracting $h^{-2}\mathcal{N}^{\mathsf{MW}}(\tau, \hbar)$ with $\mathcal{N}^{\mathsf{MW}}(\tau, \hbar)$ defined by $(13.2.9)_{(2)}$ and integrating with respect to x_1 we arrive to the following *formal*

(at least for now) equality

$$(15.1.30)\quad \int_0^\infty \Big(e(x,x,\tau,\mu,h) - h^{-2}\mathcal{N}^{\mathsf{MW}}(\tau,\hbar)\Big)\,dx_1 = (2\pi)^{-1}\mu h^{-1}\int_0^\infty \sum_{j\ge 0}\Big(\int \theta\big(\tau-\hbar\lambda_{*,j}(\eta)\big)\upsilon^2_{*,j}(\hbar^{-\frac12}x_1,\eta)\,d\eta - \theta\big(\tau-(2j+1)\hbar\big)\Big)\,dx_1 = h^{-1}\mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}(\tau,\mu h)$$

with

$$(15.1.31)\quad \mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}(\tau,\hbar) := (2\pi)^{-1}\int_0^\infty \sum_{j\ge 0}\Big(\int \theta\big(\tau-\hbar\lambda_{*,j}(\eta)\big)\upsilon^2_{*,j}(x_1,\eta)\,d\eta - \theta\big(\tau-(2j+1)\hbar\big)\Big)\hbar^{\frac12}\,dx_1$$

where in the last transition we rescaled x_1.

Recall that $\bar\lambda_j = (2j+1)$ are eigenvalues of operator (15.1.26) on the whole line $\mathbb{R}\ni x_1$ as $\hbar = 1$.

The following properties of $\lambda_{*,j}(\eta)$ are useful to know

In virtue of Proposition 15.A.1 $\tau > (2j+1)\hbar \iff \tau > \lambda_{\mathsf{D}j}(\eta)$ as $0<\eta$ is large enough and thus

$$(15.1.32)_{\mathsf{D}}\qquad \theta\big(\tau-\lambda_{\mathsf{D}j}(\eta)\hbar\big) = \theta\big(\tau-(2j+1)\hbar\big) \impliedby 0<\eta\gg 1$$

However $\tau\ge (2j+1)\hbar \iff \tau > \lambda_{\mathsf{N}j}(\eta)$ as $0<\eta$ is large enough and in this case

$$(15.1.32)_{\mathsf{N}}\qquad \theta\big(\tau-\lambda_{\mathsf{N}j}(\eta)\hbar\big) = \theta\big(\tau-(2j+1)\hbar+\big) \impliedby 0<\eta\gg 1$$

Recall that $\theta(\tau)$ is semi-continuous from the left and therefore $\theta(0)=0$. Meanwhile $\theta(\tau+)$ is semi-continuous from the right and therefore $\theta(0)=1$. Thus for Dirichlet boundary problem formulae (15.1.30)–(15.1.31) should be retained

$$(15.1.30)_{\mathsf{D}}\quad \int_0^\infty \Big(e_{\mathsf{D}}(x,x,\tau,\hbar) - h^{-2}\mathcal{N}^{\mathsf{MW}}(\tau,\hbar)\Big)\,dx_1 = h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{D},\mathsf{bound}}(\tau,\mu h)$$

with

$$(15.1.31)_{\mathsf{D}}\quad \mathcal{N}^{\mathsf{MW}}_{\mathsf{D},\mathsf{bound}}(\tau,\hbar) := (2\pi)^{-1}\int_0^\infty \sum_{j\ge 0}\Big(\int \theta\big(\tau-\hbar\lambda_{\mathsf{D},j}(\eta)\big)\upsilon^2_{\mathsf{D},j}(x_1,\eta)\,d\eta - \theta\big(\tau-(2j+1)\hbar\big)\Big)\hbar^{\frac12}\,dx_1$$

but for Neumann boundary problem they need to be adjusted to

$$(15.1.30)_{\mathsf{N}} \quad \int_0^\infty \Big(e_{\mathsf{N}}(x,x,\tau,\hbar) - h^{-2}\mathcal{N}^{\mathsf{MW}}(\tau+,\hbar)\Big)\,dx_1 = h^{-1}\mathcal{N}^{\mathsf{MW}}_{\mathsf{N,bound}}(\tau,\mu h)$$

with

$$(15.1.31)_{\mathsf{N}} \quad \mathcal{N}^{\mathsf{MW}}_{\mathsf{N,bound}}(\tau,\hbar) := (2\pi)^{-1}\int_0^\infty \sum_{j\ge 0}\Big(\int \theta\big(\tau-\hbar\lambda_{\mathsf{N},j}(\eta)\big)\upsilon^2_{\mathsf{N},j}(x_1,\eta)\,d\eta - \theta\big(\tau-(2j+1)\hbar+\big)\Big)\hbar^{\frac12}\,dx_1.$$

Proposition 15.1.6. *(i) Equalities* $(15.1.30)_{\mathsf{D}}$–$(15.1.31)_{\mathsf{D}}$ *and* $(15.1.30)_{\mathsf{N}}$–$(15.1.31)_{\mathsf{N}}$ *hold and all integrals converge.*

(ii) Alternatively

$$(15.1.33)_{\mathsf{D}} \quad \mathcal{N}^{\mathsf{MW}}_{\mathsf{D,bound}}(\tau,\hbar) = (2\pi)^{-1}\sum_{j\ge 0}\int \Big(\theta\big(\tau-\hbar\lambda_{\mathsf{D},j}(\eta)\big) - \theta\big(\tau-(2j+1)\hbar\big)\theta(\eta)\Big)\hbar^{\frac12}\,d\eta$$

and

$$(15.1.33)_{\mathsf{N}} \quad \mathcal{N}^{\mathsf{MW}}_{\mathsf{N,bound}}(\tau,\hbar) = (2\pi)^{-1}\sum_{j\ge 0}\int \Big(\theta\big(\tau-\hbar\lambda_{\mathsf{N},j}(\eta)\big) - \theta\big(\tau-(2j+1)\hbar+\big)\theta(\eta)\Big)\hbar^{\frac12}\,d\eta$$

Proof. One can prove easily that

$$(15.1.34) \qquad |x_1-\eta| \ge \epsilon(x_1+|\eta|) \implies |\upsilon_{*j}(x_1,\eta)| \le C_j(1+x_1+|\eta|)^{-s}.$$

By definition

$$(15.1.35) \qquad \int_0^\infty \upsilon^2_{*j}(x_1,\eta)\,dx_1 = 1$$

and based on these two facts and $(15.1.32)_{\mathsf{D,N}}$ one can prove (i) easily.

Inserting η in the second term in the big parenthesis in $(15.1.31)_{\mathsf{D,N}}$ through factor $1 = \int \delta(x_1-\eta)\,d\eta$, changing order of integration and calculating integral with respect to x_1 we prove (ii). □

Remark 15.1.7. From forthcoming weak magnetic field arguments it follows that in the weak sense

$$\mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}(\tau,\hbar) \sim \sum_{n\ge 0} \kappa_{*n}(\tau)\hbar^{2n} \tag{15.1.36}$$

with $\kappa_{*0} = \mp(4\pi)^{-1}\tau_+^{\frac{1}{2}}$ as $* = \mathsf{D},\mathsf{N}$ respectively.

15.2 Weak Magnetic Field

15.2.1 Precanonical Form

We will consider a general magnetic Schrödinger operator (13.2.1) in $X \subset \mathbb{R}^2$

$$A = \sum_{1\le j,k\le 2} P_j g^{jk} P_k + V, \qquad \text{with } P_j = hD_j - \mu V_j \tag{15.2.1}$$

satisfying in $B(0,1) \subset X$ assumptions (13.2.2)–(13.2.4) but in contrast to (13.2.5) we assume that

$$X \cap B(0,1) = \{x_1 > 0\} \cap B(0,1). \tag{15.2.2}$$

Then in contrast to Chapter 13 we cannot unleash a full power of Fourier integral operators as we must preserve boundary, but we can assume that x_1 is small, in fact as small as $\mu^{-1}P_j$ are: not exceeding $C\,\mathsf{max}\big(\mu^{-1}, \mu^{-\frac{1}{2}}h^{\frac{1}{2}-\delta}\big)$.

Without any loss of the generality one can assume that

$$g^{11} = F, \qquad g^{12} = 0, \qquad \big(g^{22} - F\big)\big|_{x_1=0} = 0. \tag{15.2.3}_{1-3}$$

To achieve subsequently $(15.2.3)_{1-3}$ we just reintroduce $x_1 \coloneqq \mathsf{dist}_{g/F}(x, \partial X)$ in the given metrics $(g^{jk}F^{-1})$, then reintroduce $x_2 \coloneqq \alpha(x) + \beta(x_2)$ with an appropriate function $\alpha(x)$ and arbitrary function $\beta(x_2)$ and finally chose $\beta(x_2)$.

Remark 15.2.1. In this construction F is any arbitrary positive function but we select it to be a scalar intensity of the magnetic field. We cannot however choose $\partial_{x_1} g^{22}|_{x_1=0}$ as this is defined by the curvature of the metrics $(g^{jk}F^{-1})$.

Then

$$F_{12}|_{x_1=0} = -1 \tag{15.2.4}$$

(actually it may be 1 but then we change $x_2 \mapsto -x_2$) and without any loss of the generality one can assume that $V_1 = 0$ and $V_2 = x_1 + O(x_1^2)$; we can always reach it by a gauge transformation.

So, changing V by $O(h^2)$

$$\begin{aligned} A = (hD_1)F(x)(hD_1)+ \\ \bigl(hD_2 - \mu x_1 - \mu x_1^2 b(x)\bigr)g^{22}(x)\bigl(hD_2 - \mu x_1 - \mu x_1^2 b(x)\bigr) + V(x) \end{aligned} \tag{15.2.5}$$

with $V(x)$ satisfying $(15.2.3)_3$. One can easily generalize to such operator results of the previous section.

15.2.2 Propagation of Singularities

No-Critical Point Case

In the case of a *weak magnetic field*

$$\mu_0 \le \mu \le h^{\delta-1} \tag{15.2.6}$$

we know that inside the domain the shift during the first winding is microlocally observable under condition (13.4.54) i.e. as

$$|\nabla VF^{-1}| \ge \epsilon_0. \tag{15.2.7}$$

We are going to prove that near boundary the same is true as

$$|\nabla_{\partial X} VF^{-1}| \ge \epsilon_0 \tag{15.2.8}$$

where $\nabla_{\partial X}$ is a derivative along boundary (i.e. ∂_{x_2}).

To prove this assertion one needs just to prove the following proposition:

Proposition 15.2.2. *(i) The propagation speed with respect to (x, ξ_2) does not exceed C.*

(ii) Under condition (15.2.8) *for operator in the form* (15.2.5) *propagation speed with respect to ξ_2 is of magnitude 1 as $x_1 \le C\mu^{-1}$. Namely, for time t shift with respect to ξ_2 is of magnitude $|t|$ and has the same sign as tW_{x_2} with $W = (\tau - V)F^{-1}$.*

Proof. Proof follows the very standard way of the proof propagation of singularities as in Theorems 2.1.2 and 3.1.2. Here we are using an auxiliary function $\varphi = \varphi(x, \xi_2, t)$ and not invoking actually reflections from the boundary.

Then proof of Statement (i) is then completely trivial.

To prove Statement (ii) note that modulo $O(x_1)$

$$\{a, \xi_2\} \equiv \{F, \xi_2\}(a - V) + \{V, \xi_2\} - 2\big(\xi_2 - \mu x_1 - \mu x_1^2 b\big) F \mu x_1^2 \{b, \xi_2\}$$

and the last term is $O(\mu^{-1})$ as $|a| = O(1)$; so

$$\{a, \xi_2\} \equiv \{F, \xi_2\}(a - \tau) + F^2\{(V - \tau)F^{-1}, \xi_2\} + O(\mu^{-1}) \tag{15.2.9}$$

and as $(a - \tau)$ is small everything is defined by the second term in the right hand expression.

Further details of this very simple proof are left to the reader. □

Then we immediately arrive to

Corollary 15.2.3. *Let $U = U(x, y, t)$ be a Schwartz kernel of $e^{-ih^{-1}tA}$. Let $\psi(x) = \psi'(x_2)\psi''(\mu x_1)$ with fixed functions $\psi', \psi'' \in \mathscr{C}_0^\infty$.*

Finally, let condition (15.2.8) *be fulfilled on* $\operatorname{supp}\psi'$. *Then under condition* (15.2.6) *both*

$$F_{t\to h^{-1}\tau}\chi_T(t)\Gamma(U\psi) \tag{15.2.10}$$

and

$$F_{t\to h^{-1}\tau}\big(\bar\chi_T(t) - \bar\chi_{T'}(t)\big)\Gamma(U\psi) \tag{15.2.11}$$

are negligible as $\epsilon_1\mu^{-1} \le T' < T \le \epsilon_2$ with arbitrarily small constant ϵ_1 and small enough constant ϵ_2 [2)].

Meanwhile rescaling $x \mapsto x\mu$, $h \mapsto \mu h$ we immediately arrive to

Proposition 15.2.4. *Let condition* (15.2.6) *be fulfilled and let condition* (13.4.45) *i.e.*

$$V \le -\epsilon_0 \tag{15.2.12}$$

[2)] Recall that as usual $\chi \in \mathscr{C}_0^\infty([-1, -\frac12] \cap [\frac12, 1])$, $\bar\chi \in \mathscr{C}_0^\infty([-1, 1])$ and equals 1 at $[-\frac12, \frac12]$.

be fulfilled on $\mathsf{supp}\,\psi'$. *Let* ψ *be specified in Corollary 15.2.3.*

Then as $|\tau| \le \epsilon$ *and* $T = \epsilon\mu^{-1}$

$$F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(U\psi) \equiv \sum_{n\ge 0, m\ge 0} \partial_\tau \kappa_{nm}(\tau)\mu^{2n-1}h^{2n+2m-1} + \sum_{n\ge 0, m\ge 0} \partial_\tau \kappa'_{nm}(\tau)\mu^{2n}h^{2n+2m} \tag{15.2.13}$$

where $\kappa_{nm}(\tau)$ *and* $\kappa'_{nm}(\tau)$ *are smooth coefficients.*

Combining Proposition 15.2.4 and Corollary 15.2.3 we immediately conclude that

Corollary 15.2.5. *Under conditions* (15.2.6), (15.2.8) *and* (15.2.12) *decomposition* (15.2.13) *holds with* $T = \epsilon_2$.

Therefore applying Tauberian theorem we arrive to estimate (15.2.14) below as ψ specified in Corollary 15.2.3.

Theorem 15.2.6. *Let conditions* (13.2.1)–(13.2.4), (15.2.2), (15.2.6), (15.2.8) *and* (15.2.12) *be fulfilled on* $\mathsf{supp}\,\psi$ *where* $\psi(x) \in \mathscr{C}_0^\infty(\mathbb{R}^2)$. *Then*

$$\mathsf{R}^{\mathsf{W}}_\infty := \Big|\int_X \Big(e(x,x,0) - \sum_{n\ge 0, m\ge 0} \kappa_{nm}(0)\mu^{2n}h^{2n+2m-2}\Big)\psi(x)\,dx - \int_{\partial X}\sum_{n\ge 0, m\ge 0} \kappa'_{nm}(0)\mu^{2n}h^{2n+2m-1}\psi(x)\,ds_g\Big| \le C\mu^{-1}h^{-1} \tag{15.2.14}$$

where ds_g *is a measure on the boundary corresponding to metrics* g.

Proof. So, as $\psi = \psi'(x_2)\psi''(\mu x_1)$ estimate (15.2.14) is proven; thus contribution of zone $\{x,\ x_1 \le 2C_0\mu^{-1}\}$ to the remainder is $O(\mu^{-1}h^{-1})$. This is rather a broad zone as C_0 is arbitrarily large and in zone $\{x,\ x_1 \ge C_0\mu\}$ analysis is almost as if there was no boundary. We need to use the time direction in which ξ_2 increases and therefore trajectories drift inside X. Still it is not quite as without boundary as we are forced to use cut-off functions which are scaled with respect to x_1.

However, this is technicality and we overcome it in the following way: first note that such scaling functions are admissible as long as microlocal uncertainty principle $\mu^{-1}\times\mu^{-2} \ge \mu^{-1}h^{1-\delta}$ holds as we reduced our operator

to microlocal canonical form inside domain. Here the first factor μ^{-1} is due to the scale. So, as $\mu \le h^{\delta-\frac{1}{2}}$ we can appeal to theory of Chapter 13.

However we can change variables $x_{1\mathsf{new}} = x_1 + bx_1^2$ so that

$$\xi_1 = \big(1 + O(x_1)\big)\xi_{1\mathsf{new}}, \quad \xi_2 - \mu x_1 - \mu b x_1^2 = \xi_{2\mathsf{new}} - \mu x_{1\mathsf{new}} + O(x_1^2)\xi_1$$

and then bad term does not appear at all; in old coordinates it would amount to replacing ξ_2 by $\xi_2 + O(x_1^2\xi_1)$.

This proves that in the inner zone we can take $T \asymp \mu$ in the correct time direction and most importantly, we do not scale with respect to x_2 so microlocal uncertainty principle would be $1 \times \mu^{-2} \ge \mu^{-1}h^{1-\delta}$ i.e. in our framework $\mu \le h^{\delta-1}$. Formula (15.2.14) is proven. □

Finally we need to pass to magnetic Weyl formula:

Theorem 15.2.7. *In the framework of Theorem 15.2.6*

$$\mathsf{R}^{\mathsf{MW}} := \Big| \int_X \Big(e(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{MW}}(x,0,\mu h)\Big)\psi(x)\,dx - h^{-1}\int_{\partial X} \mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}(x,0,\mu h)\psi(x)\,ds_g\Big| \le C\mu^{-1}h^{-1} \tag{15.2.15}$$

where $\mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}$ *is introduced by* $(15.1.31)_{\mathsf{D}}$ *or* $(15.1.31)_{\mathsf{N}}$ *for Dirichlet or Neumann boundary condition respectively with* $\hbar = \mu h F(x)$ *and* τ *replaced by* $-V(x)$.

Proof. To pass from (15.2.14) to (15.2.15) let us recall that coefficients are obtained by successive approximation method and notice that as ψ is fixed (non-scaled) function running successive approximation method to derive (15.2.14) leads to an extra factor h rather than μh if we differentiate ψ or g^{jk} or V or differentiate twice V_j; however exactly one such differentiation leads to 0 in the final calculations, so we conclude that at least 2 "losing" differentiations must be there, extra factor is $O(h^2)$ and the term is $O(1)$.

Thus to derive $\mathsf{R}^{\mathsf{W}}_{\infty}$ modulo $O(1)$ we should not differentiate g^{jk}, V, ψ at all and to differentiate V_j only once. However it means exactly considering a toy-model operator $A = A_y$ at each point y.

The microhyperbolicity with respect to x_2 implies that with integration (with the scale 1) over x_2 we can replace $\mathcal{N}^{\mathsf{MW}}$ by its decomposition with respect to powers of $\hbar = \mu h$ which justifies the transition from (15.2.14) to (15.2.15).

Analysis in the Boundary Zone

In what follows "formula" and "remainder" mean *Tauberian formula with* $T = \epsilon\mu^{-1}$ and the corresponding *Tauberian remainder* R^{T} until we will pass to Weyl and magnetic Weyl formula and remainder.

To cover the case when condition (15.2.8) is violated (with an extreme case $W := VF^{-1}|_{\partial X} = \mathsf{const}$) let us consider first boundary zone $\mathcal{X}_{\mathsf{bound}}$ defined by (15.1.17) where we chose a small parameter $\bar{\rho}$ later. To do so let us consider a stripe

$$\mathcal{X}_{\mathsf{bound},\rho} = \mathcal{X}_{\mathsf{bound}} \cap \{\rho \le -\xi_2 + \big(VF^{-1}\big)^{\frac{1}{2}} \le 2\rho\}. \tag{15.2.16}$$

Then the length of the hop is $\asymeq \mu^{-1}\rho^{\frac{1}{2}}$ with the possible perturbation $O(\mu^{-2})$ due to the magnetic drift (so $\rho \gg \mu^{-2}$ would suffice, but we request $\rho \ge \mu^{-1}$ anyway).

Now, weak magnetic field approach would mean that uncertainty principle is fulfilled after the first hop: $\rho \times \mu^{-1}\rho^{\frac{1}{2}} \ge h^{1-\delta}$ or equivalently $\rho \ge \mu^{\frac{2}{3}} h^{\frac{2}{3}-\delta}$. Combining with restriction $\rho \ge \mu^{-1}$ we arrive to

$$\rho \ge \bar{\rho} := \mathsf{max}\big(C_0\mu^{-1}, \mu^{\frac{2}{3}} h^{\frac{2}{3}-\delta}\big) \tag{15.2.17}$$

and our goal is to prove that under this the contribution of $\mathcal{X}_{\mathsf{bound}}$ to the remainder does not exceed $C\mu^{-1}h^{-1}$.

To achieve this goal let note first that

$$\int_{\mathcal{X}_{\mathsf{bound},\rho}\cap\{x_2=\mathsf{const}\}} dx_1 d\xi : da \le C\rho \tag{15.2.18}$$

which enables us to estimate

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(u\,{}^tQ_y\psi)| \le C\mu^{-1}h^{-1}\rho\gamma \tag{15.2.19}$$

as $|\tau| \le \epsilon$, $Q = Q(x_2, hD_2) \in \mathsf{S}_{h,\rho,\gamma}(\mathbb{R})$ and with the symbol supported in $\mathcal{X}_{\mathsf{bound},\rho} \cap \{|x_2 - \bar{x}_2| \le \gamma\}$, $\rho \ge C\,\mathsf{max}(\gamma, \mu^{-1})$, $\psi = \psi''(\mu x_1)$ and $T = T_* = \epsilon\mu^{-1}$.

Remark 15.2.8. Note that factor μ^{-1} appears here and in all similar estimates because width $\asymeq \rho$ with respect to ξ_2 matches to the width $\asymeq \mu^{-1}\rho$ with respect to x_1 on energy levels below c.

What we need is to investigate propagation until time $T = T^*(\rho)$ and prove that

$$|F_{t\to h^{-1}\tau}\big(\bar{\chi}_{T^*}(t) - \bar{\chi}_{T_*}(t)\big)\Gamma(u\,{}^tQ_y\psi)| \le C'h^s \tag{15.2.20}$$

with

$$\int T^{*\,-1}(\rho)\,d\rho \le C \tag{15.2.21}$$

then as the main part is given by Tauberian formula with $T = T_*$, remainder does not exceed

$$C\mu^{-1}h^{-1}\int T^{*\,-1}(\rho)\,d\rho dx_2 \le C\mu^{-1}h^{-1}.$$

In what follows $T^*(\rho) = \rho^{1-\delta'}$ with arbitrarily small exponent $\delta' > 0$.

To prove (15.2.20) with $T^*(\rho) = \rho^{1-\delta'}$ note first that

(15.2.22) If $|\partial_{x_2}VF^{-1}| \le c\rho^{\delta'}$ then propagation in *any* time direction remains in the zone

$$\big\{\frac{1}{2}\rho \le -\xi_2 + (VF^{-1})^{\frac{1}{2}} \le \rho'\big\} \cap \big\{|x_2 - \bar{x}_2| \le 2\gamma\big\} \tag{15.2.23}$$

for time $T = T^*(\rho)$

and

(15.2.24) If $|\partial_{x_2}VF^{-1}| \ge \frac{1}{2}c\rho^{\delta'}$ then propagation in *an appropriate*[3)] time direction remains in (15.2.23) for time $T = T^*(\rho)$;

in both cases $\gamma = C\mu^{-1}T^*(\rho') \le \epsilon\rho$ for sure where in the former case $\rho' = 3\rho$ and in the latter case $\rho' = \rho^{1-\delta''}$.

After assertions (15.2.22) and (15.2.24) are proven, we need to prove that singularities really propagate. Figure 15.2(a) shows that as $VF^{-1} = 1$ and the movement is strictly circular the length of the hop is exactly $2\mu^{-1}\big(1 - (1-\rho)^2\big)^{\frac{1}{2}}$ while in general case it will be of the same magnitude $\mu^{-1}\rho^{\frac{1}{2}}$ as $\rho \ll 1$. But obviously in the most critical zone movement in x_2 is

[3)] In which $(VF^{-1})(0, x_2)$ decays; as rotation is counter-clock-wise we take $\pm t > 0$ as $\pm(VF^{-1})(0, x_2) > 0$.

not monotone. However for sure x_2 increases with each hop as we bound ourselves with $x_1 \le \epsilon' \mu^{-1}\rho$ with small enough constant ϵ'.

The main problem are trajectories which are almost tangent to the boundary. There are two kind of them: with $\rho' \ll 1$ and with $\rho \ll 1$. Trajectories of of the first kind are not actually difficult (see proof of Proposition 15.2.11). So we start from trajectories of the second kind.

Proposition 15.2.9. *Consider zone* $\mathcal{Z} := \{\xi_2 \ge -\epsilon\}$. *Consider point* $(\bar{x}, \bar{\xi}_2) \in \mathcal{Z}$ *and its* $(\boldsymbol{\gamma}, \sigma)$*-vicinity* Ω *with* $\boldsymbol{\gamma} = (\gamma_1, \gamma_2)$ *and*[4)]

$$\gamma_1 = \sigma = \hbar^{\frac{1}{2}-\delta}, \qquad \text{as } \ \bar{x}_1 \ge \hbar^{\frac{1}{2}-\delta}, \tag{15.2.25}$$

$$\gamma_1 = \sigma = \bigl(\hbar\gamma^{-\frac{3}{2}}\bigr)^{\frac{1}{2}-\delta}\gamma, \qquad \text{as } \ \bar{x}_1 \asymp \gamma \le \hbar^{\frac{1}{2}-\delta}, \tag{15.2.26}$$

$$\gamma_2 = \hbar^{\frac{1}{3}-\delta} \tag{15.2.27}$$

and operator $Q = Q(x, hD_2) \in \mathsf{S}_{h,\gamma_1,\gamma_2,\sigma}$ *with symbol supported in* Ω.

Further, consider point $(\bar{y}, \bar{\eta}_2) \in \mathcal{Z}$ *and its* $(\boldsymbol{\gamma}, \sigma)$*-vicinity* Ω' *with* $\boldsymbol{\gamma}$ *reintroduced for this point according to* (15.2.25)–(15.2.27) *and also operator* $Q' = Q'(x, hD_2) \in \mathsf{S}_{h,\gamma_1,\gamma_2,\sigma}$ *with symbol supported in* Ω'.

Let $T \asymp \mu^{-1}$ *and*

$$|x_1 - y_1|\gamma_1^{-1} + |x_2 - y_2|\gamma_2^{-1} + |\xi_2 - \eta_2|\sigma^{-1} \ge \epsilon \qquad \forall x \in \Psi_{t,\tau}(\Omega),\ y \in \Omega' \qquad \forall t \in \operatorname{supp}\chi_T \tag{15.2.28}$$

where $\Psi_{t,\tau}$ *is a Hamiltonian flow with reflections and* ξ_1 *is defined so that* $a(x,\xi) = \tau$. *Then*

$$F_{t\to h^{-1}\tau}\chi_T(t) Q' U\, {}^t Q' \tag{15.2.29}$$

is negligible.

Proof. As we assume $\bar{\xi}_2 \ge -\epsilon_0$ we do not need to consider "short and low" hops as on Figure 15.2(b) and the time of the hop is $\asymp \mu^{-1}$.

Obviously as $\mu \le h^{-\delta}$ one can apply results of Sections 2.4 and 3.5 and justify our final conclusion.

Let us consider larger μ. To do so we need to understand how small vicinity of Hamiltonian billiard flow with reflections we must take to contain propagation.

To do so consider propagation in the different zones, step by step, and we do consider $\sigma, \gamma_1, \gamma_2$ not necessarily defined by (15.2.25)–(15.2.27).

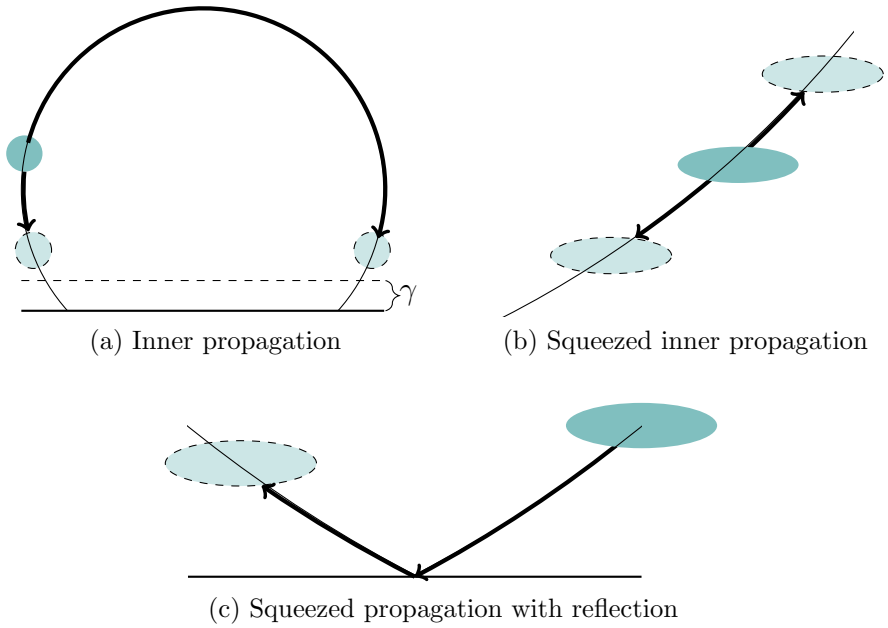
[4)] After rescaling $x \mapsto \mu x$.

(a) First of all, as $x_1 \ge \gamma \ge \hbar^{\frac{1}{2}-\delta}$ one can take any $\gamma_j \ge \gamma$ and $\rho_j \ge \gamma$. So, as $x_1 \ge \hbar^{\frac{1}{2}-\delta}$ we can take $\gamma_1 = \hbar^{\frac{1}{2}-\delta}$ and other scales different but larger. Thus,

(15.2.30) Let $\bar{x}_1 \ge \gamma \ge \hbar^{\frac{1}{2}-\delta}$ and let $\gamma_j \ge \gamma$, $\sigma \ge \gamma$. Let t be such that $\Psi_{t'}(\operatorname{supp} Q)$ does not intersect γ-vicinity of ∂X as $0 < \pm t' < \pm t$ (if $\pm t > 0$).

Then (15.2.29) is negligible, provided $\Psi_{t,\tau}(\operatorname{supp} Q)$ does not intersect (γ,σ)-vicinity of $\operatorname{supp} Q'$.

We refer to this as *inner propagation* (see Figure 15.6(a)).



(a) Inner propagation

(b) Squeezed inner propagation

(c) Squeezed propagation with reflection

Figure 15.6: Inner, squeezed inner (and similar mirror symmetric), squeezed with reflection propagations

(b) Consider now zone $C\rho \le x_1 \asymp \gamma \le \hbar^{\frac{1}{2}-\delta}$. Let us scale $x_1 \mapsto x_1\gamma^{-1}$, $x_2 \mapsto x_2\gamma^{-\frac{1}{2}}$ and $\hbar \mapsto \hbar' := \hbar\gamma^{-\frac{3}{2}}$. As after original rescaling $x \mapsto \mu x$ we had that derivatives of all coefficients were less than $C\mu^{-1}$ we conclude that after this rescaling they are less then $C\mu^{-1}\gamma^{\frac{1}{2}}$ and after division by γ they are still bounded.

More precisely: we recalled that "up to perturbation" operator was

$$\bar{A} = (\hbar D_1)^2 - (\hbar D_2 - x_1)^2 - 1 \tag{15.2.31}$$

with $|\xi_2 - 1| \le \rho$; so in the zone in question rescaling as described is justified. And therefore respectively we need to scale $\xi_1 \mapsto \xi_1 \gamma^{-\frac{1}{2}}$ and $\xi_2 - 1 \mapsto \xi_2 \gamma^{-1}$.

Now we have rather regular situation and can take $\hbar'^{\frac{1}{2}-\delta}$ vicinity. In other words, we can take

$$\gamma_1, \sigma \ge \hbar'^{\frac{1}{2}-\delta}\gamma = \left(\hbar\gamma^{-\frac{3}{2}}\right)^{\frac{1}{2}-\delta}\gamma, \tag{15.2.32}$$

$$\gamma_2 \ge \hbar'^{\frac{1}{2}-\delta}\gamma^{\frac{1}{2}} = \left(\hbar\gamma^{-\frac{3}{2}}\right)^{\frac{1}{2}-\delta}\gamma^{\frac{1}{2}} \tag{15.2.33}$$

and we can replace these right hand expressions by $\hbar^{\frac{1}{2}-\delta}\gamma^{\frac{1}{4}}$ and $\hbar^{\frac{1}{2}-\delta}\gamma^{-\frac{1}{4}}$ respectively and the latter does not exceed its value as $\gamma = \bar{\rho}$ and it is $\hbar^{\frac{1}{3}-\delta}$. This is *squeezed inner propagation* (see Figure 15.6(b)).

Furthermore, we can apply long-range propagation of Section 2.4 and replace condition $x_1 \asymp \gamma$ by a weaker condition $\gamma^{1+\delta'} \le x_1 \le \gamma^{1-\delta'}$ with $\delta' > 0$ small enough. But then we need no more than $C(\delta')$ jumps to reach from $\gamma \asymp \hbar^{\frac{1}{2}-\delta}$ to $\gamma \asymp \hbar^{23-\delta}$ or inversely.

(c) Finally, as $x_1 \le C\rho$ we can apply the same scaling with $\gamma = \rho$ and note that after rescaling trajectories meet the boundary under angle disjoint from 0. So we have a standard reflection situation. Scaling back we arrive to the same conclusion as in Part (b). This is *squeezed propagation with reflection* (see Figure 15.6(c)). □

Repeating this procedure $N \asymp \mu T$ times we arrive to

Corollary 15.2.10. *Consider $\mu^{-1} \le T \le \epsilon\rho$. Then conclusion of Proposition 15.2.9 remains true if we redefine $\sigma := \sigma_{\mathsf{old}} N$, $\gamma_j := \gamma_{j,\mathsf{old}} N$ with $N \asymp \mu T$ number of rotations.*

Now we can prove our main claim

Proposition 15.2.11. *Estimate* (15.2.20) *holds with $T_* = \epsilon\mu^{-1}$ and $T^*(\rho) = \rho^{1-\delta'}$.*

Proof. We consider a pseudodifferential partition of unity. Let $Q' = Q'(x_2, hD_2) \in \mathsf{S}_{h,\rho,\gamma}$ with symbol supported in $\epsilon(\gamma,\rho)$-vicinity of $(\bar{x}_2, \bar{\xi}_2)$ and $\gamma = \mu^{-1}\rho^{\frac{1}{2}}$ satisfy (15.2.17).

(a) Consider first $\bar{\xi}_2 \le -\epsilon_0$.

Note first that

(15.2.34) As $\xi_2 \le -\epsilon$ both operator and boundary value problem are ξ_2-microhyperbolic as $x_1 \ge 0$.

Really, $ih^{-1}[A, x_2] = hD_2 - \mu x_1 \le -\epsilon$.

Then due to results of Chapter 3 $U\,{}^tQ_y$ is negligible as $\pm t > 0$ and $\pm(x_2 - \bar{x}_2 + \epsilon\gamma) < \pm\epsilon_0 t$, which implies (15.2.20).

(b) Consider now $\bar{\xi}_2 \ge -\epsilon_0$. Note that Ψ_t after exactly one turn moves x_2 to the left by at least $\epsilon\rho^{\frac{1}{2}}$; we assume that $\rho \ge C_0\mu^{-1}$ to counter possible perturbations. Further, as $\rho \ge (\mu h)^{\frac{2}{3}-\delta}$ it exceeds γ_2 expansion due to uncertainty principle. This justifies conclusion of the proposition as $T^* = \epsilon_0\rho$ as propagation speed with respect to ξ_2, x_2 does not exceed C_0.

(c) To increase $T^*(\rho)$ notice that we can take $T^*(\rho) = \rho^{1-\delta'}$ unless $\ell \ge \rho^{\delta'}$ where

$$\ell := \epsilon_0 |\nabla_{\partial X} V F^{-1}| \tag{15.2.35}$$

as the speed of propagation with respect to ρ does not exceed ℓ and dynamics remains in the same (ℓ, ρ)-element with respect to (x_2, ξ_2).

Meanwhile as $\ell \ge \rho^{\delta'}$ we can take time direction in which ρ increases and then take $T^*(\rho) = \rho^{1-\delta'}$ anyway.

Uncertainty principle $\rho\ell \ge h^{1-\delta}$ is obviously satisfied in both cases. □

Remark 15.2.12. Surely one can improve arguments of (iii) and we will do it studying strong magnetic field. However at this moment this leads to no improvements in the remainder estimate.

Then immediately we arrive to

Corollary 15.2.13. *Contribution of zone* $\mathcal{X}_{\mathsf{bound}}$ *defined by* (15.1.17), (15.2.17) *to the remainder does not exceed* $C\mu^{-1}h^{-1}$.

Proof. Contribution of $\mathcal{X}_{\mathsf{bound},\rho}$ to the remainder does not exceed

$$C\mu^{-1}\rho h^{-1} \times T^{*,-1} \asymp C\mu^{-1}h^{-1}\rho^{\delta'} \tag{15.2.36}$$

and summation over $\rho \ge \bar{\rho}$ (i.e. integration with respect to $\rho^{-1}d\rho$) results in $O(\mu^{-1}h^{-1})$. □

Analysis in the Transitional Zone

Consider now *transitional zone* defined by (15.1.14). Obviously we get a rather rough estimate

Proposition 15.2.14. *Contribution of the transitional zone* (15.1.14) *to the remainder does not exceed*

$$C\bar{\rho}h^{-1} \asymp C\mu^{-1}h^{-1} + C(\mu h)^{\frac{2}{3}}h^{-1-\delta}. \tag{15.2.37}$$

In particular, as $\mu \le h^{-\frac{2}{5}+\delta}$ *it does not exceed* $C\mu^{-1}h^{-1}$.

Now we want to improve this estimate under some non-degeneracy condition invoking $VF^{-1}|_{\partial X}$.

Let us introduce ℓ-admissible partition with ℓ defined by (15.2.35).

Proposition 15.2.15. *On* ℓ*-element with*

$$\ell \ge \bar{\ell} := \mathsf{max}\big(C\mu^{-1}, \mu^{\frac{1}{2}}h^{\frac{1}{2}-\delta}\big) \tag{15.2.38}$$

expressions (15.2.10) *and* (15.2.11) *are negligible as* $T_* \le T \le T^*$ *with* $T_* = \epsilon\mu^{-1}$ *and* $T^*(\ell) = \ell^{1-\delta'}$.

Proof. As in Subsubsection *15.2.2.1 No-Critical Point Case* consider shift with respect to ξ_2 and it will be $\asymp \ell T$. So, uncertainty principle requests $\ell T \times \ell \ge h^{1-\delta}$ which is exactly our restriction to ℓ as $T = \epsilon\mu^{-1}$. Meanwhile $x_1 \le C_0\mu^{-1} + C\mu^{-1}\ell T$ and it remains less than $C\mu^{-1}$ as $T \le 1$. On the other hand shift with respect to x_2 does not exceed $C\mu^{-1} + C\rho^{\frac{1}{2}}T$ in virtue of Proposition 15.2.17 below and it remains less than $\epsilon\ell$ as $T = \epsilon\ell^{1-\delta'}$ unless $\rho \ge \ell^{\delta'}$ which is impossible in the transitional zone.

We surely need to keep $\rho\ell \ge h^{1-\delta}$ but one can check easily that $\bar{\rho}\bar{\ell} \ge \mu^{-\frac{1}{2}}h^{\frac{1}{2}-\delta} \ge h^{1-\delta}$. □

Corollary 15.2.16. *(i) Contribution of the part of the transitional zone* (15.1.14) *where* (15.2.38) *is fulfilled to the remainder does not exceed* $C\mu^{-1}h^{-1}$.

(ii) Contribution of the transitional zone (15.1.14) *to the remainder does not exceed*

$$C\mu^{-1}h^{-1} + C(\mu h)^{\frac{2}{3}}h^{-1-\delta}\,\mathsf{mes}_{\partial X}\big(\{x \in \partial X,\ |\nabla_{\partial X}V| \le C(\mu h)^{\frac{1}{2}-\delta}\}\big)h^{-1-\delta}, \tag{15.2.39}$$

(iii) In particular, it does not exceed

$$C\mu^{-1}h^{-1} + C(\mu h)^{\frac{7}{6}}h^{-1-\delta}, \tag{15.2.40}$$

provided

$$|\nabla_{\partial X} VF^{-1}| \le \epsilon \implies \pm\nabla^2_{\partial X} VF^{-1} \ge \epsilon \tag{15.2.41}^{\pm}$$

and expression (15.2.41) *does not exceed* $C\mu^{-1}h^{-1}$ *as* $\mu \le h^{-\frac{7}{13}+\delta}$.

While either sign in $(15.2.41)^{\pm}$ assures remainder estimate (15.2.40), in the future we will need to distinguish between different signs in this condition as dynamics will be different (see Example 15.1.4).

We finish this subsubsection by

Proposition 15.2.17. *An "average" propagation speed with respect to* x_2 *in* $\mathcal{X}_{\mathsf{trans}}$ *does not exceed* $C\bar{\rho}^{\frac{1}{2}}$.

Proof. Proof coincides with one of Proposition 15.2.9 and Corollary 15.2.10.

Surely trajectories in the squeezed reflection zone are not transversal to boundary anymore after rescaling but we do not need it as instead of $\hbar'^{\frac{1}{2}-\delta}$-vicinity we can take ϵ-vicinity and appeal f.e. to results of Section 3.4.

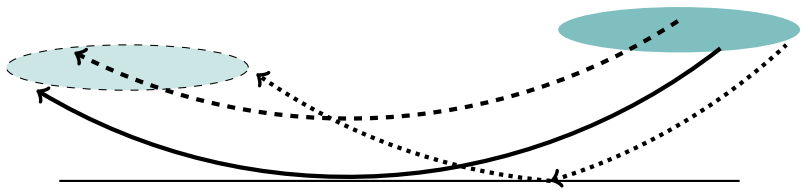


Figure 15.7: Squeezed propagation with tangency, reflections or miss the boundary

Analysis in the Inner Zone

Consider now *inner zone* defined by (15.1.16). As we know, in this zone we must assume some non-degeneracy condition to get remainder estimate better than $O(\mu h^{-1})$. In Chapter 13 we used few of such conditions rendering

different remainder estimates; all of them boiled down to the remainder estimate $O(\mu^{-1}h^{-1})$ under different restrictions to μ.

Consider first propagation of singularities.

Proposition 15.2.18. *Let $Q \in \mathsf{S}_{h,\rho_1,\rho_2,\gamma_1,\gamma_2}$ and let Ω be $(\gamma_1,\gamma_2,\rho_1,\rho_2)$-vicinity (with respect to (x,ξ)) of its symbol. Then long as trajectories started from Ω remain in $\mathcal{X}_{\mathsf{inn}}$ defined by* (15.1.16), (15.2.17)

$$U\,{}^tQ_y \equiv U^0\,{}^tQ_y \tag{15.2.42}$$

where U^0 is a propagator for operator A considered in X^0 the fixed vicinity of $\bar{X}$ (i.e. in the whole plane effectively).

Proof. Proof is trivial as

$$\rho \ge \bar{\rho} \coloneqq \mathsf{max}\big(C\mu^{-1}, \mu^{\frac{1}{2}}h^{\frac{1}{2}-\delta}\big) \tag{15.2.43}$$

as then we can apply Fourier integral operators as described in Chapter 13.

As $\bar{\rho}$ is defined by (15.2.17) one needs to apply the same arguments as in the proof of Proposition 15.2.9. Albeit in that proof trajectories "comfortably met" ∂X and now they "comfortably miss" it. □

Remark 15.2.19. This proposition however does not imply that results of Section 13.4 are automatically valid in our case as in that section we used partition elements which could be rather large in some directions (sometimes as large as $\asymp 1$ which could be replaced by $h^{\delta'}$ as we apply microlocal standard uncertainty principle rather than logarithmic uncertainty principle). Now boundary prevents us from doing this.

Still, however, as $\mu \le h^{-\delta}$ with sufficiently small exponent $\delta > 0$ these arguments of Section 13.4 remain automatically valid and leaving easy details to the reader arriving to the following proposition:

Proposition 15.2.20. *Under non-degeneracy condition* $(13.4.57)_m$ *with* $\nu = 1$ *i.e.*

$$\sum_{1\le|\alpha|\le m} |D^\alpha(VF^{-1})| \ge \epsilon \tag{15.2.44}_m$$

a contribution of the inner zone $\mathcal{X}_{\mathsf{inn}}$ to the remainder does not exceed $C\mu^{-1}h^{-1}$ as $\mu \le h^{-\delta}$ with sufficiently small exponent $\delta = \delta(m) > 0$.

Combining with results in inner and transitional zones where the same contributions were derived even without non-degeneracy condition we conclude that

Theorem 15.2.21. *Let conditions* (13.2.1)–(13.2.4), (15.2.2) *and* (15.2.12) *and non-degeneracy condition* $(15.2.44)_m$ *be fulfilled on* $\mathsf{supp}\,\psi$ *where* $\psi \in \mathscr{C}_0^\infty(\mathbb{R}^2)$.

Then the remainder does not exceed $C\mu^{-1}h^{-1}$ *as* $\mu \le h^{-\delta}$ *with sufficiently small exponent* $\delta = \delta(m) > 0$.

Proof. As in the Chapter 13 (see $(13.4.49)_\vartheta$) the contribution of $\mathcal{X}_{\mathsf{inn}}$ to the remainder does not exceed

$$C\mu^{-1}h^{-1}\int_{\mathcal{X}_{\mathsf{inn}}} T^{-1}\,dx_2 d\xi_2 + C\mu h^{-1}\,\mathsf{mes}_2(\Omega_2) \tag{15.2.45}$$

with the same definition (13.4.50) of Ω_2; here $T = \epsilon\mu^{\frac12}\rho^{\frac12}$ and $d\xi_2 = d\rho$ and integral is bounded as $\rho \le c\mu$. □

In almost all other cases we however need to take Remark 15.2.19 into account. Still there is an exception: arguments linked to evolution with respect to ξ_2 work in a bit larger zone, namely $\{(x,\xi):\ \xi_2 \le C_0\}$ and thus in zone $\{x,\ x_1 \le C_1\mu^{-1}\}$ (which is a definition of X_{bound}).

No-Critical Point Case. Assume temporarily that condition (15.2.8) is fulfilled. Then, as we mentioned, Theorem 15.2.6 and Proposition 15.2.15 cover this zone. So we need to consider zone

$$\{x:\ C_0\mu^{-1} \le x_1 \le \epsilon\}. \tag{15.2.46}$$

However under condition (15.2.8) we can take $\asymp 1$ scale with respect to x_2 and consider drift in the time direction in which ξ_2 increases; then we remain in the zone in question for time $T^* = \epsilon'\mu$. Meanwhile under this condition shift with respect to ξ_2 is observable as $|t| \ge T_* = \epsilon\mu^{-1}$. This leads us to to conclusion that

(15.2.47) Under assumption (15.2.8) contribution of this (15.2.46) zone to the Tauberian remainder does not exceed $C\mu^{-1}h^{-1}$

(i.e. the same as the contribution of zone $\{x:\ x_1 \le C_0\mu^{-1}\}$ albeit factor μ^{-1} now comes as $T^{*\,-1}$ rather than as the width of the zone).

So we arrive to

Theorem 15.2.22. *Let conditions* (13.2.1)–(13.2.4), (15.2.2) *and* (15.2.12) *and non-degeneracy condition* (15.2.8) *be fulfilled on* $\operatorname{supp}\psi$ *where* $\psi(x) \in \mathscr{C}_0^\infty(\mathbb{R}^2)$.

Then contribution of zone $\{x:\ \operatorname{dist}(x,\partial X)\le \epsilon_1\}$ *to the remainder does not exceed* $C\mu^{-1}h^{-1}$ *as* $\mu \le h^{\delta-1}$ *with arbitrarily small exponent* $\delta > 0$.

Non-Degenerate Critical Point Case. Consider now case when non-degeneracy condition (15.2.41) is fulfilled. Then obviously contribution of zone $\{x_1 \le C_0\mu^{-1}\}$ to the remainder does not exceed

$$C\mu^{-1}h^{-1} + C(\mu h)^{\frac{1}{2}-\delta}h^{-1} \tag{15.2.48}$$

where the second term comes from zone

$$\big\{x:\ x_1 \le C_0\mu^{-1},\ |W_{x_2}| \le C_0 \max\big(\mu^{-1}, (\mu h)^{\frac{1}{2}-\delta}\big)\big\} \tag{15.2.49}$$

and this is not as good as (15.2.40) because $\bar\rho \ll 1$.

Now in the zone

$$\big\{x:\ C_0\mu^{-1} \le x_1 \le \epsilon_1,\ |W_{x_2}| \ge C_0 \max\big(\mu^{-1}, (\mu h)^{\frac{1}{2}-\delta}\big)\big\} \tag{15.2.50}$$

we can use $T^* = \epsilon\mu\ell$ with $\ell = \epsilon|W_{x_2}|$ and we can even take $T^* = \ell^{1-\delta'}$; then contribution of this zone to the remainder does not exceed $C\mu^{-1}h^{-1}$.

Meanwhile contribution of zone

$$\big\{x:\ C_0\mu^{-1} \le x_1 \le \epsilon_1,\ |W_{x_2}| \le C_0 \max\big(\mu^{-1}, (\mu h)^{\frac{1}{2}-\delta}\big)\big\} \tag{15.2.51}$$

to the Tauberian remainder under this condition does not exceed

$$C\mu^{-1}h^{-1} + C\mu(\mu h)^{\frac{1}{2}-\delta}h^{-1}. \tag{15.2.52}$$

So we arrive to

Theorem 15.2.23. *Let conditions* (13.2.1)–(13.2.4), (15.2.2) *and* (15.2.12) *and non-degeneracy condition* (15.2.41) *be fulfilled on* $\operatorname{supp}\psi$ *where* $\psi(x) \in \mathscr{C}_0^\infty(\mathbb{R}^2)$.

Then contribution of zone $\{x:\ \operatorname{dist}(x,\partial X)\le \epsilon_1\}$ *to the remainder does not exceed* (15.2.52)*; in particular, it does not exceed* $C\mu^{-1}h^{-1}$ *as* $\mu \le h^{\delta-\frac{1}{5}}$.

This is exactly the same estimate as was derived in Chapter 13 without boundary under condition

$$|\nabla VF^{-1}| + |\nabla^2 VF^{-1}| \ge \epsilon. \tag{15.2.53}$$

Now let us consider derivatives of VF^{-1} with respect to x_1 which leads to the drift in the direction x_2.

Our goal is to prove

Theorem 15.2.24. *(i) Let conditions* (13.2.1)–(13.2.4), (15.2.2) *and* (15.2.12) *and non-degeneracy condition* (15.2.7) *be fulfilled on* $\mathsf{supp}\,\psi$ *where* $\psi(x) \in \mathscr{C}_0^\infty(\mathbb{R}^2)$. *Then the remainder does not exceed*

$$C\mu^{-1}h^{-1} + C\mu^2 h^{-\delta} \tag{15.2.54}$$

as $\mu \le h^{\delta-\frac12}$; *in particular remainder does not exceed* $C\mu^{-1}h^{-1}$ *as* $\mu \le h^{\delta-\frac13}$.

(ii) Additionally assume that condition (15.2.41) *is also fulfilled on* $\mathsf{supp}\,\psi$. *Then the remainder does not exceed*

$$C\mu^{-1}h^{-1} + C\mu^{\frac52}h^{\frac12-\delta} \tag{15.2.55}$$

as $\mu \le h^{\delta-\frac12}$; *in particular remainder does not exceed* $C\mu^{-1}h^{-1}$ *as* $\mu \le h^{\delta-\frac37}$.

Proof. (i) First assume that

$$\rho \ge \bar\rho := \mathsf{max}\bigl(C\mu^{-1}, \mu^{\frac12}h^{\frac12-\delta}\bigr). \tag{15.2.56}$$

Then along the whole trajectory $x_1 \ge \mu^{-1}\rho \ge \mu^{-\frac12}h^{\frac12-\delta}$ and using $\mu^{-1}h$-Fourier integral operators we can reduce operator to the canonical form of Section 13.3. We can then notice that the shift with respect to "new" x_1 is $\mu^{-1}Tk$ where $k \asymp |\nabla VF^{-1}|$ but the scale with respect to the dual variable is $\mu^{-1}\rho$ and we need to write uncertainty principle

$$\mu^{-1}kT \times \mu^{-1}\rho \ge \mu^{-1}h^{1-\delta} \tag{15.2.57}$$

or plugging $T \asymp \mu^{-1}$ and $k \asymp 1$ we get

$$\rho \ge \bar\rho := \mathsf{max}\bigl(C\mu^{-1}, \mu^2 h^{1-\delta}\bigr) \tag{15.2.58}$$

and this restriction is stronger than (15.2.56) which in turn is stronger than (15.2.17).

Therefore

(15.2.59) Under condition (15.1.8) contribution to the remainder of $\mathcal{X}_{\mathsf{inn}}$ defined by (15.1.16), (15.2.58) does not exceed $C\mu^{-1}h^{-1}$.

Meanwhile with this choice of $\bar{\rho}$ contribution to the remainder of $\mathcal{X}_{\mathsf{trans}}$ defined by (15.1.14) does not exceed $C\bar{\rho}h^{-1}$ which is exactly the second term in (15.2.54).

Statement (i) is proven.

(ii) To prove Statement (ii) we need to note that in $\mathcal{X}_{\mathsf{trans}}$ shift with respect to ξ_2 is observable as $T \asymp \mu^{-1}$ and $|W_{x_2}| \asymp \ell$ satisfies (15.2.38). Then the contributions to the remainder of all zones save $\{\mathcal{X}_{\mathsf{trans}},\ |W_{x_2}| \le \bar{\ell}\}$ are $O(\mu^{-1}h^{-1})$ and under condition (15.2.41) the contribution of this zone does not exceed $C\bar{\rho}\bar{\ell}h^{-1}$ which is exactly the second term in (15.2.55). □

Remark 15.2.25. (i) Conditions (15.1.8) and (15.2.41) are fulfilled generically at the boundary.

(ii) Obviously in the setting of Theorem 15.2.24 the inner zone provides the worst contribution to the remainder and we will need to improve it in the framework of condition (15.2.24) using the strong magnetic field approach there.

15.2.3 From Tauberian to Magnetic Weyl Formula

Now our goal is to pass from Tauberian with $T = \epsilon\mu^{-1}$ to magnetic Weyl formula and estimate remainder R^{MW}. We also consider extended Weyl formula and estimate remainder $\mathsf{R}^{\mathsf{W}}_{\infty}$.

Theorem 15.2.26. *Let $\psi \in \mathscr{C}^{\infty}(\bar{X})$ be a fixed function with a compact support contained in the small vicinity of ∂X and let conditions* (13.2.1)–(13.2.4), (13.3.1) *and* (13.4.45) *be fulfilled there. Further, let condition* (15.2.6) *be fulfilled.*

Then

(i) Under condition (15.2.8) *both $\mathsf{R}^{\mathsf{W}}_{\infty}$ defined by* (15.2.14) *and R^{MW} defined by* (15.2.15) *do not exceed $C\mu^{-1}h^{-1}$ as $\mu \le h^{\delta-1}$.*

(ii) Under condition $(15.2.44)_m$ *both $\mathsf{R}^{\mathsf{W}}_{\infty}$ and R^{MW} do not exceed $C\mu^{-1}h^{-1}$ as $\mu \le h^{-\delta}$.*

(iii) Under condition (15.2.41) *both* $\mathsf{R}^{\mathsf{W}}_{\infty}$ *and* R^{MW} *do not exceed* (15.2.52) *as* $\mu \le h^{\delta-1}$*; in particular remainder does not exceed* $C\mu^{-1}h^{-1}$ *as* $\mu \le h^{\delta-\frac{1}{5}}$.

(iv) Under condition (15.2.7) *both* $\mathsf{R}^{\mathsf{W}}_{\infty}$ *and* R^{MW} *do not exceed* (15.2.54) *as* $\mu \le h^{\delta-1}$*; in particular remainder does not exceed* $C\mu^{-1}h^{-1}$ *as* $\mu \le h^{\delta-\frac{1}{3}}$.

(v) Under conditions (15.2.7) *and* (15.2.41) *both* $\mathsf{R}^{\mathsf{W}}_{\infty}$ *and* R^{MW} *do not exceed* (15.2.55) *as* $\mu \le h^{\delta-1}$*; in particular remainder does not exceed* $C\mu^{-1}h^{-1}$ *as* $\mu \le h^{\delta-\frac{3}{7}}$.

Proof. (a) To go from R^{T} to $\mathsf{R}^{\mathsf{W}}_{\infty}$ is easy: using condition (13.4.45) (i.e. $|V| \asymp 1$) we can apply the standard results of Chapters 4 and 7 after rescaling $x \mapsto \mu x$.

Going from $\mathsf{R}^{\mathsf{W}}_{\infty}$ to R^{MW} is more subtle. Note first that we can drop all terms with $m > 0$ in (15.2.14). Therefore only surviving terms are those with $h^{-2}(\mu h)^{2n}$ with integration over X and $h^{-1}(\mu h)^{2n}$ with integration over ∂X.

(b) Consider first terms with integration over X.

Note first that under condition (15.2.8) their sum is equal to

$$\int_X \mathcal{N}^{\mathsf{MW}}(x, \mu h, \tau)\psi(x)\,dx \tag{15.2.60}$$

modulo $O\big(h^{-2}(\mu h)^s\big)$; actually we go in the opposite direction: from expression (15.2.60) to its decomposition into powers of $\hbar = \mu h$.

Consider expression (15.2.60) under condition (15.1.8); again we can replace $\theta(\tau - V - (2j+1)F\mu h)$ by derivative with respect to x_1 (of high order and with smooth coefficient) of smooth $\mathscr{C}^s$-function; so integrating by parts we again arrive to the sum of the terms in question plus the similar integral over the boundary; however the latter contains at least one extra integration with respect to τ so we get

$$(\mu h)^{2n}h^{-2}\int \big(\tau - V - (2j+1)F\mu h\big)^r_+ \phi_{n,r}(x)\,ds_g \tag{15.2.61}$$

where $r \ge 1$. If we replace in the latter term summation with respect to j by integration the error will not exceed $C(\mu h)^{r+1}h^{-2}$ i.e. $C\mu^2$ which is less than (15.2.54).

On the other hand, under condition (15.2.41) the error in question will not exceed $C(\mu h)^{r+1\frac{3}{2}}h^{-2}$ which is less than (15.2.55). So, in Statements (iv) and (v) we also can replace terms with integration over dx into $\mathcal{N}^{\mathsf{MW}}$, may be changing κ'_{n0}.

The same arguments albeit without integration with respect to x_1 work under condition (15.2.41) alone; however we gain only factor $(\mu h)^{\frac{1}{2}}$.

The similar arguments work in the framework of Statement (ii) as well.

(c) Now Statement (i) becomes the most complicated as many terms should be taken into account. We apply the following trick: consider the same operator albeit we replace D_2 everywhere by D_3:

$$\bar{A} := \sum_{j,k} \bar{P}_j g^{jk}(x_1,x_2)\bar{P}_k + V(x_1,x_2), \qquad \bar{P}_1 = hD_1,\ \bar{P}_2 = hD_3 - \mu V_2(x_1,x_2) \tag{15.2.62}$$

Then it will affect in $\mathsf{R}^{\mathsf{W}}_{\infty}$ only terms with $m \ge 1$ we do not care about. But the problem remains microhyperbolic in the variable x_2 and therefore everything works as it should. We need to consider then shifts with respect to ξ_2 only and therefore only averaging with respect to x_2 is needed.

Note then that what we get instead of $\int e(x,x,\tau)\psi\,dx$ is

$$(2\pi h)^{-1}\int e(x_1,x_1;x_2,\xi_3,\tau)\psi\,dx_1\,dx_2 d\xi_3 \tag{15.2.63}$$

where $e(x_1,y_1;x_2,\xi_2,\tau)$ is a Schwartz kernel for spectral projector for 1-dimensional operator. Here integration with respect to x_3 is not needed. Neither is needed integration with respect to ξ_2 as we pass from Tauberian expression with $T = \epsilon\mu^{-1}$ for $e(...)$ to $e(...)$ itself. Finally we change in (15.2.63) ξ_3 by ξ_2.

Also we can replace everywhere (save V_2) x_1 by 0 while V_2 we replace by

$$\bar{V}_2 = V(0,x_2) + (\partial_{x_1}V_2)(0,x_2)x_1; \tag{15.2.64}$$

it will not affect essential boundary terms. But then boundary terms in $\mathsf{R}^{\mathsf{W}}_{\infty}$ together must match to a boundary term in R^{MW} . This proves Statement (i) completely.

(d) Exactly the same arguments work for Statements (ii)–(v); we do not use condition (15.2.7) at all and in $\mathcal{X}_{\mathsf{bound}}$ defined in terms of (ξ_3, x_2) we consider shifts after hops with respect to x_3, so we do not need to integrate over x_3. Without condition (15.2.21) we use the trivial $O(\bar{\rho}h^{-1})$ estimate for contribution of $\mathcal{X}_{\mathsf{trans}}$.

Under condition (15.2.21) in $\mathcal{X}_{\mathsf{trans}}$ we consider shifts with respect ξ_2 and again integration over x_3 and ξ_2 is not needed. □

15.3 Moderate Magnetic Field

In this section we consider a case of the moderate magnetic field when the results of the previous section are not as sharp as we want (so the remainder is not $O(\mu^{-1}h^{-1})$). As under different assumption it happens under different restrictions to μ, we consider separately different cases.

15.3.1 Most Non-Degenerate Case

If condition (15.2.8) is fulfilled, we need to consider only the case of the *intermediate magnetic field*

$$h^{\delta-1} \le \mu \le h^{-1} \tag{15.3.1}$$

and then operator is x_2-microhyperbolic. Therefore as $\psi = \psi'\psi''_\mu$ with $\psi' = \psi'(x_2) \in \mathscr{C}_0^\infty$ and $\psi''_\gamma = \psi''(x_1\gamma^{-1})$ [5)] with ψ''_γ supported in $|x_1| \le C_0\gamma$, $\gamma = \mu^{-1}$,

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\psi u| \le C\mu^{-1}h^{-2}T\bigl(\frac{h}{T}\bigr)^s, \tag{15.3.2}$$

and then

$$|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\psi u| \le C\mu^{-1}h^{-1} \tag{15.3.3}$$

as $h \le T \le T^* = \epsilon_0$ where μ^{-1} comes as a measure of X_{bound} and therefore

$$\mathsf{R}^{\mathsf{T}} \le C\mu^{-1}h^{-1}. \tag{15.3.4}$$

[5)] Averaging with respect to x_1 is not needed at all.

Further advancing method of successive approximations with unperturbed operator[6)]

$$\bar{A} \coloneqq \sum_{j,k} \bar{P}_j g^{jk}(y) \bar{P}_j + V(y), \tag{15.3.5}$$

$$\bar{P}_j = hD_j - \mu V_j(y) - \mu \sum_k (x_j - y_j)(\partial_k V_j)(y) \tag{15.3.6}$$

we see that the first term results in expression (15.2.63) of the magnitude $C\mu^{-1}h^{-2}$ while any next term acquires factor h in the corresponding power and thus does not exceed the remainder estimate.

So, under conditions (15.2.8) and (15.3.1) and indicated ψ the remainder does not exceed $C\mu^{-1}h^{-1}$ while the principal part is given by the Tauberian expression for the first term in the successive approximation method.

On the other hand, if we take $\psi'' \in \mathscr{C}_0^\infty(\mathbb{R}^+)$ (supported in $(\frac{1}{2}, 1)$) and $\gamma \ge \mu^{-1}$ we can take

$$T^* \asymp \min\bigl((h^{-1}\gamma)^{1+\sigma}, \mu\gamma^{1-\sigma}\bigr). \tag{15.3.7}$$

Really, we could take $T^* \asymp \gamma^{1-\sigma}$ as

$$\gamma \ge \bar{\gamma} \coloneqq C_0\mu^{-1} + C_0\mu^{-\frac{1}{2}}h^{\frac{1}{2}-\delta} \tag{15.3.8}$$

which completely covers the case $\mu \le h^{\delta-1}$. Otherwise we can arrive to this case scaling $x \mapsto x\zeta$, $\mu \mapsto \mu\zeta$, $h \mapsto h\zeta^{-1}$ with $\zeta = \min\bigl(1, (\mu^{-1}h)^{\frac{1}{2}}, (\mu^{-1}h\gamma^{-2})^s\bigr)$ with large s.

Therefore the contribution of the strip $\{x\colon x_1 \asymp \gamma\}$ to the remainder does not exceed

$$C\gamma h^{-1}\Bigl((h^{-1}\gamma)^{-1-\sigma} + \mu^{-1}\gamma^{-1+\sigma}\Bigr)$$

and hence contribution of $\{x\colon x_1 \le \epsilon\}$ does not exceed this expression integrated over $\gamma^{-1}d\gamma$ resulting in

$$Ch^{-1}\Bigl((h^{-1}\gamma)^{-1-\sigma}\gamma\big|_{\gamma=\mu^{-1}} + \mu^{-1}\gamma^\sigma|_{\gamma=1}\Bigr) \asymp C\mu^{-1}h^{-1}.$$

So, we can take ψ fixed function rather than scaled with respect to x_1.

However let us partition it into functions supported in $\{x\colon x_1 \le 2\bar{\gamma}\}$ and in $\{x\colon x_1 \ge \bar{\gamma}\}$. Then such expression in the latter case is not affected

[6)] In comparison with (15.2.63), (15.2.64) we freeze at y not $(0, y_2)$ at this moment.

by the presence of the boundary resulting in the same expression but with approximation term calculated for the whole space.

However in the former case the presence of the boundary should be taken into account. Let us use again the method of successive approximation but use as unperturbed operator one with x_1 set to 0 everywhere save in the linear part of magnetic field; thus unperturbed operator is

$$\bar{A} := h^2 D_1^2 + (\mu x_1 - hD_2)^2 - W(0, x_2). \tag{15.3.9}$$

Again as the main part of asymptotics is of magnitude $\bar{\gamma} h^{-2}$ and each next term acquires factor $\bar{\gamma}$, so only first two terms need to be considered.

So, let us consider the second term; we claim that calculating this term one does not need to take a boundary into account. Really, as perturbation vanishes at the boundary one needs to kill x_1 before restricting to the boundary, but it can be done only by commutator and then factor h rather than $\bar{\gamma}$ appears. It is not enough but if we plug instead of $\psi''_{\bar{\gamma}}$ function ψ''_{γ} with $C_0\mu^{-1} \le \gamma \le \bar{\gamma}$ and $\operatorname{supp} \psi''$ disjoint from 0 we acquire factor $(\mu\gamma)^{-s}$ and then contribution to the error is $C\gamma h^{-1}(\mu\gamma)^{-s}$ and it boils down to $C\mu^{-1}h^{-1}$ after summation with respect to γ.

Then we get the final answer as the sum of two terms: one is for operator (15.3.5) albeit with calculation (before taking Γ) in the whole plane i.e.

$$h^{-2} \int_X \mathcal{N}^{\mathsf{MW}}(x, \mu h)\psi(x)\, dx \tag{15.3.10}$$

and the second one for operator (15.3.9) but in half-plane and subtracting the same expression for the same operator albeit in the whole plane we arrive to

$$\int_X \Big(\int \boldsymbol{e}_1(x_1, x_1; x_2, \xi_2, 0)\, d\xi_2 - h^{-2}\mathcal{N}_0^{\mathsf{MW}}(x, \mu h)\Big)\psi(x)\, dx \tag{15.3.11}$$

where $\boldsymbol{e}_1(x_1, y_1; x_2, \xi_2, 0)$ is the Schwartz kernel of one-dimensional operator

$$h^2 D_1^2 + (\mu x_1 - \xi_2)^2 - W(0, x_2) \tag{15.3.12}$$

and $\mathcal{N}_0^{\mathsf{MW}}$ refers to $\mathcal{N}^{\mathsf{MW}}$ calculated for the same operator (15.3.9).

We will transform operators (15.3.9), (15.3.12) and silently (without changing notations) transform $\boldsymbol{e}(...)$ and $\mathcal{N}_0^{\mathsf{MW}}(...)$.

Changing $x_1 \mapsto x_1\zeta$ and $\xi_2 \mapsto \xi_2\zeta\mu$ we acquire factor $\mu\zeta$ and get instead of the first term in (15.3.11)

$$(2\pi h)^{-1}\zeta\mu \int \mathbf{e}_1(x_1, x_1; x_2, \xi_2, 0)\psi'(x_2)\psi''(x_1\zeta)\, dx_1\, dx_2 d\xi_2 \tag{15.3.13}$$

meanwhile transforming operator into

$$h^2\zeta^{-2}\Big(D_1^2 + h^{-2}\mu^2\zeta^4(x_1-\xi_2)^2 - W(0,x_2)h^{-2}\zeta^{-2}\Big). \tag{15.3.14}$$

One can drop a factor in the front of operator and select $\zeta = \mu^{-\frac{1}{2}}h^{\frac{1}{2}}$ thus resulting in the answer

$$(2\pi)^{-1}\mu^{\frac{1}{2}}h^{-\frac{1}{2}} \int \mathbf{e}_1(x_1, x_1; x_2, \xi_2, 0)\psi'(x_2)\psi''(x_1\mu^{\frac{1}{2}}h^{-\frac{1}{2}})\, dx_1\, dx_2 d\xi_2 \tag{15.3.15}$$

and in operator

$$D_1^2 + (x_1-\xi_2)^2 - \mu^{-1}h^{-1}W(0,x_2). \tag{15.3.16}$$

However we need to subtract from (15.3.15) also transformed the second term in (15.3.11). We can then tend $\zeta \to +\infty$ (the error will be negligible) and the total difference will tend to

$$h^{-1}\int_{\partial X} \mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}(x_2, \mu h)\psi(x)\, ds_g. \tag{15.3.17}$$

So, the final answer is

$$h^{-2}\int_X \mathcal{N}^{\mathsf{MW}}(x, \mu h)\psi(x)\, dx + h^{-1}\int_{\partial X} \mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}(x_2, \mu h)\psi(x)\, ds_g \tag{15.3.18}$$

with $* = \mathsf{D}, \mathsf{N}$ and we arrive to the following theorem:

Theorem 15.3.1. *Let $\psi \in \mathscr{C}^\infty(\bar{X})$ be a fixed function with a compact support contained in the small vicinity of ∂X and let conditions* (13.2.1)–(13.2.4), (13.3.1) *and non-degeneracy condition* (15.2.8) *be fulfilled on* $\mathsf{supp}\,\psi$.

Then as $\mu \le h^{-1}$ formula (15.3.18) *gives* N *with an error* $\mathsf{R}^{\mathsf{MW}} = O(\mu^{-1}h^{-1})$.

15.3.2 Generic Case. Analysis in Inner Zone

Now we are interested to improve results of the previous section in the generic case i.e. when both conditions (15.2.7) and (15.2.41) are fulfilled. Then in virtue of Theorem 15.2.26(v) we can assume that

$$\mu \ge h^{\delta-\frac{3}{7}}. \tag{15.3.19}$$

We start from the simpler analysis in $\mathcal{X}_{\mathsf{inn}}$. In this case as $\rho \ge \bar{\rho} = (\mu h)^{\frac{2}{3}} h^{-\delta}$ we need to consider operator without boundary condition; however presence of the boundary as we remember manifests itself through uncertainty principle; we should take $T_* = h^{1-\delta'}\ell^{-2}$ or $T_* = \mu h^{1-\delta'}\rho^{-1}$ whatever is smaller and *at this moment* we are interested only in the zone where $T_* \ge \epsilon\mu^{-1}$.

Actually we can take here effectively even $\delta' = 0$ in the following sense: note that

$$|F_{t\to h^{-1}\tau}\phi_T(t)\Gamma\big(U\,{}^tQ_y\big)| \le C\mu^{-1}h^{-1}\rho\ell \times \big(\mu T+1\big) \tag{15.3.20}$$

as $\phi \in \mathscr{C}_0^\infty([-1,1])$, $T \ge h$ and

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\big(U\,{}^tQ_y\big)| \le C\mu^{-1}h^{-1}\rho\ell \times \big(\mu T+1\big)\big(\frac{T}{T_*}\big)^{-s} \tag{15.3.21}$$

as $\chi \in \mathscr{C}_0^\infty([-1,-\frac{1}{2}]\cup[\frac{1}{2},1])$ and $T_* \le T \le T^*$ with unspecified at this moment T^* and

$$T_* = \mathsf{min}\big(\mu h\rho^{-1}, \ell^{-2}\big)h = h\times \begin{cases} \mu\rho^{-1} & \text{as } \ \rho > \mu\ell^2,\\ \ell^{-2} & \text{as } \ \rho < \mu\ell^2.\end{cases} \tag{15.3.22}$$

Recall that $Q = Q(x_2, hD_2)$ is an (ℓ,ρ) admissible element with $\rho\ell \ge h^{1-\delta}$.

Really for one winding (i.e. $T = \epsilon\mu^{-1}$) estimate (15.3.20) is obvious, and we need to take in account $N \asymp \mu T+1$ windings.

Estimates (15.3.20) and (15.3.21) imply that

$$|F_{t\to h^{-1}\tau}\phi_T(t)\Gamma\big(U\,{}^tQ_y\big)| \le C\mu^{-1}h^{-1}\rho\ell \times \big(\mu T_*+1\big) \tag{15.3.23}$$

as $\phi \in \mathscr{C}_0^\infty([-1,1])$ and $T_* \le T \le T^*$.

Remark 15.3.2. Therefore from the point of view of the remainder estimate, rather than the final formula we need to take in account $N^* \asymp (\mu T_*+1)$ windings but in the main part of asymptotics still $(\mu T_* h^{-\delta'}+1)$ windings should be taken in account.

Let us discuss T^*. As average propagation speed with respect to x does not exceed $C_0\mu^{-1}$ and propagation speed with respect to ξ_2 does not exceed $C_0\ell$, our dynamics remains in the same (ℓ,ρ)-element for time

$$T^* = \epsilon \min\bigl(\mu\ell, \rho\ell^{-1}\bigr) \tag{15.3.24}$$

and $T_* : T^* \asymp h\rho^{-1}\ell^{-1}$.

Therefore contribution of (ℓ,ρ)-element to the Tauberian remainder with $T \ge \bigl(T_* h^{-\delta'} + \epsilon\mu^{-1}\bigr)$ does not exceed

$$C\mu^{-1}h^{-1}\rho\ell\bigl(\mu T_* + 1\bigr) \times T^{*\,-1}. \tag{15.3.25}$$

Note that in zone $\ell \le \mu^{-\frac{1}{2}}\rho^{\frac{1}{2}}$ we can reset $\ell = \ell(\rho) := \mu^{-\frac{1}{2}}\rho^{\frac{1}{2}}$ thus covering the whole zone with a fixed magnitude of ρ by a single element. Also note that $\ell(\rho)\rho = \mu^{-\frac{1}{2}}\rho^{\frac{3}{2}} \ge \mu^{\frac{1}{2}}h \ge h^{1-\delta}$ as $\rho \ge \bar\rho$.

Therefore

(15.3.26) Contribution of $(\ell(\rho),\rho)$-element to the Tauberian remainder with $T = \mu h^{1-\delta'}\rho^{-1}$ does not exceed

$$C\mu^{-1}h^{-1}\ell(\rho)^2\bigl(\frac{\mu^2 h}{\rho} + 1\bigr) \asymp C + C\mu^{-2}h^{-1}\rho.$$

Then summation with respect to $\rho \in [\bar\rho, \epsilon\mu]$ results in

$$C|\log h| + C\mu^{-1}h^{-1}. \tag{15.3.27}$$

Thus we conclude that

(15.3.28) Contribution of zone $\{\rho \ge \bar\rho,\ \mu\ell^2 \le \rho\}$ to the Tauberian remainder with $T = \mu h^{1-\delta'}\rho^{-1}$ does not exceed (15.3.27).

Remark 15.3.3. We need to keep $\ell(\rho) \ge C\mu^{-1}$ but this is definitely case as $\mu \ge h^{-\frac{2}{5}}$ and we are ensured in this by condition (15.3.19).

Similarly, consider case $\mu\ell^2 \ge \rho \ge \bar\rho$. Then automatically $\ell \ge \ell(\bar\rho)$ and $\ell\rho \ge h^{1-\delta}$ and

(15.3.29) In this zone we can reset $\rho = \rho(\ell) = \mu\ell^2$.

Really, to avoid collision with $\mathcal{X}_{\mathsf{trans}}$ we select time direction in which ρ (and thus ξ_2) increases. It is possible because as long as $|t| \le \epsilon\mu\ell$ we remain in the same $\epsilon\ell$-vicinity. Again $\ell \ge C\mu^{-1}$ in virtue of condition (15.3.19).

Therefore

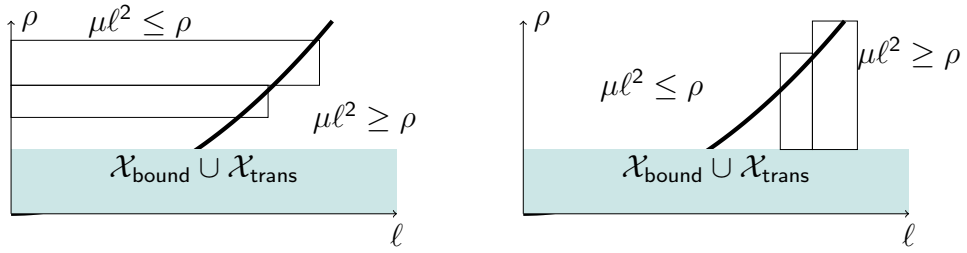
(15.3.30) Contribution of $(\ell, \rho(\ell))$-element to the Tauberian remainder with $T = h^{1-\delta'}\ell^{-2}$ does not exceed

$$C\mu^{-1}h^{-1}\rho(\ell)\bigl(\frac{\mu h}{\ell^2}+1\bigr) \asymp C + C\mu^{-1}h^{-1}\ell^2.$$

Then summation with respect to $\ell \in [\bar{\ell}, \epsilon]$ results in (15.3.27) where $\bar{\ell} = \mu^{-\frac{1}{2}}\bar{\rho}^{\frac{1}{2}}$.

Therefore we conclude that

(15.3.31) Contribution of zone $\{\rho \ge \bar{\rho},\ \mu\ell^2 \ge \rho\}$ to the Tauberian remainder with $T = \mu h^{1-\delta'}\rho^{-1}$ does not exceed (15.3.27).



(a) $\mu\ell^2 < \rho$ (b) $\mu\ell^2 > \rho$

Figure 15.8: Partition of two zones in $\mathcal{X}_{\mathsf{inn}}$

So we arrive to the following proposition:

Proposition 15.3.4. *Under assumptions* (15.2.41) *and* (15.2.7) *contribution of* $\mathcal{X}_{\mathsf{inn}}$ *to the Tauberian remainder with* $T = \mu h^{1-\delta'}\rho^{-1}$ *does not exceed* (15.3.27).

We are completely happy with this estimate unless $\mu \ge h^{-1}|\log h|^{-1}$ and we need to derive contribution of much more troublesome zone $\mathcal{X}_{\mathsf{trans}}$ before thinking if we should improve it.

15.3.3 Generic Case. Analysis in Transitional Zone

Let us consider zone $\mathcal{X}_{\mathsf{trans}}$. Recall that its contribution to the Tauberian remainder with $T = \epsilon\mu^{-1}$ (and thus with $T = h^{1-\delta}$) does not exceed $C\bar{\rho}h^{-1} = C(\mu h)^{\frac{2}{3}}h^{-1-\delta}$ in the general case and $C\bar{\rho}\bar{\ell}h^{-1} = C(\mu h)^{\frac{7}{6}}h^{-1-\delta}$ under condition (15.2.41) and therefore (as we assume (15.2.41)) we should consider only case

$$\mu \ge h^{\delta-\frac{7}{13}}. \tag{15.3.32}$$

Definitely $\mathcal{X}_{\mathsf{trans}}$ is leaner than $\mathcal{X}_{\mathsf{inn}}$ (albeit as $\mu \ge h^{\delta-1}$ it is thick enough to eliminate $\mathcal{X}_{\mathsf{bound}}$). However the main problem there is that in the current settings we are not aware of any lower bound of the propagation speed and the only bound we know is an upper bound $C_0\bar{\rho}^{\frac{1}{2}}$ in both directions.

Therefore there is no mechanism except drift with respect to ξ_2 to break periodicity and we must take

$$T_* = \epsilon h\ell^{-2} \tag{15.3.33}$$

and

$$T^* = \epsilon\bar{\rho}^{-\frac{1}{2}}\ell. \tag{15.3.34}$$

Sure we need to have $T_* \le T^*$, i.e. $\ell \ge \bar{\ell}_0$ with

$$\bar{\ell}_0 := \bar{\rho}^{\frac{1}{6}}h^{\frac{1}{3}} = (\mu h)^{\frac{1}{9}}h^{\frac{1}{3}-\delta}. \tag{15.3.35}$$

Obviously $\bar{\ell}_0 \le \bar{\ell} = (\mu h)^{\frac{1}{2}}h^{-\delta}$ unless $\mu \le h^{-\frac{1}{7}}$ the case we are not interested in.

Remark 15.3.5. Note that it it requires time $t^* \asymp \bar{\rho}\ell^{-1}$ to pierce through $\mathcal{X}_{\mathsf{trans}}$ and $t^* \le T^*$ as $\ell \le \bar{\ell}$ which is the case we are interested in. Otherwise we would be able to increase T^* further.

So, in the same manner as before contribution of $(\ell,\bar{\rho})$-element with $\ell \ge \bar{\ell}_0$ to the Tauberian remainder with any $T \ge T_*h^{-\delta}$ [7] by

$$C\mu^{-1}\bar{\rho}\ell h^{-1}\big(\mu T_* + 1\big) \times T^{*\,-1} = C\bar{\rho}^{\frac{3}{2}}\ell^{-2} + C\mu^{-1}h^{-1}\bar{\rho}^{\frac{3}{2}} \tag{15.3.36}$$

and summation over $\ell \ge \bar{\ell}_0$ results in

$$C\bar{\rho}^{\frac{3}{2}}\bar{\ell}_0^{-2} + C\mu^{-1}h^{-1}\bar{\rho}^{\frac{3}{2}}|\log h| \asymp C(\mu h)^{\frac{7}{9}}h^{-\frac{2}{3}-\delta}. \tag{15.3.37}$$

[7] As $T_*h^{-\delta} \ge T^*$ we reset $T = T^*$.

On the other hand, contribution of $(\bar{\ell}_0, \bar{\rho})$-element to the Tauberian remainder with $T \ge \epsilon\mu^{-1}$ does not exceed $C\bar{\rho}\bar{\ell}_0 h^{-1}$ which coincides with the (15.2.37).

Therefore we arrive to the following proposition:

Proposition 15.3.6. *Under condition* (15.2.41) *contribution of* $\mathcal{X}_{\mathsf{trans}}$ *with any* $T \ge T_* h^{-\delta} = h^{1-\delta}\ell^{-2}$ *(reset to* $T \ge h^{1-\delta}$ *as either* $\ell \le \bar{\ell}_0$ *or* $\ell \ge \bar{\ell}$*; see also* [7]*) does not exceed* (15.3.37)*.*

In particular, it does not exceed $C\mu^{-1}h^{-1}$ *as* $\mu \le h^{\delta-\frac{5}{8}}$*.*

Remark 15.3.7. (i) Surely we need to keep $\ell \ge C_0\mu^{-1}$ thus requiring $\bar{\ell}_0 \ge C_0\mu^{-1}$ i.e. $\mu \ge h^{-\frac{2}{5}}$ but this is a case.

(ii) We also need to keep an upper bound to speed greater than $C_0\mu^{-1}$, i.e. $\bar{\rho}^{\frac{1}{2}} \ge C_0\mu^{-1}$ i.e. $\mu \ge h^{-\frac{1}{4}}$ but this is also the case.

(iii) Further, we need to keep $\bar{\ell}_0\bar{\rho} \ge h^{1-\delta}$ i.e. $\mu \ge h^{-\frac{1}{7}}$, but this is again the case.

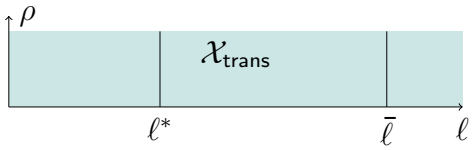


Figure 15.9: Zone $\mathcal{X}_{\mathsf{trans}}$

Can we increase T^* in these arguments? We need to do it only under condition (15.3.19). Then as we will prove later the following proposition:

Proposition 15.3.8. *Let Dirichlet boundary condition be given on* ∂X*. Then in the transitional zone* $\{|\rho| \le \bar{\rho}\}$ *as*

$$\mu \ge h^{-\frac{1}{4}-\delta} \tag{15.3.38}$$

average propagation speed in one direction (direction of hops when we have chosen time) is bounded by $C\bar{\rho}^{\frac{1}{2}}$ *and in the opposite direction it is bounded by* $C\mu^{-1}$*.*

Note, that condition (15.3.38) ensures that $\bar{\rho}^{\frac{1}{2}} \gg \mu^{-1}$.

So, assume that Dirichlet boundary condition be given on ∂X. Then selecting the time direction for given partition element so that ℓ *increases along hops* we can chose

$$T^* \asymp 1. \tag{15.3.39}$$

Really, we need to leave ℓ-element and come back. This comeback includes either going in the direction opposite of hops with the speed not exceeding $C_0\mu^{-1}$ and requires time $\asymp \mu\ell$ which is larger than (15.3.39) as $\ell \ge \mu^{-1}$ and $\mu \ge h^{-\frac{1}{4}}$ or leaving zone $\ell \le \epsilon$ which requires at least time $\asymp 1$ [8].

Actually $T^* \asymp 1$ is better (larger) than given by (15.3.34) we used before only as $\ell \le \bar{\rho}^{\frac{1}{2}}$, but this is only zone we need to care about.

So, contribution of the given element to the remainder does not exceed the left-hand expression of (15.3.36) which now becomes

$$C\mu^{-1}\bar{\rho}\ell h^{-1} \times \bigl(\mu h\ell^{-2}+1\bigr) \times \min\bigl(\bar{\rho}^{\frac{1}{2}}\ell^{-1},1\bigr) \asymp C\bar{\rho}\ell^{-1} + C\mu^{-1}h^{-1}\bar{\rho}\ell. \tag{15.3.40}$$

Summation of the second term in the right-hand expression over partition results in $O(\mu^{-1}h^{-1})$. Summation of the first term in the right-hand expression over partition with $\ell \ge \bar{\ell}_1$ results in the same term calculated as $\ell = \bar{\ell}_1$ and coincides with $C\bar{\rho}\bar{\ell}_1 h^{-1}$ which also estimates the contribution of zone $\{\ell \le \bar{\ell}_1\}$. Here again we chose $\bar{\ell}_j$ from condition $T_* \le T^*$ i.e. now we replace $\bar{\ell}_0$ defined by (15.3.35) by

$$\bar{\ell}_1 \coloneqq h^{\frac{1}{2}} \ll \bar{\ell}_0 \tag{15.3.41}$$

resulting in

$$C\bar{\rho}h^{-\frac{1}{2}} = C\mu^{\frac{2}{3}}h^{\frac{1}{6}-\delta}. \tag{15.3.42}$$

Therefore (with pending Proposition 15.3.8) we arrive to the following proposition:

Proposition 15.3.9. *Assume that Dirichlet boundary condition is given on ∂X. Then under assumption* (15.2.40) *the total contribution of $\mathcal{X}_{\mathsf{trans}}$ to the Tauberian remainder does not exceed* (15.3.42).

In particular, it does not exceed $C\mu^{-1}h^{-1}$ as $\mu \le h^{\delta-\frac{7}{10}}$ and it is always has an extra factor $\mu^{\frac{2}{3}}h^{\frac{7}{6}-\delta}$ in comparison with h^{-1}.

[8] As X is a bounded domain and $F \asymp 1$ in X this would mean run-around X along boundary which as we see later is impossible under certain assumptions.

Can we do better than this? Yes, as we can take

$$T^* \asymp \mu\ell. \tag{15.3.43}$$

provided ξ_2 and ℓ increase in the same time direction (on given ℓ-element) as $F_{12} < 0$.

Really, then selecting such time direction we remain in $\mathcal{X}_{\mathsf{trans}} \cap \mathcal{X}_{\mathsf{inn}}$ and as we reach $\ell \asymp 1$ dynamics is already in $\mathcal{X}_{\mathsf{inn}}$ where speed in both directions is $O(\mu^{-1})$.

Assuming that the critical point of $W := VF^{-1}|_{\partial X}$ is $x_2 = 0$ we note that hops are to the left (as $F_{12} < 0$). So, we select time direction of the sign of $(-x_2)$, so $\ell \asymp |x_2|$ increases.

Meanwhile those expressions have the same sign: $d\xi_2/dt$, $-\partial_{x_2} W$ and $(-\partial_{x_2}^2 W)x_2$ and our condition means that these expressions are positive, i.e. condition $(15.2.41)^-$ is fulfilled which matches to cases displayed at Figure 15.5(b), (d). So, under this condition we can select T^* according to (15.3.43), therefore replacing $\bar{\ell}_1$ defined by (15.3.41) by

$$\bar{\ell}_2 := \mu^{-\frac{1}{3}} h^{\frac{1}{3}-\delta} \ll \bar{\ell}_1 \tag{15.3.44}$$

(as $\mu \ge h^{-\frac{1}{2}-\delta}$) from condition $T_* \le T^*$ and arrive to remainder estimate

$$C\bar{\rho}\bar{\ell}_2 h^{-1} + C\mu^{-1}h^{-1} = C\mu^{\frac{1}{3}} h^{-\delta} + C\mu^{-1}h^{-1}. \tag{15.3.45}$$

So we have proven

Proposition 15.3.10. *Assume that Dirichlet boundary condition is given on ∂X. Then under assumption* $(15.2.41)^-$ *the total contribution of $\mathcal{X}_{\mathsf{trans}}$ to the Tauberian remainder does not exceed* (15.3.45).

In particular, it does not exceed $C\mu^{-1}h^{-1}$ as $\mu \le h^{\delta-\frac{3}{4}}$ and it has an extra factor $\mu^{\frac{1}{3}} h^{1-\delta}$ in comparison with h^{-1} (as $h^{\delta-\frac{3}{4}} \le \mu \le h^{-1}$).

Finally, assume that hops and magnetic drift have the same direction near point in question which is the case under condition

$$|\partial_{x_2} VF^{-1}| \le \epsilon \implies \partial_{x_1} VF^{-1} \ge \epsilon_0; \tag{15.2.7}^+$$

compare with original (15.2.7).

Then according to Proposition 15.3.8 there can be no roll-back, only run-around with the path of the length $\asymp 1$. This corresponds to Figure 15.5(a) and (b).

However if condition $(15.2.41)^-$ is also fulfilled (so we are in the framework of Figure 15.5(b)) fast run-around along boundary is not possible either, so the run around must contain the segment of the length $\asymp 1$ inside $\mathcal{X}_{\mathsf{inn}}$ (even inside $\{x, x_1 \ge \epsilon\}$) but the speed here is $O(\mu^{-1})$ and therefore $T^* \asymp \mu$. Then $T_* \le T^*$ defines

$$\bar{\ell}_3 := \mu^{-\frac{1}{2}} h^{\frac{1}{2}-\delta} \ll \bar{\ell}_2; \tag{15.3.46}$$

this leads to remainder estimate $C\bar{\rho}\bar{\ell}_3 h^{-1} = \mu^{\frac{1}{6}} h^{\frac{1}{6}-\delta}$ which is $O(\mu^{-1}h^{-1})$ as $\mu \le h^{\delta-1}$ and $O(h^{-\delta})$ otherwise. Thus we have proven

Proposition 15.3.11. *Assume that Dirichlet boundary condition is given on ∂X. Then under assumptions $(15.2.41)^-$ and $(15.2.7)^+$ the total contribution of $\mathcal{X}_{\mathsf{trans}}$ to the Tauberian remainder does not exceed $C\mu^{-1}h^{-1}$ as $\mu \le h^{\delta-1}$ and $Ch^{-\delta}$ otherwise.*

Conjecture 15.3.12. *The above Tauberian estimates hold with $\delta = 0$.*

To prove this conjecture we must reload $\mathcal{X}_{\mathsf{bound}}$ and $\mathcal{X}_{\mathsf{inn}}$ and to derive there the same remainder estimates as we proved in $\mathcal{X}_{\mathsf{inn}}$ but with $\bar{\rho} = (\mu h)^{\frac{2}{3}}$. It does not look difficult as we need just to rescale $x_1 \to x\gamma$ with $\gamma = h(\rho/\bar{\rho})^{-k}$ with arbitrarily large k. However then $h \mapsto \hbar = (\rho/\bar{\rho})^{-k}$ and it is not small enough to keep number of reflections below $\hbar^{-N}$. Really, we need to consider at least $\mu h\ell^{-2}$ number of reflections which means $\mu h\ell^{-2} \le \hbar^{-s}$ and as $\hbar$ goes to 1 we need to allow $\ell \ge (\mu h)^{\frac{1}{2}}$ only!

Another approach would be based on logarithmic uncertainty principle (albeit instead of $h^{-\delta}$ logarithmic factor $|\log h|^l$ would appear) but we do not have here theory similar to one of Section 2.3.

15.3.4 Propagation of Singularities in Transitional Zone

Let us study propagation of singularities in $\mathcal{X}_{\mathsf{trans}}$; later we assume that the Dirichlet boundary condition is given. We will use the technique developed Section 3.4. However there is a large difference: in Section 3.4 we treated basically trajectories with a single tangent point while here we need to treat μT such points in one shot.

Consider real function $\psi'(x, \xi, t, \tau)$ and by Weierstrass theorem replace it modulo $\big(\tau - a(x, \xi)\big)$ by a linear with respect to ξ_1 function

$$\psi'(x, \xi, t, \tau) = \psi_0(x, \xi_2, t, \tau) + \psi_1(x, \xi_2, t, \tau)\xi_1 = \psi(x, \xi, t, \tau) + \alpha(x, \xi, t, \tau)\big(\tau - a(x, \xi)\big). \tag{15.3.47}$$

Then as coefficient at ξ_1^2 in $a(x,\xi)$ is 1

$$\{\tau - a, \psi\} = \{\tau - a, \psi\} + \alpha_1\big(\tau - a(x,\xi)\big) \tag{15.3.48}$$

is at most quadratic with respect to ξ_1^2 and therefore the following identities hold:

$$\begin{aligned}((hD_t - A)u, \psi^{\mathsf{w}} u) = (u, (hD_t - A)\psi^{\mathsf{w}} u) + ih(hD_1 u, \psi^{\mathsf{w}} u)_{\partial X} - \\ ih(u, hD_1\psi^{\mathsf{w}} u)_{\partial X},\end{aligned}$$

$$(\psi^{\mathsf{w}} u, (hD_t - A)u) = (u, \psi^{\mathsf{w}}(hD_t - A)u) + ih(\psi_1^{\mathsf{w}} u, (hD_t - A)u)_{\partial X}$$

implying identity

$$\begin{aligned}2h^{-1}\operatorname{Re} i((hD_t - A)u, \psi^{\mathsf{w}} u) = -(ih^{-1}[(hD_t - A), \psi^{\mathsf{w}}]u, u) - \\ (hD_1 u, \psi^{\mathsf{w}} u)_{\partial X} + (u, hD_1\psi^{\mathsf{w}} u)_{\partial X} + (\psi_1^{\mathsf{w}} u, (hD_t - A)u)_{\partial X}.\end{aligned} \tag{15.3.49}$$

In this identity terms containing $(hD_t - A)u$ will be either negligible or under our control anyway; $[(hD_t - A), \psi^{\mathsf{w}}] \equiv -ih\{\tau - a, \psi\}^{\mathsf{w}}$ modulo smaller terms and only boundary terms

$$-(hD_1 u, \psi^{\mathsf{w}} u)_{\partial X} + (u, hD_1\psi^{\mathsf{w}} u)_{\partial X} \tag{15.3.50}$$

need special analysis. Under Dirichlet boundary condition we rewrite them as

$$-(hD_1 u, \psi_1^{\mathsf{w}} hD_1 u)_{\partial X} \tag{15.3.51}$$

and under Neumann boundary condition we rewrite them as

$$(u, h^2 D_1^2\psi_1^{\mathsf{w}} u)_{\partial X} = -(u, (hD_t - A)\psi_1^{\mathsf{w}} u)_{\partial X} + (u, (hD_t - A')\psi_1^{\mathsf{w}} u) \tag{15.3.52}$$

where $A' = A - h^2 D_1^2$ and the difference is that in the former case definiteness of this quadratic form is ensured by ψ_1 having definite sign but in the latter case not.

Remark 15.3.13. (i) The same difference would manifest itself as we would try to prove results of Section 3.4 for wave equation under Dirichlet and Neumann boundary condition. The truth is that the former satisfies Lopatinski condition while the latter does not: uniformity breaks in the tangent zone.

(ii) The same difference manifests itself through different behavior of eigenvalues $\lambda_{\mathsf{D},j}(\eta)$ and $\lambda_{\mathsf{N},j}(\eta)$ as $\eta \to +\infty$: while they both tend to $(2j+1)\mu h$ the former are tending to it from above and the latter from below. This implies that under Neumann boundary condition at least for a toy-model operator some singularities propagate in the direction opposite to hops and this propagation is faster than magnetic drift. Such difference will be the most transparent in the case of the intermediate and strong magnetic field in Section 15.4.

So, we assume that Dirichlet boundary condition is given on ∂X. We select

$$\psi_1 \ge 0 \tag{15.3.53}$$

and thus we should request

$$\{\tau - a, \psi'\} + \beta(\tau - a) \le 0 \qquad \text{with} \quad \beta = \beta(x, t, \xi_2, \tau). \tag{15.3.54}$$

We take originally

$$\psi' = \chi(\phi), \qquad \phi = \phi(x, \xi) \tag{15.3.55}$$

where $\mathscr{C}^\infty(\mathbb{R}) \ni \chi$ is a function of the same type as in Section 3.4: namely supported in $(-\infty, 0]$ and with $\chi' < 0$ on $(-\infty, 0)$.

Then as $\tau - a(x, \xi) = 0$ has two real roots $\pm\eta \ne 0$ we conclude that

$$\psi_1 = \frac{1}{2\eta}\Big(\chi(\phi(\xi_1 = \eta)) - \chi(\phi(\xi_1 = -\eta))\Big) \ge 0 \tag{15.3.56}$$

provided

$$-\partial_{\xi_1}\phi \ge \epsilon_0. \tag{15.3.57}$$

It does not satisfy (15.3.53) as $\tau - a' < 0$ but we will handle this in the same way as in Section 3.4).

Now, modulo terms of the type $\beta \cdot (\tau - a)$

$$\begin{aligned}\{\tau - a, \psi\} \equiv \{\tau - a, \psi'\} \equiv -\chi'(\phi) \cdot \{\tau - a, \phi\} \equiv \\ -\chi_1^2(\phi)\{\tau - a, \phi\} \equiv -\hat{\psi_1}^{\,2}\{\tau - a, \phi\}\end{aligned} \tag{15.3.58}$$

as $\chi_1 = \sqrt{-\chi'}$ is a smooth function (under correct choice of χ) and $\hat{\psi}$ is again linear with respect to ξ_1 function,

$$\hat{\psi} \equiv \chi_1(\phi)(\{\tau - a, \phi\})^{\frac{1}{2}} \tag{15.3.59}$$

and we used Weierstrass theorem again. We want

$$\{\tau - a, \phi\} \geq \epsilon_0. \tag{15.3.60}$$

Remark 15.3.14. Conditions (15.3.60) and (15.3.57) mean respectively that ϕ increases along trajectories as $x_1 > 0$ and at reflections.

Let us recall that instead of (15.3.53) we actually have a weaker inequality Namely instead of (15.3.53) we have

$$\psi_1 \geq -\chi_2(\phi)^2\chi_3(\tau - a')^2 \tag{15.3.53}'$$

with both χ_2 and χ_3 smooth functions supported in $(-\infty, 0]$ and notice that both operator $(hD_t - A)$ and Dirichlet boundary problem for it are elliptic as $\tau - a' < 0$ and we can apply elliptic arguments there.

So, repeating arguments of Section 3.4 we conclude that if

$$\mathsf{WF}^{s+1}\big((hD_t - A)u\big) \cap \big\{\phi^+ < \varepsilon\big\} \cap \{0 \leq t \leq T\} = \emptyset, \tag{15.3.61}$$

$$\mathsf{WF}^{s}\big(u|_{\partial X}\big) \cap \big\{\phi^+ < \varepsilon\big\} \cap \{0 \leq t \leq T\} = \emptyset, \tag{15.3.62}$$

$$\big(\mathsf{WF}^{s}(u) \cup \mathsf{WF}^{s}(hD_1 u)\big) \cap \big\{\phi^+ < \varepsilon\big\} \cap \{t = 0\} = \emptyset \tag{15.3.63}$$

and

$$\big(\mathsf{WF}^{s-\sigma}(u) \cup \mathsf{WF}^{s-\sigma}(hD_1 u)\big) \cap \{\phi^+ < \varepsilon\} \cap \{0 \leq t \leq T\} = \emptyset, \tag{15.3.64}$$

$$\mathsf{WF}^{s-\sigma}(hD_1 u|_{\partial X}) \cap \{\phi^+ < \varepsilon\} \cap \{0 \leq t \leq T\} = \emptyset \tag{15.3.65}$$

then

$$\big(\mathsf{WF}^{s}(u) \cup \mathsf{WF}^{s}(hD_1 u)\big) \cap \{\phi^+ < 0\} \cap \{0 \leq t \leq T\} = \emptyset, \tag{15.3.66}$$

$$\mathsf{WF}^{s}(hD_1 u|_{\partial X}) \cap \{\phi^+ < 0\} \cap \{0 \leq t \leq T\} = \emptyset. \tag{15.3.67}$$

Here $\sigma > 0$ is a sufficiently small exponents, $\epsilon > 0$ is an arbitrarily small constant and $T > 0$ is an arbitrary constant,

$$\phi^{\pm}(x_1, x_2, \xi_2, t, \tau) = \phi|_{\xi_1 = \pm\eta}, \qquad \eta = (\tau - a')^{\frac{1}{2}} \tag{15.3.68}$$

and WF^s are defined in terms of pseudodifferential operators $b(x, t, hD_2, hD_t)$.

As we can plug $(\phi - \varepsilon)$ instead of ϕ we by induction can get rid of assumptions (15.3.64), (15.3.65) (assuming that u is temperate).

We also can rescale $x \mapsto Tx$ (and $h \mapsto hT^{-1}$, $\mu \mapsto \mu T$) thus replacing ϵ by ϵT when we come back and we can also consider large T.

As $a = \xi_1^2 + (\xi_2 - \mu x_1^2) + V$ we select

$$\phi = \kappa t + (\mu x_2 - \xi_1). \tag{15.3.69}$$

In more general case we select

$$\phi = \kappa t + \mu x_2 + F_{12} p_1. \tag{15.3.70}$$

Note that (15.3.48) is fulfilled and also

$$\{\tau - a, \phi\} = \kappa - \partial_{x_1} V; \tag{15.3.71}$$

and (15.3.60) becomes $\kappa - \partial_{x_1} V \ge \epsilon$; so is fulfilled in two cases:

$$\kappa = C_0 \tag{15.3.72}$$

and

$$\partial_{x_1} V \ge \epsilon_0, \qquad |\kappa| \le \epsilon_1 \tag{15.3.73}$$

which allows us to prove respectively that "$(\mu x_2 - \xi_1)$" propagates with a speed bounded from below by $-C_0$ and, as $\partial_{x_1} V \ge \epsilon_0$ by ϵ_1. To get rid of ξ_1 we must to pass from ϕ^+ to ϕ but we need to notice that $\phi^+ \le \phi + c_0$.

Then we arrive to the following theorem:

Theorem 15.3.15. *Let Dirichlet boundary condition be given on ∂X and let $F_{12} < 0$ i.e. hops go to the left. Let $\chi \in \mathscr{C}_0^\infty([\frac{1}{2}, 1])$. Then*

(i) For $C_0 \le T \le T^*$

$$|F_{t \to h^{-1}\tau} \chi_T(t) \psi_2(x_2) U \psi_1(y_2)| \le C h^s \tag{15.3.74}$$

as

$$x_2 \le -C_0 \mu^{-1} T + y_2 \quad \forall x_2 \in \operatorname{supp} \psi_2, \forall y_2 \in \operatorname{supp} \psi_1; \tag{15.3.75}$$

(ii) Under condition (15.3.46) *for $C_0 \le T \le T^*$* (15.3.74) *holds as*

$$x_2 \le \epsilon_0 \mu^{-1} T + y_2 \quad \forall x_2 \in \operatorname{supp} \psi_2, \forall y_2 \in \operatorname{supp} \psi_1. \tag{15.3.76}$$

This theorem implies Proposition 15.3.8 and thus justifies the improved results of the previous subsection.

15.3.5 Calculations

Now we need to move from Tauberian to more explicit expressions for the principal part of asymptotics.

First of all recall that the Tauberian expression for $\Gamma\big(e(.,.,0)\,{}^tQ_y\big)$ is

$$h^{-1}\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma\big(U\,{}^tQ_y\big)\,d\tau \tag{15.3.77}$$

and if we replace $\bar{\chi}_T(t)$ by $\chi_T(t)$ [9] we will get

$$T^{-1}\int_{-\infty}^{0} F_{t\to h^{-1}\tau}\tilde{\chi}_T(t)\Gamma\big(U\,{}^tQ_y\big)\,d\tau \tag{15.3.78}$$

where $\tilde{\chi}(t) = it^{-1}\chi(t)$.

Let us list different cases depending on our assumptions

General Discussion

As Q is supported in $\mathcal{X}_{\mathsf{trans}}$ an absolute value of this expression does not exceed

$$C\mu^{-1}\bar{\rho}\ell h^{-1}T^{-1}\times \mu T = C\bar{\rho}h^{-1} \tag{15.3.79}$$

as $T\ge \epsilon_0\mu^{-1}$ and therefore an approximation error should not exceed

$$C\bar{\rho}\ell h^{-1}\times Th^{-1}\Delta \tag{15.3.80}$$

where Δ is the size of perturbation and we know that *as we replace* $V(x_1,x_2)$ *by* $V(x_1,y_2)$

$$\Delta = C_0\ell(\delta x_2) + C_0(\delta x_2)^2 = C_0\ell(\mu^{-1}+\boldsymbol{v}T) + C_0(\mu^{-1}+\boldsymbol{v}T)^2 \tag{15.3.81}$$

as $\delta x_2 = (\mu^{-1}+\boldsymbol{v}T)$ and in the first term factor ℓ comes as bound for $|\partial_{x_2}V|$. Here $\boldsymbol{v}\asymp \bar{\rho}^{\frac12}$ is an upper bound for propagation speed in $\mathcal{X}_{\mathsf{trans}}$. However we will justify that under Dirichlet boundary condition we can take *in these calculations* $\boldsymbol{v}\asymp\mu^{-1}$. The difference between $\bar{\rho}^{\frac12} = (\mu h)^{\frac13-\delta}$ increases as μ increases.

[9] Where as usual $\bar{\chi},\chi\in \mathscr{C}_0^\infty([-1,1])$ and $\bar{\chi}=1$, $\chi=0$ on $[-\frac12,\frac12]$ and later we will decompose $\bar{\chi}_T$ in the sum of $\bar{\chi}_{\bar{T}}(t)$ and $\chi_{2^{-n}T}(t)$

Neglecting the second term in (15.3.81) (to be justified later), we acquire factor

$$Th^{-1}\Delta = C\ell(\mu^{-1}+\boldsymbol{v}T)Th^{-1} \tag{15.3.82}$$

which after plugging $T = h^{1-\sigma}\ell^{-2}$ becomes

$$C\ell\mu^{-1}Th^{-1} + C\boldsymbol{v}T^2h^{-1} = C\Big(\mu^{-1}\ell^{-1} + C\boldsymbol{v}h\ell^{-3}\Big)h^{-\sigma} \tag{15.3.83}$$

and it is $O(h^\sigma)$ as

$$\ell \ge \hat{\ell} := \max\big(\mu^{-1}, \boldsymbol{v}^{\frac{1}{3}}h^{\frac{1}{3}}\big)h^{-\sigma} \tag{15.3.84}$$

and the contribution of zone $\ell \le \hat{\ell}$ does not exceed

$$C\bar{\rho}\hat{\ell}h^{-1} = C\bar{\rho}\max\big(\mu^{-1}, \boldsymbol{v}^{\frac{1}{3}}h^{\frac{1}{3}}\big)h^{-1-\sigma} \tag{15.3.85}$$

and as $\mu \le h^{\delta-1}$ modulo $O(\mu^{-1}h^{-1})$ it is

$$\bar{\rho}\boldsymbol{v}^{\frac{1}{3}}h^{\frac{1}{3}}h^{-1-\sigma} \asymp \begin{cases} \mu^{\frac{7}{9}}h^{\frac{1}{9}-\sigma} & \text{as } \boldsymbol{v} \asymp \bar{\rho}^{\frac{1}{2}} \\ \mu^{\frac{1}{3}}h^{-\sigma} & \text{as } \boldsymbol{v} \asymp \mu^{-1} \end{cases} \tag{15.3.86}$$

which is $O(\mu^{-1}h^{-1})$ as <u>either</u> $\boldsymbol{v} \asymp \bar{\rho}^{\frac{1}{2}}$ and $\mu \le h^{\delta-\frac{9}{13}}$ <u>or</u> $\boldsymbol{v} \asymp \mu^{-1}$ and $\mu \le h^{\delta-\frac{3}{4}}$.

Meanwhile contribution of an element with $\ell \ge \hat{\ell}$ does not exceed (15.3.80) which is

$$C\bar{\rho}\ell h^{-1} \times \Big(\mu^{-1}\ell^{-1} + C\boldsymbol{v}h\ell^{-3}\Big)h^{-\sigma} \tag{15.3.87}$$

and summation over $\ell \ge \hat{\ell}$ results in the same expression with $\ell = \hat{\ell}$ and it is the same (15.3.86) as before.

On the other hand, (the ratio of) second term in (15.3.81) to the first one is $(\mu^{-1}+\boldsymbol{v}T)$ to ℓ and $\ell \ge \mu^{-1}$ so only comparison is $\boldsymbol{v}h\ell^{-2}$ vs ℓ and ℓ is larger by the choice.

Then we conclude that

(15.3.88) Under condition (15.2.41) contribution of $\mathcal{X}_{\mathsf{trans}}$ to approximation error is $O\big(\mu^{\frac{7}{9}}h^{\frac{1}{9}-\delta}\big)$ for Neumann boundary condition and $O\big(\mu^{\frac{1}{3}}h^{-\delta}\big)$ for Dirichlet boundary condition.

Case of Condition (15.2.7)$^+$. Assume now that Dirichlet boundary condition is given and condition (15.2.7)$^+$ is fulfilled. Then

$$T_* = h^{-\sigma}\min\bigl(\frac{(\mu h)}{\bar\rho}, \frac{h}{\ell^2}\bigr) \tag{15.3.89}$$

and therefore the above arguments should be applied only as $\ell \ge \hat\ell_1$ with

$$\hat\ell_1 = \mu^{-\frac{1}{6}} h^{\frac{1}{3}}; \tag{15.3.90}$$

otherwise we replace ℓ by $\hat\ell_1$ (single element) and $T = \mu^{\frac{1}{3}} h^{\frac{1}{3}-\sigma}$ and $\delta x_2 = \delta x_1 = O(\mu^{-1})$; so $\Delta \asymp \hat\ell_1 \mu^{-1}$. Here we assume that $\hat\ell_1 \ge C\mu^{-1}$ as otherwise we reset it to this value which would lead to the error less than $C\mu^{-1}h^{-1-\sigma}$.

Then obviously the total error under the same replacement $V(x_1,x_2)$ by $V(0,y_2) + (\partial_{x_1}V)(0,y_2)x_1$ does not exceed

$$C\bar\rho\hat\ell_1 h^{-1} \times (\mu h)^{\frac{1}{3}} h^{-1-\sigma}\hat\ell_1\mu^{-1} \asymp C\hat\ell_1^2 h^{-1-\sigma} = h^{-\sigma}\min\bigl(\frac{(\mu h)}{\bar\rho}, \frac{h}{\hat\ell_1^2}\bigr) \tag{15.3.91}$$

which in turn is $O\bigl(\mu^{-1}h^{-1} + h^{-\sigma}\bigr)$.

Non-Degenerate cCase. Finally, under condition (15.2.7) we take $T_* = h^{1-\sigma}$ and $\Delta = \mu^{-1}h^{-\sigma}$ so each next term acquires factor $C\mu^{-1}h^{-\sigma}$ i.e. the second term is $C\bar\rho h^{-1} \times \mu^{-1}h^{-\sigma}$ which is $O(\mu^{-1}h^{-1})$ unless $\mu \ge h^{\delta-1}$, in which case it is $O(h^{-\delta})$. However in the latter case the the third term is $O(1)$ so we will need to consider the second term in approximations as well.

Boundary Zone. Here we take $T_* = h^{1-\sigma}$ and $\Delta = \mu^{-1}h^{-\sigma}$ so each next term acquires factor $C\mu^{-1}h^{-\sigma}$ i.e. the second term is $Ch^{-1} \times \mu^{-1}h^{-\sigma}$ which is $O(\mu^{-1}h^{-1-\sigma})$. However the third term is $O(1)$ so we will need to consider the second term in approximations as well.

Inner Zone In inner zone we make usual transformation and apply the standard method of successive approximations at point y rather than $(0,y_2)$.

Calculations

Calculations. I. As a result in the zone $\{x_1 \ge C_0\mu^{-1}\}$ we get

$$h^{-2}\int \mathcal{N}^{\mathsf{MW}}(x,\tau,\mu h)\psi(x)\,dx$$

and in the zone $\{x_1 \le C_0\mu^{-1}\}$ we get something like this but with $\mathcal{N}^{\mathsf{MW}}$ replaced by $\mathcal{N}_*^{\mathsf{MW}}$ temporarily denoting eigenvalue counting function for operator with the boundary conditions. So this main part would come from parametrix $\bar{G}^{\pm}$ for operator $hD_t - A$ in the direction of $\pm t > 0$ (see previous and similar chapters) and this parametrix is equal to $\bar{G}_0^{\pm} + \bar{G}_1^{\pm}$ where "bar" refers to freezing coefficients in y.

Consider first term with $\bar{G}_0^{\pm}$. While $\bar{G}_0^{\pm}$ is what it was on $\mathbb{R}^2$, Γ is not as now old Γ is replaced by $\Gamma\theta(x_1) = \Gamma - \Gamma\theta(-x_1)$ and only the first term results in $h^{-2}\mathcal{N}^{\mathsf{MW}}(y, \tau, \mu h)$.

Note that contribution of terms with $\Gamma\theta(-x_1)\bar{G}_0^{\pm}$ and $\Gamma\theta(x_1)\bar{G}_1^{\pm}$ into main part of asymptotics are of magnitudes $\mu^{-1}h^{-2} \times \mu h = h^{-1}$ where μ^{-1} is the width of X_{bound} and μh is a semiclassical parameter after rescaling. Therefore replacing y_1 by 0 will bring really the estimate we had referred to and these terms together will result in $h^{-1}\mathcal{N}_{\mathsf{corr}}^{\mathsf{MW}}$.

Justification. To justify setting of the upper bound of propagation speed μ^{-1} rather than $\bar{\rho}^{\frac{1}{2}}$ under Dirichlet boundary conditions we just note that if $A' = A - A'$ then considering sandwich $\bar{G}^{\pm}A'\bar{G}^{\pm} \dots A'\bar{G}^{\pm}\delta$ (one of $\bar{G}^{\pm}$ may be replaced by $G^{\pm}$) we can decompose $A' = A'_0 + A'_+ + A'_-$ where A'_0, A'_+ and A'_- are copies of operator A' localized as $|x_2 - y_2| \le 2c_0\mu^{-1}(T+1)$, $(x_2 - y_2) \ge \frac{3}{2}c_0\mu^{-1}(T+1)$ and $(x_2 - y_2) \le -\frac{3}{2}c_0\mu^{-1}(T+1)$ respectively.

Note that due to the fact that in direction of $\pm t$ propagation speed does not exceed $c_0\mu^{-1}$ we conclude that as we consider time direction $\pm t > 0$ sandwiches containing at least one factor $A'_{\pm}$ are negligible, and sandwiches containing at least one factor $A'_{\mp}$ become negligible after we apply $x_2 = y_2$.

So, the first term in approximation results in what we claimed as an answer.

Calculations. II. Meanwhile *as we replace* $V(x_1, y_2)$ *by* $V(0, y_2) + (\partial_{x_1}V)(0, y_2)x_1$ we notice that $\Delta = C_0(\delta x_1)^2 \asymp C_0\mu^{-2}$ as $\delta x_1 = O(\mu^{-1})$ which is smaller than (15.3.81).

The same arguments show that removing $(\partial_{x_1}V)(0, y_2)x_1$ leads to the error not exceeding

$$C\mu^{-\frac{1}{2}}\bar{\rho}h^{-1} = C\mu^{\frac{1}{6}}h^{-\frac{1}{3}-\sigma} \tag{15.3.92}$$

as we need to use $\hat{\ell}_1 = \mu^{-\frac{1}{2}}$ instead of $\hat{\ell}$ defined by (15.3.85).

Unfortunately expression (15.3.92) may be larger than anything we got before. Fortunately there are alternatives: first, replacing x_1 by $W_0^{\frac{1}{2}}(x_2)$ leads to an error in operator $O(\mu^{-1}\bar\rho)$ and to the approximation error

$$C(\mu^{-1}\bar\rho)^{\frac{1}{2}}\bar\rho h^{-1} = C\mu^{\frac{1}{2}}h^{-\sigma}; \tag{15.3.93}$$

this would mean replacing $\mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}(W_0)$ by $\mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}(W_1)$ with $W_1 = W_0 + \mu^{-1}(\partial_{x_1}W)W_0^{\frac{1}{2}}$.

Second, we can replace x_1 by $\mu^{-1}\xi_2$ i.e. use $W(\mu^{-1}\xi_2, x_2)$ instead of $W_0(x_2)$ and we do not need to remove linear term $(\partial_{x_1}V)(0,y_2)(x_1-\mu^{-1}\xi_2)$ but just simply shift with respect to ξ_2. This would lead to $O(\mu^{-2})$ shift in $W(\mu^{-1}\xi_2, x_2)$ and this shift could be ignored.

Calculations. III. Consider the second term in approximations. There are two cases when we need to do this: in the boundary zone as $\mu \le h^{\delta-1}$ and under condition (15.2.8) as $\mu \ge h^{\delta-1}$.

In the former case however we need to consider only $T \le \epsilon\mu$ and then only one winding should be considered and perturbation does not exceed $C_0\mu^{-1}$, and we can take $T = h^{1-\sigma}$ so in fact we get an extra factor $\mu^{-1}h^{-\sigma}$. However scaling shows that in fact as we replace $\bar\chi_T$ by χ_T the error will be $C\mu^{-1}Th^{-2}(h/T)^s$ and summation results in $C\mu^{-1}h^{-1}$ error. Alternatively we could employ semiclassical approximation to show the same.

In the latter case there is no boundary zone anymore. However scaling shows that the same arguments work (without going to semiclassics).

15.3.6 Final Results

Let us compare Tauberian remainder and approximation error.

(i) Under assumptions (15.2.8) both Tauberian remainder and an approximation error are $O(\mu^{-1}h^{-1})$.

(ii) Under assumptions (15.2.7) and (15.2.41) Tauberian remainder is estimated by (15.3.37) + $O(\mu^{-1}h^{-1})$ and an approximation error is estimated by (15.3.86)+(15.3.92) and expressions (15.3.37) and (15.3.86) coincide, so the total error is (15.3.86) + (15.3.92) + $O(\mu^{-1}h^{-1})$.

(iii) Under assumptions (15.2.7) and (15.2.41) and Dirichlet boundary condition Tauberian remainder is estimated by (15.3.42) + $O(\mu^{-1}h^{-1})$ and approximation error is estimated by (15.3.86)+(15.3.92) and (15.3.42) is larger than (15.3.86) so the total error is (15.3.42) + (15.3.92) + $O(\mu^{-1}h^{-1})$.

(iv) Under assumptions(15.2.7) and $(15.2.41)^-$ and Dirichlet boundary condition Tauberian remainder is estimated by (15.3.45) and approximation error is (15.3.92)+$O(\mu^{-1}h^{-1}+h^{-\delta})$ and the total error is (15.3.45)+(15.3.92).

(v) Under assumptions $(15.2.7)^+$ and $(15.2.41)^-$ and Dirichlet boundary condition Tauberian remainder is $O(\mu^{-1}h^{-1}+h^{-\delta})$ and an approximation error is (15.3.92) + $O(\mu^{-1}h^{-1}+h^{-\delta})$ and this is a total error.

Thus we arrive to the following theorem:

Theorem 15.3.16. *Let $\psi \in \mathscr{C}^\infty(\bar{X})$ be a fixed function with a compact support contained in the small vicinity of ∂X and let conditions* (13.2.1)–(13.2.4), (13.3.1) *and and* (13.4.45) *be fulfilled on* $\mathsf{supp}\,\psi$.

Further, let condition (15.3.1) *be fulfilled. Then*

(i) Under non-degeneracy condition (15.2.8) R^{MW} *is* $O(\mu^{-1}h^{-1})$.

(ii) Under non-degeneracy conditions (15.2.7) *and* (15.2.41) R^{MW} *does not exceed* (15.3.86) + (15.3.92) + $O(\mu^{-1}h^{-1})$.

(iii) Under non-degeneracy conditions (15.2.7) *and* (15.2.41) $\mathsf{R}^{\mathsf{MW}}_{\mathsf{D}}$ *does not exceed* (15.3.42) + (15.3.92) + $O(\mu^{-1}h^{-1})$.

(iv) Under assumptions (15.2.7) *and* $(15.2.41)^-$ $\mathsf{R}^{\mathsf{MW}}_{\mathsf{D}}$ *does not exceed* (15.3.45)+(15.3.92).

(v) Under non-degeneracy conditions $(15.2.7)^+$ *and* $(15.2.41)^-$ $\mathsf{R}^{\mathsf{MW}}_{\mathsf{D}}$ *does not exceed* (15.3.92) + $O(\mu^{-1}h^{-1}+h^{-\delta})$.

We leave to the reader

Problem 15.3.17. Write down correction terms $\mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound},\mathsf{corr}}$ corresponding to the procedures described Paragraph *15.3.5.2.3 Calculations. II.*. Then $\mathsf{R}^{\mathsf{MW}}_{\mathsf{corr}}$ will be the same as in Theorem 15.3.16 albeit without (15.3.92).

One of the possible modifications of $\mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}$ is given by (15.4.81).

Conjecture 15.3.18. *All these estimates hold with $\delta = 0$.*

15.4 Strong Magnetic Field

15.4.1 Preliminary Analysis

In this section we consider cases of the *strong magnetic field* covering both *intermediate magnetic field*[10)]

$$\epsilon_0 h^{-1} \le \mu \le C_0 h^{-1} \tag{15.4.1}$$

and *really strong magnetic field*

$$C_0 h^{-1} \le \mu \tag{15.4.2}$$

In the latter case operator needs to be modified: we will replace V by $V - \mu h \mathfrak{z} F$ where constant $\mathfrak{z}$ will be specified later; so operator (15.2.1) is replaced by

$$A = \sum_{1\le j,k\le 2} P_j g^{jk} P_k - \mu h \mathfrak{z} F + V, \qquad \text{with } P_j = hD_j - \mu V_j. \tag{15.4.3}$$

Then

(15.4.4) We need only to consider eigenvalues $\lambda_n(\eta)$ of the toy-model operator $L(\eta)$ defined by (15.1.26) with $n \le N := N(\epsilon_0)$.

Really, as $n = 0, 1, 2, ...$

$$\inf_\eta \lambda_{\mathsf{D},n}(\eta) \ge (2n+1) \quad (n \ge 0) \tag{15.4.5}_{\mathsf{D}}$$

$$\inf_\eta \lambda_{\mathsf{N},n}(\eta) \ge (2n-1), \quad (n \ge 1). \tag{15.4.5}_{\mathsf{N}}$$

due to Proposition 15.A.1 and our operator is modelled by $(\mu h)^{-1} L(\eta)$.

However then

$$|\lambda_{*,j}(\eta) - \lambda_{*,n}(\eta)| \ge \epsilon(N) \qquad \forall m \ne n \le N \ \forall \eta \tag{15.4.6}$$

with subscript $*$ denoting either D or N and we can decompose into eigenfunctions $\upsilon_{*,n}(\mu x_1, \xi_2)$ of the toy-model operator. So basically we consider

[10)] Note that it is more narrow definition than (15.3.1) in the previous section.

1-dimensional diagonal operator perturbed and we can diagonalize it to $\mu hF(0,x_2)\mathcal{A}_n(x_2,hD_2)$ with

$$\mathcal{A}_n(x_2,hD_2) \coloneqq \bigl(\lambda_{*,n}(\hbar D_2) - \mathfrak{z} - (\mu h)^{-1}W(0,x_2)\bigr) + ... \tag{15.4.7}$$

where in *this* section

$$\hbar = \mu^{-\frac{1}{2}}h^{\frac{1}{2}}; \tag{15.4.8}$$

preliminary we scaled $x_1 \mapsto \hbar^{-1}x_1$. Let us ignore perturbation in (15.4.7); later in subsection (15.4.5) we will show that it could be made very small, albeit W will be modified.

Remark 15.4.1. In (15.4.7) we replaced x_1 by 0. Actually the better approximation would come by replacing x_1 by $\mu^{-1}hD_2$ but a need in it will not come out instantly.

Then we need to consider only scalar operators (15.4.7) and we are looking at fixed vicinity of some point $\bar{x}_2$. What we can say about ξ_2 apart of $\xi_2 \ge -C_0$ (as $\lambda_{*,n} \to +\infty$ as $\xi_2 \to -\infty$)?

There are two possibilities: either we would be inside the spectral gap if not a boundary, or not.

15.4.2 Almost Spectral Gaps

Assume first that we would be inside the spectral gap if not a boundary:

$$|(2j+1-\mathfrak{z})\mu hF + V - \tau| \ge \epsilon_0\mu h \qquad \forall j = 0,1,2,... \tag{15.4.9}$$

where $|\tau| \le C$ and usually $\tau = 0$.

We know (see Subsection 13.6.1) that inside domain (15.4.9) means a spectral gap. However it is not the case near the boundary: looking at behavior of $\lambda_{*,n}(\xi_2)\mu h$ interpreted as *Landau levels* we can conjecture that only lower spectral gap $(-\infty,.)$ survives and even it shrinks for Neumann boundary condition.

As $\lambda_{*,n}(\xi_2) \to (2n+1)\mu h$ as $\xi_2 \to +\infty$ due to Proposition 15.A.1 again and we conclude that

(15.4.10) Under condition (15.4.9) operators in question are elliptic as $\xi_2 \ge C_0$ and we need to consider only a compact interval $|\xi_2| \le C_0$.

Note that as

$$\lambda_{*,n}(\xi_2) - \mathfrak{z} - (\mu h)^{-1} W \ge \epsilon \mu h \qquad \forall \xi_2 \tag{15.4.11}_n$$

then operator $\mathcal{A}_n$ is elliptic for all ξ_2 and the contribution of it and interval $(-\infty, \tau)$ to the asymptotics is negligible. In the framework of (15.4.9) one can rewrite above condition as

$$(2n + 1 - \mathfrak{z} - \epsilon)\mu h F + V - \tau \ge 0, \tag{15.4.12}_{\mathsf{D},n}$$

$$(\lambda^*_{\mathsf{N},n} - \mathfrak{z} - \epsilon)\mu h F + V - \tau \ge 0, \tag{15.4.12}_{\mathsf{N},n}$$

for Dirichlet and Neumann boundary conditions respectively where

$$\lambda^*_{\mathsf{N},n} = \min_{\eta} \lambda_{\mathsf{N},n}(\eta) \in (2n - 1, 2n + 1). \tag{15.4.13}$$

One then concludes easily that

Theorem 15.4.2. *Let one of assumptions* (15.4.1), (15.4.2) *be fulfilled. Further, let* $(15.4.12)_{\mathsf{D},0}$ *or* $(15.4.12)_{\mathsf{N},0}$ *be fulfilled with* $\tau = 0$ *(matching to the boundary condition).*

Then

$$|e(x, x, 0)| \le C_s \mu^{-s} \tag{15.4.14}$$

with arbitrarily large exponent s*.*

Assume now that condition (15.4.9) is fulfilled for all j but $(15.4.12)_{*,0}$ fails. Then there is a large difference between Dirichlet and Neumann cases because only in the former case in virtue of Proposition 15.A.2

$$\lambda'_{*,n} \le -\epsilon(N, C_0) \qquad \forall n \le N \qquad \forall \xi_2 : |\xi_2| \le C_0 \tag{15.4.15}$$

where here and below $\lambda'_{*,n} \coloneqq \partial_{\xi_2} \lambda_{*,n}$ etc. For Neumann boundary condition we assume that

$$|\lambda'_{\mathsf{N},n}(\xi_2)| \le \epsilon_0 \implies |\big(\lambda_{\mathsf{N},n}(\xi_2) - \mathfrak{z}\big)\mu h F - W| \ge \epsilon_0 \mu h. \tag{15.4.16}$$

So, we arrive to the remainder estimate $O(1)$; transition from Tauberian expression to magnetic Weyl expression is trivial:

Theorem 15.4.3. *Let one of assumptions* (15.4.1), (15.4.2) *be fulfilled. Further, let* (15.4.9) *and in the case of the Neumann boundary condition also* (15.4.16) *be fulfilled. Then* $\mathsf{R}^{\mathsf{MW}}_{*} = O(1)$.

However there are other mechanisms to break degeneracy for Neumann problem: first of all we know (see Proposition 15.A.3) that

$$|\lambda'_{\mathsf{N},n}(\xi_2)| \le \epsilon_0 \implies \lambda''_{\mathsf{N},n}(\xi_2) \ge \epsilon_0 \qquad \forall n = 0,1,2,... \tag{15.4.17}$$

The first non-degeneracy assumption linked to derivatives with respect to x_2 is

$$|\bigl(\lambda_{\mathsf{N},n}(\xi_2) - \mathfrak{z}\bigr)\mu h - W| \le \epsilon_0 \mu h, \quad |\lambda'_{\mathsf{N},n}(\xi_2)| \le \epsilon_0 \implies |\partial_{x_2} W| \ge \epsilon_0 \qquad \forall m = 0,1,2,\dots, \tag{15.4.18}$$

where as usual $W = -VF^{-1}$; the next one is

$$|\bigl(\lambda_{\mathsf{N},n}(\xi_2) - \mathfrak{z}\bigr)\mu h - W| \le \epsilon_0 \mu h, \quad |\lambda'_{\mathsf{N},n}(\xi_2)| + |\partial_{x_2} W| \le \epsilon_0 \implies \pm\partial^2_{x_2} W \ge \epsilon_0 \qquad \forall n = 0,1,2,... \tag{15.4.19}$$

Theorem 15.4.4. *Let one of assumptions* (15.4.1), (15.4.2) *be fulfilled. Further, let conditions* (13.3.1) *and* (15.4.9) *be fulfilled in* $B(\bar{x},1)$ *and let* $\psi \in \mathscr{C}^{\infty}_0$ *be supported in* $B(\bar{x},\frac{1}{2}) \cap \{x : x_1 \le \epsilon'\}$. *Then*

(i) $\mathsf{R}^{\mathsf{MW}}_{\mathsf{N}} = O(1)$ *under one of assumptions* (15.4.18), $(15.4.19)^{+}$ *and*

(ii) $\mathsf{R}^{\mathsf{MW}}_{\mathsf{N}} = O\bigl(|\log h|\bigr)$ *under assumption* $(15.4.19)^{-}$.

Proof. As $\mu h \asymp 1$ we are in the framework of Subsection 5.2.3 and arrive immediately to conclusion of the theorem.

Consider case (15.4.2) of strong magnetic field and adapt arguments of Subsection 5.2.3. Then first we consider $\epsilon(1,\ell)$-admissible (with respect to (x_2,ξ_2)) with $\rho = \epsilon(|\lambda'_{\mathsf{N},n}|$ partition of zone $\{|\lambda'_{\mathsf{N},n}| \ge C(\mu h)^{-\frac{1}{2}}\}$. Then for operator (15.4.7)

$$T_* \asymp \hbar\rho^{-2}, \qquad T^* \asymp \rho^{-1}, \tag{15.4.20}$$

as propagation velocities with respect to x_2,ξ_2 are $\asymp \rho$ and $O\bigl((\mu h)^{-1}\bigr)$ respectively. Then contribution of an element to the Tauberian remainder

does not exceed $C\hbar^{-1}\rho \times T_* \times T^{*-1} \asymp C$ and the total contribution of zone in question does not exceed $C\int \rho^{-1}\,d\rho \asymp C$ as operator is elliptic unless ρ has a specific magnitude.

In the remaining zone $\{|\lambda'_{\mathsf{N},n}| \le C(\mu h)^{-\frac{1}{2}}$ let us introduce $\epsilon(\rho,\ell)$-admissible partition with

$$\rho = \bigl(|\lambda'_{\mathsf{N},n}|^2 + (\mu h)^{-1}|\partial_{x_2} W|^2\bigr)^{\frac{1}{2}} + \bar{\rho}, \quad \ell = (\mu h)^{\frac{1}{2}}\rho, \quad \bar{\rho} = \mu^{-\frac{1}{2}}. \tag{15.4.21}$$

Then for operator (15.4.7) divided by μh

$$T_* \asymp \hbar\rho^{-2}, \qquad T^* \asymp (\mu h)^{\frac{1}{2}}, \tag{15.4.22}$$

as propagation velocity with respect to $(x_2, (\mu h)^{\frac{1}{2}}\xi_2)$ is $\asymp \rho$. Therefore contribution of (ρ,ℓ) element to the Tauberian remainder does not exceed $C\hbar^{-1}\rho\ell \times T_* \times T^{*-1} \asymp C$ and the total contribution does not exceed $C\int \rho^{-1}\,d\rho$ which is $O(1)$ under one of assumptions (15.4.18), (15.4.19)$^+$ as in the former case $\rho \asymp \bar{\rho}_1 = (\mu h)^{-\frac{1}{2}}$ and in the latter case operator is elliptic unless ρ has a fixed magnitude.

Further, we get $O(|\log h|)$ under assumption (15.4.19)$^-$ as in this case the integral is taken from $\bar{\rho}$ to $\bar{\rho}_1$.

Transition from Tauberian expression to magnetic Weyl expression is trivial. □

Remark 15.4.5. Following Section 5.2.3 we would be able to establish remainder estimate $O(1)$ even under assumption (15.4.19)$^-$.

Remark 15.4.6. (i) The principal part of asymptotics in question is $O(\mu h^{-1})$ and as

$$(1+\mathfrak{z}) + F^{-1}(V-\tau) \le -\epsilon \tag{15.4.23}$$

it is $\asymp \mu h^{-1}$.

(ii) As Neumann boundary condition is considered and

$$\mu h(1+\mathfrak{z})F + V - \tau \ge \epsilon\mu h \tag{15.4.24}$$

the principal part of asymptotics in question is $O(h^{-1})$ and as

$$\mu hF(\lambda^*_{\mathsf{N},0} + \mathfrak{z}) + V - \tau \le -\epsilon\mu h \tag{15.4.25}$$

it is $\asymp \hbar^{-1} = \mu^{\frac{1}{2}}h^{-\frac{1}{2}}$.

(iii) As

$$\begin{aligned} &\mu h(2j-1-\mathfrak{z})F + V - \tau_1 \le -\epsilon\mu h, \\ &\mu h(2j+1-\mathfrak{z})F + V - \tau_2 \ge -\epsilon\mu h, \qquad \tau_1 < \tau_2, \end{aligned} \tag{15.4.26}$$

then the increment of principal part of asymptotics calculated as τ increases from τ_1 to τ_2 is $O(\hbar^{-1})$ and is $\asymp \hbar^{-1}$ as $|\tau_2 - \tau_1| \asymp \mu h$. Recall that without boundary it would be $O(\hbar^s)$.

We leave to the reader the following rather easy problem:

Problem 15.4.7. Investigate under weaker non-degeneracy conditions than (15.4.19)$^{\pm}$.

15.4.3 Landau Level

Preliminary Analysis

Now consider case when condition (15.4.9) is broken. Without any loss of the generality we can assume that

(15.4.27) Condition (15.4.9) breaks only for one value of $j = \bar{\jmath}$.

Really, if $\mu h \ge C$ this assumption would be fulfilled automatically; otherwise we achieve it by considering ϵ-admissible partition of unity.

Further, without any loss of the generality we can assume that

$$\mathfrak{z} = 2\bar{\jmath} + 1. \tag{15.4.28}$$

Really, let $\nu = |\mathfrak{z} - (2\bar{\jmath}+1)| \le 1$. If $\nu\mu h \le C$ then term $\pm\nu\mu hF$ could be absorbed into V; if $\nu\mu h \ge C$ then dividing operator by $\nu\mu h$ we find ourselves in the framework of the previous subsection with $\mu_{\mathsf{new}} = \mu^{\frac12} h^{-\frac12}\nu^{-\frac12}$ and $\mu_{\mathsf{new}} = \mu^{-\frac12} h^{\frac12}\nu^{-\frac12} \le 1$.

Then for all $n \ne \bar{\jmath}$ the previous arguments work and we need to consider $n = \bar{\jmath}$ only. Further, as $n = \bar{\jmath}$ these arguments work in zone $\{\xi_2 \le C_0\}$ and we need to consider only zone $\{C_0 \le \xi_2 \le \epsilon_0\mu\}$.

As a symbol of the operator $\mu h\mathcal{A}_n$ with $\mathcal{A}_n$ defined by (15.4.7) has a either first or second derivative with respect to x_2 disjoint from 0, but derivatives with respect to ξ_2 could be pretty small, we will see that we cannot skip without reservation $O(\hbar)$ terms like those with an extra factor x_1 even as

we derive Tauberian remainder estimate but we in our assumptions will be able in Tauberian arguments only to skip $O(\hbar^2)$ terms like those with an extra factor x_1^2 so we need to modify (15.4.7) a bit[11]. To do this we first drag out $F(x)$ out of $(A-\tau)$ leaving inside

$$(hD_1)^2+(hD_2-\mu x_1)^2-W(x_1,x_2)+\ldots= \tag{15.4.29}$$
$$(hD_1)^2+(hD_2-\mu x_1)^2-W(\mu^{-1}hD_2,x_2)-$$
$$(\partial_{x_1}W)(\mu^{-1}hD_2,x_2)(x_1-\mu^{-1}hD_2)+\ldots=$$
$$(hD_1)^2+\bigl(hD_2-\mu x_1+\frac{1}{2}\mu^{-1}(\partial_{x_1}W)(\mu^{-1}hD_2,x_2)\bigr)^2-W(\mu^{-1}hD_2,x_2)+\ldots$$

with $W=-(V-\tau)F^{-1}$ resulting after shift

$$hD_2\mapsto hD_2-\mu x_1-\frac{1}{2}\mu^{-1}(\partial_{x_1}W)(\mu^{-1}hD_2,x_2) \tag{15.4.30}$$

in

$$\mu h\mathcal{A}_n(x_2,hD_2)=\mu h\lambda_{*,n}(\hbar D_2)-W(\hbar^2D_2,x_2)+\ldots. \tag{15.4.31}$$

There could also be $O(x_1)$ terms[12]

$$\alpha(x_2)x_1\Bigl(h^2D_1^2-(hD_2-\mu x_1)^2\Bigr); \tag{15.4.32}$$

then replacing $x_1\mapsto x_1+\beta(x_2)x_1^2$ we also need to replace

$$hD_1\mapsto \bigl(1-2\beta x_1+O(x_1^2)\bigr)hD_1 \quad\text{and}\quad hD_2\mapsto \bigl(hD_2+O(x_1^2)hD_1\bigr)$$

so modulo $O(x_1^2)$

$$(hD_1)^2+(hD_2-\mu x_1)^2\mapsto (1-4\beta x_1)(hD_1)^2+(1+4\beta x_1)(hD_2-\mu x_1)^2+$$
$$2(hD_2-\mu x_1)\beta\mu^{-1}h^2D_2^2$$

and choosing $\beta=-\frac{1}{4}\alpha$ we arrive to

$$(hD_1)^2+(hD_2-\mu x_1+2\beta\mu^{-1}h^2D_2^2)^2$$

---

[11] Actually effectively x_1 could be marginally more than $\hbar$.

[12] After division by F intensity of magnetic field is 1 so there could be no terms (15.4.32) with "$-$" replaced by "$+$".

and thus we need to replace (15.4.31) by

$$\mu h\big(\mathcal{A}_n(x_2, hD_2) - 2n - 1\big) = \mu h\big(\lambda_{*,n}(\hbar D_2 + 2\beta\hbar^3 D_2^2) - 2n - 1\big) - W(\hbar^2 D_2, x_2(1+) + \dots . \tag{15.4.33}$$

Remark 15.4.8. In the case of the strong magnetic field we need to consider only zone

$$\big\{\xi_2,\ |\lambda_{*,n} - 2n - 1| \le C_0(\mu h)^{-1}\big\} \tag{15.4.34}$$

otherwise operator is elliptic.

Non-Degenerate Case

Consider first case

$$|(2n + 1 - \mathfrak{z})\mu hF + V| \le \epsilon_0 \implies |\nabla_{\partial X} VF^{-1}| \ge \epsilon_0 \qquad \forall n = 0, 1, 2, ... \tag{15.4.35}$$

Then obviously one can take $T_* \asymp \hbar$. Really, the propagation speed with respect to ξ_2 is $\asymp |\partial_{x_2} W| \asymp 1$.

Meanwhile consider time direction in which ξ_2 increases; we can select it due to assumption (15.4.35). To reach $\xi_2 = \epsilon\hbar^{-1}$ we need time $\asymp \hbar^{-1}\mu h$ as for $\xi_2 \asymp \hbar^{-1}$ speed with respect to ξ_2 is $(\mu h)^{-1}$. Consider evolution with respect to x_2; speed with respect to x_2 does not exceed $C\mu h|\lambda'_{*,n}| + C\hbar$. Then we can take for sure take

$$T^* = T^*(\xi_2) \asymp \min\big((\mu h|\lambda'_{*,n}|)^{-1}, \hbar^{-1}\big) \tag{15.4.36}$$

Then contribution of $B(\bar{x}, 1) \cap \{x : x_1 \le \epsilon'\}$ to the remainder does not exceed

$$C \int \hbar^{-1} \frac{T_*(\xi_2)}{T^*(\xi_2)}\, d\xi_2 \le \int \big(\hbar + C\mu h|\lambda'_{*,n}|\big)\, d\xi_2 \tag{15.4.37}$$

as the integrand in the left-hand expression does not exceed $C\hbar$ as $|\lambda'_{*,n}| \le \hbar(\mu h)^{-1}$ and it does not exceed $C\mu h|\lambda'_{*,n}|$ otherwise. As $\lambda_{*,n}(\xi_2)$ is monotone (at least for $\xi_2 \ge C$) and integral is taken over $\xi_2 \le \epsilon\hbar^{-1}$ also satisfying (15.4.34) the right-hand expression does not exceed C.

Then we conclude that

(15.4.38) Under conditions (15.4.1) or (15.4.2), (15.4.28) and (15.4.35) fulfilled in $B(\bar{x}, 1)$ contribution of $B(\bar{x}, \frac{1}{2}) \cap \{x : x_1 \le \epsilon'\} \cap \{\xi_2 \ge C\}$ to the Tauberian remainder does not exceed C.

Generic Case

Now look what happens as (15.4.35) is also broken and replaced by conditions

$$(15.4.39)^{\pm} \quad |(2n+1-\mathfrak{z})\mu hF+V|+|\nabla_{\partial X}VF^{-1}|\le \epsilon_0 \implies \mp\nabla^2_{\partial X}VF^{-1}\ge \epsilon_0 \qquad \forall n=0,1,2,...$$

and

$$(15.4.40)^{\pm} \quad |(2n+1-\mathfrak{z})\mu hF+V|+|\nabla_{\partial X}VF^{-1}|\le \epsilon_0 \implies \mp\nabla VF^{-1}\ge \epsilon_0 \qquad \forall n=0,1,2,...$$

Inner Zone. We define this zone preliminary by

$$\mathcal{X}_{\mathsf{inn}}=\{\xi_2\ge c_0(\log\mu)^{\frac12}\}$$

which means not only that $\mu h(\lambda_{*,n}-2n-1)$ and $\mu h\lambda'_{*,n}$ are negligible but that they remain so even if we replace ξ_2 by $(1-\epsilon)\xi_2$. Then under assumption (15.4.40) we can take

$$T_*\asymp \min\bigl(\xi_2^{-1},\hbar\ell^{-2}\bigr), \tag{15.4.41}$$

$$\ell\asymp |W_{x_2}| \tag{15.4.42}$$

Really, the propagation speed with respect to x_2 is $\asymp\hbar$ but as scale with respect to ξ_2 is $\asymp\xi_2$ there, uncertainty principle means that $\hbar T\cdot\xi_2\ge\hbar$. Similarly, propagation speed with respect to ξ_2 is $\asymp\ell$, scale with respect to x_2 is $\asymp\ell$ and uncertainty principle means that $\ell T\cdot\ell\ge\hbar$.

Consider propagation in the time direction $\mathsf{sgn}(W_{x_2})t>0$ in which ξ_2 increases. Then

$$\mathsf{sgn}(W_{x_2})\frac{d}{dt}\log|W_{x_2}|=-\hbar W_{x_1}\,\mathsf{sgn}\,|W_{x_2}|^{-1}W_{x_2x_2}$$

so $\log|W_{x_2}|$ also increases provided W_{x_1} and $W_{x_2x_2}$ have opposite signs. Then we can take $T^*=\hbar^{-1}$. This would lead to contribution of $\mathcal{X}_{\mathsf{inn}}\cap\{\xi_2\ell\ge\hbar\}$ to the Tauberian remainder not exceeding

$$C\iint \hbar^{-1}\frac{T_*(\xi_2)}{T^*(\xi_2)}\,d\xi_2dx_2=C\iint \min(\xi_2^{-1},\hbar\ell^{-2})\,d\ell d\xi_2\le C.$$

On the other hand, in $\mathcal{X}_{\mathsf{inn}} \cap \{\xi_2 \ell \le \hbar\}$ we can take $T_* \asymp \xi_2^{-1}$ and $T^* \asymp \xi_2$ and contribution of this subzone to the Tauberian remainder not exceeding

$$C \iint \hbar^{-1} \frac{T_*(\xi_2)}{T^*(\xi_2)}\, d\xi_2 dx_2 = C \int \xi_2^{-2}\, d\xi_2 \le C.$$

On the other hand, as $(15.4.39)^{\pm}$, $(15.4.40)^{\pm}$ with the same signs are fulfilled we should chose between $T^* \asymp \xi_2$ and $T^* \asymp \hbar^{-1}\ell$. So, as $\ell \ge (\hbar\xi_2)^{\frac{1}{2}}$ we can take $T_* = \hbar\ell^{-2}$, $T^* = \hbar\ell^{-1}$ and contribution of this subzone to the Tauberian remainder does not exceed

$$C \iint \hbar^{-1} \frac{T_*(\xi_2)}{T^*(\xi_2)}\, d\xi_2 dx_2 = C \int \ell^{-1}\, d\ell \le C$$

as in the case of the same signs $\ell^2 + \xi_2\hbar$ must have the same magnitude or operator is elliptic; so in this subzone ℓ must have the same magnitude.

As $\ell \le (\hbar\xi_2)^{\frac{1}{2}}$ we can take $T_* = \xi_2^{-1}$, but the same ellipticity argument means that actually we can upgrade $T^* \asymp \hbar$ to $T^* \asymp \hbar^{-\frac{1}{2}}\xi_2^{\frac{1}{2}}$ contribution of this subzone to the Tauberian remainder does not exceed

$$C \iint \hbar^{-1} \frac{T_*(\xi_2)}{T^*(\xi_2)}\, d\xi_2 dx_2 = C \int \xi_2^{-1}\, d\xi_2 \le C$$

as in this subzone ℓ must have the same magnitude.

We need to extend $\mathcal{X}_{\mathsf{inn}}$ up to

$$\mathcal{X}_{\mathsf{inn}} := \{\xi_2 \ge \bar{\xi}_2^{+}\} \tag{15.4.43}$$

with

$$\bar{\xi}_2^{\pm} = \Big(\log(\mu^{\frac{3}{2}}h^{\frac{1}{2}}) - (2n+2)\log\log(\mu^{\frac{3}{2}}h^{\frac{1}{2}}) \pm C\Big)^{\frac{1}{2}} \tag{15.4.44}$$

describing a zone where $\mu h|\lambda'_{*,n}(\xi_2)| \le \epsilon\hbar$ is dominated by $|\partial_{\xi_2} W(\xi_1\hbar, x_2)|$. Then the same arguments work there albeit scale with respect to ξ_2 is now $\xi_2 - \bar{\xi}_2^{+\prime}$ $\bar{\xi}_2^{\pm\prime}$ are defined by the same formula with C replaced by $C/2$.

Further, these arguments remain valid for $\xi_2 \ge \xi_2^{-}$ provided $\lambda'_{*,n}$ and $-W_{x_1}$ have the same sign.

Thus we arrive to the following proposition:

Proposition 15.4.9. *(i) Under conditions* (15.4.1) *or* (15.4.2), (15.4.28) *and* $(15.4.39)^{\pm}$, $(15.4.40)^{\pm}$ *(with the same or opposite signs) fulfilled in* $B(\bar{x}, 1)$ *contribution of* $B(\bar{x}, \frac{1}{2}) \cap \mathcal{X}_{\mathsf{inn}} \cap \{\xi_2 \ge C\}$ *to the Tauberian remainder does not exceed* C.

(ii) Further as $\lambda'_{*,n}$ *and* $-W_{x_1}$ *have the same signs*[13] *Statement (i) remains true for* $\mathcal{X}_{\mathsf{inn}} = \{\xi_2 \ge \bar{\xi}_2^-\}$.

Boundary Zone. Consider now boundary zone temporarily introduced as

$$\mathcal{X}_{\mathsf{bound}} \coloneqq \{\xi_2 \le \frac{1}{2}\bar{\xi}_2\}$$

which actually should be intersected with zone (15.4.34).

Then we can take

$$T_* \asymp \min \hbar\Big(\xi_2\big(\mu h|\lambda'_{*,n}|\big)^{-1}, \ell^{-2}\Big). \tag{15.4.45}$$

Really, in this zone the propagation speed with respect to x_2 is $\asymp \mu h|\lambda'_{*,n}|$ and scale with respect to ξ_2 is $\asymp \xi_2^{-1}$ to keep $\lambda'_{*,n}$ of the fixed magnitude.

As $\ell \ge \big(\xi_2^{-1}\mu h|\lambda'_{*,n}|\big)^{\frac{1}{2}}$ consider propagation in the time direction of ξ_2 increasing. Then

$$T^* \asymp \min\big((\mu h|\lambda'_{*,n}|)^{-1}, \hbar^{-1}\ell\big) \tag{15.4.46}$$

provided $|W_{x_2}|$ also increases in the same direction because speed with respect to x_2 is $\asymp (\mu h|\lambda'_{*,n}|)$ as long as we remain in $\mathcal{X}_{\mathsf{bound}}$ but then drops to $O(\hbar)$ outside of $\mathcal{X}_{\mathsf{bound}}$ but x_2 can go in the opposite direction there. Our extra assumption means exactly that

(15.4.47) $W_{x_2x_2}$ and $\lambda'_{*,n}$ have the same signs[14].

Then contribution of the subzone in question to the Tauberian remainder does not exceed

$$\begin{aligned} C\iint \hbar^{-1}\frac{T_*(\xi_2)}{T^*(\xi_2)}\,d\xi_2 dx_2 &\asymp C\iint \ell^{-2}\big(\mu h|\lambda'_{*,n}| + \hbar\ell^{-1}\big)\,d\ell d\xi_2 \asymp \\ &\asymp C\int \big((\mu h|\lambda'_{*,n}|\xi_2)^{\frac{1}{2}} + \hbar\xi_2(\mu h|\lambda'_{*,n}|)^{-1}\big)\,d\xi_2 \asymp \\ &C(\mu h|\lambda'_{*,n}|\xi_2)^{\frac{1}{2}}\xi_2^{-1}\big|_{\xi_2=\hat{\xi}_2} + C\hbar(\mu h|\lambda'_{*,n}|)^{-1}\big|_{\xi_2=\bar{\xi}_2} \asymp C \end{aligned}$$

[13] Which means that under Dirichlet or Neumann boundary condition $(15.4.40)^+$ and $(15.4.40)^-$ respectively must be fulfilled.

[14] Or equivalently that under Dirichlet or Neumann boundary condition $(15.2.39)^-$ and $(15.2.39)^+$ respectively must be fulfilled.

where $\hat{\xi}_2$ is defined from (15.4.34) as solution to $\mu h|\lambda_{*,n} - (2n+1)| = C$.

Consider now subzone

$$\{\ell \le (\xi_2^{-1}\mu h|\lambda'_{*,n}|)^{\frac{1}{2}},\ \ell \ge \xi_2\hbar\}$$

where the second condition is due to uncertainty principle and scaling with respect to ξ_2.

Then T^* is defined by (15.4.45) with ℓ replaced by $(\xi_2^{-1}\mu h|\lambda'_{*,n}|)^{\frac{1}{2}}$ as we can go into direction of increasing ξ_2. Then contribution of this subzone to the Tauberian remainder does not exceed

$$C\iint \hbar^{-1}\frac{T_*(\xi_2)}{T^*(\xi_2)}\,d\xi_2 dx_2 \asymp C\hbar\int d\xi_2 \ll C$$

again. Further, in subzone $\{\ell \le \hbar\xi_2\}$ one can take $T^* \asymp \xi_2^{-1}$ and its contribution is $\ll 1$ as well.

Consider now case when

(15.4.48) $W_{x_2x_2}$ and $\lambda'_{*,n}$ have the opposite signs[15)].

Then as $\ell \ge \ell^*$ we can do nothing better than

$$T^* = \ell(\mu h|\lambda'_{*,n}|)^{-1}. \tag{15.4.49}$$

Then contribution of the subzone in question to the Tauberian remainder does not exceed

$$C\iint \hbar^{-1}\frac{T_*(\xi_2)}{T^*(\xi_2)}\,d\xi_2 dx_2 \asymp C\iint \ell^{-3}(\mu h|\lambda'_{*,n}|)\,d\ell d\xi_2 \asymp$$
$$\asymp C\int d\xi_2 \asymp C\log\mu.$$

On the other hand, for $\ell \le \ell^*$ we can improve (15.4.49) to

$$T^* = \ell^{1-\delta}(\mu h|\lambda'_{*,n}|)^{-1-\frac{1}{2}\delta}. \tag{15.4.50}$$

[15)] Or equivalently that under Dirichlet or Neumann boundary condition $(15.2.39)^+$ and $(15.2.39)^-$ respectively must be fulfilled.

Then contribution of the subzone in question to the Tauberian remainder does not exceed

$$C \iint \hbar^{-1} \frac{T_*(\xi_2)}{T^*(\xi_2)}\, d\xi_2 dx_2 \asymp C \iint \ell^{-1+\delta} \ell^{*\,-\delta}\, d\ell d\xi_2 \asymp \\ \asymp C \int d\xi_2 \asymp C \log \mu.$$

Finally, extending $\mathcal{X}_{\mathsf{bound}}$ to

$$\mathcal{X}_{\mathsf{bound}} = \{\xi_2 \le \bar{\xi}_2^{-}\} \tag{15.4.51}$$

comes with no cost at all as scale with respect to ξ_2 is $\xi_2^{-1} \asymp (\bar{\xi}_2^{-\prime} - \xi_2)$ anyway.

So we arrive to the following proposition:

Proposition 15.4.10. *(i) Under conditions* (15.4.1) *or* (15.4.2), (15.4.28) *and* $(15.4.39)^{\pm}$, $(15.4.40)^{\pm}$ *(with the same or opposite signs) fulfilled in* $B(\bar{x}, 1)$ *contribution of* $B(\bar{x}, \frac{1}{2}) \cap \mathcal{X}_{\mathsf{bound}} \cap \{\xi_2 \ge C\}$ *to the Tauberian remainder does not exceed* $C \log \mu$.

(ii) Further as $\lambda'_{*,n}$ *and* $W_{x_2x_2}$ *have the same signs*[14] *this contribution does not exceed* C.

As $\lambda'_{*,n}$ and $-W_{x_1}$ have the same signs[13] we are done. Otherwise we need to consider

Transitional Zone. $\mathcal{X}_{\mathsf{trans}}$ is defined by

$$\bar{\xi}_2^{-} \le \xi_2 \le \bar{\xi}_2^{+} \tag{15.4.52}$$

with $\bar{\xi}_2^{\pm}$ defined by (15.4.44) and in this zone $\mu h \lambda'_{*,n}$ has magnitude $\hbar$ and $\mu h \lambda''_{*,n}$ has magnitude $\hbar \xi_2 \gg \hbar^2$ and we conclude that

Proposition 15.4.11. *(i) Under conditions* (15.4.1) *or* (15.4.2), (15.4.28) *and* $(15.4.39)^{\pm}$, $(15.4.40)^{\pm}$ *(with the same or opposite signs) fulfilled in* $B(\bar{x}, 1)$ *contribution of* $B(\bar{x}, \frac{1}{2}) \cap \mathcal{X}_{\mathsf{trans}} \cap \{\xi_2 \ge C\}$ *to the Tauberian remainder does not exceed* $C \log \mu$.

(ii) Further as $\lambda''_{*,n}$ *and* $W_{x_2x_2}$ *have the same signs*[14] *this contribution does not exceed* C.

Synthesis. So, we proved that the total Tauberian remainder does not exceed $C\log\mu$. To upgrade it to C we must assume that $W_{x_2x_2}$, $\lambda'_{*,n}$ and $-W_{x_1}$ have the same signs as $\lambda'_{*,n}$ and $\lambda''_{*,n}$ have opposite signs. So we proved

Proposition 15.4.12. *(i) Under conditions* (15.4.1) *or* (15.4.2), (15.4.28) *and* (15.4.39)$^{\pm}$, (15.4.40)$^{\pm}$ *(with the same or opposite signs) fulfilled in* $B(\bar{x},1)$ *contribution of* $B(\bar{x},\frac{1}{2})\cap\{\xi_2\ge C\}$ *to the Tauberian remainder does not exceed* $C\log\mu$.

(ii) Further, as $W_{x_2x_2}$, $\lambda'_{*,n}$ *and* $-W_{x_1}$ *have the same signs*[14)] *this contribution does not exceed* C.

15.4.4 From Tauberian to Magnetic Weyl Formula

In this subsection $T=T_*\mu^{\delta}$ but we will calculate with $\delta=0$ because if we consider time interval $[T,2T]$ with $T\ge T_*$ in the estimate of its contribution there will be an extra factor $T^{-s}T_*^{s}$ and the summation with respect to T will result in the same answer albeit with $T=T_*$.

We apply the successive approximation method to operator (15.4.7)

Inner Zone

Replacing x_2 by y_2 leads to a contribution of (ℓ,ρ) element to an error does not exceeding

$$C\hbar^{-1}\rho\ell\times\frac{\hbar T_*^2}{\hbar}=C\hbar^{-1}\rho\ell T_*^2 \tag{15.4.53}$$

as the propagation speed with respect to x_2 is $O(\hbar)$ in the time scale used here and we use time scale compatible with the choice of T_* in the previous subsection.

Under non-degeneracy condition (15.2.8) we can take $T_*=\hbar$ resulting in the contribution of $\mathcal{X}_{\mathsf{inn}}$ equal to $O(1)$ as $\rho\asymp\hbar^{-1}$.

In more general generic case we estimate a contribution of (ℓ,ρ) element to an error by

$$C\hbar^{-1}\rho\ell\times\frac{\hbar\ell T^2}{\hbar}=C\xi_2\ell^2T_*^2\asymp C\hbar^{-1}\xi_2\ell^2\min\bigl(\xi_2^{-2},\hbar^2\ell^{-4}\bigr) \tag{15.4.54}$$

where we plugged T_* defined by (15.4.41); an extra factor ℓ appears as we replace x_2 by y_2 because $\partial_{x_2}W=O(\ell)$ and at this moment we take original "narrow" $\mathcal{X}_{\mathsf{inn}}$ with scale $\rho\asymp\xi_2$ in ξ_2.

Therefore the contribution of $\mathcal{X}_{\mathsf{inn}}$ to an error does not exceed

$$C\hbar^{-1}\iint \min\bigl(\xi_2^{-2},\hbar^2\ell^{-4}\bigr)\ell\,d\ell d\xi_2 \asymp C\int \xi_2^{-1}\,d\xi_2 \asymp C\log\mu. \tag{15.4.55}$$

In the remaining part of $\mathcal{X}_{\mathsf{inn}}$ defined by (15.4.44) we must replace ξ_2 by $\rho \asymp \xi_2 - \bar{\xi}_2$ as the scaling is concerned and it redefines correspondingly T_* and instead of right-hand expression in (15.4.55) we get $C\int(\xi_2-\bar{\xi}_2)^{-1}\,d\xi_2$ which is also $\asymp C\log\mu$.

Boundary Zone

Due to the standard arguments contribution of subzone $\{\xi_2 \le C_0\}$ to the error is either $O(\log\mu)$ or $O(1)$ depending if there is a saddle point or no; one can see easily that this saddle points cannot come from $\lambda_{\mathsf{N},j}$ but only from $\lambda_{\mathsf{N},n}$ with $n\ne j$ and it is possible only as $\lambda h \asymp 1$.

Consider subzone $\{\xi_2 \ge C_0\}$. Here we need to replace (15.4.53) by

$$C\hbar^{-1}\rho\ell \times \frac{\mu h|\lambda'_{*,m}|\,T_*^2}{\hbar} = C\hbar^{-2}\mu h|\lambda'_{*,m}|\rho\ell\,T_*^2 \tag{15.4.56}$$

as the propagation speed with respect to x_2 is $\asymp \mu h|\lambda'_{*,m}|$. Plugging under condition (15.2.8) $\ell = 1$, $\rho = \xi_2^{-1}$

$$T_* = \hbar\min\bigl(\xi_2(\mu h|\lambda'_{*,j}|)^{-1},1\bigr)$$

we arrive to

$$C\mu h|\lambda'_{*,j}|\rho\min\bigl(\xi_2^2(\mu h|\lambda'_{*,j}|)^{-2},1\bigr)$$

and contributions of both subzones $\{\xi_2 \ge C,\ \mu h|\lambda'_{*,j}| \ge \xi_2\}$ and $\{C\hbar \le \mu h|\lambda'_{*,j}| \le \xi_2\hbar\}$ are $O(1)$.

In the same manner (15.4.54) is replaced by

$$Ch^{-1}\rho\ell^2 \times \frac{\mu h|\lambda'_{*,j}|\,T^2}{\hbar} \asymp C\hbar^{-2}\mu h|\lambda'_{*,j}|\rho\ell^2\,T_*^2 \tag{15.4.57}$$

and plugging

$$T_* = \hbar\min\bigl(\xi_2(\mu h|\lambda'_{*,m}|)^{-1},\ell^{-2}\bigr)$$

we arrive to

$$C\mu h|\lambda'_{*,m}|\rho\ell^2\min\bigl(\xi_2^2(\mu h|\lambda'_{*,j}|)^{-2},\ell^{-4}\bigr)$$

and summation with respect to ℓ results in

$$C\mu h|\lambda'_{*,m}|\rho\ell^{*,-2} = C\rho\xi_2$$

as $\ell^* = \xi_2^{-1}\mu h|\lambda'_{*,j}|$ and summation with respect to ξ_2 results in $C\bar{\xi}_2^{-2} \asymp C\log\mu$.

Transitional Zone

In this zone we can return to (15.4.53) and plug $T_* = \hbar$ under condition (15.2.8) resulting in $O(1)$.

Further we can return to (15.4.54) and plug in the generic case either $T_* = \min\bigl(\hbar\ell^{-2}, \xi_2^{-1}\bigr)$ or $T_* = \min(\hbar\ell^{-2}, |\xi_2 - \bar{\xi}_2|^{-1})$ resulting after summation with respect to ℓ in $C\xi_2^{-1}\rho$ or $C|\xi_2 - \bar{\xi}_2|^{-1}\rho$ respectively. In the former case we instantly get $O(1)$ while in the latter after summation with respect to subzone $\{|\xi_2 - \bar{\xi}_2| \ge \hbar\}$ we arrive to $O(\log\mu)$ while contribution of subzone $\{|\xi_2 - \bar{\xi}_2| \le \hbar, \ell \le \hbar\}$ to asymptotics is $O(1)$.

15.4.5 Justification: Reduction to Toy-Model Operator

Reduction: Step 1

The problem however is that the "kinetic" part of our operator is not exactly $h^2D_1^2 + (hD_2 - \mu x_1)^2$ but is different. We need to improve construction of Subsection 15.2.1). First we can assume that $V_1 = 0$ and that $g^{jk} = \delta_{jk}$, $V_2 = 0$, $\partial_1 V_2 = 1$ as $x_1 = 0$. Further, assume that

$$g^{12} = O(x_1^k), \qquad V_2 = x_1 + O(x_1^{k+1}) \tag{15.4.58}$$

with $k \ge 1$. Then changing $x_1 \mapsto x_1$, $x_2 \mapsto x_2 + \alpha(x_2)x_1^{k+1}$ we can achieve $g^{12} = O(x_1^{k+1})$, simultaneously preserving the second relation. Then redefining $x_1 := V_2(x)$ preserves the first relation (with $k+1$ instead of k). Continuing we can make k as large as we wish and thus we can take $k = \infty$.

One needs to remember that g^{11} and g^{22} differ from 1 by $O(x_1)$. However as we consider operator $F^{-1}A$ with the intensity 1 of magnetic field we conclude that $g^{11}g^{22} = 1 + O(x_1^\infty)$.

Our goal is to get rid of this perturbation which we rewrite as

$$\mathcal{P}^{\mathsf{w}} := \mu^2\Bigl(\hbar^2 D_1\sigma D_1 - \sigma(\hbar D_2 - x_1)\sigma(\hbar D_2 - x_1)\Bigr). \tag{15.4.59}$$

Consider Poisson brackets

$$\frac{1}{2}\bigl\{\bigl(\xi_1^2+(\xi_2-x_1)^2\bigr),\alpha+\beta\xi_1\bigr\} \tag{15.4.60}$$

and note that for coefficients at ξ_1 equal 0 i.e.

$$\alpha_{x_1}-(x_1-\xi_2)\beta_{x_2}=0 \tag{15.4.61}$$

it is equal to

$$\beta_{x_1}\xi_1^2-(\beta+\alpha_{x_2})(x_1-\xi_2). \tag{15.4.62}$$

To make it equal to (15.4.59) modulo $\xi_1^2+(x_1-\xi_2)^2$ one needs to satisfy

$$\alpha_{x_2}=2\sigma(x_1-\xi_2)-\beta_{x_1}(x_1-\xi_2)-\beta. \tag{15.4.63}$$

Compatibility with (15.4.61) requires

$$(\partial_{x_1}^2+\partial_{x_2}^2)\bigl((x_1-\xi_2)\beta\bigr)=2\partial_{x_1}\bigl((x_1-\xi_2)\sigma\bigr). \tag{15.4.64}$$

Consider instead it without ∂_{x_2}, with an extra condition "$\beta=0$ as $x_1=0$". We can solve this one-dimensional equation

$$\partial_{x_1}^2\bigl((x_1-\xi_2)\beta\bigr)=2\partial_{x_1}\bigl((x_1-\xi_2)\sigma\bigr), \tag{15.4.65}$$

then

$$\beta(x_1,.)=2(x_1-\xi_2)^{-1}\int_{\xi_2}^{x_1}(x_1'-\xi_2)\sigma(x_1',.)\,dx_1'+\rho \tag{15.4.66}$$

with ρ which does not depend on x_1; extra condition "$\beta=0$ as $x_1=0$" means that

$$\rho=-\xi_2^{-1}\int_0^{\xi_2}(x_1'-\xi_2)\sigma(x_1',.)\,dx_1' \tag{15.4.67}$$

which gives us smooth function β and α.

Remark 15.4.13. As $\alpha_{x_2\xi_2}=0$ as $x_1=\xi_2=0$ due to (15.4.63) and properties of σ,β we can select α such that $\alpha_{\xi_2}=0$ there as well. This would enable further calculations.

Then

$$\frac{1}{2}\{\big(\xi_1^2+(\xi_2-x_1)^2\big),\alpha+\beta\xi_1\}= \tag{15.4.68}$$
$$(\beta_{x_1}-\sigma)\big(\xi_1^2+(x_1-\xi_2)^2\big)+\sigma\big(\xi_1^2-(x_1-\xi_2)^2\big).$$

Let us pass to operators; to do this we consider corresponding $\hbar$-quantizations, divide by $-i\hbar$ and multiply by μ^2; then

$$-\frac{1}{i\hbar}[A,\mathcal{L}^{\mathsf{w}}]=\mathcal{P}^{\mathsf{w}}-\mathcal{P}_1^{\mathsf{w}}, \tag{15.4.69}$$

with

$$A:=\hbar^2D_1^2+(\hbar D_2-x_1)^2, \tag{15.4.70}$$

$$\mathcal{L}:=\frac{1}{2}(\alpha+\beta\xi_1), \tag{15.4.71}$$

$$\mathcal{P}_1=(\sigma-\beta_{x_1}\sigma)\big(\xi_1^2+(x_1-\xi_2)^2\big) \tag{15.4.72}$$

where as we consider Weyl quantizations and symmetrized products after multiplication by μ^2 the error is $O(\mu^2\hbar^2)=O(h^2)$.

One can see easily that in our settings $\sigma=\beta=0$ as $x_1=0$ and β, α_{x_2} has 0 of the second order as $x_1=\xi_1=\xi_2=0$ while α_{x_1} has 0 of the third order as $x_1=\xi_1=\xi_2=0$. Also note that due to (15.4.64) $\beta_{x_1}-\sigma=0$ as $x_1=\xi_2$ so

(15.4.73) symbol $(\sigma-\beta_{x_1})$ is divisible by $(x_1-\xi_2)$.

Consider transformation of $A+\mathcal{P}^{\mathsf{w}}$ by $\exp(i\hbar^{-1}\mathcal{L}^{\mathsf{w}})$:

$$\exp(i\hbar^{-1}\mathcal{L}^{\mathsf{w}})\,(A+\mathcal{P}^{\mathsf{w}})\exp(-i\hbar^{-1}\mathcal{L}^{\mathsf{w}})= \tag{15.4.74}$$
$$A+\mathcal{P}^{\mathsf{w}}+\frac{1}{i\hbar}[A+\mathcal{P}^{\mathsf{w}},\mathcal{L}^{\mathsf{w}}]+\frac{1}{2}\big(\frac{1}{i\hbar}\big)^2[[A+\mathcal{P}^{\mathsf{w}},\mathcal{L}^{\mathsf{w}}],\mathcal{L}^{\mathsf{w}}]+\dots$$

where as one can see easily we left out terms which are $o(h^2)$ and due to (15.4.69)

$$\equiv A+\mathcal{P}_1^{\mathsf{w}}+\frac{1}{2}\big(\frac{1}{i\hbar}\big)[\mathcal{P}^{\mathsf{w}},\mathcal{L}^{\mathsf{w}}]+\frac{1}{2}\big(\frac{1}{i\hbar}\big)[\mathcal{P}_1^{\mathsf{w}},\mathcal{L}^{\mathsf{w}}] \tag{15.4.75}$$

Consider first the symbol of the third term

$$-\frac{1}{4}\{\mathcal{P},\alpha+\beta\xi_1\}=$$
$$-\frac{1}{4}\{\sigma,\alpha+\beta\xi_1\}\big(\xi_1^2-(x_1-\xi_2)^2\big)-\frac{1}{4}\sigma\{\xi_1^2-(x_1-\xi_2)^2,\alpha+\beta\xi_1\};$$

as

$$\frac{1}{2}\{\xi_1^2-(x_1-\xi_2)^2, \alpha+\beta\xi_1\} = \big(\alpha_{x_1}+\beta_{x_2}(x_1-\xi_2)\big)\xi_1+\beta_{x_1}\xi_1^2+(x_1-\xi_2)(\alpha_{x_2}+\beta) = 2\beta_{x_2}(x_1-\xi_2)\xi_1 + \sigma\big(\xi_1^2+(x_1-\xi_2)^2\big) - (\sigma-\beta_{x_1})\big(\xi_1^2-(x_1-\xi_2)^2\big)$$

we conclude that

$$-\frac{1}{4}\{\mathcal{P}, \alpha+\beta\xi_1\} = \Big(-\frac{1}{4}\{\sigma, \alpha+\beta\xi_1\} + \frac{1}{2}\sigma(\sigma-\beta_{x_1})\Big)\big(\xi_1^2-(x_1-\xi_2)^2\big) - \sigma\beta_{x_2}(x_1-\xi_2)\xi_1 - \frac{1}{2}\sigma^2\big(\xi_1^2+(x_1-\xi_2)^2\big).$$

Consider now the symbol of the fourth term in (15.4.75):

$$-\frac{1}{4}\{\mathcal{P}_1, \alpha+\beta\xi_1\} = -\frac{1}{4}\{(\sigma-\beta_{x_1}), \alpha+\beta\xi_1\}\big(\xi_1^2+(x_1-\xi_2)^2\big) - \frac{1}{4}(\sigma-\beta_{x_1})\{\xi_1^2+(x_1-\xi_2)^2, \alpha+\beta\xi_1\};$$

as we know the last Poisson bracket we conclude that

$$-\frac{1}{4}\{\mathcal{P}_1, \alpha+\beta\xi_1\} = \Big(-\frac{1}{4}\{(\sigma-\beta_{x_1}), \alpha+\beta\xi_1\} + \frac{1}{2}(\sigma-\beta_{x_1})^2\Big)\big(\xi_1^2+(x_1-\xi_2)^2\big) - \frac{1}{2}(\sigma-\beta_{x_1})\sigma\big(\xi_1^2-(x_1-\xi_2)^2\big).$$

Then the sum of symbols of the third and the fourth terms in (15.4.75) is equal to

$$-\frac{1}{4}\{\sigma, \alpha+\beta\xi_1\}\big(\xi_1^2-(x_1-\xi_2)^2\big) - \sigma\beta_{x_2}(x_1-\xi_2)\xi_1 + \Big(-\frac{1}{4}\{(\sigma-\beta_{x_1}), \alpha+\beta\xi_1\} + \frac{1}{2}\big(-\sigma^2+(\sigma-\beta_{x_1})^2\big)\Big)\big(\xi_1^2+(x_1-\xi_2)^2\big). \tag{15.4.76}$$

Remark 15.4.14. However correction (15.4.59) is not a correct one as we need $g^{11}g^{22}=1$ and a more precisely is $\mathcal{P}_1^{\mathsf{w}}+\frac{1}{2}\sigma^2 A$ as $g^{11}=1+\sigma+\frac{1}{2}\sigma^2+\dots$, $g^{22}=1-\sigma+\frac{1}{2}\sigma^2+\dots$.

We can skip terms here which has 0 of degree 5 at $x_1=\xi_1=\xi_2=0$; this takes care of the middle term.

By the same reason we can skip in

$$-\frac{1}{4}\{\sigma, \alpha+\beta\xi_1\} = \frac{1}{4}\sigma_{x_2}\alpha_{\xi_2} + \frac{1}{4}\sigma_{x_2}\beta_{\xi_2}\xi_1 + \frac{1}{4}\sigma_{x_1}\beta$$

the middle term where we used that $\sigma = \sigma(x)$.

Consider two remaining terms (which have 0 of the second order at $x_1 = \xi_2 = 0$ and also equal 0 as $x_1 = 0$)

$$\sigma_1 := \frac{1}{4}\sigma_{x_2}\alpha_{\xi_2} + \frac{1}{4}\sigma_{x_1}\beta; \tag{15.4.77}$$

then we can repeat the same procedure as before thus replacing the whole first term in (15.4.76) by

$$(\sigma_1 - \beta_{1\,x_1})\big(\xi_1^2 + (x_1-\xi_2)^2\big)$$

with β_1 matching σ_1. One can see easily that then neither $\mathcal{P}_1$ nor the last term in (15.4.76) would change modulo $O(h^2)$ and therefore we arrive to operator $A + \mathcal{P}_2^{\mathsf{w}}$ with

$$\mathcal{P}_2 = \tag{15.4.78}$$
$$\Big((\sigma-\beta_{x_1})+\sigma_1-\beta_{1\,x_1}-\frac{1}{4}\{(\sigma-\beta_{x_1}),\alpha+\beta\xi_1\}+\frac{1}{2}(\sigma-\beta_{x_1})^2\Big)\big(\xi_1^2+(x_1-\xi_2)^2\big).$$

In this factor the first term has 0 of the first order, other terms have 0 of the second order or higher and we can skip those which are higher. We can also skip terms divisible by $(x_1-\xi_2)^2$ as those terms are $O(\hbar)$ on energy levels in question leading to $O(h^2)$ error in the final answer. Due to (15.4.73) we arrive to

$$(\sigma-\beta_{x_1}) + (\sigma_1-\beta_{1\,x_1}) - \frac{1}{4}\{(\sigma-\beta_{x_1}),\alpha+\beta\xi_1\}$$

where the last term is

$$-\frac{1}{4}\{(\sigma-\beta_{x_1}),\alpha\} - \frac{1}{4}\{(\sigma-\beta_{x_1}),\beta\}\xi_1 + (\sigma-\beta_{x_1})_{x_1}\beta.$$

One can prove easily that due to (15.4.63), (15.4.73) (which is valid for σ_1, β_1 as well) the remaining terms vanish as $x_1 = \xi_2$.

Therefore as we skip terms containing factor $(x_1-\xi_2)^2$, what is left of perturbation is $\mathcal{P}_3^{\mathsf{w}}$ with

$$\mathcal{P}_3 := \rho(x_2,\xi_2)(x_1-\xi_2)\big(\xi_1^2+(x_1-\xi_2)^2\big), \tag{15.4.79}$$

so, $\mathcal{P}_3^{\mathsf{w}}$ is a symmetric product of ρ^{w}, $(x_1-\mu^{-1}hD_2)$ and A (as factor μ^2 should be remembered).

Reduction: Step 2

This perturbation is of the same magnitude as the original perturbation $\mathcal{P}^{\mathsf{w}}$ (albeit $\hbar^{-\delta}$ in estimates does not pop-up) but it is much easier to handle. If we had no boundary[16)] we would use $\mathcal{L} = \omega(x_2,\xi_2)\xi_1\bigl(\xi_1^2 + (x_1-\xi_2)^2\bigr)$ to eliminate it generating lower order terms but closer to factor ξ_1 forbids it unless accompanied by factor x_1. Still replacing $\rho(x_2,\xi_2)$ in (15.4.79) by

$$\rho(x_2,\xi_2) = \rho(x_2,0) - \rho_{\xi_2}x_1 + \rho_{\xi_2}(x_1-\xi_2) + ...$$

we can eliminate the second term (producing exactly such component in $\mathcal{P}_3$) and skip the third and all terms as producing $O(h^2)$ contribution. Therefore

Remark 15.4.15. Without any loss of the generality one can assume that $\rho = \rho(x_2)$ in (15.4.79).

Still it does not help us much and we cannot use obvious an transformation by $\exp(i\hbar^{-1}\mathcal{L}^{\mathsf{w}})$ with $\mathcal{L} = \omega(x_2)\bigl(\xi_1^2 + (x_1-\xi_2)^2\bigr)$ due to trouble in the next commutators. Instead we recall that basically our operator (15.4.70) multiplied by μ^2 should be equal $W + \mu h\mathfrak{z}$ with constant $\mathfrak{z}$. Actually one needs to insert there also $-hD_t$ but at energy level 0 it is really small and we can actually by multiplication by $(I+Q)$ make our evolution equation linear with respect to hD_t. We leave absolutely standard detailed arguments to the reader.

So now perturbation becomes

$$\mathcal{P}_4^{\mathsf{w}} = \mu h\rho(x_2)(x_1-\hbar D_2)\mathfrak{z} + \rho(x_2)(x_1-\hbar D_2)\mathfrak{z} \tag{15.4.80}$$

and it is completely different game as we can get rid of the first term using transformation by $\exp(i\hbar^{-1}\mathcal{L}^{\mathsf{w}})$ with $\mathcal{L} = \mu h\omega(x_2)\mathfrak{z}$ as one can see easily that there will be no problems with the next commutators. Remaining perturbation is of the type $\bigl(W_1(x,\xi)(x_1-\xi_2)\bigr)^{\mathsf{w}}$ and is of magnitude $\hbar$. So we gained factor $(\mu h)^{-1}$ which is important only in the case of the strong magnetic field so we can skip this step in the case of the intermediate magnetic field.

Reduction: Step 3

Note that the only part of new perturbation which is not necessarily $O(h^2)$ comes from $\bigl(W_1(x_2,\xi_2)(x_1-\xi_2)\bigr)^{\mathsf{w}}$ and we can use the same approach as before to eliminate it.

[16)] Or were on the distance at least $\hbar^{\frac{1}{2}-\delta}$ from it.

Actually we can continue further. We can keep power of $\hbar D_1$ below 2 replacing $\hbar^2 D_1^2$ by $-(x_1 - \hbar^2 D_2)^2 + \hbar\mathfrak{z} - \mu^{-2}W$. We can eliminate $\hbar D_1$ transforming by $\mathsf{exp}(i\hbar^{-1}\mathcal{L}^{\mathsf{w}})$ with $\mathcal{L} = \rho(x_1 - \xi_2)$. Similarly, we can eliminate $x_1^p(x_1-\xi_2)^q$ with $p \ge q$ transforming by similar operator with each ξ_1 having cofactor x_1. Therefore having x_1^n with $n \ge 2$ we can decompose it into sum of terms of the type $x_1^p(x_1 - \hbar D_2)^q(\hbar D_2)^{n-p-q}$ where either $p \ge q$ or $p = 0, q = 1$ or $p = 0, q = 0$ and eliminate the first type by the method we just discussed and the second one transforming by $\mathsf{exp}(i\hbar^{-1}\mathcal{L}^{\mathsf{w}})$ with $\mathcal{L} = \mathcal{L}(x_2, \xi_2)$. It eliminates all powers – including those we skipped before as lesser than $O(h^2)$.

Remark 15.4.16. (i) So in the end we arrive to the toy-model operator. Sure W is going to be perturbed by $O(h^2)$ albeit it may be because of smallness of ξ_2; so actually we get in the end $W_{\mathsf{eff}}(\xi_2, x_2) = -(V/F)(\xi_2, x_2) + O(\xi_2^3 + h^2)$ albeit this does not change it basic properties.

(ii) Recall that in this subsection ξ_2 in contrast to the rest of the section corresponds to $\hbar D_2$ rather than $\hbar D_2$ and $\hbar = \hbar^2$.

Conjecture 15.4.17. $W_{\mathsf{eff}}(\xi_2, x_2) = -(V/F)(\xi_2, x_2) + O(\xi_2^\infty + h^2)$ *as* $\xi_2 < \hbar^\delta$.

15.4.6 Final Results

Thus we arrive to the final contribution of zone $\{\xi_2 \le \hbar^{-\delta}\}$ (or equivalently $\{x_1 \le \hbar^{1-\delta}\}$) to the asymptotics:

$$\sum_{n\ge 0}(2\pi\hbar)^{-1}\mu \iint \theta\big(\mu h\big(\lambda_{*,n}(\xi_2) - \mathfrak{z}\big) - W_{\mathsf{eff}}(\hbar\xi_2, x_2)\big)\psi(\xi_2\hbar^{-1}, x_2)\zeta(\xi_2\hbar^{\delta})\, dx_2 d\xi_2$$

where transformation of ψ is obvious. After change of variables $x_1 = \hbar\xi_2$

$$\sum_{n\ge 0}(2\pi h)^{-1} \iint \theta\big(\mu h\big(\lambda_{*,n}(x_1\hbar^{-1}) - \mathfrak{z}\big) - W_{\mathsf{eff}}(x_1, x_2)\big)\psi(x)\zeta(x_1\varepsilon^{-1})\, dx_1 dx_2$$

with $\varepsilon = \hbar^{1-\delta}$ and $\hbar = (\mu^{-1}h)^{\frac{1}{2}}$. Here $\zeta \in \mathscr{C}_0^\infty([-1,1])$ equals 1 on $[-\frac{1}{2}, \frac{1}{2}]$.

On the other hand, the final contribution of zone $\{\xi_2 \ge \hbar^{-\delta}\}$ (or equivalently $\{x_1 \ge \hbar^{1-\delta}\}$) to the asymptotics is

$$\sum_{n\ge 0}(2\pi h)^{-1}\mu \iint \theta\big(\mu h\big(2n+1\big) - \mathfrak{z}\big) - W_{\mathsf{eff}}(x_1, x_2)\big)\psi(x)\big(1 - \zeta(x_1\varepsilon^{-1})\big)\, dx_1 dx_2$$

and the final answer is

$$\sum_{n\ge 0}(2\pi h)^{-1}\mu\iint \theta\big(\mu h\big(2n+1\big)-\mathfrak{z}\big)-W_{\mathsf{eff}}(x_1,x_2)\big)\psi(x)dx_1dx_2+$$
$$\sum_{n\ge 0}(2\pi h)^{-1}\mu\iint \Big(\theta\big(\mu h\big(\lambda_{*,n}(x_1\hbar^{-1})-\mathfrak{z}\big)-W_{\mathsf{eff}}(x_1,x_2)\big)-$$
$$\theta\big(\mu h\big(2n+1-\mathfrak{z}\big)-W_{\mathsf{eff}}(x_1,x_2)\big)\Big)\psi(x)\zeta(x_1\varepsilon^{-1})\,dx_1dx_2.$$

where now obviously we can take $\varepsilon = C\hbar|\log\hbar|$ and even $\varepsilon = C\hbar$ as we are in the spectral gap situation.

This matches (15.3.18) with

$$\mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}} :=$$
$$\sum_{n}(2\pi)^{-1}\mu\iint \Big(\theta\big(\mu h\big(\lambda_{*,n}(x_1\hbar^{-1})-\mathfrak{z}\big)-W_{\mathsf{eff}}(x_1,x_2)\big)-$$
$$\theta\big(\mu h\big(2n+1-\mathfrak{z}\big)-W_{\mathsf{eff}}(x_1,x_2)\big)\Big)\psi(x)\zeta(x_1\varepsilon^{-1})\,dx_1dx_2. \tag{15.4.81}$$

Therefore we arrive to our final theorem

Theorem 15.4.18. *Let $\psi\in\mathscr{C}^\infty(\bar{X})$ be a fixed function with a compact support contained in the small vicinity of ∂X and let conditions* (13.3.1), (15.2.7) *and* (15.2.41) *be fulfilled there. Then*

(i) R^{MW} *with* $\mathcal{N}^{\mathsf{MW}}_{\mathsf{bound}}$ *defined by* (15.4.81) *does not exceed* $C\log\mu$.

(ii) This estimate could be improved to $O(1)$ *in each of the following cases:*

- *(a) Assumption* (15.2.8) *is fulfilled.*
- *(b) Assumption* (15.4.9) *and in case of Neumann boundary problem one of conditions* (15.4.16), $(15.4.19)^+$ *is fulfilled.*
- *(c) Assumption* (15.4.9) *fails but there is Dirichlet boundary problem and both conditions* $(15.2.41)^-$ *and* $(15.2.7)^+$ *are fulfilled.*
- *(d) Assumption* (15.4.9) *fails but there is Neumann boundary problem and both conditions* $(15.2.41)^+$ *and* $(15.2.7)^-$ *are fulfilled.*

Remark 15.4.19. Here we redefined $\mathcal{N}^{\mathsf{MW}}_{*,\mathsf{bound}}$ including in it in contrast to what we used before (see f.e. Theorem 15.2.6) $W(x_1,x_2)$ rather than $W(0,x_2)$.

We leave to the reader to prove that replacing $W(x_1,x_2)$ by $W(0,x_2)$ leads to an error $O(1)$ under condition (15.4.8) and $O(\hbar^{-\frac{1}{2}}|\log\hbar|^L)$ under condition (15.2.41).

Remark 15.4.20. Recall that $\mathcal{N}_{*,\mathsf{bound}} = O(\mu^{\frac{1}{2}}h^{-\frac{1}{2}})$ and it is sharp.

15.5 Generalizations

15.5.1 Robin Boundary Value Problem

Consider boundary condition

$$\big(i\sum_{j,k}\nu_j g^{jk}P_k - \alpha\big)u\big|_{\partial X} = 0 \tag{15.5.1}$$

with real-valued $\alpha = \alpha(x) \ge 0$ where $\nu = (\nu_1,\dots,\nu_d)$ is an inner normal.

As $\alpha = 0$ we get Neumann boundary condition and in a formal limit $\alpha \to +\infty$ we get Dirichlet boundary condition.

Weak Magnetic Field. Obviously arguments of Section 15.2 remain valid. Recall that in that section we have not distinguished between Dirichlet and Neumann boundary conditions.

Moderate Magnetic Field. Obviously arguments of Section 15.3 remain valid. Further, under assumption $\alpha \ge \epsilon_0$ propagation Theorem 15.3.15 remains valid; really then boundary problem satisfies Lopatinski condition. Therefore under this assumption one can derive the same remainder estimates as under Dirichlet boundary condition.

Intermediate and Strong Magnetic Field. On the contrary, in this case we are practically in the framework of Neumann boundary condition: see Remark 15.A.8.

15.5.2 Boundary Meets Degeneration of V

The following problem seems to be rather easy and straightforward:

Problem 15.5.1. Get rid of condition (13.4.45) $V \le -\epsilon$ as $\mu h \le 1$ (we have not imposed this condition as $\mu h \ge 1$).

One should apply rescaling method and follow arguments of Subsection 13.8.1.

15.5.3 Domains with Corners

The following problem is far more interesting and challenging and I strongly believe that the detailed analysis merits a publication:

Problem 15.5.2. Consider domains with corners $\ne 0, \pi, 2\pi$ assuming that coefficients belong to $\mathscr{C}^\infty(X)$, all other assumptions are fulfilled and in the corners non-degeneracy condition $|\nabla_{\partial X} W| \asymp 1$ holds for each of two directions along ∂X.

Without any loss of the generality one can assume that locally either $X = \{x_1 > 0, x_2 > 0\}$ or $X = \mathbb{R}^2 \setminus \{x_1 < 0, x_2 < 0\}$. Then non-degeneracy condition means that

$$|W_{x_1}| \asymp 1, \qquad |W_{x_2}| \asymp 1. \tag{15.5.2}$$

We also assume that (13.4.45) is fulfilled.

Weak Magnetic Field Case

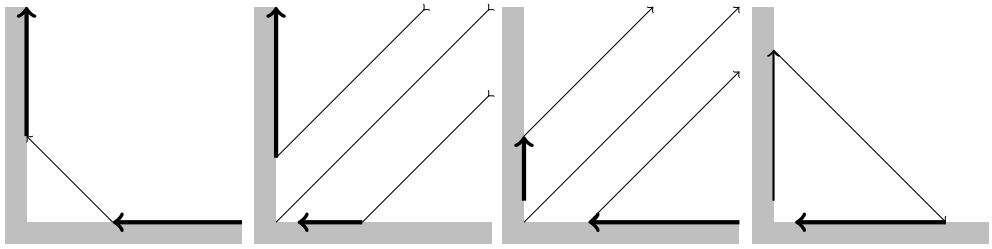
One can use rescaling method with $\ell = \epsilon|x|$ as long as $h_{\mathsf{eff}} = h\ell^{-1} \le 1$, $\mu_{\mathsf{eff}} = \mu\ell \ge 1$. In the inner zone $\mathcal{X}_{\mathsf{inn}}$ (defined exactly as before) magnetic drift is the only way to break periodicity and one can see easily that (15.3.22) should be replaced by

$$T_* := h^{1-\delta}\ell^{-1} \tag{15.5.3}$$

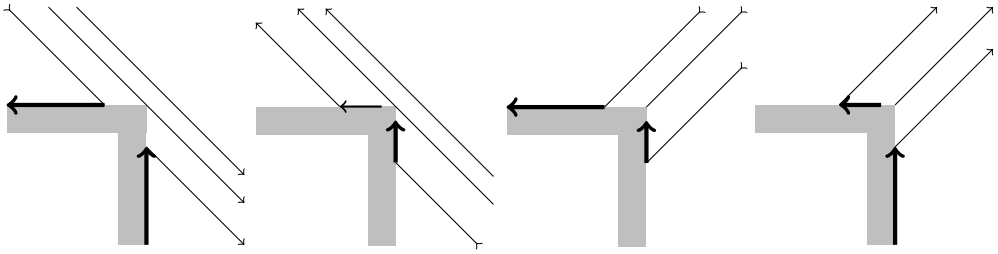
Then we are in the framework of the weak magnetic field approach as long as

$$\ell \ge \bar{\ell} := \mathsf{max}(C\mu^{-1}, \mu h^{1-\delta}). \tag{15.5.4}$$

Obviously we can take $T^* = \epsilon\mu\gamma$ with $\gamma := \mathsf{min}(|x_1|, |x_2|)$. To increase it consider dynamics on Figure 15.10.



(a) $W_{x_1} > 0, W_{x_2} > 0$ (b) $W_{x_1} > 0, W_{x_2} < 0$ (c) $W_{x_1} < 0, W_{x_2} > 0$ (d) $W_{x_1} < 0, W_{x_2} < 0$



(e) $W_{x_1} < 0, W_{x_2} < 0$ (f) $W_{x_1} > 0, W_{x_2} > 0$ (g) $W_{x_1} < 0, W_{x_2} > 0$ (h) $W_{x_1} > 0, W_{x_2} < 0$

Figure 15.10: Dynamics in the corner with angle $< \pi$ (a)–(d) and $> \pi$ (e)–(h). Bold lines show hop movement and thin lines show drift movement which is along level lines of W. Consistent with Figure 15.4.

Selecting a proper direction (away from the nearest boundary) we can take there $T^* = \epsilon\mu\ell$ and the contribution of $\mathcal{X}_{\mathsf{inn}}$ intersected with ℓ-element to the remainder does not exceed $Ch^{-1}\ell^2 \times (\mu\ell)^{-1} \asymp C\mu^{-1}h^{-1}\ell$ and summation over all inner zone returns $O(\mu^{-1}h^{-1})$.

Meanwhile contribution of ℓ-element intersected with the boundary zone $\mathcal{X}_{\mathsf{bound}}$ and transitional zone $\mathcal{X}_{\mathsf{trans}}$ does not exceed $C\mu^{-1}h^{-1}\ell \times \ell^{-1}$ as $T^* = \epsilon\ell$ here; then summation with respect to these zones returns $O(\mu^{-1}h^{-1}|\log h|)$.

One can get rid of logarithm noting that one can upgrade T^* to $T^* = \mathsf{min}(v^{-1}\ell, 1)$ as we are trying to move away from the corner; recall that in the transitional zone $\mathcal{X}_{\mathsf{trans}}$ speed in the opposite direction may be at most $v := C(\mu h)^{\frac{1}{3}}h^{-\delta} + C\mu^{-1}$ due to analysis of Section 5.4 and $\mu\ell \ge 1$. Further, in the transitional zone we have an extra factor $C(\mu h)^{\frac{2}{3}}h^{-\delta}$ due to analysis of Section 5.3.

We are left with the *corner zone* $\mathcal{X}_{\mathsf{corner}} := \{x : \ell(x) \le \bar{\ell}\}$ and in virtue of simple rescaling $x \mapsto \mu x$, $\mu \mapsto 1$ and $h \mapsto \mu h \le 1$ we can estimate its

contribution to the remainder by

$$C\mu h^{-1}\bar{\ell}^2 = C\mu^{-1}h^{-1}\big(1+\mu^4 h^{2-\delta}\big). \tag{15.5.5}$$

So, the total remainder estimate is also given by (15.5.5) which is $O(\mu^{-1}h^{-1})$ for

$$\mu \le h^{\delta-\frac{1}{2}}. \tag{15.5.6}$$

Moderate Magnetic Field Case

To improve estimate (15.5.5) (our ultimate goal is $O(\mu^{-1}h^{-1})$ as usual) as (15.5.6) breaks one needs to invoke arguments of Sections 15.2 and 15.3 and take into account dynamics near the corner (see Figure 15.10) in the same way we took into account dynamics near critical point of $W|_{\partial X}$ (see Figure 15.5) before.

Tauberian Remainder Estimate. As we mentioned in $\mathcal{X}_{\mathsf{inn}}$ one can take $T^* \asymp \mu\ell$ and $T_* = h^{1-\delta}\ell^{-1}$. Therefore contribution of ℓ-element intersected with $\mathcal{X}_{\mathsf{inn}}$ to the Tauberian remainder does not exceed

$$Ch^{-1}\ell^2\big(1+\mu T_*\big)T^{*\,-1} \asymp C\mu^{-1}h^{-1}\big(\ell+\mu h\big) \tag{15.5.7}$$

where due to arguments of Section 15.2 here and below in the estimates we can take $\delta = 0$ in the definition of T_*. Then summation over $\mathcal{X}_{\mathsf{inn}}\cap\{x, \ell(x)\ge \bar{\ell}\}$ results in $O\big(\mu^{-1}h^{-1}+|\log h|\big)$. Moreover, in cases (b), (c), (e)–(h) one can take $T^* \asymp \mu$ and the result will be $O(\mu^{-1}h^{-1})$.

The weak magnetic field arguments remain valid in $\mathcal{X}_{\mathsf{bound}}$ and its contribution to the Tauberian remainder is $O(\mu^{-1}h^{-1})$.

Meanwhile exactly as in Section 15.2 contribution of ℓ-element intersected with $\mathcal{X}_{\mathsf{trans}}$ to the Tauberian remainder does not exceed

$$C\mu^{-1}(\mu h)^{\frac{2}{3}}h^{-1-\delta}\ell \times \big(1+\frac{\mu h}{\ell}\big)\times\big(1+\frac{v}{\ell}\big)$$

as $T^* \asymp \min(1, v^{-1}\ell)$ where v is the propagation speed in the direction opposite to the hops and $(\mu h)^{\frac{2}{3}}h^{-\delta}$ is the width of $\mathcal{X}_{\mathsf{trans}}$; then the total contribution of $\mathcal{X}_{\mathsf{trans}}\cap\{x,\ell(x)\ge\bar{\ell}\}$ does not exceed

$$C\mu^{-1}(\mu h)^{\frac{2}{3}}h^{-1-\delta}\big(1+\mu h+v+\mu h v\bar{\ell}^{-1}\big);$$

meanwhile the contribution of $\mathcal{X}_{\mathsf{trans}} \cap \{x, C\hbar \le \ell \le \bar{\ell}\}$ does not exceed $C(\mu h)^{\frac{2}{3}} h^{-1-\delta}\bar{\ell}$ as we take $T^* \asymp \mu^{-1}$ here where here and below

$$\hbar := \max(\mu^{-1}, h^{1-\delta}). \tag{15.5.8}$$

Let us find $\bar{\ell}$ from $T^* = T_*$ but keep it greater than $\hbar$ i.e.

$$\bar{\ell} = C \max\bigl(\hbar, (vh)^{\frac{1}{2}}\bigr); \tag{15.5.9}$$

so the total contribution of $\mathcal{X}_{\mathsf{trans}} \cap \{x, \ell(x) \ge \hbar\}$ does not exceed

$$C\mu^{-1}h^{-1} + Ch^{-\delta} + Ch^{-1}(\mu h)^{\frac{2}{3}}(vh)^{\frac{1}{2}}h^{-\delta}.$$

Plugging $v = (\mu h)^{\frac{1}{3}}h^{-\delta}$ we arrive to

$$C\mu^{-1}h^{-1} + Ch^{-\delta} + Ch^{-\frac{1}{2}-\delta}(\mu h)^{\frac{5}{6}} \tag{15.5.10}$$

where the last term is not greater than the first two as $\mu \le h^{-\frac{8}{11}}$.

On the other hand, under Dirichlet boundary condition[17)] we can take $v = \mu^{-1}$ but then $\mu\ell \ge 1$ and we can take $T^* = 1$ and we arrive to $O(\mu^{-1}h^{-1} + h^{-\delta})$.

Remark 15.5.3. As it takes time $(\mu h)^{\frac{2}{3}}h^{-\delta}$ to punch through $\mathcal{X}_{\mathsf{trans}}$ and shift with respect to x_2 will be $v(\mu h)^{\frac{2}{3}}h^{-\delta}$ we can improve T^* as $v(\mu h)^{\frac{2}{3}}h^{-\delta} \le \ell$ which is not needed in the case of the Dirichlet[17)] problem and does not help in the case of the Neumann problem.

We are left with $\mathcal{X}_{\mathsf{corner}}$ but its contribution does not exceed $C\mu h^{-1}\bar{\ell}^2 = Ch^{-\delta}$.

Therefore remainder estimate is given by (15.5.10); if on the both sides of the corner Dirichlet[17) 18)] is given remainder estimate is $O(\mu^{-1}h^{-1} + h^{-\delta})$.

Magnetic Weyl Remainder Estimate. Transition from Tauberian to magnetic Weyl formula is obvious in $\mathcal{X}_{\mathsf{inn}}$. To run successive approximations one needs to assume that

$$(\mu^{-1} + vT_*)\,T_* \le h^{1+\delta}. \tag{15.5.11}$$

[17)] And Robin boundary condition with $\alpha \ge \epsilon$.

[18)] We can obviously mix conditions.

This is definitely the case in $\mathcal{X}_{\mathsf{bound}}$ and we need to consider $\mathcal{X}_{\mathsf{trans}}$ only. Plugging $T_* = h\ell^{-1}$ we arrive to $\ell \ge \bar{\ell}_1$ with $\bar{\ell}_1$ defined by

$$\bar{\ell}_1 = C\,\mathsf{max}\big(\mu^{-1}h^{-\delta}, (vh)^{\frac{1}{2}}\big) \tag{15.5.12}$$

which brings no extra terms in comparison with the Tauberian remainder.

So in contrast to Section 15.3 transition from Tauberian to magnetic Weyl formula does not increase an error.

Intermediate Magnetic Field Case

We need also to consider case of very strong magnetic field case $h^{\delta-1} \le \mu \le \epsilon h^{-1}$ under Dirichlet and improve remainder estimate $O(h^{-\delta})$ we got here. In this case analysis follows basically from the same arguments as in Subsection 15.3.1. Then in formula (15.5.7) one should replace $(\mu h)^{\frac{2}{3}}h^{-\delta}$ by 1 resulting in the remainder estimate $O(\mu^{-1}h^{-1} + |\log \mu|^K)$. In this approach actually corner zone becomes $\mathcal{X}_{\mathsf{corner}} = \{x, \ell(x) \le \bar{\ell}\}$ with $\bar{\ell} = C\mu^{-1} + Ch|\log h|^{K/2})$ or even $\bar{\ell} = C\mu^{-1}$.

Problem 15.5.4. (i) Investigate intermediate magnetic field case under Dirichlet[17)] and recover remainder estimate $O(\mu^{-1}h^{-1} + |\log \mu|^K)$.

(ii) Improve it under Dirichlet boundary condition to $O(\mu^{-1}h^{-1})$; is it possible?

(iii) Could be it done under Robin boundary condition?

Strong Magnetic Field Case

The similar arguments should work in the strong magnetic field case $\mu \ge \epsilon h^{-1}$ albeit we need to take $\bar{\ell} = \mu^{-\frac{1}{2}+\delta}h^{\frac{1}{2}}$, $\bar{\ell} = \mu^{-\frac{1}{2}}h^{\frac{1}{2}}|\log \mu|^{K/2}$ and $\bar{\ell} = C\mu^{-\frac{1}{2}}h^{\frac{1}{2}}$ to recover remainder estimates $O(\mu^{\delta})$, $O(|\log \mu|^K)$ and $O(1)$ respectively and we arrive to

Problem 15.5.5. (i) Investigate very strong magnetic field case under Dirichlet[17)] and recover remainder estimate $O(\mu^{\delta})$.

(ii) Improve it under Dirichlet boundary condition to $O(\mu^{-1}h^{-1} + |\log \mu|^K)$ and even to $O(\mu^{-1}h^{-1})$; is it possible?

(iii) Could be it done under Robin boundary condition?

15.5.4 Boundary Meets Degeneration of F

Set-up

Even more challenging (and in my opinion worth both publication and degree) seems to be a problem

Problem 15.5.6. Get rid of condition $|F| \ge \epsilon$.

Our goal (not necessary achievable in all cases) is to derive asymptotics as sharp as if there was no boundary. We will assume that $F \asymp \gamma(x)^{\nu-1}$ where $\gamma \in \mathscr{C}^\infty$, $\gamma(x) = 0 \implies |\nabla\gamma(x)| \asymp 1$, $x \in \partial X, \gamma(x) = 0 \implies |\nabla_{\partial X}\gamma(x)| \asymp 1$, $V < 0$.

Then we will have $X_{\mathsf{reg}} = \{x : |\gamma(x)| \ge \bar\gamma := C\mu^{-1/\nu}\}$ in the case of $\mu \le \epsilon h^{-\nu}$ and degeneration zone $X_{\mathsf{deg}} = \{|\gamma(x)| \le \bar\gamma\}$ and then we will have also four subzones:

$$X_{\mathsf{reg,inn}} = \{x : \gamma(x) \ge \bar\gamma,\ \ell(x) := \mathsf{dist}(x, \partial X) \ge C\mu^{-1}\gamma(x)^{1-\nu}\}, \tag{15.5.13}$$

$$X_{\mathsf{reg,bound}} = \{x : \gamma(x) \ge \bar\gamma,\ \ell(x) \le C\mu^{-1}\gamma(x)^{1-\nu}\}, \tag{15.5.14}$$

$$X_{\mathsf{deg,inn}} = \{x : \gamma(x) \le \bar\gamma,\ \ell(x) \ge C\mu^{-1}\bar\gamma^{1-\nu} = C\bar\gamma\}, \tag{15.5.15}$$

$$X_{\mathsf{corner}} = \{x : \gamma(x) \le \bar\gamma,\ \ell(x) \le C\bar\gamma\} \tag{15.5.16}$$

as on Figure 15.11(a) and each zone should be analyzed separately.

Remark 15.5.7. (i) Actually we need slightly increase $\bar\gamma$ as μ is close to $h^{-\nu}$ and we need increase "slightly" the threshold for $\ell(x)$ as $\gamma(x)$ is close to $(\mu h)^{-1/(\nu-1)}$ for $\mu \ge h^{\delta-1}$.

(ii) When we consider modified Schrödinger operators with $\mu h \ge 1$ so that domain $\{x,\ \gamma(x) \ge C(\mu h)^{-1/(\nu-1)}\}$ is no more forbidden, according to Section 15.4 we need to change threshold for $\ell(x)$ to "slightly more" than $\mu^{-1/2}h^{1/2}\gamma(x)^{(1-\nu)/2}$.

(iii) When we consider modified Schrödinger operators with $\mu h^\nu \ge 1$ according to Section 14.8 we need to change threshold for $\bar\gamma$ to "slightly more" than $\mu^{-1/2\nu}h^{1/2}$.

Without any loss of the generality one can assume that $X = \{x_1 > 0\}$ and $\Sigma = \{x_2 = 0\}$ and $F_{12} < 0$ as $x_2 > 0$. Then hops here are to the left (x_2 decays) and drift down (x_1 decays) because $\partial_{x_2}(-V)/F_{12} > 0$.

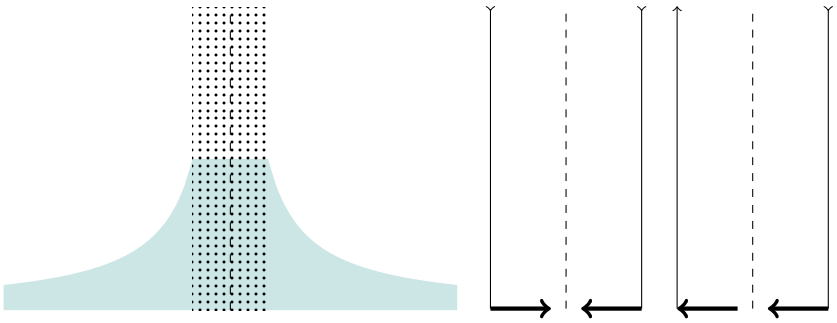


Figure 15.11: Zones (boundary zone is colored, degeneration zone is dotted) and dynamics near degeneration line of F (dashed). As $V<0$ we consider $F\asymp \gamma^{\nu-1}$ with smooth γ such that $|\nabla\gamma|\asymp 1$. Consistent with Figure 15.4.

Consider $x_2<0$; note that $F_{12}0$ changes sign and $\partial_{x_2}(-V)/F_{12}$ does not if ν is even and then hops are to the right and drift is down there (Figure 15.11(b)). On the other hand, $F_{12}0$ does not change sign and $\partial_{x_2}(-V)/F_{12}$ changes if ν is odd and then hops are to the left and drift is up there (Figure 15.11(c)).

Weak Magnetic Field Case

Using methods of the previous chapter and considering time direction in which drift up ne can prove easily that contribution of $X_{\mathsf{reg,inn}}$ to the remainder is $O(\mu^{-1/\nu}h^{-1})$ at least as $\mu\le h^{\delta-\nu}$.

Furthermore, using the methods of this chapter and and considering time direction in which hops away from Σ (and drift up) one can prove easily that contribution of $X_{\mathsf{reg,bound}}$ to the remainder is $O(\mu^{-1/\nu}h^{-1}$ at least as $\mu\le h^{\delta-\nu}$.

Consider zone $X_{\mathsf{deg,inn}}$. Then analysis of the previous chapter gives us remainder estimate $O\big(\mu^{-1/\nu}h^{-1}+(\mu^{1/\nu}h)^{1/2}h^{-1}\big)$. Recall that the last term is responsible for the correction which would come from near-periodic trajectories if $W=\mathsf{const}$. Now it is time to use the last non-degeneracy condition

$$|\nabla_\Sigma W|\asymp 1. \tag{15.5.17}$$

where V^* and $W=-V^*|_\Sigma$ are introduced by formulae (14.2.28) and (14.2.29). Then using a canonical form of the previous chapter near Σ (and thus

ignoring presence of the boundary) and considering evolution of ξ_2 one can take $T_* = h^{1-\delta}\ell^{-1}$ with $\ell \asymp |x_1|$ (and this takes in account the presence of ∂X).

As $T_* \le \epsilon\mu^{-1/\nu}$ one can then ignore all periodicity, which proves that the contribution of zone $X_{\mathsf{deg}} \cap \{x_1 \ge \bar{\ell}\}$ to the remainder is $O(\mu^{-1/\nu}h^{-1})$; meanwhile, the contribution of zone $X_{\mathsf{deg,inn}} \cap \{x_1 \le \bar{\ell}\}$ to the remainder is $O\big(\mu^{-1/\nu}h^{-1} + (\mu^{1/\nu}h)^{1/2}h^{-1}\bar{\ell}\big)$ with $\bar{\ell} = C\,\mathsf{max}(\mu^{1/\nu}h^{1-\delta}, \mu^{-1/\nu})$. By our standard technique we can actually make $\delta = 0$ in the estimate and then we arrive to the remainder estimate $O\big(\mu^{-1/\nu}h^{-1} + (\mu^{1/\nu}h)^{3/2}h^{-1}\big)$. In particular, remainder estimate is $O\big(\mu^{-1/\nu}h^{-1}\big)$ as $\mu \le h^{-3\nu/5}$.

Moderate Magnetic Field Case

Here comes the difficult part:

Problem 15.5.8. (i) Under condition (15.5.3) prove that if

$$|\xi_2 - \eta^*_\hbar W^{1/2}| \le \rho \le \ell^{1/2}, \qquad \text{with} \quad \rho\ell \ge h \tag{15.5.18}$$

then one can take $T_* \asymp h\ell^{-1}$ and $T^* \asymp 1$ and then contribution of such element to the Tauberian remainder does not exceed

$$C\mu^{-1/\nu}\rho\ell h^{-1}\big(1+\mu^{1/\nu}T_*\big)\,T^{*,-1} \asymp C\mu^{-1/\nu}h^{-1}\rho\ell\big(1+\mu^{1/\nu}h\ell^{-1}\big) \tag{15.5.19}$$

and therefore the total contribution to the Tauberian remainder of elements of this type with $\ell \ge \mathsf{max}(h^{2/3}, \mu^{-1/\nu})$ is $O(\mu^{-1/\nu}h^{-1})$.

(ii) Prove that if

$$|\xi_2 - \eta^*_\hbar W^{1/2}| \asymp \rho \ge \ell^{1/2}, \qquad \text{with} \quad \rho\ell \ge h \tag{15.5.20}$$

then one can take $T_* \asymp h\rho^{-2}$ and $T^* \asymp \rho$ and then contribution of such element to the Tauberian remainder does not exceed

$$C\mu^{-1/\nu}\rho\ell h^{-1}\big(1+\mu^{1/\nu}T_*\big)\,T^{*,-1} \asymp C\mu^{-1/\nu}h^{-1}\rho\ell\big(1+\mu^{1/\nu}h\rho^{-2}\big)\rho^{-1} \tag{15.5.21}$$

and therefore the total contribution to the Tauberian remainder of elements of this type with $\rho \ge \mathsf{max}(h^{1/3}, \mu^{-1/2\nu})$ is $O(\mu^{-1/\nu}h^{-1} + |\log\mu|)$.

(iii) Provide the same estimate for contribution of the remaining small zone $\{\rho \le \mathsf{max}(h^{1/3}, \mu^{-1/2\nu}),\ C\mu^{-1/\nu} \le \ell \le h^{2/3}, \rho\ell \le h\}$; combining with estimate for X_{corner} we arrive to the same estimate $O(\mu^{-1/\nu}h^{-1} + h^{-\delta})$.

(iv) Improve this estimate to $O(\mu^{-1/\nu}h^{-1}+1)$.

Also looks challenging the next step:

Problem 15.5.9. Pass from asymptotics with the Tauberian principal part to a more explicit ones.

There should be usual magnetic Weyl term, a term associated with the boundary and a term associated with degeneration albeit we do not expect any mixed boundary-degeneration term.

Strong and Superstrong Magnetic Field cCases

In the same way one needs to consider modified Schrödinger operator (with $\mathfrak{z}\mu hF^{\#}$ subtracted where $F^{\#}$ is "F but without absolute value") and taking into account Remark 15.5.7 follow the same path:

Problem 15.5.10. Derive spectral asymptotics for the modified Schrödinger operator:

(i) Consider the case of the strong magnetic field: $\epsilon h^{-1} \le \mu \le \epsilon h^{-\nu}$.

(ii) Consider the case of the superstrong magnetic field: $\mu \ge \epsilon h^{-\nu}$.

15.5.5 Case $h \ge 1$

The following problem does not seem to be too challenging but rather important not only on its own but due to its possible applications to the global asymptotics as in Chapter 23.

Problem 15.5.11. Extend our results to $\mu h \ge 1$, $h \ge 1$, $\mu \ge h$ (as it was the case without boundary).

15.A Appendices: Eigenvalues of $L(\eta)$

15.A.1 Basic Properties

Recall that $\lambda_{\mathsf{D},n}(\eta)$ and $\lambda_{\mathsf{N},n}(\eta)$ $n=0,1,...$ are eigenvalues of the operator[19)]

$$L(\eta) = -\partial_x^2 + (x+\eta)^2 \tag{15.A.1}$$

[19)] Obviously, transformation $x \mapsto -x$ reduces (15.1.26) to this one.

on $\mathbb{R}^-$ with Dirichlet and Neumann boundary condition respectively at 0, $u_n(x) = v_n(x+\eta, \eta)$ are (real-valued) eigenfunctions such that $\|v_n\| = 1$.

Proposition 15.A.1. *$\lambda_{\mathsf{D},n}(\eta)$ and $\lambda_{\mathsf{N},n}(\eta)$, $n = 0, 1, 2, \dots$ are real analytic functions with the following properties:*

(i) $\lambda_{\mathsf{D},n}(\eta)$ are monotone decreasing for $\eta \in \mathbb{R}$; $\lambda_{\mathsf{D},n}(\eta) \nearrow +\infty$ as $\eta \to -\infty$; $\lambda_{\mathsf{D},n}(\eta) \searrow (2n+1)$ as $\eta \to +\infty$; $\lambda_{\mathsf{D},n}(0) = (4n+3)$.

(ii) $\lambda_{\mathsf{N},n}(\eta)$ are monotone decreasing for $\eta \in \mathbb{R}^-$; $\lambda_{\mathsf{N},n}(\eta) \nearrow +\infty$ as $\eta \to -\infty$; $\lambda_{\mathsf{N},n}(\eta) < (2n+1)$ as $\eta \ge (2n+1)^{\frac{1}{2}}$; $\lambda_{\mathsf{N},n}(0) = (4n+1)$.

(iii) $\lambda_{\mathsf{N},n}(\eta) < \lambda_{\mathsf{D},n}(\eta) < \lambda_{\mathsf{N},(n+1)}(\eta)$; $\lambda_{\mathsf{D},n}(\eta) > (2n+1)$, $\lambda_{\mathsf{N},n}(\eta) > (2n-1)_+$.

Proof. Note that $\lambda_{\mathsf{D},n}(\eta)$ and $\lambda_{\mathsf{N},n}(\eta)$ are obtained by variational procedure from quadratic forms

$$Q^-(u) = \int_{x<0} \Big(|\partial_x u|^2 + (x+\eta)^2 |u|^2 \Big)\, dx, \quad Q_0^-(u) = \int_{x<0} |u|^2\, dx \tag{15.A.2}$$

respectively with Dirichlet or no boundary conditions at $x = 0$. Alternatively we can consider

$$Q^-(u) = \int_{x<\eta} \Big(|\partial_x u|^2 + x^2 |u|^2 \Big)\, dx, \quad Q_0^-(u) = \int_{x<\eta} |u|^2\, dx \tag{15.A.3}$$

respectively with Dirichlet or no boundary conditions at $x = \eta$ and we will shift notations between these two.

We know eigenvalues $\bar{\lambda}_n = (2n+1)$ and eigenfunctions of this operator on $\mathbb{R}$ (i.e. as $\eta = -\infty$). Further, we know that eigenvalues of $L_{\mathsf{D}}(0)$ and $L_{\mathsf{N}}(0)$ are $(2m+1)$ respectively with odd and even m we arrive to all assertions in Statement (i), and to all assertions in Statement (ii) except the third one.

Consider $\bar{v}_k(x)$ which are eigenfunctions of harmonic oscillator on $\mathbb{R}$, $k = 0, \dots, n$. As u belongs to their span

$$Q^-(u) = Q(u) - Q^+(u) \le (2n+1) Q_0(u) - Q^+(u) = \\ (2n+1) Q_0^-(u) + (2n+1) Q_0^+(u) - Q^+(u)$$

where Q, Q_0 denote the same forms on $\mathbb{R}$ and Q^+, Q_0^+ on $\{x > \eta\}$.

Let $\eta \ge (2n+1)^{\frac12}$. Obviously $(2n+1)Q_0^+(u) < Q^+(u)$ and therefore $Q^-(u) < (2n+1)Q_0^-(u)$ for u belonging to some $(n+1)$-dimensional space; then $\lambda_{\mathsf{N},n}(\eta) < (2n+1)$.

In Statement (iii) one needs only to prove that $\lambda_{\mathsf{D},n}(\eta) < \lambda_{\mathsf{N},(n+1)}(\eta)$. However in $(n+2)$ dimensional span of $\upsilon_{\mathsf{N},0}(x), \dots, \upsilon_{\mathsf{N},(n+1)}(x)$, functions vanishing at $x=\eta$ form $(n+1)$ dimensional subspace on which $Q^-(u) < \lambda_{\mathsf{N},(n+1)}Q_0^-(u)$ (strict inequality is due to the fact that only on $v = \upsilon_{\mathsf{N},(n+1)}(x)$ equality can be reached and this function does not belong to the subspace in question (as then $v(\eta) = \partial v(\eta) = 0$ which is impossible). □

So far we have not proved that $\lambda_{\mathsf{N},n}(\eta) \to (2n+1)$ as $\eta \to +\infty$; it will be done later.

15.A.2 More Properties

We follow M. Dauge–B. Helffer [1] here.

Consider equation on $x<0$

$$\bigl(L(\eta) - \lambda_n(\eta)\bigr)u_n = 0. \tag{15.A.4}$$

Differentiating by η and multiplying by u_n we arrive to

$$\begin{aligned}\partial_\eta\lambda_n(\eta) &= ((\partial_\eta L(\eta))u_n, u_n) = 2((x+\eta)u_n, u_n) = \\ &([\partial_x, (x+\eta)^2]u_n, u_n) = 2((x+\eta)^2u_n, \partial_x u_n) + \eta^2|u_n(0)|^2 = \\ &2(L(\eta)u_n, \partial_x u_n) + (\partial_x^2 u_n, \partial_x u_n) + \eta^2|u_n(0)|^2 = \\ &\bigl(\eta^2 - \lambda_n(\eta)\bigr)|u_n(0)|^2 - |\partial_x u_n(0)|^2.\end{aligned} \tag{15.A.5}$$

In particular,

$$\partial_\eta\lambda_{\mathsf{D},n}(\eta) = -|\partial_x\upsilon_{\mathsf{D},n}(\eta)|^2 \tag{15.A.6}_{\mathsf{D}}$$

and

$$\partial_\eta\lambda_{\mathsf{N},n}(\eta) = \bigl(\eta^2 - \lambda_{\mathsf{N},n}(\eta)\bigr)|\upsilon_{\mathsf{N},n}(\eta)|^2. \tag{15.A.6}_{\mathsf{N}}$$

We refer to them as *Dauge-Helffer formulae* [1].

We conclude immediately that

Proposition 15.A.2. *(i)* $\partial_\eta\lambda_{\mathsf{D},n}(\eta) < 0$.

(ii) $\partial_\eta \lambda_{\mathsf{N},n}(\eta) \gtreqless 0$ *if and only if*

$$\lambda_{\mathsf{N},n}(\eta) \lesseqgtr \eta^2. \tag{15.A.7}$$

Differentiating $(15.A.6)_{\mathsf{N}}$ we arrive to

$$\partial_\eta^2 \lambda_{\mathsf{N},n}(\eta) = \bigl(2\eta - \partial_\eta \lambda_{\mathsf{N},n}(\eta)\bigr)|\upsilon_{\mathsf{N},n}(\eta)|^2 + 2\bigl(\eta^2 - \lambda_{\mathsf{N},n}(\eta)\bigr)\partial_\eta \upsilon_{\mathsf{N},n}(\eta)\cdot \upsilon_{\mathsf{N},n}(\eta). \tag{15.A.8}$$

Therefore as $\partial_\eta \lambda_{\mathsf{N},n}(\eta) = 0$ in virtue of Proposition 15.A.1

$$\partial_\eta^2 \lambda_{\mathsf{N},n}(\eta) = 2\eta |\upsilon_{\mathsf{N},n}(\eta)|^2 \tag{15.A.9}$$

and therefore it is non-degenerate minimum. Thus we arrive to

Proposition 15.A.3. *(i)* $\lambda_{\mathsf{N},n}(\eta)$ *has a single stationary point*[20] η_n*, it is non-degenerate minimum, and in this point* (15.A.7), (15.A.9) *hold.*

(ii) In particular, $(\lambda_{\mathsf{N},n}(\eta) - \eta^2)$ *has the same sign as* $(\eta_n - \eta)$*.*

Therefore $\lambda_{\mathsf{N},n+1}(\eta_n) - \eta_n^2 > \lambda_{\mathsf{N},n}(\eta_n) - \eta_n^2 = 0$ implies that

$$\eta_{n+1} > \eta_n. \tag{15.A.10}$$

15.A.3 Estimates of $\lambda_{*,n}(\eta)$ as $\eta \to +\infty$

So we must investigate properties of $\lambda_n(\eta)$ as $\eta \to +\infty$. We know that then $\lambda_{\mathsf{D},n}(\eta) \ge (2n+1) \ge \lambda_{\mathsf{N},n}(\eta)$ and $\lambda_{\mathsf{D},n}(\eta)$ tends to $(2n+1)$.

Consider $\bar{\upsilon}_j(x)$. Note that

$$\int_\eta^{+\infty} \bar{\upsilon}_j(x)\bar{\upsilon}_k(x)\,dx = O\bigl(\eta^{j+k-1}e^{-\eta^2}\bigr) \tag{15.A.11}$$

(non-uniformly with respect to j,k) and as $j=k$ this is an exact magnitude.

Therefore

$$(\bar{\upsilon}_j, \bar{\upsilon}_k) = \delta_{jk} + O\bigl(\eta^{j+k-1}e^{-\eta^2}\bigr) \tag{15.A.12}$$

as our space is $\mathscr{L}^2((-\infty,\eta))$.

[20] And it must have one due to Proposition 15.A.1.

Consider bilinear form

$$Q^-(u,v)=\int_{-\infty}^{\eta}\bigl(u'v'+x^2uv\bigr)\,dx$$

(where $'$ means ∂_x). One can rewrite it as

$$Q^-(u,v)=\int_{-\infty}^{\eta}\bigl(-u''+x^2u\bigr)v\,dx+u'(\eta)v(\eta).$$

Then

$$Q^-(\bar{v}_j,\bar{v}_k)=(2j+1)(\bar{v}_j,\bar{v}_k)+\bar{v}_j'(\eta)\bar{v}_k(\eta).$$

Thus if we consider $u=\sum_{k\le n}\alpha_k\bar{v}_k$ with $\alpha_k\in\mathbb{R}$ such that $\sum_{k\le n}\alpha_k^2\asymp 1$ then

$$Q^-(u)-(2n+1)Q_0^-(u)=\sum_{k\le n}2(k-n)\alpha_k^2+O\bigl(e^{-\eta^2}\eta^{n+k+1}\bigr)$$

and this expression is negative provided $\alpha_k^2\ge e^{-\eta^2}\eta^{n+k+1}$ for some $k<n$; otherwise we can assume that $\alpha_n=1$ and

$$\begin{aligned}Q^-(u)-(2n+1)Q_0^-(u)\equiv\sum_{k\le n}\bigl(Q^-(\bar{v}_k)-(2n+1)Q_0^-(\bar{v}_k)\bigr)\alpha_k^2\le\\ \bigl(Q^-(\bar{v}_n)-(2n+1)Q_0^-(\bar{v}_n)\bigr)\equiv\bar{v}_n'(\eta)\bar{v}_n(\eta)\mod O\bigl(e^{-\frac{5}{4}\eta^2}\bigr)\end{aligned}$$

and we know that $\bar{v}_n'(\eta)\bar{v}_n(\eta)$ is negative and of magnitude $\eta^{2n+1}e^{-\eta^2}$ as $\eta\ge c_n$ and therefore due to variational principle

$$\lambda_{\mathsf{N},n}(\eta)\le(2n+1)-\epsilon\eta^{2n+1}e^{-\eta^2}\qquad\text{as }\ \eta\ge c_n.$$

Meanwhile let us replace $\bar{v}_k(x)$ by $\tilde{v}_k(x)=\bar{v}_n(x)+\phi_k$, $\phi_k=-\bar{v}_k(\eta)e^{\eta x-\eta^2}$ satisfying Dirichlet conditions as $x=\eta$. All the above conclusions except calculations of $Q(\bar{v}_n)$ remain true for these functions as well and for them

$$\begin{aligned}&Q^-(\tilde{v}_n)-(2n+1)Q_0^-(\tilde{v}_n)=\\ &\qquad\bar{v}_n'(\eta)\bar{v}_n(\eta)+2\bar{v}_n'(\eta)\phi_n(\eta)+Q^-(\phi_n)-(2n+1)Q_0^-(\phi_n)=\\ &\qquad\qquad-v_n'(\eta)v_n(\eta)+v_n^2(\eta)\bigl(\eta+O(\eta^{-1})\bigr)\asymp\eta^{2n+1}e^{-\eta^2}\end{aligned}$$

and therefore

$$\lambda_{\mathsf{D},n}(\eta) \le (2n+1) + C_n \eta^{2n+1} e^{-\eta^2} \qquad \text{as} \quad \eta \ge c_n.$$

On the other hand, consider $\mathscr{C} \ni u$ supported in $(-\infty, \eta]$ and orthogonal to $\bar{v}_0, \dots, \bar{v}_{n-1}$. Then (modulo constant factor) $u = \bar{v}_n(x) + v$ where v is orthogonal to $\bar{v}_n$ in $\mathbb{R}$ as well.

Note that

$$Q^-(u) = Q(u) = Q(\bar{v}_n) + Q(v) = (2n+1) + Q(v),$$

and $Q_0^-(u) = 1 + \|v\|^2_{\mathbb{R}}$, and

$$Q^-(u) - (2n+1)Q_0^-(u) = Q(v) - (2n+1)Q_0(v) \ge 2Q_0(v) \ge 2Q_0^+(v) = 2Q_0^+(\bar{v}_n) \ge \epsilon \eta^{2n+1} e^{-\eta^2}.$$

So, any $(n+1)$-dimensional subspace of $\mathscr{L}^2((-\infty, \eta))$ contains an element with $Q^-(u) \ge \big((2n+1) + \epsilon\eta^{2n+1}e^{-\eta^2}\big) Q_0^-(u)$ and we arrive to the left inequality of

$$\epsilon_n \eta^{2n+1} e^{-\eta^2} \le \lambda_{\mathsf{D},n}(\eta) - (2n+1) \le C_n \eta^{2k+1} e^{-\eta^2} \qquad \text{as} \quad \eta \ge c_n \tag{15.A.13}$$

as the right one has been already proven.

Finally, estimate $\lambda_{\mathsf{N},n}$ from below. Consider $\upsilon_n(x)$ and extend it as $\upsilon_n(\eta) e^{\frac{1}{2}(\eta^2 - x^2)}$ to (η, ∞). Let u be a resulting function. Note

$$Q^+(u) - (2n+1)Q_0^+(u) = |\upsilon_n(\eta)|^2 \big(\eta - 2n\Phi(\eta)\big),$$

with $\Phi(\eta) = \int_\eta^\infty e^{\eta^2 - x^2}\, dx$ and then as $n = 0$

$$\begin{aligned} \lambda_{\mathsf{N},n}(\eta) - (2n+1) = Q^-(\upsilon_n) - (2n+1)Q_0^-(\upsilon_n) = \\ Q(u) - (2n+1)Q_0(u) - Q^+(u) + (2n+1)Q_0^+(u) \ge \\ - |\upsilon_n(\eta)|^2 \big(\eta - 2n\Phi(\eta)\big) = -\frac{1}{2}\big(\eta - 2n\Phi(\eta)\big)(\eta^2 - \lambda_{\mathsf{N},n})^{-1} \partial_\eta \lambda_{\mathsf{N},n}(\eta) \end{aligned}$$

due to $(15.A.6)_{\mathsf{N}}$.Therefore

$$\big(2n + 1 - \lambda_{\mathsf{N},n}(\eta)\big)^{-1} \partial_\eta \lambda_{\mathsf{N},n}(\eta) \ge 2\big(\eta^2 - \lambda_{\mathsf{N},n}(\eta)\big)\big(\eta - \Phi(\eta)\big)^{-1}.$$

Note that $\Phi(\eta) = \frac{1}{2}\eta^{-1} + O(\eta^{-3})$ and $\lambda_n < 2n+1$. Then the right-hand side of the last inequality is greater than $2(\eta - (n+1)\eta^{-1}) - O(\eta^{-2})$ and integrating we conclude that

$$\log\bigl(2n+1-\lambda_{\mathsf{N},n}(\eta)\bigr)^{-1} \geq \eta^2 - 2(n+1)\log\eta - \log C_n$$

and

$$2n+1-\lambda_{\mathsf{N},n}(\eta) \leq \sigma_n(\eta) \coloneqq C_n e^{-\eta^2}\eta^{2n+2}$$

which is just one factor η greater than we got as an lower estimate for $(1-\lambda_n)$.

Finally, as $\lambda_{\mathsf{N},n+1}(\eta) > \lambda_{\mathsf{N},n+1}(\eta_{n+1}) > \lambda_{\mathsf{D},n}(\eta_{n+1}) > (2n+1)$ we conclude that $\lambda_{\mathsf{N},n+1}(\eta)$ and $\lambda_{\mathsf{N},n}(\eta)$ are disjoint as $\eta > C_n$ and therefore as $Q^-(\bar{v}_n) \leq Q^-(v_n) + C_n\sigma_n$ we conclude that $Q^-(v_n - \bar{v}_n) \leq C_n\sigma_n(\eta)$:

$$\|\partial_x(v_n - \bar{v}_n)\| + \|x(v_n - \bar{v}_n)\| \leq C_n\sigma_n(\eta)^{\frac{1}{2}} \tag{15.A.14}$$

where norms are calculated in $\mathscr{L}^2((-\infty,\eta))$ and then

$$|(v_n - \bar{v}_n)| \leq C_n\sigma_n(\eta)^{\frac{1}{2}}; \tag{15.A.15}$$

In particular $|v_n(\eta)| \leq C_n\sigma_n(\eta)^{\frac{1}{2}}$.

So far it was proven only for $n=0$. However we apply induction: as it was proven for $k<n$ with fast decaying $\sigma_k(\eta)$. Then $(v_n,\bar{v}_k) = O\bigl(\sigma_k(\eta)^{\frac{1}{2}}\bigr)$ for $k<n$ and extending v_n as before we arrive to $(u,\bar{v}_k) = O\bigl(\sigma_{n-1}(\eta)^{\frac{1}{2}}\bigr)$ for all $k<n$.

Then $Q(u) - (2n+1)Q_0(u) \geq -C\sigma_{n-1}$ and we arrive to

$$\lambda_{\mathsf{N},n} - (2n+1) \geq -\frac{1}{2}\bigl(\eta - 2n\Phi(\eta)\bigr)\bigl(\eta^2 - \lambda_{\mathsf{N},n}(\eta)\bigr)^{-1}\partial_\eta\lambda_{\mathsf{N},n}(\eta) - C\eta^{2n}e^{-\eta^2}$$

which implies the same conclusions.

We also conclude that (15.A.14) and (15.A.15) hold for $\bar{v}_n$ replaced by $v_{\mathsf{D},n}$ and that $|\partial_x v_{\mathsf{D},n}(\eta)| \leq C_n\eta\sigma_n(\eta)^{\frac{1}{2}}$.

15.A.4 Asymptotics of $\lambda_{*,n}(\eta)$ as $\eta \to +\infty$

Here will reproduce results of section 5 of C. Bolley–B. Helffer [1] and generalize them to arbitrary j and to Dirichlet problem (definitely their methods could do the same).

In contrast to this paper we will not build quasimodes but use Dauge-Helffer formulae. Let

$$\varepsilon_{*,n}(\eta) = \pm\big(\lambda_{*,n}(\eta) - 2n - 1\big) \tag{15.A.16}$$

with $* = \mathsf{D}, \mathsf{N}$ respectively. Then from

$$L(\eta)\upsilon_{*,n}(\eta) - \big(2n + 1 \pm \varepsilon_{*,n}(\eta)\big)\upsilon_{*,n} = 0, \qquad L(\eta)\bar{\upsilon}_n - (2n+1)\bar{\upsilon}_n = 0$$

we conclude that

$$\mp\varepsilon_{*,n}(\eta)(\upsilon_{*,n}, \bar{\upsilon}_n) = \upsilon_n'(\eta)\bar{\upsilon}_n(\eta) - \upsilon_n(\eta)\bar{\upsilon}_n'(\eta)$$

and as modulo $O\big(e^{-\frac{1}{2}\eta^2}\eta^K\big)$ $(\upsilon_{*,n}, \bar{\upsilon}_n) \equiv 1$ then

$$\mp\varepsilon_{*,n}(\eta) \equiv \upsilon_{*,n}'(\eta)\bar{\upsilon}_n(\eta) - \upsilon_{*,n}(\eta)\bar{\upsilon}_n'(\eta)$$

modulo $O\big(e^{-\frac{3}{2}\eta^2}\eta^K\big)$. Then modulo sign

$$-\varepsilon_{\mathsf{D},n}(\eta) \equiv \upsilon_{\mathsf{D},n}'(\eta)\bar{\upsilon}_n(\eta) = \big(-\partial_\eta\varepsilon_{\mathsf{D},n}\big)^{\frac{1}{2}}\bar{\upsilon}_n(\eta),$$

$$\varepsilon_{\mathsf{N},n}(\eta) \equiv \upsilon_{\mathsf{N},n}(\eta)\bar{\upsilon}_n'(\eta) = \big(-(\eta^2 - 2n - 1)^{-1}\partial_\eta\varepsilon_{\mathsf{N},n}\big)^{\frac{1}{2}}\bar{\upsilon}_n'(\eta)$$

and modulo $O\big(e^{\frac{1}{2}\eta^2}\eta^K\big)$

$$\partial_\eta\varepsilon_{\mathsf{D},n}^{-1}(\eta) \equiv \big(\bar{\upsilon}_n(\eta)\big)^{-2},$$

$$\partial_\eta\varepsilon_{\mathsf{N},n}^{-1}(\eta) \equiv (\eta^2 - 2n - 1)\big(\bar{\upsilon}_n'(\eta)\big)^{-2}$$

and

$$\varepsilon_{\mathsf{D},n}^{-1}(\eta) \equiv \int^\eta \big(\bar{\upsilon}_n(\eta)\big)^{-2}\, d\eta, \tag{15.A.17}_{\mathsf{D}}$$

$$\varepsilon_{\mathsf{N},n}^{-1}(\eta) \equiv \int^\eta (\eta^2 - 2n - 1)\big(\bar{\upsilon}_n'(\eta)\big)^{-2}\, d\eta \tag{15.A.17}_{\mathsf{N}}$$

and finally we arrive to

Theorem 15.A.4. *As* $\eta \to +\infty$

$$\lambda_{\mathsf{D},n}(\eta) \equiv 2n + 1 + \Big(\int^\eta \big(\bar{\upsilon}_n(\eta)\big)^{-2}\, d\eta\Big)^{-1}, \tag{15.A.18}_{\mathsf{D}}$$

$$\lambda_{\mathsf{N},n}(\eta) \equiv 2n + 1 - \Big(\int^\eta (\eta^2 - 2n - 1)\big(\bar{\upsilon}_n'(\eta)\big)^{-2}\, d\eta\Big)^{-1} \tag{15.A.18}_{\mathsf{N}}$$

modulo $O\big(e^{-\frac{3}{2}\eta^2}\eta^K\big)$ *with* $K = K(n)$.

Remark 15.A.5. One can see easily from $(15.A.18)_{\mathsf{D}}$, $(15.A.18)_{\mathsf{N}}$ that

$$e^{-\eta^2}\varepsilon_{*,n}^{-1}(\eta) \sim \sum_{k\ge 0} c'_{*,n,k}\eta^{-2n-1-2k}$$

with the leading coefficient $c'_{*,n,0} = \frac{1}{2}\kappa_n^{-2}$ where $\kappa_n = (n!)^{-\frac{1}{2}}\pi^{-\frac{1}{4}}2^{n/2}$ coefficient at x^n at $\bar{v}_n e^{x^2/2}$ and thus

$$e^{-\eta^2}\varepsilon_{*,n}(\eta) =\sim \sum_{k\ge 0} c_{*,n,k}\eta^{2n+1-2k} \tag{15.A.19}$$

where

$$c_{*,n,0} = 2\kappa_n^2 = \frac{2^{n+1}}{n!\sqrt{\pi}}. \tag{15.A.20}$$

Now we can estimate recurrently higher-order derivatives of $\varepsilon_{*,n}(\eta)$, $v_{*,n}(x,\eta)$ as $x = \eta$ arriving to

Corollary 15.A.6.

$$|\partial^j \lambda_{*,n}(\eta)| \asymp \eta^{2n+1+j}e^{-\eta^2} \tag{15.A.21}$$

as $\eta > c_{n,j}$.

15.A.5 Remarks

Remark 15.A.7. While we do not need it one can prove easily that

$$\lambda_{*,n}(\eta) \sim \eta^2 + \sum_{k\ge 0} c_{*,n,k}\eta^{\frac{2}{3}(1-2k)} \tag{15.A.22}$$

as $\eta \to -\infty$ with $c_{*,n,0}$ eigenvalues of operator $M(\eta) := \big(D^2 + 2x|\eta|\big)$ on $\mathbb{R}^+$ with the corresponding boundary condition (D or N) as $x = 0$ and thus are defined through zeros of Airy function or its derivative.

Remark 15.A.8. (i) For operator $D^2 + x^2$ on $\{x \le \eta\}$ albeit with the boundary condition $(u' + \alpha u)(\eta) = 0$ with $0 \le \alpha < \infty$ one can see easily that $(15.A.6)_{\mathsf{N}}$, $(15.A.17)_{\mathsf{N}}$ are replaced by

$$\partial_\eta \lambda_n(\eta,\alpha) = \big(\eta^2 - \alpha^2 - \lambda_n(\eta,\alpha)\big)|v_n(\eta,\alpha)|^2, \tag{15.A.6}_\alpha$$

$$\varepsilon_n^{-1}(\eta,\alpha) \equiv \int^\eta (\eta^2 - 2n - 1 - \alpha^2)(\bar{v}'_n(\eta,\alpha))^{-2}\,d\eta \tag{15.A.17}_\alpha$$

respectively.

(ii) One can prove easily that $\lambda_n(\eta;\alpha)$ monotonically depends on α and $\lambda_n(\eta;0) = \lambda_{\mathsf{N},n}(\eta)$, $\lambda_n(\eta;\alpha) \nearrow \lambda_{\mathsf{D},n}(\eta)$ as $\alpha \to +\infty$.

However, in virtue of (i) for all $\alpha > 0$ there is a single extremum which is a non-degenerate minimum at $\eta_n = \eta_n(\alpha) > 0$ such that $\eta_n^2 = \lambda_n(\eta_n) + \alpha^2$ and as $\alpha \to +\infty$ therefore $\eta_n(\alpha) \approx \alpha^2 + (2n+1)$ with a small negative error (see Remark 15.A.8).

Therefore as $\alpha \to +\infty$ these minima (see blue line on Figure 15.13 for $\alpha = 0$) become more shallow and move to the right and blue-like lines here can approximate red-like lines exactly as on the graphs of $e^{-\eta} - (\eta^2+\alpha^2)^{-1}$.).

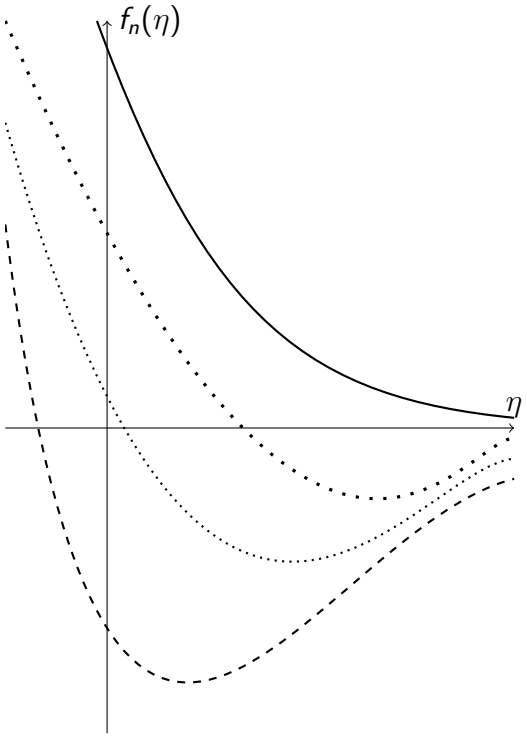

Figure 15.12: Schematics of $f_n(\eta) := \lambda_n(\eta;\alpha) - (2n+1)$.

Conjecture 15.A.9. *For each n function $\lambda_{\mathsf{D},n}(\eta)$ is convex and $\partial_\eta^2 \lambda_{\mathsf{D},n}(\eta) > 0$ while $\lambda_{\mathsf{N},n}(\eta)$ has a single non-degenerate inflection point η_n' and $\partial_\eta^2 \lambda_{\mathsf{D},n}(\eta) \gtrless 0$ as $\eta \lessgtr \eta_n'$.*

Smooth Theory in Dimensions 2 and 3 (Continued)

Chapter 16

Magnetic Schrödinger Operator: Short Loops, Pointwise Spectral Asymptotics and Asymptotics of Dirac Energy

16.1 Introduction

In this chapter we consider 2D- and 3D-magnetic Schrödinger operator (13.2.1) satisfying assumptions (13.2.2)–(13.2.5) and consider pointwise asymptotics of $e(x,x,0)$ and also asymptotics of expression (6.4.4):

$$\mathsf{I} := \iint e(x,y,0)e(y,x,0)\omega(x,y)\psi_2(x)\psi_1(y)\,dx\,dy \tag{16.1.1}$$

as well as of

$$\mathsf{J} := \iint e(x,x,0)e(y,y,0)\omega(x,y)\psi_2(x)\psi_1(y)\,dxdy \tag{16.1.2}$$

with a function $\omega(x,y)$ satisfying assumption (6.4.5):

(16.1.3) $\omega(x,y) := \Omega(x,y;x-y)$ where function Ω is smooth in $B(0,1)\times B(0,1)\times B(\mathbb{R}^2\setminus 0)$ and homogeneous of degree $-\kappa$ ($0<\kappa<2$) with respect to its third argument,

and with smooth cut-off functions ψ_1,ψ_2.

These two expressions play a role in the applications to the multiparticle quantum theory of Chapter 27. Actually, instead of asymptotics of (16.1.2) we consider related estimates of

$$\mathsf{K} := \iint \bigl(e(x,x,\tau) - h^{-d}\mathcal{N}_x(\tau)\bigr)\bigl(e(y,y,\tau) - h^{-d}\mathcal{N}_x(\tau)\bigr)\omega(x,y)\,dxdy \tag{16.1.4}$$

where $\mathcal{N}_x(\tau)$ denotes some approximation to $e(x,x,\tau)$.

We assume that V/F satisfies non-degeneracy conditions (13.4.45) and (13.4.54) i.e.

$$V \le -\epsilon_0 \qquad \text{in } B(0,1), \tag{16.1.5}$$

$$|F| \ge \epsilon \qquad \text{in } B(0,1), \tag{16.1.6}$$

$$|\nabla \frac{V}{F}| \asymp 1 \qquad \text{in } B(0,1) \tag{16.1.7}$$

in the asymptotics of expressions (16.1.1)–(16.1.2) we will be able to drop (16.1.5) and replace (16.1.7) by

$$|\nabla \frac{V}{F}| \le \epsilon_0 \implies |\det \mathsf{Hess}\, \frac{V}{F}| \ge \epsilon_0 \tag{16.1.8}$$

or

$$|\nabla \frac{V}{F}| \le \epsilon_0 \implies \det \mathsf{Hess}\, \frac{V}{F} \ge \epsilon_0. \tag{16.1.8}^+$$

As we consider Schrödinger-Pauli operator (13.6.3) and $\mu h \gtrsim 1$ conditions (16.1.7)–(16.1.8)$^+$ will be modified to

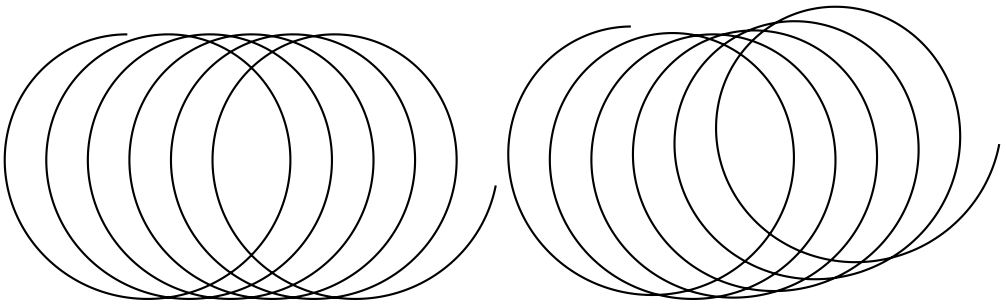
$$|\frac{V}{F} + (2m+1-\varsigma)| + |\nabla \frac{V}{F}| \asymp 1 \qquad \text{in } B(0,1)\ \forall m \in \mathbb{Z}^+; \tag{16.1.7}'$$

$$|\frac{V}{F} + (2m+1-\varsigma)| + |\nabla \frac{V}{F}| \le \epsilon_0 \implies |\det \mathsf{Hess}\, \frac{V}{F}| \ge \epsilon_0, \tag{16.1.8}'$$

$$|\frac{V}{F} + (2m+1-\varsigma)| + |\nabla \frac{V}{F}| \le \epsilon_0 \implies \det \mathsf{Hess}\, \frac{V}{F} \ge \epsilon_0 \tag{16.1.8}^{+\prime}$$

respectively.

Non-degeneracy assumptions (16.1.7)–(16.1.8)$^+$ eliminate periodicity at least as $\mu h \ll 1$ but there are plenty of loops as on figures 16.1(a) and 16.1(b) and we know that loops play the same important role in the



(a) prolate cycloid (b) perturbed prolate cycloid

Figure 16.1: Classical trajectories

pointwise asymptotics (of $e(x,x,0)$) as periodic trajectories play in the local asymptotics (of $\int e(x,x,0)\psi(x)\,dx$). There also will be many paths from x to y and back and these paths play important role in the asymptotics of expression (16.1.1).

Fortunately, even if there are plenty of looping points they are rather exceptional on the classical trajectory. Surely, one needs to remember that if we study $e(x,x,0)$ point x is fixed but direction ξ varies and thus trajectory[1)] moves so it passes through x and remains on the energy level 0 (see figures 16.2(a)–16.2(b) below). However for the geometrical simplicity we will sometimes talk about x moving along trajectory. As we study expression (16.1.1) x,y both move.

In fact, situation is more complicated than this due to the uncertainty principle: as μ increases not cyclotrons becomes smaller and tighter but the lines retain their width and become wider in comparison with the cyclotron, and symbolically we can consider figures 16.3(a)–16.3(c) below.

We also generalize Section 6.4 and we consider expression (16.1.1). It follows from Section 6.4 that $\mathsf{I} = \mathcal{I}^{\mathsf{W}} + O(h^{1-d-\kappa})$ as $\mu = O(1)$ with $\mathcal{I}^{\mathsf{W}}$ defined by the same formula but with $e(x,y,\tau)$ replaced by

$$e_y^{\mathsf{W}}(x,y,\tau) \coloneqq (2\pi h)^{-d} \int_{g(y,\xi)\le V(y)+\tau} e^{ih^{-1}\langle x-y,\xi\rangle}\,d\xi. \tag{16.1.9}$$

Then the standard rescaling technique implies the same asymptotics but with the remainder estimate $O(\mu h^{1-d-\kappa})$ provided $1 \le \mu = o(h^{-1})$.

[1)] Even if one calls them trajectories they are only *x-projections* of actual trajectories which live in (x,ξ)-space.

Let $d = 2$. Then *in the general case* it is the best remainder estimate possible while $O(\mu h^{-1})$ is the best possible remainder estimate for

$$\int e(x,x,\tau)\psi(x)\,dx; \tag{16.1.10}$$

recall that this estimate cannot be improved in the case of constant magnetic field F and $g^{jk} = \mathsf{const}$, $V = \mathsf{const}$.

On the other hand, *in the generic case* the remainder estimate for (16.1.10) is $o(\mu^{-1}h^{-1})$ and the principal part is $\int e^{\mathsf{MW}}(x,\tau)\psi(x)\,dx$ if F does not vanish and $\mu \le h^{-1}$.

Meanwhile for $d = 3$ the remainder estimate for I' is $O\big(h^{-2} + \mu h^{-1-\delta}\big)$ and under very mild non-degeneracy assumptions it is $O\big(h^{-2} + \mu h^{-1}\big)$.

Therefore our purpose is to get the sharper remainder estimate for (16.1.1) under the same non-degeneracy assumptions. This is a very daunting task since for (16.1.10) *periodic trajectories* were the main source of trouble and they were broken in the generic case; for (16.1.1) *loops* are also the source of trouble, and in the generic case former periodic trajectories generate a lot of loops.

It is rather easy to derive asymptotics with the sharp remainder estimate $O(\mu^{-1}h^{-1-\kappa})$ as $d = 2$ and $O(h^{-2})$ as $d = 3$ but with the principal part given by very implicit Tauberian formula when I^{T} is defined by (16.1.1) but with $e(x,y,\tau)$ replaced by its Tauberian approximation

$$e^{\mathsf{T}}(x,y,\tau) \coloneqq h^{-1}\int_{-\infty}^{\tau} F_{t\to h^{-1}\tau}\big(\bar{\chi}_T(t)u(x,y,t)\big)\,d\tau; \tag{16.1.11}$$

such remainder estimate is a rather easy corollary of the results of Chapter 13. However deriving of an asymptotics with the sharp remainder estimate and rather explicit principal part is much more difficult.

Plan of the chapter

In Sections 16.2 and 16.6 we consider respectively 2D- and 3D toy-models with the constant g^{jk} and F and linear V and derive representations of solutions and pointwise asymptotics as magnetic field is weak enough. We also derive asymptotics of expression (16.1.10) with $\psi(x)$ replaced by $\psi_\gamma(x)$ which is $\psi(x)$ scaled with a spatial scaling parameter γ; these asymptotics are instrumental in the asymptotics of (16.1.2) and estimates of (16.1.4).

In Sections 16.3 and 16.7 we prove the same asymptotics respectively for the general 2D- and 3D-operators; as magnetic field is strong we use explicit expressions for the toy-model operators as approximations.

In Sections 16.4 and 16.8 we prove important preliminary results and derive sharp asymptotics for expression (16.1.1) but with the Tauberian principal part.

In Sections 16.5 and 16.9 we pass from the Tauberian approximations to Weyl, magnetic Weyl or toy-model approximations.

Finally, in Section 16.10 we consider estimates of (16.1.4) with different approximations, leaving to the reader very similar asymptotics of expression (16.1.2).

The results of this Chapter are not always sharp or very explicit, but could be made either sharp or completely explicit.

16.2 Pointwise Asymptotics: 2D Toy-Model

16.2.1 Toy-Model in 2D: Propagator

Consider the *toy-model operator*

$$A = \bar{A} := h^2 D_1^2 + (hD_2 - \mu x_1)^2 + 2\alpha x_1. \tag{16.2.1}$$

We are interested in the Schwartz kernel $U(x,y,t)$ of the propagator $e^{ih^{-1}tA}$. Making h-Fourier transform with respect to $x_2 \mapsto \xi_2$ and rescaling $x_1 \mapsto \mu x_1$, $t \mapsto \mu t$ we arrive to

$$U(x,y,t) = (2\pi h)^{-1}\mu \int \boldsymbol{u}(x_1,y_1;\eta,t) e^{ih^{-1}(x_2-y_2)\eta}\, d\eta \tag{16.2.2}$$

with $\boldsymbol{u}(x_1,y_1;\eta,t)$ the Schwartz kernel of $e^{i\hbar^{-1}t\boldsymbol{a}}$ with 1D-Harmonic oscillator

$$\boldsymbol{a} = \hbar^2 D_1^2 + (x_1-\eta)^2 + 2\alpha\mu^{-1}x_1 = \underbrace{\hbar^2 D_1^2 + (x_1 - \eta + \alpha\mu^{-1})^2}_{\bar{\boldsymbol{a}}} + \mu^{-1}\alpha \underbrace{(2\eta - \alpha\mu^{-1})}_{\zeta(\eta)}. \tag{16.2.3}$$

Recall that for the Harmonic oscillator $\boldsymbol{b} = D^2 + x^2$ the Schwartz kernel of $e^{it\boldsymbol{b}}$ [2)] is

$$(2\pi)^{-\frac{1}{2}} e^{\frac{i\pi}{4}\sigma(t)} |\sin(2t)|^{-\frac{1}{2}} \exp\Big(-\frac{i}{2}\big(\cot(2t)(x^2+y^2) - 2xy\csc(2t)\big)\Big) \tag{16.2.4}$$

[2)] This is a metaplectic operator, see Section 1.2.5 or H. ter Morsche and P. J. Oonincx [1].

where $\sigma(t)$ is 2π-periodic equal to $1,2,3,4$ at $(0,\frac{\pi}{2}),(\frac{\pi}{2},\pi),(\pi,\frac{3\pi}{2}),(\frac{3\pi}{2},2\pi)$ respectively. Therefore for Harmonic oscillator $\boldsymbol{b}'=\hbar^2D^2+x^2$ the Schwartz kernel of $e^{it\hbar^{-1}\boldsymbol{b}'}$ is

$$(2\pi\hbar)^{-\frac{1}{2}}e^{\frac{i\pi}{4}\sigma(t)}|\sin(2t)|^{-\frac{1}{2}}\times \exp\Big(-\frac{i}{2}\hbar^{-1}\big(\cot(2t)(x^2+y^2)-2xy\csc(2t)\big)\Big); \tag{16.2.5}$$

one can prove it easily by rescaling $x\mapsto x\hbar^{\frac{1}{2}}$.

For operator (16.2.3) the Schwartz kernel of $e^{it\hbar^{-1}\boldsymbol{a}}$ is obtained by plugging $x:=x_1-\eta+\alpha\mu^{-1}$, $y:=y_1-\eta+\alpha\mu^{-1}$ and multiplication by $\exp\big(i\hbar^{-1}\mu^{-1}\alpha\zeta(\eta)\big)$. Therefore, multiplying (16.2.5) by

$$(2\pi\hbar)^{-1}\mu^2\exp\Big(i\hbar^{-1}\big(\mu^{-1}t\alpha(2\eta-\alpha\mu^{-1})+(x_2-y_2)\eta\big)\Big) \tag{16.2.6}$$

and integrating by η we arrive to[3)]

$$U(x,y,t)=(2\pi\hbar)^{-\frac{3}{2}}\mu^2\int e^{\frac{i\pi}{4}\sigma(t)}|\sin(2t)|^{-\frac{1}{2}}e^{i\hbar^{-1}\bar{\varphi}(x,y,\eta,t)}\,d\eta \tag{16.2.7}$$

with

$$\begin{aligned}\bar{\varphi}:=-\frac{1}{2}\cot(2t)\big((x_1-\eta+\alpha\mu^{-1})^2+(y_1-\eta+\alpha\mu^{-1})^2\big)+\\ \csc(2t)(x_1-\eta+\alpha\mu^{-1})(y_1-\eta+\alpha\mu^{-1})+(x_2-y_2)\eta+\\ t\mu^{-1}\alpha(2\eta-\alpha\mu^{-1}).\end{aligned} \tag{16.2.8}$$

We can rewrite (16.2.7)–(16.2.8) after integration by η as

$$U(x,y,t)=i(4\pi\hbar)^{-1}\mu^2\csc(t)\,e^{i\hbar^{-1}\bar{\phi}(x,y,t)} \tag{16.2.9}$$

with

$$\begin{aligned}\bar{\phi}:=-\frac{1}{4}\cot(t)(x_1-y_1)^2\\ +\frac{1}{2}(x_1+y_1+2\alpha\mu^{-1})(x_2-y_2+2t\alpha\mu^{-1})-\frac{1}{4}\cot(t)(x_2-y_2+2t\alpha\mu^{-1})^2-t\alpha^2\mu^{-2};\end{aligned} \tag{16.2.10}$$

[3)] After rescaling $x\mapsto\mu x$, $y\mapsto\mu y$, $t\mapsto\mu t$, $\mu\mapsto 1$, $h\mapsto\hbar=\mu h$; however we treat $U(x,y,t)$ and $e(x,y,\tau)$ as functions, not as densities with respect to y and it leads to the factor μ^2.

here the critical point with respect to η is

$$\eta = \frac{1}{2}(x_1 + y_1 + 2\alpha\mu^{-1}) - \frac{1}{2}\cot(t)(x_2 - y_2 + 2t\alpha\mu^{-1}). \tag{16.2.11}$$

So, we have proven

Proposition 16.2.1. *For the toy-model operator* (16.2.1) [3] *in* $\mathbb{R}^2$ *the Schwartz kernel* $\bar{U}(x,y,t)$ *of* $e^{ih^{-1}t\bar{A}}$ *is given by* (16.2.9)–(16.2.11) *and the Schwartz kernel* $e(x,y,\tau)$ *of the spectral projector is given by*

$$\partial_\tau e(x,y,\tau) = (2\pi\hbar)^{-1} F_{t\to\hbar^{-1}\tau} U(x,y,.) = (2\pi\hbar)^{-1}\int e^{-i\hbar^{-1}t\tau'} U(x,y,t)\,dt \tag{16.2.12}$$

and

$$e(x,y,\tau) = (2\pi\hbar)^{-1}\int^\tau \Big(\int e^{-i\hbar^{-1}t\tau'} U(x,y,t)\,dt\Big)\,d\tau = (2\pi)^{-1}\int (-it)^{-1} e^{-i\hbar^{-1}t\tau} U(x,y,t)\,dt \tag{16.2.13}$$

with the last integral taken in the sense of the principal (vrai) value at 0.

In the case of the stronger magnetic field we will need an alternative representation. Starting from formula for 1D-harmonic oscillator

$$e(x_1,y_1,\tau) = \sum_{m\in\mathbb{Z}^+} \upsilon_m(x_1)\upsilon_m(y_1)\theta\big(\tau - (2m+1)\big) \tag{16.2.14}$$

with Hermite functions υ_m we after the same rescaling and transition to the toy-model as before arrive to

Proposition 16.2.2. *For the toy-model operator* (16.2.1) [3] *in* $\mathbb{R}^2$ *the Schwartz kernel of the spectral projector is defined by*

$$e(x,y,\tau) = (2\pi)^{-1}\mu^2\hbar^{-1}\sum_{m\in\mathbb{Z}^+}\int \upsilon_m\big(\eta + \hbar^{-\frac12}(x_1-y_1)\big)\upsilon_m\big(\eta - \hbar^{-\frac12}(x_1-y_1)\big)\times \theta\Big(\tau - \alpha\mu^{-1}(x_1+y_1) - 2\alpha\mu^{-1}\hbar^{\frac12}\eta - \alpha^2\mu^{-2} - (2m+1)\hbar\Big) e^{i\hbar^{-\frac12}(x_2-y_2)\eta}\,d\eta \tag{16.2.15}$$

and thus

$$\partial_\tau e(x,y,\tau) = (4\pi\alpha)^{-1}\mu^3\hbar^{-\frac{3}{2}}\sum_{m\in\mathbb{Z}^+}\int \upsilon_m\bigl(\eta+\hbar^{-\frac{1}{2}}(x_1-y_1)\bigr)\upsilon_m\bigl(\eta-\hbar^{-\frac{1}{2}}(x_1-y_1)\bigr)\times e^{i\hbar^{-\frac{1}{2}}(x_2-y_2)\eta}\Big|_{\eta=\eta_m} \tag{16.2.16}$$

with

$$\eta_m := (2\alpha)^{-1}\mu\hbar^{-\frac{1}{2}}\bigl(\tau-\alpha\mu^{-1}(x_1+y_1)-\alpha^2\mu^{-2}-(2m+1)\hbar\bigr). \tag{16.2.17}$$

16.2.2 Tauberian Estimate

Consider now toy-model (16.2.1) in $B(0,1)\subset X\subset\mathbb{R}^2$. As dynamics (classical or microlocal) starts in $B(0,\epsilon)$ it is confined to $B(0,1)$ for $|t|\le T^*=\epsilon\mu$ and thus in this time interval we can use formulae of the previous subsection (modulo negligible term).

Preparatory Estimate

Let us rescale[3)] and set $x=y=0$ in (16.2.9)–(16.2.11):

$$U(0,0,t)\equiv i(4\pi\hbar)^{-1}\mu^2\csc(t)\,e^{i\hbar^{-1}\bar\phi(t)} \tag{16.2.18}$$

with

$$\bar\phi(t) := -t^2\alpha^2\mu^{-2}\cot(t)-\alpha^2\mu^{-2}t; \tag{16.2.19}$$

$$\eta = -t\alpha\mu^{-1}\cot(t)+\alpha\mu^{-1}. \tag{16.2.20}$$

We are interested in

$$F_{t\to\hbar^{-1}\tau}\bar\chi_T(t)U(0,0,t) \tag{16.2.21}$$

with $T=T^*$. Plugging (16.2.18) we arrive to

$$F_{t\to\hbar^{-1}\tau}\bar\chi_T(t)U(0,0,t)\equiv i(4\pi\hbar)^{-1}\mu^2\int \bar\chi_T(t)\csc(t)e^{i\hbar^{-1}(\bar\phi(t)-t\tau)}\,dt = \tag{16.2.22}$$

$$(4\pi\hbar)^{-1}\mu^2\int \bar\chi_T(t)\csc(t)\exp\Bigl(i\hbar^{-1}\bigl(-t^2\alpha^2\mu^{-2}\cot(t)-t\mu^{-2}\alpha^2-t\tau\bigr)\Bigr)\,dt.$$

Applying stationary phase to

$$\varphi(t) \coloneqq -t^2\mu^{-2}\alpha^2\cot(t) - t\mu^{-2}\alpha^2 - t\tau \tag{16.2.23}$$

we get

$$\mu^{-2}\alpha^2(t^2 - t\sin(2t)) = (\tau + \mu^{-2}\alpha^2)\sin^2(t). \tag{16.2.24}$$

Remark 16.2.3. Consider corresponding classical trajectory:

$$x_1 = \rho\cos(2s) + \eta - \alpha\mu^{-1}, \qquad \xi_1 = \rho\sin(2s) + \alpha\mu^{-1}s \tag{16.2.25}$$

and there is a self-intersection iff

$$\begin{cases} \cos(2s_1) = \cos(2s_2), \\ -\rho\sin(2s_1) + 2\alpha\mu^{-1}s_1 = -\rho\sin(2s_2) + 2\alpha\mu^{-1}s_2; \end{cases} \tag{16.2.26}$$

then $s_2 + s_1 = \pi k$ with $k \in \mathbb{Z}$ (because we cannot fulfill the second equation as $s_1 \neq s_2$ and $s_2 - s_1 = \pi k$); then $2s_1 = \pi k - t$, $2s_2 = \pi k + t$ and the second equation is $\rho\sin(\pi k - t) = -\alpha\mu^{-1}t$ or, equivalently, $\rho = -\alpha\mu^{-1}t\csc(\pi k - t)$.

Further, we need to satisfy $\rho\cos(\pi k - t) + \eta - \alpha\mu^{-1} = 0$ (as $x_1 = 0$ is a level of intersection) and $(\eta - \alpha\mu^{-1})^2 + 2\alpha\mu^{-1}(\eta - \alpha\mu^{-1}) + \alpha^2\mu^{-2} = \tau$ (to be on the energy level τ) and then $\rho^2\cos^2 t - 2\alpha\mu^{-1}\rho\cos(\pi k - t) = \tau - \alpha^2\mu^{-2}$.

Plugging $\rho = -\alpha\mu^{-1}t\csc(\pi k - t)$ we conclude that this equation becomes (16.2.24). We can find η to satisfy condition $\rho\cos(2s_1) + \eta - \alpha\mu^{-1} = 0$ (as $(0, .)$ is a point of intersection, or equivalently, $\eta = -\alpha\mu^{-1}t\cot(t) + \alpha\mu^{-1}$.

We need to justify the stationary phase method. Note first that the spacing between successive stationary points is $\sim \pi$. Therefore

$$t_k = -t_{-k}, \quad t_k \sim \pi k, \quad \sin(t_k) \sim \alpha\mu^{-1}\tau^{-\frac{1}{2}}\pi k \tag{16.2.27}$$

and

(16.2.28) The number of stationary points is $\sim 2\pi^{-1}|\alpha|^{-1}\mu\tau^{-\frac{1}{2}}$.

Recall that

$$\varphi'(t) = \alpha^2\mu^{-2}\big(t^2\csc^2(t) - 2t\cot(t) + 1\big) - \tau \tag{16.2.29}$$

and

$$\varphi''(t) = -2\alpha^2\mu^{-2}\csc(t)\Big(t^2\csc^2(t)\cos(t) - 2t\csc(t) + \cos(t)\Big); \tag{16.2.30}$$

therefore

(16.2.31) Let $k \neq 0$; then $\varphi''(t_k) \asymp -2\tau \cot(t_k)$ as $|\cos(t_k)| \geq C_0\varepsilon$ and moreover $\varphi''(t_k) \sim -2\tau \cot(t_k)$ as $|\cos(t_k)| \gg \varepsilon$.

Therefore as $|\sin(t_k)| \geq \epsilon$, $|\cos(t_k)| \geq \epsilon$ stationary points are non-degenerate and we can use the stationary phase method.

In the *near-pole zone* $\{|\sin(t)| \leq \epsilon\}$ we need to remember about singularity as $\sin(t) = 0$; so we need to introduce a scale $\ell \asymp |\sin(t)|$ and the stationary phase method is expected to work only as $|\varphi''|\ell^2 \geq C_0\hbar$ or equivalently $|\sin(t_k)| \geq C_0\hbar$ or, finally

$$|k| \geq \bar{k} := C_0\varepsilon^{-1}\hbar \tag{16.2.32}$$

with

$$\varepsilon := \alpha\mu^{-1}(\tau + \alpha^2\mu^{-2})^{-\frac{1}{2}}. \tag{16.2.33}$$

Summarizing, we arrive to

(16.2.34) Condition (16.2.32) is fulfilled for all $k \neq 0$ as $\varepsilon \geq C_0\hbar$; otherwise stationary phase method fails for $|k| \leq \bar{k}$. In particular, $\bar{k} = C_0\mu^2 h$ as $|\alpha| \asymp 1$, $\tau \asymp 1$ and condition (16.2.32) is fulfilled for all $k \neq 0$ as $\mu \leq \epsilon_0 h^{-\frac{1}{2}}$.

Meanwhile, there is no singularity in the *near-equator zone* $\{|\cos(t)| \leq \epsilon\}$ but there is a degeneration as $\cos(t) = 0$ and therefore we need to introduce a a scale $\ell \asymp |\cos(t)|$ and the stationary phase method is expected to work only as $|\varphi''|\ell^2 \geq C_0\hbar$ or equivalently $|\cos(t)| \geq C_0 \max(\varepsilon, \hbar^{\frac{1}{3}})$.

Definition 16.2.4. (i) $\{|\sin(t)| \leq \max(\epsilon_0\varepsilon, C_0\hbar)\}$ is a *near-pole singular zone*.

(ii) $\{|\cos(t)| \leq C_0 \max(\varepsilon, \hbar^{\frac{1}{3}})\}$ is a *near-equator singular zone*.

(iii) $\{|\sin(t)| \leq \max(\epsilon_0\varepsilon, C_0\hbar), |\cos(t)| \geq C_0 \max(\varepsilon, \hbar^{\frac{1}{3}})\}$ is a *regular zone*.

We apply the stationary phase method in the regular zone and justify it and we estimate contributions of the singular zones.

Note that the simple integration by parts brings factors $\hbar/(\varphi' \sin(t))$ and $\hbar\varphi''/(\varphi')^2$ and contribution of zones where these expressions are less than h^δ are negligible. However at this moment we want just to estimate.

Remark 16.2.5. As long as $\mu h \lesssim 1$ we will assume that $\tau \asymp 1$; while we can always achieve $\alpha \asymp 1$ by rescaling $x \mapsto |\alpha| x$, $\mu \mapsto \mu|\alpha|^{-1}$, $\hbar \mapsto \hbar$ we will need many intermediate results and it is simpler to deal with the general case $|\alpha| \le 1$ from the very beginning. Without any loss of the generality one can assume that

$$0 < \alpha \le 1 \qquad (\implies \varepsilon \le \mu^{-1}). \tag{16.2.35}$$

First, consider zone

$$\bigl\{t : \ |\sin t| \le (1-\epsilon_0)\varepsilon|t|, \ |t| \ge \epsilon_0\bigr\}. \tag{16.2.36}$$

Then $|\varphi'| \asymp \varepsilon^2 t^2 |\sin(t)|^{-2}$ and $|\varphi''| \lesssim \varepsilon^2 t^2 |\sin(t)|^{-3}$ and both factors $|\hbar/\varphi' \sin(t)|$ and $|\hbar\varphi''/(\varphi')^2|$ do not exceed $\hbar|\sin(t)|/\varepsilon^2 t^2 \le \hbar/\varepsilon|t|$ and are less than 1 as $\hbar|\sin(t)| \le \varepsilon^2 t^2$. This always holds in zone (16.2.36) if $\hbar \le \varepsilon$.

Then multiple integration by parts brings factor $C(\hbar|\sin(t)|/\varepsilon^2 t^2)^l$ with an arbitrarily large exponent l and contribution of k-th "tick"[4] to (16.2.22) does not exceed

$$C\mu^2\hbar^{-1}(\hbar|\sin(t)|/\varepsilon^2 t^2)^l |\sin(t)|^{-1}.$$

Therefore summation with respect to t along zone (16.2.36) intersected with k-th tick returns $C\mu h^{-1}(\hbar/\varepsilon|k|)^l$ as $|k| \ge \bar{k}$ with $\bar{k}$ defined by (16.2.32); then summation by k results in $C\mu h^{-1}(\hbar/\varepsilon)^l$ as $\hbar \le \varepsilon$ ($1 \le |k|$) and $C\mu h^{-1}\bar{k} \asymp C\mu^2\varepsilon^{-1}$ as $\hbar \ge \varepsilon$ ($\bar{k} \le |k|$).

In the latter case as $1 \le |k| \le \bar{k}$ we integrate by parts only as $|\sin(t)| \le \hbar^{-1}\varepsilon^2 t^2$ and contribution of k-th tick to (16.2.22) does not exceed $C\mu h^{-1}\log(\bar{k}/|k|)$ where logarithmic factor is an integral of $|\csc(t)|$ along k-th tick intersected with $\{t\colon \hbar^{-1}\varepsilon^2 t^2 \le |\sin(t)| \le \varepsilon|t|\}$. Then summation with respect to $1 \le |k| \le \bar{k}$ returns $O(\mu h^{-1}\bar{k})$ again.

Therefore we arrive to

(16.2.37) Contribution of zone (16.2.36) to expression (16.2.22) does not exceed $C\mu h^{-1}(\hbar/\varepsilon)^l$ as $\hbar \le \varepsilon$ and $C\mu^2\varepsilon^{-1}$ as $\hbar \ge \varepsilon$.

In the same time in the zone

$$\bigl\{t : \ |\sin(t)| \ge (1+\epsilon_0)\varepsilon|t|, \ |t| \ge \epsilon_0\bigr\} \tag{16.2.38}$$

[4] I.e. interval $\{t\colon |t - t_k| \le \pi - \epsilon_0\}$.

$|\varphi'| \asymp 1$ and $|\varphi''| \lesssim |\sin(t)|^{-1}$ and both factors do not exceed $\hbar/|\sin(t)|$. Again summation with respect to t along k-th tick intersected with zone (16.2.38) returns $C\mu h^{-1}(\hbar/\varepsilon|k|)^{\prime}$ as $|k| \ge \bar{k}$ and summation by k results in $C\mu h^{-1}(\hbar/\varepsilon)^{\prime}$ as $\hbar \le \varepsilon$ ($1 \le |k|$) and $\mu^2\varepsilon^{-1}$ as $\hbar \ge \varepsilon$ ($\bar{k} \le |k|$).

In the latter case as $|k| \le \bar{k}$ we do not integrate by parts and contribution of k-th tick to (16.2.22) does not exceed $C\mu h^{-1}$; summation with respect to $1 \le |k| \le \bar{k}$ returns $O(\mu^2\varepsilon^{-1})$. Therefore

(16.2.39) Contribution of zone (16.2.38) to expression (16.2.22) does not exceed $C\mu h^{-1}(\hbar/\varepsilon)^{\prime}$ as $\hbar \le \varepsilon$ and $C\mu^2\varepsilon^{-1}$ as $\hbar \ge \varepsilon$.

Note that as $\hbar \le \epsilon\varepsilon$ these considered zones (16.2.36) and (16.2.38) cover completely the singular near-pole zone. On the other hand, as $\hbar \ge \epsilon\varepsilon$ we did not integrate by parts in the second zone as $|k| \le \bar{k}$ and therefore it can be extended to $\{t\colon |\sin(t)| \ge \epsilon_0\varepsilon|t|\}$ and we arrive to

(16.2.40) Contribution of singular near-pole zone to expression (16.2.22) does not exceed $C\mu h^{-1}(\hbar/\varepsilon)^{\prime}$ as $\hbar \le \varepsilon$ and $C\mu^2\varepsilon^{-1}$ as $\hbar \ge \varepsilon$.

Claims (16.2.37), (16.2.39), (16.2.40) imply that as $|\cos(t_k)| \ge \epsilon$ we can apply the stationary phase method.

Then contribution of k-th stationary point to (16.2.22) does not exceed $C\mu h^{-1}(\hbar/\varepsilon|k|)^{\frac{1}{2}}$ and summation with respect to $k\colon \max(1,\bar{k}) \le |k| \le C_0\varepsilon^{-1}$ returns $C\mu h^{-1}(\hbar/\varepsilon|k|)^{\frac{1}{2}} \times |k|$ calculated as $|k| = \varepsilon^{-1}$ i.e. $C\mu^{\frac{3}{2}}\varepsilon^{-1}h^{-\frac{1}{2}}$ which is larger than what we got in (16.2.37)–(16.2.40) thus resulting in

(16.2.41) Contribution of zone $\{t\colon |\cos(t)| \ge \epsilon_0,\ |t| \ge \epsilon_0\}$ to expression (16.2.22) does not exceed $C\mu^{\frac{3}{2}}\varepsilon^{-1}h^{-\frac{1}{2}}$ as $1 \le \mu \le h^{-1}$.

Consider now the part of the near-equator zone $\{|\cos(t)| \le \epsilon_0,\ |t| \ge \epsilon_0\}$ not covered by (16.2.37), (16.2.39); there $(1-\epsilon)t^* \le |t| \le (1+\epsilon)t^*$ where

(16.2.42) $t^* = (k^* + \frac{1}{2})\pi$ is the closest to ε^{-1} number of the form $(k+\frac{1}{2})\pi$.

Plugging $t = t^* - s$ with $|s| \le \epsilon t^*$, $|\sin(s)| \le \epsilon$ we find that

$$\tau^{-1}\varphi'(t) = -\varepsilon^2 s(2t^* - s) + \sin^2(s) + O(\varepsilon^2) + O(\varepsilon|\sin(s)|). \tag{16.2.43}$$

Consider first zone

$$\bigl\{s\colon C_0 \le |s| \le \epsilon\varepsilon^{-1},\ |\sin(s)|^2 \le 2(1-\epsilon_1)\varepsilon|s|\bigr\}$$

where $|\varphi'| \gtrsim \varepsilon|s|$. Integrating by parts we acquire factor $(\hbar/\ell|\varphi'|) \asymp (\hbar/(\varepsilon|s|)^{\frac{3}{2}})$ because $\ell = (\varepsilon|s|)^{\frac{1}{2}}$ is the scale; thus we integrate multiple times by parts as $|s| \gtrsim \varepsilon^{-1}\hbar^{2/3}$; so contribution of k-th tick to (16.2.22) does not exceed

$$C\mu\varepsilon^{\frac{1}{2}}h^{-1}(\hbar^{2/3}/\varepsilon|k-k^*|)^{\frac{3}{2}l}|k-k^*|^{\frac{1}{2}}.$$

Then, as $\varepsilon \ge \hbar^{\frac{2}{3}}$ summation with respect to $k : |k-k^*| \ge C_0$ returns $C\mu\varepsilon^{\frac{1}{2}}h^{-1}(\hbar^{\frac{2}{3}}/\varepsilon)^l$. On the other hand, as $\varepsilon \le \hbar^{\frac{2}{3}}$ summation with respect to $k : |k-k^*| \ge \varepsilon^{-1}\hbar^{\frac{2}{3}}$ returns $C\mu\varepsilon^{\frac{1}{2}}h^{-1} \times \hbar^{\frac{2}{3}}\varepsilon^{-1} = C\mu^{\frac{5}{3}}\varepsilon^{-\frac{1}{2}}h^{-\frac{1}{3}}$.

Further, the contribution of the zone

$$\{s\colon C_0 \le |s| \le \epsilon\varepsilon^{-1},\ |\sin(s)|^2 \ge 2(1+\epsilon_1)\varepsilon|s|\}$$

is estimated in the same way. Finally, as $s < 0$ both terms in the right-hand expression of (16.2.43) have the same sign and we can extend zones in question to cover $\{s\colon \sin^2(s) \asymp \varepsilon|s|\}$ as well and we arrive to

(16.2.44) Contribution to (16.2.22) of the zone $\{s\colon |\sin(s)| \le \epsilon,\ |s| \le \epsilon\varepsilon^{-1}\}$ without subzone

$$\{s\colon s \ge C_0\max(1, \varepsilon^{-1}\hbar^{\frac{2}{3}}),\ (2-\epsilon)\varepsilon s \le \sin^2(s) \le (2+\epsilon)\varepsilon s\} \tag{16.2.45}$$

and the near-equator singular zone

$$\{s\colon |s| \le C_0\max(1, \varepsilon^{-1}\hbar^{\frac{2}{3}}),\ |\sin(s)| \le C_0\max(\varepsilon, \hbar^{\frac{1}{3}})\} \tag{16.2.46}$$

does not exceed $C\mu\varepsilon^{\frac{1}{2}}h^{-1}(\hbar^{\frac{2}{3}}/\varepsilon)^l$ as $\varepsilon \ge \hbar^{\frac{2}{3}}$ and $C\mu^{\frac{5}{3}}\varepsilon^{-\frac{1}{2}}h^{-\frac{1}{3}}$ as $\varepsilon \le \hbar^{\frac{2}{3}}$.

Obviously,

(16.2.47) Contribution to expression (16.2.22) of zone (16.2.46) does not exceed $C\mu h^{-1} \times \max(1, \varepsilon^{-1}\hbar^{\frac{2}{3}}) \times \max(\varepsilon, \hbar^{\frac{1}{3}}) = C\mu h^{-1} \times \max(\varepsilon, \varepsilon^{-1}\hbar, \hbar^{\frac{1}{3}})$.

Finally, in zone (16.2.45) we can use the stationary phase method. Recall that $\varphi'' \asymp \sin(s) \asymp (\varepsilon|k-k^*|)^{\frac{1}{2}}$; therefore the contribution of k-th tick does not exceed $C\mu h^{-1}(\hbar/|\sin(s)|)^{\frac{1}{2}} \asymp C\mu h^{-1}(\hbar/(\varepsilon|k-k^*|)^{\frac{1}{2}})^{\frac{1}{2}}$ and summation with respect to $k :\ |k-k^*| \le \varepsilon^{-1}$ returns $C\mu^{\frac{3}{2}}\varepsilon^{-1}h^{-\frac{1}{2}}$.

Combining all these estimates we arrive to estimate (16.2.49) below; adding

$$|F_{t\to\hbar^{-1}\tau}(\bar\chi\bar{\bar\tau}(t)U(0,0,t))| \le C\mu h^{-1} \tag{16.2.48}$$

which is the standard semiclassical estimate $O(\hbar^{-1})$ with an extra factor μ^2 due to rescaling we arrive to estimate (16.2.50):

Proposition 16.2.6. *For the toy-model operator* (16.2.1) *with* $\tau \asymp 1$, $\varepsilon \le \mu^{-1}$, $\mu \le h^{-1}$ *in* $\mathbb{R}^2$

$$|F_{t\to\hbar^{-1}\tau}\big((\bar\chi_T(t) - \bar\chi_{\bar T})U(0,0,t)\big)| \le C\mu^{\frac{3}{2}}\varepsilon^{-1}h^{-\frac{1}{2}} \tag{16.2.49}$$

as $\bar T = \epsilon_0 \le T \le \infty$ *and*

$$|F_{t\to\hbar^{-1}\tau}\big(\bar\chi_T(t)U(0,0,t)\big)| \le C\mu h^{-1} + C\mu^{\frac{3}{2}}\varepsilon^{-1}h^{-\frac{1}{2}}. \tag{16.2.50}$$

Tauberian Estimate

Remark 16.2.7. (i) Recall that for the toy-model operator (16.2.1) in domain X, $B(0,\ell) \subset X \subset \mathbb{R}^2$ with $\ell \ge C_0\mu^{-1}$, fundamental solution U coincides modulo negligible with one in $\mathbb{R}^2$ as $T \le T^* = \epsilon_0\mu\varepsilon^{-1}\ell$.

(ii) We have $T^* = \epsilon_0\mu\varepsilon^{-1}\ell$ rather than $T^* = \epsilon_0\varepsilon^{-1}\ell$ as in Chapter 13 only because we rescaled $t \mapsto \mu t$; without this rescaling we would have $F_{t\to h^{-1}\tau}$ rather than $F_{t\to\hbar^{-1}\tau}$ and the right-hand expressions (16.2.49), (16.2.50) should be multiplied by μ^{-1}.

Due to above we arrive to the Statement (i) of Proposition 16.2.8 below; then the standard Tauberian arguments yield that the Tauberian error does not exceed the right-hand expression of (16.2.50) divided by T^* and we derive Statement (ii):

Proposition 16.2.8. *For a self-adjoint operator in* $\mathscr{L}^2(X)$ *in the domain* X, $B(0,\ell) \subset X \subset \mathbb{R}^2$, $\ell \ge C_0\mu^{-1}$, *coinciding in* $B(0,\ell)$ *with the toy-model operator* (16.2.1) *with* $\tau \asymp 1$, $\varepsilon \le \mu^{-1}$, $\mu \le h^{-1}$,

(i) Estimates (16.2.49), (16.2.50) *hold as* $T \le T^* = \epsilon_0\mu\varepsilon^{-1}\ell$.

(ii) Tauberian estimate

$$|e(0,0,\tau) - e^{\mathsf{T}}(0,0,\tau)| \le C\big(\mu h^{-1} + \mu^{\frac{3}{2}}\varepsilon^{-1}h^{-\frac{1}{2}}\big)\mu^{-1}\varepsilon\ell^{-1} = C\big(\varepsilon h^{-1} + \mu^{\frac{1}{2}}h^{-\frac{1}{2}}\big)\ell^{-1} \tag{16.2.51}$$

holds with the Tauberian expression

$$e^{\mathsf{T}}(x,y,\tau) \coloneqq \hbar^{-1}\int_{-\infty}^{\tau}\Big(F_{t\to\hbar^{-1}\tau}\bar\chi_T(t)U(x,y,t)\Big)\,d\tau \tag{16.2.52}$$

with any $T \in (C_0\varepsilon^{-1}, \epsilon_0\mu\varepsilon^{-1}\ell)$.

Micro-Averaging

Note that the second terms in the right-hand expressions of (16.2.50), (16.2.51) are due to the loops and according to Chapter 13 these expressions would not appear if instead of $\Gamma_x e(.,.,\tau)$ we looked at $\Gamma\big(e(.,.,\tau)\psi\big)$ with the uniformly smooth function ψ. Now we want to consider $\Gamma\big(e(.,.,\tau)\psi_\gamma\big)$ where ψ_γ is γ-admissible function and $\gamma \le \ell$.

So, let us consider $\Gamma\big(e(.,.,\tau)\psi_\gamma\big)$. First of all note that all the above estimates will acquire factor γ^2 due to the integration, but there is more: integrating by parts with respect to x_1 and remembering that due to rescaling $x \mapsto \mu x$ we also rescale $\gamma \mapsto \mu\gamma$ we conclude that the contribution of k-th tick acquires factor $(\hbar/\varepsilon|k|\mu\gamma)^l = (h/\varepsilon\gamma|k|)^l$ as

$$|k| \ge \hat{k}(\gamma) \coloneqq h/\varepsilon\gamma. \tag{16.2.53}$$

This factor "forces" $|k| = \max(\hat{k}(\gamma), 1)$ in the estimate of the Fourier transform

$$F_{t\to\hbar^{-1}}\Gamma(U\psi_\gamma) \tag{16.2.54}$$

and there are four cases:

(a) $\gamma \ge h/\varepsilon$; then $\hat{k}(\gamma) = 1$ and expression (16.2.54) does not exceed $C\mu h^{-1}\min\big((\hbar/\varepsilon)^{\frac12}, 1\big) \times (h/\varepsilon\gamma)^l\gamma^2$.

(b) $h/\varepsilon \ge \gamma \ge \mu^{-1}$. Then $1 \le \hat{k}(\gamma) \le \bar{k} = \hbar/\varepsilon$ and (16.2.54) does not exceed $C\mu h^{-1}\hat{k}(\gamma)\gamma^2 = C\mu\varepsilon^{-1}\gamma$.

(c) $\min(h/\varepsilon, \mu^{-1}) \ge \gamma \ge h$. Then $\bar{k} \le \hat{k}(\gamma) \le \varepsilon^{-1}$ and (16.2.54) does not exceed $C\mu h^{-1}(\hbar/\varepsilon)^{\frac12}|\hat{k}(\gamma)|^{\frac12}\gamma^2 = C\mu^{\frac32}\varepsilon^{-1}\gamma^{\frac32}$.

(d) $\gamma \le h$. Then $\hat{k}(\gamma) \ge \varepsilon^{-1}$ and micro-averaging brings no improvement and estimates (16.2.55)–(16.2.58) below are due to estimates (16.2.49)–(16.2.51) without micro-averaging.

Therefore we arrive to

Proposition 16.2.9. *For the toy-model operator* (16.2.1) *with* $\tau \asymp 1$, $\varepsilon \le \mu^{-1}$, $\mu \le h^{-1}$ *in* $\mathbb{R}^2$ *estimates*

$$\gamma^{-2}|F_{t\to\hbar^{-1}\tau}\big(\big(\bar{\chi}_\tau(t) - \bar{\chi}_{\bar{\tau}}\big)\Gamma(U\psi_\gamma)\big)| \le C\mu\varepsilon^{-1}R^{\mathsf{T}}(\gamma) \tag{16.2.55}$$

and

$$\gamma^{-2}|F_{t\to\hbar^{-1}\tau}\bigl(\bar\chi_T(t)\Gamma(U\psi_\gamma)\bigr)| \le C\mu h^{-1} + C\mu\varepsilon^{-1}R^{\mathsf T}(\gamma) \tag{16.2.56}$$

hold as $\bar T = \epsilon_0 \le T \le \infty$ *where*

$$R^{\mathsf T}(\gamma) = \begin{cases} \mu^{\frac12}h^{-\frac12} & \text{as } \gamma \le h,\\ \mu^{\frac12}\gamma^{-\frac12} & \text{as } \min(h/\varepsilon, \mu^{-1}) \ge \gamma \ge h,\\ \gamma^{-1} & \text{as } h\varepsilon^{-1} \ge \gamma \ge \mu^{-1},\\ \varepsilon h^{-1}\min\bigl((\hbar/\varepsilon)^{\frac12},1\bigr)\times (h/\varepsilon\gamma)^{l} & \text{as } \gamma \ge h\varepsilon^{-1}. \end{cases} \tag{16.2.57}$$

Then the standard Tauberian arguments imply

Corollary 16.2.10. *In the framework of Proposition 16.2.8*

$$\gamma^{-2}|\Gamma\Bigl(\bigl(e(.,.,\tau) - e^{\mathsf T}(.,.,\tau)\bigr)\psi_\gamma\Bigr)| \le C\bigl(\varepsilon h^{-1} + R^{\mathsf T}(\gamma)\bigr)\ell^{-1}. \tag{16.2.58}$$

16.2.3 Calculations

Correction Term

We want however more explicit expression for (16.2.52) which we rewrite as

$$\hbar^{-1}\int_{-\infty}^{\tau}\Bigl(F_{t\to\hbar^{-1}\tau}\bar\chi_{\bar T}(t)U(x,x,t)\Bigr)\,d\tau + \int_{-\infty}^{\tau}\Bigl(F_{t\to\hbar^{-1}\tau}(-it)^{-1}\bigl(\bar\chi_T(t) - \bar\chi_{\bar T}(t)\bigr)U(x,x,t)\Bigr)\,d\tau \tag{16.2.59}$$

and as $\mu \le h^{\delta-1}$ the first term modulo negligible is a Weyl expression $h^{-2}\mathcal{N}_x^{\mathsf W} := (4\pi)^{-1}h^{-2}(\tau - V(x))$ (provided $V(x) \le \tau - \epsilon$) and the second expression is a *correction term* $h^{-2}\mathcal{N}_{x,\mathsf{corr}}$ and our purpose is either to estimate or calculate it.

Let us apply the stationary phase method whenever in makes sense; otherwise we just temporarily skip the corresponding zone. Then the main part of the answer is

$$\sum_{k\in\mathfrak{Z}}\frac{1}{4\pi\sqrt{\pi}}\mu^2\hbar^{-\frac12}(t_k\sin(t_k))^{-1}|\varphi''(t_k)|^{-\frac12}\times \exp\Bigl(\frac{i\pi}{4}\operatorname{sgn}\varphi''(t_k) + i\hbar^{-1}\varphi(t_k)\Bigr) \tag{16.2.60}$$

with

$$\varphi''(t_k) \sim 2\tau \cot(t_k) \qquad \text{as } |\cos(t_k)| \ge C\varepsilon^{\frac12} \tag{16.2.61}$$

and

$$\mathfrak{Z} := \{k \ne 0 : \ |\sin(t_k)| \ge \hbar,\ |\cos(t_k)| \ge C \max(\varepsilon^{\frac12}, \hbar^{\frac13})\} \tag{16.2.62}$$

where dimmed restriction is just temporary.

Estimating Correction Term

First, let us estimate the correction term. As $|\sin(t_k)| \ge \hbar$, $|\cos(t_k)| \ge \epsilon$ we have $t_k \asymp k$, $\sin(t_k) \asymp \varepsilon k$, $\varphi'' \asymp \varepsilon^{-1}k^{-1}$ and the contribution of k-th tick does not exceed $C\mu^{\frac32}\varepsilon^{-\frac12}h^{-\frac12}|k|^{-\frac32}$.

In comparison with the previous subsection we acquired factor $|k|^{-1}$ due to the factor $(-it)^{-1}$ in (16.2.59) and it is a game-changer: summation with respect to k returns $C\mu^{\frac32}\varepsilon^{-\frac12}h^{-\frac12}|k|^{-\frac12}$ with the *smallest* possible k: as $\hbar \le \varepsilon$ we sum from $|k| = 1$ and get $C\mu^{\frac32}\varepsilon^{-\frac12}h^{-\frac12}$; as $\hbar \ge \varepsilon$ we sum from $|k| = \bar{k} := \hbar\varepsilon^{-1}$ and get $C\mu h^{-1}$ which is the trivial estimate.

Further, contribution of k-th tick to the error is $C\mu h^{-1} \times (\hbar/\varepsilon|k|)^{r+\frac12}|k|^{-1}$ if we use r-term stationary phase approximation. Then summation with respect to $k : |k| \ge 1$ returns $C\mu h^{-1}(\hbar/\varepsilon)^{r+\frac12}$ as $\hbar \le \varepsilon$.

On the other hand, as $\hbar \ge \varepsilon$ summation with respect to $k : |k| \ge \bar{k}$ returns $C\mu h^{-1}$ and thus this approximation does not make any sense. Therefore

(16.2.63) We assume until the end of this subsection that $\hbar \le \varepsilon$.

This assumption takes care of many problems: it eliminates the near-pole singular zone and away from the stationary points we can many times integrate by parts; one can see easily that contribution of zones (16.2.37) and (16.2.39) does not exceed $C\mu h^{-1}(\hbar/\varepsilon)^l$ with arbitrarily large l.

Therefore we need an additional analysis only in the the near-equator zone $\{t : \ |\cos(t)| \le \epsilon,\ |t - t^*| \le \epsilon\varepsilon^{-1}\}$. It is easy to estimate its contribution to the correction term: in comparison with the previous subsection we gain factor ε (from factor $(-it)^{-1}$) and we get $C\mu^2\varepsilon^{-\frac12}h^{-\frac12} \times \varepsilon = C\mu^2\varepsilon^{\frac12}h^{-\frac12}$ which is less than the contribution of the near-polar zone. Thus we arrive to

Proposition 16.2.11. *For a toy-model operator* (16.2.1) *with* $\tau \asymp 1$, $\varepsilon \le \mu^{-1}$, $\hbar \le \varepsilon$

(i) Correction term $h^{-2}\mathcal{N}_{x,\mathsf{corr}}$ *does not exceed* $C\mu^{\frac{3}{2}}\varepsilon^{-\frac{1}{2}}h^{-\frac{1}{2}}$ *and therefore in the framework of Proposition 16.2.8*

$$\mathsf{R}_x^{\mathsf{W}} := |e^{\mathsf{T}}(x,x,0) - h^{-2}\mathcal{N}_x^{\mathsf{W}}| \le C\mu^{-1}h^{-1} + C\mu^{\frac{3}{2}}\varepsilon^{-\frac{1}{2}}h^{-\frac{1}{2}}. \tag{16.2.64}$$

(ii) In particular, $\mathsf{R}_x^{\mathsf{W}} \le C\mu^{-1}h^{-1}$ *as* $\varepsilon \ge \mu^5 h$.

Calculating Correction Term

Situation in the near-equator zone becomes more delicate if we want to estimate an error in r-term stationary phase approximation. Then the contribution of k-th tick does not exceed

$$C\mu\varepsilon h^{-1}(\hbar/|\cos(t_k)|^3)^{r+\frac{1}{2}} \asymp C\mu\varepsilon h^{-1}\bigl(\hbar/(\varepsilon|k-k^*|)^{\frac{3}{2}}\bigr)^{r+\frac{1}{2}}$$

which as $r \ge 1$ sums to $C\mu\varepsilon h^{-1}\bigl(\hbar/(\varepsilon|k-k^*|)^{\frac{3}{2}}\bigr)^{r+\frac{1}{2}}|k-k^*|$ calculated at the least possible value of $|k-k^*|$; so we get $C\mu\varepsilon h^{-1}\bigl(\hbar/\varepsilon^{\frac{3}{2}}\bigr)^{r+\frac{1}{2}}$ as we sum for $|k-k^*| \ge 1$, i.e. as $\varepsilon \ge \hbar^{\frac{2}{3}}$.

On the other hand, we get $C\mu\varepsilon h^{-1} \times \hbar^{\frac{2}{3}}\varepsilon^{-1} = C\mu^{\frac{5}{3}}h^{-\frac{1}{3}}$ as we sum for $|k-k^*| \ge \hbar^{\frac{2}{3}}\varepsilon^{-1}$, i.e. as $\varepsilon \le \hbar^{\frac{2}{3}}$. This takes care of zone (16.2.45); analysis of zones covered by (16.2.44) is easy and its contribution to the error is lesser.

Finally, the contribution to the error of zone (16.2.46) does not exceed $C\mu\varepsilon h^{-1}\max(\varepsilon, \varepsilon^{-1}\hbar, \hbar^{\frac{1}{3}})$ where in comparison with the analysis of the previous subsection we acquired factor ε.

Therefore, contribution of the near-equator zone to the error does not exceed

$$C\mu^{-1}h^{-1} + \begin{cases} C\mu\varepsilon h^{-1}\bigl(\hbar/\varepsilon^{\frac{3}{2}}\bigr)^{r+\frac{1}{2}} + C\mu^{\frac{4}{3}}\varepsilon h^{-\frac{2}{3}} & \text{as } \varepsilon \ge \hbar^{\frac{2}{3}}, \\ C\mu^{\frac{5}{3}}h^{-\frac{1}{3}} & \text{as } \varepsilon \le \hbar^{\frac{2}{3}} \end{cases} \tag{16.2.65}$$

and we arrive to

Proposition 16.2.12. *For a toy-model operator* (16.2.1) *with* $\tau \asymp 1$, $\varepsilon \le \mu^{-1}$, $\hbar \le \varepsilon$ *correction term* $h^{-2}\mathcal{N}_{x,\mathsf{corr}}$ *is delivered with* r*-term stationary phase approximation* $h^{-2}\mathcal{N}_{x,\mathsf{corr}(r)}$ *with an error not exceeding*

$$C\mu h^{-1}\bigl(\hbar/\varepsilon\bigr)^{r+\frac{1}{2}} + C\mu\varepsilon h^{-1}\bigl(\hbar/\varepsilon^{\frac{3}{2}}\bigr)^{r+\frac{1}{2}} + C\mu^{\frac{4}{3}}\varepsilon h^{-\frac{2}{3}} + C\mu^{-1}h^{-1} \quad \text{as } \varepsilon \ge \hbar^{\frac{2}{3}} \tag{16.2.66}$$

and

$$C\mu h^{-1}\big(\hbar/\varepsilon\big)^{r+\frac12} + \mu^{\frac53}h^{-\frac13} + C\mu^{-1}h^{-1} \qquad \text{as } \varepsilon \le \hbar^{\frac23}. \tag{16.2.67}$$

Micro-Averaging

In the current framework (including assumption $\hbar \le \varepsilon$) micro-averaging does not improve estimate of the correction term or the error as $|\mathsf{cos}(t)| \ge \epsilon_0$ in it unless $\gamma \ge h\varepsilon^{-1}$ (in comparison with the remainder estimate which was improved as $\gamma \ge h$). Then, as $\gamma \ge h\varepsilon^{-1}$ in estimates (16.2.66), (16.2.67) the first term gains factor $(h/\varepsilon\gamma)^l$, the last term is preserved and all other terms gain factor $(h/\gamma)^l \le \varepsilon^l$ which effectively kills them and we arrive to estimates (16.2.68), (16.2.71) below.

As $h \le \gamma \le h\varepsilon^{-1}$ the first and the last terms do not improve but all further terms gain factor $(h/\gamma)^l$ and we arrive to estimates (16.2.69) and (16.2.70) below. Finally, for $\gamma \le \mu h$ micro-averaging brings no improvement.

Proposition 16.2.13. *(i) For a toy-model operator* (16.2.1) *with* $\tau \asymp 1$, $\varepsilon \le \mu^{-1}$, $\varepsilon \ge \hbar$,

$$\mathsf{R}^{\mathsf{W}}_{x(r),\gamma} := \gamma^{-2}\Big|\int \Big(e^{\mathsf{T}}(x,x,0) - h^{-2}\big(\mathcal{N}^{\mathsf{W}}_x + \mathcal{N}_{x,\mathsf{corr}(r)}\big)\Big)\psi_\gamma\, dx\Big| \le C\mu h^{-1}\big(\hbar/\varepsilon\big)^{r+\frac12}\big(h/\varepsilon\gamma\big)^l + C\mu^{-1}h^{-1} \qquad \text{as } \gamma \ge h/\varepsilon, \tag{16.2.68}$$

$$\mathsf{R}^{\mathsf{W}}_{x(r),\gamma} \le C\mu h^{-1}\big(\hbar/\varepsilon\big)^{r+\frac12} + C\mu\varepsilon\Big(h^{-1}\big(\hbar/\varepsilon^{\frac32}\big)^{r+\frac12} + \mu^{\frac13}h^{-\frac23}\Big)\big(h/\gamma\big)^l + C\mu^{-1}h^{-1} \qquad \text{as } \varepsilon \ge \hbar^{\frac23},\ h \le \gamma \le h/\varepsilon \tag{16.2.69}$$

and

$$\mathsf{R}^{\mathsf{W}}_{x(r),\gamma} \le C\mu h^{-1}\big(\hbar/\varepsilon\big)^{r+\frac12} + C\mu^{\frac53}h^{-\frac13}\big(h/\gamma\big)^l + C\mu^{-1}h^{-1} \qquad \text{as } \varepsilon \le \hbar^{\frac23},\ h \le \gamma \le h/\varepsilon, \tag{16.2.70}$$

(ii) For a toy-model operator (16.2.1) *with* $\tau \asymp 1$, $\varepsilon \le \mu^{-1}$, $\varepsilon \le \hbar$

$$\mathsf{R}^{\mathsf{W}}_{x,\gamma} := \gamma^{-2}\Big|\int \Big(e^{\mathsf{T}}(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{W}}_x\Big)\psi_\gamma\, dx\Big| \le \mu h^{-1}\big(h/\varepsilon\gamma\big)^l + C\mu^{-1}h^{-1} \qquad \text{as } \gamma \ge h/\varepsilon. \tag{16.2.71}$$

16.2.4 Strong and Superstrong Magnetic Field

Tauberian Estimate

Consider strong $\mu h \asymp 1$ and superstrong $\mu h \gtrsim 1$ magnetic field for a Schrödinger-Pauli toy-model operator

$$A := h^2 D_1^2 + (hD_2 - \mu x_1)^2 + 2\alpha x_1 - \mathfrak{z}\mu h \tag{16.2.72}$$

which alternatively means that we assume that $|\tau - \mathfrak{z}\mu h| \le C$ in the framework of the standard toy-model (16.2.1). Formulae (16.2.15)–(16.2.16) imply that

Proposition 16.2.14. *For a toy-model operator* (16.2.1) *with* $\mu h \gtrsim 1$ *in* $\mathbb{R}^2$ *as* $|x| \le C_0$, $|y| \le C_0$

(i) $e(x,y,\tau) \equiv 0 \mod O(\mu^{-\infty})$ *as* $\tau \le \mu h - \epsilon_0$ *(the lower spectral gap).*

(ii) $e(x,y,\tau) \equiv e(x,y,\tau')$ *and* $\partial_\tau e(x,y,\tau) \equiv 0 \mod O(\mu^{-\infty})$ *as* $(2n-1) + \epsilon_0 \le \tau' < \tau \le (2n+1)\mu h - \epsilon_0$ *(other spectral gaps).*

(iii) $e(x,x,\tau) - e(x,x,\tau') \asymp \mu h^{-1}$ *as* $\tau' < (2n-1)\mu h - \epsilon_0$ *and* $\tau > (2n-1)\mu h + \epsilon_0$.

(iv) As $\varepsilon > 0$ *the following estimates hold*

$$|\partial_\tau e(x,y,\tau)| \le C\mu^{\frac12}\varepsilon^{-1}h^{-\frac32} \tag{16.2.73}$$

and

$$|F_{t\to\hbar^{-1}\tau}U(x,y,t)| \le C\mu^{\frac32}\varepsilon^{-1}h^{-\frac12} \tag{16.2.74}$$

and these estimate are sharp as $x = y$ *and* τ *is close to Landau levels* $(2n+1)\mu h$.

Further, as before $T^* = \epsilon_0\mu\varepsilon^{-1}\ell$. Then we immediately arrive to

Corollary 16.2.15. *For a self-adjoint operator in domain* X, $B(0,\ell) \subset X \subset \mathbb{R}^2$, $\ell \ge C_0\mu^{-\frac12}h^{\frac12}$, *coinciding in* $B(0,\ell)$ *with the toy-model operator* (16.2.72) *with* $\tau \asymp 1$, $\varepsilon < 0$, $\mu \ge h^{-1}$

(i) Statements (i)–(iv) of Proposition 16.2.14 remain true.

(ii) Formula (16.2.15) *holds modulo* $O(\mu^{\frac12}h^{-\frac12}\ell^{-1})$.

(iii) Moreover, formula (16.2.15) *holds modulo* $O(\mu^{-\infty})$ *as* $(2n-1) + \epsilon_0 \le \tau \le (2n+1)\mu h - \epsilon_0$.

Micro-Averaging

Let us consider micro-averaging. First let us estimate Fourier transform where as before we rescaled $t \mapsto \mu t$; formulae (16.2.15)–(16.2.16) imply immediately

Proposition 16.2.16. *For a toy-model operator* (16.2.72) *in* $\mathbb{R}^2$ *with* $\mu h \ge 1$ *and* $\mathfrak{z} = (2n+1)$

$$\gamma^{-2}|F_{t\to h^{-1}\tau}\bar{\chi}_T(t)\Gamma(U\psi_\gamma)| \le C\mu^2 + C\mu\varepsilon^{-1}R^{\mathsf{T}}(\gamma) \tag{16.2.75}$$

with

$$R^{\mathsf{T}}(\gamma) = \begin{cases} \mu^{\frac12}h^{-\frac12} & \text{as } \gamma \le \mu^{-\frac12}h^{\frac12}, \\ \gamma^{-1} & \text{as } \gamma \ge \mu^{-\frac12}h^{\frac12}. \end{cases} \tag{16.2.76}$$

Corollary 16.2.17. *In the framework of Corollary 16.2.15*

$$\gamma^{-2}|\Gamma\big(e(.,.,\tau) - e^{\mathsf{T}}(.,.,\tau)\big)\psi_\gamma| \le C\big(\mu\varepsilon + R^{\mathsf{T}}(\gamma)\big)\ell^{-1}. \tag{16.2.77}$$

16.2.5 Weyl and Magnetic Weyl Approximations

We can try to use a host of the different approximations but restrict ourselves now to Weyl approximation, which makes sense only as $\mu h \le 1$. Recall that

$$|e^{\mathsf{T}}(x,x,\tau) - h^{-2}\mathcal{N}_x^{\mathsf{W}}(\tau)| \le CR^{\mathsf{W}}, \tag{16.2.78}$$

$$\gamma^{-2}\Big|\int \big(e^{\mathsf{T}}(x,x,\tau) - h^{-2}\mathcal{N}_x^{\mathsf{W}}(\tau)\big)\psi_\gamma\, dx\Big| \le CR^{\mathsf{W}}(\gamma) \tag{16.2.79}$$

with

$$R^{\mathsf{W}} = \begin{cases} \mu^{\frac32}\varepsilon^{-\frac12}h^{-\frac12} & \text{as } \varepsilon \ge \hbar, \\ \mu h^{-1} & \text{as } \varepsilon \le \hbar, \end{cases} \tag{16.2.80}$$

$$R^{\mathsf{W}}(\gamma) = \begin{cases} R^{\mathsf{W}} & \text{as } \gamma \le h/\varepsilon, \\ R^{\mathsf{W}}(h/\varepsilon\gamma)^I & \text{as } \gamma \ge h/\varepsilon. \end{cases} \tag{16.2.81}$$

On the other hand, let us apply instead the magnetic Weyl approximation. Obviously, without micro-averaging $\mathcal{N}_x^{\mathsf{MW}}(\tau)$ cannot produce uniform with respect to τ remainder estimate better than μh^{-1} due to its own jumps. Meanwhile with an averaging (i.e. a micro-averaging with $\gamma = 1$) $\mathcal{N}_x^{\mathsf{MW}}(\tau)$

provides a better remainder estimate $O(\mu^{-1}h^{-1})$ (see Chapter 13; for a toy-model we need only assume that $\varepsilon \ge \mu^{-l}$). So, as $\mu h \le 1$ the magnetic Weyl approximation may provide a better remainder estimate as γ is not too small enough but for small γ Weyl approximation is better. Let us investigate this.

Proposition 16.2.18. *(i) For a toy-model operator* (16.2.1) *as* $\mu h \lesssim 1$

$$\mathsf{R}^{\mathsf{MW}}(\gamma) := \gamma^{-2}\Big|\int \big(e^{\mathsf{T}}(x,x,0) - h^{-2}\int \mathcal{N}^{\mathsf{MW}}\big)\psi_\gamma\,dx\Big| \le C\mu^{-1}h^{-1} + CR^{\mathsf{MW}}(\gamma) \tag{16.2.82}$$

with

$$R^{\mathsf{MW}}(\gamma) = \begin{cases} \mu^{-1}h^{-1}\gamma^{-2}(h/\varepsilon\gamma)^l & \text{as } \gamma \ge \max(\mu^{-1}, h/\varepsilon),\\ \mu^{-1}h^{-1}\gamma^{-2} & \text{as } \mu^{-1} \le \gamma \le h/\varepsilon,\\ \mu h^{-1}(h/\varepsilon\gamma)^l & \text{as } h/\varepsilon \le \gamma \le \mu^{-1},\\ \mu h^{-1} & \text{as } \gamma \le \min(\mu^{-1}, h/\varepsilon); \end{cases} \tag{16.2.83}$$

(ii) For a toy-model operator (16.2.72) *as* $\mu h \gtrsim 1$ *and* $\mathfrak{z} = 2n+1$ *estimate*

$$\mathsf{R}^{\mathsf{MW}}(\gamma) \le C + CR^{\mathsf{MW}}(\gamma) \tag{16.2.84}$$

holds with

$$R^{\mathsf{MW}}(\gamma) = \begin{cases} \gamma^{-2} & \text{as } \gamma \ge \mu^{-\frac{1}{2}}h^{\frac{1}{2}},\\ \mu h^{-1} & \text{as } \gamma \le \mu^{-\frac{1}{2}}h^{\frac{1}{2}}. \end{cases} \tag{16.2.85}$$

Proof. We need to investigate only case $\mu^{-1} \le \gamma \le h\varepsilon^{-1}$ as in all other cases we can easily pass from results for $\mathsf{R}^{\mathsf{W}}(\gamma)$.

Note that $h^{-2}\mathcal{N}_y^{\mathsf{MW}}(\tau)$ delivers $e(y,y,\tau)$ for a toy-model operator $\bar{A} := \bar{A}_y = \bar{A}_y(x, D_x)$ defined by (16.2.1) or (16.2.72) with αx_1 frozen at the point y (with respect to which we integrate later); so we consider our toy-model operator as a perturbation of this one.

Let us plug into Tauberian formula the Schwartz kernel of

$$e^{i\hbar^{-1}tA} = e^{i\hbar^{-1}t\bar{A}} + i\hbar^{-1}\int_0^t e^{i\hbar^{-1}t'\bar{A}}\big(A-\bar{A}\big)e^{i\hbar^{-1}(t-t')A}\,dt' \tag{16.2.86}$$

or its iteration for $\pm t > 0$

$$(16.2.86)_m \quad e^{i\hbar^{-1}tA} = e^{i\hbar^{-1}t\bar{A}_x} + \sum_{1\le j\le m-1} \times$$

$$(i\hbar^{-1})^j \int\limits_{\substack{\{\pm t_1>0,\pm t_2>0,\dots,\pm t_j>0,\\ t_1+t_2+\dots+t_j=t\}}} e^{i\hbar^{-1}t_1\bar{A}}\big(A-\bar{A}\big)e^{i\hbar^{-1}t_2\bar{A}}\big(A-\bar{A}\big)\cdots\big(A-\bar{A}\big)e^{i\hbar^{-1}t_j\bar{A}}\,dt_1dt_2\cdots dt_j+$$

$$(i\hbar^{-1})^m \int\limits_{\substack{\{\pm t_1>0,\pm t_2>0,\dots,\pm t_m>0,\\ t_1+t_2+\dots+t_j=t\}}} e^{i\hbar^{-1}t_1\bar{A}}\big(A-\bar{A}\big)e^{i\hbar^{-1}t_2\bar{A}}\big(A-\bar{A}\big)\cdots\big(A-\bar{A}\big)e^{i\hbar^{-1}t_mA}\,dt_1dt_2\cdots dt_m.$$

So let us plug $(16.2.86)_m$ into our expression with $\chi_T(t)$ instead of $\bar{\chi}_T(t)$. Then our standard methods imply that j-th term ($j = 0, \dots, m$) of what we got does not exceed

$$C\mu h^{-1}\big(T\|A-\bar{A}_x\|\hbar^{-1}\big)^j \times \big(1+\frac{T}{\bar{T}_2}\big)^{-l}\big(1+\frac{T}{\bar{T}_1}\big)^{-l} \tag{16.2.87}$$

with $\bar{T}_1 = C_0\mu\varepsilon^{-1}\bar{\gamma}$ where $\bar{\gamma} := \max(\mu^{-1}, \mu^{-\frac12}h^{\frac12})$ and $\bar{T}_2 = h/\varepsilon\gamma$; we leave easy details to the reader.

Then we can replace the norm by the "effective norm" which is a norm restricted to $\mu\bar{\gamma}$-vicinity of x (in rescaled coordinates) and equal to $C\alpha\bar{\gamma}$.

Note that $\bar{T}_2 \le \bar{T}_1$ as $\gamma \ge \bar{\gamma}$; then summation with respect to T returns

$$C\mu h^{-1}\big(\bar{T}_2\|A-\bar{A}_x\|\hbar^{-1}\big)^j \asymp C\mu h^{-1}\big(\bar{\gamma}/\gamma\big)^j$$

which provides required estimate (16.2.83) or (16.2.84) for all terms with $j \ge 2$.

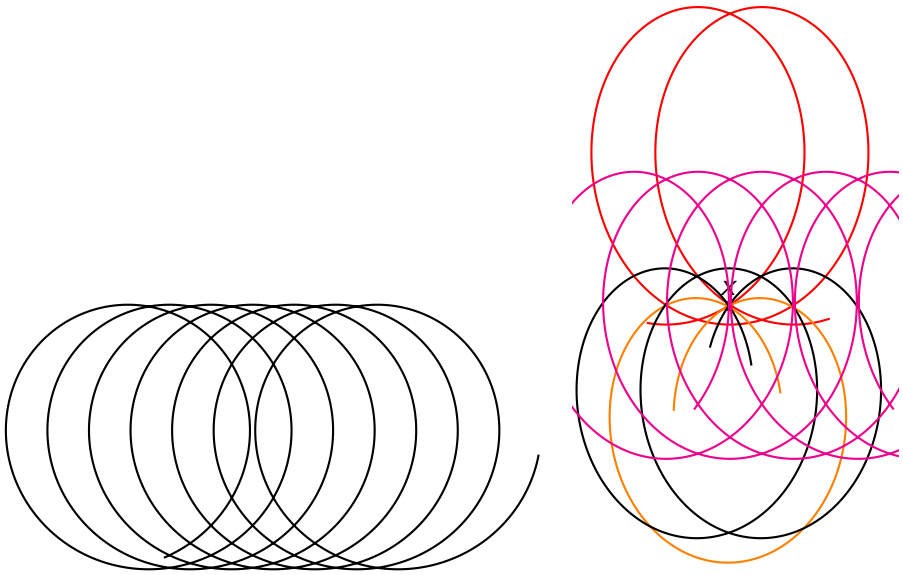
Finally note that while $\bar{A}_y(x-y, D_x)$ is even with respect to $(x-y, D_x)$ (we can always achieve it by the gauge transformation), perturbation $(A-\bar{A}_y)(x-y, D_x)$ is odd and therefore only terms with even j survive as we plug $x = y$. This takes care of term with $j = 1$. □

Remark 16.2.19. (i) For $\mu h \le 1$ magnetic Weyl formula provides better approximation as $\mu^{-1} \le \gamma \le h/\varepsilon$; otherwise Weyl formula provides either better or equally bad (μh^{-1}) approximation.

(ii) For $\mu h \ge 1$ magnetic Weyl formula provides approximation rather than just main term estimate as $\gamma \gg \mu^{-\frac12}h^{\frac12}$.

16.2.6 Geometric Interpretation

Remark 16.2.20. (i) As we mentioned t_k are length of the classical loops at point 0 (or x if we consider $e(x,x,\tau)$; then $t_k = t_k(x)$). While picture of the fixed trajectory and a point x on it (Figure 16.2(a)) is more geometrically appealing, the correct picture is of the fixed point and different trajectories passing through it (Figure 16.2(b)); due to assumption $\alpha \neq 0$ "radii" of these trajectories differ by $O(\mu^{-1})$.



(a) Intuitive (b) Correct picture

Figure 16.2: On the left more geometrically appealing picture, when x moves along given trajectory; on the right the correct one when we consider different trajectories passing through a fixed point.

Therefore, when we talk here about *loop* we mean a trajectory looping at the fixed point x rather the self-intersections of the fixed trajectory.

Similarly, when we talk about *pole* or *equator* we mean not x near a pole or an equator of the fixed trajectory but rather trajectory such that x is near its pole or equator.

So, all further remarks should be interpreted correctly.

(ii) How to interpret our results from heuristic uncertainty principle? Obviously these results mean that as $\varepsilon \gg \hbar$ then the majority of trajectories on Figure 16.2(b) do not return to the original point $x = 0$ after $k = 1$ tick[5] while otherwise this happens only after k ticks with $k\varepsilon \gg \hbar$. As the spatial shift is εk (after rescaling) this means that the thickness of the trajectory is $\asymp \hbar$ after rescaling (and therefore $\asymp h$ before rescaling).

It also means that if $|\sin(\theta)| \asymp 1$ where θ is the polar angle (between direction of the trajectory at 0 and the drift direction $(0,1)$) then we can take an interval in θ of the magnitude 1, so θ is a dual variable to x_2. Conversely, with the exception of the interval of the length $\hbar/\varepsilon|k|$ around θ_k (where θ_k corresponds to the classical trajectory returning to 0 after k ticks) trajectories do not return at 0; we can rewrite this condition as

$$|\sin(\theta - \theta_k)| \gg \hbar/(|k|\varepsilon). \tag{16.2.88}$$

This characteristic length matches to the stationary phase estimates we derived rigorously.

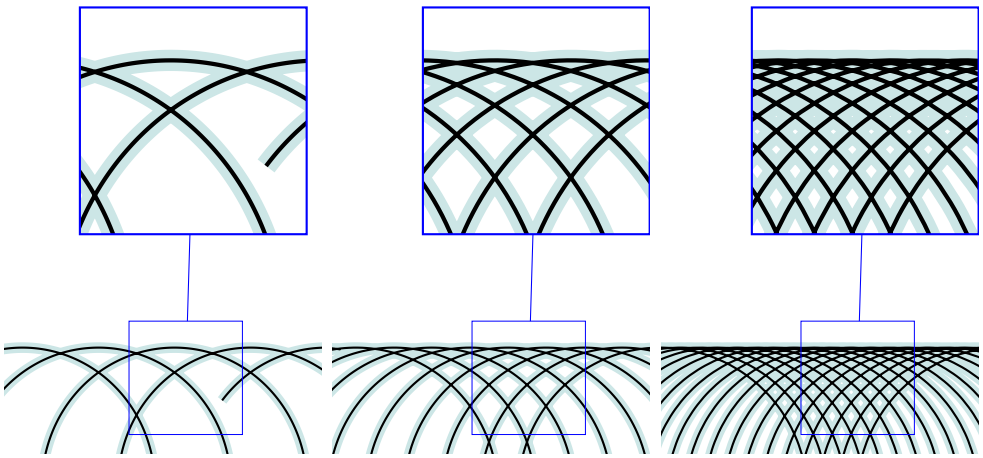


Figure 16.3: Looping near pole from microlocal point of view

(iii) Near equator situation changes drastically: spacing between self-intersections is $\asymp \varepsilon|\cos(\theta)|^{-1}$ as $|\cos(\theta)| \ge \epsilon_0\varepsilon^{\frac{1}{2}}$ and there are exceptional $0, 1, 2$

[5] In the sense that the difference between two points is observable.

self-intersections with $|\cos(\theta)| \le \epsilon_0 \varepsilon^{\frac{1}{2}}$. Uncertainty principle may prevent us to know how many of them are no matter how "not large" μ is.

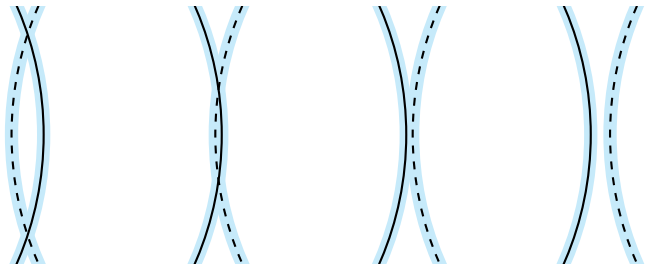

Figure 16.4: Self-intersections near equator. The first winding shown by a solid line, the closest to it near equator by a dashed one.

Consequent self-intersections are distinguishable as $|\cos(\theta)| \ge \hbar^{\frac{1}{3}}$ according to our calculations.

Problem 16.2.21. We know that estimates (16.2.73), (16.2.74) are sharp as $\mu h \gtrsim 1$. Are these estimates sharp as $\mu h \ll 1$?

16.3 Pointwise Asymptotics: General 2D-Operators

Let us recreate the approximation similar to the one of the previous section for general operators assuming that $\hbar \le \epsilon$ i.e.

$$\mu \le \epsilon h^{-1}. \tag{16.3.1}$$

We are interested in $|t| \le C_0 \mu^{-1} \varepsilon^{-1}$ for the original (not rescaled) operator because for $C_0 \mu^{-1} \varepsilon^{-1} \le |t| \le \mu^{-1} T^* := \epsilon_0 \varepsilon^{-1} \ell$ dynamics leaves $B(0, c_0 \mu^{-1})$ but remains in $B(0, \ell)$. Here

(16.3.2) $\varepsilon = \alpha^{-1} \mu^{-1}$ as we assume that $|\nabla V / F| \asymp \alpha$ in $B(0, \ell)$ with

$$C_1 \mu^{-1} \le \alpha \le 1 \qquad (\implies C_0 \mu^{-2} \le \varepsilon \le \mu^{-1}) \tag{16.3.3}$$

and $\ell \ge c_0 \mu^{-1}$ with sufficiently large constants C_1, c_0.

16.3.1 Classical Dynamics

First we consider classical dynamics starting from point $x = 0$. So far we use not-rescaled x, t. Let us freeze g^{jk} and F there and replace V_j and V by their linear germs:

$$\bar{g}^{jk} = g^{jk}(0), \quad \bar{V}(x) = V(0) + \langle \nabla V(0), x\rangle, \tag{16.3.4}$$
$$\bar{V}_j(x) = V_j(0) + \langle \nabla V_j(0), x\rangle \quad (\implies \bar{F} = F(0)),$$

denote corresponding Hamiltonian by $\bar{a}(x,\xi)$ and all the object associated with it will have bar. We consider our original dynamic system as a perturbation.

Without any loss of the generality we can assume that

$$g^{jk} = \omega^2 \delta_{jk} \qquad (\implies a(x,\xi) = \omega^2(p_1^2 + p_2^2) + V), \tag{16.3.5}$$

$$\omega(0) = F(0) = 1, \quad (\nabla\omega)(0) = 0, \tag{16.3.6}$$

$$V(0) = 0, \quad (\nabla V/F)(0) = (-\alpha, 0) \tag{16.3.7}$$

as we can achieve it by an appropriate change of variables (see footnote 9)) and

$$V_1(0) = 0, \quad V_2 = 0 \tag{16.3.8}$$

since we can achieve it by the gauge transformation.

Proposition 16.3.1. *Under conditions* (16.3.1)–(16.3.8) *as* $|t| \le c_0\mu^{-1}\varepsilon^{-1}$

(i) For drift flows $z_t = \Phi_t(0)$, $\bar{z}_t = \bar{\Phi}_t(0)$

$$z_t = \bar{z}_t + O\big(\mu^{-1}\varepsilon t^2\big); \tag{16.3.9}$$

(ii) If $F = 1$ *then for Hamiltonian flows* $(x_t, \xi_t) = \Psi_t(0,\eta)$, $(\bar{x}_t, \bar{\xi}_t) = \bar{\Psi}_t(0,\eta)$ *with magnetic parameters* μ *and* $\bar{\mu} = \mu(1 + O(\mu^{-2}))$ *defined by* (16.3.18) *on the energy level* $\tau \le c$

$$(x_t, \mu^{-1}\xi_t) = (\bar{x}_t, \mu^{-1}\bar{\xi}_t) + O\big(\mu^{-2}t\big). \tag{16.3.10}$$

Remark 16.3.2. Assumption (16.3.1) means that in $B(0,\mu^{-1})$ the constant part of ∇V dominates over its variable part and it implies that as

$$\mu^{-1}\varepsilon t^2 \le c_0\mu^{-2}|t| \le \kappa\varepsilon|t| \qquad \text{as} \quad |t| \le c_0\mu^{-1}\varepsilon^{-1} \tag{16.3.11}$$

with

$$\kappa = c_0\mu^{-2}\varepsilon^{-1} \le C_0^{-1}c_0 \tag{16.3.12}$$

and thus the perturbation of the drift is respectively small. In particular drift line deviates from the straight one by no more than $c_0\kappa$.

Also *equator* is defined as a point where x_t intersect its its first winding the last time deviates from $(\mu^{-1}, 0)$ by no more than $c_0\mu^{-1}\kappa$.

Proof of Proposition 16.3.1. (i) Proof of Statement (i) is trivial and left to the reader. Just recall that the drift flow is defined by (13.7.5) with an extra factor μ^{-1} in the right-hand expression and in our assumptions $\bar{\Phi}_t : (x_1, x_2) \mapsto (x_1 + \varepsilon t, x_2)$ after rescaling.

(ii) Recall that $p_j = \xi_j - \mu V_j(x)$, $\{p_j, x_k\} = \delta_{jk}$ and in virtue of the assumption $F = 1$

$$\{p_1, p_2\} = \mu\omega^{-2}. \tag{16.3.13}$$

According to Subsection 13.3.1 one can correct

$$\begin{aligned} y_1 &\coloneqq x_1 - \{p_1, p_2\}^{-1}p_2 = x_1 - \mu^{-1}\omega^2 p_2, \\ y_2 &\coloneqq x_2 + \{p_1, p_2\}^{-1}p_1 = x_2 + \mu^{-1}\omega^2 p_1 \end{aligned} \tag{16.3.14}$$

modulo $O(\mu^{-2})$ so that corrected expressions satisfy drift equation modulo $O(\mu^{-2})$. More precisely, in the current setup

$$\{a, y_1\} = \mu^{-1}\omega^2\Big(\{p_2, \omega^2\}(p_1^2 - p_2^2) - 2\{p_1, \omega^2\}p_1p_2 + \{p_2, V\}\Big)$$

and for $y_1' = y_1 + \mu^{-2}\beta_1 p_1 p_2 + \mu^{-2}\beta_2(p_1^2 - p_2^2)$ with

$$\beta_1 = -\frac{1}{2}\omega^2\{p_2, \omega^2\}, \qquad \beta_2 = \frac{1}{2}\omega^2\{p_1, \omega^2\}$$

we have

$$\{a, y_1'\} \equiv -\mu^{-1}\omega^2\{p_2, V\}$$

modulo terms which are $O(\mu^{-2})$ and also homogeneous polynomials of degrees 1 or 3 with respect to (p_1, p_2) and thus these terms could be corrected by adding to y_1' terms which are $O(\mu^{-3})$ and also homogeneous polynomials of degrees 2 or 4; then we arrive to

$$\{a, y_k''\} \equiv (-1)^k\mu^{-1}\omega^2\{p_{3-k}, V\} \mod O(\mu^{-3}) \qquad k = 1, 2$$

($k=2$ is considered in the same way as $k=1$). Note that the right-hand expressions are calculated at point $x=x_t$ rather than $y''=y_t''$; so we rewrite them as

$$\{a, y_k''\} \equiv (-1)^k \mu^{-1}\big(\omega^2\{p_{3-k}, V\}\big)(y'') + \sum_{j=1,2} \mu^{-2}(-1)^{j+k-1}(\partial_{3-j}\omega^2\partial_{3-k}V)(x)p_j \mod O(\mu^{-3}) \qquad k=1,2$$

and we can correct y_k'' by adding to y_k'' terms which are $O(\mu^{-3})$ and also homogeneous polynomials of degrees 2 with respect to (p_1,p_2).

Therefore

$$y_t''' \equiv z_t \mod O(\mu^{-3}t) \tag{16.3.15}$$

where $z_t=\Phi_t(0)$.

Meanwhile (16.3.13) implies

$$\frac{d}{dt}p_j = 2(-1)^j\mu p_{3-j} - (\omega^2)_{x_j}(p_1^2+p_2^2) - V_{x_j} = 2(-1)^j\mu p_{3-j} - 2\omega_{x_j}\omega^{-1}W + W_{x_j}, \qquad j=1,2 \tag{16.3.16}$$

where we replaced $p_1^2+p_2^2$ by $\omega^{-2}W$, $W=\tau-V$ (no error as τ is an energy level). Let us plug $x_1(t)\equiv z_1(t)+\mu^{-1}\omega^2(z_t)p_2$, $x_2(t)\equiv z_2(t)-\mu^{-1}\omega^2(z_t)p_1$ modulo $O(\mu^{-2})$ in the right-hand expressions; we get

$$\frac{d}{dt}\begin{pmatrix}p_1\\p_2\end{pmatrix} = J\begin{pmatrix}p_1\\p_2\end{pmatrix} + K \tag{16.3.17}$$

with

$$J \coloneqq 2\mu\begin{pmatrix} -\mu^{-2}\omega^2(\omega_{x_1}\omega^{-1}W+W_{x_1})_{x_2} & -\big(1-\mu^{-2}\omega^2(\omega_{x_1}\omega^{-1}W+W_{x_1})_{x_1}\big)\\ \big(1-\mu^{-2}\omega^2(\omega_{x_2}\omega^{-1}W+W_{x_2})_{x_2}\big) & \mu^{-2}\omega^2(\omega_{x_2}\omega^{-1}W+W_{x_2})_{x_1}\end{pmatrix},$$

and

$$K \coloneqq \begin{pmatrix}-2(\omega_{x_1}\omega^{-1}W+W_{x_1})\\ -2\omega_{x_2}\omega^{-1}W+W_{x_2}\end{pmatrix}.$$

and here we can calculate elements of J at any point of $B(0,\mu^{-1})$ we choose (and we choose 0) while elements of K are calculated at z_t. Then J becomes a constant coefficient matrix and since $\nabla\omega(0)=0$, $\omega(0)=1$

$$J=2\mu\begin{pmatrix} -\mu^{-2}(\omega_{x_1x_2}W+W_{x_1x_2}) & -\bigl(1-\mu^{-2}(\omega_{x_1x_1}W+W_{x_1x_1})\bigr)\\ \bigl(1-\mu^{-2}(\omega_{x_2x_2}W+W_{x_2x_2})\bigr) & \mu^{-2}(\omega_{x_2x_1}W+W_{x_2x_1})\end{pmatrix}$$

and its eigenvalues are $\pm 2\bar{\mu}i$ with

(16.3.18) $\bar{\mu}=$

$$\mu\Bigl(\bigl(1-\mu^{-2}(\omega_{x_1x_1}W+W_{x_1x_1})\bigr)\bigl(1-\mu^{-2}(\omega_{x_2x_2}W+W_{x_2x_2})-\mu^{-4}(\omega_{x_1x_2}W+W_{x_1x_2})^2\Bigr)^{\frac{1}{2}}$$
$$=\mu+\mu^{-1}(\Delta(\omega W))+O(\mu^{-3}).$$

Then $J=Q^{-1}\bar{J}Q$ with $\bar{J}=\bar{\mu}\begin{pmatrix}0&-1\\1&0\end{pmatrix}$ and $Q=I+O(\mu^{-2})$.

Due to (16.3.17)

(16.3.19) $$p(t)\equiv e^{tJ}p(0)+\int_0^t e^{(t-t')J}K(z_{t'})\,dt'=$$
$$e^{tJ}p(0)+\int_0^t e^{(t-t')J}J^{-1}\frac{d}{dt'}K(z_{t'})\,dt'-J^{-1}K(z_t)+e^{tJ}J^{-1}K(z_0).$$

The second term in the right-hand expression is $O(\mu^{-1}\varepsilon t)$ as $J^{-1}=O(\mu^{-1})$ and $\frac{d}{dt'}K(z_{t'})=O(\varepsilon)$. Note that with $O(\mu^{-2}t)$ error one can replace in the two last terms J by $\bar{J}$ calculated for a toy-model. Finally, with an error $O(\mu^{-1}\varepsilon t)$ one can replace $K(z_t)$ by $K(z_0)$; however $K(z_0)$ and $\bar{K}(z_0)$ coincide as $\nabla\omega(0)=0$.

Replacing J by $\bar{J}$ we reduced evolution of p to those of the toy-model albeit with $\bar{\mu}$ instead of μ. Therefore $\mu^{-1}p_t\equiv\mu^{-1}\bar{p}_t \mod O(\mu^{-2}t)$. Replacing μ by $\bar{\mu}$ does not affect drift (in the framework of the indicated precision).

But then x_t could be found from z_t and p_t and their drift also is described by a toy-model in the framework of the same error and then it is true for $\mu^{-1}\xi_t$ as well. This concludes the proof of Statement (ii), □

Consider now the general case, i.e. F different from 1 and variable. Then differential equations describing $(x(t),\xi(t))$ for $a(x,\xi)$ coincide with

equations for $F^{-1}a(x,\xi)$ with $F \mapsto 1$ and $\tau - V \mapsto F^{-1}(\tau - V)$ but with the "time" θ satisfying

$$\frac{d\theta}{dt} = F(x_t) \equiv F(z_t) + (\omega^2 F^{-1})(z_t)\big(F_{x_1}(z_t)p_2 - F_{x_2}(z_t)p_1\big) \quad \mathsf{mod}\ O(\mu^{-2})$$

where $z_t = \Phi_t(0)$. We can correct θ by $O(\mu^{-1})$ eliminating linear terms in the right hand expression and therefore

$$\theta \equiv \int F(z_t)\,dt \equiv F(0)t + \frac{1}{2}\big(\frac{d}{dt}F(z_t)\big)(0)t^2 \quad \mathsf{mod}\ O(\mu^{-1} + \mu^{-2}|t|) \tag{16.3.20}$$

with the second term in the right-hand expression $O(\varepsilon\mu^{-1}t^2)$.

From now on we use rescaling $x \mapsto \mu x$, $t \mapsto \bar{\mu}t$, $\theta \mapsto \mu\theta$. Our analysis implies immediately

Proposition 16.3.3. *Let conditions* (16.3.1)–(16.3.8) *be fulfilled*[6)]. *Then (after rescaling* $x \to \bar{\mu}x$, $t \mapsto \bar{\mu}t$*) as* $|t| \le c_0\varepsilon^{-1}$

$$|D^\beta \Psi_t| \le C_\beta \qquad \forall \beta. \tag{16.3.21}$$

16.3.2 Semiclassical Approximation to $U(x,y,t)$

Proposition 16.3.4. *Let conditions* (16.3.1)–(16.3.8) *be fulfilled*[6)]. *Then*

(i) Uniformly with respect to $|t| \le c\varepsilon^{-1}$ $e^{i\hbar^{-1}tA}$ *is an* $\hbar$*-Fourier integral operator corresponding to Hamiltonian flow* Ψ_t.

(ii) As $|\sin(2\theta)| \ge \epsilon$ *with* θ *defined by* (16.3.20),

$$U(x,y,t) \equiv (4\pi\hbar)^{-1} i(\sin(\theta))^{-1} e^{i\hbar^{-1}\phi(x,y,t)} \sum_m b_m(x,y,t)\hbar^m \tag{16.3.22}$$

with ϕ *defined by* (16.3.25)–(16.3.29) *below and satisfying (with all derivatives)*

$$\phi = \bar{\phi}(\theta) + O(\mu^{-2}\varepsilon^{-1}), \tag{16.3.23}$$

$$b_m = \delta_{0m} + O(\mu^{-2}\varepsilon^{-1}) \tag{16.3.24}$$

with $\bar{\phi}$ *defined by* (16.2.10).

[6)] Before rescaling.

Proof. Both Statements (i) and (ii) of proposition are standard as $|t| \le T = \mathsf{const}$ but we need to extend them for larger t. Further, ϕ is an *action*[7)]

$$\phi = -\int_0^t L\big(x(t'), \dot{x}(t')\big)\, dt' \tag{16.3.25}$$

with the Lagrangian

$$L(x,\dot{x}) = \big(\sum_k \dot{x}_k\xi_k - a(x,\xi)\big)|_{\xi_k=(16.3.29)} = \frac{1}{4}\sum_{j,k} g_{jk}(x)\dot{x}_j\dot{x}_k + \frac{1}{2}\sum_j \dot{x}_j V_j(x) - V(x). \tag{16.3.26}$$

which is the Legendre transformation of the Hamiltonian

$$a(x,\xi) = \sum_{j,k} g^{jk}(x)\big(\xi_j - V_j(x)\big)\big(\xi_k - V_k(x)\big) + V(x) \tag{16.3.27}$$

$$\dot{x}_j = 2\sum_k g^{jk}(x)\big(\xi_k - V_k(x)\big), \tag{16.3.28}$$

$$\xi_k = \frac{1}{2}\sum\sum_j g_{jk}\dot{x}_j + V_k(x), \tag{16.3.29}$$

$\dot{f} := df/dt'$ and we are talking about trajectories from y as $t' = 0$ to x as $t' = t$.

To extend Statements (i) and (ii) to t: $|t| \le T = c\varepsilon^{-1}$ note that

$$e^{\pi t\hbar^{-1}A} = -e^{i\mu^{-1}\hbar^{-1}B} \tag{16.3.30}$$

with $\hbar$-pseudodifferential operator B; $B = 0$ if A is a toy-model operator with $\alpha = 0$. Therefore as usual

$$e^{\pi t\hbar^{-1}A} = e^{ik\hbar^{-1}A}e^{i(t-\pi k)\hbar^{-1}A} = (-1)^k e^{ik\mu^{-1}\hbar^{-1}B}e^{i(t-\pi k)\hbar^{-1}A} \tag{16.3.31}$$

with $k = \lfloor t/\pi \rfloor$ and the right-hand expression is $\hbar$-Fourier integral operator as $|k| \le c\varepsilon^{-1}$. Statement (i) is proven.

Note that the corresponding canonical manifold is well-projected to (x,y) space ($\mathbb{R}^4$) as $|\sin(2\theta)| \ge \epsilon$ and compare it with the canonical manifold

[7)] Sign "–" is due to considering of propagator $e^{i\hbar^{-1}tA}$ rather than $e^{-i\hbar^{-1}tA}$.

for the toy-model operator; this proves Statement (ii) as either $F = 1$ or $|t| \le \epsilon_1\varepsilon$ with sufficiently small $\epsilon_1 = \epsilon_1(\epsilon)$.

But then one can represent $e^{i\hbar^{-1}tA}$ as $e^{i\hbar^{-1}t_1A}e^{i\hbar^{-1}t_2A}\cdots e^{i\hbar^{-1}t_nA}$ with $n \le c_1$ and $|t_j| \le \epsilon_1\mu$, $|\sin(2t_j)| \ge \frac{1}{2}\epsilon$ which implies Statement (ii) in the general case. □

So far we exclude both vicinities of $\sin(\theta) = 0$ which matches $x = y$ (poles) and $\cos(\theta) = 0$ which matches x and y being antipodal points of the trajectory (equator) but we need to approach both of them. Actually exclusion of the latter was no more than a precaution but poles require a modification:

Proposition 16.3.5. *Let conditions* (16.3.1)–(16.3.8) *be fulfilled*[6)]. *Then*

(i) Decomposition (16.3.22) *remains valid as* $|\cos(\theta)| \le \epsilon$.

(ii) Decomposition (16.3.22) *remains valid as*

$$C\max\bigl(\hbar, \mu^{-1}\varepsilon|t|\bigr) \le |\sin(\theta)| \le \epsilon \tag{16.3.32}$$

albeit with an error not exceeding

$$C\hbar^{-1}|\sin(\theta)|^{-1}(\hbar/|\sin(\theta)|)^{l} \tag{16.3.33}$$

and with b_m *such that*

$$|D^{\beta}(\phi - \bar{\phi})| \le C_{\beta}\varepsilon|\sin(\theta)|^{-|\beta|} \qquad \forall \beta, \tag{16.3.34}$$

$$|D^{\beta}(b_m - \delta_{m0})| \le C_{m\beta}\varepsilon|\sin(\theta)|^{-m-|\beta|} \qquad \forall \beta, m. \tag{16.3.35}$$

Proof. As

$$U(x,y,t) = \mu^{-2}\int U(x,z,t')U(z,y,-t'')\,dz$$

for $t = t' - t''$ (where factor μ^{-d} is due to rescaling U as a function) we need to consider this oscillatory integral. If we consider oscillatory integral with the propagator for the toy-model operator we note that the standard stationary phase method applies with an effective semiclassical parameter $\hbar$ as $(\cot(t') - \cot(t'')) = -\sin(t)\sec(t')\sec(t'')$ disjoint from 0 i.e. also as $|\cos(t)| \le \epsilon$.

On the other hand, an effective semiclassical parameter is $\hbar/|\sin(t)|$ near poles.

In virtue of Proposition 16.3.4 both these claims remain true for a general operator as well albeit with t replaced by θ. □

Remark 16.3.6. So far we need only $|\nabla V/F| \lesssim \mu\varepsilon$ rather than $|\nabla V/F| \asymp \mu\varepsilon$ [6)].

16.3.3 Semiclassical Approximation to $e(x,x,\tau)$

Therefore in zone $\{|\sin(\theta)| \ge C\hbar\}$ all arguments of the toy-model theory work (with obvious modifications) under non-degeneracy assumptions

$$V - \tau \le -\epsilon_0, \tag{16.3.36}$$

$$|\nabla(\tau - V)F^{-1}| \asymp \varepsilon \tag{16.3.37}$$

we conclude that

(16.3.38) Contribution of zone $\{|\sin(\theta)| \ge C\hbar\}$ to $F_{t\to h^{-1}\tau}(1-\bar\chi_1(t))\Gamma_x U$ does not exceed $C\mu h^{-1} + C\mu^{\frac32}\varepsilon^{-1}h^{-\frac12}$.

Consider now zone $\{|\sin(\theta)| \le \epsilon|\}$. Both operators A and B (defined by (16.3.30) are ξ-microhyperbolic and unless factors they are coming with (namely $(\theta - \pi k)$ (with the closest πk) and εt respectively are of the same magnitude we can use ξ-microhyperbolicity to prove

(16.3.39) Contribution of zone $\{|t| \asymp T \ge \varepsilon^{-1}\max(\mu\hbar, C|\sin(\theta)|)\}$ to $F_{t\to h^{-1}\tau}\Gamma_x U$ does not exceed

$$C\mu^2\hbar^{-2}\times T\times \varepsilon T\times (\hbar/\varepsilon T)^{l+1} = C\mu^2 h^{-1}T(\hbar/\varepsilon T)^l$$

(with arbitrarily large l) while its contribution to expression (16.2.59) does not exceed the same expression albeit without factor T i.e.

$$C\mu^2 h^{-1}(\hbar/\varepsilon T)^l,$$

where factor μ^2 is due to rescaling, $T\times\varepsilon T$ is the measure of the zone $\{\theta : |\theta| \asymp T,\ |\sin(\theta)| \le \varepsilon T\}$ and other factors are standard; recall that B comes with the factor ε and therefore effective semiclassical parameter is $\hbar/\varepsilon$. We leave easy details to the reader.

After summation with respect to T we conclude that

(16.3.40) As $\varepsilon \ge C\hbar$ contributions of zone $\{|t| \ge 1,\ |\sin(\theta)| \le c\hbar\}$ to both $F_{t\to h^{-1}\tau}\Gamma_x U$ and expression (16.2.59) do not exceed $C\mu h^{-1}(\hbar/\varepsilon)^l$

and

(16.3.41) As $\varepsilon \le C_0\hbar \le 1$ contribution of zone $\{|t| \ge C_0\hbar/\varepsilon,\ |\sin(\theta)| \le c\hbar\}$ to $F_{t\to h^{-1}\tau}\Gamma_x U$ does not exceed $C\mu^2\varepsilon^{-1}$ while its contribution to expression (16.2.59) does not exceed $C\mu h^{-1}$.

So, as $\varepsilon \ge C\hbar$ we are done but as $\varepsilon \le C\hbar$ we need to consider zone $\{1 \le |t| \le c\hbar/\varepsilon,\ |\sin(\theta)| \le c\hbar\}$ and the same arguments imply

(16.3.42) As $\varepsilon \le C_0\hbar \le 1$ contribution of zone $\{1 \le |t| \le c\hbar/\varepsilon,\ |\sin(\theta)| \le c\hbar\}$ to $F_{t\to h^{-1}\tau}\Gamma_x U$ does not exceed

$$C\mu^2\hbar^{-2} \times \varepsilon^{-1}\hbar \times \hbar = C\mu^2\varepsilon^{-1}$$

where factor μ^2 is due to rescaling, $\varepsilon^{-1}\hbar \times \hbar$ is the measure of the zone $\{\theta : |\theta| \le \varepsilon^{-1}\hbar,\ |\sin(\theta)| \le \hbar\}$ and factor $\hbar^{-2}$ is the standard one.

Combining with the results for zone $\{|\sin(\theta)| \ge c\hbar\}$ we arrive to

Proposition 16.3.7. *For magnetic Schrödinger operator in domain X, $B(0,\ell) \subset X \subset \mathbb{R}^2$ under standard smoothness assumptions and non-degeneracy assumptions* (16.1.6) *and* (16.3.36)–(16.3.37), (16.3.3) *after rescaling $x \mapsto \mu x$, $t \mapsto \mu t$ (as $\mu \le h^{-1}$) estimates* (16.2.49)–(16.2.50) *of Proposition 16.2.6 and estimates* (16.2.55)–(16.2.57) *of Proposition 16.2.9 hold as $T \le c\varepsilon^{-1}$.*

Further, estimates (16.2.78)–(16.2.81) *hold as well.*

Now we apply the standard Tauberian arguments. We are interested mainly in the case of $\alpha \asymp 1$; then automatically $\ell \asymp 1$ and $T^* \asymp \mu^2$ inside domain. However in more general case $\ell \asymp \alpha \asymp \mu\varepsilon$ automatically and $T^* \asymp \ell/\varepsilon\mu\mu^2 \asymp \mu^2$ again and we arrive to

Proposition 16.3.8. *For magnetic Schrödinger operator in domain X, $B(0,\ell) \subset X \subset \mathbb{R}^2$ under standard smoothness assumptions and non-degeneracy assumptions* (16.1.6) *and* (16.3.36)–(16.3.37), (16.3.3) *Tauberian estimates* (16.2.51) *of Pproposition 16.2.8 and estimates* (16.2.57)–(16.2.58) *of Corollary 16.2.10 hold with the Tauberian expression* (16.2.52) *and $\ell \asymp \alpha$.*

16.3.4 Stationary Phase Calculations

Let apply the stationary phase method to the Tauberian expression. To do so we need to remember that assumptions $|t| \ll \varepsilon^{-1}$, $\varphi' = 0$ yield $\varphi'' \asymp |\sin(\theta)|^{-1}$ and all other estimates hold; therefore the stationary phase construction is available there. Also this construction works as long as $|t| \le c\varepsilon^{-1}$ and $|\varphi''| \ge \epsilon$ i.e. $|t - t^*| \ge \epsilon\varepsilon^{-1}$ where $T^* = \varepsilon^{-1}$.

Moreover, $|\varphi''| \ge \epsilon_0$ as $|t - t^*| \le \epsilon\varepsilon^{-1}$ and $\varphi' = 0$ and therefore all our estimates work here, in the near equator zone as well where

Definition 16.3.9. Equator just moves to the point where $|\varphi''|$ is minimal for $\varphi' = 0$. Let us in the near equator zone redefine θ in such way that equator is $\cos(\theta) = 0$.

Let us introduce

Definition 16.3.10. Consider r-term representation (16.3.22) (i.e. with summation over $m < r$) and plug it into Tauberian expression, excepting $|t| \le \epsilon_0$ and calculate it by the stationary phase method with r terms again. Let us call the result *r-term semiclassical approximation* and denote it by $h^{-2}\mathcal{N}_{x,\mathsf{corr}(r)}$.

Then its main term is delivered by modified (16.2.60)–(16.2.62)

$$\sum_{k\in\mathfrak{Z}} \frac{1}{4\pi\sqrt{\pi}}\mu\hbar^{-\frac{1}{2}}(t_k \sin(\theta_k))^{-1}|\varphi''(t_k)|^{-\frac{1}{2}} b_0(t_k)\times \exp\Big(\frac{i\pi}{4}\operatorname{sgn}\varphi''(t_k) + i\hbar^{-1}\varphi(t_k)\Big) \tag{16.3.43}$$

with

$$\varphi''(t_k) \sim 2\tau\cot(\theta_k) \qquad \text{as } |\cos(\theta_k)| \ge C\varepsilon^{\frac{1}{2}} \tag{16.3.44}$$

and

$$\mathfrak{Z} := \big\{k \ne 0 : |\cos(\theta_k)| \ge C\max\big(\varepsilon^{\frac{1}{2}}, \hbar^{\frac{1}{3}}\big)\big\} \tag{16.3.45}$$

where t_k is a time of k-th return to x (along k-th loop), $\theta_k = \theta(t_k)$ and $\varphi(t_k)$ is the corresponding action.

Then repeating arguments of the previous section we arrive to

Proposition 16.3.11. *For magnetic Schrödinger operator in domain X, $B(0,1) \subset X \subset \mathbb{R}^2$ under standard smoothness assumptions and non-degeneracy assumptions* (16.1.6) *and* (16.3.36)–(16.3.37), (16.3.3)

(i) As $\varepsilon \geq \hbar$ estimate (16.2.64) *of Proposition 16.2.11 holds.*

(ii) Estimates (16.2.66)–(16.2.67) *of Proposition 16.2.12, estimates* (16.2.68)–(16.2.71) *of Proposition 16.2.13 and estimates* (16.2.82)–(16.2.85) *of Proposition 16.2.18 hold.*

16.3.5 Approximation by a Toy-Model Operator

Weak Magnetic Field Case

We cannot do better in this framework; however using the toy-model operator as an approximation we could improve these results. Without any loss of the generality we can assume that (16.3.5)–(16.3.7) are fulfilled.

Assume temporarily that $F = 1$. Then one can prove easily that

$$t_k = \theta(t_k) \equiv \bar{t}_k, \qquad \phi(t_k) \equiv \bar{\phi}(\bar{t}_k) \mod \mu^{-2}|k| \tag{16.3.46}$$

where bar denotes objects related to the toy-model operator. Therefore $\hbar^{-1}\bigl(\phi(t_k) - \bar{\phi}(\bar{t}_k)\bigr) = O(\mu^{-2}\hbar^{-1}|k|)$ and it is less than 1 as

$$|k| \leq \tilde{k} := \mu^3 h. \tag{16.3.47}$$

Therefore it makes sense to apply this approach only as $\tilde{k} \geq 1$ i.e.

$$\mu \geq h^{-\frac{1}{3}}. \tag{16.3.48}$$

Under this assumption let us compare r-th terms for our operator and the toy model as $|k| \leq \tilde{k}$.

One can see easily that their difference does not exceed

$$C \sum_k \mu h^{-1} (\hbar/\varepsilon|k|)^{r+\frac{1}{2}} |k|^{-1} \times \mu^{-3} h^{-1} |k| \tag{16.3.49}$$

which as $r \geq 1$ does not exceed $C\mu^{-2}h^{-2}(\hbar/\varepsilon|k|)^{r+\frac{1}{2}}|k|$ calculated for the smallest possible $|k|$ which is 1 provided $\hbar \leq \varepsilon$. Therefore we get $C\mu^{-2}h^{-2}(\hbar/\varepsilon)^{r+\frac{1}{2}}$. On the other hand in (16.3.49) one should replace the last factor by 1 as $|k| \geq \tilde{k}$.

Therefore, if we start from l-term approximation and apply estimate (16.2.66), (16.2.67) as $\varepsilon \ge \hbar^{\frac{2}{3}}$, $\hbar \le \varepsilon \le \hbar^{\frac{2}{3}}$ respectively and pass from l-term to r-term approximation we get estimate

$$
\begin{aligned}
(16.3.50)\quad & \mathsf{R}^{\mathsf{W}\prime\prime}_{x(r)\gamma} := \\
& |e^{\mathsf{T}}(x,x,\tau) - h^{-2}\mathcal{N}_{x,\mathsf{corr}(r)} - \bar{e}^{\mathsf{T}}(x,x,\tau) + h^{-2}\bar{\mathcal{N}}_{x,\mathsf{corr}(r)}| \le \\
& \qquad C\mu^{-1}h^{-1} + C\mu^{-2}h^{-2}(\hbar/\varepsilon)^{r+\frac{1}{2}} + C\mu h^{-1}(\hbar/\varepsilon)^{l+\frac{1}{2}} + \\
& \qquad\qquad \begin{cases} C\mu\varepsilon h^{-1}\big(\hbar/\varepsilon^{\frac{3}{2}}\big)^{r+\frac{1}{2}} + C\mu^{\frac{4}{3}}\varepsilon h^{-\frac{2}{3}} & \text{as } \ \varepsilon \ge \hbar^{\frac{2}{3}} \\ C\mu^{\frac{5}{3}}h^{-\frac{1}{3}} & \text{as } \ \hbar \le \varepsilon \le \hbar^{\frac{2}{3}} \end{cases}
\end{aligned}
$$

where terms $-h^{-2}\mathcal{N}^{\mathsf{W}}_x$ and $h^{-2}\bar{\mathcal{N}}^{\mathsf{W}}_x$ obviously cancel one another.

Successive Approximations

Now we need to get rid of the third term in the right-hand expression of (16.3.50) without condition $\varepsilon \gg \hbar$ which allows to eliminate it. To do this we need more sophisticated arguments. Namely, let us apply the successive approximations.

Assuming that the original operator is perturbed by $O(\mu^{-2})$ we arrive to the heuristic conclusion that

(16.3.51) Contribution of $|t| \asymp T$ to $R^{\mathsf{W}\prime\prime}$ does not exceed the previous estimate of the contribution to $\mathsf{R}^{\mathsf{W}\prime}$ multiplied by $\mu^{-2}T\hbar^{-1}$;

this statement needs justification. We can achieve a better estimate by taking more terms in the successive approximation but it leads to a rather overcomplicated formula; so we take just one term.

Then, in the framework of (16.3.51) we have three cases:

(a) $\varepsilon \ge \hbar$; then all what successive approximation does is to eliminate the third term in the right-hand expression of (16.3.50).

(b) $\mu^{-3}h^{-1} \le \varepsilon \le \hbar$; then $1 \ge \bar{k} \le \varepsilon^{-1}$ and we need to adjust our arguments treating separately $|k| \le \bar{k}$ and $|k| \ge \bar{k}$ and recalculate the second term in the right-hand expression of (16.3.50); however equator zone is not affected.

(c) $\varepsilon \le \mathsf{min}(\hbar, \mu^{-3}h^{-1})$. In this case in addition we need to recalculate the last term in the right-hand expression of (16.3.50).

Let us reconsider the second term in the right-hand expression of (16.3.50). First, expression (16.3.49) with summation over $k : |k| \ge \bar{k}$ returns $C\mu^{-2}h^{-2}(\hbar/\varepsilon|k|)^{r+\frac{1}{2}}|k|$ calculated as $k = \bar{k}$; so we get $C\mu^{-2}h^{-2}\bar{k} = C\mu^{-1}h^{-1}\varepsilon^{-1}$.

Further, as $|k| \le \bar{k}$ we need to replace $(\hbar/\varepsilon|k|)^{r+\frac{1}{2}}$ by 1; so we sum $C\mu h^{-1}|k|^{-1} \times \mu^{-3}h^{-1}|k|$ which returns $C\mu^{-2}h^{-2}\bar{k}$ again. Therefore[8)] we conclude that

(16.3.52) As $\hbar \ge \varepsilon$, $r \ge 1$ one should replace the second term in (16.3.50) by $C\mu^{-1}h^{-1}\varepsilon^{-1}$.

Furthermore, as $\varepsilon \le \mathsf{min}(\hbar, \mu^{-3}h^{-1})$ one should multiply the last term in (16.3.50) i.e. $C\mu^{\frac{5}{3}}h^{-\frac{1}{3}}$ by $\mu^{-3}\varepsilon^{-1}h^{-1}$ resulting in $C\mu^{-\frac{4}{3}}\varepsilon^{-1}h^{-\frac{4}{3}}$. Therefore[8)] we conclude that

(16.3.53) As $\varepsilon \le \mathsf{min}(\hbar, \mu^{-3}h^{-1})$, $r \ge 1$ one should replace the second term in (16.3.50) by $C\mu^{-\frac{1}{3}}\varepsilon^{-1}h^{-\frac{4}{3}}$.

Therefore we (heuristically, the proof follows) arrive to

Proposition 16.3.12. *Consider two magnetic Schrödinger operators A and $\bar{A}$ satisfying the standard smoothness assumptions, non-degeneracy assumptions* (16.1.6) *and* (16.3.36)–(16.3.37), (16.3.3) *and such that*

$$(16.3.54)\quad g^{jk} = \bar{g}^{jk} + O(\mu^{-2}), \qquad V = \bar{V} + O(\mu^{-2}), \qquad V_j = \bar{V}_j + O(\mu^{-3}).$$

Then for $r \ge 1$

$$(16.3.55)\quad \mathsf{R}^{\mathsf{W}\prime\prime}_{x(r)} \le C\mu^{-1}h^{-1} + C\begin{cases} \mu^{-2}h^{-2}(\hbar/\varepsilon)^{r+\frac{1}{2}} & \text{as } \varepsilon \ge \hbar \\ C\mu^{-1}h^{-1}\varepsilon^{-1} & \text{as } \varepsilon \le \hbar \end{cases} + \begin{cases} C\mu\varepsilon h^{-1}\big(\hbar/\varepsilon^{\frac{3}{2}}\big)^{r+\frac{1}{2}} + C\mu^{\frac{4}{3}}\varepsilon h^{-\frac{2}{3}} & \text{as } \varepsilon \ge \hbar^{\frac{2}{3}} \\ C\mu^{\frac{5}{3}}h^{-\frac{1}{3}} & \text{as } \mathsf{min}(\hbar, \mu^{-3}h^{-1}) \le \varepsilon \le \hbar^{\frac{2}{3}} \\ C\mu^{-\frac{4}{3}}\varepsilon^{-1}h^{-\frac{4}{3}} & \text{as } \varepsilon \le \mathsf{min}(\hbar, \mu^{-3}h^{-1}) \end{cases}$$

[8)] Pending (16.3.51).

and

$$\mathsf{R}^{\mathsf{W}\prime\prime}_{x(r)\gamma} \coloneqq \tag{16.3.56}$$
$$\gamma^{-2}\Big|\int \Big(e^{\mathsf{T}}(x,x,\tau) - h^{-2}\mathcal{N}_{x,\mathsf{corr}(r)} - \bar{e}^{\mathsf{T}}(x,x,\tau) + h^{-2}\bar{\mathcal{N}}_{x,\mathsf{corr}(r)}\Big)\psi_\gamma\, dx\Big| \le$$
$$C\mu^{-1}h^{-1} + C\begin{cases}\mu^{-2}h^{-2}(\hbar/\varepsilon)^{r+\frac12}(\hbar/\varepsilon\gamma)^{l} & \text{as } \gamma\varepsilon \ge \hbar\\ \mu^{-2}h^{-2}(\hbar/\varepsilon)^{r+\frac12} & \text{as } \varepsilon \ge \hbar\\ \mu^{-1}h^{-1}\varepsilon^{-1} & \text{as } \varepsilon \le \hbar\end{cases} +$$
$$C\min\big(1,(h/\gamma)^{l}\big)\times\begin{cases}\mu\varepsilon h^{-1}\big(\hbar/\varepsilon^{\frac32}\big)^{r+\frac12} + C\mu^{\frac43}\varepsilon h^{-\frac23} & \text{as } \varepsilon \ge \hbar^{\frac23}\\ \mu^{\frac53}h^{-\frac13} & \text{as } \min(\hbar,\mu^{-3}h^{-1}) \le \varepsilon \le \hbar^{\frac23}\\ \mu^{-\frac13}\varepsilon^{-1}h^{-\frac43} & \text{as } \varepsilon \le \min(\hbar,\mu^{-3}h^{-1})\end{cases}$$

while for $r = 0$

$$\mathsf{R}^{\mathsf{W}\prime\prime}_{x(0)} \coloneqq |e^{\mathsf{T}}(x,x,\tau) - \bar{e}^{\mathsf{T}}(x,x,\tau)| \le C\mu^{-1}h^{-1} + \tag{16.3.57}$$
$$C\begin{cases}h^{-1}\varepsilon^{-\frac12} & \text{as } \mu^3 h \le \varepsilon^{-1},\\ \mu^{-\frac32}h^{-\frac32}\varepsilon^{-1} & \text{as } \mu^3 h \ge \varepsilon^{-1}\end{cases}$$

and

$$\mathsf{R}^{\mathsf{W}\prime\prime}_{x(0)\gamma} \coloneqq \gamma^{-2}\Big|\int \Big(e^{\mathsf{T}}(x,x,\tau) - \bar{e}^{\mathsf{T}}(x,x,\tau)\Big)\psi_\gamma\, dx\Big| \le C\mu^{-1}h^{-1} + \tag{16.3.58}$$
$$C\begin{cases}\mu^{-\frac32}h^{-1}\varepsilon^{-1}\gamma^{-\frac12} & \text{as } \mu^{-3}\varepsilon^{-1} \le \gamma \le \min(h\varepsilon^{-1},\mu^{-1}),\\ \mu^{-2}h^{-1}\varepsilon^{-1}\gamma^{-1} & \text{as } \mu^{-1} \le \gamma \le h\varepsilon^{-1},\\ \mu h^{-1}\min\big(1,(\mu h/\varepsilon)^{\frac12}\big)(h/\varepsilon\gamma)^{l} & \text{as } \gamma \ge h\varepsilon^{-1}.\end{cases}$$

Justification

To justify (16.3.51) and thus to prove Proposition 16.3.12 we need

Proposition 16.3.13. *Consider two magnetic Schrödinger operators* A *and* $\bar{A}$ *satisfying* (16.3.54). *Then as* $|t| \le \epsilon\mu^3 h$ *and* $|\sin(t)| \ge \max\big(\epsilon\varepsilon|t|, C\hbar\big)$

$$U(x,y,t)-\bar{U}(x,y,t)\equiv (4\pi\hbar)^{-1}i(\sin(\bar{\theta}(t)))^{-1}e^{i\hbar^{-1}\bar{\phi}(x,y,t)}\sum_m b'_m(x,y,t)\hbar^m \mod O\Big(\hbar^{-2}\mu^{-3}|t||\sin(\theta(t))|^{-1}\times(\hbar/|\sin(t)|)'\Big) \tag{16.3.59}$$

with

$$|D^\beta b'_m|\le C_{m\beta}\mu^{-3}|t|\hbar^{-1}|\sin(\theta(t))|^{-m-|\beta|}. \tag{16.3.60}$$

Proof. Obviously in our assumptions

$$U(x,y,t)\equiv (4\pi\hbar)^{-1}i(\sin(\bar{\theta}(t)))^{-1}e^{i\hbar^{-1}\bar{\phi}(x,y,t)}\sum_m b''_m(x,y,t)\hbar^m \mod O\Big(\hbar^{-1}|\sin(\bar{\theta}(t))|^{-1}\times(\hbar/|\sin(\bar{\theta}(t))|)'\Big)$$

with b''_m satisfying

$$|D^\alpha b''_m|\le C_{m\alpha}|\sin(\bar{\theta}(t))|^{-m-|\alpha|}$$

and plugging it into the right-hand expression of

$$e^{i\hbar^{-1}tA}-e^{i\hbar^{-1}t\bar{A}}=i\hbar^{-1}\int_0^t e^{i\hbar^{-1}t'A}(A-\bar{A})e^{i\hbar^{-1}(t-t')\bar{A}}\,dt' \tag{16.3.61}$$

we arrive to (16.3.59). Here to cover zones where either $|\sin(t')|\le\epsilon$ or $|\sin(t-t')|\le\epsilon$ we just pass to the standard representation through non-singular oscillatory integrals (with one or two extra variable) and then apply the stationary phase method. We leave easy but tedious details to the reader. □

Corollary 16.3.14. *In the framework of Proposition 16.3.13 equality* (16.3.59) *holds with* $U(x,y,t)$ *and* $\bar{U}(x,y,t)$ *replaced respectively by*

$$(4\pi\hbar)^{-1}i(\sin(\theta(t)))^{-1}e^{i\hbar^{-1}\phi(x,y,t)}\sum_m b_m(x,y,t)\hbar^m \tag{16.3.62}$$

and

$$(4\pi\hbar)^{-1}i(\sin(\bar{\theta}(t)))^{-1}e^{i\hbar^{-1}\bar{\phi}(x,y,t)}\sum_m \bar{b}_m(x,y,t)\hbar^m. \tag{16.3.63}$$

Reduction to the Toy-Model Operator

From now we are interested *only* in the estimates without micro-averaging.

The problem however is that $\bar{A}$ at this moment is a more general operator than the toy-model: it contains linear with respect to x terms in the original (before rescaling) g^{jk} and V, and also it contains quadratic terms in $V_2 = x_1 + \frac{1}{2}\beta_{11}x_1^2 + \beta_{12}x_1x_2 + \frac{1}{2}\beta_{22}x_2^2 + ...$ all of which generate $O(\mu^{-1})$ perturbation.

However one select a conformal coordinate system in such way that $\nabla\omega(0) = 0$ [9]. Then if we know that $F = F(0) + O(|x|^2)$ we conclude that $\beta_{11} = \beta_{12} = 0$ and by a gauge transformation we can make $\beta_{22} = 0$.

Further, we can assume that $\tau = 0$ and then make $V(0) = -1$ by division $V(0) \mapsto -1$, $h \mapsto h(-V(0))^{-\frac{1}{2}}$, $\mu \mapsto \mu(-V(0))^{-\frac{1}{2}}$ before rescaling. Rescaling μ (and changing coordinate orientation if needed we can make $F(0) = 1$.

Furthermore, we can assume that $F = 1$. Really, as we can consider energy level $\tau = 0$ we starting from equation $-\hbar D_t u = Au$, go to

$$F^{-1}Au = -\hbar F^{-1}D_t u = -hD_t + \hbar F^{-1}(F-1)D_t u \tag{16.3.64}$$

and on an interval $|\tau| \le \hbar h^{-\delta}T^{-1}$ (which is completely microlocally admissible as $|t| \asymp T$ the last term is $O(\mu^{-1}\hbar h^{-\delta}T^{-1})$ and multiplying by $T\hbar^{-1}$ we get $O(\mu^{-1}h^{-\delta})$ which allows us to use the successive approximation method.

We leave to the reader to use our standard methods and solve a rather easy

Problem 16.3.15. Prove that effectively in estimates one can make $\delta = 0$.

Note that $\mu^{-1} \le \mu^{-3}h^{-1}$ as $\mu \le h^{-\frac{1}{2}}$ and therefore this new error (F is replaced by $F(0)$) does not exceed the right-hand expressions of (16.3.55) and (16.3.57) as $r \ge 1$ and $r = 0$ respectively.

Meanwhile our new error does not exceed $C\mu h^{-1} \times \mu^{-1} = Ch^{-1}$ anyway and as $\mu \ge h^{-\frac{1}{2}}$ ($\implies \varepsilon \le \hbar$) it is less than $\mu^{\frac{5}{3}}h^{-\frac{1}{3}}$ leave alone $\varepsilon^{-\frac{1}{2}}h^{-1}$ which are parts of right-hand expressions of (16.3.55) and (16.3.57) respectively. Thus we arrive to

(16.3.65) Estimates (16.3.55) and (16.3.57) hold with $\bar{A}$ which is our original toy-model operator.

---

[9] Really, changing conformal system to another conformal system is done with $y_1 = f$, $\nabla y_2 = (-f_{x_2}, f_{x_1})$ which can be satisfied iff $\Delta f = 0$; then ω is replaced by $\omega|\nabla f|$ and if $f = ax_1 + bx_1x_2 + \frac{1}{2}c(x_1^2 - x_2^2)$ then $|\nabla f| = a + bx_2 + cx_1 + O(|x|^2)$ and selecting a, b, c we can make $\omega(0) = 1$, $\nabla\omega(0) = 0$.

16.3.6 Strong Magnetic Field

Finally, let $\mu \ge h^{-1}$. Then as only matter is what is inside the circle of the radius $C_0\mu^{-\frac12}h^{\frac12}$ (we can get rid of $h^{-\delta}$ factor in estimates) we get in successive approximations $C\mu h^{-1} \times \mu^{-1}h \times \mu^{-\frac12}h^{\frac12}\varepsilon^{-1} \times h^{-1}$ where $\mu^{-1}h$ is the size of the perturbation, $\mu^{-\frac12}h^{\frac12}\varepsilon^{-1}$ is T (without rescaling); so we get $C\mu^{-\frac12}h^{-\frac12}\varepsilon^{-1}$.

We leave to the reader a rather easy

Problem 16.3.16. Prove that effectively in estimates one can make $\delta = 0$ as well in $\mu^{-\frac12+\delta}h^{\frac12}$ radius and $\mu^{-\frac12+\delta}h^{\frac12}\varepsilon^{-1}$ time.

So we arrive to

Proposition 16.3.17. *Under assumptions* (16.3.36), (16.3.37), $F = 1$ *and* (16.3.54) *estimate*

$$|e^{\mathsf{T}}(0,0,\tau) - \bar{e}^{\mathsf{T}}(0,0,\tau)| \le C\mu^{-\frac12}h^{-\frac12}\varepsilon^{-1} \qquad \text{as} \quad \mu \ge h^{-1}. \tag{16.3.66}$$

We leave to the reader yet another easy

Problem 16.3.18. Write correction to τ and may be α as $F \ne \mathsf{const}$ and $g^{jk} \ne \mathsf{const}$.

16.3.7 Main Theorem

Now we can write our main theorem of these two sections:

Theorem 16.3.19. *For magnetic Schrödinger operator in domain $X \subset \mathbb{R}^2$ such that $B(0,1) \subset X$ and satisfying conditions* (16.1.5)–(16.1.7) *the following estimates hold for $x \in B(0,\frac12)$*

(i) As $1 \le \mu \le h^{-\frac12}$

$$|e(x,x,0) - h^{-2}\mathcal{N}^{\mathsf{W}}_x(0)| \le C\mu^{-1}h^{-1} + C\mu^{\frac12}h^{-\frac12} + C\mu^2h^{-\frac12} \tag{16.3.67}$$

and

$$\begin{aligned} \mathsf{R}^{\mathsf{W}}_{x(r)} \coloneqq |e(x,x,0) - h^{-2}\big(\mathcal{N}^{\mathsf{W}}_x(0) + \mathcal{N}^{\mathsf{W}}_{x,\mathsf{corr}(r)}(0)\big)| \le \\ C\mu^{-1}h^{-1} + C\mu^{\frac12}h^{-\frac12} + C\mu h^{-1}\big(\mu^2h\big)^{r+\frac12} + \\ C\begin{cases} \Big(h^{-1}\big(h\mu^{\frac52}\big)^{r+\frac12} + \mu^{\frac13}h^{-\frac23}\Big) & \text{as} \quad \mu \le h^{-\frac25}, \\ \mu^{\frac53}h^{-\frac13} & \text{as} \quad \mu \ge h^{-\frac25}. \end{cases} \end{aligned} \tag{16.3.68}$$

(ii) As $h^{-\frac{1}{3}} \le \mu \le h^{-1}$

$$\mathsf{R}^{\mathsf{W}\prime\prime}_{x(r)} := \tag{16.3.69}$$
$$|\Big(e(x,x,\tau) - h^{-2}\mathcal{N}_{x,\mathsf{corr}(r)} - \bar{e}_x(x,x,\tau) + h^{-2}\bar{\mathcal{N}}_{x,\mathsf{corr}(r)}\Big)| \le$$
$$C\mu^{\frac{1}{2}}h^{-\frac{1}{2}} + C\begin{cases}\mu^{-2}h^{-2}(\mu^2 h)^{r+\frac{1}{2}} & \text{as } \mu \le h^{-\frac{1}{2}}\\ h^{-1} & \text{as } \mu \ge h^{-\frac{1}{2}},\end{cases} +$$
$$C\begin{cases}h^{-1}\big(\mu^{\frac{5}{2}}h\big)^{r+\frac{1}{2}} + \mu^{\frac{1}{3}}h^{-\frac{2}{3}} & \text{as } \mu \le h^{-\frac{2}{5}}\\ \mu^{\frac{5}{3}}h^{-\frac{1}{3}} & \text{as } h^{-\frac{2}{5}} \le \mu \le h^{-\frac{1}{2}},\\ \mu^{-\frac{1}{3}}h^{-\frac{4}{3}} & \text{as } \mu \ge h^{-\frac{1}{2}}\end{cases}$$

while for $r = 0$

$$\mathsf{R}^{\mathsf{W}\prime\prime}_{x(0)} := |e(x,x,\tau) - \bar{e}_x(x,x,\tau)| \le C\mu^{\frac{1}{2}}h^{-\frac{1}{2}} + \tag{16.3.70}$$
$$C\begin{cases}h^{-1}\mu^{\frac{1}{2}} & \text{as } \mu \le h^{-\frac{1}{2}},\\ \mu^{-\frac{1}{2}}h^{-\frac{3}{2}} & \text{as } \mu \ge h^{-\frac{1}{2}};\end{cases}$$

where here and in (iii) $\bar{e}_x$ *is constructed for a toy-model in* x*.*

(iii) For magnetic Schrödinger-Pauli operator with $\mu \ge h^{-1}$

$$|e(x,x,\tau) - \bar{e}_x(x,x,\tau)| \le C\mu^{\frac{1}{2}}h^{-\frac{1}{2}}. \tag{16.3.71}$$

16.3.8 Problems

Finally, let us formulate a series of the problems with probably simple parts (i) and really difficult parts (ii):

Problem 16.3.20. As $\mu \le h^{-1}$ drop condition (16.1.5) in the pointwise asymptotics:

(i) Use the simple rescaling technique $\mu \mapsto \mu\rho^{\frac{1}{2}}\mu$, $h \mapsto h\rho^{-\frac{3}{2}}$ with the scaling function $\rho(x) = \max(\epsilon_0|V(x)|, \mu h, \mu^{-1})$ reducing operator to the similar one either satisfying condition (16.1.5) or with $\mu h \asymp 1$ or with $\mu = 1$ and considered in Subsection 5.3.1; in two latter cases condition (16.1.5) is not needed.

(ii) Using propagation, improve what follows from the simple rescaling technique.

Problem 16.3.21. Derive asymptotics without condition (16.1.6) replaced by the non-degeneracy assumption (14.1.1) i.e. $|F| + |\nabla F| \asymp 1$:

(i) Use the simple rescaling technique $\mu \mapsto \mu\rho^2$, $h \mapsto h\rho^{-1}$ with the scaling function $\rho(x) = \max(\epsilon_0|F|, \mu^{-\frac{1}{2}})$.

(ii) Improve what follows from the simple rescaling technique.

Problem 16.3.22. Derive asymptotics under non-degeneracy assumption (16.1.8) rather than (16.1.7). The results of this section provide them at point x where $|\nabla V/F| \gg \bar{\gamma} := \max(\mu^{-1}, \mu^{-\frac{1}{2}}h^{\frac{1}{2}})$.

(i) Can one improve those results using that under condition $(16.1.8)^+$ and $(16.1.8)^-$ (when (16.1.8) holds but $(16.1.8)^+$ does not) the drift dynamic is elliptic elliptic and hyperbolic respectively?

(ii) Can one improve a trivial estimate $O(\mu h^{-1})$ at point x where $|\nabla V/F| \lesssim \bar{\gamma}$? Will be results affected by the difference between cases of $(16.1.8)^+$ and $(16.1.8)^-$?

16.4 Dirac Energy: 2D-Estimates

In this and the next sections we consider asymptotics of expression I defined by (16.1.2).

16.4.1 Tauberian Formula

Let us consider first contribution of the zone $\{(x,y)\colon |x-y| \ge C\gamma\}$.

Proposition 16.4.1. *Under conditions* (16.1.5)–(16.1.7) *the contribution of the zone* $\{(x,y)\colon |x-y| \ge C\gamma\}$ *to the remainder is* $O(\mu^{-1}h^{-1}\gamma^{-\kappa})$ *while the main part is given by the Tauberian approximation* I^{T}, *i.e. by the same expression* (16.1.1) *with* $e(x,y,0)$ *replaced by its standard implicit Tauberian approximation with* $T \asymp \epsilon\mu$ (16.1.11).

Proof. Recall that $e^{ih^{-1}tA}$ is the propagator of A and $U(x,y,t)$ is its Schwartz' kernel.

Consider expression (16.1.1) with $\omega(x,y)$ replaced by $\omega_\gamma(x,y)$ which is a cut-off of $\omega(x,y)$ in the zone $\{(x,y)\colon |x-y| \asymp \gamma\}$ and with the original functions ψ_1,ψ_2 replaced by 1. Let us replace *one* copy of $e(x,y,\tau)$ by $e(x,y,\tau,\tau') = \big(e(x,y,\tau) - e(x,y,\tau')\big)$ with $\tau' \le \tau$ and the second copy by $e(x,y,\tau'')$ and denote the resulting expression by $\mathsf{I}_\gamma(\tau,\tau',\tau'')$.

Now let us use decomposition

$$\omega_\gamma(x,y) = \gamma^{-d-\kappa}\int \psi_{1,\gamma}(x,z)\psi_{2,\gamma}(y,z)\,dz \tag{16.4.1}$$

with some $\psi_1,\psi_2 \in \mathscr{C}_0^\infty$; as before subscript γ means rescaling.

Then $\mathsf{I}_\gamma(\tau,\tau',\tau'')$ does not exceed

$$\sum_j C\gamma^{-\kappa}\|\varphi_j E(\tau,\tau')\varphi_j\|_1 \tag{16.4.2}$$

where $E(\tau,\tau') = E(\tau) - E(\tau')$, φ_j are real-valued γ-admissible functions supported in $C_0\gamma$-vicinities of z_j and balls $B(z_j, 2C_0\gamma)$ cover domain X with the multiplicity not exceeding C_0. Here we used that $\|E(\tau'')\| = 1$. Since $E(\tau,\tau')$ is a positive operator and $\varphi_j = \varphi_j^*$, one can replace the trace norm by the trace itself and get

$$\sum_j C\gamma^{-\kappa}\operatorname{Tr}\varphi_j E(\tau,\tau')\varphi_j = C\gamma^{-\kappa}\operatorname{Tr} E(\tau,\tau')\bar\psi \tag{16.4.3}$$

with $\bar\psi = \sum_j \varphi_j^2$.

Further, we know from the standard theory of Chapter 13 that under conditions (16.1.5)–(16.1.7)

$$\|E(\tau,\tau')\bar\psi\|_1 \le Ch^{-2}\big(|\tau-\tau'| + CT^{-1}h\big) \qquad \forall \tau,\tau' \in [-\epsilon,\epsilon],\ T = \epsilon\mu \tag{16.4.4}$$

and therefore

$$|\mathsf{I}_\gamma(\tau,\tau',\tau'')| \le C\gamma^{-\kappa}h^{-2}\big(|\tau-\tau'| + CT^{-1}h\big) \tag{16.4.5}$$

in the same framework, and therefore due to the standard Tauberian arguments we conclude that the contribution of zone $\{(x,y)\colon |x-y| \asymp \gamma\}$ to the Tauberian remainder estimate does not exceed $C\mu^{-1}h^{-1}\gamma^{-\kappa}$ which implies the statement immediately. □

However we need to consider also zone $\{(x,y)\colon |x-y|\le C\gamma\}$, complementary to one above. Assume that

$$\Omega_\kappa(z)=\sum_j D_{z_j}\Omega_{\kappa-1,j}+\Omega_{\kappa-1,0} \tag{16.4.6}$$

with the first subscript at Ω showing the degree of the singularity. Then

$$\omega_\kappa(x,x-y)\psi_\gamma(x-y)=\sum_j D_{x_j}\bigl(\omega_{\kappa-1,j}\psi_\gamma\bigr)+\omega_\kappa\psi'_\gamma+\omega_{\kappa-1}\psi''_\gamma \tag{16.4.7}$$

where $\psi_\gamma=\psi((x-y)\gamma^{-1})$ with ψ supported in $B(0,1)$ and equal 1 in $B(0,\frac12)$ while ψ'_γ is defined similarly with ψ' supported in $B(0,1)\setminus B(0,\frac12)$ and the last term gains 1 in the regularity.

After integration by parts expression $\mathsf{I}_{\kappa,\gamma}$, defined by (16.1.10) with Ω replaced by $\Omega\psi_\gamma$, becomes

$$-h^{-1}\sum_j\iint \omega_{\kappa-1,j}(x,y)(hD_{x_j})\bigl(e(x,y,\tau)\cdot e(y,x,\tau)\bigr)\,dxdy \tag{16.4.8}$$

plus two other terms: the term defined by (16.1.1) with the kernel $\Omega'_{\kappa,j}$ of the same singularity κ, albeit without factor h^{-1} and supported in the zone $\{(x,y)\colon |x-y|\ge\frac12\gamma\}$, and the term defined by (16.1.1) with the kernel $\Omega'_{\kappa-1,j}$, also without factor h^{-1} and of singularity $(\kappa-1)$.

The former term could be considered as before yielding to the same remainder estimate $O(\mu^{-1}h^{1-d}\gamma^{-\kappa})$. To the latter term we can apply the same trick again and again raising power (and these terms are treated in the same manner (but simpler) as we deal below with (16.4.8).

So, one needs to consider (16.4.8) and thus, denoting the second copy of $e(y,x,\tau)$ by $f(y,x,\tau)$ and without using that they are equal

$$\begin{aligned}&(hD_{x_j})\bigl(e(x,y,\tau)\cdot f(y,x,\tau)\bigr)=\\ &\bigl(hD_{x_j}e(x,y,\tau)\bigr)f(y,x,\tau)\ -\ e(x,y,\tau)\bigl(f(y,x,\tau)\,{}^t(hD_{x_j})\bigr)=\\ &\bigl(P_{j,x}e(x,y,\tau)\bigr)f(y,x,\tau)\ -\ e(x,y,\tau)\bigl(f(y,x,\tau)\,{}^tP_{j,x}\bigr).\end{aligned} \tag{16.4.9}$$

Recall that $P_j=hD_j-\mu V_j(x)$ and ${}^tP_j=-hD_j-\mu V_j(x)$ is the dual operator. Also recall that if $e(x,y,\tau)$ and $f(y,x,\tau)$ are Schwartz kernels of $E(\tau)$ and $F(\tau)$, then $P_{j,x}e(x,y,\tau)$ and $f(y,x,\tau)\,{}^tP_{j,x}$ are those of $P_jE(\tau)$ and $F(\tau)P_j$.

Therefore we are interested in the expressions of the type

$$h^{-1}\iint \omega_{\kappa-1}(x,y)e(x,y,\tau)f(x,y,\tau)\psi_\gamma\,dxdy. \tag{16.4.10}$$

If $\kappa\le 1$ then replacing $e(x,y,\tau)$ and $f(y,x,\tau)$ by their standard Tauberian expressions one gets an error not exceeding $Ch^{-1}\times\mu^{-1}h^{-2}\gamma^{1-\kappa}$ because $\|P_jE(\tau)\|\le C_0$, $\|P_jF(\tau)\|\le C_0$ where $F(\tau)$ is an operator with the Schwartz kernel $f(x,y,\tau)$ and also because

$$\begin{aligned}\sum_j \|\varphi_jP_jE(\tau,\tau')\varphi_j\|_1 \le \sum_j \|\varphi_jP_jE(\tau,\tau')\|_2\cdot\|E(\tau,\tau')\varphi_j\|_2 \le\\ \sum_j \|\varphi_jP_jE(\tau,\tau')\|_2^2+\sum_j\|E(\tau,\tau')\varphi_j\|_2^2=\\ \sum_j \mathsf{Tr}\,\varphi_jP_jE(\tau,\tau')P_j^*\varphi_j+\sum_j\mathsf{Tr}\,\varphi_jE(\tau,\tau')\varphi_j\\ \le Ch^{-2}\bigl(|\tau-\tau'|+C\mu^{-1}h\bigr)\qquad \forall\tau,\tau'\in[-\epsilon,\epsilon]\end{aligned} \tag{16.4.11}$$

which also easily follows from Chapter 13.

So, in this case one gets remainder estimate $O\bigl(\mu^{-1}h^{-1}\gamma^{-\kappa}+\mu^{-1}h^{-2}\gamma^{1-\kappa}\bigr)$ which is optimized to $O(\mu^{-1}h^{-1-\kappa})$ as $\gamma\asymp h$.

On the other hand, as $1<\kappa<2$ one can apply the same trick again since we did not use the fact that $e(.,.,.)$ and $f(.,.,.)$ coincide; then we arrive to the same estimates with P_j replaced by P_jP_k or even by $P^J:=P_{j_1}P_{j_2}\cdots P_{j_l}$:

$$\mathsf{Tr}\,P^JE(\tau,\tau')(P^J)^*\le Ch^{-2}(|\tau-\tau'|+\mu^{-1}h)\qquad\forall\tau,\tau'\in[-\epsilon,\epsilon]. \tag{16.4.12}$$

Finally,

Remark 16.4.2. note that as $\kappa\ne 1$, decomposition (16.4.6) is always possible. Further, as $\kappa=1$ this decomposition is possible as well provided one adds term $\varkappa(x)|x-y|^{-1}$ with an appropriate coefficient. On the other hand, if $\kappa=1$ and $\omega(x,y)=\varkappa(x)|x-y|^{-1}$ then this decomposition is also possible but with $\omega_{0,j}(x,y)=\varkappa(x)(x_j-y_j)|x-y|^{-1}\log|x-y|$.

So we arrive to

Proposition 16.4.3. *Let conditions* (16.1.5)–(16.1.7) *be fulfilled. Then*

(i) As $0 < \kappa < 2$ *and* <u>*either*</u> $\kappa \neq 1$ <u>*or*</u> $\kappa = 1$ *and* $\omega(x,y)$ *is replaced by* $\omega(x,y) - \varkappa(\frac{1}{2}(x+y))|x-y|^{-1}$ *with an appropriate smooth coefficient* $\varkappa(x)$*, with the error* $O(\mu^{-1}h^{-1-\kappa})$ *one can replace* $e(x,y,\tau)$ *by its standard Tauberian expression* (16.1.11) *in the formula* (16.1.11) *for* I.

(ii) As $\kappa = 1$ *and* $\omega = \varkappa(\frac{1}{2}(x+y))|x-y|^{-1}$*, with the error* $O(\mu^{-1}h^{-1-\kappa}|\log h|)$ *one can replace* $e(x,y,\tau)$ *by its standard Tauberian expression* (16.1.11) *in the formula* (16.1.11) *for* I.

Remark 16.4.4. (i) The arguments above show that in an appropriate sense one can consider arbitrary $\kappa \in \mathbb{R}$ and even in $\mathbb{C}$.

(ii) One needs only (16.4.12) rather than (16.1.5)–(16.1.7), and (16.4.12) holds as (16.1.7) is replaced by a weaker non-degeneracy condition $(16.1.8)^{+}$.

(iii) Furthermore (16.4.12) with an extra factor $(1+\mu h|\log h|)$ in the right-hand expression holds under condition (16.1.8).

The following problem seems to be difficult even without magnetiv field:

Problem 16.4.5. Can one prove the similar result for I_m with $m \geq 3$:

$$I_m \coloneqq \iint \omega(x^1,\dots,x^m)e(x^1,x^2,\tau)\psi_2(x^1)e(x^2,x^3,\tau)\cdots e(x^m,x^1,\tau)\psi_{m+1}(x^0)\times dx^1\cdots dx^m$$

with $x^{m+1} = x^1$, $\psi_{m+1} \coloneqq \psi_1$ etc and

$\omega(x^1,\dots,x^m) \coloneqq \Omega(x^1,\dots,x^m;\{x^j - x^{j+1}\}_{1\leq j\leq m})$ where function Ω is smooth in $B(0,1)^m \times B(\mathbb{R}^d\setminus 0)^{m-1}$ and homogeneous of degree $-(m-1)\kappa$ with respect to $\{x^j - x^k\}_{1\leq j<k\leq m}$. Moreover,

$$|D_z^\beta D_x^\alpha \Omega| \leq C_{\beta,\alpha}|z^1|^{-\kappa-|\beta^1|}\cdots|z^m|^{-\kappa-|\beta^m|} \qquad \text{as } \sum_k |z^k|^2 = 1,\ \sum_k z^k = 0$$

where $x = (x^1,\dots,x^m)$, $z = (z^1,\dots,z^m)$, etc.

Thus we arrive to

Proposition 16.4.6. *Let conditions* (16.1.5) *and* (16.1.6) *be fulfilled.*

(i) Further, let either condition (16.1.8)$^+$ *be fulfilled or condition* (16.1.8) *be fulfilled and* $\mu \le h^{-1}|\log h|^{-1}$. *Then* (16.1.11) *and Statements (i), (ii) of Proposition 16.4.3 hold.*

(ii) On the other hand, let condition (16.1.8) *be fulfilled and* $h^{-1}|\log h|^{-1} \le \mu \le h^{-1}$. *Then* (16.1.11) *and Statements (i), (ii) of Proposition 16.4.3 hold with an extra factor* $(1+\mu h|\log h|)$ *in the right-hand expressions.*

Remark 16.4.7. Under certain assumptions (see Chapter 19) this result could be generalized for $d \ge 4$. However in calculations we use that $d = 2$.

16.4.2 Strong Magnetic Field

Consider Schrödinger-Pauli operator as $\mu h \ge \epsilon_0$. Then we arrive immediately

Proposition 16.4.8. *Let* $\mu h \ge \epsilon_0$. *Then*

(i) Contribution of $\{|x-y| \ge \gamma\}$ *to* I *does not exceed* $C\mu h^{-1}\gamma^{-\kappa}$.

(ii) Further,

$$|\mathsf{I}| \le C\mu^{1+\frac{1}{2}\kappa}h^{-1-\frac{1}{2}\kappa}. \tag{16.4.13}$$

(iii) Furthermore, $\mathsf{I} = O(\mu^{-\infty})$ *provided*

$$V + \mu hF \ge \epsilon \qquad \forall x \in B(0,1); \tag{16.4.14}$$

in particular it is the case as $\mathfrak{z} < 1$ *and* $\mu h \ge C_0$.

Proof. Statement (i) trivially follows from the fact that $\mathscr{L}^2$ norm of $e(.,,,\tau)$ does not exceed $C\mu^{\frac{1}{2}}h^{-\frac{1}{2}}$.

Meanwhile contribution of the zone $\{(x,y) : x \in B(0,1), y \in B(0,1), |x-y| \le \gamma\}$ does not exceed $C\mu^2h^{-2}\gamma^{2-\kappa}$. Adding to (i) we conclude that the sum reaches its minimal $C\mu^{1+\frac{1}{2}\kappa}h^{-1-\frac{1}{2}\kappa}$ value as $\gamma = \mu^{-\frac{1}{2}}h^{\frac{1}{2}}$ which implies Statement (ii).

Finally, Statement (iii) is due to the fact that $e(x,y,0) = O(\mu^{-\infty})$ as long as condition (16.4.14) is fulfilled in one of points x, y; see Subsection 13.6.1.□

Proposition 16.4.9. *Let conditions* (16.1.1)–(16.1.5) *be fulfilled. Let* $\mu h \ge \epsilon$ *and one of the nondegeneracy conditions*

$$|\frac{V}{F} + (2m+1)\mu h| + |\nabla \frac{V}{F}| \ge \epsilon \tag{16.4.15}$$

or

$$|\frac{V}{F} + (2m+1)\mu h| + |\nabla \frac{V}{F}| \le \epsilon \implies \det \mathsf{Hess}\, \frac{V}{F} \ge \epsilon \tag{16.4.17}^{+}$$

be fulfilled.

(i) As $\gamma \ge C_0 \mu^{-\frac{1}{2}} h^{-\frac{1}{2}}$ *contribution of* $\{|x-y| \ge \gamma\}$ *to* I *does not exceed* $C\gamma^{-2-\kappa}$.

(ii) Estimate

$$|\mathsf{I} - \mathsf{I}^{\mathsf{T}}| \le C\mu^{\frac{1}{2}\kappa} h^{-\frac{1}{2}\kappa} \tag{16.4.16}$$

holds as $\kappa \ne 1$*; as* $\kappa = 1$ *this estimate holds with an extra factor* $|\log \mu|$ *in its right-hand expression.*

(iii) If instead of (16.4.15) *or* $(16.4.17)^{+}$ *we assume that*

$$|\frac{V}{F} + (2m+1)\mu h| + |\nabla \frac{V}{F}| \le \epsilon \implies |\det \mathsf{Hess}\, \frac{V}{F} \ge \epsilon| \tag{16.4.17}$$

then Statements (i), (ii) hold with an extra factor $|\log \mu|$ *in the right-hand expressions.*

(iv) $\mathsf{I} - \mathsf{I}^{\mathsf{T}} = O(\mu^{-\infty})$ *under ellipticity condition* $|V + (2m+1)\mu h F| \ge \epsilon$. *In particular, it happens as* $1 < \mathfrak{z} \notin 2\mathbb{Z}+1$ *and* $\mu h \ge C_0$.

Proof. (a) To prove Statement (i) recall that the drift speed does not exceed $C\mu^{-1}$ and therefore Hilbert-Schmidt norm of $\psi E(\tau)\psi'$ does not exceed C as ψ, ψ' are $\mathscr{C}_0^\infty$-functions with $\mathsf{dist}(\mathsf{supp}\,\psi, \mathsf{supp}\,\psi') \asymp 1$.

Really, it is true for a Hilbert-Schmidt norm of $\big(E(\tau) - E(\tau')\big)\psi$ with $|\tau - \tau'| \le \mu^{-1}h$ and then by Tauberian theorem it is true for a Hilbert-Schmidt norm of $\big(E(\tau) - E^{\mathsf{T}}(\tau)\big)\psi'$ with E^{T} operator with the Schwartz kernel e^{T} with time $T \asymp \mu$. However $\psi E^{\mathsf{T}} \psi'$ is negligible as $T \le \epsilon\mu$ due to propagation results.

Then rescaling $x \mapsto x/\gamma$, $y \mapsto y/\gamma$, $h \mapsto h/\gamma$, $\mu \mapsto \mu\gamma$ we conclude that for γ-admissible ψ, ψ' with $\mathsf{dist}(\mathsf{supp}\,\psi, \mathsf{supp}\,\psi') \asymp 1$ Hilbert-Schmidt norm of $\psi E(\tau)\psi'$ does not exceed C and therefore the contribution of

$$K(z) = \{(x,y) : |x-z| \le 2\gamma, |y-z| \le 2\gamma, |x-y| \ge \gamma\}$$

does not exceed $\gamma^{-\kappa}$; therefore taking partition we conclude that the contribution of zone $\{(x,y) \in B(0,1) \times B(0,1), |x-y| \ge \gamma\}$ does not exceed $C\gamma^{-2-\kappa}$.

(b) Statement (iv) follows from the fact $e - e^{\mathsf{T}} = O(\mu^{-\infty})$ under ellipticity condition.

(c) To prove Statement (ii) we apply the same arguments as in Proposition 16.4.3. While (16.4.1)–(16.4.3), (16.4.6)–(16.4.10) remain true, (16.4.4), (16.4.5) should be modified: factor h^{-2} must be replaced by μh^{-1}.

We claim that

(16.4.18) As $0 < \kappa < 1$ (16.4.11) holds with factor h^{-2} replaced by $\mu^{\frac{3}{2}} h^{-\frac{1}{2}}$.

Really, the same arguments are applied as before albeit now $P_j E(\tau)$ is bounded by $C_0(\mu h)^{\frac{1}{2}}$ rather than by C_0.

Then we arrive to the remainder estimate $O\big(\gamma^{-\kappa} + \mu^{\frac{1}{2}} h^{-\frac{3}{2}} \gamma^{1-\kappa}\big)$ and optimizing by $\gamma = \bar\gamma := C\mu^{-\frac{1}{2}} h^{\frac{1}{2}}$ we arrive to the remainder estimate $O(\bar\gamma^{-\kappa})$.

As $\kappa = 1$ we get the same estimate albeit with a logarithmic factor.

To tackle the case $1 < \kappa < 2$ one should replace (16.4.12) by

$$(16.4.12)' \quad \mathsf{Tr}\, P^J E(\tau,\tau')(P^J)^* \le C\mu h^{-1}(|\tau-\tau'| + \mu^{-1}h)(\mu h)^{|J|} \qquad \forall \tau, \tau' \in [-\epsilon, \epsilon]$$

as $\mu h \ge 1$; one can prove it easily as $\|P^J E(\tau)\| \le C(1+\mu h)^{\frac{1}{2}|J|}$.

Then as $1 < \kappa < 2$ we arrive to the remainder estimate $O(\gamma^{-\kappa} + \mu h^{-1}\gamma^{2-\kappa})$ and optimizing by $\gamma = \bar\gamma$ we again arrive to the remainder estimate $O(\bar\gamma^{-\kappa})$.

Finally, the above arguments imply Statement (iii). □

16.5 Dirac Energy: 2D-Calculations

16.5.1 Toy Model

Transformations

Consider toy-model operator (16.2.1). Let us rescale as before[10]. Then as $U(x,y,t)$ is defined by (16.2.9)–(16.2.10), and $e(x,y,\tau)$ is given by (16.2.13), and † means a complex conjugation we get

$$\begin{aligned}(16.5.1)\quad \mathsf{I} \coloneqq (2\pi)^{-2}\mu^{-4+\kappa} &\iint\iint \omega(\mu^{-1}x,\mu^{-1}y)(t't'')^{-1}\times\\ &e^{-i\hbar^{-1}(t'-t'')\tau}U(x,y,t')U^\dagger(x,y,t'')\,dt'dt''\,dxdy =\\ \frac{1}{4}(2\pi)^{-4}\hbar^{-2}\mu^{\kappa} &\iint\iint \omega(x,y)\csc(t')\csc(t'')(t't'')^{-1}\times\\ &\exp\Big(i\hbar^{-1}\big(\bar\phi(x,y,t')-\bar\phi(x,y,t'')-(t'-t'')\tau\big)\Big)\,dt'dt''\,dxdy\end{aligned}$$

with

$$\begin{aligned}(16.5.2)\quad \bar\phi(x,y,t')-\bar\phi(x,y,t'')-(t'-t'')\tau =&\\ -\frac{1}{4}\big(\cot(t')-\cot(t'')\big)(x_1-y_1)^2&\\ -\frac{1}{4}\cot(t')(x_2-y_2+2t'\varepsilon)^2+\frac{1}{4}\cot(t'')(x_2-y_2+2t''\varepsilon)^2&\\ +(x_1+y_1+2\varepsilon)(t'-t'')\varepsilon-(t'-t'')(\tau+\varepsilon^2).&\end{aligned}$$

Recall that in the original coordinates $\omega(x,y)=\Omega\big(\frac{1}{2}(x+y);x-y\big)$ where $\Omega(.,.)$ is uniformly smooth with respect to the first variable and positively homogeneous of degree $-\kappa$ with respect to the second one as $|x-y|\le 1$. Therefore without any loss of the generality one can assume that

$$(16.5.3)\qquad \omega(x,y)=\Omega\big(\frac{1}{2}(x+y);x-y\big)\psi(x-y)$$

where now Ω is positively homogeneous of degree $-\kappa$ and $\psi\in\mathscr{C}_0^\infty\big(B(0,1)\big)$ equal 1 in $B(0,\frac{1}{2})$; the difference would be of the same nature but with κ replaced by 0.

[10] We need to add factor $\mu^{-4+\kappa}=\mu^{-2}\times\mu^{-2}\times\mu^{-\kappa}$ where two factors μ^{-2} are coming from dx and dy and μ^{κ} from ω.

We can replace variables x, y with new variables $\mathsf{x} := \frac{1}{2}(x+y)$ and $z := (x-y)$ and rescale. Note that (16.5.2) depends on x in a very specific way: it does not depend on x_2 at all and it is linear with respect to x_1; thus (16.5.1) becomes[11)]

$$\frac{1}{4}(2\pi)^{-3}\hbar^{-2}\mu^{\kappa+2}\iint\iint \hat{\Omega}\big(2h^{-1}\varepsilon(t'-t''),z\big)\csc(t')\csc(t'')(t't'')^{-1}\times$$
$$\exp\Big(i\hbar^{-1}\Big(-\frac{1}{4}\big(\cot(t')-\cot(t'')\big)z_1^2-\frac{1}{4}\cot(t')(z_2+2t'\alpha\mu^{-1})^2+$$
$$\frac{1}{4}\cot(t'')(z_2+2t''\varepsilon)^2-(t'-t'')(\tau-\varepsilon^2)\Big)\Big)\,dt'dt''\,\psi(\mu^{-1}z)\,dz_1dz_2$$

where $\hat{\Omega}(\lambda;z) = F_{\mathsf{x}_1\to\lambda}\Omega$ is a partial Fourier transform. Rewriting the third line in (16.5.2) as

$$-\frac{1}{4}\big(\cot(t)-\cot(t')\big)(x_2-y_2+(t+t')\varepsilon)^2$$
$$-\frac{1}{4}\big(\cot(t)-\cot(t')\big)(t-t')^2\varepsilon^2-$$
$$\frac{1}{2}\big(\cot(t)+\cot(t')\big)\big(x_2-y_2+(t+t')\varepsilon\big)(t-t')\varepsilon$$

and replacing $t' = t+s$, $t'' = t-s$ we arrive to

(16.5.4) $\mathsf{I} =$
$$\frac{1}{2}(2\pi)^{-3}\hbar^{-2}\mu^{\kappa+2}\iint\iint \hat{\Omega}(4h^{-1}\varepsilon s,z)\csc(t+s)\csc(t-s)(t+s)^{-1}(t-s)^{-1}\times$$
$$\exp\Big(i\hbar^{-1}\Big[-\frac{1}{4}\big(\cot(t+s)-\cot(t-s)\big)\big(z_1^2+(z_2+2t\varepsilon)^2+4s^2\varepsilon^2\big)$$
$$-\big(\cot(t+s)+\cot(t-s)\big)s\varepsilon-2s(\tau-\varepsilon^2)\Big]\Big)\,dtds\,\psi(\mu^{-1}z)dz_1dz_2.$$

Remark 16.5.1. (i) For a sake of simplicity we assume (without any loss of the generalization) that $\alpha > 0$.

(ii) If $\alpha \ll 1$ in the above analysis applied to the general operators we need to take α-admissible with respect to x function Ω_α instead of Ω; thus

[11)] In these calculations we skip x_2 as an argument of Ω and integration by $d\mu^{-1}\mathsf{x}_2$

up to the shift we replace $\Omega(x,\cdot)$ by $\Omega(x\alpha^{-1},\cdot)$ and thus $\hat\Omega(2h^{-1}\varepsilon s,\cdot)$ by $\alpha^2\hat\Omega(2h^{-1}\varepsilon\alpha s,\cdot)$. In this case we will use notation I_α instead of I.

In the same time we need to consider separately $|z|\le\mu\alpha$ and $|z|\ge\mu\alpha$. For a while we will not assume that $\varepsilon\asymp\mu^{-1}\alpha$.

Case $\alpha^2\gg\mu h$

Assume first that

$$\alpha^2\ge\mu h^{1-\delta} \tag{16.5.5}$$

where for a sake of simplicity we assume that $\alpha>0$ (and therefore $\varepsilon>0$).

Remark 16.5.2. (i) In the virtue of the factor $\hat\Omega(2\hbar^{-1}\alpha^2 s,\cdot)$ under assumption (16.5.5) we need to consider only $|s|\le h^\delta$ and therefore we can consider separately $|t'|\le\epsilon_0, |t''|\le\epsilon_0$ and $|t'|\ge\epsilon_0, |t''|\ge\epsilon_0$.

(ii) Note that due to Section 6.4 contribution of zone $\{|t'|\le\epsilon_0, |t''|\le\epsilon_0\}$ defined by integral expressions (16.5.1) or (16.5.4) with an extra factor $\bar\chi_{\epsilon_0}(t')$ or $\bar\chi_{\epsilon_0}(t'')$ or $\bar\chi_{\epsilon_0}(t)$ differs from the same expression for non-magnetic Schrödinger operator by $O(\mu h^{-1-\kappa}\times\hbar^\kappa)=O(\mu^{\kappa+1}h^{-1})$ as $\kappa\ne1$ and by $O(\mu^2h^{-1}|\log\mu|)$ as $\kappa=1$.

(iii) Furthermore, if we remove from this expression for a non-magnetic Schrödinger operator cut-off $\{|t'|\ge\epsilon_0\}$ then the error would not exceed the same expression as well.

Let us consider contribution of the zone $\{|t'|\ge\epsilon_0, |t''|\ge\epsilon_0\}$ defined by an integral expressions (16.5.1) or (16.5.4) with an extra factor $\big(1-\bar\chi_{\epsilon_0}(t')\big)$. Due to Remark 16.5.2(i) we need to consider only t', t'' belonging to the same tick.

Let us consider first zone

$$\{|s|\ge\hbar/\alpha^2, |\sin(t)|\ge C|s|\}. \tag{16.5.6}$$

Then $\cot(t')-\cot(t'')\asymp-\sin^{-2}(t)s$ and integration by parts with respect to z delivers one of the factors

$$|s|^{-1}\hbar\big(|z_1|^2+|z_2|\cdot|z_2+\varepsilon t|\big)^{-1}|\sin(t)|^2, \tag{16.5.7}$$

$$|s|^{-1}\hbar\big(|z_1|^2+|z_2+\varepsilon t|^2\big)^{-1}|\sin(t)|^2. \tag{16.5.8}$$

Thus integrating by parts many times in the zone where both of these factors are less than 1 we acquire factors

$$\Big(1+|s|\hbar^{-1}\big(|z_1|^2+|z_2|\cdot|z_2+\varepsilon t|\big)|\sin(t)|^{-2}\Big)^{-l}, \tag{16.5.9}$$

$$\Big(1+|s|\hbar^{-1}\big(|z_1|^2+|z_2+\varepsilon t|^2\big)|\sin(t)|^{-2}\Big)^{-l} \tag{16.5.10}$$

respectively. Multiplying by $|z|^{-\kappa}$ and integrating we get after multiplication by $|\sin(t)|^{-2}$

$$\asymp |\sin(t)|^{-\kappa}|s|^{-1+\frac{1}{2}\kappa}\hbar^{1-\frac{1}{2}\kappa} \tag{16.5.11}$$

and integrating by t over one tick intersected with $\{t:\ |\sin(t)|\ge |s|\}$ we get

$$C\hbar^{1-\frac{1}{2}\kappa}\begin{cases} |s|^{-1+\frac{1}{2}\kappa} & \kappa<1,\\ |s|^{-\frac{1}{2}\kappa} & \kappa>1,\\ |s|^{-\frac{1}{2}}\big(1+|\log|s||\big) & \kappa=1.\end{cases} \tag{16.5.12}$$

This expression (16.5.12) must be <u>either</u> integrated by with respect to s: $|s|\le \hbar/\alpha^2$ <u>or</u> multiplied by $(\hbar/\alpha^2)^l|s|^{-l}$ due to factor $\hat\Omega$ and integrated over $|s|\ge \hbar/\alpha^2$, resulting in both cases in the same answer which is the value of (16.5.12) $\times |s|$ calculated as $s=\hbar/\alpha^2$ i.e.

$$C\hbar^{1-\frac{1}{2}\kappa}\begin{cases} (\hbar/\alpha^2)^{\frac{1}{2}\kappa} & \kappa<1,\\ (\hbar/\alpha^2)^{1-\frac{1}{2}\kappa} & \kappa>1,\\ (\hbar/\alpha^2)^{\frac{1}{2}}\big(1+|\log(\hbar/\alpha^2)|\big) & \kappa=1.\end{cases} \tag{16.5.13}$$

In addition to zone (16.5.6) we need to consider zone

$$\{|\sin(t')|\asymp |s|,\ |\sin(t'')|\le |s|\}; \tag{16.5.14}$$

its tween $\{|\sin(t')|\asymp |s|,\ |\sin(t'')|\le |s|\}$ is considered in the same way.

In zone (16.5.14) $|\cot(t')-\cot(t'')|\asymp |\sin(t'')|^{-1}$ and in this case (16.5.7), (16.5.8) are replaced by

$$\hbar\big(|z_1|^2+|z_2|\cdot|z_2+\varepsilon t|\big)^{-1}|\sin(t'')|, \tag{16.5.7$'$}$$

$$\hbar\big(|z_1|^2+|z_2+\varepsilon t|^2\big)^{-1}|\sin(t'')| \tag{16.5.8$'$}$$

and (16.5.9), (16.5.10) by

$$\Big(1+\hbar^{-1}\big(|z_1|^2+|z_2|\cdot|z_2+\varepsilon t|\big)|\sin(t'')|^{-1}\Big)^{-l}, \tag{16.5.9$'$}$$

$$\Big(1+\hbar^{-1}\big(|z_1|^2+|z_2+\varepsilon t|^2\big)|\sin(t'')|^{-1}\Big)^{-l}. \tag{16.5.10$'$}$$

Then, multiplying by $|z|^{-\kappa}$ and integrating we get after multiplication by $|\sin(t'')|^{-1}|\sin(t')|^{-1}$

$$\hbar^{1-\frac{1}{2}\kappa}|\sin(t'')|^{-\frac{1}{2}\kappa}|s|^{-1}; \tag{16.5.11$'$}$$

then integrating by $|t''|$ over one tick but intersected with $\{|\sin(t'')|\le |s|\}$ we get

$$\hbar^{1-\frac{1}{2}\kappa}|s|^{-\frac{1}{2}\kappa}. \tag{16.5.12$'$}$$

Finally, either integrating over $|s|\le \hbar/\alpha^2$ or multiplying by $|s|^{-l}(\hbar/\alpha^2)^l$ and integrating over $|s|\ge \hbar/\alpha^2$ we get in both cases the same answer $\hbar^{1-\frac{1}{2}\kappa}(\hbar\alpha^2)^{1-\frac{1}{2}\kappa}$ not exceeding (16.5.13).

Therefore the total contribution of zones (16.5.6) and (16.5.14) is given by expression (16.5.13). Then multiplying by $|k|^{-2}\mu^\kappa h^{-2}\alpha^2$ we get after summation with respect to $k: |k|\ge 1$ the value as $k=1$ i.e. (16.5.13) $\times$ $\mu^\kappa h^{-2}\alpha^2$.

Therefore we arrive to

Proposition 16.5.3. *For the toy-model operator with* $1\le \mu\le h^{-1}$ *and* $\alpha\ge \epsilon_0\mu^{-1}$ *under additional assumption* (16.5.5)

$$|\mathsf{I}^{\mathsf{T}}_\alpha-\mathsf{I}^{\mathsf{T}\prime}_\alpha|\le CR^{\mathsf{W}}(\alpha):= C\begin{cases}\mu^{1+\kappa}h^{-1}\alpha^{2-\kappa} & 0<\kappa<1,\\ \mu^2h^{-\kappa}\alpha^\kappa & 1<\kappa<2,\\ \mu^2h^{-1}\alpha(1+|\log(\mu h/\alpha^2)|) & \kappa=1,\end{cases} \tag{16.5.15}$$

where $\mathsf{I}^{\mathsf{T}\prime}_\alpha$ *is a Tauberian expression for* I *albeit with* $T=\epsilon_0\mu^{-1}$.

Now we need to explore the difference between $\mathsf{I}^{\mathsf{T}\prime}_\alpha$ and $\mathcal{I}^{\mathsf{W}}_\alpha$ defined by (16.1.9).

Proposition 16.5.4. *For the toy-model operator with* $1 \le \mu \le h^{-1}$ *and* $\alpha \ge \epsilon_0 \mu^{-1}$

$$|\mathsf{I}^{\mathsf{T}\,\prime}_{\alpha} - \mathcal{I}^{\mathsf{W}}_{\alpha}| \le C\mu^2 h^{-\kappa}\alpha^2. \tag{16.5.16}$$

Proof. Repeating arguments of Subsection 6.4.4 one can prove easily that

$$|\mathsf{I}^{\mathsf{T}\,\prime}_{\alpha} - \sum_{l:0\le l\le L-1, j=0,1} \mathcal{I}^{\mathsf{W}}_{(l)j,\alpha}\mu^l| \le C(\mu h)^L h^{-2-\kappa}\alpha^2 + C\mu^{\kappa+1}h^{-1}\alpha^2 \tag{16.5.17}$$

where $\mathcal{I}^{\mathsf{W}}_{(l)j,\mu^{-1}}$ is defined by (16.1.9) albeit with $\Omega(\frac{1}{2}(x+y), x-y)$ multiplied by a homogeneous polynomial of degree $(l+j)$ with respect to $(x-y)$ and for $l=j=0$ this polynomial is 1 and with integrals taken only over zone $\{(x,): |x-y| \lesssim \mu^{-1}\}$.

Since without any loss of the generality we can assume that Ω is even with respect to the second argument, all terms with odd $(l+j)$ vanish and since replacing μ by $-\mu$ we should arrive to the same result, all terms with odd l vanish and therefore

(16.5.18) In (16.5.17) all terms vanish except those with $j=0$ and even l.

Picking $L=2$ we arrive then to (16.5.16). □

Combining Propositions 16.5.3 and 16.5.4 and noting that the right-hand expression of (16.5.16) does not exceed $CR^{\mathsf{W}}(\alpha)$ we arrive to

Corollary 16.5.5. *For the toy-model operator with* $1 \le \mu \le h^{-1}$ *and* $\alpha \ge \epsilon_0\mu^{-1}$ *under additional assumption* (16.5.5)

$$|\mathsf{I}^{\mathsf{T}}_{\alpha} - \mathcal{I}^{\mathsf{W}}_{\alpha}| \le CR^{\mathsf{W}}(\alpha). \tag{16.5.19}$$

Improvement

In a certain case (under assumption (16.5.22) below) we can improve the results of the previous Subsubsection 16.5.1. To do this we note that (an easy proof is left to the reader)

Remark 16.5.6. Let $\zeta \le \varepsilon|t|$ with

$$\zeta := (\hbar/|s|)^{\frac{1}{2}}|\sin(t)|. \tag{16.5.20}$$

Then the sum of (16.5.9) and (16.5.10), multiplied by $|z|^{-\kappa}\,dz$ and integrated, does not exceed

$$C\begin{cases}\zeta^2(\varepsilon|t|)^{-\kappa} & 0<\kappa<1,\\ \zeta^{4-2\kappa}(\varepsilon|t|)^{\kappa-2} & 1<\kappa<2,\\ \zeta^2(\varepsilon|t|)^{-1}(1+|\log(\zeta/\varepsilon|t|)) & \kappa=1.\end{cases} \tag{16.5.21}$$

We need to multiply by $|\sin(t)|^{-2}\,dt$ and integrate. Then as $0<\kappa<1$ main contribution came from $\sin(t)\asymp 1$ and improvement is possible iff then $\zeta\le\varepsilon$ (as $|k|=1$ provided the large part of contribution). But as $s\asymp\hbar/\alpha^2$, $\sin(t)\asymp 1$ (which was the main contributor in the previous subsubsection) $\zeta\asymp\alpha$ while $\varepsilon=\mu^{-1}\alpha$.

So, improvement is possible only for $1<\kappa<2$. In this case main contribution came from $\sin(t)\asymp s$ and improvement is possible if then $\zeta\asymp(\hbar|s|)^{\frac12}\le\mu^{-1}\alpha$. Setting $|s|=\hbar/\alpha^2$ we have $\zeta\asymp\hbar/\alpha$ and therefore improvement is possible if

$$\alpha^2\ge\mu^2 h. \tag{16.5.22}$$

Consider zone (16.5.6) first. Then multiplication by $|\sin(t)|^{-2}\,dt$ and integration results instead of (16.5.12) in

$$C\begin{cases}\hbar^{\frac12}|s|^{-\frac12}\varepsilon^{1-\kappa} & 1<\kappa<\dfrac32,\\ \hbar^{2-\kappa}|s|^{1-\kappa}\varepsilon^{\kappa-2} & \dfrac32<\kappa<2,\\ \hbar^{\frac12}|s|^{-\frac12}\varepsilon^{-\frac12}(1+|\log(\hbar|s|/\varepsilon^2)) & \kappa=\dfrac32\end{cases} \tag{16.5.23}$$

where we set $|k|=1$. Finally, either integrating over $|s|\le\hbar/\alpha^2$ or multiplying by $|s|^{-l}(\hbar/\alpha^2)^l$ and integrating over $|s|\ge\hbar/\alpha^2$ we get instead of (16.5.13)

$$C\begin{cases}\mu^\kappa h\alpha^{-\kappa} & 1<\kappa<\dfrac32,\\ \mu^{6-3\kappa}h^{4-2\kappa}\alpha^{3\kappa-6} & \dfrac32<\kappa<2,\\ \mu^{\frac32}h\alpha^{-\frac32}(1+|\log(\mu^2h/\alpha^2)|) & \kappa=\dfrac32.\end{cases} \tag{16.5.24}$$

Consider zone (16.5.14); we apply Remark 16.5.6 albeit with

$$\zeta := (\hbar|\sin(t'')|)^{\frac12}. \tag{16.5.20}'$$

Again multiplying by $|\sin(t')|^{-1}|\sin(t'')|^{-1}$ and integrating by $|t''|$ over one tick but intersected with $\{|\sin(t'')| \le |s|\}$ and setting $|\sin(t')| = |s|$, and finally either integrating over $|s| \le \hbar/\alpha^2$ or multiplying by $|s|^{-l}(\hbar/\alpha^2)^l$ and integrating over $|s| \ge \hbar/\alpha^2$, we arrive to the same answer, not exceeding (16.5.24).

Finally, multiplying by $|k|^{-2}\mu^\kappa h^{-2}\alpha^2$ we get after summation with respect to $k : |k| \ge 1$ the following improvement to Proposition 16.5.3

Proposition 16.5.7. *For the toy-model operator with* $1 \le \mu \le h^{-1}$ *and* $\alpha \ge \max(\mu^{-1}, \mu h^{\frac12}, \mu^{\frac12} h^{\frac12-\delta})$

$$|\mathsf{I}^{\mathsf{T}}_\alpha - \mathsf{I}^{\mathsf{T}\prime}_\alpha| \le CR^{\mathsf{W}}_1(\alpha) := \tag{16.5.25}$$
$$C\begin{cases} \mu^{2\kappa}h^{-1}\alpha^{2-\kappa} & 1 < \kappa < \frac32,\\ \mu^{6-2\kappa}h^{2-2\kappa}\alpha^{3\kappa-4} & \frac32 < \kappa < 2,\\ \mu^3 h^{-1}\alpha^{\frac12}(1+|\log(\mu^2 h/\alpha^2)|) & \kappa = \frac32. \end{cases}$$

Remark 16.5.8. Right-hand expression of (16.5.25) in comparison with (16.5.15) has factor

$$C\begin{cases} (\mu^2 h/\alpha^2)^{\kappa-1} & 1 < \kappa < \frac32,\\ (\mu^2 h/\alpha^2)^{2-\kappa} & \frac32 < \kappa < 2,\\ (\mu^2 h/\alpha^2)^{\frac12}(1+|\log(\mu^2 h)|) & \kappa = \frac32. \end{cases} \tag{16.5.26}$$

While we cannot directly apply estimate (16.5.16) now as $\mu^2 h^{-\kappa}$ may be greater than $R^{\mathsf{W}}_1(\alpha)$, we can apply (16.5.17)–(16.5.18) with $L = 4$ resulting in

Proposition 16.5.9. *For the toy-model operator with* $1 \le \mu \le h^{-1}$ *and* $\alpha \ge \max(\mu^{-1}, \mu h^{\frac12}, \mu^{\frac12} h^{\frac12-\delta})$

$$|\mathsf{I}^{\mathsf{T}}_\alpha - \mathcal{I}^{\mathsf{W}}_\alpha - \mathcal{I}^{\mathsf{W}}_{\mathsf{corr}}| \le CR^{\mathsf{W}}_1(\alpha) \tag{16.5.27}$$

with $\mathcal{I}^{\mathsf{W}}_{\mathsf{corr}} := \mathcal{I}^{\mathsf{W}}_{(2)0,\alpha}$ *but taken only over zone* $\{|x-y| \le \mu^{-1}\}$.

Case $\alpha^2 \not\gg \mu h$

Assume now that $\alpha \ge \mu^{-1}$ but (16.5.5) fails. Then in contrast to the previous we will need to compute contributions of pair of ticks (k', k'') with $k' \ne k''$. Then if t', t'' belong to k'-th and k''-th ticks respectively we denote $r = k' - k''$ and $s = t' - t'' - 2\pi r$.

Contribution of $k' = k'' \ne 0$. Consider case $k' - k'' = r = 0$ first. As $\alpha^2 \ge \hbar$ applying the same arguments as before we get the same answer (16.5.13) as before. Meanwhile, as $\alpha^2 \le \hbar$ we need to integrate (16.5.12) over $\{s : |s| \le 1\}$ and we arrive to $\hbar^{1-\frac{1}{2}\kappa}$ for all $\kappa : 0 < \kappa < 2$.

Multiplication by $\mu^\kappa h^{-2}|k|^{-2}\alpha^2$ and summation with respect to k results in the right hand expression of (16.5.15) as $\alpha^2 \ge \hbar$ and

$$C\mu^\kappa h^{-2}\hbar^{1-\frac{1}{2}\kappa}\alpha^2 = C\mu^{\frac{1}{2}\kappa+1}h^{-1-\frac{1}{2}\kappa}\alpha^2 \tag{16.5.28}$$

as $\alpha^2 \le \hbar$.

Contribution of $0 \ne k' \ne k'' \ne 0$. Consider now the case $k' - k'' = r \ne 0$. As $\alpha^2 \ge \hbar$ expression (16.5.13) acquires factor $\big(|k' - k''|\alpha^2/\hbar\big)^{-l}$ and multiplying by $\mu^\kappa h^{-2}\alpha^2|k'|^{-1}|k''|^{-1}$ we get after summation with respect to $k' \ne 0$, $k'' \ne 0$ the same right-hand expression of (16.5.15) [12].

Meanwhile, as $\alpha^2 \le \hbar$ instead of (16.5.13) we get

$$C\hbar^{1-\frac{1}{2}\kappa}\big(1 + |k' - k''|\alpha^2/\hbar\big)^{-l}.$$

Multiplication by $\mu^\kappa h^{-2}\alpha^2|k'|^{-1}|k''|^{-1}$ and summation with respect to k', k'' returns

$$C\mu^{1+\frac{1}{2}\kappa}h^{-1-\frac{1}{2}\kappa}\alpha^2\big(1 + \big(\log(\hbar/\alpha^2)\big)_+\big)^2. \tag{16.5.29}$$

Contribution of $0 = k' \ne k''$. Consider now $k' = 0, k'' \ne 0$; its tween case $k' \ne 0, k'' = 0$ is addressed in the same way. To do this we need to modify our expression fo I: namely, we do not divide by t' and then take Fourier transform $F_{t' \to \hbar^{-1}\tau}$; instead we take Fourier transform $F_{t' \to \hbar^{-1}\tau'}$, then

[12] Actually, with an extra factor $(\hbar/\alpha^2)^l$ but we do not need it here.

integrate by τ' to τ and divide by $\hbar$; modifying this way (16.5.1) we arrive instead of (16.5.4) to

$$\mathsf{I}_\alpha = \frac{1}{2}(2\pi)^{-3}\hbar^{-3}\mu^{\kappa+2}\alpha^2 \int\iint\iint \hat{\Omega}(4\hbar^{-1}\alpha^2 s, z)\times \csc(t+s)\csc(t-s)(t+s)^{-1}(t-s)^{-1}\times \exp\Big(i\hbar^{-1}\Big[-\frac{1}{4}\big(\cot(t+s)-\cot(t-s)\big)\big(z_1^2+(z_2+2t\varepsilon)^2+4s^2\varepsilon^2\big) -\big(\cot(t+s)+\cot(t-s)\big)s\varepsilon-2s(\tau-\varepsilon^2)+(t+s)(\tau-\tau')\Big]\Big)\, dtds\, \psi(\mu^{-1}z)dz_1dz_2\, d\tau'. \tag{16.5.30}$$

Then repeating our above arguments we conclude that

(16.5.31) As $\alpha^2 \ge \hbar$ the resulting term (instead of (16.5.13)) does not exceed (16.5.13) $\times\, (\hbar/\alpha^2|k''|)^l \times \hbar^{-1}$ and as $\alpha^2 \le \hbar$ the resulting term does not exceed $C\hbar^{1-\frac{1}{2}\kappa} \times \big(1+\alpha^2|k''|\hbar^{-1}\big)^{-l} \times \hbar^{-1}$

and we can rewrite the result in both cases as

$$C\hbar^{-\frac{1}{2}\kappa}\big(1+\alpha^2|k''|\hbar^{-1}\big)^{-l}.$$

Multiplying by $\mu^\kappa h^{-2}|k''|^{-1}\alpha^2$ we get after summation with respect to $k'' \ne 0$

$$C\mu^{\frac{1}{2}\kappa}h^{-2-\frac{1}{2}\kappa}\alpha^2(\hbar/\alpha^2)^l \qquad \text{as } \alpha^2 \ge h, \tag{16.5.32}$$

$$C\mu^{\frac{1}{2}\kappa}h^{-2-\frac{1}{2}\kappa}\alpha^2\big(1+(\log(\hbar/\alpha^2))_+\big) \qquad \text{as } \alpha^2 \le \hbar. \tag{16.5.33}$$

So we have proven

Proposition 16.5.10. *For the toy-model operator with* $1 \le \mu \le h^{-1}$, $\alpha \ge \mu^{-1}$

$$|\mathsf{I}^{\mathsf{T}}_{(\alpha)} - \mathcal{I}^{\mathsf{W}}_{(\alpha)}| \le (16.5.15) + (16.5.32) \qquad \textit{as } \alpha^2 \ge \hbar, \tag{16.5.34}$$

$$|\mathsf{I}^{\mathsf{T}}_{(\alpha)} - \mathcal{I}^{\mathsf{W}}_{(\alpha)}| \le (16.5.28) + (16.5.29) + (16.5.33) \qquad \textit{as } \alpha^2 \le \hbar. \tag{16.5.35}$$

16.5.2 General Operators

Consider now general operators satisfying (16.1.5)–(16.1.6) and either (16.1.7) or (16.1.8) or $(16.1.8)^+$, $\tau = 0$.

First, using Proposition 16.4.1, Remark 16.4.4(i),(ii) and propagation results we conclude that

Proposition 16.5.11. *Let conditions* (16.1.5)–(16.1.6) *be fulfilled. Then*

(i) Contribution of zone $\{|x-y| \ge C_0\mu^{-1}\}$ *to* I^{T} *does not exceed* $C\mu^{\kappa+1}h^{-1}$ *and*

(ii) Under condition (16.1.7) *contribution of time* $\{|t| \ge C_0\}$ *(before rescaling) to* I^{T} *does not exceed* $C\mu^{\kappa+1}h^{-1}$.

Note that $O(\mu^{\kappa+1}h^{-1})$ is smaller than the remainder estimate $R^{\mathsf{W}}(1)$ or $R_1^{\mathsf{W}}(1)$ and as long as we are interested in Weyl approximation $\mathcal{I}^{\mathsf{W}}$ (even with correction term) we should be completely happy with it.

Under condition (16.1.7) we are done, immediately arriving to Statement (i) and related part of Statement (iii) of Theorem 16.5.13 below.

Under condition (16.1.8) let us introduce

$$\alpha(x) = \epsilon_0|\nabla VF^{-1}| + \frac{1}{2}\bar{\alpha}, \qquad \bar{\alpha} = C_0 \max\bigl(\mu^{-1}, (\mu h)^{\frac{1}{2}-\delta}\bigr) \tag{16.5.36}$$

and consider covering of $B(0,1)$ by α-admissible elements. In virtue of Proposition 16.5.11(i) we need to consider only pairs (x,y) belonging to the same element. Due to rescaling, contribution of one such element to $|I^{\mathsf{T}} - \mathcal{I}^{\mathsf{W}}|$ does not exceed $C\mu h^{-1-\kappa}\alpha^2$ and therefore

(16.5.37) Under condition (16.1.8) contribution of zone

$$\{(x,y) : |x-y| \le C_0\mu^{-1},\ |\nabla VF^{-1}| \le \alpha\}$$

to $|I^{\mathsf{T}} - \mathcal{I}^{\mathsf{W}}|$ does not exceed $C\mu h^{-1-\kappa}\alpha^2$.

Therefore we need to consider only zone where $|\nabla VF^{-1}(x)| \ge \alpha$ and $|x-y| \le C_0\mu^{-1}$. We are going to prove that

Proposition 16.5.12. *Let conditions* (16.1.5)–(16.1.6) *be fulfilled. Further, let* $\mu \le h^{-1}$. *Then*

(i) For each z *with* $\alpha(z) \ge \bar{\alpha}$ *contribution of zone*

$$\{(x,y) \in B(z,\alpha(z)),\ |x-y| \le C_0\mu^{-1}|\}$$

to $|\mathsf{I}^{\mathsf{T}} - \mathcal{I}^{\mathsf{W}}|$ *does not exceed* $R^{\mathsf{W}}(\alpha)$ *which is defined as the right-hand expression of* (16.5.15) *or* (16.5.25).

(ii) Further, as $\alpha^2 \ge \mu^2 h$, $1 < \kappa < 2$ *this contribution does not exceed* $R_1^{\mathsf{W}}(\alpha)$ *which is defined as the right-hand expression of* (16.5.25).

Note that both $R^{\mathsf{W}}(\alpha)$ and $R_1^{\mathsf{W}}(\alpha)$ contain α in the positive powers and thus after integration with respect $\alpha^{-1}\,d\alpha$ we get their values as $\alpha = 1$.

Therefore we arrive to Statement (ii) and related part of Statement (iii) of Theorem 16.5.13:

Theorem 16.5.13. *Let conditions* (16.1.5)–(16.1.6) *be fulfilled. Then as* $\mu \le h^{-1}$

(i) Under condition (16.1.7)

$$|\mathsf{I} - \mathcal{I}^{\mathsf{W}}| \le C\mu^{-1}h^{-1-\kappa} + R^{\mathsf{W}} \tag{16.5.38}$$

with

$$R^{\mathsf{W}} := C\begin{cases} \mu^{\kappa+1}h^{-1} & \text{as } \kappa < 1,\\ \mu^2 h^{-\kappa} & \text{as } \kappa > 1,\\ \mu^2 h^{-1}|\log(\mu h)| & \text{as } \kappa = 1.\end{cases} \tag{16.5.39}$$

(ii) Under condition (16.1.8)[13)]

$$|\mathsf{I} - \mathcal{I}^{\mathsf{W}}| \le C\mu^{-1}h^{-1-\kappa} + R^{\mathsf{W}} + C\mu^2 h^{-\kappa}(\mu h)^{-\delta}. \tag{16.5.40}$$

(iii) As $\mu^2 h \le 1$ *and* $1 < \kappa < 2$ *in these estimates one can replace* $\mathcal{I}^{\mathsf{W}}$ *by* $\mathcal{I}^{\mathsf{W}} + \mathcal{I}^{\mathsf{W}}_{\mathsf{corr}}$ *and* R^{W} *by*

$$R_1^{\mathsf{W}} := \begin{cases} \mu^{2\kappa}h^{-1} & 1 < \kappa < \dfrac{3}{2},\\ \mu^{6-2\kappa}h^{2-2\kappa} & \dfrac{3}{2} < \kappa < 2,\\ \mu^3 h^{-1}(1+|\log(\mu^2 h)|) & \kappa = \dfrac{3}{2}.\end{cases} \tag{16.5.41}$$

[13)] If $(16.1.8)^+$ fails the first term should acquire factor $(1+\mu h|\log h|)$ but it is important only as μ is close to h^{-1} but then the other terms dominate.

Remark 16.5.14. (i) Actually as $\mu^2 h \le 1$, $\kappa \ge \frac{3}{2}$ this correction term does not exceed $C\mu^{-1}h^{-1-\kappa}$.

(ii) Consider other terms in the estimates. Then (16.5.28), (16.5.29), (16.5.33) contain α in the positive powers and (16.5.32) contains α in the negative power and thus after integration with respect $\alpha^{-1}\,d\alpha$ we get their values as $\alpha = (\mu h)^{\frac{1}{2}}$ i.e. (16.5.28), (16.5.29) become $C\mu^{\frac{1}{2}\kappa+2}h^{-\frac{1}{2}\kappa}$ which is less than (16.5.39) and (16.5.41) while (16.5.32), (16.5.33) become $C\mu^{\frac{1}{2}\kappa+1}h^{-1-\frac{1}{2}\kappa}$ which is larger than (16.5.39). Therefore selecting $\alpha \ge (\mu h)^{\frac{1}{2}-\delta}$ saves us from all these problems for the price of $\delta \ne 0$.

Even as $h^{-1+\delta} \le \mu \le h^{-1}$ it works as $C\mu^{\frac{1}{2}\kappa+1}h^{-1-\frac{1}{2}\kappa}$ acquires factor $(\mu h)^l$ which makes it subordinate to (16.5.39).

The following problem seems to be challnging:

Problem 16.5.15. Prove above results with $\delta = 0$.

Proof of Proposition 16.5.12. (a) First of all applying Proposition 16.3.5 and the same arguments as in the analysis of Section 16.3 we arrive to

(16.5.42) Contribution of zone $\{|\sin(\theta(t'))| \ge C_0\hbar,\ |\sin(\theta(t''))| \ge C_0\hbar\}$ to the error $|\mathsf{I}^{\mathsf{T}} - \mathcal{I}^{\mathsf{W}}|$ does not exceed expression (16.5.15) or (16.5.41) (in its framework).

Therefore we need to explore contributions of three remaining zones

$$\{|\sin(\theta(t'))| \le 2C_0\hbar,\ |\sin(\theta(t''))| \le 2C_0\hbar\} \tag{16.5.43}$$

and

$$\{|\sin(\theta(t'))| \ge 2C_0\hbar,\ |\sin(\theta(t''))| \le C_0\hbar\} \tag{16.5.44}$$

(the same analysis would cover its tween zone $\{|\sin(\theta(t'))| \ge 2C_0\hbar,\ |\sin(\theta(t''))| \le C_0\hbar\}$).

Note first that the standard propagation arguments imply that we get a factor $C(|z_1| + |z_2|)^{-l}(|\sin(\theta(t'))| + \varepsilon|t'|)^l$ and the similar factor with t' replaced by t''.

(b) Consider zone (16.5.43) as $\varepsilon \ge C_1\hbar$. Then in the classical propagation shift $\varepsilon|k'|$ is always greater than $\hbar$.

Obviously contribution of zone (16.5.43), intersected with (k', k'') windings $\times\{(x,y) : |x-y| \ge \rho\}$ to the Tauberian expression does not exceed

$$C\mu^2 h^2 |k'|^{-1}|k''|^{-1}\rho^{-\kappa} \sup_t \iint |\tilde{U}(x,y,t)|^2\, dxdy \le C\mu^2 h^{2-d}\rho^{-\kappa}\alpha^d \tag{16.5.45}$$

where factor $\hbar^2$ is due to integration with respect to t', t'' and $\tilde{U}$ means cut-off of U to the energy level $|\tau| \le c$.

Plugging (as $d = 2$)

$$\rho = \varepsilon\mu^{-1}\max(|k'|, |k''|), \tag{16.5.46}$$

$\varepsilon = \mu^{-1}\alpha$ we get

$$C\mu^{2\kappa+2}|k'|^{-1}|k''|^{-1}\alpha^{2-\kappa}\big(\max(|k'|, |k''|)\big)^{-\kappa}. \tag{16.5.47}$$

Summation by k', k'' returns $C\mu^{2\kappa+2}\alpha^{2-\kappa}$ which is less than the right-hand expression of (16.5.15) or (as $\alpha^2 \ge \mu^2 h$, $1 < \kappa < 2$) the right-hand expression of (16.5.25).

Meanwhile, estimating $\tilde{U}(x,y,t)$ by h^{-d} and integrating by $|x-y| \le \rho$ and then integrating by t', t'' over $|\theta(t') - \pi k'| \le \hbar$, $|\theta(t'') - \pi k''| \le \hbar$ we get

$$Ch^{2-2d}\mu^2\rho^{d-\kappa}|k'|^{-1}|k''|^{-1}\big(h/\rho\big)^l\alpha^d \tag{16.5.48}$$

where the last factor is due to propagation results; plugging $d = 2$, (16.5.46) we get

$$C\mu^2 h^{-\kappa}|k'|^{-1}|k''|^{-1}\alpha^2\big(\hbar/\varepsilon\max(|k'|, |k''|)\big)^l; \tag{16.5.49}$$

after summation we get $C\mu^2 h^{-\kappa}\big(\hbar/\varepsilon\big)^l\alpha^2$ which is again less than the right-hand expression of (16.5.15) or (as $\alpha^2 \ge \mu^2 h$, $1 < \kappa < 2$) the right-hand expression of (16.5.25).

(c) Consider zone (16.5.43) as $\varepsilon \le C_1\hbar$. Taking sum of (16.5.47) over k', k'' with $\max(|k'|, |k''|) \ge \hbar/\varepsilon$ we get

$$C\mu^{2\kappa+2}\alpha^{2-\kappa}(1 + |\log \mu^2 h/\alpha|) \times (\mu^2 h/\alpha)^{-\kappa} = C\mu^2 h^{-\kappa}\alpha^2(1 + |\log \mu^2 h/\alpha|)$$

while taking sum of (16.5.49) we get the right-hand expression as well. Obviously, it is less than the right-hand expression of (16.5.15).

Thus we need to consider only $k', k'' : \mathsf{max}(|k'|, |k''|) \le \hbar/\varepsilon$.

Using the same arguments as before, we conclude that the contribution of zone (16.5.43), intersected with (k', k'') windings $\times\{(x, y) : |x - y| \ge \hbar\}$ to the Tauberian expression does not exceed $C\mu^2 h^{-\kappa}|k'|^{-1}|k''|^{-1}$; similarly contribution of zone (16.5.43), intersected with (k', k'') windings $\times\{(x, y) : |x - y| \le \hbar\}$ to the Tauberian expression does not exceed $C\mu^2 h^{-\kappa}|k'|^{-1}|k''|^{-1}\alpha^2$ as well.

After summation we get $C\mu^2 h^{-\kappa}(1 + |\log \mu^2 h/\alpha|)^2$ which again is less than the right-hand expression of (16.5.15).

(d) Furthermore, consider zone (16.5.44) as $\varepsilon \ge C_1\hbar$. Now shift with respect to $(x - y)$ is $\mu^{-1}\mathsf{max}\big(\varepsilon|t|, |\varepsilon t' \mp \mathsf{sin}(t')|\big)$; then repeating analysis in zone (16.5.43) we arrive to (16.5.47) for $1 < \kappa < 2$ and to (16.5.49) for $0 < \kappa < 2$; as $0 < \kappa \le 1$ one should replace (16.5.47) by

$$C\mu^{2\kappa+2}\hbar|k'|^{-1}|k''|^{-1} \tag{16.5.50}$$

with a logarithmic factor as $\kappa = 1$ and summation with respect to k', k'' results in $C\mu^{3\kappa+2}h(1 + |\log h|)^2$ which again is less than $R^{\mathsf{W}}(\alpha)$.

(e) Finally, consider zone (16.5.44) as $\varepsilon \le C_1\hbar$. With the above adjustment arguments of zone (16.5.43) work here as well. □

16.5.3 Perturbations

General Scheme

Contribution of $k' = k'' \ne 0$. Let us start from the case case $k' = k'' = k$. Assume first that $\alpha^2 \ge \hbar$.

Recall that k-th tick's contribution to I^{T} was not exceeding expression (16.5.13) multiplied by $\mu^\kappa h^{-2}\alpha^2|k|^{-2}$ i.e.

$$C\mu^{\kappa+2}\alpha^2|k|^{-2}\hbar^{-1-\frac{1}{2}\kappa}\begin{cases}(\hbar/\alpha^2)^{\frac{1}{2}\kappa} & \kappa < 1,\\ (\hbar/\alpha^2)^{1-\frac{1}{2}\kappa} & \kappa > 1,\\ (\hbar/\alpha^2)^{\frac{1}{2}}(1 + |\log(\hbar/\alpha^2)|) & \kappa = 1\end{cases} \tag{16.5.51}$$

(as $|\mathsf{sin}(t')| \le \hbar$ or $|\mathsf{sin}(t'')| \le \hbar$ one should use Proposition 16.5.12). Then we can suspect that the successive approximations bringing factor $\sigma T/\hbar$ as

U is replaced by U^0 simultaneously brings the same factor when we replace U by $\bar{U}$ in I; so contribution of k-th tick to the error is estimated by the previous expression multiplied by $C\sigma|k|/\hbar$ i.e.

$$C\sigma\mu^{\kappa+2}\alpha^2|k|^{-1}\hbar^{-2-\frac{1}{2}\kappa}\begin{cases}(\hbar/\alpha^2)^{\frac{1}{2}\kappa} & \kappa<1,\\ (\hbar/\alpha^2)^{1-\frac{1}{2}\kappa} & \kappa>1,\\ (\hbar/\alpha^2)^{\frac{1}{2}}(1+|\log(\hbar/\alpha^2)|) & \kappa=1.\end{cases} \tag{16.5.52}$$

and summation over $k:|k|\le \bar{k}:=\hbar/\sigma$ results in

$$C\sigma\mu^{\kappa+2}\alpha^2|\log\hbar/\sigma|\hbar^{-2-\frac{1}{2}\kappa}\begin{cases}(\hbar/\alpha^2)^{\frac{1}{2}\kappa} & \kappa<1,\\ (\hbar/\alpha^2)^{1-\frac{1}{2}\kappa} & \kappa>1,\\ (\hbar/\alpha^2)^{\frac{1}{2}}(1+|\log(\hbar/\alpha^2)|) & \kappa=1.\end{cases} \tag{16.5.53}$$

Remark 16.5.16. (i) Here σ is the magnitude of perturbation and as we approximate by toy-model it is $O(\mu^{-2})$ but if we are trying to use the magnetic Weyl approximation it is $O(\varepsilon)$.

(ii) Expression (16.5.53) provides us with the answer for $\alpha^2\ge\hbar$. On the other hand, if $\alpha^2\le\hbar$ we need to recall that as long as we are interested only in the zone $\{(x,y)\colon |x-y|\le C_0\mu^{-1}\}$ before rescaling then $|z|\le C_0$ and we need therefore there reset $\hbar/\alpha^2$ to 1 and also $|s|$ to 1 resulting in

$$C\sigma\mu^{\kappa+2}\alpha^2|\log\hbar/\sigma|\hbar^{-2-\frac{1}{2}\kappa} \tag{16.5.54}$$

(iii) In these settings we need to assume that $T\le C_0\varepsilon^{-1}$ i.e. $\bar{k}\le C_0\varepsilon^{-1}$ i.e.

$$\mu h\le \sigma/\varepsilon. \tag{16.5.55}$$

This inequality always holds as $\sigma=\varepsilon$ but it may fail as $\sigma=\mu^{-2}$; in this case we either reset $\bar{k}$ to $C\varepsilon^{-1}$ or reevaluate σ and analyze separately in both cases (see in the next subsubsection).

(iv) Note, as $\mu h\le\sigma/\varepsilon$ summation (16.5.51) for $k:|k|\ge\bar{k}$ brings the same expression albeit without logarithmic factor; otherwise if we reset $\bar{k}=C\varepsilon^{-1}$ this sum returns $C\mu^{\kappa}h^{-1}$.

(v) However, for the toy-model approximation we can reexamine the zone $\{(x,y)\colon |x-y|\ge C_0\mu^{-1}\}$ and improve the remainder estimate of (iv).

Contribution of $0 \neq k' \neq k'' \neq 0$. Next we need to consider $0 \neq k' \neq k'' \neq 0$. Recall that as $\alpha^2 \geq \hbar$ the contribution of such pair to I^{T} does not exceed

$$C\mu^{\kappa+2}\alpha^2|k'|^{-1}|k''|^{-1}(\hbar/\alpha^2|k'-k''|)^l\hbar^{-1-\frac{1}{2}\kappa}\times \begin{cases}(\hbar/\alpha^2)^{\frac{1}{2}\kappa} & \kappa<1,\\ (\hbar/\alpha^2)^{1-\frac{1}{2}\kappa} & \kappa>1,\\ (\hbar/\alpha^2)^{\frac{1}{2}}(1+|\log(\hbar/\alpha^2)|) & \kappa=1;\end{cases} \tag{16.5.56}$$

multiplying by $C\sigma|k'|/\hbar$ (as perturbation goes to the first "factor") we get

$$C\sigma\mu^{\kappa+2}\alpha^2|k''|^{-1}(\hbar/\alpha^2|k'-k''|)^l\hbar^{-2-\frac{1}{2}\kappa}\times \begin{cases}(\hbar/\alpha^2)^{\frac{1}{2}\kappa} & \kappa<1,\\ (\hbar/\alpha^2)^{1-\frac{1}{2}\kappa} & \kappa>1,\\ (\hbar/\alpha^2)^{\frac{1}{2}}(1+|\log(\hbar/\alpha^2)|) & \kappa=1.\end{cases} \tag{16.5.57}$$

Then summation with respect to k' of $(\hbar/\alpha^2|k'-k''|)^l$ returns $(\hbar/\alpha^2)^l$ as $\hbar \leq \alpha^2$ and summation with respect to k'' then returns (16.5.53) with an extra factor $(\hbar/\alpha^2)^l$ and therefore is less than (16.5.53).

On the other hand, as $\hbar \geq \alpha^2$ summation with respect to k' of 1 returns $\hbar/\alpha^2$ and as we recall that big left brace expression should be replaced by 1 we arrive after summation with respect to k'' to

$$C\sigma\mu^{\kappa+2}\hbar^{-1-\frac{1}{2}\kappa}(1+(\log\hbar/\sigma)) \tag{16.5.58}$$

which is (16.5.54) with an extra factor $(\hbar/\alpha^2)$ and therefore is greater than (16.5.53).

Contribution of $0 = k'' \neq k'$. If $k' \neq 0$, $k'' = 0$ we recall that $|k''|^{-1}$ should be replaced by $\hbar^{-1}$ in (16.5.56)–(16.5.57) and the perturbation brings a factor $\sigma|k'|/\hbar$, so we get instead of (16.5.57)

$$C\sigma\mu^{\kappa+2}\alpha^2(\hbar/\alpha^2|k'|)^l\hbar^{-3-\frac{1}{2}\kappa}\begin{cases}(\hbar/\alpha^2)^{\frac{1}{2}\kappa} & \kappa<1,\\ (\hbar/\alpha^2)^{1-\frac{1}{2}\kappa} & \kappa>1,\\ (\hbar/\alpha^2)^{\frac{1}{2}}(1+|\log(\hbar/\alpha^2)|) & \kappa=1.\end{cases}$$

Then summation with respect to k' returns

$$C\sigma\mu^{\kappa+2}\alpha^2(\hbar/\alpha^2)^l\hbar^{-3-\frac{1}{2}\kappa} \tag{16.5.59}$$

as $\hbar \le \alpha^2$ and

$$C\sigma\mu^{\kappa+2}\hbar^{-2-\frac{1}{2}\kappa} \tag{16.5.60}$$

as $\hbar \ge \alpha^2$; (16.5.60) is even greater than (16.5.58).

Contribution of $0 = k'$. With perturbation factors are no more of the same rights and we need to consider this case as well.

(i) If $k' = 0$, $k'' \ne 0$ we recall that $|k'|^{-1}$ should be replaced by $\hbar^{-1}$ in (16.5.56)–(16.5.57) but perturbation brings factor σ so together we get factor $\sigma\hbar^{-1}$ which falls into into case $k' = 1$, $k'' \ne 0$.

(ii) Similarly, if $k' = k'' = 0$ we fall into case $k' = 1$, $k'' = 0$.

In total we get (16.5.53)+(16.5.59) as $\alpha^2 \ge \hbar$ and (16.5.60) as $\alpha^2 \le \hbar$. So, we arrive to

Proposition 16.5.17. *Let conditions* (16.1.5)–(16.1.6) *be fulfilled in* $B(0,1)$ *and let* $\alpha := \epsilon_0|\nabla V/F(\bar{x})| \ge C_0\mu^{-1}$ *where* $\bar{x} \in B(0,\frac{1}{2})$.

Let $\bar{e}_z(x,y,\tau)$ *be a Schwartz kernel of the spectral projector of* <u>*either*</u> *the magnetic Weyl approximation (then* $\sigma = \alpha\mu^{-1}$*)* <u>*or*</u> *the toy-model approximation (then* $\sigma = \mu^{-2}$*) at point* z. *Let* $T \ge \min\bigl(\epsilon_0\hbar/\sigma, C_0\mu\alpha^{-1}\bigr) \ge 1$.

Let $\psi, \psi_1 \in \mathscr{C}_0^\infty(B(0,1))$.

(i) Then as $\alpha^2 \ge \hbar$, $\gamma = C_0\mu^{-1}$

$$\mathsf{R}_2 = \mathsf{R}_2(\alpha,\gamma) := \tag{16.5.61}$$
$$\Bigl|\int \Omega_{\alpha,\gamma}\bigl(\frac{1}{2}(x+y), x-y\bigr)\Bigl(|e^{\mathsf{T}}(x,y,0)|^2 - |\bar{e}^{\mathsf{T}}_{\frac{1}{2}(x+y)}(x,y,0)|^2\Bigr)\,dxdy\Bigr| \le$$
$$(16.5.53) + (16.5.59)$$

where

$$\Omega_{\alpha,\gamma}(x,z) := \psi\bigl(\alpha^{-1}(x-\bar{x})\bigr)\psi_1\bigl(\gamma^{-1}z\bigr).$$

(ii) As $\alpha^2 \le \hbar$, $\gamma = C_0\mu^{-1}$ *we get*

$$\mathsf{R}_2 \le (16.5.54) + (16.5.60). \tag{16.5.62}$$

(iii) Further, in this inequality one can replace $\bar{e}^{\mathsf{T}}$ *by* $\bar{e}$.

Proof. The easy albeit tedious proof following our standard technique we leave to the reader. □

Improvement

We want to apply arguments of the previous Subsubsection "Improvement" to improve results of the previous subsubsection. One can see easily that improvement makes sense only if we can improve $k' = k'' = 1$ and thus as $\alpha^2 \ge \mu^2 h$. This excludes magnetic Weyl approximation.

In this case $R_1^{\mathsf{W}}(\alpha)$ defined by (16.5.25) acquires factor $\mu^{-3}h^{-1}$:

$$C \begin{cases} \mu^{2\kappa-3}h^{-2}\alpha^{2-\kappa} & 1 < \kappa < \frac{3}{2}, \\ \mu^{3-2\kappa}h^{1-2\kappa}\alpha^{3\kappa-4} & \frac{3}{2} < \kappa < 2, \\ h^{-2}\alpha^{\frac{1}{2}}(1+|\log(\mu^2 h/\alpha^2)|) & \kappa = \frac{3}{2}. \end{cases} \tag{16.5.63}$$

This replaces (16.5.53) and (16.5.59) becomes negligible.

So, we arrive to

Proposition 16.5.18. *Let conditions of Proposition 16.5.17 be fulfilled, we consider the toy-model approximation and let* $\alpha^2 \ge \mu^2 h$. *Then*

(i) $\mathsf{R}_2(\alpha,\gamma)$ *does not exceed* (16.5.63).

(ii) Further, in this inequality one can replace $\bar{e}^{\mathsf{T}}$ *by* $\bar{e}$.

Proof. The easy albeit tedious proof following our standard technique we leave to the reader. □

Results. I

Let condition (16.1.7) be fulfilled.

Magnetic Weyl Approximation. If we are looking for the magnetic Weyl approximation, we should assume that $h^{-\frac{1}{2}} \le \mu \le h^{-1}$ and pick up $\sigma = \varepsilon = \mu^{-1}$, $\alpha = 1$ and look what happens with expressions (16.5.53) and (16.5.59). The former returns the last term in the estimate (16.5.64) below

and the latter returns the lesser expression $C\mu^{\kappa-1}h^{-2}\hbar'$. So we arrive to estimate (16.5.64) of Theorem 16.5.19 below albeit with an extra factor $\bigl(1+(\log \mu^2 h)_+\bigr)$ in front of the big left brace.

To get rid of it let us consider two-term successive approximation. Then to estimate a remainder one needs to sum the same expressions as before but with an extra factor which is either $\mu^{-2}h^{-1}|k'|$ or $\mu^{-2}h^{-1}|k''|$.

This really does not matter for $k'=k''\neq 0$ and we sum $\mu^{-2}h^{-1}$ instead of $|k|^{-1}$ from $|k|=1$ to $|k|=\mu^2 h$ resulting in 1 rather than logarithm. As $0\neq k'\neq k''\neq 0$ we get the same answer albeit with a factor $(\mu h)'$ as $\alpha\asymp 1$. If $k'=0$ and/or $k''=0$ we replace $|k'|^{-1}$ and/or $|k''|^{-1}$ by $\hbar^{-1}$ but this is more than compensated by $(\mu h)'$ but effectively $T'=\hbar$ and/or $T''=\hbar$ so in fact we reset these cases to $k'=1$ and/or $k''=1$.

On the other hand, the second term in the successive approximation refers to perturbation being strictly $\alpha(x_1-y_1)$ but this leads to 0 as Ω is even with respect to $(x-y)$. Thus we arrive to estimate (16.5.64) of Theorem 16.5.19 below.

Theorem 16.5.19. *Let conditions* (16.1.5)–(16.1.7) *be fulfilled. Then for* $h^{-\frac{1}{2}}\le \mu\le h^{-1}$

$$|\mathsf{I}-\mathcal{I}^{\mathsf{MW}}|\le C\mu^{-1}h^{-1-\kappa}+C\begin{cases}\mu^{\kappa-1}h^{-2} & 0<\kappa<1,\\ h^{-1-\kappa} & 1<\kappa<2,\\ h^{-2}(1+|\log(\mu h)|) & \kappa=1.\end{cases}\tag{16.5.64}$$

Toy-Model Approximation. If we are looking for the toy-model approximation, we should assume that $h^{-\frac{1}{3}}\le\mu\le h^{-1}$ and pick up $\sigma=\mu^{-2}$, $\varepsilon=\mu^{-1}$, $\alpha=1$. We need to consider variants:

(i) $h^{-\frac{1}{3}}\le\mu\le h^{-\frac{1}{2}}$. As $0<\kappa\le 1$ (16.5.53) becomes $C\mu^{\kappa-2}h^{-2}(1+|\log\mu^3 h|)$ (with another logarithmic factor as $\kappa=1$ and it is larger than $C\mu^{\kappa}h^{-1}$ (which is the contribution of $\{|x-y|\ge C_0\mu^{-1}\}$).

As $1<\kappa<2$ we can replace (16.5.53) by (16.5.63) which is then $O(\mu^{-1}h^{-1-\kappa})$ and $\mu^{\kappa}h^{-1}$ is also $O(\mu^{-1}h^{-1-\kappa})$.

Observing that (16.5.59) is negligible we arrive to statement (i) of Theorem 16.5.21 below.

(ii) $h^{-\frac{1}{2}}\le\mu\le h^{-1}$. In this case we note that (16.5.59) is still less than (16.5.53) but $\mu^{\kappa}h^{-1}$ may become leading term. To improve this term let us

consider contribution of zone $|x-y| \asymp \gamma \ge C_0\mu^{-1}$ into an error: we need to take $\sigma = \gamma^2$ and $T \asymp \mu^2\gamma$ so we get the estimate of perturbation

$$C\mu h^{-1}T^{-1}\gamma^{-\kappa} \times \sigma T/\hbar \asymp Ch^{-2}\gamma^{2-\kappa} \tag{16.5.65}$$

recall that unperturbed term does not exceed

$$C\mu h^{-1}T^{-1}\gamma^{-\kappa} \asymp C\mu^{-1}h^{-1}\gamma^{-\kappa-1} \tag{16.5.66}$$

because the drift propagation does not expand $B(x,\rho)$ with $\rho \ge C_0\mu^{-1}$ but merely shifts it. We sum (16.5.65) as $\gamma^2 T \le \hbar$ i.e. $\gamma^3 \le \mu^{-1}h$ i.e. $\gamma \le \bar{\gamma} = \mu^{-\frac{1}{3}}h^{\frac{1}{3}} = \mu^{-1}(\mu^2 h)^{\frac{1}{3}}$.

Then we get $Ch^{-\frac{4}{3}-\frac{1}{3}\kappa}\mu^{\frac{1}{3}\kappa-\frac{2}{3}}$ and we arrive to Statement (ii) of Theorem 16.5.21 below.

Remark 16.5.20. Obviously arguments of the magnetic Weyl approximation allowing us to get rid of logarithmic factor still work albeit the second term does not necessarily vanish as the perturbation is quadratic. The logarithmic factor in estimates (16.5.67) and (16.5.69) does not seem be worth of trouble to write this second term.

Theorem 16.5.21. *Let conditions* (16.1.5)–(16.1.7) *be fulfilled. Then*

(i) If $h^{-\frac{1}{3}} \le \mu \le h^{-\frac{1}{2}}$, *then*

$$|\mathsf{I}-\bar{\mathsf{I}}| \le C\mu^{-1}h^{-1-\kappa} + C|\log \mu^3 h| \begin{cases} \mu^{\kappa-2}h^{-2} & 0<\kappa<1,\\ 0 & 1<\kappa<2,\\ \mu^{-1}h^{-2}(1+|\log h|) & \kappa=1 \end{cases} \tag{16.5.67}$$

where

$$\bar{I} := \int \Omega_{1,1}\bigl(\frac{1}{2}(x+y), x-y\bigr)|\bar{e}_{\frac{1}{2}(x+y)}(x,y,0)|^2\,dxdy. \tag{16.5.68}$$

(ii) If $h^{-\frac{1}{2}} \le \mu \le h^{-1}$, *then*

$$|\mathsf{I}-\bar{\mathsf{I}}| \le C\mu^{-1}h^{-1-\kappa} + Ch^{-\frac{4}{3}-\frac{1}{3}\kappa}\mu^{\frac{1}{3}\kappa-\frac{2}{3}} + C|\log h| \begin{cases} \mu^{\kappa-2}h^{-2} & 0<\kappa<1,\\ \mu^{-1}h^{-1-\kappa} & 1<\kappa<2,\\ \mu^{-1}h^{-2}(1+|\log(\mu h)|) & \kappa=1. \end{cases} \tag{16.5.69}$$

Results. II

Assume now that condition (16.1.8) is fulfilled instead of (16.1.7) and estimate an approximation error again.

Magnetic Weyl Approximation Let us consider the magnetic Weyl approximation first. Then we should assume that $h^{-\frac{1}{2}} \le \mu \le h^{-1}$ and pick up $\sigma = \varepsilon = \alpha\mu^{-1}$. Recall that the contribution of $\{(x,y) : |x-y| \ge C_0\mu^{-1}\}$ does not exceed $C\mu^{\kappa}h^{-1}$ and therefore we need to consider zone

$$\{(x,y) : |x-y| \le C_0\mu^{-1},\ \alpha(x) \ge C_1\mu^{-1}\} \tag{16.5.70}$$

where also $(1-\epsilon) \le \alpha(y)/\alpha(x) \le (1+\epsilon)$ [14].

Therefore we can use α-admissible partition in zone (16.5.69) and we need just look what happens with expressions (16.5.53) and (16.5.59) after integration with respect to $\alpha^{-1}d\alpha$ as $\alpha \ge (\mu h)^{\frac{1}{2}}$ and (16.5.60) $\mu^{-1} \le \alpha \le (\mu h)^{\frac{1}{2}}$.

Obviously integral of (16.5.53) resets to its value as $\alpha = 1$ as under assumption (16.1.7); integrals of (16.5.59) and (16.5.60) reset to their values as $\alpha = (\mu h)^{\frac{1}{2}}$ which are equal and less than what we got already.

Therefore estimate (16.5.64) still holds[15] and we arrive to Statement (i) of Theorem 16.5.22 below after we apply the same arguments with two-term approximation as in the previous subsubsection to get rid of the logarithmic factor.

Toy-Model Approximation Let us consider the toy-model approximation; then again $\sigma = \mu^{-2}$. Then we need to consider two cases.

(a) $h^{-\frac{1}{3}} \le \mu \le h^{-\frac{1}{2}}$. In this case we are completely happy with the zone $\{(x,y) : |x-y| \ge C_0\mu^{-1}\}$.

As $0 < \kappa \le 1$ we need to integrate with respect to $\alpha^{-1}d\alpha$ (16.5.53) and (16.5.59) as $\alpha \ge (\mu h)^{\frac{1}{2}}$ and (16.5.60) as $\alpha \le (\mu h)^{\frac{1}{2}}$. The first integral resets to (16.5.53) as $\alpha = 1$; integrals of (16.5.59) and (16.5.60) reset to their values as $\alpha = (\mu h)^{\frac{1}{2}}$ which are equal (up to a logarithmic factor) and less than

[14] And add contribution of the zone $\{(x,y) : \alpha(x) \le \bar{\alpha} := C_1\mu^{-1},\ \alpha(y) \le \bar{\alpha}\}$ which would be $C\mu h^{-1-\kappa} \times \bar{\alpha}^2 = C\mu^{-1}h^{-1-\kappa}$ in virtue (16.1.8).

[15] Albeit the first term $C\mu^{-1}h^{-1-\kappa}$ acquires factor $|\log h|$ if assumption $(16.1.8)^+$ fails: see Tauberian estimate.

what we got already. Thus we arrive to Statement (ii) of Theorem 16.5.22 below.

As $1 < \kappa < 2$ we need to replace integral of (16.5.53) by its integral over zone $(\mu h)^{\frac12} \le \alpha \le \mu h^{\frac12}$ plus integral of (16.5.63) over zone $\mu h^{\frac12} \le \alpha \le 1$. These integrals are reset to their integrands values as $\alpha = (\mu h)^{\frac12}$ and $\alpha = 1$ respectively; the latter is larger than the former albeit not necessarily larger than integral of (16.5.60).

Thus we arrive to Statement (iii) of Theorem 16.5.22 below.

(b) $h^{-\frac12} \le \mu \le h^{-1}$. In this case the contribution of $\{(x,y) : |x-y| \le C_0\mu^{-1}\}$ does not exceed the right-hand expression of (16.5.69) but we need to reexamine zone $\{(x,y)\colon |x-y| \ge C_0\mu^{-1}\}$ which we split into two: $\{|x-y| \le \epsilon_0\alpha(x)\}$ and $\{|x-y| \ge \epsilon_0\alpha(x)\}$.

Repeating corresponding arguments of the analysis under assumption (16.1.7) we conclude that the contribution of the former zone does not exceed what we got then. In the latter zone $T \asymp \mu^2$ and its contribution does not exceed $C\mu^{-1}h^{-1-\kappa}$.

Thus we arrive to Statement (iv) of Theorem 16.5.22 below.

Theorem 16.5.22. *Let conditions* (16.1.5)–(16.1.6) *and* (16.1.8) *be fulfilled. Then*[15)]

(i) As $h^{-\frac12} \le \mu \le h^{-1}$ *estimate* (16.5.64) *holds.*

(ii) As $h^{-\frac13} \le \mu \le h^{-\frac12}$, $0 < \kappa \le 1$ *estimate* (16.5.67) *holds.*

(iii) As $h^{-\frac13} \le \mu \le h^{-\frac12}$, $1 < \kappa < 2$

$$|\mathsf{I} - \bar{I}| \le C\mu^{-1}h^{-1-\kappa} + C\mu^{\frac12\kappa-2}h^{-\frac12\kappa-2}(1 + |\log \mu^3 h|); \tag{16.5.71}$$

(iv) As $h^{-\frac12} \le \mu \le h^{-1}$ *estimate* (16.5.69) *holds.*

16.5.4 Strong Magnetic Field

Consider under assumption (16.1.8) the Schrödinger-Pauli operator with $\mu \ge h^{-1}$. Recall that according to Propositions 16.4.8(ii), 16.4.9(ii) respectively

$$|\mathsf{I}| \le C\mu^{1+\frac12\kappa}h^{-1-\frac12\kappa}$$

and

$$|\mathsf{I}-\mathsf{I}^{\mathsf{T}}| \le C\mu^{\frac{1}{2}\kappa}h^{-\frac{1}{2}\kappa}$$

(as $\kappa \ne 1$; as $\kappa = 1$ the latter estimate holds with an extra factor $|\log \mu|$ in its right-hand expression).

Let us assume that $F = 1$ to avoid some unpleasant correction terms as we reduce operator to one with $F = 1$. Recall that now $\hbar := \mu^{-\frac{1}{2}}h^{\frac{1}{2}}$ is the magnitude of the cyclotron radius.

Magnetic Weyl Approximation. Consider first the magnetic Weyl approximation. Then $\sigma = \alpha\hbar = \alpha\mu^{-\frac{1}{2}}h^{\frac{1}{2}}$ and $T = \sigma^{-1}\hbar = \alpha^{-1}\mu^{\frac{3}{2}}h^{\frac{1}{2}}$; then the the shift (unrescaled) due to magnetic drift does not exceed $C\alpha\mu^{-2}T = C\hbar$, which justifies the choice of σ.

Therefore as $\alpha \ge \bar{\alpha} = C_1\mu^{-\frac{1}{2}}h^{\frac{1}{2}}$ the contribution of α-ball intersected with $\{(x,y) : |x-y| \le \bar{\gamma} := C_0\mu^{-\frac{1}{2}}h^{\frac{1}{2}}\}$ to $|\mathsf{I}^{\mathsf{T}} - \mathcal{I}^{\mathsf{MW}}|$ does not exceed $C\mu h^{-1}\sigma \times \mu^{\frac{1}{2}\kappa}h^{-\frac{1}{2}\kappa} \asymp C\alpha\mu^{\frac{1}{2}+\frac{1}{2}\kappa}h^{-\frac{1}{2}-\frac{1}{2}\kappa}$. Then summation with respect to all such balls does not exceed $C\mu^{\frac{1}{2}+\frac{1}{2}\kappa}h^{-\frac{1}{2}-\frac{1}{2}\kappa}$, as in estimate (16.5.72) below.

Meanwhile the contributions to both I and $\bar{\mathsf{I}}$ of zone $\{(x,y) : |x-y| \ge \bar{\gamma}\}$ does not exceed $C\bar{\gamma}^{-1-\kappa}$ which is also of the same magnitude.

Finally, the contributions to both I and $\bar{\mathsf{I}}$ of zone $\{(x,y) : \alpha(x) \le \bar{\alpha},\ \alpha(y) \le \bar{\alpha}\}$ do not exceed $C\mu^{1+\frac{1}{2}\kappa}h^{-1-\frac{1}{2}\kappa} \times \bar{\alpha}^2 \asymp C\mu^{\frac{1}{2}\kappa}h^{-\frac{1}{2}\kappa}$ which is less than the right-hand expressions in both (16.5.72) and (16.5.73).

Thus we arrive to estimate (16.5.72) below.

Toy-Model Approximation. Meanwhile for the toy-model approximation $\sigma = \mu^{-1}h$ as long as $T \le T_* := \alpha^{-1}\mu^{\frac{3}{2}}h^{\frac{1}{2}}$; so we conclude that as $\alpha \ge \bar{\alpha}$, the contribution to $(\mathsf{I}-\bar{\mathsf{I}})$ of α-ball intersected with $\{(x,y) : |x-y| \le \bar{\alpha}\}$ does not exceed $C\alpha\mu^{\frac{1}{2}\kappa}h^{-\frac{1}{2}\kappa}$. After summation with respect to $\alpha^{-1}d\alpha$ we get $C\mu^{\frac{1}{2}\kappa}h^{-\frac{1}{2}\kappa}$ which is less than the right-hand expression in (16.5.73).

Now we need to consider larger T and γ; then $\sigma = \gamma^2$ and $T \asymp \alpha^{-1}\mu^2\gamma$. Then we should define $\bar{\gamma}$ so that $\sigma T \le \hbar$ iff $\gamma \le \bar{\gamma}$. Therefore we pick up $\bar{\gamma} = \mu^{-\frac{1}{3}}h^{\frac{1}{3}}\alpha^{\frac{1}{3}}$ and matching $\bar{T} = \mu^{\frac{4}{3}}h^{\frac{1}{3}}\alpha^{-\frac{2}{3}}$ and $\bar{\gamma} = \mu^{-\frac{2}{3}}h^{\frac{2}{3}}\alpha^{\frac{2}{3}}$.

Using the same arguments as above we conclude that the contribution to $(\mathsf{I}-\bar{\mathsf{I}})$ of the zone $\{(x,y) : \bar{\alpha} \le |x-y| \le \bar{\gamma}\}$ and contributions to both I and $\bar{I}$ of the zone $\{(x,y) : \bar{\alpha} \ge |x-y| \le \bar{\gamma}\}$ also do not exceed the right-hand expression in (16.5.73).

Thus we arrive to estimate (16.5.73) below.

Theorem 16.5.23. *For Schrödinger-Pauli operator under conditions* (16.1.5)–(16.1.6), (16.1.8), $\mu \ge h^{-1}$ *and* $F = 1$

$$|\mathsf{I} - \mathcal{I}^{\mathsf{MW}}| \le C\mu^{\frac{1}{2}+\frac{1}{2}\kappa} h^{-\frac{1}{2}-\frac{1}{2}\kappa} \tag{16.5.72}$$

and

$$|\mathsf{I} - \bar{\mathsf{I}}| \le C\mu^{\frac{1}{3}+\frac{1}{3}\kappa} h^{-\frac{1}{3}-\frac{1}{3}\kappa}. \tag{16.5.73}$$

16.5.5 Problems and Remarks

Remark 16.5.24. The main difference between cases $1 < \kappa < 2$ and $0 < \kappa < 1$ as $\mu h \ll 1$ is that in the former case the main contribution to the remainder is delivered by (x, y) close to one another ($|x - y| \ll \mu^{-1}$) while in the latter case by (x, y) with $|x - y| \asymp \mu^{-1}$.

We can calculate $\mathcal{I}^{\mathsf{MW}}$ and $\bar{\mathsf{I}}$ plugging corresponding expressions $e_z^{\mathsf{MW}}(x, y, 0)$ and $\bar{e}_z(x, y, 0)$ with $z = \frac{1}{2}(x + y)$ into I.

The following problems do not look too difficult:

Problem 16.5.25. Find nice expressions for $\mathcal{I}^{\mathsf{MW}}$ and $\bar{\mathsf{I}}$.

Problem 16.5.26. As $\mu h \le 1$ get rid of condition (16.1.5); according to Chapter 13 we do not need it for estimate $|\mathsf{I} - \mathsf{I}^{\mathsf{T}}|$ but we want to get rid of it in estimates for $|\mathsf{I} - \mathcal{I}^{\mathsf{W}}|$, $|\mathsf{I} - \mathcal{I}^{\mathsf{MW}}|$ and $|\mathsf{I} - \bar{\mathsf{I}}|$. To do this

(i) Assume first that condition

$$|V| + |\nabla V| \asymp 1 \tag{16.5.74}$$

is fulfilled and consider the scaling function $\alpha(x) = \mathsf{max}\big(\epsilon|V(x)|, \mu h, C\mu^{-1}\big)$.

(ii) Assume then that condition

$$|V| + |\nabla V| + |\det \mathsf{Hess}\, V| \asymp 1 \tag{16.5.75}$$

is fulfilled and consider the scaling function

$$\alpha(x) = \mathsf{max}\big(\epsilon(|V(x)| + |\nabla V(x)|^2)^{\frac{1}{2}}, (\mu h)^{\frac{1}{2}}, C\mu^{-1}\big).$$

Problem 16.5.27. Get rid of condition (16.1.6) assuming instead that $|F| + |\nabla F| \ge \epsilon$.

(i) Repeating arguments of Section 16.4 and using results of Chapter 14 one can prove easily that $|\mathsf{I}-\mathsf{I}^{\mathsf{T}}|\le C\mu^{-1/2}h^{-1-\kappa}$ as $\mu\le h^{-1}$. Derive similar estimates for Schrödinger and Schrödinger-Pauli operators as $h^{-1}\le\mu\le h^{-2}$ and for Schrödinger-Pauli operator as $\mu\ge h^{-2}$.

(ii) Introducing scaling function $\ell(x)=\epsilon|F(x)|$ in zone $\{x:\ \ell(x)\ge\mu^{-\frac12}\}$ one can rescale $\mu\mapsto\mu\ell^2$, $h\mapsto h\ell^{-1}$, $\mu h^{-1-\kappa}\mapsto\mu^{-1}h^{-1-\kappa}\ell^{-1+\kappa}$, after integration over $\ell^{-2}d\ell$ we get $C\mu^{-1}h^{-1-\kappa}\ell^{-2+\kappa}$ calculated as $\ell=\mu^{-\frac12}$ i.e. $\mu^{-\frac12\kappa}h^{-1-\kappa}$. This is an estimate for the contribution of the regular zone.

Prove the same estimate for the contribution of the singular zone as $\mu\le h^{-1}$. Derive similar estimates as $h^{-1}\le\mu\le h^{-2}$ and as $\mu\ge h^{-2}$.

(iii) Is it possible to upgrade the above estimate to $C\mu^{-\frac12}h^{-1-\kappa}$ as $\kappa<1$? Explore also cases $h^{-1}\le\mu\le h^{-2}$ and $\mu\ge h^{-2}$.

16.6 Pointwise Asymptotics: 3D Toy-Model

16.6.1 Toy-Model in 3D: Propagator

Consider the *pilot-model operator*

$$A=\bar A:=h^2D_1^2+(hD_2-\mu x_1)^2+h^2D_3^2+2\alpha x_1+2\beta x_3 \tag{16.6.1}$$

which is the sum of 2D toy-model (16.2.1) $\bar A_{(2)}$ and 1D Schrödinger operator

$$B:=h^2D_3^2+2\beta x_3 \tag{16.6.2}$$

and therefore propagator of $\bar A$ is

$$U(x,y,t)=U_{(2)}(x',y',t)U_{(1)}(x_3,y_3,t) \tag{16.6.3}$$

where $U_{(2)}(x',y',t)$ is the Schwartz kernel of the propagator $e^{ih^{-1}t\bar A_{(2)}}$ and therefore *after rescaling* it is defined by (16.2.1) while $U_{(1)}(x_3,y_3,t)$ is the Schwartz kernel of the propagator $e^{ih^{-1}tB}$ and then one can prove easily that *before rescaling*

$$\begin{aligned}&U_{(1)}(x_3,y_3,t)=\\ &(2\pi h)^{-1}\int\exp\Big(ih^{-1}\big((\zeta+\beta t)x_3-(\zeta-\beta t)y_3+\zeta^2t+\frac13\beta^2t^3\big)\Big)\,d\zeta=\\ &\frac12(2\pi h|t|)^{-\frac12}\exp\Big(ih^{-1}\big(\beta t(x_3+y_3)+\frac18t^{-1}(x_3-y_3)^2+\frac13\beta^2t^3\big)\Big);\end{aligned} \tag{16.6.4}$$

in particular

$$U_{(1)}(x_3,x_3,t)=\frac{1}{2}(2\pi h|t|)^{-\frac{1}{2}}\exp\Big(ih^{-1}\big(2\beta t x_3+\frac{1}{3}\beta^2t^3\big)\Big). \tag{16.6.5}$$

Therefore

(16.6.6) After standard rescaling $x\mapsto \mu x$, $t\mapsto \mu t$ $U(x,x,t)$ in comparison with $U_{(2)}(x',x',t)$ acquires factor

$$\frac{1}{2}\mu(2\pi\hbar|t|)^{-\frac{1}{2}}\exp\Big(i\hbar^{-1}\big(2\mu^{-1}\beta t x_3+\frac{1}{3}\mu^{-2}\beta^2t^3\big)\Big) \tag{16.6.7}$$

and therefore (16.2.23) and (16.2.24) are replaced respectively by

$$\varphi(t)\coloneqq -t^2\mu^{-2}\alpha^2\cot(t)-t\mu^{-2}\alpha^2+\frac{1}{3}\mu^{-2}\beta^2t^3-t\tau \tag{16.6.8}$$

and

$$\mu^{-2}\alpha^2\big(t^2-t\sin(2t)\big)+\mu^{-2}\beta^2t^2\sin^2(t)=\big(\tau+\mu^{-2}\alpha^2\big)\sin^2(t); \tag{16.6.9}$$

the latter equation could be rewritten as (16.2.24) with τ replaced by τ'

$$\mu^{-2}\alpha^2\big(t^2-t\sin(2t)\big)=\big(\tau'+\mu^{-2}\alpha^2\big)\sin^2(t) \tag{16.6.10}$$

and

$$\mu^{-2}\beta^2t^2=(\tau-\tau'); \tag{16.6.11}$$

the former equation shows the return times of 2D-movement on the energy level τ' and the former the looping time of 1D-movement associated with B (after rescaling) on the energy level $(\tau-\tau')$.

Remark 16.6.1. We should set $T=\epsilon_0\mu$ (in contrast to 2D-case). Really, unless we want to make assumptions outside of the ball $B(0,\ell)$ with a small constant ℓ we need to take $T\le\epsilon_0$ (before rescaling) and then $T\le\epsilon_0\mu$ (after rescaling). This absolves us from the analysis of the equatorial zone.

Let us compare solutions t_k^* of (16.6.9) and solutions t_k to (16.2.24). One can see easily that

(16.6.12) If $|k|\le\epsilon|\beta|^{-1}\mu$, then

$$t_k^*=t_k\big(1+O(\mu^{-2}\beta^2k^2)\big) \tag{16.6.13}$$

and

$$\varphi''(t_k^*)=\varphi''_{(2)}(t_k)\big(1+O(\mu^{-2}\beta^2k^2)\big) \tag{16.6.14}$$

with $\varphi_{(2)}$ defined by (16.2.23). Furthermore other properties of $\varphi_{(2)}$ are fulfilled for φ as well.

16.6.2 Tauberian Estimates

Then as $|k| \le \epsilon\mu$ in virtue of (16.6.6) and calculations of Section 16.2 contribution of k-th tick to $F_{t\to\hbar^{-1}\tau}\Gamma_x U$ does not exceed

$$C\begin{cases}\mu h^{-1}\times \big(\mu/h|k|\big)^{\frac12} & \text{as } 1\le |k|\le \bar{k},\\ \mu h^{-1}(\mu^2 h/\alpha|k|)^{\frac12}\times \big(\mu/h|k|\big)^{\frac12} & \text{as } \bar{k}\le |k|\le \epsilon\mu\ell,\end{cases} \tag{16.6.15}$$

where as before $\bar{k}=\epsilon\mu^2 h\alpha^{-1}$. Recall that without an extra factor $\big(\mu/h|k|\big)^{\frac12}$ we would have estimate for $F_{t\to\hbar^{-1}\tau}\Gamma_{x'}U_{(2)}$.

However, this extra factor is a game changer. As before there are three cases:

(a) $\alpha\ge \mu^2 h$; then we set $\bar{k}=1$ and the summation with respect to $k: 1\le |k|\le \epsilon\mu\ell$ returns

$$C\mu h^{-1}(\mu^2 h/\alpha)^{\frac12}\cdot(\mu/h)^{\frac12}\log(\mu\ell)\asymp C\mu^{\frac52}h^{-1}\alpha^{-\frac12}\log(\mu\ell).$$

(b) $\mu h\ell^{-1}\le\alpha\le\mu^2 h$; then $1\le\bar{k}\le\epsilon\mu\ell$ and summation with respect to $k:\bar{k}\le|k|\le\epsilon\mu\ell$ returns

$$C\mu^{\frac52}h^{-1}\alpha^{-\frac12}\log(\mu\ell)/\bar{k}\asymp C\mu^{\frac52}h^{-1}\alpha^{-\frac12}\big(1+(\log(\alpha\ell/\mu h))_+\big)$$

while summation with respect to $k: 1\le|k|\le\bar{k}$ returns the same expression albeit without logarithmic factor.

(c) $\alpha\le\mu h\ell^{-1}$; then $\bar{k}\ge\epsilon\mu\ell$ and we reset set $\bar{k}=\epsilon\mu\ell$ and summation with respect to k returns

$$C\mu h^{-1}\times\big(\mu/h\big)^{\frac12}\bar{k}^{\frac12}\asymp C\mu^2 h^{-\frac32}\ell^{\frac12}.$$

So we have proved

Proposition 16.6.2 [16]**.** *(i) After rescaling as* $T=\epsilon\mu\ell$, $\ell\ge C_0\mu^{-1}$

$$|F_{t\to\hbar^{-1}\tau}\bar{\chi}_T(t)\Gamma_x U|\le C\mu h^{-2}+ C\begin{cases}\mu^{\frac52}h^{-1}\alpha^{-\frac12}\big(1+(\log(\alpha\ell/\mu h))_+\big) & \text{as } \alpha\ell\ge\mu h,\\ \mu^2 h^{-\frac32}\ell^{\frac12} & \text{as } \alpha\ell\le\mu h.\end{cases} \tag{16.6.16}$$

[16] Cf. Proposition 16.2.6.

(ii) Therefore as operator A coincides with the toy-model operator (16.6.1) *in $B(0,\ell)$*

$$|e(0,0,\tau)-e^{\mathsf{T}}(0,0,\tau)|\le Ch^{-2}\ell^{-1}+ C\begin{cases}\mu^{\frac32}h^{-1}\alpha^{-\frac12}\bigl(1+(\log(\alpha\ell/\mu h))_+\bigr)\ell^{-1} & \text{as } \alpha\ell\ge\mu h,\\ \mu h^{-\frac32}\ell^{-\frac12} & \text{as } \alpha\ell\le\mu h.\end{cases} \tag{16.6.17}$$

(iii) In particular, as $\alpha\asymp\ell\asymp 1$ the right-hand expression in (16.6.17) *does not exceed $Ch^{-2}+C\mu^{\frac32}h^{-1}\bigl(1+|\log\mu h|\bigr)$ which is $O(h^{-2})$ as $\mu\le(h|\log h|)^{-\frac23}$.*

16.6.3 Weyl Estimates

Even simpler are Weyl estimates: in comparison with 2D-case they acquire factor $\mu^{\frac12}h^{-\frac12}$ and (16.2.64) becomes

$$\mathsf{R}^{\mathsf{W}}_x:=|e^{\mathsf{T}}(x,x,0)-h^{-3}\mathcal{N}^{\mathsf{W}}_x|\le C\mu^{-\frac12}h^{-\frac32}+C\mu^{\frac52}\alpha^{-\frac12}h^{-1} \tag{16.6.18}$$

and more generally we arrive to Statement (i) below

Proposition 16.6.3 [17]**.** *For a toy-model operator* (16.6.1) *with $\tau\asymp 1$,*

(i) As $\mu^2h\le\alpha\le 1$ estimate (16.6.18) *holds; moreover if we replace $\mathcal{N}^{\mathsf{W}}_x$ by $\mathcal{N}^{\mathsf{W}}_x+\mathcal{N}_{x,\mathsf{corr}(r)}$ with the correction term $h^{-3}\mathcal{N}_{x,\mathsf{corr}(r)}$ delivered by r-term stationary phase approximation then an error does not exceed*

$$C\mu^{-\frac12}h^{-\frac32}+C\mu^{\frac32}h^{-\frac32}\bigl(\mu^2h/\alpha\bigr)^{r+\frac12}. \tag{16.6.19}$$

(ii) As $\alpha\le\mu^2h$ estimate holds:

$$\mathsf{R}^{\mathsf{W}}_x:=|e^{\mathsf{T}}(x,x,0)-h^{-3}\mathcal{N}^{\mathsf{W}}_x|\le C\mu^{\frac32}h^{-\frac32}; \tag{16.6.20}$$

(iii) In particular, as $\mu\le h^{-\frac13}$ we have $\mathsf{R}^{\mathsf{W}}=O(h^{-2})$ without any assumptions to α,β: $|\alpha|\le 1$, $|\beta|\le 1$.

Recall that here we do not need to analyze the equatorial zone and therefore the difference between cases $\alpha\ge\mu\hbar^{\frac23}$ and $\alpha\le\mu\hbar^{\frac23}$ disappears together with corresponding terms in (16.2.66) or (16.2.67).

[17] Cf. Proposition 16.2.12.

16.6.4 Micro-Averaging

Micro-averaging adds yet another layer of complexity. Let us consider an *isotropic micro-averaging* with function $\psi_\gamma(x) = \psi(x/\gamma)$ and an *anisotropic micro-averaging* with function $\psi_\gamma(x) = \psi(x'/\gamma, x_3/\gamma_3)$ where $\boldsymbol{\gamma} = (\gamma, \gamma_3)$ is a scale with respect to (x', x_3).

Then one needs to integrate by parts with respect to x_3 taking in account factor $\exp\bigl(2ih^{-1}\beta t x_3\bigr)$ in (16.6.5) and rescaling with respect to t which brings factor $(\mu h/|\beta|\gamma_3|k|)^l$ as $(\mu h/|\beta|\gamma_3|k|) \le 1$ in addition to factor $(\mu h/|\alpha|\gamma|k|)^l$ as $(\mu h/|\alpha|\gamma|k|) \le 1$. Thus

(16.6.21) Micro-averaging brings factor $(\mu h/\nu(\boldsymbol{\gamma})|k|)^l$ as $(\mu h/\nu(\boldsymbol{\gamma})|k|) \le 1$ with $\nu(\boldsymbol{\gamma}) \coloneqq |\alpha|\gamma + |\beta|\gamma_3$.

Then we need to modify (16.2.53) replacing $|\alpha|\gamma$ by $\nu(\boldsymbol{\gamma})$:

$$|k| \ge \hat{k}(\boldsymbol{\gamma}) \coloneqq \mu h/\nu(\boldsymbol{\gamma}). \tag{16.6.22}$$

To understand how it affects a Tauberian estimate we need to consider the following cases:

(a) Micro-averaging has no effect as $\hat{k}(\boldsymbol{\gamma}) \ge \epsilon\mu\ell$ i.e. as $\nu(\boldsymbol{\gamma}) \le h\ell^{-1}$.

(b) Micro-averaging has a minimal effect (only decreasing the logarithmic factor) as $\epsilon\mu\ell \ge \hat{k}(\boldsymbol{\gamma}) \ge \bar{k}$. Obviously in this case $\bar{k} = \epsilon\,\mathsf{max}\bigl(\mu^2 h/\alpha, 1\bigr)$. So this case holds iff $h\ell^{-1} \le \nu(\boldsymbol{\gamma}) \le \mathsf{min}(\mu h, \alpha\mu^{-1})$. Then the logarithmic factor becomes $\mathsf{log}\bigl(\hat{k}(\boldsymbol{\gamma})/\bar{k}\bigr)$.

(c) Micro-averaging kills logarithmic factor and further leads to $\bar{k}^{\frac12}$ replaced by $\hat{k}(\boldsymbol{\gamma})^{\frac12}$ as $1 \le \hat{k}(\boldsymbol{\gamma}) \le \bar{k}$. Obviously in this case $\bar{k} = \epsilon\,\mathsf{min}\bigl(\mu^2 h/\alpha, \mu\ell\bigr)$. So this case holds iff $\mathsf{max}(h\ell^{-1}, \alpha\mu^{-1}) \le \nu(\boldsymbol{\gamma}) \le \mu h$. Then the right-hand expression in (16.6.24) becomes $C\mu^2 h^{-1}\nu^{-\frac12}\gamma^{-\frac12}$.

(d) Micro-averaging resets $\bar{k}$ to 1 and brings factor $(\mu h/\nu(\boldsymbol{\gamma}))^l$ as $\hat{k}(\boldsymbol{\gamma}) \le 1$ i.e. as $\nu(\boldsymbol{\gamma}) \ge \mu h$. Then the right-hand expression in (16.6.24) becomes $C\mu^{\frac32} h^{-\frac32}(\mu h/\nu(\boldsymbol{\gamma}))^l$.

Thus we arrive to

Proposition 16.6.4. *For the toy-model operator* (16.6.1) *with* $\tau \asymp 1$, $0 \le \alpha \le 1$, $|\beta| \le 1$, $\mu \le h^{-1}$ *in* $\mathbb{R}^3$ *estimates*

$$\gamma^{-2}\gamma_3^{-1}|F_{t\to h^{-1}\tau}\big(\big(\bar\chi_T(t)-\bar\chi_{\bar T}\big)\Gamma(U\psi_\gamma)\big)| \le C\mu R^{\mathsf T}(\boldsymbol\gamma) \tag{16.6.23}$$

and

$$\gamma^{-2}\gamma_3^{-1}|F_{t\to h^{-1}\tau}\big(\bar\chi_T(t)\Gamma(U\psi_\gamma)\big)| \le C\mu h^{-2} + C\mu R^{\mathsf T}(\boldsymbol\gamma) \tag{16.6.24}$$

hold as $T = \epsilon\mu\ell$ *where*

$$R^{\mathsf T}(\boldsymbol\gamma) = \tag{16.6.25}$$

$$\begin{cases} \mu^{\frac32}h^{-1}\alpha^{-\frac12}\big(1+(\log(\alpha\ell/\mu h))_+\big) & \text{as } \alpha\ell \ge \mu h,\ \nu(\boldsymbol\gamma)\le h\ell^{-1},\\ \mu h^{-\frac32}\ell^{\frac12} & \text{as } \alpha\ell \le \mu h,\ \nu(\boldsymbol\gamma)\le h\ell^{-1},\\ \mu^{\frac32}h^{-1}\alpha^{-\frac12}\big(1+(\log(\alpha/\mu\nu(\boldsymbol\gamma)))_+\big) & \text{as } h\ell^{-1}\le \nu(\boldsymbol\gamma)\le \min(\mu h,\alpha\mu^{-1}),\\ \mu h^{-1}\nu(\boldsymbol\gamma)^{-\frac12} & \text{as } \max(h\ell^{-1},\alpha\mu^{-1})\le \nu(\boldsymbol\gamma)\le \mu h,\\ \mu^{\frac12}h^{-\frac32}(\mu h/\nu(\boldsymbol\gamma))^l & \text{as } \nu(\boldsymbol\gamma)\ge \mu h. \end{cases}$$

In the right-hand expression of (16.6.25) two first lines correspond to the case (a).

Corollary 16.6.5. *In the framework of Proposition 16.6.4 the following estimate holds*

$$\gamma^{-2}\gamma_3^{-1}|\Gamma\big(e(.,.,\tau)-e^{\mathsf T}(.,.,\tau)\big)\psi_\gamma| \le C\big(h^{-2}+R^{\mathsf T}(\boldsymbol\gamma)\big)\ell^{-1} \tag{16.6.26}$$

Consider now how micro-averaging affects Weyl estimate (with the right-hand expression (16.6.19)). There is no effect as $\nu(\boldsymbol\gamma) \le \mu h$ and factor $(\mu h/\nu(\boldsymbol\gamma))^l$ comes out as $\nu(\boldsymbol\gamma)\ge \mu h$. Thus we arrive to

Proposition 16.6.6. *For the toy-model operator* (16.6.1) *with* $\tau \asymp 1$, $0 \le \alpha \le 1$, $\mu \le h^{-1}$ *in* $\mathbb{R}^3$

(i) As $\mu^2 h \le \alpha \le 1$ *estimate holds:*

$$\mathsf R^{\mathsf W}_{x(r)}(\boldsymbol\gamma) := \tag{16.6.27}$$

$$\gamma^{-2}\gamma_3^{-1}|\int \Big(e^{\mathsf T}(x,x,0)-h^{-3}\big(\mathcal N^{\mathsf W}_x+\mathcal N_{x,\mathsf{corr}(r)}\big)\Big)\psi_\gamma\,dx| \le$$

$$Ch^{-2}+C\mu^{\frac32}h^{-\frac32}\big(\mu^2h/\alpha\big)^{r+\frac12}\begin{cases}(\mu h/\nu(\boldsymbol\gamma))^l & \text{as } \nu(\boldsymbol\gamma)\ge\mu h,\\ 1 & \text{as } \nu(\boldsymbol\gamma)\le\mu h.\end{cases}$$

(ii) As $\alpha \le \mu^2 h$ estimate holds:

$$\mathsf{R}^{\mathsf{W}}_x(\gamma) := \gamma^{-2}\gamma_3^{-1}\Big|\int \Big(e^{\mathsf{T}}(x,x,0) - h^{-3}\mathcal{N}^{\mathsf{W}}_x\Big)\psi_\gamma\, dx\Big| \le \tag{16.6.28}$$

$$Ch^{-2} + C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}\begin{cases} \big(\mu h/\nu(\gamma)\big)^l & \text{as } \nu(\gamma)\ge \mu h,\\ 1 & \text{as } \nu(\gamma)\le \mu h.\end{cases}$$

16.6.5 Transitional and Strong Magnetic Field

Tauberian Estimate

Consider transitional $\mu h \asymp 1$ and strong $\mu h \gtrsim 1$ magnetic field for the Schrödinger-Pauli toy-model operator

$$A = \bar{A} := h^2D_1^2 + (hD_2 - \mu x_1)^2 + h^2D_3^2 + 2\alpha x_1 + 2\beta x_3 - \mu h \tag{16.6.29}$$

which alternatively means that we assume that $|\tau - \mathfrak{z}\mu h| \le C$ in the framework of the standard toy-model (16.6.1), $\mathfrak{z} = 1$.

Proposition 16.6.7. *For a toy-model operator* (16.6.1) *with $\mu h \gtrsim 1$ in $\mathbb{R}^3$ as $|x| \le C_0$, $|y| \le C_0$, $\tau \le c\mu h$*

(i) $e(x,y,\tau) \equiv 0 \mod O(\mu h^\infty)$ as $\tau \le \mu h - \epsilon_0$ (lower spectral gap).

(ii) As $\alpha > 0$ the following estimates hold

$$|e(x,x,\tau+h) - e(x,y,\tau)| \le \tag{16.6.30}$$

$$C\mu h^{-1}\max_{j\in\mathbb{Z}^+}\big(\max(|V(x) + 2j\mu h - \tau|, h)\big)^{-\frac{1}{2}}$$

and

$$|F_{t\to\hbar^{-1}\tau}U(x,y,t)| \le C\mu^2 h^{-1}\max_{j\in\mathbb{Z}^+}\big(\max(|V(x) + 2j\mu h - \tau|, h)\big)^{-\frac{1}{2}} \tag{16.6.31}$$

and these estimate are sharp as $x = y$ and τ is close to Landau level μh. Recall that in (16.6.31) *t is rescaled.*

Proof. Statement (i) is obvious. To prove Statement (ii) note that

$$e(x,y,\tau) = \int e_B(x_3,y_3,\tau-\tau')\, d_{\tau'}e_{(2)}(x',y',\tau') = \tag{16.6.32}$$

$$\int e_{(2)}(x',y',\tau-\tau')\, d_{\tau'}e_B(x_3,y_3,\tau')$$

and therefore

$$e(x,y,\tau+h)-e(x,y,\tau)= \int \big(e_B(x_3,y_3,\tau-\tau'+h)-e_B(x_3,y_3,\tau-\tau')\big)\,\partial_{\tau'}e_{(2)}(x',y',\tau')\,d\tau'. \tag{16.6.33}$$

Recall that due to our analysis in Section 16.2 $\partial_{\tau'}e_{(2)}(x',y',\tau')$ is essentially supported in $C\mu^{-\frac12}h^{\frac12}\alpha$-vicinity of Landau level and fast decays out of it.

Finally recall that due to the analysis of Subsubsections 5.3.1–5.3.1

$$|e_B(x_3,y_3,\tau+h)-e_B(x_3,y_3,\tau)|\le C(\tau')^{-\frac12} \qquad \text{as } \tau'\ge C_0h. \tag{16.6.34}$$

Combining it with estimate (16.2.73) for $|\partial_{\tau'}e_{(2)}(x',y',\tau')|$ we conclude that the left-hand expression of (16.6.30) does not exceed

$$C\mu^{\frac32}\alpha^{-1}h^{-\frac32}\times \alpha\mu^{-\frac12}h^{\frac12}\times \max_{j\in\mathbb{Z}^+}\big(\max(|V(x)+2j\mu h-\tau|,h)\big)^{-\frac12}.$$

Estimate (16.6.31) is proven; estimate (16.6.31) follows from it. □

Further, as before $T^*=\epsilon_0\mu\ell$. Then we immediately arrive to

Corollary 16.6.8. *For a self-adjoint operator in domain X, $B(0,\ell)\subset X\subset \mathbb{R}^2$, $\ell\ge C_0h$, coinciding in $B(0,\ell)$ with the toy-model operator* (16.6.29) *with $\tau\asymp 1$, $0<\alpha\le 1$, $|\beta|\le 1$, $\mu\ge h^{-1}$*

(i) Statements (i) and (ii) of Proposition 16.6.7 remain true.

(ii) Formula (16.6.32) *holds modulo $O(\mu h^{-\frac32}\ell^{-1})$.*

Micro-Averaging

Let us consider micro-averaging. First let us estimate Fourier transform where as before we rescaled $t\mapsto \mu t$; formulae (16.6.16)–(16.6.17) imply immediately

Proposition 16.6.9. *For a toy-model operator* (16.6.29) *in $\mathbb{R}^3$ with $\mu h\ge 1$, $\gamma_3\ge h$*

$$\gamma^{-2}\gamma_3^{-1}|F_{t\to h^{-1}\tau}\bar\chi_T(t)\Gamma(U\psi_\gamma)|\le C\mu^2h^{-1}\gamma_3^{-\frac12} \tag{16.6.35}$$

Corollary 16.6.10. *In the framework of Corollary 16.6.8 as $\ell\ge\gamma_3\ge h$*

$$\gamma^{-2}\gamma_3^{-1}|\Gamma\big(e(.,.,\tau)-e^{\mathsf T}(.,.,\tau)\big)\psi_\gamma|\le C\mu h^{-1}\gamma_3^{-\frac12}\ell^{-1}. \tag{16.6.36}$$

16.6.6 Magnetic Weyl Approximation

We can try to use a host of the different approximations but restrict ourselves now to the magnetic Weyl approximation. Recall (16.6.32) and note that

$$e^{\mathsf{MW}}(x,y,\tau) = \int e^{\mathsf{W}}_B(x_3,y_3,\tau-\tau')\,d_{\tau'}e^{\mathsf{MW}}_{(2)}(x',y',\tau') = \int e^{\mathsf{MW}}_{(2)}(x',y',\tau-\tau')\,d_{\tau'}e^{\mathsf{W}}_B(x_3,y_3,\tau'). \tag{16.6.37}$$

Pointwise Asymptotics

Proposition 16.6.11. *For the toy-model operator* (16.6.1) *with* $\tau \le c$, $\mu h \lesssim 1$ *and for the toy-model operator* (16.6.29) *with* $\tau \le c$, $\mu h \gtrsim 1$

$$|e^{\mathsf{MW}}(x,y,\tau) - e^{\mathsf{MW}}(x,y,\tau')| \le C \begin{cases} \mu^{\frac{3}{2}}h^{-1} & \text{as } \ \mu h \le 1,\\ \mu h^{-\frac{3}{2}} & \text{as } \ \mu h \ge 1 \end{cases} \tag{16.6.38}$$

as $|\tau-\tau'| \le h$.

Proof. Obviously the left-hand expression does not exceed

$$C\mu h^{-\frac{3}{2}} \sum_{j\le J} j^{-\frac{1}{2}} \asymp C\mu h^{-\frac{3}{2}} J^{\frac{1}{2}}$$

with $J = C_0 \max((\mu h)^{-1},1)$ which implies (16.6.38). □

Therefore one can hardly expect that the magnetic Weyl approximation provides a better error than the right hand expression of (16.6.38).

Proposition 16.6.12. *Let* $|\tau| \le \epsilon$. *Then for a toy-model operator* (16.6.1) *as* $\mu h \lesssim 1$ *and for a toy-model operator* (16.6.1) *as* $\mu h \gtrsim 1$

$$\mathsf{R}^{\mathsf{MW}} := |e^{\mathsf{T}}(x,x,0) - h^{-3}\mathcal{N}^{\mathsf{MW}}| \le Ch^{-2} + C\mu h^{-1} + C\mu h^{-\frac{5}{3}}|\beta|^{\frac{1}{3}}. \tag{16.6.39}$$

Proof. Without any loss of the generality we can assume that $x=0$, $\beta>0$. As contribution of k-th tick to the Tauberian expression is $O(\mu^{\frac{3}{2}}h^{-\frac{3}{2}}|k|^{-\frac{3}{2}})$, its contribution to the error when we replace β by 0 does not exceed $C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}|k|^{-\frac{3}{2}} \times \mu^{-3}h^{-1}\beta^2|k|^3$ and summation with respect to

$$k : |k| \le \tilde{k}_1 := \mu\beta^{-\frac{2}{3}}h^{\frac{1}{3}} \tag{16.6.40}$$

returns

$$C\mu^{-\frac{3}{2}}h^{-\frac{5}{2}}\beta^2|k|^{\frac{5}{2}} = C\mu h^{-\frac{5}{3}}\beta^{\frac{1}{3}} \tag{16.6.41}$$

On the other hand, summation of $C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}|k|^{-\frac{3}{2}}$ as $|k| \ge \tilde{k}_1$ returns $C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}\tilde{k}_1^{-\frac{1}{2}}$ which is the same expression because $\tilde{k}_1$ was defined from $\mu^{-3}h^{-1}\beta^2k^3 = 1$.

Meanwhile, contribution of k-th tick to the error when we replace α by 0 does not exceed $C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}|k|^{-\frac{3}{2}} \times \mu^{-2}h^{-1}\alpha|k|$ and summation with respect to

$$k : |k| \le \tilde{k}_2 \coloneqq \mu^2 h\alpha^{-1} \tag{16.6.42}$$

returns

$$C\mu^{-\frac{1}{2}}h^{-\frac{5}{2}}\alpha\tilde{k}_2^{\frac{1}{2}} = C\mu^{-\frac{1}{2}}h^{-2}\alpha^{\frac{1}{2}} \tag{16.6.43}$$

which is less than Ch^{-2}. On the other hand, summation of $C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}|k|^{-\frac{3}{2}}$ as $|k| \ge \tilde{k}_2$ returns $C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}\tilde{k}_2^{-\frac{1}{2}}$ which is the same expression because $\tilde{k}_2$ was defined from equation $\mu^{-2}h^{-1}\alpha\tilde{k}_2 = 1$. □

Remark 16.6.13. (i) We summed with respect to all k while it would be enough only with respect to $k : |k| \le \epsilon\mu$. However it provides us by no improvement.

(ii) So far we have not used factor $C(\mu^2h/\alpha|k|)^{\frac{1}{2}}$; using it we acquire in (16.6.41) factor $(\mu^2h/\alpha\tilde{k}_1)^{\frac{1}{2}} = \mu^{\frac{1}{2}}h^{\frac{1}{3}}\beta^{\frac{1}{3}}\alpha^{-\frac{1}{2}}$ resulting in

$$\mathsf{R}^{\mathsf{MW}} \le Ch^{-2} + C\mu h^{-1} + C\mu^{\frac{3}{2}}h^{-\frac{4}{3}}\beta^{\frac{2}{3}}\alpha^{-\frac{1}{2}} \tag{16.6.44}$$

provided

$$\alpha \ge \mu h^{\frac{2}{3}}\beta^{\frac{2}{3}}. \tag{16.6.45}$$

(iii) In contrast to 2D the magnetic Weyl approximation now is better than Weyl approximation as $\mu \ge h^{-\frac{1}{3}}$ (when it matters) but Weyl approximation with the correction terms may be better still.

Micro-Averaging

Consider now micro-averaging. We need to redo only the first step of the proof of Proposition 16.6.12 and only in the case $\mu \ge h^{-\frac{1}{3}}\beta^{-2}$ and it is useful only if $\tilde{k}_1 \ge \hat{k}(\boldsymbol{\gamma}) = \mu h/\nu(\boldsymbol{\gamma})$ or equivalently

$$\nu(\boldsymbol{\gamma}) = \alpha\gamma + \beta\gamma_3 \ge \beta^{\frac{2}{3}}h^{\frac{2}{3}}. \tag{16.6.46}$$

In this case in the left-hand expression of (16.6.41) should be reset to $\tilde{k}_1$ replaced by $\hat{k}(\gamma)$ as $\hat{k}(\gamma) \ge 1$ or by 1 with an extra factor $(\mu h/\nu(\gamma))^l$ as $\hat{k}(\gamma) \le 1$ resulting in $CR_1^{\mathsf{MW}}(\gamma)$ with

$$R_1^{\mathsf{MW}}(\gamma) := C\mu \begin{cases} \beta^2 \nu(\gamma)^{-\frac{5}{2}} \big(\mu h/\nu(\gamma)\big)^l & \text{as } \nu(\gamma) \ge \mu h,\ \alpha \le \mu^2 h, \\ \beta^2 \nu(\gamma)^{-\frac{5}{2}} & \text{as } \nu(\gamma) \le \mu h,\ \mu\nu(\gamma) \ge \alpha, \\ \beta^2 \nu(\gamma)^{-\frac{5}{2}} (\mu^2 h/\alpha)^{\frac{1}{2}} \big(\mu h/\nu(\gamma)\big)^l & \text{as } \nu(\gamma) \ge \mu h,\ \alpha \ge \mu^2 h, \\ \beta^2 \nu(\gamma)^{-\frac{5}{2}} (\mu\nu(\gamma)/\alpha)^{\frac{1}{2}} & \text{as } \nu(\gamma) \le \mu h,\ \mu\nu(\gamma) \le \alpha \end{cases} \tag{16.6.47}$$

and therefore we arrive to

Proposition 16.6.14. *Let $|\tau| \le \epsilon$ and* (16.6.46) *be fulfilled. Then for a toy-model operator* (16.6.1) *as $\mu h \lesssim 1$ and for a toy-model operator* (16.6.1) *as $\mu h \gtrsim 1$ a*

$$\mathsf{R}^{\mathsf{MW}}(\gamma) := \gamma^{-2}\gamma_3^{-1} \Big| \int \big(e^{\mathsf{T}}(x,x,0) - h^{-3} \int \mathcal{N}^{\mathsf{MW}}\big)\psi_\gamma \, dx\Big| \le Ch^{-2} + C\mu h^{-1} + CR_1^{\mathsf{MW}}(\gamma) \tag{16.6.48}$$

with $R_1^{\mathsf{MW}}(\gamma)$ defined by (16.6.47).

Remark 16.6.15. If we replace only $e_{(2)}(.,.,.)$ by $e^{\mathsf{MW}}(.,.,.)$ we can skip the last term.

16.6.7 Geometric Interpretation

Note that there are two classical dynamics: in x' and in x_1. The former has return times $t'_k := t'_k(\tau')$ where τ' is a corresponding part of energy and t'_k are defined in Section 16.2 as $t_k(\tau)$ while the latter is

$$x_3(t) = x_3(0) + 2\xi_3(0)t - \beta t^2, \qquad \xi_3(t) = \xi_3(0) - \beta t. \tag{16.6.49}$$

and has return times (to 0) $t''_k(\tau - \tau') = 2\beta^{-1}(\tau - \tau')$ and therefore the total system has return times[18] t_k and return energy partitions $(\tau'_k, \tau - \tau'_k)$ defined from the pair of equations

$$t_k = t'_k(\tau'_k) = t''_k(\tau - \tau') \tag{16.6.50}$$

[18] To point 0.

which is equivalent to (16.6.9)–(16.6.10).

Therefore relatively sets of return directions ξ_k is thinner in 3D than in 2D which explains errors acquiring lesser factor (in comparison with the principal part) in 3D than in 2D.

In particular, as $\beta = 0$ 1D-dynamics does not return at all unless it stays at 0, therefore in this case (16.6.49) mean exactly that $\tau'_k = \tau$ and $t'_k(\tau) = t_k(\tau)$.

16.7 Pointwise Asymptotics: General 3D-Operators

16.7.1 Set-up

We assume that

$$F := \Big(\sum_{jk} g_{jk} F^j F^k\Big)^{\frac{1}{2}} \tag{16.7.1}$$

is disjoint from 0, where $\boldsymbol{F} = (F^1, F^2, F^3)$ and F are vector and scalar intensities of the magnetic field respectively. Temporarily we assume that $F = 1$ (as we can reduce the general case to this one by dividing operator by F and using our standard arguments).

Further, without any loss of the generality we will assume locally that

$$F^1 = F^2 = 0. \tag{16.7.2}$$

Remark 16.7.1. (i) Due to Frobenius theorem we can make locally $g^{3j} = 0$ for $j = 1, 2$ and $F^1 = F^2 = 0$ simultaneously if and only if $f_* \wedge df_* = 0$ where $f_* = \sum_{j,k} F^j g_{jk} dx^k$ is the 1-form[19)]

(ii) Since

$$F = \Big(\frac{1}{2} \sum_{i,j,k,l} g^{ij} g^{kl} F_{ik} F_{jl}\Big)^{\frac{1}{2}}, \qquad F_{jk} = \partial_k A_j - \partial_j A_k, \tag{16.7.3}$$

under assumption (16.7.2)

$$F = \big(g^{11} g^{22} - g^{12} g^{21}\big)^{\frac{1}{2}} |F_{12}|. \tag{16.7.4}$$

[19)] Similar statement holds in the multidimensional case provided $\mathsf{rank}(F_{jk})(x) = d - 1$ at each point x; then $\boldsymbol{F}$ is defined up to a scalar factor by $\boldsymbol{F}(x) \in \mathsf{Ker}(\mathsf{F}_{jk})(x)$.

However

(16.7.5) We can assume that $F^1 = F^2 = 0$ locally and simultaneously that $g^{jk} = \delta_{jk}$ along a single magnetic line $\{x' = 0\}$[19)].

Really, we can satisfy condition $f_* \wedge df_* = 0$ changing g^{jk} but preserving them at the chosen magnetic line. Note that $\boldsymbol{F}$ then acquires some scalar factor which does not affect this condition. So, we can assume $g^{3j} = 0$ for $j = 1, 2$ and $F^1 = F^2 = 0$ at the chosen magnetic line which (after shift) becomes then $\{x' = 0\}$. Changing $x_3 \mapsto \phi(x_3)$ makes $g^{33} = 1$ along this magnetic line. Then $F^3 = \pm F = 1$ (for an appropriate orientation). Changing $x' = B(x_3)x'$ with an appropriate matrix $B(x')$ makes $g^{jk} = \delta_{jk}$ along this line.

Further

(16.7.6) In the framework of assumption (16.7.5) we can assume that $g^{31} = 0$.

Really, one can achieve it by $x' \mapsto x'$, $x_3 \mapsto \phi(x)$ with $\phi(x) = x_3 + O(|x'|^2)$.

Furthermore, one can make

$$g^{jk} = \delta_{jk} + O(|x'|^2) \qquad \text{as} \quad x_3 = 0 \quad j, k = 1, 2 \tag{16.7.7}$$

by $x' \mapsto x' + Q(x')$ with Q quadratic respect to x'.

By a gauge transform one can make $A_3 = 0$. Then $F^1 = F^2 = 0$ imply that A_1, A_2 do not depend on x_3 and therefore we can assume that $A_1 = 0$ as well:

$$A_1 = A_3 = 0, \qquad A_2 = A_2(x') = x_2 + O(|x'|^3) \tag{16.7.8}$$

where the last equality is due to $F = 1$ and assumption (16.7.5).

16.7.2 Classical Dynamics

Let us consider a classical dynamics. We know that for time $|t| \le T = \epsilon_0$ Hamiltonian trajectory starting from $\{|x| \le c_0\mu^{-1}\}$ remains confined in $C_0\mu^{-1}$-tube $\{|x'| \le C_0\mu^{-1}\}$. Then in virtue of our assumptions

$$\frac{dx_3}{dt} = 2\xi_3 + O(\mu^{-1}) \qquad \frac{d\xi_3}{dt} = -V_{x_3}(0, 0, x_3) + O(\mu^{-1}) \tag{16.7.9}$$

and therefore

$$(x_3,\xi_3)(t) = (x_3^0,\xi_3^0)(t) + O(\mu^{-1}|t|), \tag{16.7.10}$$

where here $(x_3^0,\xi_3^0)(t)$ denotes dynamics for a 1D-Schrödinger $\xi_3^2 + V(0,0,x_3)$ with the same initial data (as $t=0$).

Then one can prove easily that

$$|\xi_3(t)| \le C\big(|\beta|\cdot|t| + |\xi_3(0)|\big), \qquad |x_3| \le C\big(|\beta|t^2 + |\xi_3(0)|\cdot|t|\big) \quad \text{if } x_3(0)=0 \text{ and } |t|\le\epsilon \tag{16.7.11}$$

with

$$\beta := -V_{x_3}(0). \tag{16.7.12}$$

Then

$$\xi_3 = \xi_3(0)\big(1+O(t^2)\big) + 2\beta t\big(1+O(t^2)\big), \tag{16.7.13}$$

$$x_3 = \xi_3(0)t\big(1+O(t^2)\big) + \beta t^2\big(1+O(t^2)\big). \tag{16.7.14}$$

Let us analyze evolution of $(x',\xi')(t)$ but we start from $(p_1,p_2)(t)$. Recall that

$$\mu^{-1}\{p_1,p_2\} \equiv 1, \qquad g^{11}g^{22} - g^{12}g^{21} \equiv 1 \mod O(\mu^{-2}) \tag{16.7.15}$$

in the tube in question.

Let $p_1' := p_1 + \gamma p_3$; then $p_2' := (g^{12}p_1 + g^{22}p_2 + g^{23}p_3) \equiv -\frac{1}{2}\mu^{-1}\{a,p_1'\} \mod O(\mu^{-1})$. Then

$$\frac{1}{2}\mu^{-1}\{a,p_2'\} \equiv (g^{11}p_1 + g^{12}p_2 + g^{13}p_3)g^{22} - (g^{12}p_1 + g^{22}p_2 + g^{23}p_3)g^{12} \equiv p_1 + (g^{13}g^{22} - g^{23}g^{12})p_3.$$

So we pick up $\gamma = g^{13}g^{22} - g^{23}g^{12}$ and then

$$p_1' := (g^{22})^{-\frac{1}{2}}(p_1+\gamma p_3), \qquad \gamma = g^{13}g^{22} - g^{23}g^{12}, \tag{16.7.16}$$

$$p_2' := (g^{22})^{-\frac{1}{2}}(g^{12}p_1 + g^{22}p_2 + g^{23}p_3), \tag{16.7.17}$$

satisfy

$$\frac{1}{2}\mu^{-1}\{a,p_1'\} \equiv -p_2', \qquad \frac{1}{2}\mu^{-1}\{a,p_2'\} \equiv p_1', \qquad \mu^{-1}\{p_1',p_2'\} \equiv 1 \tag{16.7.18}$$

modulo $O(\mu^{-1})$. We set $p'_3 = p_3$.

We do not assume that $g^{13} = 0$ identically; instead its choice will be different and it would be only $O(\mu^{-1})$ in the tube in question. Note that

$$\gamma \equiv g^{13}g^{22} \mod O(\mu^{-2}) \equiv g^{13} \mod O(\mu^{-2} + \mu^{-1}|x_3|), \tag{16.7.19}$$

$$\gamma_{x_j} \equiv g^{13} \mod O(\mu^{-1}). \tag{16.7.20}$$

Really, $g^{jk} = \delta_{jk} + O(|x'|^2 + |x'| \cdot |x_3|)$ $(j = 1, 2)$, $g^{3j} = O(|x'|)$.

Let us consider again $\{a, p'_1\}$, this time more precisely. Note that

$$\{a, p'_1\} = -2\mu p'_2 + 2\sum_j \gamma_{x_j} p_j p_3 - V_{x_1} + O(\mu^{-1}) \qquad \text{as } x_3 = 0$$

as $|x'| = O(\mu^{-1})$ due to our assumptions.

Therefore we arrive to the first equation below and the second is proven in the same way

$$\{a, p'_1\} \equiv -2\mu p'_2 + 2\sum_j g^{13}_{x_j} p_j p_3 - V_{x_1}, \tag{16.7.21}$$

$$\{a, p'_2\} \equiv 2\mu p'_1 + 2\sum_j g^{23}_{,x_j} p_j p_3 - V_{x_2} \mod O(\mu^{-1}). \tag{16.7.22}$$

We want

$$g^{23}_{x_2} = g^{13}_{x_1} = 0, \quad -g^{23}_{x_1} = g^{13}_{x_2} = \kappa(x_3) \qquad \text{as } x' = 0 \tag{16.7.23}$$

which is possible to arrange as the only value at $x' = 0$ which is fixed is

$$\kappa(x_3) := \frac{1}{2}\big(g^{13}_{x_2} - g^{23}_{x_1}\big)\big|_{x'=0} = -\frac{1}{2}\big(g_{13,x_2} - g_{23,x_1}\big)\big|_{x'=0}; \tag{16.7.24}$$

one can prove easily this by transformation $x_3 \mapsto x_3 + Q(x_3; x')$ with $Q(x_3; x')$ quadratic with respect to x'. Note that

$$f_* \wedge df_* = 2\kappa(x_3) dx_1 \wedge dx_2 \wedge dx_3 \qquad \text{as } x' = 0. \tag{16.7.25}$$

Then (16.7.21)–(16.7.22) become

$$\{a, p'_1\} \equiv -2(\mu + \kappa p_3)p'_2 - V_{x_1}, \tag{16.7.26}$$

$$\{a, p'_2\} \equiv 2(\mu + \kappa p_3)p'_1 - V_{x_2} \mod O(\mu^{-1}). \tag{16.7.27}$$

Obviously

(16.7.28) We can replace in equations (16.7.26)–(16.7.27) V_{x_j} by $V_{x_j}(x_3) := V_{x_j}|_{x'=0}$ and p_3 by $p_3^0(t)$.

If $\kappa = 0$ and V_{x_j} did not depend on x_3 we would get the toy-model operator. Unfortunately, it is not the case and (16.7.26), (16.7.27) coincide with those for the toy-model only modulo $O(\mu^{-1} + |p_3| + |x_3|)$. However note that $\kappa(x_3)p_3 = \frac{d}{dt}K(x_3)$ where

$$K = \frac{1}{2}\int \kappa \, dx_3. \tag{16.7.29}$$

Therefore

$$p'(t) \equiv \Omega(t)\Omega^{-1}(0)p'(0) + \int_0^t \Omega(t)\Omega^{-1}(t')V' \, dt \qquad \mathsf{mod}\ O(\mu^{-1}|t|) \tag{16.7.30}$$

with

$$\Omega(t) = \begin{pmatrix} \cos(\mu\theta) & -\sin(\mu\theta) \\ \sin(\mu\theta) & \cos(\mu\theta) \end{pmatrix}, \quad \theta(t) = t + \mu^{-1}K(x_3(t)) \tag{16.7.31}$$

$p = (p_1, p_2)^t$, $V' = (\nabla' V)^t$, $\Omega(t)$ fundamental matrix of system (16.7.26)–(16.7.27). Expressing $\Omega^{-1}(t')$ via its derivative and integrating by parts we conclude that

$$p'(t) \equiv \Omega(t)p'(0) + \mu^{-1}\Omega(t)V'(x_3(0)) - \mu^{-1}V'(x_3(t)). \tag{16.7.32}$$

Meanwhile, as $j = 1, 2$

$$\{a, (-1)^j \mu x_{3-j} + p_j\} \equiv -\sum_{k,l} g^{kl}_{x_j} p_k p_l - V_{x_j} \quad \mathsf{mod}\ O(\mu^{-1}) \tag{16.7.33}$$

and we can replace in the right-hand expression x' by 0, p_k by p'_k and as $k = 1, 2$ we can replace p'_k by the corresponding component of $\Omega(t)p'(0)$. Then integrating by parts we arrive to

$$\big((-1)^j \mu x_{3-j} + p_j\big)\big|_{t=0}^{t=t} \equiv \\ -\int_0^t \Big(\frac{1}{2}\sum_{k,l}\big(g^{11} + g^{22}\big)_{x_j}(p_1^2 + p_2^2) + V_{x_j}(x_3(t))\Big)\, dt \equiv -\int_0^t V_{x_j}(x_3(t))\, dt \tag{16.7.34}$$

modulo $O(\mu^{-1})$ as $\big(g^{11} + g^{22}\big)_{x_j} = O(\mu^{-1})$ in virtue of our assumptions including (16.7.15). Further, considering out-of integral terms we conclude that

(16.7.35) Equality (16.7.34) holds modulo $O\big(\mu^{-1}(|t| + |\sin(2\mu\theta) + |p_3|\big)$ (where $p_3(t) \equiv p_3(0) \mod |t|$).

16.7.3 Semiclassical Approximation

So, after rescaling, the classical dynamics of the general operator is close to one of the *generalized toy-model*

$$A^0 := h^2 D_1^2 + (hD_2 - \mu x_1)^2 + h^2 D_3^2 + V^0(x), \qquad V^0(x) := V(x_3) + \sum_{j=1,2} \alpha_j(x_3) x_j \tag{16.7.36}$$

with

$$V(x_3) = V(0,0,x_3), \qquad \alpha_j(x_3) = V_{x_j}(0,0,x_3), \quad j = 1,2 \tag{16.7.37}$$

and the latter one is close albeit with a larger error to the dynamics of the toy-model (16.6.1) with $V(x_3)$, $\alpha_j(x_3)$ replaced by $V(0) + \beta x_3$ ($\beta = V_{x_3}(0)$), $\alpha_j = \alpha_j(0)$ respectively.

Proposition 16.7.2 [20]**.** *Let conditions* (16.3.1)–(16.3.3), (16.7.7)–(16.7.8) *be fulfilled*[6]*. Then after rescaling*

(i) Uniformly with respect to $|t| \le \epsilon\mu$ the propagator $e^{i\hbar^{-1}tA}$ is an $\hbar$-Fourier integral operator corresponding to the Hamiltonian flow Ψ_t.

(ii) As $|\sin(2\theta_1)| \ge \epsilon$, $|t| \ge \epsilon_0$

$$U(x,y,t) \equiv \mu(2\pi\hbar)^{-\frac{3}{2}} |t|^{-\frac{1}{2}} i(\sin(\theta_1))^{-1} e^{i\hbar^{-1}\phi(x,y,t)} \Big(\sum_m b_m(x,y,t)\Big)\hbar^m \tag{16.7.38}$$

with θ_1 defined by

$$\theta_1(t) = \theta(t) + K\big(x_3(t)\big) - K\big(x_3(0)\big) \tag{16.7.39}$$

with $\theta(t)$, $K(x_3)$ defined by (16.3.20), (16.7.29) *respectively and with ϕ defined by* (16.3.25)–(16.3.29) *and satisfying (with all derivatives)*

$$\phi = \bar{\phi}(\theta) + O(\mu^{-1}t), \tag{16.7.40}$$

$$b_m = \delta_{0m} + O(\mu^{-1}t) \tag{16.7.41}$$

[20] Cf. Proposition 16.3.4.

with

$$\bar{\phi} = \beta\mu^{-1}t(x_3+y_3) + \frac{1}{8}(x_3-y_3)^2t^{-1} - \frac{2}{3}\beta^2\mu^{-2}t^3 + \bar{\phi}_2 \tag{16.7.42}$$

with $\bar{\phi}_2$ *defined by* (16.2.10).

Proof. Easy but tedious details we leave to the reader: comparing with the toy-model or generalized toy model we see that the structure of the canonical graph is close to one of the toy-model. □

Proposition 16.7.3 [21]**.** *Let conditions* (16.3.1)–(16.3.3), (16.7.7)–(16.7.8) *be fulfilled*[6]*. Then after rescaling*

(i) Decomposition (16.7.39) *remains valid as* $|t| \ge \epsilon_0$ *and* $|\cos(\theta_1)| \le \epsilon$.

(ii) Further, after rescaling decomposition (16.7.39) *remains valid as* $|t| \ge \epsilon_0$ *and*

$$C\max\bigl(\hbar, \mu^{-2}|t|\bigr) \le |\sin(\theta_1)| \le \epsilon \tag{16.7.43}$$

albeit with an error not exceeding

$$C\hbar^{-\frac{3}{2}}|t|^{-\frac{1}{2}}|\sin(\theta_1)|^{-1}\bigl(\hbar/|\sin(\theta_1)|\bigr)^{l} \tag{16.7.44}$$

and with ϕ, b_m *such that*

$$|D^\beta(\phi-\bar{\phi})| \le C_\beta\mu^{-1}|t|\alpha^{-1}|\sin(\theta_1)|^{-|\beta|} \qquad \forall\beta, \tag{16.7.45}$$

$$|D^\beta(b_m-\delta_{m0})| \le C_{m\beta}\mu^{-1}|t||\sin(\theta_1)|^{-m-|\beta|} \qquad \forall\beta, m. \tag{16.7.46}$$

Proof. Again a tedious but an easy proof we leave to the reader. □

16.7.4 Tauberian Estimates

Remark 16.7.4. (i) Let us set $x = y$. Then we get expression (16.7.38) for $U(y,y,t)$ albeit now due to definition $\theta_1 = \theta$.

[21] Cf. Proposition 16.3.5.

(ii) Now we can continue in the same manner as before but to get a better estimate one needs to observe that the shift in x' (after rescaling) is now $\mu^{-1}\int \nabla_{x'}V\cdot F^{-1}\,dt$ and its difference with $\mu^{-1}\alpha t$ does not exceed $C\mu^{-1}|t|\cdot|\operatorname{osc}(\nabla' V)|$ where $\operatorname{osc}(W)$ means an oscillation of W along trajectory (until time t).

However this trajectory must return to $x_3=y_3$ and therefore one can see easily that along it $p_3=O(\beta\mu^{-1}t)$ and $x_3-y_3=O(\beta\mu^{-2}t^2)$ and we need to assume that this is less than $\epsilon\alpha$ i.e.

$$|t|\le T_*=\epsilon\mu\min\bigl(1,\alpha^{\frac12}\beta^{-\frac12}\bigr),\quad \alpha:=|\nabla' V(y)|,\ \beta:=|\partial_{y_3}V(y)|. \tag{16.7.47}$$

Therefore only as $|t|\le T_*$ one can use nondegeneracy condition but it makes sense to consider $t:\ T_*\le |t|\le T^*=\epsilon\mu$. Then we have the following counterpart of Proposition 16.6.2 where we need to sum (16.6.15) to $k=T_*$ and compare $\bar k=\mu^2h\alpha^{-1}$ with T: namely, $\bar k\le T_*$ iff

$$\alpha\ge \max\bigl(\mu h,\beta^{\frac13}(\mu h)^{\frac23},\mu^{-1}\bigr). \tag{16.7.48}$$

Setting here $\beta=1$ (as without spatial averaging or micro-averaging $\partial_{\|F}V/F$ is our foe and we need only estimate it from above) and thus $T_*=\epsilon\mu\alpha^{\frac12}$ we arrive to estimate (16.7.50) below.

On the other hand, if we do not use non-degeneracy condition we need to sum

$$C\mu^{\frac32}h^{-\frac32}|k|^{-\frac12} \tag{16.7.49}$$

which results in $C\mu^{\frac32}h^{-\frac32}T^{\frac12}$ and we arrive to estimate (16.7.51) below.

Proposition 16.7.5 [22]**.** *Let conditions* (16.3.1)–(16.3.3), (16.7.7)–(16.7.8), (16.1.5)–(16.1.6) *be fulfilled*[6]*. Then*

(i) Assume that conditions (16.7.47)–(16.7.48) *be fulfilled as well. Then, after rescaling as* T *is given by* (16.7.47) *with* $\beta=1$,

$$|F_{t\to\hbar^{-1}\tau}\bar\chi_T(t)\Gamma_x U|\le C\mu h^{-2}+ C\begin{cases}\mu^{\frac52}h^{-1}\alpha^{-\frac12}\bigl(1+(\log(\alpha/(\mu h)^{\frac23}))_+\bigr) & \text{as } \alpha\ge(\mu h)^{\frac23},\\ \mu^{\frac32}h^{-\frac32}T^{\frac12} & \text{as } \alpha\le(\mu h)^{\frac23}.\end{cases} \tag{16.7.50}$$

[22] Cf. Proposition 16.6.2.

(ii) In the general case as $|t| \le T^*$

$$|F_{t\to\hbar^{-1}\tau}\bar{\chi}_T(t)\Gamma_x U| \le C\mu h^{-2} + C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}T^{\frac{1}{2}}. \tag{16.7.51}$$

Then picking-up $T = T_*$ and dividing the left-hand expression of (16.7.50) by T_* or picking-up $T = T^*$ and dividing the left-hand expression of (16.7.51) by T^* we arrive to estimates (16.7.52), (16.7.53) below.

Corollary 16.7.6. *(i) In the framework of Proposition 16.7.5(i) with* $\alpha \ge (\mu h)^{\frac{3}{2}}$ *(which implies* $\mu \le h^{-1}$*)*

$$\mathsf{R}^{\mathsf{T}} := |e(0,0,\tau) - e^{\mathsf{T}}(0,0,\tau)| \le Ch^{-2}\alpha^{-\frac{1}{2}} + C\mu^{\frac{3}{2}}h^{-1}\alpha^{-1}\bigl(1 + (\log(\alpha/(\mu h)^{\frac{2}{3}}))_+\bigr). \tag{16.7.52}$$

(ii) In the general case

$$\mathsf{R}^{\mathsf{T}} \le Ch^{-2} + C\mu h^{-\frac{3}{2}}; \tag{16.7.53}$$

(iii) In particular, according to (16.7.52)*, as* $\mu \le h^{-1}$*,* $\alpha \asymp 1$

$$\mathsf{R}^{\mathsf{T}} \le Ch^{-2} + C\mu^{\frac{3}{2}}h^{-1}\bigl(1 + |\log \mu h|\bigr) \tag{16.7.54}$$

which is $O(h^{-2})$ *as* $\mu \le (h|\log h|)^{-\frac{2}{3}}$.

(iv) In particular, according to (16.7.53)*,* $\mathsf{R}^{\mathsf{T}} = O(h^{-2})$ *as* $\mu \le h^{-\frac{1}{2}}$.

(v) Estimate (16.7.52) *is better iff* $h^{-\frac{1}{2}} \le \mu \le h^{-1}$ *and*

$$\alpha \ge \mu^{-2}h^{-1} + (\mu h)^{\frac{1}{2}}|\log(\mu h)|. \tag{16.7.55}$$

16.7.5 Weyl Estimates

The proof of the following statement is rather obvious:

Proposition 16.7.7 [23]**.** *Let conditions* (16.3.1)–(16.3.3), (16.7.7)–(16.7.8), (16.7.47)–(16.7.48), (16.1.5)–(16.1.6) *be fulfilled*[6]*. Then*

[23] Cf. Proposition 16.6.3.

(i) As $\mu^2 h \le \alpha \le 1$ *estimate* (16.6.18) *holds and correction term* $h^{-3}\mathcal{N}_{x,\mathsf{corr}}$ *is delivered by* r*-term stationary phase approximation* $h^{-3}\mathcal{N}_{x,\mathsf{corr}(r)}$ *with an error not exceeding* (16.6.19)*.*

(ii) As $\alpha \le \mu^2 h$ *estimate* (16.6.19) *holds.*

(iii) In particular without any nondegeneracy condition $\mathsf{R}^{\mathsf{W}}_x = O(\mu^{\frac{3}{2}} h^{-\frac{3}{2}})$ *and it is* $O(h^{-2})$ *as* $\mu \le h^{-\frac{1}{3}}$*.*

(iv) On the other hand, $\mathsf{R}^{\mathsf{W}}_x = O(\mu^{-\frac{1}{2}} h^{-\frac{3}{2}} + \mu^{\frac{5}{2}} h^{-1})$ *as* $\alpha \asymp 1$ *and* $\mu \le h^{-\frac{1}{2}}$ *and therefore* $\mathsf{R}^{\mathsf{W}}_x = O(h^{-2})$ *as* $\alpha \asymp 1$ *and* $\mu \le h^{-\frac{2}{5}}$*.*

Combining with Corollary 16.7.6 we conclude that

Theorem 16.7.8. *Let conditions* (16.3.1)–(16.3.3), (16.7.7)–(16.7.8), (16.7.48), (16.1.5)–(16.1.6) *be fulfilled*[6)]*. Then,*

(i) In the general case

$$|e(x,x,0) - h^{-3}\mathcal{N}^{\mathsf{W}}_x(x,x,0)| \le Ch^{-2} + C\mu^{\frac{3}{2}} h^{-\frac{3}{2}}; \tag{16.7.56}$$

(ii) Under non-degeneracy condition

$$|\nabla_{\perp \boldsymbol{F}} V/F| \asymp 1 \tag{16.7.57}$$

as $\mu \le h^{-\frac{1}{2}}$ *estimates*

$$|e(x,x,0) - h^{-3}\mathcal{N}^{\mathsf{W}}_x(x,x,0)| \le Ch^{-2} + C\mu^{\frac{5}{2}} h^{-1} \tag{16.7.58}$$

and

$$|e(x,x,0) - h^{-3}\mathcal{N}^{\mathsf{W}}_x(x,x,0) - h^{-3}\mathcal{N}_{x,\mathsf{corr}(r)}| \le Ch^{-2} + C\mu^{\frac{3}{2}} h^{-\frac{3}{2}} (\mu^2 h)^{r+\frac{1}{2}} \tag{16.7.59}$$

hold.

16.7.6 Successive Approximations

Let us try successive approximation method. As an approximation we successively try the generalized toy-model operator A^0, the toy-model operator $\bar{A}$ and the magnetic Weyl approximation. As for $\mu \le h^{-\frac{1}{3}}$ Weyl approximation delivers $O(h^{-2})$ error we assume that

$$\mu \ge h^{-\frac{1}{3}}. \tag{16.7.60}$$

Generalized Toy-Model Approximation, $\mu h \le 1$

We claim that

(16.7.61) Effectively if $x = y (= 0)$ we can estimate $\|A - A^0\|$ by

$$\zeta(k) \coloneqq C\big(\mu^{-2}|k| + (\mu h)^{\frac12}\mu^{-1}|k|^{-\frac12}\big). \tag{16.7.62}$$

Really, due to our assumptions $g^{jl} = \delta_{jl} + O(|x'|^2) + O(|x'| \cdot |x_3|)$ with $|x'| = O(\mu^{-1})$, $x_3 = O(\mu^{-1}|k|)$ $(j, l = 1, 2)$, $g^{33} = 1 + O(\mu^{-2})$ (before rescaling) the only term which does not allow such estimate is $g^{j3}D_jD_3$ with $j = 1, 2$.

However for a classical trajectory to return back to time $t \asymp k$ we need to have $p_3 = O(\mu^{-1}k)$; in our analysis we will need also to satisfy uncertainty principle: $p_3^2|k| \ge \mu h$; so we estimate p_3 by $C\mu^{-1}|k| + C(\mu h)^{\frac12}|k|^{-\frac12}$ and as $g^{j3} = O(|x'|)$ this leads to (16.7.62).

Then the error in k-th winding does not exceed

$$C\mu^{\frac32}h^{-\frac32}|k|^{-\frac32} \times \big(\mu^{-2}|k| + (\mu h)^{\frac12}\mu^{-1}|k|^{-\frac12}\big) \times \mu^{-1}h^{-1}|k| \times \begin{cases} \big(\dfrac{\mu^2 h}{\alpha|k|}\big)^{r+\frac12} & \text{as } \alpha^{-1}\mu^2 h \le |k| \le (\mu^3 h)^{\frac12}, \\ 1 & \text{as } |k| \le \min\big(\alpha^{-1}\mu^2 h, (\mu^3 h)^{\frac12}\big). \end{cases} \tag{16.7.63}$$

Really, the successive approximation makes sense only as $\zeta(k)|k| \le \mu h$ which in view of (16.7.60) is equivalent to $|k| \le (\mu^3 h)^{\frac12}$.

Here as $|k| \ge \alpha^{-1}\mu^2 h$ we apply r-term stationary phase approximation as well. Also recall that this interval originally was $\alpha^{-1}\mu^2 h \le |k| \le \epsilon\mu\alpha^{\frac12}$ [24] but it is non-empty iff $\alpha \ge (\mu h)^{\frac23}$.

Then $(\mu^3 h)^{\frac12} \le \mu\alpha^{\frac12}$ and further $(\mu^3 h)^{\frac12} \ge \alpha^{-1}\mu^2 h$ iff $\alpha \ge (\mu h)^{\frac12}$. Only under this assumption we need to consider the first case in (16.7.63) but it is the most important case as it happens for $\alpha \asymp 1$.

Let us break (16.7.63) into two expressions: one with the second factor $\mu^{-2}|k|$ and another with the second factor $(\mu h)^{\frac12}\mu^{-1}|k|^{-\frac12}$.

[24] Here the upper limit meant that $|x_3| \le \alpha$ along trajectory before k-th winding. Since we look at the trajectory returning at k-th winding, $|x_3| \le (\mu^{-1}|k|)^2$ before it and we need to satisfy $(\mu^{-1}|k|)^2 \le \alpha$.

In the general case (when we do not know if $\alpha \ge (\mu h)^{\frac{1}{2}}$) summation of the first expression returns $Ch^{-2}(\mu^3 h)^{\frac{1}{4}}$ and of the second expression returns a lesser $Ch^{-2}(1+\log(\mu^3 h))$. Contribution of $k : |k| \ge (\mu^3 h)^{\frac{1}{2}}$ to the Tauberian expression is a sum of $C\mu^{\frac{3}{2}} h^{-\frac{3}{2}} |k|^{-\frac{3}{2}}$, which gives us $C\mu^{\frac{3}{2}} h^{-\frac{3}{2}} (\mu^3 h)^{-\frac{1}{4}}$ i.e. exactly the same answer. Therefore we arrive to

(16.7.64) The Tauberian expressions for the original operator and its generalized toy-model approximation differ by no more than $Ch^{-2}(\mu^3 h)^{\frac{1}{4}}$.

Assume now that $\alpha \ge (\mu h)^{\frac{1}{2}}$. Again break (16.7.63) into two expressions the same way as before. Obviously summation with respect to k of the second expression returns $Ch^{-2}\big(1+(\log(\mu^2 h/\alpha))_+\big)$ no matter what r is.

As $r=0$ summation of the first expression with respect to k returns $C\mu h^{-\frac{3}{2}} \alpha^{-\frac{1}{2}}$. One can see easily that the contribution of $k : |k| \ge (\mu^3 h)^{\frac{1}{2}}$ to the Tauberian expression does not exceed $C\mu h^{-\frac{3}{2}} \alpha^{-\frac{1}{2}}$.

Therefore we arrive to

(16.7.65) As $\alpha \ge (\mu h)^{\frac{1}{2}}$ the Tauberian expressions for the original operator and its generalized toy-model approximation differ by no more than $Ch^{-2} + C\mu h^{-\frac{3}{2}} \alpha^{-\frac{1}{2}}$.

As $r \ge 2$ summation of the first expression with respect to k returns its value ($\times |k|$) as $k = \max(1, \mu^2 h/\alpha)$:

$$C\mu^{\frac{3}{2}} h^{-1} \alpha^{-\frac{3}{2}} \times \begin{cases} \big(\frac{\mu^2 h}{\alpha}\big)^{r-1} & \text{as } 1 \ge \mu^2 h/\alpha, \\ 1 & \text{as } 1 \le \mu^2 h/\alpha \end{cases} \tag{16.7.66}$$

and as $r=1$ we get $C\mu^{\frac{3}{2}} h^{-1} \alpha^{-\frac{3}{2}} (1+\log(\alpha(\mu h)^{-\frac{1}{2}}))$. One can see easily that the contribution of $k : |k| \ge (\mu^3 h)^{\frac{1}{2}}$ to the Tauberian expression does not exceed these expressions as $r \ge 1$.

Therefore we arrive to

(16.7.67) As $\alpha \ge (\mu h)^{\frac{1}{2}}$ the Tauberian expressions with the subtracted $h^{-3}\mathcal{N}_{x,\mathsf{corr}(r)}$ i.e.

$$e^{\mathsf{T}}(x,x,\tau) - h^{-3}\mathcal{N}_{x,\mathsf{corr}(r)} \tag{16.7.68}$$

for the original operator and its generalized toy-model approximation differ by no more than

$$Ch^{-2} + Ch^{-2}(\log(\mu^2 h/\alpha))_+ + C\mu^{\frac{3}{2}}h^{-1}\alpha^{-\frac{3}{2}}\begin{cases} \bigl(1+\log(\alpha(\mu h)^{-\frac{1}{2}})\bigr) & \text{as } r=1, \alpha \ge \mu^2 h,\\ \bigl(1+\log(\mu^3 h)\bigr) & \text{as } r=1, \alpha \le \mu^2 h,\\ (\mu^2 h/\alpha)^{r-1} & \text{as } r\ge 2, \alpha \ge \mu^2 h,\\ 1 & \text{as } r\ge 2, \alpha \le \mu^2 h. \end{cases} \tag{16.7.69}$$

Combining with Corollary 16.7.6 we estimate expressions (16.7.70)–(16.7.72) below for different α; in particular, we arrive to:

Theorem 16.7.9. *Let conditions* (16.3.1)–(16.3.3), (16.7.7)–(16.7.8), (16.7.48), (16.1.5)–(16.1.6) *be fulfilled*[6)]. *Let* $e^0(.,.,.)$ *be a Schwartz kernel of the spectral projector for operator* A^0 *defined by* (16.7.36)–(16.7.37). *Then, as long as* $h^{-\frac{1}{3}} \le \mu \le h^{-1}$,

(i) In the general case

$$|e(x,x,0) - e^0(x,x,0)| \le C\mu^{\frac{3}{4}}h^{-\frac{7}{4}}. \tag{16.7.70}$$

(ii) Under non-degeneracy condition (16.7.57) *estimates*

$$|e(x,x,0) - e^0(x,x,0)| \le Ch^{-2} + C\mu h^{-\frac{3}{2}} \tag{16.7.71}$$

and

$$\begin{aligned} |e(x,x,0) - e^0(x,x,0) - h^{-3}\bigl(\mathcal{N}_{x,\mathsf{corr}(r)} - \mathcal{N}^0_{x,\mathsf{corr}(r)}\bigr)| \le{}& \\ Ch^{-2}\bigl(1+(\log \mu^2 h)_+\bigr) + C\mu^{\frac{3}{2}}h^{-1}\bigl(1+|\log \mu h|\bigr)+{}& \\ C\mu^{\frac{3}{2}}h^{-1}\begin{cases} \bigl(1+\log(\mu^3 h)\bigr) & \textit{as } r=1,\\ (\mu^2 h)^{r-1} & \textit{as } r\ge 2, \mu \le h^{\frac{1}{2}},\\ 1 & \textit{as } r\ge 2, \mu \ge h^{-\frac{1}{2}} \end{cases}& \end{aligned} \tag{16.7.72}$$

hold.

Remark 16.7.10. Replacing $\alpha(x_3)x_j$ by $\alpha(0)x_j$ we estimate the norm of the perturbation by $\zeta_1(k) = \mu^{-1}\cdot(\mu^{-2}|k|^2+\mu^{-1})$ which is less than expression (16.7.62) and thus leads to the lesser error. On the other hand, this new approximation is already a direct sum $A = A_{(2)} + B$ with the toy model operator $A_{(2)}$ and

$$B = h^2D_3^2 + V^0(x_3). \tag{16.7.73}$$

Therefore all above estimate remain valid with A^0 defined by (16.7.36)–(16.7.37) albeit with $\alpha_j = V_{x_j}(0,0,0)$.

Toy-Model Approximation, $\mu h \le 1$

Consider now the toy-model approximation $\bar{A}$ which differ from the approximation A^0 of Remark 16.7.10 by $O(x_3^2)$. Then

(16.7.74) Effectively if $x = y$ we can estimate $\|A^0 - \bar{A}\|$ by

$$\zeta(k) \coloneqq C\big(\mu^{-4}k^4 + \mu^{-1}h|k|\big). \tag{16.7.75}$$

Really, we need to estimate $O(x_3^2)$ and according to above arguments we estimate $|x_3|$ by $C\big(\mu^{-2}k^2 + (\mu h)^{\frac12}|k|^{-\frac12}\times\mu^{-1}|k|\big)$ which leads to (16.7.74).

Then we have estimate of the error in k-th winding not exceeding

$$C\mu^{\frac32}h^{-\frac32}|k|^{-\frac32}\times\big(\mu^{-4}k^4+\mu^{-1}h|k|\big)\times\mu^{-1}h^{-1}|k|\times \begin{cases} \big(\frac{\mu^2h}{\alpha|k|}\big)^{r+\frac12} & \text{as } |k|\ge\alpha^{-1}\mu^2h,\\ 1 & \text{as } |k|\le\alpha^{-1}\mu^2h.\end{cases} \tag{16.7.76}$$

The perturbation factor is $O(1)$ iff $|k|\lesssim \mu h^{\frac15}$ and we need to compare it with $\alpha^{-1}\mu^2h$: we have cases $\alpha\ge\mu h^{\frac45}$ when $\alpha^{-1}\mu^2h$ is less and $\alpha\le\mu h^{\frac45}$ when $\mu h^{\frac45}$ is less.

Case $\alpha\ge\mu h^{\frac45}$. Then we need to sum

(a) Expression (16.7.76) with the last factor 1 from $|k|=1$ to $|k|=\alpha^{-1}\mu^2h$ which returns $C\mu^{\frac12}h^{-\frac52}|k|^{\frac12}\times\big(\mu^{-4}k^4+\mu^{-1}h|k|\big)$ calculated as $|k| = \alpha^{-1}\mu^2h$:

$$C\mu^{\frac{11}{2}}h^2\alpha^{-\frac92} + C\mu^{\frac52}\alpha^{-\frac32};$$

as $\alpha \asymp 1$ the first term does not exceed $C\mu^{\frac{3}{2}}h^{-1}$ iff $\mu \le h^{-\frac{3}{4}}$ while for the second term it is always true.

(b) Expression (16.7.76) with the last factor $\bigl(\mu^2 h/\alpha|k|\bigr)^{r+\frac{1}{2}}$ from $|k| = \alpha^{-1}\mu^2 h$ to $k = \mu h^{\frac{1}{5}}$ which returns what we got earlier plus value of $C\mu^{\frac{1}{2}}h^{-\frac{5}{2}}|k|^{\frac{1}{2}} \times \bigl(\mu^{-4}k^4 + \mu^{-1}h|k|\bigr) \times (\mu^2 h/\alpha|k|)^{r+\frac{1}{2}}$ calculated at $k = \mu h^{\frac{1}{5}}$ (may be with the logarithmic term for exceptional values of $r = 4, 1$) i.e.

$$C\mu h^{-\frac{8}{5}}(\mu h^{\frac{4}{5}}/\alpha)^{r+\frac{1}{2}} + C\mu h^{-\frac{6}{5}}(\mu h^{\frac{4}{5}}/\alpha)^{r+\frac{1}{2}};$$

as $r = 1$ we get $C\mu^{\frac{5}{2}}h^{-\frac{2}{5}}\alpha^{-\frac{3}{2}}$; as $\alpha \asymp 1$ this is less than Ch^{-2} as $\mu \le h^{-\frac{16}{25}}$; note that the second term always is $O(\mu^{\frac{3}{2}}h^{-1} + h^{-2})$.

(c) $C\mu^{\frac{3}{2}}h^{\frac{3}{2}}|k|^{-\frac{3}{2}}(\mu^2 h/\alpha)^{r+\frac{1}{2}}$ as $|k| \ge C\mu h^{\frac{4}{5}}$ which returns the expression above.

In total, we get modulo $O\bigl(h^{-2} + \mu^{\frac{3}{2}}h^{-1}\bigr)$

$$C\mu^{\frac{11}{2}}h^2\alpha^{-\frac{9}{2}} + C\mu^{\frac{5}{2}}\alpha^{-\frac{3}{2}} + C\mu h^{-\frac{8}{5}}(\mu h^{\frac{4}{5}}/\alpha)^{r+\frac{1}{2}}. \tag{16.7.77}$$

Case $\alpha \le \mu h^{\frac{4}{5}}$**.** Then we need to sum

(a) Expression (16.7.76) with the last factor 1 from $|k| = 1$ to $|k| = \mu h^{\frac{1}{5}}$ which returns $C\mu^{\frac{1}{2}}h^{-\frac{5}{2}}|k|^{\frac{1}{2}} \times \bigl(\mu^{-4}k^4 + \mu^{-1}h|k|\bigr)$ calculated at $k = \mu h^{\frac{1}{5}}$ i.e.

$$C\mu h^{-\frac{8}{5}} + C\mu h^{-\frac{6}{5}};$$

here the first term is larger than $C\mu^{\frac{3}{2}}h^{\frac{3}{2}} + Ch^{-2}$ as $\mu \ge h^{-\frac{2}{5}}$ but the second term is always smaller than this.

(b) $C\mu^{\frac{3}{2}}h^{\frac{3}{2}}|k|^{-\frac{3}{2}}$ as $|k| \ge C\mu h^{\frac{4}{5}}$ which returns an above expression.

So, we get in this case

$$C\mu h^{-\frac{8}{5}}. \tag{16.7.78}$$

Thus we arrive to:

Theorem 16.7.11. *Let conditions* (16.3.1)–(16.3.3), (16.7.7)–(16.7.8), (16.7.48), (16.1.5)–(16.1.6) *be fulfilled*[6)]. *Let* $\bar{e}(.,.,.)$ *be a Schwartz kernel of the spectral projector for the toy-model operator* $\bar{A}$. *Then, as* $h^{-\frac{1}{3}} \le \mu \le h^{-1}$,

(i) In the general case

$$|e(x,x,0)-\bar{e}(x,x,0)| \le C\mu^{\frac{3}{4}}h^{-\frac{7}{4}} + C\mu h^{-\frac{8}{5}}. \tag{16.7.79}$$

(ii) Under non-degeneracy condition (16.7.57) *as* $\mu \le h^{-\frac{4}{5}}$ *estimates*

$$|e(x,x,0)-\bar{e}(x,x,0)| \le Ch^{-2} + C\mu h^{-\frac{3}{2}} + C\mu^{\frac{11}{2}}h^2 + C\mu^{\frac{5}{2}} + C\mu^{\frac{3}{2}}h^{-\frac{6}{5}} \tag{16.7.80}$$

and

$$\begin{aligned} |e(x,x,0)-\bar{e}(x,x,0)-h^{-3}\bigl(\mathcal{N}_{x,\mathsf{corr}(r)}-\mathcal{N}^0_{x,\mathsf{corr}(r)}\bigr)| \le \\ Ch^{-2}\bigl(1+(\log \mu^2 h)_+\bigr) + C\mu^{\frac{3}{2}}h^{-1}\bigl(1+|\log \mu h|\bigr)+ \\ C\mu^{\frac{3}{2}}h^{-1}\begin{cases} \bigl(1+\log(\mu^3 h)\bigr) & \text{as } r=1, \\ (\mu^2 h)^{r-1} & \text{as } r\ge 2, \mu \le h^{\frac{1}{2}}, \\ 1 & \text{as } r\ge 2, \mu \ge h^{-\frac{1}{2}} \end{cases} + \\ C\mu^{\frac{11}{2}}h^2 + C\mu^{\frac{5}{2}}C\mu h^{-\frac{8}{5}}(\mu h^{\frac{4}{5}})^{r+\frac{1}{2}}. \end{aligned} \tag{16.7.81}$$

hold.

Let us improve the above results. Note that we need only consider components of the estimate which are (in unrescaled x_3, p_3) due to $p_3 = O(\mu^{-1}k)$, $x_3 = O(\mu^{-2}k^2)$ rather than those which are due to the uncertainty principle $p_3 = O((\mu h)^{\frac{1}{2}}|k|^{-\frac{1}{2}})$, $x_3 = O(\mu^{-1}(\mu h)^{\frac{1}{2}}|k|^{\frac{1}{2}})$ as the latter brought a proper estimate in the above analysis.

Consider only case $\alpha \asymp 1$, $\beta \lesssim 1$. Then we need to consider only $\mu \ge h^{-\frac{16}{25}}$. Note that actually instead of $p_3 = O(t)$, $x_3 = O(t^2)$ we can use estimates $p_3 = O(\beta t)$, $x_3 = O(\beta t^2)$ and then our estimates acquire factor β^2 (recall that we are not discussing terms which are due to the uncertainty principle).

Case $h^{-16/25} \le \mu \le h^{-4/5}$. Consider (16.7.77) with $r = 1$; then the last term is the largest and the estimate with above improvement is $O(\beta^2\mu^{5/2}h^{-2/5})$ and it is $O(\mu^{3/2}h^{-1})$ as $\beta \le (\mu h^{\frac{3}{5}})^{-\frac{1}{2}}$. So we need to consider case

$$\beta \ge (\mu h^{\frac{3}{5}})^{-\frac{1}{2}} \qquad (\ge h^{1/10}). \tag{16.7.82}$$

As $r = 0$ we get $\mu^{\frac{3}{2}}h^{-\frac{6}{5}}$ which is less than $\mu h^{-\frac{3}{2}}$ in (16.7.71).

Case $h^{-4/5} \le \mu \le h^{-1}$. Then estimate is (modulo $O(\mu^{-3/2}h^{-1})$) $O(\beta^2\mu h^{-8/5})$ and it is $O(\mu^{3/2}h^{-1})$ as $\beta \le (\mu h^{\frac{6}{5}})^{\frac{1}{4}}$. So we need to consider case

$$\beta \ge (\mu h^{\frac{6}{5}})^{\frac{1}{4}} \qquad (\ge h^{1/10}). \tag{16.7.83}$$

Therefore we conclude that

Theorem 16.7.12. *As $\beta \coloneqq |\nabla_{\|\boldsymbol{F}} V/F| \le h^{-1/10}$ estimates* (16.7.70)–(16.7.72) *of Theorem 16.7.9 remain true for A^0 replaced by $\bar{A}$.*

So we need to consider the case when 1D-Schrödinger operator is almost non-degenerate and the corresponding dynamics is confined to zone $x_3 \le \beta$; rescaling $x_3 \mapsto x_{3,\mathsf{new}} = x_3/\beta$ we arrive to operator

$$\beta^2\Big(h_3^2D_3^2 + V_3(x_3)\Big), \qquad h_3 = h/\beta^2 \ll 1, \quad V_3(x_3) = \beta^{-2}V(x_3) \tag{16.7.84}$$

satisfies $\partial_3 V_3(x_3) \asymp 1$. Then we can construct its solution by WKB method. Note that before any rescaling

$$U_{(1)}(x_3, y_3, t) = (2\pi h)^{-1}\int \exp\Big(ih^{-1}\big(S(x_3, t, \zeta) - y_3\zeta\big)\Big)B(x_3, t, \zeta)\, d\zeta \tag{16.7.85}$$

where S solves

$$S_t = S_{x_3}^2 + V(x), \qquad S|_{t=0} = x_3\zeta \tag{16.7.86}$$

and $B \sim \sum_k B_k h^k$ in the standard way.

Then one can prove easily that

$$S = \bar{S} + O\Big(x_3^2|t| + |x_3|(|\zeta| + |t|)|t| + \zeta^2|t|^3 + |t|^5\Big) \tag{16.7.87}$$

where

$$\bar{S} = x_3\zeta + t(\zeta^2 - \beta x_3) + \zeta\beta t^2 + \frac{2}{3}\beta^2 t^3 \tag{16.7.88}$$

solves the same problem for toy-model $V = -\beta x_3$. Rescaling $x_3 \to x_3/\beta$, $h \mapsto h/\beta^2$ shows one can calculate S and $\bar{S}$ for $\beta = 0$, then plug $x_3 = x_3/\beta$, $\zeta = \zeta/\beta$ and multiply the result by β^2; (16.7.87) obviously survives but (16.7.88) improves to

$$S = \bar{S} + O\Big(x_3^2|t| + |x_3|(|\zeta| + \beta|t|)|t| + \zeta^2|t|^3 + |t|^5\Big). \tag{16.7.87*}$$

Obviously phase function

$$\bar{\phi}(x_3, y_3, t, \zeta) \coloneqq \bar{S}(x_3, t, \zeta) - y_3\zeta \tag{16.7.89}$$

is equivalent to phase function

$$\bar{\phi} \coloneqq (\zeta + \beta t)x_3 - (\zeta - \beta t)y_3 - 2\zeta^2 t - \frac{2}{3}\beta^2 t^3 \tag{16.7.90}$$

we used earlier.

Furthermore, obviously

(16.7.91) Phase function

$$\phi(x_3, y_3, t, \zeta) \coloneqq S(x_3, t, \zeta) - y_3\zeta \tag{16.7.92}$$

is 1D-action and therefore the total exponent is also 3D-action associated with the generalized toy-model.

Note that for a phase function (16.7.89) $\bar{\phi}_\zeta = 0$ iff $x_3 - y_3 + 2t\zeta + \beta t^2 = 0$ and then $\bar{\phi}_{\zeta\zeta} = -4t$ and therefore for $|t| \gg h$ we can apply a stationary phase method for both S and $\bar{S}$ and while the principal term would be of magnitude $(h|t|)^{-\frac{1}{2}}$ the error in l-term approximation will be of magnitude $(h|t|)^{-\frac{1}{2}}(h/|t|)^l$ or after all the substitution to $\boldsymbol{U}$ and rescalings it will be

$$C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}|k|^{-\frac{3}{2}} \times (\mu h/|k|)^l \tag{16.7.93}$$

in the Tauberian expression. While almost useless for μh close to 1 and $k = 1$ the last factor is very important for larger k.

Then the contribution of zone $\{k : |k| \ge m\}$ to such error does not exceed (as $l = 1$)

$$C\mu^{\frac{5}{2}}h^{-\frac{1}{2}}m^{-\frac{3}{2}} \tag{16.7.94}$$

and it is $O(\mu^{-\frac{3}{2}}h^{-1})$ as $m \ge \mu^{\frac{2}{3}}h^{\frac{1}{3}}$. Obviously $m \ll \mu h^{\frac{1}{5}}$ and $m \ll \mu^2 h$ which means that in zone $k : |k| \le m$ we could perfectly deal with successive approximations.

On the other hand, replacing B by 1 and $\phi_{\zeta\zeta}$ by $-4t$ leads to an error

$$C\mu^{\frac{3}{2}}h^{-\frac{3}{2}}|k|^{-\frac{3}{2}} \times \mu^{-2}k^2 \times \min\bigl((\mu^2 h/|k|)^{\frac{1}{2}}, 1\bigr) \tag{16.7.95}$$

which after summation becomes $\mu^{\frac{1}{2}}h^{-1} \times \mu$ which is not as good as the Tauberian estimate. This spares us from more complicated formula. We leave to the reader

Problem 16.7.13. (i) Write the approximation due to described combination of successive approximations and WKB method.

(ii) Consider $\alpha \le 1$.

Magnetic Weyl Approximation

In virtue of the above results the result of Subsubsection 16.6.6 hold for general operators.

16.7.7 Transitional and Strong Magnetic Field

The standard method of successive approximations shows that replacing operator by the generalized toy-model brings an error with the contribution of $\{t : |t| \asymp T\}$ (before rescaling) not exceeding

$$C\mu h^{-2} \times \bigl(\mu^{-1}h + C\mu^{-\frac{1}{2}}h^{\frac{1}{2}}(T^{\frac{1}{2}} + h^{\delta})\bigr) \tag{16.7.96}$$

and summation with respect to T running from h to 1 returns

$$C\mu h^{-2} \times \bigl(\mu^{-1}h + C\mu^{-\frac{1}{2}}h^{\frac{1}{2}}(1 + h^{\delta}|\log h|)\bigr) \asymp C\mu^{\frac{1}{2}}h^{-\frac{3}{2}} + C\mu^{\frac{1}{2}}h^{\delta-\frac{3}{2}}|\log \mu|$$

which is less than the Tauberian estimate. Therefore

Theorem 16.7.14. *Let conditions* (16.3.1)–(16.3.3), (16.7.7)–(16.7.8), (16.7.48), (16.1.5)–(16.1.6) *be fulfilled*[6)]. *Then as* $\mu h \gtrsim 1$

$$|e(x,x,0) - e^{0}(x,x,0)| \le C\mu h^{-\frac{3}{2}}. \tag{16.7.97}$$

Similarly, transition to the toy model brings an error not exceeding

$$C\mu h^{-2} \times \bigl(\beta^2 T^4 + h^{\frac{4}{3}}\bigr) \tag{16.7.98}$$

and summation with respect from h to T_* returns $C\mu h^{-\frac{3}{2}} + C\mu h^{-2}\beta^2 T_*^4$. On the other hand, Tauberian approach shows that the contribution of $|t| \ge T_*$ should not exceed $C\mu h^{-\frac{3}{2}} T_*^{-1}$ and minimizing it sum we arrive to $T_* = \beta^{-\frac{2}{5}} h^{\frac{1}{10}}$ and it is

$$C\mu h^{-\frac{3}{2}}\Bigl(1 + \beta^{\frac{2}{5}} h^{-\frac{1}{10}}\Bigr). \tag{16.7.99}$$

Therefore

Theorem 16.7.15. *Let conditions* (16.3.1)–(16.3.3), (16.7.7)–(16.7.8), (16.7.48), (16.1.5)–(16.1.6) *be fulfilled*[6)]. *Then as* $\mu h \gtrsim 1$

$$|e(x,x,0) - \bar{e}(x,x,0)| \le C\mu h^{-\frac{8}{5}}. \tag{16.7.100}$$

Further, if we pick up $T_* = \min(\beta^{-\frac{1}{2}} h^{\frac{1}{8}}, 1)$ we conclude that the contribution of zone $\{t : T_* \le |t| \le \epsilon\}$ to an error does not exceed $C\mu h^{-\frac{3}{2}}$. So we need to consider zone $\{t : |t| \ge h^{\frac{1}{8}}\}$. However in this zone we can apply stationary phase expression for $U_{(31)}$ which gives an error

$$C \int_T^1 \mu h^{-2} \times \big(\frac{h}{t}\big)^{\frac{3}{2}}\, dt \asymp C\mu h^{-2} \big(\frac{h}{T}\big)^{\frac{3}{2}}$$

which is $O(\mu h^{-\frac{3}{2}})$ as $T \ge h^{\frac{2}{3}}$.

Problem 16.7.16. Construct this stationary phase approximation.

Again for the magnetic Weyl approximation error we refer to Subsection 16.6.2.

16.7.8 Micro-Averaging

We are interested only in Tauberian, Weyl and magnetic Weyl estimates as we consider toy-model and generalized toy-model approximations a bit too complicated. We consider here only isotropic micro-averaging (i.e. with $\gamma_3 = \gamma$).

Tauberian Estimates

Basically everything remains as in Subsection 16.6.4 but we need to answer a question: "what is ℓ?" Or rather "what T^* we need to take?" Clearly $T^* = \epsilon \min(\alpha, \beta)$ fits but can we do better than this?

(i) Let $\beta \le \alpha$. Then as we take $\gamma_3 = \gamma$ we have $\nu(\boldsymbol{\gamma}) \asymp \alpha\gamma$ so averaging with respect to x_3 does not matter and therefore we do not need to assume that $\gamma_3 \le \epsilon\beta$ (which in this case would mean $\gamma \le \epsilon\beta$). In this case our assumption is $\gamma \le \epsilon\alpha$.

Then as $\nabla_{\perp \boldsymbol{F}} V/F$ has a less oscillation then $\epsilon\alpha$ with $\alpha = |\nabla_{\perp \boldsymbol{F}} V/F|\big|_{t=0}$ for time $T^* = \epsilon_1\alpha$ we can take $T^* = \epsilon_1\alpha$.

(ii) Let $\beta \ge \alpha$. Then as we take $\gamma_3 = \gamma$ we have $\nu(\boldsymbol{\gamma}) \asymp \beta\gamma$ so averaging with respect to x' does not matter as well as the shift and therefore we do not need to assume that $\gamma \le \epsilon\alpha$ (which in this case would mean $\gamma_3 \le \epsilon\beta$).

Then as $\nabla_{\parallel \boldsymbol{F}} V/F$ has a less oscillation then $\epsilon\beta$ with $\beta = |\nabla_{\parallel \boldsymbol{F}} V/F|\big|_{t=0}$ for time $T^* = \epsilon_1\beta$ we can take $T^* = \epsilon_1\beta$. However in this case we should not include factor $(\mu h/\alpha|k|)^{\frac{1}{2}}$ which is a loss as $\mu h/\alpha < h/\beta\gamma$ i.e. as $\mu\gamma \le \alpha\beta$.

So, in both cases we can take $\gamma_3 = \gamma$ and $T^* \asymp |\nabla V/F|$ (but we obviously need $\gamma \le |\nabla V/F|$).

Weyl and Magnetic Weyl Estimates

As we do not care about T^* anymore we simply take $\gamma_3 = \gamma \le |\nabla V/F|$.

Problem 16.7.17. As β is rather an obstacle in the toy-model approximation, it would be interesting investigate this approximation with micro-averaging.

16.8 Dirac Energy: 3D-Estimates

In this and the next sections we consider asymptotics of the quantity I defined by (16.1.2).

16.8.1 Tauberian Formula

Let us consider first contribution of the zone $\{(x,y) : |x-y| \ge C\gamma\}$.

Proposition 16.8.1 [25]**.** *Let $\mu \le h^{-1}$. Then under conditions* (16.1.5)–(16.1.7) *the contribution of zone $\{(x,y) : |x-y| \ge C\gamma\}$, to the remainder is $O(h^{-2}\gamma^{-\kappa})$ while the main part is given by the same expression* (16.1.1) *with $e(x,y,0)$ replaced by its standard implicit Tauberian approximation* (16.1.11) *with $T \asymp \epsilon$.*

Proof. Proof repeats one of Proposition 16.4.1 albeit according to Chapter 13 estimate (16.4.4) is replaced by

$$\|E(\tau,\tau')\bar{\psi}\|_1 \le Ch^{-3}\big(|\tau-\tau'| + CT^{-1}h\big) \qquad \forall \tau,\tau' \in [-\epsilon,\epsilon],\ T = \epsilon\mu \tag{16.8.1}$$

[25] Cf. Proposition 16.4.1.

with $T = \epsilon$. □

Then we immediately arrive to:

Proposition 16.8.2 [26]**.** *Let conditions* (16.1.5)–(16.1.7) *be fulfilled. Then*

(i) As $0 < \kappa < 3$ *and* <u>*either*</u> $\kappa \neq 1, 2$ <u>*or*</u> $\kappa = 1, 2$ *and* $\omega(x, y)$ *is replaced by* $\omega(x, y) - \varkappa(\frac{1}{2}(x + y))|x - y|^{-\kappa}$ *with an appropriate smooth coefficient* $\varkappa(x)$*, with the error* $O(h^{-2-\kappa})$ *one can replace* $e(x, y, \tau)$ *by its standard Tauberian expression* (16.1.11) *in the formula* (16.1.11) *for* I*.*

(ii) As $\kappa = 1, 2$ *and* $\omega = \varkappa(\frac{1}{2}(x+y))|x-y|^{-\kappa}$*, with the error* $O(h^{-2-\kappa}|\log h|)$ *one can replace* $e(x, y, \tau)$ *by its standard Tauberian expression* (16.1.11) *in the formula* (16.1.11) *for* I*.*

Proposition 16.8.3 [27]**.** *Let conditions* (16.1.5) *and* (16.1.6) *be fulfilled.*

(i) Further, let <u>*either*</u> *condition* (16.1.8) [28] *be fulfilled* <u>*or*</u> $\mu \le h^{\delta-1}|\log h|^{-1}$ *with an arbitrarily small exponent. Then* (16.1.11) *and Statements (i), (ii) of Proposition 16.8.2 hold.*

(ii) Furthermore, let $h^{-1-\delta}\mu \le h^{-1}$*. Then* (16.1.11) *and Statements (i), (ii) of Proposition 16.8.2 hold with an extra factor* $(1 + \mu h^{1-\delta})$ *in the right-hand expressions.*

16.8.2 Strong Magnetic Field

Consider the Schrödinger-Pauli operator as $\mu h \ge \epsilon_0$ which is a bit more tricky:

Proposition 16.8.4 [29]**.** *Let* $\mu h \ge \epsilon_0$*. Then*

(i) Contribution of the zone $\{(x, y) : |x - y| \ge \gamma\}$ *to* I *does not exceed* $C\mu h^{-2}\gamma^{-\kappa}$*.*

---

[26] Cf. Proposition 16.4.3.

[27] Cf. Proposition 16.4.6.

[28] Which actually could be replaced by much weaker non-degeneracy condition of Chapter 13 for $d = 3$.

[29] Cf. Proposition 16.4.8.

(ii) Further,

$$|\mathsf{I}| \le C\mu h^{-2}\begin{cases} h^{-\kappa} & \text{as } \ 0<\kappa<1,\\ h^{-1}\bigl(1+(\log \mu h)_+\bigr) & \text{as } \ \kappa=1,\\ \mu^{\frac{1}{2}(\kappa-1)}h^{-\frac{1}{2}(\kappa+1)} & \text{as } \ 1<\kappa<3. \end{cases} \tag{16.8.2}$$

(iii) Furthermore, $\mathsf{I} = O(\mu h^{\infty})$ *under condition* (16.4.14)*; in particular it is the case as* $\mathfrak{z}<1$ *and* $\mu h \ge C_0$.

Proof. Statement (i) trivially follows from the fact that $\mathscr{L}^2$-norm of $e(.,.,\tau)$ does not exceed $C\mu^{\frac{1}{2}}h^{-1}$.

Meanwhile, an estimate of the contribution of the zone

$$\{(x,y) : x\in B(0,1), y\in B(0,1), |x-y|\le \gamma\}$$

is more subtle: if $0<\kappa<1$ $\omega = \partial_{x_3}\omega'$ with $\omega' = O(\gamma^{1-\kappa})$ as $|x-y|\le\gamma$. Then

$$\begin{aligned} I_\gamma = \int |e(x,y,\tau)|^2\omega(x,y)\psi'_\gamma(x-y)\,dxdy = \\ -2h^{-1}\operatorname{Re} i\int hD_{x_3}e(x,y,\tau)\cdot e(y,x,\tau)\omega'(x,y)\psi'_\gamma(x-y)\,dxdy - \\ \int |e(x,y,\tau)|^2\omega(x,y,\tau)\cdot\partial_{x_3}\psi'_\gamma(x-y)\,dxdy \end{aligned}$$

with the first and second terms not exceeding $C\gamma^{1-\kappa}h^{-1}\times\mu h^{-2}$ and $C\gamma^{-\kappa}\times\mu h^{-2}$ respectively where we used the fact that $\mathscr{L}^2$-norm of $P_j e(.,.,\tau)$ does not exceed $C\mu^{\frac{1}{2}}h^{-1}$. Setting $\gamma = h$ finishes the proof of Statement (ii) in this case.

As $1\le\kappa<3$ we consider a partition of $\{(x,y) : |x-y|\le h\}$ to subzones $\{(x,y) : |x'-y'|\gtrsim\sigma\}$ and $\{(x,y) : |x'-y'|\lesssim\sigma\}$ and in the former zone we repeat the same arguments as before albeit with $\omega' = O(\log|x'-y'|/h)$, $\omega' = O(|x'-y'|^{1-\kappa})$ for $\kappa=1$ and $1<\kappa<3$ respectively; then contribution of this zone does not exceed $Ch^{-1}|\log\sigma/h|\times\mu h^{-2}$ and $Ch^{-1}\sigma^{1-\kappa}\times\mu h^{-2}$ respectively; as $\sigma = \mu^{-\frac{1}{2}}h^{\frac{1}{2}}$ we arrive to estimate (16.8.2) for contribution of this zone as well which proves Statement (ii).

Finally, a contribution of the zone $\{(x,y) : |x'-y'|\le\sigma, |x_3-y_3\le\gamma\}$ does not exceed $C\mu^2h^{-4}\times\int|z|^{-\kappa}\,dz$ with the integral taken over the cylinder $\{|z'|\le\sigma, |z_3\le\gamma\}$ and not exceeding $C(1+|\log\sigma/\gamma|)\sigma^2$ and $C\sigma^{2-\kappa}$

respectively as $|e(x,y,\tau) = O(\mu h^{-2})$. Again for selected γ, σ we get estimate (16.8.2) for contribution of this zone as well.

Finally, Statement (iii) is due to the fact that $e(x,y,0) = O(\mu h^{\infty})$ since condition (16.4.14) is fulfilled in one of points x, y; see Subsection 13.6.4.□

Proposition 16.8.5 [30]**.** *Let conditions* (16.1.1)–(16.1.5) *be fulfilled. Let* $\mu h \ge \epsilon$ *and one of the nondegeneracy conditions* (16.4.15) *or* (16.4.17) *be fulfilled.*

(i) As $\sigma \ge C_0 \mu^{-\frac{1}{2}} h^{\frac{1}{2}}$ *contribution of the zone*

$$\{(x,y) : \ |x'-y'| \ge C_0 \mu^{-\frac{1}{2}} h^{\frac{1}{2}}, |x-y| \ge \gamma\}$$

to I *does not exceed* $C\mu h^{-1}\gamma^{-\kappa}$.

(ii) As $\gamma \ge C_0 h$ *contribution of the zone*

$$\{(x,y) : \ |x'-y'| \le C_0 \mu^{-\frac{1}{2}} h^{\frac{1}{2}}, |x_3-y_3| \ge \gamma\}$$

to I *does not exceed* $C\mu h^{-1}\gamma^{-1-\kappa}$.

(iii) Estimate

$$|\mathsf{I} - \mathsf{I}^{\mathsf{T}}| \le C\mu h^{-1} \begin{cases} h^{-\kappa} & \text{as } \ 0<\kappa<1, \\ h^{-1}\big(1+(\log \mu h)_+\big) & \text{as } \ \kappa = 1, \\ \mu^{\frac{1}{2}(\kappa-1)} h^{-\frac{1}{2}(\kappa+1)} & \text{as } \ 1<\kappa<3, \ \kappa \ne 2, \\ \mu^{\frac{1}{2}} h^{-\frac{3}{2}}\big(1+(\log \mu h)_+\big) & \text{as } \ \kappa = 2 \end{cases} \tag{16.8.3}$$

holds.

Proof. To prove Statement (i) recall that drift speed does not exceed $C\mu^{-1}$ and therefore Hilbert-Schmidt norm of $\psi E(\tau)\psi'$ does not exceed $C\mu^{\frac{1}{2}} h^{-\frac{1}{2}}$ as ψ, ψ' are $\mathscr{L}_0^{\infty}$-functions with $\mathsf{dist}(\mathsf{supp}\,\psi, \mathsf{supp}\,\psi') \ge C_0 \mu^{-\frac{1}{2}} h^{\frac{1}{2}}$.

Really, it is true for a Hilbert-Schmidt norm of $\big(E(\tau) - E(\tau')\big)\psi$ with $|\tau - \tau'| \le h$ and then by Tauberian theorem it is true for a Hilbert-Schmidt

[30] Cf. Proposition 16.4.9.

norm of $\big(E(\tau)-E^{\mathsf{T}}(\tau)\big)\psi'$ with E^{T} operator with the Schwartz kernel e^{T} with time $T\asymp 1$:

$$\|\big(E(\tau)-E^{\mathsf{T}}(\tau)\big)\psi'\|_{\mathsf{HS}}\le C\mu^{\frac12}h^{-\frac12}. \tag{16.8.4}$$

However $\psi E^{\mathsf{T}}\psi'$ is negligible as $T\le\epsilon$ due to propagation results. This implies Statement (i) obviously.

Statement (ii) is proven in the same way but now $T\asymp\gamma$.

To prove Statement (iii) we need to estimate contribution to $\mathsf{I}-\mathsf{I}^{\mathsf{T}}$ of the zones $\{(x,y):\ |x'-y'|\le h, h\le|x_3-y_3|\le\epsilon\}$ and $\{(x,y):\ |x-y|\le h\}$. However estimate of the contribution of the former is trivial due to estimate (16.8.4). So, consider zone $\{(x,y):\ |x-y|\le h\}$.

(a) If $0<\kappa<1$ we can replace in the same way as in the proof of Proposition 16.8.4 $\omega(x,y)$ by $\omega'(x,y)=O(h^{1-\kappa})$ in this zone and one copy of $\big(e(x,y,\tau)-e^{\mathsf{T}}(x,y,\tau)\big)$ to $D_3\big(e(x,y,\tau)-e^{\mathsf{T}}(x,y,\tau)\big)$; however Subsection 13.6.4 implies the following generalization of (16.8.4):

$$\|P_3^k P'^j\big(E(\tau)-E^{\mathsf{T}}(\tau)\big)\psi'\|_{\mathsf{HS}}\le C\mu^{\frac12}h^{-\frac12}(\mu h)^j \tag{16.8.5}$$

with $P'=(P_1,P_2)$ and therefore contribution of this zone to $(\mathsf{I}-\mathsf{I}^{\mathsf{T}})$ does not exceed $C\mu h^{-1-\kappa}$. In this case estimate (16.8.3) is proven.

(b) Let $1\le\kappa<3$. Then the above arguments imply

(16.8.6) If $1<\kappa<3$ the contribution of the zone $\{(x,y):\ |x'-y'|\ge\sigma\}$ with $\sigma\ge C_0\mu^{-\frac12}h^{\frac12}$ to I does not exceed $C\mu h^{-2}\sigma^{1-\kappa}$; if $\kappa=1$ it does not exceed $C\mu h^{-2}(1+|\log\mu h|)$.

Observe that with $\sigma=C_0\mu^{-\frac12}h^{\frac12}$ we get exactly the right-hand expression in (16.8.3). Therefore we need to estimate a contribution of the zone $\{(x,y):\ |x'-y'\le\sigma, |x_3-y_3|\le h\}$ with $\sigma=C_0\mu^{-\frac12}h^{\frac12}$.

Consider case $1\le\kappa<2$ first. Note that $\omega=(3-\kappa)^{-1}\sum_j\partial_{z_j}z_j\omega$ [31] and therefore we can replace ω either by $(x_j-y_j)\omega=O(|x'-y'|\cdot|x-y|^{-\kappa})$ with $j=1,2$ or by $(x_3-y_3)\omega=O(|x-y|^{1-\kappa})$, simultaneously applying $h^{-1}P_j$ to one of the factors $\big(e(x,y,\tau)-e^{\mathsf{T}}(x,y,\tau)\big)$. Then we can replace

[31] Recall that we replace (x,y) by $(\mathsf{x},z)=(\frac12(x+y),x-y)$.

$(x_j - y_j)\omega$ by $(x_j - y_j)\omega'$ simultaneously applying $h^{-1}P_j$ to one of the factors $\big(e(x,y,\tau) - e^{\mathsf{T}}(x,y,\tau)\big)$ (the same as before or another one).

So for $j = 1, 2$ we estimate the term by $C\mu h^{-1} \times h^{-2}(\mu h)^{\frac{1}{2}} \times \sigma \times \sigma^{1-\kappa}$ with factors $(\mu h)^{\frac{1}{2}}$ and σ coming from P_j and $(x_j - y_j)$; as $\kappa = 1$ the last factor is replaced by $|\log \sigma/\gamma|$.

For $j = 3$ these factors are replaced by 1 and h respectively with the same product. Note that when we drag the last ∂_{x_3} through x_3 they may cancel one another but the power becomes $(1-\kappa)$ which we treated already (and while the gain in this power is exactly compensated by an extra factor h^{-1}.)

Plugging in σ we get a proper estimate (16.8.3).

(c) Further, the same arguments work for $2 \le \kappa < 3$ as well albeit now $\omega = (3-\kappa)^{-2}\sum_{j,k} \partial_{z_j}\partial_{z_k} z_j z_k \omega$. Note that when we drag the last ∂_{x_3} through x_3 they may cancel one another but the power becomes $(1-\kappa)$ which we treated already (and while the gain in this power is exactly compensated by an extra factor h^{-1}.) However for $\kappa = 2$ we get power -1 and then the logarithmic factor comes in. □

16.9 Dirac Energy: 3D-Calculations

16.9.1 Toy Model

Transformations

Consider first the toy-model operator (16.6.1).

Let us rescale as before[32]. Then $U(x,y,t)$ in comparison with $U_{(2)}(x',y',t)$ has factor $U_{(1)}(x_3, y_3, t)$ defined by (16.6.4). Let us consider effect of all these changes ignoring other variables; again without any loss of the generality we assume that $\omega(x,y)$ is given by (16.5.3).

We can replace variables x, y with new variables $\mathsf{x} := \frac{1}{2}(x+y)$ and $z := (x-y)$ and rescale. Note that the phase of $U_{(1)}$ is linear with respect to x_3 and we can get rid of $\mu^{-1}d\mathsf{x}_3$ integration in the same manner we got rid of $\mu^{-1}\,d\mathsf{x}_1$: we replace $\Omega(\dots, \mathsf{x}_3, .)$ by its partial Fourier transform

[32] We need to add factor $\mu^{-6+\kappa} = \mu^{-3} \times \mu^{-3} \times \mu^{-\kappa}$ where two factors μ^{-3} are coming from dx and dy and μ^{κ} from ω.

$x_3 \to -\mu^{-1}h^{-1}(t'-t'')$ with an extra factor 2π; thus in comparison with 2D case we have

(a) $\hat\Omega\big(2\mu^{-1}h^{-1}\alpha(t'-t''), -\mu^{-1}h^{-1}\beta(t'-t''), z\big)$ where $\hat\Omega(.,.,z)$ is a partial Fourier transform with respect to (x_1, x_3) (instead of $\hat\Omega\big(2\mu^{-1}h^{-1}\alpha(t'-t''), z\big)$);

(b) An extra factor which after easy reductions becomes

$$\frac{1}{4}h^{-1}(t't'')^{-\frac{1}{2}}\exp\Big(i\hbar^{-1}(t'-t'')\big(-\frac{1}{8}(t't'')^{-1}z_3^2-\frac{2}{3}\beta^2\mu^{-2}(t'^2+t't''+t''^2)\big)\Big);$$

(c) Integration with respect to dz_3 which enters both this factor and $\hat\Omega(.,.,z)$.

Taking in account all these modifications we need to replace (16.5.4) by

$$\begin{aligned}(16.9.1)\quad \mathsf{I} = {}& \frac{1}{8}(2\pi)^{-3}\hbar^{-3}\mu^{\kappa+3}\iint\iiint \hat\Omega(4\hbar^{-1}\alpha s, -\hbar^{-1}\beta s, z)\times\\ & \csc(t+s)\csc(t-s)(t+s)^{-\frac{3}{2}}(t-s)^{-\frac{3}{2}}\times\\ \exp\Big(i\hbar^{-1}\Big[&-\frac{1}{4}\big(\cot(t+s)-\cot(t-s)\big)\big(z_1^2+(z_2+2t\mu^{-1}\alpha)^2+4s^2\mu^{-2}\alpha^2\big)\\ &-\big(\cot(t+s)+\cot(t-s)\big)s\mu^{-1}\alpha-2s(\tau-\mu^{-2}\alpha^2)+\\ 2s\big(&-\frac{1}{8}(t+s)^{-1}(t-s)^{-1}z_3^2-\frac{2}{3}\beta^2\mu^{-2}(3t^2+s^2)\big]\Big)\,dtds\,\psi(\mu^{-1}z)dz_1dz_2dz_3.\end{aligned}$$

Case $\lambda^2 \gg \mu h$

Assume first that

$$(16.9.2)\qquad \lambda^2 := \alpha^2+\beta^2 \ge h^{1-\delta}.$$

Remark 16.9.1[33]. (i) We take λ-admissible with respect to x function $\Omega_\lambda = \Omega(x/\lambda, .)$.

Then the virtue of the factor $\hat\Omega(4\hbar^{-1}\alpha\gamma s, -\hbar^{-1}\beta\gamma s, \cdot)$ under assumption (16.9.2) we need to consider only $|s| \le h^\delta$ and therefore we can consider separately $|t'| \le \epsilon_0, |t''| \le \epsilon_0$ and $|t'| \ge \epsilon_0, |t''| \ge \epsilon_0$.

[33] Cf. Remark 16.5.2.

(ii) Note that due to Section 5.4 contribution of the zone $\{|t'| \le \epsilon_0, |t''| \le \epsilon_0\}$ defined by integral expressions (16.9.1) etc with an extra factor $\bar{\chi}_{\epsilon_0}(t')$, or $\bar{\chi}_{\epsilon_0}(t'')$, or $\bar{\chi}_{\epsilon_0}(t)$ differs from the same expression for non-magnetic Schrödinger operator by $O(\mu h^{-2-\kappa} \times \hbar^{\kappa}) = O(\mu^{\kappa+1} h^{-2})$ as $\kappa \ne 1$ and by $O(\mu^2 h^{-2} |\log \mu|)$ as $\kappa = 1$.

(iii) Furthermore, if we remove from this expression for a non-magnetic Schrödinger operator cut-off $\{|t'| \ge \epsilon_0\}$ then the error would not exceed the same expression as well.

Let us consider contribution of the zone $\{|t'| \ge \epsilon_0, |t''| \ge \epsilon_0\}$ defined by an integral expressions (16.9.1) etc with an extra factor $\big(1 - \bar{\chi}_{\epsilon_0}(t')\big)$. Due to Remark 16.9.1(i) we need to consider only t', t'' belonging to the same tick.

Let us consider first zone

$$\{|s| \ge \hbar/\lambda^2, |\sin(t)| \ge C|s|\}. \tag{16.9.3}$$

Then integration by parts with respect to z' delivers one of the factors (16.5.7), (16.5.8). Thus integrating by parts many times in the zone where both of these factors are less than 1 we acquire factors (16.5.9), (16.5.10) respectively.

On the other hand, integration by parts with respect to z_3 delivers factor $\hbar |s|^{-1} t^2 |z_3|^2$; therefore integrating by parts many times in the zone $\{|z_3| \ge \hbar^{\frac{1}{2}} |s|^{-\frac{1}{2}} |t|\}$ delivers factor

$$\big(1 + |s| \hbar^{-1} t^{-2} |z_3|^2\big)^{-l}. \tag{16.9.4}$$

Case $1 < \kappa < 3$**.** In this case, multiplying by $|z|^{-\kappa}$ and integrating we get after multiplication by $|\sin(t)|^{-2}$ expression (16.5.11) albeit with κ replaced by $(\kappa - 1)$ i.e.

$$\asymp |\sin(t)|^{1-\kappa} |s|^{-\frac{3}{2}+\frac{1}{2}\kappa} \hbar^{\frac{3}{2}-\frac{1}{2}\kappa}. \tag{16.9.5}$$

Integrating by t over k-th tick intersected with $\{t : |\sin(t)| \ge |s|\}$ we get (16.5.12) modified the same way i.e.

$$C\hbar^{\frac{3}{2}-\frac{1}{2}\kappa} \begin{cases} |s|^{-\frac{3}{2}+\frac{1}{2}\kappa} & 1 < \kappa < 2, \\ |s|^{-\frac{1}{2}} (1 + |\log |s||) & \kappa = 2, \\ |s|^{\frac{1}{2}-\frac{1}{2}\kappa} & 2 < \kappa < 3. \end{cases} \tag{16.9.6}$$

This expression (16.9.6) must be either integrated with respect to s over $\{|s| \le \hbar/\lambda^2\}$ or multiplied by $(\hbar/\lambda^2)^l |s|^{-l}$ due to factor $\hat{\Omega}$ and integrated over $\{|s| \ge \hbar/\lambda^2\}$, resulting in both cases in the same answer which is the value of (16.9.6) $\times |s|$ calculated as $s = \hbar/\lambda^2$ which is similarly modified expression (16.5.13) i.e.

$$C\hbar \begin{cases} \lambda^{1-\kappa} & 1 < \kappa < 2, \\ (1 + |\log(\hbar/\lambda^2)|)\lambda^{-1} & \kappa = 2, \\ \hbar^{2-\kappa}\lambda^{-3+\kappa} & 2 < \kappa < 3. \end{cases} \tag{16.9.7}$$

In addition to zone (16.9.3) we need to consider zone (16.5.14) defined as $\{|\sin(t')| \asymp |s|,\ |\sin(t'')| \le |s|\}$; its tween $\{|\sin(t')| \asymp |s|,\ |\sin(t'')| \le |s|\}$ is considered in the same way.

In zone (16.5.14) $|\cot(t') - \cot(t'')| \asymp |\sin(t'')|^{-1}$ and in this case factors (16.5.7), (16.5.8) are replaced by (16.5.7)′, (16.5.8)′ and (16.5.9), (16.5.10) by 16.5.9, (16.5.10)′ while factor (16.9.4) is preserved.

Then, multiplying by $|z|^{-\kappa}$ and integrating we get after multiplication by $|\sin(t'')|^{-1}|\sin(t')|^{-1}$ similarly modified expression (16.5.11)′

$$\hbar^{\frac{3}{2}-\frac{1}{2}\kappa}|\sin(t'')|^{\frac{1}{2}-\frac{1}{2}\kappa}|s|^{-1}; \tag{16.9.5}'$$

then integrating by $|t''|$ over one tick but with $|\sin(t'')| \le |s|$ we get modified expression (16.5.12)′ i.e.

$$\hbar^{\frac{3}{2}-\frac{1}{2}\kappa}|s|^{\frac{1}{2}-\frac{1}{2}\kappa}. \tag{16.9.6}'$$

Finally, either integrating over $\{|s| \le h/\varepsilon\lambda\}$ or multiplying by $|s|^{-l}(h/\varepsilon\lambda)^l$ and integrating over $\{|s| \ge h/\varepsilon\lambda\}$ we get in both cases the same answer (16.9.6)′ $\times |s|$, calculated as $s = \hbar/\lambda^2$ not exceeding (16.9.7).

Therefore the total contribution of zones (16.9.3) and (16.5.14) is given by expression (16.9.7). Then multiplying by $|k|^{-3}\mu^\kappa h^{-3}\lambda^3$ we get after summation with respect to $k : |k| \ge 1$ the value as $k = 1$ i.e. (16.9.7) $\times$ $\mu^\kappa h^{-3}\lambda^3$.

Therefore we arrive to analogue of Proposition 16.5.3

$$|\mathsf{I}^{\mathsf{T}}_\lambda - \mathsf{I}^{\mathsf{T}\prime}_\lambda| \le R^{\mathsf{W}}(\lambda) := C\mu^{\kappa+1}h^{-2}\lambda^3 \begin{cases} \lambda^{1-\kappa} & 1 < \kappa < 2, \\ (1 + |\log(\hbar/\lambda^2)|)\lambda^{-1} & \kappa = 2, \\ \mu^{2-\kappa}h^{2-\kappa}\lambda^{-3+\kappa} & 2 < \kappa < 3 \end{cases} \tag{16.9.8}$$

where $\mathsf{I}^{\mathsf{T}\prime}_\alpha$ is a Tauberian expression for I albeit with $T = \epsilon_0\mu^{-1}$.

Case $0 < \kappa \le 1$. In this case integration over zone $\{z : |z| \le C_0\}$ [34] and multiplication by $|\sin(t)|^{-2}$ results in

$$C|\sin(t)|^{-2}\rho^2 \begin{cases} \zeta^{1-\kappa} & 0 < \kappa < 1, \\ (1 + (\log \zeta/\rho))_+) & \kappa = 1 \end{cases} \tag{16.9.9}$$

with

$$\zeta = \zeta(s,k) = \min\bigl((\hbar/|s|)^{\frac12}|k|, 1\bigr), \tag{16.9.10}$$

$$\rho = \min\bigl((\hbar/|s|)^{\frac12}, 1\bigr) \tag{16.9.11}$$

(cf. expression (16.9.5)).

One can see easily that

(16.9.12) Integral by t over one tick intersected with $\{t : |\sin(t)| \ge |s|\}$ does not exceed $C\hbar|s|^{-1}\zeta^{1-\kappa}$ as $|s| \ge \hbar$ and $C(\hbar|s|^{-1})^{\frac12}\zeta^{1-\kappa}$ as $|s| \le \hbar$. As $\kappa = 1$ one needs to include an extra factor $|\log \zeta/\rho|$, ρ calculated as $|\sin(t)| = 1$ for $|s| \ge \hbar$ and $\sin(t)| = (|s|/\hbar)^{\frac12}$ for $|s| \le \hbar$.

Meanwhile, in the zone (16.5.14) integration over $\{z : |z| \le C_0\}$ and multiplication by $s^{-1}|\sin(t'')|^{-1}$ results in expression (16.9.11) and integration by $\{t'' : |\sin(t'')| \le |s|\}$ results in much lesser term $C\hbar\zeta^{1-\kappa}$, with some logarithmic factor as $\kappa = 1$.

Now integral by $\{s : |s| \lesssim 1\}$ does not exceed $C\hbar|k|^{1-\kappa}$ as $0 < \kappa < 1$ and $C\hbar(1 + |\log\hbar| + |\log|k|)$ as $\kappa = 1$. Finally, multiplication by $\mu^{\kappa+3}\hbar^{-3}|k|^{-2}$ and summation with respect to $k : |k| \ge 1$ results in $C\mu^{\kappa+1}h^{-2}$ as $0 < \kappa < 1$ and $C\mu^2h^{-2}|\log\mu h|$ if $\kappa = 1$.

Therefore we arrive to the following analogue of Proposition 16.5.3:

$$|\mathsf{I}^{\mathsf{T}}_\lambda - \mathsf{I}^{\mathsf{T}\prime}_\lambda| \le R^{\mathsf{W}}(\lambda) := C\mu^{\kappa+1}h^{-2}\lambda^3 \begin{cases} 1 & 0 < \kappa < 1, \\ (1 + |\log(\mu h)|) & \kappa = 1. \end{cases} \tag{16.9.13}$$

Combining with (16.9.8) we arrive to:

Proposition 16.9.2 [35]**.** *(i) For the toy-model operator with $1 \le \mu \le h^{-1}$ under assumption* (16.9.2) *estimates* (16.9.8), (16.9.13) *hold for $1 < \kappa < 3$, $0 < \kappa \le 1$ respectively.*

[34] Corresponding to $|x - y| \le C_0\mu^{-1}$.

[35] Cf. cf. Corollary 16.5.3.

(ii) In particular, as $\lambda = 1$

$$|\mathsf{I}^{\mathsf{T}} - \mathsf{I}^{\mathsf{T}\prime}| \le R^{\mathsf{W}} := \tag{16.9.14}$$
$$C\mu^{\kappa+1}h^{-2}\begin{cases} 1 & 0<\kappa<2, \kappa\ne 1,\\ (1+|\log(\mu h)|) & \kappa = 1,2,\\ \mu^{2-\kappa}h^{2-\kappa} & 2<\kappa<3.\end{cases}$$

Following the same proof as in Proposition 16.5.4 one can prove easily that

$$|\mathsf{I}^{\mathsf{T}\prime} - \mathcal{I}^{\mathsf{W}}| \le C\mu^2 h^{-1-\kappa} \tag{16.9.15}$$

which does not exceed $R^{\mathsf{W}}(\lambda)$ implying the following:

Corollary 16.9.3 [36]**.** *In the framework of Proposition 16.9.2*

$$|\mathsf{I}^{\mathsf{T}}_{\lambda} - \mathcal{I}^{\mathsf{W}}_{\lambda}| \le CR^{\mathsf{W}}(\lambda). \tag{16.9.16}$$

Remark 16.9.4. After summation with respect to partition we restore estimate (16.9.14) under some non-degeneracy assumption. Comparing with the Tauberian remainder estimate $O(h^{-2-\kappa})$ we conclude that R^{W} is lesser as $\mu \le h^{-\kappa/(\kappa+1)}$ $(0<\kappa<2)$ and $\mu \le h^{-\frac{2}{3}}$ $(2\le\kappa<3)$ (with some correction for $\kappa = 1, 2$).

In particular, $\mu \le h^{-\frac{1}{2}}$ would suffice for $\kappa > 1$ and therefore improvement as in Subsubsection *16.5.1.3 Improvement* is not needed.

Case $\lambda^2 \not\gg \mu h$

Assume now that $\mu^{-1} \le \lambda$ and $\lambda^2 \le \mu h^{1+\delta}$. Then in contrast to the previous we will need to compute contributions of pair of ticks (k', k'') with $k' \ne k''$. Then if t', t'' belong to k'-th and k''-th ticks respectively we denote $r = k' - k''$ and $s = t' - t'' - 2\pi r$.

However, we still need to distinguish cases $1 < \kappa < 3$ and $0 < \kappa \le 1$.

[36] Cf. Corollary 16.5.5.

Case $1 < \kappa < 3$. In this case we according to the previous subsection need just to take results for $d = 2$, plug $\kappa := (\kappa - 1)$, $\alpha = \lambda$ and multiply by $h^{-1}\lambda$ resulting in

Proposition 16.9.5 [37]**.** *For the toy-model operator with* $1 \le \mu \le h^{-1}$, $1 < \kappa < 3$

$$|\mathsf{I}^{\mathsf{T}}_{(\lambda)} - \mathcal{I}^{\mathsf{W}}_{(\lambda)}| \le (16.9.8) + (16.9.18) \qquad \text{as } \lambda^2 \ge \mu h, \tag{16.9.17}$$

with

$$C\mu^{\frac{1}{2}\kappa-\frac{1}{2}} h^{-\frac{5}{2}-\frac{1}{2}\kappa}\lambda^3 (\mu h/\lambda^2)^l \tag{16.9.18}$$

and

$$|\mathsf{I}^{\mathsf{T}}_{(\lambda)} - \mathcal{I}^{\mathsf{W}}_{(\lambda)}| \le (16.9.20) + (16.9.21) + (16.9.22) \qquad \text{as } \lambda^2 \le \mu h \tag{16.9.19}$$

with

$$C\mu^{\frac{1}{2}\kappa+\frac{3}{2}} h^{-\frac{3}{2}-\frac{1}{2}\kappa}\lambda^3, \tag{16.9.20}$$

$$C\mu^{\frac{1}{2}+\frac{1}{2}\kappa} h^{-\frac{3}{2}-\frac{1}{2}\kappa}\lambda^3 \bigl(1 + (\log(\mu h/\lambda^2))_+\bigr)^2, \tag{16.9.21}$$

$$C\mu^{\frac{1}{2}\kappa-\frac{1}{2}} h^{-\frac{5}{2}-\frac{1}{2}\kappa}\lambda^3 \bigl(1 + (\log(\mu h/\lambda^2))_+\bigr) \tag{16.9.22}$$

Proof. Easy details are left to the reader. □

Case $0 < \kappa \le 1$. In this case we need to modify arguments of the previous subsubsection.

(i) Consider case $k' - k'' = r = 0$ first. As we did not use $\lambda^2 \gg \mu h$ estimate (16.9.13) for contributions of such terms remains valid.

(ii) Consider now case $k' - k'' = r \ne 0$. Note that then according to (16.9.4) one should use $\zeta = |k' + k''| \cdot (\hbar|k - k'|)^{\frac{1}{2}}$

If $\lambda^2 \ge \mu h$ the last expression before summation with respect to k $(= k')$ acquires factor $(|k' - k''|\lambda^2/\mu h)^{-l}$ and we get after summation with respect to $k' \ne 0$, $k'' \ne 0$ the same right-hand expression of (16.9.13).

Meanwhile, if $\lambda^2 \le \mu h$ we get before summation (as $0 < \kappa < 1$)

$$C\mu^{\kappa+1} h^{-2}\lambda^3 |k'|^{-1}|k''|^{-1} \bigl(|k' + k''|/|k' - k''|^{\frac{1}{2}}\bigr)\bigr)^{1-\kappa} \times \bigl(1 + |k' - k''|\lambda^2/\mu h\bigr)^{-l} \tag{16.9.23}$$

[37] Cf. Proposition 16.5.10.

(with a logarithmic factor as $\kappa = 1$).

It is enough to sum with as $1 \le k''$, $k' = k'' + r$, $r \ge 1$; then the sum is

$$\asymp C\mu^{\kappa+1}h^{-2}\lambda^3 \sum_{r\ge 1} r^{-\frac{1}{2}-\frac{1}{2}\kappa}\bigl(1 + r\lambda^2/\mu h\bigr)^{-l} \asymp C\mu^{\kappa+1}h^{-2}\lambda^3(\mu h/\lambda^2)^{\frac{1}{2}-\frac{1}{2}\kappa};$$

so we get

$$C\begin{cases} \mu^{\frac{3}{2}+\frac{1}{2}\kappa}h^{-\frac{3}{2}-\frac{1}{2}\kappa}\lambda^{2+\kappa} & 0 < \kappa < 1,\\ \mu^2 h^{-2}\lambda^3\bigl(1+\log(\mu h)\bigr)^2 & \kappa = 1 \end{cases} \tag{16.9.24}$$

where case $\kappa = 1$ we left to the reader.

(iii) Consider now $k' = 0$, $k'' \ne 0$; its tween case $k' \ne 0$, $k'' = 0$ is addressed in the same way. To do this we need to modify our expression fo I: namely, we do not divide by t' and then take Fourier transform $F_{t'\to\hbar^{-1}\tau}$; instead we take Fourier transform $F_{t'\to\hbar^{-1}\tau'}$, then integrate by τ' to τ and divide by $\hbar$; modifying this way (16.9.1) we arrive instead of (16.9.1) to the expression similar to (16.5.30).

Then repeating the similar arguments of Section 16.5 with the above modification, we arrive to

$$C\mu^{\kappa}h^{-3}\lambda^3|k''|^{-\frac{1}{2}-\frac{1}{2}\kappa}\bigl(1 + |k''|\lambda^2/\mu h\bigr)^{-l}$$

instead of (16.9.23), and summation with respect to $k'' : |k''| \ge 1$ returns $C\mu^{\kappa}h^{-3}\lambda^3(\mu h/\lambda^2)^l$ as $\lambda^2 \ge \mu h$ and $C\mu^{\kappa}h^{-3}\lambda^3(\mu h/\lambda^2)^{\frac{1}{2}-\frac{1}{2}\kappa}$ if $\lambda^2 \le \mu h$.

So we arrive to

$$C(\mu h/\lambda^2)^l\mu^{\kappa}h^{-3}\lambda^3\begin{cases} 1 & 0 < \kappa < 1,\\ \bigl(1+\log(\mu h)\bigr)^2 & \kappa = 1 \end{cases} \tag{16.9.25}$$

as $\lambda^2 \ge \mu h$ and

$$C\mu^{\frac{1}{2}+\frac{1}{2}\kappa}h^{-\frac{5}{2}-\frac{1}{2}\kappa}\lambda^{2+\kappa}\begin{cases} 1 & 0 < \kappa < 1,\\ \bigl(1+\log(\mu h)\bigr)^2 & \kappa = 1 \end{cases} \tag{16.9.26}$$

as $\lambda^2 \le \mu h$.

Thus we proved:

Proposition 16.9.6. *For the toy-model operator with* $1 \le \mu \le h^{-1}$, $0 < \kappa \le 1$

$$|\mathsf{I}^{\mathsf{T}}_{(\lambda)} - \mathcal{I}^{\mathsf{W}}_{(\lambda)}| \le (16.9.13) + (16.9.25) \qquad \text{as } \lambda^2 \ge \mu h, \tag{16.9.27}$$

and

$$|\mathsf{I}^{\mathsf{T}}_{(\lambda)} - \mathcal{I}^{\mathsf{W}}_{(\lambda)}| \le (16.9.13) + (16.9.24) + (16.9.26). \qquad \text{as } \lambda^2 \le \mu h. \tag{16.9.28}$$

16.9.2 General Operators

Consider now general operators satisfying conditions (16.1.5)–(16.1.6) and either (16.1.7) or (16.1.8) as $\tau = 0$.

First, using Proposition 16.8.1 and propagation results we conclude that

Proposition 16.9.7 [38]**.** *Let conditions* (16.1.5)–(16.1.6) *be fulfilled. Then*

(i) Contribution of the zone $\{(x,y) : |x-y| \ge \epsilon_0 \mu^{-1}\}$ *(before rescaling) to* I^{T} *does not exceed* $C\mu^{\kappa+1}h^{-2}$ *and*

(ii) Under condition (16.1.7) *contribution of time* $\{|t| \ge \epsilon_0\}$ *(before rescaling) to* I^{T} *does not exceed* $C\mu^{\kappa+1}h^{-2}$.

Note that $O(\mu^{\kappa+1}h^{-1})$ either coincides or is smaller than the remainder estimate (16.9.14) and as long as we are interested in Weyl approximation $\mathcal{I}^{\mathsf{W}}$ we should be completely happy with it.

Under condition (16.1.7) we are done arriving to Statement 16.9.9 of Theorem (i) below.

Under condition (16.1.8) let us introduce the scaling function

$$\delta(x) = \epsilon_0 |\nabla V F^{-1}| + \frac{1}{2}\bar{\delta}, \qquad \bar{\delta} = C_0 \mu^{-1} \tag{16.9.29}$$

and consider covering of $B(0,1)$ by δ-admissible elements. In virtue of Proposition 16.9.7(i) we need to consider only pairs (x,y) belonging to the same element. Due to the rescaling arguments, the contribution of one such element to $|I^{\mathsf{T}} - \mathcal{I}^{\mathsf{W}}|$ does not exceed $C\mu h^{-1-\kappa}\delta^3$ and therefore

[38] Cf. Proposition 16.5.11.

(16.9.30) Under condition (16.1.8) contribution of the zone

$$\{(x,y) : |x-y| \le C_0\mu^{-1},\ |\nabla VF^{-1}| \le \delta\}$$

to $|I^{\mathsf{T}} - \mathcal{I}^{\mathsf{W}}|$ does not exceed $C\mu h^{-2-\kappa}\delta^3$; in particular, if $\delta = \bar{\delta}$ we get $O(\mu^{-2}h^{-2-\kappa})$.

Therefore we need to consider only the zone

$$\{(x,y) : |x-y| \le C_0\mu^{-1},\ |\nabla VF^{-1}| \ge \bar{\lambda}\}.$$

We are going to prove that

Proposition 16.9.8 [39]**.** *Let conditions* (16.1.5)–(16.1.6) *be fulfilled. Further, let* $\mu \le h^{-1}$. *Then for each* z *contribution of zone* $\{(x,y) \in B(z,\delta(z)),\ |x-y| \le C_0\mu^{-1}|\}$ *with* $\delta(z) \ge C_0\mu^{-1}$ *to* $|\mathsf{I}^{\mathsf{T}} - \mathcal{I}^{\mathsf{W}}|$ *does not exceed*

(i) $R^{\mathsf{W}}(\lambda)$ *which is defined as the right-hand expression of* (16.9.8) *or* (16.9.13) *for* $1 < \kappa < 3$, $0 < \kappa \le 1$ *provided* $\lambda \ge (\mu h)^{\frac{1}{2}-\delta}$.

(ii) the right-hand expression of (16.9.17) *or* (16.9.27) *for* $1 < \kappa < 3$, $0 < \kappa \le 1$ *provided* $\lambda \ge (\mu h)^{\frac{1}{2}}$.

(iii) the right-hand expression of (16.9.19) *or* (16.9.28) *for* $1 < \kappa < 3$, $0 < \kappa \le 1$ *provided* $\lambda \le (\mu h)^{\frac{1}{2}}$.

Consider components of $R^{\mathsf{W}}(\lambda)$. Note that expressions (16.9.8), (16.9.13) and (16.9.20)–(16.9.22), (16.9.24), (16.9.26) contain λ in the positive powers while expressions (16.9.18), (16.9.25) contain λ in the negative powers. Therefore after integration with respect $\lambda^{-1}\,d\lambda$ we get expressions (16.9.8) and (16.9.13) as $\lambda = 1$ (i.e. we get (16.9.14) and we get all other expressions as $\lambda = (\mu h)^{\frac{1}{2}}$; one can check easily that these latter expressions are less than (16.9.14) + $Ch^{-2-\kappa}$.

Therefore we arrive to:

Theorem 16.9.9 [40]**.** *Let conditions* (16.1.5)–(16.1.6). *Let* $\mu \le h^{-1}$. *Then,*

[39] Cf. Proposition 16.5.12.

[40] Cf. Theorem 16.5.13.

(i) Under condition (16.1.7) *estimate*

$$|\mathsf{I}-\mathsf{I}^{\mathsf{W}}| \le CR^{\mathsf{W}} + Ch^{-2-\kappa}; \tag{16.9.31}$$

(ii) Under condition (16.1.8)

$$|\mathsf{I}-\mathsf{I}^{\mathsf{W}}| \le CR^{\mathsf{W}} + C\mu^{\frac{5}{2}}h^{-\frac{1}{2}-\kappa-\delta} + Ch^{-2-\kappa}. \tag{16.9.32}$$

Proof of Proposition 16.9.8. First of all applying Proposition 16.3.5 and the same arguments as in the analysis of Section 16.3 we arrive to

(16.9.33) Contribution of the zone $\{|\sin(\theta(t'))| \ge C_0\hbar,\ |\sin(\theta(t''))| \ge C_0\hbar\}$ to the error $|\mathsf{I}^{\mathsf{T}} - \mathcal{I}^{\mathsf{W}}|$ does not exceed $R^{\mathsf{W}}(\lambda)$.

Therefore we need to explore contributions of three remaining zones

$$\{|\sin(\theta(t'))| \le 2C_0\hbar,\ |\sin(\theta(t''))| \le 2C_0\hbar\} \tag{16.5.43}$$

and

$$\{|\sin(\theta(t'))| \ge 2C_0\hbar,\ |\sin(\theta(t''))| \le C_0\hbar\} \tag{16.5.44}$$

(the same analysis would cover its tween zone $\{|\sin(\theta(t'))| \ge 2C_0\hbar,\ |\sin(\theta(t''))| \le C_0\hbar\}$).

We would like to follow the arguments of the proof of Proposition 16.5.12 but there is a problem: the magnetic drift is controlled by α and it may be much less than λ. However let us apply few general arguments.

(a) Let us consider the zone (16.5.43) as $\lambda^2 \ge \mu h$. First, if we consider the zone $\{(x,y):\ |x-y| \ge \ell\}$ (in the non-rescaled coordinates) we estimate the contribution of the corresponding pair (k', k'') by $C\hbar^2\ell^{-\kappa}|k'|^{-1}|k''|^{-1} \times h^{-d}\lambda^d$ and summation with respect to $|k'| \le \mu\lambda$, $|k''| \le \mu\lambda$ returns

$$C\mu^2 h^{2-d}\ell^{-\kappa}(1+|\log \mu\lambda|)^2. \tag{16.9.34}$$

Meanwhile, if we consider zone $\{(x,y):\ |x-y| \le \ell\}$ (in the non-rescaled coordinates as well) then estimating $U(x,y,t)$ by h^{-d} (no rescaling, $d = 2,3$) we we estimate the contribution of the corresponding pair (k', k'') by $C\hbar^2 \times h^{-2d} \times \ell^{d-\kappa}\lambda^d$ and again summation with respect to k', k'' returns

$$C\mu^2 h^{2-2d}\ell^{d-\kappa}\lambda^d(1+|\log \mu\lambda|)^2. \tag{16.9.35}$$

Comparing (16.9.34) and (16.9.35) we see that their sum is minimal

$$C\mu^2 h^{2-d-\kappa}\lambda^d(1+|\log \mu\lambda|)^2 \tag{16.9.36}$$

for $\ell = h$.

Comparing with (16.9.8) and (16.9.13) we conclude that for $d = 3$ this is less than R^{W} as $0 < \kappa < 1$, $\lambda \ge \mu h$. To deal with $1 \le \kappa < 3$ let us note first that there must be a factor

$$C\big(1+|k'-k''|\lambda^2/\mu h\big)^{-l} \tag{16.9.37}$$

before summation. Really, as $|\xi_3+\eta_3| \ge \epsilon_0\lambda$ this factor is due to the shift in (x_3+y_3) and as $|\xi_3+\eta_3| \ge \epsilon_0\lambda$ but $|\nabla' V/F| \asymp \lambda$ or $|\nabla_{x_3} V/F| \asymp \lambda$ this factor is due to the shift in $(\xi_1+\eta_1)$ or $(\xi_3+\eta_3)$ respectively.

Therefore

(16.9.38) As $\lambda^2 \ge \mu h^{1-\delta}$ contribution of $k' \ne k''$ is negligible.

This allows us also eliminate logarithmic factors in (16.9.36) and (16.9.37).

Let us apply cut-off Q by hD_{x_3} and Q' by hD_{xy_3}. Assume first that <u>either</u> $|\xi_3| \le C\rho$ on the support of (the symbol of) Q <u>or</u> $|\eta_3| \le C\rho$ on the support of (the symbol of) Q', in our estimate we acquire factor ρ and we get an expression below $R^{\mathsf{W}}(\lambda)$.

Therefore we can assume that

(16.9.39) $|\xi_3| \ge \rho := \mathsf{max}\big((\mu h)^{\frac12}, \mu^{-1}\big)$ on the support of (the symbol of) Q

(or $|\eta_3| \ge \mathsf{max}\big((\mu h)^{\frac12}, \mu^{-1}\big)$ on the support of (the symbol of) Q'.

Let us consider corresponding classical dynamics. Assumption (16.9.39) implies that in k winding it travels the "observable" distance $k\xi_3$ and if there was no "turn back" the contribution of k-th winding to estimate would not exceed

$$C\mu^2 h^{-1}|k|^{-2-\kappa}\int_{|\xi_3|\ge\rho} |\xi_3|^{-\kappa}\, d\xi_3\lambda^3$$

where integral is $\asymp 1$ if $0 < \kappa < 1$, $\asymp \log\rho$ if $\kappa = 1$ and $\asymp \rho^{1-\kappa}$ as $1 < \kappa < 3$. Obviously multiplied by $\mu^2 h^{-1}$ it does not exceed $R^{\mathsf{W}}(\lambda)$ and therefore summation with respect to k returns $O(R^{\mathsf{W}}(\lambda))$.

Now we need to consider effect of the "turn back". Let $\beta = |\nabla_{x_3} V/F|$. Note first that as $|\xi_3| \ge \beta\lambda$ there is no turn back for time $|t| \le \epsilon\lambda$. Therefore we need to consider only $|\xi_3| \le \beta\lambda$.

There is come back on k-th winding as ξ_3 is close to $\zeta^*(k) \sim \mathsf{const}\beta\mu^{-1}k$ and the distance $|x-y| \asymp \mu^{-1}|k||\xi_3 - \zeta(k)|$ and then contribution of k-th winding (as $|x-y| \ge Ch$) does not exceed

$$C\mu^{2+\kappa}h^{-1}|k|^{-2-\kappa} \int_{|\xi_3-\zeta(k)|\ge\mu h|k|^{-1}} |\xi_3 - \zeta(k)|^{-\kappa}\, d\xi_3\lambda^3 \le C\lambda^3 \begin{cases} \mu^{2+\kappa}h^{-1}|k|^{-2-\kappa} & 0<\kappa<2, \\ \mu^4 h^{1-\kappa}|k|^{-4} & 2<\kappa<3, \end{cases}$$

with a logarithmic factor $(1+\log|k| + |\log\mu h|)$ as $\kappa = 2$. The sum of the expression above is the same as this expression for $k = 1$ (we denote it temporarily by $R\lambda^3$) which obviously less than $R^{\mathsf{W}}(\lambda)$.

Finally, we need to consider the contribution of k-th winding as $|x-y| \le h$. However it is done by the standard way as $U(x,y,t)$ after cut by ξ_3 and η_3 acquires factor Ch^2.

Therefore, under assumption $\lambda^2 \ge \mu h^{1-\delta}$ we are done.

On the other hand, if $\lambda^2 \ge \mu h$ (but $\lambda^2 \not\gg \mu h$) terms with $k' \ne k''$ are no more negligible but in the estimate we can ignore due to the factor (16.9.37) them except when $k' = 0$ or $k'' = 0$.

Applying the same arguments as in 2D-case i.e. replacing in term with $k' = 0$ factor $|k'|^{-1}$ by factor $\hbar^{-1}$ we arrive to $R\lambda^3 \times 1/(\mu h) \times (\mu h/\lambda^2)^l$ which is less than term (16.9.18) or (16.9.25) as $1 < \kappa < 3$ or $0 < \kappa \le 1$ respectively.

(b) Next, let us analyze the zone (16.5.43) if $\lambda^2 \le \mu h$. In this case we apply the same arguments but now effectively we sum over k', k'' with $|k'-k''| \le \mu h/\lambda^2$ which effectively boils out to the summation over $k' = 1,\ k'' = 1, \dots, \mu h/\lambda^2$ or $k' = 0,\ k'' = 1, \dots, \mu h/\lambda^2$; the former results in $R\lambda^3 \times \mu h/\lambda^2$ and the latter results $R\lambda^3 \times \mu h/\lambda \times 1/(\mu h)$ and one can see easily that the result is less than what we claimed.

(c) Further, consider the zone (16.5.44) if $\lambda^2 \ge \mu h$. Now there is always shift with respect to $(x-y)$ which is at least $\asymp |\sin(t')|$ and therefore as

$1 < \kappa < 3$ contribution of this zone does not exceed contribution of zone (16.5.43). As $0 < \kappa < 1$ we get $C\mu^{\kappa+1}h^{-2}\lambda^3|k|^{-2}$ and summation returns $C\mu^{\kappa+1}h^{-2}\lambda^3$ which is the answer as $\lambda^2 \gg \mu h$; let us denote it by $R\lambda^3$; for $\kappa = 1$ it includes logarithmic factor $(1 + |\log(\mu h)|)$.

The same answer estimates contribution of $k' \neq 0, k'' \neq 0$ as $\lambda^2 \geq \mu h$; contributions of $k' = 0, k'' \neq 0$ and $k'' \neq 0, k' = 0$ do not exceed $R\lambda^3 \times 1/(\mu h) \times (\mu h/\lambda^2)^l$ and one can see easily that the result is less than what we claimed.

(d) Finally, consider the zone (16.5.44) as $\lambda^2 \leq \mu h$. Again as $1 < \kappa < 3$ contribution of (16.5.44) does not exceed contribution of (16.5.43) and as $0 < \kappa \leq 1$ we estimate contribution of $k' \neq 0, k'' \neq 0$ by $R\lambda^3 \times \mu h/\lambda^2$, and contributions of $k' \neq 0, k'' = 0$ and $k' = 0, k'' \neq 0$ by $R\lambda^3 \times \mu h/\lambda^2 \times 1/(\mu h)$ and one can see easily that the result is less than what we claimed. □

16.9.3 Perturbations

Consider perturbations. However due to the presence of x_3, hD_3 there are rather different components here than in Subsection 16.5.3.

Perturbations. I

Let us start from the terms $O(|x' - y'|)$. During evolution these terms are $O(\mu^{-1})$ and therefore we need to multiply by $O(\mu^{-2}h^{-1}|k|)$.

Case $1 < \kappa < 3$**.** Consider first case $k' = k'' = k$. Assume that $\lambda^2 \geq \mu h$. Recall that k-th tick's contribution to I^{T} was not exceeding expression (16.9.7) multiplied by $\mu^{\kappa}h^{-3}\lambda^3|k|^{-3}$ i.e.

$$C\lambda^3|k|^{-3}\begin{cases}\mu^{\kappa+1}h^{-2}\lambda^{1-\kappa} & 1 < \kappa < 2,\\ \mu^3 h^{-2}(1 + |\log(\hbar/\lambda^2)|)\lambda^{-1} & \kappa = 2,\\ \mu^3 h^{-\kappa}\lambda^{-3+\kappa} & 2 < \kappa < 3\end{cases} \tag{16.9.40}$$

(as $|\sin(t')| \leq \hbar$ or $|\sin(t'')| \leq \hbar$ one should use Proposition 16.9.8) and multiplying by $C\mu^{-2}h^{-1}|k|^{-1}$ we get after summation with respect to k :

$|k| \ge 1$

$$C\lambda^3 \begin{cases} \mu^{\kappa-1}h^{-3}\lambda^{1-\kappa} & 1<\kappa<2,\\ \mu h^{-3}(1+|\log(\hbar/\lambda^2)|)\lambda^{-1} & \kappa=2,\\ \mu h^{-1-\kappa}\lambda^{-3+\kappa} & 2<\kappa<3 \end{cases} \tag{16.9.41}$$

and summation with respect to λ returns the same expression as $\lambda = 1$ which does not exceed $Ch^{-2-\kappa}$.

Next we need to consider $0 \ne k' \ne k'' \ne 0$. Recall that the contribution of such pair to I^{T} does not exceed

$$C\lambda^3|k'|^{-\frac{3}{2}}|k''|^{-\frac{3}{2}}(\mu h/\lambda^2|k'-k''|)^l\times \begin{cases} \mu^{\kappa+1}h^{-2}\lambda^{1-\kappa} & 1<\kappa<2,\\ \mu^3 h^{-2}(1+|\log(\mu h/\lambda^2)|)\lambda^{-1} & \kappa=2,\\ \mu^3 h^{-\kappa}\lambda^{-3+\kappa} & 2<\kappa<3. \end{cases} \tag{16.9.42}$$

Multiplying by $C\mu^{-2}h^{-1}|k'|$ (as the perturbation goes to the first "factor") we get

$$C\lambda^3|k'|^{-\frac{1}{2}}|k''|^{-\frac{3}{2}}(\mu h/\lambda^2|k'-k''|)^l\times \begin{cases} \mu^{\kappa-1}h^{-3}\lambda^{1-\kappa} & 1<\kappa<2,\\ \mu h^{-3}(1+|\log(\mu h/\lambda^2)|)\lambda^{-1} & \kappa=2,\\ \mu h^{-1-\kappa}\lambda^{-3+\kappa} & 2<\kappa<3. \end{cases} \tag{16.9.43}$$

Then summation with respect to k' of $|k'|^{-\frac{1}{2}}(\mu h/\lambda^2|k'-k''|)^l$ returns $|k''|^{-\frac{1}{2}}(\mu h/\lambda^2)^l$ as $\lambda^2 \ge \mu h$ and summation with respect to k'' then returns the same expression as we got considering $k' = k'' \ne 0$ with an extra factor $(\mu h/\lambda^2)^l$.

On the other hand, as $\lambda^2 \le \mu h$ one should replace (16.9.7) by $C(\mu h)^{\frac{3}{2}-\frac{1}{2}\kappa}$; multiplying by $\mu^{\kappa}h^{-3}\lambda^3|k'|^{-\frac{3}{2}}|k''|^{-\frac{3}{2}}(1+\lambda^2|k'-k''|/\mu h)^{-l} \times \mu^{-2}h^{-1}|k'|$ we get

$$C\mu^{-\frac{1}{2}+\frac{1}{2}\kappa}h^{-\frac{5}{2}-\frac{1}{2}\kappa}\lambda^3|k'|^{-\frac{1}{2}}|k''|^{-\frac{3}{2}}(1+\lambda^2|k'-k''|/\mu h)^{-l} \tag{16.9.44}$$

and one can see easily that summation with respect to k', k'' returns

$$C\mu^{-\frac{1}{2}+\frac{1}{2}\kappa}h^{-\frac{5}{2}-\frac{1}{2}\kappa}\lambda^3(\mu h/\lambda^2)^{\frac{1}{2}} \asymp C\mu^{\frac{1}{2}\kappa}h^{-2-\frac{1}{2}\kappa}\lambda^2$$

and summation with respect to λ returns $C\mu^{\frac{3}{2}\kappa}h^{-1-\frac{1}{2}\kappa}$ which again is less than $Ch^{-2-\kappa}$.

If $k' \neq 0$, $k'' = 0$ we recall that $|k''|^{-\frac{3}{2}}$ should be replaced by $\hbar^{-\frac{3}{2}}$ in (16.9.42)–(16.9.43) and perturbation brings factor $\mu^{-2}h^{-1}|k'|$ so we get instead of (16.9.43)

$$C\lambda^3|k'|^{-\frac{1}{2}}\mu^{-\frac{3}{2}}h^{-\frac{3}{2}}(\mu h/\lambda^2|k'|)^l\times \begin{cases} \mu^{\kappa-1}h^{-3}\lambda^{1-\kappa} & 1<\kappa<2,\\ \mu h^{-3}(1+|\log(\mu h/\lambda^2)|)\lambda^{-1} & \kappa=2,\\ \mu h^{-1-\kappa}\lambda^{-3+\kappa} & 2<\kappa<3 \end{cases}$$

and summation with respect to $|k'|$ and then $\lambda \geq (\mu h)^{\frac{1}{2}}$ returns $C\mu^{\frac{1}{2}\kappa-\frac{1}{2}}h^{-\frac{5}{2}-\frac{1}{2}\kappa}$.

Similarly, as $\lambda^2 \leq \mu h$ we start from (16.9.44) which is replaced by

$$C\mu^{-2+\frac{1}{2}\kappa}h^{-4-\frac{1}{2}\kappa}\lambda^3|k'|^{-\frac{1}{2}}(1+\lambda^2|k'|/\mu h)^{-l}$$

and summation with respect to k' and returns $C\mu^{-\frac{3}{2}+\frac{1}{2}\kappa}h^{-\frac{7}{2}-\frac{1}{2}\kappa}\lambda^2$ and then summation with respect to $\lambda \leq (\mu h)^{\frac{1}{2}}$ returns the same answer $C\mu^{\frac{1}{2}\kappa-\frac{1}{2}}h^{-\frac{5}{2}-\frac{1}{2}\kappa}$.

As $|k'| < |k''|$ the estimate of the contribution of the pair (k', k'') to an error is obviously less than the same estimate for the pair (k'', k'); this takes care of $k' = 0$, $k'' \neq 0$. Finally for $k' = k'' = 0$ we can use the standard arguments to estimate the same way.

As the result we conclude that the error will not exceed $Ch^{-2-\kappa}$.

Case $0 < \kappa \leq 1$. The similar arguments work for $0 < \kappa < 1$. However one must reconsider zone $\{(x, y) : |x - y| \geq C_0\mu^{-1}\}$ where contribution of the pair (k', k'') to Weyl asymptotics does not exceed

$$C\mu^2h^{-2}\zeta^{1-\kappa}|k|^{-3}\lambda^3 \asymp C\mu^{\kappa+1}h^{-2}|k|^{-2-\kappa}\lambda^3 \tag{16.9.45}$$

with $\zeta \asymp \mu^{-1}|k|$ as $k' = k'' = k \neq 0$. Summation with respect to $k : |k| \geq 1$ returns then $C\mu^{\kappa+1}h^{-2}\lambda^3$ as it should.

As $k' = k'' = k \neq 0$ it results in the approximation error not exceeding

$$C\mu^2h^{-2}\zeta^{1-\kappa}|k|^{-3}\lambda^3 \times \mu^{-2}h^{-1}|k| \asymp C\mu^{\kappa-1}h^{-3}|k|^{-1-\kappa}\lambda^3 \tag{16.9.46}$$

and summation with respect to k, λ returns $C\mu^{\kappa-1}h^{-3}$.

As $0 \neq k' \neq k' \neq 0$, $|k'| \geq |k''|$ it results in the approximation error not exceeding

$$C\mu^2 h^{-2}\bigl(\mu^{-1}|k'|\bigr)\bigr)^{1-\kappa}|k'|^{-\frac{3}{2}}|k''|^{-\frac{3}{2}}\times (1+\lambda^2|k'-k''|/\mu h)^{-l}\lambda^3 \times \mu^{-2}h^{-1}|k'| \asymp C\mu^{\kappa-1}h^{-3}|k'|^{\frac{1}{2}-\kappa}|k''|^{-\frac{3}{2}}(1+\lambda^2|k'-k''|/\mu h)^{-l}\lambda^3 \tag{16.9.47}$$

and the sum with respect to (k', k'') and $\lambda : \lambda^2 \geq \mu h$ does not exceed $C\mu^{\kappa-1}h^{-2}$.

Meanwhile as $\lambda^2 \leq \mu h$ the sum with respect to (k', k'') does not exceed $C\mu^{\kappa-1}h^{-3}(\mu h/\lambda^2)^{\frac{3}{2}-\kappa}\lambda^3$ and the sum with respect to λ is less than $C\mu^{\kappa-1}h^{-3}$.

As $k' \neq 0$, $k'' = 0$ (16.9.47) becomes

$$C\mu^{\kappa-1}h^{-3}|k'|^{\frac{1}{2}-\kappa}(\mu h)^{-\frac{3}{2}}(1+\lambda^2|k'|/\mu h)^{-l}\lambda^3 \tag{16.9.48}$$

and then summation with respect to k' returns $C\mu^{\kappa-1}h^{-3}(\mu h)^{-\frac{3}{2}}(\mu h/\lambda^2)^l\lambda^3$ as $\lambda^2 \geq \mu h$ and then the sum with respect to λ is less than $C\mu^{\kappa-1}h^{-3}$.

Meanwhile as $\lambda^2 \leq \mu h$ the sum with respect to k' does not exceed $C\mu^{\kappa-1}h^{-3}(\mu h/\lambda^2)^{\frac{3}{2}-\kappa}(\mu h)^{-\frac{3}{2}}\lambda^3$ and then the sum with respect to λ is less than $C\mu^{\kappa-1}h^{-3}$.

As $|k'| < |k''|$ the estimate of the contribution of the pair (k', k'') to an error is obviously less than the same estimate for the pair (k'', k'); this takes care of $k' = 0$, $k'' \neq 0$. Finally, for $k' = k'' = 0$ we can use the standard arguments to estimate contribution by $Ch^{-2-\kappa}$.

For $\kappa = 1$ we apply the same arguments with the obvious modifications, concluding that the error does not exceed $Ch^{-3}(1+|\log \mu h|)$.

Note that in contrast to the case $1 < \kappa < 3$ now the error is larger than $Ch^{-2-\kappa}$.

To improve this remainder estimate let us notice that the second term in the approximation is 0 and the third term also acquires factor $\mu^{-2}h^{-1}|k|$ (as $k' = k'' = k \neq 0$); so we get

$$C\mu^{\kappa-1}h^{-3}|k|^{-1-\kappa} \times \mu^{-2}h^{-1}|k|\lambda^3 \asymp C\mu^{\kappa-3}h^{-4}|k|^{-\kappa}\lambda^3$$

which we should sum as $|k| \leq \mu^2 h$; we also should sum

$$C\mu^2 h^{-2}\zeta^{1-\kappa}|k|^{-3}\lambda^3 \asymp C\mu^{\kappa+1}h^{-2}|k|^{-2-\kappa}\lambda^3$$

as $|k| \ge \mu^2 h$ and both sums return $C\mu^{\kappa+1}h^{-2}(\mu^2 h)^{-1-\kappa}\lambda^3 \asymp C\mu^{-1-\kappa}h^{-3-\kappa}\lambda^3$. Summation with respect to λ returns $C\mu^{-1-\kappa}h^{-3-\kappa}$. One can estimate contribution of all all other pairs (k', k'') in the same way. As $\kappa = 1$ we get $C\mu^{-2}h^{-4}(1 + |\log \mu h|)$.

So we arrive to

Theorem 16.9.10 [41]**.** *Let conditions* (16.1.5)–(16.1.6) *and either* (16.1.7) *or* (16.1.8) *be fulfilled. Let* $h^{-\frac12}\mu \le h^{-1}$. *Then*

(i) As $1 < \kappa < 3$

$$|\mathsf{I} - \mathsf{I}^0| \le Ch^{-2-\kappa} \tag{16.9.49}$$

where

$$\mathsf{I}^0 := \int \Omega_{1,1}\bigl(\frac12(x+y), x-y\bigr)\cdot |e^0_{\frac12(x+y)}(x,y,0)|^2\,dxdy \tag{16.9.50}$$

and $e^0_z(x,y,\tau)$ *is the Schwartz kernel of the spectral projector of the generalized toy-model operator*

$$A^0_z := h^2D_1^2 + (hD_2 - \mu x_1)^2 + h^2D_3^2 + V^0(x), \quad V^0(x) := V(z_1, z_2, x_3) \tag{16.9.51}$$

which in contrast to (16.7.36) V^0 *does not contain linear terms with respect to* (x_1, x_2).

(ii) As $0 < \kappa < 1$

$$|\mathsf{I} - \mathsf{I}^0| \le Ch^{-2-\kappa} + C\mu^{-1-\kappa}h^{-3-\kappa} \tag{16.9.52}$$

and as $\kappa = 1$

$$|\mathsf{I} - \mathsf{I}^0| \le Ch^{-3} + C\mu^{-2}h^{-4}|\log \mu h|. \tag{16.9.53}$$

Remark 16.9.11. Note that the remainder estimate does not exceed $Ch^{-2-\kappa}$ for $\mu \ge h^{-1/(1+\kappa)}$ as $0 < \kappa < 1$ and for $\mu \ge h^{-\frac12}(1 + |\log \mu h|)^{\frac12}$ as $\kappa = 1$.

Perturbations. II

If we go from the generalized toy-model approximation to the magnetic Weyl approximation then we need to counter $(x_3 - y_3)\lambda$ terms and this is $O(\mu^{-1}|k'|\lambda)$ due to the finite speed of propagation. Then dealing as before we acquire an extra factor $|k'|\lambda$.

[41] Cf. Theorem 16.5.21.

Case $1 < \kappa < 3$**.** Then as $k' = k'' = k \neq 0$ we have $|k|^{-1}$ rather than $|k|^{-2}$ and the sum with respect to k contains an extra logarithmic factor $(1+\log(\mu^2 h))\lambda$ in comparison to what we got in Subsubsection *16.9.3.1 Perturbations. I.*

(a) Consider case $0 \neq k' \neq k'' \neq 0$, $|k'| \geq |k''|$. Then if $\lambda^2 \geq \mu h$ we arrive to the same expression (but with an extra factor $(\mu h/\lambda^2)^l$). However if $\lambda^2 \leq \mu h$ we need to consider $|k'|^{-\frac{3}{2}}|k''|^{-\frac{3}{2}} \times |k'|^2\lambda$ with $k', k'' : |k' - k''| \leq \mu h/\lambda^2$ which in comparison to what we got before after summation returns an extra factor $\mu h/\lambda^2 \times \lambda$ and the sum with respect to λ does not exceed what we got above.

(b) Consider $0 \neq k'$, $k'' = 0$. Again no change if $\lambda^2 \geq \mu h$ and an extra factor $(\mu h/\lambda^2) \times \lambda$ if $\lambda^2 \leq \mu h$ and the sum with respect to λ does not exceed what we got above.

(c) Therefore, as a result we get $C\mu^{\kappa-1}h^{-3}(1 + |\log \mu^2 h|)$ if $1 < \kappa < 2$ and $C\mu h^{-1-\kappa}(1 + |\log \mu^2 h|)$ if $2 < \kappa < 3$ with an extra factor $(1 + |\log \mu h|)$ if $\kappa = 2$. In both cases it is less than $Ch^{-2-\kappa}$ unless $\mu \geq h^{-1}|\log h|^{-r}$.

To improve our result in this latter case we apply three term approximation and note that the second term is 0 while the third term contains summation of $R^{\mathsf{W}}\lambda^3|k|^{-3} \times (\mu^{-2}h|k|^2\lambda)^2$ for $k : |k| \leq \mu h^{\frac{1}{2}}$ and summation of $R^{\mathsf{W}}\lambda^3|k|^{-3}$ for $k : |k| \geq \mu h^{\frac{1}{2}}$ as $k' = k'' = k \neq 0$ where $R^{\mathsf{W}} = \mu^3 h^{-\kappa}$ as $2 < \kappa < 3$, $R^{\mathsf{W}} = \mu^{\kappa+1}h^{-2}$ as $1 < \kappa < 2$ with an extra factor $(1 + |\log \mu h|)$ as $\kappa = 2$.

Other pairs (k', k'') should be modified in the same way and we leave easy but tedious details to the reader. As a result we get $R^{\mathsf{W}}\mu^{-2}h^{-1}$ without any logarithmic factor thus arriving to the same estimate as before but without logarithmic factor; as $1 < \kappa < 3$ it does not exceed $Ch^{-2-\kappa}$. So we arrive to Statement (i) of Theorem 16.9.12 below.

Case $0 < \kappa \leq 1$**.** Now expression (16.9.46) acquires factor $|k|\lambda$ and becomes $C\mu^{\kappa-1}h^{-3}|k|^{-\kappa}\lambda^4$ and summation with respect to $k : |k| \leq \mu h^{\frac{1}{2}}\lambda^{-\frac{1}{2}}$ returns

$$C\mu^{\kappa-1}h^{-3}(\mu h^{\frac{1}{2}}\lambda^{-\frac{1}{2}})^{1-\kappa}\lambda^4 \asymp Ch^{-\frac{5}{2}-\frac{1}{2}\kappa}\lambda^{-\frac{7}{2}+\frac{1}{2}\kappa}.$$

We also should sum $C\mu^{\kappa+1}h^{-2}|k|^{-2-\kappa}\lambda^3$ for $|k| \geq \mu h^{\frac{1}{2}}\lambda^{-\frac{1}{2}}$ with the same result.

Finally summation with respect to λ returns $Ch^{-\frac{5}{2}-\frac{1}{2}\kappa}$.

Other pairs (k', k'') should be modified in the same way and we leave easy but tedious details to the reader. Three term approximation does not improve results. As $\kappa = 1$ we acquire factor $(1 + |\log h|)$. So we arrive to Statement (ii) of Theorem 16.9.12 below.

Theorem 16.9.12 [42]**.** *Let conditions* (16.1.5)–(16.1.6) *and either* (16.1.7) *or* (16.1.8) *be fulfilled. Let* $h^{-\frac{1}{2}} \le \mu \le h^{-1}$. *Then*

(i) If $1 < \kappa < 3$

$$|\mathsf{I} - \mathcal{I}^{\mathsf{MW}}| \le Ch^{-2-\kappa}; \tag{16.9.54}$$

(ii) If $0 < \kappa < 1$

$$|\mathsf{I} - \mathcal{I}^{\mathsf{MW}}| \le Ch^{-\frac{5}{2}-\frac{1}{2}\kappa} \tag{16.9.55}$$

and if $\kappa = 1$

$$|\mathsf{I} - \mathcal{I}^{\mathsf{MW}}| \le Ch^{-3}(1 + |\log \mu h|). \tag{16.9.56}$$

Perturbations. III

Now in the case $0 < \kappa \le 1$ we consider the toy-model approximation. Since (16.9.55) is larger than (16.9.53) we consider improvement of the previous subsubsection only. Now as perturbation is $(x_3 - y_3)^2$ which translates into $\mu^{-2}|k'|^2$ rather than μ^{-1} expression (16.9.46) acquires factor $\mu^{-1}|k'|^2$ and becomes $C\mu^{\kappa-2}h^{-3}|k|^{1-\kappa}\lambda^3$ and we need to sum this as $|k| \le \mu h^{\frac{1}{3}}$ resulting in

$$C\mu^{\kappa-2}h^{-3}(\mu h^{\frac{1}{3}})^{2-\kappa}\lambda^3 \asymp Ch^{-\frac{7}{3}-\frac{1}{3}\kappa}\lambda^3.$$

We should sum $C\mu^{\kappa+1}h^{-2}|k|^{-2-\kappa}\lambda^3$ for $|k| \ge \mu h^{\frac{1}{3}}$ with the same result.

Finally, summation with respect to λ returns $Ch^{-\frac{7}{3}-\frac{1}{3}\kappa}$.

Other pairs (k', k'') should be modified in the same way and we leave easy but tedious details to the reader. Three term approximation does not improve results. As $\kappa = 1$ we acquire factor $(1 + |\log h|)$. So we arrive to

[42] Cf. Theorem 16.5.19.

Theorem 16.9.13. *Let conditions* (16.1.5)–(16.1.6) *and either* (16.1.7) *or* (16.1.8) *be fulfilled. Let* $h^{-\frac{1}{2}} \le \mu \le h^{-1}$. *Then as* $0 < \kappa < 1$

$$|\mathsf{I} - \bar{\mathsf{I}}| \le Ch^{-2-\kappa} + Ch^{-\frac{7}{3}-\frac{1}{3}\kappa} + C\mu^{-1-\kappa}h^{-3-\kappa} \tag{16.9.57}$$

and as $\kappa = 1$

$$|\mathsf{I} - \bar{\mathsf{I}}| \le Ch^{-3} + C\mu^{-2}h^{-4}(1 + |\log \mu h|) \tag{16.9.58}$$

where $\bar{\mathsf{I}}$ *is defined for a simplified toy-model operator*

$$\bar{A}_z := h^2D_1^2 + (hD_2 - \mu x_1)^2 + h^2D_3^2 + \bar{V}(x), \qquad \bar{V}(x) := V(z) + \partial_{z_3}V(z)(x_3 - z_3). \tag{16.9.59}$$

16.9.4 Strong Magnetic Field

Consider the toy-model Schrödinger-Pauli operator (16.2.72). Recall that according to Propositions 16.8.4(ii), 16.8.5(ii) respectively

$$|\mathsf{I}| \le C\mu h^{-2}\begin{cases} h^{-\kappa} & \text{as } 0 < \kappa < 1,\\ h^{-1}\big(1 + (\log \mu h)_+\big) & \text{as } \kappa = 1,\\ \mu^{\frac{1}{2}(\kappa-1)}h^{-\frac{1}{2}(\kappa+1)} & \text{as } 1 < \kappa < 3 \end{cases} \tag{16.8.2}$$

and

$$|\mathsf{I} - \mathsf{I}^{\mathsf{T}}| \le C\mu h^{-1}\begin{cases} h^{-\kappa} & \text{as } 0 < \kappa < 1,\\ h^{-1}\big(1 + (\log \mu h)_+\big) & \text{as } \kappa = 1,\\ \mu^{\frac{1}{2}(\kappa-1)}h^{-\frac{1}{2}(\kappa+1)} & \text{as } 1 < \kappa < 3,\ \kappa \ne 2,\\ \mu^{\frac{1}{2}}h^{-\frac{3}{2}}\big(1 + (\log \mu h)_+\big) & \text{as } \kappa = 2. \end{cases} \tag{16.8.3}$$

Let us assume that $F = 1$ to avoid some unpleasant correction terms as reduced to $F = 1$.

(a) Consider the generalized toy-model approximation (16.9.51). Then $\sigma \asymp h$ and under condition

$$|V + 2m\mu h| \ge \epsilon_0 \qquad \forall m \in \mathbb{Z}^+ \tag{16.9.60}$$

the shift with respect to x_3 is $\asymp |t|$ which implies that we need to consider only $t' \asymp t''$ as the total contribution of other intervals will be less, and that contribution of intervals $|t'| \le C_0 h$, $|t''| \le C_0 h$ does not exceed the right-hand of (16.9.2) multiplied by Ch, and that contribution of intervals $t' \asymp T$, $t'' \asymp T$ ($T \ge C_0 h$) does not exceed $C\mu h^{-1} \times T^{-\kappa}$ so summation with respect to $T^{-1}dT$ returns $C\mu h^{-1-\kappa}$.

Then the error does not exceed the right-hand expression of (16.9.3).

(b) Consider the magnetic Weyl approximation. In this case $\sigma \asymp T$ and again under assumption (16.9.60) we can consider only $t' \asymp t''$, and we estimate contribution of intervals $|t'| \le C_0 h$, $|t''| \le C_0 h$ as above, but contribution of intervals $t' \asymp T$, $t'' \asymp T$ ($T \ge C_0 h$) does not exceed $C\mu h^{-2} \times T^{1-\kappa}$ and summation with respect to $T^{-1}dT$ returns $C\mu h^{-1-\kappa}$ as $1 < \kappa < 3$. As $0 < \kappa < 1$ we sum this way only for $T \le h^{\frac{1}{2}}$ resulting in $C\mu h^{-\frac{3}{2}-\frac{1}{2}\kappa}$ and we sum $C\mu h^{-1}T^{-\kappa}$ for $T \ge h^{\frac{1}{2}}$ with the same result. As $\kappa = 1$ we get $C\mu h^{-2}(1+|\log h|)$.

(c) Consider the toy-model approximation as $0 < \kappa < 1$. In this case $\sigma \asymp T^2$ (as we pass from the generalized toy-model approximation) and again under assumption (16.9.60) we can consider only $t' \asymp t''$, and we estimate contribution of intervals $|t'| \le C_0 h$, $|t''| \le C_0 h$ as above, but contribution of intervals $t' \asymp T$, $t'' \asymp T$ ($T \ge C_0 h$) does not exceed $C\mu h^{-2} \times T^{2-\kappa}$ summation with respect to $T^{-1}dT$ returns $C\mu h^{-\frac{4}{3}-\frac{1}{3}\kappa}$ as we sum with respect to $T^{-1}dT$ for $T \le h^{\frac{1}{3}}$; for $T \ge h^{\frac{1}{3}}$ we sum $C\mu h^{-1}T^{-1-\kappa}$ with the same result.

Then we arrive to

Theorem 16.9.14. *(i) For the Schrödinger-Pauli operator under conditions* (16.1.5)–(16.1.6) *and* (16.9.60)

$$|\mathsf{I} - \mathcal{I}^{\mathsf{MW}}| \le C \begin{cases} \mu h^{-\frac{3}{2}-\frac{1}{2}\kappa} & 0 < \kappa < 1, \\ \mu h^{-2}(1+|\log h|) & \kappa = 1, \\ \mu^{\frac{1}{2}(\kappa+1)} h^{-\frac{1}{2}(\kappa+3)} & 1 < \kappa < 3,\ \kappa \ne 2, \\ \mu^{\frac{3}{2}} h^{-\frac{5}{2}}(1+(\log \mu h)_+) & \kappa = 2. \end{cases} \tag{16.9.61}$$

(ii) Further, if $0 < \kappa \le 1$

$$|\mathsf{I} - \mathsf{I}^0| \le C \begin{cases} \mu h^{-1-\kappa} & 0 < \kappa < 1, \\ \mu h^{-2}(1 + (\log \mu h)_+) & \kappa = 1 \end{cases} \tag{16.9.62}$$

and

$$|\mathsf{I} - \bar{\mathsf{I}}| \le C \begin{cases} \mu h^{-1-\kappa} + \mu h^{-\frac{4}{3}-\frac{1}{3}\kappa} & 0 < \kappa < 1, \\ \mu h^{-2}(1 + |\log h|) & \kappa = 1 \end{cases} \tag{16.9.63}$$

Let us get rid of condition (16.9.60). First, we still can assume without any loss of the generality that (16.9.60) holds for all $m \in \mathbb{Z}^+$ save $m = \bar{m}$. Then making ℓ-admissible partitions in x and y with

$$\ell = \epsilon |V + 2\bar{m}\mu h| + h^{\frac{2}{3}} \tag{16.9.64}$$

one can replace (16.9.60) by (16.1.7) and then making ℓ-admissible partitions in x and y with

$$\ell = \epsilon \big(|V + 2\bar{m}\mu h| + |\nabla V|^2\big)^{\frac{1}{2}} + h^{\frac{1}{2}} \tag{16.9.65}$$

one can replace (16.1.7) by (16.1.8) arriving to

Theorem 16.9.15. *Theorem 16.9.14 remains valid with assumption* (16.9.60) *replaced by* (16.1.8)*.*

Proof. Easy but tedious details are left to the reader.

16.9.5 Problems and Remarks

Remark 16.9.16. The main difference between cases $2 < \kappa < 3$, $1 < \kappa < 2$ and $0 < \kappa < 1$ that in the first case the main contribution to the remainder is delivered by (x, y) close to one another ($|x-y| \ll \mu^{-1}$), in the second case by (x, y) with $|x - y| \asymp \mu^{-1}$ and in the third case by (x, y) with $|x - y| \asymp 1$.

We can calculate $\mathcal{I}^{\mathsf{MW}}$ and $\bar{\mathsf{I}}$ plugging corresponding expressions $e_x^{\mathsf{MW}}(x, x, 0)$ and $\bar{e}_x(x, x, 0)$ into I.

Problem 16.9.17. Find nice expressions for $\mathcal{I}^{\mathsf{MW}}$ and $\bar{\mathsf{I}}$.

Problem 16.9.18. As $\mu h \le 1$ get rid of condition (16.1.5); according to Chapter 13 we do not need it for estimate $|\mathsf{I}-\mathsf{I}^{\mathsf{T}}|$ but we want to get rid of it in estimates for $|\mathsf{I}-\mathcal{I}^{\mathsf{W}}|$, $|\mathsf{I}-\mathcal{I}^{\mathsf{MW}}|$ and $|\mathsf{I}-\bar{\mathsf{I}}|$. To do this

(i) Assume first that condition (16.1.7) is fulfilled and consider the scaling function $\ell(x) = \mathsf{max}\big(\epsilon|V(x)|, \mu h, C\mu^{-1}\big)$.

(ii) Assuming then that condition (16.1.8) is fulfilled and consider the scaling function $\ell(x) = \mathsf{max}\big(\epsilon(|V(x)| + |\nabla V(x)|^2)^{\frac{1}{2}}, (\mu h)^{\frac{1}{2}}, C\mu^{-1}\big)$.

Problem 16.9.19. Weaken non-degeneracy condition (16.1.8) which seems to be excessive here (in contrast to 2D case).

Problem 16.9.20. Get rid of condition (16.1.6) assuming instead that $|\boldsymbol{F}| + |\nabla \otimes \boldsymbol{F}| \ge \epsilon$.

16.10 Estimates of Expression (16.1.4)

16.10.1 Basics

In the multiparticle quantum theory we need to calculate expression (16.1.2) approximating energy of the electron-electron interaction or, more often, to estimate expression

$$\mathsf{K} := \iint \big(e(x,x,\tau) - h^{-d}\mathcal{N}_x(\tau)\big)\big(e(y,y,\tau) - h^{-d}\mathcal{N}_x(\tau)\big)\omega(x,y)\,dxdy \tag{16.1.4}$$

where $\omega(x,y) = \omega_\kappa(x,y)$ satisfies assumption (16.1.3) and $\mathcal{N}$ is *some* approximation. We concentrate on (16.1.4); asymptotics of (16.1.2) could be proven by the same arguments and we leave them to the reader.

Applying partition of unity we note that both of them depend on asymptotics of expression

$$\Gamma(e\psi) = \int e(x,x,\tau)\psi_\gamma(x)\,dx \tag{16.10.1}$$

with γ-admissible function ψ_γ.

Let us denote by $\gamma^d R(\alpha,\gamma)$ an upper estimate of an error occurring when we replace in (16.10.1) $e(x,x,0)$ by $h^{-d}\mathcal{N}$ and let

$$M = Ch^{-d} + C\mu h^{1-d} \tag{16.10.2}$$

be an upper estimate for $e(x,x,0)$.

Proposition 16.10.1. *Under condition* (16.1.7)

$$|\mathsf{K}| \le C\int \bigl(R(1,\gamma)\bigr)^2 \gamma^{d-1-\kappa}\,d\gamma \tag{16.10.3}$$

and

$$|\mathsf{J}-\mathcal{J}| \le CM\int R(1,\gamma)\gamma^{d-1-\kappa}\,d\gamma \tag{16.10.4}$$

and under condition (16.1.8)

$$\begin{aligned}|\mathsf{K}| \le C\iint_{\{\gamma\le\alpha\}} \bigl(R(\alpha,\gamma)\bigr)^2 \gamma^{d-1-\kappa}\alpha^{d-1}\,d\gamma d\alpha + \\ C\iint_{\{\alpha\le\beta\}} R(\alpha,\alpha)R(\beta,\beta)\alpha^{d-1}\beta^{d-1-\kappa}\,d\alpha d\beta\end{aligned} \tag{16.10.5}$$

and

$$\begin{aligned}|\mathsf{J}-\mathcal{J}| \le CM\iint_{\{\gamma\le\alpha\}} R(\alpha,\gamma)\gamma^{d-1-\kappa}\alpha^{d-1}\,d\gamma d\alpha + \\ CM\iint_{\{\alpha\le\beta\}} R(\alpha,\alpha)\alpha^{d-1}\beta^{d-1-\kappa}\,d\alpha d\beta\end{aligned} \tag{16.10.6}$$

where for $\alpha \le C_0\mu^{-1}$ we need to modify $\alpha^{-1}R(\alpha,\gamma)$ (see below)[43)].

Proof. Due to representation (16.4.1) and definition of $R(\alpha,\gamma)$ and M contribution of the zone $\{(x,y):\ |x-z|\asymp\gamma, |y-z|\asymp\gamma\}$ (note that $R(\alpha,\gamma)\le M$) to K does not exceed $C(R(\alpha,\gamma))^2\gamma^{2d-\kappa}$ for fixed z and γ where $\alpha=\alpha(z)$ provided $\gamma \le 3\epsilon\alpha$.

Under assumption (16.1.7) summation over z results in $C(R(1,\gamma))^2\gamma^{d-\kappa}$ and summation over γ results in estimate (16.10.3); estimate (16.10.4) is proven in the same way.

[43)] As $d=3$ we denote by α what we used to denote by γ in Sections 16.6–16.9 (i.e. $(\alpha^2+\beta^2)^{\frac12}$ in these sections notations.

On the other hand, under assumption (16.1.8) summation over $z : \alpha(z) \asymp \alpha$ results in $C(R(\alpha,\gamma))^2\alpha^d\gamma^{d-\kappa}$ and summation over γ, and then over α results the first term in the right-hand expression of (16.10.5); it estimates contribution of zone $\{(x,y) : |x-y| \le 3\epsilon\alpha\alpha(x)\}$ (in which $\alpha(y) \asymp \alpha(x)$).

Further, under assumption (16.1.8) if $|x-y| \ge 2\epsilon\alpha$, $\alpha := \alpha(x)$, $\beta := \alpha(y)$ then $|x-y| \asymp \max(\alpha,\beta)$. Therefore as $\beta \ge \alpha$ the contribution of zone

$$\{(x,y) : |x-y| \asymp \beta, \alpha(y) \asymp \alpha, \alpha(y) \asymp \beta\}$$

does not exceed $CR(\alpha,\alpha)\alpha^d \times R(\beta,\beta)\beta^{d-\kappa}$ and summation over α, β returns the second term in the in the right-hand expression of (16.10.5); it estimates contribution of zone $\{(x,y) : |x-y| \ge \epsilon\big(\alpha(x)+\alpha(y)\big)\}$. □

16.10.2 Case $d = 2$

Tauberian Asymptotics

(i) Consider first case $\mu \le h^{-1}$. Now according to (16.2.58) we need just to plug in

$$R(\alpha,\gamma) = \mu^{-1}h^{-1} + \alpha^{-1}R^{\mathsf{T}}(\alpha,\gamma) \tag{16.10.7}$$

as $h^{-2}\mathcal{N}_x = e^{\mathsf{T}}(x,x,0)$. Obviously the effect of $C\mu^{-1}h^{-1}$ term to both (16.10.3) and (16.10.5) will be term $C\mu^{-2}h^{-2}$.

Plugging into (16.10.3) or (16.10.5) $R(\alpha,\gamma) = \alpha^{-1}R^{\mathsf{T}}(\alpha,\gamma)$ with $R^{\mathsf{T}}(\alpha,\gamma)$ defined by (16.2.57) we obviously eliminate from integration the last two zones (defined in (16.2.57)) as a power of γ is negative [44)] and the first one as a power of γ is positive. Thus γ snaps to its minimal value in the last two zones and to its maximal value in the first one, and only the second zone matters.

Further, in virtue of (16.2.57) $R^{\mathsf{T}}(\alpha,\gamma) = C\mu^{\frac12}\gamma^{-\frac12}$ in the remaining second zone $\{h \le \gamma \le \min(\mu h/\alpha, \mu^{-1})\}$.

Then the power of γ is positive, 0 or negative as $0 < \kappa < 1$, $\kappa = 1$ or $1 < \kappa < 2$ respectively. Thus γ snaps to $\min(\mu h/\alpha, \mu^{-1})$ as $0 < \kappa < 1$ and γ snaps to h as $1 < \kappa < 2$.

[44)] Here and below talking about powers of α or β or γ we mean in the integral with respect to $\gamma^{-1}d\gamma$ or $\alpha^{-1}d\alpha$ or $\beta^{-1}d\beta$.

Then (16.10.3) becomes

$$|\mathsf{K}^{\mathsf{T}}| \le C\mu^{-2}h^{-2} + C\begin{cases}\mu h^{1-\kappa} & 1<\kappa<2,\\ \mu\min(|\log\mu h|, |\log\mu|) & \kappa=1,\\ \mu\min\big((\mu h)^{1-\kappa}, \mu^{-1+\kappa}\big) & 0<\kappa<1.\end{cases} \tag{16.10.8}$$

Consider the first term in the right-hand expression of estimate (16.10.5). If $1<\kappa<2$ as we mentioned γ snaps to h thus resulting in the integrand $C\mu h^{1-\kappa}$ and in $C\mu h^{1-\kappa}|\log h|$ after integration with respect to $\alpha^{-1}d\alpha$.

Let $0<\kappa\le 1$. Then γ snaps to $\gamma(\alpha) := \min(\mu h/\alpha, \mu^{-1})$, thus resulting in the integrand $C\mu\min\big((\mu h/\alpha)^{1-\kappa}, \mu^{\kappa-1}\big)$ as $0<\kappa<1$ and in $C\mu\log\min\big(\mu/\alpha, (\mu h)^{-1}\big)$ as $\kappa=1$.

Then after integration with respect to $\alpha^{-1}d\alpha$ we get $O(\mu^{\kappa}|\log h|)$ as $0<\kappa<1$ or $O(\mu^{\kappa}|\log h|\cdot|\log(\mu h)|)$ as $\kappa=1$ and this is less than the estimate of the contribution of zone (16.10.9) below unless $\mu\ge h^{-1}|\log h|^{-1}$.

However in (16.10.5) we need also calculate the contribution of the zone

$$\{(x,y):\ \alpha(x)\le C_0\mu^{-1},\ \alpha(y)\le C_0\mu^{-1}\} \tag{16.10.9}$$

which is not covered by our arguments and also the second term.

The former obviously does not exceed $C\mu^2h^{-2}\times\mu^{-4+\kappa} = C\mu^{-2+\kappa}h^{-2}$ where the second factor is $\int |x-y|^{-\kappa}dxdy$ over zone (16.10.9) and this also covers zone $\{\beta\le C_0\mu^{-1}\}$ in the second term of (16.10.5). Obviously $C\mu^{-2+\kappa}h^{-2}$ is larger than anything we got before.

Consider the second term in the right-hand expression of (16.10.5). Here we have $R^{\mathsf{T}}(\alpha,\alpha)=\alpha^{-1}$ as $(\mu h)^{\frac12}\ge\alpha\ge\mu^{-1}$ and $\mu^{-1}\alpha^{-1}h^{-1}\min\big((\mu^2h/\alpha)^{\frac12},1\big)\times(\mu h/\alpha)'$ as $(\mu h)^{\frac12}\le\alpha\le 1$ and therefore β is in the negative power and snaps to α; so we arrive to

$$\int \big(R^{\mathsf{T}}(\alpha,\alpha)\big)^2\alpha^{1-\kappa}\,d\alpha.$$

In this integral α is in the negative power and snaps to μ^{-1} resulting in $\big(R^{\mathsf{T}}(\mu^{-1},\mu^{-1})\big)^2\mu^{\kappa-2} = O(\mu^{\kappa})$ which is less than we have already.

Finally, we need to consider contribution of zone

$$\{(x,y):\ \alpha(x)\le C_0\mu^{-1}, \alpha(y)\ge C_0\mu^{-1}\}. \tag{16.10.10}$$

So, we get $C\mu^{-2} \times \mu h^{-1} \int R^{\mathsf{T}}(\beta,\beta)\beta^{1-\kappa}\,d\beta$; in this integral β is in the negative power for sure as $1<\kappa<2$ and it snaps to $\beta=\mu^{-1}$ resulting in $C\mu^{-1}h^{-1}R^{\mathsf{T}}(\mu^{-1},\mu^{-1})\mu^{\kappa-2}$ which is less than we got already.

As $0<\kappa<1$, β is also in the negative power except zone $\{\mu^{-1}\le\beta\le(\mu h)^{\frac12}\}$ which is possible as $\mu\ge h^{-\frac13}$; then as β snaps to $(\mu h)^{\frac12}$ resulting in $C(\mu h)^{-\frac12-\frac12\kappa}$ and one can see easily that it is less than what we got already. The same is true for $\kappa=1$ as well.

So we arrive to estimate

$$|\mathsf{K}^{\mathsf{T}}|\le C\mu^{-2+\kappa}h^{-2}+C|\log h|\mu\bigl(\mu^{\kappa-1}+h^{1-\kappa}\bigr). \tag{16.10.11}$$

(ii) Let $\mu\ge h^{-1}$. Now we need just to plug $R(\alpha,\gamma)=\alpha^{-1}R^{\mathsf{T}}(\alpha,\gamma)\ge 1$ with $R^{\mathsf{T}}(\alpha,\gamma)$ delivered by (16.2.76). Then in (16.10.3) we need to snap γ to $\mu^{-\frac12}h^{\frac12}$ and set $R(\gamma)=\mu^{\frac12}h^{-\frac12}$. So (16.10.3) becomes

$$|\mathsf{K}^{\mathsf{T}}|\le C\mu^{\frac12\kappa}h^{-\frac12\kappa}. \tag{16.10.12}$$

Meanwhile, under assumption (16.1.8)$'$ in the first term of the right-hand expression of (16.10.5) α is in power 0 and logarithmic factor appears; we get $C\mu^{\frac12\kappa}h^{-\frac12\kappa}|\log\mu|$.

Further, in (16.10.5) we need to estimate also contribution of zones

$$\{(x,y):\ \alpha(x)\le C_0\mu^{-\frac12}h^{\frac12},\alpha(y)\le C_0\mu^{-\frac12}h^{\frac12}\}, \tag{16.10.13}$$

$$\{(x,y):\ \alpha(x)\le C_0\mu^{-\frac12}h^{\frac12},\alpha(y)\ge C_0\mu^{-\frac12}h^{\frac12}\} \tag{16.10.14}$$

and of the second term in the right-hand expression and one can see easily that these contributions do not exceed $C\mu^{\frac12\kappa}h^{-\frac12\kappa}|\log\mu|$; and so we get

$$|\mathsf{K}^{\mathsf{T}}|\le C\mu^{\frac12\kappa}h^{-\frac12\kappa}|\log\mu|. \tag{16.10.15}$$

Thus we proved

Proposition 16.10.2. *(i) For $\mu\le h^{-1}$ under condition* (16.1.7) *estimate* (16.10.8) *holds and under condition* (16.1.8) *estimate* (16.10.11) *holds.*

(ii) Let $\mu\ge h^{-1}$. Then under condition (16.1.7)$'$ *estimate* (16.10.12) *holds and under condition* (16.1.8)$'$ *estimate* (16.10.15) *holds.*

Problem 16.10.3. Prove that estimates (16.10.8) and (16.10.12) hold under conditions (16.1.8)$^+$ and (16.1.8)$^{+\prime}$ respectively.

Weyl Approximation

Now we should add to what we got for K^{T} corresponding expressions with $R(\alpha,\gamma)=R^{\mathsf{W}}(\alpha,\gamma)$ calculated according to (16.2.80)–(16.2.81) and therefore γ must be snapped to $\mathsf{min}(\alpha,\mu h\alpha^{-1})$. Then (16.10.3) becomes

$$|\mathsf{K}^{\mathsf{W}}| \le C\mu^{-2}h^{-2} + C(R^{\mathsf{W}})^2(\mu h)^{2-\kappa} = C\mu^{-2}h^{-2} + C\begin{cases}\mu^4 h^{-1}(\mu h)^{2-\kappa} & \text{if } \mu \le h^{-\frac12},\\ \mu^2 h^{-2}(\mu h)^{2-\kappa} & \text{if } h^{-\frac12}\le \mu \le h^{-1}\end{cases} \tag{16.10.16}$$

which obviously is larger than the right-hand expressions of (16.10.8) and so we can neglect the Tauberian error.

Consider the first term in the right-hand expression of (16.10.5). Note that for $\alpha \le (\mu h)^{\frac12}$ γ snaps to α and then α is in the positive power. Also note that as $\alpha \le \mu^2 h$ (16.2.80) defines $R^{\mathsf{W}}=\mu h^{-1}$ and α is in the positive power as well. Therefore as $h^{-\frac12}\le \mu \le h^{-1}$ we snap α to 1 resulting in $C\mu^2h^{-2}(\mu h)^{2-\kappa}$ prescribed by (16.10.16) and $\mu \le h^{-\frac12}$ we need to consider interval $\mathsf{max}(\mu^{-1},\mu^2h)\le \alpha \le 1$; then automatically $\alpha \ge (\mu h)^{\frac12}$ and we arrive to

$$C\int \mu^4 h^{-1}(\mu h/\alpha)^{2-\kappa} d\alpha. \tag{16.10.17}$$

Here as $1<\kappa<2$, α is in the positive power and snaps to 1 resulting in $C\mu^4h^{-1}(\mu h)^{2-\kappa}$ prescribed by (16.10.16).

On the other hand, as $0<\kappa<1$, α is in the negative degree and snaps to $\mathsf{max}(\mu^{-1},\mu^2h)$ resulting in $C\mu^4h^{-1}(\mu h)^{2-\kappa}\mu^{1-\kappa}$ for $\mu \le h^{-\frac13}$ and $C\mu^4h^{-1}(\mu h)^{2-\kappa}(\mu^2h)^{\kappa-1}$ for $h^{-\frac13}\le\mu\le h^{-\frac12}$ and while the former expression is less than $C\mu^{-2+\kappa}h^{-2}$ the latter is not (at their respective intervals).

As $\kappa=1$ we get $C\mu^5(1+|\log \mu^2h|)$.

Consider the second term in the right-hand expression of (16.10.5). Then both $\alpha\le\beta$ effectively are bounded from above by $(\mu h)^{\frac12}$ which leaves interval empty for $\mu\le h^{-\frac13}$. On the other hand then $\beta\le\mu^2h$ for $h^{-\frac13}\le\mu\le h^{-1}$ and we arrive to

$$C\mu^2h^{-2}\iint_{\{\alpha\le\beta\le(\mu h)^{\frac12}\}} \alpha\beta^{1-\kappa}\,d\alpha d\beta \asymp C\mu^2h^{-2}(\mu h)^{2-\frac12\kappa}$$

which is less than the right-hand expression of (16.10.16) unless $h^{-\frac{1}{3}} \le \mu \le h^{-\frac{1}{2}}$ and $0 < \kappa < 1$ in which case it is less than $C\mu^4 h^{-1}(\mu h)^{2-\kappa}(\mu^2 h)^{\kappa-1}$.

Therefore we arrive to

$$|\mathsf{K}^{\mathsf{W}}| \le C\mu^{-2+\kappa}h^{-2} + C\begin{cases} \mu^4 h^{-1}(\mu h)^{2-\kappa} & \text{as } \mu \le h^{-\frac{1}{2}}, \\ \mu^2 h^{-2}(\mu h)^{2-\kappa} & \text{as } h^{-\frac{1}{2}} \le \mu \le h^{-1} \end{cases} + \tag{16.10.18}$$

$$C\begin{cases} \mu^4 h^{-1}(\mu h)^{2-\kappa}(\mu^2 h)^{\kappa-1} & 0 < \kappa < 1, \quad \mu \le h^{-\frac{1}{2}}, \\ \mu^5(1+|\log \mu^2 h|) & \kappa = 1, \quad \mu \le h^{-\frac{1}{2}}, \\ 0 & \text{otherwise.} \end{cases}$$

Thus we proved

Proposition 16.10.4. *For $\mu \le h^{-1}$ under condition* (16.1.7) *estimate* (16.10.16) *holds and under condition* (16.1.8) *estimate* (16.10.18) *holds.*

Magnetic Weyl Approximation

Finally, let us deal with magnetic Weyl approximation. Now we should add to what we got for K^{T} corresponding expressions with $R(\alpha,\gamma) = R^{\mathsf{MW}}(\alpha,\gamma)$ calculated according to (16.2.83) for $\mu \le h^{-1}$ and (16.2.85) for $\mu \ge h^{-1}$.

(i) Consider case $\mu \le h^{-1}$ first. Then according to (16.2.83) γ snaps to $\min(\mu^{-1}, \mu h\alpha^{-1})$ and $R(\alpha,\gamma) = \mu h^{-1}$ and (16.10.3) becomes

$$|\mathsf{K}^{\mathsf{MW}}| \le C\mu^{-2}h^{-2} + C\mu^2 h^{-2}\begin{cases} (\mu h)^{2-\kappa} & \mu \le h^{-\frac{1}{2}}, \\ \mu^{\kappa-2} & h^{-\frac{1}{2}} \le \mu \le h^{-1}. \end{cases} \tag{16.10.19}$$

Meanwhile in the first term of (16.10.5) α snaps to its largest possible value i.e 1. Further, in the second term α snaps to its largest value which is β and then β snaps to its largest value $(\mu h)^{\frac{1}{2}}$ as $h^{-\frac{1}{3}} \le \mu \le h^{-1}$ and it becomes $C\mu^2 h^{-2}(\mu h)^{2-\frac{1}{2}\kappa}$.

Furthermore, contributions of zones (16.10.9) and (16.10.10) are estimated as before; we arrive in the end to

$$|\mathsf{K}^{\mathsf{MW}}| \le C\mu^{-2+\kappa}h^{-2} + C\mu^2h^{-2}\begin{cases}(\mu h)^{2-\kappa} & \mu \le h^{-\frac12},\\ \mu^{\kappa-2} & h^{-\frac12} \le \mu \le h^{-1}\end{cases} + C\begin{cases}\mu^2h^{-2}(\mu h)^{2-\frac12\kappa} & h^{-\frac13} \le \mu \le h^{-1},\\ 0 & \text{otherwise.}\end{cases} \tag{16.10.20}$$

(ii) If $\mu h \ge 1$ γ snaps to $\mu^{-\frac12}h^{\frac12}$ and (16.10.3) becomes

$$|\mathsf{K}^{\mathsf{MW}}| \le C\mu^{1+\frac12\kappa}h^{-1+\frac12\kappa} \tag{16.10.21}$$

Consider the first term in expression (16.4.5); integrand contains α in the positive power and therefore α snaps to 1. Meanwhile in the second term both $\alpha \ge C_0\mu^{-\frac12}h^{\frac12}$ and $\beta \ge C_0\mu^{-\frac12}h^{\frac12}$ are in the negative powers and snap to $\mu^{-\frac12}h^{\frac12}$. Estimating as before contributions of zones (16.10.13) and (16.10.14) we arrive to estimate (16.10.21) again.

All these above estimates are worse than for K^{T}; thus we arrive to

Proposition 16.10.5. *(i) For $\mu \le h^{-1}$ under condition* (16.1.7) *estimate* (16.10.19) *holds and under condition* (16.1.8) *estimate* (16.10.20) *holds.*

(ii) For $\mu \ge h^{-1}$ under either condition (16.1.7)$'$, (16.1.8)$'$ *estimate* (16.10.21) *holds.*

16.10.3 Case $d = 3$

We consider case $d = 3$. Note that

Remark 16.10.6. (i) We use notations in (16.10.5), (16.10.6): λ instead of α and λ' instead of β (in the second term only).

(ii) We cannot expect estimate better than $O(h^{-4})$ for $\mu h \le 1$. Meanwhile under condition (16.1.8) contribution of zone

$$\{(x,y):\ \lambda(x) \le \bar\lambda,\ \lambda(y) \le \bar\lambda\} \tag{16.10.22}$$

with $\bar\lambda = C_0\mu^{-1}$ to any estimate does not exceed $C\mu^2h^{-4} \times \mu^{-6+\kappa} = O(h^{-4})$. We can even take $\bar\lambda = \mu^{-2/(6-\kappa)}$ here.

Tauberian Estimates

We will use results of Subsection 16.6.4 combined with arguments of Subsubsection 16.7.8 always setting $\gamma_3 = \gamma$.

Case $\mu h \le 1$. If $\gamma_3 = \gamma$ we have $\nu(\boldsymbol{\gamma}) \asymp \lambda\gamma$, $\ell \asymp \lambda$ and (16.6.25) becomes

$$R^{\mathsf{T}}(\gamma) = \begin{cases} \mu h^{-\frac{3}{2}}\lambda^{\frac{1}{2}} & \text{as } \lambda^2\gamma \le h, \\ \mu h^{-1}\lambda^{-\frac{1}{2}}\gamma^{-\frac{1}{2}} & \text{as } \lambda^2\gamma \ge h, \lambda\gamma \le \mu h, \\ \mu^{\frac{1}{2}} h^{-\frac{3}{2}}(\mu h/\lambda\gamma)^{l} & \text{as } \lambda\gamma \ge \mu h. \end{cases} \tag{16.10.23}$$

To estimate $|\mathsf{K}^{\mathsf{T}}|$ we need to calculate

$$K(\lambda) \coloneqq \int \bigl(R^{\mathsf{T}}(\gamma)\bigr)^2 \gamma^{2-\kappa}\, d\gamma \tag{16.10.24}$$

and as $\lambda \ge \mu^{-1}$ it is equal to $C\mu^2 h^{-2}\lambda^{-1}\gamma^{2-\kappa}$ calculated for $\gamma = \min(\mu h/\lambda, \lambda)$ as $0 < \kappa < 2$ and for $\gamma = h/\lambda^2$ as $2 < \kappa < 3$ resulting in

$$K(\lambda) \le Ch^{-4}\lambda^{3-\kappa} + C \begin{cases} C\mu^2 h^{-2}\lambda^{-1}(h/\lambda^2)^{2-\kappa} & 2 < \kappa < 3, \\ C\mu^2 h^{-2}\lambda^{-1}(1 + |\log \lambda\mu|) & \kappa = 2, \\ \mu^2 h^{-2}\lambda^{-1}\min(\mu h/\lambda, \lambda)^{2-\kappa} & 0 < \kappa < 2. \end{cases} \tag{16.10.25}$$

In particular, we conclude that

(16.10.26) As $\mu h \le 1$, $|\nabla V/F| \asymp 1$

$$|\mathsf{K}^{\mathsf{T}}| \le Ch^{-4} + C \begin{cases} \mu^2 h^{-\kappa} & 2 < \kappa < 3, \\ \mu^2 h^{-2}|\log \mu| & \kappa = 2, \\ 0 & 0 < \kappa < 2. \end{cases} \tag{16.10.27}$$

On the other hand, under assumption (16.1.8) we need to calculate the first term in the right-hand expression of (16.10.5) which is equal to $\int K(\lambda)\lambda^2\, d\lambda$ and one can see easily that it is (16.10.25) calculated as $\lambda = 1$.

Finally, one needs to calculate the second term in the right-hand expression of (16.10.5) and we leave to the reader to prove that it allows the same estimate. Thus we arrive to Statement (i) of Proposition 16.10.7 below.

On the other hand, assume that assumption (16.7.57) is fulfilled i.e. $|\nabla_{\perp \boldsymbol{F}} V/F| \asymp 1$. Then (16.6.25) becomes

$$R^{\mathsf{T}}(\gamma) = \begin{cases} \mu^{\frac{3}{2}} h^{-1} \left(1 + |\log(\mu h)|\right) & \text{as } \gamma \le h, \\ \mu^{\frac{3}{2}} h^{-1} \big(1 + (\log(1/\mu\gamma))_+\big) & \text{as } h \le \gamma \le \min(\mu h, \mu^{-1}), \\ \mu h^{-1} \gamma^{-\frac{1}{2}} & \text{as } \mu^{-1} \le \gamma \le \mu h, \\ \mu^{\frac{1}{2}} h^{-\frac{3}{2}} (\mu h/\gamma))' & \text{as } \gamma \ge \mu h. \end{cases} \tag{16.10.28}$$

and in this case instead of $\gamma = h$ the lower pick is $\gamma = \mu^{-1}$ in $C\mu^2 h^{-2} \gamma^{2-\kappa}$ which becomes $Ch^{-2}\mu^{\kappa}$ and we arrive to Statement (ii) of Proposition 16.10.7:

Proposition 16.10.7. *Let $\mu h \le 1$. Then*

(i) Under either non-degeneracy condition either (16.1.7) *or* (16.1.8) *estimate* (16.10.27) *holds.*

In particular, $|\mathsf{K}^{\mathsf{T}}| = O(h^{-4})$ as <u>either</u> $0 < \kappa < 2$ <u>or</u> $\kappa = 2$ and $\mu \le (h|\log h|)^{-1}$ <u>or</u> $2 < \kappa < 3$ and $\mu \le h^{-2+\frac{1}{2}\kappa}$ (and this is true for sure as $\mu \le h^{-\frac{1}{2}}$).

(ii) Under non-degeneracy condition (16.7.57)*, $2 < \kappa < 3$*

$$|\mathsf{K}^{\mathsf{T}}| \le Ch^{-4} + Ch^{-2}\mu^{\kappa}. \tag{16.10.29}$$

In particular, $|\mathsf{K}^{\mathsf{T}}| = O(h^{-4})$ as $\mu \le h^{-2/\kappa}$ (and this is true for sure as $\mu \le h^{-\frac{2}{3}}$).

Case $\mu h \ge 1$.

Proposition 16.10.8. *Let $\mu h \ge 1$. Then under either non-degeneracy condition* (16.1.7)$'$ *or* (16.1.8)$'$ *estimate*

$$|\mathsf{K}^{\mathsf{T}}| \le C\mu^2 h^{-2} + C \begin{cases} \mu^2 h^{-\kappa} & 2 < \kappa < 3, \\ \mu^2 h^{-2} |\log \mu| & \kappa = 2, \\ 0 & 0 < \kappa < 2. \end{cases} \tag{16.10.30}$$

holds.

Proof. An easy proof based on Proposition 16.6.9 is left to the reader. □

Weyl Asymptotics

Proposition 16.10.9. *Let $\mu h \le 1$. Then*

(i) Under non-degeneracy condition (16.1.7)

$$|\mathsf{K}^{\mathsf{W}}| \le Ch^{-4} + C\mu^3 h^{-3}(\mu h)^{3-\kappa}; \tag{16.10.31}$$

(ii) Under non-degeneracy condition (16.1.8)

$$|\mathsf{K}^{\mathsf{W}}| \le Ch^{-4} + C\mu^3 h^{-3}(\mu h)^{\frac{1}{2}(3-\kappa)}; \tag{16.10.32}$$

(iii) As $\mu \le h^{-\frac{1}{2}}$ under non-degeneracy condition (16.7.57)

$$|\mathsf{K}^{\mathsf{W}}| \le Ch^{-4} + C\mu^5 h^{-2}(\mu h)^{3-\kappa}. \tag{16.10.33}$$

Proof. An easy proof based on Proposition 16.6.6 is left to the reader. □

Magnetic Weyl Asymptotics

We will apply Proposition 16.6.14. In the isotropic settings $R^{\mathsf{MW}}(\boldsymbol{\gamma})$ given by (16.6.47) becomes

$$R^{\mathsf{MW}}(\gamma) \coloneqq C\mu \begin{cases} \lambda^{-\frac{1}{2}}\gamma^{-\frac{5}{2}}\bigl(\mu h/\lambda\gamma\bigr)^{l} & \text{as } \gamma \ge \mu h/\lambda, \\ \lambda^{-\frac{1}{2}}\gamma^{-\frac{5}{2}} & \text{as } \lambda^{-\frac{1}{3}}h^{\frac{2}{3}} \le \gamma \le \mu h/\lambda, \\ \lambda^{\frac{1}{3}}h^{-\frac{5}{3}} & \text{as } \gamma \le \lambda^{-\frac{1}{3}}h^{\frac{2}{3}}, \end{cases} \tag{16.10.34}$$

which immediately implies Statements (i) and (ii) of Proposition 16.10.10 below.

Meanwhile as $\alpha \asymp 1$, $\mu h \le 1$ (16.6.47) becomes

$$R_1^{\mathsf{MW}}(\gamma) \coloneqq C\mu \begin{cases} \gamma^{-\frac{5}{2}}(\mu h/\gamma)^{l} & \text{as } \gamma \ge \mu h,\ 1 \le \mu^2 h, \\ \gamma^{-\frac{5}{2}} & \text{as } \gamma \le \mu h,\ \mu\gamma \ge 1, \\ \gamma^{-\frac{5}{2}}(\mu^2 h)^{\frac{1}{2}}\bigl(\mu h/\gamma\bigr)^{l} & \text{as } \gamma \ge \mu h,\ 1 \ge \mu^2 h, \\ \gamma^{-\frac{5}{2}}(\mu\gamma)^{\frac{1}{2}} & \text{as } \gamma \le \mu h,\ \mu\gamma \le 1 \end{cases} \tag{16.10.35}$$

which immediately imply Statement (iii) of Proposition 16.10.10 below.

Proposition 16.10.10. *(i) Let $\mu h \le 1$. Then under either non-degeneracy condition* (16.1.7) *or* (16.1.8)

$$|\mathsf{K}^{\mathsf{MW}}| \le Ch^{-4} + C\mu^2 h^{-\frac{2}{3}(2+\kappa)}; \tag{16.10.36}$$

(ii) Let $\mu h \ge 1$. Then under either non-degeneracy condition$(16.1.7)'$ *or* $(16.1.8)'$

$$|\mathsf{K}^{\mathsf{MW}}| \le C\mu^2 h^{-2} + C\mu^2 h^{-\frac{2}{3}(2+\kappa)}; \tag{16.10.37}$$

(iii) Let $\mu \le h^{-\frac{2}{3}}$. Then under non-degeneracy condition (16.7.57)

$$|\mathsf{K}^{\mathsf{MW}}| \le Ch^{-4} + C\mu^3 h^{-\frac{2}{3}(1+\kappa)}. \tag{16.10.38}$$

16.10.4 Problems

Problem 16.10.11. For $d = 2, 3$ estimate $|\mathsf{J} - \mathsf{J}^{\mathsf{T}}|$, $|\mathsf{J} - \mathscr{J}^{\mathsf{W}}|$ and $|\mathsf{J} - \mathscr{J}^{\mathsf{MW}}|$.

Problem 16.10.12. For $d = 2, 3$ consider toy-model approximation.

Problem 16.10.13. For $d = 2, 3$ compare estimates for $|\mathsf{K}^{\mathsf{W}}|$ and $|\mathsf{J} - \mathscr{J}^{\mathsf{W}}|$ to those for $|\mathsf{K}^{\mathsf{MW}}|$ and $|\mathsf{J} - \mathscr{J}^{\mathsf{MW}}|$.

Problem 16.10.14. For $d = 2, 3$ as $\mu \le h^{-1}$ get rid of condition (16.1.5) replacing it by (16.1.7), or even $(16.1.8)^{+}$, or even (16.1.8).

Problem 16.10.15. Get rid of condition (16.1.6) assuming instead that $|F| + |\nabla F| \ge \epsilon$ for $d = 2$ (which will affect estimates for sure) and $|\boldsymbol{F}| + |\nabla \otimes \boldsymbol{F}| \ge \epsilon$ for $d = 3$ (which most likely would not affect estimates).

Problem 16.10.16. For $d = 3$ investigate K^{T}, K^{W}, K^{MW} under non-degeneracy conditions (16.1.7) and $|\nabla_{\perp \boldsymbol{F}} V/F| \le \epsilon \implies |\det \mathsf{Hess}_{\perp \boldsymbol{F}} V/F| \asymp 1$.

Chapter 17

Dirac Operator with the Strong Magnetic Field

In this chapter we analyze two- and three-dimensional (generalized) Dirac operators with the strong magnetic field. In the process we look at (generalized) Schrödinger-Pauli operators as well. The results and structure of this chapter are similar to those of Chapter 13: Sections 17.1–17.4 and Sections 17.6,17.7 correspond to Sections 13.2–13.5 and Sections 13.6 and 13.8 respectively.

However, we introduce a new Section 17.6 specially devoted to the spectral gaps and we collapse Dirac equivalent of Section 13.7 into just Subsection 17.7.1 containing also problems.

17.1 Preliminary Analysis

17.1.1 Toy-Model Operator

In this chapter we consider the *generalized Dirac operator*

$$A = \frac{1}{2}\sum_{j,l} \sigma_l\big(\omega^{jl}P_j + P_j\omega^{jl}\big) + \sigma_0 m + I\cdot V, \quad P_j = hD_j - \mu V_j \tag{17.1.1}$$

where ω^{jl}, V_j, V are real-valued functions, $m \ge 0$ is a constant parameter and the following conditions are fulfilled in $B(0,1)\subset X$:

$$(17.1.2)_{1-3} \quad |D^\alpha \omega^{jk}| \le c, \quad |D^\alpha V_j| \le c, \forall \alpha : |\alpha| \le K$$

$$|D^\alpha V| \le c \min\bigl(1, \frac{1}{m}\bigr) \quad \forall \alpha : 1 \le |\alpha| \le K,$$

$$(17.1.2)_4^- \qquad (\tau_1 - m - V)_- \le c \min\bigl(1, \frac{1}{m}\bigr),$$

$$(17.1.2)_4^+ \qquad (\tau_2 + m - V)_- \le c \min\bigl(1, \frac{1}{m}\bigr),$$

$$(17.1.3) \qquad \sum_{j,k} g^{jk}\xi_j\xi_k \ge \epsilon_0 |\xi|^2 \qquad \forall \xi \in \mathbb{R}^d, \qquad \det(\omega^{jk}) > 0$$

where

$$(17.1.4) \qquad g^{jk} = \sum_{l,r} \omega^{jl}\omega^{kr}\delta_{lr}$$

is an associated metric (we have rewritten conditions $(5.3.77)^*_*$ and (5.3.7)).

Furthermore, we assume that the matrices $\sigma_0, \dots, \sigma_d$ are $\mathsf{D} \times \mathsf{D}$ matrices satisfying conditions (5.A.21) and (5.A.22) (recall that we call them *Pauli matrices*).

Remark 17.1.1. (i) We also consider the *generalized massless Dirac operator*

$$(17.1.5) \qquad A = \frac{1}{2}\sum_{j,l} \sigma_l\bigl(\omega^{jl}P_j + P_j\omega^{jl}\bigr) + I \cdot V, \quad P_j = hD_j - \mu V_j$$

(here we do not need matrix σ_0 to exist) and the *generalized Schrödinger-Pauli operator*

$$(17.1.6) \qquad A = \Bigl(\frac{1}{2}\sum_{j,l} \sigma_l\bigl(\omega^{jl}P_j + P_j\omega^{jl}\bigr)\Bigr)^2 + V(x).$$

(ii) If $\omega^{jl} = \delta_{jl}$ we have standard Dirac operator

$$(17.1.7) \qquad A = \boldsymbol{\sigma} \cdot (-ih\nabla - \boldsymbol{V}(x)) + \sigma_0 m + V(x),$$

massless Dirac operator

$$(17.1.8) \qquad A = \boldsymbol{\sigma} \cdot (-ih\nabla - \boldsymbol{V}(x)) + V$$

and Schrödinger-Pauli operator

$$(17.1.9) \qquad A = \bigl(\boldsymbol{\sigma} \cdot (-ih\nabla - \boldsymbol{V}(x))\bigr)^2 + V(x).$$

Let us observe that

(17.1.10) $e(x,x,\tau_1,\tau_2)$ does not change after *gauge transformation* $V_j \mapsto V_j + \partial_j\phi$ as equivalently we replace A by the operator $e^{-i\mu h^{-1}\phi}Ae^{i\mu h^{-1}\phi}$.

Therefore without any loss of the generality one can replace condition $(17.1.2)_2$ by condition $(17.1.2)'_2 = (13.2.2)'_2$ where the tensor intensity of the magnetic field (F_{jk}) is defined by (13.2.7).

Let us first treat the case when $X = \mathbb{R}^d$ and ω^{jl}, V and F_{jk} are constant.

Theorem 17.1.2. *Let $X = \mathbb{R}^d$, let ω^{jk}, V, F_{jk} be constant and let condition* (17.1.3) *be fulfilled. Then for $\tau_1 < \tau_2$*

$$\operatorname{tr} e(x,x,\tau_1,\tau_2) = h^{-d}\mathcal{N}^{\mathsf{MW}}(\tau_1,\tau_2,\mu h), \tag{17.1.11}$$

where

(i) If $r := \frac{1}{2}\operatorname{rank}(F_{jk}) < d/2$ then

$$\begin{aligned}(17.1.12)_1\quad \mathcal{N}^{\mathsf{MW}}(\tau_1,\tau_2,\mu h) := \operatorname{sgn}(\tau - V)\times \\ \sum_{\alpha\in(\mathbb{Z}^+)^r}\Big((\tau-V)^2 - \sum_{1\le j\le r} 2\alpha_j f_j \mu h - m^2\Big)_+^{\frac{1}{2}(d-r)}\times \\ \frac{\mathsf{D}}{2}(2\pi)^{r-d}\varpi_{d-2r}2^{-\#\{j,\alpha_j=0\}}f_1\cdots f_r(\mu h)^r\sqrt{g}\Big|_{\tau=\tau_1}^{\tau=\tau_2},\end{aligned}$$

where $f_j > 0$, $\pm if_j$ with $j = 1,\dots,r$ are all the eigenvalues of the tensor $(F_k^n) = (\sum_l F_{kl}g^{ln})_{k,n}$ which are disjoint from 0 and multiplicities are taken into account.

(ii) If $r = d/2$ then for $\tau_1 < \tau_2$

$$(17.1.12)_2\quad \mathcal{N}^{\mathsf{MW}}(\tau_1,\tau_2,\mu h) := \sum_{(\varkappa,\alpha)\in\mathfrak{Z}:\ \tau_1\le H_{\varkappa\alpha}<\tau_2} c_{\varkappa\alpha}\frac{\mathsf{D}}{2}(2\pi)^{-r}f_1\dots f_r(\mu h)^r\sqrt{g},$$

where

$$H_{\varkappa\alpha} := V + \varkappa\Big(m^2 + \sum_k 2\alpha_k f_k\mu h\Big)^{\frac{1}{2}}, \tag{17.1.13}$$

$c_{\varkappa\alpha} = 2^{-\#\{j,\alpha_j=0\}}$ *for* $\alpha \neq 0$ *and if*

$$\sigma_0\sigma_1...\sigma_d = \varsigma i^{d/2} \tag{17.1.14}$$

with $\varsigma = \pm 1$ *then*

$$\mathfrak{Z} := \{-1,1\} \times (\mathbb{Z}^+)^r \setminus (\bar{\varkappa}, 0) \tag{17.1.15}$$

and $c_{-\bar{\varkappa},0} = 2^{1-r}$ *where* $\bar{\varkappa} = \pm\varsigma$ *if by a coordinate transformation with a positive (negative respectively) determinant one can reduce the matrix* (F_k^n) *to the canonical form*

$$F_k^n = \begin{cases} +f_j & \text{for } k = 2j-1, n = 2j \quad \text{with } j = 1,\dots,r, \\ -f_j & \text{for } k = 2j, n = 2j-1 \quad \text{with } j = 1,\dots,r, \\ 0 & \text{otherwise.} \end{cases} \tag{17.1.16}$$

Corollary 17.1.3. *In the framework of Theorem 17.1.2*

(i) For $r < d/2$ *the spectrum of* A *is absolutely continuous and*

$$\operatorname{Spec}(A) = (-\infty, V-m] \cup [V+m, \infty); \tag{17.1.17}_1$$

(ii) For $r = d/2$ *the spectrum of* A *is pure point of infinite multiplicity and*

$$\operatorname{Spec}(A) = \overline{\{H_{\varkappa\alpha}, (\varkappa,\alpha) \in \mathfrak{Z}\}} \tag{17.1.17}_2$$

where $\mathfrak{Z}$ *has been introduced under condition* (17.1.14) *and* $\mathfrak{Z} = \{-1,1\} \times (\mathbb{Z}^+)^r$ *if* (17.1.14) *holds with neither* $\varsigma = 1$ *nor* $\varsigma = -1$.

Remark 17.1.4. Appendix 5.A.2 yields that without any loss of the generality one can assume condition (17.1.14) provided d is even.

Proof of Theorem 17.1.2. Proposition 5.A.5 yields that without any loss of the generality one can assume that $g^{kn} = \delta_{kn}$, that F_{kn} has structure (17.1.16), and that $\mu = h = 1$, and therefore without any loss of the generality one can assume that $P_{2j} = D_{2j} + f_j x_{2j-1}$ for $j = 1,\dots,r$ and $P_k = D_k$ for $k \neq 2, 4, \dots, 2r$. Then the arguments of the proof of Theorem 13.2.1 yield that for $\tau_1 < \tau_2$

$$\operatorname{tr} e(x,x,\tau_1,\tau_2) = (2\pi)^{r-d} f_1 \dots f_r \int \boldsymbol{n}(\tau_1,\tau_2,\xi'')\, d\xi'' \tag{17.1.18}$$

where $\xi''=(\xi_{2r+1},\dots,\xi_d)\in\mathbb{R}^{d-2r}$, $\boldsymbol{n}(\tau_1,\tau_2,\xi'')$ is the number of eigenvalues of the operator

$$\mathcal{L}(\xi'')=\sum_{1\le k\le r}\sqrt{f_j}\big(\sigma_{2k-1}D_k+\sigma_{2k}x_k\big)+\sum_{2r+1\le k\le d}\sigma_k\xi_k+\sigma_0 m+V\cdot I \tag{17.1.19}$$

in $\mathscr{L}^2(\mathbb{R}^r,\mathbb{C}^{\mathsf{D}})$, residing in $[\tau_1,\tau_2)$. Let us rewrite the parenthesis in (17.1.19) in the form

$$\frac{1}{2}(\sigma_{2k}-i\sigma_{2k-1})Z_k+\frac{1}{2}(\sigma_{2k}+i\sigma_{2k-1})Z_k^*$$

with $Z_k=x_k+\partial_k$, $Z_k^*=x_k-\partial_k$.

Let us construct a unitary operator $\mathcal{T}:\mathscr{L}^2(\mathbb{R}^r,\mathbb{C}^{\mathsf{D}})\to\oplus\sum_\alpha\mathcal{H}_\alpha$ with $\alpha\in(\mathbb{Z}^+)^r$ in the following way:

(a) Let us decompose $u(x')\in\mathscr{L}^2(\mathbb{R}^r,\mathbb{C}^{\mathsf{D}})$ into the series $u(x')=\sum_\alpha\Upsilon_\alpha(x')w_\alpha$ where $\Upsilon_\alpha(x')=\upsilon_{\alpha_1}(x_1)\dots\upsilon_{\alpha_r}(x_r)$, $\upsilon.(.)$ are real-valued orthonormal Hermite functions and $w_\alpha\in\mathbb{C}^{\mathsf{D}}$;

(b) Then using Proposition 5.A.4 let us set $w_\alpha=\oplus\sum_\varepsilon v_{\alpha,\varepsilon}$ with $\varepsilon\in\{-1,1\}^r$, $w_{\alpha,\varepsilon}\in\cap_{1\le j\le r}\mathsf{Ker}(\sigma_{2j}-i\varepsilon_j\sigma_{2j-1})$;

(c) finally let us set $u_\alpha=\oplus\sum_\varepsilon w_{\beta(\alpha,\varepsilon),\varepsilon}$ where $\beta_j(\alpha,\varepsilon)=\alpha_j+\frac{1}{2}(1-\varepsilon_j)$.

Then $\mathcal{T}u=(u_\alpha)_{\alpha\in(\mathbb{Z}^+)^r}$ defines the operator in question.

Then Proposition 5.A.4 yields that

$$\mathcal{H}_0=\bigcap_{1\le j\le r}\mathsf{Ker}(\sigma_{2j}-i\sigma_{2j-1}), \tag{17.1.20}_0$$

$$\mathsf{dim}\ \mathcal{H}_\alpha=2^{-\#\{j,\alpha_j=0\}}\mathsf{D}\qquad\text{for}\quad\alpha\ne 0; \tag{17.1.20}_\alpha$$

moreover, for $d>2r$ $(17.1.20)_\alpha$ is true for $\alpha=0$.

Furthermore, $(13.5.32)_{1-2}$ yield that

$$\mathcal{T}\mathcal{L}\mathcal{T}^*|_{\mathcal{H}_\alpha}=\sum_{1\le k\le r}\sqrt{2\alpha_k f_k}\sigma'_{k\alpha}+\sum_{2r+1\le k\le d}\sigma_{k\alpha}\xi_k+\sigma_{0\alpha}+V\cdot I$$

where matrices $\sigma_{0\alpha},\sigma'_{1\alpha},\dots,\sigma'_{r\alpha},\sigma_{(2r+1)\alpha},\dots,\sigma_{d\alpha}$ transform $\mathcal{H}_\alpha$ into itself and form a system of Pauli matrices there. Then the eigenvalue counting function of the restriction of the operator $\mathcal{T}\mathcal{L}(\xi'')\mathcal{T}^*$ to $\mathcal{H}_\alpha$ is equal to

$$\frac{1}{2}\,\mathsf{dim}(\mathcal{H}_\alpha)\ \mathsf{sgn}(\tau-V)\theta\Big((\tau-V)^2-\sum_{1\le j\le r}2\alpha_j f_j-m^2-|\xi''|^2\Big)\Big|_{\tau=\tau_1}^{\tau=\tau_2}$$

provided either $d > 2r$ or $d = 2r$ and $\alpha \neq 0$; moreover, if $d = 2r$, $\alpha = 0$ and condition (17.1.14) is fulfilled then this function is equal to $\mathsf{dim}(\mathcal{H}_0)$ for $\tau_1 \le H_{-\zeta,0} < \tau_2$ and vanishes otherwise.

This immediately yields $(17.1.12)_{1,2}$. □

Remark 17.1.5. Let us note that under the assumptions of Theorem 17.1.2 for $V = 0$

$$A^2 = \sum_{j,k} g^{jk} P_j P_k + m^2 + \frac{1}{4i}\mu h \sum_{j,k,l,s} \omega^{jl}\omega^{ks} F_{jk}[\sigma_k, \sigma_s]. \tag{17.1.21}$$

(i) Then Corollary 5.A.7 yields that multiplying by $q^\dagger$ and q on the left and right respectively with an admissible unitary matrix q we transform A^2 into a direct sum of the Schrödinger operators B_ε (where ε runs over $\{-1,1\}^r$) with potentials $V_\varepsilon = m^2 + \sum_j \varepsilon_j f_j \mu h$ and with multiplicity $2^{-r}D$ and therefore Theorem 13.2.1 is applicable to the operator A^2.

(ii) Furthermore, let $2r < d$. Then one can assume without any loss of the generality that $g^{jk} = \delta_{jk}$, $F_{jd} = 0$. Then multiplying by σ_d on the left and on the right and replacing x_d by $x'_d = -x_d$ we transform for $V = 0$ operator A into operator $-A$. Therefore in this case

$$\mathsf{tr}\, e(x,x,0,\tau) = \mathsf{tr}\, e(x,x,-\tau,0) = \frac{1}{2}\,\mathsf{tr}\, e_{\mathsf{S}}(x,x,-\infty,\tau^2) \quad \text{for } \tau > 0, \tag{17.1.22}$$

where $e_{\mathsf{S}}(.,.,.,.)$ is the Schwartz kernel for the Schrödinger operator. These arguments easily yield $(17.1.12)_1$.

(iii) Similar arguments yield $(17.1.12)_1$ for τ_1 and τ_2 not in the spectrum of A provided $d = 2r$ and there exists a unitary matrix q such that $q^\dagger \sigma_j q = -\sigma_j$ for $j = 0, \dots, d$.

Remark 17.1.6. (i) For odd d one can treat the *principally massless* Dirac operator (17.1.5), where $\sigma_1, \dots, \sigma_d$ are Pauli matrices and there exists no admissible matrix σ_0. Then the proof of Theorem 17.1.2 yields that formula $(17.1.12)_1$ also remains true in this case.

(ii) Let us note that the connection between formulae obtained here and Weyl formulae is the same as for the Schrödinger operator (see Section 13.2)

but the approximate formula $(13.A.2)_1$ is replaced by $(13.A.2)_2$ and for $d = 2r$ the term

$$(17.1.23)\quad \frac{1}{2}\varsigma D\Big(\theta(\tau - V + m) - \theta(\tau - V - m)\Big)\Big|_{\tau=\tau_1}^{\tau=\tau_2} \times (4\pi)^{-r}(\mu h)^r f_1 \dots f_r\sqrt{g}$$

should be subtracted from $\mathcal{N}^{\mathsf{MW}}(\tau_1, \tau_2, \mu h)$.

(iii) Moreover, one can replace ςD by $i^{-r}\,\mathsf{tr}(\sigma_0 \dots \sigma_d)$ and then one can get rid of condition (17.1.14). Then for $d \geq 4$ term (17.1.23) is $O(h^2)$ for $\mu = 1$ while for $d = 2$ that term is connected with formula (5.3.96) for the coefficient $\mathsf{tr}\,\kappa_1$ in the spectral asymptotic decomposition.

Remark 17.1.7. In this chapter we assume that $d = 2, 3$ and $F \neq 0$. Then Appendix 5.A yields that we need to treat the following three cases:

(a) $d = 2$, $\mathsf{D} = 2$;

(b) $d = 3$, $\mathsf{D} = 4$;

(c) $d = 3$, $\mathsf{D} = 2$ and the operator is of the form 17.1.5.

Then the spectra are respectively

(A) $\{\eta\sqrt{m^2 + 2j\mu hF}, j \geq 0, \eta = \pm 1, j \geq 0, (\eta, j) \neq (\bar{\varkappa}, 0)\}$ is a pure point spectrum, as $m = 0$ it is symmetric,

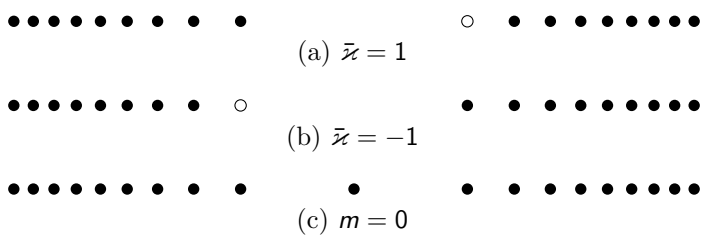

Figure 17.1: The "disappeared" point $(\bar{\varkappa}, 0)$ is not "filled"

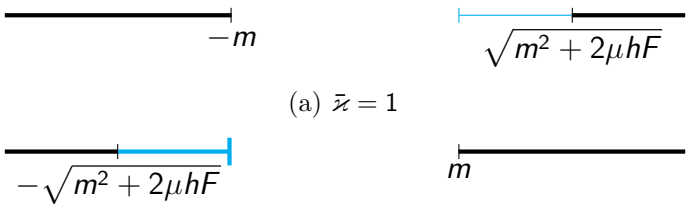
(B) $(-\infty, -m) \cup (m, \infty)$ is a continuous spectrum,

Figure 17.2: The spectrum is the same as without magnetic field

(C) $(-\infty, -m) \cup (\sqrt{m^2 + 2\mu hF}, \infty)$ (as $\bar{\varkappa} = 1$) or $(-\infty, -\sqrt{m^2 + 2\mu hF}) \cup (m, \infty)$ (as $\bar{\varkappa} = -1$) is a continuous spectrum. and if $m = 0$ there is a spectral gap between 0 and $\bar{\varkappa}\sqrt{2\mu hF}$.



(a) $\bar{\varkappa}=1$

(b) $\bar{\varkappa}=-1$

Figure 17.3: The spectrum is pure continuous and the spectrum which "disappeared" is cyan

17.1.2 Rough estimates

Let us pass from the calculations to the analytical arguments as we did in Section 13.2. Let us first treat the main spectral gap $(-m+\max V, m+\min V)$ which is empty if $\max V - \min V \ge 2m$; Theorem 17.1.2 yields that it can be extended in only one direction and only in the case $d=2r$.

Theorem 17.1.8. *Let conditions* (17.1.1)–(17.1.3) *and* (13.2.5) *be fulfilled and let*

$$\tau_1 = -m + \max_{x\in B(0,1)} V, \qquad \tau_2 = m + \min_{x\in B(0,1)} V. \tag{17.1.24}$$

Let us assume that

$$\tau_2 - \tau_1 \ge 2\epsilon(1+\mu h)(m+1)^{-1} \tag{17.1.25}$$

with $\epsilon > 0$. *Then the following estimates hold:*

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)U(x,y,t)| \le C'Th^s\mu^{-s}\bigl(\min(\tau_2-\tau,\tau-\tau_1)(m+1)+1\bigr)^{-s}, \tag{17.1.26}$$

$$|e(x,y,\tau_1',\tau_2')| \le C'h^s\mu^{-s}\bigl(\min(\tau_2-\tau_2',\tau_1'-\tau_1)(m+1)+1\bigr)^{-s} \tag{17.1.27}$$

$\forall x,y\in B(0,1-\epsilon) \quad \forall \tau,\tau_1',\tau_2' \in [\tau_1+\epsilon(1+\mu h)(m+1)^{-1}, \tau_2-\epsilon(1+\mu h)(m+1)^{-1}]$,

where $T \ge h^{1-\delta}$.

Proof. The proof of the first estimate is similar to the proof of Proposition 5.3.22, and the second estimate follows from the first one and the standard Tauberian arguments. □

One should replace Theorems 13.2.7, 13.2.9 by the exact equality

$$U(x,y,t)=0 \qquad \forall x,y\in B(0,1-C_0T): |x-y|\ge C_0T \tag{17.1.28}$$

which is due to the standard uniqueness theorem for symmetric hyperbolic systems.

Finally, one should replace Theorems 13.2.11, 13.2.13 by

Theorem 17.1.9. *Let conditions* (17.1.1)–(17.1.3) *and* (13.2.5) *be fulfilled. Let* $q\in \tilde{\mathsf{S}}^0_{h,\rho,1,K}$ *with* $\rho\ge \mathsf{max}(1,\mu h,\mu^{\frac12}h^{\frac12-\delta})$ *be supported in* $\{|\xi|\ge C_0\rho\}$, *let* $Q=\mathsf{Op}\bigl(q(x,h\xi_1-\mu V_1(x),\dots,h\xi_d-\mu V_d(x))\bigr)$ *and let* $\psi\in \mathscr{C}_0^K(B(0,1-\epsilon))$ *with* $\epsilon>0$. *Then the estimate*

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q\psi U|\le C'Th^s\mu^{-s} \qquad \forall x,y\in B(0,1-\epsilon)\quad \forall \tau: |\tau|\le m+c(m+1)^{-1} \tag{17.1.29}$$

holds with the same $C_0, C', K, \delta, s, T\ge h^{1-\delta}$ *as in theorems 13.2.11, 13.2.13.*

Proof. This proof repeats the proof of Theorems 13.2.11, 13.2.13, and for $m\ge 1$ we apply the reduction made in the proof of Proposition 5.3.22. □

17.2 Microlocal Canonical Form

In this section we reduce operators (17.1.1) and 17.1.5 to their microlocal canonical forms assuming that $d=2,3$ and conditions (17.1.1)–(17.1.3) and

$$F\ge \epsilon_0 \qquad \text{in}\quad B(0,1) \tag{17.2.1}$$

are fulfilled. Let us recall that $B(0,1)\subset X$. Then Appendix 5.A yields that we need to treat the following three cases listed in Remark 17.1.7.

17.2.1 Principal Symbol Reduction

Then one can assume that in the cases (A) and (C) $\sigma_1,\sigma_2,\sigma_0$ and $\sigma_1,\sigma_2,\sigma_3=\sigma_0$ respectively are Pauli matrices (5.A.29) while in case (B) the matrices $\sigma_0,\dots,\sigma_3$ are given by (5.A.31) with α_j denoted as σ'_j now.

We will construct a reducing operator commuting with σ_0 in the cases (A) and (B). Moreover, in the case (B) this operator will commute with σ_4

where in the framework of (B), (5.A.31) the following auxiliary matrices are used:

$$\sigma_4 = \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix}, \quad \sigma_5 = \begin{pmatrix} 0 & iI \\ -iI & 0 \end{pmatrix}, \tag{17.2.2}$$

$$\hat{\sigma}_j = \sigma_4\sigma_j = \begin{pmatrix} \sigma'_j & 0 \\ 0 & \sigma'_j \end{pmatrix} \qquad (j = 1,2,3).$$

But then the case (B) is reduced to to the case (C) at *this* step of the analysis. So, $\mathsf{D} = 2$ and we treat operators (17.1.1) with $d = 2$ and 17.1.5 with $d = 3$. Let us start with the case $m = V = 0$, i.e., let us treat the operator

$$A^0 = \frac{1}{2}\sum_{j,l} \sigma_l(\omega^{jl}P_j + P_j\omega^{jl}). \tag{17.2.3}$$

Then the $\mu^{-1}h$-pseudodifferential operator $\mu^{-1}A^0$ has the principal symbol

$$a^0(x,\xi) = \sum_{j,l} \sigma_l\omega^{jl}(\xi_j - V_j) \tag{17.2.4}$$

in which case

$$\bigl(a^0(x,\xi)\bigr)^2 = g(x,\xi)I, \qquad g(x,\xi) = \sum_{j,k} g^{jk}(\xi_j - V_j)(\xi_k - V_k). \tag{17.2.5}$$

We use the notation of Section 13.3 in this section.

Proposition 17.2.1. *Let conditions* (13.2.5), (17.1.1)–(17.1.3) *and* (17.2.1) *be fulfilled with* $K = K(N)$. *Let* Ψ *be the symplectomorphism constructed in either Proposition 13.3.1(i) or (iii) for* $d = 2$ *and in Proposition 13.3.1(ii) and Remark 13.3.2(ii) for* $d = 3$ *with* N *replaced by* $N+2$. *Then there exists a smooth unitary matrix* $J = J(x,\xi)$ *in the neighborhood of* Λ^0 *such that*

(i) For $d = 2$

$$J = \exp(iw\sigma_0), \tag{17.2.6}$$

$$J^\dagger(a^0\circ\Psi)J = \bigl(\sigma_1\xi_2 + \sigma_2 x_2\bigr)\Bigl(\sum_{0\le n\le N} B_n(x_1,\xi_1)(x_2^2+\xi_2^2)^n\Bigr) + \sum_{1\le j\le 2}\sigma_j R_j, \tag{17.2.7}$$

$$R_j \in O_{2N+3}(\Lambda^0) \quad (j = 1,2)$$

where here and below w, w_k, B_n, R_j *are real-valued scalar symbols.*

(ii) For $d = 3$

$$J = \exp(i \sum_{1\le j\le 3} w^j \sigma_j), \tag{17.2.8}$$

$$J^\dagger (a^0 \circ \Psi) J = \tag{17.2.9}$$
$$\big(\sigma_1\xi_3 + \sigma_2 x_3 + \sigma_3\xi_2\big)\Big(\sum_{0\le n\le N} B_n(x',\xi_1)(x_2^2+\xi_2^2)^n\Big) + \sum_{1\le j\le 3}\sigma_j R_j,$$
$$R_j \in O_{2N+3}(\Lambda^0) \quad (j = 1,2,3).$$

(iii) Moreover, in the both cases

$$B_0 = F^{\frac12}\circ\bar\Psi \tag{17.2.10}$$

and under the assumptions of Proposition 13.3.1(iii)

$$B_1 = \frac18 F^{\frac12}\kappa\circ\bar\Psi. \tag{17.2.11}$$

Proof. Let Ψ be the indicated symplectomorphism. Then

$$a^0\circ\Psi = \sum_j \sigma_j U_j \qquad (j = 1,\dots,d) \tag{17.2.12}$$

where $U_j \in O_1(\Lambda^0)$, the linear hulls of the sets $\{dU_j,\ j = 1,\dots,d\}$ and $\{du_j,\ j = 1,\dots,d\}$ at points of Λ^0 coincide,

$$\sum_j U_j^2 \equiv \sum_j u_j^2\varphi^2 \qquad \mathrm{mod}\ O_{2N+3}(\Lambda^0), \tag{17.2.13}$$

$$\varphi = \Big(\sum_{1\le n\le N+1} b_n(x_d^2+\xi_d^2)^{n-1}\Big)^{\frac12}, \tag{17.2.14}$$

$u_1 = \xi_2$, $u_2 = x_2$ for $d = 2$ and $u_1 = \xi_3$, $u_2 = x_3$, $u_3 = \pm\xi_2$ for $d = 3$ and the sign of ξ_2 here will be fixed later.

Let us prove that

(17.2.15) in a neighborhood of Λ^0 there exists a smooth matrix $\rho = (\rho^{jk}) \in \mathrm{SO}(d)$ [1] such that

$$u_j \equiv \sum_k \rho^{jk} U_k \varphi^{-1} \qquad \mathrm{mod}\ O_n(\Lambda^0) \tag{17.2.16}_n$$

with $n = 2N+2$.

[1] Here and in what follows $\mathrm{O}(d)$ is the group of real orthogonal $d\times d$ matrices and $\mathrm{SO}(d)$ is its subgroup of matrices with determinant equal 1.

To prove (17.2.15) let us apply induction on n. Equality (17.2.13) yields that for $n = 2$, $(17.2.16)_n$ obviously holds with appropriate $\rho \in \mathsf{O}(d)$.

Moreover, if $d = 2$ then $\rho \in \mathsf{SO}(2)$ necessarily; this follows from the positiveness of $F \cdot \det(\omega^{jk})$ and the analysis of the Poisson brackets $\{U_1, U_2\}$ and $\{u_1, u_2\}$. For $d = 3$ one can obtain $\rho \in \mathsf{SO}(3)$ by choosing the sign at ξ_2.

Let us assume now that $(17.2.16)_n$ holds, $2 \le n \le 2N + 1$. Then

$$u_j \equiv \sum_k \rho^{jk} U_k \varphi^{-1} + v_j \qquad \mathsf{mod}\ O_{n+1}(\Lambda^0)$$

where $v_j \in O_n(\Lambda^0)$ and (17.2.13) yields that

$$\sum_j u_j v_j \equiv 0 \qquad \mathsf{mod}\ O_{n+2}(\Lambda^0). \tag{17.2.17}$$

Let $\phi \in O_{n-1}(\Lambda^0)$ be a real-valued skew-symmetric matrix. Then $\mathsf{SO}(d) \ni \exp\phi \equiv I + \phi \mod O_{n+1}(\Lambda^0)$ and $(17.2.16)_{n+1}$ holds with ρ replaced by $\exp(\phi)\rho$ provided

$$\sum_k \phi^{jk} u_k \equiv -v_j \qquad \mathsf{mod}\ O_{n+1}(\Lambda^0). \tag{17.2.18}$$

Therefore the possibility of making the induction step is due to the following:

Lemma 17.2.2. *Let $d = 2, 3$ and $v_j \in O_n(\Lambda^0)$ satisfy* (17.2.17) *with $n \ge 2$. Then there exists a real-valued skew-symmetric matrix $(\phi^{jk}) \in O_{n-1}(\Lambda^0)$ such that* (17.2.18) *holds.*

This lemma will be proven later; let us first complete the proof of Proposition 17.2.1. Thus, $U_k \equiv \sum_j \varphi\rho^{jk} u_j \mod O_{2N+2}(\Lambda^0)$. Plugging into (17.2.12) we obtain that

$$a^0 \circ \Psi \equiv \sum_{j,k} \varphi\rho^{jk} \sigma_k u_j. \tag{17.2.19}$$

Let us set $\bar\sigma_j = \sum_k \rho^{jk}\sigma_k$ $(j = 1, \dots, d)$. Moreover, for $d = 2$ let us introduce $\bar\sigma_3 = \sigma_3$ $(= \sigma_0)$.

Then $\bar\sigma_1, \bar\sigma_2, \bar\sigma_3$ are Pauli matrices and $\bar\sigma_1\bar\sigma_2\bar\sigma_3 = \sigma_1\sigma_2\sigma_3 = \varsigma i I$ and hence there exists an unitary unimodular matrix $J = J(\rho)$ such that $J^\dagger \bar\sigma_j J = \sigma_j$

$(j = 1, 2, 3)$. This matrix depends analytically on ρ, is defined uniquely modulo a factor ± 1 [2)] and it can be chosen as a one-valued smooth function of (x, ξ) in a Ω because Ω is simply connected.

Every unitary unimodular 2×2 matrix is of the form (17.2.8), and one can take smooth real-valued functions w^j. For $d = 2$, the matrix J commutes with σ_3 (because $\bar{\sigma}_3 = \sigma_3$) and hence it is of the form (17.2.6). Equalities (17.2.7) and (17.2.9) follow from (17.2.19) and the definition of J if B_n are chosen such that

$$\sum_{0 \le n \le N} B_n (x_d^2 + \xi_d^2)^n \equiv \varphi^{\frac{1}{2}} \qquad \mathsf{mod}\ O_{2N+1}(\Lambda^0).$$

Then $B_0 = \sqrt{b_1}$, $B_1 = b_2/2\sqrt{b_1}$ and (17.2.10), (17.2.11) follow from (13.3.12), (13.3.13). □

Proof of Lemma 17.2.2. Instead of $O_n(\Lambda^0)$ one can use $\mathcal{P}_n$, spaces of n-th degree homogeneous polynomials of $u = (u_1, \dots, u_d)$ with coefficients depending smoothly on the remaining coordinates in which case one should replace modulo equalities by exact equalities.

(i) If $d = 2$ then $\phi = \begin{pmatrix} 0 & \psi \\ -\psi & 0 \end{pmatrix}$ and (17.2.17) means exactly that $v_1 = \psi u_2$, $v_2 = -\psi u_1$; one can fulfill these equalities with an appropriate $\psi \in \mathcal{P}_{n-1}$ because (17.2.17) yields that $u_1 v_1 = -u_2 v_2$.

(ii) Let $d = 3$; then every real skew-symmetric matrix is given by a vector product: $\phi v = \psi \times v \ \forall v$ with $\psi \in \mathcal{P}_{n-1}^3 = (\mathcal{P}_{n-1})^3$. In this case (17.2.17) and (17.2.17) mean that $\langle u, v \rangle = 0$ and $\psi \times u = -v$ respectively.

Now let $\mathcal{P}_n$ be the spaces of n-th degree homogeneous polynomials of $u = (u_1, \dots, u_d)$ with constant coefficients. Let us consider the maps

$$\Phi_s : \mathcal{P}_s^3 \ni v \to u \times v \in \mathcal{P}_{s+1}^3,$$
$$\mathcal{L}_s : \mathcal{P}_s^3 \ni v \to \langle u, v \rangle \in \mathcal{P}_{s+1},$$
$$\mathcal{L}'_s : \mathcal{P}_s \ni w \to wu \in \mathcal{P}_{s+1}^3.$$

Obviously, $\mathsf{Ran}\, \Phi_s \subset \mathsf{Ker}\, \mathcal{L}_{s+1}$ and the lemma will be proven if we prove that $\mathsf{Ran}\, \Phi_s = \mathsf{Ker}\, \mathcal{L}_{s+1}$. In order to prove this equality it is sufficient to

[2)] The map $\mathsf{SO}(3) \ni \rho \to T(\rho)$ is called a spinor representation.

prove that the dimensions of these spaces are equal. It is an easy exercise if one notes that $\dim \mathcal{P}_s = \frac{1}{2}(s+1)(s+2)$, $\operatorname{Ker} \Phi_s = \operatorname{Ran} \mathcal{L}'_{s-1}$ and hence $\dim \operatorname{Ker} \Phi_s = \dim \mathcal{P}_{s-1}$ (because $\operatorname{Ker} \mathcal{L}'_{s-1} = 0$) and $\operatorname{Ran} \mathcal{L}_{s+1} = \mathcal{P}_{s+1}$. The calculation of the dimensions in question we leave to the reader; they are equal to $(s+1)(s+3)$. □

Remark 17.2.3. For $d = 2$, the function w is uniquely defined modulo $O_{2N}(\Lambda^0)$; for $d = 3$ the functions w^j are defined modulo the term λu_j (with scalar real-valued function λ) and modulo $O_{2N}(\Lambda^0)$.

17.2.2 Final Reduction

Let $\mathcal{F}$ be a scalar $\mu^{-1}h$-Fourier integral operator corresponding to the symplectomorphism Ψ and satisfying (13.3.61) and (13.3.63). Let J be a $\mu^{-1}h$-pseudodifferential operator with principal symbol $J(x,\xi)$ such that in a neighborhood of Λ^0

$$J^*J \equiv JJ^* \equiv I. \tag{17.2.20}$$

Since $J(x,\xi)$ commutes with σ_0 for $d = 2$ one can also take J commuting with σ_0 (for $d = 2$). Then in a neighborhood of Λ^0

$$J^*\mathcal{F}^*A^0\mathcal{F}J \equiv \mathcal{A}^0 \tag{17.2.21}$$

and in a neighborhood $\mathcal{W}$ of the point $\rho \in \Lambda$ for $d = 2$ (and in a neighborhood $\mathcal{W}$ of the magnetic line Γ for $d = 3$)

$$\mathcal{F}J\mathcal{A}^0J^*\mathcal{F}^* \equiv A^0 \tag{17.2.22}$$

where for $d = 2$

$$\mathcal{A}^0 = \sum_{0\le n\le N} \mu^{-2n} B_n(x_1, \hbar D_1)\Big((\sigma_1 hD_2 + \sigma_2 \mu x_2)(\mu^2 x_2^2 + h^2 D_2^2)^n\Big)^{\mathrm{w}} + \sum_{1\le j\le 2} \sigma_j R_j \tag{17.2.23}$$

and for $d = 3$

$$\mathcal{A}^0 = \sum_{0\le n\le N} \mu^{-2n} B_n(x', \hbar D_1)\Big((\sigma_1 h D_3 + \sigma_2 \mu x_3 + \sigma_3 h D_2)(\mu^2 x_3^2 + h^2 D_3^2)^n\Big)^{\mathsf{w}} + \sum_{1\le j\le 3} \sigma_j R_j + R_4 \cdot I \tag{17.2.24}$$

where here and in what follows $\hbar = \mu^{-1}h$, $R_j = R_{0j} + \hbar R_{1j}$, $R_{\dots}$ are scalar Hermitian $\hbar$-pseudodifferential operators uniformly with respect to all the parameters[3)]. Moreover,

(17.2.25) The symbols of R_{0j} belong to $O_{2N+3}(\Lambda^0)$, $R_{04} = 0$.

Here we quantize the total expression in the parentheses with the exterior superscript w.

Furthermore, for $d = 3$ we have written lower order terms of the general form and for $d = 2$ we noted that these terms are combinations of σ_1 and σ_2 because σ_0 skew-commutes with $\mathcal{A}^0$. Really, σ_0 skew-commutes with A^0 and commutes with $\mathcal{F}$ and J.

Calculation shows that for $d = 3$ the term R_{14} does not necessarily vanish.

For $d = 3$ one can apply the additional construction motivated by Remark 17.2.3. Let J' be an $\hbar$-pseudodifferential operator satisfying (17.2.20) with Weyl symbol $\exp(i\sum_j \sigma_j u_j w)$ (modulo $O(\hbar^2)$); this expression commutes with the principal symbol of $\mu^{-1}\mathcal{A}^0$; this fact and (5.A.30) yield that

$$J'^{*}\mu^{-1}\mathcal{A}^0 J' = \mu^{-1}\mathcal{A}^0 + \mu^{-1}h\Big(\sum_j \sigma_j R'_j + R'_4\Big)$$

where the principal symbol of R'_4 is equal to $\frac{1}{2}\{b_0(u_1^2+u_2^2+u_3^2), w\}$. Therefore replacing J by JJ', choosing an appropriate function w and repeating the proof of Proposition 13.3.1 we can obtain

$$R_4 = \hbar \sum_{0\le n\le N} B'_n(x', \hbar D_1)(x_3^2 + \hbar^2 D_3^2)^n + R''_4 + \hbar^2 R_{24}$$

[3)] Including m, μ, h.

in (17.2.24), where R_4'' is an $\hbar$-pseudodifferential operator with the principal symbol belonging to $O_{2N+1}(\Lambda^0)$; N is decreased if necessary but remains arbitrarily large.

Now by induction with respect to L one can construct operators $J = J_L$ satisfying (17.2.20) such that for $d = 2$ they commute with σ_0 and (17.2.23) holds with $B_n = B_n(x_1, \hbar D_1, \hbar)$ and

$$R_j = \sum_{0\le l\le L} R_{jl}\hbar^l. \tag{17.2.26}$$

On the other hand, for $d = 3$ we obtain that

$$\mathcal{A}^0 = \sum_{0\le n\le N} \Bigl(B_n(x', \hbar D_1, \hbar)(\sigma_1 hD_3 + \sigma_2\mu x_3 + \sigma_3 hD_2)(x_3^2 + \hbar^2 D_3^2)^n\Bigr)^{\mathsf{w}} + \sum_j \sigma_j R_j + R_4\cdot I. \tag{17.2.27}$$

Here R_j $(j = 1, \dots, 4)$ satisfy (17.2.26) and in both cases R_{jl} are operators with the symbols belonging to $O_{N_l}(\Lambda^0)$ and $N_l \to \infty$ as $N \to \infty$ for every fixed l.

Namely, in this construction $J_L = J_{L-1}J_L'J_L''J_L'''$ where J_L', J_L'' and J_L''' satisfy (17.2.20), J_L' is a scalar operator, J_L'' and J_L''' are matrix operators and $(J_L' - I)\hbar^{1-L}$ and $(J_L'' - I)\hbar^{-L}$ are $\hbar$-pseudodifferential operators uniformly with respect to all the parameters[3)], for $d = 2$ the matrix J_L'' commutes with σ_0 and $J_L''' \equiv I$ and for $d = 3$

$$\bigl(J_L''' - I - i\hbar^L \sum_j \alpha^j\sigma_j\bigr)\hbar^{-L-1}$$

is an $\hbar$-pseudodifferential operator uniformly with respect to all the parameters and α^j are scalar $\hbar$-pseudodifferential operators with real-valued symbols.

Checking this construction is left to the reader. So we have proven

Proposition 17.2.4. *Let conditions* (17.1.1)–(17.1.3) *and* (17.2.1) *be fulfilled with* $K = K(N)$ *and let* Ψ *be the symplectomorphism constructed in Proposition 13.3.1(i) or (iii) for* $d = 2$ *and in Proposition 13.3.1(ii) and Remark 13.3.2(ii) for* $d = 3$.

Then there exists a $\mu^{-1}h$*-pseudodifferential operator* J *satisfying* (17.2.20) *in a neighborhood of* Λ^0 *such that*

(i) For $d = 2$, J commutes with σ_0 and (17.2.21), (17.2.22), (17.2.23) *hold with $B_n = B_n(x_1, \hbar D_1, \hbar)$ and with R_j with symbols belonging to $O_{2N+1}(\Lambda^0)$.*

(ii) For $d = 3$ and $\mathsf{D} = 2$, equalities (17.2.21), (17.2.22), (17.2.27) *hold with $B_n = B_n(x', \hbar D_1, \hbar)$ and with R_j with symbols belonging to $O_{2N+1}(\Lambda^0)$; moreover the principal symbol of R_4 vanishes.*

Now we can also treat the case $d = 3$, $\mathsf{D} = 4$:

Corollary 17.2.5. *Let $d = 3$, $\mathsf{D} = 4$ and $\sigma_0, \dots, \sigma_3$ be defined by* (5.A.31). *Let us construct $J' (= J)$ as in Proposition 17.2.4(ii) for the operator $A^{0\prime}$ defined by* (17.2.3) *with σ'_j instead of σ_j and let us now set $J = \begin{pmatrix} J' & 0 \\ 0 & J' \end{pmatrix}$.*

Then for A^0 formulae (17.2.20)–(17.2.22) *and* (17.2.27)$^{\#}$ *hold where the superscript $^{\#}$ means that for R_4 the matrix I should be replaced by σ_4 with σ_4 defined by* (17.2.2).

Remark 17.2.6. For constant F_{jk} and ω^{jk} one can choose a constant matrix $J(x, \xi)$. Therefore the stability of the reduction procedure yields that if

$$(17.2.28)_{1-3} \quad |D^\alpha \omega^{jk}| \le c\bar\nu, \qquad |D^\alpha F_{jk}| \le c\bar\nu \qquad |D^\alpha V| \le c\bar\nu (m+1)^{-1} \quad \forall \alpha : 1 \le |\alpha| \le K,$$

then

$$(17.2.29) \quad B_0 = \bar F + \bar\nu \tilde B_0, \qquad B_n = \bar\nu \tilde B_n \quad (n \ge 1), \qquad B'_n = \bar\nu \tilde B'_n, \qquad R_j = \bar\nu \tilde R_j$$

where $\bar F = \mathsf{const}$, $\tilde B_n$, $\tilde B'_n$ and $\tilde R_j$ are $\mu^{-1}h$-pseudodifferential operators uniformly with respect to all parameters[3)] and the symbols of $\tilde R_j$ belong to $O_{2N+1}(\Lambda^0)$ uniformly with respect to all parameters. Surely condition $(17.2.28)_3$ is not used *here*. Condition $(17.2.28)_4$ will be introduced in the next section.

Let us consider operator

$$(17.2.30) \qquad \hat V = J^* \mathcal{F}^* (V \cdot I) \mathcal{F} J.$$

For $d = 2$ this operator commutes with σ_0 and for $d = 3$, $\mathsf{D} = 4$ it is of the form $\hat V = \hat V' \otimes I_2$. Therefore we obtain

Proposition 17.2.7. *Under the assumptions of Proposition 17.2.4*

$$\hat{V} = W\cdot I + \mu^{-1}hW_0\sigma_0 \qquad (d=2), \tag{17.2.31}_1$$

(17.2.32)

$$\hat{V} = W\cdot I + \sum_j \mu^{-1}hW_j\sigma_j \qquad (d=3,\ \mathsf{D}=2), \tag{17.2.31}_2$$

$$\hat{V} = W\cdot I + \sum_j \mu^{-1}hW_j\hat{\sigma}_j \qquad (d=3,\ \mathsf{D}=4) \tag{17.2.31}_1$$

where $(m+1)W - \mathsf{const}$ *and* $(m+1)W_j$ *(*$j=0,\dots,3$*) are scalar* $\mu^{-1}h$*-pseudodifferential operators uniformly with respect to all parameters and the principal symbol of* W *is equal to* $V\circ\Psi$*.*

Moreover, if conditions $(17.2.28)_{1-3}$ *are fulfilled then*

$$W_j = \bar{\nu}\tilde{W}_j \tag{17.2.33}$$

for all j *where* $\tilde{W}_j$ *are* $\mu^{-1}h$*-pseudodifferential operators uniformly with respect to all parameters.*

Let us note that we can make a more advanced (but incomplete, unfortunately) reduction of the operator

$$\mathcal{A} = \mathcal{A}^0 + \sigma_0 m + \hat{V} \tag{17.2.34}$$

but in the forthcoming sections we will use another method.

17.2.3 Reduced Propagator

Let us consider what we obtained in the treatment of U, etc. Let $\mu\ge 1$, $h\in(0,1]$ and $\mu h\le 1$ (we will get rid of this condition in Section 17.5) and let $\mathcal{F}$ and T be constructed above. Moreover, let us assume that Remark 13.3.12 is fulfilled.

Let us set $\mathcal{U} = J_x^*\mathcal{F}_x^* U\, {}^t\mathcal{F}_y^*\, {}^tJ_y^*$ where U is the Schwartz kernel of operator $\exp(ith^{-1}(m+1)A)$. Then

$$\bigl(hD_t - (m+1)\mathcal{A}\bigr)\mathcal{U}\equiv 0, \tag{17.2.35}$$

$$\mathcal{U}|_{t=0}\equiv \delta(x-y)\cdot I \tag{17.2.36}$$

modulo functions f and f' satisfying (13.3.81) and (13.3.82) respectively where the operator $\mathcal{A}$ is given by (17.2.34) (for $d = 3$, $D = 2$ term $\sigma_0 m$ is absent).

Moreover, $\mathcal{U}$ satisfies (13.3.84)–(13.3.86) and (13.3.87) is replaced by

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)\big(U - \mathcal{F}_x J_x \mathcal{U}\, {}^t J_y\, {}^t\mathcal{F}_y\big)| \le C' T h^s \qquad \forall x, y \in \mathcal{W}_x \quad \forall \tau : |\tau| \le 4c \tag{17.2.37}$$

where $\mathcal{W}_x$ is the x-projection of $\mathcal{W}$.

17.3 Weak Magnetic Field

In this section we consider the case when condition (13.4.1) [4] is fulfilled and we obtain some results similar to the basic results of Section 13.4. Surely some of the auxiliary results of Section 13.4 do not remain valid here because the reduction of the operator $\mathcal{A}$ is now incomplete. For the sake of simplicity here and in Sections 17.4–17.6 below we assume that

$$m \le h^{-\bar{I}}\mu^{\bar{I}} \tag{17.3.1}$$

with some (arbitrarily large) exponent $\bar{I}$. Really, as $m \ge C_0$ we can apply reduction of Subsubsection *5.3.2.4 Asymptotics for $m \le c_0$* and arrive to the Schrödinger operator perturbed and as $m \ge h^{-\bar{I}}\mu^{\bar{I}}$ this perturbation will be negligible.

17.3.1 Analysis of Singularities. I

We start with from the analysis of singularities. First, let us prove

Proposition 17.3.1 [5]**.** *Let $d = 2, 3$ and suppose that condition* (13.4.1) *is fulfilled. Let $Q = \mathsf{Op}(q)$, $q \in \mathsf{S}_{\mu^{-1}h,\mu^{-1},\mu^{-1},K}(T^*\mathbb{R}^d)$ and let us assume that for both signs*

$$\mathsf{supp}(q) \cap \big\{\tau_1 \le \bar{W} \pm \big(m^2 + \mu^2 B_0^2(x_2^2 + \xi_2^2)\big)^{\frac{1}{2}} \le \tau_2\big\} = \emptyset, \tag{17.3.2}_{(2)}$$

$$\mathsf{supp}(q) \cap \big\{\tau_1 \le \bar{W} \pm \big(m^2 + \mu^2 B_0^2(x_3^2 + \xi_3^2 + \xi_2^2)\big)^{\frac{1}{2}} \le \tau_2\big\} = \emptyset, \tag{17.3.2}_{(3)}$$

[4] I.e., $\mu \in [\mu_0, h^{\delta-1}]$ with $\delta > 0$.

[5] Cf. Proposition 13.4.1.

for $d = 2, 3$ respectively where W is taken from $(17.2.31)_{1-3}$ *and the bar means that in this symbol we set $\hbar = 0$ and $x_2 = \xi_2 = 0$, $x_3 = \xi_3 = x_2 = 0$ for $d = 2, 3$ respectively.*

Then estimate (13.4.3) *remains true. Moreover, this estimate remains true if we replace Q_x by ${}^tQ_y$ (placed as usual to the right from U).*

Proof. The proof is by the standard elliptic methods; it is direct for $m \le C_0$ while for $m \ge C_0$ the reduction to the of Subsubsection *5.3.2.4 Asymptotics for $m \le c_0$* is used. We leave the details to the reader. □

It will be convenient for us to assume in what follows that for $m \ge 1$ one of the following conditions is fulfilled:

$$(17.3.3)_{\pm} \qquad |V \pm m| \le \frac{c}{(m+1)}.$$

In this case we obtain

Corollary 17.3.2. *Under condition* $(17.3.3)_{\pm}$ *Remark 13.4.2 remains true for $\tau_{1,2} : |\tau_j| \le 4c$.*

Theorem 17.3.3 [6]**.** *Let $d = 2, 3$ and let condition* (13.4.1) *be fulfilled with $\mu_0 = \mu_0(c, \delta)$.*

Let $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$, $q', q'' \in \mathsf{S}_{\boldsymbol{h},\rho,\gamma,K}(T^*\mathbb{R}^d)$ and condition (13.4.6) *be fulfilled.*

Furthermore, let <u>either</u> $d = 3$ and condition $(13.4.8)_{(3)}$ *and one of the conditions* $(13.4.7)_{1-4}$ *be fulfilled <u>or</u> $d = 2$ and condition* $(13.4.8)_{(3)}$ *and one of the conditions* $(13.4.7)_{1-2}$ *be fulfilled.*

Then estimate (13.4.9) *holds for $\tau : |\tau| \le 2c$.*

Proof. The proof is the standard energy (and commutator) proof (see the proof of Theorem 2.1.2) and for $m \ge C_0$ the reduction to the of Subsubsection *5.3.2.4 Asymptotics for $m \le c_0$* is used. □

Remark 17.3.4. (i) Theorem 13.4.3 and the standard elliptic arguments yield a statement similar to Statement (ii) of Theorem 13.4.3 but with an essentially stronger condition than (13.4.10) [7].

[6] Cf. Theorem 13.4.3.

[7] The left-hand expression of the inequality is the same as in (13.4.10) but the right-hand expression is essentially larger. Finding it is left to the reader.

(ii) Similarly, let us use the standard energy (and commutator) arguments with the reduction of subsubsection 5.3.2.4 for $m \ge C_0$ and with the equality

$$i[\,\sigma_1 hD_d + \sigma_2 \mu x_d\,,\, h^2 D_d^2 + \mu^2 x_d^2\,] = 2\mu h\omega(\sigma_1 hD_d + \sigma_2 \mu x_d) \tag{17.3.4}$$

for $m \le C_0$. In the latter case we write the terms in the parenthesis in the right-hand expression using $(m+1)hD_t - \hat{V}$, $m\sigma_0$ and other terms of $\mathcal{A}^0$ and we use the fact that the matrices $\omega = -\sigma_2\sigma_1$, $\omega\sigma_0$ and $\omega\sigma_3$ are skew-Hermitian. Then we can prove a similar assertion under a restriction stronger than (13.4.10), coinciding with (13.4.10) provided

$$|D^\alpha V| \le \frac{C}{(m+1)}\mu^{|\alpha|-l+d-3} \qquad \forall \alpha : 1 \le |\alpha| \le l+2-d. \tag{17.3.5}$$

Moreover, under some conditions one can prove a weakened version of Theorem 13.4.4. However we have no need for it; we will treat the case $d = 2$, $\nu < 1$ later by another method.

Theorem 17.3.3 immediately yields that Statements (ii) and (iii) of Theorem 13.4.5 remain true with $\tau : |\tau| \le c$ in estimate (13.4.20).

One can prove some statements similar to Propositions 13.4.7–13.4.9 with $\nu = 1$. However, we will now prove only a special statement; the general case will be treated in the following subsection by another method under certain additional condition (which we will get rid of later).

Proposition 17.3.5 [8)]**.** *(i) Let one of the following three conditions be fulfilled:*

$$|\nabla\big(\frac{V}{\sqrt{F}}\big)| \ge \epsilon_0 \quad \textit{in} \quad B(0,1), \qquad m \le \epsilon = \epsilon(c,\epsilon_0), \tag{17.3.6}$$

$$|\nabla\big(\frac{V^2-m^2}{F}\big)| \ge \epsilon_0 \qquad \textit{in} \quad B(0,1), \tag{17.3.7}$$

$$d = 3, \quad |\xi_2| \ge \epsilon_0 \qquad \textit{on} \quad \mathsf{supp}(q') \tag{17.3.8}$$

where $q', q'' \in \mathsf{S}_{h,\rho,\rho,K}(T^*\mathbb{R}^d)$ *with* $\rho \ge \mu^{\frac12} h^{\frac12(1-\delta)}$. *Let* $\chi, \bar\chi \in \mathscr{C}_0^K([-1,1])$, $\bar\chi = 1$ *on* $[-\frac12, \frac12]$ *and*

$$h^{1-\delta} \le T' \le T \le T^* := \mu\epsilon_0 \qquad \textit{for} \quad d = 2, \tag{17.3.9}_{(2)}$$

$$h^{1-\delta} \le T' \le T \le T^* := \epsilon_0 \qquad \textit{for} \quad d = 3, \tag{17.3.9}_{(3)}$$

[8)] Cf. Proposition 13.4.9.

with a sufficiently small constant $\epsilon_0 = \epsilon_0(c) > 0$. *Then estimate* (13.4.33) *holds for* $\tau \in [-\epsilon, \epsilon]$.

(ii) Therefore this estimate remains true if we replace $\mathcal{U}$, Q'_x *and* ${}^tQ''_y$ *by* U, $Q'_x\psi'(x)$ *and* $\psi''(y)\,{}^tQ''_y$ *respectively with* $\psi', \psi'' \in \mathscr{C}_0^K(B(0, \frac{1}{2}))$. *Then conditions* (17.3.6), (17.3.7) *do not change and condition* (17.3.8) *should be replaced by*

$$|\sum_j F^j(\xi_j - V_j)| \ge \epsilon_0 \qquad \text{on} \quad \operatorname{supp}(q'\psi'). \tag{17.3.8}'$$

Proof. The proof is similar to the proof of Corollary 2.1.17 but one should take into account the remarks made in the proof of Theorem 3.3.3. Here under condition (17.3.6) the reduced Dirac operator is treated directly while under conditions (17.3.7) and (17.3.8) the reduction of Subsubsection *5.3.2.4 Asymptotics for* $m \le c_0$ is used.

Let us note that assumption (17.3.7) yields that $m + |V| \ge \epsilon_1$ in $B(0,1)$ and that assumption (17.3.8) yields that the operator $hD_t - (m+1)\mathcal{A}$ is elliptic provided $|\tau| \le \epsilon$, $m + |V| \le \epsilon_0$. □

17.3.2 Analysis of Singularities. II

Let us now assume that

$$m + |V| \ge \epsilon_0 \qquad \text{in} \quad B(0,1). \tag{17.3.10}$$

This condition provides a reduction and we can assume that one of the conditions $(17.3.3)_\pm$ is fulfilled. Let us assume for definiteness that condition $(17.3.3)_+$ is fulfilled; then we can assume that the condition

$$(m - V) \ge \epsilon_0(m+1) \tag{17.3.11}$$

is fulfilled as well. For $m \ge C_0$ this condition is fulfilled automatically while for $m \le C_0$ one can reach it by an ϵ-admissible partition of unity in $B(0,1)$ with a small enough constant $\epsilon > 0$; in the latter case we replace A by $-A$ if necessary. Under this assumption one can apply the reduction to the equation

$$\big(-hD_t - (m+1)A\big)\,U^\pm = \pm ih\delta(x-y)\delta(t)I \tag{17.3.12}$$

directly. Recall that $U^{\pm} = \theta(\pm t)U$. Dividing U into four blocks U_{jk} and assuming that for $d = 2, 3$ the matrices σ_j are given by formulae (5.A.29), (5.A.31) respectively we obtain the following system in the zone $\{|\tau| \le \epsilon\}$:

$$\Big(-hD_t + (m+1)(V+m) - \mathcal{L}^* E \mathcal{L}\Big) U_{1r}^{\pm} \equiv \pm ihf_{1r}, \tag{17.3.13}$$

$$U_{2r}^{\pm} \equiv -E\mathcal{L}U_{1r}^{\pm} \pm ihf_{2r}. \tag{17.3.14}$$

Here E is a parametrix of the operator

$$-h(m+1)^{-1}D_t + (V - m) \tag{17.3.15}$$

which is elliptic in the indicated zone,

$$\mathcal{L} = \frac{1}{2}\sum_{j,l} \sigma_l'(\omega^{jl}P_j + P_j\omega^{jl}) \qquad \text{as} \quad \sigma_l = \begin{pmatrix} 0 & \sigma_l'^{\dagger} \\ \sigma_l' & 0 \end{pmatrix} \tag{17.3.16}$$

and

$$(f_{jk}) = \begin{pmatrix} I & -\mathcal{L}^* E \\ 0 & E \end{pmatrix} \delta(x-y)\delta(t). \tag{17.3.17}$$

In the case $d = 3$, $D = 2$ we can formally "double" our system setting $U' = U'' = U$:

$$(-hD_t + V)\begin{pmatrix} U'^{\pm} \\ U''^{\pm} \end{pmatrix} = \begin{pmatrix} 0 & -A_0 \\ -A_0 & 0 \end{pmatrix}\begin{pmatrix} U'^{\pm} \\ U''^{\pm} \end{pmatrix} \pm ih\delta(x-y)\delta(t)\begin{pmatrix} I \\ I \end{pmatrix};$$

then the above reduction can be applied to this system as well. Here and below $A_0 = A - V \cdot I$.

Let us note that without any loss of the generality one can assume that

$$|V| \ge \frac{\epsilon_0}{(m+1)} \qquad \text{in} \quad B(0,1). \tag{17.3.18}$$

In fact, for $m \ge C_0$ this condition follows from $(17.3.3)_{\pm}$ and for $m \le C_0$ one can easily see that under condition (17.3.10) the operator in the left-hand expression of (17.3.13) is elliptic for $|\tau| \le \epsilon$, $|V| \le \epsilon$ in which case all the statements below can be easily proven by means of simple elliptic arguments (instead of standard hyperbolic arguments).

Let E' be an operator with symbol equal to

$$F^{-\frac{1}{2}}\big((m - V) + (m+1)^{-1}\tau\big)^{\frac{1}{2}}$$

in the zone in question. Let us substitute $U_{1r} = E'u$ and note that

$$\mathcal{L}^* F^{-1} \mathcal{L} = \sum_{j,k} P_j F^{-1} g^{jk} P_k \cdot I + \mu h \mathcal{M}$$

where here and below $\mathcal{M}$ is a $(\mu^{-1}h, h)$-pseudodifferential operator with respect to (x,t) which we change if necessary. Then multiplying (17.3.13) by E' we obtain the equation

$$\Big(\sum_{j,k} P_j F^{-1} g^{jk} P_k + \mu h \mathcal{M} - F^{-1}\Big(\big(h(m+1)^{-1} d_t - V\big)2 - m^2\Big)\Big) u \equiv f$$

with $f = -E' f_{1r}$. One can rewrite this equation in the form

$$\Big(M + 2F^{-1}(m+1)^{-1} V h D_t - F^{-1}(m+1)^{-2}(hD_t)^2 + \mu h \mathcal{M}\Big) u \equiv f \tag{17.3.19}$$

with

$$M := \sum_{j,k} P_j (F^{-1} g^{jk}) P_k + v^{\#}, \qquad v^{\#} = \frac{1}{F}(m^2 - V^2). \tag{17.3.20}$$

Let us note that the operator in the left-hand expression in (17.3.19) is microhyperbolic in one of the directions $\pm\partial_\tau$ by condition (17.3.18); this statement remains true in what follows.

Let us consider the operator M as the Schrödinger operator of Chapter 13; then the scalar magnetic intensity equals 1. Let $\mathcal{F}$ be the corresponding reducing Fourier integral operator constructed in Section 13.3. Then (17.3.19) yields the equation

$$\Big(M' + M'' h D_t + M''' (hD_t)^2 + \mu h \mathcal{M}'\Big) u' \equiv f' \tag{17.3.21}$$

where $u' = \mathcal{F}_x^* u\, {}^t\mathcal{F}_y^*$, $f' = \mathcal{F}_x^*\, {}^t\mathcal{F}_y^* f$ and $M' = \mathcal{F}^* M \mathcal{F}$ is the reduced operator,

$$M'' = 2(m+1)^{-1} \mathcal{F}^* F^{-1} V \mathcal{F}, \qquad M''' = -(m+1)^{-2} \mathcal{F}^* F^{-1} \mathcal{F}$$

are scalar $\mu^{-1}h$-pseudodifferential operators and $\mathcal{M}'$ is an operator of the same type as $\mathcal{M}$.

We consider this equation in the zone $\{\epsilon\mu^{-1} \le |t| \le T^*,\ |\tau| \le \mu h^{1-\delta'}\}$ with $T^* = \epsilon_0$ for $d = 3$, $T^* = \mu\epsilon_0$ for $d = 2$ and with $T^* = \nu^{-1}\mu\epsilon_0$ for

$d = 2$ and some additional restriction where $\epsilon_0 = \epsilon_0(c) > 0$ is a small enough constant. The restriction $\epsilon\mu^{-1} \le T$ is due to the same reasons as in Section 13.4.

First of all the arguments used in the proof of Propositions 2.1.12 and 2.1.16 with the additional arguments used in the proof of Theorem 13.4.3 imply the following assertion:

Proposition 17.3.6 [9]**.** *(i) Let* $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$ *where* q', q'' *are symbols of type* (13.4.23) *and let*

$$|\nabla_{x',\xi'} M'(x,\xi)| \le c\gamma \tag{17.3.22}$$

on $\mathsf{supp}(q')$ *where*

$$\gamma \ge \mu^{-\frac{1}{2}} h^{\frac{1}{2}(1-\delta')} + C_0\mu h^{1-\delta'} + C_0\mu^{-l} \qquad \text{for } d = 2, \tag{17.3.23}_{(2)}$$

$$\gamma \ge h^{\frac{1}{2}(1-\delta')} + C_0\mu h^{1-\delta'} + C_0\mu^{-l} \qquad \text{for } d = 3. \tag{17.3.23}_{(3)}$$

Then estimate (13.4.9) *remains true for* u' *(instead of* $\mathcal{U}$*) for all* $x, y \in \mathbb{R}^d$ *and for all* $\tau : |\tau| \le \mu h^{1-\delta}$ *with arbitrary* T *such that*

$$T \in [\epsilon\mu^{-1}, \mu\epsilon_0] \qquad \text{for } d = 2, \tag{17.3.24}_{(2)}$$

$$T \in [\epsilon\mu^{-1}, \epsilon_0] \qquad \text{for } d = 3. \tag{17.3.24}_{(3)}$$

(ii) Moreover, let $d = 2$*, let conditions* $(17.2.28)_{1-3}$ *be fulfilled and suppose*

$$\nu \ge \bar{\nu}\mu h^{1-\delta'}, \tag{17.3.25}$$

$$\nu^{-1}(M'' - \tilde{M}) \in \mathbf{\Psi}_{\mu^{-1}h,K}(T^*\mathbb{R}) \tag{17.3.26}$$

where M'' *is obtained from* M' *by the substitution* $(\mu^2 x_2^2 + h^2 D_2^2) \mapsto \lambda \in [0, C_0]$ *and* $\tilde{M} = \mathsf{const}$*. Then under assumptions*

$$|\nabla_{x',\xi'} M'(x,\xi)| \le c\nu\gamma \tag{17.3.22}'$$

on $\mathsf{supp}(q')$ *and*

$$\gamma \ge \mu^{-\frac{1}{2}} h^{\frac{1}{2}(1-\delta')} + C_0\bar{\nu}\mu h^{1-\delta'} + C_0\mu^{-l} \qquad \text{for } d = 2 \tag{17.3.23}'_{(2)}$$

estimate (13.4.9) *for* u' *remains true for* $|\tau| \le \mu h^{1-\delta'}$ *and*

$$T \in [\epsilon\mu^{-1}, \nu^{-1}\mu\epsilon_0] \qquad \text{for } d = 2. \tag{17.3.24}'_{(2)}$$

[9] Cf. Proposition 13.4.8.

Remark 17.3.7. (i) Condition (17.3.26) means exactly that multiplying M' by an appropriate operator E'' we can obtain

$$E''M' = B(x_1, \hbar D_1) + \mu^2 x_2^2 + h^2 D_2^2$$

where B satisfies condition (13.4.11). One can use this reformulation even for $\nu = 1$ in the proof.

(ii) If $\nu \ge \epsilon_0 \mu^{-2}\bar{\nu}$ and (17.3.25) holds then assumption (17.3.26) is equivalent to

$$|D^\alpha v^\#| \le c\nu \qquad \forall \alpha : 1 \le |\alpha| \le K; \tag{17.2.28)$_4$}$$

recall that $v^\# = F^{-1}(m^2 - V^2)$.

Proposition 17.3.8 [10]**.** *(i) Let $Q' = \mathsf{Op}(q')$, $Q'' = \mathsf{Op}(q'')$ where q', q'' are symbols of type* (13.4.23) *and let*

$$\epsilon_0\gamma \le |\nabla_{x',\xi'} M'(x,\xi)| \le c\gamma \tag{17.3.27}$$

on $\mathsf{supp}(q')$ *where*

$$1 \ge \gamma \ge \mu^{\frac12} h^{\frac12(1-\delta')} + C_0\mu^{-1}. \tag{17.3.28}$$

Then estimate (13.4.33) *remains true for u' (instead of $\mathcal{U}$) for all $x, y \in \mathbb{R}^d$ and for all $\tau : |\tau| \le \mu h^{1-\delta}$ with arbitrary T satisfying* $(17.3.24)_{(d)}$.

(ii) Moreover, let $d = 2$, let conditions $(17.2.28)_{1-3}$, (17.3.25) *and* (17.3.26) *be fulfilled and let*

$$\epsilon_0\nu\gamma \le |\nabla_{x',\xi'} M'(x,\xi)| \le c\nu\gamma, \tag{17.3.27)$'$}$$

$$1 \ge \gamma \ge \mu^{\frac12} h^{\frac12(1-\delta')}\nu^{-\frac12} + C_0\mu^{-1}. \tag{17.3.28)$'$}$$

Then estimate (13.4.33) *remains true for $|\tau| \le \mu h^{1-\delta'}$ and T satisfying* $(17.3.24)'_{(2)}$.

Remark 17.3.9. (i) Both propositions remain true if we multiply Q' and Q'' by operators $\mathsf{Op}(q_1')$, $\mathsf{Op}(q_1'')$ with $q_1', q_1'' \in \mathsf{S}_{(\boldsymbol{h},h),K}(T^*(\mathbb{R}^d_x \times \mathbb{R}_t))$.

(ii) In what follows in conditions (17.3.27), (17.3.27)$'$ the parameter $\lambda = (\mu^2 x_d^2 + h^2\xi_d^2)$ is taken such that $|M'(x,\xi)| \le \mu h^{1-\delta'}$ in which case the concrete choice of λ is not essential; compare with Remark 17.3.7(i).

[10] Cf. Proposition 13.4.9.

17.3.3 Calculations

Let us pass from estimates to calculations. Here the basic result is the following statement (with arbitrary $d \ge 2$):

Proposition 17.3.10 [11]**.** *Let conditions* (17.1.1)–(17.1.3), (13.4.1), (13.4.58), $(17.3.3)_{\pm}$ *be fulfilled. Then*

(i) Statement (i) of Proposition 13.4.20 remains true albeit now

$$\operatorname{supp}(\varkappa'_{kn}) \subset \{\tau \le V(x) - m\} \cup \{\tau \ge V(x) + m\} \tag{17.3.29}$$

and we introduce only $\varkappa'_{kn}$ and $\varkappa_{kn}(x, \tau', \tau'')$ with finite τ', τ''.

(ii) Moreover, if the condition

$$V^2 - m^2 \ge \epsilon_0 \qquad \forall x \in B(0,1) \tag{17.3.30}$$

is fulfilled (instead of condition (13.4.45)*) then Statement (ii) of Proposition 13.4.20 also remains true.*

(iii) On the other hand, if the condition

$$|V^2 - m^2| + (m+1)|\nabla V| \ge \epsilon_0 \qquad \forall x \in B(0,1) \tag{17.3.31}$$

is fulfilled (instead of condition (13.4.46)*) then Statement (i) of Proposition 13.4.20 also remains true.*

(iv) Further, for $\tau_1 < \tau_2$

$$\operatorname{tr} \varkappa_{00}(x, \tau_1, \tau_2) = \int_{\tau_1}^{\tau_2} \operatorname{tr} \varkappa'_{00}(x, \tau) d\tau = (2\pi)^{-d} \frac{\mathsf{D}}{2} \sum_{\eta = \pm 1} \int_{\tau_1 \le H_\eta(x,\xi) \le \tau_2} q'_0(x,\xi) q''_0(x,\xi) \psi'(x) \psi''(x)\, d\xi \tag{17.3.32}$$

where

$$H_\eta(x,\xi) = V + \eta \Big(\sum_{j,k} g^{jk} (\xi_j - V_j)(\xi_k - V_k) + m^2 \Big)^{\frac{1}{2}} \tag{17.3.33}$$

and q'_0, q''_0 are the principal symbols of the operators Q', Q''.

[11] Cf. Proposition 13.4.20.

(v) Furthermore, for $q'_0 = q''_0 = 1$

$$\operatorname{tr} \varkappa_{00}(x,\tau_1,\tau_2) = (2\pi)^{-d}\varpi_d \frac{\mathsf{D}}{2}\sqrt{g}\times \operatorname{sgn}(\tau - V)\big((\tau - V)^2 - m^2\big)_+^{\frac{d}{2}}\big|_{\tau=\tau_1}^{\tau=\tau_2}\psi'\psi''. \tag{17.3.34}$$

(vi) Moreover, let $Q' = Q'' = I$ *and let the set of Pauli matrices contain* σ_0. *Then*

(a) $\operatorname{tr} \varkappa'_{kn} = 0$ *for odd* n.

(b) *Further, if* $d \not\equiv 2 \mod 4$ *then* $\operatorname{tr} \varkappa'_{kn} = 0$ *for even* k.

(c) *On the other hand, if* $d \equiv 2 \mod 4$ *then* $\operatorname{tr} \varkappa'_{kn}$ *does not depend on the choice of Pauli matrices of the given dimension for even* k, *and* $\operatorname{tr} \varkappa'_{kn}$ *depends only on the class of unitary equivalence of the set* $\{\sigma_0, \dots, \sigma_d\}$ *for odd* k: *namely, the replacement* $\sigma_0 \to -\sigma_0$ *yields the replacement* $\operatorname{tr} \varkappa'_{kn} \to -\operatorname{tr} \varkappa'_{kn}$.

(vii) Finally, let $Q' = Q'' = I$ *and suppose that the set of Pauli matrices does not contain* σ_0 *principally (principally massless particle; this is possible only for odd* d*). Then*

(a) *For* $d \equiv 3 \mod 4$ $\operatorname{tr} \varkappa'_{kn} = 0$ *for odd* n; *while for even* n $\operatorname{tr} \varkappa'_{kn}$ *does not depend on the choice of the Dirac matrices of the given dimension for odd* k, *and* $\operatorname{tr} \varkappa'_{kn}$ *depends only on the unitary equivalence class of the set* $\{\sigma_1, \dots, \sigma_d\}$ *for even* k: *namely, the replacement* $\sigma_1 \to -\sigma_1$ *yields the replacement* $\operatorname{tr} \varkappa'_{kn} \to -\operatorname{tr} \varkappa'_{kn}$.

(b) *On the other hand, if* $d \equiv 1 \mod 4$ *then* $\operatorname{tr} \varkappa'_{kn} = 0$ *for odd* n *and* $\operatorname{tr} \varkappa'_{kn}$ *does not depend on choice of Pauli matrices of the given dimension for even* k, *and* $\operatorname{tr} \varkappa'_{kn}$ *depends only on the class of the unitary equivalence of the set* $\{\sigma_1, \dots, \sigma_d\}$ *for odd* k: *namely, the replacement* $\sigma_1 \to -\sigma_1$ *yields the replacement* $\operatorname{tr} \varkappa'_{kn} \to -\operatorname{tr} \varkappa'_{kn}$.

Proof. (a) The proof of Statements (i)–(v) repeats the proof of Proposition 13.4.20 with the following modification: for $m \le C_0 h^{-l}$ we use direct calculation and for $m \ge C_0 h^{-l}$ we use reduction; we can choose $l \ge 0$ arbitrarily.

In order to prove Statements (vi) and (vii) let us note first that the replacement $\sigma_j \to q^\dagger \sigma_j q$ for all j with the unitary matrix q yields the replacement $U \to q^\dagger U q$ and does not change $\mathsf{tr}\, \varkappa'_{kn}$. Moreover, let us note that the complex conjugation of operator A also does not change $\mathsf{tr}\, \varkappa'_{kn}$ because A is a self-adjoint operator.

(b) Furthermore, in the case of Statement (vi) let us note that the replacement $(\mu, h) \to (-\mu, -h)$ is equivalent to the replacement $\sigma_j \to \sigma_0 \sigma_j \sigma_0$ for all j and therefore does not change $\mathsf{tr}\, \varkappa'_{kn}$; then $\mathsf{tr}\, \varkappa'_{kn} = 0$ for odd n (see also the arguments of the proof of Proposition 13.4.20 associated with the Jacobian and mollification).

Let us also note that the replacement $h \to -h$ is equivalent to the complex conjugation and the replacement $\{\sigma_0, \dots, \sigma_d\} \to \{\bar\sigma_0, \dots, \bar\sigma_d\}$ where the bar means a complex conjugation. For $d \not\equiv 2 \mod 4$ the latter set of Pauli matrices is unitarily equivalent to $\{\sigma_0, \dots, \sigma_d\}$ and for $d \not\equiv 0 \mod 4$ it is unitarily equivalent to the set $\{-\sigma_0, \dots, -\sigma_d\}$ (see formula (5.A.24)). This observation yields all the remaining assertions in (vi).

(c) On the other hand, in the case of Statement (vii) let us note that the replacement $\mu \to -\mu$ is equivalent to the complex conjugation of operator and the replacement $\{\sigma_1, \dots, \sigma_d\} \to \{\bar\sigma_1, \dots, \bar\sigma_d\}$; for $d \equiv 3 \mod 4$ these sets are equivalent and therefore $\mathsf{tr}\, \varkappa'_{kn} = 0$ for odd k. Moreover, the replacement $(\mu, h) \to (-\mu, -h)$ is equivalent to the replacement $\sigma_j \to -\sigma_j$ for all j and this observation concludes the proof of (vii) for $d \equiv 3$.

Finally, let us note that the replacement $h \to -h$ is equivalent to the complex conjugation of the operator A and the replacement $\{\sigma_1, \dots, \sigma_d\} \to \{\bar\sigma_1, \dots, \bar\sigma_d\}$. For $d \equiv 1$ these sets are equivalent and therefore $\mathsf{tr}\, \varkappa'_{kn} = 0$ for odd n. Using the replacement $\mu \to -\mu$ (see above) one can easily conclude the proof of (vii) for $d \equiv 1$. □

Repeating the corresponding arguments used in the proof of (13.4.69) one can prove the similar formula

$$\mathcal{N}^{\mathsf{MW}\prime}(\tau, \mu h) = \partial_\tau \mathcal{N}^{\mathsf{MW}}(x, \tau_1, \tau, \mu h) \sim \sum_{k \in \mathbb{Z}^+} \mathsf{tr}\, \varkappa'_{k0}(x, \tau)(\mu h)^k \tag{17.3.35}$$

in the weak sense.

In the calculation below the dependence on x is not essential and without any loss of the generality one can assume that $V = 0$.

Consider the case $d > 2r = \mathsf{rank}(F_{jk})$. Note that then $\mathcal{N}^{\mathsf{MW}\prime}(\tau, \mu h)$ is an even function of τ and therefore $\mathsf{tr}\, \varkappa'_{k0}(\tau)$ are also even functions of τ. Then one can introduce their odd (on τ) primitive functions $\mathcal{N}^{\mathsf{MW}}(\tau, \mu h)$ and $\mathsf{tr}\, \varkappa_{k0}(\tau)$.

The same is true for $d = 2r$ if we treat the even (with respect to τ) parts of $\mathcal{N}^{\mathsf{MW}\prime}(\tau, \mu h)$ and $\mathsf{tr}\, \varkappa'_{k0}(\tau)$ and the odd parts of $\mathcal{N}^{\mathsf{MW}}(\tau, \mu h)$ and $\mathsf{tr}\, \varkappa_{k0}(\tau)$. In any case one can treat $\mathcal{N}^{\mathsf{MW}}(\tau, \mu h)$ as Riemann sums given by (13.A.4) for the function

$$\mathcal{K}(\tau, z) = c_0 \big(\tau^2 - z_1 - \dots - z_r\big)_+^p \, \mathsf{sgn}\, \tau$$

with $p = \frac{1}{2}(d - 2r)$, $c_0 = (2\pi)^{r-d} 2^{-r-1} \varpi_{d-2r} \mathsf{D} \sqrt{g}$. We assert that

(17.3.36) The function $\mathcal{K}(\tau, z)$ mollified with respect to τ is smooth with respect to z.

In fact, any mollification with an even mollifying function $\phi(\tau)$ gives 0 while mollification with an odd mollifying function $\phi(\tau)$ (equal to $\phi_0(\tau^2)\tau$ with $\phi_0 \in \mathscr{C}_0^K(\mathbb{R})$) is equal to

$$\mathsf{const} \int_0^\infty \phi_0(\tau)(\tau - t)_+^p \, d\tau$$

with $t = z_1 + \dots + z_r + m^2$ where we change constants if necessary. Integrating by parts n times we obtain for $t \ge 0$

$$\mathsf{const} \int_0^\infty \phi_0^{(n)}(\tau)(\tau - t)_+^{p+n} \, d\tau$$

and the smoothness with respect to t is obvious. Therefore we have proven Statement (i) of the following

Proposition 17.3.11 [12]**.** *Let $Q' = Q'' = I$, $\psi' = \psi'' = 1$. Then*

(i) For $d > 2r$ the following equalities are true

$$\mathsf{tr}\, \varkappa_{k0} = \mathsf{D} \partial_t^k \, \mathsf{sgn}(\tau - V)\big((\tau - V)^2 - m^2 + t\big)_+^{\frac{d}{2}}\big|_{t=-0} \times \mathcal{P}_k(f_1^2, \dots, f_r^2)\sqrt{g} \tag{17.3.37}$$

[12] Cf. Proposition 13.4.22.

where $\mathcal{P}_k$ are homogeneous symmetric polynomials of degree $\frac{k}{2}$ also depending on d and r and vanishing for odd k. In particular,

$$\operatorname{tr} \varkappa_{20} = 2c\mathsf{D}\partial_t^2 \operatorname{sgn}(\tau - V)\big((\tau - V)^2 - m^2 + t\big)_+^{\frac{d}{2}}\big|_{t=-0} F^2\sqrt{g} \tag{17.3.38}$$

where c and F are introduced in Proposition 13.4.22.

(ii) For $d = 2r$ these equalities hold for the odd with respect to $(\tau - V)$ parts of $\varkappa_{k0}(\tau)$ and the even part of $\varkappa_{k0}(\tau)$ vanishes for $k \neq r$, while for $k = r$ under condition (17.1.15) *it is equal to*

$$\operatorname{tr} \varkappa_{r0\mathrm{even}} = -\bar{\varkappa}\frac{\mathsf{D}}{2}(4\pi)^{-r}\big(\theta(\tau - V + m) - \theta(\tau - V - m)\big) f_1 \dots f_r\sqrt{g} \tag{17.3.39}$$

with $\bar{\varkappa}$ introduced in Theorem 17.1.2. In particular, for $d = 2$ the coefficient in the right-hand expression is equal to $-\frac{\mathsf{D}}{8\pi}\varsigma F_{12}$.

Proof. In order to prove Statement (ii) it is sufficient to observe that outside of the discontinuity points the even part of $\mathcal{N}^{\mathsf{MW}}(\tau, \mu h)$ is equal to the right-hand expression of (17.3.39) multiplied by $(\mu h)^r$; this is due to formula (17.1.13).

Remark 17.3.12. In the manner of Remark 13.4.23 we conclude that if Q' is an operator with Weyl symbol q' even with respect to ξ and h and if $q'' = 1$, $\psi' = \psi'' = 1$ in a neighborhood of $\operatorname{supp}(q')$ then Statements (vi) and (vii) of Proposition 17.3.10 remain true.

17.3.4 Synthesis

Now, repeating the corresponding arguments of Section 13.4 we easily obtain the following statements:

Proposition 17.3.13 [13]**.** *Let conditions* (17.1.1)–(17.1.3), (17.2.1) *and* (13.4.1) *be fulfilled. Then*

(i) If one of the conditions (17.3.6), (17.3.7) *is fulfilled then estimate* (13.4.62) *holds for $|\tau| \le \epsilon$ with $T = \mu\epsilon_0$ for $d = 2$ and $T = \epsilon_0$ for $d = 3$.*

[13] Cf. Proposition 13.4.20.

(ii) Let $d = 2$ *and conditions* $(17.2.28)_{1-3}$, (17.3.25), (17.3.26), (17.3.30) *be fulfilled and let* $\tilde{Q}' = \mathsf{Op}(\tilde{q}')$, $\tilde{Q}'' = \mathsf{Op}(\tilde{q}'')$ *with* $\tilde{q}', \tilde{q}'' \in \mathsf{S}_{\hbar,\gamma,\gamma,K}(T^*\mathbb{R})$. *Moreover, let conditions* $(17.3.27)'$, $(17.3.28)'$ *be fulfilled on* $\mathsf{supp}(\tilde{q}')$ *and* $Q' = \mathcal{F}\tilde{Q}'\mathcal{F}^*$, $Q'' = \mathcal{F}\tilde{Q}''\mathcal{F}^*$. *Then estimate* (13.4.62) *holds for* $|\tau| \le \mu h^{1-\delta'}$ *with* $T = \nu^{-1}\mu\epsilon_0$.

(iii) Let $d = 3$, $\tilde{q}', \tilde{q}' \in \mathsf{S}_{\boldsymbol{h}',\gamma,\gamma,K}(T^*\mathbb{R}^2)$ *and let conditions* (17.3.30), (17.3.27), (17.3.28) *be fulfilled on* $\mathsf{supp}(\tilde{q}')$. *Let* $Q' = \mathcal{F}\tilde{Q}'\mathcal{F}^*$, $Q'' = \mathcal{F}\tilde{Q}''\mathcal{F}^*$. *Then estimate* (13.4.62) *holds for* $|\tau| \le \mu h^{1-\delta'}$ *with* $T = \epsilon_0$.

Theorem 17.3.14 [14]**.** *Let conditions* (17.1.1)–(17.1.3), (17.2.1), (13.4.1) *and one of conditions* (17.3.6), (17.3.7) *be fulfilled. Let us define*

$$\mathsf{R}^{\mathsf{W}\prime} := \Big| \iint \phi(\tau')\psi(x)\,\mathsf{tr}\big(e(x,x,\tau',\tau) - h^{-d}\sum_{0\le k\le M} \varkappa_{k0}(x,\tau',\tau)(\mu h)^k\big)\,dx d\tau \Big| \tag{17.3.40}$$

with $\phi \in \mathscr{C}_0^K([-c,c])$. *Then estimates* $(13.4.74)_{(2,3)}$ *hold for* $d = 2,3$ *respectively,* $|\tau| \le \epsilon(m+1)^{-1}$.

Proposition 17.3.15 [15]**.** *Let conditions* (17.1.1)–(17.1.3), (17.2.1), (13.4.1) *and* (17.3.30) *be fulfilled. Let* $\tilde{Q}' = \mathsf{Op}(\tilde{q}')$ *where* $\tilde{q}' \in \mathsf{S}_{\boldsymbol{h}',\gamma,\gamma,K}(T^*\mathbb{R}^{d-1})$, γ *satisfies* $(17.3.28)'$, $\mathsf{diam\ supp}\,\tilde{q}' \le c\gamma$, *and let* $Q' = \mathcal{F}\tilde{Q}'\mathcal{F}^*$. *Then*

(i) Let $d = 2$, *let conditions* $(17.2.28)_{1-3}$, (17.3.25), (17.3.26) *be fulfilled and let condition* $(17.3.27)'$, $(17.3.28)'$ *be fulfilled on* $\mathsf{supp}(\tilde{q}')$. *Let us define*

$$\mathsf{R}^{\mathsf{W}\prime\prime} := \Big| \iint \phi(\tau')\,\mathsf{tr}\big((Q'_x\psi(x)e)(x,x,\tau',\tau) - h^{-d}\sum_{k+n\le M} \varkappa_{Q'\psi kn}(x,\tau',\tau)(\mu h)^k h^n\big)\,dx d\tau' \Big|. \tag{17.3.41}$$

Then estimate $(13.4.76)_{(2)}$ *holds.*

(ii) Let $d = 3$, $\nu = 1$ *and let condition* (17.3.27) *be fulfilled on* $\mathsf{supp}(\tilde{q}')$. *Then estimate* $(13.4.76)_{(3)}$ *holds.*

---

[14] Cf. Theorem 13.4.25.

[15] Cf. Proposition 13.4.27.

Proposition 17.3.16 [16]**.** *Let conditions* (17.1.1)–(17.1.3), (17.2.1), (13.4.1) *and* (17.3.30) *be fulfilled. Let* $\vartheta = 0$. *Then*

(i) Let $d = 2$ *and let conditions* $(17.2.28)_{1-3}$, (17.3.25), (17.3.26) *be fulfilled. Then estimate* $(13.4.78)_{(2)}$ *holds where* Ω_2 *is introduced for the reduced Schrödinger operator.*

(ii) For $d = 3$ *estimate* $(13.4.78)_{(3)}$ *holds where* Ω_2 *is introduced for the reduced Schrödinger operator.*

Theorem 17.3.17 [17]**.** *Let* $d = 3$ *and let conditions* (17.1.1)–(17.1.3), (17.2.1), (13.4.1) *and* (17.3.30) *be fulfilled. Then for* $\mu \le h^{-\frac{1}{3}+\delta}$ *estimate* $(13.4.74)_{(3)}$ *holds.*

Theorem 17.3.18 [18]**.** *(i) Under the conditions of Theorem 17.3.14 estimates* $(13.4.74)_{(2,3)}$ *(with* $\vartheta = 0$*) remain true for*

$$\mathsf{R}^{\mathsf{MW}} = \Big| \iint \phi(\tau)\psi(x)\,\mathsf{tr}\big(e(x,x,\tau,0) - h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau,0,\mu h)\big)\,dx d\tau\Big|. \tag{17.3.42}$$

(ii) Under the assumptions of Proposition 17.3.16(i) estimate $(13.4.90)_{(2)}$ *(with* $\vartheta = 0$*) remains true with* V *replaced by*

$$V^{\#} = m^2 - V^2 \tag{17.3.43}$$

in the right-hand expression.

17.4 Temperate Magnetic Field

17.4.1 Separation of Variables and Decomposition

In this section we assume that

$$h^{-\delta} \le \mu \le \epsilon_1 h^{-1} \tag{17.4.1}$$

[16] Cf. Proposition 13.4.28.
[17] Cf. Theorem 13.4.25.
[18] Cf. Theorem 13.4.30.

where small enough ϵ_1 will be chosen later. The case $\mu \ge \epsilon_1 h^{-1}$ will be treated in the next section. Later conditions (17.3.30) and (13.4.1) will appear in some statements of this section. Let us make a decomposition similar to those of the proof of Theorem 17.1.2. Namely, let us note that every $\mathbb{H}$-valued function v on $\mathbb{R}$ (with $\mathbb{H} = \mathbb{C}^D$) can be written in the form

$$w = \sum_{j\in\mathbb{Z}^+} \bigl(w_j^+ \Upsilon_{j-1} + w_j^- \Upsilon_j\bigr), \qquad w_j^\pm \in \mathbb{H}^\pm, \quad w_0^+ = 0 \tag{17.4.2}$$

where $\mathbb{H}^\pm = \mathsf{Ker}(\sigma_1 \pm i\sigma_2)$, $\Upsilon_j = \Upsilon_j(x_d) = (\mu/h)^{\frac14} \upsilon_j\bigl(\sqrt{\mu/h}\, x_d\bigr)$, where υ_j are real-valued orthonormal Hermite functions satisfying $(13.5.32)_{1-2}$. Let us set $w_j = (w_j^+, w_j^-) \in \mathbb{H}$; so the isomorphism

$$\mathfrak{R} : \mathscr{L}^2(\mathbb{R}) \to \mathbb{H}^- \oplus \sum_{j\ge 1} \mathbb{H} \tag{17.4.3}$$

is introduced.

Formulae $(13.5.32)_{1-2}$ and the definition of $\mathbb{H}^\pm$ yield that for $w_j^\pm \in \mathbb{H}^\pm$

$$\bigl(hD_d\sigma_1 + \mu x_d \sigma_2\bigr)\bigl(w_j^+ \Upsilon_{j-1} + w_j^- \Upsilon_j\bigr) = \sigma_2 \sqrt{2j\mu h}\bigl(w_j^+ \Upsilon_{j-1} + w_j^- \Upsilon_j\bigr). \tag{17.4.4}$$

Similarly, every $\mathsf{Hom}(\mathbb{H},\mathbb{H})$-valued function $\mathcal{U}$ on $\mathbb{R}^2$ can be written in the form

$$\begin{aligned}\mathcal{U} = \sum_{j,k\in\mathbb{Z}^+} \bigl(&\mathcal{U}_{jk}^{++} \Upsilon_{j-1}(x_d)\Upsilon_{k-1}(y_d) + \mathcal{U}_{jk}^{+-} \Upsilon_{j-1}(x_d)\Upsilon_k(y_d) + \\ &\mathcal{U}_{jk}^{-+} \Upsilon_j(x_d)\Upsilon_{k-1}(y_d) + \mathcal{U}_{jk}^{--} \Upsilon_j(x_d)\Upsilon_k(y_d)\bigr)\end{aligned} \tag{17.4.5}$$

with $\mathcal{U}_{jk}^{\zeta\zeta'} \in \mathsf{Hom}(\mathbb{H}^\zeta, \mathbb{H}^{\zeta'})$ where for $j = 0$, $\zeta = +$ and for $k = 0$, $\zeta' = +$ the corresponding components vanish. Using these four blocks (with different ζ and ζ') one can introduce the blocks $\mathcal{U}_{jk}^{\zeta,} \in \mathsf{Hom}(\mathbb{H}^\zeta, \mathbb{H})$, $\mathcal{U}_{jk}^{,\zeta'} \in \mathsf{Hom}(\mathbb{H}, \mathbb{H}^{\zeta'})$ and $\mathcal{U}_{jk} \in \mathsf{Hom}(\mathbb{H},\mathbb{H})$.

Now let $\mathcal{U} = \mathcal{U}(x,y,t)$ be defined in Subsection 17.2.3. Then $\mathcal{U}_{jk} = \mathcal{U}_{jk}(x',y',t)$, etc., and the properties of $\mathcal{U}$ yield that

$$\mathcal{U}_{jk}(x',y',t) = \mathcal{U}_{kj}^\dagger(y',x',-t) \tag{17.4.6}$$

and

$$|F_{t\to h^{-1}\tau} \chi_{T,T'}(t)\mathcal{U}_{jk}| \le CT\mu h^{1-d}(1+|\tau|)^{d-1} \qquad \forall x',y' \in \mathbb{R}^{d-1} \quad \forall j,k \in \mathbb{Z}^+ \quad \forall \tau \in \mathbb{R}, \tag{17.4.7}$$

and Theorem 13.2.13 which obviously holds under condition (17.4.1) for the Dirac operator also yields that

$$(17.4.8)\quad |F_{t\to h^{-1}\tau}\chi_{T,T'}(t)\mathcal{U}_{jk}| \le CTh^s(1+j+k)^{-s}$$
$$\forall x', y' \in \mathbb{R}^{d-1} \quad \forall \tau \in \mathbb{R} : |\tau| \le c \quad \forall j,k \in \mathbb{Z}^+ : j+k \ge C_0\mu^{-1}h^{-1}+h^{-\delta}$$

where $T \ge h^{1-\delta}$ and T' are arbitrary.

Formula (17.4.4) yields that the operator $\mathcal{A} = J^*\mathcal{F}^*A\mathcal{F}J$ applied to $\mathcal{U}$ can be replaced[19] *in the indicated representation* by the operator

$$(17.4.9)\qquad \mathcal{A} = \mathcal{A}_0 + \mathcal{A}_1 + \mathcal{A}_2$$

where we use the same notation, $\mathcal{A}_0$ and $\mathcal{A}_1$ are of the block-diagonal type[20] and

(i) For $d = \mathsf{D} = 2$ the blocks of $\mathcal{A}_0$ are

$$(17.4.10)_j\quad \mathcal{A}_{0(j)} = \sum_{0\le n\le N} B_n(x_1,\hbar D_1,\hbar)\mu^{-2n}(2j\mu h)^{n+\frac12}\sigma_2 + \sigma_0 m + \bar W(x_1,\hbar D_1,\hbar)I \qquad (j\ge 1),$$

$$(17.4.10)_0\qquad \mathcal{A}_{0(0)} = -\varsigma m + \bar W(x_1,\hbar D_1,\hbar)I,$$

and the blocks of $\mathcal{A}_1$ are

$$(17.4.11)_j\quad \mathcal{A}_{1(j)} = \sum_{0\le n\le N} B_n(x_1,\hbar D_1,\hbar)\mu^{1-2n}h\times \bigl(\mathcal{P}'_{n-1}(2j\mu h)\sigma_1 + \mathcal{P}''_{n-1}(2j\mu h)\sigma_2\bigr)\sqrt{2j\mu h} \qquad (j\ge 1),$$

$$(17.4.11)_0\qquad \mathcal{A}_{1(0)} = 0$$

respectively, $\mathcal{P}'_{n-1}$ and $\mathcal{P}''_{n-1}$ are absolute (i.e., independent of the operator) polynomials of degree $n-1$ and the operator

$$(17.4.12)\qquad \mathcal{A}_2 = T^*\mathcal{F}^*(V\cdot I)\mathcal{F}T - \bar W\cdot I$$

---

[19] With an error $O(h^s)$ after this application.

[20] In what follows the blocks of an operator $\mathcal{B}$ of the block-diagonal type are denoted by $\mathcal{B}_{(j)}$.

has blocks

$$\mathcal{A}_{2,jk} = W_{jk}\cdot I + W^0_{jk}\sigma_0, \tag{17.4.13}$$

which for $j=0$ and (or) for $k=0$ have an additional factor Π_- and (or) $\Pi^\dagger_+$ from the left and (or) right respectively where $\Pi_\pm : \mathbb{H}\to\mathbb{H}^\pm$ are projectors and the adjoint operators $\Pi^\dagger_\pm : \mathbb{H}^\pm\to\mathbb{H}$ are embedding operators.

All these blocks can contain the following small factors: $\hbar$ arising from the commutation and surely contained in W^0_{jk} and (or) μ^{-1} (there are at least $|j-k|$ copies of this factor); moreover, there is surely a factor $(m+1)^{-1}$ and under conditions $(17.2.28)_{1-3}$ there is surely a factor $\bar\nu$. Therefore

$$W_{jk} = \bar\nu(m+1)^{-1}\mu^{-|j-k|}\big((1+j+k)\mu h\big)^{\frac12|j-k|}\tilde W_{jk}, \tag{17.4.14$_1$}$$

$$W^I_{jk} = \bar\nu(m+1)^{-1}h\mu^{-|j-k|-1}\big((1+j+k)\mu h\big)^{\frac12|j-k|}\tilde W^I_{jk} \tag{17.4.14$_2$}$$

where $W_{\dots}$ and $\tilde W_{\dots}$ here and below are $\boldsymbol{h}$-pseudodifferential operators uniformly with respect to all parameters[3)]. Moreover, for $j=k$ the operator W_{kk} surely contains either a factor $\hbar=\mu^{-1}h$ or μ^{-2} and therefore

$$W_{kk} = \bar\nu(m+1)^{-1}\mu^{-2}\big((1+j+k)\mu h\big)\tilde W_{kk}. \tag{17.4.14$_3$}$$

(ii) For $d=3$, $\mathsf{D}=4$ the blocks of $\mathcal{A}_0$ are

$$\begin{aligned}\mathcal{A}_{0(j)} = \sum_{0\le n\le N}&\big(B_n(x',\hbar D_1,\hbar)\mu^{-2n}(2j\mu h)^n\times\\ &(\sqrt{2j\mu h}\sigma_2 + hD_2\sigma_3)\big)^{\mathsf{w}} + \sigma_0 m + \bar W(x',\hbar D_1,\hbar)I \quad (j\ge1),\end{aligned} \tag{17.4.15$_j$}$$

$$\mathcal{A}_{0(0)} = \big(B_0(x',\hbar D_1,\hbar)\sigma'_3 hD_2\big)^{\mathsf{w}} + \sigma'_0 m, \tag{17.4.15$_0$}$$

and the blocks of $\mathcal{A}_1$ are

$$\begin{aligned}\mathcal{A}_{1(j)} = \sum_{0\le n\le N}&B_n(x',\hbar D_1,\hbar)\mu^{1-2n}h\times\\ &\big(\mathcal{P}'_{n-1}(2j\mu h)\sigma_1 + \mathcal{P}''_{n-1}(2j\mu h)\sigma_2\big)\sqrt{2j\mu h}+\\ &\sum_{0\le n\le N'} B'_n(x',\hbar D_1,\hbar)\mu^{-1-2n}h(2j\mu h)^n\sigma_4 \quad (j\ge1),\end{aligned} \tag{17.4.16$_j$}$$

$$(17.4.16)_0 \qquad \mathcal{A}_{1(0)} = B'_0(x', \hbar D_1, \hbar)\mu^{-1}h\sigma'_4$$

respectively, where σ'_0, σ'_3 and σ'_4 are the restrictions of σ_0, σ_3 and σ_4 to $\mathbb{H}^-$, σ_4 is defined in (17.2.2), $\mathcal{A}_2$ is defined by (17.4.12) and its blocks are

$$\mathcal{A}_{2,jk} = W_{jk} \cdot I + \sum_{l=1,2,3} W^l_{jk}\hat{\sigma}_l, \tag{17.4.17}$$

where W_{jk} and W^l_{jk} satisfy $(17.4.14)_{1-3}$ with $\bar{\nu} = 1$ and for $j = 0$ and (or) $k = 0$ the right-hand expression of (17.4.17) has an additional factor Π_- and (or) $\Pi^\dagger_+$ from the left and (or) right respectively.

(iii) Similar formulae are valid for $d = 3$, $\mathsf{D} = 2$ but in $(17.4.15)_j$, $(17.4.15)_0$ the terms $\sigma_0 m$ and $\sigma'_0 m$ are absent:

$$(17.4.18)_j \quad \mathcal{A}_{0(j)} = \sum_{0\le n\le N} \big(B_n(x', \hbar D_1, \hbar)\mu^{-2n}(2j\mu h)^n \times (\sqrt{2j\mu h}\sigma_2 + hD_2\sigma_3)\big)^{\mathsf{w}} + \bar{W}(x', \hbar D_1, \hbar)I \quad (j \ge 1),$$

$$(17.4.18)_0 \qquad \mathcal{A}_{0(0)} = \big(B_0(x', \hbar D_1, \hbar)\sigma'_3 hD_2\big)^{\mathsf{w}},$$

in $(17.4.16)_j$, $(17.4.16)_0$ the matrices σ_4, σ'_4 are replaced by I

$$(17.4.19)_j \quad \mathcal{A}_{1(j)} = \sum_{0\le n\le N} B_n(x', \hbar D_1, \hbar)\mu^{1-2n}h \times \big(\mathcal{P}'_{n-1}(2j\mu h)\sigma_1 + \mathcal{P}''_{n-1}(2j\mu h)\sigma_2\big)\sqrt{2j\mu h} + \sum_{0\le n\le N'} B'_n(x', \hbar D_1, \hbar)\mu^{-1-2n}h(2j\mu h)^n I \quad (j \ge 1),$$

$$(17.4.19)_0 \qquad \mathcal{A}_{1(0)} = B'_0(x', \hbar D_1, \hbar)\mu^{-1}hI$$

and in (17.4.17) the matrices $\hat{\sigma}_l$ are replaced by σ_l

$$\mathcal{A}_{2,jk} = W_{jk} \cdot I + \sum_{l=1,2,3} W^l_{jk}\sigma_l. \tag{17.4.20}$$

So far for $d = 3$, $W_{jk} = W_{jk}(x', \hbar D', \hbar)$ but later we will get rid of $\hbar D_2$.

17.4.2 Further Reduction

Thus we have the problem

$$\Big(hD_t - (m+1)(\mathcal{A}_{0(j)} + \mathcal{A}_{1(j)})\Big)\mathcal{U}_{jl} - (m+1)\sum_{|k-j|\le N} \mathcal{A}_{2,jk}\mathcal{U}_{kl} \equiv 0, \tag{17.4.21}$$

$$\mathcal{U}_{jl}|_{t=0} = \delta_{jl}\delta(x'-y')I \tag{17.4.22}$$

with $N = N(s,\delta)$.

Formulae (17.4.8), (17.4.7) and the uniform (with respect to all parameters[3)]) ellipticity of the operator $\big(hD_t - (m+1)(\mathcal{A}_{0(j)} + \mathcal{A}_{1(j)})\big)$ for the τ, j and ξ_2 (for $d=3$) indicated below and the fact that the operator $\mathcal{A}_{2,jk}$ surely contains the factor $(m+1)^{-1}\mu^{-1}$ yield the following

Proposition 17.4.1. *Let condition* (17.4.1) *be fulfilled with* $\epsilon_1 = \epsilon_1(c,\epsilon_0,s)$. *Then,*

(i) The estimate

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)\mathcal{U}_{jk}| \le C'Th^s(1+j\mu h)^{-s} \tag{17.4.23}$$
$$\forall x',y' \in \mathbb{R}^{d-1} \quad \forall \tau : |\tau| \le \epsilon = \epsilon(c) \quad \forall j \ge C_0\mu^{-1}h^{-1}$$

holds with arbitrary $T \ge h^{1-\delta}$, T', s.

(ii) Moreover, if $d=2$ *and condition* (17.3.30) *is fulfilled then this estimate also holds for all* $j \le \epsilon\mu^{-1}h^{-1}$ *with a small enough constant* $\epsilon = \epsilon(c,\epsilon_0) > 0$.

(iii) If $d=3$, *condition* (17.3.30) *is fulfilled and* $Q = q(x', h'D')$ *with* q *is supported in the domain* $\{|\xi_2| \le \epsilon\}$ *with a small enough constant* $\epsilon = \epsilon(c,\epsilon_0) > 0$ *then the estimate*

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_x\mathcal{U}_{jk}| \le C'Th^s \tag{17.4.24}$$
$$\forall x',y' \in \mathbb{R}^{d-1} \quad \forall \tau : |\tau| \le \epsilon \quad \forall j \le \epsilon\mu^{-1}h^{-1}$$

holds with arbitrary $T \ge h^{1-\delta}$, T', s.

(iv) On the other hand, if $d=3$ *and* q *is supported in the domain* $\{|\xi_2| \ge \frac{1}{2}C_0\}$, *then estimate* (17.4.24) *holds for all* $j \in \mathbb{Z}^+$.

In what follows $\tilde{\Omega}$ denotes the domain Ω for $d=2$ and the domain $\Omega \times \{\xi_2, |\xi_2| \le C_0\}$ for $d=3$.

Proposition 17.4.2. *(i) There exist operators* $\mathcal{T}'_{(j)} = \mathcal{T}'_{(j)}(x', \boldsymbol{h}'D', \mu^{-1}, \boldsymbol{h}')$ *with* $j \in \mathcal{J} = \{\epsilon\mu^{-1}h^{-1} \le j \le C_0\mu^{-1}h^{-1}\}$ *such that in* $\tilde{\Omega}$ *the following equalities hold:*

$$\mathcal{T}'^{*}_{(j)}\mathcal{T}'_{(j)} \equiv \mathcal{T}'_{(j)}\mathcal{T}'^{*}_{(j)} \equiv I, \tag{17.4.25}$$

$$(m+1)\mathcal{T}'^{*}_{(j)}(\mathcal{A}_{0(j)} + \mathcal{A}_{1(j)})\mathcal{T}'_{(j)} \equiv \mathcal{B}_{(j)} = \begin{pmatrix} \mathcal{B}^{+}_{(j)} & 0 \\ 0 & \mathcal{B}^{-}_{(j)} \end{pmatrix} \tag{17.4.26}$$

where $\mathcal{B}^{\pm}_{(j)}$ *are operators with principal symbols* $(m+1)\big(\bar{W}(x', \xi') \pm L_{(j)}(x', \xi')\big)I$,

$$\bar{W} = V \circ \bar{\Psi}, \tag{17.4.27}$$

$$L_{(j)} = \big(m^2 + 2j\mu h\bar{B}^2\big)^{\frac{1}{2}} \qquad \text{for } \ d = 2, \tag{17.4.28}_{(2)}$$

$$L_{(j)} = \big(m^2 + (2j\mu h + \xi_2^2)\bar{B}^2\big)^{\frac{1}{2}} \qquad \text{for } \ d = 3, \tag{17.4.28}_{(3)}$$

$$\bar{B} = \sum_{0 \le n \le N} B_n(x', \xi', 0)(2j\mu h)^n; \tag{17.4.29}$$

(ii) Moreover, the inequalities

$$|\mathcal{D}^{\alpha}D_z^{\beta}(\mathcal{T}'_{(j)} - I)| \le c_{\alpha\beta}\bar{\nu}_{\alpha}(m+1)^{-1}, \tag{17.4.30}$$

$$\begin{aligned} |\mathcal{D}^{\alpha}D_z^{\beta}\big(\mathcal{B}_{(j)} - \sigma_0 m(m+1) - (m+1)\bar{W}\cdot I\big)| \le \\ c_{\alpha\beta}\bar{\nu}_{\alpha}(m+1)^{-1} \quad \forall \alpha, \beta : |\alpha| \le K', \beta \le K' \end{aligned} \tag{17.4.31}$$

hold where here and below $\mathcal{D} = \nabla_{(x,\xi,\boldsymbol{h}',\mu^{-1})}$, $z = 2j\mu h$, j *is now any real number in the interval* $(\epsilon\mu^{-1}h^{-1}, C_0\mu^{-1}h^{-1})$, $\bar{\nu}_{\alpha} = 1$ *for* $\alpha = 0$ *and* $\bar{\nu}_{\alpha} = \bar{\nu}$ *for* $|\alpha| \ge 1$ *and we assume that conditions* $(17.2.28)_{1-3}$ *are fulfilled for* $d = 2$ *and* $\bar{\nu} = 1$ *for* $d = 3$.

Remark 17.4.3. In all the inequalities below $j, k \in \mathbb{R}^+$ (i.e., all the functions of $j, k \in \mathbb{Z}^+$ are extended to functions of $j, k \in \mathbb{R}^+$ satisfying the indicated inequalities); here $\mathcal{C}_{jj}$ and $\mathcal{C}_{jk}$ are extended separately.

Proof. The proof is obvious because for $j \ge 1$ the principal symbol of $\mathcal{A}_{0(j)}$ is unitarily equivalent to the matrix $\big(\bar{W}\cdot I + L_{(j)}\sigma_0\big)$ [21)] and the operator realizing this unitary equivalence obviously also satisfies (17.4.30). □

Let us define $\mathcal{T}'_{(j)}$ for all $j \in \mathbb{R}^+$ so that inequalities (17.4.30)–(17.4.31) are fulfilled for all j and so that $\mathcal{T}'_{(j)} = I$ for $j \le \frac{1}{2}\epsilon(\mu h)^{-1}$ and for $j \ge 2C_0(\mu h)^{-1}$. Let $\mathcal{T}' = \big(\mathcal{T}'_{(j)}\big)_{j\in\mathbb{Z}^+}$ be an operator the of block-diagonal type. Let us set $\mathcal{A}' = \mathcal{T}'^{*}\mathcal{A}\mathcal{T}'$.

Proposition 17.4.4. *There exists an operator $\mathcal{K} = \big(\mathcal{K}_{jk}\big)_{j,k\in\mathbb{Z}^+}$ such that in $\tilde{\Omega}$*

$$\mathcal{K}^*\mathcal{K} \equiv \mathcal{K}\mathcal{K}^* \equiv I, \tag{17.4.32}$$

$$(m+1)\mathcal{K}^*\mathcal{A}'\mathcal{K} \equiv \mathcal{B} + \mathcal{B}' + \mathcal{R}, \tag{17.4.33}$$

$$\mathcal{R}_{jk} \equiv 0 \qquad \forall (j,k) \in \mathcal{J}\times\mathbb{Z}^+ \cup \mathbb{Z}^+\times\mathcal{J} \tag{17.4.34}$$

where $\mathcal{B}$ is an operator of the block-diagonal type with blocks $\mathcal{B}_{(j)}$,

$$\mathcal{B}'_{jk} = \begin{pmatrix} \mathcal{B}'^{+}_{jk} & 0 \\ 0 & \mathcal{B}'^{-}_{jk}\end{pmatrix} \tag{17.4.35}$$

and for $|\alpha| \le K'$, $\beta \le K'$

$$|\mathcal{D}^\alpha D^\beta_{(z)}\mathcal{K}_{jk}| \le c_{\alpha\beta}\mu^{-|j-k|}\bar{\nu}(m+1)^{-1} \qquad \text{for } j \ne k, \tag{17.4.36}$$

$$|\mathcal{D}^\alpha D^\beta_{z}(\mathcal{K}_{jj} - I)| \le c_{\alpha\beta}\mu^{-2}\bar{\nu}(m+1)^{-1} \qquad \text{for } j = k, \tag{17.4.37}$$

$$|\mathcal{D}^\alpha D^\beta_{(z)}\mathcal{B}'_{jk}| \le c_{\alpha\beta}\mu^{-|j-k|}\bar{\nu}, \tag{17.4.38}$$

$$|\mathcal{D}^\alpha D^\beta_{(z)}\mathcal{B}'_{jj}| \le c_{\alpha\beta}\mu^{-2}\bar{\nu} \tag{17.4.39}$$

where we set $z = 2j\mu h$, $z' = 2k\mu h$, $j,k \in \big(\epsilon(\mu h)^{-1}, C_0(\mu h)^{-1}\big)$ are not necessarily integers and $D_{(z)} = D_z + D_{z'}$.

Proof. By induction on M we construct an operator $\mathcal{K} = \mathcal{K}_M$ satisfying (17.4.32), (17.4.33), (17.4.35)–(17.4.39) and with $\mathcal{R}$ such that

$$|\mathcal{D}^\alpha D^\beta_{(z)}\mathcal{R}_{jk}| \le c_{\alpha\beta}\mu^{-\max(M,|j-k|)}\bar{\nu} \tag{17.4.40}_M$$
$$\forall (j,k) \in \mathcal{J}'\times\mathbb{R}^+ \cup \mathbb{R}^+\times\mathcal{J}', \quad \mathcal{J}' = \big(\epsilon(\mu h)^{-1}, C_0(\mu h)^{-1}\big).$$

[21)] Where here and below for $d = 3, D = 2$ the notation σ_0 is used instead of σ_4.

The latter inequality with large M provides (17.4.34). Obviously, one can set $\mathcal{K}_1 = I$. Let us assume that $(17.4.40)_M$ is fulfilled and let us set $\mathcal{K}_{M+1} = \mathcal{K}_M \exp i\mathcal{L}$ where the operator $\mathcal{L}$ is Hermitian, skew-commutes with σ_0 (i.e., $\mathcal{L} = \begin{pmatrix} 0 & * \\ * & 0 \end{pmatrix}$) and the symbols of its blocks satisfy the inequalities

$$|\mathcal{D}^\alpha D^\beta_{(z)} \mathcal{L}_{jk}| \le c_{\alpha\beta}\mu^{-|j-k|}\bar\nu(m+1)^{-1}, \tag{17.4.41}$$

$$|\mathcal{D}^\alpha D^\beta_{z} \mathcal{L}_{jj}| \le c_{\alpha\beta}\mu^{-2}\bar\nu(m+1)^{-1} \tag{17.4.42}$$

and their principal symbols are defined by the equations

$$i\sigma_0(L_{(j)} + L_{(k)})(x',\xi')\mathcal{L}^0_{jk} = -(m+1)^{-1}\mathcal{R}^0_{jk} \qquad \forall (j,k) \in \mathcal{J}\times\mathbb{Z}^+ \cup \mathbb{Z}^+\times\mathcal{J} \tag{17.4.43}$$

where $\mathcal{R}^0_{jk}$ are the principal symbols of $\mathcal{R}_{jk}$. One can assume without any loss of the generality that they also skew-commute with σ_0 [22)] and the operator $\mathcal{R}$ is Hermitian.

It is easy to prove that $\mathcal{K}_{M+1}$ also satisfies (17.4.32), (17.4.33), (17.4.35), (7.4.31) and $(17.4.40)_{M+1}$. □

Remark 17.4.5. Here and in what follows the principal symbols of operators can contain the factors μ^{-1} and h separately.

Let us set $\mathcal{U}' = \mathcal{K}^*_x \mathcal{T}'^*_x \mathcal{U}\, {}^t\mathcal{T}'^*_y\, {}^t\mathcal{K}^*_y$. Then in $\tilde\Omega$

$$(hD_t - \mathcal{B}_{(j)})\mathcal{U}'_{jl} - \sum_{|j-k|\le N} \mathcal{B}'_{jk}\mathcal{U}'_{kl} \equiv 0, \tag{17.4.44}$$

$$\mathcal{U}'_{jl}|_{t=0} \equiv \delta_{jl}\delta(x'-y')I \tag{17.4.45}$$

for $j \in \mathcal{J}$. Let us decompose $\mathcal{U}'_{jl}$ into four blocks $\mathcal{U}'^{\zeta\zeta'}_{kl}$ with $\zeta,\zeta' = \pm$. Then (17.4.26), (17.4.35), (17.4.34) yields that system (17.4.44) is decomposed into four separate subsystems.

Further, if condition (17.3.30) is fulfilled then two of them are elliptic in the zone in question. Namely, subsystems with ζ such that

$$\zeta V > \epsilon_0 \qquad \text{in} \quad B(0,1) \tag{17.4.46}_\zeta$$

are elliptic. Taking into account that $\mathcal{U}'_{jk}$ also satisfies (17.4.6) and (17.4.7) we then obtain the following

[22)] Otherwise the part of $\mathcal{R}$ commuting with σ_0 can be included in $\mathcal{B}'$.

Proposition 17.4.6. *Under conditions* (17.3.30), $(17.4.46)_\zeta$ *the distribution* $\mathcal{U}'^{\zeta,}_{jk}$ *satisfies estimate* (17.4.24) *for all* $j \in \mathcal{J}$ *and* $\mathcal{U}'^{,\zeta}_{jk}$ *satisfies* (17.4.24) *for all* $k \in \mathcal{J}$.

Let us recall that the symbol of Q *is supported in* $\tilde{\Omega}$.

So we need to treat the problem

$$(hD_t - \mathcal{B}^+_{(j)})\mathcal{U}''_{jl} - \sum_{|k-j|\le N} \mathcal{B}'^+_{jk}\mathcal{U}''_{kl} \equiv 0, \tag{17.4.47}_+$$

$$\mathcal{U}''_{jk}|_{t=0} \equiv \delta_{jk}\delta(x'-y')I \tag{17.4.48}$$

where for definiteness we have assumed that condition $(17.4.46)_-$ is fulfilled and we set $\mathcal{U}''_{jk} = \mathcal{U}'^{++}_{jk}$.

Proposition 17.4.7. *There exists an operator* $\mathcal{K}' = (\mathcal{K}'_{jk})_{j,k\in\mathbb{Z}^+}$ *with scalar blocks satisfying* (17.4.32) *such that*

$$\mathcal{K}'^*(\mathcal{B}^+ + \mathcal{B}'^+ + \mathcal{R})\mathcal{K}' \equiv \mathcal{B}^+ + \mathcal{B}'' + \mathcal{R}' \tag{17.4.49}$$

where $\mathcal{R}'$ *satisfies* (17.4.34),

$$\mathcal{K}_{jk} \equiv 0 \qquad \text{for } |j-k| \ge N(1+\mu^{-2}h^{-1-\delta'}), \tag{17.4.50}$$

$$|\mathcal{D}^\alpha D^\beta_{(z)}\mathcal{B}''_{jk}| \le c_{\alpha\beta}\mu^{-|j-k|}\bar{\nu}\mu h \qquad \text{for } j \ne k \tag{17.4.51}$$

and $\mathcal{B}''_{jj}$ *satisfies* (17.4.39), $N = N(s,\delta,\delta')$ *and* $\delta' > 0$ *is arbitrary.*

Proof. We again apply induction on M fulfilling inequality $(17.4.40)_M$ at every step.

For $D = 2$ all the blocks are one-dimensional and for $D = 4$ they are two-dimensional but every block $\mathcal{B}'^+_{jk}$ is the sum of a scalar operator $\mathcal{B}'^+_{jkI}$ and an operator $\mathcal{B}'^+_{jkII}$ satisfying (17.4.51).

Let us again set $\mathcal{K}'_{M+1} = \mathcal{K}'_M \exp(i\mathcal{L}')$ where $\mathcal{L}'$ is a Hermitian operator with scalar blocks $\mathcal{L}'_{jk}$ such that

$$|\mathcal{D}^\alpha D^\beta_{(z)}\mathcal{L}'_{jk}| \le c_{\alpha\beta}\mu^{-\max(M,|j-k|)}\bar{\nu}(\mu h)^{-1}, \tag{17.4.52}$$

$\mathcal{L}'_{jj} = 0$ and the principal symbols of $\mathcal{L}'_{jk}$ are defined by the equations

$$i\big(L_{(j)} - L_{(k)}\big)\mathcal{L}'^0_{jk} + (m+1)^{-1}\mathcal{B}'^{+0}_{jkI} = 0 \qquad \text{for } j \ne k. \tag{17.4.53}$$

We see that $\mathcal{L}_{jk}$ satisfy (17.4.51).

On the other hand, even without equality (17.4.53) one can prove easily that if $\mathcal{L}'$ is a Hermitian operator with scalar blocks and $\mathcal{Q}_{(l)} = (\mathsf{Ad}\,\mathcal{L}')^l\mathcal{B}^+$, $\mathcal{Q}'_{(l)} = (\mathsf{Ad}\,\mathcal{L}')^l\mathcal{B}'^+_l$, $\mathcal{Q}'_{(l)} = (\mathsf{Ad}\,\mathcal{L}')^l\mathcal{B}''^+_{ll}$ then

$$|\mathcal{D}^\alpha D^\beta_{(z)}\mathcal{Q}_{(l),jk}| \le c_{\alpha\beta l}\mu^{-\max(M+l-1,|j-k|)}\bar\nu, \tag{17.4.54}$$

$$|\mathcal{D}^\alpha D^\beta_{(z)}\mathcal{Q}'_{(l),jk}| \le c_{\alpha\beta l}\mu^{-\max(M+l,|j-k|)}\bar\nu; \tag{17.4.55}$$

moreover, the second estimate with an additional factor μh in the right-hand expression holds for $\mathcal{Q}''_{(l),jk}$.

This yields that if $\mathcal{K}'_{M+1} = \exp(i\mathcal{L}')$ then

$$\mathcal{K}'^*_{(M+1)}(\mathcal{B}^+ + \mathcal{B}''^+ + \mathcal{R}_M)\mathcal{K}'_{(M+1)} = \mathcal{B}^+ + \mathcal{B}''^+ + i[\mathcal{B}^+, \mathcal{L}'] + \mathcal{R}'_{M+1} \tag{17.4.56}$$

where $\mathcal{R}'_{M+1}$ satisfies $(17.4.40)_{M+1}$.

Let us note that if we define $\mathcal{L}'$ by formula (17.4.53) then $(\exp(it\mathcal{L}'))_{jk} \equiv 0$ for $|j-k| > N$, $|t| \le \min(1, \mu^{1+M}h^{1+\delta'})$ and therefore $\mathcal{K}'_{(M+1)jk} \equiv 0$ for $|j-k| \ge N(1+\mu^{-1-M}h^{-1-\delta'})$.

This fact and (17.4.56) yield that $\mathcal{K}'_{M+1} = \mathcal{K}'_M\mathcal{K}'_{(M+1)}$ provides the induction step. □

Proposition 17.4.8. *There exists an operator $\mathcal{K}'' = (\mathcal{K}''_{jk})_{j,k\in\mathbb{Z}^+}$ which satisfies* (17.4.32)*, $\mathcal{K}''_{jk} = 0$ for $|j-k| \ge N$, and*

$$\mathcal{K}'^*(\mathcal{B}^+ + \mathcal{B}'' + \mathcal{R}')\mathcal{K}' \equiv \mathcal{B}^+ + \mathcal{B}''' + \mathcal{R}'' \tag{17.4.57}$$

where $\mathcal{R}''$ satisfies (17.4.34)*,*

$$|\mathcal{D}^\alpha D^\beta_{(z)}\mathcal{K}''_{jk}| \le c_{\alpha\beta}\mu^{-|j-k|}\bar\nu \qquad \text{for } j \ne k \tag{17.4.58}$$

$$|\mathcal{D}^\alpha D^\beta_z\mathcal{K}''_{jj}| \le c_{\alpha\beta}\mu^{-2}\bar\nu \qquad \text{for } j = k; \tag{17.4.59}$$

$\mathcal{B}'''$ is operator of the block-diagonal type and satisfies (17.4.39)*.*

Proof. The proof is similar to the proof of the previous proposition but now we have matrix operators $\mathcal{L}''_{jk}$ for $\mathsf{D} = 4$ which satisfy (17.4.52) with an additional factor μh in the right-hand expression; in particular, all of them are $O(\mu^{-1})$. □

Let us now set $\mathcal{U}''' = \mathcal{K}'''^{*}_{x}\mathcal{U}''\,{}^{t}\mathcal{K}'''^{*}_{y}$ with $\mathcal{K}''' = \mathcal{K}'\mathcal{K}''$. Then in $\tilde{\Omega}$

$$\big(hD_t - \mathcal{C}_{(j)}\big)\mathcal{U}'''_{jl} \equiv 0 \quad \forall j \in \mathcal{J}, \tag{17.4.60}$$

$$\mathcal{U}_{jl}|_{t=0} \equiv \delta_{jl}\delta(x'-y')I \tag{17.4.61}$$

where $\mathcal{C}_{(j)} = \mathcal{B}^{+}_{(j)} + \mathcal{B}'''_{(j)}$. The reduction is complete.

17.4.3 Tauberian Remainder Estimates

Let $H_{(j)} = H_{(j)}(x', \xi', \mu h, \mu^{-1}, \boldsymbol{h}')$ be the Weyl symbols of the operators $\mathcal{C}_{(j)}$. Our constructions yield that $H_{(j)}$ are smooth functions of $x', \xi', z = 2j\mu h, \mu^{-1}, \boldsymbol{h}'$ and

$$H_{(j)} = (m+1)\big(\bar{W} + L_{(j)}\big) + O\big(\mu^{-2}\bar{\nu}\big). \tag{17.4.62}$$

One can see easily that for $d = 2$ the operators $\mathcal{F}$ and $\mathcal{T}$ depend on μ and h only through $\mu^{-1}h$ and μ^{-2} and the operators are smooth functions of those arguments. Therefore the same is true for the operators W_{jk} and for $H_{(j)}$ as well. In particular,

$$H_{(j)} = (m+1)\big(\bar{W} + L_{(j)}\big) + \omega'_1\mu^{-2} + \omega'_2\mu^{-1}h + O\big(\bar{\nu}\mu^{-4} + \bar{\nu}\mu^{-2}h^2\big) \qquad \text{as } \ d = 2 \tag{17.4.63}$$

with yet unknown coefficients ω'_1 and ω'_2.

Repeating the corresponding arguments of Section 13.5 we see that the following statements similar to Theorem 13.5.1 and Propositions 13.5.2–13.5.3, 13.5.6 are true:

Theorem 17.4.9. *Let conditions* (17.3.30) *and* (17.4.1) *be fulfilled and let* q' *be supported in* $\{|\xi_2| \le 2\epsilon\}$ *for* $d = 3$. *Then*

(i) Let $|H_{(j)}| \ge \epsilon_0$ *for all* $(x, \xi') \in \tilde{\Omega}$. *Then for* $\mathcal{U}'''_{jk}$ *estimate* (17.4.24) *holds for* $|\tau| \le \epsilon$.

(ii) For $T \in [h^{1-\delta}, T^*]$ *with* $T^* = \mu\epsilon_0$ *for* $d = 2$ *and* $T^* = \epsilon_0$ *for* $= 3$, *estimate* (17.4.24) *holds for* $\mathcal{U}'''_{jk}$ *with* $j \ne k$; *therefore this estimate holds for* $\mathcal{U}_{jk}$ *with* $|j-k| \ge N(1 + \mu^{-2}h^{-1-\delta'})$ *as well; recall that* $T_0 = T_0(c, _0\,\epsilon) > 0$ *and* $\epsilon = \epsilon(c, \epsilon_0) > 0$ *are small enough constants.*

(iii) Let either $d = 2$ *and one of the conditions* $(13.4.7)_{1,2}$ *be fulfilled* or $d = 3$ *and one of the conditions* $(13.4.7)_{1-4}$ *be fulfilled.*

Then for $T \in [h^{1-\delta}, T^*]$ *the following estimate holds:*

$$|F_{t\to h^{-1}\tau}\chi_T(t)Q'_x\mathcal{U}'''_y\,{}^tQ''_{jk}| \le C'h^s \qquad \forall x', y' \in \mathbb{R}^{d-1} \quad \forall \tau : |\tau| \le \epsilon; \tag{17.4.64}$$

therefore this estimate holds for $\mathcal{U}_{jk}$ *as well.*

(iv) Let $d = 2$ *and let conditions* $(17.2.28)_{1-3}$, $(13.4.12)_{1,2}$ *and* (17.3.26) *be fulfilled. Then all the previous and the following statements remain true for* $T^* = \mu\nu^{-1}T_0$, $T \in [h^{1-\delta}\nu^{-1}, T^*]$ *and* $|\tau| \le \nu$.

(v) Under the assumptions of Proposition 13.5.6 (with conditions $(13.4.26)_{(2)}$ *or* $(13.4.26)_{(3)}$ *and* $(13.4.31)_{(2)}$ *or* $(13.4.31)_{(3)}$ *replaced by* (17.3.27)*) estimate* (13.5.36) *holds for* $\mathcal{U}'''$.

17.4.4 Calculations

Preliminary arguments

Let us pass from estimates to calculations. Let us note first of all that the operator $q = q(x, h'D', h')$ in the representation $\mathfrak{R}$ is transferred to the block-operator $Q = (Q_{jk})_{j,k\in\mathbb{Z}^+}$ where the symbols of the operators Q_{jk} satisfy the estimates

$$|\mathcal{D}^\alpha D^\beta_{(z)} Q_{jk}| \le c_{\alpha\beta}\mu^{-|j-k|} \qquad \forall j, k \in \mathcal{J}'. \tag{17.4.65}$$

Moreover, one can decompose these symbols into asymptotic series in μ^{-2} and h'. One can prove easily that if $\mathcal{M}$ is one of the operators $\mathcal{T}'$, $\mathcal{K}$, $\mathcal{K}'$, $\mathcal{K}'''$ constructed in Propositions 17.4.2, 17.4.4, 17.4.7 and 17.4.8 respectively (or if $\mathcal{M}$ is a product of these operators) then the operator $\mathcal{M}^*Q\mathcal{M}$ also has these properties.

Therefore using the arguments used in the proofs of Propositions 13.5.4, 13.5.5 and applying Theorem 17.4.9 we obtain the following

Proposition 17.4.10. *Let conditions* (17.3.30) *and* (17.4.1) *be fulfilled. Then*

(i) Let $d = 2$ *and* $T \in [h^{1-\delta}\nu^{-1}, T^*]$, $Q' = I$ *and let conditions* $(17.2.28)_{1-3}$, $(13.4.12)_{1,2}$ *and* (17.3.26) *be fulfilled. Then*

$$\sigma(t) := F_{t\to h^{-1}\tau}\chi_T(t)\operatorname{tr}\Gamma\big(Q'_x\psi(x)U\big) \equiv F_{t\to h^{-1}\tau}\chi_T(t)\sum_j \Gamma'(f_j\mathcal{U}'''_{jj}) \qquad \forall \tau \in [-\epsilon\nu, \epsilon\nu] \tag{17.4.66}$$

modulo $O(h^s)$ *with the summation over* $j \in \mathcal{J}$,

$$f_j = f(x', \boldsymbol{h}'D', 2j\mu h, \mu^{-2}, \boldsymbol{h}') \tag{17.4.67}$$

where f *is a smooth function of its arguments,*

$$f = f_0 \cdot I + O(\mu^{-2}\bar\nu), \qquad f_0 = \psi \circ \bar\Psi. \tag{17.4.68}_{(2)}$$

(ii) Let $d = 3$, *let* $Q = Q(x', \boldsymbol{h}'D', \boldsymbol{h}')$ *be a scalar operator with symbol supported in* $\{|\xi_2| \le \epsilon\}$, $Q' = \mathcal{F}TQT^*\mathcal{F}^*$ *and* $T \in [h^{1-\delta}, T^*]$. *Then equality* (17.4.66) *holds for* $\tau \in [-\epsilon, \epsilon]$.

Moreover, (17.4.67) *remains true and*

$$f = f_0 \cdot I + O(\mu^{-2} + h), \qquad f_0 = q_0(\psi \circ \bar\Psi) \tag{17.4.68}_{(3)}$$

where q *and* q_0 *are the symbol and the principal symbol of the operator* Q *respectively. Finally,*

$$\operatorname{supp}(f) \subset \operatorname{supp}(q). \tag{17.4.69}$$

From Tauberian to More Explicit Expression

Repeating the corresponding considerations of Section 13.5 we can easily prove that

Proposition 17.4.11. *(i) Under the assumptions of Proposition 13.5.7 and the additional condition* (17.3.30) [23] *for expression*

$$\mathsf{R}^{\mathsf{MW}}_{\infty} := \Big|\int \phi(\tau')\Big(\operatorname{tr}\Gamma\big(\tilde Q'_x\psi'(x)e\big)(\tau', \tau) - \sum_{j\in\mathcal{J}}\sum_{k,p,l\le N}\Theta_{j,kpl}(\tau', \tau)h^{1+l-d}\mu^{-1-2p-l}\Big)\,d\tau'\Big| \tag{17.4.70}$$

[23] And under the condition $\operatorname{supp}(q) \subset \{|\xi_2| \le 2\epsilon\}$ in the case $d = 3$.

estimate (13.5.43) *holds where*

$$\Theta_{j,kpl}(\tau',\tau) \coloneqq \Theta_{j,kpl}(\tau)\big|_{\tau=\tau'}^{\tau=\tau},$$

$\Theta_{j,kpl}$ *are given by formulae* (13.5.44) *with* $H_{(j)}$ *instead of* $\mathcal{A}_j$ *and with* f_{kpl} *satisfying* (13.5.45)–(13.5.46) *are fulfilled and, moreover, equality*

$$f_{000} = (2\pi)^{1-d}\frac{\mathsf{D}}{2}q'(\psi'\circ\bar{\Psi}_0) \tag{17.4.71}$$

holds instead of (13.5.47) *and we assume that* $\phi \in \mathscr{C}_0^K([-\epsilon,\epsilon])$.

(ii) Further, the right hand expression in estimate (13.5.43) $R_{1(0)}$ *is given by* (13.5.41).

(iii) Finally, under the indicated additional conditions in the assumptions of Proposition 13.5.8 estimate (13.5.51) *holds for* $\mathsf{R}^{\mathsf{MW}}_{\infty}$.

This proposition yields that in the framework of Propositions 13.5.10 and 13.5.9 as $d = 2, 3$, with $H_{(j)}$ instead of $\mathcal{A}_j$ and with $Q' = Q(I - Q'')$ instead of $Q' = I - Q''$ for $d = 3$ (provided the symbol of Q is supported in $\{|\xi_2| \le 2\epsilon\}$, $Q \sim I$ in $\{|\xi_2| \le \epsilon\}$) estimates $(13.5.60)_0$ and $(13.5.57)_0$ hold for $d = 2$ and for $d = 3$ respectively; we assume that condition (17.3.30) is fulfilled.

Moreover, applying the results of Section 5.3 to estimate contributions of zone in zone $\{\gamma \le \epsilon\}$ (as in Subsection 13.5.3) we obtain the following

Theorem 17.4.12 [24]**.** *Let conditions* (17.3.30) *and* (17.4.1) *be fulfilled and let* $\phi \in \mathscr{C}_0^K([-\epsilon,\epsilon])$, $\tau = 0$. *Then*

(i) Let $d = 2$, $Q' = I$ *and let conditions* $(17.2.28)_{1-3}$, (17.4.24) *and* $(13.4.12)_{1,2}$ *be fulfilled. Then estimate* (13.5.66) *holds under non-degeneracy condition* (13.5.62) *and estimate* (13.7.64) *holds under weak non-degeneracy condition* $(13.5.63)_m$.

(ii) For $d = 3$ *estimate* $\mathsf{R}^{\mathsf{MW}}_{\infty} \le Ch^{-2}$ *holds under condition* $(13.5.63)_m$ *and estimate* $\mathsf{R}^{\mathsf{MW}}_{\infty} \le Ch^{-2} + C\mu h^{-1-\delta}$ *holds in the general case.*

(iii) In particular, under non-degeneracy condition

$$|\nabla v^{\#}| \ge \epsilon_0 \qquad \text{in } B(0,1) \tag{17.4.72}$$

estimates $\mathsf{R}^{\mathsf{MW}}_{\infty} \le C\mu^{-1}h^{-1}$ *for* $d = 2$ *and* $\mathsf{R}^{\mathsf{MW}}_{\infty} \le Ch^{-2}$ *for* $d = 3$ *hold.*

[24] Cf. Theorem 13.5.16.

Effective asymptotics. I

Now our goal is to pass from estimates for $\mathsf{R}^{\mathsf{MW}}_{\infty}$ to estimates for

$$\mathsf{R}^{\mathsf{MW}} = \Bigl| \iint \phi(\tau')\psi(x)\bigl(\operatorname{tr} e(x,x,\tau',\tau) - h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau',\tau,\mu h)\bigr)\,dx d\tau'\Bigr|. \tag{17.4.73}$$

To this end we apply the corresponding arguments of Section 13.5.

Remark 17.4.13. Surely, now the functions $f_{\dots}$ are not necessarily polynomials of $z = 2j\mu h$; however, these functions depend smoothly on z. Taking into account equalities $(17.4.68)_{(2,3)}$ and the fact that f_{000} does not depend on z at all, we easily conclude that the transformations of Section 13.5 and the estimate (13.5.82) for the error of using numerical integration formula also remain true with an additional term in the right-hand expression; this term is due to the non-polynomial character of $f_{\dots}$. This additional term is $O(1)$ for $d = 2$ and $O(h^{-2})$ for $d = 3$ and, moreover, it is $O(h^s)$ under condition (13.4.1).

Surely, for $d = 3$ we cannot set $Q' = I$; we can only take Q' with the symbol supported in $\{|\xi_2| \le 2\epsilon\}$. In order to avoid this difficulty we temporarily assume that condition (13.4.1) is fulfilled; the case $\mu \in [h^{1-\delta}, \epsilon h^{-1}]$ will be treated later. Then for the operator $(I - Q')$ with the symbol supported in $\{|\xi_2| \ge \epsilon\}$ the results of Section 17.3 apply and therefore we obtain the corresponding estimate for expression

$$\begin{aligned}\Bigl| \iint \phi(\tau)\phi_1(\tau')\Bigl(\int \psi(x)\bigl(\operatorname{tr} e(x,x,\tau',\tau) - h^{-d}\mathcal{N}^{\mathsf{MW}}(x,\tau',\tau)\bigr)\,dx \\ h^{-d}G_0(\tau,\mu^{-1}) - h^{1-d}G_1(\tau,\mu^{-1}) - h^{-d}G_2(\tau,\mu h) - h^{1-d}G_3(\tau,\mu h)\Bigr)\,d\tau d\tau'\Bigr|\end{aligned} \tag{17.4.74}$$

(i.e., for $Q' = I$) where G_0, G_1 are polynomials with respect to μ^{-1} and G_2, G_3 are polynomials with respect to μh.

Then applying arguments similar to those of Subsection 13.5.4 we easily prove that these polynomials vanish. In this proof we start with the results of Section 17.3 and the equality

$$\iint \phi_0(\tau)\phi(\tau')e(.,.,\tau',\tau)d\tau' d\tau = \int \Phi(\tau)d_\tau e(.,.,\tau_1,\tau)$$

where the choice of τ_1 does not matter and $\Phi \in \mathscr{C}_0^K([-\epsilon,\epsilon])$ is a primitive of the function $k_0\phi(\tau) - k\phi_0(\tau)$ with constants $k_\cdot = \int_{\mathbb{R}} \phi_\cdot(\tau)d\tau$.

As a result we obtain the following series of statements where *the following notational convention is used:* $^\#$ *means that* V *and* $v = V/F$ *are replaced by* $V^\# = m^2 - V^2$ *and* $v^\# = V^\#/F$ *respectively and* $(2j+1)\mu h$ *is replaced by* $2j\mu h$*:*

Theorem 17.4.14 [25]**.** *Let* $d = 3$, $\vartheta = 0$, $\tau = 0$ *and let conditions* (17.1.1)–(17.1.4), (13.3.1) *and* (17.3.30) *be fulfilled. Then estimate* $\mathsf{R}^{\mathsf{MW}} \le Ch^{-2} + C'h^s$ *holds under the additional assumption* (13.4.1)*.*

Theorem 17.4.15 [26]**.** *Let* $d = 2$, $\tau = 0$, $\vartheta = 0$ *and conditions* (17.1.1)–(17.1.4), (17.2.1), (17.3.30) *and* (17.4.1) *be fulfilled. Then*

(i) For $\mu^3 h \le C_0$ *estimate* $(13.5.107)^\#$ *holds. Moreover, under condition* $(13.5.102)^\#$ *estimate* (13.5.108) *holds and under condition* $(13.5.109)^\#$ *estimate* $(13.5.89)_{(2)}$ *holds.*

(ii) For $\mu^3 h \ge C_0$ *estimate* $(13.5.110)^\#$ *holds. Moreover, under condition* $(13.5.102)^\#$ *estimate* (13.5.111) *holds, under condition* $(13.5.109)_+{}^\#$ *estimate* $\mathsf{R}^{\mathsf{MW}} \le C\mu^{-1}h^{-1} + C'$ *holds and under condition* $(13.5.109)^\#$ *estimate* (13.5.111) *holds.*

(iii) Moreover, for $\mu^3 h \ge C_0$ *estimate* (13.5.119) *holds for*

$$\mathsf{R}^{\mathsf{MW}\prime} = \Big|\int \phi(\tau')\Big(\int \psi(x)\big(\operatorname{tr} e(x,x,\tau',0) - h^{-2}\mathcal{N}^{\mathsf{MW}}(x,\tau',0,\mu h)\big)\,dx - \sum_{x_l\in\mathfrak{M}} \frac{1}{\mu h}\Delta(x_l)\Big)\,d\tau'\Big| \tag{17.4.75}$$

where $\mathfrak{M}$ *is the set of saddle points of the function* $v^\#$ *and at every point* $\bar{x} \in \mathfrak{M}$, $\Delta(\bar{x})$ *is defined by formulae* $(13.5.116)^\#$ *with the additional factor* $\frac{\mathsf{D}}{2}$ *in the right-hand expression,* $(13.5.117)^\#$ *and*

$$\bar{\tau} = v^\#(\bar{x}) + 2j\mu h, \quad \bar{\tau}' = \bar{\tau} + \bar{\rho}_1\mu^{-2} + \bar{\rho}_2\mu^{-1}h, \quad \bar{\rho}_k = -2\bar{\omega}_k V^\# \tag{17.4.76}$$

where we do not yet know ω_1, ω_2*.*

[25] Cf. Theorem 13.5.23.

[26] Cf. Theorems 13.5.26, 13.5.28.

Theorem 17.4.16 [27]**.** *(i) Under the assumptions of Theorem 17.4.15 estimate* (13.5.60) *with* $\vartheta = 0$ *holds for expression* (17.4.74).

(ii) Under the additional condition (17.4.1) *both Statements (i) and (ii) of Theorem 13.5.31 remain true.*

Theorem 17.4.17. *Under additional condition* (17.4.1) *the statements of theorems 13.5.32, 13.5.33, 13.5.36 and Remark 13.5.34 remain true with obvious modifications. Without this condition they remain true only with an additional term* $O(\bar{\nu})$ *in the right-hand expression.*

Remark 17.4.18. One can see easily that for $\vartheta = 0$ all the above results hold without condition (13.4.1); the only exceptions are the effective asymptotics for $d = 3$ where we applied the results of the previous case in the zone $\{|\xi_2| \ge \epsilon_0\}$.

Problem 17.4.19. Problem 13.5.35, albeit now for the generalized Dirac and Schrödinger-Pauli operators.

Effective asymptotics. II

In order to finish our analysis in the case $d = 2$ we need to calculate the coefficients ω_1, ω_2 at a critical point of the function $v^{\#}$. To this end let us consider the estimate

$$(m+1)\|Au\| \ge \eta\mu^{-1}h\|u\| \qquad \forall u \in \mathscr{C}_0^K(B(\bar{x}, \zeta\mu^{-1}), \mathbb{C}^D) \tag{17.4.77}$$

with $\eta > 0$ and with small enough $\zeta = \zeta(\eta) > 0$ independent of μ and h provided $\mu h \le \epsilon = \epsilon(\eta)$. By reduction one can easily prove that this estimate is equivalent to the estimate

$$\|(A_{\mathsf{S}} I + \sigma_0 \mu h)u\| \ge \eta\mu^{-1}h\|u\| \qquad \forall u \in \mathscr{C}_0^K(B(\bar{x}, \zeta\mu^{-1}), \mathbb{C}^D) \tag{17.4.78}$$

for the Schrödinger operator

$$A_{\mathsf{S}} = \sum_{j,k} P_j (F^{-1} g^{jk}) P_k + v^{\#};$$

namely, estimate (17.4.77) yields estimate (17.4.78) and *vice versa* (in each implication we replace η by $C_0^{-1}\eta$).

[27] Cf. Theorems 13.5.30, 13.5.31.

On the other hand, the constructions of Section 13.5 and this section yield that estimates (17.4.77) and (17.4.78) are equivalent in the sense indicated above to the inequalities

$$(m+1)\bigl|(m^2+2j\mu hF)^{\frac12}+V+\omega_1\mu^{-2}+\omega_2\mu^{-1}h\bigr|\ge\eta\mu^{-1}h \tag{17.4.79}$$

and

$$\bigl|v^{\#}+2j\mu h+\omega_1'\mu^{-2}+\omega_2'\mu^{-1}h\bigr|\ge\eta\mu^{-1}h \tag{17.4.80}$$

respectively; these inequalities should be checked for all $j\in\mathbb{Z}^+$ and for $x=\bar x$. Let us take $j\in\mathbb{Z}^+$ such that

$$(m+1)\bigl|(m^2+2j\mu hF)^{\frac12}+V\bigr|\le C^{-1}\mu h \tag{17.4.81}$$

and

$$|v^{\#}+2j\mu h|\le C^{-1}\mu h; \tag{17.4.82}$$

one can easily see that for $\mu^3h\ge C$ these inequalities define the same number j.

Let us replace $v^{\#}$ by $v^{\#}(1+\lambda)$ and let us alter V in the corresponding manner. Then the variations of ω_k and ω_k' are $O(|\lambda|(m+1)^{-1})$ and $O(|\lambda|)$ respectively and for $|\lambda|\le\epsilon'''$ these variations are are not essential in the sense that they do not change estimates (17.4.79) and (17.4.80).

Thus estimates (17.4.79) and (17.4.80) remain equivalent after replacing $v^{\#}$ by $v^{\#}(1+\lambda)$ (preserving the critical points), and the corresponding replacement of V. Taking j satisfying (17.4.81) and taking λ such that $|\lambda|\le C\mu h$ and the left-hand expression of (17.4.79) vanishes we obtain (because $\eta>0$ is arbitrary) that $\omega_k=-\omega_k'F(2V)^{-1}$ at the point $\bar x$.

However, we have formula (13.5.113) for ω_1' at the point $\bar x$ and we have proven that ω_2' vanishes at this point. So we have proven

Proposition 17.4.20. *In formula* (17.4.76) *we can calculate* $\bar\rho_1=\bar\rho$ *according to* (13.5.118), (13.5.113) *with* $v^{\#}$ *instead of* v *and take* $\bar\rho_2=0$.

Effective asymptotics. III

Now our goal is to obtain similar results in the case when condition (17.3.30) is replaced by one of the conditions (17.3.6)–(17.3.8) and, in particular, to get rid of condition (13.4.1) in Theorem 17.4.14. Recall that we used condition (17.3.30) not only in the transition from $\mathsf{R}^{\mathsf{MW}}_\infty$ to R^{MW} but also in the reduction done in Subsection 17.4.2.

Let us first of all note that

(17.4.83) If at some point $(\bar{x}', \bar{\xi}')$ the inequality $|v^{\#} + 2j\mu h| \ge \epsilon > 0$ holds, if condition (17.4.1) is fulfilled with $\epsilon_1 = \epsilon_0(c, \epsilon_0, \epsilon, s) > 0$ and if the symbol of Q is supported in the ϵ_1-neighborhood of $(\bar{x}', \bar{\xi}')$ then estimate (17.4.24) is true for all τ with $|\tau| \le \epsilon_1$.

Therefore our standard arguments yield that if condition (17.4.1) and one of the conditions (17.3.6)–(17.3.8) are fulfilled then the following estimate holds:

$$|F_{t\to h^{-1}\tau}\chi_{T,\pm T}(t)\Gamma' Q'_x \mathcal{U}_{jk}| \le C' h^s \qquad \forall \tau : |\tau| \le \epsilon_1 \tag{17.4.84}$$

where $T \in [h^{1-\delta'}, T^*]$ is arbitrary, $T^* = \mu T_0$ for $d = 2$, $T^* = T_0$ for $d = 3$ and $T_0 = T_0(c, \epsilon_0, s) > 0$ as before.

On the other hand, let us apply the standard method of successive approximations to calculate

$$F_{t\to h^{-1}\tau}\chi_T(t)\,\mathrm{tr}\,\Gamma' Q'_x \mathcal{U}_{jk}\, {}^t Q''_y \tag{17.4.85}$$

and

$$F_{t\to h^{-1}\tau}\chi_T(t)\,\mathrm{tr}\,\Gamma \tilde{Q}'_x \psi'(x) U \psi''(y)\, {}^t\tilde{Q}''_y \tag{17.4.86}$$

for $T = h^{1-\delta'}$, $|\tau| \le \epsilon_0$ with the unperturbed operator

$$\bar{\mathcal{A}} = \sigma_1 \sqrt{2j\mu h} B_0 + \sigma_0 m + \bar{W} \cdot I \qquad \text{for} \quad d = 2, \tag{17.4.87}$$

$$\bar{\mathcal{A}} = (\sigma_1 \sqrt{2j\mu h} B_0 + \sigma_3 h D_2 B_0)^{\mathsf{w}} + \sigma_0 m + \bar{W} \cdot I \qquad \text{for} \quad d = 3. \tag{17.4.88}$$

Moreover, for $m \ge C_0$ one can either do the reduction beforehand or skip this procedure. Then applying the arguments of the proofs of Propositions 13.5.4, 13.5.5 we arrive to the following equality

$$F_{t\to h^{-1}\tau}\chi_T(t)\,\mathrm{tr}\,\Gamma Q'_x \mathcal{U}\, {}^t Q''_y \equiv \sum_{j,n} T\mu h^{1-d} \int \hat{\chi}\Big(\frac{(\tau-\tau')T}{h}\Big)\Theta_{j,n}^{(n+1)}(\tau')\,d\tau' \tag{17.4.89}$$

and a similar equality for $\tilde{Q}'_x \psi'(x) U \psi''(y)\, {}^t\tilde{Q}''_y$ modulo $O(h^s)$ where $\Theta_{j,n}(\tau)$ are given by (13.5.44) with $f_{j,n}(x', \xi', \mu h, \boldsymbol{h}', \mu^{-1})$ instead of f and satisfy

$$|\mathcal{D}^\alpha f_{j,n}| \le c' \mu^{-n} \qquad \forall \alpha : |\alpha| \le K. \tag{17.4.90}$$

Therefore, in particular,

(17.4.91) The absolute values of expressions (17.4.85) and (17.4.86) do not exceed Ch^{1-d}.

Let us calculate the second expression for $\psi''=1$, $Q''\equiv I$; this calculation will be done modulo $O(\mu^{-1})$ for $d=2$ and modulo $O(h^{-1+\delta'})$ with $\delta'>0$ for $d=3$; in this section calculations with $\delta'=0$ also apply. We assume that

$$\mu \ge h^{\delta-1} \tag{17.4.92}$$

with a small enough exponent $\delta>0$. Then we should treat terms of the following five types:

(i) Principal terms of the type

$$\sum_j \mu h^{2-d}\Theta^{(1)}_{j,0}(\tau) \tag{17.4.93}$$

with $\Theta_{j,0}(\tau)$ given by (13.5.44) with

$$f_{j,0}=(2\pi)^{1-d}q'(x',\xi')(\psi'\circ\bar\Psi)(x',\xi_1);$$

these terms originate from the terms

$$\pm ih\bar G^{\pm}\delta(x-y)\delta(t)I \tag{17.4.94}$$

of the successive approximation series for $\mathcal{U}$ where $\bar G^{\pm}$ are parametrices of the operator $\bar P = hD_t-(m+1)\bar A$ with coefficients frozen for $x=y$ and with μ^{-1}, h' replaced by 0.

The total contribution of these terms is of order h^{1-d}.

(ii) Terms with total contribution of order $\mu^{-2}h^{1-d}$. These terms are associated with $\mathcal{U}_{jj}$ and originate from the terms

$$\pm ih\bar G^{\pm}(W-\bar W\cdot I)\bar G^{\pm}(W-\bar W\cdot I)\bar G^{\pm}\delta(x-y)\delta(t)I \tag{17.4.95}$$

The total contribution of the other terms of the successive approximation series is $O(\mu^{-3}h^{1-d})$ and is less than required by remainder estimate in virtue of (17.4.92).

Note that the terms of the type

$$\pm ih\bar G^{\pm}(W-\bar W\cdot I)\bar G^{\pm}\delta(x-y)\delta(t)I \tag{17.4.96}$$

have 0 diagonal blocks because $W - \bar{W}\cdot I$ has the same property; so these terms make no contribution to the final answer.

One should consider terms of this type as well as terms of the following type only for $d = 2$ and one can skip all blocks of $(W - \bar{W}\cdot I)$ with $j \neq k \pm 1$ (we use assumption (17.4.92) again; recall that W_{jk} are of order $O\big((m+1)^{-1}\mu^{-|j-k|}\big)$).

Moreover, one can consider only terms with $j \geq 2$ because the total contribution of the terms with $j = 0, 1$ is $O(\mu^{-1})$. Let us take into account that

$$W_{j,j+1} \equiv \mu^{-1}\big(\sqrt{2j\mu h}\,\Pi^{+} + \sqrt{2(j-1)\mu h}\,\Pi^{-}\big)w$$

modulo $O(h(m+1)^{-1})$ where w is a scalar operator and $\Pi^{\pm}$ are orthogonal projectors to $\mathbb{H}^{\pm}$, and let us take into account that $W_{j,j-1} = W^{*}_{j-1,j}$ and that for $d = 2$

$$\big(\tau - (m+1)\bar{A}\big)^{-1} = \big(\tau_1^2 - (m+1)^2(2j\mu h B_0^2 + m^2)\big)^{-1}\times \\ \big(\tau_1 + (m+1)(\sigma_1\sqrt{2j\mu h}B_0 + \sigma_0 m)\big)$$

with $\tau_1 = \tau - (m+1)\bar{W}$. Then we obtain terms of type

$$D_\tau^3 \int \operatorname{sgn}\tau_1 \cdot \theta\big(\tau_1^2 - (m+1)^2(2j\mu h b_0 + m^2)\big)\times \\ \mathcal{P}(j\mu h, x_1, \xi_1, \mu h, \mu^{-1}, h)\mu^{-1}\,dx_1 d\xi_1$$

where $\mathcal{P}$ is a second order polynomial of $j\mu h$ with coefficients depending smoothly on all the other variables and $b_0 = B_0^2$.

Obviously, for $m + |\tau_1| \geq 3\epsilon_1$ the integrand is a smooth function of τ and $z = j\mu h$ and is a distribution with respect to (x_1, ξ_1); this follows from condition (17.3.7) and the inequality $|\tau| \leq \epsilon_1$. Using the arguments of the proof of Proposition 17.3.11 one can easily show that for fixed (x_1, ξ_1) and for $|\tau_1| \leq 3\epsilon_1$, $m \leq 3\epsilon_1$ the integrand is a smooth function of $z = j\mu h$ and a distribution with respect to τ.

Using condition (17.3.6) we then obtain that for $|\tau| \leq \epsilon_1$ the integrand is a smooth function of $(j\mu h, \tau)$ and a distribution with respect to (x_1, ξ_1). Therefore we can replace summation with respect to j by integration with respect to $z = j\mu h$ and we then obtain that the sum is equal to

$$\varkappa(\tau)\mu^{-2}h^{-1} + O(\mu^{-1}) \tag{17.4.97}$$

with $\varkappa(\tau)$ depending smoothly on τ.

(iii) Furthermore, we have terms with total contribution of the same magnitude; they are associated with $\mathcal{U}_{jj\pm1}$ and they originate from

$$\pm ih\bar{G}^{\pm}(W-\bar{W}\cdot I)\bar{G}^{\pm}\delta(x-y)\delta(t)I \tag{17.4.98}$$

of the successive approximation series for $\mathcal{U}$. In this case the diagonal blocks of the operator $\tilde{\psi}=\mathcal{T}^*\mathcal{F}^*\psi\mathcal{F}\mathcal{T}$ are replaced by blocks $\tilde{\psi}_{j\pm1,j}$ which are of the form

$$\mu^{-1}\psi'\bigl(\sqrt{2j\mu h}\,\Pi^{+}+\sqrt{2(j-1)\mu h}\,\Pi^{-}\bigr)$$

with the scalar operator ψ'. The same arguments as before again give expression of (17.4.97) type.

(iv) Moreover, we have terms associated with $\mathcal{U}_{jj}$ and originating from the lower order terms of $\tilde{\psi}_{jj}$; these terms originate from the same terms of the successive approximation series for $\mathcal{U}$ as terms of type (i).

For $d=2$ these terms are

$$\sum_j j\Theta^{(1)}_{(j,1)}(\tau)$$

where $\Theta_{j,1}(\tau)$ are defined by (13.5.44) with the function f independent of $j\mu h$, the total contribution of these terms have the same magnitude as in Part (ii) and the previous arguments give the final expression (17.4.97).

For $d=3$ the essential terms of this type are associated with the difference between the operator $\tilde{\psi}$ and the same operator with $\mu^{-1}hD_2$ replaced by 0; we obtain 0 if the symbol of the operator Q is even with respect to ξ_2.

(v) Finally, we have terms with total contribution of magnitude $O(\mu^{-1})$ for $d=2$ and $O(h^{-1})$ for $d=3$; therefore these terms should be treated only for $d=3$ and $\delta'>0$. These terms originate from the freezing of the coefficients and commutators. Simple calculations (see Section 5.3) give 0 if the symbol of the operator Q is even with respect to ξ_2.

Let us apply the standard Tauberian arguments. Moreover, let us prove that the term $\varkappa(\tau)\mu^{-2}$ in the final answer vanishes (we compare the final answer obtained here with the results of section 17.3; here one can use averaging with respect to τ). Consequently we obtain the following statements in which we can get rid of condition (17.4.84) because these

statements were proven under condition (13.4.1) (in Section 17.3 and this section above):

Theorem 17.4.21. *Let $d = 2, 3$, $\vartheta = 0$ and suppose conditions* (17.1.1)–(17.1.3)*,* (17.2.1)*,* (17.4.1) *and one of the conditions* (17.3.6)*,* (17.3.7) *are fulfilled.*

Then estimate (13.5.85) *holds.*

Theorem 17.4.22. *Let $d = 3$, $\vartheta = 0$. Then Theorem 17.4.21 remains true with condition* (13.4.1) *replaced by* (17.4.1)*.*

In the proof of this latter theorem we use the same arguments as in the proof of Theorem 17.4.21 but in the zone $\{|\xi_2| \ge \epsilon\}$ we use the arguments of this subsection instead of arguments of Section 17.3.

The same arguments are applicable in the case when conditions (17.3.6)–(17.3.8) are skipped but there is mollification on τ; under condition (13.4.1) we use the results of Section 17.3. So the following statement is proven:

Proposition 17.4.23. *If $d = 2, 3$ and conditions* (17.1.1)–(17.1.3)*,* (17.2.1) *and* (17.4.1) *are fulfilled then the following estimates hold:*

$$(17.4.99)_{(2)} \quad \mathsf{R}^{\mathsf{MW}\prime} := \Bigl| \iint \phi(\tau)\psi(x)\bigl(d_\tau e(x,x,\tau_1,\tau) - \partial_\tau \mathcal{N}^{\mathsf{MW}}(x,\tau_1,\tau,\mu h) h^{-d}\, d\tau\bigr)\, dx\Bigr| \le C \qquad \text{for } \ d = 2,$$

$$(17.4.99)_{(3)} \qquad \mathsf{R}^{\mathsf{MW}\prime} \le C h^{\delta'-2} \qquad \text{for } \ d = 3$$

with arbitrarily small exponent $\delta' > 0$.

This proposition yields the following

Corollary 17.4.24. *Theorems 17.4.14–17.4.17, Remark 17.4.18, Proposition 17.4.20 and theorems 17.4.21, 17.4.22 remain true when the condition $\mathsf{supp}(\phi) \subset [-\epsilon_0, \epsilon_0]$ is replaced by the condition $\mathsf{supp}(\phi) \subset [-c, c]$.*

Certain improvements and generalizations of Corollary 17.4.24 will appear in Section 17.7.

17.5 Strong Magnetic Field

In this section we consider the case when

$$\mu \ge 1, \quad \mu h \ge \epsilon_0 \tag{17.5.1}$$

forbidden for the Schrödinger operator A_{S} unless we replace it by $A_{\mathsf{S}} - \mathfrak{z} F \mu h$. This case is in fact rather simple, because we actually need to consider only one Landau level.

17.5.1 Additional Reduction

Let us note that the semiclassical parameter for $d = 2$ is $\mu^{-1}h$ instead of h. Therefore in this case we can weaken the condition $h \in (0, 1]$. Namely, we replace it by the condition

$$h \in (0, 1] \qquad \text{for} \quad d = 3; \tag{17.5.2}_{(3)}$$

$$h \in (0, \mu^{1-\delta}] \qquad \text{for} \quad d = 2,\ \delta > 0. \tag{17.5.2}_{(2)}$$

In Subsection 17.5.2 even this condition will be weakened for $d = 2$.

Under conditions (17.5.1) and $(17.5.2)_{(d)}$ equalities (17.2.35) and (17.2.36) are fulfilled modulo functions f and f' respectively such that

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_x f| \le C' T \mu^{1-s} h^s, \tag{17.5.3}$$

$$|Q_x f'| \le C' \mu^{1-s} h^s \tag{17.5.4}$$

with the same restrictions on Q, T as in (13.3.81), (13.3.82) for $d = 3$ and under the condition $T \ge h\mu^{\delta'}$ with $\delta' > 0$ for $d = 2$.

Moreover, (13.3.84), (13.3.86) hold and the left-hand expression in (13.3.87) does not exceed $C' T \mu^{1-s} h^s$. Finally, the norm of the left-hand expression of (13.3.85) does not exceed $C\mu^l$ with some exponent l; this rough estimate will be improved in what follows.

Let us introduce $\mathcal{U}_{jk}$ as we did it in Section 17.4; then estimate (17.4.7) and equality (17.4.6) remain true. Moreover, the construction of $\mathcal{U}$ and the fact that we multiplied $\mathcal{U}$ by two $\mu^{-1}h$-pseudodifferential operators with symbols vanishing outside of a neighborhood of Λ^0 (one pseudodifferential operator acts with respect to x and another acts with respect to y) yield that all our estimates remain true if we replace $\mathcal{U}$ by its cutoff

$$\sum_{j,k\le N} \mathcal{U}_{jk} \Upsilon_j(x_d) \Upsilon_k(y_d) \tag{17.5.5}$$

with $N = N(s,\delta)$. We also denote this cutoff by $\mathcal{U}$. The error will be $O(\mu^{-s})$.

We need the following statement which is obvious by the standard elliptic arguments:

Proposition 17.5.1. *Let us assume that $d = 3$ and that $Q = \mathsf{Op}(q)$ with $q \in \mathsf{S}_{h',\rho,1,K}(T^*\mathbb{R}^2)$ supported in $\{\rho \le |\xi_2| \le 2\rho\}$ with $\rho \ge C_0$. Then the estimate*

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_x\mathcal{U}_{jk}| \le C'T\mu h^s\rho^{-s} \tag{17.5.6}$$

holds for $|\tau| \le c$, $T \ge h^{1-\delta}\rho^\delta$, $j,k \le N$.

Proposition 17.5.2. *There exists an operator $\mathcal{K} = (\mathcal{K}_{j,k})_{j,k\le N}$ such that in the sense of h'-pseudodifferential operators in $\tilde\Omega$ (17.4.32) is fulfilled and*

$$(m+1)\mathcal{K}^*\mathcal{A}\mathcal{K} \equiv (m+1)\big(\mathcal{A}_0+\mathcal{A}_1\big) + \mathcal{B}' \tag{17.5.7}$$

where $\mathcal{B}'$ is of the block-diagonal type and

$$|\mathcal{D}^\alpha\mathcal{K}_{jk}| \le c_\alpha\bar\nu(\mu^{-1}h)^{\frac12|j-k|}(\mu h)^{-\frac12} \qquad (j\ne k), \tag{17.5.8}$$

$$|\mathcal{D}^\alpha(\mathcal{K}_{jj}-I)| \le c_\alpha\mu^{-2}\bar\nu^2, \tag{17.5.9}$$

$$|\mathcal{D}^\alpha\mathcal{B}'_{(j)}| \le c_\alpha\mu^{-2}\bar\nu^2. \tag{17.5.10}$$

Proof. Let us construct $\mathcal{K}$ by induction with respect to M assuming that at every step (17.5.7) holds with an additional term $\mathcal{R}$ in the right-hand expression such that

$$|\mathcal{D}^\alpha\mathcal{R}_{jk}| \le c_\alpha(\mu^{-1}h)^{\frac12\max(|j-k|,M)}. \tag{17.5.11}$$

Then we set $\mathcal{K}_{M+1} = \mathcal{K}_M \exp i\mathcal{L}$ with the Hermitian operator $\mathcal{L} = (\mathcal{L}_{jk})_{j,k\le N}$ where $\mathcal{L}_{jj} = 0$ and the principal symbols of the out-of-diagonal blocks of $\mathcal{L}$ are defined by the equations

$$i(m+1)\big(\mathcal{A}^0_{(j)}\mathcal{L}^0_{jk} - \mathcal{L}^0_{jk}\mathcal{A}^0_{(j)}\big) = \mathcal{R}^0_{jk}. \tag{17.5.12}$$

Note that the distances between the spectra of the Hermitian matrices $(m+1)\mathcal{A}^0_{(j)}$ and $(m+1)\mathcal{A}^0_{(k)}$ with $j\ne k$ are not less then $\epsilon_1\big((m+1)\sqrt{\mu h}+\mu h\big)$ with a constant $\epsilon_1 > 0$. Then Appendix 3.A.1 yields that $\mathcal{L}^0_{jk}$ are defined uniquely and satisfy the inequalities

$$|\mathcal{D}^\alpha\mathcal{L}^0_{jk}| \le c_\alpha\bar\nu(\mu^{-1}h)^{\frac12\max(|j-k|,M)}(\mu h)^{-1}. \tag{17.5.13}$$

All the assertions of our proposition follow from this construction. □

Let us now set $\mathcal{U}' = \mathcal{K}_x^* \mathcal{U}\, {}^t\mathcal{K}_y^*$; then in $\tilde{\Omega}$

$$(hD_t - \mathcal{B}_{(j)})\mathcal{U}'_{jk} \equiv 0, \tag{17.5.14}$$

$$\mathcal{U}'_{jk}|_{t=0} \equiv \delta_{jk}\delta(x'-y')I \tag{17.5.15}$$

where $\mathcal{B}_{(j)} = (m+1)(\mathcal{A}_{0(j)} + \mathcal{A}_{1(j)}) + \mathcal{B}'_{(j)}$.

Then the standard elliptic arguments yield the following

Proposition 17.5.3. *(i) If the support of the symbol of Q is small enough then there exists $j_0 \in \mathbb{Z}^+$ such that*

$$|F_{t\to h^{-1}\tau}\chi_{T,T'}(t)Q_x\mathcal{U}'_{jk}| \le C'T\mu^{-s} \tag{17.5.16}$$
$$\forall \tau : |\tau| \le \epsilon_0 \quad \forall T > \mu^{-\delta'}h \quad \forall j \ne j_0$$

where $\delta' > 0$.

(ii) In particular, if $\mu h \ge C_0$ then $j_0 = 0$ and this estimate remains true with $Q = I$.

Recall that the eigenvalues of the symbol $\mathcal{A}_{0(j)}(x',\xi')$ are

$$\lambda j,\pm := \bar{W} \pm (m^2 + 2j\mu h b_0)^{\frac12} \qquad \text{for} \quad d = 2 \tag{17.5.17}_{(2)}$$

and

$$\lambda j,\pm := \bar{W} \pm \bigl(m^2 + (2j\mu h + \xi_2^2)b_0\bigr)^{\frac12} \text{for} \quad d = 3, \tag{17.5.17}_{(3)}$$

where

(17.5.18) For $j \ge 1$ all these eigenvalues are disjoint while two eigenvalues with $j = 0$ are not necessarily disjoint.

Therefore the following statement holds:

Proposition 17.5.4. *For $\mu h \ge \epsilon_0$, $j \ge 1$ there exist operators $\mathcal{T}_{(j)}$ satisfying* (17.4.25) *and*

$$\mathcal{T}_{(j)}{}^*\mathcal{B}_{(j)}\mathcal{T}_{(j)} \equiv \tilde{\mathcal{B}}_{(j)} = \begin{pmatrix} \mathcal{B}^+_{(j)} & 0 \\ 0 & \mathcal{B}^-_{(j)} \end{pmatrix} \tag{17.5.19}$$

in $\tilde{\Omega}$ where the principal symbols of the $\mathbf{h}'$-pseudodifferential operators $\mathcal{B}^{\pm}_{(j)}$ are $(m+1)\lambda j,\pm I$ with $\lambda j,\pm$ defined by $(17.5.17)_{(d)}$ with $d = 2,3$ and the blocks are $\frac{\mathsf{D}}{2} \times \frac{\mathsf{D}}{2}$-dimensional.

Let us consider the case $j = 0$.

For $D = 2$ the operator $\mathcal{B}_{(0)}$ is 1×1-matrix from the beginning and its principal symbol is equal to

$$(17.5.20)_{(2)} \qquad (m+1)(\bar{W} + \varsigma m) \qquad \text{for } d = 2$$

and

$$(17.5.20)_{(3)} \qquad \bar{W} + \varsigma \xi_2 B_0 \qquad \text{for } d = 3,\ D = 2$$

where $m = 0$ automatically in the latter case.

In the case $d = 3$, $D = 4$ the operator $\mathcal{B}_{(0)}$ is 2×2-matrix and the eigenvalues of its principal symbol are equal to

$$(17.5.20)^*_{(3)} \qquad (m+1)\big(\bar{W} \pm (m^2 + \xi_2^2 b_0)^{\frac{1}{2}}\big);$$

these eigenvalues are disjoint if either $m \ge \epsilon_0$ or $|\xi_2| \ge \epsilon_0$ in $\tilde{\Omega}$ and in these two cases there exists an operator $\mathcal{T}_{(0)}$ satisfying (17.4.25), (17.5.19) with blocks which are now 1-dimensional.

So in all with the singular exception $d = 3$, $D = 4$, $j = 0$, $m \le \epsilon_0$, $|\xi_2| \le \epsilon_0$ on $\tilde{\Omega}$ our problem is reduced to the analysis of operators with scalar principal symbols and all the arguments of Section 5.3 are applicable with the following modification:

(17.5.21) We have $(d-1)$ instead of d and there is an additional factor μ in the right-hand expressions of the estimates.

Remark 17.5.5. (i) Since the real semiclassical parameter is $\mu^{-1}h$ in the case $d = 2$, all the negligibility estimates have right-hand expression $C'\mu^{-s}T$ in this case.

(ii) For $d = 3$ we have the real semiclassical parameter h and even $h/\sqrt{\nu}$ in the case when we treat the operator with the scalar principal symbol and $v^{\#}$ (defined by (17.3.20)) satisfies the condition

$$(17.5.22) \qquad |D^{\alpha}(v^{\#} + 2j\mu h)| \le c\nu \qquad \forall \alpha : |\alpha| \le K$$

with $\nu \in [h^2, 1]$.

In this case the negligibility estimates have $C'\mu h^{-1}\big(h/\sqrt{\nu}\big)^s T$ as their right-hand expression.

Finally, let us note that the standard elliptic arguments yield that

Remark 17.5.6. (i) We do not need to treat the case $j = 0$ for $|\tau| \le \epsilon_0$, $d = 2$ and for $|\tau| \le \epsilon_0$, $d = 3$ and symbol of Q supported in $\{|\xi_2| \le \epsilon_0\}$ provided condition (17.3.30) is fulfilled.

(ii) On the other hand, the opposite condition ($V^2 - m^2 \le \epsilon_1$) excludes the case $j \ge 1$ from the analysis.

17.5.2 Estimates

Estimates as $d = 3$

It is easy to see that Proposition 17.4.10 remains true with the following modification: we discuss smoothness with respect to $z = j\mu h$ neither here nor below and we do not replace summation by integration; the transition from $\mathsf{R}^{\mathsf{MW},\prime}$ to R^{MW} is now trivial. As a result we have the following statements (we leave the proof to the reader):

Theorem 17.5.7. *Let $d = 3$, $\tau = 0$, $\phi \in \mathscr{C}_0^K([-c, c])$ and let conditions* (17.1.1)–(17.1.3), (17.2.1), (17.5.1), $(17.5.2)_{(3)}$, $(13.4.85)^{\#}$ *be fulfilled with $\nu \in [h^2, 1]$. Recall that $^{\#}$ means modification described in Corollary 17.2.5. Then*

(i) Let either $m \ge 1$ or condition (17.3.30) *be fulfilled. Then the estimate*

$$\mathsf{R}^{\mathsf{MW}} \le C\mu h^{-1-\delta}\nu^{\frac{\delta}{2}} + C' \tag{17.5.23}$$

holds with arbitrarily small $\delta > 0$. Moreover, under the condition

$$\min_{j\in\mathbb{Z}^+} |v^{\#} + 2j\mu h| + \sum_{\alpha:1\le|\alpha|\le L} |D^\alpha v^{\#}| \ge \epsilon_0\nu \tag{17.5.24}$$

the estimate

$$\mathsf{R}^{\mathsf{MW}} \le C\mu h^{-1} \tag{17.5.25}$$

holds.

(ii) If one of the conditions (17.3.6), (17.3.7) *is fulfilled then estimate* (17.5.25) *holds.*

Let us note that we cannot apply this statement in the most general case (with $m \le \epsilon_0$) because there is a term with $j = 0$. Therefore let us treat the case $j = 0$ more carefully. Let us recall that for $j = 0$ we have an operator with the principal symbol $\big(W + \varsigma\xi_2\big)$ for $\mathsf{D} = 2$ and $\big(W \cdot I + \sigma_1\xi_2 + \sigma_0 m\big)$ for $\mathsf{D} = 4$. In the former case we have a scalar operator of principal type and therefore the contribution of this term to the remainder estimate does not exceed $C\mu h^{-1}$.

In the latter case we can assume without any loss of the generality that either $m = 1$ (a case which has been treated already) or $\nu = 1$; in Section 17.7 we will show that the general case can be reduced to one of these (maybe with a small "loss of information").

Applying the arguments of Subsection 5.3.2 (see theorems 5.3.36, 5.3.39[28]) one can easily prove the following

Theorem 17.5.8. *Let all the conditions of Theorem 17.5.8 be fulfilled and let $m \le 1$. Then estimate* (17.5.23) *holds with $\nu = 1$.*

Moreover, under condition (17.5.24) *(with $\nu = 1$) estimate* (17.5.25) *holds.*

Estimates as $d = 2$

Let us treat the case $d = 2$. In this case we obtain a scalar operator for $j = 0$ as well. The theory of Section 5.3 immediately yields the following two theorems (again, we leave their proofs to the reader):

Theorem 17.5.9. *Let $d = 2$, $\tau = 0$ and let conditions* (17.1.1)–(17.1.3), (17.2.1), (17.5.1) *and* $(17.5.2)_{(2)}$ *be fulfilled. Let $\phi \in \mathscr{C}_0^K([-c, c])$. Then*

(i) Under the conditions

$$(17.5.26)_+ \qquad |v^\# + 2j\mu h| + |\nabla v^\#| \le \epsilon_0 \implies \mathsf{Hess}\, v^\# \ge \epsilon_0 \quad \forall j \ge 1$$

$$(17.5.27)_+ \qquad |V_0| + |\nabla V_0| \le \epsilon_0 \implies \mathsf{Hess}\, V_0 \ge \epsilon_0$$

with

$$(17.5.28) \qquad V_0 \coloneqq (m+1)(V - \varsigma m)$$

the estimate

$$(17.5.29) \qquad \mathsf{R}^{\mathsf{MW}} \le C$$

holds.

[28] We apply the second theorem in order to get rid of the logarithmic factor.

(ii) Under the conditions

$$|v^{\#}+2j\mu h|+|\nabla v^{\#}|\le \epsilon_0 \implies |\operatorname{Hess} v^{\#}|\ge \epsilon_0 \quad \forall j\ge 1 \tag{17.5.26}$$

$$|V_0|+|\nabla V_0|\le \epsilon_0 \implies |\operatorname{Hess} V_0|\ge \epsilon_0 \tag{17.5.27)$_$}$$

the estimate

$$\mathsf{R}^{\mathsf{MW}} \le C|\log\hat\lambda| \le C\log\mu \tag{17.5.30}$$

holds where

$$\hat\lambda = \min_{j\in\mathbb{Z}^+, x\in\mathfrak{M}_j} \hat\lambda_{j,x}, \qquad \hat\lambda_{j,x}=|v^{\#}+2j\mu h| \quad (j\ge 1), \tag{17.5.31}$$

$$\hat\lambda_{j,x}=|V-\varsigma m| \quad (j=0)$$

and $\mathfrak{M}_j$ is the set of saddle points of $v_j^{\#}=v^{\#}$ for $j\ge 1$ and $v_0^{\#}=V_0$ for $j=0$.

(iii) Finally, under the conditions

$$\min_{j\in\mathbb{Z}^+, j\ge 1} |v^{\#}+2j\mu hF| + \sum_{\alpha:1\le|\alpha|\le L} |D^{\alpha}v^{\#}| \ge \epsilon_0\nu, \tag{17.5.24)$'$}$$

$$\sum_{\alpha:|\alpha|\le L} |D^{\alpha}V_0| \ge \epsilon_0 \tag{17.5.24)$''$}$$

the estimate

$$\mathsf{R}^{\mathsf{MW}} \le C\mu^{\delta} \tag{17.5.32}$$

holds with arbitrarily small $\delta>0$.

Theorem 17.5.10. *Let $d=2$, $\tau=0$ and let conditions* (17.1.1)–(17.1.3), (17.2.1), (17.5.1), $(17.5.2)_{(2)}$ *and* $(17.2.28)_{1,2}$ *be fulfilled. Moreover, let*

$$|D^{\alpha}v_j^{\#}|\le c\nu \qquad \forall \alpha : 1\le|\alpha|\le K \tag{17.5.33}$$

and

$$\bar\nu\ge\mu^{-l}, 1\ge\nu\ge C_0\bar\nu\mu^{-1}h \tag{17.5.34}$$

as j is defined by the inequality $|v_j^{\#}|\le\epsilon_1$ with arbitrarily small $\epsilon_1>0$. Then

(i) If

$$|v_j^{\#}| + |\nabla v_j^{\#}| \le \epsilon_0 \nu \implies \det \mathsf{Hess}\, v_j^{\#} \ge \epsilon_0 \nu^2 \tag{17.5.35}_+$$

then estimate (17.5.29) *holds for* $\mathsf{R}^{\mathsf{MW}\prime}$ *and*

$$\mathsf{R}^{\mathsf{MW}} \le C\frac{\bar\nu}{\nu}. \tag{17.5.36}$$

(ii) If

$$|v_j^{\#}| + |\nabla v_j^{\#}| \le \epsilon_0 \nu \implies |\det \mathsf{Hess}\, v_j^{\#}| \ge \epsilon_0 \nu^2 \tag{17.5.37}$$

then estimate (17.5.30) *holds for* $\mathsf{R}^{\mathsf{MW}\prime}$ *and*

$$\mathsf{R}^{\mathsf{MW}} \le C\frac{\nu}{\bar\nu}\bigl(\log \frac{\mu\nu}{\bar\nu h} + 1\bigr). \tag{17.5.38}$$

(iii) If

$$\sum_{\alpha:|\alpha|\le L} |D^\alpha v_j^{\#}| \ge \epsilon_0 \nu \tag{17.5.39}$$

then estimate (17.5.32) *holds for* $\mathsf{R}^{\mathsf{MW}\prime}$.

Estimates as $d = 2$ and h is Large

Let us weaken condition $(17.5.2)_{(2)}$ as $d = 2$. Namely, let us now assume that

$$\hbar = \mu^{-1} h \in (\mu^{-\delta}, 1] \tag{17.5.40}$$

with a small exponent $\delta > 0$ and let us treat $\hbar$ as a small parameter. Now the Schwartz kernels of operators with operator norm in $\mathscr{L}^2$ not exceeding $C'\hbar^s$ where t is treated as parameter are considered negligible (before the restriction to $x = y$ and integration).

Then the presence of a cut-off with respect to x_1 and $\hbar D_1$ yields that $\mathcal{U}$ is equal to decomposition (17.5.5) modulo a negligible function.

The first difficulty is that the remainder in the transformation of $\mathcal{A}^0$ is of order $\mu\bar\nu\hbar^N$ where we assume that conditions $(17.2.28)_{1,2}$ are fulfilled. In order to make this remainder negligible (i.e., with operator norm less than $C'\hbar^N$) we assume that

(17.5.41) Conditions $(17.2.28)_{1,2}$ are fulfilled and $\bar{\nu} \le c\mu^{-1}\hbar^{-l}$.

Here we do not divide the right-hand expression of this inequality by $(m+1)$ because the standard elliptic arguments yield that the components $\mathcal{U}_{jk}^{\zeta\zeta'}$ with $\zeta = \varsigma$ or (and) $\zeta' = \varsigma$ are Schwartz kernels of operators bounded even after being multiplied by $(m+1)$ ($(m+1)^2$ respectively) and cutting with respect to hD_t; i.e., after reduction is applied.

Then assuming that $\delta = \delta(s, l) > 0$ in (17.5.40) is small enough the standard elliptic arguments yield that the functions $T^{-1}F_{t\to h^{-1}\tau}\chi_{T,T'}(t)\mathcal{U}_{jk}$ are negligible for $T \ge \mu^{\delta'}h$, $j \ge 1$, $|\tau| \le c$ with $\delta' = 1/s$. Therefore the same is true for $k \ge 1$. So the only one essential component $\mathcal{U}_{00}$ remains and

$$\bigl(hD_t - (m+1)(\bar{W} - \varsigma m)\bigr)\mathcal{U}_{00} \equiv 0, \tag{17.5.42}$$

$$\mathcal{U}_{00}|_{t=0} \equiv \delta(x_1 - y_1) \tag{17.5.43}$$

where the first equality is fulfilled modulo functions negligible in the sense indicated above (in the same sense $\mathcal{U}_{jk}$ with $j + k \ge 1$ are negligible).

Therefore our routine arguments yield the following

Theorem 17.5.11. *Let $d = 2$ and let conditions* (17.1.1)–(17.1.3), (17.2.1), (17.5.1), (17.5.40) *and* (17.5.41) *be fulfilled where $\delta > 0$ in* (17.5.40) *is small enough.*

Let us assume that V_0 satisfies $(17.2.28)_3$ with $\bar{\nu}$ replaced by $\nu \in [\hbar^l, 1]$.

(i) Then all the statements of Theorem 17.5.10 remain true.

(ii) Moreover, under condition (17.5.39) *the estimate*

$$\mathsf{R}^{\mathsf{MW}\prime} \le C\hbar^{-\delta'} \tag{17.5.44}$$

holds with arbitrarily small $\delta' > 0$.

17.6 Semiclassical Spectral Gaps

17.6.1 Existence of Spectral Gaps

The majority of this section is devoted to the case $d = 2$ because for $d = 3$ there can exist only main spectral gap, namely $(-m + \sup V, m + \inf V)$ under the condition that the first number is less than the second. On the

other hand, for $d = 2$ other spectral gaps can appear. In this section we analyze the case $d = 2$ in two different situations: under condition (17.4.1) and under the condition

$$h^{\delta-1} \le \mu; \tag{17.6.1}$$

later we join these cases. Let us start with the statements that gaps exist. By the standard elliptic arguments one can prove easily the following two propositions:

Proposition 17.6.1. *Let $d = 2$ and let conditions* (17.1.1)–(17.1.3), (17.2.1), $(17.2.28)_{1-3}$, (17.4.1), (17.3.1) *and* $(13.4.12)_1$ *be fulfilled. Then*

(i) Let condition (17.3.30) *be fulfilled and for some $j \in \mathbb{Z}^+$ let*

$$|v^{\#} + 2j\mu h| \ge \zeta^2 \ge C_0\bar{\nu}\mu^{-2} \qquad \forall x \in B(0,1). \tag{17.6.2}$$

Then for $\mathcal{U}'''_{jk}$ constructed in Section 17.4 the following estimate holds:

$$|F_{t\to h^{-1}\tau}\chi_T(t)Q_x\mathcal{U}'''_{jk}| \le C'\mu^{-s}h^s \tag{17.6.3}$$
$$\forall x, y \in \mathbb{R}^2 \quad \forall T \ge h^{1-\delta}\zeta^{-2} \quad \forall k \in \mathbb{Z}^+ \quad \forall \tau : |\tau| \le \epsilon\zeta^2.$$

(ii) In particular, if condition (17.6.2) *is fulfilled for all $j \in \mathbb{Z}^+$ then estimate* (17.6.3) *holds for all j, k and hence this estimate holds for $\mathcal{U}$ instead of $\mathcal{U}'''$, and therefore the estimate*

$$|F_{t\to h^{-1}\tau}\chi_T(t)U| \le C'T\mu^{-s}h^s \tag{17.6.4}$$

holds for the same T and τ as in (17.6.3) *and for $x, y \in B(0, \frac{1}{2})$.*

(iii) Let

$$v^{\#} \ge \zeta^2 \ge C_0\bar{\nu}\mu^{-2} \qquad \forall x \in B(0,1). \tag{17.6.5}$$

Then estimates (17.6.3), (17.6.4) *hold for x, y, T, τ indicated above and for all j, k.*

Proposition 17.6.2. *Let $d = 2$ and let conditions* (17.1.1)–(17.1.3), (17.2.1), $(17.2.28)_{1-3}$, (17.5.1), $(17.5.2)_{(2)}$ *and* (17.3.1) *be fulfilled with $\bar{\nu} \ge \mu^{-l}$. Then*

(i) For some $j \in \mathbb{Z}^+$ *let*

$$|v^{\#} + 2j\mu h| \ge \zeta^2 \ge C_0\bar{\nu}\mu^{-1}h \qquad \forall x \in B(0,1). \tag{17.6.6}$$

Then for the $\mathcal{U}'_{jk}$ *constructed in Section 17.5 estimate* (17.6.3) *holds.*

(ii) particular, if condition (17.6.6) *is fulfilled for all* $j \in \mathbb{Z}^+$ *then estimate* (17.6.3) *holds for all* j, k*; hence the estimate holds for* $\mathcal{U}$ *instead of* $\mathcal{U}'$*, and therefore estimate* (17.6.4) *holds.*

(iii) For some $j \in \mathbb{Z}^+$ *let*

$$|H_{\varkappa j}(x)| \ge \zeta^2 \ge C_0(m+1)^{-1}\bar{\nu}\mu^{-1}h \qquad \forall x \in B(0,1) \quad \forall \varkappa : (\varkappa, j) \in \mathfrak{Z}, \tag{17.6.7}$$

where

$$H_{\varkappa j}(x) = V + \varkappa(2j\mu hF + m^2)^{\frac{1}{2}}, \tag{17.6.8}$$

$\varkappa = \pm$ *and* $\mathfrak{Z}$ *were introduced in Section 17.4. Then estimate* (17.6.3) *holds.*

(iv) In particular, if condition (17.6.7) *is fulfilled for all* j *then estimate* (17.6.3) *holds for all* j *and therefore this estimate holds for* $\mathcal{U}$ *instead of* $\mathcal{U}'$ *and hence estimate* (17.6.4) *holds.*

Let us discuss the case when conditions (17.5.1) and $(17.5.2)_{(2)}$ are fulfilled and $\mu h \ge C_0$ more carefully.

In this case one should check conditions of (17.6.2)-type only for $j = 0$, $\varkappa = -\varsigma$ and in order to prove estimates (17.6.3) and (17.6.4) it is sufficient to check the microlocal hypoellipticity of the block $\mathcal{B}_{(0)}$ of the operator $\mathcal{B} = (m+1)\mathcal{K}^*\mathcal{A}\mathcal{K}$; this operator is of the block-diagonal type.

Let us note that the distance between eigenvalues of the symbol $(m+1)\mathcal{A}^0$ corresponding to $j = 0$, $\varkappa = -\varsigma$ and eigenvalues corresponding to other $(j, \varkappa) \in \mathfrak{Z} \setminus (0, -\varsigma)$ surely is not less than $(m+1)\mu h(m + \sqrt{\mu h})^{-1}$ and that blocks $(m+1)\mathcal{A}_{0j}$ are uniformly $\mu^{-1}h$-pseudodifferential operators with an additional factor $\bar{\nu}(\mu^{-1}h)^{j/2}$ as $j \ge 1$.

Therefore operator $\mathcal{M} = \mathcal{B}_{(0)} - \mathcal{A}_{00}$ is equal to $\rho\tilde{\mathcal{M}}$ where

$$\rho = \bar{\nu}^2\mu^{-2}\bigl(1 + \sqrt{\mu h}(m+1)^{-1}\bigr) \tag{17.6.9}$$

and $\tilde{\mathcal{M}}$ is a $\mu^{-1}h$-pseudodifferential operator uniformly. Moreover,

$$\mathcal{A}_{00} = \mathcal{G}^*(V - \varsigma m)\mathcal{G}(m+1) \tag{17.6.10}$$

where $\mathcal{G} = \mathcal{T}\mathcal{F}L$, L is the operator: $v(x_1) \to Lv = v(x_1)\Upsilon_0(x_2)e$ and e is a fixed element of $\mathsf{Ker}(\sigma_1 - i\sigma_2)$ with $\|e\| = 1$.

So we are interested in the microlocal hypoellipticity of the operator

$$(m+1)\mathcal{G}^*(V - \varsigma m)\mathcal{G} + \mathcal{M}. \tag{17.6.11}$$

Let us consider the map $\bar{\Psi} : \Lambda^0 \ni (x_1, \xi_1) \to x \in B(0,1)$ introduced in Section 13.3.

One can see easily that if $\psi = 1$ in a neighborhood of $\bar{\Psi}(\mathsf{supp}(q))$ and $Q = \mathsf{Op}(q)$ then $Q\mathcal{G}^*\psi \equiv Q\mathcal{G}^*$ and $\psi\mathcal{G}Q \equiv \mathcal{G}Q$.

On the other hand, if $q = 1$ in a neighborhood of $\bar{\Psi}^{-1}(\mathsf{supp}(\psi))$ then $Q\mathcal{G}^*\psi \equiv \mathcal{G}^*\psi$ and $\psi\mathcal{G}Q \equiv \mathcal{G}Q$; here Q is a $\mu^{-1}h$-pseudodifferential operator with respect to x_1 and $\psi = \psi(x)$.

These observations easily yield that $\mathcal{B}_{(0)}$ is a microlocally hypoelliptic $\mu^{-1}h$-pseudodifferential operator provided

$$(m+1)|V - \varsigma m| \ge C_0\rho \tag{17.6.12}$$

(let us note that the left-hand expression equals $|H_{-\varsigma 0}|$). Moreover, one can see easily that

$$\mathcal{M} = \rho\Big(\sum_{p,r} f^{pr}\partial_p\tilde{V}\cdot\partial_r\tilde{V} + \sqrt{\mu^{-1}h}\sum_p f^p\partial_p\tilde{V} + \mu^{-1}hf\Big)\circ\bar{\Psi} \tag{17.6.13}$$

with uniformly smooth symbols f^{pr}, f^p, f and with $\tilde{V} = (m+1)\bar{\nu}^{-1}V$. Therefore condition (17.6.12) can be replaced by the condition

$$(m+1)|V - \varsigma m| \ge C_0\rho\mu^{-1}h. \tag{17.6.14}$$

So we have proven the following

Proposition 17.6.3. *Let $d = 2$ and let conditions* (17.1.1)–(17.1.3), (17.2.1), $(17.2.28)_{1-3}$, (17.5.1), $(17.5.2)_{(2)}$ *and* (17.3.1) *be fulfilled with $\bar{\nu} \ge \mu^{-l}$, $\mu h \ge C_0$. Moreover, let condition* (17.6.14) *be fulfilled.*

Then for all j, k estimate (17.6.3) *holds and estimate* (17.6.4) *holds as well.*

In a similar way one can prove

Proposition 17.6.4. *Let $d = 2$ and let conditions* (17.1.1)–(17.1.3), (17.2.1), $(17.2.28)_{1-3}$, (17.5.1), (17.5.42), (17.5.43), (17.5.33) *and* (17.3.1) *are fulfilled with*

$$\nu \ge \hbar^{l}, \qquad \bar{\nu} \le \nu\mu^{-1}\hbar^{-l} \tag{17.6.15}$$

where $\delta = \delta(l, s) > 0$ in condition (17.5.41) *is small enough. Moreover, let*

$$|H_{-\varsigma 0}| \ge \zeta^2 \ge C_0\nu\hbar \qquad \forall x \in B(0,1). \tag{17.6.16}$$

Then the estimate

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma'\mathcal{U}'_{jk}| \le C'\mu^{1-j-k}T\nu\zeta^{-2}\hbar^{s} \qquad \forall x, y \in \mathbb{R}^2 \tag{17.6.17}$$

holds for $T \ge h\hbar^{\delta'}$, $|\tau| \le \epsilon\zeta^2$. Therefore the estimate

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\psi U| \le C'\mu T\nu\zeta^{-2}\hbar^{s} \tag{17.6.18}$$

holds for the same T and τ.

Remark 17.6.5. Surely, one can weaken condition (17.6.16) in the spirit of (17.6.12) or (17.6.14).

As $d = 3$ by the standard elliptic arguments one can prove the following

Proposition 17.6.6. *Let $d = 3$ and let conditions* (17.1.1)–(17.1.3), (17.3.1), $(17.2.28)_{1-3}$, (17.5.33) *be fulfilled with $1 = \bar{\nu} \ge \nu \ge h^2$. Moreover, let*

$$V^2 - m^2 \le -\epsilon\nu \qquad \text{in } B(0,1). \tag{17.6.19}$$

Then the estimate

$$|F_{t\to h^{-1}\tau}\chi_T(t)\Gamma\psi U| \le C'(\mu h^{-1} + h^{-2})\bigl(\frac{h}{\sqrt{\nu}}\bigr)^{s} \tag{17.6.20}$$

holds for the same $T \ge h^{1-\delta'}\nu^{\frac{1}{2}\delta'-1}$ and $|\tau| \le \nu$.

Starting from Propositions 17.6.1–17.6.4 and 17.6.6 by means of the standard Tauberian arguments we then obtain the following theorem:

Theorem 17.6.7. *Let conditions* (17.1.1)–(17.1.3), (17.2.1), (17.3.1) *and* $(17.2.28)_{1-3}$ *be fulfilled.*

(i) Let $d = 2$, *let conditions* (17.4.1), $(13.4.12)_1$, (17.3.30) *be fulfilled and let condition* (17.6.2) *be fulfilled for all* $j \in \mathbb{Z}^+$. *Then the estimate*

$$|e(x,y,\tau_1,\tau_2)| \le C'\mu^{-s}h^s \qquad \forall x,y \in B(0,\frac{1}{2}) \quad \forall \tau_1,\tau_2 \in (-\epsilon\zeta^2,\epsilon\zeta^2) \tag{17.6.21}$$

holds.

(ii) Let $d = 2$, *let conditions* (17.5.1), $(17.5.2)_{(2)}$ *be fulfilled and let* $\bar\nu \ge \mu^{-l}$.

Moreover, let <u>*either*</u> *condition* (17.6.6) *be fulfilled for all* $j \in \mathbb{Z}^+$ <u>*or*</u> *condition* (17.6.7) *be fulfilled for all* $(\varkappa, j) \in \mathfrak{Z}$. *Then estimate* (17.6.21) *also holds.*

(iii) Let $d = 2$, *let conditions* (17.5.1), $(17.5.2)_{(2)}$ *be fulfilled and let* $\mu h \ge C_0$. *Moreover, let* <u>*either*</u> *condition* (17.6.12) <u>*or*</u> *condition* (17.6.14) *be fulfilled. Then estimate* (17.6.21) *also holds.*

(iv) Let $d = 2$, *let conditions* (17.5.1), (17.5.42), (17.5.42), (17.5.33), (17.6.15), (17.6.16) *be fulfilled (and in 17.2.28 only the first two conditions should be checked) and let* $\delta = \delta(l,s) > 0$ *be small enough. Then the estimate*

$$|\Gamma\psi e(.,.,\tau_1,\tau_2)| \le C'\mu\nu\zeta^{-2}\hbar^s \qquad \forall \tau_1,\tau_2 \in (-\epsilon\zeta^2,\epsilon\zeta^2) \tag{17.6.22}$$

holds.

(v) Let $d = 3$, *let condition* (17.5.33) *hold with* $\nu \in [h^2,1]$, $\bar\nu = 1$ *in* $(17.2.28)_{1-3}$ *and let condition* (17.6.19) *be fulfilled. Then the estimate*

$$|\Gamma\psi e(.,.,\tau_1,\tau_2)| \le C'(\mu h^{-1} + h^{-2})\bigl(\frac{h}{\sqrt{\nu}}\bigr)^s \qquad \forall \tau_1,\tau_2 \in (-\epsilon\nu,\epsilon\nu) \tag{17.6.23}$$

holds.

17.6.2 Calculations in the Spectral Gaps

In what follows we assume that $d = 2$. In order to finish our analysis we need to treat only mollified asymptotics. Theorem 4.4.1 immediately yields

Proposition 17.6.8. *Let $d = 2$ and let conditions* (17.1.1)–(17.1.3), (17.2.1), (17.4.1), (17.3.1) *and* (17.3.30) *be fulfilled.*

Let $\phi \in \mathscr{C}_0^K((-\epsilon,\epsilon))$, $L \in [h^{1-\delta'},1]$. Then

$$|\int \phi\big(\frac{\tau}{L}\big)\Big(d_\tau(\Gamma\psi e)(.,\tau) - h^{-2}\int \psi d_\tau \mathcal{N}^{\mathsf{MW}}(x,.,\tau,\mu h)dx - \sum_{\varkappa,n,r:n\le 2r,1\le r\le N}\sum_j \Theta^{(n+1)}_{j\varkappa nr}(\tau)(\mu^{-1}h)^r dx\Big)| \le C'h^s \tag{17.6.24}$$

where

$$\Theta_{j\varkappa nr}(\tau) = \int \theta\big(\tau - H_{\varkappa j}\big) f_{nr\varkappa}(j\mu h,\mu^{-1},\mu h,x_1,\xi_1)\,dx_1 d\xi_1, \tag{17.6.25}$$

$H_{\varkappa j}$ are defined by (17.6.8) *and for $n = 0$*

$$f_{0r\varkappa} = \sum_{1\le|\alpha|\le K} F_{r\varkappa}(D^\alpha\psi)\circ\bar{\Psi}(j\mu h)^{\frac{|\alpha|}{2}} \tag{17.6.26}$$

and the coefficients $F_{r\varkappa}$ do not depend on ψ.
